The first layer is a full convolutional layer with $32 \times 3 \times 3$ convolutional kernels, $\text{Stride}=2$, and the output is $32 \times 28 \times 112$ feature maps; the second to sixth layers are five convolutional blocks (Blocks) in turn, and the internal expansion multiplier of the Blocks is 6, where Block1 ~ Block4 are set with a sliding step of 2 and successive down sampling, and the output feature map is $2 \times 7 \times 160$; the seventh layer is a full convolutional layer with $512 \times 1 \times 1$ convolutional kernels, which is used for feature dimensioning; the eighth layer is an adaptive averaging pooling layer, which keeps the number of feature map channels unchanged and changes the feature map size to 1×1 ; the ninth layer is a fully connected layer, which is used for feature dimensioning. The ninth layer is a fully connected layer, followed by a Softmax layer for classification. The batch normalization layer [14] is added after each network layer except the average pooling layer to speed up the training and improve the generalization ability of the model, and the ReLU6 activation function [15] is used after the batch normalization layer, and the dropout layer [16] is used after the fully connected layer to prevent the network from overfitting during training.

6. Case Studies

6.1. Visual Art Application of Chinese Characters in Packaging Design. With the continuous enrichment of technological design tools, the functional and stylistic design of packaging has significantly improved. On the basis of the design of elements such as text, colour, graphics, function, and shape, the research continues to address the artistic expression of Chinese characters in packaging design. The artistic value of

Chinese characters in packaging design is studied from a psychological perspective, and the artistic expression of Chinese characters in packaging design is analyzed in terms of imagery, digitization, visualization, and the value demanded in contemporary social development.

The visual language of imagery in Chinese characters in packaging design is an exploration of abstract traditional cultural forms, a unique artistic expression of Chinese characters that can be applied to packaging design to enhance the overall aesthetic effect of the product's taste, mainly through the brushwork of calligraphy. The visual culture of calligraphy is the main source of inspiration for Chinese character elements in packaging design. The hieroglyphic strokes of calligraphy and the structure of the cloth and white contribute to the imaginative expression of the Chinese characters in a more classical Chinese context, which, combined with the post-modern classical design trend, has a positive impact on the artistic expression of Chinese characters in packaging design. The packaging design of “One Mountain, One Immortal” (Figure 4), designed by Hello Ocean Branding Studio, combines the character “mountain” with the shape of the product and the elegant classical aesthetic mood of the product, reflecting the beauty of the Chinese character imagery to the fullest (Figure 5). Moutai Town Wine's 2019 Year of the Hexi theme packaging uses calligraphic imagery to enhance the overall effect of the packaging.

Another trend in the artistic performance of Chinese characters in modern packaging design lies in following the pace of social economy, pursuing the power of science and technology, adding a more modern visual feel to the Chinese character font design, enabling consumers to quickly accept the design principles, conforming to the modern design atmosphere of consumers' personal lives, constantly strengthening

FIGURE 5: Imaginative representation of Chinese characters in Moutai town wine packaging design.

FIGURE 6: Digital representation of the Chinese character technology in the packaging design of the “Good Night Technology” Sleeping Drink.

the visual impact of science and technology, bringing the Chinese character elements of packaging design not only to inherit the tradition, but also to find the theme of Chinese characters in the modern environment. For example, Figure 6 is a display of the packaging design for Good Night Technology Sleeping Drink. The design combines the product’s technological health theme with modern technological elements around the Good Night font. The design echoes the theme of the packaging design, which is a modern and minimalist aesthetic that makes consumers feel comfortable and healthy.

As shown in Figure 7, the application of Chinese characters in product packaging is based on the pictorial nature of Chinese characters, combining the beauty of the foot form and graphic design to show the specific image of the main idea to be expressed in the product packaging. The Chinese characters for the theme “Craftsmanship,” the use of a labyrinth design and the shape of the Chinese gossip culture, express the main idea clearly, show the strong corporate culture of the product, and enhance the publicity of the product’s high quality of hand brewing to win the trust of consumers.

FIGURE 7: The “artisanal creation” packaging design of snowflake beer in Chinese characters.

6.2. *The Influence of Traditional Visual Art Elements on Packaging Design.* Chinese traditional culture in packaging design art design elements, which are a representative of the Chinese national style, traditional visual culture of the people through society, national humanistic feelings, and the development of cultural industries, gradually formed the visual observation of artistic habits of life.

First of all, traditional graphics in packaging design are based on folk culture as the inspiration for creativity, with rich and varied styles and auspicious and simple meanings. The traditional elements of the “Fu Lu Shou Xi” and the “Tai Ji Ba Gua” and “Dragon and Phoenix Cloud” patterns are some of the more common visual cultural elements in modern packaging design (Figure 8). The visual cultural characteristics expressed in the example of Coca-Cola’s product packaging show the unique creativity of the traditional Chinese visual culture.

Secondly, the literati’s spiritual sentiment of ink and wash, the creative expression of traditional ink and wash in the artistic practice of packaging design, has a strong Chinese classical aesthetic connotation (Figure 9), visual culture packaging design of Taiwan Gaoshan tea, flower, bird, fish and insect ink painting, space extension, and clear meaning.

Thirdly, handicraft design elements of folk art provide creative inspiration for the traditional cultural and creative design of modern packaging. Folk art is a traditional art and culture passed down in the folklore, which is applied to the creative practice of modern packaging design, reflecting the representative literary style of national folk crafts (Figure 10). Also, it is a visual culture packaging designed and created by a new generation of Chinese designers, with a unique visual culture theme, expressing the creative aesthetics of local ethnic elements.

Fourthly, the paper-cutting technique breaks through the traditional new creative expression—new paper-cutting. The traditional paper-cutting technique is different from the traditional folk paper-cutting form of carving and uses a smooth and flowing cutting technique to present the beauty of life (Figure 11). The new paper-cutting packaging design by Mr Zhao Xigang, the creator of Modern Visual Culture’s “New Paper-cutting,” uses the graphic elements of “New Paper-cutting” to achieve a double harvest of professional art and ideology and culture.

7. Experiments and Analysis of Results

7.1. *Preprocessing Algorithms.* The preprocessing algorithm was tested using a total of 4,400 original images (five matches) constructed for the dataset. Since the threshold segmentation results determine the accuracy of the subsequent skew correction and ROI cropping, two control groups were set up in this article, using Otsu and global double shareholding as the shareholding methods in the preprocessing algorithm, respectively.

The preprocessing algorithm using the global double shareholding method was the fastest with an average time of 8.34 ms and an accuracy of 97.00%. As shown in Table 1, the main factor affecting the accuracy was the luminance fluctuation; the preprocessing algorithm using Otsu as the shareholding method had the lowest accuracy of 92.5%. The main factor affecting the accuracy was the difficulty in segmenting the pallet when it was close to a block with a similar grey level. The edge-assisted shareholding has good adaptability, with an accuracy of 100% and an average time of 15 ms for the preprocessing algorithm, which is a better overall performance.

FIGURE 8: Coca-cola's visual culture packaging design.

FIGURE 9: Taiwan high tea visual culture packaging design.

7.2. Identifying Networks. The proposed Chinese character packaging defect classification network (LocalNet) was trained and tested on the above constructed Chinese character packaging defect classification dataset, Nano compact deep learning module, and the Pytorch framework.

To compare the performance of this network with that of the reference network, two control groups were set up: one was the original MobileNetv2 with an input size of $224 \times 224 \times 3$, and the other was this network

(LocalNet_224) with an input size of $224 \times 224 \times 3$. All three sets of experiments were trained using Stochastic Gradient Descent (SGD) [17], and the learning rate was adjusted using a cosine annealing strategy [18], as shown in Figure 12(a), with an initial learning rate of 0.1, a minimum learning rate of 1×10^{-8} , a momentum factor of 0.9, and a weight decay factor of 0.0003. The original MobileNetv2 network converged the fastest with a stable loss of 0.004, Local Net converged the second fastest with a stable loss of 0.005, and LocalNet_224 converged the slowest with a

FIGURE 10: Visual culture packaging design for the folklore “zaohuo faces.”

FIGURE 11: Zhao Xigang's original “new paper cut” visual culture packaging design.

TABLE 1: Performance of preprocessing algorithms under different threshold methods.

Threshold method	ROI cutting accuracy (%)	Average time (ms)
Edge assist	100.00	15.00
Otsu	92.50	11.12
Global double threshold	97.00	8.34

stable loss of 0.035. Validation rates of the original MobileNetv2 and Local Net in Figure 12(c) were both 99.99%. The accuracy of both the original MobileNetv2 and Local Net in Figure 12(c) is 99.99%, and the accuracy of LocalNet_224 is 98.67%. From the experimental data, it can be seen that LocalNet_224 does not perform like MobileNetv2 in terms of training loss convergence and validation accuracy when using the input size of 224×224 , while the training loss convergence and final training loss of Local Net with the input size of 56×224 are slightly lower than that of MobileNetv2. The validation accuracy is the same as that of MobileNetv2 and significantly better than that of LocalNet_224, which verifies the effectiveness of the proposed network structure design.

To verify the classification performance of the networks in this article, tests were evaluated on the test set constructed above, and a test control experimental group was also set up, including two lightweight networks—ShuffleNetv2 [19] and Squeeze Net [20]—and two machine learning methods—Local Binary Pattern (LBP) [21] feature-based SVM and Extreme Learning Machine (ELM) [22]. The control group was pretrained on the training set.

Table 2 presents the performance comparison of different classification methods, including input size, number of parameters, accuracy, and the average time taken to detect a Chinese character region image using three different hardware conditions: GPU (NVIDIA Tesla V100), CPU (Xeon Gold 6148), and Jetson Nano. As shown in Table 2, in terms of the number of model parameters, the proposed model has 0.50×10^6 parameters, which are the lowest among the listed deep learning models. In terms of detection accuracy, ShuffleNetv2 has the highest accuracy of 99.99%, while the proposed network has 99.94%, with only 0.05 percentage points differences, and the LBP-ELM method has the lowest accuracy. In terms of detection time, the LBP-ELM method was the fastest due to the structural advantage of ELM, with 3.87 ms and 10.25 ms in the CPU environment of the computer and Jetson Nano,

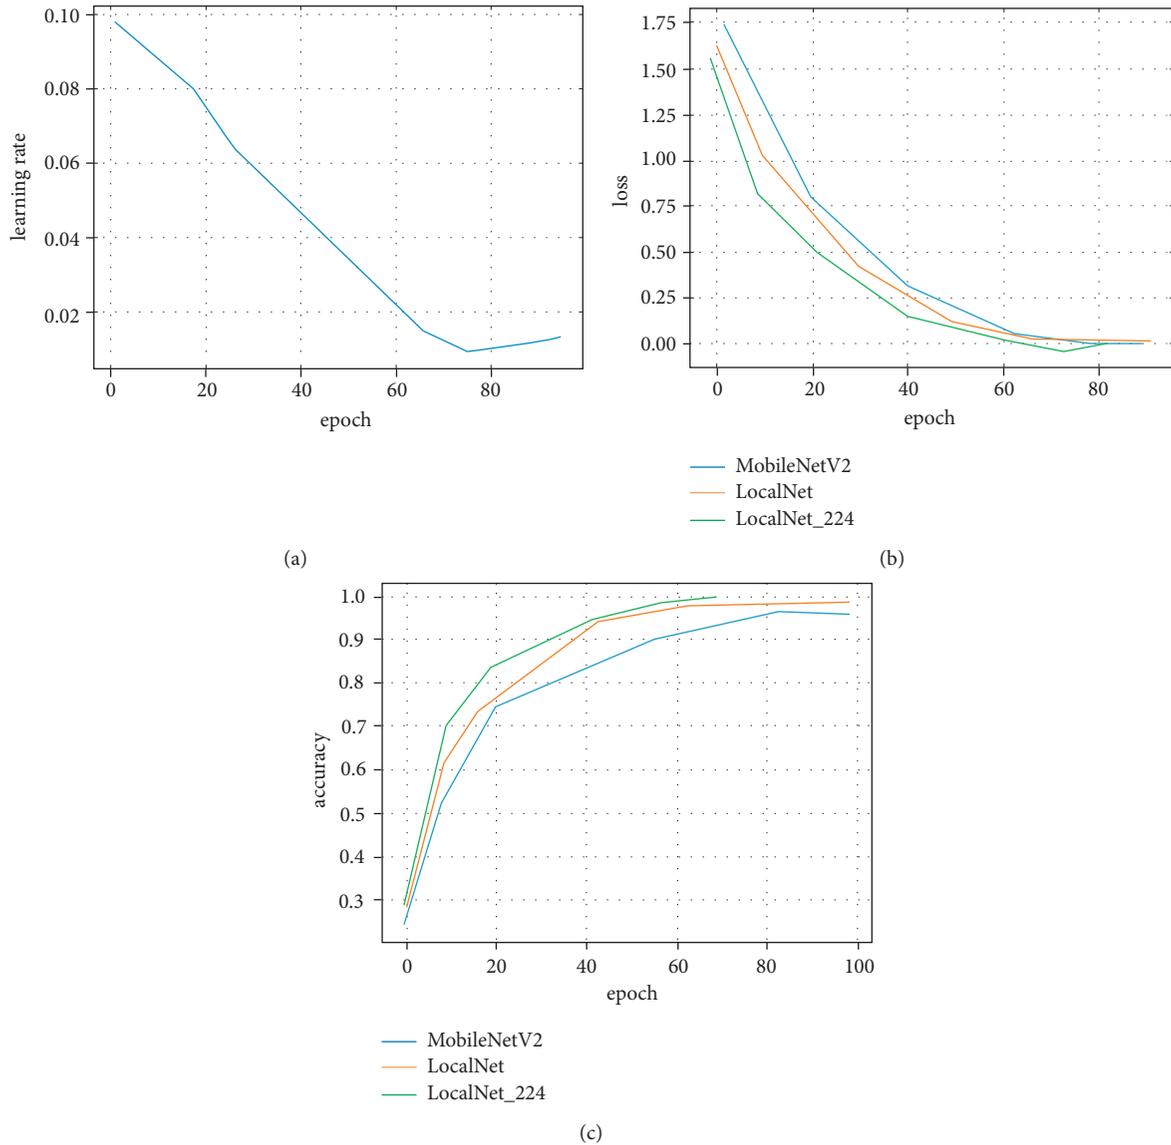

FIGURE 12: Experimental results. (a) Learning rate adjustment. (b) Loss. (c) Accuracy.

TABLE 2: Comparison of the performance of different classification methods.

Classification method	Enter size	Parameter quantity (10^6)	Accuracy (%)	Detection time (ms)		
				GPU	CPU	Jetson Nano
Squeeze Net	$224 \times 224 \times 3$	1.25	97.63	3.57	55.43	41.00
Shuffle Netv2	$224 \times 224 \times 3$	3.50	99.99	7.51	30.50	21.11
Mobile Netv2	$224 \times 224 \times 3$	3.50	99.97	6.20	31.15	20.51
LocalNet_224	$224 \times 224 \times 3$	0.5	97.89	2.23	18.17	13.45
Local Net	$56 \times 224 \times 3$	0.5	99.94	2.31	7.82	11.02
LBP-SVM	$56 \times 224 \times 3$	—	91.10	—	5.59	16.03
LBP-ELM	$56 \times 224 \times 3$	—	87.96	—	3.87	10.25

respectively; the detection time of the proposed network was the best among the deep learning models in the three hardware types, with 2.31 ms, 7.82 ms, and 11.02 ms, respectively. Although Squeeze Net has a small number of parameters, it still has a large number of conventional convolutional computations and therefore does not show

any speed advantage. This shows that the proposed network is the best among the listed methods in terms of the number of parameters, accuracy, and detection speed. When the network is deployed on the Jetson Nano platform, for example, a box of five Chinese characters is preprocessed in 15 ms, and the overall detection time of the algorithm is

70.1 ms, which can reach 14 boxes/s and meet the requirement of real-time detection in the pipeline.

8. Conclusions

This study presents a Chinese character packaging quality inspection algorithm for a small computing platform (e.g., Jetson Nano), including a preprocessing algorithm for cropping images of Chinese character packaging areas and a recognition network, by analyzing images collected on a Chinese character packaging production line and borrowing ideas from the Mobile Net series of lightweight convolutional neural networks. Through experiments, the proposed preprocessing algorithm can accurately extract the image of the Chinese character packaging area, and the recognition network can achieve an inspection speed of 14 boxes per second on the Jetson Nano platform, which is much faster than the existing manual visual inspection speed of 1 box per second and achieves an accuracy rate of 99.94%. The deployment of this algorithm on a Chinese character packaging line significantly reduces the constraints of inspection speed on production line capacity and provides technical support for the automation upgrade of the packaging line. The next step is to carry out work related to algorithm optimization, model quantification, and hardware platform adaptation to further improve the speed and accuracy of the algorithm to meet the participation requirements.

In visual communication design, the basic design elements include four types of text, graphics, colour, and layout. While the first three can be called visual elements, layout design is the functional arrangement of visual elements. Layout design is as much about making the viewer receive visual information as it is about making them feel attractive. The combination of artificial intelligence and layout design has now become a popular direction in the field of visual communication design. However, the automatic layout design process achieved through an a priori design framework still requires human involvement and is a semi-intelligent application. To solve the above problems, this study proposes a poster layout design method based on artificial intelligence. The layout composition method consists of a learner and a generator. Firstly, the learner uses the spatial transformation network to learn the classification of layout composition elements and form the initial layout design templates for different composition cases. Secondly, the generator optimises the initial template based on the LeNet architecture using the golden ratio and trilateration parameters to produce multiple optimised templates. The templates are then stored in a library of corresponding templates according to their composition and framing style. The experimental results show that the proposed poster layout composition method achieves a higher accuracy rate than existing methods.

1. Introduction

Visual communication design, often also referred to as graphic design, is a creative act that encompasses graphics, text, colour, and layout. The purpose of visual communication design is to convey emotion and information [1–5]. In the Internet era, visual communication design has long since gone beyond the design laws of traditional graphic design. Cross-border integration of visual communication design has become an important development trend. In visual communication design, the basic design elements include four types of text, graphics, colour, and layout [6–8]. The first three can be called visual elements, while layout design is a relatively independent design art.

At the present stage, artificial intelligence (AI) has developed into an intersection of computer science, psychology, philosophy, art, and other technical sciences [9, 10]. With the

development of deep learning and neural networks, AI has started to enter society, such as voice assistants and image recognition technology. How will artificial intelligence impact the field of design? In particular, design can be understood as a purposeful act of creation [11–13]. Artificial intelligence, on the other hand, can be understood as a tool with recognition functions for helping humans solve problems. Understood from this perspective, AI can be a kind of designer's aid. In recent years, more and more scholars are also exploring the combination of AI and design.

Currently, the combination of artificial intelligence and visual communication design has produced a number of intelligent applications [14–17], such as intelligent logo design, intelligent colour matching, and intelligent image search. In the case of magazine media, for example, intelligent automatic layout design has been implemented through an a priori design framework. However, this intelligent layout

design process still requires human participation and is a semi-intelligent application. Therefore, the core problem of this study is how to carry out automatic layout design through AI.

The first task in using AI for layout design is to make the computer understand the constituent elements of the layout. This research will use deep learning techniques to locate and identify the constituent elements of the layout in the target image. Machine learning is a discipline dedicated to the study of how computers can simulate the human brain [18–22]. Machine learning can use the empirical knowledge learned to continuously improve the performance of the system itself. With the continuous improvement of the computer hardware base (e.g., the rapid development of GPUs) and the large amount of data generated by various social networks, deep learning techniques have become a very important research direction in machine learning. Deep learning is a method for learning representations of data, with the advantage of replacing manual feature extraction with efficient hierarchical feature extraction. In recent years, many large Internet companies such as Microsoft, Google, Facebook, and Baidu have also set up relevant research teams. Deep learning has been widely used in various AI tasks such as speech recognition, computer vision, and natural language processing.

In traditional machine learning, the target image processing task is divided into two main steps. The first step relies on human experts to design the features manually. The second step is to provide the extracted features to a selected classifier for model training. This approach to image processing has been well used in practice in some respects. However, the process of manual feature extraction is time-consuming and labour-intensive and inevitably introduces some subjective differences due to differences in perception. It is difficult to fully standardise the execution criteria between different people or at different moments in time for the same person, which can easily result in the loss of feature information. This has limited the development of traditional machine learning to some extent. In recent years, image processing based on deep learning can solve the above problems very well. The biggest advantage is that no manual selection of extracted features is required.

Deep learning techniques can also significantly outperform traditional machine learning methods in terms of accuracy using convolutional neural network (CNN) models to autonomously learn appropriate image features. Andrearczyk et al. [23] proposed a convolutional neural network for processing handwritten digit recognition tasks. To solve large-scale computer vision recognition tasks, Zhang et al. [24] proposed an LeNet convolutional neural network model. The advantage of this network model is the use of ReLU as the activation function of the LeNet, which solves the problem of possible gradient dispersion in the sigmoid activation function in deeper network architectures. Wang et al. [25] proposed the dropout method, which effectively alleviates the problem of model overfitting during the training process of deep networks. The innovation of this method is that the neurons in the fully connected layer are inactivated with a certain probability (typically 0.5) during the training phase. The dropout method removes some of

the neurons from the forward and backward parameter propagation, greatly reducing the interdependence between neurons and thus ensuring that mutually independent important features are extracted. Samir et al. [26] proposed a local response normalisation (LRN) to create a competitive mechanism for the activity of local neurons. LRN enhances the generalisation ability of the model by expanding the values of local neurons with larger responses and suppressing other neurons with smaller feedback. In addition to this, researchers have also tried to improve image processing accuracy through a number of conventional improvements. For example, the ReLU activation function has been modified into the very good fitting Maxout activation function, which not only inherits all the advantages of the ReLU activation function but also avoids the problem of “necrosis” of neurons due to negative gradients being set to zero.

Although all of these improvements improve the learning ability of the model to some extent, the AI-based layout design process involves more elements with greater spatial variation. For this problem, the above methods are obviously not effective solutions. Therefore, a layout composition method based on a learner and a generator is proposed. The main function of the learner is to use spatial transformer networks (STNs) [27] to classify layout composition elements and finally to realise the recognition and localisation of layout composition elements for learning the layout of selected poster cases and forming the initial layout template. Once the learning of the classification of the layout elements is completed, the element positions can be located. The main function of the generator is to optimise the initial template using the LeNet convolutional neural network. As the class, number, and position of the elements are already determined in the initial template, these parameters are only used to adjust the position of the elements. The final output of the generator is a parameter-optimised template, which is stored in a template library.

The main innovations and contributions of this study include the following:

- (1) In this study, the popular LeNet convolutional neural network is used as the base network architecture and the STN is inserted in its input layer. The STN can be trained together with the LeNet and the original poster case can be automatically detected for spatial transformation during the training process, thus enabling the network model to extract more effective layout composition elements.
- (2) There is a transition state in the spatial evolution process of the layout composition. To address this problem, an angular similarity softmax (A-softmax) loss function is used to replace the original softmax loss function of the LeNet architecture, which aims to make the intra-class distance between layout composition elements of the same category smaller and smaller, while the interclass distance between layout composition elements of different categories becomes larger and larger.

The rest of the study is organised as follows: in Section 2, the poster layout composition approach analysis is studied in

detail, while Section 3 provides the detailed layout composition method based on A-softmax convolutional neural network. Section 4 provides the experiments and analysis of results. Finally, the study is concluded in Section 5.

2. Poster Layout Composition Approach Analysis

2.1. Common Ways of Composing Poster Layouts. There is currently no unified view on the composition of posters in the academic community, so there are various classification methods. This study combines the existing classification methods and summarises the commonly used poster composition methods into the following three types, namely central composition, tilted composition, and three-part composition.

Center composition places the subject on the central axis of the layout. Posters with central composition, with the main body occupying the visual center, quickly attract the attention of the audience, concise layout, and a sense of stability. Three-part composition is to place the text and the main image according to the three-part line of the layout. In the three-part composition, the subject occupies two-thirds and the rest is the text. On the whole, the three-part composition has the effect of highlighting the main body and balancing the layout. In design examples, some poster works may be difficult to be classified into a certain composition method. Because of the disorder of free layout, it is difficult to summarise and define the characteristics of composition. Therefore, to simplify the analysis, this study only studies the layout design of a single composition mode.

2.2. Selection of Layout Adjustment Parameters. At present, the most commonly used layout design method is layout segmentation based on grid system, which is characterised by the use of mathematical calculation to divide the layout, thus guiding the layout of visual elements. In the development of modern design, grid-based layout segmentation is widely used in the field of poster design. Mathematical parameters commonly used in layout design include golden ratio, Fibonacci sequence [28], Vandergraff layout structure principle, and photography three-part method. The ratio of length to width in the golden ratio is about 0.618. In layout design, the most common use is to use golden rectangle to create grid. The three-part method is a composition technique used in photography. The photographer divides the length and width of the shot into three equal parts to form four intersection points and focuses the lens on the intersection points and near the three-point line.

In this study, the golden ratio and the three parts were chosen to optimise the layout template parameters. This is mainly because these two layout composition parameters have a more established and common use in guiding graphic layouts. In particular, when using the golden ratio division in poster layout design, the layout is first divided into golden ratio areas. Then, based on a reasonable reading order, the subject is placed at the visual focal point and the position and size of the elements are adjusted according to the golden

ratio. When using the three parts, the position of the subject is first clarified, and the position of the text is used to determine the position of the subject to achieve different visual effects, such as the left and right placement of images and text, central placement, and diagonal placement.

3. Layout Composition Method Based on A-Softmax Convolutional Neural Network

Poster images present a wide variety of structures. Learning the classification of layout composition elements in poster images is the key to layout composition. However, due to the subjective nature of human extracted features, traditional machine learning methods cannot adequately characterise poster images, and complex layout composition elements are difficult to be fully described. In recent years, convolutional neural networks have been widely used in various image classification tasks due to their adaptive feature hierarchical learning capability. Compared with traditional machine learning methods, the process of feature extraction by convolutional neural networks is much simpler. The features extracted by convolutional neural networks are more capable of characterisation, and the classification accuracy has been substantially improved. Therefore, in this study, an improved LeNet architecture is proposed to achieve automatic classification learning of layout composition elements in poster images. In addition, several optimisation templates are output based on the trained classification network model.

The steps of the layout composition method based on A-softmax convolutional neural network are as follows: 1) the learner learns the layout composition elements categorically using STN to form the initial layout design templates for different composition cases and 2) the generator optimises the initial templates using the golden ratio and trilateration parameters on the basis of LeNet architecture to output multiple design solutions.

Due to the large spatial variation of layout composition elements in poster images, STN is embedded in the input layer of the LeNet as shown in Figure 1. Using STN, the whole network automatically learns more efficient layout composition elements during the training process. A-Softmax loss function is used to supervise the optimisation of the network model, forcing the network model to learn more discriminative layout composition elements and finally obtaining satisfactory classification learning results.

3.1. STN-Based Learner. As mentioned above, the proposed layout composition method is composed of a learner and a generator. The core function of the learner is to identify the classified layout composition elements. The STN is used for the recognition and classification learning of the layout composition elements. The aim is to locate and classify feature elements from an image and to obtain information on the position and size of the elements.

This study uses the popular LeNet convolutional neural network as the base network architecture and inserts an STN into its input layer, which can be trained together with the

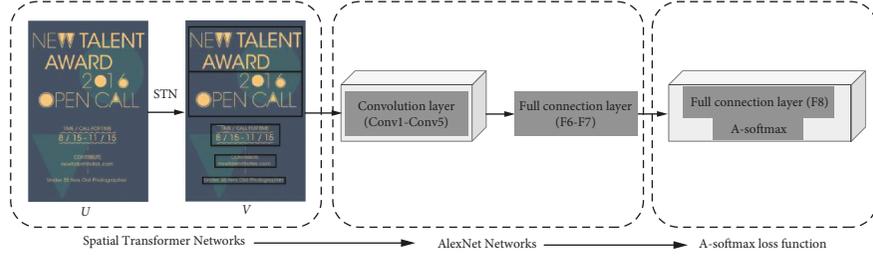

FIGURE 1: Layout composition method based on A-softmax convolutional neural network.

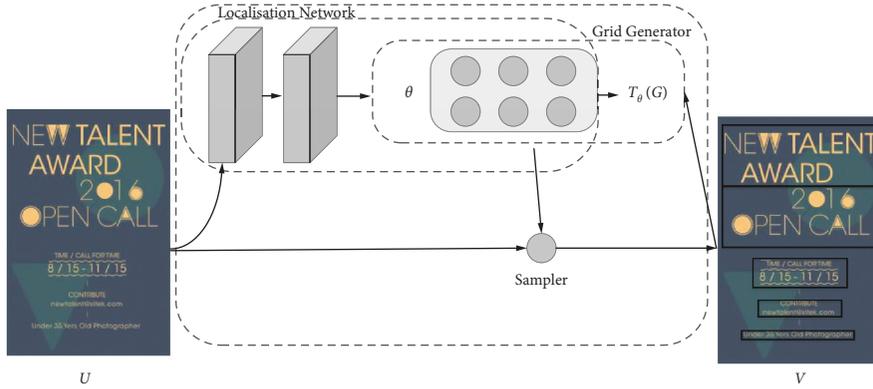

FIGURE 2: Spatial transform network model.

LeNet and can automatically detect the original poster case for spatial transformation during the training process, thus enabling the network model to extract more efficient layout composition elements. As shown in Figure 2, the STN can be divided into three parts.

As shown in Figure 2, the localisation network in the first part is a custom convolutional neural network architecture used to generate 2D affine transformation parameters. The input of learner is an initial set of poster images $U \in \mathbb{R}^{H \times W}$ with a width of H and a height of W . The output is a matrix transformation parameter θ of size $2 * 3$ obtained from the regression layer.

In the second section, the grid generator is used to solve for the mapping of each pixel coordinate with image V and initial image U . The mapping relationship between (x_i^t, y_i^t) and (x_i^s, y_i^s) is shown as follows:

$$(x_i^s, y_i^s) = T_\theta(G_i) = A_\theta \begin{pmatrix} x_i^t \\ y_i^t \\ 1 \end{pmatrix} = \begin{pmatrix} \theta_{11} & \theta_{12} & \theta_{13} \\ \theta_{21} & \theta_{22} & \theta_{23} \end{pmatrix} \begin{pmatrix} x_i^t \\ y_i^t \\ 1 \end{pmatrix}, \quad (1)$$

where T_θ represents the mapping matrix function, which is composed of the transformation parameters θ obtained in the first part. G_i denotes the mapping space grid coordinates. A_θ denotes the transformation matrix.

Finally, the sampler samples the pixel coordinates in the target image using the coordinate results obtained in the second part. Since some of the positions in the mapped initial image may be fractional, the sampling needs to be determined jointly by the other pixel values around that

coordinate, hence the bilinear interpolation method used in this study.

$$V_i = \sum_n \sum_m U_{nm} \max(0, 1 - |x_i^s - m|) \max(0, 1 - |y_i^s - n|), \quad (2)$$

where n and m denote the positions of the surrounding coordinates of the coordinates (x_i^s, y_i^s) in the initial image U , U_{nm} denotes the pixel value at a point in the initial image U , and V_i denotes the sampling value of the target image V at the i th pixel point. The above is the forward propagation process of the STN. Because the network can be trained to learn with a neural network model, the back propagation equation is shown as follows:

$$\frac{\partial V_i}{\partial U_{nm}} = \sum_n \sum_m \max(0, 1 - |x_i^s - m|) \max(0, 1 - |y_i^s - n|). \quad (3)$$

$$\frac{\partial V_i}{\partial x_i^s} = \sum_n \sum_m U_{nm} \max(0, 1 - |x_i^s - n|) \begin{cases} 0 & |m - x_i^s| \geq 1 \\ 1 & m \geq x_i^s \\ -1 & m < x_i^s \end{cases}. \quad (4)$$

Derivation of transformation parameters θ can be obtained as follows:

$$\frac{\partial V_i}{\partial \theta} = \begin{pmatrix} \frac{\partial V_i}{\partial x_i^s} \cdot \frac{\partial x_i^s}{\partial \theta} \\ \frac{\partial V_i}{\partial y_i^s} \cdot \frac{\partial y_i^s}{\partial \theta} \end{pmatrix}. \quad (5)$$

The use of convolution and maximum pooling in traditional CNNs achieves some degree of translation invariance, but the artificially set transformation rules make the network overly dependent on a priori knowledge. As a result, CNNs are neither truly translation-invariant nor feature-invariant to non-artificial geometric transformations such as rotations and distortions. However, the STN with its derivative nature does not require redundant annotation and can adaptively learn how to transform the space for different data. STNs enable spatially invariant classification network models, which have been applied to tasks such as numerical recognition and face recognition.

3.2. LeNet-Based Generator. The final output of the learner is the original layout, while the generator optimises the original layout based on the corresponding optimisation parameters and produces several optimised layout templates. The generator optimises the initial template based on the LeNet architecture using the golden ratio and trilateration parameters to produce multiple optimised templates. The golden ratio is a strictly mathematical and artistic visual feature that is commonly used in layout design, sculpture, painting, and other fields. In layout design, the use of the golden ratio can often help to achieve harmony in the layout. The use of the golden ratio is divided into two main parts: firstly, it is used for the layout of visual elements to optimise their placement; secondly, it is used to adjust the size of text elements to create a logical reading hierarchy. The three-part method is a technique commonly used in painting and photography. The three-part method starts by dividing the image into three equal parts, then placing the focus of the image on the three-quarter line or its intersection, and setting the proportion of the object on the screen according to the different weights.

LeNet convolutional neural networks have powerful image characterisation capabilities and are widely used in many image classification tasks [29]. In this study, the LeNet is used as the base classification network architecture for feature learning of poster images. The network consists of one input layer (input), five convolutional layers (C1~C5), three maximum pooling layers (S1, S2, and S5), and three fully connected layers (F6, F7, and F8), as shown in Figure 3.

Convolution layers are convolved with different types of convolution kernels to extract different features. Three maximum pooling layers are located after C1, C2, and C5 to increase the nonlinearity between features and the spatial invariance of the features. The fully connected layers (F6 and F7) can be progressed to extract more refined features. The final layer (F8) is used to generate the category labels for the posters. In addition, ReLU activation functions are added after each convolutional and fully connected layer for solving the gradient dispersion problem when the network is deeper.

To prevent the network from overfitting during training, dropout layers were added after the two fully connected layers (F6 and F7) to randomly ignore a portion of the neurons. Also, during the training phase of the network, the original poster image with an input size of $256 * 256$ was

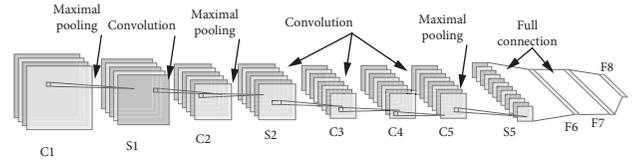

FIGURE 3: LeNet architecture.

randomly cropped ($224 * 224$) in the input layer to enhance the complexity of the data. The network also places the LRN behind the activation functions in layers C1 and C2. The aim is to improve the speed of convergence of the classification network and to enhance the generalisation ability of the network model.

3.3. A-Softmax Loss Function. In machine learning, commonly used loss functions include contrastive loss and triple loss. These two loss functions can reduce the intra-class spacing and increase the interclass distance between classes to a certain extent. However, these two loss functions require a certain degree of selectivity in the training samples, and CNNs are usually used to train large datasets, which is undoubtedly an increased workload and time-consuming. In contrast, the softmax loss function is widely used in many convolutional neural network architectures due to its simplicity and strong classification accuracy.

The original softmax loss function cannot force the intra-class distance between the same classes to become smaller. To effectively address this problem, this study uses angular similarity to extend the softmax loss function to a more general A-softmax loss function. The A-softmax loss function enables smaller intra-class distances between the same classes and larger interclass distances between different classes. In general, when the category label of the i th input feature x_i is y_i , the definition of the loss function is shown as follows:

$$L = \frac{1}{N} \sum_i L_i = \frac{1}{N} \sum_i -\log \left(\frac{e^{f_{y_i}}}{\sum_j e^{f_j}} \right), \quad (6)$$

where N is the number of training samples and f_j is the score vector of the j th category. Since f is the product of the activation function output weight W and the input x_i , f_{y_i} can be written as follows: $f_{y_i} = W_{y_i} x_i$. When ignoring offsets, f_j can also be expressed as follows:

$$f_j = \|W_j\| \|x_i\| \cos(\theta_j), \quad 0 \leq \theta_j \leq \pi, \quad (7)$$

where θ_j is the angle between the weight vector W and the input feature x_i . Thus, the softmax loss function can be expressed as follows:

$$L_i = -\log \left(\frac{e^{\|W_{y_i}\| \|x_i\| \cos(\theta_{y_i})}}{\sum_j e^{\|W_j\| \|x_i\| \cos(\theta_j)}} \right). \quad (8)$$

For a binary classification problem, the original softmax loss function will generally satisfy the condition $\|W_1\| \|x\| \cos(\theta_1) > \|W_2\| \|x\| \cos(\theta_2)$, resulting in the correct

result for the input data x as category 1. However, the A-softmax loss function is motivated by the desire to constrain the above equation more tightly by adding a positive integer variable m . Such a constraint places a higher demand on the process by which the model learns the parameters W_1 and W_2 , resulting in a wider categorical decision boundary between category 1 and category 2. Extending to the more general multiple category classification problem, the A-softmax loss function can be defined as follows:

$$L_i = -\log\left(\frac{e^{\|W_{y_i}\| \|x_i\| \psi(\theta_{y_i})}}{e^{\|W_{y_i}\| \|x_i\| \psi(\theta_{y_i})} + \sum_{j \neq y_i} e^{\|W_j\| \|x_i\| \cos(\theta_j)}}\right), \quad (9)$$

where $\psi(\theta)$ can be expressed as follows:

$$\psi(\theta) = \begin{cases} \cos(m\theta), & 0 < \theta \leq \frac{\pi}{m} \\ D(\theta), & \frac{\pi}{m} < \theta \leq \pi \end{cases}. \quad (10)$$

When $m=1$, the expression of the A-softmax loss function (9) is equivalent to the expression of the original softmax loss function (8). When m is larger, the wider the decision boundary for classification, the more difficult it is for the model to learn. In equation (10), $D(\theta)$ is a monotonically decreasing function used to ensure that $\psi(\theta)$ is a continuous function. To simplify the forward and backward propagation of the A-softmax loss function during training, $\psi(\theta)$ is defined as follows:

$$\psi(\theta) = (-1)^k \cos(m\theta) - 2k, \theta \in \left[\frac{k\pi}{m}, \frac{(k+1)\pi}{m}\right], \quad (11)$$

where k is a positive integer.

To reveal the inherent distance distribution of the poster image data so as to reflect the proximity between features, feature extraction was carried out in this study using the fully connected layer (F7) with a more complete feature abstraction. A simple Euclidean distance formula was used to calculate the distance to the test data, resulting in a distance matrix of $2184 * 2184$. This distance matrix is sometimes referred to as the phase difference matrix and is used to reflect the relative confusion between features. The formula for the Euclidean distance is shown as follows:

$$D(x)_{ij} = \left(\sum_k (x_{ik} - x_{jk})^2\right)^{1/2} \quad k \in [1, 4096], \quad (12)$$

where $D(x)_{ij}$ denotes the Euclidean distance between the i th image and the j th image feature in dataset x . k denotes a particular feature dimension for which the feature vector needs to be computed.

4. Experiments and Analysis of Results

4.1. Experimental Design and Evaluation Indicators. The aim of the experiment was to verify whether the proposed layout composition method could generate a useable design

solution. The experimental design is based on the following idea: first, a product poster case that meets the relevant requirements is selected from the current poster template library of the AI design tool. Then, a learner is used to simulate the target detection model so as to locate the coordinates of the different elements. Secondly, the generator is used to generate output multiple optimised design solutions. Finally, the order of the designed posters is disordered and the simulated design results are left unmarked, allowing the tester to score the unmarked design solutions.

As mentioned above, the A-softmax loss function is used in this study to supervise a network model generated by combining STN and LeNet. The parameter weights are optimised by stochastic gradient descent (SGD) [30] and back propagation principles (BPPs) [31]. The initial learning rate was 0.00003, which was automatically reduced to 0.1 times the initial value after the network model was iterated 5000, 8000, and 12000 times, respectively. The momentum and weight decay were set to 0.9 and 0.0005, respectively. The PC used for the experiments had a 3.8 GHz AMD 5800X CPU, and the system was Windows 10.

Considering that the A-softmax loss function makes it difficult for the network model to converge during the training process, this study adds a decay factor to the learning strategy λ .

$$f_{y_i} = \frac{\lambda \|W_{y_i}\| \|x_i\| \cos(\theta_{y_i}) + \|W_{y_i}\| \|x_i\| \psi(\theta_{y_i})}{1 + \lambda}. \quad (13)$$

The decay factor λ is a large positive integer value at the beginning of the gradient descent. As the number of generations of the network model increases, the value of the decay factor λ decreases and stops at the minimum value. In the experiments in this study, the initial value of λ is 100000 and the minimum value is 15.

No experts or scholars have yet established evaluation criteria for the layout design of posters. To quantitatively analyse the experimental results, a seven-level Likert scale was chosen to obtain the results of five (overall comprehensive evaluation, readability of textual information, consistency of information perception weights, rationality of element placement relationships, and rationality of visual paths) evaluations. The main reason for this is that the Likert scale provides quick access to the test taker's level of agreement with a viewpoint or feeling and is the most commonly used subjective evaluation tool.

4.2. Example of Layout Composition. The posters that meet the filtering criteria are first selected from the poster template library. The filtering criteria include (1) the requirement that the elements do not block or overlap each other; (2) the composition of the poster is a central composition or a three-part composition; (3) the influence of other elements in the poster, such as colour, on the visual perception of the poster layout is as small as possible; and (4) the poster is a solid colour background or a textured background that is less intrusive to the identification of the elements. Although the layout composition method proposed in this study does not take into account the influence of colour elements,

FIGURE 4: Example of a central composition design and its initial template.

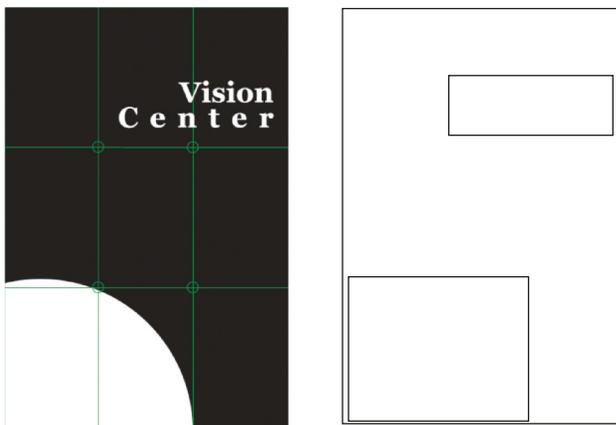

FIGURE 5: Example of a three-part composition design and its initial template.

colour can interfere more with the subjective evaluation of the audience when making an evaluation of the output design scheme. Therefore, the influence of this irrelevant variable on the experimental results should be minimised. Examples of the resulting layout composition are shown in Figures 4 and 5.

After completing the design of the experiment, the experiment used a seven-level Likert scale to obtain the evaluation results. Considering that the purpose of this experiment is to verify whether the output results of the model are useable or not. Therefore, the testers were required to have a certain foundation in design aesthetics, and factors such as the gender and occupation of the testers might have a large impact on the evaluation results, so the variables needed to be controlled reasonably. Ultimately, 55 students from art and design-related majors were selected for this experiment, of which the ratio of male to female was 1:1.

4.3. Analysis of Results. In the experiment, the posters will be presented to the testers randomly to reduce subjectivity. The average score of the 5 different indicator scores will be calculated through the experiment. Higher scores on the

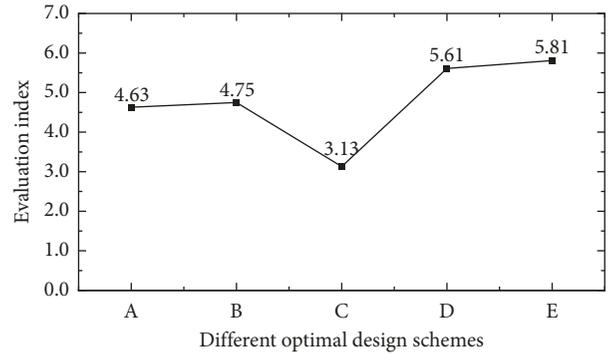

FIGURE 6: Score statistics for overall comprehensive evaluation.

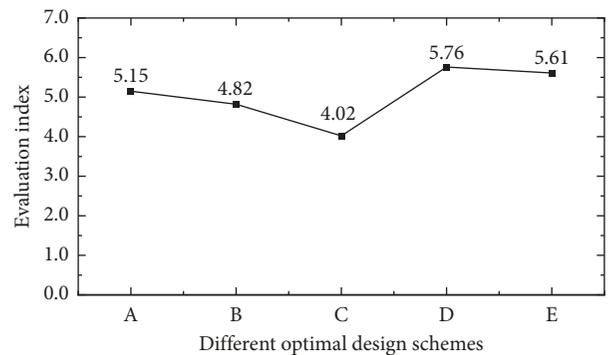

FIGURE 7: Score statistics for readability of textual information score statistics.

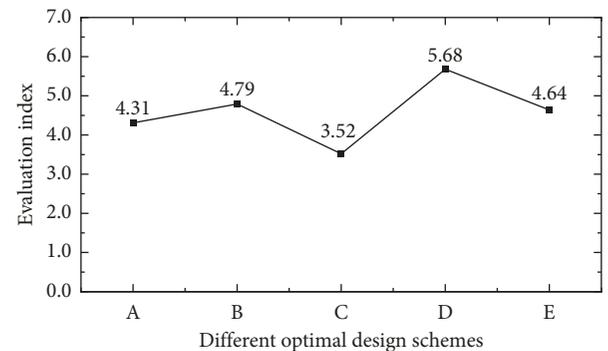

FIGURE 8: Score statistics for consistency of information perception weights.

indicators indicate a more positive evaluation, and lower scores indicate a more negative evaluation. The statistics of the scores for the five indicators are shown in Figure 6 to Figure 10.

As can be seen from Table 1, the A-softmax loss function successfully forces the network model to distinguish between more types of layout constituent elements than the original softmax loss function. As the value of m increases, the average correct rate increases, thus demonstrating the effectiveness of the supervised optimisation network model training with the A-softmax loss function in this study.

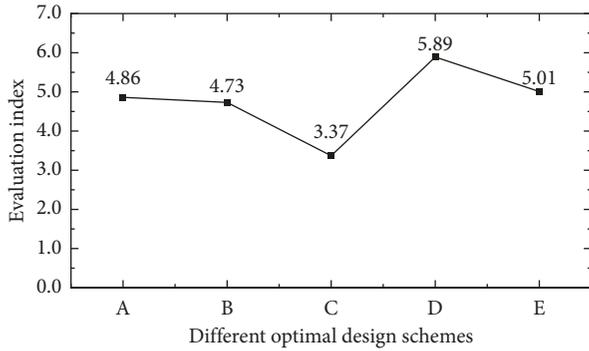

FIGURE 9: Score statistics for rationality of element placement relationships.

the STN + LeNet + A-softmax model proposed in this study was compared with the LeNet, VGGNet [32], and Inception-v4 [33] network models, as shown in Table 3.

5. Conclusion

In this study, a poster layout composition method based on STN + LeNet + A-softmax is proposed. The layout composition method consists of a learner and a generator. The learner learns to classify the layout composition elements using STN and finally realises the recognition and localisation of the layout composition elements to form the initial layout template. The generator uses LeNet convolutional neural network to optimise the initial template, and the final output is the parameter-optimised template. The results show that the combination of the STN and the LeNet allows the network model to extract more effective layout components. At the same time, the A-softmax loss function guides the network model to learn the more discriminative layout elements. Compared with existing methods, STN + LeNet + A-softmax achieves better accuracy [34].

In order to identify the communication law of network public opinion in major public health emergency, a multifactor communication model based on multiagent modeling is proposed. Based on the SEIR model and NetLogo simulation analysis, the model integrates a variety of network public opinion communication characteristics and extends the existing single network public opinion communication model. Based on these studies, a network public opinion communication management system is designed and developed with Python tools. Case analysis and simulation results show that this model can better simulate the evolution trend of network public opinion communication in major public health emergency; the key communication channels of public opinion play an important role in the evolution of network public opinion, which can control and guide the network public opinion of major public health emergency from the three communication influencing factors of total number, initial number, and communication cycle. Communication cycle refers to the number of days in the process of network public opinion dissemination of major public health emergencies.

1. Introduction

At present, the number of netizens in my country accounts for 73.7% of the total population, and the Internet penetration rate exceeds 73% [1]. With the popularization and development of smart mobile terminals and mobile communication technologies, rich and diverse social media platforms have become netizens for information sharing and a gathering place for expressing opinions and emotional exchanges. When public health emergencies occur, public opinion on the Internet also arises, and it may bring serious negative effects. From the 2003 “SARS” virus to the H5N1 virus in 2005, the H1N1 flu in 2009, the H7N9 virus in 2013, and the new coronary pneumonia to today, the derivative accidents caused by public opinion brought about the incidents, reflecting the sudden public emergency in the context of the rapid development of the Internet. The importance of timely response to and

disposal of public opinion on the Internet of health incidents is obvious.

In 2020, there was a large-scale outbreak of COVID-19 pneumonia in China. According to Baidu data, the average daily search frequency of the keyword “COVID-19 pneumonia” reached 300,000 times. As the enthusiasm of netizens gradually rises, there have been more than 700 million participations in public opinion discussions on the “COVID-19 pneumonia” on Internet platforms. In the context of public health emergencies, the facts have been focused, magnified, and distorted due to the failure of online public opinion to study and respond in time. At present, scholars’ research on online public opinion on emergencies mainly focuses on natural disasters, major cases, and social hot spots. There are relatively few studies on Internet public opinion in the context of public health emergencies [2–6]. The analysis process of the functional resonance analysis method (FRAM) is applied to China’s safety supervision

system to classify and evaluate government safety supervision functions [7] and explain the measures taken to reduce risks in the face of the current public health emergency COVID-19 outbreak [8]. After the outbreak of the epidemic, a large number of studies on treatment and response measures were quickly generated for the global pandemic of COVID-19 [9].

Based on this, how to understand and grasp the characteristics, laws, and development trends of public opinion communication of public health emergencies will help the regulatory authorities to study and judge the development trends of public opinions and take active and effective response measures in a timely manner, so as to improve the response to sudden public health emergencies, so as to improve the ability to deal with the network public opinion of major public health emergencies.

Therefore, taking the “COVID-19 pneumonia” as an example to visualize the spread of online public opinion in the context of public health emergencies, through intuitive and vivid data and images to analyze the trend and law of communication public opinion on public health emergencies, it can effectively reflect the law and characteristics of the spread of public opinion on the Internet of public health emergencies. In a quantitative way, the key nodes in the “COVID-19 pneumonia” online public opinion communication network were visually identified and analyzed, and suggestions for the management, control, and guidance of the online public opinion communication of public health emergencies were put forward.

2. Theoretical Basis

2.1. Simulation Platform

2.1.1. Gephi Visualization. Gephi provides for processing any network data that can be represented as nodes and edges and will be presented in the form of graphics images, such as data representing social relationships, information nodes, biology, ecology, physics, and other networks [10–13]. Gephi can not only process large-scale network data sets but also support mainstream network scientific algorithms. It can not only perform statistical analysis on network attributes at the node level but also use different layout algorithms to visualize the network, and it can also simulate dynamic network analysis.

2.1.2. NetLogo Simulation Platform. NetLogo is a multiagent modeling and simulation software, which is used for modeling and simulation of complex systems changing with time. NetLogo was developed by the Center for Connected Learning and Computer-Based Modeling (CCL) of Northwestern University. NetLogo simulation can provide a simple, convenient, and powerful computer tool for scientific research in various fields. Logo language is used to control and coordinate multiple disciplines to meet the needs of studying multidisciplinary laws. The simulation process is shown in Figure 1.

2.2. Online Public Opinion on Public Health Emergencies. In recent years, many public health emergencies have occurred all over the world. In order to efficiently and

reasonably respond to public opinion on public health emergencies, scholars have combined public health incidents to obtain data through Twitter and Facebook and use model construction, empirical analysis, and other methods to carry out related research. Barbara Reynolds believes that public opinion on public health emergencies should be divided into a summary evaluation stage, a calming stage, a crisis stage, a precrisis stage, and an initial stage [14]. Wang et al. summarized the characteristics of online public opinion communication of public health emergencies through case analysis [15]. Haihong et al. proposed a multichannel and multicore model to study the development of online public opinion under public health emergencies [16]. Gaspar et al. believe that different types and stages of crisis response will be different, and the comments made by netizens do not fully represent their attitude [17]. Gomide et al. believe that the development trend of public health emergencies can be monitored through relevant public opinion information on the Twitter platform [18]. Pei et al. believe that, by monitoring the news media on the Weibo platform, it is possible to predict the spread of public health event news and identify early warning signals [19]. Signorini et al. believe that analyzing the content of Twitter users’ posts can provide a basis for timely intervention in the development of public opinion on public health emergencies [20, 21]. The Center for Disease Control and Prevention of the University of Chicago and NORC conducted a network survey of state, regional, and local health departments and concluded that public health emergency preparedness and response to the cooperation of state and local health departments are the key links.

However, most domestic scholars in China choose Baidu Index and Weibo as data sources to conduct research from the perspectives of dividing communication stages, analyzing communication characteristics, and studying communication influencing factors. The “Regulations on Public Health Emergencies and Emergency Responses” believe that public health emergencies refer to infectious disease outbreaks and unexplained mass epidemics, major food poisoning, and occupational poisoning that occur suddenly and cause or may cause major losses to the public health and other public emergencies that endanger public health [22]. Cao and Lu believe that it has the three characteristics of emotional expression of netizens’ opinions, diversified communication subjects, and self-interested media [23]. Teng believes that provinces with more netizens and higher levels of economic development have a higher degree of public opinion attention on public health emergencies [24]. An Lu et al. constructed a topic evolution model for various stakeholders of public health emergencies at different life cycle stages [25]. Lin et al. established a model of factors affecting the spread of public opinion in public health emergencies [26]. Zhou made an overview and analysis of the information problems exposed at each stage of the development of the new crown pneumonia epidemic and put forward countermeasures and suggestions from the perspective of the construction of emergency information management system [27].

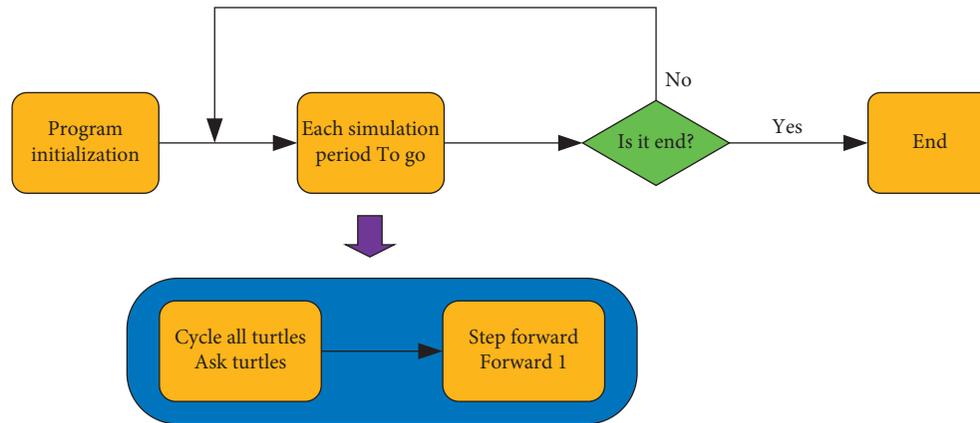

FIGURE 1: Simulation process.

Public opinion on public health emergencies is a form of public opinion on the Internet. On the basis of the scholars dividing the law of the spread of public opinion on the network of emergencies into three, four, or five stages [28, 29], based on the life cycle theory, six rules that conform to the law of spread of public opinion on the Internet of public health emergencies are proposed.

2.3. Influencing Factors of Network Public Opinion Communication

2.3.1. The Total Number of People Involved in Communication. The complexity of the network environment also makes it an influencing variable of public opinion communication. It is reflected not only in the process of personal information exchange but also in the process of emotional communication. Public opinion information communication is usually the product of emotional processing of most people in different cognitive stages. It represents the thoughts and attitudes of Internet users and has a strong cohesion to the related Internet users. Even if people together do not know each other, they may be involved in huge public opinion discussions. These pieces of unconfirmed public opinion information will spread on the network, and gradually spreading, more and more people will spread. Therefore, in the process of network public opinion communication, the more the total number of people involved, the faster the speed of public opinion information communication; the less the total number of people involved, the slower the speed of public opinion information communication. When the total number of people involved in the communication is less, the difficulty of information communication will be greater, so it is difficult to disseminate information. It is believed that public opinion information will not be disseminated, so public opinion will be controlled. Therefore, the total number of people involved in the communication is an important factor affecting the communication of network public opinion.

2.3.2. Number of Initial Spreaders. With the rapid development of network, network public opinion will produce a

lot of public opinion information. Due to the diversity of content in the network environment, in the incubation period of public opinion, the initial communicators publish text, pictures, videos, and other pieces of related content through various social platforms, which will promote the rapid communication of public opinion information and be known by other Internet users. Therefore, the initial communicators of these pieces of public opinion information have strong communication, and in order to attract the attention to increase their own flow or click rate, they will continue to disseminate public opinion information related to major public health emergencies. Therefore, the number of initial communicators of public opinion information will have a certain impact on the process of public opinion communication.

2.3.3. Transmission Cycle. Public opinion communication cycle will also affect major public health emergency network public opinion communication. In the same space, the longer the cycle of public opinion communication, the wider the scope of its communication and the more the Internet users involved in the communication. In a long communication cycle, the heat of public opinion will grow higher and higher over time, and the development of public opinion will be difficult to control. Internet users can browse the news through the network social platform, quickly understand the relevant hot topics of public opinion according to forwarding and comments, and join the network public opinion dissemination. At this time, the network public opinion information will spread rapidly. This kind of communication phenomenon will greatly accelerate the scope of public opinion communication and at the same time make the cycle of public opinion survival in the network longer, resulting in greater difficulty in the control of public opinion.

2.4. SEIR Model. The SEIR model divides the total population into the following four categories: susceptibles, denoted as $S(t)$, indicating the number of people who are not infected but may be infected by virus at t time; exposed, denoted as $E(t)$, meaning the number of people who have been lurked after being infected at t ; infectives, denoted as

$I(t)$, indicating the number of people who have been infected and become patients with infectious force at time t ; recovered, denoted as $R(t)$, meaning the number of people who have recovered from the infected at t moment. If the total population is $P(t)$, then $P(t) = S(t) + I(t) + R(t)$ SEIR differential equation is

$$\begin{cases} \frac{dS}{dt} = -\left(\frac{r\beta IS}{N}\right), \\ \frac{dE}{dt} = \left(\frac{r\beta IS}{N}\right) - \alpha E, \\ \frac{dI}{dt} = \alpha E - \gamma I, \\ \frac{dR}{dt} = \gamma I. \end{cases} \quad (1)$$

In the above equation, α corresponds to the infection probability, β corresponds to the probability that the latent person is converted to an infected person, γ corresponds to the cure probability, and r is the number of people in contact.

The equation essentially reflects the changes of the number of unit time changes of susceptible $S(t)$ latent $E(t)$, infected $I(t)$, and rehabilitation $R(t)$ with time t , and they will affect each other.

3. Law of Network Public Opinion Communication Rules of Major Public Health Emergency

Taking the network public opinion of major public health emergency as the research object and taking “epidemic situation of new corona pneumonia in Wuhan City” as an example, the Gephi visualization tool and case analysis method are used for empirical research.

3.1. Review of Event Development. On December 30, 2019, influenza and related diseases were continuously monitored in Wuhan City, Hubei Province, China. Multiple viral pneumonia cases were found, and all were diagnosed as pneumonia cases with novel coronavirus infection. Since viral pneumonia was found in Wuhan in 2019, it was temporarily named “COVID-19” by the World Health Organization on January 12, 2020. The outbreak was released by WHO as a new coronavirus pneumonia epidemic for major public health emergency of international concern. Later, the Director-General of the World Health Organization, Thadsey, announced that the new coronavirus had become a global pandemic. Table 1 is the review of the epidemic development of “epidemic situation of new corona pneumonia in Wuhan City.”

3.2. Data Source and Processing. Weibo has 212 million monthly active users and is the mainstream platform of China’s social networking platform. This paper uses Sina

Weibo as the data source and the development of online public opinion on the “COVID-19 pneumonia” epidemic as the research object. So far, according to the Baidu Index, Chinese netizens have participated in more than 800,000 daily discussions on public health emergencies, with an average spread of 5,238 items per hour. The daily search volume of high-frequency words such as “infectious disease,” “resumption of work,” “pneumonia,” and “prevention and control” related to this public health emergency reached a total of 4.5 million times. It can be seen from this that the public health emergency of the new type of coronavirus pneumonia has caused great concern among Chinese netizens.

Quantitative analysis is carried out by dividing the important time period of the network communication of this public health emergency, identifying core nodes, and using Gephi to visually analyze the law of communication. Select the number of forwarding data posted by key bloggers on Weibo from December 31, 2019, to March 1, 2020. In the communication of online public opinion information, the higher the number of fans, the greater the influence. Therefore, the key bloggers are identified based on the number of fans, and the Weibo account with the highest number of fans participating in this public health emergency is selected as the key channel for this public opinion communication. Take 5–8 Weibo accounts as the research objects in each communication stage, search for relevant Weibo information according to important time periods and time sequence, and count all the reposts of each Weibo. As of March 1, 2020, a total of 66,000 Weibo accounts with varying degrees of influence, a total of 761,333 original Weibos on the topic of “COVID-19 pneumonia,” and a total of 7,429,838 original Weibo forwarding data on key Weibo accounts have been obtained. Finally, organize the sample data table shown in Table 2. Due to the large amount of data collected in the experiment, after categorizing and counting the data, the Gephi tool is used for visual analysis, and the Gephi tool is used for visual analysis. During the drawing process, the “YifanHu” process is used for layout, and “ForceAtlas2” is used for focus.

3.3. Data Results and Discussion

3.3.1. Division of the Law of Communication Public Opinion on Public Health Emergencies on the Internet. According to the public opinion development process of “COVID-19 pneumonia” in public health emergencies, the forwarding volume of Weibo accounts in key channels of Weibo was selected as the data source, and the development trend of public opinion transmission of “COVID-19 pneumonia” was drawn in units of important time periods, as shown in Figure 1. On the whole, the public opinion of the public health emergency showed obvious stage characteristics, based on the life cycle theory combined with the time span of the public opinion of the public health emergency, the peak point, and many scholars in the early stage. On the basis of the stage division of public opinion, the redivision is in line with the current law of communication public opinion on

TABLE 1: Review of the development of the “COVID-19 pneumonia” epidemic.

Important time period (point)	Event content (situation)
2019.12.31–2020.01.15	On December 31, 2019, an unofficial network circulated a report that “patients with unexplained pneumonia were found”; on December 31, the Wuhan Health and Health Commission notified for the first time that “27 cases were confirmed, but the cause was not clear.” On January 9, the official confirmation, the pathogen was identified as the “COVID-19.”
2020.01.16–2020.01.26	The China centers for disease control and prevention were upgraded to the first-level emergency response (the highest level); subsequently, 30 provinces initiated the first-level response to major public health emergencies; Wuhan City was closed on January 23.
2020.01.27–2020.02.03	Various localities have successively issued notices on strengthening the standardized management of communities during the epidemic prevention and control period; there are too many suspected and confirmed patients, and Fangcang shelter hospitals and Huoshenshan hospitals have been established to treat patients. The WHO has listed the novel coronavirus epidemic as a public health emergency of international concern.
2020.02.04–2020.02.15	On the 11th, the World Health Organization officially named the pneumonia caused by the COVID-19 as COVID-19; Mi Feng, a spokesperson for the National Health Commission, said that, as of the 15th, the proportion of severe cases in Hubei and other provinces in the country has dropped significantly.
2020.02.16–2020.02.23	The epidemic situation in China has gradually improved, and countries outside Japan, South Korea, the United States, Italy, and other countries have begun to break out of COVID-19 pneumonia, causing domestic netizens to discuss again.
2020.02.24–2020.03.01	The new crown pneumonia epidemic has been under control, and China has lowered the emergency response level of the new crown pneumonia epidemic.

public health emergencies; that is, it is divided into six stages developed by using this as a core node is relatively sparse,

TABLE 2: Sample data table of information communication of “COVID-19 pneumonia” Weibo during important time periods.

Period	Number of participating Weibo accounts	Number of original Weibos	Select the number of Weibo accounts	Weibo forwarding volume
2019.12.31–2020.01.15	6743	7186	7	172393
2020.01.16–2020.01.26	90183	152291	6	714913
2020.01.27–2020.02.03	100995	160421	7	2215159
2020.02.04–2020.02.15	122761	180074	5	1665850
2020.02.16–2020.02.23	106618	153423	7	1827211
2020.02.24–2020.03.01	76723	107938	8	834312

of latent, fermentation, outbreak, relief, repetition, and decline, as shown in Figure 2, and is verified through the “COVID-19 pneumonia” analysis.

3.3.2. *Visualized Analysis of the Law of Communication Public Opinion on the Internet of Public Health Emergencies.*

On the basis of the above-mentioned classification of public opinion transmission rules of public health emergencies, Gephi is used to visually analyze the “COVID-19 pneumonia.”

During the incubation period of the first stage, the public is still in a state of understanding public health emergencies from unknown to understanding, and public opinion on the Internet has never occurred until it gradually ferments. At this time, public opinion begins to spread for the first time. After the unidentified pneumonia incident occurred in Wuhan, it can be seen from Figure 3(a) that it was reported as “Headline News,” “People’s Daily,” “CCTV News,” “CCS Open Class,” “People’s Daily Online,” “Xinhua Viewpoint,” Weibo accounts headed by “Xinhuanet” which are used as key communication channels, the communication network

and its influence at this stage is still relatively small.

In the second phase of the fermentation period, after the epidemic was identified as “COVID-19 pneumonia,” as shown in Figure 3(b), it was reported as “CCTV News,” “Headline News,” “People’s Daily,” and “Beijing New.” A large number of fans with scattered core nodes, led by Weibo accounts such as “Central Securities Public Courses” and “People’s Daily Online,” gradually received information. At this time, these Weibo accounts played a key role in attracting the attention of netizens and promoting the development of public opinion.

During the third stage of the outbreak, due to the initial transmission of Chinese netizens through the key communication channels of the previous stage, more netizens have learned about the occurrence of this public health emergency. At this time, the Weibo accounts of these key communication channels are playing a role. They have a great influence. As shown in Figure 3(c), the core nodes, such as “micro-blog secretary,” “micro-blog administrator,” “CCTV news,” “People’s Daily,” “headline news,” “Xinhua viewpoint,” and “He Jiong,” are rapidly expanding the

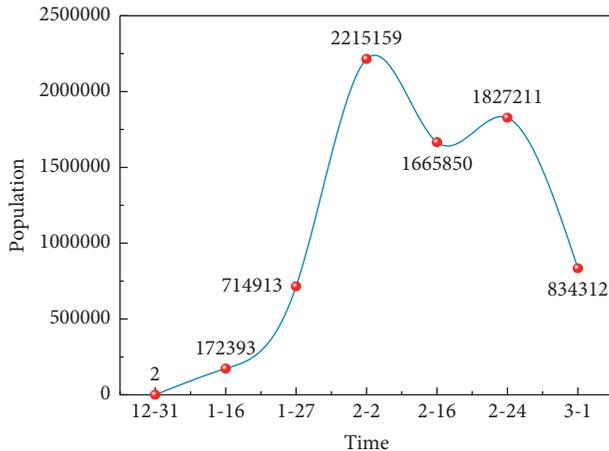

FIGURE 2: The communication trend of public opinion on the Weibo network of “COVID-19 pneumonia.”

network of public opinion communication. The density of the network of the above core nodes is very high, and the number of microblog forwarding and fans increases sharply, resulting in the highest point of network public opinion in this major public health emergency. These key communication channels have exerted a huge influence and a wide range of influence at this stage, pushing the public opinion development of the “COVID-19 pneumonia” public health emergency to the climax.

In the remission period of the fourth stage, in view of the serious public opinion impact caused by the public health emergency “COVID-19 pneumonia,” government departments have spoken out and conducted timely public opinion control, which reversed the perception of netizens. At this time, under the influence of these key communication channels, the development trend of online public opinion gradually stabilized. It can be seen from Figure 3(d) that the scope of the communication network composed of core nodes headed by “People’s Daily,” “Headline News,” “CCTV News,” “Xinhua Viewpoint,” and “people’s Daily Online” has gradually decreased, and the density of the communication network has also been reduced. Gradually decreasing, the public opinion of the “COVID-19 pneumonia” public health emergency at this stage has entered a stable period of remission.

In the fifth stage of the repetitive period, after the development of the previous stage, the development of public opinion should have stabilized. Due to the large number of rumors appearing and communication, under the influence of some key channel Weibo accounts, a large number of core nodes are connected. Fans are gradually increasing as secondary nodes, and the communication network is gradually becoming denser. Netizens’ attention to this public health emergency has risen again. As shown in Figure 3(e), this stage is based on “People’s Daily,” “Headline News,” “CCTV News,” “Xinhua Viewpoint,” and “People’s Daily.” The key communication channels led by “He Jiong” and “Ang Mi” have caused public opinion to show a trend of small climax.

In the sixth phase of the recession period, the heat for this public health emergency has been reduced to a relatively low level through the remission period. Therefore, the online public opinion of the “COVID-19 pneumonia” is about to enter recession and even die out. At this stage of the epidemic, as the epidemic was basically controlled, the panic of netizens was gradually eliminated, making public opinion tend to decline. Figure 3(f) shows that the microblogs are headed by “CCTV News,” “People’s Daily,” “Headline News,” “Xinhua Viewpoint,” “People’s Daily Online,” “Xinhuanet,” “Yao Chen,” and “China News Weekly.” As the core node of the blog account, the spread of public opinion has become smaller, and the density of the spread network has been significantly reduced. The public health emergency “COVID-19 pneumonia” network public opinion has entered a period of decline.

Based on Gephi visualization, it analyzes in detail the communication characteristics and rules of each stage of the public opinion communication network composed of some accounts of the key communication channels of Weibo as the core nodes and the amount of fan reposting as the secondary nodes and analyzes these key communication through visual graphics as shown in Figure 3. The role of channels in each stage of the process of public opinion communication is an empirical study of the proposed public opinion communication law of public health emergencies.

4. Construction of Network Public Opinion Communication Model of Major Public Health Emergency

4.1. Model Construction

4.1.1. SEIR Epidemic Model Hypothesis. When public opinion occurs, most Internet users (except witnesses) do not know about public opinion information, but they will soon obtain relevant information from various channels and make judgments on information. This paper will receive public opinion information that is easy to produce risk perception of Internet users called easy communicators; Internet users who receive public opinion information but are still suspicious of judgment and have not spread it are called carriers; when the perceived risk of public opinion information exceeds its own tolerance, the communication of public opinion information is called the communicator; otherwise the carrier state is maintained. Disseminators become immune under the influence of external factors such as truth or government intervention. With the continuous disclosure of the truth or the continuous emergence of rumors, immune people are affected by the evolution of public opinion and herd mentality and may be reintegrated into the communication of public opinion and become easy communicators.

Considering the complexity and uncertainty of public opinion communication after major public health emergency, the audience classification in the model is expanded and adjusted according to the interaction rules. The SEIR model is assumed as follows.

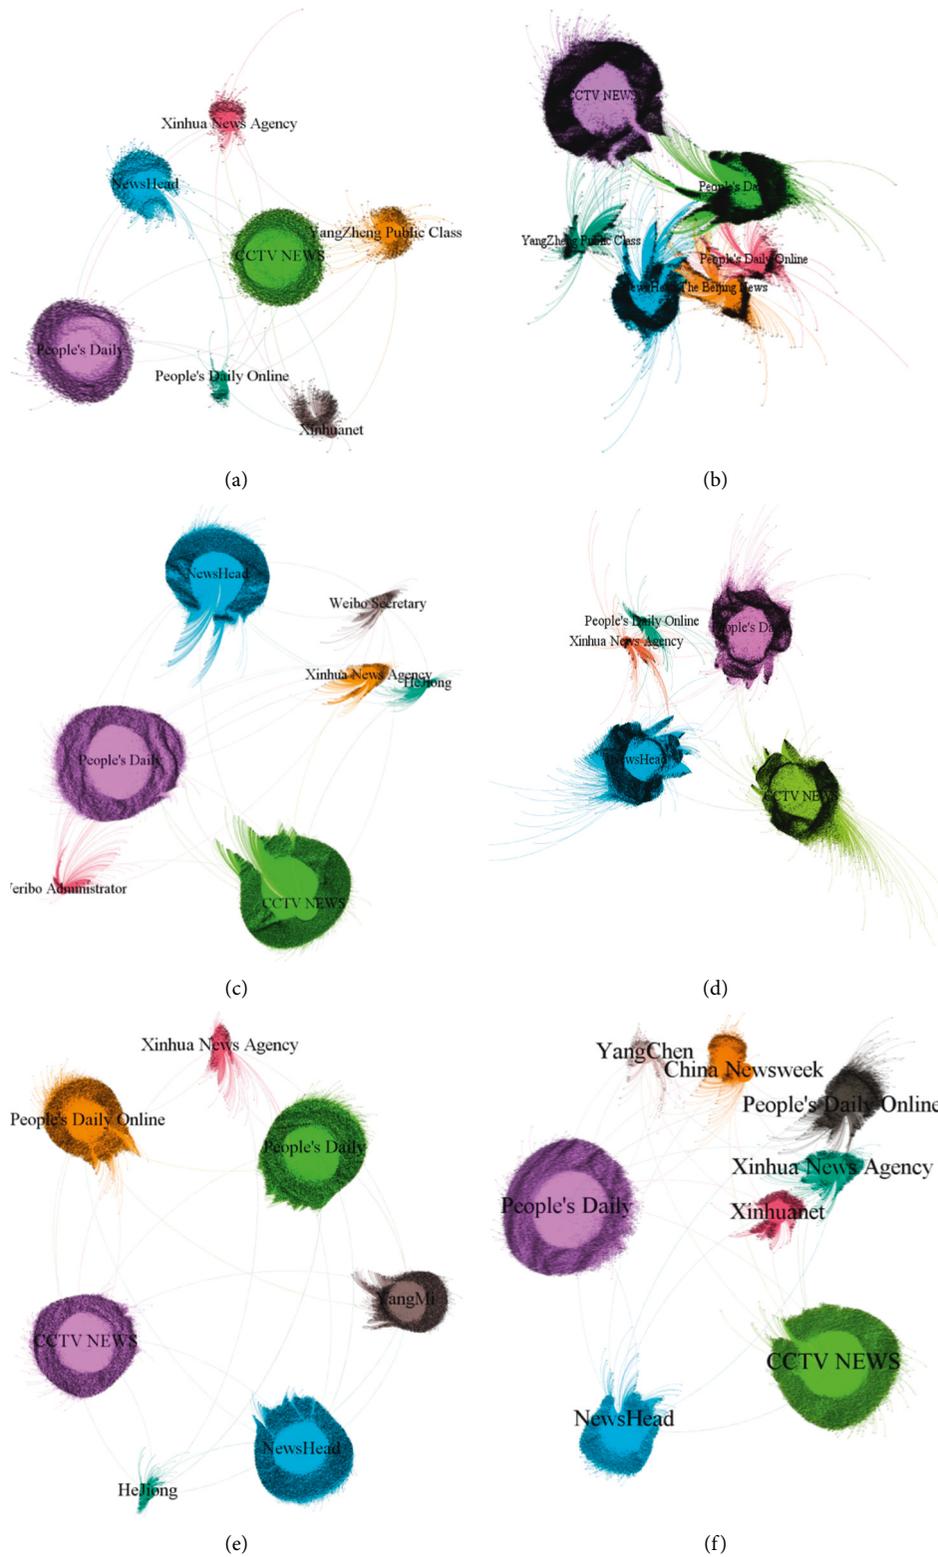

FIGURE 3: The law of the spread of public opinion on public health emergencies on the Internet. (a) Incubation period. (b) Fermentation period. (c) Outbreak period. (d) Remission period. (e) Recurrent period. (f) Decline period.

Hypothesis 1. Considering the long duration of major public health emergency and related information communication, the audience classification in the model is expanded, and the interaction rules are adjusted. The SEIR model is assumed as

follows: the total number of people in the system remains unchanged during this period, and it is assumed to be 1. According to the spread of Internet users, the Internet users are divided into easy communicator S , latent E ,

communicator I , and immune R . $S(t)$, $E(t)$, $I(t)$, and $R(t)$ are, respectively, used to represent the proportion of the four types of people in the total number at time t , which are denoted as S , E , I , and R and satisfy $S + E + I + R = 1$.

Hypothesis 2. Public opinion communication channels are not restricted, including online (network and media) channels and offline (interpersonal) channels.

Hypothesis 3. Each individual has several times of contact with information, but the transition rate between groups remains unchanged.

Hypothesis 4. In the whole communication region, only the behavior of the communicator will endanger the society, and the influence range of public opinion communication is positively correlated with the number of communicators.

4.1.2. Model Construction. According to the above infectious disease characteristics and assumptions of public opinion transmission after major public health emergency, an SEIR infectious disease model of public opinion transmission after major public health emergency is established, as shown in Figure 4.

SEIR differential equation is

$$\begin{cases} S_n &= S_{n-1} - \frac{r\beta I_{n-1} S_{n-1}}{N}, \\ E_n &= E_{n-1} + \frac{r\beta I_{n-1} S_{n-1}}{N} - \alpha E_{n-1}, \\ I_n &= I_{n-1} + \alpha E_{n-1} - \gamma I_{n-1}, \\ R &= nR_{n-1} + \gamma I_{n-1}. \end{cases} \quad (2)$$

In the formula, r is the person that every communicator can reach; α is the conversion rate from easy communicator to latent ones; β is the conversion rate from the latent person to the communicator; γ is the conversion rate from the transmitter to the immune.

4.1.3. Simulation Steps. The simulation software NetLogo is used to simulate the rumor communication model, observe the model trend diagram under different parameters, and analyze the influencing factors of public opinion communication, as shown in Figure 5.

The simulation steps are as follows: Step 1: initialize the parameters. Set a total number of initial communicators, transmission cycle, infection rate α , disease rate β , and cure rate γ . Step 2: click setup application parameters. Step 3: click Go, and then the model runs and continues to simulate. Step 4: observe the real-time curve. Record the “number-time” curve of vulnerable, latent, disseminator, and immune person. Step 5: end the simulation, data collation, and analysis. The

simulated image changes in the simulation process are shown in Figure 6.

4.2. Analysis of Simulation Experiment

4.2.1. Factors Influencing Transmission

(1) The Total Number of People Involved in Communication. In general, it is believed that, in the same limited space, maintaining the same communication cycle, the more the people are, the faster the infection will be. In order to explore the influence of the total number of people involved in the communication of network public opinion in major public health emergency on information communication, we set the total number of people (population = 1000) as the control group and then set the total number of people (population = 2000, 3000, 4000) for the comparative study, so as to maintain the initial number of people and the communication cycle unchanged. The results are shown in Figure 7.

As shown in Figure 8, when $N = 1000$, the disseminator I approximates a horizontal line, which indicates that the number of disseminator I has not increased substantially in limited space, indicating that the number of public opinion disseminators is small, and controlling the development of public opinion is the best time. When $N = 4000$, disseminator I appeared at the earliest time, and this curve rose rapidly. This shows that the heat of public opinion in limited space has risen rapidly. When the relevant departments have not officially released confirmation news, most people have begun to spread information, and the scope of public opinion has begun to expand rapidly.

(2) Number of Initial Communicators. Similarly, in order to explore the influence of the number of initial communicators on the network public opinion communication of major public health emergency and to maintain the same total number of communicators involved and transmission cycle parameters, the number of the initial communicators is adjusted for simulation experiments. The results are shown in Figure 9.

(3) Transmission Cycle. Similarly, in order to explore the influence of communication cycle on the network public opinion communication of major public health emergency, the simulation experiments were carried out by adjusting the communication cycle to maintain the same parameters of the total number of people involved and the initial communicator. The results are shown in Figure 10.

4.2.2. Comparison between Real Cases and Simulation. After processing the data obtained by the crawler, the number of communicators in each stage of the real case is obtained. The number of communicators in the model simulation is the sum of the number of latent E and communicator I . After running NetLogo simulation software, the comparison between real case data and simulation results is shown in Figure 11.

5. Network Public Opinion Communication Management System Design

The emergence of advanced information technology [30, 31] makes the design and development of network public opinion communication management system possible. Based on Python tools [32–35], the overall framework of the network public opinion communication management system is designed as shown in Figure 12.

5.1. Operation Process and System Architecture. Combined with the above research, we will design and implement the system. The modules of the system are divided into information collection module, public opinion content data preprocessing module, major public health emergency network public opinion monitoring module, and major public health emergency network public opinion evaluation module. The system operation logic diagram is shown in Figure 13.

The system architecture is shown in Figure 14.

As shown in Figure 14, the data collection layer adopts the theme crawler technology based on Python language and uses the third-party library BeautifulSoup and Urllib2 package to capture the data on the Weibo platform. The data storage layer adopts MySQL database to store the crawled data in the database. The algorithm execution layer uses Python's NumPy and JS language to bring the preprocessed data into the model established above and calculate the required results. The front-end display layer adopts HTML and CSS to realize the interaction of front-end pages, JS to realize the interaction function, AJAX technology to realize the data interaction with the server, and Echarts to draw the front-end charts.

5.2. Development Environment. The development environment is as follows:

Experimental environment: Intel quad-core processor with 8G memory and 64-bit Windows 10 operating system.

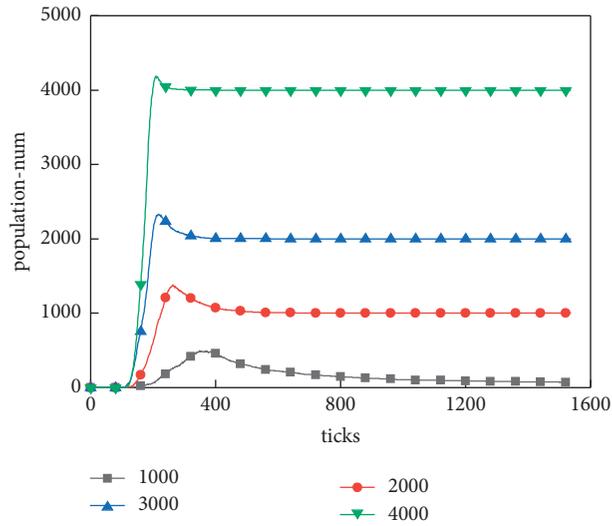

FIGURE 8: Changes in the I-curve of disseminator with different transmissions involving total numbers.

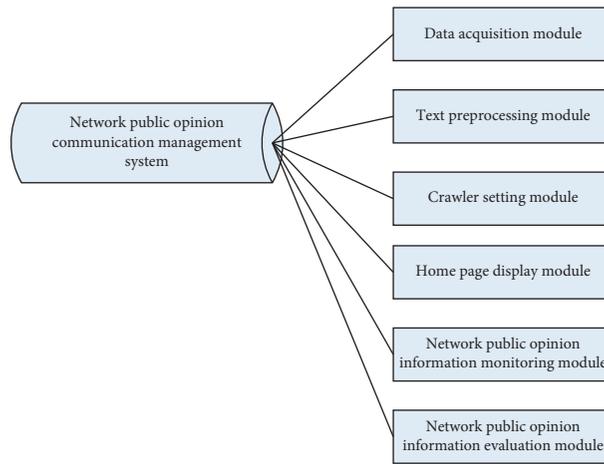

FIGURE 12: The overall framework of network public opinion communication management system.

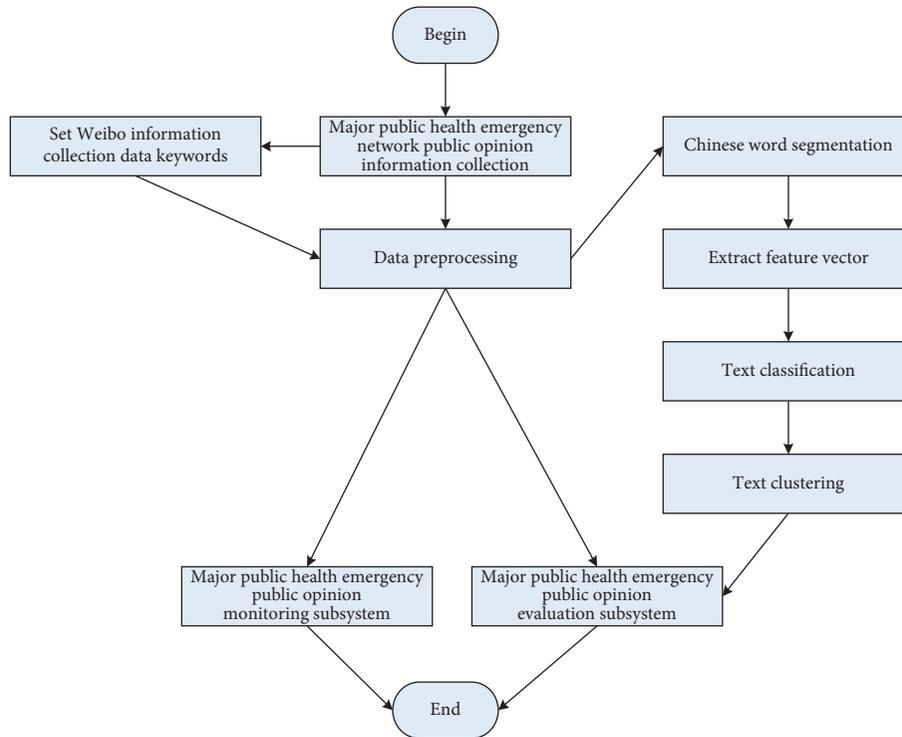

FIGURE 13: The system operation logic design.

Programming languages: Python, Java, HTML, CSS, and JavaScript.

Database: MySQL.

Development tools: PyCharm, Eclipse, and Sublime Text 3.

5.3. Database Design. For the data storage layer of the system, it is the design of the database. According to the above modeling analysis, crawled data, and preprocessed

data, the database of the network public option communication management system is designed. The main data sheets are shown in Tables 3 and 4.

Table 3 is the crawler search major public health emergency history information table. Users can query and research the search history through this table.

After preprocessing the original data, the processed data is stored in the public opinion monitoring table after compiling the monitoring algorithm in the background. The public opinion monitoring table is shown in Table 4.

6. Conclusions and Suggestions

Taking “epidemic situation of new corona pneumonia in Wuhan City” as an example, using Gephi visual analysis, this paper makes an empirical study on the law of network public opinion transmission in line with the current major public health emergency. The specific conclusions are as follows:

- (1) Put forward the law of network public opinion communication of major public health emergency. Based on the life cycle theory, taking the major public health emergency “COVID-19” as an example, and through Gephi visual analysis, the network public opinion communication law of major public health emergency is divided into six stages: latent,

fermentation, outbreak, remission, recurrent, and decline. It provides a new idea for the regulatory authorities to grasp the development law of network public opinion of major public health emergency timely and accurately and judge the possible public opinion crisis.

- (2) Construct a major public health emergency network public opinion communication model. Based on the SEIR model, taking the influencing factors of the network public opinion communication law of major public health emergency as the index, and through the NetLogo simulation, the results show that the total number of people involved in public opinion communication, the initial number of

people involved in public opinion communication, and the communication cycle are the three influencing factors of network public opinion, so as to construct the network public opinion communication law model of major public health emergency.

- (3) Key communication channels play an important role in the development trend of network public opinion in major public health emergency. Among them, “People’s Daily,” “Headline News,” and “CCTV News” are the three Weibo accounts with the largest number of forwarding, the highest number of fans, and the greatest influence. The common users connected with the three Weibo opinion leaders as the core nodes have the widest range of public opinion communication and have played a huge influence in the process of network public opinion communication of major public health emergency. Therefore, in order to prevent the negative impact of network public opinion on major public health emergency, it is necessary to intervene in key food transmission channels timely and effectively.

Epidemic development is the key to the development of network public opinion in major public health emergency. It has been found that the infection and treatment of COVID-19 pneumonia are the core to promote network public opinion. We should pay attention to and choose the appropriate time to intervene and guide the key communication channels with high influence. Through the control of public opinion, we can change the interaction between these key communication channels and Internet users’ forwarding and comments, stop the spread of negative public opinion in time, reduce the spread of rumors, and guide public opinion to the positive.

As a new green solid-state light source, semiconductor light-emitting diodes (LEDs) have the advantages of low power consumption, small size, long life, short response time, and good modulation performance. At the same time, the frequency band to which LED light sources belong does not require regulatory registration, thus alleviating the current problem of spectrum scarcity for wireless communications. However, white LED-based visible light communication (VLC) systems suffer from limited bandwidth and low energy efficiency. Therefore, an ARM-based indoor RGB-LED VLC system is proposed. Firstly, the three RGB colours are mixed into white light, thus obtaining a larger modulation bandwidth than normal white LEDs while illuminating normally. Secondly, the S3C6410 processor is used to modulate and demodulate the RGB-LEDs with biased light OFDM, thus obtaining a high spectrum utilisation while ensuring system transmission stability. Then, according to the characteristics of the light source of the VLC system, the leading and window functions used in the optical network transceiver module are designed to improve the communication energy efficiency of the system. Finally, functional tests were carried out on an ARM development board. The experimental results show that with a single RGB-LED light source, the maximum transmission distance is 5 cm, the maximum average delay is 68 ms, the maximum throughput is 25 Mbps, and the BER is controlled below 3.2×10^{-3} , which meets the basic communication requirements.

1. Introduction

With the advent of the 5G era, the demand for mobile data services is growing exponentially, and the available frequency band resources for RF communications are becoming increasingly scarce. As a result, the visible band, which has a huge bandwidth, is rapidly attracting widespread attention. Semiconductor light-emitting diodes (LEDs), as a new green solid-state light source, have the advantages of low power consumption, small size, long life, short response time, and good modulation performance [1–7]. By simply replacing conventional incandescent lamps with LEDs, the lighting can be transformed into a wireless network transmitter. Furthermore, with the development of conventional wireless communication, the limited radio spectrum resources are becoming increasingly prominent, leading to the issue of spectrum resource utilisation becoming very important.

The frequency band to which LED light sources belong does not require regulatory registration and can alleviate the current shortage of spectrum for wireless communication. Therefore, the use of white LED light sources for indoor lighting for VLC is a current research hotspot in the field of wireless communication at home and abroad. VLC is the use of specific modulation techniques to couple the data signals to be transmitted with light-emitting diodes [8–10]. At the same time, a high-speed modulated light wave signal from the LED device is used to transmit the information. The receiver generates an electrical signal based on the strength of the received light signal via a photodetector, and the signal is restored by the signal processing circuit.

LED-based VLC can greatly broaden the communication spectrum range and is one of the feasible solutions to alleviate the tight wireless spectrum resources. Its advantages are mainly reflected in these aspects [11–13]: (1) the data transmission speed is almost the same as that of optical fiber.

Under certain circumstances, it can transmit data at 1 Gbps. (2) VLC is not limited by spectrum. In contrast to RF wireless communication, VLC technology is able to allocate spectrum resources more scientifically. (3) VLC technology is green and environmentally friendly. VLC technology does not cause harm to the human eye and does not cause signal interference and impact on existing systems. (4) Good confidentiality: VLC technology is not easy to be listened to. (5) The cost is relatively low. VLC-related equipment and systems are very simple to deploy and are well compatible with current RF communication systems.

The above advantages show that if VLC technology can be applied to practical production and life, it will help completely solve the problems of spectrum resource constraint and signal interference. This shows that VLC technology has great potential for application. VLC technology can be perfectly integrated with the network access technology of today's homes. By using LED lighting in the average home as a kind of optical routing, it is possible to provide network access to the home.

VLC is a more energy-efficient and environmentally friendly way of accessing the Internet than mainstream Wi-Fi communication today. In addition, VLC can also be used for indoor positioning technology [14]. By collecting and transmitting the location information of indoor users through inherent indoor lighting devices, the precise positioning of moving people in indoor locations can be achieved. In some special spatial environments, such as aircraft, hospitals, and mines, there are a large number of electronic devices that are more sensitive to electromagnetic waves. In order to prevent serious consequences caused by electromagnetic wave interference, the use of electronic communication equipment in these situations is strictly limited. LED-based VLC is a good solution to these problems, as it does not generate electromagnetic interference.

ARM is a microprocessor with high performance and low power consumption and is favoured by the majority of terminal product manufacturers. The development of ARM terminals has become an important force in the development of information technology and the ARM platform has become the platform of choice for product development in people's lives. The implementation of visible light network access on ARM terminals will certainly greatly facilitate the exchange of information between people. Therefore, an ARM-based indoor VLC system is proposed.

2. Related Studies

VLC technology based on white LEDs is able to achieve both lighting and communication functions at a low cost and is suitable for various network access scenarios. Due to its advantages of being free of electromagnetic interference and green [15], VLC technology has attracted widespread attention and support worldwide.

Research work on VLCs first began in Japan. As early as 2000, Keio University in Japan proposed the feasibility of visible light as a light source for indoor lighting and communication [16]. In 2003, a large group of companies and research institutes formed the VLC Consortium (VLCC)

with the aim of establishing a set of industry standards applicable to VLC. In 2008, the EU developed and implemented the OMEGA project, whose main objective was to study data applications for home access networks with transmission speeds exceeding 1 Gbit/s [17], which includes VLC.

At present, one of the key technologies for LED VLC is modulation, coding, and demodulation. Currently, most VLC systems use intensity modulation (IM) direct detection systems, and most of the coding methods are binary OOK (on-off keying) codes. Xiao et al. [18] proposed a real-time visible light transmission network based on non-return-to-zero on-off keying modulation (NRZ-OOK) with a transmission rate of 550 Mbit/s. Wang et al. [19] proposed a modulation technique based on phase shift Manchester coding (PS-Manchester) and mixed time-frequency equalisation, which used RGB-LED to achieve a higher transmission rate.

The light-emitting mechanism of white LEDs makes their bandwidth limited. As a result, the transmission rate of VLC networks is not very high in the currently implemented application scenarios. In visible communication systems, the core component of the transmitter module is the white LED, which can be divided into three main types: PC-LED, RGB-LED, and UV-LED. The RGB-LED light source is a monochromatic combination of red, green, and blue light in proportion to demand. As technology has evolved, the scope of RGB-LEDs has expanded to include more than just a mixture of red, green, and blue light, and RGB-LEDs can be used to produce the desired white light by combining multiple colours in the right proportions. For this reason, the majority of current research has focused on the use of PC-LEDs and RGB-LEDs as transmitters in VLCs. As the modulation bandwidth of RGB-LEDs is higher than that of PC-LEDs, RGB-LEDs are used in the network access scheme proposed in this paper.

In addition, because OFDM can effectively combat intersymbol interference caused by multipath propagation; its implementation complexity is much less than that of a single-carrier system using an equaliser. Therefore, the use of OFDM modulation technology has good prospects for development.

To meet the demand for green communication, current wireless communication technologies not only focus on improving transmission efficiency but also pay more attention to energy efficiency. Therefore, a lot of research work has been carried out on energy efficiency in VLC systems. Marshoud et al. [20] discussed the effect of different waveforms and modulation methods on LED energy efficiency in VLC systems. Ferreira et al. [21] came up with a new multiobjective optimisation method that allows flexible switching between energy efficiency and spectral efficiency functions. Chen et al. [22] derived a closed-form expression for the energy efficiency-spectral efficiency in VLC systems assuming that the LEDs operate in the linear region.

With its unique performance, VLC has great application prospects in the future. ARM is a microprocessor with the

advantages of high performance and low power consumption, so this paper attempts to combine ARM technology and VLC technology to study the feasibility of network access based on ARM terminals, bringing into play the advantages of both and providing a hardware implementation method for ARM-based VLC systems. This paper attempts to combine ARM technology and VLC technology to investigate the feasibility of network access based on ARM terminals, exploit the advantages of both, and provide a hardware implementation method for ARM-based VLC systems.

The main objective of this research is to increase the transmission bandwidth of VLC systems and improve LED energy efficiency. This paper proposes an ARM-based indoor RGB-LED VLC system. The main innovations and contributions include: (1) considering the large modulation bandwidth of RGB-LEDs compared to ordinary white LEDs and the advantages of OFDM modulation technology with its strong anti-interference capability and high spectrum utilisation, this study attempts to combine RGB-LEDs with OFDM technology in order to improve the system transmission bandwidth; (2) based on the characteristics of the light source of the OFDM-based VLC system, the leading and window functions used in the optical network transceiver module were designed to improve the communication energy efficiency of the system; and (3) an embedded ARM platform was built for OFDM modulation and demodulation to achieve low-cost network access for visible light systems.

3. VLC System Light Source Characteristics

3.1. Operating Principles and Characteristics of LEDs. The LED is a semiconductor structure with an internal PN junction that enables the conversion between electrical energy and light energy [23–25]. Therefore, like normal PN junctions, LEDs have physical characteristics such as forward conduction and reverse cut-off. When the PN junction is subjected to a forward voltage, the holes in the P region flow to the N region, while the electrons in the N region flow into the P region. In the process of flowing, when the electrons in high-energy state collide with holes, the excess energy is radiated out in the form of light. LED's light-emitting principle is shown in Figure 1. LED's light emission is spontaneous, so its directivity is poor. We can gather the light of LED by external devices to improve the received light power at the receiving end.

This paper uses the solid-state power amplifier (SSPA) model to describe the voltammetric characteristics of LEDs, which are PN junctions made of semiconductor materials and therefore have the same voltammetric characteristics as PN junctions. The forward voltammetric characteristics of LEDs can be expressed as follows:

$$I_F = I_s \left(\frac{qV_F}{en kT} - 1 \right), \quad (1)$$

where I_s is the reverse saturation current, q is the electron charge, n is the constant, k is the Boltzmann constant, and T is the thermodynamic temperature.

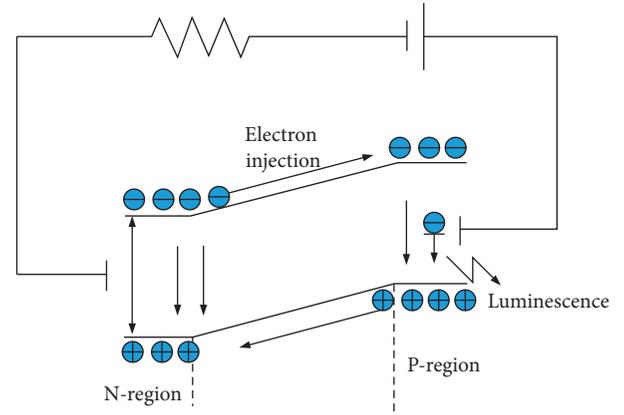

FIGURE 1: Principle of LED light emission.

The operating voltage of LEDs is divided into four regions, namely the reverse breakdown region, the cut-off region, the start-up region, and the operating region. The start and work zones are the positive zones and are the areas that the system design focuses on. The junction between the start and work zones is the LED turn-on voltage. When the forward voltage is applied to both ends of the LED and the working voltage is less than the starting voltage, the LED cannot normally emit light. At this point, the size of the current through the LED is zero. The working voltage of the LED is slowly increased. When the working voltage exceeds the starting voltage, the LED normally emits light. If we apply the reverse voltage to the LED, the LED is in the cut-off zone. If we continue to increase the reverse voltage, it is likely that the PN junction of the LED will be broken down by the reverse voltage. At this point, the critical voltage that breaks through the LED is called the breakdown voltage. When designing the transmitter circuit of a VLC system, we need to design the modulation circuit or signal coupling circuit according to the operating current of the LED.

3.2. Principle and Characteristics of the Receiving LED. For VLC receiver modules, the core device is the photodetector (PD). Photoelectric detection converts light signals into electrical signals by means of the photoelectric effect between substances. By using photodetection, the receiver can smoothly convert the received visible light signal into an electrical signal that can be recognised by the subsequent signal processing circuit. Currently, the most used photodetectors are positive-intrinsic-negative (PIN) photodiodes, avalanche photodiodes (APD), and image sensors [26].

In a multiuser scenario, each user needs a receiver to receive the signal. Although APDs are more sensitive and support a larger bandwidth, cost considerations led this study to use a PIN photodiode as the receiver. The photoreceiver used in the experiments is a silicon PIN photodiode S10784 from Hamamatsu, Japan. The S10784 has a peak wavelength of 660 nm or 780 nm, as well as a fast response time and high sensitivity. The detailed parameters of the silicon PIN S10784 are shown in Table 1.

TABLE 1: Silicon PIN S10784 parameters.

Parameters	Numerical values
Light-sensitive area	3.0 mm ²
Pixel count	1
Maximum reverse bias voltage	20 V
Spectral response range	340~1,040 nm
Peak wavelength	760 nm
Sensitivity	0.51 A/W
Dark current	1,000 pA
Cut-off frequency	250 MHz
Junction capacitance	4.5 pF

4. RGB-LED VLC Principle

4.1. Structure and Principle of RGB-LED. VLC technology uses high-speed signals emitted by LEDs to transmit data. This high-speed signal cannot be recognised by the human eye. On the transmitter side, the process of flashing light and dark LEDs at high speed is the process of sending the information. For example, “light” means “1,” and “dark” means “0.” At the receiving end, the light and dark signals are detected by a corresponding photoelectric detection device. After a series of amplification, filtering, shaping, and other processing, together with mathematical analysis and transformation methods, the information sent by the transmitter can be translated using decoding.

There are two general approaches to white LED formation [27]: PC-LED and RGB-LED. The basic structure of PC-LED is shown in Figure 2. RGB-LED produces the desired white light by mixing the various colours of light, as shown in Figure 3. By mixing the three colours of light at a certain power level, the white light perceived by the human eye is obtained. This method requires a certain electronic circuit to control the mixing ratio of these light colours. Although complex, this method provides the flexibility to obtain the desired light colour with high quantum efficiency.

The colour rendering and radiant luminous efficacy of the RGB-LED are influenced by the three lamps together. In order to make it as close to white as possible, $R_a > 80$ is required and the coordinates ($x=0.33$ and $y=0.33$) are satisfied. After several patchwork proportioning tests, the ratio of the three RGB colours was found to be 1:1.2:1. The specific proportioning data are shown in Table 2.

4.2. Solution Design for the Transmitter Side of RGB-LED VLC Systems. The transmitter side of the RGB-LED-based VLC system designed in this paper consists of an RGB-LED light source module, an RGB-LED driver module, a modulation module, and an adder-coupling module. The adder couples the RGB-LED DC drive voltage with the modulating voltage signal from the signal modulation module, which drives the RGB-LED light source module to emit a light signal loaded with useful information. A schematic diagram of the operation of the transmitter is shown in Figure 4.

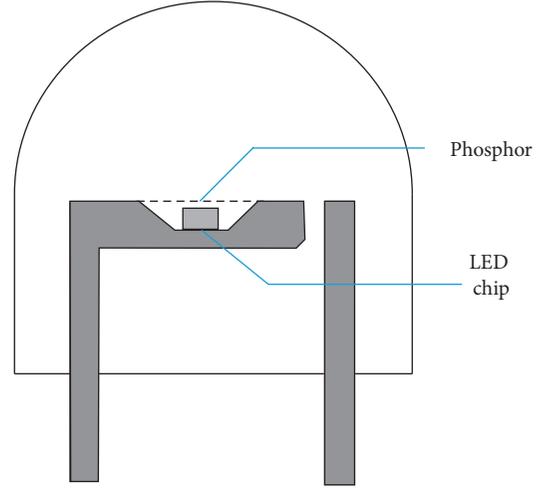

FIGURE 2: Basic structure of the PC-LED.

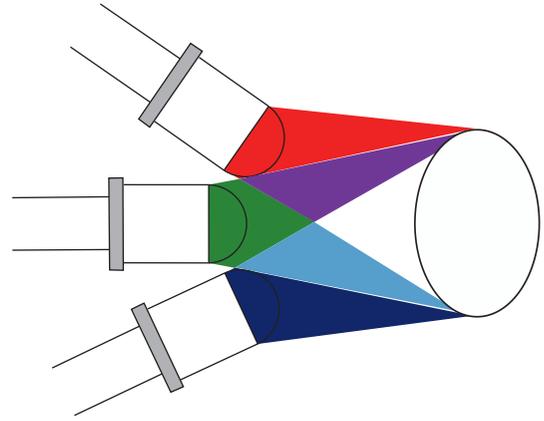

FIGURE 3: Basic structure of the RGB-LED.

5. ARM-Based Indoor RGB-LED VLC System Design

5.1. Geometric Model for Indoor VLC. Unlike traditional communication theory, the channel model in VLC is closely related to the light source, the channel, and the receiver. In this paper, only the direct line of sight (LOS) link between a single LED and a single PD is considered, and the geometrical scenarios for different layouts of indoor LEDs are considered, as shown in Figure 5. In a VLC system, the LOS optical channel can be well described by its DC gain. The channel DC gain g is defined as follows:

$$g = \frac{(m+1)A_{pd}}{2\pi d^2} \cos^m(\varphi) \cos(\theta) T(\theta) G(\theta), \quad (2)$$

where m is the Lambert emission coefficient, A_{pd} represents the effective area of the PD, φ is the angle of light emission, θ is the angle of light incidence, and $T(\theta)$ and $G(\theta)$ represent the gain of the optical filter and concentrator, respectively.

5.2. Biased Optical OFDM Modulation Scheme. In this paper, the biased optical OFDM modulation technique is applied to a VLC system. Firstly, the input binary bit stream is

TABLE 2: RGB trichromatic white LED ratios.

LED	Wavelength (nm)	Spectral bandwidth	Radiant light effect	Energy (W)	Luminous flux
Red	614	20	311.6	1	311.6
Green	546	30	640.9	1.2	769.1
Blue	465	20	54.5	1	54.5

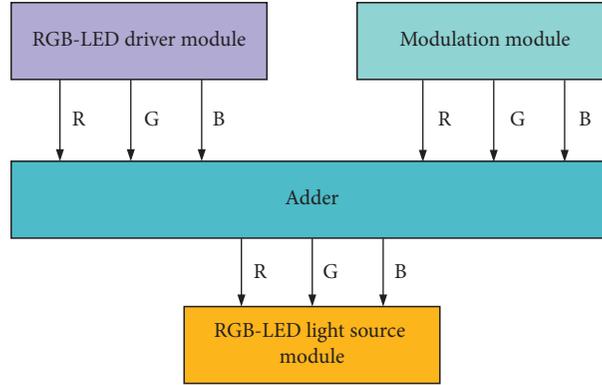

FIGURE 4: Diagram of the system on the sending end.

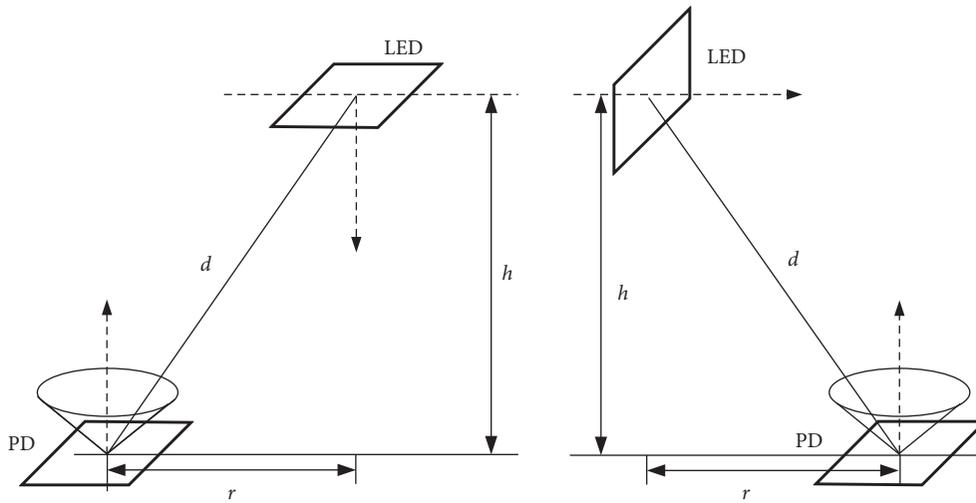

FIGURE 5: Geometric scene with different layouts of indoor LEDs.

modulated by QAM. Secondly, Hermitian symmetry is performed to obtain a frequency domain complex signal as follows:

$$X = [X_0, X_1, \dots, X_{N/2-1}, X_{N/2}, X_{N/2-1}^*, \dots, X_1^*]^T. \quad (3)$$

The Hermitian symmetry operation performed after QAM modulation is to ensure that the signal after the inverse fast Fourier transform (IFFT) operation is a real-valued signal. Without loss of generality, the real-valued OFDM symbol $x_u(n)$ can be expressed as follows:

$$x_u(n) = \sum_{k=0}^{N-1} \frac{X_k}{\sqrt{N}} e^{j2\pi nk/N}, \quad 0 < n < N-1, \quad (4)$$

where N is the total number of subcarriers.

In general, the DC bias voltage x_{DC} is defined as shown as follows [28]:

$$x_{DC} = \frac{U_{TOV} + U_{\max}}{2}, \quad (5)$$

where U_{TOV} is the LED turn-on voltage and U_{\max} is the maximum DC voltage of the LED. After superimposing the DC bias voltage on $x_u(n)$, a positive real-valued signal $x(n)$ is obtained as follows:

$$x(n) = x_u(n) + x_{DC}. \quad (6)$$

The output signal via the LED $y(n)$ can be expressed as follows:

$$y(n) = \frac{f(v_{LED})}{(1 + (f(v_{LED})/i_{\max})^{2t})^{1/2t}}, \quad (7)$$

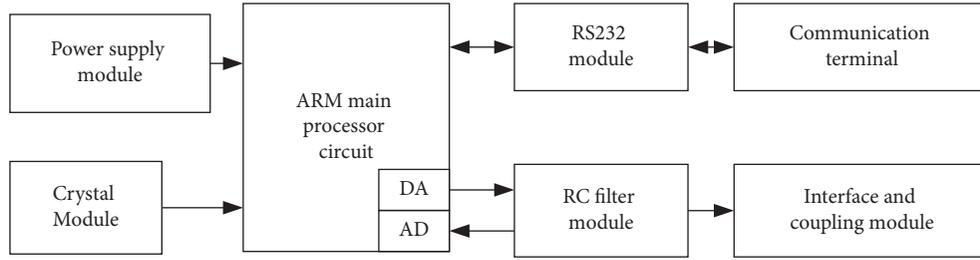

FIGURE 6: General block diagram of the system hardware.

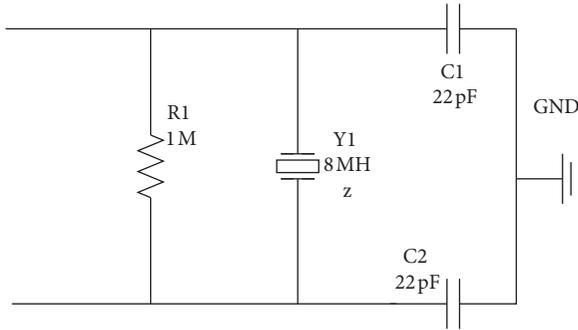

FIGURE 7: Crystal oscillator circuit of 8 M.

where v_{LED} denotes the DC voltage of the LED and $f(v_{LED})$ denotes the DC voltammetric characteristic function of the LED. At the receiver end of a biased optical OFDM VLC system, the signal received by the photodetector PD can be expressed as follows:

$$r(n) = R_{PD} [y(n) \otimes h_c(n)] + z(n), \quad (8)$$

where R_{PD} is the responsiveness of the PD, $h_c(n)$ is the equivalent VLC system channel gain, \otimes represents the convolution operation, and $z(n)$ is the zero-mean additive white Gaussian noise (AWGN). At the receiver end of a biased optical OFDM VLC system, the photodetector PD converts the received optical signal into an electrical signal and then performs the opposite operation to the transmitter end, resulting in a binary signal.

5.3. Block Diagram of the Overall Hardware Architecture.

In order to implement the functions of a biased optical OFDM VLC system, a high-performance processor is required for forward and inverse Fourier transform operations. The S3C6410 processor, based on the high-performance 32 bit ARM1176JZF-S core, was chosen after taking into account performance and cost factors. The ARM processor has lower power consumption and a rich peripheral interface, which is more suitable for OFDM system hardware implementation. The overall block diagram of the system hardware is shown in Figure 6.

5.4. Crystal Circuit Design. The system is powered directly by AC 220 V. In addition, to provide a stable 8 M frequency square wave output, the core S3C6410 processor has an

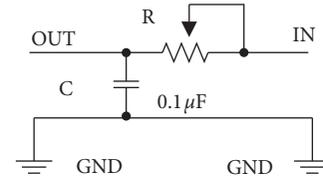

FIGURE 8: Low-pass RC filter circuit.

external 8 M crystal oscillator as the clock signal, as shown in Figure 7.

5.5. Passive Low-Pass RC Filter Circuit Module. In order to perform the necessary noise filtering on the output signal of the system, a passive low-pass RC filter is externally connected to the DA/AD interface, and the modulated OFDM signal frequency f is expressed as follows:

$$f = \frac{1}{(2\pi RC)}, \quad (9)$$

where C indicates the capacitance in this circuit. C is set to $0.1 \mu\text{F}$ in this system. R indicates the resistor in this circuit. A potentiometer is used in this system so that it can be adjusted as required. The low-pass RC filter circuit is shown in Figure 8.

5.6. Design of Leading and Windowing Functions. Energy efficiency is an important indicator in optical communication systems and needs to be maximised wherever possible. Therefore, the improvement of energy efficiency has become a key issue in optical communication systems. Therefore, this paper attempts to design the lead and window functions used in the physical layer based on the biased optical OFDM VLC system to transmit signals only in the over-zero region, so as to improve the communication energy efficiency of the system as much as possible while ensuring the system bandwidth.

In this paper, we try to use only 1/3 of the band, that is, near the over-zero zone, for the transmission of the signal during the entire photoelectric conversion cycle. Because this zone has the lowest background noise and interference, it is the most desirable time slot for communication. Therefore, a constant envelope zero autocorrelation sequence is used as a leading code in order to shorten the frame length. Specifically, a Zadoff–Chu sequence was used, the expression of which is as follows:

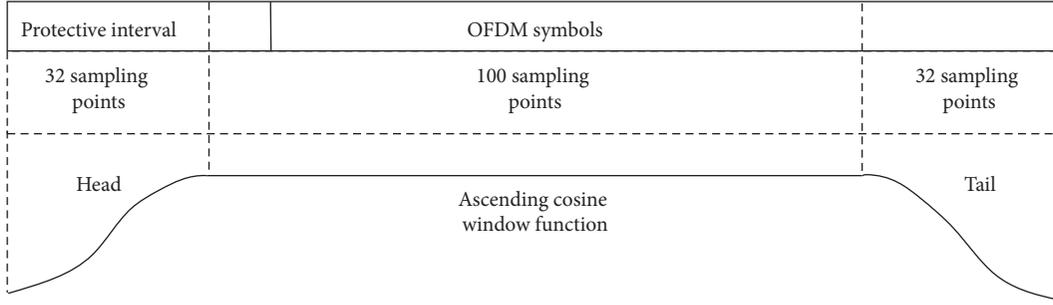

FIGURE 9: Time domain waveform of the window function.

$$a_k = \begin{cases} \exp\left[j2\pi \frac{M}{N} \left(\frac{k(k+1)}{2} + qk\right)\right], & N \text{ is odd.} \\ \exp\left[j2\pi \frac{M}{N} \left(\frac{k^2}{2} + qk\right)\right], & N \text{ is even.} \end{cases}, \quad (10)$$

where $k = 0, 1, \dots, N-1$, N denotes the length of the sequence, M is reciprocal to N , and q denotes a random integer.

The system was designed with a centre frequency of 421 kHz, and a Zadoff–Chu sequence ($N = 30$, $M = 29$, and $q = 15$) was chosen to meet the frame length parameters [29].

In order to window the OFDM signal with the aim of minimising spectral energy leakage, a rising cosine window is generally used, which is defined as follows:

$$w(t) = \begin{cases} 0.5 + 0.5 \cdot \cos\left(\frac{\pi + t\pi}{\beta T_s}\right) & 0 \leq t \leq \beta T_s \\ 1.0 & \beta T_s \leq t \leq T_s \\ 0.5 + 0.5 \cdot \cos\left(\frac{(t - T_s)\pi}{\beta T_s}\right) & T_s \leq t \leq (1 + \beta)T_s \end{cases}, \quad (11)$$

where β indicates the roll-off factor of the added window and T_s indicates the cycle length of the symbol.

In this system, $T_s = 1,174$. The raised cosine window is calculated by discrete time.

$$w(n) = \begin{cases} 0.5 - 0.5 \cdot \cos\left(\frac{\pi \cdot n}{32}\right) & 0 \leq n \leq 31 \\ 1 & 32 \leq n \leq 1141 \\ 0.5 - 0.5 \cdot \cos\left(\frac{\pi \cdot (n - 1174)}{32}\right) & 1142 \leq n \leq 1173 \end{cases}. \quad (12)$$

Therefore, the time domain waveform diagram of the window function used in this system is shown in Figure 9.

DBPSK modulation is used to implement the subcarrier modulation, and the frame length of the system is defined as follows:

$$T_{\text{frame}} = \frac{N_{\text{FFT}} \cdot N_{\text{pre}} + (N_{\text{FFT}} + N_{\text{CP}} - N_{\text{window}}) \cdot (N_{\text{FCH}} + N_{\text{DATA}})}{f_s} \\ = [1024 \times 3 + (1024 + 120 - 32) \times 5] \div (2.0 \times 10^6) \\ = 3.253 \text{ (ms)}, \quad (13)$$

where N_{DATA} indicates the length of the DATA field information, N_{CP} indicates the number of useful subcarriers, N_{window} indicates the number of window cover points, N_{FCH} indicates the number of frame control header symbols, N_{FFT} indicates the number of fast Fourier transform points, N_{pre} indicates the number of leading symbols, and f_s indicates the sampling frequency.

The results from equation (11) show that the frame length of the system is significantly reduced. Combined with the OFDM symbol power spectrogram after windowing, the planned over-zero zone signal transmission is accomplished, thus effectively improving the energy efficiency of data communication.

6. Experimental Results and Analysis

6.1. Experimental Setup. The commissioning process for the transmitter and receiver circuits of the RGB-LED VLC system is as follows:

- (1) First of all, the mechanical performance of each module should be debugged and tested; check whether each module component is well connected to each other, especially whether the installed components are normal
- (2) Check the component power supply and detect if the module is working properly
- (3) Debugging program: burn the written software program into the microcontroller to see if the program makes each module perform the desired function
- (4) Overall system debugging: debug the transmitter and receiver circuits and observe whether the output waveforms of each port meet the circuit requirements through an oscilloscope

After the selection and commissioning of the above system components, the prototype system was finally

completed. The hardware of the indoor RGB-LED VLC system is shown in Figure 10.

6.2. Communication Trials and Performance Tests. Next, the system performance will be tested in terms of the driving voltage, communication distance, light intensity, and BER. As testing the three lights separately would be somewhat repetitive, a single RGB-LED light source is chosen for testing in this paper. The following experimental tests were carried out using blue light as an example. The time domain waveform of the received frame signal at the receiver side is shown in Figure 11. We can see that one frame of the oscilloscope represents $40\mu\text{s}$ and the average period is 3 frames, so the signal frequency is 8.4 kHz.

The results of the drive voltage and light intensity tests are shown in Table 3. As can be seen from Table 3, the voltage drop of the LED is proportional to the light intensity. However, due to the limited carrying voltage of the LED, the maximum light intensity of the LED used in this system is 5,390 lux.

The relationship between the voltage intensity of the blue LED at different distances and the BER is shown in Table 4.

The BER is lowest when the light intensity at the transmitter is 3,370 lux, so the optimum communication

TABLE 4: Distance-light intensity-BER relationship.

Distance (cm)	Light intensity (lux)	BER ($\times 10^{-3}$)
1	4,220	5.2

state for this system is a transmission distance of 1.5 cm and a light intensity of 3,370 lux. The throughput of this system at distances from 1 to 5 cm was tested using a network tester, and the results are shown in Table 5.

With a packet size of 128 bytes and a throughput load of 80%, the system delay performance was tested using a network tester at different distances, and the results are shown in Table 6.

With a packet size of 128 bytes and a throughput load of 80%, the system delay performance was tested using a network tester at different distances, and the results are shown in Table 7.

As a key metric for communication systems, reliability verification is a necessary component of test validation. Using the Monte Carlo method, the ARM-based indoor RGB-LED VLC system was tested 20 times with a data transmission size of 500 frames each. The average BER results of the system are shown in Figure 12.

Overall, at a distance of 5 cm, the system has a packet loss rate of 0%, a maximum average delay of 36 ms, and a maximum throughput of 25 Mbps, all of which meet the actual broadband access requirements. In addition, Figure 12 shows that after -5 dB , the average BER of the system decreases significantly with the increase of the signal-to-noise ratio up to 4.8×10^{-3} level, which can effectively ensure the reliability of communication.

In terms of system energy efficiency, the maximum value of energy efficiency is obtained in the scenario of a horizontal LED layout when the horizontal distance $r = 1.5\text{ cm}$, which is in line with the above results (lowest BER). This is because at this position the LEDs are facing the PD and the PD can

receive most of the light energy; therefore, the maximum system energy efficiency is obtained at this position. In practical system design, the horizontal distance r can be configured according to the requirements of the different layouts of the LEDs. It should be noted, however, that the smaller the horizontal distance r , the more difficult it is to implement a biased light OFDM system.

7. Conclusion

This paper presents an ARM-based indoor RGB-LED VLC system. RGB-LEDs are combined with OFDM technology to implement a VLC system in order to improve the system transmission bandwidth. Based on the characteristics of the light source of the OFDM-based VLC system, the leading and window functions used in the optical network

transceiver module are designed to improve the communication energy efficiency of the system. In addition, an embedded ARM platform was built for OFDM modulation and demodulation to achieve low-cost network access for the visible light system. Experimental results verify the feasibility of the system. The maximum energy efficiency was obtained in the LED horizontal layout scenario when the horizontal distance $r = 1.5$ cm, and the BER was only 4.8×10^{-3} . Overall, at a distance of 5 cm, the system had a packet loss rate of 0%, a maximum average delay of 36 ms, and a maximum throughput of 25 Mbps, all of the above performance indicators meeting the actual broadband access requirements. Further research will be carried out on how to design good LED and PD arrays while increasing the transmission distance and ensuring system stability.

Artificial intelligence and big data, as emerging technologies that have attracted much attention in recent years, have broad application and development space in improving the development of intelligent and refined education in colleges and universities. The application of artificial intelligence and big data to the mental health education practice of college students has a very positive effect on accurately discovering and scientifically solving the mental health problems of college students. In order to combine big data and cloud computing platform organically, this paper introduces an intelligent algorithm based on multi-output support vector regression (MSVR) model and immune clone selection algorithm (ICSA). At the same time, we couple the two to obtain a new intelligent algorithm, namely, immune multiple output support vector regression (ICSA-MSVR) algorithm. Based on the prediction results of health education on students' knowledge and behavior by cloud computing platform, the necessary conditions for three intelligent algorithms to complete the task are summarized. Numerical experimental results show that ICSA-MSVR plays a role in both local search and global search, and is more effective in large-scale cloud computing task scheduling. In addition, in task scheduling, when the task completion time is short, ICSA-MSVR has a lower load imbalance than ICSA and MSVR, which can achieve better load balancing, and the load between virtual machines is closer. Finally, combined with the problems and the needs of students' health education, suggestions are put forward to deepen the application of technology in students' mental health education. This approach can provide corresponding ideas and reference methods for improving the scientificity, pertinence, and effectiveness of mental health education.

1. Introduction

Exercise and health education is an important part of students' knowledge and behavior, and it is an objective daily activity [1, 2]. With the development of technology, the ability to realize its value can be enhanced to a certain extent with the help of big data technology [3, 4]. How to dig, analyze, and use data in a scientific, efficient, and reasonable way, and explore the integration and development of traditional exercise and health education methods with modern information technology have become important means to release the value benefits of health education [5, 6]. In addition, the introduction of big data technology into the vision of health education can not only broaden the way of thinking of health education. This can also effectively

integrate the universality of the use of big data and the specificity of health education, and improve the adaptability and realistic effectiveness of sports health education [7, 8].

Enhancing the applicability and effectiveness of sports health education is a realistic requirement under the new situation, new laws, and new scenarios. This situation is mainly manifested in two aspects.

- (1) It is necessary to promote the renewal and reform of educational carriers here. These methods are aimed at profound changes taking place. Health education needs to strengthen the selection, update, and optimization channels of content resources and implementation methods on the basis of existing carriers, and conduct information dissemination

through normalized, personalized, and efficient carriers. This can effectively promote the achievement of the target effect.

- (2) In addition, this method can optimize the predictive analysis capabilities of education. By combining artificial intelligence methods, we can maximize the advantages of health education.

Strengthening health education is the best path to implement the concept of health first and explore the integration of sports health education and big data, facing new situations, new laws, and new requirements. This is also a topic with outstanding strategic value in the post-epidemic era.

The post-epidemic era not only deepens the connotation of health education, but also puts forward more needs and requirements for it. The application of big data cannot be simply understood as a carrier innovation or technological innovation. The effective release of its series of value benefits requires the use of systematic thinking to make an overall plan for the two and to explore more measures to effectively integrate the two.

Big data is a new stage of informationization, digitalization, and intelligent development, which is both an objective external environment and an important technical carrier for health education. Relying on the new thinking and new concept of modern big data technology [9, 10], it is of distinctive significance and value to solve the methodological problems of health education under the new situation.

Although students entering university tend to be rational and mature in terms of knowledge and mind, due to the lack of deep understanding and experience of reality, they have certain vulnerability in terms of psychological and physical quality, which makes them easy to have mental and physical health problems due to some bad experiences. In the current situation where the pace of life and study pressure continue to increase, the issue of health education has obviously become a prominent problem among college students' groups. Therefore, more and more colleges and universities have incorporated health education into the education system of college students, hoping to enhance their knowledge behavior through professional and targeted health education.

However, the diversity of students' mental states and the lack of resources for health education teachers make it difficult to effectively meet students' individual physical and mental health education needs. This will result in health education often being reduced to a public knowledge curriculum [11, 12]. In such a situation, it is necessary to improve the ability of college teachers to screen, locate, and analyze the health education problems of college students with the help of technology. Artificial intelligence and big data, as the emerging technological content of computer science and technology innovation, can meet exactly this need.

In recent years, colleges and universities have gradually begun to explore the application of artificial intelligence and big data to the practice of college student health education,

so as to enhance the relevance and effectiveness of mental health education [13, 14]. At present, the application of technology is still in the exploration stage, and no systematic and comprehensive application method has been formed.

In addition, in the field of school education, the value of focused data resources is extraordinary. However, due to the complexity of basic data resources, they do not directly serve educational activities, and their value can only be reproduced after certain processing, handling, and analysis. Only by focusing on the key points of exercise and health education and reproducing the value points can we synchronize and integrate the two to serve the educational activities. In other words, we can enhance the ability to achieve the goals of exercise and health education in a way that is driven by big data technology.

For a long time, the student population has shown a marked sensitivity to their psychological problems and is reluctant to talk about them too much. This makes it difficult to carry out mental health education for college students in an open and public way. Artificial intelligence and big data can rely on the functional advantages of the Internet platform, enabling universities and teachers to develop a personalized platform for college students' mental health education by using the Internet as a carrier. This allows students to log in to the system for content understanding and activity participation at any time and from any location on their own, truly eliminating the fear of health education for students.

Based on the above analysis, it is necessary to analyze the impact of health education on the knowledge and behavioral ability of students, especially contemporary college students, from the perspective of big data and cloud computing. This paper intends to introduce a novel big data combined with artificial intelligence approach [15, 16] (based on immune multi-output support vector regression algorithm) and discuss the application of the novel approach in this field from the perspective of health education, in order to provide an idea for future applications of big data and cloud computing.

2. Immune-Based Multi-Output Support Vector Regression Algorithm

With the rapid development of science and technology, big data and cloud computing methods can be seen everywhere for different fields around the world. For example, the aerospace field often uses big data methods to detect tiny damage in equipment. For some nonlinear phenomena or some seemingly irregular situations, the use of big data analysis can often summarize the development trend of such problems and can have a better guiding role for future planning and development. This method is not only applied in the field of science and engineering, but also favored by researchers in the research process of social science. Taking the health education involved in this article as an example, the introduction of cloud computing and big data technology can to a certain extent liberate the traditional teaching mode that only relies on the teacher's name or urging mode. This method starts from the importance of

each student, and reasonably analyzes and predicts the trend of each variable, so that a corresponding teaching mode can be formulated for each individual, and the purpose of teaching students in accordance with their aptitude is truly achieved.

In fact, the realization of big data and cloud computing is also realized on the basis of artificial intelligence or intelligent algorithms. Although big data technology and cloud computing platform seem to be simple in application, the mathematical principles contained in them are very complex. Taking the BP neural network with the simplest principle and the most convenient operation as an example, the calculation of each neuron is obtained by iteration and inversion of a series of nonlinear functions. Although this calculation is complex, with the blessing of computer engineering technology, researchers can obtain a predictable network engineering through code programming. However, it is a huge project for us to turn an initial black box into a practical network project. This requires repeated verification and trial and error to be completed.

Fortunately, with the emergence of artificial intelligence technology, more and more intelligent algorithms are applied in various fields. Compared with the early stage of research, there is only one prediction system, BP neural network, and various optimization algorithms have been introduced. Genetic algorithm is considered to be an effective method to find the optimal solution. The neural network optimized by genetic algorithm improves the solution method of weights and thresholds in its original algorithm, making the whole calculation process more reasonable.

In the process of finding the optimal solution, particle swarm optimization is also applied. Compared with the genetic algorithm, the particle swarm optimization process does not need to set too many parameters in advance. However, before the algorithm is calculated, it requires the researcher to determine the fitness function first, which requires the researcher to have certain prior knowledge.

Compared with the above two optimization algorithms, support vector machine is a new type of calculation method. It shows many unique advantages in solving small sample, nonlinear, and high-dimensional pattern recognition. At the same time, this algorithm can also be extended to other machine learning problems such as function fitting.

In deep learning, support vector machines are supervised learning models related to related learning algorithms. This computational model can be used to analyze data and identify patterns. In addition, it can also be used for classification and regression analysis.

As an upgraded version of the genetic algorithm, the immune algorithm can make up for the shortcomings of the calculation principle inherent in the genetic algorithm. Under the premise of retaining the excellent characteristics of the genetic algorithm, this intelligent algorithm tries to selectively and purposefully use some characteristic information or knowledge in the problem to be solved to suppress the degradation phenomenon in the optimization process.

The immune algorithm simulates the immune process of the human body resisting external antigens through

antibodies. It is a swarm intelligence search algorithm with an iterative process of generate and test. In the complex trial calculation process, this algorithm can maintain global convergence on the premise of retaining the best individuals of the previous generation. Therefore, this artificial intelligence algorithm has strong adaptability.

In the process of studying the influence of health education on students' knowledge behavior, this paper attempts to form a new type of prediction system by coupling support vector machine and immune cloning. In particular, we should focus on combining this coupling algorithm with big data technology and cloud computing platform, in order to make this prediction system more adaptable.

2.1. Multidimensional Output Support Vector Regression.

The support vector machine [17, 18] learning method was proposed by Vapnik et al. based on the theory of statistical learning. For each regression computational problem, they can be represented as establishing a functional mapping relationship between the input and output quantities. Here, we assume that the function is $y(x) = \omega \cdot x + b$, $\{x_i, y_i\}$ ($i = 1, 2, \dots, k$), $\{x_i, y_i\} \in R^d \times R^1$, and allow a certain amount of fitting error to exist by introducing a relaxation factor $\xi_i, \xi_i^* \geq 0$ in accordance with the structural risk minimization principle of statistical learning. In this way, the optimization problem mentioned in the text can be reduced to a minimization problem, and the optimization objective is established with the expression.

$$R(\omega, \xi_i, \xi_i^*) = \frac{1}{2} \|\omega\|^2 + C \sum_{i=1}^k (\xi_i + \xi_i^*), \quad (1)$$

where ω is the fit coefficient; ξ_i, ξ_i^* is the relaxation factor; C is the penalty factor; and k is the sample size.

The Lagrange multiplier method [19, 20] is often used by researchers to solve optimization problems for this convex quadratic optimization problem. The Lagrange function can represent the expression as follows.

$$\begin{aligned} L(\omega, b, \xi_i, \xi_i^*, \alpha_i, \alpha_i^*, \gamma_i, \gamma_i^*) &= \frac{1}{2} \omega \times \omega + C \sum_{i=1}^k (\xi_i + \xi_i^*) \\ &\quad - \sum_{i=1}^k \alpha_i [\xi_i + \varepsilon - y_i + f(x_i)] - \\ &\quad \sum_{i=1}^k \alpha_i^* [\xi_i^* + \varepsilon + y_i - f(x_i)] \\ &\quad - \sum_{i=1}^k (\xi_i \gamma_i + \xi_i^* \gamma_i^*), \end{aligned} \quad (2)$$

where $\alpha_i, \alpha_i^*, \gamma_i, \gamma_i^*$ is the Lagrange coefficient; $\alpha_i, \alpha_i^* \geq 0; \gamma_i, \gamma_i^* \geq 0; i = 1, 2, \dots, k$.

According to the KKT condition, the expression of its pairwise form maximization function can be expressed as follows.

$$W(\alpha_i, \alpha_i^*) = -\frac{1}{2} \sum_{i,j=1}^k (\alpha_i - \alpha_i^*)(\alpha_j - \alpha_j^*)(x_i \cdot x_j) + \sum_{i=1}^k (\alpha_i - \alpha_i^*)y_i - \sum_{i=1}^k (\alpha_i + \alpha_i^*)\varepsilon, \quad (3)$$

where x is the i -th sample input value and x is the j -th sample input value.

Therefore, solving the optimization problem yields the support vector regression model can be expressed as follows.

$$f(x) = \sum_{i=1}^k (\alpha_i - \alpha_i^*)(x, x_i) + b, \quad (4)$$

where x is the input value of the sample to be predicted.

The above analysis is only applicable to linear regression problems. However, for nonlinear regression, many researchers need to introduce a feature space and use a nonlinear mapping to map the data to a high-dimensional feature space for linear regression. In addition, the implementation of this algorithm requires replacing the inner product operation in linear regression with a kernel function in the high-dimensional feature space. The kernel function is defined as follows.

$$K(x_i, x_j) = \phi(x_i) \cdot \phi(x_j), \quad (5)$$

where ϕ represents the nonlinear mapping function.

After the same derivation process as linear regression, we can finally obtain the support vector model fitting function as follows.

$$f(x) = \sum_{i=1}^k (\alpha_i - \alpha_i^*)K(x, x_i) + b. \quad (6)$$

The traditional support vector regression has a one-dimensional variable (SVR) as the output variable. This artificial intelligence algorithm makes its application scenarios limited. In some complex systems, we need to build multi-input-multi-output mapping system to solve the problem. The main reason for this difference is that a 1D SVR does not perform such tasks. Therefore, some research exists to extend the one-dimensional SVR to make it applicable to multidimensional output systems to solve more complex problems in practical engineering.

We extend the one-dimensional insensitive loss function to multiple dimensions. In addition, the loss function can be defined, and its expression is expressed as follows.

$$L(u_i) = \begin{cases} 0, & u_i < \varepsilon \\ (u_i - \varepsilon)^2, & u_i \geq \varepsilon, \end{cases} \quad (7)$$

where $u_i = \|e_i\| = \sqrt{e_i^T e_i}$; $e_i^T = y_i^T - \phi^T(x_i)W - b^T$; $W = [w^1, \dots, w^Q]$; $b = [b^1, \dots, b^Q]^T$, where ϕ is the nonlinear mapping kernel function; x is the sample input row vector; y_i is the sample output row vector $i = 1, \dots, n$; n is the number of samples; and Q is the dimensionality of the output variable.

Based on the loss function shown in the above equation, we can construct the optimization objective function, whose expression can be expressed as follows.

$$L_P(W, b) = \frac{1}{2} \sum_{j=1}^Q \|\omega^j\|^2 + C \sum_{i=1}^n L(u_i). \quad (8)$$

To solve the mathematical optimization problem of multidimensional output support vector regression (MSVR) models, a large number of research results have proposed the use of iterative reweighted least squares (IRSL) to solve the problem.

In the optimization objective function of equation (8), we can approximate the loss function by replacing it with a first-order Taylor expansion.

$$L'_P(W, b) = \frac{1}{2} \sum_{j=1}^Q \|\omega^j\|^2 + C \left(\sum_{i=1}^n L(u_i^k) + \frac{dL(u_i)}{du_i} \Big|_{u_i^k} \frac{(e_i^k)^T}{u_i^k} [e_i - e_i^k] \right). \quad (9)$$

Meanwhile, we can construct a quadratic approximation of equation (9) instead of the original equation form. There are studies that confirm the approximate formula that can be used to represent the relationship between the independent variable and the response variable.

$$\begin{aligned} L''_P(W, b) &= \frac{1}{2} \sum_{j=1}^Q \|\omega^j\|^2 + C \left(\sum_{i=1}^n L(u_i^k) + \frac{dL(u_i)}{du_i} \Big|_{u_i^k} \frac{u_i^2 - (u_i^k)^2}{2u_i^k} \right) \\ &= \frac{1}{2} \sum_{j=1}^Q \|\omega^j\|^2 + \frac{1}{2} \sum_{i=1}^n a_i u_i^2 + CT. \end{aligned} \quad (10)$$

The main reason for using this approximate formulation is that W and b are decoupled in this formulation. This intelligent optimization solution does not require iteration, W and b ; the approximate solutions of W and b can be calculated directly by taking the partial derivatives of W and b equal to 0. After the optimization objective is solved, the objective is to minimize the overall loss of W and b of the sample set. By the above operation, the multi-output support vector regression model is built.

2.2. Selection Algorithm Based on Immune Cloning. The biological immune system is a complex adaptive system. The human immune system is capable of recognizing pathogens and responding to them [21, 22]. The researchers used this mechanism to give this learning system some ability to learn, remember, and pattern recognize. Immune cloning systems can be used to describe the principles and mechanisms of information processing using computer algorithms to solve scientific and engineering problems.

Castro was the first to propose a clonal selection algorithm (ICSA). The algorithm is an intelligent method for solving complex problems inspired by the human immune system and simulating the function and mechanism of action of the biological immune system. It retains several

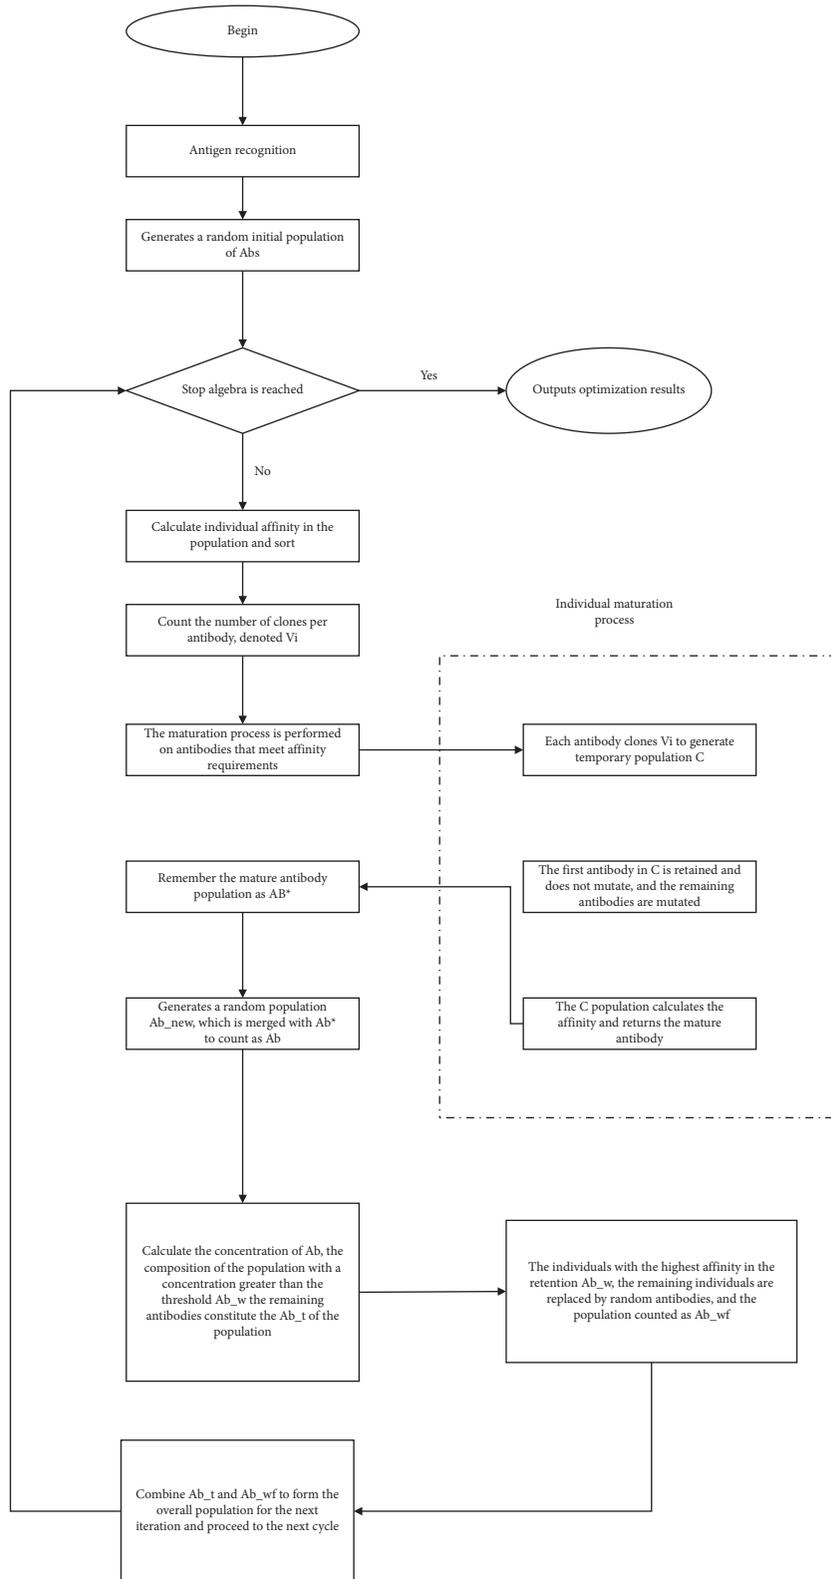

FIGURE 1: Flowchart of ICSA.

characteristics that are characteristic of the biological immune system. The advantages of this algorithm mainly include global search capability, diversity maintainer, extreme robustness, and parallel solving search process. Researchers

can introduce this intelligent algorithm idea into the process of solving optimization problems.

The coupled algorithm introduced in this paper adds a population suppression process to the ICSA to control the

average concentration of the population and avoid premature convergence of the algorithm to a local optimal solution. This operation increases the global optimization capability of the artificial intelligence. The detailed process of the ICSA is shown in Figure 1.

The typical multi-peaked function Rosenbrock function (banana function) [24] is used to test the optimization ability of the improved ICSA. Such function expressions can be expressed as follows.

$$f(X) = \sum_{i=1}^{n-1} \left(100(x_{i+1} - x_i^2)^2 + (1 - x_i)^2 \right), \quad (11)$$

where $X = [x_1, x_2, \dots, x_n] \in \mathbb{R}^N$.

The global minimum point of the Rosenbrock function is obtained when all independent variables take the value of 1, and the minimum value of the function value is 0. We use the 10-element Rosenbrock function to test the optimization effect of the ICSA for multivariate functions. The search interval of the independent variable is $(-10, 10)$, and the algorithm parameters are set in Figure 2. As shown in the figure, NP denotes the number of antibody population sizes, G denotes the maximum number of cycles, and NC represents the number of clones.

We run the optimization algorithm 10 times and find the minimum value point of the function about 4 times. The results of these 10 times of optimization are shown in Figure 3. As shown in Figure 3, the ICSA has good optimization-seeking capability for multidimensional multi-peak functions. This optimization algorithm can be applied to solve the optimization problem of MSVR model and the prediction performance of research health education based on the coupled ICSA-MSVR algorithm.

The main performance is that when the number of numerical experiments exceeds 5 times, the three algorithms show different prediction performances. When there are less than 5 experiments here, the prediction effects of the three algorithms are basically the same.

2.3. Inverse Analysis Method Based on ICSA-MSVR Coupling Algorithm. The values of the control parameters (penalty coefficients C , sensitivity coefficients ε , kernel function parameters σ) need to be specified artificially in the process of MSVR model building. In order to control the parameter values to achieve the minimum sample training error and the best generalization accuracy of the MSVR model, we propose to solve the parameters optimally by using the ICSA.

In the model training phase, the overall error function of the training sample set is defined as the optimization objective, and the error of individual samples is also adopted as the insensitive loss function. The training samples are divided into learning samples and testing samples, and we use the K-fold cross-validation method to calculate the overall sample error. This way the optimization objective function expression is expressed as follows.

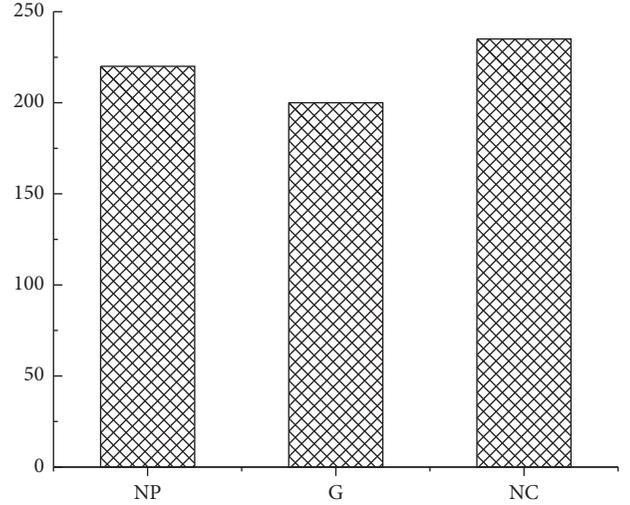

FIGURE 2: Specific application parameters of the ICSA.

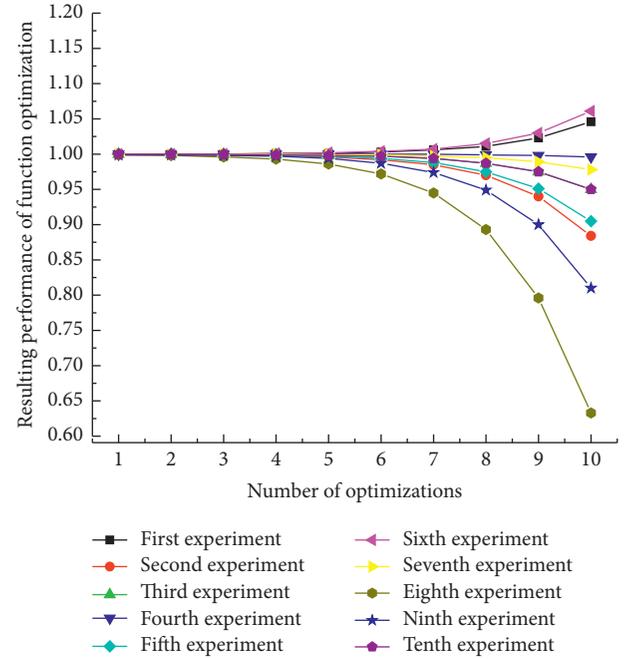

FIGURE 3: Rosenbrock function optimization results.

$$(C^*, \varepsilon^*, \sigma^*) = \arg \min_{C, \varepsilon, \sigma} L_{\text{all}}(C, \varepsilon, \sigma), \quad (12)$$

$$L_{\text{all}}(C, \varepsilon, \sigma) = \sum_{m=1}^k \sum_{i=1}^{k_m} L(u_i),$$

where $L_{\text{all}}(C, \varepsilon, \sigma)$ denotes the overall training loss function; k denotes the number of sample aliquots; k_m denotes the number of training sample aliquots; and the superscript asterisk indicates the optimal parameter.

After the MSVR model is trained, i.e., the optimal MSVR model parameters are optimized by the ICSA. This completes the process of building the prediction model for the positive method inverse analysis process.

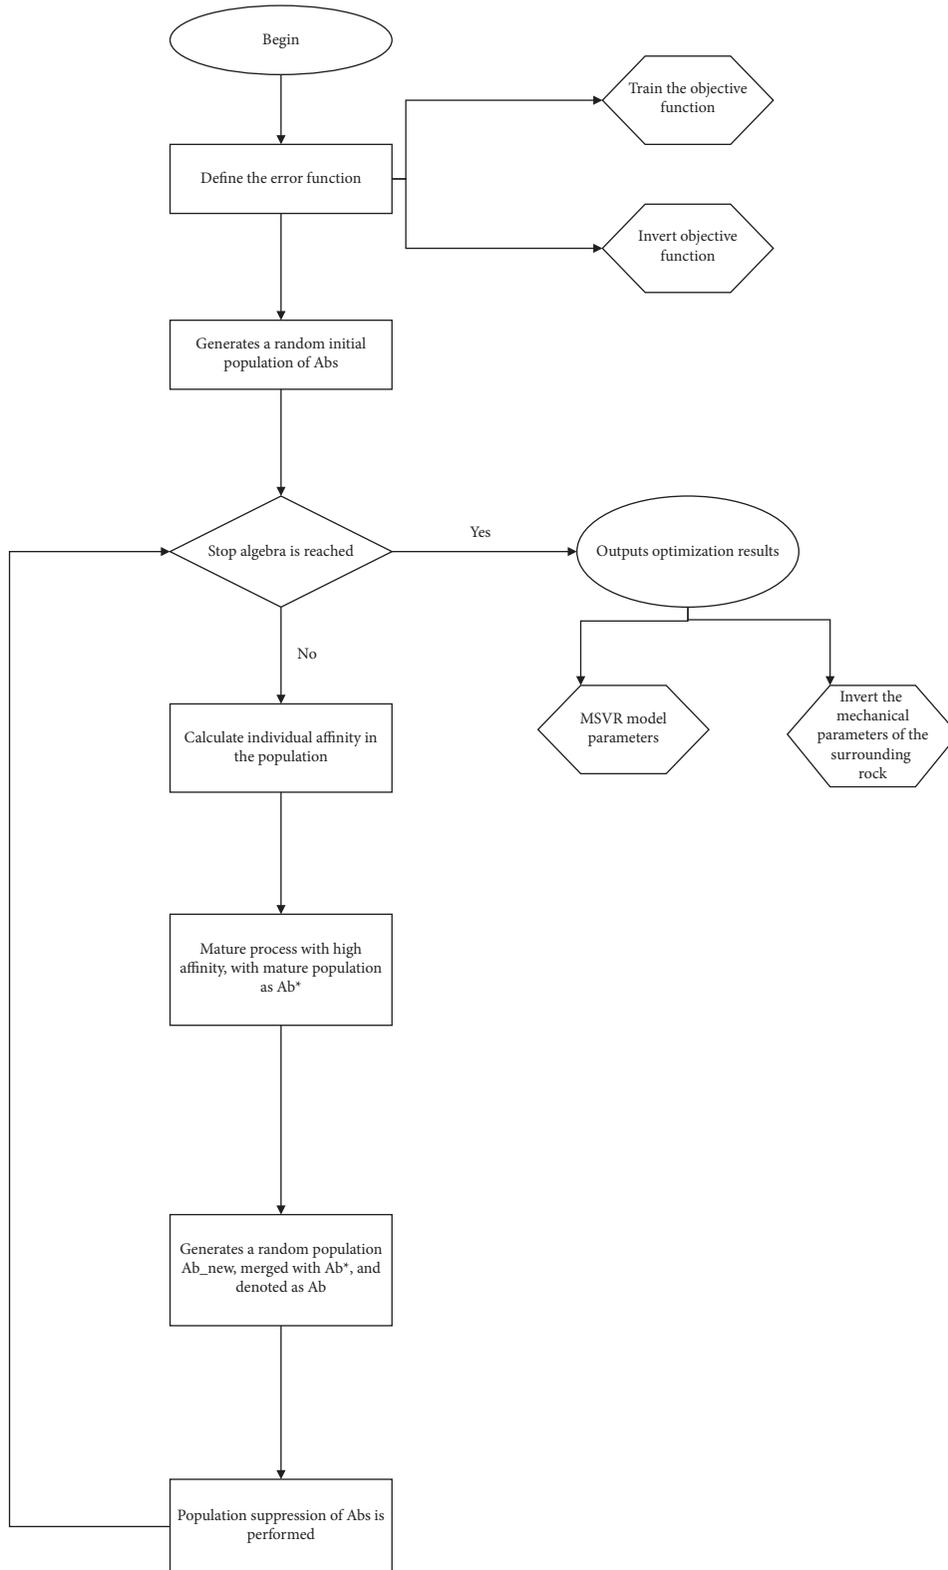

FIGURE 4: The calculation flow of the ICSA-MSVR coupling algorithm.

In the optimization process of the ICSA, in order to expand the search range of the parameters and the search efficiency, we mapped the parameters to be optimized exponentially; i.e., the range of values of the parameters in the

population is the natural logarithm of the actual range of values. In addition, in the actual affinity calculation, the antibody individuals are mapped exponentially, and the calculation formula can be expressed as follows [23, 24].

$$P' = \exp(P). \quad (13)$$

The flow of the coupled IC-SA-MSVR algorithm is shown in Figure 4. This newly introduced AI algorithm differs in the definition of the error function and the resultant output part of the model training process and the parameter identification process.

3. Simulation Results and Analysis

We take the results of a health education prediction for students' knowledge behaviors as an example and compare their task completion through the cloud computing platform. CloudSim is a cloud computing simulation platform jointly developed by the GridLab and Gridbus project at the University of Melbourne, Australia. It focuses on simulating cloud environments and testing the scheduling policies of different service models. To test the effectiveness of this paper's algorithm in cloud computing task scheduling, the CloudSim platform is used under Intel i5 processor, 12 GB RAM, and WINDOWS10 operating system. In this subsection, we compare and analyze the improved algorithm (IC-SA-MSVR), immune cloning algorithm (ICSA), and multidimensional output support vector machine (MSVR) introduced in this paper in three aspects: convergence speed, task completion time, and load imbalance of cloud computing task scheduling.

The strengths and weaknesses of the tested algorithms in terms of convergence speed are mainly reflected in the minimum number of steps to compute the iterations. At the scheduling scale of 200 cloud tasks and 10 VMs, we can compare the convergence speed of IC-SA and ICSA by the relationship between the number of algorithm iterations and task completion time. In the analysis, we set the number of antibody population size to 220 and the number of clones to 235.

As shown in Figure 5, IC-SA-MSVR converges better than ICSA, both IC-SA-MSVR and ICSA converge quickly in the first 100 iterations, and IC-SA-MSVR converges faster than ICSA. In addition, the ability of IC-SA-MSVR algorithm to develop near the optimal solution is improved and the convergence speed of the algorithm is accelerated. Meanwhile, IC-SA-MSVR gradually leveled off after 250 iterations, and the task completion time was less than that of ICSA.

The strengths and weaknesses of the tested algorithms in terms of cloud task completion time are directly reflected in the magnitude of task completion time. We set the number of virtual machines to 10 and the number of cloud tasks to 40, 80, 120, 160, and 200 [25], and then we can compare the task completion time of the three algorithms, IC-SA-MSVR, ICSA, and MSVR, in cloud task scheduling and analyze them. The specific numerical experimental results are shown in Figure 6.

As can be seen in Figure 6, IC-SA-MSVR takes less time for task completion and is better optimized than the other two algorithms. As the number of cloud tasks increases, the task completion time also increases. When the number of tasks is 40, the task completion time of IC-SA-MSVR is 8s and 20s less than that of ICSA and MSVR, respectively. The

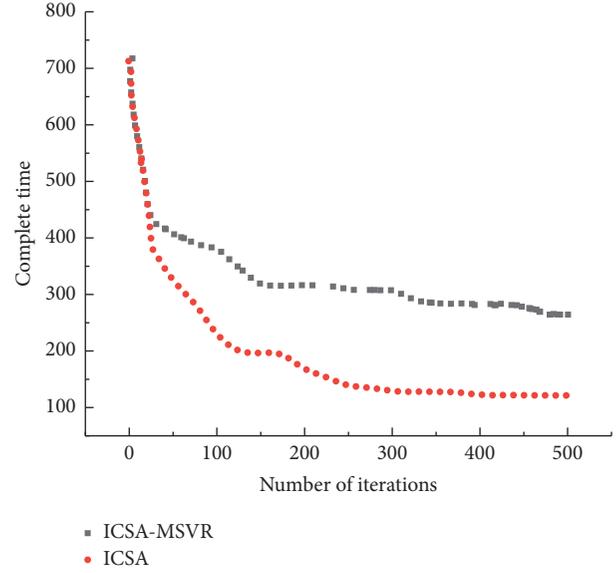

FIGURE 5: Convergence comparison of algorithms.

