Retracted: Application of Three-Dimensional Image Reconstruction Technology in Neurogenic Intestinal Nursing Tasks

Scientific Programming

Received 26 September 2023; Accepted 26 September 2023; Published 27 September 2023

Copyright © 2023 Scientific Programming. This is an open access article distributed under the Creative Commons Attribution License, which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Received 6 October 2022; Revised 21 October 2022; Accepted 24 November 2022; Published 4 February 2023

Academic Editor: Lianhui Li

Copyright © 2023 Zhoupeng Han et al. This is an open access article distributed under the Creative Commons Attribution License, which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited.

To support effectively function-driven 3D model retrieval in the phase of mechanical product conceptual design and improve the efficiency of functional semantics annotation for 3D models, an approach for functional semantics automatic annotation for mechanical 3D product model based on latent functional semantics is presented. First, the design knowledge and function knowledge of mechanical product model are analyzed, and the ontology-based functional semantics for assembly product is constructed. Then, some concept about functional region is defined, and the 3D product model is decomposed into functional regions with different levels of granularity. The similarity of the functional region is evaluated considering multisource attribute information and geometric shape. Subsequently, the similarity based on latent functional semantics annotation model for functional regions is established, which is employed for annotating automatic latent functional semantics in the 3D product model structure. Finally, mechanical 3D models in the model library are used to verify the effectiveness and feasibility of the proposed approach.

1. Introduction

More and more 3D models have been accumulated with 3D CAD software applied widely in enterprises, which are important knowledge resources and can be employed for reference and reuse during developing new products. When 3D CAD model is reused, it is very difficult for meeting the practical needs of engineering designers by retrieving the CAD model only considering the topological and geometric information. Especially, in the process of product conceptual design, engineers pay more attention to searching for 3D CAD model structures with specific functions by making use of product function requirements' information. The existing 3D model structures embodying plenty of design/assembly intent can achieve specific function requirements. However, there is no explicit and clear correlation mapping relationship between structure and function. The functional semantics tagging correspondingly to the model structure is becoming a hot issue in the 3D model reuse field.

In the process of design and development for mechanical products utilizing computer-aided design systems, designers mostly design the structure/geometry of 3D product model in terms of the product's functional requirements, parameters, and performance. The functional requirements' information and the 3D model structure are independent. In this case, there is a gap between functions and structures for the 3D product CAD model [1]. It means that there is no explicit and clear structure-function correlation for an isolated 3D CAD model, lacking of functional information that the structure can accomplish. It will have an impact on the level of 3D model reuse.

Currently, the research on the 3D CAD model retrieval is mainly grouped into two classification: geometry-based [2, 3] retrieval and topology-based [4, 5] retrieval. But these query information is uncertain and vague; at the stage of product conceptual design, it is difficult to support the reuse of 3D CAD model knowledge. With the emergence of semantic modeling tools, some researchers are concerned for visualization and semantic expression for resolving the

semantics gap between the high-level design semantics and the bottom-level geometric shape of the 3D model. To simplify the process of semantic-based 3D model retrieval, Attene et al. [6] presented a semantic description of the local shape of the 3D model, where the 3D model is segmented into regions and the segmented region is labeled with marking semantics by using ontology-based concept instance semantics. Cheng et al. [7] proposed a complex surface shape design method for the CAD model based on semantic features, where the different geometric constraints and geometric surface types are defined as corresponding semantic features, and the semantic features are used for modeling complex surfaces of the CAD model. To capture the design intent of the 3D model, Abdul-Ghafour et al. [8] integrated semantic web into the CAD system and built a common design feature ontology for feature modeling of the CAD model, where the semantics is used for modeling and reasoning, and the association relationship between the product data can be effectively managed and discovered.

The existing semantics annotation methods for 3D models mainly considered the geometric shape and topological structure information. On the basis of semantic labeled sample 3D models, machine learning algorithm is employed for automatic semantics annotation [9]. However, there are fewer researchers on functional semantics annotation of 3D models. In fact, functional semantics as a special class of semantics is not only an abstraction of geometric shapes, but also a high-level semantic description for potential information such as design or assembly intent, usage, and efficacy of the 3D model. The functional semantics annotation of the 3D model is much more difficult and complex than the shape or structure semantics annotation; it still faces many challenges for functional semantics-based retrieval of the 3D model. To meet the requirements of the CAD model retrieval at the stage of mechanical product conceptual design, Wang et al. [10] constructed function semantic ontology of 3D CAD models, where the overall functional semantics of 3D models are annotated, and the functional semantics-based retrieval of 3D models is realized. It is concerned about functional semantics annotation of the 3D part model, lacking functional analysis and annotation of the 3D assembly model at different granularity structure. Han et al. [11] proposed an approach for structure-function semantic correlation analysis and annotation of the 3D assembly model, where the 3D assembly model is divided into different functional regions for structure-function semantic correlation analysis, and the polychromatic sets is used to describe correlations of structure-function semantics. This method is concerned with the structure-function analysis of the 3D parts/assembly model, and functional semantics is labeled by the human-computer interaction mode so that the annotation efficiency is not high. Hao et al. [12] took key parts in the assembly model as the object and evaluated the similarity of the participated shape structure key parts. The functional semantics is annotated based on the shape and structure similarity, without consideration attribute information of the 3D model structure. The accuracy of the functional semantic annotation is affected to some extent. The function is not only

related to the geometric shape of the 3D model, but also related to the geometric parameters, type of kinematic pair, and so on. Therefore, a reasonable and feasible solution for structure-function semantic correlation analysis and automatic annotation of the 3D product model can be provided by comprehensively considering geometric structure and attribute information of the 3D model.

Functions can reflect the specific requirement, objective, and purpose that the product needs to achieve, which exists throughout the life of the product design. In the stage of the product conceptual design, it is usually on the premise that the product function requirements have been determined to find correspondingly the structural design scheme, that is, the product function-structure mapping. Function-structure mapping is the key process of the top-down product design, which is an approach of transforming the product function model to parametric structure model [13]. The function is the abstraction of the product structure and the purpose of structure realization, and the structure is the shape and composition structure that is shown to achieve certain functions. The mapping relation of function-structure is a many-to-many relationship, where a certain function may be completed by one structure or multiple structures, and a structure may also implement one or more functions. The current more typical design process model about function-structure mapping relation include function-structure (Function-Structure, FS) [14] and function-behavior-structure [15]. To realize the relationship between the function and structure, a behavioral layer is introduced to describe the action and principle which are performed to complete the function, and explain "how the structure realizes the function." Based on that, the models including function-behavior-state model [16] is proposed. The issue about function-structure mapping can be effectively solved by using the abovementioned approaches in the product conceptual design.

To improve the efficiency and accuracy of the structure-function semantic annotation for the 3D CAD product model, and support 3D CAD model retrieval by means of functional semantics, an approach for structure-function semantic automatic annotation of the 3D product CAD model is presented. The structure of the 3D product model is decomposed into functional regions (i.e. assembly region and flow-activity region) with different levels of granularity. Multisource attributes information and structural similarity are considered for evaluating the similarity between any two functional regions. Based on that, an approach for automatic annotation of latent functional semantics for 3D model structure based on semi-supervised learning is built for improving the accuracy and efficiency of functional semantics annotation of the 3D model structure.

This rest of the paper is organized as follows: ontology-based functional semantics is constructed for providing standard and formal terms for functional semantic annotation in the 3D product model is discussed in Section 2. In Section 3, similarity evaluation of the 3D product model structure is given by taking advantage of multisource information. A latent functional semantic annotation model of

functional regions is presented in Section 4. Cases are designed and tested in Section 5. In Section 6, the paper is concluded and further works are provided.

2. Function Ontology of the 3D Product Model

2.1. Product Function Classification. Design knowledge is mainly related to the product conceptual and detailed design phase, which contains design document, domain expert experience, and so on. The design knowledge can help capture design and assemble intent of the 3D CAD model, which can provide basis and support for design thinking analysis for the correlation between the structure and function of the 3D model. It can be obtained from design documents, PDM, BoM, machining, assembly process documents, and so on.

The function is viewed as an abstract description of the task that a system or product can accomplish, and the parameters or state changing when the system or subsystem is input/output. It is an understanding for the system from the perspective of technical realization, as explanatory description and behavior abstraction of the structure, which is the main goal and core of the product design. Product function is generally determined in the stage of the product conceptual design and has an essential role in the life of the product design.

The concept of function basis, classification of function, and flow is proposed [17]. On this basis, the function is described as “verb + object,” where the function is expressed through the verb and noun form. In this paper, the basic classifications of the function are further summarized and refined for covering the function’s description of the mechanical product as far as possible. Based on that, function ontology is constructed for providing functional semantic specification and expression of the 3D product model structure in the mechanical field. The functional classification and common terms of the mechanical product are shown in Table 1.

2.2. Function Ontology. Ontology, as explicit and formal specification of conceptualization, can offer a formal description and defining common terms, classification, and relationship for conceptualization, which can be employed to represent, storage, share, and integrate knowledge [18]. To reduce and avoid the randomness and ambiguity of functional description and ensure standardization of the definition of functional vocabulary, a function ontology should be constructed to standardize the functional vocabulary of the product, so that functional terms of the 3D product model structure have a unified and standard expression form. According to the classification of the function and flow of mechanical products, the function ontology was constructed by Protégé through the analysis of function and flow concepts and their logical relationships. Parts of function ontology are shown in Figure 1, where the solid blue line represents parent-child relationship of concepts and the dashed red line represents object attribute relationship between concepts [11]. The function ontology provides

standard terms of functional semantic annotation of the 3D product model.

3. Similarity Evaluation of the 3D Product Model Structure Considering Multisource Information

3.1. Functional Region. To analyze convenient assembly constraints of the product model, assembled parts are grouped into two categories: functional part and connector [19]. The connected relationships between assembled parts are classified into soft connection and hard connection in terms of corresponding connection relationship [20]. Connectors contain a type of part used for sealing or fastening, such as gaskets, screws, bolts, nuts, pins, keys, and other standard parts. The functional part is viewed as some function characteristics apart from connectors.

Functional Region: For a 3D product model, the function mainly reflects in the structure at different granularity level. The structure unit with certain function characteristics is considered as a functional region. Functional region may be a subassembly structure composed of multiple parts or shape structure of the part. To annotate easily functional semantics’ indifferent granularity structure for the 3D assembly model, functional regions are grouped into assembly region and flow-activity region. The functional structure of the 3D product model can be considered comprehensively by the assembly region and flow-activity region from the aspects of assembly structure and part shape. The correlation relationships between the function and structure is analyzed comprehensively from the coarse and fine-granularity structure of the 3D product model.

3.2. Functional Region Similarity Considering Multisource Information. The similarity for functional regions of the 3D product model is evaluated by considering multiple attributes and geometric shapes.

3.2.1. Multisource Information Similarity of the Assembled Part. Multisource information is mainly grouped into qualitative attribute, quantitative attribute, text attribute [21], and geometric shape. The similarity calculation rule and method of each classification information of the assembled part are given as follows [22]:

- (1) Quantitative attribute: The attributes are quantitative including size, surface area, volume, and so on. It can be expressed by a numeric value. The similarity of the quantitative attribute can be expressed as follows:

$$\text{sim_attribute}(q_k^i, p_k^j) = 1 - \frac{|q_k^i - p_k^j|}{\max(q_k^i, p_k^j)}, \quad (1)$$

where q_k^i denotes the k th quantitative attribute of part i for the product model Q and p_k^j denotes the k th quantitative attribute of part j for the product model P .

TABLE 1: Functional classification and common terms of the mechanical product.

Functional classification	Functional basis	Verb vocabulary
Branch	Separate	Isolate, disconnect, cut, and detach
	Remove	Cut, lathe, mill, drill, grind, polish, bore, and remove
	Divide	Disassembly, isolate, release, classify, group, and divide
	Refine	Extract, filter, purify, permeate, wash, clean, and refine
	Distribute	Disperse, spread, dissipate, disperse, and distribute
Channel	Import	Entry, accept, permit, capture, and import
	Export	Discharge, eject, jet, release, destroy, eliminate, and export
	Transfer	Convey, handle, carry, move, lift, conduct, communicate, and transmit
	Guide	Guide, drive, switch, move, transfer, migrate, rotate, turn, flip, limit, release, and oriented
Connect	Couple	Connect, assemble, install, tie, and couple
	Mix	Merge, merge, package, mix, add, and mix
Control	Actuate	Begin, start, launch, initiate, and actuate
	Regulate	Control, balance, limit, block, interrupt, delay, close, forbid, and allow
	Change	Adapt, correct, reverse, adjust, modify, increase, enlarge, magnify, enhance, enlarge, expand, strengthen, reduce, weaken, shrink, reduce, compress, transform, construct, form, and change
	Stop	Inhibit, protect, seal, insulate, isolate, shield, end, close, terminate, stop, interrupt, and prevent
Convert	Convert	Conversion, transform, concentrate, melt, liquefy, solidify, evaporate, fusion, integrate, and process
Supply	Store	Store, contain, include, encapsulate, enclose, accumulate, gather, collect, reserve, occupy, and retain
	Supply	Supply, furnish, fill, supplement, and expose
Signal	Sense	Sense, identify, distinguish, and confirm
	Display	Display, show, indicate, register, record, expose, choose, and select
	Measure	Measure, calculate, process, estimate, check, proofread, examine, and compare
Support	Stabilize	Stabilize, firm, and prop
	Secure	Secure, place, arrange, press, clamp, and tighten
	Position	Position, orient, limit, and guide

- (2) Qualitative attribute: The attributes are not quantified, such as face type of the part, design/assembled feature type, and so on. The similarity of the qualitative attribute is expressed as follows:

$$\text{sim_attribute}(q_k^i, p_k^j) = \begin{cases} 1, & q_k^i = p_k^j \\ 0, & \text{else,} \end{cases} \quad (2)$$

where q_k^i denotes the k th qualitative attribute of part i for the product model Q and p_k^j denotes the k th qualitative attribute of part j for the product model P .

- (3) Text attribute: The attributes are expressed mostly by string/text set for assembled constraints [23]. The set theory is employed to the similarity of the text attribute, which is expressed as follows:

$$\text{sim_attribute}(q_k^i, p_k^j) = \frac{q_k^i \cap p_k^j}{q_k^i \cup p_k^j}, \quad (3)$$

where q_k^i denotes the k th text attribute of part i for the product model Q and p_k^j denotes the k th text attribute of part j for the product model P .

- (4) Geometric shape: The geometric shape of assembled parts is taken into account during the similarity of the functional region. The similarity calculation about the geometric shape is mainly referred to the literature [24]. Here, it can be expressed as $\text{sim_shape}(q_k^i, p_k^j)$.
- (5) Multisource information similarity of parts: Based on similarity evaluation of assembled parts considering multisource information, the weight coefficient α is introduced for describing the importance degree of each factor in terms of requirements of engineering designer. The similarity of parts considering multisource attributes $\text{sim_part}(q^i, p^j)$ can be expressed as follows:

$$\begin{cases} \text{sim_part}(q^i, p^j) = \omega_1 \bullet \sum_{t=1}^T \text{sim_attribute}(q_k^i, p_k^j) \bullet \alpha_k + \omega_2 \bullet \text{sim_shape}(q_k^i, p_k^j), \\ \sum_{t=1}^T \alpha_t = 1, \end{cases} \quad (4)$$

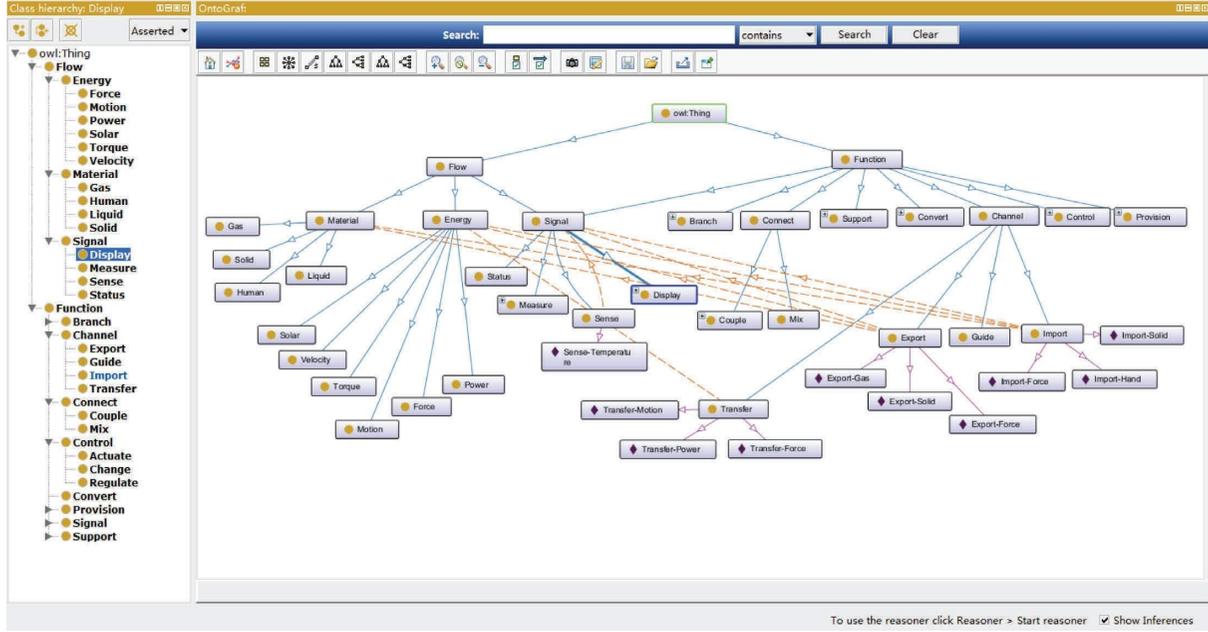

FIGURE 1: Parts of function ontology for the CAD product model.

where $\text{sim_attribute}(q^i, p^j)$ denotes the similarity of part i for the assembly region Q and part j for the assembly region P considering multisource attributes, T denotes the total number of attributes, α_t denotes the weight of the t th attribute, w_1 denotes the weight of the similarity of attribute information, and w_2 denotes the weight of the similarity of the geometric shape.

3.2.2. *Similarity Measure of the Functional Region.* The similarity of the functional region mainly contains the similarity of the assembly region and the flow- activity region.

- (1) Similarity measure of the assembly region: Similarity of assembly region should not only consider the shape structure and attribute information of assembled parts, but also take into account the information of assembly relation, such as connection form, contact form, degree of freedom, assembly feature pair and so on. By using the above similarity evaluation through multisource attribute, the similarity for assembly relationship could be expressed as follows:

$$\begin{cases} \text{sim_relationship}(q^i, p^j) = \sum_{h=1}^H \text{sim_attribute}(q_k^i, p_k^j) \bullet \beta_h, \\ \sum_{h=1}^H \beta_h = 1, \end{cases} \quad (5)$$

where $\text{sim_relationship}(q^i, p^j)$ denotes the similarity for assembly relationships between assembled parts i and j for the product models Q and P , H denotes the number of attributes for assembly relationships, and β_h denotes the weight of the h th attribute.

Considering the attributes about the assembly relationship and assembled part comprehensively, the similarity of the assembly region can be expressed as follows:

$$\text{sim_assem}(q^i, p^j) = \text{sim_part}(q^i, p^j) \bullet w_1 + \text{sim_relationship}(q^i, p^j) \bullet w_2, \quad (6)$$

where w_1 denotes the weight of similarity of the assembled part and w_2 denotes the corresponding assembly relationship similarity.

The assembly region may consist of different assembled parts. It is necessary that the assembled parts should be considered as matching problem between regions while calculating the similarity of assembly region. In fact, it has found the best assembled parts pair among two part-sets from corresponding functional regions when the total sum value of the similarity between functional region pairs is maximal. The matching problem can be solved by using maximum matching in the weighted bipartite graph. The Kuhn–Munkres algorithm [25] adopted the similarity $sim_{ass}(Q, P)$ between the assembly regions Q and P can be expressed as follows:

$$sim_{ass}(Q, P) = \frac{\sum_{l(q_i, p_j) \in L_0} sim_assem(q_i, p_j)}{\max(m, n)}, \quad (7)$$

where M denotes the maximal matching, L_0 denotes the set of corresponding edges, $l(q_i^i, p_j^j) \in L_0$ denotes the best matching between assembled parts q^i and p^j , and m, n denote respectively the number of assembled parts in assembly regions Q and P .

- (2) Similarity measure of the flow-activity region: Flow-activity area mainly refers to the shape structure of the part that does not participate in the assembly region. In fact, it specifically refers to the similarity evaluation of the part model. Similarity of the flow-activity region q' and the flow-activity region p' , $sim_{part}(q', p')$ can be expressed as follows:

$$sim_{part}(q', p') = sim_part(q', p'), \quad (8)$$

during the similarity evaluation, the weight values can be determined by domain expert and experience generally. Moreover, to avoid subjective interference, the weight values can be determined by using AHP and TOPSIS [26].

4. Latent Function Semantic Annotation of the Functional Region

Functional region as a structure with certain functions in the 3D product model, functional semantic annotation of the functional region is viewed as essentially functional semantic annotation of the model structure. Through analysis of the function region, the function that the corresponding structure of the function region can achieve will be obtained. Based on that, the corresponding latent functional semantics can be annotated. The process of latent functional semantic annotation of the functional region consists of two steps: ① functional semantic annotation of sample CAD models, that is, the structure-function is analyzed for 3D CAD product sample models, and corresponding functional semantics is annotated interactively. ② Latent functional semantic annotation based on the similarity. A latent

functional semantic prediction model is built for automatically annotating latent functional semantics in the 3D assembly model structure. The process of latent functional semantic annotation of the functional region is shown in Figure 2.

4.1. Functional Semantic Annotation of the Sample Model.

For mechanical product, functions are mainly reflected in assembly regions and flow-activity regions. Through analyzing the structure-function of the product model from the two aspects of the assembly region and the flow-activity region.

- (1) Functional semantic interactive annotation of the assembly region: The assembly region can be expressed by assembled parts, assembly feature, and corresponding attribute information involved in the assembled structure. By analyzing the part attributes, connection types, matching types, degrees of freedom, and other information in the assembly region, together with the mechanical design theory and design experience, designers can capture the assembly intent, function, and degree of freedom, which is contained in the features of the assembly region. According to the function ontology, functional semantics of the assembled structure are labeled, thereby absorbing and understanding the assembly structure knowledge.
- (2) Functional semantics interactive annotation of Flow-activity region: Flow-activity region is a description of the geometric shape with some functions in the functional parts, except for participating fit or assembled structure. The structure represented by a flow-activity region is considered as a carrier in the process of function flow from input to output. Therefore, when analyzing the flow-activity region, it is needful to consider the input and output of flow during the working process of the assembled structure. The key integral/local structures and corresponding functions in the assembled function part represented by the flow-activity region is acquired. The flow-activity region can be described by the design feature, attribute, and other information of the part, for example, the shape feature, geometric shape surface, and other attribute descriptions of the part model.

4.2. Latent Function Semantic Annotation of the Function Region. There are many-to-many mapping relationships between structures and functions, that is, the same structure will perform different functions in different products, and different structures will also achieve the same function. In most cases, structures with the same attributes may achieve the same functions for different assembly models. It is a probability event that the same structure is provided with the same function. As the similarity of the structure increases, the probability having the same function also increases. Based on that, a prediction model for latent functional

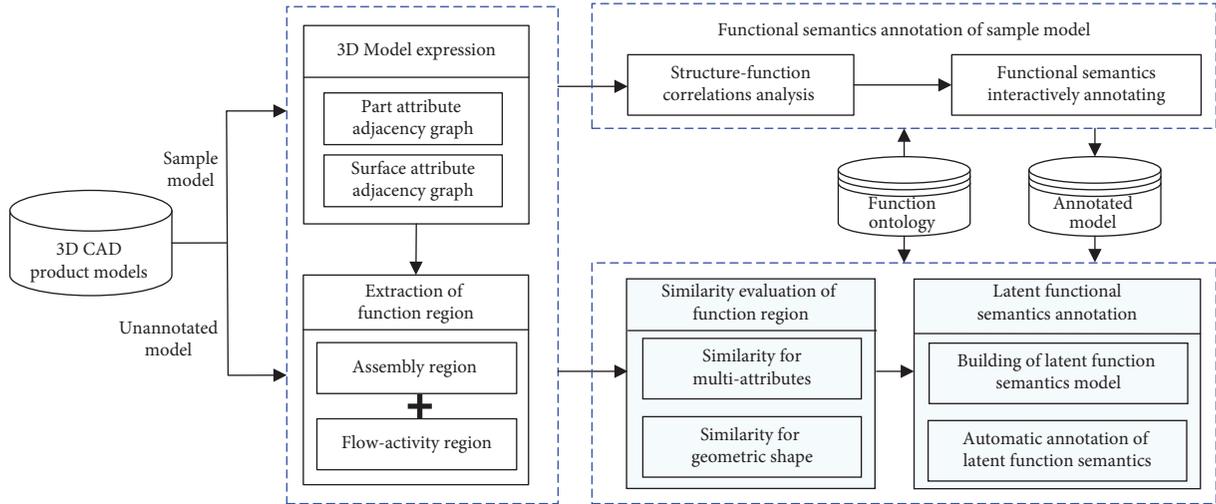

FIGURE 2: The process of latent functional semantic annotation of the functional region.

semantic annotation of the 3D CAD product model is given using sample models annotated functional semantics. Drawing on the historical information of the structure-function semantic annotation, the probability that the product model structure can achieve certain functions is inferred. Finally, combining with the participation of artificial knowledge, the functional semantics that can be realized is determined. It enhances the efficiency of functional semantics annotating to some extent.

Assuming that the annotated functional semantic model library is M , the unannotated structure (functional region) is $Stru$. The structure in the model library M that has the maximum similarity with the structure $Stru$ is $Stru_{max}$, and the latent functional semantic annotation model based on the similarity can be expressed as follows:

$$p(f_i | Stru) = \text{Sim}(Stru, Stru_{max}) * \frac{\text{count}(f_i | Stru_{max})}{\text{sum}(Stru_{max})}, \quad (9)$$

where $p(f_i | Stru)$ denotes the probability that the structure $Stru$ can achieve the function f_i . $Stru$ represents the unannotated structure (functional region). $Stru_{max}$ represents the structure (functional region) in the model library M that has the greatest similarity with the structure to the unannotated structure $Stru$. $\text{Sim}(Stru, Stru_{max})$ represents the similarity between $Stru_{max}$ and $Stru$, equations (7) and (8) are used for similarity measurement of functional regions. $\text{Sum}(Stru_{max})$ denotes the number of the structure $Stru_{max}$ in the model library M . $\text{Count}(f_i | Stru_{max})$ denotes the number of the structure $Stru_{max}$ that has the function f_i in the model library M .

5. Case Study

5.1. Function Semantic Annotation of the Sample Model. The 3D CAD model of gear oil pump is used as an example for analyzing and annotating functions in the 3D product model. The correlation relationship among the structure, function, and attribute of the 3D model is expressed by using

the polychromatic set, and corresponding functional semantics is annotated interactively. The 3D CAD product model of gear oil pump and parts information is shown in Figure 3.

The 3D model structure of gear oil pump is divided into several independent and stable assembly regions AR1~AR8. The parts and assembly feature pairs attribute information contained in the assembly region are analyzed for determining the functions that can be realized in each assembly region. The function analysis of the flow-activity region is mainly about the function analysis of the local shape structure that can transmit the flow in the 3D part model. The flow-activity region of the functional part that can transmit flow is analyzed from the perspective of the material flow, signal flow, and energy flow. Through the structure function analysis and functional semantic annotation of the flow-activity region, the key structure in the parts can be discovered and the design intent can be captured. It improves the efficiency of complex parts and key structures reuse. The functional region and functional semantic annotation in the 3D CAD model of gear oil pump is shown in Table 2.

5.2. Latent Functional Semantic Annotation Based on Similarity. Some 3D CAD product models with annotated functional semantics can be obtained through the structure-function correlation analysis and functional semantics labeling for 3D CAD product sample models. Based on that, the latent functional semantic prediction model based on the similarity can be used to automatically annotate the functional semantics in 3D CAD product models in the model library. Through equation (9), the latent functional semantics can be predicted and annotated probabilistically.

Several typical 3D models are taken as example, which is given with latent functional semantics corresponding probability, as shown in Table 3. Among them, the maximum similarity structure is the annotated model structure in the model library, and the probability of latent functional

5			F1: position-part (0.765)

semantics is calculated by equation (9). Since the calculation of probability is related to the annotated sample model library, if sample models are fewer, the accuracy of latent functional semantic annotation will be low. In this case, the designer's design history knowledge and experience should be considered for determining the final functional semantics to be annotated.

6. Conclusion

In this paper, an approach for functional semantic annotation of the mechanical 3D product model is proposed. 3D product model-oriented function ontology is constructed to provide standard, unified feature and function vocabulary for functional semantic annotation. The 3D CAD product models break up into functional regions at different granularity. Functional region is used as semantic structure unit, together with product design experience, working principle, and so on; the functional semantics of sample models is annotated interactively. The similarity of functional regions is evaluated comprehensively considering multisource information. Similarity-based latent functional semantic annotation model is given for automatic annotation of functional semantics in CAD models.

The proposed approach improves efficiency and accuracy of functional semantic annotation to a certain extent, which can assist designers accelerating the speed of the functional semantic annotation. It provides support for searching 3D CAD model using product function requirement, promotes the understanding, absorbs and reuses the complex 3D product model knowledge structure, and inspires the product design innovation. Further research will

focus on functional semantics-driven retrieval and product structure optimization of the 3D CAD model.

“Motion capture technology” refers to the use of optical sensing equipment to record the dancer’s movement trajectory during dance and then convert this movement trajectory into applicable data information in animation software. In the 3D animation software, the corresponding dancer model can be constructed, and the matching costumes can also be designed. After combining it with the motion capture data, animation and dance data can be generated. In this way, virtual simulation software can create some virtual visualization scenes and present more diverse and complex demonstration effects. This article focuses on three aspects: “an overview of the connotation of motion capture technology,” “design of virtual dance visualization scene based on motion capture technology,” and “application of virtual dance visualization scene based on motion capture technology.”

1. Introduction

“Motion capture technology” was initially applied in a very narrow field, mainly in the field of animation films. With the maturity of motion capture technology, its application fields are becoming more and more extensive, such as motion analysis and sports training. A complete motion capture system usually includes multiple parts such as signal acquisition equipment, data processing, data transmission, and sensors [1]. At present, motion capture systems mainly include optical motion capture systems, electromagnetic motion capture systems, and mechanical motion capture systems. What we call motion capture today usually refers to the use of sensors and software to transcribe the movements of real actors into the movements of digital models in 3D games or animations. As we all know, characters (including characters and animals) in animation and games must have actions, such as running, jumping, and fighting. The “optical motion capture system” has better stability and higher precision. The dance data is presented through an optical motion capture system, and the effect will be better [2].

Regarding the connotation of motion capture technology, it can be understood as a computer recognition technology, which is mainly used to recognize data information

during motion. Through motion capture technology, various real actions of people in three-dimensional space can be collected, and the collected data information can be entered into the virtual model, thereby generating a series of motion data records [3]. Mechanical motion capture relies on mechanical devices to track and measure motion trajectories. A typical system consists of multiple joints and rigid links, and angle sensors are installed in the rotatable joints, which can measure the changes in the rotation angle of the joints. When the device moves, according to the angle change measured by the angle sensor and the length of the connecting rod, the position and movement trajectory of the endpoint of the rod in space can be obtained. In fact, the motion trajectory of any point on the device can be obtained, and the rigid link can also be replaced with a telescopic rod with a variable length, and the change in its length can be measured with a displacement sensor. An early mechanical motion capture device uses joints and links with angle sensors to form an “adjustable digital model” whose shape can simulate the human body or other animals or objects. The user can adjust the posture of the model according to the needs of the plot and then lock it. The angle sensor measures and records the rotation angles of the joints. According to these angles and the mechanical dimensions of the model,

the pose of the model can be calculated, and these pose data are transmitted to the animation software so that the character model in it can also make the same pose. This is an early motion capture device, but there is still a certain market until now. Foreign countries have given this device a very vivid name: "Monkey." An application form of mechanical motion capture is to connect the moving object to be captured with the mechanical structure, and the motion of the object drives the mechanical device, which is recorded by the sensor in real time. The advantages of this method are low cost, high accuracy, real-time measurement, and simultaneous performance of multiple characters. But its shortcomings are also very obvious, mainly because it is very inconvenient to use, and the mechanical structure greatly hinders and restricts the movements of performers. The "monkey" is more difficult to use for real-time capture of continuous actions. It requires the operator to continuously adjust the posture of the "monkey" according to the requirements of the plot, which is very troublesome. It is mainly used for static modeling capture and key frame determination. Moreover, this motion data information can be well recognized by the computer. After the relevant personnel put this motion data information into the 3D animation software, they can build a "3D human body model" in the 3D animation software. The three-dimensional mannequin is both virtual and vivid and can depict the dancer's facial features according to the dancer's physical fitness. Society is progressing, science and technology are developing, and computer hardware and software equipment is becoming more and more perfect. Many researchers choose to conduct scientific research and auxiliary teaching training through computers. Motion capture technology is the latest scientific and technological research project that has been developing and growing in recent years. Through the motion capture system, the animation production of film and television entertainment, the rehabilitation of patients in the medical field, the field of sports training, and the analysis of digital human motion posture assisted by college teaching are realized, and the guidance of rigorous scientific theory is provided [4]. This paper analyzes the motion posture of the human body, proposes a posture analysis method based on eigenvector matching, and analyzes the characteristics of the motion posture of the human body based on the real-time characteristics of the optical motion capture system. This paper analyzes the development prospects and research significance of motion capture technology in sports dance teaching, provides an effective theoretical basis for scientific training, promotes the efficiency of students' learning, and effectively improves the scientific research level of education and teaching. The main research work of this paper is as follows: (1) A dance posture analysis method based on feature vector matching is proposed, which can accurately analyze the dance movement posture of the human body, obtain the difference in effective human movement, and provide theoretical support for the scientific training of dance. (2) Applying motion capture technology to the research of dance teaching in colleges and universities, by tracking, capturing, checking, recording, etc. of human movement, the dance movements are demonstrated in

sections, which solves the traditional problem of repeated demonstrations when teachers teach, get rid of the interference of students or teachers due to individual differences, psychological, physical, and other factors, and, through the effective analysis of computer data, timely find problems and correct them, which greatly improves the efficiency of education and teaching. The advantages of this study are mainly connected with the dance teaching through the optical motion capture system, which improves the intuitiveness of the learning effect. The collection and analysis of real-time data provide timely feedback for teaching. From the technical level, teaching form, and student acceptance level, it provides scientific theoretical support in terms of innovation and other aspects, gets rid of other interference factors of the traditional teaching mode, provides a reliable basis for the improvement of the teaching mode, and helps the system to improve the personalized teaching system. The next main research work is to complete the real-time analysis of human motion posture with the assistance of the optical motion capture system.

In addition, the technology can also build a variety of clothing models. Due to the large number of ethnic minorities in our country, there are also many dances with ethnic characteristics. When building costume models, you can refer to the styles of different ethnic groups and different dances. After the construction of these models is completed, they will enter the next step of construction, that is, "three-dimensional bones" [5]. In this process, the 3D skeleton is meant to correspond to the model. Only when the correspondence is good, can we lay a good foundation for "skinning" [6]. The main function of skinning is to make the bones and the model closely connected to form a whole, making it look more harmonious and unified. At the same time, the relevant personnel must match the corresponding costumes and match the costumes, bones, and models into a set. At this time, the data information transmitted by the motion capture system can make the 3D model move and become various animations that people see. According to the needs of the market and people, these animations can be placed on the virtual platform, which is mainly used to save dance information, demonstrate dance content, and create new dance materials [7].

The advent of motion capture technology dates back to the 1970s. With the rapid development of computer software and hardware technology and the improvement of animation production requirements, its application fields cover many aspects, such as film and television production, virtual reality, games, ergonomic research, simulation training, and biomechanical research [8]. In principle, the commonly used motion capture technologies can be divided into four types: mechanical, acoustic, electromagnetic, and optical. Optical motion capture is currently the most commonly used motion capture technology. It accomplishes the task of motion capture by tracking specific light points on the target [9]. At present, common optical motion capture is mostly based on the principle of computer vision. When the camera continuously shoots at a high enough rate, the movement trajectory of the point can be obtained from the image sequence, as shown in Figure 1.

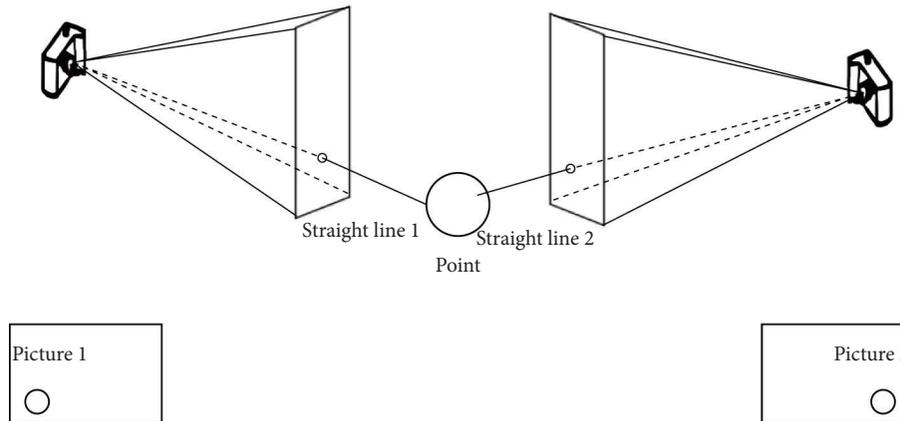

FIGURE 1: Optical motion capture system.

The advantage of optical motion capture is that the performer has a large range of motion, no cables, and the limitation of mechanical devices. The performer can perform freely and it is very convenient to use. Its high sampling rate can meet the needs of most high-speed motion measurements [10]. The disadvantage is that the system is expensive, and although it can capture real-time motion, the postprocessing (including Marker recognition, tracking, and calculation of spatial coordinates) takes long time. At present, it cannot achieve real-time driving of the character model and real-time viewing effects. Such systems are sensitive to lighting and reflections in the performance venue. The device calibration is also more complicated [11]. Especially when the motion is complex, the markers in different parts are easily confused, and the occlusion produces wrong results, which often requires manual intervention in the postprocessing process [12].

2. Related Technologies

2.1. Design of Dance Virtual Visualization Scene Based on Motion Capture Technology

2.1.1. Dance Data Collection. “Dance data acquisition” is the first step in the dance virtual visualization scene design of motion capture technology. Data acquisition is a prerequisite and foundation in the process of dance digitization. In the process of dance digitization, data acquisition is a prerequisite and foundation. Only after the data information has been collected, the data information can be presented through the subsequent virtual display platform [13]. At present, dance data collection mainly includes three parts: first, “collecting dance materials.” There are many dance materials in our country, and there are many channels for collection, such as individual performances, stage performances, and folk visits. The relevant personnel should prepare the collection equipment in advance and choose more advanced digital cameras, digital cameras, etc. Second, “digitize the material.” After the dance materials are collected, they should be systematically organized. During this process, the relevant personnel should actively listen to the suggestions of professional dancers, make reasonable use of

the dance materials, and then perform dance demonstrations based on the dance materials finally sorted out. Through the motion capture system, capture those classic dance moments and realize the digitalization of dance. Third, “Building 3D Models.” The three-dimensional model is constructed in 3ds Max. The reference is based on the general body proportions of most men and women, and the corresponding costume models are established in combination with dance characteristics. It should be noted that the models are mainly divided into two types: one is the “fine model,” which is generally not displayed on the virtual platform and is mainly saved as a kind of data which saves 360-degree video files; the other is the “simple model.” One is the “simple model,” which is mainly used for virtual platform display. There are many classifications of dance, and combined with the characteristics of different dances, it is also possible to carry out “key binding,” that is, to systematically evaluate the bound skeletal model and set relevant weights [14].

2.1.2. Dance Animation. Dance animation can be understood as the combination of “3D animation” and “motion capture data.” 3ds Max, MotionBuilder, and other software can well link 3D animation and motion capture data [15]. At this point, the work of data acquisition and dance animation is basically completed. After that, export the model file, motion data, etc. through 3ds Max, and save it in FBX format.

2.1.3. Display System. At present, the “display system” mainly uses the three-dimensional game engine UNITY 3D. This display system includes the following modules: in the opening session, just like film and television dramas, basically every three-dimensional animation video will introduce some basic information, such as production unit, content introduction, system name, which has become a conventional general title module; dress-up module - In short, this module is mainly used to change clothes, according to different regions, different dance style, and switch between different clothing animation models; camera control module: - unity 3D is a very popular 3D game engine

because it has a very powerful control ability, through the dance movements presented by the 3D model. The viewer can observe from various angles, and can basically achieve a 360-degree panorama. At this time, the viewer will feel very wonderful. The presentation of the dance and the change of perspective can be controlled by a small mouse in the hand. At present, the camera control module can be programmed independently, or the default control system can be used: the dance selection module—the classification of dance can be measured from different dimensions. The dance selection module is mainly used to select the type of dance. At present, the main types of dances are dances performed on a large scale and in a standardized manner on major holidays, some minority dances circulated in the folk, some collective dances created by people spontaneously, and some dances composed and performed by dancers with special talents, used for dances on some special occasions, with certain funny elements and commemorative meanings in Children's Day, weddings, and corporate annual meetings; gender selection module - the role of this module is well understood, which is to distinguish male dancers and female dancers. In the three-dimensional game engine U-NITY 3D display system, through the coordinated operation of these five modules, the effect of virtual demonstration is finally presented [16]. This system can now be used not only on computers but also on mobile phones.

2.2. Application of Virtual Dance Visualization Scene Based on Motion Capture Technology. By first collecting text records, taking pictures and videos, obtaining relevant text, pictures, and video-related materials of Lusheng Dance, performing dance choreography, and using motion capture equipment to record dance movements to obtain dance movement data. At the same time, 3D StudioMax is used to preliminarily establish dancer characters model. After having motion data and a dancer model, digital postproduction can be performed to realize animation display [17]. The production process is shown in Figure 2.

At this stage, the application of dance virtual visualization scene based on motion capture technology is mainly reflected in the following aspects:

2.2.1. Teaching Field. When teaching dance classes, art teachers can use the virtual display platform to digitally present dance, bring students more abundant teaching content, facilitate students to learn “dance movement decomposition,” and facilitate teachers to carry out dance-related activities. research [18].

2.2.2. Multimedia Display Field. In the field of multimedia display, the application of dance virtual visualization scene based on motion capture technology can combine traditional dance teaching content with modern technology, such as three-dimensional dynamic imaging technology, human scene synthesis technology, phantom imaging technology, and laser technology. This gives viewers a new impact. From the perspective of dance research, this is an efficient research

method, that is conducive to improving the accuracy and standardization of dance research.

2.2.3. Internet Field. The application of dance virtual visualization scene based on motion capture technology can well adapt to the Internet environment and compile and generate some dance content that can be disseminated and displayed in the Internet environment. With the increasing number of mobile phone users, the Unity 3D game engine can also compile and generate mobile apps, so that more people can enjoy this convenient service anytime, anywhere, and feel the popular educational atmosphere of dance in the new era. The dance of the public has broadened the path of inheritance and development.

3. Dance Motion Capture Technology Based on Visualization Requirements

To meet the needs of efficient and high-precision human gesture recognition methods, an efficient gesture analysis method based on similarity matching between feature planes is proposed. The human motion data is collected in real time through the optical motion capture system, and the skeleton and its human feature plane are effectively extracted. Furthermore, an efficient matching mechanism is established by taking the plane feature vector and its included angle as the judgment basis for attitude analysis. This method is combined with dance teaching. After experimental verification, it not only provides a stable and accurate analysis of human posture but can also effectively obtain the difference between human movements, thus providing good theoretical support for dancers to carry out scientific dance training [19].

3.1. Acquisition of 3D Data from Motion Capture. In this paper, an optical motion capture system is used to obtain motion data, thereby establishing a database of the human motion pose models and skeleton model. The basic process is as follows, as shown in Figure 3.

3.1.1. Real-Time Acquisition of 3D Human Motion Data. In the data collection, the performers first put on monochrome clothing with 21 markers on key parts, stand within the preset motion space, start the high-precision 3D motion capture software, set the specified time, and press. It is required to shoot the specified dance movements and use the camera to capture and track the movement of the 21 marker points. Match the captured and edited human motion data of 21 marker identification points with the actor model, activate the 21 identification points to complete the data matching with the actor, so as to complete the establishment of the database of human motion posture.

3.1.2. Establish Motion Model Database. Applying the motion capture system to analyze the motion posture of the human body is to estimate the motion posture characteristics of the human body from different perspectives. In this paper, the key points of the motion feature are used to mark

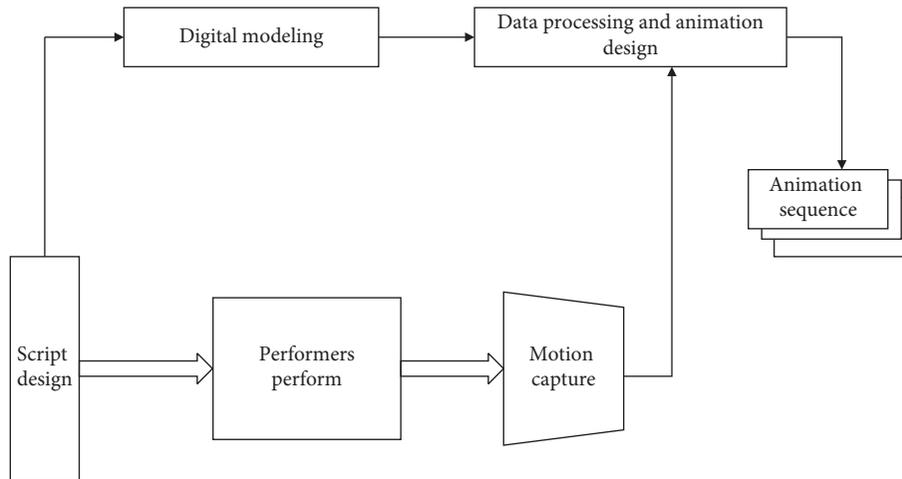

FIGURE 2: Production process.

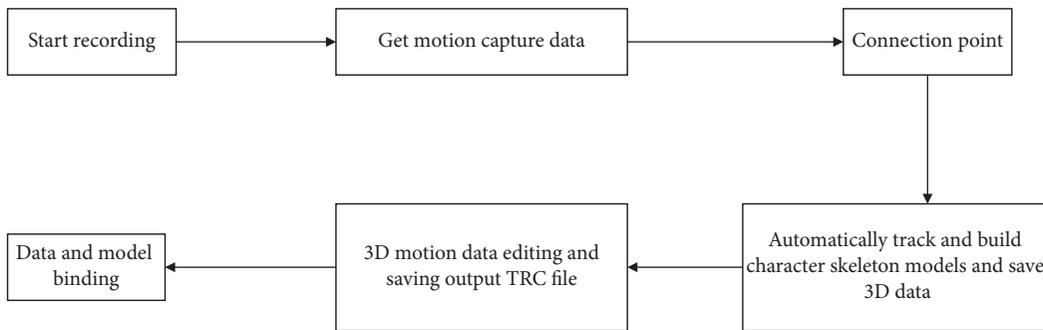

FIGURE 3: 3D data acquisition flow chart.

the key parts of the human body. The connection between the key points represents the rigid body. When they are “shape unchanged,” the connections between key points represent rigid bodies [20]. The main research on movement posture is to build a database of human movement postures based on the head, body, hips, and limbs.

3.1.3. Human Motion Pose Analysis Based on Feature Vector Matching. Movement posture analysis is the process of tracking, capturing, acquiring, and analyzing human body posture characteristics so as to obtain relevant movement posture parameters. Through the effective combination of motion analysis and teaching, the teaching system can be more personalized and featured, and the performers’ performances can be decomposed in detail, and each dance movement can be demonstrated step by step. The parameters obtained are conducive to quantitative analysis of the movement posture, providing good help for more scientific and intelligent dance teaching [21].

In order to better analyze the motion state of dance performers, a method for analyzing human motion posture using the principle of feature plane similarity matching is proposed. This method simplifies the traditional calculation of Euclidean distance based on multiple identification points to the calculation of a feature plane feature vector and its included angle [22]. In this paper, the identification points of

21 key parts are simplified into 7 feature planes to calculate the motion difference and correlation. Through verification, this method can quickly and effectively analyze the motion posture of the human body and can be applied to dance teaching to improve the efficiency of dance teaching. The specific process is as follows, as shown in Figure 4. The main steps of the analysis process include the following:

Step 1 Real-time acquisition of skeleton data: in the form of optical motion capture, real-time acquisition of dance action sequences, and storage of the coordinates of each identification point of the human body model in the space coordinate system.

Step 2 Posture analysis: determine 7 feature planes according to the feature points, extract the angle between the feature vector and the posture feature vector, and calculate the feature correlation coefficient of the human body posture according to the motion characteristics of the key parts of the dance movement.

Step 3: Analysis of the difference degree of characteristic posture: through the correlation coefficient of the characteristic vector and its included angle, analyze the difference and accuracy between the dance movements and standard movements of the students.

The motion of the human body is a complex process. Without considering conditions such as muscles and

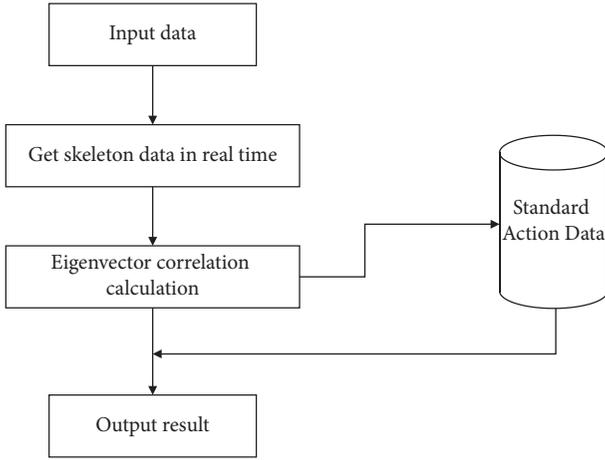

FIGURE 4: Method flow chart.

nervous systems, the motion of the human body can be abstracted into a simple chain system connected by some rigid bodies [23]. The upper limb is composed of two rigid bodies connected by the elbow joint, the upper arm, and the forearm; the lower limb is composed of the two rigid bodies of the thigh and the calf connected by the hip joint, and the thigh and the calf are connected by the knee joint. The body and hip are also represented as a rigid body by a line connecting the joint points [24].

3.2. Traditional 3D Model Similarity Matching. The similarity matching of human body poses is to realize the measure of the difference or similarity of the poses between different human bodies. The most commonly used method is the traditional Euclidean distance metric.

The traditional 3D model similarity matching is based on the Euclidean distance, and the calculation methods are as follows:

$$D = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}, \quad (1)$$

$$D = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2 + (z_1 - z_2)^2}.$$

With two identification points, the difference between the two identification points can be obtained through the calculation formula based on the Euclidean distance. If the obtained difference is less than the threshold, the threshold is set by the coach, and the two identification points are considered to be similar. If the difference is greater than this threshold, the two identification points are considered dissimilar. The standard action is compared with the trajectory of the same identification point of the action to be tested, as shown in Figure 5.

The direct comparison method based on the traditional Euclidean distance is to compare the activity trajectories of two moving targets, and the corresponding distance difference will be obtained during the comparison of each action sequence, and the data matching degree will be calculated according to the preset threshold. However, this method not only requires too much calculation but also depends on the inherent characteristics of the object to be

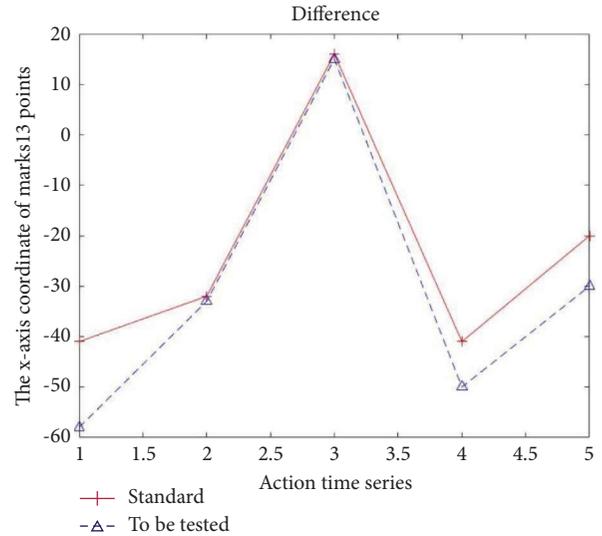

FIGURE 5: Comparison of motion trajectories in one direction between single identification points.

measured. When the body ratio of the object changes, such as height, short, fat, and thin, the distance between the marking points also changes accordingly, and it must be repeated. Therefore, due to the strict requirements for moving objects, the use of traditional methods is limited, which not only greatly reduces the computational efficiency but also lacks universality [25].

The traditional form of dance teaching is generally taught by the teacher's oral and deeds, through oral movement essentials and personal demonstration of dance movements to students, so that students can understand the essentials of movements in class. However, in traditional sports teaching, the internal reasons such as high difficulty, fast speed, difficult memory, and the instantaneousness and complexity of movements lead to increased teaching difficulty. Teachers cannot standardize each movement due to psychological, physical and other factors. It is shown meticulously that due to individual differences and different observation angles, students cannot master the essentials of movements in this class, which has an impact on the understanding of the key and difficult points of dance movements, so that teachers have to repeatedly demonstrate and explain, which affects teaching efficiency. The teacher's oral and deed teaching method has a single teaching form, and the students only focus on movement practice and lack the ability to think actively.

The combination of motion capture technology and teaching will make up for the deficiencies of traditional teaching forms and has advantages that traditional teaching does not have in the acquisition and transmission of motor skills. According to the students' own state, they can purposefully learn and demonstrate the movements, and then compare them with the standard movement postures according to the analysis results of the three-dimensional movement data and correct the standard movements in time, which is beneficial to the students' learning and performance. Teachers' teaching efficiency has been greatly improved.

The teacher's standard dance movements are made into three-dimensional teaching animations through motion capture technology. Before class, students learn the dance movements in the teaching animations by themselves, and draw gestures and movements in their minds while watching the animation. Repeated demonstrations are performed in multiangle segments, and then students perform real demonstrations. The high-precision 3D camera of the motion capture device captures the movements demonstrated by the students and compares them with the teacher's standard movements. The teacher can give students specific goals through the comparison of 3D data. The guidance helps students master the essentials of standard dance movements, and students can make self-correction according to the analysis results. Throughout the development of computer-assisted teaching, computer science, educational technology, cognitive psychology, etc have had an important impact on the development of motion capture technology-assisted dance teaching. The kinds of enlightenment that can be obtained are as follows:

- (1) From the technical application point of view, motion capture technology establishes a teaching model database and generates teaching animation videos, which makes the computing technology-assisted dance teaching more concise, easy to understand, vivid, and so on, gives full play to the role of virtual reality technology, and analyzes students' mastery. It provides learning navigation and suggestions for students' dance movement learning; students realize independent learning and inquiry learning, and teachers can assist students' learning process from the side, so that students' "learning" and teachers' "teaching" are more in line with the concept of digital teaching; it is also more feasible at the technical level.
- (2) From the perspective of teaching form, due to the innovation of teaching methods, teachers are guided to fully realize the teaching advantages of motion capture technology - 33 -, play the leading role of teachers, get rid of the shackles of traditional teaching methods, and create indoor training classrooms for different dance forms, such as ballet, Latin dance, folk, dance, can use motion capture technology to quickly, and effectively help students discover the completion of their own movements through detailed demonstrations and real-time effects feedback, thereby making up for irregular movements. Students learn the essence of the movements to be mastered in the form of self-learning, which is conducive to giving full play to the initiative of students in learning, fully realizing the main body of students' learning, enhancing the pertinence and timeliness of teaching effects, and improving the attractiveness and effectiveness of classroom education models. Infectious is conducive to enhancing the level of students' reform and innovation.
- (3) The dance teaching form based on motion capture technology is the intersection of computer science, educational science, and teaching psychology. This technology can improve teaching quality, enhance teaching appeal, and make motion capture technology make creative progress and development in the scope of computer-aided instruction.

4. Conclusion

The virtual visual scene design of dance based on motion capture technology is of great significance for the diversified presentation and inheritance of dance, especially for some relatively classic and small minority dances, because fewer people learn these dances, these dance forms are facing a crisis of inheritance. The virtual visual scene design of dance based on motion capture technology can better protect these minority ethnic dances, so that more people can see the charm of this dance and are willing to inherit and develop it.

Data Availability

The dataset can be accessed upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

In the post-epidemic era, it is difficult for farmers to sell agricultural products offline due to their characteristics, and farmers once again fall into the situation of “difficult sales.” New media marketing of agricultural products, as an emerging form conforming to the trend of the times, not only increases farmers’ income but also promotes industrial integration and development. However, as this model is still in the early stage of development, a large number of farmers are not willing to transform the traditional sales channels into new media marketing for agricultural product sales. In this study, the interview data of 76 new-type professional farmers in Fujian were analyzed by three-level coding based on programmed grounded theory. It is found that core factors, and macro- and microfactors such as farmers’ characteristics and sales situation will affect farmers’ willingness to sell agricultural products through new media. Therefore, this study deeply explores the relationship between farmers’ willingness and various factors and puts forward three suggestions for solving the actual problems of agricultural product sales.

1. Introduction

In the era of mobile Internet, agricultural products are difficult to sell due to the lack of good sales channels. Moreover, affected by the epidemic, offline sales of agricultural products have become increasingly difficult, and farmers are trapped in the predicament of “difficult sales.” The new media marketing of agricultural products is accelerating its development by virtue of its low marketing cost, rapid information dissemination, and other advantages. Under the new media, the new business form, live streaming e-commerce of agricultural products, has emerged, which not only improves farmers’ income but also promotes industrial integration and speeds up the development of the agricultural economy. In 2022, the No. 1 Central Document proposed the implementation of the project of “Revitalizing agriculture by developing digital

commerce” to enable the development of rural e-commerce through digital elements and data elements and jointly open up a new era of new media marketing of agricultural products.

At present, this new mode is still in the preliminary stage of development under the new media. With the increasingly fierce competition in agricultural product sales in the new track, the means of live streaming e-commerce and short video marketing of agricultural products are flexible and changeable. Due to the particularity of agricultural products and the lack of new media marketing talents, as well as the immaturity of operating basis, platform rules and regulations, and industry norms, a large number of farmers are unwilling to change the traditional sales channels and explore new media means for sales. In this context, it is of great significance to deeply explore the willingness and mechanism of farmers to promote the sale of agricultural products

by means of live streaming e-commerce and short video marketing from the perspective of new media, so as to solve the problem of farmers' "difficulty in selling" and realize rural revitalization through industrial revitalization.

2. Overview of Related Research

2.1. UTAUT Theory. UTAUT theory [1] holds that there are four core dimensions of factors affecting users' willingness and behaviors to adopt new information technologies. (1) PE (performance expectancy) means the degree to which an individual feels from the inside to be helpful to his or her job by using an advanced technology. The greater the degree of help is, the stronger the willingness of users to adopt. (2) EE (effort expectancy) refers to how much time and energy an individual has to invest in learning to use the technology. (3) SI (social influence) appertains to the degree to which the perception of the people around the adoption of certain information technology affects an individual. (4) FC (facilitating conditions) signifies the degree to which an individual perceives that the external environment is sufficient for the adoption of new information technology (Figure 1).

2.2. Research Studies on the Development Model of Farmers' E-Commerce. Jalali AA et al. studied the development of rural e-commerce in Iran and proposed a new practice model for its effective development. Xie et al. summarized development models of farmers' e-commerce from the perspective of regional collaborative development as A2A, A2B, and B2A. Among them, the A2B mode refers to the establishment of a relevant website with complete and timely information or an effective management platform for suppliers and purchasers to integrate resources and carry out online transactions with the help of third-party logistics [2].

Domestic scholar Lyu proposed an e-commerce model of fresh agricultural products based on supply chain integration and basic social network to deal with the unsalable products caused by excessive supply chain links of fresh agricultural products [3]. Huang and Wang conducted a study on Anhui Province's characteristic agricultural products' e-commerce based on e-commerce models such as "origin + platform + consumer" and "platform + self-support + consumer" [4].

2.3. Research Studies on Factors Affecting Farmers' E-Commerce Entrepreneurial Behaviors

2.3.1. Subjective Cognition. Berglund believed that "Entrepreneurship for survival" and "Entrepreneurship for an opportunity" are two motivations of modern farmers. According to Liu, there is a positive correlation between the willingness of e-commerce operators to sell agricultural products in virtue of e-commerce and the perceived usefulness, ease of use, and profits [5]. Social trust proposed by Wenzel and individual innovation proposed by Mao have a positive effect on the willingness to use e-commerce for sales [6].

2.3.2. Individual Traits. Yao and Zhu research showed that, with the growth of age, farmers tend to be conservative in their ideas, and farmers of different genders also have different behavioral choices [7]. Korgaonkar et al. considered that age has a negative impact on farmers' willingness to engage in e-commerce sales. In addition, Li pointed out that people with higher education are better at using emerging Internet means and computer technology to participate in the e-commerce of agricultural products [8].

2.3.3. External Environment. Arayesh [9] stated that social economy, privacy and security, infrastructure, and national policies are the main factors affecting farmers' adoption of agricultural product e-commerce. Mao said that external conditions such as the market environment, national economic policies, and related services have a greater impact on farmers' willingness to use e-commerce for sales than operators' own factors [10]. In terms of government policies, Huang believes that national policies such as e-commerce subsidies have little impact on farmers' willingness to choose e-commerce [11]. According to Su et al., external factors such as network facilities, traffic conditions, and government support at the current stage have little influence on the use of new media for marketing [12].

Studies by scholars at home and abroad mostly focus on farmers' use of marketing behavior, but rarely discuss farmers' willingness to use e-commerce, especially new media to sell agricultural products. With reference to the research of domestic and foreign scholars, this study, on the strength of the programmed grounded theory, analyzes the willingness of farmers to sell agricultural products through new media, including live streaming and short video sales to determine the corresponding relationship between key influencing factors and farmers' willingness and to explore the formation mechanism, so as to better play the role of new media marketing in solving farmers' "difficulty in selling" and helping rural revitalization.

3. Research Contents

3.1. Research Methods. Grounded theory is an exploratory qualitative research method proposed by American scholars Strauss and Glaser that obtains the original data through in-depth interviews and abstracts and condenses the original data through three-level coding, with social phenomena and problems as the research object, so that a scientific and reasonable theory and model and a bottom-up systematic theory are established to deeply analyze the existing problems.

In this study, in-depth interviews with new professional farmers in Fujian Province are conducted, and the willingness of farmers in Fujian Province to sell agricultural products through new media marketing is studied using the research paradigm of Straus' programmed grounded theory [13–16]. Nvivo12plus software is used as an auxiliary coding tool to reduce, screen, and extract the original data in the form of open coding, spindle coding, and selective coding,

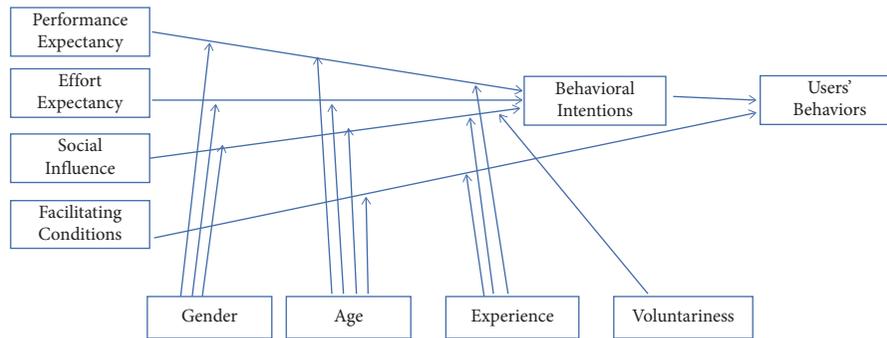

FIGURE 1: Model of UTAUT theory.

determine the concept and category, and finally establish the theoretical framework model [17–20].

3.2. Data Collection. In this study, a total of 76 new-type professional farmers are selected as the interview objects, including 40 males and 36 females, aged between 31 and 50 years, more than 90% of whom have a high school or junior college education. After obtaining the consent of the interviewees, a face-to-face semistructured interview is conducted, and the interview content is recorded by mobile phone. The average interview time is 45 minutes, the longest is 75 minutes, and the shortest is 40 minutes. The whole interview process strictly follows the research paradigm of grounded theory. Thirty five copies of text information were organized according to the recorded information, of which, 30 are randomly selected for coding analysis combined with the details such as tone and expression of interviewees marked by on-site observation, and the remaining 5 are used for the theoretical saturation test.

The interview outline and specific contents are set around the investigation of farmers' willingness to use new media for agricultural product marketing. From the four dimensions of PE, EE, SI, and FC, 26 related interview questions are designed based on the UTAUT model of "integration theory of technology adoption and utilization," involving the personal situation of farmers, application of agricultural products e-commerce to product sales, and personal attitudes towards new media marketing of agricultural products. Then, in strict accordance with the theme of new media marketing intention, these data are screened, processed, and numbered for and coding.

4. Coding Analysis and Model Building

4.1. Open Coding. In grounded theory, the first is to conduct an open coding analysis on all interview data texts; that is, the interviewer will code, conceptualize, and categorize the data in the original text records of interviewees, so as to form the original data statements, as well as initial concepts and categories. In this study, Nvivo12plus software [21–25] is used to sort out the interview materials, and more than 300 original sentences are obtained. Then, 37 initial concepts and 17 effective initial categories are generated by categorizing

the initial concepts with word frequency greater than 2 times. Specific information is shown in Table 1.

4.2. Axial Coding. Axial coding is carried out after open coding. In this process, the initial concepts formed should be first analyzed and refined through cluster analysis and then put into the local social and cultural background for practical analysis to refine the main categories and merge the secondary categories. In the second round of coding, this study extracts eight main categories: natural conditions, characteristics of agricultural products, financial costs, social culture, population structure, the government environment, and the characteristics of farmers and sales. Specific information is shown in Table 2.

4.3. Selective Coding. In this study, eight main categories [26–30] of natural conditions, the characteristics of agricultural products, financial costs, social culture, population structure, the government environment, and the characteristics of farmers and sales are first determined by axial coding to form and develop the story line of "farmers' willingness to engage in new media marketing." Then, the logical relations among the factors of each category are integrated to construct the theoretical model framework of the research problem.

4.4. Model Building. After refining 35 original texts, 17 initial categories, and 8 main categories and sorting out the "story line" through selective coding, the research model of farmers' willingness to sell agricultural products by means of new media marketing is finally constructed. The results show that farmers' willingness to sell is influenced by eight factors, including natural conditions, characteristics of agricultural products, financial costs, social culture, population structure, government environment, characteristics of farmers, and sales. The model is shown in Figure 2.

4.5. Theoretical Saturation Test. Nvivo12plus software is used here to import the five unanalyzed interview text materials into the coding verification. The results show that no new concepts and categories are found in the theoretical saturation test, and the sample data can no longer generate

TABLE 1: Open coding results of Fujian farmers' willingness to sell agricultural products by new media marketing.

Initial categories	Initial concepts	Original data statements
Growing climate of agricultural products	Status of cash crops	The climate of Wuyi mountain is suitable for growing tea, so we are planting Wuyi mountain rock tea; we mainly grow Mandarin oranges, which are greatly affected by the weather
	Status of food crops	We usually grow sweet potatoes in a small area of three or four mu
	Climate for agricultural production	The weather has been bad these years and drought led to a sharp decline in tea production; fruit production is affected by the weather
Growing temperature of agricultural products	Temperature for agricultural production	The weather is hot these two years and our planting is affected by high temperatures
	Weather for agricultural production	The sweetness of the oranges will be affected by rain, too much of which will cause oranges not to be as sweet as they used to be
Growing environment of agricultural products	Producing areas of agricultural products	We live in Zhengyan mountain farm, where the tea is sold so well for its quality that you do not even need to sell it online; our tea is in Tianxing village in Wuyi mountain, but there are fewer tourists here these years
	Quality certification of agricultural products	"San pin yi biao" agricultural products can get government subsidies; consumers are more inclined to have agricultural products of certification, such as pollution-free agricultural products, and green food; we can sell our own produce; however, if they are to be strictly examined, it may be difficult to guarantee their quality
Qualification of agricultural products	System certification of agricultural products	Food industry certification requires ISO22000, HACCP system, which is also a large amount of expenditure
	Branding of fresh products	The same produce, once branded, costs a lot more; slightly better packaged tea sells well in douyin studios
Standardization of production	Construction of standardized production system	From these years of operation, I also realize that the standardized production of agricultural products is very important
	Production technology of agricultural products	Nowadays, the management of agricultural products is also very particular about production technology; technology is now necessary for everything, such as how to store produce, and how to process it
Advanced production technology	Scientific packaging, storage, and transportation of agricultural products	Online sales challenge the supply chain; although live-streaming can bring orders, but how to deliver, how to pack, etc., must be considered clearly before live-streaming; now, a large part of the operating cost is spent on packaging, storage, and transportation
	Production of agricultural products	The product volume is relatively small, so it is not easy to sell; our own Mandarin oranges usually come to market around winter; our tea farmers pay special attention to the growth of tea leaves and dare not to use pesticides
Production costs of agricultural products	Expiration date	Because fruit has a very short shelf life, it is usually picked and sent out before it is fully ripe; otherwise, the fruit will easily rot in transit
	Product packaging costs	We do not sell our own products online because of the high cost of packaging; the packaging alone costs a lot of money, but in fact, the product itself is not expensive
Logistics costs	Logistics and delivery	The epidemic has increased the difficulty and cost of logistics operations; the epidemic has made national distribution difficult
	Costs of the operating team	I am too old to know much about Internet; a small amount of product is not worth paying someone to live stream; I cannot afford to have people conduct live streaming; typically, the cost of operation teams and platforms is high
Marketing and promotion costs	Advertising expense	It is not worth the cost; if there is no advertising, there is no traffic; without money, there would be no traffic and no consumers to buy our products

TABLE 1: Continued.

Initial categories	Initial concepts	Original data statements
Local traditions and customs	Behavioral modes	With a low level of education, we can only play on mobile phones, but do not know how to run live streaming and short videos; we watch live streams and short videos, but we cannot operate; I will use e-commerce only after many of my peers have adopted it
	Living habits	After dinner, young people watch Douyin or play cards; usually, when we are not working outside, we get together to chat and play cards
	Social experience	In our village, people who go out to start businesses have experienced many things; now, the outside world is changing a lot; we really need to learn more
Social cognition	Reflections on social activities	The women here generally do not like to talk in front of others and feel very uncomfortable; I get so nervous in front of the camera that I cannot run live streaming, and I do not know what to say; I do not feel comfortable exposing myself to cameras or interacting with fans in the studio;
	Local customs	People in our village are conservative and do not like live streaming, and we feel the same as the host; Minnan people are quite bold and willing to try new ways
Population structure	Family structure	We have a larger family and the children will come back to help when they grow up; we only have two kids, and the whole business is dependent on us, so we do not have the energy to do anything else
	Cultural structure	My own education level is low, but my kids know a little bit about it, and they will make live streaming on Douyin when they have time; I went on to a junior college later; with more communication with my classmates, I am much braver
	National policy	In recent years, the government has issued a lot of e-commerce policies to benefit farmers and provided a lot of training; our cooperative runs special e-commerce training courses, which we attend whenever we have time; thanks to good policies, times, and technology, we can sell things at home; mobile phones and the Internet are developing rapidly; If you do not learn, you will be left behind
Policy and technology development	Scientific and technological development	The county's agricultural machinery station provides farmers with e-commerce training; there are many college students in our village now
	Level of education	I opened a taobao shop a few years ago and made a little money; I was an early e-commerce entrepreneur in my village, so relatively speaking, I earn more than others
Characteristics of farmers	Scale of incomes	I have a quick temper, and I do what I decide to do; in retrospect, I made the right decision; I like making friends, more friends and more opportunities; I am ordinary and conservative
	Personalities	We should get to know more people and learn their advantages; most of the time, judgment is important, and the correct judgment comes from experience; I am used to rely on my experience
Product price	Interpersonal connections	Fruit prices have not changed much in the past two years; tea prices have been heavily affected by the pandemic
	Product price	Products are purchased by customers at a low price but sold online at a high price; live streaming can lead to better prices for produce
	Differences in different sales channels	

TABLE 1: Continued.

Initial categories	Initial concepts	Original data statements
Sales risk	Differences in sales	If products are sold to buyers, we can quickly sell out the products, but the profit is low; selling products by live streaming is a matter of luck; sometimes products sell well, sometimes they do not
	Differences in channel risk	The buyer can take all the products at once; I just wait at home; online sales take a long time; customer source depends on accumulation; the product will be easy to sell on some accounts that run for a long time
	Risk of damage	Online sales require seven days of gratuitous compensation service for bad fruit, which makes online sales more risky and in debt; what we fear most is that the fruit will spoil in transit; poor logistics will make us lose money
Investment costs	Pre-investment restriction	I Know e-commerce will be profitable, but it will take a big investment to start with; what we farmers need most is money

TABLE 2: Axial coding results of Fujian farmers’ willingness to sell agricultural products by new media marketing.

Main categories	Independent categories	Initial concepts
Natural conditions	Growing climate of agricultural products	Status of cash crops; status of food crops; climate for agricultural production
	Growing temperature of agricultural products	Temperature for agricultural production
	Growing environment of agricultural products	Weather for agricultural production; producing areas of agricultural products
	Qualification of agricultural products	Quality certification of agricultural products; system certification of agricultural products
Characteristics of agricultural products	Standardization of production	Branding of fresh products; construction of standardized production system
	Advanced production technology	Production technology of agricultural products; scientific packaging, storage, and transportation of agricultural products
Financial costs	Production costs of agricultural products	Production of agricultural products; expiration date
	Logistics costs	Product packaging costs; logistics and delivery
	Marketing and promotion costs	Costs of the operating team; advertising expense
Social culture	Investment costs	Pre-investment restrictions
	Local traditions and customs	Behavioral modes; living habits
Population structure	Social cognition	Social experience; reflections on social activities; local customs
	Family structure	Number of family members; family relationship
Policy environment	Cultural structure	Regional culture; folk customs and family traditions
	Policy and technology development	National policy; scientific and technological development
Characteristics of farmers	Characteristics of farmers	Level of education; scale of incomes; personalities; interpersonal connections
Sales	Product price	Product price; differences in different sales channels; risk of damage
	Sales risk	Differences in sales; differences in channel risk

new theories. It can be seen that the research model of farmers’ willingness to sell agricultural products through new media marketing based on the programmed grounded theory has reached theoretical saturation and thus has certain realistic explanatory power.

5. Discussion and Analysis

5.1. *Impact of Macrofactors on Farmers’ Willingness to Sell Agricultural Products through New Media.* With the wide use of new media, agricultural product marketing also ushered

in a rare opportunity for development. However, due to the late start and a weak development base of new media in China, the majority of farmers, restricted by geographical location and the overall low-level of economic development, as well as the influence of long-term traditional culture, are relatively conservative and slow to accept new things. In addition, affected by such problems as poor infrastructure and unstable Internet speed in the outward environment, new media marketing is still in its infancy with a relatively low penetration rate, although the national government has strongly supported farmers to participate in rural

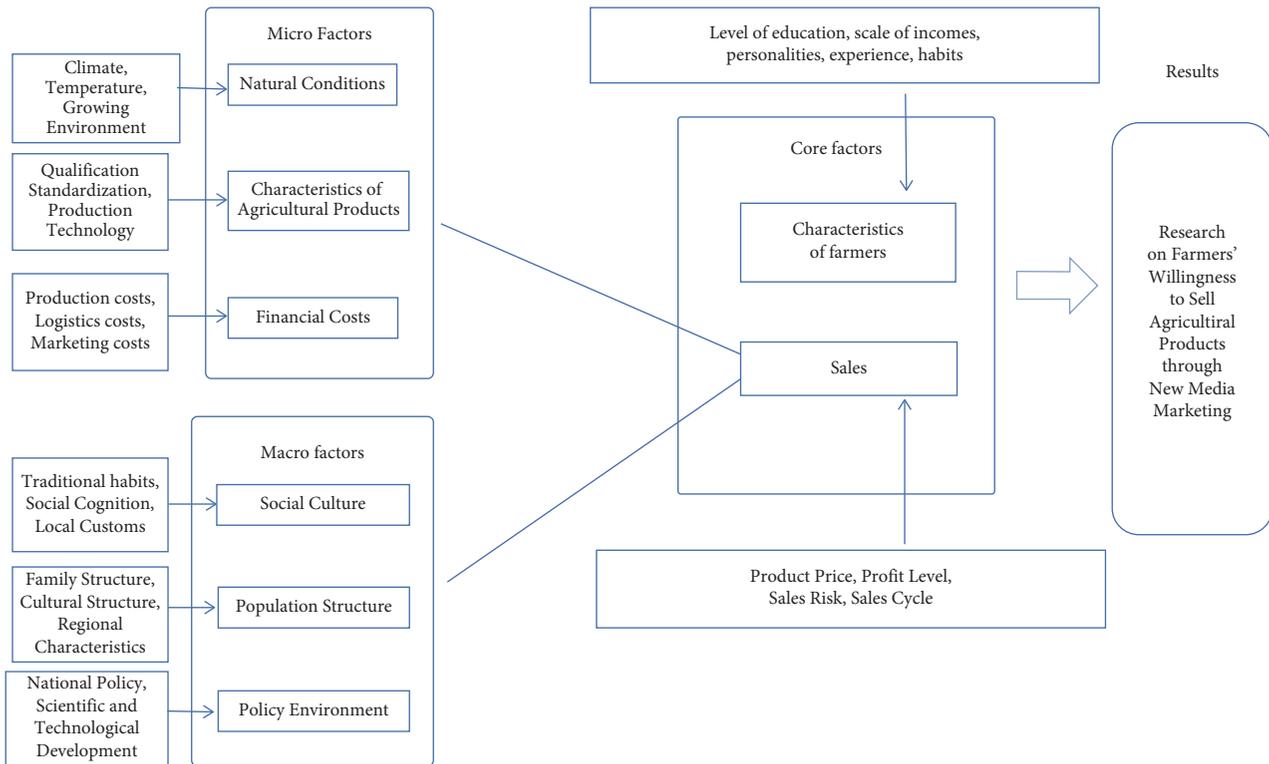

FIGURE 2: Model of factors influencing Fujian farmers' willingness to sell agricultural products by new media marketing.

e-commerce in recent years. Hence, farmers' willingness to sell agricultural products using new media is influenced by social culture, population structure, and policy environments. Moreover, in the use of new media, most farmers show a herd mentality. According to the interview data, some interviewees think that "Being an ordinary person, I am conservative and used to rely on my own experience." And when asked about "the influence of the external environment on my willingness to use new agricultural products marketing methods," some interviewees say "I will use e-commerce only after many peers around me have adopted it." Also, some interviewees express visceral resistance, saying, "Especially when it comes to 'showing up' on camera and interacting with fans in the studio, I am reluctant."

5.2. Impact of Microfactors on Farmers' Willingness to Sell Agricultural Products through New Media. Microfactors mainly refer to the natural conditions, characteristics of agricultural products, financial costs, and other key links closely related to the production and management of agricultural products.

Natural conditions include climate, temperature, and environment suitable for the production or processing of agricultural products. For a long time, the cultivation, processing, and production of agricultural products have been highly dispersed and small in size due to the influence of multiple factors, and too little sales result in the failure to form the influence of products. In the interview, when asked about "factors affecting the sale of agricultural products,"

17.81% of the farmers said that their products were small in quantity and difficult to sell. Scale and concentrated production are the premise of building agricultural products brand. The lack of a certain scale makes it costly to build information platforms, trading platforms, and circulation channels, which leads to the difficulty of unified processing and marketing of agricultural products. In the interview, nearly 60% of the interviewees think that there is no good sales channel, and 30% consider that the cost of trading on the platform is high.

Quality is the premise of building a brand and selling well. In new media marketing, when consumers can only indirectly perceive products through short videos and live streaming rooms, farmers are more needed to check the quality of agricultural products. Whether to have qualification, certification, and standardization is an indispensable "inspection rule" of high-quality agricultural products, which directly determines the quality of agricultural products. In the interview, when it came to "factors affecting the sale of agricultural products," 15.07% of farmers believe that it is difficult to guarantee the quality of their products, which affects their willingness.

Financial costs are mainly reflected as product packaging, logistics, and advertising costs to attract fans on new media platforms. In the new media marketing, it is necessary to attract consumers' "eyes" more from the sensory experience of consumers and to maximize the safety and undamaged arrival of agricultural products to consumers from the perspective of storage and transportation. Therefore, in new media marketing, farmers need to consider the cost of physical packaging and storage and transportation

packaging. In addition, new anchors and vloggers need to spend a certain amount of money to attract fans. These marketing costs are also factors influencing farmers' use of new media to sell their produce.

5.3. Impact of Farmers' Characteristics on Their Willingness to Sell Agricultural Products through New Media. The characteristics of farmers, such as personalities, long-formed habits, education level, and personal and family income level, are core factors affecting their willingness to use new media marketing. In the interview of farmers who have adopted new media marketing to sell agricultural products and obtained better income compared with the previous year, it is found that 91.78% of the farmers have a high school or college degree or above. Furthermore, 62.12% of farmers say that "I don't want to be too conservative, and I like to break through the present," and 35.17% of farmers think "I am a person who dares to think and do. I am willing to try electronic products and new things and get started quickly." In terms of "attitude towards new media marketing in rural areas," 45.21% of farmers express great interest and 41.1% express interest. Meanwhile, farmers' income status will affect their willingness since the level of income affects their personal cognition to a certain extent. Benefiting from their good economic basis, farmers with high income are more willing to explore new ways to expand sales channels of agricultural products.

5.4. Impact of Sales Status on Farmers' Willingness to Sell Agricultural Products through New Media. The sales status herein refers to the unit price, profit level, sales risk, and sales cycle of agricultural products provided by farmers for the third parties.

When the unit price of agricultural products is high, it is difficult for farmers to sell them through short videos or live broadcast rooms, and vice versa. In the interview, interviewees say that 40% of the tea produced by them that has higher price than other agricultural products are sold through offline wholesale markets, distributors, or agents, and 25% is sold online. Farmers who choose new media marketing say that "as the source producer, they can get more profits by choosing new media for sales." On the contrary, farmers who grow less profitable agricultural products are less willing to choose new media for sales.

Farmers generally believe that merchants' acquisition in traditional offline sales channels is the most stable, rapid, and convenient, but the price and sales volume of products brought by online new media marketing are unstable. Also, there is a popular belief among them that, under the background of new media marketing, the product sales cycle is affected by the individual's knowledge of new media technology, live streaming sales technology, and short video production technology. Therefore, farmers, who lack professional new media marketing technology, generally express their concern about the use of new media marketing. Nearly half of the interviewees say that they only understand the basic use of new media tools, but have some difficulty in applying them to marketing or they cannot use new media

tools. In the interview with the theme of "The most important problems to be solved in participating in rural e-commerce," most of the interviewees indicate that they are in urgent need of training and technical guidance of professional e-commerce talents or in urgent need of being trained as professional new media operation talents.

6. Strategies and Suggestions

6.1. Strengthening the Training of Farmers on New Media Marketing Techniques. Strengthening the training of farmers on new media marketing techniques of agricultural products can improve their cognition of e-commerce, psychologically shorten their distance from new sales methods, and enhance their willingness to use new media. First of all, to strengthen the training support of new media marketing, a combination of horizontal and horizontal training can be adopted to make full use of the advantages of new media marketing related majors in agricultural colleges and universities under the coordination of "government, school, industry, and enterprise" for rural revitalization. The practical operation skills of farmers should be strengthened by improving new professional farmers' educational background and training them on rural live streaming e-commerce and new media operation so that farmers can get familiar with the operation process of new media operation. Secondly, the opportunities for cooperation with large e-commerce platforms can be increased to train farmers on the production quality of agricultural products and e-commerce transactions and improve their skills in product production and network information technology processing, so as to enable them to better resist future risks and enhance their willingness to use new media to sell agricultural products.

6.2. The Government Issue a "Package" of New Media Marketing Support Policies. Governments at all levels should encourage farmers to their agricultural products using new media and promote rural revitalization through industrial revitalization. In terms of top-level design, better service and support policies should be introduced in various aspects such as industrial development planning, new media talent training, and follow-up service guarantee. First, build the brand of agricultural products. New media cloud support is provided for agricultural products with strong regional representation, a large number of employees and considerable market potential, so as to shape local characteristic brands. Secondly, prepare training materials for farmers' new media marketing, as well as supporting teaching plans, courseware and microclass short videos. To highlight the main line of selling agricultural products through new media, the electronic textbook package can adopt methods of navigation-style bookmarks, "nanny level" companionship, and the way of accessing knowledge at any time through "clicking." Thirdly, the professional new media operation team develops the operation package of "live streaming e-commerce of agricultural products" at a suitable price for farmers who are willing to buy it. By simplifying the

process of new media, this operation package enables farmers to experience the use of new media marketing methods with “low cost and zero distance,” accumulating operation experience, such as setting character and attracting fans and learning efficient output, so that farmers can become local talents of live streaming e-commerce of agricultural products with their own characteristics and the gold spokesperson of local agricultural products.

6.3. Build the Brand of High-Quality Agricultural Products by Giving Full Play to the Value of Producing Area. Brand building is a crucial link for farmers to open the market with agricultural products. In the investigation of farmers’ willingness to sell agricultural products through new media, it is found that most farmers are reluctant to sell their products through new media because of the sales difficulties caused by the lack of brand promotion. In response to the proposal to take action to improve varieties, enhance qualities, build brands, and promote standardized production of agricultural products in No. 1 Central Document for agricultural product branding construction, the government should enhance the brand construction of agricultural products. First is brand empowerment. The tourism Bureau, agriculture Bureau, and other forces and resources are integrated to form a new media marketing force to boost agriculture. The professional team will select 1-2 single agricultural products with local characteristics according to regional resource advantages and market thinking and carry out brand construction through packaging design, trademark registration, relevant certification, and other ways. The second is content distribution. A series of promotional videos, brand promotion activities, and food selection activities are launched by making full use of news media and video websites on the basis of their own media to accelerate the development of leisure agriculture and rural tourism, and other industries. The power of new media platform is used to help rural areas promote featured products and tourism resources and explore the historical and cultural deposits, so as to continuously expand the brand influence.

Neurogenic intestinal care is currently a major research topic in the medical field. In order to improve the accuracy of neurogenic intestinal care and simplify the process of neurogenic intestinal care, this paper adopts a three-dimensional analysis theory to extract the key indicators in neurogenic intestinal care. Through the analysis and calculation of the test data, the calculation results of neurogenic intestinal care under the effect of three-dimensional reconstruction technology were obtained. Through the analysis of the results, the calculation law under the action of the optimization model can be obtained. Based on the three-dimensional reconstruction theory, the contents of neurogenic intestinal care were analyzed by the three-dimensional reconstruction de-highlighting algorithm. The three-dimensional curve was used to screen the key indicators of neurogenic intestinal care, so as to obtain the optimized heavy weight model, and the three-dimensional reconstruction model can analyze the indicators of neurogenic intestinal care. It can be seen from relevant studies that different indicators have different trends in their range of change in the curve projection diagram of the 3D curve screening method. Among them, the curve shadow and curve point have obvious downward changes, while the curve deviation has U-shaped changes. The range of curve weights is relatively large. The variation rule between different data in the 3D curve segment can be obtained through the cost function. Among them, the cost function index and the cost model parameter have the same change trend, and the overall fluctuation range is relatively small through the space index. In the calculation results of neurogenic intestinal care, different factors will have a great influence on the calculation results. Neurons and intestinal peristalsis have the same change trend, while the linear characteristics of nerve endings are relatively obvious, and the fluctuation characteristics of gastrointestinal digestion are good. The health standard decreases linearly with the increase of the sample, and the dynamic reconstruction has a positive effect on the data. This study can provide research ideas for the analysis of neurogenic gut.

1. Introduction

The 3D reconstruction theory was based on the image analysis of relevant data and feature values by using 3D technology. By using the method of image analysis, the relevant indicators can be reconstructed in three dimensions, so as to obtain the original state and change process of the sample. Using this method, the original process of the sample can be analyzed, and the corresponding change characteristics and indexes can be obtained. The 3D image reconstruction theory plays a typical role in different professional fields. Related fields mainly include medical surgery [1], model reconstruction [2], ultrasound propagation

[3], three-dimensional pixels [4], etc. In the field of medical donor image reconstruction, the existing medical donor image reconstruction needs a large amount of data, and the data cannot better reflect the original shape of the medical donor, there were some problems such as poor accuracy. Based on the three-dimensional reconstruction theory [5], the data analysis method was used to describe the medical donor image, and the description was combined from the local and the whole, so as to obtain the accurate model calculation results. The results of the model can reflect the real situation of the medical donor image to a certain extent, which can provide accurate guidance for the research in the field of medical workers.

Facial contour reconstruction was very important to improve facial recognition. The existing facial contour reconstruction techniques still remain in the qualitative research, and the research on the real situation of the face was relatively poor. Based on the 3D model reconstruction technology [6], the method of data iterative analysis was used to calculate the facial contour iteratively. This method can not only show the variation characteristics of facial contour but also reflect the volatility of specific data to a certain extent, which can better reflect the technical characteristics of facial contour reconstruction. Facial contour reconstruction technology was very important to improve the recognition of facial contour. In order to verify the accuracy of the model, the experimental data and facial contour recognition parameters were compared to illustrate the accuracy of the experimental results, which reflects the broad application prospect of facial contour recognition technology. In the field of visual communication, the existing visual communication efficiency was low, which cannot reflect the real visual communication characteristics of samples. Based on the three-dimensional reconstruction technology [7], the method of neural network iterative calculation was used to optimize the existing visual transmission model. The optimization model mainly iterates on specific parameters, so as to find the optimal parameters and bring the parameters into the model, so as to obtain the visual communication optimization model based on three-dimensional reconstruction technology. The experimental verification can better illustrate the accuracy of the experimental model, which can provide a theoretical basis for the study of visual communication. The low resolution of the model grid was the main factor that disturbs the model grid, and also restricts the popularization of the model grid. Based on the 3D reconstruction technology [8], the data feature simulation method was used to optimize the mesh resolution. The optimization method mainly performs iterative analysis on the corresponding data, so as to find the optimal iterative data. The iterative data were brought back to the grid resolution model to obtain the corresponding optimized grid resolution model. The model can well and accurately explain the changing process of mesh resolution, so as to carry out targeted analysis. The research can provide guidance for mesh resolution.

The abovementioned studies mainly analyzed the application of 3D reconstruction technology from the fields of grid and visual communication, but there were few studies on the existing problems in neurogenic intestinal care. In this paper, based on three-dimensional reconstruction technology, the de-highlighting algorithm and three-dimensional curve screening analysis method were used to analyze the indicators of neurogenic intestinal care. Through the analysis, the corresponding targeted index can be obtained. Using this targeted index, the change process of divine intestinal care can be better explained, so the corresponding optimization model can be obtained. Through calculation, it can be seen that the optimization model can better reflect the change process of key indicators in neurogenic intestinal care. Finally, the corresponding

experimental data can be used to verify the accuracy of the model, which can provide support for neurogenic intestinal care.

2. Three-Dimensional Reconstruction Theory

Image quality is the basis of image algorithm, and the quality of image directly affects the effect of the algorithm [9, 10]. Before the implementation of image correlation algorithm, it is necessary to preprocess the image to suppress the useless information in the image and enhance the relevant information of the tested object [11, 12]. First, the number and initial position of the key points of the 3D model were determined according to the segmented 3D point cloud of the catheter center line. Second, the least square method is used to iteratively fit the 3D point cloud model and the initial key point line segment. Finally, the key converges to the stable optimal value to obtain the most accurate coordinate of the key point.

The 3D image reconstruction system plays an important role in many fields [13, 14]. To successfully apply it to neurogenic intestinal care, the flowchart of 3D reconstruction system as shown in Figure 1 was obtained through summary analysis. It can be seen from the figure that the 3D reconstruction system can be divided into three parts: image sequence import, image region segmentation and data processing, which can be shown as follows: In the image sequence processing module, the basic 3D image is linearized first; then, the illumination data of the corresponding image are extracted. Through the corresponding de-highlight processing, the corresponding optimized image is obtained; then, it is imported into the image region segmentation module. In the image region segmentation module, the image should be first segmented regionally, and then further refined to obtain the corresponding center line branch line through image refinement. The corresponding optimization data are obtained by segmentation and then imported into the data architecture module. In the data processing module, the center line of the space should be reconstructed first. Through the reconstruction of the center line of the space, the corresponding center line data can be obtained, and the data can be spliced. The fitting equation of 3D image data is obtained by data stitching, and the final calculation and measurement are carried out; then, the corresponding processing data are exported. First, the polar lines in adjacent images are calculated for a set of 2D curve segments of each data, and the matching points are found through the polar line geometry to generate the candidate 3D curve segments of each set of 2D curve segments. Second, the global selection problem is solved to select the most correct set of 3D curve segments from the candidate set.

2.1. 3D Image De-Highlighting Algorithm. First, the center-line coordinates of the catheter plane image were extracted, and the candidate three-dimensional curve segment set was generated according to the stereo vision principle. Second, the global selection problem is solved to select a 3D curve from the candidate set. Finally, the optimal path

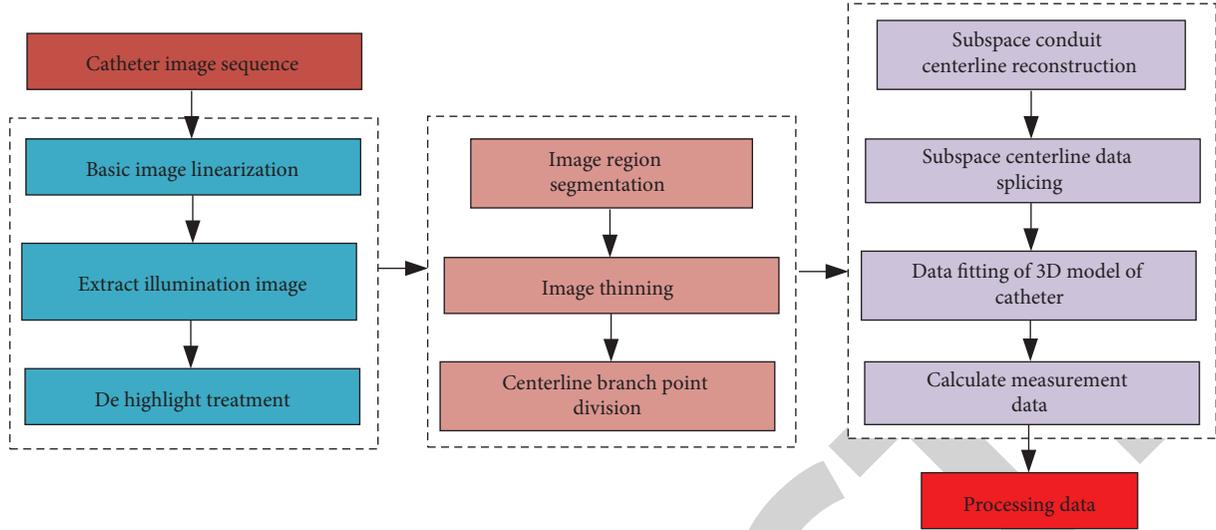

FIGURE 1: Technical route of the 3D image reconstruction system.

reconstruction catheter 3D model is found. Aiming at the phenomenon of surface highlight reflection produced by 3D reconstruction technology under intestinal care, this section adopts a highlight removal algorithm based on 2D gamma function image [15, 16]. First, the luminance component v in the channel of neurogenic intestine was extracted, and the illumination component was extracted by multiscale Gaussian blur. Second, the 2D gamma function is used to adjust the brightness component of the original image, and the highlight image is corrected on the premise of effectively retaining the effective information of the original image [17, 18]. By recovering the global topological structure of the three-dimensional curve segment, the subspace three-dimensional curve segment of the binocular system was data concatenated to find the optimal path to reconstruct the complete three-dimensional model of the catheter centerline. To solve the problem of weak texture and difficult matching of feature points on the surface of the model, the polar geometry method is used for space matching. The specific implementation steps are as follows:

- (1) The multiscale Gaussian function is used to extract the illumination component in the image of neurogenic intestine. The Gaussian function form is as follows:

$$G(x, y) = \lambda \exp\left(-\frac{x^2 + y^2}{c^2}\right), \quad (1)$$

where c represents the scale proportion and λ represents the normalization constant. By applying Gaussian blur to the original image, multiscale illumination components of the image in the neurogenic intestinal channel were extracted, and the results were as follows:

$$F(x, y) = I(x, y)G(x, y), \quad (2)$$

$$F(x, y) = I(x, y)\lambda \exp\left(-\frac{x^2 + y^2}{c^2}\right),$$

where $F(x, y)$ represents the estimated model component, and $I(x, y)$ represents the input original graph.

The corresponding 3D image de-highlighting algorithm can be obtained by 3D reconstruction theory, and the specific image data in intestinal care can be extracted by the multiscale Gaussian function [19, 20]. The corresponding Gaussian change curve can be obtained through analysis, as shown in Figure 2. It can be seen from the curve in the figure that the factors affecting the change of Gaussian mainly include as follows: input original graph, Gaussian function, and corresponding model components. The output results under the action of these three factors have different changing trends, as can be seen in detail: It can be seen from the input curve corresponding to the original figure that with the increase of independent variables, the curve first slowly increases to the local maximum value, and then gradually tends to be flat. With the further improvement of independent variables, the curve gradually fluctuates, and the fluctuation range is relatively small. Then, when the independent variable is at a higher level, the curve gradually decreases and finally tends to be stable. The change trend of the overall input original graph basically fluctuates within a small range, indicating that its influence on the output result is relatively small. With the increase of independent variables, the corresponding curve of Gaussian function decreases first and then gradually tends to be gentle, and then, the curve fluctuates further. When the independent variables are higher, the curve gradually tends to be stable. The overall variation range and variation trend are exactly opposite to the corresponding curve variation trend under the action of factors in the input original graph. This shows that the two have opposite effects on the output results, and it can be seen from the model component change curve that with the

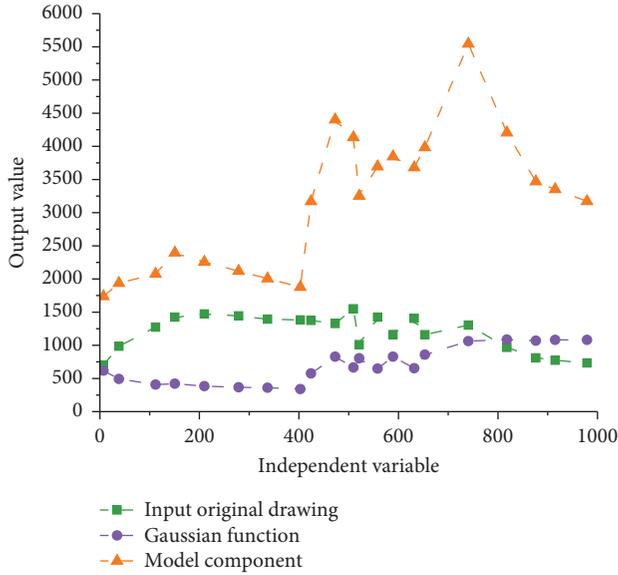

FIGURE 2: Gaussian change curve.

increase of independent variables, the curve first gradually increases to the local maximum value and then gradually decreases. The amount of decrease in the descending stage of the curve is basically the same, indicating that its linear feature is relatively obvious. Then, when the independent variable is further improved, the curve increases rapidly. Then it is shown that there is a certain jump in the data at this stage, resulting in a large fluctuation of the corresponding output results in a certain range. Then, with the further increase of independent variables, the corresponding output curve shows a trend of greater volatility. The overall fluctuation range of the curve is relatively wide, indicating that it has a great influence on the output result.

- (2) Construct the two-dimensional gamma function as shown below and use the two-dimensional gamma function to correct the image of the highlight component and reduce the brightness value of the image of the highlight part.

$$Q(x, y) = 255 \left(\frac{F(x, y)}{255} \right)^\gamma, \quad (3)$$

$$\gamma = (1/2)^p,$$

$$p = \frac{I(x, y) - m}{m},$$

where $I(x, y)$ is the input image, $F(x, y)$ is the model component image, $O(x, y)$ is the corrected output image, γ is the index value of image brightness enhancement, and m is the luminance mean value of the illumination component.

By using the multiscale Gaussian function in the theory of 3D image de-highlighting, the

corresponding trend map of neurogenic intestinal image processing can be obtained [21, 22]. By constructing a two-dimensional gamma function curve, you can analyze the different parameters in it. Through analysis, it can be seen that the influencing factors of two-dimensional gamma function mainly include input image, model component, output image, incremental index, and corresponding mean function. To illustrate the quantitative analysis of the two-dimensional gamma function curve by these five factors, the variation curve of the two-dimensional gamma function as shown in Figure 3 was obtained by calculation. It can be seen from the curve that the output results under the action of five different factors have different change trends, and their specific data have different change forms. As can be seen from the curve corresponding to the input function, with the increase of samples, the curve firstly linearly increases to the local maximum value and then gradually tends to be gentle and then slowly decreases. The decrease amount is relatively small compared with the first stage. Then, with the further increase of the sample, the curve gradually decreases and then increases again, showing a U-shaped change trend, and the overall range of change is relatively large. It shows that this factor can have a great influence on the calculation result of dependent variable. According to the corresponding curve of the graph component, it can be seen that the curve decreases linearly with the increase of the sample. When it reached the lowest value, the curve showed a trend of gradual improvement with the increase of samples. It can be seen from the change trend that the change range of the first stage is larger than that of the second stage, indicating that the first stage of the curve has a higher impact on the dependent variable. According to the corresponding curve of the output function, when the sample is low, the curve gradually tends to be gentle; when the sample is high, the curve first decreases and then increases and finally gradually tends to be stable. The overall stability of the curve is obvious. This indicates that it has little influence on the dependent variable. According to the curve corresponding to the incremental index, it can be seen that with the increase of samples, the curve first increases rapidly to the highest value. Then the sample increase will lead to the corresponding dependent variable data showing a linear decline, with a relatively small range of decline. When the number of samples is 30, the curve reaches the lowest value, indicating that the corresponding calculation result at this point has the minimum value. Then, with the further increase of samples, the output results of the corresponding dependent variable gradually tend to be stable. The curve has an obvious effect on the dependent variable sample of 12. As can be seen from the mean function, the increase of samples will lead to the linear increase of the corresponding dependent variable. Then, when

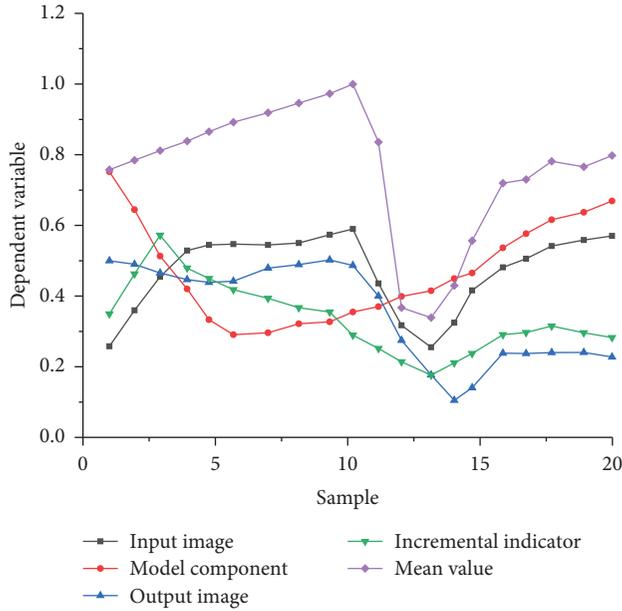

FIGURE 3: Two-dimensional gamma function graph.

the corresponding sample is gradually improved, the curve decreases first and then increases, showing a *U*-shaped characteristic. The curve shows typical linear characteristics in the first stage, and obvious nonlinear characteristics in the second stage, indicating that the curve corresponding to the mean value function has linear and nonlinear characteristics of common change.

2.2. Three-Dimensional Curve Screening. In the ideal case, there is only one candidate 3D curve segment corresponding to the 2D curve segment of the reference image [23, 24]. If there are multiple candidate 3D curve segments, it is necessary to select a correct curve segment from a set of candidate 3D curve segments by calculating the confidence degree and pairwise cost [25]. The confidence measure measures the matching degree between the 3D candidate curve segment and the curve in the third image, projects each 3D candidate curve segment onto the third image and finds the 2D curve segment in the third image with the smallest projection difference with the candidate curve segment. For the point set, u is the projection on the 3D curve segment, and v is its corresponding point closest to u on the 2D curve segment. The confidence can be calculated as follows:

$$S = \frac{\sum(u, v) + \eta(1 - t)}{s}, \quad (4)$$

where S is confidence degree, s is the sampling point, u is the curve projection, v is the curve point, t is curve deviation, and η is the weight. First, the factors affecting image processing are analyzed, and then, the method of removing highlight of image is introduced in detail, and the light source method used in the measurement system is explained. The influence of light source on image processing quality is also pointed out. Finally, the image is refined and segmented, and the center line of each image is extracted to prepare for 3D reconstruction.

Through the theory of 3D image de-highlighting, the corresponding law of image subdivision calculation can be obtained. To illustrate the role of 3D image reconstruction technology in neurogenic intestinal care, the corresponding curves of 3D images need to be screened to some extent. The curve variation law under the action of different factors was obtained by calculation. To explore the influence of different factors on the projection results in the process of curve projection, the curve projection diagram shown in Figure 4 was obtained through calculation. The influence of different factors on the curve is mainly reflected in the changing shape of the curve. Specifically, it can be seen that: With the increase of the sample points, the curve corresponding to the projection factor shows a gradual decreasing trend. The decline range of the curve in the first stage is relatively small, while the decline range in the second stage is relatively large, indicating that the sampling point has a great impact on the confidence of the data when it is high. As can be seen from the variation law of data points, the curve first increases, then decreases rapidly, and finally gradually tends to be stable, indicating that the curve will gradually tend to be stable under the action of higher sampling points. According to the curve deviation data, it can be seen that with the increase of sampling points, the curve as a whole shows a *U*-shaped change law. The curve first gradually increases to the highest value, and when the sampling point is about 35, the curve reaches the highest value, and then with the further increase of the sampling point, the corresponding confidence gradually decreases. The overall change in the curve is large in the first period and relatively small in the second period. According to the weight factor of the curve, it can be seen that it shows a typical two-stage change: the inverted *U*-shaped change range of the curve is relatively small in the first stage. When the corresponding sampling point of the curve is high in the second stage, the curve shows an inverted *U*-shaped change with a relatively large variation range. The overall variation range of the curve indicates that it has a relatively large impact on the confidence degree. Because of the disparity in the field of view, confidence alone is not enough to describe the matching degree of curve segments to resolve all ambiguities. Therefore, pairwise costs need to be calculated for further screening. Pairwise relation describes the relation between two adjacent three-dimensional candidate curve segments.

Since only one 3D curve segment needs to be selected from each candidate set, a linear constraint for each given is as follows:

$$\sum_{A \in C} X(j) = 1. \quad (5)$$

Next, we define a pairwise relation cost function d to evaluate the pairwise relation between 3D curve segments:

$$dAA = eA1 + mA2, \quad (6)$$

where e is the space distance; m is the model parameter. The correct 3D curve segment is reconstructed from a curved, continuous conduit object, along which the continuous curve segment is smoothly connected. Therefore, adjacent

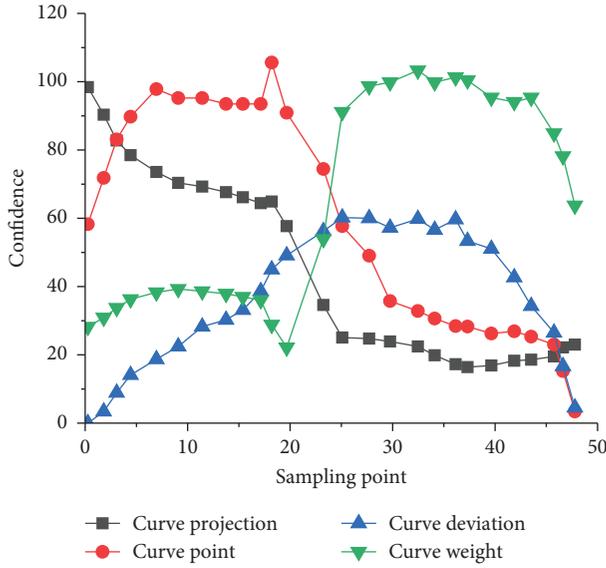

FIGURE 4: Curve projection diagram.

3D curve segments with similar angles are more likely to be the correct 3D curve segment, which provides a more effective matching cue to formalize these cues in the optimization problem.

The corresponding linear constraint law can be obtained by selecting 3D curves from different sets. The linear constraint law can reflect the change trend under the action of different cost functions, so as to explain the influence of different factors in the change law of cost functions, and then reflect the corresponding curve screening process and corresponding accurate results. The change trend of the cost function as shown in Figure 5 is obtained through calculation. It can be seen from the figure that the overall fluency of the curve is relatively good. The corresponding output results of the cost function are shown as W-shaped fluctuation changes which first decrease and then increase and then decrease and then increase. The corresponding model parameters also show the same change trend with the increase of independent variables, but under the action of higher independent variables, the curve gradually decreases, contrary to the change trend of the corresponding cost function. However, the corresponding modular space distance decreases first and then increases gradually with the change of the cost function, and the overall change range of the curve is relatively small, indicating that its influence on the output result of the cost function is relatively small.

Finally, the vector U is used to represent the combined confidence scores of all 3D curve segments, and V is the pairwise cost variable, giving U and V , minimizing X as follows:

$$\begin{aligned}
 X &= \operatorname{argmin}(U^T X + X^T V X), \\
 \forall C_i^r &= \sum_{A_j=C_i^r} X(j)1, \\
 \{x_{ij}\} &= \operatorname{argmin}_{\{k,x_{ij}\}} \sum_{i,j} x_{ij}w_{ij} + \xi k.
 \end{aligned} \tag{7}$$

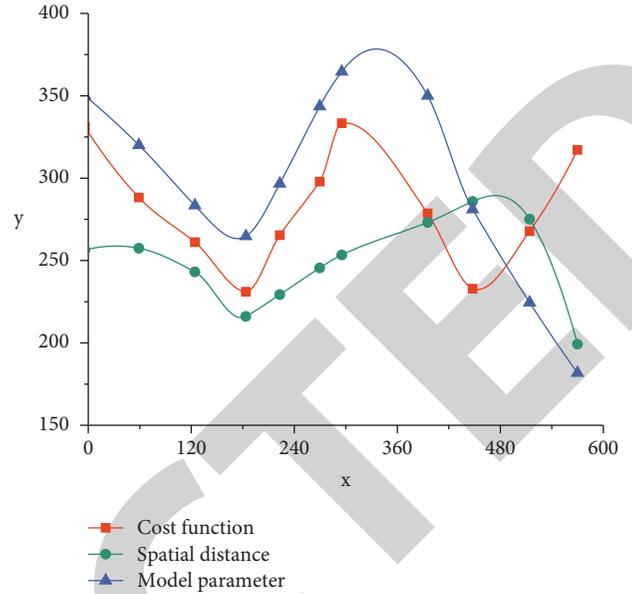

FIGURE 5: Change of cost function.

Through the above calculation, the quantitative change rule of the cost function under the action of different factors can be obtained. To research the specific changes of confidence in the three-dimensional curve, the direct line parameter analysis diagram shown in Figure 6 is obtained through calculation. It can be seen from the analysis figure that the three factors will have an impact on the output result of the dependent variable of confidence, and the curve under the action of the three factors can be seen that the overall fluctuation range is relatively large. As can be seen from the changes in the figure, with the increase of independent variables, the curve first gradually increases to the highest value and then gradually decreases to the lowest value. However, it can be seen from the cost that the curve is contrary to the confidence degree, that is, the curve gradually decreases to the highest value first and then increases gradually. As can be seen from the minimization factor curve, the curve decreases first and then increases with the increase of the independent variable. The three curves as a whole show fluctuations, and the variation range of the minimization curve is relatively small.

3. Application of Three-Dimensional Image Reconstruction Technology in Neurogenic Intestinal Care

3.1. The Main Content of Neurogenic Intestinal Care. The 3D reconstruction theory can be used to de-highlight the 3D image, so as to obtain the corresponding 3D image screening results. Through the screening results of 3D images, the application model of 3D images in neurogenic intestinal care was obtained by further analysis. First of all, we need to conduct qualitative analysis of neurogenic gut, and the

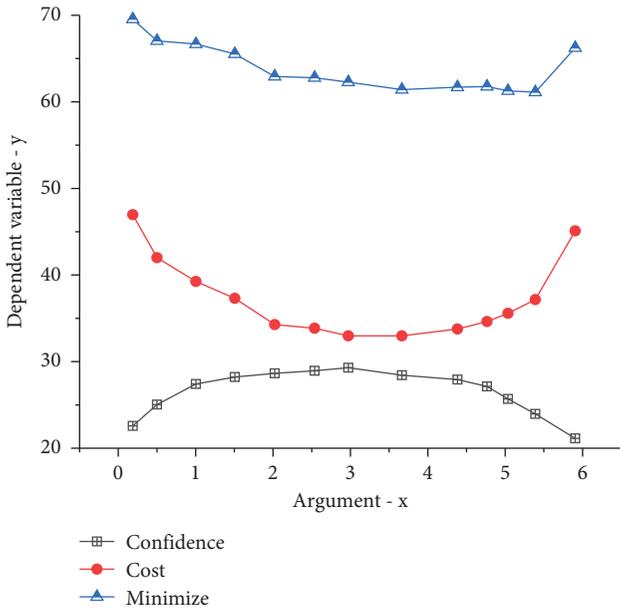

FIGURE 6: Confidence parameter analysis diagram.

corresponding neurogenic gut analysis chart shown in Figure 7 can be obtained by summarizing relevant data. As can be seen from the figure, the proportion of neurons under the action of different factors is different, so it is necessary to carry out targeted analysis. Among them, the proportion of neurons is only 10%, while the proportion of intestinal peristalsis is about 15%. The corresponding nerve terminal factors accounted for about 25%, while the corresponding intestinal digestion accounted for the highest proportion (about 35%), the health standard accounted for the lowest proportion (only 5%), and the dynamic remodeling accounted for about 10%.

3.2. Calculation and Analysis of Three-Dimensional Image Reconstruction Technology in Neurogenic Intestinal Care. There are many problems in the nursing of neurogenic intestines. To better solve the problem of low accuracy in the nursing of neurogenic intestines. In this paper, the 3D reconstruction technology is used to de-highlight the related images and screen the curves, so as to get the corresponding 3D image reconstruction model. This model can quantitatively analyze neurogenic intestines. To better illustrate the analysis process of 3D image reconstruction technology, the 3D image reconstruction analysis flowchart shown in Figure 8 is obtained by summarizing. Through the model analysis process, it can be seen that: first, graphic modeling should be carried out for 3D reconstruction technology, and the corresponding cloud generated graph should be obtained through graphic modeling. The corresponding gastrointestinal model was obtained by correcting the model. The gastrointestinal model can be calculated in the process of model cloud import, and then, the corresponding neurogenic intestinal model can be obtained. The neuronal model is mainly completed by 3D modeling in the aspect of intestinal data collection, and then, the model needs to be

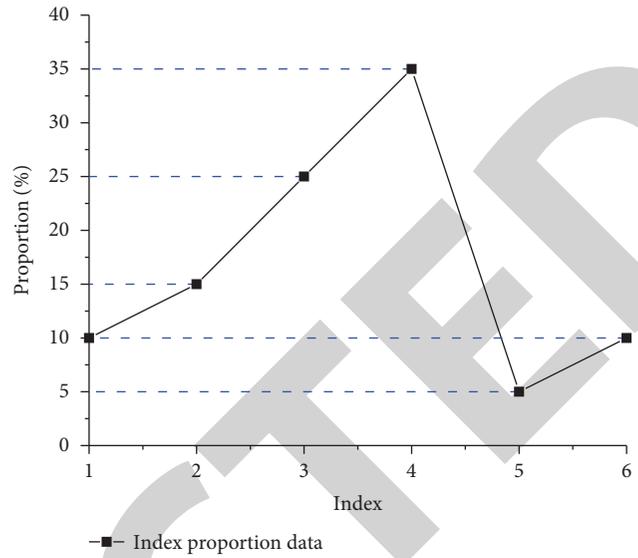

FIGURE 7: Neurogenic bowel analysis diagram.

adjusted on the basis of this model. The adjustment of 3D neurogenic intestinal model mainly includes model angle, model position, model data, and model indicators. Finally, it is visualized, and the final output result is obtained through model effect rendering. To solve the accuracy problem in 3D reconstruction, the 3D curve segments were divided by the number of intersection points of the polar lines and several candidate 3D curve segments were reconstructed. By reprojecting the candidate 3D curve segments, the 3D curve segment with the minimum projection difference was selected to improve the accuracy of catheter centerline reconstruction.

The abovementioned calculation process can be used to de-highlight the 3D image model and screen the 3D curve, so as to obtain the application of 3D image reconstruction technology in neurogenic intestinal care. The calculation results of neurogenic intestinal care were obtained as shown in Figure 9. Through the calculation results, we can see the overall change trend of different factors under the action of neurogenesis. Specifically, it can be seen that with the increase of samples, neurons show a change of first decreasing, then increasing, and then decreasing. The overall fluctuation range of the curve is relatively obvious, but the fluctuation range is relatively small. As can be seen from the curve of intestinal peristalsis, it is basically consistent with the overall change trend of neurons, that is, the curve decreases first and then increases. However, it is worth noting that the data of the intestinal peristalsis curve are larger than that of the neuron curve, indicating that its influence on intestinal care is relatively extensive. According to the corresponding curve of nerve endings, it can be seen that the curve increases first and then decreases, and the overall decline is relatively obvious, indicating that it has a negative impact on data output. According to the gastrointestinal digestion curve, it can be seen that the curve will fluctuate to a certain extent under the action of small samples, and then gradually tends to be stable under the action of high samples, indicating that different samples will have different effects on the data

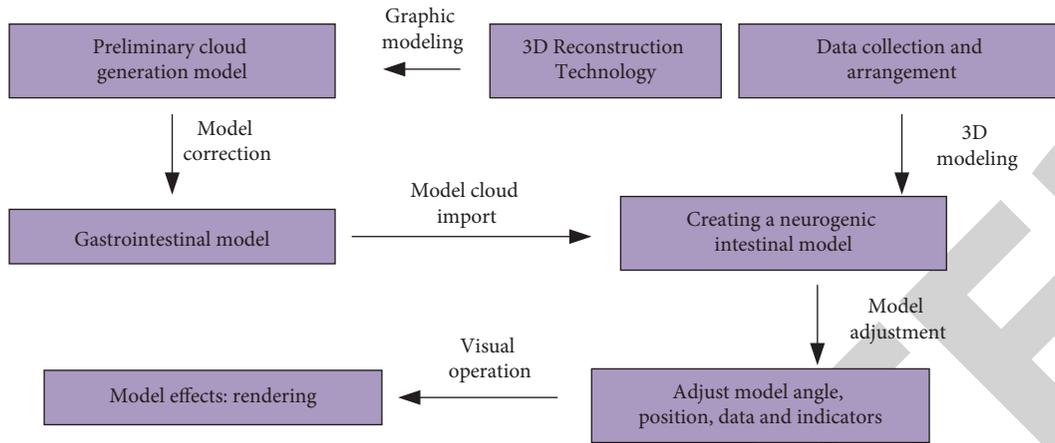

FIGURE 8: Analysis flowchart of 3D image reconstruction technology.

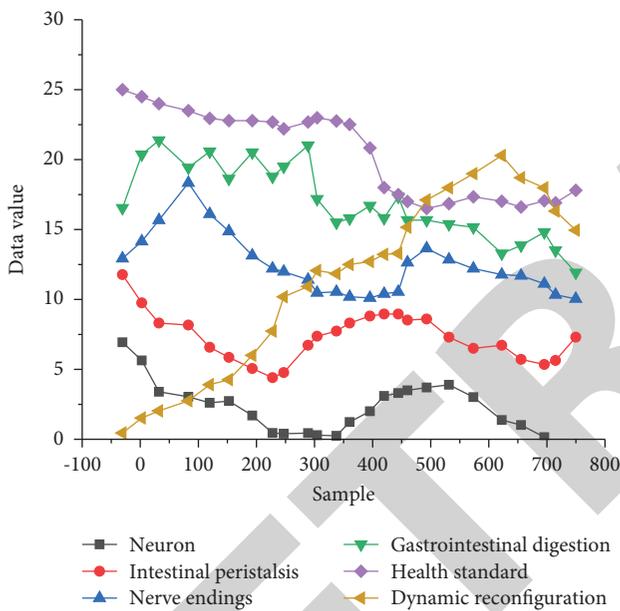

FIGURE 9: Calculation results of neurogenic intestinal care.

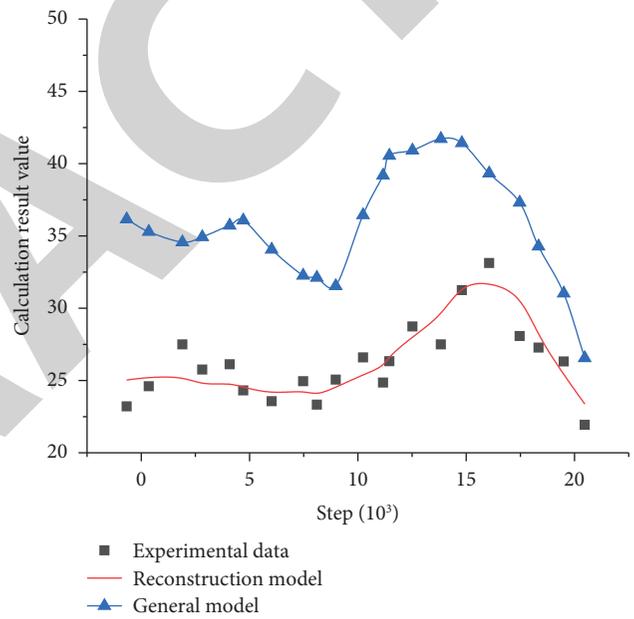

FIGURE 10: Model validation curve.

results of gastrointestinal digestion. It can be seen from the health index gradually tends to be stable with the increase of the sample and then decreases rapidly when the sample is about 400, and then gradually tends to be stable. The overall range of change is relatively small, and the curve has good stability. Through dynamic reconstruction, it can be seen that the curve shows a gradual improvement trend under the action of small samples, and the overall linear range is relatively obvious. When it reaches the highest level, the curve gradually decreases with the increase of samples. It shows that it has a certain volatility to the sample data, and the overall linear characteristics are relatively obvious, indicating that it has a positive impact on the data value. The goal is to find multiple different paths that start and end with constant lengths such that each data is contained in exactly one path. Each of these paths corresponds to a continuous 3D line of the conduit model, and each path is uniquely

determined by the edges it is composed of. The path finding problem is solved by minimizing the objective function.

4. Discussion

Based on the 3D reconstruction theory, the 3D image de-highlighting algorithm and 3D curve screening method were used to obtain the application of 3D image reconstruction technology in neurogenic intestinal care, and the corresponding optimization model was obtained through calculation. This optimization model can calculate the data of neurogenic intestine at different moments for accurate analysis. To quantitatively illustrate the accuracy of the model curve, the curve calculation results under the action of different models are obtained through calculation, as shown in Figure 10. It can be seen from the results that the corresponding test data gradually increases with a small number of iterations and then gradually decreases. The overall

volatility of the curve is relatively model. Through the conventional model curve, it can be seen that the curve decreases first and then increases with the increase of the number of iteration steps. The overall trend of change can well explain the experimental data, but there are great differences in specific values. Through the reconstruction curve, it can be seen that the curve can not only well illustrate the trend of the data at lower iterations but also the trend of the data and the trend of the curve at higher iterations. It shows that the reconstructed model has good accuracy. At the same time, it also shows that three-dimensional reconstruction technology has a good application in neurogenic intestinal care.

5. Conclusion

- (1) According to the Gaussian change curve in the 3D image de-highlighting algorithm, it can be seen that the input original image and Gaussian function have the opposite change trend. On the other hand, the component curve of the model changes significantly with the increase of independent variables, indicating that it has a high impact on the output results.
- (2) Five different factors will have different effects on the two-dimensional gamma function, among which the input function model component and the output function have the same changing trend. The corresponding incremental index fluctuates within a small range of change, and the overall linear and nonlinear characteristics are obvious through the mean value.
- (3) In the confidence analysis curve, the confidence parameter shows an inverted U -shaped change, and the curve corresponding to the cost index shows an opposite U -shaped change. The trend of the minimum value shows that its influence on the dependent variable is relatively small, and the stability of the curve is relatively good.

In the current era that consumers pursue personalized experience, in order to optimize the customer experience of new Chinese-style clothing products and improve the evaluation procedures of new Chinese-style clothing products, based on the theory of customer perceived value, this paper constructs the evaluation index and evaluation model of new Chinese-style clothing customer perceived value. This study is divided into three stages: firstly, through literature research and interview, thirty-seven elements of the evaluation index of customer perceived value of new Chinese-style clothing are defined; secondly, through questionnaire survey and exploratory factor analysis, seven dimensions of the evaluation index of the customer perceived value of new Chinese-style clothing were extracted, which were cultural and educational value, aesthetic value, creative value, green value, engineering value, social value, and quality value, respectively; thirdly, we propose a PSO-BP neural network to evaluate the customer perceived value of new Chinese-style clothing, and we choose twenty-two and eight new Chinese-style clothing as training samples and test samples, respectively. The experimental results show that the PSO-BP neural network can accurately evaluate the customer perceived value of new Chinese-style clothing, and its error is controlled by 2.5% compared with the traditional BP neural network. The research results show that enterprises can improve the quality of product design through the new Chinese-style clothing customer perceived value evaluation indicators and models, and then improve their sustainable competitive advantage, so as to achieve the sustainable development of the new Chinese-style clothing industry ultimately.

1. Introduction

With the rapid development of China's cultural and creative industries, under the influence of policy guidance, financial support, technology iteration, talent innovation, and other factors, cultural industries represented by new Chinese-style clothing, animation, etc. have gradually become the pillar industries of the national economy, and they play an important role in improving the country's cultural soft power [1]. As far as the new Chinese-style clothing (a design style that grasps the ideological connotation of Chinese style, refines Chinese design elements, and innovates in combination with current materials and technologies) industry is concerned, enterprises continue to strengthen the cultural uniqueness, fashion, and innovation of new Chinese-style clothing products through design, giving product value soul and vitality, and then promoting the sustainable

development of the new Chinese-style clothing industry [2]. But from the current market situation, the problem of "misalignment of supply and demand" of products is still a bottleneck that plagues the sustained and healthy development of the new Chinese-style clothing industry. Therefore, from the perspective of consumers, accurately grasping the changing consumer needs and consumption concepts of customers is of great significance for the development of the new Chinese-style clothing industry [3].

Modern product design is a process of a series of activities that seek design solutions to consumer demand [4]. In this activity, a crucial link in the product system analysis and evaluation is an essential basis for product design decisions. The so-called evaluation generally refers to the behavior of determining the attribute of an object according to a clear goal and turning it into the subjective utility (the degree of satisfying the requirements of the subject), that is,

the process of defining the value. In this process, we should compare the evaluated object with a particular object to determine the value of the object [5]. However, looking at the new Chinese-style clothing industry, it is found that there is no unified product evaluation index and method for China. Most of the enterprises determine the final design of products based on the subjective empirical assessment of the products from the designer's perspective, and the evaluation process often has a certain degree of one-sidedness and uncertainty. Therefore, when faced with the market reality that the personalized demand is prominent and the competition is becoming more and more fierce, in order to achieve the sustainable development of new Chinese-style clothing enterprises and industries, it has become an urgent problem for relevant enterprises and academia to build new Chinese-style clothing product value evaluation indicators guided by customer expectations, and to find scientific and reasonable product value evaluation methods, improve the design quality of new Chinese-style clothing products, and alleviate the contradiction between supply and demand.

Given this, this paper firstly introduces the customer perceived value theory. It combines the characteristics of the new Chinese-style clothing products with in-depth interviews and questionnaires with relevant consumers to build a system of measuring indicators of customer perceived value of new Chinese-style clothing products. The customer perceived value theory has received much attention since its inception and is often used to explain customers' subjective preferences and consumption behavior in specific situations. Based on this, this paper further incorporates the BP neural network method for evaluating natural case products. As an interactive evaluation method, the BP neural network can avoid the imprecision of artificially determined evaluation index weights and make the results more realistic. However, the traditional BP neural network also suffers from poor fault tolerance, the algorithm tends to fall into local minima, slow convergence, and instability in learning. To solve the above problems, this paper constructs a BP neural network evaluation model based on the particle swarm optimization algorithm. It uses the particle swarm optimization algorithm to obtain the optimal weights and thresholds for each layer of the BP neural network to further evaluate the consumer perceived value of the new Chinese-style clothing. Combined with the customer perceived value measurement index together, it will provide a more comprehensive, objective, and accurate reflection of the level of customer perceived value of the new Chinese-style clothing products, which will support the optimization of product design and the sustainable development of the company.

2. Literature Review

2.1. Sustainable Competitive Advantage and Customer Perceived Value. As an important part of the sustainable development strategy of enterprises, the sustainable competitiveness of enterprises is not only a strong support for the development of enterprises, but also the only way for the sustainable development of enterprises. Therefore, sustainable competitive advantage has always been the topic

of concern of enterprise strategy theory [6, 7]. Porter [8] first mentioned sustainable competitive advantage when discussing the company's long-term competitive advantage to obtain low cost or differentiation, and pointed out that the sustainable competitive advantage of an enterprise comes from the value it creates for customers that exceeds its cost, which ultimately depends on the value it can create for customers. Barney [9] proposed that one of the necessary conditions for obtaining the unique strategic resources of sustainable competitive advantage is that the resources are valuable; that is, they can enable enterprises to increase customer value and improve their business performance. Woodruff [10] also clearly pointed out that customer perceived value is the source of competitive advantage. Although there are great differences in the theoretical assumptions about sustainable competitive advantage and the various theoretical schools of its origin, there is a consistent understanding of the premise of obtaining sustainable competitive advantage: the degree of customer recognition of the value of enterprise products or services, and the customer perceived value determines the sustainable competitive advantage of enterprises.

The recognition and research of value from the perspective of customers began in the 1990s. For the dimensional measurement of customer cognitive value, it has also changed from the initial single dimensional measurement to multidimensional measurement. In the early days of the theory, Zeithaml [11] referred to perceived value as the subjective value that the user has in mind after measuring the gain or loss. Simultaneously, Monroe [12] defined perceived value as the perceived quality or benefit that the customer gets from the product, as opposed to the sacrifice made by the price paid, etc. The above definitions of value in trade-offs between the "get" and "give" items are seen in marketing applications due to trade-offs between quality and price and are one-dimensional value judgments. In subsequent theoretical studies, Bolton and Drew [13] argued that viewing value as a trade-off between quality and price was too simplistic. Sheth et al. [14] argued that measuring perceived value as a single construct would lack validity and therefore proposed five dimensions of customer perceived value: functional value, social value, emotional value, epistemic value, and conditional value.

With the shift in the consumer market in recent years, many clothing companies have shifted from the traditional external competitors or internal resource conditions to the customer, which is fundamental to business survival and development. Under this background, the theory of customer perceived value is widely used in the research field of clothing product design. For example, Yan et al. [15], Yu et al. [16], and Li et al. [17], based on the theory of customer perceived value and combined with the characteristics of Internet distribution, built a measurement model of customer perceived value of online clothing customization; Chen et al. [18] took the value perception of children's clothing safety as the research object and developed a set of children's clothing safety perception measurement scale including 3 dimensions and 27 measurement items; Chi [19] used a multidimensional consumer perceived value model to

explore the characteristics of consumer expected value of environment-friendly clothing, including social value, emotional value, quality value, and price value; Zhou et al. [20] took men's suits as the product object and discussed the design optimization scheme of men's suits by establishing a model between users' perceived image, suit design features, and user preferences. Through the above literature collection and analysis, the customer perceived value theory has been applied to different clothing situations, including clothing customization, green clothing products, and men's clothing. However, there is still a lack of research on new Chinese-style clothing products. The constituent elements of customer perceived value differ for different clothing products. In particular, the new Chinese-style clothing products have distinctive characteristics such as spiritual and cultural categories, aesthetic forms, and cultural symbols, which are different from the general clothing products. Therefore, it is of practical significance to study the connotation of customer perceived value of new Chinese-style clothing.

Based on the above analysis, as a subjective feeling in the customer's heart, the customer's definition of perceived value is subjective, complex, and multidimensional. Therefore, this paper will refer to the functional value, social value, emotional value, epistemic value, and conditional value proposed by Sheth et al. [14] as the basis of the new Chinese-style clothing customer perception value evaluation study.

2.2. BP Neural Network and Particle Swarm Optimization. BP neural network (back-propagation neural network), also known as error back-propagation neural network, is one of the most representative and commonly used artificial neural networks, especially in nonlinear problem-solving. The structure of the BP neural network is divided into input layer, hidden layer, and output layer. Its structure is shown in Figure 1. The process of the BP neural network can be divided into two stages: forward propagation and backward propagation. In forward propagation, the input signal is processed from the input layer through the hidden layer and then passed to the output layer, with the nodes in the previous layer only affecting the nodes in the next layer. Suppose the output layer does not get the desired output. In that case, it is transferred to the error back-propagation process by adjusting the weights and thresholds of the prediction errors to achieve a BP neural network prediction output with a good fit [21]. In Figure 1, x represents the input and y represents the output. f_1 is the activation function from the input layer to the hidden layer, and f_2 is the activation function from the hidden layer to the output layer. w_{ij} and w_{jk} represent the weights of the neural network.

From the above analysis, it can be seen that customer perceived value has the characteristics of subjectivity and complexity, and its actual evaluation belongs to a typical nonlinear problem. If traditional product evaluation methods such as AHP and fuzzy comprehensive evaluation are used, it is easy to cause distortion and bias of evaluation results by setting the premise for the operation of the linear

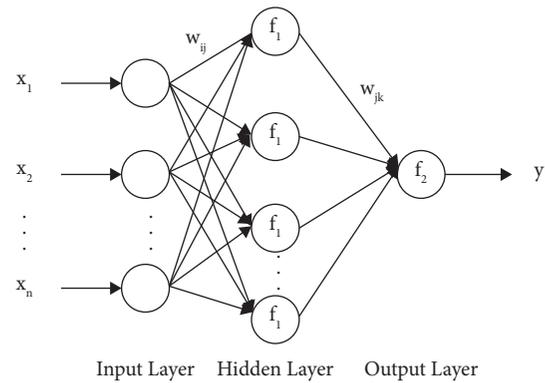

FIGURE 1: Structure of the BP neural network.

relationship between evaluation indexes. Therefore, it provides a certain theoretical basis for this paper to apply the BP neural network to evaluate the customer perceived value of new Chinese-style clothing. However, before starting training, the BP neural network randomly initializes the weights and thresholds of each layer to the value between $[0, 1]$. This kind of random initialization without optimization often slows the convergence speed of the BP neural network and easily makes the result nonoptimal [22]. As a swarm intelligence optimization algorithm, the particle swarm optimization (PSO) algorithm can map the weights and thresholds in the BP neural network to particles in the PSO algorithm, and update the speed and position of particles through iteration, so that individuals can find the optimal solution in the solution space [23]. The specific principle of PSO algorithm has been described in detail in Ref. [24], so it will not be repeated here. Therefore, this paper introduces the PSO algorithm to optimize the initial value and threshold, so as to significantly improve the training and modeling speed, stability, and solution accuracy of the BP neural network.

3. Construction and Validation of the Evaluation Index of Customer Perceived Value in the New Chinese-Style Clothing

In the analysis of this section, this paper aims at constructing the evaluation index of new Chinese-style clothing customer perceived value, and verifying the reliability and validity of the evaluation index. The specific research steps are divided into three stages: the first stage is to collect data by means of literature analysis and consumer questionnaire interview, and then sort out and code the interview contents through the research team to define the evaluation element factors; in the second stage, a large-scale questionnaire survey was conducted based on different gender, age, and educational background. Using the exploratory factor analysis method, the main aspects of the new Chinese-style clothing customer perceived value evaluation index are extracted, and based on this, the new Chinese-style clothing customer perceived value evaluation index scale is developed; in the third stage, reliability and validity analysis is used to verify the stability

and predictability of the new Chinese-style clothing customer perceived value evaluation index.

3.1. Exploring the Element Factors for Evaluating the Customer Perceived Value of New Chinese-Style Clothing. To determine the element factors that can be used to establish the evaluation index of new Chinese-style clothing customer perceived value, this paper uses literature analysis and interview method sequentially and gives the interview results to the research group for coding and screening to determine the element factors.

First of all, this paper collects and refers to the research results of Yen et al. [25]'s cultural fashion design measurement index, Liu et al. [3]'s new Chinese-style clothing purchase intention scale based on the product quality theory, Kim et al. [26]'s clothing design evaluation standard scale based on consumer perspective, Yu et al. [16]'s men's shirt custom customer perceived value evaluation scale, Chi et al. [19]'s environment-friendly clothing consumer perceived value scale, and Ahn et al. [27]'s 6-dimensional clothing product quality measurement scale oriented to customer demand. According to the above research results, an interview questionnaire was designed. The interview questionnaire is combined with the context of new Chinese-style clothing products and focuses on referring to various cases listed in the collected literature.

Secondly, this paper uses the interview method to investigate the current situation. To obtain more practical consumption demand and value preference for new Chinese-style clothing products, the author obtained a group of interviewees through a random survey, online forum invitation, and snowball recommendation. After thoroughly considering factors such as age, gender, occupation, education level, and user experience with new Chinese-style clothing products, the author finally selected 41 interviewees from different situations. The selected subjects are between 20 and 59 years old, covering the old, middle-aged, and young generations; the number of men and women in gender tends to be half (22 women and 19 men) to reduce the impact of gender factors. They have more than 3 years of experience in using new Chinese-style clothing products, and the longest is as long as 10 years. Their occupations include college students and those who have participated in the work.

The questionnaire's content is divided into three parts, with four questions in each part, making 12 questions. The first part is an interview with the basic information content of the respondent, in which the respondent explains the content of the case, the reason for purchase, and the occasion of wearing. The second part is an in-depth interview with the respondent. The respondents are encouraged to deepen further their thinking regarding the five dimensions of consumer perceived value: functional value, emotional value, social value, epistemic value, and conditional value. In the third part, in order to obtain valid interview results, we use some consumption cases (choice between well-known and ordinary brand products, different preferences between green and ordinary products, etc.) to stimulate the respondents to reflect on whether they have additional feelings

beyond the previous interview. Given the impact of the current epidemic, this paper uses a combination of online and offline interview formats.

In the sorting and analysis of qualitative data, the primary focus is on coding. Coding is a systematic method of extracting data. In the process, data are analyzed and combined according to themes, concepts, or categories. The main procedures include three steps: open coding, axial coding, and selective coding [28]. After the interview and data collection, this paper commissioned a research group composed of experts and academics (a total of five people, including two professors and three associate professors) to conduct open coding first; that is, the research group extracted important information according to the interview content and integrated the obtained information into a unified category. Secondly, based on the understanding of the research topic, the research group linked all categories according to their internal organic associations (i.e., axes), found out the spindle code and named it, and finally obtained the element factors that may affect the evaluation of the perceived value of new Chinese-style clothing. Since the coding in this paper is mainly for inductive results, it is not within the scope of discussion to pay attention to the selective coding of text storylines, so this part is omitted [29]. In the end, the analysis yielded 37 factors such as Convey cultural meaning, Show the charm of regional culture, and Traditional natural fabrics (as shown in Table 1).

3.2. Extracting the Dimension of Customer Perceived Value Evaluation Indicators for New Chinese-Style Clothing. After the first stage of the paper, 37 customer perceived value evaluation factors were coded and calculated. In the second stage, the structures and links between the 37 evaluation factors were identified through exploratory factor analysis. The constructs of the new Chinese-style clothing customer perceived value evaluation indicators were extracted.

Firstly, the 37 element factors from the pretest questionnaire were re-ranked randomly, and each element factor was converted into an item in the questionnaire. Secondly, participants were asked to select the level of agreement with the purchase of the product from a 7-step Likert scale ranging from "strongly disagree" to "strongly agree" on a scale of 1 to 7. The positive sentiments for each item increased as the scores increased. The positive sentiment for each item gradually increases as the score increases, so that the scores can be added up for subsequent analysis. Finally, through exploratory factor analysis, the element factors were analyzed, deleted, or modified to find common factors to be named to extract a suitable index profile for evaluating the customer perceived value of new Chinese-style clothing.

In this paper, the data were collected mainly through online questionnaires, and 253 valid questionnaires were obtained, meeting the sample size requirement suggested by scholars [30]. Among the 253 questionnaires, 132 were completed by women and 121 by men; in terms of age distribution, 27 respondents were aged between 18 and 25 years, 90 were aged between 25 and 32 years, 75 were aged between 33 and 39 years, 40 were aged between 39 and 46

TABLE 1: List of evaluation element factors.

No.	Evaluation element factor
1	Convey cultural meaning
2	Show the charm of regional culture
3	Positive cultural enlightenment significance
4	Long-lasting and durable performance
5	Comfortable and breathable to wear
6	Convenient for daily cleaning and maintenance
7	Easy to move after wearing
8	Excellent manufacturing technology
9	An overall sense of refinement
10	Exquisite structure
11	Highly textured crafts such as prints and embroideries
12	Compact and beautiful accessories
13	Have an attractive story or moral
14	Have practical functions
15	Bring back fond memories of life
16	Have a sense of glamour
17	Physiotherapy and healthcare fabrics
18	Green textiles
19	Traditional natural fabrics
20	Promote a sense of personal confidence
21	Become more popular
22	Enhance personal image
23	Show personal social status
24	Show professional image
25	Make people feel special
26	Originality or creativity
27	A unique way of dressing
28	Versatility
29	Partial creative design details
30	Variety of matching features
31	Good styling proportions
32	Modern and stylish
33	Harmonious and beautiful color matching
34	Exquisite decoration
35	Exquisite design details
36	Product recyclability
37	Natural dyed fabric

years, and 21 were aged 46 years or above; in terms of education distribution, 32 were with high school education or below, 53 with secondary school or college education, 113 with bachelor's degree, and 55 with postgraduate education.

In statistical analysis, data conforming to normal distribution is the basic assumption and premise of many continuous data comparison and analysis, among which skewness and kurtosis are important normality test indicators [31]. After the collection and collation of the questionnaire, first of all, through descriptive statistical analysis, we can find that the skewness values of 37 element factors are between -0.919 (Product recyclability) and -0.030 (An overall sense of refinement), and the kurtosis values are between -0.543 (An overall sense of refinement) and 0.591 (Convey cultural meaning). The absolute values of skewness and kurtosis meet the verification standards proposed by Kline [32] that the absolute value of skewness is within 2 and the absolute value of kurtosis is within 7. It indicates that the data are normally distributed, which is suitable for exploratory factor analysis and reliability and validity analysis.

Then, in exploratory factor analysis, through the first factor analysis, it was found that the five variable factor loads of Have a sense of glamour, Originality or creativity, Compact and beautiful accessories, Show personal social status, and An overall sense of refinement were not higher than 0.50, so they were eliminated. Then, the data were subjected to a second factor analysis. After the KMO and Bartlett tests, the KMO sampling fitness measure was 0.935 and the Bartlett sphericity test approximate chi-square value was 5456.231, with a significance level of 0.000, indicating that the data were valid and suitable for factor analysis [33, 34]. After passing the check, principal component analysis in factor analysis was continued to extract common constructs, with eigenvalues greater than one as the principle for selecting the number of common factors, resulting in a total of seven major constructs that explained 72.539% of the cumulative variance. Immediately afterwards, the selected conformations were pivoted by the maximum variance pivoting method, resulting in a rotated component matrix (as shown in Table 2).

Finally, the reliability and validity analysis revealed that Cronbach's alpha values of all seven dimensions were higher than 0.7, the average variance extracted (AVE) values of each dimension were greater than 0.5, and the square root values of the average variance extracted were also greater than the correlations with other factors (as shown in Table 3), which verifies that the seven dimensions have good reliability at the same time [35], and it also indicates that the dimensions have good validity [36].

Dimension 1 is mainly composed of five element factors: Convey cultural meaning, Bring back fond memories of life, Show the charm of regional culture, Have an attractive story or moral, and Positive cultural enlightenment. The factor load is between 0.819 and 0.742, and the explained variance is 11.585%. This dimension reflects consumers' pursuit of the emotional cognitive value of new Chinese-style clothing products, but different from the aesthetic value of using product modeling elements as emotional transmission media, dimension 1 emphasizes the attraction of an internal cultural gene of new Chinese-style clothing products, which provides consumers with a unique product impression and cultural attribution through the emotional association of the brain. It also edifies and promotes the spiritual level of consumers, so this dimension is named as the cultural and educational value of the product.

Dimension 2 is made up of five factors: Exquisite design details, Modern and stylish, Exquisite decoration, Good styling proportions, and Harmonious and beautiful color matching. The factor load ranges from 0.787 to 0.705, with an explained variance of 11.449%. This dimension also reflects consumers' pursuit of the emotional perception value of new Chinese-style clothing products, that is, the product shape is used as a medium to convey information through the product shape elements, allowing consumers to form a visual perception of beauty, which in turn gives them a sense of inner pleasure. As the main expression of the product's visual aesthetic features on the consumer's emotions, this dimension is named the aesthetic value of the product.

Note. Diagonal bold characters (marked with*) are the open root of mean variance extraction (AVE), and the lower triangle is the Pearson correlation coefficient.

Dimension 3 is made up of five factors: Make people feel special, A unique way of dressing, Variety of matching features, Versatility, and Partial creative design details. The factor load ranges from 0.814 to 0.696, with an explained variance of 11.419%. This dimension reflects consumers' quest for knowledge of new Chinese-style clothing products, that is, to satisfy their curiosity, novelty, and desire for knowledge by enhancing the newness of product details in design, matching, function, and wearing style. The elements of the dimension focus on expressing the uniqueness and novelty of the product, hence the name of the dimension as the creative value of the product.

Dimension 4 is composed of five factors: Product recyclability, Physiotherapy and Health Care, Fabrics, Green textiles, Natural dyed fabric, and Traditional natural fabrics. The factor load ranges from 0.837 to 0.641, with an explained variance of 11.084%. This dimension has an interactive value characteristic, reflecting the contextual value of the product. This dimension reflects the desire of consumers who are influenced by the concept of green to satisfy their pursuit of a green and healthy life through products, and is therefore named the green value of the product.

Dimension 5 is mainly composed of five highly relevant element factors, namely, Long-lasting and durable, Performance, Easy to move after wearing, Comfortable and breathable to wear, Have practical functions, and Convenient for daily cleaning and maintenance. The factor load ranges from 0.728 to 0.692, and the explained variance was 10.343%. This dimension reflects the consumers' pursuit of

the functional cognitive value of new Chinese-style clothing products and is related to the basic engineering performance of the products. Therefore, this dimension is named the engineering value of the products.

Dimension 6 is composed of the four elemental factors of Promote a sense of personal confidence, Enhance personal image, Become more popular, and Show professional image. The factor load ranges from 0.795 to 0.693, with an explained variance of 9.156%. This dimension reflects consumers' pursuit of the social perception value of new Chinese-style clothing products; that is, it emphasizes the positive role played by the products in consumers' interpersonal and social interactions, and is therefore named the social value of the products.

Dimension 7 is mainly composed of three element factors: Exquisite structure, Highly textured crafts such as prints and embroideries, and Excellent manufacturing technology. The factor load is between 0.827 and 0.763, and the explained variance is 7.503%. This dimension also reflects the consumers' pursuit of the cognitive value of the new Chinese-style clothing product function. However, different from the basic engineering performance of the product, this dimension focuses on the integrity of the product and the functional details, which can enable consumers to produce high-quality images. It needs to be highlighted through detailed design and high-level technology. Therefore, this dimension is named as the quality value of the product.

Through the above analysis, we have obtained seven dimensions containing cultural and educational value,

aesthetic value, creative value, green value, engineering value, social value, and quality value, and 32 element factors to build an evaluation index of the customers perceived value of new Chinese-style clothing.

4. Customer Perceived Value Evaluation Model of New Chinese-Style Clothing Based on PSO-BP Neural Network

This paper uses the PSO algorithm to find the optimal initial weight and threshold in BP neural network, and obtains a better neural network model to evaluate the customer perceived value of new Chinese-style clothing.

The specific steps of the experiment are as follows:

- (1) Obtain sample data of customer perceived value of new Chinese-style clothing, and preprocess and normalize the data.
- (2) Determine the number of nodes in each layer of BP neural network.
- (3) Initialize the position and velocity of particles.
- (4) Calculate the fitness value of each particle, and find the global extremum.
- (5) Update the velocity and position of particles to generate a new particle swarm.
- (6) Stop iteration if one of the following conditions is met: the number of iterations reaches the preset value; the error accuracy meets the set value. Otherwise, skip to step 5.
- (7) After the iteration stops, the optimal weights and thresholds are put into the BP neural network for training. The BP neural network is trained iteratively until the termination condition is met.
- (8) Obtain the BP neural network model optimized by the PSO algorithm.

The construction process of the model in this paper follows as shown in Figure 2.

This section designs a questionnaire based on the new Chinese-style clothing customer perceived value evaluation index constructed in Section 3 and collects the evaluation index data of new Chinese-style clothing products. A BP neural network based on the particle swarm optimization algorithm for the new Chinese-style clothing customer perceived value evaluation model was established. Twenty-two new Chinese-style clothing was selected as training samples and eight new Chinese-style clothing as testing samples, and MATLAB software was used to train and test the neural network examples.

4.1. Data Collection and Preprocessing. The main targets of this questionnaire were undergraduates and postgraduates and their families. College students and their families are potential consumers of new Chinese-style clothing. A total of 50 respondents were selected for the survey.

In this paper, a selection of new Chinese-style clothing products that are currently on the market was selected as the

tested products. There are two main processes for their selection:

- (1) Selection of new Chinese-style clothing brands: Regarding a combination of indicators such as brand awareness, brand style, the status of the brand's published online performance, and the opinions of experts in the field, the new Chinese-style clothing brands selected for this paper are as follows: ICY, INXX, Bosie Agender, HUSENJI, Hua Mu Shen, BYTEHARE, Nengmao Store, CLOT, LI-NING, ANTA, HLA, PEACEBIRD, SHIATZY CHEN, Mi Shan, and Houxu.
- (2) Selection of new Chinese-style clothing products: 1–3 products were selected from the official websites or shopping platforms of the above 15 brands according to their sales index and brand representativeness, and finally, 30 new Chinese-style clothing products were selected as experimental products for this paper.

After determining the new Chinese-style clothing customer perceived value evaluation indexes in Table 3, 30 new Chinese-style clothing products were selected. Through the online survey, 50 subjects were asked to rate the customer perceived value evaluation indexes and the overall design of 30 new Chinese-style clothes. The data of the new Chinese-style clothing products No. 1–22 were used for the training of the neural network, and the new Chinese-style clothing products No. 23–30 were used for testing the neural network. The subjects were shown the front and back pictures and pattern designs of the 30 new Chinese-style clothing products during the survey. In addition to the presentation of the picture information of the garments, the design inspiration, fabric, and accessories were presented.

When comes to statistical data, chance errors, human errors, and sampling errors can lead to outliers. To avoid a minimal number of people with solid subjective emotions or recording errors during the research process, an outlier test needs to be conducted on the scores obtained for each evaluation index and the overall design score for each new Chinese-style clothing product. To prevent outliers in the scoring from influencing the final results, this paper uses Grubbs' test (two-tailed test) to eliminate outliers [37]. The statistic for Grubbs' test (equation (1)) is shown in the following:

$$G = \frac{|x_i - \bar{x}|}{S}, \quad (1)$$

where x_i is the score of a certain indicator of a new Chinese-style clothing product, \bar{x} is the mean score of the corresponding indicator of the corresponding clothing, and S is the corresponding standard deviation.

After testing, 124 outliers, generally extreme data caused by some subjects' strong subjective emotions on some clothing's indicators, were removed. Appendix A lists the scores of some sample clothing evaluation indicators after removing outliers. The data of the input layer of the BP neural network model are the average of the scores of 50 subjects.

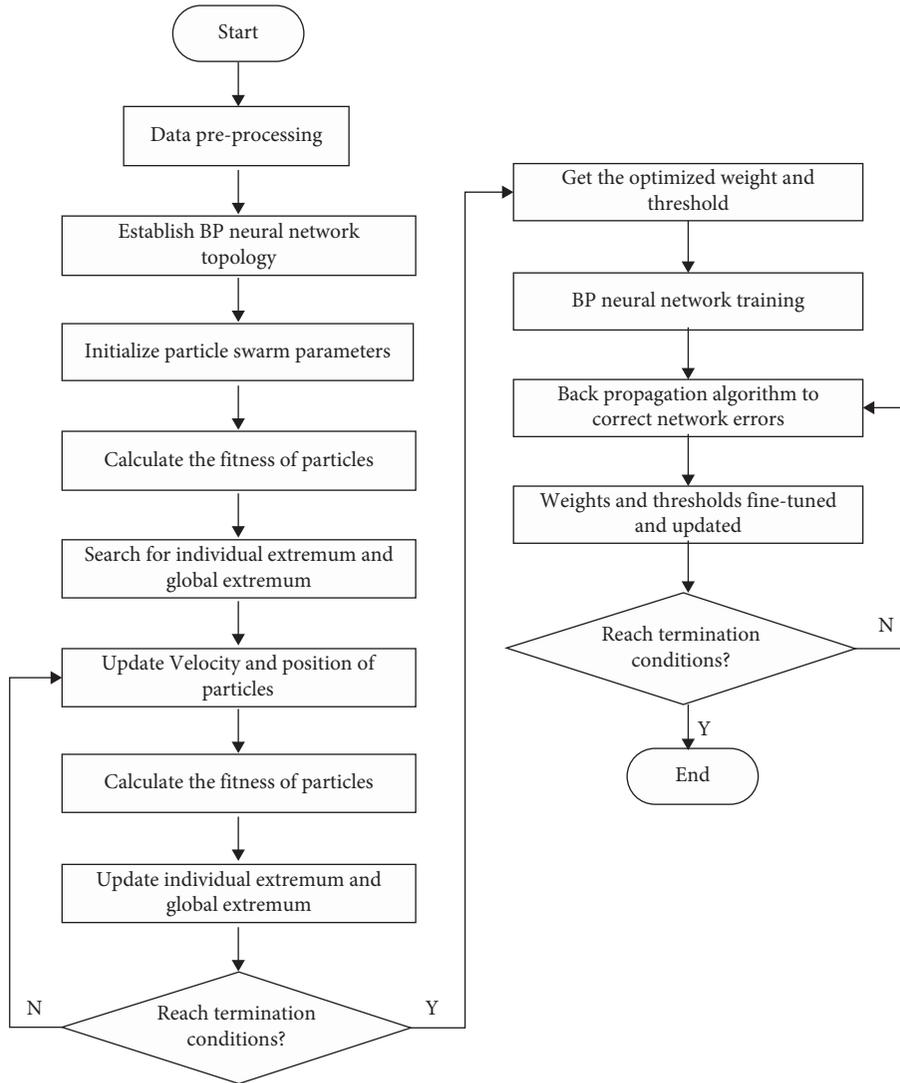

FIGURE 2: Flowchart of the PSO-BP neural network.

The 32 customer perceived value evaluation indexes data and overall design scores of 30 new Chinese-style clothing are taken as the original data. In order to improve the convergence speed of the BP neural network and the consistency of the results, it is also necessary to normalize the original data. In this paper, the min-max standardization method is adopted, called 0-1 standardization. That is, the original data were linearly transformed. To make the results distributed between 0 and 1, the function is used to process the original data linearly. The transformation function (equation (2)) is as follows:

$$y^* = \frac{y - y_{\min}}{y_{\max} - y_{\min}}, \quad (2)$$

where y^* is the standardization result, y is the sample score, y_{\max} is the maximum score of the sample, and y_{\min} is the minimum score of the sample. After the above processing of the original sample data, the scores of the new Chinese-style clothing customer perceived evaluation index are the input data of the neural network, and the scores of the overall

design of the new Chinese-style clothing are the output data of the neural network.

The raw data and normalized data of the overall design scores of samples 1-22 used for training are shown in Table 4, which is the output layer data of the neural network model.

4.2. The Selection of BP Neural Network Parameters.

Feature selection is crucial to machine learning, selecting features from all features to introduce into the model that are helpful and reduce the consumption of computational resources. The main role of feature selection is to reduce the number of features to prevent dimensional disasters, reduce training time, enhance generalization, and reduce overfitting. The random forest algorithm is chosen to filter features in this paper. The random forest algorithm is one of the most widely used supervised learning algorithms to solve regression and classification problems. The random forest algorithm provides two methods of feature selection: mean

TABLE 4: Raw data and normalized data of the overall design score of the training sample.

No.	Original value	Normalized value
1	83.793	0.7028
2	89.487	1
3	81.026	0.5584
4	83.897	0.7083
5	85.538	0.7939
6	84.846	0.7578
7	88.027	0.9238
8	81.676	0.5923
9	86.649	0.8518
10	88.703	0.9591
11	78.703	0.4371
12	80.324	0.5218
13	72.224	0.0990
14	71.810	0.0774

19	77.628	0.3810
20	85.070	0.7694
21	81.488	0.5825
22	87.395	0.8908

decrease impurity and mean decrease accuracy. This paper chooses the mean decrease impurity method, which can easily measure the relative importance of each feature to prediction. The higher the feature importance value, the more important the feature is to the model. After screening 32 features, the top 15 features with high feature importance values were finally selected, which are Become more popular, Exquisite structure, Exquisite design details, Promote a sense of personal confidence, Partial creative design details, Make people feel special, Good styling proportions, Exquisite decoration, Enhance personal image, Excellent manufacturing technology, Highly textured crafts such as prints and embroideries, Physiotherapy and Health Care Fabrics, Variety of matching features, A unique way of dressing, and Have an attractive story or moral. Therefore, the number of nodes in the input layer of the BP neural network is 15.

The number of hidden layer nodes is determined by trial-and-error method. When the number of hidden layer nodes is 9, the training error of the BP neural network is the smallest. The selection of the BP neural network parameters is shown in Table 5.

4.3. Particle Swam Optimization Algorithm. The selection of relevant parameters in the PSO algorithm is shown in Table 6. Figure 3 shows the change in the fitness value of the particles, that is, the MSE of the BP neural network training. The fitness value gradually decreases with the increase in the number of iterations.

4.4. Experiments. The established structure has 15 nodes in the input layer, 9 nodes in the hidden layer, and 1 node in the

output layer of the three-layer BP neural network. The MATLAB model is shown in Figure 4.

4.4.1. Training Experiment of PSO-BP Neural Network. The data of No. 1–22 new Chinese-style clothing are input into the PSO-BP neural network for training. The following “PSO-BP neural network model” will be referred to as “the model” for short. After 4 iterations, the termination conditions are met and the training is completed. As shown in Table 7, the actual value is the overall design score of No. 1–22 new Chinese-style clothing, and the predicted value is the output of the model after training with these 22 groups of data. The relative error is the relative error between the predicted value of the model and the actual value of 22 new Chinese-style clothing data. The relative error can reflect the

TABLE 8: Testing results of the PSO-BP neural network.

No.	Actual value	Predicted value	Relative error (%)
23	79.294	77.645	2.080
24	85.351	85.211	0.164
25	75.971	76.261	0.382
26	83.500	84.332	0.996
27	80.367	81.531	1.448
28	74.628	75.191	0.754
29	81.765	80.814	1.163
30	72.143	73.779	2.268

reliability of model prediction. The formula of relative error η is

$$\eta = \frac{|R - R'|}{R} \times 100\%, \quad (3)$$

where R is the actual value and R' is the predicted value of the model.

The overall design score of No. 19 new Chinese-style clothing is 76.226. The predicted value trained by the model is 75.314, and the relative error is 1.196%, which is the largest error in 22 groups of new Chinese-style clothing data. The relative error of No. 13 new Chinese-style clothing is the smallest, 0.004%. The average relative error of 22 groups of new Chinese-style clothing data is 0.354%, and the prediction results are accurate, so it can be concluded that the model has good learning ability and reliability.

4.4.2. Prediction Experiment of PSO-BP Neural Network.

In order to test the prediction ability of the PSO-BP neural network model, No. 23–30 new Chinese-style clothing data were selected for testing. The following “PSO-BP neural network model” will be referred to as “the model” for short.

As shown in Table 8, the actual value is the overall design score of 8 new Chinese-style clothing from No. 22 to No. 30, and the predicted value is the predicted score of the trained model for the overall design of these 8 new Chinese-style clothing. The overall design score of No. 30 new Chinese-style clothing is 72.143, the predicted value trained by the model is 73.779, and the relative error is 2.268%, which is the largest relative error among the 8 groups of data. The average relative error of 8 groups of data is 1.157%, less than 5%, which indicates that the model is reliable and has good generalization ability. This shows that the model has certain reference significance for the evaluation of customer perceived value of new Chinese-style clothing and provides a relatively objective method for the evaluation of new Chinese-style clothing design.

4.5. Comparison between PSO-BP Neural Network Model and Traditional BP Neural Network Model.

To compare the prediction accuracy of the PSO-BP neural network model and the traditional BP neural network model, the data of No. 22–30 new Chinese-style clothing were input into these two models, and the output results are compared as shown in Table 9. The following “PSO-BP neural network model” will be referred to as “the model” for short. The overall design score of No. 24 new Chinese-style clothing was 85.351, and the predicted score of the model was 85.211 with a relative error of 0.164%; the predicted score of the traditional BP neural network was 82.538 with a relative error of 3.296%. From Table 9, it is easy to find that the traditional BP neural network error fluctuates wildly, and the maximum relative error reaches 11.815%. The traditional BP neural network has the defect that it is easy to fall into the local minimum. For example, the predicted result of the customer perceived

TABLE 9: Comparison of traditional BP neural network and PSO-BP neural network prediction values.

No.	Actual value	PSO-BP neural network		Traditional BP neural network	
		Predicted value	Relative error (%)	Predicted value	Relative error (%)
23	79.294	77.645	2.080	79.472	0.224
24	85.351	85.211	0.164	82.538	3.296
25	75.971	76.261	0.382	78.592	3.450
26	83.500	84.332	0.996	84.084	0.699
27	80.367	81.531	1.448	82.601	2.780
28	74.628	75.191	0.754	72.849	2.384
29	81.765	80.814	1.163	81.816	0.062
30	72.143	73.779	2.268	63.619	11.815

value of No. 30 new Chinese-style clothing is quite different from the predicted result of the model. However, the relative error fluctuation of the model is small, and its error is controlled within 2.5%. The prediction accuracy of the model is obviously higher than that of traditional BP neural network, indicating that the model has better generalization ability and fault tolerance.

5. Conclusions

In the new Chinese-style clothing industry, sustainable development not only refers to the organic unity of industrial economic growth and ecological environmental protection, or the inheritance and development of traditional culture through products and modern fashion, but also includes the sustainable consumption of turning to the demand side and pursuing the harmony of supply and demand. In order to improve the evaluation level of the customer perceived value of new Chinese-style clothing and help enterprises more accurately grasp the consumer demand of products, this paper uses interview method, questionnaire survey method, exploratory factor analysis method, BP neural network, and particle swarm optimization algorithm to build new Chinese-style clothing customer perceived value measurement indicators and evaluation model, and obtains the following main conclusions.

Based on the results of open-ended questionnaire interviews, this paper summarizes 37 element factors of new Chinese-style clothing customer perceived value measurement indicators through coding procedures. Then, through exploratory factor analysis and reliability and validity analysis, the evaluation index dimensions of the customer perceived value of new Chinese-style clothing are extracted. The results show that after the dimensionality reduction of 37 element factors through factor analysis, seven dimensions can be summarized: engineering value, aesthetic value, green value, creative value, cultural and educational value, social value, and quality value.

This paper uses the ability of BP neural network to solve nonlinear problems and establishes a new Chinese-style clothing customer perceived value evaluation model based on the BP neural network. However, the BP neural network falls into local optimization and its convergence speed is slow. A new Chinese-style clothing customer perceived value evaluation model based on the particle swarm optimization algorithm is proposed. The experimental results show that the PSO-BP neural network has a very good learning and

predictability in the evaluation of the customer perceived value of new Chinese-style clothing. It can evaluate the customer perceived value of new Chinese-style clothing well and provide an objective evaluation model for future new Chinese-style clothing design ideas.

The use of the new Chinese-style clothing customer perceived value measurement index allows designers to design products according to the characteristics of the target customer, avoiding the misalignment between design and demand, product homogenization, and other issues, so as to enhance the sustainable competitive advantage of enterprises. Similarly, new Chinese-style clothing enterprises can also use this measurement index to classify products, and the design plan or product can be found out in advance through the new Chinese-style clothing customer perceived value measurement index to find out its unique product personality (such as focusing on cultural and educational products, aesthetic products, green products, or creative products), which will be more conducive to market planners to carry out market classification and competitor analysis as a reference. In addition, consumers can also use this measurement index in their daily lives to improve the quality of their purchase decisions, etc. and ultimately achieve the sustainable development of the new Chinese-style clothing industry.

At present, the mechanical properties analysis method of prefabricated shear wall structure based on static test is low overall simulation precision. In this paper, the finite element method is used to analyze the force performance of the prefabricated shear wall structure. Based on the shear of concrete material, elastic modulus, Poisson ratio, open fracture, the transfer coefficients of open and closed fracture, and tensile strength parameters, the finite element model is established by ANSYS. The vertical load and the horizontal load of the prefabricated shear wall structure are calculated, and the limit load value is obtained. The maximum stress change of the connector, the energy dissipation of the shear wall structure, and the change of the equivalent viscous damping coefficient are obtained by the way of loading and displacement change. The experimental results show that the simulated values of stiffness degradation, maximum displacement, maximum strain, and stress distribution obtained by this method are in good agreement with the actual values and are reliable.

1. Introduction

Along with city development scale in China more and more big, the requirements of the government for environmental protection are higher, the requirements of real estate developers for time, cost, and quality are more strict, and the requirements of owners for the building product safety and comfort performance gradually increase, which have become the bottleneck restricting the development of the construction industry [1, 2]. The prefabricated shear wall structure has come into being. The fabricated building is a building constructed by precast components at the site. It has the advantages of short construction period, high construction quality, and environmental protection. It is catering to the national policies and development requirements of housing industrialization and building energy conservation and emission reduction. With the continuous development of prefabricated shear wall structure, the stress analysis has become a hot issue in structural engineering [3, 4].

Zhang et al. [5] put forward an assembly scheme for the external wall panel for steel structure. In order to study the

lateral resistance and seismic performance of steel frames with such wall panels, the ABAQUS finite element software was used to establish the overall model and comparison model of steel frames, and the finite element analysis of uniaxial loading and low cycle reciprocating loading was carried out. The results showed that the connection of the outer wall panel could guarantee the connection between the outer wall plate and the steel frame. When the structure had large deformation under lateral load, it could limit the transfer force between the wall panels and the frames, ensured that the wall panels were in an elastic state, and avoided wall panels from falling down. The enclosure system consisting of the external wall panel and the connection node significantly improved the mechanical performance of the steel frame, the initial stiffness of the structure was increased by 1.18 times, and the bearing capacity was increased by more than 30%. The scheme could enhance the seismic performance of the structure. When simulating the low cycle reciprocating loading, the total energy dissipation of the external wall panel's steel frame model was increased by more than 90% compared with the pure frame model, but the overall simulation result was quite different from the actual value.

In view of the large discrepancy between the simulation results in the literature and the actual values, a new finite element analysis method of prefabricated shear wall structure is put forward to improve the accuracy of mechanical properties of shear wall structure analysis.

2. Finite Element Analysis of the Mechanical Properties of Prefabricated Shear Wall Structure

The prefabricated shear wall structure is a new type of wallboard. The width of a single plate with a binding body part is selected as an analysis unit. Its size is the length of 3000 mm, the width of 600 mm, the thickness of 200 mm, and the concrete grade is C30. Because the integral modeling of ANSYS is used, the reinforcement ratio of the vertical bar in the plate is 1%, and the reinforcement ratio of the horizontal bar is 0.25%.

The material parameters in finite element analysis are as follows: concrete C30, elastic modulus 3.0 GPa, Poisson's ratio 0.2, steel bar HRB335, opening crack's shear transfer coefficient 0.35, closed crack's shear transfer coefficient 0.95, and the tensile strength 1.43 MPa.

2.1. The Model is Established

2.1.1. Defining the Element Properties. The concrete is defined, the distribution unit type is SOLID65 unit, and the proper real constant and material model are selected. In considering the reinforced modeling, the internal structure of the structure is defined by the reinforcement ratio of the longitudinal reinforcement and the distribution of reinforcement in the real constant [6].

2.1.2. The Division of Grid. The grid division is divided by swept grid and the source surface grid is divided by the mapped grid. The grid precision is controlled within 100 mm [7].

2.1.3. Applying Constraint and Loads. This model is loaded by force mode. The rigid pad is added to the local compression position. The shell 63 element is adopted to prevent the stress concentration to cause that the calculation does not converge.

A fixed end is applied at the bottom of the wallboard, and the top is the free end.

2.2. Solving and Postprocessing. The nonlinear analysis of the wall panel is carried out, and the mechanical properties of the components in the force process are obtained through the general postprocessing and the time postprocessing.

In addition, the prefabricated shear wall model structure is shown in Figure 1.

The single axis strain-stress relation diagram of the concrete in Figure 1 is shown in Figure 2(a), and the stress-strain curve of steel bar is shown in Figure 2(b).

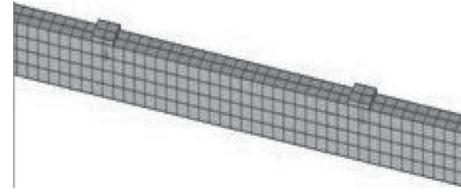

FIGURE 1: Finite element model of prefabricated shear wall structure.

According to the provisions of the "Technical specification for concrete structure of high rise buildings," under the action of representative value of neutral load, the axial pressure of the one, two, and three grade shear wall limbs is not suitable for the following restrictions: first class (9°): the limit of corresponding axial-compression ratio is 0.4, another level (6°, 7°, and 8°) the limit of corresponding axial-compression ratio is 0.5, and the limit of the axial compression ratio of second or third level is 0.6.

In this paper, the axial compression ratio is 0.4, 0.5, and 0.6 [8], and the vertical load of the prefabricated shear wall structure is calculated according to formula (1).

$$\mu = \frac{N}{(f_c * A)}, \quad (1)$$

where A represents the area of the full section of the shear wall, N represents the axial pressure value of the section of shear wall, and μ represents the load value.

According to the formula (1), there are

$$\begin{aligned} N_1 &= 0.4 * f_c * A = 686\text{kN}, \\ N_2 &= 0.5 * f_c * A = 859\text{kN}, \\ N_3 &= 0.6 * f_c * A = 1030\text{kN}. \end{aligned} \quad (2)$$

Through the above calculation, the maximum bearing capacity of the vertical load of the prefabricated shear wall structure is 1030 kN. According to the provisions of the "Technical specification for concrete structure of high rise buildings," the maximum horizontal displacement and height ratio $\Delta u/h$ of the floor layer between the floor layers under the stress load calculated by the elastic method conform to Table 1 [9, 10].

According to Table 1, the calculated maximum displacement of the wall panel is 3 mm. When the vertex displacement of 3 mm can be obtained by using the formula (3), the horizontal load of the prefabricated shear wall structure is 36 kN, that is, the horizontal load under normal serviceability limit state.

$$w_{\max} = \frac{Fl}{EI}, \quad (3)$$

where F represents the load on the model, l represents the length of the model after the deformation, E represents the modulus of elasticity of the model, and I represents the I shaped section of the model.

According to "The technical regulations of high building concrete structure," there are as follows:

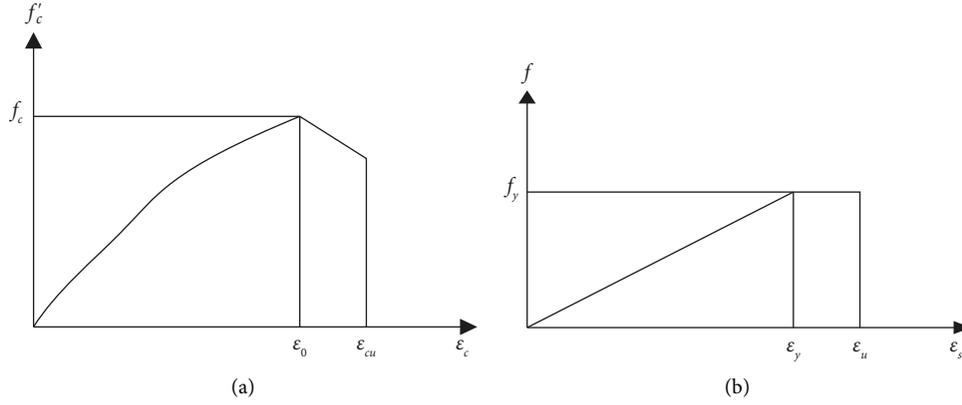

FIGURE 2: The stress-strain curve of material. (a)Single axis stress-strain relation diagram of concrete and (b) stress-strain curve of steel bar.

TABLE 1: Ratio of maximum horizontal displacement to height.

Structural system	$\Delta\mu/h$ limit
Frame	1/550
Frame-shear wall, frame-core tube, and flat plate-column-shear wall	1/800
Tube in tube, shear wall	1/1000
The transformation layer other than the frame structure	1/1000

$$V \leq \frac{1}{\lambda - 1} \left(0.5 f_y * b * h + 0.13 N \frac{A_w}{s} h \right), \quad (4)$$

where V represents displacement, A_w represents the area of I shaped or T shaped cross-section shear wall, λ represents the shear span ratio of section, s represents the horizontal distribution of reinforcement spacing of shear wall, b represents the section width, and h represents the effective height of the model.

According to formula (4), the shear capacity of the prefabricated shear wall structure is 123.8 kN; that is, the horizontal load under the ultimate bearing capacity of the prefabricated shear wall structure.

Figure 3 is the maximum stress change of the perforated rebar in the prefabricated shear wall structure, and Figure 4 is the maximum stress change of the connecting steel plate.

According to Figures 3 and 4, it is known that at the initial stage of loading displacement, the connections are in the elastic deformation stage. When the displacement is loaded to 25 mm, the maximum stress of the connecting steel plate is 227 Mpa and enters the yield stage. Then, when the displacement is loaded to 45 mm, the perforated rebar enters the yield stage, and the maximum stress is 380 Mpa. When the displacement is loaded to 52 mm, the maximum stress of the steel plate begins to increase and enters the stage of plastic hardening. When the displacement is loaded to 55 mm, the perforated rebar enters the plastic hardening stage. When the displacement is loaded to 75 mm, the connecting steel plate reaches the limit stress 310 Mpa and enters the necking deformation stage. When the specimen is completely destroyed, the connecting steel plate is completely broken, but the reinforcing bar does not destroy.

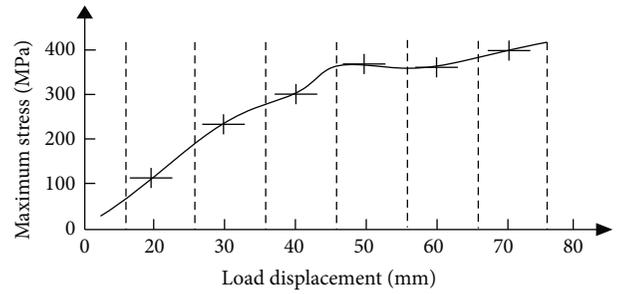

FIGURE 3: The maximum stress change of perforated rebar.

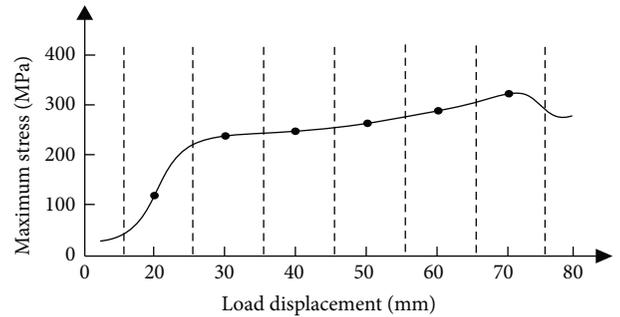

FIGURE 4: Maximum stress change of connecting steel plate.

There are two main reasons for structural vibration energy dissipation: structural damping energy dissipation and elastoplastic energy dissipation.

Damping and elasticity are one of the most important properties of the structure. When the structure is in the case of elastic vibration, the damping causes the dissipation of the structure energy. When the deformation of the structure exceeds the elastic limit, the structure will undergo plastic

deformation. After unloading, the deformation of the structure cannot be completely recovered and there will be residual deformation and energy dissipation. According to “The technical specification for concrete structures of tall buildings,” the energy dissipation capacity of specimens should be measured by the area enclosed by the load-displacement curve [11–14]. Figure 5 is a schematic diagram for calculating the energy dissipation and equivalent viscous damping coefficients of specimens.

The energy dissipation factor is the ratio of the energy consumed by a hysteresis loop to load and unload for a circle to the total energy of loading and unloading. The energy dissipation factor E' of the specimen [15–18] can be calculated by formula (5).

$$E' = \frac{S_{A'BC} + S_{CDA'}}{S_{\Delta BOE'} + S_{\Delta DOF'}}. \quad (5)$$

In the force response analysis of prefabricated shear wall structure [19–21], the equivalent viscous damping coefficient h_e is often used to carry out the pressure analysis. The equivalent viscous damping coefficient h_e can be calculated by using the formula (6).

$$h_e = \frac{E'}{2\pi}. \quad (6)$$

Figure 6 is the energy dissipation diagram for each specimen of prefabricated shear wall structure:

According to Figure 6, it can be seen that with the increase of the displacement, the hysteretic curve of the specimen tends to be full and the energy consumption increases gradually. The energy dissipation capacity of the specimens under high axial compression ratio is relatively large, whether it is the connecting steel or the connecting steel plate in the prefabricated shear wall structure [22–24].

Figure 7 is the diagram of equivalent viscous damping coefficient of each specimen in a prefabricated shear wall structure.

As can be seen from Figure 7, with the increase of displacement, the hysteresis loops of all the specimens in the prefabricated shear wall structure are gradually full, and the equivalent damping coefficient is increasing.

3. Experimental Results and Analysis

In order to verify the correctness of finite element analysis results of prefabricated shear wall structures [25–27], an experiment is needed to verify the above results. The experimental platform is built on MATLAB.

The prefabricated shear wall structure is taken as the experimental object, and the pressure is applied to record and track its bearing changes. The overall experimental results are as follows.

From Figure 8, we can see that the ultimate load of the shear wall finite element simulation is higher than the actual result, because the concrete vibration is not enough, and the specimen maintenance process is not up to standard, but the material in finite element simulation is not defective.

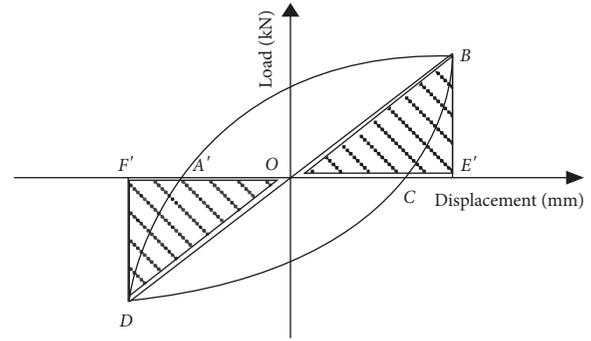

FIGURE 5: Diagram for calculating energy dissipation and equivalent viscous damping coefficient for prefabricated shear wall structure.

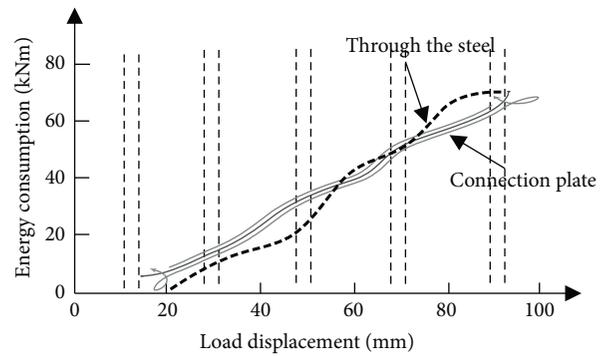

FIGURE 6: Energy dissipation diagram for each specimen of prefabricated shear wall structure.

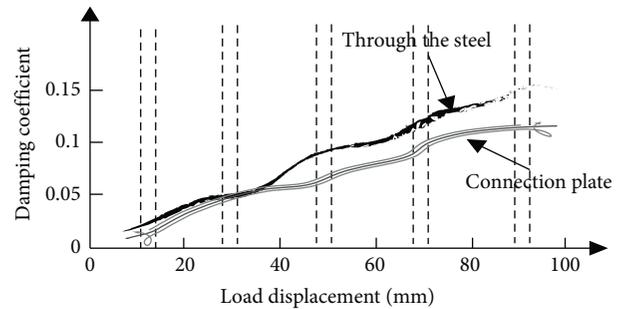

FIGURE 7: Equivalent viscous damping coefficient diagram of each specimen in prefabricated shear wall structure.

However, the hysteretic curve of the finite element simulation of prefabricated shear wall is quite different from the actual result, and it can be found that the modeling of the finite element is correct.

