Urban environmental problems have always been a major problem restricting human survival and development [10–12]. In order to achieve sustainable development, we must act in accordance with the laws of nature. The proposal of the concept of sponge city is not only the process of constructing the rainwater system of urban low-impact development, but also the process of solving urban problems according to the laws of nature. As an important carrier of sponge city construction, park green space is expected to achieve the goal of “natural accumulation, natural infiltration, and natural purification” of sponge city while realizing the original function of urban park. In fact, after the completion of the sponge park green space, what is the realization of its sponge function? What is the feedback from park users? At present, there is still a lack of theoretical research in this field. Based on this, the purpose of this study is as follows:

- (1) We need to comprehensively explore the relevant theories of green space planning and design based on the concept design of sponge city and the theory of post-use evaluation and seek a feasible method for post-use evaluation of the sponge park green space.
- (2) We hope to establish a feasible post-use evaluation system of the sponge park green space so that it can guide the post-use evaluation of the built sponge park green space.
- (3) After obtaining the results of post-use evaluation of practical cases, through the analysis of the results, we hope to promote the development and optimization of case green space and provide a reference for the construction and management of similar sponge green space in the future.

2. Overall Research Framework

Recently, the urban green space system planning in various parts of China has different methods, diverse technologies, and different quantitative indicators, so the planning has its own characteristics and has its rationality. However, how to

evaluate its rationality, whether there are some deficiencies, and places that can be improved are the main starting point of this article. If problems are found in advance, it is not necessary to adjust the planning, but if we can be aware of the existing problems and consider them in the next round of planning, it will certainly help to promote the green space system planning in a more scientific and practical direction. For urban management departments, after the rapid development of urban construction, all localities will inevitably face the planning of new and old cities.

How to make the new town not completely “start a new stove” but reflect the urban characteristics; continue the green space layout, historical context, and other traditions of the old city; and whether the existing green space system planning is still applicable in the construction of new towns with policy tendencies are the breakthrough points of introducing artificial neural network (ANN) [13–16] to evaluate the existing green space system planning in this article.

ANN is an engineering system that simulates its structure and intelligent behavior based on the understanding of the organizational structure and operation mechanism of the human brain from the perspective of microstructure and function. It is a highly nonlinear processing system formed by the extensive interconnection of a large number of processing units (neurons), which is suitable for simulating complex systems. Human brain activity is a highly nonlinear dynamic system. Although the structure and function of several neurons are very simple, the behavior of the neural network composed of a large number of neurons is colorful and extremely complex. The nature of the overall activity is not equal to the simple addition of the activities of unit neurons.

The main contents of this study include: through the detailed study of the ANN principle, taking the method of landscape ecology as the intermediary, we interpret the feasibility of using the method to evaluate the urban green space system planning and construct the green space system planning evaluation system. According to the process of urban development, we thoroughly analyze the characteristics of the green space system in the urban green space system planning. On this basis, we divide three types of green space representing the “past, present, and future” of the study area and take the “present” green space as a sample to evaluate the rationality of “future” green space planning by establishing a simulation model. ANN is used to establish the relationship model between the proportion of green space types and landscape pattern index, predict the pattern changes of planned urban green space, and provide a reference basis for the overall evaluation of the existing urban green space system planning.

By compiling the network program, we use the artificial neural network model to model the green space data and landscape pattern index, simulate the internal relationship between various green space areas and landscape pattern index based on the existing data, predict the planning development trend, and optimize the green space system planning for sponge city. The technical route of this study is shown in Figure 1.

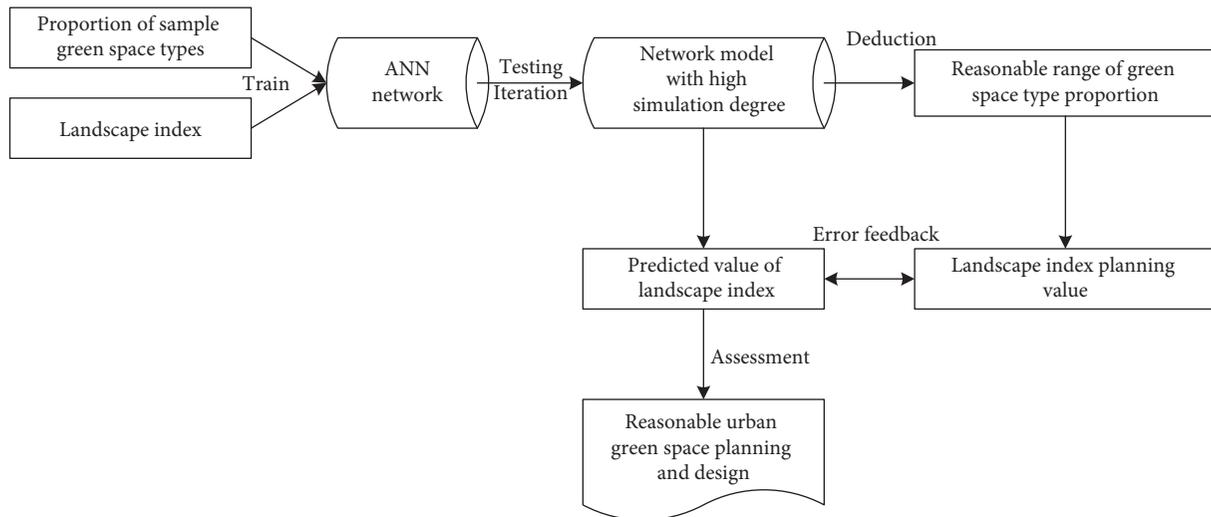

FIGURE 1: The technical route.

3. Methods

3.1. Evaluation System of the Green Space System Planning. Landscape ecological planning needs to select the influencing factors and calculate the weight of each factor to superimpose its effect. Similarly, the artificial neural network also needs to preselect the number of factors, that is the number of neurons in the hidden layer. The difference is that its factor characteristics are uncertain, which can only be identified within the network and cannot be truly expressed in language.