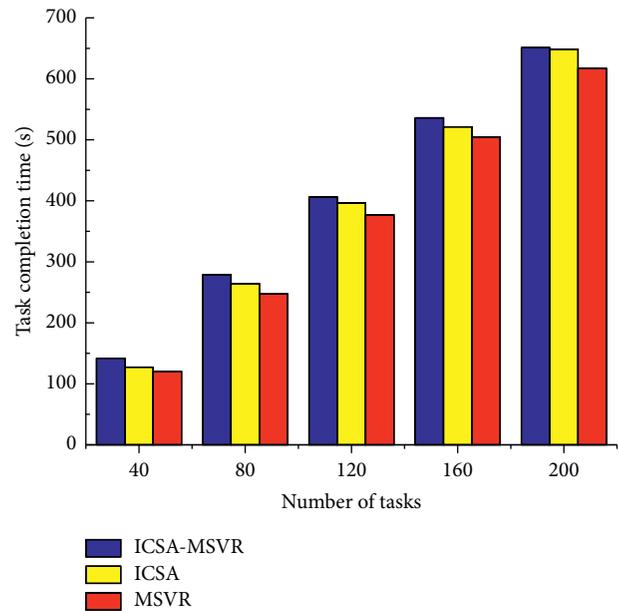

FIGURE 6: Comparison of task completion time.

number of tasks gradually increases, and the task completion time difference of each algorithm increases, and when the number of tasks reaches 200, the task completion time of IC-SA-MSVR is 24s and 35s less than that of ICSA and MSVR, respectively, which decreases by 3.7% and 5.3%. The above analysis results prove that IC-SA-MSVR works in both local search and global search, which is more effective on larger scale cloud computing task scheduling.

What we know is that the degree of load imbalance (DI) of the test algorithm is an important concept, and DI measures the degree of imbalance between virtual machines.

In this paper, we use the standard deviation to represent the imbalance DI. The smaller the DI value, the closer the amount of load among the virtual machines. The better the

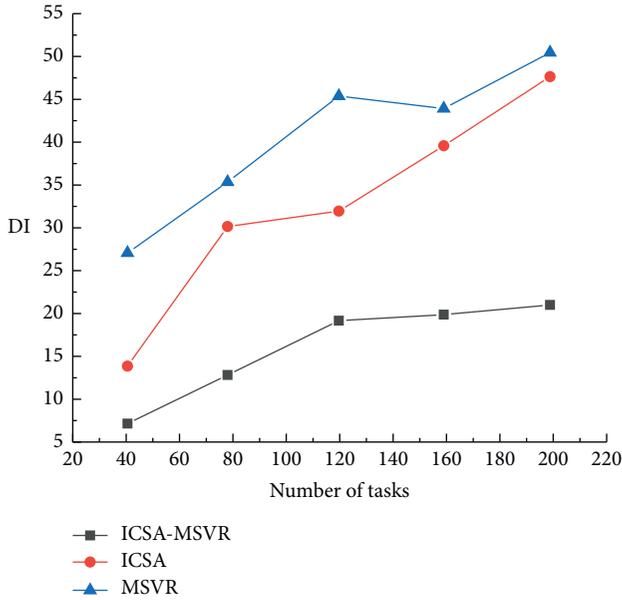

FIGURE 7: Comparison of DI values of the three algorithms.

load balance degree is, the more reasonable the scheduling policy is. The DI is expressed as follows.

$$DI = \sqrt{\frac{\sum_{j=1}^n (\text{Time} - AL)^2}{n}}, \quad (14)$$

where AL is the average load of the virtual machine and is the average task completion time of the virtual machine; Time is the load of the virtual machine; and n is the number of virtual machines.

When the number of cloud tasks is 40, 80, 120, 160, and 200, the load imbalance DI of the three algorithms, ICSA-MSVR, ICSA, and MSVR, is compared and analyzed as shown in Figure 7.

It can be seen from Figure 7 that the DI values of the three algorithms increase as the number of tasks increases, and the DI values of ICSA-MSVR are smaller than those of ICSA and MSVR. This situation indicates that in task scheduling with short task completion time, ICSA-MSVR has lower load imbalance than ICSA and MSVR, which can achieve better load balancing and closer load amount among virtual machines.

To further investigate the effectiveness of the three intelligent algorithms in the application of health education prediction of students' knowledge behavior, the next step is proposed by comparing the coefficient of determination (R^2) and the sum of squared residuals (SSE) of the three algorithms. It is well known that the closer the square of the correlation coefficient (R^2) is to 1, the smaller the sum of squared residuals (SSE) is, and the better the fit is. The R^2 and SSE corresponding to the three algorithms are plotted in Figures 8 and 9.

As can be seen from Figures 8 to 9, compared with the three algorithms, ICSA-MSVR obtained the largest coefficient of determination and the smallest sum of squared

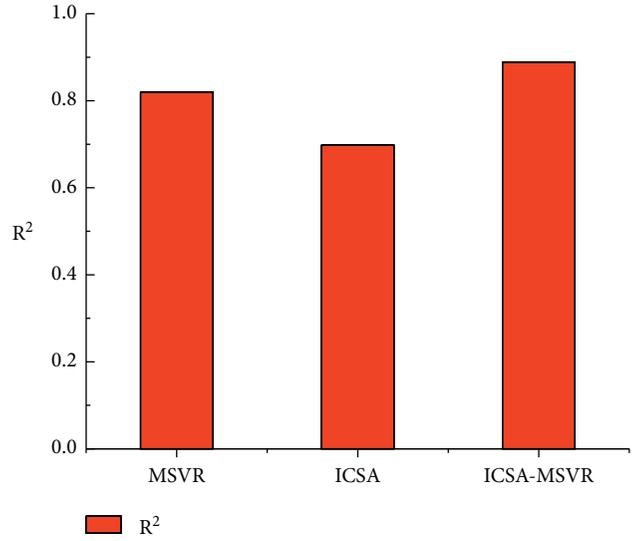

FIGURE 8: Comparison of the coefficients of determination of the three algorithms.

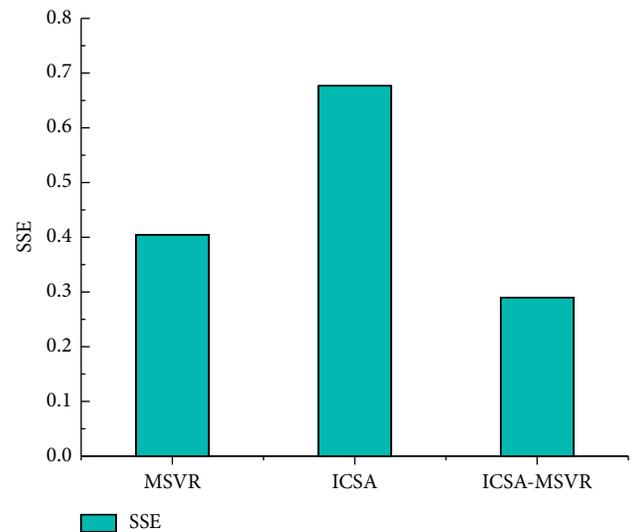

FIGURE 9: Comparison of the residual sum of squares of the three algorithms.

residuals, which can indicate that this method has the relatively best prediction performance.

In addition, we interpolated the predicted performance parameters of ICSA-MSVR for this case using the trajectory interpolation method. The processing results are shown in Figure 10. From Figure 10, we can see that the predicted performance indexes obtained by interpolation have good continuity after the optimization process of the coupled ICSA-MSVR algorithm. This method can provide some theoretical references for the subsequent analytical studies.

We can get from the above simulation case of health education analysis based on cloud computing that artificial intelligence and big data are technical contents that are emphasized and exploited in various fields in recent years, and applying them to mental health education of college

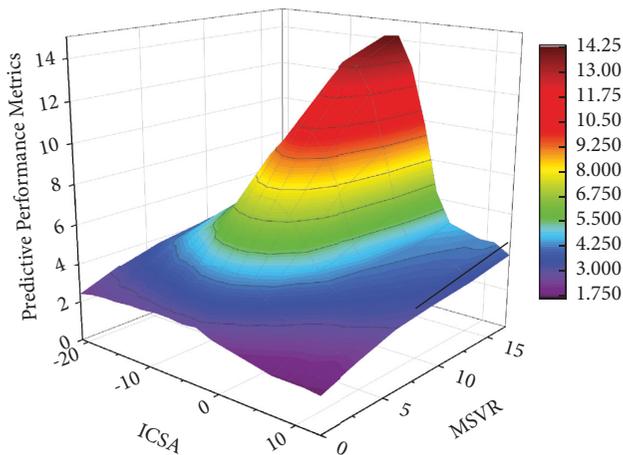

FIGURE 10: Trajectory interpolation results of ICSA-MSVR prediction performance indicators.

students can not only improve the technicality and accuracy of mental health education. At the same time, this method can also solve the current problem of effective teachers' time and energy in mental health education, which makes it difficult to meet students' personalized psychological education needs. The methods introduced above can make health education carried out in a more scientific and effective way.

4. Conclusion

- (1) In this paper, we propose an improved immune clone selection algorithm by adding a population suppression process to improve the convergence to local extrema and the prematureness of the algorithm. After the arithmetic test, the algorithm has good solving ability for multidimensional optimization problems and converges faster. This coupled optimization algorithm can accompany the cloud computing platform to perform certain prediction work on student health education problems.
- (2) Taking a certain health education prediction result for students' knowledge behavior as an example, we test the prediction performance of three algorithms, ICSA-MSVR, ICSA, and MSVR, through the cloud computing platform. The results show that ICSA-MSVR works in both local search and global search, and is more effective in scheduling larger scale cloud computing tasks. In addition, ICSA-MSVR has less load imbalance than ICSA and MSVR in task scheduling with short task completion time, allowing better load balancing. The amount of load is closer between virtual machines. In the meantime, compared with the three algorithms, ICSA-MSVR obtained the largest coefficient of determination and the smallest sum of squared residuals, which can indicate that this method has the relatively best prediction performance.
- (3) Of course, the current research and practice on the application of artificial intelligence and big data in

student health education is still in the exploratory stage, and there are more problems and shortcomings. This requires combining the needs of students' health education and deeply tapping and using the advantages of technologies such as artificial intelligence and big data to truly bring into play the positive functions of technology in education. The combination mechanism of intelligent algorithms introduced in this paper can provide some theoretical reference for such research.

An artificial intelligence (AI) design decision model is constructed to improve the efficiency of design decision evaluation and avoid the influence of the decision preference on product design and development. Using the concept of AI, the proposed model is based on a data set of product modeling design schemes, and the data set is marked with product modeling semantics. The deep learning residual network (ResNet) algorithm is used to train the data set to improve the accuracy of design decisions, transform the general design decision problem into the semantic recognition problem of design scheme images, and eliminate the design decision preference to the greatest extent. The validity and the feasibility of the proposed AI design decision-making method based on the ResNet algorithm are verified via an example of motorcycle modeling design decision-making.

1. Introduction

Modern product design integrates multiple elements such as technology, humanities, art, culture, and commerce. Design is characterized by apparent multi-disciplinary and multi-field intersection [1]. Product innovation design includes three functional units, namely, the problem, solution, and decision [2], and Analysis–Synthesis–Evaluation (ASE) is one of the typical design processes [3]. Design evaluation and decision-making are important components of modern product innovation design [4]. In part, design decisions will be directly related to the success or failure of product design and development.

The decision-making process of modern product design is usually completed by the cooperation of engineers, sales staff, consumers, designers, and enterprise managers. Differences in the cognitive backgrounds, subjective preferences, and experiences of decision-making groups cause the decision-making process to be complicated, vague, and full of uncertainty. Therefore, efficient and accurate design decisions that do not involve the personal preferences of the decision-maker are critical to successful product development [5].

Design decision-making is based on the design evaluation. There are currently three types of design evaluation, namely, experimental, mathematical, and online evaluation. Experimental evaluation primarily analyzes physical and psychological data, such as the visual perception of participants, the way to use the product, and the functional experience of the product, and then explores the product attributes. Common experimental evaluation methods include eye movement experiments [6], EEG experiments [7], and comprehensive experiments including these two methods [8]. Mathematical evaluation mainly involves the setting of evaluation indicators, the construction of evaluation models for quantitative calculation, and the scoring and evaluation of the design schemes. Common mathematical evaluation methods include the analytic hierarchy process [9], the rough set evaluation method [10], neural networks [11], and deep learning models [12]. In online evaluation, data mining technology is mainly used to acquire, cluster, analyze, and mine online user data, and is an inevitable trend in the development of network informatization. Related research methods include the use of big data [13], natural language processing [14], and text mining [15].

Deep learning is a new field of machine learning research, the core of which is a neural network that simulates the information analysis and processing of the human brain. In recent years, it has achieved great success in the fields of image and language recognition, autonomous driving, and medical care [16]. Based on the basic concepts of artificial intelligence (AI), in this study, a product group data set with product design semantics is constructed, and the data set is artificially labeled. The data set is continuously trained by deep learning algorithms, and the product design decisions are realized by AI methods. This improves the design decision accuracy and efficiency, and eliminates the decision bias.

2. Related Theories

The product design process begins with the input of the user's needs. Designers and engineers comprehensively deduce relevant design resources, design strategies, design constraints, and design methods to promote the execution of the design behaviors and the solidification of the design results. The final output is user satisfaction. When designing products, designers must analyze the user's needs based on their own knowledge reserves and experience, propose solutions and conduct comprehensive evaluations, and realize the conversion between design processes via design decisions. Design decisions are constantly iterated to finalize the design for the market.

2.1. Product Design Semantics and Design Decisions. Each product has or conveys different product semantics, via which the image characteristics of products in different usage scenarios are studied. Semantic communication between people and products is achieved through continuous iteration in the design process [17]. Via a communication method built between people and products, the product connotation, form, structure, color, and other elements are transmitted to users so that they can form a certain cognitive image of the product. Generally, in the early stage of product design, the design entrusting party or design developer will propose specific development tasks according to the product positioning, user needs, brand strategy, marketing strategy, etc. The semantic vocabulary of product design is a specific description provided before new product design and development. For example, the client will use a clear semantic vocabulary of shape and color to semantically describe the expectations of the new product, and the design team will use this semantic vocabulary as an important design input to guide the design process until a satisfactory design solution is obtained.

During the product design process, the product design plan will be analyzed, communicated, and evaluated many times, and the final design plan will be obtained via the selection and design decisions of Party A and the design expert team. Throughout this process, product design semantics are an important basis for design decisions. According to the product design process, product design semantics are proposed at the beginning of product design and development, and are communicated to designers via a

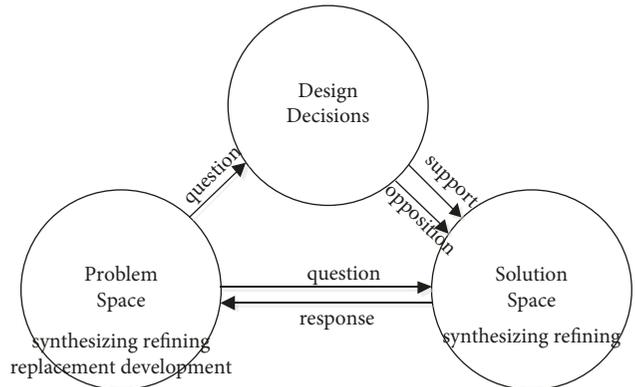

FIGURE 1: The semantic model of the problem space–design decision–solution space.

design semantic vocabulary. The design team parses and expresses the design semantic information based on their design knowledge, experience, and tools. Design brainstorming, conceptual design optimization, and detailed design proposals are then used to interpret the scheme, and the decision-making evaluation of the design scheme is carried out via the semantic matching degree between the design scheme and the design goal [18].

2.2. Semantic Model of Product Design Decisions. The process of product design is accompanied by solutions to different design problems. The solution process includes the initial state of the problem, the target state, and the solution strategy [19], and roughly undergoes the stages of sketch conception, conceptual design, scheme design, detailed design, and design refinement. Constant revision and adjustment are required to form a satisfactory solution for users. This process is the co-progression of design problems and design solutions with a basis on design decisions [20], which links the problem space and the solution space. Based on the principle of semantic models, the interrelationships between the design problem space, design decision space, and solution space were constructed (Figure 1), as were nine semantic connections used to describe the product design decision problems, namely, synthesis, refinement, substitution, expansion, questioning, support, opposition, prompt, and response.

- (i) Problem space. The problem space is used to reflect on the user needs. When user needs are not met, the problem space questions the solution space and design decisions.
- (ii) Design decisions. The design decision is the screening of the solution of the design problem, and the solution space is formed by supporting or opposing one or multiple solutions.
- (iii) Solution space. A solution space is a collection of solutions designed by designers for user needs. For any problem in the design process, the solution space must respond to it. The elements in the solution space can be further refined and synthesized to form a new solution set.

2.3. AI and Image Recognition. In the field of image recognition and processing, AI technology, including graphic preprocessing, graphic segmentation, graphic feature extraction, and judgment matching, has become relatively mature. Machines can preprocess, analyze, and judge a target image to identify various objects or targets. The field of deep learning mainly includes the use of convolutional neural networks (CNNs) and generative adversarial networks (GANs). Neural network research originated from the field of biology. In 1998, Fukushima [21] constructed a neural cognitive machine composed of alternating simple and complex cell layers, which was considered to be the first engineering implementation of CNNs. A GAN is a generative model proposed by Kim et al. [22] in 2014. For neural networks, with the increase in the number of network layers, the training difficulty of learning algorithms such as CNNs and deep neural networks (DNNs) increases, and ideal model training results cannot be obtained. Using the residual learning framework, He et al. [23] proposed the residual neural network (ResNet) algorithm, which overcomes the increase of the training difficulty of the network with the deepening of the network, thereby allowing the number of network layers to reach new heights.

In the product design stage, the analysis, communication, display, and evaluation of the design scheme are usually carried out in the form of renderings. The images of design renderings are direct carriers for conveying the information of the design language. In the evaluation of design decisions, images of design renderings can be processed by AI to obtain algorithms implementing classification, understanding, and semantic feature evaluation [24]. Therefore, the image of the rendering of the design scheme is used as the output, the resulting image is preprocessed, semantic image segmentation is performed on the key modeling areas according to the designer's requirements, and the semantic features are extracted for judgment. Finally, according to the score of algorithm reasoning and the pre-evaluation of the design scheme, the purposes of the evaluation, optimization, and decision-making of the design scheme set are achieved.

3. Method of Product Design Decision-Making Based on AI

The loss of traditional deep learning algorithms will increase with the increase of the depth beyond a certain level. The unique structure of the ResNet algorithm can accelerate the training of deeper neural networks without losing speed. The detection and segmentation effects of the ResNet algorithm are better than those of other algorithms, and its accuracy is also greatly improved. In this study, the residual unit module of the ResNet algorithm is used to study the deep learning and semantic segmentation of the design scheme, and AI design decision-making is realized via the machine learning method.

3.1. Decision-Making Framework of AI Product Design Based on a Deep Learning Algorithm. According to the general product design process, the semantics of the target product

design are used as the input, and AI design decisions are made based on the design scheme renderings of each round. A deep residual network-based AI design decision-making method is constructed, and the overall framework of which is shown in Figure 2.

After the design semantics of the target product are determined, a large amount of design proposal data of the same type are collected. These design proposals are preprocessed and semantically labeled, and a basic design proposal data set available to the machine is constructed. According to the design scheme images in these data sets, the modeling of key areas and semantic feature extraction are performed, and the data are continuously trained through the ResNet core algorithm. The deep residual network consists of three fully connected layers and 10 convolutional layers. After the first convolutional layer, the network is divided into three residual modules, each of which is divided into a main path and a shortcut. Three convolutional layers are located on the main path to extract the deep features and the features of design semantic annotation in the image features of the design scheme. To facilitate the upward propagation of residuals during training, the shortcut contains a convolutional layer. At the end of the residual module, the key features obtained from the main path and the shortcut are restacked and integrated to classify the previously obtained convolution features. The convolution features obtained previously are classified via restacking integration. During the intelligent decision-making of product design, users can set target semantics, input the design scheme images of the intermediate process into the trained deep residual network, and evaluate different design schemes via image semantic decoding.

3.2. Data Set Construction and Feature Extraction. In the field of AI, data sets are used to train and test proposed algorithms [25]. The goal of AI design decision-making is to evaluate the design and modeling semantics of the corresponding area via the semantic segmentation of the product modeling area; thus, the general outline of the target area must be given. As an example, a subject collected a large number of side views of gas motorcycles in domestic and foreign markets as the main image data, and a basic data set was constructed, as shown in Figure 3. After the completion of the basic data set, it is necessary to perform segmentation and semantic annotation on the modeling area of the basic image to further improve the evaluation efficiency and accuracy. For the image evaluation of the design scheme in combination with AI algorithms, it is necessary to segment and extract the contour lines of the image modeling area, and to combine the Kansei engineering method to extract and label the main modeling semantic parts in the images. Due to the huge data set, multi-user participation was adopted, and professional designers performed artificial semantic annotation on the feature areas of the data images.

3.3. AI Product Design Decision Model. The advantage of the ResNet algorithm is that it can quickly accelerate the training process of the neural networks [26]. The original input of the

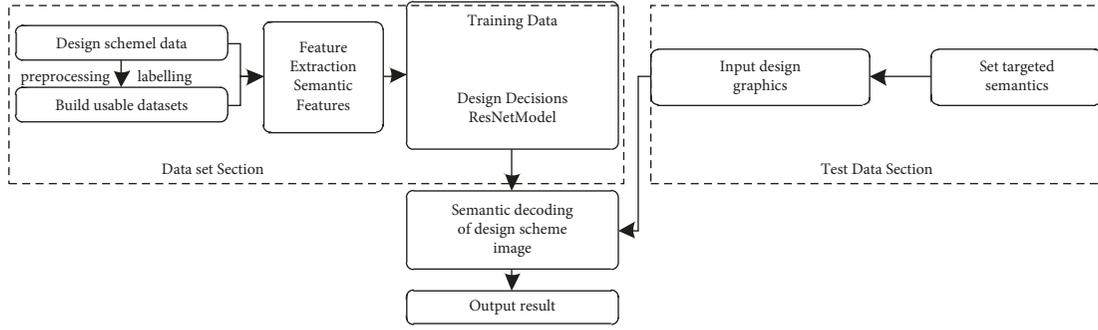

FIGURE 2: The AI design decision-making framework.

FIGURE 3: A section of the design decision data set.

entire deep network of ResNet is x , and the output is $F(x)$, which is obtained through a Conv-ReLU-Conv combination layer. By adding the output and the original output, i.e., $H(x) = F(x) + x$, the identity activation function of the original input result is superimposed on the convolution output, the stacking layer is used to fit $H(x) - x$, and the re-superposition of x will help to obtain $H(x)$ (Figure 4). To ensure that the accuracy rate decreases after the network is deepened, stochastic gradient descent can be used to propagate the response, and chain derivation can be used to obtain a faster convergence speed [27].

$$y = F(x, w_i) + x, \quad (1)$$

where x is the input, y is the output, and $F(x, w_i)$ is the residual mapping. Moreover, W_i is a linear convolution operation, in which the dimensions of x and F must be consistent. If they are inconsistent, linear mapping can be used to match the dimensions, as follows.

$$y = F(x, W_i) + W_s x_o. \quad (2)$$

The design plan image is input and scaled proportionally according to its short side, normalization (resize) processing is performed, and a cropped area with a size of 600×480 is then sampled from the image. After convolution operation with a 4×4 convolution kernel, the extracted image features include the contour features of three main regions. In the AI design decision model, the default step size of all max-pooling layers is 2, and the default step size of the convolution operation is 1. If the sizes of the output key features are different, it is usually filled with zeros; if they are the

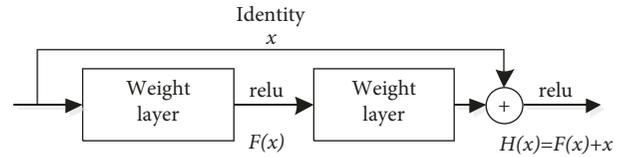

FIGURE 4: The algorithm flow of a single residual module in the ResNet algorithm.

same, the result will be used as the final output [28]. The final data of the convolution layer are converted into a 13-layer fully connected network, and the key features of the image are superimposed and merged in the residual module. The previously obtained convolution features are classified, and the recognition results are output via the softmax classifier.

4. Verification of the Decision-Making Model of AI Products

The TensorFlow deep learning framework [29] was used to implement the ResNet algorithm for AI design decisions based on the Python programming language, and the gas motorcycle design case was used as the basic data set to verify the performance of the ResNet algorithm in design decisions.

4.1. Experimental Data. In the experiment, the side view of motorcycles was used as the main image data. To ensure sufficient experimental samples, the image data of domestic and foreign motorcycles were obtained via a web crawler to construct the basic data set.

4.2. Data Preprocessing. Via web crawling, a large amount of basic image data was obtained. The basic data set was screened to eliminate the invalid samples. The basic preprocessing process and methods were as follows.

Step 1. Images with a side view or approximate side view were kept, and images taken from other perspectives were deleted.

Step 2. The image modeling area was segmented. In the styling design of gas motorcycles, the handles, wheels, and lights of the motorcycle are basically standard parts, and no additional design is required. Therefore, in the process of extracting the contour lines or boundary lines of the products in the data set, the FCN (fully convolutional network) open-source code of the UC Berkeley team was used for graph segmentation and contour extraction. Figure 5 shows the key areas of motorcycle styling design. The area marked No. 1 is the motorcycle oil tank, the area marked No. 2 is the motorcycle seat, and the area marked No. 3 is the motorcycle engine. The modeling design of these three parts forms the overall design semantics of the motorcycle. Areas No. 1 and No. 2 area are two key design areas in the motorcycle modeling design. The design of areas No. 1, No. 2, and No. 3 accounts for more than 85% of the motorcycle styling design, so they are the most important for people's visual perception and influence.

Step 3. The semantic annotation of image modeling was conducted. In current product design image research, statistical analysis and perceptual engineering methods are the most often used. The product image mainly reflects the product's design features, color, layout, structure, and other psychological perceptions of consumers. The usual product image vocabulary is "male-female, solemn-frivolous, future-past, solid-fragile, technology-conservative, rational-sensual." [30] Building on the current research progress of product modeling design images, relevant research was conducted on product modeling semantics. The research objects were designers, consumers, and enterprise managers. A total of 108 survey questionnaires were distributed, after which another three pairs of image vocabulary were included, namely, "introverted-publicized, complete-fragmented, and dynamic-stable." These nine image vocabulary pairs correspond to the semantic annotation of modeling design, as shown in Table 1.

The modeling semantics and decision-making scores were manually labeled by five design experts and obtained after conducting confidence statistics, after which images of 3000 pieces of motorcycle modeling metadata were randomly selected as the training set. After data preprocessing, a total of 3843 motorcycle images were obtained. The metadata of each image included four modeling semantic channels and two score channels, respectively, representing the modeling semantics and overall decision score of the image.

4.3. Experimental Process. The experimental process of AI design decision-making included the input layer, residual

FIGURE 5: The key labeling areas of motorcycle styling design.

module, batch regularization layer, pooling layer, and activation function.

Step 1: Image metadata was used as a data set for the input layer, and included the resulting preprocessed images, semantic labels, and scoring data.

Step 2: The final data were converted via the convolutional layer to the output of a 13-layer fully connected network. The first convolutional layer was divided into three main residual modules after the operation.

Step 3: On the main path, the deep features of the design scheme image were extracted through three convolution layers. The size of the first two layers was the same as that of the convolution kernel of the previous layer, and the size of the convolution kernel on the shortcut was doubled after the third layer.

Step 4: The shortcut controlled the number of features via a convolution layer, thus directly doubling the convolution kernel and speeding up the upward propagation of the residual during training. The main path and shortcut of each residual module obtained the key features of the design image. The numbers of feature layers and feature dimensions of the main path were kept consistent with those obtained by the shortcut, and the two were superimposed and converged at the end of the residual module.

Step 5: For the three fully connected layers, the previously obtained convolutional features were classified. The process continued to the next stage after adding and fusing at the end of the module.

In the experimental process, to speed up the training effect, the batch normalization method proposed by Ioffe and Szegedy [31] was adopted. Thus, the mean value of the features after convolution extraction was 0, the variance was 1, and each convolution layer and pooling layer was processed by batch normalization. The softmax classifier was used in the last layer to output the intelligent decision recognition results [32]. A depiction of the motorcycle shape obtained by the ResNet algorithm in the training phase is shown in Figure 6.

4.4. Experimental Results. To verify the validity and decision-making satisfaction of the proposed AI design decision-

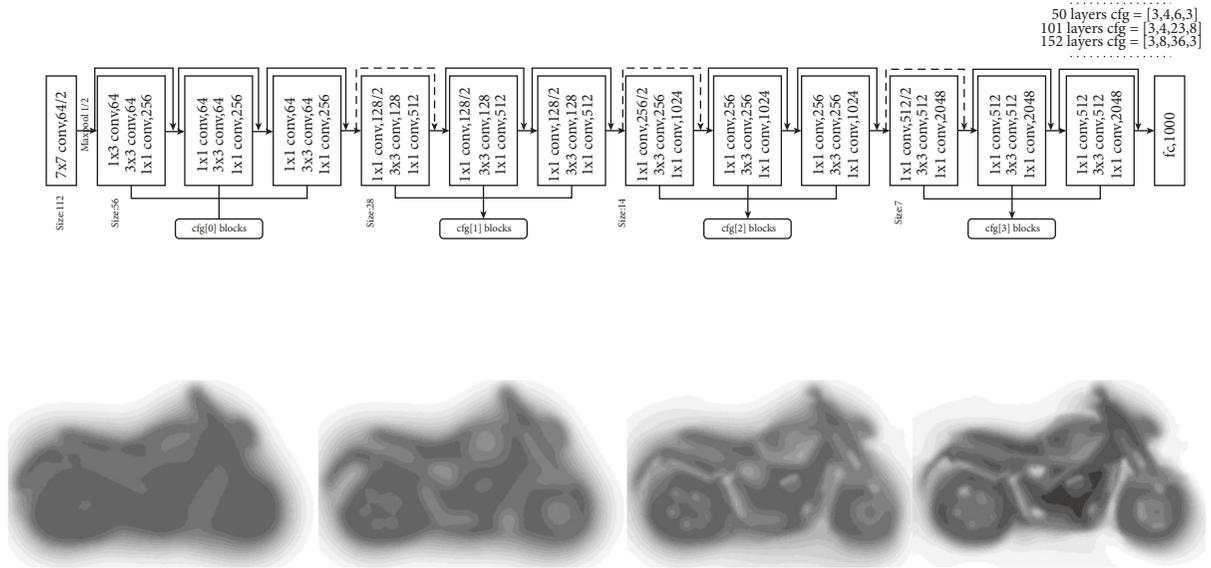

FIGURE 6: Semantic recognition at different training stages.

making model, two groups of modeling semantic input vocabulary were set. The first group included the semantic vocabulary of “future, stability, and dynamic,” and the second group included the semantic vocabulary of “technology, sensibility, and integrity”; these vocabularies represent the semantic vocabulary of motorcycle product styling design. Also, Party A and five design experts jointly participated in making design decisions about three motorcycle design schemes. Based on Party A’s scoring results of the design scheme, the full score was 10 points, and the proposed ResNet AI design decision-making model and design experts, respectively, scored the comprehensive satisfaction of the design scheme. During the experiment, the subject used the design decision accuracy curve as an indicator to analyze the experimental results. The design decision accuracy refers to the degree of fit between the scores of the proposed ResNet AI design decision model or the design expert and the score given by Party A. The higher the degree of fit, the higher the effectiveness of the tested model. In Figure 7, the abscissa of the design decision accuracy curve indicates the number of iterations, and the ordinate indicates the degree of fit.

5. Discussion

Figure 7(a) presents the change curve of the decision accuracy rate of Party A, the design experts, and the ResNet design decision model after using the three modeling image words of “future, stability, and dynamic” as the design semantic labels and inputting the renderings of such design schemes as images. With the increase in the number of iterations, the design decision accuracy of the ResNet AI design decision model gradually increased. When the number of iterations was about 160, the decision accuracy tended to be stable. The design decision accuracies of the three design schemes were, respectively, 0.83, 0.78, and 0.75, and the design decision accuracies of the design experts for the three schemes were, respectively, 0.78, 0.66, and 0.63.

Figure 7(b) shows the change curve of the decision-making accuracy rate of Party A, the design experts, and the ResNet design decision-making model after the three modeling image words of “technology, sensibility, and integrity” were used as design semantic labels. When the number of iterations was about 165, the accuracies of the design schemes obtained by the ResNet AI design decision

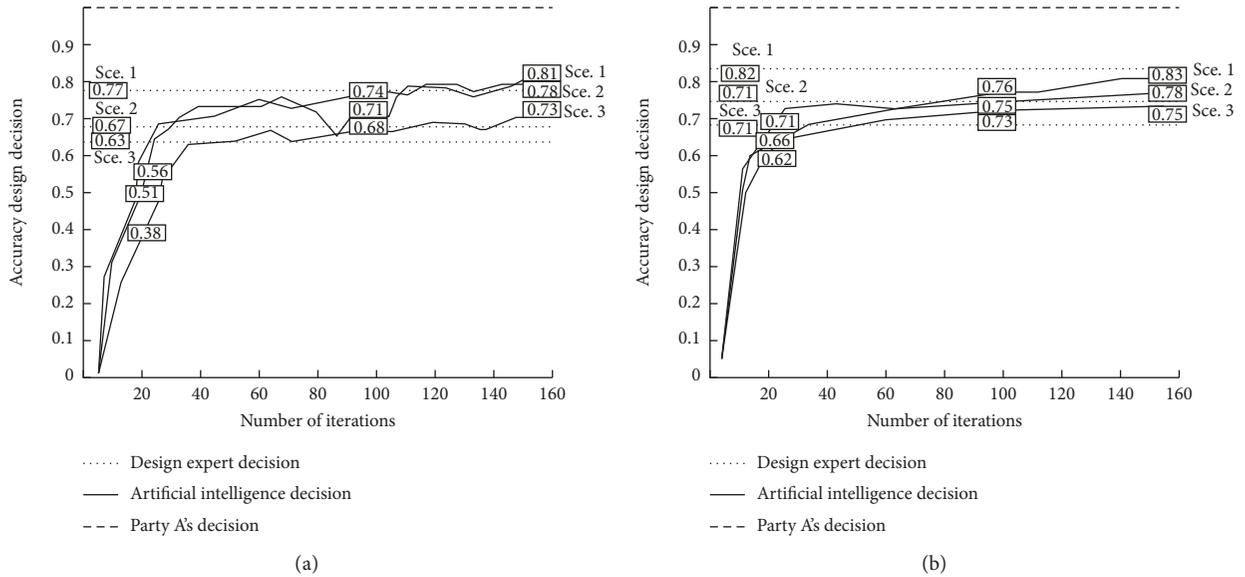

FIGURE 7: The comparison of the decision satisfaction of the (a) first and (b) second groups of modeling semantic vocabulary.

TABLE 2: The comparison of design evaluation satisfaction.

Method	Average satisfaction (%)	Average recall (%)
CNN	54.3 ± 3.4	44
DNN	57.8 ± 2.6	61
ResNet	77.6 ± 5.3	65

model were, respectively, 0.83, 0.78, and 0.77, while the design decision accuracies of the design experts for the three schemes were, respectively, 0.84, 0.76, and 0.71.

Thus, the satisfaction of the ResNet AI design decision was found to be higher than the average decision satisfaction of the design experts for both schemes.

To further verify the effectiveness of the proposed ResNet AI design decision-making model, a judgment was made based on the original data set, and the traditional CNN [33] and DNN [34] deep learning algorithms were, respectively, compared (Table 2). The average decision satisfaction and the average recall rate of the ResNet AI design decision model were found to be higher than those of the two other algorithms. The proposed ResNet AI design decision-making model performed stably in two rounds of design decision-making, and the design decision-making time was greatly shortened as compared with that of manual decision-making.

6. Conclusion

Building on the design scheme data set of product modeling semantics, this work was based on the concept of AI in combination with the characteristics of design decision-making. The data set was semantically annotated, and an AI evaluation decision model was constructed with the deep ResNet algorithm. The design decision problem was transformed into the semantic recognition problem of design scheme images, and the product design decision was realized via the AI design decision method. Finally, the

effectiveness of the proposed method was verified by a case of motorcycle modeling design decision-making. The analysis of the experimental results revealed that the proposed ResNet AI design decision-making model exhibited higher decision-making satisfaction and decision-making efficiency than traditional manual design decision-making and the CNN and DNN algorithms.

Future research will focus on the following aspects. (1) Deep residual networks have good learning performance, but in the field of design decision-making, a smaller amount of data will lead to less effective training effects. While the crawler method was used to obtain graphic data in this study, there was a large amount of irrelevant data, which increased the data preprocessing and screening time. The acquisition and preprocessing process and methods of design data will be further studied in future research. (2) A general model for product design decision-making will be constructed based on a multi-level ResNet, the general method of ResNet-based product design decision-making will be investigated, and further experimental analysis will be conducted for other types of product design.

In the current era of information technology, people's requirements for English translation are gradually increasing, and the need for a computer to understand and translate English language is becoming more urgent. In order to accurately identify phrases, this paper proposes an English translation recognition model based on optimized GLR algorithm, which can improve the accuracy of recognition by locating phrases in the text.

1. Introduction

Translatology is an important theoretical basis of language translation in China. English translation activity class under the background of artificial intelligence can provide an important boost to the development of translation studies. To ensure great achievements in Chinese English translation, artificial intelligence translation technology should be improved. In the past, it was mainly through the training of a large number of topics to let students explore the rules of translation and thus accumulate translation experience. Traditional translation tools are mostly paper dictionaries. Now, in the context of artificial intelligence, artificial intelligence translation technology can be upgraded to make it fit the concept of translation teaching to ensure that English translation can be changed with the help of new artificial intelligence translation technology.

With the rapid development of economy, the internet industry is developing rapidly, and the status of English translation in world trade is gradually improving. Machine translation technology can overcome many problems in human translation and reduce the economic consumption and time consumption of human translation [1–3]. In the current era of information technology, people's requirements for English translation are gradually increasing, and the need for a computer to understand and translate English language

is becoming more urgent [4–8]. The English translation ability of the computer directly affects the translation result, however, there will be some grammatical errors in the translation result, which will cause problems in the translation result and affect the final decision of English translation. Therefore, in the past studies, many experts have proposed automatic recognition methods for machine English translation errors, thus minimizing the errors in English translation [9, 10].

With the continuous development of global economic integration and the deepening of world trade, the contacts between countries are also constantly deepening, and the frequency of personnel exchanges between countries also increases accordingly. Language is a unique function of human beings and the main means of human communication. Because of the different language environment in each country, language barriers greatly hinder the communication between different countries. Translation robots are born to break down language barriers and enhance communication between countries. The translation robot is mainly composed of speech input and output system, language processing system, and language translation software. Through the combination of multiple software and hardware, it forms a translation platform that can understand multiple languages. The translation robot stores a large amount of language information inside and has intelligent

functions, such as automatic learning, analysis, and memory, which can help humans translate various languages and simplify the communication process between people from different countries. Nowadays, English is the most frequently used language in the world, and English translation robot has the most application scenarios and a wider range of applications. With the continuous upgrading and development of English translation robots, although they can effectively translate a variety of languages into English, translation errors are easy to occur because of the inflexible translation content, which affects people's communication. How to automatically detect the translation errors of English translation robots is one of the most urgent problems in the field of translation robots.

Because of the current machine translation results, there are certain problems. After using the server to compare the full text, the grammar and rules of each language can be obtained. It can be found that the machine translation has low accuracy and low efficiency. Therefore, we should use a more intelligent piece of technology for machine translation [11–15]. In the actual testing process of machine translation products, such as Baidu and Google translation software, the quality of translation results is quite different from that of actual professional manual translation. The current machine translation technology cannot meet the requirements, and the market urgently needs a high-performance [16, 17]. Because of the development of artificial intelligence, many researchers have sought to help with translation work through computer-aided translation (CAT). The central idea of CAT is that the translation results are usually taken as auxiliary reference, and the user usually judges the quality of the translation and then makes a choice. In addition, through the use of corpus, the vocabulary of all industries can be sorted out, more in line with the actual needs of users. The correct use of frequently translated words can greatly reduce the amount of repeated translation work and greatly improve the accuracy of translation [18–20].

For an English translation robot, translation accuracy is the main evaluation index of robot application performance. Because of the influence of internal storage information and external environment, the frequency of translation errors is high, which is not conducive to the development and application of translation robots. According to the existing research results, the existing translation error detection system cannot detect translation errors effectively because of the defects of hardware and software. Zhang et al. used the neural machine translation method to predict the Chinese and English translation results and completed the identification of translation errors in the process of prediction. Huang Dengxian compares phrase words and phrase corpus to analyze part-of-speech and syntax. The author further obtains the English syntactic structure that needs to be translated, and the errors are gradually transmitted and accumulated, which eventually leads to the disadvantage of low translation accuracy. Then, the author designs vocabulary semantics based on HowNet similarity and the logarithmic linear model, saves the corresponding bilingual

corpus in the form of Chinese-English dependency tree to string, provides structured processing of language dependencies, ensures the corresponding relationship between Chinese and English, and calculates the operation input of HowNet that needs to translate sentences with the same example. The semantic similarity of words in the source language of the library further improves the accuracy of translation, and the translation results have high accuracy [21].

Through the summary of the above literature, it is found that intelligent phrase recognition is an important step of speech recognition, and its principle is to realize automatic translation and combination by analyzing its part of speech and syntax, and output the results [22–24]. In the field of machine translation, intelligent phrase recognition is the key technology that can satisfy the selection of translation samples and the accurate alignment of parallel corpus. The technology of intelligent phrase recognition can effectively reduce grammatical ambiguity. The focus and difficulty of current English translation is structural ambiguity. Based on the GLR model in machine translation, this paper analyzes the structural ambiguity in some phrases through the syntactic function of the model, so as to facilitate the understanding of the entire semantics, solve the problems existing in the current English translation, and improve the efficiency and accuracy of the entire translation.

2. GLR Algorithm

2.1. Traditional GLR Algorithm. GLR algorithm is an extended LR analysis algorithm. The introduction of graph stack and analysis forest can effectively solve the ambiguity problem that an LR algorithm cannot handle, and its analysis speed is fast, which has great advantages in simple syntactic analysis.

In this paper, the GLR algorithm is used to identify and analyze the phrases in each fragment. The GLR algorithm is based on an extended context-free grammar, which is a five-element formula $G = (V_T, V_N, V_F, P, S)$, where V_T is a nonempty finite terminal symbol set, V_N is a nonempty finite nonterminal symbol set, and the intersection of V_T and V_N is empty. V_F is a constraint function set, which is a nonempty finite set that can be reduced by production only when the conditions are satisfied. P is the generation formula set, and $P \rightarrow \langle D, T, M \rangle$, $D \in (V_T \cup V_N)^+$, D is the right-hand symbol string of the production. $T \in V_T \cup V_N$, T is the central symbol of the production, $M \in V_F$, V_F detects the part-of-speech and semantic features of T . When the symbol string at the top of the stack can be reduced to P , specify its central symbol as T . S is the starting symbol set, $S \in V_N$.

The steps of GLR algorithm analysis are as follows:

- (1) Initialization. State O is pushed onto the stack. The analysis pointer points to the input symbol to be analyzed, and the termination flag is cleared.
- (2) Symbol mapping. If there is no end flag, the current input symbol is mapped to the analysis table terminator using a mapping function.

- (3) Check the ACTION table to determine the operation that will be performed next.
 - ① If it is moved up, the current state and current symbol will be pushed, and the analysis pointer will be moved down.
 - ② If it is a statute, The constraint function checks whether the conditions are met. If the conditions are met, the center word pointer points to the corresponding center word. If not, the end mark is marked.
 - ③ If it is terminated, it refers to the pointer to the analysis table terminator “error” the current input character is remapped to the analysis table terminator to continue analysis, and then set the end flag.
 - ④ If it is accepted, the recognizable phrase completes the analysis, pops up the syntax tree at the top of the symbol stack, and returns.
 - ⑤ If it is an error, it refers to the “error” for the terminator of the analysis table, which belongs to the analysis failure, restores the initial state, and returns.
- (4) Continue to execute the next action in sequence until the end of the analysis.

2.2. Improved GLR Algorithm. In general, the GLR algorithm is still unable to meet the existing accuracy because of its high probability of coincidence in the results. In this paper, the classical GLR algorithm is improved, and the phrase center is proposed to analyze the phrase structure. The improved GLR algorithm realizes the likelihood calculation of the prefixes and postfixes of phrases by means of quantization, as shown in formula (1).

$$G_E = (V_N, V_T, S, \alpha). \quad (1)$$

In formula (1), V_N represents the cyclic symbol cluster, $V_N \neq \emptyset$. V_T represents the termination symbol cluster. $V_T \neq \emptyset$, and the elements in V_T and V_N do not overlap. S represents the start symbol cluster, which is an element in V_N . α represents phrase action clusters.

Assuming that P is any action in α and P exists in V_N , formula (2) can be obtained by derivation.

$$P \longrightarrow \{\theta, c, x, \delta\}. \quad (2)$$

In (2), θ represents the right side of the action, C represents the center point, x represents the constraint value, and δ represents the marking mode. θ and C are located in both V_T and V_N , and δ can be located in V_T or V_N .

3. English Intelligent Recognition Algorithm

3.1. Create Phrase Corpus. Corpus is mainly used to store phrases, which can accurately mark the parts of speech in English, further standardize the function of phrases, and make machine translation more accurate.

There are more than 700,000 words in the corpus of the intelligent recognition model constructed in this paper,

which can meet the actual demand. In this paper, we distinguish English and Chinese phrase corpora by distinguishing the tenses of phrase corpora. The marking process is divided into layers, data, and processing, and the processing adopts the man-machine active communication mode to carry out the operation of English translation.

3.2. Phrase Corpus Part-of-Speech Recognition. The dependency relationship of phrases is analyzed using syntax, and the establishment of syntax tree is realized. The part-of-speech recognition of phrases is a key step in the intelligent recognition algorithm of machine translation, which can deal with the grammatical ambiguity of a large number of sentences, phrases, and words. Each sentence is divided into several words into English sentences, and the processed words are aligned to form phrases. Meanwhile, the parts of speech of the words are marked out by judging the context of the sentence. Finally, the syntactic tree of sentences is formed by analyzing the dependency of phrases. Through this method, the timeliness and accuracy of machine translation can be improved, and the processing capacity of phrase corpus can be significantly increased. GLR is a commonly used algorithm in part-of-speech recognition, which is mainly used to judge the contextual relationship of phrases. Its core theory is based on the dynamic recognition of forms and unconditional transfer statements.

In traditional GLR, the execution of each step is carried out through operation shift instruction and reduction instruction. In this process, the beginning and end of each operation are carried out according to specific standards. In the process of translation, if grammatical ambiguity is detected, it is necessary to use the geometric structure linear table of syntactic analysis to call up the analytic linear table, expand and identify the content of the phrase, select the optimal content, and transfer it to different recognition channels for recognition.

3.3. Correction Process of Phrase Intelligent Recognition Algorithm. In current machine translation algorithms, the matching results of segmented phrases and phrase corpora are often regarded as the final machine translation results, which lack the analysis of the context in which the phrases are located, and excessively rely on the part of speech analysis of phrase corpora, resulting in inaccurate final translation results. Therefore, this paper further considers to correct the results of part-of-speech analysis. In the process of part-of-speech analysis and correction for the improved GLR algorithm, in view of the error points in the part-of-speech recognition results of phrases using analytic linear tables, the correction process is carried out by checking the tagged content in the corpus, as shown in Figure 1.

However, the reduction expresses that the previous constraints have no effect or that there is a problem in the loop process, and it is necessary to clarify the syntactic function to identify the constraints again. The advance indicates that there is no structural ambiguity in the ongoing syntactic function recognition, and the phrase part-of-speech recognition result is accurate. At this time, the

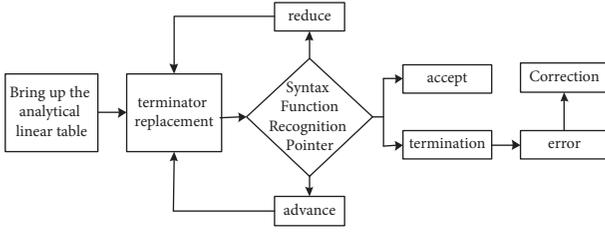

FIGURE 1: Calibration flow chart of intelligent recognition algorithm.

acceptance pointer should be selected for use. The receive pointer and the advance pointer usually appear together. If this condition is not met in the process and only a certain pointer appears, it means that there is an error in the loop or an error in the algorithm. Then, the analytical linear table needs to be called up again, and the part-of-speech recognition results that have been agreed by default before are withdrawn.

During the operation of the improved GLR algorithm, the type of pointer should be identified before the termination is replaced. If it is a protocol pointer, the constraint conditions of pointer should be detected in the phrase corpus. If it does not, it goes directly to the termination pointer.

4. English Translation Intelligent Recognition Model

The functions of the intelligent recognition model for English translation are designed. The received voice signal is obtained through the data acquisition device, and then the English signal is input to the processing system. The data signal is processed, the results are output in the display, and the user can view the automatic identification results of English translation through the display or the client.

4.1. English Signal Processing. Detailed design is required after model design, and English signals are collected and processed in a planned way. However, because of the interference factors of speech signals, the collected speech signals should be processed to improve accuracy. Figure 2 shows the processing process of English signals.

The digital filter is used for signal weighting processing, and the stress detection system is improved. Firstly, F1 is used to represent the first formant of vowel spectrum characteristics, and F2 is the second formant. Using the classifier to output confidence, the vowel intonation is obtained, and the best speech signal is selected. The calculation formula of weighting signal $Y(n)$ is as follows:

$$y(n) = T[x(n)] = ax(n) + b. \quad (3)$$

To make the analysis result of speech signal more accurate, the speech signal is divided into T frames.

$$z(n) = \frac{1}{t} y(n). \quad (4)$$

To clearly display the speech effect, select the rectangular window $W(n)$.

$$W(n) = w(n) \times z(n). \quad (5)$$

4.2. Extract Feature Parameters. To further improve the operation efficiency of the system and reduce the data interference unrelated to the voice signal, it is necessary to unify the relevant information data to find the parameter characteristics and then realize the subsequent calculation. Figure 3 shows the structure of extracted feature parameters.

The continuous spectrum of aperiodic continuous time signal is calculated by Fourier transform, however, the discrete sampling value of continuous signal is obtained in the actual control system. Hence, the signal spectrum is calculated by discrete sampling value. A finite length discrete speech signal is improved to obtain the following formula:

$$X[K] = \sum_{n=0}^{N-1} x[n]e^{-j2\pi/Nnk}, \quad k = 0, 1, 2, \dots, N. \quad (6)$$

Convert a discrete speech sequence to a Mel frequency scale.

$$\text{Mel}(f) = 2579 \lg \left(1 + \frac{f}{700} \right). \quad (7)$$

Through DTC calculation of the output filtering, the characteristic parameter P of the speech signal $W(n)$ is obtained.

$$P = \overline{Z}_{n=1}^N F(l)w(n)\cos(\pi n(M + 0.5)). \quad (8)$$

After the spectrum of a speech signal is generated, it is processed by weighting, windowing, and framing. Each short-time analysis window can get spectrum information through fast Fourier transform. Then, use the Mel filter to get an MFCC two-dimensional graph.

Using the above method, related speech signal parameters are extracted from rhythm, speed, pitch, and intonation.

5. Experiment Analysis

In this paper, three machine translators were used to translate 50 phrases and 50 network random sentences. English-Chinese translation professionals also translated the above sentences. Graders scored the results of machine translation by comparing the results of machine translation.

As can be seen from Figure 4, the machine translation results of the proposed algorithm are optimal compared with other algorithms in terms of recognition accuracy, speed, and updating ability. As can be seen from Figure 5, the improved GLR algorithm in this paper has the highest score, while the statistical algorithm has the lowest score.

The comparison experiment in this paper also adopts the experiment on actual translation cases, and the sentence ‘‘Xi ‘an Price Bureau on beef noodle Price Limit’’ is selected for

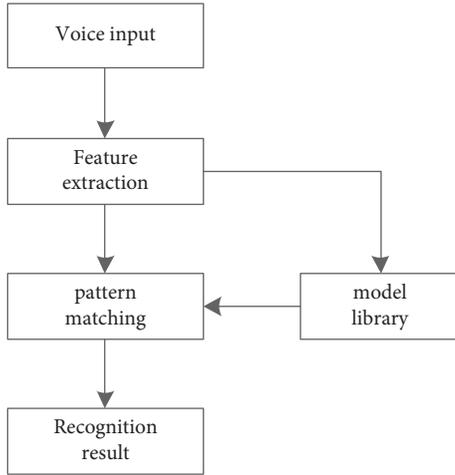

FIGURE 2: Processing of English signals.

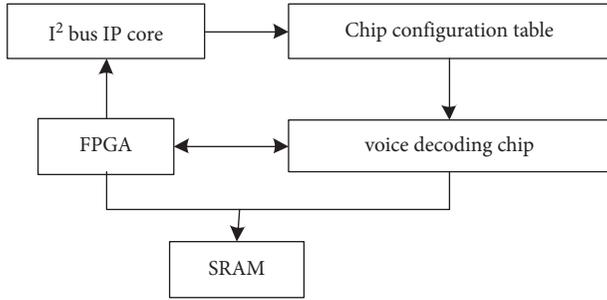

FIGURE 3: Feature parameter extraction map.

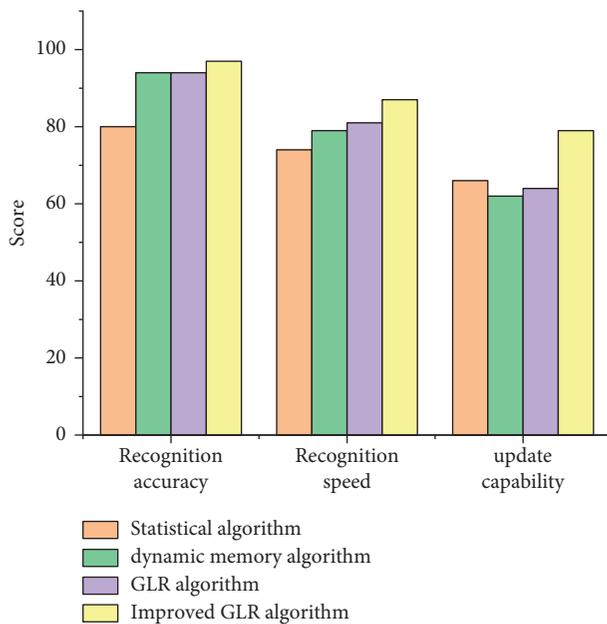

FIGURE 4: Evaluation results of four algorithms.

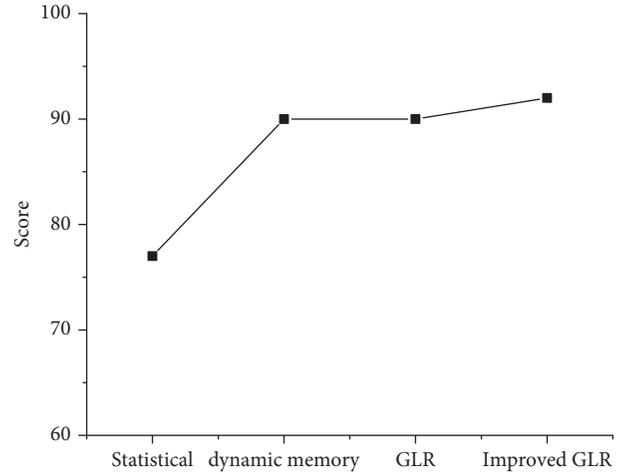

FIGURE 5: Comparison of scores of four algorithms in comprehensive test.

TABLE 1: Comparison of translation example results.

Translation method	Translate content
Improved GLR algorithm	Xi'an price bureau gives the explanations of beef noodles reduce: only because of the excessive price raises.
Human translation	Xi'an price bureau gives the explanations of price control on beef noodles: it is only because the raises have been too large.

translation. The experimental comparison results of machine translation and human translation based on statistical algorithm, dynamic memory algorithm, and improved GLR algorithm are shown in Table 1.

As can be seen from Table 1, compared with other algorithms, the algorithm in this paper is more accurate, and the recognition accuracy reaches more than 95%, reaching the same level as human translation, indicating the efficiency and feasibility of the improved GLR algorithm in machine translation.

6. Conclusion

With the rapid development of economy, the internet industry is developing rapidly, and the status of English translation in world trade is gradually improving. Machine translation technology can overcome many problems in human translation and reduce the economic consumption and time consumption of human translation. In the current era of information technology, people's requirements for English translation are gradually increasing, and the need for a computer to understand and translate English language is becoming more urgent. Computer's English translation ability has a direct impact on the application effect of translation results. In this paper, using the generalized maximum likelihood ratio detection algorithm based on improved machine translation, set the phrase corpus using

this algorithm, the library's size to 740,000 English words, and by constructing the phrase structure through the central phrase and calibrating the structural ambiguity according to the syntactic function, the content of recognition can be obtained, and the actual position range of phrases in translation can be determined, so as to solve the problems existing in current English translation and improve the accuracy and efficiency of recognition.

With the improvement of people's living standards, the traditional hotel management model has been unable to meet the needs of customers. The traditional hotel management model also has the defects of low efficiency. The hotel management model is also gradually developing towards the direction of intelligence. The combination of artificial intelligence technology and hotel management can not only improve the operation efficiency of the hotel but also solve the operation cost of the hotel. For customers, artificial intelligence technology can bring smarter and more comfortable accommodation conditions to customers. This study uses the convolutional neural network (CNN) and long short-term memory (LSTM) technology in artificial intelligence technology to conduct related research on the in-store mode, entertainment mode, sleep mode, and out-of-store mode in hotel management. CNN is used to extract the spatial features of hotel management, and LSTM is used to extract the temporal features of hotel management. The research results show that CNN and LSTM technology can help hotel management achieve intelligent management and optimization. CNN and LSTM techniques can better predict related factors in-store entry mode, entertainment mode, and sleep mode. For the correlated predictions of these four modes, the maximum prediction error is only 2.81%. The linear correlation coefficient also reached above 0.96. The relevant parameters of artificial intelligence technology are also suitable for the optimization and design of hotel information systems.

1. Introduction

With the rapid development of computer performance, information systems have been widely used in hotel management. Compared with traditional manual methods, information systems can have better efficiency in hotel management. In today's society, people begin to pursue a higher level of quality of life [1, 2]. Whether it is in the process of business trip or tourism, they not only need the level of accommodation, but they are also constantly pursuing a higher level of hotel service. This puts forward higher requirements for the management level of the hotel. Hotel management is not only limited to the management of the hotel front desk, but it also needs to achieve a higher level of management of the hotel rooms. The management of the hotel front desk needs to achieve higher efficiency and more accurate management, which will save many manpower and

material resources of the hotel front desk [3]. At the same time, efficient hotel front desk management will save more time for the occupants, and it will also provide more convenience for the occupants. The provision of hotel management level will provide occupants with a more comfortable and warmer accommodation environment, and it will also provide more convenience for hotel managers [4, 5]. With the wide application of intelligence in various fields, the intelligent management of hotels is also a popular direction. The intelligent management of hotels will not only improve the efficiency and service level of hotel front desk management but also bring certain convenience to the intelligent management of guest rooms [6, 7]. The intelligent management of guest rooms will bring more convenience, comfort, and safety to the occupants, and it will also save human and material resources for hotel operators. The intelligent development of the hotel needs to have a solution

suitable for the hotel style. It cannot ignore the feelings of the occupants just to achieve intelligence. The intelligent development of hotel management needs to make the occupants feel more technological elements, and it cannot bring more troubles to the occupants.

Artificial intelligence technology is the product of the rapid development of computer computing power and the improvement of hardware technology [8]. Artificial intelligence technology has been applied in many people's lives, and it can liberate more labor. It can also replace people to perform more dangerous and complex tasks, which has brought great convenience to people's lives [9, 10]. The core of artificial intelligence technology being able to perform these tasks is that it can process these complex data very well. For hotel management, in order to realize the intelligence of hotel management, artificial intelligence is required to process the relevant data of hotel management [11]. The advantage of artificial intelligence technology is that it can better handle nonlinear and high-dimensional data. It uses nonlinear functions to find correlations in complex data. Artificial intelligence technology mainly includes three algorithms: supervised learning, unsupervised learning, and reinforcement learning, which are the three most common learning algorithms. Among these three algorithms, supervised learning is a more common method, whether in the field of image recognition or speech recognition. Artificial intelligence technology includes CNN and LSTM algorithms, which are relatively common feature extraction methods in the field of artificial intelligence. The convolutional neural network (CNN) method can better extract the spatial features of the data [12], and it has been widely used in the fields of transportation and medical care. Long short-term memory (LSTM) recurrent neural network can better process data related to temporal features [13], and it has been widely used in speech recognition and other fields. Reinforcement learning is an algorithm with a relatively large correlation with the environment, and it is mainly used in research objects with strong environmental interference [14]. For the intelligence of hotel management, it mainly involves the spatial characteristics of data and the temporal characteristics of data.

The combination of artificial intelligence technology and hotel management is an important direction for the intelligent development of hotel management. Artificial intelligence technology can optimize the management plan of the hotel management front desk, and it can also intelligently optimize the management of guest rooms. In the process of hotel's intelligent management, these data mainly involve spatial and temporal characteristics. CNN and LSTM methods are used to study the intelligent management of hotels. The combination of artificial intelligence technology and hotel management can reduce the operating cost of hotel management, and it can also improve the operational level of hotel management. The traditional manual management mode has a large error rate. At the same time, intelligent hotel management will also meet the personalized accommodation consumption needs of the occupants, which will also improve the hotel's satisfaction rate and occupancy rate. The intelligent management of the hotel can realize the

intelligent management of check-in mode, entertainment mode, sleep mode, and check-out mode. This will not only save the hotel operator's time and human resources but also provide greater convenience to the occupants. The CNN method is used to extract the features of in-store patterns and out-of-store patterns for hotel management. The LSTM method is mainly used to extract the temporal and spatial features of entertainment patterns and sleep patterns of hotel management.

This study mainly uses CNN and LSTM algorithms to predict and study the check-in mode, entertainment mode, sleep mode, and check-out mode of hotel management. The CNN method is mainly used to map the relationship between the needs of the occupants and these four modes, and the LSTM method is mainly used to study the temporal feature analysis of hotel intelligent management. This study will be introduced from five aspects: the first section introduces the necessity of the intelligent development of hotel management and the background of artificial intelligence technology. The related research status of hotel management is analyzed in the second section. The third section mainly analyzes and introduces the system design of intelligent hotel management and the principles of CNN and LSTM algorithms. Section 4 analyzes the accuracy and feasibility of CNN and LSTM algorithms in predicting hotel management check-in patterns, entertainment patterns, check-out patterns, and sleep patterns. In Section 4, the predicted linear correlation coefficient, average error, and error hotspot distribution map of hotel rooms are used to analyze the feasibility of CNN and LSTM methods in predicting hotel management. Section 5 summarizes the research.

2. Related Work

With the continuous development of business travel and tourism boom, the hotel is a fast-growing industry. The intelligent development of hotels is also one of the research hotspots, and many researchers have done a lot of research on hotel management. Li [15] already believes that hotel management needs to meet the needs of market development in tourist cities, which is also an important part of market development. The innovative management and the provision of management level of coastal resort hotel are beneficial to improve the core competitiveness of the hotel. This study takes the management of coastal hotels as the research object, and it uses the SWOT method to analyze the relationship between the coastal hotels and the tourism supply chain. In order to realize the stable management of coastal resort hotel and improve the popularity of tourists, he proposed a platform management and construction model for coastal resort hotel. Maté-Sánchez-Val and Teruel-Gutierrez [16] have noticed that hotel location has a greater relationship with company performance and the environmental strategy of hotel management. They proposed a theoretical model to analyze the important role of hotel location in hotel management. They collected data on hotels in Barcelona as a research object, and it used peer effects to analyze the impact of hotel location on hotel performance. The results show that the variable of hotel

location has an important relationship with the hotel's explanatory coefficient characteristics. This study has important implications for the location selection of hotel managers. Zhang et al. [17] have studied the online hotel management model, which mainly focuses on the effect of online reviews on hotel management. The dataset for this study was derived from online data on hotels in New York City on Expedia. It combines data such as online comments and online replies of online data into one dataset. It also fully mines these textual information using textual similarity. It also correlatively validates text mining functions using fixed-effects panel data. The results of the study show that consumers' online reviews do not significantly affect hotel bookings. However, highly similar responses significantly reduce hotel bookings. This research has a certain reference value for the evaluation of hotel management and online booking. Obonyo et al. [18] found that the development of ICT has provided more convenience and efficiency for hotel management. More hotels are starting to invest more in ICT to improve performance. However, this situation is weaker for economically developing countries. This study mainly analyzes the actual situation of ICT application in hotel management in Kenya. He collected and quantified data on 194 hotels. The research results show that ICT has a strong correlation with human resource management and operational management of hotels, which will also affect the application of ICT in hotel management. Wang and Zhang [19] believe that the hotel industry has become a pillar industry of the tertiary industry. The hotel industry has developed rapidly under the rapid economic development, but it is also facing huge pressure. Based on the background of rapid development of information, this research uses the fuzzy analytic hierarchy process FAHP method to study the user decision-making process in hotel management. Based on the common data of the hotel management system, he established the customer model of the hotel business data by using the method of data mining. This method improves the service level of the hotel and enhances the core competitiveness of the hotel enterprise. Brahami and Adjaine [20] believe that only after the company or enterprise really understands the motivation management of knowledge and customer relationship management (CRM), the competitiveness of the enterprise can be improved. He also found that the two indicators of KM and CRM are less used in hotel management. He collected sample data of large hotels in the Algeria region, and it discussed the application effect of KM and CRM in hotel performance management. The research results show that KM and CRM methods can effectively improve hotel performance, which in turn can enhance the competitiveness of hotel management. This has certain guiding significance for the further improvement of the hotel. With the development of intelligent technology and big data technology, there are also a few researchers here who have adopted artificial intelligence technology to study the related factors of hotel management and intelligent hotel management system. Ma [21] has found that the traditional concept of hotel management can no longer keep up with the pace of the times, and this method cannot provide timely training for hotel financial personnel, which leads to the

relative lag of the hotel management model, which in turn affects the hotel benefit. To solve these problems, he designed an intelligent hotel financial management system. The results show that the support vector machine method and logistic regression method can reduce the risk of financial crisis in hotels. The response time of this intelligent hotel management system is significantly shortened, and the success rate has been improved to a certain extent. From the above literature review, it can be seen that artificial intelligence methods are rarely used in hotel management, and it rarely studies the entire process of hotel management systems. The current research is mainly to optimize and design the front desk management system of the hotel management system. This research uses CNN and LSTM methods to intelligently manage and study the hotel's in-store mode and out-of-store models.

3. The Application of Artificial Intelligence Methods in Hotel Management

3.1. *The Importance of CNN and LSTM for Hotel Management.*

This research mainly uses CNN and LSTM algorithms to predict the in-store mode, entertainment mode, sleep mode, and out-of-store mode in the hotel management mode. The CNN algorithm can map the relationship between the relevant factors of the in-store management system and the needs of the occupants. This data information is often more complex, but there is a relatively large correlation between these data. Relying on hotel managers alone to find correlations in these data is more difficult. CNN can process these data well, and the CNN algorithm has strong advantages in processing these nonlinear data. The LSTM algorithm has obvious advantages in dealing with temporal features, which can deal with time-related temporal features in hotel management. For example, in the process of predicting the entertainment mode, it can automatically adjust the air conditioning system, video system, lighting system, etc. according to the change of time. Because these factors are not only strongly related to space, but also it had strongly related to time.

3.2. *The Hotel Management Intelligent System and CNN Algorithm.*

This research will use the CNN and LSTM methods to realize the intelligent management mode of the hotel. At the same time, the in-store mode, entertainment mode, sleep mode, and out-of-store mode of hotel management will be unified as a whole for system design. These patterns are not a single pattern, because there are some correlations in the data between these patterns. Figure 1 shows the hotel's intelligent management system design scheme utilizing CNN and LSTM methods. First of all, it needs to collect more relevant data of the hotel's in-store mode, entertainment mode, sleep mode, and out-of-store mode as an obvious training set and test set. These data first go through the CNN algorithm, and the CNN algorithm will use the convolution layer, pooling layer, and activation function to extract the spatial features of hotel management. The LSTM will receive the output data from the CNN, which will be input to the network layers of the LSTM in the form of time

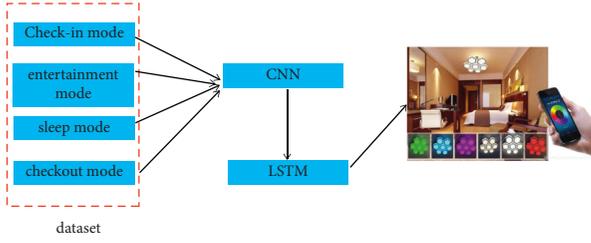

FIGURE 1: The design of hotel intelligent management system.

series. There is a backpropagation mechanism for these two networks. After the hotel management data are processed by the LSTM algorithm, it will become the control signal of the hotel room. It will automatically control the lighting system, air conditioning system, and influence system of hotel rooms. Once the model is trained, the optimal weights and biases are determined. In the actual application process, it can rely on these weights and biases to realize the prediction and analysis of the relevant data of the four modes of the hotel management information system. First, the hotel management data will be processed through data cleaning and data normalization methods. Then, these data will be processed into a matrix and input into the network layer of CNN.

CNN is a relatively common feature extraction neural network. Compared with the fully connected neural network, it has less parameters. Therefore, it allows more network layers, which guarantees the task of extracting features from hotel management system data. Figure 2 shows the workflow of CNN. A matrix operation is performed between each weight of the fully connected neural network. However, the weights of CNN will selectively perform matrix operations, which is the advantage of weight sharing. CNN is mainly composed of convolution layer, pooling layer, activation function, and fully connected layer. The convolutional layer will extract the features of hotel management data through parameters such as filter and stride. The pooling layer will further extract features by upsampling or downsampling. The parameters of the CNN will be trained and tested on the Tensorflow platform, and the weights and biases will be saved in the .h5 file. The learning rate chosen in this study is 0.001, which will speed up the training, but it will not easily get stuck in a local minimum.

CNN and fully connected neural network are similar computational methods, and it also has a backpropagation mechanism. The CNN dataset also contains actual numerical values, which is required by the backpropagation algorithm. Equation (1) shows how the backpropagation error is calculated. This study will calculate the error in the form of mean square error, which is also a commonly used error calculation method. Equation (2) is also a form of mean square error calculation, which is a form of the summation of equation 1:

$$E = \frac{1}{2} \|d - y^L\|_2^2, \quad (1)$$

$$E = \frac{1}{2} (d_{\text{out}} - O_{\text{real}})^2 = \frac{1}{2} \sum_{k=1}^t (d_k - O_k)^2. \quad (2)$$

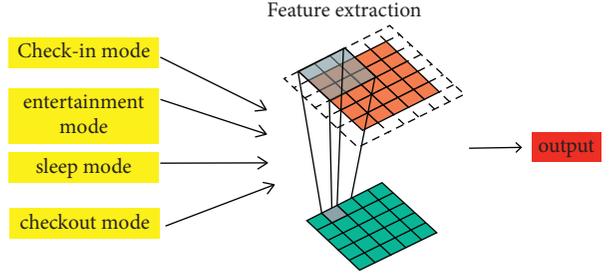

FIGURE 2: The workflow of CNN algorithm.

Many hyperparameters will be involved in the iterative calculation process of CNN, and hyperparameters will also affect the accuracy and convergence of CNN iteration. There is a certain relationship between these hyperparameters of CNN. Equation (3) shows the calculation relationship of CNN hyperparameters. Equation (4) shows the computation process of the input layer of the CNN:

$$w' = \frac{(w + 2p - k)}{s} + 1, \quad (3)$$

$$V = \text{conv2}(W, X, \text{"valid"}) + b. \quad (4)$$

This will involve many derivative operations during the CNN computation, either forward or backward. Equation (5) shows how the weight derivative is calculated:

$$\Delta\omega_{ji} = -\eta \frac{\partial E}{\partial \omega_{ji}}. \quad (5)$$

3.3. The Introduction to LSTM Algorithm. The entertainment mode and sleep mode in the hotel management mode have a strong time relationship with the lighting system, air conditioning system, and film and television system of the guest room. The advantage of the LSTM method is that it deals with time-dependent data. For the in-store mode and the out-of-store mode, these data also have a relatively strong time relationship. Therefore, this study chooses the LSTM algorithm to process these temporally correlated data. Figure 3 shows the computational process of the LSTM algorithm. It differs from CNN in that it can memorize historical information because of its obvious gate structure. This is also the reason why it can memorize historical state information. The data input form of LSTM is time series. In this study, it will accept the output data of CNN. CNN and LSTM algorithms are a continuous process. CNN first extracts the spatial features of hotel management, and LSTM extracts the temporal features of hotel management. The gate structure of LSTM algorithm mainly includes input gate, forget gate, and output gate structure. After the hotel management data are output in the output layer of the CNN, the data will be transformed by a reshape layer. These data will be transformed into labeled data by sliding windows and sliding steps. This is because LSTM is also a supervised learning algorithm.

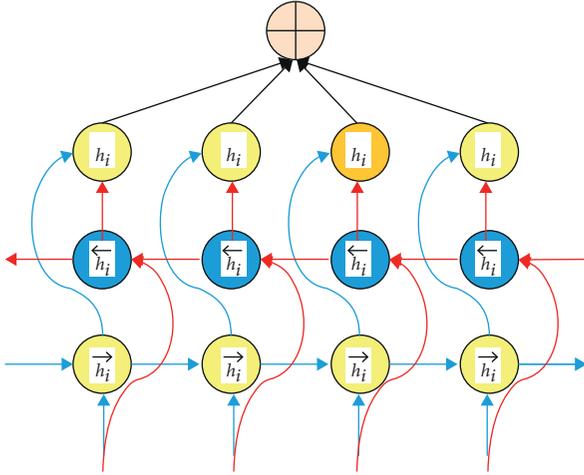

FIGURE 3: The workflow of LSTM algorithm.

The LSTM algorithm is inherited from the RNN algorithm. RNN is also an important algorithm for dealing with speech recognition. Equation (6) shows the basic principle of the LSTM method to memorize historical state information. The historical state information realizes the memory of historical state information by affecting the information of the current state. Both historical state information and current state information will be given a certain weight, which can realize the memory of historical information according to the weight. Equation (7) is the abstract structure of Equation 6. Equation 8 shows the temporal feature information that the LSTM structure needs to load. Through Equation 8, LSTM is given certain time information:

$$y(t) = f(X(t) \bullet W + y(t-1) \bullet V + b), \quad (6)$$

$$\tilde{c}(t) = f(W \bullet x(t) + V \bullet y(t-1)), \quad (7)$$

$$C(t) = C(t-1) + \tilde{C}(t). \quad (8)$$

The input gate can control the input amount of information, and it can control the input characteristics of historical state information and current state information. If all the historical state information and current state information are input into the network, it will not only cause too many parameters. It also causes poor feature extraction. Equations (9) and (10) show the calculation process of the input gate. It can selectively pass historical state information and current state information according to the size of the weight:

$$C(t) = C(t-1) + g_{in} \bullet \tilde{C}(t), \quad (9)$$

$$C(t) = C(t-1) + g_{in} \otimes \tilde{C}(t). \quad (10)$$

Equation (11) shows the calculation process of the LSTM forget gate. If the forget gates are all open, this will cause a lot of information to flow into the LSTM. The forgetting gate will assign a certain weight according to the importance of the feature, and the forgetting gate will selectively input

some historical state information features according to the size of the weight:

$$C(t) = g_{forget} C(t-1) + g_{in} \otimes \tilde{C}(t). \quad (11)$$

Equation (11) shows how the output gate of the LSTM method is calculated. The output gate will output features related to the current state information. This requires a gate structure for effective control. It can not only ensure the output of effective historical information but also ensure that the information parameters will not be too large:

$$y(t) = g_{out} \otimes f(C(t)). \quad (12)$$

4. Result Analysis and Discussion

In this study, it mainly uses CNN and LSTM algorithms to analyze the intelligent management information system of in-store mode, entertainment mode, sleep mode, and out-of-store mode in hotel management. The data used in this study come from the operation data of 40 hotels in Beijing. It uses CNN and LSTM algorithms to study the accuracy and feasibility of these four hotel intelligent management modes. Figure 4 shows the linear correlation coefficients predicted by hotel management's in-store patterns. The linear correlation coefficient can compare the degree of agreement between the predicted value and the actual value of the intuitive response. The closer the linear correlation coefficient is to the linear function $y = x$, the more accurate it is for the predicted value. From Figure 4, it can be seen that the corresponding values of the in-store patterns of the 40 hotels have a high linear correlation, and all the linear correlation coefficients exceed 0.96. Moreover, the corresponding values of the in-store patterns of these 40 hotels are distributed on both sides of the $y = x$ function, and the predicted data of the in-store patterns of these 40 hotels are relatively close to the $y = x$ function. This further illustrates the high feasibility and accuracy of CNN and LSTM algorithms in predicting the in-store patterns of hotel management. Only a few data points deviate from the $y = x$ line, but the deviation is within the requirements of hotel management.

In the information system of hotel management, the entertainment system is a key part. The prediction accuracy of this part is directly related to the accuracy of CNN and LSTM. This is because the entertainment system varies greatly, and it has a greater relationship with time and the preferences of different people. Predictions for entertainment systems are more complex. Figure 5 shows the distribution of predicted and actual values of entertainment patterns managed by the hotel information system. In Figure 5, both A and B are representative of the entertainment mode group managed by the hotel. A represents the group of predicted values of entertainment pattern data. B represents the group of actual values of the entertainment mode data. The blue curve represents the predicted value of the entertainment mode, and the red curve represents the actual value of the entertainment mode. In general, the predicted value of hotel management is larger than the actual value of entertainment mode, which is mainly because the

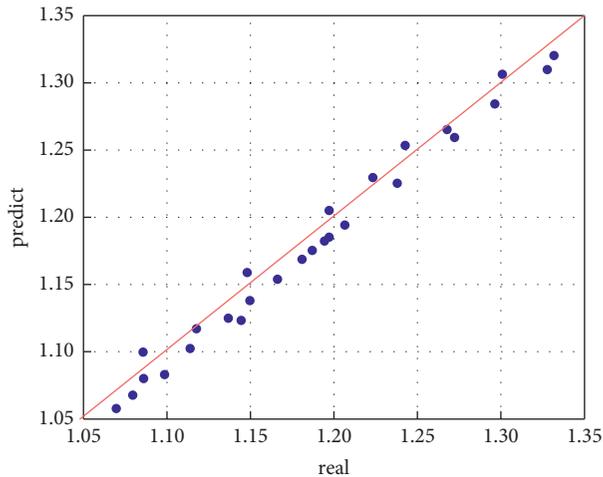

FIGURE 4: The linear correlation coefficient of in-store patterns of hotel management.

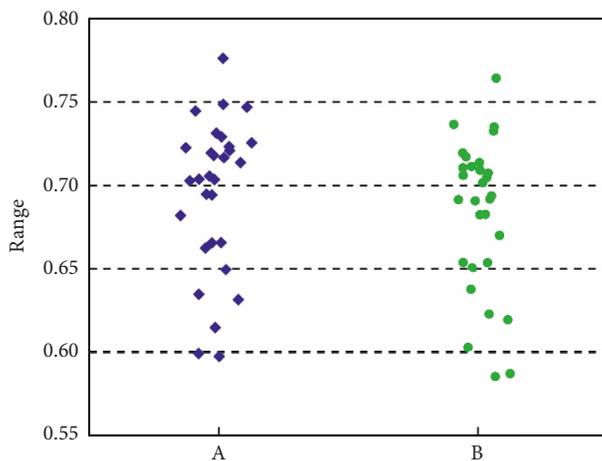

FIGURE 5: The predicted value distribution of entertainment patterns in hotel management.

predicted value of entertainment mode is in a relatively ideal environment. In general, the corresponding predicted value of the entertainment mode of hotel management has the same distribution as the actual value, and the numerical value is also well maintained. Between intervals 0.6 and 0.75, the predicted values of the hotel management entertainment mode have a good degree of agreement, and most of the corresponding values of the entertainment mode are also distributed in this interval. Only in the interval greater than 0.75 and less than 0.6, the prediction error of the data is large. Overall, CNN and LSTM methods can also better predict the corresponding values of entertainment patterns in hotel management.

Compared with the prediction of entertainment mode, the check-out mode of hotel management is easier to predict. The check-out model of hotel management has minor changes, and the check-out model of hotel management involves relatively few features. Figure 6 shows the distribution of the predicted and actual values of the hotel management system's check-out

patterns. It can also be easily seen from Figure 6 that the check-out pattern of hotel management has relatively small fluctuations. CNN and LSTM algorithms also easily predict the corresponding data and characteristics of hotel management check-out patterns. Although the hotel values between 0 and 30 have large fluctuations, the CNN and LSTM methods can also better reflect the peak and trough values of the check-out pattern. The prediction error value for the hotel management check-out mode is completely acceptable to the hotel management. Larger errors mainly appear in the data of hotels in the range of 20 to 25. The CNN and LSTM methods only predict the numerical value of the data well, but it is poor in predicting the fluctuation trend between the data.

For hotel managers and occupants, sleep patterns are an important system. Its prediction error is mainly related to the air-conditioning system, curtain control system, and so on. The sleep system has more obvious time characteristics. Figure 7 reflects the change trend between the predicted value and the actual value of the sleep pattern of hotel management. The red curve represents the predicted data of sleep patterns, and the black part represents the actual data value of the hotel management. The green area is the error area between the two. In general, the data of sleep patterns have relatively large fluctuations, and they also have relatively large fluctuations over time. However, CNN and LSTM algorithms are better at predicting data related to sleep patterns in hotel management. It can also be seen from the green area in Figure 7 that the prediction error of the sleep mode is also relatively small. It has a relatively obvious cumulative error over time. The larger error mainly exists in the interval 18 to 30, which is also one of the defects of the LSTM algorithm. In order to improve the accuracy of data prediction of this part of the sleep pattern, it is necessary to increase the data sample size of this part of the region.

The prediction errors of entertainment mode and sleep mode are mainly related to the operation of electronic equipment in the guest room. It is a critical part that the impact system, air conditioning system, and lighting system in the guest room can be adjusted in real time according to the real-time needs of the occupants. To further demonstrate the prediction error of in-room device operation, Figure 8 shows the prediction error of indoor facilities in entertainment and sleep modes. The squares represent the hotel rooms. This study will illustrate the distribution error of each area of the hotel room in the form of an error heat map. In general, CNN and LSTM have small errors in predicting the operation of indoor equipment, and the prediction error distribution is relatively uniform. Larger prediction errors are mainly distributed in the edge regions of the room. This part of the area may correspond to the video system and air conditioning system. But all the errors meet the requirements of the hotel management information system. This further illustrates that the CNN and LSTM methods can better predict the entertainment and sleep patterns of hotel management. Figure 9 shows the average errors of CNN and LSTM under four modes for predicting hotel management information systems. The largest average prediction error is only 2.81%, and this part of the error comes from the hotel management's prediction of sleep patterns. The prediction

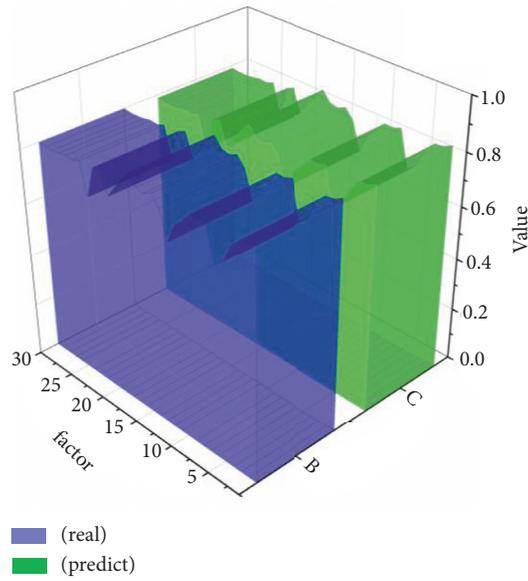

FIGURE 6: The predicted value distribution of check-out patterns for hotel management.

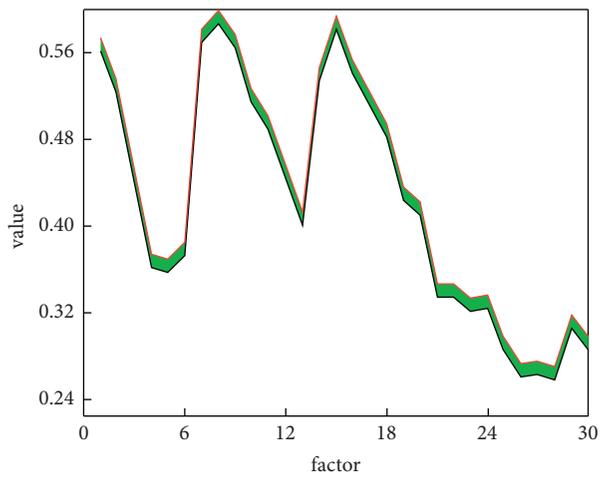

FIGURE 7: The distribution of predicted values for sleep patterns in hotel management.

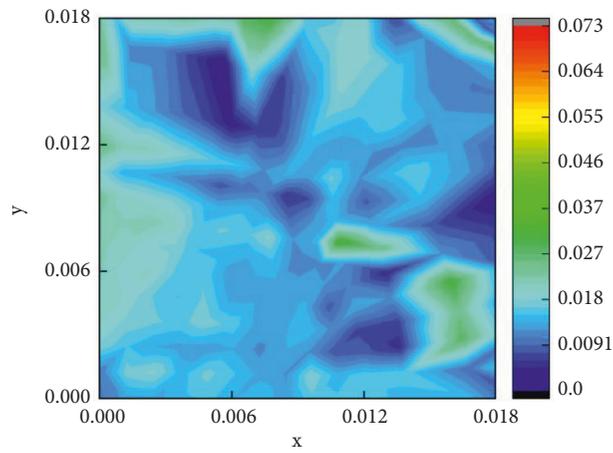

FIGURE 8: Prediction errors for indoor facilities in recreation mode.

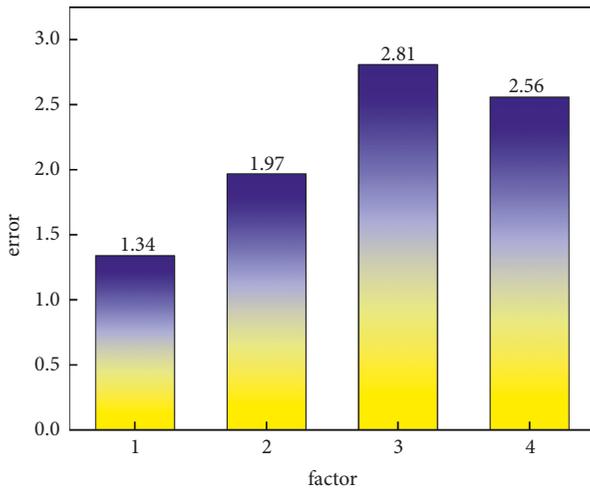

FIGURE 9: The average forecast error of four modes of hotel management.

errors of the in-store mode and the out-of-store mode are only 1.34% and 1.97%, respectively. This prediction error can not only satisfy the requirements of hotel managers, but it can also satisfy the requirements of lodging guests. In conclusion, the CNN and LSTM methods have certain feasibility and accuracy in realizing the intelligence of the hotel management information system.

5. Conclusions

The traditional manual hotel management model can no longer meet the needs of today's people's accommodation. Now, the flow of people in the hotel and the needs of the occupants have a relatively large change and a relatively large amount of information. This requires computer technology to assist hotel managers to manage. More and more hotels have begun to introduce computer information management system, but it can only assist hotel managers to realize the management of in-store mode and out-of-store mode. As for the individual requirements of the occupants, the current computer information management system cannot help the occupants to realize them very well.

This research uses CNN and LSTM methods in artificial intelligence technology to design a hotel information management system, which can realize intelligent management of in-store mode, entertainment mode, sleep mode, and out-of-store mode. It can not only improve the work efficiency of hotel managers, but it can also meet the individual needs of the occupants. In general, CNN and LSTM methods can better predict the four modes of hotel information management system. The largest prediction error is only 2.81%, and this part of the error comes from the prediction of the sleep pattern of the hotel information system. For the prediction of the in-store and out-of-store patterns of the hotel management system, the average error is only 1.34% and 1.97%. For the prediction of the entertainment mode and sleep mode of the hotel management system, the prediction error distribution of the operation of indoor equipment is relatively uniform, and most of the

errors are distributed within 2%. This shows that CNN and LSTM methods have high credibility in realizing hotel management intelligence.

With the continuous improvement of the living standards of people, the requirements of people for the environment in which they are located are gradually increasing, which makes urban landscape design work more and more important. Plant landscaping is the core component of urban landscape design. By analyzing and discussing the application of plant landscaping in urban landscape design, the quality level of urban landscape design can be further improved, thereby promoting the sustainable development of urban construction. Machine learning makes it possible to realize the intelligent processing of data and make full use of the knowledge and value contained in the data. This paper explores the way of intelligent analysis and application based on machine learning in the field of landscape architecture. First, the k -means machine learning clustering method is used to determine the types of plant landscaping required by modern urban landscape design. Experiments show that our model can be well applied to design applications of modern urban landscapes.

1. Introduction

Machine learning is a way to realize artificial intelligence and a key technology for processing big data. Machine learning algorithms can automatically analyze one or several types of data to obtain rules, discover the mechanism of action, and use the rules to predict unknown data. At present, it has become possible to apply machine learning (including deep learning) to the fields of landscape architecture, urban planning, and architecture to solve related problems such as human settlements. Scikit-learn, an open-source machine learning library based on Python language, integrates mainstream core algorithms in the field of machine learning, including classification, regression, and clustering algorithms, and data preprocessing methods; TensorFlow, an open-source deep-learning library based on Python language, uses computational graph, and automatic differentiation and customization are used for numerical calculations. Because of the emergence and rapid growth of machine learning open source libraries, and the gradual improvement of a large number of core algorithms, machine learning as a tool has been widely used in various fields, and landscape architecture is also in the exploratory stage.

Plants are an important element in the construction of garden landscapes. Today, with the continuous emphasis on the construction of ecological civilization, people are more yearning for green space, so garden plant landscaping has received more attention and attention, and its dominant position in landscape garden design has become more and more obvious. At this stage, designers often use horizontal and vertical section drawings to analyze and deliberate plans, but relying only on artificial design limits the possibility of landscape design. Therefore, designers and industry-related personnel urgently need new technology to assist them to better complete the landscaping design of garden plants. With the development of science and technology, the application of machine learning to garden plant landscaping has become a breakthrough to solve the problem.

There are many classic machine learning algorithms that have application potential in landscape architecture design. According to the focus of solving the problem, it can be divided into algorithms with efficient data classification capabilities, such as naive Bayesian algorithm, support vector machine decision tree, regression tree, and random forest [1], which are mostly used for classification problems such as landscape land classification [2]; deep learning

TABLE 1: Variety of algorithms of machine learning technology.

Learning style	Algorithms type	Algorithms
Supervised learning	Regression	Linear regression, polynomial regression, ridge regression
	Classification	Logistic regression, support vector machine, decision tree, k -nearest neighbor, etc
Unsupervised learning	Clustering	K -means, means shift, fuzzy c -means
	Association rule learning	Apriori, frequent pattern growth
	Dimensional reduction	Principal component analysis, linear discriminant analysis

algorithms, such as convolutional neural networks, recurrent neural networks, and generative adversarial networks, have powerful image recognition capabilities [3–5] and are mostly used for rapid identification and information extraction of remote sensing images and street view images [6–10], in which algorithms such as generative adversarial networks also have powerful image generation capabilities [11], which are mostly used in generative design [12]; regression algorithms such as principal component analysis and logistic regression have the ability to automatically associate data and perform functions. The ability of fitting to mine the internal relationship behind the data is mostly used for correlation analysis, such as the research on the driving force of the development of landscape patterns [13–16]; tf-idf, word2vec, BERT, CRF, LSTM in the field of computer natural language processing. Such algorithms have the ability of text recognition and processing and can classify and extract sentiment and other topics from text data in a large number of networks.

In this work, the k -means algorithm is used for the first time to perform cluster analysis on the landscape principle design of the urban landscape. And the results of the model are tested by taking Hangzhou Hupao and Beijing Biyun Temple survey image clustering as examples. The results show that the model has a good performance in the application of modern urban landscape design for generating plant landscaping. In addition, this paper also analyzes the application principles of plant landscaping in the urban landscape and the application of plant landscaping in modern urban landscape design.

2. Theoretical Basis of Machine Learning and Principles of Plant Landscaping

2.1. Machine Learning. In the field of landscape architecture, traditional computer technology requires artificially designed computing rules, while machine learning technology has powerful rule learning ability and the ability to capture implicit rules. In landscape architecture work, it is necessary to analyze the site conditions, obtain the law of site changes, and then intervene and guide the site to develop in a specific future direction according to the means of planning and design. Therefore, machine learning has great potential in the field of landscape architecture.

From the perspective of machine learning technology, machine learning technology includes a variety of algorithms with different functions and focuses (Table 1). However, because the design goals of the algorithms in the

computer field have less overlap with the landscape architecture design, they cannot directly serve the landscape architecture design, so they are used in the landscape architecture. There are not many algorithms with relatively mature applications. The common application method at present is usually to decompose the planning and design into multiple work steps and then design the corresponding algorithm according to the work target of each step.

2.2. K -Means Algorithm. In the K -means algorithm, K is the number of cluster centers, and Means is the mean. This algorithm clusters the regional data points through the iterative optimization of the mean and obtains the optimal clustering result. In this article, garden colors are divided into 7 colors. Below are the executor steps of the algorithm. (1) Set $K=7$. Seven color location data are randomly selected as the initial cluster centers of the seven categories, and the Euclidean distance formula is used.

$$D = \sqrt{(x_i - x_0)^2 + (y_i - y_0)^2}, \quad (1)$$

where D is the distance; x_0 and y_0 is the latitude and longitude coordinates of the center point D ; x_i and y_i , is the latitude and longitude coordinates of each noncenter point. Use this formula to calculate the distance from each noncluster center point to the cluster center point, and divide each noncluster center point to the nearest cluster center. (2) After the data are grouped by distance, the mean of the seven groups is calculated, respectively, and the mean of the seven groups is used as the new cluster center. (3) Iteratively calculate the distance from each noncenter point to the new center point using equation (1). (4) Iteratively calculate new cluster centers until each noncluster center data no longer move and the cluster centers no longer change.

2.3. Application Principles of Plant Landscaping in Urban Landscape

2.3.1. Ecological Principles. In the urban landscape design, the application of plant landscaping can not only create a beautiful visual environment, improve the city's ornamental value, but also improve the material environment. In plant landscaping, it is very important to strengthen the plasticity of plants and improve the ecological beauty of the surrounding environment. On the one hand, plants purify the surrounding environment very well by releasing oxygen and absorbing carbon dioxide. At the same time, there are functions such as reducing noise and adjusting the temperature. However, different types of plants have different

growth environments. Once the selected plant species is not suitable for the local ecology, it will have a great impact on its growth. On the other hand, if there is a phenomenon that the community violates the natural development law, there will be serious consequences. Therefore, it is very necessary to scientifically select plant species based on local environmental conditions.

2.3.2. Principles of Practicality. In the application of plant landscaping in urban landscape design, the principle of practicality should also be followed. The so-called principle of practicality means that in the actual process of plant landscape landscaping, some practical functions such as environmental protection should be fully considered. Harmful gases play a good role in purifying the air. If the above practical conditions cannot be met, some practical plants that can play a good role in noise reduction and dust prevention can also be selected as landscaping materials. Therefore, while beautifying the urban environment space, it can also effectively weaken the sense of tension and oppression brought about by the characteristics of urban industrialization, meet people's needs to be close to nature, reduce the urban heat island effect, and enable urban plant landscaping to achieve production and integration. The combination of ornamental and ornamental can give full play to the functional value of urban plant landscape in beautifying, ecological, and environmental protection.

2.3.3. The Selection of Plants Should Be Combined with the Characteristics of the City. In modern urban landscape design, the application of plant landscaping should not only repeat the application of a single plant, but should combine the characteristics of the local city and the actual situation of the landscape, and at the same time consider factors such as soil climate and environment. Therefore, designers need to consider the local plants with strong regionality and show the local characteristics through the planted plants, which can not only create a certain resource space for the local landscape but also allow the planted plants to better adapt to the environment, to further save plant landscaping.

2.3.4. Make Full Use of Ground Cover Plants. Among various types of plants, ground cover plants have their own unique features, such as luxuriant branches and leaves, and strong fecundity. At the same time, they have a very strong antipollution ability, and follow-up maintenance is also more convenient. Therefore, in various designs of the modern urban landscape, planting is almost indispensable, which can give people a harmonious and comfortable look and feel. From the overall look, it also makes the layering of the whole design more prominent, making people shine. The plants above can absorb light energy, and the plants below can loosen the soil surface, adjust the ground temperature, and make the growth environment of the trees above better. In addition, ground cover plants also play an important role in the garden landscape. For example, planting ground cover plants around flower beds and on both sides of the sidewalk

can form a sharp color contrast with the flowers and effectively clarify the walking routes of tourists, thereby improving the ornamental value of the landscape and at the same time alleviating people's aesthetic fatigue.

3. Judging the Plant Landscaping Style of Modern Cities Based on Machine Learning Models

3.1. Model Establishment and Training. The data of this experiment are mainly images with latitude, longitude, and elevation information taken through the actual survey of mobile phones. Divided into two groups, one group came from Hangzhou Tiger Pao. The other group came from Biyun Temple in Beijing. The specific technical route is shown in Figure 1. First, the images are read in batches in the Python programming language, because the captured images are about 4 200 pixels 2 400 pixels in size, and color analysis does not require such high precision, so the image size is reduced by compressing the image to save analysis time. Then, set the number of color theme color clusters to 7, that is, obtain 7 theme colors for each image. Colors were classified using the *K*-means clustering algorithm.

The extraction of the theme color is shown in Figure 2. After extracting the theme color of all images, they are summarized in an array. In the aspect of data enhancement visualization, 2 forms are designed: (1) scatter point form to print the theme color, which can directly reflect the urban color impression. Through the extraction of the urban theme color, the color impression sensory presentation can be used to study the urban color, which can be aimed at different urban spaces and different research times, and to analyze the changes in color. (2) Try to project the subject color of the survey images of the two places into the three-dimensional space and observe the changes of the two sets of data in the three directions of red, green, and blue.

3.2. Model Results. In machine learning clustering, sklearn integrates many clustering algorithms and compares the effects of different clustering algorithms on different data types through the actual operation of the program. In addition to applying survey photos to analyze the urban color environment, you can also use recorded video, extract images at specified frames, and perform the same analysis. In the specific data analysis, the theme color of each image can also be placed on the coordinate points of its latitude and longitude, and the clustering algorithm can be used again to cluster the areas with similar color values in the space, so that the urban color characteristic areas can be classified. And the POI data reflecting urban functions, Weibo, WeChat, and other data reflecting urban social relations are combined and analyzed to find the internal mechanism of urban color space distribution characteristics.

The clustering results of the research images of Hangzhou Hupao and Beijing Biyun Temple, and the color impression after printing the theme color in scatter form are shown in Figure 3. Hupao's theme color is gray and dark (the color of the building), mixed with green and green vegetation and blue

FIGURE 1: The technical route of using K-means clustering algorithm.

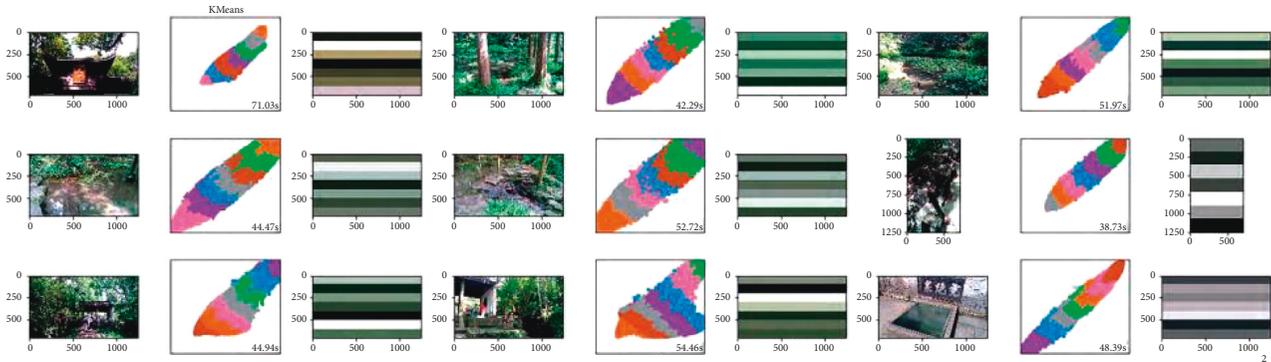

FIGURE 2: The extraction of the theme color.

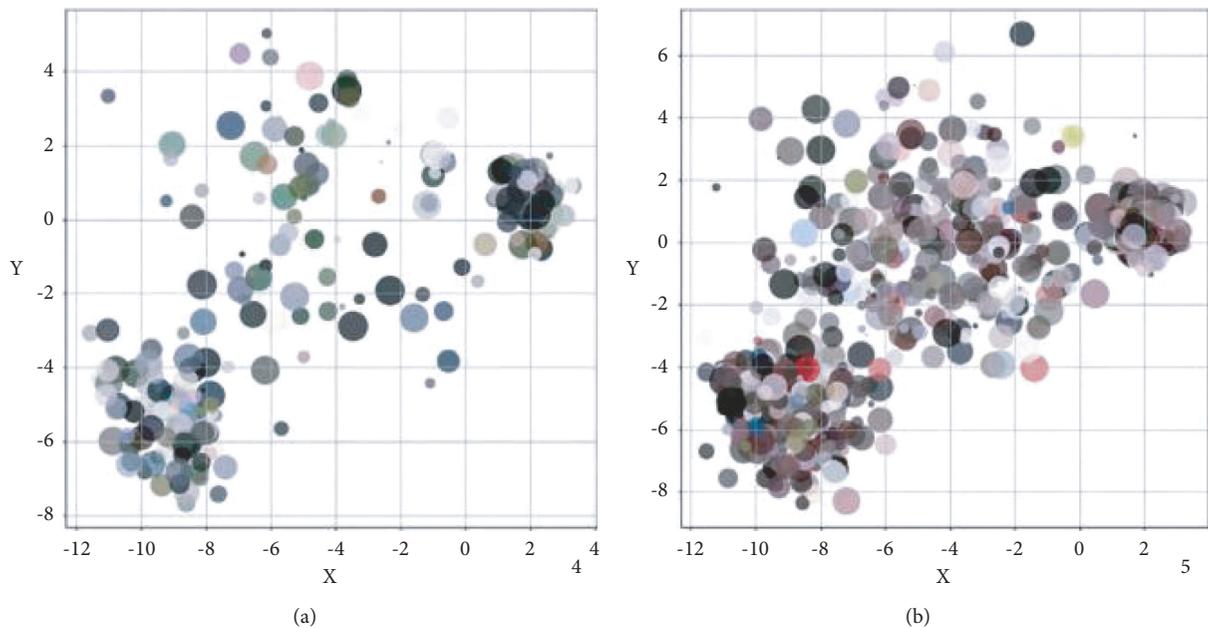

FIGURE 3: The clustering results of the research images of Hangzhou Hupao and Beijing Biyun Temple, and the color impression after printing the theme color in scatter form.

sky. Simple and elegant Biyun Temple because the building itself is mostly red, after interspersed with vegetation and the sky, the overall feeling is gorgeous and gorgeous. Through these data visualization methods, the urban color characteristics of the study area can be more intuitively reflected. If the number of research areas surges, automated batch processing can be achieved according to the established model, such as studying the color characteristics and distribution relationships of different areas of the city. Data containing color information (RGB) is projected into three-dimensional space. The changes in the red, green, and blue color components can be grasped by judging the distribution of the colors of the two regions in the three-dimensional space

domain. The color tendency of Beijing Biyun Temple is higher in the red value, while the 3-component of Hangzhou Hupao color tends to be lower. In the analysis, the color can also be converted to HSV (hue, saturation, value) and projected into the three-dimensional space domain to analyze the relationship between hue, saturation, and lightness.

4. The Application of Plant Landscaping in Modern Urban Landscape Design

4.1. Tree Landscaping. In large garden scenic spots, all kinds of towering and lush trees will always bring people many different impressions. For example, the lush ginkgo, with its

proud standing posture, brings people a beautiful feeling. It has long been called the Gongsun tree. The planting of ginkgo in the garden landscape not only reflects the virtues of the predecessors planting trees and the later generations enjoying the shade in traditional Chinese culture but also implies people's yearning for a better life in the future. The willow tree is deeply loved by garden designers because of its gentle and graceful tree shape. In spring, it is praised for its willows that are drunk with spring smoke. In summer, it is called ten thousand hanging green silks. In the winter, the weak warbler with green silk strips presents the beauty of ancient charm in different seasons. Because of its tall and straight leaves and sparse branches, the king coconut tree is often used as a street tree to green roads. The curved branch shape of mountain peach, the arch branch shape of welcoming spring, the umbrella shape of acacia, and the clump shape of the Chinese rose can all bring people different visual enjoyment.

4.2. Make Plant Landscaping in Combination with Different Terrains. In the actual plant landscaping, it is necessary to combine the different spatial topography of the city, so as to effectively highlight the natural characteristics of landscaping. For example, some trees can be planted around the ridgeline, and some short shrubs can be planted in the position of the hillside ravine. Through this landscaping configuration, it can not only effectively demonstrate the tall and straight posture of the mountains but also make the entire urban environment more harmonious and increase the three-dimensional sense. On this basis, the characteristics of some buildings such as urban pavilions and pavilions can also be combined, and plants can be arranged on the top of the mountain to promote the two to set off each other and complement each other. When creating a waterside flower border landscape by the water, make a good choice of aquatic plants, the more common ones are reed bamboo, water lily, barracuda, and parasol. To ensure a good reflection effect, it is not advisable to plant too many plants underwater. On the banks of the embankment, some trees can be planted, and the trees are sparsely distributed to form a beautiful reflection in the water.

4.3. Follow the Aesthetic Principles of the Plants Themselves for Landscaping Design. First of all, in some areas such as the corners of buildings and roads in the city, it is necessary to weaken the sharp corners to reduce the visual rigidity. In landscaping, the combination of flat slope and arbor and irrigation can be used to plant some beautiful plants, such as cedar, sycamore, and pentagonal maple. If the selected seedlings are plants with high branch points, try planting multiple seedlings in the same tree pond. At the same time, carry out scientific planting, let them grow together into a large canopy, and effectively weaken the corners. On the other hand, it is also possible to make a reasonable blank of the landscape with the help of the blanking technique of traditional Chinese painting. For example, in a relatively empty square, if you add a few delicate trees to embellish it, it

can give people an open and comfortable look. It fully embodies the principle of balanced aesthetics.

4.4. Maintaining the Stability of Native Plant Communities. Before introducing new plants, we must first ensure that the existing plant community is in a relatively stable state. Therefore, for the introduced new species, the relevant departments must do a good job in quarantine work and make a good estimate of their reproductive capacity, so as to avoid a large number of reproduction and spread after they are introduced into the urban landscape, which will cause damage to the balance of the local plant community and ecological structure very serious impact. Maintaining the stability of local plant communities can further ensure the visual effects and ecological benefits of urban plant landscaping. On the other hand, weeds should be cleaned regularly to prevent the problem of flooding due to their tenacity, and the affected areas should be restored and protected. At the same time, it is necessary to fully develop the nursery cultivation industry and market, so that plant landscaping can choose more plant varieties.

4.5. Shaping the Urban Landscape in Combination with Local Urban Culture. The culture of each city is different. Nowadays, people have begun to attach great importance to the inheritance and protection of urban culture, as well as the continuation of historical development. Therefore, in the urban landscape design, it is necessary to combine the local urban history and culture, excavate the connotation, present the cultural heritage of the city to the greatest extent, and give the city the driving force for continuous development. Therefore, in the modern urban landscape plant landscaping, it is necessary to combine urban culture, conform to the current development law of our country, and avoid destroying the surrounding ecological environment.

5. Conclusion and Future Prospects

Artificial intelligence technology based on machine learning is gradually applied to the analysis and evaluation of landscape architecture with its efficient data processing capabilities and implicit rule capture capabilities and has initially replaced some simple repetitive labor at this stage. Algorithmic generative design based on deep learning takes the creativity of artificial intelligence a step further. The cleaning and selection of data and the manual intervention of algorithms are the core bottlenecks at present.

The cleaning and selection of data are a technical challenge. Artificial intelligence is basically the exchange of artificial intelligence for intelligence, and it is supported by a large amount of basic data work (such as manual annotation). Problems such as noise and lack of data are frequent at this stage. In this context, designers appear as data analysts, and artificial intelligence methods aimed at replacing repetitive work have brought more planning and analysis and repetitive work. However, with the improvement of technology in the future, the emergence of more excellent algorithms and data sources will gradually solve the current

problems and allow designers to return to planning and design.

The manual intervention of the algorithm is a difficult problem in the application method, which directly affects the role of artificial intelligence and designers. This question is related to the question of how much artificial intelligence should be in the design. This also involves a series of questions such as whether the artificial intelligence analysis results are reliable, whether the output results are correct, and how to define correctness? As mentioned above in the planning case of Rome railway station and the case of plant configuration, the architectural form needs to conform to the form of the building base and at the same time be similar to the surrounding architectural texture. Under the constraints of these two goals, deep learning can balance the relationship between the two, aiming at approximating the base shape and searching the building database for matching, comparing, and iterative cycles. The optimal solution can be obtained only by approximating the base shape infinitely. In the plant configuration project, plants need to meet conditions that are easy to quantitatively explain such as sunshine, climate, and configuration mode. However, under this condition, attributes such as plant species, plant height, and crown width can only be constrained within an interval, so the output results are still very large. Therefore, whether the output result is correct is related to whether the target is abstract. From the computer's point of view, it is easy for computers to calculate quantitative problems with clear standard goals and regard the goals as correct. In the face of abstract problems, it is difficult for the computer to judge whether it is correct, but for designers, this is also an open problem. To this end, different scholars have made preliminary explorations, and for example, in the case of plant configuration, the abstract plant configuration theory is quantitatively explained and constrained. In the planning case of the urban central axis, the evaluation system is used to constrain the abstract scheme selection problem; Tang Jingxian's streetscape evaluation research combines the subjective evaluation system with the objective analysis results of streetscape information to realize the artificial correction of machine learning perception evaluation research. The above methods are currently tried by designers. Efforts to revise AI-generated results are also responses to abstractions in design.

To sum up, at present, plant landscaping has been widely used, which greatly improves the urban environment, allows people to live in a comfortable and environmentally friendly living environment, and further promotes the development of urban construction in China. At this stage, plant landscaping has become an indispensable part of urban landscape design. In the process of designing urban landscapes, designers must combine with more ecological elements and use different plant characteristics to make plant landscaping. The scenery is more suitable for city life.

In the future, with the training and learning of a large amount of data, the creativity of artificial intelligence will gradually increase. Landscape architecture is a subject highly related to human subjective aesthetics. In order to avoid over-reliance on artificial intelligence in planning and

design, it leads to the patterning and standardization of output results. Future research should distinguish between the repetitive and simple labor that should be performed by artificial intelligence in the planning and design process and the part that requires the designer's experience and judgment, and let artificial intelligence technology assist the design instead of leading the design.

With the expansion of teaching scale and the rapid development of educational information, a smart classroom management system based on speech recognition has been proposed and developed to improve the information level of smart classroom management. This paper discusses the application of multimedia equipment control. The system relies on the mature campus network in the way of cloud and local speech database for speech recognition. The application of the system proves that the smart classroom management system based on speech recognition in cloud architecture has more advantages than the traditional multimedia classroom management system and also has definite expansibility. It facilitates the unified management of the school, improves the efficiency of administrators, saves a lot of human and financial resources, and greatly promotes the development of school information construction. The smart classroom becomes a new direction in the application of information technology in the field of teaching and learning and is a smart learning scenario for improving the learning and teaching scenario. This paper focuses on the use of smart classroom as a supplementary teaching tool to improve Chinese language teaching and learning and illustrates the optimization of the teaching environment by smart classroom in terms of vocabulary learning and listening and speaking training.

1. Introduction

With the rapid development of modern computer science and technology, the traditional multimedia classrooms in schools have been continuously improved and upgraded to gradually form intelligent classrooms [1, 2]. The management of multimedia classrooms, from the traditional manual manipulation of various multimedia equipment to centralized control through the central control, then to remote control through the campus network, and then to the current automated management based on artificial intelligence, fully illustrates that the development process of education gradually began to apply artificial intelligence, schools focus on the construction of smart classrooms, and smart campus has become the future trend [3, 4]. Domestic construction of smart classroom design concepts and teaching models is relatively abundant but still lacks comprehensive practice [5].

The Ministry of Education proposes to promote the application of emerging technologies such as cloud computing and big data in school education and vigorously build education modernization. Regarding the active promotion of the application of “Internet+,” the guidance of the State Council marks the new technological revolution towards today’s stage [6, 7]. Therefore, it is necessary to develop a smart classroom management system based on speech recognition with cloud computing architecture. Smart campus is a comprehensive system implicating technologies from multiple fields such as cloud computing, campus network, big data, and remote control, and thus, it can only serve the students and teachers better after adequate integration and collaborative work [8, 9]. The basis for the realization of a smart campus is the Internet of Things (IoT), which relies on numerous application service systems to integrate teaching management, academic research, and

campus life of teachers and students and ultimately construct an integrated and intelligent campus environment for work, study, and life [10]. Smart classroom is the most important part of building smart campus, and it is the key work for universities to realize the strategic goal of informationization. At present, most schools have the foundation of campus network, especially some colleges and universities, and the campus network has been quite mature after many new constructions, upgrades, and renovations in the school informatization construction, which has laid a good foundation for the realization of smart classroom [11, 12]. Based on the modern technology, it is feasible to design an intelligent classroom management system by taking advantage of the existing campus network, cloud computing, and local customized voice library.

With the deepening application of big data, cloud computing, Internet of Things, and artificial intelligence technologies in education in recent years, the smart classroom has emerged as an overall solution to enhance teaching effectiveness [13, 14]. The optimization of the Chinese learning environment by smart classroom is reflected in three aspects: (i) accurate content pushing, (ii) efficient environment management and resource acquisition, and (iii) contextual setting and interactive feedback. Teachers can use the environment of smart classroom to effectively organize and manage the increasingly abundant teaching resources so as to better interact and teach students according to their aptitude.

Chinese is the foundation of language and has a significant impact on the development of habits and interest in future language learning. The use of smart classrooms to create interesting and shade-appropriate learning environments for students is the focus of this paper.

2. Technical Principle

The object of speech recognition research is speech, which is processed first, and the human voice is automatically recognized and understood by pattern recognition computers [15]. The combination and codevelopment of cloud computing and big data have contributed to the advancement of speech recognition technology to some extent. The deployment of deep learning framework in the cloud can enhance the capability of cloud computing, so the mutual promotion of deep learning, big data, and cloud computing greatly improves and enhances the ability of speech recognition models to mine and learn from complex data [16, 17]. Speech recognition systems are mainly divided into three types: embedded speech recognition systems, server-mode speech recognition systems, and cloud computing-mode speech recognition systems [18, 19]. According to the characteristics of the school, the human-computer interaction module of the intelligent classroom management system is based on speech recognition technology, while the piece of speech recognition based on cloud mode is not mature enough, and the customizable speech recognition service provided by the service provider is still at a primary level, so the speech recognition module of this system has to be divided into two parts: the speech cloud and the local

speech library. The voice cloud is responsible for the daily chat function, and the self-developed local voice library is responsible for the recognition of multimedia device control commands. The local speech library can be customized to provide speech recognition services for multimedia device control in the classroom, focusing on the reduced recognition range of these device controls and achieving higher recognition rates. The implementation of the local speech library requires the download and installation of the Microsoft Speech Recognition library, and the engine of speech recognition is driven by the speech recognition engine that comes with Windows, which can realize the ready acceptance of commands issued by the user [20].

This design currently drives three LCD displays simultaneously through this LCD driver all-in-one board; combined with the Android system software, it can realize the display of the conference theme or speaker's personal information on the upper bar screen, the lower standard screen displays the conference content, company logo, or video information, and the back bar screen carries the intelligent teleprompter system, which can display the speaker's speech content in real time.

2.1. Hardware Circuit Design. The main circuit board is a multimedia network player-LCD driver board based on Rockchip main chip RK3288. The design board can support LVDS/EDP/MIPI dot screen+HDMI dual display, LVDS+EDP dual display, LVDS+MIPI dual display, EDP+MIPI dual display, and other dual display mode options. It can drive 7-100-inch LCD and can support 4K full HD video decoding and 3840 × 2160 (for VOP_BIG) and 2560 × 1600 (for VOP_LIT) TFT LCD, and the main board contains 2 RS232, 2 UART, 4 USB HOST, 1 Ethernet, and other interfaces. It has a powerful communication function.

The design currently drives three LCD displays through this LCD driver board; combined with the Android system software, it can display conference theme or speaker personal information on the upper bar screen, the lower standard screen displays conference content, company logo, or video information, and the back bar screen equipped with intelligent teleprompter system can display the speaker's speech content in real time.

The smart podium consists of the following main parts: support structure, front face, operating table, LCD, and teleprompter. The usage frequency of each component in different application scenarios is shown in Figure 1.

The smart podium involves a total of three LCD displays, including two 28" bar screens and one 23.8" standard screen. The LCD module includes a display area, a PCB board set above the display area, and a COF (crystal coated film) set between the display area and the PCB board, the display area includes a protective film set at the front, a polarizer behind the protective film is defined as the reserved area, and the other defective area is defined as the defective area. The COF is fixed first, then the protective film and polarizer in the defective area are removed, the defective area in the display area is cut, then the lower end of the display area remaining after cutting is sealed, and finally, the

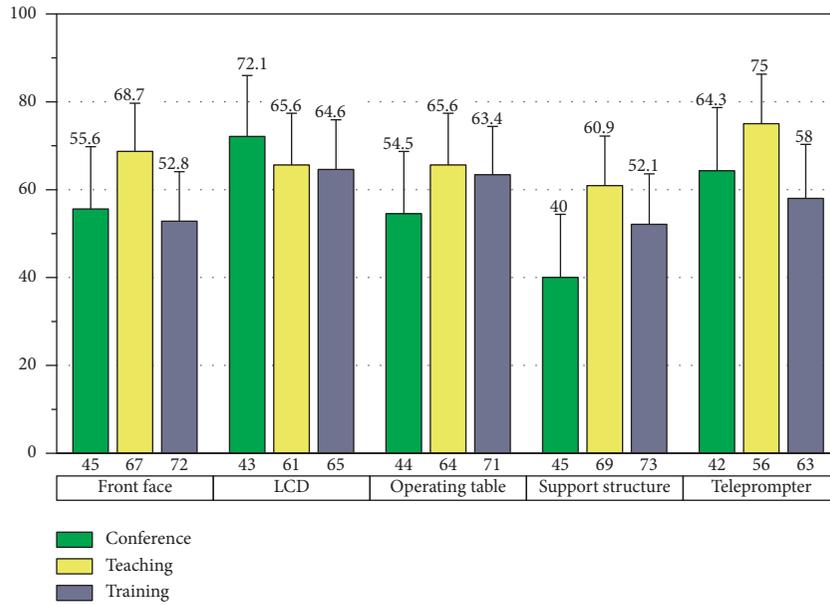

FIGURE 1: The usage frequency of each component in different application scenarios.

resolution of the sealed product is adjusted, so that the processed product can be used as a new small-size strip screen, thus achieving a novel display effect and being more widely used.

2.2. Software Function Design. The intelligent platform control software includes the information release of the first two display screens and the content display of the teleprompter system. The user can determine whether the device is online through the display status at the top of the software. Users can personalize the content of the two displays according to actual needs, including the display of pictures, videos, text font color size, and the interval of each material switch.

At the same time, the software also supports the preview function before the release of information to ensure that the information is accurately delivered to the audience, which greatly enhances the intelligence and personalization of the product, and can make the product applicable to a variety of different speech processes, which frequently can be calculated by the following equations. According to the formula (1)~(3), four teaching scenarios are selected for calculation, and the results are shown in Figure 2. It can be seen from the figure that, with the improvement of product intelligence and personalization, the audience will receive more information.

The intelligent teleprompter system software can automatically read the file content in the USB flash disk through the USB interface of the podium desktop for the speaker to deliver a speech. The operation of the speech content includes two modes: manual and automatic. In the manual mode, the speaker uses his or her voice to click the mouse to turn the page. The automatic mode is split into two categories: one is to set the automatic scrolling screen according to the speaker's personal preferences and reading speed for personalized settings, and the second is through the voice

recognition technology and teleprompter system linkage, so that the speech does not read and does not go, it has a read mark and is perfectly timed with the speaker's speech.

$$n = \sum_{i=1}^n n_i,$$

$$E_n = \sum_{m=0}^{N-1} x_n^2(m), \quad (1)$$

$$M_n = \sum_{m=0}^{N-1} |x_n(m)|,$$

where E_n is the amount of accurate information delivered to the audience; M_n is the degree of intelligence and personalization of products.

2.3. Speech Recognition System Design. The main function of the speech recognition program is to identify the voice commands that control the progress of the teleprompter system document. Speech recognition technology is divided into online speech recognition technology and offline speech recognition technology. Considering the usage environment and cost of the intelligent lectern, offline speech recognition technology is used here [21, 22].

In the traditional conference speech conditions, speakers need to bring their own paper scripts or use the way described in the previous section for automatic page turning, but none of these approaches can achieve automatic recognition of the speaker's real-time speech progress. The current artificial intelligence and speech recognition technology continues to develop, and application popularity for continuous voice recognition application technology has matured. How to more fully combine intelligent video and audio technology and conference speech needs has become the focus of application, and automatic speech recognition

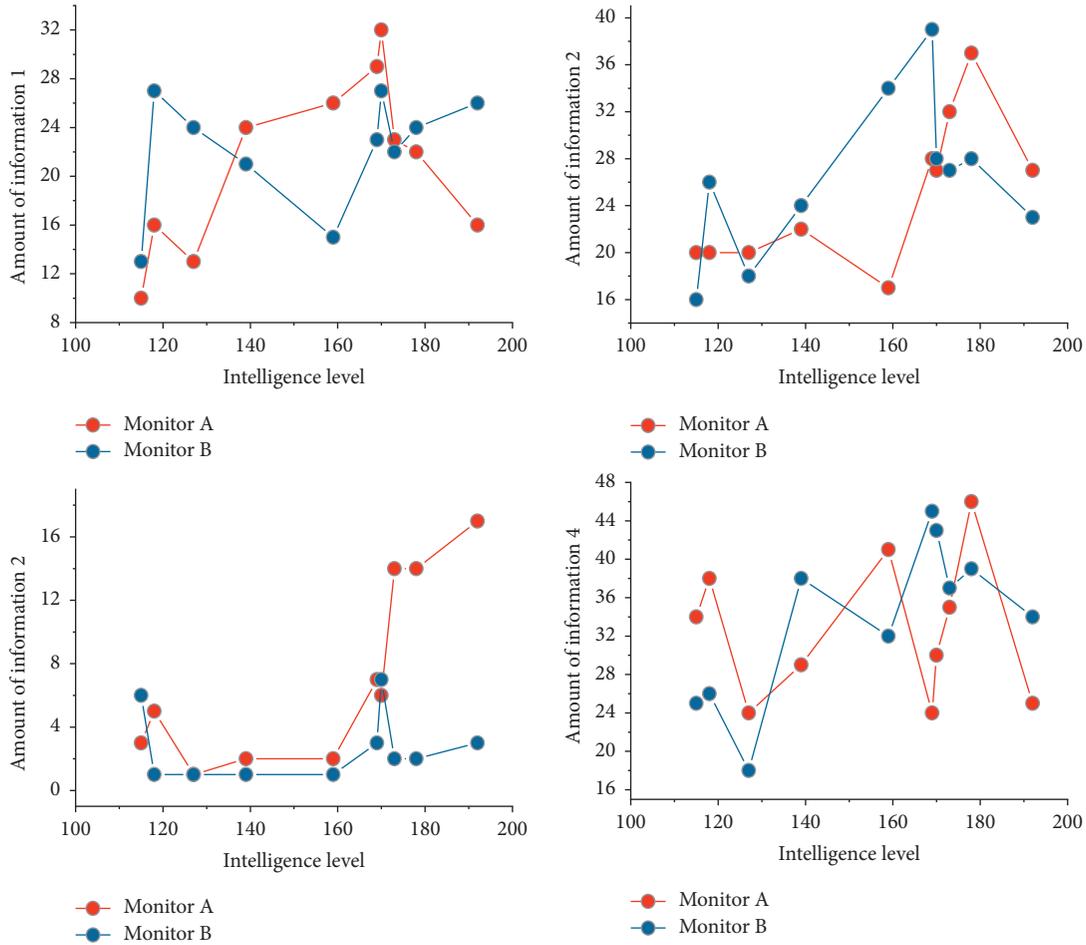

FIGURE 2: Relationship curve between the amount of information received and the product intelligence and personalization.

technology has become the “artificial intelligence + speech” breakthrough. Speech recognition system is divided into three layers: platform capability service, business software application, and speech intermediate control.

The platform capability service layer provides the intelligent speech recognition system server program, WEB server, speech capability platform service engine (speech recognition platform), database management, system resource management, and other related service functions required by the system, and on the premise of completing the basic functions, the application capability can be optimized according to the actual situation of system operation to improve the application level.

The business software application layer provides the information display function of the intelligent speech recognition system used by the speaker and provides the text display corresponding to the real-time transcribed speech and the processing function of various basic document information.

The speech middle control layer mainly provides the speech recognition middleware program, transmits data information with each other with the speech collection equipment picking port and speech recognition SDK interface, completes the functions of speech data collection, processing, storage, and network transmission, and interacts

with the speech capability platform service engine in the platform capability service layer. The intelligent speech recognition system includes speech recognition server, real-time recognition terminal, multichannel speech processor, professional conference microphone, router, and other products, among which the speech recognition server realizes the deployment engine and other types of core capability software, achieves a high degree of equipment integration, reduces capital investment, and provides recording service processing, data transmission, and other capabilities. The analytical formula between key objects is shown in the following equations. According to the formula, we can get the histogram of the relationship between the integration degree of speech recognition equipment and capital investment (three scenarios), as shown in Figure 3. It can be seen from the figure that the higher the integration degree of speech recognition server equipment, the lower the capital investment. The real-time recognition terminal is mainly used to deploy client software and provide the operation of each function of the software. The multichannel voice processor converts the audio data of analog microphone into network data through professional voice acquisition technology, which is used as the data source of the whole system voice. The system topology diagram is shown in Figure 4.

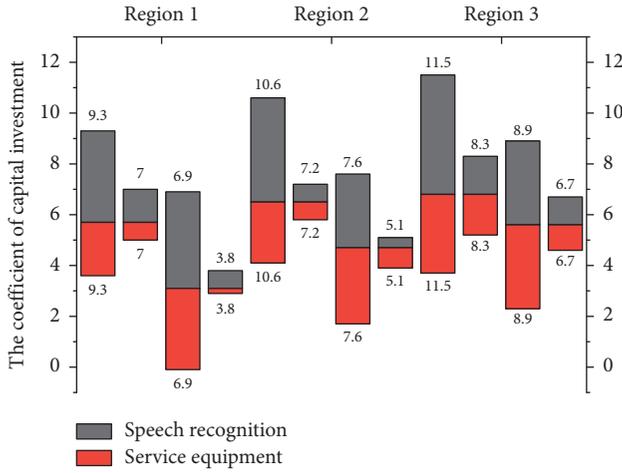

FIGURE 3: Relationship between high integration of equipment and capital investment.

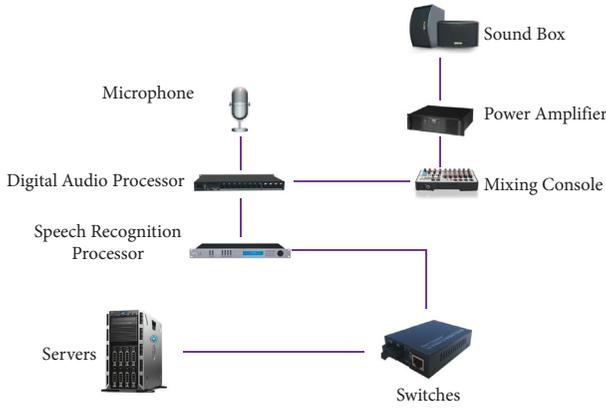

FIGURE 4: Speech recognition system topology diagram.

$$D(X, Y) = \sqrt{\sum_{i=1}^n (x_i - y_i)^2},$$

$$D^n = \sum_{i=1}^j \sum D(X, Y_i^{n-1}), \quad (2)$$

$$\delta^n = \frac{|D^{n-1} - D^n|}{D^n},$$

where D is the degree of integration of speech recognition service equipment; D^n is the degree of integration of all equipment; δ^n is the coefficient of capital investment.

2.4. Cloud Computing. In essence, cloud computing is a virtualized resource. This computing method dynamically provides service expansion through the Internet. It is a pay-per-use model to provide available, convenient, and on-demand network access. Cloud computing is an important research area for future development, in terms of application, it has low requirements for the client devices, and the

devices themselves do not need to be too highly configured because the resources used are from the cloud, and as long as the network is smooth, data and application sharing can be achieved, which can be analyzed through the following formula.

Currently, cloud computing and speech recognition technology have become emerging teaching methods in the education industry [23, 24], and the speech recognition module in the cloud architecture of the intelligent classroom management system can respond to a variety of user requests and can take advantage of a large amount of cloud data to improve the performance of the speech recognition system. Speech cloud uses cloud computing to achieve fast speech applications, which in this system mainly recognizes the human voice. Cloud mode speech recognition and interaction service is a new direction for future research and application. In this regard, the technologies of KDDI, Ali cloud, Baidu, and Tencent cloud are in the leading position in China.

$$X = \{X_1, X_2, \dots, X_m\}, \quad (3)$$

$$X_i = \{X_{i1}, X_{i2}, \dots, X_{in}\},$$

where X is the configuration parameters of equipment.

2.5. Voice Recognition. Voice recognition technology is mainly divided into two categories, that is, voice meaning recognition and voice similarity recognition. Sound meaning recognition is to transform human voice into text by analyzing the human voice and finding the characteristics of pronunciation from it, which is usually used in such fields as fast inputting information, artificial intelligence, and communication between human and computer through voice. Similarity recognition of voice is to compare the target voice object to be recognized with the voice sample and check whether the similarity between the target voice and the sample can be achieved [25, 26]. The computer and human are basically similar in terms of speech recognition processing. A complete speech recognition system is generally divided into three parts, that is, speech denoise pre-processing and extraction of features of speech, acoustic modeling and pattern matching, and language modeling and language processing. It is in the noisy environment; due to the complexity of the actual environment, noise reduction processing is of great practical significance. For the purpose of lifting up the level of speech denoising and the accuracy of speech recognition system, wavelet denoising technology is often applied to speech recognition. The flow of speech recognition is shown in Figure 5.

3. System Design

At present, the speech cloud is widely used in the general field, with a huge amount of user speech data and relatively high accuracy of speech recognition. However, in the field of education, the commands that need to be recognized in the control of multimedia equipment in school smart classrooms are relatively fixed, so the local speech library can be customized to meet the personalized needs of users and

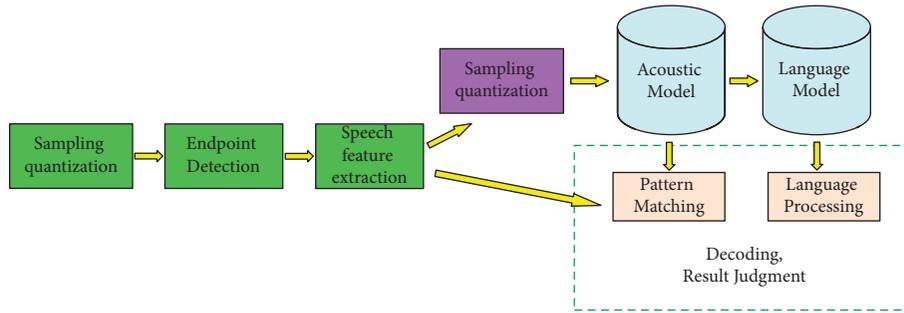

FIGURE 5: Flowchart of speech recognition.

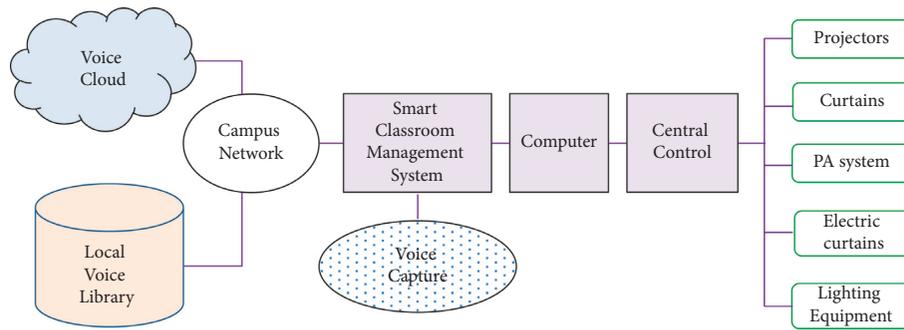

FIGURE 6: System architecture diagram.

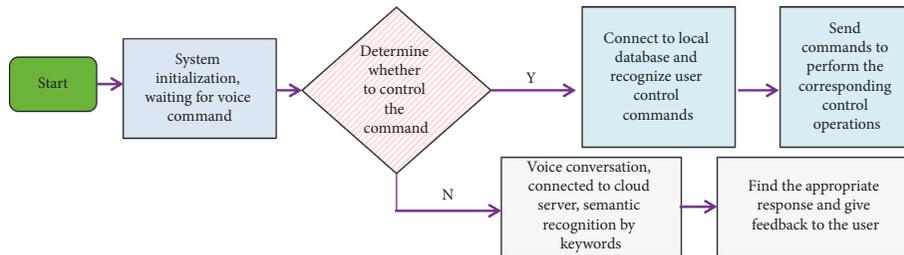

FIGURE 7: System workflow chart.

make up for the shortcomings of the speech cloud such as slow recognition speed due to too wide a search range, heavy reliance on network, multilink leakage, risk concentration, and reduced flexibility of users' control of data and technology.

3.1. System Architecture. The overall structure of the speech recognition-based intelligent classroom management system with cloud computing architecture is shown in Figure 6.

3.2. System Workflow. Generally, the computer in the smart classroom automatically opens at the set time and starts the client of the management system. First, the software loads the basic syntax package for login, initializes the login speech recognition engine, initializes the interface, and waits for the user to login; then, after successful login, it waits for the user's voice command; after the teacher user issues the correct voice login command, the system starts to judge; if it is a command to control multimedia devices, it connects to the local voice library and controls the devices through the central control serial port after recognition if it belongs to

the general chat. If it belongs to the voice conversation category of general chat, it connects to the voice cloud, finds the answer after recognition, and gives feedback to the user through voice or text. The relationship can be accurately predicted by the following formula. The flowchart of the system is shown in Figure 7.

$$\begin{aligned} \cup Q_j &= O, \\ Q_{j1} \cap Q_{j2} &= \emptyset, \end{aligned} \tag{4}$$

where Q is the voice login command which the teacher sends to the user; $1 < j < n$.

4. Practical Application

4.1. Application of Aliyun. Teachers and students realize human-computer interaction with machines, which involves human speech recognition and needs to be connected with the speech cloud. At present, the voice recognition interface of KDDI is not free, and the application and approval process of voice recognition of Tencent cloud is relatively

long and tedious. Finally, after comparing the voice clouds of Ali and Baidu, relatively speaking, Ali cloud is easier to use, so the SDK of voice recognition of Ali cloud is used. In addition, the commonly used voice recognition module is FreeSWITCH; the advantages are open-source, cross-platform, scalability, multiprotocol, and so on; it is based on Ali cloud, easy to use, and therefore popular with secondary developers. Its main development language is C, some modules use C++, and it supports SIP, H323, Skype, Google Talk, and many other communication protocols. Voice service Aliyun SDK source code is available on the Github open source platform, and using CommonRequest to invoke the SDK's core library directly is highly useful in development. The process of implementing this function is as follows: firstly, the collected user voice data will be sent to the backend, then the backend will send the received voice input stream to the Ali cloud server side, which will convert the voice into text, and finally, the processed voice data stream will be returned to the frontend.

4.2. Application of Local Speech Library. Microsoft Speech SDK is a toolkit launched by Microsoft to develop speech applications and speech engines on Windows platform [27]. It contains various components for speech recognition. There are many examples of secondary development using Microsoft's speech recognition development toolkit, and the methods and ideas from other studies are referenced here.

In order to reference the COM component provided by the SDK, the VisualStudio.NET development platform is used as an example, and the component is referenced by selecting Project|Add Reference in the menu and then clicking on the COM tab and selecting Microsoft Speech Object Library. NET for speech recognition module development mainly uses three APIs: ISpRecognizer interface is responsible for interacting with the underlying RecognitionEngine, which is the speech recognition engine interface; ISpRecoContex interface is responsible for sending and receiving messages, which is the main interface to complete the recognition task; ISpRecoGamma interface is responsible for creating, loading, and activating grammar rules and is the grammarian interface. The Microsoft Speech SDK software development kit provides components for speech recognition, and the system was developed using the C# language, which is inherently well integrated. It is also important to note that since the downloaded SDK only supports English and teachers and students mostly communicate with each other in Chinese, the SDK language package SpeechSDK51LangPack should be downloaded and installed.

4.3. Serial Port Control. At present, the centralized control system of multimedia equipment (referred to as central control) on the market is becoming more and more advanced, and some of these smart classroom products are designed to meet the needs of information-based teaching, and they apply broadcast-grade product technology to the campus, leading the new trend of smart teaching. Nevertheless, since the multimedia equipment of each school is

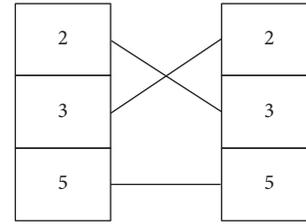

FIGURE 8: Serial control cross wire soldering diagram.

more or less different, the central control may not be able to control some multimedia equipment, so we should redevelop the module with the characteristics of the school according to the actual situation of the school.

Most computers and multimedia equipment have RS-232 interface; if not, you can also convert the USB port to RS-232 interface through the “USB to RS-232” data cable, and then, certain multimedia equipment that the central control cannot directly control can be directly connected to the computer through the device serial port with a network cable by the computer to directly control. The advantage of serial communication is that data can be transmitted over long distances, the use of ordinary network cable soldering is low cost, bandwidth can also fully meet the requirements but also customize the protocol of transmission, and data transmission is more reliable [28]. There are nine pins of the RS-232 interface, of which pin 2 is used to receive data, pin 3 is used to send data, and pin 5 is the signal ground. 9-pin serial port uses only the second, third, and fifth three of these pins to send and receive data, that is, solder wire one end of the serial port in the order of three pins, adjust the other end of the second and third pins a little, the fifth pin remains unchanged, solder wire the other end of the serial port in the order of three pins. The mathematical relationship is as follows. The final crossover line produced is shown in Figure 8.

$$\begin{aligned} Y &= \{Y_1, Y_2, \dots, Y_m\}, \\ Y_j &= F(X_i), \end{aligned} \quad (5)$$

where F is the data sending and receiving; Y is the number of serial ports; $1 < i; j < n$.

5. The Relationship between Smart Classroom and Chinese Teaching

5.1. Teaching in the Smart Classroom. Smart classroom is a product of the deep integration of information technology and education teaching, which seamlessly connects teaching and learning inside and outside the classroom and provides a personalized, intelligent, and digital learning environment. The smart classroom environment effectively integrates core functional elements such as teaching resource management, real-time content delivery, learning scenario collection, instant feedback and evaluation, and member interaction and communication by using “cloud service + mobile application” to efficiently organize the three teaching links of teachers and students before, during, and after class.

Smart classroom is student-centered, emphasizing students' autonomous learning and collaborative learning

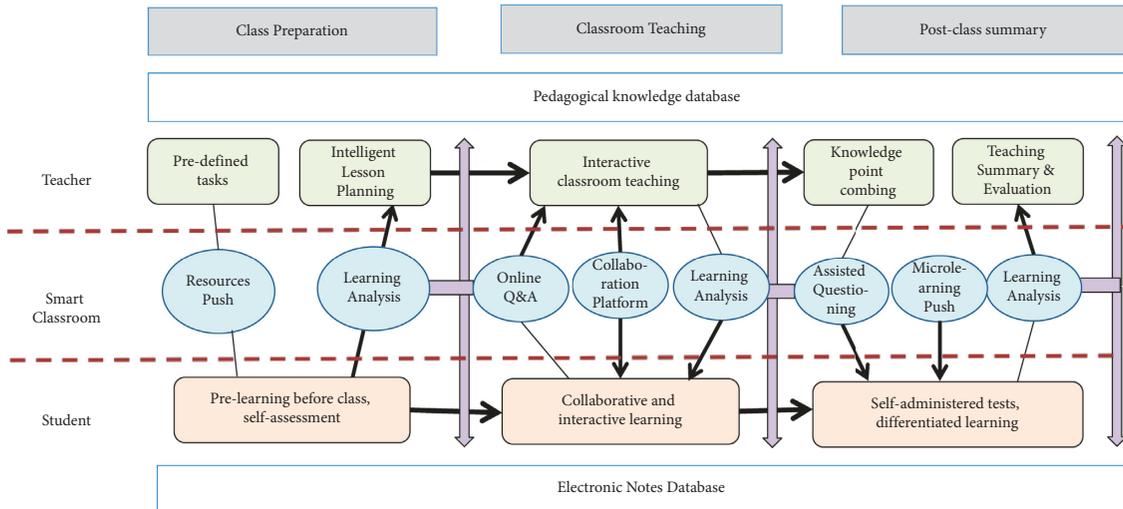

FIGURE 9: Chinese learning model in smart classroom.

among students. Teachers in the smart classroom are more likely to create, collect, and organize educational resources, set goals and assessment criteria, monitor the progress of student-initiated learning in the classroom, and provide timely feedback on questions raised by students. These features of teaching and learning in the smart classroom also fit the requirements of the language teaching process.

5.2. Characteristics of Chinese Language Teaching and Learning. First, language teaching emphasizes the learner as the root and stresses that students should be active participants and language constructors in the learning process, and teachers are collaborators and facilitators of learning. Consequently, teachers need to create rich interactive conditions to promote the smooth interaction between teachers and students.

Second, analyzed from the perspective of the language teaching environment, teaching Chinese in the native language environment should try to create a relaxed and natural language atmosphere. Therefore, teachers need to simulate and create language situations and use text, graphics, sound, and video in a comprehensive way to push language information and stimulate learners from multiple senses as much as possible.

Finally, language teaching relies on rich language contexts and the need to obtain timely feedback on learning effects during repeated language training, to achieve interactive communication and personalized learning.

5.3. The Chinese Learning Model in the Smart Classroom. In general, the integration of smart classroom and Chinese teaching is an interactive, repeated, and circular process, which runs through the teaching process of preclass preparation, classroom teaching, and postclass summary. This paper moderately simplifies the “universal learning model in the smart classroom” given in the related literature and builds a set of learning models in the smart classroom environment based on the teaching knowledge database and

the electronic notes database, using three times of learning situation analysis as the feedback mechanism (Figure 9). The learning model contains only five teacher activities and three student activities, while the smart classroom platform takes up the tasks of resource pushing, information interaction, and learning situation analysis, making the process of smart teaching more simplified and easy to carry out.

5.4. Improvement of Chinese Teaching Tasks in the Smart Classroom. In this paper, we focus on two learning tasks in Chinese teaching, namely, vocabulary and listening, and use the Xunfei Smart Education Platform as a support to explain in detail the improvement methods and technical advantages of the smart classroom for these two teaching tasks.

First, the smart classroom environment can provide students with repeatedly trained vocabulary learning scenarios, push related vocabulary resources, and generate differentiated vocabulary memorization strategies.

Second, the smart classroom environment can provide immersive Chinese listening and speaking contexts, provide students with an interactive and self-directed learning environment before and after class sessions, and use language recognition technology to enhance the effectiveness of listening and speaking interactions in the classroom.

6. Optimization of Vocabulary Learning Methods in the Smart Classroom

6.1. Characteristics of Vocabulary Learning. Vocabulary is the foundation of Chinese learning and plays a crucial role. However, most vocabulary teaching activities are one-way communication and lack of association, which leads to students’ poor impression of the learned vocabulary and easy forgetting. There are two main reasons for the unsatisfactory effect of vocabulary learning. First, vocabulary teaching does not create relevant context and ignores cultural factors. The second is the lack of effective vocabulary learning strategies, mechanical memory, and ease of forgetting.

6.2. *Vocabulary Learning in the Smart Classroom.* With the learning model of smart classroom, the vocabulary teaching process for teachers and students is concentrated in two stages, before and after class.

6.2.1. *Preclass Preparation Stage.* The teacher gives students clear vocabulary learning tasks, and the resource pushing module of smart classroom pushes the basic word meanings, pronunciation, and lexical properties of vocabulary, as well as the related vocabulary with synonymy, antonymy, multiple meanings, and homophones and homonyms to students. After students finish vocabulary preview, the intelligent classroom provides Dictation Training tools and tests to check students' vocabulary learning effect. Learning analysis can summarize students' questions and guide teachers in preparing lessons intelligently. Smart classroom assists students in preclass prereading and records knowledge points and wrong information in electronic notes.

6.2.2. *Postclass Summary Stage.* Smart Classroom provides a punch card tool to urge students to study words in a planned manner. As the number of vocabulary exercises increases, the granularity of error information in smart classroom's eNotes is refined not only to count which words are error-prone but also to record what types of errors are made (e.g., spelling errors, mispronunciation, word meaning errors, lexical errors, and associated word errors), which can guide students to more scientific vocabulary learning strategies. Differentiated learning strategies will guide the problem setting module and microclass push module of the intelligent classroom platform to help students master error-prone knowledge more accurately and effectively.

7. Optimization of Listening and Speaking Training under Smart Classroom

7.1. *Characteristics of Listening and Speaking Training.* The improvement of Chinese listening and speaking ability requires continuous training in language scenarios, and the teaching time of the Chinese classroom is difficult to meet the repeated practice requirements, which leads to the traditional teaching environment where teachers emphasize reading and writing but not listening, and students are unwilling to spend energy on listening and speaking training, making it difficult to improve listening and speaking ability. With the gradual maturity of Xunfei's speech recognition technology and deep learning technology, the classroom integrates independent listening and speaking training scenes and makes use of the openness, sharing, and interaction of the platform to make up for the deficiency of listening and speaking training in actual Chinese teaching.

7.2. *Hearing and Listening Training in the Smart Classroom.* The biggest advantage of smart classroom in improving listening and speaking training is that it provides an immersive language learning environment, which not only

develops students' listening and speaking skills but also improves students' independent learning ability. The listening training platform has a set of training tools for listening, pronunciation, and conversation.

Teachers can use these tools to organize videos and audios related to the course and associate them with a bank of test questions in an easy-to-follow format. Students play the audio and follow along and record it, and the platform uses voice recognition technology to give pronunciation accuracy, which unifies students' listening and speaking skills.

Smart classroom's listening and speaking training platform can also set up common conversational scenarios such as study, life, business, travel, and dating, allowing students to train oral communication skills with the help of human-computer interaction. At the same time, there are also language environments that promote interest in learning English, such as online dubbing of movie clips and MTV of Chinese songs. These environments have a positive effect on enhancing students' interest in listening and speaking.

8. Conclusion

Informationization in higher education enters the stage of smart campus, while classroom is the main position of teaching, and the construction of smart classroom is the major trend of future development. After improving and optimizing the construction of digital campus, insisting on building a smart campus with service as the main line, it is the primary task of the school information center to let teachers and students enjoy the convenient effect brought by the information service of the school. Smart classroom realizes active and autonomous learning, audio-visual equipment is intelligent and humanized, and the information services of the Internet and campus network are applied to the field of teaching. In terms of human-computer interaction, the cloud-based approach combined with the local voice library for speech recognition and self-developed management system can save financial and material resources, enhance the security of school data and information, and provide higher flexibility for future upgrades and optimization of the system, as well as improving the development and practical application capabilities of the school's research team. At present, face recognition, as one of the successful applications in the field of image analysis and processing, is gradually integrated into people's lives. Then, the construction of smart campus and smart classroom, in addition to improving the accuracy of voice recognition, should also study the application of face recognition technology in this area in the future so that artificial intelligence technology can bring greater convenience to all aspects of people's lives.

Smart classrooms bring changes to the existing teaching methods and can assist teachers and students in gaining a new learning experience. This paper takes vocabulary learning and listening and speaking training, two tasks suitable for independent learning, as the starting point to show the improvement of the smart classroom for the

Chinese teaching environment and its advantages for enhancing learning interest and accumulating knowledge. The teaching model under smart classroom is a new direction for future teaching development, which needs to be continuously practiced, optimized, and improved by front-line teaching staff.

Some sensitive data in the network will be leaked due to the loopholes or weaknesses of the web system itself, which will bring potential harm to the society or the public. Aiming at this, this study carries out the design of web security penetration test system. A test scheme comparing single method with an automatic comprehensive test method is designed. Based on this scheme, an automatic penetration test system script used under the terminal operation page is tested and designed. A security evaluation algorithm based on the prediction results of the game between attack and defense is proposed. Through this algorithm, different website systems are evaluated and scored, and the test results are compared through scoring. The automatic penetration test integration system designed and implemented in this study can meet the main objectives of web security and the protection requirements of websites against general, routine, and universal security attacks. The proposed evaluation algorithm is more detailed, accurate, and reference in scoring.

1. Introduction

With the popularization of Internet and the rapid development of web application technology, Internet provides an important basic platform for web applications, on which more and more web applications are set up [1–6]. Common online shopping malls, online banking, and other web applications have greatly changed people's lifestyle [7–10]. They can easily shop or deal with financial problems without leaving home. However, these new technologies not only bring convenience to our work life and even learning but also bring great risks that we have never had before. Due to the maturity of network technology, the threshold of web application attack technology is getting lower and lower. Hackers gradually transfer the attack object from the network server to the web application [11–14]. According to Gartner's survey data, 75% of information security attacks occur on Web applications, not on the network level. At the same time, it is also found that two-thirds of web applications are very vulnerable and vulnerable to attacks. However, it is a pity that many enterprises spend a lot of energy and financial resources on network security and server security

and do not pay attention to the security problems of web applications, leaving an opportunity for hackers [15–17].

The main reason for the vulnerability of web applications is that users can submit data arbitrarily, but the server-side does not carry out reasonable verification. From the perspective of the software itself, the main reason is that the cycle of web application development is getting shorter and shorter, and the level of developers is uneven, which leads to the incomplete consideration of security issues in the process of software development. From the perspective of software deployment and configuration management, the staff may be careless, so there are great security risks. A comprehensive penetration test must be conducted on the web application before the attacker launches an attack to ensure the security of the web application and prevent it from happening [16, 17]. Due to the uneven level of web application developers and the shorter development cycle, it is inevitable for web applications to have security vulnerabilities. The traditional way to ensure network security is through firewall and IDS/IPS. It works on the network layer, while the security penetration test process works on HTTP protocol. It can make up for the deficiency of firewall relative static

defense. The two complement each other and jointly ensure the security of web applications.

Web application penetration testing technology is to simulate the attack means and attack methods of hackers, actively detect web applications, transform malicious URLs, send them to the server, and determine whether there are security vulnerabilities in web applications by analyzing the response returned by the server. Through penetration testing, we can understand the vulnerabilities of web applications in advance before they are attacked, classify the level of vulnerabilities, and find corresponding mitigation schemes according to the severity and urgency of vulnerabilities so as to greatly reduce the risk of web applications being attacked.

Due to the unsatisfactory efficiency and accuracy of manual penetration testing, security workers have tried to develop some security penetration testing tools. However, many security penetration testing tools can only test one or several vulnerabilities, and the test effect is not satisfactory. The purpose of this research is to design and develop a web application security penetration testing tool, which can comprehensively and automatically detect some common web application vulnerabilities and can give a more detailed vulnerability detection report.

2. Overall Demand Analysis and Design

In the whole process of the penetration test, it is necessary to formulate a test plan in advance, and various factors will affect the final test conclusion and results. The whole process is divided into three steps: penetration test, design and implementation of automated penetration test system, and safety assessment. Safety assessment is interspersed in the penetration test and automated penetration test. The overall process is shown in Figure 1.

2.1. Penetration Test Requirement Analysis. In the whole process, it is necessary to carry out penetration attack against the test target, and on the premise of not damaging the system, find out the problems existing in the system as much as possible, join other websites for testing, and compare the results, which is more convincing. The overall test is based on Kali Linux system [18, 19], including the use of mainstream test tools and the design of an automatic penetration test system. The specific test contents are shown in Figures 2 and 3.

2.2. Security Assessment Needs Analysis. The overall safety assessment is carried out according to the penetration test results and the calculation results of the assessment algorithm. Security assessment refers to a series of security assessments for websites, systems, and platforms. At present, web security assessment [20, 21] is mainly carried out from internal and external aspects. Internal evaluation adopts black-box test or white-box test. Black-box test refers to the evaluation test without knowing the detailed information of

the system, while white-box test refers to the evaluation test with a certain understanding of the information and conditions of the system.

External evaluation refers to the remote evaluation of the server and system initiated by the outside. Testers discover the security problems exposed by the system by simulating the malicious scanning and detection behavior of attackers. Internal evaluation refers to the internal security inspection conducted by testers for the server, code design, and configuration of the system. Compared with external testing, internal evaluation testing can find the problems of the system from a deeper level. The working process of safety assessment is shown in Figure 4.

The overall assessment is carried out by establishing the assessment model and method. At the same time, the requirements of the test objectives for safety assessment are analyzed and understood. The specific aspects should be considered from these aspects as shown in Figure 5.

- (1) *Protection requirements.* At present, there are many security attack technologies, and the methods are updated quickly. Therefore, it is required that the cycle of security evaluation must be shortened to ensure the security protection and attack prevention of the whole network.
- (2) *Isolation requirements.* Many security attacks are gradually infiltrated from the external network to the internal network. Although many enterprises and units have separated the internal and external networks on physical lines, when it comes to business activities and external information exchange, they will cancel some of the isolation instead of using special machines for access.
- (3) *Verification requirements.* Network security is a multifaceted problem, which involves not only attack and protection but also authorization, authority, confidentiality agreement, and other internal problems. Different identity and authority verification for different login users can reduce the risk of being penetrated into the intranet to a certain extent.
- (4) *System intrusion detection requirements.* Today's systems and platforms are basically protected by firewalls, but in our continuous research and testing, we also found that although firewalls are stable and can immediately tension access, they are static after all, while network attacks are dynamic, and there are countless methods. Therefore, intrusion detection methods and security evaluation methods must be equipped.
- (5) *Vulnerability threat requirements.* Because the website system and platform are artificially coded and designed, errors often occur in the writing and logical specification of the code in the design. Most of them ignore the simplicity and preciseness of the code on the premise of realizing the function,

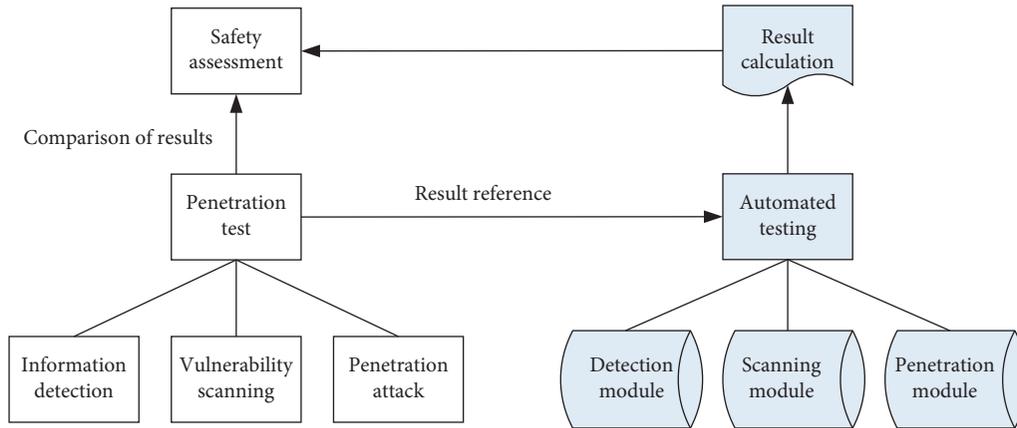

FIGURE 1: The overall process.