As shown in Figure 9, the stiffness degradation values in the initial stage of the literature method and the proposed method are in high agreement with the actual values and are in a state of basic level. But with the changing value of displacement, the simulated value of the literature methods gradually deviated from the actual value curve. In the process of small displacement loading, the stiffness of all the specimens in the structure degenerates greatly and the loading continues to continue. The proposed method

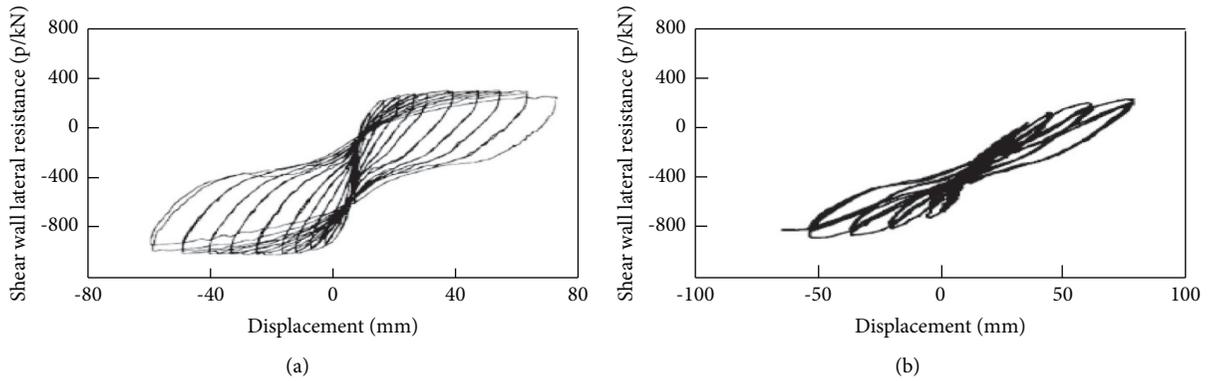

FIGURE 8: Agreement between hysteretic curve of the shear wall structure by using the proposed method with the actual value. (a) Hysteretic curve of simulated prefabricated shear wall structure and (b) hysteretic curve of actual prefabricated shear wall structure.

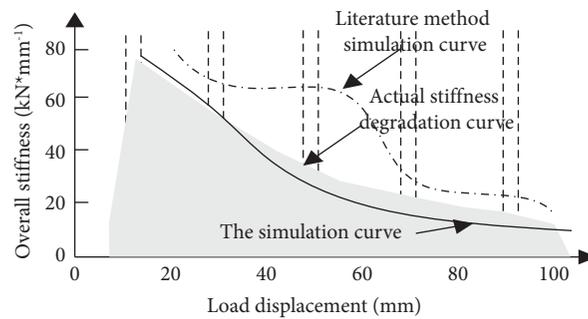

FIGURE 9: Agreement between simulated values of the overall stiffness degradation of prefabricated shear walls by different methods and actual values.

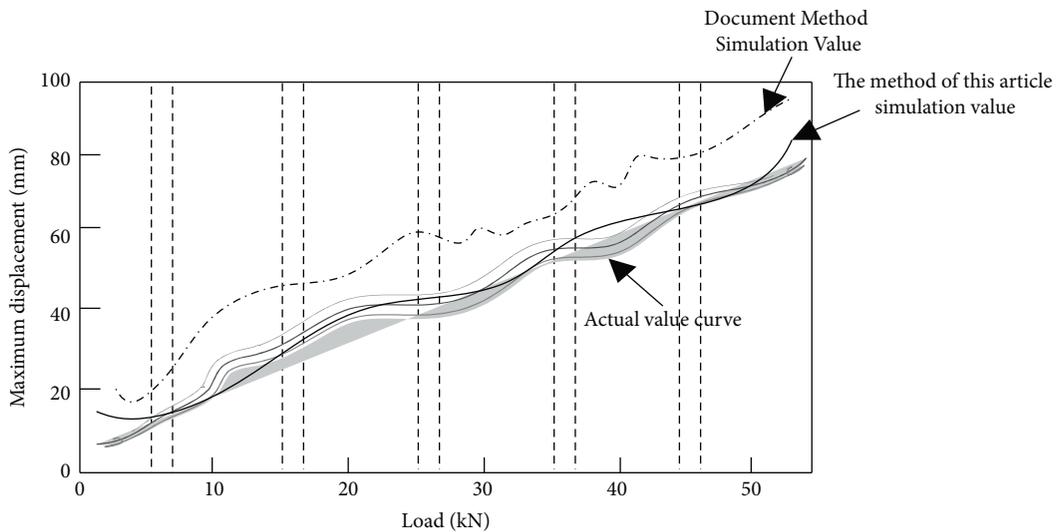

FIGURE 10: The fitting degree of the maximum displacement and load relation between the simulated value of the different methods and the actual value.

presents the advantages and is in a relatively consistent state with the actual stiffness degradation curve.

Figures 10–13 show the fitting degree of the maximum displacement and load relation between simulated values of different methods and actual values; the fitting degree of the maximum strain and displacement relationship between the

simulated value of different methods and the actual value; the fitting degree of the simulated values of different methods and the actual values between the stress distribution and the load relation; the fitting degree of the displacement changes of different methods and the actual value under the different friction coefficients.

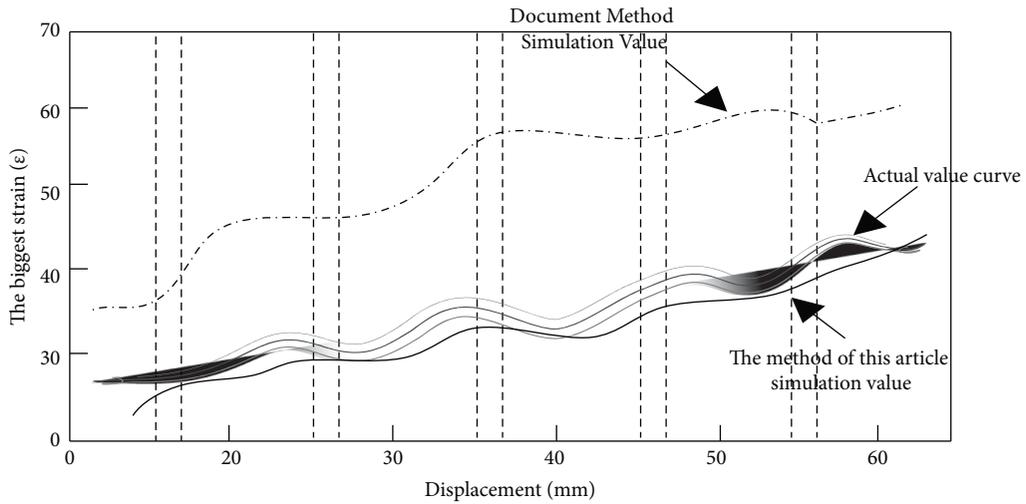

FIGURE 11: The fitting degree of the maximum strain and displacement relation between the simulated values of different methods and the actual values.

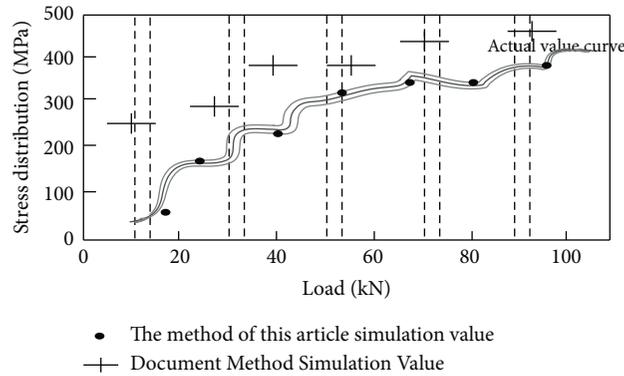

FIGURE 12: The fitting degree of stress distribution and load relation between the simulated values of different methods and the actual values.

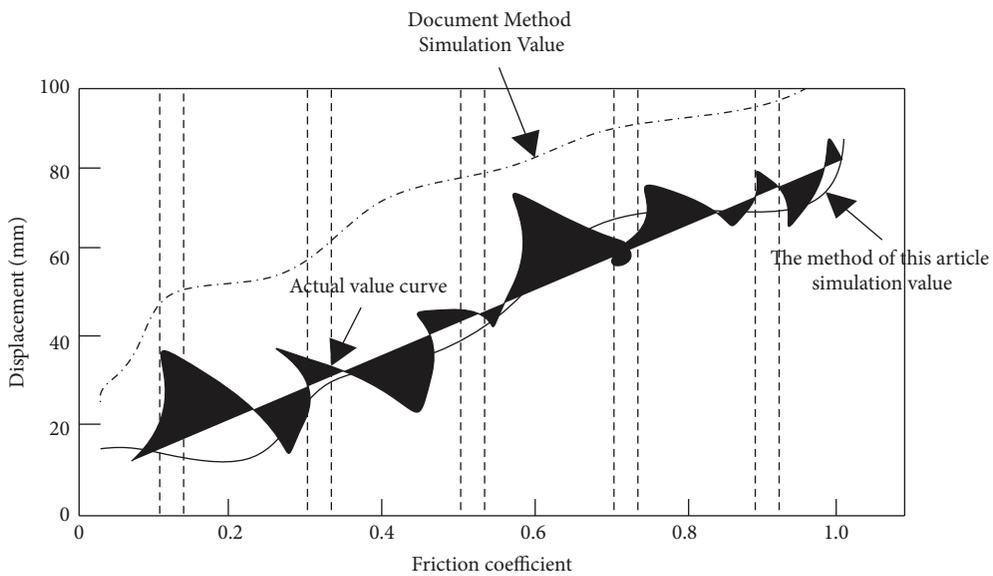

FIGURE 13: The fitting degree of the displacement changes of different methods and the actual value under the different friction coefficients.

The analysis of Figures 10–13 shows that the simulated value of the maximum displacement and load relation of the proposed method are fitted to the actual value. The maximum strain and displacement relation between the simulated value and the actual value is fitted, and the relationship between stress distribution and load relation of the simulated value and the actual value is fitted. The fitting degree of the displacement changes of different methods and the actual value under the different friction coefficients is better than that of the literature method. This is because in the establishment of finite element model of prefabricated shear wall structure, the grid is divided by using sweep grid division, the control of grid precision is within 100 mm, and the force analysis of the model is always carried out according to “The technical specification for concrete structure of high rise buildings.” Moreover, the energy dissipation of shear wall structure and the equivalent viscous damping coefficient are analyzed in detail, and the overall analysis accuracy of the method is improved.

4. Conclusions

Prefabricated shear wall structure is a highly applied energy-saving building material. Its stress performance analysis is the key to promote the development of technology in this field. At present, there are various problems in the analysis of the force performance. Aiming at these problems, this paper puts forward a new research method, to construct the finite element model of prefabricated shear wall structure by using the ANSYS and prove the feasibility of the proposed method through experiments, which can provide a scientific basis for the development of this field.

Digital human resource management can improve the organizational and operational efficiency of enterprises. In order to improve the efficiency of enterprise digital management and solve the problems of low security level and insufficient stability of 2D face recognition, we introduce 3D face recognition into the digital human resource management system. We propose a face recognition method based on a multistream convolutional neural network and local binary pattern and build a digital face recognition management system. We first build the system computer vision scene. Then a local binary mode facial expression feature extraction scheme is designed according to the depth camera image extraction method. Considering that face 3D features are easy to be missed, we build a multistream convolutional neural network to learn facial 3D features. Finally, we validate the effectiveness of the method in selecting a public face dataset. Experiments prove that our method can reach 98% face recognition accuracy, which is significantly better than other methods.

1. Introduction

An efficient human resource management (HRM) approach is necessary to maintain organizational efficiency and helps to enhance efficient iterations of organizational change at the company level. Most HRM teams are currently introducing intelligent management systems into their company's personnel management work, reducing workload and lowering HRM costs. Many researchers have proposed many research methods in intelligent HRM, and a large number of research results have been achieved. The intelligent HR management system is a system with a huge system [1, 2]. Considering the multifunctionality and complexity of the HR system, combined with our recent research, we will start the research around the HR punch card assist system. The one that has been applied more in the clock-in aid system is the face recognition clock-in system [3–5].

The human face is a unique biological feature, and each person's face contains features such as expressions, facial features, and contours. The rational use of facial biology in an ethical scope can create great economic benefits, but facial expression feature extraction and analysis is a difficult task.

How to correctly extract facial expression features is a major research hotspot, and after extracting facial features, how to efficiently utilize them and incorporate them into automatic feature learning networks is also a major challenge. Initially, in facial recognition research, researchers favored machine learning methods. Initially, facial recognition was only at the 2-dimensional level [6–9]. Commonly used machine learning methods include principal component analysis and support vector machines. However, traditional machine learning methods require a high level of manual feature design and cannot automate the feature labeling process. In addition, it is difficult for traditional machine learning methods to maintain the stability of the model in the irregular changes of an unstructured environment, as a result, machine learning methods are gradually replaced by deep learning methods in the subsequent research. Deep learning methods require a large database as the training set, and the number of training sets determines the accuracy of deep learning models for face recognition. The initial deep learning-like face recognition methods also started from the 2-dimensional level and were mainly based on pixel features. The 2-D facial features always have the problems of

information occlusion and missing information, which cannot complete the high precision facial biometric feature learning. Three-dimensional facial feature analysis based on deep learning is more accurate, and intelligent systems of three-dimensional facial recognition are chosen in some places or companies with high-security level requirements. For a three-dimensional facial recognition algorithm, the requirements for computer vision scene construction are relatively high. Ordinary RGB camera intelligently captures two-dimensional pixel features. If you want to capture three-dimensional facial biometric features, you need to use depth cameras to obtain depth information of the visual scene, and then through depth information data reduction, three-dimensional scene reconstruction, and other operations. The same depth camera is configured in the equivalent 3D facial recognition system for scanning face information [10–14].

To enhance the security of digital management of enterprises. We introduce 3D face recognition into the digital human resource management system. We propose a face recognition method based on a multistream convolutional neural network and local binary pattern and build a digital face recognition management system. We first build the system computer vision scene. Then we designed a local binary mode facial expression feature extraction scheme based on the depth camera image extraction method. We also constructed a multistream convolutional neural network to learn facial 3D features.

The rest of this paper is arranged as follows. Section 2 describes the research related to face recognition. Section 3 details the principles and implementation process associated with improved local binary patterns and multistream neural networks. Section 4 presents the relevant experimental datasets and an analysis of the results. Finally, Section 5 reviews our findings and reveals some additional research.

2. Related Work

The literature [15] was one of the first studies to propose a face recognition system, where the authors built a face pixel autocorrelation matrix to fit the pixel computation model around a feature neural network. Face images require manual production of datasets and each face label needs to be preprocessed and labeled with its data source. The face database requires pixel-level normalization and coordinated positioning for training set and test set classification. However, the method does not perform well enough in the experiments. Researchers in the literature [16] upgraded on previous face recognition studies and the authors proposed the face algebraic database replacement method. The face pixel data is directly converted into a computable feature matrix during the face data collection preprocessing process, which optimizes the substitutability of face data. Researchers in the literature [17] proposed a face feature residual coding structure to determine the three-point pixel localization of the eyes and nose, which solves the undesirable problem of the least constrained environment such as insufficient light.

Considering that face recognition is strongly influenced by unstructured environmental factors, researchers in the literature [18] experimentally analyzed the efficiency of

principal component analysis methods and also compared the range of action of fisher faces and local binary patterns. It was found that for the pixel computation of grayscale maps, the monotonic transformation matrix and the face pixel features cannot be converted with a uniform rotation matrix. However, the pixel features obtained from the face pixel texture are more accurate in distinguishing the features of the five senses. The researchers of the literature [19] explained the shortcomings of the local binary pattern approach through experimental data and presented the superiority of the viola-jones approach. Considering the effects of nonstructural environmental factors, the authors also analyzed various optimization methods proposed in the literature [20, 21], detailing the best solutions in various situations such as occlusion, background differences, and noise effects, providing stable technical support for subsequent studies.

Researchers in the literature [22] developed experiments around the effect of light changes on face recognition. In the paper, the authors present common solutions to face recognition lighting variations and point out the drawbacks of each method. In a later experiment, the authors proposed a face facial light transformation balancing method based on distance transformation and kernel feature extraction. The method is based on facial texture features, and for the problem of robust illumination normalization, the authors explain how the method maintains stable extraction of facial features in facial illumination transformations, using facial pixel noise as an example. Researchers in the literature [23] also took a noise treatment approach between face recognition and balancing of illumination. To address the problem that high-level noise has a high impact on facial Lupin features and facial edge detection is weakened, the authors take inspiration from the backpropagation shear wavelet operation. The authors first divide the face into different regions uniformly at the pixel level, each region corresponds to an independent classifier, and the high-level noise can be eliminated by fitting facial features with the same characteristics by similarity at the terminals of the combined face regions, and finally by reorganization. The method achieves a noise elimination rate of 86% in experimental validation, which improves the robustness of the face recognition model.

To improve the accuracy of face recognition, the local binary pattern method is the first approach of most researchers. Optimization and fusion based on local binary patterns can improve the overall model efficiency. With the emergence of deep learning methods, researchers have tried to incorporate convolutional neural networks into face recognition models, while the literature [24] presents a real-time multiplayer face recognition method, which is an embedded system developed in a GPU system and also configured with computer vision scenes that can achieve functions such as face tracking and fast recognition. The method is an example of the successful application of a neural network in a face recognition model, and this face recognition system provides great reference value to the subsequent face system construction. The researchers in the literature [25] introduced and affirmed the former research

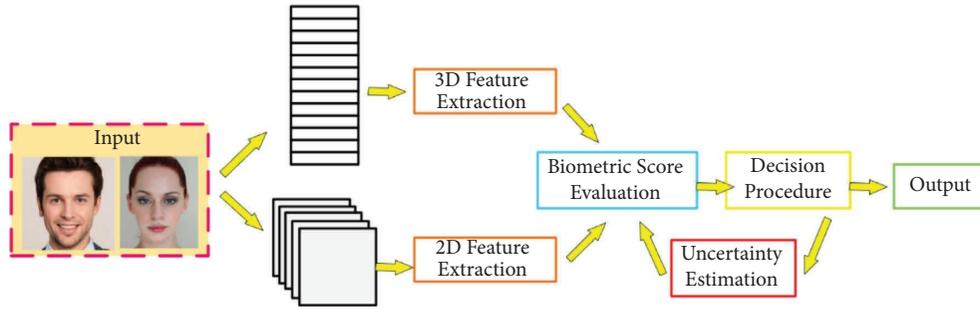

FIGURE 1: The composition of the face recognition system.

results in their article, and the authors elaborated their research ideas and methodological sources from a new perspective. Starting from a binary histogram algorithm, the article decomposes facial expressions of human faces between low-level and high-level pixels and extracts high-level and low-level features of expressions by pixel enhancement. The experimental results demonstrate that the method can enable face recognition models to obtain generalizability. The literature [26] analyzes in detail the differences and efficiency of local binary models and support vector machines and incorporates a particle swarm algorithm based on support vector machines. The recognition accuracy of this model was improved by 10 percentage points in the test of the public database of faces. Researchers in the literature [27] focused more on the random forest law, and the authors chose facial texture features as a measure of the fusion of symbolic and magnitude features. In the face public dataset supplement experiments, the authors compared the method with the local binary pattern method. The experimental results show that the method is more efficient in the classification of facial expressions.

3. Method

3.1. Face Recognition Pipeline Overview. We have reconstructed the face recognition method and designed a three-dimensional space-based face recognition network. First, we build a digital computer vision scene with three depth cameras REALSENSE, each depth camera's RGB image sensor and depth infrared sensor are in linkage, sharing frame rate to avoid frame loss. The facial RGB image information and depth information are simultaneously input to the face recognition model, and firstly, the physical feature calculation unit is used to fuse the depth information and RGB information to generate 3D facial information. The 3D facial information contains two sets of 3D facial contour features and data stream face classification theme scores. The weight in the estimated score of RGB image information is relatively large, and the features are extracted by a specific face estimation algorithm. The different levels of features in the database are generated by iterative iterations and are used to correct the weight parameters for the score estimation. For uncertain estimates, they will be directly input to the decision layer within the range of small probability events. Finally, all the features will be input to the decision layer and the decision algorithm will make a feature response

to the face based on the subject category, and confidence level. The feature response will be directly connected to the human biological database and can be associated with the real company employee information through a mapping matching relationship, thus achieving the function of face recognition. The composition of the face recognition system is shown in Figure 1.

3.2. Local Binary Pattern Network Reconstruction. Most researchers have demonstrated that local binary pattern neural networks have good results in the field of face recognition. We have also experimentally verified the efficiency of the local binary pattern framework, considering the shortcomings of the method in terms of accuracy and network structure. In our work, we will use the local binary pattern as the basis of the framework and focus on improving the recognition accuracy and speed of face recognition systems in unstructured environments. We also optimize feature details at the pixel level and generate facial attribute feature points adaptively.

In the first layer of the face recognition network, we first set up the image information preprocessing layer, assuming that α represents the face image contrast adjustment parameter and β represents the face contour size scale value. During the experimental test, we measure the α and β values in infinite approximation, and we find that the image preprocessing effect is best when $\alpha=1.5$ and $\beta=0.3$. The preprocessing layer function relationship is shown below.

$$g(x, y) = \alpha * f(x, y) + \beta. \quad (1)$$

In our previous experiments, we found that when the convolutional neural network filter processed the face RGB image, each convolutional operation was performed, then the specific curve was biased with higher pixel values in the region around the specified pixel. As the filter passes through each region of the image, it changes depending on the type of filter. Considering this problem, we have borrowed filter design rules from other studies, and most of them collectively show that the more similar the filter features are to the convolutional computed image features, the higher the probability of filter activation and more accurate filtering results. To this end, we set up independent experiments to verify the feature similarity of the Gaussian fuzzy filter [28], median filter [29], and bilateral filter [30] in the face recognition framework, respectively. The experimental results

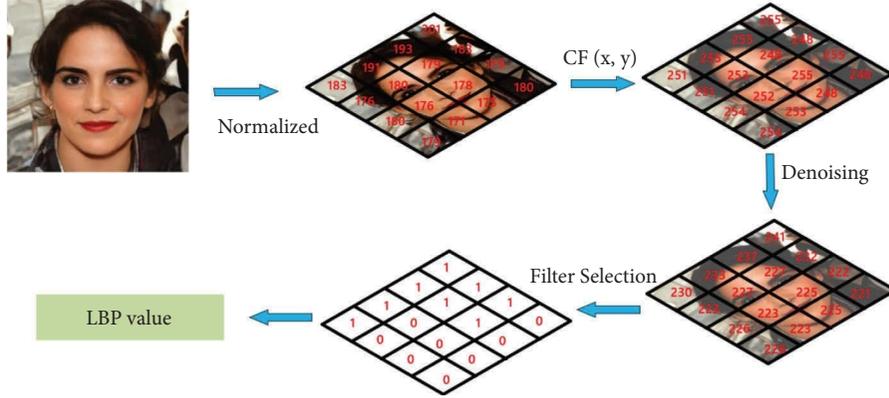

FIGURE 2: The modified local binary pattern operator.

show that the bilateral filter can obtain filtering results that are more similar to the facial image features. Therefore, we place the bilateral filter in the second layer of the face recognition network, and the bilateral filter mathematical equation is shown in the following formula.

$$F(x, y) = \frac{\sum_{x=-N}^N \sum_{y=-N}^N I(x, y)W(x, y)}{\sum_{x=-N}^N \sum_{y=-N}^N W(x, y)}, \quad (2)$$

where $W(x, y)$ represents the weighting function of the facial RGB input in the convolution calculation, $I(x, y)$ represents the pixels in the neighborhood of the filtered image area, respectively, and $F(x, y)$ represents the linear summation of the filtering weighting function, and it also represents the result of the bilateral filter applied on a $2N + 1$ neighborhood. Assuming that $CF(x, y)$ represents the fusion result of the input facial image with the noise reduction algorithm, the mathematical equation is shown in the following formula.

$$CF(x, y) = g(x, y) * F(x, y). \quad (3)$$

We regard it as the image noise control contrast weighting. Where $g(x, y)$ represents the facial image contrast and $F(x, y)$ represents the type of filter used in the convolution calculation. In the experiments of pixel equalization operation for facial images, we found that facial images are prone to the problem of global low noise. To avoid this problem, we adopt the image histogram method and perform parameter weighting operation based on this method, and the mathematical equation expression is shown in the following equation. Experiments prove that the method can effectively solve the problem of global low noise.

$$Eq = H'(CF(x, y)), \quad (4)$$

where H' represents the linear normalization operation, and the optimization of the researchers' line linear normalization in the literature [31] suggested that the local binary pattern behaves more stably in a fixed neighborhood window, and its principle of action is shown in Figure 2.

We also used the local duality mode operator as a basis, and the expression of its underlying mathematical equation is as follows.

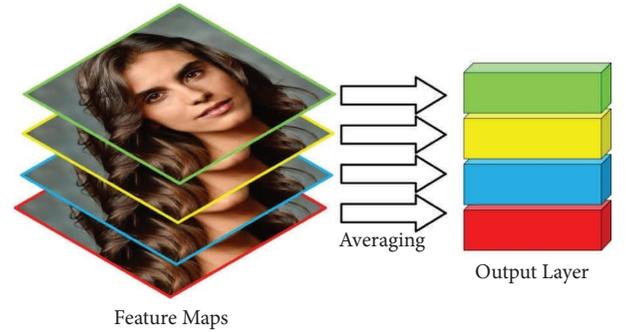

FIGURE 3: The global average pooling layer.

$$LBP_{p,r}(X_c, X_c) = \sum_{p=0}^{p-1} 2^p S(i_p - i_c), \quad (5)$$

where (X_c, Y_c) represents the threshold of the center of the face pixel, i_p and i_c represent the intensity of the neighboring pixels with the center pixel of the face as the dispersion point, and p represents the computed range of the center dispersion pixel with radius r .

3.3. Multistream Convolutional Neural Networks. Convolutional neural networks have high generalizability and robustness in image processing. In a face recognition system, the neural network model can give full play to its advantages of weight sharing and local connectivity. In the process of facial contour feature extraction and reorganization learning, the reconstruction of facial appearance pixel features can be avoided and the computational cost is reduced. As mentioned in the computer vision reconstruction, we used three depth cameras to reconstruct the computer vision scene and visually capture face features from different angles of the same horizontal plane. To echo the computer vision scene, the multistream convolutional neural network we adopted processes the facial features from different angles separately. All integrated features are separated according to biological categories, and the local detail features of the face are learned by convolution, then the number of feature map network parameters is reduced by connecting pooling layers, and the global average pooling is shown in Figure 3. Finally,

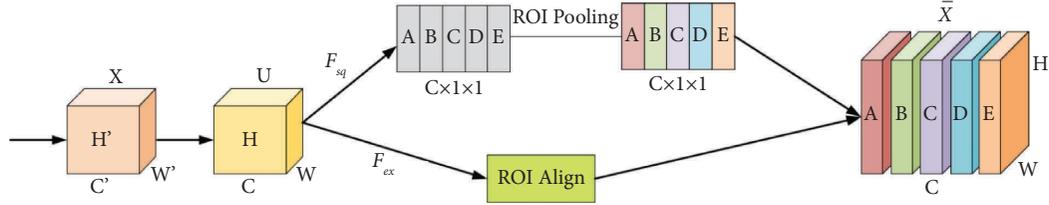

FIGURE 4: The reconstructed convolutional neural network architecture.

the global information is generated by connecting fully connected layers. We chose a nonlinear activation function to classify the output biological category feature mapping values.

The disadvantage of multistream convolutional neural networks is that the networks are too cumbersome when optimizing the spatial layout of a multistream convolutional neural network. Considering the fusion of local face features and channel features, referring to the SE architecture methods in the literature [32, 33], we compressed the multistream neural network by setting the excitation function in the mid network and resetting the parameters of all neural network layers at the end. Such a network architecture approach helps to establish inter-channel dependencies, improve the perceptual field, and suppress the facial features with low weight coefficients. Our convolutional neural network architecture is shown in Figure 4.

For multistream convolutional neural network compression, the face space depth features are the first input, and the face features are reset and encoded using global average pooling, which is represented in the mathematical equation as follows.

$$z_c = F_{sq}(u_c) = \frac{1}{H \times wW} \sum_{i=1}^H \sum_{j=1}^W u_c(i, j) z \in R^C, \quad (6)$$

where C represents its output feature map size, and H and W denote the height and width of the feature map at the pixel level. After the convolutional layer compression, the excitation function is added in the middle of the network, and we choose the sigmoid function as the excitation function. A gating mechanism is also added to the network to balance the mapping rate between channels.

$$S = F_{ex}(z, W) = \sigma(g(z, W)) = \sigma(W_2 ReLU(W_1, z)), \quad (7)$$

where $W_1 \in R^{C/r \times C}$, $W_2 \in R^{C/r \times C}$. In order to improve the robustness and generalization of the model, the following output can be obtained by matching the feature activation values with the original biometric feature library.

$$\bar{x}c = F_{scale}(u_c, s_c) = u_c \times s_c. \quad (8)$$

We also added two layers of bottleneck structure at the tail of the network, the first layer is composed of a fully connected layer, and we set the dimensionality reduction parameter as r . The second layer is composed of a ReLU activation layer, and each face RGB channel has the corresponding position and original input activation value. The multistream convolutional neural network face recognition process is shown in Figure 5.

4. Experiment

4.1. Setting. According to the project requirements, the digital face recognition system contains a computer vision unit, a deep convolutional neural network algorithm unit, a GPU accelerated computing unit, a data storage unit, and a PC control unit. In the computer vision unit construction, we use the stereo system architecture platform AVT Pike to assist face image and depth information acquisition, with cameras placed at 45 degrees and kept at the same level. Camera No. 1 is facing the face, and cameras No. 2 and No. 3 are spaced 45 degrees apart from camera No. 1. The interval between the cameras and the face is 1000 mm. The effective range of the three cameras acting together is 500 mm. We use IEEE_1394 firewire to connect the lenses of the three cameras to the central console. The details of the computer vision system build are shown in Figure 6. One of the deep convolutional neural network units uses TensorFlow as the base network framework, and the algorithm editing language is python. The face recognition model training platform is a NVIDIA Quadro P6000 graphics card, the computer memory is 64 GB, and the processor is Intel(R) Core(TM) i9-9900 K CPU@3.6 GHz x8. The network training process uses a hierarchical training model with layer-by-layer update iterations to optimize the training parameters.

4.2. Analysis of Face Area Weighting. To divide the face from a 3D level, we split the five senses in terms of facial region division, and we analyze the degree of biometric matching of the five senses of the face. According to the facial region association, in the experiment, we strictly control the light angle to obtain the facial five senses shading. Since multistream convolutional neural network feature learning is more biased toward light reflection and motion blur, the facial images are divided into three angles for shooting. To ensure the uncertainty caused by unstructured environmental factors in the image acquisition, we adopt iterative iterations to update the facial five senses feedback features during the training process.

From the experimental results in the above Table 1, it can be seen that in the facial recognition facial five senses partitioning experiments, the eyes occupy a larger proportion of the weight, and the recognition accuracy of the eyes is higher. The weight proportion of the mouth is second only to the eyes because the change of mouth shape will affect the overall configuration of the face contour. The other five senses occupy a smaller proportion and have little influence on facial recognition. In summary, it can be seen that face recognition accuracy is more closely related to the

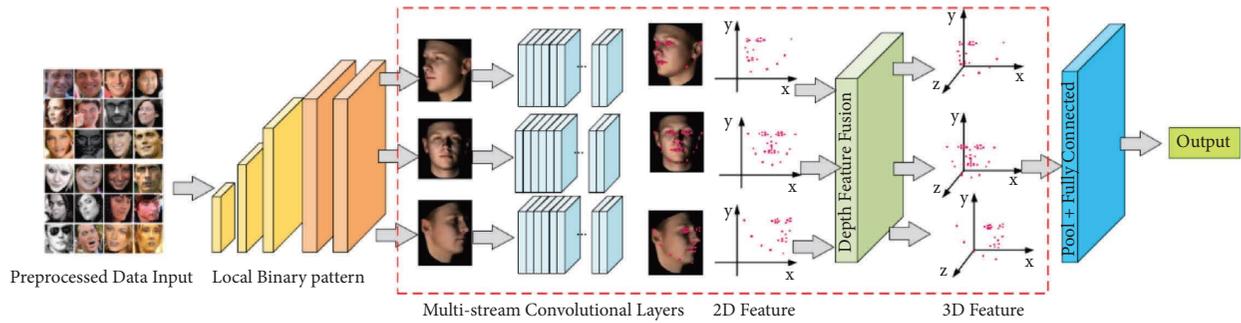

FIGURE 5: The multistream convolutional neural network face recognition process.

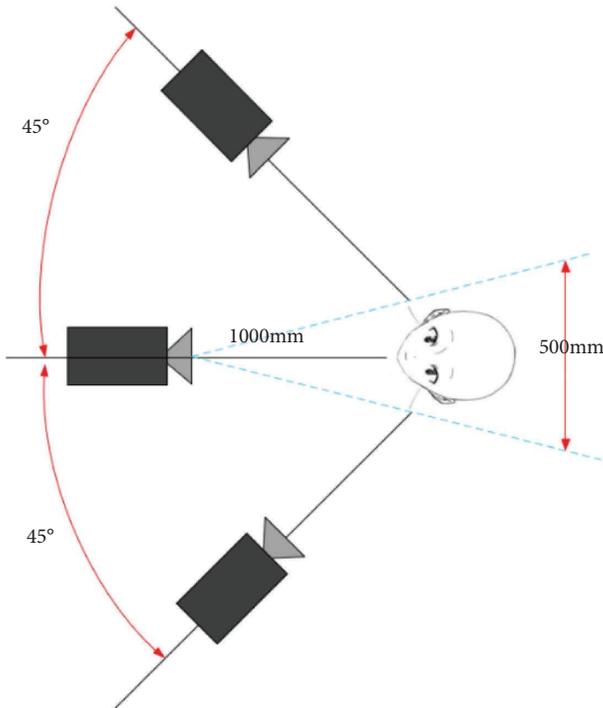

FIGURE 6: The computer vision system.

TABLE 1: The weighting of the five facial regions.

Area	Weight	Precision (%)
Eyebrow	0.89	98
Eyes	1.98	96
Nose	1.06	96
Mouth	1.61	95
Jaw	0.21	92

biological features of the eyes and mouth, and the post-training parameter adjustment of the neural network should take the five features with higher weights as the main reference factors.

4.3. Face Recognition Experiment Results. To verify the validity of the method, we first selected public datasets as the experimental validation set, and we chose PubFig: Public Figures Face Database, Large-scale CelebFaces

Attributes (CelebA) Dataset, and Colorferet as the base datasets. To maintain the suitability of the datasets to the face recognition model, we adopted the same preprocessing means for all the datasets. The preprocessing process is shown in Figure 7.

All datasets are grayscale images of 384×286 pixels at the input side for testing positive face angle correction. For RGB correction, all datasets were set to 384×286 pixel channel controllable images. The preprocessed output is stored in the format "FACE_XXXX.pgm." Details of the datasets are shown in Table 2.

In concurrent experiments, we conducted independent experimental tests on support vector machines (SVM) [34], local binary patterns (LBP) [35], and convolutional neural networks (CNN) [36]. To balance the variability between each method, we use a closed-form parameter adaptive correction method for each method and migrate to face recognition model training when the parameters reach the optimal state. The comparative experimental results of the various methods are shown in Table 3.

where A_{TP} denotes the recognition efficiency per 100 face samples. p denotes precision and R denotes recall. From the experimental results in Table 3 above, it can be seen that the SVM method produces a large number of misidentified samples in the face recognition dataset test, and the precision is only 77%. Compared with machine learning methods, deep learning methods perform better in face recognition, and convolutional neural network methods are more advantageous in the field of image recognition, with 92% accuracy. Our method incorporates a deep learning network and LBP algorithm framework and achieves 98% accuracy, which is better than other algorithms, thus showing that our method performs best in face recognition. To restore the influence of interaction between network layers, we also added independent network layer performance test experiments, and the experimental results are shown in Table 4.

From the experimental results in the above table, we can see that the multistream convolutional neural network we use has outstanding advantages in the layer-by-layer stacking experiments, and the best face recognition results are obtained when the multistream branch value is 4. After the multistream branch exceeds 4, the accuracy rate starts to decrease. In the final experiments, we also adopt the training scheme with a multistream branch of 4.

5. Conclusion

In this paper, to reduce the cost of human resource management and improve the efficiency of enterprise digital management, we propose a face recognition method based on multistream convolutional neural networks and local binary patterns and build a digital face recognition management system. We first build the system computer vision scene. Then a local binary mode facial expression feature extraction scheme is designed according to the depth camera image extraction method. Considering that face 3D features are easy to be missed, we build a multistream convolutional neural network to learn facial 3D features. Finally, we validate the effectiveness of the method in selecting a public face dataset. Experiments prove that our method can reach 98% face recognition accuracy, which is significantly better than other methods. Also, we proved the scientific efficient of multistream convolutional neural networks by ablation experiments.

Although our method performs well in terms of accuracy, the face recognition system is input to the embedded standalone system. The model implemented by our method requires high hardware facilities for the standalone system, which leads to the low stability of model fusion with the standalone system. In our later research, we will work on reducing the algorithm parameters, reducing the computational cost, and improving the compatibility of the algorithm with the standalone system.

With the rapid development of artificial intelligence, big data, blockchain, and other technologies, the impact of intelligent environment on the development of education has become more and more profound. Other developed countries have realized that education reform is urgent in the intelligent environment. So as to seize the major strategic opportunity of artificial intelligence development, my country has optimized the teaching content, teaching methods, and teaching methods of traditional piano teaching on the basis of respecting the traditional piano teaching concept. Upgrade to achieve the innovation of the relationship between teaching and learning in piano education in normal schools, and create a new situation for piano teaching in normal schools. Based on the current situation of piano education for musicology majors in normal schools, this paper takes the intelligent piano as the research object, compares the advantages and disadvantages of the application of smart pianos and traditional pianos in the environment of normal schools, combines the intelligent technology provided by smart pianos, and explores the application of technology to pianos in normal normal schools. The path of teaching reflects the value and use value of intelligent piano in piano teaching in normal schools and explores the value of intelligent piano teaching.

1. Introduction

The rapid development of information technology has promoted the development handle of educational informatization and the modernization of educational means. Taking the rapid development of the Internet as the horizontal axis, artificial intelligence, personal customization, and network communication as the vertical axis, the high and steady upward curve has been recognized by more researchers, and even mentioned the “fourth industrial revolution,” which is the “smart age.” Emerging technologies have penetrated all aspects of life, and have gradually occupied an irreplaceable position in the field of learning. Relying on the benefits brought by new science and technology and the Internet, whether teaching or receiving education will reduce the constraints brought by tradition and gradually become an intelligent education system. In the field of music education, intelligent teaching has also become the general trend [1–3]. In the traditional “one-to-one” teaching, teachers mainly impart knowledge to students in an oral way, and a good teacher-student relationship is built between students and teachers. Normal school students’

piano learning is mainly based on repertoire skills and is relatively lacking in autonomous learning and classified learning. At the same time, the demonstrations in the piano classes in normal schools are mainly based on the teacher’s personal demonstration, and the students learn the repertoire by imitating the teacher as the main learning method. In this way, although students can learn more intuitively about the teacher’s playing skills, they lack their own creativity. After graduation, the students trained under the piano education in normal schools are mainly faced with primary and secondary schools, which requires that the piano education and training in normal schools should meet the requirements of normal schools and meet the actual job needs of students. The rapid development of information technology in the 21st century has promoted the development of educational informatization and the modernization of educational means. With the gradual deepening of education reform, the piano education in normal schools has gradually shifted from “examination-oriented education” to “quality education,” which requires piano teaching in normal schools to reposition the teaching according to the new needs of cultivating compound music education talents

[4–6]. Therefore, the intelligent piano teaching in colleges and universities under the information technology came into being. It is a new type of teaching with more integration, interaction and creativity. It allows students to form a more comprehensive understanding of music art in the process of piano learning, the systematic acquisition of professional skills adapted to actual work needs [7].

How to speed up the strength and progress of the integration of piano teaching and information technology in normal schools has become an important research topic. Therefore, this paper will focus on the application of intelligent piano in colleges and universities supported by information technology, through in-depth analysis of the evolution of intelligent piano, comparison with traditional piano teaching, and its unique intelligent technology, so as to explore a new type of piano. The new piano course teaching mode provides a certain reference for the future intelligent piano teaching [8–10]. This paper mainly conducts a practical and theoretical exploration of the application of intelligent pianos supported by information technology in the piano classrooms of musicology majors and piano performances in normal high schools, hoping to arouse more musicians, learners, and researchers to the intelligent for the emphasis on the piano. It provides a reference for improving the autonomy, creativity, and practicality of piano learning in normal teachers. And by carrying out piano course teaching research, adding modern technology to the process of piano course teaching, optimizing the resources and teaching process of piano teaching in normal schools, providing a new idea and method for the reform of normal school education, and providing theories for the innovation research of piano education in normal schools' support.

2. Research Status of Intelligent Piano in Piano Teaching Methods at Home and abroad

In the foreign literature, I have only found two descriptions and researches on smart pianos, and there is no relevant research on the combination of smart pianos and music teaching in normal colleges. Among them, “IntelligentPianoAndSystem” analyzes the piano keyboard from the keys, the indicator module, the first data communication module, the key detection module, the MIDI data processing module, the MIDI synthesizer, the audio encoder, the audio amplifier, and the speaker, to show that the smart piano can be realized for the functions of personnel identification, correction, scoring, sound quality replacement, composition, etc., and heighten the efficiency of piano learning. Another article “Intelligent Tutor System For Piano Learning” introduces the invention of the “Piano Learning” intelligent tutor system, which is designed for the piano learners, especially for piano practice after class, and guides piano teachers to effectively teach through intelligent operation methods and processes, guide students how to heighten their piano skills more effectively through this system.

There has been some research on the application of smart pianos in piano education in Chinese normal schools. Relatively large part scholars have thought about the

feasibility of combining smart pianos with music education in normal schools from multitudinous perspectives and put forward some ideas at the same time. Chen pointed out that the emergence of smart pianos is caused by various aspects such as science and technology, human needs, and the market, and it is an inevitable combination of old and new. Whether its practicality, its own performance, or its influence and acceptance, it provides an important foundation for research and development. However, the emergence of new things must have a process that is well known to the public, as well as its own selling point compared with traditional pianos, and problems such as the inability of propaganda to accurately locate the target group make smart pianos unable to accurately impress consumers and market sentiment [11]. Yu and Peng believes that the smart piano is now a very important part of the learning field, and its proportion in the market is increasing year by year, which is attributed to him and his influence. Its own characteristic is to use new science and technology on the existing performance of traditional piano, reorganize some internal structures, update use functions, and at the same time integrate some successful scientific research results into it; rational use is a powerful addition to modern music education. One way [12]: Lian integration of science and technology into music teaching itself is a way to heighten autonomy, interactivity, and points of interest, which invisibly reduces a lot of resistance for students in the process of learning music again in a passive position. For him to break through the traditional teaching mode and adopt this kind of teaching mode with more resource integration ability, interaction ability with students, and individualized creativity ability, it is a reform plan for cultivating personalized, innovative, and technological talents in the 21st century music department. It is also the development direction of music education in the future [13]. Zhan and Wu are using questionnaires to conduct sampling surveys to understand the situation of piano teaching based on the quality development of college students in multitudinous regions. The piano teaching method has become an important part of the new quality education. The data shows that it has certain reference for future education and is worth further exploration. The research shows the current development direction of quality education in colleges and universities through this set of data, so as to view the problem in an all-round way and solve the problem in the rapidly advancing education [14].

In the related research on the implementation of children's music education using emerging technology as an investigation method, Mo and Li talked about the comparison between modern and past teaching models, and shortcomings such as knowledge structure lines no longer exist. Nonlinear network structure, diversification of presentation forms has become the characteristic of education in this era [15]. Wei pointed out that modern society is in the environment of the Internet and emerging technologies. The influence of technological development has penetrated into all aspects of study and life, and intelligent communication equipment has also made a significant contribution to this. The development of the smart piano and its introduction

into the market is also due to its own performance, which can bring more teaching benefits and more scientifically formulate a more suitable knowledge system for multitudinous student groups and higher practicability. It has been continuously studied as a direction, and explore Rauscher et al. [16]. In the related research on the use of emerging technologies as an investigation approach, Zhang proposed to make good use of the advantages and characteristics of Internet music software, and integrate it into the teaching of harmony in normal schools. This method makes better use of the accuracy of computers, is more convenient for students to learn, and maximizes the characteristics of harmony. At the same time, it integrates theory and teaching into teaching, and the teaching efficiency is significantly improved compared to before. It also broadens the thinking of students, increases creativity, makes teaching more intelligent and modern, and has a significant impact on my country's music education [17]. In the age of the Internet, Yan et al. have also combined piano teaching with it, using multitudinous educational cloud, database, and other approaches to research and explore the application scheme of cloud computing in the curriculum and constantly develop a form more suitable for modern education. Courses that are more suitable for students' age and comprehension ability enable educated people to better grasp knowledge, and the drawbacks of traditional teaching have been significantly improved [18]. *Tubo* is a piano concerto digital performance training system based on a set of computer music production tools and the ROM function of digital pianos. It is an orchestra software that develops and produces ten piano concertos. The live performance of the piano and the orchestra is an old performance mode, while the digital orchestra is to make the orchestra part of the piano concerto into audio through music production software and use it in students' daily practice, so as to strengthen the students' understanding of the piano concerto. The ability to perform in this genre helps students gain a more comprehensive understanding of the essence of Western music culture. The smart piano can be applied to the music education of the normal school with reference to the digital orchestra model of the concerto, as an auxiliary tool for the music learning of the normal school [19, 20].

To sum up, from the data I collected, there has been some research on the application of smart pianos in piano education in Chinese normal schools, but there is a lack of attempts to explore specific measures to achieve innovation in piano teaching in normal schools. Theory cannot be connected with practice and cannot really heighten the current situation of piano teaching in normal colleges. Therefore, the intelligent technology of intelligent piano is added, the teaching and learning modules are developed according to the characteristics of piano teaching in normal schools, the intelligent piano teaching in normal schools supported by information technology is established, and the implementation is carried out to improve the current situation of slack in music education in normal schools; make full use of the school. The existing intelligent piano equipment and the hardware facilities to be improved will provide theoretical support for building a modern platform

for piano teaching innovation in normal colleges, which is the important research purpose and significance of this paper.

3. Research on Functional Modules of “Smart Piano”

The “smart piano” system has rich learning resources, and its huge resource library provides a reliable guarantee for the “smart piano” teaching activities. The resource library can provide information technology support for teachers to formulate teaching plans and teaching plans. At the same time, students need to use the information in the resource library for after-class preview, practice, review, and assessment [21, 22]. As shown in Figure 1, the resource library expands on the basis of traditional piano teaching materials, digitizes music scores, teaching materials, and articles, and provides information retrieval functions for students and teachers to facilitate teachers and students to access resources.

3.1. Recognition of Playing, Practice with Lights, Intelligent Error Correction. In the existing teaching system, intelligence and multimedia have become very common. Not only has multimedia teaching been widely used in primary and secondary school classrooms, but also in music colleges, teaching and information technology are generally integrated, which is a kind of sublimation from blackboard to whiteboard for the development of education [23–25]. Teachers need to improve the traditional teaching methods in piano courses, keep pace with the times, and make full use of the Internet and “smart piano” terminals to make up for relatively large part defects in traditional teaching. In the past, the piano course was one-on-one teaching with teachers and students, and then students practiced for a week after class. This handle was repeated until the work was completed. For students in higher normal schools, this method is inefficient, and there are not enough teacher resources to realize the whole handle of traditional teaching. Therefore, using the “smart piano” system can solve the problem of teachers, and at the same time improve the fun and efficiency of learning, reduce the learning pressure of piano courses, free up more time for the learning of other courses, and effectively improve the comprehensive quality of students. The core of the “smart piano” is the teaching guidance module, which is divided into two parts: computer guidance and teacher guidance. Among them, computer guidance is the advantage of “smart piano” over traditional teaching methods. The “intelligent piano” connects teachers and students with the network, completes human-computer interaction at the same time, and completes teaching and learning under the dual action of computer and network.

The “smart piano” presents the electronic music score to the students through the display screen. In the initial learning stage, the students can play the audio of the work first, and mark the progress of the audio on the music score in real time, so that students with weak notation ability can follow the music mentally. By listening to the music scores, students have a preliminary and overall understanding of the

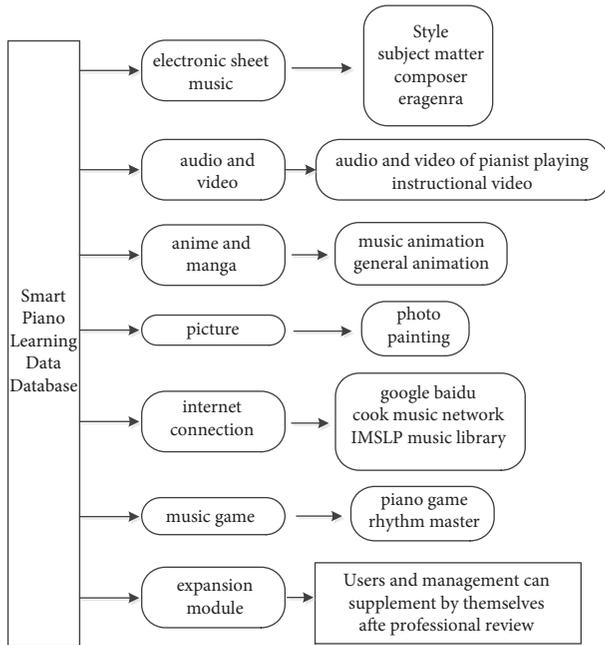

FIGURE 1: Expansion diagram of intelligent piano learning data.

work. Students can adjust the playback speed according to their own abilities and habits, and listen to the individual stages of the work repeatedly.

3.2. Gradient Teaching Method. The gradient teaching module is designed to evaluate students' learning progress and performance level, then provide guidance for the formulation of learning plans, match students data with individual models, and provide students with appropriate learning content based on their learning needs, as shown in Figure 2 shown.

3.2.1. Primary Assessment. When students use the "smart piano" for the first time to learn, they need to test and evaluate their actual performance ability and music knowledge. Students with a good foundation can directly choose the difficulty of the test, judge the performance level through the computer's evaluation of speed, accuracy, and artistic processing, and finally formulate a corresponding learning plan according to the performance level. Students with poor or zero foundation can skip the test and just fill in the questionnaire, input their preferences and expected learning progress to the computer, and then the computer will directly formulate a learning plan based on the data model.

3.2.2. Intermediate Assessment. The purpose of the intermediate assessment is to investigate the students' learning status and to test the students' learning progress and learning stage achievements, so as to fill in the gaps and prepare for future learning. The intermediate assessment consists of three parts, one of which is self-assessment. The self-evaluation system aims to improve students' self-

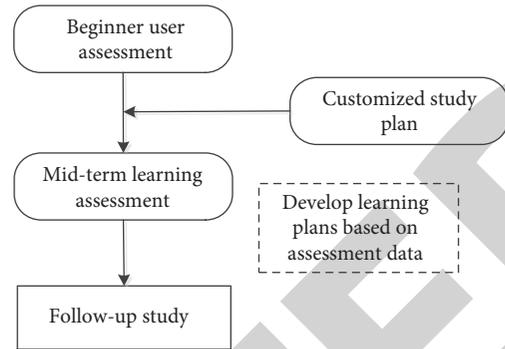

FIGURE 2: Gradient teaching flow chart.

learning ability, so that they can have a clear understanding of their own level, and can accurately guide their students when they go to teaching positions in the future. Self-evaluation includes self-satisfaction, scores, and learning difficulties. The second is computer evaluation. The computer scores the basic elements of performance according to the sensor data and makes a preliminary judgment on the students' performance level. The third is teacher evaluation and student mutual evaluation. Students upload their performance videos to the Smart Piano cloud platform, and teachers and classmates will score and fill in relevant comments. Finally, the computer comprehensively evaluates the three parts to give concrete results.

3.2.3. Study Schedule. The computer formulates a corresponding learning progress table according to the data filled in by the individual and the test results, which mainly includes two elements, one is the student's performance level, and the other is the student's artistic accomplishment and repertoire preference. The performance level data is obtained from the combination of the computer's primary assessment and the teacher's assessment. According to the final score, the difficulty matching repertoire is selected as the learning target. Learn step by step towards deeper levels of difficulty. The data on artistic accomplishment and repertoire preferences are obtained from questionnaires filled out by the students, and corresponding questions will be arranged in the questionnaires. At the same time, according to the data mining of the search engine, the computer will summarize the students' preferences. Finally, based on the above information, a learning schedule is formulated.

4. Analysis of the Functional Modules of Intelligent Piano in Piano Teaching in Normal Schools

4.1. Intelligent Piano Solo Teaching. The teaching process using the smart piano as a platform is mainly divided into three stages, namely, self-study, online guidance, and face-to-face teaching. The sixth week is face-to-face with teachers. The computer adjusts the teaching progress in real time according to the learning situation and detection data and gives full play to the teaching advantages of the intelligent piano.

4.1.1. Learning Points and Difficulties. Preliminarily master the style and characteristics of the work, understand the writing background of the work, accurately play the notes and musical terms in the work, and complete the basic elements of music, especially pitch, dynamics, and fingering. At the same time, combining network and multimedia means in piano teaching to assist students in learning music-related knowledge, improve students' artistic accomplishment in an all-round way, deepen their understanding of music works, and cultivate more sensitive hearing. Solo works are often difficult to perform, and works of different composers and styles need to be played with relative skills. Therefore, mastering scientific and reasonable practice methods and overcoming difficulties in performance skills is the top priority.

4.1.2. Self-Study Stage. After the teacher assigns the task, the students first watch the relevant performance videos and asynchronous online classes, and read the relevant text materials. In this way, we can understand the relevant background information of the work and have a preliminary understanding of the overall overview of the work. Then, under the guidance of electronic scores and computers, students will be familiar with the fingerings and notes of the works by performing reading and primary exercises. For the more difficult skills in the works, such as fast running, interval jumping, and two-tone running, first try to practice at a slow speed by yourself to explore the tricks of playing. If it cannot be solved, the online class or face-to-face class will be guided by the teacher. When it can be played completely, the qualification rate of basic musical elements such as pitch and rhythm is detected by the computer. Then adjust the study plan and guide students to practice in a targeted manner.

4.1.3. Online and Face-to-Face Teaching. In online classes and face-to-face classes, teachers first listen to students' complete performances of the whole piece, and explain the performance methods and practice methods of difficult skills in the class, and at the same time teach students how to understand music and process works. After the teacher's guidance, the students perform the whole song completely, and the computer and the teacher jointly give a comprehensive score to test the learning results. The computer stores the comprehensive score in a database for use in subsequent study planning.

4.2. Analysis of Intelligent Piano Teaching Design. The teaching handle using the smart piano as a platform is mainly divided into three stages, namely, self-study, online guidance, and face-to-face teaching. The sixth week is face-to-face with teachers. The computer adjusts the teaching progress in real time according to the learning situation and detection data and gives full play to the teaching advantages of the intelligent piano. As a graduate student of a normal university, I have been allowed to carry out teaching practice in the school, and the practice object is the first-year

undergraduate students of the school. I have verified whether it is feasible to apply the intelligent piano to the piano teaching of the normal school.

Design 1: The traditional piano is integrated into the teaching of intelligent piano, and the piano solo is used as a teaching case. According to the comparison between the intelligent feedback of the smart piano and the feedback of the artificial teacher as the experimental data, the experiment is a six-week system teaching cycle of the smart piano, and the feedback of the artificial teacher to make a summary and analysis of the progress and quality of the course. The first and second weeks take the form of intelligent piano group lessons, the third and fourth weeks take the form of intelligent piano individual lessons, and the fifth and sixth weeks take the form of traditional piano individual lessons. The teaching selects "Chopin's Ballade in G Minor" as the case repertoire. Starting from the first week, various aspects of teaching are gradually carried out. Based on the students' adaptability, basic piano skills, and the playing complexity of "Chopin's Ballade in G Minor" as the premise, the teaching will be carried out. The process adopts the normal step-by-step and complementary teaching methods, analyzes the students' weekly feedback and draws conclusions, and finally evaluates the students' completion, thus reflecting the advantages of the new intelligent teaching model, as shown in Table 1.

Design 2: Taking piano solo teaching as an example, the religion arrangement is carried out in the form of traditional piano individual lessons. Six weeks are used as a systematic religion cycle. Based on the combination of the artificial teacher feedback and the intelligent feedback of the smart piano in the sixth week as the experimental tracking data, the weekly class situation is summarized and analyzed. Weeks 1 to 6 take traditional piano individual lessons. Taking the example of "Chopin's Ballade in G Minor" as a case, the religion is carried out from the first week to the sixth week, and the combination of students' acceptance ability, basic piano ability, and the difficulty level of "Chopin's Ballade in G Minor" is as follows: in the light of the data obtained from students' feedback every week, the students' completion degree is finally checked, as shown in Table 2.

Through design analysis and comparison with the same religion content, different class forms and religion methods, from the data of teaching practice and the data and feedback of the summary table, a new teaching mode was adopted in the six-week class schedule. This is a piano religion mode of "main + assistant," "human + instrument," and "complementary." This approach further mobilizes the enthusiasm of students and increases their participation in the classroom. It combines the religion advantages of artificial intelligence and intelligence to make up for the shortcomings of traditional piano religion. This "human + device," "complementary," and "remote" piano religion mode is more able to

TABLE 1: The combination of intelligent piano and traditional piano teaching-take Chopin's Ballade in G Minor as an example.

Teaching time (week)	Class form	Teaching content	Teaching method	Student recognition	Teaching feedback	Student completion
First	Intelligent piano group class	Creative background	(1) Play the original audio (2) Introduce the creative background (3) Introduce the content of the track	Excellent	Have an intuitive perception of the work	85%
Second	Intelligent piano group class	Music analysis	(1) Form analysis (2) Thematic analysis (3) Harmonic gaps to familiarize students with	Generally	Raise awareness and performance with smart media	75%
Third	Intelligent piano individual lessons	Melody and rhythm	(1) Play recording intelligent error correction melody (2) Intelligent error correction rhythm (3) Analyze the cause of the problem	Excellent	Novel teaching methods improved melody and rhythm problems	90%
Fourth	Intelligent piano individual lessons	Emoticons	(1) Play the recording, (2) Add emoji to playing	Generally	More mechanized and Constrains musical performance	65%
Fifth	Intelligent piano individual lessons	Performance skills	(1) Point out repertoire skills (2) Preliminary practice	Excellent	Into the teaching of performance skills is more efficient	90%
Sixth	Traditional piano individual lessons	Performance skills	(1) Point out repertoire skills (2) Track summary	Excellent	Improves the ability of works and the delicacy of performance	90%

TABLE 2: Traditional piano solo teaching-take Chopin's Ballade in G Minor as an example.

Teaching time (week)	Class form	Teaching content	Teaching method	Student recognition	Teaching feedback	Student completion
First	Traditional piano individual lessons	Creative Background	(1) The teacher plays the selected excerpts (2) Oral introduction of the creative background and the connotation of the repertoire	Bad	The impression of the work is limited and forgotten quickly	55%
Second	Traditional piano individual lessons	Music analysis	(1) Form analysis (2) Thematic analysis (3) Harmonic gaps to familiarize students with	Bad	Inconvenient in instructional media	55%
Third	Traditional piano individual lessons	Melody and rhythm	(1) Play the recorded manual error correction melody (2) Manual error correction rhythm (3) Analyze the cause of the problem	Good	Novel teaching methods improved melody and rhythm problems	80%
Fourth	Traditional piano individual lessons	Emoticons	(1) Play the recording, (2) Add emoji to playing	Generally	Constrains students' imagination and expressiveness of music	65%
Fifth	Traditional piano individual lessons	Performance skills	(1) Point out repertoire skills (2) Preliminary practice	Generally	Playing skills are less affected by preteaching	70%
Sixth	Traditional piano individual lessons	Performance skills	(1) Point out repertoire skills (2) Track summary	Generally	Playing skills are less affected by preteaching	70%

mobilize the enthusiasm of students. The percentage of students' completion in this religion mode reaches 90%, while the traditional religion method reaches only 70%. The emergence of this model is an attempt to update the religion concept in the light of the inheritance of the traditional religion model, combined with the intelligent technology of the smart piano.

5. Conclusion and Outlook

5.1. Summary. Comparing different class forms and teaching methods, it can be seen that the teaching mode combining intelligent piano and traditional piano teaching has certain feasibility and promotion. Existing piano teaching can try to add "smart piano" teaching into it. The piano lessons under the "smart piano" application adopt two types of lessons: individual lessons and group lessons, and the combination of traditional individual lessons is no longer mechanized and simplified. This new teaching form mainly relies on intelligent technology. Through intelligent technology, the knowledge that needs to be taught to students in the form of oral and text can be taught to students with pictures and audio. This mode is more intuitive and can mobilize students. The facial features meet the students' auditory and visual requirements. Compared with the traditional teaching mode, this has stricter requirements on students' learning quality, broadens the path for students to acquire knowledge, and improves teaching efficiency and quality.

5.2. Prospect. The piano teaching mode of "human+instrument." The "person" here refers specifically to the teachers and students participating in the music class. Since the piano major itself has its own particularity, it is an active output and an active acceptance of such a teaching method. In the classroom, teachers need to use methods such as playing demonstrations, music appreciation, and verbal communication to help students heighten their professional abilities from the perspective of creative background, music analysis, and performance skills. "Device" refers to the use of smart pianos in the classroom. It has functions such as intelligent recognition of rhythm and pitch, switching between multiple versions of smart scores, audio, and video, etc., which undoubtedly provides practical teaching for the improvement of teaching quality.

The diminishing natural sand has facilitated the booming of the sand manufacturing industry, and intelligent management of sand factories, in a time- and cost-efficient way, has become a growing tendency for the future. A role has been played in achieving intelligent management by constructing a smart supply chain. However, the smart sand factories are hardly involved in previously reported studies, which is inconsistent with related studies on smart factories and the Industrial Internet of Things (IIoT). In this paper, a smart supply chain management system (SSCMS) is constructed to realize the intelligence and automatization of the management of sand factories, using edge-computing and deep learning techniques. Along the supply chain, the deep learning model is used to realize the automatic identification of sand, avoiding the disadvantages of human identification, while improving the quality of sand factory operations. In order to relieve the pressure of network bandwidth, reduce system delay, and improve system operation efficiency, we use edge-computing technology to process data at the edge. To verify the performance of the constructed system, a sand factory simulation platform is established. Experiments show that the most critical indicator in the system, the accuracy rate of sand type identification, is above 98%, and the sand type identification time is only 0.022 s. In general, compared with traditional supply chain management, the constructed smart supply chain improves the quality and efficiency of sand factory operations, and all indicators of the designed system have achieved satisfactory results.

1. Introduction

Sand and aggregate are the largest, irreplaceable, and indispensable material for infrastructure construction, and it is closely related to the survival and development of human. Sand and aggregate account for 60% to 75% of the volume of concrete, and it is the main component of concrete. Therefore, human needs to consume tens of billions of sand and aggregate to build and transform the world every year. Sand commonly can be divided into natural sand and machine-made sand. Natural sand refers to naturally occurring sand, artificially mined with a particle size of less than 5 mm. Machine-made sand is the finished product processed through multiple processes using the sand-

making machine. The characteristics of machine-made sand are that the finished product has good granularity. Moreover, various specifications of sand can be produced according to different material requirements during the manufacturing process. As the exploitation of natural sand resources continues, the natural sand resources that can be exploited are gradually decreasing. The reduction of exploitable natural sand resources has promoted the vigorous development of the sand-making industry, and therefore the number of sand-making factories has gradually increased.

The Internet of Things (IoT) is an intelligent network. It makes all devices connected to the network, and related communication is carried out through the network [1]. After the concept of IoT was proposed, scholars started to use IoT

technology in different fields. Concepts such as smart medical healthcare [2, 3], smart buildings [4, 5], smart grid [6, 7], and smart transportation [8, 9] have begun to be proposed. The Industrial Internet of Things (IIoT) means the use of IoT technology in the industry, which makes industrial manufacturing intelligent [10, 11]. The development of IoT technology will undoubtedly make life smarter in the future.

With the improvement of computer computing power, deep learning has become popular. Deep learning is the process by which computers learn associations between known data and eventually process unknown data as intelligently as humans do [12]. Recently, more and more research has introduced deep learning technology to the IoT [13, 14]. Generally, the use of deep learning to process data requires computers with high-performance computing capabilities. Therefore, many researchers transfer data collected by edge devices to cloud servers with large computation power for processing [15]. However, this method has certain drawbacks. On the one hand, the increasing number of IoT devices will lead to an increasing amount of data being generated. If all the data generated by IoT devices at the edge were to be transmitted to cloud servers for processing, this would be a huge challenge for network bandwidth. On the other hand, the transmission of data will inevitably cause some delay, which is very unfriendly to applications that need to react in real-time.

Edge computing is defined as the processing of data on the side close to the source of generation [16]. The inclusion of edge computing in the IoT can solve the problem of network congestion caused by massive data transmission [17]. Edge computing becomes especially important when deep learning models are used in IoT devices to process data [18].

Field Programmable Gate Array (FPGA) is a typical parallel computing chip featured by the fast celerity, high stability, robust flexibility of computing properties. In contrast to the traditional algorithm, the computing speed of FPGA has increased by dozens, even hundreds of times while with power dissipation and economic cost declined comparatively [19]. FPGA has become popular in the field of deep learning due to its fast parallel computing characteristics [20]. Recently, it has become common to deploy FPGA in data centers [21], but it is an innovative research direction to use FPGA to accelerate programs in IoT. And there is no relevant research involved in deploying FPGA to the edge. But this is an exciting study because deploying FPGA to the edge can achieve more ideal real-time performance, which is good news for applications that require real-time response.

The supply chain is a functional network chain structure, which takes the enterprise as the core, uses raw materials to make final products, and finally delivers the products to consumers through the sales network [22]. Sand-making factories play the roles of suppliers, manufacturers, warehouses, and distribution centers in the supply chain. Building an intelligent supply chain is the key to achieving intelligent management of sand factory. At present, the management of the sand factory is still in the artificial management stage, and traditional supply chain technology

is still used in the management process, which inevitably has the following problems:

- (1) Most sand factories are still in the traditional mode of operation. Mechanical processing of sand, sand weighing, sand type identification, vehicle access management, and charging management all require a lot of human resources. Therefore, the labor cost of the sand factory accounts for a large proportion of the operating cost of the sand factory.
- (2) Scattered distribution of sand resources and long distances between different sand factories. Managers need to spend a huge amount of time and effort to manage multiple sand factories.
- (3) The sale of sand is the direct economic income source of the sand factory, and the unit price of different sand types is different. At present, when the sand factory sells the sand, the identification of the sand type is carried out by manual identification, which will inevitably cause problems such as errors in the identification of the sand type and corruption. These problems will directly lead to the loss of the benefits of the sand factory.
- (4) The sand factory has a large number of large-heavy industrial vehicles and equipment operating in the sand factory. Therefore, there are potential mechanical hazards that may cause construction accidents. It will increase the risk of personnel disputes and accidents.

As Industry 4.0 evolves [23], IoT technologies are commonly used in the industry. And the proposed concept of Industry 4.0 has driven the development of smart supply chains [24]. Smart supply chain is an intelligent technology and management system built within the enterprise, integrating IoT technology with modern supply chain management theories, methods, and technologies [25]. How to construct the smart supply chain is a hot topic [26, 27], and the introduction of smart supply chain technology in sand factories can promote the realization of intelligent management of sand factories.

Aiming at the existing problems in the sand factory, we used edge-computing and deep learning technology to construct a smart supply chain management system (SSCMS) for the sand factory to realize the intelligence and automation of the sand factory management. In the system, we use the deep learning model to realize the automatic identification of sand types and use edge computing to deploy the model to the edge. At the edge, we have also innovatively added the FPGA to accelerate deep learning models. The use of edge servers and the FPGA can effectively alleviate network congestion, reduce communication delay, and decrease the burden on the cloud server. The overall performance of the system has been significantly improved.

The proposed work has the following contributions:

- (1) Combining cloud computing, IoT, edge computing, deep learning, FPGA technology, and modern supply chain management theories and methods to

design a SSCMS for sand factories. The system can realize the intelligence and automation of sand factory management. It is specifically manifested in intelligent identification of sand loading vehicles, intelligent identification of sand types, automatic weighing of sand weight, cloud deduction of fees, and cloud management of sand factories.

- (2) Identifying sand by deep learning approach relies on several dataset, but there are no publicly available relevant data sets. To achieve accurate sand identification, we collected a large number of pictures of different sand types and created our data set for sand identification.
- (3) To deploy the sand recognition model to the edge, we propose an edge-based convolutional neural networks (CNN) model. Since the computation power of edge-computing nodes is far inferior to cloud servers, we optimized the parameters of the CNN model. The models deployed to the edge can reduce the amount of required computation while maintaining high recognition accuracy.
- (4) We innovatively propose deploying FPGA at the edge to accelerate deep learning models. The use of FPGA reduces the processing delay of the system. And this study is innovative and there are no related studies on this subject.
- (5) A microsand factory simulation platform is designed. The platform is used to simulate the operation process of a real-life sand factory. This simulation platform allows us to verify the performance of our designed SSCMS. We evaluate our method by experiments. The results show that our designed system realizes the intelligent management of the sand factory, and all indicators have achieved satisfactory results.

The rest of this paper is presented below. In Section 2, we describe in detail the basic architecture of the system being constructed. In Section 3, we present the design of the proposed edge-based CNN model for sand identification and analyze the model. In Section 4, we introduce the setup of the simulation platform and conduct experiments. Finally, we conclude in Section 5.

2. System Design

In this section, we mainly present the system architecture and workflow of the SSCMS. The architecture is mainly consisted of five parts, that is, sand factory gate system, license plate recognition system, weighing system, sand recognition system, and cloud platform management system, as shown in Figure 1.

Since sand resources are scattered, sand factories will have divisions in different locations. There are several IoT devices in each division. If the data generated by IoT devices in the factory of all divisions are transmitted to the cloud server for processing, the processing procedure will require a very large network bandwidth and cloud computation

ability. The transmission of large amounts of data also impacts the transmission of control signals in the system.

Edge computing allows the processing of data on the side closer to data sources. We have deployed edge servers in each division of the sand factory, and the edge servers in different divisions process the data generated by IoT devices in their respective divisions. The edge server only needs to send the processed results back to the cloud server. Thus, it greatly reduces data transmission and improves system performance.

A complete sand purchase process is shown in Figure 2.

First, when the sand-purchasing vehicle enters the sand factory, the license plate recognition system activates the camera to capture the license plate picture and transmits the recognized license plate number as the user's ID to the edge server.

The gate system is opened, and then the sand-purchasing vehicle enters the sand identification weighing area, the system will count the weight of the empty vehicle and transmit the weight information back to the edge server. After obtaining the weight information, the edge server will associate the empty vehicle weight with the user information. After the weighing is completed, the sand-purchasing vehicle drives to the sand loading area. Then, the sand is loaded through the automatic device.

Then the sand identification weighing area is entered again, and at this time, the sand recognition system, weighing system, and license plate identification system will operate simultaneously. The sand recognition system identifies and uploads the type of sand purchased. The weighing system measures and uploads the weight information of the sand-purchasing vehicle. The license plate recognition system identifies and uploads the vehicle's identity information. The edge server will associate the uploaded sand type information, sand weight information, and user information.

Finally, by using the empty weight of the sand-purchasing vehicle, the loaded weight of the sand-purchasing vehicle and the type of sand, the cost of this sand purchase is calculated. If the user's balance of the account is sufficient, the edge server can automatically deduct the fee for the corresponding user. After the deduction is successful, the gate system opens and the sand-purchasing vehicle can leave the sand factory.

2.1. Cloud Platform Management System. The web interface of the cloud platform is developed by XOJO software. XOJO is a cross-platform programming language and visual development interface development tool. Compared with other tools, it supports cross-platform development and can develop multiplatform applications. Through cross-compilation, you can develop Linux system and Mac OS X system applications on Windows system. In addition, you can also develop multiple types of platform programs on the same system, such as desktop applications, network programs, console programs, and iOS mobile platforms. The web interfaces development of the cloud platform uses the development function of its network program. The cloud

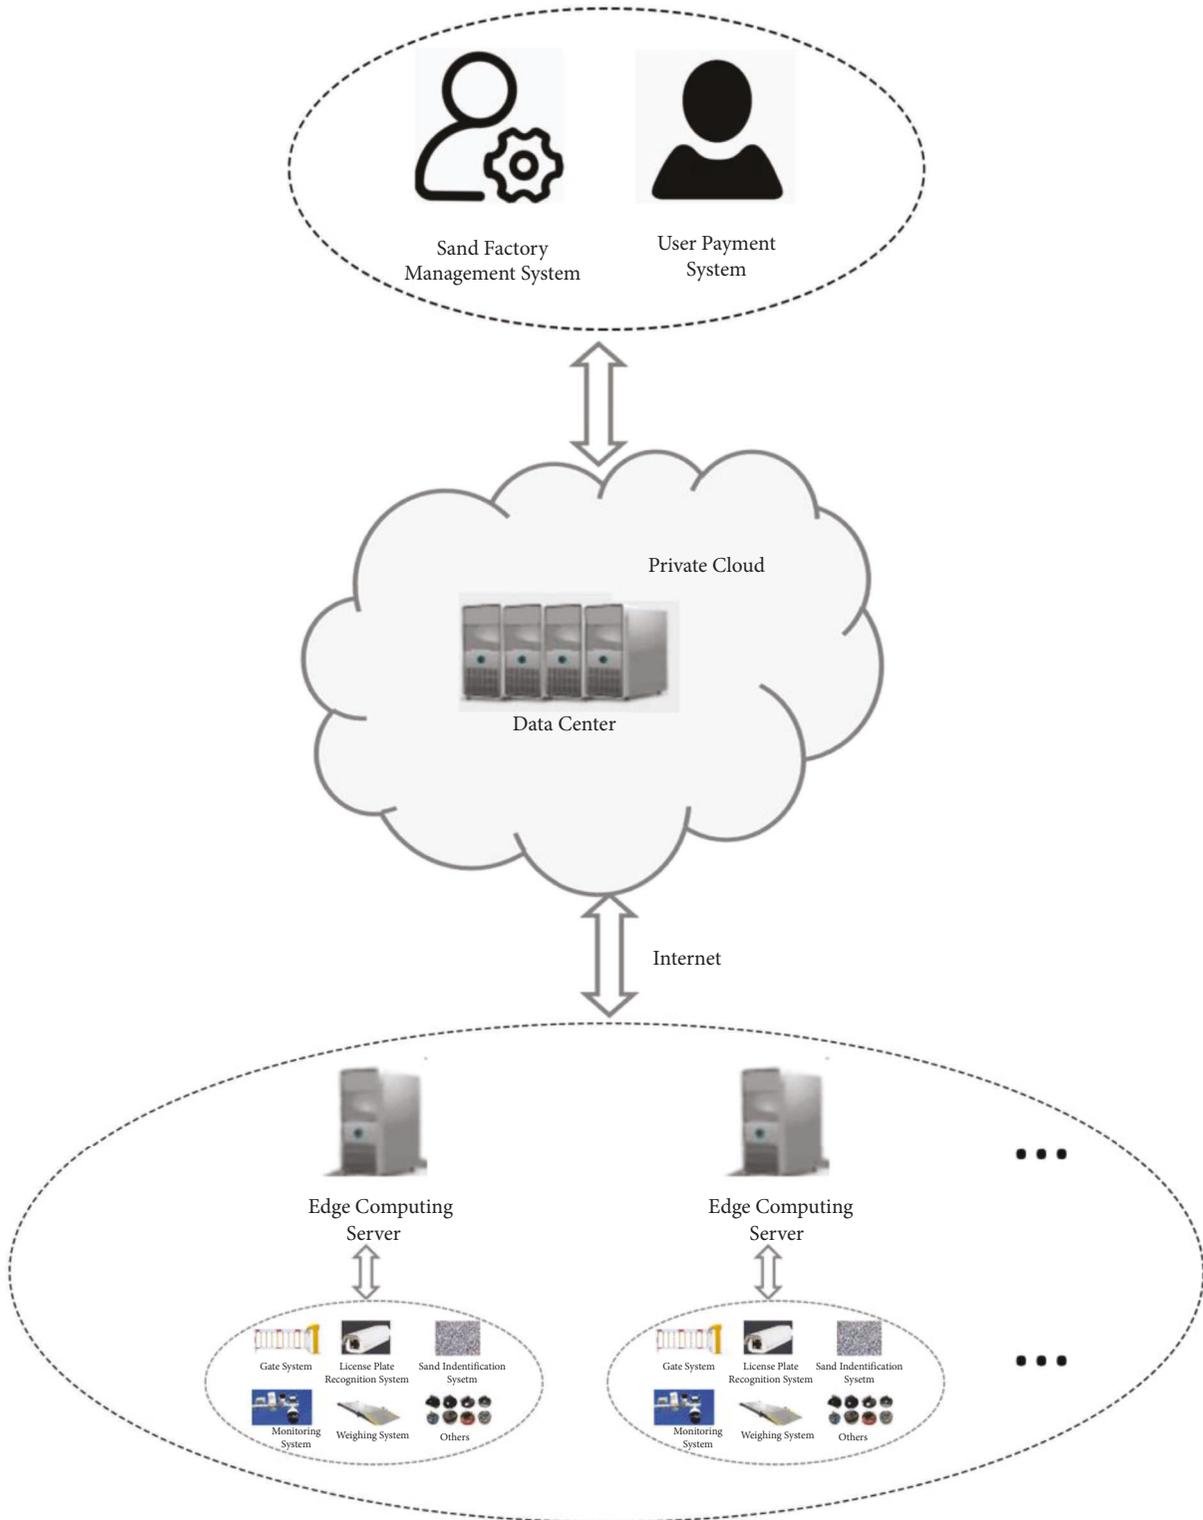

FIGURE 1: The system architecture of SSCMS.

platform is developed using the B/S architecture, with the client browser as the main application. This approach avoids the need for various applications on the client-side and concentrates on the core part of the system functionality implementation on the server. This approach simplifies the development, maintenance, and use of the system.

Only one browser is required to be installed on the client of this system. The edge server installs the MYSQL database and the executable program used on the edge side. They communicate with XOJO and are finally deployed on the web page and pushed to the client. This design makes the client application not restricted by the user's system

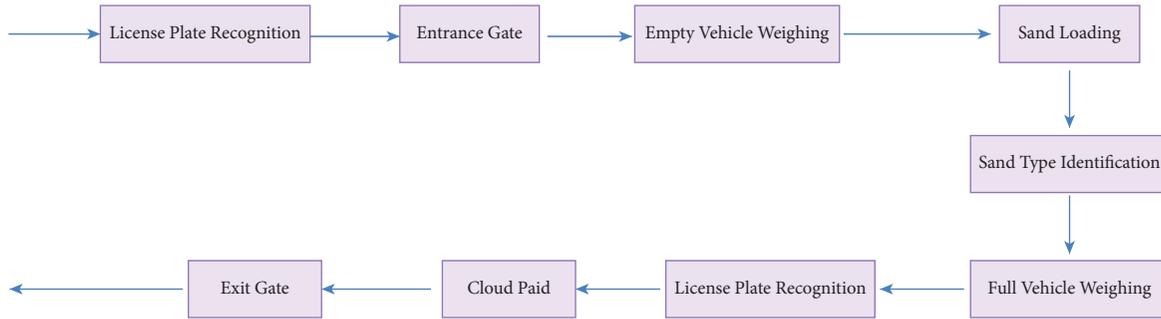

FIGURE 2: Sand purchase process.

platform and can be expanded on the mobile platform. Some algorithms with a relatively small amount of calculation and some database operation management can be implemented on the XOJO platform, but for algorithms with a relatively large amount of calculation, such as deep learning programs, it is necessary to use the program on the edge side to accelerate the network, that is, the program is placed in the server and it runs in the background. The cloud platform framework is shown in Figure 3.

Different from XOJO's network program, the edge-side program is not executed on the network channel but resides on the server-side in the form of an executable program group. The user sends a message through the browser, parses it through the XOJO web platform, and transmits it to the corresponding executable program. Once the program responds to this command, the client receives the corresponding result via the Internet. The platform is heterogeneity because the executable program on the edge side can be generated by any programming language, such as VS.net, Python, and MATLAB. At the same time, we designed to provide unified standard interface parameters to form an Algorithms Kernel module. Using this method, multiple developers can use different development tools to simultaneously develop programs in different programming languages, and the executable program group only needs to interact with XOJO in the end. This approach greatly shortens the development cycle of the entire cloud platform.

For some time-consuming algorithms, such as deep learning models, to ensure that the entire IoT system achieves an instant response, we use a combination of GPU + FPGA to accelerate the algorithm. FPGA is directly connected to the edge server and interacts with XOJO.

The cloud platform web interface includes the sand factory management interface and the user payment interface.

The web interface of sand factory management is designed to facilitate sand factory administrators to monitor the data of the sand factory at any time. It contains site operation, entering and exiting vehicles, the amount of sand sold on that day, the total amount of sand resources remaining on that day, the turnover of the sand factory, etc. The cloud platform web interface is shown in Figure 4 (the content in the colored area is for supplementary explanation). The administrator interface mainly includes four aspects: IoT system management,

private cloud database management, user information management, and sand factory resource management. Among them, the IoT management system can manage all the IoT modules and also can view the operation of each module in real-time to achieve real-time monitoring. The database management systems can be used to check data in real-time. The user information management system can add or delete users and recharge the corresponding one. The sand factory resource management system can set the unit price of different sands, query the flow records of the sand factory, and export relevant data for verification.

The web interface of the user payment cloud platform is to provide sand factory clients with a convenient and fast way to purchase. The user payment cloud platform provides users with the option to reserve in advance the type of sand they need to purchase, the weight of the sand, and the time for arriving at the sand factory to load the sand. After the reservation is completed, the sand-purchasing vehicle can enter the sand factory for sand loading within the corresponding time. Moreover, users can also check their purchase records as well as their bill history.

2.2. License Plate Recognition System. The role of the license plate recognition system is to obtain the identification information of the sand-purchasing vehicle. In a complete sand purchase process, the sand-purchasing vehicle needs to be identified twice. The first plate recognition is to record the vehicle information of the sand-purchasing vehicle when it enters the sand factory. A second plate recognition and a second vehicle weighing are carried out when the sand-purchasing vehicle is loaded with sand. The purpose of this license plate recognition is to correlate the sand-purchasing vehicle information, the sand purchase type, and the sand-purchasing vehicle load information.

License plate recognition system mainly adopts the technology of image processing and deep learning. The procedure can be divided into three steps, namely, image preprocessing, license plate detection, and license plate recognition. The first step is to preprocess the captured images, followed by license plate localization, and character segmentation. The license plate recognition system is directly deployed on the edge server-side with reference to existing research [28].

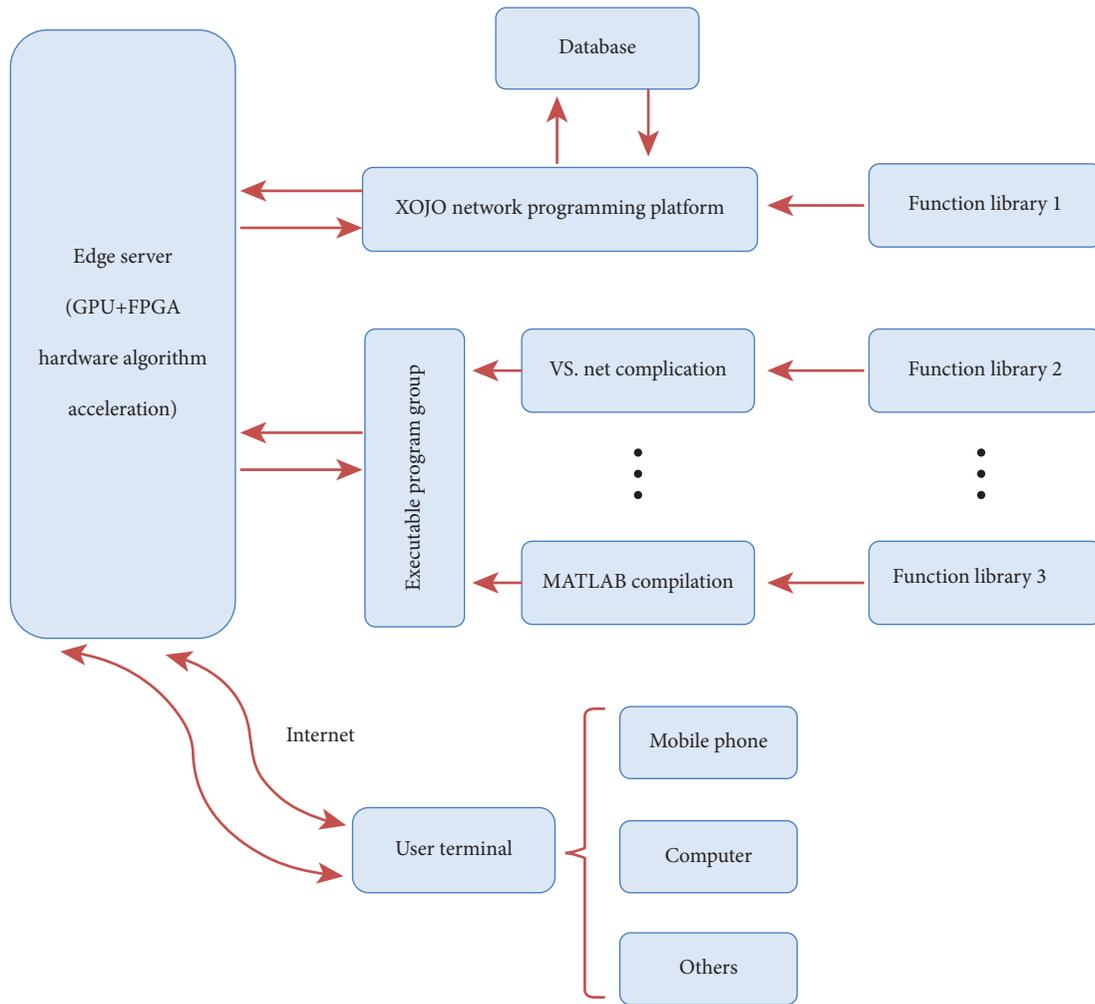

FIGURE 3: Cloud platform system framework.

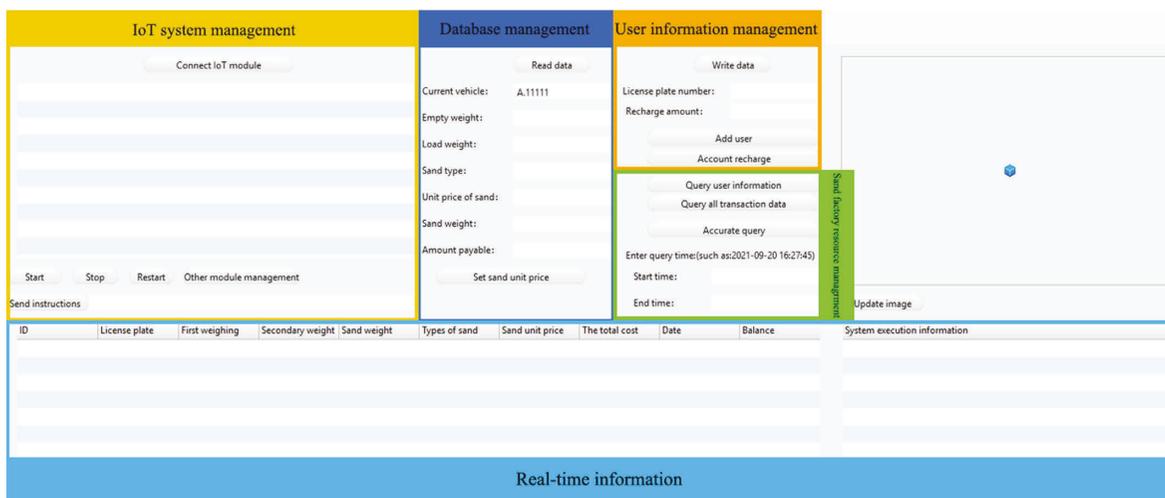

FIGURE 4: Web interface of sand factory management cloud platform.

2.3. Sand Weighing System. The sand weighing system mainly includes the weighbridge system and the IoT module. In a complete sand purchase process, the vehicle needs to be weighed twice. The weight when the vehicle is empty is recorded as W_0 , the weight after loading with sand is recorded as W_1 , and the weight of sand W is calculated as follows:

$$W = W_1 - W_0. \quad (1)$$

After the weighbridge system obtains the vehicle weight information, the relevant information needs to be transmitted to the edge server using the IoT module.

The unit prices of different sand types are saved in the cloud, and let the unit price of sand be calculated as P . The unit price of sand can be set on the server. Then the total cost of this sand purchase C is as follows:

$$C = P * W. \quad (2)$$

2.4. Sand Recognition System. Sand recognition system is to identify the type of sand. We use the CNN model to identify the type of sand. The identification of sand involves the processing of high-resolution images. If the images are transmitted to the cloud server for processing, it will be a severe challenge to the network bandwidth and will inevitably cause communication delays. The transmission of large amounts of data will affect the transmission of cloud server control signals, which will directly weaken the performance of the IoT system. Therefore, we propose an edge-based CNN model to identify the type of sand. Because the computing power of the edge server is far inferior to the cloud server, the parameters of the model are optimized. This enables us to reduce the amount of computation without losing recognition accuracy. And we put the recognition of sand in the FPGA at the edge to accelerate.

The workflow of the sand recognition system is as follows: the camera collects the sand pictures in the sand-purchasing vehicle, then transmits the pictures to the nearest edge server for picture preprocessing, and finally the pictures are preprocessed and transmitted to the FPGA for sand recognition. After the sand type is successfully identified, the FPGA will send the result back to the edge server.

2.5. Gate System. Gate system is to control the entry and exit of vehicles. For the sand-purchasing vehicles, before entering the sand factory, the vehicle information is recorded through the license plate recognition system. After that, the gate system opens the gate and releases the vehicle. When the sand-purchasing vehicle is loaded and the corresponding user's deduction is completed in the cloud, the gate system opens the gates to allow sand-purchasing vehicles to leave. At this point, the entire sand purchase process is completed. Besides, we can preload the corresponding license plate in the cloud and then automatically release the vehicles of the staff inside the factory.

3. CNN Model Design

This section mainly introduces the deep learning model design for sand recognition.

3.1. Data Collection and Preprocessing. The sand type recognition method based on deep learning has extremely high requirements for data sets. It is generally believed that the larger the dataset, the higher the recognition accuracy. However, there is no relevant available public sand dataset, so we collect sand pictures to make the dataset by ourselves.

At present, the sand factory mainly includes three types of sand. They are fine sand, coarse sand, and natural sand, respectively. Among them, natural sand is produced by natural forces, mainly rock particles, interspersed with a small amount of rock debris and mud debris sediment of rivers, lakes, and seas, and the grain size of rock particles is below 5 mm. Machine-made sand is the artificial mechanical crushing of hard and unweathered rock. The specifications of the machine-made sand are divided into three types: coarse, fine, and natural, according to the average particle size. The average particle size of coarse sand is 0.5 mm or more. The average particle size of fine sand is 0.25 mm to 0.35 mm. We collected pictures of three kinds of sand: fine sand, coarse sand, and natural sand. The representative pictures of different sands are shown in Figure 5. Figure 5(a) shows the fine sand, and the average particle size of the sand is 0.35 mm–0.25 mm, which is smaller than coarse sand and has less mud than natural sand. Figure 5(b) shows coarse sand, with an average particle size of 0.5 mm–0.35 mm. Compared with fine sand, the particle size of coarse sand is larger, and compared with natural sand, there is only a small amount of mud. Figure 5(c) shows the natural sand, the particle size is between fine sand and coarse sand and contains more mud.

The acquisition process is as follows: first, we spread the sand in the container. Second, we fixed the camera at 1.5 meters directly above the container. A different type of sand was used each time for the photographs. The final collection were 990 pictures for each type of sand.

The deep learning model used for sand recognition is deployed in the edge server, but the computation power of the edge server is far inferior to the cloud server. Therefore, we compressed the collected sand pictures to reduce the computational pressure on the edge server. Each compressed picture of sand is 256×256 pixels.

3.2. Optimal Convolutional Neural Network Structure. Deep Learning is currently the most popular machine learning method. CNN is the most common and stable technology for image classification and recognition. CNN enables images to be used as input to the network model and can automatically learn the training data. It overcomes the accumulation of errors generated by traditional manual feature extraction and achieves the extraction of higher-level features [29]. Combining the traditional CNN model with edge deployment, we propose an optimized CNN model suitable for sand classification.

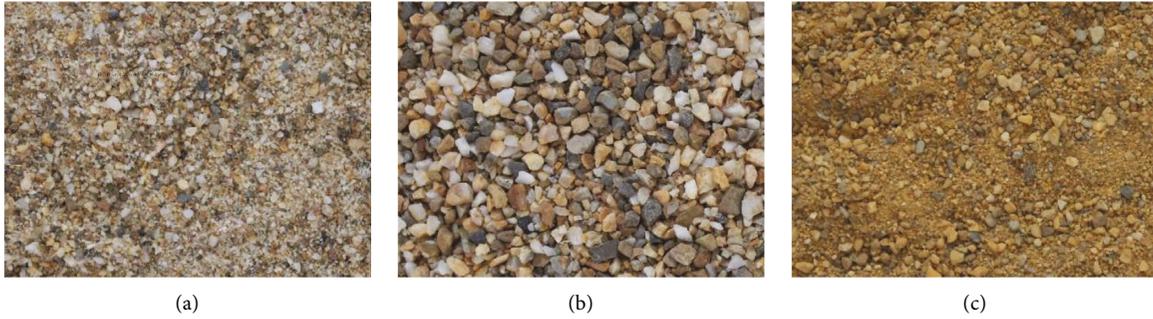

FIGURE 5: Representative images of different types of sand: (a) fine sand; (b) coarse sand; (c) natural sand.

The dataset for each type of sand is 990, for a total of 2970. In the initial experiment, we randomly divided all sampled data into training, validation, and test sets in the ratio of 0.7 : 0.15 : 0.15. We set the learning rate to 0.01. With the training method of momentum stochastic gradient descent, we set the momentum parameter to 0.9, MiniBatch to 64. First of all, the number of layers of convolutional layers needs to be determined by a quantitative experiment, as it is the most important parameter that directly affects the performance of the CNN model. Generally, convolutional layers (Conv) are used in combination with rectified linear unit (ReLU) layers and batch normalization (BN) layers. Therefore, we combine them. The performance of different Conv_ReLU_BN layers is shown in Figure 6.

Figure 6 shows the effect of the number of layers of Conv_ReLU_BN on the classification accuracy and training speed of the CNN model, where x axis represents the number of Conv_ReLU_BN layers, and y axis represents the values of classification accuracy and training speed. From the figure, it can be obtained that when the number of layers of Conv_ReLU_BN is greater than 4, the accuracy no longer fluctuates substantially; when the number of layers of Conv_ReLU_BN increases, the training time increases. Therefore, we have chosen to keep 4 convolutional layers for feature extraction, and Table 1 shows the detailed parameters.

Secondly, the number of fully connected layers (FC) needs to be determined. FC is one of the key factors affecting the performance of the CNN model. Based on 4 Conv_ReLU_BN layers, we find the optimal number of FC layers by testing the effect of different numbers of FC layers on the CNN classification results. Figure 7 shows the effect of adding 1 to 5 FC layers on the classification results of the CNN model. In the figure, the x axis represents the number of FC layers, and the y axis represents the value of accuracy and training speed. It can be seen from the figure that when the number of FC layers is greater than 2, the accuracy rate tends to be stable and less time-consuming at this point. Therefore, 2 FC layers were selected for classification, and the detailed parameters are shown in Table 2.

In addition, learning rate tuning is also an indispensable step to establishing a CNN model. The size of the learning rate will directly affect the convergence speed of the model. To make the 6-layer CNN model (4 Conv + 2 FC) converge faster with a higher accuracy rate, we choose different learning rates for experiments to find the best learning rate.

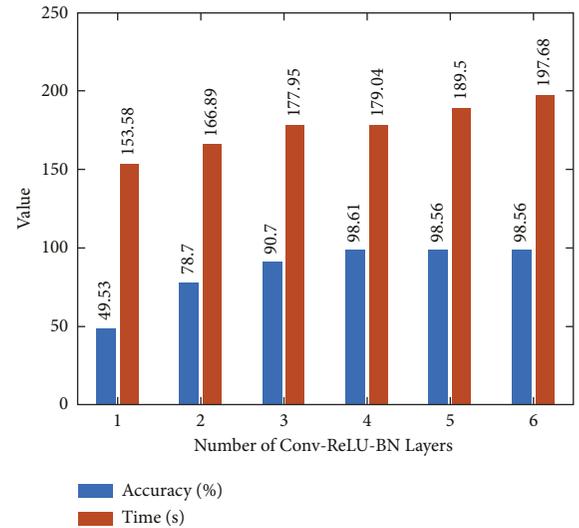

FIGURE 6: Optimal number of Conv_ReLU_BN layers.

TABLE 1: Feature extraction layers in proposed CNN structure.

Index	Layer name	Filter/pool size	No. of filters	Stride	Padding
1	Conv_ReLU_BN	5	16	1	2
	Maxpool	2		2	0
2	Conv_ReLU_BN	5	32	1	2
	Maxpool	2		2	0
3	Conv_ReLU_BN	5	64	1	2
	Maxpool	2		2	0
4	Conv_ReLU_BN	5	128	1	2
	Maxpool	2		2	0

Figure 8 shows the average result of 10 runs on the dataset. In the figure, the x axis represents the learning rate, and the y axis represents the value of accuracy and training speed. As can be seen in Figure 8, the accuracy is maximum and the time consumed is relatively short when the learning rate is 0.01. Therefore, the optimal learning rate is determined to be 0.01.

Finally, in the experiment, we use the momentum stochastic gradient descent method. Thus, we need to determine the optimal MiniBatch. Other parameters were set as mentioned in the previous text, and we conducted ten experiments by changing the size of MiniBatch. Figure 9 shows

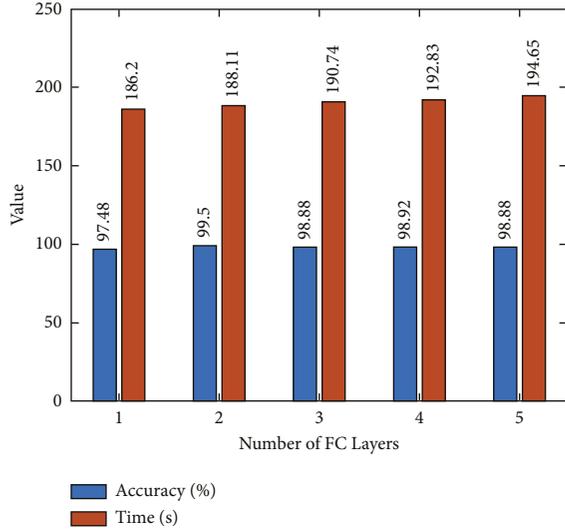

FIGURE 7: Optimal number of FC layers.

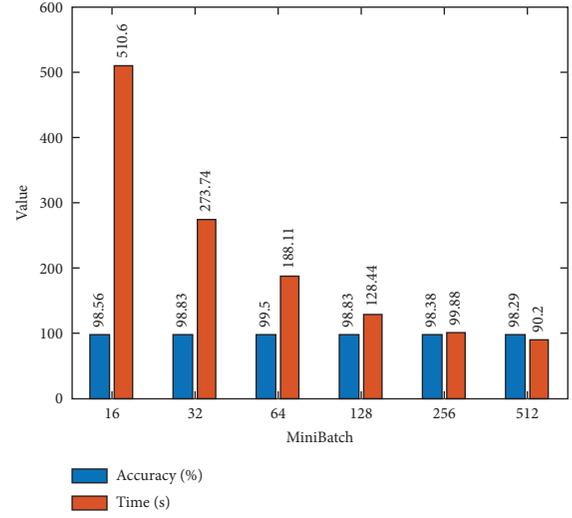

FIGURE 9: Optimal value of MiniBatch.

TABLE 2: Classification layers in proposed CNN structure.

Index	Layer name	Weights	Bias
5	FC_1	256×8192	256×1
6	FC_2	3×256	3×1
	Softmax		

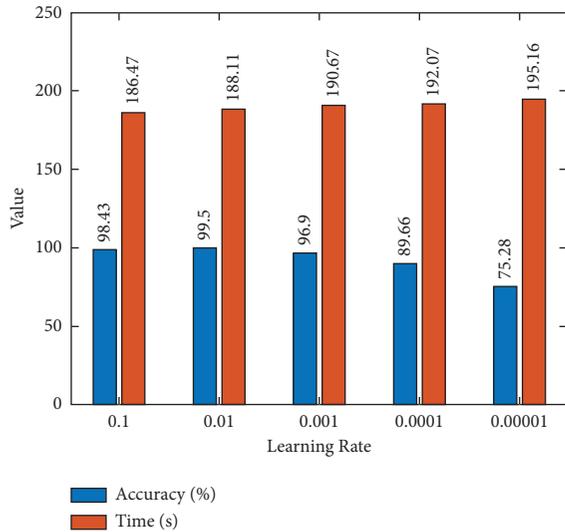

FIGURE 8: Optimal value of learning rate.

the average value after 10 experiments. In the figure, the x axis represents the size of MiniBatch, and the y axis represents the value of accuracy and training speed. As we can observe from the figure, the highest accuracy and shorter time is achieved when MiniBatch is set to 64. Therefore, we determined the optimal MiniBatch size to be 64.

In summary, the optimal structure and hyper-parameters of the CNN model are determined. The optimal structure is 4 Conv_ReLU_BN layers, 2 FC layers, and softmax layer; the learning rate and MiniBatch are 0.01 and 64, respectively.

The training results of the optimal CNN model are shown in Figure 10.

As shown in Figure 10(a), the training accuracy of our CNN model increases with the number of iterations. Moreover, since 64 data are randomly selected at each update time, the curve fluctuates significantly before leveling off. In Figure 10(b), the training loss of the proposed CNN model decreases as the number of iterations increases and finally tends to zero. Figure 10 shows that the hyper-parameters we have chosen are effective and they ensure the convergence of CNN.

3.3. Model Analysis. Generally, the number of convolutional layers will directly affect the model complexity. Then, the model complexity will directly affect the computational requirements in the model training process. And usually, the convolutional layer is followed deployed with the corresponding pooling layer. The total calculation time of the model can be calculated according to the number of convolutional layers and pooling layers, that is

$$T = \sum_{i=1}^n \left[N_c (L_{K_i}^2 + 1) L_{I_i}^2 + \left(\frac{L_{I_{i+1}}}{L_{P_i}} \right)^2 \right] N_{F_i}, \quad (3)$$

where T represents the total calculation time, i represents the number of inputs, N_c represents the input image's number of channels, L_{K_i} represents the length of the convolution kernel, L_{I_i} represents the length of the input feature, L_{P_i} represents the size of the pooling layer, and N_{F_i} represents the number of convolution filters.

From (3), the time complexity of the model can be obtained as follows:

$$O \left(\sum_{i=1}^n L_{K_i}^2 L_{I_i}^2 N_{F_i} \right). \quad (4)$$

We compare the designed model with the popular LeNet-5 model [30] and the VGG-16 model [31]. The convolutional layers of the LeNet-5 model and VGG-16

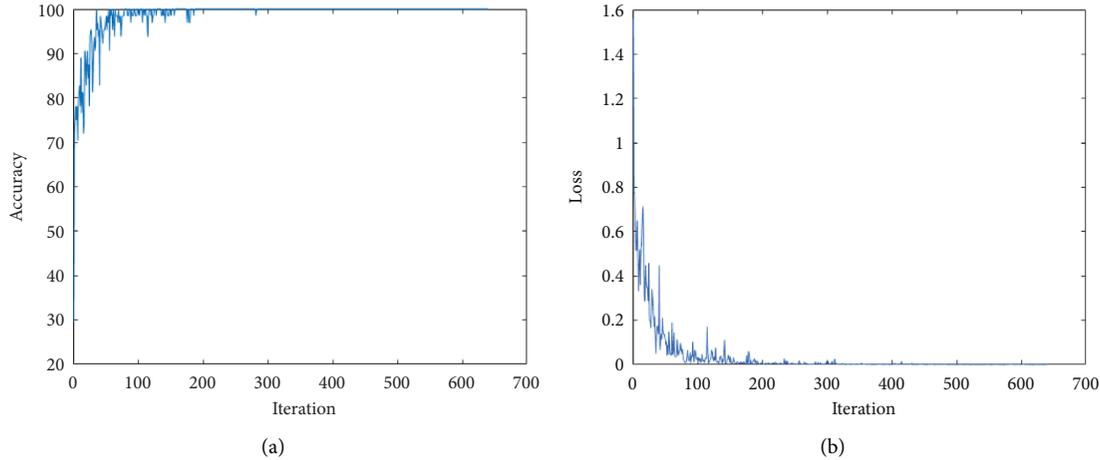

FIGURE 10: Training results of the optimal CNN model: (a) training accuracy; (b) training loss.

model are 6 and 16, respectively, while the model proposed in this paper uses only 4 convolutional layers. According to formula 3, the larger the number of convolutional layers, the greater the computational requirements of the model, so the model we propose requires the lowest computational requirements.

3.4. FPGA Design. After the model is determined, we use the FPGA to accelerate the designed deep learning model. The FPGA we used in the experiment was the Zynq UltraScale + MPSoC series board from Xilinx. The development process using the FPGA acceleration is shown in Figure 11.

After obtaining the model parameter file, we need to use Vitis AI Optimizer to trim the redundant connections in the neural network and reduce the overall required operations. Of course, this step is not necessary. After the model is simplified, the Vitis AI Quantizer tool needs to be used to quantify the model parameters, that is, floating-point to fixed-point. Vitis AI Quantizer can reduce computational complexity without loss of prediction accuracy. After the floating-point number is fixed-point, the network model requires less memory bandwidth, so it will provide faster speed and higher power efficiency than the floating-point model. Vitis AI Compiler compiles the quantized model into an efficient instruction set and data stream and can also perform complex optimizations, such as layer fusion, instruction scheduling, and reuse on-chip memory as much as possible. Vitis AI Profiler can conduct in-depth analysis on the efficiency and utilization of AI inference implementation. It can track function calls and running time and can also collect hardware information, including CPU, deep learning processing unit (DPU), and memory utilization. Vitis AI Library is a set of high-level libraries and APIs, which are built for efficient AI inference using the DPU. Vitis AI Library provides an easy-to-use and unified interface by encapsulating many efficient and high-quality neural networks. The Xilinx Runtime library enables applications to use a unified high-level running API at the edge, making edge deployments seamless and efficient.

4. Results

This section describes the relevant experiments and evaluates and analyzes the experimental results.

4.1. Experiment Platform. We designed a microsand factory for simulating a real-life sand factory, as shown in Figure 12. In addition, we verified the functionality of the system using the designed SSCMS simulation platform.

In the simulation platform, we used the smart sand car to simulate the sand-purchasing vehicle in practical operation. As we discussed previously in Section 2, the red dotted areas in Figure 12 are the corresponding system modules for the simulation. In addition, all our subsystems use Wi-Fi wireless communication modules for communication with the server. The appearance of the wireless communication module used is shown in Figure 13.

4.2. System Verification. In this section, we perform functional tests of the SSCMS deployed in a microsand factory simulation platform. The configuration of the edge server is 2.5 GHz, 24-core CPU frequency, 32 G memory, and NVIDIA GeForce GTX 1650, with 8 T storage. Conducting the first step of the experiment, we connect the FPGA to the edge server, open the web interface of the sand factory management cloud platform on the edge server, run the executable program group, and connect the relevant IoT modules. When the smart sand car drives to the license plate recognition area, the license plate recognition system will capture the license plate information and verify the vehicle identity. The empty vehicle will be weighed after successful identity verification. The relevant data of the weighing will be associated with the license plate information on the server. At this time, the web interface of the sand factory management cloud platform is shown in Figure 14.

Next, after the smart sand car is loaded with sand, it will go to the sand identification weighing area to identify the type of sand. Then the edge server preprocesses the acquired

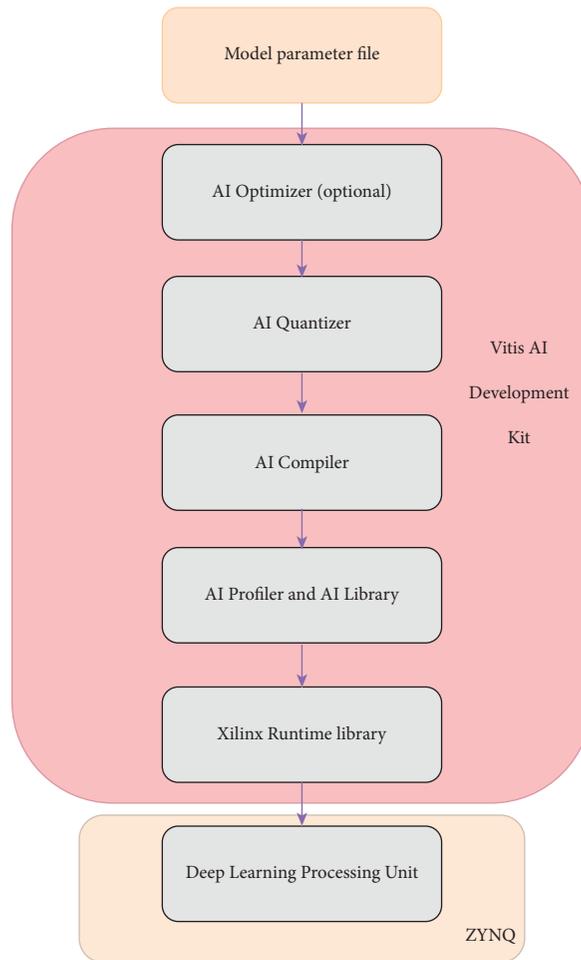

FIGURE 11: FPGA development process.

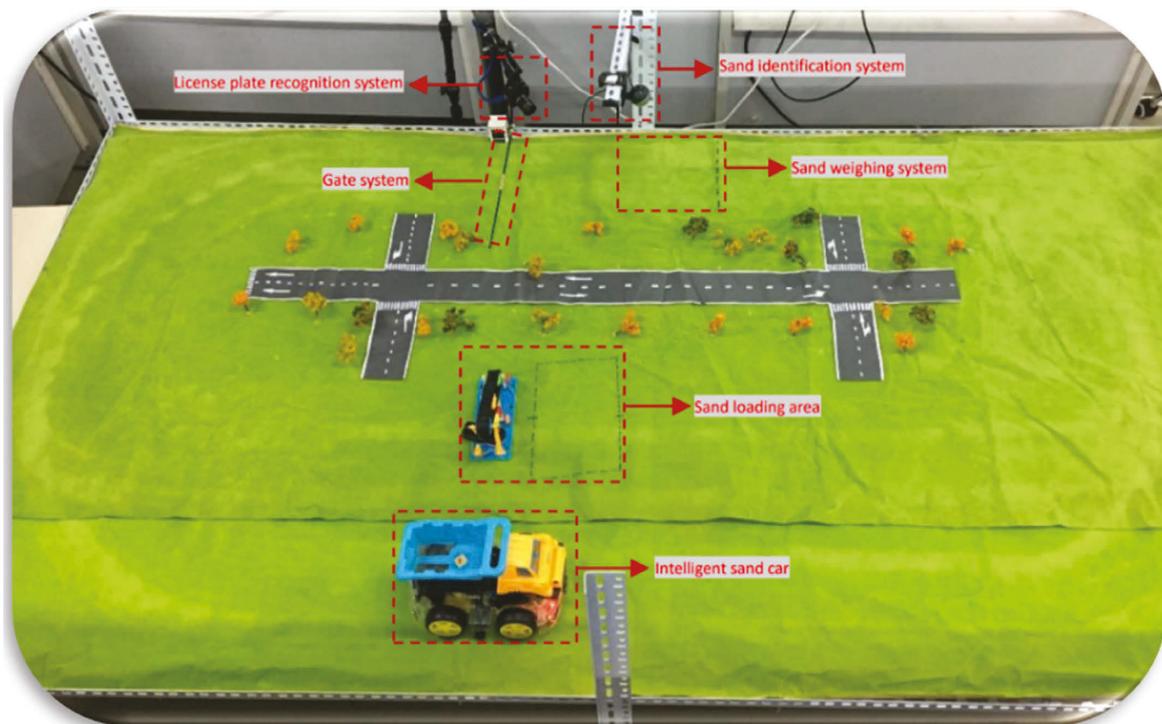

FIGURE 12: Microsand factory simulation platform.

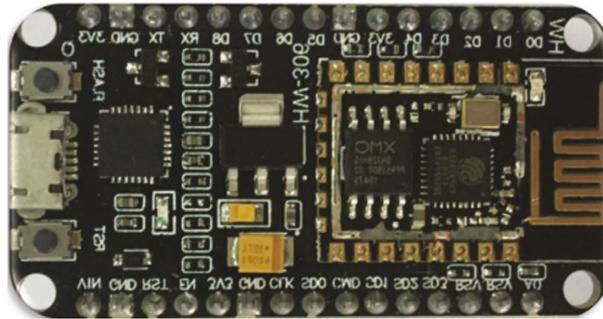

FIGURE 13: Wi-Fi wireless communication module.

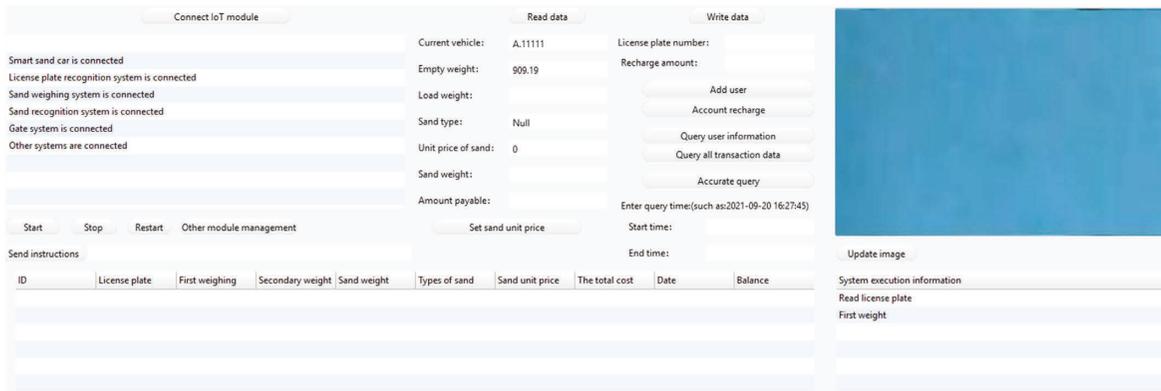

FIGURE 14: The web interface of empty vehicle status.

sand image, and the preprocessed image will be transferred to the FPGA, and the FPGA will use the designed CNN model to accelerate the identification of the sand type. At this time, the edge server will recognize the license plate and weigh the sand. Finally, vehicle information, sand type, and sand weight will be associated on the edge server-side. The unit price of sand can be set on the edge server-side, and different unit prices can be set for edge servers located in different locations. Using (1) and (2), we calculate the cost of this purchase and display it in the web-side interface of the cloud platform.

We set the unit price for three different types of sand. The unit prices of coarse sand, fine sand, and natural sand were set in the sever to 80, 100, 70, respectively. The operating results are shown in Figures 15–17 respectively. The edge server will calculate the cost of this purchase and then deduct the fee for the corresponding user. After the fee is successfully deducted, the gate will open to let the smart sand car drive out.

In the web-side interface of the sand factory management cloud platform, we can access the user's identity information. Including license plate number, the weight of empty vehicle, weight of loaded vehicle, the weight of sand, type of sand, and the cost of this purchasing. We can obtain a picture of the captured sand from the right of the interface. From the figure, the system can accurately identify different types of sand and their weight information. Eventually, the system will calculate the total cost accurately based on the set unit price of sand.

To test the performance of the built system, we run the system 100 times. Moreover, we have conducted statistic accuracy on sand recognition, license plate recognition, and sand weighing. In these 100 experiments, the type of sand, the license plate number, and the weight of the sand were changed for each experiment. After 100 experiments, the results are shown in Table 3.

In Table 3, the accuracy rate of sand recognition, license plate recognition, and sand weighing of our system is all up to 98 and above.

In our paper, the use of edge servers makes it possible to process data in each division, and the use of the FPGA relieves the computing pressure of the edge server and reduces the system latency. After the data is processed at the edge, it is only necessary to transmit the processing results back to the cloud server. The sand recognition system and the license plate recognition system use deep learning models. The time consumed by model inference is a key metric for evaluating a system. The use of edge servers can significantly reduce data transfer, thereby reducing the time consumed by data transfer. Therefore, we deploy the models to the edge server to avoid unnecessary image transmission. Similar to the recognition accuracy experiments in the previous section, we run the deep learning model system deployed to the edge 100 times. We count the running time of the sand recognition and license plate recognition system. The average value of the results are shown in Table 4.

Table 4 illustrates the very short recognition time of this deep learning model deployed to the edge. Compared to the model deployed to the cloud server, this method reduces the

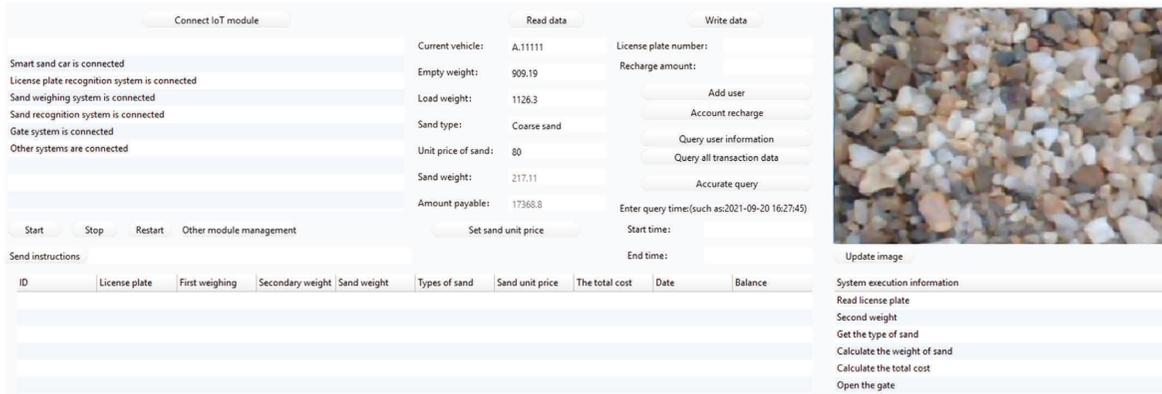

FIGURE 15: Web interface for coarse sand recognition.

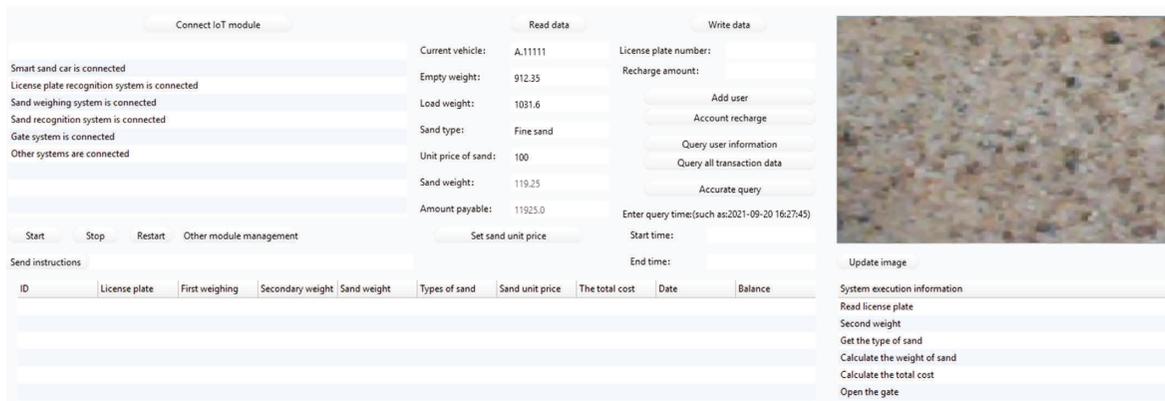

FIGURE 16: Web interface of fine sand recognition.

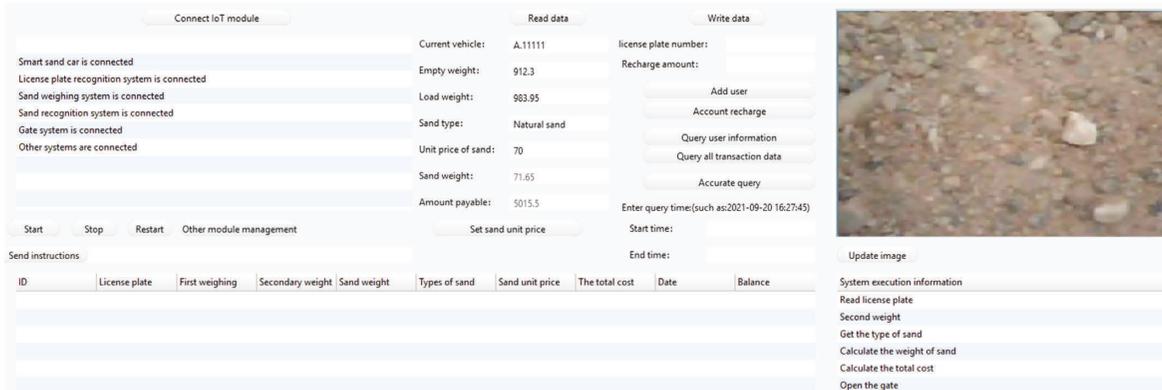

FIGURE 17: Web interface of natural sand recognition.

TABLE 3: System recognition accuracy.

Function	Accuracy (%)
Sand recognition	98
License plate ecognition	98
Sand weight	99.3

time consumed by the image transfer. The recognition of sand is accelerated in the FPGA, and the license plate recognition is performed in the edge server. In the table, the sand type recognition time is significantly lower than the license plate recognition time because we use the edge server

TABLE 4: System recognition time.

Function	Time (s)
Sand recognition	0.022
License plate recognition	0.073

combined with FPGA to accelerate the sand type recognition, while the license plate recognition only uses the edge server for inference. The experimental results show that the use of FPGA can greatly reduce the computing pressure of edge servers and improve computing performance.

In summary, the SSCMS we have constructed has enabled intelligent and automated management of the sand factory, with satisfactory results in all indicators. Different from the cloud server-based model, our designed edge-based model avoids the time consumed by a large amount of data transmission, thus improving the performance of the entire system. Compared with traditional supply chain management, the constructed smart supply chain improves the operation quality and efficiency of the sand factory. Compared with the traditional supply chain, the constructed smart supply chain has the following advantages: stronger technology penetration, stronger visualization, stronger information integration, stronger extensibility, stronger collaboration, and stronger agility.

5. Conclusion

This paper addresses the drawbacks of the traditional supply chain and constructs a SSCMS to realize the intelligent management of sand factories. It is specifically manifested in intelligent identification of sand loading vehicles, intelligent identification of sand types, automatic weighing of sand weight, cloud deduction of fees, and cloud management of sand factories. Along the supply chain, we build the optimal deep learning model, which achieves automatic sand identification, avoiding the drawbacks of manual identification and improving the quality of sand factory operations. In addition, considering that edge-computing technology can reduce the transmission of a large amount of data, thus serving to relieve the pressure on network bandwidth and reduce system latency, we make full use of the superiority of edge-computing technology to effectively improve the operational efficiency of the sand factory. A sand factory simulation platform was established to verify the performance of the system. Experiments show that all indicators of the designed system have achieved satisfactory results. In general, compared with traditional supply chain management, the constructed smart supply chain improves the quality and efficiency of sand factory operations.

Recently, we have also deployed the designed system to the actual sand factory for testing. In reality, the applicability of our model has also been verified and we achieved a satisfactory result both in accuracy and speed. In the next research, we will make more efforts in promoting the practical application of the system and continue to improve the system for new problems.

This study proposes the first fully deep learning-based structural response intelligent computing framework for civil engineering. For the first time, from the data side to the model side, the structural information of the structure itself and any loading system is comprehensively considered, which can be applied to materials, components, and even structures, system and other multi-level mechanical response prediction problems. First, according to the characteristics of structural calculation scenarios, a unified data interface mode for structural static characteristics is formulated, which preserves the original structural information input and effectively reduces manual intervention. On this basis, an attention mechanism and a deep cross network are introduced, and a structural static feature representation learning model PADCN is proposed, which can take into account the memory and generalization of structural static features, and mine the coupling relationship of different structural information. Then, the PADCN model is integrated with the dynamic feature prediction model Mechformer and connected with the designed general data interface to form an end-to-end data-driven structural response intelligent computing framework. In order to verify the validity of the framework, numerical experiments were carried out with the steel plate shear wall structure as the carrier, in which a data augmentation algorithm suitable for the field of structural calculation was proposed to alleviate the problem of lack of structural engineering data. The results show that the deep learning model based on this framework successfully predicts the whole-process nonlinear response of specimens with different structures, the simulation accuracy is better than that of the fine finite element model, and the computational efficiency exceeds the traditional numerical method by more than 1000 times, achieving a qualitative improvement. It is proven that the intelligent computing framework has excellent accuracy and efficiency.

1. Introduction

Deep learning is the product of a new round of scientific and technological revolution and industrial transformation. It permeates all aspects of human social activities and production activities. Intelligent machines and equipment will definitely replace human large-scale manual labor and work in extremely harsh environments. In the field of civil engineering, artificial intelligence technology is deeply integrated into the entire life cycle process of architectural planning, design, construction, and operation, profoundly changing the development of civil engineering, and comprehensively improving the level of mechanization, automation, informatization, and intelligence

[1]. The use of machine learning in the architectural planning phase is a new approach. Machine learning is at the heart of artificial intelligence, improving optimization algorithms based on data and previous experience through machine learning of the existing surrounding environment, geological conditions, objective factors, and needs of big data such as human and traffic behavior, combined with virtual reality situation reproduction technology, to create a new model of planning and design, and to avoid possible errors in reality, providing a greener building environment to achieve intelligent planning [2].

The whole world is working hard on the industrial transformation of the new generation of information

technology, modern manufacturing, and producer services. Internationally, in 2012, Germany launched the “Industry 4.0 Plan” focusing on “smart factories.” In December 2016, the United Kingdom published “Artificial Intelligence: Opportunities and Implications for Future Decision Designation” [3]. France released its Artificial Intelligence Strategy in March 2017. Japan has designated 2017 as the first year of artificial intelligence to promote the construction of a “super-intelligent society 5.0.” In 2018, the United States released a national strategy for artificial intelligence. China is one of the countries with the earliest and fastest AI action in the world. In July 2015, the State Council issued the “Guiding Opinions on Actively Promoting the “Internet” Action,” which clearly listed “Internet + AI” as a key action. On July 20, 2017, the State Council issued the “New Generation Artificial Intelligence Development Plan,” which clearly pointed out that artificial intelligence is the core technology of a new round of scientific and technological revolution and industrial transformation. Compared with other industries, although both steel (steel structure) and concrete (concrete engineering) are products of industrialization, the degree of mechanization, automation, intelligence, and informatization of infrastructure is still relatively low. Artificial intelligence technology will permeate all aspects of human social activities and production activities, and human large-scale manual labor and work in harsh environments will be replaced by machines or robots. In the field of civil infrastructure, artificial intelligence technology deeply integrates the whole life cycle of civil infrastructure planning, design, construction, and maintenance, and profoundly changes the development of civil engineering [4].

Building Information Modeling plays an extremely important role in the design phase. BIM technology is a data-based tool for engineering design, construction, and management. By applying BIM technology, virtual reality, cloud computing, and other technologies, it can eliminate design problems such as mistakes, omissions, and defects, reduce the cost of simulation analysis and optimization calculation of design schemes, and effectively to shorten the construction period, improve the visualization level of the design results, and significantly improve the design efficiency and quality [5]. For example, the data from the Shanghai Center project survey show that the use of BIM technology can eliminate 40% of engineering changes, eliminate 90% of drawing errors, reduce rework by 60%, and shorten the construction period by 10%, greatly improving project benefits.

2. Basic Research Fields of Artificial Intelligence

Four basic research areas: natural language processing, computer vision, speech recognition, and cross-cutting areas.

2.1. Natural Language Processing. Natural Language Processing (NLP) is the processing of human-specific natural language by a computer as a medium, so that computers can

“process” and “understand” natural language like humans [6]. In the field of civil engineering, NLP has shown great application prospects from basic semantic similarity, and dependency syntax analysis to applied human-computer interaction, report analysis, etc. It can be transformed into unstructured risk information using NLP. The construction organization plan information is transformed into structured information, so as to mine the tacit knowledge (such as dangerous objects, dangerous locations, accident causes, and accident types) of the daily documents of civil engineering construction projects [7].

In 2016, Tixier et al. proved that the use of NLP can eliminate reporting errors caused by manual information analysis. Using the NLP system can automatically scan and quickly analyze a large number of unstructured reports with an accuracy rate of over 95%. We obtained a large number of reliable structured data sets from the information report database, so as to extract new safety information and improve project safety management; in 2018, Wang Fei et al. reviewed the development of natural language processing driven by deep learning and believed that deep learning promoted natural language advances in processing and natural language processing to provide broader application prospects for deep learning; in 2019, Kim et al. proposed an NLP-based knowledge management system for construction accident cases, as shown in Figure 1. In this system, the information retrieval model can be used to query accident cases that are more than 97% related to user intentions, and the information extraction model can be used to automatically analyze tacit knowledge in accident cases to achieve efficient risk management; in 2020, Li Zhoujun et al. proved that static and dynamic pretraining technology combs new pretraining methods including BERT and XLNet and gives the future development direction.

Based on the current research status, the research depth and application scope of NLP are still relatively low [8]. First of all, it is manifested in the poor generality of the thesaurus in the construction field, which leads to the low quality of file preprocessing, which will affect the text data segmentation and part-of-speech tagging in the NLP process. Procedures adversely affect; then there is a limited formulation of information extraction rules, that is, in the field of civil engineering; it is difficult to obtain all project data (such as project contracts, etc.), making it difficult to develop all possible rules for information extraction; In addition, NLP, the deep learning training model, is related to local languages. The same model cannot process text information in different languages, so effective transfer learning cannot be carried out. Finally, the current NLP is mostly used in the construction stage, while the application in the design, maintenance, and other phases is carried out in the subsequent phases. It leads to low efficiency and quality of document management in the whole life cycle of civil engineering [9].

2.2. Computer Vision. Computer vision uses an imaging system instead of the visual organ as an input sensing means, and an intelligent algorithm instead of the human brain as a

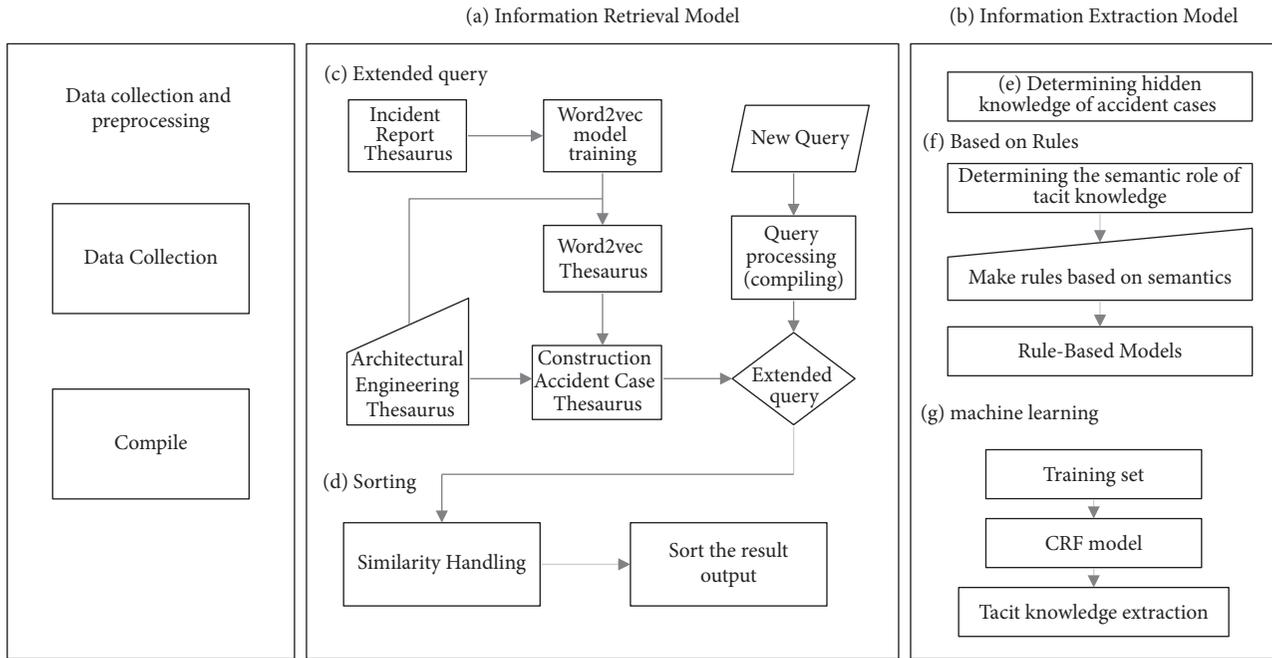

FIGURE 1: Construction accident case knowledge management system.

processing and analysis hub, extracting symbolic and digital information from images and videos for target recognition, detection, and tracking, and finally. It enables computers to “observe” and “understand” the world through vision like humans [10]. Computer vision has received a lot of research in the field of civil engineering in concrete crack detection, structural damage identification, construction site safety monitoring, etc. and has a very broad application prospect [11].

In 2011, Zaurin et al. proposed the use of computer vision for health monitoring of bridge structures, combining images and videos with computer vision technology to detect, classify and track different vehicles, and use sensor data to determine the standardized response of bridge structures; in 2015, Seo summarized the computer vision-based construction site safety and health monitoring methods, divided the previous computer vision research into three categories: target monitoring, target tracking, and action recognition, and proposed a general framework for computer vision-based safety and health monitoring; in 2018, Han Xiaojian et al. used computer vision technology to conduct research on crack detection on concrete surfaces and established a deep convolutional neural network crack recognition model that can automatically locate cracks and obtain crack widths from images, with a recognition accuracy of over 98%; in 2020, Zhou et al. proposed that a noncontact automatic identification method of vehicle load based on computer vision technology and deep learning algorithm is proposed, and 8624 vehicle image data sets are established and deep convolutional neural network training is carried out. Finally, transfer learning is combined with the general features extracted by ImageNet, and the recognition degree under the reinforcement learning strategy can reach up to 98.17%; in 2020, Song Yanfei and others proposed a three-dimensional model reconstruction method of the

space grid structure using binocular stereo vision technology and image recognition technology, and passed the actual test of the grid model to verify the feasibility of the method [12].

With the development of software and hardware technologies such as parallel computing, cloud computing, big data, and deep learning, computer vision technology has been continuously improved, but there are still many technical challenges and application problems at this stage [13]. For example, the research of computer vision in structural health monitoring is still in its infancy. How to reduce errors caused by hardware factors, algorithm factors, environmental factors, etc. is an important research direction in the future. How to improve the application efficiency and reliability of computer vision is a follow-up research focus; in addition, computer vision has achieved good results in detecting whether construction workers wear safety helmets, but how to trigger the alarm system and human-machine coupling in later applications needs further research.

2.3. Speech Recognition. Speech recognition is a process in which the computer recognizes and understands the input speech signal and converts it into text output, so that the computer can have the “hearing” function like a human being.

In the building environment, voice recognition can be used for garage switches and voice password locks; in the home environment, voice recognition can be used for remote sensing of home appliances; in addition, voice recognition can also be used for keyword retrieval, number voice query, etc. In future application research, speech recognition can provide assistance for building intelligent installation, such as building route voice navigation and robot human-computer interaction, and can also provide assistance for the effective identification of life after disasters [14].

In the field of civil engineering, there are few related researches and applications of speech recognition at present, and the research difficulties mainly focus on noise processing, robustness, and speech model. First, various noises often appear when inputting speech signals, and improving the noise processing is an important part of improving the accuracy of speech signal recognition; second, the existing speech signal recognition systems generally relies on the environment. High, different environments will lead to large differences in the recognition accuracy of speech signals, and enhancing the robustness of the speech recognition system will help to achieve the practical application of the system; finally, during speech interaction, semantics, speech rate, and emotion will all be affected. It affects the real meaning of speech, so the optimization of the speech model is also a difficult research point.

2.4. Cross-Domain. Interdisciplinary fields refer to numerous interdisciplinary subject groups, reflecting the trend of scientific research toward comprehensive development, with high complexity, breadth, and diversity. The intersection of artificial intelligence and civil engineering can greatly improve the engineering quality and work efficiency of infrastructure projects.

In 2015, Tang Hesheng et al. established a model for predicting the yield strength of rectangular concrete columns based on artificial neural networks, analyzed the key factors affecting the yield performance of concrete columns, and used Garson sensitivity analysis to prove the rationality of the model; in 2019, Ding Yang proposed that taking the process of mass concrete pouring as an example, a prediction model for the internal temperature of concrete hydration and heat release was established to provide a basis for monitoring, prediction, and early warning of subsequent maintenance. A fire monitoring method based on YOLO-BP neural network is proposed. The accuracy rate of using this method to monitor the fire in the repair stage of ancient buildings is 93.9%. In 2021, Zhao Yannan et al. proposed a tree structure intelligent form-finding based on BP neural network. The method can be used to intelligently locate the lower-level hierarchical nodes, so as to realize the intelligent form-finding of the overall geometric shape of the tree structure [15].

With the deep integration of industrialization, informatization, and intelligence, the traditional civil engineering industry is facing profound changes. The key to promoting the intelligent development of the entire life cycle of civil engineering is to comprehensively carry out the technology research and development and practice of intelligent design, intelligent construction, and intelligent maintenance, and strengthen the construction of the interdisciplinary system of artificial intelligence and civil engineering. In addition, in the construction of the interdisciplinary system of artificial intelligence and civil engineering, civil engineering should be adhered to as the main body, artificial intelligence as the auxiliary, and artificial intelligence technology should be used to support and promote the intelligent development of civil engineering throughout the life cycle.

3. An Intelligent Computing Framework for the Whole-Process Response of Civil Engineering Structures Based on Deep Learning

3.1. Structural Static Characteristics Unified Data Interface Mode. The structure is complex and diverse. In order to establish an end-to-end general computing framework, it is first necessary to solve the problem of how to organize multiple types of structures in an orderly manner, so as to facilitate the unified processing of subsequent deep learning programs. In order to meet the requirement of fidelity structure construction of original information, this study introduces the concept of a feature module, which can decompose, organize, and classify the static features of the structure by referring to the assembly idea of “from part to whole” of fine finite element technology [16].

A feature module corresponds to a certain structural property of a structure and contains many aspects of the structure. Taking the steel plate shear wall structure as an example, an embedded steel plate feature module can be set, and the feature information such as the width, height, and thickness of the steel plate can be recorded in the module. In order to consider the repeatability of construction, define two types of static feature modules: variable-length static feature model and fixed-length static feature model, and specify that any feature module is only one of the two [17]. For example, the opening feature of the steel plate embedded in the steel plate shear wall structure is a typical variable-length static feature module, because one or more openings may be set, and each hole can have its own geometric information. Frame top beams are usually a fixed-length static feature module because there is usually only one top beam. Further, the sub-features in the feature module are divided into dense features and sparse features: dense features mean that the feature value type is a continuous real number (or integer), the value size is comparable, and algebraic operations can be performed. The sparse feature means that the feature value type is discrete, and it represents the category or dummy feature. For example, whether the steel plate shear wall structure has out-of-plane constraints can be 0 to indicate no, 1 to indicate yes; the shape feature under the opening feature module Use 0 for a circle, 1 for a square, and so on. These numbers are not comparable in size and have no operational meaning. In the deep learning model, they will be converted into one-hot representation to avoid the ambiguity of discrete features under the Euclidean space distance metric, and ensure that the distances between discrete features are the same and equal [18].

3.2. PADCN Model. According to the definition of variable-length and fixed-length feature modules, combined with the characteristics of actual structural calculation and analysis, two functions that need to be realized by the structural static feature learning model can be summarized: (1) the internal sub-feature sequence of the variable-length feature module can be reasonably integrated; (2) the coupling relationship between each feature module and each other can be mined. Because of the influence of various factors such as material

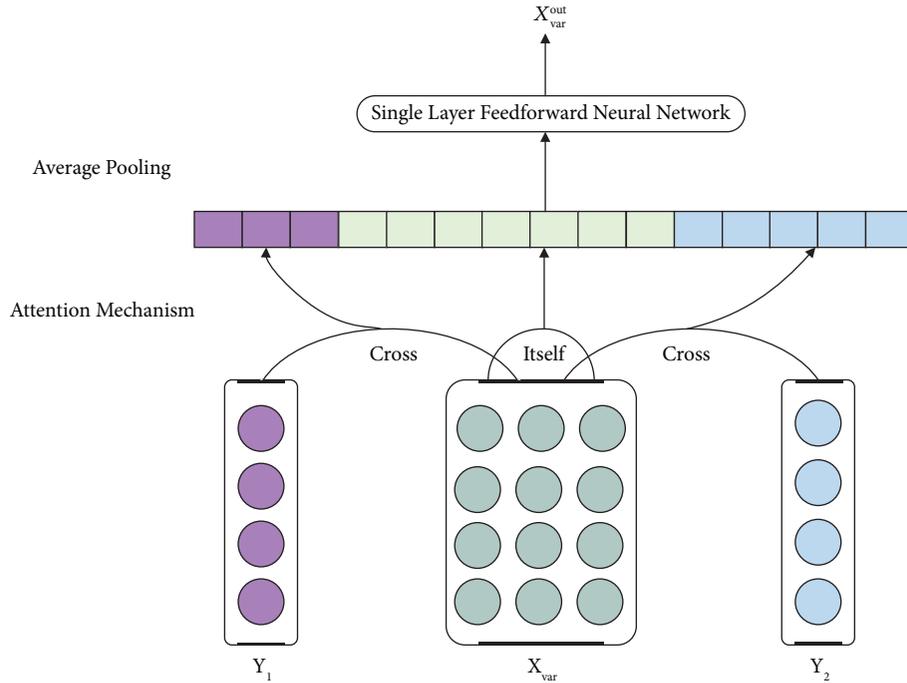

FIGURE 2: Attention mechanism preprocessing layer.

and geometric nonlinearity, each structure usually does not satisfy the simple superposition principle. Therefore, structural static feature learning is a complex feature processing scenario: there are both sequence features and general fixed-length features, and there is an interactive relationship between the two [19].

The joint feature problem is rare in computer vision and natural language processing, the two main research fields of artificial intelligence, but it is very similar to the recommendation system scenario, one of the core businesses of the Internet industry. In order to recommend a product to a user, the following three categories of information are generally collected and processed: user portrait, product information, and user behavior sequence. Among them, user portraits and product information can be regarded as fixed-length feature modules, and user behavior sequences correspond to variable-length feature modules, and it is also necessary to mine the deep interaction between the user side, the product side, and the user behavior sequence. In this way, the deep learning model of the recommender system can be used to process the static features of the structure [20].

First, we consider the sub-feature sequence integration problem of variable-length feature modules. The purpose of the integration is to form a fixed-length vector, similar to the embedding vector in the recommender system, which contains the main information of the feature module. We adopt the standard multi-head attention mechanism to preprocess the sequence features, including the self-attention mechanism and cross-attention mechanism, as shown in Figure 2. Taking the steel plate shear wall stiffener feature module as an example, the self-attention mechanism can explore the interaction between the stiffeners, because the staggered stiffeners work together rather than independently

to delay the buckling of the plate; the cross-attention mechanism is in order to introduce the interaction between the structures in advance, such as the intersection of the feature module of the embedded steel plate and the feature module of the stiffener, it can be expected to integrate the information of the plate into the stiffener expression in advance, which is more helpful for the subsequent extensive cross-learning. After the attention mechanism is implemented, the representation vector of the variable-length feature module is obtained using average pooling and dimensional transformation through a single-layer feed-forward neural network [21].

After the variable-length feature module completes the preprocessing, all feature modules are converted into feature vectors of certain dimensions, which facilitates the mining of coupling relationships. One of the mainstream deep learning models in the recommender system field is introduced into the deep and cross-network, which is connected with the attention mechanism preprocessing layer to form the PADCN model, which realizes the complete structural static feature representation learning, as shown in Figure 3. The structure of the DCN model is derived from thinking about the effectiveness of traditional recommendation system algorithms (such as SVD and FM): first, the memory of user habits, that is, a user must have fixed preferences for a long time. For example, if user A likes electronic products, then as long as the recommendation model can provide popular and latest products such as computers and mobile phones, the possibility of A's positive feedback on the recommendation results is definitely not low; the second is the generalized exploration of user preferences. There are no related products in the browsing footprint, and it is also very likely that you like digital peripherals, such as game figures. In

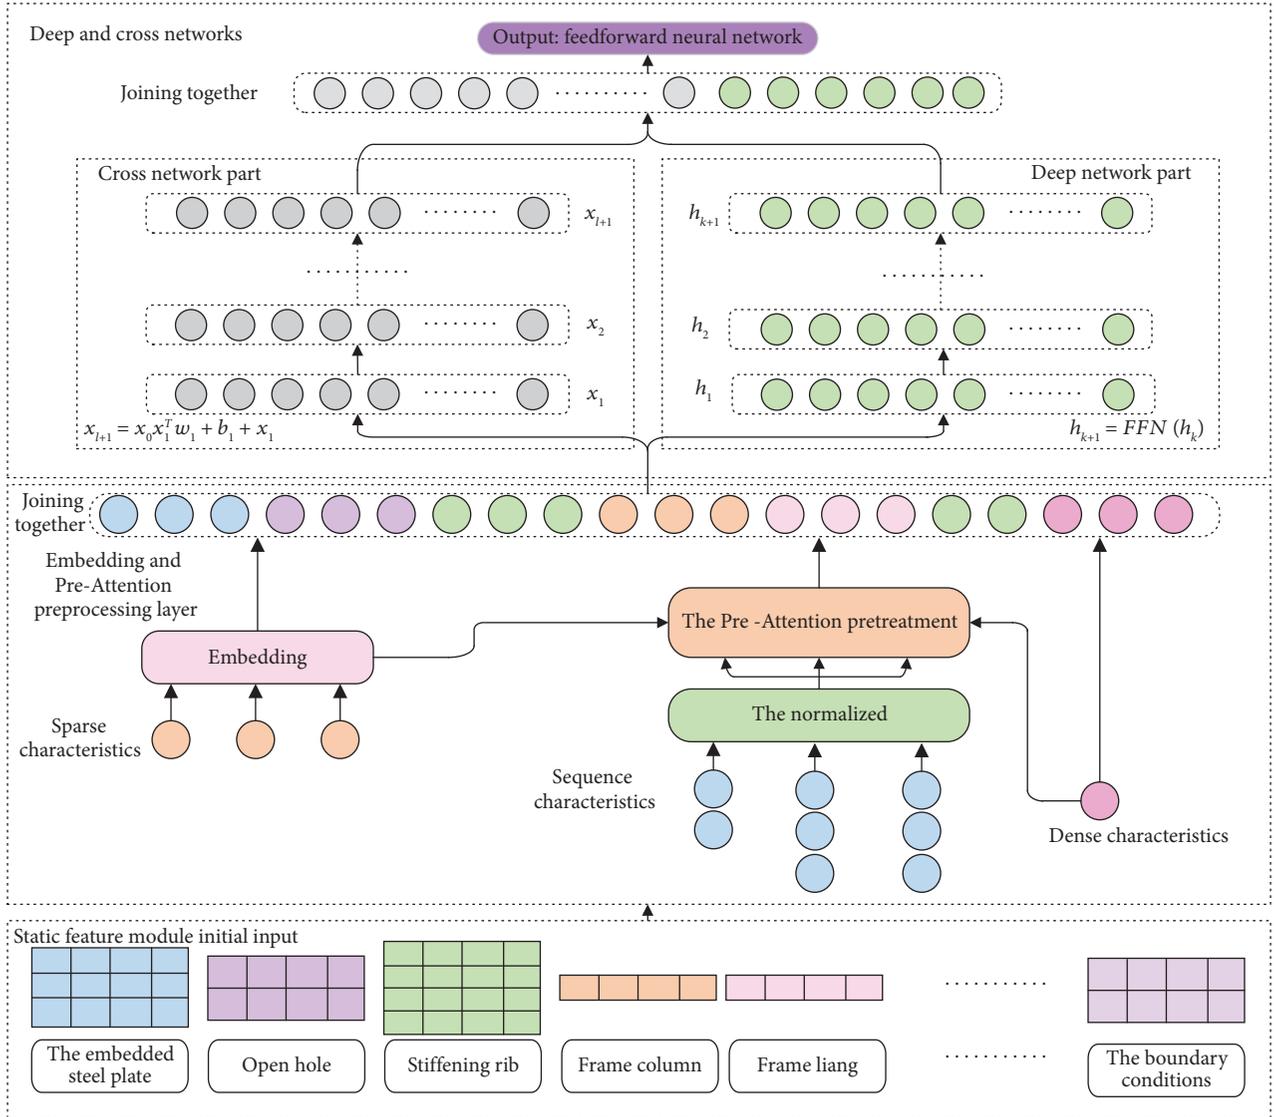

FIGURE 3: Structural static feature representation learning model PADCN.

conclusion, a high-quality model needs to take into account the two attributes of memory and generalization at the same time. This is also applicable to structural response simulation: the hysteretic responses of structurally similar components are usually not much different, which belongs to memory; and if the model training set contains artificially developed central circular openings. For specimens with holes and central rectangular openings, after learning, it is expected that the model can simulate the mechanical response of a uniform matrix with multiple openings, which belongs to generalization [22].

The method of DCN to take both into consideration is to divide the model into two parts, as the name suggests, one is the cross-network part, which is used to memorize historical patterns. Finally, the two are spliced together for output [23]. The deep network part is a common feedforward neural network, which will not be described in detail. In the intersecting network part, the features themselves are constantly intersected, and then the higher-order

interactions are mined; at the same time, the residual connection structure is used to ensure the complete transmission of the initial information.

$$x_{i+1} = x_0 x_1^T w_1 + b_1 + x_i. \quad (1)$$

Expanding and analyzing the above formula, it can be found that what the first l layer learns is the polynomial of the input feature itself $l + 1$, and the polynomial contains all terms less than or equal to $l + 1$ the order, and there is no information loss of any order [24]. In addition, the complexity of each layer of the cross-network part $O(d)$ realizes the automatic upgrade of the coupling relationship, which effectively avoids the common combination explosion problem in pairwise cross-action learning.

So far, the unified data interface formulation and representation learning of structural static features have been completed. Then, by splicing the representation vector learned by the PADCN model with the input of the

Mechformer model, an end-to-end structural intelligent computing framework based on deep learning can be formed, which comprehensively covers the data side and the model side, and can fully consider the static and dynamic characteristics of the structure, so as to realize the whole-process mechanical response prediction of different structures.

3.3. Numerical Test. This section will use the steel plate shear wall structure as the carrier to verify the effectiveness of the structural intelligence computing framework based on the PADCN-Mechformer model.

3.3.1. Data Preparation. The initial training data are mainly derived from experimental reports in historical documents and generated by means of high-precision and precise finite element technical parameter analysis. However, in practical applications, the initial data volume may not be able to support the training requirements of large-scale deep learning models due to limitations such as high experiment costs and low computational efficiency of finite element models [25]. Therefore, data augmentation algorithms need to be considered.

In the field of computer vision, operations such as rotating, cutting, scaling, and coloring the input image are performed to increase the amount of data. These methods are obviously not suitable for real-valued sequence fitting problems in structural calculations. With the richness of language meaning, the field of natural language processing can use synonym interchange, back translation (that is, translating a sample to another language with an existing model, and then translate it back), based on mask replacement, random deletion, and insertion. Methods such as language noise, in which back-translation can be analogized to the use of fine finite element models for data generation, and the addition of noise can provide inspiration for structural response data augmentation algorithms.

Noise addition methods based on random deletion and insertion cannot be directly applied, because unlike the flexibility and robustness of language (many sentences can be understood by humans even with a large number of typos), the structural response curve once the amplitude points are randomly deleted, etc. data, or randomly interpolating a point that deviates significantly from the loading trajectory, may cause a noticeable change in the shape of the hysteresis curve, impairing the model training process [26].

Corresponding to the random deletion method, a piecewise proportional downsampling algorithm based on amplitude points is proposed for the structural response curve. The flowchart is shown in Figure 4, and the schematic diagram of the results is given on the right side by taking Lubell's SPSW2 test song as an example. The principle of the algorithm is that the test curve usually contains a large number of data points due to the high sampling frequency of the equipment, and the step size between two adjacent points is very small, so reasonable downsampling will not change the overall shape of the response curve and the key mechanics it reflects. At the same time, samples of different step lengths can be obtained to enhance the robustness of the deep learning model. The reason

for the segmentation is that the hysteresis curve is highly nonlinear. Generally, the plastic segment is longer, the elastic-plastic transition segment is the second, and the elastic segment is the shortest. The plastic transition is the most prominent and is the key region to control the shape of the curve. If the entire half-ring is directly sampled uniformly, most of the sampling points fall in the plastic segment, and the elastoplastic transition segment is not fully described, resulting in serious curve distortion. Therefore, it is necessary to set the segmentation ratio, roughly frame the range of each segment, and give each segment a reasonable sampling ratio. After testing, the more suitable subsection ratio is {0.1, 0.15, 0.25, 0.5} (the elastic-plastic transition section is further divided into two parts: elastic transition and plastic transition), and the sampling ratio of each section is {0.05, 0.4, 0.25, 0.3}. After the preliminary sampling is completed, it is recommended to refine the sampling curve. Some segments may have a small amount of data, repeated sampling occurs, and the data needs to be deduplicated. In addition, due to test measurements and other reasons, the maximum point of the displacement amplitude of the hysteretic half-ring of some test curves may not correspond to the point of the maximum load amplitude. The previously extracted displacement time history amplitude data and load time history amplitude data are corrected for relevant points.

Using the above algorithm flow, multiple new hysteresis response curves can be generated by setting different sampling points and trying to change the segmentation ratio and sampling ratio. The parametric analysis results show that for most of the response curves with more than 3000 data points, only 20% of the data points can reproduce the original curve with a high degree of coincidence. Therefore, the sub-scale downsampling algorithm based on amplitude points can generate a considerable number of new samples.

3.4. Simulation Accuracy Metrics. At present, the evaluation of the accuracy of the structural response curve simulation is usually based on the qualitative observation of the researchers, and most of the literature will claim to be "good fit." In order to more reliably compare the accuracy of simulation results with experimental curves, it is necessary to establish relevant quantitative indicators. In structural performance analysis, mechanical indicators such as ultimate bearing capacity and overall (or average) energy consumption are generally used. Both of these two indicators have important physical meanings, but they also have certain limitations: the former is a single-point indicator, suitable for the design stage, and obviously not explanatory for the accuracy of the whole process simulation; the latter can be regarded as a certain sense. For the mean value index, since the number of hysteresis loops experienced by the simulation and the test is the same, the overall energy consumption is determined by the average energy consumption of each cycle. Therefore, this index lacks the control of the variance index and is also not comprehensive. For example, there may be a situation where the final average energy consumption of the hysteresis curve is similar because some segments consume too much energy and some segments consume less

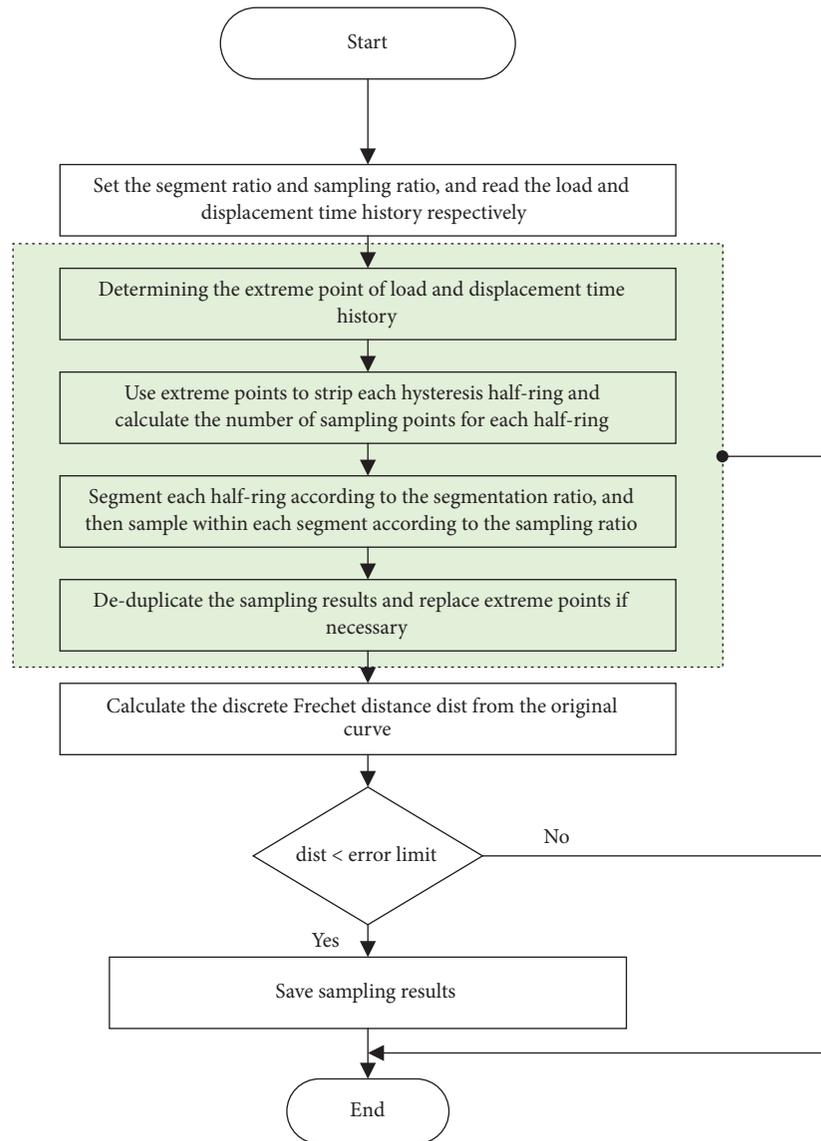

FIGURE 4: Segmented proportional downsampling algorithm based on amplitude points.

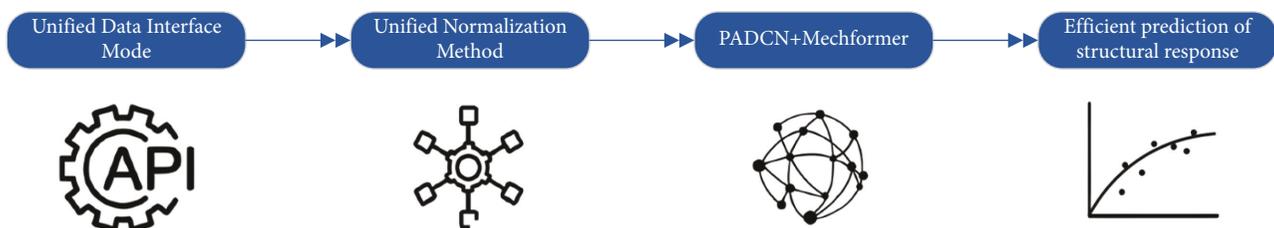

FIGURE 5: Framework diagram of structural intelligence computing based on deep learning.

energy, but the simulation accuracy is actually low. Therefore, a more comprehensive metric needs to be explored.

3.5. *Framework Verification.* Through experimental data collection, fine finite element generation, and the expansion of a series of data augmentation algorithms in Section 3.1,

the length of the loading regime sequence was controlled between 200 and 3000 data points. We divide 512 samples as a training set, 256 samples as a validation set, and 256 samples as a test set, of which test samples and their data augmentation in the training set account for 58.3%.

The deep learning-based structural whole-process response intelligent computing framework proposed in this

study is universal in the whole process and is suitable for any structural computing and analysis tasks: as shown in Figure 5 (1) First, we establish a database according to the data interface mode specified in Section 1. This step can digitize the inherent properties of the target object “what you see is what you get,” almost without manual experience pre-processing; (2) the user specifies the reference value of each physical feature, and the program automatically adopts the reference value scaling method proposed by the author to carry out unified de-dimensioning and normalization; (3) the program uses the PADCN-Mechformer model for training and testing; (4) a deep learning model that can be used for actual structural response prediction is obtained, with high accuracy and far superior to traditional numerical methods computational efficiency.

4. Conclusion

This study proposes an end-to-end structural response intelligent computing framework based on deep learning, including structural static feature data interface mode, data augmentation algorithm, and core deep learning model. It is suitable for multi-level mechanical response prediction problems such as materials, components, and even structural systems.

Modern landscape greening plays an important role in the construction of modern cities and plays a positive role in improving the natural environment of cities and building a good image of cities. With the continuous progress of society and technology, human's understanding of artificial intelligence is deepening, and intelligent technology is gradually integrated into all aspects of life. Because media technology has rich design elements and can carry out rich design structures, it will be more intuitive to use multimedia means for garden landscape design. Therefore, for meeting people's requirements for the diversification of modern urban gardening construction, this study makes a deep analysis of the current status and problems of landscape design and tries to study the effective application methods of artificial intelligence technology in landscape design, to promote the combination of landscape design and artificial intelligence design. At the same time, the combination of AI lighting planning, AI water landscape planning, AI sprinkler planning, and AI paving planning is used to illustrate the application of AI in the specific project design of landscape design. The use of artificial intelligence not only promotes the innovation and optimization of landscape design, but also ensures the quality of modern landscape design and effectively improves the efficiency of modern landscape design.

1. Introduction

In the contemporary society, with the development of society, the design ideas, and methods of landscape architecture are increasingly enriched, coupled with the continuous improvement of social economy and technology level, people also put forward higher requirements for landscape design. People's economic level has been greatly improved, and their comprehensive quality has been improved. Their taste is also very different from that of the past, which can be reflected in all aspects of life. For example, theme parks and fitness squares have more and more requirements for landscape architecture. In addition, with the rapid development of science and technology, it has entered the era of big data, and landscape architecture design has also undergone great changes. With the development of modern civilization, modern landscape gardening design means are increasingly rich. At the same time, the steady development of social economy and technology has also led to the improvement of the requirements for modern urban

landscape greening. The current stage of modern landscape architecture design is restricted by backward design concepts and inconsistent design schemes with reality, which is not conducive to improving the quality and efficiency of modern landscape architecture design, nor can it meet people's growing spiritual and entertainment needs [1–5]. Artificial intelligence technology has been rapidly applied to many fields of landscape architecture because of its high-efficiency data knowledge transformation ability, strong analytical ability, strict reasoning, and accurate ability to select the best. Artificial intelligence technology can not only convert the complex qualitative description in landscape architecture into quantitative analysis through efficient and accurate calculation of some relevant data, but also solve some difficult problems in landscape architecture research and reveal the internal mechanism behind the phenomenon through the establishment of intelligent models, so it is widely used in landscape architecture research.

From the point of view of today's society, landscape design has some limitations in the following areas, which

limits the development of landscape design. First, the design concept of landscape architecture is not advanced enough. According to the current situation of landscape design in Chinese gardens, traditional experience and imitation of other works are often the main design methods. In this application scenario of landscape architecture design, it will inevitably lead to innovation and uniqueness in landscape design [6–8]. At the same time, there is no certain concept of environmental protection in the design process, such as blind pursuit of beauty. Therefore, its design is often difficult to effectively play the actual utility of the landscape in the garden. At the present stage, China advocates the development of green economy. The precondition of green economy is to protect the environment and then promote the rapid development of economy on the basis of it again [9]. In addition, due to the involvement different cities, there will be great differences in culture, coupled with the existence of the same human characteristics, and landscape design can only fully reflect these different characteristics to meet the real needs of landscape design. However, in the current landscape design, these different properties are ignored, leading to appear in the landscape design a lot of similar scenes.

Second, the technical level of landscape design needs to be further improved. In the design of landscape architecture, art, and technology are usually integrated, which not only involves many fields, but also requires designers to have a rich variety of professional knowledge and technology, so that more different styles of landscape design can be completed with high quality and efficiency. However, in the current landscape design, designers do not have more professional expertise and technology, and cannot integrate art and technology [10–12]. Therefore, it will have a certain impact on the quality and effect of landscape design. In addition, due to the relatively backward construction technology of gardening landscape in our country at this stage, even if a large number of high-quality designs are developed, it is difficult to implement them in gardens, which will lead to the setback of gardening landscape design.

Finally, there are often differences between design and reality. From the original intention of landscape design, it is a way to reflect the improvement of living environment and landscape design. However, for different areas, their living environment also has different characteristics, and considering different places, the climate and culture are also different. Therefore, when designing landscape architecture, it should be based on local actual needs to ensure that the landscape design conforms to the actual situation [13]. In the real society, some landscape gardens have invested a lot of manpower, material, and financial resources in the design process, but they have not got relatively excellent design scheme. This is because before the gardening landscape design work, no comprehensive collection and collation of data, coupled with the fact that the city is not the main basis, will have a big impact on the effect of the entire design [14].

On this basis, in order to ensure that the design of landscape architecture can be synchronized with the times, improve the efficiency of design planning, and develop high design technology. Therefore, the introduction of advanced

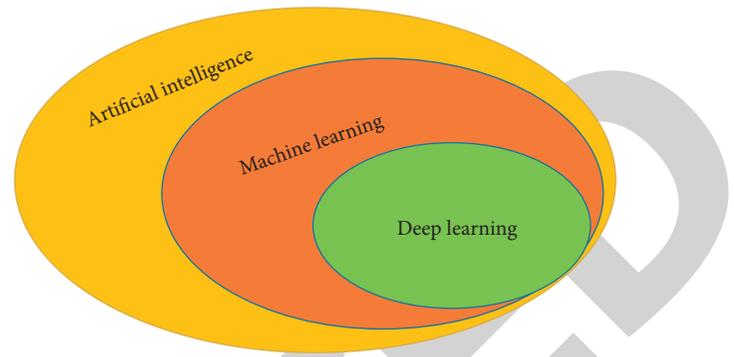

FIGURE 1: Scope of AI technology.

AI technology ensures that the leading technology in combination with landscape design, so as to maximize the effectiveness of landscape design.

2. Principles of Artificial Intelligence Platform

Artificial intelligence (AI) is a comprehensive technology to simulate various human behaviors with the help of high-performance computing platform on the basis of studying human behavior rules and thinking modes [15–17]. It mainly includes machine learning and in-depth learning technology, as shown in Figure 1. Until now, in the research of AI technology, the practical significance of intelligence has not been well reflected, often closely combined with human. However, through nearly 50 years of research, AI technology has been widely developed in all areas of the world. For example, in machine manufacturing, these technologies fully reflect the advantages of AI. Further development of AI technology can create a more intelligent society for people. From this aspect of landscape design, designers often combine artistic features with science and technology to artificially transform a certain area of the city and create a harmonious and beautiful urban atmosphere between people and nature, which is landscape design. Therefore, virtual tour technology, media, and multimedia technology are mainly used in landscape design [18].

2.1. AI Technology. There are two types of artificial intelligence: simulation, deduction, demonstration, and algorithm. The simulation deduction and demonstration further subdivide artificial intelligence into “reasoning type” capable of logical reasoning and theorem proving; “learning type” capable of deep learning and support vector machine; it is a “knowledge-based” expert system. The algorithm divides artificial intelligence into “symbolism” type that uses logical reasoning method to deduce the whole theoretical system to simulate the process of human like intelligence; the “connectionist” type that uses machines to simulate the neural system and connection mode of the human brain; a new method of controlling intelligence through behavioral activities is “behaviorism” with quantitative research attributes. According to the functions and attributes of artificial intelligence technology and its application in landscape architecture research, there are three types of artificial

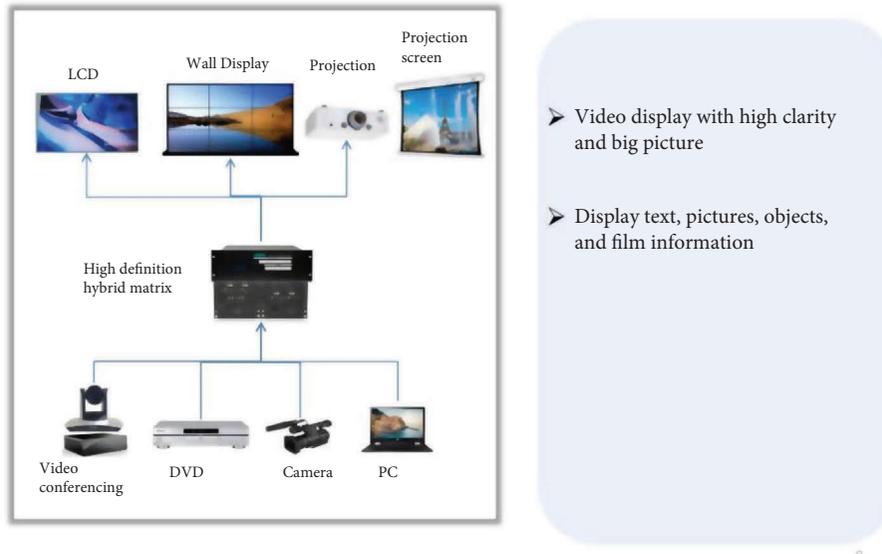

FIGURE 2: Virtual roaming technology architecture.

intelligence technology currently applied in landscape architecture: intelligent random optimization, artificial life, and machine learning.

Random optimization method is an optimization algorithm that generates and utilizes random elements. Randomness includes two aspects, one is the randomness of the data, and the other is the randomness of the algorithm itself. In the research of landscape architecture, intelligent random optimization method is mainly used to seek the optimal solution of optimization problems. Because the time cost of trying all possible solutions to find the optimal solution is too high, and the random optimization method speeds up the search process, it is easy to find the global optimal solution. Genetic algorithm and simulated annealing are common stochastic optimization methods.

Machine learning includes three types: (1) it directly simulates the tree process of human judgment on concepts, and its representative algorithm is decision tree, which is called semiotic learning. (2) Connectionist learning, represented by artificial neural network, has the best application effect in the field of engineering. (3) It mainly combines the theoretical achievements of inferential statistics, which is represented by support vector machine, so it is called statistical learning. Machine learning can mainly solve the impact of each element on landscape results, scoring problems, and classification problems in landscape architecture. Connectionist learning and symbolism are widely used, such as convolutional neural networks, artificial neural networks, random forests, and decision trees and so on.

2.2. Virtual Roaming Technology. In recent years, with the rapid development of virtual three-dimensional technology, there are many new branches of virtual reality technology, among which virtual tour is an innovative development of virtual reality technology [19–21]. Virtual tours are often used to showcase design results and put people in a virtual three-dimensional environment. Through dynamic

interaction, the immersion type of multi-angle and omnidirectional inspection of future buildings is carried out. This is beyond the traditional architectural effect maps. Virtual tour technology showcases the design results while also considering the overall audience. The architecture of the multimedia system is shown in Figure 2.

2.3. Landscape Design with the Media or Multimedia. With the continuous development of science and technology, various countries have increased their research efforts on new media, an emerging industry, and promoted the development of new media in many fields. In urban landscape design, multimedia is designed from a more scientific, advanced, and diversified perspective, matching with the information network of modern society, broadening the scope of design, broadening people's horizon, and changing the traditional design theory. The perfect integration of new media and landscape design marks the initial formation of modern urban landscape design, and also reflects the inextricable connection between them. The emergence of new media has made the Chinese urban landscape design transition and transformation from traditional artificial design to more modern design. New media art can not only give modern landscape design a new life, but also help designers directly absorb nutrients and knowledge through the visual experience and intuitive feeling conveyed by new media. New media use computers and other equipment to process information and images, use information and digital technology means for landscape design, expand the creative space, so that the human design concept and computer together organically, and is an important breakthrough in design [22, 23]. This has significantly broadened the original boundaries and scope. Using only multimedia for landscape design, as shown in Figure 3, is more intuitive with animation effects and certain visualizations.

In modern garden landscape design, we adopt advanced digital media technology, give full play to the advantages of

FIGURE 3: Visualization of landscape design using multimedia technology.

digital media technology, integrate landscape design resources, combine the application of modern design elements, form diversified design styles, and meet the personalized needs of modern people for landscape with the support of rich landscape design content. During the use of digital media technology, we can integrate the elements of the times, adjust the design style and scheme content, and automatically convert and process different design forms, so as to ensure that design is no longer limited to traditional paper design, but with the help of digital media technology, we can introduce innovative design ideas and modern design elements to form a more diversified and three-dimensional aesthetic orientation. Using digital media technology to carry out garden landscape design can integrate application, transform application, refine application design elements, integrate with modern social elements, and improve the aesthetics of design. On the one hand, digital media technology is used in the specific design. With the support of advanced technology, various artistic elements are readjusted and processed to integrate into modern design and enhance the sense of design art; on the other hand, through the network platform in digital media technology, we can provide a variety of aesthetic options, so that the design content is full of strong sense of art, and increase the artistic expression channel of the design, so that we can collect more creative content and elements of garden landscape design with the help of advanced digital media technology, and fundamentally improve the aesthetics of the design. In the process of innovative use of advanced digital media technology, the quality and level of each design can be improved. The application of digital media technology can broaden the scope of relevant design, integrate art theoretical knowledge and design practice, and broaden the source channel of design art and creativity; ensure the depth of design, create a mature landscape design system, ensure the efficient implementation of design work, and fundamentally improve the design quality and effect; by using the analog system and design research system in digital media technology, this

paper analyzes whether there are problems in landscape architecture design and puts forward corresponding rectification suggestions and countermeasures. Through effective measures, complete the tasks of landscape architecture design, improve the current development situation, highlight the positive role and advantages of digital media technology in landscape architecture design, and form a systematic working mode and system.

3. Relationship between Landscape Design and Artificial Intelligence

In the modern landscape design, the design concept is backward and the technical level is not high. Design divorced from practical problems, the emergence of artificial intelligence technology, can solve these problems to a large extent. Changing landscape design with intelligent design not only allows us to play better, but also to engage with our environment more effectively, like smart lighting. In this way, we are not only protected from light pollution, but also can be a free man living in harmony with ourselves [24]. The combination of intelligent public facilities and background music not only brings people a kind of enjoyment, but also helps relieve people's psychological pressure. A large part of the carrier of landscape design is green plants and public facilities. In the past, park landscape was mostly for its own amusement, and artificial intelligence landscape can share the source, protect the environment, and help each other. Intelligent garden design is also conducive to the promotion of local cultural customs and do complement each other. Under the premise of not violating the law of nature, set a variety of interests as one.

The elements of landscape planning and design include natural landscape elements and artificial landscape elements. Among them, natural landscape elements mainly refer to natural landscapes, such as large and small hills, ancient and famous trees, stones, rivers, lakes, oceans, etc., The artificial landscape elements mainly include cultural relics, cultural

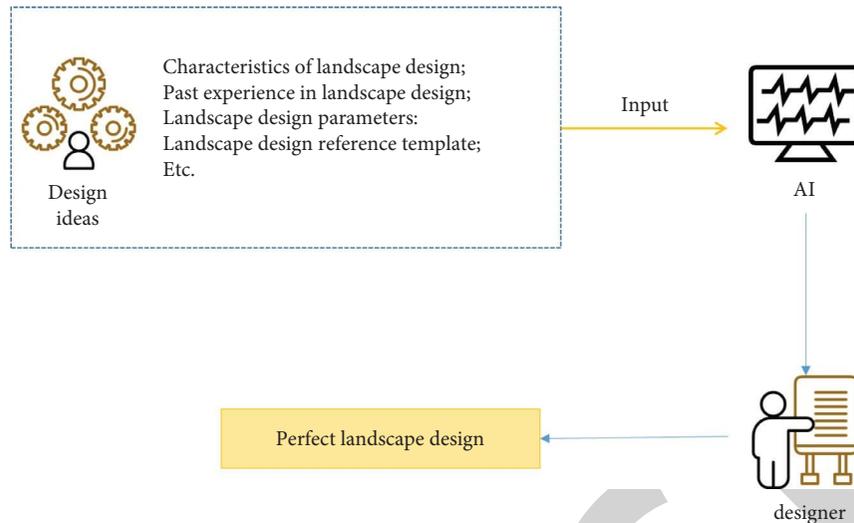

FIGURE 4: Relationship between designer and AI landscape design.

sites, landscaping, art sketches, trade fairs, buildings, squares, etc., These landscape elements provide a lot of materials for creating a high-quality urban space environment. However, to form a unique urban landscape, it is necessary to systematically organize various landscape elements and combine geomancy to form a complete and harmonious landscape system and an orderly spatial form.

The gradual improvement of scientific and technological level has played a great role in promoting the development of AI technology [25]. In landscape design, the application of AI technology can often effectively solve many adverse factors in the process of landscape design. In the past, some technical problems were often involved in the work of landscape design. It is difficult to ensure efficient and fast solution of problems when some technicians do not have enough knowledge reserve. In the long run, the quality and effect of landscape design will be affected. The application of artificial intelligence technology in landscape design not only helps to avoid light pollution, provides opportunities to get along with nature, but also alleviates psychological pressure. In addition, landscape design focuses on green plants and public facilities. On this basis, the application of artificial intelligence technology can achieve artificial intelligence landscape, promote resource sharing, provide favorable conditions for the complementary of landscape design and local culture, and ensure the maximum improvement of the actual benefits of the landscape.

At present, the concept of landscape design is still not closely related to society, so it is easy to see scenes where the design scheme does not conform to the actual situation. Therefore, the application of AI technology to design can greatly avoid such problems. In the process of landscape design in the current society, a large amount of information needs to be collected and sorted out in advance by designers, and there are also many technical problems that need to be adjusted, which requires designers to have enough knowledge reserve. Through the application of AI technology, computer programs will complete their own retrieval, collation and display of required data, technical data, similar

designs, which to some extent reduces the difficulty of design. The relationship between designers and AI design is shown in Figure 4. At the same time, the introduction of AI into landscape design can provide better conditions for the combination of human and environment. For example, according to AI lighting technology, light pollution can be effectively adjusted, and the actual utility of landscape can be further enhanced.

Rebuilding landscape design with intelligent design not only allows us to have a better recreation, but also allows us to participate more effectively in the environment. Intelligent lighting, for example, not only keeps us free from light pollution, but also makes us a free person living in harmony with nature. The combination of intelligent public facilities and background music can not only bring people a kind of enjoyment of life, but also help to alleviate people's psychological pressure.

4. The Role of Artificial Intelligence in Landscape Design

As shown in Figure 5, each step of the landscape design phase can be participated in by AI technology.

4.1. Site Condition Analysis Phase. Investigation and analysis of site conditions is a key task of modern landscape design and a basic element to ensure the high practicability of design schemes. In this stage of practice, many projects can be completed using artificial intelligence technology.

For example, in the process of remotely scanning and taking pictures of a hill using an unmanned aerial vehicle, a 3D image of the hill in the range needs to be generated in the software and the corresponding vertical information obtained. In this section, manual operations are still required during the above operations. Once the routes are set, the UAV can automate the acquisition of required data information based on the settings. Similarly, in the landscape design, human behavior needs to be considered, and the

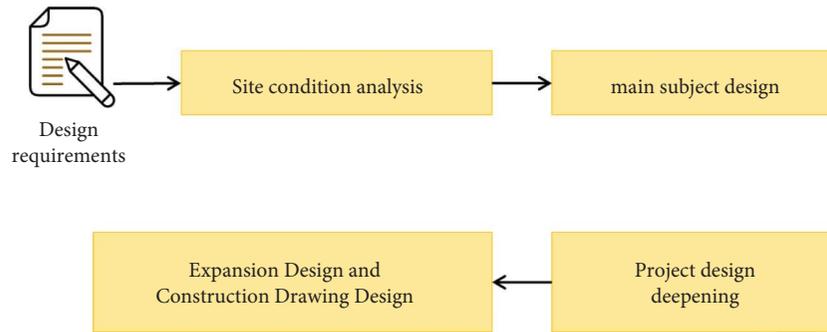

FIGURE 5: Landscape design stage steps.

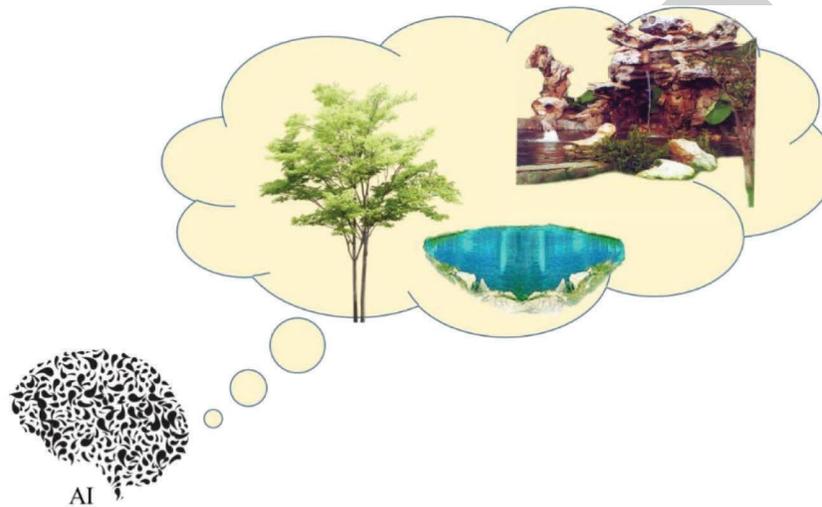

FIGURE 6: Design elements and drawings in AI.

behavior of human in the landscape needs to be analyzed in advance in Guilin. The traditional way of working for this task is to make final design decisions based on-site survey, planning information and work experience around the site. By using AI technology, the software system can automatically analyze and determine the direction and pattern of crowd gathering, avoiding the subjectivity of experience.