The most famous supervised algorithm is the error back propagation (BP) algorithm of a multilayer feedforward artificial neural network [17–20]. Structurally speaking, the network is composed of layers or layers above, that is the input layer, the hidden layer, and the output layer. Neurons in each layer form a full connection, while neurons in the same layer have no connection [21–25]. In the same network, there can be more than two hidden layers, as shown in Figure 2. The network with only one hidden layer is a basic network model.

For the BP network, there is a very important theorem, that is any continuous function in a closed interval can be approximated by a single hidden layer network, so a three-layer network can complete any dimension to dimension mapping. The selection of the number of neurons in the hidden layer is more complex. At present, it is mainly determined according to the previous experience and many experiments. So far, there is no ideal analytical formula to calculate. The number of hidden layers is not the more the better. It is directly related to the requirements of the problem and the number of input and output units. Too much number will lead to too long learning time, not necessarily the best error, poor tolerance, and unable to identify samples that have not been seen before. Therefore, there must be an optimal number of hidden units. The empirical formula can be used as a reference formula for selecting the best number of hidden layer neurons, or the number of hidden layer neurons can be determined by

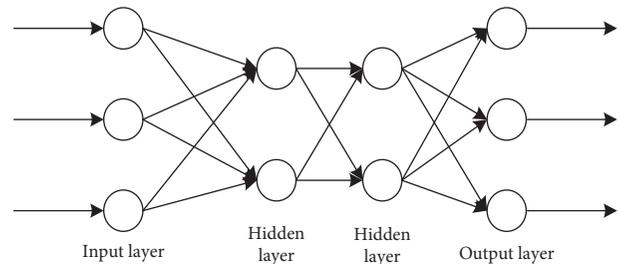

FIGURE 2: BP network.

experimental method without formula calculation. The process of this method is: initially put enough neurons and eliminate those that do not work through learning until they cannot contract; or start to put in fewer neurons. After learning a certain number of times, if it is unsuccessful, increase the number until it reaches a more reasonable number.

In the process of landscape ecological planning, between the current situation and planning, many factors need to participate in the planning process. Each factor has a corresponding weight proportion when it plays its role. The determination process of this weight is equivalent to the calculation process of the function, which is completed through the incentive function or transfer function. The relationship between the input layer and the output layer of the network is represented by a function as the carrier, which is the excitation function. The excitation function is an important weaving part of the network. It must be continuously differentiable so that it can be calculated by a gradient method.

3.2. Construction of Network

3.2.1. Input Layer. The selection principle of the input layer is to intuitively express the variables of research events. These variables should be measurable (e.g., distance and

length), searchable (e.g., quantity), or statistical. In relevant studies, elevation, slope, geomorphic zoning, population density, distance from the core landscape, and other indicators are mostly used as the input layer. Most of these indicators are objective or natural factors, which can reflect the impact of natural driving forces and human interference on the landscape to some extent and can better explain the significance of the network. In fact, in urban planning or green landscape planning, in addition to the basic ecological factors that need to be considered in urban construction, in more cases, the factors with practical guiding significance established based on these factors, or “secondary factors,” such as land use punishment, population distribution, etc., or these basic “ecological sensitive factors” are often only used for reference without actual expression status.

In view of the above reasons, in the landscape ecological network of this article, the percentage of the area of various types of landscape is considered to be selected as the input variable, and multiple input variables composed of each sample together constitute the input layer matrix [21]. It is one of the basis to help us determine the dominant landscape elements in the landscape, and it is also an important factor to determine the ecosystem indicators such as biodiversity, dominant population, and quantity in the landscape. In fact, the process of forming the area percentage of various types of landscape in the city has integrated the repeated influence of all ecological, social, land use, and other factors. It can be said to be the “semi-finished product” of green space pattern. Researching on this basis may produce some errors, but this choice can directly adopt the existing achievements and strengthen the application and promotion ability of research, which has certain application value.

3.2.2. Output Layer. The data of the output layer are generally indicators that can reflect the essence or deep meaning of the event. These indicators have a logical connection with the data of the input layer that are not obvious but has a high internal correlation. At present, there are many kinds of landscape pattern indexes, and new indexes have been put forward by scholars. However, these indexes have a great correlation in essence, and the indexes do not meet the requirements of mutual independence [23, 24]. Therefore, using multiple indexes at the same time often cannot add “new” information. Naturally, using these indexes with great correlation to describe landscape pattern is not convincing enough. Theoretically, there must be an index system of landscape pattern, which is enough to describe the landscape pattern, but not redundant.

Therefore, the analysis of the mutual independence of landscape index has become an important research topic. Combined with the actual situation of this study, four landscape pattern indexes of patch density, Shannon diversity index, average perimeter area ratio, and spread degree are selected as the output layer of the network, as shown in Table 1. Based on the principle of landscape pattern index representing green space change and spatial allocation, it is expected to study the relevant characteristic process and

change development trend of green space through these four indexes.

- (1) Patch density, which is the number of patches per unit area, reflects the overall degree of patch differentiation or fragmentation of the landscape. The change of its value can reflect the intensity and direction of human interference. The high patch density indicates that there are many heterogeneous landscape elements in a certain area, with small patch size and high degree of fragmentation. For urban green space landscape, the degree of landscape fragmentation indicates the contribution and ability of urban green space landscape to biodiversity maintenance. Generally, under the condition of equal area, the higher the degree of fragmentation, the smaller the urban green space landscape patch unit, the simpler the function of the landscape unit, and the more unfavorable to biodiversity protection.
- (2) Shannon diversity index indicates that the whole landscape is composed of only one patch. The increase of this index indicates that the patch types increase or the patch types are distributed in a balanced trend in the landscape. This index can reflect the landscape heterogeneity, especially sensitive to the unbalanced distribution of patch types in the landscape, that is it emphasizes the contribution of rare patch types.
- (3) The average perimeter area ratio is one of the important indicators of the complexity of landscape spatial pattern. It represents the complexity of irregular objects and is used to measure the complexity of shapes. The lower the value is, the simpler the patch boundary is, and the less conducive to the maintenance of biodiversity.
- (4) The spread degree, with a value of 0-1, is one of the most important indexes to describe the landscape pattern. This index describes the degree of agglomeration or extension trend of different patches in the landscape. Theoretically, a small value indicates that there are many small patches in the landscape. The landscape is a dense pattern with many elements. When the degree of fragmentation of the landscape is high, it indicates that some dominant patches in the landscape have formed good connectivity.