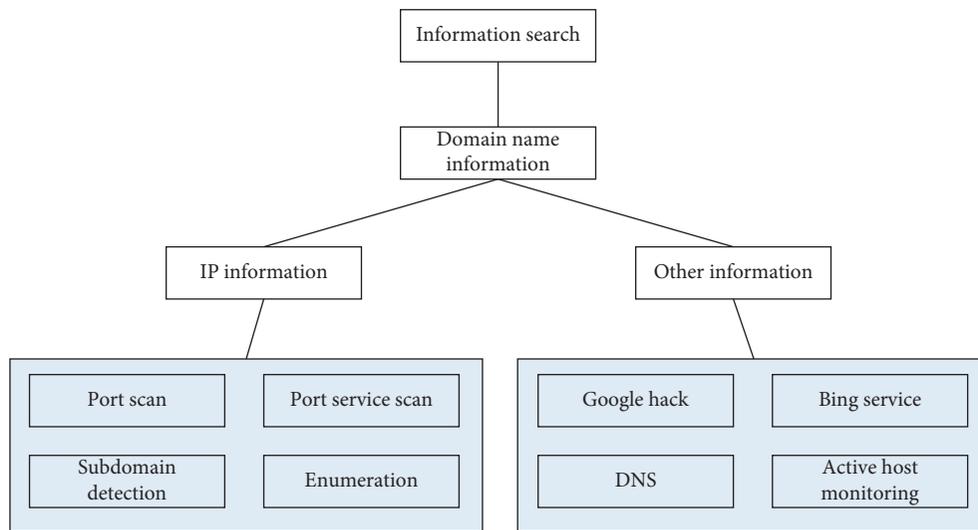

FIGURE 2: Information search.

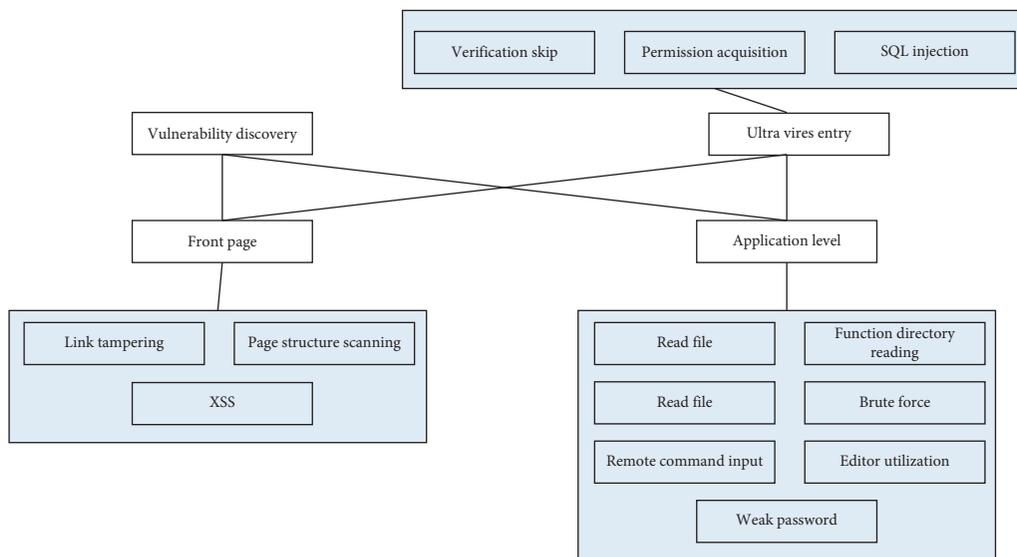

FIGURE 3: Vulnerability discover.

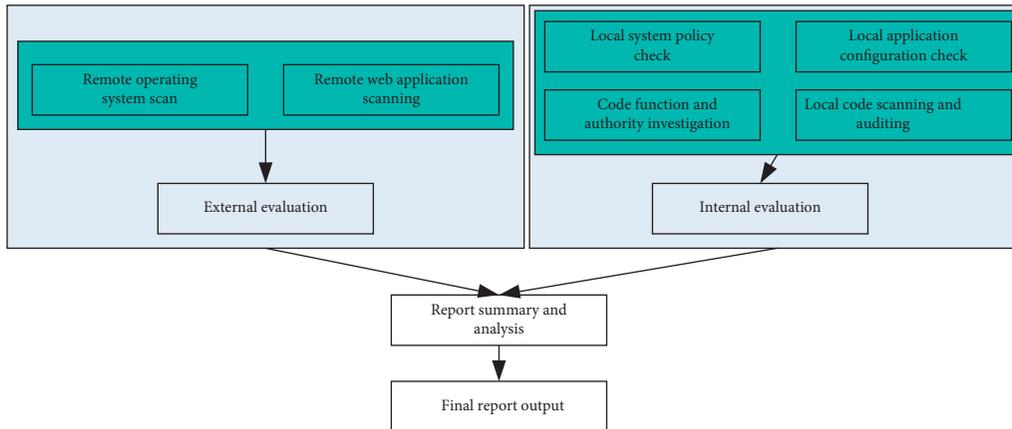

FIGURE 4: The working process of safety assessment.

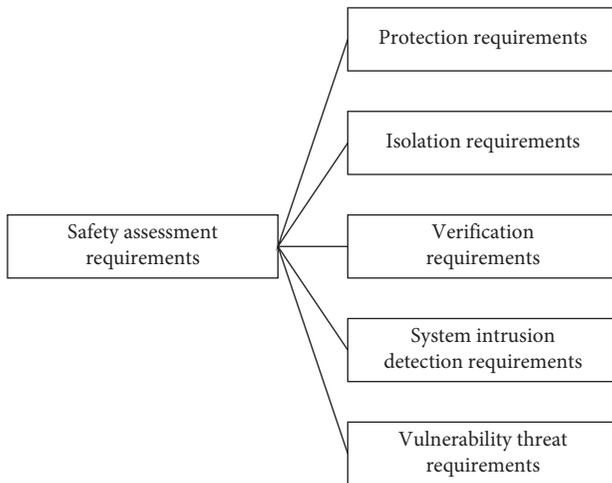

FIGURE 5: Safety assessment requirements.

resulting in attack vulnerabilities. Irregular vulnerability scanning and security evaluation can effectively deal with this, find and repair the imperfections of code design and system design, and can effectively prevent network attacks.

3. Penetration Test Method Design

In the actual operation, the penetration test [22] will be divided into three parts and stages. Different angles will make the differentiation methods different. For example, it is divided into preparation stage, penetration test stage, and overall comparison and evaluation stage on the theoretical basis, while in the technical operation, it is divided into three stages: detection, attack penetration, and target permission acquisition. The specific implementation of penetration test needs to consider the following factors: the scale of the client, the distribution of the network, and the composition of the system. In the content of the scheme, it is necessary to specify the test purpose and scope, time, place, personnel information, risk avoidance means and methods, overall plan, process, etc.

The overall test includes three parts: information collection and detection, vulnerability scanning, and penetration attack (as shown in Figure 6). In the detection stage, it is mainly to collect information and investigate. First, it is necessary to use the single dimension method to test.

- (1) *Detection phase.* We use the main software and tools in the market to test two different websites, compare the results, and then design the detection module in the design of the automatic penetration test integration system.
- (2) *Vulnerability scanning phase.* It mainly uses scanning tools to scan the website, obtain vulnerability information, summarize the scanned vulnerabilities, and summarize the advantages and disadvantages of each scanning tool, which can be used as a reference for the design of scanning module in automatic penetration test integration system.
- (3) *Infiltration stage.* We use terminal operation and graphical interface operation to penetrate the website, find the security problems existing in the website, analyze the test results in detail, repair the existing security problems and vulnerabilities, and design the penetration attack module of the automatic integrated test system.
- (4) *Automated penetration testing phase.* We design and implement the automatic penetration test system and use the system to conduct automatic penetration test on the website. By comparing the test results with the previous single dimension method, we draw some conclusions and the advantages and disadvantages of the two methods so as to provide experience for website security maintenance in the future.

4. Safety Assessment Method Design

Security risks need to be quantified, which is not only conducive to the quantitative calculation of risk value but also allows the client to feel the security of the website and system more intuitively [23, 24]. The flow chart of the safety assessment is shown in Figure 7.

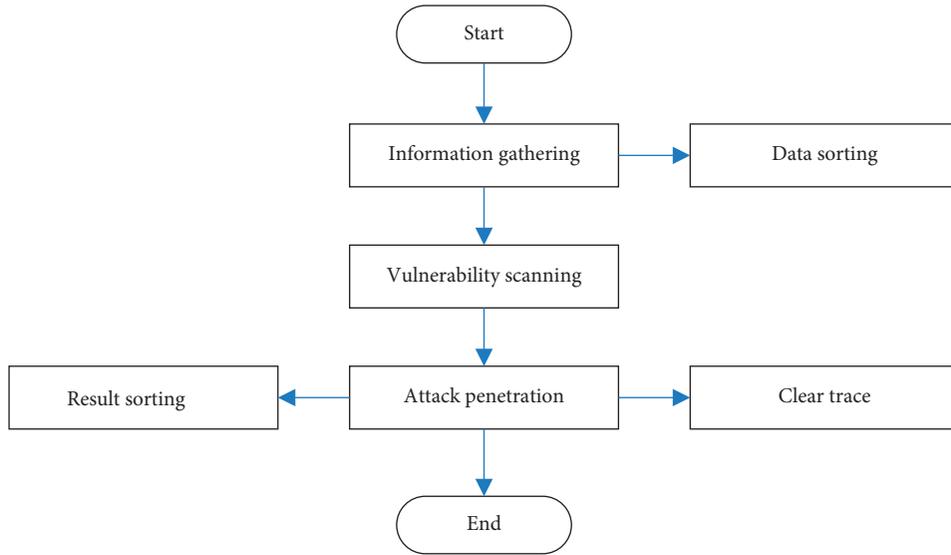

FIGURE 6: Penetration test flow.

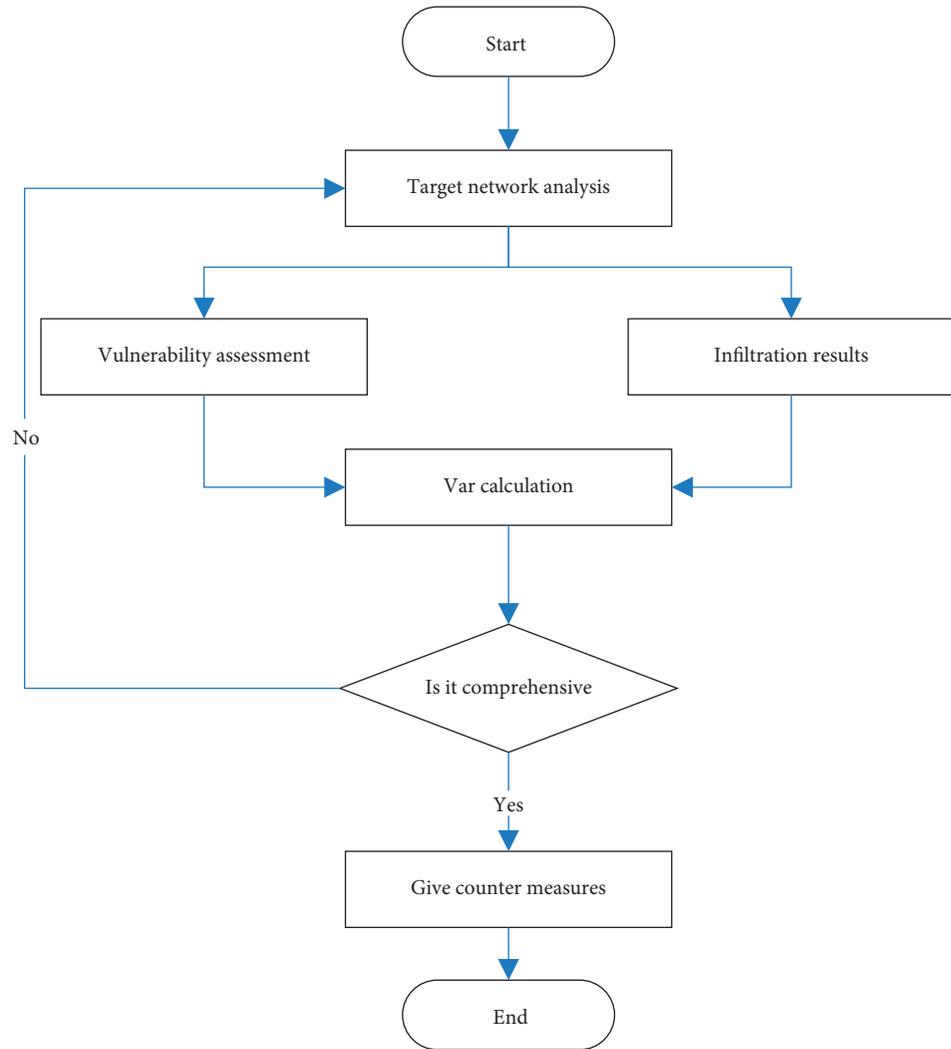

FIGURE 7: Safety assessment flow.

Before formulating the algorithm of security risk calculation, the selection of variables is very key. Most of the previous evaluation algorithms calculate with one or two variables. The advantage of such calculation is that it is convenient to get the result and will not make mistakes, but the disadvantage is that there are too few reference factors. There are often many indicators that affect the security of a system. When scoring, they need to be taken into account, it is relatively feasible to focus on several main factors and calculate the weight with other factors as a reference. Vulnerability risk quantification is one of the most important factors in the whole security assessment process. The overall security of the system depends on the weakest part. Which risk quantification value of the detected vulnerability is greater will determine the weakness of the whole system. The quantitative value needs to be calculated by the set evaluation algorithm, and the quantitative evaluation of system security can be effectively obtained according to the calculated results.

Most quantitative value algorithms pay more attention to the quantification of vulnerability threats. By quantifying the threats of existing vulnerabilities and detected vulnerabilities, the security factor is evaluated according to the quantitative value, and a vulnerability threat quantitative table calculated by the algorithm is obtained. Through this table, the threat quantitative value of each vulnerability can be seen intuitively so as to use this value as a reference to obtain the website security evaluation coefficient. However, there are still some deficiencies in these evaluation methods. One of them is also the improved part of the algorithm proposed in this paper, that is, it is necessary to consider the test evaluators and website maintainers. As the attacker and defender, they also need a quantitative value for the judgment of system setting and network structure, and these factors cannot be considered after the test.

Many security attacks and risks are sudden, and there is no time to make a temporary response. Countermeasures need to be given in advance, and these countermeasures need to estimate the possible results of the two sides in the process of playing chess in advance. The security evaluation algorithm based on the prediction of attack and defense game results proposed in this paper adds the evaluation of system maintenance personnel on various structural factors of the network and system and the predictive evaluation of the whole website by using the existing knowledge system through the prior understanding of the website system. After the final test, based on the test results, we make an overall evaluation with reference to the quantitative value of vulnerabilities. Combined with the previous evaluation of maintenance personnel, we get the final score through the algorithm. The relevant variables are described below.

Evaluation of website by website maintenance personnel.

Taking each page and structure of the website as variables, a score of X_i is obtained, where i ranges from 1 to N , X_i

ranges from 0 to 10, and the score results are expressed as A . That is

$$A = \sum_{i=1}^n X_i. \quad (1)$$

Here, A is the sum of the scores given by the maintenance personnel on each page of the website, and then, we calculate the average to obtain the score B of a single maintenance personnel.

$$B = \frac{A}{n}. \quad (2)$$

The score of each page and structure constitutes a vector.

$$\vec{Z}_i = (Z_1, Z_2, \dots, Z_n). \quad (3)$$

Here, n is still the number of website pages and structures, and each page also needs to have a proportion. It also needs to be evaluated by maintenance personnel. It is defined as $V_i V_i$. C represents the whole weight vector, then

$$\vec{C} = (V_1, V_2, \dots, V_n). \quad (4)$$

Here, $V_1 + V_2 + \dots + V_n = 1$.

Therefore, the score of the whole website is the inner product of two vectors. Through the calculation of the inner product, the results can be obtained more accurately. D is defined as the importance score of each module of the website, then

$$\vec{D}_i = \vec{Z}_i * C. \quad (5)$$

The first is the comprehensive scoring algorithm of the maintenance personnel for the website, and the next is the evaluation algorithm of the tester. Since the tester needs to simulate the attacker's destruction of the website to the greatest extent, we need to consider the strength of penetration testing and focus on the algorithm for some serious vulnerabilities detected.

Common Vulnerability Scoring System (CVSS) is a standard for vulnerability assessment, which intuitively reflects vulnerability risk by using numbers ranging from 0 to 10. The whole evaluation system of CVSS [25, 26] is composed of basic score, temporary score, and environmental score. The whole evaluation process is to integrate the scores of these three factors. First, calculate the values of each part according to the formula and then get the final score according to the summarized formula. A high score represents a high threat, and a low score represents a low threat. The overall evaluation process is shown in Figure 8.

We combine the accurate score based on the CVSS scoring standard with the importance score of each module of the website to obtain:

$$\alpha = \frac{B + D/n}{2} \times 0.4 + C \times 0.6. \quad (6)$$

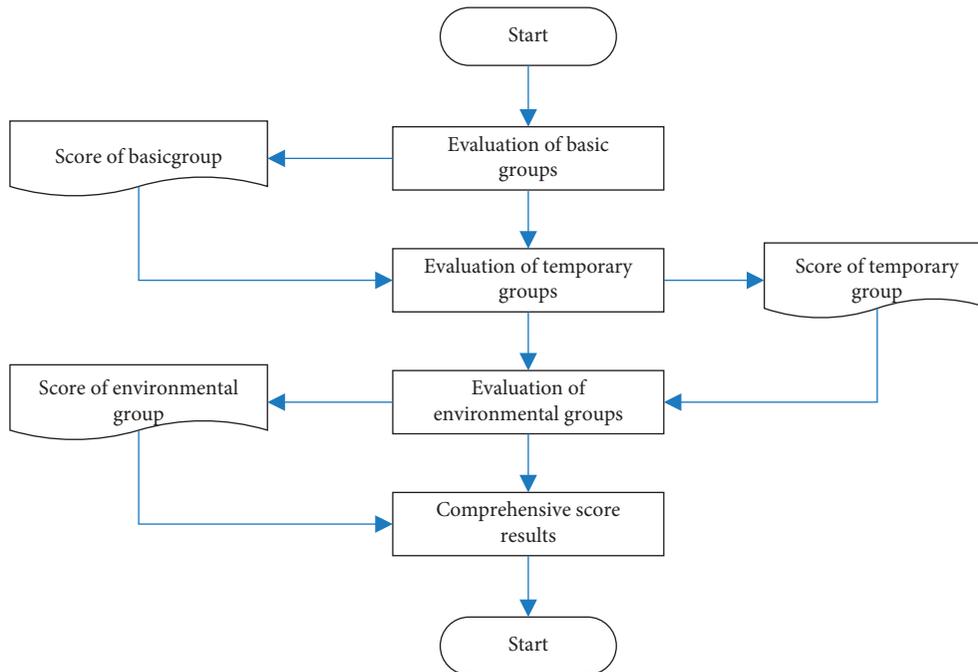

FIGURE 8: The overall evaluation process of CVSS.

Here, C is the score after CVSS optimization calculation. Since the system maintenance personnel may lack knowledge of system security vulnerabilities and security-related knowledge, they are given a base of 0.4 in weight distribution. Although the security testers are very good at security attacks, they are unable to have a detailed understanding of the overall structure, page blocks, and logic of the system in a short time, so the base is given as 0.6.

5. Design of Web Security Penetration Testing Tool

5.1. Overall Framework. We crawl for the target web application, obtain a large number of URLs and web page content, modify the parameters in the URL or construct abnormal HTTP requests to imitate the operation of malicious users, realize malicious injection, determine whether there are vulnerabilities in the web application by analyzing the response, and generate the corresponding report.

The classic MVC architecture is used to separate the view layer, business logic layer, and data layer and separate the functions of this tool. Using the modular design theory, the user interface module and vulnerability report module are mainly designed in the view layer, and the control engine module, crawl module, injection module, and analysis module are designed in the business logic layer. Due to the huge number of crawls and the need to use multithreading, the thread pool module in the common component is designed. The injection process needs to construct abnormal HTTP requests and analyze the response, so the HTTP proxy module is designed. Because there is some global processing information in the whole process, in order to better solve the migration and reuse of code, the configuration file module

needs to be used. In the data layer, it mainly designs URL database, injection database, and analysis database. These independent modules only complete their own functions and do not need to pay too much attention to the functions of other modules. They communicate through some predefined interfaces to transfer parameters, which can improve the reusability of modules, and the modification or addition of new modules of some modules will not affect the normal work of other modules.

The overall frame design is shown in Figure 9.

5.2. User Interface Layer. The user interface layer is the bridge between the security penetration tester and the tested web application. In this module, testers can set the types of attacks that the tested web application wants to test (such as XSS and SQL injection) or test all types and then submit these information to the control engine to perform subsequent tasks.

This module can also generate a vulnerability report form to clearly show all scanning results to testers.

5.3. Logic Control Layer

5.3.1. Design of Web Crawler Module. The main function of the crawler module [27–29] is to crawl the web page, obtain the URL contained in the page through web page analysis, format and filter the obtained URL, and save it to the database. Of course, in the design process of the crawler module, considering the huge number of crawls and the long crawling time of using a single thread, multithreading is introduced, and the thread pool is mainly used here. In order to detect as many vulnerabilities as possible, we need to crawl the web page in sufficient detail. The crawl component we

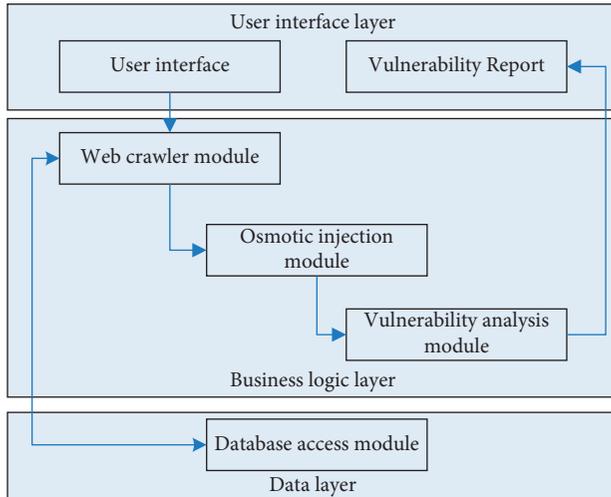

FIGURE 9: The overall frame design of web security penetration testing tool.

designed adopts the breadth-first strategy. The so-called breadth first is layer crawling, which indexes, processes, and grabs web pages according to the distribution and layout of layers. Because the web pages of many websites contain a large number of files and it is time-consuming to use a single thread, the general crawling components need to be set as multithreaded, which greatly reduces the crawling time and improves the crawling efficiency.

The flow chart of the web crawler module is shown in Figure 10.

5.3.2. Design of Penetration Injection Module. Penetration attack is to simulate the operation of malicious users and send malformed HTTP requests to the server. There are two methods for the HTTP request sent by the web application and the server. One is the GET method, and the other is the POST method. Therefore, the injection point is also divided into two kinds. For GET method, it only needs to modify the obtained URL, send the request to the server, and determine whether there is a vulnerability in the web application through the server-side response. For the POST method, it needs to use HTTP proxy to intercept the post request, modify the parameters, construct abnormal requests, and detect the vulnerabilities on the web application server.

Security penetration injection is mainly to send the modified HTTP request to the target web application. A large number of URLs can be obtained in the crawler module, and these URLs are stored in the database. We need to take out these URLs, find the injection attack point, and call the vulnerability detection plug-in to simulate the attack. The structure diagram is shown in Figure 11.

The penetration attack module mainly designs a control engine and several vulnerability attack plug-ins. The control module is the main thread of the program, controls the underlying vulnerability attack plug-ins, and contacts with the web crawler module. The main thread obtains the

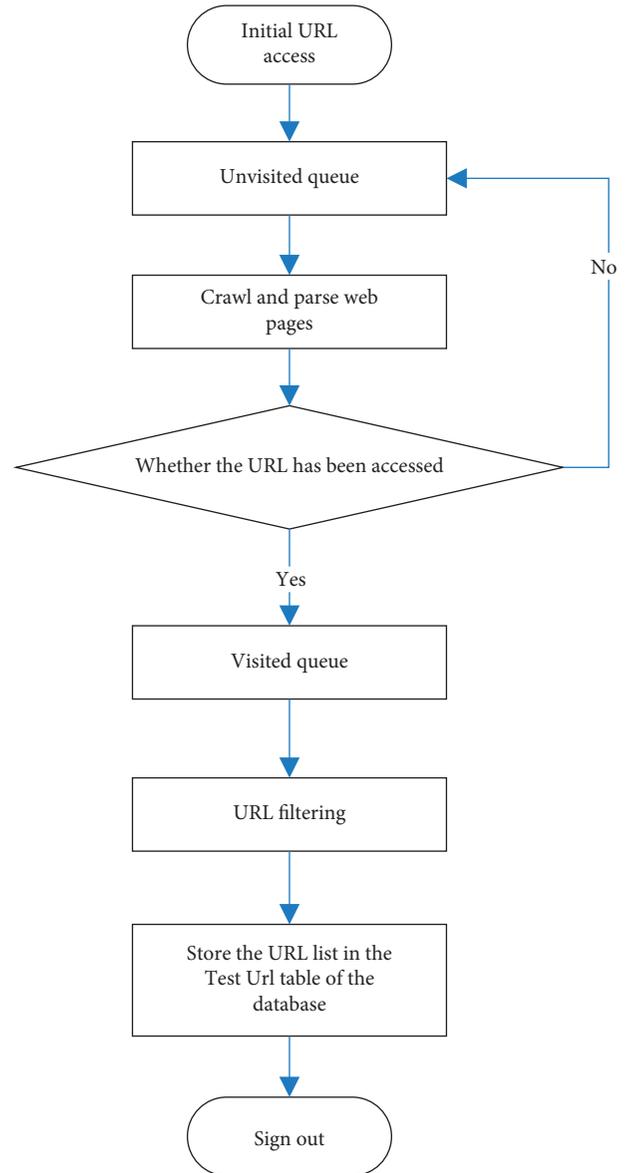

FIGURE 10: The flow chart of web crawler module.

application data through the web crawler module and gives it to the control module, which is responsible for transmitting the obtained data to each subthread. After receiving the data from the main thread, each subthread waits for the main thread to call the subthread and perform different types of vulnerability injection, respectively. Specifically, the tester can select a URL or all URLs for testing. After receiving the instruction, the control engine starts to call each vulnerability plug-in, construct a malicious attack connection, and complete the penetration injection process.

The design of the control engine is to separate the control logic from the specific execution module and achieve the decoupling effect. In this way, even if a new module is added or the original module is modified in the future, there is no need to modify the overall architecture of the tool, just add a new one in the interface class.

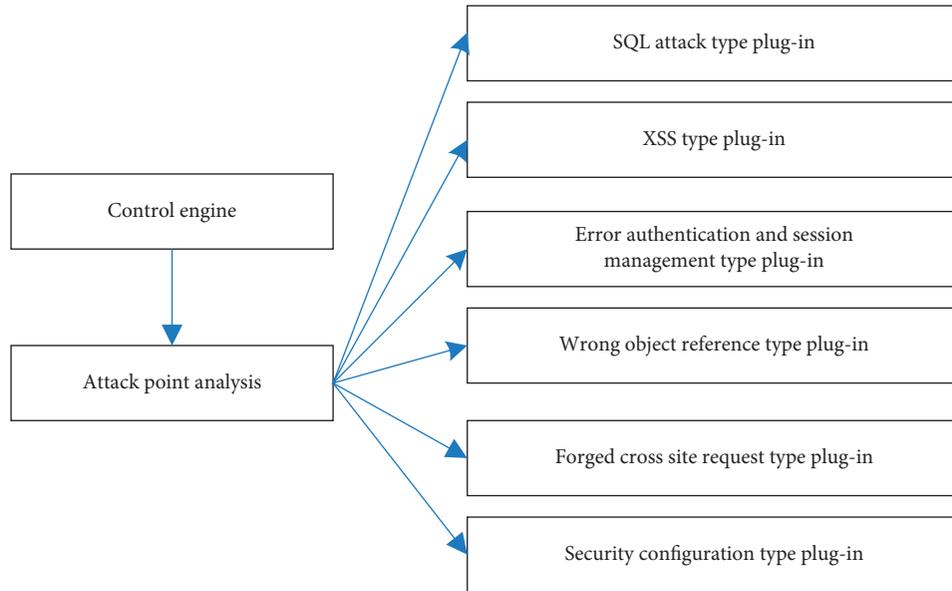

FIGURE 11: The structure of security penetration injection.

TABLE 1: Spider URL data table.

Field name	Field type	Is it nonempty	Record content	Remarks
ID	Int	Yes	Primary key	Self-increasing
URL	Varchar (25)		Requested URL

RESPONSE_HEADER	Varchar (20)		HTTP response header	
RESPONSE_BODY	Varchar (256)		HTTP response body	

5.3.3. Design of Vulnerability Analysis Module.

Vulnerability analysis and injection complement each other. After the penetration injection attack is completed, the server will give a response and determine whether there are vulnerabilities in the web application by analyzing the response. Its main principle is to match the obtained response with the preset output. If the matching is successful, it indicates that there are loopholes. If the matching is not successful, it indicates that there are no loopholes.

Since the judgment rules of each vulnerability injection type are written in the corresponding vulnerability injection plug-in, after each vulnerability injection plug-in is called and a malicious link is sent, the returned response should be

dynamically matched with the plug-in to determine whether there is such a vulnerability.

5.4. Data Layer. Due to the convenience of the database, the tool in this paper uses the database as the support. When the web crawler runs, it will save some important data to the database, and these data will also provide a solid foundation for the penetration injection module. The specific design of the data table involved is shown in Tables 1 and 2.

6. Conclusions

With the rapid development of network technology and web application technology, web application has penetrated into

every bit of people's life. However, the security problem of the web application has become more and more prominent and the most important technical challenge in this information age.

Through the research on the common vulnerabilities of web applications and the penetration testing technology to detect vulnerabilities, this study first designs and implements the web crawler module. The web crawler adopts the breadth-first crawling strategy. In the process of multi-threaded crawling, it obtains all the URLs of the target website through web page parsing, URL formatting, and filtering. Then, the security penetration injection module is designed and implemented, the principle of the penetration injection module is analyzed in detail, the injection points and injection parameters of get type in the request of URL as well as the injection points and injection parameters of post type are analyzed, and the constructed malicious URL is sent to the server by using the automatic injection mechanism. Finally, the analysis module is designed and implemented.

Data Availability

The data set can be accessed upon request.

Conflicts of Interest

The authors declare that there are no conflicts of interest.

According to the character of frequent fault occurrence, difficult diagnosis of large reciprocating compressor valves, an early fault diagnosis model of reciprocating compressor valve based on multiclass support vector machine and decision tree is designed. A series of simulation experiments of the suction valve and exhaust valve on a large-scale reciprocating compressor experimental bench are made and the valve fault principle is analyzed. Using the advantages of fast and efficient decision tree classification and the prominent characteristics of support vector machine in small sample binary classification, a multivariate classification and recognition model is constructed. The typical characteristic parameters of gearbox vibration signal are extracted as the fault feature vector training model under different fault conditions, and the samples are tested. The experimental results show that the recognition effect of this method is significantly better than that of the neural network method in the case of small samples, and the recognition efficiency is improved more than that of the conventional multivariate support vector machine method which can be effectively applied to reciprocating compressor valve fault diagnosis.

1. Introduction

There are a large amount of dynamic equipment of different categories in the oilfield west of China. All different kinds of equipment for powering, frequency converting, ventilating, and fluid transporting are connected into a chain with series connection or parallel connection, and a complex system comes into being [1]. It is a big challenge to build a model due to mutual coupling, multiple fault models, and complicated patterns and even with implication. Reciprocating compressor has become the critical equipment of oilfield west of China due to the advantage of wide range and high efficiency of pressure and exhaust coupled with stable pressure when adjusting the gas volume. But its structure is complex and most of its components are susceptible to failure. According to the statistics, valves, packing seal, and piston ring are the components with the top failure rate which may cause irregular shut down of reciprocating

compressor, among which the shut down due to the failure of the valves accounts for more than 36% [2]. The valves and cylinders have to endure high pressure and temperature. In addition, valves must inhale and exhale the high velocity gas within a short period. The working condition is very serious. How to extract feature parameters from complex and changeable signals is critical for diagnosis. It presents even stricter requirements for the diagnosis model due to tremendous difficulties in extracting feature parameters and unobvious characterization resulting from weak energy change of the feature parameters during the early fault.

The traditional diagnosis method is based on the statistical analysis of a large amount of samples. As a matter of fact, the amount of samples, especially the fault samples, is quite limited and even in the absence [3] in a real test. With the development of information science [4–7], various new theories and ideas begin to enter the field of fault diagnosis [8–11]. Support Vector Machine (SVM) theory presents the

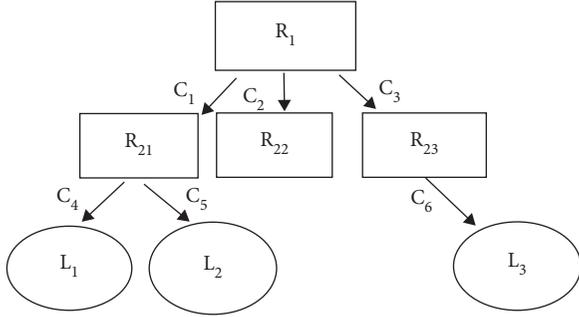

FIGURE 1: Structure of decision tree.

advantage of the small size of training samples, great generalization ability, and easiness of getting an optimal global solution. It has been widely applied to multiple areas such as electricity, economy, and medical science and diagnosis [12–14]. A decision tree is one kind of inductive learning algorithm based on data. It aims at finding the classification rules from a set of nonsequence and nonrule data. It can be applied to build a classifier and a prediction model which can be used to reduce the training amount of Support Vector Machine and improve the efficiency and accuracy of classification [15–18]. By adopting the method with the combination of a decision tree and Support Vector Machine to build a multiple classifier, the recognition effect and efficiency are much improved compared with the traditional neural network method and conventional multiclass Support Vector Machine.

2. Support Vector Machine Based on Decision Tree

2.1. Basic Principle of Decision Tree. The decision tree is a forecast model which represents the mapping relationship between the attribute of the object and the value of the object [19]. As is shown in Figure 1, a decision tree is comprised of nodes and branches, and the nodes include both internal nodes and leaf nodes. Each internal node, such as R1, R21, R22, and R23 in the figure, represents one attribute. Each leaf node, such as L1, L2, and L3 in the figure, represents one category. Each leaf node, such as c1, c2, c3, c4, and c5 in the figure, represents one test value of the attribute. Two steps are included in the whole process of the classification of the decision tree. The first step is to establish and refine a decision tree based on the clusters of the training sample and to set up the model of the decision tree. As a matter of fact, it is a process to obtain knowledge from data and undertake machine learning as a whole which normally can be divided into 2 stages: establishing and pruning. The second step is to analyze the new data by using the decision tree established [20, 21].

One classification subtask will be performed for each node in the tree. In the classification stage, the bottom-up aggregation algorithm is used to generate the logical structure of the decision tree [21]. Because there is no need to traverse all classifiers, the operation time and classification accuracy are relatively high.

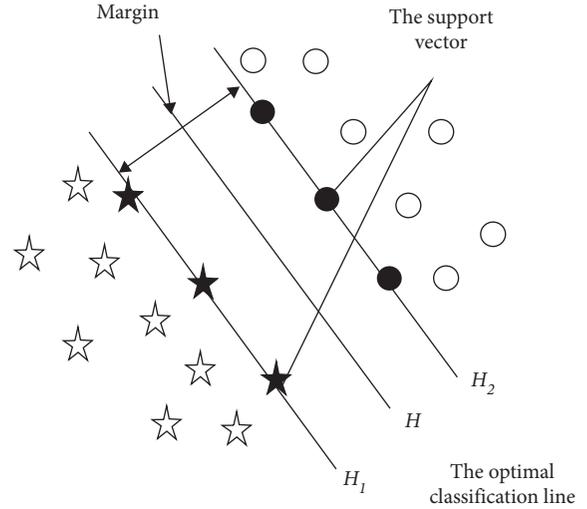

FIGURE 2: The diagram of optimal hyperplane.

2.2. Basic Theory of Support Vector Machine. The support vector machine method is used to propose the optimal hyperplane in the linearly separable case. As is shown in Figure 2, the star and the circle in the optimal hyperplane represent two types of samples separately, H represents the classification line, H1 and H2 represent the samples closet to and in parallel with the classification line in each category the distance between which is called classification margin [22].

Expanded to the linear nonseparable case, considering that some of the samples can not be correctly classified, the constraint condition of hyperplane can be expressed as follows: $y_i(x_i\omega + b) - 1 \geq 0$, in which b is the threshold value and ω is the normal vector of the hyperplane. The Lagrange multiplier method should be adopted to achieve the solution of the nonlinear optimal hyperplane.

$$L(\omega, b, a) = \frac{1}{2} \|\omega\|^2 - \sum_{i=1}^l a_i [y_i (x_i \omega + b) - 1], \quad (1)$$

where $a_i \geq 0, i = 1, 2, \dots, l$;

The extreme point of L is the saddle point. The minimum value of L for ω and b is set as $\omega = \omega^*, b = b^*$, and the maximum value for a set as $a = a^*$.

Therefore, the original problem under linear separable condition is converted into a dual problem. The maximum value of the following dual formula is to be solved:

$$\max(a) = \sum_{i=1}^l a_i - \frac{1}{2} \sum_{j=1}^l \sum_{i=1}^l a_i a_j y_i y_j x_i x_j, \quad (2)$$

$$s.t. \begin{cases} a_i \geq 0, \\ \sum_{i=1}^l a_i y_i = 0. \end{cases}$$

With regard to linear nonseparable problems, the sample x can be mapped to a high dimensional feature space H and the linear classifier is to be applied in H . Therefore, through adopting the appropriate inner product function $K(x_i, x_j)$ in the optimal hyperplane, we can achieve a linear classification

by nonlinear transforming without adding any computation complexity. So the objective function becomes as follows:

$$W(a) = \sum_{i=1}^l a_i - \frac{1}{2} \sum_{j=1}^l \sum_{i=1}^l a_i a_j y_i y_j k(x_i, x_j),$$

$$s.t \begin{cases} 0 \leq a_i \leq C, \\ \sum_{i=1}^l a_i y_i = 0, \end{cases} \quad (3)$$

where constant C is the penalty coefficient for the samples over the boundary controlling the degree of punishment for misclassification samples.

If a_i^* is the optimal solution, the decision function can be expressed as follows:

$$f(x) = \sum_{i=1}^l y_i a_i^* K(x_i, x_j) + b^*, \quad (4)$$

where $b^* = 1/2 \left\{ \max_{\{i|y_i=-1\}} [\sum_{j \in (sv)} a_j y_j k(x_i, x_j)] + \max_{\{i|y_i=+1\}} [\sum_{j \in (sv)} a_j y_j k(x_i, x_j)] \right\}$.

The detailed derivation process can be seen in reference [23].

Different support vectors can be obtained by choosing different kinds of kernel functions. There are four kinds of frequently used kernel functions among which the radial basis kernel function is most commonly used [24].

2.3. Multivariate Classification Support Vector Machine

2.3.1. One-to-Many Support Vector Machine. The one-to-many algorithm [25] is first used for multivalued classification of Support Vector Machine. This method uses a two class support vector machine classifier to distinguish each category from all other categories in sequence. For a problem of n categories, n support vector machines will be trained by the one-to-many method, namely, to adopt n separating hyperplanes to classify.

However the disadvantages of this method are as follows: on one hand, there are requirements for the number of positive and negative samples which will greatly reduce the accuracy of classification by adopting the one-to-many method. On the other hand, because all the training samples shall be used in the training of each support vector machine, the computation efficiency is very low.

2.3.2. One-to-One Support Vector Machine. For a problem of n categories, one support vector machine is built for each of n categories of the samples by adopting a one-to-one method. So $n(n-1)/2$ support vector machines will be trained in total [26]. This method requires more samples, but the training speed is faster than that by using the one-to-many method. By comparison of above-mentioned classification methods of multivalued support vector machine with each other, the one-to-one method is believed to have the better classification effect with more expense. The one-to-many method has an ordinary classification effect with less expense.

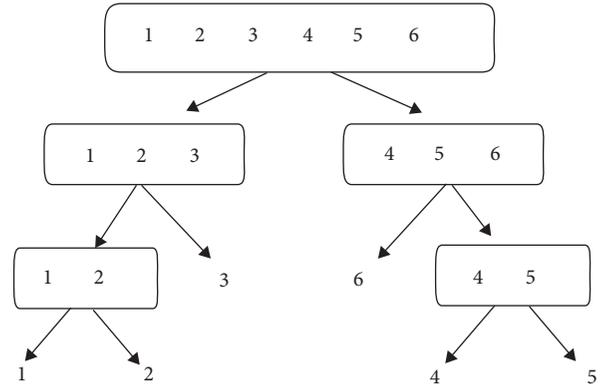

FIGURE 3: A sketch diagram of decision tree structure for multi-classification SVM.

2.3.3. Support Vector Machine Based on Decision Tree.

Support vector machine has excellent generalization performance in the case of small training samples. But for multiclassification problems, it is often necessary to build multiple classifiers and the diagnosis efficiency is low. In this paper, a multiclass fault identification model of a reciprocating compressor valve is established by combining the decision tree and support vector machine.

Through this model, the multiclassification problem is decomposed into a series of two value classification problems, which are distributed in each node of the decision tree. In the classification, the decision tree root node and the branch node are divided into several subsets level by level according to the different attributes, until all the leaf nodes are obtained. One-to-many or one-to-one support vector machine model will be chosen according to the actual situation when dividing into subsets according to the attribute. As an example of dividing into 6 categories, Figure 3 is one kind of decision tree classification diagram, which shows the process of dividing 6 types of input samples into corresponding categories level by level. As can be seen from Figure 3, the advantages of the small number of vector machines of the one-to-many classification model, high classification identification accuracy of the one-to-many classification model, and high classification efficiency for decision tree classification are considered comprehensively in the support vector machine based on the decision tree.

The main failure parts of the valve include the valve seat, spring, and valve plate. The valve seat is the main part of the valve. The valve seat and lift limiter form the space of the valve set. The concentric convex surface of the valve seat and the valve plate form a sealing structure of the gas. The imperfect sealing of the valve sealing structure will result in the gas return, inefficiency of suction and exhaust, and abnormal thermal parameters such as gas temperature and pressure. It will also cause vibration signal and noise change. Therefore by adopting the vibration method, not only the air leakage of the valve can be monitored, but the size of the leakage gap can be determined. The main forms of the spring failure include broken and the elasticity change. If the elasticity becomes small, the closing of the valve plate will be delayed which will cause temperature and pressure changes of the circulating gas.

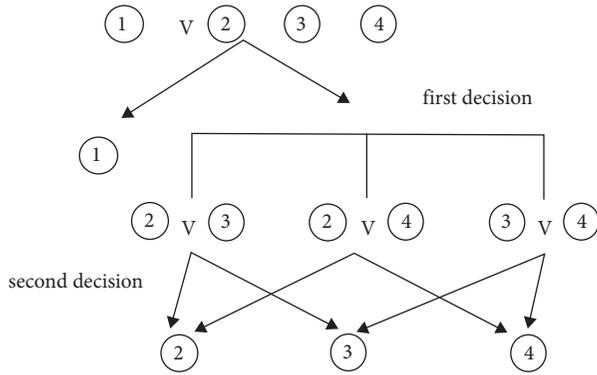

FIGURE 4: The classification diagram of DT-SVM.

The impact strength of the valve plate on the lift limiter will be increased which accordingly makes the impact vibration and noise increase. If the elasticity becomes large, air pressure can not make the valve plate stick to the lift limiter surface when opening the valve which will cause the vibration of the valve plate. A broken spring can cause complex vibration, blocked valve movement, nonuniform force on the valve plate, etc. Therefore, spring failure will be reflected in the thermodynamic and dynamic parameters. The vibration diagnosis method can diagnose the fault of spring break or elastic change. The valve plate is the key part of the valve the role of which is to close the air passage after the suctioning or exhausting. The main forms of valve plate include deformation and fracture. With the nonuniform force resulting from the valve plate deformation, the impact force is becoming stronger. However, complex vibration will be caused by fragmentation of the valve plate.

In this paper, the experimental object is a reciprocating compressor valve fault. Based on the analysis of the fault of the valve of the reciprocating compressor, the fault diagnosis model of multiclassification support vector machine is built by applying the principle of the decision tree support vector machine. As an example to identify the four kinds of faults such as normal valve, valve plate fracture, valve plate wear, and spring failure of the valve plate, the classification model is shown in Figure 4. As the device is in normal operation most of the time, it is quite easy to obtain the samples of the normal running status of the valve plate in the actual test. At the same time, distinguishing the normal operation from other faults of the compressor valve is relatively easy. Therefore, the main purpose of the decision for the first level is to exclude nonfault samples. Nonfault samples can be quickly identified by adopting a one-to-many classifier. At the second level, the three kinds of faults can be identified, respectively, by applying the one-to-one Algorithm. Three one-to-one classifiers will be required during this process. Only four support vector machines will be required in total for this model. Compared with $4 * (4 - 1) / 2 = 6$ required in 2.3.2, two support vector machines will be reduced. In theory, it will take less time to train and test and diagnosis efficiency will be improved.

The location of the fault may be involved in the valve seat, spring, valve plate, and other key parts. Because each

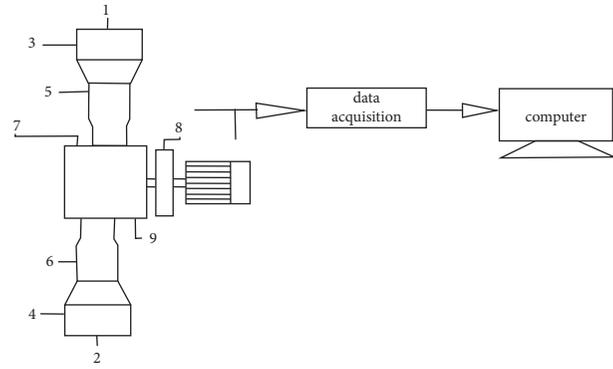

FIGURE 5: System of Valve of reciprocating compressor fault signal acquisition.

component has its own fault type, in order to improve the diagnostic efficiency, the fault component should be identified first and the specific type of failure of the component can be determined later. Therefore, in the case of an unknown valve fault of a reciprocating compressor, the first level of decision-making can be designed to identify the faulty components and the second level decision is to determine the fault type of the specific parts.

3. Experimental Investigations

3.1. Experiment Platform. The equipment used in the experiment is a reciprocating compressor of the double cylinder and double acting which is very close to the compressor used in the actual production of refining and petrochemical companies. A series of related destructive tests are designed for the suction valve and exhaust valve on the experimental platform of the real reciprocating compressor. Using the sensor to collect the vibration signal of the compressor set and temperature signal of the valve, the signal most similar to fault data of the real situation can be collected to the maximum extent. The specific operating parameters of the compressor are shown in Table 1.

The actual situation is shown in Figure 5, where 1 and 2 are cylinder head impact point and acceleration sensor; 3 and 4 are temperature measuring point and install platinum thermal resistance sensor; 5 and 6 are cross head impact point and acceleration sensor; 7 and 9 are crankcase outer surface, internal vibration measuring point, and acceleration sensor, respectively; and 8 is the key phase measuring point and eddy current sensor.

Four types of operating conditions such as normal valve, valve fracture, valve plate wear, and valve spring failure are simulated under the exhaust pressure (gauge) of 0 Mpa, 0.1 Mpa, and 0.2 Mpa, respectively. In this experimental

	5	0.3724	0.1976	0.2524	0.7095	0.9471	④

platform, the valve is simulated with 4 scenarios, respectively: 1 as normal valve, 2 as valve fracture, 3 as valve plate wear, and 4 as valve spring failure. With experiments performed many times for each typical fault, multiple sets of feature vectors can be obtained and used as the sample of this kind of fault training which can reflect the fault rule. The vibration signal is measured in normal mode, and then the fault valve is tested. In the experiment, the piezoelectric IEPE acceleration sensor is used to collect the vibration data, and the sampling frequency is set at 10 KHz. 20 groups of original samples are extracted for each status with continuous sampling.

3.2. Feature Extraction of Reciprocating Compressor Valve.

Different kinds of characteristic parameters of vibration signal will show different aspects of fault information. Sensitive parameters to the fault are chosen from the time and frequency domain such as amplitude maximum in the frequency domain, frequency domain mean, and dynamical indicators in the time domain (peak value, absolute value, effective value, and variance value). In reference [27], the following characteristic quantities are selected to describe the characteristic of the wave of the signal. Normalized treatment has to be done to make them into [0,1] data before building the model because of the different dimension between the parameters in the time and frequency domain. Feature vectors of the fault are shown in Table 2.

3.3. Learning and Training. Select 5 sets of samples of reciprocating compressors from each type of all the four types. A total of 20 sets of signal samples are used to learn and train according to the model in Figure 4 and the decision function of the corresponding support vector machine is built. Based

on the fault diagnosis model of the reciprocating compressor valve established by using the multiclassification support vector machine, the radial basis kernel is chosen after the analysis. The training steps are as follows:

- (1) Data format conversion to the recognizable format required by the libsvm software package
- (2) Transform the scale of the training sample and map the sample set to [-1,1]
- (3) Train model parameters (Penalty factor C and kernel function parameter σ)
- (4) With parameters C and σ obtained in step 3, the training samples after scaling in step 2 can be used for training by using this model
- (5) Input test samples into the trained model and check the classification result

Using the above-mentioned sample data to train the support vector machine classifier in sequence and obtaining the optimal classification function. Finally, the optimization of the parameters of the classifier is obtained with the penalty factor C equal to 2 and radial basis parameter σ of the kernel function equal to 2.

BP($\delta = 0.05$)	30	23	15	76.7

3.4. *Test.* In order to test the effect of the classifier, 8 groups of samples which are known to be tested are used to verify the classifier. The generalization ability and accuracy of the classifier are to be tested. Table 3 gives the output of different decision functions of the support vector machine for samples to be diagnosed. As is shown in the first column, normal valve ① is distinguished from fault valves ②, ③, and ④ quickly. If the result is positive, it will be a positive sample which means a normal valve. The identification ends; If the result is negative, it will be classified into the other three types which mean fault valve. As is shown in columns 2, 3, and 4, a further one-to-one classification and identification will be needed.

According to the membership of the output of the independent support vector machine in the decision structure, the classification of the test sample is diagnosed. When one of the SVM_{i,j} is determined to be classified as fault *i* for fault sample *x*, class *i* gets one vote. Vice versa, class *j* will get one vote. The fault type of each sample will be determined according to the respective score in each fault type of such sample. The final vote of each test sample is shown in Table 4.

As can be seen in Table 4, the diagnosis results are in complete agreement with the fault types preset for the samples, which are based on the decision rules for diagnosis set up in this paper.

3.5. *Comparison with Conventional Methods.* To further compare the classification results, 20 groups of samples are used to test different models. The classification effect is shown in Table 5.

As can be seen from Table 5, the recognition effect of the decision tree support vector machine established based on the actual fault is the same as that of the conventional multiple support vector machine. But it is obviously better than the recognition effect of the traditional neural network method. However, the classification and recognition time of the decision tree support vector machine is saved by about 35% compared with that of a conventional multiple support vector machine.

4. Conclusion

In this paper, with the advantages of the high efficiency of the decision tree combined with the advantages of the “one-to-one” and “one-to-many” multivalued classification method of SVM, the fault identification model of a reciprocating compressor valve based on decision tree and support vector machine is designed. Applying the model to the fault identification of a small sample number of reciprocating compressor valves, it can be seen from the test results and training classification results that the decision tree support vector machine diagnostic method has strong recognition ability and good classification result which is obviously better than the traditional neural network method when used in small sample cases and early fault diagnosis of the air valve.

Decision tree and support vector machine are used to construct a support vector machine model in the form of a decision tree the recognition effect of which is equivalent to a one-to-one multisupport vector machine, and the time for learning training and testing of which is much shorter than the conventional support vector machine. The effect is more obvious with the increase of the number of classification. Therefore, the DT-SVM is more efficient than the conventional support vector machine.

In the ever-evolving vibrant landscape of our times, it is crucial that a peaceful environment is ensured taking into account all the likely ecological parameters along with humidity and temperature while conserving energy. Thus, besides mechanical and electric control systems, it has become vital to ensure that artificial intelligence (AI) is assimilated and deployed into the systems so as to raise the well-being of the environment. By disseminating intelligence across the building by utilizing the new internet of things (IoT) technology, along with control formats, local open standard data, AI algorithms, and cloud-based predictive analytics, the heating, ventilation, and air conditioning (HVAC) mechanism renders the capability to acclimatize to use patterns, alterations in use patterns, and equipment breakdown. By tracing human activity coupled with analysis of noise, energy, and temperature in the building, its occupants and facility managers can obtain vital insights for planning, optimum use of space, and behavioral changes, in turn ensuring more content and safer inhabitants and considerably more efficient structures. Moreover, fuzzy modeling shows its applicability factor with the execution of human rationale and reasoning with if-then rules as attained from the system's input-output info for model setup and training. Additionally, it presents advantages pertaining to predictive functions for tackling nonlinearity and uncertainty as well as studying the capability of the models recommended. Thus, the multi-dimensional model recommended in this study outlines a system architecture as an implementation methodology and how it harmonizes prevailing systems while offering comprehensive knowledge to HVAC systems for the accomplishment of lower energy consumption and inhabitant safety and well-being on the basis of the fuzzy modeling. With tolerance for CO₂ discharges moving towards zero, the recommended multi-dimensional model provides substantial advantages for the HVAC sector for meeting the essential objectives while taking into account enhanced sustainability in vibrant and nonlinear environments for enhancing the accuracy and fairness of the assessment outcomes.

1. Introduction

Assimilation of proficiency and uncertainty processing is vital for managing and regulating systems that are dependent on AI and data analytics. The input uncertainty is considered by means of fuzzy numbers as diverse fuzzy

inputs and parametric architectures. Nonlinear functions, here, aid the assimilation of the concerned solutions along with tuning and adjustment for attaining viability and sustainability [1]. Most individuals spend around 80% to 90% of their time within indoor settings [2]. Control methodologies for HVAC systems in buildings have been

recommended by several researchers for inhabitants' optimal comfort while reducing utilization of energy [3–6]. Nonetheless, recent research works have demonstrated that data-propelled control approaches through analytics and IoT can further enhance the security and comfort of the inhabitants [7–10].

HVAC today accounts for around 60% of the energy used up in buildings, and this includes domestic, major commercial, and industrial structures [11, 12]. Those responsible for management are presently encountering irregularity in energy pricing, jeopardizing financial planning for buildings and other structures. According to Saidur et al., the air conditioning in an office building accounts for the most energy utilization (57%), followed by illumination (19%), elevators (18%), pumps, and other tools (6%). In the past three decades, the significant economic progress in Malaysia has led to an intense rise in energy usage. Many research works have deduced a positive relationship between utilization of electricity and economic progress [13]. In other words, HVAC systems have to be more energy-effective and fitting [14]. In view of this, Raffaele et al. recommended an IoT-based design for executing the model predictive control (MPC) of HVAC mechanisms in smart buildings [15]. The mechanism recommended by the authors comprises a suite of smart actuators and sensors, a database server, a gateway, a control unit, and an easy interface or console, and these are all networked and linked to the Internet. The particular control algorithm augments online, within a closed-loop control mode, the indoor thermal comfort as well as the associated energy utilization for a single-zone setting. Hence, it allows the end users to regain information regarding comfort and ecological indices and to manage the temperature and the control functions of the system remotely. Notably, the system is focused more on thermal comfort and does not take into account other parameters such as air quality and visual comfort, which are vital in office settings. Furthermore, the majority of the researchers did not deploy IoT in the HVAC environment, which might lead to a dearth of enhancement and creativity in the development of the HVAC sector. In other words, HVAC systems have to be more energy-effective and fitting [14].

Controlling and monitoring carbon dioxide levels indoors are critical for everyone's health, safety, and building energy efficiency. Buildings also require fresh air to function properly. In a building, ventilation is the process of exchanging stale air with new air. Buildings without engineered ventilation become vulnerable to stagnant air, mildew, bacteria, and potentially dangerous gases such as radon, VOCs, and carbon dioxide. Long-term exposure to these elements can cause "sick building syndrome," in which inhabitants suffer from acute health and comfort problems [16]. Thus, it has turned into an urgent matter to bring the CO₂ emissions essentially to zero (or lower) for the related structures. CO₂ levels in the workplace should be between 350 and 900 ppm. Drowsiness and poor air quality are common when CO₂ levels exceed 1,000 ppm. With CO₂ levels over 2,000 ppm, headaches, poor focus, lack of attention, increased heart rate, and minor nausea may develop.

Recently, it has been increasingly claimed that changes in an occupant's mood, well-being, and overall happiness with the built environment can demonstrably influence their thermal comfort [17]. It has been claimed that if an occupant's assessment of thermal comfort is considered a cognitive process, then perceived thermal comfort may be influenced by the psychological effects of a variety of physical circumstances that occupants encounter in the built environment, not just thermal factors. Artificial intelligence has been used in research around the world to address ventilation strategies to minimize CO₂ and other pollutants (AI). Intelligent control modeling for improving occupant environment comfort employs fuzzy logic (FL), artificial intelligence (AI), and machine learning (ML) [18–20].

Fuzzy logic is used in various systems due to a few of its notable attributes such as not needing robust mathematics or an accurate dynamic model [21]. One of the crucial reasons why the usage of fuzzy logic has increased swiftly is that it offers the deployment of human thinking and rationale with if-then rules from the system input-output data, spawning the fundamental model structure (structural identification) and parametric identification or model training [22]. One more element of fuzzy logic when blended with fuzzy logic neural networks is dealing with uncertainty and studying the capability of the recommended model for forecasting reasons [23]. When pertaining studies in the literature are appraised, it is noted that Siham et al. emphasize the significance of a fuzzy expert mechanism for HVAC systems for ensuring a convenient environment with regard to ecological parameters coupled with humidity and temperature without omitting the objective of conserving energy [24]. Goswami et al. recommended the use of a learning algorithm for multivariable data analysis for advanced regulation in HVAC setups for buildings. The objective is to deal with the control issue by utilizing a fuzzy classification methodology that does not entail a mathematical model of the system or the plant [25].

As per Perumal et al., many works on indoor environmental supervision were conducted, such as Smart House, Gator Tech, and IDorm [18]. These accomplishments are a few of the innovative explorations with tailored execution, aimed at stowing and regaining data. There is a dearth of systems wherein data are acquired from the environment and treated to attain info that can aid in making decisions accordingly in a smart home environment. There are multiple modes to enhance the quality of the HVAC setup with human convenience. Notably, the HVAC setup in the market is depicting a dearth of the intelligence factor as of now. It is now essential that artificial intelligence is deployed into the system for raising the well-being of the environment. A suite of appropriate artificial intelligence attributes has to be recommended for prospective HVAC setups and for improving occupant environment comfort.

In the present work, we have emphasized the data analytic segment to augment the knowledge and competence in the HVAC sector as against manual comfort. It is devised to encapsulate how a building is utilized by the inhabitant in real-time and to offer analytical insights into systems, which primarily concentrated on the smart air-conditioning

setups. Human comfort and safety benchmarks too would be encompassed in the system to optimize the level of comfort of the air-conditioning setup. The study will be carried out as per the lifecycle of the data analysis. The discovery stage emphasizes determining insightful data and knowledge from the IoT data collection. Then, we will elucidate how the acquired data and data preprocessing have been dealt with. During the model planning stage, the vision of the study, essential for the problem-solving, is introduced. The model building related to project planning is already implemented at this stage. The outcomes for ensuring precision and sustainability in ambiguous and nonlinear vigorous environments are presented in the final phase.

The work in the research article is divided into five sections: Section 2 provides the decision related to thermal comfort. Section 3 describes the materials and methods used in this research. The results and discussion part are presented in Section 4, and the conclusion of this study is presented in Section 5.

2. Thermal Comfort

According to the research done previously, thermal comfort is the next trend in developing HVAC systems. The factors that manipulate thermal comfort can be divided into three groups, which are concerned with the environment, humans, and psychology. Figure 1 illustrates the important parameter to be considered in categorizing thermal comfort factors.

To achieve thermal comfort, many researchers have considered temperature as the main factor. However, humidity should also be taken into consideration in the Malaysian climate and environment. The environmental factors include temperature, humidity, airflow, and heat radiation. In addition, human factors such as individuals' physical activities and metabolism level need to be taken into consideration regarding human comfort aspects. Another main factor of the overall human comfort could be visual comfort. Different situations and environments need different kinds of visual comfort. For example, a restroom should have a warmer light, but an office should have enough amount of light. The environmental factors that determine visual comfort are illumination, optimal luminance, glare, contrast condition, colors, and intermitted light. The factors that determine visual comfort could be uniform illumination, optimal luminance, no glare, correct colors, adequate contrast, and the absence of intermittent light. According to Lu et al. [26], carbon dioxide (CO₂), total volatile organic compound (TVOCs), and volatile organic compound concentration (VOCs) will be the three factors of air quality comfort. The 800 ppm of concentration of carbon dioxide will be the desired level for most of the environment. If there is a huge increase the carbon dioxide level, it will bring about various health problems and even death.

There exists a lot of research on HVAC systems that specialized in human comfort. According to Fakhruddin et al., air-conditioning systems have already become an essential part of our daily lives [27]. They proposed the fuzzy system the consideration of various input parameters and

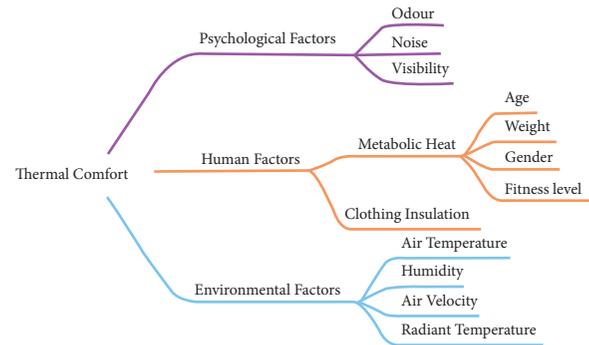

FIGURE 1: Categorization of thermal comfort factors.

applying the fuzzy logic system to the air conditioner. The fuzzy input in the proposed system is user temperature, temperature difference, time of day, dew point, and occupancy. Then, the output variable of the system is compressor speed, fan speed, mode of operation, and fin direction. Another research by Hang and Kim predicted mean vote (PMV) is used to control the indoor temperature of the environment by using the PMV index [28]. This research outlines an enhanced MPC system for measuring the human comfort index and maintaining indoor thermal comfort at the optimal level. An MLR-based PMV predictive model is proposed with a simplified PMV equation. The simulation results of the research show that the proposed control strategy can maximize indoor thermal comfort and also helps reduce energy consumption.

Shah et al., in “A Review on Energy Consumption Optimization Techniques in IoT Based Smart Building Environment,” stated that the area of the energy management system has already existed for many years [29]. Fuzzy controllers have become more important in the study of energy controlling and optimization methods. The technique is basically to improve the comfort index by using the references of user preferences. From the paper, we understand that the primary objective of the control system is trying to satisfy the user's thermal preferences, energy-saving, and monitoring. The rule base was designed well to solve the problem of energy overshooting. Therefore, automated controls and energy management systems could have a great potential to improve individual comfort and reduce energy consumption.

3. Materials and Methods

Fuzzy logic is an approach that will rather use a “degree of truth” than the usual “true or false” computing. For example, in fuzzy logic, we are more focusing on the uncertainty between 1 and 0, but the usual computing is more to 1 and 0 only. Fuzzy logic is a form of many-valued logic in which the truth values of the variable may be any real number between 0 and 1, as we considered it “fuzzy.” Fuzzy logic has been further improved to handle the concept of uncertainty, where the truth-value may vary from the range between completely true and completely false.

In this case, fuzzy modeling is implemented accordingly for the prediction of human comfort level. Human comfort

levels may vary between completely comfortable and completely the discomfort. Fuzzy modeling is capable of handling perceptual uncertainties such as the vagueness and ambiguity involved in a real system. The most crucial task in constructing a fuzzy model is to perform structure identification, which is concerned with determining the number of rules and parameter values that will provide an accurate system description. The results of transforming numeric data into fuzzy sets are used directly in making a rule-based system.

The structure identification is concerned with determining the number of rules and the parameter estimation. Various approaches have been proposed to construct the fuzzy model and its best parameter. One of the popular techniques for fuzzy modeling is the fuzzy *c*-means clustering algorithm. The fuzzy *c*-means produce a fuzzy partition of the input space by using cluster projections. The results of transforming numeric data into fuzzy sets are used directly in constructing a rule-based system.

We consider the problem of approximating a continuous multi-input and single-output (MISO) to clarify the basic ideas of the presented approach. The essence of fuzzy modeling is inherently associated with the inference schemes of approximate reasoning.

$$\begin{array}{r}
 x \text{ is } A \\
 \text{if } x \text{ is } A_i \text{ then } y \text{ is } B_i, \quad i = 1, 2, \dots, N \\
 \text{-----} \\
 y \text{ is } B,
 \end{array} \tag{1}$$

where B is a fuzzy set of conclusions to be determined. A and A_i are defined in a finite input space X , $\dim(X) = n$ while B_i and B are expressed in the output space Y with dimensionality, $\dim(Y) = m$. The set of indexes of the rules is denoted by N ; in this case, it is simply a set of N natural numbers indexing the rules, $N = \{1, 2, \dots, N\}$.

There is a wealth of realizations of the inference schemes with a large number of optimization mechanisms. In a nutshell, though, the inference scheme is realized by determining the activation levels of the individual rules (their condition parts) implied by some A . This is typically done by computing a possibility measure of A and A_i , $\text{poss}(A, A_i)$. Denoting the possibility value by λ_i , the conclusion B is taken as a union of B_i weighted by the activation levels (possibility values), namely

$$B(y) = \max_{i = 1, 2, \dots, N} (\lambda_i(x) \wedge B_i(y)), \tag{2}$$

where \wedge stands for the minimum operation. There are numerous variations of this inference scheme nevertheless the essence of the underlying reasoning process remains the same. Figure 2 shows how the fuzzy inferences system works.

To get the research done, the choice of machine learning or data analysis tools is very important. There are eight suggested applications for big data analytics that are well described and examined with the performance available, namely Apache Hadoop, Apache Spark, Apache Storm, Apache Cassandra, MongoDB, R programming Environment, Neo4J, and Apache SAMOA. In this research, we use

R programming because this research involves machine learning and a fuzzy inference process. A wide range of libraries in R programming enables the project to be done smoothly. Besides R programming, according to <http://www.mathworks.com>, MATLAB also provides a fuzzy inference system function for users to create a fuzzy modeling system. Fuzzy Logic Toolbox software provides command-line functions and an app for creating Mamdani and Sugeno fuzzy systems. The website is detailed with many kinds of functions that are related to fuzzy inference systems, for example, creating fuzzy systems, specifying membership functions, specifying fuzzy rules, evaluating and visualizing fuzzy systems, importing and exporting, creating the fuzzy membership function, and constructing custom fuzzy systems, as the main functions required to be considered to develop a fuzzy inference system.

4. Experimental Results and Discussion

4.1. Data Set Description. The current study has employed 39,636 instances in the data set. Due to there being different sensors will be placed in different locations of the office, the sensor will be denoted to different UnitID in the data set. Based on the data set provided, 45 sensors are functioning in the HVAC data collection. Next, data are collected in a time series. Based on the rough understanding of the data, the `data_time` feature is formatted as DD/MM/YYYY HH:MM. The data is recorded every second, but not as a fixed or uniform timeline. Table 1 shows the data that will be used in this research. All the data will be denoted as noise (dB), light (lux), temperature ($^{\circ}\text{C}$), CO_2 (ppm), and humidity (%).

In this phase, we need to understand the data obtained for this research. Every feature/variable included in the data set should have a high understanding so that we know which features in the data set are suitable for this research development. The histogram function has been used to see the distribution of the data. The histogram is a chart representing a frequency distribution. Then, correlation analysis has also been carried out in this research at the same time. Correlation analysis is a statistical method that allows us to compare the strength of the relationship between the attributes in the data set. The higher the correlation between two attributes is, the higher the relationship between the two attributes is. A weak correlation value indicates that the variables are not related to each other.

To observe and examine the correlation, linearity, and histogram of the data, we used `ppclust`, `factoextra`, `dplyr`, `cluster`, `fclust`, and `psych` library in the RStudio library. Then, by calling the `pairs.panels(x, method = "Pearson")` function, we can get a multi-info chart that includes histogram, correlation value, and linearity diagram. Figure 3 presents the result of the functions for three months.

Figures 3–5 show that the data distribution of the three months data are almost the same. First, the noise value histogram shows that the data are right-skewed, which means the surroundings always have a low noise value. The light value data are also skewed to the right; we can see that most of the light values are near 0; and we assume that maybe the light sensor is not sensitive enough to collect the

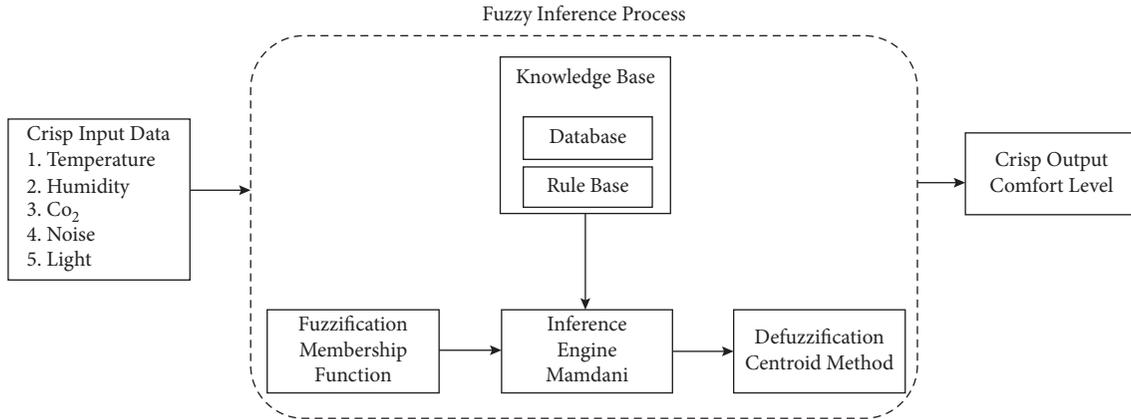

FIGURE 2: Fuzzy modeling inference system concept.

TABLE 1: The data set information for the study.

Parameters	Min	Max	Denomination
Temperature	15	35	°C
Humidity	0	100	%
CO ₂	200	2,000	ppm
Noise	40	80	dB
Light	0	400	Lux
Comfort level	0	10	Level

accurate data. This conclusion can be drawn because an office should not have such low light intensity for productivity. Next, temperature and humidity values both have the normal distribution depicted in the figures provided. Based on the histogram, the workers are feeling comfortable at a temperature of 25°C in the office area due to its highest count in the data. Besides that, the temperature in the office will always maintain from the lowest 20°C to the highest 30°C, from which it can be inferred that an area with 30°C; the meeting room not often used by the workers or the data is recorded during night time, which is after the office hours. Lastly, the carbon dioxide and volatile organic compounds in the office area are considered to be at a slightly higher level. According to some studies, the acceptable carbon dioxide level and volatile organic compounds in air quality should be maintained below 500 ppm and 1,000 ppm, respectively. The data recorded for this both attributes are higher than the expected value of about 500 ppm; company should have a solution to solve this problem after this analysis has been done.

From these points, it can be noted that noise and light have the most positive correlation in Figures 3–5, followed by noise and carbon dioxide. We may have an assumption that the noise level is increasing with light and carbon dioxide value because there is an occupant for the covered area. These three attitudes are correlated with each other because the carbon dioxide and noise level will increase if a worker is using that area and whether or not he or she will be using the area with the lights.

In this section, we shall discuss the result of clustering. To provide an unsupervised learning–clustering, Visual Studio Code has been used to provide a better processing speed to achieve the task. The data are clustered into three

clusters with six attributes (temperature, humidity, CO₂, VOC, noise, and light). The algorithm used to perform clustering is the k-means algorithm. The algorithm nicely clustered the data into three parts. We need to decide whether the data clusters belong to categories of good, normal, and bad since it is unsupervised learning.

Table 2 shows the results of the k-means clustering of the data set. The results are transformed into a table form, in which the values are recorded, in mean value. From the table, we can see that the surrounding temperature of the office range from 24.5°C to 26°C. The clustered temperature for these 3 clusters is not much different that only has a mean of 25°C to 26°C. Based on the research, the best temperature for a working environment, especially, the office, should be kept at 21°C to 22°C. Therefore, the working environment is warmer compared to the ideal temperature. Next, the optimum humidity level of an office as per research is between 40% and 60%. Based on the results obtained, the humidity level for the data set remains between 55% and 60% that is considered to be under the good category. Furthermore, the humidity value of cluster 2 was 55.9%, which is very good for a human working environment. Next, for the CO₂ level, cluster 2 contains the highest mean value of CO₂ level that is abnormally high, 1,075 ppm. The carbon dioxide level in the office is maintained at approximately 600 ppm for clusters 1 and 3. Meanwhile, the CO₂ level for cluster 2 achieves a less healthy level that is 1,000 ppm due to the crowd in location and being a small area. Although the researcher stated that 2,000 ppm of carbon dioxide will cause harm to human health, 1,000 ppm of carbon dioxide did not bring about many benefits to the worker because it will cause sleepiness. The VOC level also has a big range of average value based on the clustered result, cluster 3 has a 2,298 ppm of the highest amount of VOC, which is bad for health. The light and noise value does not have much difference in terms of the three clusters obtained. The noise data is also an important attribute of this data set since it has a high correlation with other attributes. The noise level in the office is maintained at the level between 47 dB and 52 dB in this data set. The environment of the office is comfortable if the reading is at 47 to 52 dB because it is considered to be a quiet environment for a worker. Workers can stay focused all the time

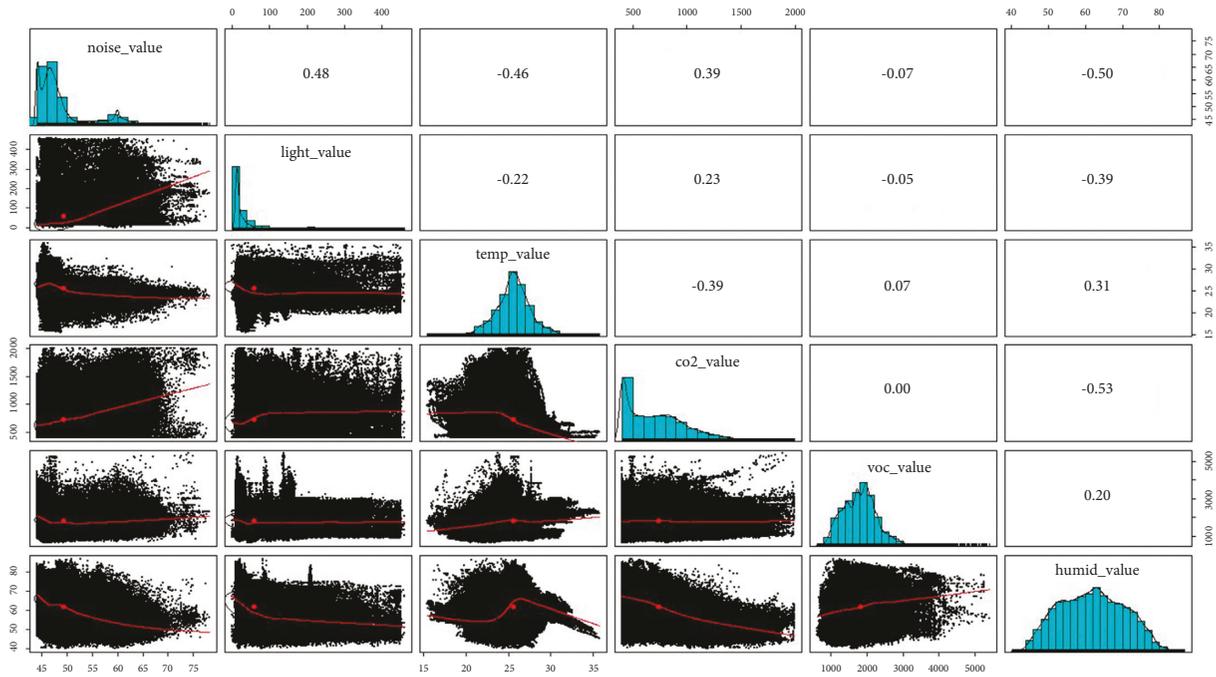

FIGURE 3: Correlation of input data for the first month.

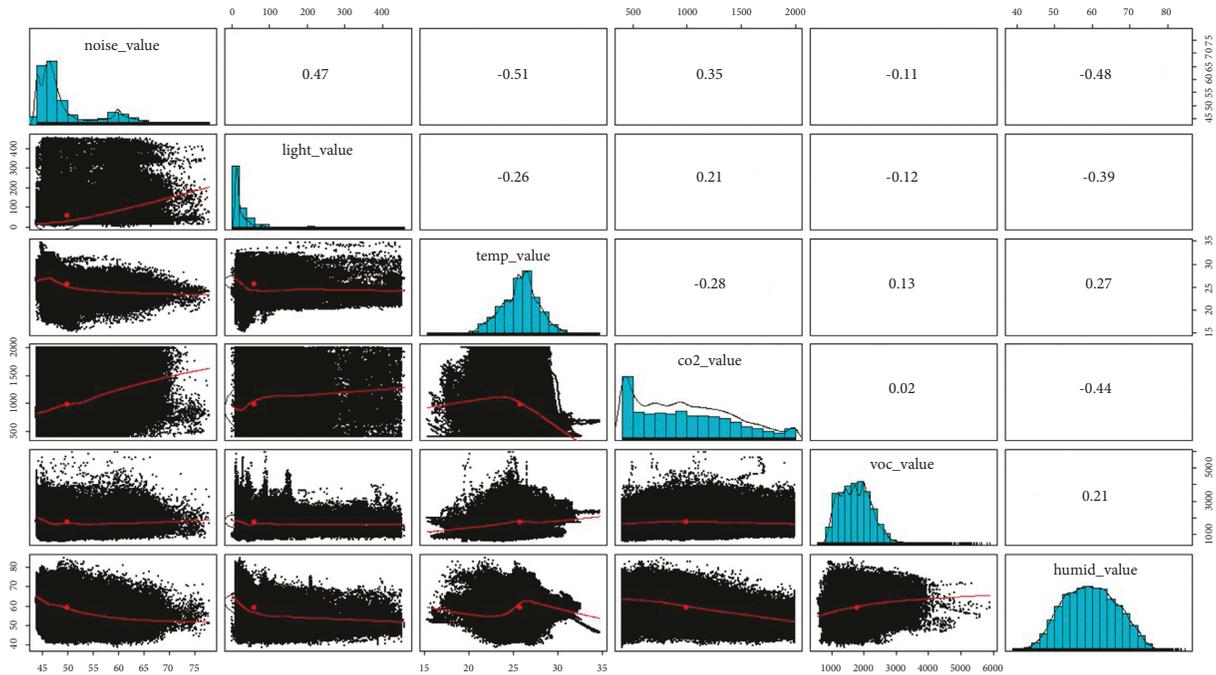

FIGURE 4: Correlation of input data for the second month.

in this range of noise. Furthermore, workplace lighting may also affect the efficiency of a worker. A recommended light level is more common in the range of 500 and 1,000 lux, depending on the activity. The highest mean value of the light data is only 76 lux. This indicates that the light power for this company is not enough for the activity. Besides that, there is also a probability that the sensor is placed at a coordinate that

may not be a strategy to collect light data, which has affected the results. Last but not least, the volatile organic compound in the office is also recorded in this data set. As the table depicts, the volatile organic compound has a 1,000 ppm difference between the maximum and minimum levels. This part has not been included in this discussion part because VOC is the least correlated data attribute in this data set.

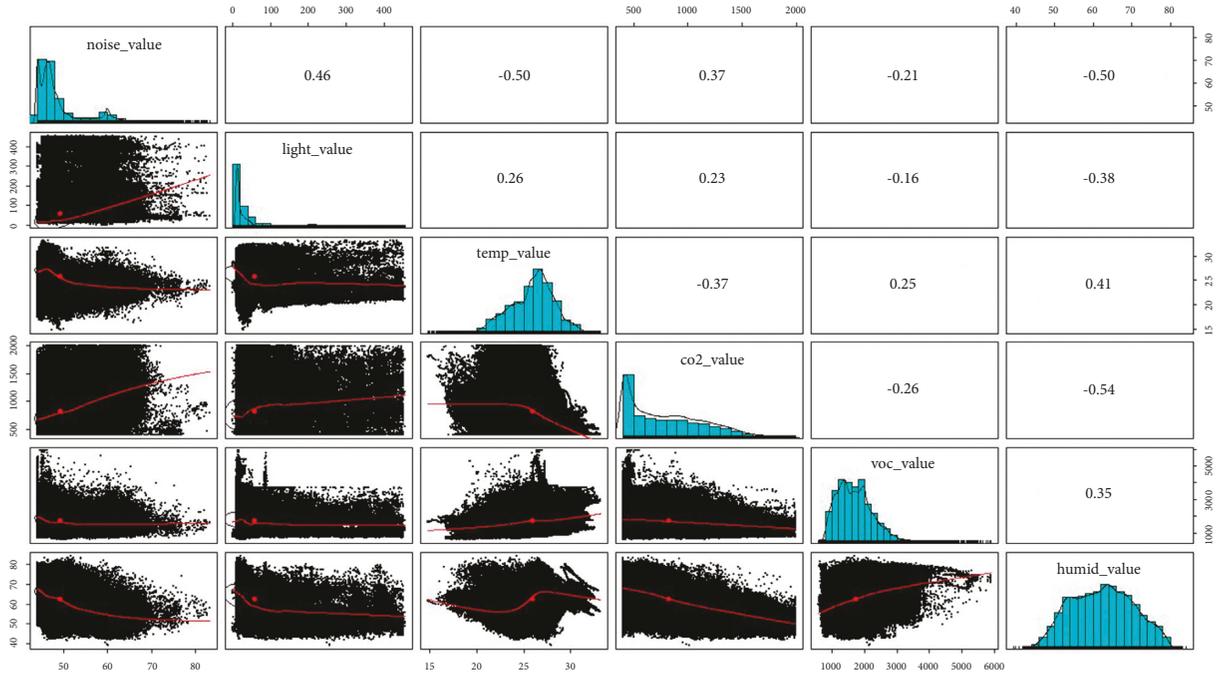

FIGURE 5: Correlation of input data for the third month.

TABLE 2: Average values for six attributes categorized into three clusters.

No. of cluster	Temp	Humidity	CO ₂	VOC	Noise	Light
1	25.65765	62.24335	613.9729	1,388.163	48.79849	57.72873
2	24.5565	55.98562	1,075.342	1,768.494	51.69869	76.28403
3	26.05804	65.39577	637.2665	2,298.839	47.89209	47.63216

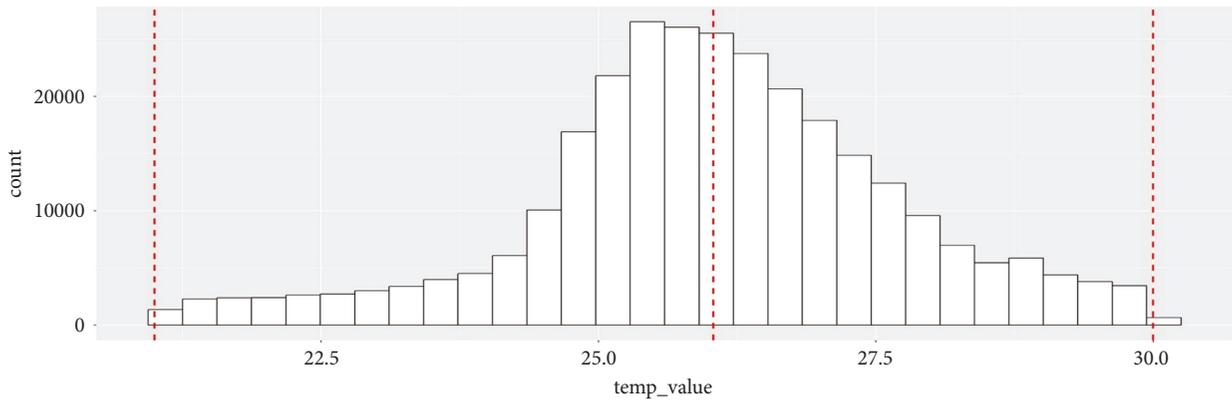

FIGURE 6: Histogram of temperature.

4.2. *Frequency Analysis.* A histogram is a plot that allows us to discover and show the underlying frequency distribution (shape) of a set of continuous data. The shape of the histogram will be a factor in designing the fuzzy inference system. The subsequent part explains the findings from the histogram.

Figure 6 depicts that the shape of the temperature histogram is normally distributed. The histogram has an approximate minimum value ranging from 20°C to an

approximate maximum value of 30°C. Based on the peak and the mean of the histogram, the office is usually comfortable at a temperature range of 25°C–26°C.

Figure 7 presents the histogram concerning the humidity parameter. The shape of the histogram is normally distributed. Based on the histogram, the environment of the office is usually located between 60% and 70%.

Figure 8 shows the histogram of carbon dioxide, and the shape is skewed to the left. This left-skewed

histogram shows that the data of carbon dioxide in the office are less than 400 ppm of carbon dioxide that is the comfortable range in terms of health.

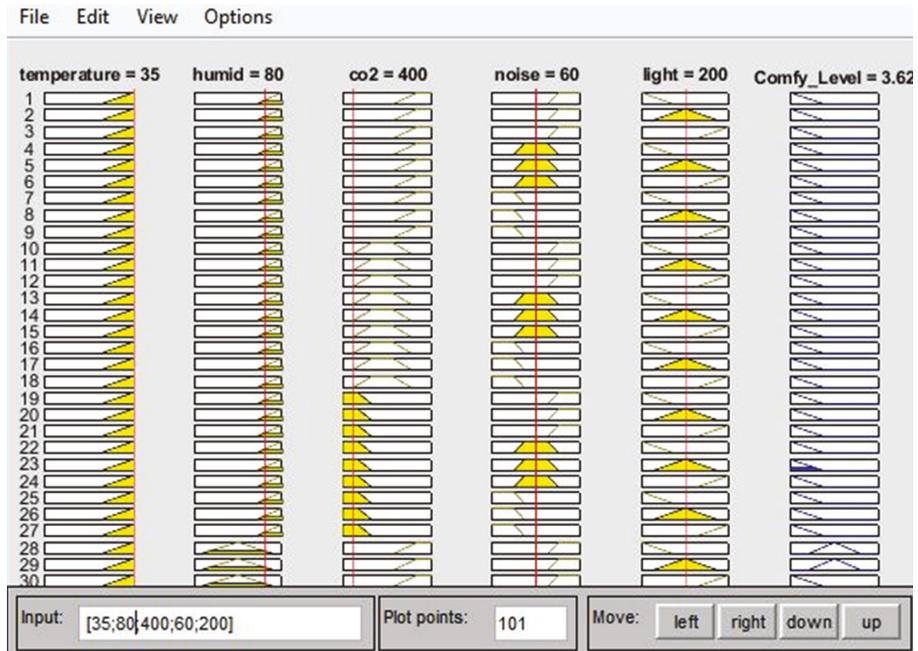

Figure 9 shows the histogram of VOC. The shape of the histogram is in the form of multimodal distribution. It is observed that the highest amount of the volatile organic compound is approximately 2,000 ppm from the data collected. However, the volatile organic compound is normally around ranging from 1,000 ppm to 2,000 ppm.

Figure 10 shows the histogram of noise, and the noise in the office is not very loud. The noise in the office is less than 55 dB, which means that it is a very comfortable place to work. Yet, the results of this data may be different from the real experience because the location of the sensor is a critical matter to be taken into consideration.

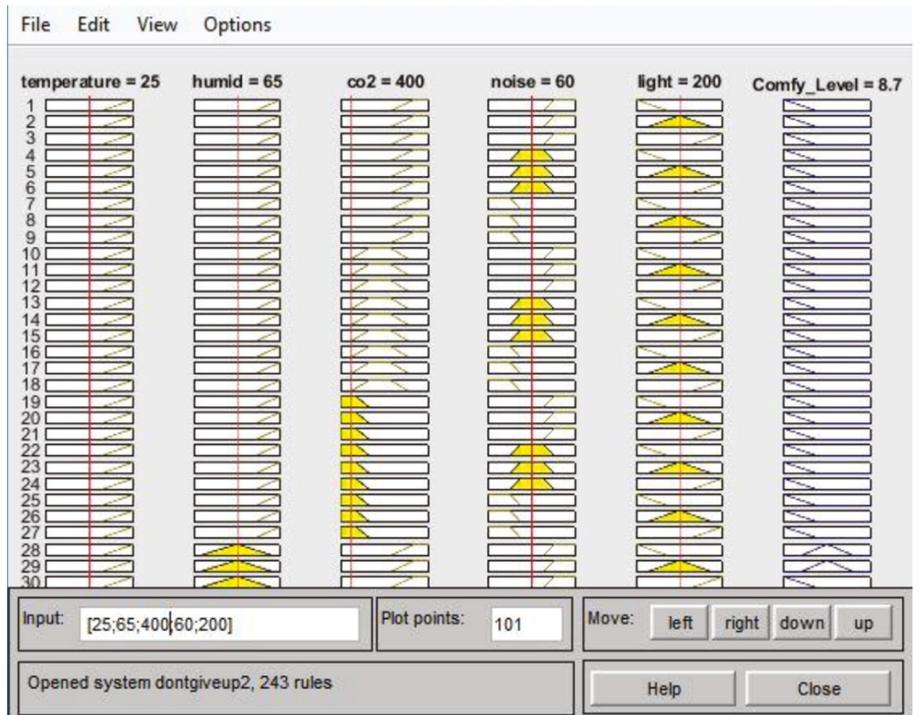

4.3. Nonlinear Fuzzy Inference System for Human Comfort.

Based on the literature review and the analytic results from the previous chapter, a data-driven fuzzy inference system based on human comfort has been carried out. The objective of this fuzzy inference system is to predict or analyze the human comfort level in an environment. The organic volatile compound (VOC) will be excluded from the fuzzy inference system input because the correlation analysis shows that the VOC does not have an impact on human comfort. Therefore, the input of the fuzzy inference system will consist of five factors, which are temperature value, humidity value, carbon dioxide value, noise value, and light values. These five inputs will be created based on the analysis results, and they have their membership function to have an accurate human comfort level results in the output.

Fuzzy control input and output values are defined in three linguistic expressions as four different parameters:

(a)

(b)

FIGURE 13: Rule viewer: (a) comfortable environments and (b) less comfortable environments.

temperature, humidity, CO₂ level, light level, and noise level. Two parameters are chosen as output-comfort level. The features and fuzzy linguistic operations of the input and output system are provided in Table 3, respectively.

The membership degree quantifies the grade of membership of the element to the fuzzy set. The value 0 means that is not a member of the fuzzy set; the value 1 means that is fully a member of the fuzzy set. The values between 0 and 1

characterize fuzzy members, which belong to the fuzzy set only partially. After the results of the histogram are observed and interpreted, three membership functions have been obtained regarding the temperature that is high, medium, and low. The range of high temperatures will vary from 27.5 to 36. Then, the temperature for the medium is from 20 to 30. Lastly, 15 to 22.5 will be the membership range for low temperatures, After the results of the histogram are observed

and interpreted, three membership functions are obtained for humidity that is high, medium, and low. The range of high humidity will vary from 75% to 90%. Then, the humidity for the medium is from 43% to 86%. Lastly, 40% to 55% will be the membership range for low humidity. Figure 11(b) shows the membership function of humidity. The results of the histogram show that three membership functions have been obtained for CO₂ that is high, medium, and low. The range of high CO₂ will vary from 1,200 ppm to 2,000 ppm. Then, CO₂ for the medium is from 400 ppm to 1,600 ppm. Lastly, 200 ppm to 800 ppm will be the membership range for low CO₂. Figure 11(c) describes the membership function of CO₂. The results of the histogram show that three membership functions have been obtained for noise that is high, and medium, low. The range of high noise will vary from 65 dB to 80 dB. The noise for the medium is from 50 dB to 70 dB. Lastly, 40 dB to 55 dB will be the membership range for low noise. Figure 11(d) shows the membership function of noise. Three membership functions have been obtained for the light that is high, medium, and low. The range of high levels of light will vary from 250 lux to 400 lux. Then, the light for the medium is from 50 lux to 350 lux. Lastly, 0 lux to 150 lux will be the membership range for low noise. Figure 11(e) shows the membership function of light. In order to make the understanding easy, we have decided to use a simple scale that is 1 to 10 as the parameter of human comfort level. One represents the worst situation, and 10 refers to the most comfortable and optimal situations. Figure 11(f) shows the membership function of comfort level.

In a standard fuzzy partition, every fuzzy set will correspond to a linguistic concept, for instance, low, medium, and high that are being used in this comfort level fuzzy inference system. Fuzzy rules are always written as If situation-Then conclusion. In this research, 243 rules have been used to get the best performance of the fuzzy inference system. Figure 12 shows the rule editor for this system.

In Figure 13, input of 25°C, 65% humidity, 625 ppm of CO₂, 60 dB of noise, and 200 lux of light was used. The comfy level generated by the fuzzy model by using the histogram analysis method is 8.7 out of 10.

5. Conclusions and Future Directions

The ever-changing dynamic landscape of our time requires that a comfortable environment is ensured considering all the possible environmental parameters, temperature, and humidity while saving energy. Thus, in addition to the electric and mechanical control system, it has become critical and required that artificial intelligence (AI) be integrated and implemented into the systems in order to increase the comfortability of the environment. Moreover, the applicability of the fuzzy model is evident since it includes the implementation of human thinking and reasoning with if-then rules as obtained from the input-output data of the system for model structure and training. The fuzzy model is also advantageous pertaining to purposes of prediction to deal

with uncertainty and nonlinearity and to investigate the ability of the models proposed. The strength of the current research is that we can obtain a lot of information from the data set by using a statistical analytic method. It is possible to encounter some missing important data if we just read the real-time data from the dashboard. By using statistical analytic means, we can combine all the data into one graph or chart to see the pattern of the data. For instance, it can be ensured to know that the light of the office is low for a workplace or maybe the sensor needs some improvement in collecting light data. There is a lot of information that we can actually extract from a set of data. In the present study, human comfort data have been used as the main part of the research. By interpreting the data provided, we can clearly know about the comfort level of the working environment that affects the health and productivity of a worker indirectly. The office management may take action based on the result obtained in the future to improve their workers' efficiency. The fuzzy model could also be regarded as another strength and motivational aspect of this research. The fuzzy model can predict human comfort based on the six attributes provided in the data set. In the future, researchers may improve the fuzzy model and implement it into a smart building system in order to get an intelligent controller for occupants' comfort. Thus, it may be concluded that it will be more humanized if there is a larger data set available for us to deal with. This research can still be improved by using another data set, and the results will be more interesting. The more attributes and duration are involved in a big data set, the more closely it may be possible to achieve the intended objectives while considering optimized sustainability in dynamic and non-linear environments towards improving the accuracy and objectivity of the evaluation results. This proposed prediction model is only valid for similar input data having similar statistical properties. The proposed study can help the researchers and professionals to predict the comfort level inside the office building and its effect on individual health. In future work, efficient machine learning models with large data sets can be used to predict the comfort level of various parameters like visual comfort and acoustic comfort.

Data Availability

The data sets generated and/or analyzed during the current study are available from the corresponding author upon reasonable request.

Conflicts of Interest

The increasing complexity of the international situation intensifies the changes of the economic environment. People's demand for information represented by accounting earnings, such as judging the profitability and risk coefficient of the company, is becoming more and more urgent. This study puts forward the theory of predicting accounting earnings through accounting earnings factors in a nonlinear way and designs an accounting earnings forecasting model based on artificial intelligence. Integrating LSTM, seq2seq, and reinforcement learning and combining with self-attention like mechanism, a complex multifactor time series forecasting model is established, and reinforcement learning is used to stabilize the model to prevent overfitting, which puts forward a new solution to the multifactor time series forecasting problem of complex relationship. The experimental results and comparative analysis show the effectiveness of the enhanced recurrent neural network accounting earnings prediction model designed in this study.

1. Introduction

As a discipline that provides economic information reflecting the financial status and operating results of enterprises, accounting reflects the performance of the entrusted responsibilities of the enterprise management by providing the users of financial accounting reports with accounting information centered on the operation of enterprises, which is helpful for the users of financial accounting reports to make economic decisions [1–5]. Accounting surplus is the most important concept and index in accounting information. Its decision usefulness is the foundation of financial accounting and the main means to judge the value of the company [6].

In the information view of accounting, it is considered that the market is incomplete and full of uncertain factors [7]. No accounting method can get the real income of an enterprise, but accounting earnings information is a signal to investors that is helpful to judge and estimate economic income, which can improve the accuracy of investors' prediction of the future situation of the company. The

valuation view of accounting further complements the role of accounting earnings information. It is believed that investors will take the corresponding accounting data (with profit as the core) as the model change when valuing the company, so that the accounting earnings information and stock price affect each other. In other words, through the value of accounting earnings, we can infer a lot of information related to accounting earnings and use the earnings information to analyze the company's operation, risk, future profitability, stock price change trend, etc. Therefore, the prediction of accounting earnings and the analysis of earnings information have always played a very important role in corporate management, investment, and other economic behaviors.

The research of earnings information system can be traced back to the relationship between the intensity of expected income change and stock price adjustment. From the beginning of being concerned to today's research, many scholars have been exploring the correlation between accounting earnings and earnings information based on the company's stock price. In these studies [1, 8–11], a large

number of theoretical and empirical studies show that the relationship between accounting earnings and stock returns (usually expressed by earnings response coefficient) changes alternately. Many studies also found that the stock price will fluctuate in the window period of accounting earnings information announcement such as annual report. In other words, earnings information will have an impact on the expected stock price in the future. At the same time, the stock price will also affect the future surplus.

In the current research, considering the weakness of the linear correlation between accounting earnings and stock return and the limitations of relevant assumptions, scholars have been seeking to establish a nonlinear correlation to uncover the secrets between accounting earnings, stock price, earnings announcement, annual report, and other factors, so as to judge the value of the company and help investors analyze and make decisions. The characteristics of this nonlinear system coincide with the nonlinear properties of neural networks [12, 13]. Moreover, accounting earnings and related data are time series data. As a neural network that can display dynamic time series and use its internal memory to process the input sequence of any time series, recurrent neural network (RNN) [14–20] can predict earnings fluctuation and reflect the stock price behavior at this stage in combination with the influence of different time series data. Reinforcement learning can intelligently solve complex problems, get rid of the constraints of the current theoretical analysis of accounting earnings value, and bring more possibilities for the research and development of earnings information.

Therefore, driven by artificial intelligence [12–20], this paper constructs an overall model of various accounting earnings value related factors, such as earnings (here refers to the specific number of earnings, which can be equivalent to profits), earnings announcement, stock price, assets and liabilities, and company cash flow, based on the neural network for time series and combined with parameter self-tuning means such as reinforcement learning. Based on earnings forecasting, an enhanced RNN earnings forecasting model is proposed, which can be nonlinear and can automatically adjust the importance of factors related to earnings value through model learning.

2. Accounting Earnings Value Forecast Model

2.1. The Basic Idea. The current two types of models (time series analysis model [21, 22] and multiple cross-sectional regression model [23, 24]) have their advantages and disadvantages. The time series analysis model can have a more stable output because it considers the dependencies that pass over time. Still, it is also difficult to obtain its data, and the model is too ideal. The multiple regression model based on cross-sectional data starts from reality, considers the correlation between earnings factors, and can achieve a more accurate output than the time series analysis model. However, the limitation of the linear model makes it impossible to include the time-dependent relationship at the same time, and the effect on multiple factors is also limited, so it is limited to instability and further development.

Due to the superiority of RNN in processing time-series data and the excellent ability of the neural network in fitting complex models, we hope to combine the advantages of the time series analysis model and multivariate cross-section regression model. The mainstream research factors of the accounting earnings system are unified into a nonlinear earnings forecasting model. The purpose is to realize an earnings forecast model that can reflect the relationship between accounting earnings factors and output more accurate accounting earnings forecast results by improving and enhancing the RNN infrastructure.

As a model that can transmit data time relationships and input multiple influencing factors simultaneously, RNN has many points to pay attention to when used as the basis of the whole model. The simplest RNN is prone to failure to converge when the factors are too complex; therefore, in the impact of multiple accounting earnings factors, next, this paper forms a preliminary model framework inspired by the multistep prediction based on seq2seq. Here, we use the seq2seq structure to improve LSTM. Because the seq2seq structure is a structure of encoder-decoder, after using seq2seq to improve LSTM, our earnings forecasting model can implement variable-length inputs. In this way, even if the value of each factor related to the value of accounting earnings that we choose is not null, it will not affect the model's output. Another feature of this improved seq2seq structure is that it can use the joint probability of previous values to predict the next value, making the entire prediction model more stable and reflecting the relationship between earnings-related factors.

With the improvement of seq2seq [25, 26], we can incorporate many factors related to earnings value into the earnings forecast model. However, many parameters still need to be manually adjusted in the entire forecast model. From this point of view, the model will have similar problems as the multisection regression model: too many parameters, challenging to adjust, and then affect the effect of the model. To address this shortcoming, we use reinforcement learning to improve the whole prediction model. Through reinforcement learning, we can make the whole prediction model adjust through prediction, receiving feedback and feedback. This idea realizes the self-tuning of the prediction model and avoids the problem that the prediction model is difficult to complete the training caused by too many parameter adjustments. Under the guidance of the above improvement ideas, the accounting earnings forecast model is designed as shown in Figure 1, which can represent our earnings forecast's primary process and key steps.

2.2. Accounting Earnings Forecast Algorithm Model. In the above, we have proved the basic idea of the overall model and the main architecture and algorithms used. In this part, we will explain the structure and improvement of each module in detail and introduce the basic model used, the way of improvement, the flow of data in it, process functions etc. We start with the seq2seq structure in the model, first explain the most basic data processing framework, then

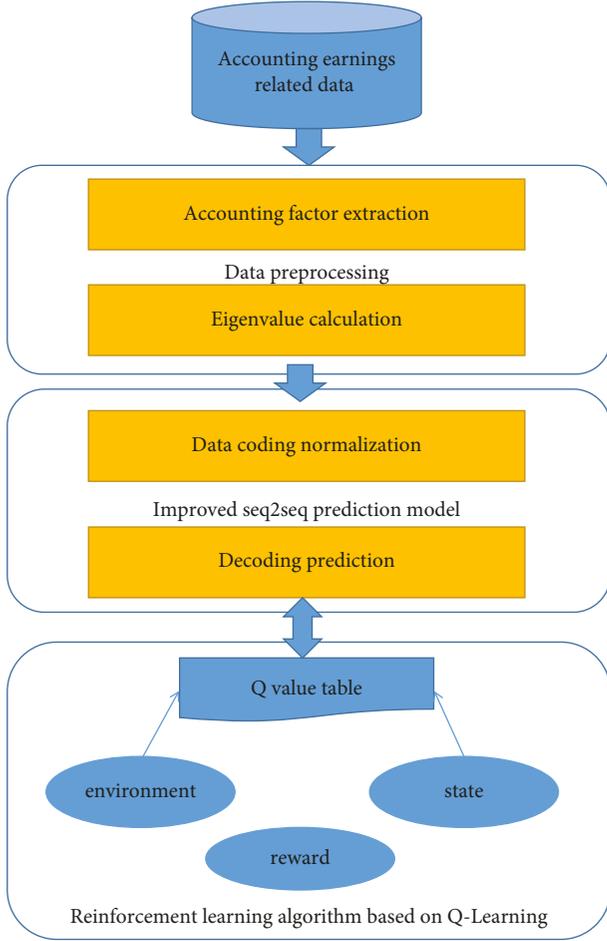

FIGURE 1: Accounting earnings forecast model.

introduce the reinforcement learning algorithm based on seq2seq, and further explain the key functions in the model and the improved weighting method.

2.2.1. Improved Seq2seq Model. In the above, we summarized the types of accounting earnings factors and analyzed the relationship between different accounting earnings factors. We explained in Section 2.2 that seq2seq could use the joint probability of prior values to predict the characteristics of the following value. The commonly used seq2seq has two structures. Here, we use the second structure of seq2seq to simulate the characteristics that accounting earnings factors affect each other and act on the final forecast value of earnings. Combined with our first three-level relationship of the surplus factors analyzed in the chapter, we explained the reason for using LSTM in the seq2seq structure before, so we use Figure 2 to represent our final seq2seq structure.

The LSTM cell starts from reading the input data and the two states c_t and h_t of the previous cycle. z_f , z_i , and z_o are all formed by the input data x_t and the previous cycle h_{t-1} after splicing according to different weights through the activation function σ_θ (). Calculated, these three variables are

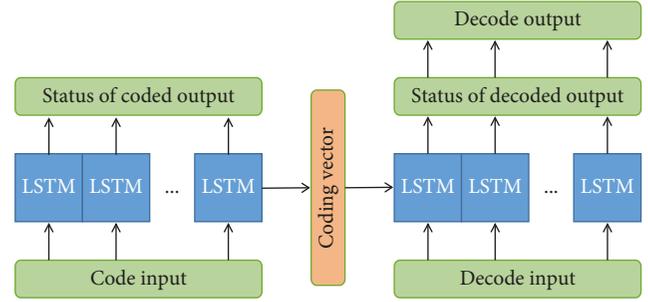

FIGURE 2: Partial structure of seq2seq.

gated states, the LSTM cell starts from reading the input data x_t and the two states c_t and h_t of the previous cycle. z_f , z_i , and z_o are all formed by the input data x_t and the previous cycle h_{t-1} after splicing according to different weights through the activation function σ_θ . Calculated, these three variables are gated states, but in fact, the actual input is z calculated by the activation function φ_θ .

The first step of LSTM is controlling the input information by the forget gate. We discard the relatively unimportant part of the input data through this step. In this process, the LSTM cell controls the previous cell state c_t by calculating z_f as the gate of the forget gate removal and retention of information in c_{t-1} . Then, the LSTM cell processes the input, where the input gate z_i will control the selective input of x_t . In this process, the previously calculated z is performed together with z_i , which we express with (2)-(1). The symbol \odot represents the multiplication of corresponding elements in the operation matrix.

$$c_t = z_f \odot c_{t-1} + z_i. \quad (1)$$

The output stage will determine all the outputs regarded as the current cycle. Here, z_o is used as the output gate. The calculation methods of h_t and y_t are listed in (2) and (3). In general, y_t is obtained by h_t transformation.

$$h_t = z_o \odot \varphi_\theta(c_t), \quad (2)$$

$$y_t = \sigma_\theta(w_l \cdot h_t). \quad (3)$$

After processing the encoding part, the encoding vector enters the decoder for actual prediction, and the value of the decoder part is calculated according to the process in Figure 2. Assuming that the encoder part obtains the final hidden layer state value is h_{T_e} , the decoder at the time of $t+1$. The state value of the part is calculated by (4), and the predicted value \hat{y}_{t+1} at this moment is calculated by (5).

$$s_{t+1} = \varphi_\theta\left(\frac{y_{t+1}^s}{h_{T_e}}, c_t\right), \quad (4)$$

$$\hat{y}_{t+1} \sim \pi_\theta(y|\hat{y}_t, s_{t+1}). \quad (5)$$

If we make the actual value to be predicted y , then the loss function at this time can be expressed by (6), and X represents the input data sequence.

$$L_\theta = - \sum_{t=1}^T \log \pi_\theta(y_t | y_{t-1}, s_t, c_{t-1}, X). \quad (6)$$

Considering that the surplus data is negative or positive and the characteristics of LSTM itself, we choose the sigmoid function as the σ activation function (7), the tanh function as the φ_θ function (8), and the SoftMax function as the π_θ function (9).

$$f(x) = \frac{1}{1 + e^{-x}}, \quad (7)$$

$$f(x) = \frac{1 - e^{-2x}}{1 + e^{-2x}}, \quad (8)$$

$$f(x) = \frac{e^x}{\sum_i e^i}. \quad (9)$$

If the accounting earnings factor is put into the model, we use Figure 3 to represent the input and relationship composition of the earnings factor in seq2seq.

The encoding vector is composed of the three output vectors of the encoder part. The importance of these three types of accounting factors is different, and the three types of accounting factors can be roughly determined through existing model research. Therefore, in order not to further complicate the model, we only draw on the idea of attention mechanism (10), directly weight these three vectors, and then obtain the input of the decoder part.

$$\text{Attention score}(\text{query}, \text{source}) = \sum_{i=1}^T \text{similarity}^{\text{imery}}(e\gamma y_i) \cdot \text{value}_i. \quad (10)$$

However, under the seq2seq model at this time, the optimization problem of the loss function is still not solved. Under such conditions, it is difficult to make the model have the best optimization strategy, making the instability produced by the model indistinguishable from the multiple regression cross section models. Therefore, we use reinforcement learning to improve this problem of the seq2seq model, hoping to make the prediction results more accurate.

2.2.2. Reinforcement Learning Algorithm Integrating Seq2seq.

The earnings forecast model to be established in this study is based on a long time series. During this process, the relevant data are constantly changing, and according to the Introduction section, we know that there is also a correlation between the accounting earnings data of the same year, that is, the model we need is not a mapping of inputs to outputs, but a pattern between earnings-related information. However, pure LSTM not only has independent and identically distributed input but also cannot learn this ‘‘pattern.’’ We have constructed the relationship dependence between surplus factors through the seq2seq structure, so we continue to use reinforcement learning to make seq2seq balance; then, after exploration and development, choose the most rewarding and most effective behavioral mode.

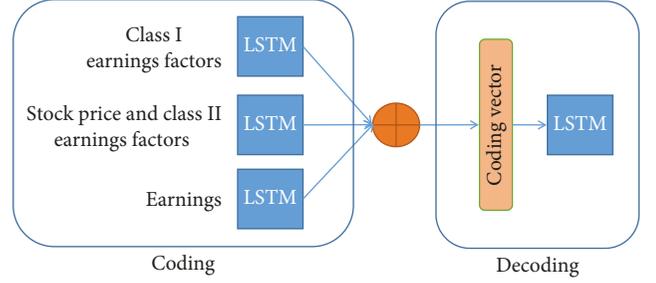

FIGURE 3: Input and relationship composition of the earnings factor in seq2seq.

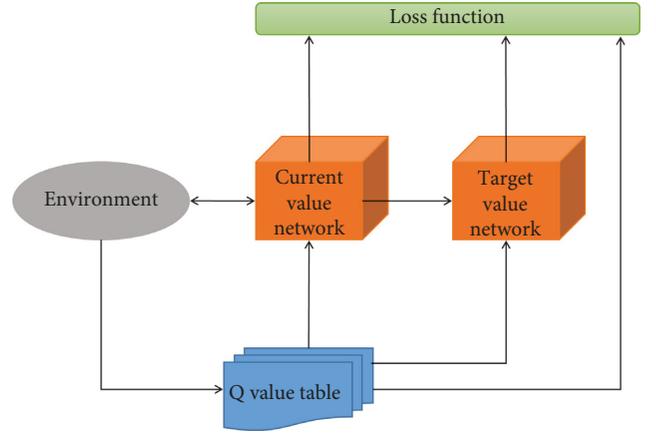

FIGURE 4: Reinforcement learning algorithm structure in the overall model.

Because the final model is a value prediction model, we need to choose a type of reinforcement learning algorithm suitable for value analysis. We mentioned in Section 1 that the most typical reinforcement learning algorithm for value prediction is Q-learning. Therefore, we integrate the algorithm idea of Q-learning with the seq2seq model constructed in Section 2.2.1 to form the overall reinforcement learning algorithm model shown in Figure 4.

In this process, our purpose is to maximize the expectation of reward through the interaction between the agent and the environment and action. We use (11) to solve the reinforcement learning that integrates seq2seq, which is the same as Q-learning; Q_π represents the utility function under policy.

$$\max_{E_{\hat{y}_1, \dots, \hat{y}_T \sim \pi_\theta(\hat{y}_1, \dots, \hat{y}_T)}} [r(\hat{y}_1, \dots, \hat{y}_T)], \quad (11)$$

$$L_\theta = -E_{\hat{y}_1, \dots, \hat{y}_T \sim \pi_\theta(\hat{y}_1, \dots, \hat{y}_T)} [r(\hat{y}_1, \dots, \hat{y}_T)]. \quad (12)$$

At this time, the loss function can be calculated by (12); then by (13), we can obtain the value of the corresponding maximum partial derivative, we make the output of the decoder part before SoftMax is O_t , and then the partial derivative can be rewritten as (14) and solved by (15). R_b is a baseline reward value that does not depend on the seq2seq part.

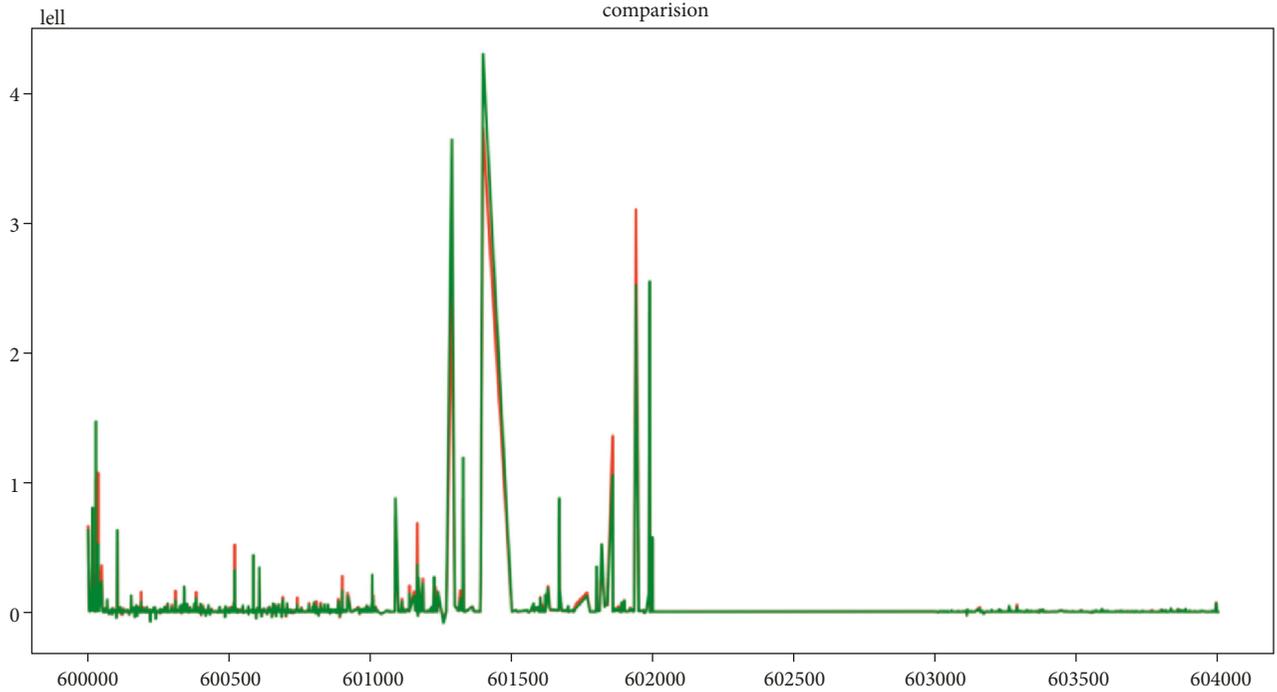

FIGURE 5: Earnings forecast value by the designed model for Shanghai A shares (green) and its actual value (red).

$$\nabla_{\theta} L_{\theta} = -E_{\hat{y}_{1,\dots,T} \sim \pi_{\theta}} \nabla_{\theta} \log \pi_{\theta}(\hat{y}_{1,\dots,T}) r(y_{1,\dots,T}), \quad (13)$$

$$\begin{aligned} \nabla_{\theta} L_{\theta} &= \frac{\partial L_{\theta}}{\partial \theta} \\ &= \sum_t \frac{\partial L_{\theta}}{\partial \theta_t} \cdot \frac{\partial \theta_t}{\partial \theta}, \end{aligned} \quad (14)$$

$$\frac{\partial L_{\theta}}{\partial \theta_t} = (\pi_{\theta}(y_t | \hat{y}_{t-1}, s_t, c_{t-1}) - y_t) (r(\hat{y}_1, \dots, \hat{y}_T) - r_b). \quad (15)$$

3. Model Implementation and Experimental Analysis

Due to the large number of companies involved in the forecast results and the vast difference between the forecast results, in Figure 5, the horizontal axis is the company code, the vertical axis is the unit length, and the green polyline represents the 2018 earnings of Shanghai A shares predicted by the enhanced recurrent neural network earnings forecast model. The red polyline is the actual earnings of these companies in 2018. Figure 5 includes 1512 forecast values, and the vertical axis value of other nonexistent company codes is 0. It is impossible to judge the quality of the specific forecast situation only by the particular forecast value. Therefore, according to the calculation method in Section 2, we calculate the metric value of the forecasted earnings in 2018 by the designed model.

Table 1 also shows the same index values calculated from the prediction results of the basic LSTM model on the same data set (because no accounting analysis is involved here, the

TABLE 1: Forecasting result comparison of the designed model and LSTM.

Indicator	The designed model	LSTM
AE (unit: CNY)	31393488.66	974744257.7
AAE (unit: CNY)	655956316.2	1141490405.0
DE	12.48%	22.05%
ADE	20.77%	25.13%
DS	16.182%	6.182%

R2, ERC, and ICC indicators of the designed model are not compared with LSTM). Due to the large amount of data involved in the experiment and carried out on a personal host, the running time of LSTM and the designed model is more than one day, but considering that the accounting earnings forecast itself is in units of years, the time required for the experiment has little impact, far less than the accuracy and other evaluation criteria, so the evaluation of the results by the time of the experiment is not considered here.

From Table 1, only through the comparison of AE, can we find that the designed model significantly improves prediction accuracy compared to the LSTM base model. At the same time, it is not difficult to find that the results predicted by the designed model are still optimistic in general (i.e., the overall forecast of earnings will be larger than the actual value). Compared with the LSTM model, the difference between AE and AAE is more significant. To a certain extent, it reflects that the designed model has a higher sensitivity when the company generates negative earnings. But at the same time, the stability (DS) of the model is not as good as that of the LSTM model, but the DS value of the designed model is still within an acceptable range.

TABLE 2: Forecasting result comparison of HVZ and the designed model.

Indicator	HVZ	The designed model
DE	27.76%	12.48%
R^2	0.988	0.969
ERC	0.031	0.044
ICC	0.081	0.048

At the same time, we compare the DE values of the prediction results of the designed model and LSTM, and it is easy to find that the designed model fits the curve of the actual value more than LSTM. The comparison between DE and ADE further shows that the overall prediction trend of the LSTM model is far more optimistic than the designed model. It also makes the accuracy of the designed model higher than that of LSTM in the case of a downward trend in earnings.

In addition to comparing the prediction accuracy with the LSTM model, this experiment further compared with the HVZ model [27] and further analyzed the prediction results of the designed model in the accounting sense. The HVZ model needs long-term data to be computationally meaningful. In the data collected in this experiment, the amount of data that meets the requirements of the HVZ model is insufficient. Therefore, we use the empirical data of Li and Mohanram [28] to compare with the designed model (Table 2), and we mainly compare the accuracy of the forecast results and whether they have accounting significance.

From Table 2, we can find that the prediction result of the designed model is more accurate than that of HVZ. When using data with a period of up to 40 years, the DS value of the prediction result of the HVZ model can even be reduced to less than 10%. But overall, the designed model is more accurate than HVZ in more general cases. The fit of the HVZ model is slightly better than the designed model, but considering the limited regression parameters used by the HVZ model, this does not mean that the designed model has a worse fit. In addition, the ERC value of the designed model is slightly higher than that of HVZ. The designed model is relatively more representative of market expectations, which may be because the designed model uses the basic structure of LSTM to transmit the time relationship in the accounting earnings correlation system or because the input data includes the impact of the announcement on the market. However, the ICC value of HVZ is higher than that of the designed model, indicating that the HVZ model has a higher correlation with actual returns. It also shows that there is room for further optimization of the input data of the designed model, which needs to be further adjusted according to accounting factors.

4. Conclusions

An accounting earnings forecasting model is designed based on artificial intelligence. From the perspective of financial accounting, more accurate judgment of the designed model on the company's profit trend itself is helpful for investment analysis and company decision-making. At the same time, it

is difficult for traditional models to judge the sudden negative turn of company profits under volatile market conditions. The designed model can find out whether the company has profitability faster than the general model. It is easy to find out through the two common indicators of ICC and ERC. The designed model has a more sensitive response to the market and is more consistent with the company's actual income. The forecast results are more conducive to analyzing the company's problems in the face of adversity and can even further infer industry risks.

In general, the designed model has higher accuracy in a broader sense when forecasting earnings. It relaxes the data requirements for forecasting and the high standards for the company's accounting years. On this premise, it can further improve the accuracy of earnings forecasts and maintain high stability. This also shows that different companies have similar accounting earnings correlation systems, and this accounting earnings correlation system can be used to build earnings forecast models for various companies. At the same time, the earnings predicted by the designed model have accounting significance, and the forecast results can reflect the market's expectations and reflect the correlation between the forecast results and actual earnings. The experimental results also show that the selection of accounting earnings-related factors has a particular impact on the results of earnings forecasting.

This paper uses the data of Chinese A-share listed companies from 2003 to 2019 to study the impact of venture capital holdings on the dividend policy of listed companies. The research findings show that venture capital holdings increase the willingness to pay cash dividends and the payment level. This conclusion still stands after using the PSM matching method and other robustness methods, indicating that there is causality between venture capital holdings and the dividend policy of listed companies. Further research finds that the course of action for venture capital holdings to increase the willingness of listed companies to pay cash dividends and their dividend payment level is to increase the dividend payout ratio by alleviating the company's agency level. Further research finds that different types of venture capital will also have an impact on the dividend policy. Foreign investment venture capital organizations are more favorable for increasing the willingness of listed companies to pay cash dividends and their dividend payment level. In addition, the impact of venture capital holdings on the dividend policy is more obvious in the central and western regions where economic development is relatively backward and is less obvious in the eastern regions. Based on J2EE, a venture capital information management platform is designed and developed. The research of this paper shows that venture capital shareholding plays an important role in promoting dividend payment of listed companies, and has enriched the research results of the value-added role of venture capital. At the same time, from the perspective of dividend policy, it has brought to light the corporate governance effectiveness of venture capital and has provided certain theoretical evidence for the assertion that capital can better serve the real economy.

1. Introduction

The cash dividend policy is an important way for investors to share the business gain of an enterprise, an important means to protect the interests of investors, and an important tool to maintain the stability of the capital market [1]. In China, due to the short development cycle of the capital market, it takes time to uncover many development problems, and there is a large time lag in the follow-up of the regulatory system. Therefore, most listed companies do not pay cash dividends, and this has

become a “unique landscape” that accompanies the development of the Chinese capital market. The study of Lu and Wang [2] pointed out that the proportion of listed companies that did not distribute dividends in 1994 was about 9.28%, while the proportion of companies that did not distribute dividends rose sharply to 58.44% in 1998. Concomitantly, there is the problem of abuse resulting in a large amount of idle funds and free cash flow. In order to protect the interests of small and medium investors, restrain the excessive investment of listed companies, and promote the healthy development of the capital market,

the China Securities Regulatory Commission has continuously issued relevant policies since 2001 to encourage listed companies to distribute cash dividends. In 2004, a relevant policy was issued, stating that listed companies that have not distributed profits in the past three years are not allowed to issue shares publicly. In 2006, relevant policies were issued, requiring that the accumulated profits distributed by listed companies in cash in the past three years should not be lower than 20% of the average annual distributable profits achieved in the past three years. Additional revisions were made in 2008 to increase the profit distribution ratio to 30%. In 2012, the regulatory authorities further improved the regulations on dividend distribution, with a view to increasing return of investment for investors and thus promoting the healthy and sustainable development of the capital market. With the continuous improvement of policy perfection, China has gradually formed a special phenomenon of the “semimandatory” dividend policy, and the corresponding research is also plentiful. However, according to current documentary research findings, the implementation effect of the semimandatory dividend policy is not ideal, which also indirectly confirms the complexity of the “dividend policy problem”. The semimandatory dividend policy may affect the financial flexibility of growing companies, which is not conducive to their investment and development [3, 4], but it is still difficult to form strong policy constraints against the “Iron Roosters” listed companies that do not pay cash dividends [5, 6].

According to Jensen’s research [7], venture capital is a kind of special shareholder, that is, an “active investor”. One of the characteristics of venture capital that distinguishes it from other equity investments is that it will actively participate in the governance activities of investee companies, optimize the corporate governance structure, and ultimately achieve the goal of maximizing the value of its own investment. For the purpose of maximizing investment returns, will the venture capital holdings collude with major shareholders to “hollow out” the listed company, or will they constrain major shareholders, actively promote the distribution of cash dividends, protect the interests of small and medium shareholders, and alleviate the type II agency problem? If venture capital holdings can help alleviate the type II agency problem, then what mechanism will venture capital use to influence the dividend policy of listed companies?

In order to explain the above problems, this paper uses the data of all A-share listed companies in China from 2003 to 2019 to study whether venture capital holdings can help increase listed companies’ willingness to pay cash dividends and their level of dividend payment. The research results show that, compared with companies without venture capital holdings, companies with venture capital holdings have a stronger willingness to pay dividends and a higher level of dividend payment. Its impact mechanism is to promote the distribution of cash dividends by alleviating the agency problem of listed companies. In addition, the different characteristics of venture capital and the difference in

the level of economic development between different regions will have an impact on the cash dividend policy of investee companies.

The possible marginal contributions of this paper are as follows: Firstly, it enriches the relevant literature on the value-added role of venture capital. Previous studies have mostly focused on the impact of venture capital promotion on the listing of investee companies, promoting the specialization of investee companies, and affecting the investment and financing behavior of investee companies. However, there are few studies on the dividend policy of listed companies. Secondly, it expands research in the fields related to dividend policy. Previous studies on the influencing factors of cash dividends have focused on the impact of corporate profitability, company size, company growth ability, and ownership structure at the microlevel. However, there is less literature involved in research on the special shareholders of venture capital, and the research in this paper makes up for this gap.

The structural arrangement of the rest of this article is as follows: the second part is hypothesis; the third part is research design; the fourth part is empirical results; the fifth part is robustness and endogeneity checks; the sixth part is further research; the seventh part is design and implementation of venture capital information management platform based on J2EE, and the last part is the conclusion and implications.

2. Theoretical Analysis and Research Hypothesis

Will the participation of venture capital in the corporate governance of investee companies as an “active investor” help promote the distribution of cash dividends of listed companies?

First, from the perspective of the motivation of venture capital to actively participate in the governance of investee companies and influence the dividend policy of listed companies, there are two motives that affect the behavior of venture capital: on the one hand, the essence of venture capital is “financial investors”, and its ultimate goal is to obtain investment income [8]. Venture capital can obtain cash dividends and increase return on investment by actively encouraging investee companies to issue cash dividends. On the other hand, the operation mechanism of venture capital determines the fact that it will not hold the shares of listed companies for a long time, but will obtain capital gains and return on investment by successively reducing the shares of listed companies [9]. The impact of venture capital on dividend policy can play a role in providing the market with internal information of the company. According to the dividend signaling theory (signaling hypothesis), investors can know the company’s current operating conditions and future earnings expectations from its dividend announcements, so they can make corresponding investment choices and ultimately affect the stock price. If a listed company pays high level of cash

dividends, investors may think that the company has positive expectations for future earnings, and may be optimistic about the company's future development prospects, thereby driving up the stock price. If the listed company does not distribute cash dividends, investors may think that the earning capacity of the company is poor, and are affected in their judgment of the company's future value, which in turn leads to a drop in the stock price. Therefore, changes in dividend policy will cause stock price volatility [10, 11]. Research on China's capital market has also confirmed the signaling effect of dividend policy. For example, Chen et al. [12] confirmed that the first dividend distribution has a signaling effect, and Yu and Cheng [13] confirmed that dividend announcements also have signal transmission. Therefore, by influencing the cash dividend policy of investee companies, venture capital releases positive signals to the market about the company's future profit prospects, which helps to stabilize and even increase the stock price of listed companies, thereby increasing the capital gains of venture capital.

Second, from the perspective of the way that venture capital actively participates in the governance of investee companies and affects the dividend policy of listed companies, it is understandable how venture capital affects the cash dividend policy of listed companies. On the one hand, a large number of previous literature have confirmed that venture capital can provide all kinds of resources needed for the development of investee companies [14–18]. Dividend distribution will affect the investment and financing decisions of listed companies [19]. The implementation of the cash dividend policy requires listed companies to balance the relationship between profit distribution and subsequent retention of sufficient funds to meet subsequent development needs. Research on cash dividends has found that the cash dividend policy may reduce financial flexibility and increase the difficulty of financing growing companies [20]. In response to this problem, venture capital can help listed companies solve financing problems through their accumulated network resources and bring convenience to external debt and equity financing [21, 22]. The Gorman and Sahlman [23] survey found that 75% of US venture capital organizations not only provide funds directly to companies, but also actively help companies obtain equity or bond financing from other channels. Therefore, venture capital can effectively alleviate the financing pressure of listed companies for redevelopment after cash dividends are issued. On the other hand, previous studies have also fully certified the supervisory function of venture capital [24–27]. Venture capital can effectively restrain major shareholders from transferring residual income, abusing free cash flow to blindly expand investment, and establishing corporate empires that are detrimental to the interests of small and medium shareholders by playing an active supervisory role [28]. By promoting the distribution of cash dividends, the purpose of returning income to investors and protecting the interests of small and medium shareholders is realized.

Based on the above discussion, venture capital has sufficient motivation to actively participate in the supervision of the promotion of the cash dividend policy of listed companies. There are also ways to alleviate the possible negative effects of cash dividends, promote the governance role of cash dividends, and protect the interests of small and medium shareholders. In view of the above, this paper proposes the following hypotheses to be tested:

H1a: Companies that have acquired venture capital holdings are more likely to distribute cash dividends than companies that have not received venture capital holdings;

H1b: Companies that have acquired venture capital holdings have a higher cash dividend payout ratio than companies that have not received venture capital holdings.

3. Research Design

3.1. Sample Data. In this paper, all A-share listed companies from 2003 to 2019 are used as initial samples, and initial samples are screened and cleaned up according to the following criteria: (1) delete the samples of listed companies in the financial industry; (2) delete the samples of ST and *ST companies; (3) delete variable samples with missing values; and (4) in order to exclude the influence of extreme values, all continuous variables are winsorized.

3.2. Variable Setting

3.2.1. Dependent Variable. Willingness to pay dividend ($Div_{i,t}$): First, this paper uses $Div_{i,t}$ to measure the company's cash dividend distribution propensity. $Div_{i,t}$ is a dummy variable. For company i , when distributing cash dividends in year t , $Div_{i,t}$ takes 1; otherwise, it takes 0.

Dividend payment level ($Pay_{i,t}$): Second, this paper uses $Pay_{i,t}$ to measure the company's cash dividend payment level, $Pay_{i,t}$ is equal to listed company i , and the cash dividend paid in year t is divided by the company's net profit in that year.

3.2.2. Independent Variables. Venture capital ($VC_{i,t}$) is the main research object of this paper, and thus, this paper takes the existence of venture capital organizations among the top ten shareholders of listed companies as the main explanatory variable. $VC_{i,t}$ is a dummy variable. When there are venture capital organizations holding shares among the top ten shareholders of the listed company, the value of $VC_{i,t}$ is 1; otherwise, it is 0. First, venture capital organizations are identified according to the classification of shareholders of listed companies in the China Stock Market and Accounting Research (CSMAR) Database. Second, using the Stata software, the names of venture capital organizations are matched with the characteristics information of venture capital organizations obtained from the CVSource database. Finally, drawing on the practice of predecessors (Wu et al., 2012; Wang et al., 2014) [29, 30], the results of matching the

names of shareholders of listed companies and the full names of venture capital organizations are manually confirmed again.

3.2.3. Control Variables. In order to control the influence of other factors, this paper refers to previous studies and sets the following control variables: performance variable (*Roe*), which represents the company's earning capacity; company size (*LnSize*), which is the natural logarithm of the company's total assets at the end of the period; growth level (*Growth*), which is the year-on-year growth rate of the operating income at the end of the period; debt-to-asset ratio (*Lev*) which is total liabilities at the end of the period divided by total assets at the end of the period; cash flow (*Cash*), which is the net cash flow generated by operating activities per share; the ratio of independent directors (*Ind*), which is the ratio of the number of independent directors to the total number of the board of directors; the size of the board of directors (*BoardSize*), which is the total number of the board of directors; the shareholding ratio of the largest shareholder (*Top1*), which is the shareholding concentration of the largest shareholder; CEO duality (*Dual*), if the chairman is concurrently the general manager, take 1, otherwise take 0; property rights (*Soe*), when the listed company is a state-owned holding company, take 1, otherwise take 0; finally, dummy variables such as industry and year are controlled. The variable definition is shown in Table 1.

3.3. Empirical Models. First, in order to test the impact of venture capital stockholding on the company's willingness to pay cash dividends, this paper draws on the practices of Wang et al. (2007) [31] and Wang et al. (2014) [30] to construct the following Logit model.

$$\text{Div}_{i,t} = \beta_0 + \beta_1 \times VC_{i,t} + \beta_2 \times \text{Controls}_{i,t} + \text{Industry}_{FE} + \text{Year}_{FE} + \varepsilon_{i,t}. \quad (1)$$

In formula (1), the dependent variable is company's willingness to pay cash dividends $\text{Div}_{i,t}$ in the basic test, this paper uses pretax cash dividends per share to represent it; $\text{Div}_{i,t}$ is dummy variable, if the listed company i distributes cash dividends in year t , that is, the pretax cash dividend per share is not 0, then $\text{Div}_{i,t} = 1$; otherwise, it is 0. The independent variable is, whether there are venture capital organizations among the top ten shareholders of the listed company ($VC_{i,t}$). If the listed company i has venture capital organizations among the top ten shareholders in year t , then $VC_{i,t}$ takes the value 1; otherwise, it is 0. $\text{Controls}_{i,t}$ is a series of control variables. In addition, the industry and year fixed effects are controlled, and $\varepsilon_{i,t}$ is the residual term.

Second, in order to test the impact of venture capital holdings on the company's cash dividend payment level, this paper draws on the practices of Wang et al. [30] and Wu et al. [22] to construct the following OLS model.

$$\text{Pay}_{i,t} = \beta_0 + \beta_1 \times VC_{i,t} + \beta_2 \times \text{Controls}_{i,t} + \text{Industry}_{FE} + \text{Year}_{FE} + \varepsilon_{i,t}. \quad (2)$$

In formula (2), the dependent variable is the company's cash dividend payment level $\text{Pay}_{i,t}$; in the basic test, it is represented by the dividend distribution rate in this paper. $\text{Pay}_{i,t}$ is the listed company i , the cash dividends distributed in the t -th year are divided by the net profit of the company i in the current year. The independent variable is whether there are venture capital organizations among the top ten shareholders of the listed company ($VC_{i,t}$), if there are venture capital organizations among the top ten shareholders of listed company i in year t , then ($VC_{i,t}$) takes the value 1; otherwise, it is 0. $\text{Controls}_{i,t}$ is a series of control variables. In addition, the industry and year fixed effects are controlled, and $\varepsilon_{i,t}$ is the residual term.

4. Empirical Results

4.1. Descriptive Statistics. Descriptive statistics results are shown in Table 2. In terms of dependent variables, during the sample statistics period, the average dividend payment willingness of listed companies ($\text{Div}_{i,t}$) is 0.735, indicating that 73.5% of companies distributed cash dividends; the dividend payment level of listed companies, the mean value of the dividend distribution rate ($\text{Pay}_{i,t}$) is 0.08, and the standard deviation is 0.131. In terms of independent variables, the mean value of venture capital holdings ($VC_{i,t}$) is 0.182 and the standard deviation is 0.386, which indicates that companies that have obtained venture capital during the sample period accounted for about 18.2% of the total sample.

4.2. Basic Test. Table 3 is one of the basic empirical test results of this paper. The influence of venture capital holdings ($VC_{i,t}$) on the willingness of listed companies to pay dividends is shown in the table. Among them, the empirical results in column (3) show that having controlled a series of factors of the possibility of venture capital holdings influencing the propensity of listed companies to pay dividends, as well as the fixed effects of industry and year, venture capital holdings ($VC_{i,t}$) is significantly positive at the 5% significance level with a net effect value of 0.087, assuming that H1a is confirmed, that is, companies that have acquired venture capital holdings have more propensity to pay cash dividends than companies that have not acquired venture capital holdings.

Table 4 is one of the basic empirical test results of this paper. The impact of venture capital holdings ($VC_{i,t}$) on the dividend payment level ($\text{Pay}_{i,t}$) of listed companies is shown in the table. The empirical results in column (3) show that the estimated coefficient of venture capital holdings ($VC_{i,t}$) is significantly positive at the 1% significance level with a net effect of 0.006, assuming that H1b is confirmed, that is, companies that have acquired venture capital holdings have a higher cash dividend

TABLE 1: Variable definition.

Variable name	Variable symbol	Variable description
<i>Main variable</i>		
Willingness to pay dividends	$Div_{i,t}$	Indicates whether the listed company i will issue a cash dividend in the t year. If the pretax cash dividend per share is $\neq 0$, then $Div_{i,t} = 1$; otherwise, it is 0
Dividend payout level	$Pay_{i,t}$	Represents the dividend payment level of the listed company i in year t , which is equal to the cash dividend issued by listed company i in year t divided by the net profit of the year
Venture capital	$VC_{i,t}$	Dummy variable, if the company has VC holdings in the current year, the value is 1; otherwise, it is 0
<i>Control variable</i>		
Enterprise size	$LnSize$	Natural logarithm of total assets at the end of the current period
Growth	$Growth$	The growth rate of operating income at the end of the current period relative to the operating income at the end of the previous period
Cash holdings	$Cash$	Net cash flow from operating activities per share
Assets-liabilities ratio	Lev	Debt to asset ratio at the end of the period
Performance variable	Roe	Return on net assets
Proportion of independent directors	Ind	Proportion of independent directors = number of independent directors/size of the board of directors
Board size	$Boardsize$	Number of board of directors at the end of the year
Two jobs in one	$Dual$	When the two positions of the chairman and general manager are combined as one, take 1, otherwise take 0
The largest shareholder	$Top1$	The shareholding of the largest shareholder as a percentage of the total share capital
Nature of property rights	Soe	The nature of the property rights of the listed company, if the company is a state-owned enterprise, take 1, otherwise take 0
Industry dummy variable	$Industry$	According to the 2012 version of the industry classification standard of the China Securities Regulatory Commission
Year dummy variable	$Year$	The standard deviation of the stock's daily return for the year

payout ratio than companies that have not acquired venture capital holdings.

4.3. Mechanism Test: Alleviating the Agency Problem. As one of the top ten shareholders of listed companies, venture capital holds shares of listed companies, and one of the ways to encourage listed companies to increase their willingness to pay dividends and the level of dividend payment is to play an active role in supervision and governance, and to promote active dividend distribution of listed companies, thereby alleviating and restraining tunneling of major shareholders and other problems that

damage the interests of small and medium shareholders, that is, by alleviating the agency problem between large shareholders and small and medium shareholders, improving corporate governance, thereby improving the dividend payment willingness and the dividend payment level of listed companies. Specifically, as an active investor, venture capital has motivation and the ability to actively alleviate the agency problem of listed companies. First, the motivation aspect. The operation mode of venture capital institution determines its need to maintain good social reputation. Reputational capital is a manifestation of the fund management level of venture capital organizations, and it is one of the important guarantees for venture capital

organizations to continue financing new funds and participate in investment activities of high-quality investee companies [32–34]. Therefore, by alleviating the agency problem of listed companies, venture capital increases the willingness of listed companies to pay dividends and their level of dividend payment, effectively protects the interests of small and medium shareholders and improves the company's governance level, which is conducive to the accumulation of its own reputational capital. Second, in terms of ability. The rich post-investment management experience of venture capital organizations has been confirmed by a large number of studies [22, 24, 25, 27, 29, 35–38]. Venture capital can effectively alleviate the conflicts of interest between large shareholders and small and medium shareholders by providing consultation for listed companies, thereby promoting the improvement of their own governance level, and dividend payment willingness and level.

In view of the above, the following inferences are made as follows.

Inference 4–1: The effect of venture capital holdings on the company's dividend policy is more pronounced in companies with more serious agency problem.

In reference to the research of Wang and Guo (2021) [39], dividend information is a part of the company's information disclosure, and the company's overall information disclosure level is an important response to agency problem. Therefore, drawing on the research of Dechow et al. [40] and Kothari et al. [41], the absolute value of the controllable accrued profit is selected as the proxy variable (*DA*) of the company's information disclosure level. This section groups the samples according to the median of the information disclosure level, and divides the samples into two groups: companies with higher information disclosure quality ($DA \leq MidDA$) and companies with lower information disclosure quality ($DA > MidDA$).

Table 5 reports one of the test results of inference 1, namely, the effect of the quality of corporate information disclosure on the willingness to pay dividends. Among them, column (1) is the group with better information disclosure quality, and column (2) is the group with poor information disclosure quality. As can be seen from Table 5, in the group with better information disclosure quality, although the coefficient of venture capital is

positive, it is not significant. However, in the group with poor information disclosure quality, the coefficient of venture capital is significantly positive. The above regression results show that in the sample of companies with poor information disclosure quality, the role of venture capital in alleviating the agency problem is more obvious, which proves that venture capital can promote the inference of listed companies' willingness to pay dividends by alleviating the agency problem.

Table 6 reports one of the test results of inference 1, that is, the impact of the quality of corporate information disclosure on the level of dividend payments. As can be seen from Table 6, in the group with better information disclosure quality, although the coefficient of venture capital is positive, it is not significant. But in the group with poor information disclosure quality, the coefficient of venture capital is significantly positive. The above results show that in the companies with poor information disclosure quality, the role of venture capital in alleviating the agency problem is more obvious, which proves the inference that venture capital encourages listed companies to improve the level of dividend payment by alleviating the agency problem. The above results show that inference 1 in this section is confirmed.

5. Endogeneity and Robustness Checks

5.1. Endogenous Processing. The basic test above proves the influence of venture capital on the dividend policy of listed companies, but the above results are likely to be affected by selection bias, that is, because of the "selection effect" of venture capital on the investee company, there may be existing differences between the treatment group and the control group, which leads to the difference between the dividend policies of the treatment group and the control group. In order to alleviate the endogeneity issue caused by sample selection bias, this paper uses the propensity score matching method (PSM) to select a group of new control groups with the most similar characteristics for companies that have acquired venture capital holdings, thereby reducing the systematic differences between firms with venture capital holdings and firms without venture capital holdings. The specific matching method is as follows: Taking 2003–2019 as the sample period, the control group is companies that are not selected by venture capital during the sample period, and the variables that affect the choice of

TABLE 7: PSM matching balance effect.

Variable	Unmatched matched	Mean		% bias	% reduct bias	t -test t	$p > t $

venture capital holdings are sorted out, including specifically, performance variables, company debt ratio, cash holdings, the ratio of CEO duality, the size of the board of directors, the shareholding ratio of the largest shareholder, the nature of corporate property rights, and the size of the company, and use them as covariates to perform logit regression, to obtain propensity matching scores, and to find a suitable control group for the experimental group according to the nearest neighbor 1 : 1 matching method, among them, the caliper radius is selected as 0.01.

The balance test results in Table 7 can reflect the matching effect of PSM. From the t -test, except ROE, other covariates show significant differences before matching, but after PSM, the differences between covariates disappear, illustrating the fact that PSM reduces the systematic difference between the experimental group and the control group, and the effect of PSM is better than that of the control group. In addition, from the perspective of deviation percentage, the standardized differences of covariates are all below 10%. Compared with what is before matching, the standardized deviations of most variables are greatly reduced. Based on the above analysis, PSM satisfies the equilibrium assumption better.

The regression results based on the samples after the propensity score matching method are shown in Table 8. It can be seen from Table 8 that after using propensity score matching, the influence coefficient of venture capital holdings on the dividend payment willingness and the dividend payment level of listed companies is still significantly positive. It shows that after controlling possible endogeneity problem, the results are still robust.

5.2. Robustness Check

5.2.1. Replacing Dependent Variables and Models. In order to enhance the robustness of the basic test results, in reference to the methods of Wu et al. [29] and Wang et al. [30], this section firstly uses the method of replacing

variables and corresponding models to check the robustness of the basic test results. Specifically, this subsection replaces the measurement method of the dependent variable and selects the dividend per share (DPS) instead of the dividend payout ratio. The formula is as follows: dividends per share = dividend distribution rate * earnings per share, and the Tobit model is used accordingly to recheck the null hypothesis. The results are shown in Table 9. Column (3) of Table 9 shows that after changing the dependent variable measurement method and using the corresponding model, the coefficient of venture capital ($VC_{i,t}$) is still significantly positive at the 1% significance level, and the net effect is 0.005. That is to say, venture capital holdings can effectively increase the dividend payment level of listed companies.

5.2.2. Substitution of Independent Variable. In reference to the research of Wang et al. [30], this section uses the method of replacing independent variables to test the robustness of basic test results. Specifically, it is to use venture capital holdings ($VCholding$) to replace the original independent variable if there is existing venture capital ($VC_{i,t}$) among the top ten shareholders and repeat regression. The results are shown in Tables 10 and 11.

It can be seen from column (3) of Table 10 that after replacing the independent variable, the regression coefficient of venture capital holdings ($VCholding$) on the willingness of listed companies to pay cash dividends ($Div_{i,t}$) is significantly positive at the 1% significance level with a net effect of 0.007. That is to say, the larger the venture capital's holdings, the more favorable it is to increase the willingness of listed companies to pay dividends.

It can be seen from column (3) of Table 11 that after replacing the independent variable, the regression coefficient of venture capital holdings ($VCholding$) on the level of cash dividend payment ($Pay_{i,t}$) of listed companies is significantly positive at the 1% significance level, with a net effect of 0.001. That is to say, the greater the amount of venture capital

holdings, the more conducive it is for increasing the payment level of cash dividends of listed companies.

In conclusion, whether it is concerning the willingness to pay cash dividends or the level of cash dividend payment, the null hypothesis still stands after the independent variable is replaced, and the conclusion remains robust.

6. Further Research

6.1. Venture Capital Experience. The value-added services and supervision responsibilities of venture capital organizations to investee companies will be affected by the different characteristics of venture capital. In their research, Zhang and Liao [42] divided the background of Chinese venture capital organizations into four categories, namely, state-owned, private, foreign investment, and mixed backgrounds. Venture capital organizations of different backgrounds have different operating mechanisms, different scope and capabilities of resource acquisition, and large differences in the demand for return on investment. Therefore, the shareholding of venture capital organizations of different backgrounds will have significantly different impacts on the

business decisions of investee companies. From the perspective of operation mechanism, as the development of China's venture capital market is far behind in comparison with the international venture capital market, foreign venture capital organizations have rich international investment experience superior to other types of venture capital organizations [43]. Therefore, in each stage of venture capital, including the selection of investment projects, the cultivation, and supervision of investment projects, a relatively standardized and mature mechanism has been formed. However, China's local venture capital organizations have a short development cycle and limited market experience. In particular, venture capital organizations with a state-owned background have special strategic objectives, and their operating mechanisms cannot be completely market-oriented [44, 45], as previous studies have also proved this. For example, Yu et al. [46] shows that, compared with venture capital organizations of other backgrounds, venture capital with a state-owned background does not significantly promote corporate innovation. From the perspective of resource acquisition, because the foreign venture capital industry started earlier and developed more maturely, the accumulation of resources is more abundant, including good

cooperation with investment banks, underwriters, law firms, and accounting firms, as well as political resources, such as government agencies, etc. These relationship networks can provide important support in the process of corporate governance. Organizations of other backgrounds, on the one hand, have a slight disadvantage in terms of resource advantages compared with foreign venture capital, and on the other hand, their investment demands may be quite different from foreign venture capital; especially for state-owned venture capital organizations, their investment demands are not limited to capital returns, and even to a certain extent, capital return demands give way to strategic demands, for example, in recent years, China has successively established two phases of the State-owned Enterprise Structural Adjustment Fund, and in September 2021, the National Energy Group Green and Low-Carbon Development Investment Fund was established. This type of venture capital often undertakes the important political mission of promoting the realization of important national strategic goals and promoting industrial and regional economic development [47, 48]. Based on the above analysis, in this section, venture capital organizations are divided into foreign investment capital and nonforeign investment capital according to the capital background of venture capital, and it is expected that listed companies held by foreign investment capital will have

Note. The marking criteria for statistical significance in this table are as follows: * is $p < 0.10$, ** is $p < 0.05$, and *** is $p < 0.01$; all regression coefficient estimates are based on robustness adjusted for corporate clustering standard error.

a stronger willingness to pay cash dividends. The results are shown in Table 12.

The results in Table 12 show the effect of venture capital holdings on the willingness of listed companies to pay dividends. The results in column (2) show that the coefficient of the foreign investment group is significantly positive at the 10% significance level, while the nonforeign investment group is not significant. Therefore, the inference of this subsection is confirmed. The venture capital with foreign investment background, using its own experience, has played an active supervisory role, effectively restrained the agency behavior of listed companies, and increased the willingness of listed companies to pay dividends.

6.2. Regional Development Level. As China is a large country with a vast territory, there are large cultural gaps between regions, and the level of economic development is very unbalanced [49, 50]. In terms of the degree of market-oriented development, the market-oriented development degree of the eastern coastal provinces has matured progressively, while the nonmarket-oriented factors in the economic development of the central and western regions

still occupy relatively important regions. The imbalance of regional development affects the supervision and governance of venture capital in at least two aspects. First, the degree of legal perfection. Regions with developed markets tend to have better legal facilities, more robust investor protection mechanisms, and more standardized corporate governance-related policies. In the event there are behaviors that harm the interests of investors, investors can hold the company accountable in a more timely manner, and at the same time, when the regulator is unable, they can still more efficiently punish behaviors that harm the interests of investors [51]. Second, information transparency. The eastern coastal area was the first to complete the reform and opening up, and in the development of the market economy, the development of various standardized facilities is relatively complete. In the central and western regions, where economic development is relatively backward, the corporate governance mechanism, supervision mechanism, and information disclosure mechanism may be more backward than those in the eastern region, information transparency is low, and there are more nonmarket factors interfering with the company's operations and decision-making. In conclusion, in regions with a low level of economic

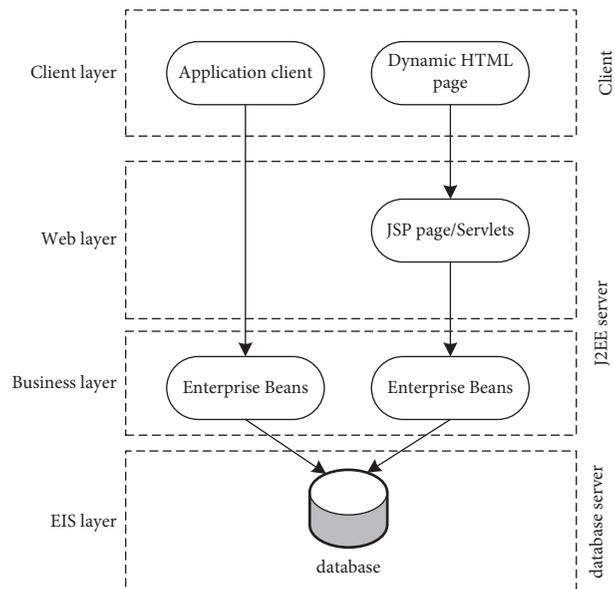

FIGURE 1: J2EE architecture.

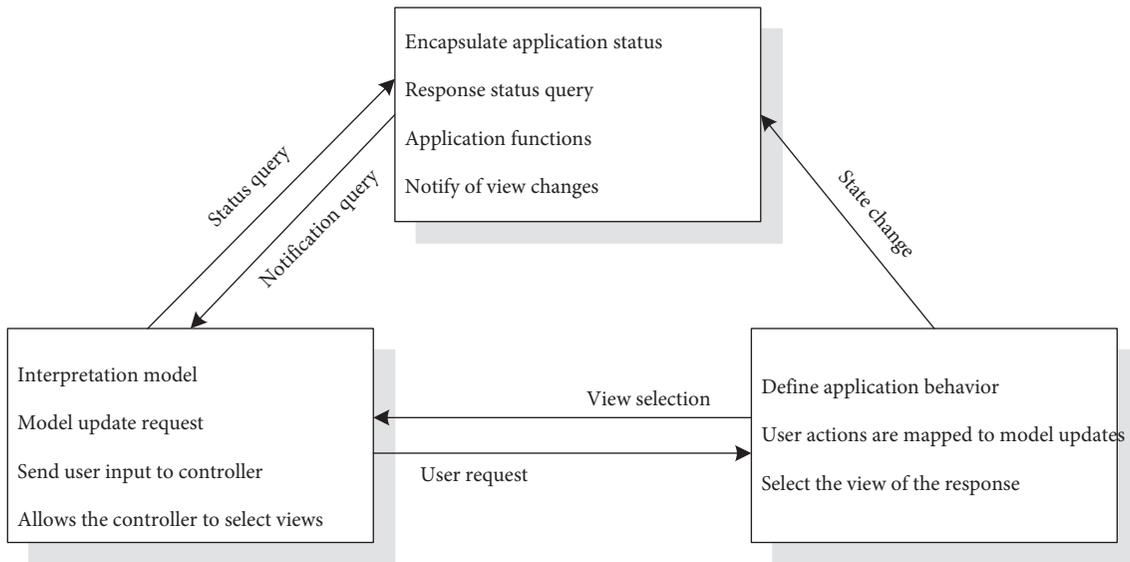

FIGURE 2: MVC mode.

development, the role of venture capital in supervision, governance, and consultation can better reflect the stage of increasing marginal returns. However, in regions with a higher level of economic development, the marginal returns of supervision and consultation may decline [52]. Therefore, this section infers that the supervision and consultation role of venture capital is more significant in the central and western regions.

The results in Table 13 show the effect of venture capital holdings on the willingness of listed companies to pay dividends. Among them, column (2) shows that the impact of venture capital in the central and western regions on the willingness to pay dividends is significantly positive at the 5% significance level, and the net effect is 0.174. However, in column (1), the coefficient of venture capital is not significant in the eastern region sample. The above results confirm the inference of this section, that is, the impact of venture capital holdings on relatively underdeveloped central and western regions is more significant [53].

7. Design and Implementation of Venture Capital Information Management Platform Based on J2EE

The vigorous development of information technology makes it possible to design and develop venture capital information management platform based on the research conclusions of this paper [54–59]. The design, development technology, and development mode of information service system are very important, which affects the performance of the system. For later maintenance and function expansion, there are two main development platforms: J2EE and .NET. The system developed by .NET runs on Windows operating system, while the system developed by J2EE can run on Linux, UNIX, and Windows operating system, so it is more suitable for the software and

hardware environment in this paper. Therefore, J2EE is used as the development platform here. Based on J2EE [56, 59], a venture capital information management platform is built.

The multitier distributed application model of J2EE divides the different layers in the two-tier model into many layers, as shown in Figure 1.