4.2. Project Conceptual Design Phase. In the concept stage of landscape greening, designers are required to complete the preliminary design drawings according to the actual needs. However, due to some subjective and relatively abstract needs, the current level of AI technology can hardly be completed by itself, and manual help is still needed. However, it is not impossible to design with AI. Current AI technology has a high advantage in collecting information. In the original process of finding ideas, designers tend to store according to their previous experience, relying on the past design, although it will be efficient, but easy to produce uniform but poor results. But now, with the help of AI technology, AI can automatically retrieve and store related designs, or it can automatically design based on large data. The elements and design drawings in AI are shown in Figure 6. Designers just need to enter keywords into the AI system to get new designs and enhance their uniqueness.

4.3. Design Deepening Stage. AI technology plays a more advantageous role in the design deepening phase, especially because the conceptual framework has been initially defined in the previous conceptual design phase of the project. So, this stage only needs to start the specific work layout, including material selection, color matching, determining the size of each detail part, each streamline relationship, the distribution of each function space, and so on. At this point, AI technology can help designers make decisions.

4.4. Expansion Design Phase and Construction Drawing Design Phase. When this stage is reached, the landscape design scheme has initially emerged, which can quickly achieve the operability of the scheme according to AI and solve its potential minor imperfections. At the same time, if the design needs need to be changed, AI technology can give full play to its advantages and help designers to adjust and change the landscape design through artificial intelligence technology.

Taking artificial neural network (ANN) as an example, ANN can interact with the real world like biological neural system and is composed of simple units and parallel interconnected networks. In the field of cognitive science and machine learning, artificial neural networks have learning ability. The network will automatically recognize

similar images through learning. This function is of a great significance to the prediction problem in the field of landscape architecture; moreover, it has strong expression ability and can fully approach complex nonlinear relations. The ability of associative memory is also a feature of artificial neural networks. When modifying or adding new features, only the parameters corresponding to the new features are trained, which has little effect on the original network parameters. Therefore, artificial neural network can provide scientific and efficient research methods and theoretical basis for landscape architecture design and resource management. In recent years, artificial neural networks have been widely used in simulation prediction, evaluation, and landscape classification.

5. Application of AI in Landscape Design

Through the intervention of AI technology, the landscape construction has begun to transform from traditional to modern, and the design mode of AI has endowed the modern landscape construction with new significance. In the past, traditional design concepts pursued practicality and function, ignoring the satisfaction of aesthetic feelings. AI uses computers to make perfect processing in graphics, sound and animation, and brings wonderful visual experience to people, so as to produce beautiful effects. The new design method innovates the landscape design, satisfies people's pursuit of beauty, and makes the modern landscape design enter a new era. [26–28]. Artificial intelligence will energy technology applied in the landscape construction, can make up for the inadequacy of human technology, break through the technical problems, artificial unable to complete the construction work, for example, in the early stages of the design, artificial intelligence can be used to calculate the accurate virtual images, simulate the real design, improve design scheme is practical and scientific nature in the design stage of implementation. artificial intelligence can calculate the actual topography, climate, temperature, and other corresponding plant and structural material types through a large amount of data, so as to carry out site construction more scientifically and effectively, and achieve the purpose of improving the quality of the project [29, 30].

5.1. Application of AI in Landscape Architecture Construction.

The application of artificial intelligence technology in gardening construction can make up for the shortage of artificial technology, break through the technical difficulties, and complete the construction work that cannot be completed by artificial. For example, at the beginning of the design, artificial intelligence is used to calculate accurate virtual images and simulate real design scenarios, so as to improve the feasibility and scientific of the design scheme. In the design and implementation stage, AI can calculate plant species and building materials corresponding to the actual terrain, climate, and temperature through large data, so as to carry out field construction more scientifically and effectively, and to achieve the purpose of improving the project quality.

5.2. *Application of AI in Water Landscape Design.* Water landscape plays an important role in landscape design, and its design is often closely related to the effect of the whole landscape design. In the past landscape design, fake waterfalls, artificial hills, simulated fountains, and so on will be introduced to expand and enrich the landscape of the whole garden. Such a design can bring visual appreciation to a certain extent, but lacks vitality, cyclicity, and sustainability, and has a relatively high maintenance costs in the later stage, and is easy to cause tourists to fall into aesthetic fatigue. Based on this, AI technology will play a very important role in water landscape design.

In practice, the role of smart sensor technology can be fully used to form light shadows pools, music fountains, and so on, to build a water landscape system with sustainable recycling performance, giving more vitality to the water landscape. For example, you can set up an open space in the center of a fountain and install a gravity sensor on its bottom. When the gravity of the corresponding surface area reaches a certain value, the flow of water and light from the surrounding fountain turns on and stops within 30–60 seconds. At this time, people can take photos and play in the center of the fountain to interact with the water view. In this way, the purpose of improving the effect of water landscape design is achieved, and the upgrade of the whole modern landscape design is also promoted, the flow of which is shown in Figure 7.

5.3. *Application of AI in Ground Paving.* In landscape design, the paving of the ground should first have a hardening effect and preferably be enjoyable to enhance the visual aesthetics. However, the traditional floor paving only has a hardening effect, it is just an ordinary paving, wasting the value of appreciation [31]. Using large data in AI technology for color analysis and changing the color of the ground paving according to different natural light can make the paving not only have hardening effect, but also display certain visual effect, and achieve the unified design effect of aesthetics and function.

Ground paving is also an important content in modern landscape design. On the basis of guaranteeing its intensity (guaranteeing its function), we need to further optimize its visual effect and aesthetic level. However, in the past landscape paving design, under the condition of ensuring the overall function, it is difficult to obtain more rich and diverse visual effects, and the overall aesthetic feeling is not ideal. With the application of artificial intelligence technology, the above design goals can be achieved and the coexistence of function and aesthetics can be achieved. In practice, large data technology can be used to carry out color analysis, adjust the color of ground paving according to natural light, and improve the aesthetic degree of garden tiles, as shown in Figure 8. At the same time, it can also play the advantage of projection technology, put dynamic images on the ground, and promote the upgrade of landscape ground paving design.

In addition, when carrying out ground paving design relying on artificial intelligence technology, you can also

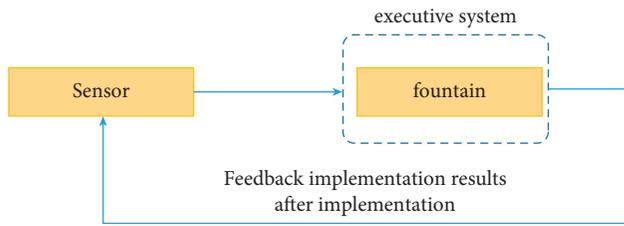

FIGURE 7: Intelligent water landscape design diagram.

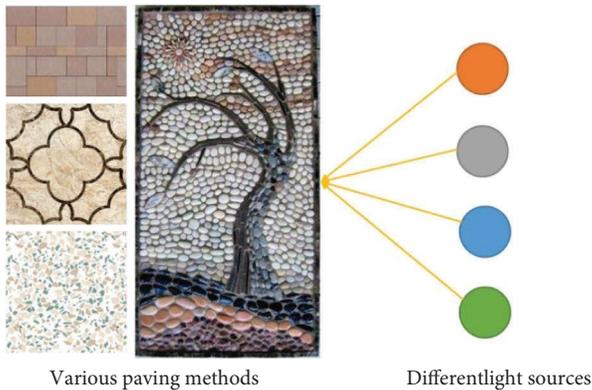

FIGURE 8: Dynamic adjustment of the paving image under different light sources.

refer to the setting of “stair piano” to create similar landscapes such as “ground piano board,” which will attract people to the landscape garden experience, realize the interaction between the landscape and people, and enrich people’s experience. This will make the landscape interact with people and enrich their experience.

5.4. The Application of Artificial Intelligence in Visual Lighting.

In the past, in landscape design, lighting paid more attention to function (lighting) and atmosphere adjustment, and relatively ignored the aspects of humanization and interaction. The emergence of artificial intelligence technology has brought a new visual experience to lighting design. The application of artificial intelligence technology can bring more rich visual experience to people and make up for the defects of lighting landscape design in the past landscape architecture. For example, smart lighting includes an intelligent sensor system that can effectively perceive the light in the environment, and on this basis, adjusts the light intensity and color of the lighting to reflect the humanization and interaction of the lighting landscape.

In practice, artificial intelligence technology is widely used in three aspects of modern landscape lighting design:

- (1) time controller and latitude and longitude controller. Based on the change of latitude and longitude in different areas, the accurate prediction of time change can be achieved, and on this basis, the landscape lighting system can be intelligently controlled.
- (2) GPRS wireless landscape lighting remote monitoring device. With this equipment, the gardening

administrator can grasp the actual operation of all the lights in the gardens in real time, comprehensively and truthfully. Through the analysis of these data information, the parameters such as the electrical power of lighting fixtures can be determined, which can provide data information support for fault analysis and treatment, and ensure the long-term stable operation of the lighting system in gardens.

- (3) Semiconductor landscape lighting. Depending on the reasonable adjustment of lighting time and intensity, and on the basis of meeting the actual lighting needs of modern landscape gardens, the use of electric energy is reduced.

In the future, landscape design and artificial intelligence technology can also be applied in more areas, such as: the intellectualization of background music, combining people with music, can not only heal the mind, enlighten life, but also promote national culture; intelligent lighting not only combines buildings with people organically, but also creates a living place free from light and pollution to better entertain the public without affecting others. Intelligence of public facilities, such as changing some garbage cans to smart robot garbage cans, can be moved to facilitate garbage disposal etc.,

6. Discussion on the Application of AI in Landscape Design

Will designers be replaced by AI? What is the meaning?

It is found that the algorithm can summarize the universal laws of site design through a large number of mature cases, such as “the relationship between layout and site conditions,” “the relationship between the layout in the park and the layout outside the park,” “the relationship between spatial functions and specific design language,” and even summarize some abstract design feature information. However, the design work is far from this. Take a common example of design work. Assuming that a large-scale country park is to be planned at this time, it is likely to experience the following situations: party A proposes that it should adhere to national policies and make “characteristics,” but the budget is not high. After a week of discussion, we finally decided to take “carbon neutrality” as the main goal. At this time, I immediately encountered a new problem: how to calculate the carbon reserves? How to balance the revenue and expenditure of carbon source and carbon sink? After another week of discussion, the overall technical route was finally defined. However, once the report was made, there was a new problem: how to make features? At this time, we need to summarize the existing relevant planning and design cases, study the characteristics of the site, and study how to put forward a scientific and objective overall planning and design scheme for the site under the condition of low budget. In the course of design revision, we will also face various problems, ranging from land policy and ecological pattern to special budget, materials, and plant selection. In contrast, a designer is an expert in solving problems, and landscape architecture is a comprehensive discipline that balances society, nature, and economy. These are the meanings of

designers' existence, and also abstract problems that cannot be solved by AI alone. Therefore, automatic design is only a link in the design work.

Therefore, the application of artificial intelligence in landscape architecture design belongs to the exploration of new productivity in landscape architecture industry and the exploration of new production forms in landscape architecture industry. As the landscape architecture industry has become normal to work overtime and stay up late for repetitive drawing, the generation system driven by artificial intelligence can also achieve the production efficiency of thousands of solutions per second. Why is such an amazing productivity meaningless? And mining the universal laws in planning and design with the help of generative confrontation network to build a new human-machine collaboration method, which is only focused on the application research of a small stage in the design industry workflow. The comprehensive intelligent upgrading combining BIM, Lim, UAV, Internet of Things and other cutting-edge technologies will come in the near future, and the new human-machine cooperation forms matching the new productivity will also be accelerated.

7. Conclusion

Explore a more technical parameterized design method for architectural landscape design, combining artificial intelligence with landscape planning and design, and developing a landscape planning and design method that integrates artificial intelligence parameterized analysis. This is a new design branch, which is an extension of landscape design method based on artificial intelligence technology.

Multimedia is becoming more and more important in landscape applications. Due to the public demand and the diversity of social strata, contemporary landscape also shows a diversified trend. Although the future landscape may not necessarily be developed in the direction of multimedia, the future landscape will increasingly use multimedia technology, which represents one of the future directions of landscape development.

Electronic information expressed by multimedia devices has become an important element of landscape design, carrying the fusion of different cultures and technologies in a new form.

8. Limitations and Future Work

Although artificial intelligence technology is more and more applied in landscape architecture research, the ability of artificial intelligence to solve the uncertainty and complexity problems of landscape architecture still fails to meet people's pre-requirements, and it is even more difficult to integrate the uncertainty and complexity problems of landscape architecture into a system framework. First of all, the technology of integrating a variety of artificial intelligence methods is not perfect. At present, there is no more suitable advanced architecture for integrating a variety of artificial intelligence methods. Secondly, to build an artificial intelligence model in landscape architecture research, we need

not only landscape architecture knowledge, but also computer science, geography, biology, and other multidisciplinary knowledge. If there is a lack of professional knowledge, we cannot build an ideal artificial intelligence model. This requires that each modeler should have a wide range of knowledge. Although the application of artificial intelligence technology in landscape architecture is not mature at present, with the rapid development of artificial intelligence technology, more artificial intelligence will be applied to landscape architecture research. The intelligent development of landscape architecture in the future needs to actively try to integrate a variety of technologies to establish a landscape model with mixed artificial intelligence methods, and accelerate the automation level of landscape architecture research.

In the era of “Internet +,” the deep integration of party building in colleges and universities and information technology is the objective need for the modernization of the party’s government in colleges and universities and the realization of science. Starting from the concept of the smart party-building platform in colleges and universities, this study analyzes the current situation of the informatization and intelligence of party-building work in colleges and universities. Combined with the current development needs of the party-building work in colleges and universities, starting from the significance of the construction of the smart party-building platform in colleges and universities, the ideas and main research studies on the construction of the smart party-building platform in colleges and universities are expounded. Contents describe the construction path and implementation method of the university wisdom party-building platform in order to construct a reasonable and efficient university wisdom party-building platform construction plan.

1. Introduction

With the rise of “Internet +,” the self-construction of grassroots party organizations in colleges and universities, and the continuous increase in the scale of party members, the pressure on party affairs’ management staff has increased, and some colleges and universities have begun to seek more intelligent management models’ concept which came into being. The so-called smart party building in colleges and universities [1] is the era title of informatization and digitization of party building in colleges and universities in the new stage of informatization development [2]. The level of party members of teachers and students expands the party’s presence and digital influence in colleges and universities, improves the service level of party organizations in colleges and universities, and consolidates the new platform, new model, and new form of party organization management

ability in colleges and universities [3]. The formation of smart party building in colleges and universities [4, 5] has gone through a process from scratch, from slogan to initial realization. In the beginning, everyone focused on the research on the necessity and possibility of Internet + party building in colleges and universities, and how to build the Internet + The new system of party building in colleges and universities has become the main theme of the reform of major colleges and universities [6]. The focus of the research is on how to integrate party building in colleges and universities into the mobile Internet platform [7]. Subsequently, a very small number of colleges and universities began to carry out research on the realization and application of smart party building, trying to take “Internet + student growth” as their work idea, such as the “NetEase Class” of Southwest Petroleum University. However, in general, the existing research on high-intelligence party building

platforms [8] is still at a relatively shallow level, and the constructed platforms also generally have the characteristics of a single function, weak data sharing, and poor versatility.

Smart party building is a new application of information technology in the field of party building in the “Internet +” era [9]. Making full use of information technology means building a new smart party building platform to give full play to the smart party building platform to closely connect with the masses, standardize the management of party members, and improve service levels and scientific levels [10]. It is a necessary measure to train qualified builders and reliable successors of the party and the country, and it is an inevitable choice to promote the quality of party-building management in my country’s colleges and universities [11–13]. Contemporary college students are all post-90s and digital natives. Almost every college student has more than one mobile phone or mobile terminal. Contemporary college students are very active netizens, who provide sufficient prerequisites for the “Internet + Smart Party Building Platform.” It is realistic to build a smart party building platform and strengthen the innovative practice research of college students’ party building work, and it is a necessary way to make the party building work in colleges and universities intelligent in the new era [14].

To build a reasonable platform for party building wisdom in colleges and universities, it is necessary to grasp the important advantages of smart party building in colleges and universities from the perspective of theory and practice, strengthen the integration of network, information technology, and party building, and integrate resources so that the management of party building in colleges and universities will become informatized and the forms of publicity will become diversified [15]. Party-building services are becoming smarter, and the following points must be done. (1) Clarify the new tasks and new requirements of the smart party-building platform in colleges and universities, make full-use of the communication power of the mobile Internet, use big data means to integrate resources, and actively explore the use of modern information [16]. (2) Establish a platform for smart party building in colleges and universities. Establish an party member electronic information management system to achieve unified, refined, and standardized management of all party members, and achieve scientific and orderly management of party member information and oral work; establish an online party member examination system to make party member development work smarter; establish an online party school classroom. Develop the APP client of the party building learning platform, transfer the ideological education of colleges and universities to the Internet, and realize the normalization of online education through theoretical learning [17]. (3) Explore the management methods of the smart party building platform in colleges and universities. Strengthen the analysis and judgment of data, improve the accuracy of services, and use relevant policy support and technical means to ensure the safe and effective operation of the party-building platform [18]. Functional modules of the smart party building platform are shown in Figure 1.

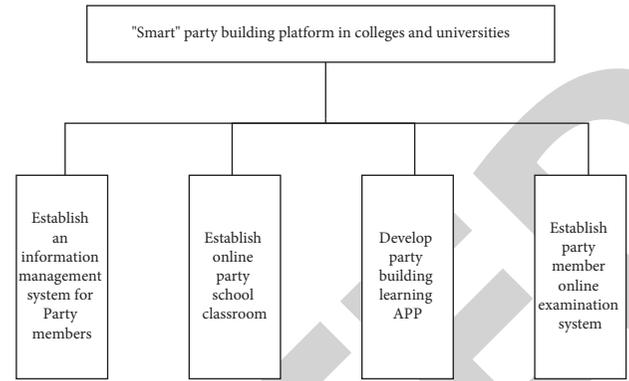

FIGURE 1: Functional modules of the smart party building platform.

2. The Goal of Building a Party Building Platform That Integrates Internet Technology

In order to implement the requirements of the central party building work, the party and government departments of colleges and universities should make full use of information technologies such as the Internet, cloud computing, big data, and artificial intelligence. Smart management: through the establishment of a smart party building platform, party members are connected to the Internet, the organization is built on the cloud, and the Internet can be integrated into the work, life, and study of party organizations and party members in a timely and effective manner, so as to realize scientific decision-making, learning, and education of party organizations. Use data to achieve precision, use intelligence to achieve prediction, and help provide comprehensive services for teachers, students, and party members in colleges and universities in the digital space [19].

The current smart party building work is carried out in various forms [20]. It is no longer bound by traditional methods. Instead, it uses the Internet to realize party building informatization, establish a smart party building system, and facilitate the implementation of the party’s line, principles, and policies, so as to realize the realization of the party central committee. With the proposed goal of strictly governing the party, the smart party building platform provides platform convenience, time convenience, and space convenience for realizing the party building work goals.

The construction of party-building cloud platforms in colleges and universities must be closely integrated with the spirit of the 19th National Congress of the Communist Party of China; it must be integrated with the political and ideological work of schools. The content of the platform should be in line with national conditions, party conditions, and school conditions, and in line with the law of teacher and student growth. Clarify the purpose of building a cloud platform for smart party building in colleges and universities under the new situation and fully reflect the practicality, practicability, and effectiveness of the platform [21] so that teachers and students can learn more efficiently and work well, and party building organizations are more effective, so as to ensure end customers. The number of party members

engaged in online self-learning facilitates, to the greatest extent, the study and lives of the majority of party members, teachers, and students. Second, optimize the top-level design and improve the platform functions. Under the background of “Internet +,” the smart party building work in colleges and universities is highly political, professional, and systematic. The construction of the smart party building cloud platform should be regarded as part of the smart campus construction, and college leaders should attach great importance to the smart party building cloud platform. Top-level design and overall planning: give full play to the advantages of the network platform, summarize the main characteristics of the new era and new technology applications, analyze the main problems, and study how to establish and improve the platform design and guarantee mechanism. Establish the concept of “big party building” and improve the platform modules and functions [22], including party building publicity, party member service, party affairs management, party member education, party discipline supervision, party member evaluation, and other modules. Use learning platforms, such as portal terminals, mobile apps, and WeChat public accounts, to give full play to the intercommunication, mutual integration, and interaction functions of “Internet +” and realize the design goal of the smart party building cloud platform. The rapid development of “Internet +” technology has brought great changes to the management of colleges and universities. At present, most domestic colleges and universities have their own complete website construction. With the increase in party affairs’ work, it is imperative to open a special portal website for party building on the school homepage. The portal website must have a group of professional management personnel and work according to national laws, top-level reality, and the actual situation of the school. Do a good job in the planning of each module, daily update of content, interconnection and interaction, question answering, background management, etc., and do a good job in the management of WeChat public account platform and mobile APP receiving platform, rather than one or several topics at present module link, and manage lax state. It can really play the role of the portal website and bring convenience to the study and lives of party members. Second is the construction of the WeChat public account platform of the Object Wisdom Party Building. Relying on “Internet +” thinking, the WeChat public account receiving platform for college wisdom party building can transmit text, pictures, videos, and other information anytime and anywhere, allowing college party members and cadres to break the limitations of time and space to browse and read the party’s policies and information anytime, anywhere, and learn the latest. The tasks and priorities of the work are well illustrated and immersed. Online party member education is carried out through the WeChat public account, interactive communication, understanding of party members’ ideological dynamics, and understanding of the deficiencies in party building work so as to improve the management level and improve the effect of learning and education. Third is the construction of the mobile APP platform of the object wisdom party building. Under the “Internet +”

environment, the construction of the party building mobile APP platform is very convenient. For example, the “Learning to Strengthen the Country” mobile APP platform that all our party members are paying attention to every day is good learning receiving platform. Use the mobile phone APP smart party building platform to push news content from time to time, carry out online comments and points learning, and regularly promote the Communist Party members’ mobile newspapers with clear themes and vivid content to attract the attention of party members and cadres. Improve the attention of party members and cadres through points ranking, points exchange, etc., so that party members and cadres can improve themselves through learning and fully understand the importance of learning to strengthen the country and the school.

To achieve platform convenience [23], the smart platform built by the smart party building contains a variety of functions, which are intended to transfer the offline activities of the smart party building work to the online, which is more conducive to the development of the smart party building work, and the offline activities are transferred to the online, so that more party members can view and participate at the same time, and there will be no crowding when offline activities are carried out. The party building platform solves this problem very well. Give full play to the supervisory role of the masses. To achieve time convenience, traditional party building work requires smart party building to commute to get off work regularly. When there is a need for study, training, or business trips, you cannot participate in the party-building work of the unit, and you can only go back to the unit to carry out tutoring, resulting in tight working hours; the effect of tutoring is also unsatisfactory. Due to the inconvenience of space, the traditional party building work is difficult to convey information due to the inconvenience of space, and the policies and lines of the Party Central Committee may be “changed” when they are communicated to the grassroots. The establishment of the smart party building platform has solved this problem very well. Party members can use the examination function to strengthen the study of party regulations and party constitutions. The party rules and regulations are imprinted in the heart. The “smart party building” platform system is different from other party building platforms used in colleges and universities in the past [24]. The objects it serves not only are limited to party members and comrades but also include all party identities inside and outside the party, from party applicants to official party members (Figure 2).

The significance of artificial intelligence and Internet technology applications in party building work is mainly reflected in the following three aspects. The use of big data technology to achieve innovation in party building work: after the adoption of cloud computing big data technology, on the one hand, the teaching and labor party branch and student party branch of our college party affairs’ workers at the highest level can understand the work dynamics of party organizations in a timely manner based on real-time data and clarify the direction of each party affairs’ activity. Data technology provides great convenience. On the other hand, through the analysis of online data on the platform [25], we

FIGURE 2: Service objects of the “smart team building” platform system.

can more accurately understand the needs of each party member in terms of learning dynamics, work and life, etc., which is conducive to the higher-level party organizations carrying out intraparty care and drawing closer relationships with teachers and students.

3. The Construction of the Platform

For the construction of the cloud platform for smart party building in colleges and universities, it is necessary to grasp the principles and construction methods of platform construction according to the tasks and goals of platform construction. At the same time, plan and design each functional module, build it in one step, and formulate a sound management system to ensure the normal operation of the platform.

3.1. Technical Route. The platform technology architecture is divided into four layers. The bottom layer is the hardware layer, which adopts a safe and reliable elastic cloud platform, which can be elastically expanded according to the size of party members. The data layer is the three core databases of the three party building platforms. The middle layer is the business layer, with the AI intelligence engine as the core, providing a storage engine, search engine, analysis engine, content engine, learning engine, data cache, and other capabilities. The top layer is the user access layer, which is mainly used for external publicity and serving party members and the masses. There are four access methods for the server: portal website, mobile app, WeChat public account, and interactive terminal all-in-one. Party workers, party members, and the masses can easily obtain party building resources and services through different channels. Party organizations can conduct organizational work, content updates and decision-making analysis through a unified management platform [26]. The technology roadmap is shown in Figure 3.

3.2. Functional Framework. A functional framework is shown in Figure 4. The three core databases of the platform include the party member and organization information database, party building information and learning content database, and party member and organizational behavior database, which are used to support the realization of “party building publicity, learning, and education, interactive services, party affairs’ management, and party member evaluation.” The Party Building Propaganda Center is a column where the party organization publishes important news within the party, and it is a new frontier for party building propaganda; the Learning and Education Center is the “handheld party school” for party members, providing party members with original texts, VR, courses, and other

forms of learning content; the party member interactive service center allows party members to post “work, achievements, and highlights” to form a party building work atmosphere that loves interaction and diligent sharing; the party affairs’ management center can help party organizations at all levels manage party member information, carry out organizational life, and transfer online. Receive party work such as organizational relations and online collection of party dues; the party member evaluation center generates a medical report by conducting consultations on party members’ learning effects and recommends learning content to improve party members’ learning effects; the scientific decision-making center for party building provides party organizations at all levels. The AI intelligent engine is the core of the system. Through natural language analysis of party members’ speeches and discussions, it depicts party members’ portraits and knowledge maps and accurately recommends learning content based on the analysis results.

3.3. Functional Module Design. Platform functions need to be divided and designed from the perspective of user usage habits according to business needs and business processes and follow the standards of identity authentication, information security, sharing, and exchange of the national organization system.

3.3.1. Party Building Information. Party organizations at all levels can publish hot information, advanced models, and clean government models through the party building information module and provide innovative and dynamic propaganda content such as audio and video integration, pictures, and texts. Party members can learn the basic knowledge and theory of the party anytime and anywhere through the three access methods of the platform. Information must be reviewed by the administrator before it can be placed in the corresponding section. The system follows the principle of “which level is the approval level and which level is the release level.” For example, the information approved by the branch secretary is open to view by all party members under the branch; if the information has been submitted to the higher-level organization department for approval, all party members under the party organization can view it. In terms of information content recommendation, the platform realizes personalized and accurate push of learning content based on the correlation characteristics and popularity characteristics of party member portraits, learning environment, and party-building content so that the majority of party members can keep abreast of the party and public sentiments they are concerned about. The organizational activity management process is shown in Figure 5.

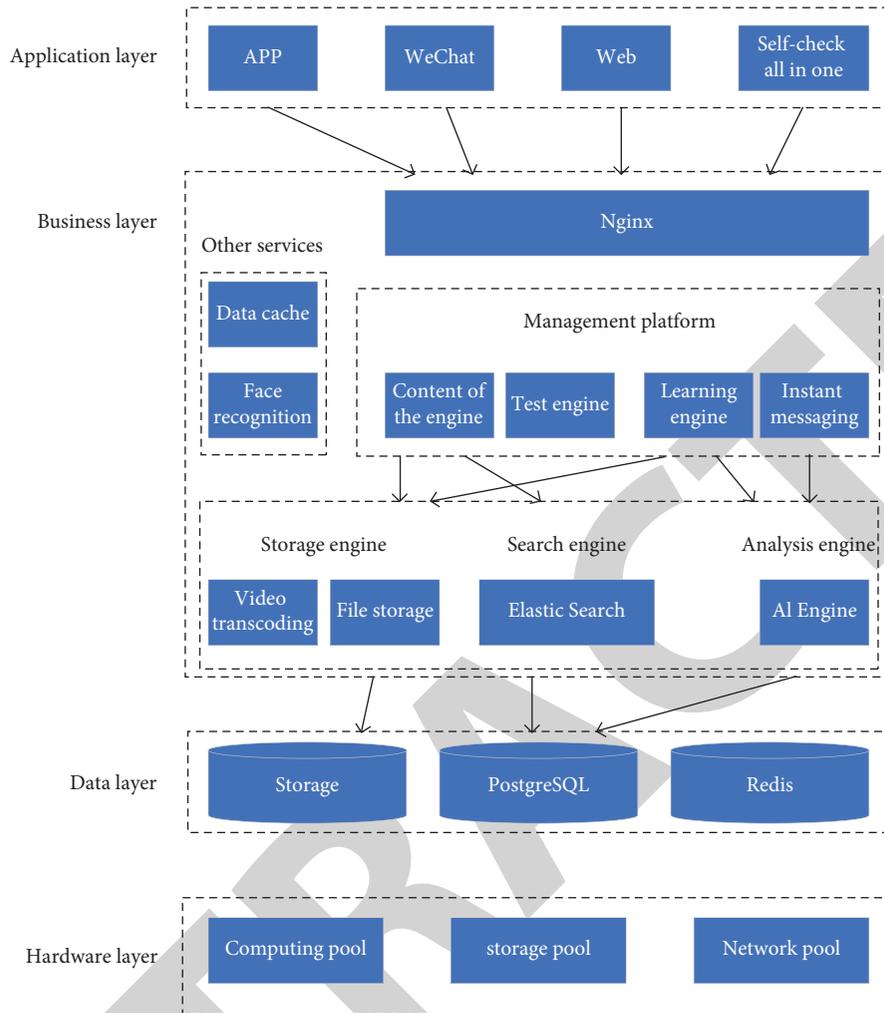

FIGURE 3: Technology roadmap.

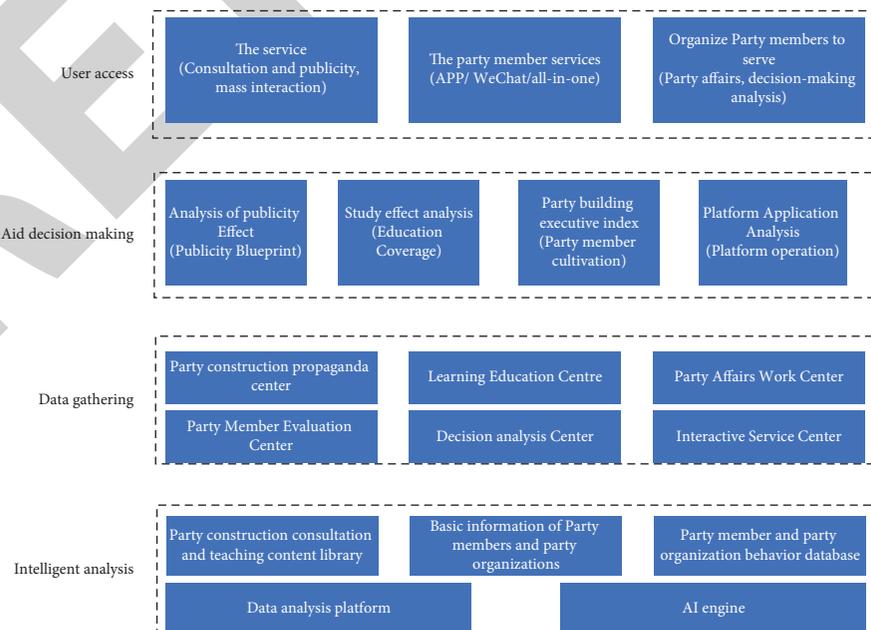

FIGURE 4: Functional framework.

Party workers initiate organizational activities through the app and set the theme, time, and participants of the event. Before the event starts, the platform automatically pushes information to each party member. After receiving the event notification, individual party members can feed back their opinions to the branch. After the event starts, party members check in after locating them through the app, and the system automatically records and counts the check-in situation. After the event, party workers can upload event pictures and event summaries, and party members can share their experiences.

3.3.2. Party Member Interaction. The party member interaction module realizes the real-time networking of party member management and organizational life. Party members can share their experience and thoughts on party building work, advanced deeds and pioneer stories around them, or the effectiveness of paired assistance work on the platform in the form of a “circle of friends.” On the basis of giving full play to the vanguard and exemplary role of the Communist Party members, we launch extensive propaganda. Let the communication and interaction between party members and party organizations and party members and nonparty members no longer be limited by time and space and be able to initiate communication and interaction at any time and any place; changing the previous study relying on on-site lectures, opinions must be presented face-to-face, and evaluations are all thrown around.

3.3.3. Party Affairs’ Management

(1) Organizational Management. The organization management module is used to maintain the information database of party organizations and party members and realize the management of adding, deleting, and querying information for party organizations and party members. Party organization information includes party organization code, party organization name, superior party organization code, party organization type, party organization structure, location information, and other information. Support a multilevel tree organization tree, which is consistent with the data format of the Central Organization Department system. Party member information includes name, gender, ethnicity, place of origin, education background, date of birth, contact number, ID number, whether the party has lost contact, job position, code of party organization affiliation, administrative region affiliation, and other information. The format of party members conforms to the “Regulations for Information Collection and Reporting of the National Party Member Information Database of the Organization Department of the Central Committee.”

(2) Work Ledger. This module provides two categories of work ledger management of party organization and party affairs work. The party organization ledger includes the party committee work ledger, the party general branch work ledger, and the party branch work ledger. The platform for party building work standardizes the configuration of work

items, and this module can provide two categories of work ledger management of party organization and party affairs’ work according to the organization. The party organization ledger includes the party committee work ledger, the party general branch work ledger, and the party branch work ledger. The platform party building work standardizes the configuration of work items and can be stratified according to the organization.

(3) Work Assessment. This module provides an online assessment function for party (general) branches and party members. Party (general) branch assessment includes branch self-assessment, branch mutual assessment, leading group scoring, and publicity of assessment results. The assessment of party members includes self-assessment of party members, democratic assessment, scoring by the leading group, and publicity of assessment results. The platform automatically provides the basis for assessment indicators and calculates quantitative scores based on party-building data, which greatly reduces the complexity and workload of assessment work and improves assessment standardization and transparency.

(4) Task Management. The party building work management department can decompose and issue various daily or periodic important work items to the responsible department or person in charge for processing, set the type and completion time of the task, and conduct real-time tracking and penetrating supervision of the task. Party workers can use text messages to remind or urge the responsible person, and the responsible person can also give feedback on the implementation of the work in the task management process. The platform can centrally monitor and summarize key tasks, which is conducive to strengthening the implementation of various party-building work items and forming efficient cooperation in party-building work.

(5) Cadre Management. This module establishes a complete information file of party members and cadres, records the basic information of party members and cadres, resumes, work experience, family situation, important social relations, elected representatives, and committee members, and realizes the daily management of cadres, learning, and examination, assessment, and selection. Full coverage standardizes the whole process of management cadre assessment, provides cadre selection and appointment and management assessment supervision mechanism, and provides information support for colleges and universities to select and employ personnel and conduct cadre assessment.

3.4. Online Teaching. Online teaching is divided as follows.

3.4.1. Online Learning. Relying on “new media” for learning and interaction has become the new normal in the education and training of party members and cadres. The online learning module can provide party members with content such as national policies, party history MOOCs, school regulations, party work priorities, party affairs research,

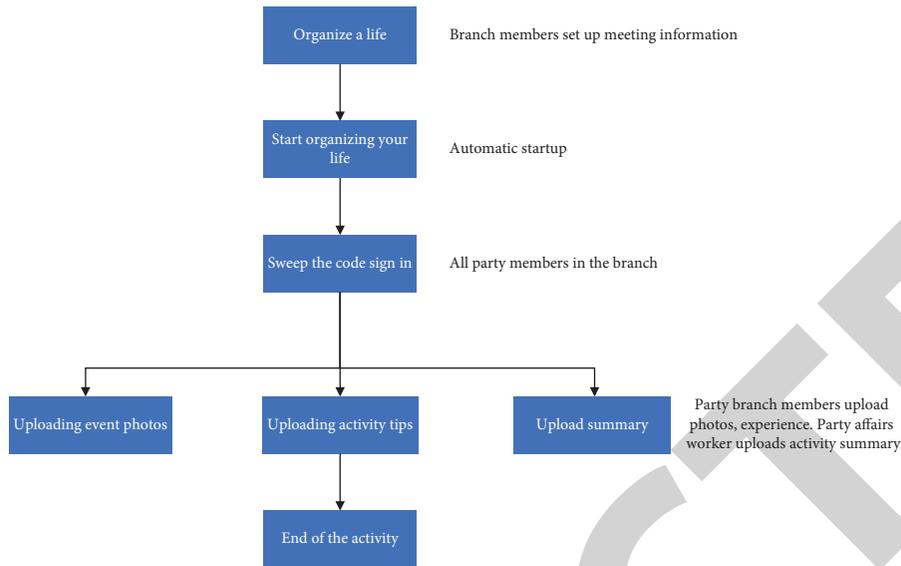

FIGURE 5: Organizational activity management process.

agricultural history and school history, and VR representation of red scenic spots. The platform records the learning content, time, comments, and other learning behavior data of party members for evaluation and analysis of learning effects.

3.4.2. Exam Management. Exam management is divided into three parts: question management, paper management, and examination management. The range of test questions includes the platform’s own question bank and a user-uploaded question bank, and the types of questions are multiple-choice, multiple-choice, and judgment. Administrators can batch import test questions through an Excel spreadsheet. Before the test, the administrator can automatically generate test papers with random questions from the question bank or manually select the test questions to form the test paper and set the test time, question score, test object, and other information on the test paper. After party members submit test papers through computers or mobile phones, the platform will automatically grade the papers and calculate the total score.

3.5. Intelligent Analysis. Intelligent analysis is as follows.

3.5.1. Portraits of Party Members. The image of party members and cadres is related to not only the mass base, influence, and appeal of the party members and cadres but also the image of the party and the prestige of the party organization. This module creates three-dimensional portraits of party members from 26 categories and 145 sub-categories. The platform intelligently analyzes the learners’ thinking patterns of perceiving and processing information from the semantics and context of comments and categorizes the work behavior styles of party members into four categories: perception, observation, thinking, and hands-on. The machine learning algorithm based on feature extraction

compares the text features of the comments with the built-in keyword knowledge base of the system. The level outlines the overall level of party members’ learning effects, synthesizing the semantic, context, and keyword features of the review text and mining the relatively stable and lasting characteristics of the learners in most cases, that is, the personality traits through the learners’ behavior forms in different times and situations. And from the personality traits of 16 dimensions such as gregariousness, self-discipline, and intelligence, it provides a reference for personnel placement, adjustment, and rational use of party member resources.

3.5.2. Party Building Decisions. The party-building decision-making module realizes the function of supervising and controlling the work of party members and party organizations online. Party workers can supervise the attendance of party members and track and manage the activities of lower-level party organizations and grassroots party organization meetings. This module visually displays the statistical data of the party organization, the statistical data of organizational life, the statistical data of democratic appraisal, the statistical data of the “three meetings and one lesson” learning, the statistical data of the party members’ learning effect, etc. Through trend analysis, party affairs’ workers can understand the work of grassroots party building and changes in party building indices, and review the effect of special education in real time, so as to adjust and optimize party member education strategies in a targeted manner to achieve precise policy implementation.

4. Conclusion

To sum up, under the background of “Internet +,” information technology provides a more complete and convenient way for the cloud platform of smart party building in colleges and universities and promotes the advancement of party member education, management, and service with the

times. In the construction of the smart party building cloud platform, it is necessary to clarify the construction goals to ensure the wisdom of the party building management work. With the innovation and improvement of the smart party building cloud platform, it promotes the development of party building work in colleges and universities, enhances the vitality of party building work, and brings new vitality to party building work. At the same time, it also provides new ideas for the development of college construction work, promotes the progress of grassroots teachers and students in colleges and universities, and ensures the quality of grassroots party members. The online education management method of party members will improve the efficiency of party affairs' work. The four advantages of the "smart party building" platform will also be the necessary methods and means of party building work in the future. From the perspective of "Internet + big data," party building work will surely move forward steadily on the road of high efficiency and technology.

The traditional topic-based auditing model lacks the ability of multi-object and multi-abnormal correlation auditing, which makes it impossible to solve the multi-scenario and multi-factor correlation-based auditing problem. This paper designs an intelligent power marketing audit model based on a knowledge graph. First, an entity identification and relationship extraction method for power marketing business based on NLP (natural language processing) and sequence annotation technology is proposed, and the description content is imported into the knowledge graph database; then, semantic disambiguation and knowledge are carried out by using bidirectional encoder representation from transformers (BERT). Link to build a knowledge map of business audit rules: Finally, an experimental analysis is carried out by taking the copying and receiving business with a large business volume in the marketing audit work as an example, and it is verified that the proposed model can effectively improve the information analysis ability and the audit accuracy of the audit work.

1. Introduction

As a basic work of power supply enterprise, power marketing audit plays a very important role in ensuring the economic market order of power enterprises and improving their economic interests [1]. It is not only related to the survival and development of the power supply enterprise itself, but also directly affects the smooth operation of the entire power system and even determines whether the national economy can continue to develop rapidly [2]. The development process over the years can be roughly summarized into the following three stages. The first stage: According to the work experience, conduct random inspection of the marketing business, the main purpose is to find problems. The second stage: Based on the statistical sampling technology, referring to the business audit scoring system, the overall marketing business is audited, and the main purpose is to evaluate the marketing business of each department. The third stage: Build a three-in-one audit system, including online audit, sampling audit, and special audit, to supervise the quality of marketing business from

different dimensions, the main purpose is to reduce the problem rate of marketing business to the greatest extent and improve the level of marketing business.

However, with the continuous acceleration of smart grid construction, the business scope of power marketing is more extensive [3]. The current electric power inspection work faces some difficulties, such as the traditional inspection work mode can no longer meet the requirements of current social development, and there are still problems such as backward inspection methods and low efficiency. Therefore, effective measures must be taken to solve these problems. It is necessary to reform and innovate it, use intelligent inspection to improve the continuity and integrity of marketing inspection work, and promote the continuous improvement of marketing management level [4].

As a new type of semantic network analysis technology, knowledge graph connects all knowledge points in series through the correlation between things, displays them in the form of graphs with different structures, and has significant information analysis capabilities [5–7]. In this paper, the construction of an intelligent power marketing audit model

based on knowledge graph is introduced by taking the copy-checking and collection business with a large business volume in the marketing audit work as an example. According to the traditional marketing audit sampling plan, this business will be allocated more audit samples, so it must invest more manpower and material resources. However, because the sample problem rate of this business is relatively low, most of the audit personnel's time is spent checking samples without problems, resulting in a waste of human resources. Through the use of deep learning algorithms to complete knowledge identification and extraction, realize the construction of business audit rules knowledge map, greatly improve the accuracy and control efficiency of this marketing business audit, and effectively ensure the management ability and work efficiency of business audits.

The main contributions of this paper are the following triple:

- (1) Propose an entity identification and relationship extraction method for power marketing business based on NLP natural language processing and sequence labeling technology, break through the original audit topic labels, and realize the construction of a three-dimensional label database that combines the basic attributes of customers with hierarchies and classifications.
- (2) Carry out semantic disambiguation and knowledge linking based on bidirectional encoder representation from transformers (BERT), generate a knowledge map of business audit rules, check and analyze business content according to its own search rules, and realize intelligent management and control of audit business.
- (3) According to the constructed intelligent power marketing audit model based on knowledge graph, take the copying and receiving business with large business volume in marketing audit work as an example to carry out experimental analysis to verify that the proposed model can effectively improve the information analysis ability of audit work.

2. Status Quo of Electric Power Marketing Business Inspection and Research

2.1. Current Status of Research on Extraction of Knowledge Elements in Power Marketing Business Inspection. The research of foreign experts and scholars on power marketing audit management mainly focuses on the mode of marketing audit and the division of supervision power [8]. After research, Li et al. concluded that the functions of power inspection mainly include: inspection, investigation, and execution [9].

The degree of marketization of electricity in the United States is relatively high, and the state-level government enjoys great autonomy. Therefore, the supervision of marketing activities in the United States is not unified by the state, but each state conducts it separately under the guidance of national laws. This model makes the marketization of the power industry very deep, but it is not

conducive to the overall regulation and management of the power grid [10].

From the perspective of foreign advanced power companies, some power companies with advanced management have incorporated marketing audit work into their daily marketing work, and rely on the strong support of information systems to effectively monitor data [11]. For example, the marketing information system of Tokyo Electric Power Company of Japan is inclined to the checking of relevant data and logic, and through the automatic review and judgment of the system, the correctness of business execution is ensured [12]. Due to the different business environment of foreign power companies, customers have less breaches of electricity usage and electricity theft, and the internal management of power supply companies is relatively complete. Considering the operating costs, they rarely consider setting up special inspection departments. The inspection of the industry mainly focuses on the supervision of the legal operation and service quality of the electric power enterprises by the electric power supervision department. Of course, in the foreign situation, through systematic analysis and design, streamlining business categories and simplifying business processes is also the key to improving the quality of marketing work [13].

In China, the State Grid Corporation of China was formally established on December 29, 2002. Its main business is power network operation and power market sales. It is mainly engaged in power transmission, and is responsible for voltage conversion, user power distribution, wholesale power sales, and other businesses. It is closely related to the country. The important state-owned backbone enterprises of energy security and national economic construction are the guarantee for the stable development of the national economy and society. The current development of my country's power industry has entered a new stage, and the market-oriented reform will be further accelerated. However, the current level of power marketing in our country cannot meet the needs of the development of the times, the development of demand-side response is not in place, power companies have not deeply studied the potential information of users, lack the necessary system support technology, and lack a perfect service system and user behavior analysis methods. We need to change marketing concepts, adjust marketing strategies, and study new marketing models to meet market demands [14].

The power marketing audit work is in the early stage, but the power enterprises have realized that in the current process of power system reform, the power marketing audit work, as a business control within the enterprise, is particularly important for the improvement of their own management quality [15]. In recent years, electric power companies have also attached more importance to marketing audit work, but it is only a staged and temporary work arrangement. Marketing audit has not been deeply studied and implemented as an independent topic, and a scientific and systematic management system has not been formed. Therefore, there are still many problems. For example, the closed-loop management of marketing audit work is not in place, and there is a lack of tracking and monitoring of the

work. Many of the problems found have not been solved in the end [16]; there is no effective real-time monitoring system for key business windows and front-line service specifications; it lacks a powerful online inspection function and fails to plug loopholes from the source [17]; at the same time, in the face of the ever-expanding mass of customer information and data, it is impossible to pass the traditional method. Effective inspections are carried out manually, and there are problems such as the lack of a professional work team.

In order to solve the work bottleneck of power marketing audit, in 2009, the State Electricity Regulatory Commission issued the “Opinions on Further Doing a Good Job in Electric Power Marketing Audit,” requiring that the marketing audit work of power supply enterprises should be increased in all power systems and properly handled in accordance with the laws and regulations. Electricity violations of laws and regulations can comprehensively and effectively maintain the order of the electricity market [18]. On the basis of the theoretical research on marketing audit, State Grid Corporation has issued a series of guiding documents on marketing audit to guide the power supply enterprises in various provinces and cities to strengthen the construction of marketing audit, strive to improve the level of information management, and establish a unified power marketing audit and monitoring platform.

2.2. Research Status of the Construction of Power Marketing Business Inspection Rule Map. Through the vigorous promotion and widespread use of smart meters and power consumption information collection systems, researchers have a large amount of user power consumption data to carry out management and operation decisions based on power data analysis and optimize power supply services [19]. However, in the operation and maintenance business of the domestic power sector, most power sectors use traditional statistical analysis methods or simple threshold determination to detect abnormalities. This method has great limitations. Not only is it difficult to detect the event information contained in abnormal electricity consumption data, but the utilization rate and accuracy of electricity consumption data are also low. The earliest prototype of the knowledge graph was developed from the ontology knowledge base. With the development of time, the World Wide Web appeared, and the concept of data link was introduced, which made the nodes in the semantic web linked and formed a network-like structure. The concept of knowledge graph was formally proposed by Google in 2012 [20]. It is a semantic network knowledge base that stores, uses, and displays existing knowledge in the form of a structured multi-relationship graph. By fusing multiple entity-relationship triples, a multi-relationship graph containing multiple different entity nodes and multiple types of relationship edges is formed, that is, a knowledge graph. The existing larger knowledge graphs include the English Google Knowledge Graph, and the data comes from Freebase, CIA’s World Profile and Wikipedia, etc.; the Chinese General Encyclopedia Knowledge Graph (CN-DBpedia) proposed by

Fudan University [21], the data comes from many encyclopedia websites. The above knowledge graphs are all general domain knowledge graphs, and in recent years, research on the construction of domain knowledge graphs has also been widely carried out in the fields of power grid, medicine, and finance.

In the field of electric power, Meng et al. [22] used dependency parsing combined with rules to extract entity-relationship triples in the electric power field. Based on the domain dictionary combined with the remote knowledge base, this paper aligns the entity-relationship triples of the encyclopedia corpus, uses the LTP tool to perform Chinese word segmentation, part-of-speech tagging and constructs the dependency syntax table, combines the rules to mine entity triples, and constructs the domain knowledge of power dispatching Atlas. Finally, Neo4j is used for storage, and the visualization page that comes with the graph database is used to display the knowledge graph structure. Based on the power user dictionary, Ref. [7] used syntactic information combined with part-of-speech association rules to analyze the main parts and components of the power transformer operation regulations. Knowledge extraction is performed for corresponding operations, a knowledge graph of power transformer operation specifications is constructed, and Neo4j is used to store it; in [23, 24], authors used deep learning and conditional random field model for entity extraction, and uses attention mechanism combined with bidirectional threshold recurrent neural network for relation extraction, build a power dispatching knowledge graph, and use the Redis database for storage.

3. Marketing Business Audit Rules Information Collection

To construct digital audit rules, first of all, we must collect and sort out the business audit information content required by the enterprise, and complete the work of entity extraction and relationship mining. For the marketing business, because the tasks undertaken by each department have a certain degree of dispersion and independence, it is necessary to collect scattered management rules in a unified database. The internal digital audit rules of each department are systematically copied and extracted, sorted by department, and the data is preprocessed according to the content of the business rules of the data processing system.

After integrating all the normal digital audit rules, the relationship mining of business rules is carried out. According to the audit theme and core rules formulated by the enterprise, relevant audit rules matching the theme core rules are formulated. In the business rule database, relevant keywords are extracted according to the content requirements of the rules and sorted according to the degree of association. The associated business rules construct the association relationship according to the business rules to which the keywords belong. The knowledge map information business relationship is shown in Figure 1.

The above analysis tentatively builds the connection between digital audit rules. To make the knowledge map of digital audit rules intelligent, it is necessary to use relevant

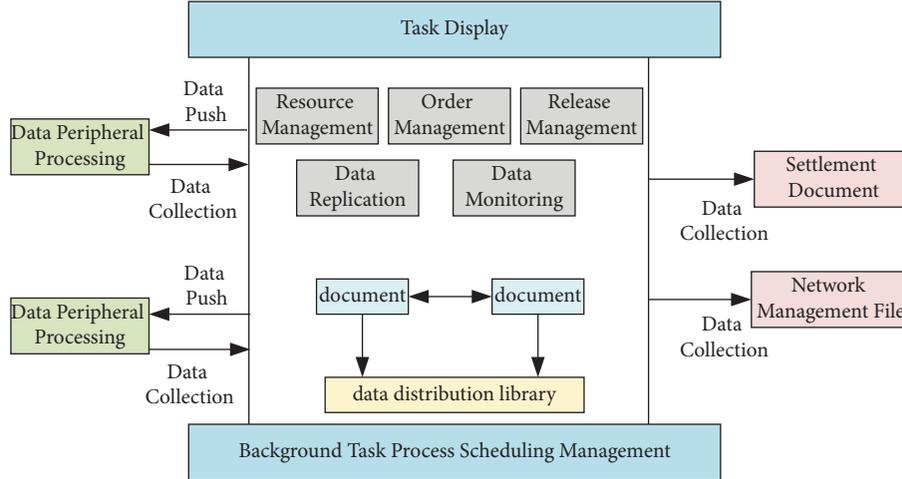

FIGURE 1: Knowledge graph information business relationship.

languages to describe the content and keywords of business rules. The content of the initially generated digital audit rules with associated relationships is retrieved through the system retrieval program to retrieve the relevant description content and participate in the knowledge map of the digital audit rules, which helps to make the knowledge map more intelligent.

4. The Construction of Intelligent Power Marketing Inspection Model

The construction process of the intelligent power marketing inspection model based on knowledge graph includes three main links: knowledge element identification, relationship analysis, and inspection rule graph construction.

4.1. Knowledge Element Identification and Relation Extraction of Power Marketing Business Audit Rules. Use natural language processing (NLP) and deep learning model algorithms to perform entity recognition on digital audit knowledge. The digital audit rule information source collected and sorted in the early stage is transmitted to the data processing system. The system data processing program first determines the content knowledge entity from the business rule content, extracts the keyword features of the determined knowledge entity, mainly including lexical features, language features, and related features, gives relevant descriptions of knowledge entities according to the characteristics, and then marks the description information as the content of knowledge entities accordingly.

NLP is mainly responsible for the mutual conversion of business rule content with relevant language descriptions in computer language and natural language, so as to realize natural language communication between humans and machines. Identify and analyze knowledge entities in knowledge graphs based on natural language processing technology. Knowledge entity recognition usually builds a knowledge map of digital audit rules based on related dictionaries, and the related dictionaries of business audit

rules can be selected as the identification basis. The key words in the dictionary and their related features are introduced into the recognition program, and then the deep learning algorithm is used to realize the association operation of the power marketing business rules knowledge graph sample information data. The relationship between knowledge entities and related terms is determined based on the degree of association obtained by the operation. The keyword feature determination formula of knowledge entity and relationship recognition operation is as follows:

$$s = \begin{cases} 1, & e = E \\ 0, & e \neq E \end{cases}. \quad (1)$$

In formula (1), s represents the feature determination result of the word, e represents its corresponding description feature, and E represents a related word. The closer the operation result is to 1, the higher the correlation between the two words, and the stronger the relationship between words. Then calculate the frequency of the word appearing in the document or web page to which it belongs. The formula is as follows:

$$P = c_i n_i \times \log \frac{W}{t_i}. \quad (2)$$

In formula (2), P represents the frequency of the word appearing in the document or web page to which it belongs, $c_i n_i$ represents the number of times the word c_i appears in the document or web page n_i , W represents the total number of documents in the knowledge graph database, and t_i represents the occurrence of the word c_i in the document. Related vocabulary tree: According to this formula, the importance of vocabulary and related documents can be obtained, and then the relationship between multiple documents can be obtained.

Based on the feature method, the relationship recognition and judgment of key words are carried out, and the obtained feature recognition result is shown in Figure 2.

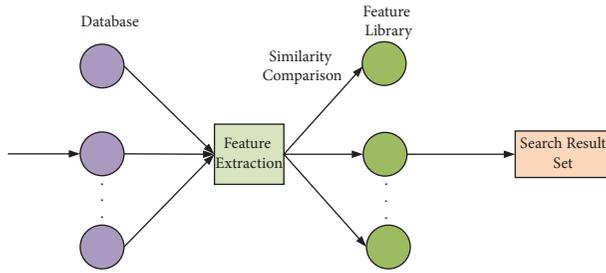

FIGURE 2: Feature recognition results.

It can be seen from Figure 2 that there is language processing and relationship recognition between the acquired knowledge entity vocabulary and its related vocabulary and documents. Taking knowledge entity language as the analysis object, various recognition methods such as character features, part-of-speech features, and meaning content are selected according to the description features. More specifically, the characteristic relationship can be determined based on the relevant vocabulary classification in the digital auditing rules, such as person name, place name, institution name, and professional work vocabulary. The key words or languages of the knowledge graph of digital audit rules mainly include audit targets, problem descriptions, quick output, audit topics that match the audit targets, and business control rules.

Based on the descriptive features, analyze the feature recognition of related words and sentences, infer the nature of the relationship between the two, give the definition of the relationship, add the description of the related entry, and the subordinate documents of both parties participate in the establishment of the relationship map between the two words or languages. For the determination of the content relationship of the document, it is necessary to take the correlation degree of the two sides of the keyword as the starting point, integrate the determination results of the relationship description in other languages and the relationship judgment results, establish the relationship, and annotate the relationship description entry.

4.2. Construction of Knowledge Map for Power Marketing Business Inspection. After the knowledge feature extraction and relationship identification of the power marketing business audit rules are completed, the relationship processing data resources between them are integrated into the construction of the knowledge map of digital audit rules. The knowledge entity information and related data after analysis and processing are divided according to a certain relationship, and imported into the model building system database in batches. The system uses Cypher language to write the framework program of the vocabulary and document relationship model. Cypher can perform key description queries on associated nodes and all relational features in vocabulary or documents on the system resource database and the Internet platform, and based on the retrieved relational results, further improve the relational network and relational description between words. The

layers are progressive, and a network of interconnected relationships is established. At the same time, Cypher can also individually judge the degree of association between them according to the queried relational information, and construct relational networks with different degrees of closeness according to the degree of association. Therefore, after the user uses this knowledge graph, the system will recommend the information content with a greater degree of relevance according to the degree of relevance between the search keywords, while the number of recommendations for other content will decrease in turn according to the degree of relevance, and the user can enjoy the relative individuality, and intelligent retrieval services. In addition, the graph is in a synchronous connection state in the system database, the retrieval content will be associated and recorded, the input information resources will be updated constantly, and the knowledge graph will be maintained in real time, ensuring that the business audit rules and related work content of the enterprise unit are recorded truly and completely.

At the same time, the digital audit based on the knowledge graph has an inspection function, which can check and analyze the business content according to its own search rules. For the problematic parts, it can automatically point out errors, modify and correct, intelligently analyze the original information of the audit work order and the description of the reasons for the audit, and propose the audit. Verification steps, guidelines for rectification measures and other feedback information, judging the type of cause of abnormal situation, labeling the cause of the problem, assisting business personnel to operate, improving the efficiency of inspection rules creation and maintenance management, providing intelligent support for business management and control, using Python language to train knowledge graphs module operation. Figure 3 shows the workflow of digital inspection based on a knowledge graph.

Select the quarterly business work order of the enterprise as the experimental object to conduct problem inspection to examine the problem type. The content of the company's business work order and other information resources are sent to the knowledge graph processing system. Through vocabulary extraction, classification, and feature extraction, the relationship between vocabulary and language based on their respective characteristics and related descriptions is described and marked, and then the business rules are tested through the information dataset. Whether the content of the information is correct can be used to determine whether there is a problem with the work order information. The knowledge graph system internally judges the content of the information about the degree of association between different files or words based on its keywords and relationship descriptions. If there is a problem, mark the cause of the problem, and finally display it through the user. The interface outputs the test results.

5. Experimental Study

In order to test the practical application effect of the intelligent power marketing inspection model research based

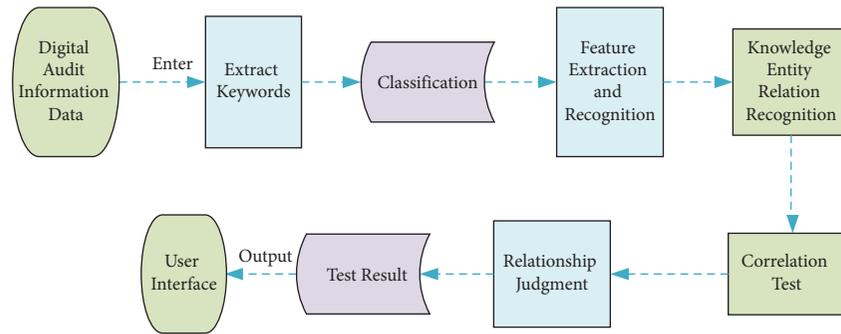

FIGURE 3: Digital audit workflow based on knowledge graph.

TABLE 1: Data information.

Abnormal electricity bill	Label
Community supporting charges are not standardized	Inaccurate billing standards
	Charges are not timely
Abnormal charges for high reliability power supply	Inconsistency in the amount charged
	The supporting fee is not implemented for the newly built public-transportation station area
Abnormal charges	Inaccurate billing standards
	Receivable but not received
Abnormal refund	Excess charge
	Wrong fee type
Abnormal charges	Receivables do not match
	Escape fees
Abnormal refund	There is a record of overdue payment
	Payment takes too long
Abnormal refund	Late payment of fees
	Phased allocation not implemented
Abnormal refund	The same account pays more than 3 times in a single day
	Advance receipt is not timely
Abnormal refund	Too many cheques returned in the current year
	Irregular refund
Abnormal refund	Cash refund is not standardized
	Cancellation prepaid but not refunded

on knowledge graph, this paper conducts experimental research. This paper uses Python as the programming language to simulate the running environment of the method in this paper as the following configuration: The system configuration is Windows 11 Home Chinese version, the processor configuration is 12th Gen Intel (R) Core (TM) i7-12700H 2.30 GHz, 16G RAM.

The data source selects the abnormal electricity bill label as the experimental sample, the collected information is shown in Table 1, and the knowledge map is drawn through the intelligent electricity marketing inspection model of the knowledge map.

According to Table 1, the knowledge graph construction based on tags is shown in the following figure.

From the information in Figure 4, it can be seen that the intelligent electricity marketing inspection based on the knowledge graph can construct a knowledge graph according to the abnormal electricity bill labels, and can

intuitively see the connection between various abnormal expenses. Mining and integration. It connects structured and unstructured data and uses it as a whole to mine previous hidden knowledge and simplify complex business problems.

Combined with the characteristics of the audit model, it is fully applied to various channels such as online audit, special audit, and on-site audit. In the first half of 2021, the audit model was applied to mine 84 failure points of front-end risk management and control, and 67,300 cases of various businesses were corrected, mainly including: 12,400 cases of electricity and electricity billing, 13,700 cases of reporting and installation management, and 5,200 cases of electricity bill management. For example, 3,500 cases of meter reading management, 12,800 cases of electric energy meter elimination management; 16.32 million yuan of errors in electricity bills and business expenses were corrected.

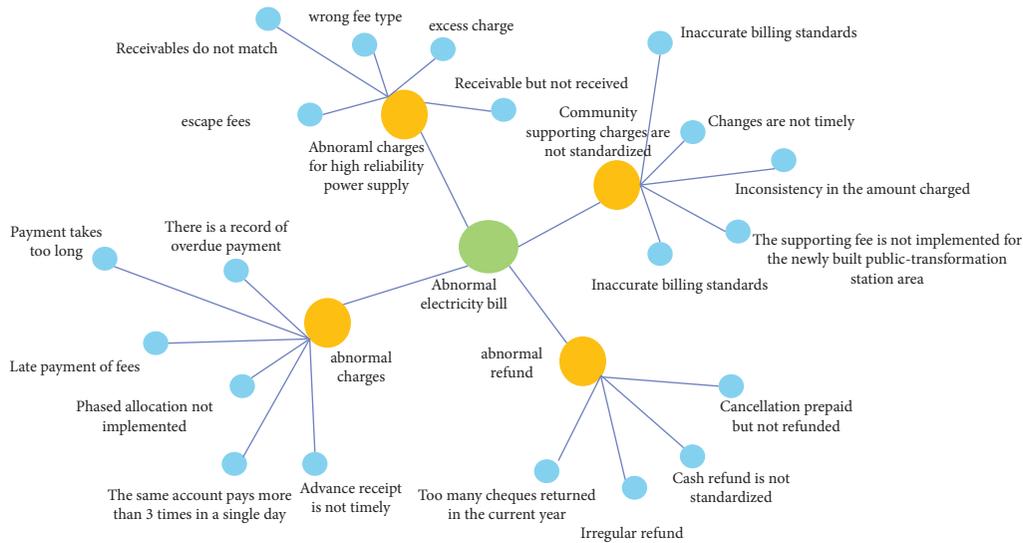

FIGURE 4: Construction of knowledge map of power marketing inspection rules.

6. Conclusion and Outlook

The application of the audit model in power marketing management gradually builds a closed-loop iterative closed-loop working method for online auditing of marketing business errors, including risk mining, model building, verification evaluation, and classified application. Based on the visualization value of knowledge graph, this paper proposes a new idea of applying knowledge graph to marketing audit work. And by selecting typical application scenarios in actual work, the practicability and effectiveness of the proposed model are verified by cases. The results show that the model can gradually restore complex scenes by using graphs, accurately find abnormal points, and effectively improve marketing lean, digital management level.

In the follow-up research, big data will become the basic driving force for power supply companies to mine risks and improve efficiency. Only by embedding “abstract” data into the audit model can marketing data reflect its value for me. In the future business process of big data, through data mining and knowledge graph to realize the visualization of audit management, look for business loopholes, innovate business methods, and constantly improve the defense system for marketing business errors.

Based on the internal and external constraints of serious disease insurance and commercial serious disease insurance, the logistic model of “whether you are willing to connect with commercial serious disease insurance on the basis of serious disease insurance” and “to understand the objective conditions of the connection between serious disease insurance and commercial serious disease insurance” is designed. Based on the empirical research on the micro survey panel data of 6 municipal districts in W City in April 2020, the following research results are obtained: among the many influencing factors, “health status,” “per capita family income,” “gender,” “age,” “education level,” “number of children,” “operating rules,” “public value recognition,” “settlement linkage” Internal Factors of “Information Mastery” and “Implicit Restrictions.” Therefore, the family should be insured in the optimal allocation of family members in the order of “family pillar-children-the elderly” and the scientific layout of insurance products on the basis of family per capita income. The government should promote the institutional integration by strengthening the mechanism construction, building an information platform, and optimizing the management system, so as to promote the health big data sharing, and provide a superior environment for the connection between serious disease insurance and commercial serious disease insurance.

1. Introduction

As the social environment changes, people’s health is threatened. In particular, serious diseases have a great impact on patients and their families. According to statistics, about 44 million families worldwide face high medical costs every year due to serious diseases. Of these, about 25 million families and more than 100 million families are trapped in poverty due to spending money for curing serious illness [1, 2]. However, serious illness insurance can reduce family medical expenses, improve family labor participation, and achieve poverty reduction. Due to the rapid rise of “non-compliance” medical expenses, the unreasonable “threshold” of serious illness insurance, the development trend of younger diseases, the out-of-pocket expenses, and out-of-pocket burden cannot be reduced, and the incidence of

catastrophic expenditure is still on the rise. Therefore, commercial serious illness insurance receives more and more attention [3–5]. Commercial serious illness insurance is a kind of supplementary medical insurance set according to the market demand to make up for the lack of social medical security [6]. Compared with serious illness insurance, commercial serious illness insurance has more types and a higher level of security. In the face of serious disease risk, it is necessary to choose commercial serious disease insurance [7–9]. On the basis of medical insurance reimbursement method and medical insurance payment method selection, the implementation of one-time payment method can alleviate the economic problems after the occurrence of serious diseases. This is also in line with the requirements outlined in the 2016 Healthy China 2030 Annual Plan Outline, such as “a sound multilevel medical security system

with basic medical security as the main body and various other forms of supplementary insurance and commercial medical insurance systems.”

On the basis of commercial serious illness insurance, this paper deeply analyzes the factors that affect the cohesion of commercial medical insurance and social medical insurance from both internal and external aspects, uses questionnaire data to verify the reliability of the constraints, and accordingly proposes a linkage mechanism for the insured and the government to promote the two, so as to further optimize China's medical insurance mechanism..

2. The Choice of Factors

2.1. Intrinsic Constraints

2.1.1. Per Capita Family Income. At present, the purchase cost of commercial serious illness insurance is generally higher, and the insurance amount is not too high. If the amount of insurance increases, the family burden increases. Family per capita income is high, the economy is relatively loose, the insurance premium payment ability is higher, and the willingness to buy commercial serious illness insurance is higher. For families with relatively high family per capita income, their daily living expenses are also relatively high, and the demand for buying commercial serious illness insurance is also relatively high.

2.1.2. Number of Children. For the connection between serious illness insurance and commercial serious illness insurance, the number of family children can affect commercial serious illness insurance. The more children, the greater the financial pressure, and the lower the family's ability to resist risk. To reduce the risk and transfer the risk, the higher the need to buy commercial critical illness insurance. The fewer the children, the less the financial pressure of the family, the higher the family's ability to resist risks, which will not attract purchases, and the lower the desire to buy.

2.1.3. Personal Age. With the growth of age, children's growth, education, and marriage, the demand for economy is growing, and the source of economy is getting weaker. Facing the pressure of work and economy, in order to prevent health risks, people turn to commercial serious illness insurance to strengthen the cohesion of purchasing intentional serious illness insurance and commercial serious illness insurance.

2.1.4. Health Status. Their health status is directly related to the purchase intention. In the face of some possible hidden diseases, once it appears, the family cannot bear it. Therefore, people with poor health will have strong desire to buy commercial serious illness insurance, affecting the connection between serious disease insurance and commercial serious illness insurance.

2.1.5. Gender. In terms of the development law of human function, women and men suffer from serious diseases differently, and the probability of serious diseases in different diseases is also different. Therefore, gender affects the connection between serious disease insurance and commercial serious disease insurance.

2.1.6. Education Level. People with relatively high education level have a strong sense of insurance awareness, coupled with the nature of their work, and their willingness to buy commercial serious illness insurance is stronger than those with relatively high education level. Therefore, the level of education affects the connection between serious disease insurance and commercial serious disease insurance to a certain extent.

2.2. External Constraints

2.2.1. Operation Rules. Due to the professional connection between serious disease insurance and commercial serious disease insurance, the insured do not understand the operation norms and detailed rules of the connection. Therefore, we need to be clear in the relevant systems and policies of serious disease insurance or commercial serious disease insurance, but at present, we need to be clear in the deep connection of the two and coordinated development operation guidance basis. As the insured, only by mastering these foundations, can we better promote the connection between the two.

2.2.2. Integration. In recent years, many local governments have entrusted serious disease insurance to insurance companies to improve their professionalism. Some local governments also purchase insurance companies on serious disease insurance services, which are all operated by insurance companies. As an important product project of insurance companies, commercial serious illness insurance can strengthen the integration and development of the two based on the operation mode of serious illness insurance, and lay a foundation for the connection between serious illness insurance and commercial serious illness insurance.

2.2.3. Invisible Limit Clause. Serious disease insurance is the second reimbursement after basic medical treatment insurance reimbursement. It strictly follows the condition requirement of basic medical treatment insurance implementation, its clause is clear, and limit condition is clear. However, for commercial serious illness insurance, insurance companies have strict restrictions on serious illness compensation in order to improve profits. They usually stipulate in the contract documents that at first glance there are many clauses, but once the disease occurs, they do not meet the conditions of the contract. These “invisible restrictions” are not conducive to coordination with serious illness insurance, and it is difficult to provide a higher level of security, which restricts cohesion.

2.2.4. Information. In the connection between serious illness insurance and commercial serious illness insurance, data sharing is the key point. The emergence of information bottlenecks tends to lead to the lack of data in both serious illness insurance and commercial serious illness insurance, and the inability to share data related to disease treatment and inspection. Insurance companies, in particular, are unable to master basic medical information. Information acquisition is lagging behind, and residents' health is difficult to be accurate. This is not conducive to the price and safety of commercial serious illness insurance, and the cost performance is low. Therefore, promoting the data and information sharing of serious disease insurance and commercial serious disease insurance is conducive to the connection between the two.

2.2.5. Public Value Recognition. Serious disease insurance is essentially a national medical insurance, which needs to cover all the basic medical insurance of the participants. However, the coverage rate of commercial serious disease insurance is about 10%. It limits the selectivity of people, such as limiting age groups and high-risk occupations. Human identity affects the public value attribute of commercial serious illness insurance to a certain extent.

2.2.6. Settlement Linkage. As the serious illness insurance and commercial serious illness insurance belongs to different institutions or units, the cohesion will need to optimize the cost settlement platform and realize the linkage development. Under the asymmetric information of the medical system, how to strengthen the optimization of settlement, especially the issue of advance funds for serious illness insurance, and build a cost linkage cooperation platform between insurance companies and hospitals is conducive to serious illness insurance and commercial serious illness insurance.

3. Empirical Analysis

3.1. Data and Models

3.1.1. Data Procurement. This paper gives questionnaires to urban and rural residents who buy basic medical insurance and investigates 600 residents in a city on “whether they are willing to connect commercial serious illness insurance on the basis of serious illness insurance” and “whether to understand the objective conditions for the connection between serious disease insurance and commercial serious illness insurance.”

The questionnaire was jointly carried out both on the Internet and on the spot.

The distribution scope of the questionnaire included 6 districts such as WC, HK, HP, DXH, JX, and CD districts. A total of 600 questionnaires were issued and 562 were recovered, including 548 valid questionnaires with an effective rate of 97.5%.

In view of the internal constraints of the connection between serious disease insurance and commercial serious

illness insurance, a questionnaire survey was conducted on the family per capita income, number of children, personal age, their own health status, gender, education level of urban and rural residents who have purchased basic medical insurance, and whether they are willing to connect with commercial serious illness insurance on the basis of serious disease insurance. For the external constraints on the connection between serious illness insurance and commercial serious illness insurance, from the aspects of operation rules, integration, implicit constraints, information, public value recognition, settlement linkage, product design, etc., questionnaire survey on whether urban and rural residents who purchase basic medical insurance understand the objective conditions for the connection between serious illness insurance and commercial serious illness insurance. Considering that some variables are ranging variables, all variables are assigned to facilitate processing, and the assignment situation of each variable is shown in Table 1.

In order to test the statistical value of the questionnaire, the reliability and validity were tested. KMO test coefficient is 0.874, its value is greater than 0.5, Bartlett spherical test P value is 0.002, less than 0.001, the questionnaire validity is statistically significant. p value is 0.002, less than 0.001, questionnaire validity has statistical value. Cronbach α system value is 0.898, and the questionnaire's reliability is good and has statistical value”.

3.1.2. Model Specification. Since the dependent variables of this paper “whether you are willing to connect with commercial serious disease insurance on the basis of serious disease insurance” and “whether you understand the objective conditions of the connection between serious disease insurance and commercial serious disease insurance” are both virtual variables, the linear regression model is estimated to make the research results bias for this discontinuous variable. In addition, considering that the selected internal constraints have different attributes in the demographic category, while the external constraints all belong to distance variables, the correlation between each independent variable is low, and the logistic regression model is sensitive to multiple colinearity of independent variables, the logistic model is used for analysis. Among them, the following calculation formula [10–15] for the internal constraints is studied:

$$\ln\left(\frac{p_i}{1-p_i}\right) = \beta_0 + \sum_1^n \beta_{i,n} X_{i,n}. \quad (1)$$

In the above formula, p_i denotes i respondents are willing to connect on the basis of serious illness insurance, $1-p_i$ denotes i respondents are unwilling to connect on the basis of serious illness insurance, $X_{i,n}$ denotes gender, age, education, family per capita income, health, and children, $\beta_{i,n}$ denotes gender, age, education, family per capita income, health, children, and other independent variable regression coefficient, β_0 denotes constant items. As the external constraints of classification number is greater than 2, here

TABLE 1: Variable assignment of both intrinsic and external constraints.

Intrinsic constraints	Variable classification	Assignment	External constraints	Variable classification	Assignment
Sex	Man	1	Rules of operation fusion situation invisible restrictions	Has not yet been introduced	1
	Woman	2		Understand a little	2
Age	<30	1	Information mastery public value recognition settlement linkage	Be familiar with	3
	30-45	2		Insufficient fusion	1
	>45	3		Fusion in general	2
Degree of education	High school and below	1	Products design external constraints rules of operation	The fusion is very good	3
	Undergraduate degree and junior college degree	2		Disagree	1
	Bachelor degree or above	3		Self-identity	2
Household incomes per capita	RMB 2,500/month or less	1	Fusion situation invisible restrictions information mastery	Strongly agree with	3
	RMB 2501-5000 yuan/month	2		Information sharing has not yet been implemented	1
	More than 5,000 yuan/month	3		Understand a little	2
Health condition	Preferably	1	Public value recognition Settlement linkage products design	Familiar with information	3
	Same as	2		Does not match with social security	1
	Range	3		There is a certain commonality	2
Number of children	Not have	1	External constraints rules of operation fusion situation	Match with social security	3
	1	2		Linkage and cooperation have not yet been realized	1
	≥ 2	3		Understand a little	2
			Invisible restrictions	Understand thoroughly	3
				Has not yet been developed	1
				Understand a little	2
			Understand thoroughly	3	

the second and third categories are expressed to understand to study into 0-1 variables. But $X_{i,n}$ denotes the operating rules, public value recognition, settlement linkage, information grasp, invisible limit terms, fusion, product design, and other independent variables, $\beta_{i,n}$ denotes the regression coefficient of their respective variables.

3.2. Intrinsic Constraints. The misjudgment matrix was constructed to compare the difference size between the predicted value and the actual value. Secondly, each explanatory variable was introduced into the model one by one, and the rationality of the logistic regression model was judged by the significant level of the variables. After the introduction of a new variable, if the variable-2 log-likelihood value is less than the results in the previous step and the p After introducing a new variable, if the logarithmic likelihood value of the variable - 2 is less than the result of the previous step, and the p value is less than 1%, it indicates that the explanatory variable has a significant correlation with the explanatory variable “on the basis that the major disease insurance is willing to join the commercial major disease insurance,” and the logistic regression model “on the basis that the major disease insurance is willing to join the commercial major disease insurance” is reasonable [16–20]. Table 2 shows the regression results in the final step, and the odds ratio reflects the explanatory variables screening process and regression system, the final model includes

“health status,” “sex,” “per capita income,” “gender,” “age,” “education,” and “number of children.” Logistic regression model variables in the p value of each explanatory variable coefficient is less than 0.05 significance level, so on the basis of serious disease insurance, linear relationship is retained in the model equation.

Comparing the misjudgment matrix of the initial situation and the misjudgment matrix after introducing all the explanatory variables, the following can be found (see Table 3): in the process of gradually introducing the explanatory variables, the accuracy rate of the model gradually increases from 54.7% to 89.7%, and the prediction accuracy is relatively high. To sum up, “on the basis of serious illness insurance is willing to join commercial serious illness insurance,” logistic regression model analysis shows that “health,” “family per capita income,” “gender,” “age,” “education,” “children,” and so on for residents on the basis of serious illness insurance cohesion commercial serious illness insurance will restrict. Therefore, in the serious illness insurance and commercial serious disease insurance, we should pay attention to combine the above six factors design of policy-holder, in order to enhance the purchase intention of the policy holder.

3.3. External Constraints. Similar to the analysis of intrinsic constraints, a misjudgment matrix was first constructed to compare the magnitude of the difference between the

Number of children	0.390 * * * (0.007)	1	1.476
Constant term	-6.629 * * * (0.000)	1	0.001

Note. *p* value in parentheses; * * * is significant at 1%.

TABLE 3: Results of logistic progressive regression model.

Observed			Predicted		Percent correction
			Connect with commercial serious illness insurance		
			Yes	No	
Step 0	Connect with commercial serious illness insurance total percentage	Yes	0	248	0.0
		No	0	300	100.0
		—	—	—	54.7
Step 1	Connect with commercial serious illness insurance total percentage	Yes	130	118	52.4
		No	83	217	72.3
		—	—	—	63.3
Step 2	Connect with commercial serious illness insurance total percentage	Yes	181	67	73.0
		No	65	235	78.3
		—	—	—	76.2
Step 3	Connect with commercial serious illness insurance total percentage	Yes	189	59	76.2
		No	55	245	81.7
		—	—	—	79.5
Step 4	Connect with commercial serious illness insurance total percentage	Yes	195	53	78.6
		No	49	251	83.7
		—	—	—	81.7
Step 5	Connect with commercial serious illness insurance total percentage	Yes	206	42	83.1
		No	38	262	87.3
		—	—	—	85.7
Step 6	Connect with commercial serious illness insurance total percentage	Yes	218	26	89.3
		No	28	272	90.7
		—	—	—	89.7

predicted value and the actual value. Secondly, each explanatory variable was introduced into the model one by one, and the rationality of the logistic regression model was judged by the significant level of the variables [21–26]. If the log-likelihood value of each newly introduced variable is less than the result in the previous step, and the *p* value is less than 1%, it indicates a significant correlation between the explanatory variable and “understand the objective conditions of the connection between serious disease insurance and commercial serious disease insurance.”

Table 4 shows the regression results of the final step. The final model includes explanatory variables such as “operating rules,” “recognition of public value,” “settlement linkage,” “information mastery,” and “invisible restriction clause”. Since the *p* value of each explanatory variable coefficient is less than 0.05 significance level, the linear

relationship of serious disease insurance and commercial serious disease insurance in the logistic regression model is significant in the model equation.

In the process of gradually screening, the final model failed to enter the fusion situation and product design of two explanatory variables. Due to the introduction of the two explanatory variables after probability *p* value of 0.099 and 0.140, respectively, more than 0.05 lead to “the serious illness insurance and commercial serious illness insurance cohesion objective conditions understanding.” Logistic regression model linear variable linear relationship is not significant and, therefore, is not retained in the model equation.

To sum up, “the understanding of the objective conditions for the connection between serious illness insurance and commercial serious illness insurance”

TABLE 4: Logistic regression results of external factors linking between commercial critical illness insurance and serious disease insurance.

TABLE 5: Results of the progressive regression model.

Observed		Predicted		Percent correction	
		Understand the objective conditions of connecting commercial serious disease insurance	Yes		No
Step 0	Understand the objective conditions of connecting commercial serious disease insurance	Yes	0	246	0.0
		No	0	302	100.0
	Total percentage		—	—	55.1
Step 1	Understand the objective conditions of connecting commercial serious disease insurance	Yes	90	156	36.6
		No	82	220	72.8
	Total percentage		—	—	56.6
Step 2	Understand the objective conditions of connecting commercial serious disease insurance	Yes	114	132	46.3
		No	87	215	71.2
	Total percentage		—	—	60.3
Step 3	Understand the objective conditions of connecting commercial serious disease insurance	Yes	154	92	62.6
		No	84	218	72.2
	Total percentage		—	—	68.1
Step 4	Understand the objective conditions of connecting commercial serious disease insurance	Yes	187	59	76.0
		No	71	231	76.5
	Total percentage		—	—	76.6
Step 5	Understand the objective conditions of connecting commercial serious disease insurance	Yes	201	45	81.7
		No	54	248	82.1
	Total percentage		—	—	82.2

Logistic regression model analysis shows that “operating rules,” “public value recognition,” “settlement linkage” information, and “hidden restrictions” have an impact on the objective situation of the connection between serious illness insurance and commercial serious illness insurance. Therefore, in the connection between serious illness insurance and commercial serious illness insurance, attention should be paid to combining the applicant's demand for mastering the above five factors, strengthen design and optimization.

3.4. Internal-External Constraints. The internal and external constraints are introduced into the model, and the model is used to be tested again, in order to screen the constraints more accurately. The model regression results are presented in Table 6.

First, the p value of the parameter likelihood ratio test of the logistic regression model was less than 0.05, indicating a

statistical significant OR value for at least one of the 13 variables, so the fitted model was statistically significant. Second, the p value (0.409) of the Hosmer and Lemeshow tests is greater than 0.05, indicating that the information in the current data has been fully extracted, and the model has a better goodness of fit. Finally, the results of the logistic regression for each intrinsic and extrinsic factor indicate that the six intrinsic factors and the five extrinsic factors described above are plausible, and that there is no multicollinearity between the internal and extrinsic factors.

Therefore, in the process of connecting commercial serious illness insurance and serious illness insurance, we pay attention to the design of the “health status,” “family per capita income,” “gender,” “age,” “level,” “education,” “number,” and other children, to enhance the purchase intention of the insured. In addition, we should fully obtain the understanding of the “operation rules,” “public value recognition,” the “settlement linkage,” “information

mastery,” and “invisible restrictions” and strengthen the design and optimization of insurance products.

4. Linkage Mechanism between Commercial Serious Disease Insurance and Serious Disease Insurance

4.1. Promote the Connection between Serious Disease Insurance and Commercial Serious Disease Insurance Based on Internal Factors

4.1.1. *Optimize the Insurance Order and Insurance Items of Family Members Based on Their Age and Health Status.* When purchasing health insurance, families first consider children, but from a professional perspective, adhere to the configuration order of family pillars, children, the elderly, and optimize the insurance order of family members. Not only that, as far as insurance projects are concerned, family support is the safety foundation of families. We need to adhere to the insurance principle of “income pillar should be given priority,” strengthen the purchase of commercial critical illness insurance to supplement basic medical insurance and serious illness insurance, and ensure that family pillars will not cause family difficulties when they are ill; For children, its premium is relatively low. Adhere to the principle that “child protection should be comprehensive.” It can be comprehensive and long-term. Try to buy an insurance with comprehensive protection function. If the insurance amount of commercial serious disease insurance can be increased, promote its protection from the perspective of physical protection. In terms of product selection, you can choose partial payment products. For the elderly, especially family members over 50 years old, the insurance premium is high and the protection is not strong. Therefore, we can purchase products from accident insurance and cancer prevention insurance by adhering to the principle that accidental cancer prevention is necessary for the elderly.

4.1.2. *Scientific Layout of Insurance Product Allocation Sequence Based on Family per Capita Income.* First, the priority guarantee type to buy financial management type. On the basis of the basic “security” insurance allocation, the per capita family income is surplus, we can consider financial insurance products, and even some wealthy families can use commercial serious disease insurance to do a good job in asset inheritance. Second, choose commercial serious illness insurance according to the per capita family income. The family per capita income is low and can buy consumer commercial serious disease insurance. This kind of insurance is usually paid every year. This kind of premium takes into account the risks of different ages, and also from the gender perspective. Different people, different genders, different ages, different premiums, small amount of insurance benefits, and high leverage ratio.

4.2. Link Serious Disease Insurance with Commercial Serious Disease Insurance Based on External Conditions

4.2.1. *System Integration.* First, strengthen the construction of market mechanism. Serious disease insurance should not only rely solely on the government but also give full play to the market mechanism. Let alone exclude the market allocation of insurance resources. We should leave enough market space for commercial serious disease insurance, so as to ensure the scientific use of insurance resources. The common development of the two mechanisms of serious disease insurance and commercial serious disease insurance needs to start with the top-level design and constantly optimize the service supply connecting the serious disease insurance and commercial serious disease insurance. Second, strengthen the construction of a multiagent coordination mechanism. Relevant government departments shall take the lead in establishing the coordination structure of medical insurance, to give full play to the leading role of the government, promote strengthened cooperation among relevant subjects, and jointly discuss and formulate

specific methods and detailed rules for the connection between serious disease insurance and commercial serious disease insurance. To increase the government's support for commercial critical illness insurance, the relevant government functional departments and medical institutions can establish a cooperative promotion mechanism with insurance companies to interpret the public value, supporting policies and insurance conditions of commercial critical illness insurance to the public, so as to stimulate the public's demand for medical treatment and health security.

4.2.2. Build a Cohesion Platform. First, establish a health big data information platform. From the perspective of collaborative public management, build health big data information platform, realize the information data sharing between the related subject, help to reduce adverse selection risk and moral hazard, effectively improve the efficiency of medical insurance costs, is also conducive to the insurance institutions using health data information platform accurate positioning, according to different groups design, develop personalized commercial health insurance, such as health insurance products. Second, promote the integration construction of commercial health insurance, hospital, and medical insurance fee settlement platforms. Commercial insurance institutions shall be encouraged and guided to participate in the development, construction, and maintenance of unified settlement platforms for commercial health insurance compensation expenses, such as medical expenses and commercial serious disease insurance, so as to provide convenient direct compensation and claim settlement services for the insured.

4.2.3. Optimize the Management System. First, strengthen operational risk management to provide a superior environment for the connection between serious disease insurance and commercial serious disease insurance. Develop an innovative new model of medical insurance cooperation. Commercial health insurance institutions should establish a service framework combining insurance provision and health management, try to get involved in medical institutions through investment and establishment, merger and acquisition, and strategic cooperation, and increase the complementary advantages and win-win development of insurance industry and medical and health service industry. Second, we will strengthen the reform of the medical system to build a benign space for the connection between serious disease insurance and commercial serious disease insurance. We will strengthen the construction of the government's supervision capacity for the health industry, and at the same time, improve the patient reporting channels, establish a sound and effective supervision network, and strictly investigate and punish any violations found in time. We will resolutely crack down on illegal and unreasonable acts such as arbitrary fees and excessive medical treatment and ensure

that medical institutions return to formality and public welfare. We will improve the environment for the orderly development of social security, constantly promote the sustainable development of social security programs, and serve the well-being of the people.

5. Conclusion

This paper is based on the basis and feasibility of connecting commercial serious illness insurance and serious disease insurance, centering on the internal constraints and external constraints of the participants of serious disease insurance and commercial serious disease insurance, respectively. The logistic model of "whether you are willing to connect with commercial serious disease insurance on the basis of serious disease insurance" and "to understand the objective conditions of the connection between serious disease insurance and commercial serious disease insurance" is designed. Based on the microsurvey panel data of the six municipal districts of W city in April 2020, the model was estimated using the maximum likelihood estimation method. The study found that, among many influencing factors, "family members," "health status," "family per capita income," "gender," "age," "education level," "number of children," internal factors as well as external factors such as "operation rules," "public value recognition," "settlement linkage," "information mastery," and "hidden restriction clauses" "have a significant constraint on residents" willingness to connect commercial serious disease insurance on the basis of serious disease insurance. "Fusion situation" and "product design" and other factors have no obvious impact on it. Accordingly, the family should adhere to when being insured "family pillar-child-old man," and the order optimizes the insurance order of configuration family members, with "income pillar wants priority," "children safeguard should be comprehensive," "old man accident prevents cancer prevention is very necessary." The principle chooses appropriate insurance project. At the same time, insurance products should be scientifically distributed based on the per capita family income of families and give priority to the basic "guarantee" insurance allocation of commercial serious disease insurance + serious disease insurance. On the basis of the surplus of the per capita family income of families, financial management insurance products should be considered. In view of the external constraints, the problems existing in the connection process between commercial serious disease insurance and serious disease insurance are imperfect, the connection information sharing and information platform construction need to be promoted, and the connection management system still needs to be strengthened. System integration should be promoted by building market mechanism, improving the coordination mechanism, improving commercial insurance legal system, promoting the interconnection and information sharing of health big data and integrated settlement platform of commercial health insurance, hospital and medical insurance expenses, and competition mechanism.

With the development of the times, building a learning community in ideological and political teaching has become an urgent need for teaching reform. In ideological and political teaching, the common vision of teachers and students is to carry out cooperative exploration and ultimately realize the progress and growth of common teachers and students, and implement the core of political science. Learning community in ideological and political teaching has the characteristics of group symbiosis, common value, cooperation and sharing, and democratic openness. Therefore, building a learning community in ideological and political teaching is conducive to the formation of a new teaching model of cooperative inquiry and the establishment of equality and democracy. The new teacher-student relationship can cultivate students' higher-order thinking and promote more meaningful learning. It has been proved by practice that it is valuable to construct a learning community in the ideological and political teaching of universities. Teachers and students should change the traditional teaching concept. University political teachers should carefully prepare lessons, set up teaching design, be considerate to students, be close to reality, be close to knowledge itself, enhance the communication and interaction between teachers and students, and students and students, and actively build a learning community in the process of ideological and political teaching. To enable students to get new knowledge, solve challenging problems, and finally achieve progress and growth.

1. Introduction

At present, core literacy has become a topic that the country and even the world focus on. Countries try to use "core literacy" as a guide for curriculum reform; explore curriculum standards, teaching reforms, and teaching practices that match the cultivation of students' core literacy; and make it gradually become a practical concept of international education. Our country also conforms to the development trend of international education reform and pays attention to the core literacy of students, and the ideological and political course, as a subject with the fundamental task of morality and cultivating people, has naturally become an important position for cultivating students' core literacy. The cultivation of subject core literacy is very important. However, in the current ideological and political teaching, there are still various shallow teaching problems such as

aiming at "exam-oriented education," overemphasizing the authority of textbook knowledge, formalizing the teaching process, paying attention to the performance of open classes, and flashy teaching results. This is not conducive to the cultivation of students' core literacy and will limit their all-round development. In-depth teaching is a reform of shallow and formalized teaching. The purpose of studying in-depth teaching is to propose effective solutions to the problems existing in current teaching. The teaching of ideological and political courses from the perspective of core literacy is to pay attention to the dialogue between students and knowledge, especially the value and meaning behind knowledge, in an open form so that students can gradually cultivate their knowledge in the process of mining the value and meaning behind knowledge. The core qualities of political identity, scientific spirit, awareness of the rule of law, and public participation are all innovations that promote

teaching activities. It has the functions of being conducive to the independent construction of students' knowledge, the development of scientific thinking, and the implementation of emotional education. However, there are still some problems in the practice of in-depth teaching of ideological and political courses that need to be improved and perfected. In the current teaching of ideological and political courses, due to the limitations of teachers' unclear grasp of the concept of in-depth teaching, the deep-rooted thinking of teachers in exam-oriented education, and the attitude of teachers who have no intention of in-depth teaching, the problem design ability of teachers' core literacy of ideological and political courses and the core literacy of ideological and political courses are not enough. The ability of teaching implementation and the teaching reflection ability of the core literacy of ideological and political courses need to be improved. Students are accustomed to passively accepting knowledge, graffiti-style learning, "picture reading," and other learning methods. Their learning methods are lagging and cannot adapt to in-depth teaching, and the evaluation system is not perfect. Teachers' enthusiasm and other reasons have hindered the practice of in-depth teaching, which is not conducive to the cultivation of students' core literacy. With the research on in-depth teaching, the theoretical and practical system of in-depth teaching is gradually being established and improved, which has reference significance for the teaching practice of ideological and political courses in the future. [1-5].

2. Related Works

The research on deep learning can be traced back to the mid-1950s. Some scholars start from the learning process of students and use shallow learning and deep learning as the reading methods of academic papers for college students so as to adjust the teaching methods according to these two states. American scholars Ference Marton and Roger Saljo were the first to make this point. They believe that shallow learning is passive and mechanical, students' inquiry process lacks self-awareness and the ability to think independently, the content of learning is boring and far from students' life, and students lack emotional experience and thinking skills during learning. On the contrary, deep learning emphasizes the initiative and comprehension of students' learning, emphasizes that students should use critical thinking to understand knowledge; attaches importance to new and old knowledge, knowledge of various disciplines, and the connection between theory and practice; and improves students' transference. Since then, many scholars have conducted comparative studies on the two, put forward the value of deep learning, and explored strategies to promote deep learning for students. For example, "problem-based learning (PBL)" originated from medical education uses "problems" as clues to students' learning and activities, prompting students to change their previous learning methods and change from passive acceptance to active inquiry. Another scholar proposed "self-directed learning." A typical example is an American scholar Tough, A who proposed in 1971 that "students should learn to plan, monitor, and reflect on their

own." Students establish learning goals in autonomous learning. Through the learning process, they can have a deep understanding of the content, form a summary, and reflect in the learning process. Another scholar proposed the deep learning route (DELIC), the deeper learning cycle. For example, Eric Jensen and LeAnn Nickelsen proposed in "7 Powerful Strategies for Deep Learning" to carry out in-depth learning from seven perspectives: "design standards and courses, pre-assessment, building a learning culture, pre-viewing prophets, acquiring new knowledge, deep processing of knowledge, and learning evaluation," which enriches the practical strategies of deep learning. In recent years, the research of some scholars has gone beyond the previous research vision, not only based on the aspects of educational technology such as instructional design and learning technology but also based on the new concept of learning and knowledge, research, and new interpretations. The most representative of them is the research carried out by the "Learning in Depth" (LID) project team led by Professor Egan of Fraser University in Canada, which implements deep learning based on experiments. The path and the basic principles of its implementation are discussed, and the role of deep learning on student learning, teacher professional growth, and school reform is analyzed. The research focuses on classroom learning and teacher teaching, and even research on deep learning focuses on teachers' guidance on how students learn and how they learn. Aigen's deep learning research has made it clear that teachers also attach importance to the guidance of teachers in the process of deep learning, guide students to focus on the in-depth understanding of knowledge, and promote students to deepen their understanding of knowledge in the process of gradual in-depth learning. Eigen's research on deep learning pays attention to the importance of teachers to students' deep learning, and the connection between deep teaching and deep learning, so the focus of the research gradually shifts from a single learning technology to a two-way activity that combines teacher teaching and student learning. The research on deep learning also shows the characteristics of the combination of deep learning and deep teaching. [6-12].

3. Related Theories and Research Methods

3.1. Community. A community is a tightly connected whole. From the perspective of the etymology, "common" means "everyone does it together; what belongs to everyone is public"; "body" means "group, collective,;" and the community is that everyone does things together, belongs to everyone's collective, mutual help, and no one can do without another, mainly emphasizing that there is a deep emotional foundation between members and a collective or collective organization that depends on each other. The word community comes from the German "Gemeinschaft" and is translated as Community in English; the most common meaning is "society," with derived meanings of "residents" and "regions."

The earliest description of the community was by the German classical sociologist Tönnies. He divided the community into several aspects: the community linked by blood,

the community linked by emotional needs, and the community linked by region. They are all interdependent, share weal and woe, recognize and tolerate each other, and have a strong sense of collective belonging. The concept of “community” originated in the field of sociology, has gradually been widely studied in other fields such as education and politics, and has enriched the connotation and extension of the community from different angles, such as the political community in the field of politics, the scientific community in the field of natural and human sciences, etc. With the rise of research on the community, community not only emphasizes the close relationship between members because of blood relationship and geographical location but also emphasizes the organization of collective members relying on common goals. In pedagogy, the commonly mentioned community refers to the learning community, such as Palmer’s theory of debate; he believes that “the real community is recognized through debate,” and the composition of community members is not limited by blood regions, etc. More emphasis is placed on organisms that identify with each other by arguing with each other. At the same time, the debate process is not closed, but open and shared. The format of the debate is not monotonous for the sake of debate, but to encourage members to fully express and listen to their views, learn together, and achieve common goals. Such communities are more focused on emphasizing the learning process. Although the community in pedagogy and the community in sociology have similarities, they both emphasize mutual recognition and sharing, but there are great differences between the two. Community in pedagogy emphasizes that learners cooperate with each other and grow together in the learning process, while the community in sociology is based on relevant research based on factors such as region, blood relationship, and spirituality. Even so, the concept of community in the field of sociology can also serve as a reference for the concept of community in pedagogy. The concept of community in pedagogy relies on the concept in the field of sociology, but it is not equivalent to its connotation in sociology. The vast groups with different identities in different regions can be summarized as a collective with common goals, mutual cooperation and sharing, mutual recognition, and close connection. [13].

3.2. Learning Community. The learning community idea can be traced back to Dewey’s empirical education theory. Dewey believes that the essence of education is: “education is life, school is society, education is growth, education is the reorganization and transformation of experience.” In fact, what is emphasized is that schools are not only places to learn knowledge and skills but they also advocate various social activities, emphasize exchanges and cooperation between people, and promote the all-round development and personality development of each student. The concept of the learning community is derived from the learning organization theory. In 1990, the scholar Peter Senge put forward the famous learning organization theory, which refers to the collective that each subject can release their sense of

collective identity, cultivate their personality, expand their abilities, and continue to learn together. [14] The learning organization mainly includes five elements: common vision, system thinking, common learning, self-realization, and mental model. Although he did not directly point out the concept of the learning community, he accelerated the process of the concept of the learning community becoming known to the world. In 1995, Boyer put forward the concept of the learning community for the first time. He believed that a learning community is an organization where members share common goals and communicate and cooperate with each other. After 2000, Sato, known as the first person in Japanese educational theory, further developed the learning community theory according to the problems of lonely learning in Japan at that time and regarded the learning community as a new teaching model and a new type of learning community. Learning the organizational form, he believes that the main purpose of the learning community is to accept all differences, that is, to respect and accommodate the differences of each member. And in the description of the global picture of the “classroom revolution” in the 21st century, the school reform philosophy based on the “learning community” is expounded.

3.3. The Elements of the Learning Community in Ideological and Political Teaching in Colleges and Universities. Scholars have different generalizations of what constitutes a learning community. Some scholars believe that it includes five elements: learners, facilitators, learning tools, resources, and learning contexts; some scholars divide it into seven elements: learning subjects, resources, learning methods, curriculum knowledge, shared vision, learning context, and target effects. According to the analysis of the concept and constituent elements of the learning community and the characteristics of the ideological and political teaching of college students, this study believes that the constituent elements of the learning community in the ideological and political teaching of college students mainly include learners, common vision, interactive means, learning situations, and learning resources—5 aspects. All elements influence and depend on each other and jointly promote the sustainable development of the learning community in the ideological and political teaching of college students. [15].

3.3.1. Learners. College students and ideological and political teachers are the main learners of the learning community in the ideological and political teaching of college students. Through certain teaching activities, teachers and students can communicate and interact. Teachers and students are learners with equal status. Teachers and students have their own advantages and personalities. In the ideological and political teaching of college students, ideological and political teachers and students help each other, share knowledge, and jointly solve challenging problems. Special attention should be paid here. Teachers do not blindly instill knowledge but guide and help students in the teaching process. Ideological and political teachers are not managers, but more of a service provider for students’ learning. At the

same time, they are also learners. Lifelong learning, or more reflective dialogue with students, can better promote the effective and sustainable development of the learning community in the ideological and political teaching of college students. [16].

3.3.2. Common Vision. The common vision and the common goal are closely related, but in addition to the common goal itself, the common vision also emphasizes that members take the initiative to achieve the learning goal based on the common emotional needs, that is, the common goal of the community. The “Ideological and Political Curriculum Standards” proposes that “the fundamental task of college students’ ideological and political teaching is to build morality and cultivate people, further strengthen the education of socialist core values, and emphasize the construction of an active subject curriculum dominated by cultivating the core literacy of ideological and political subjects.” Therefore, college students’ thinking of the common vision of the learning community in political teaching should not be limited to the achievement of knowledge and skills but should focus more on building morality and cultivating people, implementing the core literacy of disciplines, and promoting the all-round development of each student.

3.3.3. Interaction. Internet+tradition is an interactive means of the learning community in the ideological and political teaching of college students. For students in the traditional ideological and political teaching of college students, generally a class is a group. Although everyone knows each other, the communication and interaction with each other is not enough, and it is only limited to the interaction in the school classroom. Therefore, from the perspective of the composition of the learning community in the ideological and political teaching of college students, it is very important that the interaction means among the members of the learning community. In today’s information age, knowledge is updated rapidly, and traditional means of interaction are no longer the main way. More members will use some popular communication tools, such as e-mail, Weibo, QQ group, WeChat group chat, etc. The real-time synchronous and non-real-time asynchronous communication of network media tools promotes the exchange and feedback of information among the participants of the learning community in the ideological and political teaching of college students.

3.3.4. Learning Situation. Carrying out the activity-based curriculum oriented to implement the core literacy of the discipline is the main learning situation of the learning community in the ideological and political teaching of college students. The learning situation is also an important factor in the teaching process of ideological and political courses. It is the so-called “flesh worms, fish withered worms.” It emphasizes the importance of internal environmental changes to the development of things, and the reference to teaching also reflects the learning situation.

Wang Fuzhi, a Confucian scholar in the late Ming and early Qing dynasties, believed that people’s ideology and behavior are closely related to the environment in real life, and the natural learning situation is closely related to people’s thinking and behavior. The environment of ideological and political teaching has the characteristics of being extensive, dynamic, specific, and creative. Therefore, it is necessary to pay attention to the creation of the learning environment of the learning community in the ideological and political teaching of college students, not only to consider the environment and characteristics of ideological and political teaching but also to consider the personality and characteristics of the students. Appropriate learning situations can promote ideological and political teaching to achieve a multiplier effect. [17].

3.3.5. Learning Resources. Explicit knowledge + invisible knowledge is the learning resource of the learning community in the ideological and political teaching of college students. Learning resources are an indispensable element and the learning information of the learning community in the ideological and political teaching of college students and generally exist relying on certain carriers, such as books, courseware, exercises, cooperation, and dialogues. Therefore, learning resources include both explicit knowledge and implicit knowledge. Traditional teaching tends to ignore the learning resources in cooperation and exchange, and the learning community attaches great importance to the learning resources obtained in the process of communication, cooperation, and reflective dialogue between teachers and students and between students and students. This is also in line with the activity-based curriculum emphasized by the ideological and political curriculum standards for college students, which promotes the activity of the curriculum content and the curriculum of the activity content and realizes the common progress of teachers and students in the blending of explicit knowledge and invisible knowledge. [18].

4. Construction of College Students’ Ideological and Political Teaching Community Based on the Learning Community

4.1. Teaching Design Based on the Concept of the Learning Community. According to the connotation of the learning community, the value of the learning community should be recognized. First of all, it is necessary to form a correct cognition of the learning community, instead of putting wrong labels such as time-consuming and formalism. According to the connotation of the learning community, it can be understood that the learning community is an organic organization for teachers and students, students and students to learn from each other, help each other, achieve common goals, and cultivate socialist core values. Based on this, building a learning community in the ideological and political teaching of colleges is conducive to forming a new teaching model of cooperative inquiry, establishing a new teacher-student relationship of equality and democracy, and, at the same time, cultivating students’ higher-order thinking and promoting more

meaningful learning. The content of this lesson is selected from “Truth is Concrete and Conditional” in “Life and Philosophy.” The whole teaching design is shown in Table 1.

4.2. Teaching Implementation Based on the Concept of the Learning Community

4.2.1. *Correct Concept.* Form a correct cognition of the learning community. According to the connotation of the learning community, the value of the learning community should be recognized. First of all, it is necessary to form a correct cognition of the learning community, instead of putting wrong labels such as time-consuming and formalism. According to the connotation of the learning community, it can be understood that the learning community is an organic organization for teachers and students, students and students to learn from each other, help each other, achieve common goals, and cultivate socialist core values. Based on this, building a learning community in the ideological and political teaching of colleges is conducive to forming a new teaching model of cooperative inquiry, establishing a new teacher-student relationship of equality and democracy, and, at the same time, cultivating students’ higher-order thinking and promoting more meaningful learning. [19].

4.2.2. *Clear Goals.* Play the leading role of the common vision in the ideological and political teaching of the university. Because the learning community has the characteristics of political identity and cooperation and openness, it should play the leading role of the common vision in the learning community. A shared vision is a common goal that members of a learning community have and are willing to work towards. In other words, a shared vision includes both common goals and emotional appeals that members are willing to work towards. A shared vision is not simply equivalent to the improvement of academic performance, it is more focused on exploring and solving problems in cooperation and communication and ultimately enables students to actively build new knowledge and promote the achievement of key abilities and necessary characteristics.

4.2.3. *Positioning Practice.* We should fully respect the dominant position of students, carry out interactive teaching that stimulates students’ interest in learning, and promote students to actively build new knowledge in the process of teacher-student and student-student cooperation and interaction. Interactive teaching emphasizes two-way interaction, which is different from teacher-led and invalid interaction or blind interaction of students. It is necessary to change the traditional single self-directed and self-acted teaching but to develop a dialogue and communication method that includes multiple factors such as cognition, behavior, and emotion. Interactive teaching is based on an equal and harmonious modern teacher-student relationship. Students and students, teachers and students understand each other, respect each other, and achieve common progress and common development in the process of cooperative exploration. In the

current ideological and political teaching in universities, there is more interaction on the surface, the form is lively, and there is no real knowledge. For example, in the class “Entering the International Society,” a teacher guided students to hold a debate on whether China and the United States are rivals or partners. This does not conform to the cognitive characteristics and processes of students. In the information age, many students understand that China and the United States are both rivals, but also partners. Therefore, such debates can easily lead to ineffective interactions. The dialectical thinking that China and the United States are both opponents and partners is not easy to form in this debate. Interaction exists all the time, but effective interaction is rare. How to really achieve effective “interaction?” First, the interaction method must be properly combined with subject knowledge. That is to say, the selection of interactive materials or methods should not be separated from the corresponding subject knowledge. To truly realize the curriculum of the activity content and the activity of the course content, the two should not be separated from each other, but must be closely integrated. Change the traditional curriculum content curriculum, but also avoid the ineffective interaction of the activity content. Second, the interactive way should be promoted to stimulate students’ interest in learning. The material selected or the situation created should be based on the psychological characteristics of students, which can stimulate students to learn actively. Failure to unilaterally understand interaction is commonly used in front and back discussions between four people. The selected discussion topics are not close to students, close to life, and close to reality. Effective interaction will definitely not be possible, and students will feel tired of learning. [20].

Third, the layout of traditional learning spaces should be changed. Do a good job in the spatial setting of the learning community and the spatial distance of students’ seats is closely related to the psychological distance between teachers and students, and students and students. The narrowing of the space distance can shorten the psychological distance between teachers and students, which makes it easier to listen, communicate and cooperate, and achieve effective interaction. Japanese scholar Sato Xue believes that the physical space environment of learning can be changed to promote the effective interaction between teachers and students, and students and students. The traditional seedling-style desks and chairs cannot carry out more nonverbal communication, which is not conducive to attentive listening between teachers and students, and students and students, and is not conducive to mutual in-depth exchanges and cooperation. The sitting situation in the classroom is to form a classroom that listens attentively to each other and build the physical foundation of a learning community. Generally, there are the following requirements: as shown in the figure below, the group members should sit face-to-face and look at each other; appropriate distance will neither affect the communication between group members nor the connection between groups; the arrangement of the classroom should be as flexible as possible to facilitate students to change the group form; as far as possible, all students should always be with their own group companions together, as shown in Figures 1–3.

TABLE 1: Learning community concept instructional design sheet.

Textbook analysis	The content of this lesson is selected from “Truth is Concrete and Conditional” in “Life and Philosophy.” This article mainly explains the conditionality and specificity of truth and the relationship between true questions and falsehoods and then understands that the process of pursuing truth is never-ending and not smooth, so we begin the process of pursuing truth.
Study situation analysis	Students have acquired certain philosophical thinking ability in the study of relevant philosophical knowledge points. However, their understanding is relatively scattered, simple, and one-sided, so teachers need to teach systematically to help students comprehensively master knowledge, broaden their understanding, and improve their rational thinking ability. In view of the situation of this course, students have already mastered the relevant knowledge of “truth” and they need to further study the characteristics of truth and the relationship between truth and falsehood.
Teaching objectives	<ol style="list-style-type: none"> 1. Master the conditionality and specificity of truth and understand the relationship between truth and error. 2. Cultivate students to identify with the philosophical method of dialectical materialism, enhance the ability to actively participate in life and know how to use dialectical thinking to deal with real-life problems, and at the same time improve students’ practical ability. 3. Cultivate students’ scientific spirit of rational analysis of truth, encourage students to take on the important responsibilities of the times, and strive to pursue the truth.
Teaching focus	<p style="text-align: center;">Truth is conditional</p> <p>Set by</p> <ol style="list-style-type: none"> 1) First of all, students have learned the relevant knowledge of truth, but they do not have a special understanding of the relationship between truth and falsehood, and the applicable conditions of truth. 2) Second, combined with the requirements of core literacy and the new curriculum concept, it is necessary to cultivate students to establish a scientific spirit and the ability to guide life using the method of dialectical materialism—this is the focus of teaching. <p>How to stand out</p> <ol style="list-style-type: none"> 1) Carry out activity-based courses, teachers and students interact and communicate, analyze and demonstrate knowledge points in turn, and help students fully understand that truth is a conditional philosophical principle. Under the guidance of teachers, students can intuitively experience the changing process of the two experiments of “black wolfberry soaking in water,” actively build new knowledge, and understand that truth has its own applicable conditions and scope. 2) Make the content of the course active and the content of the activities into a curriculum, through the interaction between teachers and students, strengthen the guidance of students’ values, and cultivate students’ scientific spirit.
Teaching difficulties	<p style="text-align: center;">Truth is concrete</p> <p>Set by</p> <ol style="list-style-type: none"> 1) Concrete is a word that is often used in daily life, but for students, the specific understanding of truth is not deep enough, and it is easy to ignore the two dimensions of time and space contained in it, and then they cannot better grasp the truth and falsehood. <p>How to break through</p> <ol style="list-style-type: none"> 1) Use case analysis to analyze from the two dimensions of space and time so that students can understand that the truth must conform to the actual situation of the local and the time.
Teaching method	Pedagogy is based on the concept of the learning community

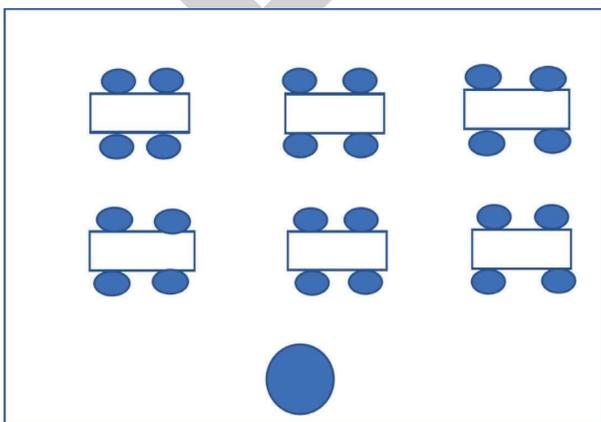

FIGURE 1: Sitting in a row in the classroom of the learning community: sitting in groups around the front and back.

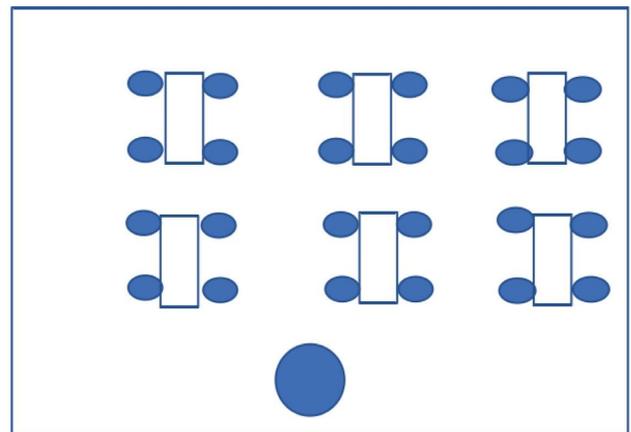

FIGURE 2: Sitting in a row in the classroom of the learning community: sitting in groups around the left and right sides.

4.2.4. *Specific Implementation.* First, the spatial arrangement should be completed. In the classroom teaching of “Truth is Concrete and Conditional,” it is necessary to build

a learning community. First, a classroom atmosphere centered on listening must be created. To cultivate the relationship of mutual trust and mutual respect between

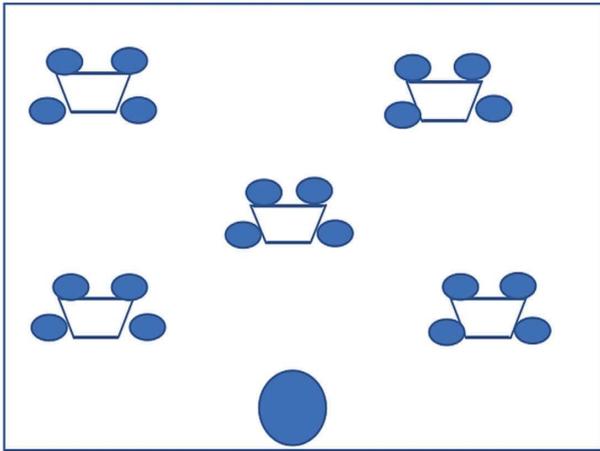

FIGURE 3: Sitting in a row in the classroom of the learning community: U-shaped sitting in groups.

teachers and students, and students and students, it is necessary to change the traditional classroom space layout, create a space layout that facilitates face-to-face communication and cooperation between peers, remove the podium, and reduce the spatial distance between teachers and students. Teachers should take turns walking around different groups, as shown in Figure 4 below.

Figure 5 shows the classroom space layout of the learning community.

Second, assigning team members. The team members should be matched according to the actual situation. Since the selected experimental class has 48 people, it is determined in advance that every four people will form a group. First of all, let the students apply for registration independently, which students are willing to form a group with, and explain the reasons for the application. Then, according to the teacher’s daily observation and understanding and the students’ evaluation of others and other factors, the group members are preliminarily determined. Finally, the list of group members is announced to the students, and those who are dissatisfied can make corrections according to the actual situation. After the four members of the group are determined, based on self-recommendation, democratic recommendation, and teacher evaluation, a leader, a timekeeper, a main speaker, and a recorder are determined for each group. During the actual operation, their identity can also be adjusted appropriately. It is convenient for everyone to communicate and cooperate in depth in the three cooperative exploration activities in the class “Truth is Concrete and Conditional,” and complete the active construction of knowledge. [21–23].

Third, establishing a common vision. Before the class, the teacher guides everyone to understand that the goal we need to accomplish together in this class is to cooperate in depth based on mutual trust with peers and teachers, to master the conditional and specificity of truth, and to understand the relationship between truth and falsehood; and the ability to actively participate in life and know how to use dialectical thinking to deal with real-life problems, to develop the scientific spirit of rational analysis of truth, to be

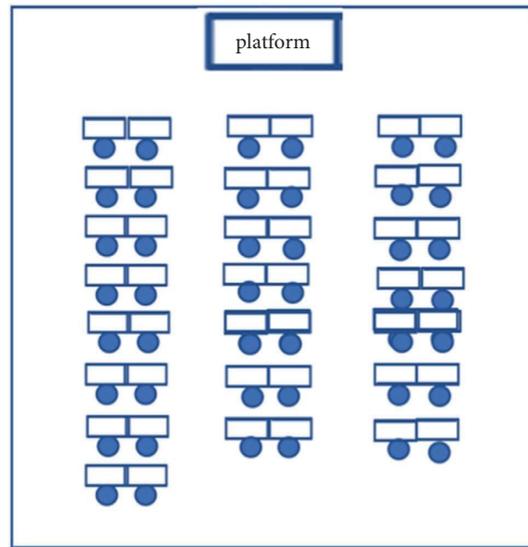

FIGURE 4: Traditional classroom space layout.

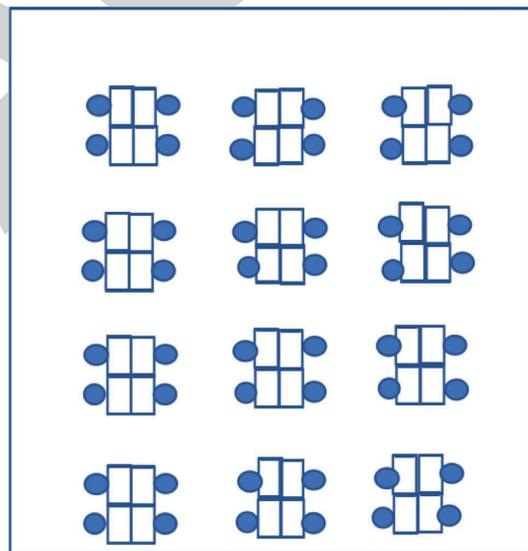

FIGURE 5: Classroom space layout based on the learning community.

brave to take on the important tasks of the times, and to strive for truth.

Fourth, solving challenging problems. The goal of building a learning community is that students can solve problems and consider the unity of learning and use. Teachers organize students to review textbooks in advance to understand the connotation of truth, so that students can solve problems independently in the teaching process, understand that truth is conditional and specific, and at the same time understand the reasons. This also requires teachers to focus on giving guidance in the teaching process, rather than directly giving answers or results, so that students can explore independently; actively build knowledge; solve challenging problems; and implement the core literacy of disciplines, scientific spirit, and political identity.

TABLE 2: Comparison of the effect of classroom teaching based on the learning community and the effect of traditional classroom teaching.

Compare items	Traditional classroom teaching	Classroom teaching based on the learning community
Degree of organization	Emphasize pre-class presupposition	Emphasize classroom generative
Learning purpose	Utilitarian (emphasizes the difficulty of the exam)	Nonutilitarian, self-fulfillment
Learning process	Passive participation in the classroom; the classroom atmosphere is dull	Actively participate in the classroom; the classroom atmosphere is active
Learning outcomes	Mechanical memory knowledge, unable to complete challenging problems	Deep learning, capable of solving challenging problems
Evaluation method	Based on external evaluation	Based on self-evaluation
Learning value	Simply acquire knowledge	While mastering knowledge, also acquired the ability of unity and cooperation
Study time	Long time, low efficiency	Short time, high efficiency

Fifth, evaluating group cooperation. After class, the evaluation is made based on the teacher's observation and the record of each group's recorder. The method of evaluation can be either self-evaluation or other evaluation, and the content of evaluation is also diverse. It can be the evaluation of students' completion of teaching tasks, the effect of group cooperation and exploration, and the teaching design of teachers. According to the evaluation results of teachers and students, it is necessary to analyze which aspects can be done better, which aspects have what kind of achievements and experience, etc.

4.3. Evaluation of the Effect of Teaching Implementation Based on the Concept of the Learning Community. On the whole, the effect of classroom teaching based on the learning community is obviously better than that of traditional classroom teaching. According to the evaluations of teachers, students, and teachers listening to the lectures, it is found that in the classroom teaching based on the learning community, students actively participate in the teaching process, actively explore new knowledge, actively communicate and interact with group members, and can solve challenging problems. The degree, learning purpose, learning process, and learning results are superior to traditional classroom teaching in many aspects as shown in Table 2.

From the perspective of solving challenging problems, building a learning community in the ideological and political teaching of colleges is an efficient teaching method. Through experiments, it is found that building a learning community in the ideological and political teaching of colleges seems to be time-consuming, but in fact it is highly efficient. Taking "truth is specific and conditional" as an example, the spatial layout was changed, the division of labor among group members was determined, and interactive teaching was carried out under the guidance of a common vision, in a democratic and equal teaching atmosphere, and students not only master the truth, but also transfer knowledge, solve the problems of low classroom participation, difficult to understand course knowledge, and mostly mechanical memory methods under the traditional teaching mode. Practice has proved that building a learning community in the ideological and political teaching of

universities can save time and achieve efficient learning. The traditional misunderstanding that it is a waste of time to build a learning community is not valid in the teaching process of teachers and the learning process of students. Although the time spent by ideological and political teachers in preparing lessons will increase, it is not a waste of time, but a responsibility that should not be shied away.

5. Conclusion

High school ideological and political teaching based on the learning community is a teaching model that emphasizes the coexistence of cognition and emotion and combines respect for individuality and all-round development under the background of the new curriculum reform. In this kind of course teaching, teachers and students, students and students cooperate with each other, have dialogue and reflection, and achieve common growth and progress, which is also the requirement of ideological and political courses in the new era. In the process of frontline ideological teaching, there are still problems in the teacher-student relationship, classroom interaction, evaluation system, etc., which seriously hinder the effective implementation of the learning community. Entering the new era, higher requirements have been placed on high school political teachers in terms of comprehensively advocating and implementing the core values of socialism, promoting the all-round development of students, and cultivating students' key abilities and necessary characters. Building a learning community in ideological and political teaching aims to break through the traditional political indoctrination education, change the discordant and unequal teacher-student relationship, and reshape the curriculum of the activity content and the political classroom of the activity of the curriculum content. Based on the zone of proximal development theory and the principle of teaching and learning, students are promoted to actively build knowledge and complete challenging problems, change their prejudice against political classrooms, enhance their sense of political learning, and make them love and enjoy political classrooms again.

With the rapid development of deep learning, its application in the field of education has gradually attracted attention. This study introduces a deep learning-based moral education evaluation system for college students. The evaluation of the ideological and political education of college students is an important driving force to strengthen and improve the ideological and political education of college students, and its connotation is very rich. However, at present, there are many difficulties in the evaluation of ideological and political education in colleges and universities, such as narrow evaluation objectives, monotonous evaluation structures, lack of pertinence in the evaluation process, and subjective evaluation standards. The internal mechanism and external mechanism of the evaluation mechanism, the qualitative analysis and quantitative analysis of the evaluation method, the absoluteness and relativity of the evaluation standard, the dynamic and static evaluation process, and the systematic and specialized evaluation are combined to ensure the college students' thinking the objectivity and effectiveness of political education evaluation.

1. Introduction

As the evaluation of the ideological and political education of college students is an important evaluation [1] and feedback on the development of ideological and political education, it is effective for discovering, analyzing, and correcting the dilemma of ideological and political education and constructing [2, 3]. Carrying out ideological and political education is an important task in colleges and universities, and the sustainable development of ideological and political education is an important subject entrusted by the times. Under the new historical conditions, facing the complicated new situation at home and abroad, the ideological and political education of college students can only be strengthened and not weakened. It has become an urgent task of higher education to realize the sustainable development of ideological and political education for college students. A sustainable ideological and political education system for college students plays an important role in improving the overall effect of ideological and political education and promoting its in-depth development. The

evaluation system of college students' ideological and political education is a systematic project, and its connotation is also rich [4–6]. Bloom regards evaluation as the most fundamental factor in a hierarchical model of human thinking and cognitive processes. According to his model, evaluation and thinking are the two most complex cognitive activities in the model of human cognitive processing. He believes that evaluation is the process of making value judgments on certain ideas, methods, and materials [7]. It is the process of using criteria to evaluate the accuracy, effectiveness, economy, and satisfaction of things. Taking various factors into consideration, evaluation refers to the process of quantitative and nonquantitative measurement of all aspects of the evaluation object by the evaluator according to the evaluation criteria and finally drawing a reliable and logical conclusion [8]. Among them, the so-called evaluator, who is also called an evaluator, is mainly a subjective agent who evaluates a certain object. The second is the system, which generally refers to the whole of a certain range or the same kind of things combined according to a certain order and internal connection, which is a system composed of

different systems. The content in the system should involve subjects, objects, laws, principles, standards, etc. The last is the ideological and political education of college students, which defines the scope and content; that is, the process of evaluation, analysis, and construction of the system should be carried out around the ideological and political education of college students [9]. When defining the evaluation system of ideological and political education for college students, it is necessary to base it on these keywords, and the key points should be considered from the following aspects.

First, there must be a definite subject in evaluating the ideological and political education of college students. To study the promoting effect of ideological and political education on the economy, we must first recognize the essence of ideological and political education and then explore at what level it can have a functional connection with the economy. It will clarify the nature of ideological and political education and study its effects on the economy from the macro- and microlevels. This subject should include both macro- and microaspects. Judging from the current domestic specific participation in the evaluation, the subjects are mainly the relevant national education administrative departments, education supervisory and scientific research institutions, and ideological and political educators in colleges and universities [10].

Second, the ideological and political education of college students must have a definite object. The object of ideological and political education evaluation of college students is throughout the whole process of ideological and political education [11, 12]. There is content at the top of the ideological and political education system, such as educational policies, educational principles, and educational goals, as well as ideological and political education. The middle end is the content of the process, such as educational content, educational methods, forms, and means of education, and the content of the lower end of ideological and political education, such as the evaluation of ideological and political educators, and the evaluation of college students receiving ideological and political education [13].

The third is the method of ideological and political education for college students [14]. The methods and means of ideological and political education for college students should be diverse, which is a combination of qualitative and quantitative analysis. Especially with the upgrading of modern statistics and analysis methods, the means and methods of evaluation should also keep pace with the times, using advanced measurement methods. Statistical technology uses the latest theoretical and practical achievements in natural science and social science to scientifically analyze the collected data. The current ideological and political education evaluation system lacks a clear line in the operation process, and there is no unified standard. The ideological and political education evaluation system that has been recognized in practice has not yet been established. Educational measurement believes that the essence of educational evaluation lies in value judgment, and the object threshold lies in the development and change of the educated and various factors that constitute the change [15]. The evaluation process of ideological and political education of college

students reflects the process and nodes of evaluating the implementation of ideological and political education of college students. Whether the evaluation process is smooth, orderly, and scientific directly determines the final evaluation result. At present, the evaluation process of the ideological and political education of college students in my country involves a wide range of aspects, and the system is too large. Especially, in the connection between evaluation and the definition of responsibilities, there is a disordered state to a certain extent, which leads to rupture and blurred boundaries in the evaluation process. At the same time, the evaluation relies too much on quantitative methods, emphasizes too much on the application of scientific methods and technical methods of evaluation, and integrates some comprehensive educational issues and in-depth activities of ideological and political education that cannot be quantified and activities that reflect changes in college students' ideological and political education. The final purpose of the evaluation is to formulate corresponding policies and systems based on this [16].

2. Related Works

Most of the existing intelligent teaching systems use technologies such as image recognition, AR/VR, and speech recognition and rarely use deep learning.

The design of deep learning evaluation is a process of reasonably selecting evaluation methods and organizing evaluation content according to learning objectives. Bloom's educational goal classification theory, which is the most influential and widely used in the world today, divides educational goals into three areas: cognition, motor skills, and emotion. The specific classification rules commonly used in the corresponding fields are Bloom's cognitive goals. The taxonomies used are Simpson's Motor Skill Target Taxonomy, and Kraswall's Affective Target Taxonomy. These three classification methods are also the theoretical basis for the design of deep learning evaluation, according to which a deep learning evaluation system of cognition, motor skills, and emotion can be constructed, and the goal level to be achieved by deep learners can be comprehensively clarified.

Although Bloom has made a detailed division and elaboration of cognitive goals, there are still some limitations: the change in learner behavior is the evaluation goal, but the description of behavior goals is not clear enough, especially when the target is relatively high. When thinking activities of higher order, take the linear accumulation of thinking complexity as the classification clue, simply use the transfer to explain the transformation from low-level target learning to high-level target learning, and artificially distinguish the knowledge content from the process, ignoring the high-level target learning, a way to evaluate thinking ability. Famous educational psychologists Biggs and Chris put forward the SOLO taxonomy, aiming at the complexity of thinking structure in their reflection on Bloom's taxonomy, in order to make up for the deficiency of Bloom's taxonomy in the evaluation of higher-order thinking ability. The development of higher-order thinking is closely related to the realization of deep learning. Deep learning is to learn

the inherent laws and representation levels of sample data, and the information obtained during these learning processes is of great help to the interpretation of data such as text, images, and sounds. Its ultimate goal is to enable machines to have the ability to analyze and learn like humans and to recognize data such as words, images, and sounds. Deep learning is a complex machine learning algorithm that has achieved results in speech and image recognition far exceeding previous related technologies. Deep learning is higher-order learning with higher-order thinking as its core feature. Therefore, in the evaluation of deep learning, the evaluation of learners' thinking quality, especially the level of higher-order thinking ability, is particularly important.

To sum up, since deep learning has the commonality of general learning forms, the evaluation of deep learning can be based on the three perspectives of traditional cognition, motor skills, and emotion. The theoretical basis of the motor skills target classification and Kraswall's affective target classification, and the achievement of expected goals such as unstructured deep knowledge, higher-order cognitive skills, and high-level motor skills is the realistic standard. However, considering the particularity of deep learning, with higher-order thinking as the core feature, it is obvious that the evaluation of deep learning should pay more attention to the development of learners' higher-order thinking, that is, based on Biggs' SOLO classification method, to evaluate the level of the learner's thinking structure, which then determines the level of cognitive development. Therefore, in the traditional three-dimensional learning evaluation system of cognition, motor skills, and emotion, the SOLO taxonomy, which pays more attention to the development of higher-order thinking, should be incorporated to construct a theoretical system of deep learning evaluation, as shown in Figure 1. The learning objectives of these four dimensions of cognition, thinking structure, motor skills, and emotion are not isolated and mechanically segmented individuals, but an interconnected organic whole, which together provides theoretical guidance for comprehensive evaluation of the effect of deep learning. However, in practice, free combination, organic integration, and flexible application should be carried out according to the nature and objectives of the curriculum.

Bloom's classification of educational goals and educational evaluation theory has had a huge impact on the field of education since they were put forward, and his classification of cognitive goals is still widely used today. According to the level of thinking and the cognitive level attained by the learner, he divides cognitive goals into six levels from low to high: knowing, comprehending, applying, analyzing, synthesizing, and evaluating. This taxonomy defines knowledge and cognitive skills at the operational level, which can better guide the measurement and evaluation of learning outcomes, but does not clarify how to convert knowledge into skills. To address the relationship between knowledge and cognitive skills, Anderson et al. revised the taxonomy, classifying learning outcomes in the cognitive domain into factual knowledge, conceptual knowledge, procedural knowledge, and metacognitive knowledge. There are four

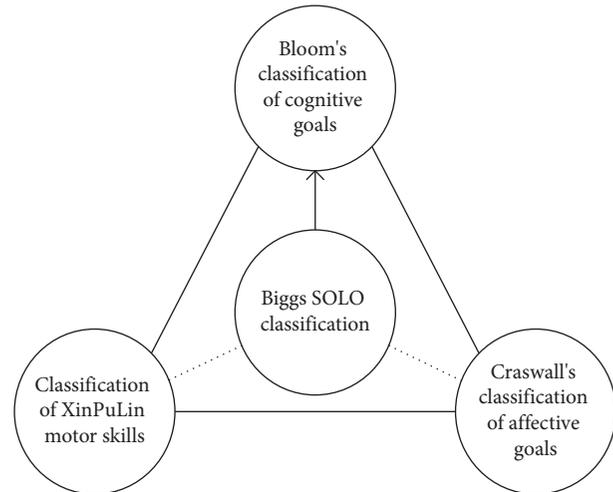

FIGURE 1: Deep learning evaluation of the multidimensional theoretical system.

types of knowledge, and the cognitive process of acquiring this knowledge is divided into six levels from low to high: memory, understanding, application, analysis, evaluation, and creation.

According to the understanding of deep learning and shallow learning, shallow learning focuses on scattered, isolated, and currently learned knowledge and is all structured shallow knowledge such as specific facts, information, details, and concepts; deep learning requires learners to establish connections between old and new knowledge in order to master unstructured knowledge such as tacit knowledge, complex concepts, and deep knowledge. Therefore, shallow learning is a simple description, memory, or copy of shallow knowledge, and its cognitive level stays at the lower level of "memory and understanding," which involves low-level mechanical memory, simple retrieval, and shallow understanding. On the contrary, deep learning is a deep understanding and transfer application of knowledge, and its cognitive level is at a higher level of "application, analysis, evaluation, and creation," and most of the activities involved are ill-structured problem-solving metacognition, creative thinking, and other higher-order thinking activities, which require the acquisition of higher-order cognitive skills.

3. The Design of the Student Moral Education Evaluation System

3.1. Research on the Classification of Students' Moral Education Based on the CHAID Decision Tree. CHAID analysis, chi-square automatic interactive detection, is a classification method that uses chi-square statistics to determine the best segmentation and build decision trees. CHAID is a commonly used decision tree, which can automatically search for multiple independent variables, generate the scheme of the maximum difference variable, and finally, output an intuitive tree structure graph. This topic is to find multiple variables (disciplinary items) in the moral education data of students and use chi-square statistics to find the best

segmentation and subcase to build a tree in several moral education periods (normal period, education period, dangerous period, and semester processing period), a framework for reshaping the structure. Through the results of the decision tree, we find out the factors that affect the variables (disciplinary items), finally classify the moral education period (normal period, education period, dangerous period, and semester processing period), and finally get the corresponding rules for each semester through the CHAID decision tree.

3.2. System Architecture Design. Today, the mainstream system architectures are C/S and B/S[17]. These two structural technologies are very mature and have their own characteristics. The B/S system is the abbreviation of Browser/Server. Customers only need to install a browser (Browser) on their personal computer, and the server-side (Server) installs the database. The B/S architecture is a network-based architecture. A C/S distributed mode is a computer term. C refers to Client, S refers to Server, and C/S mode refers to client/server mode. It is a mode in which computer software works together, usually with a two-layer structure. The server is responsible for data management, and the client is responsible for completing the task of interacting with the user. The server side is maintained by professional managers, and the client side is the browser on the client. All operations of the user are sent by the client's browser and then sent to the server through the network. The server processes the client's request accordingly and then returns the request to the client. The structure of the B/S mode is shown in Figure 2.

The advantages of the B/S architecture are that the server side is managed and maintained by professionals, the client side only needs a browser to complete the corresponding request operation, and the technical difficulty is low. Based on the B/S architecture, schools do not need to purchase new equipment, and the moral education system is applied to the local area network, so the ease of use and security are improved.

3.2.1. Theoretical Knowledge of Frame Design.

- (1) Performance prediction based on the BP neural network model: the BP neural network algorithm is a supervised classification method. The main idea of the performance prediction model is to input learning samples and use the backpropagation algorithm to determine the weights and biases of the network. Repeated adjustments and training are performed to make the output vector as close to the expected vector as possible. When the sum of squared errors of the output layer of the network is less than the specified error, the training is completed, the weights and deviations of the network are saved, and the classification model is trained. The BP neural network can be used to predict the corresponding offline learning performance by analyzing the characteristics of online learning behavior. A

fully connected network is a feedforward network consisting of an input layer, an output layer, and several hidden layers. As shown in the figure below, the input layer is composed of ddd neurons, which are used to input each feature value of the sample; the network can have several hidden layers, and the number of neurons in each hidden layer is also uncertain. Compared with the current fully connected networks of deep learning, the simple BP neural network can maintain a lower computational complexity under the condition of achieving the same effect.

- (2) Online learning behavior regularity is analysed by analyzing the user's online learning behavior definition and calculating the corresponding actual entropy value to evaluate the individual's learning behavior regularity and analyze the relationship between the regularity and the user's performance. Theoretically, by calculating the number of days between each time a student logs in, plus the number of logins in an experimental period, the online learning time distribution can be accurately depicted. The user's learning time characteristics are mapped to a two-dimensional coordinate system for visualization, and a user's learning time scatter diagram is made. The maximum, minimum, and average time intervals of each user's login time interval and the truncated average value of the maximum and minimum values are separately counted, and the relationship between them and the performance is analyzed. The most relevant ones are selected and added to the model to enhance the prediction accuracy of the model.
- (3) Student sentiment analysis based on micro-expression recognition and clustering of the article recognizes the facial microexpressions of users during online learning, including 6 categories of anger, doubt, happiness, fear, dullness, and sadness, to clarify the students' learning emotions and network links between online learning behaviors. Users with different emotions and learning habits are classified by the clustering algorithm. This study proposes an offline classroom quality two-way evaluation system based on classroom information, which has good interactivity and practicability and can provide teaching feedback, classroom discipline supervision, intelligent attendance, and other functions.

3.2.2. System Architecture. The schematic diagram of the structure of the offline classroom quality two-way evaluation system designed in this study is shown in Figure 3, including student terminals, classroom terminals, educational affairs terminals, and cloud servers, in which each terminal and cloud server are connected through mobile network communication.

The industry name for cloud servers is actually called computing units. The so-called computing unit means that

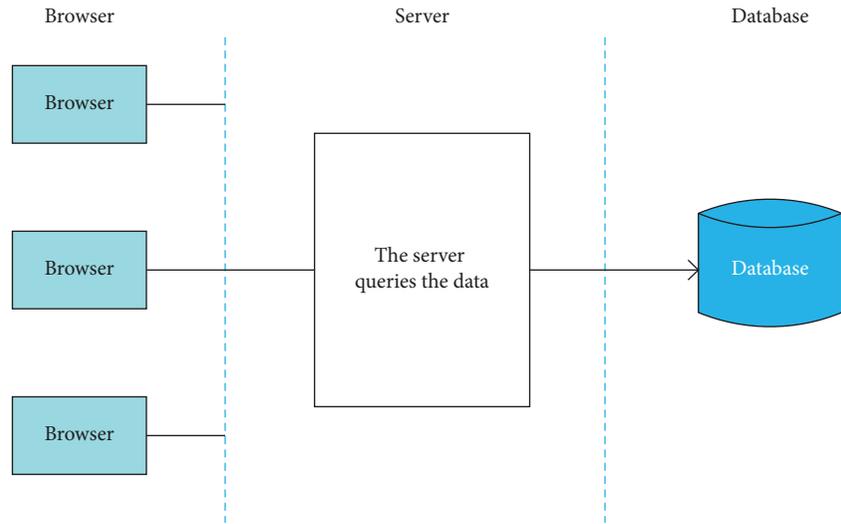

FIGURE 2: B/S mode.

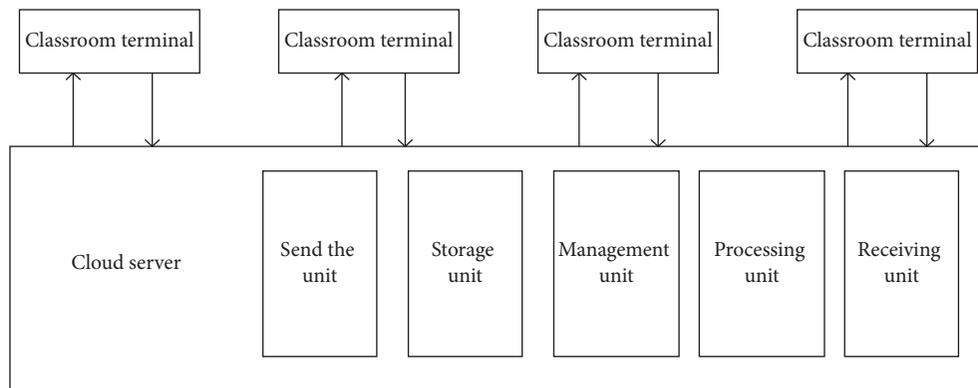

FIGURE 3: Structure diagram of the two-way assessment system for classroom quality.

this server can only be regarded as a person’s brain, which is equivalent to the CPU of an ordinary computer, and the resources inside are limited. If you want to get better performance, one solution is to upgrade the cloud server, and the other is to deploy other software that consumes computing unit resources on the corresponding cloud service. For example, the database has a dedicated cloud database service, and static web pages and pictures have a dedicated file storage service. In this study, through the development of the front-end client of the mobile intelligent terminal and the classroom terminal, combined with the construction of the cloud server and the establishment of the background database, a two-way evaluation system is formed. The use of the client and the data collection of the classroom terminal are based on image processing technology, and classroom data are collected by using a camera and through frame processing. At the same time, a cloud server is built based on deep learning technology, and the collected classroom information is identified and analyzed through the image target detection model, face segmentation, and face detection models, so as to improve and update the stored information and feedback information. In addition, the cloud server is also used for data transmission between clients,

classroom terminals, and databases, forming a two-way evaluation system.

The classroom terminal is setup in the classroom; as shown in Figure 4, it consists of a network communication unit, a data acquisition unit, a terminal control unit, and a frame processing unit. The network communication unit communicates with the cloud server and receives the control signal sent by the cloud server. The terminal control unit controls the data acquisition unit to collect classroom data according to the control signal received by the network communication unit, and the classroom data include images and videos. The frame processing unit cuts the collected video into frame images in chronological order and judges the current frame image. If the similarity between the current frame image and the previous frame image is greater than the set similarity threshold, the current frame image is deleted. Implement frame acceleration and processing of video streams. The network communication unit sends the video frames processed by the frame processing unit and the collected images and videos to the cloud server for storage and processing.

As mobile clients, the teacher terminal, educational affairs terminal, and student terminal mainly have the

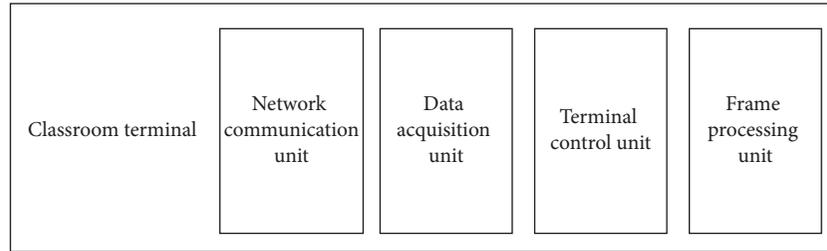

FIGURE 4: Schematic diagram of the composition of the teacher's terminal.

functions of sending, receiving, and displaying, that is, sending image and text information to the cloud server and receiving and displaying the data returned by the cloud server. The cloud server is mainly used to perform attendance analysis, class attendance analysis, classroom behavior analysis, classroom expression analysis, classroom seat analysis, etc., on the received data, and feedback the analysis results to the mobile client terminal. Among them, the subunit composition of the processing unit is shown in Figure 5, including the attendance analysis and feedback subunit, class attendance analysis and feedback subunit, classroom behavior analysis and feedback subunit, classroom expression analysis and feedback subunit, and classroom seat analysis and feedback subunit. These five subunits all use deep learning models to analyze and provide feedback on classroom data.

3.2.3. System Modules. Fast R-CNN takes the entire image and a series of candidate boxes generated on the image as input and calculates the feature map through the convolutional layer and the pooling layer. For each candidate box, a fixed-length feature vector is extracted from the feature map region corresponding to each candidate box using the ROI pooling layer described below. After the fixed-length feature vector is calculated by several fully connected layers, it is divided into two branches. One branch uses the SoftMax method to classify the images in the candidate frame, and the other branch returns the offset and scaling of the target frame relative to the candidate frame.

- (1) Target detection module based on FastR-CNN: the main function of the target detection module in the offline system is to detect and identify students' classroom behavior and students facial expressions in classroom video frame images. The steps of using the FastR-CNN network to identify objects include
 - (1) Extract features using the CNN model [18, 19].
 - (2) Selection and mapping of candidate regions.
 - (3) Target classification and boundary regression.
 The schematic diagram of the structure of FastR-CNN used in this study is shown in Figure 6.

The image is input into the CNN network, and the feature map is obtained through a series of convolution and pooling operations [17, 20–22]. Then, the selection and mapping of candidate regions are carried out. The selection of candidate regions refers to prefinding the position of possible targets from the

original image, that is, the region of interest (RoI). FastR-CNN uses the selective search method to select about 2000 candidate regions. This method combines exhaustive search and segmentation methods, which greatly reduces the search time of candidate regions and improves selection accuracy. The mapping of the candidate region refers to mapping the position of the candidate region in the original image to the feature map. FastR-CNN achieves a reduction in computational complexity by adding an RoI pooling layer after the convolutional layer to map each candidate region into a single fixed-scale feature vector.

Finally, target classification and boundary regression are performed. FastR-CNN uses SVD decomposition to calculate the feature vectors obtained in the previous step through their respective fully connected layers to obtain two output vectors for classification and regression. [23].

- (2) Face detection module based on FaceNet.

The main functions of the face detection module in the offline system are the detection and recognition of students' faces in-classroom images. Based on the high cohesion of the same face photos and low coupling of different face photos, FaceNet uses the CNN network model and the TripleLoss function for face detection [24]. Firstly, CNN feature extraction is performed, the face image is input into the CNN network, the feature vector is obtained after convolution and pooling operations, and the mapping of the face to the Euclidean space is realized. The network is trained on the condition that the distance between the face and the object is always smaller than the distance between different individual faces.

The goal of the TripleLoss function is to map the face features of the same individual to the same area of space so that the distance between the faces of the same individual is smaller than the distance between different individuals; that is, the intraclass distance is smaller than the interclass distance. Specifically, the triplet consists of Anchor, Positive, and Negative. Anchor represents a random sample in the dataset, Positive represents a sample belonging to the same class as the Anchor, and Negative represents a sample belonging to a different class from the Anchor. In the training process, the ternary loss

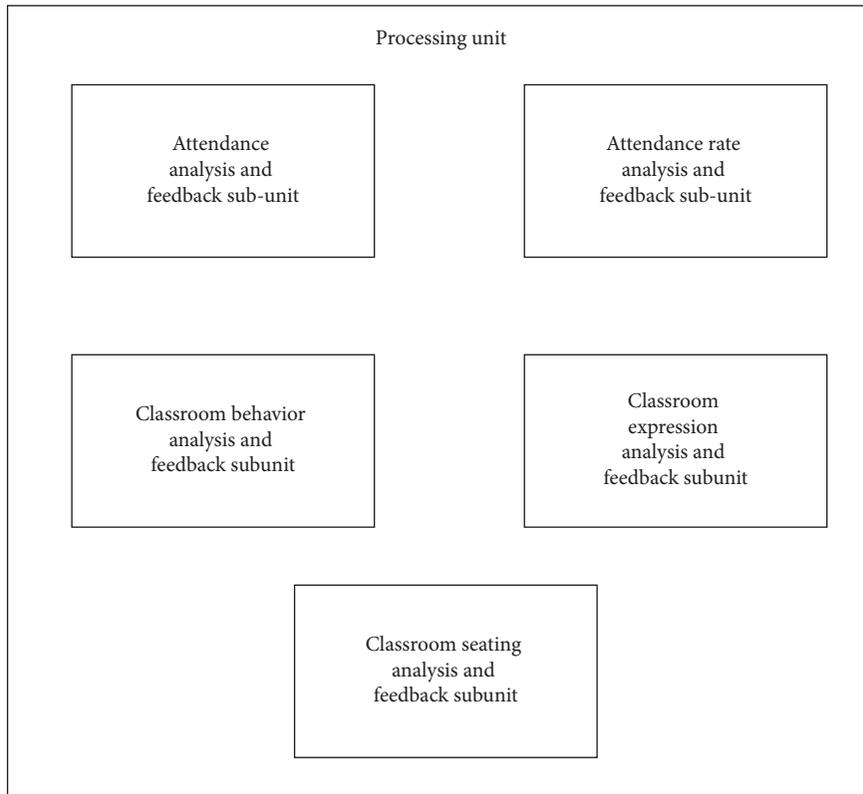

FIGURE 5: Schematic diagram of the subunit composition of the processing unit.

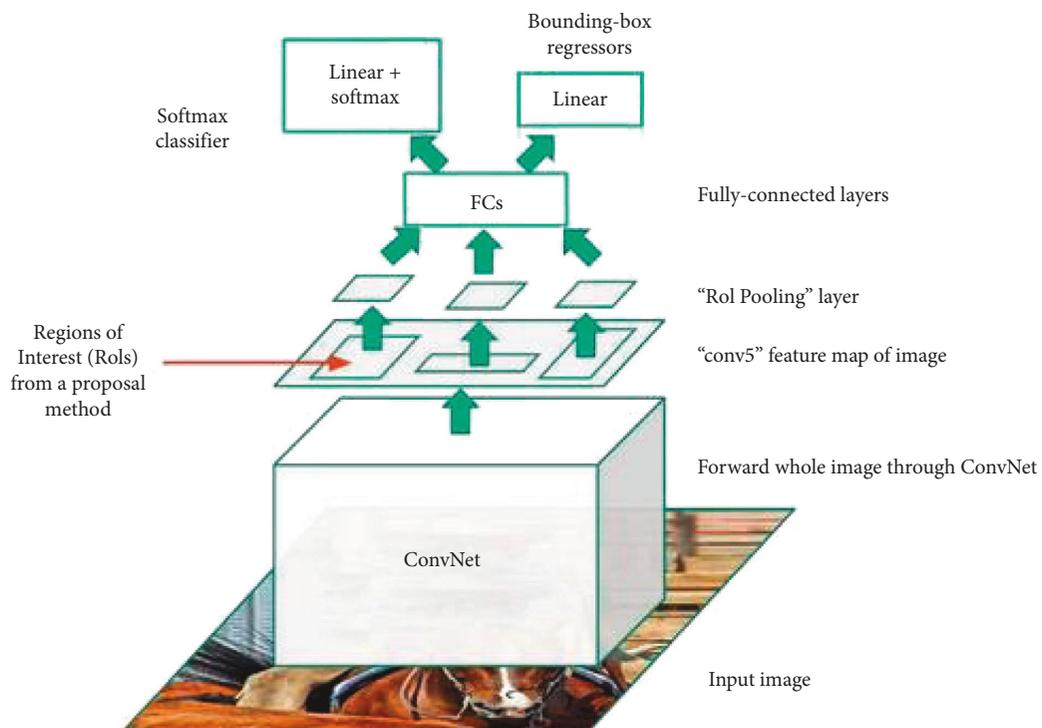

FIGURE 6: Schematic diagram of the structure of FastR-CNN.

function makes the distance between Anchor and Positive as small as possible and the distance between Anchor and Negative as large as possible and makes a gap between intra-class and inter-class distances [25].

- (3) Face segmentation module: The main function of the face segmentation module in the offline system is to detect the number of faces in the classroom images and combine them with the face detection module for data analysis. The specific process of the face segmentation model to achieve face segmentation is to input the original image, create an image pyramid based on a certain scaling factor, and obtain scaled images of different scales and resolutions. The Resnet-101 network is used for feature extraction and candidate frame boundary regression for all zoomed images, and the frame that best matches the face position is obtained.

Then, the nonmaximum suppression method (NMS) is used to fuse the bounding boxes corresponding to all the zoomed images to obtain the final detection result, that is, the coordinate value of the face. And according to the returned coordinate values, the cv2 module in OpenCV is used to crop, segment, and temporarily store the face.

For group photos of a class, too many people will lead to smaller faces or too little information. In order to minimize the impact of these situations on the results, the surrounding information (such as shoulders and hair) is positioned for auxiliary positioning and returns the position coordinates of each face.

3.3. Experimental Results and Analysis.

- (1) Analysis of online learning regularity: after obtaining the maximum, minimum, and average values of each user's online learning time interval and the truncated average value after removing the extreme values at both ends, each experimental object is divided into 4 values. The rank-ordering. At the same time, the user's real evaluation results are sorted.

Calculate the user's actual entropy function, give the corresponding ranking, and then draw the Spearman correlation scatter diagram between the actual entropy and the score ranking according to the user's actual score, as shown in Figure 7.

It can be calculated that the Spearman correlation has obvious positive correlation characteristics. Intuitively, users with more regular learning time periods are more self-disciplined. In learning, users periodically review the knowledge they have learned, and their performance in performance evaluation is better. Combining the abovementioned rank correlation of time difference and the rank correlation of actual entropy function, the study adds the score of actual entropy function as the dimension of time regularity into the model, conducts relevant training on the BP neural network, and finally makes the test

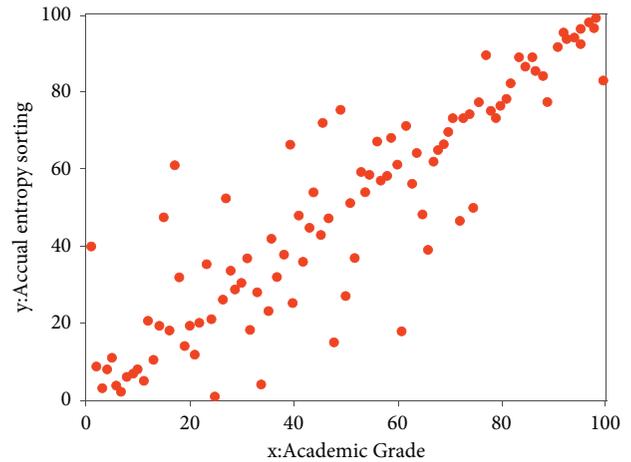

FIGURE 7: Actual spearman correlation scatter plot.

set's score. The accuracy rate rose to 74.7900%, achieving the purpose of enhancing the prediction accuracy of the model by fully mining the learning log records of online users.

- (2) Sentiment analysis based on microexpression recognition and clustering: according to the micro-expression analysis of users during online learning, the number and proportion of various expressions were counted, and the emotional scores of 101 users in four dimensions were obtained in the experiment. The k-means clustering algorithm is an iterative clustering analysis algorithm. The steps are as follows: predivide the data into K groups, randomly select K objects as the initial clustering centers, and then calculate the clustering of each object and each seed. Cluster centers and the objects assigned to them represent a cluster. Each time a sample is assigned, the cluster center of the cluster is recalculated based on the existing objects in the cluster. This process will repeat until a certain termination condition is met. Termination conditions can be that number (or a minimum number) of objects is reassigned to different clusters, number (or a minimum number) of cluster centers changes again, and the sum of squared errors is locally minimized. The emotional dimension data obtained by processing are subjected to K-means clustering analysis to obtain the emotional classification results. The K-means clustering results show that when $K = 3$, the clustering results are the best, that is, the measurement function values of the distances between each point and various centroids. Minimum: according to the emotional data, the emotional attributes of 101 users are divided into three categories. Through the processing of the similarity matrix, the users are exchanged for the rows and columns of the matrix, and the users who are in the same category are exchanged together. In this way, users of the three categories are all concentrated together, and in the visualization of the heat map, you will see that there

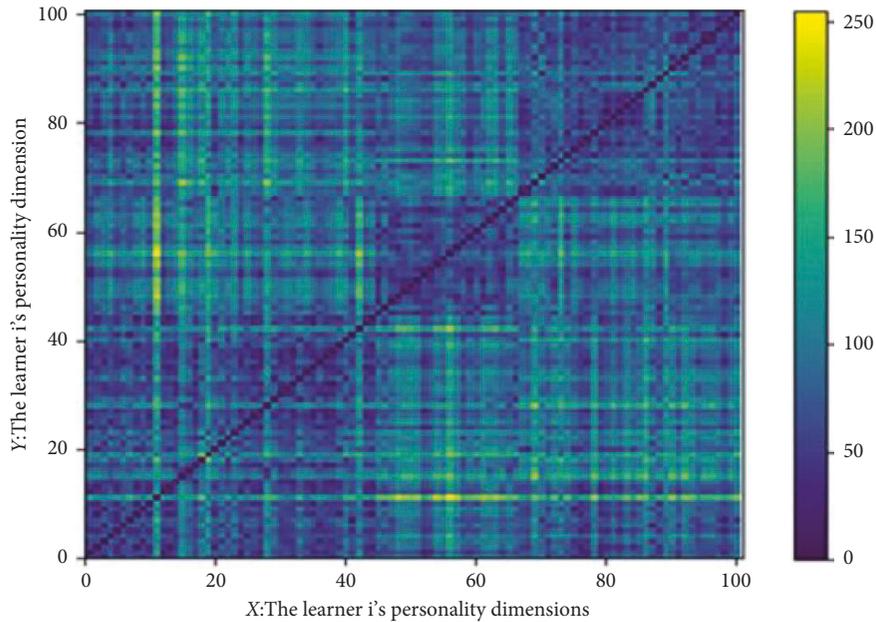

FIGURE 8: Visualization of the similarity matrix heatmap after clustering.

are three diagonal blocks on the diagonal, which indicates that the clustering effect is obvious. The similarity matrix heat map after clustering is shown in Figure 8.

In these three categories, students with higher academic performance are obtained; that is, students whose performance category is marked as level 1, and the union of their common online learning characteristics is extracted.

The classroom behavior analysis and feedback subunit retrieves and uses the trained image target detection model to detect classroom behaviors (such as students raising their hands, standing, sleeping, and teacher interaction) in the video frame images in the data storage module and uses face segmentation. The detection model recognizes the location of students and counts the types and times of classroom behaviors, updates the student identity to the classroom behavior data and student feedback information; and updates the location of students with classroom behaviors and behavior types and times to the classroom behavior data. According to the classroom behavior, the total number of behaviors in the data calculates the interaction rate (the ratio of the number of interactions to the total number of people), evaluates the teaching quality of teachers, and updates the interaction rate and evaluation results to the classroom behavior data and teacher feedback information. Expression Analysis and Feedback Subunit uses the face segmentation and face detection models to identify the student's face in the video frame image in the data storage module and uses the image target detection model to identify and classify the student's expression, including angry, doubtful, happy, afraid, plain, and sad⁶. Class: Classify and count the recognition results of students' expressions, and calculate the proportion of each expression and further evaluate the teacher's teaching method according to the expression data so that the teacher can make corresponding adjustments to

the teaching method according to the results. Students with a large number of times generate corresponding reminder suggestions for course preview, update the expression ratio results to the classroom student data and teacher feedback information, and update the reminder suggestions to the student feedback information.

4. Conclusion

“The assessment and evaluation system of the teaching of ideological and political theory courses in colleges and universities should focus on the unity of the internalization and externalization of the course content and the unity of knowledge and action.” It is worth thinking about and exploring to solve the difficult problems in the construction of ideological and political education in colleges and universities. The innovation of the evaluation mechanism of the ideological and political theory course requires not only the research and development of technical personnel but also the cooperation of the ideological and political theory course educators and educated. However, no matter what kind of innovation, the focus is still “people-oriented.” The most important thing about technological innovation is to help people's practice. Using deep learning technology to innovate the evaluation mechanism of ideological and political theory courses in colleges and universities will help educators fully understand the dynamic absorption of educated and educational content and will play an important role in improving the effectiveness of ideological and political theory courses in colleges and universities.

Classroom teaching activities have always been the focus of research in the field of pedagogy. The main body of classroom teaching activities is students, and students' classroom behavior status can reflect classroom efficiency to a certain extent, making it an important reference index for classroom quality assessment. With the rapid development of artificial intelligence, school education is gradually becoming more intelligent. At present, most of the classrooms are equipped with video equipment. These videos record the real behavior status of the students in the classroom. For example, by analyzing the data, combining artificial intelligence, deep learning, and other related technologies with education to develop behavioral intelligence, the analysis system has a certain positive effect on helping the reform of classroom education. This study proposes an improved SSD behavior recognition model. The network model is optimized and the model convergence speed is accelerated based on the RMSProp optimization algorithm. Through a database of 2,500 images of five behaviors, including raising hands, sitting up, writing, sleeping, and playing with mobile phones, and using them as object detection datasets, we use the OpenCV library to extract frames from classroom screen recording videos as image data sources for student behavior recognition and face recognition. Finally, an improved method is proposed to change the virtual network to MobileNet and complete the fusion function. The results show that compared with the traditional SSD method, the improved model has a significantly improved effect in recognizing small objects and the recognition speed is not significantly reduced.

1. Introduction

Nowadays, legal education is mainly based on teaching in class. In the traditional teaching model, the students are passive and have scattered knowledge. The cultivation of character, emotion, ability, and other aspects has not achieved the best effect. The various disadvantages appear gradually and cannot adapt to the requirements of modern society [1]. The legal teaching in the class includes civil law, criminal law, labor law, and other law departments. The knowledge is scattered and complex, lacking the complete knowledge structure system that cannot be systematically in-depth learning, resulting in the teaching in class being still at the surface level of understanding. The learning effect has not been substantially changed [2]. With the acceleration of the popularization of higher education in China, knowing

how to guarantee and improve the quality of teaching and ensure the quality and scale of coordinated development is one of the main problems faced by Chinese colleges and universities.

Under this profound background, it is an effective way to comprehensively deepen the curriculum reform to carry out the construction of a classroom mode of promoting in-depth learning, research methods and strategies based on questions and tasks and summarize the application rules of in-depth knowledge [3]. The shallow monologue and infusing filler in class are gradually replaced by new paradigms such as cooperative inquiry and in-depth dialogue and communication. The new paradigms with exchange and communication as the central theme make classroom teaching achieve a qualitative leap. Deep learning emphasizes the deep digging of knowledge and the inquiry into the nature of things for

students, which requires the students to master the connection between knowledge generation and the knowledge system. It focuses on cultivating critical thinking and problem-solving skills for the students, which are necessary to adapt to society and still have learning abilities after entering the organization [4, 5].

As the main body of classroom teaching, their classroom behavior reflects their acceptance of knowledge and directly affects the teaching quality of teachers. The traditional education in the classroom and the status of the students can only be understood through the teacher's observation in the class, the workload is enormous, and the results are relatively one-sided. The target detection method is used to identify student behavior that can count the number of each behavior quickly in class, which is convenient and has high accuracy compared with the manual method. Therefore, the deep learning that is used to analyze classroom status and the development of artificial intelligence to improve teaching quality is the critical direction of educational research in the future, which has significant research value.

2. Related Work

The theoretical research of deep learning and classroom practice analysis is carried out almost simultaneously in foreign countries. The academic study of deep learning provides a strong foundation for classroom teaching research. Meanwhile, classroom practice research also directly enriches the theoretical investigation of deep understanding.

Rushon [6] investigated the influence of assessment methods on deep learning and highlighted the vital role of formative assessment in promoting deep understanding. The use of formative assessment for teachers to encourage students' deep learning was advocated. Hornby et al. [7] experimented on the first-year students for three cycles, and the design philosophy of Meyers and Nulty was adopted. Through the comparison between the experimental group and the control group many times, improvement and adjustment updates proved that deep learning could improve students' learning effects. Khosa et al. [8] conducted, through experimental research, pre-test and post-test that were arranged in the form of questionnaires, the promotion effect of collaborative learning on deep learning was discussed, and students were advocated to achieve the goal of deep learning through collaborative learning. Aubrey and Raath [9] clarified the learning degree through case studies that deep learning and shallow learning under problem learning mode could promote geography standard university students to achieve the goal of deep understanding. Nina [10] guided critical thinking by enhancing the interaction between teachers and students in the network environment. The research focuses on deep learning practice in the classroom. James and Richard [11] designed a comprehensive evaluation method based on constructivism to guide and promote deep learning.

Above all, deep learning mainly focuses on classroom teaching in the practical application and technical support of deep learning research in foreign research. The experimental application research had an extended period. Though the

repeated verification experiment to reach appropriate strategy and methods can promote deep learning and provide a reference for the development of classroom teaching, the support of technology for deep understanding was mainly reflected in deep knowledge in the information environment, which responded to the requirements of learning levels in the information age and promoted the effective development of deep learning for higher education learners.

Unlike foreign studies, the research of deep learning in China only stayed at the stage of logical thinking in philosophy. Deep knowledge was combined with practical teaching only in recent years.

Xu [12] combined textbook drama with deep learning. It expounds on the primary connotation of deep learning and puts forward effective strategies to promote deep learning. Wu [13] took political teaching as an example, which pointed out that teachers play an essential role in promoting deep learning and putting forward a teaching model and teaching strategy based on deep learning. Zhang et al. [14] compared deep learning with shallow learning and concluded with the critical understanding that deep learning advocated active learning, lifelong learning, and emphasis on knowledge. Zeng and Dong [15] found that deep learning was mainly "deep" in three aspects:

- The achievement of training objectives and results
- The level of thinking processing
- The level of multidimensional input

Guo [16] carried out a series of research on depth teaching and proposed that depth learning cannot be separated from the guidance and help of teachers and stressed that learners should carry out depth learning under the direction of teachers.

Through the research on the teaching practice in the classroom of deep learning in China, although existing studies have noticed the critical role of the school in promoting deep understanding, most of the research remained at the descriptive level, lacking the support of theories and experiments. Based on MobileNet's deep separable convolution structure and feature fusion theory, this paper proposed an improved SSD algorithm, constructed behavioral data sets, and trained the improved SSD network model. The SSD and enhanced models were used to identify the five behaviors of sitting in class, raising hands, writing, sleeping, and playing with mobile phones, and the recognition results were compared. The research aimed to respond to the requirements of learning levels in the information age and promote the effective development of deep learning for higher education learners.

3. The Theory and Technology of Classroom State Analysis

3.1. The Deep Learning Theory

3.1.1. Activation Function. Neural networks are commonly used in deep learning networks, the smallest of which are

neurons, in which two functions are linear and nonlinear, respectively. The former output has no relationship with the number of layers and is always linear, so the use field is limited[17]. However, in reality, neural networks are required to deal with various nonlinear problems, so a function is used to activate the results, and the web, after processing, can solve nonlinear problems. The calculation process of the activation function is shown in Figure 1, the input is put into the neuron, and the neuron performs the linear calculation on it and outputs it into the activation function; thus, a nonlinear result can be obtained [18]. The neural network with an activation function is more powerful.

(1) *Sigmoid Function*. The sigmoid function originated in the biological field, and another name for it is the logistic function. The output is controlled between 0 and 1, so it is used to activate the output results of the network layer [19]. The formula is as follows: The sigmoid function is often used in dichotomous problems, and the results are better in some aspects, but the derivation calculation is cumbersome, and the phenomenon of disappearing gradient exists.

$$f(z) = \frac{1}{1 + e^{-z}}, \quad (1)$$

where $f(z)$ is the loss function and z represents the input value.

(2) *ReLU Function*. The linear rectifying function is widely used in image recognition and computer vision. The output is the maximum value of input X and 0. The formula is as follows. Compared with the Sigmoid function, this method has complex power operation and fast calculation speed. In the calculation process, some neurons will be set to 0 to make the network become sparse and effectively reduce the overfitting phenomenon[20].

$$f(x) = \max(x, 0), \quad (2)$$

where $f(x)$ is the loss function and x represents the input value.

(3) *SoftMax Function*. This function, also known as the normalized exponential function, computes the output between 0 and 1, and the sum of the probabilities of all the outputs is 1. The formula is as follows: The SoftMax function works well for multicategory tasks but not well for keeping the same categories close together and separating different categories.

$$f(x)_j = \frac{e^{x_j}}{\sum_{k=1}^k e^{x_k}} \quad (j = 1, 2, \dots, k), \quad (3)$$

where $f(x)_j$ is the loss function, x_j is the JTH value of the input, and k is the number of input values.

3.1.2. Convolutional Neural Network. Convolutional neural networks, also known as convnets, are the foundation of deep learning, and their design is based on biological ideas. They refer to areas of interest in an image. The primary network structure is divided into three layers: input data, output data, and the middle layer. The input layer can

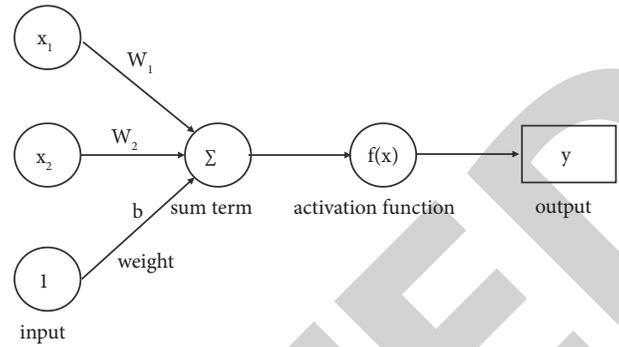

FIGURE 1: The calculation process for the activating function.

process multidimensional data before data are input to the network, which should be unified in the channel, time, and frequency. The output layer outputs corresponding results for different problems, and the middle layer is divided into the convolution layer, pooling layer, and whole connection layer.

The main mechanism of convolutional neural networks is that when the network is connected to a network, two neurons are related, but convolutional neural networks are only partially protected. I have an $N-1$ layer of neurons connected to N layers of neurons [21–25]. As shown in Figure 2, the special part connects layer $N-1$ and layer N . The left is the fully connected mode and the right is the partially connected mode. The parameter on the right is much smaller than the parameter on the left.

3.2. Face Recognition Method. MTCN face detection algorithm, affine transform face alignment, and NSightface face comparison algorithm. The face data set is first prepared, and the MTCNN algorithm and affine transformation complete face detection and alignment. Finally, the aligned faces were put into InsightFace for face comparison, and the results were obtained.

The face recognition algorithm refers to the recognition of video images in the face recognition model extracted by artificial features and the model selected in this paper. The comparison result of the artificial feature extraction method is 0.9, and the comparison result of MTCNN-InsightFace is 0.95. The accuracy of the MTNC-InsightFace face recognition model is 4% higher than that of the manual feature method, and the speed is much faster, which fully meets the needs of the actual attendance function.

3.3. Image Preprocessing Method. The influence of image noise will affect the information effect, so to ensure the required quality of the image used for operation, it is necessary to deal with it before using it. The commonly used methods include denoising, histogram equalization, normalization, and grayscale image generation.

3.3.1. Grayscale Method. The RGB model color images can get more than 16 million values for one pixel, which will increase the workload of image recognition processing.

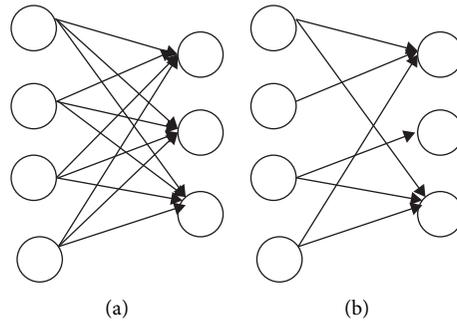

FIGURE 2: Comparison of full connection (a) and local connection (b).

Graying is $R = G = B$, ranging from 0 to 255 for a single pixel. There are many kinds of grayscale methods, mainly by seeking the average value of each pixel to grayscale, seeking the maximum value of pixels to grayscale, and seeking the weighted mean value of pixels to grayscale, the corresponding function in OpenCV tools is often used.

3.3.2. Denoising Method. The standard denoising methods include mean filter, median filter, Gaussian filter, and bilateral filter. Mean filtering belongs to linear filtering. The average of each pixel value and the surrounding pixel value is taken as the pixel value of the point. Mean filtering will destroy image details in denoising and is suitable for Gaussian noise. Median filtering is to sort the values of a pixel point and the surrounding pixels and find the intermediate value as the final pixel value, which is suitable for denoising impulse noise. The goal of Gaussian filtering is to take the mean of each pixel and the surrounding pixels after weighting and replacing the original pixel. The weight of the center point of Gaussian filtering is more significant than that of the periphery, highlighting the key points more than that of the mean filtering. However, only the spatial distance of pixel value is considered without considering the similarity, which is sufficient to cause image blur. Bilateral filtering takes spatial distance and similarity as indexes and can protect edge characteristics while removing noise.

4. Improvement of the SSD Behavior Recognition Algorithm

The behavior in class helped analyze the quality of listening and teaching effects. Five common postures, including sitting in class, raising hands, writing, sleeping, and playing with mobile phones, were selected for identification and research. The shortcomings of the target detection SSD algorithm were obtained by analyzing the characteristics of students' behavior, and an improved SSD algorithm was proposed. Meanwhile, the implementation process of the classroom behavior recognition model was introduced in detail.

4.1. The Construction Process of the Recognition Model for Behaviors in Class. The model construction mainly includes determining network structure, preparing training data,

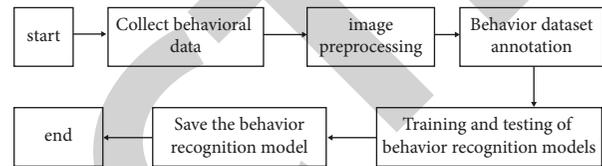

FIGURE 3: Identification process of behavior in class.

model training, and testing, etc. The behavior recognition model design process was obtained as shown in Figure 3. [2, 22, 26].

The first step was to prepare student behavior images. Two thousand five hundred images were collected, including raising hands, sitting, writing, sleeping, and playing with mobile phones, with 500 pictures for each behavior. Then, they built a behavior recognition database. The collected 2500 images were preprocessed and labeled, and the photos were divided into three parts: a training set, a test set, and a verification set according to proportion. Finally, the model was trained and tested. The initial model was obtained by putting the training set into the behavior recognition network model for training. The validation set was used to verify the model, and the network model parameters were adjusted according to the verification results. We put the test data into the model to get the results, analyze the results, and determine any differences from expectations. We decide whether to continue the training model according to the comparison results and saved the behavior recognition model with a better effect for subsequent class behavior recognition.

4.2. Improved SSD Algorithm. The improvement strategies were proposed for the primary network and small target detection of the traditional SSD algorithm. Instead of VGG16, a lightweight network was used to reduce the number of parameters to improve the detection speed. The high-level semantics were fused to the low level to enhance the small target detection effect. The improvement principle and process will be introduced in detail as follows:

4.2.1. Improvements to the Underlying Network. The goal of improving the primary network was to replace the original backbone network, VGG16, with a lightweight network. The

TABLE 1: Comparison of VGG16 and MobileNet in the imagenet dataset.

Model	ImageNet accuracy (%)	Million mult-adds	Million parameters
MobileNet	70.6	569	4.2
VGG16	71.5	15300	138

MobileNet network used deep devolution instead of ordinary convolution to reduce the number of parameters. MobileNet had only 4.2 million parameters compared with 133 million parameters in VGG16. By analyzing the test results of both in the ImageNet data set, as shown in Table 1, the speed of MobileNet was greatly improved. At the same time, the accuracy was only 0.9 percentage points lower than that of VGG16. Therefore, based on the original MobileNet, this paper was used as SSD's primary network after some modifications.

(1) *Improvement of MobileNet.* MobileNet was faster and less computational than VGG16 because it had two differences. First, depth separable convolution was used for network composition. On the other hand, the width coefficient and resolution coefficient were also used. When the image was input into the network, a set of graphs containing feature information should be obtained through deep convolution operations, respectively, and some other feature graph information should be received by point convolution operations after the BN and ReLu operation of the feature graph, and then, the results should be obtained through BN and ReLu operations again. We change the MobileNet input size from 224×224 to 300×300 . In order to increase the information capacity of the feature map and improve detection accuracy, increasing the input size can make essential preparation for the combination of the two networks.

(2) *Replacement of SSD Primary Network.* The first 14 improved deeply separable convolutional layers were selected from the improved MobileNet(300×300) network to replace VGG16 as the backbone network of the enhanced algorithm. In order to increase the feature extraction capability of the model, eight ordinary convolutional layers of decreasing size were connected behind the replaced primary network in order to further obtain deeper information about the image. The size of the eight convolutional layers is shown in Table 2.

Finally, a classification layer for judging categories and a nonmaximum suppression layer for screening regression boxes were connected to the end of the network to complete the replacement of the primary network. The basic network structure after the replacement is shown in Table 3. Deep convolution and subsequent 1×1 point convolution were regarded as one layer, and there were 14 layers, respectively, denoted as Conv0 to Conv13, where s_1 represents step size 1, s_2 represents step size 2, and Conv DW represents deep convolution and then convolved with a 1×1 point to process the channel.

The same as with the original SSD, 6 feature layers were selected to complete feature extraction and target detection. The depth of layers was considered in the selection, as it was

too shallow to extract enough image information. The 6 characteristic layers selected in this paper were Conv11, Conv13, Conv14_2, Conv15_2, Conv16_2, and Conv17_2, which decrease in size from front to back to achieve multi-scale prediction.

4.2.2. *Feature Fusion of the Network Model.* The replacement of a primary network improved the detection speed but did not improve the accuracy of small target detection. Improving model performance by integrating features of different scales was the common improvement strategy [9, 27].

Combined with the structure of the network model and the characteristics of each feature fusion method, the ADD feature fusion method was selected by the researchers for the network fusion operation. During the fusion, the fusion layer was selected first. Conv17_2 and Conv16_2 were too small to have much information. Only Conv11, Conv13, Conv14_2, and Conv15_2 were chosen for the fusion operation. The specific fusion steps were as follows:

In the first step, the size of Conv15-2 changed from 3×3 to 5×5 after up-sampling, and then, it was fused with Conv4-2 by the add method. Finally, the fusion results were normalized to obtain the characteristic layer.

The second step: an upsampling operation was carried out on conv14_2_r with the size of 5×5 to make it the same size as Conv13 with the size of 10×10 . The two were fused and normalized by the ADD method to obtain the new feature layer CONV13_r.

The third step: the feature layer conv13-R obtained in the previous step was up-sampled to receive the exact size of 19×19 as Conv11. The add feature fusion method was also used for fusion, and finally, normalized.

4.2.3. *Model Optimization Algorithm.* Model training requires continuous attention to the change of loss function. The constant decrease in loss function value indicates that the result of model training was closer to the natural consequence. In order to accelerate the decline speed, optimization algorithms were usually used, such as Momentum, RMSprop, and Adam. This paper adopts the RMSProp (Root Mean Square Prop) optimization algorithm proposed by Geoffrey E. Hinton. In this algorithm, the historical gradient of each dimension was squared and superimposed. The decay rate was introduced simultaneously to obtain the sum of the historical rise. The learning rate was divided by the result obtained above when the parameters were updated. After using the algorithm, the gradient direction changes in a small range, which speeds up the convergence of the network. The specific calculation formula was shown as follows:

TABLE 2: Size of eight convolution layers.

Name of the layer	Conv 14-1	Conv 14-2	Conv 15	Conv 15-2	Conv 16-1	Conv 16-2	Conv 16-1	Conv 17-2
Layer size	10×10	5×5	5×5	3×3	3×3	2×2	2×2	1×1

	Conv/s1	$1 \times 1 \times 512 \times 1024$	$10 \times 10 \times 512$
Conv13	Conv dw/s1	$3 \times 3 \times 1024dw$	$10 \times 10 \times 1024$
	Conv/s1	$1 \times 1 \times 1024 \times 1024$	$10 \times 10 \times 1024$

$$S_{dR} = \beta S_{dR} + (1 - \beta)(dR)^2, \quad (4)$$

$$R = R - \rho \frac{dR}{\sqrt{S_{dR} + a}}$$

where, β is the rate of decay, S_{dR} is Cumulative gradient variable, ρ is learning rate, a is the constant that is not zero, and R is the parameter.

4.3. Behavioral Database Building Methods. The good classification effect of the deep learning network model should be based on a large number of data, which constitute an image database. At present, there was no database specially used for classroom behavior recognition.

4.3.1. Data Set Acquisition and Enhancement. The data set came from classroom surveillance videos and network pictures. In order to ensure the recognition effect, the video images need to be processed before being used as the data set, from which video segments including raising hands, sitting up, sleeping, and writing were selected. OpenCV was used for frame sampling of the selected video, and the

pictures containing the above five actions were selected for saving. 1000 image data were collected in this experiment, and some graphic data are shown in Figure 4.

The precision of model training needed a large amount of data as support, so data enhancement was used to increase the amount of data, which included flipping the image horizontally, left-right, and randomly, translating the image horizontally and vertically, and randomly changing the color of the image. After data enhancement, the dataset for this paper contains 2500 images.

4.3.2. Data Set Preprocessing. The collected color image would increase the model trained workload, and the image was prone to contain noise due to the influence of the external environment, so the data set needs to be processed by grayscale and denoising methods, and sharpened by the object enhancement method.

(1) Grayscale processing. The mean value of each pixel point was calculated to realize grayscale processing. The calculation formula was as follows. The comparison before and after gray processing used the formula as shown in Figure 5.

FIGURE 4: Comparison of NMS effects on graphic data (hand up, mobile phone, sleep, lecture, writing).

$$R = G = B = \frac{(R + B + G)}{3}, \quad (5)$$

where, R , G , and B are three color channels.