3.2.3. Network Training. “Network training” integrates two inseparable processes of learning and training. In principle, it is a process of looking for a set of useful weights and thresholds. The popular explanation is a process of learning and integrating the network into the network’s own knowledge and experience through the existing data [21–25]. The connection weight is the knowledge reserve required by the neural network to solve practical problems. The training process of the network can be described as forward propagation of working signal and back propagation of error signal. First, training is to provide a training set, which is

TABLE 1: Landscape pattern indexes.

Index name	Patch density	Shannon diversity index	Average perimeter area ratio	Spread degree
Exponential space representation	Nonspatial component	Nonspatial component	Space configuration	Space configuration
Value range	>0	=0	>0	[0, 1]
Characteristic	Landscape fragmentation	Spatial heterogeneity	Landscape spatial structure	Optimal landscape pattern
Practical significance	It reflects human interference	Complexity of structure and function	Complexity of shape	Agglomeration degree or extension trend of different patch types

composed of several groups of input samples and the corresponding expected output. At the beginning of network construction, the ownership value and training value contained in the middle of the problem to be solved are unknown. Generally, the initial value of the network is randomly generated. Until the useful weight is found, the artificial neural network cannot represent this problem.

Step 1. The system randomly selects a learning sample; calculates the input of each neuron in the hidden layer with the input sample, initial weight, and threshold; and then calculates the output of each neuron in the hidden layer through the excitation function.

Step 2. The output of each neuron in the output layer is calculated by using the output matrix, initial weight, and boudoir value of the hidden layer, and then the response of each neuron in the output layer is calculated by the excitation function, that is the actual output of the sample.

Step 3. The generalization error of each neuron in the output layer is calculated by using the expected output of the sample and the actual output of the network. The generalization error of each unit in the hidden layer is calculated by using the initial weight of the hidden layer, the generalization error of the output layer, and the output of each neuron in the hidden layer.

Step 4. The generalized error is propagated back to the input layer, and the weights and thresholds of the input layer and the hidden layer are gradually corrected.

Step 5. The next learning sample is randomly selected and returned to the first step until all learning samples are trained.

Step 6. A group of input and output matrices is randomly selected from the learning samples again and returned to the first step until the global error of the network is less than a preset minimum, and the network training ends and reaches convergence.

From the above training process, it can be seen that the core of e-learning consists of four parts. First, the “signal forward propagation” of the input data from the input layer through the hidden layer to the output layer. Second, the error signal between the actual output and the expected output of the network is “error back propagation,” which modifies the weight layer by layer from the output layer to the input layer through the hidden layer. Third, the network “memory training” process of repeated cycles of “signal

forward propagation” and “error inverse propagation.” Fourth, the global error of the network tends to the preset minimum, that is the process of network learning convergence.

4. Application of Urban Green Space Planning and Design Network

The trained network should also carry out a performance test. The test method is to select the test sample data and provide it to the network to test the correctness of the network’s output. The test sample data should have a pattern similar to the learning data. These samples can be obtained by direct measurement or simulation. When the sample data are small or difficult to obtain, they can also be obtained by adding appropriate noise to the learning samples or interpolating according to certain rules. In order to better verify the generalization ability of the network, a good test sample set should not contain the same pattern as the learning sample.

When using ANN to simulate the existing urban green space system planning [26, 27], the omnidirectional expression of the landscape index should be considered on the whole green space landscape as far as possible and the index change should be evaluated after the construction of the network from the following aspects:

- (1) Evaluate whether the type and proportion of planned green space are reasonable

The amount of green space reflects the level of urban green space, and the type proportion of green space can reflect the integrity and spatial structure of urban green space and will indirectly affect the function of green space.

- (2) Evaluate whether the landscape fragmentation of the planned green space is reasonable

The size of patch density will directly reflect the degree of landscape fragmentation. The greater the patch density, the higher the degree of fragmentation. At the same time, it further reflects the living standard of urban residents, the quality of living environment, and the ecological level of the city.

- (3) Evaluate whether the landscape diversity of planned green space is reasonable

The level of landscape diversity mainly depends on the number of landscape components and the

proportion of each landscape component. In the landscape system, the more the landscape components and the higher the degree of fragmentation, the greater the information content and uncertainty, the higher the landscape diversity index, and the higher the landscape heterogeneity.

- (4) Evaluate whether the landscape fractal dimension of planned green space is reasonable

Landscape fractal dimension mainly measures the complexity of green space shape. The index selected in this study is the average perimeter area ratio. If the urban green space is greatly disturbed by human beings, the patch shape is regular and simple, and the landscape fractal dimension is low, which is unfavorable to the maintenance and construction of biodiversity. By evaluating the rationality of landscape fractal dimension, we can detect whether we pay too much attention to regular design and whether there are too heavy artificial carving traces in the process of green space design, so as to strengthen the attention to the naturalization, ecology, and diversification of green space.

To sum up, the type proportion of green space is related to the fragmentation and diversity of landscape, and there is a certain contradiction between fragmentation and diversity. In the process of evaluation and analysis, we must pay attention to this contradiction and comprehensively weigh and consider the value of landscape index.

5. Case Study

Based on the landscape ecological network, the network is constructed through the network command Newff built in MATLAB, and the hyperbolic tangent sigmoid (Tan-SIGMOD) function and linear function are selected as the excitation functions of the hidden layer and the output layer, respectively. In terms of performance setting, the maximum number of training is 6000, the learning rate is 0.01, and the preset expected error is 0.0001. The preset expectation error is too large and has no popularization value. The preset expected error cannot be set too small, because the number of samples is limited and the error setting is small, which will affect the generalization ability of the network, and there may be large errors in application.

According to the empirical formula of hidden layer design and the actual situation of this case, the number of hidden layer neurons in the network to solve this problem should be between 5 and 15. Therefore, it is necessary to design a network with a variable number of hidden layer neurons for debugging in advance and determine the optimal number of neurons through error comparison and trade-off consideration. In order to improve the training speed, set each index to a higher value during debugging, such as learning rate 0.05 and preset expected error 0.005, and the training error results are shown in Table 2.