With the rapid development of Internet, how to construct the three-tier B/S structure quickly and effectively has become a research hotspot. MVC divides web applications into three layers: model, view, and controller. Its structure is shown in Figure 2.

As shown in Figure 2, (1) the model refers to the business logic layer, which is usually composed of Java, JavaBean or EJB, or Java + EJB. All businesses are processed by this layer; (2) view refers to the presentation layer, that is, functional web page display. JSP plays a major role in this layer; and (3) the controller is used to accept and distribute the request to the business layer, and pass the data returned by the business logic to the view layer for presentation to the requester.

The corresponding relationship between MVC and J2EE architecture is shown in Figure 3. The view is in the web layer and the client layer, usually JSP/servlets. The controller is also in the web layer and is usually implemented with servlets. The model is in the business logic layer and is usually implemented with server-side JavaBeans or EJB.

7.1. Requirement Analysis. According to the above research, the system requirements of venture capital information management platform include the following:

- (1) Realize the release and sharing of venture capital information, including investment projects, financing projects, investment and financing hotspots, investment and financing institutions, and other information

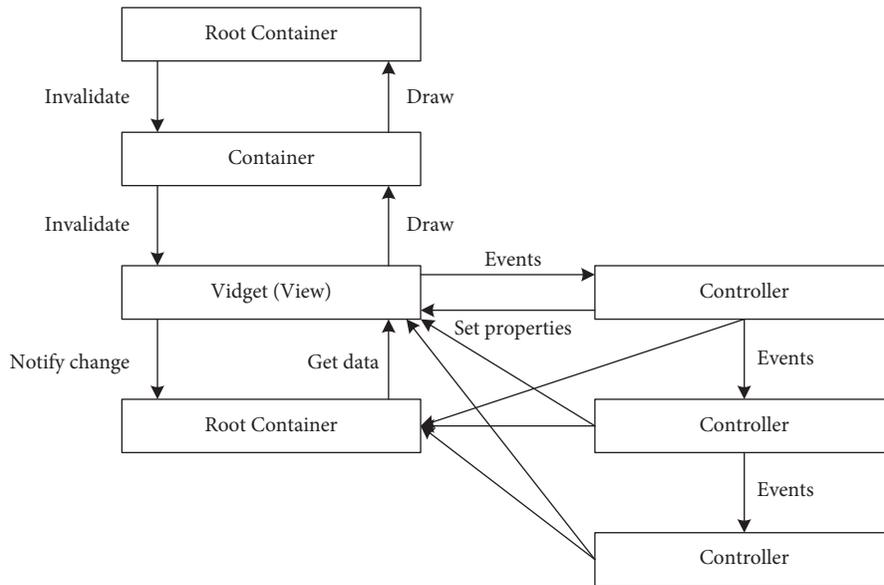

FIGURE 3: The corresponding relationship between MVC and J2EE architecture.

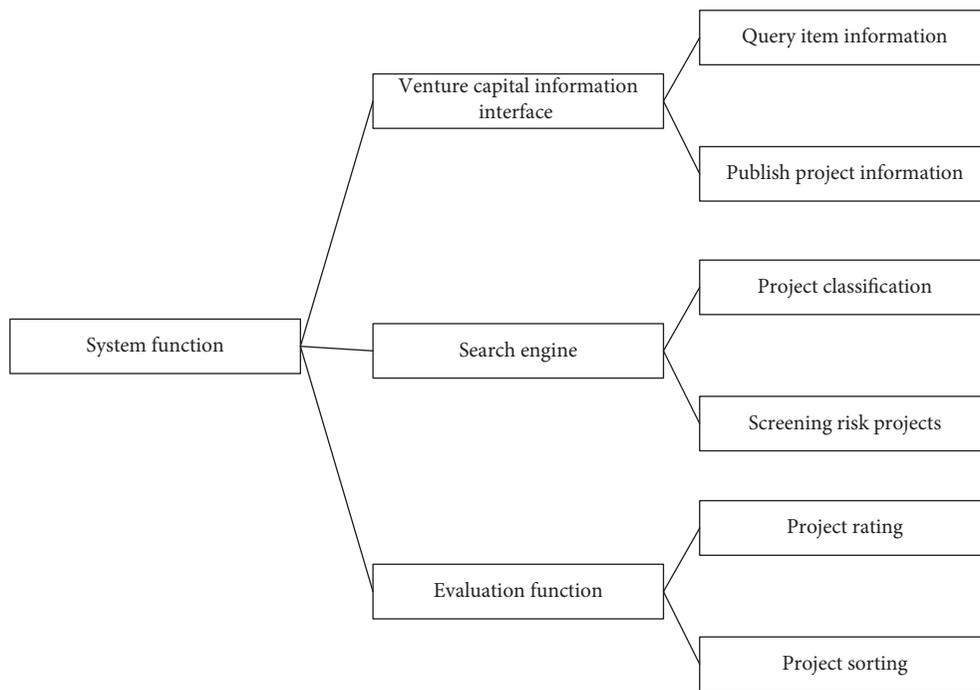

FIGURE 4: Functional planning of the designed platform.

- (2) Realize the classification and retrieval of venture capital information, including project classification and retrieval, organization classification and retrieval, ranking list of hot investment, and financing projects, etc.
- (3) Realize the rating of venture capital projects, including the government’s rating of venture capital institutions, the rating of venture capital projects, and rating release

For these requirements, the functional planning of the platform is shown in Figure 4.

7.2. Use Case Model. Use case is a dynamic description of system behavior. Through use case modeling, it describes the external roles interested in the system and their functional requirements for the system. According to the analysis of

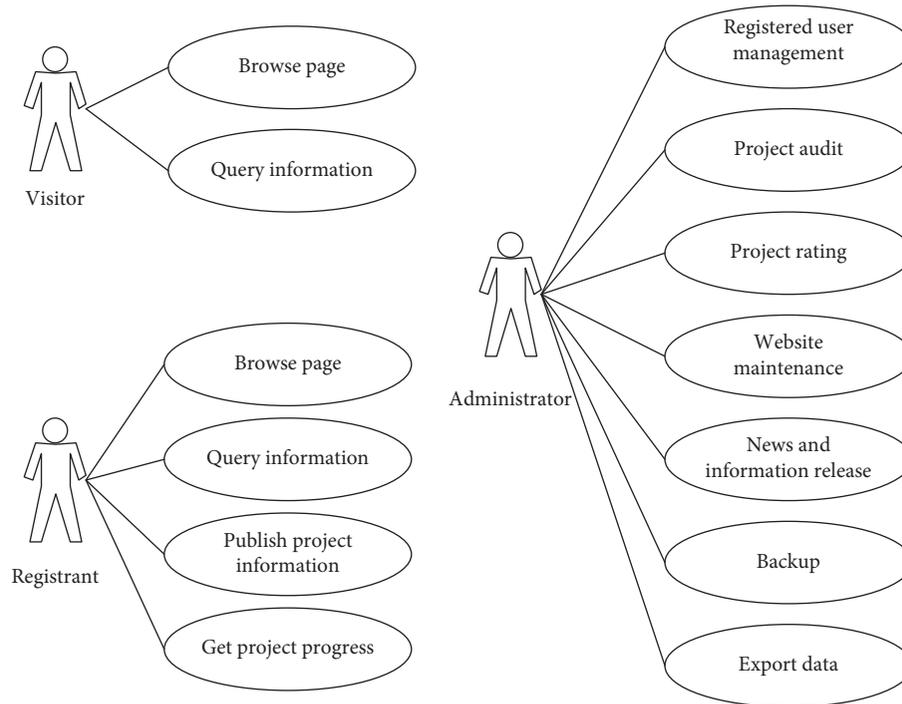

FIGURE 5: Use case diagram.

user behavior, users are divided into tourists, registered users, and administrator users. When different users carry out relevant operations, they have relatively different permissions.

Visitors can only browse the web and query information. Registered users can browse web pages, query information, publish project information, and obtain project related progress. Administrator users can manage the registered users of the website, review the investment and financing projects, rate the investment and financing projects, and be responsible for the maintenance of the website and the release and update of relevant news information. Their use case diagram is shown in Figure 5.

7.3. System Design. The system design of venture capital information management platform is an important stage in the process of system construction. The platform adopts a three-tier structure of standard database layer, data processing layer, and dynamic web page presentation layer. The database is mainly responsible for data storage, retrieval, change, and deletion. The data processing layer is mainly responsible for the generation of SQL statements, database state feedback, data information inspection, etc. The dynamic web page presentation layer is responsible for generating relevant web pages according to the obtained data or web page requests, and finally displaying them on the browser. The overall architecture of the platform is shown in Figure 6.

The object relation model is designed as follows: The object of the platform consists of three objects: enterprise, project, and project index. The project index object can be included in the project object, so as to reduce the number of

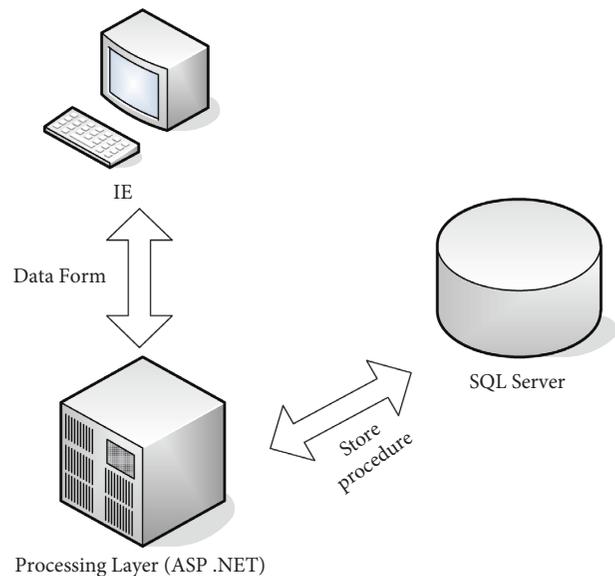

FIGURE 6: The overall architecture.

objects and simplify the object relationship. However, considering that the project index and project rating are the core content of the website, and the project rating itself is flexible, it may be added and changed according to the actual situation within a certain period of time. Therefore, project indicators are listed here as a special object. Although it brings some system overhead, it reduces the coupling of the system model and conforms to the characteristics of the system itself. An entity-relationship (E-R) diagram is shown in Figure 7.

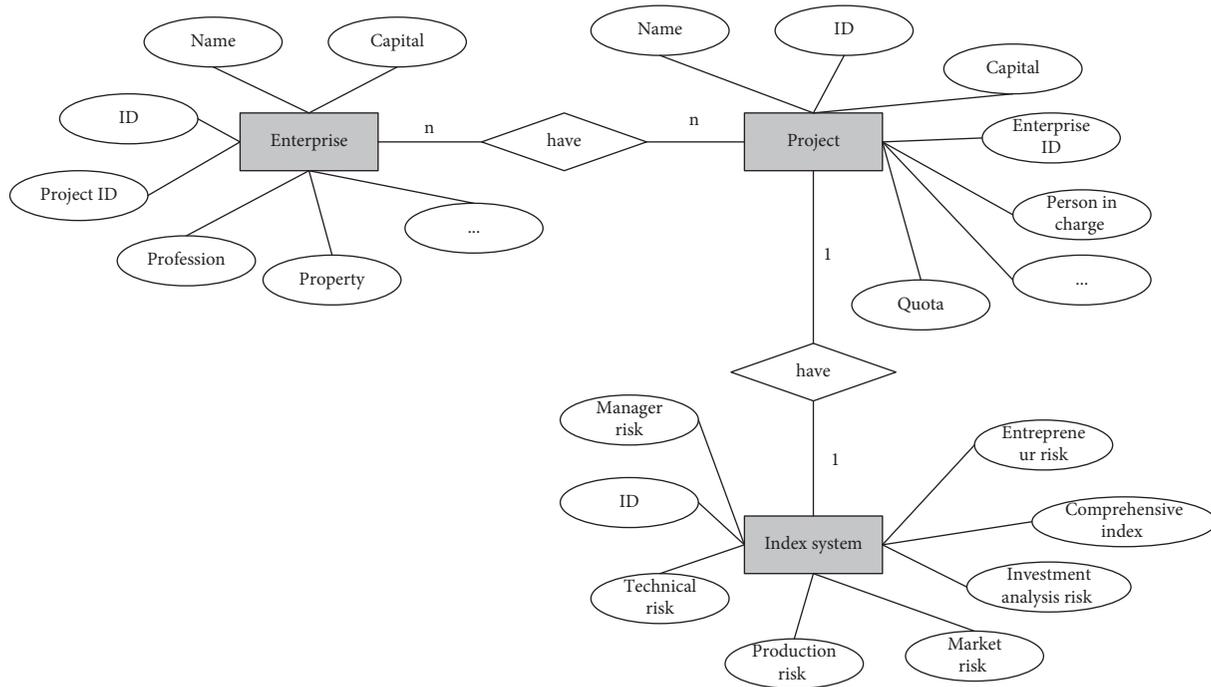

FIGURE 7: E-R diagram.

TABLE 14: The specification design.

Definition of platform	Medium-sized government level website
Number of people online	<3000
Number of registered users	>10000
Home page hits/day	<5000
Home page unique IP	<5000
Total flow	<5G
Page views	<300000
Platform access frequency	<500 times/second
Home page flow/day	<1G
IP quantity	<50000

7.4. *Specification Design.* The venture capital information management platform developed by the project is a medium-sized government level website. The website visit frequency supports less than 500 people per second, supports online access of less than 2000 people, and supports the registration of tens of thousands of users. The specification design is shown in Table 14.

8. Conclusion

This paper takes all A-share listed companies from 2003 to 2019 as samples, and studies the impact of venture capital holdings on the dividend policy of listed companies. This paper examines the effects of venture capital holdings on the willingness of listed companies to pay dividends and their level of dividend payment. The research results are as follows: First is the basic test. By constructing the logit model, it can be seen that companies that have obtained venture capital holdings have a stronger willingness to pay dividends than

companies that have not obtained venture capital holdings. By constructing the OLS regression model, it can be seen that the listed companies with venture capital holdings among the top ten shareholders have a higher level of dividend payment. Second is the mechanism test. According to the derivation logic of this paper, the influence of venture capital on the dividend policy of listed companies is achieved by exerting its supervisory function and alleviating the agency problem of listed companies. Therefore, this paper examines the difference in the impact of venture capital on the dividend policy of listed companies at different levels of agency problem. The results show that in the group with more serious agency problem, the positive promotion effect of venture capital on the dividend payment willingness and the dividend payment level of listed companies is more significant. Third is endogeneity and robustness checks. In order to alleviate the possible problems of sample selection, this paper designs a propensity score matching method to control the possible endogeneity problem. The results show that the sample regression results after propensity score matching are still robust. At the same time, in order to enhance the robustness of the conclusion, a series of robustness checks, such as replacing the dependent variable, replacing the estimated model with the Tobit model, and replacing the independent variable, have been carried out successively, and the conclusion still holds. Fourth is further research. Further research finds that venture capital organizations of different backgrounds have different effects on the cash dividend policy of investee companies. The situation is reflected in the following aspects: companies with foreign investment venture capital holdings are more inclined to distribute cash dividends, and at the same time, the cash dividend payment rate is higher because foreign investment

venture capital has a more complete corporate governance experience. At the same time, the uneven level of regional development and the difference in the degree of marketization will also affect the role of venture capital supervision and governance. In the central and western regions, where the level of economic development is relatively backward, the impact of venture capital on the promotion of the dividend policy of listed companies is more significant.

Taking the cash dividend policy of listed companies as the starting point, this paper studies the specific role of venture capital shareholding in corporate governance, and provides empirical evidence on dividend policy for the research on the role of venture capital governance.

From the conclusion of this paper, we can get the following two implications: First, as far as the regulatory bodies are concerned, the China Securities Regulatory Commission has continuously issued relevant policies since 2001, in order to encourage listed companies to actively distribute cash and strengthen the protection of the interests of small and medium shareholders, thereby increasing the returns of capital market investors. However, the promotion effect of the semimandatory dividend policy is far from satisfactory. The research in this paper effectively proves the positive role that venture capital organizations play in the governance of listed companies. Therefore, as far as the regulatory bodies are concerned, actively guiding social capital to participate in social and economic construction in an orderly and steady manner has a positive driving effect on promoting the healthy development of the capital market and alleviating the “new normal” situation that China’s economy is currently in. Second, as far as listed companies are concerned, actively introducing financial intermediaries such as venture capital and “active investors” and relying on the rich industry experience and complete corporate governance experience of such investors will help alleviate the internal agency problem of listed companies, so as to enhance the company’s efficiency and increase the company’s value.

With the rapid development of society, the risk management of personal health and assets has become an important content that cannot be ignored in all walks of life. With the in-depth advancement of risk management, most of the construction risks of prefabricated buildings adopt qualitative research based on experience and intuitive judgment and quantitative research on quantitative mathematical statistics, but there are few models for risk assessment of prefabricated buildings with dynamic characteristics to adapt to the rapid development of prefabricated buildings and the lack of prefabricated construction in various stages and complex environments, with risk prediction and effective response capabilities. Based on this, this paper attempts to propose a fuzzy neural network risk research method for prefabricated building construction, making full use of the fuzzy neural network's qualitative knowledge expression and quantitative numerical computing advantages, to establish a set of strong fault tolerance and better adaptive ability: fuzzy neural network evaluation model for extensive prefabricated building construction risk. Through the design of the fuzzy network model structure, the membership vector of the qualitative and quantitative indicators of the fuzzy comprehensive evaluation of the risk of prefabricated building construction is used as the input vector of the neural network, and the evaluation result is used as the output of the neural network. The samples were trained, programmed, and debugged, and it was found that the training results of the samples were in good agreement with the expected output results, which further verified the feasibility and applicability of the fuzzy neural network in the risk assessment process of prefabricated buildings. It is of good guiding significance to conduct continuous observation and formulate effective risk aversion and response plans.

1. Introduction

With the continuous advancement of construction industrialization, prefabricated buildings have achieved unprecedented development, injecting new kinetic energy into the advancement of global climate governance. With the continuous emergence of green construction appeals, the new construction method of prefabricated buildings will become more and more popular. Meanwhile, it is widely used in industry and residences because of its high production efficiency, high production accuracy, small environmental impact, and high degree of industrialization. Compared with traditional building forms, prefabricated buildings have different quality, technology, and construction period requirements in the detailed design stage, prefabrication

transportation stage, and hoisting stage. In order to reduce and avoid risk losses, prefabricated buildings are effectively risked [1, 2].

Management is particularly important. In risk management, risk assessment is an important basis for risk management. It aimed to find, analyze, and predict the dangerous and harmful factors existing in the project and the system and the severity of the accident that may be caused, then propose reasonable and feasible safety countermeasures, and guide the source of danger [3, 4]. Monitoring and accident prevention are done to achieve the lowest accident rate, the least loss, and the best return on safety investment. Traditional risk assessment methods are divided into qualitative assessment and quantitative assessment. The qualitative method is mainly based on experience and

intuitive judgment, while the quantitative method is based on a large number of experimental results and extensive statistical analysis of accident data. Both of these two methods have certain defects, which limit their application, and the method combining qualitative and quantitative can make up for the shortcomings of traditional methods [5].

Therefore, this paper adopts the fuzzy evaluation method based on neural network to study the risk management of prefabricated construction. Applications can also be a good way to overcome subjectivity in evaluation.

2. Related Work

In terms of risk management research on prefabricated building construction, the predecessors have conducted statistical modeling and analysis of various building risk factors such as cost, safety, and energy for analysis, evaluation, and decision-making for enterprises. For example, by combining factors such as the construction period of prefabricated buildings, energy consumption in the construction process, and seismic performance of prefabricated buildings, the dynamic case analysis research method is used to analyze the high probability risk of prefabricated buildings and the use of residential target comfort and prefabrication. The data monitoring of the prefabricated buildings explains the construction management risks of prefabricated buildings and the degree of influence of various risk factors on the public [6]. Lee et al., through literature review and detailed analysis of risk factors at the construction site, combined with the impact of the risk factors on the site of prefabricated building construction, used AHP to establish a weight system for risk indicators. According to the classification of risk factors in the construction management of conventional buildings, comprehensively use the statistical analysis method of accident cases and risk matrix to carry out risk assessment [7]. Hinze and others put forward suggestions on the safety management of prefabricated buildings and evaluate the construction risks of prefabricated buildings through the concept of leading indicators [8].

Through the construction of the F-QRAM model, Pinto evaluates inaccurate and vague risk variables, determines the key risk factors of prefabricated building construction, provides guidance for safety risk management during project construction, and guides decision makers in the process of risk assessment. It provides enterprises critical, scientific, and objective guidance for risk response [9]. Xiao et al., through the construction of a fuzzy-based prefabricated building risk assessment model, used the direct rights method to calculate the weights of various indicators, effectively reducing the deviation caused by subjective weighting [10]. Based on the existing research and analysis combined with rough set theory, Guo et al. discussed and analyzed DM (data mining) technology and redefined the risk factors affecting prefabricated buildings. Through the quantitative assessment of risk factors, redundant risk factors are reduced to form the final efficient and quick decision-making method [11].

Staub-French et al. use BIM applications and REPCON (Project Progress Management Program) to combine the Internet and prefabricated buildings to simulate and adjust the construction progress and the process of project implementation, so as to formulate effective control for the quality and safety in the construction management of prefabricated buildings measures [12]. Li et al. used SNA to identify various risk factors in precast concrete projects. Through BIM-centered strategic recommendations, the probability of risk occurrence can be reduced and the communication of target stakeholders can be promoted [13]. Sinha conducted in-depth research and analysis on the construction management of prefabricated frame systems based on the research foundation of predecessors, conducted research on various types of supporting structural components and evaluated construction management risks, and proposed the use of standardized supporting frame systems in construction, to ensure the quality of the structure and reduce the risk factors of construction management [14].

3. Related Theories

3.1. Fuzzy Theory. Fuzzy theory is developed on the basis of fuzzy mathematics. The theory is attached to the basic concept of fuzzy sets and the theory of continuous membership functions [15]. A large number of facts show that many things are put before the cart because of excessive pursuit of precision. If a suitable mathematical language is found to describe the ambiguity of things, proper fuzzy processing can achieve a more precise purpose.

3.1.1. Fuzzy Set. A fuzzy set has an indistinct boundary. For a fuzzy set, an element can both belong to the set and not belong to the set, and the boundary is blurred. In fuzzy logic based on fuzzy sets, the truth of any statement or proposition is only a certain degree of truth, that is, fuzziness. It reflects the uncertainty of events, which can be characterized by the degree to which an element belongs to a certain set, and a numerical value belonging to $[0,1]$ —a membership function. In [16], fuzzy sets and membership functions are defined as follows: Given a universe of discourse X , any mapping from X to the closed region $[0,1]$:

$$\begin{aligned} \mu_A: X &\longrightarrow [0, 1], \\ x &\longrightarrow \mu_A(x). \end{aligned} \quad (1)$$

μ_A is called the membership function of the fuzzy set A , and $\mu_A(x)$ is called x is the membership function of A . The degree of membership can also be denoted as $A(x)$.

3.1.2. Membership Function. Professor Zadeh first proposed the concept of membership function in 1965, which is used to describe the degree of membership of the element u to the fuzzy set U . Due to the uncertainty of this relationship, it is generally used from the interval $[0,1]$. The value taken replaces the two values of 0 and 1 to describe the “true degree” of an element belonging to a fuzzy set. Through membership

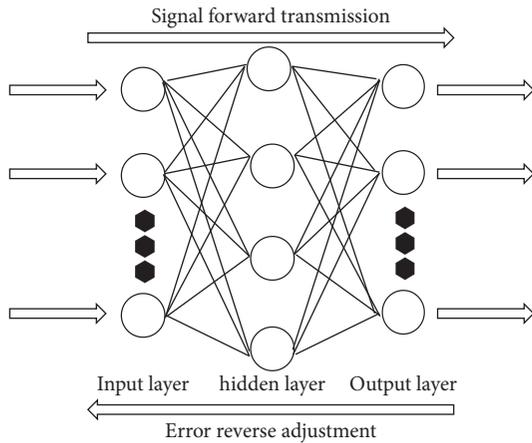

FIGURE 1: BP neural network structure.

function, a fuzzy concept can be expressed transitionally from “not belonging at all” to “belonging completely,” and it is easier to quantitatively analyze and express all fuzzy concepts.

The qualitative description of objective things by membership function is relatively objective in nature, but different individuals have different cognitions to the same fuzzy concept, so there is subjectivity. The determination of the membership function is still based on experience and experiments, and there is no effective systematic method. At present, the common determination methods include fuzzy statistics method, assignment method, expert experience method, and so on. These methods improve the rough membership function through continuous “learning” and “practice,” so as to achieve the unity of the subjective and the objective.

3.1.3. Fuzzy Logic System. Fuzzy logic system refers to a system including fuzzy concepts and fuzzy logic. When it exercises control function, it is called fuzzy logic controller.

Due to the randomness in fuzzy concept and fuzzy logic selection, fuzzy logic systems with various states can be constructed. For example, the combination of various fuzzy neurons constitutes a neural network logic system with fuzzy information processing functions.

3.2. BP Neural Network Algorithm

3.2.1. Principle of BP Neural Network. The BP neural network consists of three parts: input layer, hidden layer, and output layer. Each layer involves a large number of neurons, and these three layers are also organically combined by these neurons to form the integrity of the model [17–20].

In the BP neural network model, the feature vector is input from the input layer to carry out the model network. After the feature vector is recognized in the input layer, it is transmitted to the hidden layer by the neuron and performs certain data processing. Finally, it is also transmitted to the output layer by the neuron. The data is processed and compared according to the given expected value. When the output conditions are not met, the output layer starts to

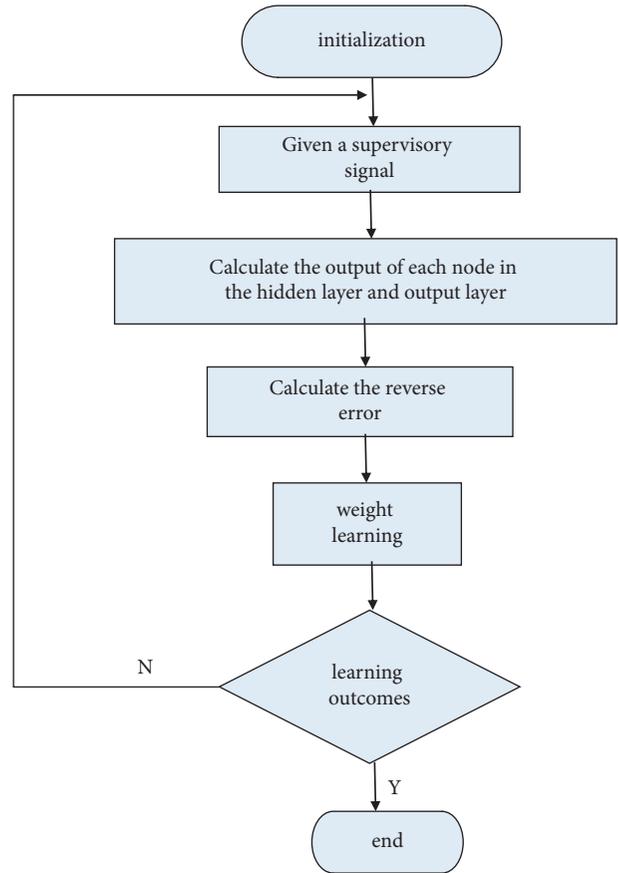

FIGURE 2: Flowchart of BP algorithm.

perform reverse transfer and weight adjustment, and this cycle is repeated until the output reaches the preset expected value. It can be seen that the BP neural network is an intelligent model that can continuously learn and self-adjust, and its structure is shown in Figure 1.

The learning of the BP neural network is mainly to adjust the connection weights between the neurons only through the learning algorithm, so that the output results are closer to the expected value. Guided learning with a tutor is divided into four processes: forward transmission of information, reverse adjustment of errors, model training, and “learning convergence.”

3.2.2. Learning Algorithm of BP Neural Network. The flowchart of the BP neural network learning algorithm is shown in Figure 2; initialization is to select the initial weight of the network, generally a small random number around zero. When the specified number of learning times or the expected output error index is reached, or the change of the error index is less than a certain closed value, the learning ends; otherwise, the learning continues.

Combined with Figure 1, it is assumed that the input learning sample is p , the number of input neurons is n , the number of hidden layer neurons is m , the number of output neurons is r , and the conversion function adopts a sigmoid function, namely: $f(x) = 1/1 + e^{-x}$, the weight correction process is as follows:

(1) Forward propagation of information

① The output of the j th neuron in the hidden layer is

$$S_j = f(\text{net}_j) = f\left(\sum_{t=1}^n \omega_{ij}x_{ti} + \theta_j\right), \quad (2)$$

$$j = 1, 2, \dots, m; t = 1, 2, \dots, p,$$

where x_{ti} is the input of the i -th neuron in the t -th sample, and ω_{ij} is the weight from the i -th neuron to the j th neuron.

② The output of the k th neuron in the output layer is

$$\begin{aligned} S_k &= f(\text{net}_k) \\ &= f\left(\sum_{j=1}^m \omega_{jk}S_j + \theta_k\right), \quad k = 1, 2, \dots, r, \end{aligned} \quad (3)$$

ω_{jk} is the connection weight from the j th neuron to the k th neuron.

③ Define the error function:

$$\begin{aligned} E &= \frac{1}{2} \sum_{k=1}^r (S_k - s_k)^2 \\ &= \frac{1}{2} \sum_{k=1}^r (e_k)^2, \end{aligned} \quad (4)$$

where S_k is the expected output of the k th neuron in the output layer.

(2) Weight change and backpropagation of error

① The weight change of the output layer

The weights from the j th input to the k th output are

$$\begin{aligned} \Delta\omega_{jk} &= -\alpha \frac{\partial E}{\partial \omega_{jk}} \\ &= -\alpha \frac{\partial E}{\partial S_k} \cdot \frac{\partial S_k}{\partial \text{net}_k} \cdot \frac{\partial \text{net}_k}{\partial \omega_{jk}} \\ &= \alpha (S_k - s_k) \cdot f'(\text{net}_k) \cdot S_j = \alpha \delta_{jk} S_j. \end{aligned} \quad (5)$$

Among them, $\delta_{jk} = (S_k - s_k) \cdot f'(\text{net}_k)$
Similarly:

$$\begin{aligned} \Delta\theta_k &= -\alpha \frac{\partial E}{\partial \theta_k} \\ &= -\alpha \frac{\partial E}{\partial S_k} \cdot \frac{\partial S_k}{\partial \text{net}_k} \cdot \frac{\partial \text{net}_k}{\partial \theta_k} \\ &= \alpha (S_k - s_k) \cdot f'(\text{net}_k) \\ &= \alpha \delta_{jk}. \end{aligned} \quad (6)$$

② Changes in hidden layer weights

The weights from the j th input to the k th output are

$$\begin{aligned} \Delta\omega_{ij} &= -\beta \frac{\partial E}{\partial \omega_{ij}} = -\beta \frac{\partial E}{\partial S_k} \cdot \frac{\partial S_k}{\partial S_j} \cdot \frac{\partial S_j}{\partial \text{net}_j} \cdot \frac{\partial \text{net}_j}{\partial \omega_{ij}}, \\ &= \beta \sum_{k=1}^r (S_k - s_k) \cdot f'(\text{net}_k) \cdot \omega_{jk} \cdot f'(\text{net}_j) \cdot x_{ti} \\ &= \beta \delta_{ij} x_{ti}. \end{aligned} \quad (7)$$

Among them, $\delta_{ij} = e_j \cdot f'(\text{net}_j)$, $e_j = \sum_{k=1}^r \delta_{jk} \omega_{jk}$

$$\begin{aligned} \Delta\theta_j &= -\beta \frac{\partial E}{\partial \theta_j} = -\beta \frac{\partial E}{\partial S_k} \cdot \frac{\partial S_k}{\partial S_j} \cdot \frac{\partial S_j}{\partial \text{net}_j} \cdot \frac{\partial \text{net}_j}{\partial \theta_j}, \\ &= \beta \sum_{k=1}^r (S_k - s_k) \cdot f'(\text{net}_k) \cdot \omega_{jk} \cdot f'(\text{net}_j) = \beta \delta_{ij}. \end{aligned} \quad (8)$$

Among them, α and β are called the step size of the gradient search algorithm, also called the convergence factor. The larger the value, the faster the weight adjustment. Generally, the values of α and β can be larger without causing oscillation.

(3) The error backpropagation process is actually by calculating the error e_k of the output layer and then multiplying it by the first derivative $f'(\text{net}_k)$ of the activation function of the output layer to obtain δ_{jk} . Since the target vector is not directly given in the hidden layer, the δ_{jk} of the output layer is used to transfer the error backward to obtain the change $\Delta\omega_{jk}$ of the output layer weight and then calculate $\sum_{k=1}^r \delta_{jk} \Delta\omega_{jk}$ and then multiply e_j by the first derivative of the activation function of the hidden layer $f'(\text{net}_j)$ to obtain δ_{ij} , so as to obtain the variation of the weight of the previous layer $\Delta\omega_{ij}$.

(4) Weight correction

① Use δ_{jk} to correct the weights and thresholds between the output layer and the hidden layer

$$\begin{aligned} \omega_{jk}(t+1) &= \omega_{jk}(t) + \Delta\omega_{jk} = \omega_{jk}(t) + \alpha \delta_{jk} S_j, \\ \theta_k(t+1) &= \theta_k(t) + \Delta\theta_k = \theta_k(t) + \alpha \delta_{jk}. \end{aligned} \quad (9)$$

② Use δ_{ij} to correct the weights and thresholds between the input layer and the hidden layer

$$\begin{aligned} \omega_{ij}(t+1) &= \omega_{ij}(t) + \Delta\omega_{ij} = \omega_{ij}(t) + \beta \delta_{ij} x_{ti}, \\ \theta_j(t+1) &= \theta_j(t) + \Delta\theta_j = \theta_j(t) + \beta \delta_{ij}. \end{aligned} \quad (10)$$

Calculate the function E after the corrected error again; if E is less than the specified upper limit of error, the algorithm ends; otherwise, the number of learning times $t = t + 1$ is updated, and the weights and thresholds are rechecked.

There are two ways to train the network with the BP network algorithm. One is to modify the weights every time a

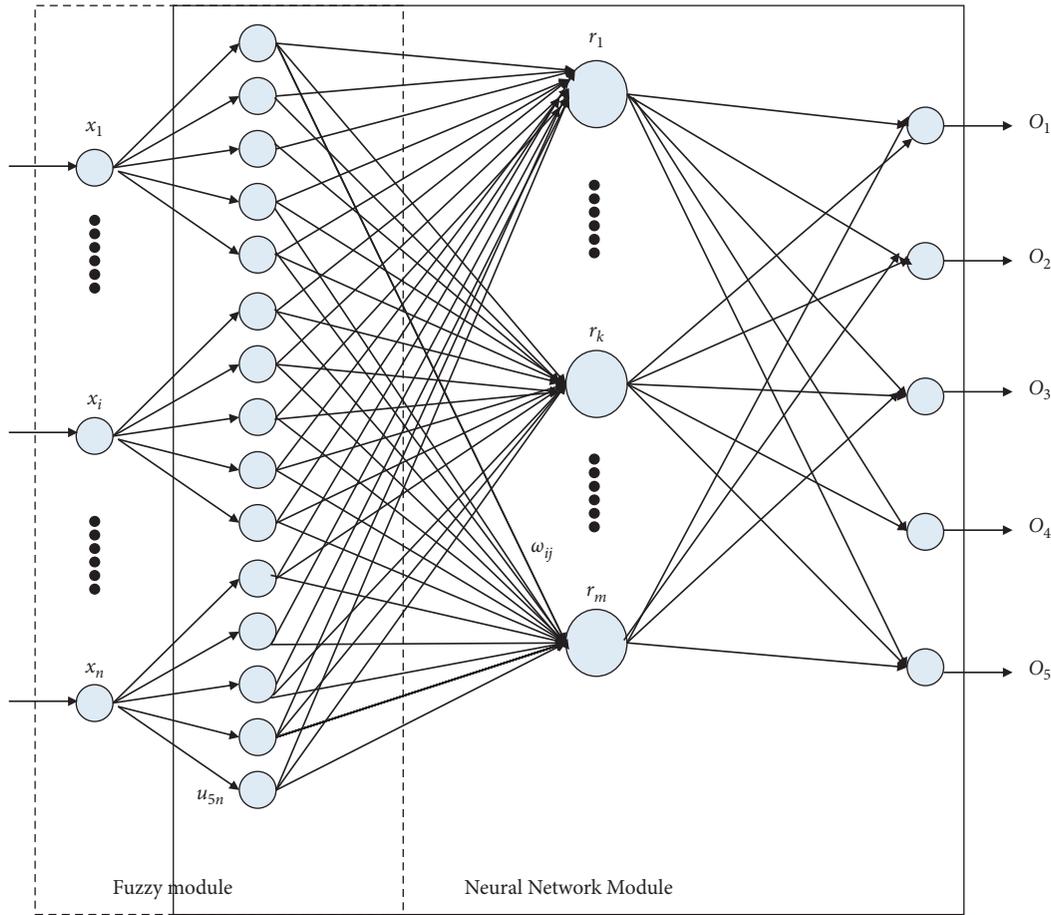

FIGURE 3: Fuzzy neural network topology diagram.

sample is input, which is the standard error propagation method; the other is the batch method, that is, all the samples that constitute a training cycle are computing the total average error after one input is a truly global gradient descent method. The number of corrections in the latter is significantly reduced, which can save learning time, but since the average of all mode errors is used, oscillations may occur in some cases.

4. Risk Assessment Model of Prefabricated Construction Based on Fuzzy Neural Network

4.1. Fuzzy Neural Network Model Construction. Fuzzy neural network can be divided into fuzzy neural network calculated according to fuzzy numbers and fuzzy neural network formed based on the logical reasoning process of fuzzy rules [21–24]. Based on the characteristics of knowledge management, this paper builds a 4-layer fuzzy neural network based on the first type of fuzzy neural network. The first and second layers are fuzzy modules, and the second, third, and fourth layers are neural network modules, as shown in Figure 3.

The first layer is the input layer, which is responsible for the input of the fuzzy neural network. Each node represents an input variable (risk index). According to the reliability and validity test in Chapter 2, the input layer has a total of 7 nodes.

The second layer is the fuzzification layer, whose role is to fuzzify the input variables and make them the input layer of the neural network module. This layer uses a Gaussian function as the membership function:

$$\mu x_i = \exp \left[-\frac{1}{2} \left(\frac{x_i - \mu_i}{\sigma_i} \right)^2 \right]. \quad (11)$$

Among them, μ_i is the center of the membership function, σ_i determines the width of the membership function, and the mean value of all samples of the index x_i on the input layer is the μ_i value of the index at the corresponding level; the membership of the index on the fuzzification layer. The function width takes the following value:

$$\sigma_i = \sqrt{\frac{1}{n} \sum_{j=1}^n (x_i - \mu_i)^2}. \quad (12)$$

The third layer of fuzzy reasoning layer is also the hidden layer of the fuzzy neural network. It mainly realizes the mapping from the fuzzy value of the input variable to the fuzzy value of the output variable and determines the number of nodes according to the above algorithm.

The fourth layer is the output layer, which outputs the result of fuzzy evaluation.

4.2. *Learning Steps of Fuzzy Neural Network.* The specific learning steps are as follows:

Step 1: Cluster the sample data using the K-means method, set the number of clusters to 5, and obtain the mean μ_i and variance $\sigma_i \in \{1, 2, 3, 4, 5\}$ of each category, respectively.

Step 2: Transform the input sample X_k $h \in (1, 2, \dots, P) \dots$ through the membership function to realize the fuzzification process, so that n nodes are mapped to $5n$ fuzzy layer nodes and used as the input of the fuzzy inference layer.

Step 3: Set the number of learning times $t=0$, assign small random numbers to the network weights and thresholds, $\omega_{ij}(t) \in [-1, 1]$, $\omega_{jk}(t) \in [-1, 1]$ $\sigma_j(t) \in [-1, 1]$; $\sigma_k(t) \in [-1, 1]$.

Step 4: Input a sample (X_h, T_h) ; P is the number of samples, $X_h \in R^p$, $T_k \in R^r$.

Step 5: Calculate the actual output of the fuzzy inference layer and the output layer, respectively; $S_j = f(\text{net}_j)$, $S_k = f(\text{net}_k)$, where $f(x)$ is a sigmoid function.

Step 6: Calculate the fuzzy inference layer error σ_{ij} and the error σ_{jk} of each node in the output layer.

Step 7: The t -th correction is made to the weights and the stop values, $\omega_{jk}(t+1) = \omega_{jk}(t) + \alpha \delta_{jk} S_j$, $\theta_k(t+1) = \theta(t) + \alpha \delta_{jk}$; $\omega_{ij}(t+1) = \omega_{ij}(t) + \beta \delta_{ij} S_j$, $\theta_j(t+1) = \theta(t) + \beta \delta_{ij}$;

Step 8: Calculate the error function E ; if $E < \varepsilon$, the network training ends; otherwise, go to Step 5.

5. Risk Assessment and Analysis of Prefabricated Building Construction Based on Fuzzy Neural Network

In this section, on the basis of the relevant literature [25–33], the risk management evaluation index system and theoretical system of prefabricated building construction will be proposed, and the evaluation indicators will be integrated, and the empirical research on the risk evaluation of prefabricated building construction will be carried out by using the fuzzy neural network method, and the indicators will be verified. Verify the rationality and effectiveness of the index system and the operability of risk assessment work.

In the verification process, the computer is used as the realization tool, and the research methods combining BP neural network and SPSS statistical analysis are used, respectively. The generalization ability and training speed of the network can reduce the probability of the BP network falling into a local minimum point, and the BP neural network program is written by using the neural network toolbox in the MATLAB language program to provide decision support for the research on risk management of prefabricated buildings.

5.1. Prefabricated Building Construction Risk Data Acquisition

5.1.1. *Acquisition of Input Layer Data.* The acquisition of input layer data is mainly achieved through the factor score of each sample, that is, how the common factor is represented by a linear combination of statistical indicators, which refers to the estimated value F_j of the common factor $\hat{F}_j \hat{F}_j$:

$$\hat{F}_j = b_{j1}X_1 + b_{j2}X_2 + \dots + b_{jp}X_p, \quad j = 1, 2, \dots, 7; p = 25. \quad (13)$$

Since this study uses correlation coefficient matrix for factor analysis, it is assumed that x_1, x_2, \dots, x_p are standardized variables of influencing factors; $b_{i1}, b_{i2}, \dots, b_{ip}$ are factor score coefficients; \hat{F}_j is the estimated value of the j th factor, as shown in Table 1.

5.1.2. *Fuzzy Layer into Data Acquisition.* K-means clustering is performed on the 5 common factors of the sample, and the number of clusters is set to 5, which correspond to the high, high, medium, low, and low of the construction risk of prefabricated buildings; the clustering method of common factors adopts Iterate and Classify. The clustering method continuously iterates and replaces the center position on the basis of the starting class center and assigns the observations to the nearest class; after 10 iterations, the cluster center matrix is obtained, as shown in Table 2.

After the samples are classified, run the Analyze Compare Means command in SPSS 20.0 software to obtain the value of the membership function width δ_i of each factor at the corresponding level. The results are shown in Table 3.

According to the Gaussian function, the membership degree of each factor in each category in the sample can be obtained. As the output of the second layer of the fuzzy neural network, there are 25 in total.

5.2. Evaluation Results and Analysis of Construction Risks of Prefabricated Buildings

5.2.1. *Determine the Number of Hidden Layer Nodes.* Run MATLAB 2016a; use 160 sample data to train the neural network and 10 sample data to test the neural network to find the optimal number of hidden layer nodes. According to the relevant theory in Section 3.2.1, the optimal hidden layer of BP neural network should be between 7 and 16, and the number of nodes in the output layer is 5; (1,0,0,0,0), (0,1,0,0,0), (0,0,1,0,0), (0,0,0,1,0), (0,0,0,0,1) represent the low, low, medium, high risk status of prefabricated building construction, respectively.

Run the following program in MATLAB, and adjust the number of hidden layer nodes between 7 and 16 in turn. After repeated training, the results are shown in Table 4.

```
p = []; % training sample data
t = []; % training sample target output
net = newff(minmax(p), [7, 5], ('logsig,' 'logsig,'
'traingd')); % Adjust the number of hidden layer nodes
in turn
```

16	$9.4784e-006$	$2.9405e-005$

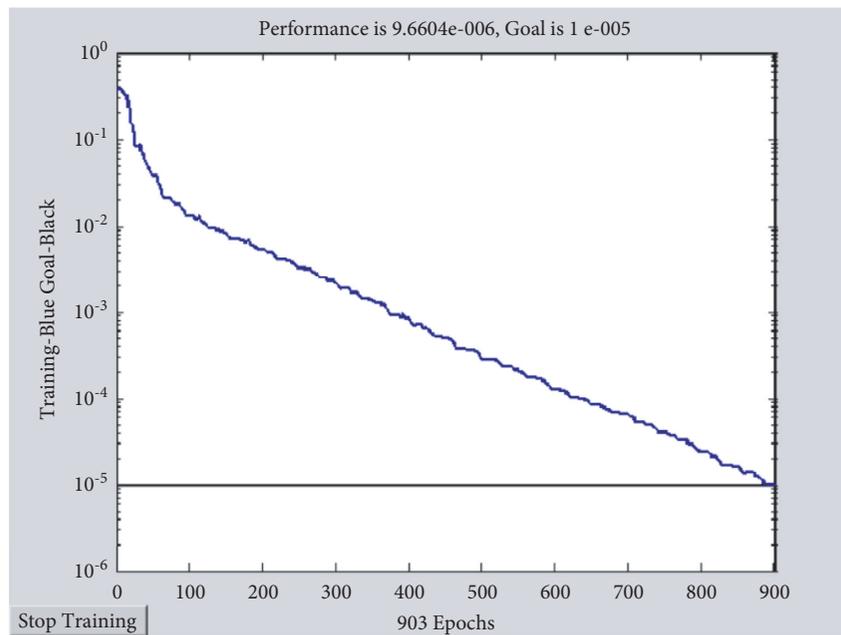

FIGURE 4: The training graph with the hidden layer node of 14.

```

net.trainParam.show = 100;
net.trainParam.goal = 1e - 5;
net.trainParam.epochs=8000;
net.trainParam.lr = 0.08;
net.trainParam.lr_inc = 1.4;
[net,tr] = train(net,p,t);
Y = sim(net,p); e = t - y;
Q = mse(e)
% output training error
ptest = []; % test sample data
ttest = []; test sample target output
a4 = sim(net,ptest);
E = ttest-a4;
Perf = mse(E)
% output test error

```

(1) *Save Net/ Net*. In Table 4, as the number of hidden layer nodes increases, the training error gradually decreases, but the test error slightly oscillates after more than 14. Therefore, the relationship between the number of hidden layer nodes, training error, and test error is comprehensively considered. And the number of nodes in the hidden layer is determined to be 14. It is not that the more the nodes in the hidden layer, the better the performance of the network. When testing samples, it was found that the training error first decreased and then gradually increased with the increase of the number of nodes in the hidden layer. Although the increase is not very large, it is enough to affect the performance of the neural network.

Figure 4 shows that, with the increase of training times, the network training error gradually decreases. When the training times reaches 903 times, the network reaches the set error; that is, the network completes the training.

5.2.2. *Evaluation Results and Their Analysis*. The actual output results and the expected output results of the 10

TABLE 5: Network output and expected output comparison table.

Sample	Network output	Expected output
1	(0.0000 0.0000 0.0000 1.0000 0.0000)	(0 0 0 1 0)
2	(0.0009 0.0012 0.9900 1.0000 0.0000)	(0 0 1 0 0)
3	(0.0000 0.0000 1.0000 1.0000 0.0066)	(0 0 1 0 0)
4	(0.0021 0.0007 0.0000 1.0000 0.9922)	(0 0 0 0 1)
5	(0.0000 0.0000 0.0000 0.0000 1.0000)	(0 0 0 0 1)
6	(0.0005 0.0000 0.0001 0.9876 0.0000)	(0 0 0 1 0)
7	(0.0000 0.0021 0.0000 0.9993 0.0022)	(0 0 0 1 0)
8	(0.4790 0.0000 0.0000 0.0000 0.9961)	(0 0 0 0 1)
9	(0.0000 0.0013 0.0000 0.9939 0.0000)	(0 0 0 1 0)
10	(0.0000 0.0000 0.7505 0.0000 1.0000)	(0 0 0 0 1)

sample data are shown in Table 5. It is found that the training results of the samples are in good agreement with the expected output. It can be seen that the trained fuzzy neural network can well obtain and store expert knowledge, experience, and judgment. It can be seen that the data-based serial fuzzy neural network has good scientificity, rationality, and practicability in the process of risk assessment of prefabricated buildings.

Through the above research, it can be seen that the neural network overcomes the inaccuracy of the fuzzy algorithm due to the insufficient discrimination of each component in the evaluation vector. And it can make the analysis results more realistic and convincing. The fuzzy evaluation of aspects and the principle of maximum membership ignore other evaluation information. Fuzzy BP neural network evaluation method not only has strong fault tolerance, but also has the characteristics of self-adaptation and self-correction, which will be more widely used in risk management in other fields.

6. Conclusion

As an emerging green construction method, prefabricated buildings have gradually accelerated with their development. In addition, the construction standards of ordinary construction teams are uneven, and the difficulty of risk management has also increased. Traditional risk assessment is mainly based on qualitative research and analysis. It is empirical and intuitive judgment. But quantitative research is based on a large number of experimental results and indicators or laws obtained by extensive statistical analysis of accident data to perform quantitative calculations. In different organizational management and project construction processes, the risks of prefabricated buildings have various forms and the size of the risks are also different. Therefore, the model for its evaluation should also have dynamic characteristics, so as to facilitate the reasonable prediction and control of risks. This paper attempts to apply the fuzzy neural network to the risk assessment and management of prefabricated buildings and does the following research:

- (1) With the help of fuzzy theory to quantify risk factors and the advantages of BP neural network's effective intelligent behavior, learning ability, self-adaptive mechanism, and high flexibility, a prefabricated

construction risk assessment model based on fuzzy neural network is established.

- (2) In the design of fuzzy neural network, the number of hidden layer nodes usually needs to be determined by multiple experiments or experience. This paper proposes a method to select the optimal number of hidden layer nodes according to the formula and past experience. The method is concise, which can reduce the number of verifications, and it has good reference and use value.
- (3) Through programming and debugging, the fuzzy neural network is trained, and it is found that the training results of the samples are in good agreement with the expected output results, which verifies the feasibility and applicability of the fuzzy neural network in the risk assessment process of prefabricated buildings. The dynamic characteristics of risks can be continuously observed, and effective risk aversion and response plans can be formulated with good guiding significance.

With the continuous development of science and technology, we have completely entered the information age. The amount of data around us increases linearly, and everyone lives in a pile of data. Enterprises also need to use big data technology in the process of operation and management to mine data and realize various data management functions. For the current enterprise, the operation of data will not only affect the management cost of the enterprise but also affect the future development of the enterprise. Based on the problem of enterprise management cost, this paper proposes to effectively use big data technology to solve the problem of enterprise cost management. The article also uses big data technology to optimize the management cost of the enterprise and uses big data technology to innovate and apply the management method of the enterprise. This paper constructs a cost management model based on data mining and expounds on the objects, sources, and calculation methods of data mining. Under this model, the company's data was mined, a specific plan was proposed, and an improved association algorithm was proposed to test the completion and consolidation of tasks. In the case of a large number of tasks, in order to efficiently realize the selection and merging of data, this paper proposes a new cost forecasting scheme based on a fuzzy model. Use time series for cost forecasting, and the accuracy is relatively high. In the process of forecasting, our forecasting method is suitable for the human reasoning process and can have better adaptability. Finally, we applied the research results of the thesis to actual business management to meet the management needs of the business, thus verifying the feasibility of the method proposed in this article.

1. Introduction

With the advent of the era of economic globalization, the competition among enterprises is becoming increasingly fierce. If every enterprise wants to remain competitive and invincible in the torrent of economic globalization, it needs to innovate and explore its own management mode and management tasks. If a company wants to succeed, it must control its own costs. In cost management, we need to recognize the status of cost management and the significance of cost management. In the process of cost management, the concept, technology, and method of cost management will affect the future development of the enterprise and even determine the success or failure of the enterprise. At present, the management strategies described by the existing cost management schemes in the market are mostly described in

words, and there is no quantitative management scheme. With the advent of the information age, we can realize intelligent cost management so as to innovate the solutions and methods of cost management. Enterprises will face competition in the process of operation. This is inevitable. Only when enterprises continue to attach importance to their own management process, continuously deepen the process of informatization, and accumulate cost data year by year, this will become a valuable resource for the company. To promote the further development of the enterprise, with the advent of the era of big data, traditional database queries can no longer perform detailed queries on all information. Because the amount of information is too large, it is difficult for us to distinguish which data is valid and which is invalid. As a result, when we process data, much data will be destroyed before it is processed, and much data will be

processed repeatedly. Because there are so much data and the types of data are very complicated, it is very difficult for us to find useful information from the huge data. At the same time, we also need to manage the information. The emergence of data mining technology has solved this thorny problem, and people can transform data into valuable information for application.

In the process of cost management, it is necessary to calculate the cost, which is the most basic and core part. Cost accounting provides basic data for enterprises to carry out cost management. If the calculated cost is not accurate enough, it will eventually affect other aspects of cost management. The object of data mining is for a large amount of data. In the process of cost management, we need to mine the cost data, which requires the use of data mining technology. It is very important that we should refine the cost accounting method as much as possible and improve the accuracy of cost accounting. By integrating big data technology into the cost management process, this paper can not only meet the achievements of technology development but also improve management efficiency. With the continuous development of science and technology, big data technology and Internet of things technology are more and more widely used in life, and we have completely entered the data age. The amount of big data is very large, and there are many kinds of data. We must study more advanced methods to achieve faster data processing. In the era of big data, enterprise managers should be able to obtain information faster, manage and make decisions on information, and combine big data technology in the process of processing information to improve processing efficiency. At the same time, it discusses the optimization process of enterprise cost management under the background of the big data era and combines big data technology with enterprise cost management technology.

2. Related Work

In the mid-fifteenth century, cost accounting began in various companies. Around 1820, some theories about cost management began to appear. Literature [1] mentioned some methods that can improve management efficiency and reduce management costs. This method separates the planning department from the executive department. This also lays the foundation for subsequent management work. Management thinking has become more and more scientific. The cost is getting lower and lower. Literature [2] put forward a concept of value engineering. This concept is mainly to set up some products under the premise of market demand so as to obtain benefits. In order to ensure that the function and cost of the product are matched, the value of the product must be fully utilized during the entire production and sales process, and the consumer must do its best to gain the recognition of consumers. Literature [3] puts forward a concept of strategic management accounting. This concept is to say that the company's performance evaluation should be based on each person's own evaluation. In the process of management, we must also pay attention to the management of employees themselves. The company can

not only analyze problems from within the company but also vertically compare other companies in the market and compare the direction of the market. Literature [4] mainly analyzes the management awareness of managers and also conducts in-depth analysis and exploration of the relationship between management knowledge and management effects. The analysis results show that there is a certain correlation between management awareness and management knowledge of managers. Literature [5] believes that in order to manage costs, companies need to control their own costs and understand their own production processes, all of which can affect the company's operating results. Literature [6] pointed out that the cost management of enterprises will also be affected by the environment. Different enterprises are in different environments and face different risks. These risks will affect the cost of the company and, thus, the profit of the company. Make an impact. Literature [7] mainly explains that in the process of cost production, structural costs and management costs are combined and analyzed. Only by focusing on financial performance can we better manage costs. In the process of management, we should not only focus on the supply chain but also on other aspects. Literature [8] mainly studies the management of project costs and proposes that costs should be managed in accordance with global unified standards. Literature [9] proposes that the arrival of the big data era may cause an industrial revolution in information technology. This revolution involves not only the Internet of Things technology but also cloud computing. This information revolution will also affect other industries and even our corporate activities and business operations. Literature [10] pointed out that this information technology revolution will have a certain impact on the business management style of enterprises and will also affect the decision-making work of enterprises. Literature [11] proposes that big data technology will become the basis for the management of the majority of enterprises in the future, and many mistakes can be avoided. Literature [12] proposes that data mainly faces three major challenges: data generation, data processing, and data storage. If we want to use big data technology to optimize the industry, we must explore the problems ourselves and propose our own solutions. Literature [13] proposed that in a big data environment, all our information will be recorded, and all information will be stored in the form of data. Literature [14–18] proposes that in a big data environment, all data needs to be accessed and extracted multiple times and will be used in different places. Different processing methods for big data will lead to different processing results, and sometimes two completely opposite results may occur. For the impact of such uncertain factors, we need to provide solutions. Literature pointed out that in the era of big data, the operation of enterprises will be affected by the results of big data, but the results of data analysis will affect the decision-making of enterprises, and it can also provide enterprises with some scientific suggestions to affect product development and enterprises. Literature proposes that Europe has already applied big data technology in legal ethics and other fields. Literature pointed out that in the future, we still need to further explore big data, seize the opportunity to make a

comprehensive evaluation, and then apply it to people's lives. Literature pointed out that the era of big data brings both opportunities and challenges to people. We need to use the cognitive prediction function of big data to analyze potential users so that people can recognize big data technology. Literature [19] proposes that when managing costs, companies should not only consider the internal supply chain costs but also the external environment. The company should strategically control the supply chain management and coordinate the internal supply chain. Literature [20] pointed out that there are many factors that affect the operating cost of a company, such as the strategy of the company and the management style of the manager [21, 22]. From the current research, scholars analyze cost management and supply chain management.

3. Based on the Internal Data Mining and Information Management System Design

3.1. The Establishment of Enterprise Production Cost Data Warehouse

3.1.1. The Process of Enterprise Data Mining. Before the application and analysis of the enterprise production cost data information management module, we need to use the codes of some attribute data to store the data and then use the dictionary for comparison in the process of comparison. We first need to encode the preprocessed data. Some quantitative attributes are discrete, and all attributes are divided into different categories. Among them, Table 1 shows the results of discretized character attribute values. Table 2 shows the values of the converted sample data, as shown in Figure 1.

3.1.2. Data Warehouse Design Structure. First, extract the data, then transform it, finally store the data in the warehouse, and use the data mining tool for data mining. When designing the data warehouse, we mainly divided it into four parts, and its structure is shown in Figure 2. In the first part, we mainly store the basic information of the company and the information and processes in the production process. This information is relatively discrete and difficult to use [23]. The second part is used to store data in the center. It also includes some multidimensional data and raw data. These data have been preprocessed to make it easier to store and analyze. The third part is used to store application services, mainly including various data mining technologies and data analysis technologies. The fourth part is mainly used to display information, display processing results, and display users.

3.1.3. Data Conversion Method. In the process of data selection and data analysis, we need to convert the data format. We need to check the stored data one by one, convert the data format of each field, and reorganize the data. If there are some vacant fields in the stored data, we should also set corresponding values to keep the data standardized. In the process of data conversion, we must pay attention to the

TABLE 1: Discretization of decision attribute values.

Category code	Numerical range	Profitability
1	(0, 2520)	Relatively low profit
2	>2520	Relatively high profit
3	(-2520, 0]	Less loss
4	<-2520	More losses

TABLE 2: Decision table sample data after data conversion.

...

conversion of some inconsistent data but also pay attention to the validity of the data and the corresponding rules. Some data represent the same meaning, but the unit is different. Here, we also need to convert. In order to meet the task requirements of data mining, we must perform data conversion in a unified format. All date formats must follow certain rules, all measurement formats must be unified units, and all to themselves must be converted into long bytes. Type conversion is to convert one data type into another data type. Using the same data type can ensure the validity of the data and better meet the needs of data mining tasks.

3.2. Application Analysis of Enterprise Production Cost Data Information Management Module. In the application analysis of the production cost data informatization management module, enterprises need to preprocess the data, calculate according to the value, then obtain the minimum attribute value, consolidate the records, and finally detect the enterprise data information management system through the algorithm.

3.2.1. Data Preprocessing. We use the encoding of some attribute data to store the data and then use the dictionary for comparison in the process of comparison. We first need to preprocess the encoding of the data. Some quantitative attributes are discretized, and all attributes are divided into different categories. Table 1 shows the result of discretizing the character attribute values. Table 2 shows the values of the converted sample data.

3.2.2. Data Mining and Cost Knowledge Transformation. After preprocessing the data, we need to calculate based on the value, then get the smallest attribute clip, and merge the records. Table 3 shows our most simplified rule.

Transforming the original function into the objective function is as follows:

$$L(w, b, \alpha) = \frac{1}{2}\|w\|^2 + \sum_{i=1}^n \alpha_i (1 - y_i (W^T X_i + b)). \quad (3)$$

Among them, the partial derivative is as follows:

$$\left\{ \begin{array}{l} \frac{\partial L(w, b, \alpha)}{\partial w} = w - \sum_{i=1}^n \alpha_i y_i x_i, \\ \frac{\partial L(w, b, \alpha)}{\partial b} = \sum_{i=1}^n \alpha_i y_i. \end{array} \right. \quad (4)$$

Let it be 0 to get the following:

$$\left\{ \begin{array}{l} w = \sum_{i=1}^n \alpha_i y_i x_i, \\ b = \sum_{i=1}^n \alpha_i y_i. \end{array} \right. \quad (5)$$

Converted into a duality problem, the formula is as follows:

$$\max_{\alpha} -\frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n \alpha_i \alpha_j y_i y_j (x_i^T x_j) + \sum_{i=1}^n \alpha_i, \quad (6)$$

$$s.t. \quad \sum_{i=1}^n \alpha_i y_i = 0 \quad \alpha_i \geq 0, i = 1, 2, \dots, n.$$

The final dual problem is as follows:

$$\min_{\alpha} \frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n \alpha_i \alpha_j y_i y_j (x_i^T x_j) + \sum_{i=1}^n \alpha_i, \quad (7)$$

$$s.t. \quad \sum_{i=1}^n \alpha_i y_i = 0 \quad \alpha_i \geq 0, i = 1, 2, \dots, n.$$

The iterative optimization algorithm SMO can solve the dual problem of SVM, and the optimal solution satisfies the following:

$$y_j ((w^*)^T x_j + b^*) - 1 = 0. \quad (8)$$

Use KKT to get the following:

$$\left\{ \begin{array}{l} w^* = \sum_{i=1}^n \alpha_i^* y_i x_i, \\ b^* = y_j - \sum_{i=1}^n \alpha_i^* y_i (x_i^T x_j). \end{array} \right. \quad (9)$$

The final classification decision function is as follows:

$$f(x) = \text{sign} \left(\sum_{i=1}^n \alpha_i^* y_i ((x_i)^T x) + b^* \right). \quad (10)$$

Rewrite the formula optimization problem as follows:

TABLE 4: Confusion matrix.

Confusion matrix	Predictive value		
	Invade	TP	FN
Actual value	Invade	TP	FN
	Normal	FP	TN

$$\min_{w, b, \xi} \frac{1}{2}\|w\|^2 + C \sum_{i=1}^n \xi_i, \quad (11)$$

$$s.t. y_i (w^T x_i + b) \geq 1 - \xi_i \quad \xi_i \geq 0, i = 1, 2, \dots, n.$$

The dual problem of this optimization problem is as follows:

$$\max_{\alpha} \frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n \alpha_i \alpha_j y_i y_j (x_i^T x_j) + \sum_{i=1}^n \alpha_i, \quad (12)$$

$$s.t. \quad \sum_{i=1}^n \alpha_i y_i = 0 \quad 0 \leq \alpha_i \leq C, i = 1, 2, \dots, n.$$

The final classification decision function is as follows:

$$f(x) = \text{sign} \left(\sum_{i=1}^n \alpha_i^* y_i ((x_i)^T x) + b^* \right). \quad (13)$$

3.4. System Performance Simulation Results and Analysis

3.4.1. Experimental Data Set. The data characteristics in each data set are very close to the network attack data. The main advantages of data sets are as follows. Firstly, the new dataset deletes a large number of duplicate records in the original dataset and tests the duplicate records so that we can improve the performance of the system and save testing time. In the preprocessing process, each data set is evaluated only once, which can reduce the deviation. I have figured it out clearly. I cannot go yet. The total number of records in different difficulty sets is inversely proportional to the number of data sets, which will lead to great differences in the performance of tasks solved by different machine learning methods, which can be applied to evaluate the performance of machine learning methods. When setting the number of records, we must select appropriate parameters for setting and budget the complete data set to make it more reliable.

3.4.2. System Evaluation Indicators. A new data mining and management system based on data mining is proposed. We need to check the effectiveness of the intrusion detection method of the system. In the detection process, we use the confusion matrix to calculate its accuracy and other indicators. Table 4 shows the basis of our intrusion detection using a confusion matrix.

Calculated as follows:

The accuracy calculation formula is as follows:

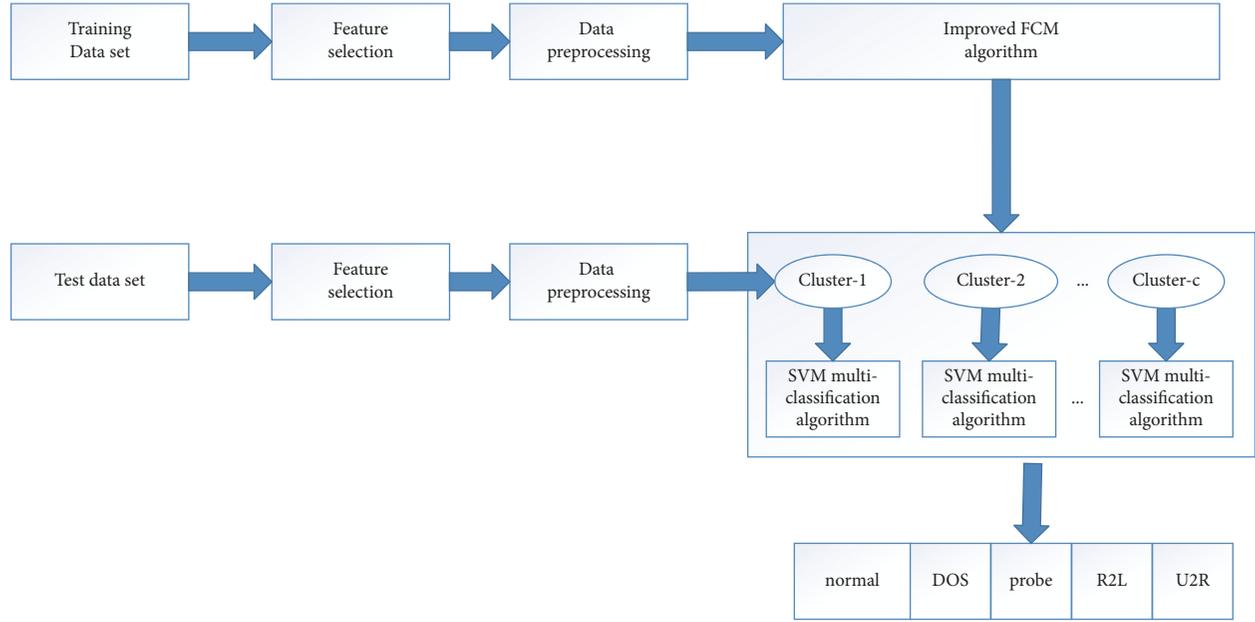

FIGURE 3: The structure diagram of the integrated intrusion detection method in the training and testing process.

TABLE 5: The clustering results of the improved FCM algorithm on the NSL-KDD data set.

Cluster	Normal	Probe	DOS	R2L	U2R
1	12	107	3370	1	0
2	5024	1	101	166	12
3	727	2038	933	266	1

TABLE 6: Confusion matrix of the method proposed in this paper.

Actual category/Forecast category	Normal	Probe	DOS	R2L	U2R
Normal	2453	7	3	6	1
Probe	8	910	2	1	0
DOS	1	0	1886	0	1
R2L	8	0	0	176	0
U2R	0	1	1	1	3

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FN + FP} \quad (14)$$

The calculation formula of the detection rate is as follows:

$$DR = \frac{TP}{TP + FP} \quad (15)$$

The formula for calculating the false alarm rate is as follows:

$$FPR = \frac{FP}{TN + FP} \quad (16)$$

The formula for calculating the false-negative rate is as follows:

$$FNR = \frac{FN}{TP + FN} \quad (17)$$

3.4.3. Integrated Intrusion Detection Method. We also need to test the effectiveness and feasibility of the system. We mainly use some test data sets to evaluate its performance. We use clustering to divide the data in the test data set, which will roughly classify different attack types, and then use the SVM model to further predict and estimate performance. The training and testing method of the system is shown in Figure 3.

3.4.4. Experimental Results and Analysis. The improved FCM algorithm can also divide the data set. Our main attack type is DOS. In normal network behavior, there are very few other attack types. In the third data set, probe type attacks are mainly used. The use of the SVM algorithm can ensure that all features of the system are learned, and the data is shown in Table 5.

TABLE 7: Use of big data technology to control procurement costs.

Procurement cost	Measures to reduce costs	Big data technology used
Order cost	Analyze the cost of purchase	Use big data for analysis
	Develop purchasing plan	Use data for analysis and prediction
Cost of purchase	Establish a database to record supplier information	Use big data technology for data storage, mining, and analysis
	Monitor and evaluate suppliers	Use big data for real-time monitoring
Transaction cost	Real-time price adjustment of products	Use big data for real-time monitoring
	Automatic replenishment of goods	Use big data to analyze and predict technology
Information cost	Feedback on procurement quality	Use big data for quality inspection and product identification

TABLE 8: Using big data technology to control inventory costs.

Inventory cost	Measures to reduce costs	Big data technology used
Customer's cost	Forecast inventory requirements	Use big data for analysis and mining
	Manage receipts	Utilize radio frequency identification technology
The cost of warehousing	Manage warehousing	Use big data for analysis
The cost of out of stock		Utilize big data analysis technology and radio frequency identification technology
Labor cost	Manage outbound	

TABLE 9: Using big data technology to control marketing costs.

Marketing cost	Measures to reduce costs	Big data technology used
The cost of market research	Forecast sales	Use big data technology for data storage and mining
	Optimize products and services	Use big data technology for data storage and mining
Marketing cost	Precision marketing	Use big data technology for data storage and mining

When the naive Bayes algorithm is used for intrusion detection, the false alarm rate is only about 6%, while the false alarm rate of intrusion detection methods based on vector machines is less than 1%. From the data presented in Table 6, we can see that the false alarm rate of the method proposed in this paper is close to the false alarm rate of the vector machine and even lower than the false alarm rate of the vector machine. The false alarm rate of the intrusion detection system is very normal and acceptable, and it will not affect our final results. If the false alarm rate is too high, it will not only take up network resources but also waste time. The false-positive rate of this method proposed by me is not high, and it does not cost much resources and time.

4. Research on Enterprise Cost Accounting Management Control and Optimization under the Background of Big Data Intelligence

4.1. The Overall Program Design of Enterprise Cost Management under the Background of Big Data. In the era of big data, our cost management can promote the development of enterprises and can also promote the optimization and reform of enterprise processes. Big data not only optimize the business process of an enterprise's supply chain but also enables more effective cost management. When a company conducts cost management, it includes all links, from research and development to procurement and finally to sales. All costs must be included. Enterprises should adopt some scientific and technological means, such as big data

technology to provide support for cost management, and promote the improvement of cost management technology through professional technology.

4.2. The Design of Each Module of Big Data in Enterprise Cost Management

4.2.1. Optimization of Cost Management in Procurement and Inventory Links. The cost of the supply chain mainly includes the cost of procurement and the cost of sales. The efficiency of the supply chain is also affected by the efficiency of the entire process. We must adjust our supply chain according to market demand so that we can better manage costs. We can share information through the big data information platform, build a supply chain model, and achieve the goal of reducing costs. In recent years, procurement has become a multiparty collaborative process. We need to establish some good partners to reduce our inventory. At the same time, we should strengthen the management of the supply chain to ensure that the supply of goods is sufficient. Table 7 shows the main cost components in the procurement process, and Table 8 shows the measures we use big data technology for inventory cost management in the era of big data.

4.2.2. Optimization of Cost Management in Marketing Links. In the process of cost management, we need to reduce the cost of research and the cost of sales. In this era of big data, we must reduce some nonessential costs, improve operational efficiency, use big data technology to provide

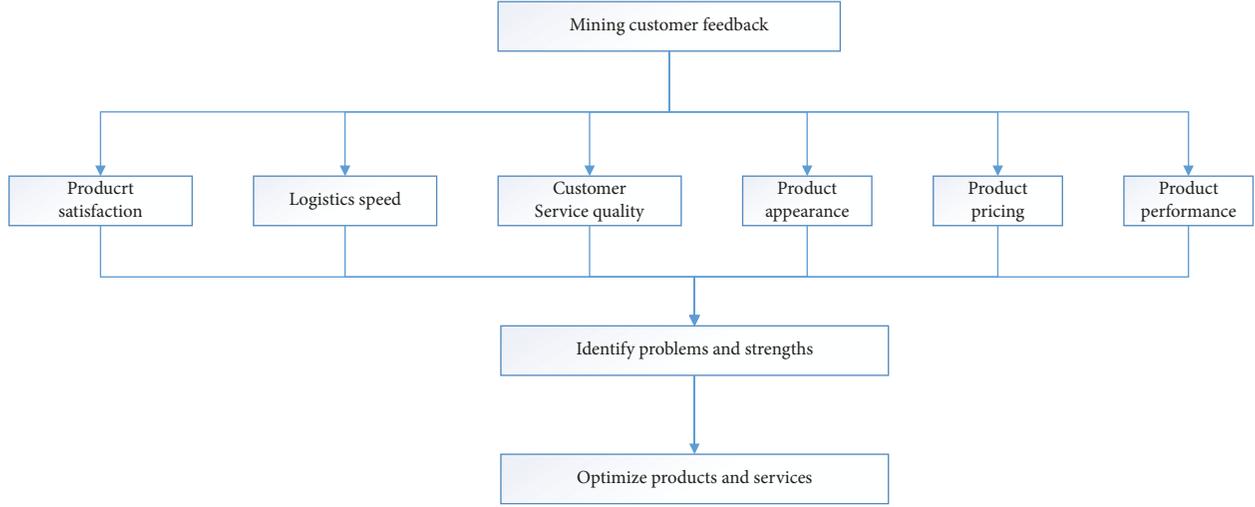

FIGURE 4: The application of big data in optimizing products and services.

reasonable solutions, and manage costs. Table 9 mainly shows the main measures to use big data technology to reduce costs.

In this era, the competition among enterprises has become increasingly fierce, and the phenomenon of product homogeneity has become more and more serious. The prices of the products of each company are very close, and the company cannot obtain an advantage from the price, so it can only provide better services and guide customers in choosing products. At the same time, consumers are also very concerned about service levels. Enterprises should pay attention to establishing service mechanisms and optimizing their products and services. The process is as in Figure 4.

4.2.3. *Data Cluster Analysis and Dissimilarity Measurement.* The objective function of the FCM algorithm is as follows:

$$\min J(U, V) = \sum_{i=1}^c \sum_{j=1}^n u_{ij}^m \|x_j - v_i\|^2. \quad (18)$$

The constructed unconstrained Lagrangian function is as follows:

$$F = \sum_{i=1}^c \sum_{j=1}^n u_{ij}^m \|x_j - v_i\|^2 + \alpha \left(\sum_{i=1}^c u_{ij} - 1 \right). \quad (19)$$

Its partial derivative is as follows:

$$\frac{\partial F}{\partial u_{ij}} = m(u_{ij})^{m-1} \|x_j - v_i\|^2 + \alpha. \quad (20)$$

$$\frac{\partial F}{\partial v_i} = -2 \sum_{j=1}^n u_{ij}^m (x_j - v_i). \quad (21)$$

Make it equal to 0 to get the following:

$$u_{ij} = \frac{1}{\sum_{k=1}^c \left(\|x_j - v_i\| / \|x_j - v_k\| \right)^{2/m-1}}. \quad (22)$$

$$v_i = \frac{\sum_{j=1}^n u_{ij}^m x_j}{\sum_{j=1}^n u_{ij}^m}. \quad (23)$$

In the process of using clustering to analyze, the selection of appropriate metrics determines the performance of clustering. The formula for calculating the Euclidean distance is as follows:

$$\begin{aligned} d(x_i, x_j) &= \|x_i - x_j\|_2 \\ &= \sqrt{\sum_{k=1}^q (x_{ik} - x_{jk})^2}. \end{aligned} \quad (24)$$

Calculate its Manhattan distance as follows:

$$d(x_i, x_j) = \sum_{k=1}^q |x_{ik} - x_{jk}|. \quad (25)$$

Calculate the Chebyshev distance as follows:

$$d(x_i, x_j) = \max_k (|x_{ik} - x_{jk}|). \quad (26)$$

Calculate its Minkovs distance as follows:

$$d(x_i, x_j) = \left(\sum_{k=1}^q |x_{ik} - x_{jk}|^r \right)^{\frac{1}{r}}. \quad (27)$$

4.3. *Implementation of Enterprise Cost Accounting Management Guarantee Strategy under the Background of Big Data.* According to the experimental results of 3.4.4, enterprises should build their own business and financial integration platforms, and in the process of cost management, they

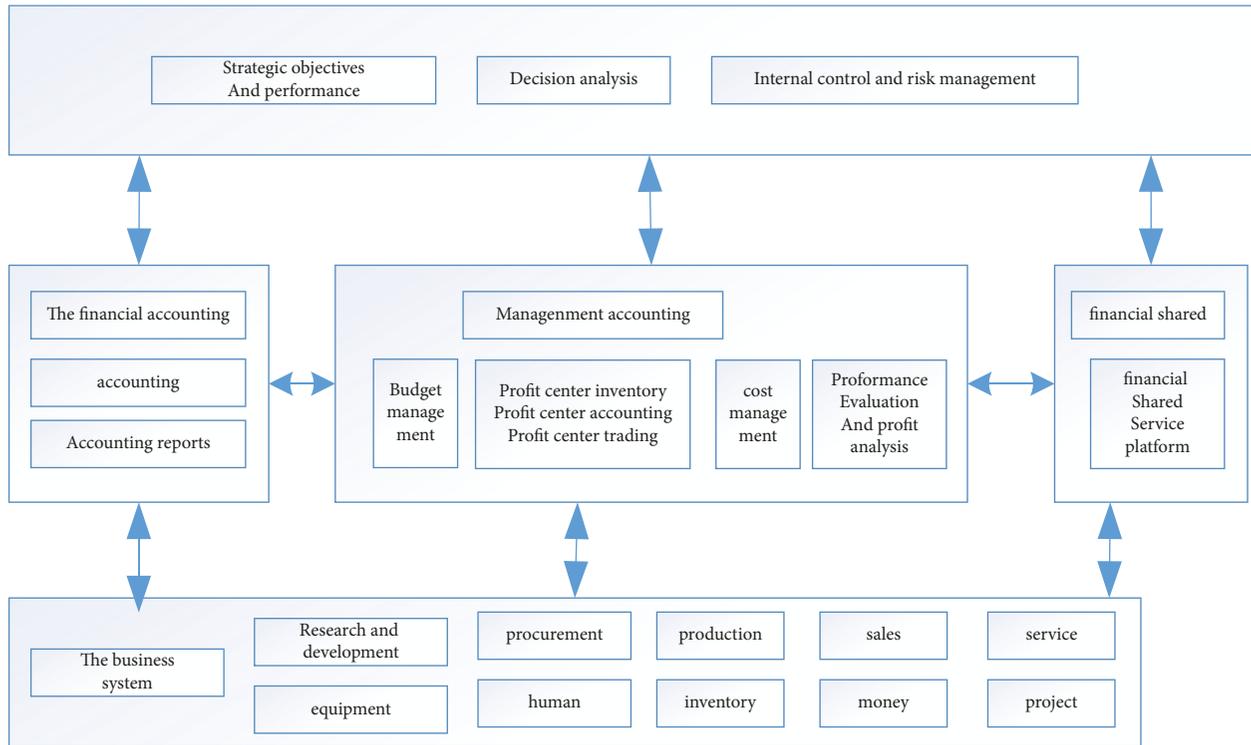

FIGURE 5: Industry and finance integration platform.

should strengthen informatization construction and talent team construction to ensure the efficient and stable operation of enterprise cost data.

4.3.1. Build an Integrated Platform for Business and Finance.

In the information age, companies will face a variety of data. How to deal with data is an important issue that companies need to solve. Companies should establish a platform for business and financial integration and use information technology to build their own management system. Enterprises should actively adopt some business intelligence technologies to handle the data monitoring that occurs, improve the relationship between the data in each process, promote the integration of the process, and use science and technology to optimize the processing of each process, realize the sharing of data resources, and truly play the role of financial management. Figure 5 shows the design process of a business integration platform.

4.3.2. Strengthen the Construction of Financial Management Informatization.

In the process of enterprise production management, financial management is very necessary. Most of the current financial management work is based on big data, and the traditional financial management model has not matched the development of modern enterprises. The traditional financial management model cannot provide effective information for corporate management and will increase corporate risks. The financial management system designed in the era of big data can not only standardize the financial management process but also provide reliable

financial management. Basis to further promote the development of finance: Informatization construction of an enterprise can promote the integration of enterprise resources, and it can also bring closer links between various departments. Financial management informatization can liberate financial personnel and promote the reform of financial management. The financial staff can better control the financial information, and the information processing ability can be further improved. It can be seen from this that it is very necessary to carry out informatization construction on the financial management of enterprises, which can promote the development of enterprises. When building a financial management information system, we need certain technical support. Integrating big data technology into the construction of the financial management information system can not only make the information management process more standardized but also promote the construction of the information management system. In order to ensure the effective operation of the informatization process, enterprises must control internal resources, understand their own needs, and constantly adjust their structure to adapt to the development of the times. Enterprises must also plan for the information work process and rationally divide labor so that everyone can stay in their own positions and develop and lay the foundation for subsequent financial work.

4.3.3. Strengthen the Construction of Big Data Talent Team.

With the advent of the era of big data, Internet technology has been further developed, technology is being updated faster and faster, and the competitiveness of enterprises is

also increasing. If an enterprise wants to occupy a favorable position in the competition, it must have strong R&D capabilities, as well as core technical support and innovation capabilities. In the process of product development and operation, companies must continuously invest in new knowledge and technology. In addition to enhancing their own R&D capabilities, companies should also attach importance to the training of high-quality talents to enhance their R&D capabilities and innovation capabilities. Enterprises should reduce production costs as much as possible and increase profits. In order to ensure the success of an enterprise, it is very important to cultivate talents. If an enterprise wants to establish a big data analysis platform and use big data technology for analysis, it needs to bring in corresponding talents. In the process of enterprise management, data analysis experts are needed to analyze the enterprise data. In the process of handling the company's business, if the company's financial management is lagging behind and is not familiar with the company's production model, some relevant talents can be introduced to make up for these problems. Enterprises should actively accelerate the construction of talents, establish high-quality teams and organize specialized talent teams so that talents can become familiar with the company's management mode and technology as soon as possible, and they must also understand advanced scientific knowledge to meet the needs of outstanding talents. In the process of managing the enterprise, massive amounts of data are generated every day. Financial personnel must ensure the accuracy of the data when performing analysis and at the same time, predict daily financial data. Using big data technology and data mining technology can find some potential problems in the process of financial management. At the same time, companies need to train some information technology talents to solve these problems and promote the development of technology.

5. Conclusion

In the process of enterprise management, if there is no systematic management in the process of cost management, it is impossible to process a large amount of data at one time. Some enterprises have not done an in-depth cost analysis, and some cost data cannot be solved. Combined with big data technology and cost management technology, this paper puts forward the optimal strategy of cost management in the era of big data. At the same time, the strategy is applied to the actual company. Big data technology and data sharing technology have solved the practical problems of enterprise management and production. Enterprises using big data technology can not only optimize management costs but also optimize their management functions, which can better solve the problems that many data will be repeatedly processed, data types are complex, and it is difficult to find useful information from massive data. At this stage, the amount of data in the enterprise is huge, the production cost is also very high, and the production process is very complex. Using big data technology for enterprise cost management can not only control the cost of enterprises but also standardize enterprise processes and promote enterprise

optimization. At the same time, we combine big data technology with cost management technology to provide the basis for the follow-up intelligent management of enterprises.

In order to explore the pollution of heavy metals in the soils around the mined rare-earth mines, this paper used the geoaccumulation index method, the Nemerow pollution index method, and the potential ecological risk index method during the high water period and the withered water period, respectively, to analyze and assess the pollution characteristics and ecological risks of Mn, Cu, Cr, As, Cd, Ni, Pb, and Zn in the soils of the study area. The results showed that all the eight heavy metals in the soil of the study area have accumulated to varying degrees, and the accumulation indices were $Pb > Mn > Zn > Cd > Cu > Ni > Cr > As$ in descending order, with Pb and Mn accumulating most seriously. According to the results of the Nemerow pollution index, more than 25% of the sampling points in the soil were lightly contaminated, the Nemerow index of heavy metal Pb was greater than 2, which was moderately contaminated, and Cd was lightly contaminated in the withered water period. The potential ecological risk index showed that the heavy metal Cd was moderately ecologically hazardous, while the other seven heavy metals were all mildly ecologically hazardous. The heavy metals Pb and Mn in the soils of the study area were more seriously polluted, and there was also a certain degree of heavy metal Cd pollution during the withered water period, and the more seriously polluted areas were mainly located around the open pit of the rare-earth mines. Based on Java, the software platform of soil heavy metal pollution characteristics and ecological risk assessment around rare-earth mines is realized. The overall structure of the platform is designed, the background development framework is planned based on SSM, and the database is designed with SQL Server.

1. Introduction

As one of the technical problems in ecological restoration and environmental management of mines, the excessive heavy metal contamination of soil in mining areas has been a widespread concern of experts and scholars at home and abroad [1]. How to solve the problem of heavy metal contamination in soil left behind by mining has become an important part of the development of ecological protection in China, so the identification of its pollution characteristics and ecological risk assessment has become the first priority to solve the pollution problem. Heavy metal contamination of soils can cause health hazards through the food chain [2]. The occurrence of food safety problems such as “cadmium

rice,” “blood lead,” and “cadmium wheat” in recent years has also sounded the alarm for the assessment and prevention of heavy metal pollution in soil [3]. When farmland is contaminated with heavy metals, these contaminants will enter the human body through the crops and thus cause harm to the human body. Some scholars have divided heavy metals into two parts according to the extent to which they are needed for crop growth: those that are extremely harmful to humans but less so for plant growth, such as Cd, Hg, and Pb, and those that are needed for both human and plant growth but are harmful to humans if they exceed certain standards, such as Zn and Cu [4].

Rare-earth mines, due to their special mining process, are extremely harmful to the ecological environment around

the mines, especially in terms of heavy metal contamination of the soil. On the one hand, the heavy metals present in the massive piles of tailings may migrate to the soil, causing heavy metal contamination of the soil [5]. On the other hand, the residual leaching agent in the ore will displace heavy metal ions such as Fe^{2+} , Cd^{2+} , Pb^{2+} , Zn^{2+} , Mn^{2+} , and Cu^{2+} , which will migrate to the soil in and around the mine area under the natural action of rainwater washing, resulting in heavy metal pollution of the soil [6–8].

At present, the assessment methods of heavy metal pollution in soils at home and abroad are mainly summarized as index method, model method, GIS-based analysis method, and other mathematical methods [9–12]. The index method can reflect the relationship between the actual measured value and the background value of heavy metal concentration in the soil of the region more intuitively and is more widely used in the assessment of heavy metal pollution in soils [13]. Some scholars have suggested that heavy metal pollution in soils is a complex process and different assessment methods need to be selected according to different pollution situations. However, there are limitations in a single assessment method, so a combination of multiple assessment methods is adopted to make the assessment results more relevant to the actual situation [14]. In this study, a total of 146 soil samples were collected during the high and withered water periods. The geoaccumulation index method, the Nemerow comprehensive pollution index method, and the potential ecological risk index method were used to analyze and assess the pollution characteristics and potential ecological risks of heavy metals Mn, Cu, Cr, Cd, Ni, Pb, Zn, and As in the soil, so as to provide a reference for the formulation of heavy metal pollution control and prevention measures for soils in the study area. At the same time, the software platform is preliminarily planned and developed, which provides practical support for the application of the theoretical method of this study.

2. Materials and Methods

2.1. Overview of the Study Area. Gannan, the geographical abbreviation for the southern region of Jiangxi Province (the abbreviation of Jiangxi Province is “Gan.”), is mainly composed of 18 counties (3 districts, 13 counties, and 2 county-level cities) under the jurisdiction of the prefecture-level Ganzhou City, with an area of 39,379.64 km², accounting for about 25% of the total area of Jiangxi Province [15]. The region is rich in mineral resources, and Ganzhou is known as the “Kingdom of Rare Earth,” with the reserves of ionic heavy rare earths being the highest in China [16]. The study area is located in the East Asian monsoon region, with a mild climate, abundant light, heat and rainfall, belonging to the humid climate of the central subtropical monsoon. The average annual precipitation in the region is 1500–1600 mm, but the spatial and temporal distribution is uneven, with large interannual variations and uneven rainfall distribution, with the most rainfall in June and the least in November to December throughout the year. The soil types are paddy soil, tidal soil, purplish soil, red soil, and hilly yellow soil, with soil pH mostly between 5 and 6.

2.2. Sample Collection and Experimental Analysis. In this study, the sampling points were mainly arranged along the area of farmland affected by the rare-earth mine and the area of the open pit, and a total of 146 soil samples were collected for testing and analysis during the high and withered water periods in 2020, respectively. The sampling points were mainly selected in places with obvious characteristics of the soil type being mined, and the terrain was relatively flat, stable, and well vegetated; the distribution of the sample collection points is shown in Figure 1. When the authors collected soil samples, the depth and sampling points of each sampling site were basically uniform, with the sampler entering the soil perpendicular to the ground, the collection depth was 0–20 cm, and the spacing between collection points was 500–2500 m.

The collected soil samples were air-dried, ground, and sieved in the laboratory, and the content of Mn, Cr, Cu, Zn, Pb, Ni, Cd, and As in the soil was measured according to the regional geochemical sample analysis method (DZ/T0279-2016) using an ICAP6300MFC two-way observation plasma emission spectrometer (D466), an Agilent 7700x inductively coupled plasma mass spectrometer (D483), and an AFS-8800 dual-channel Atomic Fluorescence Photometer (D460) to measure the content of Mn, Cr, Cu, Zn, Pb, Ni, Cd, and As elements in the soil, as well as an FE28 PH meter (acidity meter) (D554) to measure the pH of the soil samples according to the agricultural soil testing standard (NY/T1121.2–2006).

2.3. Assessment Methodology

2.3.1. Geoaccumulation Index Method. The geoaccumulation index (I_{geo}) method, which determines the contamination of heavy metals by the relationship between the total concentration of heavy metals in the soil and the background value, is an effective way to determine the level of heavy metal contamination in the soil and to classify the level of contamination according to the value of the geoaccumulation index (I_{geo}). [17, 18] The geoaccumulation index equation is

$$I_{\text{geo}} = \log_2 \frac{w_i}{kB_i}, \quad (1)$$

where I_{geo} is the geoaccumulation index, dimensionless. w_i is the measured value of heavy metal i in the soil sample, $\text{mg}\cdot\text{kg}^{-1}$; B_i is the background value of heavy metal i in the surface soil of Ganzhou City, $\text{mg}\cdot\text{kg}^{-1}$; k is a coefficient characterizing the difference in soil background values due to differences in rock backgrounds in different places, and the value of k in this study is 1.5 [19, 20].

The assessment criteria are shown in Table 1.

2.3.2. Nemerow Comprehensive Pollution Index. The Nemerow pollution index is the most common method for comprehensive soil pollution assessment at home and abroad. The assessment method highlights the maximum pollution effect and is in line with the criteria of the maximum pollution level as the soil pollution level for soil

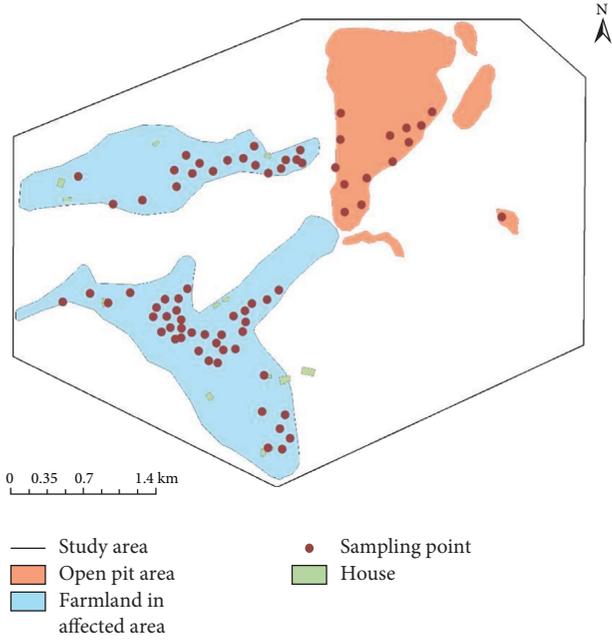

FIGURE 1: Distribution of soil sampling sites in the study area.

TABLE 1: Criteria for assessment of soil pollution with geo-accumulation index.

The values of I_{geo}	Class	The cumulative degree
$I_{geo} < 0$	I	Clean
$0 \leq I_{geo} < 1$	II	Mild accumulation
$1 \leq I_{geo} < 2$	III	Mild-to-moderate accumulation
$2 \leq I_{geo} < 3$	IV	Moderate accumulation
$3 \leq I_{geo} < 4$	V	Mild-to-heavy accumulation
$4 \leq I_{geo} < 5$	VI	Heavy accumulation
$I_{geo} \geq 5$	VII	Severe accumulation

assessment in China. The Nemerow index is calculated by the following formula:

$$P = \frac{C_i}{S_i},$$

$$P_Z = \sqrt{\frac{P_j^2 + P_{i_{max}}^2}{2}},$$
(2)

where P is the one-factor index for that sampling point, dimensionless. C_i is the measured value of heavy metal i at that point, $\text{mg}\cdot\text{kg}^{-1}$. S_i is the standard value of heavy metal i . In this study, S_i is the risk screening value of heavy metal i in the Soil Environmental Quality Standard (GB 15618-2018) (the background value of heavy metal Mn in the surface layer of Ganzhou soil is used), $\text{mg}\cdot\text{kg}$; and P_Z is the Nemerow index for the point, dimensionless. P_j is the mean value of the single factor index at the point, dimensionless. $P_{i_{max}}$ is the maximum value of the single factor index for heavy metal i at the site [21–24], dimensionless; the assessment criteria for the Nemerow index are shown in Table 2.

2.3.3. *Potential Ecological Risk Index.* The potential ecological risk index is a method proposed by the Swedish

TABLE 2: Criteria for assessment of soil pollution with Nemerow pollution index.

The values of Nemerow pollution index	Pollution class	Pollution levels
$P_Z \leq 0.7$	I	Clean
$0.7 < P_Z \leq 1$	II	Moderately clean
$1 < P_Z \leq 2$	III	Slightly polluted
$2 < P_Z \leq 3$	IV	Moderately polluted
$P_Z > 3$	V	Heavily polluted

scientist Hakanson, which takes into account not only the content of heavy metals in the soil but also the toxicity level, the concentration of contamination, and the sensitivity of the environment to heavy metal contamination [25–30]. The expression is as follows:

$$RI = \sum_{i=1}^n E_i,$$

$$E_i = T_i \times C_{f,i},$$
(3)

where RI is the composite potential ecological risk hazard index, dimensionless. E_i is the potential ecological hazard index of heavy metal i in the soil at the sampling site, dimensionless. $C_{f,i}$ is the ratio of the measured value of heavy metal i in the soil at the sampling site to the background value of heavy metal i in the surface soil of Ganzhou City, dimensionless. T_i is the toxicity response coefficient of heavy metal i , dimensionless, where the toxicity coefficients of Mn, Cu, Cr, As, Cd, Ni, Pb, and Zn are 1, 5, 2, 10, 30, 5, 5, and 1, respectively. [29] The assessment criteria for the comprehensive potential ecological risk index RI and the potential ecological risk index E_i [31–39] are shown in Table 3.

3. Results and Discussion

3.1. Characteristics of Heavy Metal Content in Soils

3.1.1. *Characteristics of Heavy Metal Content in Soils during the High Water Period.* The average contents of heavy metals Mn, Cu, Cr, As, Cd, Ni, Pb, and Zn in the soils of the study area during the high water period were 448.97, 18.92, 30.33, 3.00, 0.14, 13.13, 92.99, and $64.18 \text{ mg}\cdot\text{kg}^{-1}$, which were 1.85, 1.25, 0.88, 0.34, 1.56, 1.06, 2.72, and 1.11 times higher than the background values of heavy metal contents in the surface layer of soils in Ganzhou City, respectively, which can be seen in Table 4 [33]. Among them, the contents of heavy metals Cd, Cr, Cu, Ni, Zn, and As were all lower than the screening values for soil pollution risk on agricultural land (GB15618-2018), while 37 sampling points of heavy metal Pb exceeded the screening values for soil pollution risk on agricultural land, with an exceedance rate of 50.68%, and the maximum content value of Mn was 5.57 times higher than the soil background value. The above data indicate that there is a certain degree of contamination of heavy metals Pb and Mn in the soil during the high water period. The heavy metals in descending order of coefficient of variation are Cd, Cr, As, Mn, Pb, Cu, Ni, and Zn, with Cd having a coefficient of variation of 446%, which is a very

TABLE 3: Criteria for assessment of soil pollution with the potential ecological risk index.

The values of RI	The values of E_i	Pollution levels
$RI < 150$	$E_i < 40$	Light pollution
$150 \leq RI < 300$	$40 \leq E_i < 80$	Moderate pollution
$300 \leq RI < 600$	$80 \leq E_i < 160$	Moderate-to-heavy pollution
$600 \leq RI < 1200$	$160 \leq E_i < 320$	Heavy pollution
$RI \geq 1200$	$E_i \geq 320$	Extreme-intensity pollution

TABLE 4: Characteristics of heavy metals in the soil surface layer of the study area.

Sampling time	Projects Projects	Content ($\text{mg}\cdot\text{kg}^{-1}$) content ($\text{mg}\cdot\text{kg}^{-1}$)							
		Mn	Cu	Cr	As	Cd	Ni	Pb	Zn
High water period	Minimum value	164	3.54	3.6	0.96	0.025	2.23	45.1	42
	Maximum value	1354	44.7	135.8	13.4	0.27	27.9	377.6	95
	Average value	448.97	18.92	30.33	3.00	0.14	13.13	92.99	64.18
	Standard deviation	239.75	9.33	22.44	1.80	0.58	6.40	47.36	11.00
	Coefficient of variation	53%	49%	74%	60%	414%	49%	51%	17%
Withered water period	Minimum value	126	1.16	5.09	1.02	0.113	<2	35.7	32.4
	Maximum value	1111.3	41.7	71	12.2	0.541	24.2	214	96
	Average value	471.12	16.48	27.28	3.12	0.26	11.97	94.01	61.07
	Standard deviation	289.18	9.31	15.36	1.61	0.09	5.63	35.90	12.52
	Coefficient of variation	61%	56%	56%	52%	35%	47%	38%	21%
Background values for topsoil in Ganzhou		243	15.17	34.56	8.85	0.09	12.35	34.19	58.05
Background values for topsoil in Jiangxi		259	20.8	48.0	10.4	0.10	19.0	32.1	69.0
Background values for topsoil in China		540	20.0	53.9	9.2	0.07	24.9	23.6	67.7

strong variation. The larger the coefficient of variation value is, the more unevenly distributed the heavy metal is in the region and the greater the anthropogenic influence is [34, 35].

3.1.2. Characteristics of Heavy Metal Content in Soils during the Withered Water Period. The average contents of heavy metals Mn, Cu, Cr, As, Cd, Ni, Pb, and Zn in the soils of the study area during the withered water period were 456.24, 16.48, 27.28, 3.12, 0.26, 11.97, 94.01, and 61.07 $\text{mg}\cdot\text{kg}^{-1}$, respectively, which were 1.94, 1.09, 0.79, 0.35, 2.89, 0.97, 2.75, and 1.05 times higher than the background values of heavy metals in the surface soils of Ganzhou City, as shown in Table 4 [35, 36]. Among them, the content values of the heavy metals Cr, Cu, Ni, Zn, and As were all lower than the screening value of soil pollution risk on agricultural land (GB15618-2018). 37 sampling points of Pb exceeded the screening value of soil pollution risk on agricultural land, with an exceedance rate of 50.68%, 15 sampling points of heavy metal Cd exceeded the risk screening values for soil contamination on agricultural land, with an exceedance rate of 20.55%, and the maximum value of heavy metal Mn content was 4.57 times higher than the background value of the soil. The above data indicate that there is a certain degree of pollution of heavy metals Pb, Cd, and Mn during the withered water period. The heavy metals in descending order of coefficient of variation are Mn, Cu, Cr, As, Ni, Pb, Cd and Zn, with Mn having the largest coefficient of variation of 61%. Some studies have shown that a coefficient of variation

of over 50% indicates that the spatial distribution of this heavy metal content is very heterogeneous and the possibility of point source pollution exists [36].

3.1.3. Differential Characteristics of Heavy Metal Content in Soil during the High and Withered Water Periods. The mean values of Cu, Cr, Ni, and Zn in the soils of the study area were lower in the withered water period than in the high water period, while the contents of the heavy metals Mn, As, Cd, and Pb were higher than in the rich period. The above data show that the content of heavy metals in the soils of the study area fluctuates to a certain extent between the high and withered water periods, with the average content of Cd in the withered water period being 1.86 times higher than that in the high water period, while the content of the other seven heavy metals fluctuates less. The heavy metal pollution in the soil during the high water period is mainly Pb and Mn, while the heavy metal pollution in the soil during the withered water period is mainly Pb, Mn, and Cd. Cd pollution occurs in the withered water period compared to the high water period, and the Cd pollution in the soil during the withered water period is mainly distributed in the open pit mining area of the mine.

3.2. Assessment of Heavy Metal Contamination of Soils

3.2.1. Geoaccumulation Index Assessment. The geoaccumulation index values for the heavy metals Mn, Cu, Cr, As, Cd, Ni, Pb, and Zn in the soil during the high water

period were 0.15, -0.51, -1.15, -2.32, -0.15, -0.74, 0.74, and -0.46, respectively, while the geoaccumulation index values for Mn, Cu, Cr, As, Cd, Ni, Pb, and Zn in the soil during the withered water period were 0.10, -0.89, -1.21, -2.23, -0.86, -0.88, 0.78, and -0.54, respectively, as shown in Table 5. Except for the heavy metal As in the withered water period, the accumulation of heavy metals Mn, Cu, Cr, Cd, Ni, Pb, and Zn occurred to varying degrees in the high and withered water periods; see Figures 2 and 3. Among them, the accumulation of heavy metals Pb and Mn was the highest and that of As was the lowest. 95.89% and 97.26% of the sampling sites showed varying degrees of accumulation of heavy metal Pb and 53.43% and 45.21% of the sampling sites showed varying degrees of accumulation of heavy metal Mn during the high water and withered water periods, respectively.

3.2.2. Comprehensive Assessment of the Nemerow Pollution Index. The results of the Nemerow pollution index show that 39.72% of the sampling points were under alert and 26.03% were lightly polluted during the high water period; 39.72% of the sampling points were under alert and 30.14% were polluted to varying degrees during the dry water period, of which 28.77% were lightly polluted and 1.37% were moderately polluted; see Figure 4. The Nemerow pollution index values for Cu, Pb, Zn, Cr, Ni, Cd, and As were 0.68, 2.03, 0.39, 0.66, 0.36, 0.71, and 0.24, respectively, during the high water period and 0.63, 2.19, 0.40, 0.36, 0.32, 1.22, and 0.22, respectively, during the withered water period, as shown in Table 6. The heavy metal Pb was moderately polluted, and Cd was under alert during the high water period and lightly polluted during the withered water period. The Nemerow pollution index of Mn was evaluated according to the Ganzhou soil surface background value as the standard value, and its Nemerow pollution index values were 4.16 and 3.51 during the high water period and withered water period, respectively, indicating that there is also a certain degree of Mn pollution in the soil.

3.2.3. Potential Ecological Risk Index Method. The comprehensive potential ecological risk index RI and potential ecological hazard index E_i were calculated based on the potential ecological risk hazard index formula; see Table 7. According to the comprehensive potential ecological risk index RI, all the sampling sites in the study area were mildly ecologically hazardous during the high water period, 82.19% of the sampling sites were mildly ecologically hazardous during the withered water period, and 17.81% of the sampling sites were moderately ecologically hazardous. According to the potential ecological hazard index E_i , the heavy metals Mn, Cu, Cr, As, Ni, and Zn were all mildly ecologically hazardous; Pb was mildly ecologically hazardous in 98.63% of the sampling sites during the high water period, moderately hazardous in 1.37% of the sampling sites, and mildly hazardous in all sampling sites during the withered water period. Cd was mildly ecologically hazardous in 36.99% of the sampling sites during the high water period,

moderately ecologically hazardous in 58.90% of the sampling sites, and moderately to heavily ecologically hazardous in 4.11% of the sampling sites, while it was lightly ecologically hazardous in 1.37% of the sampling sites during the withered water period, moderately ecologically hazardous in 53.42% of the sampling sites, moderately to heavily ecologically hazardous in 43.84% of the sampling sites, and heavily ecologically hazardous in 1.37% of the sampling sites. Although the content of the heavy metals Pb and Mn in the soil was high, their toxicity coefficient values were small and therefore the ecological hazard risk was low. The potential ecological hazard index for the heavy metal Cd was evaluated to be high due to the large toxicity coefficient values of Cd.

4. Software Platform

4.1. Overall Structure. The user requirements of heavy metal pollution characteristics and ecological risk assessment platform contain functional and nonfunctional requirements [40–43]. Functional requirements analysis is based on the most basic in-depth study of the functions required by the system, that is, the requirements with specific contents and functions that the system must contain. From the perspective of system nonfunctionality, nonfunctional requirements analysis mainly covers the development and use principles of the system and the characteristics of the system.

As shown in Figure 5, the platform is divided into four functional modules: system login module, heavy metal pollution characteristics and ecological risk monitoring module, heavy metal pollution characteristics and ecological risk standard evaluation module, and heavy metal pollution characteristics and ecological risk early warning module.

Nonfunctional analysis mainly restricts the platform from the perspectives of performance, availability, and maintainability [44–47].

- (1) Security. User authentication and data required by the system need to be encrypted in the transmission process, and the security of users and data needs to be effectively guaranteed.
- (2) Compatibility and flexibility. The system can operate on different types of terminal equipment, support multiple hardware platforms, and support information sharing with data of other systems.
- (3) Real time and effectiveness. The data transmission and display shall be effective in real time. When the data is obtained, the background will automatically start the online assessment and evaluation calculation.
- (4) Maintainability. The system shall adopt the principle of high coupling and low cohesion, with high independence between modules for later modification and maintenance.

The overall structure of the platform is shown in Figure 6. The structures of heavy metal pollution characteristics and ecological risk standard evaluation and ecological risk standard evaluation modules are divided into three parts:

TABLE 5: The geoaccumulation index of the heavy metals in soils.

Sampling time	The average values of geoaccumulation index							
	Mn	Cu	Cr	As	Cd	Ni	Pb	Zn
High water period	0.15	-0.51	-1.15	-2.32	-0.15	-0.74	0.74	-0.46
Withered water period	0.10	-0.89	-1.21	-2.23	-0.86	-0.88	0.78	-0.54

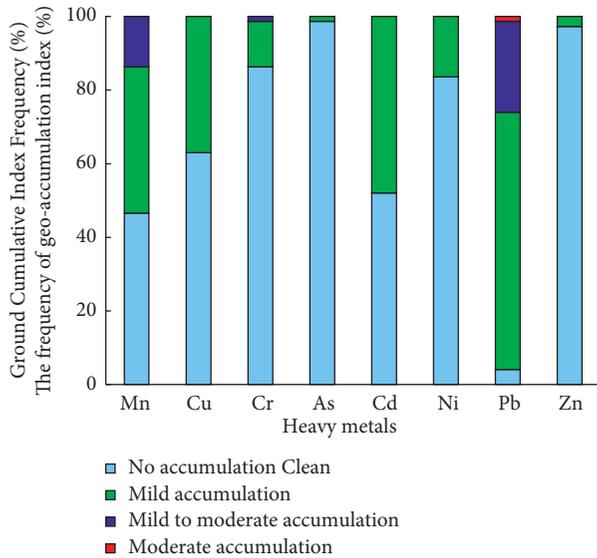

FIGURE 2: Frequency distribution of geoaccumulation index of heavy metals in the high water period.

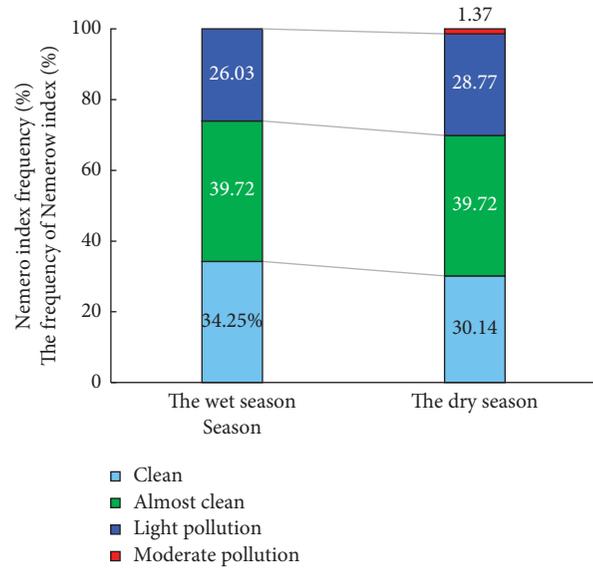

FIGURE 4: Frequency distribution of Nemerow pollution index of heavy metals in the study area.

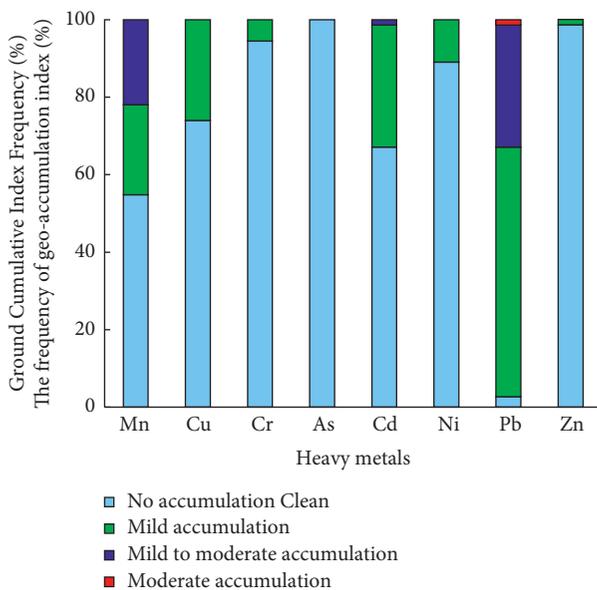

FIGURE 3: Frequency distribution of geoaccumulation index of heavy metals in the withered water period.

monitoring layer, transmission layer, and user layer. Each monitoring section of the monitoring layer can monitor the type and concentration of heavy metal pollution targets.

TABLE 6: Nemerow pollution index of the heavy metals in soils.

Sampling time	P_i						
	Cu	Pb	Zn	Cr	Ni	Cd	As
High water period	0.68	2.03	0.39	0.66	0.36	0.71	0.24
Dry period	0.63	2.19	0.40	0.36	0.32	1.22	0.22

Different sensors transmit the monitoring data to the data center through the environmental monitoring collector. In the development and design of the platform, the required monitoring data are obtained from the database interface, and the monitoring information and calculation results are displayed on the front-end display screen of the mobile application through model calculation on the back of the platform.

4.2. *SSM Background Development Framework.* SSM framework includes two open-source frameworks, Spring and MyBatis [45–47]. Spring architecture is based on a container that uses JavaBean attribute and can develop any Java application. The core idea of Spring is IOC (inversion of control), which gives Spring the right to create objects without having to “new” an object by themselves. Spring provides unique data access abstraction and transaction management abstraction and can provide a consistent model in various underlying transactions such as JDBC. Spring

TABLE 7: Potential ecological risk index of the heavy metals in soils.

Sampling time	Projects	Comprehensive potential ecological risk index RI	Potential ecological hazard index E_i								
			Mn	Cu	Cr	As	Cd	Ni	Pb	Zn	
High water period	Minimum value	31.00	0.67	1.17	0.21	1.08	8.33	0.90	6.60	0.72	
	Maximum value	129.83	5.57	14.73	7.86	15.14	90.00	11.30	55.22	1.64	
	Average	77.94	1.88	6.24	1.76	3.39	45.28	5.31	13.60	1.11

	Maximum value	203.60	4.57	13.74	4.11	13.79	180.33	9.80	31.30	1.65	
	Average	118.15	1.94	5.43	1.58	3.52	86.23	4.85	13.75	1.05	

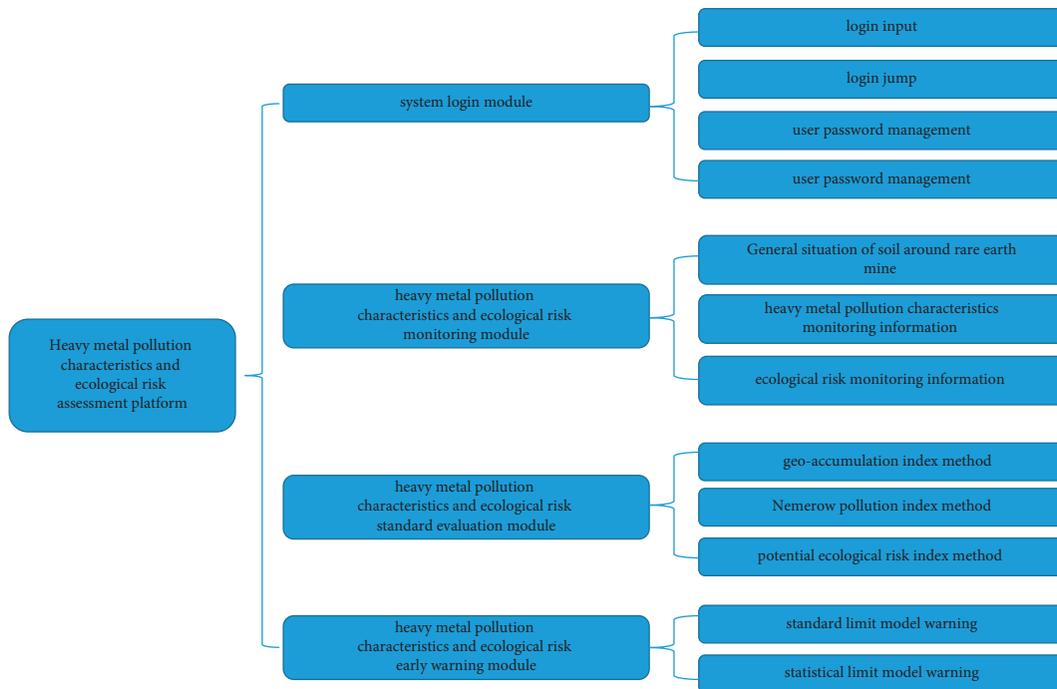

FIGURE 5: Functional modules of the platform.

framework solves the complexity of enterprise development and makes J2EE development easier to use.

MyBatis is an encapsulation of JDBC, which makes the underlying operation of the database transparent. It only needs to provide SQL statements, avoiding manually setting parameters and obtaining result sets. MyBatis supports customized SQL, stored procedures, and advanced mapping. MyBatis uses XML to configure and map files, builds SqlSessionFactory instances, obtains SqlSessions, and executes mapped SQL statements. Its functions are divided into API interface layer, data responsibility layer, and basic support layer.

MVC, namely, model view controller, is a framework that integrates model, view, and controller into independent

programs. It provides loose coupling between these three elements, reduces code repeatability, simplifies grouping development, and provides a clear logical framework for software design and development.

- (1) *M* refers to the model side, including DAO classes and databases. DAO accesses the database to manipulate data and abstract business logic into a model.
- (2) *V* refers to the visual layer, which visualizes the data model and renders it in the user interface.
- (3) *C* is the controller, which can update the model to the view layer. It is not only the link between the model layer and the view layer but also the bridge between the user and the system. It receives and processes the

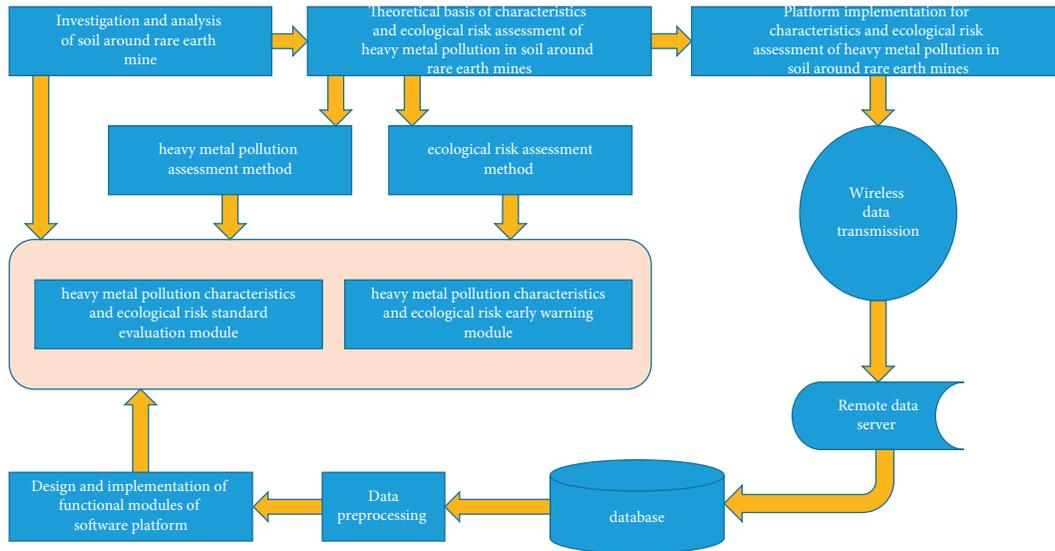

FIGURE 6: The overall structure of the platform.

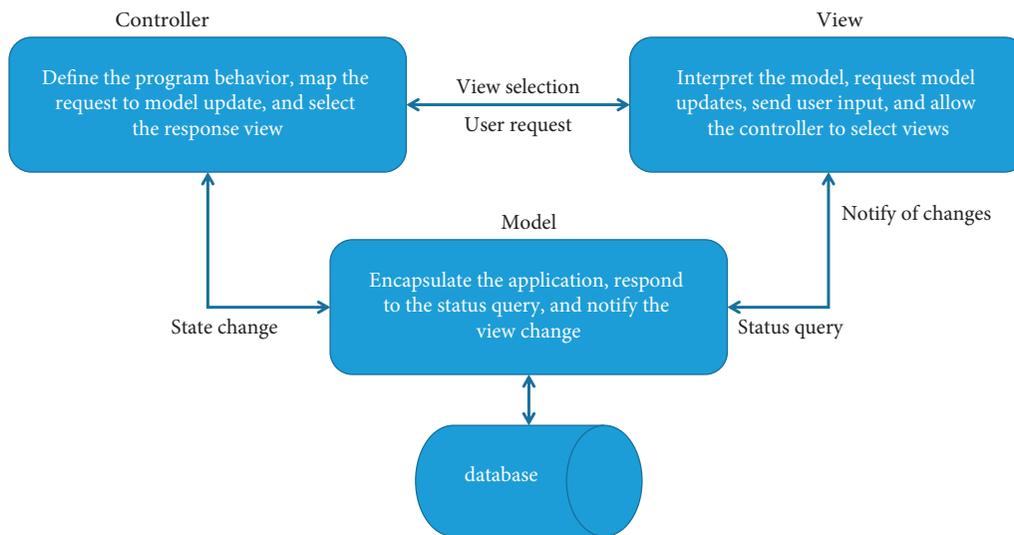

FIGURE 7: MVC component relationship.

response to the user’s request, calls the DAO method to obtain the required data from the database, processes the library, and then returns to JSP for display in the view layer.

As shown in Figure 7, the basic idea is that the controller receives the user’s request, decides how to process it, calls the data interface in the model layer through the DAO, processes and modifies the data, and sends it to the view layer for presentation. When the data of the model layer changes, it will be transmitted to the view layer in the form of time notification, and the view layer will modify the user interface accordingly.

4.3. Database Design. The database can be regarded as an electronic warehouse, which stores an organized and shareable data set for a long time in a certain way. Users can add, delete, modify, and query the data in the file. This study uses relational database and SQL Server for database operation. By combining the required data, it is determined that the monitoring data information table, heavy metal pollution characteristics and ecological risk assessment table, and heavy metal pollution characteristics and ecological risk early warning table need to be established, and the field name, identifier, type and length, null value, and primary key of each table are designed and compiled as shown in Tables 8–10.

TABLE 8: Monitoring data information table structure.

Serial number	Field name	Identifier	Type and length	Primary key
1	Soil area number	JC_CD	Varchar (40)	Y
2	Soil area name	JC_NM	Varchar (40)

3	Over standard warning index	YJ_CB	Char	
4	Excess multiple	YJ_BS	Varchar (40)	
5	Time	JC_TM	Date time	

5. Conclusion

The main findings of this study include the following:

- (1) The contents of heavy metals Cr, Cu, Ni, Zn, and As in the soils of the study area were all lower than the risk control screening values for agricultural land, 50.68% of the sampling sites exceeded the risk control screening values for agricultural land soils for the heavy metal Pb, and 20.55% of the sampling sites exceeded the risk control screening values for agricultural land soils for Cd during the withered period. The maximum value of Mn content was 5.57 times higher than the soil background value, and its contaminated sites were mainly located in the sampling area of the mine open pit, indicating that the mining of rare-earth mines has caused a certain degree of enrichment of heavy metals in the soil.

- (2) The results of the geoaccumulation index assessment showed that the accumulation of heavy metals Mn, Cu, Cr, As, Cd, Ni, Pb, and Zn in the soils of the study area occurred to varying degrees, and the geoaccumulation indices of these eight heavy metals were, from largest to smallest, $Pb > Mn > Zn > Cd > Cu > Ni > Cr > As$, with the accumulation of Pb and Mn being the most serious.
- (3) The assessment results of the Nemerow pollution index showed that 26.03% and 28.77% of the sampling points in the study area were lightly polluted during the high water period and the withered water period, respectively, with one sampling point being moderately polluted during the withered water period. The Nemerow pollution index values for Pb, Cd, Cu, Cr, Zn, Ni, and As were 2.11, 0.97, 0.66, 0.51, 0.40, 0.34, and 0.23 respectively, with Pb being moderately polluted, Cd and Cu being in the alert

state, and the other four heavy metals being in the clean state.

- (4) The results of the assessment of the potential ecological risk index showed that only the heavy metal Cd was moderately contaminated in the soil of the study area, while the other seven heavy metals such as Cu, Cr, and As were all lightly contaminated.
- (5) The accumulation of heavy metals Pb and Mn in the soils of the study area was relatively serious, and there was also heavy metal Cd pollution during the withered water period, but the toxicity coefficients of Pb and Mn were small, and their potential ecological risks were small, while the potential ecological risks of Cd were large. The authors suggest that land use planning in the study area should take full account of the contamination of heavy metals in the soil and take a certain degree of antipollution measures, vigorously advocate clean mining, gradually reduce the damage to the ecological environment caused by traditional mining techniques, and emphasize the development of the concept of "treatment and recovery while mining." At the same time, the local climate conditions are combined with the selection of suitable plant or microbial species to explore the promotion of bioremediation of the soil, advocating the concept of mine ecological restoration of green mines and green restoration.

The software platform planned and developed by this research institute can provide practical support for the application of the theoretical methods of this research.

At present, with the popularity of multimedia, people's appreciation and interest in ink painting art have been deepened. In the research of art works, this paper proposes a rendering method of three-dimensional ink painting effect based on deep learning model, which can simulate the painting skills of ink painting in terms of intensity and distance. Specifically, first construct a two-dimensional ink texture, then map the horizontal component of the texture using the contour information of the model, and finally adjust the ink tone by controlling the coordinates of the vertical component of the texture through the attribute function. Linear attribute function, quadratic attribute function, and attribute function with light source factor are used for simulation. The results show that this method can be used for ink and wash simulation of three-dimensional scene, making the image more layered and more in line with the artist's actual technology.

1. Introduction

The use of computer programs to simulate hand-made artworks is one of the key goals of nonrealistic drawing techniques. To date, researchers in the field of computer graphics have developed many nonrealistic algorithms to simulate Western artworks, such as oil paintings, watercolours, drawings, and prints.

In the last decade, many scholars in China have also started to work on nonrealistic algorithms for traditional Chinese ink painting styles. One approach is to extract the contour lines of the model [1, 2], then stylize the contour lines [3], and then control the stylized parameters to simulate the drawing of the brush. This approach is more complex to implement, and the extraction of contour lines in the graphics space and the visible judgement of stylisation can affect the real-time rendering speed. The second method is based on the traditional cartoon rendering algorithm [4, 5], which controls the ink texture mapping by designing a specific lighting function to achieve the ink style rendering effect, which is simple, realistic, and has good real-time performance.

In 1997, Curtis pioneered the use of Kubelka-Munk (KM) theory in the simulation of watercolours [6]. In that

paper, the user selects the reflection values of the pigments against a black and white background so that the K and S values can be calculated, and the final colour output is then calculate using the superimposition and mixing formulae of the KM colour model. In 2003, Rudolf used the same theory for the simulation of crayon paintings based on Curtis, who used KM theory to solve the problems that arose when composing two layers of images. 2004 saw Yamamoto use the KM theory for the simulation of watercolours. In 2004, Yamamoto also used KM colour theory in his study of the conversion of digital images into pencil drawings, but it allowed for user-defined colour transparency, i.e., assuming that the value of the colour parameter would not change on a white background, but setting a parameter to a certain scale on a black background, thus controlling the transparency of the colour. The above are all simulation of Western painting, in the case of ink painting [7], Suarez [8] tried to introduce the KM colour model during the final colouring.

The study of diffusion of different pigments was presented by [9], but did not really address the diffusion and superimposition effects of different pigments. Only a single KM colour model was used to simulate the colour of different pigments. Since there is no substantial improvement

of the diffusion model, the simulation of the final effect cannot be satisfactorily obtained.

The literature [10] gives an interactive 3D virtual brush model that uses subdivision surfaces around a skeleton based on a spring system to represent the geometry of the brush; this method is not suitable for generating the bifurcation effect of the brush. [11] proposed calculating the deformation of the brush hair based on the physical properties of the springs based on the theory of elasticity, which is difficult to achieve in real time when the number of hair is large. [12] proposed a model based on the bristle entity, which simulates the bifurcation using replication parameters to generate bristles with the same structure resulting in a lack of close correlation between the bristles and an unrealistic shape of the bifurcated bristles. The quill model constructed by [13] constrains the spring deformation by means of energy minimisation. This method is only applicable to small-scale deformations and works better for simulating wet brushes without bifurcation.

The first paper model of 2D fibre structure was proposed by [14] that plane was proposed to be divided into small regions, and a large number of curves with random orientations were distributed within each region to simulate fibre bundles. Then [15–17] and others proposed their own paper models. This type of paper model achieves better results to some extent, but there are still several fundamental problems: first, it does not consider the effect of different types of rice paper on the diffusion effect and is an uncontrollable paper model that lacks scalability; second, it also does not take into account how to represent the paper texture.

In Pingping [18], based on a summary of previous work, the smallest unit of the paper plane is partitioned into paper cells (one pixel corresponds to multiple paper cells), while multiple adjacent paper cells containing paper fibres form fibre clusters, which are connected by fibre bundles, and the transport of ink and water takes place between the fibre clusters through the fibre bundles.

The first one-dimensional brush depiction models were proposed by [19], where a brush is defined as a one-dimensional array of brush hairs; in a method based on the contour of a brush path [20], the path is described as a number of continuous Bezier or B-spline curves. [21] modeled the brush as consisting of a number of bristles randomly distributed over a circular area, with each bristles drawing a separate curve as the brush moves, and all the curves together forming a single stroke. [22] illustrates the principle of the generation of the black edge phenomenon in ink painting. [23] proposed an automatic cell-based computational model to simulate the movement of water and ink particles. [24] used a fluctuation rule to represent the flow of ink particles. [25] proposed a water absorption force balance algorithm to calculate the diffusion amount of adjacent paper cells. [5] proposed a pseudo-Brownian motion method based on a particle system to simulate the diffusion process, taking into account the effects of water absorption, humidity, evaporation rate, and background texture. [26] complemented the algorithm by proposing an exchange threshold value as an exchange condition and an exchange

rate to control the amount of exchange. However both values are static in the diffusion process. [27] used a local equilibrium model and a three-layer paper model to simulate the effect of ink diffusion. This method can simulate simple stacking effects, and Young gave a graph of the stacking effect. [28] proposed a diffusion model with concentration difference as the driving force for diffusion, but did not present a theoretical basis, [29] proposed to simulate the diffusion of ink particles with Fick's first law of steady-state diffusion [30], but in reality the diffusion process is a nonsteady-state process, [31, 32] proposed to use a fluid based on LBE (Lattice Boltzmann Equation) to simulate ink diffusion. The diffusion model is easy to parallelize, has good real-time performance, and can produce very realistic ink and wash wet brush painting effects. However, by treating both water and ink particles as equally sized particles, the particle diffusion model is not a true particularised model, but simply a diffusion model under the rule of concentration correspondence. This method does not allow for differences in the diffusion of multiple pigments.

As can be seen, KM colour models have been chosen to solve the problem of colour setting, both in colour simulation for Western painting and in colour setting for ink painting. The problem of colour calculation is complicated by the diffusion of pigments in ink painting, especially when multiple pigments are diffused together. How to apply the KM colour model's superimposition and mixing formulae through layering based on the characteristics of diffusion is one of the main focuses of this paper. Based on the second type of method, this paper proposes an ink rendering algorithm based on two-dimensional texture mapping, which can simulate the traditional ink painting technique of intensity and distance. This paper uses attribute functions to control the huge changes in the vertical component of ink textures to simulate the shadow and distance techniques of ink painting. Compared with the existing algorithms, the 2D texture mapping of the attribute function provides richer rendering effects. In the ink rendering of the 3D scene, the effects of light and shade and distance are added, which makes the image more layered and closer to the painter's painting skills.

2. Principle of the Algorithm

The main objective of the algorithm in this paper is to achieve a simulation of the intensity and distance technique while obtaining a traditional ink and wash rendering. The difference from traditional 3D ink rendering is the inclusion of the processing and use of 3D depth information. By constructing an attribute function with the 3D depth information as the independent variable for texture mapping, and then controlling the colour tones of the textures to express the changes in the 3D depth information, the effect can be obtained in terms of the intensity of the ink strokes in the near distance and the lightness of the strokes in the far distance. This idea is based on traditional cartoon rendering techniques [6] and the X-TOON system [7].

Bella developed the X-TOON system based on the traditional cartoon rendering algorithm, which extends the

1D cartoon texture to a 2D texture, using the vertical component of the texture to express the colour tone changes and then controlling the texture mapping to obtain a richer cartoon effect.

This paper uses the X-TOON systematic approach to produce two-dimensional ink textures. The hue of the horizontal component of the texture (first dimension) is associated with the model contour edge information, and the texture coordinates are controlled by calculating $N-V$, where N is the unit normal vector of the spatial surface and V is the unit vector of view. The vertical component of the texture (second dimension) is associated with the colour hue (represented in the article by the attribute function D), and the texture coordinates are controlled by the attribute function D . Each value in the vertical component is associated with its own 1D ink texture, so the whole 2D texture can be seen as a superposition of 1D ink textures of progressively increasing hue. The ink texture generate is shown in Figure 1.

2.1. Chafing Renderer. There is a wide variety of shops in ink and wash work, and the differences in expression between the various crops are large, while the painter is more spontaneous in using this technique it is not possible to propose an algorithm for each of these techniques. It is therefore not possible to propose an algorithm for each chap. The texture map is then drawn based on a two-step texture mapping method.

The regularised chunking set has been obtained after chunking feature analysis $S_k^{\text{texture}} = \{s_i | i = 1, 2, 3, \dots\}$ Itexturek first determines the number of interpolated textures. Multiple textures are now connected by line blending [11] to form a large mapped texture map. Item N , let chapped textures μ_A and μ_B , is $|N = |\mu_A - \mu_B|/k$ averaged over the H information. The smaller the coefficient, the greater the degree of variation between individual chops. Then k is used to control the degree of jump in the transition between the chapped textures; the larger k is. The smaller N is, and the greater the degree of variation between the individual chappings. The text uses $k=5$. The interpolated image between A and B is then I_{between} .

$$I_{\text{between}} = \alpha \cdot A + (1 - \alpha) \cdot B, \alpha = 1, \frac{N-1}{N}, \frac{N-2}{N}, \dots, 0. \quad (1)$$

Figure 2 shows the final composite mapping texture after the difference.

2.2. S-O Two-Step Texture Mapping. To optimise the rendering results, the S-O two-step texture mapping method is used to chisel the model. This method was proposed by [13]. The basic idea is that instead of directly texturing the 3D model surface, an intermediate transition surface is introduced and the mapping process is decomposed into a two-step operation: the first step is the mapping from the textured plane to the transition surface, i.e., $T(u, v) \rightarrow S(x', y', z')$, which becomes the S mapping; the first step is the mapping from the transition surface to the 3D model surface, i.e., $S(x', y', z') \rightarrow O(x, y, z)$, which

becomes the O mapping. The transition surfaces in S mapping are usually simple 3D surfaces such as spheres, cylinders, and cubes, as shown in Figure 3.

There are 12 combinations of S-mapping and O-mapping. In this paper, we take a spherical surface as the transition surface for S-mapping and modify the third O-mapping method for chaffing.

The sphere of the transition surface is divided into two parts symmetrical along the x -plane, and the texture is mapped to the two parts symmetrical to the sphere using a mapping algorithm with an area-equivalence constraint [14]. As in Figure 4, gave a 2D texture coordinate system ν , the centre of the texture plane coincides with the origin of the coordinate system at any point $p(u, v)$, which can be expressed in polar coordinates (ρ, α) . Given a three-dimensional coordinate system x, y, z , the centre of a spherical planet of radius R coincides with the origin, and any point $Q(x, y, x)$ on the spherical plane is expressed in spherical coordinates as (R, γ) . Due to the symmetry, the sphere can be divided into two hemispheres by the xy plane, and the mapping method is the same in both hemispheres.

Let a point P on the texture plane be mapped to a point on the hemisphere. In order to effectively reduce texture distortion, an area-equivalence constraint Q [4] is used here to construct the mapping relationship between the two points. The area equiproportionality constraint, i.e., the ratio of the area of the texture plane to the area of the corresponding mapped area on the sphere is transversely equal to the constant K :

$$K = \frac{\pi \cdot \rho^2}{2\pi R^2 (1 - \cos \phi)}. \quad (2)$$

This gives $\rho = 2\pi R^2 (1 - \cos \phi)$ another $\alpha = \theta$. The texture coordinates can be calculated as

$$\begin{cases} u = \rho \cdot \cos \alpha = \sqrt{2KR^2 (1 - \cos \phi)} \cdot \cos \theta, \\ v = \rho \cdot \sin \alpha = \sqrt{2KR^2 (1 - \cos \phi)} \cdot \sin \theta. \end{cases} \quad (3)$$

When $10 \leq \phi \leq \pi/2$, the mapping results in the upper hemisphere; when $\pi/2 \leq \phi \leq \pi$, the mapping results in the lower hemisphere.

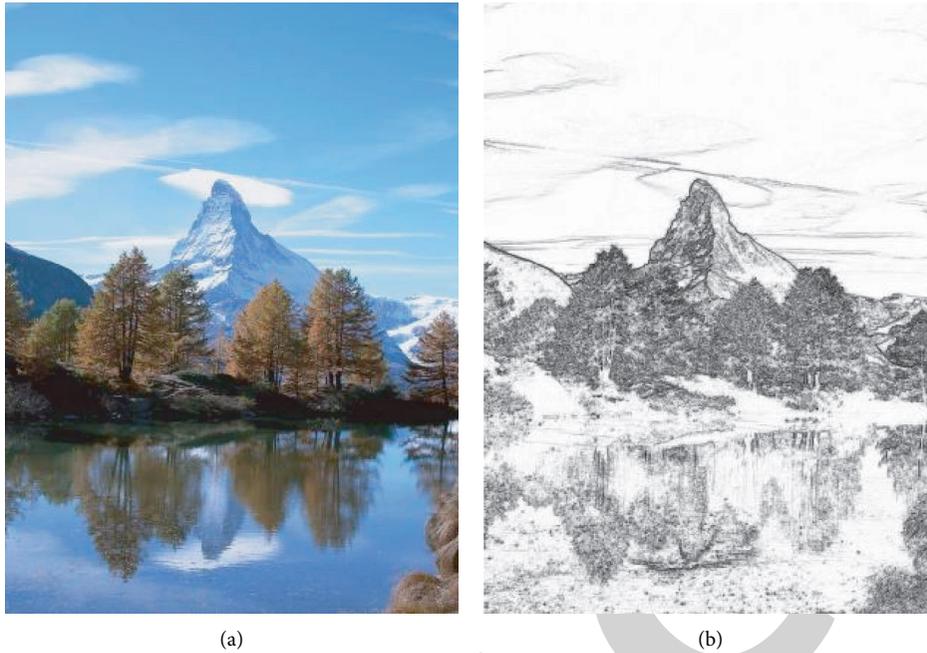

Since the origin of the texture coordinates is generally located in the lower left corner. The above equation is modified:

$$\begin{cases} u = \rho \cdot \cos \alpha = 0.5 + \sqrt{2KR^2 (1 - \cos \phi)} \cdot \cos \theta, \\ v = \rho \cdot \sin \alpha = 0.5 + \sqrt{2KR^2 (1 - \cos \phi)} \cdot \sin \theta. \end{cases} \quad (4)$$

Experimentally, when using a mapped texture map of 512×512 size, take $R=1.0$, $K=0.12$.

The third mapping method is used for the O mapping, i.e., the texture at the vertex $V(x, y, z)$ on the surface of the model, taking the ray formed by the line from the centre of the object to this vertex, and the texture at the intersection with the transition surface $V'(x', y', z')$.

The centre point of a model is usually complex, the algorithm for finding the centre point is as follows: let the

(a)

(b)

FIGURE 1: Ink painting with two texture.

(a)

(b)

FIGURE 2: Synthetic results after image interpolation. (a) Lotus leaf chap and (b) phi chap.

coordinates of a vertex in the xyz three-dimensional coordinate space be $P(v_x, v_y, v_z)$, calculate the sum of all the vertex coordinate vector values, and then find the average of all the coordinate vectors, then get the location of the object's centre point coordinates $P'(c_x, c_y, c_z)$. By the centre point and a vertex direction vector is $PP' = (v_x - c_x, v_y - c_y, v_z - c_z)$, and then determine it is in the sphere and thus the coordinates of uv are calculated from the above equation.

3. Ink and Watercolor Rendering

The horizontal component of the texture is first mapped using the contour area information to sketch the shape of the model, and then the vertical component of the texture is mapped using the attribute functions to control the colour tone information to achieve the ink and wash rendering effect.

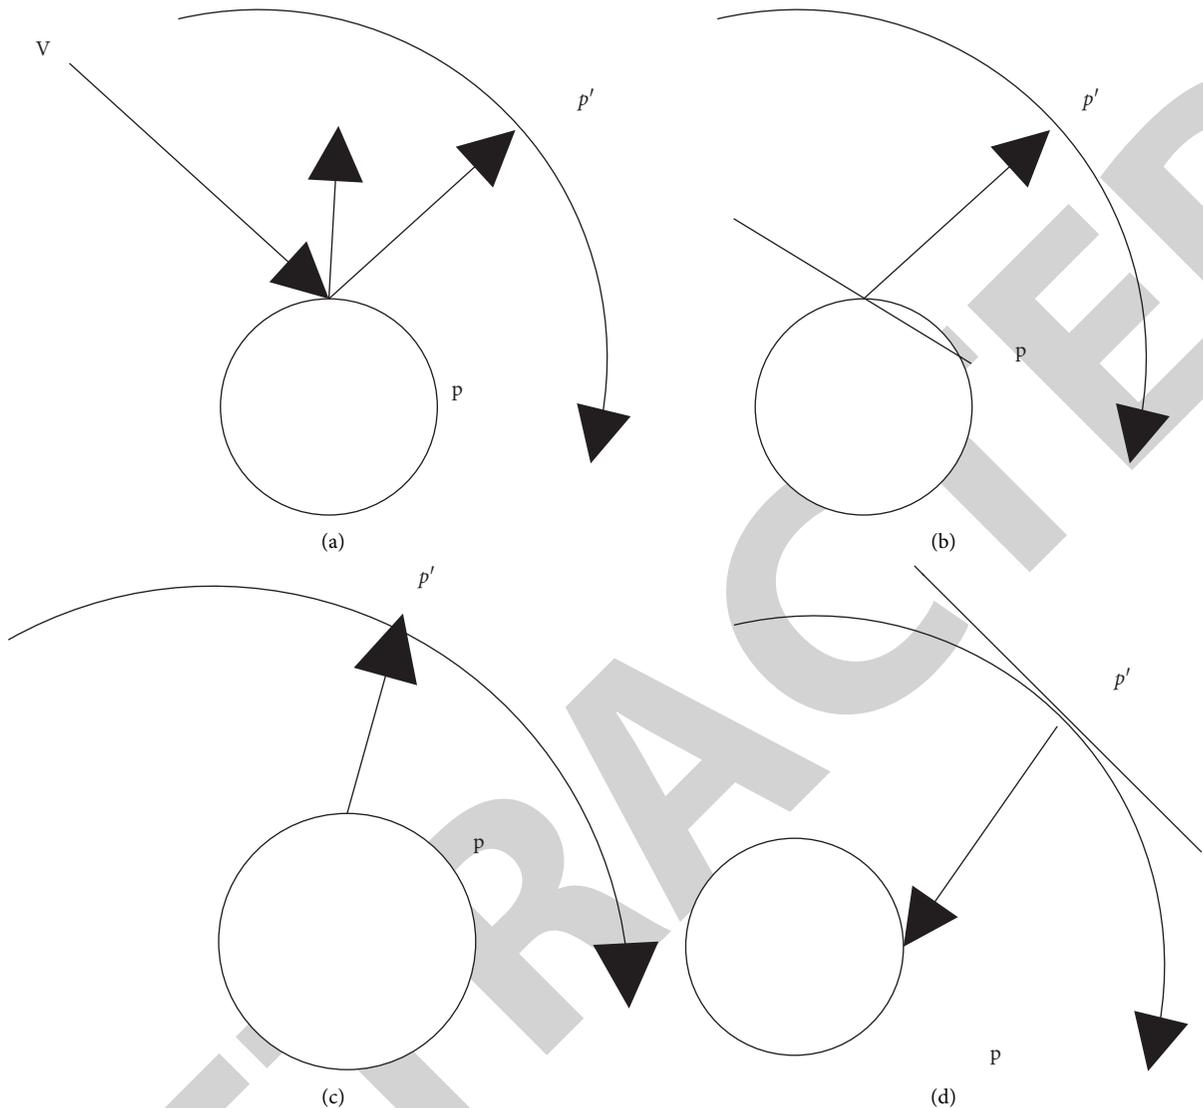

FIGURE 3: Four ways of O mapping.

3.1. *Drawing Model Shapes.* In ink painting, when the artist uses ink to paint a scene, it often spreads and soaks through the rice paper, giving the brushstrokes that depict the outline of the object in a certain area. For this reason, instead of extracting single-pixel contour lines from the model, the shape of the model is outlined by mapping the texture around the contour lines to a certain area.

The simulation process is implemented in the OpenGL shading language. In the vertex shading, the absolute value of the dot product of the unit normal vector and the unit apparently vector is calculated separately for each vertex, and a is passed to the pixel shading as a mutable variable. In the pixel shading, a is used to control the texture coordinates of the horizontal component of the texture. In order to achieve the effect of white space in an ink painting, a threshold λ can be set so that when $a > \lambda$, the pixels of the slice are set to the colour of the white space in the ink texture. The larger value of the threshold λ , the smaller the white area. Figure 5 shows the rendering effect on a fixed vertical

component texture coordinates. With λ values of 0.5 in Figure 5(a) and 0.7 in Figure 5(b).

3.2. *Control of Colour Tone Information.* This step performs the texture mapping of the vertical component and is the heart of the algorithm. In order to simulate the fade technique, elements closer to the point of view are assigned textures with stronger tone. In contrast, elements that are further away from the viewpoint are assigned lighter textures.

To do this, an attribute function is designed for the vertical component texture mapping, starting with the depth information in 3D space as the independent variable. For the selection of depth information, two methods can be used: (i) the Euclidean distance from the 3D point to the viewpoint is used as the depth information (e.g., Figure 6(a)); (ii) the distance from the 3D point to the viewpoint along the focus axis is used as the depth information (e.g., Figure 6(b)). The

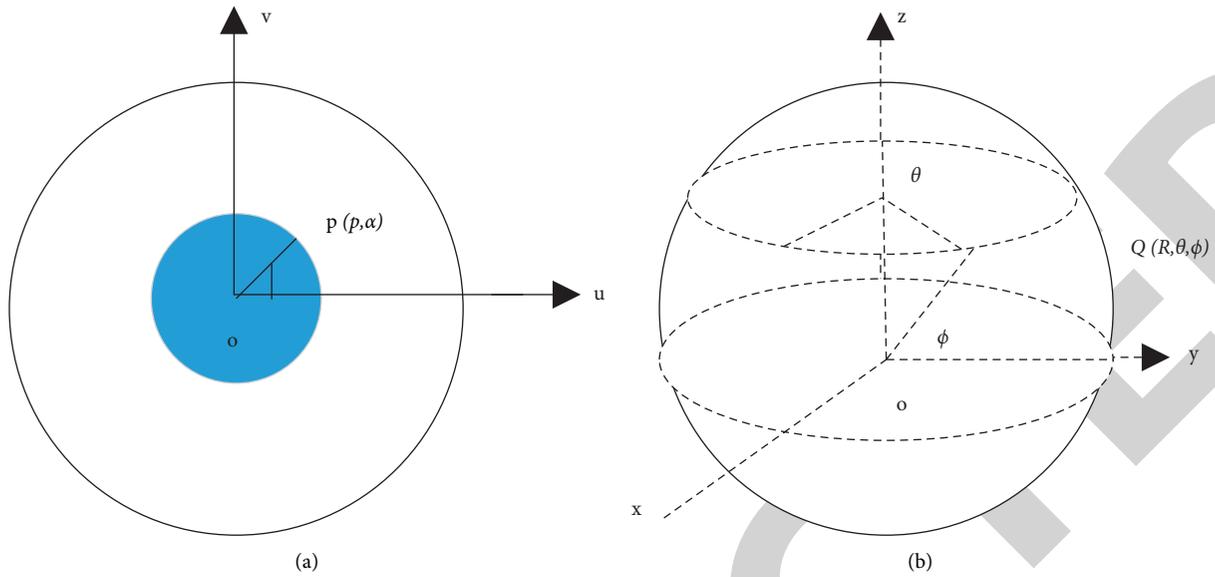

FIGURE 4: Schematic diagram of the spherical S mapping.

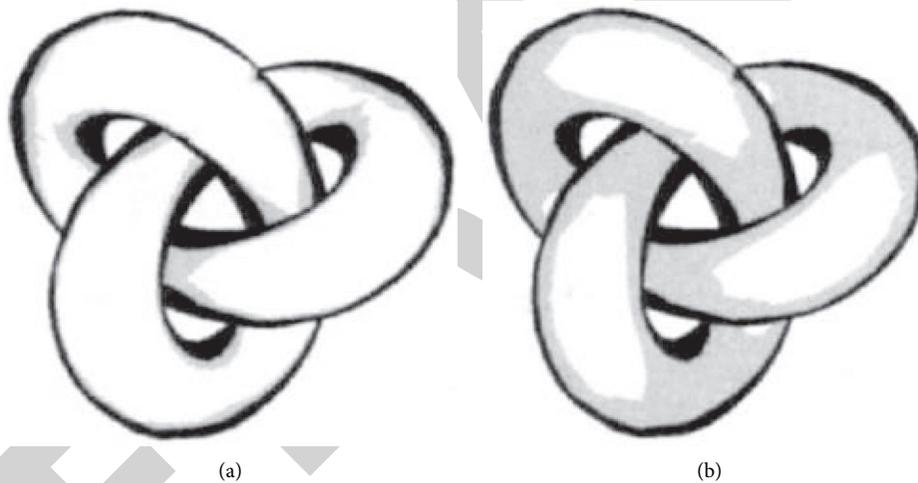

FIGURE 5: Ink rendering with fixed vertical component texture coordinates.

second calculation method was found to be better for simulating the effect of ink and wash painting in terms of intensity and distance.

For the attribute function D , the following constraints are imposed: ① the range of D is between 0 and 1, thus corresponding to the range of texture coordinates; ② set the threshold d_{\min} , when the distance from the point on the model to the viewpoint is less than or equal to d_{\min} , the value of D is 1, and when the distance is greater than d_{\min} , the value of D gradually decreases; ③ set the threshold $d_{\max} = r \times d_{\min}$, when the distance from the model point to the viewpoint is equal to d_{\max} , the value of D is 0, where the value of r is greater than 1.

Different types of functions can be constructed to meet the above requirements. Line attribute functions, quadratic attribute functions, and attribute functions that take into

account the effects of illumination are designed to simulate the ink effect in 3D models. The simplest method is to use linear property functions:

$$\begin{cases} D = 1, & d \leq d_{\min}, \\ D = \frac{1}{((1-r) \times d_{\min} \times d + r/(1-r))}, & d \geq d_{\min}, \end{cases} \quad (5)$$

where d is the current depth property value of the 3D point and r and d_{\min} are adjustable parameters. In the slice shader, the result is calculated as the coordinate value of the vertical component of the ink texture, and the function value decreases linearly when the current depth value of the model exceeds the threshold d_{\min} . Using the point of view as a reference, the larger vertical component texture coordinates are taken in the near area, corresponding to the darker tones

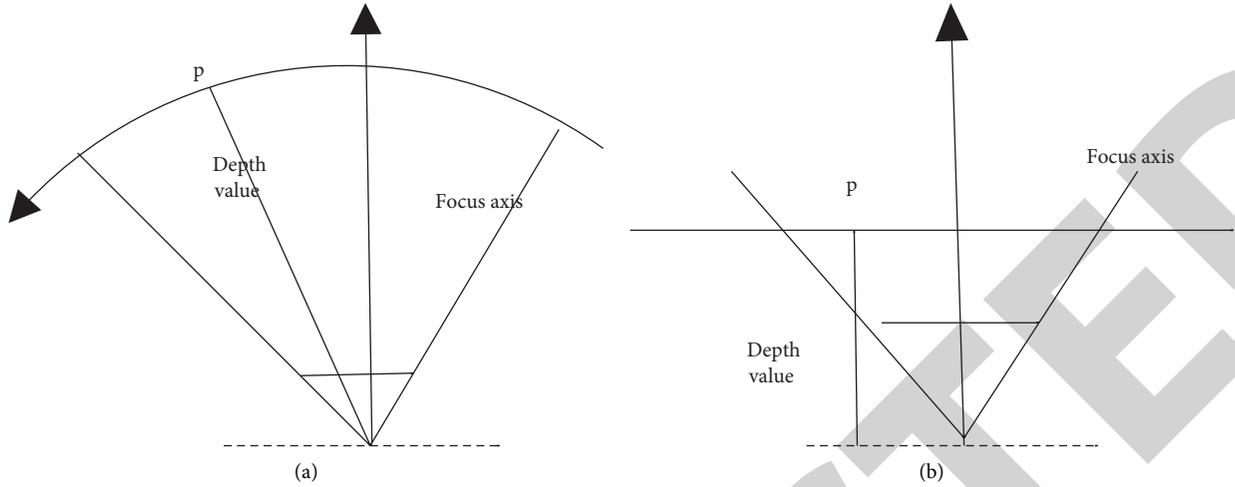

FIGURE 6: Calculation of depth attributes.

in the ink texture, and the smaller vertical component texture coordinates are taken in the far area, corresponding to the lighter tones in the ink texture, thus obtaining the effect of intensity and distance.

If you want a more intense contrast, you can use the secondary attribute function:

$$\begin{cases} D = 1, & d \leq d_{\min}, \\ D = \frac{(d - r \times d_{\min})^2}{((1 - r)^2 \times d_{\min}^2)}, & d \geq d_{\min}. \end{cases} \quad (6)$$

The light source direction is introduced as a weighting factor to influence the attribute function, which can obtain the effect of the intensity and distance of the white left in the highlights of the illuminated surface and the thick ink of the shadows on the backlit surface. The direction factor constructed in the experiment is $(N - L)\gamma$, where N is the unit normal vector of 3D points, L is the normalised light source direction vector, and γ is the light factor. The attribute functions are

$$\begin{cases} D = 1 - \log 0^{d/d_{\min}}, \\ D = \alpha \times \frac{(d - r \times d_{\min})^2}{((1 - r)^2 \times d_{\min}^2)} + (1 - \alpha) \times (N \cdot L)^\gamma, & (N \cdot L)^\gamma \leq \beta, \end{cases} \quad (7)$$

where α is a weighting factor that controls the weight of light and depth information on the hue and β is an adjustable parameter that controls the area of shadows.

4. Simulation of Ink and Wash Painting Materials and Their Physical Processes

Ink painting is a complex process due to the special nature of the painting material and the use of various painting and calligraphy techniques. The study is based on a simulation of the natural medium and its physical processes. The

simulation method of simulating the natural medium and its physical process is based on the mechanism of ink painting, and the main drawing tools and materials such as brushes, rice paper, ink, and pigments are studied. The method is based on the mechanism of ink painting, modelling the main drawing tools and materials such as brushes, rice paper, ink and pigments, and simulating their inherent physical properties and dynamic interaction behaviour. The aim is to simulate realistic ink and wash effects. The research results can be broadly divided into three parts: Xuan paper. The simulation of Xuan paper, the simulation of brushes, the simulation of ink diffusion, and the simulation of colour modelling.

4.1. Xuan Paper. Xuan paper is in contact with the brush on the one hand, accepting the ink from the bristles, and on the other hand acting as a carrier for the ink and wash that eventually becomes the painting. The modelling of the paper is therefore important, as it is directly related to the quality of the ink and wash effect simulation. The most important aspect of modelling rice paper is its fibre structure and its role in guiding and blocking the diffusion of ink and water. The advantage of this method is that the resolution is improved, and the irregular shape of the fibre masses will achieve better results on the boundary, as shown in Figure 7, but at the same time, the randomness of the fibre mass composition and the irregularity of the shape make it more difficult to describe and process the ink in it, making it difficult to use graphics hardware resources.

4.2. Hairbrush. With the development of NPR, virtual brush research has attracted more and more researchers. The 2D brushstroke model approach [13, 30], although able to simulate many of the effects of ink painting, reduces the freedom of the artist to create because of the overemphasis on the final simulation effect, reducing the unique writing effect of ink painting, as in Figure 8. The authors of [10] use a parametric gradient “raindrops” to simulate the contact area

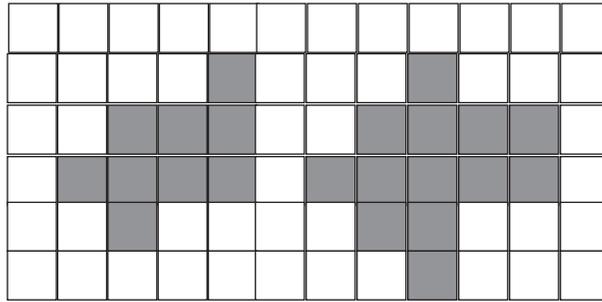

FIGURE 7: Model of the remaining paper fibre mass.

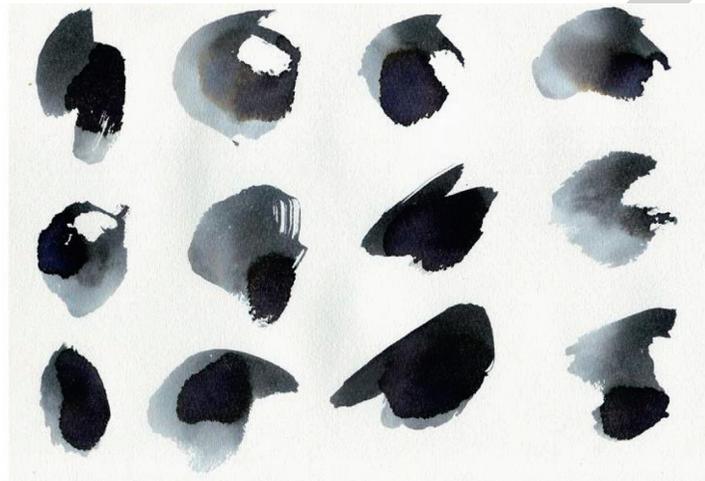

FIGURE 8: Schematic diagram of the two-dimensional brush stroke model.

between the paper surface and the brush, simplifying the parameter settings and operations, but with a single brush stroke, many artistic effects cannot be realized.