(2) *Bilateral filtering denoising technology*. The bilateral filtering denoising technology was adopted. In an operation similar to Gaussian filtering, each pixel of the image was scanned once, and the weighted sum of the pixel values and corresponding position weights was added on the basis of the operation of obtaining the weighted sum of each pixel value in the field and corresponding position weights. In the calculation, the closer the center was, the greater the weight was, and the closer the pixel value was, the greater the weight was. The specific formula was as follows.

$$G_s = \exp\left(-\frac{\|p - q\|^2}{2\sigma_s^2}\right), \quad (6)$$

$$G_r = \exp\left(-\frac{\|I_p - I_q\|^2}{2\sigma_r^2}\right),$$

where G_s is the spatial distance weight, G_r is the Pixel weight, q is the central store of Window, p is any point, I_q is the input image, and I_p is the filtered image.

$$W_q = \sum_{p \in S} G_s(p) G_r(p)$$

$$= \sum_{p \in S} \exp\left(-\frac{\|p - q\|^2}{2\sigma_s^2}\right) \exp\left(-\frac{\|I_p - I_q\|^2}{2\sigma_r^2}\right), \quad (7)$$

where W_q is the sum of the weights of each pixel value.

Gaussian filtering mainly played the role of image smoothing. In the critical part of the image, there would be obvious color or light and shade transformation, which was reflected at the pixel level, that was, the pixel values on both sides differed greatly, and the difference gradually increased with the distance. In this case, the G_r value was close to 0, and the whole filter result was also 0. The two images that were, respectively, processed by the method used in this paper (left) and Gaussian filtering (right) are shown in Figure 6.

FIGURE 5: Image grayscale noise comparison.

FIGURE 6: Image denoising.

(3) *Objective to enhance*. Unsharpen Mask (USM) was used to enhance the target. The input image was processed with a low-pass filter to obtain the low-pass component, and the difference between the original image and the component was calculated to obtain the high-pass component, and the sharpened image was obtained by superposition the high-pass component on the basis of the original image. The Gaussian fuzzy method was usually used to obtain low-pass components. The calculation formula was as follows.

$$y = \frac{(x - w \times z)}{(1 - w)}, \quad (8)$$

where y is the output image, x is Gaussian Blur, ranging from 0.1 to 0.9, usually 0.6, z is the weight value.

We input each pixel in the image for USM operation and obtain the pixel value after sharpening each pixel, thus forming the whole sharpened image to complete the target enhancement. The classroom behavior imaged after target enhancement is shown in Figure 7.

4.3.3. *Data Set Annotation*. Annotation tool uses the LabelImg image annotation tool. The software processes the image according to the format of the Pascal VOC data set. Before labeling, the preprocessed image needed to be saved in Pascal VOC format. After labeling, some basic information about the image, including storage location, size, and category name, was automatically saved in XML files.

5. Experimental Study on the Improved SSD Algorithm

The traditional SSD algorithm, the unimproved MobileNet-SSD algorithm, and the improved MobileNet-SSD algorithm were compared and analyzed from three aspects of training difficulty, detection accuracy, and detection speed.

5.1. Experimental Environment and Parameter Setting. The 500 images were selected for each action in the test training set and 2500 images were selected for each action in

the test set. During the training, batch size was set to 4, 625 batches were needed for 2500 training sets, and the epoch was set to 100, that was, 62500 iterations in total. Among them, the learning rate of the first 5000 times was 10^{-4} and the learning rate of the latter was 10^{-5} . The test environment is shown in Table 4.

5.2. Model Evaluation Criteria. In this paper, the model was evaluated by single frame image detection time and Mean Average Precision (mAP) of image detection, which was the mean value of all AP values. AP was the area below the curve

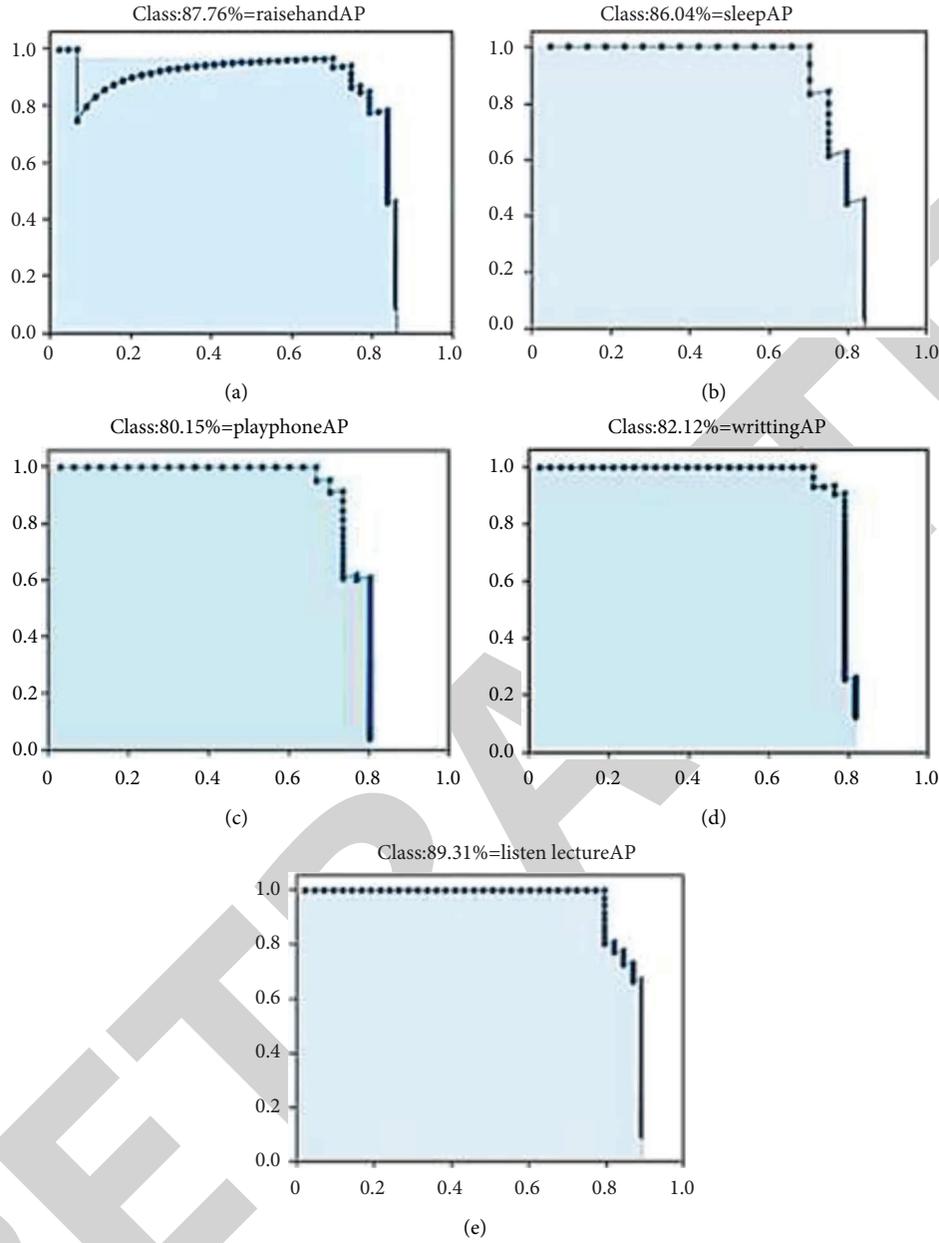

FIGURE 9: Identify accuracy.

composed of precision and recall. The formula for accuracy was as follows:

$$\text{Precision} = \frac{TP}{TP + FP}, \quad (9)$$

where TP is the classifier that divides the target into positive samples and the number of samples that are actually positive samples and FP is the number of samples that the classifier considers positive but is actually negative.

The whole formula represents the proportion of positive samples considered by the classifier to positive samples recognized by the whole classifier, reflecting the model's precision function.

The recall rate formula was as follows:

$$\text{Recall} = \frac{TP}{TP + FN}, \quad (10)$$

where FN is the number of samples that the classifier treats as negative samples but is actually positive samples.

The whole formula represents the proportion of the samples considered positive and confirmed positive by the classifier to all positive classes, reflecting the model's recall function.

5.3. Model Experiment Process

5.3.1. Preparation of Documents Required for the Test. Before model training, the train. txt file was generated by running the code, which was used to store the training set information.

5.3.2. The Model Training. The training started with an image file load call `annotation_path = "train.txt"` to reference the resulting train. Then, we identify the category setting. The test needed to identify five behaviors and backgrounds, a total of six categories, namely, `NUM_CLASSES = 6`. Finally, the network structure was loaded and trained, The model = `r_mSSD300()` method was used to load the improved model and then accorded to the parameter settings for training. Repetitive training can obtain a better model and save as the behavior recognition model in this paper.

5.4. The Analysis of Model Experiment Results. The traditional SSD algorithm, MobileNet-SSD, and mobile net-SSD with feature fusion were trained in the same experimental environment and parameters, and the three algorithms were compared through the test set. The data used in the test were self-made data sets. The average accuracy and detection speed (detection time per frame) of classroom behavior detection obtained by different models are shown in Table 5.

As seen from Table 4, classroom behavior recognition experiment, compared with the traditional SSD algorithm, the feature fusion MobileNet-SSD improved the detection speed by 2 frames per second, and the average detection accuracy reached 83.08%. Compared with a mobile net-SSD model without feature fusion, the speed was reduced by 2.5% and the accuracy was improved by 6.94% due to the increase in network parameters by fusion. The analysis results showed that the detection speed and recognition accuracy of the proposed algorithm was improved obviously.

The difficulty of model training can be judged by comparing the curve of the loss function during training. With the same parameters, the loss function curve of mobile net-SSD and SSD models with feature fusion was taken when the epoch was 100 iterations for 50000 times, as shown in Figure 8. The loss values of both models continued to decrease, proving that both models were reasonable. During the training, it took 6 days for the loss of the model used in this paper to drop below 0.5, while the original SSD model took 8 days. In addition, the loss value of the model in this paper decreased rapidly, so the training difficulty of the model in this paper was less than that of the traditional SSD model.

The mobile Net-SSD model with SSD and feature fusion was used to test the five actions of students in the test set: listening in class, raising hands, writing, sleeping, and playing mobile phones. The detection accuracy (AP) of each action is shown in Table 6.

It can be seen from Table 6 that compared with the original SSD algorithm, the mobile net-SSD algorithm based on feature fusion in this paper had improved the detection effect of small targets in the five actions, among which the writing improvement reached the highest level of 3.03%, indicating that the model in this paper had improved in small target recognition. Observing the mobile net-SSD recognition result of feature fusion, among the five

movements, listening accuracy was the highest, followed by raising hands, and writing and playing on mobile phones were the lowest. Through analysis, the reasons for this result were as follows: compared with other movements, the two activities were more prone to occlusion, especially in the recognition process. It was easy to be confused with other hand movements, so the correction effect was not as good as the other three movements. To more intuitively display the recognition accuracy rate of the model in this paper on the five actions, the line graph is shown in Figure 9, where the shaded area was the accuracy rate.

6. Conclusion

Because of the subjective one-sidedness of traditional legal classes in which students' state was observed artificially, intelligent analysis was introduced into the category, and the deep learning method was proposed to identify students' classroom behavior. The model algorithm was integrated into the system to expand it, and the legal class state analysis system was designed and implemented. The following conclusions were drawn:[28].

- (1) The design process of the class behavior recognition model was analyzed, and the images of listening in class, raising hands, writing, sleeping, and playing with mobile phones were selected as the student behavior database after grayscale, noise reduction, and image enhancement practice improved behavior recognition models.
- (2) Based on the principle of deeply separable convolution, the improved SSD method was used to analyze student states. Changing the original SSD base network from VGG16 to the improved MobileNet network, using add feature fusion method to replace the network, reducing the basic network parameters, and integrating in-depth information into the shallow layer, the detection effect and speed of small targets were improved.
- (3) The improved model was trained and used for student behavior recognition. We identify the population distribution of five behaviors in a class, obtain the population's proportion in the set severe, good, average, poor, and other five states, and complete the analysis test of student status.
- (4) The university class state analysis system based on deep learning helps users intuitively analyze the state information of students in a single or multiple classes which is convenient for understanding the class situation of law students and provides a reference for course adjustment.

With the rapid development of agricultural economy, people are paying more and more attention to how to apply high-efficiency technologies that save resources to improve agricultural production efficiency, so water-saving irrigation technology has gradually developed. China's agricultural irrigation technology is relatively backward. In addition to the inappropriate irrigation methods and irrigation systems, problems such as siltation, seepage, and frost heave damage in irrigation canals have seriously affected the durability and service life of the canals. The backward irrigation technology seriously restricts the development of agricultural water-saving irrigation. Compared with large irrigation channels, the fabricated reinforced concrete small irrigation channels studied in this paper are less prone to frost heave damage and infiltration problems, and have the advantages of standardized production, simple transportation and installation, and convenient maintenance. In order to study the durability issues such as the basic characteristics, frost heave damage, and service life of fabricated irrigation channels, this paper takes the channel concrete and the formed channel as the research objects, and discusses the research on the properties of the channel concrete through theoretical research, numerical analysis, experiments, and other methods. Strength properties, water penetration resistance, cyanide ion penetration resistance and frost resistance; simulate the seasonal frost heave failure process of the channel; finally, on the basis of the test data, the service life aims to explore the safety and applicability of the fabricated reinforced concrete irrigation channel during the design use period.

1. Introduction

With population growth and social development, water shortage has become a prominent problem faced by our country. Coupled with serious water pollution and uneven distribution of water resources, the contradiction between water supply and demand has become prominent and worsened, which has seriously affected people's quality of life and restricted the social progress and economic development. For a large agricultural irrigation country like China, the country's largest water consumption is agricultural water. According to the 2014 China Water Resources Bulletin, China's total water resources are about 2.73 trillion m³, a decrease of 1.6% compared to previous years. Water

consumption accounts for 22.3% of it, of which agricultural water consumption is about 386.9 billion m³, accounting for 2/3 of the total water consumption, and the water used for the development of irrigation has reached 90%~95% of agricultural water consumption. Therefore, the channel Low water delivery efficiency directly affects the benefits of agricultural production in irrigated areas. According to calculation and analysis, the national average irrigation water utilization coefficient is 0.502, which is far lower than 70% to 80% of the irrigation water utilization rate in developed countries. The waste of water resources will also cause the groundwater depth to rise in some areas, leading to soil salinization, reducing the area of arable land required for agriculture and increasing investment costs. Channels are

still the main water delivery facilities in China's irrigation areas. The annual water loss of canal system engineering is about $1730 \times 108 \text{ m}^3$. Channel engineering using antiseepage technology can reduce water loss by 70% to 90%. Water agriculture and alleviating the contradiction between supply and demand of water resources, it is necessary to establish a set of safe and reliable transmission and distribution canal system to improve the effective utilization of agricultural irrigation water. With the wide application of channel antiseepage technology in water-saving irrigation, the area of water-saving irrigation projects in China reached 407 million mu by the end of 2013, of which the channel antiseepage irrigation area accounted for about 27% of the total area. According to the plan of the Ministry of Water Resources, before 2020, the area of irrigation projects in the country should be increased to more than 60% of the effective irrigation area, the efficient irrigation area should be increased to more than 30% of the effective irrigation area and, the effective utilization coefficient of agricultural irrigation water should be raised to more than 0.55. It can be seen that the construction of channel lining and antiseepage projects directly affects agricultural production and plays a vital role in improving agricultural water use efficiency and the development of water-saving agriculture [1–7].

Through statistical research, there are relatively serious frost heave damage problems in canal buildings in many irrigation areas across the country. According to the frost heave disaster investigation of canal engineering, water transmission channels without antifreeze heave measures generally have frost damage problems, and frost heave produces many cracks. Under the action of water flow, the canal base stop will gradually get swept away, and then slumps will occur, causing channel damage and affecting the normal use of the channel. Therefore, the prevention of frost heave damage in the irrigation channel is also one of the key research issues of channel antiseepage technology. The small prefabricated buildings of the irrigation canal system have many advantages and are also widely used in farmland water conservancy and land improvement projects. However, there is a lack of systematic theoretical and experimental research on the durability performance of small prefabricated buildings in irrigation canal systems. This paper intends to simulate the durability of small prefabricated buildings in irrigation canal systems through laboratory tests, theoretical analysis, and numerical simulation.

2. Related Work

In the study of the most complex structural buildings in hydraulic engineering, the many advantages of prefabricated buildings have been favored by designers. In 1932, the structure of the powerhouse and the lock equipment of the Swell Hydropower Station used prefabricated concrete structures. The Sydney built in 1985. The Mo Hydropower Station became the largest prefabricated hydropower station in the world at that time. The research and application of prefabricated water conservancy projects was carried out. In 1955, in order to improve the engineering quality of power

plants, speed up the construction progress, and reduce the labor force, the Soviet Union proposed the industrialization of construction, the development of prefabricated infrastructure, and the maximum mechanization of manufacturing and installation. In the 1970s, the United States became popular with prefabricated products, and successively issued a series of strict standards of industry behavior, which have been used to this day. Ballar and Harper optimized the installation scheme of prefabricated walls, columns, beams, and slabs using genetic algorithms from the perspectives of efficiency and construction technology. And its research results show that in the case of reasonable design and organizational design, the prefabricated technology is superior to the traditional construction method in terms of technology and efficiency. The connection method of prefabricated buildings is the technical difficulty of prefabricated building technology, and it is also the key point in the development process of prefabricated buildings. A reasonable connection method not only improves the quality of prefabricated buildings, but also facilitates construction and reduces prefabrication time. Piltant expounds the prefabrication principle and method of using bolts to connect statically indeterminate prestressed members. It is also pointed out that due to the statically indeterminate characteristics of concrete structures, their manufacture is standardized, the assembly work is reduced to a minimum, and its standardization can greatly reduce the weight of concrete structures. The craftsmanship of prefabricated buildings is different from that of traditional buildings, and the proportion of concrete materials used will also change accordingly. Optimal design requires continuous development to obtain an ideal mix of precast concrete with high early strength, good workability, and economical utility. Jinglin chooses low alkalinity sulfate cement to mix with ordinary Portland cement and adds polycarboxylate superplasticizer and sodium sulfate. The ideal prefabricated concrete mix ratio with higher early strength was selected through orthogonal tests. The research on prefabricated buildings for water conservancy projects in my country began in the 1950s and 1960s. In 1955, at the National Water Conservancy Construction Conference held by the Ministry of Water Resources, Heilongjiang Province introduced the construction experience of prefabricated aqueducts. Since then, this advanced design and construction method has begun to attract attention from all over the world. In 1956, 80% of the hydraulic structures in Zhanjiang were prefabricated, and more than 40,000 structures were built successively, with more than 20 types of structures. In the initial stage of promotion, it was mainly in the form of "building blocks," and light-weight structures were gradually applied, and then steel mesh cement and prestressed concrete components were used. The prefabricated building mold developed by Gaoyou City has gone through the development process from wood mold to steel-wood combination to mechanized assembly line production. At present, three series of irrigation, drainage, and transportation have been formed, with 10 varieties and 38 models, which can be used for clay and sandy areas in hilly, polder,

and plain areas. This achievement has passed the ministerial-level appraisal in November 1992. With the development of information technology, the combination of prefabricated building components and digital technology is the research direction of more and more researchers. The organization and management of information technology can add icing on the cake to the development of prefabricated buildings and promote the development of prefabricated buildings in the direction of modernization. Among them, Mei Yue finds the way of thinking of digital architecture and its corresponding assembly construction and general construction process method and applies it to small design practice activities. With the country's increasing investment in water conservancy project construction year by year, prefabricated slab bridges are also widely used in various water conservancy projects, but as the connection method of prefabricated slab bridges, hinge joints are one of the most prone to disease. [8–14].

3. Durability Parameter Test of Small Prefabricated Buildings in Irrigation Canal System

The object of this test study, the prefabricated concrete U-shaped channel, is mainly used as a water conveyance and diversion channel. In practical engineering applications, the main technical indicators are strength, antiseepage, anti-freeze, antichloride ion penetration, and so on. In order to more clearly understand the durability of prefabricated concrete U-channel, it is necessary to test the above indicators of concrete. In this research, by designing different concrete compounding, the concrete test specimens were prepared in the laboratory. The strength characteristics, impermeability, frost resistance, chloride ion permeability resistance of concrete, etc., select the concrete mix ratio suitable for different conditions to meet the working conditions of the corresponding project. The durability can provide the necessary quantitative parameters. In this concrete durability test, the concrete design strength of the fabricated U-shaped channel is C 30, and the design slump is 160–180 mm, which is fluid concrete.

3.1. Test Raw Materials. All know, the quality of the raw materials used for mixing concrete may lead to great differences in the performance of concrete. Therefore, the selection of concrete raw materials is crucial to the durability of concrete in the concrete-reduction test. The raw materials required for this experimental study are as follows: cement, coarse and fine aggregates, tap water, mineral powder, fly ash, mineral powder, and water-reducing agent [15].

3.1.1. Cement. In engineering production, cement is an extremely important building material and engineering material, and together with steel and wood, it is called the three major materials of capital construction. This test uses P0.42.5 cement, the chemical composition of cement is shown in Table 1, and its main mechanical properties are shown in Table 2. The properties of various materials are

TABLE 1: Chemical composition of cement.

Chemical cost of cement (%)

22.03	8.52	3.76	6 1.37	2.23	2.01

introduced below. Selecting reasonable materials in engineering construction is the key to engineering quality [16].

3.1.2. Coarse Aggregates. The aggregate in concrete accounts for about 3/4 of its total volume. Rock particles with a particle size of less than 5.00 mm are called fine aggregates, while those larger than 5.00 mm are called coarse aggregates. Commonly used coarse aggregates include pebbles and gravel. This concrete test uses 5–25 crushed stone on the market. After indoor measurement, the physical index of coarse aggregate is shown in Table 3 and its gradation is shown in Table 4.

3.1.3. Fine Aggregate. Divided into natural sand and artificial sand according to their different production processes and methods. Natural sand can be divided into river sand, sea sand, and mountain sand according to their different sources. Artificial sand can be divided into coarse sand, medium sand, fine sand, and extrafine sand according to the size of the fineness modulus. This test uses medium and fine sand in the building materials market. The fineness modulus of the sand is $Mx=2.6$, the physical index is shown in Table 5, and the sand particle gradation is shown in Table 6.

3.1.4. Fly Ash. Fly ash is a pozzolanic material with a certain activity. When fly ash is probed into concrete, it can improve the workability of concrete, reduce water consumption, reduce water-cement ratio, and increase the strength of concrete. In this test, the fly ash used is F-class TI grade fly ash with a fineness of 11% and a water demand ratio of 97%.

3.1.5. Mineral Powder. Mineral powder is a concrete admixture obtained by grinding granulated blast furnace slag. It is a powder material that reaches the specified activity index after drying and grinding of granulated blast furnace slag. When grinding slag, a small amount of grinding aid is allowed. The input should be below 144. Mineral powder has potential hydraulic properties, and the main mechanism of action in cement concrete is the cementation effect and the microaggregate effect. The mineral powder that has been separately ground has a surface roughness smaller than that of cement particles, so it also has a certain morphological effect, which can reduce water and increase the fluidity of concrete. In this test, S95 grade granulated blast furnace slag powder was selected, and its surface area was 428 F/kg. The main chemical components are shown in Table 7 [17].

3.1.6. Water Reducer. Adding water reducer to concrete can change the rheological properties of cement paste, thereby changing the internal structure of concrete, thereby

improving other properties such as concrete mechanics. In this concrete test, polycarboxylate water-reducing agent was selected as the water-reducing agent.

3.2. Test Mix Ratio. When mixing concrete in engineering construction, the durability of concrete will be completely different when different proportions of materials are adopted. Therefore, in order to obtain concrete that meets the requirements of design quality, it is necessary to calculate the proportion of various materials in the concrete, and through experimental comparison, the concrete mix ratio that meets the durability requirements under the corresponding construction conditions and operating environment is obtained.

In order to study the strength characteristics and durability of the concrete of the prefabricated irrigation canal under different working conditions, three kinds of concrete mix ratios are listed in this experimental study, including the original mix ratio (the mix ratio adopted by the manufacturer) (I), the Add fly ash (II) on the original basis, and then

add water-reducing agent (III). The purpose of designing three different concretes is to compare various performance parameters of concrete with different mix ratios, study the applicable environment of concrete with various mix ratios, and meet the safe and applicable durability performance of the channel. See Table 8 for the description of the proportions of three different concretes. [18].

In calculating fly ash in the mixing ratio of (mineral powder) concrete, fly ash (mineral powder) is usually added in two different ways, namely, the method of replacing cement with an equal amount and the method of replacing cement with an excess amount [19].

(1) Equal replacement of cement method, refers to the replacement of cement by the probing fly ash (mineral powder) in equal amount, which can reduce the calorific value of concrete, and can significantly improve the workability and impermeability of concrete, and is often used in mass concrete. The sand replacement method keeps the amount of cement in the concrete unchanged, and hangs fly ash (mineral powder) to reduce the fine aggregate. This kind of concrete has excellent cohesion, water retention

TABLE 8: Test concrete mix description.

Group	Describe	Water-cement ratio	Sand rate
I	Original mix	0.50	0.41
II	Add fly ash	0.45	0.41
III	Add fly ash, water reducer	0.45	0.41

workability, and impermeability. (2) Oversubstituting cement method, that is, based on the reference concrete mix ratio, according to the principle of equal strength, using the oversubstituting method to adjust the proportion of cement. When calculating the mix ratio in this concrete test study, according to the actual situation of the project, it is planned to use the excess substitution method to design the concrete mix ratio. The use of the excess substitution method to design the mix ratio can determine an economical concrete mix ratio. The design method is completed through testing and trial matching.

3.3. Fabrication and Maintenance of Concrete Specimens. This concrete test plans to complete the concrete strength (tensile, compressive) test, penetration test, freeze-thaw test, and chloride ion resistance penetration test. After statistics, the test pieces to be produced for each group of mix ratios are shown in Table 9. In order to prevent the loss of specimens during the test, there should be excess concrete specimens in each group of mix ratios.

According to the “Standard,” the concrete specimens that are formed and demolded should be sent to a standard curing room with a temperature of $20 \pm 2^\circ\text{C}$ and a relative humidity of more than 95% in time for curing. And the concrete sample should not be washed with water directly. The standard curing age is 28 d, and the test specimens for 7-day compressive strength test shall be taken out for testing at 7 d, and other specimens shall be treated at the corresponding time according to the specifications.

3.4. Experimental Study on the Properties of Concrete Mixtures. The concrete mixture is made by mixing the constituent materials in a certain proportion, and its workability is the most important property of fresh concrete. The workability of the mixture refers to the performance of the mixture that can meet the requirements of the concrete construction process (mixing, transportation, pouring, and vibrating) under the premise of no segregation and bleeding.

The workability of concrete mixture includes fluidity, cohesion, and water retention. Because of its complex connotation, “slump” is used to measure the fluidity, cohesion, and water retention of concrete mixture, so as to evaluate concrete workability of the mixture. During the process of obtaining the mixture in this test, the slump of the mixture was measured, and the statistics are shown in Table 10 [20–22].

4. Durability Analysis and Prediction of Small Prefabricated Buildings in Irrigation Canal System

For any building structure, when designing and constructing, the designer will consider the probability that the building will be used in the expected life time in the future, which is an important basis for judging the “cost-effectiveness” of the building structure. The basic purpose of hydraulic structure design is to make the structure meet various functional requirements predetermined by the design within the predetermined service period, so as to be safe, reliable, economical, and reasonable. The functional requirements of general engineering structures mainly include three aspects.

Safety, serviceability, and durability are commonly referred to as structural reliability. In the design process, in order to obtain the structural reliability that meets the requirements, it is necessary to properly handle the relationship between the two opposites in the structure. On the one hand, the load effect caused by the action (load) applied to the structure, time external force on the structure (such as self-weight, live load, wind load, and water pressure), and other loads (such as humidity deformation, foundation settlement, and earthquake action) cause deformation of the structure. The structural resistance (R) composed of the section size, the number of reinforcements, and the strength of the material is mainly related to the degree of agreement between the structural size of the structural member, the number of reinforcements, the material properties, and the calculation mode of the resistance to the actual situation.

The above load effects and structural resistance R are functions of random variables, so the design of building components is mainly to study the structural resistance R used when these two random functions satisfy a certain probability.

4.1. Structural Limit States and Failure Probability. Reinforced concrete structures are widely used in engineering. In the process of design and construction, with the accumulation of experience, the design theory also develops continuously. The process can be divided into three stages: the design method according to the allowable stress, the design method according to the failure stage. The lifetime and prediction in this paper are based on the limit state design concept.

In the engineering field, the limit state of a building structure is generally divided into “bearing capacity limit state” and “normal service limit state” value, mainly considering the applicability and durability of the structural reliability, while the ultimate bearing capacity state refers to the structure or component reaching the maximum bearing capacity or reaching the deformation that is not suitable for continuous bearing. The main consideration is the safety of the structure. The limit state of the structure can be represented by the limit state function Z . In general, many

TABLE 10: Measured slump of mixtures.

Group	I		II		III	
	Measurements	Average value	Measurements	Average value	Measurements	Average value
Slump (mm)	175.0	168.3	165.0	168.7	175.0	169
	168.0		172.0		164.0	
	162.0		169.0		168.0	

factors that affect the limit state are represented by two variables: load effect and structural resistance R , then,

$$\begin{aligned} Z &= g(R, S) \\ &= RS \end{aligned} \quad (1)$$

Obvious from the above equation that, when $Z > 0$ (i.e., $R > S$), the structure is safe and reliable; when $Z < 0$ (i.e., $R < S$), the structure fails; and when $Z = 0$ (i.e., $R = S$), it means that the structure is positive in the limit state, so when $Z = 0$ is called the limit state equation of the structure. Since, both R and S are random variables, function B is a random function whose value is not a fixed value and should be described by means of probability theory. In probability theory, failure probability P is generally used to represent the reliability of the structure.

Assuming that $F(Z)$ is the probability density distribution function of the functional function Z , then when $Z < 0$, the formula (2) of the failure probability represents the area of the shaded part of the probability distribution curve in Figure 1.

$$\begin{aligned} p_f &= P(Z < 0) \\ &= \int_{-\infty}^0 f(Z) dz \end{aligned} \quad (2)$$

If it is assumed that the two random variables, the structural resistance R and the load effect S , obey the normal distribution, and their mean and standard deviation are μ_R, μ_S, σ_R , and σ_S , respectively, it can be known from probability theory that the functional function B obeys a positive distribution, with the mean and standard deviation of Z being μ_z and σ_z , respectively. Then, the probability density function of the Z normal distribution is as follows:

$$f(z) = \frac{1}{\sqrt{2\pi}\sigma_z} \exp \left[-\frac{(z - \mu_z)^2}{2\sigma_z^2} \right]. \quad (3)$$

Putting equation (3) into equation (2), we can get the following equation:

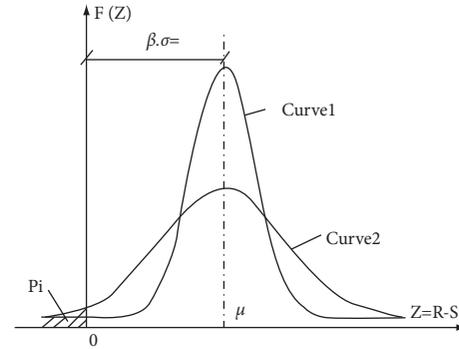

FIGURE 1: The probability density distribution curve of Z , β , and p_f relationship.

$$p_f = \int_{-\infty}^0 \frac{1}{\sqrt{2\pi}\sigma_z} \exp \left[-\frac{(z - \mu_z)^2}{2\sigma_z^2} \right] dz. \quad (4)$$

In the actual engineering design, it is more complicated to use formula (4) to calculate the failure probability P , so the reliability index is generally used to measure the reliability of the structure.

When the building structure resistance R and load effect S obey the overall distribution, the corresponding relationship between the failure probability p_f and the reliability index β is listed in Table 11. In the design process, when the structural reliability index is determined, the structural failure probability can be obtained, and then the limit state method is adopted to design the structure.

In the design of concrete structures, the probabilistic limit state design concept is mainly used for structural design, so the basic theory adopted in the life prediction of fabricated reinforced concrete irrigation canals is the limit state design theory. The following is the prediction of the service life of the prefabricated irrigation canal under the carbonization condition and the chloride ion environment based on the probability reliability theory, and a certain reference is given for the durability evaluation of the canal concrete.

4.5	3.40×10^{-6}

4.2. *Life Prediction of Fabricated Irrigation Channels under Carbonation Conditions.* The life of the fabricated reinforced concrete irrigation channel under carbonation mainly includes two stages: (1) the time from the concrete surface to penetrate the steel surface; (2) the steel bar begins to corrode until the structural failure occurs. For the corrosion of steel bars, the participation of water and chloride ions is required, so the life prediction part is placed in the later stage of chloride ion steel corrosion. This section only analyzes the time required for the carbonization of the concrete cover.

For the prediction of the concrete carbonation life of the fabricated reinforced concrete irrigation channel, we should first measure the thickness of the steel protective layer, and obtain the average value, mean square error and variation coefficient of the concrete protective layer thickness.

According to the empirical formula, the carbonization rate coefficient of the channel concrete is obtained, the mean square error and variation coefficient of the concrete carbonization coefficient are obtained, and the carbonization life of the concrete is obtained according to formula (4). After measuring the thickness of the protective layer of the irrigation channel in the manufacturing factory, the sample data obtained are shown in Table 12.

According to the knowledge of statistical theory, the average thickness of concrete protective layer can be obtained as μ_c ,

$$\mu_c = \frac{1}{N} \sum_{i=1}^N x_c = \frac{1}{40} \sum_{i=1}^{40} x_c = 24.9 \text{mm} . \quad (5)$$

Its mean square error σ_c is,

$$\begin{aligned} \sigma_c &= \sqrt{\frac{1}{N} \sum_{i=1}^N (x_c - \mu_c)^2} \\ &= \sqrt{\frac{1}{40} \sum_{i=1}^{40} (x_c - \mu_c)^2} \\ &= 3.12 \text{mm} \end{aligned} \quad (6)$$

According to the above equation, the carbonization coefficient (in years) is calculated by formula (5), as follows:

$$K = \gamma_1 \gamma_2 \gamma_3 \left(12.1 \frac{W}{C} - 3.2 \right). \quad (7)$$

In formula 5: the main reference values are γ_1 , γ_2 , and γ_3 .

For the concrete of the prefabricated irrigation channel of the research object, in formula (7), since slag cement is used, the γ_1 value is 1.0; the content of fly ash is 14%, the γ_2 value is 1.1; the channel is mainly used in the northern region, and γ_3 the value is 1.1. Value 1.1: Calculated according to the mix ratio, the water-cement ratio is 0.45, and the above parameter values are taken with AR.

$$K = 1.0 \times 1.1 \times 1.1 \times (12.1 \times 0.45 - 3.2) = 2.72. \quad (8)$$

According to the research, the K value obeys the normal distribution. According to the experience, the mean value μ_k is taken as 2.58 and the standard deviation σ_k is obtained according to the error function. In this study, the value is 0.65.

Substituting $\mu_c = 24.9$ mm, $\sigma_c = 3.12$ mm, $\mu_k = 2.58$, and $\sigma_k = 0.65$ into formula (7), and then according to the corresponding values of failure probability P_f and reliability in Table 11, it can be obtained carbonation life of fabricated reinforced concrete irrigation channels. According to the calculation, when the failure probability P is 2.28×10^{-2} , its reliability β is 2.0, and the life period $t = 394.4$ years is obtained. The probability of layer carbonization is $P_f = 2.28 \times 10^{-2}$.

After calculation, it is obtained that the service life of the prefabricated reinforced concrete irrigation canal under the carbonation condition is very long. But only under ideal carbonization conditions, there are not many factors considered in the analysis of the carbonization rate coefficient, so this does not represent the service life of the actual channel. The corrosion time of steel bars is solved in the next section.

4.3. *Prediction of Channel Life under Chloride Erosion.* To analyze the life of concrete in the chloride ion environment, that is to analyze the time T_1 , T_2 , and T_3 of the three stages of steel corrosion, and finally unify the three times, that is, the concrete is caused by chloride ions. The time of destruction is analyzed from three aspects.

4.3.1. T_1 . The time T_1 is the time for chloride ions to reach the steel bar from the concrete surface. It can be considered here that in the original concrete, the nitrogen ions on the steel bar surface are very small, which is not enough to cause the steel bar to corrode. The time T_1 is when the concrete is exposed to the chloride ion environment until the surface of the steel bar begins to accumulate chloride ions.

This time, the approximate probability design method is mainly used to analyze the time T_1 . Considering the partial coefficients in the analysis, the endurance limit state equation of the concrete structure corroded by chloride ions can be expressed as follows:

TABLE 12: The measured value of the thickness of the protective layer of the irrigation channel (mm).

22.8	27.4	22.6	22.3	31.8	21.5	28.1	22.6	20.6	23.1
22.6	26.0	26.0	27.7	26.3	27.8	21.3	25.7	22.5	24.3
22.6	25.6	23.9	21.6	22.5	22.4	23.3	25.1	27.4	22.7
35.8	23.2	27.3	23.2	30.4	25.2	23.1	26.4	28.6	23.7

TABLE 13: Parameter value table.

Parameter category	k	h_0	θ	λ
Value	12.5 a/mm	0.15 mm	0.01 mm	6.0

$$\begin{aligned}
 g &= c_{cr}^d - c^d(x, t) \\
 &= c_{cr}^d - c_{s,cl}^d \left[1 - \operatorname{erf} \left(\frac{x^d}{\sqrt{{}^2 D_{cl}^d(t_{SL}) \cdot t_{SL}}} \right) \right] \\
 &= 0,
 \end{aligned} \quad (9)$$

where c_{cr}^d is the design value of critical chloride ion concentration for steel corrosion, $c_{s,cl}^d$ is the set value of chloride ion concentration on the concrete surface, x^d is the statistical value of the thickness of concrete protective layer survey, $D_{cl}^d(t_{SL})$ is the test value of nitrogen ion diffusion coefficient of concrete, and t_{SL} is the exposure time of concrete elements.

It can be seen from the above formula that the life estimation model that determines the resistance of concrete to chloride ion damage mainly depends on four parameters: the thickness of the concrete protective layer, the chloride ion concentration on the concrete surface, the critical chloride ion concentration, and the nitrogen ion diffusion coefficient. Given these four parameters, the service life and durability design diagram of the channel concrete can be estimated. This paper only needs to predict the service life, and it can be solved directly by the endurance limit state equation. DuraCrete gives the endurance limit state equation for calculating the durable service life of concrete structures.

$$\begin{aligned}
 g &= c_{cr}^d - c^d(x, t) \\
 &= c_{cr}^d - c_{s,cl}^d \left[1 - \operatorname{erf} \left(\frac{x^d}{\sqrt{{}^2 t / R_{cl}^d(t)}} \right) \right], \\
 &= 0
 \end{aligned} \quad (10)$$

When predicting the service life of concrete, considering that the repair cost is lower than the cost required to reduce the risk, the time B when the steel bar begins to corrode can be passed. The following expression can be obtained:

$$t_i^d = \left[\left(\frac{2}{x^c - \Delta x} \cdot \operatorname{ref}^{-1} \left(1 - \frac{c_{cr}^c}{\gamma_{c,d} \cdot A_{C,cl}^c} \right) \right)^{-2} \frac{R_{0,cl}^c}{K_{c,cl}^c \cdot K_{c,cl}^c \cdot t_0^{n_{cl}^c} \cdot \gamma_{R,d}} \right]^{1/1-n_{cl}^c} \quad (11)$$

Small prefabricated building irrigation canal system, which is the research object of this paper, is similar to the external channel environment, the example in DuraCrete is referred to when determining the parameters and partial coefficients.

The model analyzed in this section is a fabricated concrete irrigation channel. The average thickness of the protective layer is $x^c = 24.9$ mm, its safety margin is $\Delta x = 5$ mm, and its antichloride ion permeability coefficient is $D_{RCM,0} = 9.41 \times 10^{-12}$ m²/s (using the value of the third group mix ratio), correspondingly $R_{0,cl}^c = 3.3698 \times 10^{-3}$ year/mm², the environmental parameter is 0.92, and the curing condition parameter value is 0.79, the test period is 28 days, the attenuation coefficient is 0.37, and the corresponding subitem coefficient is 3.25. Substitute the above values into equation (9) we get the following equation:

$$\begin{aligned}
 t_i^d &= \left[\left(\frac{2}{x^c - \Delta x} \cdot \operatorname{ref}^{-1} \left(1 - \frac{c_{cr}^c}{\gamma_{c,d} \cdot A_{C,cl}^c} \right) \right)^{-2} \frac{R_{0,cl}^c}{K_{c,cl}^c \cdot K_{c,cl}^c \cdot t_0^{n_{cl}^c} \cdot \gamma_{R,d}} \right]^{1/1-n_{cl}^c} \\
 &= \left[\left(\frac{2}{25 - 5} \cdot \operatorname{ref}^{-1} \left(1 - \frac{0.8}{1.2 \cdot 7.76 \times 0.45 \times 1.2} \right) \right)^{-2} \frac{3.3698 \times 10^{-3}}{0.92 \times 0.79 \times 0.0767^{0.37} \times 3.27} \right]^{1/1-0.37}
 \end{aligned} \quad (12)$$

Solution: $T_1 = 6.9$ years.

4.3.2. T_2 . In actual engineering, the natural environment in which the concrete building structure is located is quite complex. In the process of research and analysis, it is difficult to determine the depassivation time of concrete. Usually, we think this time period is a random variable. Many research results show that when the concrete structure is in an environment with a relatively stable chloride ion source, the depassivation time of the steel bars in the concrete is shorter because the speed of cyanide ions intrusion into the concrete is much faster than the carbonization speed. In the corrosion life, the depassivation time is often considered to be zero, that is, the steel bar is always in an activated state.

4.3.3. T_3 . Time B is the development stage of steel bar corrosion, and the steel bar begins to undergo pitting corrosion, which then develops into pit corrosion, and finally produces rust, causing rust expansion and cracking. The corrosion pit at this stage reaches a certain depth, which is usually called the critical depth. In the limit state design method based on probability theory, we regard the depth of the steel corrosion pit reaching a critical depth as the limit state of the durability life of the reinforced concrete. After research, it is considered that the pit corrosion depth on the steel bar obeys the Poisson distribution, and the time length of the steel corrosion development stage based on the failure probability is proposed, and the expression is as follows:

$$T_3 = k\theta \ln \left\{ \frac{\ln [1 - F_T(t)] (1 - \exp (h_0/\theta))}{\lambda} + 1 \right\}. \quad (13)$$

In the above formula, k is proportionality constant, also known as reinforcement corrosion rate, h_0 is the depth of the pit at the limit state, θ is the average depth of the initial pits, and λ is Poisson flow strength in a Poisson distribution.

For steel bars in fabricated concrete irrigation, by comparing the statistical analysis data of steel bar corrosion in other chloride ion environments, the parameters in formula (13) can be determined as shown in Table 13.

Substitute the parameters in the table into formula (9), and taking the failure probability as 5%, we get the following equation:

$$\begin{aligned} T_3 &= k\theta \ln \left\{ \frac{\ln [1 - F_T(t)] (1 - \exp (h_0/\theta))}{\lambda} + 1 \right\} \\ &= 12.5 \times 0.01 \times \ln \left\{ \frac{\ln [1 - 5\%] (1 - \exp (0.15/0.01))}{6.0} + 1 \right\} \end{aligned} \quad (14)$$

It can be seen by calculation: $T_3 = 12.8$ years, which means that the probability of corrosion damage to the steel bars of the prefabricated irrigation canal concrete after being exposed to the nitrogen ion environment for 12.8 years is 5%.

To sum up, the time required for the corrosion damage of the steel reinforcement of the fabricated concrete

irrigation channel in the chloride ion environment is $T_1 + T_2 + T_3 = 6.9 + 0 + 12.8 = 19.7$ years. The service life in the chloride ion environment is 20 years, which meets the life cycle of the general channel.

5. Conclusion

Water-saving irrigation technology refers to the general term for irrigation methods, measures, and systems that significantly save water than traditional irrigation technologies. There is a lack of systematic research on the strength, penetration, freeze-thaw, and other durability of fabricated reinforced concrete irrigation channels. Some durability problems arising from the production and operation of fabricated irrigation channels are analyzed for research.

This study firstly introduced the carbonization mechanism, carbonization rate, and influencing factors of the concrete protective layer, gave the concrete soil carbonization model and life criterion, and predicted the life of concrete under carbonation conditions according to the probability limit state method. Then, the corrosion mechanism of reinforced concrete in nitrogen ion environment and the model and random model of chloride ion intrusion into concrete are introduced, the life criterion of concrete in chloride ion environment is given, and the use of concrete in chloride ion environment according to the probability limit state method is analyzed.

By comparing and analyzing the carbonization life of concrete and the service life in the chloride ion environment, we get that the concrete life in the chloride ion environment is much smaller than the carbonization life. Of course, in the actual engineering structure environment, it is not possible to only carbonize the concrete, but there is often the corrosion of the steel bar by nitrogen ions and the electrochemical reaction. Therefore, in the follow-up research, the service life and durability evaluation of channel concrete should be predicted in the case of concrete carbonation and other coupling conditions.

Based on the design structure matrix, the changing dependency analysis method is used to study the law of change propagation between parts in the process of product change, in view of the complexity of the product structure and the strong correlation between parts. First, the product components are divided into different modules according to different requirements, and a design structure matrix with weights is established according to the change dependencies between the components within the modules; then, a part changes propagation network is established to analyze the change dependency degree between parts and the influence of the part propagation mode on change propagation and to analyze the possible change propagation impact of part changes. The feasibility and rationality of the method are verified using the frame module as an example. The experimental results show that the method is effective in predicting the changing risk of a part and analyzing the change propagation impact arising from a part change.

1. Introduction

In the context of economic and trade globalization, manufacturing companies face the challenge of changing market rules, the emergence of relevant new technologies, and the rise of individual customer needs. In order to maintain their competitiveness in the market and to meet the diverse needs of their products, companies inevitably have to make engineering changes to their products. In the engineering change process, module change propagation means that: a change in one component causes a change in other components within the same module, which may also have a change impact on other modules and thus on the whole product [1]. The study of change propagation is a major element in engineering change, and the direction of change propagation affects the outcome of engineering change.

When changes are made to modules, further research is required into the impact of module change propagation, where the prediction of module change outcomes is central to change propagation. In terms of the risk of change

communication, Eckert et al. [2] studied the basic causes of product changes and the risks arising from the changes, providing an in-depth analysis of the problems arising from the product change process. Loch et al. [3] used five strategies to reduce the processing time of engineering change orders: capacity flexibility, load balancing, combining tasks, sharing resources, and batch size reduction, with special attention to the impact of engineering changes; Rui et al. [4] predicted the impact of change propagation by clustering and grading parts through a graph-theoretic approach based on a design structure matrix, specifically analyzing the characteristics of three types of change propagation: water-wave propagation, bloom propagation, and avalanche propagation; Xiang et al. [5] constructed a risk analysis model for engineering changes in complex products from two perspectives: direct and indirect impacts between Hub nodes in a complex product design network. Yupeng et al. [6] applied complex network theory to model the structure of complex products by considering three factors, namely, function, structure, and change risk, in the modular division of complex products and established a

network model of complex product parts with parts as nodes and the association relationship of parts as edges. Liang et al. [7] analyzed the propagation of engineering changes in complex products by combining the design structure matrix, defined the risk of engineering changes in two dimensions of direct and indirect influence, and constructed a risk analysis model of propagation of engineering changes in complex products of the perspective of comprehensive risk. Fan et al. [8] studied change propagation from the aspect of feature association, classified the types of feature association units in product design, and analyzed the change propagation characteristics, change propagation mode, and change propagation process of association units; Zhongwei et al. [9] analyzed the causes and characteristics of avalanche propagation with respect to the constraint conflicts and the number of affected parts and predicted the avalanche propagation by using the directed graph method and knowledge related to complex networks.

In the context of changing communication research methods, Cohen et al. [10] proposed a C-FAR method to evaluate and predict the results of engineering changes, modeling the product information about the EXPRESS language, demonstrating the propagation process of engineering changes, and qualitatively evaluating the results of engineering changes. Congdon et al. [11] applied multiple network theory about complex product modeling to analyze the influence mechanism of different association relationships of the propagation of engineering changes, in view of the fact that the joint effect of multiple association relationships between parts and components was not considered comprehensively in the traditional complex product engineering change propagation impact assessment process. Yongze et al. [12] developed software for engineering change analysis based on the directed graph method of engineering change propagation analysis, which can analyze the propagation, coordination, absorption, and control of part changes in engineering changes and can improve the accuracy and efficiency of engineering change analysis and evaluation. Qin et al. [13] tracked and collaboratively sensed change propagation and predicted the impact range of change propagation through engineering change management. Mengze et al. [14] established a complex product part network model by taking the part connection relationship as the edge and defining the change propagation intensity as the edge weight while considering the change propagation intensity. Xianfu et al. [15] represented the association relationship between product parts based on the design structure matrix, analyzed the association propagation path of master parts, calculated the module association dependency, and determined the priority order of modules. According to the change propagation characteristics of components, Jianfen et al. [16] constructed a multi-objective optimization model and used a nondominated ranking genetic algorithm to solve the model and obtain the Pareto optimal solution set, which can provide an important basis for designers to select the optimal design change solution. All of the above are studies of change propagation for components or basic elements of a product, whereas in

practice, there are numerous components in a product, and it would be a large and difficult task to conduct a change study for each component.

On the basis of the above research, this paper establishes a change propagation model within a complex product module by dividing the complex product into modules and dividing it into a number of basic module units, taking the module as the basic elements of change propagation research, as shown in Figure 1, to research the change propagation impact of the module. Firstly, we analyze the change propagation impact on parts and components within the module where the changed parts are located and find out the change impact produced by the changes of the parts in the module.

1.1. Type of Propagation of Component Changes within a Module. There is a strong correlation between the components in any given module. The parts are related to each other in a network, which is complex and uncertain. In the network, when a change occurs to a component, the change will propagate along different paths according to the relationship between the components and will have a change propagation effect on the associated components. How to determine the scope of change that the change may cause is key. Change propagation between components and parts can be divided into six forms: direct propagation, bi-directional propagation, indirect propagation, circular propagation, diffusion propagation, and clustering propagation.

- (1) Direct propagation: the effect of a change in part A is propagated in one direction to part B causing a change in part B. This change propagation relationship can be observed directly.
- (2) Two-way propagation: the effect of a change in part A is propagated to part B, and the change in part B in turn affects part A. The two affect each other.
- (3) Indirect propagation: The effect of a change to part A is propagated to part B and then indirectly to part C. There is no direct link between part A and part C and this change propagation is not easily observed directly.
- (4) Circular propagation: The influence of changes in part A is propagated to part B and then indirectly to part C. Changes in part C in turn acts on part A, causing the part itself to change repeatedly and iteratively, but this does not mean that the cycle is dead, and can be stopped by the coordination of changes in part or the absorption of changes by parts.
- (5) Diffusion propagation: The effect of a change to part A is simultaneously propagated to parts B and C at the next A level, and change propagation occurs. During the change propagation process, diffusion increases the number of parts involved in and affected by the change propagation, which may eventually lead to an avalanche of propagation, making the change propagation impact uncontrollable.

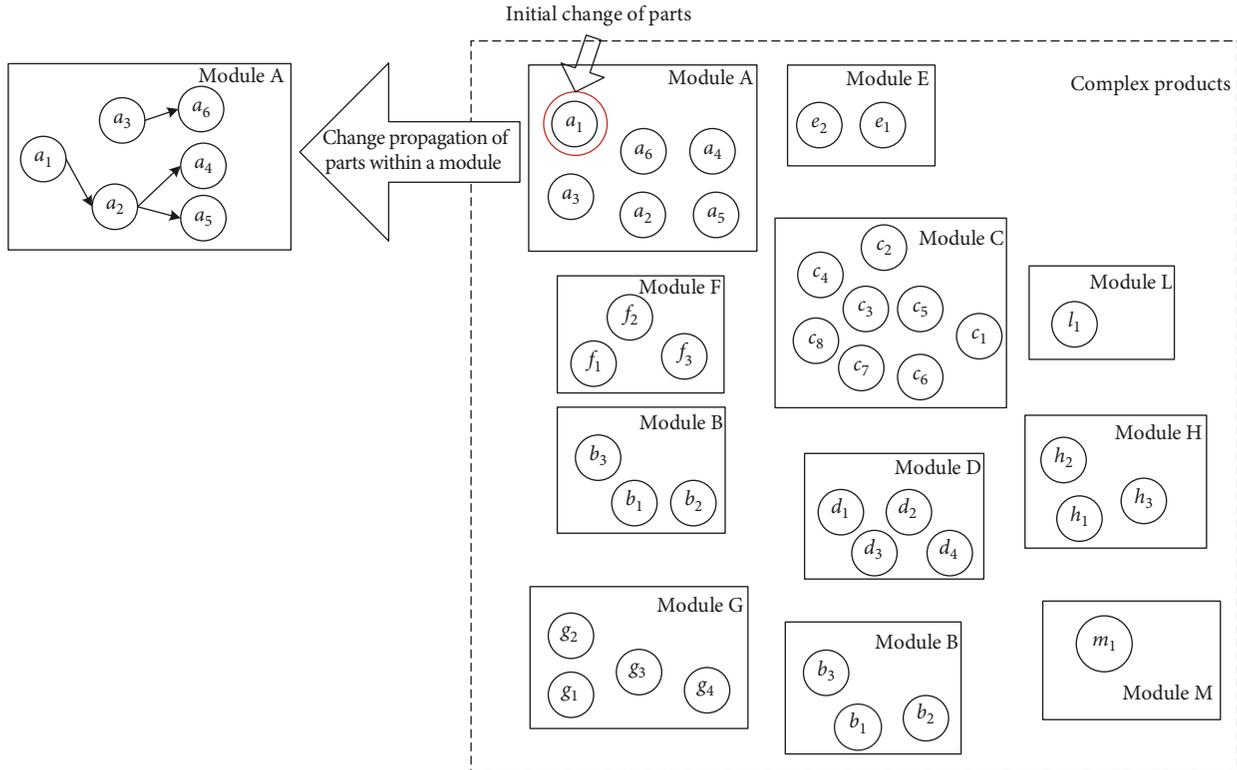

FIGURE 1: Change propagation model within a complex product module.

TABLE 1: Types of inter-part change propagation.

Number	Illustration	Type
1		Direct transmission
2		Two-way transmission
3		Indirect transmission
4		Ring transmission
5		Spread transmission
6		Gather transmission

(6) Clustered propagation: The change impact on part A and part B is propagated to part C at the same time, and the change propagation is clustered so that part C has to meet the change design requirements of both part A and part B. In the change propagation process, clustering reduces the number of parts involved in the change propagation and the number of parts affected by the change, reducing the area affected by the change propagation.

The six types of change propagation are represented in a table, as shown in Table 1.

2. Establishing a Parts Change Communication Network

The Design Structure Matrix (DSM) is the primary method for studying the propagation of changes in product design. The link between the elements of the matrix rows expresses the change dependencies that exist on parts. In the binary Boolean DSM, a “0” means that no change dependency exists on two parts and a “1” means that a changing dependency exists on two parts. In actual manufacturing, the degree of change dependency on parts varies, with some parts having a strong change dependency and others having a weak dependency. It is not possible to classify the dependencies on parts into just two types: those with change dependencies and those without. This is defined by the five-

	a_1	a_2	a_3	a_4	a_5	a_6
a_1	-	1	0.7	0	0	0
a_2	1	-	0.7	0	0	0.5
a_3	0.7	0.7	-	0.3	0.5	0.3
a_4	0	0	0.3	-	0	0
a_5	0	0	0.5	0	-	0
a_6	0	0.5	0.3	0	0	-

FIGURE 2: Digital DSM.

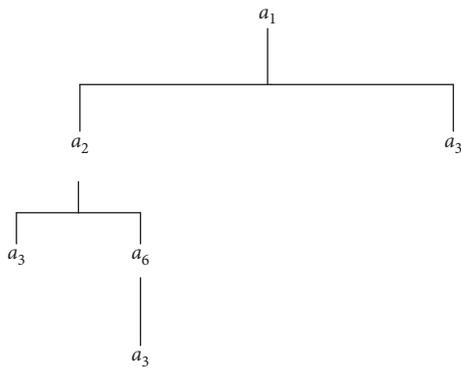

FIGURE 3: Change propagation impact tree.

point weighting method [17] using a number between 0 and 1, depending on the strength of the changing dependency on two parts. The number 1 indicates that there is a strong change dependency on two parts, and a change in one part will have a change impact on the other part, while the number 0 indicates that there is no change dependency on two parts, and a change in a part will not have a change impact on the other part. According to the change dependency relationship between parts and the change dependency strength, the numerical design structure matrix is established, as shown in Figure 2.

The change dependency on two elements can be visually represented by a numerical DSM, which reveals the change impact on a change to part a_1 from part a_2 . This change propagation influence is a direct change influence and there are also indirect change influences on the change propagation process, for example, a change in part a_1 can cause a change to parts a_3 and a_6 through a change to part a_2 . The design structure matrix does not represent the indirect change impact, so a change impact tree is created based on

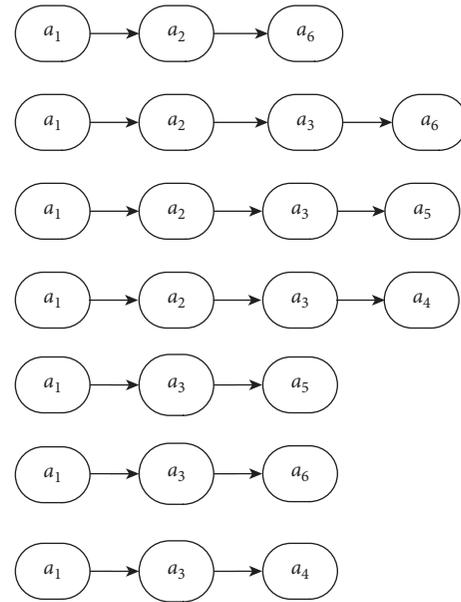

FIGURE 4: Change propagation chain.

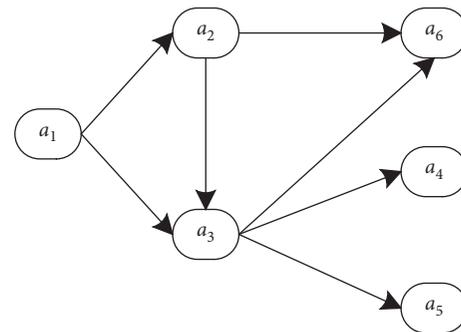

FIGURE 5: Change dissemination network.

the numerical DSM created. Assuming that part a_1 is the initial changed part and a_3 is the change termination part, create a change impact tree for part a_1 to part a_3 as shown in Figure 3.

During the change propagation process, a part is said to be the initial change part when a change in a part causes the change propagation to occur. Change propagation starts with the initial change part and proceeds according to the change dependencies on the parts until the change is terminated. Firstly, parts in a changing dependency on the initial changed part will have a change impact, with different change dependencies having different change impacts on the part, and secondly, the part affected by the change will also have a change impact on the parts with which it has a changing dependency until the change propagation ends at a particular part. An analysis of the change propagation influenced tree created shows that when the initial parted a_1 starts to make changes, it directly affects parts a_2 and a_3 for changes, while changes to part a_2 affect a_3 and a_6 for changes, and changes to part a_6 have a change influence on a_3 . It can be seen that during the propagation of changes in $a_1 \rightarrow a_3, a_1$

can affect a_3 directly and a_1 can also have an indirect change impact on a_3 through other parts.

The indirect effects of change propagation cause change to be propagated through a number of different propagation paths, each of which can be represented by a propagation chain, as shown in Figure 4.

Using the digital DSM as a tool, the change propagation network in the network is represented by a directed graph $G(V, E)$, where $V = \{x \mid x = 1, 2, 3, \dots, n\}$, denotes the set of directed graph vertices and x denotes a part within a module. $E = \{(x, y) \mid x, y \in n, x \neq y\}$ is a directed edge, indicating the existence of a change propagation relationship between part x and part y . In a directed graph $G(V, E)$, the individual change propagation chains described above intersect with each other to form a change propagation network [18]. This is shown in Figure 5.

The change propagation networks to provides a clear view of the initial change parts in a module and the change effects of the initial change parts in other parts, as well as a general view of the paths along which changes are propagated [19]. In the change propagation network, not only direct change effects on parts can be identified, but also indirect change effects. In a network, however, it is not possible to know exactly the magnitude of the propagation dependencies on parts, to determine along which specific paths the change propagation will take, and also to determine the magnitude of the change propagation range. Therefore, there is still a need to study and analyze the change dependencies on parts.

3. Change Propagation Impact Analysis Method Based on Change Dependencies

3.1. Changing Dependencies. When a change activity occurs to a product, due to the high degree of cohesion within the module, there is a high degree of correlation between parts in the module and a high degree of change dependency. When a part starts to change, the change propagates according to the dependencies on the parts, and the complex dependencies between the parts make there are multiple paths for change propagation, the change propagation has a wide range of influence and it is difficult to control the direction of change propagation. If the change propagation path of a part in a module can be determined, the change propagation impact on the part change in the module in which it is located is discovered, the propagation impact between modules is then studied, and the product change results are eventually discovered. If the propagation of change in parts affects the module in which it is located to change in size, structure, or function, then this module will be used as the initial change module, and the propagation impact on the initial change module on other modules will be further investigated between modules to discover the propagation impact on changes in the product. However, when the change propagation of the part will not have a change impact on the module in which it is located, then this module will not change and will not have a change impact on other modules.

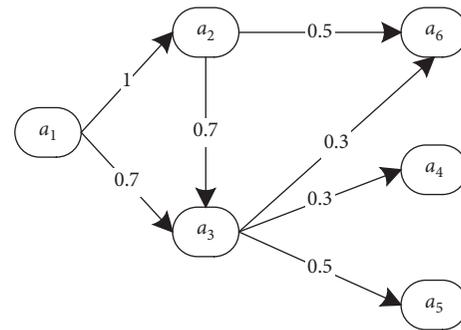

FIGURE 6: Change dependencies between parts in the change propagation network.

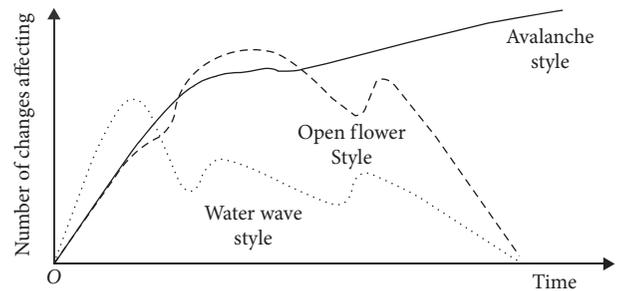

FIGURE 7: Change propagation impact.

Parts in the same module have strong dependencies on each other, and too much dependency between parts can lead to change propagation going along multiple paths, increasing the scope of change propagation impact. The greater the dependency on parts, the greater the degree to which changes in a part affected changes in another part, and the greater the change transfer of the two parts, making change propagation more difficult to control. Combining the numerical DSM and the change propagation network, the changing dependency on two elements x and y in adjacent cells are represented by $W(x, y)$ and takes a value in the range $[0, 1]$. The value of $W(x, y)$ is obtained according to the numerical DSM established. The value of W is obtained according to the numerical DSM established. $W(x, x)$ represents the degree of change dependency on the component itself and takes the value of 1. Figure 6 shows the addition of change dependencies on the change propagation network [20].

Figure 6 shows that the change propagation of part a_1 spreads and has a simultaneous change impact on parts a_2 and a_3 . Due to the close direct change dependency between part a_1 and part a_2 , the change impact of part a_1 on part a_2 is greater and change propagation is easily formed.

3.2. Part Change Propagation Impact Analysis. Change propagation impacts are divided into three types: ripple propagation, blossom propagation, and avalanche propagation, as shown in Figure 7.

As can be seen in Figure 7, the water-wave propagation, the initial change causes a part of the parts to be changed, but after a short period of time, the number of parts involved in

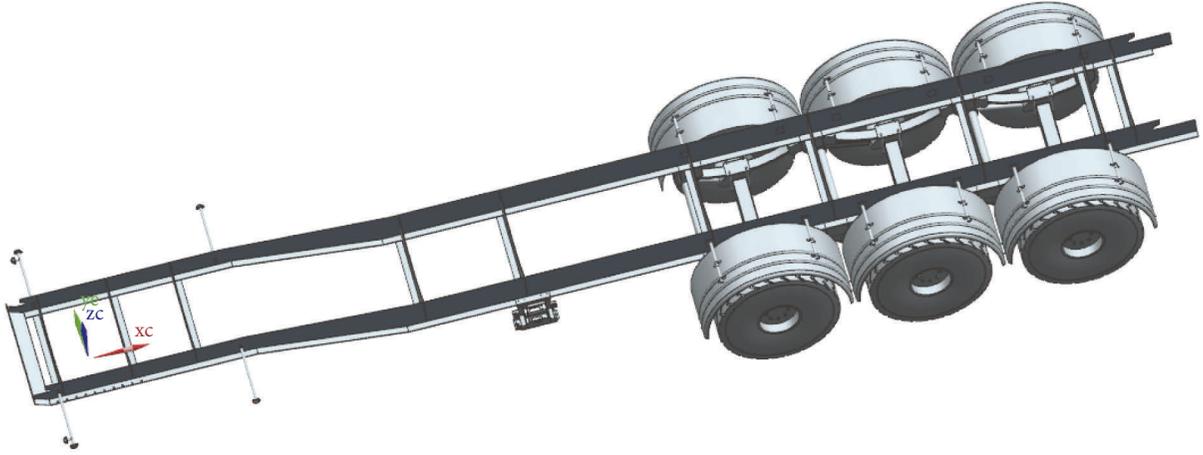

FIGURE 8: Schematic diagram of the frame module.

the change rapidly decreases and eventually stays at a certain number, because the propagation method of parts is mainly direct propagation, so the change propagation influence is weak. Blossom propagation, where the initial change causes a large number of parts to change, and after a while, the number of parts involved in the change begins to decrease and eventually remains at a reasonable number, due to the existence of indirect and diffusion propagation between parts, which can lead to a rapid increase in the number of changed parts. After a period of time, the number of parts involved in change propagation decreases because, during the change propagation process, some parts have a certain ability to absorb the change. The parts affected by the change propagation absorb the change propagation completely or partially so that the parts with which there is a propagation dependency do not need to be changed or only partially changed, and therefore the change propagation stops or decreases. In avalanche propagation, the initial change causes a large number of parts to change, with the increase of time, the number of changes continues to grow, eventually leading to the number of change impact that is difficult to control, as the avalanche effect, due to the propagation of parts for the diffusion of propagation, the impact of change of a part will be spread to several parts with its change dependency at the same time, making the propagation of change spread, increasing the scope of change propagation impact, and this increases the development cost and reduces the productivity of the product [21]. Therefore, an avalanche of change propagation should be avoided as much as possible.

As can be seen in Figure 6, part a_1 is the initial change part. In the entire change propagation network, the propagation of part a_1 to parts a_2 and a_3 is diffuse, with changes to a_1 affecting changes to both a_2 and a_3 , causing changes to propagate along both change paths. The propagation of changes from part a_2 to part a_3 and part a_6 is diffuse, extending the change propagation range. The change propagation of part a_6 is agglomerative and absorbs the change propagation of part a_2 and part a_3 , reducing the

change propagation impact and creating a blossoming change propagation impact. Part a_3 has both diffuse and convergent propagation. If the change propagation is absorbed in whole or in part at part a_3 , the change propagation will be reduced, making the propagation path manageable, but if the change propagation is diffused at part a_3 , increasing the range of change propagation, an avalanche of change propagation may occur, making the change propagation difficult to control. Part a_3 is therefore more likely to change and has the greatest impact on changes to the module as a whole. When studying the impact of changes to parts within a module, it is important to prioritize the analysis of the risk of change propagation for part a_3 in order to better control the scope of change propagation.

From the above analysis, it can be concluded that the change propagation impact is mainly determined by the changing dependency between parts and the change propagation mode of the parts. All parts within a module are affected by the initial change. In order to avoid uncontrollable effects of the design change on the product, the changing risk of the part should be analyzed and predicted before the change is made, in order to avoid an avalanche of change propagation effects [22]. In this paper, the change risk value is used to represent the magnitude of the comprehensive change risk of a part, and the change impact that the change propagation of the initial change part will have on the module in which it is located. The changing risk value is expressed in terms of R . Combining the change dependency degree $W(x, y)$ between parts, the changing risk valued calculation formula is obtained as follows:

$$R = \frac{1}{k} \sum_{j=1}^n \frac{\sum_{i=1}^m W(x_i, y_j)}{m}. \quad (1)$$

In the formula, k indicates the number of all parts in the module; m indicates the number of parts that have a change propagation effect on the change part; y_j the

	a_1	a_2	a_3	a_4	a_5	a_6	a_7	a_8	a_9	a_{10}	a_{11}	a_{12}

FIGURE 9: Digital DSM for the change of components in the frame module.

number of parts that produce the propagation effects of the change; and n indicates the number of change parts in the module.

By calculating change risk values for key nodes and comparing the magnitude of the change risk values, larger values indicate that an avalanche of change propagation impacts are likely to occur, and therefore, changes to the part need to be controlled so that change propagation is within manageable limits.

4. Example Validation

Using the frame module in Figure 8 as an example, the effect of change propagation on the components within the frame module is investigated when the cross member is the initial change part, and the content of this chapter is verified.

As can be seen in the schematic diagram of the frame module, the components contained in the frame module are the wing, web, cross member, front cover, axle, bearings, tires, fenders, struts, spare wheel carrier, front tail light, and side indicators, 12 components.

Due to the change dependencies on components, changes do not occur in isolation. Changes in the initial component will cause changes in other components that are related, and changes will continue to propagate until an equilibrium is reached. In the actual change propagation process, the change propagation method is divided into the direct propagation method and the indirect propagation method. The direct change relationship between two components can be expressed by establishing a design structure matrix with links between the elements of the matrix. The change dependencies on parts result in several different propagation paths, which are

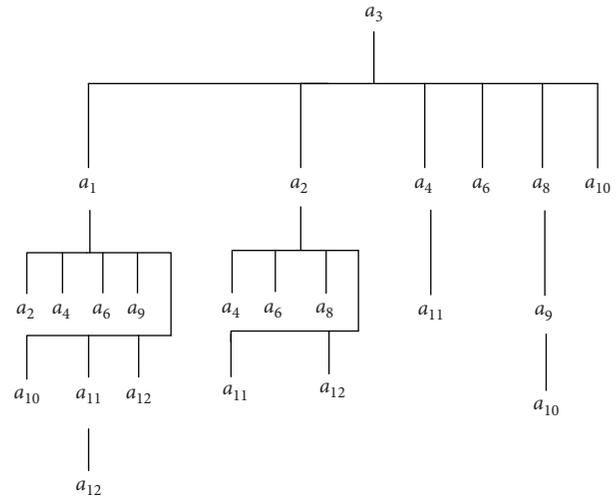

FIGURE 10: Part change propagation impact scope tree.

represented by the change propagation chain to parts. Finally, the change propagation chains are intersected in a directed graph to form a change propagation network of the parts.

4.1. *Creation of Digital DSM for Component Changes in the Frame Module.* By means of the five-point weighting method, the change dependencies on the 12 components in the frame module are specified by numbers between 0 and 1, and the components are arranged in a uniform order above and to the left of the matrix to create a 12×12 order numerical DSM, as shown in Figure 9.

From the diagram it can be observed that the initial change to part beam a_3 has a direct change propagation impact on parts $a_1, a_2, a_4, a_6, a_8,$ and a_{10} , while part a_2 also has a change impact relationship on parts $a_4, a_6, a_8, a_{11},$ and a_{12} , so a change to part a_3 may also have an indirect change propagation impact on parts a_{11} and a_{12} . A change propagation tree based on the numerical DSM for part changes is shown in Figure 10.

4.2. *Chain of Propagation of Component Changes.* Through the part change propagation influence range tree, it can be seen that there are multiple change propagation paths to part change propagation. A change propagation chain is used to represent a propagation path to represent all part change propagation paths within the frame module, as shown in Figure 11.

4.3. *Establishing a Network for the Dissemination of Component Changes within the Frame Module.* The change propagation network in the network is represented by a directed graph $G(V, E)$, where $V = \{x | x = 1, 2, 3, \dots, 12\}$, the set of directed graph vertices, x represents the parts in the frame module, and $E = \{(x, y) | x, y \in 12, x \neq y\}$ is a directed edge, indicating that there is a change propagation

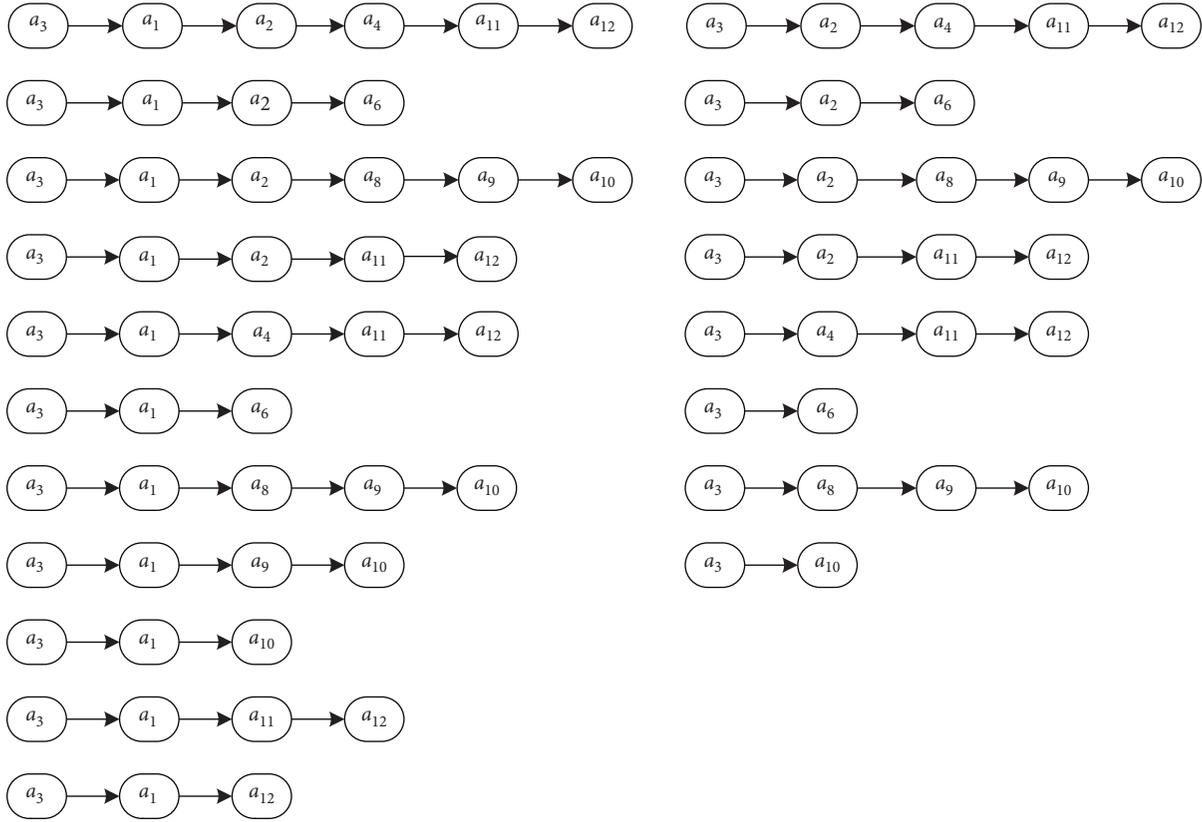

FIGURE 11: Part change propagation chain.

relationship between parts and parts. In the directed graph $G(V, E)$, the change propagation chains of each part in Figure 11 are intersected to form a part changed propagation network, combined with a numerical DSM, with $W(x, y)$ representing the changing dependency between two elements x and y of adjacent cells, taking a value range of $[0, 1]$, to establish a change propagation network containing change dependencies between parts as shown in Figure 12.

It can be seen from Figure 12 that when the initial change part a_3 produces a change, the change propagation of part a_1

and part a_3 in the whole change propagation network is diffusion propagation, and there are many parts affected by the change of part a_1 and part a_2 . Therefore, when studying the change propagation impact on parts in the frame module, the part change risk value [23] is calculated according to (1), and the change propagation risk of part a_1 and part a_2 is analyzed in priority in order to better control the change propagation range.

The change risk value for change propagation through part a_1 after the initial change in part a_3 is:

$$R(a_1) = \frac{1}{12} \left(0.7 + 1 + 1 + \frac{0.5 + 0.5}{2} + \frac{0.7 + 0.5}{2} + 0.3 + 0.3 + \frac{0.5 + 0.3}{2} + \frac{0.3 + 0.3}{2} + \frac{0.3 + 0.3}{2} \right) = 0.45. \tag{2}$$

Then the change risk value for change propagation through part a_2 after the initial change in part a_3 is

$$R(a_2) = \frac{1}{12} \left(\frac{1 + 1 + 0.5 + 0.5 + 0.3 + 0.5 + 0.3 + 0.3 + 0.3/2 + 0.3 + 0.3/2}{2} \right) = 0.196. \tag{3}$$

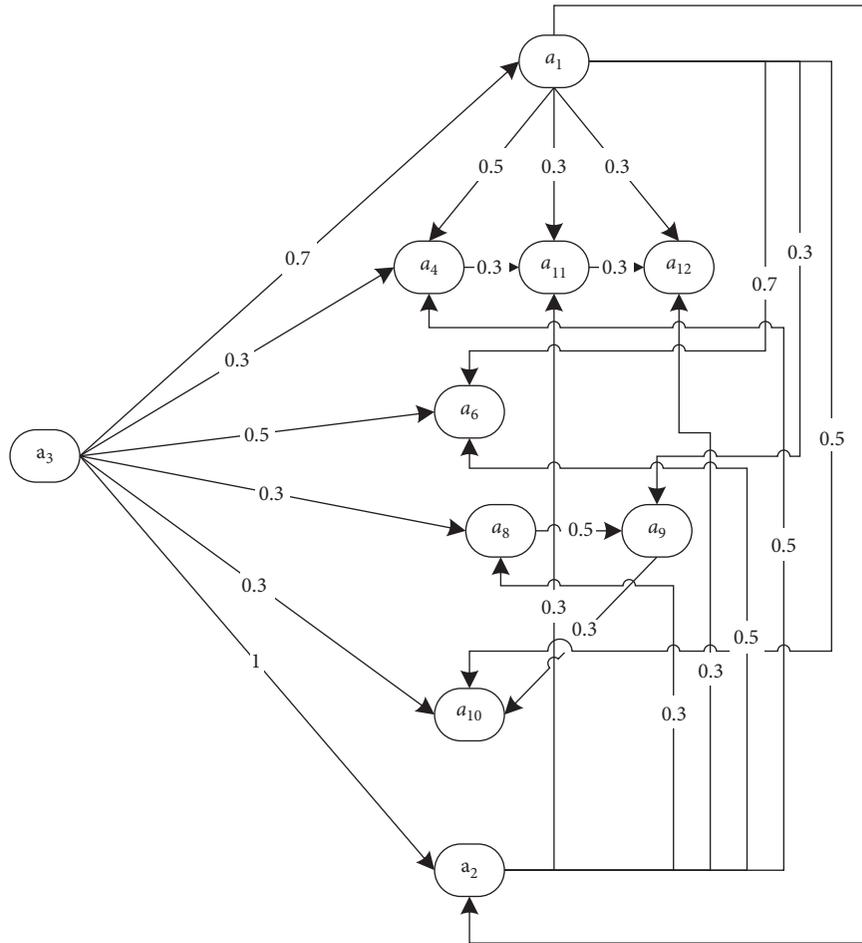

FIGURE 12: Change propagation network with change dependencies.

It can be seen that $R(a_2) < R(a_1)$, which indicates that the change in the initial part a_3 cross member has a greater impact on the propagation of the change to the part a_2 wings than to the part a_2 web, and therefore the risk of change propagation through part a_1 is greater, indicating that if changes are made to the wing during the frame change process, it may cause the number of change parts to increase, and there is also the possibility of avalanche changed propagation, so attention should be paid to the propagation impact of the change from changes to the wing during the change process.

5. Conclusions

This paper focuses on the change propagation impact on parts within a module. Based on the direct change propagation relationship between parts, a digital DSM of parts is created for parts in the same module, the indirect change propagation relationship between parts is assessed through the DSM, a change propagation chain of parts is constructed, and finally, a change propagation network is formed in the directed graph to describe the propagation path of part changes. By analyzing the degree of change dependency on each part and the impact of the part propagation method on

change propagation, the possible paths of change propagation are determined, and based on the calculation of the change risk value, the change risk value of the key node is calculated, the possible change propagation impact of the part change through this node is evaluated, the changing risk of the part is predicted, and the change of the part is controlled in advance to avoid the uncontrollable impact of the change design on the product.

Language is a symbol reflecting ideas and is an important medium for people to realize information transfer and communication. Culture is all the material and spiritual wealth created during the historical development of human society. Language and culture are inseparable. When we learn a language, we must also understand the cultural content it contains. Learning English requires an understanding of the culture of British and American countries, and thus teachers must necessarily teach culture in the English classroom. At present, the software and hardware of Internet technology in our country have been developed in-depth, and the total amount of big data has been in the trend of growth, and China has officially entered the era of big data. This paper takes the reform of teaching mode of British and American culture courses as the main research object and explores how to build a diversified and blended teaching mode based on the existing teaching mode and integrating various online teaching resources under the premise of various technologies in the background of “big data.” In order to accelerate the integration and optimization of such course resources, promote the development of theoretical teaching and practical teaching of such courses and improve students’ professional ability.

1. Introduction

With the in-depth development of the Internet of Things, computer networks, mobile self-media, and other technologies, the total amount of global data has shown explosive growth according to the set, and human society has entered the era of accelerated development of big data. The concept and value of big data have been gradually accepted by the public; workers are also fully aware of the typical application and extensive prospects of big data in the field of education [1]. At present, many colleges and universities are actively exploring various forms of curriculum practice teaching reform programs according to the actual needs of teaching work, drawing on the existing advanced teaching models, and adjusting teaching and training programs in real-time [2–5].

Once upon a time, students could only ask their teachers for advice if they had knowledge or problems they did not understand, but with the advent of the big data era, many problems students can solve by looking up relevant

information through the Internet. The blended teaching mode is a new teaching mode adapted to the era of big data. This teaching mode not only retains the traditional class teaching but also makes full use of the advantages of the network information platform and rich network resources. The application of blended teaching mode makes a major breakthrough in British and American culture education, which not only improves students’ learning initiative but also enhances their comprehensive learning ability and lays a solid foundation for their future study and work [6].

A qualified teacher of English culture needs to have a solid knowledge of culture in addition to background knowledge of the culture of English-speaking countries. A good teacher should not only have a broad knowledge of culture but also make it an important task to develop students’ cultural sensitivity and self-awareness. Good teachers should be able to familiarize themselves with “the deep and hidden culture of the national psychology, values, and ways of thinking of the target language” [7, 8] and develop their own cultural literacy in English. In addition to professional

competence, qualified and excellent teachers should have high intercultural communication skills, be able to actively explore cultural teaching, and pay attention to the cultivation of students' intercultural awareness and intercultural communication skills [9].

This paper aims at the problems such as the low flexibility and inactive classroom atmosphere in the traditional cramming English culture teaching, face the theoretical, technical, and application challenges, and address the fundamental issues of how to analyze and model big data on teaching and learning, how to build a diversified blended model based on big data analysis, and study its application in teaching British and American culture in order to give full play to the leading role of teachers and yet stimulate students' learning autonomy in many ways.

2. Concept Explanation

2.1. Big Data. Big data era is a new era of mass production, dissemination, and utilization of data with the rapid development of Internet technology. Big data are a huge collection of data, and the scale of data contained in the collection is huge, far beyond the scope of the traditional sense. The processing power of traditional computers cannot meet the needs of the big data era, and traditional tools and software cannot be used to store, analyze and manage big data. In order to solve this problem, computer scientists apply cloud computing to human data computing. Cloud computing technology can effectively solve the problem of storing human data and can calculate, analyze, and predict human data [10]. This can enable us to do effective use of big data and to dig deeper into the hidden data.

The arrival of the big data era provides people with opportunities and capabilities to conduct in-depth research in more fields. People use cloud computing technology to analyze, process, integrate, and mine big data, so as to obtain new knowledge and explore the laws of the real world. This has brought influence and changes to the teaching of British and American culture.

In the field of educational learning, five major applications of big data technologies include [11]: prediction: awareness of the likelihood of anticipated facts. For example, to have the ability to know when a student has intentionally answered incorrectly despite the fact that he or she is in fact capable. Clustering: discovering data points that are naturally clustered together. This is useful for grouping students with the same learning profile and interests together. Modeling: using learning models developed through big data analysis. Associations: discover relationships between variables and decode them for future use. This is useful for exploring the reliability of students' ability to answer questions correctly after asking for help. Decision-making: create a visual reference for decision-making in instructional management. For clarity, Figure 1 counts six areas, where big data and education intersect.

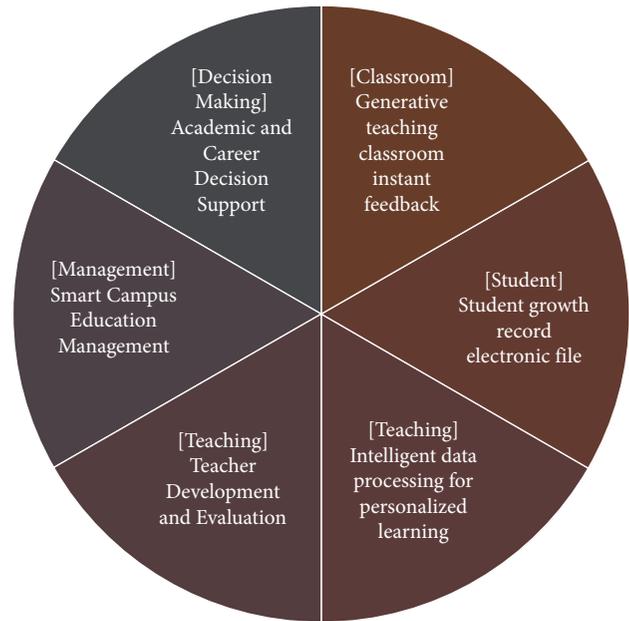

FIGURE 1: Six areas where big data and education intersect.

2.2. Diversified Blended Teaching Mode. Diversified blended teaching refers to a diversified and multiplatform teaching method that combines the advantages of traditional classroom teaching with information technology [12]. Blended teaching optimizes the selection and combination of all teaching elements to play the leading role of teachers to guide, inspire, and monitor the teaching process, while fully reflecting the initiative, enthusiasm, and creativity of students as the subjects of the learning process [13]. The key to the blended teaching model is the use of appropriate technological means for content presentation and transmission for specific teaching contents and learners.

In terms of form, blended instruction includes a mix of both offline and online learning, a mix of teacher-led activities and active student participation, a mix of student-led learning and collaborative group learning, a mix of multiple teaching resources, a mix of multiple learning environments, and other different dimensions. It should be noted that multiple blended teaching should combine teaching objectives and students' characteristics. For example, a classroom with mastery of knowledge as the main teaching goal can adopt the traditional classroom teaching mode based on teacher activities to highlight systematic lectures and training, while when the teaching goal is to strengthen practical skills development, teachers should adopt more information-based teaching mode to highlight students' independent learning and active exploration [14, 15]. In a word, blended teaching is neither a teaching model that simply emphasizes the application of an online learning environment and ignores the importance of classroom teaching nor a teaching model that unilaterally

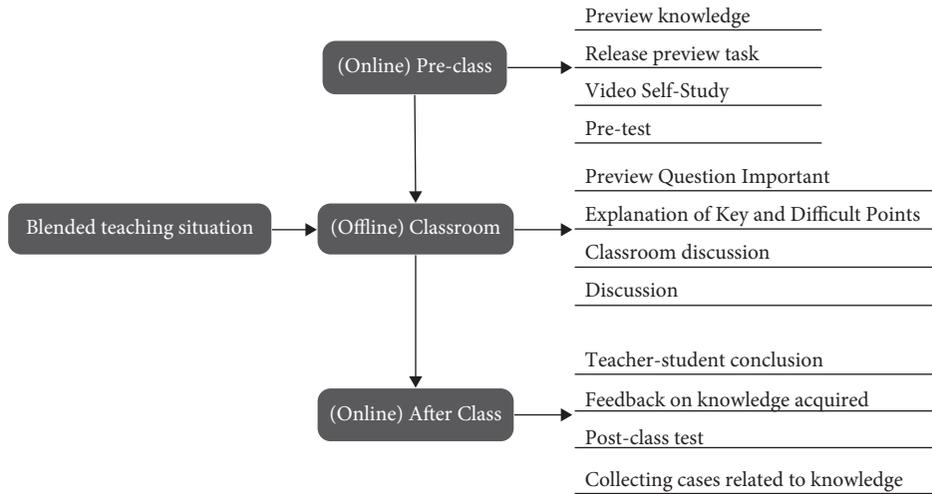

FIGURE 2: The flow of the diversified blended teaching model.

focuses on students and ignores the leading role of teachers; blended teaching both faces the advantages of traditional classroom and fully reflects the characteristics of the information age. The process of blended teaching model is shown in Figure 2.

2.3. Definition of Culture

2.3.1. Culture. Ancient and modern interpretations of the concept of culture are inseparable from those of nature and human society. Culture is an evolution of the concepts of astronomy and humanities, referring to the composition of natural celestial bodies and their laws, and the composition of human society and its laws, respectively. Culture is an evolution of the concepts of astronomy and humanities, referring, respectively, to the composition of natural celestial bodies and their laws and the composition of human society and its laws. The original meaning of culture is to teach and educate with literature, which is an abbreviation of human culture, and “the cultivation of human temperament and the education of moral character” are all part of cultural education. Culture is explained in the dictionary in a narrow sense as the ideology of society and the institutions and organizations that correspond to it, and in a broad sense as the sum of all the material and spiritual wealth created in the course of human social and historical practice [16]. Whatever is good for human development in material and spiritual terms is called culture. Culture is present throughout life activity; it is an innate, humanistic phenomenon. In general, culture is the sum of what people think, say (verbal and nonverbal), do, and feel [17].

In English, “culture” is an evolution of the Latin “cultus/cultura,” which means “to dwell, to cultivate, to practice, to pay attention to, and to fear the spirits” [18]. It also has a derivative meaning for the cultivation of human temperament and moral character. Samuel Pufendorf first introduced culture as an independent concept, arguing that “culture is the sum of what is created by human activity and depends on man and society for its existence.” Louis Kroeber

and Clyde Kluckhohn, after compiling more than 300 definitions of culture from experts in several fields of study, grouped culture into six categories, including “descriptive, historical, normative, psychological, structural, and genetic.” Meanwhile, an integrity definition of culture was made, that is, culture is a kind of “external and internal behavior patterns,” and culture enables us to obtain and convey information using symbols.

Throughout the different definitions of culture by scholars, both material and spiritual dimensions are inseparable from the analysis. The concept of culture used in this study refers to the material and spiritual wealth created by human society in the course of its historical development.

2.3.2. Cultural Infiltration. Culture is a valuable asset created during the historical development of human society. “Infiltration” refers to the flow of water between the pores of the soil, within the cracks of hydraulic buildings, and between intersections, and also refers to the operations of the army to secretly infiltrate into the enemy’s interior and rear by taking advantage of gaps in the enemy’s deployment. It can also be used as a metaphor for the gradual entry of a force into other areas. In present-day terms, cultural infiltration is the use of media, multinational corporations, etc., by more developed countries or regions to promote their own culture to other countries, thus achieving both economic benefits and assimilation into other countries. The interpretation of culture as a medium for the powerful forces to instill values in the weaker countries is a passive and unconscious process of accepting foreign culture. Cultural infiltration is the infiltration of cultural factors into language teaching, which can be done through the operation of lexical mining, grammatical prompting, and translation comparison.

The cultural infiltration explored in this study refers to the active and conscious understanding or introduction of foreign cultures in order to enhance cross-cultural awareness and achieve the ability to communicate appropriately

and effectively across cultures. From the learner's perspective, cultural penetration refers to the language learner's active and conscious action to learn about foreign cultures. From the teacher's perspective, cultural penetration refers to the teacher's activities in teaching culture in the classroom.

3. Review of Research on Teaching British and American Culture

3.1. Research on Teaching British and American Culture Abroad

3.1.1. Teaching Awareness. Between the 1940s and the 1960s, academic research on the culture of the target language and the culture of the native language gradually shifted to the study of the teaching of cultural penetration in foreign language teaching. Fries Charles theoretically discussed the connection between language teaching and culture teaching, and the importance and necessity of culture teaching in foreign language teaching. He argued that cultural learning and language learning are inseparable and that the process of learning a language is also the process of forming students' cultural awareness, and that cultural factors should be infused into language learning. By enhancing students' knowledge of the culture of the target language, they can effectively master and use the target language [19]. Lado stated that by studying the linguistic differences and learning barriers between learners' native language and the target language, concluded that appropriate comparative analysis of native language and target language culture in language teaching can help achieve effective second language teaching. Brooks Atkinson conducted a study on the practical aspects of culture teaching, and he emphasized that culture teaching should always be carried out throughout the whole process of foreign language teaching, and teachers should choose different cultural contents at different teaching stages [20].

From the 1970s to the beginning of the 21st century, research on culture teaching and learning gradually flourished. The discussion of culture teaching in this period focused on the positive effects of culture teaching on language learning. Chastain Kevin discussed the reasons for conducting culture teaching in terms of the need for cultural understanding, the realization of intercultural communication, and personal interest [21]. Louise Damen argued that "culture, although excluded from the curriculum, cannot really be ignored by teachers in language teaching, it is hidden in foreign language learning and should be one of the basic skills for mastering a foreign language." Byram argued that "one acquires culture as one acquires language" [22]. Klippel John stated that cultural knowledge plays a supporting role in teaching culture and that mastering the cultural knowledge behind a language is the beginning of learning a language. Eugene Nida introduced culture into the translation of the English language. Kim discussed the current situation of culture teaching in English classrooms in urban and rural elementary schools in Korea from the perspective of teachers and students. From the study, it was concluded that teachers and students recognize the role of

English culture in English education, but in practice, teachers still fail to adequately teach culture and students do not receive adequate cultural education [23]. Leshem conducted a period of observation in an Israeli junior high school English classroom to study the distance between the cultural background of teachers and students and the culture of the target language. The classroom observations concluded that there is a general problem of implicit cultural dynamics in English language teaching, i.e., the extent to which learners' knowledge of the target language culture affects the effectiveness of teachers' language instruction [24].

3.1.2. Teaching Strategies. From the 1980s to the 1990s, the idea of teaching cultural penetration in the classroom was generally recognized, and foreign scholars' research on teaching cultural penetration lies in exploring specific and feasible cultural penetration strategies. Hans argued that in foreign language teaching, the content of cultural introduction should focus on people in the target language country, such as their lifestyles, behavioral habits, and ways of thinking [25]. Thomas James pointed out that pragmatic language failures and communicative language failures are the root causes of cross-cultural pragmatic failures. Seelye introduced culture capsules, culture clusters, and culture assimilators. Seelye introduced classroom culture introduction methods such as culture capsules, culture clusters, and culture assimilators, and discussed how to measure the effect of culture learning [26]. Byram Mike, after studying audiovisual and auditory methods, suggested that grammar and cultural introduction should also be linked together in ELT [27].

At the beginning of the 21st century, cultural infusion strategies began to focus on design from the perspective of teachers and learners. Patrick Moran advocated teaching culture through experiential language instruction that reinforces cultural connotations, student interventions, expected or achieved outcomes, learning content, and the intrinsic connections between teachers and students. Frank has investigated how teachers can integrate cultural knowledge into the English classroom in the English classroom. He suggested that teachers can promote learners' cross-cultural understanding by organizing activities that increase cultural awareness, such as assigning networking tasks, role-playing, and cultural observation [28].

3.2. Research on Teaching British and American Culture in China

3.2.1. Teaching Awareness. From the end of the 20th century to the beginning of the 21st century, improving learners' intercultural communication skills is one of the insurmountable topics of cultural penetration studied by domestic scholars. Cao believed that culture teaching in English language teaching is composed of both cultural knowledge and cultural understanding. Cultivating students' intercultural communication skills requires a

combination of the strengths of both cultural knowledge and cultural understanding, with emphasis on both the learning of cultural knowledge and the cultivation of cultural understanding. Tan Ling proposed that English teaching in colleges and universities should implement a joint approach of language teaching and cultural background knowledge transfer from the perspectives of the connotation of intercultural awareness, the importance, and necessity of strengthening intercultural awareness, and gives suggestions on the ways to enhance intercultural awareness. Gao Dongjun, from the perspective of the relationship between language and culture, explained the role of learning the culture behind language in enhancing students' language application and intercultural communication skills and calls for teachers to introduce English culture in their teaching. Lv believed that "the real purpose of English teaching is to achieve accurate, appropriate and effective communication," and that this goal needs to be achieved by paying attention to the cultivation of students' intercultural communication skills so that they can become intercultural communication talents with a high level of intercultural literacy.

Cultural penetration in the classroom has been recognized by most researchers, and research has begun to focus on the cultural teaching experiences of teachers and learners. Xiao Bin discussed the necessity of cultivating students' intercultural awareness of the dialectical relationship between language, culture, and teaching, and suggested that vocabulary teaching and organizing cultural activities can be used in English teaching to cultivate students' cultural awareness. Shi Rui researched cultural teaching in the higher-level English classroom and concluded that cultural input while teaching English is the key to solving students' linguistic errors. Language and culture run through the English classroom, and classroom teaching should increase cultural input in English to improve students' practical English application skills. Li suggested that cultural differences determine language differences and it is important to include an introduction to the background of cultural knowledge of the language in teaching. Cultural teaching should go hand in hand with language teaching. Cultural teaching is helpful to help students understand the culture behind the language, improve their perception of the cultural differences between Chinese and Western cultures, and enhance their intercultural communication skills. Yu Zhihao and He Huibin studied the issue of developing Anglo-American cultural awareness in a special group of ethnic minority students. They talked about the dilemmas faced by cultivating the British-American cultural literacy of minority students from the issue of supplementing cultural knowledge to constructing students' humanistic spirit and suggested that students should be guided to transform their perspectives and concepts in the teaching process and learn British-American cultural knowledge with a developmental perspective. From the meaning of intercultural awareness, Lu Kaifeng analyzed the significance and necessity of intercultural awareness in English learning. He suggested that teachers should make full use of multimedia technology to infuse intercultural

awareness into classroom teaching. Zeng Lili reflected on the status quo of teachers' old teaching concepts and single way of evaluating teaching effects in English teaching and advocates that teachers should study teaching concepts and adopt diversified teaching modes and evaluation methods in culture teaching.

3.2.2. Pedagogical Strategies. Starting from 2010, the research on teaching strategies of cultural penetration has been characterized by the development of theoretical teaching strategies and teaching-aid technology. Wu Xianyun proposed that strengthening the learning of British and American culture and enhancing the awareness of cross-cultural communication meet the needs of English teaching reform. Teachers should make full use of existing multimedia aids, such as using pictures, audio, and video in teaching, to increase students' active participation in class. Based on the theory of multiple intelligences, Lu Tian suggested that teachers need to adopt diversified teaching designs in classroom teaching to provide more development opportunities for cultivating students' intercultural communication skills. Du Haiyan proposed that teachers can stimulate students' interest in cultural learning through the comparison method, test correction, and the creation of cross-cultural situations in response to the negative perceptions of students in the process of cultural teaching. Sun Lei introduced idioms as "concise phrases or short sentences that have been used by language users for a long time," through which English learners can learn the language and Western culture and improve their intercultural communication skills. Li believed that teaching culture can be carried out by comparing cultural differences, using online media, expanding cultural resources in English textbooks, and organizing English-related activities. Mao Mingming believed that cultural penetration is an important part of high school English reading teaching, through which students' reading speed and comprehension can be improved, and is an important way to develop students' cross-cultural awareness and cross-cultural communication skills. Guan Jiangang researched the strategies of teaching English culture in high school and proposed three forms to cultivate students' cross-cultural awareness, such as innovating English teaching theories, creating English teaching contexts, and organizing extracurricular activities.

4. Construction of Blended Teaching Model Based on Big Data Analysis

In order to accelerate the integration and optimization of the resources of these courses, promote the development of theoretical and practical teaching of these courses, and improve the ability of students in related majors to solve practical problems, we explore and practice in the British and American culture courses that have been offered in our university. The blended teaching model constructed in this paper contains the following three parts: the analysis model of teaching behavior based on educational big data, the construction of a blended teaching platform for British and

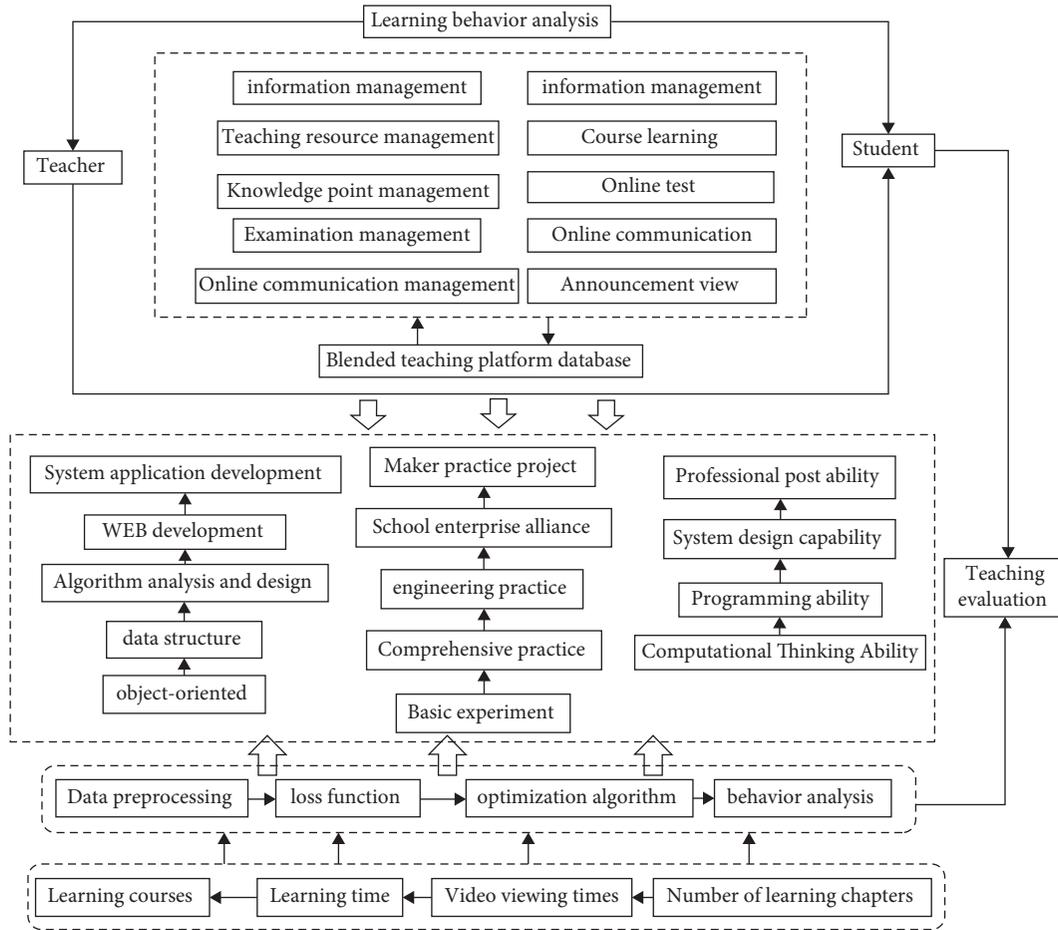

FIGURE 3: The overall structure of the diversified blended teaching model.

American culture courses, and the construction of a blended teaching model based on big data background. The overall structure diagram is shown in Figure 3.

4.1. Teaching Behavior Analysis Model Based on Education Big Data. Under the teaching environment of “Internet+,” the teaching process will generate a large amount of teaching-related data. How to make full use of these teaching big data and analyze students’ learning behaviors based on their related information and learning records is the first theoretical problem that needs to be solved in this paper. In view of the lack of abundant teaching data for British and American culture courses, this paper adopts the open data set of MOOC platform to analyze and establish the learning behavior analysis model. The existing learning behavior records include course code, course name, registration time, start time, end time, course days, number of students enrolled, number of students who passed the exam to obtain the certificate, pass rate, and other record information. In this paper, learners’ age, gender, educational background, learning time, number of learning events, number of sampling statistics learning, number of watching videos, number of learning chapters, and number of posting on learning forums are selected as the basis of learning effect

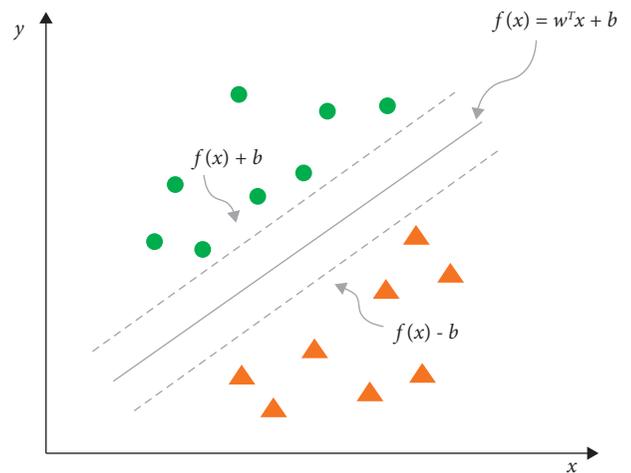

FIGURE 4: Mathematical model of support vector machine regression algorithm.

evaluation, and the support vector machine regression (SVR) algorithm is used to predict the learning behavior. The mathematical model of the support vector machine regression algorithm is shown in Figure 4, in which $f(x)$ denotes the learning effect, x denotes the relevant evaluation basis affecting the learning effect, w denotes the weight

obtained by regression, and b denotes the deviation, then its regression model expression is given as follows:

$$f(x) = w_1x_1 + w_2x_2 + \cdots + w_nx_n + b. \quad (1)$$

4.2. The Construction of Blended Teaching Platform Based on Learning Analysis. The theory of blended teaching shows that in the teaching process, the teacher's leading role should be played; at the same time, the main role of students should be reflected, and the students' learning initiative should be fully stimulated. In the blended network teaching mode, in order to reflect the teacher's leading role in monitoring the learning process, the teacher needs to upload all relevant teaching materials, teaching videos, and other tutorial materials in advance; while students can complete classroom teaching, after-class homework and discussion, and communication independently through the network teaching platform according to the teaching arrangement given by the teacher. On the other hand, teachers and students will generate a large amount of teaching-related data in the process of completing teaching through the online platform. For example, the number of times of login, login time, students' learning content, learning hours, homework times, homework time, test times, test time, test scores, and many other teaching-related data, how to collect, analyze, count and visualize these data, and establish learning analysis and prediction model according to the relevant course characteristics, so as to implement real-time monitoring of students' learning process and learning effect, and provide a dynamic reference for teachers. It provides a visual reference for teachers' dynamic management and provides relevant management data for teaching managers.

Based on the abovementioned analysis, the blended teaching platform based on learning analysis built in this project contains the following contents: (1) teacher module: the teacher function module contains personal information management, teaching resource management, teaching announcement management, teaching knowledge point management, test question management, and other parts; (2) student module: the student function module contains personal information management, course learning, online communication, announcement viewing and other functions; (3) learning analysis module: the learning analysis module contains functions such as learning data collection, online communication analysis, online learning analysis, and learning test analysis. The system function diagram of this platform is shown in Figure 5.

4.3. Construction of Blended Teaching Mode Based on Big Data Analysis. The blended teaching mode based on big data analysis is constructed in this paper, taking the British and American culture course of our university as the research object, using the blended teaching platform based on learning analysis as the teaching means, and taking various engineering practice projects of our university as the carrier, collecting the practical teaching links such as course experiment, course design, professional practical training and

graduation design, and adopting the basic teaching principle of combining online/offline to realize the integration and optimization of teaching resources, guidance and supervision of teaching process, and overall improvement of teaching quality. It adopts the basic teaching principles of online/offline combination to realize the integration and optimization of teaching resources, supervision of teaching process, and overall improvement of teaching quality.

The project collects teaching data online and adopts a big data analysis model to analyze, visualize and give feedback on teaching data, providing data basis for teachers' teaching process, students' learning planning, and teaching evaluation. The teaching mode constructed in this paper contains the following core contents: (1) project-oriented blended teaching mode: for the characteristics of theoretical courses and practical projects of programming courses, the blended teaching mode oriented to creative practice projects, joint school-enterprise projects, engineering practice projects, comprehensive practice projects, and basic experiment projects is constructed. Based on the blended teaching platform that has been built, various forms of online/offline blended teaching are carried out to effectively improve students' programming levels. (2) Data analysis-oriented multiple blended evaluation mode: based on the blended teaching platform, the platform teaching data are collected in real-time, and the teacher-student two-way evaluation mechanism is implemented. Based on the two-way evaluation results, combined with the platform teaching data, a reasonable teacher-student teaching evaluation model is established to build a foundation for reasonable tracking and evaluation of teaching quality.

4.4. Upgrading and Reengineering of the System under Big Data. The research on big data in education has developed a cone mesh educational system structure, which includes more directions of educational data mining and also a basic system architecture with new resources, and originally, relatively independent resource systems have been opened up to form a system framework with multiple elements. The cone mesh structure requires more management systems, there must be more teaching elements, and many related elements must also have their own independent small modules, and after integration, the overall teaching system framework is formed. Traditional classroom teaching and network distance learning resource system include many teaching resource database building systems, which can form a recursive system structure. The teaching and learning system under education big data can form independent minisystems by studying the correlation relationship, which can add more elements to the teaching and learning system.

The concept of educational big data includes more sources of educational data with multiple types of data. Traditional educational data does not have a large amount of information, but this educational big data contains a large amount of information. The data can bring together more pedagogical elements, which can be relatively independent or can be built into a simpler pedagogical system structure so

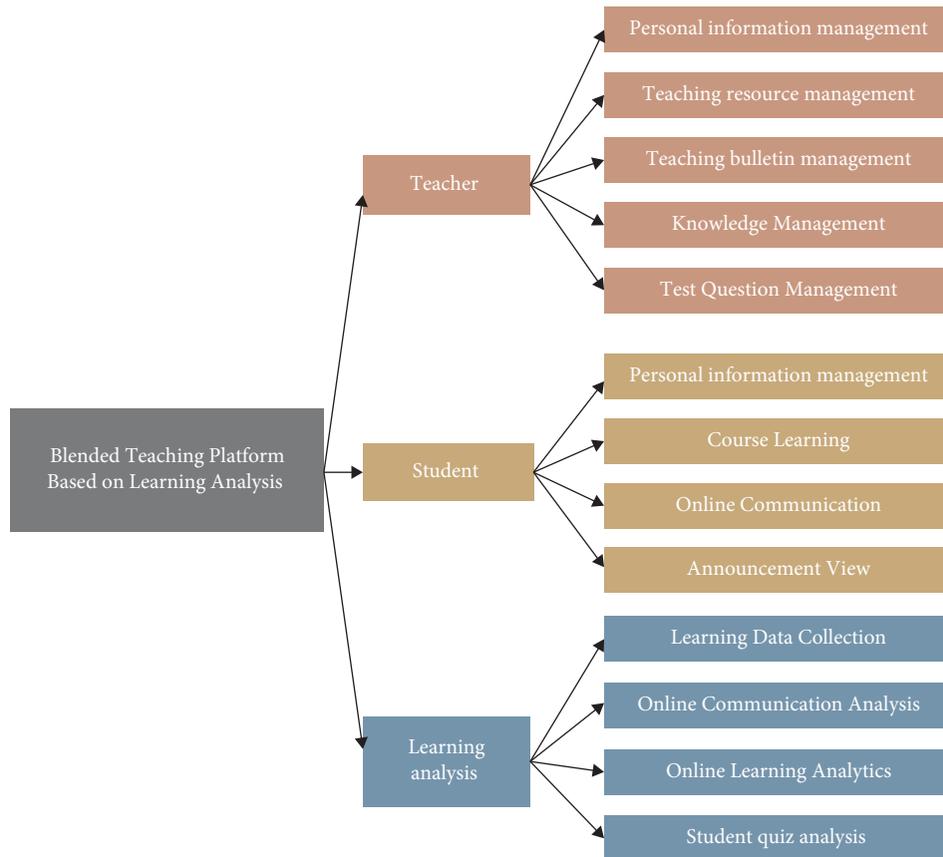

FIGURE 5: The system function diagram of this platform.

that it can better meet the standards related to the documentation of learning resources and can better meet the needs of scalability. In the beginning, the simplified system does not have much big data or perfect functions. In the subsequent use, the data need to be improved continuously, and the structure and functions of the system must also be improved, but the current data of the new teaching system structure has certain limitations, and the functions of the simplified system are relatively limited and must be upgraded only after manual intervention. The construction of the simplified system structure needs to learn the principles of design configuration before it can have perfect functions. The teaching support system can be better constructed in conjunction with the teaching content and can improve the system's functions to make it faster and more relevant.

With the development of artificial intelligence technology, data construction has become a new research trend. Building a simple teaching system includes rules and teaching cases, the system does not involve other cases, but it cannot be limited to the relationship between the data, but also can focus on upgrading the teaching system, education big data research constructs a cone mesh structure, this model has better internal modules and system as a whole, the platform is more good openness, avoiding some unreasonable construction. The study of educational big data can be more clear educational objectives, and clarify the design of teaching and learning, combined with the relationship

between the elements, can have more problem-solving ideas. Education big data integrates the teaching system, realizes the deduction problem, and can send the problem to the teacher actively, the teacher can study according to the learning environment, build advanced teaching logic thinking, promote the formation of advanced teaching architecture, can make the university have more scientific teaching system management.

5. Conclusion

This paper takes the reform of teaching mode of British and American culture courses in our university as the main research object and explores how to analyze teaching data and predict teaching behavior under the technical premise of "big data" background; how to build a blended teaching platform with data analysis function based on existing multiple online teaching resources; and explore and practice in the British and American culture courses that have been offered in our university. In addition, we will explore and practice in the British and American culture courses offered by our university to build a blended teaching model based on data analysis. The teaching method of multivariate mixed mode based on big data analysis is to teach British and American cultures to students. Unlike traditional instillation teaching, through the analysis of data, teachers can better follow the principle of students' subjective initiative in learning and conduct cultural teaching in a heuristic-

induced way. For example, in the knowledge question-and-answer session, teachers give representative keywords by constantly asking questions, and guide students to correct themselves and find answers themselves. At the same time, teachers consider the differences in knowledge acceptance among students, strictly control the process of cultural teaching, and ensure the implementation of effective cultural teaching activities. We will accelerate the integration and optimization of the resources of these courses, promote the development of theoretical and practical teaching of these courses, and improve the ability of students in related majors to solve practical problems.

Furniture is one of the most enduring items that children grow up with. However, there is a big gap between children's rapidly growing physical and mental needs and existing children's furniture. It is necessary to design children's furniture that is both interesting and multifunctional from the perspective of children's physiology and psychology. In the context of artificial intelligence, this paper applies the artificial intelligence design concept to the design of children's furniture and discusses the necessity and design principles of its application in the design of children's furniture from the aspects of society, children, and development trends.

1. Introduction

For modern residents with ever-increasing living environment requirements, it is also necessary to provide children with a living environment that is more in line with their physical and mental growth. After investigation, it was found that the central consumers of modern families tend to be children. Therefore, the proportion of furniture sales of series furniture specially made for children continues to grow, which has also attracted the interest of many manufacturers. However, the segmentation of China's furniture market is not enough, and the children's furniture market has yet to be developed [1]. According to relevant data, children with separate bedrooms and furniture account for about 10.2% of Chinese families, and about 45.6% of families want to buy furniture for children. China's furniture industry has a profound history, and its manufacturing theory system is also becoming more and more mature. However, as a rising star, children's furniture is still in its infancy in terms of design and R&D, and production and lacks a theoretical system with guiding significance [2]. In the early 1980s, furniture for children was designed and manufactured only by individual adult furniture manufacturers. Due to the lack of designers in the professional field, the finished

product is just a miniature version of adult furniture. It was not until 1998 that the production scale of children's furniture gradually expanded. With the continuous development of the times, children became the main group of consumers, and more and more manufacturers turned their attention to the children's furniture market. In 2001, children's furniture began to form an independent category separated from furniture design, formed its own design and manufacturing system, and gradually improved. At the same time, a number of local children's furniture brands have emerged in China [3].

Through the analysis of China's furniture market, the development situation of furniture designed for adults is relatively optimistic. Compared with adult furniture, children's furniture is still in its infancy. There are only a handful of designer teams specializing in the field of children's furniture. Secondly, the size of children's furniture does not take into account the physical and psychological development characteristics of modern children, and can only meet short-term use. Once again, it reflects the necessity of applying the concept of growable design in the design of children's furniture. In the article "A Preliminary Study on the Grow ability Design of Children's Furniture," the author Min Lihong [4] pointed out that because children are in the

stage of continuous growth, the fixed size of furniture cannot meet the needs of children's continuous physical and psychological growth, and should design a set of furniture that accompanies the growth of children. However, this study only discussed the growability of children's furniture from a shallower level and did not specifically and deeply study the growth characteristics of children at various stages and the changes in needs [5].

After the birth of a child in Western countries, parents have already prepared a children's room for the child. This way of parenting is very different from China. At the same time, the research on children's environment design and home furnishing design in developed countries started earlier, and the research on manufacturing and production and theoretical system research is also relatively complete and mature. In the United States, children's furniture pays more attention to personalized design. Modular furniture design and the concept of multifunction are also very mature [6]. Designers in some parts of Europe, on the other hand, pay more attention to safety, and their furniture pays more attention to environmental protection and health. In terms of materials, natural solid wood is often used. The focus of the design is firstly to understand children's physical and mental development needs, secondly to take children's behavior as a design guide, and finally to help children grow in a safe and comfortable environment, which also reflects the care for children's growth. Therefore, versatility, practicality, and flexibility have become synonymous with foreign children's furniture design. Flexibility means that children's furniture can be flexibly adjusted according to children's growth needs and grow with children [7]. It can be seen that foreign designers have also applied the concept of growth to the design of children's furniture. Although children's furniture rose early in Western countries and had relatively complete theoretical and practical foundations, the main research object is the physiological and psychological characteristics of Western children, which is not fully applicable to Chinese children. Moreover, the design thinking of the growth concept applied to children's furniture has not been systematically summarized and summarized. However, their design research methods and design ideas are still worthy of study and reference by Chinese designers and some local enterprises [8].

In the concept of biology, the word "growth" is summarized as the process of growth and maturation of living organisms from small to large. When "growth" is used as the guide of children's furniture design, it is understood that in the process of children's physical and psychological growth, children's furniture can make corresponding adjustments and improvements according to the changes in their growth, so as to meet the different needs of children, age period requirements [9]. In the article "Research on the Growable Design of Children's Furniture," Liu Bowen mentioned that the design of the growable includes two meanings: (1) *Intuitive Growth*. In order to meet the needs of children's growth, the scale of the furniture can be adjusted freely, such as the extension of length and width. Functionally, it can be extended and transformed according to children's different life states, such as life, learning, or time periods such as

games. The shape can be changed by adding, subtracting, or replacing parts according to the child's preference. Modular design is a good example. (2) *Indirect Growth*. This is a relatively invisible growth, not easy to detect. But this kind of growth has a subtle effect on children's physical and mental effects [10].

2. Research Ideas for the Subject

2.1. Definition of Research Objects. The term "child" in the United Nations Convention on the Rights of the Child refers to "any person under the age of 1, unless the law applicable to him stipulates that the age of majority is less than 10 years." In the development of psychology, there is a very important research feature, that is, age segmentation. Most psychologists agree that the development of people's lives in different age groups presents different rules, so the age-based research method has become popular and also has scientific rationale. American psychologist Robert Feldman divides it like this: prenatal period (fertilization to birth), infancy and toddler period (birth to 3 years old), preschool (3 years to 6 years old), middle childhood (6 years old to 12 years old), adolescence (12 years old to 20 years old), and early adulthood (20 years old to 40 years old), middle adulthood (40 years old to 60 years old), and late adulthood (60 years old to death) [11]. After reading the relevant psychological works, the author found that the views were recognized by most of the research scholars. The special research carried out from the age group can help the author to carry out the special research. According to the combination of children's growth characteristics and developmental psychology, this subject takes 3- to 12-year-old children as the research object. Because the age group of 0-3 years old is usually called infants and young children, they usually cannot take care of themselves in daily life, and the requirements for furniture are also different, and the age group of 12-18 years old is also called the juvenile chapter, which is a child at this stage. Children aged 3-12 are selected as the research objects, including between preschool and adolescence. There is a big change in the living environment of children at this age, and the center of life gradually shifts from home to school. For children, this stage marks the beginning of formal education, and in this stage, the physical and cognitive development is very obvious [12]. Changes in the status of children, changes in environmental pressure, and changes in the living environment make children's psychology take a qualitative leap. This stage is also an important period of personality development. The research on children at this stage is of great value in guiding the design of children's furniture. Therefore, selecting children at this stage as the research object and analyzing their physiological and psychological characteristics can provide an important basis for the design and research of children's furniture at this stage [13].

2.2. Research Methods

2.2.1. Document Law. We consult domestic and foreign monographs and periodicals on children's furniture design and children's physical and psychological growth such as

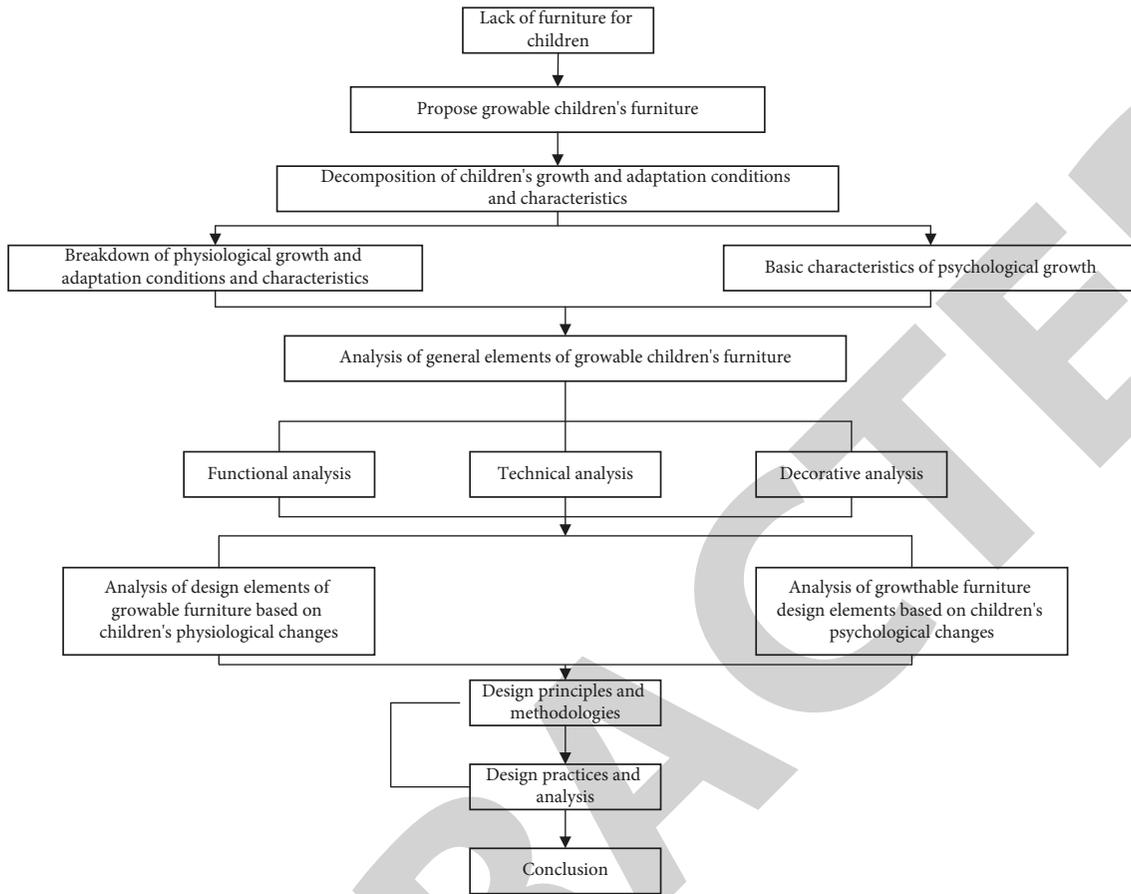

FIGURE 1: Research technology roadmap.

“Research on Contemporary Furniture Design Theory,” “Furniture Modeling Design,” “Introduction to Furniture Design,” and other monographs, as well as “Forest Products Industry,” “Decoration,” “Packaging Engineering,” “International Wood Industry,” “Wood Industry,” “Furniture” and “Interior Decoration,” “Furniture,” and other professional journals and professional websites such as Tiantian Furniture Network and Design Online.

2.2.2. Comparative Research Method. We compare different research objects and different themes to design research procedures and methods, and find out the basic ideas and methods of research. In the course of the research, the physiological and psychological characteristics of children in different periods were compared and analyzed to find out their different physiological and psychological characteristics at different ages.

2.2.3. Deductive Method. The connotation related to the design of the research object is deduced, and the content of the furniture design work is deduced according to the general principles.

2.2.4. Induction. Through the analysis of elements at different levels and different connotations, the basic principles

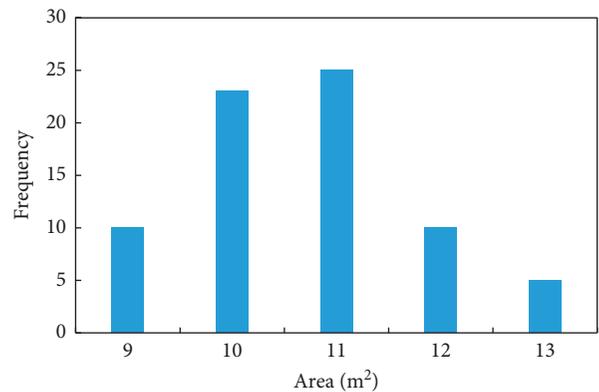

FIGURE 2: Histogram of indoor area of children's room.

and methods of the design of children's furniture that can grow are summarized.

2.3. Technical Circuit. The technology roadmap is shown in Figure 1.

2.4. Research on Children's Room Space

2.4.1. Survey on the Area of Children's Rooms. Here, bedroom refers to the living room. The so-called space is the area

where the specific things that the eyes can see and the hands can touch. The child's room space refers to the room where the child lives. In such an area, it can not only be used to place the furniture used by the child but also provide a certain activity space for the child [14].

Take an ordinary family of three with two bedrooms as an example, such a family will basically arrange a children's room. The area of children's rooms is generally not very large, and most of them are small bedrooms. When consumers buy furniture for their children, they generally configure corresponding furniture items according to the indoor area. Therefore, the small size of children's room should be considered as a constraint factor when designing children's furniture [15]. Through the investigation of the area of some children's rooms in a certain area, the following results are obtained as a histogram, as shown in Figure 2.

In Figure 2, we can see the area of children's room is mainly between 9 and 13 square meters, of which the small area of about 11 square meters occupies most of the room. That is, the space of only ten square meters is often a comprehensive activity place for children to rest, play, and learn.

The design of the children's room affects the child's character and the healthy growth of body and mind to a certain extent. For a small space, how to arrange the children's furniture reasonably and leave a spacious play space for them is a question worth considering.

2.4.2. Division and Layout of Children's Living Room Space.

The quality of the environment affects a person's growth, especially for children in early childhood. In their environment, only the children's room can be arranged and arranged by parents. So for the majority of small-area living rooms, how can a reasonable division and layout create a healthy and safe growth environment for children?

2.4.3. Functional Area Division of Children's Room.

Every young child will perform some essential activities in daily life, such as sleeping, dressing, learning, playing, and so on. According to the needs of these daily activities, we can divide the children's living space into five functional areas, namely, sleeping area—area for sleeping and resting; storage area—area for placing clothes and toys; learning area—area for reading and drawing; game area—area for building blocks and playing games; and communication area—area for communicating with friends. The following mainly starts from the necessity of each functional area, the environment required for the development of children's characteristics, and the cultivation of good habits, and conducts specific analysis and discussion on the above functional areas [16]:

Sleeping functional area: the sleeping area is the most important functional area in the children's room. Sleep plays a very important role in human life, especially for young children [17]. Good and adequate sleep quality is conducive to promoting the growth and development of young children and enhancing disease resistance.

The main piece of furniture in the sleeping area is the bed, the place where the toddler can rest and recover. Secondly, other auxiliary furniture can be added according to actual needs, such as bedside tables, which can be used to store books, dolls, etc. Excessive energy during the day makes it difficult for children to fall asleep at night. At this time, a quiet and comfortable environment is especially needed so that children can fall asleep early [18]. The layout of the bed should avoid affecting the sleep of children, such as doors, windows, and objects that stimulate children's vision, or place the bed in an area with weak light to create a good resting environment for children. In addition, parents should guide their children to form good sleep habits from an early age to ensure that children have adequate sleep [19].

Storage function area: children will inevitably have many clothes, hats and toys, so the children's room is inseparable from the necessary storage space. Since the children's room itself is not large in size and there are many types of toys, it is very necessary to allocate storage space reasonably. It can be classified and partitioned according to the needs of children's activities, which not only improves the activity efficiency but also makes the room beautiful [20].

Children like to throw and litter, which makes the originally small space more messy and disorderly. If you put a few activity storage boxes in the game area, you can not only summarize many scattered toys but also take them easily when playing. In addition, puppet toys can be placed on the clapboard at the head of the bed, which can be displayed on the one hand, and can be hugged to sleep when the child sleeps; and clothing items can be stored in a low closed wardrobe, preferably both at the same time. The multifunctional locker not only uses one thing for multiple purposes but also frees up more space for the freedom and comfort [21].

Learning functional area: when children are three years old, they will enter kindergarten to learn knowledge, and learning will become an indispensable part of their life. Therefore, there should be desks, chairs, and other reading and drawing areas in the children's room.

Early childhood is an important period for the development of speech and thinking, and the development of these mental abilities is closely related to the development of intelligence. Through various learning activities, a large amount of specific and rich knowledge and experience and a higher language level can be accumulated for children, which can promote the development of children's thinking ability and improve their cognition [22]. Attention in early childhood is dominated by highly developed unintentional attention, and it is easy to be attracted by bright and novel things. Therefore, the desk can be placed near the window to avoid objects such as beds and dolls that cause unintentional attention of young children; secondly, the height of the seat should be suitable for

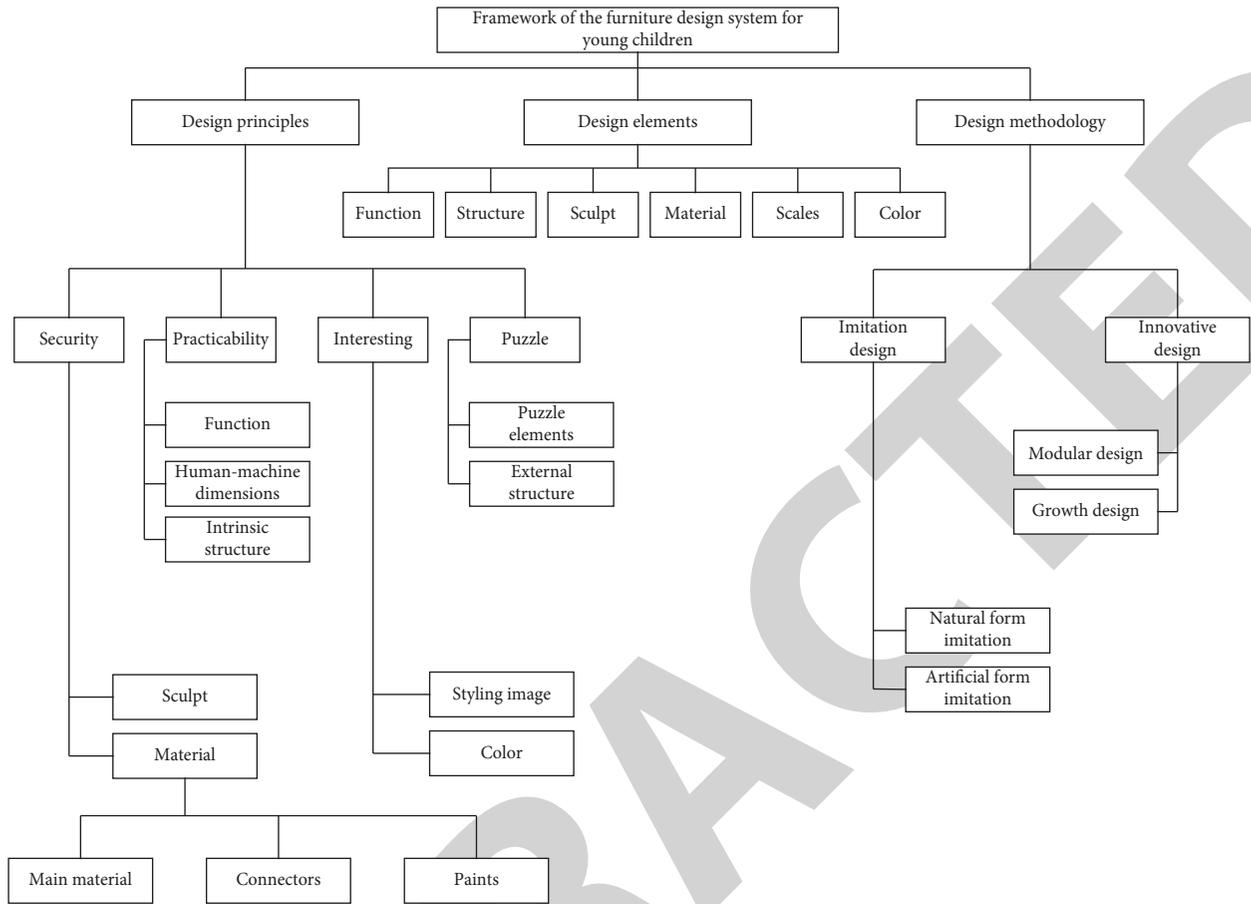

FIGURE 3: Framework diagram of children’s furniture design system.

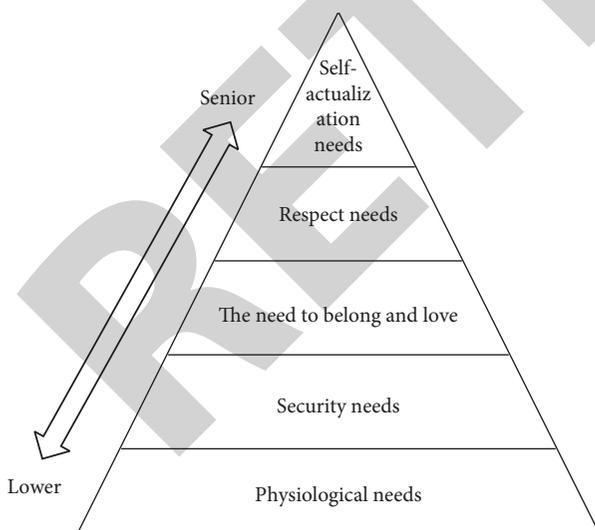

FIGURE 4: Maslow’s hierarchy of needs diagram.

children’s physical conditions, which is conducive to the formation of good writing posture and study habits. A table and chair with growth is a good choice. It can not only adjust the height to meet the growing needs of children but also prolong the use of furniture life [22].

Game function area: Mr. Chen Heqin, a famous educator in our country, said: “Children are born active, and play is their life.” Indeed, play is their most basic and favorite activity, especially for preschool children, the place to play is an integral part of life, so the extra floor space in the children’s room becomes the children’s play main venue.

The lively and energetic nature of young children makes the play area as regular and wide as possible to ensure the safety and comfort of the children’s play environment and avoid unnecessary bumps and squeezes [23]. The play area must be fun and beneficial so that children can enjoy themselves and promote cognitive development. Therefore, some interesting and educational toys can be prepared for young children, so that they can recognize the world around them while playing. In addition, the play area needs a certain storage space to store children’s various toys, such as toy storage boxes can play an excellent role, can be stacked and stored to keep the room in order, and toys can also be classified according to the color of the storage box, which is convenient for children to find. You can also arrange one or two storage boxes with pulleys for children, which can be packed as they play, which can better cultivate children’s good habit of timely storage and do-it-yourself [24].

Communication function area: if the indoor space of the children's room is sufficient, a relaxed communication world can be arranged for the children. This space does not need to be deliberately arranged. It can be a few soft cushions placed on the free ground, high and low steps, or a rippling swing. In this happy and comfortable little world, you can communicate happily with your partners, and you can also tell your parents about your heart and bring closer the parent-child relationship.

3. Establishment of Children's Furniture Design System Based on ABAQUS

Because of the guidance of mature theoretical knowledge, furniture designers have designed a large number of furniture products with unique shapes and different styles. The design of children's furniture started late, and the design system of children's furniture still needs to be improved and developed. The practice has proved that only with systematic and perfect theoretical guidance, it is possible to design good furniture products, and the same is true for children's furniture design. Figure 3 shows the frame diagram of the children's furniture design system.

3.1. Design Principles of Children's Furniture

3.1.1. Security. Safety is one of the indispensable design principles in product design, and it is also the first principle of furniture design for children. Products are designed for people, and ultimately serve people, to ensure that people are safe and pleasant in the process of use. If a commodity does not even have the most basic safety guarantee, no matter how good-looking it is, it has no real use value, and there is no market. In recent years, the safety of children's furniture has been frequently exposed on the Internet, TV, newspapers, and other media. The health and safety of children cannot be guaranteed, which makes parents feel confused and worried when purchasing furniture. In view of the safety problems existing in the use of children's furniture, some parents choose to buy it in advance, while others use thick and soft accessories to hide the places with potential safety hazards. The style turned to the safety and environmental factors of furniture to ensure that children grow up in a healthy environment. According to the current market research data, there are certain safety hazards in children's furniture mainly in terms of materials and shapes.

Figure 4 shows the schematic framework of Maslow's hierarchy of needs theory. Maslow puts people's physiological needs at the bottom, indicating that this is the foundation and guarantee of all human activities, and puts safety needs at the penultimate level, that is, on the premise of ensuring that people are fed, clothed, warm, and sheltered well, and people's safety will be the number one need. Scholars such as Xu Deshu have different views on this and especially believe that in today's world, Maslow's hierarchy of needs theory needs to be revised.

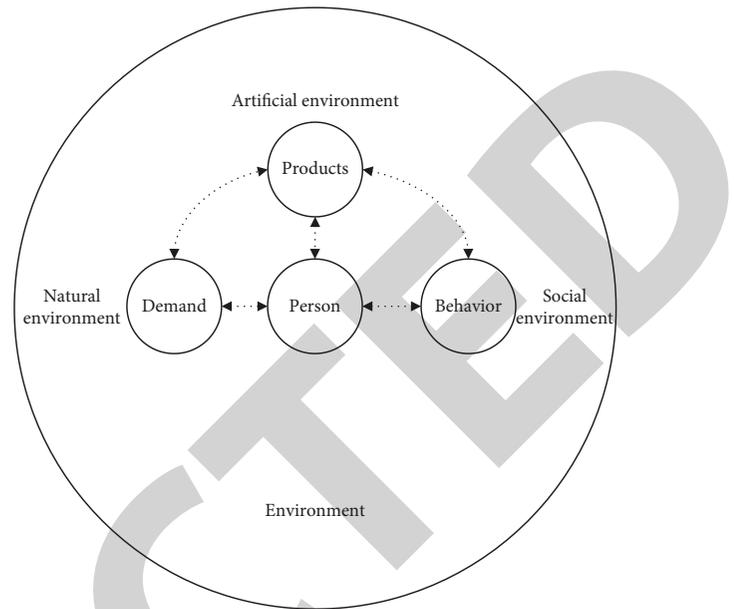

FIGURE 5: Complete human-machine system.

3.1.2. Practicality. Buying furniture for young children is not only about the aesthetics of the bedroom, but the practicality of the furniture is also very important. Here, practical means that the furniture must have a variety of perfect functions and ensure that the use of the furniture is maximized. For children in early childhood, furniture should first meet its own direct use, meet the physical and psychological needs of children, and be sturdy and durable, children's different use requirements, so as to create a comfortable and convenient environment for learning and life [9]. The practicality of children's furniture is mainly considered from three aspects: function, size, and structure.

3.1.3. Interesting. In addition to meeting people's basic functional needs, furniture should also reflect modern people's needs for visual and psychological aesthetics such as novelty, strangeness, and fun. Children are often curious about interesting things and yearn for beautiful and novel things. We can design interesting furniture according to this characteristic of children. The interesting design of children's furniture, generally through the use of imitation, abstraction, deformation, and other methods, reflects the things in nature and real life into the furniture, so as to satisfy children's curious childlike psychology, thereby bringing more happiness and surprises to children, to create a relaxed and happy living atmosphere. The fun of children's furniture can be reflected in the shape and color.

3.1.4. Intellectual Property. For young children, everything in the world is novel and interesting, and there is a lot of knowledge that they need to learn and master. According to child psychology researchers, 95% of young children can acquire more knowledge and skills in the atmosphere of the play. In early childhood, the main daily activity is games, and the furniture that accompanies them to grow

up will also become part of their entertainment games. It can be seen that furniture also plays a positive role in children's puzzle and inspiration. Early childhood is an important period in the development of various abilities in a person's life. At this time, children have a wide range of interests and hobbies, and their curiosity and thirst for knowledge are strong. It is the best and fastest period to absorb knowledge and learn various skills. Therefore, in the functional design of furniture, while the furniture meets the needs of children and the appearance is beautiful, we can fully consider how to allow children to acquire cognition, develop intelligence, and accelerate various intelligences in the colorful environment stimulation and simple and pleasant furniture operation, and the development of nonintellectual factors, such as attention, observation, spatial imagination, logical thinking, hands-on ability, hand-eye coordination, social skills, and so on. Young children are lively and active, their self-control is still in the developing stage, and they cannot keep a long focus on something or something. Therefore, in the process of furniture design for children, according to this characteristic of children, various knowledge, such as different shapes, colors, and numbers, can be subtly integrated into furniture products, and at the same time, the furniture should be full of interest, so as to stimulate children's interest and arouse their attention, and to cultivate their good habit of love to learn.

3.2. The Application of Ergonomics in Product Design. In product design, the most important point is to make the product match the physiological characteristics of human beings; otherwise, it will cause the product to be unsmooth and even cause harm to people. The significance of ergonomics for product design is as follows: first, it provides human-scale parameters for the consideration of "human factors" in industrial design. The study of ergonomics provides data such as human body structure scale, human physiological scale, and human psychological scale for product design to comprehensively consider "human factors," which can be effectively used in product design. The second is to provide a basis for the functional rationality of "products" in product design: how to optimize the various functions of "products" related to people and create "products" that are in harmony with people's physiological and psychological functions, and it is a new topic in the functional problem of today's product design. The third is to provide design guidelines for considering "environmental factors" in product design: by studying the human body's response and adaptability to various physical factors in the environment and analyzing the impact of environmental factors on the human body's physiology, psychology, and work efficiency. Figure 5 is a schematic diagram of the complete human-machine system.

The definition of safety ergonomics is an emerging discipline that uses the principles and methods of ergonomics to solve the safety problems of the human-machine interface from the perspective of safety. As a branch of the applied discipline of ergonomics, it takes safety as the goal

and ergonomics as the condition, an important branch. Human refers to the person who is active, that is, the security subject; machine is a broad sense, which includes labor tools, machines (equipment), labor means and environmental conditions, raw materials, technological processes, and other substances related to people.

Specifically, the task of safety ergonomics is to provide engineering technical designers with reasonable theoretical parameters and requirements for the human body, such as (1) the comfortable range of human work (optimal state); (2) the allowable range of the human body (guarantee work efficiency); (3) the safety range of the human body (minimum and environmental requirements that will not cause harm); and (4) how all safety protection facilities adapt to various human use requirements:

- (1) The research scope and content of safety ergonomics mainly include the following aspects:
 - (1) Study on the various characteristics of people in the human-machine system. The characteristics of people in the human-machine system refer to the physiological characteristics and psychological characteristics of people. Physiological characteristics include human morphological skills, static and dynamic human scales, human biomechanical parameters, human information input, processing, and output mechanisms and capabilities, and physiological factors for human operational reliability. Psychological characteristics include people's psychological process and personality psychological characteristics, people's psychological state during labor, psychological factors of safe production, and analysis of psychological factors of accidents. These characteristics are the basic theoretical part of safety ergonomics and the main basis for solving safety engineering technical problems.
 - (2) Research on the rational distribution of human-machine functions. The main contents of this research are as follows: the respective functional parameters of human and machine, the adaptability and the conditions for exerting their functions, and the methods of human-machine function allocation in various human-machine systems.
 - (3) Research on various human-machine interfaces. Human-machine interface is the field in which human-machine contacts or interacts with each other in information exchange or function. The main contents of the control human-machine interface research are as follows: the matching of machine displays device and human information channel characteristics, the matching of machine manipulator and human motion characteristics, and the matching of display and manipulator performance, so as to research different systems. For the tool-like human-machine interface with the largest number in the field of life and production, its applicability and comfort are mainly

studied, that is, how to make it match the shape function, size range, feel, and somatosensory of the human body. For the environment, it mainly studies the impact degree, threshold range and control methods of the physical environment, chemical environment, biological environment, and aesthetic environment of the operation on people. For special environments, it is also necessary to study the human life support system.

- (4) Research on operation methods and workload. The research on working methods includes the research on working posture, body position, force, working order, reasonable working tools and work card measuring tools, etc. The purpose is to eliminate unnecessary labor consumption. Workload research mainly focuses on the measurement, modeling (using simulation technology to establish biomechanical models of various operations), and analysis to determine the appropriate workload, work rate, schedule, and study work fatigue and its safety, production relations, etc.
 - (5) Analysis and research of work space. The main research is on the space range required to ensure safe and efficient operation, including the best viewing area for people, the best working area, the least assembly time, and the minimum safety protection range.
 - (6) Research on accidents and their prevention. According to a large number of foreign statistics, nearly 80% of accidents are caused by human error. Therefore, the research on accidents and their prevention is not only the foothold of safety ergonomics but also its fundamental purposes such as human factors, human error analysis, and preventive measures.
- (2) The application of ergonomics in the design of children's furniture:

In the design of children's room environment, it is necessary to consider its functionality from the perspective of ergonomic "human factors," furniture scale, and visual quality. In terms of furniture scale, children are small and grow quickly, so there are special scale requirements for the choice of children's furniture design. In the design of children's furniture, it should pay attention to the following issues:

- (1) The height of the furniture should be suitable for children, so that their hands can reach the things on it. For example, the height of the clothes rail in the wardrobe should be suitable for children to take it.
- (2) The doors and drawers of the cabinet should be easy to push and pull, and not too tight; otherwise, the child will lose interest; the size of the drawers in the wardrobe should also be in line with the child's usage habits.

- (3) Tables and chairs should conform to ergonomic principles, so that children can develop good sitting and lying habits. The discomfort caused by poor sitting posture and furniture will affect the healthy development of children. Flexibility is also a practical aspect. Children are always growing. When buying children's furniture, we pay attention to whether the furniture can be used continuously. The sustainable use mentioned here does not refer to the service life of a set of furniture, but to meet the needs of children in various growth periods, and will not lose practicality due to age. For example, you can choose desks and chairs that can be adjusted in height to suit the needs of children's growth.

4. Summary

At present, the children's furniture industry is still in an immature stage. The concept of artificial intelligence also needs to be continuously researched and summarized. The application of mature artificial intelligence concepts in children's furniture design is not only conducive to the development of children's physical and mental health but also to the cultivation of their creative ability, hands-on ability, and parent-child interaction, and communication has a certain promotion effect. The application of its concept in the design needs to start from the two aspects of children's body and mind. The design principles proposed in the article must also be based on the standardization of furniture and hardware components. Through the research on children's furniture design, the design theory of artificial intelligence concept provides a theoretical reference for the design of children's furniture. At the same time, in the future design of children's furniture, designers should consider how to improve the quality of children's furniture, reduce the cost of children's furniture that can be grown, and, from the perspective of children, to truly serve children and create for good living environment for them.

The comprehensive reasons for the cross-regional flow of enterprises in their own economy are studied in this paper. Most traditional enterprise migration research focuses on the impact of a single factor. Even the research on the influence of multiple factors often ignores the interaction of various factors. Therefore, this paper proposes and logicalises the “push and pull” mechanism of enterprise migration to address the limitations of previous research. Through bibliometric analysis and investigation, we systematically think about the factors that affect the corporate migration mechanism and improve the Push-Pull Theory. Besides, by deploying a conceptual system dynamics model, this paper explains how various factors affect enterprise migration. In addition, we discussed how to adopt systems thinking to promote the development of emerging economies. We selected and tested 6 companies that migrated in China, and the results are in line with reality. The conclusion supports the theory that systematic thinking and decision-making influence corporate behaviour.

1. Introduction

With the deepening of globalization, cross-border migration and investment of enterprises have become very common [1]. However, due to market orientation or cost orientation, many enterprises choose to migrate within their territory [2]. This situation has been increasing in emerging economies under economic transition in recent years [3–5]. The migration of enterprises in the country affects the flow of capital, personnel, and market structure change [6]. Therefore, it is essential and urgent to study the antecedents of enterprise migration when considering the impact on the overall regional economy.

The existing literature expands our understanding of the antecedents of enterprise migration from a single factor affecting enterprise migration [2, 7–11]. However, as a microeconomic system, the migration of enterprises is not affected by just a single factor but by a series of interactive economic factors [12]. The existing research has not considered the influencing factors of enterprise migration behaviour from the enterprise’s overall internal and external

environment, which is regrettable. On the one hand, it is common for enterprises to be affected by external factors (such as administrative orders) and internal governance structure, especially in emerging economies [2, 9]. For example, some enterprises in Dongguan City, Guangdong Province, China, have moved to Northwest China due to the combined effect of environmental protection regulation requirements and enterprise human resource costs. On the other hand, relevant studies show that the migration behaviour of enterprises has anthropomorphic characteristics at the same time, which is deeply influenced by corporate symbols such as executives [13]. Especially when the executive power structure is relatively centralized, relocation behaviour is usually affected by the executive team’s background. In the existing research, there is a lack of systematic consideration of the above factors [14].

1.1. Overview of Push-Pull Theory. In this study, to narrow the gap between the above theory and practice, we use system dynamics theory and high-level echelon theory for

reference to develop our theoretical model. At the same time, we build a Push-Pull theoretical model of the interaction between internal and external factors and finally explain the motivation system model of enterprise migration behaviour. Specifically, we believe that enterprises' choice of migration behaviour is affected by internal and external factors. The influence of these two parts does not act alone on enterprises' strategic decision-making but interacts with each other. We define this mechanism as the Push-Pull Theory. We explain the Push-Pull Theory model from three aspects: first, the external environment of the enterprise is constantly changing, which promotes or inhibits the migration of the enterprise; second, the internal environment of the enterprise is continually evolving, enabling the enterprise to change or driving the enterprise to maintain the status quo; third, the external environment of the enterprise interacts with the internal information of the enterprise, comprehensively promoting the enterprise to make migration decisions or driving the enterprise to maintain the current business strategy.

1.2. The Logic of Push-Pull Theory. We make a detailed theoretical analysis of the above three aspects. According to the organizational change management theory within the enterprise, there are two forces to promote organizational change and maintain the enterprise's current situation [15, 16]. We believe that the power to encourage organizational change is reflected in the process of enterprise migration, which represents the internal thrust of the enterprise; the strength of maintaining the current situation of the organization is reflected in the process of enterprise migration, which is expressed as the pull force within the enterprise. At the same time, we deduce the deeper mechanism of these two forces and the game process. Based on the high echelon theory, our theory holds that the senior management team, as the direct decision-maker of the enterprise, has a direct impact on the operation of the enterprise according to the signal transmission theory [17]. Therefore, the will of the senior management team plays a vital role in the internal decision-making of the enterprise [18]. Specifically, we believe that the top management team's attachment to the current location of the enterprise is a pull that hinders the migration behaviour of the enterprise [19]. At the same time, the yearning and pursuit of the top management team for the target location of enterprise migration is the thrust to promote the migration behaviour of enterprises. In such a "push-pull" game, enterprises eventually have a preference for whether to migrate internally.

Outside the enterprise, the macroenvironment has a significant impact on the enterprise, and our theory divides this influence into the dual effect of government and market [20]. In terms of the power of market entities on enterprise migration decisions, we use the Push-Pull Theory to supplement the commonly used "cost-profit" orientation theory [21]. Different positions of enterprises in the market affect their decision-making, which is reflected in market share, upstream and downstream bargaining power, and so on

[22]. However, the ultimate goal of enterprises is to achieve greater profits. In the market environment, the overall industrial development represents the difficulty for enterprises to obtain profits [22]. With mature development and close to perfect competition, enterprises will face lower entry costs and smaller profits in the market and industry. In unknown or immature markets and industries, enterprises face more significant development costs and higher profits. We believe that cost and profit will become an important reason to drive or hinder enterprise migration [23]. At the same time, we also include exogenous factors not considered in traditional theories, such as the overall market prospect and market public opinion environment, into the Push-Pull Theory [19, 24]. We believe that these exogenous factors will promote or hinder migration with a multiplier effect. The power of "push" and "pull" is more direct in the impact of the government on the decision-making of enterprise migration. The government's influence on enterprises due to compulsory policies such as environmental regulation is the "push" power of enterprise migration [25]. The government's tax preference and financial support are the "pull" power of enterprise migration [26]. The interaction between the push power and pull power constitutes the external constraints of the government on enterprise migration. According to the theory of new structural economics, the influence of government and market on enterprises is not acting alone, their mechanism of action is dynamically related to the social context [27, 28]. We incorporate this relationship into the Push-Pull Theory to explain the game impact of two factors on enterprises. Due to the resource endowment and resource allocation, the market will guide the agglomeration and migration of enterprises. To optimize the allocation of regional economic structure and achieve some noneconomic objectives of the government, the government will use government authority, such as administrative regulation and tax guidance, to enable enterprises to achieve agglomeration and migration [9]. However, when the market fails to realize the authority appeal of the government, the administrative regulations of the government will affect the location choice of enterprises in a way contrary to market forces. For example, high-polluting enterprises in China's coastal areas will migrate to inland areas with high costs and small profits due to environmental protection regulations [29]. Market tax is the cornerstone of government finance.

Furthermore, governments can use market taxation as a powerful tool for environmental regulation [29]. However, when the government's administrative regulation affects industrial development to a certain extent, the government's authority will be weakened. Then the government will reduce the restrictions on companies' migration behaviour. The game between government power and market power will promote or pull the migration of enterprises in the form of environmental impact.

The above two internal and external factors will also produce a "push-pull" effect inside enterprises. Due to the association between the internal senior management team and government personnel, the government has a direct impact on the production factors such as tax preference and

land rental of the enterprise and promotes the internal migration intention of the enterprise to the place where the government is located [30]. Moreover, the market has a more direct impact on the inner mood of the enterprise. First, the market cost and the profits obtained by the enterprise in the current regional market are relatively transparent, and the development prospect of the enterprise's industry in the current regional market is also relatively transparent, which will directly or indirectly promote or stimulate the generation of internal decisions of the enterprise migration. The "narrative economic theory" discusses the influence of market emotion and narration on the people [31, 32]. We extend this influence to enterprise decision-making and improve the Push-Pull Theory. Specifically, we believe that the market public opinion environment will trigger the emotional fluctuation of the enterprise's senior management team. Because the senior management team is not an entirely rational person, this emotional fluctuation will affect the enterprise's decision-making to a certain extent [33]. Therefore, we have made a relatively complete explanation for the Push-Pull Theory.

1.3. Push-Pull Theory and Reality Connection. There are three reasons why this paper chooses China as the actual comparison of the model construction of this paper. These three reasons can prove that our research has practical significance. Cross-border mergers, acquisitions, and corporate migration are becoming more common. This trend is closely related to the development of information technology [34]. The migration trend of multinational enterprises is constantly active and has attracted the attention of academic circles. However, different from the cross-enterprise migration, the cross-regional migration of enterprises in their own country has the same beginning as the migration of multinational enterprises. Still, its internal logical mechanism and migration process is different. As the largest developing country, China has a large geographical area and different degrees of development. The cross-regional migration of enterprises is in line with the goal of global enterprise migration from resource allocation. However, in terms of internal motivation, due to the convergence of Chinese culture, it also meets the characteristics of domestic enterprise migration in a general sense [35]. At the same time, China has a perfect industrial chain, and the domestic migration needs of Chinese enterprises are different from the migration demands of traditional multinational enterprises seeking to embed themselves into the international industrial chain. At the same time, due to the advantages of the whole industrial chain, Chinese enterprises consider more the conditions of government and market economy in migration and make more rational and wise decisions to adapt to the ecosystem. This decision-making consideration is from the enterprise itself, considers the industry and social development, and may contribute. As China's economy is undergoing transformation and enterprises are also experiencing the process from initial development to digital production, this creates much space for enterprises to migrate and seek better development [36, 37]. Some studies

show that the migration behaviour of domestic enterprises in China has become active in recent years [2].

Second, China has a vast geographical area, in which the degree of economic development in each region is uneven. At the same time, due to different considerations, local governments provide various policies for different types of enterprises, which creates excellent and low-cost conditions for enterprise migration [38–40]. By observing and analyzing the choice of enterprises under different conditions, it is found that the decision of enterprise migration in different countries has different meanings. For emerging economies such as Southeast Asia, learning from China's experience is helpful to realize the optimal allocation of domestic resources. For developed economies such as the United States, the migration process plays a guiding role in attracting overseas enterprises to return and the migration of domestic enterprises [41–43]. For example, the investment and establishment process of the Chinese enterprise "Fuyao Glass" in the United States is similar to the enterprise migration mechanism studied in this paper. This paper hopes that this research will make academic contributions to the realization of "Reindustrialization" in the United States.

Third, the existing research on the antecedents of enterprise migration mainly focuses on a single factor and few studies on the antecedents of enterprise migration from a comprehensive and dynamic perspective.

1.4. Possible Contribution of Push-Pull Theory. This study has made marginal contributions to the antecedents of enterprise migration and the application of new fields of system dynamics. Firstly, this study constructs a dynamic Push-Pull Theory affecting enterprise migration. In recent years, the literature mainly analyzes the enterprise migration behaviour from the perspective of "benefit-cost" from enterprises. Related to this kind of literature, we focus on enterprises' decision-making under the influence of internal and external environment and find that enterprises' migration behaviour is a dynamic decision-making process rather than a simple element in the market-oriented dynamic decision-making, which is a discovery about enterprises' migration behaviour. Secondly, this research combines the method of bibliometric analysis with systematic thinking. By doing so, we ensure that the internal and external factors affecting enterprise migration are as comprehensive as possible to analyze the migration behaviour of enterprises in line with reality. Finally, this research analyzes the help of systematic thinking and decision-making for the government and enterprises through the systematic discussion of government policies and enterprise policies.

1.5. Introduction to Each Part of the Paper. In order to report our findings, this paper is organized as follows. In the introduction part, our theory is proposed and logicalised. This discussion about our theory is not only based on practical considerations but also based on classical literature and theory. Section 2 conceptualizes our theory in the form of index summary. These selected important indicators come from important literature. Therefore, in this part, this paper reviews the literature related to enterprise migration

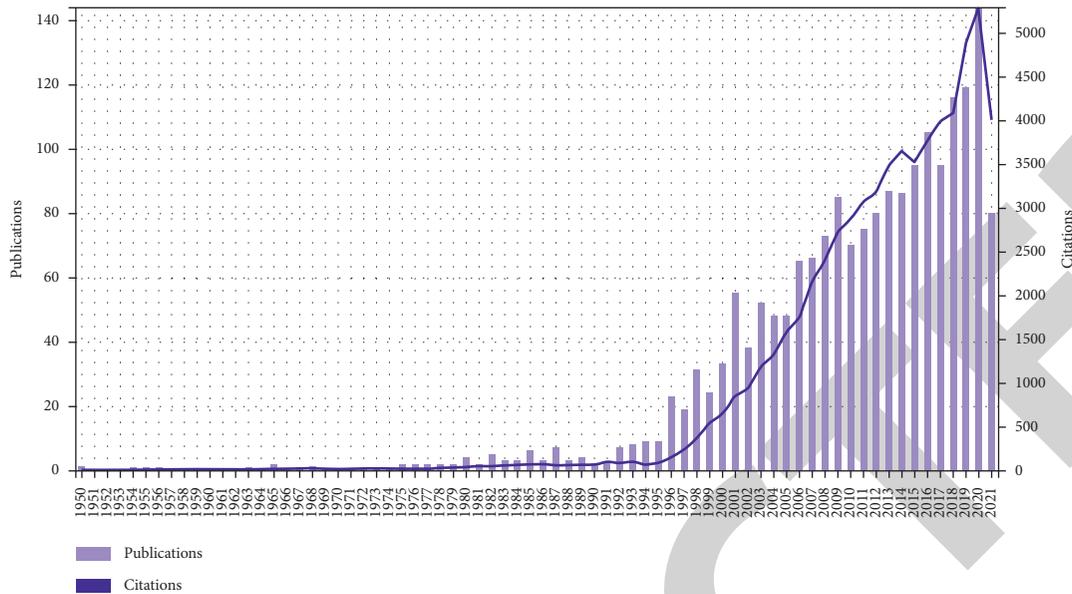

FIGURE 1: Thematic research trend chart.

behaviour on the basis of literature measurement. Section 3 systematizes our theory through the system dynamics model. The causal relationship between each indicator element is analyzed and displayed in this part. Section 4 discusses our theory in reality. This part discusses the policies that the government may adopt and their impact and how enterprises can make better development by means of relocation. In addition, we discussed how to use systematic thinking to promote the development of emerging economies.

2. Theoretical Background and Literature Review

2.1. Data Collection and Research Trends. This paper takes the core database in the Web of Science as the source for literature retrieval. To ensure the total quantity of literature collection, this paper selects “article” and “conference paper” and searches the literature with the theme of “firm migration.” After deleting irrelevant information documents, 1513 core documents with the theme of “firm migration” from 1996 to 2021 were obtained. On this basis, this paper analyzes the research trend of enterprise migration behaviour. Figure 1 shows the research trend of enterprise migration behaviour from 1996 to 2021.

As shown in Figure 1, the trend of enterprise migration behaviour research is on the rise. After 2017, the research enthusiasm continues to rise. In 2020, the number of researches on enterprise migration has increased significantly month on month compared with 2019, indicating that the research on enterprise migration behaviour is currently in the field of hot academic topics.

2.2. Literature Cocitation Analysis. The research network of scientific research citation is the knowledge base of scientific research. The cocitation clustering of Cite-Space literature can reflect the frontier of discipline research. At the same

time, the cocitation paper can explain the high academic value of the article. The following literature collection of this paper will start with the factors affecting enterprise migration adopted in the cocitation contribution.

As shown in Figure 2, the cluster is named by the LLR algorithm. Among the cocitation clustering, there are seven categories with more than 25 pieces of literature. We analyzed the seven cluster pieces of literature and collected and sorted the top 100 cited pieces.

2.3. Literature Review and Index Selection. The location of economic activities has been a concern by scholars since its birth. Previous studies mainly provided three methods: neoclassical, behavioural, and institutional [44]. Neoclassical method believes that the location of enterprises for economic activities is based on the strategy of profit maximization and cost minimization. The behavioural approach holds that the motivation of enterprise migration is to better deal with imperfect market information and market uncertainty. Unlike the neoclassical method, the behavioural method believes that the decision-making process of business owners is based on noneconomic factors. The institutional approach holds that, in the process of enterprise location selection, we should not only consider whether the economic environment of the location is suitable for the development of the company but also consider the institutional environment of the location, for example, customers, suppliers, trade unions, regional systems, and government.

At present, the research on the antecedents affecting enterprise migration behaviour generally believes that three groups of main factors affect enterprise migration. They are internal enterprise characteristics, site characteristics, and regional characteristics [12]. Through these three factors and the internal characteristics of enterprises, we consider the site characteristics and regional characteristics of enterprises’ moving places and moving places. This research idea is to

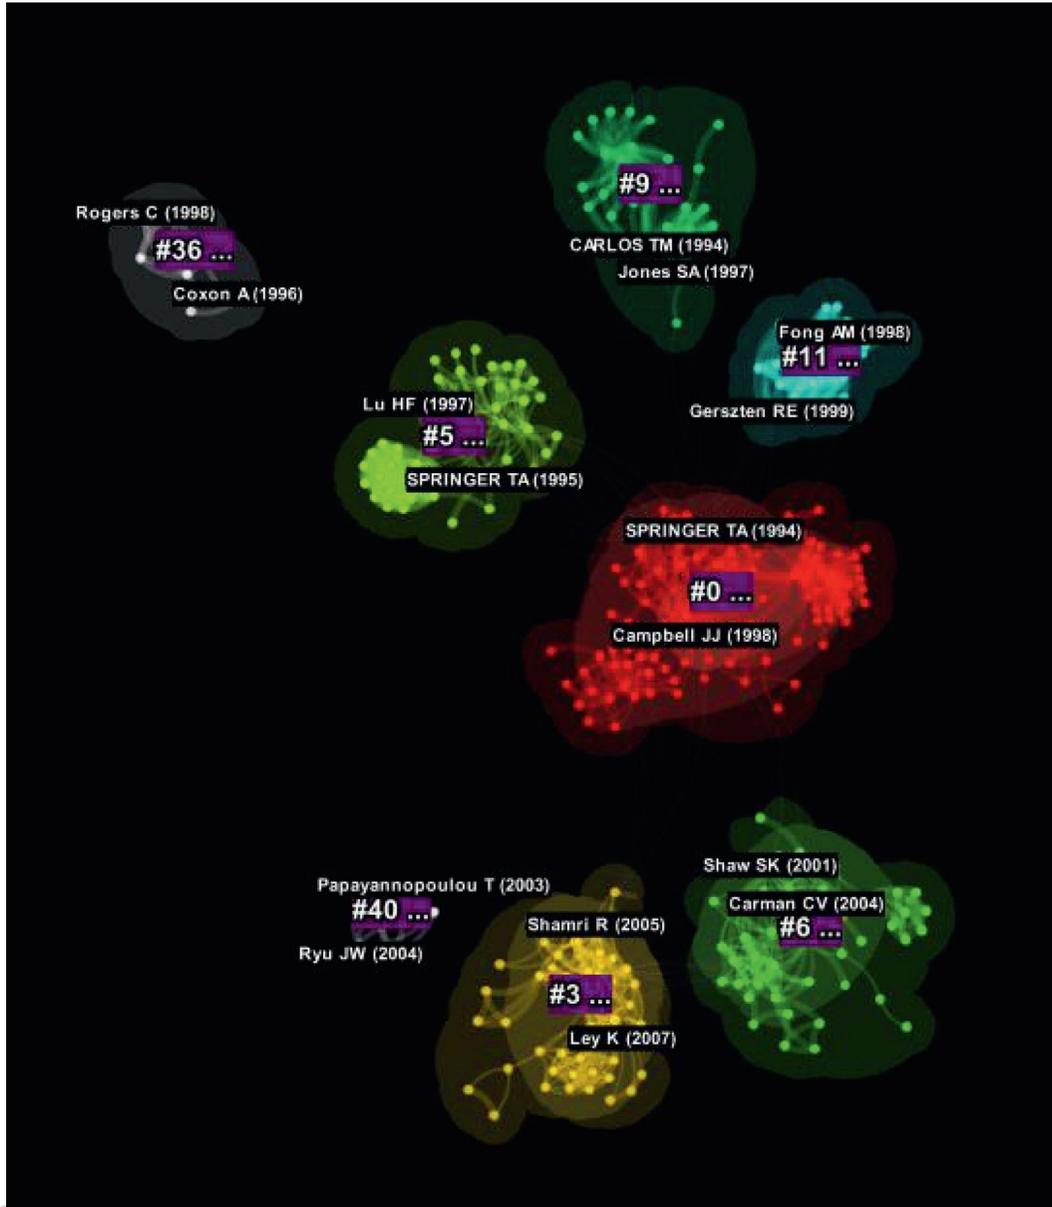

FIGURE 2: Literature clustering results.

expand institutional methods, which comprehensively consider the influencing factors in enterprise migration.

The neoclassical research viewpoint about how relocated enterprises determine where to move in is generally accepted. Economic factors will affect the migration of enterprises. While integrating the institutional approach into the research, the existing research [11] believes that the policy elements under regional characteristics will affect enterprise migration. For China, an emerging economy with a strong government call, it is more important to consider the impact of policies. Previous studies have shown that the main factor of company relocation is the internal characteristics of the enterprise. Specifically, it is mainly due to the lack of expansion space and the personal factors of business owners [45]. Therefore, when introducing the Push-Pull Theory and considering the internal factors of enterprises,

this paper analyzes the internal characteristics of enterprise migration through the interaction and game between considering enterprise development strategy factors and considering enterprise owners' emotional factors.

2.3.1. External: Economic Market Indicators. Firstly, we review the literature and select the indicators related to the economic market in enterprise migration. Some studies show that [46], in the process of overall migration, enterprises will first analyze the current economic level in the region and the economic level in the target region and target to bring their industries into the macroeconomic level to evaluate their industrial development. In the case of enterprise move, the factors that promote the decision to relocate are mainly related to the enterprise's performance

indicators. The consensus that explains the location and relocation of enterprises is that enterprises often look for the most profitable location for relocation and give up their current location. In previous studies [10, 45–49], the relocation behaviour of an enterprise can be conceptualized as a trade-off between the expected cost and expected benefit of the new location compared with the current location. We accept this consideration and fully consider the cost and expected income of the enterprise. In terms of enterprise cost, land cost, raw material cost [50], labor cost, management cost, and transportation and logistics cost [45] in the business process of enterprises are regarded as essential costs in the traditional perspective. We also consider the two costs considered in the new enterprises that attach importance to innovation: the degree of information, technology circulation and the degree of talent activity [12]. When making choices, enterprises should consider the cluster effect caused by the agglomeration of other enterprises. The impact of agglomeration externality on enterprise cost mainly lies in the scale benefits of the cluster allocation of resources and its contribution to the high production process of competitors [10]. We consider the degree of this industrial cluster. Previous studies on industrial agglomeration have been very mature. The positive externalities caused by the spatial concentration of companies in the same industry and the interdependence between companies in different industries are often taken into account in relocation research [51]. Predecessors used various specialization and diversity indicators to capture the externalities caused by agglomeration. See the studies by Groot et al., Mameli et al., and Hong for an overview [52–54]. In previous studies, it is generally believed that the agglomeration has a one-way impact on enterprise decision-making. We believe that the benefits brought by industrial clusters lie in the production cost of enterprises. Due to the accumulation of enterprises, it also reacts to the industry, promotes the full development of the industry and market opening, and improves the degree of complete market competition. In the open market, the market public opinion environment tends to be good [55]. At the same time, due to the increase of industrial enterprise clusters, the cluster externality and strategic interaction between enterprises are increased. For the enterprise, the overall industrial supporting degree is improved, and the market is promising for the industrial market in the region [56].

2.3.2. External: Policy Indicators. We review the literature and select indicators of policy-related influencing factors in the process of enterprise migration. It is found that land rent has an essential impact on enterprise agglomeration and enterprise migration (geographical location spillover). Similarly, land preference is also a form of land rent reduction in China. At the same time, in the development of enterprises, to reduce their costs, they pay great attention to tax and credit (see the studies by de Mooij and Ederveen's literature review in 2003) [57]. In China, due to the different preferential tax policies issued by various regions, the impact on enterprise migration is also different. Most of China's banks and other financial institutions are owned by the state.

Their credit payment level is closely related to the local government's policies, which also affects the financial support of enterprises. Worldwide, the openness and transparency of government are essential for enterprises. Recent research on the investment of Chinese enterprises in Cambodia shows that [58] the Cambodian government has an inhibitory effect on the degree of market opening and reduces the desire of enterprises to invest locally due to corruption and other acts. For China, due to the different attitudes of local governments toward investors, they have different administrative efficiency in the face of the relocation demands of relocated enterprises, affecting the operating costs in the process of enterprise relocation and constituting different operating environment characteristics. At the same time, in addition to practical considerations such as space scale [59], the Chinese government has strict restrictions on whether enterprises can enter the local area due to factors such as environmental regulation and total factor productivity. These restrictions together constitute a level playing field in the local market. Generally speaking, the government constructs the hardware environment and cost of local enterprise clusters through investment, credit, land rent, and other dimensions, restricting the migration of enterprises through policy regulation, environmental regulation, access approval, and other methods. These "push" or "pull" play a regulatory role in the development of enterprises. Together, they constitute the policy environment for enterprises to move in and out.

2.3.3. Interior: Strategy. The enterprise's strategy is essential in the choice of location. The role of internal factors is well known in the literature on relocation. In particular, Sleuwaegen and Pennings [50] found that older companies are more integrated into their spatial environment and therefore show less mobility behaviour. Other empirical studies have also confirmed this characteristic [60]. Generally speaking, the essential strategy of enterprises lies in profitability. The profitability of enterprises promotes the growth of enterprises and finally realizes the promotion of enterprise scale. Company size is another crucial factor affecting relocation costs and organizational tasks, which will affect relocation tendency [59, 61, 62]. In particular, because these problems are significant for large companies, the more the employees, the lower the mobility tendency [11]. At the same time, recent studies have found that enterprise size has an important impact on enterprises' overseas investment. After considering the external financial indicators of the enterprise, we found that the enterprise's decision-making has the characteristics of "personification." For example, previous studies found that the tertiary industry companies, especially commercial services, are more "loose" [51, 61, 63, 64]. The degree of enterprise internal control effectively promotes the perfection of the enterprise decision-making process, especially in the significant behaviour of enterprise migration. According to the signal transmission theory, enterprises' perfect information disclosure will release good signals to the market and promote the popularity of enterprises. Due to government policy, environmental protection regulation, market public opinion supervision, environmental

protection, and social responsibility performance are also considered in the enterprise migration behaviour. At the same time, another enterprise feature that affects the relocation choice is the industry [51]. When the enterprise creates and upgrades, it will tend to the area where innovation factors gather, but when the enterprise's industry concentrates on the industrial chain, it will tend to the developed areas of the supply chain [64]. The strategic decisions of the enterprise for different objectives jointly promote the migration decision-making output of the enterprise. We analyze the game of the enterprise's internal strategy through the explicit indicators of the enterprise and deduce the "push-pull" game process.

2.3.4. Interior: Executive Behaviour. In the traditional research on enterprise migration behaviour, it is considered that enterprise migration is entirely rational. However, in the research process of enterprise migration, Chinese scholars bring the branding theory into the research field of vision and find that the migration behaviour of enterprises has a particular location preference. There is evidence that certain aspects of the living environment, such as cultural and natural facilities [65], make specific locations more attractive to companies. We use the Push-Pull Theory to construct this irrational decision-making process within the enterprise. Specifically, the preference of business owners or decision-making teams for particular locations in enterprises is the pull of enterprise migration.

In contrast, the "strangeness" and maladjustment of business owners or decision-making teams to the current environment are the thrust of enterprise migration. Specifically, this location preference is related to the adventurous spirit of business owners and local complexes. According to the high echelon theory, enterprises are affected by the decision-making behaviour of senior managers [66], which is quantified by the characteristics and background of senior managers [67]. In China, an emerging economy, many business owners and managers leave their original areas to seek higher salaries and more promising development prospects. At the same time, the cultural background of different regions has different effects on managers' behaviour and decision-making, which plays an essential role in China's enterprise migration and investment cases. For example, some managers in Fujian Province of China choose to establish manufacturing factories in their birthplace because they can attract the capital of returned or overseas Chinese with their hometown geographical advantages. This influence is primarily reflected in the executive education experience [68]. At the same time, as the current situation, many managers choose to operate in areas away from their original regions, which is related to the managers' adventurous spirit [69]. At present, the overseas background of executives is widely used to quantify the adventurous spirit of executives [70]. In the nonnative place, the enterprise managers pull enterprise migration out of their attachment to the native environment. In the original place, enterprise managers yearn for a better market environment, resulting in the pull of enterprise migration.

The Push-Pull Theory in two different situations constitutes an implicit expression of the internal migration

choice of the enterprise. We attribute this expression to the "push-pull" interaction between the "adventure spirit" of the enterprise background and the "local complex" of the enterprise background. On the explicit background expression of enterprise internal decision-making, we mainly build a Push-Pull Theory through the "rationality" and "sensitivity" of enterprise managers' decision-making to demonstrate the manager's straight game behind the explicit enterprise decision-making. Precisely, executive power will determine the degree of decision-making in the enterprise, which is determined by the executive team, which is very important for the migration behaviour of the enterprise. The excessive power of the top management team will make managers have overconfidence [71], which will have a short-sighted effect when managers make decisions [72], thus affecting rational judgment [73].

The existing research on relocation decision-making of enterprises generally believes that the academic background of executives encourages executives to take more rational considerations in decision-making output. This allows companies to consider market conditions and corporate social value when making relocation decisions rather than rely on personal preference. The interweaving of rationality and perceptual feelings among the senior management makes the management team face the "push and pull" of internal changes when deciding to relocate. At the same time, we consider that executives' political background, overseas background, and education experience all have an important impact on executives' behaviour. We believe that executives and the government of the region where the enterprise is located have a political background, which will create a pull to hinder enterprise migration due to branding theory and rent-seeking behaviour. However, the political background that senior executives do not have with the target location's local government will push the enterprise migration. This game of "push-pull" forces plays moderating effect in enterprise decision-making. We have also fully considered selecting indicators to ensure that they align with reality and academic reality.

3. Establishment of System Dynamics Simulation Model

3.1. Model Conceptualization. The system boundary is determined in the following ways. The system behaviour of system dynamics research is based on the interaction of internal factors of the system [74]. It is assumed that the system behaviour is not affected by the changes in the system's external environment and is not controlled by internal factors of the system. Therefore, the system boundary is to determine which indicators should be taken into account in the model. Within the boundary, all indicators related to the research conceptual models and variables crucial to emotional problems should be considered; on the contrary, those concepts and variables outside the boundary should be excluded from the model. Our boundary is determined as the composition of the above-screened variables.

Based on determining the boundary, we carry out a causal analysis. The research of system dynamics focuses on

the system dynamics of the self-feedback mechanism. To study the feedback structure of the system, we have to first analyze the relationship between the whole and part of the system, tracing the causality and mutual relationship and reconnecting the variables to form a loop. In system dynamics, we often use a causality diagram to show the loop and analyze the factors and events in the enterprise relocation behaviour with various cause-effect diagrams, flow charts, and tree structure analysis diagrams.

For our system, we use the following causal loop to analyze the relationship between various variables. We believe that the variables we select guide the enterprise to generate behaviour through causality. We divide this guidance process into four subsystems, and their relationship is shown in Figure 3.

In the economic subsystem, there is such a relationship. Land, labor, management, transportation, and logistics costs will hinder the development of the industry to which the enterprise belongs. It should be noted that there are many similar cost factors, and we only select some more important ones for representative demonstration. Similarly, rich raw materials, timely information and technology, promising talents, and an open market can promote the enterprise's industry. As a critical element, innovation ability plays a similar role as a catalyst in a regional economy. Therefore, we will build a separate dimension for the relevant variables to promote enterprise innovation, and it will play a moderating effect. The number of colleges and universities, science and technology investment, and education economy in the region-cost input and the number of employees in high-tech industries can play an essential role in the vitality of industrial innovation. At the same time, the innovation industry will be widely concerned for it is closely related to the market public opinion environment. All these factors are significantly associated with the overall economic level of the region. Regional industrial development level and regional economic level of regional inequality are cause and effect. This relationship is shown in Figure 4.

We express this causal logic according to the following formula:

$$\begin{aligned}
 & \text{regional industrial development level} \\
 & \quad \rightarrow \text{degree of market openness} \\
 & \quad \rightarrow \text{positive market public opinion} \\
 & \quad \rightarrow \text{industrial development assistance} \\
 & \quad \rightarrow \text{regional industrial development level,} \\
 & \text{industrial development assistance} \\
 & \quad \rightarrow \text{degree of industrial cluster} \\
 & \quad \rightarrow \text{degree of industrial supporting} \\
 & \quad \rightarrow \text{regional industrial development level} \\
 & \quad \rightarrow \text{degree of market openness} \\
 & \quad \rightarrow \text{favorable market public opinion} \\
 & \quad \rightarrow \text{industrial development assistance.}
 \end{aligned} \tag{1}$$

There is such a relationship with the subsystem of government policies. Due to the outstanding macrocontrol ability of the Chinese government, we pay attention to the policy ability in China. The government will directly impact the production cost of enterprises through land rent preference and tax preference. At the same time, the government will set up an industrial guidance fund. Through credit support, it will affect the technology and finance index of the region, thus affecting the financing cost of enterprises. These measures will be directly reflected indirect or invisible industrial inputs. The result of these industrial inputs is the industrial supporting facilities in the government's location, thus affecting the overall production infrastructure and environment. The government sets negative clearing for enterprises in some industries. It has a poor business environment due to its corruption and rent-seeking, which hinders the improvement of the fair competition environment index. Government administrative efficiency plays a regulatory role in this cause and effect. This relationship is shown in Figure 5.