It can be seen from Table 2 that in the error test with 5–15 as the number of hidden layer neurons, when the number of hidden layer neurons is less than 7, the network error is greater than 0.005, the preset target error value cannot be

TABLE 2: Number of neurons in the hidden layer and its training error.

Training sequence	Number of neurons in the hidden layer	Error (10^{-3})
1	5	13.5056
2	6	8.4855
3	7	4.9513
4	8	4.3522
5	9	4.4355
6	10	1.9509
7	11	2.8112
8	12	4.4413
9	13	0.9422
10	14	2.6122
11	15	2.5234

reached, and the network cannot converge. In the 6th experiment, when the number of hidden layers reaches 10, the error reaches a lower value, and the error fluctuates with the increase of the number of neurons. In the 10th training, that is when the number of hidden layers reaches 12, the error tends to a stable decline state, the training time is significantly shorter, and the training times are reduced. After less than 20 training, the error can reach the preset expected value. The network can converge without enough training, and the error is very small. Such a network can achieve high accuracy after training. However, when it comes to testing, it is likely to cause great errors, so its generalization ability is very poor and does not have generalization. To sum up, although the minimum error occurs in the network with 13 neurons in the hidden layer, its training time and times are too low and less than the number of samples. Therefore, it is more appropriate to select 10, which can not only ensure the training accuracy, but also improve the generalization ability of the network.

After the network is created, it cannot be directly put into use. It can only be used as an urban green space model after training to meet the requirements. In neural network analysis, the sample data are generally divided into three parts: one part is used for network training, the other part is used as confirmation samples, and the other part is used as test samples. When using, the samples must be classified. According to their role in network analysis, they are divided into training samples (18 randomly selected), test samples (4), and simulation samples. In the selected samples, the protective green space and strip green space are evenly distributed, the roadside green space and community park are concentrated and scattered, and the ecological green space and comprehensive park are more concentrated in some samples. Training sample output layer data are shown in Table 3.

As can be seen from Table 3, the error of the network decreases sharply in the first 20 times of learning, and then gradually tends to be stable. After 135 times of learning, the network converges to reach the preset expected error value. There are two obvious fluctuation periods in the training process. The first occurs when the number of training times is times. At this time, all samples have just participated in a

network training, and the substantial error adjustment is over. The second time occurs when the number of training times reaches 80, that is each sample has participated in the network correction for an average of 4 times. The network has adapted to the information contained in all samples. At this time, the network error no longer fluctuates, but decreases steadily until it reaches the set expected value.

After the network training, it must be tested to confirm its stability and popularization ability before it can be put into use. Its purpose is to determine whether the network meets the requirements of practical application. Test sample input layer data are shown in Table 4, and test sample output layer data are shown in Table 5.

We input the above data into the trained network, and the error is shown in Table 6.

As can be seen from Table 6, except that the diversity index error of samples 2 and 11 is large, the others maintain a high degree of coincidence, that is the network can better simulate the relationship between green space types and landscape pattern and has good popularization ability. The large error in the edge area of network data reflects the disadvantage of insufficient network samples. With the continuous increase of the number of samples, this error is bound to decrease gradually.

6. Conclusions

At present, the impact of green space on urban residents' life and urban environmental quality, urban characteristics, and historical and cultural preservation is becoming greater and greater. Urban green space has become a comprehensive function of urban residents' rest place, urban environmental maintenance, urban morphological structure guidance and control, and urban ecological security. The urban green space system planning, as a special planning of urban planning, has always been in a subordinate position of urban planning. In terms of preparation procedures, it is required

to further deepen the content of urban planning green space and put forward systematic and controlling planning points for urban green space construction, which is difficult to avoid the lag of planning.

The theories and methods of landscape ecology provide a theoretical basis for the study of urban green space spatial pattern. The application of GIS and artificial neural network in the analysis of landscape ecological pattern provides technical support for the study of urban green space layout. Through its learning ability, the artificial neural network can well simulate the relationship between urban green space composition and green space landscape pattern. After repeated training and testing of the network, a green space network with strong generalization and promotion ability can be obtained. On this basis, it can predict the quadrats of various green space proportions to judge whether it is in line with the actual situation of green space development in the study area.

In this paper, the K-nearest neighbor algorithm and the convolutional neural network will be used to train the handwritten digit recognition model, respectively. To establish a reasonable model structure, and through the training data, the model can learn to reflect ten different handwritten number features and finally give the probability of predicting number corresponding to the likelihood of each number. Taking the learning process of the handwritten numeral recognition algorithm based on deep learning as a clue, from deep learning to convolutional neural network, from simple to deep, the relevant basic concepts, model construction, and training process of deep learning are learned and understood. Finally, the deep learning framework uses MNIST as the training dataset to train a model with high recognition rate and then combines it with Open CV technology to realize the identification of handwritten numbers. A reasonable model structure is used to accurately identify the handwritten numbers in the test set. The neural network of deep learning is established with TensorFlow to realize the classification and recognition of handwritten numbers. Various deep learning methods such as CNN and KNN are learned and compared to complete the construction of deep learning architecture. The MNIST dataset was preprocessed, features extracted, and identified. The program is to complete the training of neural network and the recognition of numbers in the image, the recognition results of deep learning methods used are counted and analyzed, and the recognition rates of two different methods are compared to find ways to optimize these methods and improve the recognition rate.

1. Introduction

1.1. Research Background. With the rapid development of the current era and the great progress of the society, the machine gradually began to liberate people from the heavy work. With the progress of science and technology, people can no longer be satisfied with the artificial operation of machines and gradually move forward to learn the capable of artificial intelligence. Now, artificial intelligence is getting closer to people's lives. Machine learning, as the core of artificial intelligence technology, is a fundamental way to make computers intelligent. Deep learning is a new key technology and research direction in the field of machine learning, with high research price and application value. Deep learning [1, 2] enables machines to simulate human audio-visual, thinking, and other activities; solves many complex pattern recognition problems; and makes great progress in artificial intelligence-related technologies [3–5].