The use of alpha map mapping on the hair bundle surface after bifurcation limits the richness of the variation, as shown in Figure 9.

The focus of the brush simulation is to simulate the interaction behaviour between the brush, the rice paper, and the ink. Most of the above studies have ignored the effect of the structure of the rice paper on the ink and water transfer process. There is a need to reduce the computational complexity to ensure real time. There is also much room for improvement in describing the behaviour of the brush accurately and efficiently. [3] proposed a practical A practical 3D brush modelling system is proposed in [3] to accurately simulate the geometry of the brush and its dynamic interaction behaviour such as movement and bending. The method improves computational efficiency while effectively simulating the dynamic changes of the brush during the artistic creation process, as shown in Figure 10.

4.3. Diffusion Processes. The special feature of ink painting is that the brush bristles contain a large amount of water, and the pigment diffuses within the rice paper by the action of the water. The study of diffusion is indispensable in order to fundamentally simulate the effect of drawing ink paintings. [15] proposes to analyse ink and wash from the viewpoint of

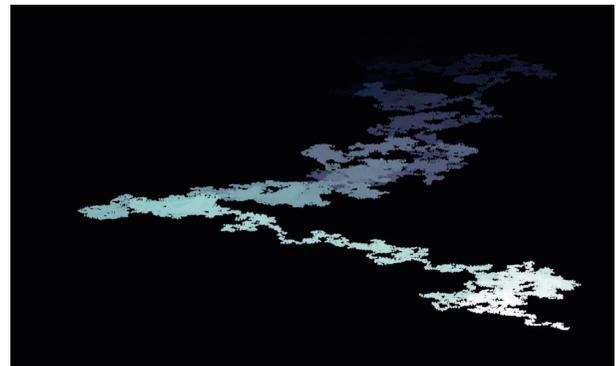

FIGURE 9: Brush surface mapping.

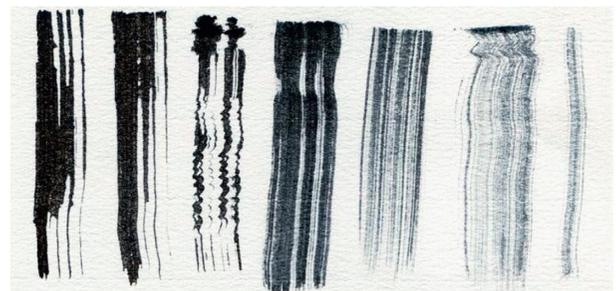

FIGURE 10: Potential energy-threshold controlled pen movement.

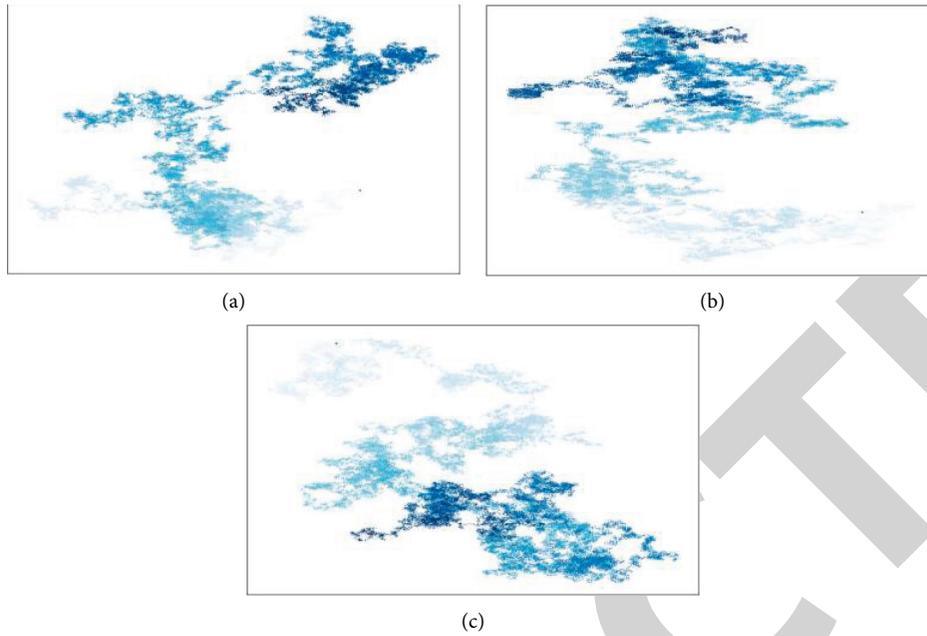

FIGURE 11: Linearly varying ink and wash effects of shade and distance (a-c).

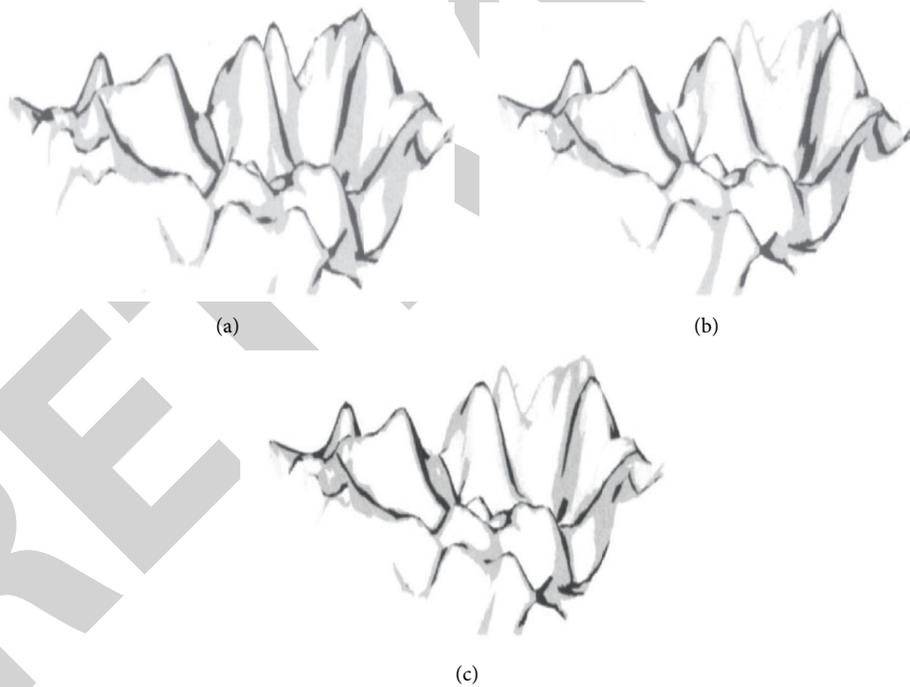

FIGURE 12: Comparison of three ink rendering effects. (a) Ink rendering without the depth attribute function (b) Ink rendering with linear attribute functions. (c) Ink rendering with quadratic attribute function.

particle systems, they are all composed of tiny particles that satisfy the condition of doing Brownian motion, and they undergo a complex movement in the fibre structure of the paper until the ink dries, finally forming an ink painting work. Throughout the process, this includes the diffusion of ink particles, the collision of particles with each other, the deposition of ink particles, and the evaporation of water particles, among other forms. The task of ink diffusion

modelling is to study the mechanism of movement and simulates these movement patterns to obtain the final ink distribution information and finally display the output.

The diffusion of ink and pigments is the most complex part of the ink painting simulation. As can be seen from the above analysis, existing algorithms are not yet able to reproduce this process comprehensively, accurately and in real time, and previous simulations of diffusion

superimpositions are limited to two aspects: first, particle-based diffusion has been proposed, but none of them are particle-based diffusion in the true sense. Second, they are limited to the diffusion of a single ink particle and do not include the diffusion of all the essential properties of the various pigments. Third, there is no in-depth study of the reality of the superposition of different pigments.

5. Results and Discussion

5.1. Algorithm Effect. The algorithm presented above has been implemented in VC++ 6.0 and the OpenGL graphics engine programming environment and has been tested on a PC with a 1.8 GHz CPU, DDR 1G RAM, and an ATIRHD 2400 graphics card.

In the experiments, the equations were verified separately as property functions, and the same parameters and sampling points were set for both experiments in order to compare the two. Figure 11 shows the effect of linking with increasing values of depth d . Figure 11(a) shows the effect when $d < d_{\min}$, which is closer to the point of view and the ink is thicker; 11(b) and 11(c) show the effect when $d > d_{\min}$ and d is gradually increased, which shows that the ink is getting lighter. Figure 12 shows a comparison between the traditional ink simulation without the depth attribute function, the ink simulation with the linear attribute function and the ink simulation with the quadratic attribute function when drawing the mountain model, with the parameter d_{\min} at 100 and r at 10. The traditional 3D ink rendering algorithm does not consider the effect of the depth attribute on the rendering effect, so no matter how the depth value of the model vertices is changed, it is difficult to produce a strong or light. The results obtained by the algorithm in this paper vary with the depth value, as shown in Figures 12(b) and 12(c), with a stronger sense of hierarchy using the secondary attribute function. The reason for the different degrees of intensity is the variation in the value of the attribute function.

From the experimental results, it can be seen that the algorithm of this paper can be used to simulate the technique of intensity and distance better, and by changing the attribute function model and the relevant parameters of the function, the rendering effect with different contrast of intensity and distance can be obtained, which is a simple and practical method and provides an effective way for the 3D ink rendering of large-scale scenes.

Other attempts have been made to apply the attribute function. In artwork, there is often a technique of detail abstraction, where the details of something are detailed in the near distance, and only the general outline is drawn in the far distance, while the internal details are sketchy or not even portrayed. It is worth noting that the detail abstraction simulation here is different from the LOD technique, which only uses property functions and texture mapping techniques to obtain a sensory abstraction effect, without any processing of the 3D model mesh.

The traditional pencil drawing simulation requires a set of pencil drawing textures, and then uses the lighting function to control the weight of the different textures, and finally mixes the textures. The depth value is also taken into account, and the depth value is calculated by adding a white texture to the original pencil texture, and then using a linear property function to control the weighting factor of the texture, the final result is shown in Figure 13. It can be seen that the method can be used to simulate a detailed abstraction technique.

5.2. Drawing Effect. Figure 14 shows work by Qi Baishi when he was 80 years old, which mainly uses the technique of writing, using the intensity of ink colour to represent the object. From the experimental results, it can be seen that for different styles of input work, the algorithm is able to pass the basic stylistic features to the 3D model and render the ink accordingly, resulting in output images of similar styles.

6. Conclusions

The paper uses attribute functions to control the huge changes of the vertical components of the ink textures to simulate the ink painting technique of shade and distance. Compared with the existing algorithms, the 2D texture mapping by the attribute function provides a richer rendering effect, and in the ink rendering of 3D scenes, the addition of the effect of shade and distance makes the image more layered and closer to the painter's painting technique.

In order to provide a richer surface detail of the 3D model, the radial curvature of the model surface can be calculated, which is one of the directions for the future work.

Data Availability

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

Conflicts of Interest

The authors declare that they have no conflicts of interest regarding this work.

Acknowledgments

The authors would like to thank Qi Baishi for provides the painting.

With the wide application of the Internet and the rapid development of network technology, microblogs and online shopping platforms are playing an increasingly important role in people's daily life, learning, and communication. The length of these information texts is usually relatively short, and the grammatical structure is not standardized, but it contains rich emotional tendencies of users. The features used by custumal machinery schooling methods are too sparse on the vector space model and lack the semantic information of short texts, which cannot well identify the semantic features and potential emotional features of short texts. In response to the above problems, this paper proposes a bidirectional long-term and short-term memory network model based on emotional multichannel, combining the attention mechanism and convolutional neural network features in deep learning and learning the short text by combining shallow learning and deep learning. The semantic information and potential emotional information of the short text can be improved to promote the effective expression of short-text emotional features and improve the short-text emotional classification effect. Finally, this paper compares the above models on multidomain classification data sets such as NLPPIR and NLPCC2014. The accuracy and F1 value of the model proposed in this paper have achieved good improvement in the field of short-text sentiment analysis.

1. Introduction

These days, people want to check the latest current affairs, online shopping, news gossip, and financial stocks; people are no longer limited to reading newspapers or sitting in front of the TV to watch hot topics but have more ways to participate in the discussion of hot topics such as Weibo, Taobao, Douyin, Zhihu, and WeChat public platforms and other media. As an Internet platform, Weibo, Taobao, and Douyin, in another aspect, realize information sharing and dissemination by virtue of user relationships, attracting a large amount of individuals to participate, and are favored by people; on the other hand, a large amount of posts published by users are text mining and provide a huge amount of data. Sun et al. found that Weibo information can reflect changes in people's attention to hot spots [1] and can even infer the current emotional condition of users based on Weibo user information. In addition, Weibo sentiment analysis also provides reference opinions for some industries, such as stock trading decisions [2], movie box office

predictions, and election predictions [3, 4]. Literature provides reference opinions for consumers to purchase products by mining online shopping platform product review information and establishing a review sentiment analysis model [5–7] and guidance for merchants to adjust production plans and product improvement and also promotes online shopping platforms. Users are provided with a more efficient quality of service. With the vigorous development of online social media and the rise of artificial intelligence, more and more experts, scholars, and scientific research institutions are now turning their attention to the analysis.

1.1. Research Status of Text Sentiment Analysis. Text sentiment analysis is an indispensable link in natural language handling. In the past, relatively large part experts and scholars have carried out research in the light of sentiment dictionary. Li and Hong reviewed sentiment analysis methods, respectively [8, 9].

- (1) The medium in the light of the vocabulary for expressing emotions and emotional tendencies mainly judges the sentiment climate. It needs to manually construct the vocabulary for expressing emotions and emotional tendencies mainly or use the internal statistics Mutual Information (MI), Symmetric Conditional Probability (Symmetric Conditional Probability), external statistics (Branch Entropy and Access or Variety), and other methods to expand the sentiment dictionary. In text orientation analysis, well-known sentiment dictionaries are HowNet2, WordNet [10], and ConceptNet [11].
- (2) The feature-based method is to use statistical knowledge to screen features from a large quantity of corpora, use features to represent the entire text, and then use relatively unnovel algorithms in machine schooling to classify the text. This method requires high feature engineering and feature selection. The results directly affect the classification effect. For a long time, features have occupied an important position in text classification, the classification matrix has not been greatly improved, and it has indirectly led to the problem of overfitting, which is called the Hughes effect [12–14]. In reality, training a large number of features requires enough samples, where obtaining enough samples requires time and labor.
- (3) Based on deep learning methods, features such as words, sentences, and chapters can be mapped to high-dimensional spaces to learn deeper feature representations in text data. Wang added a self-attention mechanism (Attention Mechanism) after the output storey of the LSTM network [15] and obtained the context information of the LSTM output unit attention means for relevant automatic acquisition. The experimental results show that the attention mechanism can recognize the emotional information in the text [16, 17]. The model first inputs the word vector into the Bidirectional LSTM net to learn the textual content and emotional information, and then uses the self-look mechanism to extract emotional representations of monolingual and bilingual texts, respectively. Based on the above work, in the work of sentiment analysis, each word in the text has a multitudinous collision on the overall emotional climate of the text, especially some emotional words, which can often directly reflect the emotional climate of the text, and through the look mechanism, the importance of words can be obtained, and the potential representation information in the text can be learned.

1.2. Research Status of Short-Text Sentiment Analysis. (1)

In the method based on the sentiment dictionary, Xiao constructed a sentiment dictionary by analyzing the emotional part of speech and the domain words in the topic domain (World Cup, iPhone, and NBA games) in the context of microblogs [18] and proposed a sentiment

lexicon-based sentiment analysis strategy. Chen improved the mutual information algorithm [19] and obtained emotional words in microblogs on the Chinese microblog sentiment dictionary constructed in the light of mutual information.

- (2) In the modus in the light of machine learning, Xie et al. combined sentiment dictionary, context features. and topic features [20] and proposed an SVM-based sentiment classification method. Li and Ji extracted features such as words, negative words, and special symbols to construct an SVM model and a CRF model to perform sentiment analysis on microblog data [21] and concluded that the appropriate choice should be made under different circumstances. Conclusions of the model.
- (3) In the method based on deep learning, Zhou integrated part-of-speech features and word embedding features in the research on sentiment classification of product reviews [7]. The experiments are higher than the traditional text convolutional neural network. Chen proposed a microblog using part-of-speech features of emotional words and learning more hidden information [22]. The experiments verified the proposed model is robust to different data.

Because the short text is relatively short, it will bring about the problem of lack of text semantics, which brings challenges to the short-text sentiment analysis. Although the existing short-text sentiment analysis methods have done some feature extraction, feature selection, and model selection, many works still do not fully consider the context of short texts and deeply dissect semantic features. Some new words may not be recognized in the word segmentation stage. In order to improve the shortcomings of existing methods in feature selection, this paper extracts shallow learning features such as emotional part of speech, location information and dependencies of words from short texts, as well as deep learning features such as word vector features, convolutional neural network features, and emotional attention features. Learning features enrich the textual feature representation of short texts.

In the near future, deep learning has also been widely used in sentiment analysis of short texts. Its concept comes from the research of artificial neural network. Its purpose is to explain the feature information existing in the data by imitating the thinking structure and learning mechanism of the human brain and build a neural network for machine analysis and learning. Compared with the use of nonlinear network structure to make up for the shortcomings of the algorithm, it also has the following two shortcomings:

- (1) In deep learning, the amount of training data is required by the model. When the scale of the model is large enough, the connection between short-text data can be fully captured. However, in most cases, facing the problem of short-text sentiment orientation classification and other classification problems, sufficient training data cannot be found, and a lot of data are manually annotated, and the model is

difficult to achieve optimal, which is common in the industry.

- (2) Due to the “black box” nature of the features learned by the deep schooling network model, it is difficult to fundamentally find out where the learned features come from, and it is also difficult to explain the specific meaning of the learned features.

2. Relevant Theoretical Basis and Technical Introduction

In recent years, the analysis and mining of time series data have been gradually applied to many fields. Natural language processing is a typical application [23–26]. In the research of many scholars in the scope of natural language processing, the text sentiment analysis task has two important steps. The first is to convert the text information into coded information that can be recognized by the computer, and the second is to analyze the sentiment tendency of the text. Since the words in the text cannot be directly fed into the network model, the first task is to convert the text into a digital representation. The word vector is to map the words in the text into a digital vector representation. According to the different encoding methods, word vectors are mainly divided into discrete word vectors and distributed word vectors.

2.1. Text Representation. Natural language is a complex system that expresses a given intention and thought. It is generally composed of words and punctuation marks. One, two or more words are spliced into a word, and several words are connected to form a sentence. After continuous combination, it forms paragraphs and chapters. Unlike humans, machines cannot directly understand the emotional information in language but need to obtain the corresponding information in language by establishing certain rules or models [27], in which only one bit is 1 and the rest are 0. Under the one-hot rule, the words after word segmentation are discretized and mapped to the Euclidean space by the implementation of row vectors, but in large-scale data sets, the vocabulary size of a data set may reach tens of thousands of dimensions or even ten of thousands of dimensions, and vectors at this time will undoubtedly bring huge memory consumption. At the same time, the large-scale vocabulary makes the constructed word vector matrix too sparse, which brings great inconvenience to the feature schooling. In view of the fact that one-hot encoding will have problems such as dimensional disaster, word similarity, and poor model generalization ability in natural language modeling, Google proposed the word2vec model in 2013, also known as the word embedding model. Each position in the model-trained and the general value range is between -10 and 10 . Taking “I appreciate one country, two systems” as an example, the 200-dimensional word vector representation is set as shown in Table 1.

2.2. Related Methods of Sentiment Analysis. Sentiment analysis is essentially a text classification problem. Deep learning can learn deep features in data and bring about

brilliant bonanza in odd spheres. Therefore, profound learning has also been diffusely used in sentiment decomposition tasks in recent years. Neural networks commonly used in text sentiment decomposition include CNN, recurrent neural networks, and LSTM networks. These networks can better mine the latent information hidden in the text and outperform most custumal machinery schooling methods.

Since RNN adds a loop structure to the traditional neural network, the content of the loop body will be executed at each step, but when the number of historical nodes input to the RNN decreases, the RNN cannot memorize information far from the current node. LSTM is an improved model of RNN. The main improvement is the introduction of three phylums when memorizing information: input gate, forget gate, and output gate. Through these three gates, LSTM can bridle the information passing through the cell and can selectively add information or delete existing information according to the needs of the result, and specific LSTM network structure and internal structure are shown in Figure 1.

At the outset, LSTM used the forget gate to fix the message that the cell demands to discard. Forget phylum calculates a value among zero and one based on the historical message of the former condition and the current input communication as the condition of the cell information at the previous moment to determine what information to keep and discard. Among them, 0 means to discard all the communication of the historical condition, and 1 means to keep all the communication of the historical condition, where $f(t)$ delegates the input value at time t , $h(t-1)$ delegates the worth of the concealed stratum at time $t-1$, and $U(f)$, $W(f)$, and $b(f)$ are the degree of seriousness of the worth of LSTM of the concealed stratum in the forget phylum, the degree of seriousness of the current input, and the bias in the forget phylum, respectively, σ is the activation function of sigmoid, and $f(t)$ is the information discarded by cells. The specific calculation is shown in the following equation:

$$f^{(t)} = \sigma\left(\sum h^{(t-1)} \cdot U^{(f)} + x^{(t)} \cdot W^{(f)} + b^{(f)}\right). \quad (1)$$

LSTM determines the information stored in the cell through the input phylum. The input phylum calculates a value from 0 to 1 by sigmoid, the key in news to modernize the condition of the current node, that is, what information needs to be updated or stored. Among them, 0 means not accepting new information and 1 means accepting all the input information. LSTM generates a new memory $C(t)$, which is the input memory, not the final memory. The condition is determined by the previous output and the current input, which are the worth of the concealed stratum of LSTM in the new memory, the degree of seriousness of the current input, and the degree of seriousness of the current input. The specific calculation of the bias in the new memory is shown in the following equation :

$$\tilde{C}^{(t)} = \tanh\left(\sum h^{(t-1)} \cdot U^{(c)} + x^{(t)} \cdot W^{(c)} + b^{(c)}\right). \quad (2)$$

TABLE 1: Word2vec training word vector table.

Words and phrases	Word embedding

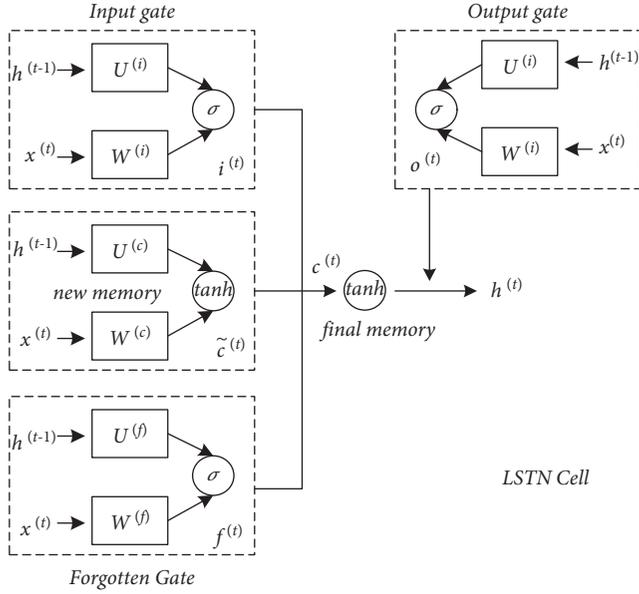

FIGURE 1: LSTM text classifier model.

The final desired memory is generated by the part to be remembered and the part to be forgotten. Through the calculation of the previous two phylums, we already know the proportion $i^{(t)}$ of new information retained, the proportion of old information that needs to be forgotten, and the new memory and old memory $f^{(t)}$. In the final step, the output phylum is used to determine the upshot of the final cell output. The output phylum calculates a value between 0 and 1 by sigmod—the input information to calculate the proportion of information that the cell finally outputs. Among them, 0 indicates that no information is output and 1 indicates that all the final memory results are output. The specific calculation is shown in the following equation:

$$C^{(t)} = i^{(t)} \odot \tilde{c}^{(t)} + f^{(t)} \odot C^{(t-1)}. \quad (3)$$

In a classical recurrent network, the condition and output are always transmitted from front to back. However, in some problems, the transmission and output of the condition are not only related to the previous condition but also related to the subsequent condition such as prediction. A missing word is not only related to the preceding text but also to the following text. Among them, BiLSTM is a common neural network model that considers the contextual relationship. It is based on Bi-RNN. One LSTM module propaphylums from front to back, and another LSTM module propaphylums from back to front. BiLSTM builds a double-storey network model. The input is forwarded to the

LSTM and the reverse LSTM, respectively, and the final output result is the vector superposition of the LSTM output results in two different directions. Finally, the entire output result is fully connected, and then, the sigmod output is the final output result, where BiLSTM is trained in the same way as LSTM [28–30].

3. Sentiment Classification Model Based on Deep Learning

Considering that the custumal machinery schooling methods and profound learning methods are insufficient in feature representation, this paper makes two improvements to the custumal machinery schooling methods and profound learning methods: one is to use shallow learning features as one of the input features of profound learning. Add a look mechanism to the network layer to allow the model to better learn the underlying semantic features in the text.

3.1. A Bidirectional Long- and Short-Term Memory Network Model Based on Emotional Multichannel. So as to make full use of the unique emotional resource information in the text sentiment decomposition task, this paper proposes BiLSTM Based on Sentimental Multichannel, referred to as BM-ATT-BiLSTM based on multichannel sentiment. The learning storey builds multiple channels to improve sentiment classification performance. BM-ATT-BiLSTM is a left-to-right multistorey neural network structure mainly composed of 5 parts: input layer, semantic learning layer, emotional attention layer, merging storey, and sentiment classification output storey. The input storey inputs are composed of features and shallow features (emotional part-of-speech features of words, location information features, and dependency features). The traditional LSTM model can obtain the forward semantic information in the text but ignore the reverse semantic information of the text. In response to this paper, let LSTM learn backward directions of the sequence. Feed the data in both directions into the BiLSTM model, and the calculation method is relatively simple, by calculating the emotional weight of each word. If the previous storey of the BiLSTM network is multiplied, it will be normalized and fused batch. Use the fully connected layer of the model to output the feature matrix, use softmax to normalize the feature matrix, and finally get the classification result.

3.2. Experimental Parameter Setting. Different hyperparameters may have different effects on the experimental results. Although parameter tuning itself is not the main research content of this paper, for the sake of fairness, this paper considers the overall effect of the experiment and

finally determines the hyperparameters of BM-ATT-BiLSTM. Some hyperparameters of the BM-ATT-BiLSTM model are shown in Table 2.

3.3. Experimental Environment and Comparative Experiments. The computer hardware configuration used in the experiment in this paper is as follows: the CPU is Intel Core processor i5-9400f, and the GPU series is NVIDIA GTX; the operating system is configured as Windows 10; the programming software used is PyCharm, the programming language used is Python, and the support library used in profound learning is pytorch10, keras11, and gensim12.

3.4. Experimental Results and Analysis. Since the NLPPIR and NLPCC2014 data sets do not contain many training samples, too many iterations may lead to overfitting problems, and if the number of iterations is insufficient, it is troublesome for the matrix to be taught effective features. Therefore, 20% of the data set is divided into the validation set, 16% is divided into the test set, and 64% is divided into the drilling battery. Precision, Recall, and F1-measure are selected as evaluation indicators. So as to make the experiment more fair, the evaluation index results in this paper take the average of 50 experimental results. The detailed experimental results are shown in Table 3.

- (1) Compared with LSTM, the overall effect of CNN is weaker than that of LSTM. In the process of extracting features, CNN mainly captures multiple different N-grams of text, and there are many different convolution kernels for one N-gram. Useful information is extracted from different angles, but the experimental data sets are all short texts, and the amount of data is not large, so the use of CNN to extract features may lead to insufficient features and adds emotional attention to CNN, and the effect is obviously promoted.
- (2) The results of CNN and CNN + SVM show that using SVM instead of softmax can improve the classification effect. The reason is that the loss function of SVM can get faster convergence on the three data sets of text, and the output of softmax is only a probability of compressed data, and the probability distribution of softmax is deviated from the actual result.
- (3) Among all the LSTM memory networks involved in the comparative experiments, BM-ATT-BiLSTM has the best effect. An important reason is that the emotional attention mechanism is added, and more potential emotions can indeed be learned from the text through attention. According to Table 3, the BM-ATT-BiLSTM method outperforms other models in terms of precision and recall. This effect is essentially due to the time series characteristics of natural language. Cells in the LSTM model can effectively record the time series information in the text. The BiLSTM model structure is used to learn the semantic information in the text, in order to enhance

TABLE 2: BM-ATT-BiLSTM model hyperparameter settings.

the capability of the mold to learn the reverse text, and strengthen the capability to seize the news of the text context. Combining the emotional parts of speech, location information of words, as well as word embedding features, emotional attention features, and features extracted by convolutional neural networks, this paper proposes three neural network models, which are the foundations of emotional multichannel features—BiLSTM classification model, convolutional neural network in the model mechanism increases the attention, and multikernel convolutional neural network in the model mechanism increases the attention. Tentatives show that the BM-ATT-BiLSTM recommended in this paper has the best performance; therefore, it can be concluded that adding the above shallow learning features and profound schooling features to the short-version sentiment decomposition can improve the classification manifestation of the mold.

4. Conclusion and Outlook

Combining the emotional part of speech features, location information features, and dependency features of words, as well as word embedding features, emotional attention features, and features extracted by convolutional neural networks, this paper proposes three neural network models, which are emotional multichannel features—BiLSTM classification model, convolutional neural network in the model mechanism increases the attention, and multikernel convolutional neural network in the model mechanism increases the attention. Tentatives show that the BM-ATT-BiLSTM recommended in this paper has the best performance, so it can be concluded that adding the above shallow

learning features and profound learning features to the short text sentiment analysis.

4.1. Summary. In a bidirectional LSTM based on emotional multichannel, shallow learning features and word embeddings and profound learning features of emotional attention are fused. Experiments show that the model integrates shallow learning features such as emotional part of speech, location information, and word dependence, and the classification effect is better than CNN and other models. In the profound learning model based on convolutional neural network, word embedding, emotional attention feature, and convolutional neural network feature are fused. Experiments show that feeding profound learning features into SVM can improve the performance of classification, and the model works best compared to other convolutional neural networks.

There are two main contributions of this paper.

- (1) This paper puts forward a bidirectional LSTM memory network model based on emotional multichannel, which integrates shallow learning features and profound learning features at the feature level, so the model can heighten the expression ability of text semantic information and learn the potential emotion of the text. The test outcome is also multifeature prefusion, which is very helpful for sentiment climate analysis.
- (2) This paper adopts CS-ATT-CNN and CS-ATT-TCNN to solve the problem of sentiment climate analysis of short texts. The model effectively combines machine learning and profound learning, the training time is short, and the model is better than the traditional convolution—Neural network classification model and TCNN model.

Theoretically, the semantic information of the LSTM model text is good, but from the practical point of view, the LSTM model still has deficiencies, and the BM-ATT-BiLSTM method in this paper combines the emotional part-of-speech features, location information features, and dependency features of words. As well as from the emotional attention feature, we can learn the underlying emotional regularity in the text so as to capture the important information that affects the emotional climate of the text. The BM-ATT-BiLSTM proposed in this paper is good, but there is one more factor that should be considered in the forget phylum, and it takes a lot of time to detect these meaningless communications can achieve better experimental results in a short time.

4.2. Prospect. Judging from the current situation and the experiments of this paper, there is still a long way to go in the analysis of sentiment climate of short texts. There are many challenges and opportunities, and there are many problems that deserve further study and improvement. The following two points can be used as the next step for research.

- (1) This paper only mines text data and does not consider the author's user attributes. If user attributes,

user's Weibo or online shopping comments, and posting time and other information are fully considered, the accuracy of text orientation analysis may be greatly improved. In the experiment, this paper only uses the data of Wikipedia as the corpus of the training word vector, and the data of Weibo and product reviews can be added as the expanded corpus of the training word vector in the future. Due to the complexity and diversity of the network environment and Chinese, some new words may not be recognized in the word segmentation stage, and there is a polysemy problem in Chinese. In the future, a new word dictionary can be constructed in combination with the context.

- (2) There are some sarcastic sentences in Weibo and product reviews. This paper cannot identify the emotional polarity of such sentences well. Therefore, we can add sarcastic sentences to transform the model of this paper. If you combine the knowledge graph to do sentiment decomposition, consider each word as an entity in the knowledge graph, and form a many-to-many relationship between entities and entities, and it is very possible to dig out the emotional connection between words and words. In the next step, we will combine some actual Internet projects to verify more combined models to reflect their socio-economic value.

With the current exchange and communication between different countries becoming more and more frequent, the language conversion of different countries has become a difficult problem. The analysis of a series of problems in cross-language discourse conversion, the study of the discourse conversion path, and innovation motivation based on the deep learning theory of cross-language transfer, it has theoretical and practical significance. This paper aims at the technical difficulties in speech conversion methods to effectively utilize the local mode information of signal time spectrum and the long-term correlation of speech signal. A discourse conversion method based on convolutional recurrent neural network model is proposed. In the model, the extended convolutional neural network is used to model the long-term correlation of speech signals. In the part of speech fundamental frequency estimation, the prosodic information generated by the decomposition of the fundamental frequency by continuous wavelet transform is used as the training target of the fundamental frequency estimation model. The experimental results show that the speech transformation method based on the convolutional cyclic network model proposed in this paper has better quality and intelligibility than the speech transformed by the contrast method.

1. Introduction

In the face of the diversity of social values and cultural diversity, coupled with the development of new media technology, traditional ideological and political education discourse is facing inevitable challenges. In the process of dealing with challenges, its disadvantages and problems are constantly exposed. For example, most of the discourse content is still confined to the propaganda of documentary language and policy discourse, which lacks effective connection with the daily life of the audience [1]. In the form of discourse, one-way indoctrination is more than two-way interaction; there are more grand narratives and less elaborate descriptions; more empirical life language, less rigorous academic discourse; and there are more referential words but less original ones extracted from practice. There are more empty and stale words than up-to-date ones; there are many words of conformity, but few words of independent thinking [2]; and the lack of ideological discourse power in the field of network. In this discourse field,

therefore, how to use by educators to understand, trust, and open discourse established the ideological and political education position, the spread of the ideological and political education content, firmly grasp the ideological and political education, in turn, say, raise new era the pertinence, effectiveness and validity of ideological and political education, and ideological and political education has become the key problem facing. [3–6].

With the rise of deep learning and artificial intelligence, traditional speech conversion methods based on statistical models can no longer meet the requirements of large amounts of corpus data involved in training, and the performance of traditional language conversion models deteriorates rapidly in the case of large amounts of corpus data involved in training. DNN [7] has strong data fitting ability and can better explain various complex data features, which is very suitable for the scenario where a large amount of corpus data participates in training. Deep belief network (DBM) maps speakers' spectrum features to higher order eigenspace, thus realizing the transformation between speakers' spectrum features.

Based on dnnvc (deep bidirectional long-term and short-term memory recursive neural network), it has recursive neural network, Dblstm RNN) to construct the discourse transformation model. Because dblstm-rnn can capture the forward and backward time relationship of the speaker's speech spectrum characteristics, the performance of the conversion model is significantly improved [8]. The proposal of convolutional neural network (CNN) [9] is a milestone in the field of deep neural network, which greatly promotes the development of deep learning and artificial intelligence. The depth generation network model based on convolutional neural network has been proposed and applied to the field of discourse conversion. Conditional variational automatic encoder network (CVAE) is used to unlock the content and timbre characteristics of the input speech spectrum [10]. Completely nonparallel many-to-many discourse transformation [11]. Star creative adversity network VC (stargan VC) method makes use of the advantages of the cvae-vc method and the cyclegan VC method, respectively. Multi-speaker multi to multidiscourse conversion is realized by using speaker identity tag thermal vector, which is the best in the current nonparallel multi to multi discourse conversion methods. The improved methods of VAE series and Gan Series in deep generation neural network model have been recognized and affirmed by many scholars, and a series of novel methods have been proposed, such as vawgan VC [12], vqvae-vc [13], cdvae VC [14], acvae-vc [15], adagan VC [15], cyclegan-vc2 [16], and stargan-vc2 [17].

Based on the above research, this paper innovatively uses the deep neural network model of cross-language transfer to solve the discourse conversion problem. In order to solve the problem that existing speech conversion methods cannot effectively utilize the acoustic mode information in the speech time spectrum, and it is difficult to effectively model the long-term correlation of speech signals, a novel convolutional recurrent neural networks based on convolutional recurrent neural networks is proposed. CRNN, which uses extended convolutional network to describe the pattern information of the discourse spectrum and model the long-term correlation of signals, and BiLSTM conduct the time sequence modeling. The performance of this method is better than that of BiLSTM.

2. Model Theory

In order to effectively describe the acoustic pattern information of speech in the time-frequency domain, model the long-term correlation of signals, and improve the naturalness of translated speech, a convolutional recurrent neural network with continuous wavelet transform is proposed in this paper. This CRNN model combined with the advantages of neural network, signal processing theory, and depth can use signal processing methods to obtain more suitable for the acoustic characteristics of the task and to make full use of the depth of the neural network nonlinear description ability to the words the local characteristics of spectrum and long correlation model, so as to achieve better performance of discourse transformation [18].

2.1. Discourse Conversion Model of Convolution Recurrent Neural Network with Continuous Wavelet Transform. Continuous wavelet transform (CWT) is a commonly used time-frequency analysis tool [19]. The traditional fixed-window transform algorithm (such as Fourier transform) determines the size and shape of the time-frequency window after selecting the window function and has the same ability to analyze both high and low frequencies. However, in practical signal analysis, we usually expect the algorithm to have different time-frequency resolution in different frequency bands. Continuous wavelet transform is an algorithm to solve this kind of problem, and its calculation process is shown in formula (1):

$$WT_f(a, \tau) = \langle f(t), \psi_{a,\tau}(t) \rangle = a^{-1/2} \int_R f(t) \overline{\psi\left[\frac{t-\tau}{a}\right]} dt. \quad (1)$$

In the formula, $F(t)$ represents the original signal, A represents the scale factor in the wavelet transform, τ represents the translation factor, and the wavelet basis function ψ increases with the increase of the scale factor, the time window function also increases, and the frequency resolution of the unit increases correspondingly, otherwise, the time resolution increases. When the wavelet basis function meets the admissible condition, the algorithm has contravariant transformation, and the Morlet wavelet basis satisfying the condition is adopted in this paper. The fundamental frequency component predicted by the model can be reconstructed into the fundamental frequency feature by inverse wavelet transform. The inverse wavelet transform formula is as follows:

$$\begin{aligned} x(t) &= \frac{1}{C_\psi} \int_0^{+\infty} \frac{da}{a^2} \int_{-\infty}^{+\infty} WT_x(a, \tau) \psi_{a,\tau}(t) d\tau, \\ &= \frac{1}{C_\psi} \int_0^{+\infty} \frac{da}{a^2} \int_{-\infty}^{+\infty} WT_x(a, \tau) a^{-1/2} \psi\left(\frac{t-\tau}{a}\right) d\tau. \end{aligned} \quad (2)$$

$X(t)$ represents the reconstructed signal, where the calculation method of admissible conditions is given by formula (3):

$$C_\psi = \int_0^{\infty} \frac{|\psi(aw)|}{a} da < \infty. \quad (3)$$

2.2. CNN Model. CNN is a commonly used neural network structure. Different from fully connected networks, the neurons of CNN are usually arranged in three dimensions. In the field of audio processing, 2d convolutional neural networks are usually used. In 2d convolutional kernels, the height and width correspond to the size of the time-frequency window of the convolution kernels, that is, the time-frequency range of each convolution of the convolution kernels. The depth of the convolution kernel corresponds to the number of channels of features after convolution. Usually, the depth of the convolution kernel used is gradually increased at the beginning of the model to improve the

fitting ability of the model, while the depth of the convolution kernel is gradually reduced at the output end of the model to map features to the target dimension. Figure 1 shows a schematic diagram of a two-dimensional convolution kernel.

Assuming that the input feature of this example is C^l , the eigenvalue of the output of the convolutional network is C^{l+t} , and the target feature is C^{ture} , the convolution operation can be expressed by formula (4):

$$C^{l+1}(i, j) = [C^l \otimes w^{l+1}](i, j) + b^{l+1} = \sum_{k=1}^{kl} \sum_{x=1}^f \sum_{y=1}^f [C_k^l(s * i + x, s * j + y) * w^{l+1}(x, y)] + b^{l+1},$$

$$\left(i, j \in \{0, 1, \dots, L_{l+1}\}, L_{l+1} = \frac{L_l + 2 * z - f}{s} + 1 \right).$$
(4)

In the formula, w and B , respectively, represent the weight matrix and bias of the convolution kernel; I and j represent the number of pixels of the feature graph; f , z and s correspond to the size, filling number, and step size of the convolution kernel. The training of convolutional network requires the setting of loss function, and the commonly used MSE loss function can be expressed by formula (5):

$$\text{MSE} = \left[\frac{1}{D} \sum_{i=1}^D \left(\frac{1}{2} (C^{\text{ture}} - C^{l+1})^2 \right) \right],$$
(5)

where D represents the corresponding feature dimension.

The extended convolutional neural network is a special convolutional network whose filter is discontinuous. Studies have found that such network structure with spacing between filters can make the convolution kernel have a large receptive field with minimal precision loss. The following figure shows the schematic diagram of the receptive field range of an ordinary $3 * 3$ convolution kernel and an extended $3 * 3$ convolution kernel.

The rectangular block in Figure 2 represents the feature graph, and the deepened part represents the convolution region of the convolution kernel filter. As can be seen from the figure, in the case of the same convolution kernel size, the receptive field of the extended convolutional network is larger than that of the ordinary convolutional network. This feature enables the model to have a larger receptive field under the same conditions and enables the network model to be capable of modeling longer context information.

2.3. CRNN Model. CRNN is mainly used to recognize text sequences of indeterminate length end-to-end, without cutting a single text first, but transforming text recognition into a sequence-dependent sequence learning problem, which is image-based sequence recognition. Figure 3 shows the structure diagram of the CRNN model used in this paper. After the acoustic features of ear discourse are input into the model, the feature extraction module is used to obtain the local features of the discourse spectrum.

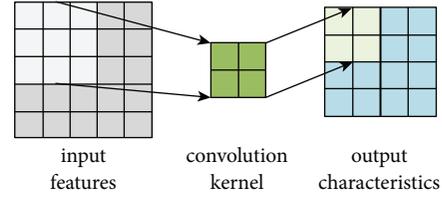

FIGURE 1: Schematic diagram of two-dimensional convolution kernel.

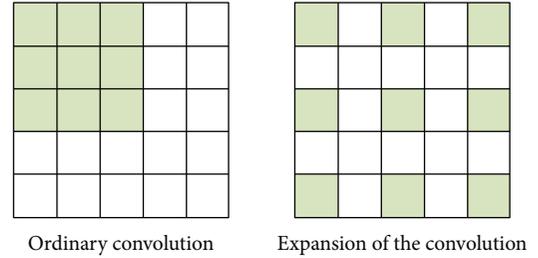

FIGURE 2: Comparison of receptive fields of different convolution structures. (a) Ordinary convolution, (b) Expansion of the convolution.

Feature extraction module is composed of two sets of two-dimensional dilated convolution. One set of convolution layer uses a convolution kernel with a size of $3 * 3$. The first dimension of the convolution kernel corresponds to the time direction of the discourse feature sequence and makes the convolution layer perform dilation in the time domain direction, which is called the time domain dilated convolution layer. Another set of convolution layers performs frequency domain expansion using convolution kernels of the same size.

The characteristic graph output by the time-frequency expansion module is connected and reconstructed into one-dimensional features and then input into the time-domain modeling module. The time-domain modeling module consists of a group of time-domain expansion blocks, whose structure is shown in Figure 3. To model discourse long-term correlation, one-dimensional dilated convolution was used in each dilated block and Gated Linear Units (GLUs) were used to improve the stability of the model during training. The calculation process of GLUs is shown in formula (6):

$$y = \sigma(x * W_1 + b_1) \otimes (x * W_2 + b_2),$$
(6)

where W_1 and W_2 represent the weight of the convolution layer, b_1 and b_2 represent the corresponding bias term, σ represents the sigmoid activation function, and \otimes represents the element-by-element multiplication symbol. The calculation process of the MISH activation function used in the expansion block can be expressed by formula (7):

$$\text{MISH} = x * (\tanh(\text{softplus}(x))).$$
(7)

In the formula, TANH and Softplus represent corresponding activation functions, respectively, and the calculation process of softPLu function is described in formula (8).

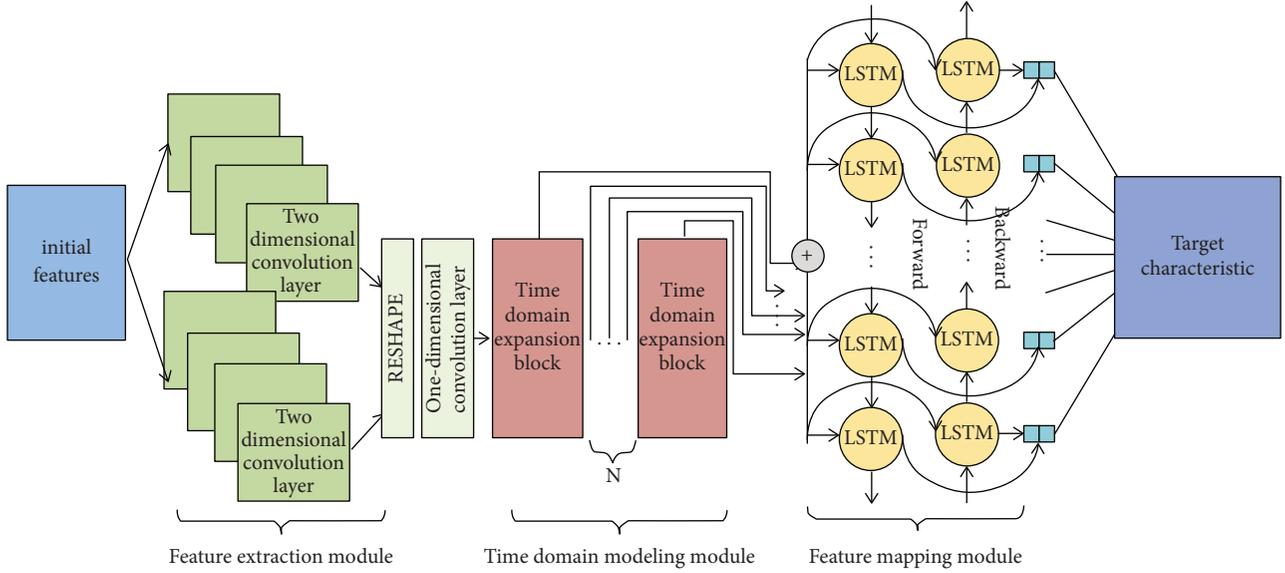

FIGURE 3: Structure of utterance conversion model based on CRNN.

$$\text{softplus} = \log(1 + e^x). \quad (8)$$

It can be seen from formula (8) that the function has a small number of negative intervals, which provides an additional flow interval for the gradient flow, thus alleviating the gradient problem of the network. The input of adjacent time domain expansion block is the output A of the previous expansion block, and the input of feature mapping module is obtained by adding the output B of each expansion block element by element.

The output of the feature mapping module is calculated by the two groups of memory cells with opposite directions, and the calculation process can be expressed by the following formula:

$$\begin{aligned} \vec{h}_t &= \text{lstm}(x_t), \\ \overleftarrow{h}_t &= \text{lstm}(x_t), \\ y_t &= W_{hy} \vec{h}_t + W_{hy}^- \overleftarrow{h}_t + b_y. \end{aligned} \quad (9)$$

The calculation process of LSTM in the above formula can be expressed by the following formula:

$$\begin{aligned} i_t &= \sigma(W_{xi}x_t + W_{hi}h_{t-1} + W_{ci}c_{t-1} + b_i), \\ f_t &= \sigma(W_{xf}x_t + W_{hf}h_{t-1} + W_{cf}c_{t-1} + b_f), \\ c_t &= f_t c_{t-1} + i_t \tanh(W_{xc}x_t + W_{hc}h_{t-1} + b_c), \\ o_t &= \sigma(W_{xo}x_t + W_{ho}h_{t-1} + W_{co}c + b_o), \\ h_t &= o_t \tanh(c_t). \end{aligned} \quad (10)$$

In the above formula, I , F , O , and C correspond to the input gate, forgetting gate, output gate, and cell state in the cell structure, respectively. O represents the commonly used Sigmoid activation function, and W and B represent the weights and bias items to be learned during network training. Because the time-domain modeling module uses a

large number of extended convolutional neural networks, the feature graph input by each neuron in the circular layer of the feature mapping module contains the whole discourse context information of the input model, which is beneficial to the model to describe the long-term correlation of signals.

2.4. Proposed Ear Discourse Conversion. The proposed ear discourse conversion method based on the CRNN model is shown in Figure 4. During the model training, the STRAIGHT model was used to extract the characteristic parameters of the two kinds of discourse, respectively. As mentioned above, the STRAIGHT model is a classical parametric vocoder, which has been widely used in speech analysis and synthesis tasks. After extracting relevant parameters, DTW algorithm is used to align feature sequences. Then, the spectral envelope features are converted to MCC features, and the normal speech fundamental frequency is decomposed by continuous wavelet transform. Finally, the MCC feature estimation model (CRNN_mcc) was trained using MCC features of ear speech and normal speech.

In the transformation stage, the extracted ear speech spectrum envelope is converted into MCC features, then the MCC features are input to the two transformation models after training to obtain the MCC features and nonperiodic components estimated by the model, and then the MCC features estimated by the model are input to the CRNN_f0 model to obtain the estimated fundamental frequency components. Then, the inverse of the estimated MCC feature is transformed into a spectral envelope, and the obtained fundamental frequency component is reconstructed into the speech fundamental frequency by inverse wavelet transform. Finally, the spectral envelope, aperiodic component, and fundamental frequency predicted by the model are reconstructed into transformed discourse by the STRAIGHT model.

Table 1 shows that the input and output parameters of two-dimensional convolution are frame number, frequency channel, and characteristic image channel in turn. The

parameters of convolution layer represent the size, expansion rate, and number of convolution kernels, respectively. The input and output parameters of one-dimensional convolution are tonnage and frequency channel in turn. The convolution layer parameters have the same meaning as two-dimensional convolution. In order to keep the temporal characteristics of discourse unchanged, zeroing is applied to all convolution layers to maintain the consistency of input and output dimensions. Only one set of time domain block parameters is

shown in the table, and three sets of time domain expansion blocks with the same parameters are stacked in the model. The TD block represents the time domain extension block. The output of recurrent neural network is the symbiosis of the output of two groups of neurons. Therefore, this paper splices the output of two groups of LSTM and uses the full connection layer to map the feature map to the target dimension.

This method uses the function shown in formula (11) as the training error function in the training process:

$$\text{loss} = \frac{1}{N} \sum_{t=1}^N \frac{10}{\log 10} \sqrt{2 \sum_{i=1}^m (y_i - Y_i)^2}. \quad (11)$$

In the above formula, y_i and Y_i represent target feature and prediction feature, respectively.

3. Experimental Simulation and Result Analysis

3.1. Experimental Data and Evaluation Indicators. To further evaluate the performance of the proposed method in the auditory speech conversion task, 348 auditory utterance and corresponding target sounds from the wTIMIT discourse database were selected as experimental data. The selected corpus has a sampling rate of 8000 Hz and is stored in 16 bit PCM format. When extracting speech features, the frame length is 40 ms, the frame offset is 5 ms, and 1024 point fast Fourier transform is used for each frame of speech. In total, 313 auditory utterances and their corresponding normal utterances were randomly selected as the training set, and the other 35 corpora were used as the test set. The relevant test set has strong adaptability.

All the above methods use the straight algorithm to analyze the reconstructed discourse. The GMM method and the DNN method in the comparison method are limited by the model structure and cannot be modeled by using the dynamic correlation between frames of discourse. In order to improve the algorithm performance of the comparison method and make the effectiveness of the proposed method more convincing, the dynamic characteristics of speech frames are taken as the training parameters of the two methods. The calculation formula of dynamic characteristics is given by formula (12).

$$\text{sp-dy}_k = \frac{(-2 * \text{sp}_{k-2} - \text{sp}_{k-1} + \text{sp}_{k+1} + 2 * \text{sp}_{k+2})}{3}, \quad (12)$$

sp-dy_k represents the corresponding dynamic feature.

The specific parameter configuration of the comparison method is described as follows: in the gMM-based ear speech conversion method, three models, GMM_mcc, GMM_ap, and GMM_f0, are, respectively, trained to estimate the MCC, aperiodicity and fundamental frequency of normal sounds. The Gaussian component number of GMM MCC and GMM_f0 is set to 32, and the Gaussian component number of GMM_ap is set to 16. In the DNN ear speech conversion

method, three DNN models are trained to estimate the MCC feature, nonperiodic component and fundamental frequency of target speech. The structure of THE DNN model is 30 × 30-900-1024-2048-1024-1024-900/7710/30. The Dropout technology is used for the hidden layers of the model to improve the model and reduce overfitting. The Dropout parameter value is set to 0.9, and the three dimensions of the output layer correspond to the three different characteristics of the prediction. For BiLSTM, three BiLSTM models are also trained, respectively, to estimate the acoustic characteristics of transformed discourse. The BiLSTM used contains two hidden layers with 512 units. All comparison methods adopted MSE objective function, and Adam algorithm was used to optimize model parameters, with a learning rate of 0.0001.

3.2. Model Parameter Selection. In order to evaluate the influence of extended convolution in the time-frequency domain of the feature extraction module on the translated speech quality, the traditional 3 × 3 single-size convolution kernel and the extended convolution in the time-frequency domain used in this paper were used to conduct the speech conversion experiment. It is obvious from Table 2 that the time-frequency expansion convolution adopted in this paper is conducive to improving the discourse conversion performance of the model. The specific comparison of discourse quality after transformation is shown in Table 2.

In order to explore whether the time domain expansion block in the time domain modeling module can effectively improve the performance of the discourse conversion method, the transformed discourse of CRNN discourse conversion method in three cases is compared. Table 3 shows the comparison of discourse quality after transformation under the three conditions, where CRNN_nt represents the CRNN model without time domain dilators and CRNN_ot represents only one group of time domain dilators. As can be seen from Table 3, the CRNN model without the time-domain expansion block has the worst performance of discourse conversion. The prediction accuracy of the CRNN model that only uses a group of time-domain dilators is lower than that of the method in this paper, because the CRNN model that only contains a group of time-domain dilators is difficult to use the context information of the

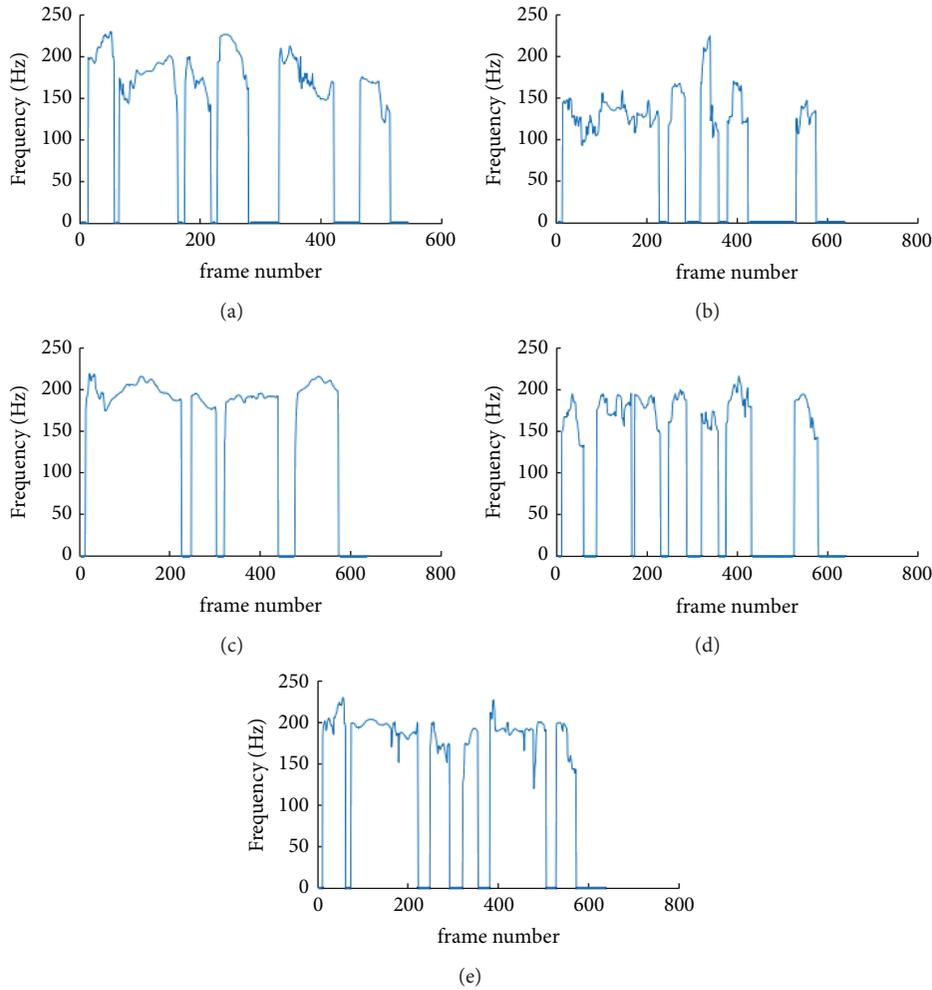

FIGURE 5: Fundamental frequency curves obtained by different conversion methods. (a) Enter the words, (b) GMM, (c) DNN, (d) BiLSTM, (e) CRNN.

whole input discourse, and the model has a small receptive field, which makes it impossible to effectively model the long-term correlation of discourse. Therefore, this paper finally sets up three groups of time domain expansion blocks in the CRNN network.

3.3. Comparative Analysis of Experimental Results. To demonstrate the effect of CRNN discourse conversion model, GMM, DNN, and BiLSTM are used as comparison models. Table 4 shows the evaluation results of transformed discourse. The performance of the GMM model is poor because the modeling ability of GMM is weaker than that of the neural network model. Although the DNN method can well represent the nonlinear mapping relationship, it cannot model the long-term correlation of discourse, and the effect of discourse conversion is not ideal. Compared with the DNN method, the BiLSTM method can make better use of the interspeech correlation. When the time step is large, the BiLSTM method can also model the long-term correlation of discourse, so the conversion effect is better than the GMM method and the DNN method. However, BiLSTM is difficult

TABLE 6: MOS of converted speech by different methods.

Model	GMM	DNN	BiLSTM	The model in this paper
MOS	2.35	2.51	2.82	2.90

to effectively utilize the local features in the time-frequency domain of discourse, resulting in some spectral errors in the transformed discourse. As can be seen from Table 4, compared with the comparison method, the effect of the CRNN speech conversion model under the quality assessment of different conversion speech methods is 4.5163 s in the disc time; 1.3201 s in the ticker; and 1.3201 s in the station time 0.6104 s, the utterances transformed by this method in this paper have the best inhomogeneous quality and intelligibility.

Table 5 shows RMSE values of fundamental and target tones predicted by four conversion methods, where, CRNN indicates that CWT is not used to convert the discourse fundamental frequency in the training process. As can be seen from Table 5, GMM is difficult to accurately estimate the fundamental frequency characteristics of utterances, and BiLSTM has better fundamental frequency estimation

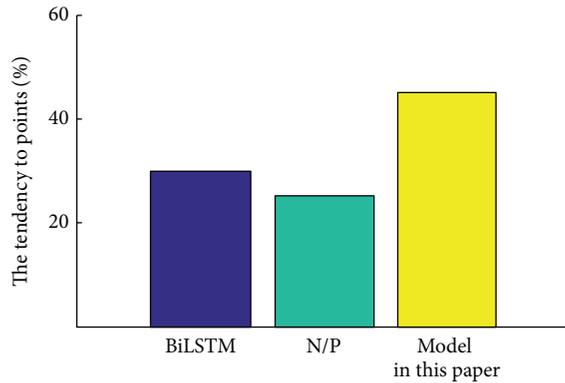

FIGURE 6: ABX test.

performance than DNN. In the process of model training, CWT decomposition of fundamental frequency can improve the prediction accuracy of the model to a certain extent. A horizontal comparison of the five methods shows that the difference between the fundamental frequency predicted by the proposed method and the target fundamental frequency is the smallest, which proves that the proposed method has higher fundamental frequency prediction accuracy compared with the comparison method.

It can be seen from Figure 5 that the GMM speech conversion method is difficult to fit the fundamental frequency curve of target speech effectively, and the fundamental frequency of transformed speech is greatly different from that of the target speech. The DNN method can only estimate unvoiced speech conversion, but cannot accurately predict the fundamental frequency curve. The fundamental frequency curve estimated by the BiLSTM method has a certain similarity with the target curve, but there is still a great difference with the expected target in details such as 170–190 frames and 230–270 tons. However, the overall trend of the speech fundamental frequency curve estimated by the proposed method is close to that of the target fundamental frequency, which indicates that the proposed method has better fundamental frequency estimation performance.

Table 6 shows MOS scores of discourse obtained after four methods of transformation. As can be seen from Table 6, the comfort level of discourse listening sensation after GMM conversion is poor, which is not suitable for discourse conversion task. Because BiLSTM can effectively make use of the dynamic interframe correlation of utterances, the transformed utterances have stronger continuity and better comprehensibility, thus achieving a better subjective score. The method in this paper can effectively use the acoustic model information to establish a long-term correlation model of utterances and use the prosodic features of utterances as the learning objective of the model. Therefore, the naturalness of statements transformed by the method in this paper is high, and the opinions are emotional, thus achieving the highest subjective score.

In this paper, ABX test is used to further evaluate and compare BiLSTM discourse conversion method with this method, which has better subjective score. Figure 6 shows

the results of the ABX test method. After several rounds of listening tests, the auditioners generally believe that the transformed utterances in this paper are closer to the target utterances.

4. Conclusion

This paper mainly introduces the discourse conversion method based on convolution recurrent neural network with continuous wavelet transform. Compared with the existing statistical model-based discourse conversion methods, the following conclusions can be drawn:

- (1) The existing discourse transformation methods usually only consider the differences between discourse spectra and rarely consider the characteristics of discourse itself from the perspective of the internal characteristics of discourse. This paper uses the local connection feature of CNN network to effectively extract the local features of discourse.
- (2) Discourse signals have long-term correlation, and existing discourse conversion methods are limited by model structure, so it is difficult to model the long-term correlation of discourse. Inspired by the extended convolutional neural network in the task of discourse synthesis, the method in this paper stacks multiple one-dimensional extended convolutional network layers in the model, so that the feature mapping module of the model can use the whole discourse context information for modeling, so as to describe the long-term relevance of discourse more effectively.
- (3) Due to its special motivation source and vocal form, the overall listening sensation of the utterance lacks of tonal change and the naturalness of the listening sensation of the utterance is poor. The converted utterances have better listening comfort, and continuous wavelet transforms are used to decompose the fundamental frequency features instead of the original declarations when training the model. The decomposed fundamental frequency can represent the prosodic characteristics of utterances. Taking the decomposed essential frequency component as the training target can give the transformed speech a better subjective hearing evaluation. At the end of this paper, a number of experimental results show that the discourse conversion method proposed in this paper has better discourse conversion performance compared with the contrast method, and the transformed discourse has better performance in both subjective and objective evaluation.

With the continuous development of the economy and the continuous improvement of information network technology, the information age brings not only the innovation of social lifestyle but also the innovation of enterprise development management mode and management concept. It is more likely to cause financial information leakage and human risk out of control in the big data environment. Faced with these risks, it is necessary to actively explore ways of risk control and create a good early warning and monitoring mechanism. It aims to study the principle and data processing mechanism of the company's financial early warning monitoring, and the establishment and analysis of the early-warning monitoring model in the big data environment. Help managers find and put forward early warning signals when the company has just had a financial crisis, and remind the company to take countermeasures.

1. Introduction

With the rapid development of the economy and technology, we are now in an era of big data composed of computers and the internet. Big data brings countless convenience and opportunities to the development of enterprises [1, 2]. At the same time, it also brings many risks and challenges to enterprises. Making the competition between enterprises more intense, investors and enterprises pay more attention to the important role of financial crisis early warning in enterprise management. However, enterprise financial crisis early warning has always been a difficult problem in enterprise management. Therefore, when enterprises are preventing and responding to financial risks, in order to better adapt to the current environment, it has become an important task for enterprises to establish and improve the early-warning and monitoring system of financial accounting indicators adapted to the era of big data [3].

Scholars at home and abroad have conducted relevant research on financial early-warning indicators, the construction of early-warning model, big data information acquisition, and processing technology [4]. Aziz et al. found that the financial early-warning model using cash flow

indicators has the best early-warning effect, which can better reflect the actual situation of listed companies [5]. Su and Wang proposed a financial early-warning computer big data model for listed real estate companies based on extension theory, and by combining them with each company, the specific actual data are verified to quickly and dynamically provide suggestions for the development of listed real estate companies [6]. Liang et al. used big data analysis to explore new economic risk early-warning methods, built a risk monitoring and early-warning platform, and realized rapid and scientific economic decision-making [7].

The application of big data in the financial field has long taken shape. At present, it is mainly active in the analysis of the stock market. Antweiler and Frank's research pointed out that the information between the volatility of the target company's market and the volume of stock transactions can be predicted [8]. Shin et al. found that the prediction effect of the BP neural network model is not as good as that of the support-vector machine (SVM) model in the aspect of enterprise financial early warning [9]. Min and Lee found that the SVM model had the best effect by comparing the multiple discriminant analysis (MDA), logit, and BP models [10].

Big data and financial early-warning monitoring are the common focus of researchers, but there is relatively little research on the application of big data to early-warning monitoring and analysis of corporate financial accounting indicators. This study mainly discusses the company's financial early-warning and monitoring principle and data processing mechanism, and the establishment and analysis of the early-warning and monitoring model under the background of big data. It aims to help managers take effective measures to avoid the recurrence of financial crisis when receiving the company's financial early warning.

2. Related Theoretical Analysis

2.1. Company Financial Crisis and Early Warning. According to the definition of financial crisis given by domestic and foreign research institutes, it mainly covers the following situations: first, enterprises that are insolvent; second, enterprises that cannot repay the principal and interest of the loan; third, enterprises in legal bankruptcy proceedings; and fourth, enterprises that have gone bankrupt. Judging from past foreign research studies, "bankruptcy" in the legal sense is basically the criterion for a company's financial crisis, but this criterion has much inappropriateness [3, 11, 12]. This study holds that financial crisis should be a broad concept, that is, the so-called financial crisis includes not only economic failure, technical insolvency, insolvency, and bankruptcy but also various situations between these states. The financial crisis is not only a state result but also a process. Economic failure is the beginning of the financial crisis. Insolvency and insolvency indicate that the company has been in a serious state of crisis. Bankruptcy is an extreme form of the financial crisis and the result of the financial crisis.

Financial early warning is the prevention of a financial crisis. The financial warning of an enterprise refers to analyzing the financial data generated by the enterprise in the past and predicting whether there will be a financial crisis in the future. Financial early-warning research can use relevant theories such as finance, statistics, and enterprise management [13]. According to the financial statements or other financial data provided by the enterprise, the financial situation of the enterprise is analyzed and predicted by using the analysis methods such as ratio analysis and mathematical modeling [14]. The financial crisis early-warning model can distinguish between financial crisis companies and normal companies, and judge the possibility of the financial crisis through the statistical analysis of early-warning indicators. Financial early warning can remind the enterprise of financial abnormalities that will occur and assist the enterprise management personnel to find the existing problems of the enterprise as soon as possible.

2.2. Big Data. Enterprise big data covers a very wide range, including the entire dataset in the field related to the financial status of the enterprise, and also includes the dataset that can be captured, stored, processed, and analyzed by software that takes longer than tolerable time. Corporate

financial big data not only has the characteristics of big data 5 V (scale, diversity, high speed, growth, and value) but also has the relevance and real time in the financial field [15, 16]. (1) According to the main body of the data, it is the data generated by the emotional expression of the stakeholders of the enterprise, such as investors, consumers, related government agencies, enterprises, and institutions involved. (2) According to the data source, the financial big data of the enterprise comes from the network platform that can obtain the emotional expression of the abovementioned stakeholders or organizations. (3) According to the origin of data, corporate financial big data originates from corporate network public opinion.

The big data indicator is a new concept proposed by combining big data and the concept of network public opinion. The current research's commonly used method is to quantify sentiment classification and combine various types of information and data to study together. Most of the big data indicators are researched by using the network public opinion data obtained from the internet, mainly through the big data indicators quantified by sentiment analysis of the network public opinion. Big data indicators have strong data acquisition feasibility and strong data quantification feasibility.

The theory of signal transmission is actually caused by information asymmetry. The transmission of information in the crowd can be natural without human intervention. It plays a very important role in regulating the phenomenon of information asymmetry in the economic market. Based on the information purification function of the network comment platform, it can provide effective big data information for the financial early-warning research of enterprises. The prediction deviation caused by using only financial indicators is corrected, and the research of financial early warning is assisted to break through the bottleneck period limited to financial indicators.

In general, enterprise big data can be more specifically understood as the existence of multiple data sources, structures, and forms of enterprise-related datasets, which will eventually form an available dataset after certain sorting. The dataset includes structured data, unstructured data, and semistructured data, including basic data, historical data, and real-time data.

3. Early-Warning Monitoring Principle and Data Processing Mechanism

3.1. Principles of Company Financial Early-Warning Monitoring. Big data embodies the characteristics of group wisdom, and the density of valuable information is very low, which makes some artificial modification intentions. Under the balance of group behavior, the value of information is often not greatly affected, which can avoid being blinded by relying only on information providers [17]. With the development of big data technology, the acquisition of this information is more objective and comprehensive than the information obtained through company announcements, surveys, conversations, and other means in the past, and this information can include the embedded influence of the company in the social network.

In the social environment, the existence of the company is based on the recognition of stakeholders, including customers, investors, supply chain partners, governments, and so on. Taking into account the company's business behavior, it will affect the relevant information on the Internet [18]. Therefore, this study regards all netizens as "sensors" of the company distributed on the network. According to the stakeholder theory, some of these "sensors" reflect the internal operation state of the company, some reflect the overall market environment of the company, and some reflect the operation state of the relevant parties of the company. Thus, a model of corporate financial early warning based on big data is constructed, as shown in Figure 1.

3.2. Data Processing Mechanism. The financial early-warning system of big data companies does not exclude the traditional indicators available in financial reports. On the contrary, the traditional financial indicators should be part of the content of big data. Various behaviors are related to the company of internet users, such as the number of times the internet users clicked on news, comments, news messages published by reporters, etc. These contents include the reactions of offline people to the company due to their contact with the company. These reactions cover various possible situations such as customer satisfaction with products, investor attitude, policy orientation, and so on due to people's different roles in the social network. All this information is mapped to the internet through offline. Through interaction on the internet, the emotions of netizens are collected and integrated into the signal flow to form the online real-time signal of sensors of relevant companies [11]. The general intuitive external manifestation of this real-time signal is the company's online public opinion.

In the specific processing process, the company's sensor signals can be semantically analyzed, and these signal flows can be quantified through emotional indicators to form a comprehensive indicator of various behaviors. The specific data processing process is shown in Figure 2.

Netizens who play the role of "sensor" of the company have various role relationships with the company offline. According to the stakeholder theory, the interaction between these roles and the company will produce different responses, which will stimulate these roles to have different emotions toward the company [19]. Only by mapping the emotions of the group to the internet can this information be preserved and acquired by us. These different emotions are gathered, excluded, and integrated into the interaction process on the internet, and finally collective wisdom will be generated. A certain angle reflects a certain state of the company.

4. Establishment of Early-Warning Monitoring Model and Data Analysis

4.1. Sample Company Selection. When selecting the sample listed companies, in order to avoid the error caused by the enterprise scale, the sample enterprise scale is basically the same, and it is obtained by random sampling under the condition of meeting various requirements. The standard of

crisis enterprises is that they have been listed for more than 5 years. This special treatment is the first time since listing [20]. The main reasons for the special treatment are losses for two consecutive years and negative net profit. The sample selection standard of normal enterprises is the enterprises that have been listed in Shenzhen and Shanghai for more than 5 years or have not been specially treated since listing.

When considering the extraction ratio of normal companies and crisis companies, in order to objectively study the availability of the early-warning model, we should not too subjectively assume the research conclusion. After combining the actual market situation, it is found that the proportion of ST enterprises in listed enterprises is very small, so the selection of research samples should also be in line with the market proportion as much as possible, but if the number of crisis enterprises is too small, it will affect the learning ability of the model. Therefore, 40 listed companies with the same scale of enterprises will be collected, including 27 normal enterprises and 13 crisis enterprises. The sample of crisis enterprises comes from the enterprises specially handled by Shanghai and Shenzhen stock exchanges in 2016 and 2017, including 5 crisis enterprises in 2016 and 8 crisis enterprises in 2017.

This study will collect online public opinion data related to 40 listed companies. The source of information is mainly through the collection of company-related public opinion information from the Oriental Fortune Forum [20]. The collected data are filtered for spam and obvious false information, and duplicate content is deleted. It is estimated that more than 60,000 pieces of effective online public opinion information will be obtained in the end. The details of ST sample companies and normal sample companies are shown in Tables 1 and 2.

4.2. Indicator Screening

4.2.1. Screening of Financial Indicators. The theoretical study of financial early warning is a complex process. Since the research needs huge theoretical support, there is no clear standard for which indicators should be selected as variables in the financial early-warning model, and researchers need to make specific investigations according to the research situation. In the face of this situation, many researchers at this stage build a financial index system based on the ability of enterprise development and improve the indicators in combination with the indicators concerned by enterprise managers in their actual work. After strict and careful screening, the financial indicators involved in the final study will involve six aspects of ability [12, 21].

- (1) *Solvency.* Whether an enterprise has the ability to pay cash and repay debts is the key to its healthy survival and development. The solvency of an enterprise is an important symbol reflecting the financial situation and operating ability of an enterprise. The solvency of an enterprise is an important aspect of its credibility. If the solvency is good, it can not only reduce the difficulty and cost of raising funds in the future

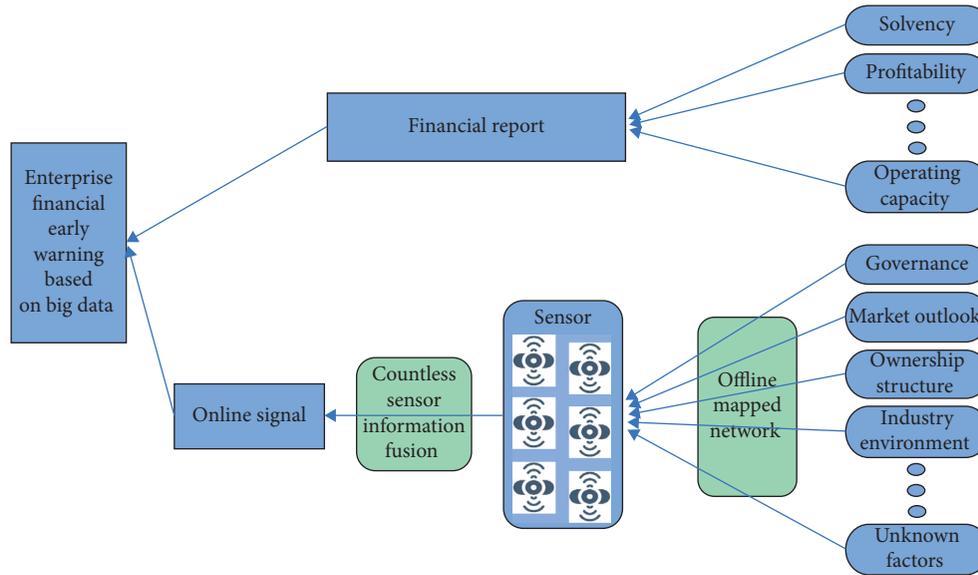

FIGURE 1: Principles of corporate financial early-warning monitoring.

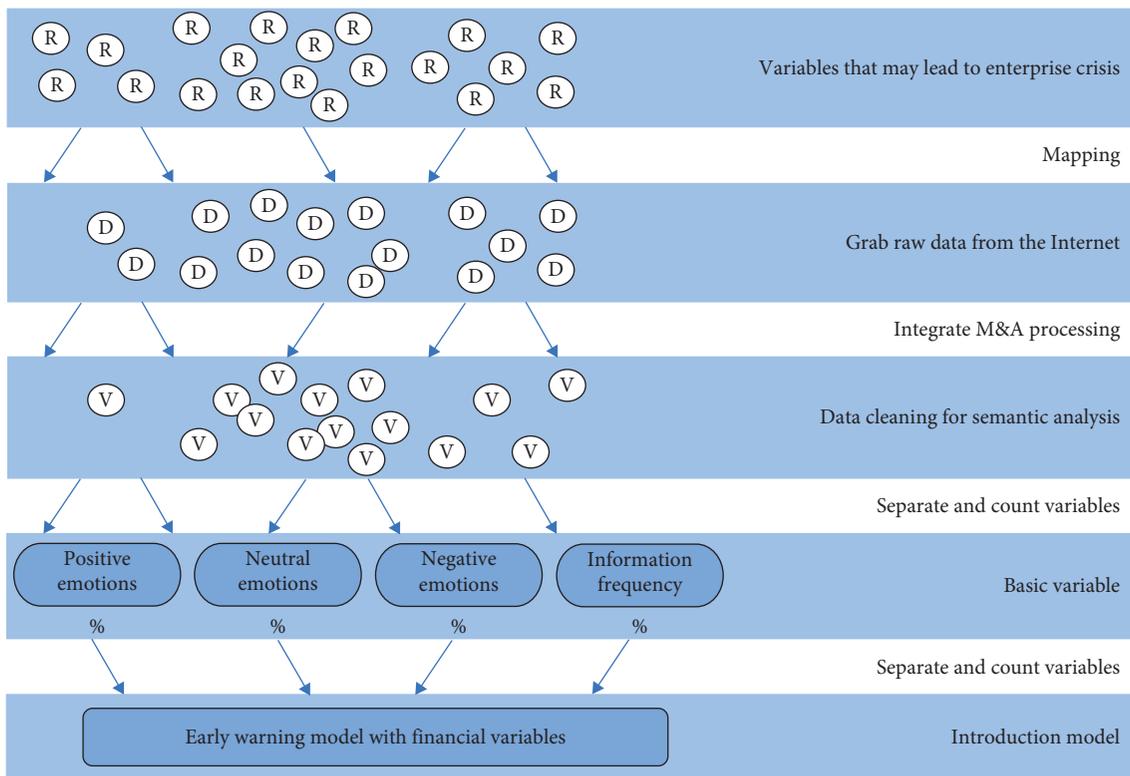

FIGURE 2: Data processing mechanism for financial early-warning monitoring.

but also prevent the enterprise from falling into a business crisis.

(2) *Profitability*. Profitability refers to the ability of enterprises to obtain profits, also known as the capital or capital appreciation ability of enterprises. It is usually expressed as the amount and level of enterprise income in a certain period of time. Profitability indicators mainly include operating profit

margin, cost profit margin, surplus cash guarantee multiple, return on total assets, return on net assets, and return on capital. For operators, the higher the profit rate, the stronger the profitability. Through the analysis of the profitability, problems in the operation and management can be found. The analysis of the company's profitability is the in-depth analysis of the company's profit margin.

27	C002291	002291	ST&SAT

(3) *Growth Ability*. Enterprise growth capability refers to the growth and development of an enterprise in a specific period of time. Some scholars have found that compared with mature and stable enterprises, enterprises in the growth and the rising period grow faster and have stronger development capabilities. While the development capability is strong, the possibility of the financial crisis will be greater compared to those large enterprises with relatively mature and stable development. Financial early warning for these small and medium-sized enterprises can often get more information from online forums, because the more the uncertain factors of enterprises in vigorous development, the higher the public attention.

(4) *Operating Capacity*. Operational capacity is an indicator that reflects the efficiency of enterprise asset turnover. If a listed company wants to have a good operating ability, it needs to have a high-efficiency operation. If the asset turnover speed is fast, it means that the speed of various business links of the enterprise is fast, and the cycle of revenue and profit generated is shorter. Therefore, the asset turnover rate of listed companies will also affect the financial situation of listed companies.

(5) *Cash Flow*. Cash flow is an important indicator to measure the liquidity of assets. If the listed company has a good cash flow situation, it can indicate that the company is operating well at the current stage and has the ability to repay the corporate debt. Therefore, cash flow-related indicators are also important indicators to measure whether an enterprise will have a financial crisis. The higher the cash flow indicators, the lower the possibility of the financial crisis.

(6) *Capital Structure*. Enterprise capital structure can reflect the ability of enterprises to deal with various crises. Enterprises with a relatively high ratio of fixed assets to intangible assets have a higher ability to deal with risks [22]. In the preliminary selection of

variables for financial indicators, this study selects 32 financial indicators from the six abilities concerned by enterprise managers and financial researchers as variables to be tested. The specific financial indicators are shown in Table 3.

The solvency of the enterprise is reflected by the indicators X1–X5, the profitability of the enterprise is reflected by the indicators X6–X12, the cash flow of the enterprise is reflected by the indicators X13–X14, the capital structure of the enterprise is reflected by the indicators X15–X16, the growth ability of the enterprise is reflected by the indicators X17–X28, and the operating capacity of the enterprise is reflected by the indicators X29–X32.

4.2.2. *Big Data Indicators*. The big data indicators used in this study are multiangle and multidimensional information related to enterprise development obtained through online public evaluation. This information is obtained by obtaining the evaluation of enterprises from many netizens. The evaluation information of many netizens is characterized by real time, many information sources, and complex structure. They can find out the situation of enterprise business activities from the network evaluation of people who pay attention to enterprise development. Such data are difficult to be manipulated by individuals, with relative objectivity

TABLE 3: Company financial indicators.

Financial indicator	Symbol	Indicator name
Solvency	X1	Working capital
	X2	Cash ratio
	X3	Current ratio
	X4	Quick ratio
	X5	Asset-liability ratio
Profitability	X6	EBIT
	X7	Operating net interest rate
	X8	Net profit margin of total assets
	X9	Return on net assets
	X10	Operating profit margin
	X11	Proportion of main business profit
Cash flow	X12	EBIT/total assets
	X13	Sales income cash flow
Capital structure	X14	Return on total assets
	X15	Intangible asset ratio
Growth ability	X16	Fixed asset ratio
	X17	Net profit growth rate
	X18	Operating income growth rate
	X19	Operating profit growth rate
	X20	Main business income growth rate
	X21	Growth rate of total profit
	X22	Total asset growth rate
	X23	Growth rate of net flow generated by operating activities per share
	X24	Growth rate of net assets per share
	X25	Growth rate of earnings per share
	X26	Retained earnings/total assets
	X27	Growth rate of net assets
X28	Rate of capital accumulation	
Operating capacity	X29	Accounts receivable turnover
	X30	Current asset turnover
	X31	Total asset turnover
	X32	Inventory turnover rate

and group intelligence, and the fragmentation of big data information, so many characteristics meet the relevant definitions of big data [20]. In order to further ensure the effectiveness and authenticity of online evaluation information, information collection has been made on the background information, enterprise scale, corporate governance, share structure, and audit opinions of each enterprise. When manually marking the comment samples, if you are not sure about the authenticity of individual comments, you can check the data in time. A few comments that cannot be confirmed will not be included in the data statistics.

In order to improve the efficiency and accuracy of emotion classification, this study adopts the method of artificial emotion classification. This method can also accurately judge the emotional bias of text information. In order to improve the efficiency of emotional assignment, the number of comments extracted from the network is controlled at about 60,000. This study will classify all online public opinion text data and mark the comments. The emotional bias of all effective comments shall be counted according to the established way for further analysis.

4.3. Model Establishment. The 40 samples selected in this study have 12 early-warning indicators, and a 40 * 15 matrix will be formed at the input end, which is equivalent to inputting 15 feature vectors for the support-vector machine (SVM) model [15]. The indicator system includes two parts: financial indicators and emotional indicators of online comments, including 12 financial indicators and 3 emotional indicators of online comments. Among them, the financial indicators are enterprise solvency indicators X2, X3, X4, and X5, profitability indicators X7 and X10, cash flow indicators X13 and X14, capital structure indicators X15 and X16, and operating capacity through indicators X31 and X32. The emotional indicators of online comments are the positive-emotion index, negative-emotion index, and total comments. These vectors constitute a 15-dimensional feature vector. The judgment of the support-vector machine model is one of two choices. That is, enterprises will fall into financial crisis and enterprises will not fall into financial crisis. This means that the output vector of the model is a two-dimensional feature vector.

The support-vector machine cannot directly make selection judgment on existing samples. It needs to effectively learn the known samples first. Only after the model learns these features can it make an efficient judgment. Therefore, this study divides the overall sample into two parts, one part is used to train the model, and the other part is used to test the accuracy of the model. There will be two types of enterprises with and without a financial crisis in the two parts of the dataset. The support-vector machine model abstracts the problem of the enterprise financial early warning and uses the model to learn the data features in the training set, so as to determine the optimal classification hyperplane of the two enterprise samples and the kernel function and find the optimal related parameters. Finally, the decision function of enterprise financial early-warning model based on big data can be obtained according to these. The overall construction process of the support-vector machine model is shown in Figure 3.

4.4. Early-Warning Monitoring Analysis. The results of early-warning analysis based on traditional financial indicators are shown in Figure 4. The blue circle in the figure indicates the prediction result of the model, and the red triangle indicates the actual situation of the enterprise. If the position of the blue circle coincides with the position of the red triangle, it indicates that the prediction of the model is correct. The test focused on 12 normal enterprises, 0 were wrongly judged, 5 were ST enterprises, and 4 were wrongly judged. Therefore, it is found that the accuracy of the model in judging ST enterprises is low. The test results after integrating the early-warning indicators of comment big data are shown in Figure 5. The predictions of 12 normal companies and 5 ST companies are all correct, that is, the correct rate of this test set is 100%.

As can be seen from Figures 4 and 5, the use of financial indicators and the addition of big data indicator models to the judgment of normal enterprises have a very high

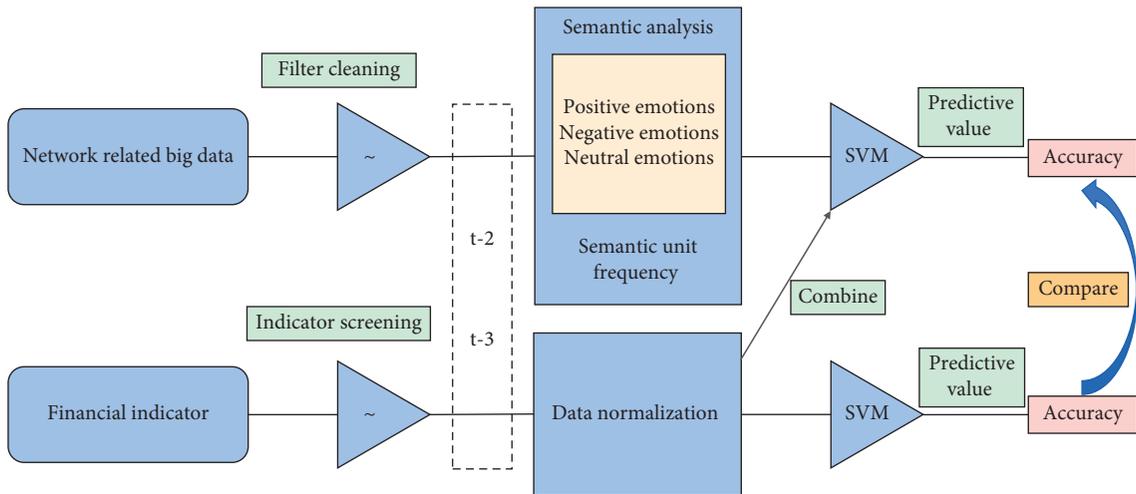

FIGURE 3: Model-building process.

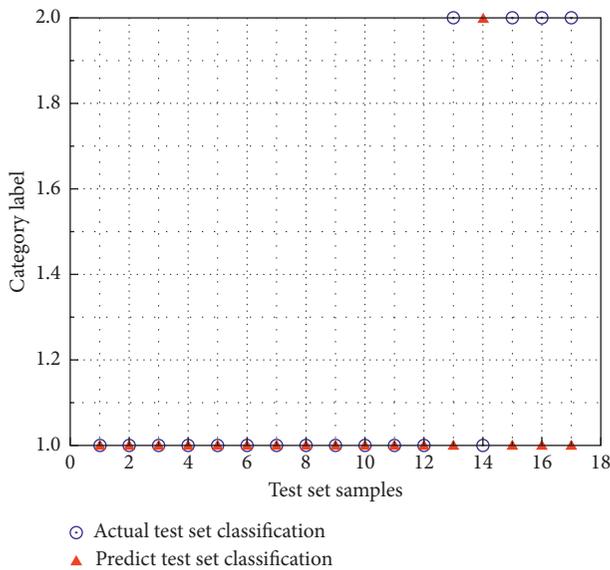

FIGURE 4: Test results of financial indicator model.

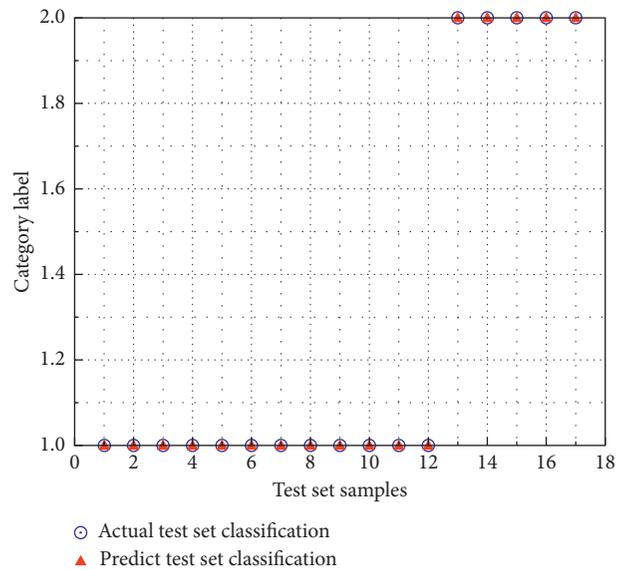

FIGURE 5: Test results based on big data indicator model.

accuracy rate, and the accuracy rate is as high as 100%. However, in the correct rate of the judgment of ST companies, only the model with financial indicators only reached 20.00%, and the correct rate of the judgment of the overall sample was only 76.47%. When the big data indicators of network sentiment are integrated, the correct rate of the judgment of normal enterprises is still 100%, and the correct rate of the judgment of ST enterprises has also reached 100%.

Therefore, it can be seen that the financial early-warning model containing big data indicators has greatly improved the prediction accuracy. It is also obvious in our test that the accuracy rate is significantly better than that of the financial indicator model. This shows that the prediction model that introduces big data indicators has a certain degree of improvement in the prediction of ST enterprises. At the same time, the prediction ability of non-ST enterprises is not inferior to the financial indicator model.

5. Conclusions

The vigorous development of big data technology provides new ideas and technologies for research in many fields. Therefore, in terms of financial early warning, big data technology can also be used as an auxiliary prediction tool to improve prediction accuracy. This will help the research on financial early-warning indicators to overcome the bottleneck period and make network sentiment indicators become big data indicators to correct the deviation of financial indicator early warning. It has important theoretical value for breaking through the predicament of stagnant financial crisis warning effect and provides support for enterprise financial crisis management.

A forecast approach of water structure based on GM (1, 1) of the gray system is proposed. Based on economic and water information of Hebei Province from 2000 to 2018, the water use structure of Hebei's industrial sector from 2019 to 2030 is forecasted according to the composition data and gray system GM (1, 1) model. The forecasting results by the proposed approach shows that the water structure of the tertiary industry has changed from 62.8:10.3:26.9 in 2018 to 60.5:10.2:29.3 in 2030. The proportion of water used in the primary and secondary industries has decreased slightly, the proportion of water used in the tertiary industry has increased, and the proportion of water used in the tertiary industry has not changed significantly.

1. Introduction

Regional water resources are both driving economic growth and improving the living standards of the people. The improvement of the quality of material life and the enhancement of the ability to survive are also key conditions for achieving sustainable human development. Faced with the contradiction between the shortage of large-scale water resources and the demand for water resources in economic development, new industrial restructuring will be inevitable to achieve greater economic efficiency in the face of shortages. Under the constraints of limited available water resources, the current economic growth model and water supply and consumption structure need to be optimized and adjusted to ensure the sustainable utilization of regional water resources and the healthy and sustainable development of economy and society [1–7].

How to make rational development and utilization of limited water resources and make it exert the maximum utility under the premise of sustainable development has become an important problem faced by human society. This is the motivation of this study.

Scholars have studied the relationship between industrial structure and water use structure, and achieved a lot of results. Jia et al. [1] proposed to first improve the efficiency of

industrial water use, upgrade the secondary industry, and optimize the industrial structure to reduce water consumption. Few authors [2, 3] advocate the transfer of high-water-consumption industries to small-water-consuming industries to increase efficiency in water resources utilization. Su et al. [4] studied the impact of water resources on industrial structure adjustment in Henan Province by means of cointegration, vector error correction estimation, impulse response, and variance decomposition. Jiao et al. [5] analyzed the temporal and spatial variation characteristics of the coupling coordination degree of water resources and industrial structure in Henan Province by establishing a coupling evaluation model. Fan and Wen [6] made quantitative analysis and comparison between industrial structure and water use system in Gansu Province based on the correlation analysis method and gray system theory, and put forward the direction of industrial structure adjustment. Jia et al. [7] used the system dynamics method to construct the collaborative evolution model of regional water use structure and national economy, and predicted and analyzed the collaborative evolution path and evolution law of water use structure and national economy industrial structure in Shandong Province.

The development of information technology and artificial intelligence has brought new opportunities to the

prediction and research of water use structure [8–15]. West and Dellana [16] carried out an empirical analysis of neural network memory structures for basin water quality forecasting. Bai et al. [17] proposed a variable-structure support vector regression model for the dynamic forecast of daily urban water consumption. Wei et al. [18] forecasted the structure of water consumption based on compositional data to promote inclusive water governance and made a case study of Beijing.

The existing studies have more single variable analysis of regional industrial structure and water use structure, but there are the following deficiencies. The method is relatively simple and lacks the analysis of industrial structure development under the constraints of water resources. There are many studies on the relationship between water resources and industrial structure, but there is a lack of in-depth exploration on the coordinated development relationship between water resources and industry.

This paper mainly analyzes the evolution of industrial structure and water structure through the collection and collation of economic data and water information in Hebei Province for 2000–2018. The relationship between the two countries is to reveal the coordination between them, and to forecast the water structure in Hebei province in 2030, and to propose the direction for research on industrial restructuring.

2. Research Methodology

There are certain conditions between the three secondary industries and water use, that is, the proportion of the output value of the three secondary industries and the sum of the proportion of water used in the three secondary industries are equal to one. By analyzing the time trend of a single indicator, the result will inevitably appear in each forecast year. The proportion of output value of the three industries and the proportion of water used in the three industries will no longer equal 1. Therefore, a single indicator prediction method cannot be used for a set of constrained variable indicators [19, 20].

Statistically, a combination of the individual share data for a set of constrained variables is called the component data (generally assuming that the sum of the shares of each variable is equal to 1), in under this constraint, economic models are established, and trends in variable composition are analyzed and predicted in a comprehensive manner. The gray system theory considers the socioeconomic system to be a native gray system [21]. It treats random processes of varying amounts of gray over a range of time as gray processes. The metric amount corresponding to a time series is the gray amount that is changing and the process of change can be considered gray. For this reason, the method of dedimensional [22] of component data was used. Combined with the GM (1, 1) model of the gray system, the basic steps for modeling the prediction of component data are given, and the three industrial structures and water structures of Beijing, Tianjin, and Hebei have been analyzed in a prediction and are of satisfactory results.

Definition 1. $X = \{(x_1, x_2, \dots, x_m) \in R^m / \sum_{i=1}^m x_i = 1, 0 \leq x_i \leq 1\}$. X is called the component data series, and x_i is the component data for the component i .

Definition 2. $X^t = \{(x_1^t, x_2^t, \dots, x_m^t) \in R^m / \sum_{i=1}^m x_i^t = 1, 0 \leq x_i^t \leq 1\} t = 1, 2, \dots, T$. t indicates the time.

The basic question of modeling forecasts for time component data: given the time component data sequence x^t , how to build a mathematical model, and predict $T + l$ the component data for the moment x^{T+l} .

Using the component data dedimensional approach and the gray GM (1, 1) prediction method, the basic ideas for solving problems are presented, with the following steps:

- (1) Make a nonlinear transformation of the original data

$$\begin{aligned} y_i^t &= \sqrt{x_i^t}, i \\ &= 1, 2, \dots, m; t \\ &= 1, 2, \dots, T. \end{aligned} \quad (1)$$

Remember $Y^t = (y_1^t, y_2^t, \dots, y_m^t)$, $t = 1, 2, \dots, T$. Then, there are

$$\begin{aligned} Y^{t2} &= \sum_{i=1}^m (y_i^t)^2 \\ &= 1. \end{aligned} \quad (2)$$

- (2) For any, the $t = 1, 2, \dots, T$ $Y^t = (y_1^t, y_2^t, \dots, y_m^t) \in R^m$ is distributed over m a spherical face with a radius of 1, as can be seen by the formula (2). Change $Y^t = (y_1^t, y_2^t, \dots, y_m^t)$, $t = 1, 2, \dots, T$ from the right-angle coordinate system to the spherical coordinate system $(r^t, \theta_2^t, \dots, \theta_m^t) \in \theta^m$, because there is a mapping relationship (where $(r^t)^2 = Y^{t2} = 1R^m \rightarrow \theta^{m-1}$ $0 < \theta_i^t \leq \Pi^2 i = 2, 3, \dots, m$),

$$\begin{aligned} y_1^t &= \sin\theta_2^t \sin\theta_3^t \cdots \sin\theta_m^t, \\ y_2^t &= \cos\theta_2^t \sin\theta_3^t \sin\theta_4^t \cdots \sin\theta_m^t, \\ y_3^t &= \cos\theta_3^t \sin\theta_4^t \cdots \sin\theta_m^t, \\ &\vdots \\ y_{m-1}^t &= \cos\theta_{m-1}^t \sin\theta_m^t, \\ y_m^t &= \cos\theta_m^t. \end{aligned} \quad (3)$$

- (3) The component data are reduced from the original dimension space to $m(m - 1)$ the dimension space $m(m - 1)$ during the conversion from the right-angle coordinate system to the spherical coordinate system, so that the original linear-related variables are converted into independent variables (corners), and the angle variables are obtained by recursion according to the formula (3).

$$\begin{aligned}\theta_m^t &= \arccos y_m^t, \\ \theta_{m-1}^t &= \arccos \left[\frac{y_{m-1}^t}{\sin \theta_m^t} \right], \\ \theta_{m-2}^t &= \arccos \left[\frac{y_{m-2}^t}{\sin \theta_m^t \sin \theta_{m-1}^t} \right], \\ &\vdots \\ \theta_2^t &= \arccos \left[\frac{y_2^t}{\sin \theta_m^t \sin \theta_{m-1}^t \cdots \sin \theta_3^t} \right] t = 1, 2, \dots, T.\end{aligned}\quad (4)$$

(4) Using the calculated angle data from the formula (4), $\{\theta_i^t, t = 1, 2, 3, \dots, T\}, i = 2, 3, \dots, m$, create a gray $G(m-1)M(1, 1)$ forecast model, which predicts the angle of the moment $T + l\theta_i^{T+l}, i = 2, 3, \dots, m$.

(5) Use the formula (3) to calculate the forecast for the time of day $T + lY^{T+l} = (y_1^{T+l}, \dots, y_m^{T+l})$. Obviously,

$$\sum_{i=1}^m (y_i^{T+l})^2 = 1. \quad (5)$$

(6) Use formula (1) to get the forecast value of the component data at the time of day: $T + l$

$$\begin{aligned}x_i^{T+l} &= (y_i^{T+l})^2, i \\ &= 1, 2, \dots, m.\end{aligned}\quad (6)$$

(7) Create a GM (1, 1) model to predict the value of the angle in 2030.

GM (1, 1) Modeling process:

2.1. Additive Generation. Set original number column: $x^{(0)} = \{x_1^{(0)}, x_2^{(0)}, x_3^{(0)}, \dots, x_t^{(0)}\}$ number of columns total. To reduce uncertainty, add up to get a new set of numbers listed:

$$\begin{aligned}x^{(1)} &= (x_1^{(1)}, x_2^{(1)}, x_3^{(1)}, \dots, x_t^{(1)}), \\ x_t^{(1)} &= \sum_{i=1}^t x_i^{(0)}.\end{aligned}\quad (7)$$

In the formula, $x_t^{(0)}$ is the data of the original number column; $x_t^{(1)}$ is the data of the cumulative number column.

2.2. Mean Calculations.

$$z_t^{(1)} = \frac{1}{2} [x_t^{(1)} + x_{t-1}^{(1)}]. \quad (8)$$

In the formula, the initial value: $t = 2$.

2.3. Curve Fit. To establish a differential equation,

$$\frac{dx^{(1)}}{dt} + ax^{(1)} = u. \quad (9)$$

In the formula, a is a factor and is taken in the range $[2]$; a, u is a gray contribution $\hat{a} = \begin{pmatrix} a \\ u \end{pmatrix}$; the matrix is formed, using the smallest two-multiplication solution.

To create a matrix and constant item vector for a new array created by the additive: BY

$$\begin{aligned}B &= \begin{bmatrix} -z_2^{(1)} & 1 \\ -z_3^{(1)} & 1 \\ \vdots & \vdots \\ -z_t^{(1)} & 1 \end{bmatrix}, \\ Y &= \begin{bmatrix} x_2^{(0)} \\ x_3^{(0)} \\ \vdots \\ x_t^{(0)} \end{bmatrix}.\end{aligned}\quad (10)$$

\hat{a} is calculated, then,

$$\hat{a} = (B^T B)^{-1} B^T Y. \quad (11)$$

It will be substituted and evaluated for solution $dx^{(1)}/dt + ax^{(1)} = u$.

$$\hat{x}_t^{(1)} = \left(x_1^{(0)} - \frac{u}{a} \right) e^{-a(t-1)} + \frac{u}{a}. \quad (12)$$

Or

$$\hat{x}_{t+1}^{(1)} = \left(x_1^{(0)} - \frac{u}{a} \right) e^{-at} + \frac{u}{a}. \quad (13)$$

$\hat{x}_t^{(1)}$: the ratio of accumulated output value in the forecast year (%), $x_1^{(1)}$: the specific weight of the new series (%) for the forecast value of the starting year, and a, u : the parameter.

2.4. Residual Analysis. By predicting the forecast value of the original series and doing a residual analysis with the original value, the residual difference is smaller and can be predicted directly with the model, which is much needed. Make corrections to the residual series data by creating a gray model.

The difference between the new agricultural series and the year of adjacent water consumption is the predicted annual demand:

$$V_t = \hat{x}_t^{(1)} - \hat{x}_{t-1}^{(1)}. \quad (14)$$

The residual differential is calculated as

$$\varepsilon_t^{(0)} = V_t^{(0)} - V_t. \quad (15)$$

The relative error is calculated as

$$\delta_t^{(0)} = \frac{\varepsilon_t^{(0)}}{x_t^{(0)}} \times 100\%. \quad (16)$$

2.5. *Postdifferential Inspection.* The accuracy level for the postdifferential inspection is shown in Table 1 [23].

Residual mean value calculation formula is as follows:

$$\bar{\varepsilon} = \frac{1}{n} \sum_{t=1}^n \varepsilon_t. \quad (17)$$

Residual differential calculation formula is as follows:

$$S_1^2 = \frac{1}{n} \sum_{t=1}^n [\varepsilon_t - \bar{\varepsilon}]^2. \quad (18)$$

The original mean value calculation formula is as follows:

$$\bar{x} = \frac{1}{n} \sum_{t=1}^n x_t. \quad (19)$$

The formula for calculating the original value variance is as follows:

$$S_2^2 = \frac{1}{n} \sum_{t=1}^n [x_t^{(0)} - \bar{x}]^2. \quad (20)$$

The formula for calculating the postcheck ratio is as follows:

$$C = \frac{S_1}{S_2}. \quad (21)$$

Small probability of error calculation formula is as follows:

$$P = P\{|\varepsilon_t - \bar{\varepsilon}| < 0.6745 \times S_2\}. \quad (22)$$

3. Water Structure Forecast

Using the composition data and the gray system GM (1, 1), it is predicted that the water structure in Hebei Province will be used in 2030 to calculate the water bias between Hebei industry and industry. The difference factor compared with 2018 will be used to analyze water structure in Hebei Province for the next decade [24–27].

According to water data of the three secondary industries in Hebei Province 2000–2018, we establish a model of the dynamic distribution of water usage patterns in Hebei's industrial water structure and forecast water structure for Hebei industry in 2030 [28–31]. The angle values for the nonlinear mapping of the three-way industrial water structure are shown in Table 2.

The forecast for the angle of water structure of the three industrial sectors in Hebei Province is performed, θ_2^t, θ_3^t are calculated, and the average fit error is shown in Table 3.

The accuracy of the prediction of the angle of water structure is shown in Table 4.

According to Table 1, the angle forecast model for the industrial water structure of Hebei Province meets the level 2

TABLE 1: Forecast model accuracy level judgment.

	The postcheck differential value C	Probability of error P
Class 1 (good)	$C \leq 0.35$	$P \geq 0.95$
Level 2 (qualified)	$0.35 < C \leq 0.5$	$0.8 \leq P < 0.95$
Level 3 (barely)	$0.5 < C \leq 0.65$	$0.7 \leq P < 0.8$
Level 4 (nonconformance)	$C > 0.65$	$P < 0.7$

accuracy requirement (qualified), which is qualified. $t = 2019, 2020, 2021, \dots, 2030$. The angle forecast is shown in Table 5.

The forecast of water usage structure for the three subindustries in Hebei Province is shown in Table 6.

Based on the actual value of the three-way industrial water structure, 2000–2018, and the forecast value of the three-way industrial water structure, 2019–2030, the evolution of industrial water use structure in 2019–2030 is shown in Figure 1.

Figure 1 shows the evolution of water structure in three industrial sectors of Hebei Province from 2000 to 2030. The coarse point part is the data from 2000 to 2018 and the fine point part is the prediction from 2019 to 2030. As can be seen from the diagram, (1) Component data modeling combined with the gray system GM(1,1) model predicts that Hebei Province will have a good fit for its future industrial water structure. (2) The proportion of water used in the first industrial sector in Hebei Province has been slowly decreasing, the proportion of water used in the second industry has been gradually decreasing, the proportion of water used in the third industry has been increasing slowly, and the gap between the proportion of water used in the first industry has gradually narrowed. According to the results of the calculation of the model and according to the forecast

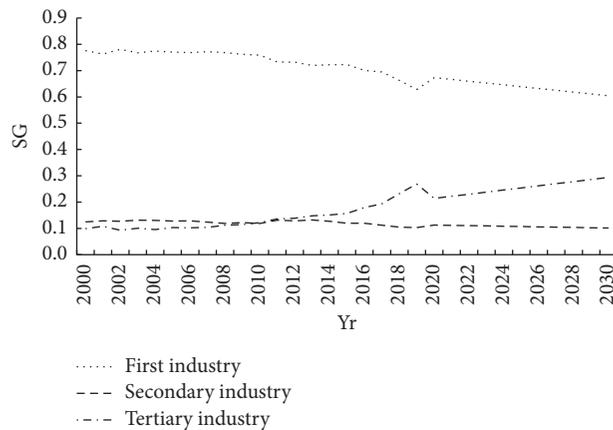

FIGURE 1: Trends in the evolution of the water structure of the three secondary industries, 2000–2030.

development trend, by 2030, the water structure of the three subindustries in Hebei province will be adjusted to 60.4% of the water use in the first industry, 10.2% of the water use in the second industry, and 29.4% of the water use in the third industry.

Based on the analysis of the forecasting results, the growth of domestic water and industrial water may be due to the improvement of economic level, the acceleration of urbanization and the rapid development of industrial enterprises. The increase in water use for ecological environment is mainly due to the improvement of awareness of greening and environmental protection. On the one hand, the slow growth of agricultural water consumption is due to the vigorous development of tourism in many places and the

transformation of many farmlands into landscape land, resulting in the reduction of the effective area of farmland irrigation. On the other hand, the continuous upgrading and transformation of agricultural water-saving measures and the construction of high standards of farmland have increased the coefficient of farmland irrigation water, thus reducing the consumption of agricultural water.

The industrial structure restricts the proportion of water used by different users and affects the overall water use efficiency. The improvement of water use efficiency can produce greater economic value and promote the optimization and adjustment of industrial structure. Through the correlation analysis between industrial structure and water use, combined with the analysis of the coordinated

relationship between water resources and industrial development, the scale of economic and social development and the range of water use efficiency under the constraint of water resources can be obtained.

4. Conclusions

As we can see from the above results, with the development of comprehensive water conservation activities in Hebei Province and the readjustment of the industrial structure, the water quality of the three industries has been continuously improved and the water efficiency has been improved. It is consistent with the law of economic and social development. The water structure of the tertiary industry has changed from 62.8:10.3:26.9 in 2018 to 60.5:10.2:29.3 in 2030. The proportion of water used in the primary and secondary industries has decreased slightly, the proportion of water used in the tertiary industry has increased, and the proportion of water used in the tertiary industry has not changed significantly. From this, it is evident that the water use structure of Hebei's industrial sector is in line with the future industrial development plan.

There are some problems in modern English education, such as difficulties in classroom teaching quality evaluation, lack of objective evaluation basis in teaching process management, and quality monitoring. The development of artificial intelligence technology provides a new idea for classroom teaching evaluation, but the existing classroom evaluation scheme based on artificial intelligence technology has a series of problems such as high system cost, low evaluation accuracy, and incomplete evaluation. In view of the above problems, this paper proposes a solution of English classroom concentration evaluation system based on deep learning. The program studies the evaluation methods of students' class concentration, class activity, and enrichment degree of teaching links, and constructs an information evaluation system of students' learning process and class teaching quality. Based on the edge computing system architecture, a hardware platform with cloud platform AI+ embedded visual edge computing devices managed by an FPGA deep learning accelerated server was built. The design, debugging, and testing of classroom evaluation and student behavior statistics-related functions were completed. This scheme uses edge computing hardware architecture to solve the problem of high system cost. Deep learning technology is used to solve the problem of low accuracy of classroom evaluation. It mainly evaluates the classroom objectively by extracting indicators such as the students' attention in the classroom, and solves the problems of the students' inattentiveness in the classroom. After the test, the classroom evaluation system designed by the paper runs stably and all functions run normally. The test results show that the system can basically meet the requirements of classroom teaching evaluation application.

1. Introduction

In the early stage of college English course learning, the score is often determined by the final exam results, which cannot fully reflect the students' learning situation, is not conducive to finding problems in the teaching process, improving teaching, and is not conducive to mobilizing students' learning enthusiasm [1]. Students often play with mobile phones or sleep in class. With the continuous development of technology, it provides a new idea for intelligent teaching to automatically obtain the attention state of students in English class by using facial expression recognition method. Facial expression recognition, as a noninvasive method, is more suitable for application in actual classroom teaching, which has a huge space to play both online and offline teaching [2].

In 2006, Geoffrey and Ruslan formally proposed the concept of deep learning [3]. A solution to the problem of "gradient disappearance" is proposed, which is to train the algorithm layer by layer by unsupervised learning method and then tune it by supervised back propagation algorithm. In 2012, the deep neural network (DNN) jointly led by the famous Professor Wu of Stanford University and the world's top computer expert Jeff Ade is the amazing achievement in the field of image recognition [4], successfully reducing the error rate from 26% to 15% in ImageNet evaluation. In 2016, Facebook's DeepFace project based on deep learning technology achieved an accuracy rate of more than 97% in face recognition, almost the same as that of human recognition [5]. At present, for face recognition, the face pixel in the image is required to be at least 64×64 , preferably 128×128 .

In general, face recognition needs to provide a positive face image; for a certain angle of the face image, as long as the demarcated face feature points can be recognized, the face can also be recognized [6].

Based on the above background, by analyzing the main problems existing in the classroom evaluation system at the present stage, this paper puts forward the modern English classroom concentration evaluation system based on deep learning, analyzes the design requirements from the actual needs, puts forward the system design scheme, and expands the specific design and implementation process in detail.

2. Related Work

2.1. Research Status of Facial Expression Recognition Based on Deep Learning. Different from traditional methods, deep neural networks can automatically obtain required features from a large number of data samples according to specific tasks. In addition, with the support of GPU computing technology, the deep learning model can be designed to be complex enough to contain hundreds of trillions of parameters, learn the semantic information of a different granularity in the samples, successfully avoid the complex operation of manual feature extraction, and achieve great success in the expression recognition task.

Yang et al. proposed a residual expression recognition algorithm that could filter emotion-irrelevant elements in the paper: faces were divided into two categories—faces with expression and neutral faces without expression, and each expression generation model was trained through cGAN network. The model can generate a neutral face for any input face image, and the expression information is stored in the middle level. Then, for neutral faces, the pixel-level or feature-level methods are no longer used to identify expressions, but a new method is used to learn and generate part of the facial expression information left in the middle level of the model, so as to generate the final classifier [7].

Yang designed an expression recognition structure dependent on images and image sequences, and proposed an illumination enhancement strategy, which can reduce the over-fitting phenomenon in model training. Without significantly reducing the recognition performance, the structure has fewer convolution kernels than the general model, which is convenient for deployment in mobile terminals. Moreover, data sets in three different scenarios are collected to verify the validity of the model [8].

Shi et al. believed that there are many mislabeled data in large-scale facial expression data sets, which may make the model overfit and merge and affect the effective features learned by the model. Based on this, a self-cure network (SCN) method is proposed to suppress the uncertainty in facial expression data sets. By extracting image features through CNN, we learned the weight of each image to obtain the importance of samples, arranged the weights in descending order, divided them into two parts of high attention and low attention by calculating the average weight,

and re-marked those samples considered to be wrong by estimating the probability. In this way, the sample label error is effectively solved [9].

Yuan et al. studied the application of facial expression recognition in the field environment. Since there are not too many constraints in the field, problems such as unfixed head posture, facial deformation, and motion blur often exist. In this paper, a convolution vision converter method is proposed: firstly, the attentional selection fusion module is used to fuse the feature images generated by the two branches, and the global attention fusion is used to fuse multiple feature images to capture the distinguishing information. The fused features are tiled into the sequence of visual words, and the relationship between the visual words with global self-attention is modeled [10].

2.1.1. Research Status of Facial Expression Recognition in Classroom Environment. In the current classroom teaching scenario, teachers want to obtain students' concentration in class in real time mainly through on-site questioning and visual observation, which requires extra energy and is highly subjective. With the development of facial expression recognition technology, it has become a new trend to use computers to automatically identify students' emotional states in class.

Cheng et al. designed an intelligent teaching model, which consists of four parts: emotion, course, student, and teacher. The system captures students' emotions through visual tracking technology and facial expression recognition technology, and carries out certain emotional feedback behavior [11].

Whitehill et al. studied the measurement of students' participation in class listening in 2014. It is pointed out that the popular methods of participation measurement include self-report, observation list and rating scale, automatic measurement, and automatic recognition based on computer vision. Computer vision analyzes facial cues, body postures, and gestures and provides an unobtrusive way to estimate student engagement [12].

Sun et al. studied the application of emotion recognition in intelligent teaching and proposed that the basic facial expressions defined by Ekman are not suitable for direct application in teaching scenarios, and multiple facial expressions are not highly correlated with students' emotions in class. The "cognitive skill training" experiment is suitable for classroom use. The data sets obtained are analyzed by using boost (BF) algorithm with box filter feature, support vector machine with Gabor feature, and multinomial logistic regression algorithm with expression output, and the model that can automatically identify student participation is obtained [13].

Cui et al. have implemented a student expression analysis system in the classroom environment, which is used to identify three expressions of students in class: ordinary, happy, and confused [14].

Ahuja et al. constructed a three-dimensional learning state space in his research, in which the horizontal coordinate represents the pleasure dimension of learning

emotional state and measures the recognition of learning. The longitudinal axis is the arousal dimension of learning emotional state, which measures learning fatigue, while the vertical axis is the interest dimension of students' emotional state, which measures learning avoidance. At the same time, a total of 9 expressions, including basic expressions, contempt, and confusion defined by Ekman, are introduced, and different weights are set for these expressions according to the measurement standard as the values on the horizontal axis [15].

3. System-Related Technologies and Algorithms

This paper uses Tengine deep learning framework and OpenVINO development tool suite to implement the deep learning algorithm at the edge end and server end, respectively. In the deep learning algorithm, MTCNN is used to achieve face detection and face image interception function, MobileNet-V2 to achieve face recognition function, and VGG-16 to achieve head posture recognition, head recognition, facial expression recognition, and human posture recognition and other classroom behavior recognition functions. This paper mainly introduces the structure of three neural networks, namely, MTCNN, MobileNet-V2, and VGG-16, as well as the deep learning framework Tengine, which is used to run the deep learning algorithm on the edge of the system, OpenVINO, which is used to run the deep learning algorithm on the server.

3.1. Tengine. In order to realize the functions of face detection, face image capture, and classroom behavior recognition at the edge end of the system, the paper adopts EAIDK-610 development board jointly developed by ARM and Open AI Lab as the core processing platform at the edge end of the system [16]. The EAIDK-610 development board is equipped with an embedded AI development platform, including support for heterogeneous computing library HCL, embedded deep learning framework Tengine, and lightweight embedded computer vision acceleration library BladeCV.

Tengine is a lightweight, high-performance, modular embedded deep learning framework. The deep learning framework is optimized for ARM embedded devices, does not rely on third-party libraries, and can be used across platforms. It supports Android and Linux, and supports GPU and DLA as hardware-accelerated heterogeneous computing resources.

Tengine deep learning framework has the following features:

- (1) Lightweight tailoring. Tengine relies only on C/C++ libraries; standard edition volume 3M, lite edition volume 300K; original support for ARM CPU.
- (2) Running memory optimization. Shared memory technology dramatically reduces memory requirements.

- (3) Support model compression and encryption. Tengine customizes model formats, supports model compression to reduce size, supports model encryption and packaging, and protects intellectual property rights.

According to the neural network operators currently supported by Tengine, the deep learning networks currently supported by Tengine include the following:

- (1) Squeeze net, mobile net, mobilenet-v2, ResNet50, AlexNet, GoogleNet, ImageNet classification networks, such as Inception-V3, Inception-V4, and VGG-16;
- (2) MTCNN;
- (3) SSD, YOLO-V2;
- (4) MobileNet-SSD;
- (5) Faster RCNN;
- (6) Lighten CNN;
- (7) Network model can be converted into Tengine model based on other deep learning frameworks.

In the deep learning network supported by Tengine, MTCNN, SSD, YOLO-V2, and other networks can realize face detection function. As the real-time requirement of face detection is not very high, the paper adopts MTCNN algorithm with slow execution speed but higher accuracy to realize the face detection function at the edge. For the classroom behavior recognition function of the system, it is necessary to use the classification network to identify and classify all kinds of classroom behaviors. Because it is necessary to conduct real-time classroom behavior recognition for students in the classroom, and there is not much classification of head, facial expression, and human posture in the recognition process, VGG-16 and ResNet50 networks are selected for testing on the premise of ensuring accuracy. After the test, it is found that ResNet50 has a better effect when the number of classification is large. However, in the class behavior recognition of this system, the number of classification of the recognition results of the head, facial expression, and human posture is small, and the recognition results obtained by using VGG-16 network are better. VGG-16 network is finally adopted to realize the algorithm of the class behavior recognition at the edge.

3.2. OpenVINO. In order to realize the face recognition function on the server side of the system, the paper adopts the FPGA accelerated cloud platform launched by Intel as the system server-side processing platform. The platform is loaded with OpenVINO tool suite developed for CPU + FPGA architecture.

OpenVINO (Open Visual Inference & Neural Network Optimization) is a tool suite that can speed up the development of high-performance computer vision and deep learning visual applications, as described in literature [17]. It

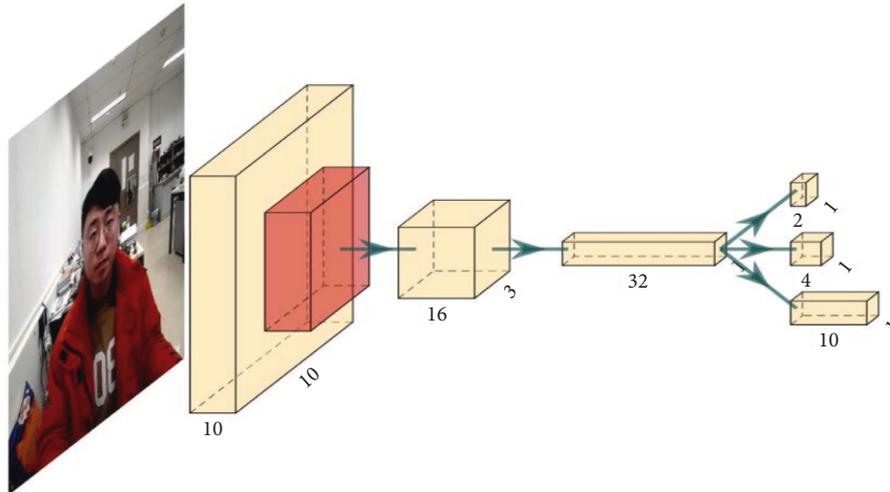

FIGURE 1: Structure diagram of P-Net.

supports deep learning on various Intel platform hardware accelerators and allows direct heterogeneous execution.

For AI workloads, OpenVINO provides the Deep Learning Deployment Toolkit (DLDT), a suite of tools that can deploy models trained by various open-source frameworks online.

DLDT is divided into two parts:

- (1) Model Optimizer. The model optimizer is a Python scripting tool for converting a model trained using an open-source framework into an intermediate representation (IR, intermediate representation) that the inference engine can recognize, that is, two files: the XML file representing the network structure description and the bin file storing the weights, respectively. The model optimizer is used for offline model transformations.
- (2) The inference engine is from the inference engine. Reasoning engine is a set of API interfaces supporting C++ and Python, requiring developers to implement their own reasoning process development.

The inference engine is the AI payload deployed to run on the device.

OpenVINO currently supports many network models under mainstream deep learning frameworks. Considering the balance between real-time performance and precision of deep neural network running under embedded hardware, the paper finally uses the improved MobileNet-V2 lightweight network to realize face recognition function on the server side.

3.3. MTCNN. Multi-task convolutional neural network (MTCNN) is a multi-task neural network model proposed by Shenzhen Research Institute of Chinese Academy of Sciences in 2016 for face detection task, as described in literature [18]. The proposed network and refine network output network are used in this model for

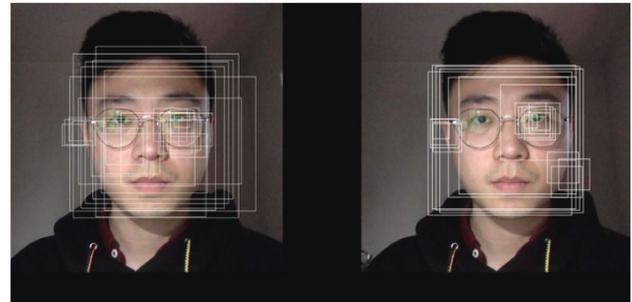

FIGURE 2: Input and output images of P-Net.

fast and efficient face detection. The model also uses image pyramid, border regression, and nonmaximum suppression techniques.

P-Net (proposal network) firstly modified all training samples into $12 \times 12 \times 3$ images, obtained $1 \times 1 \times 32$ feature map (feature map after convolution) through three convolution layers, and finally obtained three multidimensional outputs through three different 1×1 convolution kernels: the $1 \times 1 \times 2$ face probability, $1 \times 1 \times 4$ face candidate box coordinates, and $1 \times 1 \times 10$ face 5 marker anchor point coordinates. Its network structure is shown in Figure 1.

The input and output images of P-Net are shown in Figure 2.

Refine Network (R-Net) modifies all training samples to $24 \times 24 \times 3$ images; after convolution and pooling, the corresponding coordinate positions are output, respectively. Its network structure is shown in Figure 3.

The input and output images of R-Net are shown in Figure 4.

O-Net (output network) modified all training samples into $48 \times 48 \times 3$ images. Like R-Net, the output was face probability, face candidate frame coordinate, and face 5 marker anchor point coordinate, respectively. Its network structure is shown in Figure 5.

The O-Net input and output images are shown in Figure 6.

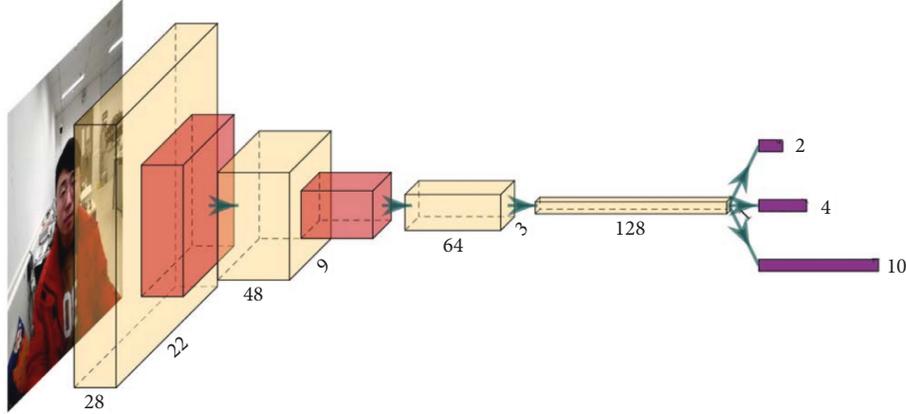

FIGURE 3: Structure diagram of R-Net.

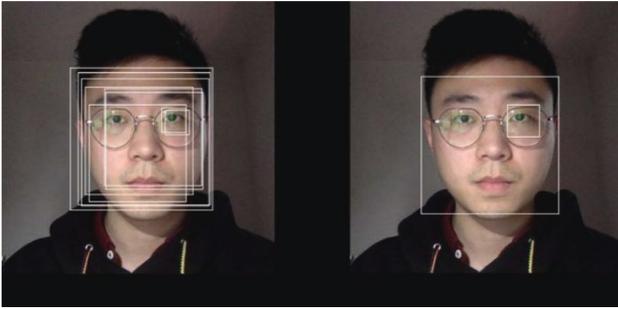

FIGURE 4: Input and output images of R-Net.

From P-Net to R-Net to O-Net, the larger the size of the input image is, the deeper the network structure is, and the more expressive the extracted features are.

Training MTCNN requires convergence of the following three tasks: face probability, face candidate frame coordinate, and face 5 marker anchor point coordinate.

The following cross drop loss function is used for human face, as shown in

$$L_i^{\text{det}} = -(y_i^{\text{det}} \log(p_i) + (1 - y_i^{\text{det}})(1 - \log(p_i))) y_i^{\text{det}} \in \{0, 1\}. \quad (1)$$

For regression of each candidate box, the following sum of squares loss function is adopted to calculate regression loss through Euclidean distance, as shown in

$$L_i^{\text{box}} = \|\hat{y}_i^{\text{box}} - y_i^{\text{box}}\|_2^2 y_i^{\text{box}} \in R^4, \quad (2)$$

where \hat{y}_i^{box} is the coordinate obtained through network prediction and y_i^{box} is the actual real background coordinate, both of which are quaternions.

The following sum of squares loss function is used to calculate the Euclidean distance between the predicted landmark position and the actual real landmark, and the distance is minimized. The calculation formula is shown in

$$L_i^{\text{landmark}} = \|\hat{y}_i^{\text{landmark}} - y_i^{\text{landmark}}\|_2^2, \quad y_i^{\text{landmark}} \in R^{10}, \quad (3)$$

where $\hat{y}_i^{\text{landmark}}$ is the marking coordinate obtained through network prediction and y_i^{landmark} is the actual real marking

coordinate. Since there are 5 marker points for left eye, right eye, nose, left corner of mouth, and right corner of mouth, each point has 2 coordinate values, and y_i^{landmark} is a tuple of ten.

Because each network performs different works, different types of training data are needed during training. The training formula of multiple input sources is shown in

$$\min \sum_{i=1}^N \sum_{j \in \{\text{det}, \text{box}, \text{landmark}\}} \alpha_j \beta_i^j L_i^j, \quad \beta_i^j \in \{0, 1\}. \quad (4)$$

The learning process of the whole training is to minimize the formula above, where N is the number of training samples, α_j is the importance of the task, β_i^j is the sample label, and L_i^j is the loss function mentioned above. When training P-Net and R-Net in MTCNN, $\alpha_{\text{det}} = 1$, $\alpha_{\text{box}} = 0.5$, and $\alpha_{\text{landmark}} = 0.5$; when training O-Net, $\alpha_{\text{det}} = 1$, $\alpha_{\text{box}} = 0.5$, and $\alpha_{\text{landmark}} = 1$.

3.4. MobileNet-V2. The deep separable convolution is applied in MobileNet-V1, the previous generation of MobileNet-V2, which makes the neural network maintain the accuracy and greatly improve the operation speed. A new structure is proposed in MobileNet-V2 and may be referred to as Inverted Residuals with Linear Bottleneck. This structure first enlarged the dimensions of the input feature map with 1×1 convolution, then operated with 3×3 convolution, and finally reduced the dimensions with 1×1 convolution operation. After the completion of convolution, ReLU activation function is no longer used, but linear activation function is used to retain more feature information and ensure the expressive ability of the model. Its structure is shown in Figure 7.

To improve network performance, the linear convolution part of Inverted Residuals with Linear Bottleneck structure in the network is modified into SE module. Figure 8 shows the structure of an SE block.

Given an input whose channel number is Channel1, a feature whose channel number is Channel2 is obtained through a series of transformations. The feature is input into SE block, and the obtained feature is re-demarcated through three operations:

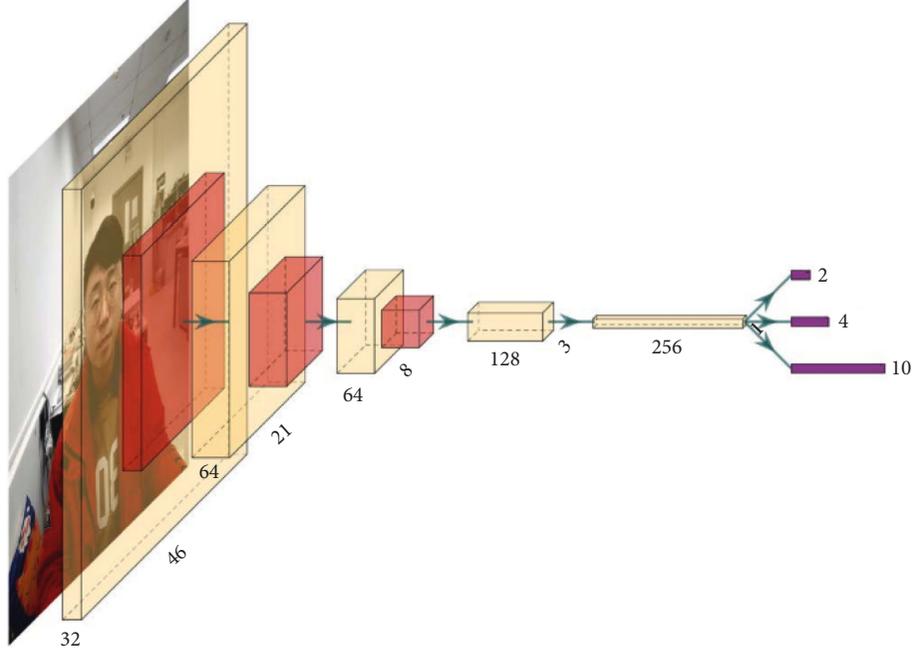

FIGURE 5: Structure diagram of O-Net.

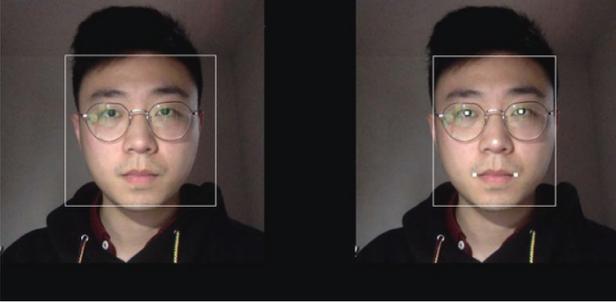

FIGURE 6: Input and output images of O-Net.

$$s = F_{\text{ex}}(z, W) = \sigma(g(z, W)) = \sigma(W_2 \delta(W_1 z)). \quad (6)$$

The calculation formula of parameter W is shown in

$$W_1 \in \frac{C}{r} \times C, W_2 \in \frac{C}{r} \times C. \quad (7)$$

r is a scaling parameter, whose purpose is to reduce the number of channels and thus reduce the computation. The dimension of the final output is $1 \times 1 \times C$, where C represents the number of channels. s is used to represent the weights of C feature maps.

(3) After obtaining s , use formula (8) for operation [20].

$$\tilde{x}_c = F_{\text{scale}}(u_c, s_c) = s_c \cdot u_c, \quad (8)$$

where u_c is a two-dimensional matrix and s_c is the weight, which is equivalent to multiplying every value in the u_c matrix by s_c . The modified Inverted Residuals with Linear Bottleneck structure is shown in Figure 9.

The network inputs a 128×128 image each time, extracts face feature points and feature vectors, respectively, on the image, and finally outputs a row vector containing 256 floating point values, and the row vector is the abscissa and ordinate values of the face feature vector. The cosine distance between the output feature vector and the coordinate value of the feature vector of the reference face image is calculated, and the wide value of the cosine distance is set. If the cosine distance is less than the wide value, the recognized face can be judged as the student himself.

(1) Squeeze operation, use global average pooling to compress features along spatial dimensions, convert each two-dimensional feature channel into a real number, and the output dimension matches the input feature channel number [19]. Its formula is shown in

$$z_c = F_{\text{sq}}(u_c) = \frac{1}{H \times W} \sum_{i=1}^H \sum_{j=1}^W u_c(i, j). \quad (5)$$

(2) The weighting for each attribute channel is generated by the parameter W , where the parameter w is learned to explicitly model the correlation between the attribute channels. Multiply W_1 by the squeeze operation to get z , which is a fully joint operation, and then pass through a ReLU layer with the output dimension unchanged; then, multiply by W_2 , which is also a full connection; then finally, through the sigmoid function, you get s . Its formula is shown in

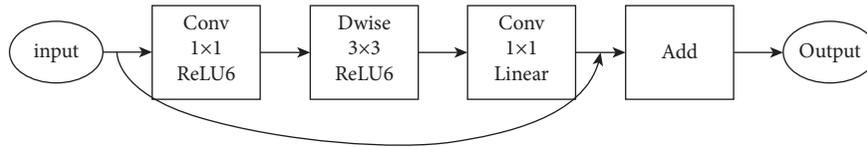

FIGURE 7: Structure diagram of Inverted Residuals with Linear Bottleneck.

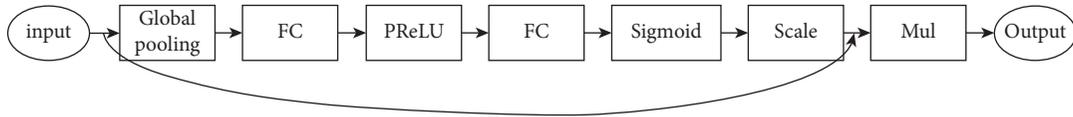

FIGURE 8: Structure of SE block.

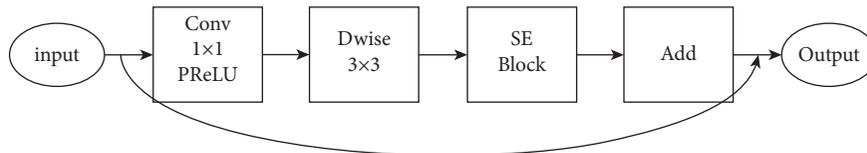

FIGURE 9: Modified structure of Inverted Residuals with Linear Bottleneck.

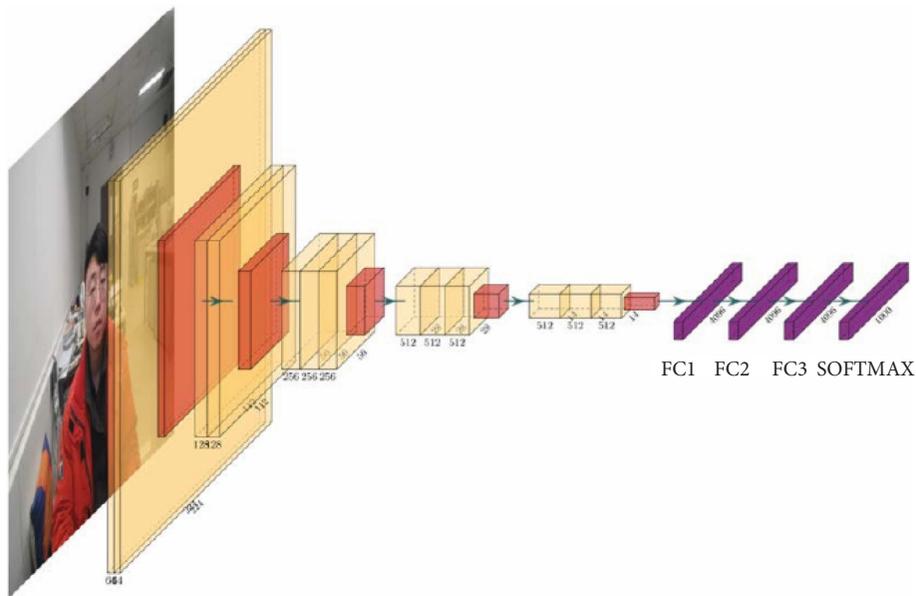

FIGURE 10: Structure diagram of VGG-16 network.

3.5. VGG-16. VGG is a convolutional neural network model proposed by Simonyan and Zisserman, whose name is derived from the abbreviation of Visual Geometry Group of Oxford University where the authors work [21].

VGG can be divided into six configurations, A, A-LRN, B, C, D, and E, according to the different convolution kernel size and number of convolution layers. Among them, D and E are more commonly used, called VGG-16 and VGG-19, respectively. Therefore, the system uses VGG-16 architecture.

Figure 10 shows the network structure of VGG-16.

The input data of VGG-16 are $224 \times 224 \times 3$ pixel data. After five-layer convolutional network and pooled network

processing, the output is a 4096-dimensional feature data and then processed by three-layer fully connected network, and the final classification result is obtained by Softmax specification. The dimensions of the Softmax layer can be adjusted according to the number of classifications for different purposes.

4. The Realization of the Analysis System for the Characteristics of English Class Students' Concentration

4.1. System Test Environment. In this paper, the classroom evaluation system based on deep learning is completed on

TABLE 1: Parameters of system edge computing-end hardware test environment.

EAIDK-610 embedded artificial intelligence application development platform	
SoC master chip	RK3399
CPU	2 × Cortex A72 + 4 × Cortex A53
GPU	ARM Mali-T860

EAIDK-610 embedded artificial intelligence application development platform jointly developed by ARM company and Open AI Lab, and FPGA acceleration cloud platform of Intel Company, combined with webcam and PC. The edge end, the server end, and the client all realize the stable data interaction through the network data transmission module. The hardware test environment parameters of the edge end of the system are shown in Table 1.

Table 2 shows the server hardware test environment parameters of the system.

The software test environment parameters of the system are shown in Table 3.

4.2. System Function Test. According to the analysis of functional requirements, the classroom evaluation system based on deep learning designed in this paper should have the functions of classroom behavior identification, classroom quality evaluation, and student classroom behavior statistics. The following are the functional tests for the above functions [22]. The test was carried out in the laboratory, and the test was set to 10 people, but actually to 9 people. In addition to the two attendance tests, a total of 80 classroom behavior identification test time points were set.

The EAIDK-610 development board is used to control the head and focal length of the camera through the network, so that the camera can aim at the whole student area in the classroom, so that the camera can collect all the students on the seat at the same time and then carry out head posture recognition, head posture recognition, facial expression recognition, and human body posture recognition.

The camera recognizes the head posture of the student in the seat. The system sets a total of 80 test time points for head posture recognition, so the result of head posture recognition after the course has a total of 80 time points of the number of students looking at the platform.

During the same period, the camera looked up at the students in their seats. The system sets a total of 80 test time points for head recognition, so the result of head recognition after the course has a total of 80 time points of head rate data.

During the same period, the cameras recognize the faces of the students in the seats. The system sets a total of 80 test time points for facial expression recognition, so the result of facial expression recognition after the end of the course has a total of 80 time points of the number of students listening carefully.

During the same period, the camera recognizes the posture of the student in the seat. When it is recognized that all students are “sitting down,” the class state is defined as “teacher lecturing,” and the result value of this state is written as “1.” When a student is identified as “standing,” the class state is defined as “teacher-student interaction.” If the gesture of “raising hands” appears before the gesture of “standing,” the result value of the state of “students answering questions independently” is written as “1.” If there is no “hand gesture” before the “standing” gesture, the result value of the “teacher calls the roll to answer the question” status is marked as “1.” When the student is identified as “writing,” the class state is defined as “classroom homework” and the result value of this state is marked as “1.”

At the same time of human posture recognition, the system records students’ hands raising and sleeping, so there will be data of the number of hands raising and sleeping at the corresponding time point after the course.

Reading face recognition results, head posture recognition results, head posture recognition results, facial expression recognition results, human posture recognition results, and evaluation index calculation according to the class of paper, respectively, calculate the attendance score of the course, head posture correct rate of scoring, serious expression rate hand score, score up rate, rate of score, score not sleep rate, the link of the lecturer score, students’ answering question score, teacher roll call to answer questions such as the secondary indicator, class attendance score, class concentration score, class activity score, class link richness score, and other first-level indicators, as well as class evaluation score. Upload the score to the appropriate location on the course evaluation sheet in the database. The database classroom evaluation table is shown in Figure 11.

At the same time, the statistical results of students’ classroom behavior are also uploaded to the corresponding position in the statistical table of students’ classroom behavior in the database. The statistical table of classroom behavior of students in the database is shown in Figure 12.

After testing, the system designed by the paper has realized the function of classroom evaluation.

4.3. System Performance Test. According to the system design requirements, the factors affecting the system

performance include face detection rate, face recognition rate, head posture recognition rate, facial expression

recognition rate, human posture recognition rate, and system stability.

FIGURE 16: Human posture recognition test pictures and test results.

TABLE 4: Technical parameters of system.

Category	Face detection	Face recognition	Head posture	Identify the rise	Identify expression	Recognition of human posture
Test times	50	50	10	10	10	10
Identification of success times	45	47	8	9	8	8
Detection rate	90%	94%	80%	90%	80%	80%

(1) Face detection test

Face detection test is carried out using MTCNN.

(2) Face recognition test

Face recognition is tested using MobileNet-V2 network.

(3) Head posture recognition test

VGG-16 network was used to test head pose recognition.

(4) Header recognition test

The header recognition test is carried out using VGG-16 network.

(5) Facial expression recognition test

VGG-16 network was used to test human pose recognition.

(6) Human posture recognition test

VGG-16 network was used to test human pose recognition.

(7) System stability test

The system stability test tests whether the system is interrupted operation or cannot work normally, the situation. After testing, the system is basically stable.

Test pictures and test results are shown in Figures 13–16.

4.4. Summary of Test Results. Through the function test and performance test of the system, it can be seen that the classroom evaluation system designed in this paper has good human-computer interaction and has realized the functions

of automatic classroom attendance, classroom behavior identification, and classroom overall evaluation. The face detection rate, face recognition rate, head posture recognition rate, facial expression recognition rate, and human posture recognition rate of the classroom evaluation system designed in this paper all meet the design requirements. The system stability basically meets the design requirements. The technical parameters of the system are summarized in Table 4.

5. Conclusion

On the basis of functional requirements and design requirements, the paper elaborated the whole development process of classroom evaluation system based on deep learning from the aspects of scheme design, relevant algorithms, detailed design, etc., and carried out functional test and performance test of the designed classroom evaluation system. The test results show that the system has realized the expected function, and all the performance parameters meet the design requirements. The work of the thesis is as follows:

- (1) Complete the overall scheme design of the system. According to the research background and application scenarios of the paper, the functional requirements of the system are analyzed to determine the system design requirements, and on this basis, the overall scheme design of the system is proposed, including the hardware platform construction scheme design and software scheme design.

- (2) The paper adopts EAIDK-610 embedded artificial intelligence development platform jointly developed by ARM and Open AI Lab as the core processing platform at the edge of the system. On the basis of this platform, the paper realizes the functions of pin-top and focal length control, face detection and interception, classroom behavior recognition, and so on, combined with the spherical webcam. In this paper, Intel FPGA accelerated cloud platform is used as the core processing platform of the system server, and the face recognition, classroom evaluation index calculation, and other functions are realized on this platform.
- (3) The paper uses PC as the system client to realize the design of user interaction interface on the client. In addition to the above functions, according to the functional requirements of the system, the paper implements the functions of sending and receiving data transmission on the edge end, server end, and client end, respectively. Finally, the paper realizes the system of classroom behavior recognition of students in fixed positions in the classroom and obtains the function of classroom evaluation according to the above results.
- (4) The function test and performance test of the classroom evaluation system based on deep learning designed in this paper are carried out, and the test results are summarized.

Data Availability

The data set can be accessed upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

In the field of catalysis, the support of the catalyst is often composed of hollow carbon materials. In order to monitor the preparation of nitrogen-doped carbon-based bimetallic copper-cobalt catalysis and its hydrogenation reaction in furfural, using *m*-aminophenol as the nitrogen source, formaldehyde as a carbon source, and P123 as a template agent, a nitrogen-doped bimetallic copper-cobalt mesoporous carbon catalyst Cu-Co@N-MPC-500 was synthesized by the hydrothermal method. The morphology, structure, and chemical composition of the catalyst were analyzed by means of TEM, XRD, BET, and XPS, respectively. The results show that the nitrogen-doped mesoporous carbon has a stable structure, uniform pore size distribution, and the nano-copper-cobalt particles are uniformly dispersed in the mesoporous carbon surface. Through furfural hydrogenation, the catalyst selectivity and cycle stability were discussed. Under the furfural conversion rate of 96.1%, the yield of cyclopentanone could reach 76.2%. After 5 cycles, the catalytic efficiency of the catalyst did not decrease significantly. It shows that Cu-Co@N-MPC-500 has excellent application prospects in the field of industrial production.

1. Related Introduction

Porous carbon materials come from a wide range of sources, including mesoporous carbon, activated carbon, carbon nanotubes, graphene, amorphous carbon black, nanofibers, and carbon aerogels. Porous carbon materials are widely used in catalysis, adsorption electrochemical [1–3], and other important fields. However, pure carbon porous materials do not perform well in many applications, and carbon materials need to be further modified to improve their application performance.

In the field of catalysis, porous carbon materials are often used as catalyst supports. Introducing other atoms into the carbon atomic layer to modify porous carbon materials to improve the reactivity of catalysts has been a research hotspot in recent years. The introduction of sulfonic acid groups into the porous carbon support can effectively introduce acid sites into the catalyst, thereby changing the acid value of the catalytic material. Kasakov et al. used glucose and cellulose as porous carbon sources to prepare a sulfonic

acid group-modified Ni/C-SO₃H catalyst, which showed excellent catalytic activity in the liquid-phase hydrogenation of phenol to cyclohexane. After reacting at 200°C for 6 h, the conversion of phenol and the yield of cyclohexane can reach 100% and 90%, respectively. Onda et al. [4, 5] used activated carbon (AC) as the carbon source to prepare a sulfonic acid group-modified platinum catalyst Pt/AC-SO₃H by modifying the carbon material. The activity of the catalyst was tested in the reaction of hydrolysis of polysaccharides to gluconic acid; the results show that the catalyst Pt/AC-SO₃H modified by sulfonic acid group has a significantly higher catalytic effect than the traditional carbon-based supported catalyst. N doping is one of the most common carbon-based support modification strategies. N atoms are doped into carbon to make the carbon structure more disordered, which will increase the defect sites of the carbon support and make N-doped carbon materials have unique properties [6]. The use of nitrogen-doped carbon-based supports can effectively improve the hydrophilicity and conductivity of the catalyst, strengthen the interaction between the carbon support and

the metal active components, improve the stability of the catalyst, and at the same time play a role in regulating the supported metal active components [7]. Lei [8] et al. used the hard template method to mix SBA-15 with aniline and then carbonized and removed the template at high temperature to prepare a nitrogen-doped ordered mesoporous carbon-supported metal Pt catalyst, which was investigated in the catalytic oxidation of methanol. The results show that there is a strong interaction between the nitrogen element in the carrier and the metal active component Pt nanoparticles. The higher the doping amount of nitrogen in the carrier, the higher the dispersion degree of Pt metal nanoparticles. Moreover, the prepared catalyst showed good reactivity in methanol oxidation reaction. Chan-Thaw et al. [9] prepared a nitrogen-doped carbon nanotube-supported palladium metal catalyst, which showed better catalytic performance in the catalytic oxidation reaction system of benzyl alcohol than the traditional activated carbon nanotube-supported palladium metal catalyst. There are many application reports on the use of modified carbon materials as catalyst supports to support single metals, but there are few reports on the use of modified carbon materials to support nonprecious bimetallic components.

The related research study in this paper is mainly based on using $\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$ and $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ as the precursors of metal active components, by using the triblock compound P 123 as the soft template and m-aminophenol as the nitrogen source, formaldehyde was used as the carbon source, and then a nitrogen-doped carbon-based bimetallic catalyst 2Cu-Co@N-MPC-500 was prepared through a one-step hydrothermal reaction, high-temperature carbonization, and H_2 reduction. The catalyst structure and components were characterized and analyzed, and the performance of the prepared catalyst was examined in the hydrogenation of biomass molecule furfural to cyclopentanone.

2. Related Theoretical Methods

The RNN network is also composed of an input layer, hidden layer, and output layer. Each layer contains a different number of neurons. In the traditional neural network model, the neurons of each layer are not connected to each other, but the RNN network is different, and the nodes between its hidden layers are connected. Therefore, the biggest difference between the RNN neural network and traditional neural network model is that RNN neural network not only has feedforward connection, but also has feedback of internal connection, which plays the role of "circulation." This kind of information flow similar to feedback inside neurons makes the network have memory function. At a certain time t , the difference between the neurons of the BP neural network and the neurons of the RNN network is shown in Figure 1:

There are many variants of the RNN network model, among which, Figure 2-1 is expanded in time series, and the classic RNN network model structure is shown in Figure 3:

In the above figure, the meaning of each parameter is as follows:

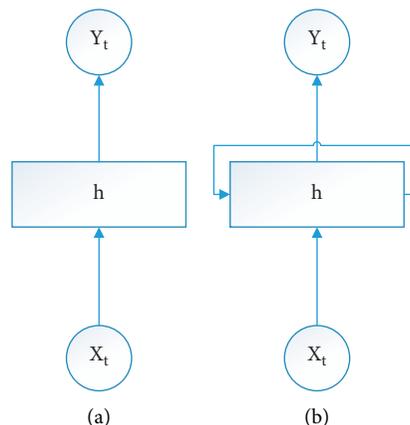

FIGURE 1: (a)BP neuron and (b) RNN neuron.

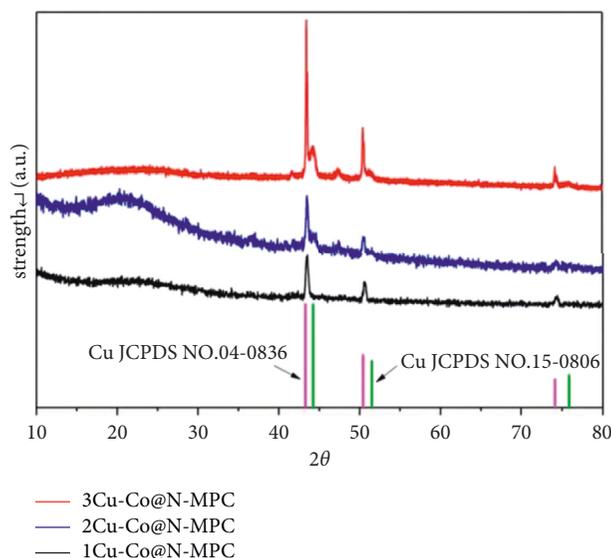

FIGURE 2: XRD characterization results of different Cu-Co loadings.

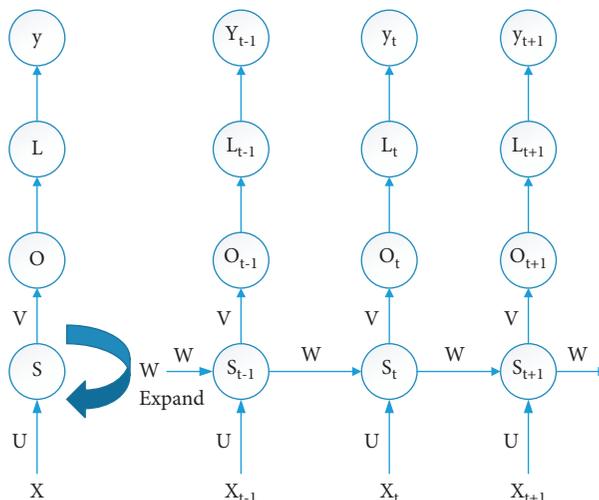

FIGURE 3: RNN network structure diagram.

- (1) U , V , and W are three matrices, which represent the input weight, the output weight, and the last output as the weight of this input, respectively. These three matrices are the linear relationship parameters of the model. The reason why the RNN network can have memory depends on these three matrices.
- (2) x represents the input layer data. Also, s_{t-1} , s_t , and s_{t+1} represent the input values at $t-1$, t , and $t+1$, respectively.
- (3) s represents the hidden layer state. Similarly, s_t represents the state of the hidden layer at time t . As shown in Figure 2-2, both x_t and s_{t-1} will affect s_t .
- (4) o represents the output of the model. As can be seen from the figure, o is only associated with s_t .
- (5) L is the loss function of the model.
- (6) y is the true observed value of the predicted time series data. As can be seen from Figure 2-2, in the RNN network, the hidden state s_t at any time can be obtained by the following equation:

$$s_t = \sigma(Ux_t + Ws_{t-1} + b). \quad (1)$$

In formula (1) and the following equations, σ is the activation function and b is the bias of the linear relationship.

After obtaining the state s_t of the hidden layer of the model at time t , the model output o_t at this time can be obtained by the following: t to

$$o_t = VS_t + c. \quad (2)$$

In formula (2), c also represents the bias, so the final output predicted by the RNN network can be obtained from the following:

$$\hat{y}_t = \sigma(o_t). \quad (3)$$

After the predicted output value is obtained, the cost function can be used to quantify the loss of the RNN model at the current time t , that is, the gap between the predicted value \hat{y}_t of the model and the original real data y_t . Common cost functions include cross-entropy cost function, mean squared error, root mean squared error, etc. This is actually the forward propagation algorithm of the RNN network model. In this paper, the preparation of a nitrogen-doped carbon-based bimetallic copper-cobalt catalyst based on in-depth learning and its monitoring application in furfural hydrogenation are studied. The main reason is that the relevant experimental results are monitored by computer technology.

3. Experimental Part

3.1. Reagents and Equipment. The reagents prepared in the relevant experiments in this paper mainly include “triblock compound P123, (Mn: 2000–5800) obtained from Annaiji; analytical grade m-aminophenol, aqueous formaldehyde solution, and furfural purchased from Sinopharm Chemical Reagent Co. Ltd.; analytical grade copper nitrate trihydrate,

cobalt nitrate hexahydrate, anhydrous hexanol, and ethyl acetate obtained from Aladdin.”