We describe the causal logic of the policy dimension according to the following formula:

$$\begin{aligned}
 & \text{business environment index} \\
 & \quad \rightarrow \text{fair playing field index} \\
 & \quad \rightarrow \text{administrative efficiency} \\
 & \quad \rightarrow \text{the level of improvement of regional policies} \\
 & \quad \rightarrow \text{business environment index,} \\
 & \text{business environment index} \\
 & \quad \rightarrow \text{tax preference} \\
 & \quad \rightarrow \text{government investment in industrial parks} \\
 & \quad \rightarrow \text{government industrial supporting facilities} \\
 & \quad (\text{degree of perfection}) \rightarrow \text{infrastructure index} \\
 & \quad \rightarrow \text{regional policy supporting index} \\
 & \quad \rightarrow \text{the level of improvement of regional policies} \\
 & \quad \rightarrow \text{business environment index.}
 \end{aligned} \tag{2}$$

Internally, we also consider the enterprise strategy subsystem. From a financial perspective, enterprise profitability will directly affect enterprise growth. The enterprise growth process is reflected in the enterprise's existing scale, and the enterprise scale supports the enterprise's investment strategy. These investment processes affect the enterprise's spatial distribution strategy, such as the establishment of branches. At the same time, in the capital market, due to the theory of signal transmission, the investment strategy of enterprises also interacts with the popularity of enterprises. The interaction between enterprise internal control and governance and enterprise popularity affects enterprise information disclosure in the explicit social dimension. The existing studies generally believe that enterprises with better information disclosure systems will better fulfil their social responsibilities. In space, on the other hand, corporate behaviour is closely related to social responsibility and social value. This relationship is shown in Figure 6.

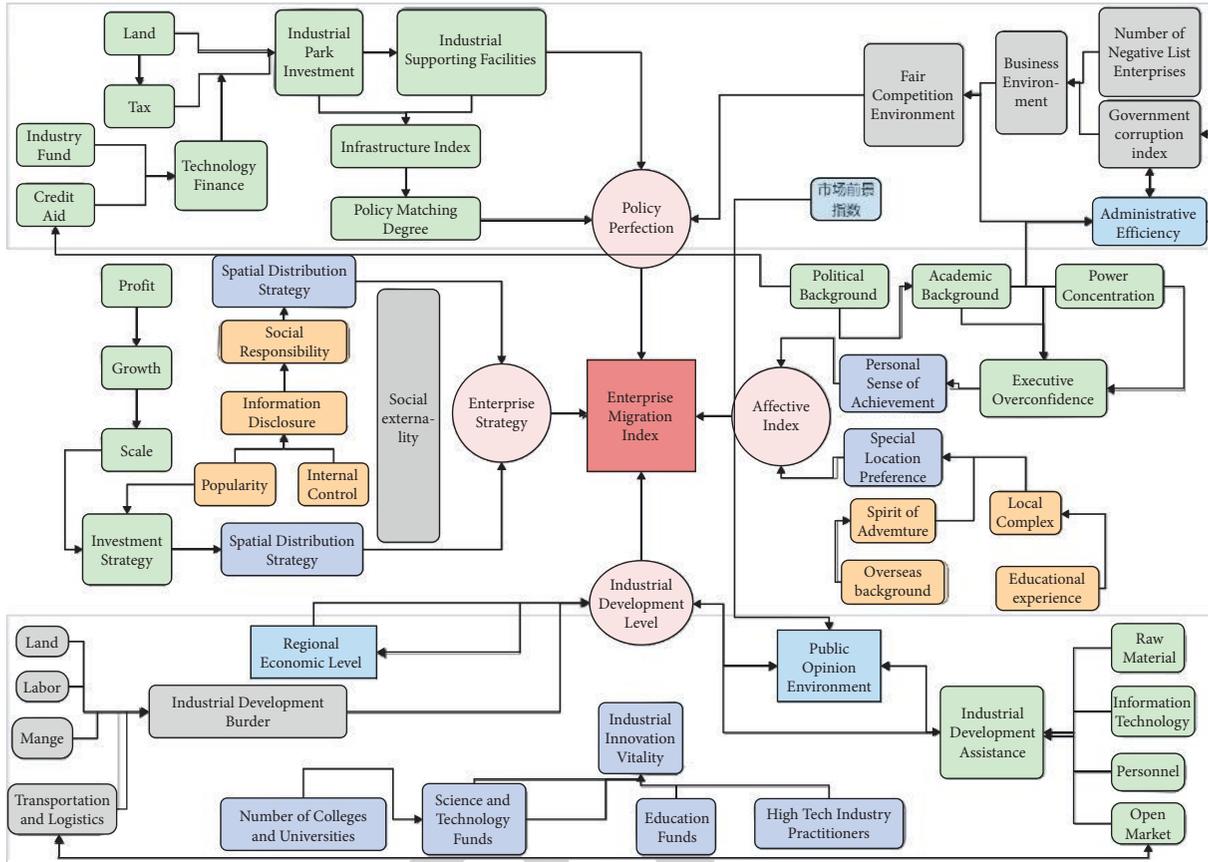

FIGURE 3: Model causality diagram.

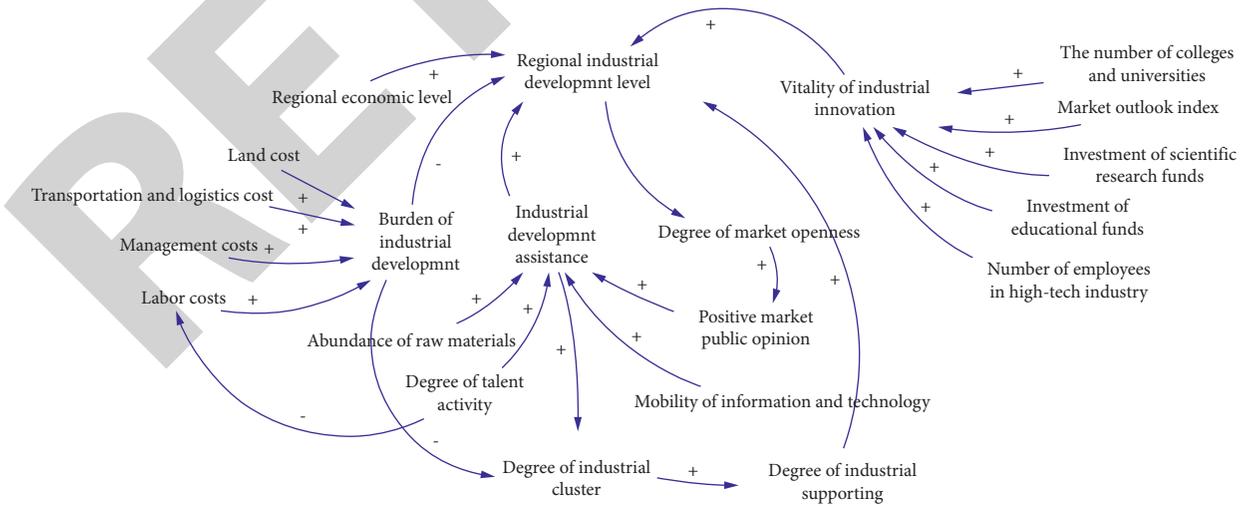

FIGURE 4: Economic factors.

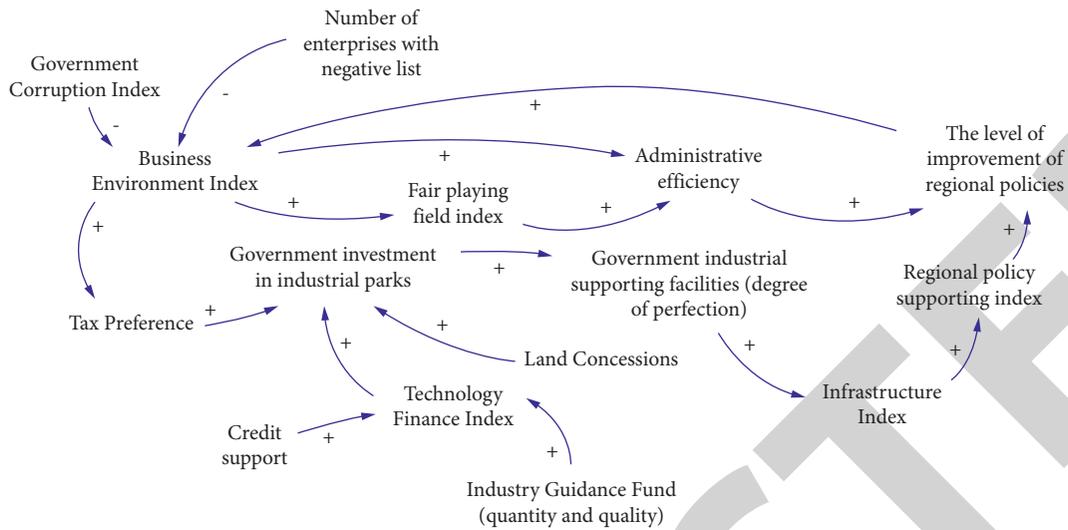

FIGURE 5: Policy factors.

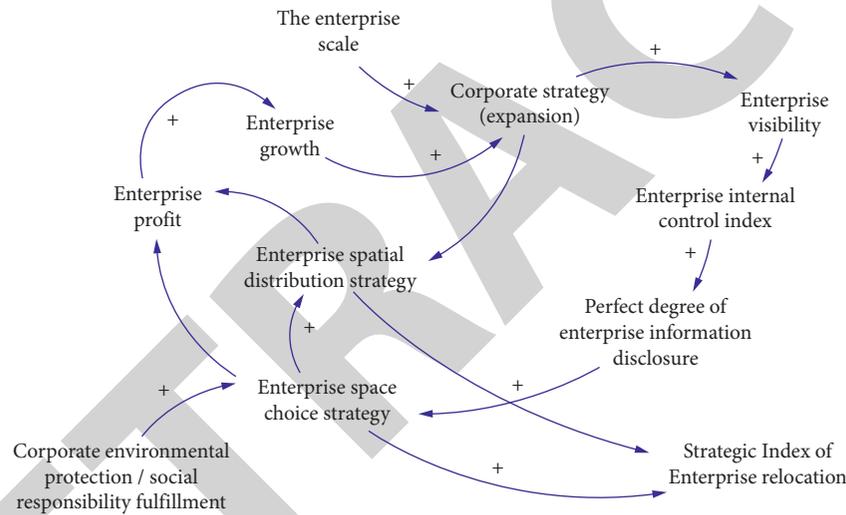

FIGURE 6: Enterprise strategy.

The internal logic of the enterprise has the following causal relationship:

- enterprise growth
- enterprise strategy (expansion)
- enterprise visibility
- enterprise internal control index
- perfect degree of enterprise information disclosure
- enterprise spatial choice strategy
- enterprise spatial distribution strategy
- enterprise profit
- enterprise growth.

(3)

political background of senior executives will affect the land preference and tax preference given to enterprises by the local government. Due to the unique background of Chinese culture, the political background, academic background, and centralized power of senior executives will affect the overconfidence of senior executives. This kind of self-confidence affects executives' sense of personal achievement. At the same time, we also consider the growth background of executives. Executives' overseas background and educational experience will affect their extroversion and willingness to return, thus affecting executives' particular location preferences. This relationship is shown in Figure 7.

The main causal loops are shown in the following formula:

$$\text{local complex} \rightarrow \text{adventurous spirit.} \quad (4)$$

After considering the completion of the external subsystem of the enterprise, we analyze the causality of the internal subsystem of the enterprise's migration. The

Based on this, we constructed the causal circuit diagram as shown in Figure 8.

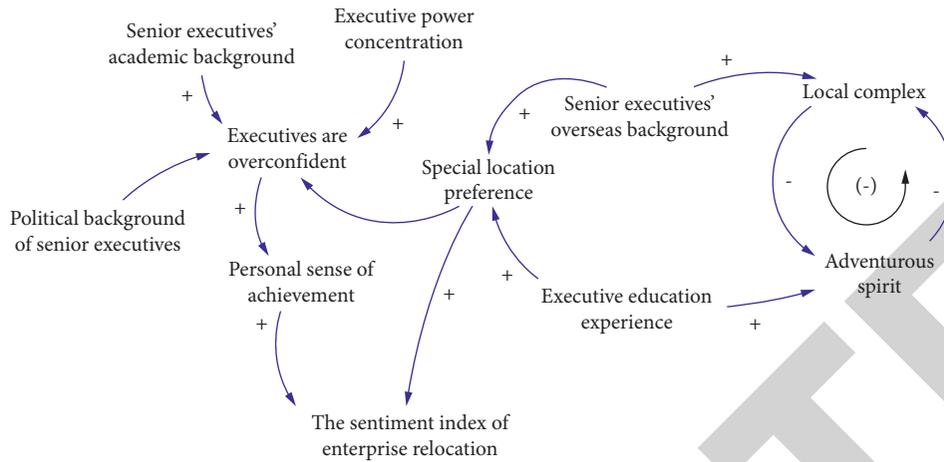

FIGURE 7: Enterprise emotion.

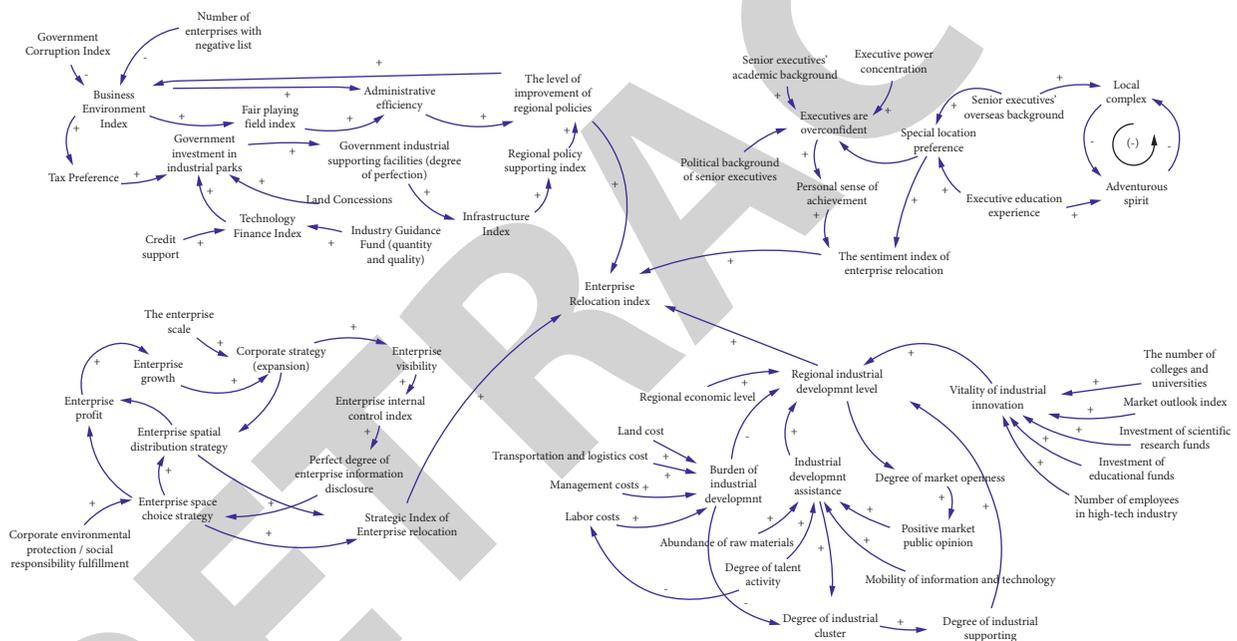

FIGURE 8: Total cause and effect diagram.

3.2. Model Parameterization. There are five kinds of system dynamics equations, namely, horizontal equation (L), rate equation (R), auxiliary equation (a), constant equation (c), and initial value equation (n). The horizontal equation and rate equation are the core of the model.

Horizontal equation (L) is the basic equation of system dynamics; that is,

$$L_{(t)} = L_{(0)} + \int_0^t (\sum R_{in}(t) - \sum R_{out}(t))dt. \quad (5)$$

In the dynamic formula, $L_{(t)}$ represents the value of the quantity L in the state at time t . $L_{(0)}$ represents the initial value, and $\sum R_{in}(t)$ represents the input flow of the state variable. $\sum R_{out}(t)$ represents the output stream of the state variable. $\sum R_{in}(t) - \sum R_{out}(t)$ represents the net inflow of the state variable.

The above integral equation shows that the value of the state variable at time t is equal to the initial value of the state variable plus the accumulation of net flow change over time. What needs to be explained here is that we mainly consider the characteristics of such variables when setting variables belonging to flow and interface data.

In addition, the rate equation is expressed as a function of state variables and constant.

$$R = f(L, \text{constant}). \quad (6)$$

The purpose of designing a system flowchart according to the relationship between various factors in the system of enterprise relocation behaviour is to reflect the characteristics and characteristics of different variables that cannot be reflected in the causal relationship of the system. The flow

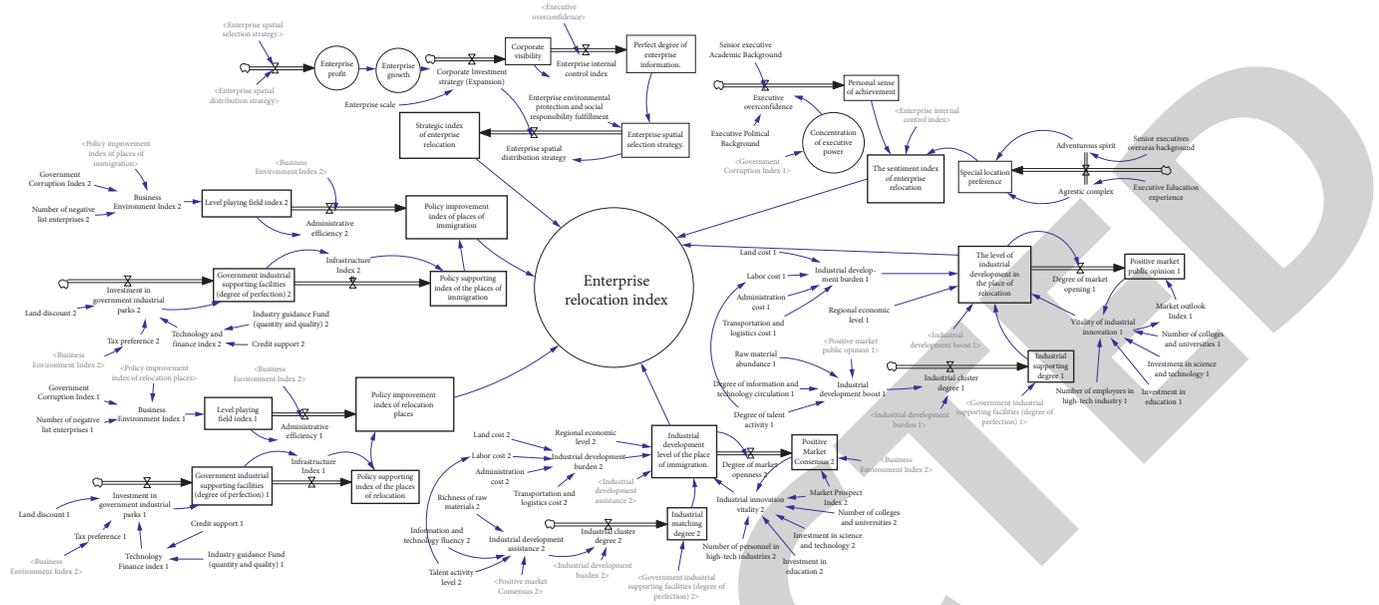

FIGURE 9: Flowgraph.

diagram makes the internal mechanism of the system clearer, further quantifying the variables in the causality diagram and finally realizing the simulation of enterprise relocation behaviour. The flow diagram of the simulation system is shown in Figure 9.

The model successfully passes the conventional system dynamics confidence-building tests using the practical guide provided by Barlas [74]. We also analyze the six enterprises from China through the above model to ensure that our model is in line with reality. These companies have the same characteristics: they have migrated. At the same time, we compared their simulation index with the actual situation and found that this model can better simulate the process of enterprise relocation.

4. Discussion

This part discusses the policies that the government may adopt and their impact and discusses how enterprises can make better development by means of relocation. In addition, we discussed how to use systematic thinking to promote the development of emerging economies. As a supplement, we analyze the possible contributions and shortcomings of this paper. Future research is also planned.

4.1. Government Policy

4.1.1. Government Policy A: Administrative Convenience. In our theory, we systematically consider the government’s impact on administrative facilitation given to enterprises. Local governments are easier to attract enterprises to relocate because administrative facilitation such as preferential land rent and credit support is given to firms. The case of Policy A is verified in Case 1. However, the reality is that enterprises often relocate to the local area due to administrative convenience and then relocate out of the area again

due to the low degree of market opening or other policy disadvantages. We contend that other disadvantages in the system offset the attractiveness of administrative convenience for firms in such cases.

The government’s effective measures should combine more significant attraction with more vital constraint conditions for enterprises. Specifically, the government can transfer land rights with low added value. For example, the case of Guangdong Province, China, shows that the government transferred the right to develop unexplored islands far from cities to high-tech enterprises. The government has given away land with low value-added. Enterprises have obtained almost zero cost of production land, a win-win situation for both parties. Once the enterprises invest in this place, their desire to relocate is reduced because of sunk costs. Conditional and substantial credit support works equally well, and such policies can reduce the relocation behaviour of enterprises.

4.1.2. Government Policy B: Environmental Regulation.

Governments have imposed environmental regulations on high-polluting enterprises within their borders to protect the environment in emerging economies. Such regulations encourage companies to move out and find lower-cost locations for production. For more developed regions, such in-laws and policies can help themselves achieve environmental protection and industrial structure optimization. However, it would be an environmental disaster for the rest of the economy. The whole economy is a dynamically adjusted system. In our theory, such restrictive environmental regulations reduce the openness of regional markets. It will reduce the attractiveness of the business and increase the cost of doing business.

Effective government measures should combine environmental regulation with administrative facilitation. It

promotes its sustainable development while ensuring that the overall utility of the enterprise remains roughly unchanged. To be specific, the government should regulate the pollution emission of enterprises by-laws or policies but, at the same time, provide credit support to enterprises to help them upgrade equipment to achieve sustainable production. This policy can achieve higher efficiency and more sustainable production of enterprises and avoid the relocation of enterprises.

4.1.3. Discussion: Systematically Building Policy Systems for Sustainable Development. Theory suggests that policy alone plays a small role in the circular loop. Changes in other factors often offset it. Due to irrational policies, it sometimes has the opposite effect to that intended by policy settings. Real cases from China validate this view.

Therefore, the systematic construction of the policy system should be emphasized. In the overall system that affects enterprise migration, policies can help enterprises achieve sustainable development in the case of realizing the coordination of multiple policies. This development is not just good for business. It also helps local governments develop sustainable and economic requirements. In reality, such systematic policy system construction requires policymakers to systematically consider the interaction mechanism between various policies and requires that policy implementers engage in systematic policy practices geared toward sustainable development goals.

4.2. Enterprise Strategy

4.2.1. Enterprise Policy A: Market Orientation. When an enterprise is first established, it often does not reasonably estimate its development prospects. This leads to obstacles to market expansion after a certain point of development. This encourages companies to move closer to the market. However, with the increase in informatization, the time lag between enterprise decision-making in emerging economies has decreased. At the same time, with the improvement of infrastructure and the reduction of logistics and transportation costs, the distance from the market is no longer the primary consideration for enterprises to consider when facing the market. However, there is undeniable that enterprises tend to gain more significant market opportunities after relocating to the region close to the market.

Enterprises should also pay attention to the following factors when making market-oriented migration decisions. First, enterprises need to estimate the current location and destination costs reasonably. Such cost estimation should include the direct cost and consider the implicit cost such as corporate reputation and cultural adaptation. All costs will have a comprehensive effect on the enterprise and reduce the development expectation. Second, companies should consider the sustainability of migration destination development. For example, large cities have a high steel demand, but they are more likely to introduce environmental regulations. Then iron and steel enterprises to migrate for this unsustainable production should be estimated.

4.2.2. Enterprise Policy B: The Game between Cost and Innovation. When making migration decisions, enterprises often grapple with low cost or potential innovation. Due to the accumulated advantages of the current location of the enterprise, the production cost of the enterprise is low. However, enterprises have less incentive to innovate products. On the contrary, although the production cost of enterprises in some highly developed cities is higher, the innovation potential of enterprises is higher due to the rich resources and fierce competition. For the current development of enterprises, enterprises may choose the current location to reduce costs. However, enterprises can only achieve sustainable innovation.

Enterprises need to consider many aspects when migrating. In the perfect competitive product market, enterprises focus on innovation to achieve sustainable development. However, the enterprise's product innovation should consider factors such as its current financial status and the vitality of the internal personnel structure of the enterprise. These factors are crucial to the success of an enterprise's innovation. In the oligopoly product market, enterprises can realize market barriers only by cost priority strategy. For example, Coca-Cola's global localization production strategy and cost control strategy have promoted Coca-Cola's monopoly position.

4.2.3. Discussion: Systematic Decision-Making for Sustainable Development. The migration decision of an enterprise has an important systemic connection with the enterprise itself and the external environment of the enterprise. In the process of decision-making, enterprises can adopt systematic thinking to make decisions on behaviour. This kind of systematic decision-making does not only consider factors that affect the enterprise. A reasonable assessment of the company's own conditions should be made to analyze the impact of the interaction of the company's decision-making with external conditions. The impact of this feedback on the company itself should also be considered. In reality, companies often pay too much attention to external factors and neglect their own internal environment. This neglect causes the enterprise to affect the internal structure of the enterprise after its decision-making behaviour, thus causing unsustainable consequences for the enterprise.

Based on the above, companies should systematically think and make decisions when making migration decisions and other major business behaviours. This kind of systematic decision-making requires enterprises to embed themselves in the overall economic system and rationally analyze the impact and secondary impact of decision-making.

4.3. Theoretical Contributions. The possible marginal contributions of this paper in theory and practice mainly include the following two aspects. First, in terms of theoretical innovation, we systematically put forward the Push-Pull Theory for the internal logical motivation of enterprise migration behaviour. We supplement existing research on enterprise migration behaviour from dynamic evolution and factor game theoretical perspectives. In the existing studies,

the promotion and pull of factors are put forward for the migration behaviour of enterprises to a certain extent [75–79]. However, this theory is scattered and analyzed by fewer factors. Therefore, we combine the relatively mature factors affecting enterprises in academia with reality, incorporating the essential decision-making factors into the enterprise migration game and integrating the enterprise migration process into the factor game of the overall macroenvironment. We express it concisely in the form of “push-pull,” which is a powerful supplement to the improvement of the theory of enterprise migration. At the same time, in addition to the systematic evolution analysis of the explicit factors of enterprise migration, we also include the internal implicit factors affecting enterprise migration into the research theory for more comprehensive research on enterprise migration.

The above factors have essential research value under the background of the optimal allocation of the global industrial chain and the reindustrialization of developed countries. In practical considerations and concerns, our research provides a theoretical basis for the government and the market to analyze enterprise migration’s internal motivation and logical mechanism. This Push-Pull Theory helps the government to optimize the regional industrial layout and enterprises to make reasonable decisions through systematic thinking.

4.4. Practical Implications. The possible practical contributions of this paper are mainly in the following three aspects. First of all, this paper proposes systematic thinking and policy systems for emerging economies that hope to complete economic transformation through enterprise migration. Secondly, this paper puts forward methods and cases of systematic thinking about how companies can achieve sustainable development through migration. Finally, this paper gives realistic cases and systematic countermeasures to the behaviour mechanism of the economic system for microsubjects.

4.5. Future Research Directions. Further research can be carried out from the following two aspects: first, the expansion and improvement of the enterprise migration system, such as adding more dimensions, and second, the relocation behaviour of enterprises in other countries with unique political and economic conditions, which are valuable to study to promote the universality of the system structure.

5. Conclusions

With the development and transformation of emerging economies, many companies are facing an urgent need for migration. Although there are many explanations for corporate migration behaviour in existing studies, they all ignore the systemic reasons and systemic effects of corporate decision-making. This research attempts to explain the behavioural mechanism and impact of corporate migration through systematic thinking.

This paper constructs a Push-Pull theoretical model of the interaction of internal and external factors in the enterprise and finally explains the motivation of the enterprise’s migration behaviour. Specifically, the choice of migration behaviour of enterprises is affected by internal and external factors. The influence of these two parts does not act on the strategic decision-making of the enterprise alone but interacts. We define this mechanism as the Push-Pull Theory. We explain the Push-Pull Theory from three aspects: (1) The external environment of the company (economic environment and government regulations) is constantly changing, which promotes the migration or stay of the company. (2) The internal environment of the company (senior management’s emotions and management decision-making) is constantly changing, which promotes enterprise reform or drives the enterprise to maintain the status quo. (3) The external environment of the enterprise interacts with the internal information, comprehensively promoting the enterprise to make a migration decision or pulling the enterprise to maintain the current business strategy. This paper conceptualizes the theoretical mechanism and summarizes the influencing factors of these three aspects through bibliometric analysis and the actual situation. Besides, it systematizes these factors and explains the causal feedback of the enterprise migration mechanism by constructing a system dynamics model. Furthermore, it discusses the Push-Pull Theory in the real world. Through a systematic and logical analysis of the policy impact of the government and enterprises, we reiterated the importance of systematic thinking in the process of sustainable economic development.

The migration behaviour of enterprises is closely related to the overall economic system. The upgrading of the industrial structure and sustainable development of emerging economies requires not only attention to current resources but also consideration of the overall impact of changes in the location of enterprises. The challenges ahead are huge if we want companies and economies to develop efficiently. This trend requires systematic thinking and practice.

A convolutional neural network (CNN) is a machine learning method under supervised learning. It not only has the advantages of high fault tolerance and self-learning ability of other traditional neural networks but also has the advantages of weight sharing, automatic feature extraction, and the combination of the input image and network. It avoids the process of data reconstruction and feature extraction in traditional recognition algorithms. For example, as an unsupervised generation model, the convolutional confidence network (CCN) generated by the combination of convolutional neural network and confidence network has been successfully applied to face feature extraction.

1. Origin and Development of Convolutional Neural Network

With the development of society, people cannot process data with general statistical knowledge due to the increasing amount of data and the increasing number of dimensions; therefore, processing big data has become a significant problem we face. Machine learning can be divided into supervised learning and unsupervised learning. The core is to classify the characteristics of the data. It can be labeled as data characteristics and by the supervision of learning, these labels can be classified, thus achieving the purpose of feature classification, such as data feature if there is no label, and you can only rely on unsupervised learning to identify these features for clustering [1]. On the other hand, deep learning, commonly referred to by people, relates to machine learning through deep networks, namely multiple networks, such as convolutional neural networks (CNN). The concept of deep learning comes from the research of artificial neural networks, which is a method of data representation learning in machine learning. Deep learning has made breakthrough achievements in image classification, speech recognition, target detection, and other aspects in recent years, showing its excellent learning ability [2]. With the research's

deepening, the convolutional neural network structure is constantly optimized, and its application field is gradually extended. For example, Alibaba, Baidu, Google, and other companies are conducting deep learning research on speech recognition. And the use of face recognition, image search, and human behavior recognition is a reasonable prospect of technology. It can be used in medicine, biology, and other fields. Deep learning can also be divided into supervised and unsupervised learning.

CNN first originated in 1962. Biologists Hubel and Wiesel found that Ding is a cell that covers the whole visual well and is very sensitive to the local, visible input space area, called the receptive field. In 1980, Fukushima proposed a neocognitron with a similar structure based on the receptive field. Neocognitron is a self-organizing multilayer neural network model that can stimulate the upper layer's local receptive field to respond to each layer. At the same time, it is also the primary learning method for convolutional neural networks in early learning. Subsequently, Saad et al. proposed and designed the convolutional neural network LeNet-5 model for character recognition based on neocognitron [3]. The basic structure of LeNet-5 comprises an input layer, a revolutionary layer, a pooling layer, a complete connection layer, and an output layer. The system succeeded

in small-scale hand and number recognition but still has significant limitations. In 2012, CNN made a historic breakthrough. The emergence of alexnet2 made CNN the core algorithm model in image classification. Compared with the traditional CNN model, Alexie improves the algorithm and realizes multi-GPU parallel computing. With the support of a large amount of data, the error rate of the top-5 is getting lower and lower, which has now reduced to about 3.5% [4]. Recently, GoogLeNet, with a deeper VGG structure and network in network structure, has emerged, and the emergence makes it possible to train hundreds or even thousands of neural networks.

2. Characteristics of Convolutional Neural Network

2.1. Local Perception Method. The local sensing method uses a convolutional neural network method to reduce the number of data parameters. From local cognition to global cognition is a method of people's understanding of the outside world, which is also applicable in image processing. The spatial connection of images is also closely related to the relationship of local pixels, but if the interval is far away, the relationship with spatial pixels is weak.

As in conventional neural networks, neurons in the input layer need to be connected to neurons in the hidden layer. But here, instead of connecting every input neuron to every hidden neuron, connections are created only in a local region of an image.

Therefore, each neuron on the convolutional neural network must only perceive it locally. Then the complete connection layer will comprehensively analyze and summarize the locally perceived parameter information to obtain the global information parameters.

The correlation between local pixels is strong and the correlation between distant pixels is weak. Inspired by the human visual reception system, visual neurons receive only local information, i.e., each neuron does not respond to the global. Our observation of the outside world is from local to global, not pixel by pixel but area by area, through which we get local information and then the aggregation of this local information before we get the global information. Assuming that each implicit layer neuron is constructed by perceiving only two input neurons. It can also be 3 or 4, which is mainly related to the size of the image and the size of the feature that we want to obtain.

2.2. Weight Sharing. Compared with the local sensing method, weight sharing has more significant advantages. The Lenet-5 model proposes the weight-sharing network. The Lenet-5 model proposes the weight-sharing network because of too many parameters. The weight-sharing network first simplifies the structure, then reduces the number of training parameters with more application space. This means that all neurons in the first hidden layer detect the same feature at different locations in the image. This mapping from the input layer to the hidden layer is also called feature mapping (or filters, kernels), because the weights are shared so that the

features are detected in the same way. The weights of this feature mapping are called shared weights, and its deviation is called shared bias.

For example, a neuron in a nerve needs 100 information parameters, so these 100 information parameters are equivalent to an extraction method and are independent of location [5]. A convolutional neural network can extract the corresponding features from these 100 parameters and then apply them to other parts of the image. Generally speaking, it is to randomly pull a small amount from a large-scale image to an image to extract a small amount from a large-scale painting randomly. Then the extracted small part can be learned to become a feature detector, which can be applied to any image. Then through convolution learning processing with the original image, different characteristic values at different positions in the original image can be obtained.

2.3. Multiconvolution Kernel. In the weight-sharing network, the local features extracted by observing the case cannot meet the requirements of image processing, so the help of a convolution kernel is needed. Each shared weight parameter is a convolution kernel, and multiple convolution kernels can solve this problem [6]. Each convolution kernel will generate an image after local feature extraction and weight sharing, and multiple convolution kernels will form various photos, which can be regarded as multiple channels. As shown in Figure 1, the process of convolution operation with four convolution kernels, that is, four channels, is offered. In this process, the convolution results on the four channels are added first, and then the value of the function is taken. The value obtained is the value of $W1$ and $W2$.

2.4. Model of the Convolutional Neural Network. Because of their high fault tolerance and nonlinear description ability, neural networks have been widely studied and applied, especially in pattern classification. Their primary classification mode of pattern classification is based on feature classification, so some features must be extracted before sorting. The classification model is shown in Figure 2. Samples are extracted from the input and required features $F_1, F_2 \dots F_n$, then classifies to get the output.

A convolutional neural network is a feedforward neural network that can extract the topology structure from a two-dimensional image and use the backpropagation algorithm to optimize the network structure and solve the unknown parameters in the network. A convolutional neural network is often used to study two-dimensional image recognition problems. It only needs a small preprocessing; the recognition range is vast and can allow the image to change. The traditional classification model is shown in Figure 2. Firstly, the image should be input, and complex preprocessing is carried out to extract features. Then, the classification is done according to the extracted features, and the results are given at the output end. The difference between the classification model of a convolutional neural network and the traditional model is that it can directly input a two-dimensional image into the model and then give the classification result at the output end, as shown in Figure 3. Its advantage is that it does

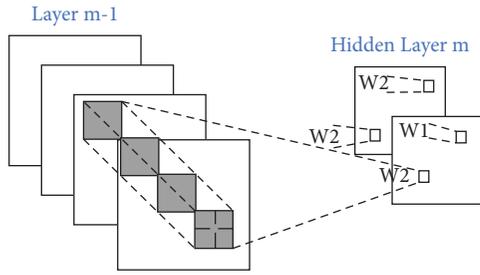

FIGURE 1: A multiconvolution kernel.

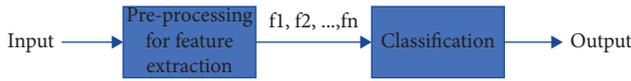

FIGURE 2: Classification model.

not need complex preprocessing and ultimately puts feature extraction and pattern classification into a black box. It obtains the required parameters of the network through continuous optimization and gives the required type in the output layer. The core of the network is the structural design of the network and the solution of the network. This solution structure has higher performance than many previous algorithms, such as complex texture processing, good feature extraction effect but boundary extraction algorithm, feature processing based on wavelet network, and SVM with special classification effect. These algorithms require much computation when extracting features.

3. Remote Sensing Image Research Based on Convolutional Neural Networks and Its Application in the Design Field

Convolutional neural networks have made significant breakthroughs in machine learning in recent years, mainly thanks to big data and computer performance. Studies have shown that constantly deepening network layers can effectively improve network expression of identities of vast amounts of dataset [7]. The network structure of wider deepen let convolutional neural network become very complex, and depth of retraining a convolution of the new model via the network requires a lot of training samples to adjust the network weights. This is not the reality for small datasets. The proposed migration theory enables small data sets to share the development results of convolutional neural networks and deploy large networks into practical applications.

Remote sensing is a comprehensive Earth observation technology developed in the 1960s that has become one of the leading technologies for studying Earth resources and the environment. After years of development, remote sensing technology has achieved the ability to perform hyperspectral, high spatial resolution, and real-time Earth observation. Currently, the ground resolution of remote sensing images can reach a centimeter level. Remote sensing image classification is one of the essential applications of remote sensing technology, which has critical applications in

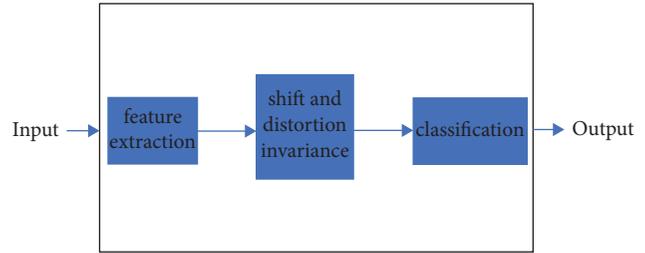

FIGURE 3: Convolutional neural network classification model.

land use, urban planning, environmental monitoring, etc. It has vital significance for battlefield environment analysis in the military [8]. This paper applies the migration theory to the classification of remote sensing images with the pre-trained VGG-16, GoogLeNet, and RESNET-152. Training tests were carried out on the remote sensing image datasets UC Merced and Siri-WHU, and the experimental results were analyzed in detail [9].

3.1. Migration Theory. For a multilayer convolutional neural network, the initial layer extracts more general features of the image. As the network structure becomes deeper, shallow features are combined into advanced features and further transformed into semantic features to achieve classification. For the convolutional neural network trained on ImageNet's extensive image data set, the bottom layer of the convolutional neural network has been prepared with much detailed information, and what needs to be trained prepared is in the combination information of these features at the top layer and the classification information of the final fully connected layer, which also proves that the convolutional neural network has the ability to transfer learning to a certain extent. There are usually two ways to apply transfer theory to convolutional neural networks.

- (1) The trained network model is used as a feature extractor. The last complete connection layer of the trained network is removed, and the rest of the network is used as a feature extractor. For the Alex grid work, removing the last convolutional layer will generate a 4096-dimensional feature vector, which will be used to train a linear classifier for practical tasks [10].
- (2) They are fine-tuning the trained network with new data sets. For networks pretrained on large databases, the weight parameters of the network are fine-tuned on the new database by a backpropagation algorithm. The features extracted from the first few layers of the pretrained network are usually general. In contrast, those removed from the last layer are related to the task of data set classification. During fine-tuning, you can adjust the parameters of different network layers. You can adapt and change the parameters of all network layers. You can also change the parameters of the first several network layers and fine-tune the parameters of the last network layers.

3.2. Deep Convolutional Neural Network

3.2.1. GoogLeNet Network Model. Lenet-5, AlexNet, and VGGNet are the accumulation of multiple convolutional layers, only deepening in depth. GoogLeNet expands the width of the network while increasing the network depth. The network depth of GoogLeNet is 22 layers [11]. Its primary grouping unit, inception, is shown in Figure 4.

The features of different scales can be obtained by using multiple convolutional kernels of different scales at the same layer, and better features can be obtained by fusion of the accepted elements than by using a single convolutional kernel. The initial Inception architecture does not use a $1 * 1$ convolutional kernel, which has the advantage of reducing a large number of network parameters. For an input with a 256-dimensional feature, the parameter can be reduced by 1/9 by using $1 * 1$. The parameters of GoogLeNet are 1/12 of those of 8-layer AlexNet [12].

3.2.2. ResNet-152 Network Model. ResNet is a residual network model that solves the gradient dispersion problem of the original deep learning network as the number of network layers increases. As a result, shallow network parameters cannot be updated in the backpropagation process, and the network depth cannot be further deepened. ResNet uses a shortcut to connect the inputs and outputs of a module during model design. In the process of backpropagation updating weights, ResNet gradient signals can be directly transmitted to the upper network through shortcuts, which solves the problem of gradient disappearance and makes the network layers of the deep learning network reach 152 layers. The essential components of ResNet are shown in Figure 5.

4. Application of Convolutional Neural Network in Clothing Design

With the rapid development of computer technology, computer-aided design has emerged endlessly and is widely used in business, industrial medicine, art design, entertainment, and other fields. At present, the applications of juice computers in the clothing industry include clothing computer-aided design (clothing CAD), clothing enterprise management information system (MIS), and clothing cutting machine technology system, as well as clothing sales system, clothing fitting system, and contactless clothing measurement system.

Clothing CAD (computer aided design) technology; that is, computer-aided clothing design technology, is a unique technology that uses computer software and hardware technology to input, design, and output new clothing products and clothing processes according to the basic requirements of clothing design [13]. It is a comprehensive high-tech that integrates computer graphics, databases, network communication, and other computer and other fields of knowledge to realize product technology development and engineering design. It is called the interdisciplinary subject of art and computer science. It is a new art

school based on cutting-edge science, which is different from any prior art. Clothing CAD technology integrates designer Ding's ideas and technical experience and, through the powerful computing function of the computer, makes clothing design more scientific and efficient and provides a modern tool for clothing designers. It is an essential means of future fashion design [14].

The clothing CAD system mainly includes fashion design system, pattern design system, grading system, marking system, fitting design system, and management system.

4.1. Introduction to Garment Design CAD. The clothing CAD was developed in the United States in the early 1960s. Currently, the popularity of clothing CAD in the United States, Japan, and other developed countries has reached more than 90%. China's clothing CAD technology started late; although the development speed is breakneck, there is still a big gap with foreign technology.

The popularization, application, and popularization of clothing CAD is a vital and long-term task of clothing technology transformation in China. Garment CAD software is a common standard in the modern garment industry, and it also improves the production efficiency and product quality of garment enterprises [15]. After entering the WTO, China's clothing industry will further develop rapidly. Therefore, using and promoting clothing CAD software is an inevitable trend for further developing China's clothing industry.

4.2. 3D Digital Design Technology. In the current international manufacturing field, manufacturing technology is developing from traditional manufacturing methods to advanced manufacturing technology. The informatization of the manufacturing industry has become an important trend in the development of the manufacturing industry. The core of the digital construction of manufacturing enterprises is the digital design and manufacturing of products and the integration of related digital technologies. Three-dimensional digital design technology is gradually becoming a hot spot in the application of enterprise design, and it is also a necessary tool for enterprises to deepen their application. As an essential part of information technology, CAD combines the high-speed and massive data storage, processing, and mining capabilities of computers with people's comprehensive analysis and creative thinking capabilities and plays a vital role in accelerating the development of engineering and products; it shortens the design and manufacturing cycle; improves quality; reduces costs; and enhances the market competitiveness and innovation ability of enterprises. Whether it is military or civil industry, construction or manufacturing, processing industry, machinery, electronics, light textile products, literature and sports, film and television advertising production, three-dimensional digital design technology is indispensable [16]. Three-dimensional digital design technology is an essential technical basis for enterprise informatization, and it is also an admission ticket for enterprises to enter the international market.

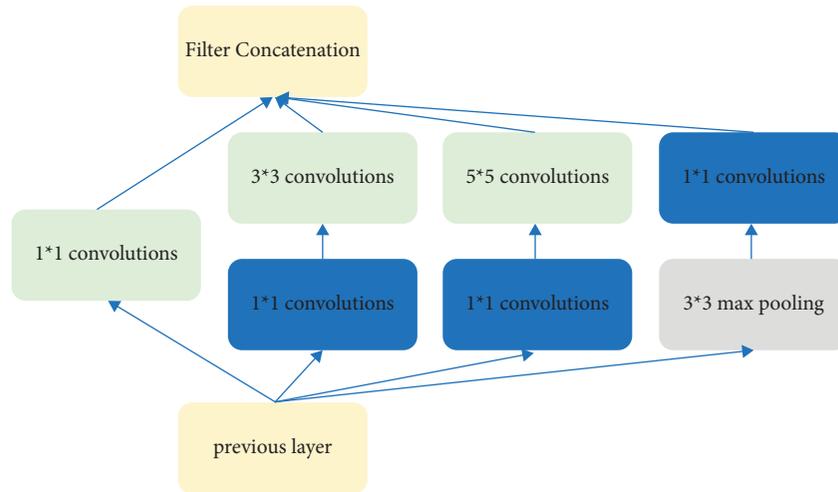

FIGURE 4: GoogLeNet network.

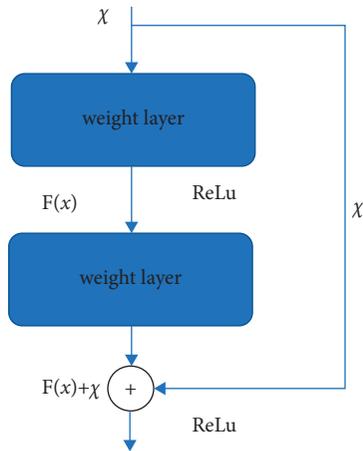

FIGURE 5: ResNet workflow model.

4.2.1. *Working Principle of 3D CAD Technology.* The clothing size based on the mass production of clothing cannot accurately reflect the body characteristics of people. The establishment of human body databases of all kinds of people is being carried out at home and abroad. Through three-dimensional anthropometry on many people with different skin colors, regions, ages, and heights, we collect various body size data of the human body and establish a database to provide essential data for formulating clothing specifications and sizes [17].

Three-dimensional anthropometry generates a virtual three-dimensional human body by acquiring the human body's vital geometric parameters, establishing a static and dynamic human model, and forming a complete set of systems with the functions of virtual human body display and dynamic simulation. On this basis, 3D clothing CAD generates the three-dimensional effect of clothing fabric, realistically displays the three-dimensional color image of the dressing impact on the screen, and expands the three-dimensional design into plane clothing pieces [18]. Using

advanced computer image capture and recognition technology, laser measurement and positioning technology, numerical control technology, three-dimensional computer software, and data processing technology, the working principle of the system is standing on a unique working platform. Four laser heads are used that can move up and down scan the human body from the top of the head to the heel in four directions and read the position and color information of the human body into the computer and then use special software to process the measured human body information to obtain detailed and accurate size and color information of each characteristic part of the human body and generate standard data formats that can be read by 3D CAD software and animation software.

The basis of 3D garment CAD is 3D anthropometry [19]. The three-dimensional human body measurement system has been commercialized abroad, and its technology has been relatively mature. France, the United States, Japan, and other countries can complete the three-dimensional human body using the natural light grating principle in 40 milliseconds, 10 seconds, and 1.8 seconds, respectively, measurement data. The commonly used three-dimensional anthropometry technology in the world is generally non-contact. The image formed by the light projected onto the human body surface is captured by photosensitive equipment. Then the three-dimensional characteristics of the human body are described by computer image processing. The three-dimensional human body measurement system has many advantages over traditional measurement technology, such as short measurement time and extensive data.

4.2.2. *Application Status of 3D Garment CAD.* At present, there are two main types of applications of 3D garment CAD in foreign markets:

First, it is used for customization: to measure the human body parameters of specific customers and their specific requirements for clothing styles (such as relaxation, length, width, and other preference information), carry out clothing design, and regenerate into corresponding plane clothing

samples [20]. Such products can be remotely controlled through the Internet, among which the systems of the United States, Britain, France, Germany, Japan, and Switzerland are more advanced.

Second, it is used to simulate the fitting system. Interactive clothing design is carried out through the three-dimensional measurement of a customer's body shape, and the corresponding plane clothing samples are regenerated. Such applications can also be realized by using the Internet for remote control of e-commerce. For example, Lands' End company in the United States can establish a virtual human model of customers on the Internet. Through simple operations, customers can try on the company's clothes and carry out the three-dimensional interactive design until they are satisfied.

Presently, some foreign products can realize three-dimensional clothing wearing, matching design and modification, reflect the animation effect of clothing wearing comfort, simulate the three-dimensional suspension effect of different fabrics, and realize 360-degree rotation and other functions [21]. Among them, the three-dimensional garment CAD software developed by the United States, Japan, Switzerland, and other countries is relatively advanced, such as the concept 3D garment design system launched by CDI company of the United States, the 3D plan of Lick company of France, the am-ee-sw3d system of Gerber company of the United States, the 3D system of Pad Company of Canada, the 3D design of Toyo textile company of Japan, etc.

4.2.3. Huge Benefits of 3D CAD Technology. 3D CAD technology can significantly improve the design efficiency and quality of products and projects, working conditions, and competitiveness of products and projects in the market [22]. Statistics from foreign countries show that the application of 3D CAD design technology can reduce engineering design cost by 13%–30%. It can reduce the time from product design to production by 30%–60%, improve product quality by 5–15 times, and increase the breadth and depth of problem analysis by 35 times. Also, it improves product productivity by 40–70% and increases the productivity of input equipment by 2–3 times while reducing the processing process by 30%–60% and labor costs by 5–20%. The research, development, and wide application of 3D digital design technology can promote the development of China's software industry, especially the development of the application software industry [23]. This will accelerate the technological transformation of traditional industries and products and promote the rapid development of conventional disciplines. The resulting direct and indirect economic benefits are enormous, and their social benefits are immeasurable.

5. Development Trend of Garment CAD Technology

5.1. Development Status of Three-Dimensional CAD for Clothing. With the development of computer technology and the social economy in China, people have higher and

higher requirements regarding clothing quality, fit, and individuality. The existing two-dimensional clothing CAD technology can no longer meet the CAD application requirements of the textile and clothing industries. It is urgent to develop clothing CAD from the current plane to a three-dimensional design. Therefore, in recent years, three-dimensional clothing CAD, virtual reality clothing design, and other aspects of theoretical research and practical applications both at home and abroad.

According to Autodesk's widespread application of CAD statistics. Currently, about 30% of the users in the world use 3D CAD for product design, and the remaining 70% still use 2D CAD design [24]. Three-dimensional CAD has been widely used in the world. Still, in the clothing field, the development and application of three-dimensional CAD are lagging because clothing is not like solid products in the machinery and electronics industry; its texture is flexible and will change with different external conditions, so it is not easy to simulate. In particular, the transformation of garment CAD from two-dimensional to three-dimensional needs to solve the technical problems of fabric texture and dynamic performance, three-dimensional reconstruction, realistic and flexible surface modeling, and the transformation from a three-dimensional garment design model to a two-dimensional plane garment. These problems lead to a long development cycle and great technical difficulty in 3D garment CAD.

5.2. Development Trend of Garment CAD Technology. In recent years, the CAD technology in achieving rapid development at the same time also exposed the problems in the story; the main problem is the unit's placing too much emphasis on the development of technology, emphasizing the system's generality and ignoring the product's whole life cycle of the design process-oriented design, dismissing the application of network technology, ignoring butyl database, the development of the characteristic library, and so on [25]. Given these problems, combined with the latest evolution of manufacturing information technology, CAD technology developers put forward a three-dimensional digital design system for industry and process (product life cycle). This system has become a hot spot for research and development at home and abroad. It is regarded as the only way to deepen CAD technology's application and leap in evolution.

The original CAD system and its supporting technology have been integrated into CIMS (Computer Integrated Manufacturing System) [26]. Another garment CAD system development trend is establishing the interface and integration with CAM, MIS, PDM, ERP, etc.

With the rapid development of the Internet in recent years, it is expected that online fashion design will gradually become mainstream. Under the increasingly specialized and globalized production and management mode, the CAD system based on the network can realize data sharing and standardization. The parallel product design will also support the efficient and rapid CAD system. To effectively enhance the market size and product profits, the integration of apparel CAD and e-commerce is also an inevitable trend.

An Internet-based remote data transmission and monitoring system for garment enterprises is coming out, which also provides adequate technical support for the networking of garment design and the informatization of garment enterprises.

In recent years, the United States, France, Germany, Japan, and Switzerland have also developed the research and development of Virtual garment CAD and started the application research of ultra-dimensional garment design [27]. Is the so-called super-d clothing design, super-dimensional visual design, for fashion designers in fashion design not only consider a one-dimensional line, two-dimensional plane, three-dimensional body, 4 d, and 5 d design elements such as the meaning of, and feel the person's psychology, the aesthetic view of people's vision, and the interest of the people, and many other factors, paying attention to the use of environmental psychology and ornamental psychology. Through visual, auditory, and tactile means, clothing designers use virtual reality design technology, virtual reality computer display environment for clothing designs, virtual reality design technology and virtual reality computer display environment for clothing design. This virtual clothing CAD technology, the use of network transmission, and the creation of virtual reality technology make the designer able to work in the environment of virtual garment design; the outdoor reading computer hardware equipment still needs data gloves, clothing, and so on for digital human body sensor and helmet stereoscopic display devices such as displays, shutter glasses, and other related equipment [28]. This virtual reality design technology realizes the automation of clothing design.

Currently, all clothing CAD products are more complex, and it takes professional and technical personnel a considerable amount of time to learn and apply them thoroughly, which is also an important reason for the slow popularization of CAD products [29]. Therefore, it is expected that garment CAD products in the future will develop towards high intelligence. More garment model modules and design wizards will be established to provide intelligent support for designers. This academic support includes self-learning, self-organization, self-adaptation, self-correction, parallel search, associative memory, pattern recognition, automatic knowledge acquisition, and other intelligent technologies [30] which step by step become easy to learn like WINODWS operating software. In the future, with the development of hardware technology, embedding software into the human body measurement instrument to become a brilliant clothing design silly machine will become a reality.

Since AlexNet made a breakthrough in the ImageNet competition in 2012, deep learning based on the convolutional neural network has become a common research hotspot for various enterprises and many scholars and has made great breakthroughs in natural images, language processing, and other aspects. With theoretical innovations and improved computational performance, modern convolutional neural networks are evolving in a wider and deeper direction, but eschewing the development in depth. But it is necessary to increase the depth of network computation to improve the learning ability of the model for

better region classification and interclass differences. The clothing design work can rely on computer-aided design, fabric organization, pattern, and clothing modeling design out. Based on the CAD system, this paper presents the situation of the fabric directly and improves the efficiency of garment design. To sum up, under the diversified network environment, computer technology develops rapidly and has a wide range of applications, which are applied in all aspects of clothing design, production, and sales. According to the content and requirements of clothing design, the content and form of computer-aided design can be flexibly used to minimize the production costs in the process and improve the quality and efficiency of clothing design and production. Through the prediction, the garment fabric, style, color, and other popular elements, trends have an intuitive understanding of comfort, fit, beautiful quality clothing design to meet the needs of consumers and for China's garment industry to open up a broader space for competition and development.

In order to improve the problems of poor accuracy and low efficiency in tobacco leaves disease recognition and diagnosis and avoid the misjudgment in tobacco disease recognition, a disease recognition and spot segmentation method based on the improved ORB algorithm was proposed. The improved FAST14-24 algorithm was used to preliminarily extract corners. It overcame the deficiency of the sensitivity of the traditional ORB corner detection algorithm to image edges. During the experiment, 28 parameters were obtained through the extraction of color features, morphological features, texture, and other features of tobacco disease spots. Through the experimental comparisons, it was found that the fitness of the improved ORB algorithm was 96.68 and the cross-checking rate was 93.21%. The validation and recognition rate for samples was 96%. The identification rate of tobacco brown spot disease and frog eye disease was 92%, and the identification rate of 6 categories in different periods was over 96%. The experimental results verified the effects of the disease identification fully.

1. Introduction

Tobacco is an important economic crop of China. The tobacco-related industry is also an important industry in China's social economy [1, 2]. The tobacco industry provides an important support for social and economic development every year. At the same time, the existence of tobacco diseases also seriously restricts the output and the overall quality of tobacco, which directly affects the economic development of the tobacco industry and the overall income of tobacco farmers. Therefore, many Chinese scholars have never stopped their research on tobacco diseases. The effective identification and rational control of tobacco diseases not only relate to the physiological health of tobacco leaves but also directly relate to the yield and the final quality of tobacco leaves. And for different regions and different types of tobacco, the corresponding disease types are also different. And the pathology of leaf disease is relatively complex [3, 4]. In order to deal with the problems of poor accuracy and low efficiency in tobacco disease diagnosis, a better and an improved ORB algorithm for disease recognition and

disease spot segmentation was proposed and the effects of the disease recognition were verified through experiments.

2. Literature Review

At present, the research on plant disease identification mainly focuses on crop and cash crop diseases. The traditional disease detection was mainly based on manual recognition. The method of manual recognition was low in efficiency and accuracy. Before the rise of deep learning, the traditional disease recognition methods were mainly based on shallow machine learning algorithms, such as SVM and Bayesian classifiers [5, 6]. Some scholars used the statistical learning method of the naive Bayes classifier to realize the classification and recognition of maize leaf diseases, and the diagnostic accuracy of five maize leaf diseases was above 83%. Based on H-threshold segmentation, iterative binarization, image morphology operation, contour extraction, and other algorithms, the texture, color, and shape features of the disease image were extracted. The genetic algorithm was used to optimize the selection of classification features,

and the Fischer discriminant method was used to identify three common maize leaf diseases. According to the features of the maize leaf disease images, a multiclassifier composed of a support vector machine (SVM) was proposed to identify the maize leaf diseases. Experimental results showed that this method was suitable for a small sample and achieved a good classification effect. A support vector machine (SVM) was used to classify cucumber diseases, and the shape, color, texture, and onset time of the disease spots were extracted. The SVM classifier was used to select four common kernel functions for recognition. The results showed that the SVM method had a good classification effect in dealing with small sample problems [7, 8]. A tobacco disease image retrieval method based on the spot feature fusion was proposed to diagnose 7 common tobacco diseases with high recognition accuracy. Five common tobacco diseases were studied and an image processing method based on SVM and ResNet was proposed to diagnose tobacco diseases with an accuracy of 89%. By using image processing and data mining methods, some scholars introduced the disease recognition system based on the double clustering technology. The leaf image was captured by a nonlocal median filter and the noise was removed. Through the double clustering method, anthrax and white leaf diseases of grapes, cucumbers, and tomatoes were segmented. The pattern matching method was used to compare the segmented parts with diseased leaves, which achieved a high recognition accuracy. A method of identification and classification of leaf diseases by digital image processing and machine vision was proposed. Firstly, the leaf images were preprocessed and the features were extracted. And, the leaves were identified by the training and classification based on the artificial neural network. Secondly, the defect region segmentation based on K-means, the feature extraction of the defect part, and the classification of diseases in leaves based on ANN were carried out. A method of tea leaf disease recognition (TLDR) was proposed [9, 10]. The tea image was clipped, resized, and converted into the threshold value in the image processing. Then, the feature extraction method was adopted and the neural network integration was used for the pattern recognition. The recognition accuracy was 91%. Three different convolutional neural network architectures were proposed. Context nonimage metadata were integrated into the image-based convolutional neural network. Combined with the advantages of learning from the entire multicrop dataset, the complexity of the disease classification task was reduced. VGG16 and SingingV3 networks were used to detect and identify the rice pests and diseases, and a two-level small CNN architecture was proposed. Compared with MobileNet, NASNet-Mobile, and SqueezeNet networks, the identification accuracy was 93.3% [11, 12].

3. The Improved ORB Algorithm

3.1. The Improved FAST Corner Detection Algorithm. FAST algorithm is a fast corner detection algorithm at present, but it will produce false detection of some edge points, resulting in the existence of some false corners. Point p is a point on the edge, but it is not a corner point. If the

traditional FAST9-16 algorithm is used for detection, it meets the requirement that the gray value of more than 9 continuous pixels in the neighborhood of 16 pixels is sufficiently different. So, the system will identify it as a corner point, and the point p is only an edge point [13, 14].

Therefore, in order to exclude the interference of such edge points on the detection results, the FAST algorithm is improved as follows: 24-pixel points around the pixel point p are taken as the detection template, the gray value of the point p is I_p , and a threshold T is set. If 14 consecutive pixel points among 24-pixel points have a gray value greater than $I_p + T$ or less than $I_p - T$, then the point p is a corner point. And taking the p point as an example, the improved FAST14-24 algorithm does not identify the p point as a corner point, overcoming the deficiency of the traditional FAST9-16 corner point detection algorithm which is sensitive to edges.

3.2. Feature Descriptor Design. The comparison criterion of the gray mean is defined as follows:

$$\tau(p; x, y) = \begin{cases} 1, & p(x) < p(y), \\ 0, & p(x) \geq p(y). \end{cases} \quad (1)$$

In formula (1), $p(x)$ is the mean pixel value of pixel point 5×5 neighborhood. If there are m comparison point pairs, then the m bits binary descriptor is generated.

$$f_n(p) = \sum_{1 \leq i \leq m} 2^{i-1} \tau(p; x, y). \quad (2)$$

Suppose the coordinate of the feature point is O , then OC is the direction of the feature point, and the calculation formula of the direction angle is as follows:

$$\theta = a \tan 2(m_{01}, m_{10}). \quad (3)$$

In formula (3), the centroid of the image gray expression is as follows:

$$C = \left(\frac{m_{10}}{m_{00}}, \frac{m_{01}}{m_{00}} \right). \quad (4)$$

Add the direction of feature points obtained from formula (3) to the descriptor. We define a $2 \times m$ matrix Q as follows:

$$Q = \begin{pmatrix} x_1, x_2, \dots, x_{m-1}, x_m \\ y_1, y_2, \dots, y_{m-1}, y_m \end{pmatrix}. \quad (5)$$

In formula (5), (x_i, y_i) is a test point pair. Let the corrected feature point pair matrix be

$$Q_\theta = R_\theta Q. \quad (6)$$

In formula (6), R_θ is the rotation matrix corresponding to the direction of the feature point θ . The descriptor with rotation invariance obtained is as follows:

$$g_m(p, \theta) = f_m(p) | (x_i, y_i) \in Q_\theta. \quad (7)$$

The Shi-Tomasi algorithm is used to optimize feature points. The Shi-Tomasi algorithm takes the smaller of the

two eigenvalues and compares it with the given minimum threshold. If it is larger than the minimum threshold, a strong corner point will be obtained [15, 16]. The Shi-Tomasi algorithm detects corners by calculating the gray level of local small windows $W(x, y)$ moving in all directions. The gray scale change $E[u, v]$ generated by the window translation $[u, v]$ is as follows:

$$E[u, v] = [u, v]W \begin{pmatrix} u \\ v \end{pmatrix}. \quad (8)$$

In formula (8), M is the autocorrelation matrix of 2×2 , which can be calculated by the derivative of the image as shown.

$$M = \sum_{x,y} w(x, y) \begin{pmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{pmatrix}. \quad (9)$$

The two eigenvalues λ_{\max} and λ_{\min} of the matrix M are analyzed. Since the uncertainty of larger curvature depends on smaller corner points, the corner response function is defined as λ_{\min} . The Shi-Tomasi algorithm is used to calculate the corner response function λ_{\min} of each point for the feature points initially extracted by the improved FAST corner detection algorithm. According to λ_{\min} , the point with the maximum response value of the first N is determined as the feature point. There are at least two strong boundaries in different directions around the screened feature points, which are easy to identify and are stable [17, 18].

The feature descriptors in the research are designed by a retina-like model. The distribution of sampling points is similar to the structure of the retinal receptive field. The location of feature points is the central point, and the sampling points are evenly distributed on 7 concentric circles, with 6 sampling points on each concentric circle. In terms of the value of sampling points, the research takes the gray mean of the sampling point field as the description of sampling points, just like the ORB algorithm. The difference lies in that ORB uses an equal field to describe sampling points. The research uses square neighborhood descriptions with different side lengths for sampling points on concentric circles [19, 20]. From the intermediate feature point outwards, the sampling side length of each layer is 1, 3, 5, 7, 9, 11, 13, and 15, respectively.

The improved retina-like descriptors are obtained by comparing the results of the neighborhood gray mean of sampling points. Let F be a feature point descriptor, then

$$F = \sum_{0 < i < N} 2^i T(P_{ab}), \quad (10)$$

$$T(P_{ab}) = \begin{cases} 1 (I(P_a) - I(P_b) > 0), \\ 0, \text{ others.} \end{cases} \quad (11)$$

N is the dimension of the feature vector ($N=512$ in the research). P_a is the position of the sampling point to the midpoint a . P_b is the position of the sampling point to the midpoint b . $I(P_a)$ and $I(P_b)$ are the gray mean values of the sampling point in the sampling neighborhood.

For the matching of binary feature description vectors, the Hamming distance is generally used as the similarity measure between descriptors. The Hamming distance is as follows:

$$HM_{\text{distance}} = F_1 \oplus F_2. \quad (12)$$

By determining the threshold of the Hamming distance, the matching of feature vectors can be judged.

3.3. MSRCR. The reflectivity is determined by the object itself and varies without the influence of the emitted light. That is, the object image can be expressed as the product of the reflected image and illumination image, as shown in the formula:

$$S(x, y) = R(x, y) \cdot L(x, y). \quad (13)$$

After the logarithmic processing of both sides of formula (13) is carried out, the following formula can be obtained:

$$\log(R(x, y)) = \log(S(x, y)) - \log(L(x, y)). \quad (14)$$

In formula (14), $S(x, y)$ is the image of the object, $R(x, y)$ is the reflection component of the object itself, and $L(x, y)$ is the illumination component.

By constructing the Gaussian surround function, the Gaussian surround function is used to filter the three channels of RGB image to obtain the estimated light component. The reflection component can be obtained by subtracting the original image and light component in the logarithmic domain; thus, obtaining the output image as shown in the formula.

$$\begin{aligned} r_i(x, y) &= \log(R_i(x, y)) = \log\left(\frac{S_i(x, y)}{L_i(x, y)}\right) \\ &= \log(S_i(x, y)) - \log(S_i(x, y) * G(x, y)). \end{aligned} \quad (15)$$

The formula for the color recovery factor is calculated as follows:

$$C_i(x, y) = \beta \left(\log(\partial S_i(x, y)) - \log\left(\sum_{i \in (R,G,B)} S_i(x, y)\right) \right). \quad (16)$$

The MSRCR algorithm can not only ensure the gray level of the disease image and remove the influence of the uneven lighting during the shooting but can also improve the saturation of the image color to a certain extent when processing the disease image, which has the best color retention effect on the image.

3.4. Analysis of Experimental Results. All experiments were performed on a P computer environment with a 2.20 GHz CPU and 4 GB memory, and VC++ programming language was used in VS2010.

3.4.1. Analysis of the Distribution of Feature Points. To evaluate the merits and demerits of feature point detection methods, the repetition rate method is often used, so that m_1

and m_2 feature points are detected in two images to be matched. Then, the repetition rate is calculated as follows:

$$R = \frac{C(m_1, m_2)}{\min(m_1, m_2)}. \quad (17)$$

In formula (17), $\min(m_1, m_2)$ is the least number of feature points in the two images. $C(m_1, m_2)$ refers to the corresponding feature points, and the corresponding feature points should meet the following two definitions.

- (1) Position error of feature points:

$$\varepsilon_L = |x_a - H \cdot x_b| < 1.5 \text{ pixel}. \quad (18)$$

- (2) Surface error of feature area:

$$\varepsilon_s = \left| 1 - s^2 \frac{\sigma_a^2}{\sigma_b^2} \right| < 0.2. \quad (19)$$

In formula (19), s is the actual scale scaling factor between images and σ_a, σ_b is the feature scale of two feature points.

The ORB feature point detection algorithm and the improved algorithm in the research are used to calculate the repetition rate of feature points for images, respectively, as shown in Table 1.

As can be seen from Table 1, for images with scale transformation, rotation change, illumination transformation, noise interference, and perspective transformation, the improved feature point detection algorithm in the research has improved the repetition rate compared with the ORB feature point detection algorithm. This is because the improved FAST14-24 algorithm is used in the research to eliminate some pseudo-corner points on the edge and eliminate certain interference. In the process of the feature point optimization, the Shi-Tomasi algorithm is used to select feature points with large curvature changes, which are easy to identify and are stable [21, 22]. The feature point matching performance test is conducted on the test images, and the correct matching point pairs of each image are counted as shown in Table 2.

As can be seen from Table 2, the improved ORB feature extraction algorithm in the research improves the matching accuracy by about 18%~65% compared with the traditional ORB algorithm. Specially for the images with light changes, the matching accuracy of the proposed algorithm is significantly better than that of the traditional ORB algorithm, with an increase of 65.8%. Experimental results show that the proposed algorithm is superior to the traditional ORB algorithm in both matching accuracy and robustness for various types of image matching.

4. Identification and Extraction of Tobacco Leaf Disease Data and Segmentation of Disease Spots

4.1. Feature Extraction of Tobacco Spot Image

4.1.1. *Color Features.* The color feature is widely used in image recognition because of its intuitiveness. In a broad

sense, it can be understood that color feature, like texture feature, is used to express the surface attribute information of the scene in the image, but the attribute information expressed by the two is different. It describes the surface properties of the scene corresponding to the image region and is also a global feature. In the research, color moments are used to extract color features based on experimental requirements [23, 24]. The color moment can be understood as saving the information of the image color channel in the form of numerical size. The features of color moments are also different in terms of color information presented by different color channels. In an image, first-order moment (mean), second-order moment (variance), and third-order moment (skewness) are used to express the sufficient color information distribution according to the distribution of all information contained in the color. For example, most of the pictures we often come in contact with are RGB color space models, and there are 9 kinds of information to be extracted from this space model. In the three components R, G, and B, the corresponding first-, second-, and third-moment information is extracted from each component.

In the research, color moment features of RGB and HSV channels need to be extracted, and each extracted color moment has a total of 9 features. The corresponding color moments of the three components of the image constitute a 9-dimensional histogram vector, and the color feature information extracted from each image has a total of 18 dimensions. The model information is shown in Tables 3 and 4.

4.1.2. *Morphological Features.* The methods of morphological feature extraction [25–27] are as follows: the first is the boundary feature method, which is used to obtain shape parameters of image data information by describing boundary features. The second is the Fourier shape descriptor method, which is based on the mathematical idea of Fourier transform as a shape description, using the closure and periodicity of binary image boundary to reduce its dimension. The third is the shape parameter method for the quantitative measurement of fixed shape, which is based on the representation and matching of shape. The fourth is the shape invariant moment method, which is based on the moment of the region occupied by the target as a shape description parameter. According to the different appearance features of tobacco disease spots in different periods, four feature parameters of tobacco disease spots are extracted, including rectangularity, roundness, complexity, and compactness. The details are shown in Table 5.

4.1.3. *Texture Features.* Texture features describe the surface properties of the image, such as the patterns on the surface of butterflies, zebra lines, tree rings, and so on [28, 29]. The feature information is based on the statistical features of the whole gray image. Texture features have rotation invariance and strong resistance to noise. In the research, according to the features of spots in the early, middle, and late stages of the two diseases, six texture feature parameters, namely, energy, contrast, correlation, entropy, homogeneity, and

uniformity, are needed as texture feature parameters as shown in Table 6.

4.2. Image Feature Optimization of Tobacco Leaf Spots Based on PSO and ORB

4.2.1. Algorithm Principle. Particle swarm optimization takes the feasible solution space of the optimization problem as its search space and randomly generates the initial population in the search space. An individual is a particle without volume or mass [30]. The spatial position of each particle is a feasible solution to the optimization problem. The fitness of a particle is a measure of its position in space. The particle dynamically adjusts its flight speed and space position in the search space to search for the optimal space position and for finding an optimal solution to the problem [31, 32]. The PSO algorithm is used to reduce the original data dimension, and relatively few features are used to achieve better results. In the research, the PSO algorithm was used for the feature optimization of color features, texture features, and shape features extracted above. The algorithm flow is shown in Figure 1.

The ORB algorithm is a fast feature point extraction and description algorithm [33, 34]. To extract feature points, a scale pyramid is first constructed to make feature points meet scale invariance to a certain extent. Secondly, for each layer of the image pyramid, the FAST algorithm is used for the preliminary extraction of corner points. If the gray value of a pixel and enough pixels in its surrounding area differ sufficiently from the gray value of the point, the pixel is considered a FAST corner point. Furthermore, the Harris corner detection method was used to sort the feature points according to the response function of feature points. And, the first N corner points with good curvature are selected as the feature points according to the sorting results. Finally, the gray center of the mass method is used to determine the direction of feature points, and Rosin defines the moments of image blocks.

For discrete problems, the spatial position of the particle is represented as a vector composed of 0 and 1. For each iteration, it becomes difficult to calculate the velocity and spatial position of the particle in the search space.

4.2.2. Feature Selection Results. A total of 28 normalized features are selected in the early, middle, and late stages of brown spot disease and frog eye disease. After using the particle swarm optimization algorithm for 15 times, the feature selection results are derived which are shown in Table 7.

Table 7 shows that the fitness of the tenth group of data is 95.23, and the cross-validation rate is 93.31%. The recognition rate of the verification set is 96%, which also reaches the maximum value. The feature optimization is a 13-dimensional feature parameter. Therefore, the tenth group of optimization results is selected for the next step of classification recognition, namely, R1, B2, H1, S1, H2, V2, S3, rectangularity, complexity, energy, contrast, entropy, and average grayscale.

4.3. Classification and Recognition of Tobacco Leaf Disease Spots Based on SVM. Pattern recognition refers to the analysis and processing of all kinds of information representing things through computer technology. It is an integral part of artificial intelligence. Classifiers, also called discriminant models, are used in pattern recognition. The support vector machine (SVM) is one of the commonly used classifiers, which is commonly used in image retrieval, target tracking, face recognition, and other fields. In this research, a support vector machine (SVM) was used to classify the optimized feature parameters, so as to realize the classification and recognition of the early similar diseases of tobacco leaves (brown spot disease and frog eye disease) and the early, middle, and late stages of the two diseases.

In real use, most are discrete, namely, nonlinear. Through the nonlinear mapping, the space samples are mapped to a high-dimensional feature space, constructing the optimal separating hyperplane again. At this time, considering that there is still linear inseparability caused by a small number of samples after nonlinear mapping to a high-dimensional feature space, relaxation variables need to be added. The penalty factor is added to the objective function, which plays a role in controlling the punishment degree of misclassification samples. The discrete classification problem can be regarded as a quadratic programming problem. The SVM is a binary classification algorithm, which can separate two different types of samples. But in the research process, six types of samples will appear at most, so it is necessary to construct appropriate multiclassifiers. Currently, there are two main methods to construct SVM multiclassifiers: direct method and indirect method. In this research, the one-to-one classification method of indirect method is used to design an SVM between any two different samples. Therefore, samples of N different categories need $n(n-1)/2$ SVMs. During the classification, the category with the most votes is the category of samples, as shown in Figure 2. The one-to-one classification method of the SVM function is adopted in MATLAB, and there are at the most six types of data in the research study. Figure 2 is an example diagram of the one-to-one classifier of the support vector machine. In this study, the main research is aimed at the early diseases of tobacco brown spot and frog eye disease, and the middle and late stages of tobacco brown spot and frog eye disease are added as the references in the classification process.

Two kinds of classification problems are solved, that is, the sample of one class at a time is selected as the positive class sample, and the sample of the negative class becomes only one class (called the "one-to-one" method). According to the maximum category adopted in the research, there are six categories. For this pair of one-category devices, the first one only answers "is it the first or the second," the second one only answers "is it the first or the third one," and the third one only answers "is it the first or the fourth one". There should be 15 such classifiers ($n(n-1)/2$ SVM classifiers are constructed if there are n categories). Although the number of classifiers is increased, the total time spent in the training stage is less than that of the "one-to-others" method, which is a directed acyclic graph, so this method is also called the DAG SVM.

TABLE 6: Selected texture feature information of six images of tobacco brown spot disease and frog eye disease in the early, middle, and late stages.

	Energy	Contrast	Correlation	Entropy	Homogeneity	Uniformity
Early stage of brown spot disease	0.9785	11.0598	0.9669	0.2087	0.9923	1.0851
Middle stage of brown spot disease	0.9065	31.3123	0.9880	0.8315	0.9638	7.3023

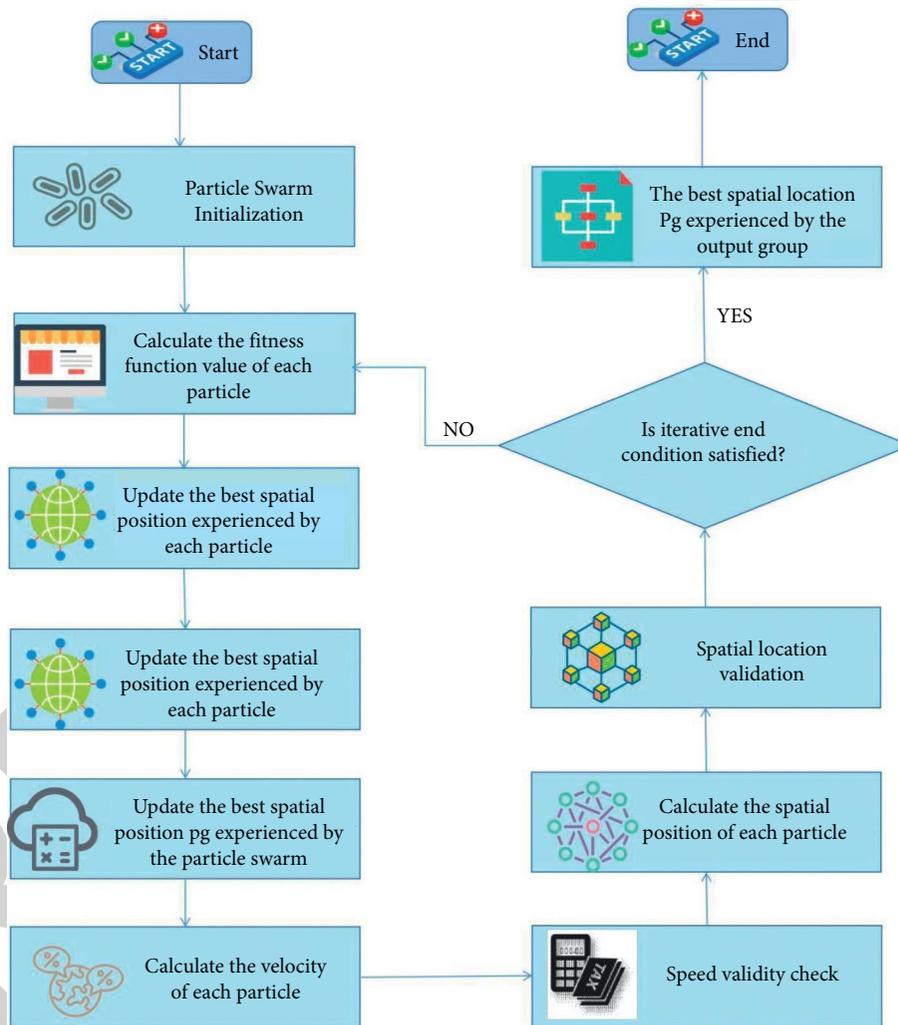

FIGURE 1: Flow chart of the PSO algorithm.

The classifier used in the research determines whether these categories belong to the first or the sixth category in the “1 to 6” classification process. It continues to judge the category according to the order shown in the above figure and runs the judgment until all six categories of data are identified. At this time, 15 classifiers are actually called, which can accurately distinguish different classes.

4.4. Analysis of Identification Results. The total number of samples in the research is 1200 groups, including 600 groups of tobacco frog eye disease and 600 groups of brown spot disease, including 200 groups in the early, middle, and late stages, respectively. 150 groups are selected as the training data, and 50 groups are selected as the test data. The color features, morphological features, and texture features extracted above are normalized and optimized by the

particle swarm optimization algorithm. Finally, the SVM classification model is established for recognition. The test recognition results are shown in Table 8.

The identification rate of early disease samples of frog eye disease is 90% and that of brown spot disease is 94%. According to Figure 3, the external morphology of frog eye disease and brown spot disease in the early stage is very similar. Brown spot disease has patches of different widths around the spot in the early stage, but frog eye disease does not. The early stage of brown spot disease is characterized by round spots, and the color of the spots is mostly yellowish brown. The early stage of frog eye disease is characterized by round spots which are brown, tawny or dirty white, or mostly brown. The identification rate of frog eye disease is lower than that of brown spot disease based on the color and halo of frog eye disease and brown spot disease and is shown in Table 9.

The number of identification errors in the early, middle, and late stages of frog eye disease samples is 4, 1, and 1, respectively. The number of identification errors in the early, middle, and late stages of brown spot disease samples is 4, 2, and 0, respectively. The early stage of frog eye disease is characterized by round spots which are brown, tawny or dirty white, or mostly brown. There is no significant difference in the area of the middle and late stages of frog eye disease. The actual measurement shows a width range of 0.5 cm-1 cm. The middle stage of frog eye disease is gray parchment in the center, and the gray mold layer and perforation damage are produced in the late stage of frog eye disease. The early stage of brown spot disease is characterized by round spots, and the color of the spots is mostly yellowish brown. In the middle stage, there are obvious rims and the area of the lesion gradually becomes larger. The actual measurement in the field shows a width range of

	Middle	150	50	49	98
	Late	150	50	49	98
Frog eye disease	Early	150	50	48	96
	Middle	150	50	45	90
	Late	150	50	50	100
Total		900	300	288	96

0.6 cm-2 cm. The width of a single spot in the late stage ranges from 4 cm to 10 cm, and the whole leaf surface will be necrotic if multiple disease spots are linked together.

On the other hand, in order to further improve the efficiency of recognition, a deep learning framework is used. After the data enhancement, a total of 2668 original crop leaf disease images are analyzed. 20 labels are assigned to each image in the dataset, each label representing a crop disease. Through the data enhancement, the original data images are extended to the sample set with 32016 images. Through transfer learning, the parameter weights of the last layer are retrained, and then the recognition accuracy of the four groups of experiments on several deep learning frameworks is compared with the verification set. Other parameters are shown in Table 10.

First, it is determined that the dataset contains 32,016 images after data enhancement of the original images, and the influence of different center loss weights λ on the supervision effect is tested. Then, in the best λ case, four groups of experiments are carried out to cross-verify the influence of data enhancement and joint supervision on the model. The verification combination is shown in Table 11.

The specific experimental results are presented in Figures 4 to 6.

After the abovementioned figure is iterated, the recognition accuracy curve gradually becomes stable and rises. Similarly, after 5000 iterations, the loss gradually declines gently. Experimental results show that the two-stage AD-GACCNN network structure can effectively improve the generalization ability of the model and reduce the

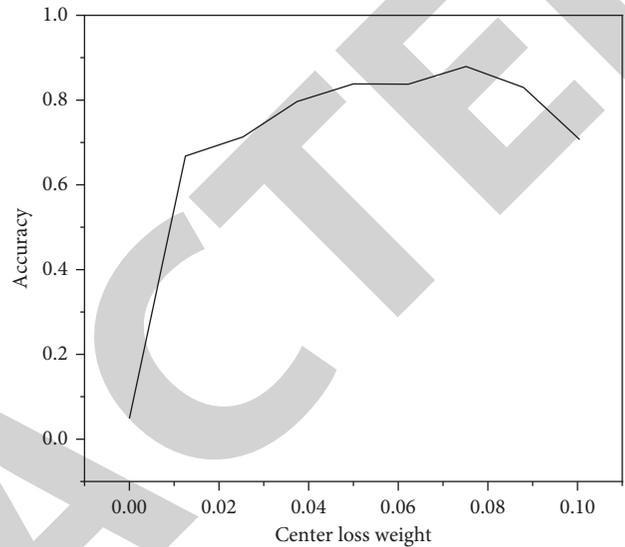

FIGURE 6: Influence of the weight loss of test center on the recognition accuracy of B + C sets on GoogleNet.

occurrence of the overfitting phenomenon. When using the central loss function and softmax function as the joint supervision mechanism, the model can effectively reduce the intraclass distance and increase the interclass distance. When the two methods are simultaneously applied to the model, the recognition accuracy of the model is increased by nearly 10% compared with that of the model without either method. It can be seen that it has obvious significance for spot recognition tasks for small samples under complex backgrounds and also has reference significance for other types of recognition tasks.

5. Conclusion

The main content of the research was to investigate the early segmentation and recognition of brown spot disease and frog eye disease, which have high similarities to tobacco diseases. The images of two tobacco diseases (brown spot disease and frog eye disease) under complex background were used as segmentation objects.

- (1) The commonly used segmentation methods and theories of crop diseases, especially tobacco leaf diseases, were summarized, and the segmentation methods of tobacco leaf diseases under complex backgrounds were emphatically investigated. In view of the difficulty in segmentation of images of two tobacco leaf diseases (brown spot disease and frog eye disease) under complex background in field

practice, a multistep segmentation method based on saliency detection and seed point selection was proposed, which combined the mean shift smoothing preprocessing with simple linear iterative clustering preprocessing. It was suitable for image segmentation in a complex field environment, and the effectiveness of the method was proved.

- (2) According to the realization forms of the two diseases in different periods, the color features, morphological features, and texture features were extracted, with a total of 28 dimensions of color feature information. After that, the particle swarm optimization algorithm was used to optimize the features and reduce the dimensions to 13 dimensions, greatly reducing the workload in the recognition classifier.
- (3) According to different external forms of brown spot disease and frog eye disease in the early, middle, and late stages (six categories), the different diseases of the image color features, shape features, and texture features were extracted. A total of 28 dimensional data features were extracted from each category. Then, feature optimization was carried out by the particle swarm optimization algorithm, and finally, 13 dimensional feature parameters were obtained. The recognition rate of the verification test set reached 96%. In the recognition process, a support vector machine was used to classify tobacco brown spot disease and tobacco frog eye disease. The recognition rate of tobacco brown spot disease and frog eye disease in the early stage reached 92%, and the recognition rate of six categories of the early, middle, and late stages of the two diseases reached 96%.

Now, the use of deep learning technology to solve the problems of the low multiclassification task detection accuracy and complex feature engineering existing in traditional intrusion detection technology has become a research hotspot. In all kinds of deep learning, recurrent neural networks (RNN) are very important. The RNN processes 41 feature attributes and maps them to a 122-dimensional high-dimensional feature space. To detect multiclassification tasks, this study proposes an intrusion detection method based on fully connected recurrent neural networks and compares its performance with previous machine learning methods on benchmark datasets. The research results show that the intrusion detection system (IDS) model based on fully connected recurrent neural network is very suitable for classification of intrusion detection. Classification methods, especially in multiclassification tasks, have high detection accuracy, significantly improve the detection performance of detection attacks and DoS attacks, and it provides a new research direction for the future attempts of intrusion detection methods for industrial control systems.

1. Introduction

With the achievements of deep learning in image recognition, speech recognition, etc, it also provides a new method and idea for researchers in the field of intrusion detection to carry out related work.

Recurrent neural networks (RNN) were important. In 2007, Rachid et al. applied RNN and standard neural network to the field of intrusion detection and conducted experiments on the constructed small sample dataset. The experimental results showed that the detection and classification performance based on the RNN was relatively general on the small sample dataset, which was lower than the neural network under the same conditions. In 2010, Mansour et al., considering the complexity of the fully connected neural network structure, constructed a partially connected RNN, and the features between groups were constructed into a fully connected recurrent neural network, and there was no information between the features between

groups [1–3]. Contact feedback to reduce model training time and achieve better detection results on the datasets you build. Although the locally connected recurrent neural network structure shortens the training time, the features were artificially classified, and the connections and roles between different groups of features were not considered.

After in-depth analysis, this study proposes an intrusion detection model based on fully connected recurrent neural network. Forty one feature attributes were processed and mapped into a 122-dimensional high-dimensional feature space, and features were no longer grouped and classified. Considering the relationship between features, this study investigates the detection ability of fully connected recurrent neural networks under multiclassification tasks.

2. Recurrent Neural Network (RNN)

Currently, recurrent neural networks (RNN) are mainly used to solve dynamic system problems involving time series

of events. Structurally, a RNN includes a hidden layer, an input layer, and an output layer [4–6]. The current output is related to the previous output, and the nodes of each hidden layer are no longer disconnected. Therefore, the main work is achieved through the loop of the hidden layer itself. Essentially, an RNN is a unidirectional information flow from the input layer to the hidden layer, combined with a unidirectional information flow from the last sequential hidden layer to the current hidden layer. Figure 1 visually compares the differences between traditional neural networks and RNN.

Figure 2 shows the structure of the RNN after expansion. All states before time series t will be represented as outputs at time series $t-1$ and affect the time series t . Therefore, a RNN is a learning model with a dynamic deep structure. If the hidden unit is regarded as the storage space of the entire network, when the RNN is expanded according to the time series, it can be considered that the RNN has memorized all the information so far, which is a typical end-to-end learning method. Theoretically, a RNN can learn arbitrarily long sequence information and can remember end-to-end information, reflecting the “depth” of deep learning.

Obviously, in training, the training of RNN includes forward pass and backward pass. Similar to the traditional neural network training algorithm, the forward pass is output according to the time sequence, and the reverse pass is to pass the accumulated residuals of the previous period back through the RNN. During forward propagation, the hidden layer output (h_t) is

$$h_t = \sigma(Wx_t + Uh_{t-1} + b_h), \quad (1)$$

where σ is the activation function, x_t is the input vector of the time series t , h_t is the output of the hidden layer, W is the weight matrix, U is the self-circulating weight matrix, and b_h is hidden layer bias.

2.1. Intrusion Detection System (IDS) Based on Fully Connected Recurrent Neural Network. The overall framework of the intrusion detection model is shown in Figure 3, which mainly includes five steps [7–10].

Obviously, the training of the FCRNN-IDS has two aspects: forward propagation and weight fine-tuning. The forward propagation was responsible for the operation of the output data, and the fine-tuning of the weights was to update the weights by passing the accumulated residuals [11], which was no different from ordinary neural network training. The training was divided into two steps: first, the forward propagation algorithm was used to calculate its output value for each training sample of the input model. Then, using the weight fine-tuning algorithm, the entire model parameters were fine-tuned through backpropagation, and finally, a complete fully connected RNN classification model was obtained.

According to Figure 2, Algorithm 1 is a forward propagation algorithm, and Algorithm 2 is a weight update algorithm, respectively. Calculate the output \hat{y}_i of each instance x_i using the forward propagation algorithm.

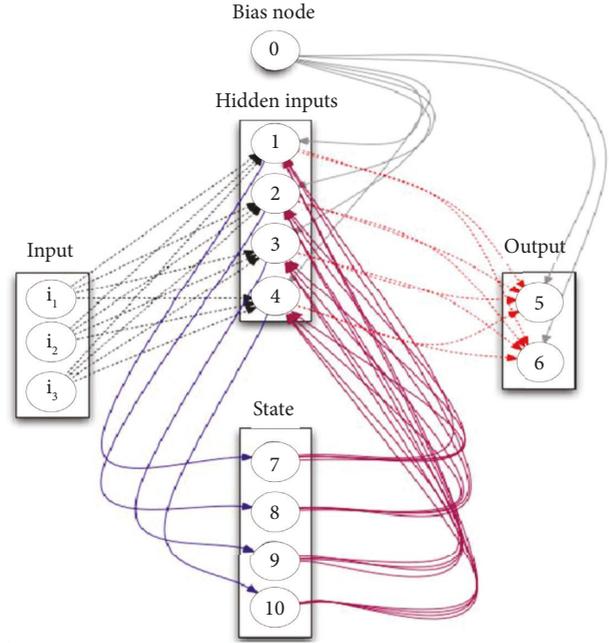

FIGURE 1: RNN structure.

3. Experiment

3.1. Data Sources. The dataset used in the experiment is a new benchmark dataset NSL-KDD [12–15]. This dataset is widely used.

3.2. Data Feature Extraction and Selection. Each connection record in the NSL-KDD contains 41 feature attributes [16–19]. Among them, 41 features can be divided into 4 categories:

- (i) Basic features (9 types in total, numbered 1 to 9)
- (ii) Content features (13 types in total, serial numbers 10 to 22)
- (iii) Time-based network traffic statistics (9 types in total, serial numbers 23~31)
- (iv) Host-based network traffic statistics (10 types in total, serial numbers 32~41)

3.3. Data Preprocessing. Using the NSL-KDD dataset, each connection record consists of 41 feature attributes, including 3 non-numeric feature attributes. Data preprocessing mainly includes two parts: numericalization of nonnumerical feature attributes. After one-hot encoding, the attribute feature 'protocol_type' corresponds to the binary feature vectors (1, 0, 0), (0, 1, 0), and (0, 0, 1). The other two nonnumerical attribute properties “service” and “flag” have 70 and 11 values, respectively. After such digital processing, the original 41-dimensional feature vector was converted into a 122-dimensional high-dimensional feature vector. On the one hand, one-hot encoding solves the problem of non-numerical data conversion, making the calculation of “distance” between features more reasonable.

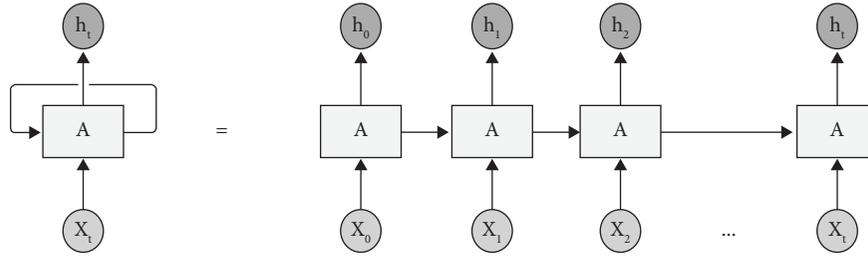

FIGURE 2: Unrolled RNN.

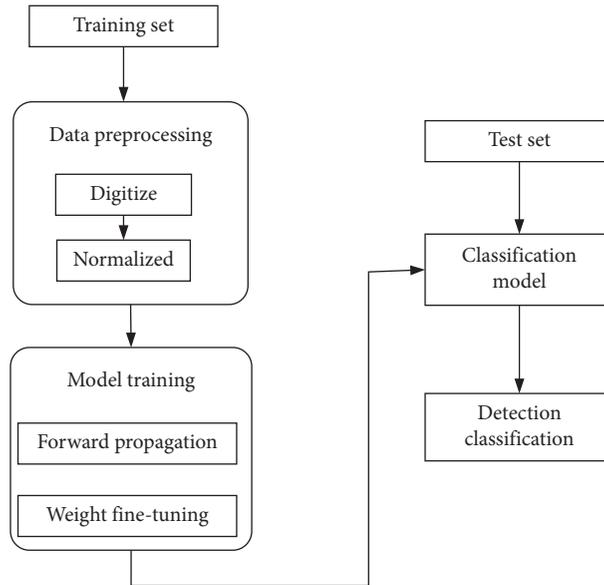

FIGURE 3: Framework of intrusion detection system based on fully connected recurrent neural network (IDS-FCRNN).

Input: the training sample was x_i ($i=1, 2, m$), the weight matrix was W_{hx} , W_{hh} , and W_{yh} , the bias was b_h and b_y , the activation function e uses the sigmoid function, and the classification function g uses the SoftMax function.

Output: the output value \hat{y}_i corresponding to the training sample X_i

- (1) for x_i from 1 to m do
- (2) $t_i = W_{hx}x_i + W_{hh}h_{i-1} + b_h$
- (3) $h_i = \text{sigmoid}(t_i)$
- (4) $s_i = W_{yh}h_i + b_y$
- (5) $\hat{y}_i = \text{SoftMax}(s_i)$
- (6) End for

ALGORITHM 1: Forward propagation algorithm.

Input: the training sample was (x_1, y_1) ($i=1, 2, \dots, m$).

Initialization: the initialization model parameter was $\theta = \{W_{hx}, W_{hh}, W_{yh}, b_h, b_y\}$

Output: the fine-tuned model parameter was $\theta = \{W_{hx}, W_{hh}, W_{yh}, b_h, b_y\}$

- (1) For each sample x_i , input a fully connected RNN, the output \hat{y}_i of x_i was calculated by Algorithm 2.1
- (2) Calculate the cross-entropy $L(y:\hat{y}_i)$ between the output value of each sample and the label value:
 $L(y:\hat{y}_i) \leftarrow -\sum_i \sum_j y_{ij} \log(\hat{y}_{ij}) + (1 - y_{ij}) \log(1 - \hat{y}_{ij})$
- (3) For each network model parameter θ_i in θ , calculate the partial derivative δ_i : $\delta_i \leftarrow dL/d\theta_i$
- (4) Make the error propagate back along the network and update each network model parameter θ_i in θ :
 $\theta_i \leftarrow \theta_i + \eta \delta_i$
- (5) If $t=k$, save the model parameters and the algorithm ends
- (6) If $t < k$, then $t=t+1$, turn to 1.

ALGORITHM 2: Weight fine-tuning algorithm.

The first step was that the data value space was too large. Feature attributes such as “duration[0, 58329],” “dst_bytes[0,1.3×109],” and “src_bytes[0,1.3×109],” which were correspondingly scaled by the logarithmic correction method as “duration[0, 4.77],” “dst_bytes[0, 9.11],” and “src_bytes[0, 9.11];” then, make each instance lie on the same order of magnitude on this feature. The second step was to normalize the data to the [0, 1] value range according to the following formula:

$$x_i = \frac{x_i - \text{Min}}{\text{Max} - \text{Min}}, \quad (2)$$

where x_i was the attribute eigenvalue, Min was the minimum value, and Max was the maximum value.

3.4. Test Plan. This study adopts the comparative test method to detect the accuracy of FCRNN-IDS.

3.4.1. Comparative Experiment 1: Comparison with Traditional Machine Learning Methods. Using the same dataset NSL-KDD, the detection accuracy of seven traditional machine learning algorithms [20–33] such as decision tree, Naive Bayes, Naive Bayes tree, random tree, random forest, support vector machine, multilayer perceptron, and the detection accuracy of the FCRNN-IDS model in the case of 2-class (normal, abnormal) and 5-class (normal, probe, Dod, R2L and U2R) were studied and compared.

In [5], the authors investigated the anomaly detection performance of the above 7 classification algorithm models on the NSL-KDD benchmark dataset using Weka machine learning and data mining tools. Under the 2-class task, Figures 4 and 5 show the detection accuracy of KDDTest+ and KDDTest-21 by seven traditional machine learning methods, respectively. This study takes the research results of [5] as one of the comparative experiments; under the 2-class task, it was compared with the detection model based on fully connected recurrent neural network.

3.4.2. Comparative Experiment 2: Comparison with Recent Similar Literature. Wang and Cai [8] studied the performance of artificial intrusion detection systems under two and five types of tasks based on the same benchmark dataset NSL-KDD. The experimental results show that, under the dataset KDDTest+, the highest detection rate of the model was 81.2% under the 2-class classification; the highest detection rate of the model was 79.9% under the 5-class classification.

Deng et al. [9] proposed three-layer partially connected recurrent neural network architecture with 41 features as input and 4 intrusion categories and normal category as output. Taking the KDD99 dataset as the benchmark, some connection records were selected as the training set and the test set, respectively. The results show that the highest detection accuracy of the model was 94.1%. On the test set, the training time was set at 1383 seconds.

4. Results’ Analysis

4.1. Experimental Results of 2-Class Tasks. As mentioned earlier, the 41-dimensional feature vector was mapped to a 122-dimensional feature vector, so in the 2-class experiment. Figure 6 shows the detection accuracy of the FCRNN-IDS model on the training set with different structures and Learningrates.

As shown in Figure 7, it shows the detection accuracy of the FCRNN-IDS model on the test set KDDTest+ with different structures and Learningrates. As can be seen from Figure 7, when the Learningrate was 0.1 and the number of HiddenNodes was 80, the detection accuracy of the model on the test set KDDTest+ was 83.28%.

Figure 8 shows the detection accuracy of the FCRNN-IDS model on KDDTest-21 with different structures and Learningrates. As can be seen from Figure 8, when the Learningrate was 0.1 and the hidden node was 80, the model has the highest detection accuracy on KDDTest-21, which was 68.55%.

The experimental results were as follows.

As shown in Table 1, the number of HiddenNodes was 80 and the Learningrate was 0.1, which obtains high detection accuracy. Figure 9 details the variation in detection accuracy of the FCRNN-IDS model iteratively trained on the KDDTrain+, KDDTest+, and KDDTest-21.

Ashfaq e al. [5] studied the detection accuracy of classification algorithms such as J48, Multilayer Perception, Naive Bayes, Support Vector Machine, and Random Forest. The results are shown in Figures 4 and 5; the artificial neural network algorithm has the highest detection accuracy on the test set KDDTest+ in the 2-class task, reaching 81.2%, which was the latest literature on the application of related algorithms. The above model experimental results were all based on the dataset NSL-KDD, so they had similar comparison conditions.

As shown in Figure 10, the three algorithm models showed good classification and detection performance, especially the Naive Bayesian tree on the test sets, KDDTest+ and KDDTest-21. Better classification and detection performance: the detection accuracy of this method was high, 82.02% and 66.16%, respectively.

Compared with the detection method based on artificial neural network proposed in [8], FCRNN-IDS has the highest detection accuracy under the 2-class task, which was 81.2%, and the detection accuracy under the 2-class task was also higher. Table 2 shows the confusion matrix of the ANN-based detection model on the test set KDDTest+ when performing the 2-class task. Table 3 presents the confusion matrix of FCRNN-IDS on KDDTest+ under the 2-class task.

Therefore, when performing 2-class tasks, FCRNN-IDS further improved the detection ability of attack behavior, improved the accuracy, and reduced the false positive rate.

4.2. Experimental Results of Multiclassification Tasks. Figure 11 shows the detection accuracy of FCRNN-IDS on the training set with different structures and

HiddenNodes = 240, Learningrate = 0.5	99.87%	80.97%	63.69

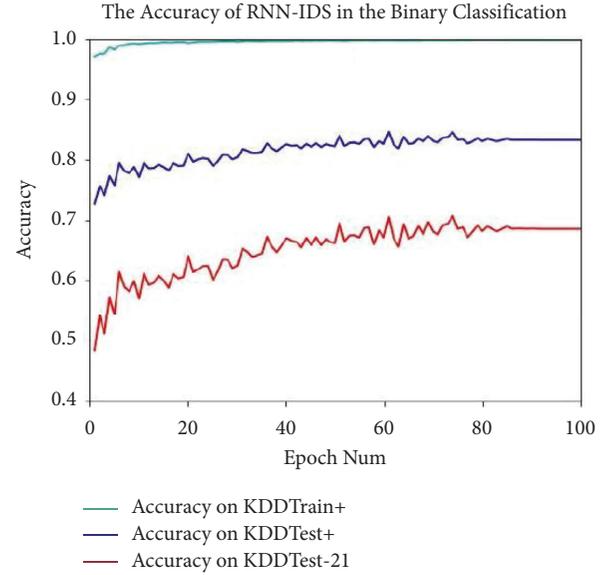

FIGURE 9: Detection performance of the model on the dataset (2-class).

Learningrates. As can be seen from the figure, when the Learningrate was 0.5 and the hidden node was 60, the model has the highest detection accuracy on the training set, which was 99.87%.

As shown in Figure 12, from the detection accuracy of FCRNN-IDS on the test set KDDTest+ under different structures and Learningrates, it can be seen that the Learningrate was 0.5 and the hidden node was 80; the model has the highest detection accuracy in the test set KDDTest+, which was 81.29%.

As shown in Figure 13, from the detection accuracy of FCRNN-IDS on the test set KDDTest-21 under different structures and Learningrates, the Learningrate was 0.5 and the number of HiddenNodes was 80; the model has the highest detection accuracy on the test set KDDTest-21, which was 64.67%.

Table 4 shows the detection accuracy of FCRNN-IDS on the training set and 2 test sets when performing multiclass detection tasks with different network structures and different Learningrates. Obviously, the experimental results on multiclassification tasks show that different network structures and Learningrates can affect the detection ability of the FCRNN-IDS. As shown in Table 4, when the hidden layer of the FCRNN-IDS was set to 80 nodes and the Learningrate was set to 0.5, the model has higher detection accuracy on the KDDTest-21 and KDDTest+ test sets, which was 81.29% and 64.67%.

In order to compare the detection accuracy of various algorithms, similar to the 2-type task experiment, J48, Naive Bayes, Random Forest, and multilevel models were established through data mining software Weka and open source machine learning. Using 10 layers of cross-validation in the training set KDDTrain+, model training was performed using 7 machine learning algorithm models including layer perceptrons and support vector machines, and then, the model detection accuracy was tested in the

Normal	298	9413(↑)

test set. The experimental results are shown in Figure 14. Compared with the previous 2-class task, the detection accuracy of the traditional classification model generally drops under the multiclass task. Multilayer perception has the highest detection accuracy on the test sets KDDTest+ and KDDTest-21, 78.10% and 58.40%, respectively.

Under the same conditions, the neural network-based classification model achieves a detection accuracy of 79.9% when performing multiclassification tasks. Obviously, FCNN-IDS performs better than other neural network-based detection models when performing multiclassification tasks.

Tables 5 and 6 show the confusion matrices of the neural network-based detection model and the fully connected recurrent neural network-based detection model on the test set KDDTest+, respectively.

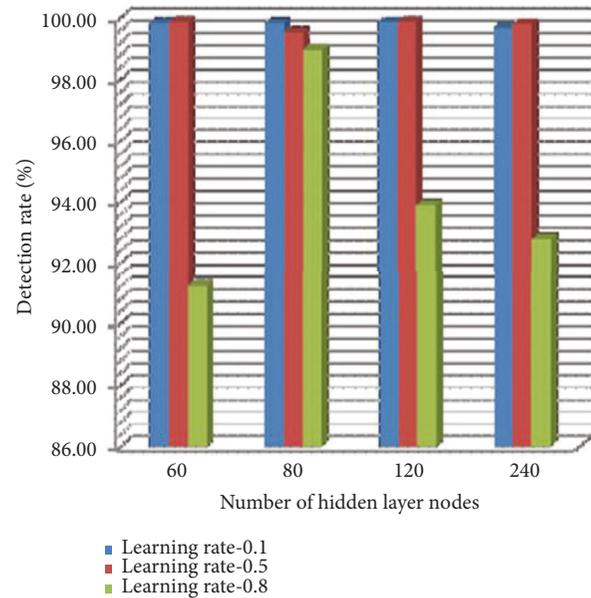

FIGURE 11: Detection rate of the model on the training set (multiclass).

Comparing the detection results in Tables 5 and 6, it can be seen that, in terms of correctly detecting DoS attacks, detection attacks, and U2R attacks, the detection model based on the RNN was fully connected to correctly detect more than 429 and 165 detection models based on neural networks, respectively, 2 contact records. Of course, in terms of correctly detecting normal connection records and R2L attack categories, the detection model

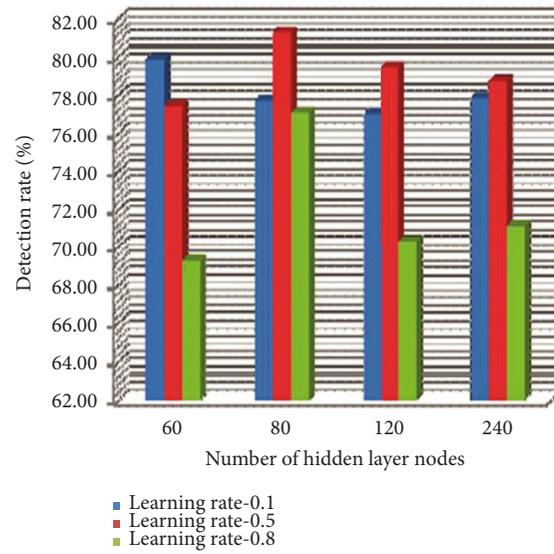

FIGURE 12: The detection rate of the model on the test set KDDTest⁺ (multiclassification).

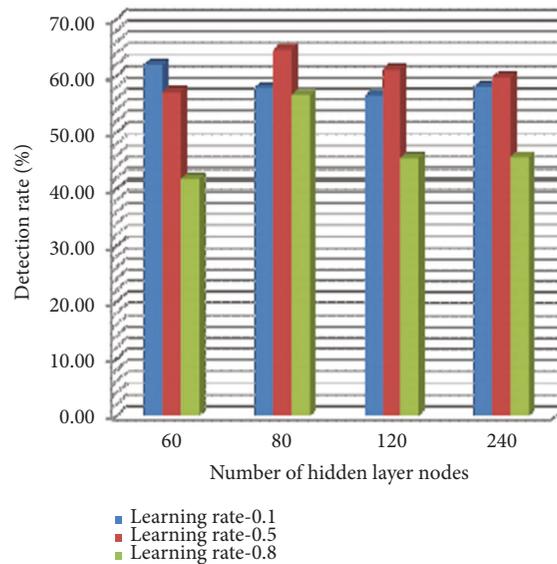

FIGURE 13: Detection rate of the model on the test set KDDTest⁻²¹ (multiclassification).

based on the fully connected RNN correctly detected 20 and 272 fewer connection records than the neural network, respectively.

The confusion matrices of the four attack types detected by the model on the test set KDDTest⁺ are shown in Tables 7–10. Table 10 shows that the model false positives and recalls vary according to the type of attack. Table 11 shows the recall and false positive rates for different attack types.

In order to compare the detection performance of the fully connected neural network model and the partially connected RNN model proposed in [9] for intrusion detection, the training set and test set were constructed

according to the method mentioned in [9], as shown in Table 12. In the experiments, the model was set to 20 HiddenNodes, the Learningrate was 0.1, and the training epoch was 50 times. The detection accuracy of the trained model on the test dataset reaches 97.09%, which was higher than 94.1% in the literature.

As shown in the experimental results above, the fully connected model proposed in this study has stronger feature space modeling ability and higher accuracy. Of course, without GPU acceleration, the model training time based on the fully connected RNN was 1765 seconds, which was higher than the training time of the model based on the partially connected RNN at 1383 seconds.

5. Conclusion

Compared with traditional machine learning classification models, fully connected recurrent neural network, as a deep learning method, has stronger feature representation ability, can more comprehensively map high-dimensional feature space into low-dimensional feature representation, and has the ability to express complex functions. Therefore, the detection model based on the fully connected RNN can detect a large number of abnormal attack records in binary and multiclassification tasks, improve the accuracy of intrusion detection, and reduce the false positive rate. For example, in terms of correctly classifying abnormal records, the fully connected recurrent neural network-based detection model correctly detected 462 more records than the neural network-based detection model when performing a 2-class task [34].

The main contributions of this study are as follows:

- (1) A new intrusion detection system based on fully connected recurrent neural network (FCRNN-IDS) was proposed, the training method of the model was studied, and the detection rate of models with different structures and different Learningrates was studied.
- (2) Using the dataset NSL-KDD, the detection performance of seven traditional machine learning methods in 2-class and multiclass tasks was studied, respectively. It lays a foundation for FCRNN-IDS with traditional learning methods.
- (3) The detection accuracy of FCRNN-IDS in 2-class and multiclassification tasks was studied, the performance of FCRNN-IDS in detecting various types of attacks was deeply analyzed, and the performance of FCRNN-IDS in detecting various types of attacks was compared.

We can hear sweet and touching music in our daily life. We like listening to music because music can affect our emotions. Dynamic music makes us very excited. When we are sad, hearing beautiful music can make us happy. In physiology, music affects many physiological processes. It can inhibit fatigue and affect pulse, respiratory rate, and blood pressure level. “Listening music helps improve mood.” Although the pursuit of personal happiness is likely to be considered a self-centered adventure, research shows that happiness is positively correlated with socially beneficial behavior, better health, higher income, and better interpersonal relationships. Another reason why we like music and music can be used very effectively for various therapeutic goals is that music is used in many ways in our society. When a group of people come together to sing a chorus or engage in musical activities, concerts establish new ties between people and make them closer. People grow up listening to lullabies from birth. When they die, they end their lives with funeral music (songs). It may be said that one’s life begins with music and ends with music. Through music, we sing about social phenomena, express ourselves, and communicate with others. The themes and hidden contents that the music production society is unwilling to express publicly are not limited by any judgment. It should be noted that the functions of the above music are flexibly applied according to personal conditions, rather than being classified and limited by functions.

1. Introduction

Music is a wonderful sound composed of tone, timbre, and rhythm, which gives people unique aesthetic experience [1]. Therefore, if we need to know more about these experiences, we need more empirical research from outside the laboratory. At present, exploratory research has measured the aesthetic experience (emotion and absorption caused by music) of 95 participants, as well as the research on the response of fast-paced and slow-paced music to people’s physiology [2]. These participants played romantic, classical, rock, and modern music in four concerts. One of the musical movements of modern works is deduced from the recording. So, the first result emphasizes the influence of two key parts of the framework on aesthetic emotion: (1) unfamiliar contemporary works lead to higher negative emotion, which is caused by the rising and falling trajectory of emotion by the programming sequence. Nevertheless, this experience is

printed into a highly praised concert as a whole. (2) Compared with the low participation of live recorded music, the vitality factor becomes obvious. Secondly, the participants’ reactions made them observe how more musical works were perceived [3]. The opening and closing movements caused more positive responses, compared the characteristics of the internal parts, and caused lower arousal and complex emotions. However, will the speed of music rhythm affect people’s emotional and physiological indicators? Edworthy and Waring found in previous studies and their own that fast-paced music can cause positive performance of participants better than slow-paced music. In the study by Brownley McMurray and Hackney, fast-paced music can improve the physiological response of participants better than slow music [4]. And, some scholars (Nethery, Harmer, Taaffe, etc.) have discussed the impact of inserting music during sports on athletes and how different music affects them, which has also produced many different

arguments and opinions, so 26 athletes were invited to do experiments. The results showed that the heart rate of athletes with music was higher, and the exercise time with music insertion was longer than that without music insertion. Therefore, they believe that music can affect athletes' psychological and physiological reactions during sports because music can stimulate athletes' blood flow [5].

1.1. Aesthetic Experience of Live Concert. Although there are still emotional frameworks and aesthetic experience in music at present, there are still problems of ecological effectiveness in listening and stimulation. Up to now, research is usually carried out in a highly controlled laboratory environment, using relatively short music works or single movements and short films. Classical laboratories usually neither include works of whole or multiple movements nor do they choose the so-called key influence of the framework of auditory generation. Although in theory, the background and scene are considered to be the combination of artistic visual aesthetic experience. The main purpose of this study is to explore the aesthetic experience of listening music in the current real environment, that is, performing music live in the concert hall, including the string quintet of contemporary composers Brett Dean, Ludwig van Beethoven, and Brahms. These writers are very representative in contemporary times. For example, Ludwig van Beethoven's concert has been widely spread until now, and they are very famous pianists. This study takes their works as an experiment, which is very representative. In a fixed course, dedicated listening is the framework of the concert. We chose a term introduced by a sociologist Irving Goffman, namely, framework Goffman [6] in order to understand the relationship between music-related behavior and situational factors. According to Goffman, these frameworks will also affect aesthetic experience and appreciation, and the impact of the contemporary realistic environment, situation, framework, or background is also recognized by the institute. For example, cinemas [7], theatres (Cardizzi et al., 2020) [8], and so on. In fact, research shows that some concerts enhance the experience of music listening, and live music performance provides people stronger (positive) response [9]. Compared with the same performance, the live performance of the video in the Church can arouse the emotional input and feelings of the participants [10] and can be appreciated with more concentration. A series of works performed in the concert are presented in the expected order. Emotions fluctuate during the performance of different musical works [11]. During the performance of classical works, complex and positive emotional fluctuations rise, contemporary works decline, and romantic works rise again. Tension and excitement fluctuate greatly in contemporary works and are significantly higher than classical and romantic works [12]. It can be seen that the emotional range of the less familiar works is different from that of the other two familiar works. Classical concerts put it in famous classical works through different arrangement ideas, including new works, so as to increase people's love for it.

2. Measurement of Aesthetic Experience

In the measurement of aesthetic experience, we use the mixed test experimental model because the conclusions obtained from different model experiments are more comprehensive and illustrative. We select models from different latitudes and test the physiological and psychological data to get a high aesthetic experience. Aesthetic experience has many dimensions, but the most critical is the emotion and absorption induced by music. Other scholars' research data show that people can get more emotional experience beyond music itself from music through physiological response [11], for example, perception of beauty, pleasure, excitement, and so on. Studies have shown that people can witness faster heart rate and respiration when listening music, resulting in an increase in the frequency of skin conductive response—shivering [13]. The key of absorption in the aesthetic discourse of classical music has been discussed by music history literature. This is related to the perception of participants and is different from the “daily” psychological state [14]. The valuable measure of music aesthetic experience at the concert is the performance of absorption state and the difference between the feeling emotion we need and the feeling emotion [17]. In addition, the measurement of experienced emotions through continuous, nonintrusive methods is the use of cardiovascular, electromechanical, and skin conductive responses such as heart and respiratory rate and sweat gland secretion increases (measured by skin conductive response), which is activated by sympathetic nervous division of the autonomic nervous system to stimulate events and, from this reaction, to increase sensory participation. And, facial muscle activity is also known as a measure of behavior, and it can feed back the imitation of several discrete emotions and induce emotions to a certain extent [16]. The emotion of music is generated within the audience. Using the concept of latitude (valence arousal) or classification (such as sadness and happiness) emotion, studies have shown that “happy” music can evoke higher skin conductive induction amplitude than “sad,” and thus faster heart rate and breathing. Through the combination of sound and lyrics, many different types of information can be conveyed [17]. For example, music can depict and create a self or group image, and music can also be used to exchange political information. Research shows that music can convey emotional information. And, the speed of the rhythm will affect people's vitality. Speeding up the rhythm will lead to a greater possibility of sympathetic arousal. Using the measurement of skin conductive response, in the following experiments, we compare slow-paced and fast-paced classical music with rock music excerpts and silence [5]. As expected, the frequency of skin conductance response (SCR) during music processing was higher than that during silence. Skin conductive response level (SCL) data show that fast-paced music can “enhance information or emotional content” more than slow-paced music. Using people's psychological response to music to improve sympathetic nerve and finding higher skin conductive response in fast-paced music, people can expect

various emotions induced by music, so as to get a better aesthetic experience.

2.1. Aesthetic Experience of Vision and Hearing. In the aesthetic experience of vision and hearing, we use the principle of the mixed test experimental model. By comparing live concerts with recorded concerts, we draw a conclusion in these experimental model assumptions that there is not much difference. At the same time, the research theory believes that the combination of visual and auditory information may be more easily aroused in music aesthetic experience [16, 17] and enhance the experience by enhancing the uniqueness and creativity in the current performance. We expect that live concerts will cause a stronger positive aesthetic experience than recorded concerts. According to the current research, compared with 256 movements, the participation of live performance will be greater, the degree of liking will be higher, and the attention will be more focused. This is due to the lack of a major factor, namely, vitality [20]. This is true even if you are watching the same performance of the same musician. However, compared with other studies, namely, visual recording [10] and live performance, recorded visual and live performance did not show other differences in self-report and physiological reactions. This leads to the assumption that the situation regulates the aesthetic experience and points out that the framework [6] is a key component of modeling the aesthetic experience. In other words, the emotional difference is related to the framework of the concert site, and it is not necessarily due to the recording. The aesthetic experience of vision and hearing cannot be judged because of whether it is also on the spot. According to experimental research, it is not on the spot that the aesthetic experience is better than that of recording screen. On the contrary, it is more important whether it can attract people's attention and be more energetic. The higher the degree of liking, the stronger the aesthetic experience of vision and hearing.

3. The Adjustment of Music to Emotion

Different music has different effects on emotion. Some studies have shown that, under various emotional conditions, the relaxation degree of self-report of participants who are silent and self-selected is the highest, while the relaxation degree of self-report of rock listeners is the lowest, and there is no obvious physiological difference between groups. Rickard combined self-report of enjoyment, familiarity, and emotional impact with psychophysiological tests to evaluate the effect of music on emotional regulation. Physiological and psychological measurements include shivering, muscle tone, skin temperature, and skin conductance. Although the plot of the film is a song with strong emotional power and strong emotional power of self-selection and although easy and exciting music does not have emotional power, it can regulate emotions. Rickard found that 95 people who attended the concert thought they were in a good mood, and their self-reported measurement scores would be higher, resulting in the largest increase in skin conductance and

shivering [21]. However, no correlation was found between these effects and participants' music training or gender. Krumhansl [22] discussed how college students' emotions are stimulated by the peripheral nervous system of the brain. When listening, half of the participants made dynamic emotional judgments from their feelings of music and collected their physiological data from the other half of the participants. All participants' feelings in the work will be filled in a questionnaire for evaluation. From this, we can know that, in all music, no matter what discrete emotions you show, your respiratory rate and blood pressure will increase, and your heart rate will decrease. In addition, all extracts will lead to sympathetic nervous system measurements (i.e., finger temperature and skin conductivity). In Krumhansl's research data, discrete emotions also have a major impact. What can lead to greater sympathetic activation is the excerpt of happiness, followed by fear and sadness. The dynamic characteristic of this effect over time is a statistical analysis of the Pearson r value between the calculation time and the skin conductivity level. As we expected, given the deceleration nature of autonomic nerve activation during the experiment, the results showed that the negative correlation was greater with the development of music over time. Research on mood in testing mode (major or minor) and rhythm shows that increasing rhythm will affect mood more than mode. Kent [23] and Kellaris and Kent [24] asked the participants to listen to original works, marking these works as tonal (atonal, minor, and major), textural (popular and classical), and rhythmic. Participants reported their excitement and pleasure from these original works. The results showed that the greater self-report pleasure was the increase of rhythm from classical music, but in pop music, it was more able to mobilize participants' emotions, and the tone had nothing to do with the awakening of self-report. But there is no doubt that music can "transmit" emotions and regulate emotions [25]. However, there are still differences in the literature of music psychologists on how to better empirically and theoretically solve this problem 26–30. The first is that the cognitive calculus that prompts the need for recognition in the score is excluded by emotionalists, and this kind of musical emotional response is described as another emotion, which is different. The other is the cognitive approach, which describes the emotional response of music as the cognitive recognition of the clues of the music audience to the music itself. There are two ways to interpret music: social influence and cultural influence. However, there are still many differences in music's emotional expression and quotation [31].

4. The Influence of Music on Sports

Scholars have long pointed out that the insertion of music can improve the performance of athletes. If inserting music can improve the performance of athletes, the use of music in competition or training is very important. But there is still no way to clearly say the impact of music on people's psychology and physiology. However, there are traces of music use in many sports fields. Many studies have shown that music has an impact on sports performance and can

improve sports performance [32, 33]. In terms of discussing whether music has an impact on people's exercise, Eliakim et al. conducted experiments on 26 athletes, inserted music in their warm-up stage, and tested the temperature and heart rate after the warm-up. The results showed that the group with music insertion has higher temperature and heart rate, and the peak value of anaerobic exercise is also higher than other groups with music insertion [34]. It was also found that those with music insertion lasted longer than those without music insertion. In sports, people often affect sports performance because of physiological and psychological factors inside the human body, such as pain and anxiety. Nethery [35] showed that the level of wakefulness measured during exercise in the inserted music group was lower than that in the distracted and undisturbed group. In Nethery's study, it was verified that the degree of arousal in the music group was lower than that in the nonmusic group and the video group. The fact proved that if the athletes had a small amount of attention, they could be stimulated by some attention diversion, such as music insertion, and the stimulation was received by the sensory receiver to form some short-term memories caused by music stimulation [36]. If the impact of this short-term memory was large enough, it can cover the working memory formed by pain or anxiety caused by exercise, so that the brain can preferentially check the stimulation given by music so as to forget the pain and anxiety caused by exercise. Therefore, music can effectively reduce the level of wakefulness and distract athletes to a large extent [32]. Figure 1 is a general model of the theory that music stimulates the brain. But in the future, we need to further understand the impact of music on sports, such as whether the same music has the same impact on male athletes and female athletes and whether male and female athletes are more sensitive to aesthetic music, which is worthy of our experimental research.

5. Experiment

Different music choices are selected among rock music, swing music, and classical music types, and the following assumptions are tested according to similar experimental designs [37]:

H1: in the selection process of different music, participants showed less deceleration in SCL when listening to fast-paced music than slow-paced music.

H2: there will be genre \times rhythm interaction, which is activated on the sympathetic nervous system. Increasing rhythm will lead to greater SCR activity in classical music than rock and swing music types we are more familiar with.

5.1. Method. To better solve these assumptions, we designed and implemented a 2 (type) \times 3 (rhythm) \times 6 (presentation order) hybrid test experiment. The two main internal factors are music rhythm (fast rhythm and slow rhythm) and genre (rock, swing, and classical).

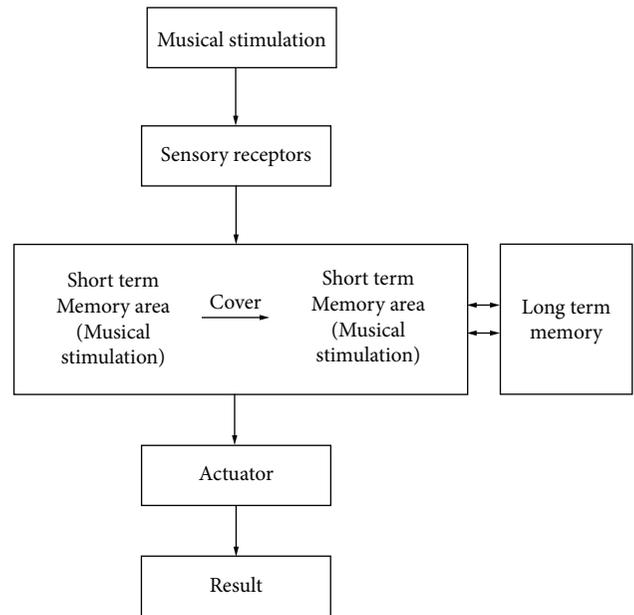

FIGURE 1: Theoretical model of how music stimulates the brain.

5.2. Experimental Process. In the experiment, six participants were randomly assigned, and the theme factor was the order of presentation. Twenty-seven graduate students agreed to participate in the experiment in exchange for graduate course credits. However, due to equipment failure, the skin conductance data of 7 students could not be used, and these 7 students also received the same credit reward. During the experiment, these participants heard the following six music clips, including slow classical, slow rock, fast classical, fast rock, and two silent clips. The slow-paced (75 BPM) classic clip features Pachelbel's "Canon in D major." The slow tempo (74 BPM) swing clip features the Squirrel Nut Zippers' Mean to Be. The fast-paced (140 BPM) classical editing features the ending of Rossini's "William Tell Overture." The fast-paced (138 BPM) rock clips are taken from the cut's "She Sellers Sanity." In the video, these sounds divide the system into six unique sequences. After each auditory choice, the movie clips of pop music will follow closely, and the time will be maintained between 90 seconds and 115 seconds. These six movie clips are sorted by the system according to different types, so that there is not only any music choice next to each movie clip. As far as the current test is concerned, what is more relevant is that the research results are applied to the speed of music rhythm, which is consistent with the more subjective arousal level of interest during programming, rest, and programming sequence [38]. The SCR frequency data presented in these six movie clips is 2 (rhythm) \times 3 (genre) repeated test MANOVA. Although the figures of these SCR frequencies are similar to those we predicted, the only surprising result is the main influence of genre ($f(2, 40) = 6.947, P = 003, \epsilon_2 = .2207$). Regardless of the rhythm, classic genres can more arouse the activation of participants. In order to solve hypothesis 1, participants' SCL in fast-paced music was compared with slow-paced music, the change value was

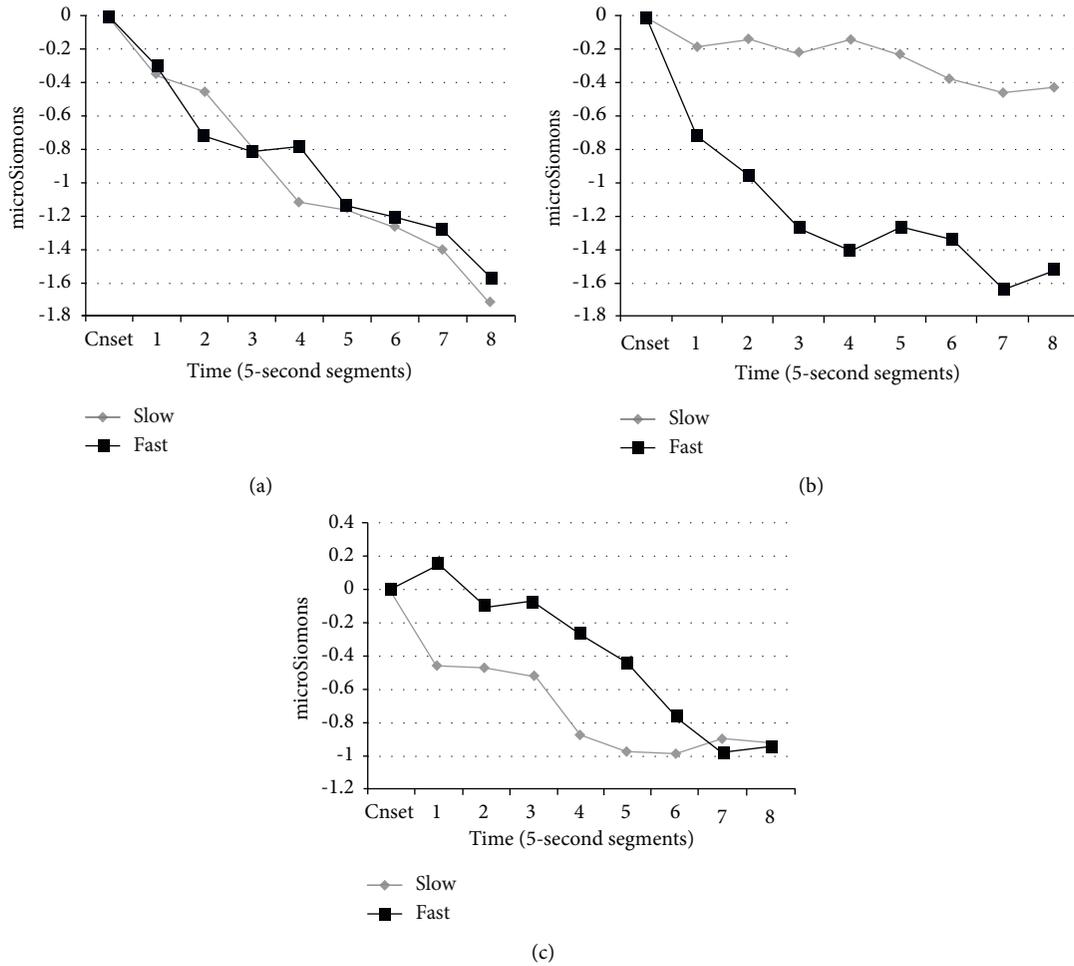

FIGURE 2: Tempo \times genre \times time on SCL. (a) Rock genre. (b) Classical genre. (c) Swing genre.

submitted to 2 (rhythm) \times 3 (genre) \times 8 (time) repeated test MANOVA, and the result was close to significance ($f(16256) = 1.502, P = 099, \epsilon 2 = .0287$).

5.3. Results and Experimental Analysis. This group of experiments attempts to test two broad hypotheses. First, when participants hear fast-paced music, they show less deceleration in SCL than slow-paced music. Second, the increase of rhythm will lead to greater SCR activity of classical music than rock and swing music types we are more familiar with [38]. According to the collected participant data, these two hypotheses have been confirmed. The data show that, as time goes on, rock music is not affected by rhythm. However, rhythm has obvious influence on the other two types. However, faster rhythms increase sympathetic activation in the swing type and decrease activation in the less familiar classical type, as shown in Figure 2, which is contrary to our expectations. In the selection of classical music that may be less familiar, the activation response of slow rhythm (even if the change score is initially higher than the baseline level) is greater in fast rhythm than in relatively familiar swing music. Therefore, by analyzing the experimental data, it is

proved that the familiarity assumption around classical and rock proposed by hypothesis 2 is not tenable in accurately predicting the direction of this interaction. The experiment uses psychological and physiological factors to verify the existence of any music, whether slow or fast-paced, classical music or rock music, which will increase the excitement of people's sympathetic nervous system. Over time, the genre of music may alleviate the impact of any rhythm on skin conductance. Through data analysis, when using SCL as attribute measurement to confirm the dynamic characteristics of music processing, it is predicted that music with a slower beat will cause less sympathetic activation than music with a faster beat. People are using all the spontaneous SCR frequency counts, so the whole listening period is summarized across time, and no major impact is found. On the contrary, in the interaction with genres, the increase of rhythm in the processing of rock music leads to a significant increase in SCR, while the increase of rhythm in the processing of classical music leads to a significant increase in SCR. In slow-paced classical music, participants can adapt to the expected genre and the rapid start of a single note in the rhythm pairing [39]. Through the analysis of the two hypotheses, we can better confirm that the speed of rhythm and

genre are related to the presentation of SCL, but it is untenable to propose that it is related to familiarity, and in the interaction of genres, classical music is higher than rock music SCL.

6. Conclusion

The extraction of key words in this paper is a relatively extensive field. The psychological construction of music combines psychological and physiological signals. That is, the collection of aesthetic experience and physiological experience created by emotion and absorption caused by music. The type of music and the speed of rhythm can convey many different types of signals through different combinations [40]. Based on the scenes of classic classical concerts, this paper discusses the aesthetic experience of music works with different musical styles and fast and slow rhythms, as well as the adjustment of music to our emotions and sports performance. According to the research data, the speed of rhythm can increase the excitability of the sympathetic nervous system, and if in the same type of music, fast-paced music is easier to activate the sympathetic nerve than slow-paced music. Emotional reactions and some physiological reactions reflect the changes in the form of sonata represented by motor function in familiar classical music works. Of course, it does not follow such a trajectory in unfamiliar contemporary works [40]. Use music to reduce athletes' arousal and divert attention, reduce sports pain, and improve sports performance. Moreover, music can improve our psychological feelings, promote the motivation of activities, and increase their attachment. In addition, some scholars Zhou [41] believe that not the same kind of music has the same impact on everyone. Some scholars have also proposed that a type of music has an impact on one person, but not necessarily on others. So far, many scholars' research on the impact of music intervention on the human body is still growing. André Previn said, "there are a million things in music that I do not know. I just want to narrow this number [42]." In addition to the speed of the music rhythm, we should also evaluate the type. Perhaps, as our understanding of the awakening caused by music increases, our ability to predict the effect of music will be improved. Then, we can start to study the impact of music on human psychology and physiology, so as to make our research more in depth and breadth [41].

This research topic investigates the inquiry on how national cultures shape the organisational management cultures. Similarities and differences between the national cultures of China and the USA are being scrutinised for the purpose to examine the impacts of such features on the management cultures and strategies of organizations located in these two main world financial centres so as to achieve a majority of data to confirm how national culture relates and assists to shape the organisational management. This research uses the data collection methods of non-governmental organizations, including the invitation of participants or volunteers via social media, working emails, and invitation letters, involving the issues such as designing human rights and privacy. The result has established that high mobilization of culture differences in the USA had a notable positive consequence on companies' organisational management culture. Alternatively, the Chinese cultures may bring some positive effect to the companies' culture, but it was only significant to shape management culture influence in their domestic companies, excluding most of the multinational companies. Moreover, the differences in national cultural characteristics will greatly affect each organisation to choose their own management strategies. Raising up for cross-cultural and transnational management will be a huge challenge for organizations to take, especially if countries wish to establish bilateral or trilateral business relations and partnerships.

1. Introduction

1.1. Research Background. One of the key formation factors in an organisation's culture includes its national culture's history and environment, and it has been proven by studies that national culture affects the organisational management system greatly in many aspects [1]. Although national and organisational cultures are used to be classified as different phenomena, it is interesting to investigate the linkage between them and discover how national culture can influence an organisation's practices. In this case, the similarities and differences between the national cultures of China and the USA will be analyzed, and the outcome of the analysis will be used for further investigation on the impacts of management cultures of organizations located in these two countries. By this approach, this research can recall the attention of building up a well-established organisational management

culture, which is essential to take national cultures into account since national culture conducts the employees' decisions, devotions, and standards of behaviour [2]. The aim and objectives of this essay is to guide readers for understanding that the national culture formed the common characteristics of human. This will further influence the responses to its organizations, resulting in a company's identical organisational management cultures, especially in a country's domestic companies. Therefore, it is essential and important to recognize the relationship between the national and organisational culture, proving that the differences in national cultures will have a great influence on how managers chose their strategies and supervised their organizations. Additionally, the challenges of high mobilization of culture differences faced by cross-cultural and multinational companies will be discussed for the purpose of examining some practicable solutions.

TABLE 1: Definition of national cultures.

Authors	Years	Classification of national culture systems
Kluckhohn and Strodtbeck	1961	Human nature orientation and time orientation based on relationship
Tony Morden	1985	It is defined as the collective mental programming in a society. Organisation's management and human resources supplies were mostly included environmental and local aspects
Trompenaars and Hampden-Turner	1997	Idea of individualism vs. communitarianism; universalism vs. particularism; internal direction vs. outer direction
Hofstede	2001	Power distance such as equality; individualism vs collectivism; focus on the level how employees are essential for a future-oriented running system rather than a short-term oriented running system
House et al.	2004	Focus on the points related to future orientation, gender equality, and power distance
Tony Smale	2016	National culture establishes human behaviour and cognition as a salient way since it is a psychological process of initiative, creativity, and innovation
Mike Berrell	2021	National culture generally describes the beliefs, value, and behaviours shared by the population of a sovereign nation and particularly refers to specific national characteristics such as religion, history, language, and ethnic

1.2. Theoretical Background

1.2.1. Theory of National Culture. Culture is not fabricated, but it is something that evolves with human, and it is the fundamental sources to create nationalism of a country. Since the nineteenth century, national culture is given by the definition of a comprehensive and multiplex system mixed with the elements of action, values, history, knowledge, and beliefs, which are identical by the particular social community and form their own practices. Hofstede realized that according to the past of historical process, nations were created as a part of social organisation, leading to a concept of culture to be closely related to the nation rather than the states [3]. If the countries obtain some particular historical practices nor heritages, it is likely to favour the further integration, original language, education system, and political system that are the examples of the most significant symbolic signature of a country since they obtain an excessive emotional load.

1.2.2. Organization and Management Culture. The reason why organisational culture has more than one interpretation is because this culture is made by the combination of values fabricated by humanity. To be more attributed to this notion, social sciences described organisational culture as everything generated by human themselves without arising from nature, and this culture reflects the deliberated situation and human activity gaining from the past [4]. The organisation and management theory is used to evaluate organisational cultures as a rational action, which is acceptable to identify the organisation with their effectiveness. To conclude the refinement of the organisational culture, we can apply the definition in the following statements:

- (i) Organisational management culture is the creation of social network that assists in maintaining the organisation.
- (ii) Organisational management culture is holistic and used to unite the company, remains stable, and minimises uncertainty to achieve internal integration and provide a working environment for the employees.
- (iii) The process of organisational culture is shaped and developed with a long history, and it will be inertial

(ongoing). When the process has finished, the result will be shown during the deal in environmental problems and other internal coordination.

- (iv) Organisational management culture shows the process of cultural evolution and the process of socialisation.

1.3. Research Review

1.3.1. Section 1: National Culture Concept and the Corresponding Scopes. In general, cultures are separated according to the levels starting from individual, group, organisational, industrial, national, and geographic regions [5]. It is arranged according to the internal elements such as work outlook, history, goals and values, work role, communication mode, technical practice, customary rules, and other cultural activities, as well as cultural systems such as law, education, religion, economy, politics, and family status. Meanwhile, the term national is defined as the combination of economic, social, political institutions and culture group as to influence organizations on managing their people in divergent environments. Hofstede defined national culture as the general formation of the mind behaviour that helps to distinguish different human groups from one another. To be more precise, national culture can be used as the assumptions of practise by a given group because they are commonly influenced by the same attitudes, values, and beliefs of the same group members since they were young [6]. Hence, national cultural concepts are the collective programming activities made of and values from the past experiences [7]. Table 1 shows the definition of the national culture concept since 1961 to 2020 to explain how the dimensions changed over the past several decades.

1.3.2. Section 2: Hofstede's Six Dimensions of Culture

(1) Power Distance. Solutions to money and power problems because in some countries, hierarchical status and inequality may often occur in specific cultures [8]. This degree of inequality is measured by Power Distance Index (PDI). A low PDI marks also represent that power in the society is equally shared and dispersed, and citizens will be expected to reject if

TABLE 2: Hofstede's power distance index.

Country	PDI	Power distance index				LTO
		IDV	MAS	UAI		
Malaysia	104	26	50	36		
Guatemala	95	6	37	101		
Panama	95	11	44	86		
Philippines	94	32	64	44	19	
Mexico	81	30	69	82		
Venezuela	81	12	73	76		
China	80	20	66	40	118	
South Africa	49	65	63	49		
Hungary	46	55	88	82		
Jamaica	45	39	68	13		
United States	40	91	62	46	29	
Netherlands	38	80	14	53	44	
Australia	36	90	61	51	31	
Costa Rica	35	15	21	86		
Germany	35	67	66	65	31	

power was distributed unfairly [9]. With the references of the map, a high PDI country like Malaysia that scored 100 marks is not going to initiate any action of unfairness but willing to be guided and follow the instructions by the governments.

(2) *Individualism vs. Collectivism*. The dimension of this emphasis is the unity of culture. Starting with the individualistic cultures, most people will have the mentality of independent and put themselves in the first place. People is likely to focus on the advantages of themselves and immediate family first, leading to a less tightly knit society. On the other hand, the collectivist cultures present the concept of “we” as a replacement of “I.” Citizens are connected with each other's closely and willing to cooperate together. Psychologists believed that a country will be more benefited as a group than the self-esteem from the group mentality because citizens will have a higher sense of belongings [10]. This dimension is normally the easiest to perceive from the culture. According to the individualism versus collectivism score (IDV), countries such as America and Australia have a high score in individualism (IDV), indicating that they have weak interpersonal connection and the marketing campaign started in this country can be accepted and well understood. In contrast, cultures in countries such as China and Japan score low in individualism. Citizens are likely to work for their own intrinsic rewards and care less for others.

(3) *Masculinity Versus Femininity (MAS)*. This dimension focuses on the distribution of works and responsibilities between men and women. Masculine societies present that the gap between men and women is less, while men are expected to acquit themselves assertively. The action of showing the success to others and voice out your feeling are seen to be positive characteristics in the society. However, feminine societies appear to be a great overlap between the female and male roles. A good relationship between the supervisors will be placed at first to prevent arguments [11]. The largest gap between the value of men and women is in Austria and Japan, and their MAS score is 79 and 95,

respectively. The reason why they have such high scores is basically the men showed their “tough” during work and behaviours. By the studies of Samsung companies in Japan, the working style is closely related to the hierarchical and deferential style. The long working hours and low percentage for female employees to achieve advancement are developed to their organisational culture [12]. The USA and China have scored a close mark of 62 and 66, respectively, according to Table 2. This similarity can prove that although earning money and gaining achievement in both countries are important, citizens in the USA and China are also eager to maintain their relationship more orientally and achieve the quality of life. Workers may focus more on work-life balance and the flexibility in workspace. Therefore, the organisational management team of these countries can adjust their environment and workload according to this culture.

(4) *Uncertainty Avoidance*. This dimension can demonstrate how well the citizens can cope with anxiety and try to control their life in predictable and manageable methods. Alternatively, countries with a low uncertainty avoidance index are described with an open, relax, and inclusive living style. However, Hofstede pointed out that countries with high score may also acquire the personality of risk adverse, and they are likely to reduce ambiguities as low as they can in order to escape from failure [13]. With the glance of Hofstede's model, countries with a low UAI scale can also represent the cultural tendency with a safe and conservative decision style, and this can be represented by Singapore that has scored a low mark of eight. The USA and China have scored a close mark in the Uncertainty Avoidance Index too. The citizens in both countries are likely to have the national culture of innovation and desperate to take opportunities on their own life instead of following behind others.

(5) *Long-Versus Short-Term Orientation*. Long- and short-term orientation can display how a culture choose its decisions when dealing about the questions of the present and future. The characteristics of a country with long-term

orientation are described as more modest and pragmatic, and the citizens will prevent from any changes but emphasize more on customs and traditions [14]. As for short-term oriented countries, citizens are likely to focus on short-term gains and stick with consistency and truth. The USA is defined as a short-term orientation since the country reflects a great sense of social standards and nationalism. In term of business, this measure can measure how successful can a business be. If the business has a short-term orientation style, their goal is to get quick results as soon as possible on a quarterly basis. Meanwhile, a business with long-term orientation tends to be more patience and accepts short-term losses to achieve long-term gains [15].

(6) *Indulgence vs. Restraint*. As for the final dimension, it focuses on the natural human response, which is the level of urgent to satisfy desire. Different cultures will answer this dimension by choosing either appreciate (indulgence) or reject (restraint) this desire. Restrained culture countries tend to obtain characteristics such as pessimism and cynicism, and they stick closer with moral rules that contrast with those indulgence countries. Indulgence countries are prone to grab the chances of opportunities, be more carefree, and enjoy their spare time, and they have a low IVR score too. Eastern European countries and China are the good examples with a low IVR score. Employees only allow themselves a little time on leisure activities. At the same time, they are controlled with a restrained culture and present themselves in a more pessimistic way. The USA culture is different as they are more optimistic and allow the freedom of speech of citizens, feedback, and mentoring, which will prioritize at the first place to improve the countries [16, 17].

The six cultural dimensions will be scored on the scale within 0 to 100 for each dimension, and they will intertwine with each other and influence the countries when time passes. For instance, countries with long-term orientation will likely correlate the countries with the characteristics of uncertainty avoidance since both characteristics are related to the adherence of traditions. By applying Hofstede's six dimensions of culture models, it can provide a correct framework for organizations to compare and contrast every culture and achieve success by choosing suitable strategies. In the case of the USA, high individualism is their historical significance. Therefore, organizations can apply employees' rights and individual freedom to maintain their loyalty to the companies.

1.4. Comparative Analysis of the National and Organisational Management Cultures in China and the USA

1.4.1. *China National Culture*. The long history of the Chinese traditional culture has formed their unique characteristics. The national culture values have influenced the Chinese people to become harmonious, wise, honest, loyal, and hard-working [18–22]. Since the core value of harmony is described as “balancing the coordination between working,” it has been proven that the working performance of the Chinese is based on the personal relationship and used to be peaceful. The organizations will put more focus on the

social relationship among the employees since the management teams are used to organise team-building regularly. The outstanding team spirit and loyalty lead to the practice of organisation to be prudence and obedient. The Chinese organizations are used to follow all the rules and laws without any reformation in the practices. Moreover, the situation of working overtime in China is common too since the Chinese are taught by the idea on sacrificing themselves in order to accomplish others when they were young. Therefore, the work-life balance is comparatively poor in China.

1.4.2. *The USA National Culture*. Studies have listed out that the American national culture is basically recognized as being freedom oriented and individualistic. Americans advocate privacy and equality, and their personalities are accustomed to independence, individualism, hospitality, and future achievement orientation. Comparing with Hofstede's formation of national cultures, Americans are described as a high individualistic group of people who may not cooperate well during the group missions. The independent and aggressive personality may lead them to decision-making based on their self-interest instead of the positive benefits for the economy at large scale, affecting the loyalty as well. However, Americans are described as creative and future achievement oriented due to the education system when they were young; therefore, they may be likely to break the rules and innovate new ideas for the organizations. The working overtime practice is rare in the USA since they are more aware on the work-life balance and health practices.

In contrast, the managers in the USA are likely to be more individualistic, the management cultures may be more sensitive to the relative power of division managers and the power struggles, and the employees may have a greater competition among themselves. Interesting, China and the USA have a similar score in masculinity and has a biggest gap between individualism, displaying a phenomena that both countries are driven by the desire of achievement and success. However, the citizens in China may have a greater sense to achieve success for a society as a whole, while the USA has a stronger desire to attaining personal goals instead of assisting the countries.

2. Research Methods and Processes

2.1. *Research Methods*. For the purpose to disclose the research questions mentioned in Section 1.2.2, a combination of quantitative and qualitative methods that were applied to reveal the affection of national culture shapes the organisational management cultures. The research method comprises two major approaches of data collection: (1) a free anonymous questionnaire with employees and directors working in China, the USA, or multinational companies and (2) semi-Zoom interviews with employees or directors who volunteer to participate when filling the questionnaire e-mail. The Zoom interviews are held in different subareas within the same organizations so as to achieve the maintenance of common institutional context.

TABLE 3: Questionnaire.

Questions	The content of the problem
Question 1	Home countries you grew up before 18 years old?
Question 2	Which characteristics will you use to describe the citizens and society in your home countries?
Question 3	Type of companies you are working for?
Question 4	Which national culture variables have influence the most in the company you are working?
Question 5	Which organisational management variables are essential in your workplace?
Question 6	Challenges faced by your companies?
Question 7	To what extent you agreed that national culture variables shaped the organisational management cultures?
Question 8	To what extent you concern about work-life balance?
Question 9	Do you agree that China and the USA companies have different organisational management cultures?
Question 10	Possible solutions to shape an appropriate organisational management culture for multinational employees?

2.2. Research Processes

2.2.1. *Data Collection and Recruitment.* The empirical data in this research is observed from some major market within China and the US, and data is collected from open databases, questionnaire survey, and on-site observation to identify how national culture helps to shape the organisational management culture. The questionnaire is set up in Table 3.

Four research questions were superscribed within the options in the questionnaire. The reason for applying questionnaires to collect both qualitative and quantitative data is to ensure the consistency, while the questionnaire can provide the opportunity to analyze significant trends and differences between China and the USA cultures statistically. The survey is composed by the online questionnaires to prove the relationship between the national culture and organisational management cultures, and responses are collected in a costless and efficiency way. The survey has collected 166 suggestions from both genders of employees and directors located in the United States and Shanghai, China, with the age over 18 years old. Sheets of questionnaires are presented to participants though working e-mail and letter, and participants are accepted to fill in the answer anonymously to protect their privacy. Participant information sheets were sent and provided in the attachment of mail and website with the description about the aim of this research. Data is legally saved in the data protection system and will be deleted after the data analysis has been finished. Although the questionnaire may produce less in-depth responses, it can reveal the ideas of society directly. The responses are open ended and being taken for a grounded approach, and key categories can be identified through the data results. Responses may be answered with more than one option, and the multiple options will be classified as sophisticated responses. Following question 2, we get the following example (Table 4).

Throughout the quantitative analysis via correlational research, research object can be further refined so as to facilitate the understanding of the nature of things and predict the future of research. Data will be collected and analyzed using Microsoft Excel and “Survey Monkey” to conduct quantitative analysis.

TABLE 4: Meta-ethical questionnaire response options (question 2).

Answer choices	Responses (%)
(i) The most important priority	19.05
(ii) A top priority, but not the most important	14.29
(iii) Not very important	57.14
(iv) Not important at all	9.52

TABLE 5: Group of participants collected in the questionnaire.

Home countries	Male	%	Female	%	Total
China	56	67.47	27	32.53	83
The USA	47	66.20	24	33.80	71
Europeans	4	80.00	1	20.00	5
Others	2	28.57	5	71.43	7
Total	109	65.66	57	34.34	166

2.2.2. Data Analysis

(1) *Section 1: Participants.* Gender, age, and the employment times are collected before the questionnaires started. The collective data has achieved upon 166 responses, and the breakdown of the group of participants is shown in Tables 5 and 6, representing the similar pattern of response in terms of the whole questionnaires.

(2) *Section 2: Questionnaire and Zoom Interview Analysis.* From the questionnaire, more than half of the participants are having their home countries in China, and they agreed that national culture has changed their personality during the teenage stage, influencing their working attitude when they joined into the organizations. During the zoom interview, two participants who are working in Apple, which is a multinational company, revealed that they avoid changing any management style but prefer to stay with the management scheme. Alternatively, the employers in the USA Apple department prefer an effective management style with appropriate communication and feedback collections from the workers and costumers. The differences of organisational management culture are most significant in questions 6 and 8 of the questionnaire. Organisations in China are used to

TABLE 6: Type of companies collected in the questionnaire (question 3).

Answer choices	Responses (%)
(i) Registered or incorporated companies	4.76
(ii) Multinational companies	33.33
(iii) Companies limited by guarantee	14.29
(iv) Unlimited companies	14.29
(v) Public company	9.52
(vi) Private company	14.29
(vii) One person company	4.76
(viii) Country-based company	4.76

have less concern about the components of leadership since they have an uncertainty avoidance and restraint personality. As a result, companies in China are likely to provide a regulations guide based on bureaucracy and leaders did not accept the opinions from the perspective of his/her teams. Long-term improvement is not increased as fast as the USA since the US organizations prefer an impersonal strategy of rules to satisfy every employees. In China, important decisions can be only determined by directors since they believed that they have more authority and knowledge. For example, the outcome statistics of question 2 in the questionnaire (Table 7):

According to the result of question 4 in the questionnaire, there is a close relationship between language and management cultures since the two variables affect each other interactively. Culture is empowered and developed though its original home language, and the way of presenting the language can become the method of employees to express and receive information directly. More than 70% of the participants agreed that language is an essential component to shape an organisational management culture, proving the importance of adopting appropriate language skills that can motivate employees and enhance efficiency during workplace. Question 4 in the questionnaire of empowerment within organizations leading to high productivity and high performance has revealed that the empowerment in language within the organizations can assist the leadership skills and achieve high productivity and performance to satisfy the needs of goals of companies (Table 8).

During the interview of managers in the USA Apple, the results have shown that they are desperate to learn about different cultures in order to adapt the modern way of business management from the parent company in the United States of America. Set up Table 9 as follows:

In the questionnaire, both managers chose to set up a department to sense the culture in an organization and enhance their own communication system to solve the problems faced by the multinational companies. This management culture has positive correlated with the indulgence and low uncertainty avoidance in their national culture characteristics. Comparing with the management style in the USA, China organizations are not able to bring the essence of the USA management into their organizations because of the reason on their high power distance,

TABLE 7: Characteristics to describe the citizens and society in your home countries.

Answer choices	Responses (%)
(i) Oligarchy	4.00
(ii) Absolute monarchy (absolutism)	16.00
(iii) Concern in power distance	4.00
(iv) Individualism	76.00
(v) Collectivism	20.00
(vi) Masculinity	8.00
(vii) Uncertainty avoidance	4.00
(viii) Long-term orientation	72.00
(ix) Short-term orientation	12.00
(x) Indulgence	12.00
(xi) Restraint	56.00

TABLE 8: National culture variables that influence the most.

Answer choices	Responses (%)
(i) Language religion	72.00
(ii) History and traditions	32.00
(iii) Social organization	20.00
(iv) Value and attitudes	24.00
(v) Education practice	64.00
(vi) Political system (including rules and regulations)	28.00

individualism, and relative high collectivist culture. Since China is classified as a short-term orientation culture, the USA companies may have achieve a more effective and efficient working style compared with the Chinese subsidiary. Communicating with foreign employees had revealed the most concerned questions by the questionnaires. When facing the misunderstandings of communication, the managers with the USA national cultures are likely to be keen on finding the reasons and solutions even they felt frustrated, proving that a high significant influence of national culture helps to shape the managing and communicating practices in the USA organizations. Table 10 shows the national culture variables that influence the most (questionnaire question 4).

Finally, a social organisation presenting the importance level of family as well as the level of spirituality is revealed as comparatively different in China and the USA. Participants from the USA appear to have indulgence characteristics, and the national variables are revealed in question 8 of the questionnaires. According to the OECD Better Life Index, the United States ranked 28th in work-life balance and it is higher than China, which is not disclosed in the top 40 of the list in this category. Governments in the USA are likely to provide welfare state and listen to the opinions of the society, resulting in a better work-life balance compared with China. This will further affect the organisational management culture since the directors in the companies may care on the pressure of employees and prevent them from over working hours. This is a healthy working condition, and China should adopt this culture from the USA. Table 11 shows to what extent you concern about work-life balance (question 8).

TABLE 9: Interview questionnaire.

3. Conclusion

This research uses the data collection methods of non-governmental organizations, including the invitation of participants or volunteers via social media, working emails, and invitation letters, involving the issues such as designing human rights and privacy. The survey conducted by this research project has been conducted ethically, keeping in mind privacy, consent, and appropriate reporting of those involved in this study. All data are saved anonymously and will be erased from the database after the analysis is completed. After completing the entire study, it was found that the result has established that high mobilization of culture differences in the USA had a notable positive consequence on companies' organisational management culture. In addition, after the study, it was also found that raising up for cross-cultural and transnational management will be a huge challenge for organizations to take, especially if countries wish to establish bilateral or trilateral business relations and partnerships. For a large part, China is geographically far away from the United States. However, the data size may be too small to represent each of the

characteristics of the national cultures. The survey focuses on the company's case in the United States of America and China, representing that the results drawn from the questionnaires and analysis are only applicable to China and its similar cities. Not all participants taken part in the survey are working in a multinational companies, resulting in the challenges and solutions to multinational companies that may face the differences in data. The questionnaire results and recommendations may be suitable for the future development and management strategies in China and the USA due to the cultural and geographical differences.

Data Availability

The dataset can be accessed upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

In order to further improve the identification efficiency of tobacco mildew, a rapid identification model of tobacco mildew based on random forest algorithm was proposed in this study. In order to ensure the feasibility and pertinence of the model study, this study takes redried leaf tobacco as the research object, selects high-temperature and high-humidity environment as the experimental conditions, and obtains the sample data of the degree of tobacco mildew under different experimental conditions. At the same time, this paper constructs a rapid identification model of tobacco mildew with the help of random forest algorithm. Through the model experimental results, it is found that the accuracy of the model for the rapid identification of training samples can reach 93.82%, while the accuracy of independent testing is 94.84%. The experimental results fully reflect the availability and efficiency of the random forest algorithm model in the rapid identification of tobacco mildew.

1. Introduction

Tobacco leaf is a special leaf plant. In most cases, tobacco leaves need to be stored for a period of time after harvest, and tobacco leaf storage is directly related to the quality of tobacco leaves, because the tobacco leaves in the mature stage can only enter the cigarette production after being harvested through special processes such as baking, purchasing, transportation, redrying, and aging. However, it takes a long time for the tobacco leaves to be harvested and made into finished cigarettes. If the tobacco leaves are not properly managed in the storage process, it is easy to mildew and then form mold. Mold is a relatively wide range of fungal microorganisms. Its growth environment is relatively simple. As long as it meets the requirements of appropriate temperature and humidity, it will quickly reproduce, and then the tobacco leaves will become moldy, which will seriously affect the quality of tobacco leaves and even cause the deterioration of tobacco leaves. Based on this background, this

paper starts with the process and key points of tobacco mildew and combines random forest algorithm to identify tobacco mildew more accurately and efficiently.

2. Literature Review

There are many related research works on the detection technology of the internal components of tobacco leaves after mildew, which can be roughly divided into the following types: using the near-infrared technology to detect specific components, such as using the near-infrared spectroscopy technology to establish and verify the quantitative prediction model of ergosterol, establish the GBA algorithm, screen the characteristic wavelengths of the basic spectral data, and establish the PLS-DA discrimination model [1]. The model is applied to the identification of tobacco leaf samples, and the accuracy is as high as 95.79%. The characteristics of grain respiration and microbial activity were explored by using carbon dioxide technology detection,

reserve pest detector, and colony counting method, so as to obtain the characteristics of carbon dioxide gas produced by grain respiration and microbial activity, respectively. Amino acid analyzer was used to determine the specific content of free amino acids in moldy tobacco leaves. At the same time, the changes of amino acid content were divided into two categories: the absolute content increased and the absolute content decreased. GC-MS technology was used to determine the changes of volatile components in tobacco before and after mildew. Some studies have shown that substances with large changes are obtained by comparing before and after mildew, and then the content changes of these substances are used to establish a model, so as to infer whether it is mildew [2].

At present, the most widely used control technology is chemical control, which uses a variety of reagents. The most common antifungal agents in food include benzoic acid, sodium benzoate, sorbic acid, and propionic acid, but the mechanism of action is too small, and harmful gases may be generated after high temperature. Therefore, only staying in the previous research on antimildew agents cannot meet the needs of modern social development and people's attention to health. For this reason, many researchers began to turn to other chemical control agents with less toxic and side effects and better effects [3]. Some scholars pointed out that dimethyl fumarate has the strongest inhibitory effect on mold in tobacco leaves. Some researchers selected four kinds of fungicides, 75% dakonine, 40% hexin, 98% kangzhuolin, and 100% dimethyl fumarate, for toxicological and antimildew tests. The results showed that, through bioassay, 40% nucleostar had the best antibacterial spectrum and antibacterial effect, and dimethyl fumarate was the second. Kangzhuoling is also a safe and efficient biological fungicide. Some scholars have used organic acid mold inhibitor KMC-LF2 to conduct mold proof test on corn and found that it has good mold proof effect [4]. In recent years, some researchers have also studied the control of microwave technology. Some scholars have studied the effects of pulse microwave on the mortality of rice weevil and parasitic *Aspergillus*, rice temperature, broken rice rate, and burst waist rate of rice and their sensory quality. The results showed that, with the increase of pulse microwave intensity, the mortality of rice weevil and parasitic *Aspergillus* increased, the hatching rate of insect eggs decreased significantly, the sensory quality remained basically unchanged, the rice temperature increased gradually, and the broken rice rate and waist burst rate also increased [5].

3. Introduction to Random Forest Algorithm

Random forest (RF) is an aggregation distribution algorithm that contains multiple decision trees and poll strategies. The main idea of RF is to select randomly (not all) vectors to grow a tree in a class, and the only difference between them when designing a tree is a small number of differences [6]. In other words, implementation variables and patterns are randomly divided. This random number is called random existence because it is used in division or regression analysis. The final decision tree is generated by voting through the

potential random vector tree; that is, select the "class" with the most votes as the category of the corresponding sample [7].

3.1. Decision Tree. Deciduous trees are formed by root nodes, leaves, and petals. The algorithm can be seen from the 1970s and 1980s. The most commonly used algorithms are the ID3 logging algorithm, the C4.5 logging algorithm, and the push logging algorithm [8].

3.1.1. ID3 Decision Tree Algorithm. ID3 algorithm is based on entropy in information theory. Suppose that an event has k optional results, and the probability of each result is shown in the following formula:

$$P_i (i = 1, \dots, k). \quad (1)$$

After observing the result of this event, its information is described by entropy, and the definition is shown in the following formula:

$$I = -(P_1 \log_2 P_1 + P_2 \log_2 P_2 + \dots + P_k \log_2 P_k) = - \sum_{i=1}^k P_i \log_2 P_i. \quad (2)$$

If the characteristic divides N samples into m parts and there are N_m samples in each part, the impurity reduction is expressed by the two following formulas:

$$\Delta I(N) = I(N) - (P_1 I(N_1)) + (P_2 I(N_2)) + \dots + (P_m I(N_m)), \quad (3)$$

$$P_m = \frac{N_m}{N}. \quad (4)$$

First, calculate the entropy purity of the samples in the current leaf node, split the current node with different features, compare the information gain in the split node, that is, the uncertainty reduction (3), and take the feature with the maximum information gain as the best node feature. If the subsequent nodes only include one type of samples, the branches and leaves stop growing, and the final node is called a leaf node. If the subsequent nodes include different kinds of sample sets, continue to iterate the above steps until each branch reaches the leaf node [9].

3.1.2. C4.5 Decision Tree Algorithm. C4.5 algorithm uses information gain rate replacement formula to obtain information gain, as shown in the following formula:

$$\Delta I_R(N) = \frac{\Delta I(N)}{I(N)}. \quad (5)$$

Moreover, C4.5 algorithm can also solve the characteristic problems with continuous values. The basic principle is as follows: assuming that the numerical characteristic x has n values in the training sample, arrange these values in order from small to large, and obtain the following formula:

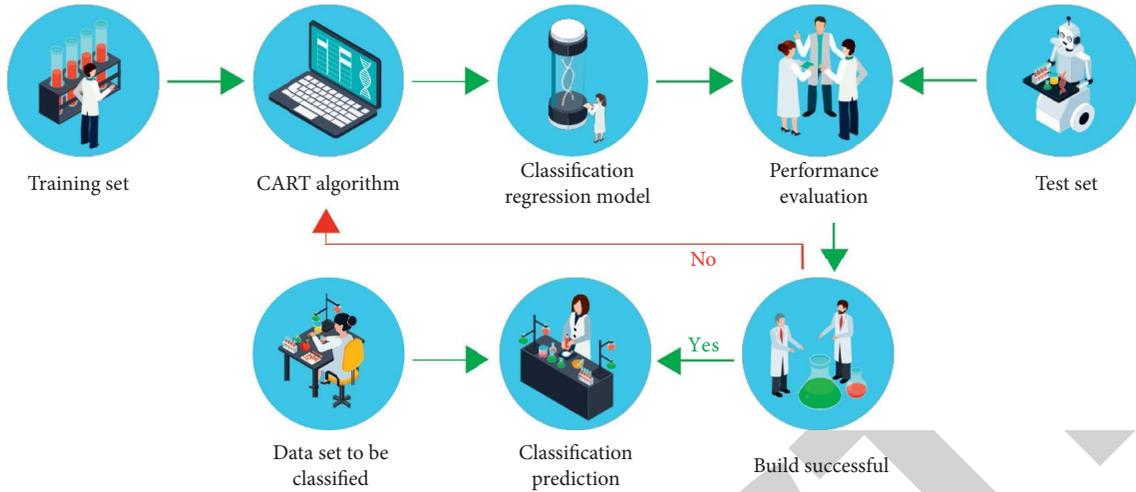

FIGURE 1: Flow chart of constructing classification regression tree.

TABLE 1: Advantages and disadvantages of decision tree.

Advantages

1. There is no need to introduce a priori assumption.
2. The decision tree is relatively simple to understand, its logical thinking is easier for people to understand, and it is easy to realize in practical application.
3. It has good stability for outliers and noise. The decision tree does not classify the data according to the specific value, and the outliers in the data have little impact on the whole result.

Disadvantages

1. In the process of top-down recursive construction, nodes store less and less information, and too little information will cause data fragmentation.
2. In the process of modeling, the unstable splitting of leaf nodes will cause overfitting.

$$v_i (i = 1, \dots, n). \tag{6}$$

Using dichotomy to divide the array, there are $n - 1$ kinds of division methods. The information gain rate of each partition method is calculated. The continuous feature vector is changed into binary feature by selecting the method with the maximum gain rate, and then the decision tree is constructed together with other nonnumerical features. For the problem of feature discretization into multiple numerical values, the principle of the algorithm is the same; just increase the number of division methods.

3.1.3. Cart Decision Tree Algorithm. When constructing the classification regression tree model, we first randomly divide the sample set into training set and test set and then use cart algorithm to build the model in the training set, so as to obtain the classification regression model. Then we evaluate its performance through the test set. After successful construction, we apply this model to classify and predict the data of unknown categories. If the model construction fails, we return to the modeling process again and then conduct effective modeling and analysis through appropriate eigenvalues until the model is successfully constructed. Figure 1 shows the flow diagram of constructing classification regression tree [9].

Compared with neural network, support vector machine, and Bayesian algorithms, decision tree has its own advantages and disadvantages, as shown in Table 1.

3.2. Random Forest Model. Random forest is a model established by using a large number of decision trees (7).

$$\{h(x, \theta_k), k = 1, \dots, K\}, \tag{7}$$

where $\{\theta_k\}$ represents a random vector subject to independent identically distributed, K is the number of decision trees, and each tree is the known variable x for optimal voting.

For the training sample set (8), N is the total number of samples, the object in X has an M -dimensional feature vector, and Y includes F different categories of information.

The classifier overemphasizes the classification of training samples, which makes the prediction of test samples worse. This phenomenon is called overfitting [10]. In the process of model construction, a variety of error analysis will be introduced. For random forest, generalization error is the key point to describe the overfitting problem. The generalization error is described by the edge function as follows:

$$mg(X, Y) = av_k I(h_k(X) = Y) - \max_{j \neq Y} av_k I(h_k(X) = j). \tag{8}$$

This function expresses the difference between the average value of correct votes obtained by correctly classifying random vector X into Y and the average value of votes obtained by other categories. The larger the function value is, the higher the classification accuracy is. Then the generalization error is defined as follows:

$$PE^* = P_{X,Y}(mg(X, Y) < 0). \quad (9)$$

According to the inference of the theorem of large numbers, the generalization error will eventually converge to the extreme value as the number of decision trees k increases, as shown in the following expression:

$$\lim_{k \rightarrow \infty} PE^* = P_{X,Y} \left(P_\theta(h(X, \theta) = y) - \max_{j \neq y} P_\theta(h(X, \theta) = j) < 0 \right). \quad (10)$$

By solving the expected value of the edge function and the inference of Chebyshev inequality, an upper bound of the generalization error can be obtained as follows:

$$PE^* = \frac{\bar{\rho}(1-s)^2}{s^2}, \quad (11)$$

where $\bar{\rho}$ represents the mean value of the correlation factor ρ between trees and s represents the performance strength of the classifier. In order to better analyze the final performance of the classifier, the correlation factor and performance intensity are described by c/s^2 ratio, and the smaller the ratio, the better the effect of the classifier, which is defined as follows:

$$\frac{c}{s^2} = \frac{\bar{\rho}}{s^2}. \quad (12)$$

3.3. Random Forest Algorithm Regression Model. Suppose that the training set is taken from the distribution of random variables X and Y , which is similar to many predictors (see the following equation):

$$E_{XY}(Y - h(X))^2. \quad (13)$$

The above formula is the mean square random error, where $h(X)$ is the predicted value of the classifier. Since the predicted value is the average value of all trees, the form of mean square random error is as follows:

$$E_{XY}(Y - av_k h(X, \theta_k))^2. \quad (14)$$

When the total number of trees K is increasing, it is finally expressed as follows:

$$E_{XY}(Y - av_k h(X, \theta_k))^2 \rightarrow E_{XY}(Y - E_\theta h(X, \theta_k))^2. \quad (15)$$

The regression function is expressed as follows:

$$Y = E_\theta h(X, \theta_k). \quad (16)$$

In practical application, it is often considered that the value of K is large enough and is replaced by the following:

$$Y = av_k h(X, \theta_k). \quad (17)$$

The average generalization error PE can be expressed in the form of a single tree as follows:

$$PE(\text{tree}) = E_\theta E_{XY}(Y - h(X))^2. \quad (18)$$

Through mathematical derivation and calculation, the average generalization error $RE(\text{forest})$ of random forest has an upper bound, and the form is as follows:

$$RE(\text{forest}) \leq \bar{\rho} PE(\text{tree}), \quad (19)$$

where $\bar{\rho}$ ($0 < \bar{\rho} < 1$) is the correlation factor. This formula shows that the generalization error of the whole random forest is $\bar{\rho}$ times that of a single decision tree, and rational design of the random forest model can better reduce the generalization error.

3.4. Incremental Random Forest. In the process of incremental random forest growth, we need to pay attention to two necessary factors: one is to sample the data set online, and the other is to reconstruct the splitting rules of nodes. Random forest generates a large number of test sets according to the characteristic randomness and then continuously calculates the quality measure of the test set to select the best splitting criterion. There are a large number of test sets at the nodes of each random tree when splitting. If the random forest randomly selects the set threshold instead of the threshold for a certain feature, it is called extreme random forest. The modeling time is long and the data cannot be updated in real time, but the accuracy of classification has been greatly improved. Tables 2 and 3 show the updating and node splitting conditions of the incremental random forest model.

This section selects 6 groups from UCI database 1 [9–11] as experimental data: Colon, Leukemia, Prostate, Lung,

TABLE 4: Comparison results of data classification.

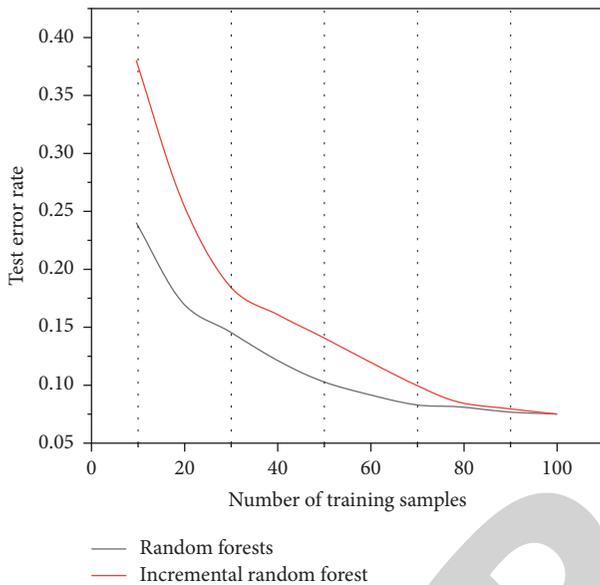

FIGURE 2: Effect of training sample number.

Lymphoma, and SRBCT. In the experiment, the total number of random trees is set to 100, and the number of randomly selected features is set to 10. In the experiment, the data are repeated 5 times and the average value is calculated. The standard deviation of classification error is shown in Table 4. The classification result of incremental random forest is very similar to that of original random forest. The prediction performance of the two methods is more accurate than that of OAB algorithm [11]. The main reason for the poor performance of OAB algorithm is that OAB algorithm can only solve the binary classification problem and cannot obtain the overall distribution of multifeature space in the data training process. Change the number of samples in the SRBCT data and compare the test error rates of the two methods. It can be concluded from Figure 2 that, with the gradual increase of the number of samples, the performance of the incremental random forest converges to the original algorithm.

4. Tobacco Mildew Image Recognition Based on Random Forest Algorithm and Neural Network

4.1. *Simulation Experiment.* In order to verify the effectiveness of the convolution neural network model for tobacco image classification, the tobacco image data set

TABLE 5: Experimental environment configuration.

Deep learning framework	PyTorch

produced in this paper will be used to carry out experiments on the convolution neural network model and four classical convolution neural network models. During the whole experiment, each model was trained by multiple epochs to obtain the best parameters of the model, and the accuracy change curve of the training set and the test set was obtained, so as to visually see the effect and comprehensive performance of each model [12].

4.1.1. *Experimental Environment and Data Set.* The experiment in this chapter is carried out under the PyTorch framework. The specific software and hardware environment configuration of the computer used in the experiment is shown in Table 5. The main experiment environment is to use Ubuntu19.10 system + PyTorch deep learning framework + Python 3.6 and use the GPU with NVIDIA GeForce GTX 1080 Ti and 64g display memory to accelerate the experiment. The data set used in the experiment is a self-made tobacco leaf image data set. The tobacco leaf image data set mainly includes four categories of tobacco leaf image data: normal tobacco leaf, moldy tobacco leaf, green miscellaneous tobacco leaf, and variegated tobacco leaf. Each category has 3500 tobacco leaf images in the three categories of moldy tobacco leaf, green miscellaneous tobacco leaf, and variegated tobacco leaf. There are 4500 pieces of tobacco leaf data in the normal tobacco leaf category, and there are 15000 pieces of tobacco leaf image data in total. The tobacco leaf image data set is divided into 2 subsets in the ratio of 4:1, including 12000 training sets and 3000 test sets, so as to facilitate the use of experiments [13].

4.1.2. *Experimental Design.* In this paper, the tobacco leaf image data set is used as the experimental data, and the simulation experiments are carried out on four classical convolutional neural network models and the convolutional neural network model built in this paper. In the process of experiment, after many experiments, the model parameters and learning rate that can optimize the performance of the model are finally obtained. Then, they are applied to the

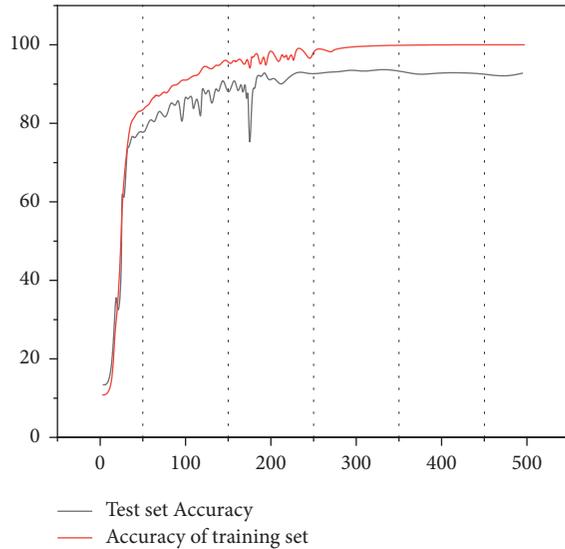

FIGURE 3: AlexNet model experiment results.

tobacco leaf image test set made in this paper for recognition [14]. During the experiment, the convolution neural network model has passed through 500 epochs, and the accuracy of the model test set is relatively stable. In addition, the visualization tool TensorboardX of PyTorch is used in the experiment. Its main function is to save and upload the data after model training to TensorboardX. TensorboardX is used to upload the coordinate data of the corresponding points of accuracy and generate csv files during model training. As the number of epochs increases, the accuracy change curve in the experiment is drawn. According to the change of the curve, we can more intuitively see the accuracy change and model effect of this test [15].

4.2. Analysis of Experimental Results

4.2.1. Results. Input the tobacco leaf image data set to AlexNet model for experiment. The network parameters are set as follows: the learning rate is set to 0.001, the dropout is set to 0.5, and the batch size is set to 64. This simulation experiment is based on 500 epochs and has been tested for many times. The accuracy change curve of AlexNet model simulation experiment is shown in Figure 3.

According to the experiment, the classification accuracy of AlexNet model test set is 95.5%. As can be seen from Figure 3, the convergence speed of the model is slow, and the accuracy of the model test set is relatively stable.

4.2.2. Result Analysis. We have made statistics on the test set loss value, training time of each epoch, and test set accuracy of the convolutional neural network model and four classical convolutional neural network models built in this paper [16]. The statistical results are shown in Table 6.

For the traditional image classification technology, this paper uses the HOG + SVM and HOG + KNN image classification methods. The main process is to first extract the HOG (histogram of oriented gradient) feature of the tobacco

ptdata image and then use the support vector machine (SVM) algorithm and KNN algorithm for image classification [17]. The specific experimental process of traditional image classification method in this paper is as follows:

- (1) HOG + SVM image classification method. Firstly, the moldy tobacco leaves, green miscellaneous tobacco leaves, and variegated tobacco leaves in the data set are taken as positive samples, and the normal tobacco leaves are taken as negative samples. Then the HOG features of positive and negative samples are collected to establish Feature Engineering, and then the support vector machine is used for image classification. As for support vector machine, LibSVM is used in this paper. It is a software library of support vector machine. It has the advantages of less input parameters and fast operation speed. It can easily classify or regress data.
- (2) HOG + KNN image classification method. Firstly, take the moldy tobacco leaves, green miscellaneous tobacco leaves, and variegated tobacco leaves in the data set as positive samples and normal tobacco leaves as negative samples, and then collect the HOG characteristics of positive and negative samples to establish Feature Engineering [18]. For the KNN algorithm, this paper uses the KNeighborsClassifier function encapsulated by sklearn, where the K value is set to 3. The experimental results of the convolution neural network model built in this paper are compared with the experimental results of the traditional image classification methods. The comparison results are shown in Table 7.

The structure of the actual circulatory neural network formed when the image data generated in this form is used for image distribution. This text is much larger than the traditional image distribution method. In terms of runtime, the training time for curved neural network structures is much longer than that for traditional image distribution

methods, but traditional image distribution methods require more time to remove image features and establish functional engineering before splitting [19].

5. Fast Identification Experiment of Tobacco Mildew

5.1. Materials and Instruments. 116 kinds of redried leaf tobacco collected from 2015 to 2017 were selected from different places of origin, different parts, and different grades, so as to fully consider the different effects of different places of origin, different parts and grades, and different types and quantities of mold in tobacco leaves on the mildew of tobacco leaves. The samples were provided by a tobacco company. The instruments are as follows: TRH-1250 constant temperature and humidity box (for sample mildew test); MPA Fourier transform near infrared spectrometer; KBF constant temperature and humidity chamber (for microbial counting experiment); Double Biocao RNA/DNAultra clean workbench; Ba-2s flapping sterile homogenizer; MS204 balance; Milli-Q Integral 10 ultra pure water machine [20].

5.2. Preparation of Moldy Samples. Put the redried tobacco leaf sample under the environment of temperature ($22 \pm 2^\circ\text{C}$) and humidity ($60 \pm 5\%$) for 48 h. Put the balanced samples into the constant temperature and humidity box, adjust the temperature and humidity to 25°C and 85%, respectively, and carry out the tobacco mildew test. Take 21 days as the cycle, and take samples according to the following methods:

- (1) The first sampling shall be carried out on day 0, that is, before putting the sample into a box with a constant temperature of 25°C and humidity of 85%.
- (2) On the 3rd to 9th day, take the 2nd to 4th sampling, respectively, at the interval of 3 days.
- (3) On the 11th to 21st day, take the 5th to 10th sampling, respectively, at 2-day intervals.

This process can completely collect the sample state that the redried tobacco leaves have never been mildewed to near mildewed and then to mildewed.

5.3. Mould Counting Test. According to YC/T 472-2013 microbiological examination of tobacco and tobacco products mold count, the mold count of redried tobacco samples with different degrees of mildew was detected. According to the mold count test results, the mold degree is divided into the following: nonmoldy samples (mold count $< 2 \times 10^3$ CFU/g), adjacent moldy samples (2×10^3 CFU/g \leq mold count $< 10^4$ CFU/g), and moldy samples (mold count $\geq 10^4$ CFU/g).