1.2. Research Meaning. With the development of computer technology and the advancement of information wave, how to input the massive digital information on paper into the computer has become a major research hotspot. For example, the manual input of bank bills, invoices, checks, tax bills, and other bills, often need to manually deal with a lot of information, will inevitably make mistakes, and there may be high labor cost, low efficiency, large workload, and other problems. The computer automatic identification input instead of manual input not only can complete the task in a high-precision way but also can liberate the relevant staff so that the workload can be greatly reduced. According to the different ways of digital sources, the current digital recognition problems can be divided into handwritten digital recognition, printed digital recognition, optical digital identification, and natural scene digital recognition, which has great practical value. For example, handwritten digit recognition can be applied to the recognition of bank money

order numbers, greatly reducing labor costs. Print digital identification can be applied to the automatic identification of postal codes. Optical digital recognition and natural scene digital recognition can be applied to license plate number identification in vehicle detection. Thus, it can be seen that the handwritten digital recognition technology has considerable application prospect and value. How to apply deep learning algorithms to the recognition of handwritten digits is a more popular research.

1.3. Domestic and Foreign Research. In recent years, the popularity of artificial intelligence has been greatly increased, and people's requirements for machine vision have become more and more demanding. Researchers around the world have devoted themselves to the research of handwritten digital recognition and made many achievements in this field.

1.3.1. Foreign Research. Liang uses 10 structural features, such as profile features, self-structure features, and curvature, combined with eight classifiers on the test set of CENPARMI, CEDAR, and MNIST databases and achieves a test identification rate of 99.58%. However, the calculation and storage costs of this method are high [6–9]. Guangbin et al applied existing biological vision to build a handwritten digital recognition model, which extracted linear separable features and reduced the error rate to 0.59% [10] in the MNIST training set. Guo et al proposed a method for integrating statistical and structural information on unconstrained handwritten digit recognition. The method improves the modeling of state time in conventional HMM by using state duration adaptive transition probability, using the macro states overcoming the difficulty [11] of HMM modeling pattern structure. There is a great improvement in speed and accuracy [12].

1.3.2. Domestic Research. Liu Gang and Zhang Honggang used the BP neural network based on handwritten digital recognition system designed by visual C++ 6.0 to verify the feasibility of BP neural network for handwritten digital recognition, with a good recognition rate of [13]. Wang proposed a new method, combining PCA (principal component analysis) and CNN method, and conducted experiments on the SVHN dataset, trying to improve the recognition rate of characters in natural scenes. Geng et al constructed and realized the handwritten digital recognition model based on Hopfield neural network, whose error identification rate and accuracy rate are more ideal [14, 15] than the identification method of BP network. However, due to the dependence of research on test samples, test images need to be similar to training images. With the gradual expansion of the scale of data collection, the requirements of test pictures and training pictures are gradually reduced, but the requirements of writing regularity are increased. In short, in this era, handwritten numeral recognition applications can replace manual writing in occasions with a high degree of standardization, such as bank checks [16].

1.4. Handwriting Number Identification Difficulties. Similar numeric distinction: However, only ten numbers are used, and the strokes are very simple, but different numbers can be written in the book, and there are significant regional characteristics. The writing method of a number is different, and people from different places are also different, so it is very difficult to create a universal high recognition digital recognition model [6–8].

The data are not large enough: seven billion people around the world in Arabic numbers, everyone has different writing habits, and existing any kind of dataset in the world cannot completely include everyone style handwritten digital pictures. Arabic digital user grow much faster than the dataset content, so the data are not big enough to handle this problem, which will become more obvious in the future [9–11].

1.5. Application of the Handwritten Digital Recognition System. Occasion 1: in the schools, students and teachers are senior intellectuals, writing Arabic numerals is very standard, and the handwritten number recognition system applied in the test paper results in summary can greatly reduce the workload of teachers [12].

Occasion 2: in the government, the government staff are high cultural literacy, writing Arabic numerals is very standard, and in the absence of handwritten digital recognition technology, the government office form is by artificial input, but this requires huge human input, and the emergence of handwritten digital recognition technology will liberate civil servants and improve the efficiency of government workers [17].

Occasion 3: in the banks, bank staff to deal with many checks every day, bills and forms of handwritten digital information, and long processing monotonous handwritten numbers will make bank workers to produce visual fatigue and greatly affect their work efficiency. The use of handwritten digital recognition technology will greatly reduce manpower and improve the efficiency and accuracy of bank workers [18].

2. Foundation and Model of Deep Learning

2.1. Introduction to Basic Principles

2.1.1. The Concept of Deep Learning. The concept of deep learning originated from the study of artificial neural networks. With the study of artificial neural networks, neural networks with multiple hidden layers have gradually entered people's vision. The deep learning based on the neural network training model with single output, multi hidden layers and single output structure has begun to attract scholars' attention [19–24]. The concept of deep learning was proposed by Hinton et al. in 2006. Its simplest deep learning model is shown in Figure 1.

$$\text{output} = x_1w_1 + x_2w_2 + x_3w_3 + \dots \quad (1)$$

In the above formula, x_1 , x_2 , and x_3 represent the input; output represents the output; and w_1 , w_2 , and w_3 represent

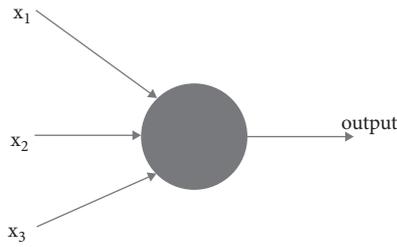

FIGURE 1: Monolayer neural network.

weights when delivered in the neural network, indicating the extent to which the input affects the output, which is more important. The larger w is (even over 1), the less important the input is, and the closer w tends to 0. In general, a typical deep learning model refers to a neural network with multihidden layers, representing more than three hidden layers, and deep learning models usually have eight or nine or more hidden layers. With more hidden layers, the corresponding neuronal connection weight parameters are more [25], [26]. This means that the deep learning model can automatically transfer many complex features, and the number of hidden layers can be transferred deeper on the neural network. A rigorous and mature neural network can realize complex functions and even realize mechanical intelligence, namely, artificial intelligence. The deep learning model diagram of the multihidden layer neural network is shown in Figure 2.