The main equipment prepared in this paper for related experiments are “superconducting nuclear magnetic resonance spectrometer (VNMRS600), Agilent Technologies, USA; X-ray photoelectron spectrometer (ESCA/CAB250), Thermo Fisher, USA; X-ray diffractometer (X-ray diffractometer ‘Pert PRO MPD type), PANalytical company, Netherlands; scanning electron microscope (SU8020 type), Hitachi, Japan; elemental analyzer (vario EL cube), Germany Elementar company; tube roasting furnace (GSL-1500X type), Hefei Kejing Materials Co., Ltd.; gas adsorption instrument (Autosorb-IQ3 type), American Quanta; and a gas chromatograph (GC16901FJ type), Hefei Jiedao Equipment Co. Ltd.”

3.2. Preparation of Catalysts. The preparation of the catalyst is mainly prepared by the hydrothermal method, and its main principle is to carry out the index through the hydrothermal reaction kettle, namely, the preparation of N-doped mesoporous carbon catalysts by the hydrothermal method: 1.01 g $\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$ and 0.62 g $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ with a molar ratio of 2:1 were dissolved in 50 mL of ethanol and 50 mL of deionized mixed solution of water, 4.5 g of m-aminophenol and 1.0 g of templating agent P123 were sequentially added, and stirred until completely dissolved. Then, 4.5 g formaldehyde solution (37 wt%) was slowly added to the solution using a dropping funnel, and the dropwise addition time was controlled to be 1 h. After the dropwise addition was completed, the reaction was continued at room temperature for 2 h.

The solution was transferred to a hydrothermal reactor, sealed, and placed in a drying oven at 65°C for 5 h. The obtained reaction mixture was filtered with deionized water and ethanol solution, and the filter cake obtained by filtration was dried in a vacuum drying oven at 60°C overnight. The dried solid was taken out and ground into powder using a mortar. The obtained powder was placed in a tube furnace for high-temperature carbonization. The tube furnace was heated from 25°C to 500°C at a heating rate of 1°C/min, and kept at 500°C for 2 hours. The carbonization process was carried out in a mixed atmosphere of nitrogen and hydrogen. A nitrogen-doped ordered mesoporous carbon was obtained, which was denoted as 2Cu-Co@N-MPC-500, where 2 represents the molar ratio of metal Cu and Co and 500 is the calcination temperature.

As a comparison, traditional activated carbon supported catalysts were prepared by the impregnation method. First, 1.01 g $\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$ and 0.31 g $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ were added to 90 mL of dilute nitric acid (5 wt%) solution at a temperature of 60°C and stirred rapidly for 2 h, and then it was put into an ultrasonic instrument for ultrasonic treatment for 2 h, 2.3 g of activated carbon was added into the above solution, and mechanical stirring was performed for 2 h; then the above mixture was filtered and washed. The filter cake was transferred to an oven at 60°C for vacuum drying and then ground into powder using a grinder. The obtained powder is placed in a tube furnace for high-

temperature carbonization, and the carbonization conditions are the same as those for preparing the catalyst by the hydrothermal method. An activated carbon-supported catalyst was obtained, which is denoted as 2Cu-Co@AC-500 as shown in Figure 4.

3.3. Characterization of Catalysts. The catalytic materials were analyzed for specific surface area, pore volume, and pore size distribution using a fully automatic surface area analyzer (BET). The specific method is as follows: 0.1 g of the sample was weighed, and after 4 hours of treatment under vacuum conditions, the adsorption and desorption test was carried out in a liquid nitrogen atmosphere. The specific surface area of the material was calculated using the BET (Brunner–Emmet–Teller) formula, and the pore size distribution was calculated using the BJH formula. The bulk structure analysis of nitrogen-doped catalysts was performed using X-ray powder diffraction analysis (XRD). Using Cu-K α as the X-ray radiation source, the scanning speed is 8°/min; the scanning test angle range is 20°–90°, and the working voltage and current of the instrument are 40 kV and 55 mA, respectively. The metal elements in the catalysts were quantitatively and qualitatively analyzed by X-ray photoelectron spectroscopy (XPS), and the metal grain size was calculated by the Scherrer formula. Using transmission electron microscopy (TEM) to conduct microscopic analysis of the apparent morphology and structure of the catalytic materials, qualitative and semiquantitative analysis of the composition of the catalytic materials can also be carried out. Before testing, the samples were ground to powder, and then dispersed evenly in ethanol solution, sonicated for 1 h with an ultrasonic instrument, and then the suspension was evenly spread on the copper mesh for testing. The metal content components in the catalysts were detected by an inductively coupled plasma analyzer (ICP-AES). Before detection, concentrated nitric acid was used to dissolve a certain amount of the sample catalyst, and then diluted to constant volume for sample detection.

3.4. Performance Test of Catalysts. In the furfural hydrogenation reaction, it needs to be carried out in a batch autoclave, and the activity of nitrogen-doped mesoporous carbon-supported metal copper-cobalt catalysts is prepared by a temperature controller and a 25 mL batch autoclave with magnetic stirring.

The experimental operation is as follows: accurately weigh 0.2 g of furfural and 0.1 g of the prepared catalyst, add them into the autoclave, then add 10 mL of deionized water, put in the magnet, seal the autoclave, and pass 1.0 MPa hydrogen gas, replace the gas 5 times, then add the hydrogen pressure required for the reaction, heat to the temperature required for the reaction under magnetic stirring at 700 rpm/min, and adjust the heating program and the reaction time by a temperature controller. After the reaction, the mixed solution was transferred to 10 mL of ethyl acetate solution containing quantitative internal standard DMF, and then the reaction solution was filtered, and the filtrate obtained after filtration was detected and analyzed by gas chromatography.

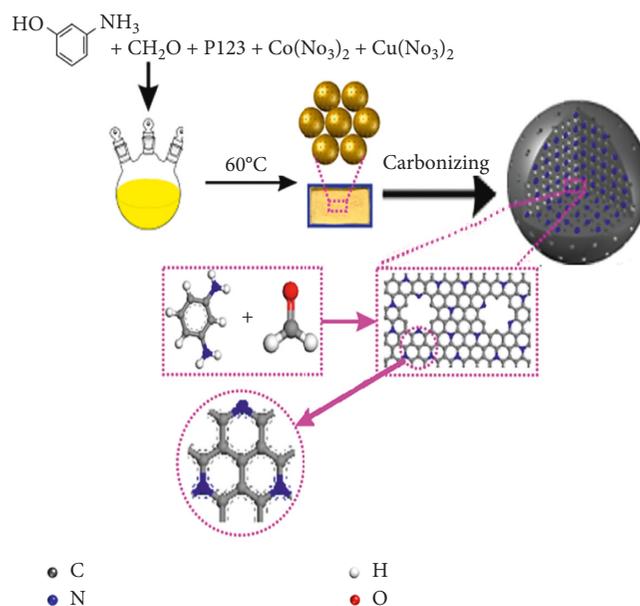

FIGURE 4: Preparation process of the N-doped mesoporous carbon catalyst.

The furfural hydrogenation reaction products were analyzed by gas chromatography. After the reaction, furfural, furfuryl alcohol, cyclopentanol, cyclopentanone, and tetrahydrofurfuryl alcohol mainly exist in the solution. The detection conditions of the gas chromatograph are as follows: FID detector; chromatographic column; DM-Wax capillary column; detection chamber temperature: 280°C; vaporization chamber temperature: 260°C; carrier gas pressure: 0.1 MPa; column oven initial temperature: 50°C; standard substance: DMF; and sample injection volume: 0.1–0.2 μ L.

3.5. Cyclic Performance Test of Catalysts. After each test reaction, the reaction solution was filtered and washed, and the obtained solid filter residue was washed with deionized water and ethanol solution for many times and then sealed and dried in an oven for continued use in the next cycle. In the next cycle experiment, the same mass of the recovered catalyst was weighed as in the last experiment, and control other reaction conditions are set to be the same as the last time.

4. Results and Discussion

4.1. Catalyst Characterization Analysis

4.1.1. XRD Analysis. It can be seen from Figure 2 that the as-prepared Cu-Co@N-MPC exhibits strong diffraction peaks around 43.4° and 50.5°, corresponding to the diffraction peaks of elemental Cu (JCPDS 96-901-2955) [10]. By comparing the peak intensities of catalysts with different Cu loadings, it is found that with the increase of Cu loading, the diffraction peaks of Cu are also continuously enhanced. The diffraction peak observed at about 2θ of 44.8° corresponds to

the diffraction peak of Co, but the peak intensity is weak, which may be due to the good dispersion and small particle size of Co metal nanoparticles. In order to further determine the existence form and valence state of each element in the catalyst, the catalyst was further characterized by XPS.

4.1.2. XPS Analysis. Figure 5 shows the XPS spectrum of 2Cu-Co@N-MPC-500. It can be seen from Figure 4(a) that strong peak signals mainly appear at the binding energies of 932.5 eV and 934.6 eV. The peak at 934.6 eV is the characteristic peak of Cu^{2+} , while the peak at 932.5 eV is the characteristic peak of Cu^+ and Cu^0 [11], and the area ratios of Cu^0 and Cu_2O to CuO are 82.3% and 17.7%, indicating that the Cu-Co@N-Cu in MPC mainly exists in the state of Cu^0 and Cu_2O , and the reduction of metal Cu is relatively sufficient. The XPS spectrum of Co in 2Cu-Co@N-MPC is shown in Figure 4(d), the binding energy peaks of Co mainly appear at 778.0 eV corresponding to the characteristic peak of Co^0 (2p 3/2), 780.9 eV and 797.6 eV, respectively. For the characteristic peaks of Co^{3+} (2p 3/2) and Co^{3+} (2p 1/2), 783.5 eV and 796.5 eV correspond to the characteristic peaks of Co^{2+} (2p 3/2) and Co^{2+} (2p 1/2), respectively, indicating that the main forms of copper are CoO and Co_3O_4 , and cobalt is less reduced. The metal grain size was calculated to be 13.8 nm by the Scherrer formula. XPS analysis results showed that the metal active centers of the prepared catalysts were mainly Cu^0 , Cu_2O , and CoO_x .

Figure 5(c) is the XPS characterization spectrum of 2Cu-Co@N-MPC-500N. It can be seen from the figure that the peak of the N1s binding energy in Cu-Co@N-MPC-500 appears at 400.9 eV, which corresponds to graphite nitrogen bonding.

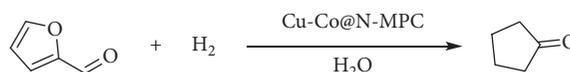

The peak at 398.9 eV corresponds to the binding energy of pyridine nitrogen. The ratio of graphitic nitrogen to pyridine nitrogen is close to 1:1. Elemental analysis of the synthesized 2Cu-Co@N-MPC catalyst showed that the nitrogen content in the catalyst was 5.29%. It shows that N in 2Cu-Co@N-MPC is well introduced into the catalyst support and mainly exists in the form of graphitic nitrogen and pyridine nitrogen.

4.1.3. N_2 Desorption Analysis. The pore size distribution of the catalyst support and the internal structure of the pores have a great influence on the catalytic activity. By observing the N_2 isotherm adsorption and desorption curves (Figure 6), it can be seen that the prepared 2Cu-Co@N-MPC-500 has obvious pore structure characteristics, and the specific surface area of the catalyst calculated by the formula is $20.16 \text{ m}^2 \text{ g}^{-1}$. It can be seen from the pore size distribution curve that the pore size distribution of the mesoporous carbon spheres is uniform, and the average pore size is about 4.9 nm, which belongs to the mesoporous range.

4.1.4. TEM Analysis. Through the detailed observation of TEM, as shown in Figure 7, the prepared catalyst carrier has obvious spherical characteristics, and it can be seen that the N element is uniformly distributed, and the N element is well

introduced into the catalyst carrier. The copper-cobalt nanoparticles were well-dispersed in the pore size of the mesoporous carbon spheres, and there was no obvious metal agglomeration phenomenon, indicating that the prepared nitrogen-containing mesoporous carbon carrier had a good dispersing effect on the metal copper-cobalt nanoparticles.

4.2. Catalyst Performance Test. Taking furfural hydrogenation to cyclopentanone as a model reaction, the catalytic hydrogenation performance of the catalyst 2Cu-Co@N-MPC-500 was investigated. The reaction temperature, reaction pressure, and reaction time conditions were optimized. Under the mild reaction conditions of 150°C , 2 MPa H_2 , and 2 h, the 2Cu-Co@N-MPC-500 catalyst showed the best catalytic activity and selectivity. A furfural conversion of 96.1% and a cyclopentanone yield of 75.2% were obtained. Subsequently, the effect of nitrogen content in the carrier on the catalytic activity and the cyclic stability of the catalyst were investigated in depth.

4.2.1. Effect of Nitrogen Content in the Catalyst Carrier on the Reaction Activity. The catalytic performance of catalysts with different nitrogen content in furfural hydrogenation was tested experimentally, and the results are shown in Figure 6. Using the traditional activated carbon-supported bimetallic catalyst 2Cu-Co@AC-500 under the optimal reaction conditions, 78% furfural conversion and 35% cyclopentanone yield can be obtained. However, the as-prepared N-doped catalyst 2Cu-Co@N-MPC-500 was able to achieve close to 100% conversion and 75% cyclopentanone yield under optimal reaction conditions, suggesting that the use of the N-doped mesoporous catalyst is beneficial. The carbon material as a carrier can effectively improve the activity of furfural hydrogenation and the selectivity to cyclopentanone. In order to better understand the role of N-doped support in the catalytic hydrogenation of furfural, the nitrogen content in the support was adjusted by changing the molar ratio of m-aminophenol to formaldehyde to test the addition of catalysts with different N contents in the support. Hydrogen activity, the results are shown in Figure 8. With the increase of N doping content from 2.46 % to 6.67 %, the furfural conversion showed a trend of increasing first and then tending to be stable, while the yield of cyclopentanone kept increasing. When the nitrogen doping in the carrier is 2.46 %, the furfural conversion and cyclopentanone yield are 86% and 59%, respectively. When the nitrogen doping in the carrier is increased to 5.92 %, the furfural conversion and cyclopentanone yield are 86% and 59%, respectively. The yields of ketones reached 95% and 75%, respectively, which indicated that proper N doping was very important to improve the hydrogenation activity and selectivity of furfural. For the type of N-doped support, the main forms of N in the catalyst support are pyridine nitrogen and graphitic nitrogen, and

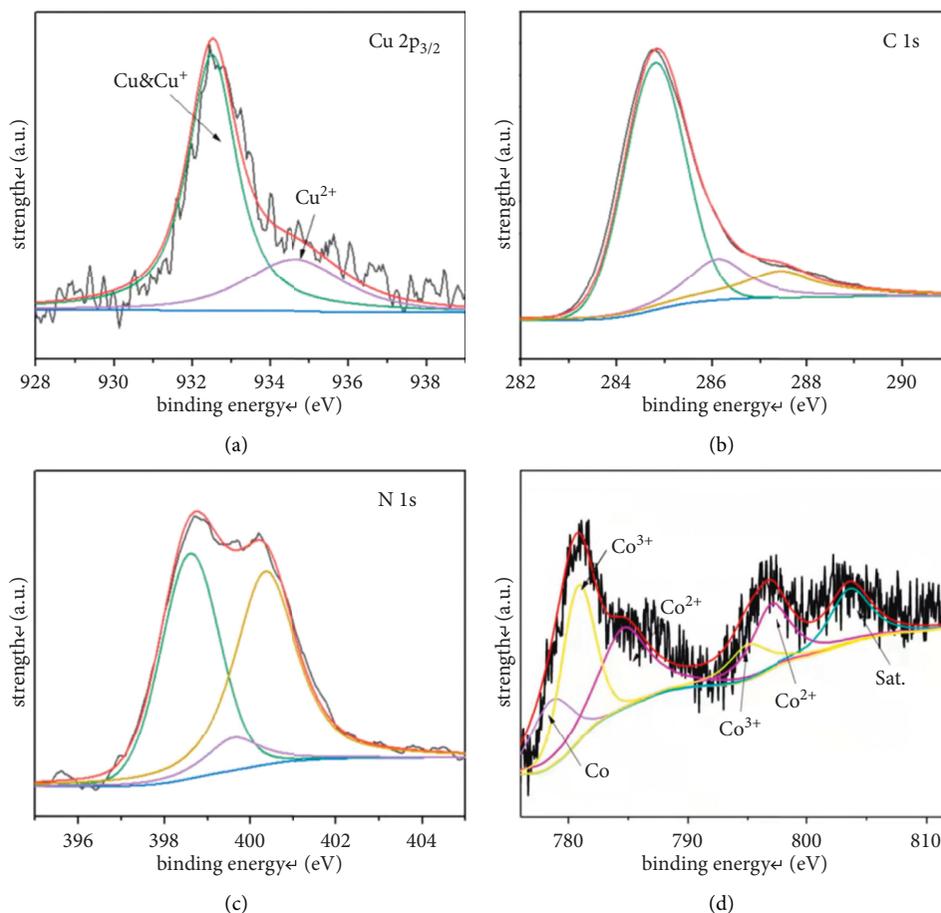

FIGURE 5: XPS characterization of 2Cu-Co@N-MPC-500.

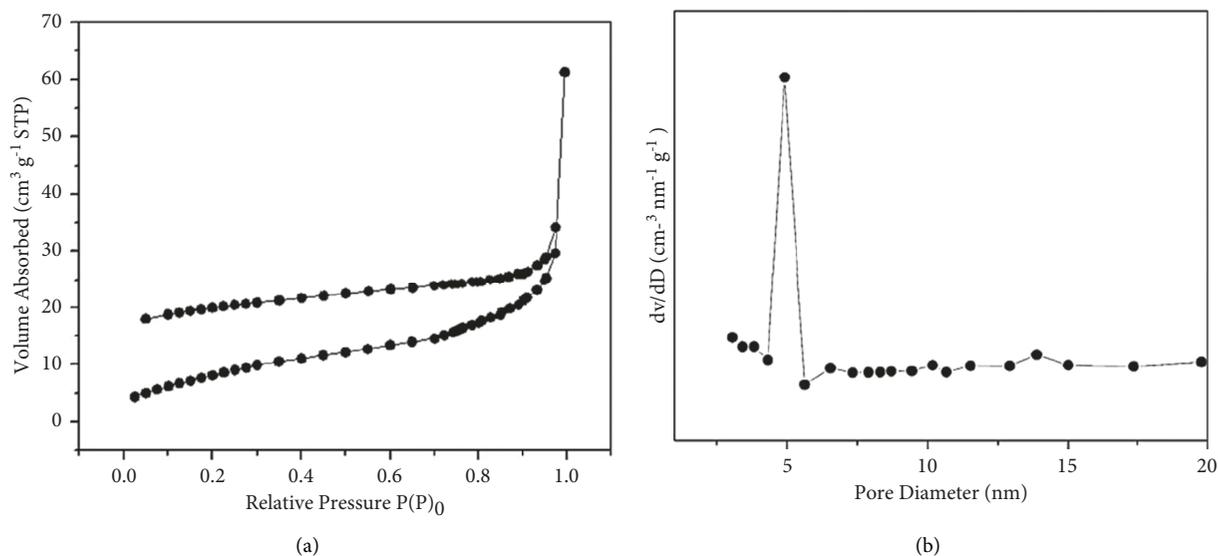

FIGURE 6: BET characterization of 2Cu-Co@N-MPC-500.

the presence of pyridine nitrogen and graphitic nitrogen plays a positive role in the hydrogenation of furfuryl alcohol to cyclopentanone. The summary includes the following

reasons: (1) The introduction of nitrogen into the catalyst can provide an anchor for the nanometal particle components, form metal-N bonds, enhance the interaction between

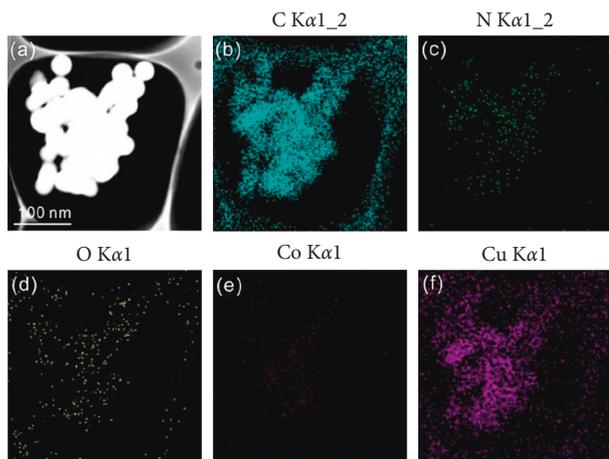

FIGURE 7: TEM and EDX characterization images of 2Cu-Co@N-MPC-500.

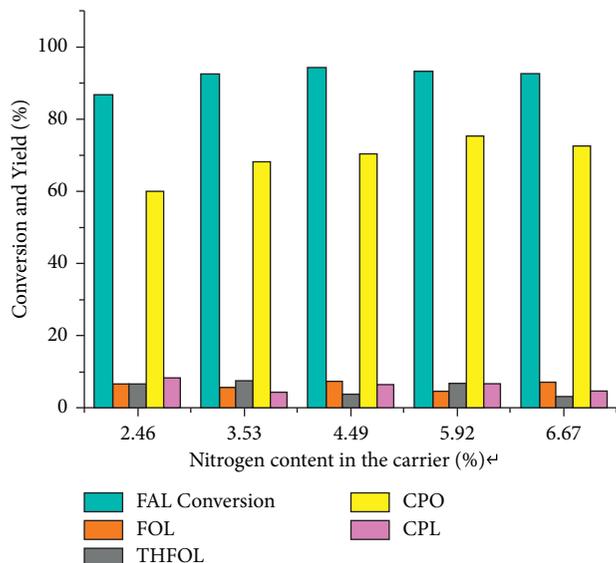

FIGURE 8: Effect of nitrogen content in the carrier on the catalytic activity.

the metal active components and the support, and effectively regulate the metal activity. The size and dispersion of the components make it difficult for the metal particle components to agglomerate; (2) the pyridine nitrogen present in the catalyst carrier can increase the Lewis basic site and enhance the adsorption effect on the reactants; (3) the introduction of N in the carrier doping can effectively improve the electron transfer rate and increase the electron density of the catalyst metal particles, thereby increasing the interaction between it and the reactant furfural [12–18]; (4) the introduction of nitrogen in the carrier can effectively increase the catalyst's efficiency. Hydrophilic, there is a ring-opening process in the hydrogenation of furfural to cyclopentanone, and water plays an indispensable role in the ring-opening process, which has an important impact on improving the reactivity and selectivity.

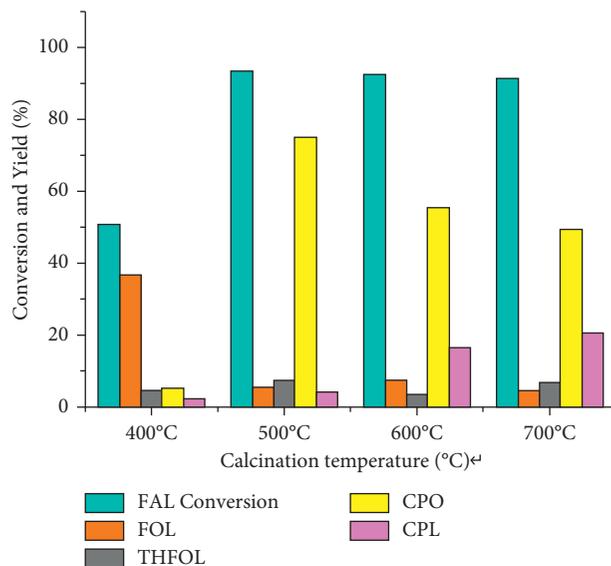

FIGURE 9: Catalyst cycle performance diagram.

4.2.2. Catalyst Cycle Performance Test. The 2Cu-Co@N-MPC-500 catalyst was subjected to cycling experiments, and the specific experimental results are shown in Figure 9. The experimental results show that the yield of cyclopentanone is only slightly decreased after the catalyst is recycled for 5 times, and the furfural is basically completely converted. The furfural conversion and cyclopentanone yields can still reach 90% and 71%, respectively, in the fifth cycle.

Through ICP-AES analysis, it was found that the Cu and Co contents in the initial catalyst were 3.48% and 1.62%, respectively. After 5 cycle experiments, the metal contents of Cu and Co in the catalyst were 3.22% and 1.35%, respectively, and only a small part of the active metal was lost in the cycle reaction. The 2Cu-Co@N-MPC-500 catalyst was used in furfural hydrogenation. It exhibits good reusability and high stability in the selective formation of cyclopentanone. The excellent stability is attributed to the carbon support that can well immobilize and protect the bimetallic nanoparticles, while the doping of nitrogen forms metal-N bonds, which increases the interaction between the support and the bimetallic Cu-Co [19, 20].

5. Conclusion

In this paper, based on the preparation of nitrogen-doped carbon-based bimetallic copper-cobalt catalysis and its monitoring application in furfural hydrogenation, by using m-aminophenol as the nitrogen source, formaldehyde as the carbon source, and P123 as the template agent, a nitrogen-doped carbon-based metal catalyst 2Cu-Co@N-MPC-500 was hydrothermally synthesized and characterized by XRD, XPS, BET, and TEM. The catalyst was analyzed, and the results showed that the catalyst had a stable carbon sphere structure, uniform pore size distribution, and uniform dispersion of metal nanoparticles. It exhibits excellent selectivity and cycle stability in the hydrogenation of furfural to cyclopentanone. Under the optimal conditions, the conversion rate of furfural reached 96.1%, the yield of

cyclopentanone reached 76.2%, and the catalyst was cycled 5 times without obvious deactivation.

This paper makes in-depth research on data mining, especially association rule mining, improves the FP-tree algorithm in both the algorithm itself and the data source, and finds out a mining algorithm suitable for learner characteristics. Association rule algorithm for actor feature model mining. By establishing the characteristic model of learners in modern distance music classroom, simulation experiments are carried out on FP-tree and three improved algorithms. This paper improves the FP-tree algorithm. Firstly, we improve the algorithm itself; aiming at the problem of too many frequent itemsets, an improved key item extraction algorithm KEFP-growth based on FP-growth is proposed, which ignores the frequent itemsets that are not concerned in the analysis. Then, improvements were made in terms of data sources. In view of the problem that the data source is too large, the mining efficiency is low, and the FP-tree cannot be loaded in memory, this paper proposes a data projection algorithm, which adopts the idea of divide and conquer, divides the frequent 1-itemsets of the database into database subsets of each frequent 1-itemsets, and then mines the database subsets separately and then merges them. Finally, the KEFP-growth algorithm and the projection algorithm are combined, which can not only eliminate the mining of meaningless frequent items but also divide the data when there is a large amount of data. This paper also compares the performance of the three improved algorithms and the original FP-tree algorithm through experiments. The experiments show that the combination of the KEFP-growth algorithm and the database projection algorithm is the most suitable one for the learner feature mining of the adaptive learning system. (1) The KEFP-growth algorithm reduces the number of frequent items output by the original FP-tree algorithm by about 50%, and the mining time is reduced by 50%. (2) The data projection algorithm is more suitable for data mining with less support. When the support is 10%, the mining time of the data projection algorithm is reduced by 80% compared with the FP-tree algorithm. (3) When the support degree is 10%, the running time of the hybrid algorithm is reduced by 10% compared with the KEFP-growth algorithm and the data projection algorithm.

1. Introduction

Learner characteristics refer to the psychological, physical, and social characteristics that have an impact on the learner's learning, that is, the learner's personality factors. Wenger believes that the student model represents all the behavior and knowledge about the student [1]. Subsequently, many scholars have defined learner models based on different learning environments. Vanlehn believes that "a learner model is a data structure that represents the student's current state of knowledge" [2]. Asarta and Schmidt believe that "the learner model can be represented as a quadruple (P ,

C , T , H), where P represents procedural knowledge; C represents conceptual knowledge; T represents individual characteristics (traits) of individual; and H represents the learning history [3]. Holt et al. believe that the learner model is an abstract representation of the learner's belief by the computer system, that is, the learner model represents the system's cognition of the student [4]. Later, many scholars define learner models based on different learning environments. Currently, the representative learner characteristic systems are as follows: (1) classical learning characteristic analysis system [5] and (2) distance learning model theoretical analysis system for educating students [6] (the

theoretical analysis system has seven dimensions (general data, demographic data, sociological data, geographic data, situational state data, motivational data, and opinion and evaluation data)).

The modern distance music education classroom learner characteristic model is a guiding form that provides personalized learning paths and learning resources for learners according to their characteristics and behavioral tendencies in the distance learning environment. It is ultimately to achieve the purpose of teaching students in accordance with their aptitude.

In the era of big data, technology transforms all behaviors in the educational process into educational data, which helps to observe the performance of each student, promotes educational research from macro-groups to micro-individuals, and is conducive to the “tailoring” of teaching and the realization of data-driven personalization.

In 2012, the United States pointed out in the report “Promoting Teaching and Learning through Educational Data Mining and Learning Analysis” that “with the support of big data and cloud computing, the core trend of international information education technology development is personalized learning” [7]. The “2016 National Educational Technology Plan” in the United States, “Learning for the Future: Reshaping the Role of Technology in Education,” also emphasizes the development of personalized learning based on big data analysis.

China’s “Ten-Year Development Plan for Education Informatization (2011–2020)” clearly pointed out that “it is necessary to build an information-based environment and provide individualized learning services for each student.” The Ministry of Education’s “Thirteenth Five-Year Plan for Educational Informatization” also proposed that “the construction of online learning space should meet the needs of personalized learning and realize “one space for every life, and every life has its own characteristics.”” The Horizon Report of the American New Media Alliance has also pointed out many times that adaptive learning is the trend of information technology development in higher education. According to the 2016 Key Issues in Teaching and Learning Report released by the Higher Education Information Association (EDUCAUSE), the focus of teaching and learning is not advanced technology, but the learners themselves and how to use technology to provide a personalized learning experience. Adaptive learning technology can provide learners with personalized learning services [8]. Zhu and Shen believe that with the rapid development of educational big data and data science, personalized adaptive learning will become an important part of the new paradigm of educational technology and smart learning environment, and it is necessary to carry out systematic and in-depth research on it [9].

2. Related Theories

2.1. Data Mining. Data mining is the non-trivial process of obtaining valid, novel, potentially useful, and ultimately understandable patterns from large amounts of data.

2.1.1. Data Mining Process. Data mining is a process of discovering various models, summaries, and derived values from known datasets. A general experimental procedure suitable for data mining problems includes the following steps [10].

- (1) State the problem and clarify the hypothesis.
- (2) *Data Collection.* There are usually two methods: “design experiment method” and “observation method.”
- (3) *Data Preprocessing.* It usually includes at least two common tasks: (1) outlier detection (and removal); (2) scaling, encoding, and feature selection.
- (4) *Model Evaluation.* Selecting and implementing appropriate data mining techniques is the main task of this stage.
- (5) Explain the model and draw conclusions.

2.1.2. Data Mining Algorithms. Data mining tasks include concept description, association analysis, classification analysis, cluster analysis, outlier analysis, evolution analysis, etc. Among them, association rule mining is the most active and deeply researched field.

(1) Association Rule Mining Algorithm. Association rule mining is to search for valuable associations between data items from a given dataset. Association rule mining in a transactional database can be described as follows [11].

Let $I = \{i_1, i_2, \dots, i_m\}$ be a set of items, the transaction database $D = \{t_1, t_2, \dots, t_n\}$ is composed of a series of transactions with a unique identifier TID, and each transaction $t_i (i = 1, 2, \dots, n)$ corresponds to a subset on I .

Definition 1. Let $I_1 \subseteq I$, and the support of itemset I_1 on dataset D is the percentage of transaction D containing I_1 :

$$\text{support}(I_1) = \frac{\|\{t \in D | I_1 \subseteq t\}\|}{\|D\|} \quad (1)$$

Definition 2. For itemset I and transaction database D , all itemsets in T that satisfy the minimum support specified by the user are called frequent itemsets or maximum itemsets. Picking out all frequent itemsets that are not contained by other elements in the frequent itemsets is called maximal frequent itemsets or maximal large itemsets.

Definition 3. An association rule of the form $I_1 \Rightarrow I_2$ defined on I and D is given by satisfying a certain degree of credibility, trust, or confidence. The so-called credibility of the rule refers to the ratio of the number of transactions including I_1 and I_2 :

$$\text{Confidence}(I_1 \Rightarrow I_2) = \frac{\text{support}(I_1 \cup I_2)}{\text{support}(I_1)}, \quad (2)$$

where $I_1, I_2 \subseteq I, I_1 \cap I_2 = \emptyset$.

TABLE 1: FP-tree algorithm.

Algorithm: use the FP-tree algorithm to mine frequent patterns through pattern segment growth
Input: transaction database- D : minimum support threshold min_sup
Output: the complete set of frequent patterns.
Method:
(1) Follow the steps to construct FP-tree;
(a) Scan D once. Collect a set F of frequent items and their support. Sort F in descending order of support, and the result is the frequent item table L .
(b) Create the root node of the FP-tree, marking it with “null.” For each transaction in D , execute:
Select the frequent items in transaction and sort them by the order in L . Let the sorted frequent item table be $[p|P]$, where p is the first element and P is the list of remaining elements. Call $\text{insert_tree}([p|P], T)$.
The process is performed as follows. If T has child N such that $N.\text{item-name} = p.\text{item-name}$, then N 's count is incremented by 1; otherwise, a new node N is created with its count set to 1, linked to its parent node T , and it is linked to nodes with the same item-name through a node chain structure. If $P \neq \emptyset$, $\text{insert_tree}(P, N)$ is called recursively.
(2) The mining of FP-tree is realized by calling $\text{FP_growth}(\text{FP_tree}, \alpha)$. The process is implemented as follows:
Procedure $\text{FP_growth}(\text{Tree}, \alpha)$
(1) If tree contains a single path P then
(2) For each combination of nodes in the path P (denoted by β)
(3) Generate a pattern $\beta \cup \alpha$, whose support = $\text{support}(\beta)_{\text{minimum}}$;
(4) Else for each α_i at the head of tree {
(5) Generate a pattern $\beta = \alpha_i \cup \alpha$, and its support degree $\text{support}(\alpha_i)$;
(6) Construct the conditional pattern basis of β , and then construct the conditional FP-tree β of β ;

Definition 4. The association criterion that satisfies the minimum support and the minimum trust degree on I is called the strong association criterion.

At present, there are many algorithms for mining association rules, which are mainly divided into two categories: generating candidate sets and not generating candidate sets. In order to improve the efficiency of the algorithm, this paper adopts the association rule algorithm that does not generate candidate sets. Han et al. proposed FP-tree algorithm [12], and Liu proposed the Relim algorithm [13]. Among them, the FP-tree algorithm is the most typical one. Compared with the FP-tree algorithm, the Relim algorithm has a simple structure, high space utilization, and runs faster when mining datasets with high minimum support or few frequent rules. The tree algorithm is effective and scalable for mining long and short frequent patterns, while the FIMA algorithm occupies less memory and has high algorithm execution efficiency, but it can only mine Boolean association rules, not quantitative association rules. The FP-tree algorithm only performs 2 database scans. It does not use candidate sets, directly compresses the database into a frequent pattern tree, and finally generates association rules through this tree. The specific mining process is shown in Table 1.

2.2. Learner Characteristics. Learner characteristics refer to the psychological, physical, and social characteristics that have an impact on the learner's learning, that is, the learner's personality factors.

The characteristics of learners involve many aspects, but the characteristics that have an important impact on learning mainly involve two aspects: intellectual factors and non-intellectual factors. The characteristics related to intellectual factors mainly include the general characteristics of learners, knowledge base, cognitive ability and cognitive

structure variables, etc., and the characteristics related to non-intellectual factors include interest, motivation, emotion, learning style, anxiety level, will and personality, learner's cultural and religious background, etc.

Through the analysis of specific learner characteristic systems, we find that they have their own characteristics. For example, Ding Xingfu's theoretical analysis system for distance education students is relatively comprehensive, covering a wide range of aspects, covering almost all the characteristics of learners. However, it is too large and lacks follow-up research to combine learner characteristics with specific applications, and the operability is not very strong. Considering the implementation problem, this paper intends to use the learner characteristic analysis system in network distance education in Tempelaar's "Construction of learner characteristic analysis system in network distance education and the design of student model" [14] as a prototype. For research, the feature analysis system mainly includes six major items, each of which includes many minor items, a total of 52 minor items:

- (a) *Intelligence.* Intelligence refers to the ability of people to recognize and understand objective things and use knowledge and experience to solve problems, such as memory, observation, imagination, thinking, and judgment. Intelligence mainly includes intelligence and five components of Professor Hanbidge [15] (observation, memory, imagination, thinking, and attention). Intelligence includes language intelligence, mathematical logic intelligence, etc.
- (b) *Learning Style.* Learning style is a continuous and consistent way of learning with individual characteristics, and it is a combination of learning strategies and learning tendencies. Learning styles are mainly divided into physiological elements, cognitive

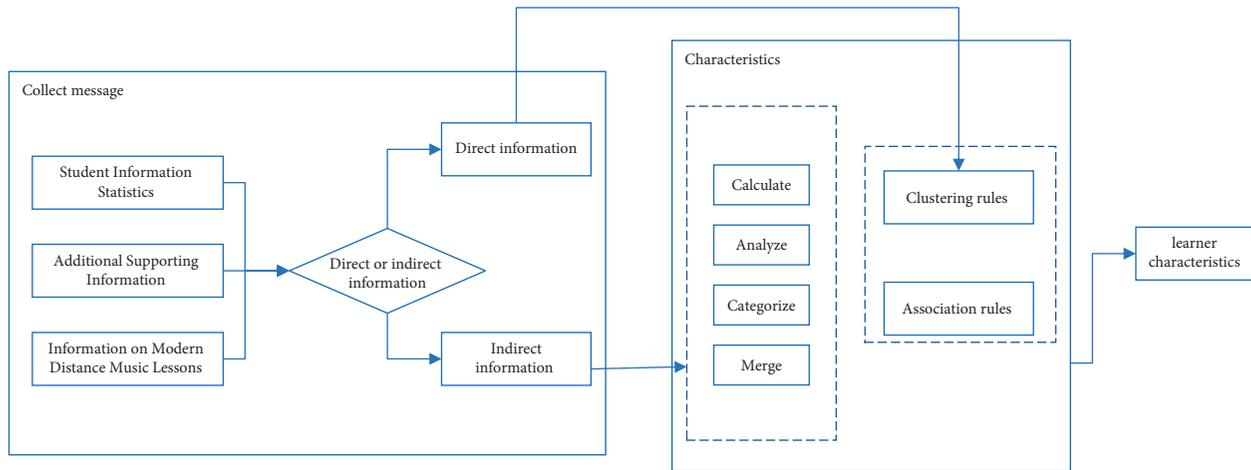

FIGURE 1: Framework diagram for the analysis of learners' characteristics in modern distance music classrooms.

elements, emotional elements, brain function, and personality. Physiological factors include time preference, perceptual response, and sound preference. Cognitive elements include perceptual style (verbal-spatial preference, discriminating skills, etc.), thinking style (analytical and non-analytical, scattered/concentrated, etc.) confidence processing style, memory style, and problem-solving style.

- (c) *Study Preparation.* Learning readiness refers to the adaptability of students' original knowledge level or psychological development level to new learning. Learning preparation includes motivation, cognitive structure, and learning attitude.
- (d) *Web Learner Characteristics.* We take this class into account since learners need to use computers and networks for adaptive learning. This category includes four subitems: technical level, information literacy, online learning adaptability, and online psychology.
- (e) General information includes demographic and sociological data and opinion and evaluation data.
- (f) *Others.* Since there are many repetitions of non-intellectual factors and learning styles, non-intellectual factors (excluding items that overlap with learning styles) are classified into this category, including knowledge interest, learning enthusiasm, learning responsibility, dominance, competitiveness, and self-confidence.

3. Analysis of Characteristics and Model Assumptions of Learners in Modern Distance Music Classrooms

3.1. Analysis Framework. Collect learners' behaviors from different perspectives and explore the deep reasons behind the behaviors, as a basis for formulating teaching procedures. Combining with domestic and foreign learning feature analysis models, combined with the basic elements of learner characteristics in the modern distance environment,

this research proposes an analysis framework for learner characteristics in the modern distance environment, as shown in Figure 1.

3.2. Learner Feature Model. Using appropriate technology to build a personality feature model can obtain the learning status of learners in real time and effectively support personalized learning. The construction methods of personality feature models include coverage model, lead model, perturbation model, machine learning technology, model based on cognitive theory, constraint-based model, fuzzy logic technology, Bayesian network, and semantic web ontology model. Among them, the cover model and lead plate model are the most common modeling techniques.

The coverage model, proposed by Jaques et al., is a method commonly used to describe the user's level of knowledge about each concept. When using the coverage method to construct the knowledge level model of the learner, the domain knowledge model represents the expert level knowledge of a certain subject, and the learner model is regarded as a subset of the domain knowledge model. The lead plate model was introduced into the GRUNDY system by Rich to build a user feature model [16]. The core idea is to group and cluster all potential users in ALS according to specific characteristics, and each group is a user lead plate. Both perturbation and constraint-based models are modeled based on learner errors/misunderstandings. The perturbation model, also known as the deviation model, is an extension of the coverage model. The researchers of this model believe that the knowledge of the learner includes not only the partial knowledge possessed by the domain experts but also the wrong knowledge that the learner may generate.

The ultimate goal of the development of educational big data is to return to the essence of education and realize "teaching according to aptitude." The biggest drawback of the "one-size-fits-all" unified teaching model is that it ignores individual differences of learners and analyzes learners' personality characteristics including knowledge level, errors/misunderstandings, emotional characteristics,

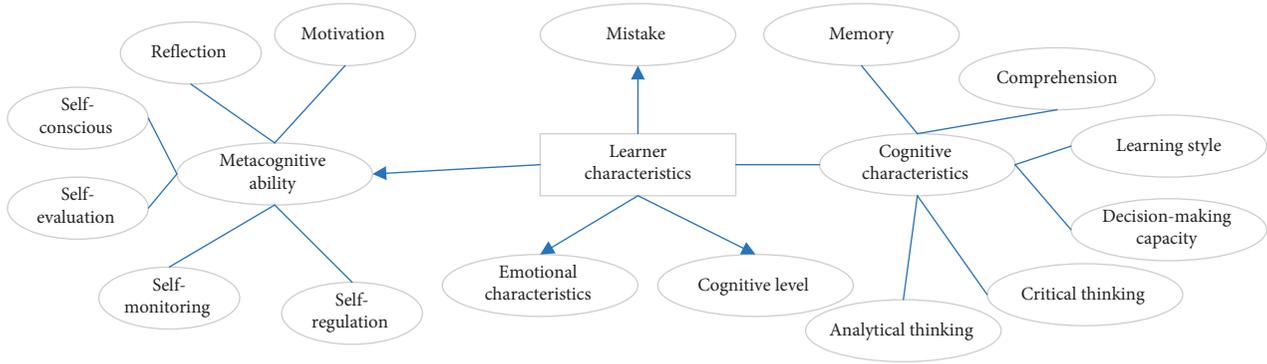

FIGURE 2: Learner characteristics.

TABLE 2: KEFP-growth algorithm.

Input: transaction database D ; minimum support threshold min_sup
 Output: frequent itemsets including key items

(1) Construct FP-tree according to the following steps

(i) Scan the D once. Collect a set F of frequent items and their support. Sort F in descending order of support, and the result is a frequent 1-item set L

(ii) Create the root node of FP-tree and mark it with null. For each transaction trans in D , execute:
 Select frequent items in trans and sort by the order in L . Let the sorted frequent item table be $[p|P]$,
 Where, p is the first element, and P is the list of remaining elements. Call $\text{insert_tree}([p|P], T)$. Execution of the process as follows.
 If T has child N such that $N.\text{item_name} = p.\text{item_name}$, then increment N 's count by 1; otherwise create a new node N with its count set to 1, linked to its parent node T , and it is linked to nodes with the same item-name through a node chain structure. If $P \neq \emptyset$, $\text{insert_tree}(P, N)$ is called recursively.

(2) Select key items and divide the header table into key item table $L1$ and non-key item table $L2$

(3) The mining of FP-tree is realized by calling $\text{KEFP_growth}(\text{Tree}, \alpha)$. The process is realized as follows:
 Procedure $\text{KEFP_growth}(\text{Tree}, \alpha)$

- (1) If (tree contains a single path P)
- (2) {
- (3) If (α contains key items)//check whether the frequent items in α appear in $L1$
- (4) Output the union of each node in the tree and α ;
- (5) Else
- (6) { //All items in the key item node are key items, all items in the non-key item node are non-key items key item
- (7) Tree nodes are divided into key item node $N1$, non-key item node $N2$
- (8) Output the combination of any item in $N1$ and the union of α ;
- (9) Output the union between the connection of the combination item of $H1$ and the combination item of $H2$ and α ;
- (10) }
- (11)}
- (12) Else if (key items are included in α)
- (13) Output the union of each frequent item and α in the tree header table;//output the frequent item set
- (14) Else
- (15) { //All items in the key item header table are key items, and all items in the non-key item header table are non-key items
- (16) The header table of tree is divided into key item header table $N1$ and non-key item header table $N2$;
- (17) Output the union of frequent items and α in $H1$;//only output frequent itemsets containing key items
- (18)}

cognition and metacognitive abilities, etc., as shown in Figure 2. It is the precondition to realize self-adaptive learning. Applying appropriate technology to build a personality trait model will help ALS provide accurate and personalized learning services.

3.3. Improvement of FP-Tree Algorithm

3.3.1. *KEFP-Tree Algorithm.* FP-tree algorithm mining will generate a large number of frequent itemsets, but although some frequent itemsets satisfy the minimum support, it affects the user's analysis and judgment and reduces the

efficiency of mining. The purpose of this paper is to discover the relationship between learner behavior and learner characteristics in distance music classrooms and to determine learner characteristics based on some learning behaviors of learners, that is, to find out "learner behavior => learner characteristics" such as association rules. A meaningful frequent itemset should contain both learner behavior attribute items and learning strategy attribute items. When mining frequent itemsets, frequent itemsets that only contain learner feature items or only learning strategy items can be ignored [17]. The specific implementation steps are shown in Table 2.

TABLE 3: Database projection algorithm.

Input: transaction database D ; minimum support threshold
Output: complete set of frequent patterns
Algorithm:

- (1) Scan the D for the first time, get the items that satisfy the minimum support degree and arrange them in descending order, get the set L of candidate 1-itemsets, delete the items whose support degree is less than the minimum support degree in L , and get the set L of frequent 1-itemsets.
- (2) Scan the source data for the second time, and rearrange the items in each transaction according to the support counts of the frequent items contained in each transaction, and get the database as D' .
- (3) According to the support count of the items in the frequent 1-item set L , build the database subsets of items from small to large according to the following rules, and use the FP-growth algorithm to mine frequent items: for each term in L $I_i (i = m, m-1, \dots, 1)$
 - (a) Scan the database D' , extract all transactions containing item I_i from it, then delete the items whose support degree is less than the support degree of this item in these transactions, and the resulting transaction set is the database subset D_i of item I_i .
 - (b) For the database subset D_i , use the FP-growth (Tree, α) algorithm to mine frequent itemsets containing item I_i . The mining process is as follows:
 - (i) If tree contains a single path P then
 - (ii) For each combination of nodes in path P (denoted as β)
 - (iii) Generate the pattern $\beta \cup \alpha$, whose support degree $\text{support} = \text{support}(\beta)_{\text{minimum}}$;
 - (iv) Else for each α_i at the head of tree {
 - (v) Generate a pattern $\beta = \alpha_i \cup \alpha$ with $\text{support} = \alpha_i.\text{support}$;
 - (vi) Construct the conditional pattern basis of β , and then construct the conditional FP-tree β of β ;
 - (vii) If $\text{Tree}\beta \neq \emptyset$ then
 - (viii) Call $\text{FP-growth}(\text{Tree}\beta, \beta)$;
- (4) After the frequent items of all items in L are mined in turn, and these frequent itemsets are merged, all the frequent itemsets in the database D can be obtained.

3.3.2. *Database Projection Algorithm.* The performance study of the FP-tree algorithm shows that under normal circumstances, the FP-tree algorithm is about an order of magnitude faster than the Apriori algorithm. However, the FP-tree algorithm has a disadvantage, that is, it needs to occupy a lot of memory during tree building and mining. When the database is very large or the support is very small (the total number of generated 1-frequent itemsets is too large), it needs to be loaded into the memory. A large amount of data will cause the running speed to become very slow, and it is even impossible to build a memory-based FP-tree. A good solution is to first partition the database into subsets of the database and then construct an FP-tree on each database subset and mine it and finally combining these frequent itemsets can get the frequent itemsets of the entire database.

The database projection algorithm first scans the database for the first time and finds the 1-frequent itemsets that satisfy the minimum support degree. Each database subset uses the FP-growth algorithm to mine frequent items to obtain the frequent itemsets of each database subset. Finally, these frequent itemsets are combined to obtain the final frequent itemsets. The specific implementation process adopts the algorithm proposed in [18], and the specific algorithm is shown in Table 3.

3.3.3. *Hybrid Algorithm.* Combining the KEFP-growth algorithm with the database projection algorithm can not only eliminate the mining of meaningless frequent itemsets but also project the data when there is a large amount of data. The idea of combining the two improved algorithms is very simple, because the mining of FP-tree is realized through FP-growth, and the KEFP-growth algorithm is based on FP-

growth plus keyword judgment, so only the projection algorithm needs to be used. By replacing the FP-growth algorithm with the KEFP-growth algorithm, the two algorithms can be combined. In addition, before dividing the database into subsets, the 1-frequent itemsets obtained from the first scan of the database should be counted [18]. If the value is greater than the given 1-frequent itemsets total number threshold, the database needs to be divided into subsets. The specific implementation process is shown in Table 4.

4. Simulation Results

4.1. *Experimental Data.* In order to collect real data on the characteristics of learners in modern distance music education classrooms, this study selected learners who participated in H University's online music elective courses as the research objects. H University's online music elective course conforms to the general characteristics of modern distance education teaching and can reflect the characteristics of learners in the modern distance environment to a certain extent.

In this study, the characteristics of learners in a modern remote environment are analyzed with the help of the online compulsory course "Music History" of H University's online learning on the Chaoxing Xuetong platform. The distance music learning course consists of three parts: courses, resources, and micro-applications. The course module includes multiple learning sections, and the course teaching form covered by each learning week includes three steps: learning guidance, learning content, and learning activities, that is, complete teaching, learning, practice, and examination. The main learning methods of distance learners are the combination of sight, hearing, and practice, and they can

TABLE 4: Hybrid algorithm.

Input: transaction database D ; minimum support threshold; 1—threshold of total items of frequent items
Output: complete set of frequent patterns

(1) Scan the D for the first time, get the items that satisfy the minimum support degree and arrange them in descending order, get the set L of candidate 1-itemsets, delete the items whose support degree is less than the minimum support degree in L , and get the set L of frequent 1-itemsets, and the value C is obtained by counting the set L at the same time.

(2) If ($C > 1$ -threshold of the total number of items of frequent items)

```

{
  (i) Scan the source data for the second time, rearrange the frequent items in each transaction according to the support count of each item, and rearrange the items in each transaction, and get the database as  $D'$ 
  (ii) According to the support count of the items in the frequent 1-item set  $L$ , build the database subsets of items from small to large according to the following rules, and use the FP-growth algorithm to mine frequent items:
  For each term in  $L$   $I_i (i = m, m - 1, \dots, 1)$ 
  (a) Scan the database  $D'$ , extract all transactions containing item  $i$  from it, then delete the items whose support degree is less than the support degree of this item in these transactions, and the resulting transaction set is the database subset  $d_i$  of item  $I_i$ .
  (b) For database subset  $D_i$ , use KEFP_growth (tree,  $\alpha$ ) algorithm to mine frequent itemsets containing item  $I_i$ 
  (iii) After the frequent items of all items in  $L$  are excavated in turn, these frequent itemsets are merged to get all frequent itemsets in database  $D$ 
}

```

Else

```

{
  Create the root node of the FP-tree, marking it with "null." For each transaction trans in  $D$ , do: select the frequent items in trans and sort by the order in  $L$ . Let the sorted list of frequent items be  $[p|P]$ ,
  Where  $p$  is the first element and  $P$  is the list of remaining elements. Call insert_tree ( $[p|P], T$ ). The process is performed as follows. If  $T$  has child  $N$  such that  $N.item - name = p.item - nam$ , then  $N$ 's increment the count by 1; otherwise create a new node  $N$ , set its count to 1, link to its parent node  $T$ , and link it to a node with the same item-name through a node chain structure. If  $P \neq \emptyset$ , insert_tree ( $P, N$ ) is called recursively.
  (3) Mining FP-tree by calling KEFP_growth (Tree,  $\alpha$ )
}

```

interact and ask questions according to their learning needs. The course has a total of 20 study sections. After the course is over, the academic performance of distance learners will be assessed according to a percentile system, which consists of two parts: the formative assessment and the final assessment. Formative grades refer to the usual grades, which are mainly composed of the learners' online answers and the interaction of the number of posts, accounting for 30%; the final examination assessment refers to the learners' final grades, which are mainly obtained from the learners' final assessment results. According to an online test, it accounts for 70%.

4.2. Experimental Design

- (1) Data source is Superstar learning platform background data; number of project transactions is 20000; dataset is 60 (1.3M); algorithms are FP-tree algorithm and KEFP-tree algorithm; results are running time and total number of frequent itemsets.
- (2) Using the background data of the Superstar Learning Platform, select a dataset (2.2 M) with 40,000 itemset transactions and 60 different items, using the original FP-tree algorithm and database projection algorithm under different minimum support degrees. The dataset is mined and the time of its run is recorded separately.
- (3) Using the background data of the Superstar Learning Platform, select the dataset (1.8 M) with 30,000

itemset transactions and 60 different items (1.8 M), and use the KEFP-growth algorithm, data projection algorithm, and combination algorithm to achieve different minimum support degrees. The dataset is mined below, and its running time is recorded separately.

4.3. Experimental Results. The experimental results of the original FP-tree algorithm mining on the 1.3 M dataset and the 2.2 M dataset are shown in Table 5:

When the minimum support degree is high, that is, when the number of generated 1-frequent itemsets is small, the original FP-tree algorithm runs fast and has high mining efficiency. However, when the minimum support is low, the running speed will be greatly reduced due to the large number of 1-frequent itemsets generated. The number of sets is very large, which will cause the running speed to be greatly reduced and even the situation that the memory-based FP-tree cannot be built.

The experimental comparison results of the FP-tree algorithm and the KEFP-growth algorithm mining on the 1.3 M dataset are shown in Table 6.

It can be seen from the table that under different support degrees, the KEFP-growth algorithm reduces the number of frequent items output by the original FP-tree algorithm by about 50%, and the mining time is reduced by 50%. This is because the output of irrelevant frequent itemsets can be reduced by using the KEFP-growth algorithm, thereby shortening the time spent in selecting useful items from

useless frequent items, significantly improving the efficiency of mining, and meeting the original intention of mining.

The experimental comparison results of the original FP-tree algorithm and the database projection algorithm on the 2.2 M dataset are shown in Table 7.

Experiments show that when the minimum support is reduced to a certain threshold or the amount of data to be mined is greater than a certain level (the total number of items in the frequent 1-item set is too large), the original FP-tree algorithm cannot build a memory-based FP-tree, which will cause the excavation to fail. The data projection algorithm can divide the frequent 1-itemsets of a large database into several database subsets and then mine the database subsets, respectively. Because each database subset occupies a small memory, it can overcome the data of 1-itemsets. The problem that the amount is too large makes the memory unable to load the FP-tree, so that the data mining can proceed smoothly. In addition, experiments also show that the data projection algorithm is more suitable for data mining with less support. When the support is 10%, the mining time of the data projection algorithm is reduced by 80% compared with the FP-tree algorithm. When the minimum support is large or the amount of data to be mined is small (that is, the total number of frequent 1-itemsets is small), the running speed of the new algorithm is

not as fast as that of the original FP-tree algorithm. The reason for this phenomenon is that the cost of the original FP-tree algorithm lies in tree building and frequent itemset mining, while the data projection algorithm has the cost of dividing the database subset in addition to the cost of tree building and frequent itemset mining. When the database support degree is large, the total number of 1-frequent itemsets generated by the database is small, so the two algorithms have little difference in the time cost of building trees and mining frequent itemsets, but the database projection algorithm divides the database subsets. There is a time overhead in the aspect of FP-tree, so the mining speed of the original FP-tree algorithm is faster than that of the database projection algorithm. With the increase of the minimum support, the memory and time overhead of the original FP-tree algorithm increase, resulting in slower and slower mining speed, while the database projection algorithm also increases the cost of generating database subsets. However, the memory overhead and time overhead of building a database and mining frequent itemsets are less, so the overall running speed is faster than the original FP-tree algorithm.

The experimental comparison results of the three improved algorithms' mining on the 1.8 M dataset are shown in Table 8.

TABLE 8: The experimental comparison results of the three improved algorithms.

Support (%)	Number of frequent itemsets	Operation hours		
		KEFP-growth algorithm	Database projection algorithm	Hybrid algorithm
50	46	12	38	15
40	90	27	65	29
30	545	64	90	65
20	2351	167	157	146
10	7648	998	985	833
1	1987	—	5786	3756

Experiments show that the mining efficiency of the hybrid algorithm and the FEFP-growth algorithm is not much different when the minimum support is large, but when the minimum support is small to a certain extent, the mining efficiency of the hybrid algorithm is higher than that of the KEFP-growth algorithm. When the support degree is 10%, the running time of the hybrid algorithm is reduced by 10% compared with the KEFP-growth algorithm and the data projection algorithm. When the support degree is large, the KEFP-growth algorithm branch is combined with the algorithm, and when the support degree is small (the total number of 1-frequent itemsets generated is large), the database projection algorithm combined with the KEFP-growth algorithm is used. In addition, it can be seen from the experimental results that the hybrid algorithm is better than the database projection algorithm when the support is small or large. This is because the KEFP-growth algorithm used in the hybrid algorithm removes many irrelevant frequent itemsets, thereby reducing the amount of excavation. Comprehensive analysis shows that the hybrid algorithm is better than the first two improved algorithms.

5. Conclusion

This paper makes in-depth research on data mining, especially association rule mining, improves the FP-tree algorithm in both the algorithm itself and the data source, and finds out a mining algorithm suitable for learner characteristics. By establishing the characteristic model of learners in modern distance music classroom, simulation experiments are carried out on FP-tree and three improved algorithms.

Compared with the original FP-tree algorithm, the number of frequent items output by the KEFP-growth algorithm is much less, and the mining time is also significantly reduced.

- (1) The KEFP-growth algorithm reduces the number of frequent items output by the original FP-tree algorithm by about 50%, and the mining time is reduced by 50%.
- (2) The data projection algorithm is more suitable for data mining with less support. When the support is 10%, the mining time of the data projection algorithm is reduced by 80% compared with the FP-tree algorithm.

The mining efficiency of the hybrid algorithm and the KEFP-growth algorithm is not much different when the

minimum support is large. However, when the minimum support is small to a certain extent, the mining efficiency of the hybrid algorithm is higher than that of the KEFP-growth algorithm. When the support degree is 10%, the running time of the hybrid algorithm is reduced by 10% compared with the KEFP-growth algorithm and the data projection algorithm.

Aiming at the problem of supply-demand matching of online reading, an analysis method of children's online reading behavior oriented for family education has been put forward. The data-based classification method is constructed to classify the sample population by statistical methods, and the traditional index classification is carried out by using K-medoids clustering and logistic regression analysis. The matching degree of population classification is discussed through comparison. R language and Mplus are used to analyze the data for the objective classification of the sample data set. Based on the reading response behavior of children's online reading users, a differential item functioning (DIF) test of socioeconomic status is carried out. At the same time, the population is divided by traditional economic classification indicators to carry out a DIF test and explore the differences in the reading ability of different classification groups. By comparing the results of the two grouping methods, the main family socioeconomic status factors affecting reading performance are explored and targeted countermeasures are put forward. The experimental results show that when analyzing children's online reading behavior, using machine learning algorithms such as cluster analysis, logistic regression analysis, and so on can get consistent results and then using the DIF test to explore the responses of category groups can effectively distinguish group differences.

1. Introduction

In the information society, the radiation range of computer networks and digital technology is becoming wider and wider, which has become a necessity for people's daily communication and reading [1–7]. For the younger generation growing up with the Internet, known as the “net generation,” online reading has become one of the indispensable reading methods [8, 9].

“Demand” refers to the various needs for objective things derived by people (including individuals, groups, strata, and the whole group) to maintain their own growth and continuity. The whole process of users purchasing and using products is a process of meeting their needs. In this process, the old and new needs of users may appear alternately. User needs generally have the following characteristics: explicit needs and implicit needs coexist. Explicit needs are the needs that users themselves can clear, know, and express and

implicit needs are the needs that users cannot express or even perceive. Different users have their own particularity, so the demand also shows the characteristics of coexistence of individuality and commonness. In addition, the demand also has hierarchy and fuzziness. Users' demand for online reading is high-quality reading content, and users of different natures have different needs for online reading. As reading is a branch of humanities, it is more vulnerable to the influence of multidimensional index systems such as regional culture and economic level. Therefore, we need to use appropriate methods to carry out family education oriented analysis and study the impact of regional and economic differences on children's online reading behavior. Differential item functioning (DIF) [10–12] has been paid more and more attention. From the initial fairness research to the consideration of the validity and reliability of the test itself, DIF research has always played an important role. DIF refers to that when subjects with the same ability from

different groups have different response probabilities when answering the same question, and there is a deviation in the question. With the continuous in-depth exploration of DIF methods, DIF methods have a wide variety and rapid development, moving towards a more comprehensive and scientific direction. DIF analysis is also increasingly used in the field of psychometrics, language testing, intelligence testing, educational evaluation, and other fields to detect the deviation of project level.

Online reading users come from all over the world, with different economic and cultural backgrounds, and their needs for the types of reading vary from person to person. Based on the online reading comprehension test of grade 2 in primary school, developed by an internet education enterprise, this paper investigates the subjects of grade 2 in primary school in 19 provinces, cities, and autonomous regions, and recovers 1309 valid data.

The technical scheme of this study is that when discussing the differences in reading ability of different groups, we can get more consistent results by using machine learning algorithms such as cluster analysis, potential category analysis, k -nearest neighbor algorithm, discriminant analysis, and logistic regression analysis, and then exploring the responses of category groups by the DIF test, which can effectively distinguish group differences.

2. Related Works

2.1. Gender Differences in Reading. Breland and Lee [13] observed the scores of reading, writing, and listening of male and female candidates in the English Language Ability (ELA) test, and found that there were significant differences in the scores of men and women in the writing part, which was more beneficial to boys. In the PISA2009 reading literacy assessment, Chen and Jiao [14] took gender as the traditional dominant group variable and found five medium DIF items, which were obviously biased towards boys. In other gender studies on reading literacy, Aryadoust [15] used a recursive segmentation Rasch tree to investigate the DIF source of reading comprehension test. One of the grouping variables used is gender. In the test, candidates with high grammar scores are affected by gender differences, and girls are at a disadvantage. It can be seen that when investigating the gender differences of the DIF in reading test research, there is a consistent bias, which may be related to the objective and fixed gender grouping.

2.2. Socioeconomic Status Differences in Reading. Chen and Jiao [14] explored the DIF items with economic, social, and cultural status (ESCs) as nontraditional dominant group variables in the PISA2009 reading literacy assessment, and found that three DIF items were more favorable for subjects with high ESCs. Cadime et al. [16] took urban and rural areas as the division standard of economic level, tested the DIF items of the reading test of Portuguese students in high and low economic level groups, and found that five moderate DIF items were beneficial to students in high economic level groups from cities. Little et al. [17] showed that living in the

neighborhood of communities with poor economic conditions can also predict lower reading test scores. Leu et al. [18] analyzed the students in economically developed school districts and economically less developed school districts, respectively. The results showed that due to the imbalance of economic development levels, students' online reading ability was significantly predicted. Morrow [19] believes that the difference in the regional economic situation of the school is the main reason for the differences in the application strategies of middle school students in online reading. However, some studies have pointed out that family economic status has no significant impact on children's reading performance [20].

In conclusion, in the DIF analysis, gender grouping is the most basic and important traditional dominant grouping variable. Due to the clear grouping boundary, the DIF results are usually consistent. In some areas of reading comprehension test, question answering is more beneficial to boys, and such test results appear. However, when the grouping variables are nontraditional explicit grouping variables such as socioeconomic status and cultural region, the results are often different or even contradictory. This may be related to the uncertainty of nontraditional dominant grouping variables.

Analyzing the concept and composition of socioeconomic status, it is not difficult to find that with the progress of measurement technology and the accumulation of socio-economic achievements, the conceptual boundary of socioeconomic status as a multiindex system is gradually blurred and the extension is gradually expanded. When researchers choose the classification index of SES, it is impossible to be completely consistent, and the classification results have a direct impact on the DIF test, so they can get a variety of DIF test results.

Summarizing the above research, it can be found that when researchers try to explore the differences of the online reading ability of different types of users, they usually need to classify users. When a multiple index system (such as SES) is selected as the classification basis, the classification method is usually more empirical and subjective, resulting in the reduction of the reliability of the results. At that time, when objective criteria were used for analysis (such as DIF), more consistent conclusions could be obtained and multiple indicators (family income, parents' education level, and parents' professional status) could not be divided. Whether cluster analysis and latent category analysis can be used to objectively classify online reading users under multiple indicators and then to explore the response of category groups by DIF is the main problem of this study. This study will take the online reading test of grade 2 of primary school as an example to investigate the influence of socioeconomic status on students' online reading tests, and achieve the analysis goal of children's online reading behavior oriented for family education.

3. Overall Research Framework

Reading is not only an important way for people to obtain information but also a basic way to improve their literacy. The strength of reading ability determines a person's

knowledge reserve to a certain extent. Especially in the context of the rapid popularization of online reading, users' demand for high-quality content is increasing. The key to developing high-quality content is to fully meet the reading needs of different people and develop content and test questions suitable for reading at different ages and levels. It is particularly important to analyze children's online reading behavior for family education. The most appropriate method to detect the availability of content topics specifically for different groups is DIF.

The population of online reading users is diverse and complex, which is different from the deterministic population with school classes as units. Moreover, the population with different socioeconomic status (SES) discussed in this study is usually not a single grouping variable, but a compound or multidimensional grouping variable, that is, a multiindex evaluation system. There is no unique standard for the population category, so it needs to be objectively classified with the help of statistical classification methods based on the data itself.

The above literature analysis shows that the biggest advantage of cluster analysis is when the population is not clearly classified. It can be better classified according to the real characteristics of the data itself. In addition, latent category analysis is a common method to classify latent variables. Therefore, based on a more robust clustering analysis method K-medoids [21–23], this study first classifies the subjects and verifies them with potential category analysis to clarify the rationality of secondary classification by using statistical methods. Research on the influencing factors of reading ability has always been a topic of continuous exploration by researchers. Based on K-medoids clustering grouping, taking the second grade online reading test as an example, this paper carries out the DIF test to investigate the impact of socioeconomic status on students' responses to reading tests, and realizes children's online reading behavior analysis oriented for family education.

The main significance of this study is as follows:

- (1) This study explores and empirically uses quantitative research methods for user analysis, provides a new idea for the general environment that focuses on qualitative research, makes the demand for research clearer and clearer from a multidimensional perspective, and obtains an objective and scientific division of the population on the basis of statistical classification methods.
- (2) This study explores the important family socioeconomic status factors affecting users' reading ability and can provide corresponding countermeasures and suggestions for vulnerable reading users. Therefore, this study can improve user product experience satisfaction and increase user stickiness and retention rates for enterprises.

The content of this study is mainly divided into the following two parts:

- (1) In order to analyze the online reading needs of users with different socioeconomic statuses, it is necessary

to classify the population first. Due to the variety of traditional SES classification indicators, it is necessary to classify with statistical methods to ensure the true characteristics of response data and realize objective grouping. The R language is used to make the clustering analysis diagram under the K-medoids clustering analysis method and then use latent category analysis (LCA) to verify the reliability and stability of clustering results.

- (2) Based on K-medoids cluster grouping, the DIF test was carried out to study the differences of children with different economic levels in the reading test. This paper probes the influence of the difference of families' socioeconomic status on students' responses to reading test. Reasonable suggestions are put forward for enterprises according to the results of project function differences. When it is unable to meet the reading needs of the two groups at the same time, matching the reading materials launched with the economic situation one by one is focused on.

The overall research framework is shown in Figure 1.

4. Research Methods

The main purpose of this study is to analyze the reading ability level of the two groups of subjects with high and low economic level by using the DIF test. By clarifying the differences, the influencing mechanism of family socioeconomic status is explored and the corresponding improvement measures are put forward.

4.1. DIF

4.1.1. MH Method. The reading test in this study is objective in the form of two-level scoring. Therefore, the Mantel–Haenszel method [24], abbreviated as the MH method, is one of the most widely used methods for DIF detection. The method starts by grouping the subjects according to their ability level. They were divided into five groups from lowest to highest according to test scores or ability θ . This process is automatically realized in R software. The MH method calculates statistic α MH by comparing target groups with the frequency of correct and wrong answers on each question. The value of α MH is between (0, + ∞). α MH = 1 is no DIF in this item. α MH > 1 is beneficial to the target group. α MH < 1 is beneficial to the reference group. In order to represent project functional uniformity with 0, α MH is logarithmically converted to the following formula:

$$\Delta\text{MH} = -2.35 \ln(\alpha\text{MH}). \quad (1)$$

When Δ MH is positive, the project is beneficial to the target group. When Δ MH was negative, the project benefited the control group.

Educational testing service (ETS) classifies DIF entries into three levels based on the MH method. Grade A is negligible. Grade B should be modified. Grade C is a problem path that has very serious project functional differences and should be removed.

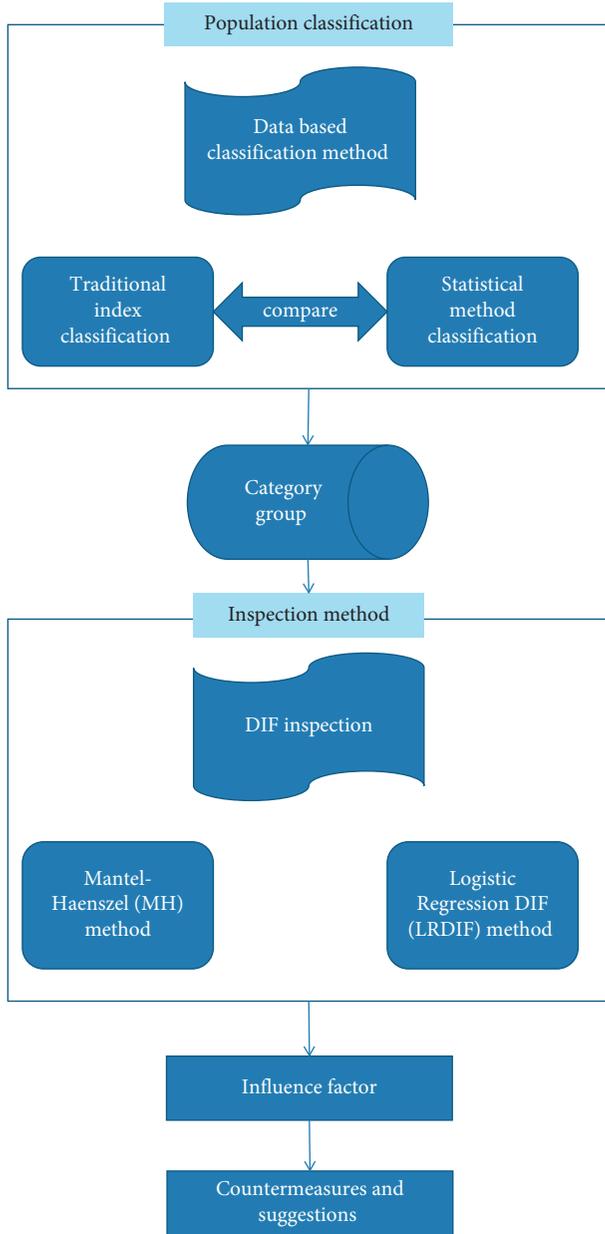

FIGURE 1: The overall research framework.

4.1.2. LRDIF Method. It is found that different methods have different statistical test power and unique advantages. Therefore, a variety of methods used together can play their own advantages. This makes detection results more scientific and effective [25]. In this study, the LRDIF method was used to test. LRDIF is a DIF test method proposed by Swaminathan and Rogers [26] that is suitable for 0, 1 scoring, and multistage scoring tests. Again, this method can take test scores as matching variables. Its biggest advantage is that it can calculate both consistent and inconsistent DIF. The LRDIF method uses the model comparison to test the significance of each parameter in the following formula:

$$P(Y = 1|X_1, X_2) = \frac{\exp(\beta_0 + \beta_1x_1 + \beta_2x_2 + \beta_3x_1x_2)}{1 + \exp(\beta_0 + \beta_1x_1 + \beta_2x_2 + \beta_3x_1x_2)} \quad (2)$$

The logarithm is taken to obtain

$$\ln\left(\frac{p}{1-p}\right) = \beta_0 + \beta_1x_1 + \beta_2x_2 + \beta_3x_1x_2. \quad (3)$$

Y is the dependent variable and can be 0 or 1. x_1 is the test score, x_2 is the grouping variable, and x_1x_2 is the interaction term. Regression parameters β_0 , β_1 , β_2 , and β_3 were estimated by the maximum likelihood method (MLE) or the least square method (LSM). Different test results have different implications for DIF detection. If only β_0 and β_1 are significant in the equation, there is no DIF in this item. If β_0 , β_1 , and β_2 are significant in the equation, it indicates that the item has consistent DIF. If the interaction parameter β_3 is also significant, then the problem has a nonconsistent DIF.

4.2. Reading Achievement Difference Inspect. The reading achievement difference inspect is shown in Table 1.

According to Table 1, the scores of students in the group of high socioeconomic status were significantly higher than those in the group of low socioeconomic status. Specific performance included the average wage classification group ($t = -7.322$, $p < 0.001$, Cohen's $d = 0.411$), per capita disposable income classification group ($t = -0.951$, $p < 0.05$, Cohen's $d = 0.208$), regional GDP classification group ($t = 8.762$, $p < 0.001$, Cohen's $d = 0.487$), and East-West geographical and economic division classification group ($t = -11.134$, $p < 0.001$, Cohen's $d = 0.452$). According to Cohen's standard, except for the small effect size of 0.2 in per capita disposable income classification group, the all other three effects reached the standard of medium effect size of 0.4 [27].

4.3. DIF Inspection. In order to explore whether reading score difference comes from the real difference of subjects or from deviation, we need to do further inspection of the project function differences.

4.3.1. Unidimensional Test. Before the DIF test, it needs to meet the unidimensional hypothesis, so a unidimensional test is conducted. The commonly used method to prove the unidimensionality of the test is factor analysis. The fitness test of factor analysis shows that the KMO of this study sample is $KMO = 0.944$ and Bartlett sphericity test $X^2(2016) = 16468.933$, $p < 0.001$. Therefore, sample data are suitable for factor analysis. If the ratio of the eigenvalue of the first component to the eigenvalue of the second component in factor analysis is greater than 3, the test can be considered as one-dimensional [28]. In this study, the eigenvalue of the first factor was 11.767 and the eigenvalue of the second factor was 1.721. The ratio of the two is much greater than 3, so it meets the regulations.

It can be seen from Figure 2 that the eigenvalue curve in the lithotripsy diagram tends to be flat after the first factor. Combined with the result that the ratio of the first eigenvalue to the second eigenvalue is greater than 3, a factor is finally retained. Therefore, it is considered that the test conforms to the unidimensional hypothesis.

TABLE 1: Reading achievement difference inspect.

	Average wage	Per capita disposable income	Regional GDP	East-West geographical and economic division
Low economic level ($M \pm SD$)	42.06 \pm 11.877	42.83 \pm 10.642	38.99 \pm 10.873	42.06 \pm 11.868
High economic level ($M \pm SD$)	44.39 \pm 9.951	43.51 \pm 10.825	45.55 \pm 10.221	45.78 \pm 9.591
t	-7.322	-0.951	8.762	-11.134
Cohen's d	0.411	0.208	0.487	0.452
p	0.000***	0.039*	0.000***	0.000***

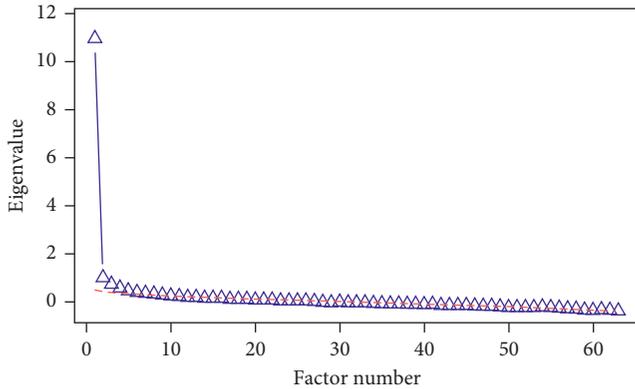

FIGURE 2: The relationship between eigenvalue and factor number.

4.3.2. *DIF Results of Traditional Grouping.* The MH method and the LRDIF method were used to test the two groups of high and low economic levels under the four traditional economic index groups. The calculation results of the MH method are divided into three levels according to the calculation standard of ETS in the United States, that is, based on the absolute value of ΔMH . If its absolute value is less than 1, it is marked as grade A DIF. If its absolute value is between 1 and 1.5, it is marked as grade B DIF. If it is greater than 1.5, it is a serious DIF item and will be marked as grade C DIF.

The effect size of the LRDIF method is Nagelkerke's R^2 . According to Zumbo & Thomas standard labeling grades, (0, 0.13) is classified as grade A, namely slight DIF. (0.13, 0.26) is classified as grade B, namely moderate DIF. (0.26, 1) is classified as grade C, namely severe DIF.

The DIF inspection results of the average wage grouping are shown in Figure 3.

The DIF inspection results of per capita disposable income grouping are shown in Figure 4.

The DIF inspection results of East-West geographical and economic division grouping are shown in Figure 5.

The DIF inspection results of the regional GDP grouping are shown in Figure 6.

The DIF analysis was performed on 64 items of the online reading test in grade 2 using the MH and LRDIF methods. Two DIF test methods are used to test the DIF items under the grouping of the average wage, per capita disposable income, East-West geographical economic division, and regional GDP. As can be found, the regional GDP grouping has the largest number of DIF items, and

most of them belong to grade A DIF, while the small numbers are grade B and C DIF.

The reading ability module results reflected by DIF items are further analyzed, as shown in Figure 7. In Figure 7, groupings 1, 2, 3, and 4 represent the groupings of the average wage, per capita disposable income, East-West geographical economic division, and regional GDP, respectively.

The online reading test includes six ability modules: language foundation, information extraction, understanding and inference, transfer and application, overall perception, and appreciation evaluation. As can be seen from Figure 7, DIF items detected in the four traditional grouping methods include the six ability modules. Moreover, the proportions of the modules are almost evenly distributed. It is difficult to distinguish which subdivision of reading ability the DIF items focus on.

4.3.3. *DIF Clustering Results.* Due to the low consistency of the four traditional groups in the initial group and the final DIF test results, the statistical grouping method of cluster analysis is used to conduct the DIF test again for the responses of online reading users. Compared with previous research results, the results obtained are shown in Tables 2 and 3 and Figure 8.

As can be seen from Tables 2 and 3, the number of detected DIF items is greatly reduced after grouping by the cluster analysis method. The results of the DIF test were consistent with those of the two methods. The distribution of modules also shows obvious rules. The details are as follows: first, only 5 DIF items were detected by the two methods, respectively, among which 3 questions overlapped. Second, as shown in Figure 8, 60% of the five titles detected by the two methods focus on the language foundation module and 20% or more focus on the understanding and inference module. The MH method detected three language foundation titles, 33, 49, and 57 as positive, which is favorable to the high economic level group.

5. Discussion

Previous studies have pointed out that socioeconomic status is one of the main influencing factors of reading. Using the existing population categories and DIF test, this study can clarify the impact mechanism of family socioeconomic status on children's online reading users. Firstly, the difference test of reading performance shows that the reading scores of the four traditional index groups are significantly

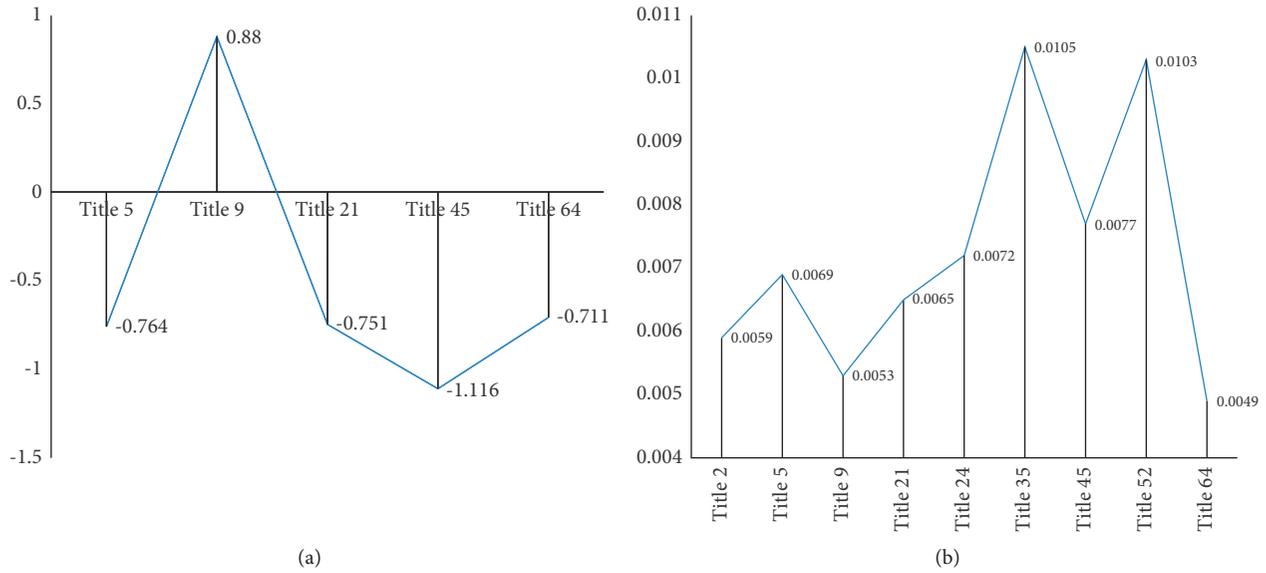

FIGURE 3: DIF inspection results of the average wage grouping. (a) ΔMH . (b) R^2 .

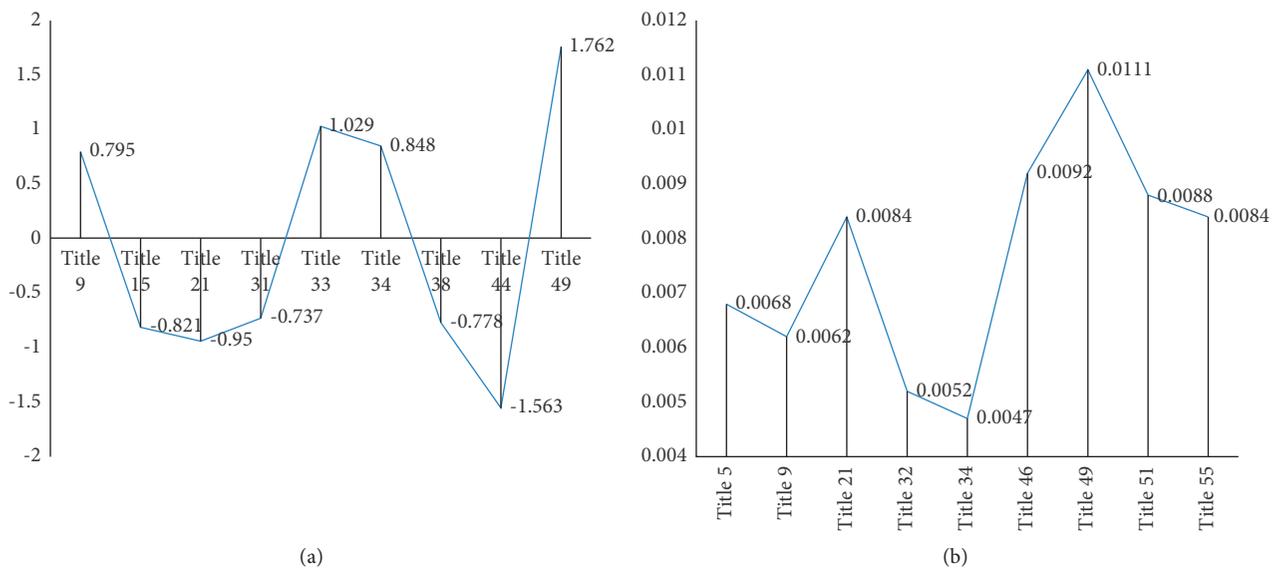

FIGURE 4: DIF inspection results of per capita disposable income grouping. (a) ΔMH . (b) R^2 .

different. Secondly, continuing to do the DIF test, it is found that the difference in reading performance comes from the difference in the item function of the test. Under the four traditional groups, the number of DIF items detected is large, and the law is not obvious. The language basis, understanding and inference, information extraction, transfer and application, overall perception, and appreciation evaluation modules of DIF items in the reading test are distributed, which means that the subjects in the low socioeconomic status group are very inferior in their overall reading ability, that is to say, they are unable to put forward targeted demand suggestions to users. Then, it will be more difficult to continue reading practice, and the effect of improving reading level cannot be estimated. It is speculated that this situation may be related to inconsistent grouping.

When the two types of subjects grouped by clustering and LCA are used as the target group and the reference group for the DIF test, it is concluded that the number of DIF items is significantly reduced, and there are rules to follow, which is reflected in the language foundation and understanding inference module, and the students with low socioeconomic status are at a disadvantage. This is also the part of reading ability that students are most exposed to and mainly trained in daily learning. It is the module that is most likely to open the gap, which is consistent with the research expectation.

Reading comprehension is the ability to extract and construct meaning from text. Vocabulary and world knowledge are the two main predictors of reading comprehension test. The DIF items focus on the "language

14	Understanding and inference	0.0066
33	Language foundation	0.0088
36	Information extraction	0.0053
49	Language foundation	0.0057
57	Language foundation	0.0073

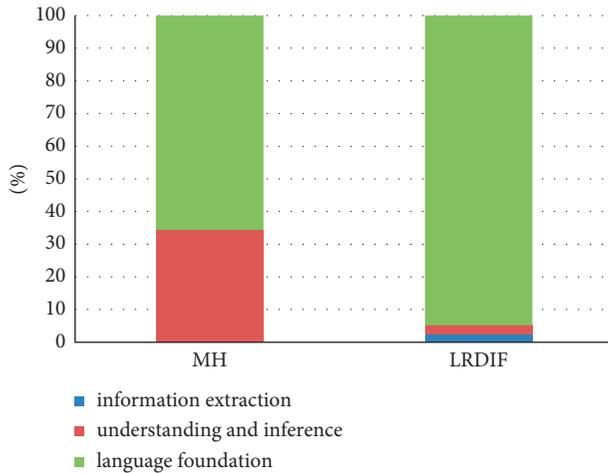

FIGURE 8: DIF ability module map.

foundation” and “understanding and inference” modules in the reading test, and the subjects in the high-level economic group perform better in answering questions. It can be inferred that superior family conditions can provide children with a better family language environment and a variety of ways to help children understand text information. The Family language environment includes both software and hardware. Hardware refers to hard conditions such as entity language learning materials, books, and CDs, while software refers to the language quality input by children and their families. Studies have demonstrated that language environment and family input are closely related to children’s language development. The interaction between parents and children in high SES families has richer additional language, stronger modification, less punitive, and imperative language. The differences in the language models of parents in families with different economic statuses determine the differences in the development of the children’s language foundation.

Therefore, for children with low family socioeconomic status, online reading enterprises should provide more reading text exercises focusing on the improvement of basic language ability and even launch picture books with voice functions to let children listen and read together and fundamentally improve their basic language ability. For the cultivation of understanding and inference ability, businesses should focus on thinking exercise books in recommended books so that children can think wirelessly, enhance their learning motivation, and gradually improve their thinking, reasoning ability, and understanding. The supporting test questions can use VR technology to detect the changes of students’ mouth shapes during pronunciation and reading aloud to the greatest extent and give feedback, so as to ensure the accuracy and quality of children’s practice. On the other hand, for children from high SES families with a good foundation, enterprises should develop reading text contents and exercises conducive to the cultivation of high-level abilities such as overall perception, transfer application, appreciation, and evaluation, so that children can gradually develop the ability to think

independently, form the habit of thinking and solving problems independently, draw inferences from one instance on reading materials of the same nature, and lay a foundation for learning complex reading texts in the senior grade.

6. Conclusions

This study explores the important family socioeconomic status factors affecting children’s reading ability and can provide corresponding countermeasures and suggestions for vulnerable reading users. So as to improve children’s product experience satisfaction and increase user stickiness and retention rate from the perspective of enterprises. Provide guidance and suggestions for future product iteration and updates and combine practical research with theory to make products that users are more inclined to agree with. This study explores and demonstrates the quantitative research methods suitable for user demand analysis and supplements the research by focusing on qualitative research to analyze user demand and user experience. The exploration from multiple perspectives makes the research on user needs closer to the real needs of users, and the population is objectively and scientifically classified on the basis of statistical classification methods.

The limitation of this study is that the online reading of other grades remains to be discussed. There are many methods of data classification, and other methods will be introduced in future research. The design of the topic content may not be balanced enough. In addition, this study is limited to actual sampling, which is difficult. When investigating the differences of family socioeconomic status, it is represented by the regional economic level, which has a certain deviation. Future research will focus on improving these aspects. When analyzing children’s online reading behavior oriented to their family education, we only start with gender and socioeconomic status differences in reading, which is not comprehensive enough. This is the biggest limitation of this study. Children’s growth environment, personality, and other factors will be taken into account in future research.

College students' anxiety, depression, inferiority complex, interpersonal sensitivity, and a series of mental health problems have a very serious negative impact on individuals, families, and society. In order to obtain better psychological emotion recognition effect of college students, this paper proposes a psychological emotion recognition algorithm based on multisource data. One-dimensional convolutional neural network (1D-CNN) was used to mine students' online patterns from online behavior sequences. According to the consumption data of students in the canteen, abnormal scores are calculated to depict the dietary differences among students. At the same time, the students' psychological state data provided by the psychological center are used as labels to improve the shortcomings of the questionnaire. Five kinds of common classification algorithms are trained by training set, and the classifier with the best effect is selected through evaluation of verification set, which is used to identify students with mental health problems in the test set. Experimental results show that precision, recall, and *F1*-measure reach 0.68, 0.56, and 0.67, respectively. 75% of students with mental health problems are identified. The psychological and emotional recognition system of college students based on deep learning provides systematic method and theoretical support for the school to find students with psychological problems in time and provide intervention.

1. Introduction

With the rapid development of knowledge economy and the increasing popularity of higher education, the number of college students is increasing day by day, and there are more and more students with psychological problems [1]. College students, as a part of high-level talents, have always been regarded as the outstanding generation of the society, with strong psychological quality by default, but the fact is disappointing. All kinds of pressures such as study, social relationship, and employment make college students mentally exhausted, and timely detection of abnormal students has become one of the most concerned and intractable problems in universities [2].

People's psychological characteristics can be expressed through daily living behaviors and work-and-rest rules. Researchers have mined information that can reflect the

mental health state from the daily behavior data of college students. Research shows that there is a close relationship between mental health and online behavior. Jorm proposed an algorithm to predict mental health problems through online use behavior. Based on web usage behavior, a computational model for predicting scores of SCL-90 dimensions was established [3]. Nie [4] proposed a new method to predict the future mental illness severity (MIS) of users sharing posts on Instagram in 2014. Paola [5] discussed the universality and treatment of college students' psychology and psychosis, proposed the uniqueness of college students' development stage and environment in terms of psychological abnormalities, and summarized the influence of college students' psychological problems [6]. Zanganeh [7] (2018) explored the role of emotional factors in doctoral students' online information retrieval. Domestic scholars have conducted relevant research on this topic [8]. Tang [9]

used SCL-90 scale to measure the mental health of graduate students, established a prediction model through BP neural network to analyze and predict the mental health status of students, and put the model into practical application [10]. Wang Yinmei et al. [11] used symptom measurement scale to investigate 532 college students and found that college students' mental health varies in different grades, mainly influenced by interpersonal relationship, diet and sleep in college, and students of different majors have different psychological conditions [12]. Zhu [13] (2019) proposed a new method to detect depression through time-frequency analysis of network behaviors. A classification model was established to distinguish the high SDS group from the low SDS group, and a more accurate prediction model was established to identify the psychological state of the depression group [14].

To sum up, this paper carries out an analysis and research on students' mental health state through the data of students' education in school and excavates the relationship between college students' behaviors and their mental health state, which plays an important role and shows significance for university student managers to carry out early intervention for students with psychological abnormalities.

2. Principle of Deep Learning Algorithm

Deep learning is the process of using computers to imitate human learning behaviors. In the process of learning, new knowledge and experience are constantly accumulated, and their own knowledge structure is established according to this knowledge so as to improve their learning ability [15]. The research in this paper is a binary classification problem, and five commonly used classification algorithms are used in the experimental process, including decision tree, random forest, naive Bayes, gradient ascending tree, and BP neural network. In the feature extraction process, in order to reflect the dining situation of students, k -means clustering is used to cluster the dietary data of students.

2.1. k -Means Clustering. The main idea of k -means clustering algorithm: firstly, select K sample points randomly from the sample set and take them as the center of the cluster. Then, according to the distance between each sample and the k centroids, it is divided into the nearest cluster, and then the centroids of each cluster are recalculated [16]. Euclidean distance is used in this paper, and the calculation formula is shown as

$$d(x, C_i) = \sqrt{\sum_{j=1}^m (x_j - c_{ij})^2}, \quad (1)$$

where x is the data object, C_i is the i th cluster center, m is the dimension of the data object, x_j , C_{ij} are the j attribute values

of x and C_i . The calculation formula of error square and SSE of the whole data set is shown as

$$SSE = \sum_{i=1}^k \sum_{x \in C_i} |d(x, C_i)|^2. \quad (2)$$

2.2. Decision Tree Algorithm. The different decision tree algorithms according to different split attribute algorithms are as follows. ID3 algorithm selects the optimal attribute for splitting by calculating the information gain, and the attribute with the maximum information gain after partitioning is the optimal attribute [17]. The information gain is calculated on the basis of information entropy, which is shown as

$$\text{Entropy}(D) = - \sum_{i=1}^m p_i \log_2 p_i. \quad (3)$$

Among them, m is the number of categories in a data set D , and p_i is the first i category of probability. The smaller the value of (D) is, the higher the purity of D is.

If attribute a in the data set is used, the possible values of a are $v = \{a^1, a^2, a^3, \dots, a^v\}$, which can be calculated according to formula (4) to attribute a classified information entropy D^v , because the various values of a sample are different, add weight to each branch node $|D^v|/|D|$, when dividing the data set with property a , can according to the formula to calculate the sample set of type D information gain.

$$\text{Gain}(D, a) = \text{Entropy}(D) - \sum_{v=1}^v \text{Entropy}(D^v). \quad (4)$$

However, the information gain tends to favor attributes with more values. In order to improve this defect, the famous C4.5 algorithm is proposed [7], which uses the information gain rate when selecting attributes, as shown in formula (5). The detailed attribute selection process is as follows: firstly, the information gain of the attribute is calculated, and the attribute whose information gain is higher than the average value is selected, and then the highest gain rate is selected from these attributes for classification.

$$\text{Gain_ratio}(D, a) = \frac{\text{Gain}(D, a)}{\text{SI}(a)}. \quad (5)$$

$$\text{SI}(a) = - \sum_{v=1}^v \frac{|D^v|}{D} \log_2 \frac{|D^v|}{D}. \quad (6)$$

CART algorithm uses Gini index to select the optimal splitting attribute, and the calculation speed is faster than the information gain rate [13]. The purity of dataset D can be measured by Gini index, as shown in (7). The smaller (D) is, the higher the purity of the data set is. Therefore, which

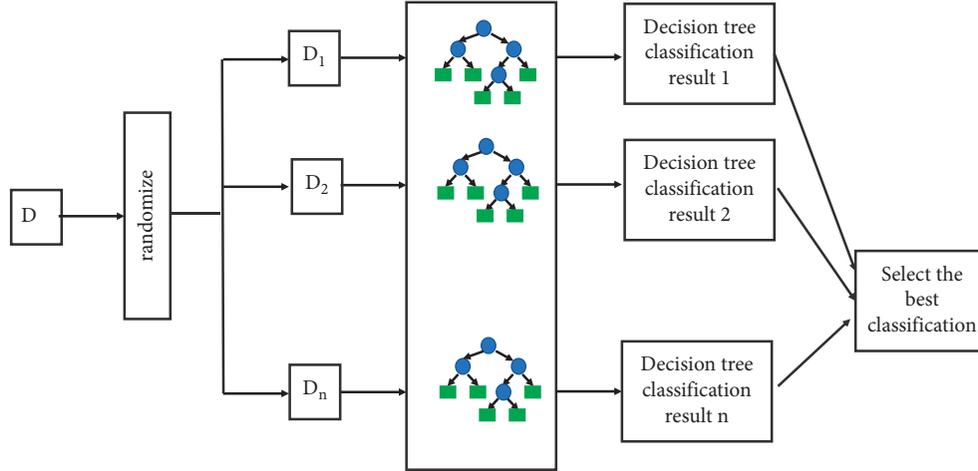

FIGURE 1: Random forest workflow.

attribute is the optimal splitting attribute can be judged according to the size of Gini index.

$$\text{Gini}(D) = 1 - \sum_{i=1}^n p_i^2. \quad (7)$$

The idea of decision tree algorithm is simple, easy to understand, and easy to extract rules. Insensitivity to data can process both nominal and numerical data and can process unrelated features. However, it also has some disadvantages. First, it is easy to produce overfitting, and second, it is easy to ignore the correlation between attributes.

2.3. Random Forest Algorithm. The random forest algorithm takes decision tree-based classifier and combines Bagging construction with random attribute selection. Its workflow is shown in Figure 1. Specifically, random forest determines the category of samples by voting, and each base classifier has one vote to determine the category of samples according to the principle of majority rule. The randomness of the random forest in random attribute selection, for each node base classifier, randomly selected from the set from the current node attributes first k attribute a subset, and then according to the attribute selection algorithm from subset to calculate the optimal split attribute, rather than the traditional decision tree from the current node, find out the best in all of the attributes of the attribute. The parameter k is introduced to reflect the randomness of the random forest Algorithm 1.

2.4. Naive Bayes. Naive Bayes algorithm takes Bayes algorithm as the premise and introduces the “independence” hypothesis, whose assumed attributes are independent of each other [18]. Under this assumption of independence, naive Bayes algorithm is especially suitable for solving multiattribute problems. Naive Bayes algorithm is currently

recognized as a simple and effective probability classification method, and its classification process is as follows:

- (1) Assume that each sample has n attributes. Each sample is represented by an n -dimensional eigen-vector $d = \{d_1, d_2, d_3, \dots, d_n\}$.
- (2) Suppose there are m categories $c = \{c_1, c_2, c_3, \dots, c_m\}$. Given an unknown data sample d , the classification predicts that d belongs to the class with the maximum posterior probability, that is, if and only if $p(c|d) > p(c|d)1 \leq j \leq m$ and $j \neq i$, The Bayesian classification assigns the sample to be classified to class c_i , and the value of $p(c_i|d)$ can be calculated by the conditional probability formula in probability theory, as shown in the following formula.

$$P(c_i|d) = \frac{P(d|c_i)P(c_i)}{P(d)}. \quad (8)$$

- (3) Since the sample set is known and the value of $P(d)$ can be calculated, the maximum value of $P(c_i|d)$ can only be calculated by the maximum value of $p(d|c_i)p(c_i)$. Without knowing the prior probabilities of the classes, assume that each class is equally likely, so you just maximize $(d|c_i)$. Otherwise, maximize $(d|c_i)(c_i)$.
- (4) In the case of multiple attributes, the overhead of calculating $(d|c_i)$ may be very large. In this case, we can make the naive assumption of class condition independence to reduce the overhead of calculating $(d|c_i)$. The classes of a given sample are labeled, assuming that the attributes are independent of each other.

$$P(d|c_i) = \prod_{j=1}^a P(d_j|c_i), \quad (9)$$

- (i) Input: data set $T = \{(x_1, y_1), (x_2, y_2), \dots, (x_m, y_m)\}$, loss function L
- (ii) Output: Additive model $f(x) = f_M(x)$
- (1) Initialize the base classifier $f_0(x) = \arg \min_{\gamma} \sum_{i=1}^N L(y_i, \gamma)$
 - (2) Each base classifier needs to perform the following operations:
 - ① According to the loss function, the negative gradient of each sample in the current model is calculated and used as an estimate of the residual $r_{im} = -[\partial L(y_i, f(x_i))/\partial, f(x_i)]$.
 - ② For a given Γ_{im} , the leaf node R_{mj} , R_{mj} , $j = 1, 2, \dots, J$, J is the number of leaf nodes
 - ③ For leaf nodes, calculate $c_{mj} = \operatorname{argmin}_c \sum_{x_i \in R_{mj}} L(y_i, f_{m-1}(x_i) + c)$.
 - ④ Update regression tree $f_m(x) = f_{m-1}(x) + \sum_{j=1}^J c_{mj} I(x \in R_{mj})$.
 - (3) Output gradient lifting tree $\hat{f}(x) = f_M(x)$.

ALGORITHM 1

where $(d_1|ci)$, $(d_2|ci)$, \dots , $P(dj|ci)$ can be computed from the sample set.

- (5) When classifying classified sample d , calculate $(d|ci)(ci)$ for each class c_i in turn. If and only if $(d|ci)(ci) > P(d|cj)P(j)$, $1 \leq j \leq m$, $j \neq i$, sample d to be classified is divided into class c_j .

2.5. BP Neural Network. BP neural network is a multilayer feedforward neural network trained according to error reverse propagation algorithm. The training process of BP neural network is divided into two parts: one is signal forward propagation, and the other is error reverse propagation, as shown in Figure 2. Among them, BP neural network has many advantages such as strong nonlinear mapping ability, generalization ability, and fault tolerance ability due to its error back propagation learning process.

BP neural network consists of three parts: input layer, hidden layer, and output layer. Among them, the number of training sample attributes determines the number of neurons in the input layer, and the number of target classification determines the number of neurons in the output layer. For example, for a binary classification problem, there are only two neurons in the output layer. Users can freely define the number of hidden layers and the number of neurons in each hidden layer. The lines between each layer represent the weights.

BP neural network has the following advantages: first, it has strong adaptability and self-learning ability, which can continuously learn and correct path weight and save learning content during training. Second, the nonlinear mapping and fault tolerance ability can better solve the internal mechanism of the more complex nonlinear mapping. However, BP neural network has some defects, such as slow training speed, no corresponding standard for hidden layers, and number of neurons.

2.6. Pearson's Correlation Coefficient. Pearson's correlation coefficient is used to measure the linear correlation between two variables in most cases. It is defined as the quotient of covariance and standard deviation between two variables, and its calculation is shown in the following formula.

$$\rho_{X,Y} = \frac{\operatorname{cov}(X, Y)}{\sigma_{X,Y}} = \frac{E(XY) - E(X)E(Y)}{\sqrt{E(X^2) - E^2(X)}\sqrt{E(Y^2) - E^2(Y)}} \quad (10)$$

where X and Y represent two random variables, $\operatorname{cov}(X, Y)$ represents the covariance between X and Y , $\sigma_{X,Y}$ represents the standard deviation between X and Y , and E represents statistical mathematical expectation.

Pearson's correlation coefficient ranges from -1 to 1 . A positive value means a positive correlation between two variables (1 means a complete positive correlation), a negative value means a negative correlation between two variables (-1 means a complete negative correlation), and a 0 value means there is no linear correlation between two variables. When comparing the correlation between feature and target problem, the larger the absolute value of correlation coefficient is, the more relevant the feature is to target problem.

3. Student Mental Health Problem Identification Algorithm Based on Multisource Data

The experimental process of identifying students with psychological and emotional problems based on multisource data includes data acquisition and preprocessing, feature extraction, model training, and recognition. In the experiment, students' consumption data, access control data, network data, historical performance data, and psychological center data were collected.

3.1. Algorithm Framework. The overall framework of the student mental health problem recognition algorithm based on multisource data is shown in Figure 2. The whole algorithm process is divided into three parts, including data acquisition and preprocessing, feature extraction, and model training and recognition. In the stage of data acquisition and preprocessing, we obtained four data sources, namely, network log, access control data, achievement data, and consumption data. In the feature extraction stage, the relevant features such as students' online pattern and consumption abnormal score are extracted from the four data

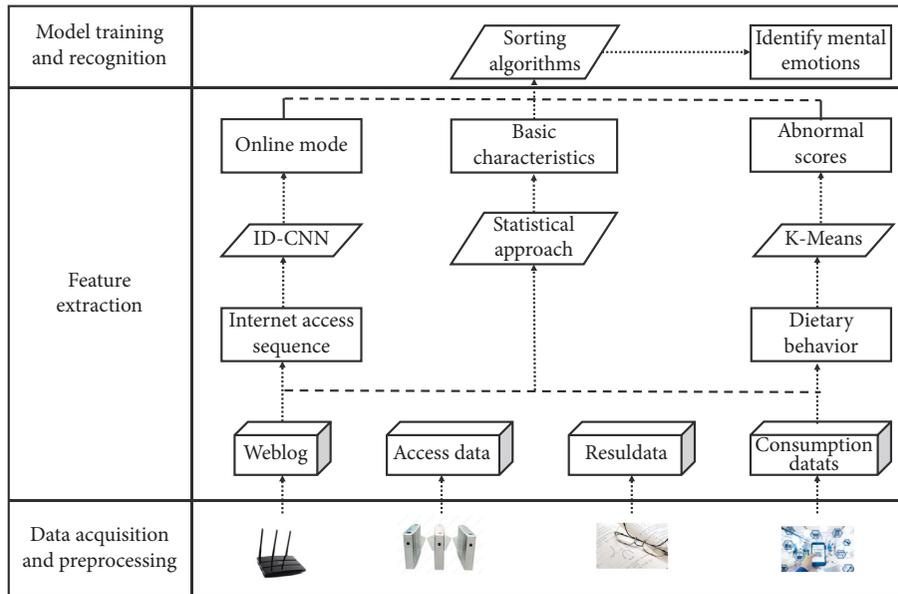

FIGURE 2: Multisource data-based student mental health problem recognition algorithm framework.

sources. The optimal classifier is selected from five common classification algorithms.

3.1.1. Data Acquisition and Preprocessing. After applying to relevant departments and obtaining students’ informed consent, this study obtained a variety of behavioral data of students, including students’ consumption data, historical performance data, network logs, access control and card swiping data, and psychological state data.

(1) *Consumption Data.* There will be a record every time students swipe the campus card. There are three tables of consumption data, namely, consumption flow chart, student account information table, and shop account information table. According to the shop account, connect the shop account information table with the consumption table and the student account information table, and the results are shown in Table 1.

(2) *Access Control Data.* At present, college students can enter and leave dormitories only after swiping their card through the access control system using a Metro Card. Every time a student swipes the card, an entry-and-exit record will be generated, and these records are stored in the access control information table, as shown in Table 2.

The access control information not only reflects the time trajectory of students entering and leaving the dormitory, but also calculates the duration of students in the dormitory according to their entering and leaving states. Students usually go in and out of dormitories with friends, and digging in this direction may also reveal interesting information, such as friend relationships.

(3) *Students’ Network Log Records.* Table 3 shows the network log information. Network logs record students’ online activities, including online time and browsing

content. How to dig out the patterns and characteristics of students’ online behavior from these records is a problem we need to solve.

With the approval of the school network center and the informed consent of the students, we obtained the log files of the students’ Internet access. We understand and analyze the network log; the format of the network log looks very simple, but the information it contains is very complex. The URL is divided into seven types, respectively: (1) comprehensive, (2) adult, (3) entertainment, (4) news, (5) publicity, (6) shopping, and (7) learning.

(4) *Students’ Historical Performance Data.* There is a significant negative correlation between mild, moderate, and severe mood disorders and academic performance [19], and students’ historical performance data reflect their past learning status and process. With the approval of the faculty and the informed consent of the student, this table details the students for the first time to attend this exam year students (XN), the first time to attend the exam of semester exam (XQ), students take the exam last time last year (QDXN), students take part in this exam semester (QDXQ), students, student id (XH), course name (KCMC), test scores (KS CJ), credits (XF), GRADE points (JD), grade points (XFJD), and credit acquisition methods (QDFS), including preliminary courses, retakes, and make-up exams, as shown in Table 4. Each record in the student history grade table reflects the student’s learning of a certain course, and the student’s comprehensive learning situation can be understood through the student number.

In the analysis and understanding of the student history score table, we found that the scoring method of the examination score (KSCJ) is not uniform; some courses use the hundred-mark system, while some use the five-level system [19]. For the convenience of calculation and analysis, we change the five-grade system into a percentage system, and

the corresponding relationship is as follows: excellent (95), good (85), medium (75), pass (60), and fail (50).

It is found that there are missing values in the grade point column of the student's history grade table. Since credits are the product of grade points multiplied by course credits, a loss of grade points results in loss of corresponding credits. By observing the existing GPA, find out the calculation rule of GPA, where $CGPA_i$ stands for GPA of the course i , $Score_i$ stands for GPA of the course i , and the corresponding relationship between the calculated GPA and GPA is shown in Table 5. Next, according to the formula to calculate the credit grade point of the problem, $CGPA_i$ stands for the first i course credit grade point and $Credit_i$ stands for the first i course credits.

$$GPA_i = \frac{(Score_i - 50)}{10}, \quad (11)$$

$$CGPA_i = Credit_i \times GPA_i.$$

TABLE 5: Conversion relationship between grade points.

Designation	Conversion relationship						
Results	>90	89	88	61	60	<
Grade point	4	3.9	3.8	1.1	1	0

(5) *Psychological State Data*. With the approval of the psychological center and the informed consent of the students, the psychological state table of the students was obtained. Each record in the table contains the student's student ID, gender, department, grade, class, attention level, and update time. The concern level includes mild, moderate, and severe. "Mild" means suffering from mild mental health problems; "moderate" means having moderate mental health problems; and "severe" means having severe mental health problems [11].

In this study, we targeted a dichotomous problem, namely, students with mental health problems and normal

students. Students whose concern level is light, medium, and heavy in the psychological state table of students were taken as positive samples, and other students who were not reported were taken as normal students.

3.1.2. Feature Extraction. This section mainly describes the process of extracting student behavior characteristics from data sources. The behavior of students on campus is rich and colorful. We divide the behavior characteristics of students into four types: consumption characteristics, access control characteristics, Internet access characteristics, and performance characteristics [9].

(1) Consumption Characteristics. Some studies have found that people with mental health problems will have eating disorders, especially depression [19]. Based on this fact, the consumption records of students in the canteen were extracted through the shop names to analyze their eating patterns. Pay special attention to students' breakfast/lunch/dinner routines. Set breakfast from 6 to 9, lunch from 11 to 13, and dinner from 17 to 19:30. Since there are often multiple records for each meal, use the time of the first swipe as the meal time. For example, if there are three records in a breakfast, the time of occurrence is 7:20, 7:21, and 7:22, use 7:20 as the breakfast time. The regularity of a behavior can be considered repeatable and will be measured by entropy of the probability that the behavior occurs at a particular time interval. Assuming that there are n time intervals $T = \{t_1, t_2, t_3, \dots, t_n\}$, for any given student, the probability $p_v(T = t_i)$ of behavior $v \in V = \{\text{breakfast, lunch, dinner}\}$ occurring within time interval t_i is calculated according to formula (12), where $n_v(t_i)$ represents the frequency of behavior v occurring within time interval t_i . Then, calculate the entropy, which is calculated by formula (13). Assume that for the three behaviors of morning/afternoon/dinner, each time interval span is half an hour.

$$P_v(T = t_i) = \frac{n_v(t_i)}{\sum_{i=1}^n n_v(t_i)}, \quad (12)$$

$$E_v = - \sum_{i=1}^n P_v(T = t_i) \log P_v(T = t_i). \quad (13)$$

The $b_entropy$, $l_entropy$, and $d_entropy$ values for breakfast/lunch/dinner can be calculated from formulas 12 and 13. Meanwhile, according to formula (12), the smaller the entropy value of a behavior is, the more concentrated its probability distribution is over time, and the higher its regularity is. If one student only goes to the canteen occasionally during a concentrated period of time, while the other student goes to the canteen frequently, although the regularity of the two students' dining in the canteen is not the same, they will also have similar entropy values. In order to better distinguish the two types of students, the number of breakfasts/luncheons/dinners for each student was calculated separately. k -means clustering algorithm is used to cluster entropy and meal times. It is considered that students

have three common dining behaviors: less frequent dining, poor dining regularity, and good dining regularity. Therefore, the number of clustering k is set as 3. The clustering results are shown in Figure 3.

The goal was to find students with abnormal eating habits. It is assumed that the smaller the cluster a student is in, and the further away from the center of the cluster, the higher the abnormal score (20) according to the formula to calculate the abnormal scores for students, which is c_i student of n in the cluster centroid of C_i , said all the students, $|c_i|$ clustering C_i number of students, $|C|$ represents all the students, students n the distance to the center of mass of $(n, c_i)c_i$ said. In this experiment, Euclidean distance is used to calculate the distance.

$$AS = D(n, c_i) * \left(1 - \frac{|C_i|}{C}\right). \quad (14)$$

(2) Characteristics of Access Control. It is found that the more difficult the interpersonal communication is, the worse the mental health level is, and the stronger the interpersonal communication ability is, the better the mental health level is [5]. The dormitories of undergraduate students in colleges and universities are usually divided according to classes, and students in the same dormitory generally have the same entry and exit schedule. The interpersonal relationship of students in the dormitory can be reflected by calculating the times of students and roommates entering and leaving the dormitory together, which is called card swiping in front and back foot. The rule is as follows: if two students are roommates, the difference in credit card time is less than 20 seconds, and both students enter or leave the dormitory at the same time. Further analysis of the card swiping data from front and back showed that some students' values were less than 10 or even 0.

(3) Characteristics of Internet Access The overall framework of the one-dimensional convolutional neural network designed in this study consists of five neural network layers. In the training of the model, the input of each student is a network sequence, that is, a one-dimensional vector. Since the length of the network sequence is inconsistent, 0 is used to fill it. The operation of the convolution layer is shown in formula (15), where x_j^l is the feature graph of the j convolution operator of the l layer, x_i^{l-1} represents the input, k_{ij}^l represents the j convolution kernel of the l layer, b_j^l represents the bias of the j convolution operator, $f(\cdot)$ represents the activation function, and $*$ represents the multiplication operation.

$$x_j^l = f \left(\sum_{i \in M_j} x_i^{l-1} * k_{ij}^l + b_j^l \right). \quad (15)$$

The second and fourth neural network layers adopt the pooling layer, and the pooling mode is divided into average pooling and maximum pooling. In this study, the pooling mode is maximum pooling. The operation of the pooling

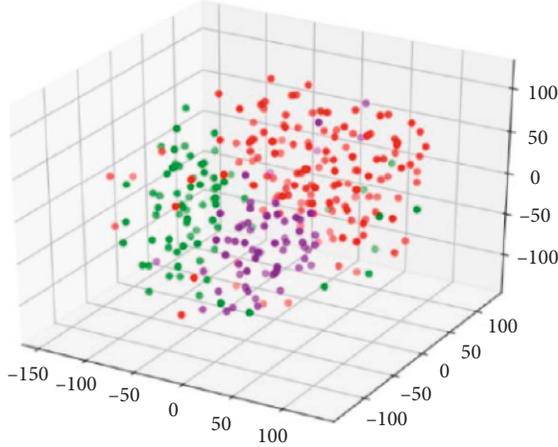

FIGURE 3: Clustering results based on entropy and frequency of breakfast, lunch, dinner.

layer is shown in formula (16), where x_j^i , w_j^i , b_j^i , $\text{down}x_j^i$ represents the input, weight matrix, bias, and downsampling function, respectively.

$$\hat{x}_j^l = f(w_j^l) \text{down}(x_j^l) + b_j^l. \quad (16)$$

The fifth layer uses a full connection layer, and the operation of the full connection layer is shown as follows:

$$s^{\text{pat}} = f(w^{(5)} * x^4 + b^{(5)}). \quad (17)$$

For parameter setting, the number of convolution kernels of the two convolution layers is 16 and 32, respectively. ReLU was used as the activation function and Adam as the optimization algorithm. Additionally, to prevent overfitting, we use three dropout layers with parameters 0.15, 0.15, and 0.5. In the model training stage, 70 positive samples and 70 negative samples were used to train the model. In the feature extraction stage, all the experimental samples were input into the trained 1D-CNN model, and finally the results of the full connection layer spat were output as the online mode.

(4) *Performance Characteristics.* (1) Grade point average students' mental health problems are often caused by external factors, and grade pressure is one of the external factors, so it is necessary to extract grade-related characteristics to reflect students' performance. GPA plays a decisive role in the school's evaluation and award, and the calculation formula is as follows:

$$\text{GPA}_{\text{avg}} = \frac{\sum_{i=1}^n \text{CGPA}_i}{\sum_{i=1}^n \text{Sore}_i}. \quad (18)$$

(2) Failing credits for college students: failing credits are the best characteristic of performance pressure. Failing credits are counted by traversing a student's history score sheet and counting the corresponding credits as failing credits if the QDFS value is a make-up exam. Two characteristics, GPA and failing credits, are extracted from historical achievement data. Finally, a total of 69 features

were extracted from consumption data, access control data, and network logs and historical performance data.

3.1.3. *Model Training and Recognition.* The research objective of this paper is a binary classification problem. Five common classification algorithms are selected as candidate algorithms, including random forest (RT), gradient ascending tree (GBDT), Naive Bayes (NB), neural network (NN), and decision tree (DT). We hope to select a classification algorithm with the best performance as the classifier of the algorithm.

The data set is divided into training set, verification set, and test set, and each classification algorithm is trained with the training set, and then each classification algorithm is evaluated with the verification set. Obfuscation matrix is an index to evaluate model performance, which is mainly used to judge the performance of classifier. The confusion matrix has four basic elements, which are True Positive (TP), False Negative (FN), False Positive (FP), and True Negative (TN). The meanings of these four elements will be introduced in detail below.

However, the obfuscation matrix is only a statistical quantity. When the sample number is very large, it is difficult to evaluate the performance of the model only by calculating the quantity. Therefore, the confusion matrix extends some evaluation indexes based on the statistical quantity. In educational data research, there are five commonly used evaluation indicators, including accuracy, precision, recall, F1-measure, and AUC (area under curve) [19]. In this experiment, precision, recall, and F1-measure were selected as evaluation indexes.

Precision refers to the proportion of students who are truly positive samples among the students who are predicted to be positive samples, and its calculation formula is shown as follows:

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}}. \quad (19)$$

Recall refers to the proportion of students who are predicted to be positive samples among students who are real and positive samples, and its calculation formula is shown as follows:

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}. \quad (20)$$

Precision and recall are two important indicators. However, when evaluating the performance of several models, precision of one model is often higher than that of other models, but recall is lower than that of other models. Therefore, the optimal model cannot be selected. A comprehensive index F -measure was introduced, and precision and recall were weighted and averaged. The calculation formula is shown as (21). The larger the F -measure is, the better the model performance is. When α is equal to 1, it is commonly used $F1$ -measure, and $F1$ -measure is used in this study.

$$F - \text{Measure} = \frac{(\alpha^{2+1})\text{Precision} * \text{Recall}}{\alpha^2 * \text{Precision} + \text{Recall}} \quad (21)$$

The training process of the model is the process of parameter selection; how to choose the optimal parameter is a key problem. In this algorithm, the way of permutation and combination is used to select the optimal parameter combination. For each classification algorithm, we adjust only a few important parameters and use the default values for the rest parameters. After trying different parameter combinations, the optimal parameter combinations of each candidate classification algorithm are selected.

4. Experiment and Result Analysis

4.1. Experimental Data. Among the 280 undergraduates who participated in the survey, 70 students were assessed as students with mental health problems by experts at the university's psychological center in May and June 2019. Their mental health levels were classified as mild, moderate, or severe. In addition, 210 undergraduates were randomly selected from the entire school. Finally, the proportion of students at each mental state level is shown in Figure 4.

Students were divided into two groups, with a positive sample for mild, moderate, and severe cases, and a negative sample for students without mental health problems. The label has high credibility and avoids the drawbacks of concealing facts in questionnaires. In order to protect students' privacy, the student id was encrypted throughout the experiment. As the psychological state is a short-term state, generally lasting from half a month to one month, only the consumption data access control data and network logs in April 2021 are used.

4.2. Training Set and Test Set. The essence of deep learning is the process of model selection. However, only parameters of the model are unknown. By using various tuning methods, an optimal value can be obtained, which enables the model to map independent variables to dependent variables well. In practice, it is not always easy to sample data evenly. So, the actual process is random. In this experiment, the data set sample is 280 students, among which 70 students are positive samples and 210 students are negative samples; that is to say, the ratio of positive samples to negative samples is 1 : 3. In order to make the sample ratio of the training set and the test set 1 : 3, 49 and 147 students were randomly selected from the positive and negative samples of the data set, respectively, as the training set, and 25% of the data were used as the verification set, and the positive and negative sample ratio was 1 : 3. Meanwhile, the ratio of positive and negative samples in the test set was 1 : 3.

4.3. Comparison and Analysis of Experimental Results. The extracted features are input into the classification algorithm for model training and prediction. Five common machine learning classification algorithms, including random forest (RT), gradient ascending tree (GBDT), Naive

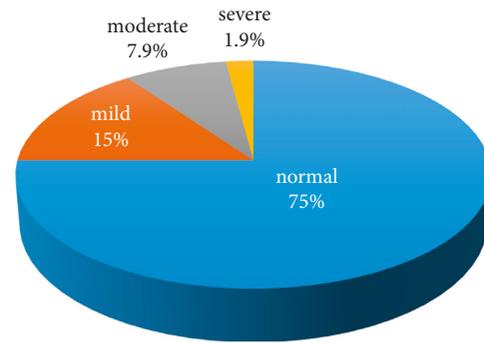

FIGURE 4: Proportion of each mental state in the data set.

Bayes (NB), neural network (NN), and decision tree (DT), are compared. The experimental results are shown in Table 6.

First of all, it can be obviously observed that in all models, precision is higher than recall, and recall is only 0.58 at its highest, indicating that few samples can be correctly identified. Secondly, decision tree has the best comprehensive performance, especially recall. Therefore, we choose decision tree as the classifier of mental health recognition algorithm based on multisource data.

To verify the generalization ability of the algorithm, we input the test data set into our algorithm and obtain the following experimental results: precision 0.68, recall 0.56, and $F1$ -measure 0.67. Based on the test set experiment results, our algorithm was able to identify 56 percent of students with mental health problems. Table 7 lists 20 characteristics with high Pearson's correlations.

It can be seen from the table that 7 of the first 8 positive correlation characteristics are related to early rise. In general, students' courses are arranged by week, and students have the same class time every week. The larger standard deviation or average value of early rise may be caused by lateness or truancy. There was a positive correlation with mental health problems. Working day and day of rest time to stay in the dormitory all show the negative correlation. There is a negative correlation between the time spent in the dormitory on weekdays and rest days. The students spend more time in the dormitory and less time in club activities, student work, and dinner parties. These students have poor interpersonal communication and are more likely to have mental health problems, consistent with people's intuitive feelings. This kind of students have generally poor interpersonal, namely, interpersonal communication; the worse the student, the more possible mental health problems, which is consistent and intuitive feeling of people. Students who spend more money in the canteen on weekdays and holidays may seldom participate in dinner parties, which may also reflect poor interpersonal communication. In addition, the correlation coefficient of students' swiping times is high and negative. On the one hand, students who swiped cards less often participated in fewer activities and had poorer interpersonal communication. On the other hand, students who swipe their credit cards only a few times a month should live off-campus and be the focus of attention. The insomnia rate (correlation coefficient 0.1058), the number of takeout orders (correlation coefficient 0.1024), GPA_avg, and failed

credits were all weakly correlated, but still valuable for analysis.

Through the above analysis, some characteristics related to mental health problems are obtained, and the impact on mental health is in line with common sense. Moreover, these related features come from multiple data sources, which shows that the use of multisource data can improve the recognition effect from one aspect.

5. Conclusion

This paper proposes a mental health problem recognition algorithm based on multisource data, trains five common classification algorithms, evaluates through the verification set, and establishes a recognition system to judge the psychological emotions of college students, and analyzes the results of the system verification test. The following conclusions can be drawn:

- (1) Analysis of student behavior data can be used to identify students with mental health problems.
- (2) Using a variety of behavioral data can improve the identification effect of students' mental health problems and can identify 75% of students with mental health problems.

To establish college students' mental emotion recognition system, this paper through the prediction results can

identify the students with risk of mental health problems and counselors for school administrators to better understand the students' psychological condition, giving psychological help to the student as soon as possible and targeted intervention method provides the theory support, able to prevent the further deterioration of the psychological condition of students.

Data Availability

The dataset can be accessed upon request to the corresponding author.

Conflicts of Interest

The authors declare that they have no conflicts of interest regarding the publication of this paper.

With the development of digital technology, it is possible to organize the deep relationship of public landscape elements. Design inspiration is no longer static and manual imitation of natural representations but can be dynamically self-organized. The design under the digital design theory shows obvious characteristics: multiparameter action, bottom-up, dynamic iteration, and optimal result orientation. The design chain, or meta-design, has since formed the basic digital design chain. Based on morphogenesis and combined with the existing landscape design creation methods, this study summarizes an operable logic system of digital design based on morphogenesis. It is hoped that through digital technology, it is possible to establish the relationship between various spatial organizations in the public landscape system. It uses the theory of morphogenesis and digital research to expand the cognition of landscape morphology and stimulate the innovation of design methods and build a landscape design logic system based on program algorithms. This study uses the subsystem design and completes the generation process from the design concept to the space formation from the graphic concept, which proves that this design logic system is feasible and has obvious advantages to a certain extent.

1. Introduction

With the development of the economy and the improvement of computer technology, people's requirements for landscape design are also constantly increasing. The traditional landscape design methods can no longer meet the needs of urban development. Our country's landscape design has entered the stage of digital design. However, there are still some deficiencies in the current domestic landscape design, such as how to combine computer technology with landscape design? How to more rationally present every aspect of landscape design, instead of relying on intuitive design and empirical design? The essential problem of morphogenesis is to explore how to establish living systems. Through the research and summary of plant morphology, two different discussions have been drawn, namely, "the theory of preformation" and "the theory of postformation." With the development and extension of postformation theory, it has gradually become the ideological basis of morphogenesis. In a research discussion meeting on urban renewal in New York, it was proposed that

"it is necessary to pay attention to the application of morphogenetic concepts and learn the growth process of life, so as to produce excellent landscape design, which is always in dynamic like a dynamic city." Digitization is to build a model of a complex system or process with the help of a computer, to test the model, then, to have an in-depth understanding of the various behavior mechanisms of the model system, and to control the various means and methods of the model system. Modern computer simulation application technology is an emerging discipline based on operations research, mathematical statistics, and computer science. Based on the methods and concepts of morphogenesis and digital design, this study is reading the existing theories of morphogenesis and digital graphics, especially the related theories of landscape digital graphics and the research theories and research results of landscape morphogenesis, and summarizes the process methods of morphogenesis and digital graphics in landscape design. Based on the two theories of complex adaptive system and morphogenesis, using bottom-up and digital design thinking, using algorithm design and digital

design methods, and the methods and methods of digital design of landscape design based on morphogenesis are studied [1–5]. This study mainly summarizes the development, characteristics, and logic of morphogenesis and digital diagrams. Combined with the existing landscape design creation methods, it summarizes an operable logic system of digital diagram design based on morphogenesis.

2. Related Work

At present, in the exploration of complexity science, designers represented by Steven Johnson have published a series of papers, such as “emergence-connecting with the life, brain, city, software of ants,” which has an impact on reality in this study, and the application mode of digital technology has been deeply analyzed, which has an important impact on the morphogenesis mechanism. With the gradual development of diagrams and other spatial theories, it has brought new promotion to the thought and biological logic of digital design. Second, in the research of digital design, designers represented by Rego Lynn published a series of works, such as “Folding, Body and Bubbles,” on “dynamics” and “force field”. The application of the theory in the process of morphogenesis is described in detail, and it is believed that any design based on the coordinate reference system will show a continuous expansion of the internal logic system and the corresponding information place. At the same time, the UK’s AD magazine also summarizes the thinking of contemporary designers and conducts in-depth research on theories such as skin, folding, and emergence. Based on the two theories of complex adaptive system and morphogenesis, this study uses bottom-up and digital design thinking and uses the methods of algorithm design and digital design to study the methods and methods of digital design of landscape design based on morphogenesis [6–11]. The research contents include the following: (1) theoretical thinking and design thinking of landscape design under morphogenesis, (2) digital morphogenesis of landscape under morphogenesis, (3) theoretical thinking and design thinking of landscape design digital illustration, (4) landscape methods of designing digital graphics, and (5) digital graphical program for landscape design.

3. Related Theoretical Methods

3.1. Morphogenesis

3.1.1. Overall Design Thinking. As the sum of individual relationships, only when the landscape system is deeply analyzed from the overall level, its characteristic attributes and general laws will be highlighted. In the process of analyzing the landscape system as a whole, it is necessary to add a linked relational network, a progressive operation mechanism, and events from a time and space perspective, so as to ensure that it will not lose its original relationship and performance. Therefore, it is necessary to integrate the overall design thinking in order to include the dynamic evolution process of the landscape system [12].

3.1.2. Bottom-Up Process Thinking. Combined with the processing logic of morphogenesis, designers need to find out various influencing factors in the landscape system and use them as a bottom-up driving mechanism. This requires designers to screen the initial information and, at the same time, conduct an in-depth analysis of the project, in order to obtain the correct direction of morphological evolution [13].

3.1.3. Relational Thinking of Interactive Adaptation. In traditional theoretical cognition, it is customary to disassemble the system into different individuals and then explain this hierarchical relationship through linear thinking. As a nonlinear system, each factor in the landscape system is not independent but a system that restricts each other and finally reaches a balanced steady state. The landscape needs to be regarded as a complex system rather than a specific object, and its internal nonlinear spatial logic needs to be correctly constructed [14].

3.2. Digital Morphogenesis of Landscape

3.2.1. Topology Occurrence. Topological geometry is the basic property of how geometric figures remain unchanged in continuous homeomorphic deformation, and it is a geometric theory specializing in the study of the continuity of geometric figures. Homeomorphic deformation means that in the process of deformation, as long as the deformation does not break or overlap, the overall structure of the original topology will not be destroyed. The homeomorphic deformation of landscape topology is a series of topological structure levels derived from the original topological level based on the prototype of the original diversity and unity. In terms of design, the enlightenment of topogenesis is not only in geometric shape but also has an important influence on its logical thinking, and it is used as the theoretical basis and internal mechanism of morphogenesis. For some time, the digital design practice of landscape has stayed in the exploratory stage. It is hoped to use topology generation as a way of spatial structure layout to realize the transformation from the natural landscape to artificial landscape and to create a new landscape design method to make people aware of topology [15–18].

3.2.2. Parameters and Algorithm Generation. The algorithm is to use the overall method to describe the mechanism of dealing with the problem, and it is one of the important contents of the parametric design method. The program of parametric design is to convert the design elements and requirements into computer programs and use the corresponding calculation rules to express the generation process of the shape, so as to obtain the final program shape. The algorithm only needs to calculate the logic with the help of simple rules, so as to obtain complex results, and the designer only needs to select and optimize the results. Due to the large amount of information in the landscape system, it is

difficult to completely express the landscape system by using traditional design methods. With the help of algorithms and parametric technology, a corresponding digital landscape model can be built to simulate and express the relationship between the internal and external influencing factors of the landscape, which can effectively allow designers to obtain the most suitable landscape in a short time [19–21].

4. Construction of a Digital Design Program for Urban Public Landscape Based on Morphogenesis

4.1. Digital Design Based on Program Algorithms. No matter what kind of diagram logic is, it all depends on the program algorithm. This design method based on a program algorithm is the basic design chain of the digital diagram—“meta-design.” Since the process of landscape design is preliminary analysis-asking questions-design concept-design plan-preliminary design-construction drawing design, it has much in common with the process of architectural design, so its design method and process are inspired by landscape design. It should be noted that the main content studied in this study is in the generation stage of the general landscape plan design. Three elements must be included in the meta-design: a parameterized prototype, a measure of the performance evaluation of the solution, and a machine algorithm that controls the loop in the direction of optimization, as shown in Figure 1. No matter what kind of diagram logic is, it all depends on the program algorithm. This design method based on a program algorithm is the basic design chain of the digital diagram—“meta-design.”

In the meta-design system, it is necessary to separately classify the landscape system according to the basic research of the landscape and the objects of its role (the actors in the landscape system). In the landscape digital design system of meta-design, the landscape parameters are completely included in a system where the three systems of people, landscape, and environment adapt to each other, so the landscape system is divided into two basic levels, namely, the internal system (landscape system) and external system (environmental system and human system), as shown in Figure 2.

Using a computer programming language, combined with digital design methods to build an automatic decision-making model, at the same time, according to specific constraints, the relationship between different types of landscape units and adjacent units is calculated, and the individual coordination index is obtained, on this basis, the optimal next-generation individuals are selected, repeated in this way, a population composed of individuals after the global optimal convergence can be finally obtained, and the most suitable design scheme is found. Program algorithm design fundamentally puts forward the basic logic of digital design, but the design process is still largely influenced by the designer’s subjective experience and esthetic concepts. Under the existing conditions, computer logic and subjective logic jointly affect the composition of graphic design. Results: The judgment and feedback of meta-design results

based on subjective experience and esthetic concepts have become an important part of the digital graphical design system. In particular, the esthetic value is the long-term precipitation of designers based on design feedback, which is more in line with the public’s cognition than program algorithm design results. At the same time, the designer’s subjective concept is preconceived, and the program algorithm design based on this construction also constitutes a digital design method in a broad sense.

4.2. Digital Design Procedures

4.2.1. Digital Design Method and Selection of Simulation Platform. After the design concept is determined, an overall analysis of the project is required to determine the digital design approach. There are two types of digital design methods: one is to start from the design concept and use traditional landscape design methods and procedures to divide the landscape system into traffic system, functional system, landscape node system, and plant system, and perform parametric simulation, respectively. The prototype of the design scheme is obtained, combined with the simulation analysis of the sunlight and wind environment, and the basic shape of the design is obtained; the other is to start from the design concept, determine the relationship between the various influencing factors in the system, convert them into parameters, input them into the simulation model in the environment, and then simulate to get the prototype of the design. According to the basic design conditions of the project, the digital design method must be reasonably chosen, specifically as shown in Figure 3. This study prefers the latter.

In the selection of simulation platform, the development of computer-aided design platform has become more and more mature, but the industries targeted by each software platform are different, and the computer software platform for landscape professional has not yet been determined. Therefore, for the landscape major, the most direct solution strategy is to comprehensively use the currently developed computer software platform to assist the landscape design and achieve the design purpose. According to the basic situation of the project, the main digital simulation platform selected in this article is Rhinoceros + Grasshopper.

4.2.2. Subsystem Simulation Analysis. With the help of the site prototype theory, according to the composition characteristics of the landscape system itself and the traditional landscape design method and process, this study divides the landscape design process into four steps: traffic system design, functional system design, landscape node system design, and plant system design. The key point is to determine the corresponding digital simulation method for the system corresponding to each step after determining the design concept of the project and the digital diagram method, extract the influencing factors in each system, conduct a separate parametric simulation analysis, and then, fit the simulation analysis results of each subsystem to get the basic prototype of the design. It is a landscape design logic

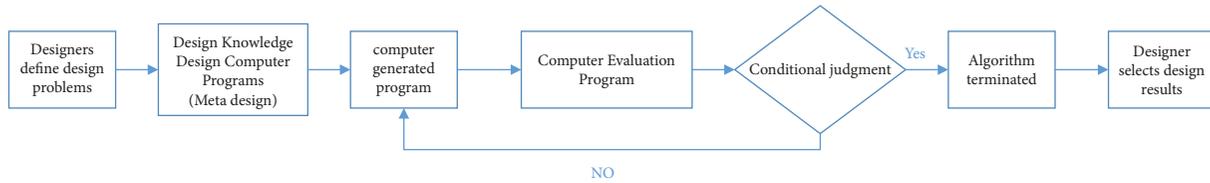

FIGURE 1: Meta-design—basic design chain.

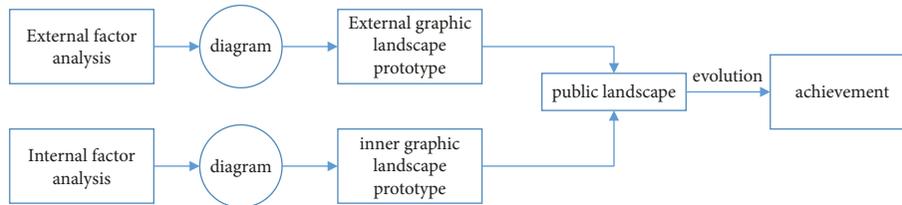

FIGURE 2: Hierarchical decomposition of landscape system.

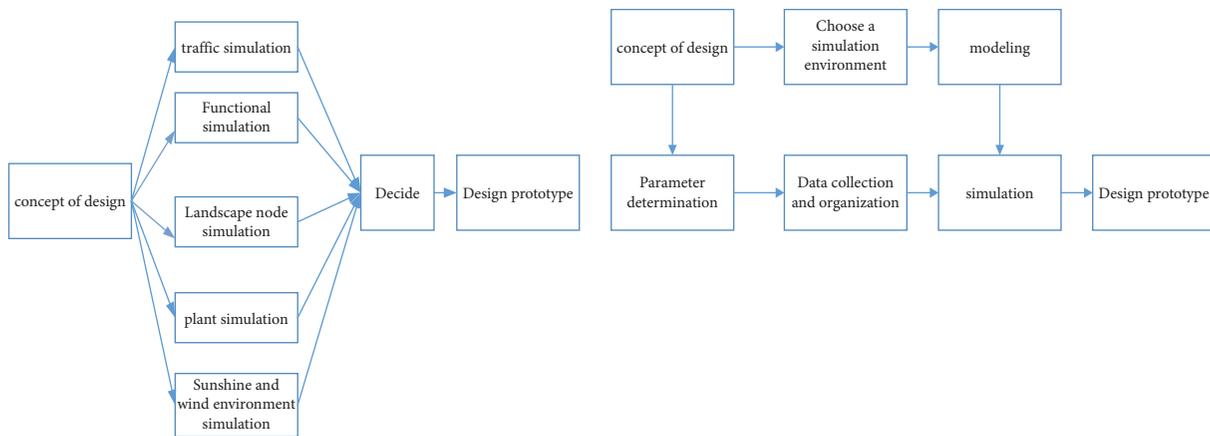

FIGURE 3: Two ways of digital design.

system based on morphogenesis as the basic theory and digital graphic design method, as shown in Figure 4.

4.2.3. Sunshine and Wind Environment Simulation Optimization Design. The sunshine environment of the site affects the layout of the internal functional system, landscape node system, and plant system to a certain extent, while the wind environment of the site determines the layout of the interior landscape space to a certain extent. By simulating and analyzing the sunlight and wind environment of the original site, it can play a guiding role in the formation of the prototype of the landscape design scheme. After the preliminary plan of landscape design is generated, the sunshine and wind environment should be simulated and analyzed again to check the rationality of the design plan, and the design plan should be optimized and adjusted according to the analysis results to obtain the prototype of the final design plan, as shown in Figure 5.

4.2.4. Generation of Landscape Morphology. After the simulation analysis of the subsystem and the simulation analysis of the sunlight and wind environment, the

corresponding design prototype is obtained. Combined with the designer’s subjective experience and esthetic concept, the design scheme is subjectively adjusted and optimized to obtain the final design scheme shape, as shown in Figure 6.

5. Landscape Digital Design Practice Based on Morphogenesis

In the digital graphic design logic system, it is suitable to use the graphic concept as the starting point of the design, combine the program algorithm to design the subsystems, and finally find the optimal design scheme through the fitting between the various systems.

5.1. Digital Design Logic Mining

5.1.1. Analysis of Influence Factors of Landscape System. During the whole project development process, there are many factors outside the site that affect the landscape design: local cultural environment, geographical environment, surrounding environment, business distribution, traffic relationship outside the site, sunlight, wind direction, and the owner’s functional requirements for the entire park. Among

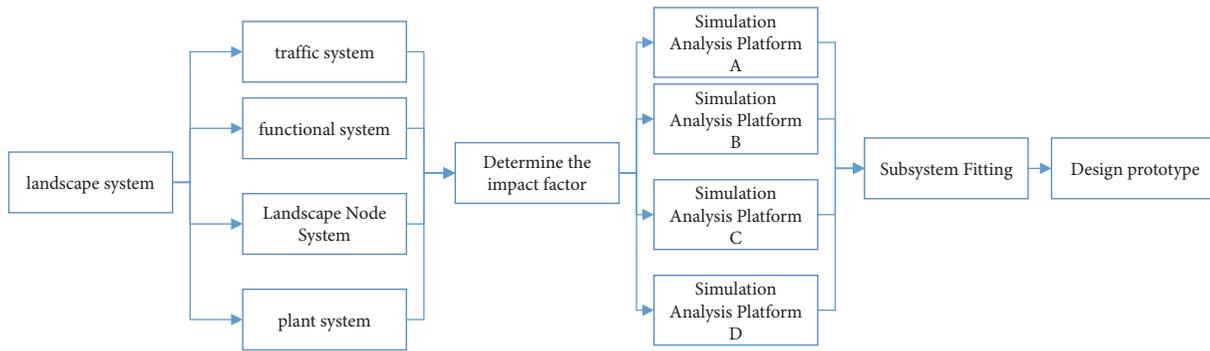

FIGURE 4: Flowchart of subsystem simulation analysis.

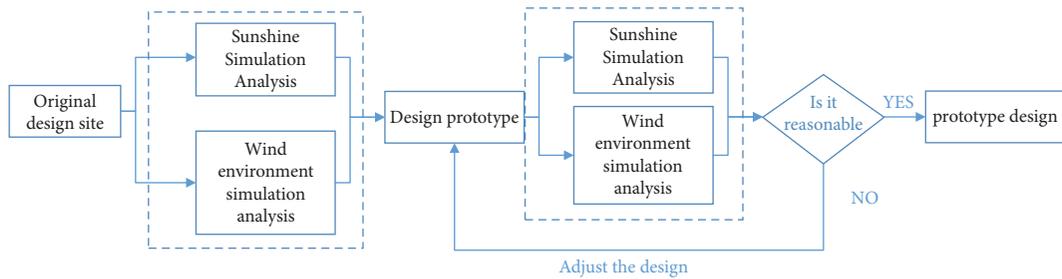

FIGURE 5: Flowchart of optimal design of sunshine and wind environment simulation.

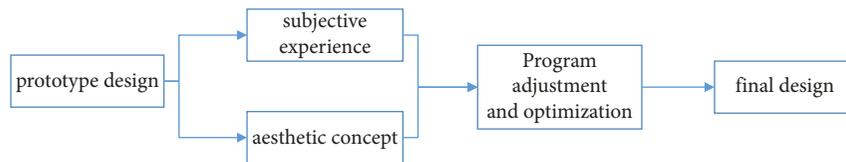

FIGURE 6: Landscape morphology optimization process.

them, the context and geographical environment will directly affect the extraction of design elements and the formation of spatial texture; the surrounding environment, business distribution, and external traffic on the site will affect the direction of the flow of people and have a direct connection with the internal traffic on the site; the owner’s function of the project demand determines the prototype of the functional partition; and the sunlight and wind direction will affect the layout of the interior space of the site and the design of landscape sketches, which will guide the entire design, as shown in Figure 7.

5.1.2. Influence Factor Analysis of Landscape Internal System. During the whole project development process, there are many factors that affect the landscape design inside the site: functional system, traffic system, landscape node system, and plant system. Among them, the functional system inside the site determines the relationship between the functional space and users; the traffic system inside the site determines the flow of people in the park, which directly affects the user’s experience in the park; and the landscape node system is affected by the user’s viewing experience. The influence of sight line needs to be combined with ergonomics to carry out a reasonable line of sight section design,

while the plant system has an inseparable relationship with the landscape effect of the entire park, and the use of plant landscaping has a direct impact on the park landscape, as shown in Figure 8.

5.2. Design Process and Design Results of Digital Design. The diagram of the traffic system diagram process is shown in Table 1. A global coupling path across the site is established as shown in Table 1, representing all possible paths of the site. The east-west direction is the image surface of the site, with fewer openings, retaining the integrity of the interface, and more openings in the north-south direction. According to the opening spacing greater than or equal to 150 meters, too many unnecessary paths should be avoided. As shown in *b* in Table 1, the screening rules are as follows: the connection between the site and the original urban road is too small ($<20^\circ$) as a redundant road; the connection with the corresponding point on the opposite side is too large ($>60^\circ$). A plausible semicoupled traversal path is thus generated. As shown in *c* in Table 1, random points are generated in the field to represent the possibility of any position in the field. After testing, the random point is at a certain threshold, which does not affect the final result, but the distribution state of

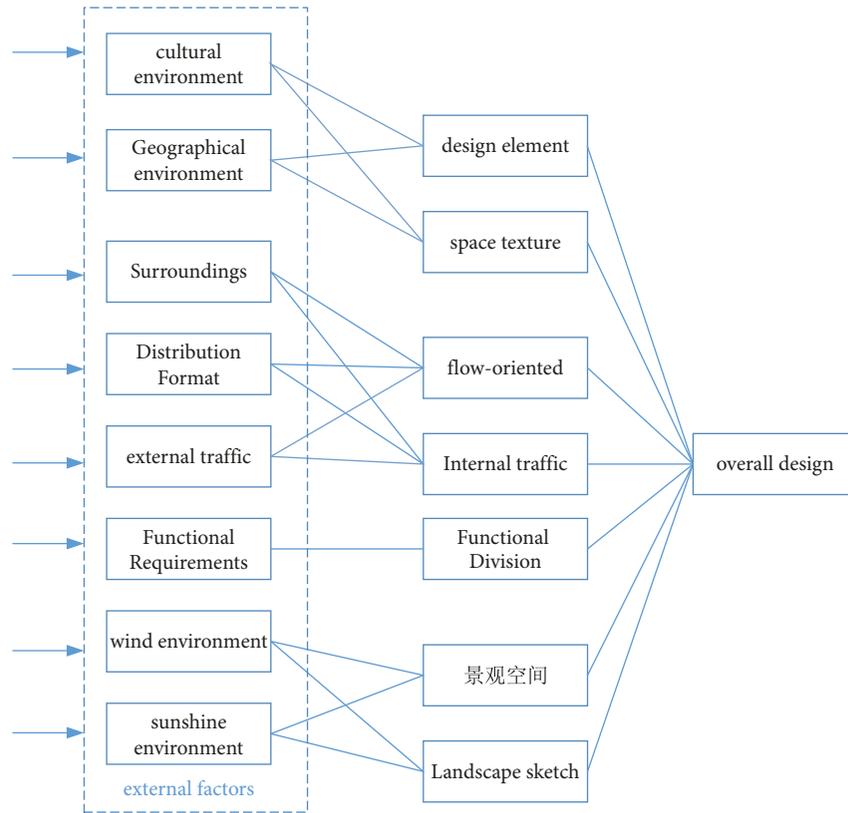

FIGURE 7: Analysis of external influence factors.

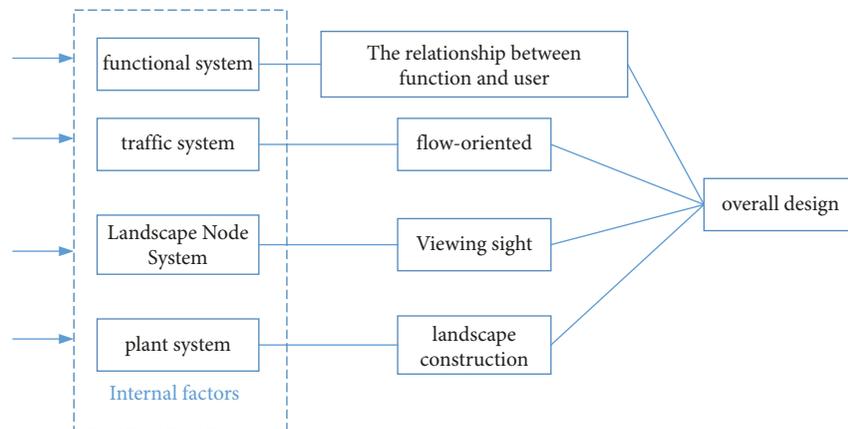

FIGURE 8: Analysis of internal impact factors.

the random point affects the result. As shown in *d* in Table 1, the filtered semicoupling path is divided into equal parts, and the divided points in turn constitute the path of the path, control point. After testing, the bisection point does not affect the final result within a certain threshold. As shown in *e* in Table 1, the optimal road network is fitted. The path bisection point moves to the nearest random point, and the new bisection point becomes the control point of the path, which generates a new path.

For a comprehensive comparison, result 4 in Table 2 is selected as the path network of the site, the path is taken as the basic structure, it is optimized as the road according to the subjective esthetic feeling, and then, the function and density of each block are judged according to the subjective analysis to generate the road network structure of the entire site. Among them, the center of the structure becomes the central landscape of the site, and the path from south to north through the core landscape is selected as the landscape avenue and the pedestrian entrance.

TABLE 2: Comparative analysis of design results.

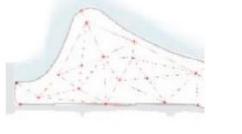

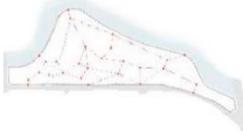

Serial number	Result 1	Result 2	Result 3	Result 4
Result				
Advantage	The plot division is relatively compact, which is convenient for spatial organization.	The site structure is reasonable, with obvious primary and secondary traffic	There is obvious primary and secondary traffic, and the structure is reasonable.	The central area is obvious. The road runs through most of the site and is closely related to the main road. The site is reasonably divided, so as to generate the optimal path of the plot.
Shortcoming	The road network and plots are too complex, which are not conducive to traffic.	North-south openings are dense and do not meet relevant regulations.	South-facing openings are dense with no apparent center.	—

TABLE 3: Functional simulation graphical process.

Serial number	A	B	C	D

Illustrate	Initial placement of each functional space	Each function restricts and combines with each other	Primary and secondary functional space fitting	Final fitting result

The diagram of the functional system diagram process is shown in Table 3:

- (1) Before selecting a parametric model, the utility of each function point should be individually evaluated, and then each function point should be fit.
- (2) When choosing a parameter model, the utility evaluation function of a function point is as follows:

$$F = \alpha * A + \beta * B + \gamma * C + \delta * D + \theta * E * \dots * \xi$$
Among them, A represents the importance of a function to the crowd, B represents the attractiveness of the function points near the function corresponding to the A parameter, C represents the lighting conditions of the function point in the lot, D represents the accessibility of the function within the site range. E represents the accessibility degree of the function point within the lot range, and F represents the visibility of the function point and the visibility of the surrounding structures.
- (3) As shown in a in Table 3, by establishing a parametric model, different functional spheres represent different functional spaces, and each functional space is initially placed according to its own attributes.
- (4) As shown in b in Table 3, according to the connection between functional spaces, different functional spheres are restricted and combined with each other.
- (5) As shown in c in Table 3, according to the relationship between the primary and secondary functional spaces, the functional space is fitted by setting different parameters.
- (6) As shown in d in Table 3, each functional space is fitted to form the final design result.

The simulation of the functional space is carried out through the computer, combined with the adjustment of the subjective intention, and finally, a reasonable design of the functional space is obtained, as shown in Figure 9. Among them, the corresponding open space is arranged along the north side of the waterfront; the south side is arranged with a small outdoor sports space to meet the needs of users; and the middle of the site is arranged with a point-like activity space. Through different point-shaped activity spaces, each space is reasonably connected in series.

The schematic diagram of the landscape node system is shown in the table as follows:

- (1) As shown in a in Table 4, in the semiopen space, the corresponding landscape nodes should be placed. Considering that the best viewing angle is 30° for

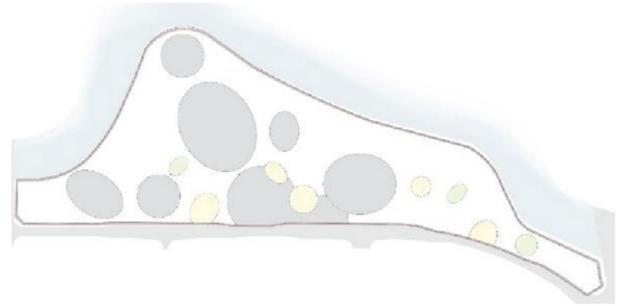

FIGURE 9: Final functional bubble diagram.

elevation and 30° for looking down when the human body is lying down, the best view should be arranged within this line of sight.

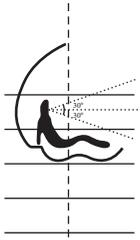

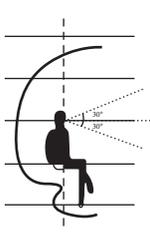

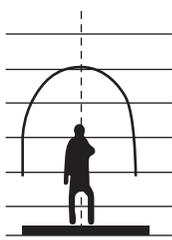

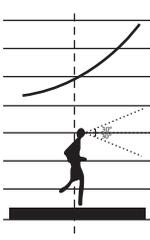

- (2) As shown in b in Table 4, when the user is walking, the best line of sight is straight ahead, and at this time, it is best to use the garden route as the layout route of the landscape nodes.
- (3) As shown in c in Table 4, at the resting place of the landscape node, the landscape should be arranged for the shade on the back, and the viewing line should be opened from the front to enrich the viewing experience of users.
- (4) As shown in d in Table 4, in an open space, the best viewing line of sight for the user is straight ahead, that is, effect landscape.
- (5) As shown in e in Table 4, when the user is exercising, the range of sight is 30° in elevation and 30° in top view. The layout of landscape nodes should be dominated by trees with upper contour lines.

According to the structure of the optimal path in the site and the rational arrangement of the functional space, each landscape node can be preliminarily arranged. After the preliminary arrangement, through the establishment of the corresponding parametric model, the landscape line of sight is reasonably designed. Using the principle of ergonomics, the landscape section design is carried out, and finally, it is fitted with the traffic system to generate the prototype of the shape. The design result of landscape node distribution is shown in Figure 10.

Diagram of the process of a plant system diagram, as shown in Table 5:

- (1) As shown in a and b in Table 5, since the road network structure and functional space will directly affect the formation of plant space, the site road

network structure and functional space are implanted in the site as key influencing factors

- (2) As shown in *c* in Table 5, the site is divided into grid units of $10\text{ m} \times 10\text{ m}$, the site is divided into grids, and the plant space of the site is divided according to the two key factors of road network structure and functional space

According to the road network structure and the site space model, the corresponding parametric model is established. Combined with the program algorithm, the parameters of the influencing factors are adjusted, and the preliminary arrangement of the site plant system is carried out. Then, through subjective adjustment and optimization, the prototype of the plant system space is generated, as shown in Table 6.

The graphic process of the site sunshine analysis is shown in the table: the light environment of the site affects the layout of the site's internal functional system, landscape node system, and plant system to a certain extent. Through the analysis of the light environment of the site, it can play a

guiding role in the overall design of the site. Through parametric technical means, the simulation analysis is carried out on the sunlight environment inside the original site and the site sunlight environment after preliminary design, and the layout of each system is further adjusted. The analysis and simulation process are as follows:

- (1) As shown in *a* in Table 7, the original design site is divided into grids with a unit of $10\text{ m} \times 10\text{ m}$, the analysis precision is set to 0.01, and the simulation analysis of the sunshine hours on the summer solstice of the original site is carried out.
- (2) As shown in *b* in Table 7, the original design site is divided into grids with a unit of $10\text{ m} \times 10\text{ m}$, the analysis precision is set to 0.01, and the simulation analysis of the winter solstice sunshine hours of the original site is carried out.
- (3) As shown in *c* in Table 7, the original design site is divided into grids with a unit of $10\text{ m} \times 10\text{ m}$, the analysis precision is set to 0.01, and the simulation

analysis of the annual sunshine hours of the original site is carried out.