5.4. Near-Infrared Spectrum Data Acquisition. MPA Fourier transform near-infrared spectrometer was used in the experiment. The spectrum acquisition range was $4000 \sim 12000 \text{ cm}^{-1}$, the resolution was 8 cm^{-1} , and the scanning times were 64. The tobacco samples with different degrees of

mildew were loaded into the sample cup, and the near-infrared spectra of each sample were collected as the basic spectral information of each tobacco sample. Repeat the loading and determination for each sample twice, and then calculate the average result as the final spectrum [21].

Near-infrared spectroscopy is affected by a series of chemical and physical factors of samples. It is necessary to take mathematical pretreatment methods to reduce system noise, such as baseline change and light scattering. In this study, after comparing the first derivative (1-Der), second derivative (2-Der), multivariate scattering correction (MSC), standard normal variable (SNV) correction, and other preprocessing methods, discrete wavelet transform (DWT) is used to preprocess near-infrared spectral data [22].

The essence of wavelet transform is to decompose the signal into wavelet subspaces with different scales and frequencies. Choosing various mother wavelets according to the waveform or length makes wavelet transform more effective and flexible than other signal preprocessing methods in extracting the features of signals. Through wavelet transform, the signal is decomposed into low-frequency signal and high-frequency signal, approximation coefficient, and detail coefficient [23–29]. When wavelet transform is used to preprocess the near-infrared spectrum, there are two ways to establish the correlation model between independent variables and near-infrared signals: first is to reconstruct the spectrum with approximate coefficients and detail coefficients after denoising or data compression and to establish a model between the reconstructed spectrum and independent variables; second, the wavelet coefficients obtained by wavelet decomposition are directly used as variables to establish the model. Obviously, the latter method is much more convenient, time-saving, and widely used. In this study, wavelet coefficient was used as a variable to establish a prediction model for the mildew degree of redried tobacco leaves.

6. Results and Discussion

6.1. Classification of Moldy Tobacco Leaves. After the mildew experiment, 1160 tobacco samples with different degrees of mildew were obtained from 116 kinds of single flue-cured tobacco, which were sampled 10 times at different stages. Microbiological tests were carried out on 1160 samples according to YC/T 472-2013 microbiological examination of tobacco and tobacco products mold count. The research results of some scholars show that when the mold number reaches a certain amount (about 104 CFU/g), it will start to grow rapidly. In order to give early warning of tobacco mildew, it is necessary to prejudge the samples near mildew. Therefore, 104 CFU/g is taken as the critical point to judge the “near mildew” samples. According to the method of determining the degree of tobacco mildew, the tobacco mildew was finally divided into three categories: nonmildew, near mildew, and mildew. The three types of samples obtained from mildew test are shown in Table 8.

6.2. Near-Infrared Spectral Pretreatment. The original near-infrared spectra of 1160 redried tobacco samples with

TABLE 8: Classification of mildew degrees of tobacco leaf samples.

Primitive harmonic	2074	69.73	73.15	30.88	73.82

different degrees of mildew can be obtained from the original near-infrared spectra during the mildew process of redried tobacco. According to the principle of near-infrared spectroscopy, the near-infrared spectral absorption band of the sample is the frequency doubling and merging of hydrogen containing groups (O-H, N-H, C-H) in the mid infrared spectral region, as well as the superposition of differential absorption bands. When tobacco is mildewed, the organic substances such as C source and N source in the sample will change due to the catabolism of mold, and some chemical components related to the composition of mold cell wall such as ergosterol and chitin will be produced. Therefore, in theory, the near-infrared absorption bands of tobacco leaves with different degrees of mildew will change with the change of chemical composition in the sample. However, on the one hand, it is due to the serious overlap of near-infrared spectra; on the other hand, tobacco mildew is a complex process, and the changes of chemical components are also extremely complex. It is difficult to directly extract the information related to the degree of mildew from the near-infrared spectra of tobacco leaves and give a reasonable spectral analysis. It can be seen from the final results that the absorption bands related to mildew in the near-infrared spectra of tobacco leaf samples are difficult to be directly judged from the spectra.

In this study, discrete wavelet transform (DWT) was used to decompose the original near-infrared spectra of redried tobacco leaves in the process of mildew. When using DWT to process NIR spectra, there are two factors to be considered: the selection of mother wavelet and the determination of decomposition level. At present, there is no theory to follow for the selection of mother wavelets. The study investigated the influence of 15 mother wavelets, five Daubechies series wavelets (db2, db4, db6, db8, and db10),

five Symlets series wavelets (sym2, sym4, sym6, sym8, and sym10) and five Coiflets series wavelets (coif1, coif2, coif3, coif4, and coif5), on the recognition accuracy of moldy tobacco leaves. The results of Daubechies series wavelets are basically the same, but, in general, the prediction results are better than those of the other two types of wavelets. Finally, db6 is determined as the mother wavelet. When determining the decomposition level, the dimension n of the input data should generally be considered, which generally does not exceed $\log_2(N)$. For the extraction of useful information, the decomposition level should be as large as possible. In this study, there are 2074 data points in the near-infrared spectrum, so this paper selects 11 as the decomposition level of wavelet transform. After each level of decomposition, a detail coefficient vector and an approximate coefficient vector are obtained. The approximation coefficient is further decomposed to obtain the detail coefficient and approximation coefficient until the 11th decomposition level. Finally, the vectors obtained by wavelet transform include the approximate coefficients (ca) of the spectral signal of each sample at the last decomposition level and the detail coefficients (cd) at all decomposition levels. A total of 12 groups of wavelet coefficients, ca11, cd11, cd10, ..., cd1, are obtained.

6.3. Establishment of Identification Model of Tobacco Mildew Degree. To compare the reception results of the different models, 1160 models were divided into training and test modes. Approximately 2/3 of the models are used as training, and 1/3 of the models are based on experiments. Finally, 773 models were selected for the training, of which 365 were standard, 68 were standard, and 340 were standard. The remaining 387 models were used as standardized

TABLE 10: Comparison of training results of cigarette model, cut tobacco model, cigarette end model, and comprehensive model.

Model	Total recognition rate/%	Recognition rate_1/%	Recognition rate_2/%	Recognition rate_3/%
Smoke model	93.40	93.42	91.17	93.82
Cut tobacco model	94.05	94.25	91.17	94.41
Smoke model	94.95	95.62	92.65	94.71
Integrated model	80.60	80.55	73.53	82.06

TABLE 11: Prediction results of test set based on [cd4, cd5] random forest model.

Parameter	Unmodified samples	Adjacent moldy samples	Moldy samples	Total
Number of test set samples	183	34	170	387
Accurately predict the number of samples	175	31	161	367
Correct prediction rate/%	95.63	91.18	94.71	94.84

experiments. This document categorizes mold-free designs, mold designs, and multimold designs as “1,” “2,” and “3,” respectively. The accuracy of the training procedures and examination procedures is determined by the fees and assumptions.

It can be seen from Table 9 that the number of variables from cd1 to cd11 and ca11 and from 1051 to 29 decreases in turn. Among them, the random forest model constructed by the wavelet coefficient cd4 with a small number of variables (92) has the highest recognition rate: the total recognition rate is 90.04%, the recognition accuracy rate of nonmildewed samples is 90.68%, the recognition accuracy rate of near mildewed samples is 80.88%, and the recognition accuracy rate of mildewed samples is 93.24%, which are higher than the recognition ability of other wavelet coefficients.

As can be seen from Table 10, from the perspective of model accuracy, the prediction accuracy of the end of tobacco model > cut tobacco model > piece tobacco model > comprehensive model is similar to those of the end of tobacco model, cut tobacco model, and piece tobacco model.

In the measurement model, the flue gas model was used to calculate the sample size, and the calculated results are shown in Table 11. As shown in Table 11, 175 of the 183 models were correctly calculated, not moldy. The accuracy is 95.63%. Out of 34 samples close to the fungus, 31 samples were calculated correctly, with an accuracy of 91.18%; 161 out of 170 yeast samples were calculated correctly, with an accuracy of 94.71%. The accuracy of the test lumped forecast is 94.84%. The results showed that the model established by this method could effectively identify tobacco samples with different degrees of mildew.

7. Conclusion

In this study, the redried tobacco leaf was taken as the research object, the experimental conditions were high-temperature and high-humidity environment, and the sample data of tobacco mildew degree were obtained under different experimental conditions. In this paper, a rapid identification method of tobacco samples with different degrees of mildew was established by near-infrared spectroscopy, which provided a basis for early warning of tobacco mildew. The

wavelet transform was used to process the spectral data, and [cd4, cd5] was selected as the spectral variable to establish the random forest recognition model of tobacco leaves with different degrees of mildew. The recognition rate and prediction rate of the model were 93.82% and 94.84%, respectively. The satisfactory recognition rates were achieved for the normal tobacco leaves, the adjacent moldy tobacco leaves, and the moldy tobacco leaves. It can be seen that near-infrared spectroscopy combined with wavelet transform and random forest algorithm can effectively identify tobacco samples with different degrees of mildew. This method can be considered feasible to quickly predict the degree of tobacco mildew.

The number of hearing-impaired people is increasing year by year; robotic cochlear drilling surgery is one of the safest methods to treat deafness. Looking at the issue of low efficiency of temporal bone posture positioning in cochlear implantation robotic drilling, a novel auxiliary ring marker temporal bone positioning method was proposed to improve temporal bone posture positioning efficiency, optimize the operation time, and reduce auxiliary injuries caused by the surgery. First, the temporal bone visual positioning assistant ring was designed based on the requirements for cochlear robotic drilling surgery. The target detection was conducted on the auxiliary ring and image processing and feature point extraction methods were designed. Then, the three-dimensional coordinates of the measured feature points were obtained by binocular vision, and the auxiliary ring and temporal bone postures were estimated. Finally, the auxiliary ring and temporal bone localization methods were validated. The experiment results indicated that the temporal bone was located quickly and effectively in a total time of about 33 ms, which was faster and more accurate than traditional visual localization methods and could satisfy real-time temporal bone localization during surgery. This study can reduce the time of temporal bone visual positioning in cochlear implant drilling operations, greatly improving the robot's capabilities to extract visual information during the operation, which has a better auxiliary role for future research and applications of the cochlear implant drilling operation.

1. Introduction

Cochlear implant drilling is a new surgical procedure that optimizes the surgical method and reduces surgical trauma [1, 2]. As robot technology has developed, robot drilling surgery has gradually become more acceptable [3, 4]. Compared with human-performed operations, robotic operations for cochlear drilling have shown far more advantages than the former, which is conducive to an effective, quick, and safe methodology for cochlear drilling [5]. Human beings have innate advantages in visual information perception and can quickly extract and identify information and content during surgery; however, there is no perfect computer model in this field, and the weak visual

information processing ability is the key to the challenges facing robotic surgery for cochlear implant drilling [6]. In recent years, temporal bone visual localization as the core technology for robotic drilling surgery has garnered an increasing amount of attention. The goal is to map the positions of key tissue structures in the ear and plan the drilling path of surgery by using the postures of human temporal bones [7].

Currently, many scholars are studying the rapid temporal bone localization method, but most of them still abide by the traditional image detection marker method. Cho et al. proposed registering the locations of surgical wounds using a tripod visual calibration rod as a marker [8]. The calibration rod could provide reliable geometric feature

information and facilitate calculating wound location, but the registration method for implanting the calibration rod was cumbersome and would easily affect the operating space. Dillon et al. used titanium screw implantation on temporal bones to simplify the challenges inherent to marker implantation [9], but the locations where the titanium screws were implanted were random and riddled with uncertainties, and it is difficult for computers to obtain such random information. Jia et al. proposed a short-flow visual registration method of the malleus, which can effectively improve registration accuracy for intra-aural structures and reduce any damage caused by the registration process [10], but this method requires a surgeon to have a lot of clinical experience.

In conclusion, the temporal bone localization markers used now cannot satisfy the requirements for rapid detection in computer vision. To solve the aforementioned problems, this paper proposed a temporal bone localization method based on an auxiliary ring, named the Deep (DL-M), and functions based on a combination of deep learning target detection, computer vision, and medical requirements of cochlear implant drilling surgery. The DL-M reduces extraction time for feature points and matching calculation of irrelevant features through image processing. Compared with BM, SGBM, and other methods, DL-M is faster, and its overall duration is about 40 ms, which meets the requirement for real-time detection of more than 20FPS. The average detection accuracy of the auxiliary ring is less than $\pm 0.63^\circ$.

2. Principles of Auxiliary Temporal Ring Bone Localization

In the robotic drilling operation for a cochlear implant, a surgical approach from the mastoid surface of the temporal bone to the tympanic step needs to be drilled, so it is necessary to locate the temporal bone in the body to determine the drilling point and the direction of approach [11]. Since there is no fixed and easily identifiable feature information for the temporal bone, it is difficult to calculate its pose through vision. Therefore, it is necessary to plant external markers to establish the spatial relationship between the markers and the temporal bone and to detect and calculate the pose information for external markers to obtain the current pose information for the temporal bone. Therefore, during robotic cochlear implant drilling surgery, temporal bone position and pose information detection are obtained by detecting temporal bone visual markers.

2.1. Temporal Bone Positioning Auxiliary Ring. During cochlear implant drilling, the temporal bone with implant markers was initially scanned with high-precision CT, and its three-dimensional image was reconstructed. Then, the relative position of the tissue structure in the ear was calculated to plan the drilling path based on the surgical conditions, and the relative postural relationship between the path and markers was calculated. Finally, the robot drills the planned surgical approach through the relative postural

relationship between the postural information from the markers and the path [12, 13]. Therefore, temporal bone markers should not only have a clear shadow in a CT scan but also visual features that can be detected by machine vision. The traditional locating method with external markers is random and subjective, and the irregular pattern is not conducive to machine vision detection and analysis. There are three main effects of robotic drilling. First, the spatial location of marker planting is too single, which will affect the calculation of depth information, which will lead to a large relative position error between marker and tissue structure. Second, too many marker points will cause secondary damage to the temporal bone. Third, it is difficult for robots to detect and analyze the traditional irregular planting location distribution. To resolve these issues, a robotic drilling auxiliary ring for cochlear implantation was proposed and designed, as shown in Figure 1.

The auxiliary ring is structurally divided into three parts: the inner ring, the outer ring, and the attached titanium sphere. The inner ring is nested in the outer ring, and the titanium sphere is attached to the torus of the outer ring and is sequentially mapped. The effects of traditional markers and auxiliary ring implantation are shown in Table 1. By using the auxiliary ring as the temporal bone visual registration marker, up to three wounds on the temporal bone can be fixed, thus reducing temporal bone injuries in the implanting process. The use of a circular structure is more in line with human engineering properties. The titanium spheres attached to the outer ring can be used as markers in CT scan reconstruction instead of titanium nails. The inner and outer ring structure adds visual features that are easy to detect on the auxiliary ring surface. The feature points of colors, fixed shapes, and distribution laws are beneficial to computer vision processing and analysis.

2.2. Binocular Vision Measurements. In the cochlear implant drilling operation, the auxiliary ring spatial position should be calculated, and real-time feedback of image information during the operation is needed. Binocular vision was used to locate the auxiliary ring. Based on the parallax principle, binocular vision reconstructs the three-dimensional coordinates of the target in space according to the two-dimensional coordinates of the measured target in the left and right images combined with the transformation relationship between each coordinate [14]. Binocular ranging needs to calibrate the binocular camera, determine the transformation relationship between the world coordinate system, pixel coordinate system, and camera coordinate system, and finally calculate the rotation matrix and translation vector between the internal and external camera parameters and the left and right cameras. The calibration tool for the STEREO Camera Calibrator in MATLAB was adopted, and Chang's calibration method was employed to calibrate the internal and external parameters of the left and right cameras. The calibration results are shown in Figure 2.

According to the mapping relationship between the projections, external parameters, and internal parameters, the distortion coefficients were obtained after the left and

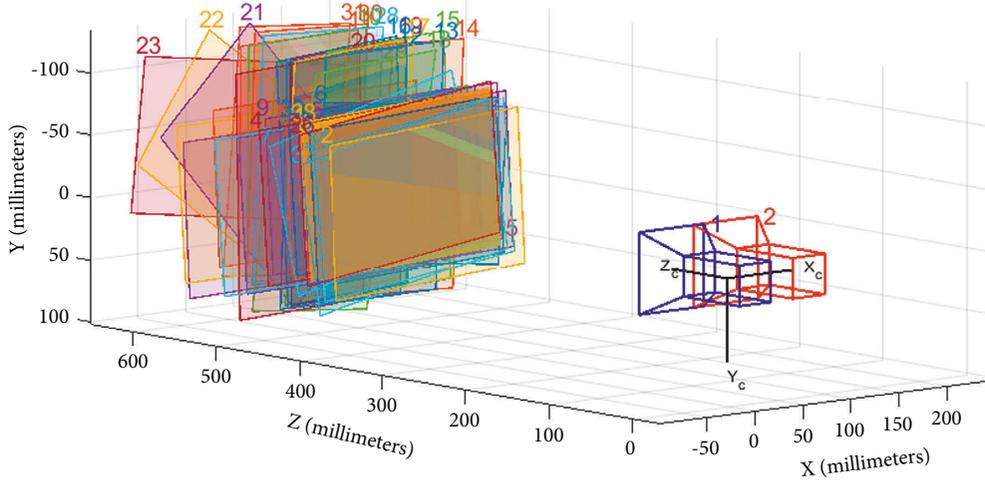

FIGURE 2: Binocular vision stereo calibration.

right cameras were calibrated, and the projection matrices of the cameras were M_l, M_r , respectively, allowing the world coordinates of any point in space to be (X, Y, Z) , then the following formula can be obtained:

$$\begin{cases} Z_{cr} \begin{bmatrix} u_r \\ v_r \\ 1 \end{bmatrix} = M_r \begin{bmatrix} X_c \\ Y_c \\ Z_c \\ 1 \end{bmatrix} = \begin{bmatrix} m_{11}^r & m_{12}^r & m_{13}^r & m_{14}^r \\ m_{21}^r & m_{22}^r & m_{23}^r & m_{24}^r \\ m_{31}^r & m_{32}^r & m_{33}^r & m_{34}^r \end{bmatrix} \begin{bmatrix} X_c \\ Y_c \\ Z_c \\ 1 \end{bmatrix} \\ Z_{cl} \begin{bmatrix} u_l \\ v_l \\ 1 \end{bmatrix} = M_l \begin{bmatrix} X_c \\ Y_c \\ Z_c \\ 1 \end{bmatrix} = \begin{bmatrix} m_{11}^l & m_{12}^l & m_{13}^l & m_{14}^l \\ m_{21}^l & m_{22}^l & m_{23}^l & m_{24}^l \\ m_{31}^l & m_{32}^l & m_{33}^l & m_{34}^l \end{bmatrix} \begin{bmatrix} X_c \\ Y_c \\ Z_c \\ 1 \end{bmatrix} \end{cases} \quad (1)$$

In the above formula, Z_{cr}, Z_{cl} is the distance from the projection of a point in space on the optical axis to the

optical center; M_r, M_l is the projection matrix of the camera; and (X, Y, Z) is the world coordinate of a point in space.

3. Auxiliary Ring Positioning Method

The temporal bone auxiliary ring positioning method DL-M proposed in this paper for cochlear implant drilling surgery can generally be divided into three parts: target region detection, feature point extraction, and position and pose a solution. The specific realization process is shown in Figure 3. First, the outer ring of the input image and the target region of the characteristic titanium spheres are detected by the trained deep learning model. Next, the feature points in the boundary box are extracted quickly, and the image coordinates are calculated. Then, binocular vision measures the three-dimensional coordinates of the feature points. Finally, the pose information for the auxiliary ring is solved according to the three-dimensional coordinates of the feature points.

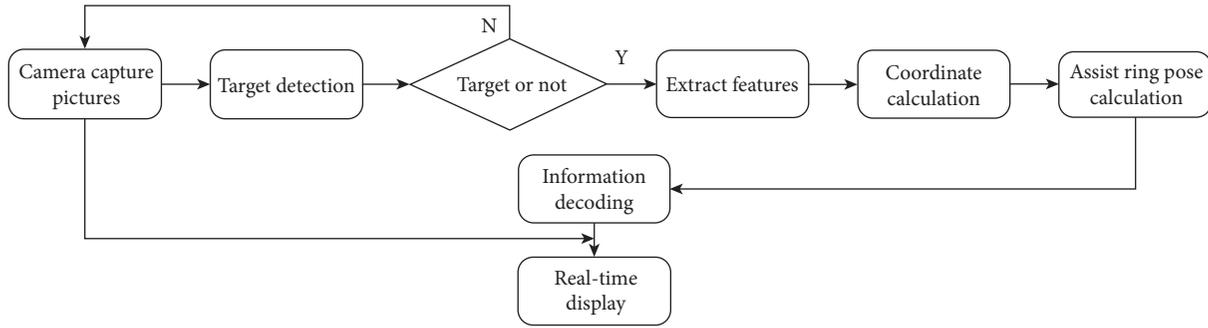

FIGURE 3: Auxiliary ring positioning method flow.

3.1. Auxiliary Ring Target Detection. How to efficiently identify an object to be measured is always one of the most important challenges for machine vision. Due to the influence of light, blood stains, instruments, and other factors, it is difficult to obtain the characteristic information of the auxiliary ring quickly and accurately through traditional detection methods in cochlear implant drilling surgery. Due to the development of the Convolutional Neural Network, deep learning algorithms based on the Convolutional Neural Network, it has gradually become the main method of target detection. Compared with traditional detection methods, deep learning algorithms are more advantageous in terms of speed, precision, and structure [15, 16]. In drilling surgery, the deep learning target detection algorithm can quickly and accurately identify the characteristic information of the auxiliary ring in complex surgical environments and accelerate auxiliary ring positioning.

To accurately and quickly detect the target auxiliary ring in a complex surgical environment, the YOLOV3 method was employed in this paper to detect the target related to the auxiliary ring [17]. The outer ring and titanium spheres were used as detection models for training auxiliary rings to obtain the boundary information of the outer ring and titanium spheres. The K-means clustering algorithm was used to calculate the prior parameters of anchor points in the data set, and the method for initiating random numbers in the clustering algorithm was changed. By analyzing the data set, 9 anchor points are given for the initial calculation, which can help the network better adjust the size of the bounding box while learning. In this experiment, the outer ring region and titanium sphere regions from about 650 images of the auxiliary rings with a different attitude in different environments were labeled, and the PASCAL VOC2007 dataset was established.

3.2. Feature Extraction. After the target features of the outer ring and titanium spheres were obtained by target detection, the target feature information in the boundary box should be further extracted, as shown in Figure 4. Firstly, the image of the attitude auxiliary ring was preprocessed by filtration and equalization. Secondly, the contour information in the boundary box of the outer ring was detected, screened, and fitted, and the fitted contour dataset was reconstructed by using relevant mathematical functions. Then, the

reconstructed ellipse dataset was matched with the original contour dataset to determine whether the contour was the target contour that met the conditions. Finally, the center of the fitted ellipse was calculated, which was the two-dimensional coordinate of the center of the auxiliary ring.

To reduce the image processing duration, ROI segmentation was conducted on the original image in the range of the bounding box information output after target detection, and image pre-processing was conducted within ROI to reduce the amount of image pre-processing calculations. Bilateral filtering removed the noise in images in the region of interest and the image edge information was retained. Then the target feature points were extracted by ellipse detection and a region growing algorithm. Finally, the feature points of the left and right cameras are matched to provide reliable matching points for binocular vision calculation.

3.3. Posture Calculating. After the matching target feature points were obtained, the characteristic coordinates of the auxiliary ring were obtained through the principles of binocular vision, and the auxiliary ring position and pose information were further calculated. The specific process is shown in Figure 5.

The feature points matched by the left and right images were substituted into (1), and irrelevant variables were eliminated. The least square fitting method solved the three-dimensional coordinates for the feature points. $(x_i, y_i, z_i) i \in (1, 5)$, (q_x, q_y, q_z) represented the coordinates of the centers of the corresponding 1–5 titanium spheres and the corresponding inner ring. The obtained coordinates were the three-dimensional space coordinates for the auxiliary ring from the image plane coordinates. Given the world coordinates of the camera, the coordinate values of the auxiliary ring in the world coordinates can be obtained through coordinate transformation. To coordinate with each serial number corresponding to an individual sphere, this paper combined with the distribution rules of auxiliary ring attached titanium ball, and designed the coordinate collation of feature points by considering the intensive degree of space points. The intensive degree ρ_i of the coordinate distribution concerning the titanium cue ball was calculated by using the formula (5), the feature points were ordered by relative intension of ρ_i , and, thus, the titanium

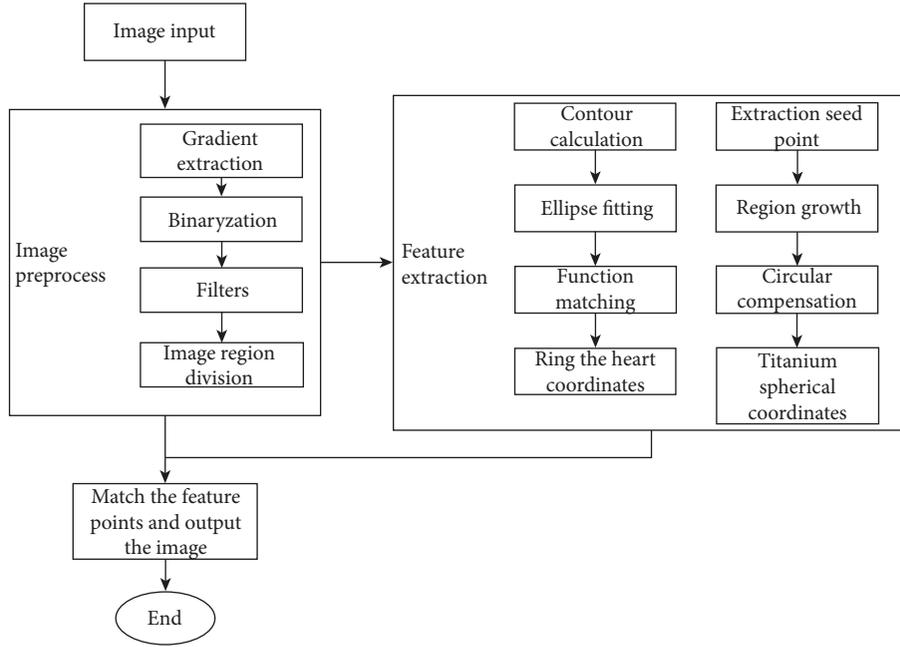

FIGURE 4: Feature point extraction process.

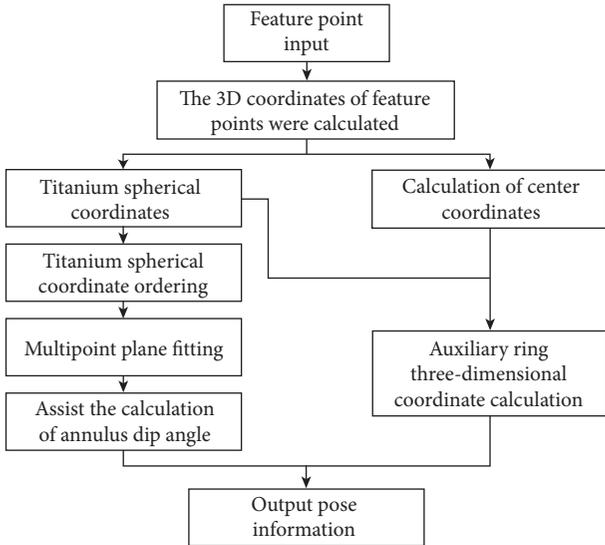

FIGURE 5: Pose and pose calculation process.

spherical coordinate in the image corresponded with the actual serial number of the ball. It can provide accurate characteristic correspondence information for the ring attitude solution.

According to the regular distribution of titanium spheres, a virtual average point of titanium spheres is:

$$p^{avg} = \frac{\sum(p^j)}{j} \quad (2)$$

Find the square of the absolute distance between each point and the average point.

$$\rho = \frac{1}{d^2} = (p^j - p^{avg})^2, \quad (3)$$

(2) and (3) are simultaneously established, and the irrelevant variables are eliminated to obtain:

$$\rho_i = \frac{1}{\sum_k \left(P_k^i - \frac{5}{j=1} P_k^j \right)^2} \{k = (x, y, z)\}, \quad (4)$$

Setting the auxiliary ring attitude as the initial attitude when the width coordinate of the line between the No. 1 titanium sphere and the ring center is perpendicular to the image. The rotation angles around the X, Y, and Z coordinate axes are defined as $\theta_x, \theta_y, \theta_z$, respectively. The initial angle is defined as when the No. 2 titanium ball and the No. 3 titanium ball are parallel to the X-axis of the spatial coordinates. The connection between the center of the No. 2 titanium ball and No. 3 titanium ball is parallel to X, so the rotation angle around the z-axis can be obtained only by calculating the tangent value of the connection and X, so θ_z can be expressed as:

$$\theta_z = \tan^{-1} \left(\frac{y_3 - y_2}{x_3 - x_2} \right). \quad (5)$$

To reduce errors in angle calculation caused by visual detection and feature extraction, the three-dimensional coordinates of the spherical center were substituted into the spatial plane equation to fit the auxiliary ring plane by the spatial multipoint SVD plane fitting method to reduce the errors caused by binocular vision measurements and optimize the attitude calculation results.

$$AX = \begin{bmatrix} x_1 - \bar{x} & y_1 - \bar{y} & z_1 - \bar{z} \\ x_2 - \bar{x} & y_2 - \bar{y} & z_2 - \bar{z} \\ x_3 - \bar{x} & y_3 - \bar{y} & z_3 - \bar{z} \\ \dots & \dots & \dots \\ x_n - \bar{x} & y_n - \bar{y} & z_n - \bar{z} \end{bmatrix} \begin{bmatrix} a \\ b \\ c \end{bmatrix} = 0. \quad (6)$$

Taking the residual difference between the selected feature points and the fitting plane as the goal of minimization optimization, the fitting objective function is $\min \|AX\|$, with constraint $\|X\| = 1$ through a singular value decomposition $A = UDV^T$. The feature vector corresponding to the minimum singular value was the coefficient vector of the fitting plane. The geometric meaning of a, b, c was the coordinate component values of the normal plan vector, so θ_x, θ_y can be expressed as:

$$\begin{cases} \theta_x = \tan^{-1}\left(\frac{a}{c}\right) \\ \theta_y = \tan^{-1}\left(\frac{b}{c}\right) \end{cases}. \quad (7)$$

Through the aforementioned coordinate calculation of feature points and plane fitting operation, the spatial coordinate position of the auxiliary ring under the camera plane was obtained. Since the spatial relationship between the temporal bone and the auxiliary ring was obtained by preoperative CT scanning, the spatial position of the temporal bone and structural tissue in the ear could be obtained by coordinate transformation.

4. Rapid Extraction of Auxiliary Ring Features

In the temporal bone auxiliary ring visual positioning method, the key to pose detection is to extract the set features quickly and accurately. The more traditional BM or SGBM needs to calculate the pixel points of an entire image, and the algorithm takes a long time and is prone to producing parallax holes, which is not conducive to extracting specific feature points. In this paper, the DL-M feature point extraction scheme can quickly and accurately extract target features and, through improved ellipse matching, regional growth point selection and matching methods, accelerate target feature extraction.

4.1. Ellipse Matching Based on Image Moments. While detecting contour ellipse in the auxiliary ring, because the input contour was not screened in the Hough ellipse fitting, it is impossible to judge whether the original contours before fitting are an elliptic contour. To solve this problem, based on the concept behind the Hu moments image moment, this paper calculated the Hu-moment for the fitting contour and the original contour and judged it, which greatly eliminated any interference from nonelliptical contours. On this basis, a contour screening mechanism was added to reduce the computational burdens for ellipse recognition. After fitting the selected contour, the mathematical expression for the

fitting ellipse was established by using the rotation matrix information returned by the fitting, and the fitting ellipse pixel group was reconstructed. The calculation formula is:

$$V_{\text{ponit}}(x, y) = \begin{cases} P_i^x = x \cos \varphi - \sqrt{\left(1 - \frac{x^2}{a^2}\right)} b^2 \sin \varphi \\ P_i^y = \sqrt{\left(1 - \frac{x^2}{a^2}\right)} b^2 \cos \varphi + x \sin \varphi \\ \varphi = \frac{\text{angle} * \pi}{180} \end{cases} \quad (8)$$

The geometric moments for the reconstructed elliptic contour and the original image contour were calculated, and the reciprocal deviations of the geometric moments were calculated to accumulate the moment errors in the original contour and reconstructed contours. The specific calculation formula is:

$$M_x = \sum_{i=1}^M \sum_{j=1}^N i^p j^q f(i, j), \quad (9)$$

$$I(A, B) = \sum_{i=1}^7 \left| \frac{1}{m_i^A} - \frac{1}{m_i^B} \right|.$$

The accumulated error function was then normalized. When the fitted ellipse contour was similar to the original contour, $I(A, B)$ approached 0; otherwise, it approached 1. The maximum threshold was set to limit the errors between its geometric moments, and then the similarities between the two were judged.

4.2. Obtaining the Planar Center of the Titanium Spheres. While calculating the titanium sphere centers by the angle of view, part of the titanium sphere boundaries will be blocked by the outer ring plane, so they cannot be completely detected in the image. In this paper, the region-growing algorithm [18] and circle compensation were used to calculate the image coordinates of the titanium sphere centers. The challenge for the regional growth algorithm was selecting the seed starting point. Usually, the seed point is judged artificially, or the starting point of the seed is obtained by using a clustering algorithm adhering to a certain set of rules. This method was difficult to apply to the seed point selection for the titanium spheres because of their small size and indistinct features.

To solve the aforementioned problem, the region growth algorithm was designed in combination with the titanium sphere boundary box information obtained from YOLOV3 target detection. The specific process is shown in Figure 6. The midpoints of the titanium sphere beam boxes were utilized as the growth starting points, and the shape of the visible portions of the titanium spheres were described, and the field pixel values and growth sizes at the midpoints of the titanium sphere beam boxes was limited to exclude any incorrectly detected targets during target detection. The

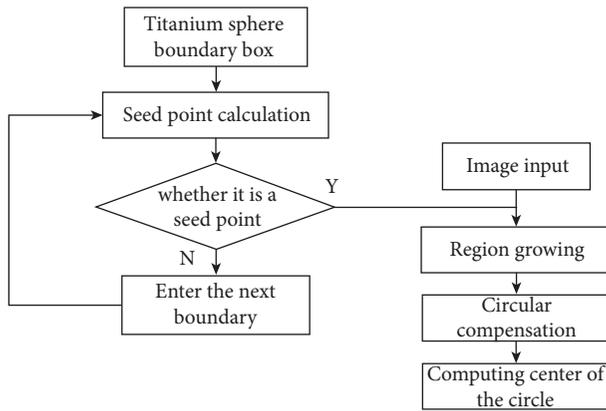

FIGURE 6: Calculation process for center coordinates.

minimum circumferential circle was used to complete the spherical surfaces of the titanium spheres, and their centers were calculated.

4.3. Feature Point Matching Based on Polar Constraints.

After the feature points on the auxiliary rings from the left and right images were obtained through the aforementioned calculation, the order of the titanium spheres in the left and right images was different. Based on the concept of polar constraints, this paper matches the feature points of the titanium spheres, and the main process is:

- (1) Calculated the polar equation on the right image plane through the coordinates of the characteristic points of the centers of the titanium spheres on the left image plane.
- (2) Calculated the distances between the feature points in the right image and the polar line, and found the right feature points with the smallest distances after feature traversal. The smallest point was the matching point of the left image in the right image.
- (3) The matching feature information was stored, and the distance error was analyzed. If the error was greater than the set value, the point was brought into the region again for growth calculation.

With this method, the target feature points for the centers of the titanium spheres could be accurately matched. When compared with the traditional matching methods BM or SGBM based on polar line constraints, the calculation of useless coordinates during feature matching can be reduced. In addition to accelerating the matching speed, the precision of regional growth feature points was also calculated and analyzed.

5. Results and Discussion

In this paper, the method that calls for drilling an auxiliary ring for cochlear implants was used as the test object to detect features and calculate position and pose information. Firstly, the trained auxiliary ring model was tested on the test set, and the average detection rate, the missed detection rate,

and the false detection rate were calculated, and the effect of the model was evaluated by comparing it with the detection method. Then, the method of extracting feature points is verified to evaluate its reliability. Finally, the pose information of the auxiliary ring under different positions and postures is measured and the error is analyzed.

In the target detection experiment, 130 test pictures were tested, and some of the test results are shown in Figure 7. Among them, the number of auxiliary rings was 130, and the number of titanium spheres was 650. The number of detections, missed detections, and false detections for the model was statistically analyzed, and the results are shown in Table 1. It can be observed that the model presented in this paper has a high recognition rate for both the outer ring and the titanium spheres on the auxiliary ring, and the detection effect for the outer ring was better than that of the titanium sphere.

Using auxiliary ring structure characteristics of the feature point extraction scheme design, by combining deep learning target detection and image processing with a feature point detection method that incorporated a feature point matching method based on polar constraints, a large number of target detections were decreased, and the time needed for binocular image feature matching quickly extracted accurate target feature points. The specific process and effects are shown in Figure 8.

To better evaluate the current morphology and measurement data for the auxiliary ring during the operation, this paper used QT to design the image interactive interface. Multithreading displayed current image information in real time and controlled target detection, image processing, and information transmission programs, as shown in Figure 9. In the figure on the left, the image content obtained in real time by the left and right cameras was provided for real-time observation during the experiment. The image on the right is the target detection effect. The image in the lower right corner displays the current coordinate information of the auxiliary ring in real time. The interface of information transmission is also reserved in the program, which makes preparation for the interaction between the surgical robot and visual information.

The auxiliary ring was fixed on the experimental platform with a variable dip angle, and the auxiliary ring position and attitude were measured by changing the platform angle and setting the auxiliary ring dip angle. The binocular camera was placed about 25 cm above the experimental platform. To eliminate any error interference caused by the camera's own attitude, the camera was fixed, and the error between the actual and measured angle changes was calculated through the differences in experimental angle measurement. The position and attitude information of the auxiliary ring under random different attitudes were measured several times (greater than 50), and the standard deviations and maximum deviations obtained from all measurements were counted. The test results are shown in Table 2. Experimental data shows that the method has relatively high accuracy and small measurement fluctuations in the test environment, and the measurement results have good stability.

In robotic surgery, the use of titanium nails as markers does not give a fixed structure. The use of a triangulation bar usually requires the secondary calibration in the operation, which takes time and has a certain impact on the operating

space. The auxiliary ring of cochlear implant drilling used in this paper adopts the combination of simple shapes, colors, and materials, which not only meets the positioning requirements of the auxiliary robot cochlear implant drilling

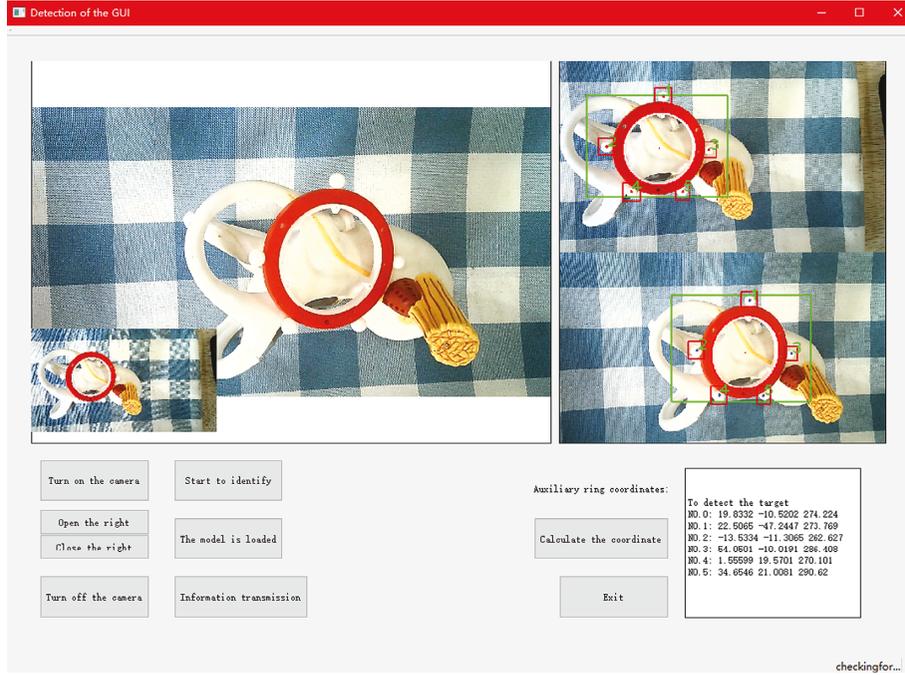

FIGURE 9: GUI interactive interface.

surgery but also provides enough operating space. It has certain advantages compared with titanium nail implantation or the use of a visual calibration rod. The effects of traditional markers and auxiliary ring implantation are shown in Table 3.

In this paper, the deep learning algorithm was combined with the binocular vision image processing auxiliary ring detection method DL-M. The neural network method is used to train the model of specific auxiliary rings in advance, and the deep learning target detection method is applied to medical-assisted detection, which is faster and more accurate than the traditional target detection method, and the detected perceptual region helps to reduce the computational effort and difficulty in the subsequent feature extraction. Compared with the traditional binocular vision matching algorithms, such as BM and SGBM, the detection speed and matching effect were improved. The DL-M method used in this paper is similar to the BM matching algorithm in speed, but the effect is more accurate. In this

paper, the DL-M method eliminated the duration of useless feature point matching and 3D coordinate calculation and utilized a fast image processing method to increase the accuracy of effective feature extraction for the auxiliary ring. In this paper, an image with a resolution of 1280 * 720 was used to compare three visual matching algorithms, and the results are shown in Table 4.

Based on the aforementioned experiments, it can be seen that the DL-M method designed to detect the temporal bone in cochlear implant surgery using the auxiliary ring as the temporal bone marker in this paper can quickly and accurately detect the auxiliary ring, extract the features, solve the relative pose information, and then calculate the temporal bone pose. It reduces the duration spent on temporal bone localization while the cochlear implant robot drills, and the average detection and calculation efficiency is about 25FPS, which is a great improvement over traditional medical image navigation systems and binocular matching algorithms. The average attitude measurement accuracy is

TABLE 4: Comparison of method effects.

Method	Duration (ms)	Matching effect
BM	41	Poor
SGBM	305	Better
DL-M	40	Best

about $\pm 0.6^\circ$. The high frequency detection ability can further compensate for measurement errors and meet the requirements for the real-time acquisition of temporal bone postures in cochlear implant drilling surgery.

6. Conclusions

Combined with target detection, image processing, and binocular vision, this paper proposes a fast and real-time detection and calculation method for temporal bone marker localization in cochlear implant robot drilling surgery. The detection rate for auxiliary ring features is about 97%, and the overall detection and calculation time is about 40 ms. The average attitude measurement accuracy is $\pm 0.63^\circ$. The position and attitude information of the auxiliary ring can be obtained quickly, and the rapid calculation for the auxiliary ring position and pose can reduce the time of temporal bone visual positioning in cochlear implant drilling operations, greatly improving the robot's capabilities to extract visual information during the operation, which has a better auxiliary role for future research and applications of cochlear implant drilling operation. Since the accuracy of visual positioning is closely related to the binocular camera itself, the positioning accuracy of this method is still very limited. The accuracy of measurement may not yet fully meet the requirements of surgical positioning. The accuracy of the detection calculation is limited by camera performance, and the future research direction is to improve the accuracy of target detection and visual measurement, and our team will continue to conduct in-depth research in this direction. With the improvements in binocular vision technology and camera performance, this method will also make the research results more robust, and the use of this method will also obtain higher measurement accuracy, which our team will investigate here next.

The rapid development of computer software and hardware, network technology, and various Internet platforms has brought mankind into a new era. In recent years, “virtual reality” can be regarded as a huge hot spot, whether in the field of industry, education, or research. At present, although the heat has subsided a little, the technical teams involved in various fields are also working collectively to continuously innovate. Based on the mixed teaching mode of English education, this article conducts in-depth research on deep learning and virtual reality technology, integrates deep learning and virtual reality learning environment, and builds a learning model of English education learning environment based on virtual reality. The teaching design of the course aims to fully combine the main content of deep learning with the virtual reality environment. Through experimental research, it is explored whether the learning environment based on virtual reality can promote deep learning. The relevant data of the experimental class and the control class are collected through questionnaires, starting from the four dimensions of motivation dimension, investment dimension, strategy dimension, and result dimension, and conduct a comparative analysis, and use the auxiliary interview method to understand the experience of students and teachers on virtual reality equipment and put forward relevant suggestions.

1. Introduction

With the continuous development of society and the continuous integration of education and information technology, the country's education informatization has also ushered in rapid development. The continuous popularization of the Internet, virtual technology, cloud computing, etc. provides education with an interactive and cooperative teaching environment of “Internet +.” The rapid development of these technologies will promote the development of education and teaching, and change the demand for talents and the form of education. Among them, the rise and development of virtual reality (VR) technology will have an increasingly important impact on future education forms. As a new technology applied to the field of education, virtual reality has gradually become a brand-new educational method to help teachers teach and promote the development

of education, enriching the dimension of education from the aspects of the learning process and results. Different from the traditional teaching mode and teaching environment where the teachers of traditional education stand on the podium, Internet technology and virtual reality technology are fully utilized, so that the teaching mode and students' learning environment have undergone great changes, and they can intuitively feel the real and specific. This kind of learning environment relieves the pressure on schools and learner resources, can help students become participants in the learning environment, knowledge is more easily accepted and recognized by students, and promotes students' enthusiasm for learning. The continuous improvement of learning enthusiasm can make students' thinking continue to expand, and also can make students' interest in learning continue to improve, which has a very important positive effect on students' learning efficiency. It can be seen that the

in-depth application of virtual reality technology in education and teaching and the exploration of innovative education and teaching models are highly valued by the country, and the application of virtual reality in education has also become one of the main directions of virtual reality research and development. Its application will inject new vitality into traditional teaching. In the era of an increasingly informatized and globalized knowledge economy, learners are faced with complex and diverse social and learning environments. Based on this, American scholars and all walks of life have launched “deep learning” activities to help students be able to have a comprehensive understanding of people’s daily life, daily work, and university life in the future. In order to achieve the goal of deep learning, teachers should adopt new and effective teaching modes and teaching strategies, so that students are not limited to shallow understanding, but stay at the shallow learning level. Students build new knowledge on the basis of existing knowledge and experience and transfer it to new situations, so as to achieve deep learning. The immersion, interactivity, and conception of virtual reality technology provide technical support for deep learning. It can not only create and reproduce the existing scenarios in reality but also create and conceive scenarios that cannot be experimented with or not in reality, which helps to effectively enhance the state of students’ deep learning. Therefore, the deep learning and virtual reality learning environment integrate, build a learning model of English education blended teaching based on the virtual reality learning environment, and carry out teaching design according to the learning model and related courses, aiming to fully combine the main content of deep learning and virtual reality environment, so that students can learn more. The state of learning has been effectively improved, and the students’ learning efficiency has been continuously improved [1–10].

2. Related Works

With the continuous change of VR technology, virtual reality has been widely used in medicine, education, film and television, and other fields and in the educational application of virtual reality technology. The earliest country to apply virtual reality technology in education is the United States, where it is widely used in military teaching. The research and application of VR technology in the United Kingdom is the most advanced country among all European countries; at the same time, the University of Nottingham has achieved excellent results in the application of virtual reality technology in the field of education. VR technology is used in the field of education to help students with physical disabilities and learning difficulties to further improve their learning efficiency. In virtual reality, learners interact with the learning environment according to the specific object content. This interaction is immediate, and the virtual environment can react in real-time based on the learner’s behavior, for example, providing language input to learners in a targeted manner. The combination of virtual technology and education can also improve student outcomes. Research has found that students in VR English teaching classes get higher grades

than other students, and VR also helps with memory retention. EdTech reports on a recent study that showed a nearly 9% increase in memory retention for students who learned in a VR immersive environment. Virtual reality technology has a wealth of practical experience in the field of education. However, there are obvious limitations in the application of virtual reality technology in today’s education field. Deep learning makes virtual reality education more rigorous. Using new software and hardware equipment and combining intelligent learning environments for deep learning can better promote students’ self-learning and lifelong learning. Learning, thus cultivating new talents to adapt to the development of the times. The application of virtual reality education not only provides unique advantages for learners in the learning environment, interactive environment, and experimental environment but also requires strengthening and improving the self-awareness and initiative of learners in autonomous learning, which is in line with the established goals of deep learning at all stages. Immersion, interactive functions, and conception in the virtual reality environment provide support for deep learning. Deep learning is a situation-based learning method. If knowledge cannot be applied to new and real situations to solve problems, only superficial understanding, mechanical memory, and simple copying, then this kind of learning will still remain on a shallow learning level. This research will be based on virtual reality technology combined with English education mixed teaching courseware, allowing students to experience English learning in virtual scenes, so as to carry out in-depth learning. In the process of English mixed teaching practice, virtual reality technology can provide the interaction of real role models and dialogue scenes [11–15].

3. Related Theories and Technical Methods

3.1. Virtual Reality Technology

3.1.1. Virtual Reality System. Virtual reality is a simulation technology that uses a computer to create a near-real virtual environment that is dynamic, three-dimensional, and fully immersive when the user interacts with it. According to different functions and implementation methods, virtual reality systems can be divided into four categories such as wearable virtual reality systems, desktop virtual reality systems, augmented virtual reality systems, and distributed virtual reality systems. According to the scenario materials and suggestions in the learning activities in the English teaching curriculum standards, combined with the results of the school’s pre-investigation, the virtual reality system in this study is planned to use a wearable virtual reality system. Due to the uneven situation of VR hardware in schools at this stage, the selection of the type of virtual reality system will be based on the VR teaching resources and hardware status of the selected high schools’ virtual reality system. Wearable virtual reality systems are also known as “immersive virtual reality systems.” Users enter a virtual environment with hardware devices such as virtual reality glasses and digital helmets and then interact with the virtual environment through sensing devices such as data gloves (Figure 1) [16].

FIGURE 1: Selected school virtual reality device.

3.1.2. VR Teaching Resources. English teaching resources refer to many materials and conditions that can be used by teachers in all aspects of English teaching, including English course textbooks, English teaching cases, relevant English video pictures, PPT English teaching courseware, as well as teachers' resources, teaching aids, and teaching infrastructure such as desks. In a broad sense, English teaching resources can refer to all elements used by teachers in the process of English teaching, including people, money, materials, and information that support and serve teaching; in a narrow sense, English teaching resources (learning resources) mainly include teaching materials, teaching environment, and teaching support system. The VR English teaching resources in this study belong to the narrow English teaching resources in the broad and narrow sense, including (1) VR hardware equipment: wearable complete sets of virtual reality glasses for English teaching, virtual reality all-in-one machine. (2) VR software resources: virtual reality software resources that are matched with equipment, related to courses, and developed maturely. (3) VR supporting classrooms: VR supporting classrooms that can properly store and easily access VR-related hardware equipment, have enough space for students to interact and explore independently with the virtual environment, and have an interactive learning space design.

3.2. Deep Learning Theory. According to the subject core literacy and course objectives of the English blended teaching course, carefully analyze the English textbooks used, collect data on virtual reality and deep learning, and draw lessons from the famous teaching reform experts LeAnn Nickelsen and Eric Jensen in their works. Based on the study of learning, a detailed process system is constructed, and based on each link of the model, a complete deep learning process is formed (Figure 2) [17].

Based on the theoretical framework of deep learning, this research constructs a deep learning model based on a virtual reality environment (Figure 3).

Analyze the current students' understanding of virtual reality, based on the deep learning model, combine virtual reality and English courses, follow the basic principles of

teaching design, and construct a virtual reality environment-based English mixed teaching curriculum design framework (Figure 4) [18–20].

4. Research Design and Result Analysis of Mixed Deep Learning in English Education Based on Virtual Reality Environment

4.1. Experimental Design

4.1.1. Experimental Theme. Through the case of a VR educational game called “In Order To Dr.,” an experimental class and a control class were set up, and the traditional teaching methods and the teaching methods with the help of VR educational games were used to conduct comparative experimental teaching in the English mixed teaching classroom. Taking Unit 1: Where did you go on vacation? For the experimental class in the first week as an example, the teaching objectives are drawn up, as shown in Table 1 [21].

4.1.2. Experimental Variable. Independent variable: whether to adopt the English blended teaching-learning mode based on a virtual reality environment.

Dependent variable: whether it helps to promote deep learning, that is, whether it has achieved the promotion of problem-solving ability, communication, active cooperation, knowledge processing level, and reflective evaluation level.

Irrelevant variables: students' initial cognition, operational level, mastery of basic knowledge, and grades in English class.

Number of students, teachers, English teaching content, study hours, etc.

4.1.3. Experimental Hypothesis. In view of the existing problems in the current English mixed teaching and the current teaching practice research of virtual reality, the design and construction.

The deep learning teaching mode of the English blended teaching course is based on the virtual reality environment,

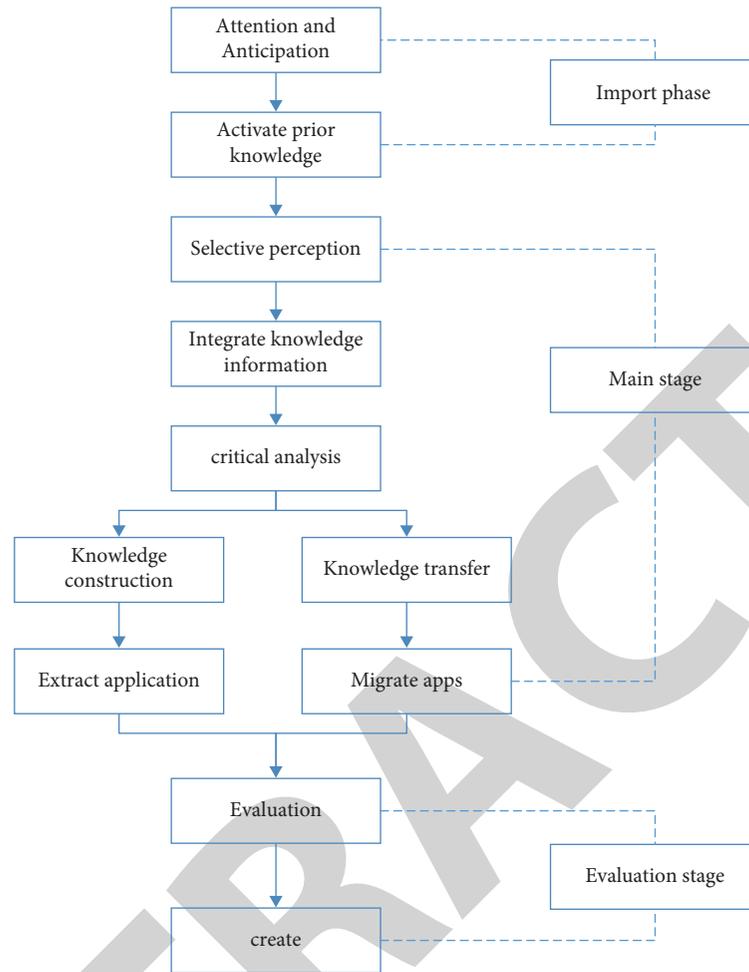

FIGURE 2: The deep learning process.

and the experimental research on the effectiveness of this teaching mode. The experimental hypotheses proposed in this experimental study are as follows:

Hypothesis 1. the level of deep learning in the English learning environment based on virtual reality is significantly improved compared with the control class in the traditional teaching environment.

Hypothesis 2. the motivation level in the English learning environment based on virtual reality is significantly improved compared with the control class in the traditional teaching environment.

Hypothesis 3. the problem-solving ability in the English learning environment based on virtual reality is significantly improved compared with the control class in the traditional teaching environment.

Hypothesis 4. the ability of communication, communication, and cooperation in the English learning environment based on virtual reality is significantly improved compared with the control class in the traditional teaching environment.

Hypothesis 5. the knowledge processing level in the English learning environment based on virtual reality is significantly improved compared with the control class in the traditional teaching environment.

Hypothesis 6. the level of reflective evaluation in the English learning environment based on virtual reality is significantly improved compared with the control class in the traditional teaching environment.

4.1.4. Experiment Process. According to the specific content of the research topic and the actual situation, the specific process designed in this article is shown in Figure 5.

4.2. Matching of VR Teaching Resources. Learn about school VR equipment availability. The classroom is a smart classroom that integrates modern educational technologies such as smart blackboards, smart tablets, smart recording and broadcasting, and VR teaching equipment. In order to promote students' communication and discussion, the desks are set up with closed polygons, and the classroom setting conforms to the characteristics of the teaching mode designed in this study, which is mainly based on

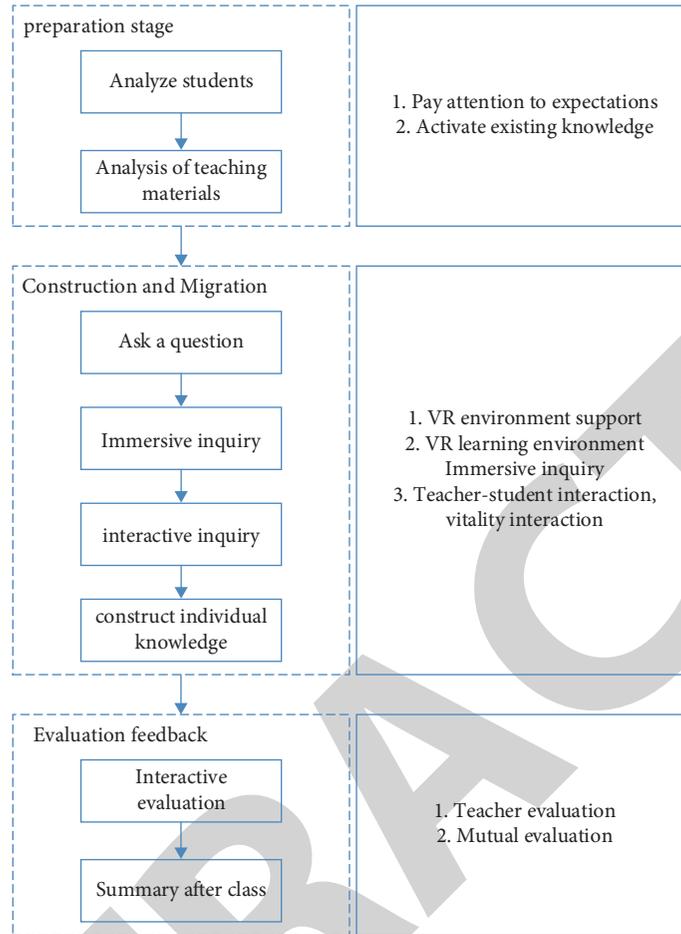

FIGURE 3: Deep learning model based on virtual reality environment.

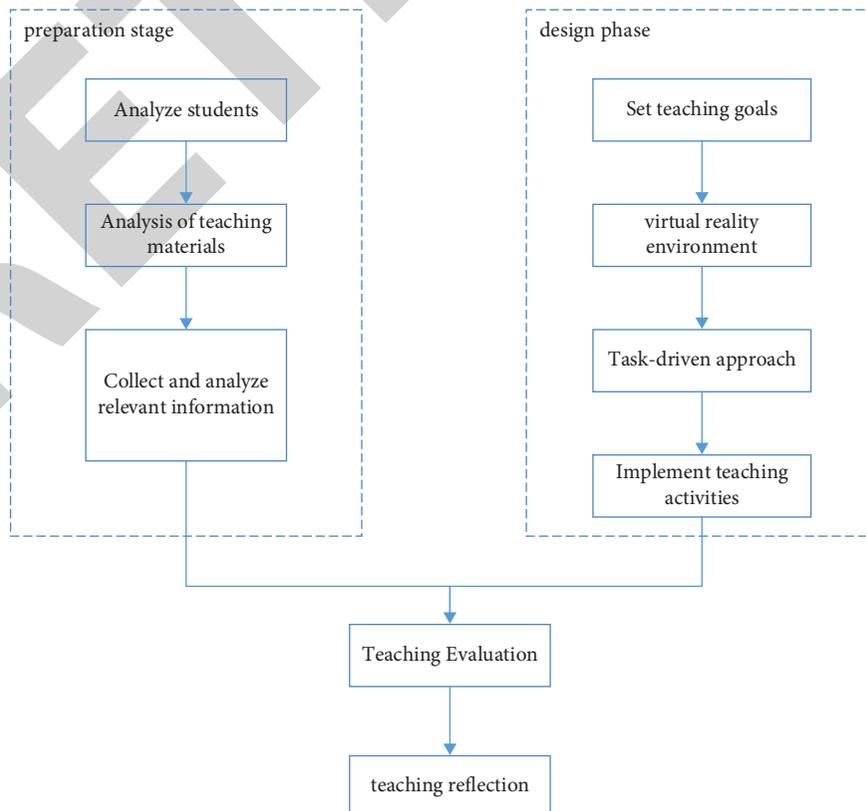

FIGURE 4: Instructional design framework.

TABLE 1: English teaching objectives.

Teaching objectives	<p>1. Knowledge and skills: understand the meaning and usage rules of indefinite pronouns, learn to use Where and How to ask questions in English activity conversations, and learn to use Did to ask questions about what happened in the past. Master the following words: wonderful, most, something, nothing, of course, everyone, myself, yourself, anyone, anywhere. Master the following sentence patterns: a. Where did you go on vacation?—I went to the mountains. b. Where did Tina go on vacation?—he went to the beach. c. Did you go with anyone?—Yes, I did./No, I didn't.</p> <p>2. Process and method: the teacher's demonstration and the VR educational game explain the use of the context in the simple past tense. Conduct group inquiry learning to complete the contextual use of the simple past tense in VR educational games. Use special interrogative sentences in the simple past tense, general interrogative sentences, and their affirmative and negative answers.</p> <p>3. Emotional attitudes and values: feel the convenience of past tense in English expression, and improve the ability to use information technology to solve problems in real contexts. In the process of learning with VR educational games, cultivate a rigorous and realistic learning attitude.</p>
Difficulties in teaching	Past tense in the correct context, the use of reflexive pronouns such as yourself, myself, and the use of the indefinite pronoun something, anything, someone, anyone, and other words.

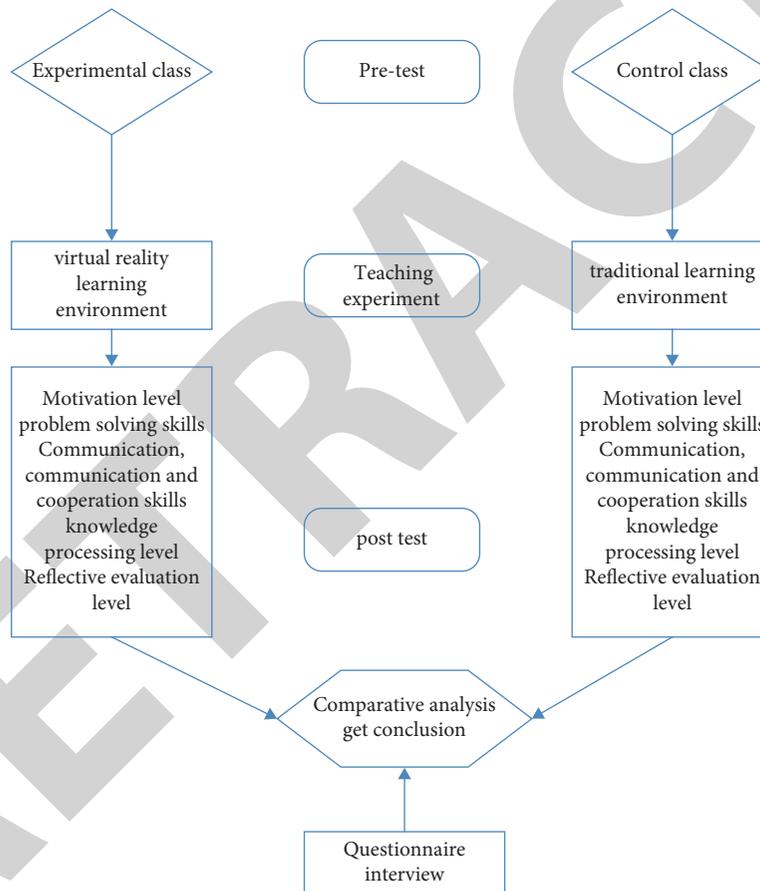

FIGURE 5: Experimental process design.

independent inquiry and cooperative inquiry. High school B sets up the VR teaching equipment in an independent VR classroom. As shown in Figure 6, the desks of the students in this classroom are set in rectangles, and the teachers have no other educational information equipment except VR equipment.

VR Science Corner is the first VR Science Corner in China that truly combines VR technology with science education. It aims at popular science knowledge points; uses virtual reality technology and virtual reality equipment; is based on high-quality VR science resources; breaks the

traditional form of science education courses. Time provides immersive science knowledge learning and experience in order to realize various personalized teaching methods such as independent learning and inquiry-based learning, and enhance students' interest in learning. As shown in Figure 7.

However, each VR classroom is equipped with only one VR all-in-one machine, which is difficult for classroom teaching. Therefore, in the English classroom, another VR equipment for English classroom teaching is set up. VR/AR education brand Class VR product, its initial interface is shown in Figure 8.

FIGURE 6: VR classroom.

FIGURE 7: Placement of VR all-in-one.

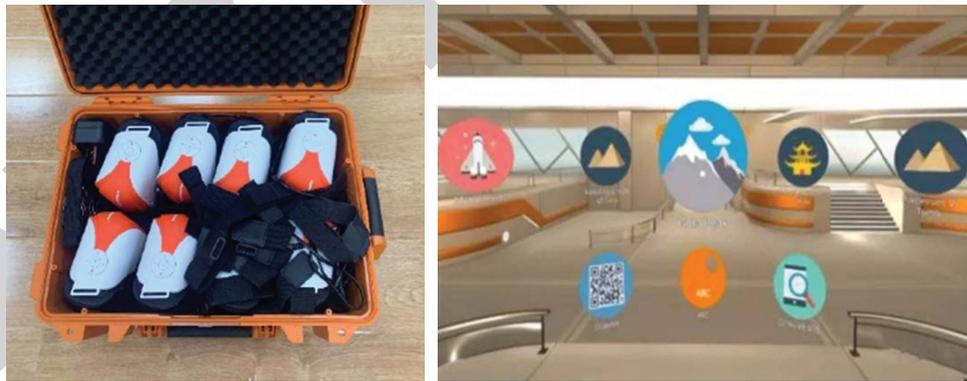

FIGURE 8: Class VR and initial interface.

4.3. Teaching Objective Design. To promote deep learning of English education blended teaching. Through the implementation of a virtual reality-based teaching model designed to promote deep learning in English education blended teaching courses, through quasi-experimental research, to explore whether the virtual reality learning environment can help promote students' deep learning.

4.3.1. Design of Teaching Activities. Teaching activities to promote students' in-depth learning means that students, under the guidance of teachers, carry out constructive

activities based on existing knowledge, solve problems in different situations through experiments, analysis, summarization, etc., and finally form higher order thinking and complete shallow learning. The design of activities to promote deep learning mainly includes the form of activities, the selection of teaching resources, and the methods of implementing activities. These designs need to be closely combined with the in-depth learning objectives determined in the design of teaching objectives, especially the activities necessary for driving questions and content questions determined according to the objectives, to ensure the development of students' core literacy of English subjects and the

construction of self-knowledge systems, so as to promote high-level learning. The formation of order thinking.

At present, students' lack of initiative in learning English and lack of enthusiasm for learning are actually related to the current "dead" classroom. How to make the classroom really live, it is definitely necessary to design a variety of activities. The rational use of VR teaching resources is the key to changing this situation. Therefore, important activities that require teacher guidance should be given sufficient time for students to prepare in the classroom, and secondary students or activities that students are expected to be capable of should be completed after class. The purpose of deep learning includes the acquisition of disciplinary thinking methods, the cultivation of higher order thinking, etc., all of which require students to truly carry out activities independently, which cannot be achieved by teachers' elaboration alone. Of course, to ensure the quality of the activity, it is necessary to integrate various factors, such as whether the activity design is in line with the goals of deep learning; whether the students are given enough time; whether the students have enough opportunities to experience; the activity design of each link; and whether it is organically combined and matched with the purpose. Therefore, the teaching mode in this study requires teachers to design a study guide program for students to use in the course content in the teaching process. The purpose is to gradually guide students to achieve in-depth learning in the stages of autonomous exploration of VR experience and group discussion and cooperative exploration. Make students enter the virtual environment with questions to explore, and take part in group discussion and exploration with tasks.

4.3.2. Teaching Evaluation Design. In fact, most learners cannot complete deep learning the first time, and most people can only complete simple learning, that is, the "knowledge" level. The completion of deep learning requires continuous evaluation and feedback. It can be said that without evaluation and feedback mechanisms, it is almost impossible for learners to learn abstract and complex cognitive skills. Many studies have shown that evaluation can promote the improvement of course performance, promote learners to consolidate and internalize information, and is conducive to the path to understanding, comprehension, synthesis, evaluation, higher order thinking, and deep learning. Provide continuous evaluation to students so that as students engage in learning activities, they can continue to see, hear, and experience the results of their efforts.

4.4. Experimental Results and Analysis. By randomly distributing questionnaires to other students, the purpose is to ensure the rigor and rationality of the questionnaires, and the reliability and validity of the recovered effective questionnaires are tested using SPSS 23.0. This questionnaire sets the current situation of students' deep learning into four dimensions: motivation dimension, investment dimension, strategy dimension, and outcome dimension, which are mainly reflected in the level of reflection and evaluation, knowledge processing level, active cooperation ability,

communication ability, problem-solving ability, and motivation. Basic information such as level mainly includes the following types of questions and the details are given in Tables 2 and 3.

4.4.1. Questionnaire Reliability and Validity Analysis. The Cronbach's alpha coefficient of the posttest questionnaire dimension is 0.929, which is greater than 0.8, indicating that this questionnaire has very high consistency and the design content of this questionnaire is reasonable.

The KMO value of the posttest questionnaire is 0.717, which is greater than 0.6, indicating that the questionnaire has good validity and is suitable for exploratory primer analysis; the significance of Bartlett's spherical test value is less than 0.05, reaching a significant level, indicating that the questionnaire contains items suitable for performing factor analysis.

4.4.2. Group Statistics

(1) Dimensional analysis. From the analysis in Table 4, we can see that from the perspective of motivation, the averages of the experimental class and the control class are 4.8308 and 4.2923, respectively, with a difference of 0.5385; from the perspective of investment, the averages of the experimental class and the control class are 4.7322 and 4.1994, respectively, with a difference of 0.5385. 0.5328; from the perspective of the strategy dimension, the averages of the experimental class and the control class are 4.7590 and 4.3949, respectively, with a difference of 0.3641; from the perspective of the result dimension, the averages of the experimental class and the control class are 4.7885 and 4.3590, respectively, with a difference of 0.4295; thus it can be seen that the mean value of each dimension of the experimental class is greater than the mean value of each dimension of the control class.

(2) Ability level analysis. From the analysis in Table 5, it can be seen that from the perspective of motivation level, the mean of the experimental class is 4.8376, and the mean of the control class is 4.8376.

The average value of the experimental class is 4.2735, a difference of 0.5641; from the perspective of problem-solving ability, the average value of the experimental class is 4.7650, and the average value of the control class is 4.4017, a difference of 0.3633; from the perspective of communication, communication, and cooperation ability, the average value of the experimental class is 4.7564, and the average value of the control class is 4.7564. The average value of the experimental class is 4.3419, a difference of 0.4145; from the perspective of knowledge processing level, the average value of the experimental class is 4.7607, and the average value of the control class is 4.2393, a difference of 0.5214; from the perspective of reflection evaluation level, the average value of the experimental class is 4.7404, and the average value of the control class is 4.7404. It is 4.3173, with a difference of 0.4231; it can be seen that the mean value of each dimension

TABLE 2: The distribution of deep learning according to dimension question type.

Dimension	Number of questions	Question number

	Control class	39	4.2393	0.46641	0.07469
Reflective evaluation level	Experimental class	39	4.7404	0.39982	0.06402
	Control class	39	4.3173	0.44040	0.07052

of the experimental class is greater than the mean value of each dimension of the control class.

(3) *Independent sample t-test.* An independent sample *t*-test was performed on the data of the survey results using SPSS data statistical analysis software. The analysis of the results is carried out from four dimensions (motivation dimension, investment dimension, strategy dimension, and outcome dimension). From Table 6, we can see that the independent sample *t*-test results of the motivation dimension of the experimental class and the control class show that there are significant differences between the two teaching environments ($t = 7.389, p < 0.001$), the motivation dimension of students based on virtual reality learning environment is significantly higher than that of students based on traditional teaching form; the independent

sample *t*-test results of the input dimension of experimental class and control class show that the two teaching environments exist significant difference ($t = 6.479, p < 0.001$), students based on virtual reality learning environment have significantly higher input dimension than students based on traditional teaching form; independent sample *t*-test results of strategy dimension of experimental class and control class show that the two. There is a significant difference in the teaching environment ($t = 4.193, p < 0.001$), and the students' strategy dimension based on the virtual reality learning environment are significantly higher than that of the students based on the traditional teaching form; the independent sample *t*-test results of the experimental class and the control class's outcome dimension. It shows that there is a significant difference between the two teaching environments ($t = 5.033,$

TABLE 6: Sample t -test in four dimensions of posttest.

	t	Degrees of freedom	Significance (two-tailed)	Mean difference	Standard error
Motivation dimension	7.389	63.664	p	0.53846	0.07288
Input dimension	6.479	76	p	0.53276	0.08223
Policy dimension	4.193	76	p	0.36410	0.08683
Outcome dimension	5.033	76	p	0.42949	0.08683

TABLE 7: Independent sample t -test for posttesting five ability levels.

	t	Degrees of freedom	Significance (two-tailed)	Mean difference	Standard error
Motivation level	8.081	70.303	p	0.56410	0.06980
Problem-solving skills	4.405	68.954	p	0.36325	0.08247
Communication, communication, and cooperation skills	5.373	76	p	0.41453	0.07715
Knowledge processing level	5.799	66.395	p	0.52137	0.08990
Reflective evaluation level	4.442	76	p	0.42308	0.09525

$p < 0.001$), and the outcome dimension of students based on the virtual reality learning environment is significantly higher than that of students based on the traditional teaching form. The experimental results show that there are significant differences in the four dimensions of the experimental class and the control class, and the experimental class is significantly higher than the control class in the four dimensions of motivation, investment, strategy, and results.

Use SPSS data statistical analysis software to conduct an independent sample t -test on the data of the survey results. From the analysis in Table 7, it can be seen that the independent sample t -test results of the motivation level of the experimental class and the control class show that there are significant differences between the two teaching environments ($t = 8.081$, $p < 0.001$), the motivation level of students based on virtual reality learning environment is significantly higher than that of students based on traditional teaching form; the independent sample t -test results of the problem-solving ability of experimental class and control class show that there are significant differences between the two teaching environments ($t = 4.405$, $p < 0.001$), the problem-solving ability of the students based on the virtual reality learning environment was significantly higher than that of the students based on the traditional teaching form; There is a significant difference between the two teaching environments ($t = 5.373$, $p < 0.001$). The students' communication, communication, and cooperation abilities based on the virtual reality learning environment are significantly higher than those based on the traditional teaching form. The independent sample t -test results show that there is a significant difference between the two teaching environments ($t = 5.799$, $p < 0.001$), and the knowledge processing level of students based on the virtual reality learning environment is significantly higher than that of students based on traditional teaching form. The independent sample t -test results of the reflective evaluation level showed that there was a significant difference between the two teaching environments ($t = 4.442$, $p < 0.001$), and the reflective evaluation level of students based on the virtual reality learning environment was significantly higher than that of students based on traditional teaching form.

5. Conclusion

In the information society, the progress of science and technology is reflected in all aspects, and high technology and new technology are constantly integrated into us.

The integration of modern technology into education and teaching can better improve the quality of teaching. As a modern technology, virtual reality technology, its interactive and immersive characteristics can make users feel immersive and inject into education. New vitality, the combination of virtual reality technology and education will create a different spark, which will also help deep learning.

In this study, the teaching application of virtual reality, the research level of deep learning and the two learning theory, embodied cognitive learning theory, and situational cognitive learning theory, an instructional design based on virtual reality to promote students' deep learning is constructed and applied in the actual English class, observe students' performance through teaching experiments, collect questionnaires and analyze data by distributing questionnaires after teaching is completed, and find that the learning environment based on virtual lines is conducive to the improvement of students' in-depth learning, whether it is classroom discipline or group discussion, The overall engagement of the students in the experimental class is significantly higher than that of the students in the control class. Based on the analysis results of the four dimensions of motivation, engagement, strategy, and outcome of the deep learning questionnaire, the experimental class has a higher level of engagement in each dimension. The performance level is higher than that of the control class, which provides a new idea for promoting the deep learning of English courses.

Virtual reality provides a new teaching environment for teaching. Virtual reality technology needs to be skillfully combined with the teaching mode, which subverts the traditional teaching environment and provides a more effective way for the realization of deep learning. Due to the limitations of the research, this research is only at the initial stage of related research, and future research can add experimental measurement methods, collect, and use a variety of data, such as comprehensive analysis through eye trackers,

With the growing development of the era of big data, data acquisition and analysis have become hot spots, and Python-based crawler technology is one of the most widely used tools in data analysis work at present. In this paper, we apply Python crawler key technology to acquire data of movie list and hot movies on Cat's Eye movie network, analyze data based on Python development environment Spyder, use the Numpy system to store and process large data, Chinese Jieba word separation tool to crawl data for word separation text processing, SnowNLP library to process text sentiment, and finally by the word cloud map and web dynamic map display information such as viewers' emotional tendency and movie rating statistics, and provide decision support for users' movie viewing.

1. Introduction

With the rapid development of web technology, the amount of web information is also growing rapidly [1, 2]. In order to better meet the personalized needs of users, various recommendation systems have emerged, which automatically establish the connection between users and information by studying their interest and preferences, thus helping users to discover their potential needs from the huge amount of information. Python is an open source, free, cross-platform interpreted high-level dynamic programming language, and its powerful functions and simplicity make it the preferred language for Internet application development.

Scholars at home and abroad have also made many contributions to the research of film rating prediction. Karl Persson collected the attribute and feature information of 3,376 Hollywood movies from the IMDB website and constructed a random forest model and a support vector machine model to predict the movie ratings. Liu Changming proposed a hybrid prediction model of movie scoring based on the machine learning algorithm and movie features and

predicted movies on Douban [3, 4]. Lu Junzhi (Spark Mllib machine learning framework, 2018) built a movie score prediction model through the random forest regression algorithm, with good results. In general, domestic and foreign scholars have studied the prediction of films, but the prediction of foreign film is more mature, and there is still room for improvement in domestic research on film prediction models.

In this paper, the movie data are obtained from Douban website, and a total of 91,368 movie records are crawled for movie ratings, number of ratings, number of stars, genres and tags, etc [5, 6]. The data are analyzed based on Python's integrated development environment, using Numpy for storing and processing data, pandas for data analysis, and matplotlib, and this data analysis project is mainly composed of three parts: production and quality analysis of the movie industry, analysis of Douban rating factors, and prediction of rating models, which can be used to intuitively grasp movie-viewing orientation and quickly find preferred high-quality movies through data visualization.

2. Python-Based Movie Data Acquisition

2.1. Introduction to Python. Python is a high-level combination of interpreted, compiled, interactive, and object-oriented scripting language that is powerful, syntactically simple, and easy to maintain. It is a great language for beginners because of its highly readable design, its more distinctive syntax than other languages, and its support for a wide range of applications [7, 8].

2.2. Movie Ranking Acquisition Techniques. For the movie ranking acquisition, we mainly use the `re` module and the request the HTTP client library to get the data of the Hot 100, Most Anticipated, Domestic Box Office, North American Box Office, and Top 100 lists. We use the browser to login to the CatEye movie page, view the html body data of the page, analyze the html structure of the page, extract the URL information using regular expressions, and then collect the data in the next step. The key code is as follows:

```
def getOnePage(url)
    response = requests.get(url, headers = header)
    if response.status_code == 200:
        allTop = re.findall("<dd>. *?board-index-(\d+). *?
        title = \"(. *?)\". *?/p>. *? </dd>\"", response.text, re.S)
        return allTop, response.text
```

2.3. Movie Data Fetching Techniques. The movie data acquisition mainly uses requests HTTP client library, json package, random library, csv function package, datetime module, and re module. re module and requests library and random library are mainly used to crawl data, json package is used to convert the acquired data format to json format, datetime module the csv function package is used to store the data [9, 10]. The User-agent proxy mechanism is used to represent the requester's information, the User-agent can be collected and saved, and the User-agent can be dynamically changed during the crawling process to prevent the data from being terminated due to frequent acquisition. In this paper, the movie "Spirited Away" is selected for analysis according to the hot word-of-mouth list, and finally, 13318 records are obtained for visualization using Python crawler technology.

3. Acquisition of Douban Top 250 Movie Data

3.1. Introduction of Concepts Related to Douban Top 250 Movie List. Douban is a sharing and review community website that provides users with information about books, movies, music, and others. Douban.com is a community website that provides users with information about books, movies, music, and other works, with descriptions and comments provided by users, and is one of the most unique Web 2.0 websites [11, 12]. As an important part of Douban.com, Douban Movies provides users with movie-related information, such as descriptions, schedules, ticket prices, and reviews of currently released movies. The Top 250 movie list is based on the number of people

who have seen each movie and the reviews it has received and represents the movie preferences of the majority of users.

3.2. Data Acquisition and Cleaning. In this paper, we choose Octopus collector to crawl the information of Douban Top 250 movie list and enter the URL of Douban Top 250 movie "https://movie.douban.com/top250" on the home page to enter the interface of the collection process [13, 14]. The total number of information crawled was 250, and 20 fields were obtained after data cleaning with the Pandas library in Python, namely, movie name, score, number of ratings (num), number of five-star ratings (star5), number of four-star ratings (star4), number of three-star ratings (star3), number of two-star ratings (star2), and number of one-star ratings (star1). (star1), short reviews (short), director (director), writer (writer), actor1, actor2, actor3, type1, type2, region of production (region), year of release (year), month of release (month). year, month, and time.

4. Exploratory Analysis of Douban Top 250 Movies

4.1. Number of Movies in Each Region. The origins of Douban Top 250 movies are divided into UK, USA, Italy, France, Korea, Japan, and China, as shown in Figure 1. Since the number of movies from the remaining regions is small, it is not shown in this paper. In the Douban Top 250 movie list, there are 114 American movies, accounting for 45.6% of the overall total. This is followed by a total of 41 Chinese movies, including 16 movies from Mainland China, 19 movies from Hong Kong, and 6 movies from Taiwan. In addition, there were 32 Japanese films, 17 British films, and 10 Korean films [15, 16]. It can be seen that Western countries have some influence on Chinese film culture. Since most of the users of Douban are young people, the reason why American movies are highly rated by young people is inseparable from their movie culture and dissemination. In addition, further analysis of Japanese movies shows that most of the movies are anime, which is an important part of Japanese soft culture and reflects the preference of young people for anime culture.

4.2. The Overall Distribution of Movie Ratings. Because the list of Top 250 movies is selected, the ratings of movies are relatively high, concentrated in the range of 8~10, and the number of movies with each score is shown in Figure 2.

As we can see from Figure 2, the lowest rating among the movies crawled is 8.3 and the highest is 9.7.93.2% of the movies which are rated 8.5~9.3, and most of them are rated 8.5 and above, indicating that the quality of these movies is relatively high. In addition, there are very few movies with high ratings, which shows that audiences have different preferences for movies, and movies that seem to be highly rated by some people are not liked by all [17, 18].

4.3. Analysis of Movie Genres. In order to better understand the movie genres that viewers pay attention to, we first use the wordcloud word generation library in Python to create a word cloud map of Douban Top 250 movie genres.

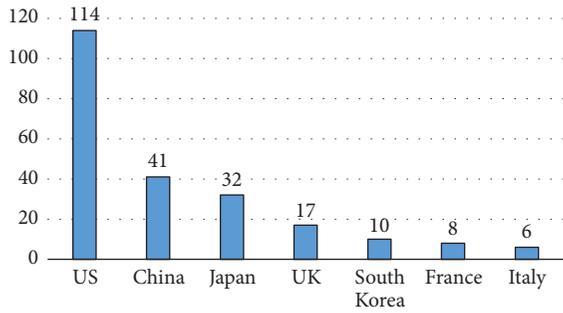

FIGURE 1: Number of movies in each region.

The movies with the highest frequency in the list are romance movies. This is followed by comedy, suspense, family, and drama movies, and song and dance movies appear very infrequently [19, 20]. After further statistical analysis, the movie genres in the Douban Top 250 movie list are mainly divided into 20 types, such as romance, comedy, suspense, family, drama, action, and crime. According to the classification and number of movies, the movie genres with more than 10 movies were selected for the analysis of the number of movies and rating averages, as shown in Figure 3.

As can be seen from Figure 3, there are ten categories of movies with a number of movies greater than 10. The most movies are in the romance category, with 42 movies in total. The next category is comedy, with 32 movies. There are 22 suspense movies, 19 family movies, 19 drama movies, and 16 action and crime movies. The number of movies in the fantasy, animation, science fiction, and thriller categories is relatively small, but all of them have more than 10. In addition, the average rating of most types of movies is around 8.9 points. The highest is drama movies with an average rating of 9.07, and the lowest is thriller movies with an average rating of 8.75.

5. Python-Based Visual Analysis of Movie Data

5.1. Sentiment Analysis and Word Cloud Generation. Snow NLP is a class library of Python, which can easily process Chinese text content, call the classification method under sentiment, and score the emotional tendency of the review, between 0 and 1; the more positive emotional tendency corresponds to a higher score, as shown in Figure 4. We can find that the user reviews of the movie “Spirited Away” are mostly positive tendency words, which means the movie has more positive comments.

Using the lexicon-based sentiment analysis method, the text is borrowed and analyzed through the sentiment dictionary and rules, and the sentiment value is calculated by traversing the sentiment words, degree words, negation words, matching words, and exclamation words, and finally, the sentiment value is used as the basis for the sentiment tendency of the text [21–23]. The specific operation process is “text preprocessing, text word splitting—exact pattern word splitting, customizing common word removal database, removing individual words, doing

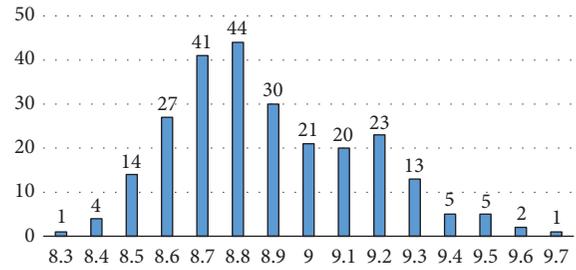

FIGURE 2: Number of movies for each score.

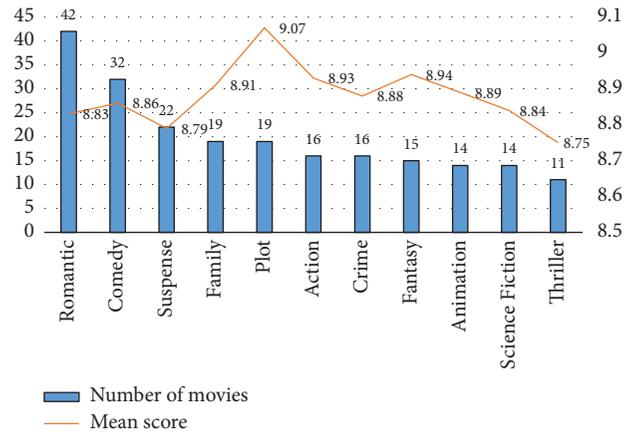

FIGURE 3: Number of movies for each score.

word frequency statistics on word splitting, getting the top 100 most frequent words, reading positive and negative word database, counting positive words and negative words, and drawing word cloud.” Through the word cloud chart, we found that the overall feeling of the audience for the film is good and classic, and we also found that the most watched cities in China are Beijing, Guangzhou, Shenzhen, and Shanghai.

5.2. Movie Star Rating Analysis. The Pie component in the Pyecharts library is imported and used to generate pie charts [24, 25]. Pandas incorporates a large number of libraries and some standard data models, providing the tools needed to manipulate large data sets efficiently, and the movie ratings are grouped and summed using Pandas to derive the percentages, which are finally displayed in the form of dynamic graphs on web pages, as shown in Figure 5.

Three pieces of information are captured according to the html structure: the rating level for each account; the review message for each account; and the http link to jump to the next review page. After acquiring all the information and processing the information, the total number of each star rating and how many accounts in total were rated were calculated [26–28]. Through the results, it can be found that 78.97% of the viewers were five-star positive, and the overall rating of the movie was high and worthy of recommendation. The key code for star rating analysis is as follows.

```
import pandas as pd from pyecharts import Pie #
Import Pie component for generating pie charts.
```

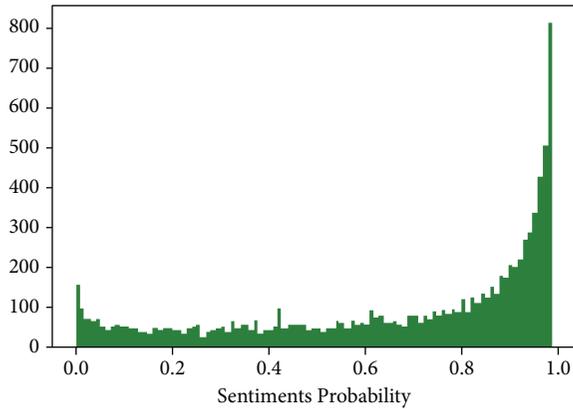

FIGURE 4: Effect diagram of emotion analysis.

```
# pandas.
df = pd.read_csv("D:comments.txt", encoding = "gb18030", names = ["id", "NickName", "userLevel", "cityName", "content", "score", "startTime"])
attr = ["one-star", "two-star", "three-star", "four-star", "five stars"]
score = df.groupby("score").size() # sum by group.
value = [
score.iloc[0] + score.iloc[1] + score.iloc[1],
score.iloc[3] + score.iloc[4],
score.iloc[5] + score.iloc[6],
score.iloc[7] + score.iloc[8],
score.iloc[9] + score.iloc[10],
]
pie = Pie("Spirited Away Star Ratings Ratio,"
title_pos = "left," width = 600)
pie.use_theme("dark")
pie.add("rating," attr, value, center = [40, 50], radius =
[25, 75], rosetype = "raea," is_legend_ show = True,
is_label_show = True)
pie.render("rating-star.html")
```

6. Douban Top 250 Movie Rating Prediction

In this paper, the random forest regression algorithm, regression tree algorithm, and gradient boosting regression algorithm were selected to train and predict the ratings of Douban Top 250 movies. By evaluating the prediction results of the three algorithms, the gradient boosting regression algorithm was selected to predict the ratings of the experimental data [29, 30].

6.1. Introduction of the Algorithms

6.1.1. Random Forest Regression Algorithm. The random forest regression algorithm is a fusion algorithm constructed based on a decision tree classifier, which is composed of multiple decision trees. The algorithm performs multiple sampling from the sample data by sampling with put-back,

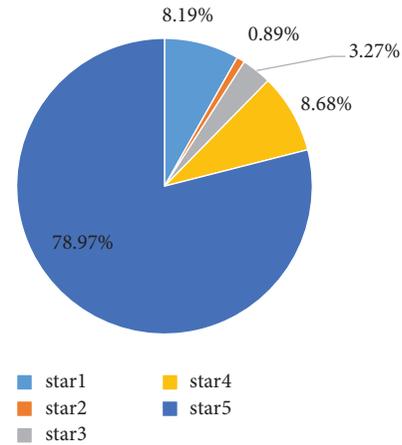

FIGURE 5: Scale diagram of star evaluation.

constructs a corresponding decision tree for each sample subset, then averages or votes on the prediction results of all decision trees, and then selects the optimal prediction result. The advantage of this algorithm is that it is insensitive to the correlation between variables and avoids the effect of multicollinearity [31–33].

6.1.2. Regression Tree Algorithm. The decision tree regression algorithm is a relatively common algorithm for regression and classification, where data are regressed by rules in order to construct a regression tree model. Creating a decision regression tree requires using the values obtained from the observed data to establish a rule for constructing a model in which each characteristic attribute is a variable, and after classifying, a variable according to the rule so that the sum of squared residuals of the two parts is minimized to form a regression tree with good results.

6.1.3. Gradient Boosting Regression Algorithm. The gradient boosting regression algorithm is a representative algorithm in machine learning algorithms, which can be used for regression or classification problems, and the common gradient boosting algorithms include AdaBoost and gradient boosting algorithms. In this paper, the gradient boosting algorithm is used to predict movie ratings, and the principle of the gradient boosting algorithm is to evaluate the reliability of the model using a loss function [34, 35]. According to the established loss function, each iteration of the model will refine the model according to the direction of gradient descent, gradually reducing the value of the model's loss function. The gradient boosting algorithm is based on regression trees for model construction, and the residuals of the previous tree are used as the next learning target, so as to construct new regression trees until the residuals of the model reach the allowed range.

6.2. Model Construction and Result Analysis

6.2.1. Feature Selection and Data Processing. By processing the feature information, this paper selects 9 feature variables

for modeling according to the characteristics of each feature information and referring to related literature, which are score, num, star5, star4, star3, star2, short, time, and year, where score is used as the target variable and the other 8 variables are used as predictor variables [36, 37]. In this paper, we divide 250 data into training set and test set by `train_test_split()` in `sklearn.model_selection`, then standardize both training set and test set data of predictor variables by using `StandardScaler()`, and use the standardized data to build the prediction model.

6.2.2. Model Construction. In this paper, the random-forest classifier and gradient boosting regressor in `sklearn.ensemble` are used to implement the random forest algorithm and the gradient boosting regression algorithm, and the tree package in `sklearn` is used to implement the regression tree algorithm. The processed training set data are used to construct the random-forest regression model, gradient boosting regression model, and regression tree model, respectively, using these three algorithms, and the corresponding values, i.e., movie ratings, are predicted for the test set using the `predict()` method.

The error results obtained from the three models are shown in Table 1.

From Table 1, we can see that the gradient boosting regression model has the best evaluation result, with the model prediction accuracy reaching 91.16%, the mean square error only 0.5974, and the average absolute error 0.6268, which is obviously better than the other two models. Therefore, the gradient boosting regression model is selected in this paper for movie rating prediction of experimental movie data. The prediction results are shown in Table 2. It can be seen that the errors between the predicted and actual ratings of the five movies are small, and the prediction results are highly accurate [38].

7. Thinking and Countermeasures

In recent years, the habit of movie-going in China has not only created the prosperity and development of the movie market but also put forward higher requirements for movie workers. China is undoubtedly a big movie country, but there is still a small gap from being a strong movie country, and how to get out of the country and further enhance the cultural influence of domestic movies is perhaps the next step that should be considered.

7.1. Improve the Quality of Movies. People often hope that a “good movie” with high rating can get a high box office to match it, instead of relying on publicity and marketing and the participation of big popular stars, so as to promote the benign development of the film industry and promote more high-quality films [29]. The era of relying on large-scale marketing and publicity to obtain the market has long passed, and the final factor that attracts the audience to enter the theater is still the film’s choreography and production. As a big movie country, the rate of bad movies is much higher than that of other countries, so it is important for all

TABLE 1: Error comparison of the three models.

Model	Accuracy rate	R^2	MSE	MAE
Random-forest	0.2540	0.7040	2.0000	1.0793
Regression tree	0.74860	0.7486	1.6984	0.9683
Gradient boosting	0.9116	0.9116	0.5974	0.6268

TABLE 2: A part of the movie score prediction results.

Movie	Prediction score	Actual ratings
Gone with the Wind	9.1775	9.3
Contratiempo	8.8002	8.8
Little Woods	8.9806	9.0
How to Train Your Dragon	8.7177	8.7
Days of Being Wild	8.5237	8.5

filmmakers to set the right attitude and do a good job in film arrangement and production, not to meet the market demand, but to make films that really resonate with the public and cause society to think [39].

7.2. Create Diversified Cinema Lines. The full explosion of the movie market is destined to be accompanied by the diversification of people’s movie-going preferences [30–39]. In the future development of domestic movies, under the influence of the new film industry pattern, movie genres will become more and more abundant, and traditional comedies and romances will join hands with new genres such as suspense and crime to the screen. It will be difficult to summarize the genre of a movie with one or two genres, and there will be more and more movies with multiple genres at the same time, and their structure and methods will be more mature.

8. Conclusion

In this paper, we use Python crawler technology combined with Python library to analyze the data of movie information on Douban website, clean and analyze the scattered movie data, and use word cloud and charts to visualize and display the data to achieve self-interpretation. The user evaluation data are focused in multiple dimensions and levels, and the patterns and features of the data are discovered to make it have reference value for the audience’s movie viewing behavior. For the construction of the movie score prediction model, three algorithms of random forest, regression tree, and gradient lifting are adopted. The model evaluation results show that the best prediction effect is the gradient boosting regression model, with an accuracy of 91.16%. This model was used to score the five films, and the prediction score and the actual score were very close. In the next step, the program will be further extended so that it can be developed into a complete film evaluation visualization system equipped with a user interface for smooth operation. At the same time, it will focus on dynamic data crawling for mobility so that it can achieve multiple data acquisition and evaluation and can play a greater role in public opinion analysis in the future.

Data Availability

The dataset can be accessed upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

With the rapid development of computer science and Internet technology, face recognition technology is widely used in such as public security, judicial and criminal investigation, public security, information security and access control system, such as public security system need to find out the criminals in the system library, or from the entrance control system quickly identify and match the identity of relevant personnel information. As a stable, intuitive and highly recognizable biometric feature, human face is being paid more and more attention by researchers. Compared with other bioinformation recognition methods, face recognition is characterized by direct, friendliness and convenience. Users are not easy to resist, and compared with other recognition technologies, they are easy to be accepted by users, so it has received attention and research. This paper designs a face recognition system based on a convolutional neural network. Compared with the traditional face recognition method, the convolutional neural network model does not need manual complex and time-consuming feature extraction algorithm design, only need to design an effective neural network model, and then end-to-end training on a large number of training samples for simple and efficient training, can get a good identification effect. The design uses the target detection algorithm to conduct accurate, real-time, efficient face recognition, and can accurately identify the people in the camera.

1. Introduction

1.1. Research Background. The narrow sense of facial recognition technology refers to a computer vision technology that performs authentication or search by analyzing and comparing facial visual feature information. Some of the more common recognition technologies in daily life, such as fingerprint recognition, belong to the same field and the field of biological information recognition, and facial recognition technology is also widely used in daily life. This authentication method has many advantages compared with the traditional identity authentication. Password, card, certificate as the featured authentication technology, biometric technology is difficult to forge, and there will not be lost, biometric technology has become the most secure and the most reliable authentication technology in the world.

In the information age, information protection is particularly important, and China attaches great importance to public security, and the demand for security protection

application of new technologies and new products is strong. Face recognition technology uses the difference of individual facial characteristics to realize human identity characteristics recognition. Face is the most direct performance and the most unique biological feature in biology, which makes face recognition technology have unique recognition advantages. Based on this advantage, face recognition has shown great potential in the application of many fields, especially to the public security investigation system [1].

In today's Internet + environment, O2O, P2P, B2C, B2B and other forms of network business model gradually emerging, and in various network business model the most important key technology is network payment, network payment security problem determines the development of business model, so safe, fast network payment is the urgent need of modern society, face recognition is easy to forget, theft, and convenient and fast, security has become a new way of network payment [2].

Face recognition technology as the security of the city, realize the convenient life core technology, with the

construction of intelligent information city in China, some high-tech company investment and strategic transfer, make the application of face recognition technology more and more wide, brush face payment, brush face clock function application, can say the new era of face recognition application has come.

1.2. Research Meaning. Face recognition has some characteristics that other recognition methods do not have, making it has unique advantages in specific applications [3, 4]:

1.2.1. Non-Contact, Imperceptible. Face recognition is generally carried out under conditions with visible light or infrared interaction with visible light and if the face is exposed to light, it is difficult to camouflage and change. Therefore, face recognition can easily access to identity information but cannot be detected and disgusted. This can play a great role in the arrest process of criminal suspects, because criminal suspects generally have a high vigilance, it is difficult to gain their trust, get their identity information. Face recognition does not require direct contact between people and the device, and other methods such as fingerprint recognition require contact with the device. On the one hand, it is not easy to be noticed that the collection can be completed inadvertently, without too much intervention from the staff. The collection person will not resist, because the face compared with fingerprint, iris and other characteristics are exposed characteristics, and we can accept it. On the other hand, it is clean and hygienic, and will not spread infectious diseases. During the epidemic prevention and control period, non-contact even reflects the unique advantages that other identification methods do not have [5, 6].

1.2.2. Concurrency, Equipment Requirements are Single. Face recognition for equipment requirements are mainly high pixel camera, the equipment requirements of a single. With the improvement of smartphone front camera pixels, more and more smartphone brands regard human recognition as an important way to unlock it. With people's increasing requirements for urban security, the urban video surveillance system is increasingly perfect, and the number of high-performance cameras is increasing greatly. Compared with fingerprint recognition, iris recognition and other recognition devices, face recognition has obvious hardware basic advantages. And the price of face recognition equipment has significant advantages compared with the price of other recognition devices, and the price of face recognition equipment belongs to the acceptable range of users [7]. At the same time, with the improvement of the monitoring system, it can also be used to find the lost property and accurately crack down on the crime of population trafficking and other functions, because the surveillance can save the video and restore the scene at that time, which is impossible for other recognition methods. With the increasing accuracy of face recognition, face recognition will become a large-scale social recognition technology [8].

1.2.3. Natural Advantage. The advantage of nature is simply being able to distinguish with human eyes, rather than having to be processed by the device to distinguish [9]. Face recognition is very simple, just a few seconds after standing in front of the camera, users do not need to be trained, and do not need to carry documents. It also improves security. Fingerprint and iris recognition humans cannot be distinguished by the naked eye and must be scanned through devices, so they are not natural. Criminals have the opportunity to cheat devices by collecting fingerprints and iris to commit crimes [10, 11].

1.3. Development Trends

Stage 1: The initial stage of face recognition technology. In the initial stage of face recognition technology to Parke, mainly on the face gray scale graph model research, at this stage has no key progress, basic in practical application is with artificial to identify, identification efficiency is very low, recognition effect is poor, it is easy to identify error, and manual operation is too large, the system has no automatic recognition ability [12, 13].

Stage 2: The transition stage of face recognition technology. The excessive stage of face recognition technology has achieved many very important results, pointing out the direction for face recognition technology. After going through the initial stage, the researchers study face recognition as one of the pattern recognition problems. The geometric structure features of the human face, such as the relative position and distance of the nose, eyes and mouth, constitute the feature vectors, which are matched for face recognition. The main characters are AJ Goldstein [5], LD Harmon and AB Lesk use geometric feature parameters to represent the front image of the face; Kaya uses statistical methods to study the Euclidean distance as the face features; Kanade [6] has designed a semi-automatic backtracking recognition system. The Turk of MIT and the characteristic face method proposed by Pentland are of great significance, and they are the most representative method during this period. Face Recognition technology Test has created its own FERET face image library, using it to evaluate various algorithms and look for algorithm flaws and improvements [14].

Stage 3: Face recognition technology gradually mature stage. With the improvement of computer computing power, the concept of artificial intelligence and machine learning, face recognition technology has had a new development. At this stage, automatic face recognition has been available. At this stage, the research focus has gradually shifted to face recognition under non-ideal conditions. The current face system will still be affected by expression changes, posture changes, light conditions. The main characters include face recognition based on light cone model under multi-pose and multi-illumination conditions proposed by Georgiades, face image recognition based on

multi-pose and 3D deformation model under multi-illumination conditions proposed by Blanz, and face recognition method for statistical learning of support vector machine SVM.

2. The Theoretical Basis of the Convolutional Neural Networks

2.1. *Artificial Neural Nets.* Artificial neural network is a mathematical model that mimics the coping mechanism of the human neural system and the process of external excitation, according to the principle of various information, as shown in Figure 1. This mathematical model has some features similar to biological systems, such as nonlinearity, robustness, non-limitation, very qualitative, fault tolerance, and fuzzy information that can be processed. Therefore, this model has achieved good results in pattern recognition, image processing and other aspects. Simply put, the artificial neural network first provides some data with the input-output mutual response relationship, and then analyzes the relationship between the two, to get the law, and to predict the corresponding results of the new input data according to this law. Convolutional neural network belongs to a kind of artificial neural network, so mastering artificial neural network is beneficial to understand convolutional neural network. Figure 1 shows a cerebellar model arithmetic computer.

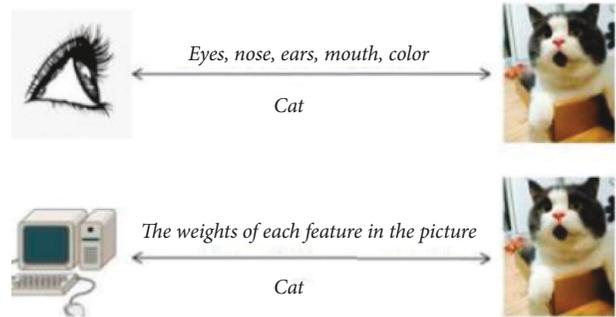

FIGURE 1: Cerebellar model arithmetic computer.

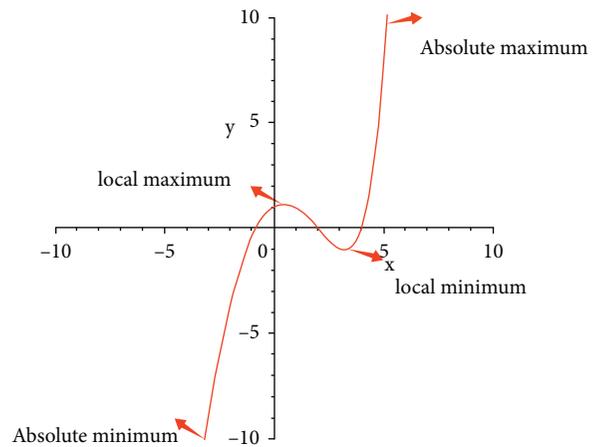

FIGURE 2: A function image of a certain loss function.

2.1.1. *Loss Function.* The loss function [9] is used to measure how well the model predicts results at a time. Using the input and output of a set of data to adjust the parameters in the model to achieve the required performance, the process is supervised learning. Take it as an example, and arbitrarily choose a model that corresponds to a function, and for any input, the model will output a corresponding output result. The output may be the same as the true value, but there may be some error. At this point, a function is needed to describe the error of the model output, which is known as a loss function.

2.1.2. *Gradient Descent.* In order to reduce the error between the output of the model and the real value, the minimum value of the loss function is actually found. In practice, we generally iterate through gradient descent to find the minimum value of the loss function, a function image shown in Figure 2.

Assuming that the vertical axis of the function curve is the loss function value of the model, and the horizontal axis is a certain parameter value of the model, the loss function of the best predicted model that we want to obtain must be minimal. As can be seen from Figure 2, the image has two stagnation points, respectively, the maxima and minima of the function, but the minimum value of the function is only one. For machine learning models, the vast majority of them cannot directly obtain the minimum value through calculus, so we can only try to obtain the global minimum value through the step-by-step iteration method.

For a unary function, you can find the minimum value of the function method can be divided into several steps, each time along the derivative is negative way. For multivariate functions with multiple independent variables, it can be gradually found gradually along the direction of its gradient descent, which is the gradient descent algorithm. To get the minimum value of the loss function, you need to get the gradient of the loss function, and then update it in the direction where the gradient is negative, where parameter η is known as the learning rate, the gradient descent convergence case at different learning rates is shown in Figure 3.

It can be seen that either too large or too small of the learning rate setting will affect the convergence effect, so a suitable learning rate is very important for the convergence of the model.

2.1.3. *Optimizer.* The learning rate parameter has a great impact on the quality of the trained model, but this parameter is not easy to set, either too large or too small. Therefore, one hopes that the model can both converge quickly and get a good result during the training process. Some scholars have proposed an optimizer that can automatically adjust the learning rate. By introducing the concept of momentum to adjust the speed of gradient descent, so that it can accelerate the decline when it should fall faster, and then converge quickly. There are many such optimizers,

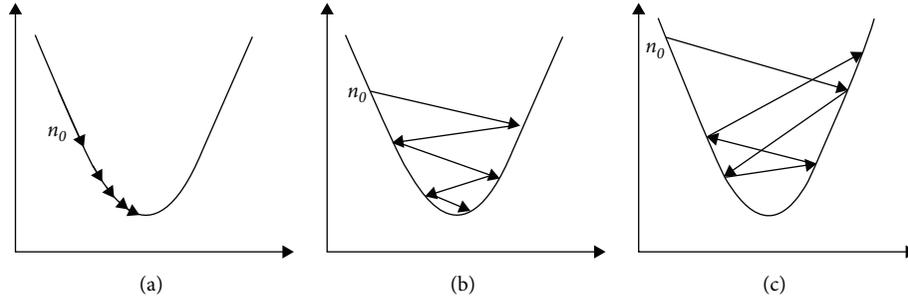

FIGURE 3: Convergence case of the gradient descent at different learning rates. In Figure 3 (a) the learning rate is too hours. The small learning rate setting can find the minimum, but the convergence rate is slow and easier to enter the local minimum. (b) When the learning rate is set to moderate. The convergence process of the model is oscillating and converges faster. (c) This is shown when the learning rate is set to be too large. The convergence process of the model is violently volatile and difficult to converge.

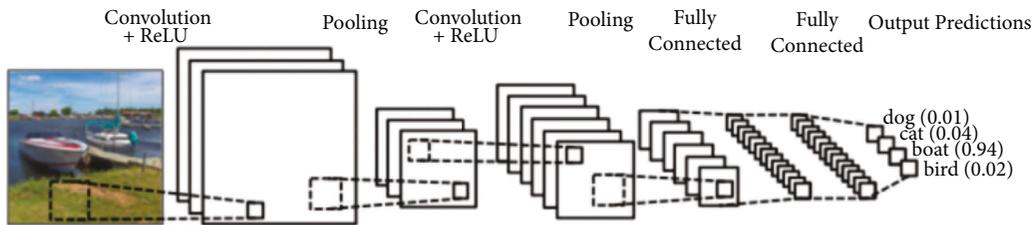

FIGURE 4: Traditional convolutional neural network architecture.

such as RMSprop, Adagrad, Adadelata, Adam, etc. This design uses the Adam optimizer, which mainly has significant advantages:

- (i) Easy to use, fast operation speed
- (ii) Memory footprint is not high, and the computer configuration requirements are low
- (iii) Suitable for the unstable objective functions.

In general, the Adam optimizer is highly efficient, simple to call to, and it is perfect for this design.

2.1.4. Error Backpropagation Algorithm. The error backpropagation algorithm in the 1980s is one of the most widely influential, Rumhart et al. the core content of the error backpropagation algorithm [11] is to divide the learning process into forward propagation process and backpropagation process. The forward propagation process is the input sample from the input layer, and the output layer from the hidden layer. If the actual output of the output layer does not match the desired output, the backpropagation process enters the error. Error backpropagation is to input the output error to the input layer through the hidden layer in some form, and the main purpose error is apportioned to all the units in each layer to obtain the error signal of each layer and correct the weights of each unit.

2.2. Convolutional Neural Network. Convolutional neural network is a feedforward neural network with deep structure composed of many layers. As shown in Figure 4, a typical convolutional neural network architecture is seen. The

structure of convolutional neural network (CNN) includes convolutional layer, pooling layer, rectifier linear unit (ReLU), and fully connected layer.

2.2.1. Convolutional Layer. Convolutional layer [12] is the main building module used by convolutional networks, which performs most computationally heavy work. The main work of the convolutional layer is to extract the feature [13] from the input data of the image. Convolution preserves the spatial relationships between pixels by learning image features using small squares of the input image. Input images were convolved by using a set of learnable neurons. A feature graph or an activation graph is generated in the output image, which is then input to the next convolutional layer as input data. Layers of deep convolution is designed to extract the information of the various dimensions of the image, as shown in Figure 5, and the different features in the images are obtained through multiple extraction.

2.2.2. The ReLU Activation Function Layer. ReLU [14] is a nonlinear function, also known as a modified linear unit, and is a common activation function commonly used in artificial neural networks, as shown in Figures 6. This means that the operation will be applied to each pixel, reconstructing all negative values in the feature graph to zero. To understand how ReLU works, we assume that there exists a neuronal input with an input of x , whose function is defined as:

$$f(x) = \max(0, x). \quad (1)$$

As shown in the schematic diagram of the neuron model in Figure 7, from formula $y = \sum (w * x) + b$, the function of

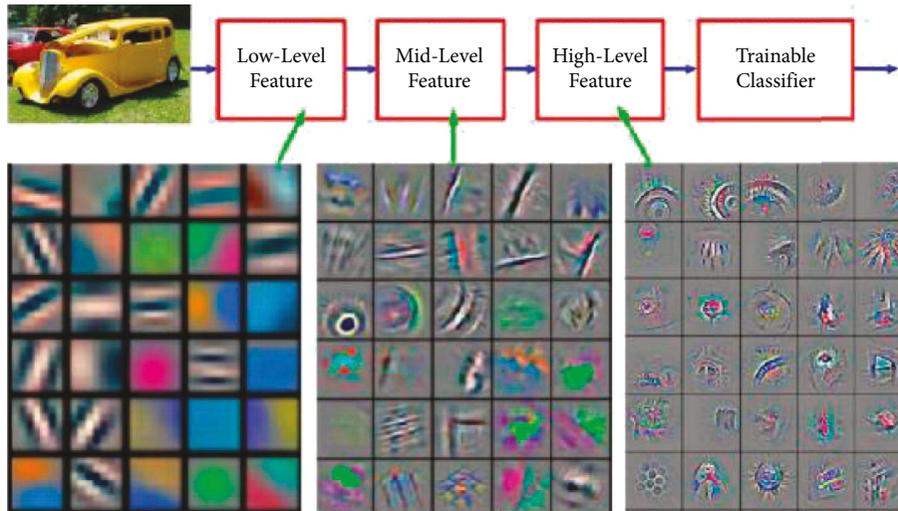

FIGURE 5: The effect of multiple convolutions.

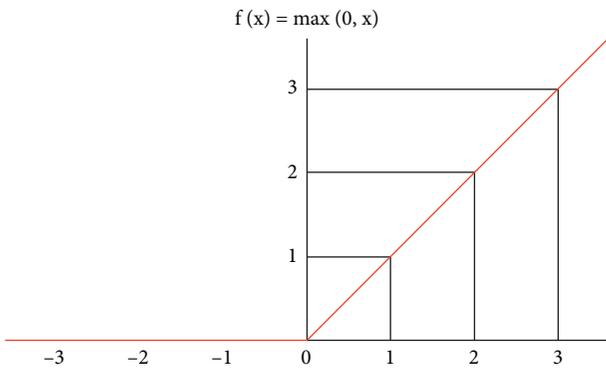

FIGURE 6: ReLU function.

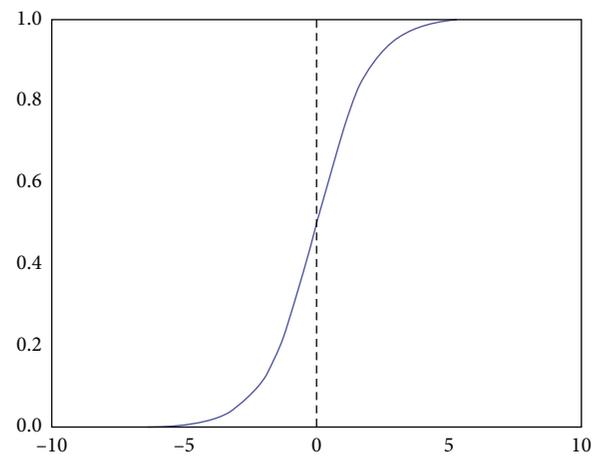

FIGURE 8: The Sigmoid function image.

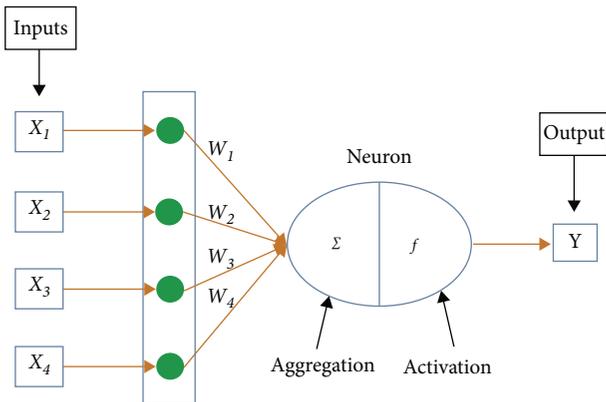

FIGURE 7: Schematic representation of the neuronal model.

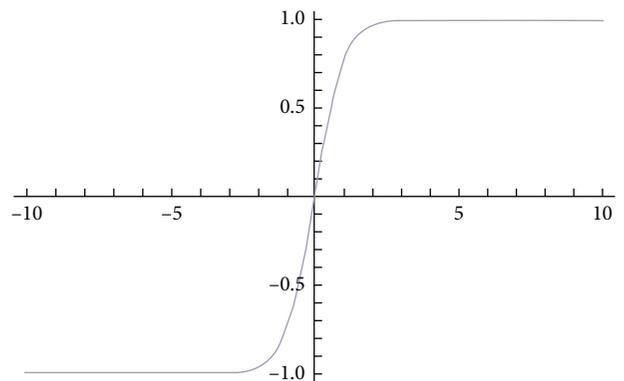

FIGURE 9: Tanh functional image.

using the ReLU activation function is to change the original linear output to the nonlinear output, and in practical industrial applications, more often, there are various nonlinear distributions.

The activation function also has the Sigmoid function and the Tanh function, as shown in Figures 8 and 9. The output of these two functions when x tends to infinity is 0 and 1, -1 and 1 , respectively, but finding the gradient

requires the first partial derivative of the function. When the value of the function is constant, the partial derivative of the function is 0, and the gradient does not exist, which is called gradient vanishing. Eventually the weight w , and the bias b cannot be updated. However, when the ReLU function approaches 0 at x , the derivative of the ReLU function exists

with a value of 1, which can reduce the computational amount of backpropagation. The gradient explosion problem occurs in the Sigmoid function, because the Sigmoid function is an exponential function, causing the problem of too large data in the result.

2.2.3. Pooling Layer. The function of the pooling layer is to reduce the size of the matrix, and can reduce the amount of operation in subsequent operations. The pooling layer reduces the broadband and height of the matrix and does not change the depth of the matrix to extract the main features of the matrix. However, there is no denying that after the pooling layer, the characteristics of the matrix will be lost. Pooling layers generally subsample each region through nonlinear operations such as average pooling or maximum pooling. Thus achieving better generalization, faster convergence, and better robustness to translation and distortion. The pooling layer is usually located behind the convolution layer. The process of maximum pooling is shown in Figure 10.

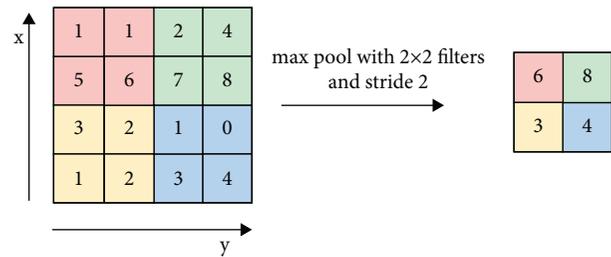

FIGURE 10: Maximum pooling process.

2.2.4. Fully Connected Layer. The convolution layer is the extraction of local features, the full connection is the extracted local features reintegrated through the weight matrix into a new graph, because all the extracted local features are called the full connection layer (Figure 11).

After layers of convolution and pooling, to extract the local features in the picture, and the first connected layer has activated a part of the neurons, the role of the fully connected layer is to integrate the relevant output to the second fully connected layer of some neurons, through the combination we can know that these features integrated is a cat.

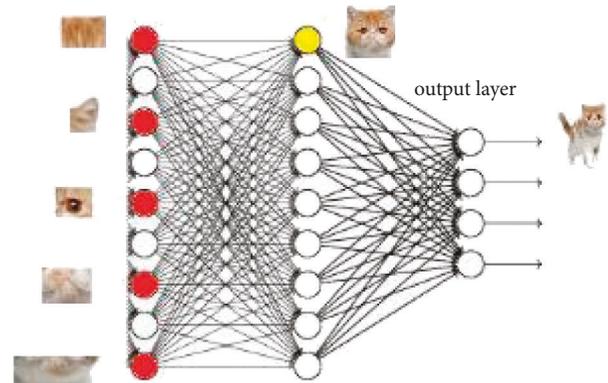

FIGURE 11: The role of the fully connected layer.

3. Design of the Face Recognition System

3.1. Overall Flow of the System. The convolutional network-based face recognition system is designed to detect the faces from the camera display images and compare them with the previously trained faces in the database to determine whether they belong to be the same person.

- (i) Photo collection: complete video image acquisition from the camera.
- (ii) Face detection: detect whether there is a face in the image, and send the picture input to the image for pre-processing. If there is no face, return to the collection stage.
- (iii) Image pre-processing: face correction and cutting of face pictures.
- (iv) Image feature extraction: face feature extraction through convolutional neural network.
- (v) Feature matching: the extracted feature vector is compared with the feature vector of the face pictures in the library to get the judgment results.

3.2. Introduction of the Development Language and Library. Python is a fully object-oriented language. The most obvious feature that distinguishes the Python language from other

languages is its simplicity. Python is the most concise of all programming languages, although it is also easy for beginners to learn from python languages, and python has many excellent libraries to help you develop. In addition, compared to other programming languages, Python can often achieve the same function with the shortest code.

3.2.1. OpenCV Storeroom. Mention computer perspective has to mention OpenCV, it is a very widely used computer vision library, OpenCV contains hundreds of computer vision, machine learning, image processing and other related algorithms, it not only contains the classic algorithm also contains now the most advanced computer vision and machine learning algorithm, it can be used to detect and identify the face, extract 3 d model of objects. Its powerful capabilities make OpenCV widely used in many fields, such as robot navigation and searching for objects, stitching together street scenes in cities, autonomous driving by unmanned cars, and so on. In this design, the OpenCV library needs to be used for processing the images.

3.2.2. Tensor Flow. Tensor Flow is a very important software library that often appears in the field of machine learning and deep learning, and its function mainly is to perform some high-performance numerical calculation and analysis. Tensor is a tensor, which represents the transmission of data between nodes, and Flow is a data stream, which refers to the various nodes of the data operation diagram in the form of a stream.

3.2.3. Numpy Storeroom. The Numpy library is the basic library of Python in the field of scientific computing, and many machine learning and deep learning studies rely on the Numpy library. The Numpy library mainly implements the computation of matrices, which can calculate the higher order, a large number of matrices, vectors, and also have relatively rich functions. The Numpy library is an important scientific computational library.

3.3. Overall Design of Face Recognition System

3.3.1. The Design of the Convolutional Neural Network. Convolutional neural network design is the core content of this design. The main principal of convolutional neural network is the face feature extraction and the training of neural network model, so the structure of convolutional neural network will determine the effect of face recognition behind [15–28]. The convolutional neural network system has designed eight layers of neural network, including three convolutional layers, three pooling layers, one fully connected layer and one output layer.

The first convolution layer: The layer of depth convolution is to extract the information of various dimensions in the image, increase the number of channels of the image, and the size of the image remains unchanged. The input image size is $64 \times 64 \times 3$, and the image size output after convolution is $64 \times 64 \times 32$. The convolution kernel size is (3, 3), the convolution step length is 1 step, and the padding fills the SAME and the image boundary pixels during the convolution process. The number of input channels is 3, and the number of output channels is 32.

The second maximum pooling layer: The main purpose is to reduce the size of the matrix, and it can reduce the amount of operation in subsequent operations. At this time, the input image size is $64 \times 64 \times 32$, the sampling size of the pooling layer is 2×2 , and the output image length and width are generally the input image, so the output of the pooling image is $32 \times 32 \times 32$, which reduces the calculation amount of the image. The drop layer randomly drops some neurons with a certain probability to obtain a faster training speed.

The third convolution layer: with the input image size $32 \times 32 \times 32$, output image size $32 \times 32 \times 64$, convolution core size (3, 3), input channel 32, output channel 64, and convolution step size 1.

The fourth pooling layer: the input image size is $32 \times 32 \times 64$, the sampling size of the pooling layer is 2×2 , and the output of the pooling image is $16 \times 16 \times 64$, which further reduces the information of the image, and is conducive to the calculation.

The fifth convolutional layer: with input image size $16 \times 16 \times 64$, output image size $16 \times 16 \times 64$, convolution kernel size (3, 3), input channel 64, output channel 64, and convolution step size 1.

The sixth pooling layer: The input image size is $16 \times 16 \times 64$, the sampling size of the pooling layer is

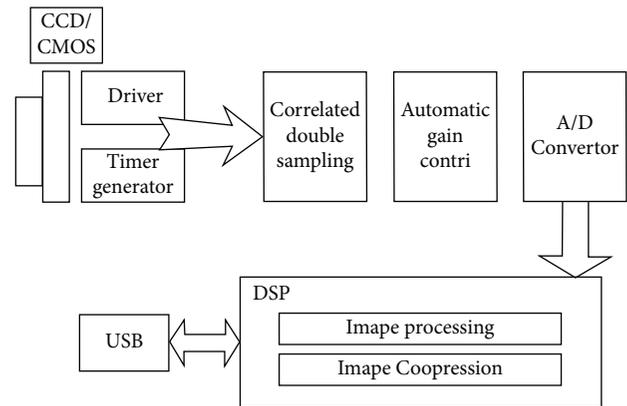

FIGURE 12: How the USB camera works.

2×2 , and the output of the image after pooling is $8 \times 8 \times 64$.

The seventh fully connected layer: In order to enhance the nonlinearity of the neural network and limit the size of the network, a fully connected layer is fully connected. Each neuron of the fully connected layer is connected to the neurons of the previous layer, and the picture of the input of $8 \times 8 \times 64$ is compressed into a one-dimensional vector of 1×512 .

The eighth layer output layer: The output of the system is divided into two categories, one is the face saved in the database, the other one is not saved in the database face, so as to realize the recognition function. The input picture of the output layer is 1×512 , and the output picture is 1×2 .

3.3.2. Monitoring Picture Acquisition Subsystem. This design uses a USB digital camera using a new data transmission digital camera. It can be inserted directly into the computer USB interface, which is easy to operate, and the cost is lower compared with the traditional surveillance camera. The working principle is shown in Figure 12. First, the image screen is collected by the lens, and then the light sensor components and control components inside the camera process the image into a digital signal, and finally input to the computer through the port or USB connection.

3.3.3. Face Detection. Dlib comes with a Hog-SVM-based face detector, a widely used face detection model consisting of five HOG filters forming forward, left, right, forward but left, forward but right.

This recognition pattern is the fastest method to detect on the CPU, which is suitable for both frontal and slightly negative faces, and also works properly under small occlusion, and basically this method satisfies most cases. The main drawback is the inability to detect small faces, as the minimum face size trained by the authors is 80×80 . Therefore, you need to ensure that the face size should be greater than the face size in the program. Not suitable for side and extreme facade, such as overlooking and

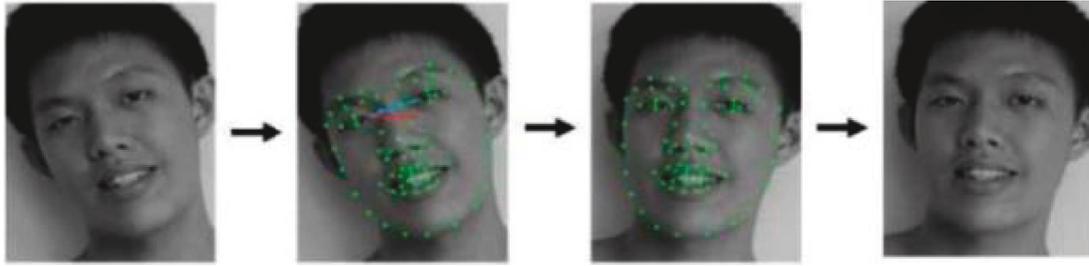

FIGURE 13: Face alignment process.

overlooking, face detect face detected. It also does not work under severe shielding.

3.3.4. Image Processing. Preprocessing of an image usually includes image grayscale processing, image data normalization processing, and transforming the dimensions of an image, and the like. Face correction is because to the photos of the machine whether crooked head, bow or head, position is not right, so need to cut the face first, for each feature little positioning, then according to the point positioning a coordinate, compared with the coordinates of the real face, the Angle of the difference, is the Angle of the head crooked, the reverse rotation image, the image is positive, as shown in Figure 13 below.

The gray scale of the image is to reduce the information of the image and reduce the amount of calculation of the computer, and the size transformation of the image is to minimize the impact of the image background on the picture.

3.3.5. Eigenvector Contrast. The known face feature vectors are stored in the database, so for face recognition, the feature vectors must be compared. First, we need to send the face images in the video to the convolutional neural network, which generates the image feature vector through the convolution and pooling operations. The extracted face features will be used as the main basis for judgment, calculating the similarity of the feature vector of the picture in the video and the extracted feature vector of the face. The vectors have both size and direction, and if the angle between the two vectors is very small, then the two vectors are very close. By comparing the angles between vectors, the two targets are similar. The same face has smaller vector angles; different faces have larger vector angles.

4. Implementation of the Face Recognition System

4.1. Implementation of the Face Recognition System. Face detection is conducted through Dlib's frontal_face_detector feature extractor, and the face interception is detected, while adjusting the contrast and brightness of the picture. The contrast and brightness values are random, which can increase the diversity of the sample. Finally, the size of the picture is re-set to 6464 and saved in the database. In this way, I collected 10,000 pictures of my own camera monitoring faces, in which the brightness of the background,

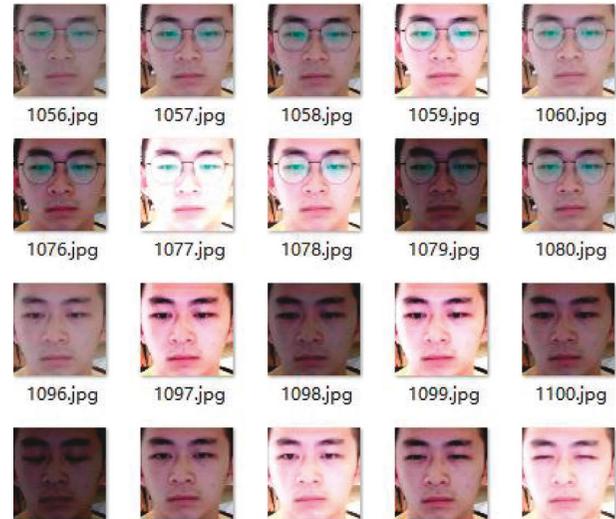

FIGURE 14: Face picture collection.

human expression and posture, facial shielding, glasses removal and other aspects were changed. The process of face image collection is shown in Figure 14.

After building one's own face library, you also need other people's faces to train the convolutional neural network. Other people's face photos can be extracted on the Internet through python, or some face databases in the face recognition field have been made, such as Yale Yale Faces, Cambridge ORL Faces, and FERET Faces of the US Department of Defense. In this design, choose to use the LFW face database, which was produced by the University of Massachusetts, and is an unconstrained face picture in a natural scene dataset collected from the Internet. The database stores images of more than 5,000 prominent faces and nearly 14,000 photos. It is well known in academia and often appears in a variety of deep learning papers related to face recognition. After downloading the LFW face library on the official website of the University of Massachusetts, do the same operation, intercept the face picture, change the size of the picture to 6464, and save it in the face database, as shown in Figure 15. So far, the face library needed for this design is established.

4.2. Training of Convolutional Neural Networks. The main training step of the convolutional neural network is to first read into the made face database, and transform the data and