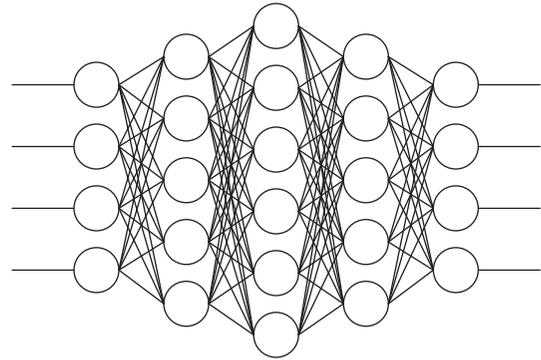

FIGURE 2: Multilayer neural network.

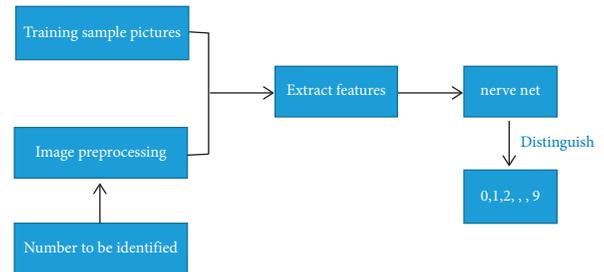

FIGURE 3: Flow chart of handwritten digit identification.

2.1.2. Deep Learning Algorithms—Classification of Neural Networks. In addition to the learning method, the deep learning algorithm is classified into networks containing only the encoder parts, networks containing only the decoder [6]parts, and networks with both the encoder and decoder parts. According to the application mode of technical structure, it is divided into differentiated depth structure, generative depth structure, and mixed structure. It can also be divided into a mentor network and a no-mentor network.

2.1.3. Sample Dataset for the Trained Neural Networks—MNIST Dataset. Flow chart of handwritten digital image recognition based on deep learning is shown in Figure 3.

In this graduation design, MNIST dataset is a widely used in the field of handwritten digital dataset because of small memory and easy to become the current learning handwritten number recognition students, so we use MNIST database for the experimental sample set to train the research method of the graduation design. The MNIST database serves as a standardized dataset with Arabic digital images of 0 to 9, all of which have been normalized and are aggregated into images of the same size and place numbers in the center. A uniform size of grayscale images is $28 * 28$, where the pixels range from 0 to 255. The representation of the data is expressed in the form of a vector, and in the TensorFlow, the pixel values of each pixel point can be viewed by the print corresponding array. The MNIST dataset contains 70000 handwritten digital images, of which 60000

handwritten digital images are training sample sets and 10000 handwritten digital images are test sample sets.

Some images of the MNIST dataset are as shown in Figure 4.

The dataset stores common handwritten numbers, including the value of 0, 1, 2, 3, 4, 5, 6, 7, 8, and 9 and the Arabic numerals of 10. For each number, it contains a wide variety of strange forms. A lot of numbers are not the normal standard form of writing, so many images in the MNIST dataset are hard to identify, for example, the Arabic numeral “9,” as shown in Figure 5 and 6. We can still see that the morphological difference of the same number in the entire MNIST database is quite large. It is precisely because there are so many different handwritten numeral images that MNIST data sets can have good recognition accuracy no matter how strange handwritten numerals are. However, this has also become a disadvantage of this recognition system and over-reliance on the big data of the dataset; once the picture is separated from the dataset, the accuracy is difficult to guarantee.

2.1.4. Working Framework for Deep Learning. With the gradual popularity of deep learning, scholars and research staff at home and abroad have developed a lot of deep learning work environment, such as Caffe, Torch, Theano, and TensorFlow; Caffe used to more applications in the field of image recognition, Torch and Theano used in programming and import process is slow, and TensorFlow used as the software, which become the most widely used deep learning framework. A large number of tedious handwritten data are transmitted into the artificial intelligence neural network, using the built neural network for research and

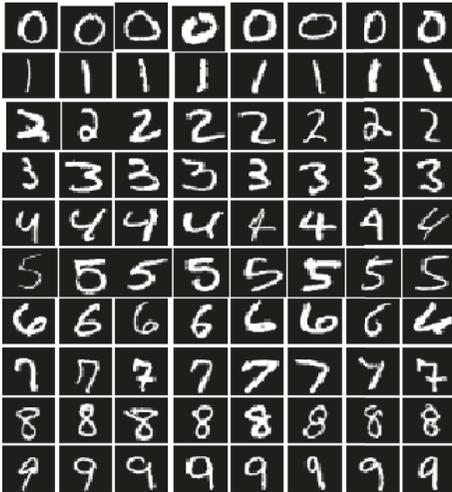

FIGURE 4: A part of the sample examples of the MNIST dataset.

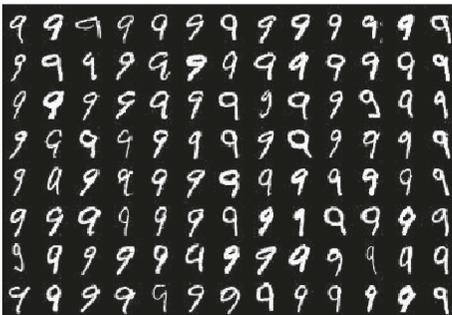

FIGURE 5: Training samples of 9 within the MNIST dataset.

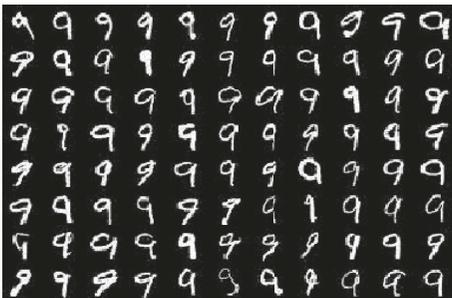

FIGURE 6: Test samples of 9 within the MNIST dataset.

processing, and finally get the output we want. TensorFlow was developed by Google in 2015 and attracted the attention of scholars all over the world once it was proposed. Just four years later, TensorFlow has become the most popular research and development software in the current era, and almost every deep learning lover is using TensorFlow.