- (4) As shown in *d* in Table 7, the preliminary design site is divided into grids in units of $10\text{ m} \times 10\text{ m}$, the analysis accuracy is set to 0.01, the structures and buildings are modularized, and the summer solstice sunshine of the preliminary design site is determined, that is, time for simulation analysis.
- (5) As shown in *e* in Table 7, with a unit of $10\text{ m} \times 10\text{ m}$, the preliminary design site is divided into grids, the analysis precision is set to 0.01, the structures and buildings are modularized, and the winter solstice sunshine of the preliminary design site time for simulation analysis is determined.
- (6) As shown in *f* in Table 7, with $10\text{ m} \times 10\text{ m}$ as the unit, the preliminary design site is divided into grids, the analysis precision is set to 0.01, the structures and buildings are modularized, and the annual sunshine

FIGURE 13: Overall effect diagram.

of the preliminary design site is checked, that is, time for simulation analysis.

According to the above simulation design results, with the central landscape as the core, the field of the space unit is constructed, as shown in Figure 11.

The design plane is optimized, combined with subjective adjustment, the overall design plane is fine-tuned, and the design result is shown in Figure 12:

The entire park is a sports park, and combined with the needs of the use of the site, a landmark landscape gallery is designed that integrates sports function and viewing. The final design result is shown in Figure 13.

6. Conclusions

By summarizing the development of digital design, combined with most of the design processes and methods at this stage, this basic design chain of meta-design is summarized. On the basis of meta-design, through subsystem design, the traffic system, functional system, landscape node system, and plant system are designed and optimized, and then, the fitting between each system is carried out. Finally, according to the value judgment and general plane control, the indicators of each space are configured, the basic park design is completed, and it is supplemented and summarized into a feasible digital graphic design system that takes into account both objective factors and subjective experience. At the same time, through the preliminary use of digital design and design in the Xiangyang Dongjin Sports Park project, it guides the design generation process of the park. Compared with the traditional design process, the digital design and design logic system can quickly generate a variety of comparison schemes based on the same logic. Or based on a certain quantitative index to form an optimal solution, the process of continuous trial and error and correction in traditional design is completed in an instant on the digital platform. This dynamic and efficient design system that generates multiple solutions in a short period of time has become a realistic and feasible design framework. In this study, the author has completed the generation process of the park from the design concept to the space formation by using four kinds of meta-designs: subsystem design, wool thread path network simulation, "cellular flow" graphic concept park texture generation, and cellular automata. This design logic system is feasible to a certain extent and has obvious advantages. For the construction of the digital graphic design system of the project and the base itself, the plot design is completed in a complete and reasonable manner, forming a unified park form, and the whole and parts are harmonious and unified.

In recent years, wireless sensor networks have developed rapidly, and at the same time, they are also an important support for the Internet of Things and have attracted worldwide attention. A wireless sensor network is composed of many self-organized sensor nodes, which provide a good foundation for it. As a wireless communication technology, ZigBee technology can realize energy-saving and high-efficiency wireless communication. Its sensor nodes are usually small computing devices with radio antennas. They are usually equipped with sensors that can detect one or more environmental parameters. The energy is limited. The function is simple. With the development of the Internet of Things and 5G technology, the scope of wireless sensor networks is becoming wider and wider. This article will apply it to vehicle driving. In today's society, more and more people use cars as a means of transportation, resulting in a large number of road traffic every year. The accident caused a large number of casualties and material losses. For traffic accidents caused by these factors, the collision between a car hitting a person and a car is the most common, so the research on how to avoid a car collision is urgent. Among the many factors that cause road traffic accidents, the driver is the main reason. Therefore, the combination of the driver's abnormal driving behavior and the implementation of the vehicle approaching reminder can effectively reduce traffic accidents. At the same time, the vehicle's collision avoidance warning system is also a vehicle. One of the most important content in driving, we also made research. Through the research of wireless sensor network, this paper applies its relatively mature zigBee technology to the devices and systems of vehicle driving, so that the vehicle approach reminder device and anticollision warning system are developed vigorously.

1. Introduction

The wireless sensor network appeared in the 1970s. It was gradually formed with the continuous development of semiconductor technology, information technology, and network technology. In recent years, with the development of the Internet of Things, wireless sensor networks have attracted worldwide attention, and countries have increased their investment in related research [1]. Among them, ZigBee technology is a new wireless communication technology and also an advanced product [2].

The wireless sensor network is composed of sensor technology, microelectromechanical technology, advanced network, and wireless communication end-to-end intelligent computing platform. It has broad prospects. It is one of

the most popular researches in the computer field, and it is also a major technology that will change future life. This article will apply it to the research of vehicle collision avoidance warning system [3]. The system can be divided into three modules, namely, signal acquisition module, signal processing module, and execution module. The signal acquisition module includes obstacle detection, distance measurement, and road condition selection [4]. Regarding obstacle detection, this research mainly uses millimeter wave radar and CMOS camera to confirm the existence of obstacles and then uses millimeter wave radar to confirm the location of obstacles and to see obstacles [5]. Whether the object is within the collision range of the vehicle, the millimeter wave radar is used to measure the relative distance between the obstacle and the vehicle. Early warning

technology to prevent vehicle collisions is an important part of vehicle active safety. In practical applications, it mainly analyzes the driving conditions of the vehicle and the traffic environment around the vehicle and provides early warning to the driver of possible road accidents [6]. Then, in order to reduce road traffic accidents, this article has also done a lot of research on vehicle collision avoidance, which is broken down by data collection methods, including machine-based vehicle collision warning, distance measurement-based reminder vehicle approaching device and communication-based vehicle collision avoidance warning; among them, vehicle approaching reminder devices include infrared, ultrasonic, millimeter wave, and laser methods; communication-based vehicle collision avoidance early warning includes DSRC, LTE-V, Zigbee, cellular networks, and other methods [7]. The research on collision avoidance systems is a hot topic today, and will continue to pave the way for future driverless driving [8]. At present, the research of anticollision warning system mainly uses one of the vehicle sensors (ultrasonic, laser, radar, infrared, machine vision, etc.) to detect and identify objects outside the vehicle [9]. Wireless sensor network is a key tool to realize the intelligent perception and interconnection of heterogeneous elements in the physical world. The digital twin system realizes the dynamic real-time interaction between the physical world and the digital world [10–12]. The vehicle approval reminder device based on ZigBee wireless sensor network studied in this paper also provides a certain degree of support for the realization of the digital twin system in the vehicle field.

The focus of the entire research is on the accuracy of signal acquisition, real-time signal processing, accurate obstacle detection, real-time distance tracking, correct road pattern recognition, and organic fusion of received data and finally making the correct decision quickly, so as to avoid collisions and reduce traffic accident [13].

The remainder of this paper is organized as follows. Section 2 presents the methods used in the designed vehicle approaching reminder device based on Zigbee wireless sensor network, which contains theoretical basis, algorithm principle, and the detailed methods. Section 3 is the main research content, which contains vehicle driving road mode selection, model of vehicle approaching reminder device, communication and braking influence factors and algorithm simulation, and evaluation. Section 4 discusses the research results and designs the device software and hardware and data processing module, which is followed by concluding remarks in Section 5.

2. Methods

2.1. Theoretical Basis. Wireless sensor networks are currently an interdisciplinary and highly integrated hot research direction, and they have received considerable attention all over the world. The development of sensor technology, microelectromechanical systems, modern networks, and wireless communication has contributed to the emergence and development of modern wireless sensor networks [14]. The wireless sensor network expands people's ability to collect data, connects the physical data of the objective world

to the transmission network, and provides humans with the most direct, efficient and reliable data on the next-generation network. This section is mainly a basic introduction to wireless sensor networks, mainly introducing the architecture, key features, design, and applications of wireless sensor networks [15]. The sensor node is usually an embedded system. Owing to the limitation of size, price, and power, its processing power and storage capacity are relatively small, and the data transmission distance is also very limited [16]. In terms of network functions, each sensor node has the dual functions of collecting and routing data. In addition to collecting and exporting data locally, it must also store, manage, and integrate data sent from other sites and perform certain tasks in collaboration with other sites [17, 18]. The receiver node usually has powerful processing, storage, and communication skills.

2.2. Algorithm Principle. The weighted average method can divide the three components of R , G , and B more reasonably, so as to obtain a more reasonable gray image. In the MATLAB simulation software, the weighted average of the three components of the system function R , G , and B is as follows:

$$f(i, j) = 0.30R(i, j) + 0.59G(i, j) + 0.11B(i, j). \quad (1)$$

The formula expression is as follows:

$$R = \text{mid}\{z_k | k = 1, 2, 3, \dots, 9\}. \quad (2)$$

The gray value of the gray image is between 0 and 255. In order to better identify the target image and extract the edge, the gray value must be redesigned and set. This is a binarization process. Image binarization is a basic image processing technology. Binarization technology plays a very important role, whether it is compressing image data, extracting edges, or analyzing shapes.

$$g(x, y) = \begin{cases} 255, & f(x, y) \geq T, \\ 0, & f(x, y) < T. \end{cases} \quad (3)$$

2.3. Research Methods. The transmitted signal of millimeter wave radar is as follows:

$$x(t) = \cos(2\pi f_0 t + \phi_0). \quad (4)$$

The received signal of the millimeter wave radar is as follows:

$$x_R(t) = \cos[(2\pi f_0(t - t_x) + \phi_0)], \quad (5)$$

where: t_x —delay time.

$$t_x = \frac{2}{c - v_x} (R_0 - v_x t). \quad (6)$$

The distance between the car and the stationary obstacle is as follows:

$$R_t = R_0 - v_x t. \quad (7)$$

It can be seen from earlier that the relationship between vehicle distance and delay time is as follows:

$$R_t = \frac{ct_x}{2}. \quad (8)$$

When the millimeter wave radar is working, the continuous waveform emitted by the transmitter will be decomposed into signals when it hits an obstacle in front of it. When the front barrier is a fixed object, the echo frequency received by the receiving end is the same as the frequency of the transmitted signal, as shown in Figure 1.

3. Results

3.1. Vehicle Driving Road Mode Selection. Nowadays, the four driving modes of the car are quiet and stable pure electric mode (EV), efficient and energy-saving economic mode (ECO), stable normal mode (NORMAL), and surging sport mode (SPORT). When the EV pure electric mode runs at low speed and short distance, the vehicle only works on the power provided by the battery. At this time, the engine does not intervene, the noise of the vehicle is almost equal to zero, and zero emission is realized at the same time. When switching to sport mode, the energy output of the battery will increase instantaneously, the power response will be rapid, and the steering operation will be obvious. At the same time, traction control system and vehicle stability control system will reduce the intervention in driving.

A moving car uses an emergency braking system in an emergency. The car has a certain distance when braking. This distance is called the braking distance. Different cars have different braking distances on different roads. When designing a collision warning, the determination of the safety distance of the vehicle in the execution phase is mainly based on the braking distance of the vehicle. In addition, the braking distance is mainly determined by these road conditions. Therefore, before investigating the braking distance, first determine the road on which the car is traveling. The current investigations of roads at home and abroad are mainly based on the relationship between sliding speed s and adhesion coefficient μ . The maximum μ value is determined using the μ - s ratio graph and the slope of the small slider in the speed range. When installing the sensor, tilt the position of the sensor to the front of the vehicle so that the sensor can detect the road conditions in front of the vehicle during operation, thereby predicting the road conditions ahead and keeping the vehicle in the best position safely. The sensor used to detect road traffic in this article is an ultrasonic sensor. As the waveform attenuates during transmission and along the same path, the attenuation of the waveform is different under dry and wet conditions, resulting in different received waveforms. The waveform received in this way can be used for spectrum analysis of the spectrum difference to distinguish path types. Signal analysis and feature removal are mainly based on time domain, frequency domain, or time-frequency domain. When extracting attributes from the time domain, if the signal is uncertain or the weather changes, or an unknown interference signal appears during transmission, its robustness should be considered. When

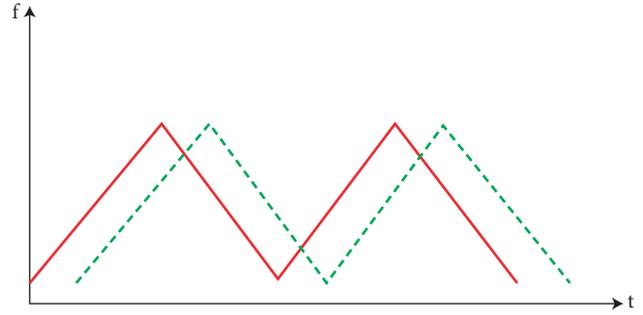

FIGURE 1: The millimeter-wave radar range finding diagram of stationary obstacles.

extracting attributes from a frequency range, it is only for a limited signal interval, so the signal time range must be cut off, which leads to information leakage, and the amplitude, frequency, and phase of the resulting individual spectrum can lead to further errors.

As shown in Table 1 for the impact data of the vehicle braking distance, it can be seen from the table that the driver's reaction and braking distance increase with the increase of speed.

Figure 2 shows the relationship between starting speed and stopping distance under various road conditions after simulation. It can be seen from the figure that the braking distance of a car is different on different roads, and the braking distance is the largest under icy roads.

3.2. Model of Vehicle Approaching Reminder Device. As shown in Figure 3, based on the automatic tracking theory, the Berkeley safety distance model and the hidden Markov model, a collision warning system that can objectively and accurately calculate and assess traffic hazards has been designed, including an improved safety distance model, through the analysis of vehicles. The characteristics of different stages of braking and the characteristics of car-following behavior of the vehicle optimize the safety distance model. The risk assessment process of the early warning model is introduced, the problem of low accuracy of risk assessment based on vehicle data is optimized, and the hidden Markov model is used to conduct risk assessment according to the observation sequence of the periodic process. At the same time, an improved safety distance model is used to mark the state of vehicle data, and the K-Average method is used to classify and discretize the observation data. The evaluation of the early warning situation is based on the statistics of the angle of the vehicles on the road section, and according to different direction values, the current scene is regarded as a circular arc, a straight road or an intersection.

According to the car-following theory, this provides a theoretical basis for analyzing vehicle braking and assessing the possibility of collision. As shown in Figure 4, assuming that the driver detects a dangerous situation ahead and the vehicle starts to brake, he should depress the brake pedal with his right foot while the vehicle is running until the vehicle maintains a minimum safe distance from the vehicle.

TABLE 1: Data comparison of different initial speeds and adhesion coefficients on braking distance.

Initial speed of vehicle (km/h)	Driver reaction distance (m)	Dry asphalt pavement Adhesion coefficient 0.7	Wet cement pavement Adhesion coefficient 0.6	Wet asphalt pavement Adhesion coefficient 0.5	Snow pavement Adhesion coefficient 0.2	Icy road Adhesion coefficient 0.1

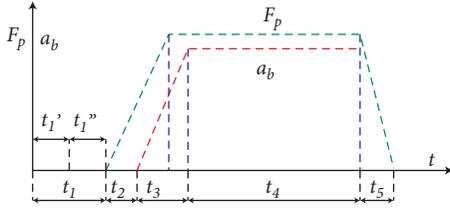

FIGURE 4: Automobile braking process.

The driver depresses the brake pedal to brake until the vehicle is out of danger and the entire braking process is completed.

3.3. Communication and Braking Influence Factors. V2X communication technology is an important research direction for vehicle intelligence and networking. Among them, the dedicated short range communication (DSRC) standard was mainly formulated in the United States, Europe, and Japan in the 1990s; and C-V2X (Cellular Vehicle to Everything) was developed by 3GPP (Cooperative Project No. 3) Development. Table 2 shows the main indicators of DSRC and C-V2X. The comparison shows that C-V2X has greater advantages over DSRC in terms of transmission distance, delay, and evolution.

The application scenarios of the future intelligent networked vehicles include traffic safety, traffic efficiency, and information services, of which 19 are safety, 12 efficiency categories, and 9 information service categories. Table 3 shows intersection collision warning, frontal collision warning, and a statistical table of 8 typical V2X safety applications such as side collision warning.

The C-V2X standard is composed of the LTE-V2X standard and the 5G V2X standard and can seamlessly develop from LTE-V2X to 5G V2X. The C-V2X standard includes two modes of operation: direct data transmission and mobile communication. The different operating modes correspond to the communication interface PC5 and the communication interface Uu. The PC5 communication interface can support vehicle-to-vehicle V2V communication, V2I vehicle-to-road communication, and V2P human-vehicle communication through the Uu communication interface. Figure 5 shows the network architecture of the DSRC system and the network architecture of the C-V2X system.

First, the braking process is analyzed for the reaction time. The factors related to the process performance can complement the driver's response time. It is often believed that a rear-end collision between two vehicles must be related to the following distance and the driver's reaction time. However, the following distance and reaction time need to be considered. Therefore, in this section, we will analyze the characteristics of the braking behavior process and find the relationship between each driving mode and reaction time. Factors related to response time include braking response time, initial monitoring distance (IHD), and distance (BHD). The statistical data of the relevant variables are shown in Table 4. Behavior 1, Behavior 2, Behavior 3,

TABLE 2: DSRC and C-V2X key index table.

Key indicators	DSRC	C-V2X
Transmission distance (m)	301~501	1001
Adapt to vehicle speed (km/h)	201	501
Transmission rate (Mbps)	28	501
Delay (ms)	51~101	51
Network deployment	Need to deploy RSU	Base station
Maturity	High	Middle
Evolutionary	Weak	Powerful
Business potential	Low	High

TABLE 3: Statistical table of typical security V2X applications.

Category	Serial number	Application name	Serial number	Application name
Safety	1	Intersection collision warning	5	Side collision warning
	2	Emergency brake warning	6	Rear collision warning
	3	Reverse overtaking collision warning	7	Early warning of abnormal vehicles
	4	Forward collision warning	8	Vehicle out of control warning

Behavior 4, Behavior 5, and Behavior 6, respectively, represent the normal driving state that occurs under normal driving conditions, and the emergency events that occur under the conditions of communication behavior, voice information behavior, chat and drinking, yawning, and so on, and give abnormal driving behavioral reaction time and following distance.

Table 5 shows the significant difference results of different driving behavior variables. The analysis of variance shows that different abnormal driving habits have a significant impact on the reaction time of the driver in the braking process ($F=8.971$, $P=0.003 \leq 0.05$), the initial following distance and braking following distance are related to the driver's braking response Time does not significantly affect the relationship.

The nonparametric K-M estimation method is used to estimate the survival probability of different driving behaviors according to the braking reaction time, as shown in Figure 6.

3.4. Algorithm Simulation and Evaluation. The simulation value of the vehicle position prediction result in Figure 7 basically fits the curve of the horizontal position and the longitudinal position. In this test case, the prediction error of the horizontal position is -0.015 ± 0.252 m, and the prediction error of the longitudinal position is 0.089 ± 0.207 m.

The prediction error of the vehicle speed is calculated based on the expected speed and the actual speed. The analysis of the results in Figure 8 shows that in this test case, the prediction error of the lateral speed is -0.028 ± 0.279 m/s, and

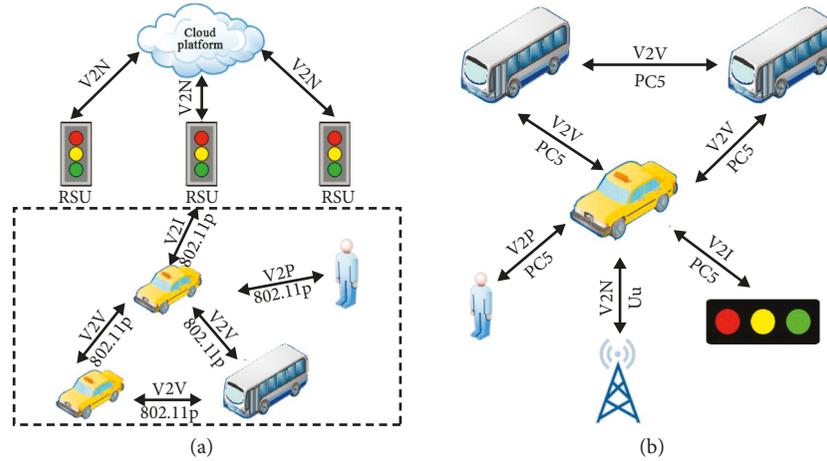

FIGURE 5: Network architecture diagram of the Internet of Vehicles system: (a) DSR Internet of Vehicles network architecture diagram and (b) C-V2X Internet of Vehicles network architecture diagram).

TABLE 4: Statistics of related factors under different driving behaviors.

Emergency braking event	Quantity	BRT (s)		IHD (m)		BHD (m)	
		Mean	SD	Mean	SD	Mean	SD
Behaviour 1	55	1.92	0.76	35.04	10.17	18.05	9.96
Behaviour 2	27	2.41	0.83	25.06	13.11	15.21	6.88
Behaviour 3	27	2.72	0.88	30.05	12.08	17.75	10.81
Behaviour 4	35	2.02	0.71	23.08	10.77	14.61	5.77
Behaviour 5	44	2.38	0.91	34.71	14.61	19.71	10.97
Behaviour 6	26	2.21	0.75	34.51	13.67	15.97	7.65

TABLE 5: Significant difference results under different driving behaviors.

Variable	F value	P value
BRT (s)	8.972	0.004
IHD (m)	3.005	0.068
BHD (m)	2.402	0.067

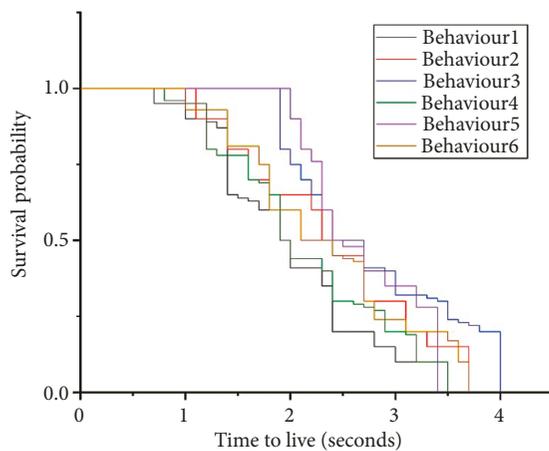

FIGURE 6: Survival probability curve diagram of different driving behaviors corresponding to braking reaction time.

the prediction error of the longitudinal speed is 0.064 ± 0.231 m/s. The simulation results show that the prediction data of the prediction algorithm has a small error with the actual data, and the prediction results can be used in the vehicle collision avoidance system.

4. Discussion and Design

4.1. Device Software and Hardware Design. According to demand analysis and hardware design block diagram (Figures 3 and 4), it can be concluded that the hardware platform of the whole system is mainly divided into main control module, DSRC wireless communication module, GPS module, CAN bus module and USB module, and power supply module. The main control module selects the i.MX6 DualLite processor produced by Freescale, and the core board integrates the CAN controller required by the procurement system. The communication module adopts the integrated module model THE0-P173 of Cohda Wireless, which combines a wireless radio frequency transceiver module and a protocol converter unit, and can use the 5.9 GHz frequency band to complete DSRC communication. The pins of the NEO-M8U chip are connected in series with the LED light, and the status of the LED light is used to indicate the working status of the GPS module. Steady ON indicates that the module is turned ON but not inserted; flashing indicates that the positioning is successful and GPS location information is sent. The CAN bus module

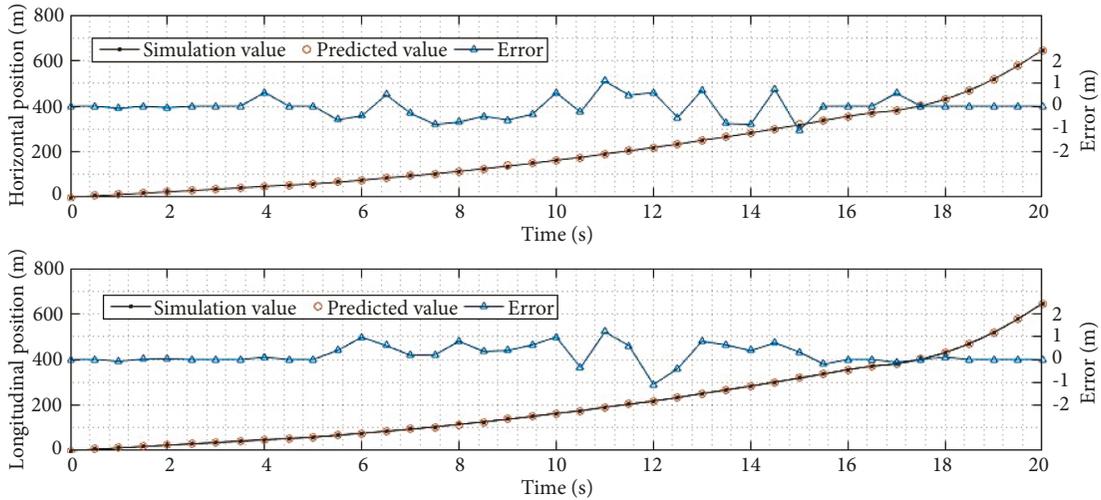

FIGURE 7: The result of vehicle position prediction: (a) horizontal position and (b) longitudinal position.

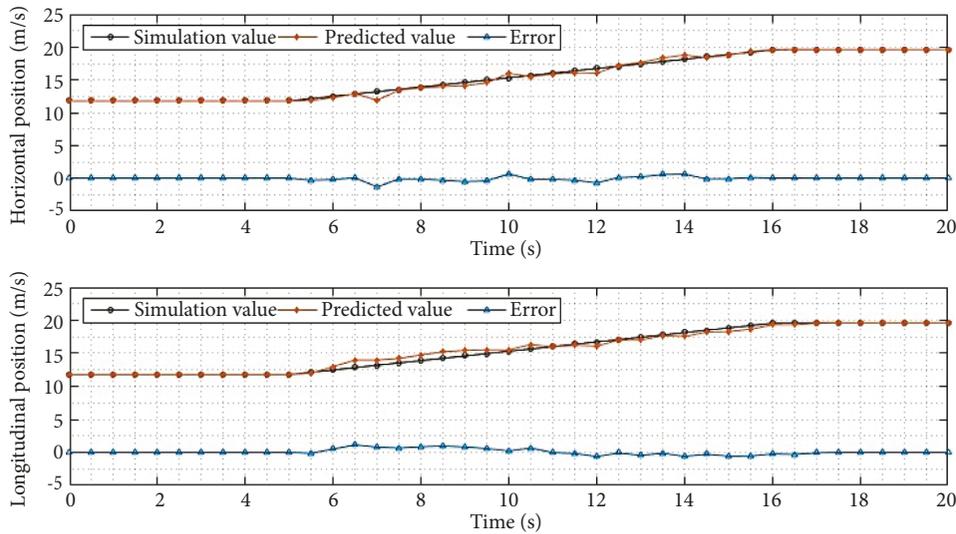

FIGURE 8: The result of vehicle speed prediction: (a) horizontal position and (b) longitudinal position.

uses the FlexC AN module integrated inside the I.MX6DL microprocessor.

The vehicle collision avoidance warning system software based on V2X communication consists of three parts: middleware program, terminal application program and socket communication. The middle layer application is developed on the basis of the Linux operating system. Its task is to collect vehicle data, convert it into BSM data, and send it within a certain period of time through the V2X communication module. At the same time, it receives BSM data sent by other vehicles. As a high-level application, the user terminal is developed using QT software, which mainly realizes socket communication with the middle layer, realizes data reception, data preprocessing, use of early warning algorithms, and early warning prompts. The program has multiple I/O functions. In order to avoid I/O deadlock, multiple I/O technologies are used, so that multiple I/O functions can be reused in the same query block, allowing the program to process multiple I/O's at the same

time. Each I/O request becomes single-threaded time. The query function independently creates a pollfd structure for each monitored file graph, which determines the appearance of the file graph. In the main function, first initialize each module of the system, including the initialization of the GPS module, CAN module, and communication module P1609 layer. The structured data are stored in the StateStore structure. The channel synchronization event triggers the BSM message every 50 ms. The data stored in the structure must be recorded before each transmission, as defined in the BSM message in the compiled message format and must be adapted to the structure of the data storage structure in the StateStore. After the P1609 layer encodes the BSM message, it encapsulates it as a WSM message and sends it to the receiving device. The transmitted data packet can be saved in a log file; the P1609 layer of the receiving device receives the data packet in accordance with the SAE J2735 standard. The BSM message is decrypted, and the received data packet can also be saved in the log file.

First set the serial port GPS parameters such as baud rate and stop bit, open the serial port, and start receiving the serial buffer data stream; after receiving the data, process the data frame starting from \$GPRMC, and extract the corresponding fields in the chassis value, such as current time. The vehicle position and angle convert the ASCII code into a real number and then into an unsigned integer to receive and store the vehicle data. When other threads need GPS data, they are read from the memory structure; when the GPS update time expires, they continue to read the next data stream to obtain the latest vehicle position information. After the data are updated, the top-level application initiates an event update every 50 ms, encapsulates the BSM message and sends the request to the WSMP protocol layer [16]. The request contains the required parameters. When the WSMP layer receives a request to send a WSM message, it first checks the validity of the length of the data packet sent by the request. If it meets the specified length requirement, it adds WAVE data element, version and other extended header information values to the WSM message. Encapsulated in the WSM message and sent its MAC layer and PHY layer, after LLC lower layer processing, the data packet is sent to the WSMP protocol layer. The WSMP layer determines whether the packet format is a standard WSM message [19,20]. If the PSID value matches, the hit is successful, and it is sent to the upper unit corresponding to the PSID value, otherwise it is discarded [21].

4.2. Device Signal and Display Processing. The collected signal is sent to the signal processing module for digital processing, which is called digital signal processing (DSP). Digital signal processing is a series of processes such as conversion, filtering, enhancement, and compression of the received signal in the form of a computer or special equipment to obtain necessary or useful information [22].

TMS320F28335 digital signal processor uses 176 pins, and its compression method is PGF/PTP thin four-channel flat package (LQFP). Its main features are as follows: (1) CMOS technology is a high-performance static technology with an instruction cycle of only 6.67 ns and a base frequency of up to 150 MHz; (2) the processor is a 32-bit high-performance processor, and the arithmetic unit is a single-precision floating-point number. (3) The 16-bit words of 256 KB of flash memory, 16-bit words of 34K SARAM memory that can be accessed in a single cycle, and 16-bit words of 1K OTPROM that can be programmed once are all password-protected; (4) With TMS320F281X series processors. In comparison, it contains eight external interrupts, but there is no special interrupt pin; (5) The processor contains two CAN modules (CANTXA, CANRXA and CANTXB, CANRXB), using standard IEEE1149.1 chip scan simulation interface (JTAG). This product uses 12864 liquid crystal displays for visual display. 12864 LCD is a graphic dot matrix liquid crystal display, which is composed of a row controller, a column controller and a 128 × 64 dot matrix liquid crystal display. It can not only display 8 × 4 16 × 16 dot matrix Chinese characters, but also display graphics, realize cursor display, screen movement, and custom icon and sleep mode [23].

4.3. Data Processing Module Design. Based on the analysis of the on-board terminal, the on-board terminal functions are mainly divided into on-board data collection and communication functions, which are mainly used to support data in collision avoidance warning applications [24]. In order to facilitate the retrieval and use of data at the application algorithm layer and weaken the connection between the application layer and the underlying functional modules, this paper designs a data acquisition module between the basic layer and the application layer as an intermediate layer, and the data cache module supplements the data management function [25]. The anticollision software structure is divided into three layers according to the hierarchical structure. The lower layer is a data acquisition module and a communication module, which provides initial data support for the middle layer; the middle layer is a data cache module, which is used to manage the data structure for ease of use and application layer efficient retrieval of data saves program use time; the application layer includes a module that evaluates the driver's reaction time and an adaptive collision avoidance warning module, which uses the collected data to determine the data of the vehicle's early warning situation [26].

The data acquisition module can also be called the data acquisition module, which mainly uses equipment to measure and collect physical data during the driving process of the vehicle. It is the basis for the accurate operation of the collision warning system. The data collection module mainly includes the collection of vehicle position data, vehicle attitude data or CarMaker simulation data.

The main purpose of collecting vehicle position data is to read the NMEA0183 command information provided by the GPS/BDS positioning module through the UART serial port of the processor, and then use the following commands to analyze: \$GPRMC, \$GPGGA, \$GPGSA, \$GPGSV, and \$GPRGA. GPS-pa required by GPVTG is mainly information such as latitude and longitude, angle, time, date, and altitude. The terminal installed in the car first initializes the accelerometer and gyroscope module; initializes the registers, and then can periodically read the three-dimensional acceleration and three-dimensional angle data of the vehicle. Since the GPS/BDS positioning module updates data slowly, and the data update cycle of the accelerometer and gyroscope modules is short, the data collected by the IMU module can be used to supplement the calculation of the vehicle position data, thereby shortening the update cycle of the vehicle position data. As there are many external factors that affect the accuracy of the test during the actual vehicle test during the test phase. Therefore, it is necessary to carry out the simulation test of the algorithm in real time before the actual vehicle test and improve the error correction of the algorithm.

The communication module also represents a component of the underlying module. The communication module enables the communication between vehicles, the communication between vehicles and roads, and the communication between the terminals installed in the vehicles and the mobile terminals to be carried out stably. Through the network communication module, the vehicle-mounted terminal can

send anticollision warning information to the mobile terminal to realize the sound and light warning for the driver; the vehicle-mounted terminal device can use the Bluetooth communication module and the vehicle-mounted OBE device to receive vehicle body usage data; the vehicle can send the vehicle to the mobile terminal through the V2X communication module. The surrounding vehicles send their own vehicle information, and at the same time receive the vehicle motion data sent by the surrounding vehicles, so as to realize the communication between the vehicles. Owing to the rapid development of the mobile Internet, mobile devices are ubiquitous. Mobile devices can warn drivers not only through visual animation, but also through audio transmission without affecting the driver's visual awareness. The terminal installed in the vehicle calculates the vehicle collision avoidance warning and then sends the warning result to the mobile terminal, and the mobile terminal reminds the driver based on the calculation result of the collision avoidance warning algorithm. If the vehicle-mounted terminal is connected to the Internet through a 3G/4G mobile communication device or WiFi communication device, it can interact with the mobile terminal through the network communication module, send an anticollision warning algorithm, and determine the warning situation from the vehicle to the mobile terminal to the mobile device. At the same time, the vehicle-mounted terminal can also send the traffic data and road information received by the roadside device to the mobile terminal through the network communication module, thereby displaying information out of sight to the driver in advance, improving the driver's field of vision and driving experience.

5. Conclusion

Aiming at the problem of node power constraints in wireless sensor networks, this paper uses the general characteristics of wireless transmission and the temporal and spatial correlation of data collected in the network, and uses energy-saving routing protocols and data compression and aggregation technologies, such as compressed sensing, network coding, and predictive models. Reduce the amount of data collected and transmitted in the wireless sensor network, reduce the energy consumption of the nodes in the network, and alleviate the problem of node energy limitation, and then apply it to the current research status of vehicle collision warning technology. For traditional collision warning algorithms without considering the impact of abnormal driving behavior on the collision warning algorithm, which leads to problems such as incompatibility of collision warning applications, a vehicle-vehicle cooperative collision avoidance warning method based on driving behavior is proposed. In this paper, combined with the emergency braking process of the vehicle, the influence of abnormal driving behavior on the driver's braking reaction time is studied, and the driver's braking response time is simulated according to the driving behavior. According to the software function requirements, this paper designs a collision avoidance early warning software architecture based on layered thinking. The software architecture is divided into three layers, namely the bottom layer, the middle

layer, and the application layer. The bottom layer includes a data acquisition module and a communication module, the middle layer is a data cache module and application programs, and the application layer is an anticollision warning module.

With the increase of car ownership year by year, the contradiction between people and vehicles in China's transportation system is becoming more and more serious. As the core technology of developing intelligent transportation system, vehicle road cooperation technology can not only improve the traffic efficiency in the transportation system but also play a key role in improving the safety of people and vehicles in the transportation system. This research plays an important role in promoting the information interaction of vehicle road collaborative system.

With the continuous progress of the times, the reform of physical education teaching in colleges and universities has to be promoted day by day. The most important task in the process of reform is how to improve the quality of physical education teaching. Only by reforming colleges and universities can we transport outstanding talents into the society. It is very important to improve the teaching quality by improving the physical education quality evaluation system. As artificial intelligence technology has been more and more widely used in different fields, various educational administration systems based on information management have been established in various colleges and universities. On the one hand, it has brought great convenience to the management of physical education in colleges and universities and improvement of the efficiency of sports education management, but on the other hand, there are many shortcomings in the process of practical application. For example, the application of the database does not fully reflect its function and convenience, and it is only used at the level of query and statistics. Therefore, a better evaluation system of physical education teaching quality has become the common expectation of all colleges and universities. This paper makes a powerful analysis of the current quality evaluation of physical education in colleges and universities and proposes a method of establishing a basic framework through expert systems, filling in details with the idea of knowledge base and fuzzy sets, and further using a three-layer B/S framework model to design universal teaching quality assessment system. When discussing the requirements, functional framework, and actual development of the teaching evaluation system, the characteristics of the traditional physical education evaluation model are deeply analyzed, and the system's interactivity, flexibility, accuracy, and fairness are emphasized in the implementation process. Object-oriented design and analysis are carried out on the requirements of the system, and finally, black-box testing is carried out to ensure the reliability and correctness of the system logic.

1. Introduction

With the promotion of artificial intelligence to the national strategy, it will have a profound impact on various industries. Colleges and universities should keep up with the trend of the times, seize the pace of the “artificial intelligence” era, and apply “artificial intelligence” to the education of college sports students. The reform is in progress, but how should the “artificial intelligence +” road go? This article will discuss the application of artificial intelligence to physical education teaching reform in colleges and universities and build a

teaching reform quality evaluation model through artificial intelligence technology. If colleges and universities want to better combine artificial intelligence technology with physical education, they need to have an in-depth understanding of artificial intelligence technology and a clear direction and overall design for how to use it; discuss which technologies of artificial intelligence can be applied to the reform of physical education, what kind of changes will be produced, and how to change; and discuss the application of intelligence in the construction of the quality evaluation model system in the reform of physical education and how to

use intelligence for teachers in the future. Applying to optimize teaching, students using intelligent applications to achieve personalized learning, and teaching administrators using intelligent applications to improve work efficiency, etc., have guiding significance to reduce the burden [1–5]. In this paper, the design and implementation of the physical education quality evaluation system are designed by constructing the artificial intelligence course teaching mode for college sports students. After testing, the system has good applicability.

2. Related Work

Countries around the world pay close attention to teaching reform because education is closely related to the development of economy, society, and culture, and people hope to promote teaching reform through technology. With the help of 47 papers published in the journal *Artificial Intelligence in Education*, Roll I and Wylie R analyzed the research focus and application scenarios in the field of artificial intelligence in education and predicted two parallel studies in education in the next 25 years according to the research results: first, it is the evolutionary process of physical education, focusing on the existing sports practice, cooperation with teachers, and the diversification of technology; the second is the transformation process of physical education, which should embed sports technology into students' daily life and support students' culture and practice and target. Ozbey N et al. put forward an optimization method for factors affecting students' learning process by analyzing the factors affecting students' learning by artificial intelligence technology. In addition, some scholars have conducted research on the changes caused by the application of artificial intelligence to specific disciplines. For example, Tiffany Barnes and others have conducted research on the application of artificial intelligence to computer teaching, pointing out that artificial intelligence is a more efficient means of promoting computer science learning and teaching. Kanda conducted a practical evaluation of teaching robots in assisting primary school students in English learning, and the results show that teaching robots can promote learners' English learning [6–10]. From the current point of view, teaching reform is a major development and change in education in various countries, especially with the development of artificial intelligence technology, the development path of teaching reform will become wider.

3. Related Theoretical Methods

3.1. Artificial Intelligence. When understanding artificial intelligence, usually we are mainly divided into two parts: “artificial” and “intelligent.” “Artificial” refers to man-made and produced by human beings. “Intelligence” focuses on human intelligence. Artificial intelligence is relative to human's natural intelligence. It refers to the use of artificial methods and technologies to develop intelligent machines or intelligent systems to imitate, extend, and expand human intelligence; realize intelligent behavior and “machine thinking”; and solve problems that require human experts,

issues that can be dealt with. As a branch of computer science, artificial intelligence is a comprehensive subject covering mathematics, philosophy, computer science, psychology, and other disciplines. The main research fields involve expert systems, virtual reality, image recognition, games, natural language processing, problem-solving, machine learning, intelligent database, language recognition, intelligent robot, pattern recognition, etc. To sum up, artificial intelligence is not only a rising emerging technology but also a multidisciplinary comprehensive discipline. The main research is to use new technical means to simulate the process of the human brain engaged in related thinking activities, that is, to use machines to simulate human intelligence [11]. The application of artificial intelligence technology to the quality assessment of physical education teaching in colleges and universities will accelerate the progress of physical education teaching reform.

3.2. The Theory of Educational Change. Educational change theory points out that education is in constant change, and change is the driving force for the dynamic development of education. Educational change experts RG Havelock and CV Goode divide educational reforms into two categories: planned educational reforms and natural educational reforms: “Planned educational reforms” refer to deliberate educational reforms implemented through certain programs, generally referred to as educational innovations., educational reform, and educational revolution are all planned educational reforms; “natural educational reforms” are the opposite of planned educational reforms and refer to changes that are not planned and artificially implemented. Educational change theory believes that educational change has the characteristics of nonlinearity and complexity. Nonlinearity means that the educational reform is not a linear process from initiation to implementation, and the top-down educational reform from the organizational structure may not achieve ideal results; complexity refers to the object of educational reform—the educational system is nonlinear and dynamic. It is a complex system with both natural and social nature, and it is difficult to predict the development of the system. The nonlinear and complex characteristics of educational reform determine the uncertainty of educational reform. Not all educational reforms are positive and beneficial. The results of educational reform may be “positive” or “reverse.” The theory of educational change has important guiding significance for this research: artificial intelligence to promote teaching reform belongs to the category of planned educational reform. Changes in the nature of things are called reforms, but teaching reforms are not a complete denial of traditional teaching but on the basis of inheriting the advantages and wisdom of traditional teaching, optimizing the process of teaching and learning, and innovating teaching and learning methods and means. The process of teaching reform should also follow the “law of quantitative change and qualitative change.” Only on the basis of the full integration of artificial intelligence and physical education teaching will physical education be fundamentally changed, and then, the entire physical education structure will be changed. Therefore, the

physical education reform discussed in this study is a process of changing the status and role of various elements of physical education based on the specific teaching environment and the effective support of artificial intelligence, including changing the form of teaching resources, teaching organization, and learning activities, and learning evaluation methods, among which the status and role of each element are important indicators to evaluate the effect of teaching reform [12–15].

4. Construction of Teaching Mode of Artificial Intelligence Course for College Sports Students

4.1. *Establish an Evaluation Index System.* An excellent physical education quality evaluation index system needs to meet the characteristics of authenticity, specificity, and convenience. Table 1 is based on the summary and arrangement of all the elements of the physical education quality evaluation system, showing a comprehensive set of multidimensional and multilevel three-dimensional evaluation index system [16–18]. The establishment of the entire physical education quality evaluation index hierarchy is mainly established from two aspects: firstly, the current status of the teaching quality evaluation system at home and abroad and, secondly, combined with the country’s policy development orientation.

The entire physical education reform evaluation index structure can be divided into three layers: the first layer is the target layer; the second layer is the criterion layer, and there are two factors here: $P = (P1 + P2)$; and the third layer is the indicator layer. This part is divided into two parts according to the two factors of the previous layer, where $T_1 = (t_{11}, t_{12}, t_{13}, \dots, t_{19})$, $T_2 = (t_{20}, t_{22})$ [19].

4.2. *Design Quality Comprehensive Evaluation Model.* If there is a set of factors to evaluate things $U = \{u_1, u_2, u_3, \dots, u_m\}$, $V = \{v_1, v_2, v_3, \dots, v_m\}$ is a set of decision comments, R is the fuzzy mapping between U and V , and $r_{ij} (i = 1, 2, \dots, m; j = 1, 2, \dots, n)$ describes the beginning of the i th factor, produces the result of the j th factor of the evaluated physical education teacher and establishes the following fuzzy evaluation matrix:

$$R = \begin{bmatrix} r_{11} & r_{12} & \cdots & r_{1n} \\ r_{21} & r_{22} & \cdots & r_{2n} \\ \vdots & \vdots & \cdots & \vdots \\ r_{m1} & r_{m2} & \cdots & r_{mn} \end{bmatrix}. \quad (1)$$

$A = (a_1, a_2, a_3, \dots, a_m)$ is a very important set of U . When both R and A are known, the fuzzy transformation method can be used to obtain the model $B = A \times R = (b_1, b_2, b_3, \dots, b_m)$.

4.3. Methods of Comprehensive Evaluation

4.3.1. *Constructing a Comprehensive Evaluation Factor Set X.* A set of excellent physical education quality evaluation system often contains a variety of factors. However, if the factors to be considered are too complicated, it will be

difficult to evaluate. For comprehensive consideration, a set of evaluation factors is set up: $X = \{\text{The content of the lesson preparation is detailed and the teaching attitude is correct; the classroom knowledge is rich, and the priority is clear; help understanding; interact, mobilize the learning atmosphere; teach students in accordance with their aptitude, pay attention to the exercise of ability; be strict with oneself, set an example for students; care for students, deeply loved by students}\}$ [20]. The construction of the evaluation system in this study draws lessons from the hierarchical method of index system construction in intelligent manufacturing project evaluation [21].

4.3.2. *Establish Evaluation Set Y.* Whether the teaching quality of physical education teachers is good or bad can be reflected through the evaluation set, in which different grades represent the degree of teachers’ physical education teaching quality. $Y = \{\text{excellent, good, fair, poor}\}$, and the evaluation result is reflected by membership degree. The four grade values in the evaluation set Y are determined by a range of values, which are very vague and difficult to calculate accurately. So, in the actual evaluation process, a specific range of values can be used to limit the levels included in Y . Based on the above analysis, the domain of discourse can be set to $[50, 100]$ and then divided into four decreasing intervals. If the obtained scores are placed in the interval $[80, 100]$, the median value of 90 can be taken, that is, the teaching situation of this physical education teacher can be evaluated as “excellent”; if the obtained grade is placed in the $[70, 90]$ interval, the median value of 80 can be taken, that is, the teacher’s teaching situation can be evaluated as “good”; if the obtained grade is placed in the $[60, 80]$ interval, then the median value of 70 can be taken. That is to say, the teacher’s teaching situation can only be evaluated as “average”; if the obtained grade is placed in the $[50, 70]$ interval, the median value of 60 can be taken, that is, the teacher’s teaching situation is not ideal and expressed as “poor.” However, it is actually stipulated that the median value of each achievement interval represents the basis of grade division, and the parameter column vector can be set as $Y = [90, 80, 70, 60]^T$. The result is shown in Figure 1 [21].

4.3.3. *Establish the Weight Set of Evaluation Factors.* Each factor occupies a different key position in the evaluation factor set, that is, the weight is different, so it is very important to formulate the weight of different factors. How to reasonably distribute the weights of each factor determines the accuracy of the evaluation results. The Delphi method is an authoritative method of assigning weights. The core idea of the Delphi method is to anonymously ask experts for their opinions. After sorting and summarizing, they are anonymously passed on to the experts. The experts give their opinions again. An ideal set of weights can be obtained. The evaluation scores given by experts listening to teachers’ lectures are used to verify the scientificity of the fuzzy evaluation method. Take two classes in a certain semester as an example. Both classes A and B have 200 students. According to the evaluation of experts, the scores are ranked

TABLE 1: Hierarchical structure of physical education quality evaluation indicators.

Target layer	Criterion layer	Indicator layer
Physical education quality	Teacher teaching situation	T1 / fully prepared before class and serious teaching attitude
		T12 The key points are highlighted and the teaching content is substantial
		T13 reflect the latest achievements, link theory with practice
		T14 teacher-student interaction is appropriate, and teaching methods are flexible
		T15 diverse teaching methods, using modern technology
		T16 strengthen ability training and focus on teaching students in accordance with their aptitude
		T17 care for students and strictly require management
		T18 pay attention to teaching and educating people and be a teacher everywhere
		T19 comprehensive teaching effect
		T20 course content
	Course information	T21 course load

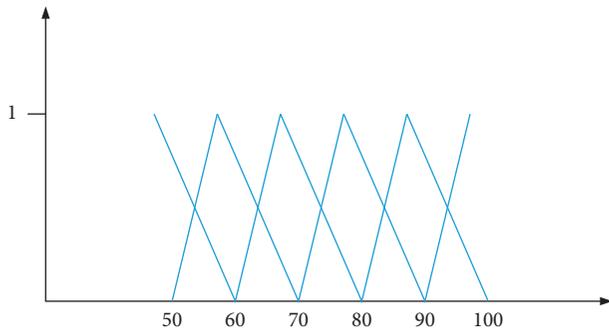

FIGURE 1: Four standard fuzzy partitions of the universe of discourse $Y = [50, 100]$.

6th and 8th. Randomly check the data in the database of their class, from the beginning of the evaluation to the end of the evaluation, a total of 11 sampling points are selected, and the evaluation results are obtained.

4.3.4. *Establishment of Fuzzy Relationship Matrix.* All evaluation personnel give objective evaluations based on the daily behavior of physical education teachers in various factors, establish a fuzzy relationship matrix R through induction and sorting, and further obtain the possibility measure. Suppose there are 200 people who participate in the evaluation to give an evaluation to a certain aspect of physical education teachers, of which 140 people’s evaluation results are “excellent,” 40 people determine “good,” and 20 people determine “average,” so the result is “excellent.” The probabilities are as follows: $140/200 = 0.7$; the probability of “good” is $40/200 = 0.2$; the probability of fair” is $20/200 = 0.1$; the probability of poor” is $0/200 = 0$.

4.3.5. *Obtaining Fuzzy Comprehensive Evaluation Results.* The following fuzzy evaluation model based on weight set A and fuzzy relation matrix R can be obtained:

$$B = A \times R = (b_1, b_2, b_3, \dots, b_4).$$

Use.

$$S = B \times V = 90 * b_1 + 80b_2 + 70b_3 + 60b_4.$$

The obtained value can be used as the final evaluation score of the evaluated physical education teacher. If the fuzzy evaluation matrix of a physical education teacher is

$$R = \begin{bmatrix} 0.418 & 0.348 & 0.201 & 0.033 \\ 0.625 & 0.218 & 0.115 & 0.042 \\ 0.740 & 0.165 & 0.080 & 0.015 \\ 0.365 & 0.424 & 0.169 & 0.042 \\ 0.732 & 0.168 & 0.170 & 0.019 \\ 0.620 & 0.219 & 0.118 & 0.043 \\ 0.431 & 0.358 & 0.202 & 0.034 \\ 0.755 & 0.155 & 0.075 & 0.015 \\ 0.632 & 0.214 & 0.114 & 0.039 \end{bmatrix} \quad (2)$$

$$B = A \times R = (0.534, 0.286, 0.146, \dots, 0.034).$$

Use.

$$S = B \times V = 90 * b_1 + 80b_2 + 70b_3 + 60 * b_4.$$

The comprehensive evaluation value $S = 83.2$ is obtained by calculation. According to the range in the evaluation set Y , it can be known that the teaching quality of the physical education teacher is evaluated as “good.”

5. Design and Implementation of Physical Education Teaching Quality Evaluation System

5.1. *Overall Design.* The most commonly used and widely implemented architectural design pattern includes three parts: presentation layer, business logic layer, and data access layer. The main idea of this architecture pattern is to simplify a complex problem by decomposing it. More importantly, it can efficiently reuse business logic and maintain the connection with resources to further control the development cycle of the system. Then, the physical education quality evaluation system is mainly based on the model of the three-tier B/S architecture.

5.1.1. *Model of Three-Tier B/S Architecture.* Hierarchical structure is a representative and most classic structure in the software system design process. The three-tier architecture has matured over the years and has been welcomed by developers. This commonly used application architecture is usually divided into three layers: data access layer, business logic layer, and presentation layer.

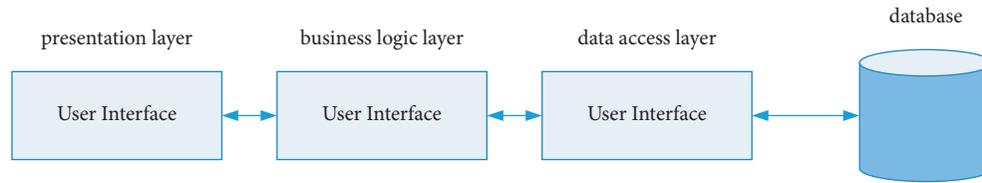

FIGURE 2: Schematic diagram of three-layer B/S structure.

The presentation layer includes all forms of controls and components involved in the interactive interface, the business logic layer includes how to complete all business rules and logic, and the data access layer includes all database components as shown in Figure 2. Architecture design is the primary task of a system design. A simple and functional system architecture can facilitate developers and users to maintain and expand the system, and the reusability can also be greatly improved. The operability, practicality, extensibility, and development cycle of this system have been improved. The architecture-building process clarifies the concept of packages and describes how packages interact and communicate.

The three-layer B/S mode is extended to the two-layer mode. The graphical operation interface implemented in the presentation layer is helpful for users to digest and master the efficient operation and positioning application services as soon as possible; the business logic layer is in the middle layer, and the purpose is to realize the application method, encapsulate the application mode, and associate the client application with the data service involved. Together, the data access layer is at the bottom, and its main task is to define, query, and modify data and respond to requests sent by application services to data.

5.1.2. System Planning and Analysis. For users, it is very convenient to use the web method. They can log in to the system in the browser to query the results without downloading the client. Taking into account user demands and excellent system processes, an evaluation system should follow the following principles:

- (i) Allow users to generate questionnaires to evaluate the survey through a variety of evaluation index systems;
- (ii) Allows users to define the importance of any indicator system by selecting models with differences;
- (iii) Allow users to select a certain index system to generate any batch of questionnaires;
- (iv) Managers can inquire about the progress of the investigation and manage it at any time;
- (v) Users can evaluate the questionnaire by using different evaluation models and conduct a comprehensive analysis of the results obtained. In order to meet the above requirements, this system applies a three-tier B/S model and uses the structure in Figure 2 to plan and deploy, using SQL Server as the background database.

The staff controls the whole evaluation process. The evaluation form, the relevant data of the participants, and the relevant data of the people being evaluated are all stored in the SQL Server database. As for how to determine the weight and how to determine the results of the comprehensive evaluation, all these data need to be processed by the staff. It is presented to the server through the web side, and then, the server calls the corresponding program for management and finally delivers the result to the presentation layer. Participating evaluators can fill in the price list on the web page, and the final evaluation results of the evaluators can be viewed via the web page.

5.1.3. Functional Design. The purpose of this system is to provide online teaching evaluation services: evaluators can use this system to evaluate all teachers online and adjust teachers' work through comprehensive evaluation results. This system covers system entry, relevant quantity input, determination of evaluation system indicators and weights, real-time scoring, evaluation result confirmation, evaluation result sorting, evaluation data maintenance, and other functions. The functional frame structure is shown in Figure 3. The relevant function windows can meet the needs of current teachers during the trial operation.

5.2. Evaluation Process. The evaluation process consists of index design, real-time evaluation, data query statistics, and result analysis as shown in Figure 4.

5.3. Front-End System Implementation. The system can be run on the campus network and uses a three-layer structure model. The front desk is mainly developed with Active Server Page program, and Excel is used to query and export the results and print the report.

"Evaluation" includes "student evaluation," "peer evaluation," and "expert evaluation", and "inquiry" includes "personal inquiry" and "department inquiry."

Student evaluation: the purpose is to evaluate all teachers in the current semester and can only evaluate once, and students can also maintain information and passwords.

Peer evaluation: the purpose is to evaluate the teaching situation of other teachers in the same semester. The method is that any course can only be evaluated once, and teachers can also check their own evaluation scores and maintain their personal passwords.

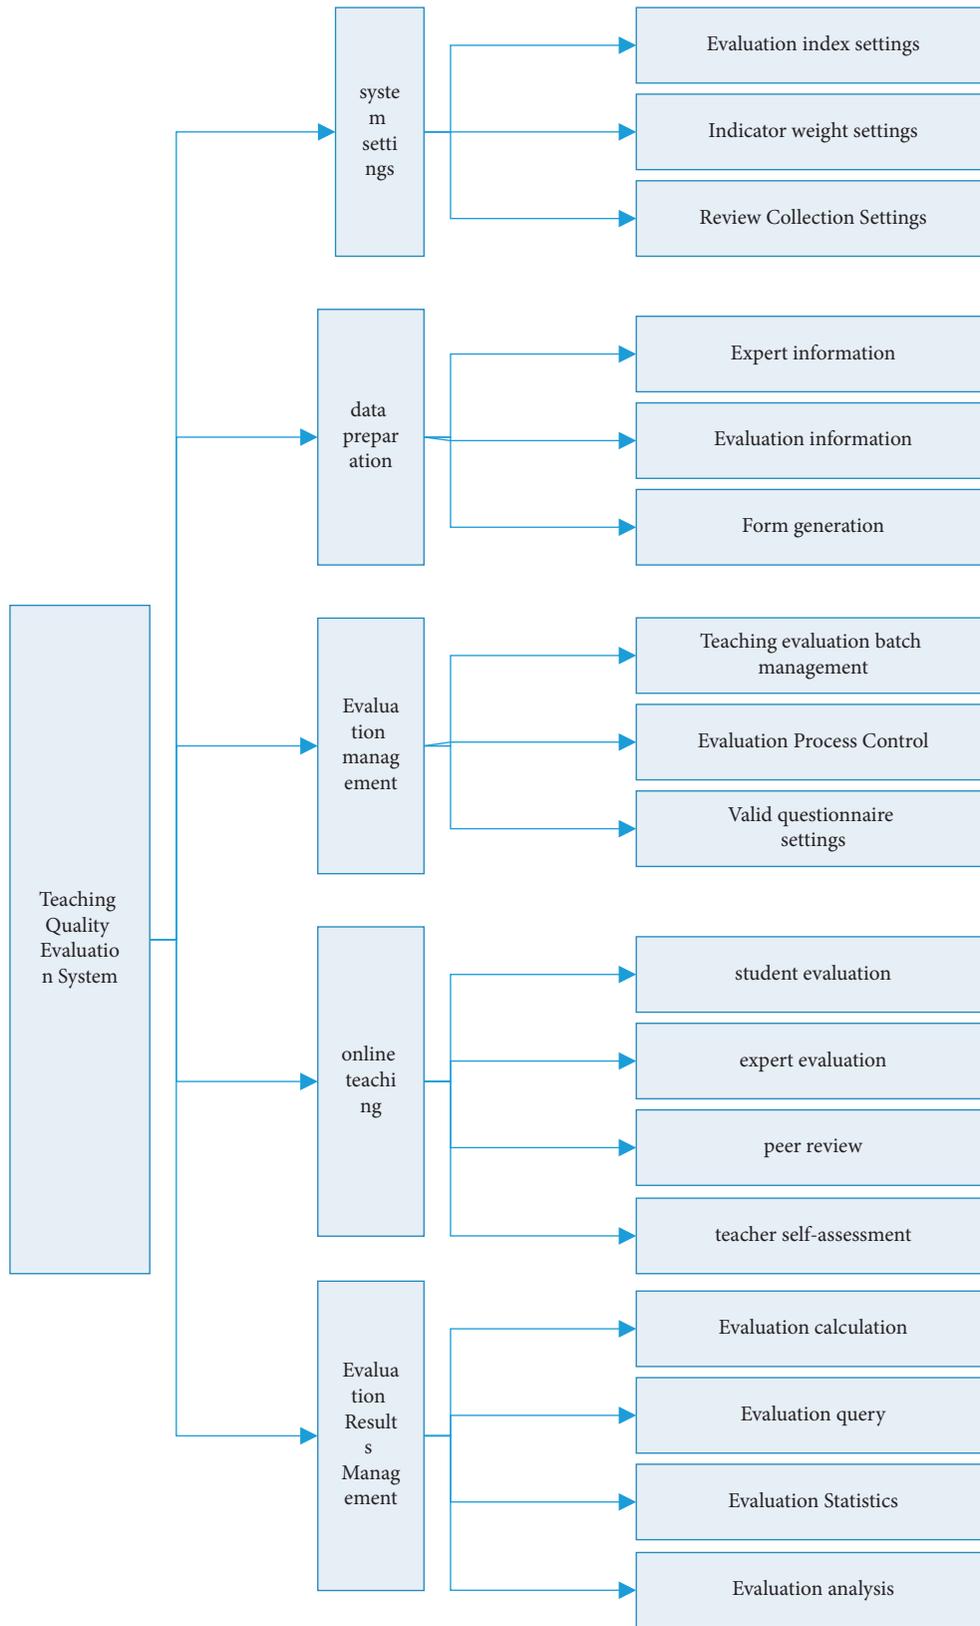

FIGURE 3: System function block diagram.

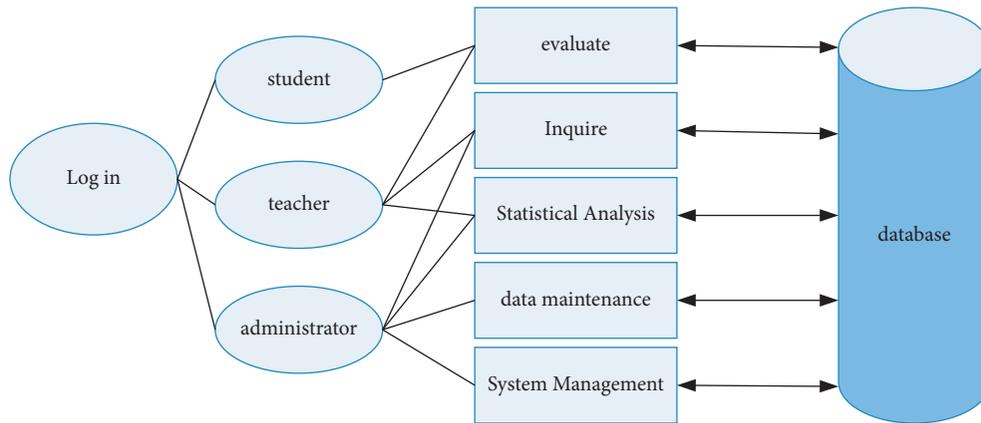

FIGURE 4: Evaluation process.

Expert evaluation of teaching: the purpose is for experts to evaluate all teachers in the current semester, can only evaluate once at the same time, and can also maintain the personal information and passwords of experts.

5.4. *System Test.* The system test is carried out in order to achieve two conditions: first to check whether the system can meet the expected expectations and second to check the possible errors during the operation of the system and modify them in real time. The purpose of error checking is to comprehensively retrieve possible errors so that it can be modified before the system works normally to avoid the avoidable difference that may occur after the system works. Generally speaking, software testing generally includes white-box testing and black-box testing. The white-box test is also called structure or logic-driven test. The principle of this test method is to test the program according to the internal structure of the program so as to check whether there is any behavior that violates the design regulations in the product and whether any path in the program can be tested. This testing method regards the test object as an open box. The tester refers to the internal logic structure of the program, designs or selects the example, and tests all the logic paths of the program. After checking the state of the program at each point, to confirm the state that appeared to meet the expected goals. Black-box testing is also known as functional testing or data-driven testing. This testing method is to know all the functions that the product should have in advance and test these functions to verify whether any function can operate normally. During the test, the program is assumed to be a black box that cannot be opened. At the same time, under the condition of ignoring the internal structure and coding nature of the program, the tester can test whether the function of the program can realize the normal operation of the function described by the software function by testing at the

TABLE 2: Dividing equivalence classes.

		(13) greater than 31

program interface and whether the program can reasonably receive input data and output information that meets expectations while ensuring the integrity of external information. The black-box method focuses on the structure outside the program, does not take the internal logic structure of the program into consideration, and tests the interface and function of the software at the same time. The black-box method is a typical exhaustive input testing method. Only by testing all possible situations can all errors in the program be detected by this method. In fact, there should be an infinite number of such tests, and workers need to test not only all legal possibilities but also illegal but possible inputs. In general, white-box testing and black-box testing have different applications. White-box testing is suitable for code rereview and individual testing phases, but in the case of combined testing and system testing, black-box testing is best used. In this case, the method of dividing equivalence classes in black-box testing is used, and the dividing equivalence classes are shown in Table 2.

Examples of selected test cases in black-box testing are shown in Table 3.

6. Conclusion

As we all know, the content involved in pedagogy at this stage can be mainly divided into three fields, which are the research of basic theory, education development theory, and education evaluation system, and there is a certain internal connection between these three modules. Among them, the education evaluation system has a very prominent position and role in the evaluation of educational research and the actual education system. The primary reason is that it can not only evaluate the level of students but it can also evaluate the level of teachers, truly feedback the state of the education system, and evaluate the education of colleges and universities. It also has the function of detecting the educational reform achievements of colleges and universities, which provides a good basis for improving the educational system. This paper uses the structure of teaching quality evaluation based on the fuzzy overall evaluation method. At the same time, the uncertainty in the system is solved by the method of fuzzy mathematics, and the evaluation index system is constructed by the standard fuzzy division method and the Delphi method. The ambiguity of the data has been improved, and the combination of quantitative and qualitative analysis makes the teaching evaluation system more comprehensive, which greatly improves the authenticity and credibility of the evaluation results. Based on the three-tier B/S system framework, combined with ASP and SQL Server technologies, a web-based teaching quality evaluation system is researched and developed. However, there are still some areas that need to be improved and optimized. For example, in the actual process of software design, developers need to maintain communication with users in order to achieve a better dynamic user interface that meets user

needs. It is necessary to further improve teaching methods and provide ideas to improve teaching quality and efficiency.

Human recognition models based on spatial-temporal graph convolutional neural networks have been gradually developed, and we present an improved spatial-temporal graph convolutional neural network to solve the problems of the high number of parameters and low accuracy of this type of model. The method mainly draws on the inception structure. First, the tensor rotation is added to the graph convolution layer to realize the conversion between graph node dimension and channel dimension and enhance the model's ability to capture global information for small-scale tasks. Then the inception temporal convolution layer is added to build a multiscale temporal convolution filter to perceive temporal information under different time domains hierarchically from 4-time dimensions. It overcomes the shortcomings of temporal graph convolutional networks in the field of joint relevance of hidden layers and compensates for the information omission of small-scale graph tasks. It also limits the volume of parameters, decreases the arithmetic power, and speeds up the computation. In our experiments, we verify our model on the public dataset NTU RGB + D. Our method reduces the number of the model parameters by 50% and achieves an accuracy of 90% in the CS evaluation system and 94% in the CV evaluation system. The results show that our method not only has high recognition accuracy and good robustness in human behavior recognition applications but also has a small number of model parameters, which can effectively reduce the computational cost.

1. Introduction

Computer vision technology is a key link in the realization of artificial intelligence, and its emergence has given artificial intelligence great potential in visual perception. Among them, human action recognition is the most challenging technology in computer vision. The implementation of this technology can add to intelligent applications such as pedestrian following and behavior analysis. The most widely researched human behavior recognition methods are based on the human skeleton and, of course, image-based human behavior recognition methods. Human skeleton-based and image-based approaches are very different [1–4]. Skeleton-based methods take human skeleton recognition data as input, focus on analyzing the depth, spatial and temporal information of human skeletal joints, and then combine all features to achieve a behavior prediction result. Compared with image-based methods, human skeletal data are denser and reduce the computational cost by replacing a large number of pixel points with dense skeletal data. The

skeleton-based action recognition method also performs better in the working environment of multiple targets and complex backgrounds [5–7].

Traditional skeleton-based methods rely on skeletal joint trajectories, with all method models based on recurrent neural networks of skeletal joint point data [8–11]. Some researchers would prefer to adopt deep neural network models, for which there is already relevant literature demonstrating their substantial advantages as well as their shortcomings. The skeletal data distribution is rather fragmented, and each skeletal joint point data are not locally linked. Therefore, for deep neural networks, a separate neural network needs to be tailored to accommodate the structured skeletal data to coordinate with all the skeletal joint point data [12, 13].

In the deep recurrent network model, only the connections in the feature point space can be analyzed, and the connections between features at the temporal level cannot be obtained. To solve this problem, researchers in the literature [14, 15] used a long short-term memory network (LSTM)

[16] to feature extraction from skeletal data, where the authors first divided the skeletal data into slices, each corresponding to an individual LSTM unit, and merged all. Such an architectural design improves the model's spatial perception of the skeletal data. However, this method suffers from the manual architecture predetermined to the rule limitation, which reduces the generalization ability and robustness of the network [17]. Considering the spatial and temporal features of skeletal data, the literature [18] introduced a graph convolutional network, which breaks the limitation of 2-dimensional data and can handle any graph structure. It transposes the computation of graph convolutional network to skeletal nodal data, which can dimensionally integrate the connections between spatial feature points. The literature [19] presented a spatial-temporal graph convolutional neural network based on the previous study, which can represent each skeletal data point in a graph structure and then perform feature extraction in a graph convolutional pattern as a way to obtain the spatial features between skeletal joint points [20–22]. In addition, the model adds a temporal convolution unit to integrate the temporal links between skeletal joint points, estimate the trajectory of skeletal joints, and finally predict the class of behavior [23].

Based on preliminary research and experiments, this paper proposes the Inception-ST-GCN (IST-GCN) method, which aims to reduce the complexity of building the neural network architectures while capturing the global information of the graph. In this paper, a tensor rotation module will be added to rotate the graph dimension to the RGB dimension and use the one-dimensional convolution Conv 1×1 to capture the global information afterward. A new inception layer multiscale temporal convolution filter is added to divide it into four branches with different temporal perception domains to capture richer temporal information and greatly decrease the volume of model parameters. The IST-GCN method achieves a compact and efficient network. To test the effectiveness of the method in this paper, we perform experimental validation on the public dataset NTU RGB + D. The results show that the number of parameters of the method in this paper is greatly reduced compared with the original ST-GCN model, and the accuracy and precision of action recognition are greatly improved.

The remainder of this paper is laid out as follows: Section 2 introduces the construction of the basic network and the principles of mathematical equations. Section 3 details the principles and implementation procedures related to the improved human action recognition network. Section 4 presents the relevant experimental datasets and analysis of the results. Finally, Section 5 reviews our findings and reveals some additional research.

2. Basic Network

Through our preliminary examination, we apply the graph convolutional neural network as the base network, and its network structure is shown in Figure 1. This network is an upgrade for the graph convolutional network, aiming to optimize the perceptual domain of the graph convolution and increase the joint of the graph convolutional network for

the feature relations at the temporal level. The main purpose of this network is sequence encoding the skeletal data and predict the joint behavior by the spatial features and temporal associations between skeletal joint points. For skeletal feature acquisition, we usually use the OpenPose [24] algorithm to localize the human body using 25 skeletal points and the connections among different skeletal points as human joints. The input is usually a video sample in AV format, and each frame of the sample video corresponds to this set of joint coordinates. The OpenPose algorithm can split and resolve each set of joint coordinates and map them to each skeletal unit map node of the human body, using the joints and the edges of the human body as boundaries to build a complete spatial-temporal map. In other words, the input of OpenPose can also be understood as a set of joint coordinates of skeletal points in the same way as the 2-dimensional pixel intensity vector input of the convolutional neural network. To obtain a wider range of information, the graph convolutional network is then stacked and all outputs are then fed into the classifier in parallel.

The input in Figure 1 is a fixed skeleton sequence, assuming that T represents the constituent sequence of the total number of skeletons, V represents the number of skeletal joints, and $G = (N, E)$ denotes the set of constructed skeleton spatial-temporal sequences, where $N = \{v_{ti} | t = 1, \dots, T, i = 1, \dots, V\}$ traverses the skeleton joints obtained along with all-time sequences, and v_{ti} denotes all nodes. E denotes the set of connections between joints, and consists of E_T and E_S . An arbitrary human skeleton joint (i, j) , $E_S = \{(v_{ti}, v_{tj}) | i, j = 1, \dots, V, t = 1, \dots, T\}$ denotes the composition of skeleton intra-joint connections within time t . The subset of intra-skeletal connections E_S is divided into K disjoint regions in the center of gravity rule and is represented using the adjacency matrix encoding $\tilde{A}_k \in \{0, 1^{V \times V}\}$. $E_T = \{(v_{ti}, v_{(t+1)i}) | i = 1, \dots, V, t = 1, \dots, T\}$ denotes the union of connections between all skeletal joints in a continuous time series. The fusion of the above features results in a sequence diagram that can be extended in the spatially mapped temporal dimension.

The literature [25] optimized the spatial submodule of the spatial-temporal graph convolutional neural network and proposed the following graph convolution equation:

$$\begin{aligned} f_{\text{out}} &= \sum_k^{K_s} (f_{\text{in}} A_k) W_k, \\ A_k &= D_k^{(-1/2)} (\tilde{A}_k + I) D_k^{(-1/2)}, \\ D_{ii} &= \sum_k^{K_s} (\tilde{A}_k^{ij} + I_{ij}), \end{aligned} \quad (1)$$

where \tilde{A}_s denotes the adjacency matrix of internal connections of skeletal nodes, I denotes the unit matrix, K_s denotes the size of the convolution kernel in spatial dimensions, and W_k denotes the training weights. The temporal convolution module is $1 \times K_t$. In 2D graph convolution, and the perceptual field of the convolution kernel is not considered when operating (C_{in}, V, T) in the (V, T) dimension, where K_t denotes the number of frames.

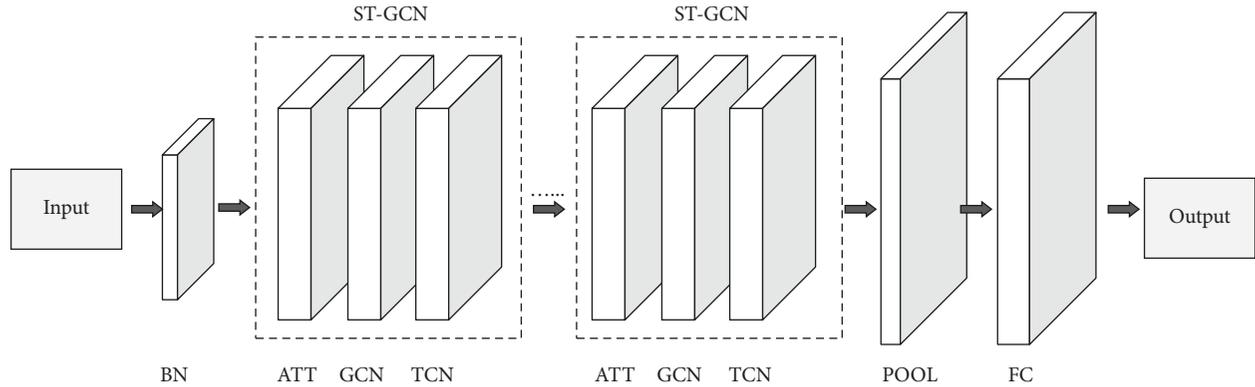

FIGURE 1: ST-GCN network.

The graph structures in graph convolution are pre-defined, and to increase their adaptability, the literature [26] uses a fixed adjacency matrix and proposes an adaptive graph convolution formula as follows:

$$f_{\text{out}} = \sum_k^{K_s} f_{\text{in}} (A_k + B_k + C_k) W_k, \quad (2)$$

where B_k denotes the parameters learned in training and C_k denotes the connected vertices determined with the over-similarity function.

3. Improved Action Recognition Network

The spatial-temporal graph convolution model uses a pre-defined structural graph as a topological constraint to achieve the ability of different time-step graphs to share the same topology, and such a structure leads to the inability of the graph task to fully capture the relevant features of the hidden joint layer. To solve this problem, our most common approach is to build a regional neural network using a local perceptual domain as the starting point and a small-scale graph task in the experimental region. This can easily produce global information omission. To simulate the principle of computation of pixel points by convolutional neural networks, each graph node and adjacent graph nodes become the key nodes for graph convolution computation in the graph convolution task. Considering the problem of density heterogeneity and narrow local structure between neighboring nodes, in our improved network, we employ node features of fixed size for feature learning in the temporal dimension, selectively ignoring the size of cluster features, and being able to capture more features in the temporal dimension. Therefore, we present the inception spatial-temporal graph convolutional network (IST-GCN), which applies the inception structure to some network layers as a way to reduce the model parameters, broaden the network width, and enhance the robustness of the model.

3.1. Inception Module. The inception module is a sparsity structure proposed in 2015, which has excellent feature expression capability and local topology capability. When

the image is input, the pixel point population is involved in a series of convolution operations and pooling operations to obtain features at different scales from different scales of convolution kernels. All the output results are taken for parallel processing to filter out the best image features. The original structure of inception is shown in Figure 2. Its network structure mainly contains three scales of convolutional kernels and a 3×3 pooling, through which a combination of 1, 3, and 5 convolutional kernels can fully acquire large-scale sparse features and small-scale nonsparse features. Such structures not only increase the network width but also increase the adaptability of the network to different scales. Finally, all features are synthesized by a concatenation operation to obtain the nonlinear properties of the features.

3.2. Graph Convolutional Layer Improvement Strategy.

Our proposed IST-GCN model originates from a two-part optimization of the spatial-temporal graph convolutional network. The first part is to optimize the graph convolutional network layers; the second part is to add the inception layer. In the graph convolutional layer, the original model aims to obtain spatial location information between the human skeletal joint points to achieve the representation of the joint points. It should start from the initial neighboring nodes to build up a local perceptual domain, in which a large number of sample nodes are generated. Although many false samples are generated at this point, adding topological angle restrictions in the subsequent process of filtering the sequence in Euclidean space can filter the false samples. When all sample nodes are in Euclidean space, all sample nodes can be considered as point from the global level view, and the sequence of points is considered as a one-dimensional vector. In this case, to capture a large number of sample node features, a large-scale graph convolution sum is required, whose size is consistent with the number of nodes. To properly solve this problem, we propose a tensor rotation strategy. We add a tensor rotation module, which we call Rotate tensor GCN (R-GCN), at the beginning and end of the graph convolution layer. The detailed network structure is shown in Figure 3.

By the action of the tensor rotation module, each sample node can share the same set of identical topological matrices,

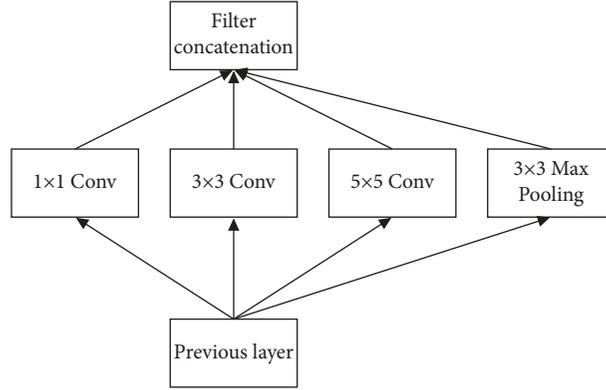

FIGURE 2: Inception network.

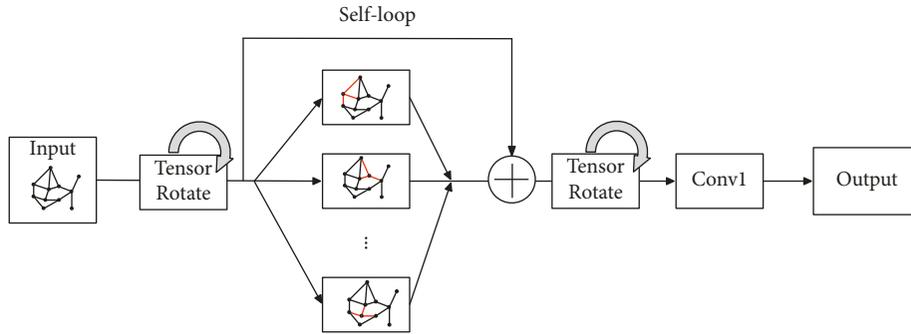

FIGURE 3: R-GCN network.

and all nodes can participate in the process of capturing global information. Taking human nodes as an example, each graph contains 25 nodes, and in the fully connected layer, we choose a filter of size 25. The rotation tensor module will rotate a tensor according to the different nodes separately so that the dimensionality of the nodes and the dimensionality of the channels remain the same. By tensor rotation, the predefined topological matrix is discarded and the global features are learned adaptively according to the self-cycling unit for joint relevance. Finally, the global information is integrated through the tail-Conv 1×1 dimensionality reduction. Such a structural design can effectively reduce the use of higher-order polynomial estimation layer by layer to capture higher-order features, thus achieving a reduction in the number of parameters.

3.3. Inception Layer Design Strategy. We consider using the inception structure to broaden the spatial-temporal graph convolutional network because of the sparse structure advantage of inception. More feature information can be obtained by the layout of the sparse structure while avoiding the increase in the number of parameters. We refer to the optimization process of inception from V1 to V4 and discover the one-dimensional convolutional dimensionality reduction method [27–29]. We are building the inception time convolution network (I-TCN), and the expansion of parameters is exacerbated by the exponentially growing expansion coefficients in the time convolution layer to widen

the network. In contrast, the inception tiling structure is incremented according to layers, and each branch is preceded by adding Conv 1×1 dimensionality reduction to assign different expansion settings to each branch, allowing the time-scale information to be graded into the inception branches and achieving information integration in different time dimensions. Through the above structure of time coefficient assignment, the exponential growth of coefficients is avoided and the purpose of reducing the number of parameters is achieved.

Two two-layer I-TCN layers are added at the end of each IST-GCN cell, and the TCN is divided into 4 branches according to the hierarchical principle, with each branch producing output to the corresponding group, whose structure is shown in Figure 4. The initial value of the expansion coefficient n of the network is 1. As the network deepens, the layer units increase step by step, and the maximum value of the expansion coefficient is 4. This external connection refers to the residual structure, which passes through a one-dimensional convolution with a step size of 2 in the middle, and this design can avoid the gradient dispersion problem. Improving the temporal convolutional network by inserting the inception structure allows for capturing more time-scale information while reducing the number of network parameters by a large amount and reducing the computational cost. A compact and efficient temporal feature extraction network is achieved by using different temporal filters to adaptively select the best feature information to optimize the classification problem.

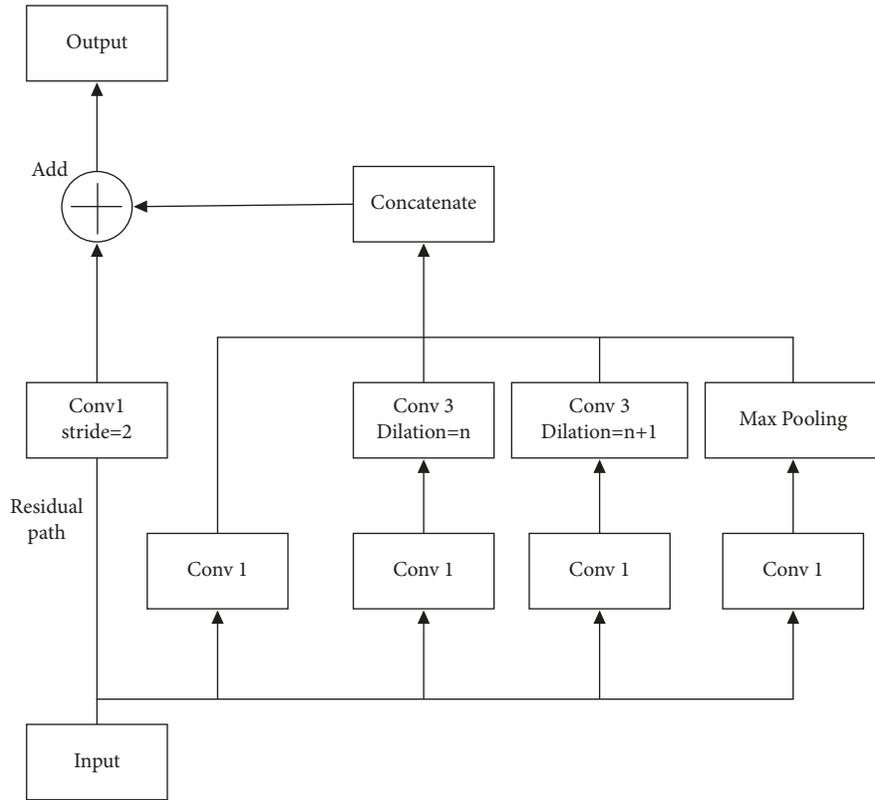

FIGURE 4: I-TCN network.

3.4. IST-GCN Action Recognition Process. The process of human action recognition based on the IST-GCN model is shown in Figure 5. Firstly, the sample video data are input, and the video data are processed in frames during the analysis process. The human joints under different frames have the problem of position change, but the set of all joint points in different frames obeys random distribution. Therefore, we first select the batching standard module (BN) in the first layer of the network hierarchical distribution to normalize the joint point data at the temporal level and spatial level to make the input skeletal data more standardized, reduce the error volatility, and optimize the algorithm's convergence. In the second layer of the network, we choose the attention mechanism (ATT), which connects our new R-GCN layer and the I-TCN layer in the next network. The R-GCN layer relies on the tensor rotation operation to obtain global information, after which the obtained global features are input into the I-TCN to analyze the linkage relationship among the nodal features at the temporal level, supplemented by the ATT mechanism to weaken the non-conforming features that do not conform to the bounded range of the model and filter features of different time-scales. The whole network consists of nine IST-GCN units sequentially connected to fully capture and fuse the graph feature information, then perform average pooling, then classify the features through the fully connected layer, and finally output the behavior prediction results according to the classification weights.

4. Experiment

4.1. Datasets. To validate the performance of our method, we chose the public dataset NTU RGB + D [30] for experimental test validation. This dataset is one of the more comprehensive datasets covering categories in human action recognition studies. The dataset contains a total of three types of production specifications, which are the two-person interaction dataset, the medical interaction dataset, and the daily interaction dataset. It can be subdivided into 60 categories of actions based on action types, with a total of 56880 sample sequences. All videos are stored in a uniform dataset standard, and the maximum video frames of each sample video do not exceed 300 frames. At the same time, all sample data are preprocessed by OpenPose human skeleton detection, and the corresponding skeleton data and Jason files are stored separately. In addition, a set of independent evaluation criteria, namely, Cross-Subject (CS) and Cross-View (CV), is proposed for this dataset. The CS evaluation system is evaluated based on the ID number of the person in the dataset as a sequence, and the CV evaluation system is evaluated based on the camera ID number as a sequence. The detailed volume of the training and testing datasets are shown in Table 1.

4.2. Experimental Details. In the action recognition experiments, we mainly focus on action jogging as the control standard to verify whether the action recognition results

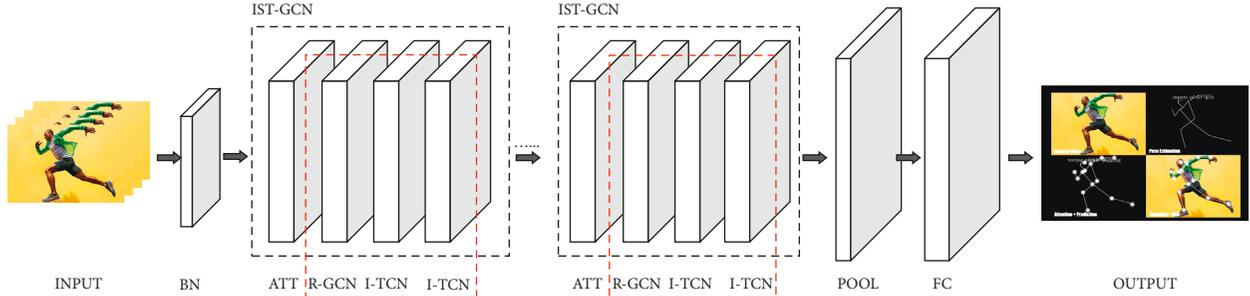

FIGURE 5: IST-GCN human action recognition process.

TABLE 1: The detailed information of datasets.

	NTU RGB + D	
	CS	CV
Train	40320	37920
Test	16560	18960
Total	56880	56880

match with the real action, each test sample is 300 frames, while the experiments are divided into single-player action recognition experiments and multiplayer action recognition experiments to test the performance of the improved method hierarchically while comparing with the spatial-temporal map convolutional neural network model.

4.2.1. Single Action Recognition Experiment. The performance of single-person recognition result is shown in Figure 6, it can be seen that the action recognition result matches with the experimental preset result, the effect is better and the action recognition result is accurate.

Compared with the spatial-temporal map convolutional neural network model, the single-person action recognition effect is not much different, and the comparison experiment is shown in Figure 7. Although there are a few frames that recognize the action as a triple jump and occasionally misrecognition occurs, the final score voting result still matches the real action and has little impact on the overall action recognition result.

4.2.2. Multiplayer Action Recognition Experiment. The performance of multiplayer recognition result is shown in Figure 8, which shows that the action recognition effect is good, and a few frames appear to misrecognition situation, but it does not affect the overall action recognition, and the recognition result is accurate.

Compared with the original spatial-temporal map convolutional neural network model, the recognition effect of our method is superior, and the comparison of the action recognition effect is shown in Figure 9.

As shown in Figure 9 Experiment A, two-thirds of the frames of the original ST-GCN method identify the action as triple jump, although there are also some frames identified as real action jogging, but the overall triple jump action score is higher, so the final action recognition result is triple jump.

Our method uses different scales of time windows to capture information and has better control of global information, so it performs well in the multiperson action recognition experiment and the recognition results are accurate. From Figure 9, experiment B in the recognition effect of the original ST-GCN algorithm, one person was obscured and although the skeletal information was recognized, the action could not be classified, and then the overall action was recognized as roller skating, which could not be matched with the real action. The effect of multiperson action recognition experiments is not as good as that of single-person recognition experiments. The more the number of people, the lower the accuracy of human skeleton recognition and the efficiency of action classification. We try to control the multiperson action recognition experiment to less than three people in the experiment. Our method can recognize and correctly categorize the occluded part of the action, further highlighting the advantages of our proposed IST-GCN method.

4.3. Experimental Results Analysis. Our proposed IST-GCN method involves the improvement of two main parts, namely, the rotated tensor module in the graph convolution layer (R-GCN) and the inception structure embedding in the temporal convolution layer (I-TCN). To verify the effect of each, ablation experiments were performed. First, the GCN in ST-GCN was replaced with R-GCN, and the group of experiments was named with the letter *R* to construct the R-GCN efficiency testing experimental group. Secondly, the TCN in ST-GCN was replaced with I-TCN, and the group was named with the letter *I*. The experimental group was constructed to verify the performance of the I-TCN module. The above two groups were validated with the spatial-temporal map convolutional neural network and our proposed IST-GCN on the NTU RGB + D dataset. The results were compared in terms of accuracy (Acc), bone recognition accuracy (Bone), joint recognition accuracy (Joint), and number of parameters (Param) levels as shown in Table 2.

The R-GCN technique improves overall accuracy by 3.7 percent, and the number of parameters is lowered proportionally, as shown in Table 2. The I-TCN approach improves overall accuracy by 7.5 percent and reduces the number of parameters by half. The results reveal that I-TCN has a greater impact on overall performance than R-GCN, although less effective than I-TCN in terms of overall

FIGURE 6: Single-person action recognition.

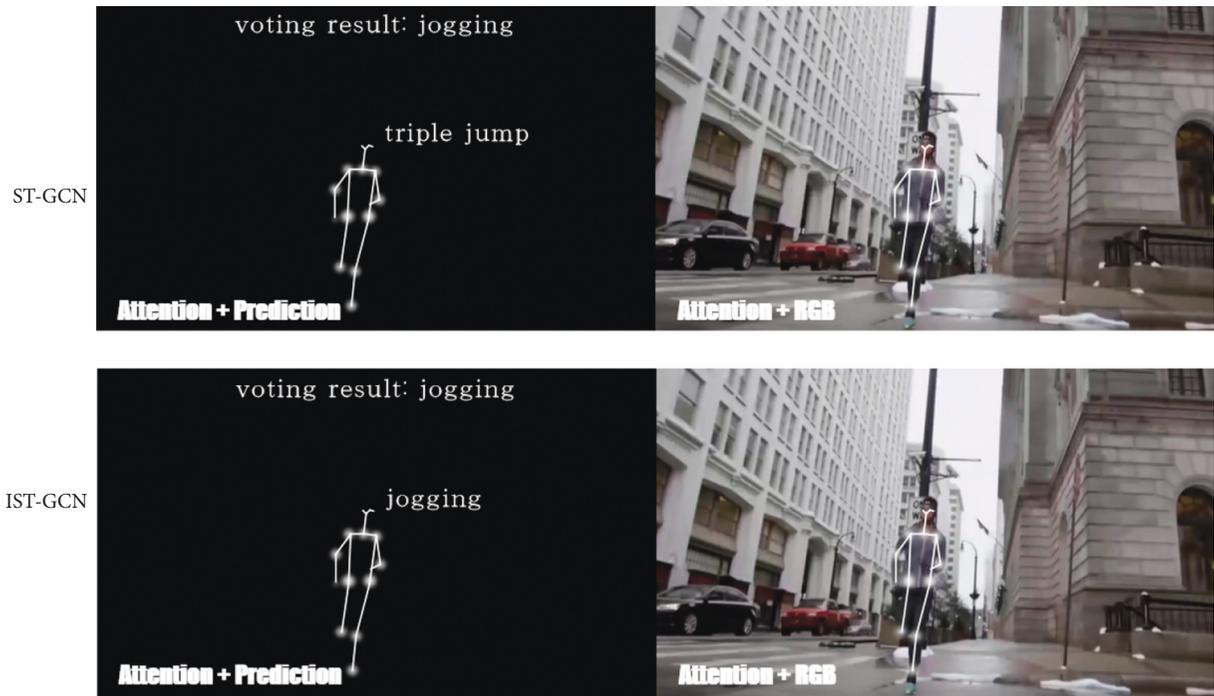

FIGURE 7: Comparison of ST-GCN and IST-GCN single-person action recognition effects.

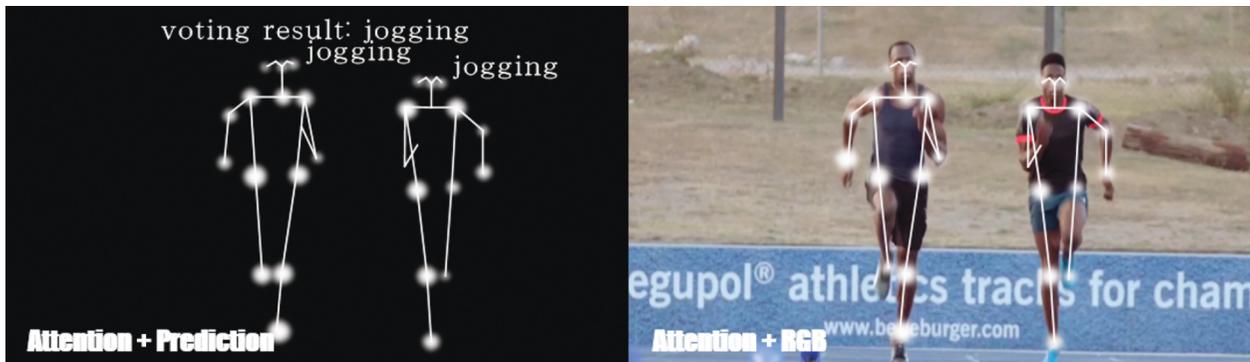

FIGURE 8: Multiperson action recognition.

performance improvement, is indispensable in capturing the global feature level. The two optimizations mirror each other and prove the effectiveness of the IST-GCN method.

To verify the effectiveness of our IST-GCN, we compare four different kinds of skeleton-based action recognition models, dynamic skeleton [31], ST-GCN [18], P-LSTM [30]

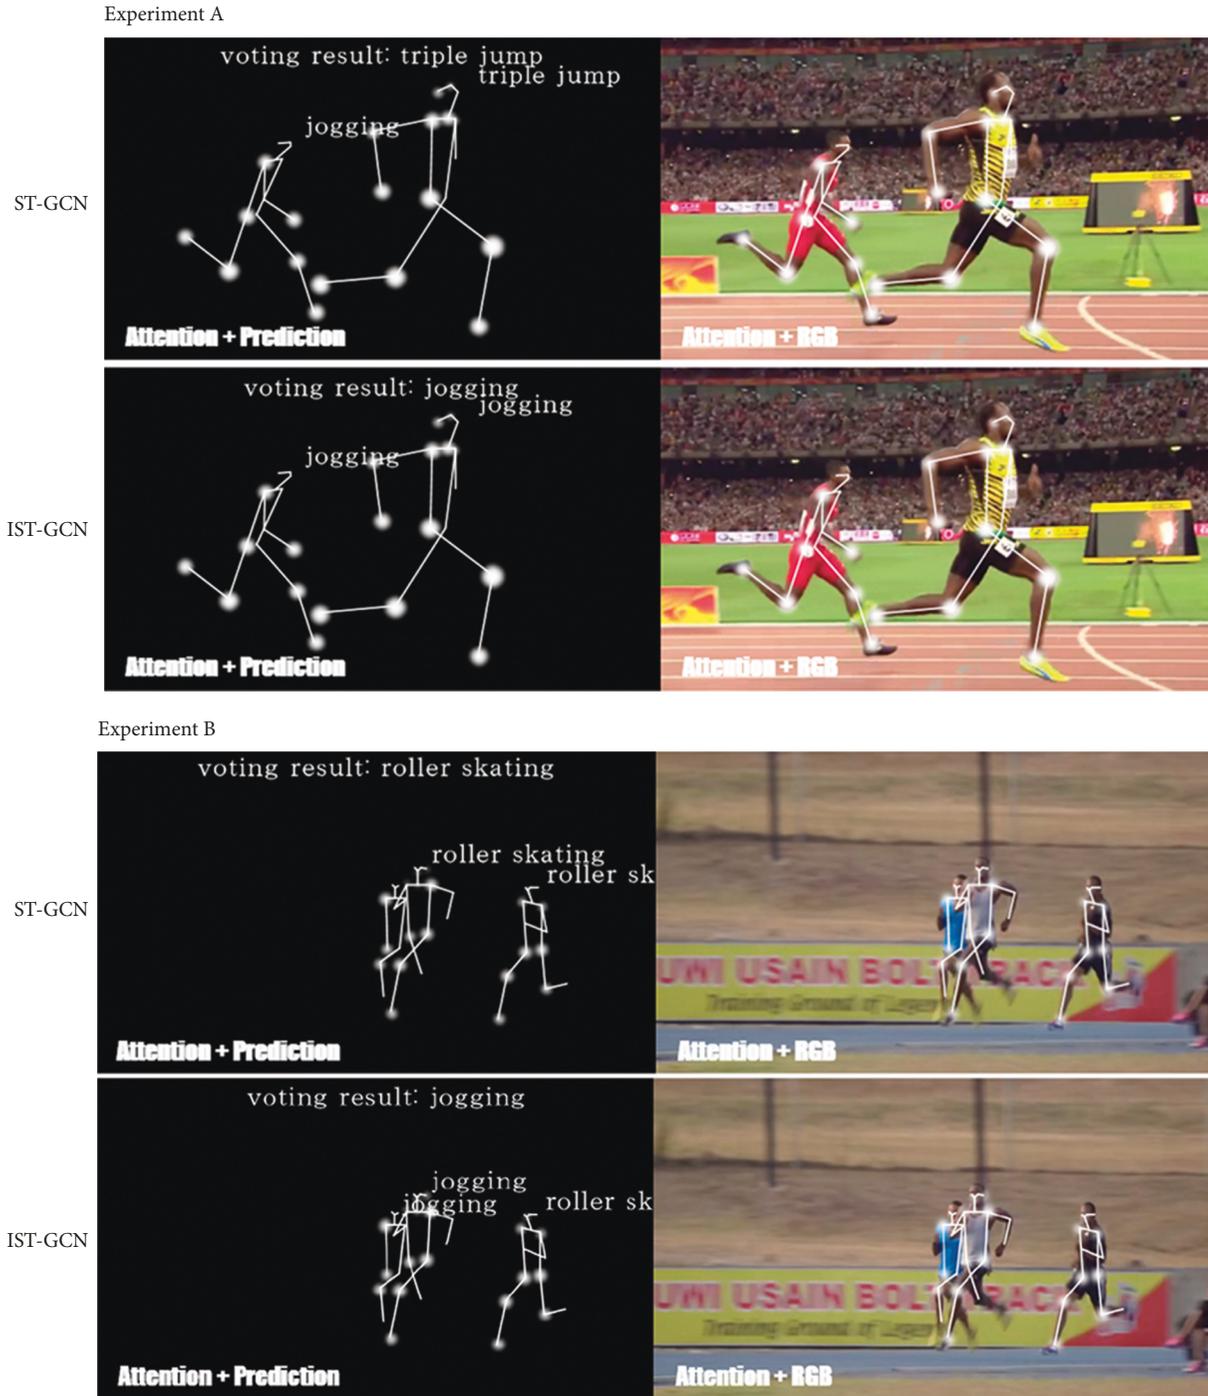

FIGURE 9: Comparison of multiperson action recognition effects between ST-GCN and IST-GCN.

ST-GCN	81	88
Ours	90	94

TABLE 4: Comparison of our method and similar optimized action recognition methods.

Method	Params(M)	Acc (%)
ST-GCN	3.03	81
AS-GCN	4.21	84
2S-AGCN	3.52	87
NAS-GCN	6.62	87
Shift-GCN	7.34	95
Ours	1.43	91

and TCN [32]. The dynamic skeleton represents a series of action recognition models based on hand-crafted labels, P-LSTM denotes a series of recurrent neural network classes, TCN denotes a series of convolutional neural network classes, and ST-GCN denotes a series of hands-on models based on graph convolutional neural networks. The above four methods and our method are validated on the NTU RGB + D dataset. The experimental data is shown in Table 3.

The experimental comparison results in Table 3 indicate that in the validation experiments of the dataset NTU RGB + D, the GCN-based action recognition method greatly outperforms other types of action recognition methods, proving that graph convolutional networks have great advantages. Our method compared with the spatial-temporalspatial-temporal graph convolutional neural network model improves the accuracy in CS metrics by 9%, reaching 90% and in CV metrics by 6% and reaching 94%.

To verify the effectiveness of our method among similar optimization methods for graph convolutional neural networks, we compared four algorithms that perform better among current variant methods for graph convolutional neural networks in terms of both number of parameters (Params) and accuracy (Acc), namely AS-GCN [33], 2S-AGCN [26], NAS-GCN [34], and Shift -GCN [35]. The validation was carried out in dataset NTU RGB + D with CS evaluation metrics, and the comparison results are shown in Table 4.

Table 4 reveals the findings of the experimental comparison. The comparison results between AS-GCN, 2S-AGCN, and NAS-GCN under the evaluation index of CS indicate that our method has better efficiency with an accuracy of 91%, both in the number of model parameters and accuracy. Given the Shift-GCN method, which introduces a more complex hyperbolic space structure, the classification accuracy is further optimized. Even though the accuracy is not as good as that of Shift-GCN, the number of model parameters in this paper adopts the inception structure to form a more compact model, and the number of model

parameters in our improved method is only one-fifth of that of the Shift-GCN method, which greatly decreases the computational cost. Furthermore, there are fewer parameters in this model than in previous ones. All of this demonstrates the efficacy of our strategy.

5. Conclusion

In this paper, we present a deep learning method for human action recognition based on the IST-GCN framework, which optimizes the recognition accuracy of the model by reducing the model parameters. First, we add a tensor rotation module in the graph convolution layer to better capture the global features of the graph task. Then we add the inception structure in the temporal convolution layer to build a multiscale temporal convolution filter to obtain temporal information in different temporal perceptual domains and reduce the arithmetic power. Finally, we perform experimental validation on the public dataset NTU RGB + D. The accuracy of CS evaluation reaches 90% and the accuracy of CV evaluation reaches 94%. The results reveal that our optimized method is robust and accurate, which not only improves the efficiency of the graph topology learning process but also greatly decreases the volume of parameters. Compared with the spatial-temporalspatial-temporal graph convolutional neural network model and similar graph convolutional optimization algorithms, the advantages of our method are outstanding.

As can be seen from the experimental results in Table 4, there is still a certain gap between the accuracy of our method and the Shift-GCN. Although we have a clear advantage in the number of parameters, accuracy is always the first assessment index as the effect of human action recognition. In the next work, we will consider using hyperbolic spatial structure to optimize the accuracy, and also ensure that the volume of parameters is small. To achieve a human action recognition model with high accuracy, few parameters, high robustness, and good stability.

There is a lack of objective and rapid methods to evaluate and extract design elements in the development of museum cultural creation products. Aiming at this, an analysis method of museum cultural creation from the perspective of cultural industry is proposed. The order relation method and entropy weight method are applied to extract cultural characteristics. The optimality evaluation of the features based on the ordinal relation method aims to make a preliminary judgment on the representation value of the feature. At the same time, the entropy weight method is introduced to make decisions among various categories of cultural features. Combining the two methods makes the feature extraction process both objective and scientific. It also ensures that the selected design elements are distinct in priority and do not conflict with each other. Taking the museum cultural creation product design based on brocade patterns in the Qing Dynasty as an example, it is proved that the proposed method can effectively extract and transform the cultural features of the cultural relics, which provides a reference for the development of cultural and creative products of the museum.

1. Introduction

Cultural creation industry, which flourished in European and American countries in the 1990s, has become a well-deserved sunrise industry in the post industrial era and under the background of knowledge economy [1]. Museum cultural creation refers to the cultural creation and development based on the specific cultural relics, culture, regional style, and spirit in the museum. Museums and their collections carry the unique culture and memory of a country, a city and a place, and become the main body of the development of museum cultural and creative industry [2].

The development and sales of cultural creation products can bring additional income to museums and play a better role in promoting and educating the culture and realizing its social value [1–3]. When designing museum cultural creation product, whether it emphasizes interest or marketing methods, the cultural relics in their collections must be used as a source of inspiration for design and innovation to ensure that cultural creation products have cultural attributes and are closely related to the culture they represent.

2. Related Works

The museum's tens of thousands of collections provide rich materials for cultural creation products. Still, the mix and stack of style elements are insufficient to design excellent cultural creation products. Whether the public can recognize the sales of cultural creation products depends on whether cultural symbols can be matched with specific design carriers in the design. In the research on the design of cultural creation products with museums as the main body, Liu et al. proposed that museum cultural creation products not only have a symbolic role but also bring a sense of public awareness by maintaining consistency with museums based on qualitative interviews and quantitative questionnaires [4]. At the same time, the higher the correlation between cultural creation products and the exhibits in the museum, the more likely it is to be accepted by the audience. Prameswari et al. explored the cognitive process of cultural creation products from the perspective of cultural schema and constructed a framework for cultural identification which contains general mode, plot input, and instantiation model [5]. Gao et al.

pointed out that the collections are systematic and can be serially designed using their associations and combinations [6].

Because of the large number and complexity of a series of cultural relics with the same theme in the collection, the extraction of relevant cultural factors is particularly important. Wang et al. proposed Yantu cultural creation products design idea by which design factors were extracted from representative cultural relics, the aspect was evaluated and screened by combining eye movement experimental correlation and Kansei engineering, and finally a set of tea sets was designed [7]. Li et al. proposed an evaluation method for cultural creation product modeling based on fuzzy set theory by which an evaluation index system for product modeling design was established through AHP. The example of fuzzy evaluation shows that this method can effectively reflect the satisfaction of users, and the analysis and screening of design elements can improve the quality of design results [8]. In addition, multiattribute decision-making [9–14] also provides an idea for museum cultural creation analysis from the perspective of cultural industry.

However, in the above research, there is still a lack of a method for evaluating and extracting design elements for collection resources. As the main body of cultural creation development, museums are ambiguous in using their resources. Therefore, in the design process, we must first excavate the cultural relics in the museum collection around a certain theme, analyze the cultural characteristics that are most consistent with the design proposition or have the most extended value, and assign cultural factors to cultural creation products. This process is usually obtained by visiting and surveying designers, and the opinions are often subjective without considering the entire creative product development process. The selected cultural characteristics, that is, the design elements derived from the connotation and externality of cultural relics, are important factors for expressing regional culture in products and indirectly determine the quality of design results.

Therefore, it is necessary to apply scientific methods to analyze and evaluate them, so as to avoid the strong subjective will of R&D personnel, resulting in the final inability of cultural and creative products to convey basic semantics.

3. Museum Cultural Creativity Process Analysis

Based on a specific cultural and creative product development theme, the cultural features are divided according to explicit and recessive factors through interviews, surveys, and collection of relevant cultural relic information, that is, the interpretation of cultural features. Secondly, taking the target user as the object of analysis, the process of using and feeling the product is explored and the perceptual vocabulary is obtained. The key to the development of museum cultural creation products is to extract cultural characteristics from the collection resources, so the early design stage needs to extract many cultural features comprehensively [15–17].

The process includes combining perceptual vocabulary and other index factors, superiority assessment of cultural characteristics, and obtaining the representative

characteristics of each category and using the entropy weight method to obtain the most valuable cultural characteristics, that is, the key dominant characteristics. Based on the feature extraction results, the transformation process of designers' design cultural features is guided. Finally, the effectiveness of the method is verified by taking a representative cultural creation product design as an example. The process of cultural feature extraction and application is shown in Figure 1.

3.1. Cultural Feature Extraction. In the extraction of design elements of museum cultural relics, it is necessary to comprehensively consider the influence of the various attributes of the cultural relics evaluated on the design results of creative products, such as the dominant features of the beauty of the product's external form and the recessive features of the cultural properties of the cultural relics themselves.

The explicit appearance of cultural relics collections carries people's intuitive experience of the past culture, such as shape, color, material, texture, pattern, and graphic decoration. The dominant characteristics of four dimensions, including shape, color, material and texture, have been established through relevant literature and field research. Recessive features provide the significant cultural value of museum cultural and creative products, which have traditional cultural connotations that general commodities do not have. Recessive features include two dimensions: semantic layer and connotation layer. They are shown in Figure 2.

The semantic level of cultural relics reflects its essential meaning and spiritual outlook, and it is a particular emotion integrated into the creation. The audience can experience it by appreciating and browsing the cultural relics; the connotative level refers to the context and allusions hidden behind the cultural relics: history and other deeper cultural information. The stories behind these cultural relics reflect the spiritual core of the times, so they need to be embodied in the design of cultural and creative products.

The evaluation indicator is very important for the implementation of this study. Evaluation indicator system refers to an organic whole with internal structure composed of multiple indexes representing the characteristics of all aspects of the evaluation object and their interrelations. Cultural feature extraction needs to establish evaluation indicators and consider the following factors:

- (1) The matching degree between users' attitudes and emotional preferences in the process of using cultural creation products and the perceptual images of cultural characteristics: a higher matching degree can avoid the problem of unclear semantics of cultural creation products, and users can feel the connotation and temperament of the collection.
- (2) Feature scalability: it refers to the elements that can provide scalability in terms of line, outline, color, and so on. The more complex and changeable the external form of cultural relics, the more evidence-based the design of cultural and creative products, and the more ornamental the final result.

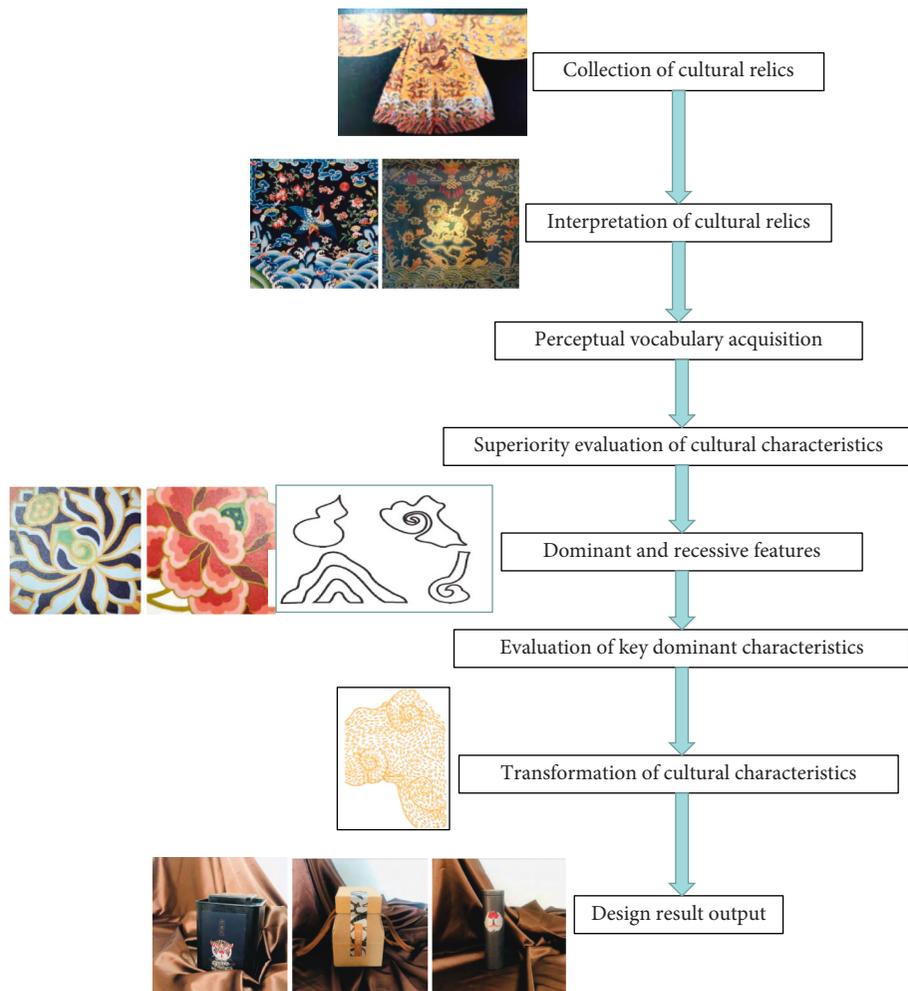

FIGURE 1: Museum cultural creativity process analysis.

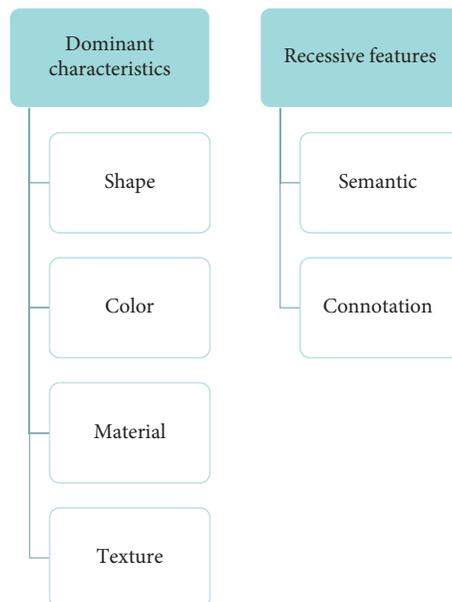

FIGURE 2: Dominant and recessive features.

- (3) Feature identifiability: it refers to whether cultural features are specific, intuitive, and easily understood by the public. The higher the identifiability, the more representative and salient the feature it is easier to reflect in creative product design and stimulate users' cultural identity.

Since the recognition and extensibility of recessive features do not have an external form, they are abstract connotations. Therefore, the evaluation of the two implicit features only considers the relevance of perceptual semantics, so scalability and identifiability will not be included in the evaluation indicators.

Finally, the explicit and implicit cultural characteristics of the cultural relics in the collection are explained, and the legend and text description of each characteristic are listed. At the same time, designers with experience in product modeling and design are invited to score the preliminarily selected series of cultural relics and cultural characteristics. They use four groups of perceptual word to score the recognizability and scalability. Scores are all measured using the Likert seven-level scale.

3.2. Cultural Feature Evaluation. Analyzing and evaluating the indicators of cultural feature can achieve the extraction of cultural feature of cultural relics in the collection. Extracting cultural features that are highly recognizable, highly scalable, and fit with the emotional preferences of cultural creation product users can ensure the rationality of cultural creation design results. The weight coefficient is determined by the subjective weighting method. Then, the overall evaluation value of each type of cultural feature is obtained, and they are sorted separately to get the ranking of the features.

Subjective weighting methods include set-valued statistical iteration method, AHP, G1 method (order relation method), and G2 method, among which AHP and order relation method are the most commonly used. The ordinal relation method improves some of the defects of the AHP. It can achieve that there is no need to construct a judgment matrix and no need to carry out a consistency check, thereby significantly reducing the amount of calculation, and the method is highly operable. The evaluation steps of order relation method [18, 19] are shown in Figure 3.

Its details are as follows:

- (1) Determine the order relationship. Under a certain evaluation criterion (or objective), the evaluation indicators x_1, x_2, \dots, x_m of cultural characteristics of cultural relics are arranged according to the importance, that is, $x_1^* > x_2^* > \dots > x_m^*$; it is considered that x_1, x_2, \dots, x_m has established an order relationship according to " $>$." Here, x_j^* is the i -th evaluation index ($i, j = 1, 2, \dots, m$) after $\{x_i\}$ is sorted according to the order relation " $>$ ". To avoid losing generality, the order relation is written as $x_1 > x_2 > \dots > x_m$.
- (2) Determine the degree of importance. Let the expert's rational judgment on the importance ratio w_{k-1}/w_k between the evaluation indexes x_{k-1} and x_k of cultural characteristics of cultural relics be

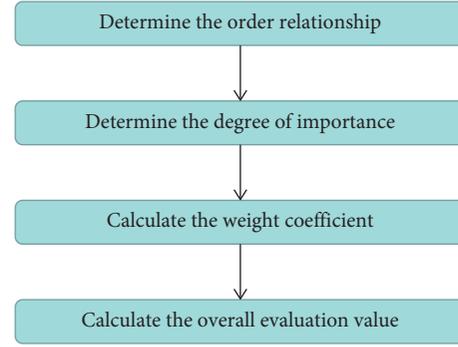

FIGURE 3: Order relation method for cultural feature evaluation.

$$r_k = \frac{w_{k-1}}{w_k}, \quad k = m, m-1, \dots, 3, 2. \quad (1)$$

For two indicators x_{k-1} and x_k , the assignment of r_k is as follows:

- (i) When x_{k-1} and x_k are equally important, $r_k = 1$
- (ii) When x_k is slightly more important than x_{k-1} , $r_k = 1.2$
- (iii) When x_k is obviously more important than x_{k-1} , $r_k = 1.4$
- (iv) When x_k is strongly more important than x_{k-1} , $r_k = 1.6$
- (v) When x_k is extremely more important than x_{k-1} , $r_k = 1.8$
- (vi) 1.1, 1.3, 1.5, and 1.7 correspond to the middle of two adjacent judgments

- (3) Calculate the weight coefficient, that is,

$$w_k = \left[1 + \sum_{k=2}^m \prod_{i=k}^m r_i \right]^{-1}, \quad (2)$$

$$w_{k-1} = r_k w_k, \quad k = m, m-1, \dots, 3, 2.$$

- (4) Calculate the overall evaluation value of each feature as follows:

$$y_i = \sum_{j=1}^n b_{ij} w_j \quad (i = 1, 2, \dots, m). \quad (3)$$

Among them, b_{ij} is the value of each evaluation index of cultural characteristics of cultural relics.

3.3. Key Dominant Features Determination. There is no absolute relationship between the optimal evaluation results of different types of cultural characteristics. If they are directly applied in a superimposed manner, the design will be unreasonable and even the elements will conflict with each other. Therefore, it is also necessary to conduct an overall evaluation of dominant features (shape, color, texture, and material), clarify which features have the most representative value, regard them as key dominant features, and focus on them in the process of cultural feature transformation.

Considering that the subjective weight calculation method inevitably has the risk of being affected by subjective factors, the weighting method is based on the difference-driven principle; that is, the objective weighting method is used to evaluate the representative value of each dominant feature. Objective weighting methods commonly include meaning square error, range, open grade, and entropy weight. This paper uses the entropy weight method [11, 12] to determine the corresponding weight coefficient according to the amount of index information, avoiding the influence of experts' subjective factors on the index weight.

Let X_{ij} be the j -th indicator for the i -th cultural feature ($i = 1, 2, 3, \dots, m; j = 1, 2, 3, \dots, n$). For a given index j , the greater the difference of X_{ij} , the more information it contains and transmits, and the greater the impact on the entire system. The steps of using the entropy weight method to evaluate the dominant feature are shown in Figure 4.

Its details are as follows:

- (1) Normalize the decision matrix as $X = (x_{ij})_{mn}$.
- (2) Calculate the entropy weight. Let the entropy weight of the j -th index be e_j , then

$$p_{ij} = \frac{x_{ij}}{\sum_{i=1}^m x_{ij}},$$

$$e_j = \frac{-1}{\ln(m) \sum_{i=1}^m p_{ij} \ln(p_{ij})}, \quad (4)$$

where p_{ij} is the feature proportion of the i -th evaluation object of the j -th indicator.

- (3) Calculate the objective weight of each indicator element as

$$w'_j = \frac{(1 - e_j)}{\sum_{j=1}^n (1 - e_j)}, \quad j = 1, 2, \dots, n. \quad (5)$$

- (4) Calculate the overall evaluation value of each dominant feature as

$$y'_i = \sum_{j=1}^n b_{ij} w'_j, \quad i = 1, 2, \dots, m. \quad (6)$$

3.4. Cultural Feature Transformation. The reason why cultural relics can continue and spread cultural values is that it has a symbolic function for its characteristics, which together constitute the cultural symbols of cultural relics. Cultural feature extraction for cultural relics in museum collections is to reconstruct the symbols representing the semantics of cultural relics and apply them to the development of cultural and creative products.

Step 1. Obtain the optimal results of key dominant features by the entropy weight method and use them as the core elements of cultural and creative product modeling. After feature variation, extension, and other operations, and at the same time, cross and combined experiments with different

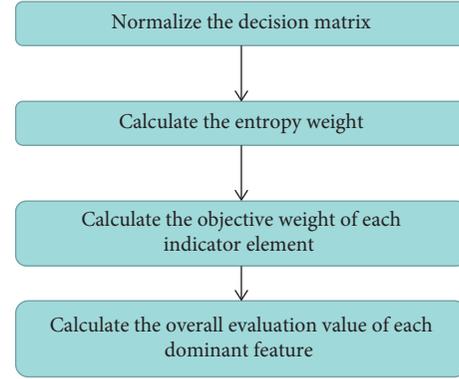

FIGURE 4: Entropy weight method to evaluate the dominant feature.

dominant feature optimization results are carried out to form product design schemes.

Step 2. Use the methods of metaphor, symbolism, and exaggeration to combine invisible features with the use and interaction of products and integrate them into the design elements of cultural and creative products as an added value.

4. Case Study

Based on the above processes and methods, we apply the proposed method to actual design cases for verification. Buzi pattern of Nanjing Yunjin in the Qing Dynasty is taken as the development object of cultural creation products and used to design daily necessities. After on-site visits and investigations, six cultural relics in the collection are selected, as shown in Figure 5. The cultural features of cultural relics are interpreted according to the meaning of explicit and implicit characteristics. For example, the cultural features of the sample cultural relics can be split and named as the shape feature F_{11} , the color feature F_{12} , the texture feature F_{13} , the material feature F_{14} , the implicit semantic feature F_{15} , and the connotation feature F_{16} . A table of interpretations of cultural characteristics of cultural relics in the collection is established for subsequent evaluation, which is shown in Figure 5.

In the early design stage, it is necessary to analyze the attitudes and perceptual images in the target population (such as history lovers, tourists, collectors) towards cultural creation products to provide a reasonable basis for evaluating and extracting cultural characteristics. By consulting books and literatures, we collected 346 words from user comments on the online platform that could express target population's perceptual attitudes toward cultural creation products, remove similar and repeated words, and preliminarily select 80 effective words, including positive and negative attitudes.

K-means cluster analysis method [20, 21] is used to divide the perceptual vocabulary into four categories, and the samples with the closest Euclidean distance to the center are selected according to their classification. The four groups of word pairs are obtained, respectively, as shown in Table 1.

The various cultural characteristics of cultural relics are evaluated by the order relation method. The four groups of perceptual word pairs and the degree of feature recognition

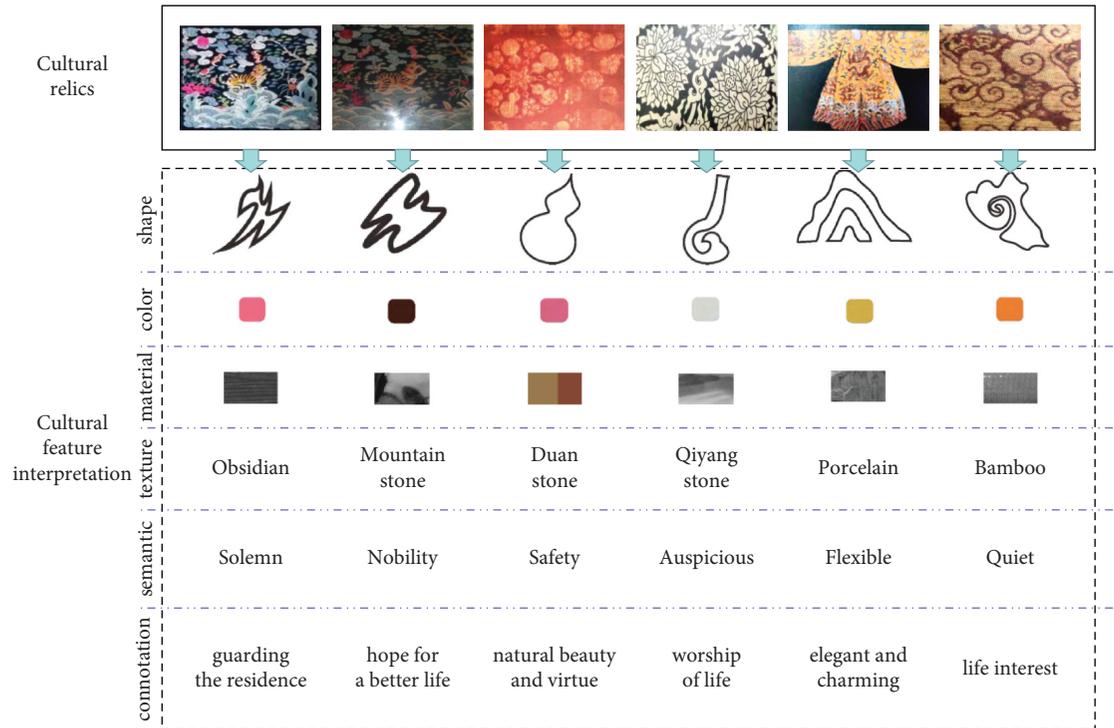

FIGURE 5: Cultural relics and their cultural feature interpretation.

and the degree of feature expandability are recorded as X_1, \dots, X_6 in turn. As mentioned above, 20 designers with experience in cultural and creative product design were invited to score each characteristic element in the cultural characteristic definition table according to 6 indicators.

For example, the experts' scores on the morphological and cultural characteristics of 6 cultural relics were calculated by the average and variance. The ranking of the evaluation indicators by experts is as follows: mild/incisive > feature recognition > feature expandability > flamboyant/steady > masculine/feminine > delicate/dignified, establishing an order relationship: $X_2 > X_5 > X_6 > X_1 > X_4 > X_3$; the ratio is $r_2 = 1.4$, $r_3 = 1.0$, $r_4 = 1.5$, $r_5 = 1.2$, and $r_6 = 1.2$. Therefore, the weight coefficients $w_1 = 0.1312$, $w_2 = 0.2751$, $w_3 = 0.0913$, $w_4 = 0.1093$, $w_5 = 0.1971$, and $w_6 = 0.1972$ are obtained.

Based on the screened scoring results, the overall evaluation value of the morphological characteristics of each cultural relic is obtained as $y_1 = 4.8955$, $y_2 = 4.1889$, $y_3 = 4.3645$, $y_4 = 3.9322$, $y_5 = 3.1666$, and $y_6 = 3.5731$. The optimality ranking is $F_{11} > F_{31} > F_{21} > F_{41} > F_{61} > F_{51}$, indicating that the cultural relics of the brocade tiger pattern in Qing Dynasty have the best evaluation results of morphological characteristics and are most suitable for use in the design of cultural creation products.

In the same way, the rest of the dominant cultural characteristics (color, texture, and material) are evaluated and processed using the ordinal relation method. When evaluating the implicit features, the two indicators of recognition and scalability are omitted. Only the matching degree between the semantics and connotation of cultural relics and the four sets of perceptual word pairs is considered. The assessment results for all cultural features are shown in Table 2.

The entropy weight method is used to evaluate the four dominant features and analyze their importance. First, the expert scoring results of the six sample cultural relics are averaged according to each feature, and the overall evaluation scores of the features shown are obtained by rearrangement as shown in Table 3.

The weights of the six evaluation indicators can be obtained as follows: $w'_1 = 0.1072$, $w'_2 = 0.1471$, $w'_3 = 0.1263$, $w'_4 = 0.1204$, $w'_5 = 0.1002$, and $w'_6 = 0.3962$. Then, the overall evaluation value of each dominant feature can be obtained: $y'_1 = 3.9234$, $y'_2 = 3.7228$, $y'_3 = 3.6808$, and $y'_4 = 3.8664$. The order of dominant features is obtained: shape > material > texture > color. Therefore, shape and material are the key dominant features, and the corresponding features F_{11} and F_{54} are the most worthy of application in the design of cultural creation products.

In the design and application of cloud brocade patterns in the Qing Dynasty, the first is to carry out design positioning, that is, select reasonable products and analyze the product category, actual function, target population, and so on. Then, the brocade pattern of the Qing Dynasty is organically integrated with the product as a cultural and artistic symbol, so as to increase the cultural added value of the product itself, realize the functional transformation of brocade art in the contemporary era, and realize the inheritance and promotion of Chinese culture. Based on the results of cultural feature extraction, an artistic and creative product of daily necessities and its packaging design is developed for the museum. While reflecting the theme, it expresses the long history of Chinese traditional culture, so it is named "white tiger" series design, and poster design is carried out to promote the design as shown in Figure 6.

TABLE 1: Four groups of word pairs.

Type no.	Word pairs
1	Flamboyant/steady
2	Mild/incisive
3	Delicate/dignified
4	Masculine/feminine

TABLE 2: The assessment results for all cultural features.

Cultural feature	Assessment result
Shape	$F_{11} > F_{31} > F_{21} > F_{41} > F_{61} > F_{51}$
Color	$F_{22} > F_{32} > F_{12} > F_{42} > F_{52} > F_{62}$
Material	$F_{53} > F_{13} > F_{23} > F_{63} > F_{33} > F_{43}$
Texture	$F_{34} > F_{24} > F_{44} > F_{64} > F_{14} > F_{54}$
Semantic	$F_{15} > F_{25} > F_{55} > F_{45} > F_{65} > F_{35}$
Connotation	$F_{26} > F_{16} > F_{66} > F_{36} > F_{56} > F_{46}$

X_5	3.7833	3.8541	4.1012	3.8002
X_6	4.022	3.7044	3.4567	4.0002

FIGURE 6: The poster design of “white tiger” series design.

5. Conclusion

Brocade patterns in the Qing Dynasty have high aesthetic value and cultural value and are very valuable Chinese traditional cultural heritage. In the new era, we need to promote and inherit this traditional art by enhancing the spiritual function and artistic modernity. Taking the four grade tiger pattern of military officer as an example, we extract the artistic elements and make secondary artistic innovation and regenerate the design and application of the brocade pattern of the Qing Dynasty in combination with modern design and current aesthetics, so as to better inherit this excellent cultural heritage and make contemporary people better understand the brocade culture. At the same

time, the design application of “white tiger” series design also reflects the organic integration of tradition and modernity, provides new ideas for the inheritance of traditional culture and the improvement of the added value of modern products, and can be used as a reference for the design of visual cultural and creative products.

Using museum collection resources to develop and market cultural creation products can present culture and exhibition content vividly to the public, which are the common needs of museums and society. In the designing of cultural creation products for a certain theme, the cultural symbols need to be incorporated into the shape and the emotional preferences of the target group need to be fit. Therefore, it is necessary to integrate perceptual factors into assessing cultural relic features.

The cultural feature application is based on the feature extraction results. Some features are taken as the key content to be expressed in the design, and relying on human-computer interaction, the “lively and flexible” semantic features can be shown by the designed products. The final design example proves that the order relation entropy weight method can effectively extract and transform the cultural features of the cultural relics, which provides a reference for the development of cultural and creative products of the museum. With the continuous development of artificial intelligence and many other technologies, the evolution of its enabling interactive experience from graphical interactive interface to natural interactive interface has become an inevitable trend. Museum cultural creation design research also needs to actively explore new research fields under artificial intelligence, emotional computing, and emotional recognition from the perspective of interaction design and experience design.

At present, sports dance teaching still tends to “demonstration” training. Students have limited time and space for autonomous learning, and their enthusiasm for participation is not high, which leads to a decline in classroom learning efficiency. In view of this, video teaching has become popular in sports dance classrooms, providing a new model for sports dance teaching. Video recommendation is particularly important for the improvement of teaching quality. A sports dance video recommendation method based on style is proposed. The factorization machine model is used to combine features and process high-dimensional sparse features, the deep neural network model is adopted as the value function network of the deep Q-learning algorithm, and the deep Q-learning algorithm is used as the decision function to solve the recommendation accuracy and diversity question. Through the application experiment of sports dance video recommendation, it is resulted that the recommendation accuracy of the proposed model is slightly higher than that of traditional recommendation algorithm and the recommendation diversity is obviously better than that of traditional recommendation algorithm. The advantages and feasibility of the proposed model are verified.

1. Introduction

Sports dance is a way of sports, which needs refining, organization, arrangement, and technical processing. Its main mean of the expression is to show the flexible footwork and beautiful dance posture of various rhythms of the human body, and express feelings and reflect social life through this artistic form [1–3]. It is mainly composed of 10 dance types in two series: modern dance and Latin dance. With the progress of society, there has been an upsurge of national fitness, and there has been an upsurge of popularizing and popularizing sports dance in the society. Due to the accelerated pace of life today, many people are busy with work and hope to enrich their spare time activities. However, because dance learning is usually taught by participating in training courses, many people do not have much time to learn. Therefore, it has become a trend to teach students sports dance by recording videos and video recommendations.

The traditional manual teaching process of sports dance is mainly divided into two parts: teachers’ explanation of theoretical knowledge and teaching purpose, learning, and guidance of practical courses [4–7]. The second part is the focus of learning. It includes teachers’ dance demonstration performance and explanation, correct requirements and practice of dance posture, decomposition practice of turning step and flower step, mutual cooperation between male and female partners, dance practice, dance appreciation, harmonious practice of music, etc.

The sports dance video recommendation system actually uses the existing computer technology to present the process of sports dance teaching to students in the form of video recommendation and applies the recorded sports dance teaching video course to real teaching [5, 7]. The design and development of sports dance teaching video recommendation system make the teacher’s teaching content displayed in the form of video. Through the real-time recording of the

teacher's dance scene, students can learn more clearly and quickly. At the same time, it also plays a positive role for students to watch the teaching process repeatedly and take care of students at different levels. In addition, through computer technology, the video teaching of sports dance can also be presented to the students in the form of forums or discussion groups so that the students can no longer learn at a single point, but can learn and communicate with other students in time through the network, learn from each other's strengths, and make up for their weaknesses, to promote communication among students, improve students' learning interest, and stimulate students' learning enthusiasm [7].

It can be seen that sports dance video recommendation is of great significance to improve the quality of sports dance teaching. The research on sports dance video recommendation method not only solves the learning constraints of time and space in the process of sports dance teaching but also makes the teaching process reproducible and decomposed, and provides support for the development of video teaching.

2. Related Works

Recommendation systems [8, 9] have gradually produced a variety of solutions and become an independent discipline now. Many achievements have been achieved in industry applications. The recommendation system itself analyzes and studies the behavioral preferences of users through data information mining and establishes a user-specific interest model, thereby recommending information that may satisfy their interests. Traditional recommendation system algorithms can be roughly divided into three types: collaborative filtering recommendation, content-based recommendation, and hybrid recommendation.

Although traditional recommendation algorithms can solve most information filtering problems, they cannot solve the problems of data sparseness, cold start, and repeated recommendation problems. In recent years, many companies have used deep learning, multi-arm gambling machines, and other algorithms to improve and have obtained good recommendation results in response to the above issues. YouTube [10] used deep learning for video recommendation prediction for the first time in the recommendation system. It successfully filtered and extracted the video content users were interested in from the large-scale data volume and recommended it. Acar et al. [11] proposed an offline evaluation method and controlled experiment based on streaming data. Karatzoglou et al. [12] systematically proposed to apply deep learning to traditional recommendation systems, adding deep learning to the conventional content recommendation and collaborative filtering recommendation methods to deal with recommendation prediction of large-scale data volume. Therefore, deep learning has become a hot spot in current recommendation system research.

At present, most of the recommendation algorithms are based on the static recommendation process and generate a fixed recommendation strategy by collecting and processing a large amount of data information, such as multicriteria

decision-making method [13–22], which has a significant improvement in solving the diversification of information recommendation. The problem of cold start is also unable to adapt to the short-term interest changes of users and make effective information recommendations. Therefore, many scholars began to try to use reinforcement learning [23] to solve the problems in the recommendation system. Reinforcement learning is a learning algorithm based on the interaction of the environment. It has developed independently from the two fields of animal behavior research and optimal control. It has been abstracted and formalized as a Markov decision process problem. Later, through the study of many scientists, a relatively complete system, approximate dynamic programming was formed. Reinforcement learning [23] is a dynamic interactive learning strategy algorithm. Therefore, reinforcement learning is used to solve cold start problems and the inability to adapt to users' short-term interest recommendation in recommendation algorithms. Taghipour et al. [24] first proposed to use the Q-learning algorithm combined with web page information to solve the problem of web page recommendation. However, the Q-learning learning algorithm cannot effectively solve the recommendation task of the Markov decision process with large state space and action space. Choi [25] proposed a biclustering learning algorithm to alleviate the above problems, but the effect was not expected. The deep Q-learning deep reinforcement learning algorithm [26] used the value function estimation method, and it solves the problems existing in the Markov decision-making process [27] by iterating the Bellman equation to achieve convergence to the optimal value function. The proposal of policy gradient solves the problem that the value is difficult to calculate, and this method can directly learn the policy.

3. Markov Decision Process

Markov decision process is a mathematical model of sequential decision. It is used to simulate the randomness strategy and return that can be realized by agents in the environment where the system state has Markov nature.

Markov decision process is built based on a set of interactive objects, that is, agents and environment. The elements include state, action, strategy, and reward. In the simulation of Markov decision process, the intelligent experience perceives the current system state and acts on the environment according to the strategy, so as to change the state of the environment and get rewards. The accumulation of rewards over time is called reward.

The theoretical basis of Markov decision process is Markov chain, so it is also regarded as a Markov model considering action. The Markov decision process established in discrete time is called "discrete-time Markov decision process"; on the contrary, it is called "continuous time Markov decision process." In addition, Markov decision process has some variants, including partially observable Markov decision process, constrained Markov decision process, and fuzzy Markov decision process [27].

The factorization machine algorithm is used to combine features and deal with high-dimensional sparse features,

effectively learn the cross-hidden relationship between features, and then use the deep Q-learning algorithm to solve the optimal value of the recommendation decision. First, the core point of sports dance video recommendation is to simulate the recommendation process as a Markov decision process. The initial state of the agent is s_0 , and then, an action a_0 is selected from the action set to execute. After execution, the agent will follow the action a_0 . The agent s_0 changes to the next state s_1 according to the reward function of action a_0 , and then, the action a_1 is selected, and the above steps are continuously looped until a strategy chain reaches the reward accumulation value, which is selected.

Combined with sports dance video recommendation, the Markov solution process can be more refined. The user and the recommendation system can be simulated as two dynamic interactive objects, as shown in Figure 1. In a time slice t , the recommendation system obtains the user's viewing record s_t , trains the action set A through the reward function of s_t , and then selects the sports dance video with the highest reward value in A to recommend to the user, obtain the user's rating for the video, and put it into the experience pool to continue training the recommendation strategy.

In general, the Markov decision process is a Markov reward process with decision making, which means that all states have Markov properties, that is, when a random process is given a current state and all past states. In the case of the conditional distribution probability of its future state depend only on the current state, the Markov property can be expressed in mathematical form as a state s_t has Markov property if and only if it satisfies

$$P[S_{t-1}|S_t] = P[S_{t+1}|S_1, \dots, S_t]. \quad (1)$$

A Markov decision process can consist of quintuples $\langle S, A, P, R, \gamma \rangle$.

S is the set of all environmental states, and $s_t \in S$ represents the current Agent's state s_t at time t . The evaluation of sports dance video is used for testing, and s is defined as $s_t = \{\text{movie}_t^1, \dots, \text{movie}_t^n\}$, here denoted as the top n videos watched and rated by the user.

A is the set of limited executable actions of the agent, and A is the set of all videos recommended to the user. The text $a_t \in A$ is represented as the recommended action obtained by the agent through the reward function training at time t , that is, the sports dance video advised by the recommendation system agent to the user through s_t at the current time.

P is the state transition probability matrix, and the mathematical formula is as follows:

$$P_{ss}^{a_t} = P[S_{t+1} = s' | S_t = s, A_t = a_t], \quad (2)$$

where S_t represents the state at time t , S_{t+1} represents the state at time $t + 1$, and A_t represents the actions of different videos recommended by the recommendation system agent to the user at time t . When the time t ends, it turns to time $t + 1$, and then, the recommendation system agent will update the state S_{t+1} at time $t + 1$ to $s_{t+1} = \{\text{movie}_t^1, \dots, \text{movie}_t^n, a_t\}$.

R is the reward function of the current Markov reward process [10]. At time t , state s_t is the reward expectation obtained by A entering state s_{t+1} . The mathematical formula is defined as follows:

$$R_s = E[R_{t+1}|S_t = s]. \quad (3)$$

For the videos recommended by the recommendation system agent, users have different scores of movie ratings to generate various movie feedback, so at time t , the recommendation system agent will obtain instant rewards according to varying feedback as $R_t = (s_t, a_t)$. γ is the discount factor, and its value range is generally specified as $\gamma \in (0, 1)$. The discount factor is used to adjust the impact of future rewards on the current accumulated rewards. If $\gamma = 0$, it means that the recommendation system agent pays more attention to the earned reward in time; when $\gamma = 1$, it means that the recommendation system agent pays more attention to the long-term accumulated reward.

From the above definition, it can be concluded that the task of the recommendation system agent is to achieve the learning process of maximizing the reward function through the optimal recommendation strategy [11]. At time t , the mathematical definition of reward G_t is as follows:

$$G_t = R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \dots = \sum_{k=0}^{\infty} \gamma^k R_{t+k+1}. \quad (4)$$

4. Algorithm

4.1. Concepts. One-hot coding combined with the FM model is used to preprocess the data, and then, the deep Q-learning algorithm in deep reinforcement learning is used as the sports dance video recommendation algorithm. The deep Q-learning algorithm is based on the approximate iteration of the value function. It uses a deep neural network as a Q-value network to extract complex features. One-hot encoding can represent the discrete features in the dataset with numbers. Still, one-hot encoding will introduce the problem of sparse features, so the factorization machine algorithm is used to solve the problem of difficulty in dealing with combined features under the condition of light features.

The ultimate goal of using the deep Q-learning algorithm for a sports dance video recommendation is to obtain the optimal recommendation strategy by maximizing the long-term cumulative reward. The first step is to perform feature extraction on the original data and use the user's rating for the movie as the reward value. Figure 2 shows the corresponding original data structure. Due to the existence of discrete features in the original data set, the deep Q-learning algorithm cannot directly use it as the input data of the value function network.

Therefore, one-hot coding encodes the discrete features and expands the discrete features into the Euclidean space. The values of discrete features can correspond one-to-one with points in Euclidean space. From the aspect of model training, not only can the distance between different features be calculated more reasonably, but also can the nonlinear ability of the model be improved. The principle of one-hot

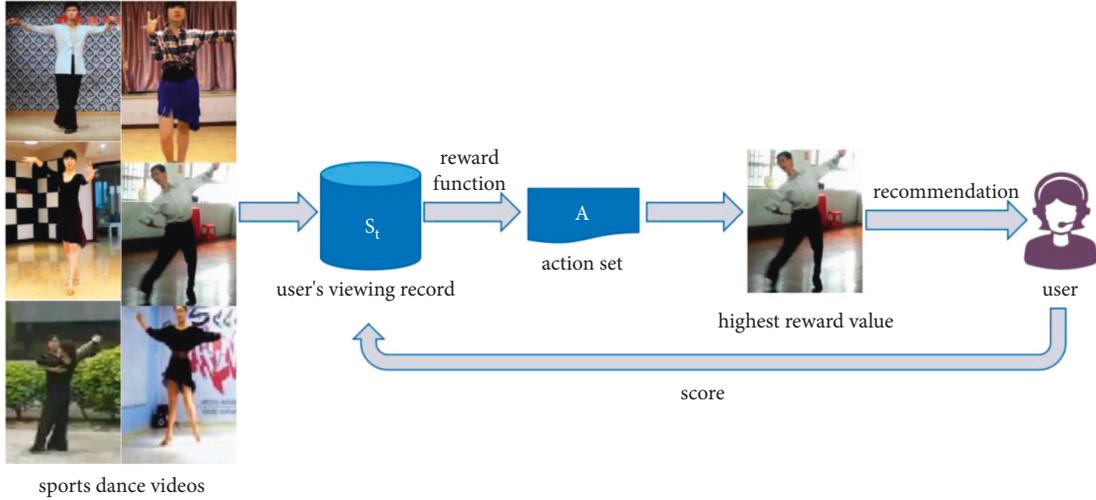

FIGURE 1: Reinforcement learning basic architecture.

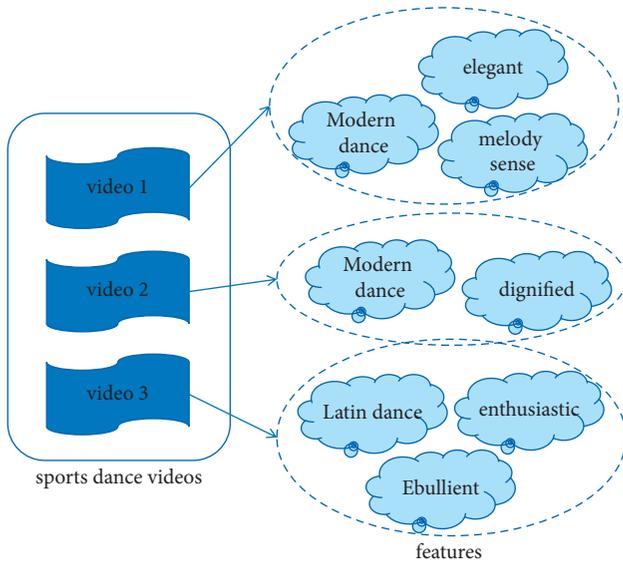

FIGURE 2: Sports dance video and its features.

encoding is to use the N -bit status register to encode n states with different codes, each attribute has its independent register bit, and only one bit indicates whether it is valid or not at any time. As shown in Table 1, the feature set is processed by using one-hot encoding.

Since one-hot encoding will introduce the problem of feature sparseness, which will cause the dimensional disaster of the neural network, the factorization machine algorithm is used to perform further feature processing on the feature set. A second-order polynomial model is used. A combination of features x_i and x_j is used, where $x_i x_j$ represents the combined feature, x_i is the value of the i^{th} feature, and n represents the number of features of the sample. w_0 , w_i , and w_{ij} are model parameters, respectively. The second-order polynomial model is as follows:

$$y(x) = w_0 + \sum_{i=1}^n w_i x_i + \sum_{i=1}^{n-1} \sum_{j=i+1}^n w_{ij} x_i x_j. \quad (5)$$

Matrix decomposition is used to solve w_{ij} . It is known that in model-based collaborative filtering, the user matrix and the sports dance video matrix can form a unique rating matrix. For each user and video, a hidden vector can be used to represent it. Different users and videos are represented as different two-dimensional vectors. The dot product of the user vector and the movie vector is the user's rating of the movie in the matrix.

It can be seen from the definition that for any $N \times N$ real symmetric matrix, this real symmetric matrix has N linearly independent and can be orthogonalized to get a set of eigenvectors, which are orthogonal and have a module of 1. So, the real symmetric matrix A can be decomposed into

$$A = \zeta \Lambda \zeta^T, \quad (6)$$

where Λ is defined as a real diagonal matrix, and Q is defined as an orthogonal matrix.

Similarly, suppose there is asymmetric matrix W consisting of all the current quadratic parameters w_{ij} ; in that case, this matrix can be decomposed in the form of $W = V \Lambda V^T$, where the j th column of V is defined as the latent vector of the j th dimension feature. The inner product of the latent vector corresponding to x_i and the latent vector corresponding to x_j is equal to the cross-term coefficient of the feature components x_i and x_j , so each parameter of the symmetric matrix can be defined as $w_{ij} = \langle v_i, v_j \rangle$.

The deep Q-learning algorithm uses a deep neural network with a weight parameter of θ as the network model of this deep neural network's action-value function. The weights and biases are represented by θ and γ , respectively. The loss function of the deep neural network model is as follows:

$$L_i(\theta_i) = E \left[\left(r + \gamma \max_{a'} Q(s', a', \theta_i) - Q(s, a, \theta_i) \right)^2 \right]. \quad (7)$$

The structure diagram of the deep neural network is shown in Figure 3.

It can be seen from the structure diagram that the deep neural network consists of an embedding layer and three

TABLE 1: Sports dance video feature set based on one-hot encoding.

Sports dance videos	Features						
	Modern dance	Latin dance	Elegant	Melody sense	Dignified	Enthusiastic	Ebullient
Video 1	1	0	1	1	0	0	0
Video 2	1	0	0	0	1	0	0
Video 3	0	1	0	0	0	1	1

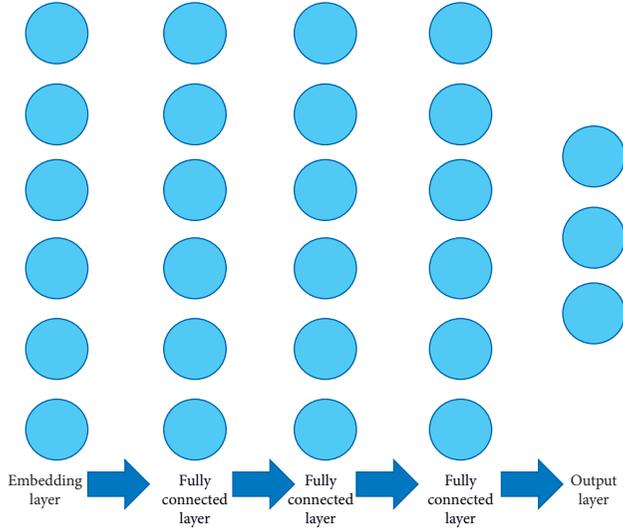

FIGURE 3: Deep neural network structure.

fully connected layers, and each neuron will use the activation function for calculation before outputting the result. Sigmoid function is used as the activation function of the deep neural network to meet the requirements of effectively learning sparse features.

To facilitate the calculation, the number of neuron nodes in the embedding layer and the fully connected layer is set to the exponential power of 2. The depth of the network is increased in multiples of 2 in turn. Assuming that the number of sports dance videos in the recommendation system is M , the number of output nodes is M , and the output node will output the predicted reward value of each video after it is recommended.

4.2. Deep Q-Learning Algorithm for Sports Dance Video Recommendation. Due to using the same network to generate the following target Q and estimate the current Q , it can lead to oscillations and even divergence. Therefore, deep Q-learning uses experience replay and target network methods to solve this problem.

Experience playback means that during the interaction between the agent and the environment, the experience is stored in the experience pool D . Each training will randomly sample a small batch of data from D for training to eliminate the correlation between samples. Its function is to destroy the correlation between the series and solve the correlation between the Q -value and the target Q -value. The target network does not interact with the environment, nor is it updated at every step, only at certain stages. Each update assigns the current network parameters directly to it.

The process of the deep Q-learning movie recommendation algorithm is as follows:

- (1) Initialize experience pool D with capacity N , which is used for historical experience recovery. Use the deep neural network as the network model of the current predicted action-value function Q value, and initialize the weight parameter θ of the network model. Set the number of rounds of model training as M , the maximum number of training times the agent can perform. Initialize the input of the Q -value network model, information the scoring matrix processed by the FM algorithm, and calculate $\varphi_1 = \varphi(s_1)$.
- (2) Repeat the single empirical trajectory time step from $t = 1$ to T .
- (3) Repeat the sports dance video recommendation training for each user from $u = 1$ to U .
- (4) Take the user's initial rating as the initial movie recommendation state S , and select a random movie plan with probability ε for recommendation.
- (5) If the recommended movie is a movie that the user likes, update the current movie recommendation state as

$$S_{t+1} = S_t \cup a. \quad (8)$$

- (i) Then set the reward to $r = 1$, and calculate the input sequence as follows:
- (6) If the recommended movie is a movie that the user likes, update the current movie recommendation status to $S_{t+1} = S_t$, set the reward to $r = 0$, and add $(\varphi_t, a, r, \varphi_{t+1})$ to the experience pool D , and compute the input sequence $\varphi_{t+1} = \varphi(S_{t+1})$ for the next time step.
- (7) Randomly sample a small batch of stored samples $(\varphi_t, a, r, \varphi_{t+1})$ from the experience pool D .
- (8) If the current state is an end state, set $y_i = r_i$, if the current state is a nonend state, then set

$$y_i = r_i + \gamma \max_{a'} Q(\phi_{j+1}, a', \theta). \quad (10)$$

- (9) Calculate loss function using gradient descent algorithm

$$L_i(\theta_i) = E \left[\left(r + \gamma \max_{a'} Q(\phi_{j+1}, a', \theta) - Q(s, a, \theta_i) \right)^2 \right]. \quad (11)$$

- (10) Output value function network.

The flow chart of the algorithm is shown in Figure 4.

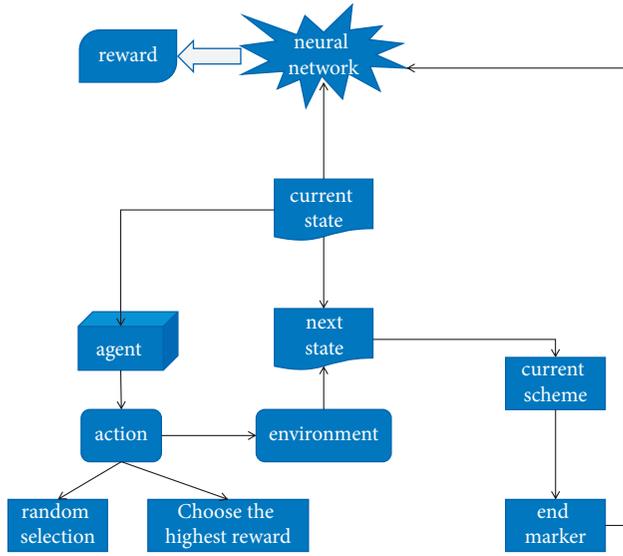

FIGURE 4: Sports dance video recommendation algorithm.

5. Case Study

Experimental hardware environment is one PC, 8 GB memory, and 256 GB hard disk. The operating system of the testing platform is Windows 10, the programming language is python language, and the programming is carried out on the Jupyter Notebook. The experiment uses the dataset of sports dance video evaluation, including 10000 rating records for 100 sports dance videos by 400 users (teachers and students).

To verify that the video recommendation algorithm based on deep reinforcement learning is better than the traditional collaborative filtering algorithm, we will compare the deep Q-learning algorithm (DQLA) and the collaborative filtering algorithm (CFA) on recommendation accuracy and video recommendation diversity at the same dataset and then analyze the two algorithms.

The recommendation accuracy in the experiment is defined as the proportion of users' scores for sports dance videos, and the diversity of videos recommendations in the experiment is defined as the proportion of the types of recommended videos in the total types.

According to the experimental design, the accuracy of the two algorithms is compared. The comparison results are shown in Table 2.

A comparison of recommendation accuracy of DQLA and CFA is shown in Figure 5.

It can be seen from the comparison chart that when the recommendation number of sports dance videos is less than 45, the accuracy of DQLA is slightly lower than that of the traditional CFA. Still, its recommendation effect shows an upward trend. When the recommendation number of sports dance videos is more than 45, the recommendation accuracy of DQLA is obviously better than that of CFA; when the peak of the optimal number of recommendations is reached, the

TABLE 2: Recommendation accuracy of DQLA and CFA.

Number of sports dance videos	Recommendation accuracy	
	DQLA	CFA
15	0.1609	0.2122
25	0.1768	0.2036
35	0.1877	0.2001
45	0.1956	0.1944
55	0.2066	0.1912
65	0.2102	0.1867
75	0.1978	0.1841
85	0.1861	0.1812

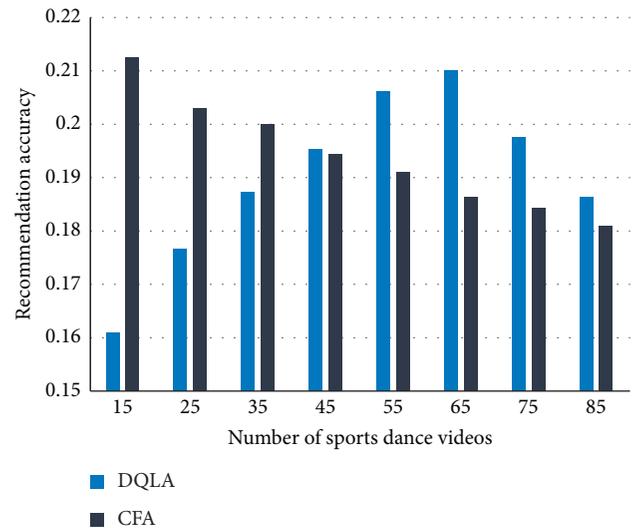

FIGURE 5: A comparison of recommendation accuracy of DQLA and CFA.

recommendation accuracy gradually decreases, but it is also higher than the recommendation accuracy of CFA under the same conditions. This shows that under the premise of increasing the number of video recommendations, the recommendation accuracy of DQLA is significantly higher than that of CFA. Therefore, it is proved that using the deep Q-learning algorithm of deep reinforcement learning for sports dance video recommendation is beneficial to improve the accuracy of recommendation.