FIGURE 15: LFW face database face extraction.

```

step: 0 . accuracy: 0.57
step: 1 . loss: 82.8182
step: 2 . loss: 0.796026
step: 3 . loss: 2.57887

labels of the face images into arrays. These images are then divided into test set and training set. In this design, the ratio between test set to training set is 20:1, and it is normalized. Finally, the face pictures were introduced into the convolutional neural network for training.

The training process is shown in Figures 16–18. It can be seen that as the value of the continuous training loss function becomes smaller and smaller, the accuracy of the model identification is also more and more high, which is the advantage of the convolutional neural network.

4.3. Implementation of Face Recognition. The main realization step of face recognition is to open the camera to obtain pictures and grayscale. Face detection is conducted through the `frontal_face_detector` feature extractor brought by Dlib, import the convolutional neural network that has been trained, and finally the face recognition function is realized through feature vector comparison.

After realizing the function of face recognition, in order to simply understand the recognition effect of the system, the system was conducted a simple test, the content of 100 face tests, the test results of 97 times successfully identified author’s face and other people’s faces, as shown in Figure 19.

FIGURE 19: Successfully identifying.

FIGURE 20: Failure to identify the human face in the mobile phone.

Sometimes, it failed to identify someone else’s face on the phone, which could be affected by the camera resolution and the brightness of the phone’s display, as shown in Figure 20.

There were 2 more times of identifying other people’s face as author’s, as shown in Figure 21.

4.4. Advantages and Disadvantages of the System. After many experiments, the system has the following advantages:

- (i) The system can identify the face relatively accurately and stably, and can quickly conduct image pre-processing, and the face contour is surrounded by a frame.

FIGURE 21: Identify someone else's face as mine.

- (ii) The system's recognition and response speed is fast. The system uses the GPU for computational acceleration, which greatly accelerates the response speed of the system. Basically can meet the requirements of real-time identification.
- (iii) The system is not sensitive to the light transformation, and the light conditions are constantly changing during the experiment, but the system can still be accurately identified, which is conducive to the application in real life.
- (iv) The recognition rate of the system is high. In addition to a few identification errors, the system recognizes most of the time to meet the design requirements. The system has good posture, expression and without cover.
The system mainly has the following shortcomings:
 - (i) To achieve a good recognition effect requires a lot of face picture training. If fewer pictures participate in the training, the recognition effect will be relatively poor.
 - (ii) High requirements for computer hardware. The training of convolutional network requires graphics cards with computing power above 3.0, and high CPU, memory and graphics card video memory occupancy.
 - (iii) The functions of the system can be further improved, such as the number of faces in the database can be increased, and the logging function can be increased to save the data of people in and out to view.
 - (iv) The functions of the system can be further improved, such as the number of faces in the database can be increased, and the logging function can be increased to save the data of people in and out to view.

5. Conclusion

Face recognition is an identification technology through human facial information. Convolutional neural network has been active in the field of AI deep learning in recent

years. This design realizes a face recognition system based on convolutional neural network. And the development process of biometric recognition, face recognition technology was investigated and made a brief introduction, and the advantages of face recognition technology were summarized and summarized. The basic theoretical knowledge loss function of convolution neural network, gradient descent algorithm and error backpropagation algorithm are also summarized. A convolutional neural network model is designed, and using its excellent feature extraction ability, combined with monitoring screen collection and face detection modules to design a convolutional neural network-based face recognition system, with good recognition effect.

Although the face recognition system completed in this paper has a good recognition effect, there is still a big gap with the best recognition ability at present, and we still need to continuously improve the recognition ability of the system in the future work. In addition, the system functions are too few, but also can add many functions such as diary recording, face tracking function.

In order to improve the quality and management efficiency of music education, research on the music education system based on J2EE is carried out. The music education system adopts J2EE technology, UML modeling technology, SQL Server 2012 database, Web programming technology, MVC mode, etc., which can effectively guarantee the operation performance and security performance of the system in the later application. By analyzing the background, current situation, and demand for the music education system, the design and implementation of the music education system based on J2EE are proposed, the overall realization of system management functions, music teaching management functions, music course management functions, and other functions.

1. Introduction

With the popularization of concept-based teaching methods such as quality education and comprehensive education in schools, my country has invested more energy in art education. In particular, cultivating evangelists in art education, the Art Department of Yun Normal University has entered a new stage in its music teaching management under this background. Through a series of means to make teaching more scientific and standardized. The rapid economic and social development has changed people's long-standing production and living patterns to a considerable extent. In terms of education, the increasingly accelerated social rhythm makes the traditional face-to-face centralized teaching mode gradually unable to meet people's increasing learning needs [1]. In recent years, with the rapid development of computer and multimedia technology, and information-based online teaching method based on the Internet has been gradually accepted and recognized by people. At present, the popularity of the Internet in my country is increasing day by day, and the online teaching mode has gradually become a normalization that relies on

and complements the traditional offline teaching mode due to its advantages of fast dissemination, wide-coverage, and less impact on time and space. Educational model [2]: at the end of 2019, the novel coronavirus pneumonia (COVID-19) outbreak broke out all over the world, and people's social environment was greatly affected. Due to the epidemic, the teaching of domestic primary and secondary schools and colleges and universities was also unable to provide normal classroom teaching activities as scheduled, making the online teaching-based remote teaching mode the main teaching method of various educational institutions during the epidemic. Although the epidemic situation in my country has basically been effectively controlled, the development of the epidemic situation is still relatively severe on a global scale. Therefore, effectively reducing social activities through online teaching is still one of the main methods to effectively prevent and control the epidemic. In this context, people's attention to music teaching system research has gradually increased [3].

The realization process of the music education system is very complicated, and it is necessary to study the practical activities of music education based on theoretical

knowledge. However, many current ITS systems do not have this basic knowledge, so the educational process achieved is too simple [4]. This paper starts from the development status of music education at home and abroad and develops a music education system based on J2EE according to the basic requirements and characteristics of music education. This paper adopts J2EE development technology, overall use of UML modeling, SQL Server 2012, JAVA language, MVC mode, and Web programming technology from the actual needs, to provide a basic guarantee for music education. The specific content of the music education system based on J2EE is mainly reflected in the following aspects: design and implementation of system management functions, design, and implementation of music resource management functions, design and implementation of music course management functions, etc. [5].

With the increase of music teaching needs and users, the demand for music teaching curriculum resource data and network bandwidth resources has also shown explosive growth. The service provision capability of traditional music teaching systems has been unable to meet the increasing demand for music curriculum data dissemination. Therefore, it is very necessary to use the more advanced cloud computing distributed network technology and network load balancing algorithm to optimize and upgrade the service provision capability of the music teaching system [6].

This paper analyzes the existing problems and status quo of the music teaching model of the Department of Art of Yunshi University and uses the object-oriented analysis and design ideas in combination with the actual situation, combined with J2EE computer technology, to realize the informatization, scientific, and standardization of music teaching. This system uses the open-source SSH (Spring Struts Hibernate) as the basic framework of the system and uses SQL Server with excellent security and operability as the database [7]. Using the MVC model to design the Struts architecture ensures that the system has good maintainability and at the same time enhanced data. The importance of music teachers in the traditional teaching mode is relatively high, and most of them teach in the form of face-to-face teaching. The traditional teaching mode has a single method and lacks of change in content, which leads to poor information transmission in a short period of time [8]. At present, the desire of students who study music in schools is relatively high, and the "narrow" information input forms a great contrast with reality, which cannot meet the needs of students who study music. Through this complete system, it can be a good teaching environment. It is an improvement of the teaching system, which makes music teaching appear in multiple dimensions while reducing the teaching pressure on teachers. On the other hand, it can meet the needs of students for music learning. Processing power: realizes the separation of data and view, and technology makes the system into a system with strong scalability and maintainability. This paper mainly assists students in the initial construction of a new model of music teaching from the aspects of cultivating students' interest in learning, adjusting teaching goals, expanding teaching content, innovation, teaching evaluation, and improving teaching methods [9].

The teaching mode emphasizes the coordination of covering music, performance, and enjoying unified comprehensive teaching so that students can get a comprehensive and rich music aesthetic experience, and learning can create a new realm of their own personality, and gradually improve the quality and personalization of modern music. Comprehensive healthy development. This subject takes the informatization of the music teaching system as the research content and realizes the teaching system based on WEB, which can not only optimize knowledge but also apply the project-based collaborative teaching mode technology to the informatization of the music education system. This teaching system builds applications on the B/S structural framework development environment and multilayer system architecture to assist music teaching activities [10].

2. Introduction to Related Technologies

2.1. J2EE. J2EE includes the following three component types: one is the in-app program, which is mostly used for internal training computers; the second is Servlet and JSP components, which are often used in some Internet; the third is the EJB component, which completes its functions on the server-side. J2EE belongs to JAVA, and its programming method is similar to JAVA, but there are some substantial differences. J2EE components can be used in application programs, and at the same time, they can be consistent with the J2EE specification [11].

Since J2EE has a complete set of specifications, in general, J2EE can be regarded as a constraint of the JAVA2 platform on music education. In addition, J2EE has many advantages; for example, it can meet various requirements of the bottom layer of the system through containers, and the development speed of system personnel has been greatly improved. J2EE uses the middle-tier integration framework for program development, which reduces the cost of system development, and not only improves its performance but also ensures the security of system operation [12].

2.2. JAVA Language. At the end of the 20th century, in order to design a cross-platform and distributed software system, Sun Computer Systems researched and launched the JAVA language in the United States, which is an object-oriented design language. For software developers, learning JAVA is simpler to use, and can also perform exception handling and automatic collection of discards. The programming language has functions such as porting and interpretation, so it has been widely used after its launch [13].

After continuous development, JAVA has been continuously expanded on the basis of the original programming language and has become a mainstream technology in the computer software industry. Chip technology, Internet connection technology, and other fields [14]: based on the many advantages of JAVA, its application is also very wide, and its main application directions include game systems developed in large numbers today and mobile Internet-related systems. At the same time, it is also widely used in many colleges and universities, such as educational

administration, college teaching, and other management systems. At the same time, due to its various advantages, it is often used in the relevant information systems of government departments [15].

2.3. UML Modeling Technology

2.3.1. Introduction to UML. UML (Unified Modeling Language) is the best way to represent program visualization. It is commonly used in current program design. In short, using this UML pattern to design programs makes the program layering more obvious, and the later testing of software design. And the maintenance is simpler, for developers, it will greatly reduce their development and testing time [16].

In this mode, graphical structural use case diagrams, sequence diagrams, activity diagrams, class diagrams, and state diagrams are used. These diagrams can realize many functions, including the whole process of a subject from production to demise. The standard is separated, and the original complete program is divided on the basis of these three blocks, so as to facilitate the operation of the program [17].

The UML view is mainly used to display the results of program processing. The relevant programmers can analyze the program according to the display. When using the WEB for related operations, the MODEL needs to be converted into the HTML running mode first. In the operating environment of the system, its own visual graphics can display the program, UML is a program that helps to generate view-related content and interact efficiently with clients [18].

M in UML design mainly refers to the data model object. In the whole process, the control layer of the use case diagram transfers the relevant model objects that need to be processed to the view layer, and the related operations are displayed in the view layer. In the whole process, the data model is a designed complex of calculation rules, processing flow and analysis rules, through which data is processed and displayed. The control layer is the bridge linking the view and the model layer, matching the two to facilitate processing and operation, which also makes the data and logic interfaces between the various layers of the program more coupled under the UML design. The use of this technology makes the systematic testing of music education systems simple and convenient [19].

2.3.2. Advantages of UML and Its Application in This System. The most important function in UML, the realization of visualization technology, has always been one of the basic application frameworks on the Web, and its practical cases can be seen everywhere. Its basic core includes use case diagrams, sequence diagrams, and class diagrams. Key content: the first function is to realize the application demonstration function of system-related functions, the second function is to realize the business logic layer demonstration function, the third function is to realize the data access demonstration function, and the last main function of the domain model layer is to solve modeling problems. Each layer performs its own duties in its own field and has its own

tasks. UML separates and isolates the entire interface operation function of the system as a whole, and reduces the degree of interaction and coupling, which is important for the subsequent maintenance and expansion work. It is of great help to the design scheme and technical development of the entire research and development process of Web applications [20].

2.4. MVC Pattern. The abbreviation of the three concepts of model, view, and controller is represented by MVC. Through these three parts, the software design part in the WEB development process is realized, the rapid development, upgrade and maintenance of the system is realized, and modularization is provided for designers selection, which greatly optimizes the efficiency of program development. The schematic diagram of the MVC mode function implementation is shown in Figure 1 [21].

2.5. SQL Server 2012 Database Technology. SQL Server 2012 is based on the research and design of the previous version of SQL Server. It has been greatly improved on the previous version, and its cohesion, practicality, integration, and other properties have been further strengthened. Therefore, the software is more widely used in practical applications and can adapt to the daily data management needs of various software with increasing update frequency. Its practical application market is very large, but it is mainly used in the data information management system of large and medium-sized enterprises [22].

This version inherits the layered structure of its previous version. The first is the protocol layer. This layer is mainly used to operate and process-related data information, such as format changes, data-related operations, and structural responses of operations. Developers can directly operate this layer, and perform a series of required operations on the data through this layer. At the same time, developers can use this layer to change the format of data information and change its format to the desired pattern that can be recognized. The result of its modification is sent to the next layer, where the data is converted again as required. This time the data can be converted to the data information format that can be recognized and used by the user, so as to facilitate the user to match the required data and access to the data information, so it is called the access layer [23].

The characteristics and advantages of this system are summarized in the following four points: (1) broad applicability, (2) strong security, (3) high availability, and (4) scalability.

2.6. Web Programming Technology. The WEB programming technology adopted by the music education system is the current mainstream development technology system, including the development of the WEB terminal, the development of the mobile terminal, the development of the web interface and the development of database, and the development of the system realized from multiple perspectives. The development technology used for the system studied in

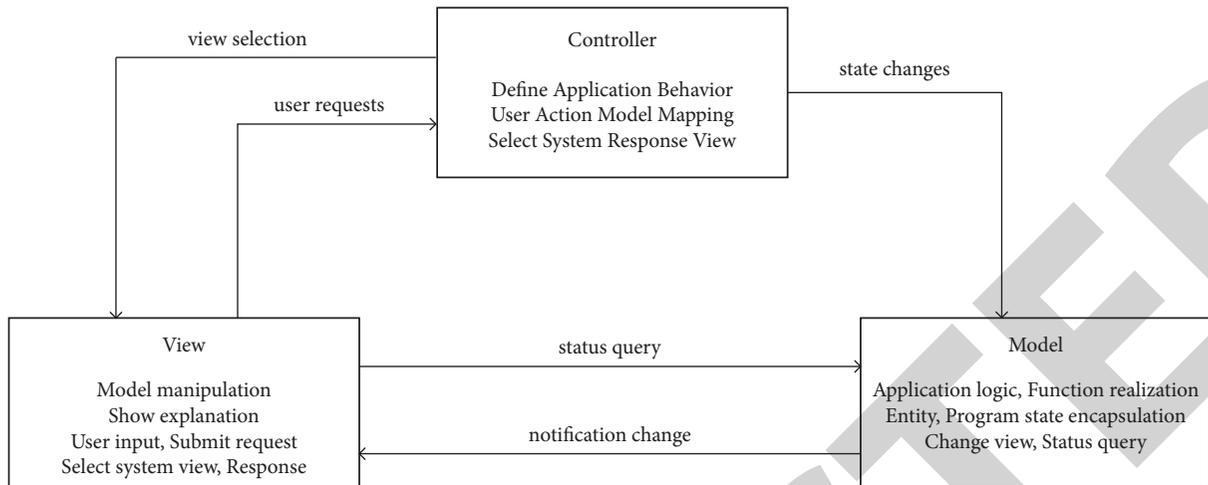

FIGURE 1: Schematic diagram of MVC mode function implementation.

this paper is implemented based on a three-tier architecture, including the design of the presentation layer, the business logic layer, and the data persistence layer, and is developed around the object instance of the music education system [24].

3. Demand Analysis of the Music Teaching System

3.1. Analysis of Functional Requirements

3.1.1. Information Release Module. The information release management part mainly includes two functions, one is to release news information, and the other is to release announcement information. The news information is for all users of the music teaching auxiliary system, and the management content includes news editing, news release, and news maintenance; the announcement is mainly for registered users, that is, teachers, students, or administrators, similar to news management.

3.1.2. Document Management Module. The music teaching auxiliary management system includes part of the official document management function, which manages the official document processing in the school teaching and office process. Official document management mainly completes the entire process from drafting, and approval to document issuance in learning. With the help of network technology and computer technology, the school's office work can be paperless, improve work efficiency, and supervise the circulation process of official documents.

3.1.3. Teaching Resource Management Module. The teaching resource management module mainly realizes the management of self-study resources, including music audio and video, homework exercises, music knowledge popularization, and other parts.

3.1.4. Auxiliary Teaching Management Module. The auxiliary teaching management module is mainly responsible for the system administrator, which realizes the management of courses, management of students' online examinations and exercises, interactive management of Q&A, discussion, and performance analysis.

3.1.5. System Management Module. The system management in the music teaching assistant is mainly used to serve the related activities of students and teachers, provide support for the normal operation of the system, and coordinate the collaboration and communication of different modules. This part of the management can be divided into music-assisted teaching, log management, and user management. The specific contents are as follows:

- (1) Music-assisted teaching: auxiliary teaching management is mainly through the statistics and analysis of existing data; school leaders or teachers conduct auxiliary decision-making management in order to improve teaching quality and management level.
- (2) Log management: the log management part is divided into two parts: operation log and system log. The operation log completes the management of all functional operation records; the system log completes the record management of the system running process.
- (3) User management: manages user identities such as teachers, students, leaders, and managers, as well as user basic information.

3.2. Model Analysis

3.2.1. Object Model Analysis. The needs of music teaching auxiliary management are mainly reflected through the use case model, which can build a bridge between ordinary customers and system implementers, allowing users to describe their own needs and the functions to be achieved by the required system in the most detailed way. There is a

particularly important relationship between the refinement of the use case diagram and the modularity of the use case diagram. The modeling of this system is to use UML to visualize the system functions and specific feasible methods. To achieve the goals of all parties, the first is customer needs, which must be easy for users to understand, and the second is to allow developers to fully understand so that development work can begin [25].

The establishment of use cases must focus on system participants. From this point of view, the premise of use case determination should be to conduct a series of analyses on the actual participants in the system and their related information and then combine the actions and behaviors of all participants. Only in this way can the functions required by customers be realized, and then specific and available use case analysis can be obtained. The language used for unified modeling can describe the use case from several aspects, and its participants and various subtle interrelationships between them. Solving these problems can specifically determine the construction of the use case.

We do the design work required for the use case from the top down, and the principle is progressively deeper. We will first establish the most basic use cases according to the specific needs of the project at the beginning, and then refine the use cases step by step on this basis to achieve deeper customer needs and target analysis. Figure 2 shows the school leadership using a case diagram.

School leaders mainly carry out operations such as official document handling, news and announcement browsing, and auxiliary decision-making management (music teaching).

Music teachers mainly carry out operations such as music examination question bank management, music courseware management, student field communication, and homework and examination management. The example of music teachers is shown in Figure 3.

Students mainly conduct music-related question consultation, online learning, and online testing, among which question consultation includes music knowledge, exam-related, and amateur discussions. The example of student use is shown in Figure 4.

System administrators mainly perform user management (including teacher management, student management, and authority management, leaders belong to teacher management and assign higher-level authority), log management, system settings and information release (including news management and announcement management), and other operations.

3.2.2. Data Model Analysis. The analysis of the data model is mainly carried out by means of the data flow chart, which can systematically and comprehensively describe the data logic of the music teaching auxiliary management system. In the process of information storage, processing, and flow reflection, the data flow diagram is mainly realized by means of centralized and general symbols. The characteristics of the data flow graph are mainly composed of the following two aspects:

- (1) **Abstraction:** abstract data information into specific information storage, processing and flow, and reduce unnecessary object processes
- (2) **Generality:** express all requirements as a whole, and associate all related information or business processing

A data flow diagram consists of the following four basic elements, namely, external entities, data flow, processing (function), and data storage. Each module uses a data flow diagram to represent the source of data and the relationship between data. The top-level data flow of the system is shown in Figure 5.

3.3. Analysis of Nonfunctional Requirements

3.3.1. Performance Requirements

(1) **Performance.** The safe and reliable operation time of the music teaching auxiliary platform is not less than ten years; the number of simultaneous online teachers and students is not less than 400; the response time of business processing shall not exceed five seconds; in order to adapt to the continuous increase of functions, automatic expansion support is required; all data transmissions must be stable and secure;

(2) **Security.** Security requirements mainly include data transmission encryption, data backup, and virus prevention.

Data transmission encryption: different levels of users set different access rights, and MD5 encryption is performed for user authentication; Data backup: data backup is performed regularly to ensure safe operation; Virus prevention: because it is in the form of a network, virus prevention and awareness enhancement are required.

(3) **Scalability.** In the process of music teaching, various teaching methods, teaching modes, and functions are changing with each passing day, and need to be maintained and upgraded from time to time. Therefore, the auxiliary teaching system must be scalable and configurable.

The auxiliary management of music teaching is realized by modularization, which improves the reusability and maintainability of the code by reducing the association between different modules.

The upgrade of the system must not affect the normal operation and only needs to be upgraded online on the server-side.

3.3.2. Design Goals. The design goals of the music teaching assistant management system based on J2EE mainly include the following aspects:

Practicality: simultaneously design information functions based on traditional operation methods to provide a concise and clear operation interface for teachers and students when teaching or learning music; **Fault tolerance:** when data errors are caused by a program running or

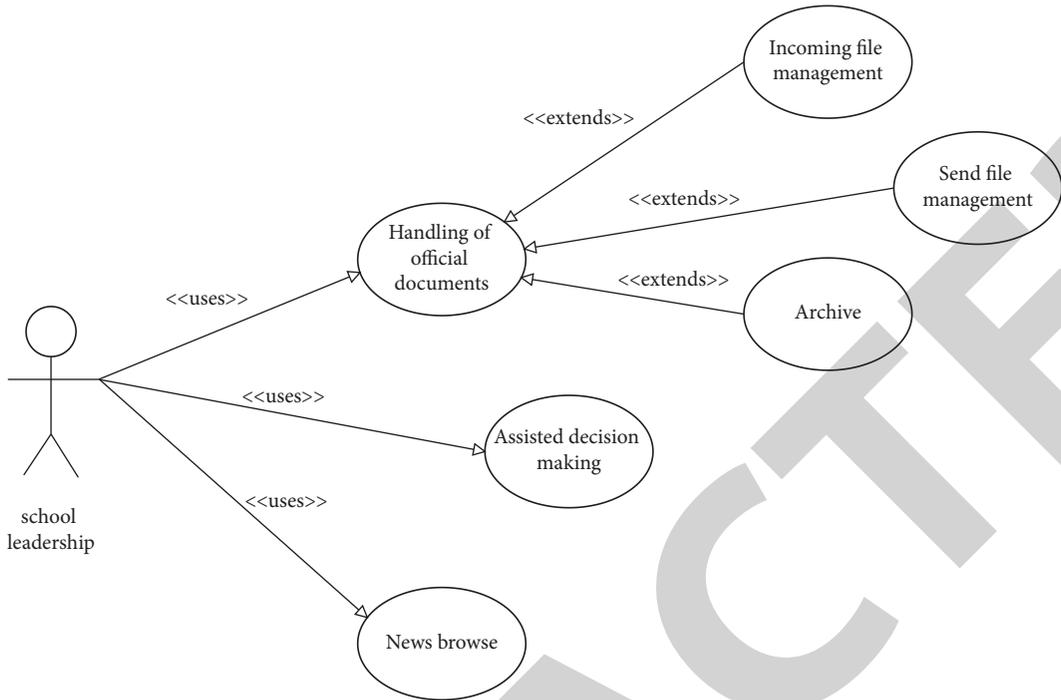

FIGURE 2: School leadership use case diagram.

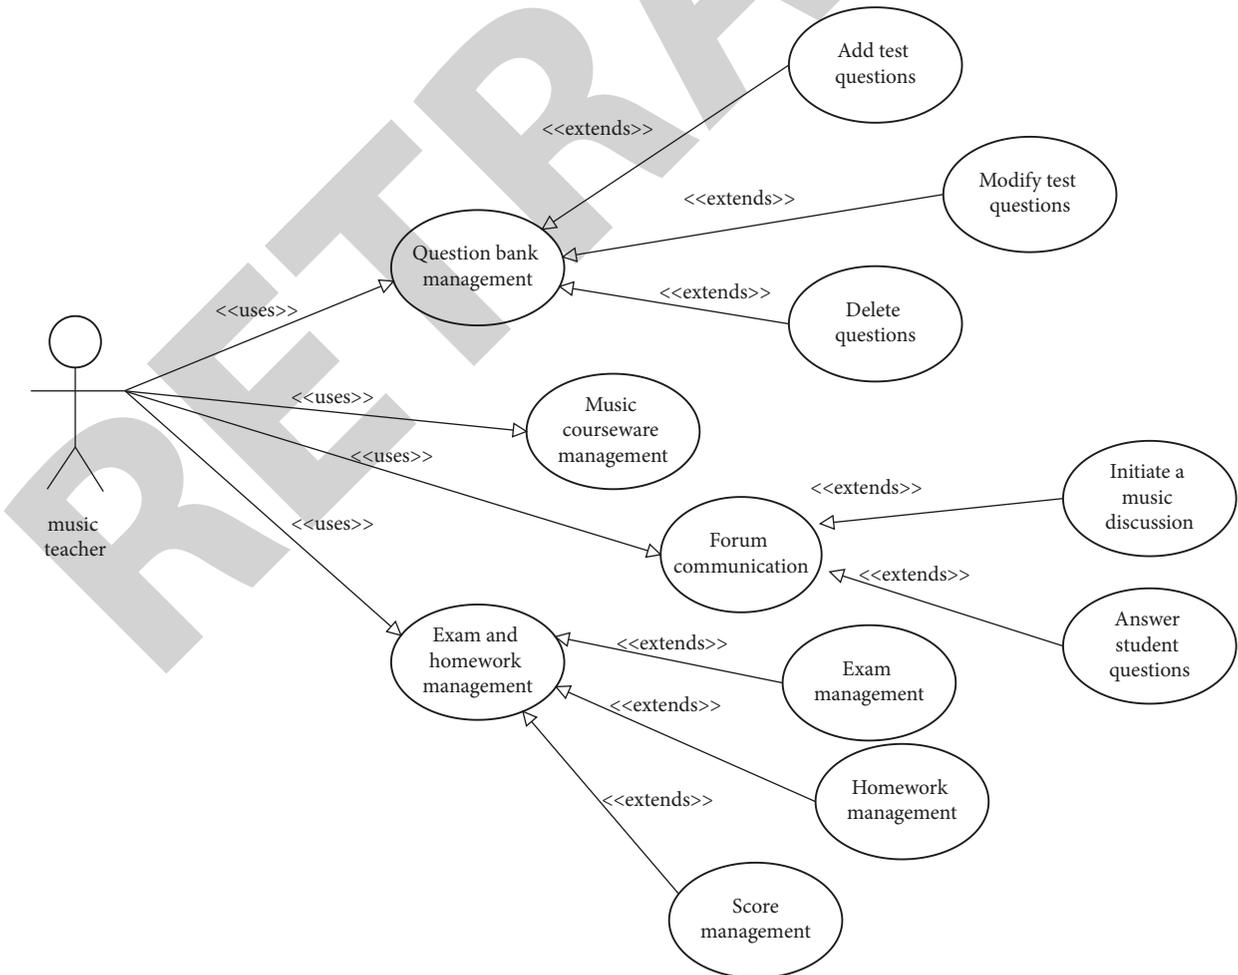

FIGURE 3: Music teacher use case diagram.

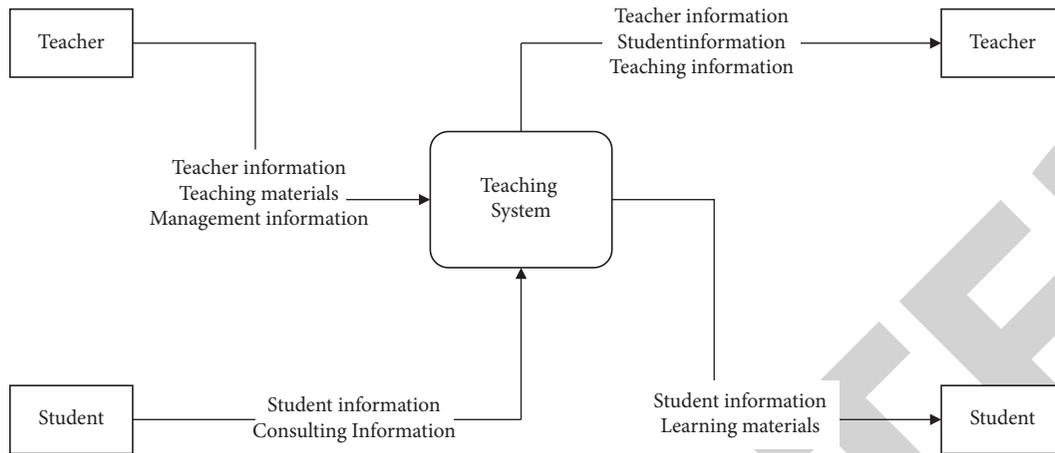

FIGURE 4: System top-level data flow diagram.

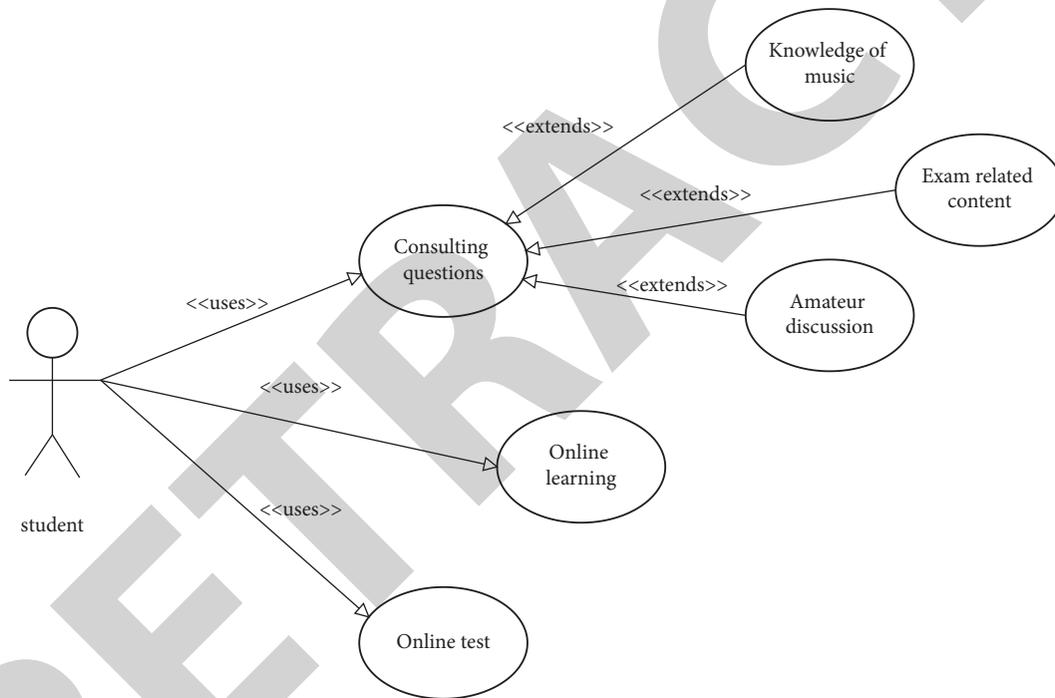

FIGURE 5: Student use case diagram.

misoperation, the system must have good fault tolerance capabilities, such as error prompts and automatic rollbacks, and both security and reliability must be guaranteed during the fault tolerance process.

Versatility: the system cannot be limited to a specific browser access form to meet the needs of learners and operators' operating habits;

Openness: the system adopts a standardized processing form and provides a good extension interface in the research of music teaching curriculum setting to ensure that the system can be used in multiple platforms and environments.

Timeliness: as long as there is a network, the learning and management of music-related courses and knowledge can be carried out at any time.

Stability: we use a data management system to achieve data management, use J2EE technology and MVC design pattern to achieve system development, and ensure the stability of system operation.

The music teaching assistant management platform has the characteristics of real-time communication, functional versatility, and object openness.

4. Design of the Music Teaching System

4.1. Overall Design. The overall design of the system includes functional structure design and architecture design, which can generally be simplified as a modular design. When carrying out modular design, not only should the entire system be divided into components, but also the

communication between modules, module continuity, module protection, module solvability, and module combination should be designed. If you want to improve the continuity principle, you need to maintain the black box characteristics between modules, which are transparent to other modules. If the protection of the module needs to be improved, it is necessary to protect the variables inside the module to prevent the misuse of other modules, and special consideration should be given to the exception handling of the module.

When carrying out the modular design of the system, it is necessary to meet the loose coupling between modules and the high cohesion characteristics within the modules. Modules must be able to function independently to complete the design, but the size of the modules needs to be controlled. The nature of modules can be summarized as interchangeability, pluggability, and boundedness, which mainly include three aspects: (1) When the internal requirements of a module change, the changes do not affect the normal operation of other modules; (2) When a module needs to be deleted, only the functions handled by this module are affected; (3) If a new module implements the same function and has the same operation interface, it will not affect the operation of the entire system after replacement.

4.1.1. Functional Structure Design. The music-assisted teaching management system is mainly composed of modules such as information release, official document management, teaching resource management, auxiliary teaching management, and system management. The information release module is further divided into school news, notice announcements, and BBS. Document management, document receipt management, and filing management; teaching resource management includes courseware management such as music videos, homework management, and music knowledge management; auxiliary teaching management is divided into course management, online examinations, Q&A discussions, and performance analysis; system management is divided into teachers student management, system settings management, log management, and auxiliary decision-making management. The functional structure of the music-assisted teaching management system is shown in Figure 6.

4.1.2. Architecture Design. The design of the music teaching assistant management system adopts a three-tier system structure. The architecture of the system is mainly divided into three layers: Web Server layer (display layer), Application Server layer (control layer), and Database Server (data access layer). The display layer is mainly composed of the Web UI Layer and Web Service Layer, using JSP and other technologies to achieve interaction with the client; the control layer mainly uses the core frameworks such as Spring to complete the business logic processing of the auxiliary teaching system, calls the data access layer to process the business request sent by the client, and displays the processing result to the user. The specific form of interaction is displayed to the client for users to view and browse; the data

access layer mainly realizes the interaction between the business logic layer and the database, preventing business requests from directly accessing the database, causing data inconsistency, and ensuring data security and integrity.

4.2. Database Design. In the process of information service, information management, and resource development, system users and design developers have concluded an important experience that database technology is the most effective way to manage data. With the advancement of network technology and computer technology, data management through databases has become an important consensus. In order to complete the sharing, integrity, and consistency of system data, both large-scale management systems and small-scale transaction processing are using database technology to complete data management. At present, the important criteria for measuring the degree of a country's informatization construction are the frequency of database use, the amount of database information, and the scale of the database.

4.2.1. Database Design Principles. The database design of the music-assisted teaching management platform mainly serves the business knowledge base of music-assisted teaching management. Through the management of the database, the processing of knowledge data and business data is optimized. When designing a database, the following aspects are considered important criteria:

- (1) Verification is based on database design specifications, and data structure design is carried out in a standardized form to ensure the consistency and normal operation of data operations.
- (2) Normative naming: the naming specification is helpful for unified management and upgrades maintenance in the later stage. Therefore, when designing databases and tables, the naming must strictly follow the normative standards and annotate all column information.
- (3) Data redundancy and the standardization of data paradigms will affect the retrieval speed of later data. Therefore, when designing data tables, it is necessary to master various degrees in order to achieve the highest value of retrieval and reduce system response time.
- (4) Security: strict identity authentication management is implemented, and users with different permissions have different degrees of access to data and operations to improve data security.
- (5) Concurrency control: through the use of triggers and stored procedures, the simultaneous operation of the table is strictly controlled to ensure the control of simultaneous modification access, and reduce data inconsistency, and the query can be exempted from this control. Through the above analysis, it can be seen that when designing the database of the music teaching assistant management platform, in order to

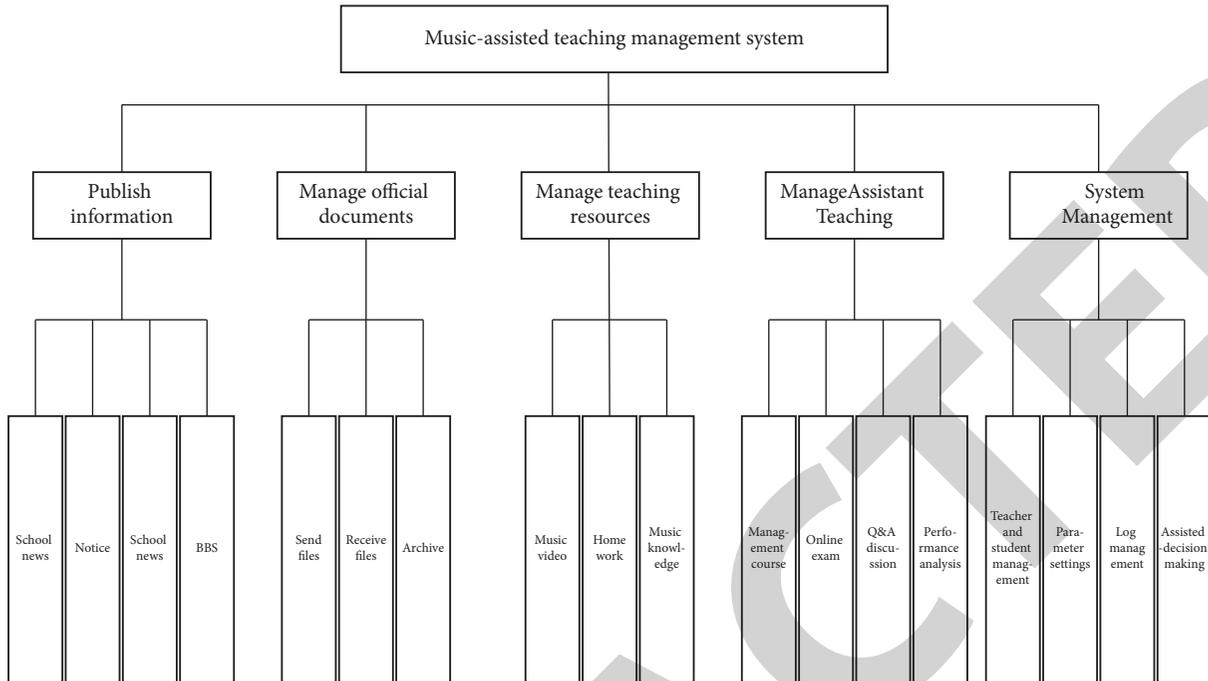

FIGURE 6: System function structure diagram.

realize the BC paradigm mode, the third paradigm should be used as the main basis.

4.2.2. *Conceptual Structure Design.* The conceptual schema design of the database is to abstract the existing data. Abstraction refers to the man-made processing of concepts, affairs, and relationships between people, extracting common features that are needed, and ignoring unnecessary parts. The extracted features are described in detail and finally form a certain model structure. This system adopts SQL Server2005 as the database development tool to realize the design and realization of a relational database.

5. Summary

This dissertation mainly studies and expounds on the design and development of the music teaching assistant system. First of all, this thesis analyzes the development significance, application, and development feasibility of the interactive multimedia network teaching system from the background and feasibility analysis. In the requirement analysis stage, the analysis of the system needs and the compilation of related manuals is to list all the requirements of the user for the system to be designed, to establish the model of the music teaching assistant system to be developed, and the design and implementation of its functions to facilitate the development of this system. Let our software design team have a very thorough knowledge of the functions to be completed by the entire software so that we can know what to do when developing and designing, which is beneficial to software development and development progress control and quality control. In addition, it also provides a basis for further upgrades in the future, so that the corresponding

deficiencies can be quickly located during the upgrade, and the development cycle of software upgrades can be improved. The development of this system has reached a good level in function and technology, but it still has its own defects. First of all, it is not perfect in terms of module functions, and secondly, some functions are not considered enough, but I believe that through the continuous improvement of our team, this system will eventually be put into practical use.

Aiming at the problems of low accuracy and large limitations of the current personalized course recommendation method in the educational big data environment, a personalized course recommendation method based on learner interest mining in the educational big data environment is proposed. First, a corresponding online course recommendation model framework is proposed by adopting GRU, which can effectively solve the problems of gradient disappearance and gradient explosion in the process of training the RNN neural network. Then, by introducing an auto-regressive language model, XLNet (Generalized Autoregressive Pretraining for Language Understanding), the information missing problem under the Mask mechanism in the BERT model is effectively optimized, and bidirectional prediction is achieved. Finally, by introducing a temporal attention mechanism into the model, enough attention is assigned to highlight local important information on key information, which improves the quality of hidden layer feature extraction, and a high-accuracy personalized course recommendation based on learner interest mining is realized. The proposed algorithm is compared with the other three collaborative filtering algorithms and the RNN algorithm through simulation experiments. The results show that the precision, recall, and $F1$ -measure of the proposed algorithm in the personalized course recommendation results for different types of courses under the condition of the same database are all optimal. The largest values were 92.1%, 89.3%, and 90.7%, respectively. The overall performance is better than other comparison algorithms. This method can improve the accuracy and optimization limitations of personalized courses and can fully tap the interests of learners. It is of great significance for learners to choose personalized courses in the current educational big data environment.

1. Introduction

Since entering the twenty-first century, people's production and lives are changing with each passing day under the influence of the Internet. In terms of education, learners' learning methods have also undergone great changes. The "education informatization" and "Internet + education" are just bred under the new trend of the Internet, and are also the only way for future educational development [1–3]. Education under the Internet environment helps to promote the development of personalized education and promotes the reform of the education system and education mode. The personalized education concept that varies from person-to-person breaks the traditional education and teaching methods. At the same time, various educational institutions also take this opportunity to build online learning platforms,

constantly enrich high-quality educational resources, and provide students with more convenient learning experiences and high-quality online learning courses. Supporting education modernization through education informatization, unremittingly helping the innovation and development of education, forming a new education service system, and creating a new mode of integrated development of online and offline education [4–6].

The widespread sharing of a large number of high-quality curriculum resources under the internet environment provides convenience for learners. Learners can arrange learning according to their own time to meet their personalized learning needs [7, 8]. However, online learning has changed people's learning styles, which also shows some disadvantages. There are three specific problems. First, at present, there are many kinds of courses on the online

learning platform. Different courses are often classified by simple labels and course names, and the unstructured text information in the course description is not fully utilized, resulting in an unclear classification of courses [9, 10]. Second, in view of the rapid development and expansion of the online learning platform, the learning resources on the platform are gradually accumulated. In order to increase the activity of the platform, some online platforms simply pursue the number of courses on the platform and do not do good supervision on the quality of resources on the platform, resulting in the poor quality of some course resources on the platform. Because these inferior resources are not filtered, it has a great impact on the learning effect of the learners [11, 12]. Third, for the learners of the course, the online learning platform cannot provide targeted learning guidance and personalized recommendation to the learners based on the user's learning style preference and the similarity between the course content and the prerequisites of the course. As a result, users often lose their direction when faced with many online courses and cannot quickly find which courses they need. It ultimately reduces the user's learning experience and learning efficiency [13–15]. Therefore, in view of the above problems, this paper proposes a personalized course recommendation method based on learner interest mining in the educational big data environment to solve the problem of low accuracy and limitations of the personalized course recommendation method in the current educational big data environment.

2. Related Works

Aiming at the problems existing in the current network education field, it is an important work in the field of intelligent education to study how to fully mine and explore the valuable data of the online education platform and find the relationship between learners and learning resources. On this basis, we accurately recommend the required courses for learners by using multi-source heterogeneous learning behavior data [16, 17]. Reference [18] calculated the importance of external attribute tolerance and internal attribute quality value on the course and built the LDA user interest model on this basis to calculate the user's preference for the topic and realize the recommendation of personalized learning resources. However, this method does not actually divide the user's access sequence into different interest segment sequences according to time, so the recommendation accuracy is low. Reference [19] developed an ontology-based hybrid filtering system framework for the recommendation and selection of higher education courses in universities, that is, ontology-based personalized course recommendation. This method is used for personalized course recommendations according to users' personal needs. However, this method is slow in computation and weak in generalization. Reference [20] designed a personalized online education platform based on a collaborative filtering algorithm by applying the recommendation algorithm in the recommendation system to the online education platform. This method is based on the hybrid programming mode of

cross-platform compatible HTML5 and a high-performance framework. But this method does not give a new personalized recommendation algorithm. It is inefficient for a large-scale online learning system. Reference [21] proposed a deep learning method of recommending MOOC (massive open online courses) to students based on the multiattention mechanism of learning record attention, word-level review attention, sentence-level review attention, and course description attention. This method integrates multiple data sources, takes students' learning behavior as the basic basis, and realizes personalized course recommendations. However, the computational efficiency of this algorithm will decrease significantly with the increase in data volume, and it cannot be well applied to the case of sparse data. Reference [22] studied and analyzed the English course recommendation technology by combining the bee colony algorithm and the neural network algorithm. Through the deep learning model, the document vector was used to train the acquired text, and the collaborative filtering method was used to realize the recommendation of user courses. However, this method has limitations when it is used in large-scale E-learning systems due to the complexity of computing requirements. Based on the recommendation standard of traditional MOOCs, reference [23] constructed the ontology model of learning participants for the matching process of the personalized recommendation system introduced by MOOC. This method comprehensively considers the knowledge level, ability, and learning speed of learners. However, this method is difficult to obtain the prior distribution, and it is difficult to characterize the high-dimensional semantics of users. Reference [24] analyzed the research status of robust recommendation technology based on the text vector model and support vector machine and constructed the corresponding sustainable economic learning curriculum recommendation model. However, the recommendation accuracy of this method is low and needs further improvement.

Based on the above analysis, a personalized course recommendation method based on learner interest mining in the education big data environment is proposed to solve the problems of low accuracy and large limitations of the personalized course recommendation method in the current education big data environment. The basic ideas are as follows: ① using GRU to solve the problems of gradient disappearance and gradient explosion in the process of RNN training. ② Based on the autoregressive language model XLNet, the bidirectional prediction is realized by learning the sequence feature information of different sorting. ③ Time attention mechanism is used to calculate the probability weight of the word vector at different times through the probability weight distribution so that the important words get more attention. Compared with the traditional personalized course recommendation method, the innovation points of the proposed method are

- (1) The GRU-coded module can reduce parameters while obtaining the equivalent result value and eliminate the gradient disappearance and explosion problems in the training process.

- (2) Using the autoregressive language model XLNet, the problem of missing information under the Mask mechanism in the BERT model is effectively optimized.
- (3) The temporal attention mechanism is used to allocate sufficient weight to improve the quality of feature extraction of the hidden layer.

3. Personalized Course Recommendation Method Based on Learner Interest Mining in the Education Big Data Environment

3.1. *Model Framework (XATGRU)*. A recurrent neural network (RNN) is a kind of a time recurrent network, which can be regarded as the result of the same neural network structure circulating on the time axis many times. Compared with other deep neural networks, RNN is better at processing sequence data because of its structural characteristics. Theoretically, RNN can process any length of time series data, but in practical application, it is found that gradient disappearance and gradient explosion will occur in the process of RNN training. This is because the traditional RNN model tends to update in the right direction according to the weights at the end of the sequence. Small GRU parameters reduce the risk of overfitting, and the GRU solves the problems of gradient disappearance and gradient explosion in the process of RNN training neural network and can retain the information from a long time ago. The network structure of GRU is generally similar to that of RNN, but the structure of the hidden layer is more complex. The online course recommendation model framework based on GRU is divided into input, processing, and output sections according to functions, as shown in Figure 1 below.

The input part is mainly to convert the records that the user initially learned into the data format needed for GRU network computing, that is, the vector representation of each user's learning course. The processing part mainly processes the input data through the GRU network and then obtains the output result. It is necessary to determine the structure of the GRU network, including the total number of layers, the step length of time, and the connection settings between layers. This paper takes the number of courses as the number of eigenvalues, which defines the dimensions of input data and output data, namely the number of neurons in the input layer and output layer. The length of the user's learning sequence determines the time step required for each calculation. The maximum time step is defined as the maximum value of the user's learning sequence. At the same time, the length of the sequence should be specified when reading each user's learning sequence. Thus, the structure of the entire GRU network model is clear. The Softmax layer maps the value of the output vector of the GRU processing layer to the (0, 1) interval, and the output part can take the last dimension of the Softmax layer processing result to determine the final recommended course vector. Because the role of the softmax layer is to convert the output results of the neural network, the output results are expressed in the form of probability.

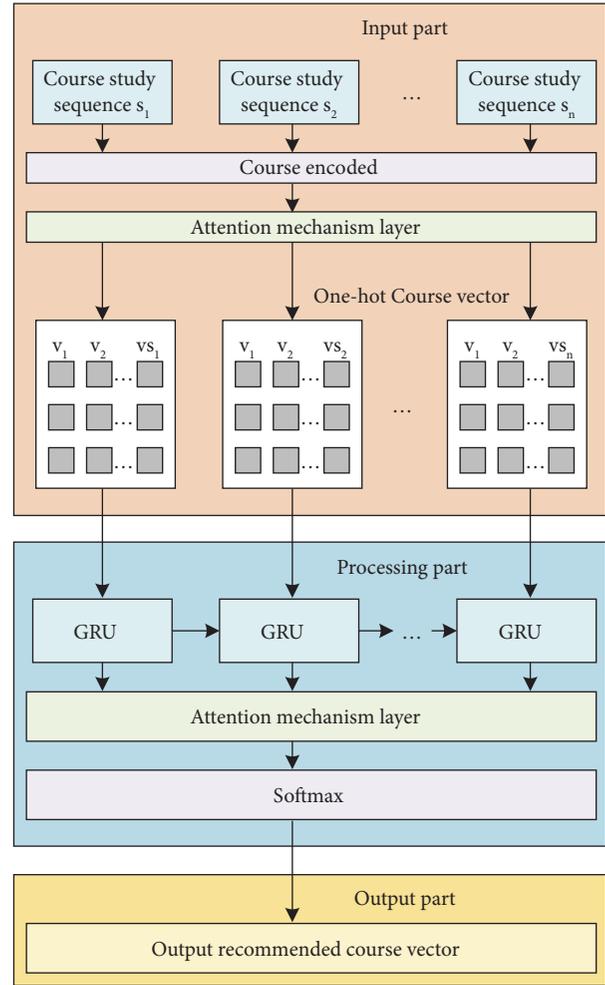

FIGURE 1: Personalized course recommendation model framework.

3.2. *XLNet Pre-Training Model*. Unsupervised learning models are divided into Auto-Regressive (AR) language model and Auto-Encoding (AE) language model. Different from the traditional AR language model, the AE language model represented by BERT realizes bidirectional prediction. XLNet realizes bidirectional prediction based on the AR language model. Its core idea is to rearrange the input sequence through the Attention Mask matrix in Transformer. At the same time, it does not change the original word order, and effectively optimizes the information missing problem under the Mask mechanism in the BERT model. Because the mask mechanism in the pretraining stage mainly predicts the words out of the mask by masking some words. The Mask mechanism of XLNet is shown in Figure 2.

In Figure 2, the light-colored circle indicates that the model can take its position information into account, and the dark-colored circle indicates that the model cannot take the position information into account. Taking the input vector $x = (x_1, x_2, x_3, x_4, x_5)$ as an example, a rearrangement combination of x is represented by $\tilde{x} = (x_3, x_2, x_5, x_4, x_1)$. As for the vector \tilde{x} , since x_3 is located at the first position of the sequence, other word information cannot be used, and only the previous implicit state

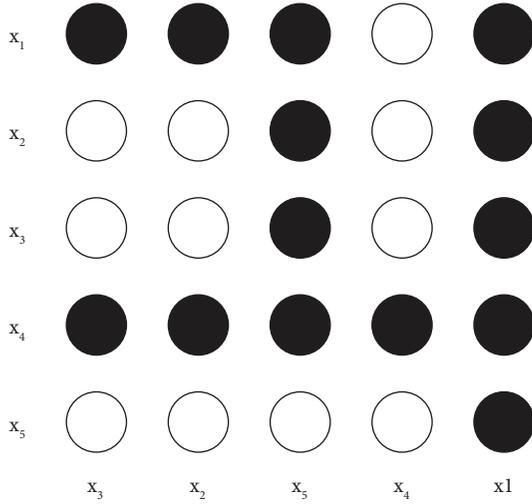

FIGURE 2: The realization principle of the Mask mechanism of XLNet.

information can be used. x_5 is located at the third position in the sequence, and the first three position information can be used.

Given that the sequence length is A , the total number of sorting methods $n = A!$. The model can learn various contexts through n various sorting methods. In practical application, XLNet randomly takes samples of partial permutation in n . The formula of the full permutation model is shown in the following formula:

$$\max(\alpha) S_{w \sim W_A} \left[\sum_{a=1}^A \lg P_{\alpha}(x_{w,a} | X_{w < a}) \right], \quad (1)$$

where S represents the sequence set. $w \sim W_A$ represents all possible text arrangements. $x_{w,a}$ represents the current word. $X_{w < a}$ represents the previous words of $a - 1$. P represents the probability that the prediction result is the current word. α represents a parameter.

The core of XLNet is Transformer-XL, which introduces the idea of relative position encoding and recurrent mechanism on the basis of transformer structure. The transformer specifies that the input sequence is a fixed length sequence in the training. After the long sequence is segmented in the training, the model cannot make use of the links between the segments, which will cause the problem of missing information. Transformer-XL inserts implicit state information between segments. The prediction of the current segment can use the information of the previous segment through implicit state information, so the model can learn more long-term semantic information. The information transmission mode of the recurrent mechanism between the two segments is shown in Figure 3.

In Figure 3, the red dotted line represents the memory information. The cache information from Segment 1 can be used in Segment 2 training. XLNet realizes the transfer of historical information through this mechanism.

The Transformer encodes the absolute position into a vector in the form of a sine function. The upper layer can learn the relationship between the relative positions of two

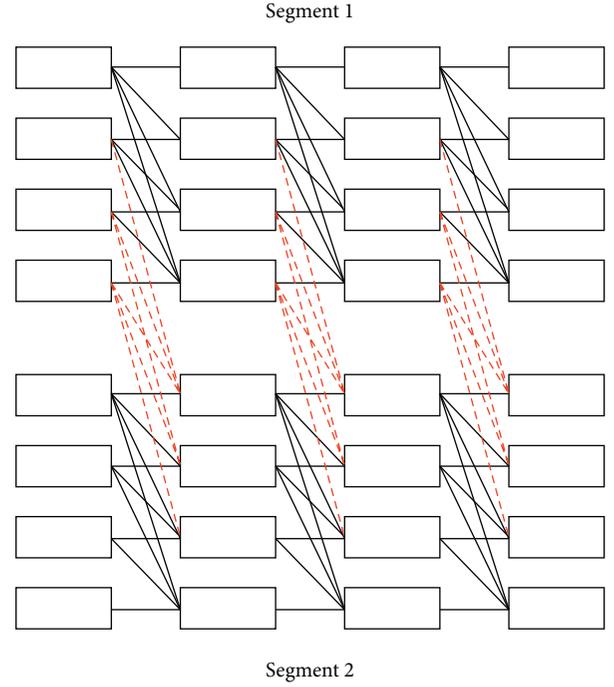

FIGURE 3: Information transmission mode of recurrent mechanism between two segments.

words through this vector. The calculation formula is shown in the following formula:

$$\begin{cases} e_{t+1} = f(e_t, L_{t+1} + U_L), \\ e_t = f(e_{t-1}, L_t + U_L), \end{cases} \quad (2)$$

where e_t represents vector encoding at time t . L represents the position encoding of the current segment text vector. U_L represents the position code, which is the same in different segments. The model cannot accurately determine the specific position of each segment through vectors. The absolute position code is the same for the same position encoding of each segment, while Transformer-XL can use the historical information of different segments. Considering that different segments and words with the same position code have different information contributions to the current segment, Transformer-XL uses the idea of relative position encoding, which calculates the relative distance according to the current position and the position to be used when calculating attention.

Taking the Transformer-XL framework as the core, XLNet can obtain more accurate word vector representation by introducing the recurrent mechanism and relative position encoding. XLNet considers bidirectional semantic information and mining long-term historical information.

3.3. Data Normalization. The neural network usually needs to normalize the input data before calculation to limit the data to a certain range, which ensures that the model can converge quickly and have the same metric for data characteristics. Here, One-Hot encoding is used to normalize the input data. The one-hot encoding adopts binary vector form,

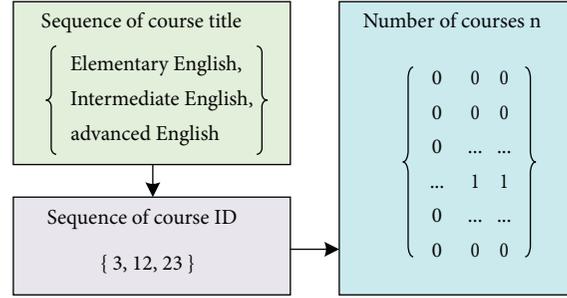

FIGURE 4: Data normalization.

so courses need to be mapped into integer values. That is, each course corresponds to a course number. Then, the course number is represented as a binary vector. The value of the element whose subscript is the number in the vector is marked as 1, and the other elements are all 0. For example, $\{0, 0, 1, 0, \dots, 0\}$ represents the course whose course number is 3. First, the original learning records of users in the database are read and converted into the format of the user's course sequence. Then, each course in the course sequence is represented by a vector. The method of representing the user course sequence by vectors is shown in Figure 4.

3.4. GRU. GRU is a variant of RNN and has fewer parameters than LSTM. The basic structure of GRU is shown in Figure 5.

The data update formula of the basic unit in GRU is shown in the following formula:

$$\begin{cases} g(t) = \sigma[\omega(g)x_t + U(g)h_{t-1}], \\ c(t) = \sigma[\omega(c)x_t + U(c)h_{t-1}], \\ h_{0t} = \tanh[c(t) \circ U h_{t-1} + \omega x_t], \\ h_t = [1 - g(t)] \circ h_{0t} + g(t) \circ h_{t-1}, \end{cases} \quad (3)$$

where $g(t)$ is the update unit module, which is responsible for determining how much h_{t-1} pass to h_t . If $g(t) \approx 1$, h_{t-1} will almost be directly copied to h_t . On the contrary, if $g(t) \approx 0$, it will not be directly passed to h_t . The reset gate $c(t)$ determines how much of the previous memory module information will flow to the current h_t . The symbol \circ represents the operation of dot product. Compared with LSTM encoding, GRU encoding modules not only have fewer parameters but can also obtain equivalent result values. The bidirectional GRU module can not only use the past information but also combine the future word information.

3.5. Attention Mechanism. The attention mechanism is outstanding in speech recognition, machine translation, part of speech tagging, and other serialized data. The attention mechanism can be used alone or as a layer of other hybrid models. It can be placed after the text vector input layer or after the training data of other network models. Through automatic weighting transformation of the data, connecting

two different parts to make the whole system perform better and highlight keywords. The attention mechanism is like the principle that the human brain observes something, such as people observing a painting in order to describe the content of some paintings. They will first observe the words in the title of the picture, and then they will observe the part of the picture that expresses the theme purposefully according to their judgment. When describing this painting, people often describe the most relevant content of this painting first, and then describe other aspects. The attention mechanism is a mechanism that highlights local important information by allocating sufficient attention to key information. It can generally be divided into two types: temporal attention mechanism and spatial Attention mechanism. The temporal attention mechanism is mainly used here. The attention mechanism is a kind of attention resource allocation mechanism similar to the human brain. It calculates the probability weights of word vectors at different times through probability weights, so that some words can get more attention and finally improve the quality of feature extraction of the hidden layer. The basic structure of the attention mechanism is shown in Figure 6.

4. Experiments and Analysis

4.1. Experimental Environment and Dataset. The relevant parameters of the simulation experiment environment are shown in Table 1.

The experimental dataset comes from the actual operation data of an online teaching website, with 14370 users and 816 courses, it is mainly related to some courses related to computer subjects. The data mainly includes the user's learning records and scoring records. From May 2018 to July 2021, a total of 157825 records were recorded. Among them, the training set accounts for 80%, a total of 126260 records, and the test set account for 20%, a total of 31565 records.

4.2. Evaluation Index. The performance of the model is measured by the results of the model extraction and the actual results. The evaluation indexes include precision (P), recall (R), and $F1$ -measure ($F1$). The calculation methods of different evaluation indexes are shown in the following formulas (4)–(6).

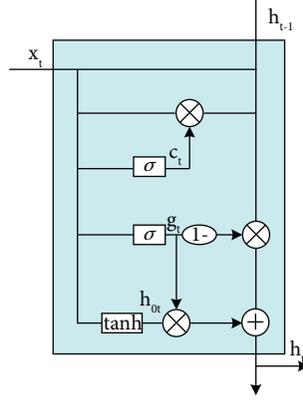

FIGURE 5: Basic structure of GRU.

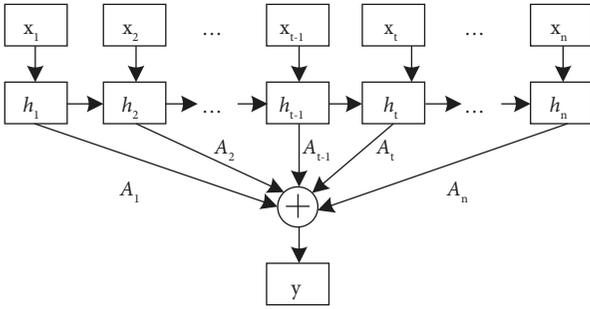

FIGURE 6: The basic structure of the attention mechanism.

$$P = \frac{S_T}{S}, \quad (4)$$

$$R = \frac{S_T}{S_G}, \quad (5)$$

$$F1 = 2 \cdot \frac{P \cdot R}{P + R}, \quad (6)$$

where S_T is the number of knowledge entities and relationships correctly identified by the model. S is the number of knowledge entities and relationships identified by the model. S_G is the number of all labeled knowledge entities and relationships.

4.3. Model Training. In order to verify the effect of our model, the comparison model is the classical Pipeline model. The experimental results on the dataset are shown in Table 2.

The overall $F1$ of the two models is shown in Figure 7.

From the above experimental results, it can be seen that for the task of entity recognition and relationship extraction, the proposed personalized course recommendation model XATGRU based on learner interest mining in the education big data environment has improved in precision, recall, and $F1$ -Measure compared with the Pipeline model.

4.4. Experimental Comparison and Analysis. In the following, the personalized course recommendation method

TABLE 1: Simulation experiment environment parameters.

proposed in this paper is compared with the collaborative filtering algorithm in reference [20, 21, 23]. The indexes of recommendation results of different methods under the same dataset are shown in Table 3.

The following is a comparative analysis of the personalized course recommendation method proposed in this paper and the RNN algorithm. The indexes of recommendation results of different methods under the same dataset are shown in Figure 8.

It can be seen from Table 3 and Figure 8 that when the same database is used, compared with the collaborative filtering algorithm in reference [20, 21, 23] and the traditional RNN algorithm, the precision, recall, and $F1$ -Measure of the proposed algorithm for personalized recommendation results of different types of courses are optimal, and the maximum values are 92.1%, 89.3%, and 90.7%, respectively. This is because the introduction of GRU solves the problems of gradient disappearance and gradient explosion in the training process. The XLNet model based on autoregressive language is used for bidirection prediction. The missing information caused by the Mask mechanism in the BERT model is effectively optimized and greatly improves the accuracy of personalized course recommendations.

5. Conclusion

In view of the low accuracy and large limitations of personalized course recommendation methods in the current education big data environment, a personalized course recommendation method based on learner interest mining in the

education big data environment is proposed. The proposed method is verified by simulation experiments. The results show that the network structure of GRU is more complex, but it can effectively solve the gradient disappearance and gradient explosion problems in the training process of RNN, and the number of parameters is small, which can reduce the risk of overfitting. This neural network can improve the accuracy of personalized course recommendation methods and solve the problem of large limitations. XLNet based on the autoregressive language model can effectively optimize the information missing problem under the Mask mechanism in the BERT model and realize bidirectional prediction. The temporal attention mechanism can change the importance of different words by means of probability weight distribution, thus improving the quality of feature extraction in the hidden layer and the accuracy of personalized course recommendations. This method is of great significance to solve the problem of low accuracy and limitations of personalized course recommendation methods in the current educational big data environment. Future work will further study the relationship between course reviews and courses. On this basis, consider mining the information from course reviews to discover the relationship between courses from a diversified perspective and to achieve more accurate personalized course recommendations.

In recent years, because of the popularity of the internet and mobile devices, the dissemination of new media in social networks has attracted extensive attention from scholars and the industry. Scale prediction or propagation speed prediction is to use the initial data to predict the propagation scale of the network. In the complex and changeable social network, how to accurately predict the cascading scale of new media information is the biggest problem at present. In the process of new media information transmission, because of the role of new media information transmission in guiding public opinion, the current hierarchical model of new media information transmission lacks the overall and local models. To solve this problem, a global structure modeling method is proposed. In addition, because of the uncertainty of new media information dissemination, a method of bidirectional recurrent neural network prediction and algorithm complexity is used, and a new method based on large-scale graph neural network is constructed. A prediction method of new media information dissemination speed and scale based on large-scale graph neural network. Through comparative experiments with previous research models, it is found that the NWIDF model constructed in this paper has a good prediction effect.

1. Introduction

In recent years, the modeling and prediction of new media information cascade has attracted extensive attention in the academic field and industry [1]. In recent years, with the improvement of computing power, prediction models based on deep learning have been successful in many tasks.

Existing models based on deep learning can be roughly divided into three categories: (1) models based on information content, such as text, image, video, and other multimedia content, which usually use technology from the field of computer vision and natural language processing to learn the effective representation of information content. (2) Based on time series model, it relies on recurrent neural network, pooling mechanism, and attenuation mechanism to linearly model the information cascade in social networks and [2] (3) model based on the graph structure, such as information cascade graph or global graph. As per reference

[3], these models typically use graph neural networks and graph representation learning techniques to learn efficient structures of nodes, edges, and graphs to represent information. Other deep learning technologies, such as variational reasoning and reinforcement learning, are also used for information cascade scale prediction. In many cases, multimode, multiscale, and multitask learning techniques can be used to improve prediction performance. Deepcas [4] is the first model to model and predict the scale of information cascade using graph representation learning technology. It borrows the idea of deepwalk model [5] and uses the random walk method to sample the information cascade graph. The sampled node sequence is input into the bidirectional gated loop unit [6], and then the node embedding is obtained in cooperation with the attention mechanism [7]. The prediction of the deepcas model is end-to-end, and therefore, it does not depend on the manual functional design. Subsequently, in document [8], the author proposed

the dcgt model, which adds the modeling of node content to deepcas. The purpose of the deephawkes model [9] is to combine the advantages of the generated model with the advantages of deep learning technology, so as to simultaneously consider the predictability and good prediction performance. The ANPP model [10] uses glove [11] for the text embedding of information content and node2vec [12] for user graph embedding. ANPP uses the attention mechanism to aggregate the obtained representations and time-series feature vectors. The Dtcn model [13] predicts the popularity of Flickr images by learning user and image embedding, pore context of shared sequences, and multistep temporal attention mechanism. The dtcn model uses RESNET [14] and long-term and short-term memory artificial neural networks [15] to simulate the visual and temporal dependence of pictures, respectively. The recursive cascade convolution network [16] regards the information cascade graph as a series of subinformation cascade graphs, and then, it uses the dynamic multidirectional graph convolution network to learn the structural information of the information cascade.

Although the model based on deep learning has achieved good results in the information cascade prediction task, it also faces many limitations and challenges. The computational consumption of the deep learning model is generally greater than that of the other two types of models. To obtain satisfactory prediction results, engineers usually need to perform complex parameter optimization and model training and face the risk of data overfitting. At the same time, in the prediction of the cascade scale of new media information, there is a lack of modeling of global and local communication structures, ignoring hierarchical modeling, and it is unable to cope with changes and uncertainties in the process of information dissemination. Therefore, the article starts from this angle, and relevant research is carried out.

2. Related Work

The modeling and prediction of new media information cascades have attracted extensive attention in academia and industry in recent years [1]. In recent years, with the improvement of computing power, prediction models based on deep learning have been successful in many tasks.

Existing deep learning-based models can be roughly divided into three categories: (1) models based on information content, such as text, images, videos, and other multimedia content, these models usually use technologies from the fields of computer vision and natural language processing to effectively represent the content learning of information; (2) time-based models of sequences, which linearly model information cascades in social networks and rely on techniques such as recurrent neural networks, pooling mechanisms, and attention mechanisms [2]. (3) Models based on graph structures, such as information cascade graphs or global graphs, etc. [3], usually use graph neural networks and graph representation learning techniques to learn effective structural representations of nodes, edges, and graphs. Other deep learning techniques, such as variational inference, reinforcement learning, etc., are also

used in information cascade scale prediction. In many cases, techniques, such as multimodal, multiscale, and multitask learning, are used to improve the prediction performance. DeepCas [4] is the first model to use graph representation learning techniques to model and predict the scale of information cascades. It borrows the idea of the DeepWalk model [5] and uses a random walk method to sample the information cascade graph. The sampled node sequence is input into the bidirectional gated recurrent unit [6], and it cooperates with the attention mechanism [7] to obtain the node embedding. The predictions of the DeepCas model are end-to-end and thus do not rely on manual feature design. Subsequently, in literature [8], the authors propose the DCGT model, which adds the modeling of node content to DeepCas. The purpose of the DeepHawkes model [9] is to combine the advantages of generative models with the advantages of deep learning techniques, thereby taking into account both predictive interpretability and good predictive performance. The ANPP model [10] uses GloVe [11] for the textual embedding of information content and node2vec [12] for user graph embedding. ANPP uses an attention mechanism to aggregate the acquired representations and time series feature vectors. The DTCN model [13] predicts the popularity of Flickr images by learning user and image embeddings, sharing temporal context of sequences, and a multistep temporal attention mechanism. The DTCN model uses ResNet [14] and Long Short-Term Memory Artificial Neural Network [15] to model the visual and temporal dependencies of pictures, respectively. Recurrent Cascade Convolutional Networks [16] treat the information cascade graph as a series of subinformation cascade graphs, and then, it use a dynamic multidirectional graph convolutional network to learn the structural information of the information cascade.

Although deep learning-based models have achieved good results on information cascade prediction tasks, they also face many limitations and challenges. The computational consumption of deep learning models is generally larger than that of the other two types of models. The main reason is that deep learning learns the deep nonlinear network structure, and its essence is to approximate complex functions and represent the distributed representation of the input data. Deep learning can learn the essential characteristics of the dataset. But the problem may often involve causal reasoning, logical reasoning, and dealing with uncertainty, which is obviously beyond the ability of traditional deep learning methods. Hence, the predictions of deep learning models lack interpretability, because neural networks are essentially a “black box model.” Secondly, the computational consumption of deep learning models is generally higher than that of feature engineering-based prediction models and probability-based generation. The model should be bigger. To achieve satisfactory prediction results, engineers often need to perform complex parameter tuning, model training, and face the risk of overfitting the data. At the same time, in the prediction of the cascade scale of new media information dissemination, there is a lack of modeling of the global and local dissemination structure, ignoring hierarchical modeling and inability to deal with

changes and uncertainties in the process of information dissemination. Therefore, the paper starts from this perspective, and related research is conducted.

3. Related Theories

3.1. Bayesian Graph Neural Network. A Bayesian network is a probabilistic graphical model. By adjusting the preset parameters or the prior knowledge of the model through sample data, the parameters of the Bayesian network or the posterior probability of the model are inferred to express uncertainty. The uncertainty of the node characteristics of new media information dissemination is mainly manifested in the uncertainty caused by noise data, missing or repeated data, etc., in the process of feature extraction and the uncertainty of the relationship between different characteristics of nodes and node labels. A probabilistic graph model that can solve uncertainty through the Bayesian graph neural network identifies hot topics in new media information, compares the prediction of node labels under different features, integrates the prediction of node labels by all features, and then judges the uncertainty of node features.

In the dissemination of new media information, as the network structure is not fully known and constructed by domain experts, it usually leads to missing important edges, adding false edges and other problems, resulting in poor model prediction effect and poor robustness.

This paper needs to propose a way to add missing important edges and prune irrelevant and spurious edges. In other words, the network structure needs to be reconstructed. The Bayesian graph neural network is used to solve the uncertainty problem of the node relationship in the reconstructed network.

Generally speaking, a neural network can be regarded as a conditional distribution model $p(Y|X, W)$, i.e., the distribution of labels Y under the condition of input feature X and neural network weight W . Then, the learning process of the neural network can be regarded as maximum likelihood estimation. Based on this, the researchers proposed a Bayesian neural network [17], which, firstly, obtained the weight probability $p(W|D)$ of the neural network based on the dataset not only to find its maximum posterior value but also to be used for the neural network. Networks introduce uncertainty. The prediction Y for a new input x can be obtained by integrating the posterior distribution of W , and the process can be expressed as follows:

$$p(y|x, X, Y) = \int p(y|x, W)p(W|X, Y)dW. \quad (1)$$

However, since the posterior distribution (formula (1)) of the Bayesian neural network is often difficult to calculate directly, researchers have adopted different methods to approximate it [18–21].

This paper considers reconstructing the network structure with a random graph generation model to solve the uncertainty of the network structure.

3.2. Random Block Model. The random block model is a generative model for random graphs. The model tends to generate graphs that contain populations, i.e., subsets characterized by a certain edge density interconnected. For example, edges may be more common within a community than between communities. The stochastic block model is important in statistics, machine learning, and network science, and in graph data, it serves as a useful benchmark for the task of recovering community structure. Reconstructing the network structure in this way can aggregate nodes with strong correlations in the network, while nodes with weak correlations will have certain edges if they are directly pressed.

The random block model has the following parameters:

- (1) The number of vertices n
- (2) Divide the vertex set $\{V_1, V_2, \dots, V_n\}$ into disjoint subsets C_1, C_2, \dots, C_r called groups
- (3) A symmetric matrix P of edge probabilities

Randomly sample the edge set: any two nodes $V_p \in C_i$ and $V_q \in C_j$ are connected by an edge with probability P_{ij} .

Its generation process is shown in Algorithm 1.

The group membership of each node depends on the context, i.e., each node may have different memberships when interacting with or being interacted with by different nodes. Statistically, each node is a mixture of group-specific interactions. After the random block model is represented by a generative graph, the network can be reconstructed and applied to the graph neural network to solve the uncertainty of the network structure.

3.3. New Media Information Dissemination Mechanism. In this paper, we mainly explain the mechanism of new media information dissemination from two perspectives, namely information cascade graph and user social network (global graph).

Cascade graph: given the new media information microblog I and its corresponding forwarding information cascade C , the information cascade graph can be defined as $\zeta_c = (v_c, \varepsilon_c)$, where $v_c = \{u_i | 1 < i \leq M\}$ is a part of the user nodes participating in the information cascade, $\varepsilon_c \in v_c \times v_c$ is a set of edges with a number of $M = |C|$, representing all user interactions in the information cascade graph. A schematic diagram of a cascade graph growing over time is shown in Figure 1.

$$C(t_0) \longrightarrow \dots \longrightarrow C(t_n). \quad (2)$$

Global Graph: the global graph contains all the nodes and edges in the social network, which can be defined as $\zeta_g = (v_g, \varepsilon_g)$. The edges represent different node relationships in the information cascade. An example of a typical global graph is the user's follow du and followed network in TikTok.

In this paper, the information cascade graph represents the local propagation characteristics of information in the network, while the global graph represents the associations between nodes in the whole network. Taking TikTok as an

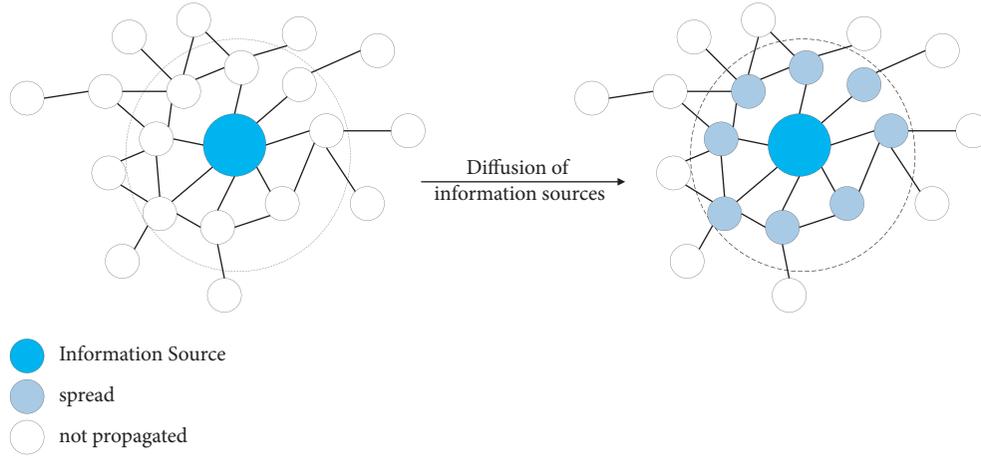

FIGURE 1: Cascading diagram of media information.

example, the following relationships, forwarding relationships, and historical behaviors among users can all be reflected in the structure of the global graph. The previous work [8–10] simply used features, such as the number of followers of the user (which can be regarded as the degree of nodes) as the structural features of the user, which cannot fully capture the user’s influence, preference, and other attributes. There are a few other works [14, 17] that use other types of structural features. But, they also all make strong assumptions about the intrinsic mechanism of information dissemination, or face the risk of overfitting on specific data, resulting in their poor generalization performance, and when migrating to other applications or data platforms (with different propagation mechanism or propagation mechanism unknown) is less effective.

4. New Media Information Dissemination and Scale Prediction Path Based on Large-Scale Graph Neural Network

4.1. The Overall Architecture of the Prediction Model. This section builds the general framework of the NWIDF prediction model. It consists of four parts: structure learning, time series propagation, new media information uncertainty propagation, and predictor. Structural learning mainly captures and models the contextualized structural patterns in information cascade graphs and the implicit relationships of users in social networks. It leverages techniques from graph signal processing to learn structural representations of information cascades: local structure modeling based on wavelet maps and user global structure modeling based on sparse matrix factorization. Temporal propagation uses a bidirectional recurrent neural network to model temporal dependencies in information propagation. The uncertain propagation of information in new media uses a variational autoencoder to model changes and uncertainties in information propagation and information growth, and it uses a regularized flow to estimate the posterior distribution of hidden variables for a series of complex and flexible transformations. The predictor combines recurrent neural

networks and variational inference to learn high-order representations of the information cascade, and finally, it uses a multilayer perceptron to make predictions about the final size of the information cascade, as shown in Figure 2.

As the core of the NWIDF model system, the new media information person is the main body of information production, transmission, processing, and management. Information people usually include are users and platforms. Users can enhance the quality impact of new media platforms by accepting feedback and continuously optimizing. New media information technology is the support of information activities. Through the collection, processing, dissemination, and feedback of information, the continuous operation of the NWIDF model system is realized.

4.2. Modeling of New Media Information Cascade Structure under Large-Scale Graph Neural Network

4.2.1. New Media Information Cascade Learning Structure. In the new media information dissemination mode, the cascade graph is introduced $C_i(t)$, which is represented as an adjacency matrix, and a self-loop is added to each node, as shown in Figure 3. Then, according to the arrival time of each node in the cascade graph $C_i(t)$, one-hot encoding (One-Hot Code) is performed to represent the node characteristics. Divide the observation window $[0, T]$ into disjoint fine l -grained time intervals, then encode each time interval.

At the t_m ($0 < m < l$) moment, the node V_i forwards to the node. Then, V_j the adjacency matrix of the $a_i^{t_m}$ cascaded graph at this moment $C_i(t)$ is 1, and the rest are 0. The adjacency matrix embedding for the cascaded graph $C_i(t)$ is encoded as follows:

$$A_i^T = \{a_1^{t_1}, a_2^{t_2}, \dots, a_i^{t_{i-1}}\}, t_j \in [0, T], j \in [1, l]. \quad (3)$$

To capture the global graph structure information in the process of cascading information diffusion in new media, we use a graph convolutional network to learn the Markov process embedded in [22] information diffusion, i.e., it will converge to a stable value after a period of diffusion. Normal distribution will converge to a stable distribution after a

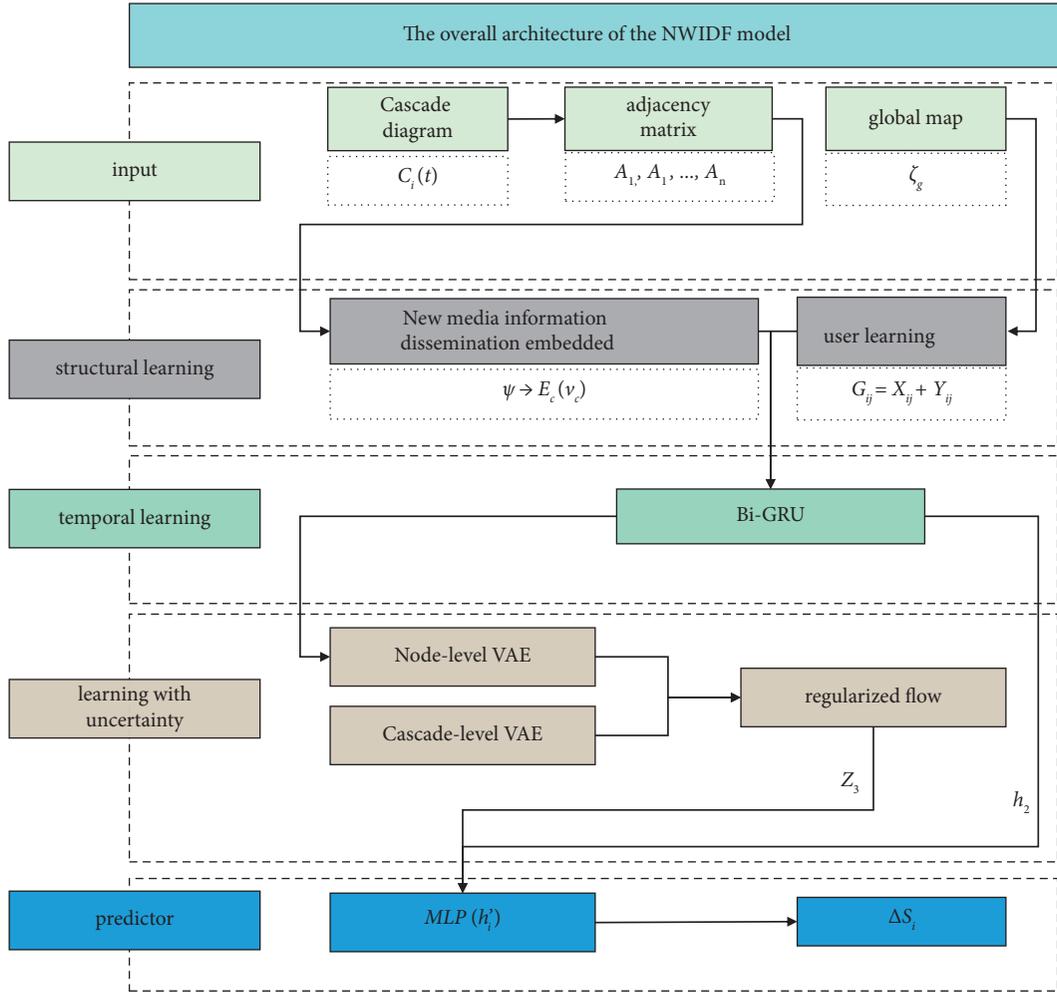

FIGURE 2: The overall architecture of the NWIDF model.

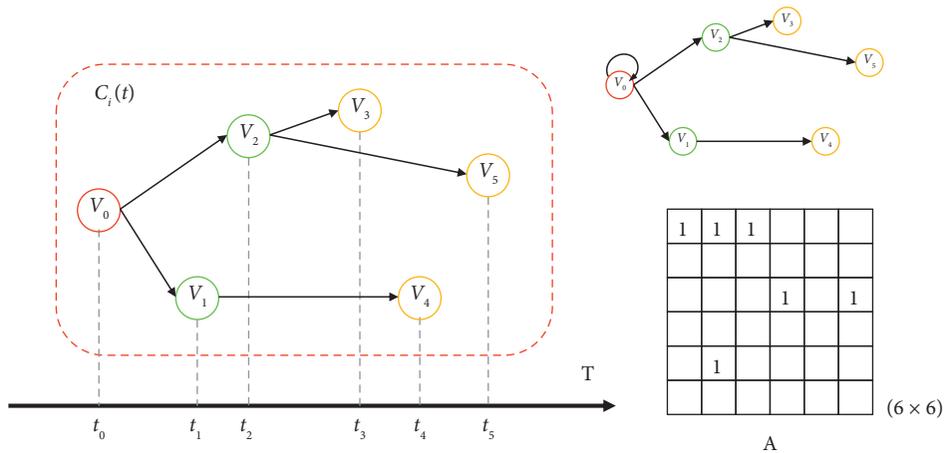

FIGURE 3: Cascaded subgraph sequence sampling representation.

period of time, similar to the normal distribution [23]. Therefore, let the cascaded Laplacian matrix Δc conform to the random walk characteristics of the cascaded graph, and

let the Markov state transition probability matrix $P = D^{-1}A$. According to the graph convolution network formula, the Laplacian matrix can be obtained Δc as follows:

$$\Delta c = D^{-1/2}(D - A)D^{-1/2} = D^{-1/2}(I - P)D^{-1/2} \approx \Phi^{1/2}(I - P)\Phi^{-1/2}. \quad (4)$$

D represents the degree matrix of the cascade graph, and K represents the number of captured neighborhood layers.

$\Lambda = \text{Diag}(\lambda_0, \lambda_1, \dots, \lambda_{M-1})$ is the eigenvalue of the adjacency matrix satisfying the condition of $\lambda_0 < \lambda_1 \leq \dots \leq \lambda_{M-1}$, where U is the eigenvalue decomposition. We can then compute $u_i \in v_i(t_0)$ the graph wavelet for each node $\Psi_{u,s}$ as follows:

$$\Psi_{u,s} = U \text{Diag}(g_s(\lambda_0), \dots, g_s(\lambda_{M-1})) U^T \delta_u, \quad (5)$$

where δ_u is the one-hot encoded vector of node u , and the filter kernel g_s is a continuous function defined on R^+ . Here, we use the Heat kernel function $g_s(\lambda) = e^{-\lambda s}$, where s is a scale parameter defined on the spectrum $(\lambda_l)_{l=0, \dots, M-1}$.

In particular, for a given node u_i and a scale parameter s , the empirical feature function is formally defined by the following formula:

$$\varphi_{u,s}(p) = \frac{1}{M} \sum e^{ip\Psi_{m,u,s}}, \Psi_{m,u,s} = \sum_{l=0}^{M-1} g_s(\lambda_l) U_{ml} U_{ul}, \quad (6)$$

where $\Psi_{m,u,s}$ is the m^{th} wavelet coefficient of $\Psi_{u,s}$. Then, the embedding of node u_i in the information cascade graph can be obtained by concatenating the real and imaginary parts.

$$E_c(u_i) = [\text{Re}\varphi_{u,s}(p), \text{Im}\varphi_{u,s}(p)]_{p1, p2, \dots, pd} \quad (7)$$

The dimension of the node embedding $E_c(u_i)$ is $d_c = 2d$, and the first element of the embedding is set as the weight of the node edge, which is defined and regularized by the following formula:

$$W_u = \frac{(t_j - t_0)}{t_0} \in [0, 1], 0 < t_0 \leq t_j. \quad (8)$$

From the perspective of sentences, the emotion of a long sentence is mainly determined by several keywords connected to the root node, and the function of other words is ignored, resulting in the lack of key information. In recent years, the rapid development of Internet+ has made the sentiment analysis of comment texts occupy a certain proportion in user-based big data analysis. Compared with the inflexibility of traditional machine learning methods, deep learning methods can be more efficient and accurate. The emotional information is contained in the text, so obtaining text emotional information through deep learning is a relatively popular research field at present, and it has achieved good research success. Since the machine cannot directly recognize the plain text input, it is necessary to vectorize the text to convert the text into a numerical form that the machine can recognize.

To solve the problem of the adjacency matrix generated by the dependency tree containing a large number of zero elements, there may be information loss and data sparseness. In this paper, a global graph matrix is

constructed, and a layer of identity matrix is added to the original adjacency matrix, which is the global graph matrix. The construction of the global matrix in this paper is shown in equations (11).

$$X_{ii} = 1, \quad (9)$$

$$X_{ij} = 1, \text{ OR } X_{ij} = 0, \quad (10)$$

$$Y_{ij} = 1, \quad (11)$$

$$G_{ij} = X_{ij} + Y_{ij}. \quad (12)$$

$X_{ii} = 1$ means that all elements on the diagonal of the adjacency matrix are set to 1, which means that each node in the graph performs a self-loop operation. The formula $X_{ij} = 1$ indicates that the i^{th} node has a directed connection to the j^{th} node. $X_{ii} = 0$ indicates that there is no connection between the $Y_{ij} i^{\text{th}}$ node and the j^{th} node, and when generating the adjacency matrix, a unit matrix is added, which means that an edge is added between each node in the graph structure to connect. This allows the graph structure to contain global dependency information. G_{ij} represents the connection of all nodes in the graph, which is the global graph matrix. This operation allows each word to play a corresponding role, avoiding data sparse and incomplete information.

Compared with the node embedding in the information cascade graph, the node embedding in the global graph expresses a very different concept of information propagation in the global graph. For the information cascade graph, whether for those influential nodes, hub nodes connecting different communities, or inconspicuous leaf nodes, nodes with similar structural positions will have similar node embeddings even if they are very far apart in the graph. This positional property is captured by the propagation mode of the graph wavelet. For the global graph, the low-dimensional continuous embeddings learned by the model preserve the neighbors of nodes in the global graph. Hence, nodes with similar preferences and behaviors will have similar spatial embeddings.

Unlike information cascade graphs, global graphs often contain up to millions of nodes and edges, making representation learning on them very difficult. Existing graph learning models [15, 18] are difficult to directly apply to practical information cascade prediction problems. The text uses sparse matrix factorization to process and model large-scale global graphs efficiently and in a scalable manner $\zeta_c \zeta_g$.

4.2.2. Temporal Propagation Build. In the above, we used graph wavelets and sparse matrix factorization to generate embeddings that encode the structural information of users in information cascade and global graphs. In particular, they are characterized by the following: (1) structurally equivalent nodes in an information cascade graph will have similar embeddings (refer to [20]). For

example, hub nodes have stronger propagation capabilities than leaf nodes. (2) Adjacent nodes in the global graph will have similar embeddings, i.e., adjacent nodes will have similar preferences for disseminating specific information.

In addition to the structural information contained in the information cascade, time series information is considered to be one of the most important features in the scale prediction problem of the information cascade, and it has a key impact on the final scale of the information cascade. To capture the temporal nature of information cascades, we use bidirectional gated recurrent units (BiGRUs) to model the cascade effects in information. Recurrent neural networks are widely used in the modeling of time series data, and they are used to model time series features in information dissemination. The calculation formula of BiGRU is shown in formulas (12)–(14), which can be expressed in the formula. The hidden state of the forward output at the moment is expressed in watts. The hidden state of the reverse output at time, Q_c , represents the hidden state of the output, ω_c represents the input, and ω_c and v_c represent the weight matrix, where b_c is the bias vector.

$$\vec{Q}_c = GRU(\vec{Q}_{c-1}, \omega_c), \quad (13)$$

$$\bar{Q}_c = GRU(\bar{Q}_{c-1}, \omega_c), \quad (14)$$

$$Q_c = \omega_c \vec{Q}_c + v_c \bar{Q}_{c-1} + b_c. \quad (15)$$

BiGRU includes the process of forward GRU and reverse GRU transfer. Bidirectional GRU can enrich the representation of contextual information based on aspect words and enhance the interaction of information in a complementary form, so that more useful information can be captured compared to unidirectional GRU. Usually, two-way GRU will also perform better than one-way GRU. Deep BiGRU is to continuously expand the depth of the neural network. On the basis of one layer of BiGRU, the method of superimposing multiple layers of BiGRU is to use the output of each BiGRU layer as the input of the corresponding node of the next layer of BiGRU.

However, only using the hidden state of the last layer of the RNN has certain drawbacks for information cascade prediction. It is because of the flat sequence generation process in recurrent neural networks, where the embedding of each node is dependent on the node embedding at the previous time. The problem is that the model is forced to generate all higher-order information in a deterministic and step-by-step manner. This setting has significant limitations for exploring uncertain dependencies in information cascades. In addition, because of the limitations of RNNs themselves, these models cannot handle long-term dependencies, and their predictive performance may drop significantly when the length of the information cascade is very long.

4.2.3. Uncertainty Modeling of New Media Information. An information cascade C consists of a growing sequence of participants, each of which is associated with a learned representation that represents a specific stage of information dissemination. In the above, for each node in the information cascade graph and global graph, we use graph wavelet and sparse matrix factorization to learn its embedding representation $E_c(u_i)$ and $E_g(u_i)$ for the node, respectively. In a more general sense, any other type of graph representation learning method can be used to enhance the learning ability of the model, for example, text and image embeddings. Without causing ambiguity, we use R_i , ($i \in |v_c|$) to represent each participant in the information cascade C , i.e., $R_i = \text{Concat}(E_c(u_i), E_g(u_i))$.

Let $\text{Enc}(\bullet)$ be the input encoder and $\text{Dec}(\bullet)$ be the reconstructed input decoder. The deep variational autoencoder based on neural network can be defined as follows:

$$\begin{aligned} z_i &= \text{Enc}(R_i), \bar{R}_i = \text{Dec}(z_i), \text{ for } i = 1, 2, \dots, M, \\ u_i &= NN(R_i), \log \sigma_i^2 = NN(R_i), z_i \sim N(u_i, \sigma_i^2), \end{aligned} \quad (16)$$

where \bar{R}_i is the reconstructed input and $z_i \in R^d$ is the hidden vector. The variational autoencoder accepts high-dimensional data as input and generates a compressed hidden representation that is sampled from a conditional prior distribution with standard deviation μ and variance $\log \sigma^2$. The original input is then reconstructed from this hidden representation.

In order to learn an efficient probability-based representation from the information cascade data, which captures the variation and uncertainty of the information cascade propagating in the network, the variational autoencoder samples $\log \sigma^2$ and μ and from the output vector of the encoder. Then, use the reparameterization trick to sample the hidden vectors from the Gaussian distribution [22].

$$z_i = u_i + \sigma_i \varepsilon, \varepsilon \sim N(0, 1). \quad (17)$$

Given a hidden random variable $Z \in R^{d_z}$ (in this paper, it is referred to Z_2 learned in higher-order variational autoencoders, the regularization flow is a class of generative models that transforms the observed vector Z into the required target hidden vector Z^k . The transformation consists of a series of K invertible mappings (invertible mappings). The Jacobian matrix of the transformation is computable, and the function is differentiable. In more detail, the regularization flow uses the mapping function $f : Z \rightarrow Z^k$, which is defined as follows:

$$q(Z^k) = q(Z) \left| \det \frac{\partial f^{-1}}{\partial Z^k} \right| = q(Z) \left| \det \frac{\partial f}{\partial Z} \right|^{-1}, \quad (18)$$

where $q(Z)$ is the distribution of the random vector Z and the transfer function f is invertible. To obtain an effective probability density $q_k(Z^{(k)})$ from the initial density $q_0(Z)$, a series of hierarchical transformations of K regularization flows successively use equation (15) to calculate the target density.

Step 1: for each node V_n do
 Step 2: constructing K -dimensional mixed membership vectors $\pi_n \sim \text{Dirichlet}(\alpha)$
 Step 3: for each node pair (V_p, V_q) do
 Step 4: constructor class initialization indicator variable $Z_{p \rightarrow q} \sim \text{Multinomial}(\pi^p)$
 Step 5: construct category indicator variable receiver $Z_{q \rightarrow p} \sim \text{Multinomial}(\pi^q)$
 Step 6: sample their interaction values $Y(p, q) \sim \text{Bernoulli}(Z_{p \rightarrow q} B Z_{q \rightarrow p})$

ALGORITHM 1: Generation process.

$$Z^k = f_k(Z^{(k-1)}) = f_k(f_{k-1}(\dots f_2(f_1(Z))))$$

$$\ln q_k(Z^{(k)}) = \ln q_0(Z) - \sum_{k=1}^k \ln \det \left| \frac{\partial f_k}{\partial Z^k} \right| = q(Z) \left| \det \frac{\partial f}{\partial Z^{(k)}} \right|. \quad (19)$$

If the mapping function is appropriate, then the learned mixture distribution of hidden random vectors more closely matches the distribution of the real data than the simple independent Gaussian distribution.

4.2.4. New Media Information Dissemination Speed and Scale Effect Predictor. Previous studies have found that information cascades have a time decay effect, i.e., the influence of one node on other nodes decreases over time [57]. In this paper, a nonparametric time decay function is used $\lambda_{f(T-t_j)}$, and according to the literature [25], we get the following:

$$h'_i = \sum_{j=1}^{R_i(T)} \lambda_{f(T-t_j)} h'_j. \quad (20)$$

Among them, $f(T-t_j) = \lfloor t_j - t_0/T/l \rfloor$, and R_T indicates the forwarding amount of h'_i new media information, indicating that the time decay function is considered.

The hidden state of the number.

The last part of the NWIDF model is composed of fully connected layers (MLP). According to the previous calculation h'_i , it can be calculated ΔS_i as follows:

$$\Delta S_i = \text{MLP}(h'_i). \quad (21)$$

The final task is to predict the increment of information dissemination within the specified time interval, introducing MeanSquare Log-Transformed Error (MSLE), namely, the following:

$$\text{MSLE} = \frac{1}{N} \sum_{i=1}^N (\log \Delta S_i; -\log \tilde{\Delta S}_i)^2. \quad (22)$$

As the loss function loss, use the Adam optimizer to optimize the loss value to make it optimal (minimum).

Through the above synthesis, the following training process can be performed as shown in Algorithm 2.

5. Experiment Setup and Results Analysis

5.1. Test Setup

5.1.1. Dataset. To evaluate the effectiveness and scalability of NWIDF models in information cascade prediction, experiments are conducted using publicly available datasets and compared with previous studies. The data information statistics of the dataset are shown in Table 1.

Weibo [25]: this dataset selects all the original posts generated by Sina Weibo on June 1, 2016, and tracks all retweets of each post over the next 24 hours, including a total of 119,313 posts. Figure 4(a) shows the distribution of the cascade size; Figure 5(a) shows the prevalence of the cascade, showing that after 24 hours, the prevalence reaches saturation. This paper follows a similar setup to CasCN [26], i.e., observation time window $T=1, 2, 3$ hours. Finally, the stacks are sorted according to the stacking time after preprocessing, and the top 70% of the stacks are selected as the training set for the stacks, and the rest are equally divided into the validation set and the test set.

HEP-PH [27]: the HEP-PH dataset (High Energy Physics Phenomenology Dataset) comes from the electronic version of the arXiv paper citation network. The data covers papers from January 1993 to April 2003 (124 months), in which there are citations for all 34,546 papers. If paper i cites paper j , the paper citation graph contains directed edges from i to j . If a paper cites or is cited by a paper outside the dataset, the graph will not contain information about this. Figure 4(b) shows the distribution of cascade sizes, and Figure 5(b) shows the prevalence of cascades. For the observation window, $T=3, 5$, and 7 years were chosen, corresponding to the prevalence reaching 50%, 60%, and 70% of the final scale, respectively, as shown in Figure 5(b). Then, 70% of the cascades are collected for training, and the rest are split equally into validation and test sets.

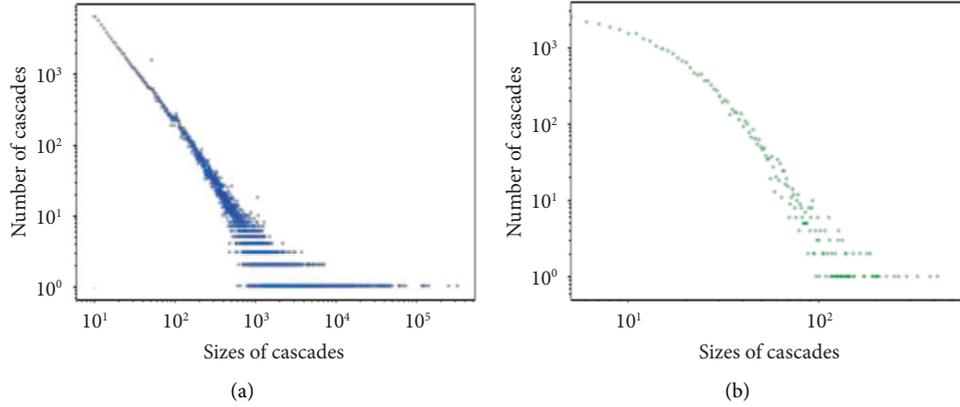

FIGURE 4: Cascade size distribution graph, the X -axis is the cascade size, and the Y -axis is the number corresponding to different cascade sizes. (a) Weibo dataset. (b) HEP-PH dataset.

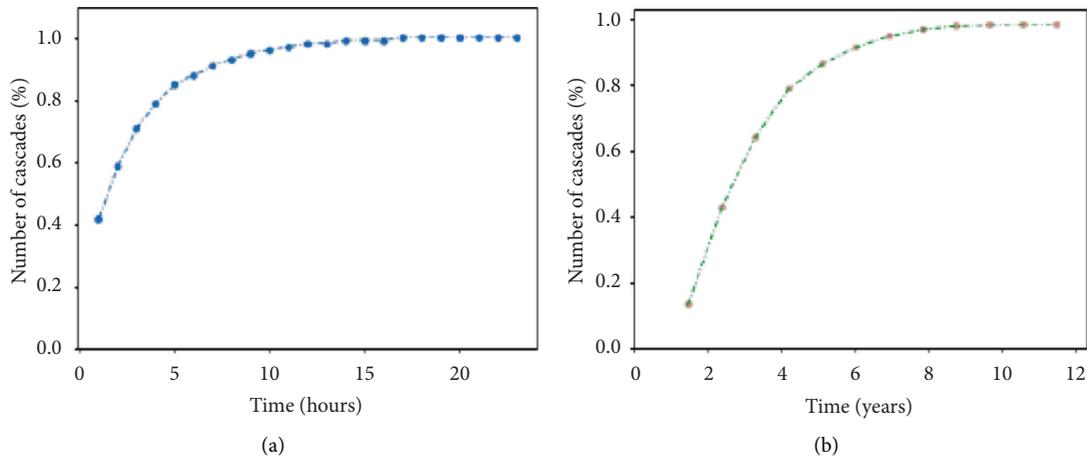

FIGURE 5: Percent distribution between time and number of cascades. (a) Weibo dataset. (b) HEP-PH dataset.

5.1.2. Benchmark Model Selection. From traditional cause analysis methods, hydrological statistics methods, time series analysis methods, etc., to modern artificial neural networks, wavelet theory, gray system and turbidity theory, each method has its own advantages because of its different mechanisms and applicable environments. To verify the effectiveness of our proposed NWIDF model in predicting the scale of information cascades, we choose three basic models: a feature engineering-based model (Topo-LSTM model [29]), a statistical generative model-based DeepHawkes model [25], and a deep learning based model CasCN model [26]. The comparative model is the latest model with high reliability in the research field, which can supplement and improve the comparative analysis research.

5.1.3. Parameter Setting. All experiments in this paper are performed on Ubuntu 16 operating system, Intel Core i9-9980XE CPU, 128G memory, and NVIDIA TiTan RTX (24G) graphics card.

For DeepCas [28], DeepHawkes [25], Topo-LSTM [29], and CasCN [26], refer to DeepCas to set the user's

embedding dimension to 50. The number of hidden units in the fully connected layer of the recurrent neural network is 32 and 16, respectively. The user learning rate 5×10^{-4} , and the other learning rate is 5×10^{-3} . The batch size of each iteration is 32, and when there are 50 consecutive iterations, the loss of the validation set does not drop, and the model training process will stop. The time interval for Weibo dataset was set to 10 minutes, and the time interval for HEP-PH was set to 2 months.

This paper uses Tensorflow to implement the NWIDF model and uses the Adam optimizer to optimize the parameters through gradient descent. Except that, the embedding neighborhood layer of graph representation learning adopts $K=2$, and the rest of the model parameter settings are consistent with the above models.

5.1.4. Evaluation Indicators. According to the existing work, a standard evaluation metric, MSLE (see equation (22)), is selected in the experiment to evaluate the linking accuracy. Note that the smaller the MSLE, the better its prediction performance.

input: cascade graph C , sequence of cascade graph adjacency matrices $A = \{A_1^T, A_2^T, \dots\}$, time window of observation $\Delta c = \{\Delta c_1, \Delta c_2, \dots\}$
output: predicted information cascade incremental scale $\Delta S = \{S_1, S_2, \dots\}$

- (1) the Laplacian matrix of the Δc concatenated graph C ;
- (2) the graph wavelet $\varphi_{u,s}$ for each node u_i ;
- (3) compute the node embeddings of the information cascade graph $E_c(v_c)$;
- (4) Calculate the node embedding of the global graph $E_g(v_g)$;
Calculate the global matrix $G_{ij} = X_{ij} + Y_{ij}$
- (5) while not converge do
- (6) Train a bidirectional gated recurrent unit to acquire h_2 ;
- (7) for $|v_c|$ each user in the pair i do
- (8) calculate z_i
- (9) end for
- (10) get $\vec{Z}_1 = \{z_1, z_1, \dots, z_{|v_c|}\}$;
- (11) Train a cascaded variational autoencoder to obtain Z_2 ;
- (12) Obtained by K transformations Z_3 ;
- (13) Combining sums h_2 and Z_3 sums $\Delta S_i = MLP(h_i)$ to make final scale incremental forecasts;
- (14) end while

ALGORITHM 2: Learning process of the NWIFD model.

5.2. Result Analysis

5.2.1. Experimental Comparative Analysis

(1) *Performance Comparison of the Benchmark Version.* The benchmark version of the NWIFD model proposed in this paper will be experimentally compared with previous cascade prediction models on real datasets.

The DeepCas model [28] is the first deep learning architecture for information cascade prediction, which represents a cascade graph as a set of random walk paths, piped through a bidirectional GRU neural network with an attention mechanism to predict the size of the cascade. It mainly uses the information of structure and node identity for prediction.

The DeepHawkes model [25] integrates the predictive power of end-to-end deep learning into the interpretable factors of the Hawkes process for popularity prediction. The combination between deep learning methods and cascade dynamics modeling processes bridges the gap between the prediction and understanding of information cascades. This method belongs to both generative and deep learning-based methods.

The Topo-LSTM model [29] is a directed acyclic graph structure (DAG structure) RNN that takes a dynamic DAG as input and generates topology-aware embeddings as output for each node in the DAG, thereby predicting the next node.

Pak et al. proposed a particulate matter (PM) prediction model (CNN-LSTM) based on spatiotemporal convolutional network and long short-term memory network and applied it to the concentration prediction of PM2.5 in Beijing. Using mutual information to analyze the spatial-temporal correlation, considering the linear and nonlinear correlation between the target and the observed parameters and combining the historical air quality and meteorological data, the spatial-temporal eigenvectors reflecting the linear

and nonlinear correlation between the parameters are constructed. (STFV), CNN-LSTM prediction model extracts the inherent relationship between PM2.5-related latency air quality and meteorological input data through CNN and reflects the long-term historical process of input time series data through LSTM, using 384 monitoring stations across the country for 3 years. The validity of the model is verified by the air quality data and meteorological data. [26].

Singh et al. used deep learning for stock prediction and proposed a stock prediction model based on 2-dimensional principal component analysis (PCA) and deep neural network (DNN), which combined the closing price, highest price, and lowest price. 36 indicators, such as opening price, are used as the input of the stock prediction model, and the original data matrix is projected into the projection matrix by (2D)2PCA. The dimension of the input sample is reduced, and then the dimension-reduced data is used as the input of DNN in the prediction model. Finally, get the predicted closing price. Compared with the radial basis function neural network (RBFNN), in the stock forecast of Google in Nasdaq, the network (RBFNN) rate is improved by 4.8%, and the actual return (i.e., the correlation coefficient with the predicted return of information dissemination) is 17.1% higher than that of RBFNN [27].

The CasCN model [26] combines the deep learning framework of structure and time, uses graph convolutional network to capture network spatial structure information, and incorporates temporal decay function using a recurrent neural network to achieve the more efficient use of temporal information. This model is a deep learning method.

Table 2 summarizes the performance comparison between the NWIFD model and other model benchmarks on the Weibo and HEP-PH datasets. The comparison of the NWIFD model with the DeepCas model proves that it is not enough to simply embed nodes as a graph representation, and it cannot represent the graph as a set of random paths. Because DeepCas fails to consider timing information and

TABLE 2: Performance comparison table (MSLE).

Data set	Weibo (hours)			HEP-PH (year)		
	1	2	3	3	5	7
DeepCas	2.958	2.689	2.647	1.765	1.538	1.462
Topo-LSTM	2.772	2.643	2.423	1.684	1.653	1.573
Deep-Hawkes_	2.441	2.287	2.252	1.581	1.47	1.233
CasCN	2.242	2.036	1.916	1.004	0.917	0.887
NWIDF	2.123	2.012	1.776	0.939	0.843	0.812

topology of cascaded graphs, its performance is worse than other deep learning-based methods. Topo-LSTM also lacks the processing of timing information, resulting in its poor performance. Although the DeepHawkes models cascades in a generative manner, it does not perform optimally because of its weak ability to learn structural information. CasCN considers temporal information and spatial topology but ignores the fusion between the two features. Finally, the NWIDF model proposed in this paper performs information cascade prediction (tweet retweets and paper citations) on both datasets, which is significantly better than other models. For example, in the Weibo dataset for 1, 2, and 3 hours, the MSLE values were 2.123, 2.012, and 1.776, respectively. Observing in the HEP-PH dataset for 3, 5, and 7 years, the MSLE values are 0.939, 0.843, and 0.812, respectively. The data shows that a good prediction effect has been achieved. Compared with CasCN, the prediction errors of the NWIDF model proposed in this paper are reduced by 5.31%, 1.18%, 7.31%, and 6.47%, 8.07%, 8.46%, respectively, thus confirming the effectiveness of the model.

5.2.2. The Influence of Global Graph on Information Cascade.

NWIDF-All: we removed the structure learning module in the NWIDF model. For NWIDF-All, all nonroot nodes in the information cascade graph are directly connected to the root node, and we do not use global graph information.

Firstly, the validity of the bidirectional recurrent neural network is verified, and experiments are designed. Construct a shortened version of NWIDF-GRU, namely, BiGRU in the benchmark version, and then compare it with CasCN, which is equivalent to NWIDF-GRU, adding attention mechanism on the basis of the CasCN model. During the experiment, the

TABLE 3: Global graph for information cascade prediction performance comparison table (MSLE).

Data set	Weibo (hours)			HEP-PH (year)		
	1	2	3	3	5	7
CasCN $K=2$	2.242_	2.036_	1.916_	1.004_	0.917_	0.887_
NWIDF-All $K=1$	2.136_	2.074	1.858_	1.02_	0.892_	0.842_
NWIDF-All $K=2$	2.099_	2.028_	1.835_	0.92_	0.907_	0.867_

parameters of the two are the same, and the experimental results when the sampling neighborhood layers $K=1, 2$ are shown in Table 3.

The performance comparison of the embedding layer $K=1, 2$ and the CasCN model $K=2$ is given in Table 3. According to Table 3, it can be seen that when $K=2$, the NWIDF model proposed in this paper is better than the CasCN model because the node embedding of the global graph is considered, which can couple the timing information and the spatial structure information. When $K=1$, after observing in Weibo for 2 hours, the MSLE of NWIDF-All is larger than that of CasCN. As $K=1$, the spatial structure information taken is insufficient, resulting in slightly lower results.

Then, the effect of timing information on cascade prediction is verified. Analyze the variant NWIDF-BiGRU of NWIDF, i.e., remove the bidirectional recurrent neural network from the NWIDF model proposed in this paper, and use BiGRU to compare with CasCN, which is equivalent to NWIDF-BiGRU, which is generated by replacing LSTM in the CasCN model with the BiGRU model. From the data in Table 4, it can be seen that when $K=2$, the MSLE = 1.783 observed by Weibo for 3 hours and the MSLE = 0.84 observed by HEP-PH for 7 years are better than the MSLE of CasCN. Thus, the importance of timing information in information cascade is confirmed.

Finally, to verify the impact of time series information and spatial information on cascade prediction, we use BiGRU on the basis of CasCN, add a structure learning mechanism, and then adjust the number of embedded neighborhood layers K to compare with CasCN, respectively. It can be seen from the data in Table 5 that when $K=1$,

TABLE 4: Time series network impact cascade prediction performance comparison table (MSLE).

Data set	Weibo (hours)			HEP-PH (year)		
	1	2	3	3	5	7
CasCN $K=2$	2.242_	2.036_	1.916_	1.004_	0.917_	0.887_
NWIDF-BiGRU $K=1$	2.198_	2.075_	1.872_	0.995_	0.845_	0.884_
NWIDF-BiGRU $K=2$	2.17_	2.065_	1.783_	0.946_	0.826_	0.84_

TABLE 5: Time series space impact cascade prediction performance comparison table (MSLE).

Data set	Weibo (hours)			HEP-PH (year)		
	1	2	3	3	5	7
CasCN $K=2$	2.242_	2.036_	1.916_	1.004_	0.917_	0.887_
NWIDF $K=1$	2.18_	2.032_	1.801_	0.973_	0.819_	0.807_
NWIDF $K=2$	2.123_	2.012_	1.776_	0.939_	0.843_	0.812_

2 on Weibo and HEP-PH datasets, MSLE values are smaller than those of CasCN, indicating that the model proposed in this paper is better than CasCN in terms of time series information and spatial topology information. The capture is more comprehensive, which improves the efficiency of the model and reduces the loss rate.

The above experiments show that time series information and spatial structure information have an important impact on the information cascade prediction effect. The combination of the two can better ensure the accuracy of prediction. The capture of information is also more comprehensive, which also makes the model more generalizable.

6. Conclusion

Under the background of the wrong public opinion orientation caused by the rapid spread of new media information and its wide spread, it is of great practical significance to carry out the prediction of the spread of new media information and the scale effect. Based on the fact that the current hierarchical model of new media information dissemination lacks global and local models, this paper starts from the characteristics that new media information conforms to node dissemination and conducts prediction research on the speed and scale effect of new media information dissemination. The main research contents are as follows [24]:

- (1) The modeling method of local and global propagation of the characteristics of new media information propagation is proposed, and considering the uncertainty and scale effect of information propagation, a graph neural network-based NWIDF model is proposed, which starts from the information cascade structure. Graph the structure learning for information propagation based on locality and globality.

- (2) On the two large-scale information cascade datasets of Facebook and TikTok, the current mainstream and advanced prediction models are applied to carry out experimental research, and it is found that the NWIDF model has better prediction effect and performance. To a certain extent, it can predict the spread and scale of new media information and public opinion, control the rapid spread of wrong public opinion, and quickly cut off the communication channel to provide more advanced ideas.

In this paper, the NWIDF model is the hotspot of current network and graph neural network research. The main difference in speed is the large-scale graph and scale effect of new media information dissemination, and other types of features are caused by the complexity of the research content. In this paper, the NWIDF model is not extended to other types of features, such as learning various content features (number of user attention, h-index of authors, historically published articles, etc.). However, it provides a richer theoretical and practical basis for the future use of more powerful and complex graph neural networks, such as heterogeneous information networks with multiple node types and edge types. The model can be generalized to other types of graph-based business applications, such as virus information diffusion, interpretable information prediction, rumor detection, epidemic control, etc.

As an important resource under the background of digital design technology, 3D assembly model plays a great role in many complex product design occasions. Based on the existing 3D model database, how to find and reuse the effective information that meets their own needs in many models is one of the important ways to provide design efficiency. The research content of this paper is to build a general assembly model according to the requirements of 3D assembly model. Based on the common structure, the general structure aims to integrate as much model information as possible to meet the design needs of designers in different periods and conditions. Due to the large number of components in the 3D assembly model, blindly improving hardware cost is the root of the problem. To improve quality and efficiency from the source, we need to start with the source of input. This paper simplifies the analysis of 3D assembly model information, which can not only improve the construction efficiency of the general structure of 3D assembly model but also highlight the assembly characteristics of 3D assembly model and facilitate the matching of assembly features during the construction process. Firstly, based on the attributes of assembly features and matching relationship, combined with the idea of conjugate, the matching problem between two features in the model is solved by using the idea of conjugate subgraph matching. Secondly, based on the Ullmann algorithm, combined with the definition of conjugate subgraph and related optimization operations, a conjugate subgraph matching algorithm based on vertex screening is proposed. Finally, the construction process of the general structure is proposed, and the general structure of 3D assembly model is established.

1. Introduction

With the progress of the times and the innovation of science and technology, CAD model has made a qualitative leap in the traditional function. 3D assembly model contains much reusable information reflecting the design intention, such as structure, function, and attributes. In the design and manufacturing of products, scholars at home and abroad have done a lot of research on the mining and reuse of relevant information for CAD models [1–8]. In the process of information reuse, designers often pay more attention to local similarity comparison. Because the overall similarity almost does not exist, and the local similarity is easy to analyze and obtain, it can also better realize the reuse of model information. The construction of the general structure of 3D assembly model and the related research on design reuse are essentially the matching process of

subgraph isomorphism. The process of building a general structure is mainly isomorphic matching and updating, until a comprehensive and general 3D assembly model general structure is generated. The design reuse of 3D assembly model mainly carries out subgraph isomorphic matching and semantic information matching with the general structure according to the information corresponding to the design intention provided by the designer, to provide a series of model structure information with reference value. For the NP complete problem of subgraph isomorphism, scholars at home and abroad have conducted in-depth research and achieved many results, which have been widely used in many fields.

Ullmann [9], based on the backtracking method, simplified the mapping matrix in the matching process and carried out corresponding isomorphic matching according to the adjacency relationship between vertices. Wang [10]

combined the advantages of Ullmann algorithm and VF2 algorithm, first pruned through the adjacency relationship between vertices based on Ullmann algorithm. Then, based on VF2 algorithm, the vertex matching order is changed to realize fast pruning. Ma et al. [11] proposed filtering and simplification based on Ullmann algorithm. The corresponding isomorphic matching process is carried out through neighbor filtering, partial simplification, and the selection order of adding matching graph vertices. Choi et al. [12] considered various design problems and analyzed the incremental hybrid genetic algorithm for subgraph isomorphism problem to improve the performance of the algorithm. Fehér et al. [13] proposed a subgraph isomorphism algorithm based on MapReduce framework to match font patterns in any large map. Chen et al. [14] provided a method to solve the isomorphism problem of the maximum common subgraph by generating a weighted graph, in which the weight represents the probability that the associated link is in the maximum common subgraph of two input graphs. Xu et al. [15] proposed extended subgraph matching and, combined with the different characteristics of Ullmann algorithm and QuickSI, gave the corresponding edging algorithm to optimize the processing of distance information. Rong et al. [16] constructed the information representation of process model based on attribute adjacency graph and improved the subgraph isomorphism algorithm to obtain processing features. Tang [17] proposed a similarity evaluation method based on improved random walk graph matching for 3D part models and a similarity evaluation method based on tree graph matching for 3D assembly models, to improve the matching efficiency. Dong et al. [18], based on algebraic theory, taking unlabeled graph as the research object, established subgraph isomorphism algorithms from two aspects of eigenvalue construction and degree sequence, to realize the graph isomorphism matching of directed graph and undirected graph.

This paper studies the model representation method based on attribute assembly feature adjacency graph and puts forward a general structure construction method of 3D assembly model. Firstly, this method analyzes the related concepts such as assembly features and assembly relationship, introduces the idea of conjugate, and gives the definition of practical guiding significance between the matched part features. Based on the matching algorithm of conjugate subgraphs, the matching problem is solved by combining the matching algorithms of conjugate subgraphs. Finally, the construction process of general structure is formed, and the general structure of 3D assembly model is established.

2. Materials and Methods

2.1. Method for Representation of 3D Assembly Model Information. The representation of 3D assembly model information should include topological structure information that can express the structural resources related to the model, semantic information such as part name, type, and function, and some characteristic information that can express the matching relationship between parts.

Graph model representation takes graph theory as a tool and is mainly composed of nodes and edges. Graph model can be used to describe the connection relationship between structures of 3D assembly model. In the process of design and manufacturing, there are also mature methods and properties to solve relevant problems based on graph theory. Therefore, the representation method of graph model is favored by scholars and applied to many research fields.

2.1.1. Definition of Feature Adjacency Graph of Attributed Assembly

Definition (1): Attributed Adjacency Graph (AAG). It mainly takes the part face as the node and the adjacency relationship between faces as the edge of the graph representation model to represent the topological relationship of the part, which is often expressed by $G = \{V, E, \alpha, \beta\}$, wherein V represents the set of nodes, and any element v_i in the set meets the corresponding relationship with one side in the part; E represents the set of edges, which is the adjacency relationship of faces, and any element in the set has an element in V corresponding to it, mainly including the geometric type of faces, the number of edges of faces, and so on; and β represents the attribute set of edges, and any element in the set has an element in E corresponding to it, mainly including the type of edges and the position relationship of adjacent faces.

In this paper, the shape features of the model are divided into assembly features and nonassembly features. The assembly features include the assembly information in the parts, which is used to construct the main shape of the parts, which plays a decisive role in the assembly process of the 3D assembly model. Nonassembly features are auxiliary features in parts, which are local modifications of part information, and play little role in the assembly process of 3D assembly model. Based on the AAG of 3D model, this paper first maintains the assembly feature information in the part model and then uses semantic nodes to replace other information in the model, so as to construct the attributed assembly feature adjacency graph of parts. Its definition is as follows.

Definition (2): Attribute Assembly Feature Adjacency Graph. It is a graphic representation that focuses on the assembly features in the part model, which is represented by $G = \{V, E, \alpha, \beta, V_o\}$, where V represents the set of nodes, and any element v_i in the set corresponds to one side f_i in the part assembly feature; E represents the set of edges, and any element e_j in the set corresponds to the side composed of adjacent faces f_n and f_m in the part assembly feature; α represents the attribute set of the node, mainly including the geometric type of the face, the number of sides of the face, and so on; and β represents the attribute set of edges, mainly including the type of edges and the positional relationship of adjacent faces and so on. $V_o = \{I_N, I_F, I_C\}$ represents the semantic node of the part. It is the semantic expression of other information in the part except assembly features, including semantic information such as part name (I_N), function (I_F), and category (I_C).

2.1.2. Construction of AAG of the 3D Assembly Model.

From the 3D model assembly, designers can obtain comprehensive assembly information. For example, two parts in contact with each other in an assembly can be divided into contact connection and assembly connection by judging whether they have assembly properties, while assembly link represents the fact that the two parts have assembly properties and then analyzes the connection relationship. The assembly properties can be divided into riveting, key connection, pin connection, thread connection, and so on. In the process of model reuse, designers should focus on the mating connection between parts. This paper classifies and codes the connection relationship of assembly link and the contact type of mating surface, as shown in Tables 1 and 2. For example, the code “a3” represents the fact that the part assembly link relationship is riveting, and the contact type of mating surface is cylindrical-cylindrical contact.

Taking the assembly process of the 3D assembly model shown in Figure 1 as an example, the 3D assembly model shown in Figure 1(c) is assembled and combined by part A shown in Figure 1(a) and part B shown in Figure 1(b). By searching the assembly features corresponding to the model and relevant process documents, it can be obtained that the connection relationship between parts is “threaded connection,” and the contact type of mating surface is “cylindrical-cylindrical contact.”

Based on the construction steps of AAG of 3D assembly model, parts A and B are represented by graph models as shown in Figures 2(a) and 2(b), and the shaded part represents the mating surface. Then, code according to the contact coding rules of the mating surface above, so that the mating surfaces are assembled into a node, which is named as the mating node, that is, the node marked “d3” in the figure (“d” refers to “threaded connection” and “3” refers to “cylindrical-cylindrical contact”). Thus, the model AAG is constructed, and the results are shown in Figure 2(c).

2.2. General Structure Construction of the 3D Assembly Model Based on Conjugate Subgraph.

Based on the model representation method in Section 2.1, this section realizes the construction of general structure of 3D assembly model through three steps. Firstly, the related concepts such as assembly features and fit relationship are analyzed, and the idea of conjugate is introduced to give the definition of matching part features with practical guiding significance. Then, based on the graph isomorphism algorithm and the related properties of conjugate subgraphs, the matching problem of assembly features in 3D assembly model is solved by conjugate subgraph matching algorithm based on vertex screening. Finally, the construction process of general structure is formed, and the general structure of 3D assembly model is established.

2.2.1. Relevant Definitions and Concepts

(1) *Assembly Features*. In the current industrial design and manufacturing, most of the features are defined as the combination of shape and function. The feature is the specific mapping of relevant shapes and is endowed with specific multisource information. In the 3D assembly model,

TABLE 1: Classification code of connection relationship type.

Serial number	Code	Connection relationship type
1	<i>a</i>	Riveting
2	<i>b</i>	Key connection
3	<i>c</i>	Pin connection

5	<i>e</i>	Other

TABLE 2: Classification code of contact type of mating surface.

Serial number	Code	Contact type of mating surface
1	0	Plane-plane contact
2	1	Tooth-tooth contact
3	2	Plane-tooth contact
4	3	Cylindrical-cylindrical contact
5	4	Other

the assembly feature is the information that represents the assembly attributes of parts; that is, it represents the assembly information such as methods and attributes contained in the cooperation between parts [19].

(2) *Assembly Relationship*. In the 3D assembly model, the assembly relationship plays an important role in the model expression, which can be regarded as the constraint relationship among the corresponding points, lines, and faces in the model. Analyzing the assembly relationship from the perspective of engineering design, there are many forms of assembly relationships in the actual design and manufacturing such as surface fitting, alignment, isometric surface reversing, isometric surface of the same direction, coaxial, etc., same direction isometric, coaxial and so on [20]. However, the most commonly used assembly relationships mainly include surface fitting and coaxial assembly for the consideration of assembly stability and economy.

- (1) *Face fitting*: the two surfaces of parts in the assembly contact with opposite normal vectors. In the bolt connection shown in Figure 3, the end faces of part A and part B fit together, and the red part indicates the assembly part of surface fit.
- (2) *Coaxial assembly*: the axes of two feature surfaces are collinear. In the bolt connection shown in Figure 3, part A and part B are coaxial with the bolt respectively, and the blue part indicates the coaxial assembly position.

(3) *Conjugate Subgraph*. In the actual design and manufacturing, there are many matching relationships such as those shown in Figure 3. Through the analysis of many assembly relationships, it can be observed that the topological structures of the two parts to be assembled in the 3D assembly model are usually the same, and the surface normal vector and edge attributes are often opposite. Based on the attribute assembly feature adjacency graph of parts, the idea of conjugate is introduced to express the assembly relationship between 3D assembly models. Yoke in life refers to the shelf on the back of two cows. It can play the role of allowing two cows to walk synchronously. Conjugation means that two parts are assembled with each other

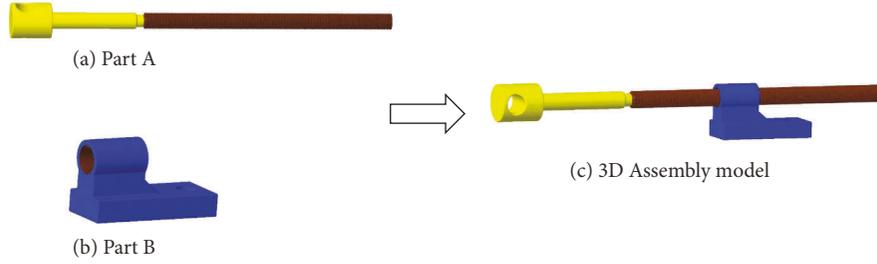

FIGURE 1: Assembly diagram of 3D assembly model. (a) Part A, (b) part B, and (c) 3D assembly model.

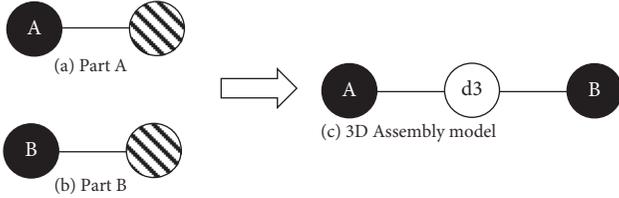

FIGURE 2: Construction diagram of AAG of the 3D assembly model. (a) Part A, (b) part B, and (c) 3D assembly model.

according to specific laws, commonly known as twinning. Twins are similar in general and slightly different in detail. Therefore, the definition of conjugate subgraph is as follows.

Definition (3): Conjugate Subgraph. In the 3D assembly model, there are two parts assembled with each other, and their attribute assembly features are adjacent to some assembly feature parts (subgraphs) represented by the graph. The two subgraphs have the same topological connection form, but the edge attributes in the graph are just opposite, so the two subgraphs are called common yoke subgraphs.

A 3D assembly model of a slider coupling is composed of Part 1, Part 2, and Part 3, shown in Figure 4. Traverse each face of the three parts of the slider coupling, and extract the geometric attributes and relevant semantic information of the fitting surface of the part assembly features as the node attributes based on the relevant definitions of the attribute assembly feature adjacency graph and conjugate subgraph. Identify the relationship between adjacent faces as the attributes of corresponding edges, so as to construct the corresponding attribute assembly feature adjacency diagram of each part, as shown in Figure 5. Among them, the two corresponding subgraphs in the green coil are conjugate subgraphs with assembly relationship between parts.

By observing the conjugate subgraph shown in Figure 5, the following properties can be obtained:

- (1) Conjugate subgraphs have the same topology
- (2) The face type, assembly requirements, and other attributes of each corresponding vertex in the figure are the same, but the face normal vector is opposite
- (3) The attributes of the corresponding edges in the figure are opposite; for example, the concavity and convexity are opposite

(4) *General Structure of the 3D Assembly Model.* The common structure of the 3D assembly model is known. Each

part in the common structure has several assembly features. Each part in the common structure is matched through the conjugate subgraph to match the parts and components with conjugate relationship, because, in the current assembly scene, there are often more than one component matching with the assembly features of the part. After conjugate subgraph matching, a set of AAG that meet the assembly requirements may be obtained. Therefore, a general set corresponding to the part is constructed, and its definition is shown in Definition 4.

Definition (4): General Set. The function of this set is to store the AAG of parts and components that meet the conjugate relationship with a part, which is expressed by a formula. Any graph in the set and all the adjacency graphs meet the conjugate subgraph matching with the attribute assembly feature adjacency graph of the part.

Until all the parts and components in the current scene are matched, the general set corresponding to each part meeting the conjugate relationship in the common structure is constructed, and finally a complex AAG is obtained, which is the general structure of 3D assembly model.

2.2.2. Method for Assembly Feature Matching Based on the Conjugate Subgraph. The matching problem of assembly features is basically the matching problem of conjugate subgraphs. The matching problem of conjugate subgraphs is essentially the matching problem of subgraph isomorphism. The main process includes the following steps: in the current matching environment, convert the components to be matched into the corresponding AAG representation. The conjugate subgraphs are matched with the parts and components in the common structure of the 3D assembly model, that is, the conjugate subgraphs that meet the same structure, the same node surface type, assembly requirements, and other attributes, and the opposite surface normal vector and the opposite edge attributes are searched for matching.

(1) *Ullmann Algorithm.* Ullmann algorithm mainly stores the matrix of the mapping relationship between the vertices of any two graphs, to judge the isomorphism of the two graphs. After one operation, this algorithm can enumerate all *isomorphic* subgraphs, so it is also called enumeration algorithm.

It is known that there are two AAG G_A and G_B , n_A and n_B represent the number of vertices of the two graphs, respectively, s_A and s_B represent the number of edges of the two

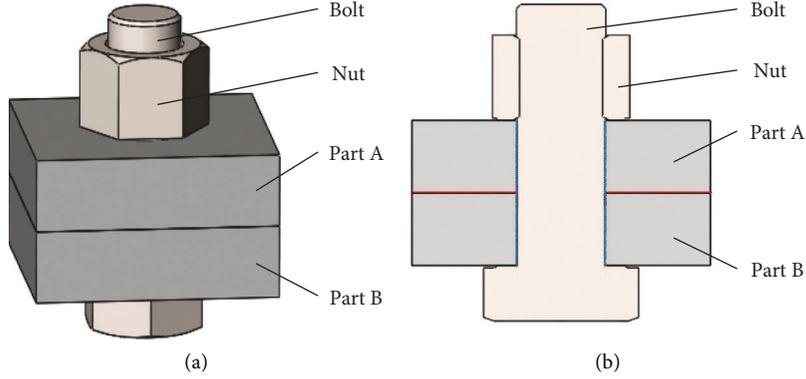

FIGURE 3: Bolt connection and bolt connection section. (a) Bolted connection. (b) Bolted connection section.

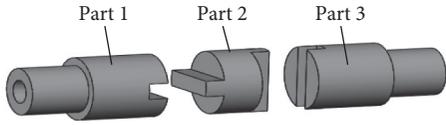

FIGURE 4: Slider coupling.

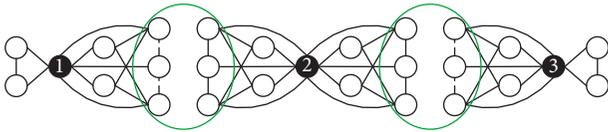

FIGURE 5: Attribute assembly feature adjacency diagram of slider coupling.

graphs, respectively, $n_A < n_B$, and $s_A < s_B$. $M_A = [a_{ij}]$ and $M_B = [b_{ij}]$ represent the adjacency matrix of the two graphs, respectively. The vertex correspondence between G_A and G_B is represented by vertex mapping matrix M , where M is $n_A \times n_B$ matrix and m_{ij} is an element in M , which mainly refers to the elements in row i and column j of the matrix, representing the matching relationship between node i of G_A and node j of G_B . If there is no mapping relationship between node i of G_A and node j of G_B , then $m_{ij} = 0$. If there is a mapping relationship between node i of G_A and node j of G_B , then $m_{ij} = 1$. If and only if each row in M has only one element $m_{ij} = 1$ and each column has at most one element $m_{ij} = 1$, it is said that the subgraphs of G_A and G_B are isomorphic.

When G_A and G_B satisfy the isomorphism condition of subgraphs, the elements in vertex mapping matrix M will remain unchanged. This is because when the element in M conforms to the formula

$$(\forall x)((a_{ix} = 1) \Rightarrow (\exists y)(m_{xy} \bullet b_{yj} = 1)) \quad (1)$$

$$(1 \leq x \leq n_A, 1 \leq y \leq n_B).$$

Then, in M , the elements $m_{ij} = 1$ will not change. Therefore, M constructs the vertex mapping relationship between G_A and G_B . If any two vertices in G_A have adjacency relationship, two adjacent vertices with vertex mapping relationship with G_A can also be found in G_B , so that the edge also has corresponding mapping relationship.

The basic idea of Ullmann algorithm is as follows: in the whole process of isomorphic matching, always check whether each row in M has an element $m_{ij} = 1$. If the element is not found, it means that there is no corresponding vertex in G_B that matches the vertex of G_A , and then the isomorphism condition is not tenable, so exit the program. If this element exists, then the matrix M is traversed in turn, and finally an isomorphic subgraph that meets the needs of the designer can be matched.

To sum up, the basic steps of Ullmann algorithm are as follows:

Input: G_A and G_B

Input: isomorphic subgraph.

Step 1. Initialize the vertex mapping matrix M and the incidence matrix M_0 , whose size is $n_A \times n_B$.

Step 2. Define Atlas G_0 to store matching pairs of vertices.

Step 3 Starting from $r = 1$, traverse each row $r = r + 1$ in M . If there is an element $m_{ij} = 1$, store the vertex matching pairs of graphs G_A and G_B corresponding to m_{ij} in G_0 . The matching value of the vertex of the corresponding graph G_B in M_0 and other vertices is 0. Until $r = n_A + 1$, jump to step 6.

Step 4. Traverse all vertices in Atlas G_0 ; if there is a corresponding mapping relationship between the two vertices, $m_{pq} = 1$. If not, $m_{pq} = 0$.

Step 5. In the mapping matrix obtained by traversing step 4, if each row of the matrix has only one 1, and each column has at most one 1, then the subgraph of G_0 is isomorphic, and step 3 is repeated according to the matrix elements in M_0 . Otherwise, the subgraph is not isomorphic, and step 3 is returned.

Step 6. At the end of the algorithm, the vertex pairs in G_0 , that is, the isomorphic subgraphs of G_A and G_B , are output.

Ullmann algorithm adopts the method of depth first in matching. The whole process uses Boolean matrix to record relevant data. When there is no mapping relationship between them, it returns the nearest matching node and reexplores other matching objects. At the same

TABLE 3: Symbolic meaning.

Symbol	Meaning

L	Row count

time, while matching, check the adjacency of matching point pairs, eliminate mismatched nodes, and improve the efficiency of the algorithm. Ullmann algorithm is a mature graph isomorphism algorithm with high retrieval efficiency.

Although Ullmann algorithm is relatively mature, its retrieval efficiency is better. However, in practical engineering applications, the working time of Ullmann algorithm is exponentially related to the size of AAG. Therefore, in contrast, the whole matching process is also time-consuming. The local structure of the assembly model obtained by matching isomorphic subgraphs is also mixed. Therefore, it does not achieve better economic value and social value, and its retrieval accuracy needs to be improved accordingly. The main reasons for the poor retrieval accuracy include the following: first, in the matching process, the attributes contained in the vertices are limited and cannot be matched accurately. The consequence of fuzzy matching is the low accuracy. Secondly, isomorphic matching focuses mostly on vertices and has less constraints on edge attributes, resulting in low accuracy and efficiency.

(2) Conjugate Subgraph Matching Based on Vertex Filtering.

In order to improve the retrieval accuracy of subgraph isomorphism and the efficiency of the algorithm, and to meet the needs of constructing the general structure of 3D assembly model, a conjugate subgraph matching algorithm based on vertex screening is proposed. The algorithm is mainly based on Ullmann algorithm and improves the algorithm through the following aspects:

- (1) Before the algorithm starts running, the vertices of the two input graphs are filtered by using the same properties of the node attributes of the conjugate subgraph. The face type is one of the main constituent elements of the node attribute. In the 3D assembly model, if the face type is a plane, the corresponding graph should also have a plane, and if the face type is a surface, the corresponding graph should also have a surface. If there is no corresponding face type in the graph, there is no need to enter the algorithm for conjugate matching and return directly. Secondly, if the number of vertices of the subgraph is more than that of the large graph, it is impossible for the subgraph to be isomorphic and return directly. Finally, if there are a certain number of specific graphs in the subgraph, but the graph does

not exist in the large graph or the number is less than the subgraph, the isomorphism cannot succeed and is returned directly. Through the above judgment, many invalid matches can be eliminated to a great extent, so as to reduce the complexity of conjugate subgraph matching algorithm and improve work efficiency.

- (2) The conjugate subgraph matching model is represented based on the attribute assembly feature adjacency graph. Therefore, the attribute assembly feature adjacency graph of the model contains semantic nodes representing semantic information such as part name, category, and function, as well as matching nodes of connection relationship. In the matching, relevant information is extracted, vertex- and edge-related attributes are added, and the similarity calculation method in [21] is used to judge in the conjugate matching process, so as to make the conjugate matching achieve accurate matching, remove invalid matching as much as possible, and improve the matching accuracy.
- (3) When the algorithm is in normal operation, according to the principle that the subgraphs formed by the vertex set V_A on the current small graph and V_B on the large graph must also be isomorphic, it can judge whether the subgraphs composed of V_A and V_B are isomorphic, and whether the attributes of the edges corresponding to the corresponding vertices meet the opposite properties of the corresponding edge attributes of the conjugate subgraph, so as to judge the effectiveness of the newly found columns, effectively eliminate invalid matches, and improve matching accuracy and efficiency.

In order to facilitate the description of conjugate subgraph matching algorithm, the definitions of relevant symbols in the algorithm are shown in Table 3.

To sum up, the basic steps of the algorithm are as follows.

Step 1. Pretreatment.

The specific content of preprocessing is to initialize M according to the relevant properties of conjugate subgraphs, mainly to judge the elements with the value of 1 in M to see whether 1 can be set to 0. Since the number of elements with 1 in M is also limited, the steps of preprocessing process are also limited until no element in M can be set to 0. The specific principles are as follows.

If the vertex attributes of the two graphs do not conform to the conjugate subgraph, and the corresponding node attributes of each conjugate subgraph are the same, the elements corresponding to the vertices in matrix M are set to 0.

After initialization, perform vertex filtering. If the following conditions are met, exit conjugate subgraph matching; if not, enter step 2:

- (1) In M , if none of the elements in a row is 1, this indicates that a node in the matched subgraph does not exist in the large graph to be retrieved.
- (2) In M , if $r > c$, it means that the matched subgraph is larger than the large graph to be retrieved.
- (3) The number of nodes in the matched subgraph is greater than the number of similar nodes in the large graph to be retrieved.

Step 2. Initialize V_1 and V_2 so that $V_1 = 0$ and $V_2 = 0$.

Step 3. Start traversing from the first row of matrix M . If element $m_{rc} = 1$, add the vertices corresponding to this element to V_1 and V_2 , respectively, and set O_c as true, B as false, and L as r .

Step 4. $r + 1$, traverse matrix M . If B is false, enter this line and run step 5. Otherwise, go back to line r and run step 6.

Step 5. Traverse row I in M , starting from column 0:

- (1) If $m_{ij} = 1$, and the column is not occupied, add the matching vertices to V_1 and V_2 , respectively, and judge the conjugate subgraph matching. If the conditions such as the same conjugate subgraph structure, the same vertex face type and other attributes, the opposite face normal vector, and the opposite edge attributes are met, set O_j to true and execute step 10. Otherwise, delete the matching vertices, $L + 1$.
- (2) Otherwise, $L + 1$.

Step 12. O_c in row r is false. Delete the matching vertex and traverse row I of the matrix from column $c + 1$:

- (1) If $m_{ij} = 1$, and the column is not occupied, add the matching vertices to V_1 and V_2 , respectively, and judge the conjugate subgraph matching. If the conditions such as the same conjugate subgraph structure, the same vertex face type and other attributes, the opposite face normal vector, and the opposite edge attributes are met, set O_j to true and B to false, and execute step 10. Otherwise, delete the matching vertex, $L + 1$.
- (2) Otherwise, $L + 1$.

Step 13. If the number of columns of L and M is equal, or $c + 1$ in step 12 is equal to the number of columns of M , set B to true and step back one row. Otherwise, go to the next line.

Step 14. After traversing M , if V_1 and V_2 sets are not empty sets, the vertices in the set are the matched conjugate subgraphs and output. Otherwise, the algorithm ends and the subgraph is not conjugate.

To sum up, compared with Ullmann algorithm, the conjugate subgraph matching algorithm based on vertex filtering first initializes the mapping matrix based on the characteristic attributes of the conjugate subgraph in the preprocessing stage and, at the same time, carries out vertex filtering before the conjugate subgraph matching to screen and eliminate the subgraphs that do not meet the requirements, reduce the number of invalid matching processes, and improve the matching efficiency of the conjugate subgraph. Then, in the process of conjugate subgraph matching, according to the principle that the subgraphs composed of two matched sets of V_1 and V_2 must be isomorphic, combined with the relevant properties of conjugate subgraphs, judge the newly added vertices and edges and screen and eliminate the vertices that do not meet the requirements, so as to improve the matching efficiency of conjugate subgraphs.

2.2.3. Construction of General Structure. The general structure of 3D assembly model takes the common structure as the main body and combines the multisource and discrete noncommon structure information with it through the assembly feature matching algorithm based on conjugate subgraph to construct a complex and comprehensive expression form of 3D assembly model. Not only can the general structure reflect the reusable common structure information such as functions, structures, and attributes in a group of 3D assembly models, meet the needs of the public, and provide designers with the general structure of the group of models and relevant functions, attributes, design experience, and other information, but it also can reflect the relevant information of many personalized structures and include as many qualified structures as possible, so as to meet the various personalized needs of designers at different stages and under different conditions and provide comprehensive and detailed reusable information for designers in design and manufacturing.

To sum up, the construction steps of general structure of 3D assembly model are as follows:

Step 1: define n general sets (n is the number of parts in the common structure of the 3D assembly model) and initialize them to store the AAG that satisfies the conjugate matching with the part in the matching process.

Step 2: input the common structure of the 3D assembly model and the AAG Atlas corresponding to the parts and components to be matched. The Atlas mainly stores the AAG corresponding to each part and component in the model.

Step 3: based on the matching algorithm of conjugate subgraph in Section 2.2.2, traverse each part in the common structure of 3D assembly model, and match each component in the current component graph set with the AAG of the current part in turn. For the k -th part in the common structure,

- (1) If the conjugate matching is satisfied, the AAG corresponding to the component is added to the

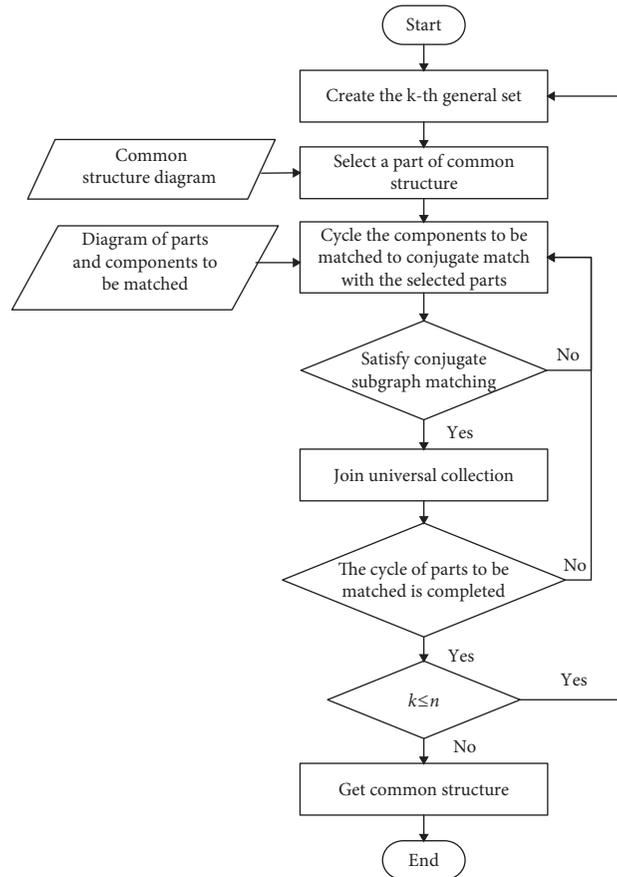

FIGURE 6: General structure construction flowchart of the 3D assembly model.

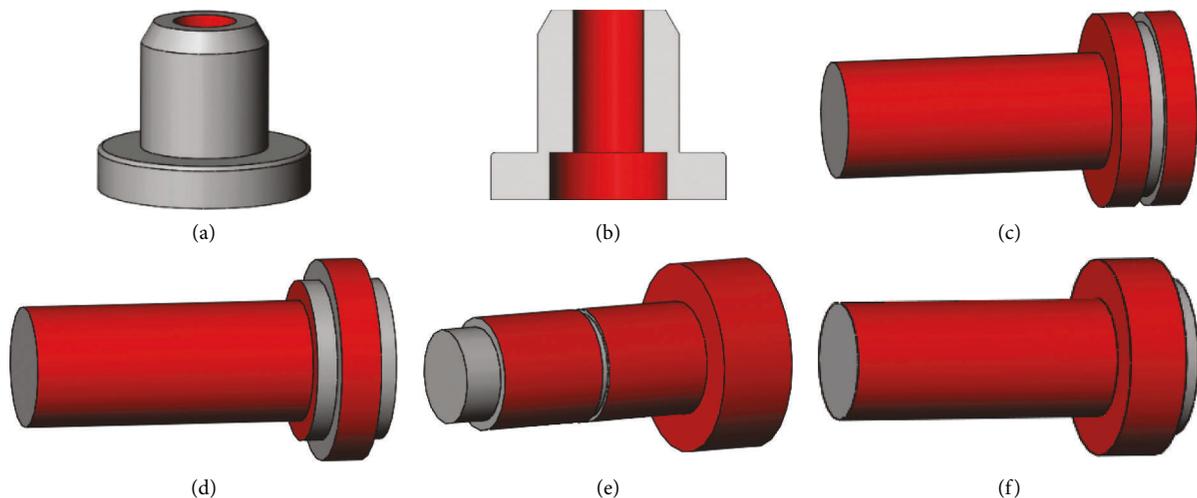

FIGURE 7: Hydraulic piston cylinder and piston rod. (a) Piston cylinder. (b) Piston cylinder section. (c) Piston rod 1. (d) Piston rod 2. (e) Piston rod 3. (f) Piston rod 4.

general set corresponding to the k -th part, the general structure state of the added 3D assembly model is updated, and the next component to be matched is selected to continue to judge the conjugate subgraph;

(2) If the conjugate matching is not satisfied, skip directly, and select the next component to be matched to continue to judge the conjugate subgraph.

Step 4: until all components in the current component diagram set to be matched are traversed, the general set

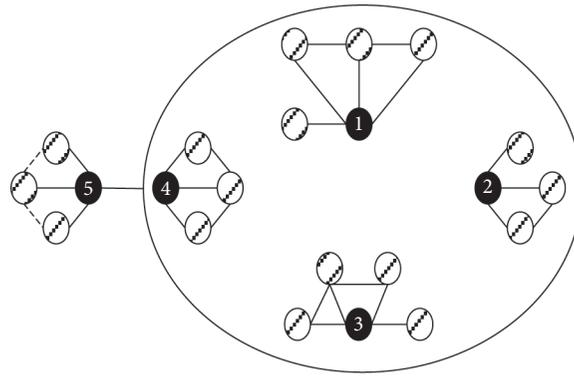

FIGURE 8: Example of general set of 3D assembly model. 1: piston rod 1; 2: piston rod 2; 3: piston rod 3; 4: piston rod 4; 5: piston cylinder.

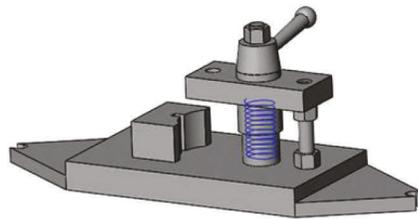

FIGURE 9: Fixture 3D assembly model.

corresponding to the part is constructed, and the part in the next common structure is selected to enter step 3.

Step 5: repeat the above steps until all parts in the common structure of the 3D assembly model are traversed, and the corresponding general set of parts is obtained, so that the general structure of the 3D assembly model can be constructed. The general assembly flowchart is shown in Figure 6.

As shown in Figure 7, there are one piston cylinder part and four piston rod parts of hydraulic transmission in machine tool accessories. Figures 7(a) and 7(b), respectively, represent the 3D model and sectional view of piston cylinder parts, parts 7(c)–7(f), respectively, represent piston rod parts of different specifications and models, and piston rod parts 1–4 meet the conjugate subgraph matching with piston cylinder parts, which can be assembled with piston cylinder parts. In the figure, the red part is the assembly feature part, and the gray part is the nonassembly feature part.

For the piston cylinder parts and piston rod parts in Figure 7, the assembly feature information is retained, and the nonassembly feature information is simplified, so as to construct the attribute assembly feature adjacency diagram corresponding to each part respectively. According to this information, the general structure is constructed, and the corresponding general set is established. The results are shown in Figure 8. The part circled by the coil is the relevant content represented by the general set. The shaded part is the assembly feature part matched between parts, and the virtual and real lines used for the connection between conjugate nodes represent the edges with opposite attributes in the assembly feature of parts.

To sum up, this method constructs the general structure of 3D assembly model based on comprehensively considering the relevant information of common structure and noncommon structure of 3D assembly model, which has a certain reference value for obtaining design commonness and mining and reuse of 3D assembly model meeting design individuality.

3. Discussion

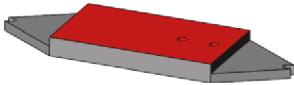

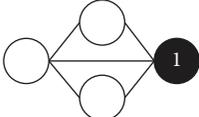

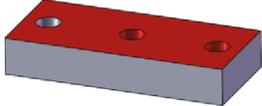

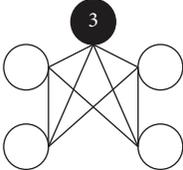

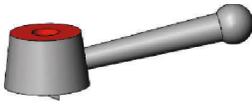

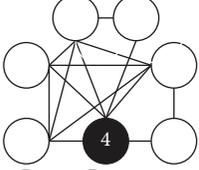

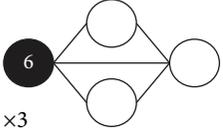

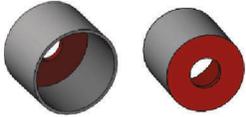

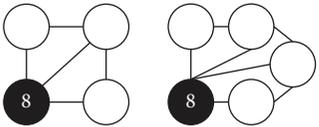

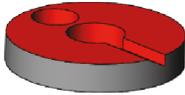

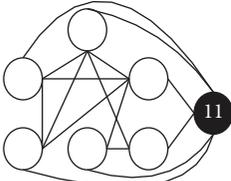

In order to verify the feasibility of the general structure construction of the 3D assembly model based on conjugate subgraph, the 3D assembly model of a machine tool fixture is selected as the research object, and the method in this paper is used to describe it in detail and step by step to verify the rationality and feasibility of the relevant methods.

Taking the 3D assembly model of a machine tool fixture shown in Figure 9 as the verification object, a detailed example verification process is carried out based on the general structure construction of conjugate subgraph.

Firstly, based on the AAG, the relevant information of assembly features in the 3D assembly model is retained, and semantic nodes are used to replace other information of parts. The corresponding attribute assembly feature adjacency graph is constructed for all parts in the model. The representation results are shown in Table 4. In the table, the red part in the part model corresponds to the assembly feature part of the part. The black node of the attribute assembly feature adjacency graph corresponds to the semantic node containing much semantic information of the part.

Then, based on the construction method of AAG of 3D assembly model, the corresponding AAG of 3D assembly model is constructed, and the representation results are shown in Figure 10.

TABLE 4: Attribute assembly feature adjacency diagram of each part in the fixture.

Serial number	Part name	Part model	Attribute assembly feature adjacency graph
1	Floor		
2	Positioning block		
3	Pressing plate		
4	Handle		
5	Support 1		
6	Nut		
7	Spring		
8	Spring protective sleeve		
9	Support 2		
10	Cylindrical pin		
11	Rotating parts		

The conjugate subgraph matching algorithm based on vertex screening goes through the general structure construction process in turn and then establishes a comprehensive and rich general structure expression. The experimental results are shown in Figure 11.

By analyzing the general structure of the 3D assembly model constructed in Figure 11, it can be seen that the structure displayed outside the coil is the common structure of the 3D assembly model, which represents the general composition of the model components, mainly including bottom plate, pressing plate, positioning block, support, nut, and other parts. The part circled by the coil is

the general set corresponding to Part 9 (support 2) in the general structure of the 3D assembly model, that is, the noncommon structure of the 3D assembly model, which represents the product structure of different designers according to different application scenarios, functional requirements, structural optimization, and other different design concepts.

Through the above analysis, designers have a specific understanding of the general composition of this group of 3D assembly structures, and the corresponding general set contains many personalized structures to meet the design needs of different designers.

4. Conclusion

By analyzing the concepts of assembly feature, assembly relationship, and conjugate in 3D assembly model, a general structure construction method based on conjugate subgraph is proposed in this paper. On the basis of relevant definitions and concepts, based on the relevant characteristics of

conjugate subgraphs and preprocessing, the efficiency is improved, and the conjugate subgraph matching algorithm based on vertex screening is used to solve the matching problem of assembly features in 3D assembly model. On this basis, taking the common structure as the core, the construction steps of the general structure of 3D assembly model are designed, so as to build a general structure expression

form with comprehensive information, reduce the matching times in the process of information retrieval, and improve the reuse efficiency of model design.

In the process of product design and manufacturing, designers have many objective and subjective requirements for the information of 3D assembly model, which have many uncertainties. Therefore, the design intention can be analyzed concretely in the follow-up, and its constituent characteristics can be summarized to build a more comprehensive semantic information expression standard that highlights the design personality.

In the era of rapid development of science and technology, in order to attract the public's attention, many architectural designs unilaterally pursue nonmainstream design, completely ignoring the surrounding environment and historical context. The original spatial features and scales have disappeared, and the root cause is that the spatial shaping is separated from the urban context. Urban design that continues the urban context is not only a method to solve specific urban space problems and contradictions but also an important means to build a beautiful urban space and achieve sustainable development. The urban design of the two banks of the Pinghe River in the east of Foshan is based on the sorting and analysis of the material and spiritual elements of the context of the base. This article will go back to the trend of Western architectural contexts and discuss how to design new buildings while respecting the historical context of the city through rational speculation on the two dimensions of contextualism architectural theory, space and time, combined with architectural cases.

1. Introduction

In the 1930s, many Chinese architects returned from overseas and brought back Western modernist architecture. In the 1980s, the trend of Western architectural theory arose again in my country. People gradually realize that Western architectural theory is an effective design method, and more architects try to apply these theories to modern architectural urban design. While studying western architectural theory, it is also necessary to emphasize the confidence of national culture, and the attention to architectural urban context has become a focus topic. Looking at the development of Chinese architectural culture in recent years, the buildings that are deliberately symbolic, strange and vulgar, and extremely discordant with the surrounding environmental conditions are increasing. Many buildings with strange images have become a topic of discussion among netizens after dinner, and there is even a list of the top ten ugly buildings in China that is reviewed every year. Either the company's products are unmodified as the appearance model, or the model expresses the blind worship of sexual

culture, or imitates and plagiarizes Western architecture. Many buildings try to use the "ugly" name. A lot of buildings try to make a name for themselves as "ugly." Architecture is a part of a specific history and a specific urban background, and it is a macro-spatial combination, which should fully consider its environment and historical background. There have been many great cities in Chinese history, such as Yencheng and Chang'an, which were planned in an orderly manner. The symbols of history should not be forgotten, and the design of the building should be completed in the macro urban context. It should be done in a macro urban context. Recalling the trend of Western architectural theory, contextualism has always been controversial. Many buildings produced under contextualism are not coordinated with the existing environment, and the design is conservative. In modern architectural design, we should hold a rational and speculative attitude, understand contextualism, use it as a technique of urban design, and consider and learn from the architectural environment and history [1].

The word context originated from the field of linguistics. It is a historical category developed in a specific space, and its

extension contains extremely broad content, which is interpreted as the context of the culture in a narrow sense [2]. The thought of context has a long history. In China, it was first introduced into the field of architecture and then gradually extended to cities. Due to the lack of in-depth research on the ambiguity and uncertainty of the context theory and its slow development, it has not formed an independent theoretical system and has been widely used in architecture, cities, and landscapes in the form of theoretical concepts. Today, the meaning of context in the city has been comprehensively updated and inherited [3]. “The current context is based on the specific situation of our country, drawing on Western contexts to develop and innovate, giving Chinese culture a way of interpreting it, and imbuing it with new cultural connotations. It not only represents the cultural essence of the past but also points to the most current cultural essence. Vibrant cultural genes pay more attention to the potential for future cultural innovation. The systematic project of promoting and inheriting culture is called “New Context Doctrine.” In the concept of the new context doctrine, the understanding of context is no longer limited to the old and the new. To solve the problem of cohesion, we should conduct an in-depth and three-dimensional excavation of its connotation, adapt to the needs of sustainable development of urban culture, and reveal the evolution law of context [4].

In terms of ideology, the development of the “city color pulse” is rooted in the concept of the collective unconscious created by Jung, which is an inherent deep unconscious. “The level of the collective unconscious is unconscious, and it contains the influence of the experiences accumulated by all generations in the past, including distant ancestors [5].” The fundamental reason for its formation is the common environment, that is, the environment with the social and cultural place, and it includes all indoor and outdoor man-made environments and natural environments. The fundamental feature of this environment is what Schultz calls the “spirit of place,” which creates and perpetuates the collective unconscious and its archetypes that exist in the deepest part of the human spirit. The traditional color ideology was formed earlier; from ancient times, the color cognition was developed from the fear of life to the ideology of color symbols as totem worship. In the Yangshao culture, Xia, and Shang dynasties, the color aesthetic psychology gradually formed. In the Zhou dynasty, the simple materialist worldview “Five Elements Theory” was combined with the worship of five colors, five numbers, heaven, Earth, human beings, and gods, forming a combination of time, space, human relations, and ritual system, the “Five Elements of Color Science” [6]. During the Tang and Song dynasties, the traditional “five-color aesthetics” was finally formed. Nowadays, with the introduction of the rational western color theory system, the traditional “five elements of color theory” has been gradually ignored. Although the simple color concept has not formed a color science system, the aesthetic awareness of the five colors has been deeply rooted in the hearts of the people and has become a national color feature [7] (as shown in Figures 1–3).

FIGURE 1: A corner of the square.

FIGURE 2: Landscape greening screenshot.

The connotation of architectural “context” includes two main lines of cognition: One is the spatial dimension, which refers to the physical space environment in which the building is located, including the natural environment and artificial environment; the other is the time dimension, which refers to the generation and development of buildings and the social and cultural background on which it depends. The so-called continuity of spatial context emphasizes the expression of the building in the spatial relationship of the neighborhood and respects the regionality of the building [8]. Robert Stern believed that “Architecture is a part of the whole” and “The new building should be adapted to the environment” [9]. In 1950, Venturi believed that architecture does not exist in isolation by itself but should be related to the whole between architecture and urban space, and form part of the whole of urban space. This is consistent with the “whole prior to the part” view emphasized in Gestalt psychology and the “text prior to sentence” idea advocated by Frege in the field of linguistics [10]. Whether there is a unified context between the building and other buildings reflects whether the relationship between the part and the

FIGURE 3: Square stone bench.

whole is harmonious. When a building is harmonious in its site, it will likely disappear into the site and the urban environment. People often think that this is a lack of design and is just a replica. However, the overall connotation of the city is magnified, and a new building that is in harmony with the urban context should be a work that skillfully uses the connotation of contextualism and design skills, rather than a simple and crude plagiarism [11].

2. The Concept, Spatial Value, and Constituent Elements of the Urban Context

2.1. The Concept of the Urban Context. The word context is derived from “Context.” As a term used to express the logical relationship between upper and lower contexts, it can also indicate the background and conditions in which things occur. Things can only develop if they are connected with a specific background environment. If the context is the soil of urban development, then the space shaped by urban design is the creation based on the context and soil. Context is the background of urban development and is related to many essential elements that affect urban development. All explicit and implicit elements related to the formation and development of a city can be included in the category of urban context [12].

Context is the connection in time and space between things created by human beings and things. It has both the “synchronicity” of horizontal time and space and the “diachronic” of vertical time and space [13]. By extension to the field of urban research, the basic connotation of urban context can be obtained, that is, in the process of historical development and under specific conditions, there is a dynamic and internal relationship between people and the natural environment, the built environment, and the corresponding social and cultural background, and the sum of essential connections [14].

After fully considering the style and morphological characteristics of the existing buildings on the plot, first choose to carry out roof renovation for the buildings with a north-south strip in the block volume, and make certain innovations in the sloping roof, connecting with glass in the

middle to adapt to the building volume. The problem of lighting difficulties caused by it; second, repair the facades of the buildings along the street, strengthen the interface characteristics of the buildings along the street, try to control the height of the buildings on both sides of the alley and the parking lane, and ensure the integrity and unity of the style along the street. Through historical research, sorting out the width of the street and the height of the buildings on both sides, and on the premise of respecting the history, the comfort of the street is improved and adjusted to a certain extent, and the width of the two streets and alleys is controlled to be about 3.0~3.5 m. The building height is controlled below 5 m. Finally, when repairing the original courtyard with missing texture, the newly added building should echo the style and volume of the original building and make appropriate adjustments on the premise of respecting the history to adapt to modern life and create a comfortable living environment [15].

2.2. The Spatial Value of Urban Context. Public space is the main place where residents work and live and is an important part of urban space (as shown in Figure 4). The public space that concentrates on the urban context and public activities can fully demonstrate the city’s heritage, charm, and vitality [16]. With the continuous acceleration of the urbanization process, driven by the short-sighted construction goals, the problems of monotony and low-quality urban space have become increasingly prominent, and the original spatial characteristics and scales have disappeared. The root cause of this problem is that today’s spatial shaping is divorced from the context of the city. First of all, the internal streets and alleys should be fully sorted out, and the additional buildings should be demolished to make the originally narrow and blocked internal streets and alleys open and transparent so as to enhance the comfort of the living space and further solve the hidden dangers of safety. The facades of the buildings on both sides of the streets should be unified in style, embellished with appropriate historical and cultural elements, and appropriate building concessions should be made to create micro-ecological nodes to create street landscape ecological corridors. Second, on the basis of dismantling buildings with incompatible styles, guided by the spatial layout of traditional courtyards in the old city, dismantling structures that destroy the courtyard pattern, rebuilding new buildings in areas where the pattern is vacant, and ensuring that it is compatible with the existing historic buildings and the traditional courtyards are in harmony, fully continuing the courtyard space pattern of the historical and cultural blocks, and creating a comfortable living and leisure space for the residents. Finally, retain the existing ancient trees in the plot, use them to create landscape space nodes, recreate the historical living space scene of the block, and create a comfortable and livable external living space [17].

Therefore, it is necessary to clarify the relevant elements of urban context and urban space design, comprehensively use urban design methods and context analysis and refinement methods, continue the context, and focus on the

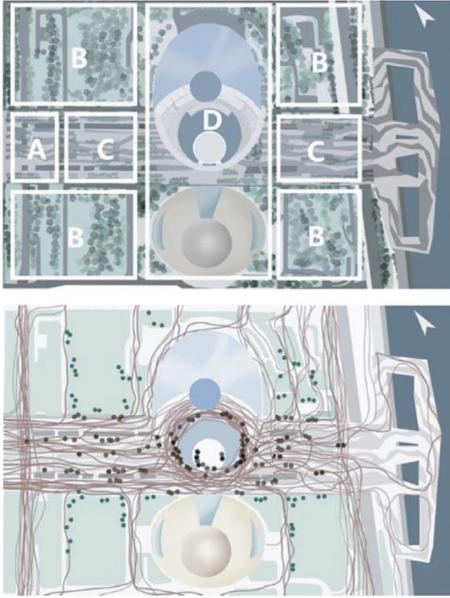

FIGURE 4: Functional zoning, crowd movement trajectory, and parking location of the civic square.

inheritance and innovation of the context in the design of urban public spaces so as to create a “cultural context.” The key to establishing a city’s image, increasing its charm, and enhancing its competitiveness is to realize the harmony between man and the environment, and the harmony between history and modernity [18].

2.3. Elements of the Urban Context

2.3.1. Material Elements. It is divided into two categories: one is the structural elements formed by the long-term accumulation of urban space; the other is the spatial form elements formed from the local climate, materials, and culture [19].

Structural elements include urban pattern, urban context, and urban texture. Structural elements are closely linked to the daily activities of residents through the perception of macro-spatial relationships such as axes, geographic markers, and skylines, and local structural elements should be respected in urban design. Spatial form elements refer to a variety of elements including urban skylines, urban landmarks, historical relics, dynamic place areas, and distinctive local spaces (such as spatial scale, shape, texture, color, interface, etc.) [20].

2.3.2. Spiritual Elements. Spiritual elements mainly refer to the regional culture of a city. It is the sum of various spiritual resources, including the morals, beliefs, customs, and arts of the city, as well as the habits and all other abilities learned by each city member [21]. Spiritual elements, as an abstract concept, are the essential attributes of “people” that govern activities in a specific urban space. Only by thoroughly analyzing and classifying urban regional culture, creating suitable local culture and habits in specific urban places, and

providing unique cultural activity space can we create an urban space full of vitality and a sense of place belonging [22].

3. Urban Space Construction Methods from the Perspective of Context

For urban design, context continuation is to advocate in the design of specific sections, through the analysis and research of the urban context, to maintain the continuity of the original space, culture, and life and highlight the characteristics of the city. This concept limits the problem of urban characteristics to the category with space as the basic research object, which makes the work goal of urban design clear. By summarizing excellent cases at home and abroad and the continuous improvement of urban design experience, the urban design method based on the purpose of context continuation can be summarized in the following three points [23]. Through the urban design, the spatial elements of the base are sorted out, the original “Wang Jigang-Green Island Lake” space corridor is retained, and the axis of “Green Island Lake-Jihua Road” is listed as the two major axes; at the same time, through sorting out, the topography and local settlement texture have extracted four characteristic elements of “lakes, hills, islands, and swells.” As an open public activity space, “lake” is one of the important ecological landscape elements, and various public activities can be carried out; it is the core area of public activities and the core of gathering popularity; “Chong” is an important link for the functional connection of various groups. On the axis, this urban design clarifies the original landscape axis of “Green Island Hu-Wang Jigang,” which serves as the principal basis for urban design to organize space and connect the two banks of the river. In terms of group relationships, the base is divided into three groups with different themes. Each group grows from existing elements and connects with the road network, rail transit stations, and water buses. The “S”-shaped lake gushing texture belt connects the “three groups on both sides of the strait” to form a spatial pattern of “one belt, three centers, two axes, and three groups”, and based on this, the spatial layout of urban design is guided. The Green Island Lake Smart Group not only concentrates on the main production and service functions of the Shanxi area but also owns the important water system resource of Green Island Lake. Therefore, the urban design positions this group as a comprehensive display of the cultural characteristics of Lingnan water towns and a provision for the Guangfo area. The intelligent highland of comprehensive services, through this intelligent group, strives to integrate the vitality of multiple waterfronts, realize the organic complementarity of main functions, and make it a springboard for connecting the two banks of the Dongping River and realizing the integrated development of the Ronghe River, creating the iconic core of Shanxi space. The central wisdom island is the core area of the entire design, and it is also the area that the axis of Wang Jigang and Lvdao Lake traverses. In the urban design, the spatial development model of the landscape city should be introduced, that is, to follow the natural

landscape space and create architectural space. Make it complement each other with the landscape axis accumulated in the context. The building space is created with green buildings and earth-covered buildings as the core elements, and the second-floor platform is organically combined with the platform across the embankment to build a core space with good accessibility and fun and at the same time reflect the image of a waterfront city [24].

3.1. Capture of Context. The development of a city must be accompanied by the renewal of space. The context allows people to find the basis for the creation of spatial characteristics from the traditional and localized content and forms from time to time. By extracting the elements of local context and summarizing their unique arrangement, urban design can subtly inject a localized atmosphere that strengthens environmental history and continuity into new spaces and enhances the place appeal of the space [25].

3.2. Transplantation of Context. In the process of urban design, the issues of “new” and “dilapidated” must be considered. For many issues such as whether to keep the urban context elements as they are after refining the urban context elements, and whether the original urban space cannot coexist with the new development, the author believes that the key lies in whether the context elements can be transformed into design principles in the design. We transform the complex “semantics” of the original context elements into a simple space “language” so that the urban design integrates and presents the structural relationship and characteristic symbols of traditional space.

3.3. The Shaping of the Contextual Characteristic Space. After extracting the local contextual elements and completing the transplantation work, the basic materials of urban design are obtained. By clarifying key areas, shaping a new spatial structure system, sorting out and arranging elements at all levels, and optimizing the arrangement of original elements, the new space has both historical continuities and adapts to the requirements of the new era. In terms of details, through the introduction of new functions, new materials, and new technologies, symbolic traditional cultural elements are added so that the precipitation of history and time can be displayed in the new urban space [26].

4. Optimization and Promotion Strategies of Urban Square Public Space from the Perspective of Contextualism

Public space is an important part of the urban innovation ecosystem. It is not only an important part of the material elements of the urban innovation zone but also the specific bearing and expression of economic and network elements, and is the spatial basis for “stimulating agglomeration.” Through the understanding of the theoretical basis of the urban innovation zone, this paper believes that the public

space of the urban innovation zone should reflect the characteristics of its three components, so the construction of the public space of the urban innovation zone should comply with the three principles of accessibility, openness, and network.

The physical elements of the urban innovation district enhance the innovation ecosystem by providing a compact and efficient mix of functions and street connections, so the public spaces of the urban innovation district need to be accessible to enable the connection between the physical elements. Public space is an important part of physical elements, including neighborhood scale public space. In order to make full use of the high quality public space, it is necessary to integrate the public space with exhibitions, concerts, restaurants, residences, and so on into a compact, functional mixed area. Connectivity that connects Category 1 (public realm) and Category 2 (private realm) physical assets is critical to public spaces in urban innovation districts, including walkable and cyclable street networks, among others. Based on the same concept, high-quality and convenient public transportation serves the interconnection of cities and regions. The transportation infrastructure such as Barcelona’s ring road and high-speed rail to Paris, Boston’s Silver Line, and Sydney’s northern M2 railway line are all urban infrastructure. The public space of the innovation district brings a large flow of people.

The management of the public space of the urban innovation district needs to follow the principle of openness to promote the diffusion of innovative activities and creative ideas in the public space. The urban innovation zone emphasizes the importance of spatial proximity and aggregation of economic activities. However, due to the blurred boundary of the urban innovation zone and the blurred boundary between work and life, the public space and the private space have proximity to economic activities. Circulating information has the characteristics of “liquid” and lack of openness, and information spillover cannot be realized, so the appearance of good ideas will disappear without circulation and diffusion. According to the Twelve Principles of Urban Innovation Districts published by the Brookings Institution, public spaces make innovation visible and open. Open innovation events help spark the curiosity of potential innovators, spark dialogue among neighbors, and spread innovations. Thus, in the urban innovation district, the public space becomes an outdoor testing ground for testing the initial results of innovation. The Boston District District Hall is itself a product of innovation, creating a new public space for the purpose of promoting a culture of innovation, the Innovation Hall. Opening District Hall in the BSID as a pilot project also accommodates a variety of innovative activities.

The social element of the city innovation district emphasizes the importance of social interaction, which not only lies in the strong ties between similar fields and departments but also focuses on the establishment of new ties between fields and departments, that is, weak ties. The public space serves as a key container for establishing weak ties, providing opportunities for chance encounters, networking, and knowledge spillovers. Creating an innovative atmosphere is

a new public interest represented by public space in urban innovation zones under the background of sharing economy and technological innovation. Networking is essential for public spaces, such as a series of activities to learn and develop new skills and build social interaction. High-frequency social interactions among innovative populations tend to be concentrated in a few specific “hot spots,” which may occur naturally. In addition, the innovation district requires a series of catalyst activities to reactivate neglected public spaces. Therefore, public space is the link between these “innovation hotspots.” In addition to forming a visible public network, it is more important to establish an internal interactive network relationship of competition, collaboration, and learning.

Spatial location is an important factor affecting the layout and form of public space in urban innovation districts. The Huanghuagang Science and Technology Park area is located in the old city of Guangzhou. Due to the tighter land use, the development intensity is often greater and the construction density is higher, showing the characteristics of compact urban space. During the process of urbanization, the surrounding living facilities are gradually supplemented. The surrounding communities are more closely connected, forming a mixed-function area. The overall layout of the land is larger, and the layout mode of multiple independent parks is adopted, which has more flexibility; at the same time, it has more abundant natural resources, and the planning considers the natural ecology, the interaction of the environment. In general, the core area of the main city is limited due to the limited urban space and limited space development of the science and technology park. The main open space is arranged along the road, and the street has become an important vitality center. On the other hand, due to the lack of interaction between public innovation space and public open space, the low degree of innovation openness is also the reason for the lack of vitality of public space.

A reasonable layout can improve the utilization rate of local accessibility of public space in the innovation zone. Traditional parks are generally relatively closed, and physical measures such as the establishment of walls are used to isolate the park from the residential community, which is not conducive to the integration of the park into the surrounding communities. Improving the local accessibility of public spaces in the urban innovation zone is conducive to keeping the park open and flowing. MPID has designed a variety of options for walking or cycling into the Lane Cove National Park from the track site while enhancing the density of the road network combined with the road network layout of public spaces to improve the accessibility of public spaces. Shenzhen Huaqiangbei District was born out of Shangbu Industrial Zone and continued the characteristics of openness of industrial blocks. The pattern of “small plots, dense road network” broke down the walls that were drawn as the ground to enhance the communication between plots, making the streets easier to communicate with each other. It has become a highly accessible public space in itself, which is friendly and approachable to pedestrians. In the practice of Guangzhou in recent years, the urban design and control

planning optimization of Pazhou West District emphasizes the urban development concept of “compact, intensive, efficient, and complex.” The arcade street of more than 2 kilometers is implemented on the ground, the three-dimensional park platform is built in the air, and the underground is connected through the vertical traffic module, ground, and air public spaces to realize the interconnection of public spaces. Figure 5 shows the optimization strategy proposed in this paper.

Providing a walkable environment in public space is an important condition for crowds to gather. High-density technology parks need to avoid rapid and massive traffic and people; planning new technology parks should avoid lack of consideration of spatial scale and one-sided pursuit of landscape ecology. The effect is to blindly build wide green isolation belts and huge square nodes. Shared communication space is an important feature that distinguishes the urban innovation district from other urban spaces. Similar to the community service center in each community, the shared communication space is a special public space built by the urban innovation district to stimulate innovation vitality, providing an open place for the exchange of ideas for the innovation district, allowing more people to get in touch with the ongoing innovation activities and promote the improvement of the innovation ecosystem. The purpose of building a shared communication space is to encourage knowledge sharing and information exchange. From the perspective of economic factors, building a rich and available shared communication space is conducive to promoting the exchange and collision of ideas. Around the world, regions building urban innovation districts actively build shared exchange spaces to provide venues for knowledge flow. Innovation districts in Barcelona and Stockholm, for example, have developed workshops and informal meeting spaces to encourage such exchanges; Research Triangle Park in North Carolina is a successful cluster, but they have found that the lack of venues for the exchange of ideas limits the. They go further; they try to redevelop their physical spaces to allow for active interaction.

Network innovation is created from the bottom up. Urban innovation districts cannot be achieved with a single order. Various event planning and construction are needed to promote collaboration between industries and departments and to foster innovative networks and a culture of exchange and sharing. Providing a public space that promotes communication and interaction is a prerequisite for nurturing weak interpersonal ties, and an innovative atmosphere is a catalyst for building a weak interpersonal network. The atmosphere is closely related to various scenarios, such as rich innovative activities, street art, nightlife, etc., to enhance social vitality and business interaction, attract, retain, and nurture innovative people and innovative enterprises. The existing newer science and technology parks in the urban area are located in the core area of the main city and often have a certain compact and mixed physical space foundation, such as Huanghuagang Science and Technology Park, Keyun Road, Longkou East Community, etc. At the same time, the limited space and the early construction period bring problems such as a single type of public space

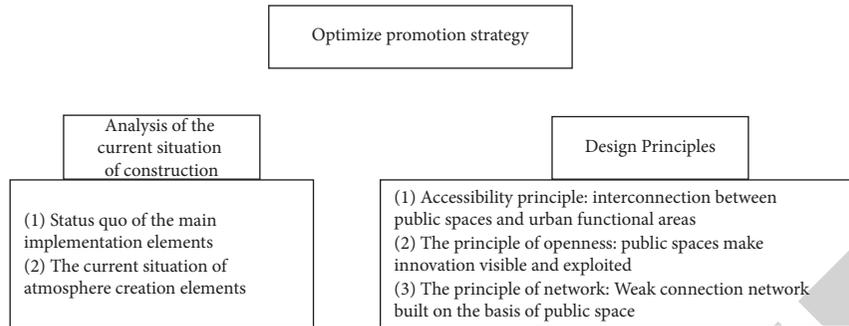

FIGURE 5: Optimization promotion strategy.

and outdated facilities. Aiming at the main contradiction of limited development space, the optimization strategy can control and guide the interaction and continuity between the existing building space and the public space so as to expand the shared communication space with suitable functions and the public retail space with various choices. Therefore, the strategies for improving the openness of the existing urban renewal technology parks can be summarized as follows: focus on the combination of dots and lines in the surrounding area to create a public space with a continuous interface, encourage the opening of the ground floor of the building to improve the interface quality of the public space, and pay attention to street management to avoid sidewalks and subways. The entrance and exit become the storage yard for shared bicycles.

5. Conclusion

In the process of rapid urbanization, the urban design with the theme of continuation of the urban context adheres to the spirit of the “Beijing Charter”, advocates cultural diversity, maintains cultural diversity, and adheres to the path of regionalization and modernization of modern buildings to demonstrate the Chinese characteristics of modern regional cities. The urban design of the two banks of the Pinghe River in the east of Foshan adopts the methods of extraction, abstraction, and construction and adopts the design idea of respecting the city’s history and culture so as to achieve the sustainable development of the city’s vitality and cultural continuity. Urban design that continues the urban context is not only a method to solve specific urban space problems and contradictions but also an important means to build a beautiful urban space and achieve sustainable development.

This paper firstly conducts a theoretical analysis on the digital transformation of enterprises. Theories such as Marxism and new institutional economics related to the digital transformation of enterprises are sorted out. Secondly, it conducts an empirical analysis on the digital transformation of high-tech enterprises. This paper summarizes the three major transformation paths of the existing production service digitization, marketing model digitization, and industrial digitization. Based on the data analysis of the questionnaire, this paper summarizes the difficulties of digital transformation of high-tech enterprises, mainly due to the lack of transformation ability, resulting in “cannot transfer”; the lack of self-development conditions and digital transformation, resulting in “will not transfer”; digital transformation lacks full guarantee, resulting in “do not dare to turn.” And based on the analytic hierarchy process, the influencing factors of the digital transformation of high-tech enterprises are analyzed, and the relative importance of each factor is obtained.

1. Introduction

With the introduction of new development and new development strategies, China's economic development has undergone tremendous changes. The term “digital economy” was first coined in government work in 2017, and it has had a profound effect on the optimization of the economy by the prosperity of emerging industries such as the digital economy. And accelerating the development of the digital economy and promoting the combination of digital economy have become a hot topic. With the rise of digital technologies such as big data, cloud computing, and artificial intelligence, digital technology has become an important means for modern enterprises to adapt to the changes of the times, implement national strategies, and improve their competitiveness. According to a survey report by IDC on CEOs of 2,000 companies, up to now, 67% of companies regard digital transformation as the core of their corporate strategy, and 70% of China's 1,000. The “2019 Chinese Enterprise Digital Transformation Index Research” published by Accenture on September 10, 2019, shows that China's “ideal digital company” was a measure in 2018, with

a comprehensive score of 45, up from 37 in the same period last year, 20%. This shows that China's e-commerce has entered a new stage, and it is also a new digital age [1].

In order to maintain the stable development of enterprises, it is necessary to conform to the development trend of the times and the digital age although many companies regard digital transformation as a strategic focus and have invested in many companies' systems and equipment on the basis of digitalization [2, 3]. However, the “2019 Chinese Enterprise Digital Transformation Index Research” pointed out that although China has achieved a substantial increase in revenue and sales, in terms of digital transformation, only 9 aspects have achieved obvious results, and many companies are still unable to achieve expected goals and effect, facing the difficulty of transformation. How to promote the digital economy of enterprises to achieve higher performance has become an important topic of concern to the industry and theoretical circles. This dissertation takes high-tech companies as the center and discusses their digital transformation. Most of the previous literature on the transformation of high-tech companies has discussed the transformation strategies of high-tech companies from a

macro perspective, but the results are inconsistent with the digital transformation trend of high-tech companies; only a few scholars have focused on the digital transformation of high-tech industries. However, due to the lack of accurate understanding, their digital research mainly focuses on the network. In the digital age, the digital transformation of high-tech industries involves a relatively narrow scope and a relatively shallow level.

2. Overview

2.1. Digital Economics. The “digital economy” was first proposed in 1994, and its meaning is constantly changing. The connotations of various concepts and researches on the digital economy are getting richer and richer. So far, there is no consensus on this issue, whether domestically or in academia. The definition of digital economy in European and American countries is mostly defined from the perspective of industry and products, which focuses on the interaction between technology and people, but the definition of industry is relatively simple in general, involving telecommunications, audio-visual, software, Internet, and other industries [4]. And on this basis, the communication, audio-visual, and other technologies have been deeply analyzed. When China defines the digital economy, what it considers is the entire relevant behavior, that is, the changes that occur on the basis of the occurrence and development of an economic system, that is, the combination of economy and technology. The “G20 Digital Economy Development and Cooperation Initiative” was officially released by China at the 2016 G20 Summit. The initiative focuses on China’s ideas in promoting economic growth and strengthening cooperation with other countries. The digital economy is a kind of production factor that uses digital technology as the medium to effectively utilize digital technology to achieve economic optimization and improve efficiency. It is pointed out that the digital economy is the combination of industry and industry with communication as the main content. In the context of the digital economy, digital information is regarded as the main means of production. The new socioeconomic form came into being after the two major development forms of agriculture and industry [5]. Compared with the conventional model, the new economic model has brought a large amount of digitalization of production and operation, and these new means of production are new means of production based on data. In short, the digital economy is a huge economic change. Its combination with modern technology allows enterprises and users to communicate efficiently, so that the circulation of products and services will develop in a more convenient and scientific direction. Through the digital economy, all aspects of each link can be effectively integrated, so as to achieve better development.

2.2. Data Processing. “Digitalization” is an important part of the digital economy. With the passage of time and the continuous innovation of technology, the meaning and

external expansion of numbers have become more and more diverse. Digital technology is the integration and optimization of traditional information systems. Through integration and optimization, the operation of enterprises can be improved, and new technologies can be improved through new technologies, so that they can meet the needs of digitalization.

2.3. Digital Conversion. How to carry out digital transformation has become a common concern of both the theoretical and practical circles. Huawei believes that digital transformation is the use of a new generation of digital technologies to build a digital society with full perception, full link, full scene, and full intelligence, thereby reconstructing traditional management and business models. By innovating and reconstructing the way of operation of the enterprise, we can obtain the victory of the enterprise. Kingdee regards digital transformation as the digital transformation of enterprises; that is, enterprises use digital technologies to apply technologies such as the Internet of Things, cloud computing, big data, mobile, and intelligence to enterprises and plan and implement business model transformation, management, and operation transformation. Enterprises and employees bring new digital value enhancement and continuously improve the new core competitiveness of enterprises in the digital economy environment [6].

There are differences in the understanding of “digital transformation” in academic circles. Gemini believes that digital technology is the fundamental improvement of company performance through digital technology and through the use of digital technology to break down the information barriers between various departments, thereby improving the efficiency of company operations. Experts such as Berman believe that the essence of digital transformation is to reconstruct the value of customers and use digital technology to change the way of production and operation, thereby changing the value and operation of traditional manufacturers, thereby promoting their development in the digital age. The main proposition of Wang Hua in China is as follows: digital transformation means that the company’s production and services can be realized through digital technology, the company’s operations and operations can be combined with digital technology, and the company, customers, and the market can achieve, through comprehensive technological transformation, interaction and communication and constantly promote the comprehensive innovation of the market, business system, and customers, thereby improving operating efficiency.

Based on the above theories and the actual experience of enterprises, the concept of enterprise digital and the innovation of product models and business models accelerate the transformation and upgrading of enterprises through digital means and seek new paths for innovation and development. Big data application, intelligence, and networking are important features of the transformation of the digital economy.

3. Mechanism Analysis of the Driving Force of Digital Transformation of Enterprises

With the development of economy and society, and the continuous progress of the times, emerging industries such as the Internet and e-commerce have emerged as the times require. In the research of emerging fields, the basic principles of Marxism can still be used as the basic theory to build the theoretical logic of related research. Based on the actual national conditions of China, it still has extremely important practical guiding significance to apply the basic principles of Marxism directly or indirectly to the research of economic or social topics in the new era. The pursuit of excess profit is the subjective motivation and fundamental driving force of the digital transformation of enterprises [7]. Marx believed that the productivity of social labor is affected by many factors. With the integration and development of large industry and the digital economy, the creation and accumulation of real wealth depend more on the average level, iteration speed, and application of science and technology in the current society, rather than the simple accumulation of labor time. Therefore, the advancement of digital technology is a key factor in promoting the transformation of social productivity, resulting in changes in the economic form and gradually forming a digital economy.

3.1. Digital Technology Lays a Technical Foundation for the Digital Transformation of Enterprises. The development and progress of digital information technology have laid the necessary technical foundation for enterprises to carry out digital transformation. On the one hand, the advancement of digital information technology can improve the labor productivity of enterprises in digital production. Using Marx's relevant viewpoints for analysis, we can see that the development and application of digital information technology determine the proportion of capital divided into constant and variable parts. However, in the current situation where the nature of society is certain and the speed of development is relatively stable, the accumulation of wealth is closely related to the development of human beings. Therefore, when the production department of the enterprise is reasonably and effectively equipped with digital software and hardware facilities and high-tech talents, the labor productivity of the production department of the enterprise will be greatly improved [8]. In the era of digital economy, as long as a certain department takes the lead in completing digital transformation and realizes the transformation of production methods, "it will inevitably lead to changes in the production methods of other departments." It is worth noting here that, in the process of digital production, digital information technology and the corresponding digital hardware and software facilities "always enter the labor process in their entirety but always only partially enter the value appreciation process." Digital technology and digital production equipment itself do not create value, but they gradually transfer their own value to the digital products they produce or the digital services they provide. In this

sense, digital technology and digital production equipment are a digital component of the value of a product or service.

On the other hand, the advancement of digital information technology promotes the digitization of collaboration and the specialization of division of labor among various departments of the enterprise, which is conducive to promoting the digital transformation of enterprise organizations. The development of digital information technologies such as the Internet and SG makes collaboration not limited by time and space, which is conducive to expanding the scope of collaboration and greatly improving the efficiency of collaboration [9]. The digital production operation of an enterprise under the technological progress itself is a huge and complex system, which requires a large number of local workers to divide and cooperate. As Marx put it: "Not to mention the new forces arising from the fusion of many forces into one total force, in most productive labor, social contact alone evokes a sense of competition and a peculiar invigoration of energy that elevates everyone. The application of digital information technology provides technical support for expanding the influence of this social contact, promotes the digital and efficient transformation of enterprise organizations, and greatly improves the work efficiency of enterprise workers."

3.2. Participation and Distribution of Data Is a Necessary Condition for Digital Transformation of Enterprises. The reason why nonphysical data can participate in the distribution is that it is gradually capitalized with the development of the digital economy. It has the nature of capital and is also a special kind of capital. Combined with the analysis of the basic principles of Marxism, it can be seen that, in the digital network formed by the application of related, the data generated in the daily use of social media will be transformed into capital through two stages:

First, the commercialization stage: users need to consume a certain amount of physical and mental energy in the process of using social media, and the relevant data generated based on this exists in the form of labor products; when these digital labor products are "exchanged, transferred to use as use value, and use it in the hands of people," it becomes a data commodity; that is, in the market economy, the data generated through digital labor is exchanged for the purpose of profit, and it exists in the form of a commodity.

The second is the capitalization stage: the digital labor that users use various software to generate data in their daily life is unpaid labor and still has the nature of "exploitation." Large-scale Internet companies such as Amazon, based on the volume of their digital business and the advantages of related digital technologies, freely occupy the digital labor of users and the data value they generate [10, 11]. According to the needs of business development, the relevant data generated by the digital labor that they possess for free are extracted, processed through digital technology to form a data group, exchanged, and sold, and their data products are sold, "and most of the money obtained from this are reconverted into capital" and used for the additional

production materials and labor required for the continuous digital development of enterprises, and data commodities are transformed into digital capital. In this process, data exists in the form of capital.

Participation in the distribution of data mainly involves two aspects: on the one hand, data as a factor of production participates in the distribution. According to the relevant theoretical analysis of factor distribution theory, data has become a special production factor, and its distribution principle is determined by social production relations. In a capitalist society, how data is distributed as a factor of production is determined by the owners of the data, the capitalists. In a socialist society, public data resources are shared by the whole people, while nonpublic data resources are distributed by the market under established legal conditions. Another aspect is that data participates in distribution as the final product. In China, the distribution of data products needs to meet the relevant requirements of the basic distribution system, which is mainly determined by the amount of labor paid by the laborers in the process of data collection, analysis, and application.

3.3. Pursuit of Excess Profit Is the Fundamental Driving Force for Digital Transformation of Enterprises. In the digital age, the “labor” expounded by Marx in the labor value theory combines digital information and other modern technologies to form a new form of labor, that is, digital labor. According to the relevant elaboration of labor value theory, digital labor includes concrete labor and abstract labor. A user posts videos, images, comments, etc. in social media. This kind of labor consumption based on a certain purpose constitutes the specific labor of digital labor. The specific content published can meet certain needs of people. Therefore, there is the specific labor of digital labor. The generated data information can create use value for the economy and society; the digital behavior of all users, such as web page search and browsing behavior, has no specific form. Human labor in the general sense forms the abstract labor of digital labor, which is given to commodity producers. The demand information about the size, shape, and function of the designed product can be produced based on the application of related technologies to create value, which reflects the relationship between data producers, information users, and commodity sellers in the social production process in the digital age social relationship. The amount of value of goods produced based on the use of digital technology is determined by the socially necessary labor time [12]. The higher the “development level of science and the degree of its application in craftsmanship” in the field of digital information are, the higher the productivity of digital labor is, and the smaller the value of the digital goods it produces. From the relevant analysis of the theory of surplus value production, it can be seen that, in the early stage of the development of the digital economy, individual entrepreneurs used digital information technology to improve the labor productivity of enterprises and carried out digital production and operation. The labor time consumed by the same

commodity shows that the commodity value produced by individual entrepreneurs based on digital information technology is lower than the social value, thus obtaining excess surplus value. Based on this, the individual production price of the commodity will be lower than the social production price, and enterprises that use digital information technology for digital operations will obtain additional profits that are more than average profits, that is, excess profits. Due to the existence of the law of market competition, the practice of individual entrepreneurs using digital information technology for production and operation to obtain excess profits will be replicated and promoted by other entrepreneurs in their industry, which will eventually attract more enterprises to improve their digital production and operation capabilities and conduct digitalization [13].

To sum up, the pursuit of excess profit is the fundamental driving force and subjective motivation for enterprises to improve production technology and carry out digital transformation. In the era of digital information, the pursuit of excess profits by various entrepreneurs is conducive to improving the level of labor productivity in society and promoting the pursue more Excessive profits, thus forming a virtuous circle.

4. Big Data Model for Digital Evaluation of High-Tech Enterprises

There are currently three ways to distribute the income of estimating the coefficients of the digital combination: one-way ANOVA, historical simulation, and Monte Carlo simulation.

4.1. The Variance-Covariance Method. This method is one of the most common VaR values and belongs to the parametric method. On this basis, the statistical method is used to predict the income distribution of the digital coefficient, and the historical data are used to estimate it, such as variance and correlation coefficient, thus obtaining an overall under certain credibility. The VaR value of the asset is

$$\text{VaR} = z_{\alpha} \sigma_p \sqrt{\Delta t}, \quad (1)$$

where σ_p is the standard deviation of the entire portfolio return, z_{α} is the quantile of level α , and Δt is the holding period. According to the above formula, the VaR value can be obtained only by calculating the variance. The commonly used variance prediction methods include the RiskMetrics method and the GARCH method.

4.1.1. Risk Metrics Method. The RiskMetrics digital control model was launched by the digital management department of JPMorgan in October 1994. It is the world’s first quantitative VaR model. Its main idea comes from the exponential moving average method (EWMA), which takes unequal weights on the data in the time series. To simplify the assigned weights, it introduces a parameter λ , called

attenuation factor, whose value is between 0 and 1. For the estimation of λ , the principle of root mean square error (RMSE) is usually used; that is, the value of λ that minimizes the root mean square error of the prediction is selected:

$$\sigma_t^2 = (1 - \lambda) \sum_{i=1}^{\infty} \lambda^i r_{t-i}^2. \quad (2)$$

The exponential moving average method estimates the standard deviation of returns. The variance estimation formula can be written in an iterative form, which will help the use of computers process huge data. RiskMetrics based on the normal method has some drawbacks: it relies on the normality of position returns and is a partial method and a thoroughly linear method, while being computationally cumbersome.

4.1.2. GARCH Class Methods. The 2003 Nobel Laureate in Economics Robert Engle first introduced the ARCH model in 1982 to model variance. In 1987, Bollerslev extended the autoregressive conditional heteroscedasticity (ARCH) model and developed it into a generalized ARCH model, namely, the general autoregressive conditional heteroscedasticity (GARCH) model. Over the years, GARCH models have become a large family of many different types. A large number of empirical studies have shown that GARCH-type models have the characteristics of good description of financial time series, that is, the ability to deal with the time-varying and thick-tailed distribution of variance.

$$r_t = \mu + \varepsilon_t, \quad (3)$$

where μ is the unconditional mean and ε_t is the disturbance term. The conditional variance equation of GARCH-like models provides a simple analytical form for the stochastic volatility process in financial return data. The GARCH (p, q) model predicts volatility as follows:

$$\sigma_t^2 = \omega + \alpha_1 \varepsilon_{t-1}^2 + L + \alpha_p \varepsilon_{t-p}^2 + \beta_1 \sigma_{t-1}^2 + L + \beta_p \sigma_{t-p}^2 \cdot (\omega > 0, \alpha_1, L, \alpha_p \geq 0, \beta_1, L, \beta_p \geq 0). \quad (4)$$

The choice of the conditional variance equation and the assumption of the independent and identical distribution of the residuals are two key factors. With the application of GARCH-type models in the financial field, two obvious problems have gradually emerged in general GARCH-type models: first, the nonnegativity constraints on coefficient parameters are too strong, which excessively restricts the dynamics of conditional variance. Second, the conditional variance σ_t in GARCH-like models is a symmetric function of ε_t , which depends only on the magnitude of ε_t and not on its sign. Obviously, this is not true because interest rate movements in financial markets have a leverage effect, and the rise and fall of stocks will have an uneven impact, and the fall of stocks will have a greater impact on subsequent volatility. This means that the preferred mode handles both positive and negative types of residuals in an asymmetric manner.

4.2. Historical Simulation Method. By analyzing the frequency of portfolio income in a certain period, the method finds the historical rate of return and the current minimum rate of return of the index within a certain confidence interval [14]. The model does not need to assume the statistical distribution of various market factors and can fully reflect the real changes of various market factors, so that it can solve the problem of abnormal distribution. The simulation algorithm is easy to implement and suitable for various types of positions and digital calculations in various markets. However, because this model assumes that future market factors and past historical changes are exactly the same, which is inconsistent with the real financial market, especially in the recent large-scale range, past data cannot be used to predict future stock markets and make accurate expectations, so historical simulation techniques are employed without any warning of unforeseen numbers. In addition, it is difficult to meet the above requirements because of the many specific data required for historical allocation of portfolio returns.

4.3. Monte Carlo Simulation. Return on assets or market factor returns are not derived from historical observations, but we use tools to generate a huge amount of possible random data that conform to historical distributions, thereby constructing a portfolio, possible gain or loss, and then get an estimate of the digitized value at a given confidence level [15]. This method is extremely efficient and flexible because it does not require normality assumptions about the distribution of asset values, can be used for arbitrarily distributed return assumptions, does not require linear relationships between digitized factors, and also applies to variance changes with time, when the distribution is tail, in extreme value scenarios, and other special situations. However, the process used to generate data in the simulation process is random, which makes it subject to a certain degree, and this method has a large amount of calculation, a long calculation time, and is more complicated than other methods.

5. VaR Measurement Analysis of Market Digitization of Small- and Medium-Sized Private Enterprises

By processing the closing prices of 423 small- and medium-sized private listed companies from January 4, 2016, to December 31, 2020, a logarithmic daily rate of return sequence containing 1215 data was obtained.

5.1. Basic Statistical Data Analysis. The normality test of financial time series can generally be tested by calculating the mean, skewness, kurtosis, and Jarque–Bera statistics. The daily rate of return was analyzed using EViews software to obtain the histogram and descriptive statistics of the logarithmic daily rate of return series (Figure 1).

From the chart, we can see that the deviation value of the portfolio is above 0, and the distribution is positive, indicating that there is a right tail in the return distribution.

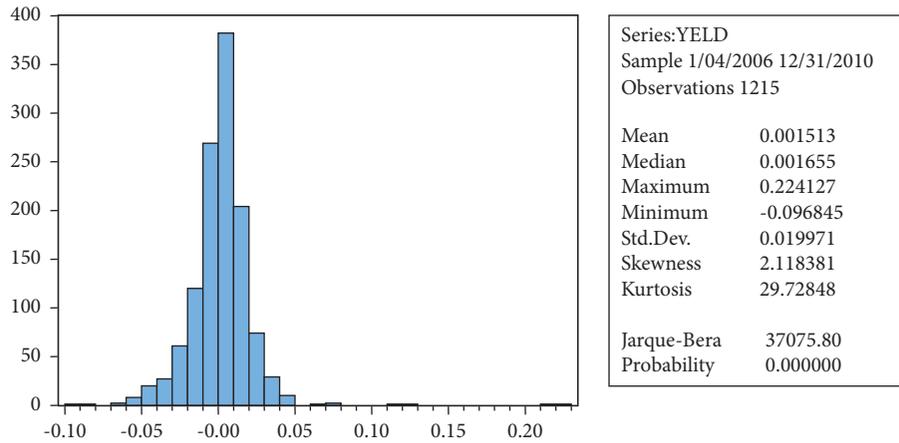

FIGURE 1: Descriptive statistics of log daily returns and their histograms.

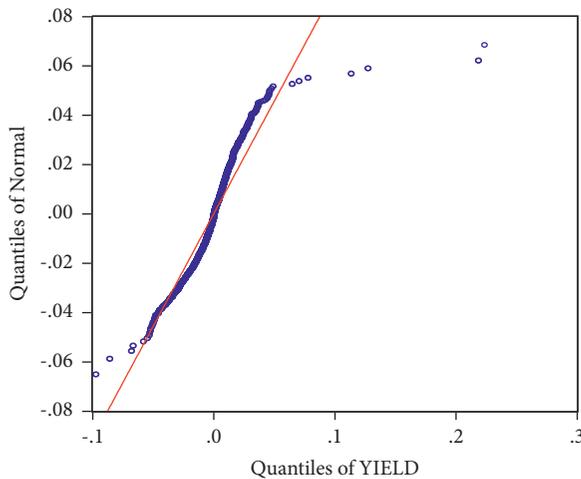

FIGURE 2: QQ plot of log daily returns.

Kurtosis is used to describe this type of steep slope, which is much higher than the normal 3 peaks, which means that the frequency distribution is much more dense than normal. The Jarque–Bera statistic is used to detect the normal distribution of a series, and the threshold for 5% significance of this statistic is 5.99 under the assumption that the condition is 2. The value of the Jarque–Bera standard test statistic here is above the threshold of 5.99, which, in terms of the probability of the JB statistic, shows that a 0 assumption negates a normal distribution. The average return is not too far from zero, and it is also insignificant compared to the standard deviation. It is clear from the curve that there is a sharp rear tail in the distribution of returns. The average daily returns of small- and medium-sized board stocks show abnormal characteristics.

In addition, the QQ chart can more directly detect the normal distribution of returns (Figure 2).

The QQ plot compares the quantiles of a sample with the quantiles of a normal distribution. If the return distribution of the index is a normal distribution, then it should be a straight line on the QQ chart, and it can be seen from the figure that the line is a curve rather than a straight line, so the

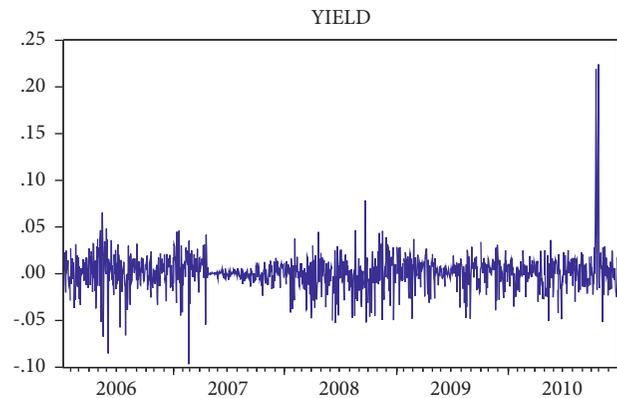

FIGURE 3: Logarithmic daily return time series chart.

distribution of the logarithmic daily return series is not a normal distribution. In addition, looking at the time series of the logarithmic-day yield series in Figure 3, we can see that there is a clustering effect in yield fluctuations. The QQ plot also shows that this thick-tailedness is asymmetric.

5.2. Stationarity Test. The ADF method controls for higher-order serial correlations by adding a lagged difference of the dependent variable y_t to the right-hand side of the regression equation, as shown in Figure 4.

$$\Delta y_t = \gamma y_{t-1} + \sum_{i=1}^p \beta_i \Delta y_{t-i} + u_t, t = 1, 2, \dots, T, \quad (5)$$

$$\Delta y_t = \gamma y_{t-1} + \alpha + \sum_{i=1}^p \beta_i \Delta y_{t-i} + u_t, t = 1, 2, \dots, T, \quad (6)$$

$$\Delta y_t = \gamma y_{t-1} + \alpha + \delta t + \sum_{i=1}^p \beta_i \Delta y_{t-i} + u_t, t = 1, 2, \dots, T. \quad (7)$$

5.3. ADF Inspection. Model (7) is a time variable, which represents a certain trend of the time series over time. The null hypotheses are all $H_0: \gamma = 0$; that is, there is a root of unity

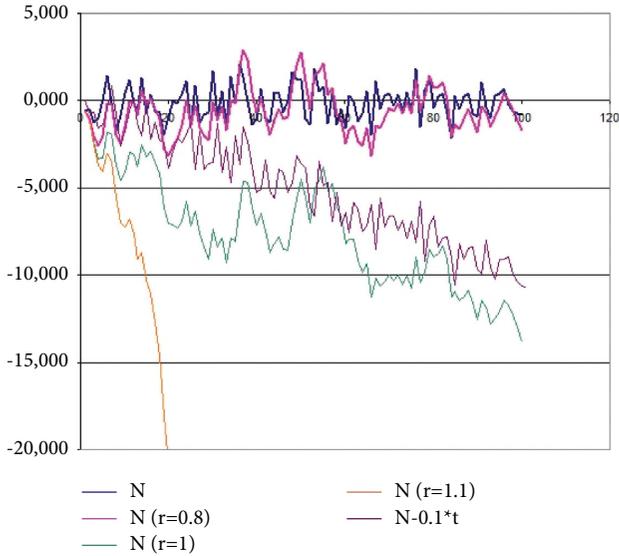

FIGURE 4: Stationarity test.

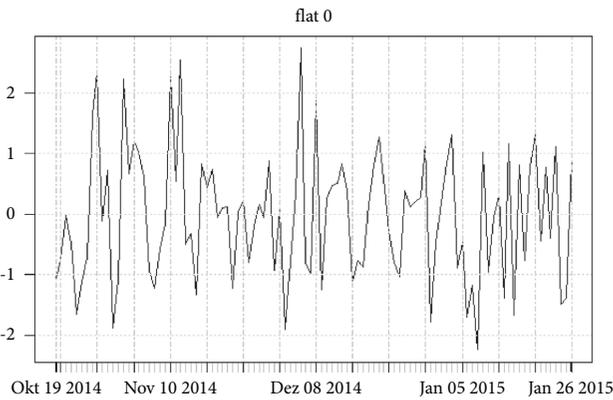

FIGURE 5: ADF test.

TABLE 1: ADF test.

Null hypothesis: Yield has a unit root			
Lag Length: 0 (fixed)	t-statistic	Prob.*	
ADF test statistic	-29.73025	0.0000	
1% level	-3.435523		
5% level	-2.863712		
10% level	-2.567977		
Akaike Info criterion	-5.0105	Schwarz criterion	-5.00209

(Figure 5). The difference between model (7) and the other two models is whether it contains constant term and trend term. The actual test starts with model (7), then (5), (6): when to reject the null hypothesis, that is, the original sequence does not have a unit root and is a stationary sequence, and when to stop testing. Otherwise, continue to check until (5) is completed. The results shown in the table were obtained under the principle of minimum AIC and SC (Table 1).

From the test results, at the three significance levels of 1%, 5%, and 10%, the critical values of the unit root test are -3.435523, -2.863712, and -2.567977, the hypothesis H_0

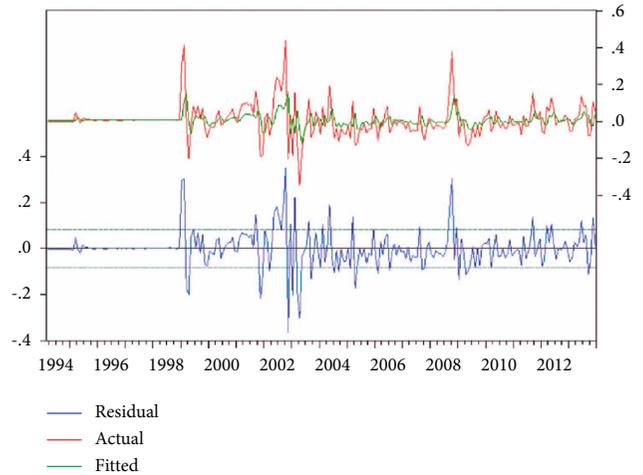

FIGURE 6: ARCH effect test.

TABLE 2: ARCH-LM test.

F-statistic	46.35092	Probability	0.00000
Obs * R-squared	133.56369	Probability	0.00000

indicates that the difference series of daily returns does not have a unit root, and the logarithmic daily returns are stationary series.

5.4. *ARCH Effect Test.* In 1982, Engle proposed the Lagrangian multiplier test, namely, the LM test, to test whether there is an ARCH effect in the residual sequence. This particular specification of autoregressive conditional heteroskedasticity is due to the discovery that, in many financial time series, the magnitude of the residuals is related to the most recent residual value. The LM test statistic was calculated by an auxiliary test regression (Figure 6). There is no ARCH effect in the residual sequence up to the p -order, and the following regression is required:

$$u_t^2 = \beta_0 + \left(\sum_{s=1}^p \beta_s u_{t-s}^2 \right) + \varepsilon_t, \quad (8)$$

where u_t is the residual. This formula represents a regression of the residual squared u_t^2 on a constant and lag u_{t-s}^2 up to the p -order residual squared. This test regression has two statistics:

- (1) The F statistic is an omitted variable test for the joint significance of the lags of all squared residuals;
- (2) The $T * R^2$ statistic is Engle's LM test statistic, T is the number of observations, and R^2 is the regression test. The exact finite-sample distribution of the F statistic under the null hypothesis is unknown, but the LM statistic is in general asymptotically subject to the $\chi^2_{(p)}$ distribution.

Table 2 is the test result of ARCH-LM, and the result shows that the P value is zero, rejecting the null hypothesis. This indicates that the residual series has an

ARCH effect; the residual squared correlation plot shows that the Q statistic of the residual squared series is significant, which also indicates that the residual series has an ARCH effect.

6. Discussion of Results

As an important part of developing the digital economy and an important part of China's digital strategy, the digital transformation of enterprises is of great significance to boosting the Chinese economy. Based on the data of high-tech listed companies from 2016 to 2020, this paper studies the impact of digital transformation on enterprise performance from multiple perspectives such as dynamic effects and heterogeneity and studies the mediation of its impact. Finally, robustness and endogeneity tests were carried out. This paper mainly draws the following conclusions: first, digital transformation can effectively improve enterprise performance and can continue to improve enterprise performance for a long time, and the effect is more obvious in enterprises with a high degree of digital transformation. Second, considering that differences in the company's own attributes and macro-environmental conditions may have different effects on corporate performance, we empirically test the impact of digital transformation on the effects of digital transformation from a micro perspective (property nature, corporate age) and a macro perspective impact on business performance [16]. It is found that, compared with non-state-owned enterprises, digital transformation can significantly improve enterprise performance in state-owned enterprises, but for non-state-owned enterprises, it does not play a boosting role; from the perspective of enterprise age, digital transformation can effectively improve enterprise performance, but compared with young enterprises, mature enterprises have better performance improvement effect; from the perspective of macroeconomic environment, no matter the macroeconomic environment is good or bad, digital transformation can improve enterprise performance, but the performance improvement effect is more effective when the environment is good for obvious reasons; digital transformation can improve business performance as far as the financial cycle is concerned, but it works better in a bull market [17]. Third, from the perspective of the transmission mediation path, operating costs and labor productivity have a partial mediating effect in the relationship between digital transformation and corporate performance; that is, digital transformation improves corporate performance by reducing operating costs and improving labor productivity. Fourth, considering that the impact of digital transformation on enterprise performance is inseparable from government support, we further embedded government governance elements to study the paradigm of "digital transformation and enterprise performance." The policy effect exerted is inefficient, while the government focuses on refined governance in the micro-field; that is, the policy effect exerted in the form of targeted subsidies is extremely efficient.

This research provides important practical implications for exploring new driving forces for improving corporate performance and thus promoting the high-speed and high-quality development of the digital economy: first, to promote enterprises to actively promote digital transformation, drive flexible production, intelligent manufacturing, and digital management and sales. Promote the value of data, accelerate the deep integration and integration of new-generation technologies such as big data, cloud computing, Internet of Things, and 5G with enterprises, promote cloudification and integration of core systems, and continuously promote enterprises to digitalize transformation of modern business models. Strengthen the interconnection of data, knowledge, and services between enterprises, tap synergies between enterprises, promote the online, intelligent, and digitalization of commercial trade, realize the rapid matching of data and services, and improve the agility to respond to changes in business needs. Customers provide personalized customized services to form a digital ecological cluster that "gets what they need, mutual benefit and win-win," so as to improve corporate performance. For example, home appliance companies can use the smart TV terminals sold by the company as the basis to develop third-party businesses, such as cooperating with Internet companies to collect statistics and data on users' use of watching videos, music, education, games, and other content services, conducting in-depth analysis of these data, and using public services and other means to spread brands to users and gradually form a ten million-level user platform and realize the development model of "user + terminal." In addition, we should also pay attention to the digital transformation of non-state-owned enterprises and young enterprises, promote small-scale enterprises to go to the cloud platform, improve the external economic environment of enterprises, and promote the sustainable development of all-round overall digital economic benefits. Second, help enterprises to improve labor production efficiency through digital transformation and promote the quality and efficiency of digital transformation. In-depth mining, collection, and analysis of enterprise internal data information such as enterprise equipment, personnel, and logistics focus on analyzing this data information and classify and refine it. Identify possible integrated processes and steps that can be omitted and rationally use data core resources to promote intelligent, digital, and networked reforms in the manufacturing industry and promote enterprise innovation [18]. Promote the coordinated development of upstream and downstream enterprises in the industry chain and increase the added value of products based on the transformation needs of key business scenarios [19–21]. For example, companies can rely on the company's procurement channels, distribution systems, and terminal network advantages and use digital technology to eliminate information between upstream and downstream enterprises in the supply chain. Asymmetric tangerine is innovating the supply chain service model and improving the circulation efficiency of the supply chain; on the other hand, it extensively collects and stores consumer group information and conducts in-depth analysis to form

customer portraits and implement precise marketing, thereby improving labor production efficiency, reducing operating costs, management costs, and investment costs, and improving enterprise performance and sustainable competitiveness, based on long-term development [22–28]. Finally, strengthen government governance, and distribute government subsidies in a reasonable and targeted manner. As an important driving force for enterprises' digital transformation, the government must give full play to the "promising government" effect. Relying on ABCD technology to promote government digital management, establish a professional information consulting platform, technical guidance platform, etc., to achieve efficient, active, precise, and flexible government governance, formulate a digital governance system that matches the digital economy, and give full play to the market role of resource optimization and allocation in digital transformation, creating a good external ecological environment for digital transformation and improving the efficiency of government digital services [29–33]. Strengthen the construction of infrastructure, optimize the industrial structure, form a digital development strategy, actively introduce relevant policies to provide technical support for the digital transformation of enterprises, and provide targeted financial support for the transformation of enterprises, so as to alleviate the financial difficulties faced by enterprises. In addition, attach importance to the protection and open sharing of data, break down digital barriers, and appropriately and reasonably open part of the data resources for commercial purposes within the scope of government monitoring to reputable companies, reducing the difficulty and cost of data collection. Improve the level of communication and interaction between government and enterprises, understand the actual difficulties of enterprises, and help them get out of the predicament.

7. Conclusion

Digital transformation is the all-round reshaping of internal and external processes, production methods, and management methods of enterprises in the digital economy era in the face of big data, Internet of Things, cloud computing, 5G, and other information technologies. There are many intermediary paths for corporate performance, and the current research on the impact of the digital transformation of physical enterprises on performance from the perspective of the digital economy mainly studies such as communication and collaboration costs and investment costs, agency costs, logistics costs, research, and development costs. Regarding the intermediary path in terms of cost, relatively, this paper mainly reveals the intermediary path that digital transformation affects enterprise performance, such as reducing costs and improving labor productivity, and then enriches and improves the mediation path in the paradigm of digital transformation and enterprise performance in this field.

Through the analysis of the application and development of deep learning in the field of book design and publishing, the article expounds on the positive impact of deep learning on book design and publishing, discusses the shortcomings of deep learning in creative ability, aesthetic ability, emotion, etc., and then discusses the design and publishing of books. The future development direction of intelligent aided design and intelligent personalized design is proposed to provide a reference for researchers in deep learning and book design and publication.

1. Introduction

Deep learning was first proposed at the Summer Symposium on Deep Learning at Dartmouth College in Hanover, the USA, in 1956 [1]. Due to the wide range of research fields, the concept of deep learning is also divided. At present, the more recognized definition in the academic circle comes from the book “Deep Learning: A Modern Approach” by Stuart Russell and Peter Norvig: “deep learning” is the research and design of “intelligent agents” [2], and “an intelligent agent refers to a system that can observe the surrounding environment and take actions to achieve the goal.” Today, deep learning has been widely used in speech recognition, machine vision, data mining, etc., and the cross-border between deep learning and publishing and design has gradually emerged [3]. Content is the starting point of book publishing, and content is often summarized and compiled by writers and scholars through learning, reading, investigation, and research, and this process requires a lot of time and energy to complete. In ancient times, people recorded text and image content by handwriting, and it was not until the advent of printing that books published close to modern times were widely disseminated. In recent years, we can even use speech recognition technology to allow computers to quickly convert language into text through “dictation,” which is just the tip of the iceberg for deep learning [4]. In

September 2015, Tencent developed a manuscript writing robot, Dreamwriter, which can generate manuscripts in a very short time. After more than two years of development, Dreamwriter has been able to generate templates through automatic learning, which has expanded from the initial financial field to movies, cars, games, and many other fields. In addition, Xinhuanet, Yicai, and other media also put the writing robot into use, and the content is mainly based on event description and analysis data. Poems and novels that require more complex rhetoric and grammar can also be completed by robots. For example, the poems created by Xiaobing, a poetry-writing robot developed by Microsoft (Asia) Internet Engineering Institute, have been submitted to newspapers and periodicals under multiple pseudonyms, and all of them have been received to publish invitation [5].

Since the end of 2013, a senior researcher from Microsoft Research Asia and an information design expert from the Academy of Arts and Design of Tsinghua University have been working on research in the field of the automatic layout. This research combines aesthetic principles in design with computable image features to creatively propose a computable prototype of an automatic typesetting framework. The prototype optimizes a series of key issues, such as the visual weight of text and pictures, the weight of visual space, the color harmony factor in psychology, and the importance of information in visual cognition and semantic

understanding. The prior knowledge of experts in the fields of text semantics, design principles, and cognitive understanding is integrated into the same multimedia computing framework, creating the research direction of automatic visual text layout design [6]. At the 2017 Yunqi Conference Shanghai Summit, Alibaba iDST algorithm experts shared research titled “Visual Design in the Era of Deep Learning,” proposing that automated and controllable visual content can be generated through deep learning. The process of intelligent design includes the spatial layout of design elements, color matching, background adaptation, font synthesis, style recommendation, intelligent interaction, etc. Among them, “automation” can automatically adapt to various sizes, automatically learn various styles, and automatically adapt to the number of elements; “controllable” means predictable and modifiable results. The introduction of deep learning into other fields seems unstoppable. In fact, most of the time, deep learning cannot be presented as an independent subject, and deep learning is more about transforming the process and mode of work in other fields [7].

Jane Hazus, the chief economist at Goldman Sachs Group, said: “In general, AI seems more likely to capture more valuable things in statistics than the last wave of innovation, and deep learning can reduce costs, reduce labor input for high value-added production types.” China’s modern book publishing industry is still dominated by paper media, and a series of work in publishing activities from topic selection, drafting, editing, and reviewing, to design publishing, and distribution is required. High value-added artificial brain power is to participate in the completion. Deep learning can improve the efficiency of book design and publication in the following three aspects [8].

The first is intelligent topic selection. The terminal of book publishing and distribution must be readers. The pain point of the traditional publishing topic selection process is that the distance between publishers and readers is too far. Book publishing forms a one-way process, and readers can only passively accept it. Or the publishing house obtains the data required by readers through traditional research and consultation methods and then selects a topic for publication and distribution, which must go through a long period of time. For some books whose market demand changes rapidly traditional data acquisition, the way will bring hysteresis [9]. It can be seen that data will be the source of future productivity. Based on deep learning and big data, readers’ purchase and reading behaviors can be effectively recorded, the needs of the audience can be outlined through data, and the direction of topic selection will be more accurate.

The second is smart editing. The traditional editing work mainly includes drafting, revision, and proofreading. It should be said that each part requires a lot of time, and the error rate that occurs manually cannot be ruled out. Deep learning can be said to be the core technology of the current deep learning development. After the speech recognition and natural language processing technology has developed to a certain level, the language and grammar in the work can be corrected, and then, it can undertake a lot of tedious and

time-consuming work. These problems can be solved by deep learning technology based on massive data support and with deep learning capabilities. However, modern editors can shift the focus of their work to the core values of judgment and decision making that cannot be completed by deep learning for the time being [10].

The third is intelligent design [11]. As a very important work in book publishing, book design affects the sales of books to a certain extent, and people are not satisfied with absorbing text content when reading. The graphic arrangement part of book design is the part of the largest workload after the overall creative design positioning of the book is completed in the early stage, and now, it is mainly completed by designers using arrangement software. According to the application research content mentioned above, the designer can analyze the reading audience according to the deep learning, propose a highly targeted book planning and design plan, and use the automatic layout software to arrange and adjust the content, effectively improving the work efficiency, and reduce the work intensity of design practitioners.

2. Knowledge about Deep Learning

2.1. Basics of Convolutional Neural Networks. Convolutional neural network (CNN) is a type of artificial neural network. It draws on the sparse response characteristics of biological neural networks and replaces the original fully connected layer with local connections to avoid overfitting in the training process due to too many model parameter problems [12]. The weight-sharing network structure of a convolutional neural network significantly reduces the complexity of the network, reduces the number of weights, and reduces the demand for training data. It is a research hotspot in the fields of speech analysis, image recognition, and target detection [13].

The general working principle of the convolutional neural network is as follows: first, the entire image is input into the convolutional neural network, and the network starts from the bottom pixel to learn the filters. These filters are used to extract the local edge and texture features of the image and then the middle layer filters. We learn the feature map processed by the upper-level edge filter and then extract the features that can describe different types of targets, and then learn those global features that describe the entire target by the high-level filter, and finally realize the target in the image through the nonlinear fitting of the activation function [14]. In the whole image recognition process, the network automatically learns the parameters of various types of filters from the image data. Its rich feature expression ability realizes the target recognition in the image and solves the problem of the traditional image recognition algorithm. Perform manual feature extraction and data reconstruction on image data. Figure 1 shows the development of convolutional neural networks.

The starting point of the development of convolutional neural networks is the neurocognitive machine model. LeCun, the originator of deep learning, proposed the first convolutional neural network model LeCun in 1989. Since

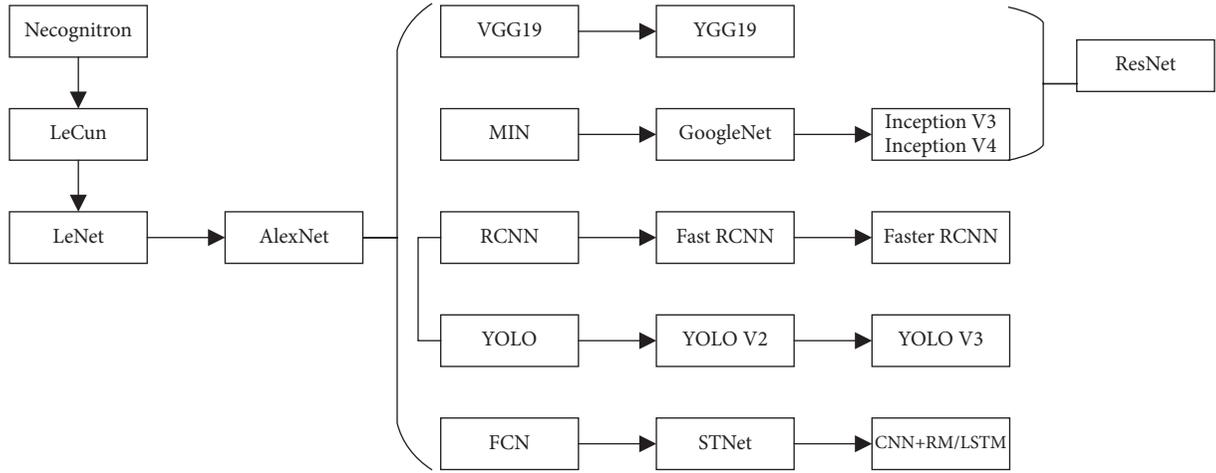

FIGURE 1: Development of convolutional neural networks.

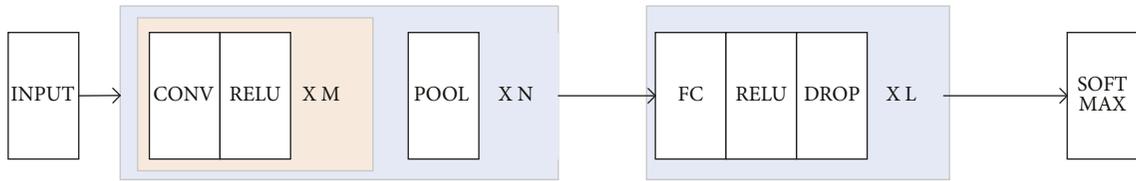

FIGURE 2: Classic convolutional neural network framework.

then, LeCun proposed the LeNet neural network model in 1998, but at that time, due to the superiority of hand-designed SVM and other classifiers, the convolutional neural network did not attract public attention along with the proposal of methods such as ReLU and Dropout, as well as the historical opportunities brought by GPU and big data, and the proposal of AlexNet in 2012 ushered in a historic breakthrough in convolutional neural networks. The evolution process of the convolutional neural network after AlexNet mainly consists of four directions: increasing the number of network layers and deepening the depth; enhancing the function of the convolutional layer from classification tasks to detection tasks; and adding new functional modules [15].

2.2. Convolutional Neural Network Architecture. A classic convolutional neural network for image classification mainly consists of five parts: input layer, convolutional layer, pooling layer, fully connected layer, and softmax layer. Usually, the network has only one input layer and one softmax output layer, and the convolution layer in the network can appear multiple times. The pooling layer is often located between the convolutional layers for data dimensionality reduction. The convolutional layer and the pooling layer are often connected in several adjacent convolution and pooling layers like this, which constitute a feature extraction layer of the network [16]. After multiple feature extraction and compression, the image data are input to the fully connected layer, and finally, the probabilistic classification result is output through the softmax layer. Figure 2 shows a classic convolutional neural network structure, in which M , N , and L are integers greater than

zero to indicate the number of repetitions of the unit where it is located.

2.2.1. Convolutional Layer. The convolutional layer is the core part of the convolutional neural network. Its function is to extract the features of the input image. The convolutional layer completes the feature extraction through the convolution kernel. Each convolution kernel contains parameters such as size, stride, and edge padding. In shallow networks, convolution kernels extract low-level features, such as edges and corners, and in high-level networks, convolution kernels extract high-level features, such as faces, dogs, and cars [17]. Figure 3 shows the convolution operation process in the convolution layer.

In Figure 3, the input picture is a two-dimensional activation map K obtained after the convolution layer operation of the convolution kernel K , and its size is obtained by the following formulas:

$$h_{out} = \left(\frac{h_{in} - h_f + 2p}{s_h} \right) + 1, \quad (1)$$

$$w_{out} = \left(\frac{w_{in} - w_f + 2p}{s_w} \right) + 1, \quad (2)$$

$$d_{out} = k. \quad (3)$$

In formulas (1)–(3), h_{out} and w_{out} are the height and width of the output image, h_{in} and w_{in} are the height and width of the input image, as well as the height and width of the h_f convolution kernel, w_f is the width of the s_h

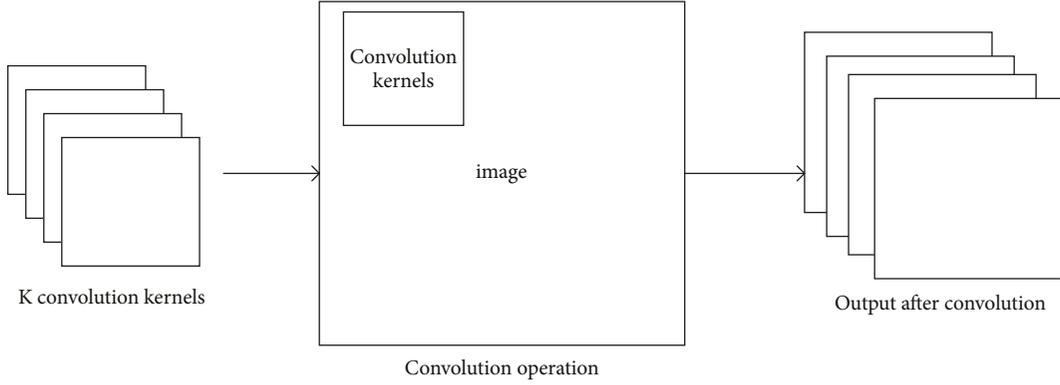

FIGURE 3: Convolution operation process in the convolution layer.

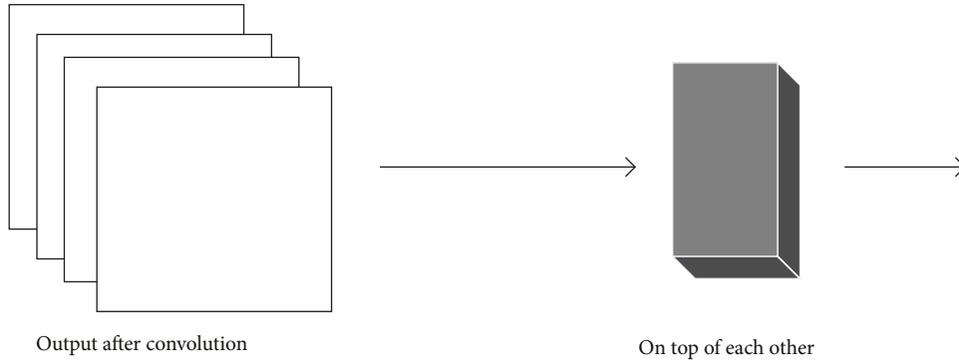

FIGURE 4: Activation maps are stacked and fed into the next convolutional layer.

convolution kernel, the sliding step size of the convolution kernel in the vertical direction and the s_w convolution kernel. The sliding step size in the horizontal direction p is the number of pixels to be supplemented by the edge, in which d_{out} is the dimension of the output.

Figure 4 shows that the K activation maps obtained after the convolution operation are stacked as the input to the next convolutional layer.

2.2.2. Pooling Layer. The function of the pooling layer is mainly to reduce the size of the feature map, and it is often used in the middle of two convolutional layers to reduce network parameters and reduce the overfitting of the model. Common types of pooling operations are max pooling and average pooling [18]. The maximum pooling operation is usually used in the middle of the convolutional network to reduce the size of the feature map, and the average pooling operation is generally used at the end of the network to replace the fully connected layer and reduce network parameters. Common pooling sizes are 2×2 and 3×3 , and strides are usually 1×1 and 2×2 .

If the size of the input feature map is $w_{in} \times h_{in} \times d_{in}$, the size after the pooling operation is

$$w_{out} = \left(\frac{w_{in} - w_f}{s_w} \right) + 1, \quad (4)$$

$$h_{out} = \left(\frac{h_{in} - h_f}{s_h} \right) + 1, \quad (5)$$

$$d_{out} = d_m. \quad (6)$$

In equations (4)–(6), w_{out} and h_{out} are the width and height of the output feature map, w_f and h_f are the width and height of the pooling window size, s_w and s_h are the horizontal and vertical strides, and d_{out} are the output dimensions. After the pooling operation, the size of the feature map is reduced to varying degrees according to the pooling window size and stride size [19].

2.2.3. Activation Layer. The main function of the activation layer is to introduce a nonlinear activation function, thereby increasing the nonlinearity of the network. The commonly used nonlinear activation functions are Sigmoid, Tanh, ReLU, ELU, Leaky ReLU, etc. Usually, an activation layer immediately follows each convolutional layer. For the input $w_{in} \times h_{in} \times d_{in}$ feature map, the output size after the activation layer is

$$w_{out} = w_{in}, \quad (7)$$

$$h_{out} = h_{in}, \quad (8)$$

$$d_{out} = d_{in}. \quad (9)$$

From equations (7)–(9), the activation layer usually does not change the size of the input feature map.

2.2.4. Fully Connected Layer. The convolution layer and pooling layer are mainly to complete the extraction of image features, while the fully connected layer is mainly to complete the classification task [20]. The fully connected layer is located at the end of the convolutional neural network, and the fully connected layer is usually followed by a softmax layer to calculate the final output of the network for each classification probability.

2.3. Data Augmentation. In deep learning, the training of the model often relies on a large amount of data to learn the parameters of the network, especially the deep network. However, in reality, it is often difficult to obtain enough data due to the limitation of practical conditions, and sometimes, a lot of manpower and material resources are wasted [21]. Data enhancement is to make some changes to the original data, but for the network model, it is “new” datum, thus easing the data requirements for deep learning model training. Data augmentation can improve the generalization ability of the model and improve the robustness of the model. Common data augmentation methods are flipping, rotating, scaling, cropping, translation, adding noise, etc. Compare model performance on the test set with and without data augmentation. It can be seen from the experiments that for the same model and the same dataset, when data augmentation is used, the accuracy and recall rate of the model on the test set are much better than when data augmentation is not used. It can be seen that, without adding any additional investment, the performance of the model can be significantly improved only through data augmentation operations.

2.4. Transfer Learning. Transfer learning refers to the simple adjustment of a model trained on one problem to make it suitable for a new problem. There are two common types of transfer learning. One is to use models trained on other datasets such as ImageNet datasets such as VGG, ResNet, and Inception as feature extractors, remove the final classification layer of the model, and replace it with new ones. This kind of transfer learning is suitable for the classification problem of the original model [22]; the other is fine-tuning that refers to replacing the last classification layer of the trained model with the classification layer of the new problem, initializing the classification layer, keeping the parameters of other layers unchanged, and then training the

new classification layer separately, after a few rounds of iteration (warm-up) “Unfreeze” other layers to continue training, fine-tuning the parameters of the entire model. This method is suitable for a relatively large dataset of new problems and is similar to the problem of the original model. Since the first layer of the convolutional neural network generally extracts low-level features such as texture, corners, and colors, the features extracted by the closer convolutional layers are more advanced, abstract, and task-oriented, so during training, you can “Unfreeze” the later convolutional layers of the original model, keeping the initial convolutional layer parameters unchanged [23].

3. Modern Book Packaging Design Based on BBE Network Aesthetic Evaluation

3.1. Object Detection Task Overview. Image classification, object detection, and image segmentation are the three major tasks of deep learning applied to the field of image processing. Image classification means that when an input image is given, the deep learning algorithm needs to analyze and identify what all the objects in the image are, that is, the category they belong to; target detection means that when an input image is given, the deep learning algorithm needs to detect the specific positions of all objects in the image, and also be able to identify the category to which they belong; the image segmentation task is aimed at pixels in the image, which means that the deep learning algorithm needs to distinguish all pixels in the input image, that is, determine which pixels in the image belong to which targets [24].

3.2. Book Packaging Design Based on Object Detection. Object detection tasks in deep learning are classified into two-stage algorithms and one-stage algorithms.

3.2.1. Two-Stage Algorithm. The two-stage algorithm is characterized by high detection accuracy and slow detection speed. With the development of the two-stage algorithm, the tasks of each stage of target detection are integrated into a deep neural network [25]. Two-stage algorithms include RCNN, SPPNet, Fast-RCNN, Faster-RNN, and Mask-RCNN. The first two-stage algorithm was the R-CNN algorithm, followed by Fast R-CNN and Faster R-CNN gradually enabling object detection to be trained end-to-end. The principle of the two-stage algorithm is multistep. First, a large number of candidate frames are generated in the image, and then, the features of the selected regions of the candidate frames are extracted. Finally, according to the results of the feature extraction, more refined classification and localization operations are performed in the high-level network. It is precise because of the step-by-step detection process of the two-stage algorithm that the detection accuracy of the algorithm is high, and the detection speed is relatively slow.

The Faster R-CNN model is shown in Figure 5, and the algorithm completes the target detection step by step. First, we complete the work of extracting features from the input image. Then, the extracted feature maps are filtered through the region generation network. Finally, using the filtered feature map, the

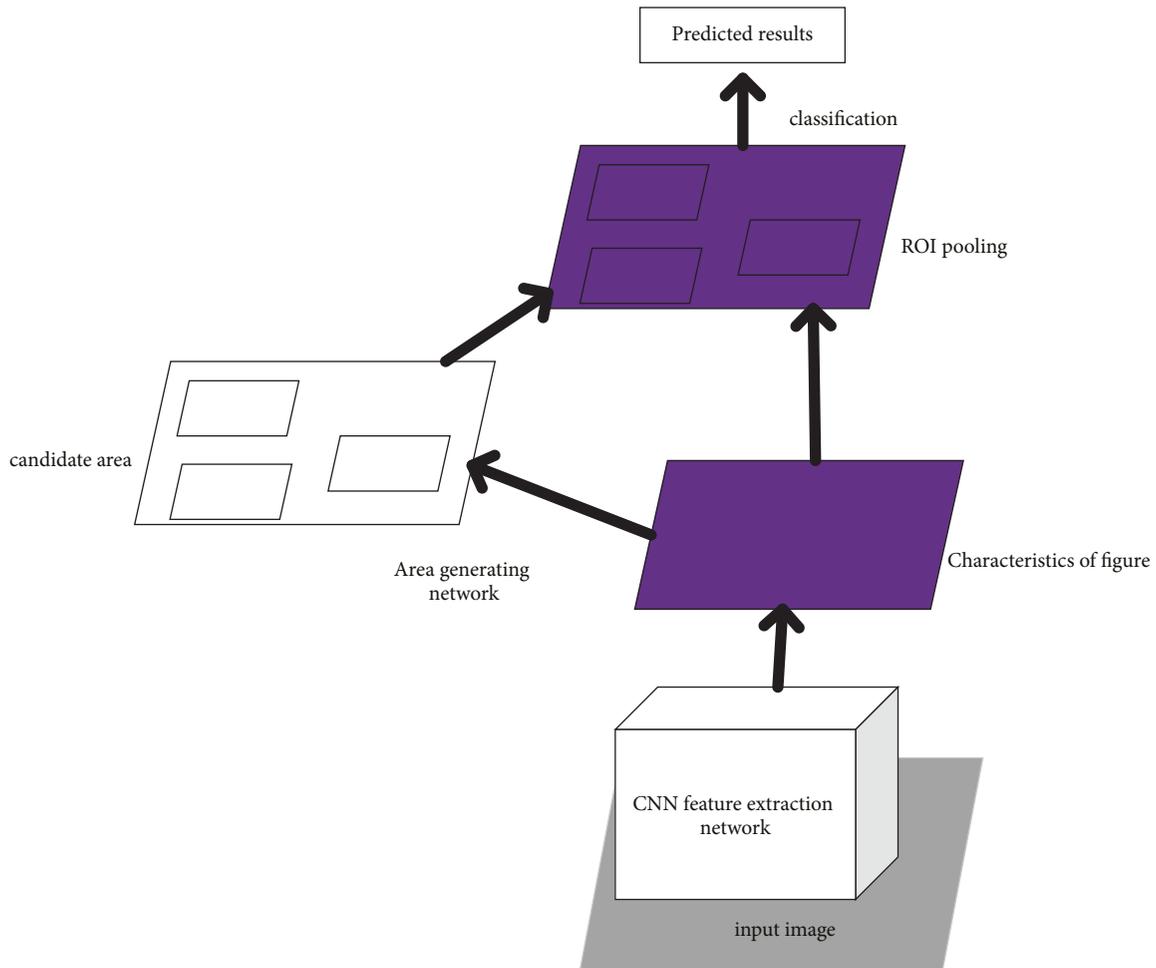

FIGURE 5: Faster R-CNN network model.

classification and localization of the target object are completed. Faster R-CNN has a unique area generation network, which enables the algorithm to perform more refined detection and identification. At the same time, because of the more complex network structure, the detection speed and training speed of the algorithm are relatively slow, and the computing performance of the hardware device is required high, and it is generally difficult to achieve real-time detection [26].

3.2.2. One-Stage Algorithm. The classic one-stage algorithm can be mainly divided into two series, namely, YOLO and SSD. The one-stage algorithm integrates feature extraction, classification, and regression into a deep learning network framework, and the detection speed is very fast.

YOLO is a representative of a one-stage target detection algorithm. The principle of the algorithm is to generate a large number of a priori frames on the input image, and then directly classify and locate the area selected by the a priori frame, that is, directly output the target object in the input image. Specifically, the image is first divided into grids, and then, a large number of prediction boxes are generated for each grid, and finally, the final prediction box is obtained through operations such as nonmaximum suppression and

threshold analysis. Figure 6 shows the model architecture of the YOLO network, in which the input image is divided into 7×7 grids, and each grid has 30 data, including the coordinate offset of 2 bounding boxes, the target confidence, and the probability over a class. The YOLO algorithm does not perform well in detecting objects that are close to each other and small objects, because each grid of the algorithm only predicts two bounding boxes that belong to only one class, and when target objects with different aspect ratios appear in the image, the generalization ability of the algorithm is weak.

The difference between the SSD algorithm and YOLO is that the SSD algorithm directly uses CNN for detection. The SSD network has the following characteristics. First, SSD uses a multiscale strategy to detect target objects of different sizes in the image by extracting feature maps of different scales in the image, which helps to improve the detection accuracy of the network. Second, in order to simulate the size of different target objects in the image, the SSD network uses a priori frames with different aspect ratios and different sizes, which helps to improve the detection effect of the network on small target objects. Positioning will be more accurate. In general, the SSD algorithm not only takes the advantages of the YOLO algorithm but also draws on the candidate region generation network of the two-stage

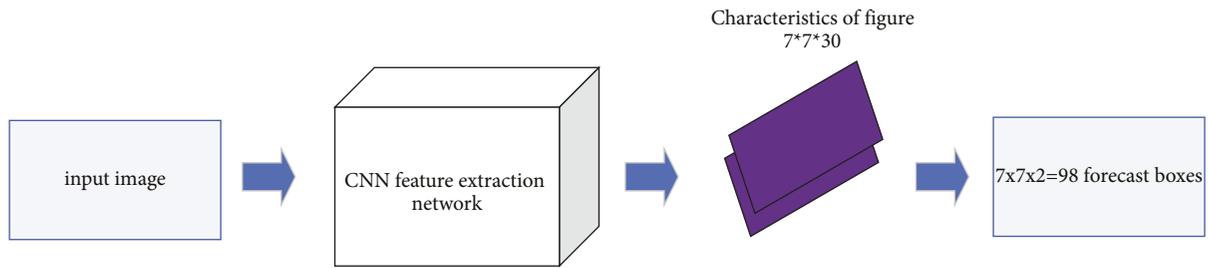

FIGURE 6: YOLO network model.

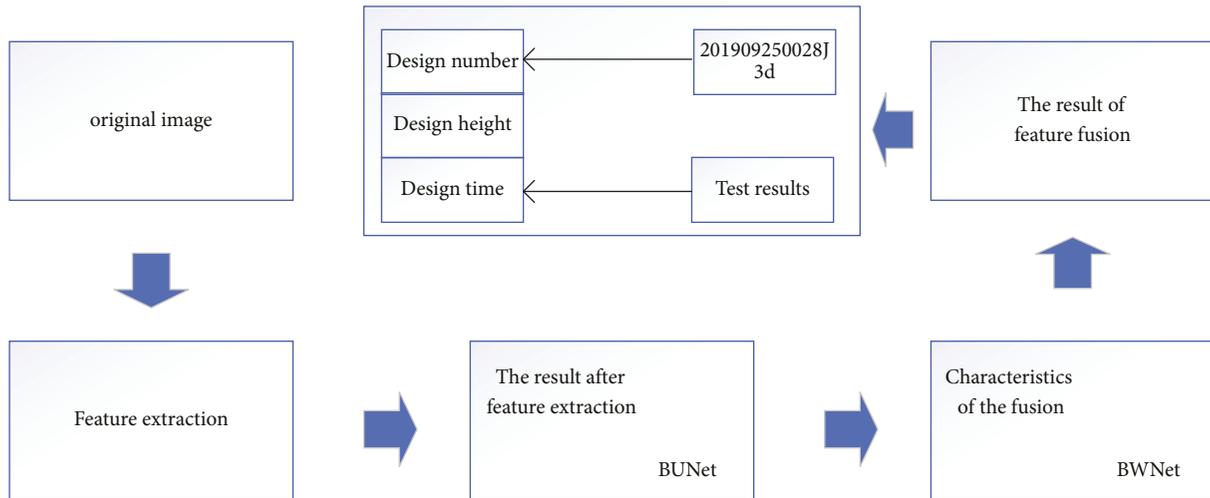

FIGURE 7: Overall design.

algorithm to achieve the speed of the one-stage algorithm and the accuracy of the two-stage algorithm, which is a relatively balanced accuracy and speed algorithm [27].

3.3. Overall Scheme and Algorithm Framework Design. The detection method of target detection can realize the end-to-end detection of inkjet character defects. However, due to the diversification of book design types, a large number of training sample datasets are required, and the detection accuracy is also easily interfered with by various factors. It is difficult to meet the requirements of industrial applications. The idea of the detection algorithm in this paper is to first obtain the category and position of each book through target detection. The overall design scheme is shown in Figure 7.

The BBE target detection network based on convolutional neural network has powerful feature extraction ability and has high detection accuracy and speed, which is very suitable for practical industrial detection. First, the collected images are input into the feature extraction network BUNet designed based on the EfficientNet core module for processing, and then, the extracted effective features are input into the designed feature fusion network BWNNet for feature refinement and abstraction, and then, the fused features are classified and positioned through the classification network and the regression network, respectively. Finally, the quality inspection standards (number of code, height, and time) are

set. We compare them to obtain the final overall detection result.

The structural framework of the BBE network, the feature extraction network, the feature fusion network, and the classification and regression network constitute the main frame structure of the algorithm network. The feature extraction network BUNet achieves good recognition with a small amount of parameters. The backbone of the feature extraction network is a general convolutional layer, which is used to perform convolution processing on the input image, and then continuously extract the depth features of the inkjet characters by connecting 7 basic modules with a total of 23 basic units (basic unit). It is based on the improvement of the core structure of EfficientNet. Based on the feature map pyramid network (FPN), the feature fusion network BWNNet adds many connections to the network, fuses the feature maps of multiple intermediate layers, and continuously performs up and down weighted sampling and fusion features. It is a fast normalized multiscale weighting feature map pyramid network. The classification and regression networks are separate, the classification network classifies the target in the prior box, and the regression network adjusts the size and position of the prior box until the final prediction box is obtained. Finally, the redundant prediction frame is removed by the operation of nonmaximum suppression, and the category and position information of the inkjet characters are obtained.

3.4. Feature Extraction Network Design

3.4.1. EfficientNet Algorithm. EfficientNet network was proposed by Google in 2019. On the basis of other networks, it improves the detection accuracy while greatly reducing the network parameter calculation, and has high detection accuracy and speed. To improve network performance, the following points should be paid attention to: (1) first, the network must be able to converge and be able to be trained; (2) the amount of parameters of the network should be minimized to ensure the high precision and speed of the network, and the model should be easy to train; and (3) improve the network structure, enabling it to learn useful deep features. The EfficientNet network does the above points well, and the network model uses a small amount of parameters to obtain good accuracy.

The construction of CNN often has the following characteristics: (1) increase the depth through the residual structure to improve the expressive ability of the network; (2) increase the number of feature layers extracted by each layer of the network, realize the extraction of multiscale features, and improve the width of the network and learn more features; and (3) increase the resolution of the input image, enrich the feature information that the network can learn, and improve the accuracy of the network. The EfficientNet network combines the above characteristics and adjusts the depth, height, and resolution of the input image to obtain a series of lightweight networks with balanced speed and accuracy.

3.4.2. Feature Extraction Network: BUNet. The feature extraction network in this paper is based on the core module of EfficientNet, which is designed, and the algorithm is based on a modular design, and the feature extraction capability of the network can be changed according to the needs of the task. The backbone of the network is a stack of 7 basic modules (23 basic units) with powerful feature extraction capabilities. At the end of the network are two max pooling layers of size 3×3 , which are mainly used to downsample the extracted feature maps to make the obtained features more refined. Finally, 5 effective feature layers are selected from the network as output features. Among them, $(BUConv_k, 3 \times 3) \times n$ is the basic unit based on the inverted bottleneck structure, BU is the basic unit, k is the number of convolution kernels, n is the number of basic units, and the size of the convolution kernel is 3×3 . Since the feature extraction network in this paper is continuously stacked by the same basic unit (basic unit), it is named BUNet.

3.5. Basic Unit. The basic unit of this paper is an inverted bottleneck structure as a whole, and many optimization strategies are added. After each calculation by a down-sampling module, the resolution of the feature map is reduced to 1/2 of the original. First, the input channel is subjected to 1×1 convolution, BatchNorm normalization, and Swish activation operations, and then calculated by an improved depthwise separable convolution (xDepthwise Conv2d), which also performs normalization and activation

operations, and then increases. An attention mechanism on channels is finally reduced by 1×1 convolution and normalized, and then connected to the large residual edge. The two most important operations in the base unit are the depthwise separable convolution and the inversion bottleneck structure.

3.5.1. Depthwise Separable Convolution. Depthwise separable convolution is composed of depthwise convolution and point-by-point convolution. Different from ordinary convolution operations, depthwise separable convolution reduces a lot of convolution calculations, which is widely used in most lightweight detection networks. For a three-channel input image, a depthwise convolution kernel is used to process one of the channels, and then, the number of channels of the output feature map is adjusted by point-by-point convolution. Point-by-point convolution is actually a 1×1 convolution, which can be used to adjust the number of output channels of the network, which plays a role in feature fusion to a certain extent and ensures the information exchange between each channel in the input feature map.

3.5.2. Inverted Bottleneck Structure. Residual structure and bottleneck structure are proposed in the ResNet network, which can solve the problem of gradient disappearance and gradient explosion caused by the deepening of the network, thus solving the problem that deeper networks are difficult to train. The residual structure has a bypass branch to connect the input directly to the output, so that the subsequent network layers can directly learn the residual between the input and the nonlinear convolution output, which not only protects the integrity of the input information but also simplifies the network. *Learning Goals and Difficulty.* The bottleneck structure first uses a 1×1 convolution to reduce the number of input channels. After the convolution calculation is completed, a 1×1 convolution is used to restore the number of output channels. This structure can not only improve the expressiveness of the network but also the computational complexity of the entire network can be reduced.

The inverted bottleneck structure first uses a 1×1 convolution to increase the dimension of the input channel. After the convolution calculation is completed, a 1×1 convolution is used to restore the number of output channels; that is, channel expansion is performed first, and then, channel compression is performed. The inverted bottleneck structure can learn more deep features in the middle convolutional layer of the network by first expanding the input feature map, and finally summarize and filter out useful features; that is, the inverted bottleneck structure can learn more about the input channel. Useful features have stronger feature extraction capabilities. The depthwise separable convolution (DWConv) is also applied in the inverted bottleneck structure. The operation of dilating and then compressing the feature channel does not increase the amount of computation, and the memory efficiency of the inverted design is much higher. The experimental effect is also better.

3.6. *Network Optimization.* The optimization strategy in the basic unit is elaborated below.

3.6.1. *Improved Depthwise Separable Convolution.* This section improves the depthwise separable convolution. Specifically, the number of input feature channels is adjusted by point-by-point convolution, and then, the feature extraction operation is completed by depthwise convolution. Among them, the depth convolution of 3×3 is split into two asymmetric convolutions of 1×3 and 3×1 , which will not affect the function of the convolution, but can greatly reduce the calculation amount of the convolution. This can not only speed up the calculation speed of the network but also deepen the depth of the network and improve the nonlinear expression ability of the network.

3.6.2. *Channel Attention Mechanism.* After completing the convolution calculation for feature extraction, an attention mechanism is applied to the feature channels, which allows the network to learn and pay more attention to the channel where the effective features are located. First, perform global average pooling on the features extracted by the convolution operation, and reshape the feature channel into a dimension that can be convolved, then compress and expand the feature channel through 1×1 convolution, and use the Sigmoid function to obtain a ratio between 0 and 1. The probability value between them is the attention level of the channel. Finally, different feature channels are multiplied by their attention levels to obtain different levels of depth features.

3.6.3. *Linear Activation Dimensionality Reduction and Element-Level Reduction Operations.* The nonlinear activation function in the network can enhance the nonlinear expression ability of the network, and at the same time, it will also cause the model to lose part of the feature information, and the downsampling operation itself will also discard part of the feature information. If the feature channels are downsampled and processed with nonlinear activation functions at the same time, the expressive ability of the network will be reduced and the performance of the model will be reduced. In this paper, when 1×1 convolution is used to reduce the number of feature channels, the Swish function is not used as the activation function, and it is directly activated linearly to retain more feature information, ensure the expressive ability of the network, and thus ensure the performance of the model. The operation of using linear activation to retain more feature information is also mentioned in the MobileNet-v2 network model.

Element-level operations will not bring too much extra computation, but too many element-level operations will increase the memory consumption of the computer, reduce the calculation speed, and affect the performance of the model. Finally, the output channel after dimensionality reduction and the large residual edge (input) are stitched and fused by point convolution.

4. Conclusion

With the advancement of science and technology, digital technology has developed rapidly, and technological innovation has made people's cognition of the world more intuitive and vivid. The original perceptual cognition method is reorganized with a rigorous mathematical model, and various design elements are presented rationally and digitally. This new expression method will definitely bring a new design thinking and artistic presentation. The evolution of art design is rooted in society, and so it is the rise of digital media art. With the continuous development of digital art, the form and function of art design are constantly enriched and improved. As a discipline, we should also cater to the diversified development trend of design, and build a new theoretical system and thinking mode for the cultivation of artistic talents in line with social development. We should not only pay attention to the inheritance of traditional culture and the learning of advanced design theory but also keep up with the pace of the times, quickly master digital technology, continuously expand creative thinking, and comprehensively improve our operational capabilities. Only in this way can a scientific and sustainable design teaching system be built.

Sewage discharge has become a key issue affecting the quality of the water environment, and how to effectively monitor and manage sewage discharge behavior has become a key factor to avoid water pollution and improve water quality. However, the current domestic sewage discharge monitoring system is not perfect, resulting in the lack of effective monitoring of enterprise sewage discharge by regulatory authorities, which provides an opportunity for enterprises to steal discharge. In the background of sewage treatment plant, the comprehensive design of sewage monitoring and alarm system is carried out based on the idea of physical information fusion. The design adopts a four-layer information physical architecture, which is divided into four parts: perception communication, fusion processing, push, and execution. In the fusion treatment part, the neural network intelligent algorithm is used to predict the dissolved oxygen, and the oxygen delivery is adjusted according to the predicted value to achieve accurate aeration and optimize the effluent quality. The push and execution parts adopt multiparameter monitoring to realize the smooth operation of equipment and ensure the system security. A new optimal control strategy of dissolved oxygen based on neural network is proposed. Through a large number of experiments and historical data, the intake index and dissolved oxygen value of the aeration tank under the condition of optimal outlet water are obtained as samples. According to the sample training, the BP neural network optimized by particle swarm optimization algorithm is adopted to achieve accurate prediction of dissolved oxygen under different inlet water conditions. The smooth operation of sewage treatment equipment is accomplished by the lower machine and the upper machine. In sewage treatment, each process section collects the equipment status in strict accordance with the order of sewage monitoring facilities. Then the communication network between the upper computer and the lower computer and the sensor is designed. The lower machine adopts PLC as the core, programming PLC through STEP7, and uses PID algorithm to control dissolved oxygen. The PC is developed in C language, so as to realize user login, real-time data display, over-limit fault alarm, report query, user management, etc. The PC integrates MATLAB neural network on the platform to predict dissolved oxygen through mixed programming quantity. The sewage alarm system based on improved artificial neural network is sensitive and has excellent performance. It provides a new idea for intelligent sewage detection and real-time monitoring.

1. Introduction

“Gold mountains and silver mountains are not as good as lucid waters and lush mountains.” Water resources protection has always been a major national policy of our country. The Party Central Committee has thoroughly implemented the sustainable development strategy for many years, promoted the construction of a resource-saving and environment-friendly society, improved water treatment and discharge standards, and

continuously increased large investment in the construction of livelihood projects related to sewage treatment. From 2011 to 2018, the daily treatment capacity of urban sewage in our country increased from 113.03 million cubic meters to 168.8 million cubic meters, and the number of sewage treatment plants increased from 1,588 to 2,321, an increase of 46% in 8 years. According to relevant policies and regulations, our country will achieve full coverage of sewage treatment in 2020, requiring the urban sewage treatment rate to reach 90% [1–3].

In recent years, more and more attention has been paid to sewage treatment in China. The increase in the number of sewage plants requires more skilled operators and consumes a lot of money. By contrast, automated monitoring systems that manage equipment according to established procedures can reduce the stress of staffing [4]. At the same time, through the accurate measurement of data by measuring instrument, the timely transmission of data by stable high-speed communication network, and the personification of data by intelligent control method, the sewage treatment process can be effectively managed on the basis of energy saving. Therefore, according to the actual needs, the introduction of intelligent control methods and advanced automation equipment, based on the design of sewage treatment monitoring system, has important significance for the development of economic society, in line with the requirements of industry development [5].

In the past decades, technological innovation has brought great changes to our lives, and intelligent algorithms have been widely applied in various fields [6]. The concept of intelligent algorithm has been widely recognized around the world since its introduction. Scholars from all countries agree that it is necessary to give full play to the excellent achievements made by human beings in the field of electronic information, closely combine information and physics, turn industrial system to intelligence, and form cyberphysical system [7]. A mature and intelligent sewage treatment monitoring system can realize real-time monitoring of various parameters of the equipment and, through intelligent methods, according to different sewage water quality, adjust the treatment strategy and adjust the parameter settings in key steps. This can not only reduce energy consumption but also optimize the quality of the effluent after treatment; the intelligent monitoring system can also improve the stability of the equipment and the level of intelligent informatization and reduce production costs; in the end, it can liberate labor and allow technicians. A lot of energy is put on the improvement of sewage treatment process and the development of sewage treatment equipment, so as to realize the requirements of constructing economical production and develop productivity.

2. Related Work

After the industrial revolution in the 19th century, economic and social changes took place in foreign countries, which also led to a series of environmental pollution problems, including water pollution. So far, the sewage treatment system has gone through the stages shown in Table 1.

In foreign countries, the problem of water pollution caused by the development of industrialization appeared earlier. During the 1950s and 1960s, developed countries gradually realized the need for early detection and treatment of sewage.

The United States, with the strongest comprehensive national strength, had built more than 20,000 sewage treatment plants, of which four-fifths were secondary treatment plants. Sweden had a small population and a

well-developed sewer system that can collect almost all sewage. Britain and Germany had a sewage treatment plant for every 7,000 people on average, and the treatment effect could basically achieve the effect of secondary treatment, and Germany was the country that developed sewage treatment industry earlier. The largest sewage treatment plant in the United States in the 20th century had a maximum capacity of 5 million cubic meters per day, while Japan's largest sewage treatment plant had a capacity of nearly 2.5 million cubic meters per day.

Now automatic control systems are widely used in sewage treatment plants abroad. A variable number of on-site detection instruments are used, such as physical treatment (precipitation, filtration), drug delivery and pump room and other sewage treatment of each link to monitor, and then measured data through the network to the central control room computer, convenient data recording, storage, and fault alarm. The role of automatic control was not only reflected in the control of equipment but also reflected in the actual processing process. Pierson John used the relationship between ORP (REDOX potential) and the removal rate of COD and ammonia nitrogen to control the ORP in the pretreatment process of poultry wastewater and successfully controlled the content of COD and ammonia nitrogen in effluent below 7% and 65% [8]. Zipper et al. used ORP as a control parameter to shorten the nitrification cycle, reduce the sludge load, and save energy while improving the sewage treatment rate [9]. Puznava et al. kept dissolved oxygen between 0.5 and 3 mg/L in the aeration process through active intervention, extended the denitrification reaction time in nitrification and denitrification, and reduced the aeration capacity in the aeration tank by half on the basis of meeting the water quality discharge standard, which played an energy-saving role [10].

Some detection instruments are placed in the equipment, respectively, and the data in the sewage is collected through the PLC CPU. The lower computer PLC controls and handles the fault, and alarms are sent in time to remind the staff to eliminate the fault. Compared with the Ohio sewage discharge monitoring system in the United States, the chromatographic monitoring method at the river inlet and sending the information back to the computer in the central control room for analysis and processing has achieved good results in organic pollution treatment. At the same time, the control of sewage treatment in developed countries has also achieved a high degree of modernization: according to the process and treatment needs, a multilevel control system is adopted, which is divided into control stations according to its own different conditions. Different intelligent control methods are adopted to realize the automatic control of different control objects. High tech water quality analysis instruments are used to monitor the sewage treatment process online in real time, and the data are transmitted to the computer in the form of reports [11]. For example, the sewage treatment plant built in Geneva in 1989 is unattended, and operators can monitor the system at any time through mobile phones, the Internet, and other media. In Paris, France, the central server effectively monitors and warns organic pollutants by monitoring water quality and

TABLE 1: Sewage treatment control stages.

Development phase	Characteristic
Manual control stage	Manual detection, recording data, by human control
Semiautomatic control stage	Instrument detection data, manual recording data, mechanical operation
Automatic control stage	Instrument detection record data, storage data, central control operation
Information control stage	Automatic control, engineering optimization, information management, group management

processing data, but the cost is high and information sharing is difficult [12]. Now, almost all factories in the United States have automatically controlled the main process parameters. As regards Macon's sewage treatment plant in the Middle East, although the daily treatment capacity of a single equipment is not strong, its process is relatively perfect. The plant has achieved 24-hour telephone alarm duty, and there are no other staff on duty except normal office workers.

To sum up, the foreign sewage automatic control system has such characteristics: advanced water quality intelligent analysis instrument was used to monitor the water quality of each link of sewage treatment, and the measured accurate data was transmitted to the subcontrol station, which would adjust the control parameters according to the preset intelligent control program. At the same time, it was transmitted to the computer in the central control room by the subcontrol station to record data, generate reports, and generate trend curves. These control stations had different control objects and different control strategies. Both the central control computer and the subcontrol station had redundancy design to ensure the reliability and security of the system. Operators could use telemetry and remote control devices (such as mobile phone networks, telephone lines, Internet, etc.) to respond to alarm information from afar.

3. Improved BP Neural Network Intelligent Prediction Model by Particle Swarm Optimization

3.1. Particle Swarm Optimization. The specific process of particle swarm optimization algorithm is not complicated. At the beginning, a group of particles are randomly generated in the solution space, and each of them represents a possible solution in the space and has a fitness value, which depends on the optimization function. Each particle has another speed to control the direction and distance of its movement. The particles then adjust their search strategy according to the current best particle. The particle adjusts its speed by referring to two extreme values. The first extreme value is the optimal solution found by the particle itself, which is called individual extreme value (p_{best}). The second is the optimal solution currently found for all particles, which is called the global extreme value (g_{best}).

The dimension of solution space that defines particle motion is D , and the number of particles in the initial generated particle group is N , so any particle represents a D -dimensional vector. Here, I particles are taken as an example.

$$X_i = (x_{i1}, x_{i2}, \dots, x_{iD}), (i = 1, 2, \dots, N) \quad (1)$$

The velocity of particle i is also a D -dimensional vector.

$$V_i = (v_{i1}, v_{i2}, \dots, v_{iD}), (i = 1, 2, \dots, D). \quad (2)$$

The best position that particle i can find at the moment is the individual extremum:

$$p_{\text{best}} = (P_{i1}, P_{i2}, \dots, P_{iD}), (i = 1, 2, \dots, N). \quad (3)$$

The best position that can be found for all particle swarms is the global extremum:

$$g_{\text{best}} = (P_{g1}, P_{g2}, \dots, P_{gD}). \quad (4)$$

After the individual and global extreme values are determined, the individual particle changes its velocity and orientation according to the following equation:

$$\begin{aligned} v_i^{k+1} &= w * v_i^k + c_1 r_1 (p_{\text{best}_i} - x_i^k) + c_2 r_2 (g_{\text{best}_i} - x_i^k), \\ x_i^{k+1} &= x_i^k + v_i^{k+1}. \end{aligned} \quad (5)$$

w in the above equation is called the inertial weight, and c_1 and c_2 are called the learning factors. r_1 and r_2 are random numbers between 0 and 1. In equation (1), the first term on the right side of the equal sign can be understood as a kind of "inertia" that particles are subjected to in the D -dimensional space. This inertia can give particles the ability to keep themselves moving towards the original direction. It provides the particles with an incentive to stay in their original motion. The middle term on the right side of the equation is usually understood as "own experience." Just as people can choose the best way to solve problems according to their previous experience, particles modify their movement strategy according to the best solution they have found before. The right-hand end of the equation is usually understood as "social experience," in which particles communicate through knowledge transfer to obtain the orientation of the best solution in the whole group and then modify their movement strategy according to this orientation, similar to interpersonal communication in human society. Parameter IV represents the speed of the particle itself. $v_i \in [-v_{\text{max}}, v_{\text{max}}]$, v_{max} represents the maximum speed that the particle can obtain. The setting of the maximum speed ensures that the particle will not lose control of speed [13–15].

3.2. Further Optimization by Particle Swarm Optimization

3.2.1. Improvement of Inertia Weight. In the traditional equation (1), the inertial weight w is set to a constant real number. This method will confine the convergence speed and convergence precision of particles to a specific value, and what is needed in this paper is that particles can choose and adjust their own search strategy according to their own

search period. According to the analysis, it is better to have large w in the equation of PSO at the beginning of searching, which can make the whole group move at a high rate. At the end of the search, it is better for the equation to have smaller w , which enables the whole group to move more precisely to the optimal position. In this paper, a method is designed to decrease as the number of iterations increases, and its slope keeps changing all the time:

$$w(k) = w \left(w_{\min} * \exp \left[-15 \left(\frac{k}{\text{MAXEPOCH}} \right)^3 \right] \right)_{\min}, \quad (6)$$

where k is the current iteration number of particle swarm; MAXEPOCH is the maximum number of iterations of particle swarm. In this design, $w_{\max} = 0.9$, $w_{\min} = 0.4$, and MAXEPOCH = 1000 are set.

3.2.2. Learning Factor Improvement. In equation (1), c_1 represents “self-experience” and c_2 represents “social experience.” Similar to the change of the weight factor, the particle swarm can acquire more “own experience” and less “social experience” at the beginning of the search period, which can make the overall movement rate of the swarm higher. At the end of the search, there is less “self-experience” and more “social experience,” which enables the group as a whole to move more accurately to the optimal position. This requires c_1 to start large and then small and c_2 to start small and then large, and, after experimental analysis, linear change is difficult to meet the requirements of the system, the design also adopts nonlinear change, and the specific implementation method is [16–19]

$$c_1 = \frac{4}{\{1 + \exp[\rho * (k/\text{MAXEPOCH}) - 0.5]\}}, \quad (7)$$

$$c_2 = 4 - c_1. \quad (8)$$

To control the descent speed ρ , this design takes 4.

3.3. Specific Flow of Particle Swarm Optimization.

Step 1: initialize the particle swarm, and give the particle number, dimension, initial position, speed, and other parameters.

Step 2: calculate the value according to the fitness equation, and give the overall best position g_{best} and individual best position p_{best} .

Step 3: reset the particle’s velocity and orientation according to equations (1)–(5).

Step 4: after particle movement, if the current position is better than p_{best} , then reset p_{best} to the current particle position. If it appears that the current position is better than g_{best} , the best position of the entire particle swarm, then g_{best} is reset to the current particle position.

Step 5: if the value of the fitness equation is lower than the set stop value or the frequency of particle updating position exceeds the set maximum number of

iterations, the optimal particle position is output. If the two conditions are not met, go back to Step 3.

3.4. Improved BP Neural Network by Particle Swarm Optimization. BP algorithm adopts the strategy of gradient descent and shows excellent local searching ability under nonlinear condition. If the parameter adjustment is already around the best parameter during the algorithm execution, the global optimization can be achieved in a short time. However, if the parameter adjustment is far from the optimal solution, it may fall into the trap of local optimization. Since BP algorithm adopts the strategy of gradient descent to correct system parameters, here is a vivid analogy: To find the optimal solution, the BP algorithm needs to search in a valley with multiple bumps. The algorithm error is very large. Particle swarm optimization (PSO) belongs to the category of algorithms based on global search. When the search starts, the convergence rate is relatively high. When it approaches the best solution of the whole, the convergence rate of its algorithm is relatively low, and sometimes it cannot meet the requirements. Therefore, such complementary advantages and disadvantages provide us with a way of thinking. If the two can be combined, local optimization can be avoided, while fast convergence can be achieved at the overall optimal point [20–22]. Particle swarm optimization belongs to the category of algorithms based on overall search. When the search starts, the convergence rate is relatively large. When it is close to the overall best solution, the convergence rate of the algorithm is relatively small, and sometimes it cannot meet the requirements. Therefore, the complementary advantages and disadvantages provide us with a way of thinking. If we can combine the two, we can avoid local optima and quickly converge at the overall optima.

In the design, using the design idea of particle swarm, the BP algorithm is optimized through the initial weight and threshold so that the particles can search for the best solution vector in the weight and threshold, and then set the weight of the BP algorithm and the corresponding solution vector of the threshold, and train again. The detailed execution process is as follows: Set the search space dimension of particle swarm optimization algorithm to be equal to the total number of weights and thresholds in BP algorithm, and then the position to which the particle moves is a solution of the weight threshold. The fitness function of particle swarm is shown in the following equation:

$$f = \frac{1}{n} \sum_{j=1}^n \sum_{k=1}^m (y_k - t_k)^2. \quad (9)$$

In the above equation, n is the number of sample groups collected by training BP network, m is the number of neurons in the last layer of BP network, y_k is the actual efferent value after input sample, and t_k is the ideal efferent value. Given (9), the optimization process can be thought of as keeping f in the equation as small as possible. If the size of f during the operation of the algorithm is lower than the set stop quantity or the frequency of particle updating position

exceeds the set stop number, the algorithm ends. At this point, the weight threshold represented by the optimal particle position is set as the initial weight threshold of the BP network, and then the BP neural network is trained.

3.5. Improved BP Neural Network Algorithm Flow

Step 1: set BP network parameters, such as the number of nodes at each layer. Set the number of individuals in the particle swarm, dimension (threshold number, weighted value number), and other parameters.

Step 2: give the initial position of the particle, assign the corresponding value of the initial particle position to the neural network, calculate the value according to equation (6), and give the overall optimal position g_{best} and individual optimal position p_{best} .

Step 3: reset the particle's velocity and orientation according to equations (1)–(5).

Step 4: after particle movement, if the current position is better than p_{best} , then reset p_{best} to the current particle position. If it appears that the current position is better than g_{best} , the best position of the entire particle swarm, then g_{best} is reset to the current particle position.

Step 5: check whether f in equation (6) is lower than the set stop quantity or the frequency of particle updating position exceeds the set stop number, and go to the next step. If not, go back to Step 3.

Step 6: set the weight threshold represented by the optimal particle position as the initial weight threshold of the BP network, and then train the BP neural network.

3.6. Dissolved Oxygen Improved BP Neural Network Prediction Model Simulation. The initial range of each particle is between $[-1, 1]$. According to the guidance of literature, the initial individual number of particle swarm $m=100$, the minimum training stop error is set to 10^{-4} , the maximum iteration number is set to 1000, and the learning factor starts to calculate $c_1=2.4861$ according to formulas (7) and (8). $c_2=1.5139$, $w_{max}=0.9$, $w_{min}=0.4$, v_{max} is set to 2, and ρ is set to 4. The training target precision is 10^{-5} , and the training cycle times are set as 1000 times. Simulation results are shown in Figure 1.

As can be seen from the figure, the fitting effect of the improved neural network is very good, and the error is relatively small, which meets the standard of industrial application.

4. Design of the Lower Computer of the Sewage Monitoring System

4.1. Collecting System Hardware. According to the needs of the overall design scheme of intelligent monitoring in this study, and taking into account the characteristics of each technological process and equipment and facilities in this

study, we considered the following points when selecting the collection equipment: First, the collection equipment selected in this study came from regular manufacturers, the industry has a good reputation in the after-sales service, its product quality is superior, and the product maintenance is guaranteed. Second, it is strictly economical, is not blindly demanding the high-end equipment, and, on the premise of ensuring the quality of monitoring, chooses more domestic brands. Then it is necessary to take into account the waterproof performance and corrosion resistance of hardware equipment; the composition of sewage is complex, and the equipment with good water and corrosion resistance effect can work stably. Hardware acquisition system was similar to human perception cells, mainly composed of instruments and sensors. With the booming of intelligent automation industry, its figure widely existed in various plant equipment so as to provide sensory information for monitoring personnel. Because this perceptual information was the basis of subsequent processing, the selection of instruments and other hardware equipment should be fully considered to ensure the effect.

In this paper, the data collection instruments were mainly COD meter, total nitrogen, total phosphorus determination apparatus, suspended solid concentration meter, electromagnetic liquid flowmeter, PH dollars, thermometer, DO dissolved oxygen meter, and liquid level meter, and equipment was started by reading relay internal register [23].

4.2. Programmable Logic Controller (PLC). The core of the lower system of this project was the programmable logic controller, and PLC was used to coordinate the actions of the whole lower system. PLC used its own receiving unit to receive digital or analog signals collected by hardware equipment such as field instruments and transmitted the signal from the upper computer to the lower actuator to control the action of the actuator. All signals must pass through its processing. All signals must pass through its processing and relay, so it is particularly important.

After absorbing the advantages of previous products, the S7 PLC produced by Siemens in Germany integrates the world's most advanced information technology and scientific achievements, especially in processing speed, code running, error self-checking, and information communication. S7 series could be divided into S7-200 type, S7-300 type, and S7-400 type according to the number of input and output ports.

Figure 2 shows the Siemens PLC structure diagram, the hardware modules are relatively independent in layout, but cooperate closely with each other, which is conducive to distributed control, and is also convenient for expansion and maintenance. Programming Languages Multiple programming languages are supported. And supports a variety of communication protocols, fully adapting to the instruments and sensors for parameter collection of various lower computers in sewage plants.

4.3. Communication System Design. The lower computer and the upper computer were connected by industrial Ethernet, which is the most extensive local area network

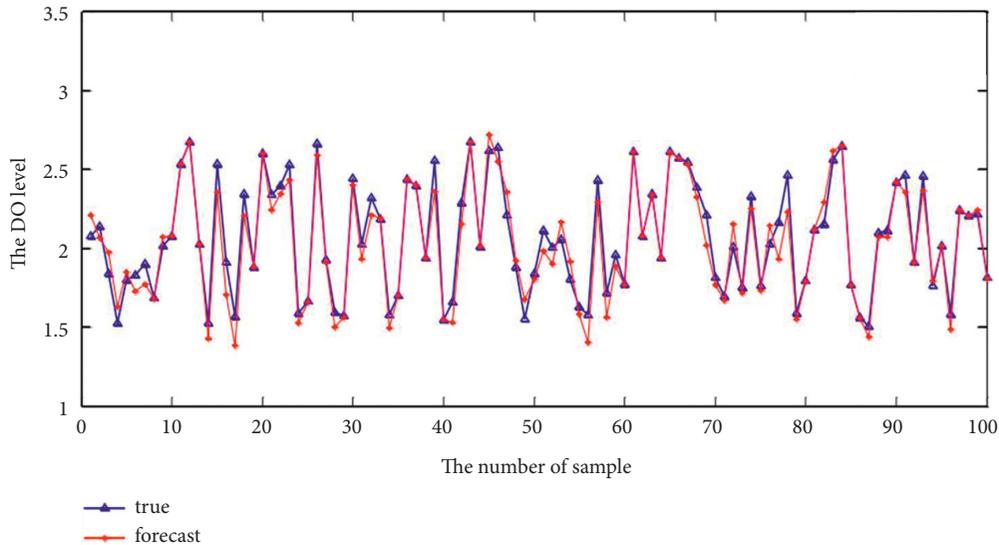

FIGURE 1: Improved neural network prediction results.

based on the IEEE 802.3 standard and is widely recognized in the world. Comprehensive consideration of industrial Ethernet in quality, compatibility, transmission timeliness, data stability, robustness, attack prevention, and other aspects had been greatly improved. Considering the cost performance, transmission rate, and safety and reliability factors, 100 Mb/s ring network optical fiber industrial Ethernet was selected.

Signals involving digital and analog quantities were directly connected to the input and output ports of the equipment on the corresponding module of PLC. Digital input and output signals were high- and low-level signals, PLC according to the transmission of high level or low level to monitor the state of the field equipment, switch, start and stop, and so forth, in this design was mainly through the relay to operate. Analog signal had two kinds: voltage and current signal; PLC accorded to the numerical conversion formula to convert input and output values [18].

4.4. Programming the Lower Computer. STEP7 development platform was developed by Siemens, which was specially applied to the configuration and programming debugging of PLC of its owned brand. The software function of STEP7 contained many development modules: process equipment management module, symbol table module, program module, and others. When writing the program, the user can choose to connect PLC or not to connect, which will not have a bad influence on the program effect. STEP7 platform could easily set up a complete set of industrial control system solutions. Figure 3 shows the process of establishing the whole industrial control system solution. The programming languages used for S7-300 are Ladder Logic (LAD) programming language, Instruction List Language (STL), and Function Block Diagram (FBD). The Ladder Logic programming language is a unique graphical representation method of the STEP7 programming language. Its grammar

rules have many similarities with the relay ladder logic diagram: for example, if information is transmitted to each connection and finally reaches the output, we can find the entire transmission process of the signal according to the diagram.

The PID control program of the system used the PID controller function module FB41 integrated in STEP7 software, and the PID control program was stored in the timing cycle interrupt OB35. When the system starts, FB41 is called through OB35, and the background data block DB20 is created for the function module.

The core control of the lower machine of the system is here. Firstly, the influent COD, suspended solid SS, total nitrogen content, total phosphorus content, flow rate, PH value, and aeration tank temperature were collected by the sensor and stored in the DB block of PLC. The communication network was transmitted to the upper computer, and the upper computer predicted the precise dissolved oxygen (DO) value through intelligent algorithm. It was transmitted down through the communication network and stored in DB block at the address of DB3.DBD208. The actual measured DO value in the aeration tank was also stored in DB block at the address of DB3.DBD32. DB3.DBD208 was connected with SP_INT of FB41 module in PLC (set value), and DB3.DBD32 was connected with PV_IN of FB41 module in PLC (current time value). The algorithm's flow chart is shown in Figure 4.

5. Monitoring System Upper Computer Design

The application development of the upper computer was a very critical task in the intelligent sewage project. The upper computer collected all the information in sewage treatment, and the staff could monitor the sewage treatment site comprehensively through the upper computer in the control room, which not only reduced the amount of operator activity but also saved time. In this study, the key parameters

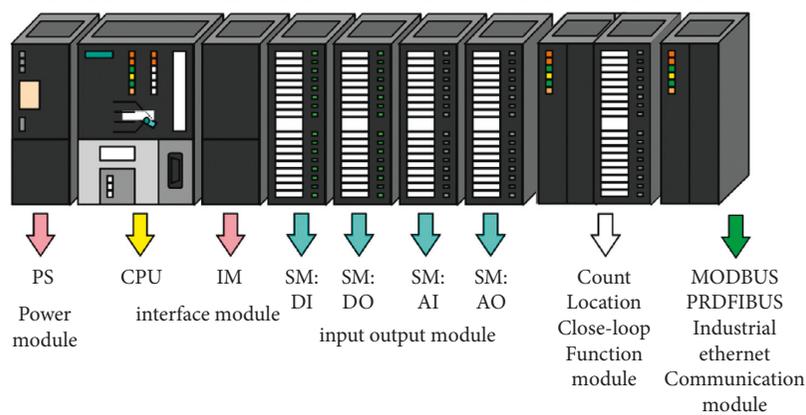

FIGURE 2: Siemens PLC structure drawing.

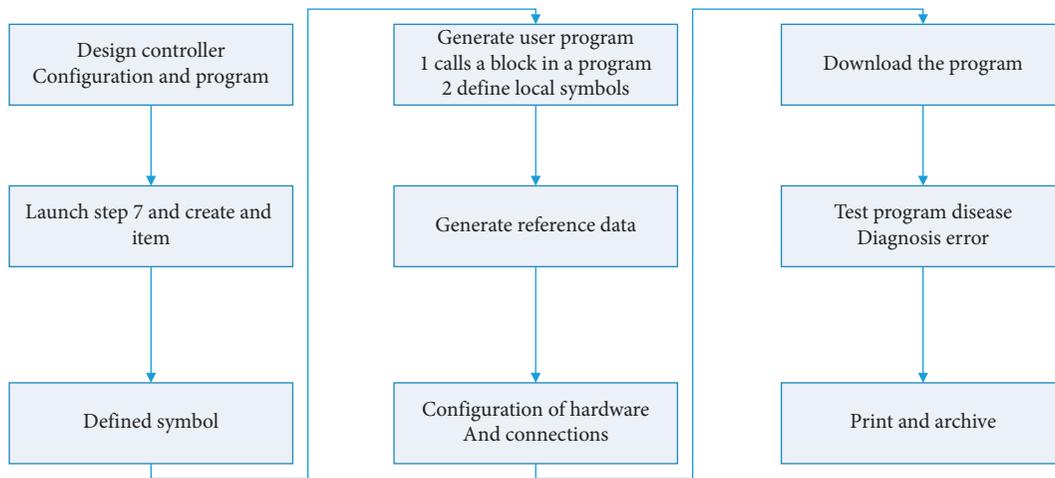

FIGURE 3: Steps to create an automated project.

of each process section of the factory should be displayed on the main interface first, and then the intelligent dissolved oxygen control algorithm should be integrated into the software and the parameters should be transmitted to the lower computer. The upper computer client software was developed on Visual Studio 2010 platform, and the data was stored and managed in SQL Server 2012 database. The development language was C#.

5.1. C# Communication Implementation. The design of the upper computer hardware used Yanhua brand industrial computer, with excellent performance, through the Ethernet link and Siemens S7-300 PLC to establish a connection. In this design, the IP address of PLC was set as 192.168.0.1. Communication mode was MODBUS/TCP mode of Ethernet network architecture, port number was set as MODBUS, corresponding to 502, and the specific configuration of C# program is as follows:

```

?xml version = "1.0" encoding = "utf-8" ?
<configuration>
  <appSettings>
    <!--Modbus TCP configuration-->
  
```

```

5.2. Database Design. The database uses SQL Server 2012, which was mainly divided into three parts. The first part was the report data part, which mainly stored the periodically inserted real-time display data. The second part was the alarm data part, which contained various alarm related information. The third part was the user part, which contained the user related information. Redundant fields were added between each table to realize join query of each table. There were other secondary tables, of course, but only five tables that were closely related to business logic are detailed here. The process section table and data table, respectively, are shown in Tables 2 and 3 [23].

The alarm data part consists of two tables. The first is table of alarms, which displays alarm information, and the second is alarm settings table, and they are shown in Tables 4 and 5, respectively.

The table of users is shown in Table 6.

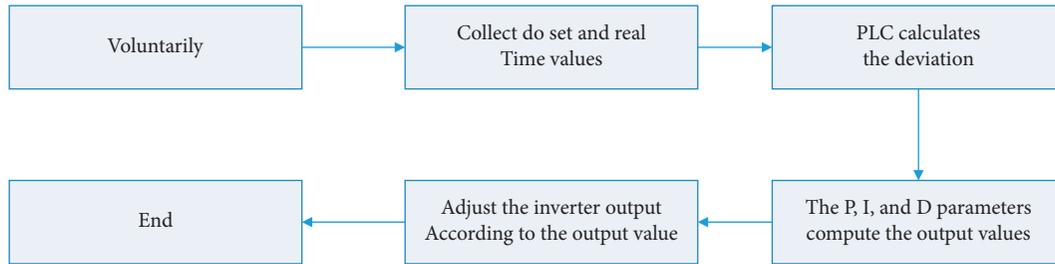

FIGURE 4: Flow chart of DO control.

5.3. *Host Client.* The user login module mainly checked the security of the users who entered the remote intelligent management system, so as to prevent the illegal users from misoperating the system or controlling the system illegally after logging in. After the login window was opened, only the legitimate user account could log in to the system. The legitimate user account was manually assigned by the administrator.

The main interface after logging in is the real-time parameter display interface. By directly reading the PLCDB block, it can directly send data and detect key indicators of each process section, including liquid level, PH value, COD, SS, nitrogen and phosphorus content, influent water flow, temperature, whether the device is running, running status, etc.

When the parameter exceeds the threshold or the device displays a fault, the C# program will execute to insert a data into the alarm table in the database, including the alarm date and time (accurate to second) and alarm information, and this data will be extracted by the program in the alarm management interface. The remarks field at the back of each data was manually operated by technicians. When the technicians debug and eliminate the fault, the processing button on the right of the list is manually clicked, and the fault status changes to processed. In this case, a piece of data is inserted into the UserId field of the alarm table in the database, namely, the login user name of the software platform. The value of UserId represents the fault handler, namely, the login user. The data was extracted and displayed in the handler column.

The design and verification of the measurement model of dissolved oxygen in aeration tank were completed by testing and simulation on Matlab platform. For neural networks, which needed a lot of matrix calculation, Matlab modeling and simulation had twice the result with half the effort. At present, scholars at home and abroad in the field of neural network research also relied on Matlab simulation results for comparison. Therefore, the design and performance verification of the dissolved oxygen measurement model mentioned were all carried out in the Matlab environment. In practical application, the running results of Matlab could be called in Windows form written under VS platform through mixed programming and the predicted results could be displayed.

TABLE 2: Table of process sections.

Field name	Type	Explanation
ProcessId	Int	Process segment ID
ProcessName	String	Name of process section

TABLE 3: Table of data.

Field name	Type	Explanation
DataId	Int	dataID
DataName	String	Data name
DataValue	Float	Data value
IsAlarm	Bool	To alarm or not to alarm
ProcessId	Int	Process segment ID
SampleTime	Datetime	Data insertion time

TABLE 4: Table of alarms.

Field name	Type	Explanation
AlarmId	Int	The police ID
AlarmDesc	String	The police described
AlarmTime	Datetime	Time of fire alarming
IsDeal	Bool	Processed or not
DealTime	Datetime	Processing time
UserId	Int	ID of the login user

TABLE 5: Table of alarm settings.

Field name	Type	Explanation
DataName	String	Data name
ProcessId	Int	Process segment ID
AlarmHigh	Float	Alarm upper limit
AlarmLow	Float	Alarm lower limit
AlarmPRI	Int	Priority

TABLE 6: Table of users.

Field name	Type	Explanation
UserId	Int	UserID
UserName	String	User name
Password	Varchar (50)	User password
RoleType	Int	Character types
RoleName	String	Role name

6. Conclusion

With population growth and water pollution becoming more and more serious, secondary treatment of sewage is an effective way to reduce water pressure and an important measure to control environmental pollution. Sewage problem is a major problem in China's development; sewage treatment has risen to the national strategy. Design was based on improved artificial neural network; a new system of a set of automatic alarm intelligent monitoring and optimization for wastewater treatment equipment provides a new technical point of view, based on the advanced sewage treatment technology and sewage disposal characteristics, as well as the monitoring and optimization of demand, with the main ideology of physical information fusion and intelligent algorithm as the core. Combining information technology and communication technology to comprehensively monitor various parameters of the sewage plant, once the limit is exceeded, an alarm will be issued, so that the dissolved oxygen in the sewage treatment can be better controlled, so that the equipment of the plant runs smoothly and the effluent quality is better. The design work is summarized as follows:

- (1) Using A2/O process, a new optimal control strategy for dissolved oxygen is designed for the key control of dissolved oxygen. Through a large number of experiments and combined with historical data, the intake index and dissolved oxygen value of aeration tank were obtained as samples under the condition of optimal outlet water. According to the samples, the neural network was trained to predict the optimal value of dissolved oxygen under different inlet water conditions. The improved BP neural network is improved by particle swarm optimization. Compared with the traditional BP neural network, the improved neural network has better characteristics.
- (2) The sewage treatment in each process is based on the configuration sequence of the monitoring equipment, the design of the upper computer and the lower computer, the communication network between the lower computer and the sensor, and the design of the lower computer system is successfully realized through STEP7 PLC programming.
- (3) C# in Visual Studio 2010 was used to develop the upper client platform, and the database used was SQL Server database. The platform realizes user login, real-time data display, overload and fault alarm, report query, and user management, and, through mixed programming, the dissolved oxygen prediction neural network written by Matlab is integrated in the upper computer platform. The parameter value of dissolved oxygen is set through the communication of upper and lower machine [24].

In logistics distribution systems, the constrained optimisation of the cargo dispensing problem has been the focus of research in related fields. At present, many scholars try to solve the problem by introducing swarm intelligence algorithms, including genetic algorithm, particle swarm algorithm, bee swarm algorithm, fish swarm algorithm, etc. Each swarm intelligence algorithm has different characteristics, but they all have certain advantages for the optimisation of complex problems. In recent years, the Wolf Pack algorithm, an emerging swarm intelligence algorithm, has shown good global convergence and computational robustness in solving complex high-dimensional functions. Therefore, this article chooses to use the Wolf Pack algorithm to solve a multi-vehicle and multi-goods dispensing problem model. First, the principle and process of the Wolf Pack algorithm are introduced, and two improvements are proposed for the way of location update and the way of step update. Then, a mathematical model of the multi-vehicle and multi-goods dispensing problem is developed. Next, the mathematical model is solved using the proposed improved Wolf Pack algorithm. The experimental results show that the proposed improved Wolf Pack algorithm effectively solves the cargo dispatching problem. In addition, the proposed improved Wolf Pack algorithm can effectively reduce the number of vehicles to be dispatched compared with other swarm intelligence algorithms.

1. Introduction

With the progress of science and technology, after reducing the cost of raw materials and improving labour productivity, modern logistics has become a “new source of profit” for enterprises and has received widespread attention from the logistics industry and even from the business community [1, 2]. Especially in the field of commodity circulation, different types of large-scale modern logistics enterprises have emerged. With the rapid development of the logistics industry, the study of logistics distribution has also attracted more widespread attention [3, 4]. How to reduce costs and at the same time improve efficiency, as well as obtain more economic and social benefits, has become a topic of research for experts and scholars.

In modern logistics, the biggest cost of logistics and distribution is the transport cost, which in turn has a lot to do with the vehicle. Therefore, when carrying out distribution operations, the load capacity and volume of the

vehicle should be fully considered [5, 6]. By selecting the right transport vehicle, the optimum utilisation of the transport vehicle (100% utilisation) is achieved as far as possible, which is an effective way to reduce distribution costs. However, in practical situations, the space utilisation and load capacity of the vehicle often cannot be maximised at the same time due to the type of goods, packaging methods, etc. These situations can waste transport power and cause an increase in transport costs. In logistics and distribution systems, the issue of cargo dispensing is the most fundamental item [7, 8]. Reasonable dispensing can improve distribution efficiency on the one hand and reduce distribution costs on the other. At present, in the actual cargo dispensing business, it is usually done based on manual estimation methods. There is no uniform planning based on experience alone, which wastes both manpower and material resources [9, 10]. Therefore, the rational allocation of goods is conducive to improving distribution efficiency, reducing distribution costs, and achieving higher

vehicle utilisation. Therefore, due to its extensive application background and important theoretical value, the study of cargo dispensing has become an important research content in the logistics and distribution industry [11, 12].

The key to the cargo dispensing problem is how to maximise the vehicle's capacity and volume, thereby reducing distribution costs and improving distribution efficiency. It is a complex discrete multi-constrained combinatorial optimisation problem, which belongs to the NP problem like the traveler problem and workshop scheduling problem [13, 14]. And for solving NP problems, heuristic algorithms or intelligent optimisation algorithms are the most commonly used techniques. Solving cargo dispensing problems often requires the use of heuristic algorithms or intelligent optimisation algorithms to approximate the optimisation solution.

There have been a number of studies on heuristic algorithms for cargo dispensing and loading problems. For example, Tran et al. [15] constructed a three-dimensional multilayer loading layout optimisation model with the maximisation of combined vehicle load and volume utilisation as the optimisation objective and designed a heuristic algorithm that can quickly develop a reasonable loading solution. Chua et al. [16] combined the two problems of vehicle dispensing optimization and transport path optimization into one and used the classical Dijkstra's algorithm and the improved C-W saving algorithm to solve the optimisation problem for the full-load transportation case and the optimisation problem for the non-full-load transportation case, respectively. Experimental results show that the solution is effective. Du et al. [17] developed an intelligent cargo dispensing model with multidimensional constraints and proposed a hybrid algorithm based on heuristic ideas and fuzzy principles. The test results showed the effectiveness of this intelligent dispensing model. Chao et al. [18] established a cargo dispensing model with the optimisation objective of maximising revenue and minimising expenditure and used a heuristic algorithm to solve it. Finally, the effectiveness of this algorithm was verified by example. However, heuristic algorithms tend to rely too much on personal experience. When the problem is large, heuristics can become "combinatorially explosive." As a result, heuristics are not very efficient when solving large-scale problems and lack global optimisation capabilities, giving only approximate or locally optimal solutions to the problem.

Swarm intelligence algorithms are all inspired by the evolution of organisms in nature, foraging, clustering, and information exchange. At present, the main swarm intelligence optimisation algorithms are simulated annealing algorithms, genetic algorithms, particle swarm algorithms, ant colony algorithms, immune algorithms, etc. These intelligent optimisation algorithms are all easy to implement and have good robustness. When solving complex optimisation problems, the advantages of swarm intelligence algorithms are more obvious. For solving large-scale, multi-constrained complex problems, swarm intelligent optimisation algorithms are more widely used. For example, Jamrus et al. [19] used a genetic algorithm to investigate the optimal placement of containers and developed a corresponding single-vehicle transport dispensing model, while Miao et al. [20]

designed a hybrid genetic algorithm and applied it to a multi-species cargo dispensing model. The experimental results showed that the above model could fully utilise the load and volume of the loading tools in a balanced manner. Sicilia et al. [21] used an ant colony algorithm to solve a bi-objective bulk cargo loading model and verified that the proposed model and algorithm were feasible through experiments.

As an emerging swarm intelligence algorithm, the Wolf Pack algorithm exhibits good global convergence and computational robustness in the process of solving complex high-dimensional functions [22, 23]. During the hunting process, each wolf is classified into Alpha, Beta, or Omega wolves according to its different roles. Alpha wolves are always the strongest wolves in the pack and are responsible for directing the pack to capture prey without participating in the roaming, running, or siege process; Beta wolf is an elite unit of wolves, responsible for searching for prey; and Omega wolf is the attack force of wolves and is responsible for quickly closing in on the Alpha Wolf's direction when the Alpha Wolf initiates an attack command, in order to capture prey. Zhu et al. [24] proposed a Wolf Pack algorithm based on ant colony optimisation for solving the TSP problem. An ant colony algorithm was used to initialise the population in order to implement a heuristic crossover operator, while adaptive adjustment of the crossover probability and variation probability was employed. This algorithm achieves good optimisation results for smaller TSP problems. However, when the scale is larger, this algorithm needs further improvement. As an efficient intelligent optimisation algorithm, the Wolf Pack algorithm can provide a practical and effective solution to the cargo dispensing problem, thereby effectively reducing logistics costs (improving dispensing efficiency).

Therefore, this study aims to use the Wolf Pack algorithm to solve the cargo dispensing problem in logistics distribution, so that it can effectively improve the solution quality. Although the Wolf Pack algorithm has good global search performance and superiority-seeking ability, the number of iterations and convergence speed need to be further improved. Therefore, this article improves the traditional Wolf Pack algorithm. In addition, this article provides a brief introduction to the components and classification of the cargo dispensing problem in logistics distribution and establishes a multi-vehicle, multi-goods mathematical model. The improved Wolf Pack algorithm in this article is used to solve this model in order to reduce the number of vehicles used, which can effectively improve the solution quality. The final experimental results validate the performance and application value of the improved algorithm.

The main innovations and contributions of this article include:

- (1) Through an in-depth study of the Wolf Pack algorithm, it was found that the location update method of Beta and Omega wolves has certain shortcomings, so the location update and step update of the Wolf Pack algorithm were improved respectively to achieve better optimisation search results.

- (2) A mathematical model is described and developed for the multi-vehicle, multi-goods dispensing problem. The constraints of the model are deformed and transformed into a penalty function added to the fitness function. The model is solved using the proposed improved Wolf Pack algorithm to reduce the number of vehicles used, thus effectively improving the quality of the solution.

The rest of the article is organised as follows: In Section 2, the Wolf Pack algorithm is studied in detail, while Section 3 provides the improvements to the Wolf Pack algorithm. In Section 4, the multi-vehicle, multi-goods dispensing problem based on the improved Wolf Pack algorithm is studied in detail, while Section 5 provides experimental results and analysis. Finally, the article is concluded in Section 6.

2. Wolf Pack Algorithm

2.1. Principle of the Wolf Pack Algorithm. Each wolf is classified as an Alpha, Beta, or Omega wolf, depending on the role it plays in the hunting process [25, 26]. Alpha wolves are always the strongest wolves in the pack and are responsible for directing the pack to capture prey without participating in the roaming, running, or siege process; Beta wolf is an elite unit of wolves, responsible for searching for prey; and Omega wolf is the attack force of wolves and is responsible for the [27, 28]. The principle of the Wolf Pack algorithm is shown in Figure 1.

When a wolf perceives a greater concentration of prey than the current Alpha wolf, we consider that wolf to be more likely to capture the prey. That wolf will then replace the Alpha wolf and call the surrounding Omega wolves to approach the current location [29]. When the prey is caught, the earlier the wolf catches the prey, the more food it gets, which approach allows wolves capable of capturing prey to maintain sufficient stamina [30, 31]. Wolves with sufficient physical strength are more likely to catch prey in the later hunting process, thus ensuring the development of wolves.

The total number of wolves is assumed to be N and the total number of variables is D . The state of an artificial wolf is represented as $X_i = (x_{i1}, x_{i2}, \dots, x_{iD})$, where x_{id} denotes the position of the i th artificial wolf in the d th dimension. The objective function is $Y = f(x)$, where Y denotes the concentration value of prey perceived by a wolf, that is the degree of adaptation.

2.1.1. Generation of Alpha Wolves. An Alpha wolf is an optimal value in the initial solution. An Alpha wolf is not fixed. During the iteration, the position of each wolf is updated continuously. If a better solution appears, the Alpha wolf is replaced by another wolf [32, 33].

2.1.2. The Wandering Process of Beta Wolves. Among N artificial wolves, the number of Beta wolves is S_num . The scale factor is denoted as a , the number of directions is h , and the wandering step is $step_a$. The fitness value of the Beta wolves in the initial solution is Y_i . The Beta wolves then take

a step forward in a direction ($p = 1, 2, \dots, h$) based on their current position. The position of the advancing Beta wolves in the d th dimension is updated.

$$x_{id}^p = x_{id} + \sin\left(2\pi \times \frac{p}{h}\right) \times step_a^d \quad (1)$$

After updating the Beta wolf's position, the adaptation value Y_i of the Beta wolf's current position is compared with the adaptation value Y_{lead} of the Alpha wolf. If $Y_i > Y_{lead}$, this Beta wolf replaces the Alpha wolf, and the Omega wolf is called to run towards the current position; otherwise the wandering continues until the maximum number of times T_{max} is reached.

2.1.3. The Long-Range Raiding Process of Omega Wolves.

Except Alpha wolf and Beta wolf, the remaining artificial wolves are Omega wolves. The number of Omega wolves is $_num$. When an Omega wolf receives a call from an Alpha wolf, it will run in the direction of the Alpha wolf. The step length of the long-range raid is $step_b$. The position of the Omega wolf in the d th dimension is updated at the $(k+1)$ th iteration.

$$x_{id}^{k+1} = x_{id}^k + step_b^d \times \frac{(g_d^k - x_{id}^k)}{|g_d^k - x_{id}^k|}, \quad (2)$$

where g_d^k is the position in the d -th dimension of the Alpha wolf at the $(k+1)$ th iteration.

When the distance between the Omega wolf and the Alpha wolf is less than d_{near} , it enters into a siege process of its prey.

$$d_{near} = \frac{1}{D \times \omega} \times \sum_{d=1}^D |\max_d - \min_d|, \quad (3)$$

where ω is the decision factor and $[\max_d - \min_d]$ is the range of values for the d th dimensional variable.

2.1.4. The Siege Process of Prey. Because Alpha wolves are closest to the prey, the position of Alpha wolves is considered to be the position of the prey G_d^k . The siege step of the wolves in the prey siege process is $step_c$. Location updates are calculated as follows:

$$x_{id}^{k+1} = x_{id}^k + \lambda \times step_c^d \times |G_d^k - x_{id}^k|, \quad (4)$$

where λ is a random number between [1].

There is a relationship between the step sizes of the three different stages.

$$step_a^d = \frac{step_b^d}{2} = step_c^d \times 2 = \frac{|\max_d - \min_d|}{S}. \quad (5)$$

During the siege process of a wolf pack, the position is updated if the adaptation of the current position is greater than the adaptation of the original position; otherwise, the position remains unchanged.

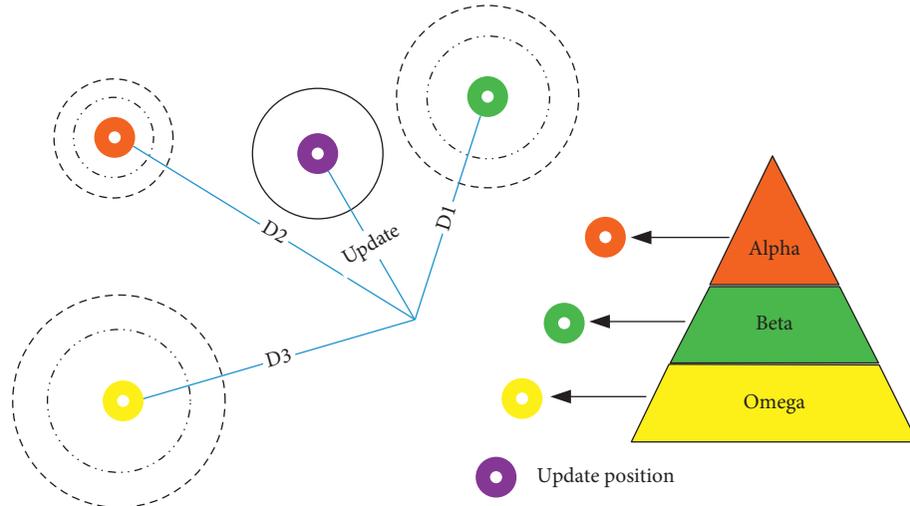

FIGURE 1: Principle of the Wolf Pack algorithm.

2.1.5. Renewal of Wolf Pack. In order to maintain the quality of the wolf population while preserving the diversity of the pack, the least adapted wolves are selected for culling and new artificial wolves are randomly generated [34–37]. The number of eliminated artificial wolves is the same as the number of newborn artificial wolves. The number of retirements needs to be determined by human experience.

2.2. Flow Chart of the Wolf Pack Algorithm. Figure 2 shows the flow chart of the Wolf Pack algorithm.

The detailed steps of the Wolf Pack algorithm are as follows:

Step 1: Initialise the number of artificial wolves N , the position X_p , the maximum number of generations to be selected k_{\max} , the scale factor a , the maximum number of wanderings T_{\max} , the distance determination factor ω , and the step size factor S .

Step 2: Follow equation (1) for position update. If the Beta wolf's fitness value Y_i is greater than the Alpha wolf's fitness value Y_{lead} , replace Alpha wolf and jump to Step 3; otherwise, the Beta wolf continues to wander until the maximum number of wanderings T_{\max} is reached.

Step 3: Follow equation (2) for position update. If the fitness value of an Omega wolf Y_i is greater than the fitness value of an Alpha wolf Y_{lead} , replace the Alpha wolf; otherwise, the Omega wolf continues to long-range raid until the distance to the prey is less than the judged distance d_{near} .

Step 4: Begin the wolf pack siege process and carry out the position update according to equation (5), together with the Alpha wolf update.

Step 5: Update Wolf Pack.

Step 6: Determine whether the maximum number of iterations is reached or the optimisation accuracy is achieved. If yes, the output of the optimal solution is carried out; otherwise jump to Step 2.

3. Improvements to the Wolf Pack Algorithm

After an in-depth study of the Wolf Pack algorithm, it was found that position update methods have certain shortcomings for Beta wolf and Omega wolf. Therefore, in this article, the Wolf Pack algorithm is improved in order to achieve better merit-seeking results.

3.1. Location Update. The Beta wolf's position during the wandering phase [38] was updated as follows:

$$x_{\text{id}}^p = x_{\text{id}} + \sin\left(2\pi \times \frac{p}{h}\right) \times \text{step}_a^d, \quad (6)$$

where h is the number of directions in Beta wolf's wandering process.

In most cases, the value of h is 4. The calculation shows that there are only two values for updating the position of the Beta wolf.

$$\begin{aligned} x_{\text{id}}^1 &= x_{\text{id}} + \text{step}_a^d, \\ x_{\text{id}}^3 &= x_{\text{id}} - \text{step}_a^d, \\ x_{\text{id}}^2 &= x_{\text{id}}^4 = x_{\text{id}}. \end{aligned} \quad (7)$$

That is, when Beta wolves wander in each of the four directions, they are only able to obtain two values that are different from their original position. This increases the computational effort and weakens the ability of Beta wolves to wander [39].

Therefore, the updated formula for the wandering phase has been improved in this article.

$$x_{\text{id}}^p = x_{\text{id}} + \cos\left(\pi \times \frac{p}{h}\right) \times \text{step}_a^d. \quad (8)$$

When h takes the value of 4, the Beta wolf's position is updated with a value of 3.

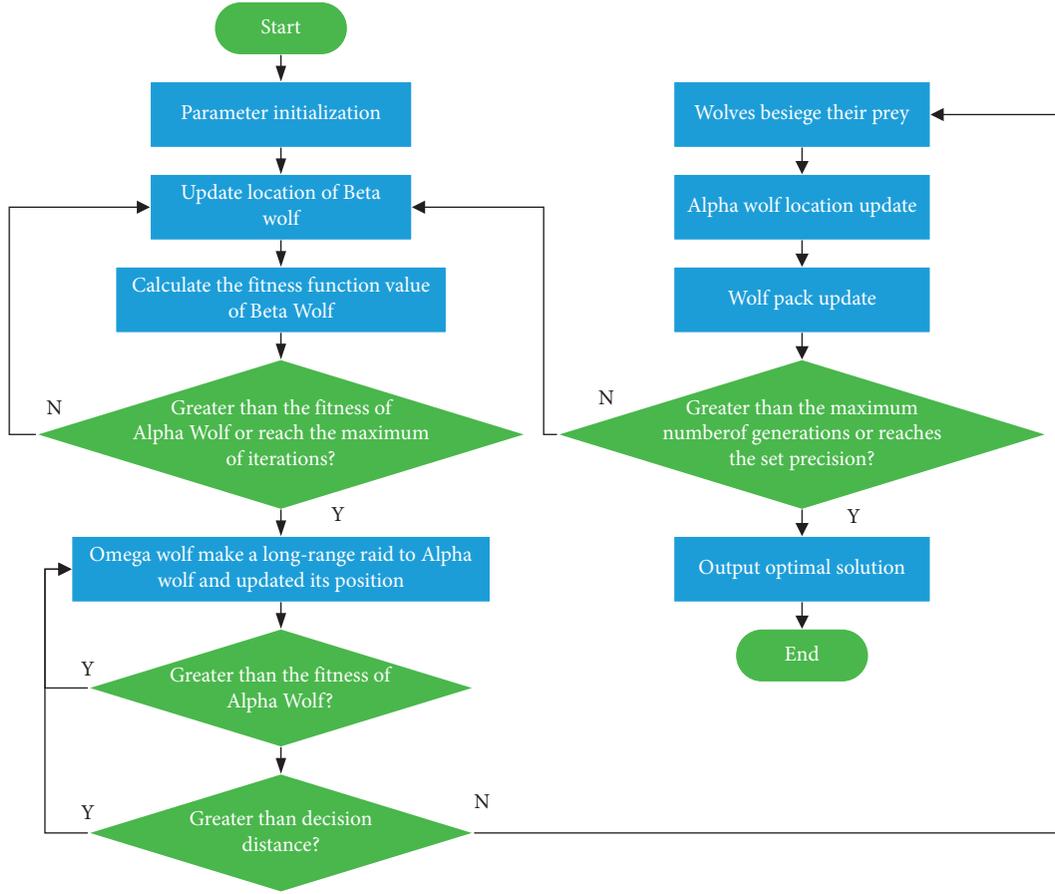

FIGURE 2: Flow of the Wolf Pack algorithm.

$$\begin{aligned}
 x_{id}^1 &= x_{id} + \frac{\sqrt{2}}{2} \text{step}_a^d, \\
 x_{id}^3 &= x_{id} - \frac{\sqrt{2}}{2} \text{step}_a^d, \\
 x_{id}^4 &= x_{id} - \text{step}_a^d.
 \end{aligned} \tag{9}$$

The improvement ensures that when Beta wolves wander in more than one direction, at most one value can be the same as the original position value.

3.2. Step Size Update. The step size of the long-range raiding and the step size of the siege are always fixed. However, as the distance between the wolves and their prey decreases (increasing number of iterations), both step values should decrease adaptively.

Therefore, this article uses an adaptive approach to improve the update process of the step size.

$$\begin{aligned}
 x_{id}^{k+1} &= x_{id}^k + \frac{(1-k)}{k_{\max}} \times \text{step}_b^d \times \frac{(g_d^k - x_{id}^k)}{|g_d^k - x_{id}^k|}, \\
 x_{id}^{k+1} &= x_{id}^k + \lambda \times \frac{(1-k)}{k_{\max}} \times \text{step}_c^d \times |G_d^k - x_{id}^k|,
 \end{aligned} \tag{10}$$

where k is the current number of iterations and k_{\max} is the maximum number of iterations.

4. Multi-Vehicle, Multi-Goods Dispensing Problem Based on the Improved Wolf Pack Algorithm

4.1. Description of Cargo Dispensing Problems. As a fundamental part of logistics and distribution, the quality of the cargo dispensing has an impact not only on the efficiency of distribution, but also on the operational efficiency of the entire logistics centre. Therefore, a reasonable cargo dispensing can reduce logistics costs, on the one hand, and improve the efficiency of distribution on the other. The dispensing problem is a complex discrete multi-constrained combinatorial optimisation problem, which belongs to the same NP problem as the travel merchant problem (TSP) and the workshop scheduling problem. The main components of the cargo dispensing problem are goods, vehicles, constraints, objective functions, etc. [40]. The volume and weight of the cargo are the basis for the decision of vehicle allocation. When the volume or weight of the cargo exceeds the volume or capacity of the vehicle, multiple transport vehicles are required to distribute it. A general description of the cargo dispensing problem is shown in Figure 3.

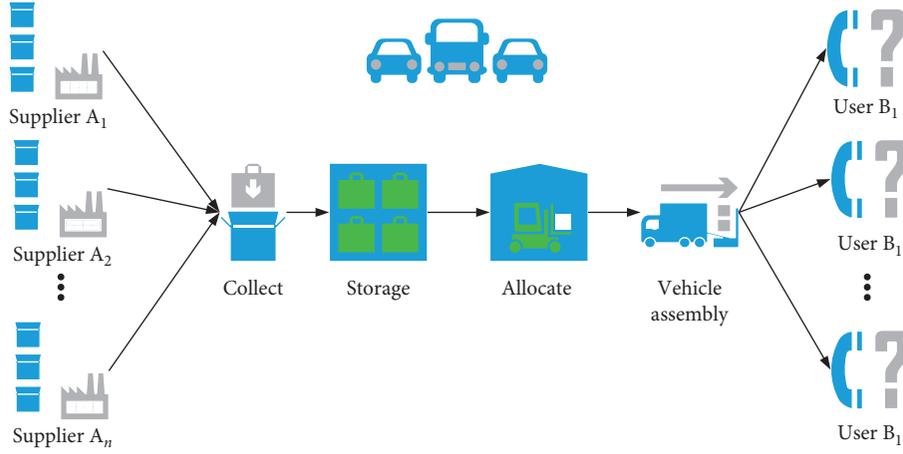

FIGURE 3: General description of the cargo dispensing problem.

4.2. Problem Description and Mathematical Model. Real-life cargo dispensing problems are very complex, and to facilitate modelling and solution, some cases are simplified: (1) the goods are all shipped to the same distribution centre; (2) the goods are intermixable and not incompatible; (3) there is no priority of goods.

Problem description: In a distribution centre, there are m vehicles of different types. Each vehicle has a maximum weight and a maximum volume of w_k and v_k ($k = 1, 2, \dots, m$), respectively. There are n different goods to be dispensed, with weights and volumes of w_i and v_i ($i = 1, 2, \dots, n$), respectively. Under the condition that the goods are relatively limited, the number of vehicles to be used is required to reach a minimum value.

The mathematical model for the multi-vehicle, multi-goods dispensing problem presented in this article is shown as follows:

$$\min f = \sum_{k=1}^m y_k, \sum_{i=1}^n x_{ki} w_i \leq y_k W_k, \sum_{i=1}^n x_{ki} v_i \leq y_k V_k, \sum_{k=1}^m x_{ki} = 1, \quad (11)$$

$$y_k = \begin{cases} 1, & \text{The } k\text{th vehicle is selected,} \\ 0, & \text{The } k\text{th vehicle is not selected,} \end{cases} \quad (12)$$

$$x_{ki} = \begin{cases} 1, & \text{The } i\text{th shipment is loaded into the } k\text{th vehicle,} \\ 0, & \text{The } i\text{th shipment is not loaded into the } k\text{th vehicle.} \end{cases} \quad (13)$$

The objective function is (11). It can be seen that the objective function is a minimum optimisation problem, that is, the number of vehicles used is the least. The constraint indicates that the total weight of the cargo on the k th vehicle does not exceed the capacity of the vehicle. (12) and (13) represent the constraints on the values taken by the variables y_k and x_{ki} .

4.3. Fitness Function. Fitness function is the optimisation index of wolf pack algorithm and the important basis of survival of the fittest in the siege process. In the mathematical model of multi-vehicle and multi-goods allocation,

the objective function cannot be directly used as the fitness function due to more constraints. Therefore, this article uses the penalty function to construct the fitness function.

$$\min F = f + c \sum_k^m ([\max(0, g_k)]^2 + [\max(0, h_k)]^2),$$

$$g_k = \sum_{i=1}^n x_{ki} w_i - y_k W_k, \quad (14)$$

$$h_k = \sum_{i=1}^n x_{ki} v_i - y_k V_k,$$

where c is the penalty factor.

The optimisation process of the Wolf Pack algorithm is a maximum value problem, so a further transformation has to be performed to obtain the optimisation fitness function of the Wolf Pack algorithm.

$$\max \text{Fit}(F) = -F. \quad (15)$$

5. Experimental Results and Analysis

5.1. Experimental Environment and Setup. In order to verify the effectiveness of a multi-vehicle, multi-cargo dispensing model based on the improved Wolf Pack algorithm, simulation tests were carried out using MATLAB. The hardware and software environments associated with the experiments are shown in Table 1. In addition, all experiments involved in this study were carried out in the same hardware and software environment. The parameter settings for the improved Wolf Pack algorithm during the experiments are shown in Table 2.

5.2. Typical Test Function Verification. Five typical continuous complexity functions are selected to verify the effectiveness and feasibility of the proposed improved wolf pack algorithm and to compare it with the traditional wolf pack algorithm.

TABLE 1: Experiment-related software and hardware environment and parameter settings.

Specification	Parameters
Processor	Intel Core i7
Memory	8 GB
Hard disk	500 GB
Operating systems	Windows 10 Professional
Programming software	MATLAB R2012a

TABLE 2: Parameter settings for the improved Wolf Pack algorithm.

Parameters	Numerical values
Wolf population	50
Maximum number of iterations	20
Scale factor for Beta wolves	4
Maximum number of wanderings for Beta wolves	20
Number of directions for Beta wolves	4
Distance determination factor	500
Step size factor	1000
Updating the scale factor	6

$$F_1 = x_1^2 + x_2^2, -5 \leq x_i \leq 5, i = 1, 2,$$

$$F_2 = 100(x_1^2 - x_2)^2 + (1 - x_1)^2, -2.048 \leq x_i \leq 2.048, i = 1, 2,$$

$$F_3 = [1 + (x_1 + x_2 + 1)^2(19 - 14x_1 + 3x_1^2 - 14x_2 + 6x_1x_2 + 3x_2^2)] \times$$

$$[30 + (2x_1 - 3x_2)^2(18 - 32x_1 + 12x_1^2 + 48x_2 - 36x_1x_2 + 27x_2^2)], -2 \leq x_i \leq 2, i = 1, 2, \quad (16)$$

$$F_4 = \left(4 - 2.1x_1^2 + \frac{1}{3}x_1^4\right)x_1^2 + x_1x_2 + (-4 + 4x_2^2)x_2^2, -3 \leq x_i \leq 3, i = 1, 2$$

$$F_5 = 10 \cos(2\pi x_1) + 10 \cos(2\pi x_2) - x_1^2 - x_2^2 - 20, -5.12 \leq x_i \leq 5.12, i = 1, 2.$$

In order to illustrate the convergence and optimisation seeking ability of the improved Wolf Pack algorithm in this article, a comparison was made with the genetic algorithm and the traditional Wolf Pack algorithm on the above five test functions. Figure 4 shows the optimisation process curves of the three algorithms on the test function F_1 . Figure 5 shows the optimisation curves of the three algorithms on the test function F_2 .

It can be seen that the genetic algorithm can only converge to a local optimum. Both the traditional Wolf Pack algorithm and the improved Wolf Pack algorithm can converge to the global optimum, while the improved Wolf Pack algorithm converges faster, indicating that the improved Wolf Pack algorithm in this article can greatly improve the efficiency of the search for the optimum. In order to further illustrate the optimisation finding ability of the improved Wolf Pack algorithm in this article, 100 calculations were carried out for each of the five test functions. Then, four metrics, the best value, the worst value, the average value, and the average deviation value (the deviation of the average value from the theoretical optimum value), were used to evaluate the results. A comparison of the test function optimisation results is shown in Table 3.

The best, worst, and average values show that the solution quality of the improved Wolf Pack algorithm is significantly better than that of the genetic algorithm and the traditional Wolf Pack algorithm. The highest accuracy was obtained by the improved Wolf Pack algorithm. In terms of the average deviation value, the improved wolf pack

algorithm has the smallest value, that is the smallest difference from the theoretical optimum.

The global search capability of the three algorithms was then judged by the number of convergences. A comparison of the convergence results on the five test functions is shown in Table 4. The maximum number of evolutionary generations was set to 1000. 100 tests were performed for each algorithm. The convergence accuracy was 10^{-3} . These algorithms were considered to have reached the convergence condition when the difference between the optimised value and the theoretical optimum was less than 10^{-3} .

It can be seen that the improved Wolf Pack algorithm converges 100 times on all five test functions, indicating that it is able to achieve global convergence with 100% probability, that is it is more stable. The genetic algorithm has the worst convergence, with only 4 out of 100 experimental tests, indicating that it is prone to fall into the local extreme value trap. Compared to the traditional wolf pack algorithm, the improved wolf pack algorithm takes 40% less time to reach convergence, indicating that it can converge to the global optimum more quickly. Overall, the number of convergence iterations and convergence time of the improved wolf pack algorithm are the lowest.

5.3. Experimental Cases. Suppose a distribution centre has 20 delivery vehicles with a load and volume of $6t$ and $10m^3$, respectively. There are 42 different types of goods to be dispensed. The goods now need to be rationally dispensed

and the minimum number of vehicles to be used are required. The numbers, weights, and volumes of all goods are shown in Table 5.

The experiment was carried out for 40 calculations. Both the conventional Wolf Pack algorithm and the modified Wolf Pack algorithm yielded an optimal solution of 12 after 40 calculations, which indicates that a minimum of 12 vehicles are required. An optimal dispensing solution is shown in Table 6.

When using the improved particle swarm algorithm (IPSO) to solve the same multi-vehicle, multi-goods dispensing problem, the best value is 13 in 35 out of 40 operations and the worst value is 16. When using the improved genetic algorithm (IGA) to solve the same vehicle dispensing problem, the best value is 13 in 36 out of 40 operations and the worst value is 17. The results of the different algorithms are compared in Table 7 and Figure 6. It can be seen that the improved Wolf Pack algorithm has better optimisation

capability and better stability in solving multi-vehicle and multi-goods dispensing problems.

6. Conclusion

In this article, a mathematical model of a multi-vehicle and multi-goods dispensing problem is established and constraints are transformed into penalty functions. Simulation results of five typical test functions show that the proposed improved wolf pack algorithm achieves better performance in terms of accuracy and convergence time. Compared with the traditional Wolf Pack algorithm, the time required for convergence of the improved Wolf Pack algorithm is reduced by 40%. The simulation results

of the logistics case show that the improved Wolf Pack algorithm has stronger optimising performance and better stability in solving the multi-vehicle and multi-goods dispensing problem, thus effectively reducing the number of vehicles. As the number of vehicles is often limited in actual logistics distribution, subsequent research will consider more realistic constraints to further improve the dispensing model.

This study aims to analyze the development trends of intelligent device interface improvements, specifically the car dashboards, by applying liquid crystal display technology. The methodology used in this study is mainly a comparison and analysis of the improvements that have been made. The objects in the study were several old version dashboards display instruments that were compared against the improved version of the LCDs. This paper analyses the requirements of car operators, with various proficiency for drivers' information, in enhancing the modern car dashboards displays. Besides, this study further delves into ways through which instrument interface intelligently can be improved to adapt effectively to all kinds of drivers. This study also touches on an analytical view of information targeting drivers. This is a scientific technique to determine the extent of information needed from drivers in different circumstances by having precise or averaged information about the drivers; it is easier to integrate this information into the human interface that helps in these modern car operations. The results of the study show that the current LCD Dashboards are valuable, accurate, precise user friendly, and improved with integrated ICT pieces of equipment. This makes them much better than the older traditional systems of the car dashboards.

1. Introduction

The methodology used in this study is mainly a comparison and analysis of the improvements that have been made, to analyze the development trends of intelligent device interface improvements, specifically the car dashboards, by applying liquid crystal display technology. This study shows that current LCD dashboards have been improved by integrating ICT equipment, which makes them much better than the old traditional car dashboard systems. The study reveals the evolution and improvement of modern vehicle dashboard display systems.

The old dashboard display version mainly consisted of mechanics and several movable parts. This made it difficult for the drivers to handle the cars at times. The rate at which the drivers were to multitask to gain full control of these machines was a daunting task. The rates of traffic jams, low speed, and road crashes were significantly high. Besides, it took a long time for one to learn how to manipulate all the

instruments on the car's dashboard fully. With a relatively high number of instruments to read, the information provided by these instruments sometimes failed to reflect the real conditions of the car. There are significant steps that have been taken to improve the ancient dashboards. Nonetheless, for high efficiency to be achieved in this human-machine interface, significant developments were also incorporated, both in design and also efficiency. A milestone change from mechanical to digital intelligence dashboard whose contents keep changing was achieved. As demonstrated by the incorporation of the new displays of LCDs and the future transparent dashboards, this Human Machine Interface has more advantages than disadvantages to automobile Human-computer Interaction and Automobile Human-machine Interface [1]. The flexibility of applying the full liquid crystal technology in the dashboard interface in an automobile is a modern method that is software-dependent [2] with more knowledge of science and technology across the globe. Tremendous improvements have been suggested,

and some implemented on ancient automobile products in the right direction in the intelligitization of human-computer interaction. The principle of this change depends on the rapid development and application of corresponding technological advancement, especially in automobile electronics, automobile human-computer interaction, automobile, and human-machine interface. It is projected that several vehicles will fully adopt the liquid crystal display dashboard in the future [3]. This will be integrated by the emergence of varying new dashboard interfaces in the automobile Human-computer Interaction and Automobile Human-machine Interface.

Externally, the design of these brand-new interfaces has a lot of modern development compared to traditional dashboards, suggesting a new requirement for design content and techniques. Besides, there are dynamics in the contents displayed by the new automobile dashboard interface. The displays are variable and diversified-unlike in the traditional mechanical dashboard in which pointers and scale were applied as the generation of hardware. The colors and style of operation are permanent. Furthermore, the liquid crystal display dashboard is a combination of a whole screen [3]. This implies that the kind of pointers, scales, numerals, and texts are simple images displayed and colors whose styles can be changed at will. This helps to meet the demand of different users in different scenarios [2]. It is both entertaining and interactive. Because of the different functions in the display, the dashboard can achieve various functions. For instance, it can display targeted prompts according to various driving procedures and environmental conditions that alert the drivers of the required information. This helps the drivers in quick decision-making. The alert system onboard has been instrumental in helping drivers with poor vision and hearing problems. These warning devices are pivotal in avoiding accidents [4].

The dashboard systems are intergraded with images and audio systems that can be read and heard. This interactive design provides advanced options lacking in old vehicle models. The other important tool in this category is the information demand level interface display. It enables the driver to be flexible, Drivers can make choices promptly, and it also allows for various styles and content according to their taste, driving norms, and varied information required [5]. Sometimes challenges are met in due course of implementing this technology. That is instrument interface cannot fully work out for all drivers.

For most developers to salvage this situation, analytic hierarchy processes have been proposed. Besides simple, effective index weight analysis technique that dwells much on the new liquid crystal display technology in the intelligent development procedure of automobiles, this could help satisfy the drivers' demand that depends on foregoing technology [5]. Furthermore, there is a method that helps in evaluating the demand level of different drivers for varied types of information during driving. From these reviews, it is evident that several changes have been in place to improve the old dashboards to a much better dashboard that is based on the liquid crystal display. There is a possibility of

eradication of the traditional dashboard soon if the LCDs are made cheap for all vehicle manufacturers.

2. Related Improvements in Human-Machine Interface Design in Modern Vehicles

Several factors like market demands show advantages of the improved LCD car dashboards. The number of cars sold due to the enhanced dashboards on LCD versions has improved greatly, as shown in Figure 1, along with the market demand for LCDs in different parts of the world for different models. The stiff competition in the market must, therefore, be handled technologically. This is achievable by the introduction of Human Interface Machines, which will be ideal and unique to attract more customers. Besides, Asian countries have the best-growing economy among their rivals worldwide. The growth in the Asian country's economy provides the best business arena and research platform for improved modern vehicles. Through market analysis, the taste for automatic vehicles has taken the day [3], substituting the old manual fashioned vehicles with improved dashboards such as automobile human-computer interaction and automobile human-machine interface. The need to improve their dashboards and other software-related interfaces in the current automated vehicles is greatly a good idea whose time has come [7]. Automated vehicles require a well-integrated human interface that will reduce risks such as accidents through a quick grasp of the information played by the LCD dashboards [8, 9].

Through the improvements of the displays, errors have been greatly reduced since most of the information on the performance of the vehicle is read by machines through a computerized interface system [10]. For this reason, Asian countries like China, Japan, and India have greatly contributed to the improvement that is deemed necessary for the best quality of automobiles they launched in the market. The USA and European car manufacturers have not been underscored in this analysis. The duos have also tried to pump financial and human capital to facelift their modern car production to unmatched standards [5]. I must relate that Russia, Europe, and America produce some of the most sophisticated motor vehicles in the modern world. They boast of their skilled manpower, availability of research funds, and also the staunch willingness to stay aloft among their competitors.

These multifaceted nations have enjoyed producing and selling cars in almost every niche of automobile transport. Their car production cuts across sports, heavy-duty, general transport, military, media, health education, and research. By being capable of extensively researching the current needs, China, America, Russia, Europe, and other stakeholders have played a pivotal role in modernizing their cars [11]. Their industries began by building manual vehicles with too many mechanical systems of display like the pointer speedometer and the oil gauge. These mechanical parts dashboards, with instruments having movable parts, were prone to mechanical breakdown [3]. They also had a short life with low work efficiency. The modern (improved car

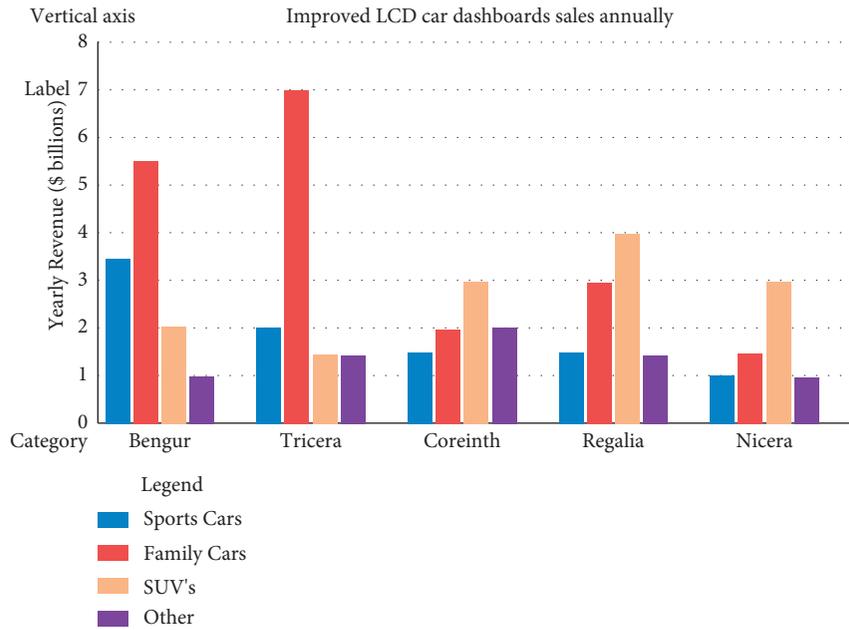

FIGURE 1: Market demand for LCDs in different parts of the world for different models [6].

dashboards) depend on minimal movable parts. Most of the display mechanisms are electronic-based, and their efficiency is highly improved. Quick readings can be taken at a glance. This reduces the energy spent by the drivers to obtain vital information like engine speed on their car dashboards.

Asian countries have contributed to the development and production of motor cars since the early 1980s. Countries such as Japan, India, China, and Russia are well-known champions of the automobile industry. Due to the growing automobile market, Asian countries have continued to remain relevant in the market to level their production against the USA (Ford), European (British Motor Works) countries, and other parts of the world. The backbone of the economy of these Asian countries is greatly dependent on motor vehicle assembly. Nonetheless, other Asian countries like India and China also offer favorable competition in the manufacture of vehicles in their regions. India produces a good number of its TATA brand vehicles in various models [12]. The market for cars and other heavy-duty automobiles has speedily increased. This is because cars are considered lucrative goods worldwide [3]. With the adoption of this new LCD technology, the dashboard interface design has a lot of importance, aimed to improve, convince, create comfortability, and even lessen driving rules [2]. By doing this, the safety of the drivers and general users is tremendously improved before creating any Human Machine Interface.

Since the advent of the first modern (i.e., digital) automotive display, designers and manufacturers have made significant progress in improving image quality and enhancing device durability [13], facilitating the development of modern automotive HMI designs. Takatoh et al. proposed a new type of optical device with variable transmittance based on the incident angle direction. These devices consist of two liquid crystal devices (LCDs) with a half-wave plate between them, a wide range of transmittances was obtained because no polarizer was used [14]. Yoon et al. [15] proposed

a homogeneously aligned liquid crystal device in which the liquid crystal director does tilt as well as twist deformation in a confined area by both vertical- and fringe-electric fields, exhibiting about two times faster decay response time than that of conventional FFS mode with suppressed luminance in the upward direction. In the vehicle display field, the brightness of the backlight is almost more than 10000 cd/m^2 , which may enlarge small defects in the display screen to impact display quality. As black uniformity is a crucial characteristic of image quality, Hua et al. [16] reduced the interference stress by controlling the flatness of the backlight and the metal frame, optimizing the design of the buffer strip, and reducing the bending stress by optimizing the structure and shape. The black uniformity of the module was improved by more than 80%. Wang et al. [17] designed a programmable digital power supply TFT liquid crystal display (LCD) screen touch display system based on STM32F7, the system has a clear display effect and fast control response.

3. Research Methodology and Design

3.1. Comparison and Analysis of the Improvements. The research methods were mainly a comparison between old traditional dashboards and modern LCD-based ones. The comparison offered a reflection of the tremendous work done to achieve the current dashboard displays. The popularity of LCDs is due to the high-tech Displays, Customized information, and the true reflection of Information Technology in the application of these great Human Machine interface tools. Up to now, it is premature to conclude that the development is fully done. Nonetheless, the LCD dashboards have a shred of clear evidence to capture the attention of all automobile manufacturers. This technology has proven important due to its unlimited advantages. Factors such as the orientation of the car and the global

TABLE 1: Comparison between the traditional and the current LCD-based dashboards.

Old car dashboards	LCD car dashboards
Had several mechanical parts	Few mechanical parts
Consumed more electrical power	Consumed less electrical power
Had limited functions	More functions and quite flexible
Manual operations	Dependable on programming
Difficult to operate required more attention	Easy to operate requires less attention
Time-consuming to repair and overhaul	Little time for repair and maintenance
Could not be linked to wireless devices, and the Internet	It can be linked to wireless devices like the Internet

positioning of the vehicles can easily be obtained on an LCD dashboard [18]. The major types of designs available in the market include mechanical meters with LCD Displays, pure mechanical meters, and all LCD.

Furthermore, The LCDs are available in different sizes and measurements, ranging from 4.3 inches to 12.3 inches, depending on their purpose. Wide choices and preferences are well taken care of. The improved versions of car dashboards are integrated with LCDs. The drivers can read the engine temperature, fuel gauge, and speedometer quite easily [19]. The application of computers to program the LCDs is also catered to in the new design. This has also enabled the connection of the current dashboards with wireless devices and even the Internet. The introduction of the touch smart LCDs is also an integral improvement on the car dashboards. The touch screens are easily operated since they don't require many complex mechanical systems. The comparison between the traditional and current LCD-based dashboards is demonstrated in Table 1.

The improved versions of car dashboards are integrated with LCDs. The application of computers to program the LCDs is also catered to in the new design. This has also enabled the connection of the current dashboards with wireless devices and even the Internet.

Among the cars that have adopted the incorporation of the LCDs fully on their dashboard is the EcoJet car. This car runs on a 650-horsepower run by biodiesel fuel. The display is a two-screen mounted on the front part (dashboard). This car entirely depends on the improved dashboard display, which provides basic information about the general state of the vehicle. Microsoft Windows Vista runs the LCDs for the multimedia and navigation control systems. This gives the car an enhanced ability of word processors and the web on the same dashboard. The rare views are also taken care of. The screen can successfully display the rear part of the car, and this display is connected to the camera. The dashboard is quite fascinating and entertaining. The LCDs are fully touch smart enabled. The audio system of this car is embedded with high graphics that can also recognize speech through a series of microphones onboard. This car is a postulation of future vehicles that will fully rely on the improved LCDs. The car borrows a lot of design from the jet airplane. The use of LCDs is not only limited to car displays but general automotive-like high-speed railways [20].

3.2. Evaluation of the Requirements of Car Operators. The operators require displays that can multitask, as shown in Figure 2. The need to display numerous information at once

is among the choices and preferences of the current drivers. User-friendliness, entertainment, and beauty are the evaluated factors that the driver requires in their modern LCD dashboards.

3.3. Evaluation of Dashboard Interface in Automobiles. In the early ages (from 1940s to 1960s) of car manufacturing by American companies, the dashboard was less readable. The instruments were chrome-laden and with transparent plastic covers, which at that time were seen as the best methods and styles. The reflection on the chrome surfaces, especially from the sunlight, could even make it difficult for the drivers to take correct readings. This trend continued until the 1980s when wood and chrome were still rampant on building the dashboard displays. Most of the improvements were made in Europe and the Asian-based car manufacturing companies. The dashboards started looking attractive with increased research to make them look much better by these companies. In the wake of the inception of LEDs, LCDs integration in the electronic arena and the possible displays were then made. The current automakers have gone far beyond this age within 20 years. The LEDs and, ultimately, the LCDs have taken the subject of discussion in-car dashboard displays. With the ability to convert the mechanical motion into electrical signals and then into the screens through computer programming, the car displays are much better. The car dashboard displays as major Human Machine Interface increases by adding stylish modern technology in the displays of these machines, as shown in Figure 2 Full interchangeable LCD Dashboard touch smart enabled. The other models of car that included the LCDs on their dashboards were the Audi Quattro. This was a sports car in the early 1990s. The LDC displays in these cars were simpler than the current full liquid crystal displays. The analog systems were reduced in this model in 1991.

Several companies have even gone a notch higher to incorporate the fuel economy gauges in a cluster of some vehicles, e.g., Honda, Mercedes, and British Motor work for companies. This fuel gauge helps in real-time monitoring of these vehicles' fuel consumption, as shown in Figure 3. Further, engine real-time and even mileage readings have been developed in the 2010s to improve the awareness of the drivers on the car performance. These transitions from the ammeters to voltmeters and finally, proper gauges have been developed and improved through the integration of the LCDs and the computer software, as demonstrated in Figure 4. These developments and further improvements have taken time to complete the evolution. With speculations and

FIGURE 2: Full interchangeable LCD dashboard touch smart enabled [12].

Color-coded fuel economy display

FIGURE 3: A color-coded fuel economy is not only beautiful but also easy to read: left photo, right column photo [21].

research which is still on to better the dashboard systems, more is yet to be achieved. Car tracking systems have been made possible by this new technology.

Along with influencing factors like the competition for the market, this study also offers a succinct and comprehensive knowledge of the facets like the future of these current developments in the automobile industry [11]. Capturing areas like the market growth for the improved human-machine interface profoundly delves into the crystal liquid display dashboards. Full liquid crystal technology in the dashboard interface in an automobile has a benefit for both the car developers and the car users [5]. The developers are earning cash from their skills and ideas by developing better equipment like the liquid crystal technology in the automobile dashboard interface. Furthermore, car drivers get quality services offered by the designed interfaces while driving, as demonstrated in Figure 3. This is a win-win situation for both the equipment vendors and consumers.

The LCDs in the car display come with various values and functions. Some of the improved display systems help tell the distance between the driver’s car and the next car in front. The distances to be estimated by the driver’s car can also be adjusted to varied abilities, which helps drivers with high-speed cars to keep safe distances from cars [23]. It avoids accidents since the car drivers can slow down at convenient distances and times, even at sharp bends. Drivers with poor vision have also benefitted from this improved dashboard display [11]. To safely drive, the drivers get the exact distance between the two cars even under poor visibility brought about by the weather. Some of the improved version of these displays is shown below in Figure 5.

LCDs are designed such that their function shifts, the improvement here is that the screen can display some information discretely or as set by the driver, and some situations prompt reverse driving. The strain to turn while the drivers sit to view the back of the car during reverse has also been catered for [24]. The above model LCD is designed in such a manner that during reverse, the display picks the back view movement of the vehicle through some camera at the back. This aids the drivers in making smooth turns by avoiding hitting objects. In modern urban areas, parking a car in front of schools, offices, Walmarts, and even supermarkets has faced a high number of cars with little or no space for parking. It becomes difficult for the lucky ones who get parking spaces again to unpark the car and get to the road [25]. The emergence of this improved version of the Human Machine Interface provided back the vision of the car during

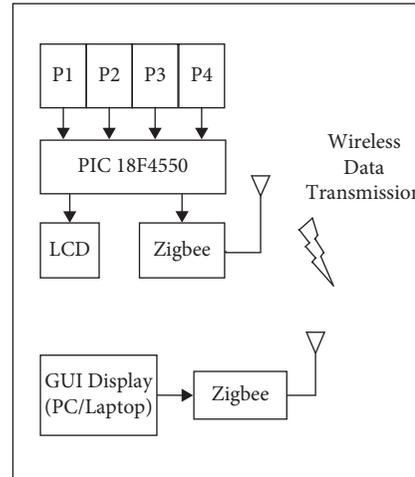

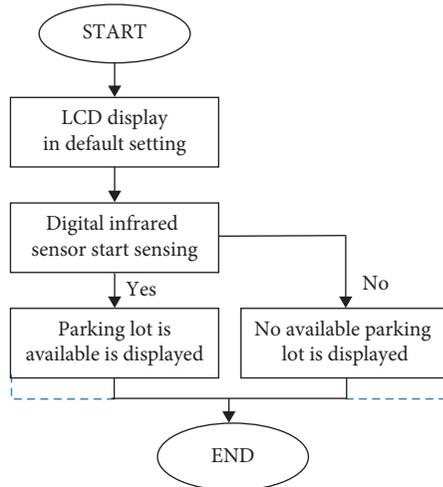

FIGURE 4: A computerized LCD with android operating systems [22].

FIGURE 5: Distance gauge Integrated into the car windscreen for easy reading [4].

FIGURE 6: Night vision aid LCD [4].

reverse. The drivers find it easier to get the car safely in reverse mode. The improved display is shown below in Figure 6 and Figure 7 during usage.

The application of the above LCDs has dramatically improved the efficiency of the current drivers. The need to be increasingly dependable. The interfaces act as an aid to humans both for safety and accuracy. It is not a matter of production, but the main issue is producing quality at speed. It is equally imperative to highlight the improvements in the design of the LCDs. Through active projects, there are several designs of programmable LCDs [27]. Through these designs, they significantly employ the instrument cluster as an important element of the safety automobiles' passive safety channel and systems [28]. This state of art invention shows the driver the situation of the car through some signals. The energy distribution in the car LCDs is also shown below in Figure 8.

The warnings are informed of collision warnings, terrain warnings and potholes, vision and audio support, parking aids, and even adoptive speed controls. There are several eventualities that prompt signal warnings on the dashboard of a car [29]. Moreover, the car dashboard display systems are smaller to cater to all warnings. Therefore, multitasking designs are integrated into the crystal display system that allows the car to send more than one warning per instrument [30]. This design chiefly helps to create more useful gadgets for a small area in the car dashboard. Another important improvement is the incorporation of an integrated

FIGURE 7: Reverse assistance LCD [26].

instruments cluster, which has more areas to exploit in terms of visual space [31].

The runtime configurations and flexibility are the key priorities that make these designs important too. This ensures that the driver can make changes due to the prevailing conditions of the road (Bellotti et al.). It is quite clear that the designs play a key role in the adoption of this Human Machine Interface in the motor car industry. These adorable communications tools have made driving more desirable and enjoyable, as they limit the energy and tasks of the driver. These communication tools are equally imperative in line with safety and containment. The best part is the existence of research to improve the improved designs through lab road tests [32].

FIGURE 8: Consumption and energy monitor of a modern improved car (generation Toyota Prius, 2010).

The car developers may choose a number of these OS, depending on the requirements of the display systems. Besides, these operating systems also make it possible to bring plug-and-play and wireless devices into the car. Bluetooth, Wi-Fi, and Ethernet can be connected with the LCDs courtesy of the computer science contributions [33]. The computerized display system also helps link the car to the outside world through the Internet. Connecting the dashboards to the 3G and 4G is possible if the dashboard is compliant [34]. This means that the integration of the Operating System dependent LCDs is not only for the beautiful graphical but also a research and interlinking tool altogether. Every opportunity has got a challenge. Despite the praises heaped on the Human Machine Interface, several challenges such as space and overheating in the dashboards due to the circuit boards of these LCDs are the challenges that continue to face their use [29]. The cars and the software developers have endeavored to develop and harmonize both software and hardware that are compact, small size, and efficient car dashboard LCDs. This technical problem has derailed the full adoption of all LCDs in the current vehicles.

4. Discussion

All this improvement can be achieved through the following techniques: first and foremost, for this behavioral dashboard interface intelligent to be implemented in automobiles, checking the driving conditions is Key [5]. This can be done by analyzing the driver's behavior, and installing all kinds of sensors should be fully implemented; secondly, choosing and deciding which information should be fed onboard computers based on a designer framework adhering to rules and standards. And finally, the information displayed on the dashboard interface should be a man based on the decision-making results.

From the above analysis, the improved car displays by application of the LCDs have indeed brought a turnaround in the automobile industry. These improvements aim to make the use of modern cars as easy as possible. Besides, the development in information technology has equally boosted the Human-machine Interface Systems like an entire LCD car dashboard [12]. In as much as the technology may face challenges in the application. There are many advantages attached to it in the end. This ranges from accuracy to the

safety of the road users and the drivers [11]. The fully LCD dashboard was only typical in the luxurious cars that dominated the global market. It is good news to realize that through research, cheap cars are also embarking on adopting all LCD dashboard systems, which shows a milestone improvement that has taken place since the inception of the LCDs [6]. Some challenges come with every bit of technology. For instance, cars that are computer-dependent are also liable for hacking. Cyber-attacks are currently a menace in every sector like health, finance, transport, and communication. With the advent of this crime, it is pretty challenging to develop dashboards that are computer dependable but free from cyber-attack risks. Taxi companies like UBER face technical and crime problems. Another upcoming challenge that drags behind the implementation of the LCD Car dashboards is the maintenance cost that they come. For a long time in history, the development of LCDs has depended on a better research foundation, which calls for funds for starting and maintaining the automakers that integrate the computer and LCD display in their automobiles.

This Human Machine Interface has also improved and speeded up future designs of the expected cars that will be electric and solar energy-dependent. It is also pivotal to acknowledge the roles played by the computer technicians in integrating all LCDs in the car display system through their scientific knowledge and unwavering spirit of the invention. They have made it possible to coalesce computer science and mechanical science to come up with a human-machine interface [29]. Besides, it is pivotal to note that the core of the LCD dashboard displays has been immensely improved through software development in computer science. The backbone of clear communication between LCDs, the car, and humans lie in the operating system, which is computer software. QNX, WinCE, Android, Linux, and Windows operating systems have made it possible to develop the LCD car dashboards display [34]. These operating systems greatly assist in programmable LCDs.

As the terminal information gate of the IoT era, the LCD devices will also extend to the smart area, which is the intelligent display. On the one hand, the display effect will reach the real world and achieve "zero error output." On the other hand, the display equipment can detect the emotional state of human beings and automatically switch the

information they present in real-time according to their wishes, and then realize “human-machine interaction” [35].

LCD has many advantages and is the main development direction. However, physical interaction is considered the most reliable and efficient [36, 37]. LCD is susceptible to environmental factors, resulting in unstable performance [37]. With the improvement of technology, these problems will eventually be overcome, and the LCD industry will further develop and play an essential role in human-computer interaction.

5. Conclusion

This study shows that the current LCD dashboards are valuable, accurate, precise user friendly, and improved with integrated ICT equipment. This makes them much better than the older traditional systems of the car dashboards. The result indicates the availability of several improved versions of the car dashboards integrated with LCDs. The application of computers to program the LCDs is also catered to in the new design. This has also enabled the connection of the current dashboards with wireless devices and even the Internet. Therefore, the study reveals the evolution and improvements in the modern car dashboard display systems.

This work focuses on the published liquid crystal display technology, studies the development trend of smart device interface improvement, how to apply the still researched and unpublished liquid crystal display technology into smart devices, achieving high human-computer interaction efficiency and accuracy requires other researchers to investigate further. In recent years, the popularity of keywords such as human-vehicle interaction and autonomous driving has continued to increase, and liquid crystal technology, human-computer interaction technology, sensors, and information technology have continued to develop. These all provide research opportunities for researchers. This work is expected to offer broad prospects for future research and help researchers discover potential opportunities for human-vehicle interactions.

The development of the urban economy and the effect of linkage radiation are inseparable from the urban transportation system's efficient operation. In the context of the new era, environmental pollution caused by economic development has gradually become an invisible killer that endangers human health and the atmospheric environment. It is a pillar industry of economic development, a key part of urban infrastructure construction, and a necessary guarantee for urban residents to travel and live, and it is important to develop a low-carbon, environmental-friendly, energy-saving, and emission-reduction potential for urban transportation systems. On the basis of a large number of literature research, this paper attempts to establish the role of an urban rail transit system in energy conservation and emission reduction in three aspects: residents' travel behavior, ground transportation operation, and low carbon, energy conservation, and reduced emission under the influence of the urban rail transit system. Based on the temporal and spatial distribution characteristics of urban rail transit passenger flow, a relatively complete energy-saving and emission-reduction evaluation model is established. Through case analysis, it is verified that the model can effectively evaluate the effect of energy saving and emission reduction under different rail transit settings and its spatial and temporal distribution characteristics, and provides ideas and technical guidance for multidimensional quantitative analysis of urban rail transit carbon environmental protection, energy conservation, and emission reduction.

1. Introduction

The rapid development of urban economy and scale has brought earth-shaking changes to people's lives. However, at the same time, this leap-forward development process that exceeds the speed of perfecting urban supporting facilities also makes people pay a corresponding price. Environmental pollution and energy consumption are increasingly threatening the living environment of human beings and the realization of sustainable urban development goals. "Energy saving and emission reduction" has become a huge challenge faced by all fields worldwide. As the pillar industry of urban economic development, the urban transportation system is a key part of urban infrastructure construction, and a

necessary guarantee for urban residents to travel and live, energy conservation and emission reduction for the urban transportation system is imperative.

As one of the most important public travel tools in the modern urban transportation system, urban rail transit is a breakthrough to achieve energy conservation, reduced emission, and sustainable development. Compared with the traditional ground transportation mode, urban rail transit, as a large-capacity passenger vehicle driven by electric energy, has developed rapidly in major cities around the world in recent years due to its advantages of low pollution and low energy consumption. Considering the problems faced by the sustainable development of the urban transportation system, it is the key to carry out the energy-saving and emission-

reduction strategy of the urban transportation system. Since the passenger flow of urban rail transit is complex and has significant spatial and temporal distribution characteristics, its energy-saving and emission-reduction effects will have corresponding spatial and temporal differences due to the size of the passenger flow. The mechanism of action has not been fully considered and explored, and there are certain limitations in the application of the model.

Therefore, this paper will make up for the insufficiency of the traditional evaluation model in the analysis of the action mechanism, analyze its energy-saving and emission-reduction action mechanism through the multidimensional influence of the urban rail transit system, build a more reasonable quantitative evaluation method for the energy-saving and emission-reduction effect, and provide technical support and theoretical basis for the implementation of emission-reduction strategies.

2. Related Work

With the continuous deterioration of urban rail transit pollution around the world, researchers in the field of environmental engineering aim to establish regional emission inventories, which are represented by MOBILE [1], COPERT [2], and HBEFA [3]. The research shows [4] that this will lead to the emission measurement results being about 30% higher than the actual emission level, but the construction idea of the MOBILE model has reference significance for the development of the emission model. At this stage, similar modeling ideas are adopted in the widely used urban rail transit energy conservation and emission-reduction evaluation models, that is, by establishing urban transit system scenarios with or without rail, comparing rail transit and rail transit alternative modes of transportation and the emission difference between the two, and then drawing the conclusion of rail transit energy saving and emission reduction. Sostenibile et al. [5] believe that the essential reason for urban rail energy saving and emission reduction is to effectively reduce the per capita emission intensity to achieve the purpose of energy saving and emission reduction. Hodges et al. [6] compared the per capita CO₂ emission factors of different transportation vehicles and found that there is a certain multiple relationship between different transportation vehicles and unit emission factors. Obviously, only the per capita emission intensity of different transportation modes cannot reflect the impact of the complexity of transportation on its emission results. Therefore, Wang et al. [7] established a city-level comprehensive transportation emission model, combined with urban rail transit passenger flow data and average haul distance data to compare the differences in emissions of different modes of transport with macro emissions. The problem with the above model is that its focus is on the emission of urban rail transit, and it cannot truly quantitatively evaluate the emission reduction of urban rail transit.

Therefore, analyzing the quantitative substitution relationship between urban rail transit and other modes of transportation is a solution to break through this bottleneck. The model estimation method of the emission impact after

returning the passenger flow to the original travel mode is simple and easy to implement [8, 9], but it is unreasonable to summarize the emission factors under all conditions only with a single comprehensive emission factor value. Based on Chen et al. [10], the above model is optimized, and the model solves the shortcomings of the original model to a certain extent. In recent years, with the increase in the proportion of environmental indicators in urban transportation planning schemes, the research on the evaluation model of urban rail transit energy conservation and emission reduction has also introduced a traffic demand forecast model, which provides a basis for the construction of urban rail transit energy conservation and emission-reduction models and new ideas [11, 12].

The study found that most scholars have discussed and analyzed the evaluation model of urban rail transit energy conservation and emission reduction, and established effective research models from different perspectives; however, there is a lack of full consideration and exploration of the mechanism of urban rail transit energy conservation and emission reduction; there are certain limitations in considering the model application scenarios. The passenger flow of urban rail transit is complex and has significant spatial and temporal distribution characteristics. Therefore, it should be noted that there are corresponding spatial and temporal differences in its energy-saving and emission-reduction effects. Regarding this point, no scholars have yet found a multidimensional analysis of the energy-saving and emission-reduction mechanism of urban rail transit systems to form a more comprehensive and reasonable quantitative evaluation method for energy-saving and emission-reduction effects.

3. Related Theories

3.1. Multidimensional Influence Relationship between Urban Rail Transit and Urban Transportation System. The research goal of this paper was to quantitatively evaluate and explore the energy-saving and emission-reduction effects of urban rail transit on the urban transportation system to which it belongs. Therefore, the impact of the construction and operation of urban rail transit on the urban transportation system is the entry point for the analysis of its energy-saving and emission-reduction mechanism. Based on the research of the previous part, the urban transportation system is a complex system composed of people, vehicles, and roads, and the impact of urban rail transit on the system is shown in Figure 1, including the travel behavior of travelers, the transfer of transportation modes, and ground transportation running changes.

3.2. Characteristics of Urban Rail Transit Passenger Flow Transfer. In the process of the subway network gradually, the attraction degree of urban rail transit to passenger flow is mainly related to the nature of land use along the line and the service level of replacing buses. With the increase in development intensity, residential area density, and population density along the line, the passenger flow will increase, which

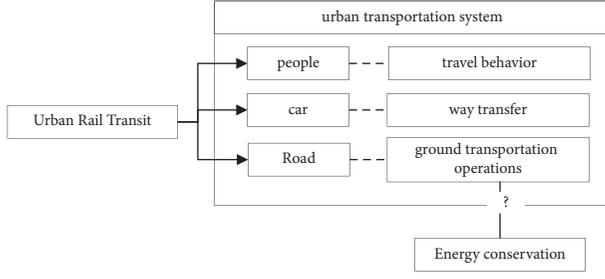

FIGURE 1: Multidimensional influence of urban rail transit on the urban transportation system.

will also promote the growth of the passenger flow in the original section.

The passenger flow of urban rail transit generally includes three parts: trend passenger flow, transfer passenger flow, and induced passenger flow [13].

3.2.1. Trend Passenger Flow. Trend passenger flow refers to the normal growth of the passenger flow at rail stations and along the line.

3.2.2. Transfer Passenger Flow. Diverted passenger flow refers to the passenger flow that is attracted and transferred to urban rail transit by other modes of transportation, and this part of the passenger flow is usually caused by competition between modes of transportation. A small part of the diverted passenger flow comes from private cars and taxis, while most of them come from regular bus and bicycle trips.

3.2.3. Induced Passenger Flow. Induced passenger flow means that with the rapid construction and operation of urban rail transit lines, land development and population agglomeration along the lines are promoted, the accessibility between different areas of the city is improved, the city's subway service level is improved, and residents' travel intensity is increased, thereby increasing traffic.

3.3. Influencing Factors of Emission Measurement in the Urban Rail Transit Emission Model. This paper will refer to Xie et al. [14] to establish the link between ground transportation operation data and emission measurement results to analyze the mechanism of energy conservation and emission reduction. The established urban road traffic emission model shows that the calculation of ground traffic emissions is shown in formulas (1) and (2):

$$E_{\text{mission}_{i,j}} = EF_{i,v} \times VKT_{i,j}, \quad (1)$$

$$E_{\text{mission}_{\text{net}}} = \sum_i \sum_j E_{\text{mission}_{i,j}}, \quad (2)$$

$E_{\text{mission}_{i,j}}$ represents emissions of vehicle i on road segment j (g); $E_{\text{mission}_{\text{net}}}$ represents total emissions from the road network (g); $EF_{i,v}$ represents the emission factor for model i

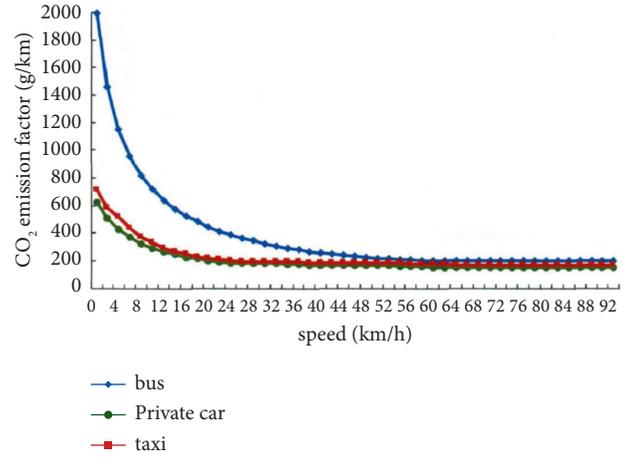

FIGURE 2: CO₂ emission factor variation curve of different vehicle models with speed.

at speed v (g/km); $VKT_{i,j}$ represents the vehicle mileage of vehicle type i on road j (pcu-km); i, j, v represent the model, road segment, and speed, respectively.

According to the calculation formula of the transportation emission model shown above, it can be found that the emission factor and VKT are two important components of the road network emission measurement, and they are also the factors that directly affect the emission measurement results.

3.3.1. Relationship between Emission Factor and Speed Change. The emission factor is defined as the amount of emissions produced by a motor vehicle per unit mileage, which is composed of the distribution of vehicle driving conditions and the emission rate as shown in the following formula:

$$EF_{i,v} = \frac{\sum VSP \text{Distribution} \times ER_i}{\bar{v}}, \quad (3)$$

where $VSP \text{Distribution}$ represents the vehicle driving condition distribution based on VSP characterization; ER_i represents the emission rate of model i (g/s); \bar{v} is the average speed (km/m).

From the calculation formula of the emission factor, it can be found that different vehicle types have different emission factor values at different average driving speeds. Therefore, the emission factor is characterized by a distribution curve that changes with speed as shown in Figure 2. The emission factor gradually decreases with the increase in speed, and the emission factor value in the low-speed range is much larger than that in the high-speed range; from the perspective of the relationship between the emission factor and the vehicle model, the emission factor curves of different models have obvious differences with the speed. The low-speed interval is more significant. At the same speed, the emission factor of buses is the largest, followed by social vehicles, and the emission factor of taxis is the smallest.

3.3.2. The Relationship between VKT and Road Flow Calculation. VKT (vehicle kilometer traveled) is the number of kilometers traveled by motor vehicles, which reflects the

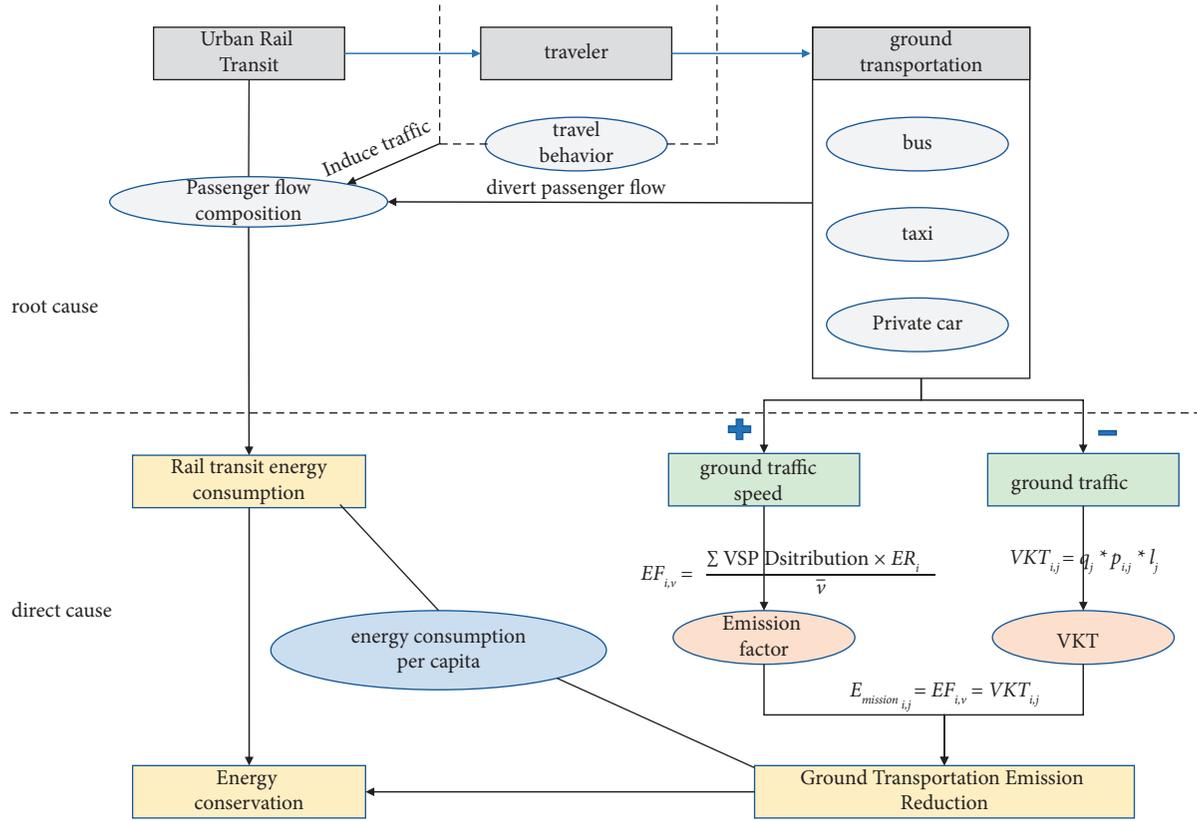

FIGURE 3: Analysis of the mechanism of low-carbon, environmental-friendly, energy-saving, and emission-reduction action of urban rail transit.

traffic activity level of motor vehicles. It is multiplied by the emission factor to obtain the total emission and emission inventory. It is a key parameter for the coupling of the traffic model and the emission model. The calculation method is shown in the following formula:

$$VKT_{i,j} = q_j * p_{i,j} * l_j, \quad (4)$$

where $VKT_{i,j}$ represents the vehicle mileage of vehicle type i on road j (pcu-km) q_j represents the traffic flow on road segment j (pcu); $p_{i,j}$ represents the proportion of traffic of vehicle i on road j to the total traffic; l_j is the length of road segment j (km).

It can be found that VKT is composed of three parts: road traffic volume, road length, and vehicle model ratio. Therefore, there is a linear positive correlation calculation relationship between VKT and road flow; that is, when the ratio of road and vehicle models is determined, the greater the flow of the road is, the greater the calculation result of VKT is, and the greater the final discharge result of the road is.

3.4. Mechanism and Distribution Characteristics of Low Carbon, Environmental Protection, Energy Saving, and Emission Reduction in Urban Rail Transit

3.4.1. Mechanism of Action. This study summarizes the mechanism of energy saving and emission reduction of urban rail transit based on the corresponding literature

[14–22], as shown in Figure 3. It can be found that the mechanism of energy saving and emission reduction of urban rail transit is relatively complex, which is the result of comprehensively considering the multidimensional impact of urban rail transit on the urban transportation system.

The direct reason for energy saving and emission reduction of urban rail transit lies in its impact on the “road” dimension of the urban transportation system. The opening and operation of urban rail transit lines share the traffic pressure in the area where the line radiates, and part of the ground transportation travel demand is transferred to urban rail transit. The traffic flow on the ground is reduced, and the traffic operation in the surrounding area of the line is improved.

The fundamental reason for urban rail transit energy conservation and emission reduction lies in its impact on the two dimensions of “people” and “vehicles” in the urban transportation system. Urban rail transit lines affect the travel behavior of travelers on the line, and on the one hand, some people originally travel on different grounds. Passengers who have completed their trips by means of transportation are transferred to the subway, and on the other hand, it has induced some travelers to generate new travel needs. It can be found that the impact of urban rail transit on the two dimensions of “people” and “vehicles” is also the reason for the formation of urban rail transit passenger flow.

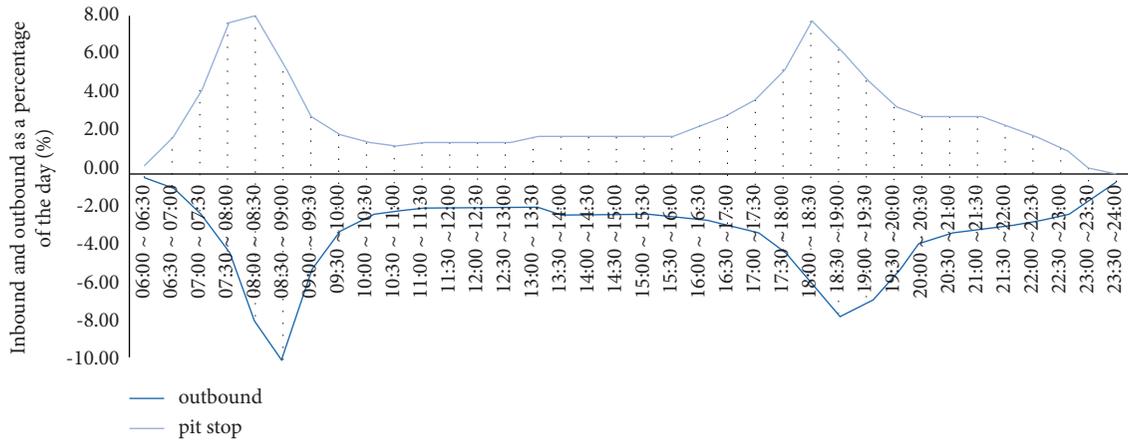

FIGURE 4: Time distribution of passenger flow in and out of rail transit stations.

3.4.2. *Spatial and Temporal Distribution Characteristics of Passenger Flow.* Using the urban rail transit AFC (automatic fare collection system), that is, the automatic fare collection system swiping data to analyze the spatiotemporal distribution characteristics of urban rail transit passenger flow, it has the following characteristics.

(1) *Imbalance.* In the lines or stations of the urban rail transit system, there is a specific phenomenon of the mismatch between the supply of transport capacity and the demand for passenger flow in time, space, and direction. With the formation of the rail transit network, the share of rail transit in urban public transport has gradually increased. The main purpose of travel for passengers is commuting. People who work and go to school take the subway at a fixed time every day. Therefore, in terms of the rail transit network, within one day, the fluctuating state of the passenger flow of the railway shows the unbalanced characteristics of two peaks in the morning and evening, and the time distribution of rail transit passenger flow in and out of the station is shown in Figure 4.

(2) *Travel periodicity.* In the urban rail transit system, the passenger flow presents a periodic change in a fixed period of time. Since the commuter passenger flow accounts for a large proportion of the daily passenger flow, and its work cycle is carried out in a weekly cycle, the rail transit passenger flow generally presents a cyclical change in the weekly time unit throughout the year. The daily passenger flow curve of rail transit is shown in Figure 5.

(3) *Travel tidal nature.* In the lines or stations of the urban rail transit system, there are a large passenger flow in one direction and a less passenger flow in the opposite direction at a certain period of time, but the phenomenon of the opposite passenger flow characteristics occurs in another period of time. With the continuous expansion of the city scale, the rail transit system has become an important mode of transportation connecting the central city and surrounding suburbs. Passengers will have different travel modes due to different travel purposes such as work, school,

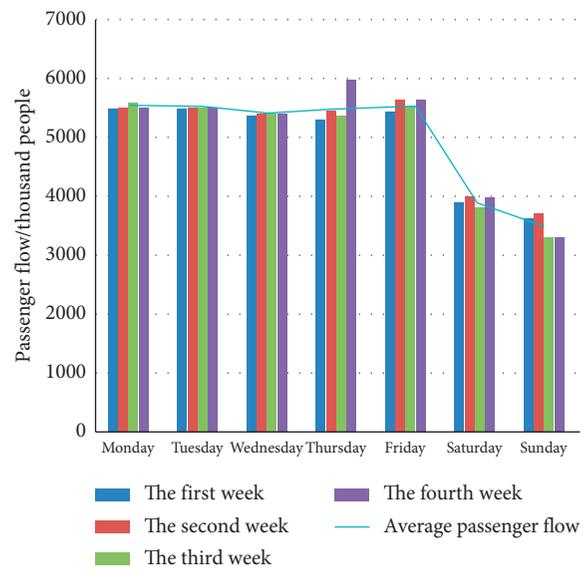

FIGURE 5: Curve of daily passenger flow of rail transit.

shopping, and business, and rail transit travel presents significant tidal characteristics. During the morning peak period on weekdays, the passenger flow is reflected in the commuting passenger flow generated by passengers going to work and school, and passengers flow from the place of residence to the place of work. In the evening rush hour on weekdays, the passenger flow is reflected in the commuter passenger flow generated by the passengers getting off work and school. The basic flow direction of the passenger flow is opposite to that of the morning rush hour. Passengers flow from the office to the residence. During weekends, there is no obvious morning and evening peak period, and a large number of passengers travel between residential areas, shopping areas, and tourist areas due to travel purposes such as shopping and tourism. In lines with obvious tidal phenomena, the passenger flow of rail transit is unevenly distributed in time and space, which is very likely to cause tension in the capacity of some lines.

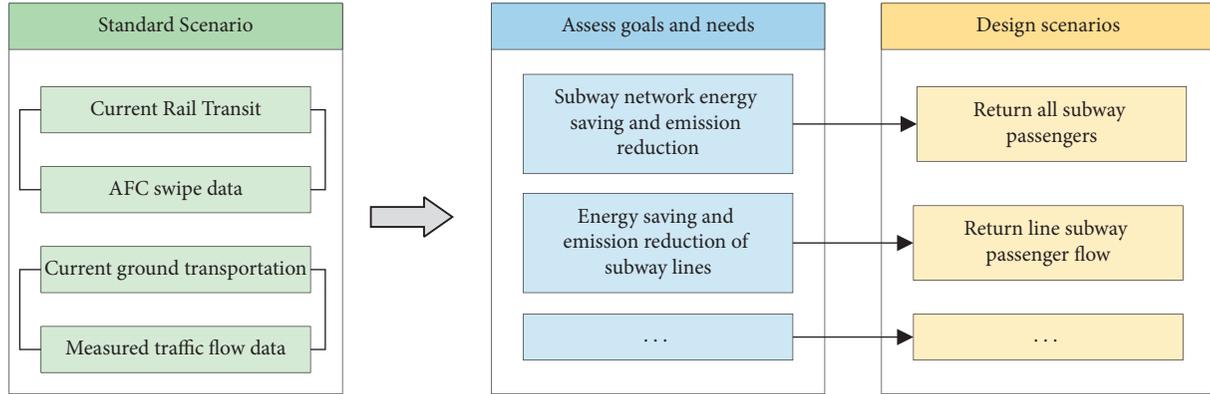

FIGURE 6: Scenario design flow idea based on low-carbon, environmental protection, energy conservation, and emission-reduction assessment targets.

4. Construction of the Low-Carbon, Environmental-Friendly, Energy-Saving, and Emission-Reduction Evaluation Model for Urban Rail Transit

4.1. Model Building Ideas

4.1.1. Model Assumptions and Scenario Design. From the previous research and analysis, it can be seen that the direct reason for energy conservation and emission reduction of urban rail transit is that the construction and operation of the urban rail transit network shares the passenger flow of ground transportation, improves the operation of ground transportation, and then achieves the effect of energy conservation and emission reduction of urban transportation system. Based on this, this paper makes a reasonable inversion and assumes that when there is no rail transit in the urban transportation system, passengers who originally traveled by subway will return to ground transportation to complete their travel needs. At the same time, considering the complexity and diversity of urban rail energy conservation and emission-reduction assessment targets and needs, this paper takes the current urban rail transit setup as the standard scenario, and forms corresponding design scenarios according to different assessment targets and needs, as shown in Figure 6. Then, this paper analyzes the ground transportation operation under the influence of the standard scenario and the design scenario, respectively, and measures the ground transportation emission difference under the different scenarios, that is, the ground transportation emission reduction under the design scenario and the urban rail transit energy saving and emission reduction of the design scenario. The evaluation of the scenario design helps in comparative analysis and improves the applicability of the model.

Figure 6 shows the scenario design idea of urban rail transit. It can be found that the energy-saving and emission-reduction evaluation model constructed in this paper is suitable for various evaluation objectives, including the evaluation of the energy-saving and emission-reduction effect of the existing subway operation network in the city and energy conservation and emission-reduction assessment. It should be noted that in order to ensure the use of the traffic

demand forecast model to analyze the ground traffic operation under its influence in the design scenario, the current urban traffic situation is considered, so the standard scenario in this paper is based on the current urban rail transit and ground traffic as a reference. Therefore, the ground traffic operation situation under the standard scenario is calculated through the measured traffic flow data, and only the design scenario is predicted using the traffic demand forecasting model established in the literature [23] that considers the impact of urban rail transit.

4.1.2. Low-Carbon, Environmental-Friendly, Energy-Saving, and Emission-Reduction Model Framework for Urban Rail Transit. As shown in Figure 7, the urban rail transit energy conservation and emission-reduction evaluation model consists of two parts, namely, ground transportation emission reduction and urban rail transit operation energy consumption. The calculation method is shown in the following formula:

$$E_{\text{save}} = \Delta E_{\text{road}} - \Delta E_{\text{rail}} = (E_{B,\text{road}} - E_{A,\text{road}}) - (E_{A,\text{rail}} - E_{B,\text{rail}}), \quad (5)$$

where E_{save} represents the energy saving and emission reduction of urban rail transit in urban transportation system (g); ΔE_{road} represents the urban rail transit affecting the energy saving and emission reduction of the ground transportation system (g); ΔE_{rail} represents the emission reductions added by urban rail transit to urban transportation systems (g); $E_{A,\text{road}}$ and $E_{B,\text{road}}$ represent surface transportation emissions for standard and design scenarios (g), respectively; $E_{A,\text{rail}}$ and $E_{B,\text{rail}}$ represent rail transit emissions for standard and design scenarios (g), respectively.

Since the emissions generated by the operation of urban rail transit are mainly due to the carbon emissions generated by the consumption of electric energy, the existing research on energy conservation and emission reduction of urban rail transit often only uses carbon emission reduction as the only energy conservation and emission-reduction evaluation index. However, this study believes that the traffic pollution situation including NO_x, PM, and other pollutants has become more and more serious in recent years [24]. Based on this, the pollutants and emission indicators evaluated in

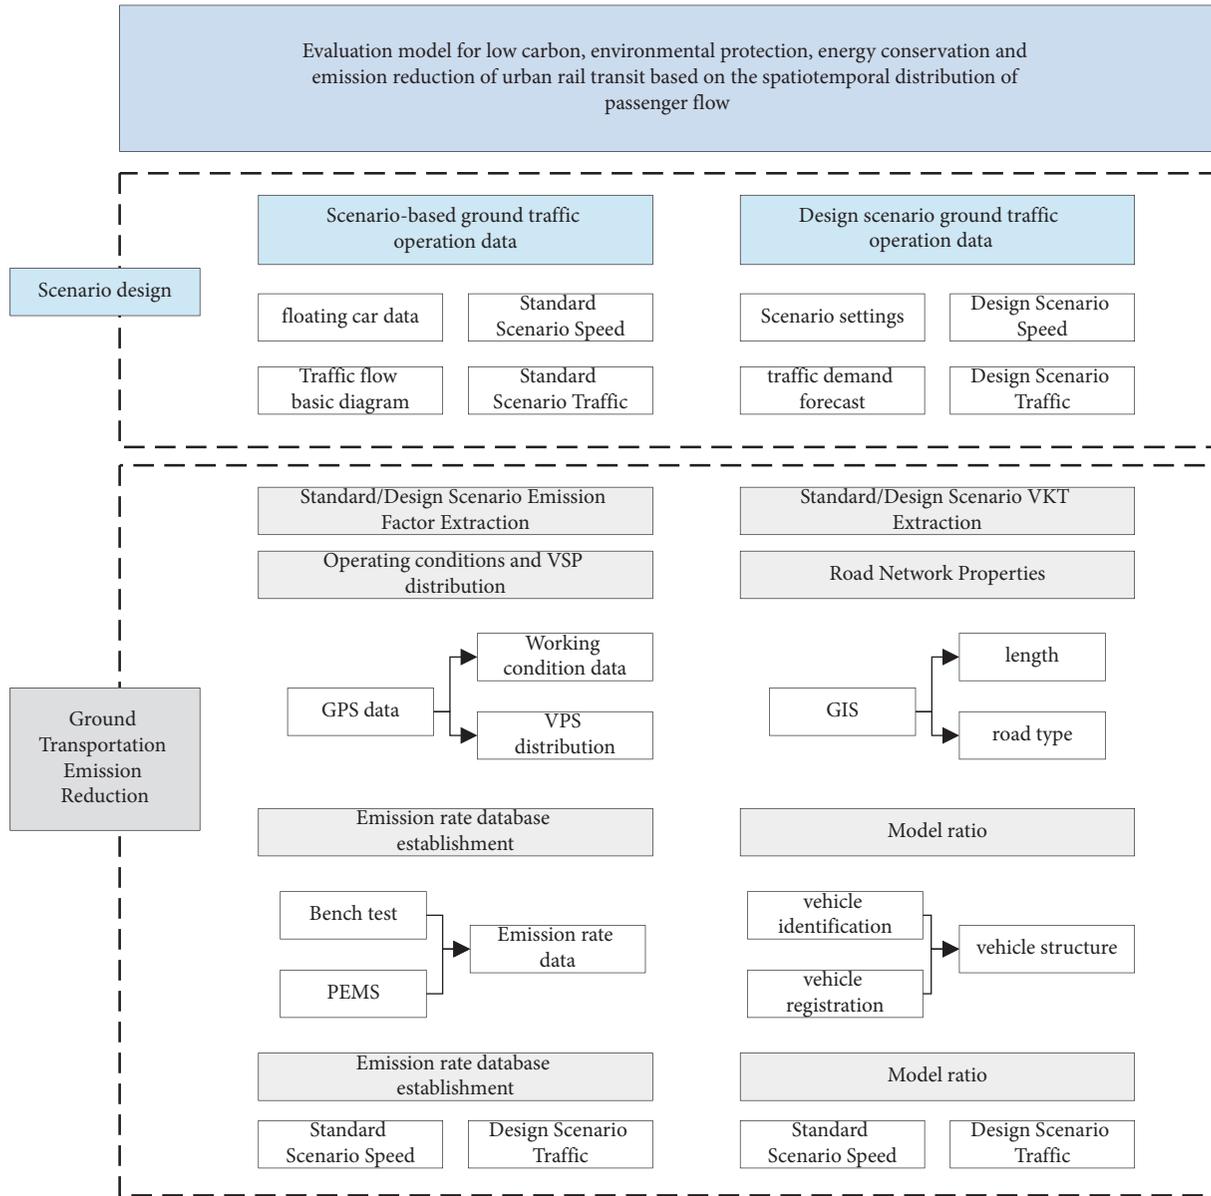

FIGURE 7: Architecture of the low-carbon, environmental-friendly, energy-saving, and emission-reduction model of urban rail transit.

TABLE 1: Evaluation indicators for energy conservation and emission reduction.

	Transportation	Emissions	Energy-saving emission indicators
Urban transport system	Rail	CO ₂	Indicator 1
		CO ₂	Indicator 2
		NOx	Indicator 3
	The traffic	CO	Indicator 4
		HC	Indicator 5
		PM	

this paper for energy conservation and emission reduction are shown in Table 1.

4.2. Calculation of Ground Transportation Emission Reduction under the Influence of Urban Rail Transit. The measurement of ground transportation emission reduction under the

influence of urban rail transit is one of the important components of the urban rail transit energy conservation and emission-reduction evaluation model constructed in this paper, and it is also an indicator that reflects the mechanism of urban rail transit energy conservation and emission reduction. Combining the model technical route in Subsection 4.1 and the calculation formula of the

transportation emission model in 3.3, the calculation method of ground transportation emission reduction is shown in formulas (6) and (7):

$$\Delta E_{road} = \sum_{i,v}^j EF_{i,v} * VKT_{i,j} = \sum_{i,v}^j EF_{i,v} * (l_j * q_j * p_{i,j}), \quad (6)$$

$$\Delta E_{road} = \sum_{i,v}^j EF_{i,v^A} * (l_j * q_j^A * p_{i,j}^A) = \sum_{i,v}^j EF_{i,v^B} * (l_j * q_j^B * p_{i,j}^B), \quad (7)$$

where $EF_{i,v}$ represents the emission factor for model i at speed v (g/km); $VKT_{i,j}$ is the number of kilometers traveled by vehicle i on road j (km); v^A and v^B represent the ground traffic operating speeds for standard and design scenarios, respectively (km/h); q_j^A and q_j^B are the traffic routes of section j in the standard scenario and the design scenario, respectively (pcu); $p_{i,j}^A$ and $p_{i,j}^B$ —are the proportion of vehicle i on road j in the standard scenario and the design scenario, respectively.

According to the above formula, it can be found that the measurement of ground transportation emission reduction under the influence of urban rail transit is mainly composed of emission factor and VKT. The emission factor is mainly affected by the change in ground transportation operating speed under different scenarios, while VKT is mainly affected by the impact of changes in ground traffic flow and vehicle model proportions under different scenarios.

4.2.1. Calculation of Emission Factors under Different Scenarios. According to the introduction of the establishment process of emission factor database and the acquisition method of ground transportation speed data under different scenarios, establishing the relationship between emission factors and speed requires the coupling of traffic operation data and traffic emission data. Therefore, the emission factor database established in this paper is composed of vehicle driving condition distribution data based on specific power and measured vehicle emission rate data.

This section uses the MOVES model developed by the US Environmental Protection Agency (EPA) to establish the vehicle specific power (VSP) parameter to describe and analyze the distribution of vehicle driving conditions. VSP is defined as the output power per ton of mass (including self-weight) moved by the motor vehicle engine [25], and the calculation method is shown in the following formula:

$$VSP = \frac{Av + Bv^2 + Cv^3 + mva}{f}, \quad (8)$$

where v and a are the instantaneous speed and instantaneous acceleration of the motor vehicle, respectively, in m/s and m/s^2 ; M is the vehicle quality (t); A , B , C , and f are model constant coefficients, only relevant to the vehicle type.

The emission rate is the amount of vehicle emissions per unit time, in g/s. The collection of emission rate data is completed by the bench test based on NEDC (New European

Driving Cycle), and the test data cover CO_2 , CO , HC , NO_x , and PM of various models. Through VSP clustering and interval division, the average emission rate (g/s) of each pollutant and pollutant in each VSP interval can be obtained, that is, the mass of pollutants emitted by the motor vehicle per unit time of driving under specific operating conditions, as shown in Figure 8.

The actual driving speed on the road is an important factor affecting the emission of motor vehicles, which is often ignored in traditional emission models. Therefore, in order to accurately quantify the impact of speed on the emission factor, it is necessary to calculate the emission factor of motor vehicles based on the average speed and to establish speed correction models for emission factors of different vehicle types and fuel types. The calculation method of the emission factor in the usual emission model is shown in the following formula:

$$EF_V = \frac{3600 * \sum VSPDistribution_i * ER_i}{v}, \quad (9)$$

where EF_V represents the emission factor at average velocity v (g/km); ER_i represents the average emission rate for VSP interval i (g/s); $VSPDistribution_i$ represents the distribution ratio of VSP interval i .

To sum up, this paper established an emission factor database covering 36 vehicle types and 3 road classes, including CO , CO_2 , HC , and NO_x emissions. Emission factors for some speed ranges are shown as examples in Table 2.

4.2.2. VKT Calculation in Different Scenarios. The ground traffic flow under the influence of different scenarios is a key step to measure the emission reduction of ground transportation, and it is also the main factor affecting VKT. The ground traffic operation under the influence of the design scenario is based on the analysis of the traffic demand forecasting model established by the literature considering the impact of urban rail transit after the inversion of the subway passenger flow, while the standard scenario is based on the analysis of the current ground traffic operation. In this paper, with the help of the existing research results of the basic traffic flow diagram [26], the relationship between the three elements of the traffic flow of the road segment can be established based on the Van Aerde model, as shown in equations (10)–(12).

$$v = v_f e^{-\rho/\rho_m}, \quad (10)$$

$$q = \rho v_f e^{-\rho/\rho_m}, \quad (11)$$

$$q = -\rho_m v \ln \frac{v}{v_f}, \quad (12)$$

where q represents the hourly traffic on a single lane (veh/h); v is the average speed of the road (km/h); ρ is the average density of road sections (veh/km); v_f is the free-flow velocity of the road type to which the segment belongs (km/h); ρ_m is the road segment critical density (veh/km).

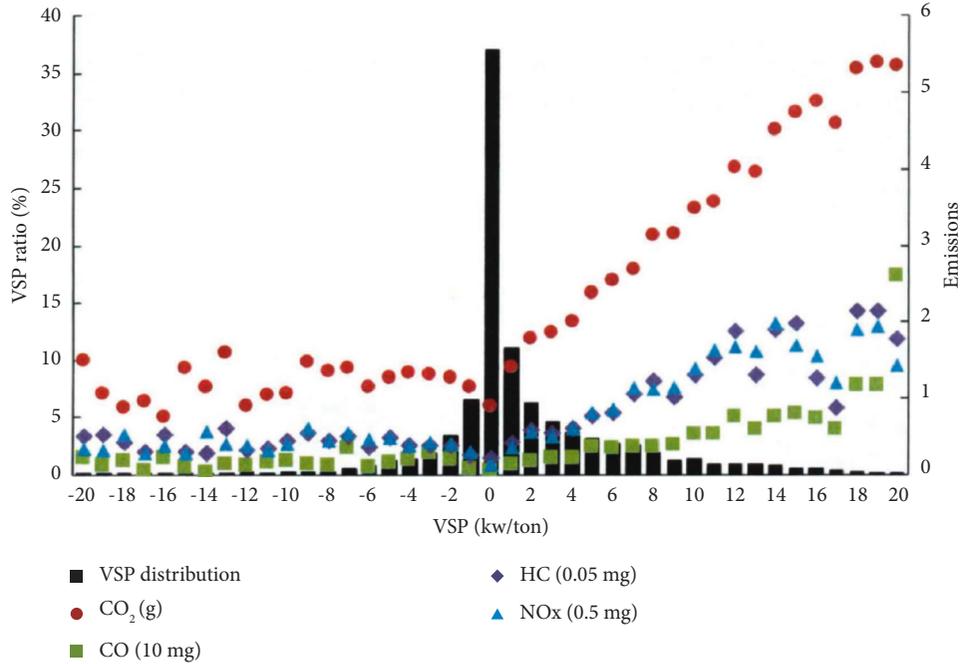

FIGURE 8: Distribution of emission rates in different VSP intervals.

Note. Road type 11 represents the roads on the left and right sides for vehicles, with six roads on each side including motor vehicle lanes and nonmotor vehicle lanes.

According to the relationship between flow and speed established by the traffic flow basic map, this paper combines the measured floating car data in City A with the traffic flow basic map formula to carry out data regression analysis, and at the same time can calculate the speed-flow inversion method that conforms to City A, as shown in the following formula:

$$q = -\frac{v}{\delta_i} \ln \frac{v}{v_{f_i}}, i = 1, 2, 3, \quad (13)$$

where δ_i and v_{f_i} are model constant parameters; $i = 1, 2, 3$ represent expressway, main road, and sub-branch, respectively.

Due to the large differences in the emissions of the same model, after obtaining the traffic volume and length of a road section, it is necessary to analyze the model structure of the traffic volume of the road section, and then combine it with

the corresponding emission factor to calculate the emission. In the actual operation process of road traffic, the proportion of models changes in real time, but it is difficult to obtain the proportion of dynamic models. In this paper, the proportion of models in the standard scenario of fixed model ratio is used for calibration, and the proportion of models in the standard scenario is corrected to obtain the models in the design scenario.

Proportion. The proportion of vehicle models in the standard scenario in this paper is obtained by combining the video recognition data of the license plate and the vehicle management registration data. When a motor vehicle passes through a road section with a camera installed, the license plate number will be recorded. At the same time, by querying the vehicle management registration information, the vehicle model corresponding to the license plate number can be determined to obtain the model proportion data. The proportion data of some models is shown in Table 3.

5. Evaluation and Analysis of Low Carbon, Environmental Protection, Energy Saving, and Emission Reduction in Rail Transit

5.1. Rail Transit Carbon Emission Calculation. The urban rail transit energy conservation and emission-reduction evaluation model constructed in this study considers the energy consumed by rail transit in the operation process. This section takes the track lines covered by City A as the research scope. As shown in Figure 9, based on the AFC credit card data, the average transportation distance and passenger flow of different track lines are counted, and the carbon emission coefficient per person-kilometer of different track lines is combined to calculate the area of rail transit carbon

TABLE 3: Sample table of model proportion data.

Expressway, main road, and sub-branch		Highway (%)	Main road (%)	Secondary branch (%)
Bus	Class A	2.0	2.0	2.0
	Class B	1.0	1.0	1.0
	Class C	0.0	0.0	0.0
Social vehicle	Class A	0.3	0.3	0.4
	Class B	1.8	1.7	1.9
	Class C	7.5	7.4	8.3
	Class D	10.0	9.8	10.9
	Class E	41.2	40.6	45.1
	Class F	3.3	3.3	3.7

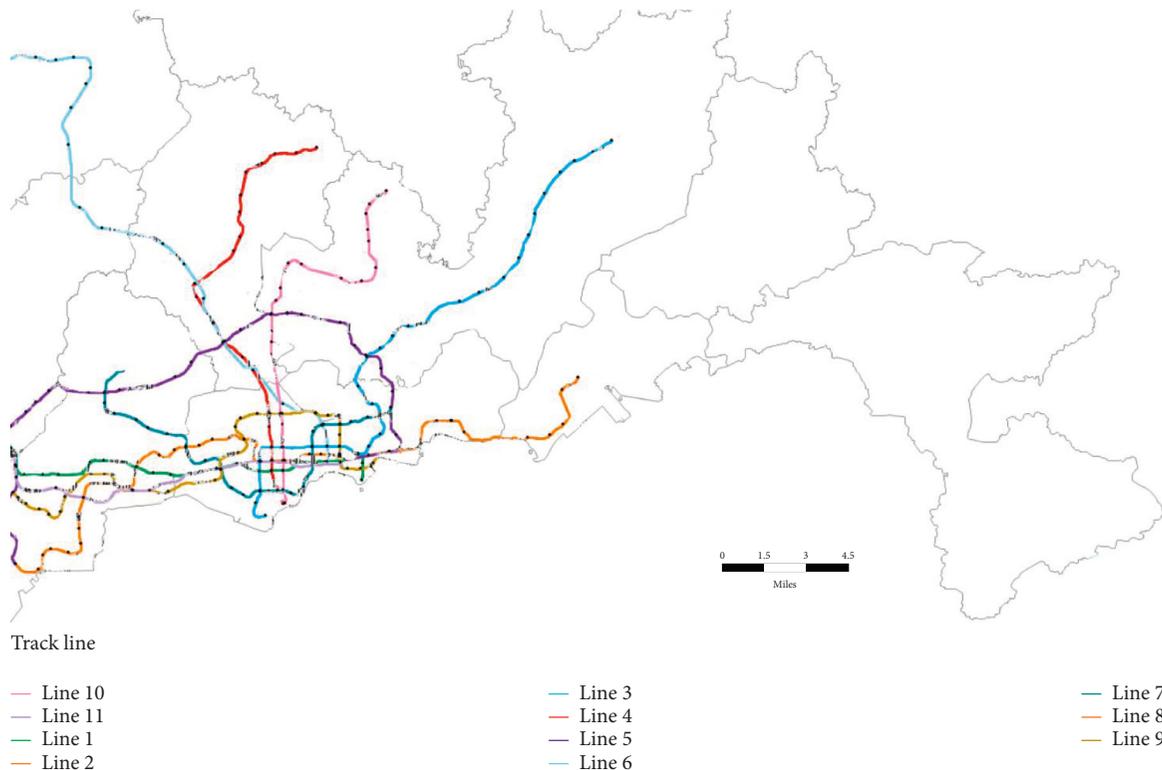

FIGURE 9: City-covered track route map.

emissions. Figure 10 shows the average transportation distance (km/person) and line occupancy ratio (ratio of average transportation distance to line length) of 11 subway lines within City A. It can be found that the average transportation distance of different lines is quite different. The average haulage occupancy ratio shows that the track occupancy ratio in the surrounding areas of City A is large, while the urban occupancy ratio is small, which is closely related to the spatial separation of passengers' work and residence, which is in line with the characteristics of passenger travel.

In this study, the energy consumption of rail transit is calculated based on the carbon emission coefficient of person-kilometers of different rail transit lines. Therefore, in addition to the average transportation distance of different lines, it is also necessary to calculate the passenger volume of each line. Generally speaking, with the change in subway

passenger flow, the subway operating company will adjust the departure interval and station service equipment, so there is a linear correlation between passenger volume and rail transit energy consumption, and considering the urban rail transit constructed in this study. The low-carbon, environmental protection, energy-saving, and emission-reduction evaluation model is based on the temporal and spatial distribution of rail transit passenger flow. Therefore, based on the AFC credit card data, I calculate the morning peak (7:00–9:00) and evening peak (17:00–19:00), respectively. The passenger flow of the line in the three periods of Pingfeng (12:00–14:00) is shown in Figures 11–13. It can be found that the passenger flow of different lines is the largest during the morning peak, the evening peak is slightly lower than the morning peak, and the passenger flow during the flat peak period drops significantly, accounting for only about 20% of the morning peak passenger flow. At

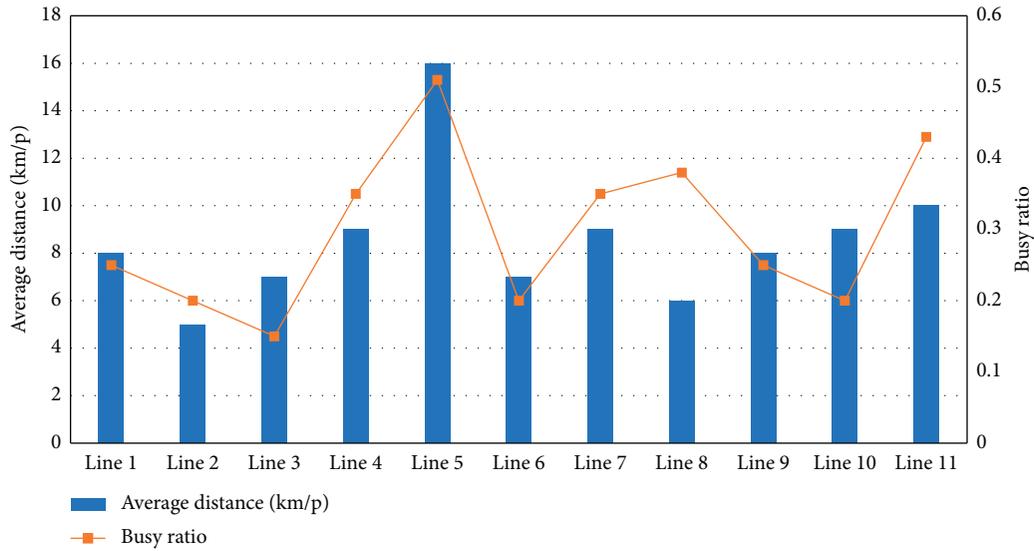

FIGURE 10: Average distance of rail transit lines in City A.

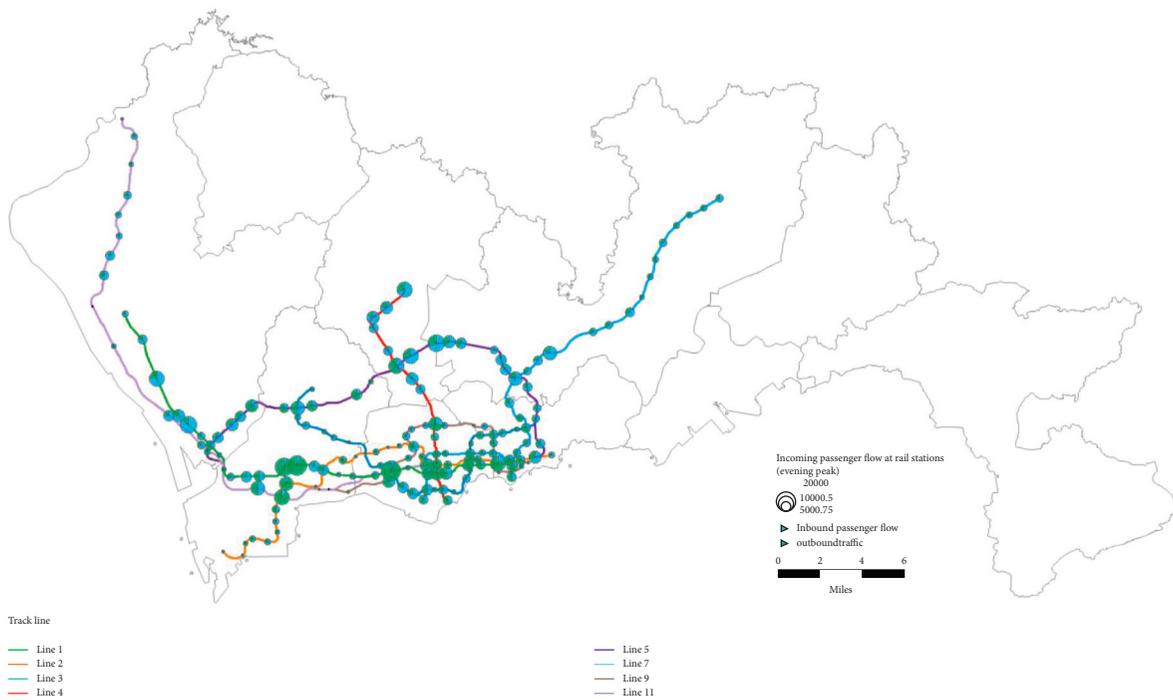

FIGURE 11: Passenger flow diagram of the rail transit lines in City A in the morning rush hour.

the same time, the difference in passenger flow between lines is also more obvious. The passenger flow of Metro Line 1 and Line 5 is the highest, the passenger flow of Line 2, Line 3, and Line 11 is relatively close, while the passenger flow of Line 4 and Line 9 is the lowest.

To sum up, this study obtained the carbon emission coefficients of 7 subway lines in City A, calculated the average transportation distance of the lines, and counted the passenger volume of each subway line in different periods according to formulas (5)–(14). The carbon emission

measurement of rail transit lines can be carried out, and the calculation results are shown in Table 4.

5.2. Energy Conservation and Emission-Reduction Assessment Results. The evaluation indicators of energy conservation and emission reduction in this study include five pollutants and emissions, including CO₂, NO_x, CO, HC, and PM. Among them, only CO₂ emissions are generated during the operation of urban rail transit itself. Therefore, the ground

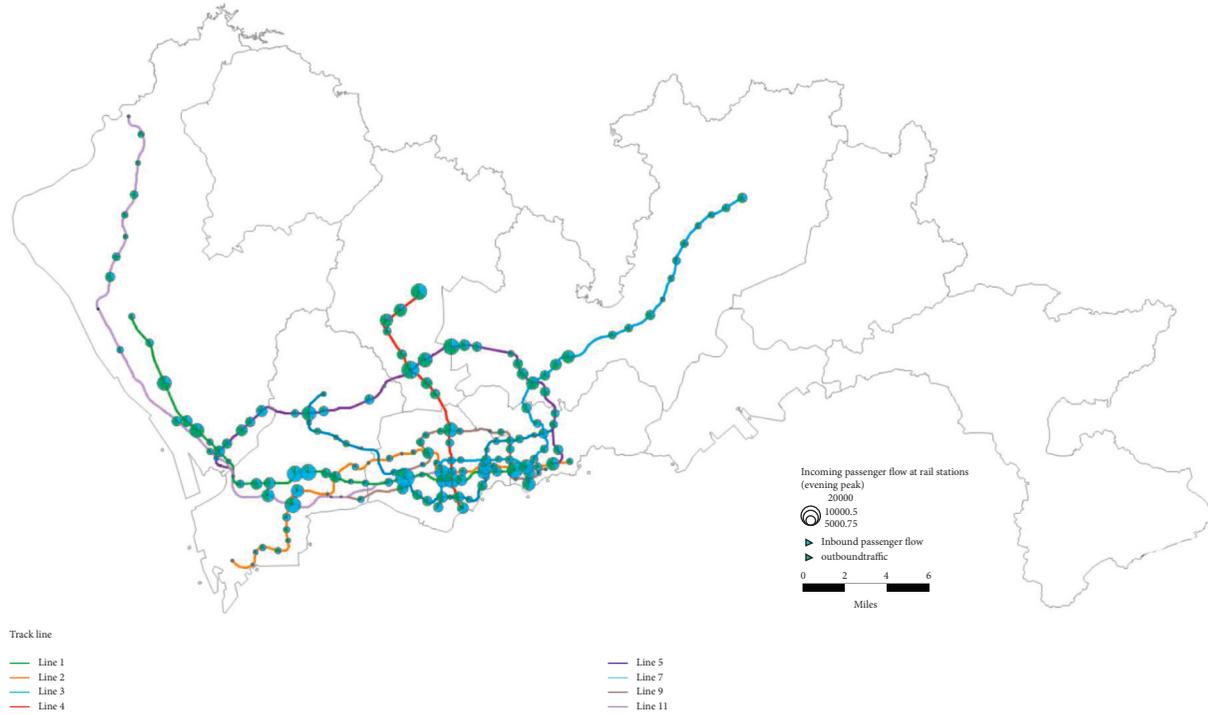

FIGURE 12: Passenger flow in and out of stations in the evening peak of the rail transit lines in City A.

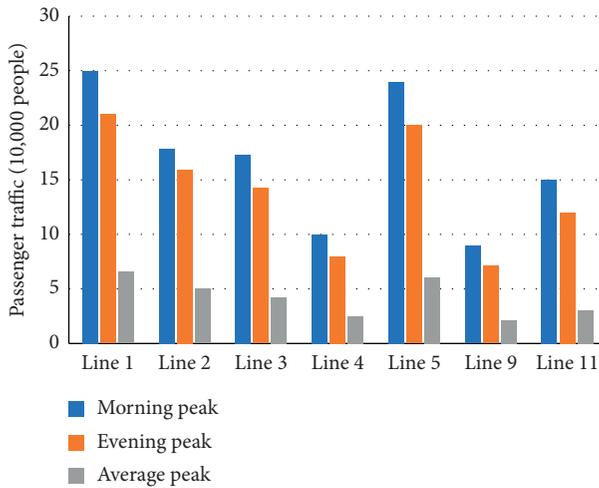

FIGURE 13: Passenger flow in different periods of rail transit lines in City A.

transportation under the influence of urban rail transit and the CO₂ emission reduction of urban rail transit to the urban transportation system need to be calculated separately, while the ground transportation emission reduction of the remaining four pollutants is the evaluation result of urban rail transit emission reduction, and the calculation methods are shown in the following formula:

$$\begin{aligned}
 E_{CO_2-save} &= (E_{B,CO_2-road} - E_{A,CO_2-road}) - (E_{A,CO_2-rail} - E_{B,CO_2-rail}), \\
 E_{Other-save} &= E_{B,Other-road} - E_{A,Other-road}
 \end{aligned}
 \tag{14}$$

TABLE 4: CO₂ emissions of rail transit lines in City A during each period.

Line	Morning peak (t)	Evening peak (t)	Average peak (t)
Line 1	59.8	50.7	15.1
Line 2	25.1	21.4	6.5
Line 3	58.2	47.2	13.8
Line 4	37.2	31.3	8.8
Line 5	62.4	52.0	3.9
Line 9	12.9	10.0	2.8
Line 10	149.7	126.1	34.2
Total	405.3	286.7	85.1

where E_{CO_2-save} represents the CO₂ emission reduction (t); $E_{Other-save}$ represent emissions of pollutants other than CO₂(t); E_A represents standard scenario emissions (t); E_B represents design scenario emissions (t).

It should be noted that the result calculated according to the above formula is the emission increase in the design scenario compared with the standard scenario, and it can be considered as the emission reduction of the standard scenario compared with the design scenario, that is, the emission reduction of urban rail transit on the urban transportation system quantity.

5.2.1. CO₂ Emission Reduction. According to formula (14), it can be found that the evaluation of energy conservation and emission reduction based on the CO₂ indicator is more complicated than that based on other emission indicators. Table 5 summarizes the CO₂ emission values and emission reductions of ground transportation in the standard and design scenarios at different time periods. It can be found

TABLE 5: CO₂ emission reduction of ground transportation under the influence of urban rail transit.

Period	Standard-ground (t)	Design-ground (t)	Ground emission reduction (t)	Ground emission-reduction ratio (%)
Morning peak	3297	4451	1154	35.0
Evening peak	3782	4778	996	26.3
Average peak	2876	3207	331	11.5

TABLE 6: CO energy saving and emission reduction under the influence of urban rail transit.

Period	Ground transportation emission reduction (t)	Rail transit emissions (t)	Rail transit emissions (t)	Total emission-reduction ratio (%)
Morning peak	1154	646	508	12.9
Evening peak	996	542	354	8.2
Average peak	331	152	179	6.1

TABLE 7: Emission reduction of other indicators under the influence of urban rail transit.

Index	Period	Standard scenario (t)	Design scenario (t)	Emission reduction (t)	Emission-reduction ratio (%)
CO	Morning peak	15.3	21.9	6.6	43
	Evening peak	18.2	24.1	5.9	32
	Average peak	10.7	12.9	2.2	21
NO _x	Morning peak	2.6	3.6	1.3	38
	Evening peak	3.1	3.9	0.8	26
	Average peak	1.7	0.3	18%	18
HC	Morning peak	1.7	2.5	0.8	47
	Evening peak	2.1	2.7	0.6	29
	Average peak	1.2	1.4	0.2	17
PM	Morning peak	0.077	0.104	0.027	35
	Evening peak	0.089	0.112	0.023	26
	Average peak	0.046	0.054	0.008	17

that in the standard scenario, the ground transportation emissions in the evening peak are 3782 t, slightly higher than the 3297 t in the morning peak. After calculating the emission reduction of ground transportation emissions in the design scenario, the emission reduction of ground transportation CO₂ reached 1154 t in the morning peak period, and the emission-reduction ratio was as high as 35%, followed by about 23% in the evening peak period. Therefore, the CO₂ emission reduction is relatively low, and the emission-reduction ratio is less than 15%. To sum up, it can be considered that urban rail transit effectively reduces the CO₂ emissions of ground transportation. This is consistent with the passenger flow distribution law of urban rail transit and the spatiotemporal distribution law of ground traffic operation under the influence of urban rail transit.

The CO₂ emission reduction of ground transportation is only a part of evaluating the effect of urban rail transit on energy conservation and emission reduction of the urban transportation system. Combined with the measurement results of rail transit carbon emissions in different time periods in Subsection 5.1, the calculation and statistics of the CO₂ emission-reduction results of urban rail transit within City A are shown in Table 6. It can be found that although rail transit generates CO₂ emissions through energy consumption, in the case of this study, urban rail transit still plays a role in reducing CO₂ emissions in the entire urban transportation system, and the emission-reduction effect in

the morning peak is still due to the other two. During this period, the total emission-reduction ratio was 12.9%, and the evening peak period was 8.2%. During the off-peak period, due to the less CO₂ emissions generated by rail transit, the total emission-reduction ratio for this period also reached 6.1%.

5.2.2. Reduction of Other Indicators. In addition to CO₂, the energy-saving and emission-reduction evaluation indicators include NO_x, CO, HC, and PM.

The emission of the above four pollutants will not be generated during the transportation operation, so the emission reduction of pollutants in the standard scenario compared with the design scenario is the emission-reduction effect of urban rail transit on the urban transportation system. Therefore, the emission-reduction effects of the above four indicators in different time periods are calculated as shown in Table 7. It can be found that in the evaluation results of the four evaluation indicators, the emissions under the urban rail transit scenario are lower than those under the no rail transit scenario. The emission-reduction effect of the four pollutants is the most obvious during the morning peak. The emission reduction of HC in the morning peak is as high as 47%, followed by the emission-reduction effect of CO, which also exceeds 40%. The emission-reduction effect of the two pollutants of PM is slightly lower, but the emission-

reduction ratio during the morning peak still reaches 38% and 35%, respectively. During the evening peak period, the emission-reduction effect of the four pollutants decreased compared with that during the early peak period, and the emission-reduction ratios of the four pollutants were all within the range of 26%–32%. Compared with the morning and evening peaks, the emission-reduction effect during the flat peak period is significantly lower, and the emission-reduction ratio is about 20% or less. From the comparison results of the emission-reduction effects of the four pollutants in different time periods, it can be found that the emission-reduction effects of different pollutants maintain a good time consistency, and this consistency is directly related to the passenger flow distribution of rail transit.

Through the above analysis of the energy-saving and emission-reduction effects of the urban rail transit network on the urban transportation system during the morning peak hours, evening peak hours, and flat peak hours, it can be found that for the ground traffic speed and flow data in the urban rail transit scenario, it is found that the urban area of City A in the rail transit network within the area effectively relieves the operating pressure of ground traffic in the area, and improves the operating conditions of ground traffic, and the improvement effect has a time-space variation law consistent with the distribution of rail transit passenger flow. For the CO₂ emissions generated by different rail transit lines in different periods of operation, it is found that the CO₂ emissions of rail transit have obvious line differences and time differences. By calculating the emissions of CO₂, NO_x, CO, HC, and PM in the presence or absence of urban rail transit, it is found that the construction and operation of urban rail transit reduces the emissions of different emissions, achieving the effect of energy saving and emission reduction. And there are temporal and spatial variation laws consistent with the distribution of rail transit passenger flow.

6. Conclusion

With the rapid development of the economy, the systematic construction and operation of urban rail transit plays a vital role in further improving business efficiency. However, with the intensification of environmental pollution and energy consumption problems, it continues to threaten the living environment of human beings and the sustainability of cities. To achieve the development goals, the research on the emission of urban rail transit has certain practical significance. This paper attempts to take the urban rail transit route as the entry point, deeply and multidimensionally analyzes many factors affecting carbon emissions, and does the following research:

- (1) Comprehensively considering the multidimensional impact of urban rail transit on the urban transportation system, a set of relatively complete mechanisms of urban rail transit energy conservation and emission reduction is established, which is the basis for the quantitative evaluation model analysis of urban rail transit low carbon, environmental protection, energy conservation, and emission reduction.

- (2) Considering the ground traffic operating speed data in different scenarios, the establishment of the relationship between the emission factor and the speed requires the coupling of the traffic operating data and the traffic emission data, getting rid of the rate for a single emission factor, the establishment of emission factor database, getting rid of the limitations of model scene application, and the improvement of the applicability of model evaluation.
- (3) The characteristics of the temporal and spatial distribution of passenger flow were analyzed, and the carbon emissions in different scenarios of morning and evening peaks were quantitatively analyzed. The temporal and spatial variation law of rail transit passenger flow distribution is consistent.

Since this paper uses a certain proportion of vehicles in the calculation of emissions, and the proportion of vehicles changes in real time during road driving, in future research, a dynamic vehicle proportion database can be established to make the calculation of emissions closer to reality.

In order to analyze sentiment data of foreign literary works, this paper proposes an algorithm for sentiment classification of literary works. We do this by fusing different features of literary works, which in turn captures more feature information for the classifier. As traditional word embedding models are difficult to achieve fusion with the sentiment features of literary works, we consider a multifeature fusion approach of word embedding features and lexical features of literary works. A two-channel and single-channel comparison is also used to analyze the classification accuracy based on the two feature fusion methods, and a parallel CNN and BiLSTM-attention two-channel neural network model proposed. Finally, the proposed model was evaluated using a real dataset of sentiment reviews of literary works and compared with different classification algorithms in the experiments. The experimental results show that the new hybrid approach has better classification accuracy, recall, and F1 metrics. The proposed methodology is an important guide for the creation of literary works and their screenplays, as it can be used to judge whether a work appeals to readers and, importantly, can also be considered as one of the criteria for the success of a film adaptation of a literary work.

1. Introduction

Since the beginning of the new era, people's attention to contemporary literature has gradually increased, both in terms of genre and content, which is very different from traditional literature, especially in the three areas of values, ideology, and emotional values. Modern and contemporary foreign literature has a more humanistic approach to emotional values than traditional literature, as well as reflects the individual emotions of the author. In the development of foreign literature, the embodiment of emotional value in modern and contemporary foreign literature is more focused on the experience, and through reading it, one can understand the humanistic and personal feelings embedded in the work and thus grasp the author's personality and spiritual experience. In contrast to traditional foreign works, contemporary foreign literature is more open in its expression and more emotive.

A popular foreign work of literature contains a wealth of emotion. The extraction of emotion from a literary work has

become a reality, and it is vital to systematically analyze the time series of emotion extracted [1]. Emotion is the soul of a literary work, and existing studies have largely addressed the importance of emotion to a literary work from a qualitative perspective and how the emotion of a literary work changes. This paper will use complexity science methods to quantitatively analyze emotion in foreign literature and its applications.