Installation of the working frame

Step 1. Install the anaconda environment, log in to the anaconda official website, download the corresponding version of the anaconda installation package, and install it normally according to the prompts.

Step 2. Enter command line mode for the Windows system, enter [conda-version] to verify whether anaconda is successfully installed.

Step 3. Activate the TensorFlow environment and enter [pip install-upgrade--ignore-installed TensorFlow] in the command-line mode of the Windows system.

Step 4. In the TensorFlow environment, enter [python] and continue entering [import TensorFlow as tf]. If there is no error code reported, then the TensorFlow module is called successfully, which means that the installation is successful.

2.2. Handwritten Digital Image Recognition Based on the Convolutional Neural Network

2.2.1. Identification Principles of Convolutional Neural Networks. Convolutional neural network (CNN), as a class of feed-forward neural network with convolutional computing and deep structure, performs well in identifying handwritten numbers. The visual file convolution neural network includes convolution operation, pool operation (also known as down sampling) and full connection operation, the processed handwritten digital image, and the lenet-5 model in the handwritten digital feature sequence in the picture.

Convolution operation (Figure 7):

Green indicates the original image element value, red indicates the parameters in the convolution core, and yellow indicates the convolution core sliding on the original image. The right graph represents the feature map generated after the convolution operation. The results were calculated as the sum of each primary pixel value and the parameters in the convolutional kernel.

Pooling (*subsampling*) (Figure 8):

One pixel for pooling replaces a number of adjacent pixels on the original image, squeezing its size while retaining the feature map features. The effect of pooling can prevent the data explosion and save the operation amount and operation time, and it can be used to prevent overfitting and overlearning.

Full connection (Figure 9):

The final result is made based on the output of the full connection. There are generally two full connection layers for handwritten digit recognition.

Activation function ($y = f$) (Figure 10, and 11):

Linear function is as follows:

$$f(x) = k * x + c. \quad (2)$$

Ramp function is as follows:

$$f(x) = \begin{cases} T, & x > c \\ k * x, & |x| \leq c \\ -T, & x < -c. \end{cases} \quad (3)$$

Threshold function is as follows:

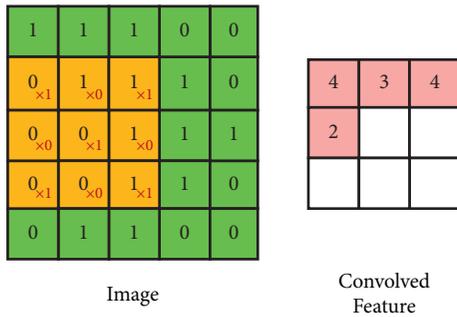

FIGURE 7: Schematic diagram of the convolution operations.

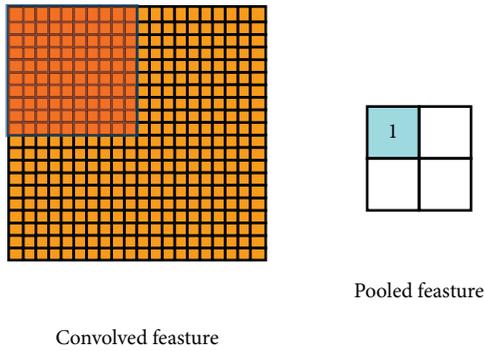

FIGURE 8: Schematic diagram of pooling.

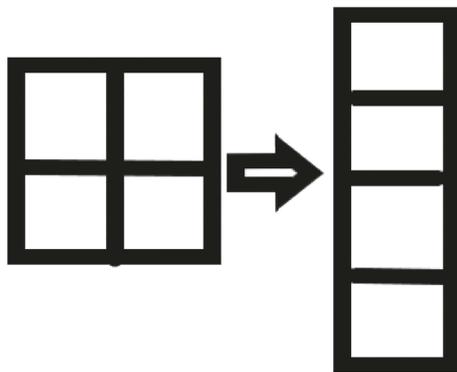

FIGURE 9: Schematic diagram of pooling.

$$f(x) = \begin{cases} 1, & x \geq c \\ 0, & x < c. \end{cases} \tag{4}$$

Type-S function is as follows:

$$f(x) = \frac{1}{1 + e^{-ax}} \quad (0 < f(x) < 1),$$

$$f'(x) = \frac{ae^{-ax}}{(1 + e^{-ax})^2} = af(x)[1 - f(x)]. \tag{5}$$

Bipolar S-type function is as follows:

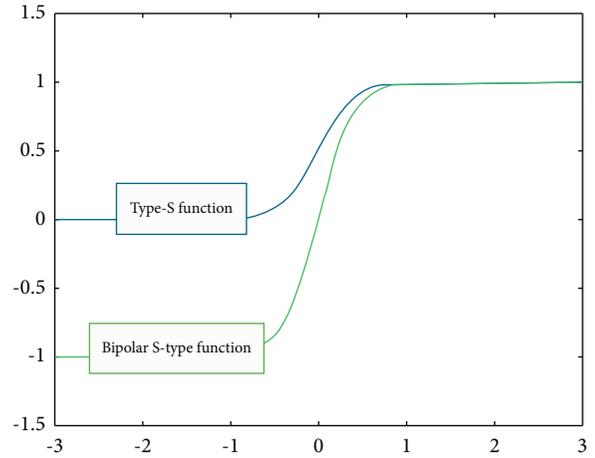

FIGURE 10: Function images of two functions.