According to the experimental design, the recommendation diversity of the two algorithms is compared. The comparison results are shown in Table 3.

A comparison of recommendation diversity of DQLA and CFA is shown in Figure 6.

It can be seen from the comparison chart that DQLA always has a higher diversity ratio of sports dance video recommendation than CFA in the sample interval, and its diversity recommendation effect has been on the rise. This shows that when the deep Q-learning algorithm of deep reinforcement learning is used for sports dance video recommendation, the diversity effect of video recommendation has been significantly improved.

25	0.4801	0.4388
35	0.4878	0.4431
45	0.4892	0.4492
55	0.4913	0.4551
65	0.4934	0.4580
75	0.4966	0.4652
85	0.4981	0.4698

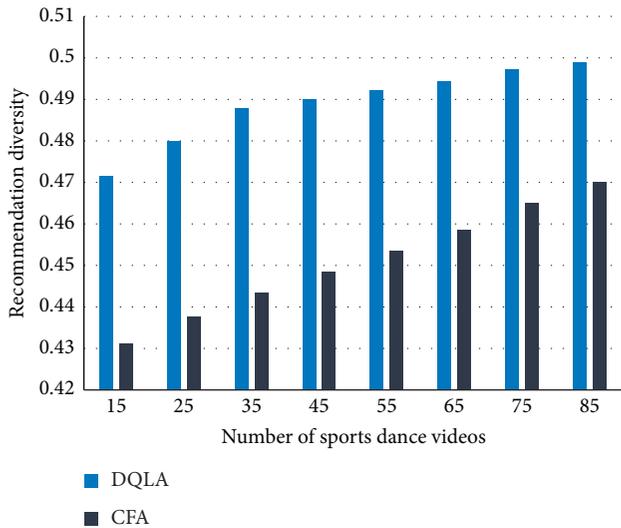

FIGURE 6: A comparison of recommendation diversity of DQLA and CFA.

6. Conclusion

By using the deep reinforcement learning method, the deep Q-learning algorithm is used for sports dance video recommendation training and compared with the collaboration filtering algorithm in the accuracy and the diversity of sports dance video recommendation. The comparison results show that the accuracy of sports dance video recommendation is better than the traditional collaboration filtering algorithm when the number of sports dance video recommendation reaches a specific number, and the diversity of sports dance video recommendation is obviously better than that of the collaboration filtering algorithm. It can be proved that the application of deep reinforcement learning to sports dance video recommendation can effectively solve the problems of inaccurate recommendation of traditional recommendation algorithms and single recommendation content. At the same time, the deep reinforcement learning algorithm can better learn the user's interest characteristics to provide a better video recommendation solution for the user. However, the deep Q-learning algorithm cannot solve the cold-start video recommendation problem. Therefore, next we will be to study how the recommendation system can still accurately locate the user's video of interest when there is no user's video viewing history data.

Data Availability

The dataset can be accessed upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

As an emerging multimedia technology, VR technical ability has gradually become the discuss direction of many scholars. The 3d virtual space created by computer allows users to get the feeling and depth of the real environment in VR interaction.. The application of VR technical ability in relevant disciplines that integrate both ideological and political aspects is to promote ascension of the limitations of time and space in the teaching process, to add more impetus to politics, and to continuously innovate ideas in academies and universities. The diversification of political teaching models is heightened, and teaching effects in multiple dimensions are improved.

1. Introduction

In the wake of vigorous becoming different of high and new technology, information technology has built a digital world, digital survival has become a new form of human survival, and VR technical ability has gradually become a field of research by scholars in current social development and application. Virtual reality technology uses sensing devices to enable experiencers to interact with things in all directions in virtual space without limit [1]. VR technical ability is considered to have the general characteristics of high immersion, interaction, and imagination. By simulating reality realistically, VR technical ability has a profound impact on people's practical activities, cognitive activities, and ways of thinking [2, 3]. Guide College deeply roots their patriotism and strives to become newcomers of the era who are responsible for national rejuvenation. Therefore, the integration is of great significance to enhance the effectiveness of education, and it is also an urgent task for college educators [4].

2. The Application Status of Ideological and Political Education of Virtual Reality Technology

VR technical ability is an original computer that gradually grows and reaches certain heights in 20th-century

technology. “Father of Virtual Reality” Jaylen Lanier creatively pointed out in his book “Virtual Reality: A New Beginning of Vientiane” that virtual reality is a medium that can carry the hope of dreams [5–7].

2.1. Application of VR Technical Ability in Ideological and Political Education Courses. The essence of the application of VR technical ability in thought together with political courses is the innovation of guiding pattern, specifically the integration of online and offline and virtual and real teaching. Although the virtual reality teaching mode can improve the single, it cannot completely replace the conventional guiding pattern and it still occupies a central position. Therefore, it is required to interact online and offline and combine virtual and reality [8, 9].

- (1) VR technical ability connects historical and real knowledge, enriching the guiding content of thought together with political courses in the five thousand years of Chinese history, and it is a significant resource and material for thought together with political teaching. Crouch said that “All history is contemporary history.” Different histories stand in different eras and have different interpretations and understandings. For the study of former times, David Tebrau once proposed the “history room.” As an

educational environment, the “history room” can help scholars better understand specific historical figures or complex historical events and help them see Qing’s position in constant up-growth in former times. VR technical ability is equivalent to providing a “history room” in thought together with political guiding, which can restore the substance of the former times in a virtual form, and educated people can feel and experience from a contemporary perspective. History is engaged, learned, and analyzed. The spark of knowledge created by the combination of the former times and modernity not only enriches the content of thought together with political lesson but also broadens the thinking and thinking of the educated. An analogy is made: CCTV launched a digital online exhibition hall of the same name, which uses panoramic virtual technology to display 360 degrees. Visitors can get an immersive and roaming viewing experience with their mobile phones or computers and experience the great history and brilliant achievements of the 70 years.

- (2) VR technical ability promotes the combination of theory and practice and improves the guiding function of thought together with political courses. Practice is the basis of cognition, and cognition in turn has a guiding part in practice. The development of thought together with political guiding activities requires the combination of theory and practice. The presentation of the effect of thought together with political guiding is also a process from internalization to externalization, from theory to practice. In the process of thought together with political teaching, classroom teaching focuses on the learning of theory, while practical teaching emphasizes the application of theory. Only the combination of the two can achieve the best teaching effect. The application of VR technical ability in thought together with political lesson is a simulated experiential teaching that transforms theory into practice. Visiting teaching practice can be realized without leaving home. An analogy is made, and the Beijing Institute of Technology used virtual technology in thought together with political lesson to implement activities to retake the Long March, allowing learners to experience the hardships during the Long March. The use of virtual technology can inspire educators far beyond the general class explanation. This immersive teaching mode enables the educated to feel the spirit of the Long March more truly in the immersive practical learning, which is more conducive to internalizing the spirit of the Long March in the heart and externalizing it in the action [10].

2.2. Problems Existing in the Ideological and Political Education Curriculum

- (1) The teaching mode is single. The environment is one of the significant factors affecting the effect of

thought together with political guiding. Time and space together constitute the environment of thought together with political teaching. However, due to the limitations of space and time, the thought together with political teaching mode is single [11]. First, the limitation of space makes the teaching mode single. Conventional thought together with political teaching is limited to without end 60 square meters of classrooms, most of which are taught by teachers and indoctrinated theoretical guiding that learners listen to, which limits the diversity of guiding modes in space. Second, the limitation of time makes the guiding mode single. The thought together with political education is a comprehensive discipline involving political science, education, psychology, ethics, and other disciplines. Due to the large guiding task and limited classroom time, some teachers adopt the method of scripting to complete the guiding task. This single guiding mode makes thought together with politics class boring and greatly reduces the enthusiasm of the educated.

- (2) The guiding effect is not good. Theory and practice complement each other. In thought together with political guiding, only when theory is used in practice the curriculum can be effective. At present, my country’s thought together with political courses focuses on theoretical guiding, and its main form is classroom instillation of theoretical education, and the indicator to measure the guiding effect of thought together with political courses is the level of scholars’ test scores. This test-oriented guiding and evaluation method only attaches importance to the improvement of scholars’ theoretical knowledge and ignores the cultivation of practical ability. As a result, scholars are seriously separated, resulting in poor guiding effect of thought together with political lesson.

3. Feasibility Analysis of VR Technical Ability in Ideological and Political Education

The virtual reality instructing of thought together with political theory relevant subjects taught by the school conforms to the needs of the development of the times and the growth of students. In the Internet era where everything is interconnected, the wave of digitization, informatization, and virtualization has had a significant and far-reaching influence on individual behavior habits and manner of thinking. College students are the main force active in the network society in the 5G era. They are keen to obtain information from social networking platforms such as forums BBS, Weibo, and WeChat and like to make friends, shop, entertain, and study in the online world. The mobile Internet makes the survival mode of college students move from realistic survival to virtual survival. The digitization, informatization, and virtualization of the survival mode of college students pose challenges to the guiding of thought together with political education theory courses in colleges

and universities. VR technical ability helps teachers reproduce specific social scenes or build virtual simulation classrooms for guiding and eliminates limits in time and space as so to students can experience virtual guiding situations and accept thought together with relevant subjects taught by the school without leaving home. The virtual reality classroom of thought together with relevant subjects taught by the school conforms to the needs of individual virtual survival and the development of the era of fragmented learning.

3.1. Technical Feasibility Analysis. The basic technical lines of the immersive virtual reality classroom are as follows: first, it is the initial setting and the entire application development process, and the setting of the connection points between the software and the hardware; the second is the three-dimensional construction: the model is divided into two parts from the perspective of the role and the model; the third is motion capture: this part has two parts: body motion capture and expression capture; the fourth is VR/AR: giving character animations and expressions; the fifth is Android APK: the scene and character are imported into the Unity 3D project, and the Android SDK package is used to output the APK software package; and the sixth is the effect test. The virtual reality classroom is mainly composed of two core components, one is to create a virtual reality classroom scene. Maya is the mainstream 3D animation software used in the field of 3D visual art creation at home and abroad [12]. The Maya software is used to realize the modeling, material, lighting, and camera of the basic scene, construct a three-dimensional object model, and create an immersive guiding environment. The Maya software has comprehensive functions, and the interface is simple and easy to operate. The Maya software combination tool is used to construct the 3D model required for guiding. The Maya software takes the standard primitives as the modeling basis and converts them into two-dimensional plan views of editable polygons and then constructs complex shapes by adding lines, turning, adjusting points, twisting, extruding, and chamfering. The second, Unity 3D, is mainly used to realize the interactive function of virtual reality classroom. Unity 3D is a professional game development engine that can visualize virtual scenes, create terrains, add sky backgrounds, create first- and third-person perspectives, and more. The 3D model built by Maya software is imported in Unity 3D in FBX format, and JavaScript language is used to write programs for virtual objects to achieve interactive settings for virtual objects. VRP 3D art virtual reality software is directly applied to fully realize the construction of virtual interactive scenes [13].

3.2. Economic Feasibility Analysis. The immersive virtual reality classroom effectively fills the deficiencies guiding by visualizing abstract theoretical knowledge, transferring dangerous experience to the computer interface, and converting expensive experience equipment into digital information. At the same time, the immersive virtual classroom expands the time and space of practical guiding of thought together with political theory courses, which is conducive to

strengthening the effectiveness of practical guiding. Building a virtual reality classroom mainly uses Maya and Unity 3D software packages. Maya and Unity 3D software technology is mature, powerful, and easy to operate. After training, teachers of thought together with political theory courses can use software to create virtual simulation guiding and reduce guiding expenses. The classroom is shared, which can realize remote guiding. Through the extensive application of virtual reality classrooms, students in areas where guiding funds and resources are scarce can enjoy high-quality guiding resources, promote education fairness, and have good economic and social effects. Virtual reality guiding can better develop students' subjectivity. The college students who grew up in the network environment are different from the conventionally educated people. They have the consciousness of independent learning, and they have psychological needs such as longing for interpersonal relationships with peer groups and showing their individuality. Therefore, they are not used to passively listening to guiding and prefer independent exploration way of learning. Virtual reality is an advanced human-machine interface with a sense of immersion, presence, and multidimensionality [14]. Students can interact with the computer through a variety of sensory channels and learn through the mode of "subject-object" or "subject-object-subject" and "all-to-all communication," which stimulates the enthusiasm for independent learning and highlights the learners' subject position.

4. Research on the Application of VR Technical Ability to Ideological and Political Education in Colleges and Universities

Virtual reality as an academic term originated from Sutherland's (1965) paper "The Ultimate Display." "Computers, drawing tools, and other corresponding equipment use virtual reality to make participants feel three-dimensional, and the multiple senses of the body are integrated with the environment. Let the participants experience the response between behavior and the environment, so that the environment and people can achieve deep interaction and integration." [15] As a novel multimedia technology, VR technical ability has attracted widespread attention and heated discussions. With the help of this new media technology, "The work related to politics has been effectively improved and deeply integrated with the related information technology of conventional thinking" will promote the effectiveness and interest of thought together with political guiding.

- (1) Virtual reality guiding courseware is developed to promote the integration of VR technical ability and the guiding content of thought together with political theory courses in colleges and universities [16]. The form and the content complement each other, and the form must fully exert its function and cannot be separated from the right content. As a tool and method, VR technical ability is the carrier or "form" of the guiding content of thought together with the politics curriculum [17]. With the help of modern virtual

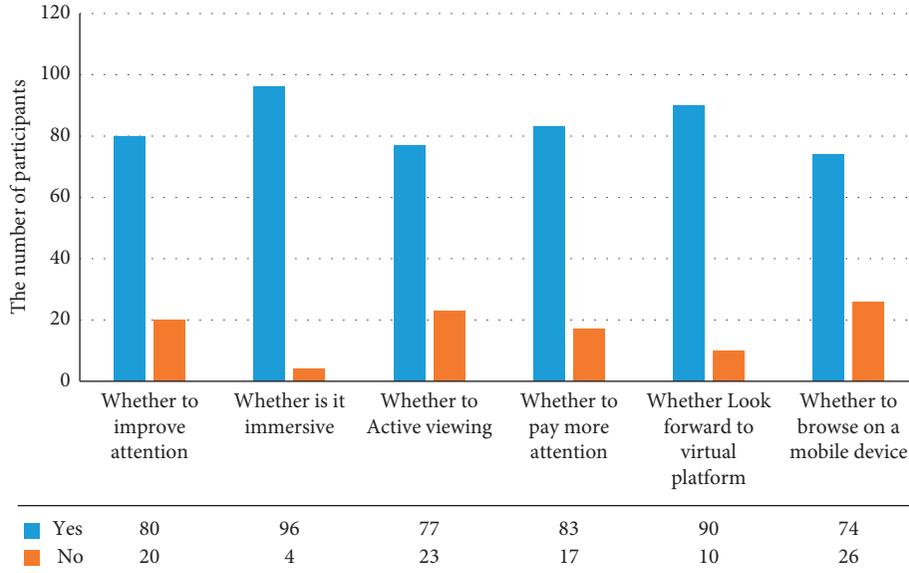

FIGURE 1: Statistical results of questionnaires on the integration of virtual reality technology into ideological and political education.

reality technology, instructing of thought together with the politics curriculum in colleges and universities designs simulation interactive situations based on the theme of guiding content and creates “guiding games” that students can operate according to certain procedures and rules to achieve guiding goals. The virtual simulation technology in form is improved, the shortcomings of dizziness caused by the experience of using the helmet are overcome, and the application of virtual simulation technology on mobile phones is gradually expanded to ensure the update and upgrade of the virtual simulation system. In terms of content, guiding content or guiding topics are selected through collective lesson preparation, research, or consultation with experts, cases with thought together with political education value are selected, and virtual reality classrooms are created according to the principle of “combining the virtual with the real, being able to be true, and complementing each other.” Theoretical knowledge is effectively integrated into the simulation practice guiding activities.

- (2) Looking to teacher guidance, the integration of VR technical ability and instruct methods of thought together with political theory class in colleges and universities is boosted. The materialist view of former times believes that in the process of transforming the world, only by promoting the unity of the subject and the object we can achieve the “consistency between the change of the environment and the change of people’s activities or self.” Instructing of thought together with political theory class in colleges and universities must adhere to the unity of dominance and subjectivity. On the one hand, the virtual reality instructing of thought together with politics class fully mobilizes the subjectivity of learner and opens up a broad space for

TABLE 1: Student users make multi-dimensional evaluation of VR experience results.

Variable	Mean	Standard deviation
Immersion	4.66	0.24
Interactivity	4.55	0.27
Conceptual	4.29	0.22
VR environment adaptability	4.21	0.35
Problem-solving skills	3.96	0.27

scholar to learn independently, explore independently, and construct knowledge. Students independently establish learning goals, select appropriate virtual guiding content on the online guiding platform, and carry out self-education learning. On the other hand, to achieve good results in virtual reality guiding in thought together with political theory curriculum also depends on the active guidance of teachers. Teachers should actively discuss learning goals with students and provide suggestions for students to develop learning plans. In the virtual reality studying of the thought together with political theory course, the interactive communication link between the designers and the students is encouraged to retell the experience process and talk about the guiding feelings and gains. Teachers listen carefully to students’ speeches, grasp keywords to guide students to use theoretical knowledge to think and analyze problems, and enhance the effectiveness of virtual reality schooling [18].

5. Conclusion

In terms of quality, to ensure the application effect of VR technical ability in thought together with politics class, it is necessary to increase the research and development of this

technology and constantly innovate the virtual environment, so that the intrusive feeling of characters is more real, and the scenes and modes are more diverse. “Students can forget the interference of the surrounding environment and immerse themselves in the environment of autonomous learning, which can achieve a historic breakthrough in changing passive acceptance learning to active autonomous learning” [19]. VR technical ability is currently only a guiding method, and it will be developed into a way of thought together with political education art in the future. This art mainly reflects the creation of virtual environment that fully considers the cultivation of students’ values of truth, goodness, and beauty [20].

5.1. Case Analysis of the Application of VR Technical Ability in Ideological and Political Theory Courses. The application of VR technical ability in the field of thought together with political education needs to be evaluated in many aspects. A University’s School of Marxism randomly selected 100 students to experience the “Nineteenth National Congress of the Communist Party of China Virtual Reality Simulation Platform” and complete the questionnaire survey (see Figure 1). In addition, 100 students experience the virtual reality work “The Last Battle” in which Chinese soldiers stubbornly resisted the Japanese army in the Anti-Japanese War and conduct multidimensional evaluations on the experience results. The five dimensions of VR environment adaptability and problem-solving ability are evaluated. Immersion is used to evaluate the user’s concentration, interactivity is used to evaluate the system’s human-computer interaction ability, and conception is used to evaluate the user’s ability to patriotic feelings and firm beliefs during the experience process. To reflect whether the user is adaptable to the VR experience environment, and “problem-solving ability” is used to obtain whether the user’s subjective feeling after experiencing the virtual reality system is in line with the official theme goal. The above five dimensions are, respectively, evaluated with 0–5 points. Each user experience system needs to be scored from each dimension.

After the students experience, the five dimensions were evaluated without distinguishing between genders, and the mean and standard deviation were used for statistics. The statistical results are shown in Table 1. Research shows that all students highly agree with the two dimensions of virtual reality immersion and virtual reality interactivity; in the conceptual evaluation of virtual reality, $SD=0.22$, the standard deviation is the smallest among the five dimensions, reflecting all of students have highly consistent evaluations on the conception of thought together with political schooling produced by the virtual reality system, and the mean value of feedback is $M=4.29$; in the dimension of “fitness to VR environment” $M=4.21$ and $SD=0.35$. Although the standard deviation of the VR environment fitness evaluation is the largest among the five dimensions, the average value is still at a good level. It can be considered that most students can adapt to VR environment guiding; the average value is shown in the dimension of “problem-solving ability.” The lowest value ($M=3.96$) indicates that

there is still some gap between the ideological and educational purposes brought by the VR system to the experimenter and the expected purpose, but the value is still close to a good level.

The above analysis can verify the previous research plan; that is, VR technical ability can enhance student attention, learning initiative, and sense of experience in the process of thought together with political education and enhance the effectiveness of thought together with political culture in colleges and universities. In practice, we have verified the advantages of VR technology, and the characteristics and advantages of VR technical ability can bring new educational territory and guiding method innovation to thought together with political schooling [21]. Virtual reality equipment will become more and more convenient, which will provide a better learning space and a good practice platform for thought together with political schooling, expand educational ideas, and innovate educational and guiding methods. This study proposes immersion methods, interactive methods, and role-playing methods for the integration of VR technical ability into thought together with political education. It advocates the increase in virtual reality communication media in thought together with political education communication media and conducts virtual simulation experiments and simulation experiments on 100 students. After the questionnaire survey, the feasibility of the plan was verified, and the guiding method was also welcomed and praised by the students. Because of its technical advantages and thought together with political education goals, VR technical ability is highly compatible with the goals of thought together with political culture.

5.2. The Future Prospect of VR Technical Ability in Ideological and Political Theory Courses

- (1) The application of VR technical ability in scale and quantity is popularized, and a network of thought together with political courses between “virtual” and “real” is built. The Beijing Institute of Technology’s application of VR technical ability in student training has achieved initial results, and it has built a “three-step process”: using VR technical ability to build an emotional intelligence gas station; building a simulation platform for students’ professional quality and assessment; and releasing the “I do my own way” system; the concept of “Internet + quality education” is gradually formed, the whole process is tracked and recorded, and a quality database of domestic college students is gradually established, in line with General Secretary Xi Jinping’s speech in the 2016 National thought together with political theory class “To do a good job of thought together with political work in colleges and universities, we must change it according to the situation” [22]. The organic integration of information technology and ideological and party political courses produces “re-walking the long march” and explores the application of VR technical ability in the guiding of ideological and

governmental courses. At present, with the development of the times, the application of VR technical ability in thought together with political theory courses in colleges and universities has become possible. In the future, VR technical ability will be introduced into more ideological and governmental classrooms in colleges and universities on a larger scale to fully mobilize students' enthusiasm for learning. The overall improvement of guiding effect is realized; let VR technical ability become a multimedia bridge between teachers and students, guiding and learning, and dynamic and static and truly make the guiding mode of ideological and politics class develop in line with the times. Of course, to realize the expansion of VR technical ability in scale and quantity, it is necessary for colleges and universities to configure a professional R&D team of virtual reality technology, improve the guiding innovation awareness of thought together with political teachers, form thought together with political courses between schools, and realize VR technical ability [23]. The "real" experience beyond the limitations of time and space is pursued, and the thought together with political guiding into a network of "virtual" and "real" is connected, the contact method is "virtual," and the learning and communication are "real"; the guiding environment is "virtual," and the guiding content is "virtual."; situational experience "virtual"; and emotional training "real."

- (2) The application of VR technical ability is deepened in depth and quality, and a good campus with ideological, political, and cultural atmosphere is built. At present, the submission of VR technique in courses that combine politics and ideas is only in the primary stage, and it is only a guiding method used by some colleges and universities and a few classrooms. We must play its radiating and leading role. At the same time, we should also consider deepening the submission of VR technique in courses that combine politics and ideas in terms of depth and quality. VR technical ability not only serves classroom guiding and social practice but also should serve the central link of cultivating people with morality, which runs through the whole process of subjects that combine ideology with politics, and finally, it can "achieve the whole process of educating people, educating people in all directions, and strive to create A new situation in the development of higher education in my country." In the future, classrooms and campuses should be connected, study and life, and be committed to building a good campus ideological, political, and cultural atmosphere, so as to have a subtle impact on students. An analogy is made, and some things have happened in today's society, which are contrary to the core values of socialism. It is difficult to stimulate students' in-depth reflection on the incident with the guidance of

teachers alone. We might as well place students in the environment at that time. Teachers conduct timely guidance and education by observing students' every move, so that students truly understand the core socialist values instead of empty slogans. Everyone should strive to be "a firm believer, an active communicator, and a model of the socialist core values [24, 25]."

The application of VR technical ability in the guiding of ideological and politics class in colleges and universities has broad prospects, and it can be specifically applied in the guiding links of four ideology together with politics classes to make an analogy, and the guiding of moral and legal-related content in "Ideological and Moral Cultivation and Legal Foundation" can be combined with specific social events to develop relevant special software courses, such as the simulation of court scenes and related software courses in the guiding of "Outline of Modern History." VR technical ability can bring students back to the field scene, mobilize students' enthusiasm for learning, and then improve the guiding effect of ideology together with political courses through VR technology. Subjects that combine ideology with politics in colleges and universities are an major part of thought together with political work. The application of virtual reality technology ability can combine ideological and political courses, enhance the attractiveness and attraction of ideological and political courses, and promote college students to establish correct national, national, and cultural concepts.

With the rise of digital campuses, online learning platforms, and the improvement of educational technology, the interaction between teachers and students has entered a new stage. Especially under the influence of CSCL (Computer Supported Collaborative Learning), computer-assisted collaborative learning, and E-learning (Electronic Learning) network digital learning that emerged in recent times, new technologies are changing the way people learn. Students' learning is not limited to one-way absorption of knowledge taught by teachers, and the interaction between students and teachers, students and students, and the interaction between students and the teaching environment are increasingly appearing in modern teaching classrooms. This paper optimizes the physical education management based on the clustering algorithm under the background of big data, uses the popular Java language to write codes to realize all the functions of the algorithm, and uses some small examples to prove the correctness of the fuzzy clustering algorithm. The algorithm reads a file through the input and output streams `FileReader` and `BufferedReader`. The content of the file is the relevant information of the physical education mode. It gives the methods to calculate the cluster center (i.e., the center of mass), calculate the distance, correct the fuzzy classification matrix, and display the matrix. (i.e., output matrix), conversion to deterministic classification method, calculation of classification coefficients, and basic functions such as average fuzzy entropy. According to the data, if the FCM clustering method is not used, but the previous average method is used as the evaluation basis, there will be results that we do not want to see, but if we use the FCM algorithm, the evaluation result is that what we want to see is more specific. From the analysis results, thematic teaching + basic teaching seems to be the most popular mode of physical education.

1. Introduction

With the rapid development of today's society, a large amount of data are generated due to people's close communication. This era has promoted the rise of big data and the development of the Internet, and the data are also increasing. Cloud computing makes it difficult to use big data. It became easy to use. Data mining based on the clustering algorithm has become the future development trend of physical education model optimization, and data mining technology will provide new innovation points for future education reform. Clustering is a process of dividing things without any prior knowledge. Through clustering, the similarity between things can be found, so that the results

can be better revealed. First of all, the quality of teaching is clear. In addition to the evaluation of teaching facilities, teaching tools and other hardware, the evaluation of teaching quality also includes the level of teaching and the seriousness of teaching. This paper selects the most widely used FCM clustering algorithm, but it is difficult to achieve the optimum by relying only on the FCM algorithm, and it also has many limitations. This paper introduces some improved algorithms of the FCM algorithm. The popular improvement is generally carried out from the selection of the cluster center and the adjustment of the cluster center. After the program is improved, we need to verify whether the algorithm is effective or not through simulation experiments. The physical education management model

designed by the clustering algorithm in this paper mainly includes the design model to analyze teaching data and student information, including comprehensive evaluation of students, evaluation of student performance, evaluation of classroom teaching, student status, student achievement, classroom teaching, student affairs, psychology health, comprehensive assessment, and many other information can also teach students according to their aptitude according to the clustered information [1–9]. The research results of this paper, combined with the current teaching management methods, can reduce the unreasonable and unscientific defects of the evaluation caused by subjective factors in the previous evaluation system and can make the teaching evaluation more scientific and reasonable.

2. Related Work

At present, the current physical education teaching system in colleges and universities in our country is not standardized enough, and the evaluation methods that have been used such as AHP, fuzzy comprehensive evaluation method, one-way analysis of variance, neural network method, and so on. Although there are many teaching evaluation methods, we cannot get the information we need from the evaluation data obtained, or what we finally find are some superficial and worthless information. Therefore, we need to obtain hidden valuable information. Clustering methods are generally divided into hard clustering and soft clustering. Hard clustering is an algorithm whose degree can only be 1 or 0. It takes less time and can draw conclusions quickly. However, this algorithm also has significant shortcomings because this algorithm ignores the connection between the data, which makes the obtained results have a large error from the correct results. The fuzzy clustering algorithm is an algorithm that requires the sum of the membership degrees of the data to be 1. This regulation greatly improves the correctness of the clustering results because this algorithm does not only consider the membership of the data. It also takes into account the influence of noise data on the clustering results. This algorithm can avoid the influence of noise data on the final result and is suitable for cluster analysis with noisy data. The research on the optimization of teaching mode is carried out through the improvement of the method. In the early twenty-first century, people's main research direction is to use more complex mathematical models to process teaching information, and the fuzzy comprehensive evaluation method is a typical example. Some domestic scholars have proposed the methods of UML and KDD. They have carried out detailed research on the subject and process of teaching, but they are still only in the stage of theoretical verification, which is still far from practical application. Data mining technology integrates fuzzy mathematics, statistics, machine learning, logical reasoning, and many other fields. It has now received extensive attention in many fields such as business, finance, medical care, education, Internet, and government. Based on the background of big data, this paper conducts a cluster analysis on the physical education teaching mode and

optimizes it through quantitative analysis based on the current physical education teaching mode [10–14].

3. Related Theoretical Methods

3.1. Big Data. The definition of the connotation of relative big data mainly focuses on three aspects. As shown in Table 1, big data can summarize their connotation from the data set, technical system, and way of thinking. First of all, from the perspective of datasets, big data is an information dataset with enormous value. Different from the previous data sets, the characteristics are the diversification and complex association of data objects. This is because the data source of big data is not only the regular data of the information system but also the scraped data of network logs and the original content data of users. The emergence of new mobile devices such as mobile phones and tablets, as well as sensors and the Internet of Things, has accelerated the diversification and high growth of data. Among them, data forms include structured, semi-structured, and unstructured data, and semi-structured and unstructured data account for the majority. Structured data mostly refer to databases that have been artificially organized in advance, while unstructured data refer to actively generated data such as videos, voices, web logs, and original texts. Big data can also be called massive data. Second, from a technical point of view, big data are a technology to obtain valuable information from massive data, including a series of technical systems such as new data storage technology, mining technology, data processing technology, data analysis technology, and data visualization technology. The most widely used technology in education are educational data mining, learning analysis technology, and technology applications in large-scale online education platforms. Third, in terms of mindset, big data have a broader meaning. This study reflects the connotation of big data from this perspective with the help of the discussion in “The Age of Big Data”. Big data are a worldview, a quantitative worldview of “the essence of the world is data”; big data are an empirical methodology, including three major thesis “not samples, but all data”, “not causality but correlation”, “it is not accuracy but hybridity”; it forms a big data value chain with massive data and data technology series, which are intertwined vertically and horizontally to form a big data system. However, as far as the nature of big data is concerned, big data are a technology for recognizing and solving problems, and its role lies in people's rational control over it. Mass data are the realistic basis and environment for generating and using technology. Analysis and other technologies are the realization paths to accomplish its purpose, and its data thinking is the value load of the technical connotation, which specifies the purpose and means of the technology [15].

3.2. Cluster Analysis. Clustering is a very common data mining method. The general algorithm is good at dealing with spherical clustering without isolated points. The CURE algorithm can better solve the spherical problem and can also better solve the isolated point problem. Its advantage is

TABLE 1: Definition of the connotation of big data.

Angle	Description	Application in the field of education
Data set	Very large data collections, which are different from typical databases in terms of data objects and data forms are more diverse and complex, and have exceeded the ability of traditional databases to acquire, store, manage and analyze data	Massive teaching resources (text, video) and student learning behavior data, student learning logs, teacher-student interaction, student original data, etc.
Technology system	Big data technology for mining data value, new data acquisition, data storage, data analysis, data interpretation, data warehouse, data query, data visualization technology, etc.	Educational data mining and learning analysis technology, adaptive learning system, MOOCs, and other open education platforms
Way of thinking	Quantitative worldview and quantitative empirical methodology, full-sample data analysis methods, pursuit of correlation, tolerance for hybridity	Educational quality quantification and evaluation thinking, etc.

that it can better handle the problem of outliers. It selects c points from the cluster and shrinks them to the centroid by a shrinking factor. The clusters represented by these points can better represent the shape of the cluster. Clustering is a kind of classification that does not rely on any prior knowledge, but only relies on the characteristics of the data, and finds out the same set of objects with higher density of objects in one area than other areas. In cluster analysis, outliers are a special class of points. In data analysis, we want to avoid the impact of these outliers on cluster analysis because outliers behave differently from other points. When analyzing, they should be excluded, which is the only way to reduce the impact of these outliers on cluster analysis [16–19].

Fuzzy C-means clustering algorithm (i.e., FCM) is a widely used algorithm in cluster analysis. It is one of the most commonly used algorithms. It is widely used in data analysis and pattern recognition. Its essence is mountain climbing. The FCM algorithm is a clustering algorithm based on fuzzy partitioning, because the parent target of fuzzy clustering is not a convex function. If the initialization is not done well, the final result will converge to the local extreme point. At this time, the resulting classification of the data is not optimal. This algorithm is very time-consuming for processing large amounts of data, which is a big disadvantage in practical industrial and scientific applications. The fuzzy C-means clustering algorithm is obtained, that is, the FCM algorithm. The criterion for evaluating the clustering degree of the FCM algorithm is measured by the membership function. Its objective function is evolved from the objective function of HCM. The clustering algorithm is obtained by applying the fuzzy theory. The difficulty of the FCM algorithm is the selection of the C value. It is difficult to determine the C value only based on experience when we do not know what the data are distributed according to.

Many scholars have improved the FCM algorithm, and the FCM algorithm based on information entropy is one of the improvements. This improvement helps to reduce the error generated in the iteration and improves the efficiency of the system. Weighted coefficient helps to improve the accuracy of the initial value of the cluster center. The FCM algorithm based on information entropy is an algorithm that

uses information entropy to initialize cluster centers. After initialization, the number of cluster centers can be obtained, which has a great effect on reducing errors. It is easy to obtain an algorithm with high operating efficiency, which greatly reduces the possibility of local optimum caused by improper selection of the initial value of the traditional fuzzy C-means clustering algorithm. The fuzzy C-means clustering algorithm based on entropy weighting evolves on the basis of the appeal algorithm, and the weighting coefficient is quoted in the traditional fuzzy clustering algorithm. Such an algorithm can continuously select the center of the cluster in the clustering and make it as close as possible to the actual cluster center position.

Assuming a P-order vector X , the object is divided into c cluster sets by the clustering algorithm, and the centroid of each set is a P-order vector V , and the set composed of the fuzzy classification method is defined as follows:

$$\mathfrak{F}_{fc} = \left\{ U \in \mathcal{R}_{cn} \mid \begin{array}{l} \forall \\ 1 \ll r \leq c \\ 1 \ll k \leq n \end{array} \right\} u_{ik} \in [0, 1], \quad (1)$$

$$\sum_{i=1}^c u_{ik} = 1, 0 < \sum_{i=1}^n u_{ik} < n.$$

R is a matrix of c rows and n columns with an objective function as follows:

Among them, \mathfrak{F}_{fc} is the weight coefficient, and the distance between the element X_k and the centroid V_i of the i th cluster is as follows:

$$J(U, V) = \sum_{i=1}^c \sum_{k=1}^n (u_{ik})^m d_{ik}^2. \quad (2)$$

Among them, $U \in \mathfrak{F}_{fc} V \in \mathfrak{R}_{pc}$, $m \in [1, \infty)$ is the weight coefficient, and the distance between the element X_k and the centroid V_i of the i th cluster is as follows:

$$d_{ik}^2 = \|x_k - v_i\|_i^2. \quad (3)$$

By optimizing the objective function, the FCM algorithm obtains the fuzzy classification of the object set by iterative optimization of the objective function.

4. Construction of the Optimization Model of Physical Education Teaching Mode Based on Cluster Analysis under the Background of Big Data

If teachers are regarded as an observation object, the scores of each teacher will form a matrix X , which is the data object. We know that the optimization of the physical education management system is a fuzzy process, and the FCM algorithm is a mature algorithm to a certain extent, so we choose this fuzzy clustering algorithm in the teaching management system.

4.1. *Model Construction.* We built the model shown in Figure 1 below based on the above ideas, where A is the clustering process, X is the teacher's score, c (the number of categories, the initial setting is 5), and m (smoothing coefficient, the initial setting is 5) (2) is a parameter.

4.2. *Example of Cluster Analysis Model Implementation.* The scores of each teacher on the 10 factors constitute a 10-column vector, the number of columns is the same as the number of teachers, thus forming a matrix X , which will be used as the initial data for the clustering algorithm.

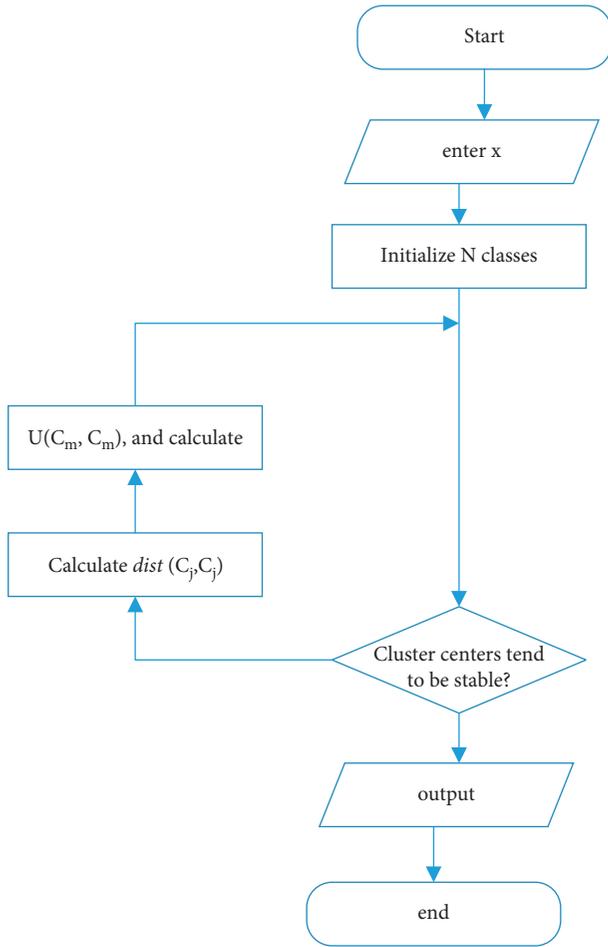

FIGURE 2: Flowchart of the clustering algorithm.

4.2.1. Clustering Algorithm

(1) Algorithm steps. ① Each teacher is a sample point in the 10-dimensional space defined by the system, and each such sample point is initialized into a class before the program runs and ② the distance between the sample point and the class is calculated. In this system, we choose the Euclidean distance. ③ Next, the two points with the smallest distance as a cluster is defined and the cluster center is set as the middle point of these two points. ④ Steps 2 and 3 are continued to run until the cluster center becomes stable. (2) The flowchart of the clustering algorithm, as shown in Figure 2.

Fuzzy Mean Clustering Algorithm: The fuzzy mean clustering algorithm used in this paper is more complicated than the systematic clustering algorithm. We set m as a fixed value and c as a variable.

(1) Algorithm steps:

- (i) ① Set an initial c , and randomly select c samples from the sample points as the cluster center;
- (ii) ② For all i , update $U(t)$ to $U(t+1)$;
- (iii) ③ Update the centroid $V(t+1)$ according to $U(t+1)$;

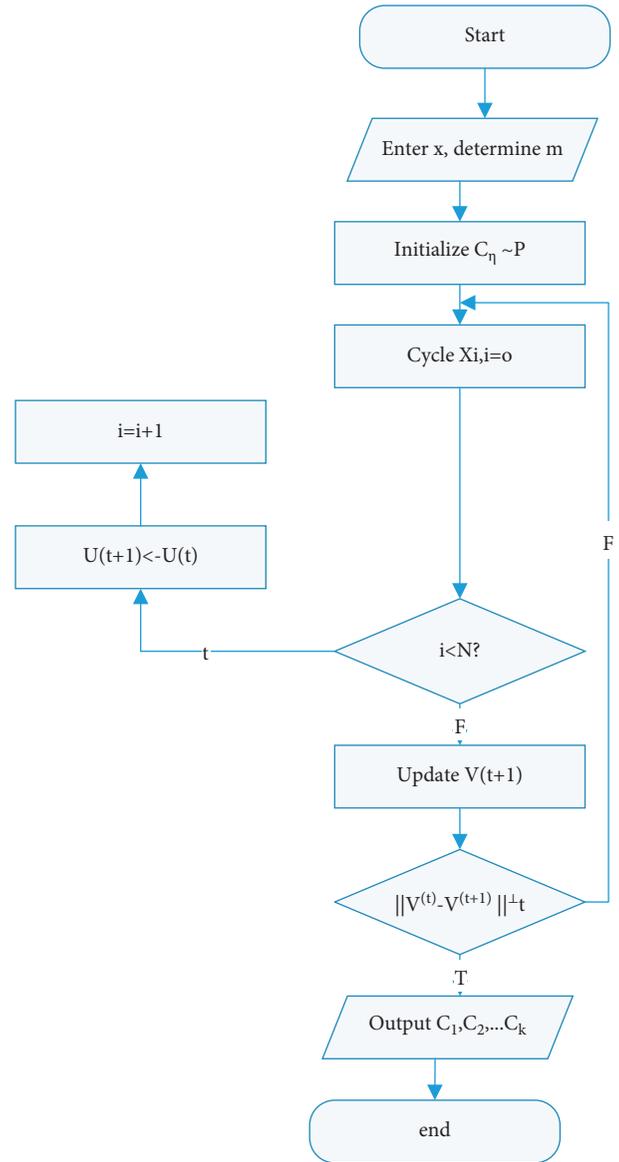

FIGURE 3: Flowchart of fuzzy clustering algorithm.

- (iv) ④ Compare $v(t)$ and $v(t+1)$, if $\|V(t) - V(t+1)\| \leq t$, the algorithm terminates; otherwise, let $t = t + 1$, go to step 2. (where ϵ is set to 0.001).

(2) The flow chart of the algorithm is shown in Figure 3.

5. Optimization Model Analysis of Physical Education Teaching Mode Based on the Fuzzy Clustering Algorithm under the Background of Big Data

5.1. Several Optimized Physical Education Teaching Modes. Aiming at the problems brought by the prominence of different categories of characteristics of college students to education and teaching, this paper proposes a teaching mode optimization plan of classified teaching and teaching students in accordance with their aptitude. That

TABLE 2: Four different types of optimized teaching modes.

Types of	Teaching mode	Standard
Class A	Active exploratory teaching + basic teaching	
Class B	Guided teaching + basic teaching	Differentiated assessment against teaching objectives
Class C	Attractive teaching + basic teaching	
Class D	Theme-based teaching + basic teaching	

```

is to say, on the basis of knowing the teaching objectives and the groups to be taught, it is necessary to have a detailed understanding of the groups to be taught and analyze their category characteristics. There are four types of students involved in this paper, as shown in Table 2, among which:

Class A is active exploratory teaching + basic teaching, mainly on the basis of the basic teaching model, adding active exploratory teaching methods, which not only improves their subjective self-learning ability but also helps divergent thinking and strengthens language organization and expression ability, further deepening understanding of theoretical knowledge.

Class B is guided teaching + basic teaching. On the basis of the basic teaching model, students add guided teaching methods to enhance their learning initiative.

Class C is attraction-based teaching + basic teaching, which is based on the basic teaching method and adds attraction-based teaching.

Class D is subject-based teaching + basic teaching, and subject-based teaching is added on the basis of basic teaching methods. In this way of teaching students in accordance with their aptitude and targeted education, it is expected to comprehensively promote the cultivation of college students' ideological awareness and behavior habits, knowledge, and skills.

```

1 public double[][]FCMCenter(double R[][],double X[][],int N,int M,
2 int C,double Q){

5.2. Fuzzy Clustering Code Writing

5.2.1. File Reading. First, you need to read a file through the input and output streams `FileReader` and `BufferedReader`. The content of the file is the relevant information of teaching quality evaluation:

5.2.2. Calculating Distance. The code to calculate the distance is as follows:

5.2.3. Calculating Cluster Centers. The following code implements the calculation of cluster centers (aka centroids).

```

1 public double[] ClassFactor(double R1[][],int N,int C){
2 int i,j;double ClassF[]={0,0};
3 for(i=0;i<C;i++)for(j=0;j<N;j++){
4 ClassF[0]+=Math.pow(R1[i][j],2);
5 ClassF[1]+=R1[i][j]*Math.log(R1[i][j]);
6 }
7 ClassF[1]=ClassF[1]/N; //Classification coefficient
8 ClassF[2]=-ClassF[2]/N; //Average fuzzy entropy
9 return ClassF;
10 }

```

FIGURE 8: Calculated classification coefficients and average fuzzy entropy related codes.

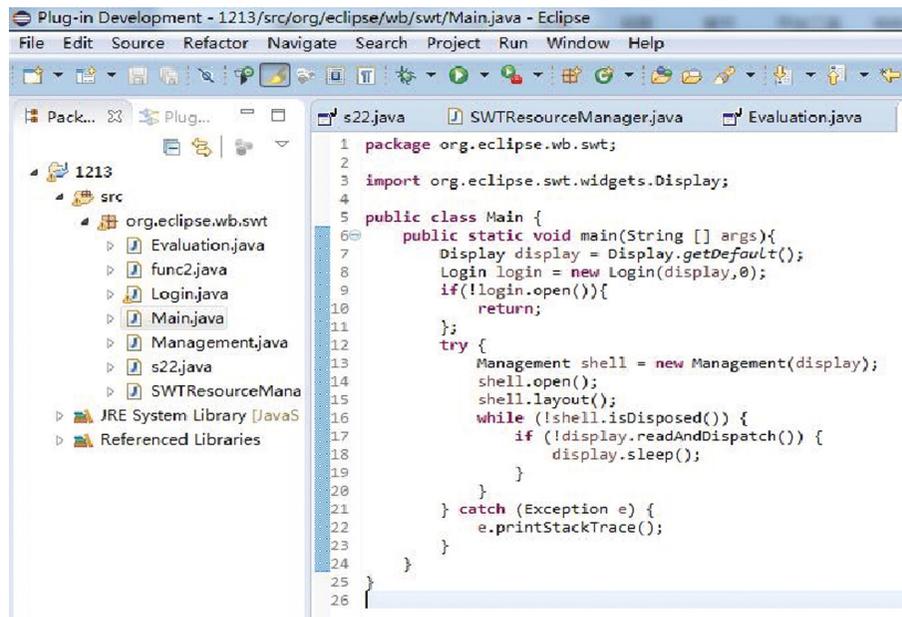

FIGURE 9: Teaching mode optimization structure hierarchy.

TABLE 3: Scores under different PE teaching modes.

Types of	Teaching mode	Score
Class A	Active exploratory teaching + basic teaching	7.759
Class B	Guided teaching + basic teaching	8.652
Class C	Attractive teaching + basic teaching	8.375
Class D	Theme-based teaching + basic teaching	9.615

5.2.4. Revised Fuzzy Classification Matrix.

5.2.5. Calculate the Classification Coefficient and Average Fuzzy Entropy.

5.3. Teaching Mode Optimization Structure Hierarchy.

Figure 9 shows the structure levels under different teaching modes.

5.4. Statistical Results of Teaching Evaluation.

The statistical results are shown in Table 3.

5.5. Results and Analysis. The final output of the code is a number of non-fixed matrices composed of 1 and 0. The input data are clustered and calculated. According to the obtained data, if the FCM clustering method is not used, the previous average method will be used as the evaluation basis. The following results appear: Category *D* has the highest score and should focus on inquiry-based teaching + basic teaching. According to the results of FCM clustering, but the classification results of fuzzy clustering are fixed, the evaluated indicators are clustered and the threshold of clustering is delimited, so as to achieve the effect of clustering and complete fuzzy clustering. It can also be used to evaluate the management mode of physical education teaching.

6. Conclusion

The clustering algorithm is a very commonly used algorithm, and fuzzy clustering is a clustering algorithm that applies the fuzzy theory. This paper first gives a brief overview of the background of big data and the development status of cluster analysis at home and abroad. Next, it mainly introduces the operating environment and language for developing the algorithm and organizes and presents some codes. This paper studies the teaching management system for the fuzzy clustering algorithm. Among many clustering algorithms, the FCM clustering algorithm is the most widely used algorithm. It can deal with these problems by transforming the principle of nonlinear programming. It can process these physical education data by transforming the principle of a nonlinear programming. It is a fuzzy clustering method, and each iteration moves in the direction approaching the minimum point. Although the FCM algorithm also has many imperfections, with the continuous improvement of this algorithm by scholars, this algorithm has a good prospect. The main task of this paper is to construct a new teaching mode optimization algorithm, improve the original physical education teaching mode, and propose a new cluster analysis model. Judging from the research results, thematic teaching + basic teaching seems to be the most popular mode of physical education.

An automatic intelligent coloring model of animation sketch based on enhanced deep learning is proposed. In the proposed model, generative adversarial networks (GANS) are adopted. The U-net network based on the Swish function residual enhancement is used in the generative model, and the ResNet network is used in the discriminant model. The U-net embedded with the Swish Gate module is adopted to transmit feature map information. The perceptual network on the discriminator is used to perceive the perceptual features of the generated image and the actual image and calculate the perceptual loss. Experiment results show that perceptual loss can better capture the difference between black-and-white images and color images, so as to better train the network end-to-end. After comparative analysis, it can be concluded that compared with the existing methods, the proposed model has greater advantages in processing animation sketches. The color images it generates have higher visual quality and richer color diversity and matching.

1. Introduction

At present, the coloring of animation sketches mostly depends on the hand-painted coloring of professional animation painters, which will spend a lot of time and energy. At the same time, the coloring effect is also affected by individuals [1, 2]. The emergence of convolutional neural networks [3] provides a new perspective for the coloring of gray images. Its emergence makes it possible to complete many tasks in computer vision at the same time. It is necessary for the computer to automatically color the animation sketch. At the same time, for some ordinary people, they can use this method to color the line sketch and create their favorite color pictures. These methods can automatically colorize animation line art to generate rich color pictures; in addition to manual selection of specific colors color to color, the coloring time is much faster than hand-painted coloring. However, generative adversarial networks (GANS) have always had a long training time, unstable generation effect, and non-convergence of the network [4, 5]. These problems can lead to poor quality of color

pictures generated by the GANS-based animation line art coloring model. For example, the color filling is unreasonable, the filling color exceeds the filling area, and the color brightness is inconsistent.

As far as GANS-based coloring models are concerned, it is challenging to meet the actual needs, and the coloring results also need to be screened. Some color pictures of poor quality are inevitable, time-consuming, and laborious. GANS consists of a generator and a discriminator [5]. When the animation line art is colored, the generator inputs the animation line art and outputs the colored image. Moreover, the choice of the generator network structure and loss function will directly affect the quality of the final output color picture. Therefore, designing a suitable stable network and a suitable loss function can improve the quality of generated color images. The role of the discriminator is to discriminate whether the generated color image is close to the effect of artificial coloring avoidance. The final output is a color image with poor quality, and the discriminator will affect the training stability of GANS. Training GANS needs to achieve the Nash

equilibrium; the discriminator network needs to be further optimized to ensure training stability.

2. Related Works

In recent years, GANS has received increasing attention in deep learning. A generative adversarial model usually consists of a generator and a discriminator. The generator captures the underlying distribution of actual samples and generates new data samples. The discriminator is often a binary classifier that distinguishes real examples from generated samples as accurately as possible. The discriminator guides the training of the generator, and the alternating movement between the two models is used for continuous confrontation. Finally, the generative model can better complete the generation task. With the emergence of more and more GANS variants, GANS has achieved significant results in various fields of images. In image coloring, GANS also occupies an important position in mainstream algorithms. At present, the deep learning-based automatic coloring model mainly adopts the architecture of GANS.

Pix2Pix [6] is also a significant variant of GANS, using conditional generative adversarial networks (CGANS) to achieve image-to-image conversion; it can do many things, such as drawing sketches, convert outlines to pictures, converting night scenes to day scenes, auto colorize, and more.

Moreover, Style2paints, as a style transfer coloring model variant of GANS, needs to provide a reference image for color use in advance when converting the anime line art into color images [7]. The generator network proposed by Style2paints also uses U-net with residual enhancement. In the web, a residual module is added between each level in the right half of the network to enhance the coloring detail texture, and an auxiliary classifier is added to the generator network structure. The discriminator can distinguish the true and false of the generated image and classify its related styles to achieve style transfer.

PaintsChainer, which is now widely used, uses an unconditional discriminator and has achieved remarkable results [7]. Users only need to input an animation line art picture to get a color picture, and they can also get the effect under the color style by adding the color they want. However, because no labels make it easy to pay too much attention to the relationship between lines and feature maps, the image composition will lead to overfitting, and the line filling will be confusing.

It can be seen that to improve the performance of the GANSs network, much research has been done on its network structure. Moreover, GANSs have also achieved outstanding results in animation line art coloring. U-net has been proven to have an excellent effect on the coloring of anime line drafts. Still, the biggest problem is that the up-sampling convolutional layer and the down-sampling convolutional layer of U-net are directly spliced [8, 9]. When the first layer is discovered, it can simply jump-connect all the features directly to the last layer of the decoder, thus minimizing the loss, which results in the middle layers of the network not being able to learn anything, no matter how

many times it is trained. In the network, there will be a problem of gradient disappearance in the middle layer.

A deep learning model for animation line draft coloring is proposed to solve the above problems. The overall structure of the model is an adversarial generative network model. The generator structure of the model uses the improved residual-enhanced U-net network structure, and the discriminator uses the ResNet network structure [10–12]. Inspired by the ResNet network, the original U-net network sampling up-convolutional and down-sampling convolutional layers changed directly. The method is no longer a jumper connection. The Swish activation function is used, and two connection modules are proposed. The proposed Swish module can better filter the feature information transmitted in the network and improve the network's learning ability. When the low-level convolutional layer completes the task, the high-level convolutional layer can still obtain the filtered feature information for learning. After coloring the animation line draft, the color details are confused, and the gradient disappears during the training process. In addition, the discriminative network is used as a perceptual network, and the perceptual features of the generated image and the actual image can be obtained to calculate the perceptual loss. The coloring model with perceptual loss can generate qualitatively better color images.

3. Coloring Model of Animation Sketch Based on Enhanced Deep Learning

U-net network is a U-shaped convolutional neural network structure, which is initially used in the field of image segmentation. It has two branches, the left one is the encoding network structure, and the right one is the decoding network. U-net has also been widely used in image synthesis. However, it is easy to form gradient disappearance in the middle layer during network training. The emergence of non-linear activation functions makes neural networks more expressive.

To improve the quality of the generated color images, a generative adversarial model for coloring animation sketch is proposed, as shown in Figure 1. The generator network uses the residual enhanced Swish activation function based on U-net to convey feature map information. The selection in the discriminator uses a ResNet network. It has the following advantages.

- (1) Two kinds of connections are proposed based on the residual module and the Swish function. This can solve the problem of the gradient disappearance of the middle layer in the U-net network training process, better filter the feature map, better learn the feature map of each level, will not cause the gradient to disappear, and the convergence curve can also converge faster.
- (2) Propose using perceptual loss to better capture reference images and the difference between the generated image, making the resulting color image more textured and color-to-color transitions are smoother.

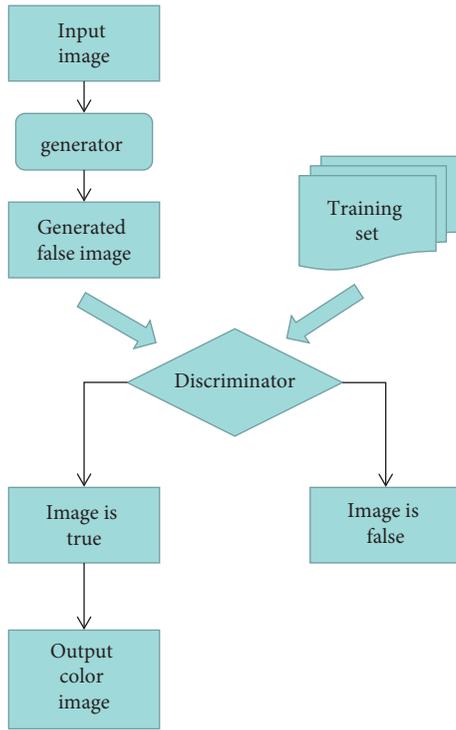

FIGURE 1: Overall structure of the network.

- (3) The experimental results in the Anime Sketch Colorization Pair dataset show that the coloring effect of the method proposed in this paper is better than the current coloring method and is close to the impact of artificial coloring.

3.1. *Whole Network Structure.* The generator network structure is based on an improved version of U-net, as shown in Figure 2, which is a Swish U-net network structure enhanced by residuals. The network has six different resolution levels, and as the level increases, the resolution gradually decreases. Like U-net, Swish U-net can also be regarded as the left and right branches. Still, a Swish Mod is embedded between the left and right components of the same resolution level to filter the information transmitted from the encoding path to the decoding path; instead, of the original jumper, Swish Mod can speed up the convergence speed of the network and improve the performance of the network. Each green dotted box in Figure 2 is a Swish Gated Block, and there are 10 in total. In the left branch, the output of each Swish Gated Block consists of the feature map output by the residual part and the feature map filtered by Swish Mod; In contrast, in the right department, the output of each Swish Gated Block consists of three parts, which are the feature map output by the residual part, the feature map filtered by the input Swish Mod, and the feature map filtered by the Swish module corresponding to the left branch.

Except for the last convolutional layer of the network, all convolutional layers use normalization and LReLU functions. The input of the Swish Gated Block of the i -th layer is the output of the Swish Gated Block of the $i-1$ layer for 1×1

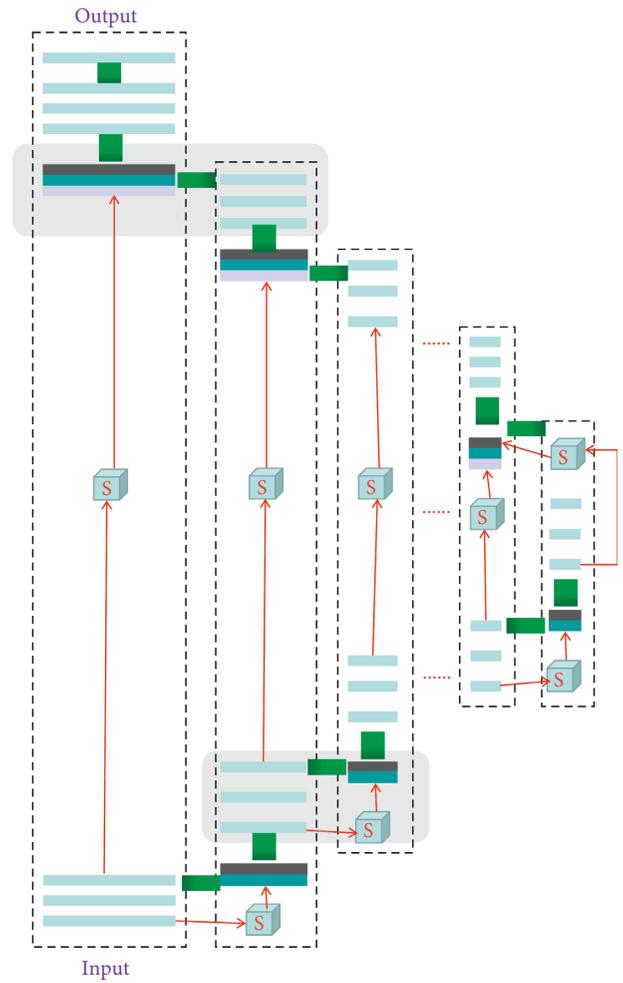

FIGURE 2: Network structure of Swish U-net.

convolution obtained after the operation. In addition, the number of convolution kernels for the 1×1 convolution operation in the i -th layer is the same as the number of convolution kernels for each convolutional layer in the i -th layer. From resolution level 1 to resolution level 6, in each resolution level, the number of convolution kernels of each convolutional layer is 96, 192, 288, 384, 480, and 512 in turn. The last convolutional layer will output the final color image, consisting of 27 1×1 convolution kernels, and no normalization and activation functions are used.

Generally speaking, the role of the discriminator is to distinguish between authentic images and generated images. ResNet is selected as the discriminator network on the discriminator. Here, the discriminator has two tasks: (1) It discriminates between generated images and authentic images. (2) The generated and authentic images' perceptual features are extracted by calculating the perceptual loss as a perceptual network. The discriminator network is finally normalized to improve the stability of network training. Then, the ReLU activation function is used to make network training faster while preventing gradients from disappearing.

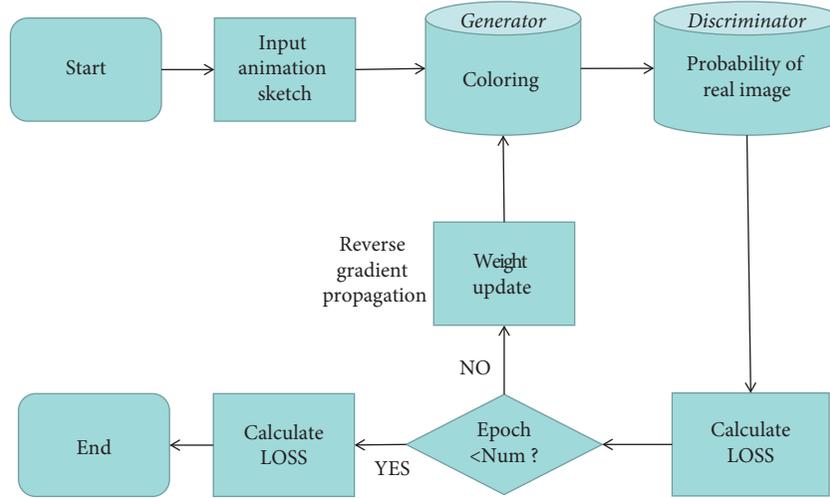

FIGURE 3: Training process of the network.

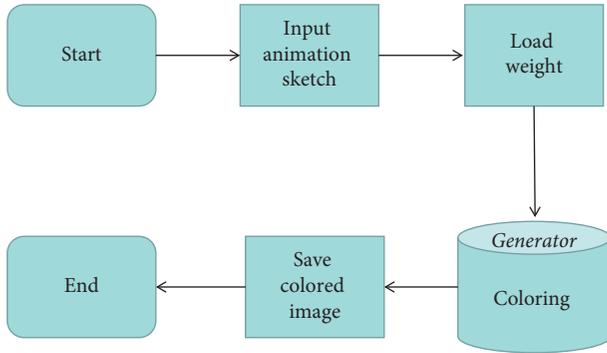

FIGURE 4: Prediction process of the network.

Figure 3 shows the training process. Each step includes two processes of forwarding propagation and back-propagation. The two processes are completed once as one epoch. When the number of times is less than the set training value Num, it will continue to cycle; Figure 4 shows the prediction flow chart after the model is trained, only forward propagation.

3.2. Swish Module and Loss Function. The new residual module Swish Gated Block proposed in this paper improves the residual module in ResNet [12–14]. The Swish Gated Block is composed of Swish module and residual, Swish module contains a convolutional layer and Swish activation function. In the structure of the proposed residual module, x represents the input data, $F(x)$ represents the residual, $F(x) + x$ is the output of the residual module, and “+” represents the corresponding addition of pixel points, $G(x)$ denotes the result of the convolutional layer in Swish module, “.” means the corresponding multiplication of pixels; $T(x)$ represents the output of the convolutional layer in Swish Gated Block after the non-linear LReLU function, $S(x)$ is the output of Swish module, “ \oplus ” represents the splicing between feature maps, and “ $T(x) \oplus S(x)$ ” is the final output of Swish Gated Blok.

In the residual module, the input data x are directly added to the residual without processing; In Swish module, x is processed, and the Sigmoid function is used; its advantage is that it can control the magnitude of the value, and in the deep network, the importance of the data can be kept from significant changes. In addition, non-linear LReLU is used for the convolutional layer in SwishGatedBlock, which has a better effect than ReLU for generating classes. Swish module filters the input data x , like a gate that controls the transmission of the input data x from the bottom layer to the high layer through a shortcut feature map. Swish module is defined as follows:

$$S(x) = X \cdot \sigma(G(x)), \quad (1)$$

where $S(x)$ is the output of Swish module, x is the input data, $G(x)$ is the output of the convolutional layer, $\sigma(\bullet)$ represents the Sigmoid function, and “ \cdot ” represents the multiplication of the corresponding pixels.

The output of Swish Gated Block is as follows:

$$y = T(x) \oplus S(x), \quad (2)$$

where $T(x)$ is the residual part in the module, $S(x)$ is the information filtered by Swish module, and finally spliced together to output the obtained feature map.

The generator and discriminator proposed in this paper are trained separately, using pairs of matching images as a data set of images. Anime line art is the input data, and paired color images are the labels. For colorization tasks, simply comparing the pixel colors of the generated image and the reference color image can seriously affect the quality of the output image. Because a black and white image is given, the hair color can be silver or black. The black and white image has a one-to-many relationship with the colored image. Still, there is only one label, so it is unreasonable only to consider the L1loss of each pixel. Perceptual missing is proposed for this purpose, which can help capture the difference between the generated color image and the reference image, and L2 regularization is added to prevent the model from overfitting

FIGURE 5: Colored images obtained from animation sketch.

[13]. The perceptual loss is calculated based on the feature map and expressed as follows:

$$L_g = \sum_1 \lambda_1 \|\varphi_l(T) - \varphi_l(G)\|_1 + \alpha \sum_{l=1}^n \lambda_l^2. \quad (3)$$

Among them, 1 takes the value [0, 5], T represents the generated image, G represents the actual image, $\varphi_0(G)$ represents the convolution operation with the network structure of the discriminator, φ represents no convolution operation, represents the original image, $\varphi_1(G)$ denotes the output result (feature map) of the first layer of convolution, representing the perceptual feature, and so on. $\lambda_1 = \{0.88, 0.79, 0.63, 0.51, 0.39, 1.07\}$, indicating the weights of different

layers. The regularization coefficient $\alpha = 0.009$, and the optimizer adopts Adam.

The network of the discriminator uses ResNet, and the data are normalized after the convolutional layer so that the data will not be too large and lead to unstable training [14, 15]. The loss of the discriminator here is the discriminator loss proposed by GANs.

$$L_d = -E[b\sigma(D(T)) + lb(1 - \sigma(D(T)))], \quad (4)$$

where G represents the actual image, T represents the generated image, D represents the discriminator, $\sigma(\cdot)$ represents the sigmoid function, and E represents the mathematical expectation.

FIGURE 6: Comparisons of Swish U-Net model (with perceptual loss), SwishU-Net-WPL model (without perceptual loss) and U-Net model.

4. Case Study

4.1. Datasets and Evaluation Indicators. To verify the performance of the proposed method, training is performed on large datasets, Anime Sketch Colorization Pair, which has a large number of paired anime line art images and anime colorization images. Training is conducted on 15432 anime line drawings and their corresponding color images, and all

pictures of the experiments are resized to 512×512 resolution. Assessing the quality of generated images has always been a complex problem. The colors generated by different coloring models in other areas of the same coloring image are also different during the coloring process. In addition to differences in color, images generated by different shader models also vary significantly in image quality (texture, shading, brightness) and visual quality of images. Therefore,

TABLE 1: Comparisons of SwishU-Net model (with perceptual loss), SwishU-Net-WPL model (without perceptual loss), and U-Net model on four quantitative indicators.

	FID	PSNR	SSIM	FSIM
Swish U-net model	108.23	18.55	0.85	0.86
U-net model	115.96	17.62	0.87	0.85
Swish U-net-WPL model	119.25	15.97	0.84	0.84

we use several standard image quality quantitative indicators to evaluate and compare SwishU-net and other existing colorization methods. The quantitative evaluation indicators used in the experiments include peak signal-to-noise ratio (PSNR), structural similarity (SSIM), and feature similarity (FSIM) [15–17]. To confirm the role of perceptual loss in the colorization model, we use Fréchet inception distance (FID) [15–17] as an evaluation criterion to quantify the quality of color images. Figure 5 shows the coloring results of the proposed coloring model. To get a color image of eight different colors, only an animation line draft is needed to input.

4.2. Experimental Results. Figure 6 shows a comparison of two colorization models with and without perceptual loss. It can be seen that the color image generated by the shading model with perceptual loss is more vivid and complete, especially the color gradient is smooth, the shadow distribution is reasonable, and there is no sense of violation; the color image generated by the shading model without perceptual loss. The colors are not rich enough, and there are fewer gradients of color changes. In addition, the color image generated by the colorization model without perceptual loss is also low in color saturation, and there is no apparent boundary between the characters and the background in the picture. Therefore, the perceptual loss significantly influences the shading effect, and the image texture generated by the shading model with the perceptual loss is more detailed. The transition between colors is also smoother.

To further investigate our approach, quantitative analysis was used to evaluate the quality of the generated images, as shown in Table 1. We used FID as a quantitative indicator to assess the generated color images’ quality (sharpness) and color diversity. The automatic colorization model is a one-to-many transformation, where FID is used to determine the quality of the generated color images; SwishU-net without perceptual loss is abbreviated as SwishU-net-WPL. In addition, PSNR, SSIM, FSIM are used here to evaluate the performance of the three algorithms, and the best results are shown in bold. SwishU-net achieves the best performance on all metrics. SwishU-net without perceptual loss has the worst performance on all metrics, indicating that perceptual loss plays a vital role in the colorization model. The quality of the color image generated by the proposed Swish module residual enhanced network is better than the image generated by the U-net network, indicating that the Swish module residual enhanced generative model has a better coloring effect.

TABLE 2: Comparisons of the Swish U-Net model, Style2paints model, and PaintsChainer model on average running time and model complexity.

	Average running time	Model complexity
Swish U-net model	≈30	≈58000
Style2paints model	≈41	≈70000
PaintsChainer model	≈46	≈77000

4.3. Algorithm Complexity Calculation. Table 2 compares the algorithmic complexity of SwishU-net and the current mainstream algorithms. All algorithms are based on python language and implemented on GPU; only 512×512 images are tested here. 16 parameter layers are selected for the above experiments to balance performance and computational efficiency.

It can be seen that Style2paints and PaintsChainer consume much time due to the complex optimization process. At the same time, the generative network of SwishU-net reduces the running time by not using normalization layers. Despite using a lightweight framework, the average running time and the number of parameters results show that SwishU-net performs better after quantitative analysis.

5. Conclusion

It takes time and energy to color the animation sketch by manpower. As a popular color generation technology of network animation sketch, GANS has not achieved certain results in the past few years. There are some basic problems, such as color confusion, poor color gradient, unreasonable color sketch, and so on. Therefore, the GANS network based on a Swish function module proposed in this paper can better learn the details of sketch during color filling and avoid color confusion when the color exceeds the filled area. At the same time, it can directly carry out end-to-end training from animation sketch to color picture. The module can automatically color the sketch and generate color pictures with rich colors and clear textures. The experimental results show that this method has better coloring ability than the existing methods and can obtain more realistic and better visual effect color images. In the future, if there are better conditions, it will make up for the shortcomings of this paper, use the GPU with stronger performance to increase the network parameters, and expand the network scale, in order to generate higher resolution images and solve the problems of complexity and diversity. Although the U-net network structure has better generation effect than the self-encoder, it also increases the parameter quantity and complexity of the model. In the future, we will consider looking for a more suitable network structure as the discriminator model to reconstruct the image, so as to achieve better generation effects while simplifying the model.

With the continuous innovation of Internet technology and the substantial improvement of network basic conditions, e-commerce has developed rapidly. Online shopping has become the mainstream mode of e-commerce. In order to solve the problem of information overload and information loss in the selection of e-commerce online shopping platform, a personalized recommendation system using information filtering technology has come into being. An e-commerce online shopping platform recommendation model is proposed based on integrated multiple personalized recommendation algorithms: random forest, gradient boosting decision tree, and eXtreme gradient boosting. The proposed model is tested on the public data set. The experimental results of the separate model and mixed model are compared and analyzed. The results show that the proposed model reduces the recommendation sparsity and improves the recommendation accuracy.

1. Introduction

Internet technology has been innovating and developing continuously in recent years. As the representative of digital technology, it affects all fields of economy and society and has become a strong driving force for the consumption upgrading. With the growth of mobile Internet users and the rapid development of mobile payment, e-commerce transaction applications are constantly upgraded and further integrated into people's life [1–7]. With the cooperation and integration of online and offline transactions and the efficient development of the logistics express industry, online shopping has become a major trend of economic development [8–10].

For businesses, promoting and selling products through an e-commerce platform can expand the business and expand consumer groups more quickly and conveniently and save a lot of costs. Under the condition that the state promotes the reform and upgrading of retail, more businesses use the way of online and offline integrated development to sell products simultaneously, further optimize the user

experience, and improve the user value. For consumers, online shopping makes them get rid of the restrictions of time and place, and it is easier to compare the types and quality of goods horizontally. In addition, online shopping allows customers to buy goods rarely seen in physical stores. Cross-border e-commerce, which has developed well in recent years, has met the needs of consumers in this regard.

Personalized recommendation system [11–13] is an advanced business intelligence platform based on massive data mining. It recommends goods for users and meets their personalized needs. E-commerce recommendation system can greatly improve the turnover of online shopping mall. Amazon has increased the sales volume of online shopping mall by 35% through personalized recommendation system. Compared with traditional search engines, personalized recommendation system finds users' interest points by studying users' behavior, so as to guide users to find products they are interested in faster. A good recommendation system can not only improve users' purchase efficiency but also establish a good relationship with users and improve users' sense of belonging.

However, traditional recommendation algorithms, such as collaborative filtering algorithm, still have problems such as data evacuation, cold start, poor scalability, and difficulty in extracting multimedia information features. In order to solve the above problems, scholars introduced users' demographic information, social information, and trust into similarity calculation, which have specific instructions on solving data sparsity and cold start problems, respectively [14,15]. How to effectively solve these two problems simultaneously requires further research. Therefore, an e-commerce online shopping platform recommendation model is proposed based on integrated multiple personalized recommendation algorithms. The data set of real online shopping platform is used to preprocess user behavior data. Through visual analysis to understand the underlying business logic, the platform selects meaningful features from the dimensions of users, goods, and interactions within them. Experimental results show that the performance of the proposed fusion model is better than that of other models.

2. Personalized Recommendation and Algorithms

2.1. Recommendation System. Recommendation system can successfully solve the problems of information overload and information loss by using information filtering technology. As one of the main applications of personalized service, it has attracted extensive attention. Its typical application is in the field of e-commerce, such as Amazon, eBay, and Taobao, which have invested a lot of research and development in the recommendation system. The recommendation system can effectively improve the utilization of the platform and enhance the user's dependence on the platform, so as to achieve greater economic benefits. At present, the widely recognized informal definition of recommendation system is "using e-commerce websites to provide users with product suggestions, help users make purchase decisions, simulate marketing, and enable users to complete the purchase process" given by Resnick and Varian in 1997 [16].

The recommendation system consists of three parts: input module, output module, and recommendation algorithm. The input module collects and records the user's historical behavior and other information and converts it into user interest data. After the calculation of the recommendation algorithm, the items suitable for the user are given. Finally, the output module presents the recommendation results for the user. The whole recommendation process includes three basic elements: users, items, and recommendation methods. How to model user and item information and what recommendation strategy to adopt are the core issues of recommendation system. The recommendation system model is shown in Figure 1. The recommendation system models the user according to the implicit or explicit information obtained from the input module, models the items at the same time, and selects the best recommendation object to present to the user through the matching of the recommendation algorithm.

The mathematical expression of the recommendation system is as follows: set the user set as C and the

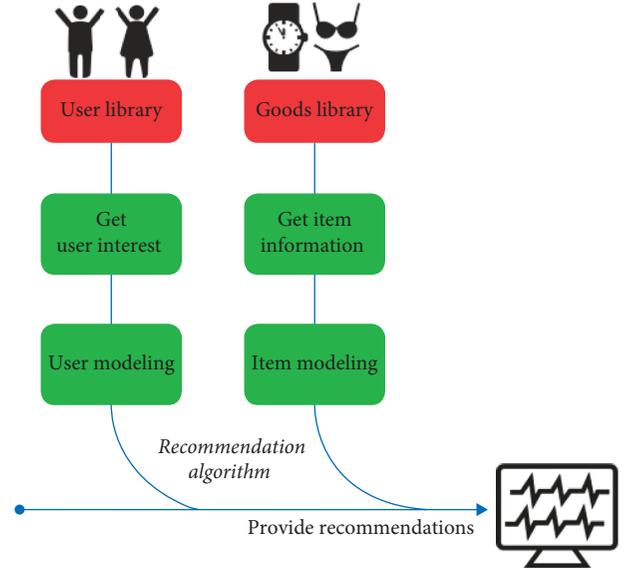

FIGURE 1: Recommendation system model.

recommendation object set as S . The scale of C and S sets is usually large, and S can be any object recommended to users, such as goods, articles, advertisements, and songs. The utility function $u()$ can calculate the recommendation degree of object s to user c , which can be expressed as

$$u: C \times S \longrightarrow R, \quad (1)$$

where R is a fully ordered nonnegative real number in a certain range.

The problem of the recommendation algorithm is to find the object S^* that can maximize the recommendation R calculated by $u()$, which can be expressed as

$$\forall c \in C, S^* = \arg \max_{s \in S} u(c, s). \quad (2)$$

The utility value of the recommended object is expressed by score, which represents a user's preference for an object. The utility function $u()$ changes according to the actual recommendation scenario and recommendation strategy. Because the utility value of the recommended object is not given in the whole space, how to build a recommendation engine to estimate it is the core of the recommendation problem.

2.2. Classification of Recommendation System. The recommendation system adopts different recommendation strategies and technical means [17], which can be divided into three categories according to the degree of providing personalized services for users as shown in Figure 2.

- (1) *Nonpersonalized Recommendation System.* General recommendation: The recommendation system will not generate recommendations according to the user's personal characteristics but through the marketing strategy formulated by the background operator of the web system or the statistical analysis tool based on the background of the system. This

kind of recommendation system is not targeted to users but presents the same recommendation results for all users. Specific forms of recommendation include advertising recommendations and sales ranking recommendation.

- (2) Semipersonalized recommendation system: The system obtains the user's preference information and generates recommendations by analyzing the user's browsing behavior or current shopping data. The user's behavior data affect the recommendation results, and its degree of personalization is higher than that of nonpersonalized recommendation system.
- (3) Fully personalized recommendation system: The user's historical information in the system is retained according to its value extracted from personalized features, such as user's browsing information, purchase history, registration information, scoring data, collection list, and registration information. Because this kind of recommendation system makes use of the long-term data of users, it can build a relatively stable user preference model and analyze it in combination with the current behavior of users, so it can provide users with fully personalized recommendation services. This kind of recommendation service has the highest degree of personalization and is generally only for registered users.

From the perspective of algorithm and implementation, recommendation systems can be divided into the following categories: content-based recommendation system, collaborative filtering algorithm-based recommendation system, association rule-based recommendation system, knowledge-based recommendation system, and hybrid recommendation system, which are also shown in Figure 2. The recommendation system based on collaborative filtering algorithm and content-based recommendation system have the longest research time and the most applications.

2.3. Recommendation Algorithms. In the recommendation of e-commerce online shopping platform, multicriteria decision-making [18–24] is a common method, but this method has been proved to have many shortcomings, such as uncertainty and subjectivity in the decision-making process [25–28]. Many researchers classify recommendation algorithms differently from different perspectives. From the perspective of information technology, they can be divided into collaborative filtering and content-based recommendation according to the algorithm and generation mechanism of recommendation results.

Collaborative filtering algorithm is a mature recommendation algorithm recognized in the industry. Goldberg et al. [29] first proposed the collaborative filtering algorithm and applied it to the Tapestry e-mail filtering system. The algorithm mainly recommends items based on users' previous preferences and the choices of users with similar interests. Different from Tapestry's single-point filtering mechanism, Resnick et al. [30] proposed a cross-point and cross-system news filtering mechanism, GroupLens. This

automatically helps people find what they like from a large number of articles available. The drawback of the above nearest neighbor method is that it requires a lot of calculation. Therefore, Verbert et al. [31] proposed a collaborative filtering algorithm based on items. The algorithm replaces the nearest neighbor method by finding similar goods. Online computing costs have nothing to do with the number of users or items. It can generate high-quality recommendations in real time on huge amounts of data. The advantages of collaborative filtering algorithm are obvious. In engineering, the model is simple, effective, and versatile. If the scale of the e-commerce system expands, the rapid increase of user and project data will lead to data sparsity. In addition, it also has a serious cold start problem. Pereira et al. [14] introduced user demographic information into the recommendation algorithm. This forms the hybrid collaborative filtering recommendation algorithm, which can solve the cold start problem well. Shambour et al. [15] incorporated the idea of project rating trust into the traditional user-based collaborative filtering recommendation algorithm. They abandoned the traditional method of similarity calculation. Experiments show that this algorithm can alleviate the problem of data sparsity.

In addition, the content-based recommendation algorithm can effectively solve the cold start problem of the collaborative filtering algorithm and its whole operation process. In the collaborative filtering recommendation algorithm, if the condition that the project is evaluated by many relevant users is met, it will make recommendations for other relevant users. In content-based recommendation algorithm, feature vectors describing related content are established by extracting features from content for users. Then, the preferences of the users are calculated to determine whether to recommend relevant content to the users.

A review of relevant research found that the online shopping platform has specific business scenarios for product recommendations. It needs to select an efficient recommendation algorithm from the perspective of accuracy, efficiency, and explainability of the algorithm. In addition, collaborative filtering and content-based recommendation algorithms have their own advantages and difficulties. In fact, most recommendation systems carry out a hybrid recommendation by integrating different recommendation algorithms in various forms. It can use the results of the respective models to carry out the weighted combination and waterfall mixing. Therefore, random forest (RF), gradient boosting decision tree (GBDT), and eXtreme gradient boosting (XGBOOST) models are selected as the basic models.

Random forest (RF) is composed by Breiman et al. [32] on the basis of a classification and regression tree (CART). Its principle is to form different data sets by randomly sampling the original data set. By training decision trees on a single dataset, multiple decision trees are combined to form a classifier. The specific steps are shown in Figure 3.

The first step is to preprocess the RF model. The downsampling method was adopted to avoid the influence of sample imbalance on the experimental results (the ratio of positive and negative samples in the original data set was 1 : 1100).

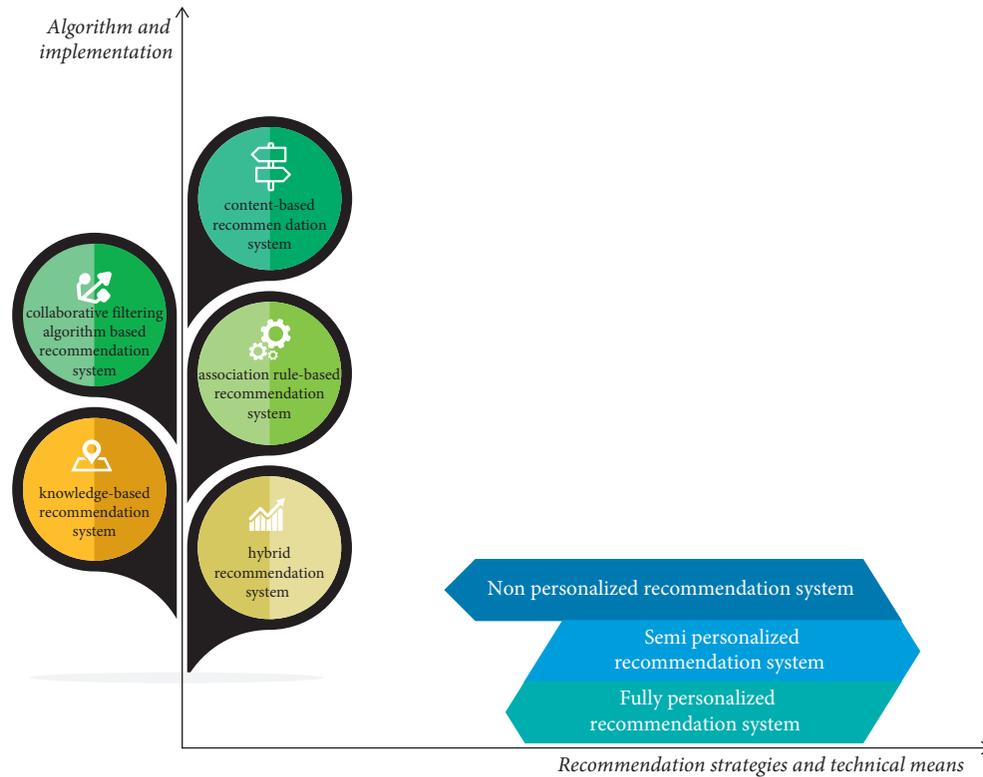

FIGURE 2: Classification of recommendation system.

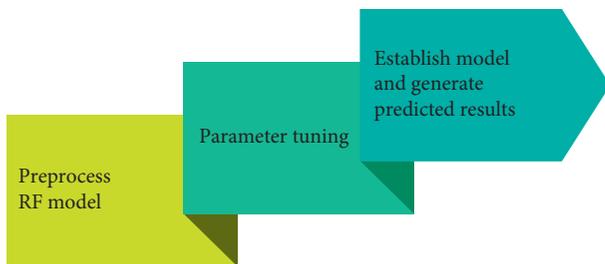

FIGURE 3: Random forest model.

- (1) K-means clustering algorithm is used to cluster negative samples
- (2) Based on the subsamples of each group set with the same ratio, the optimal ratio is selected through testing in random subsamples
- (3) RF model is used to train and predict the lower sample set.

The second step is parameter tuning.

- (1) The imbalance rate N/P of positive and negative samples was optimized.
- (2) The number of forest scale trees is optimized.
- (3) For the setting of the probability wide value, the predicted value can be obtained by inputting the sample characteristics of the trained model. The predicted value is the probability value. The default value is 0.5. By constantly adjusting and modifying the condition that the probability value

reaches the broad value, the purchase prediction classification label for the user and the sample is changed.

The third step is using `RandomForestClassifier()` in `sklearn` package to establish the model and train to generate a subset P of predicted results.

GBDT [33] belongs to boosting algorithm, which is different from the bagging algorithm to RF. Boosting algorithm adopts a series serialization model. Individual learners are strongly correlated; that is, the new model generates training results based on the old learning model. GBDT algorithm is learned from the generated CART classification regression tree. Samples with large residuals output from existing models and actual samples. So, generation is selected to generate a new CART tree. Through the above training methods, residuals are constantly reduced to ensure the accuracy of the results. The specific steps are shown in Figure 4.

The first step is to use k-means clustering to cluster negative samples. The second step is to select the optimal ratio by adding human GBDT into the random subsample based on the subsample of each population with the same ratio. Third, GBDT classifier selects the best parameters.

- (1) The imbalance rate N/P of positive and negative samples was optimized
- (2) GBDT selects the best number and learning rate of forest scale trees
- (3) The best maximum depth value of the base tree, the minimum number of samples required for internal

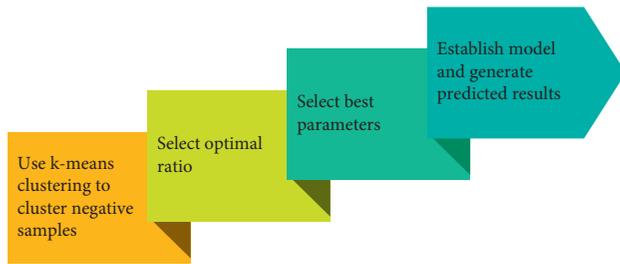

FIGURE 4: GBDT model.

node subdivision, and the minimum number of samples for leaf nodes are selected

- (4) Probability wide value is tuned

The fourth step is using `GradientBoostingClassifier()` in sklearn package to establish the model and train to generate a subset P of predicted results.

Both of them belong to boosting algorithm, and XGBOOST efficiently implements and optimizes GBDT algorithm. In the choice of the base learner, XGBOOST [34] model can adopt the tree model and other models (such as LR). Therefore, it is not limited to the CART tree defined by the GBDT algorithm. XGBOOST learns new functions and fits residuals through continuous feature fission of the tree. The specific steps are shown in Figure 5.

The first step is to train XGBOOST model parameters for analysis.

- (1) Use higher learning rate to adjust the number of optimal forest size trees
- (2) Adjust the maximum depth value and the minimum sum of sample weights in subnodes
- (3) Adjust parameter γ
- (4) Adjust input and A
- (5) Reduce the learning rate and cycle to obtain a more stable parameter combination

The second step is using `GradientBoostingClassifier()` in sklearn package to establish the model and train to generate a subset P of predicted results.

3. Experimental Data

The experimental data construct a product recommendation model based on real desensitization data from an online shopping platform, which comes from the Tianchi big data platform competition of Alibaba. The dataset contains the user's mobile behavior data over a 30-day period. The user table contains six fields, including user ID, brand ID, user location ID, product classification ID, user interaction behavior, and behavior time. The specific data amount is as follows. The number of users is 92302, the number of commodity subset is 65221, and the number of commodity user interaction data is 22560328.

The experimental data include the data of Taobao's shopping festival on December 12. After analyzing the total operations of users in this month (browsing, collecting, adding to the shopping cart, and purchasing behavior), it is found that

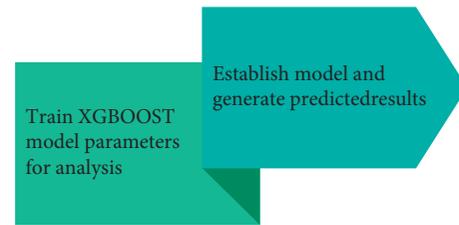

FIGURE 5: XGBOOST model.

the purchase behavior doubled at 0 on the 12th and was obviously abnormal data. Therefore, the data of this day are eliminated. In the process of e-commerce website data statistics, there are repeated data, abnormal data, and other problem data. Therefore, the above repeated values and invalid values will be directly eliminated in the data cleaning process at this stage. The ratio of positive and negative samples in the original data set is about 1:1100. Therefore, it may cause the algorithmic prediction model to treat the positive sample set as noise data and thus bias the negative sample set data. Positive samples are more likely to be misclassified than negative ones. Therefore, the random downsampling method is adopted to avoid the above problems.

3.1. Feature Construction. According to the data preprocessing results and combined with the business characteristics of the online shopping platform, data characteristics are reconstructed. Feature construction is completed from the three dimensions of user feature, commodity feature, and commodity category feature and their combination, which is shown in Figure 6. If this experiment is treated as a dichotomous problem, the output variable Y labels are 1 (purchased) and 0 (not purchased), respectively.

The characteristics of user behavior are as follows:

- (1) User activity: it refers to the sum of users' behaviors in the recent N days, reflecting users' purchasing habits
- (2) User conversion rate: it reflects the user's buying decision operation habit

The commodity characteristics are as follows:

- (1) Commodity activity: it refers to the total number of user operations on the category in the previous N days, reflecting the popularity of the product
- (2) The conversion rate of goods: it reflects the operation characteristics of purchasing decision (such as high value and long decision time)

The characteristics of the commodity category are as follows:

- (1) Activity of commodity category: it refers to the total number of user operations on this category in the last N days, reflecting the popularity of this category
- (2) Purchase conversion rate of commodity category: it reflects the characteristics of purchase decision operation of the commodity category

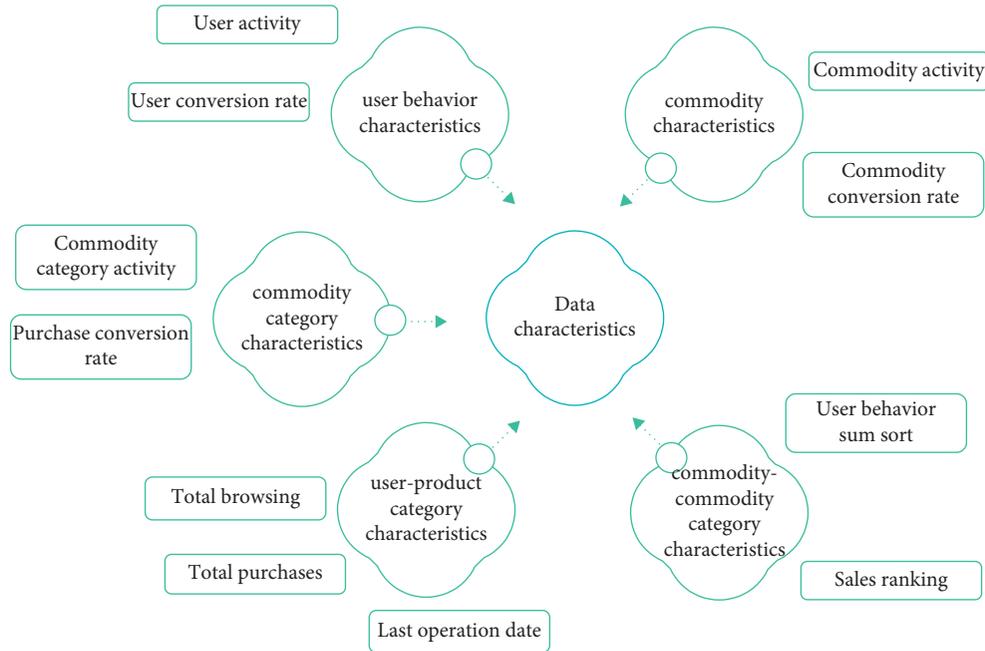

FIGURE 6: Data characteristics.

The user-product category characteristics are as follows:

- (1) Total browsing of user-product category
- (2) Total purchases of user-product category
- (3) Last operation date of user-product category

The commodity-commodity category characteristics are as follows:

- (1) User behavior sum sort of commodities in the category
- (2) Sales ranking of commodities in the category

3.2. *Division of Data Set.* This experiment divides the data set into two parts, including the training set and test set. The learning and training process is shown in Figure 7.

The data preprocessing results are shown as follows. The user click conversion rate of this dataset is less than 1%; that is, it takes an average of 100 interactions (including browsing, clicking, and adding products) for each user to generate one transaction. The amount of data is relatively large.

If all interactive behaviors of users in the whole time period are taken as characteristic data, the calculation speed of the model will be greatly reduced. Due to the time decay of user interest, the accuracy of the model will be reduced. Therefore, when dividing the data set, it can be divided into four groups with weeks as the interval unit, including a group of abnormal data. The reason for elimination has been explained above.

4. Case Study and Algorithm Analysis

4.1. *Algorithm Evaluation Indicator.* F1-score is a comprehensive indicator that can be considered when user ratings are sparse or missing. It is characterized by harmonic

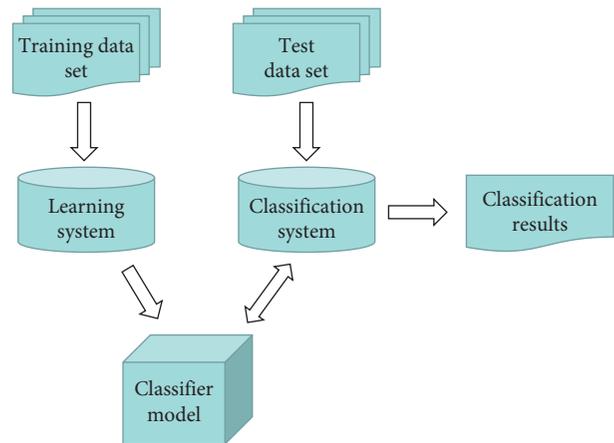

FIGURE 7: Process of the training data model.

precision α and recall rate β . The basic meanings of these three indicators are as follows:

$$\alpha = \frac{tp}{tp + fp},$$

$$\beta = \frac{tp}{tp + fn}, \tag{3}$$

$$F1 = \frac{2\alpha\beta}{\alpha + \beta},$$

where some concepts of confusion matrix are involved, tp means true positive, fp means false positive, fn means false negative, and tn means positive.

Combined with the recommendation scenarios of online shopping platforms, harmonic precision α and recall rate β can also be expressed as

TABLE 1: The training result of separate model.

	LR	RF	GBDT	XGBOOST
F1	0.0611	0.0872	0.0836	0.0896
Harmonic precision	0.0568	0.9033	0.0959	0.0811

TABLE 2: The training result of mixed model.

	LR/GBDT	LR/XGBOOST	RF/GBDT	RF/XGBOOST	GBDT/XGBOOST	LR/GBDT/XGBOOST
F1	0.1022	0.0966	0.0865	0.0956	0.0867	0.1122
Harmonic precision	0.0633	0.0564	0.0819	0.0980	0.0895	0.0823

$$\alpha = \frac{\eta \cap \mu}{\eta}, \quad (4)$$

$$\beta = \frac{\eta \cap \mu}{\eta},$$

where η means recommended quantity, and μ means serviceable quantity.

Higher precision means more accurate recommendation, and higher recall rate means more acceptance of recommendation. Only when both are high, the performance of the recommendation algorithm is good. Therefore, F1-score is taken as the main indicator.

4.2. Experimental Environment. The operating system of this experiment is Windows 10–64 bit, with CPU: Intel(R)Core(TM) 15–5200U CPU @ 2.20 GHz (4 CPUs), 2.2 GHz, and Python version 3.7.2. It is implemented based on software packages such as PANDAS and sklearn.

4.3. Separate Model Training. First, the LR model was trained, but the result was not ideal. When RF, GBDT, and XGBOOST are used, the effect is significantly improved. In the three integration algorithms, XGBOOST has only a slight advantage in F1-score compared with RF, but the model implementation time is shorter than RF. LR models are simple, and run time is short, but its accuracy is poor compared with other algorithms. The three integration models (RF, GBDT, and XGBOOST) show strong generalization ability for such data with complex features. The training result of the separate model is shown in Table 1.

4.4. Mixed Model Training. All kinds of recommendation algorithms have their own advantages and difficulties in implementation. In fact, most recommendation systems carry out a mixed recommendation by integrating different recommendation algorithms in various forms.

- (1) **Weighted mixing:** Weighted hybrid combination is a common way. The recommendation results and scores can be combined to generate the final recommendation set by a weighted combination of the deduction results of respective models. Through a reasonable weighting method, the result of a comprehensive algorithm is better. But there are also

some problems such as a large amount of computation and complex systems.

- (2) **Waterfall mixing:** waterfall hybrid mode adopts the principle of “filtering” and takes the filtering result of one model as the input data of another model. Generally, taking GBDT + LR model as an example and combining the respective advantages of the LR model and GBDT model, the OUTPUT results of the GBDT algorithm are directly output as LR input features, which improves the utilization rate of data information and the learning efficiency of LR model step by step.
- (3) **Graded mixing:** In industry, this kind of hybrid method makes the hybrid algorithm simple and efficient. Combined with different scenes, according to the characteristics of different algorithms, the high-precision algorithm is first used. Other algorithms are used to get subsequent results.

The training result of mixed model is shown in Table 2.

In the experiment, the models are fused according to the independent training results of the previous model. The experiment involves a lot of steps of data processing, feature selection, and parameter adjustment. The results of the experiment are as follows:

- (1) Under normal circumstances, the fusion between models will improve performance. However, when the performance of a single model is poor, the fusion with other models will reduce the effect of its fusion model.
- (2) In the mixed recommendation, the direct fusion effect is poor; for example, the simple weighting can adopt the hierarchical strategy. Efficiency is improved by taking the output of one model as the input of another.
- (3) When the experimental performance of the models is similar, the fusion effect will not be significantly improved.
- (4) The final results show that the model combining LR, GBDT, and XGBOOST has the best effect.

5. Conclusion

With the continuous innovation of Internet technology and the substantial improvement of network basic conditions, e-commerce has developed rapidly. As the mainstream

mode of e-commerce, online shopping has added great vitality to the development of the economy. The online shopping platform recommendation algorithm is explored. An e-commerce online shopping platform recommendation model based on integrated personalized recommendation is designed and implemented. The later research of this paper can be carried out from the perspectives of real-time recommendation, visual recommendation result generation, and user interest model mining combined with scenes. The model used in the recommendation system can be further improved. In the future, user data from various sources can be integrated, and attribute tags can be added to make the personalized recommendation model more accurate. In addition, according to the different business needs of the application, the personalized recommendation system can add more recommendation scenarios to meet the needs of users more comprehensively.

In future software system development based on the model proposed in this study, the preliminary system function module planning is as follows. It is mainly divided into the foreground function module and the background function module. The foreground function module includes the system home page submodule, registration and login submodule, alternative platform display submodule, and personal center submodule. The background function module includes a platform management submodule, order management submodule, merchant management submodule, and security authority submodule. The function of the software system is tested by the method of unit test.

It is a very interesting and practical task to transform real-world images such as portraits or scenery into creative animation images. Since this concept was put forward, it has aroused extensive research interest in the field of computer vision. The generative adversarial networks (GAN) model is widely used in this field. Depth convolution GAN (DCGAN) and Wasserstein GAN (WGAN) improve the original GAN, but there are still problems existing in creative animation generation such as model collapse. To solve these problems, the Wasserstein distance is introduced to replace the JS divergence in the GAN model to measure the gap between the sample distribution generated by the generator and the real distribution, and the loss function is improved. In order to achieve a better animation generation effect, the training of the model is further optimized through the adjustment of the network model structure and the setting of parameters. Through the comparison with DCGAN and WGAN models in the animation data set and CelebA data set and the quantitative analysis and comparison of the generation effects of different models, the effectiveness and generalization of the improved GAN model are verified.

1. Introduction

It is a very interesting task for computers to be used to generate creative animation images with artistic style. This task is mainly studied through image style transfer. Image style transfer focus uses a computer to stylize the content in an image, presenting a specific artistic style while the original content can be recognized [1, 2]. This is a new research direction in computer vision in recent years. Style transfer technology allows computers to create art “autonomously.” Therefore, the concept has attracted people’s attention since it was put forward.

Convolutional neural networks (CNN) and generative adversarial networks (GAN) learning models are basically adopted in the study of image style transfer [3, 4]. These models can add an art style to the target image, which has artistic properties. In image style transfer, firstly, CNN or GAN is used to learn style patterns from the specified style

images. Then, they are converted into oil paintings, cartoons, Chinese landscape paintings, and other different artistic images, or the transformation of seasons and textures on the image is realized after it is applied to the target image.

GAN model is unstable and difficult to optimize in training. Many style migration efforts improve it from a loss function perspective. In these improved models, DualGAN [5] and CycleGAN [6] can complete the image style transfer work well. However, these GAN models can only migrate either style or content during style migration. In this paper, by improving the generator structure, the model achieves a better balance in the simultaneous transfer of style and content. The improved model is applied to the style transformation from natural images to animation illustrations. The experimental results show that the model can retain the content of the original natural scene and have a very excellent animation illustration style effect.

2. Related Works

As the most widely used generation model in the field of deep learning, GAN is also one of the models with the best visual effect on image generation. It is a new network model proposed by Ian Goodfellow of OpenAI in 2014 [4]. The model has attracted the attention of many scholars. The image quality generated by generating a countermeasure network model is higher than that of traditional generation models, such as variational self-encoder, and the training of the model is faster than that of the autoregressive model. However, the original GAN model also has some disadvantages, such as poor training stability and mode collapse. With the continuous research of scholars, various improved models have emerged one after another, and the performance of the generated countermeasure network has been greatly improved.

In view of the phenomenon that the training speed of the model is slow, the gradient is not updated in time, and even the model collapses when using the original GAN model. Mao et al. proposed the least squares GAN (LSGAN) [7], and the gradient of the model will be reduced to 0 when the data distribution is completely consistent with the real sample. The problem of gradient disappearance in model training caused by using Sigmoid and other functions as activation functions is avoided.

However, the real problem of GAN is how to better measure the gap between generated sample distribution and real sample distribution so that the generator can learn better. This problem did not make a major breakthrough until Wasserstein GAN (WGAN) was put forward.

WGAN was proposed by Arjovsky et al. [8]. The model uses Wasserstein distance instead of JS distance in traditional GAN as the standard to measure the difference between distributions. The common problem of JS divergence is that it is unable to measure the distance between two non-coincident distributions, and the gradient often disappears in the process of model training. Using Wasserstein distance can better measure the gap between the generated sample distribution and the real sample distribution, effectively alleviate the problems of mode collapse and training instability in network model training, and achieve good experimental results without a complex network model structure.

Ishaan Gulrajani et al. proposed WGAN's improved model WGAN-GP on the basis of WGAN [9]. In the model, the gradient penalty method is used to replace the weight clipping in WGAN to achieve the approximate 1-Lipschitz restriction effect on the discriminator network, and the normalization operation is cancelled in the discriminator network. David Berthelot et al. proposed the boundary equilibrium GAN (BEGAN) model and designed a new way to evaluate the generation quality of generators [10]. By estimating the difference between the distribution of distribution errors instead of the traditional generation, they can directly estimate the generation distribution and the real step-by-step errors in the antinetwork model. The model can also be trained stably under the standard GAN structure, and the model can converge quickly. At the same time, a super

parameter is added to adjust the quality and diversity of the image generated by the generator.

The improvement methods mentioned above are to improve the original generated countermeasure network model from the loss function of the model. In terms of the structural improvement of the generated countermeasure network, the earliest is the deep convolution GAN (DCGAN) [11] proposed by Alec Radford et al. The model combines the powerful convolution neural network with the generator and discriminator that generates the countermeasure network, replaces the pool layer in the original generated countermeasure network with the convolution layer with step size, and uses the batch normalization operation [12] in the generator network and discriminator network to cancel the full connection layer in the network so that the generator can better learn the characteristic information of the image. The generated image has higher quality. Zhang et al. proposed self-attention GAN (SAGAN) [13] and added a self-control module to the model structure of the generation countermeasure network. The self-attention module can well deal with the long-range and multilayer dependence of image information. When generating the image, it can coordinate the details of each position and the details of the far end. At the same time, spectral regularization is added to the discriminator, which has achieved good results in the field of image generation. Andrew et al. proposed the BigGAN [14] model, which has achieved a major breakthrough in the field of image generation. The model not only increases the batch size but also increases the number of filters in each layer of the network. Through the shared embedding between network levels, the random noise and input conditions are spliced and input to each batch normalization layer of the generator network model, which greatly improves the quality of the generated image.

In order to apply the GAN model to a wider range of fields, Mirza and Osindero proposed conditional GAN (CGAN) [15]. By adding additional label information conditions to the generation network and discrimination network to guide the data generation process, the network can generate specific image samples according to the additional condition information. Phillip et al. proposed the pix2pix model [16] on the basis of CGAN and applied GAN to the field of image style migration. The model adds a U-net structure [17] to the generator network and an L1 regularization term to the loss function to realize the image translation task. In the image style conversion, the most popular is the cycle neural network GAN (cycle GAN) [18] proposed by Zhu et al. It realizes the conversion between images of two different styles (such as the conversion from horse to zebra) and the conversion between different painting styles. Different from the pix2pix model, the cycle GAN model can be trained in non-paired data set, while the training data and data of the pix2pix model must be paired. Yunjey et al. proposed the star GAN [19] model to realize the conversion between multiple different style fields through fewer generators. Star GAN realizes the image cross style conversion under different data sets with less training cost by adding one hot condition feature and mask vector to the model.

In the field of more widely used image restoration and image super-resolution reconstruction, there is the Deblur GAN [20] model proposed by Orest Kupyn et al. Based on conditional GAN structure and content loss, it realizes image deblurring through end-to-end learning.

In the practical application of image super-resolution reconstruction, the more popular is the SRGAN model [21] proposed by Christian et al. The generation network model of SRGAN adopts the deep-seated residual network as the network structure and adds the perception loss based on the VGG network [50] to the loss function so that GAN has more real details in generating super-resolution images and faster training speed.

3. Principles of GAN

GAN is also a generative model. But it does not have to explicitly express the probability distribution of the sample. It is the idea of adversarial learning. The intrinsic distribution of data is implicitly learned through a zero-sum game between generator and discriminator [22–25]. When the generator and discriminator reach a Nash equilibrium state, the data generated by the generator can have the same inherent properties as the real data. This allows using generators to get real data [25].

The GAN model consists of two basic modules: generator G and discriminator D . Generator G and discriminator D can be any learning model with generative and discriminant capabilities. Compared with the traditional shallow machine learning model, the deep model has richer parameters and stronger learning ability. In particular, CNN has unique advantages in processing image data. Therefore, CNN is generally used as a discriminator in the GAN model. CNN with transpose convolution structure is used as a generator.

When using the GAN model to generate image data, random noise vector Z needs to be input for generator G . The output result $G(z)$ is obtained by transposing convolution – upsampling – non-linear activation – batch normalization. $G(z)$ has the same structure and size as real training data. They will be fed into discriminator D along with real training data X . Their labels are usually separated by zeros and ones. If the input sample is $G(z)$, then discriminator D should determine its category label as 0. If the input is true sample X , the category label of it is judged to be 1. In the training process, discriminator D needs to maximize the accuracy of label prediction for X and $G(z)$. Generator G , meanwhile, tries to make the generated $G(z)$ indistinguishable from the x from the real training set. Thus, generator G and discriminator D will constantly play against each other throughout the training process. The generative and discriminant abilities of both will be improved continuously. The output of the final generator will have the same appearance as the real data. Judge D will not be able to distinguish the true source of the data. The classification probability of both the real sample and the “false” data generated by G will approach 1/2. At this point, you can assume that generator G has learned the inherent distribution of real data. The “fake” data it generates already has

the same properties as the real data. This enables data distribution without explicitly expressing it. The goal of the intrinsic distribution of training data is obtained through adversarial learning.

The learning objectives of the GAN model can use the following form of expression:

$$\min_G \max_D L_{\text{GAN}}(D, G) = E_{x \sim p_{\text{data}}} [\log D(x)] + E_{z \sim p_z} [\log(1 - D(G(z)))], \quad (1)$$

where p_{data} is the probability distribution obeyed by real training sample x . $p_z(z)$ is the probability distribution that noise z obeys. $E_{x \sim p_{\text{data}}}[\cdot]$ and $E_{z \sim p_z}[\cdot]$ are the mathematical expectation of x and z classification probability output by discriminator D , respectively.

4. Animation Style Migration Model

A deep convolution generated countermeasure network (DCGAN) is an improved model of generating countermeasure network GAN. Its principle is consistent with that of GAN. The biggest improvement is the perfect combination of convolution neural network, which is most widely used in image processing, and generated countermeasure network. Deep convolution generated countermeasure network uses convolution neural network structure for both generator and discriminator in the model. At the same time, some changes are made to the structure of the added convolutional neural network to improve the performance of the network model.

4.1. Improvement of Loss Function. Since GAN was proposed in 2014, although it has been widely used in the field of machine vision and achieved good results, the initial GAN model often has problems such as training difficulties, unbalanced training between generator and discriminator, and insufficient diversity of samples generated by the generator. In the original GAN model, KL (Kullback–Leibler divergence) is used to measure the gap between the sample distribution generated by the generator and the real distribution. The loss function used in the standard generation countermeasure network model is shown in formula (1).

From formula (1), it can be calculated that when the parameters of generator g are fixed, it is the optimal discriminator D . The calculation process is as follows:

$$\min_G \max_D V(D, G) = E_{x \sim p_r(x)} [\log D(x)] + E_{x \sim p_g(x)} [\log(1 - D(x))], \quad (2)$$

where $E_{x \sim p_r(x)} [\log D(x)]$ represents the probability distribution that sample x belongs to real data and $E_{x \sim p_g(x)} [\log(1 - D(x))]$ represents the probability distribution that sample x belongs to the sample data generated by the generator.

Then the contribution of x to the loss function is

$$\text{contribution}(x) = p_r \log D(x) + p_g \log(1 - D(x)). \quad (3)$$

By taking the derivative of formula (3) to $D(x)$ and making its derivative value 0, it can be obtained that

$$\frac{p_r}{\log D(x)} + \frac{p_g}{\log(1-D(x))} = 0. \quad (4)$$

By simplification, the best discriminator can be obtained as follows:

$$D(x) = \frac{p_r}{p_r + p_g}. \quad (5)$$

The above results show that the task of the discriminator is to judge the possibility that the input sample x comes from real data and generated data. When $p_r(x) = 0$ and $p_g(x) \neq 0$, the discriminator can easily determine the source of x . When $p_r(x) = p_g(x)$, it indicates that the probability that the sample belongs to the real sample is equal to that of the generated sample. At this time, the output of the optimal discriminator is 0.5, which means that the generator and the discriminator have reached Nash equilibrium. The sample generated by the generator is enough to confuse the true with the false so that the discriminator cannot make a correct judgment on the input sample. If the obtained optimal discriminator is replaced back into the loss formula of the original GAN, the following can be obtained:

$$\begin{aligned} & E_{x \sim p_r(x)} \left[\log \frac{p_r}{p_r + p_g} \right] + E_{x \sim p_g(x)} \left[\log \left(1 - \log \frac{p_r}{p_r + p_g} \right) \right] \\ &= \int_{x \in X} p_r \log \frac{p_r}{p_r + p_g} dx + \int_{x \in X} p_g \log \frac{p_r}{p_r + p_g} dx \\ &= \int_{x \in X} p_r \log \frac{2p_r}{p_r + p_g} dx + \int_{x \in X} p_g \log \frac{2p_r}{p_r + p_g} dx - 2 \log 2 \\ &= KL \left(p_r \parallel \frac{p_r + p_g}{2} \right) + KL \left(p_g \parallel \frac{p_r + p_g}{2} \right) - 2 \log 2 \\ &= 2JS(p_r \parallel p_g) - 2 \log 2. \end{aligned} \quad (6)$$

It can be seen from the above results that the form of the optimal discriminator can be obtained according to the loss function in the original generated countermeasure network. When the discriminator is in the optimal state, the generator loss defined by the original generation countermeasure network can be equivalent to minimizing the Jensen-Shannon (JS) divergence between the real sample data distribution and the generated data sample distribution.

However, there is often a problem when optimizing JS divergence. No matter whether the two data distributions are very close or far apart, as long as there is no overlap between the two data distributions or the overlap can be ignored, JS divergence will not be updated and will always be the fixed value $\log 2$. This also means that the gradient vanishing problem will occur when using the loss function of the original GAN for training.

In the process of generating countermeasure network training, especially at the beginning of training, the input of the generator is random noise, so there is no intersection

between the large probability of the sample distribution generated by the generator and the real sample distribution. As a result, the JS divergence is fixed at the constant $\log 2$, and the gradient is 0, so the gradient descent method cannot be used to train the network parameters. At this time, for the generator network, there will be no gradient information fed back from the discriminator network, which leads to the disappearance of the gradient in the network training. Therefore, the training instability and model collapse often occur in the original generated countermeasure network. On the one hand, when the discriminator network is trained too well, the gradient fed back to the generator network will disappear, and the generator network cannot be updated and optimized. On the other hand, when the discriminator network is not trained well, the correct gradient cannot be fed back to the generator network to guide the generator network to optimize better.

Therefore, we use the loss function of the WGAN model to replace the loss function of the original generated countermeasure network and use Wasserstein distance instead of JS divergence to measure the distance between two data distributions, which effectively reduces the instability of model training. Wasserstein distance is also called earth-mover (EM) distance, which is defined as follows:

$$W(p_r, p_g) = \inf_{\gamma \sim \prod(p_r, p_g)} E_{(x,y)} [\|x - y\|]. \quad (7)$$

The advantage of Wasserstein distance over KL divergence and JS divergence in the original generated countermeasure network is that it can reflect the distance between the two data distributions without overlapping.

In order to add Wasserstein distance to the loss function, a constrained discriminator is proposed, that is, it satisfies 1-Lipschitz continuity, and the Lipschitz continuity condition limits the maximum local variation amplitude of a continuous function. In order to meet the constraints, the weight updated during backpropagation is forcibly trimmed to the specified range by weight clipping, and then the $V(G,D)$ is maximized to realize the training of the model.

The proposed loss function is

$$V(G,D) = \max_{D \in 1\text{-Lipschits}} E_{x \sim p_{\text{data}}} [D(x)] - E_{x \sim p_G} [D(x)]. \quad (8)$$

The larger the value of the proposed loss function, the closer the generated data distribution is to the real data distribution, and the better the network training.

4.2. Structure of the Migration Model for Creative Animation Generation. Similar to the general GAN model, the animation illustration style transfer model proposed in this paper is also composed of generators and discriminators. The internal distribution of data can be obtained by leaning against each other. In order to better retain the original content of images and achieve the transfer of artistic styles in animation illustration style transfer, we design the generator structure of the deep learning-driven migration model for creative animation generation as shown in Figure 1. Taking ResNet-18 as the basic model, the generator structure

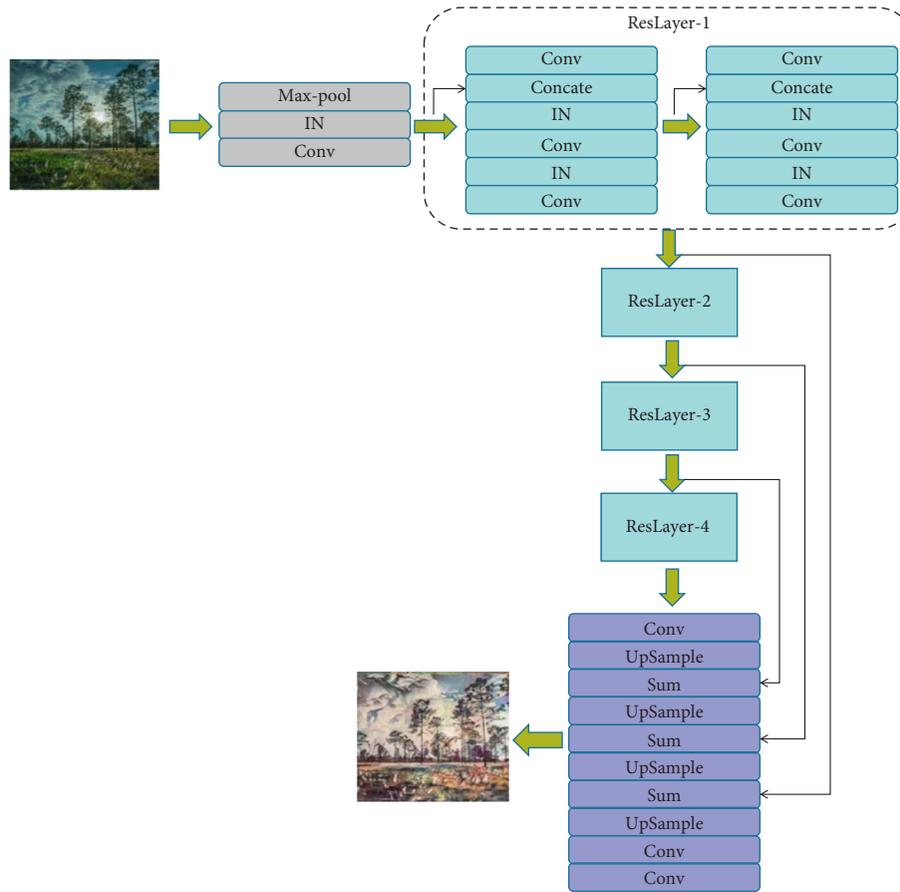

FIGURE 1: The generator structure of the deep learning-driven migration model for creative animation generation.

divides image generation into two parts, including downsampling and upsampling.

The downsampling part of the image is composed of a basic convolution module and four residual layers (reslayer-1–reslayer-4). However, the basic convolution module consists of four layers: Conv – Instance Norm (IN) – ReLU – MaxPooling. The convolution kernel used is 7×7 . This makes the convolution operation have a relatively large receptive field. In the four residual layers, each residual layer contains two residual blocks. Their internal structure is Conv-IN-ReLU-Conv-IN. The output of the latter IN layer will concatenate with the input of the entire residual layer. And then it goes through another convolution layer. The entire residual block has the same short-circuit connection structure as Bottleneck in ResNet. This allows the input of the entire residual layer to be reused. It can effectively improve the gradient propagation performance of network optimization. In the downsampling part, each convolution layer uses a 3×3 convolution kernel. After each residual layer, 1/2 horizontal and vertical downsampling is done.

After the basic convolution module and four residual layers, the size of the feature map will be 1/16 of the original image. It will then be upsampled. First, the feature graph output by reslayer-4 is convolved. It is then upsampled to restore the feature image to 1/8 of the original image. As shown in Figure 1, add it to the output of reslayer-3 for

upsampling. This operation is then repeated until the output of reslayer-1 is added. Such a short circuit connection makes the details of the feature map of the previous processing better preserved. This avoids damage to the content of the image when migrating styles later. After a short circuit connection and addition, the feature graph passes through two convolution layers. It will be transformed back into a three-channel image again. In the convolution operation of the upsampling part, the convolution kernel of the first two convolution layers is 1×1 . The convolution kernel at the last layer is set to 7×7 . Tanh activation function is used before conversion to a three-channel image.

PatchGAN discriminator structure of 70×70 was used in the discriminator in this paper. Compared with the general convolutional neural network structure, the PatchGAN discriminator has fewer parameters and can receive images of arbitrary size. The PatchGAN discriminator contains three convolution blocks. Each block contains two convolution layers. In terms of the number of channels in the convolution kernel, this paper sets the output channel of the first convolution layer as 64. The number of channels is doubled in each subsequent block.

In the loss function design of the model, this paper adopts the same cyclic consistency loss as that in CycleGAN. For image transformation G and F , CycleLoss means that the result of source image transformation after $x \rightarrow G(x) \rightarrow$

FIGURE 2: The original representative partial face image.

$F(G(x))$ should have the attribute of $F(G(x)) = x$. Similarly, for the target image through $y \rightarrow F(y) \rightarrow G(F(y))$ should also be $G(F(y)) = y$. When L1 distance is used to measure the difference between the result after cyclic transformation and the original image, CycleLoss can be expressed as follows:

$$L_{\text{cyc}}(G, F) = E_{x \sim p_{\text{data}}} [\|F(G(x)) - x\|_1] + E_{y \sim p_{\text{data}}} [\|F(G(x)) - y\|_1]. \quad (9)$$

When using the CycleLoss training model, we need to consider not only the cyclic consistency loss from source image to target image to source image but also the backtracking CycleLoss from target image to source image to target image. Therefore, two pairs of generators and discriminators need to be set up simultaneously in the model. It was also trained with CycleLoss in formula (2). The final loss function can be expressed as follows:

$$L(G, F, D_x, D_y) = L_{\text{GAN}}(G, D_x) + L_{\text{GAN}}(F, D_y) + \lambda L_{\text{cyc}}(G, F), \quad (10)$$

where D_x and D_y refer to the discriminators of source image x and target image y , respectively. λ is the equilibrium parameter set based on experience.

4.3. Image Evaluation Index. In the image generation task, the evaluation of the result quality of the generated image not only can rely on the subjective judgment of human vision but also need to analyze the generated image quantitatively. It is mainly considered from two aspects: (1) the quality of the generated image itself, that is, whether the image content is realistic and whether the image details are clear, and (2) for the diversity of generated images, a good generation should generate a variety of images rather than a fixed number of similar types of images. At present, in the field of image generation, the evaluation indicators are IS (inception score) and FID (Fréchet inception distance).

4.3.1. IS. It uses the pretrained inception neural network as the classifier, inputs the image samples generated by the generator into the classifier, and statistically analyzes the output value of the classifier. Its calculation is

$$IS(G) = \exp\left(E_{x \sim p_g} KL(p(y|x) \| p(y))\right), \quad (11)$$

where $x \sim p_g$ means that x is the image sample generated from p_g , $KL(p(y|x) \| p(y))$ means that KL divergence is used to measure the distance between two distributions, $p(y|x)$ represents the probability that the image sample x is

FIGURE 3: The animation generated by the original DCGAN model.

classified as y , and $p(y) = \int_x p(y|x)p_g(x)$ represents the edge distribution of all categories of images.

The larger the IS value, the better the image generated by the generator model.

4.3.2. FID. It is a method to evaluate the image quality by calculating the distance between the feature vector of the real image and the generated image, and the feature vector of the image is extracted after removing the last layer of the network through the perception neural network. The calculation is

$$\text{FID}(P_r, P_g) = \|\mu_r - \mu_g\|^2 + \text{Tr}\left(\sum r + \sum g - 2\sqrt{\sum r \sum g}\right), \quad (12)$$

where μ represents the mean vector of the real image and the generated image in the feature space, \sum represents the covariance matrix of the real image and the generated image in the feature space, and Tr represents the trace of the matrix.

On the contrary to IS, if the FID value is smaller, it means that the similarity between the generated image and the real image is higher, indicating that the generation effect of the model is better.

5. Experimental Results and Analysis

5.1. Experimental Data. The animation avatar data set used in the model training in this paper is randomly crawled from the animation material website SafeBooru through the web crawler and screened it. Finally, 150,000 animation images are obtained; 60,000 images are randomly selected as the training samples; and the image size is uniformly processed to 96×96 for the experiment.

In order to verify the generalization of the improved model, experiments were carried out on CelebFace data set. A total of 10,200 samples and 202,677 face data were collected in this data set, and the face styles in the images were quite different. All the image sizes were 178×218 . However, if all the data sets were used as training data, the training time of the model would be too long, so 100,000 images are used as training data in this experiment. At the same time, the size of the original image is 178×218 , which is not conducive to the construction of the neural network model. It is necessary to preprocess the original image and change it to the size of 128×160 , which not only can ensure the simplicity of the network model but also can ensure the image proportion.

FIGURE 4: The animation generated by the original WGAN model.

5.2. Experimental Configuration. PyTorch deep learning framework was used in the Ubuntu 18.04 environment. It uses an NVIDIA-1080 GPU with CUDA10 for acceleration. An SGD optimizer with a learning rate of 0.002 was used to optimize the model as 200 Epochs. It was then used to test the generation of animation illustration-style images.

5.3. Results and Discussion. Figure 2 is the original representative partial face image, which shows the training results obtained from the CelebA data set. Due to the excessive number of original sample sets, 100,000 face images are randomly selected as training samples in order to reduce training time.

In order to verify the performance of the improved model proposed in this paper in animation generation, comparative experiments are carried out on the original DCGAN model and the original WGAN model in the 100,000 face image data set shown in Figure 2. The comparative experimental results are shown in Figures 3–5. Through the steps of facial emotion recognition and information aggregation, Figures 3–5 show the effects of three different GAN methods in the animation data set. Figure 3 shows the animation generated by the original DCGAN model; Figure 4 shows the generation results of the WGAN

model; and Figure 5 shows the animation effect generated by the proposed algorithm.

It is not difficult to see that although the images generated by the three different methods have good identifiability.

However, compared with other methods, the animation image content generated by traditional DCGAN lacks authenticity, and the facial details of the generated animation characters are seriously lost, which gives people a sense of disharmony, and the whole image appears the phenomenon of information collapse.

For the animation generated by the WGAN model, it performs well in the color brightness of the whole image, but the image quality is significantly lower than the other two methods, and the facial features of the animation avatar in the generated image are not clear.

Compared with these two methods, the improved GAN model designed in this paper combines the respective advantages of the original DCGAN and WGAN. The generated animation avatar is closer to the real sample; the details generated on the image are clearer; and the color saturation is high and has stronger authenticity.

The above only analyzes and compares the generation effects of the original DCGAN model, WGAN model, and the algorithm model in this paper on the same data set from

balance between the image style and the original image content. Aiming at the problem of model collapse that often occurs in the process of network model training, in order to avoid this problem, this paper uses Wasserstein distance instead of JS divergence as the measurement standard. In order to make the weight meet the constraints, the model adopts the method of weight forced cutting, which is not conducive to the learning of the network model. In the next work, we will consider using gradient punishment instead of weight forced cutting to make the weight meet the constraints.

The rapid development of network technology and the popularity of the Internet have made people rely more and more on the exchange and sharing of network information, and the demand for obtaining information about people from the Internet has gradually increased, but the massive amount of network data has made the information about people fragmented and disorganized, and the existing work on portraits has mainly focused on the extraction of people's attributes. In this paper, we examine the artistic construction and characterization of Wuthering Heights on the basis of a tasting of the book, with the aim of presenting the "alienated personalities" hidden in the depths of the characters' consciousness and showing the author's unique creative art through an analysis of thematic ideas, the use of temporal elements, and the tracing of the creation of the characters' original forms. In the aspect of character social relationship extraction, first, the method of expanding the seed dictionary by means of synonym word forest is used to build a character relationship lexicon, which avoids the inefficiency caused by manual lexicon collection; second, a character relationship extraction algorithm based on the combination of rule matching and syntactic tree is proposed, which effectively overcomes the disadvantage of low recall rate caused by rule matching, and the average F-value of this algorithm reaches 82.61% in the experiment. The algorithm achieves an average F-value of 82.61% in the experiment, which is a significant advantage over other methods.

1. Introduction

Emily Brontë's novel Wuthering Heights died of depression and low critical acclaim until the 20th century, when her reputation grew and the novel was considered a "complete and profound insight into human nature and life." The novel is a unique artistic construction, based on the love-hate relationship between two generations and the distorted human nature of life in the aberrant English society of the time. This article explores and examines the artistic construction and characterization of Wuthering Heights from the perspective of a taster [1, 2].

The theme is clearly stated. Set in 18th-century Yorkshire, Wuthering Heights tells the story of Heathcliff, an orphaned boy who is adopted by Earnshaw, the old owner of the cottage, and goes out to earn money after being

humiliated and losing his love. When he becomes rich, he returns to take revenge on the landowner Linton and his children, who have married his girlfriend Catherine. Heathcliff's transformation from an orphan to avenger is a reflection of the perverse society of the time [3]. Heathcliff is discriminated against by the society he describes, and this is the trigger for his fierce rebellion. His frenzied revenge against Wuthering Heights and the Painted Hills is an indictment of a heartless society [4].

When it comes to the organization of character information, traditional methods often use manual editing and collation, which can achieve a high accuracy rate but is inefficient, and users are eager to get global information about the target character in a simple and quick search. If global information about people could be automatically extracted and collated from people data scattered all over the

Internet, and the scattered and fragmented data could be brought together to form a portrait of people and stored in a structured manner, this would greatly improve the efficiency of users in obtaining global information about people and facilitate human work and life [5].

Of course, in addition to search engines, users can also obtain information about people through specific people search systems. The most mature people search engines in the market today are Youku (<https://www.ucloo.com/>), Yahoo People Search (<https://people.yahoo.com/>), Microsoft People Cube (<https://renlifang.msra.cn/>), etc [6]. These people search engines for people are mainly biased toward the basic information of the person's gender, age, and place of origin, and do not present the trajectory of the person's activities, i.e., the Wuthering Heights incident that the person was involved in as reported on the Internet. Generally, when people are learning about a character object, they not only want to get basic information about the object but are more eager to get information about when and where the character was involved in what events with whom, the emotional evaluation of the character on the Internet and the size of the character's hotness, to grasp information about a character as a whole.

In this paper, we study the character portrait mining technique of text data represented by Wuthering Heights, focusing on three aspects: extraction of characters' social relations, tracking of characters' participation in events, and analysis of characters' hotness and emotions. First, the text data are divided into words and lexical annotations to extract the character entities, and at the sentence level, the social relations of characters are extracted using shallow syntactic analysis; second, the features of individual texts are extracted according to the corresponding feature extraction algorithm, and the clustering algorithm is used to achieve the aggregation of similar events, taking characters and time as clues to form a time-based character event activity; finally, the combination of Wuthering Heights' coverage. The hotness value and emotional tendency of the characters are calculated by combining various factors such as the amount of reports, comments, readings, and time span of Wuthering Heights. The above analysis results are combined to form a character portrait, and the research results can be applied to character search systems, specific target tracking, and online celebrity detection.

1.1. Related Work

1.1.1. Personality Information Extraction. In the area of character information organization, existing work has focused on the field of character biography and character search. After the authors of [7] proposed the concept of biography, many scholars have worked on this area, resulting in a variety of methods for the extraction of biographies, mainly including methods based on multidocument summarization techniques, ontology-based and character-tracking-oriented. The authors of [8] realized the extraction of biographies using multi-document summarization techniques. The method combines linguistic

knowledge and statistical theory to extract the basic information of an object, including name, gender, education, etc., from multiple documents to form a biographical text. The authors of [9] implemented a multidocument biographical summary system, mainly using the idea of classification to divide sentences into corresponding clusters of classes, first formulating a classification of sentences about the biography: social relations, educational background, place of origin, work, etc., and then using a classification algorithm to obtain the sentences that best characterize the characteristics of the person, which are eventually combined to form the biography. The authors of [10] proposed the concept of "meta-events" and applied it to the field of character information extraction, where "meta-events" are acts consisting of three named entities: people, time, and place. The authors of [11] proposed constructing an ontology of events for people and to realize this through an ontology description language.

Personal information extraction on the other hand is a research work for personal search engines, which started late. The ArnetMiner system [12] developed by [13] mainly targets experts in academic fields and mines personal information from their personal homepages, published papers, social networks, and other data. The authors of [14] proposed a personal information mining tool for social media such as LinkedIn and Facebook. The authors of [15] proposed a rule-based algorithm for extracting personal information, focusing on summarizing rules such as place of origin, date of birth, and political appearance and developed a semistructured personal information extraction system. The authors of [16] proposed a person information extraction based on trigger words, realizing the extraction of person attribute information from Baidu's encyclopedia web pages, first by developing a trigger word list through linguistic analysis and second by automatically discovering candidate rules based on the word field around the person's name using statistical principles. The authors of [17] for information extraction in the field of teachers, first used SVM to classify the crawled down web pages and selected those containing person information, second developed a rule base for person attribute extraction, and finally used the rules to achieve information extraction of computer teachers in universities. The authors of [18] proposed a method based on double-layer cascaded text classification to extract personal information from resumes. The authors of [19] extracted personal information from personal homepages and CVs by a method based on trigger words and rules. The authors of [7] proposed a personal information extraction algorithm based on semantic context analysis, which incorporates the theory of hidden Markov model, semantic analysis, natural language processing, and information extraction.

1.2. Organization of Character Events. The current research on the organization of personal information is mainly focused on the extraction of personal information, and there is still a need to go further into the character activity events or the tracking of character events. In the work of [2], the concept of

“personal tracking” is proposed, which applies topic recognition and tracking to the extraction of personal events and proposes that personal events consist of three elements: time, place, and event description. The authors of [3] proposed a single-pass-based topic recognition algorithm, which is simple and fast, but the biggest drawback is that it is sensitive to the order of text arrival; the authors of [4] proposed a cohesive hierarchical clustering algorithm to solve the problem of hierarchical topic detection for the situation that multiple topics may exist in a text (i.e., there may be intersection between texts at multiple levels). The authors of [5] used the K-Means clustering algorithm to achieve topical recognition, clustering K points in the text as the centers of class clusters and dividing all texts into the closest class clusters at once, and then by continuous iteration.

To address the shortcomings of the single-pass algorithm, which is sensitive to the input order of the text, the concept of batch processing is introduced to improve the accuracy of the clustering algorithm by first clustering a batch of arriving text, then comparing it with existing classes and introducing the process of adjustment and “resurrection.” In the study of [3], the automatic prediction of the number of clusters is investigated to address the shortcomings of K-Means, which requires the prior determination of the number of clusters and is sensitive to noise points and initial points. The authors of [8] proposed a new treatment for the determination of the initial centroids.

2. Main Characterization

2.1. Paranoid and Brutal Heathcliff. Heathcliff was tough, rude and rebellious, but a man with a passion for love. He was a childhood friend of Catherine’s, but after the death of old Earnshaw, Heathcliff was reduced to being a servant of Sindre, deprived of an education, and the chance to become a civilized man. However, Heathcliff’s love for Catherine would have allowed him to endure any torment from Hindley, something that would have been difficult for ordinary people to do. Heathcliff, who was from a humble background in a materialistic society at the time, was filled with a deep sense of depression and inferiority and was acutely aware of the inequality of treatment brought about by the disparity in status and money. His hatred for Sindre, who is a member of the upper class, is so great that he can only endure it when he is unable to retaliate, but deep down, he has already developed the idea and intention of revenge. Admittedly, the change of role from outcast to avenger suggests that he was not born that way, but because of Sindre’s servitude and abuse and the disappointment of love [12]. When Catherine married Linton of Painted Hills, he was completely broken by the absence of that powerful love in his heart. Faced with an awkward situation, the darker side of his character begins to surface and he leaves with anger and hatred. He returned a few years later, rich and burning with the fire of revenge, believing from the beginning that he would be happy with the torment of the past as long as he could succeed in his revenge. It is not difficult to explain his subsequent desperate attempts to acquire the two great estates and his vast family fortune.

3. Selfish and Wild Catherine

Wild and untamed, Catherine and Heathcliff are a matched made in heaven. Catherine is the only person in Wuthering Heights who gives Heathcliff a solace of mind, and both young are spontaneous, brave, and strong in their approach to love. However, when they break into Wuthering Heights, Catherine begins to waver between the naked idea of true love and the rich and noble reality, secretly comparing the rich, gentle, and civilized Linton and the poor, rude, and primitive Heathcliff. After her marriage, Catherine also tried to be a graceful, polite lady, creating the illusion of true love for Linton, but this inevitably involved concealing and repressing herself and hiding a different spiritual world from Linton. The prolonged separation of spirit and body caused the otherwise lively and energetic Catherine to suffer and spend her days in depression.

4. Mainstream and Secular Linton

Catherine’s husband, Linton, was a wealthy, gentle, and generous man, a typical heroic figure in the Victorian fiction. His gentlemanly manners and unique charm had fascinated Catherine, and his upper class label of wealth, civility, and elegance made Heathcliff jealous. Linton was accommodating, courteous, and caring toward Catherine. He treats his relatives and servants with the same kindness and humanity that shine through at all times. He is the embodiment of the prevailing values of society, the guardian of the secular moral order, and the bearer of civilized order and decency for generations. He is also weak, introverted, and hypocritical.

5. Ruthless Cowardly Sindre

As a result of the accidental appropriation of his father’s love, Sindre becomes cold, brutal, and even self-absorbed. The absence of his father’s love is the origin of Hindley’s hatred, and Heathcliff’s arrival gives him an object of hate. After his father’s death, he uses all means to abuse and mistreat Heathcliff, which is the key point of the entire novel.

6. Innocent Helpless Second Generation

Hindley’s son Harington could have been a gentleman in mainstream society, but his mother died soon after his birth and without his mother’s care he went from innocent and sweet boy to the rebellious and disobedient brat. Moreover, all this change comes at the hands of Heathcliff, who torments and persecutes Harington in the same way that Hindley persecuted himself. Fortunately, his love for young Catherine makes Harington aware of his own shortcomings, awakening his self-respect and good nature, and eventually, through his own efforts, he becomes a handsome, civilized young man.

The entire act of revenge carried out by Heathcliff, involving different degrees of human distortion shown by each individual on different occasions, is also a true and objective reflection of the distortions and struggles of human nature in the social context of the work.

7. Character Relationship Extraction based on a Combination of Rule Matching and Syntactic Trees

This section deals with the automatic extraction of social relations of characters from texts. The social relations of characters are the general term for the mutual relations formed by human beings in the material conditions of their common life, e.g., “father,” “daughter,” “friend,” “colleague,” etc. “The term “relationship” or “character relationship” is used later to refer to the social relationships of people. As people are in a large community, they are inevitably connected to other people in a variety of ways, and if relationships can be automatically extracted from Wuthering Heights reports on the Internet about characters, this is essential to the portrayal of characters. Phrases describing character relationships tend to be fragmented, and if the character relationships implicit in the sentences can be extracted through syntactic analysis, this will help to improve the effectiveness of the relationship extraction.

The paper proposes a character relationship extraction algorithm based on a combination of rule matching and syntactic trees, which broadly consists of the following steps:

- (1) Data preprocessing: first, the text is divided into words and lexical annotation; second, the personal names and relationship words are identified, and finally, candidate sentences with possible personal relationships are filtered out in terms of sentences.
- (2) Rule matching-based personal relationship extraction: first, building a rule base, second, using the rules to match the candidate sentences obtained in the data preprocessing step to achieve the first extraction of personal relationships.
- (3) Character relationship extraction based on a syntactic tree: syntactic analysis is performed on candidate sentences that do not satisfy the rules, a syntactic tree is built, and the second extraction of character relationships is performed through the path distance between the relationship words and the two character entities in the syntactic tree.
- (4) Character relationship determination: after obtaining all relationship words between two characters through the extraction of the large-scale corpus, the relationship words with the highest weight are selected as the final character relationship determination by merging the relationship synonyms.

The specific flowchart of the character relationship extraction algorithm based on the combination of rule matching and syntactic tree is shown in Figure 1, and the details of these parts are described below.

8. Data Preprocessing

Before proceeding to the subsequent relationship extraction algorithms, the data first need to be preprocessed, including word separation and personal identification. Second, subsequent rule-based matching and syntactic tree-based

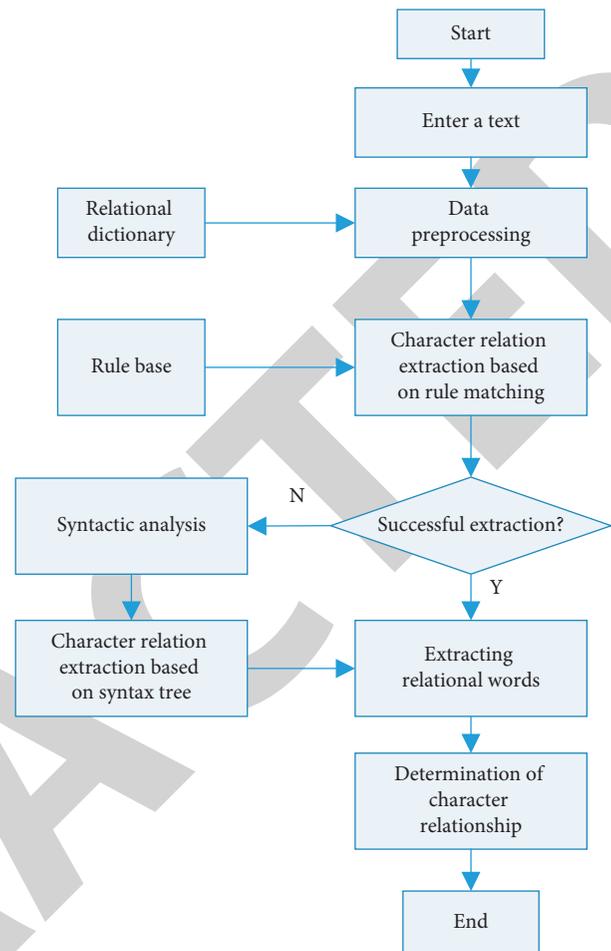

FIGURE 1: Flowchart of the character relationship extraction algorithm.

relationship extraction methods are all based on sentences. Since a large number of sentences in the text do not contain person relationships, it is necessary to first perform sentence separation (the sentences are separated according to the sentence separator in the Chinese grammar) and then perform sentence screening, and the valid sentences selected are used as an input for the subsequent algorithm. This can filter a large number of irrelevant statements and improve the efficiency of the algorithm. The flowchart of data preprocessing is shown in Figure 2.

8.1. Rule-Based Matching for Character Relationship Extraction. The person relationship candidate sentences have been obtained through the data preprocessing stage, this stage will elaborate on the extraction of relationships using rule matching on person relationship candidate sentences, this part of the work is mainly to improve the accuracy rate and to prepare for the later extraction of person relationships based on syntactic trees. The first step in the rule-based matching approach is to develop a complete and accurate rule base. As the social relationships between people are described in a relatively fixed way in the text, the thesis adopts a manual collection approach for the

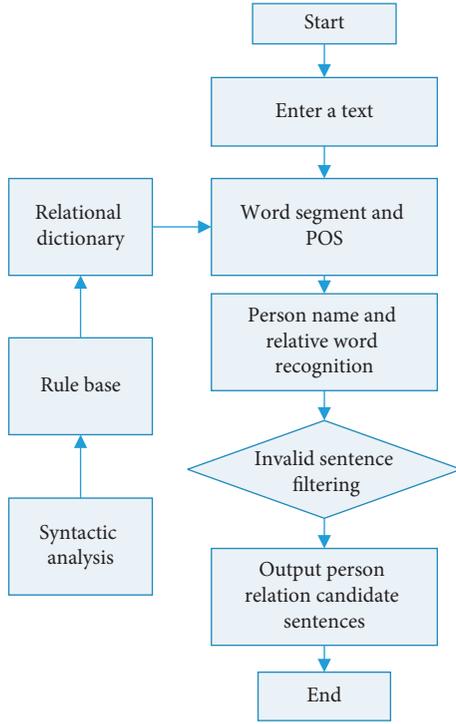

FIGURE 2: Flowchart of data preprocessing.

development of the rule base, which can ensure the accuracy of the rules.

Candidate sentences for character relations that have been split are matched separately using each regular expression in the rule base, in the order of highest to lowest frequency of rule occurrences when matching, which will play a role in improving the accuracy of the algorithm, while reducing the number of irrelevant sentences matched. If a sentence cannot be matched by all rules, it is used as the input to the subsequent syntactic tree-based algorithm for the next extraction step.

9. Syntactic Tree-Based Character Relationship Extraction

The syntactic tree based person relationship extraction includes three steps as follows: (1) constructing a syntactic tree by syntactic analysis of person relationship candidates; (2) pruning the syntactic tree to eliminate a large number of non-joint points to form the shortest path containing tree (SPT tree); and (3) calculating the weight of each relationship word based on the path distance between the relationship word and person pair, (p_i, p_j) in the SPT tree, and finally determining the relationship word that best represents person pair, (p_i, p_j) by using the weight of the relationship word.

The flowchart of the syntactic tree based character relationship extraction is shown in Figure 3.

The thesis uses the Stanford Parser syntactic parser for syntactic tree construction, a context-independent syntactic parser based on probabilistic statistics developed in Java by the Stanford University NLP Research Group, which is fully

open source and supports English, Chinese, German, and French. Stanford Parser can obtain the dependencies between components in a sentence and the syntactic tree of the sentence. For the processing of Chinese, Stanford Parser provides five training models.

In this paper, we focus on the processing of simplified mainland texts and therefore use the Xinhua corpus. In terms of model selection, the Factored and PCFG were compared in terms of time and space consumption when processing sentences of different lengths. Stanford Parser version 3.5.2.1 was used for the comparison [20].

Once the SPT tree has been obtained, the structure of the SPT tree needs to be parsed to determine the best relational words to describe the character pairs (p_i, p_j) . In this case, it is necessary to obtain the distance of each relation to each character pair. The smaller the distance, the more relevant the relation is to describe the relationship between the character pairs. The following definitions are given first:

Define a SPT tree in which the node corresponding to person p_i is node_{*i*}, the node corresponding to relation r_k is node_{*k*}, and the nearest common parent of node_{*k*} and node_{*i*} is root, then the distance $\text{dis}(r_k, p_i)$ of relation r_k to person p_i is defined as follows, where d denotes the shortest path length of node_{*i*} back up to root.

$$\text{dis}(r_k, p_i) = d. \quad (1)$$

Define the distance r_k of the relation (p_i, p_j) to the character pair, $\text{dis}(r_k, \langle p_i, p_j \rangle)$ defined by the following:

$$\text{dis}(r_k, \langle p_i, p_j \rangle) = \text{dis}(r_k, p_i) + \text{dis}(r_k, p_j). \quad (2)$$

In the SPT tree shown in Figure 4, the nearest common parent of the node corresponding to the relation “Dad” and the character “Li Ping” is the “NP” node numbered 1 in the diagram, then the shortest path of the character “Li Ping” up to the nearest common parent node is NP(NR) → NP → DNP → NP, i.e., $\text{dis}(\text{Dad}, \text{Li Ping}) = 3$, and similarly $\text{dis}(\text{Dad}, \text{Li Jiantao}) = 1$. Therefore, using the definition, the distance $\text{dis}(\text{Dad}, \text{Li Ping and Li Jiantao})$ is for the character pair Li Ping and Li Jiantao. The distance of $\text{dis}(\text{Dad}, \text{Li Ping, Li Jiantao}) = 4$.

The process of the SPT tree based person relationship extraction algorithm is as follows: let the set of relationship words in a person relationship candidate sentence S be $Q = \{r_1, r_2, \dots, r_m\}$ and the set of person names be $P = \{p_1, p_2, \dots, p_n\}$; first, the distance $\text{dis}(r_k, p_i)$ between each relationship word r_k ($1 \leq k \leq m$) and each person name p_i ($1 \leq i \leq n$) is calculated, second, the weight $\text{dis}(r_k, \langle p_i, p_j \rangle)$ of the relationship words to the person pair (p_i, p_j) is calculated, and $\text{dis}(r_k, \langle p_i, p_j \rangle)$ in ascending order of size are arranged, and finally the relationship description of the person pair, in order of the smallest distance and the relational word that fits within the threshold is selected as the relational description of the person pair (p_i, p_j) . If a relation is already identified as the relation description of a character pair [21], it will not be used as the relation description of other character pairs in the sentence. The flow of the extraction of the character pair, (p_i, p_j) relations is shown in Figure 5.

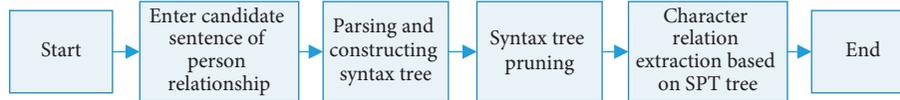

FIGURE 3: Flowchart of the syntactic tree based character relationship extraction algorithm.

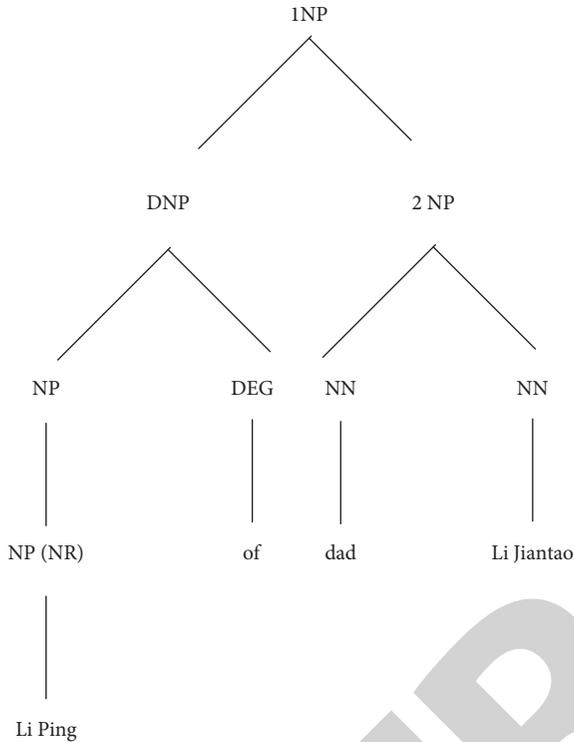

FIGURE 4: Schematic diagram of the SPT tree.

10. Results and Analysis of Character Relationship Extraction Experiments

In order to verify the performance of the personal relationship extraction algorithm, the 10,000 experimental data were divided into sentences and the personal relationship candidates (i.e., sentences containing at least two names and a relationship word) were selected as the input to the algorithm. 4685 sentences were personal relationship candidates, of which 2,437 contained personal relationships and 2,248 did not contain personal relationships.

10.1. Experiments on the Selection of Path Thresholds. In syntactic tree-based character relationship extraction, the choice of path thresholds is crucial to the algorithm results; therefore, this section first selects different path thresholds for experimentation and compares the results to select the best threshold. The results are compared and the best threshold is selected. The paper first selects 200 relationships out of 4685 candidate sentences as training data, and manually annotates 107 relationships and 93 relationships with no relationships [22, 23]. Using the syntactic tree based relationship extraction algorithm, different path thresholds $\theta = 2, 3, \dots, 14$ are chosen, and the accuracy, recall, and F-value for each threshold are shown in Table 1.

Figure 6 shows the accuracy, recall, and F-value of the syntactic tree based personal relationship extraction algorithm for different path thresholds. As can be seen from the figure, the recall rate increases with increasing, but the accuracy rate decreases, with a maximum value of 78.19% being achieved at $\theta = 6$. In the subsequent experiments, the paper chose $\theta = 6$ as the path threshold.

10.2. Accuracy and Performance Comparison of Character Relationship Extraction Results. For the extraction of character relations, the thesis first performs the first step of character relation candidate sentence extraction by rule matching. If rule matching is not successful, a syntactic tree is built and the second step is performed by the syntactic tree based personal relationship. The second step of extraction is carried out by a syntactic tree-based character relationship extraction algorithm. The rule matching algorithm yields a very high accuracy rate, but a low recall rate. The syntactic tree-based approach is able to obtain a higher recall, but the accuracy is correspondingly lower [24, 25]. The combination of the two can give relatively good results. In the following, the rule matching, syntactic tree-based, and combined methods are investigated for different datasets. The following experiments compare the accuracy and performance of rule-based matching, syntactic tree based matching and the combination of the two methods. The results of each of the three algorithms are presented in Table 2.

The experimental results of the rule-based matching character relationship extraction algorithm with different data sets are shown in Table 2.

The experimental results of the syntactic tree-based character relationship extraction algorithm with different data sets are shown in Table 3.

The experimental results of the personal relationship extraction algorithm based on a combination of rule matching and syntactic trees Figure 7 for different data sets are shown in Table 4.

Figures 7–9 show the comparison of the results of the three algorithms in terms of accuracy, recall, and F-value on different datasets, respectively. From the above three figures, it can be seen that the rule-based matching algorithm is able to obtain a high accuracy rate but a relatively low recall rate, and the syntactic tree-based algorithm is able to obtain a high recall rate but a very low accuracy rate. The algorithm based on the combination of rule matching and syntactic tree is able to achieve a compromise between accuracy and recall and is able to obtain a high F-value, indicating that the algorithm of the thesis is effective.

Figure 10 shows a comparison of the time consumed by the three methods on different datasets. As syntactic analysis involves the process of sentence component analysis, the relationship between the components and the construction

of a syntactic tree, whereas rule matching is simply a string comparison, syntactic analysis consumes a very high amount of time, whereas the rule-based matching algorithm is very fast. In the algorithm combining rule and syntactic tree, as part of the character relationship candidate sentences that can be matched by the rule are already extracted in the first step, there is no need to build a syntactic tree, so there is some improvement in time consumption compared to the method based on syntactic tree only, but the time consumption is also much more than that of the rule-based method.

10.3. Comparison with Other Methods. The final results of the paper were averaged from the experimental results of the different data sets and compared with other methods in the literature compared with other methods in the literature, as shown in Table 5. The literature [53] used a feature

extraction algorithm based on character annotation. The literature [54] classified character relationships into six categories, selected character pairs of contextual features, distance features, and syntactic features as feature vectors, and finally used support vector machine classification methods to identify the relationships. The literature [55] used a convolutional tree kernel function to extract character relationships. Comparison with other methods shows that the method proposed in the thesis and the method based on convolutional tree kernel have no obvious advantage in terms of accuracy, but they all have significant improvement in terms of recall compared with the other three methods, and finally, the comprehensive evaluation index F-value is higher than the remaining three methods. Therefore, the character relationship extraction algorithm based on the combination of rule matching and syntactic trees proposed in the thesis can improve the relationship extraction effect to a certain extent. The time element is properly used.

Wuthering Heights condenses all the elements of a rich and rigorous scene, and author Emily presents a sophisticated and detailed chronology of text time and story time in a clever way, unfolding the plot in a staggering reversal of time and highlighting Table 5 the theme in a complex

interweaving of chronology. The descriptions of the weather and seasons bring the emotions and actions of the novel's characters to life, making the scenes more vivid and dramatic, and greatly enhancing the lively nature and mystery of this thrilling and original novel.

Based on SVM	60.8	61.82	61.33
Based on convolution tree kernel	85.8	71.1	61.33

11. Conclusions

This paper mainly describes the algorithm of person relationship extraction based on the combination of rule matching and syntactic tree, which is divided into four parts: the first part is data preprocessing, as the basic preparation part, first, it describes the use of ICTCALs for word separation and person name recognition and gives the relevant definitions to be used subsequently; it describes the person relationship extraction based on rule matching, including the establishment of rule base, regular expression. The algorithm of character relationship extraction based on the syntactic tree is proposed. First, the syntactic tree is built using Stanford Parser, second, the syntactic tree is transformed into an SPT tree by pruning out the non-joint points, and then the character relationships are extracted according to the SPT tree.