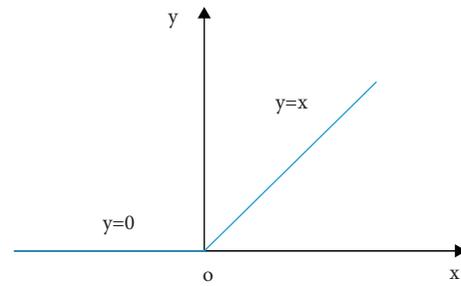

FIGURE 11: ReLU functional image.

$$f(x) = \frac{2}{1 + e^{-ax}} - 1 \quad (-1 < f(x) < 1),$$

$$f'(x) = \frac{2ae^{-ax}}{(1 + e^{-ax})^2} = \frac{a[1 - f(x)^2]}{2}. \tag{6}$$

ReLU function is as follows:

$$f(x) = \begin{cases} x, & x > 0 \\ 0, & x \leq 0, \end{cases}$$

$$f'(x) = \begin{cases} 1, & x > 0 \\ 0, & x \leq 0. \end{cases} \tag{7}$$

Considering the above algorithm and according to the LeNet-5 model, a complete CNN-based handwritten digit identification workflow is shown in Figure 12.

- (i) Step 1. Handle write font picture conversion into a pixel matrix.
- (ii) Step 2. The first layer of convolution of the pixel matrix is to generate six feature maps.
- (iii) Step 3. Subsample each feature map to reduce the amount of data while retaining the feature maps. Six small graphs are generated, which look similar

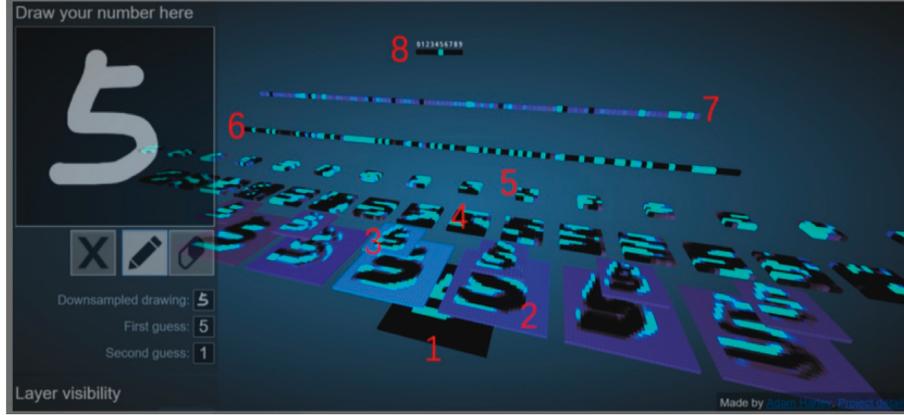

FIGURE 12: A visual interface for the complete workflow.

to the respective feature map of the previous layer, but are reduced in size.

- (iv) Step 4. The second convolution of six small graphs is to generate more feature map s .
- (v) Step 5. Subsample the feature map is generated by the second convolution.
- (vi) Step 6. The first layer is a full connection layer.
- (vii) Step 7. The second layer is a full connection layer.
- (viii) Step 8. Gaussian connection layer to generate output results.

The CNN internal processing formula is as follows:

- (i) Part 1: convolution formula

$$X_j^i = f\left(\sum_{i \in M_j} X_i^{l-1} * k_\theta^l + b\right). \quad (8)$$

- (ii) In formula (8), X_i^{l-1} represents the element covered by j l-1 layer feature graph convolution; k_θ^l is the element in the l layer convolutional kernel; b refers to the offset; M_j is the region covered by the j th convolution core; $f(*)$ represents the activation function.

- (iii) Part 2: pool formula

$$X_j^i = f(\mu_j^{l-1} + b). \quad (9)$$

- (iv) In formula (9), μ_j^{l-1} is the output obtained after downsampling of l-1 layer image block; X_j^i is the output of l-1 layer and the input element of l layer.
- (v) Part 3: full connection formula

$$Y^l = f(w^l X^{l-1} + b). \quad (10)$$

After convolution and pooling, the image output advanced features are weighted by the fully connected layer, and the final output is obtained through the activation function. For example, X^{l-1} is the output feature diagram of

the previous layer and w^l is the weight coefficient of the fully connected layer.

2.2.2. Handwritten Digital Image Recognition Based on KNN.

One of the simplest methods in the K-nearest neighbor classification algorithm (KNN), which is a data mining classification technology, is a theoretically mature method. The term K-nearest neighbor means that each sample can be represented by its nearest k neighbors. The core idea of the KNN algorithm is that if a sample has the k most adjacent samples in the feature space belong to a certain category, the sample also belongs to this category and has the characteristics of samples on this category. KNN is a commonly used opponent to write numbers to identify classification. A simple version of the algorithm is easily implemented by calculating the distance from the test examples to all stored examples, but it is massive for large training sets. Even for large datasets, the KNN is computationally tractable by using an approximate nearest neighbor search algorithm. Many more recent neighbor search algorithms have been proposed over the years. These are often designed to reduce the number of distance assessments actually performed. Euclidean distance, Manhattan distance, Minkowski distance, and cosine distance are as follows:

Part 1: Euclidean distance is as follows:

The Euclidean distance was taken as a distance measure, but this applies only for continuous variables

$$d = \sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2}. \quad (11)$$

Distance of the n-dimensional space is as follows:

$$\begin{aligned} d &= \sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2 + \dots + (x_n - y_n)^2} \\ &= \sqrt{\sum_{i=1}^n (x_i - y_i)^2}. \end{aligned} \quad (12)$$

Part 2: Manhattan distance is

$$d = |x_1 - y_1| + |x_2 - y_2|. \quad (13)$$

Part 3: the Minkowski distance

For two points x and y in n -dimensional space, the Minkowski distance between two points x and y is as follows:

$$d = p \sqrt[p]{\sum_{i=1}^n |x_i - y_i|^p}, \quad (14)$$

where p represents the dimension of the space, the Manhattan distance when $p=1$, the Euclidean distance when $p=2$, and the Chebyshev distance when p tends to infinity. Then, the Chebyshev distance between two points is the maximum of the absolute difference in the coordinate values between the two points

$$\max(|x_1 - y_1|, |x_2 - y_2|). \quad (15)$$

3. Design and Implementation

3.1. Install. OpenCV is a library file established by Intel in 1999. With the development of recent years, OpenCV has developed into an open source cross-platform computer vision library, with very good compatibility and perfectly compatible with Linux, Windows, and Mac OS operating systems. The OpenCV provides a transparent interface for the Intel. There is a special optimized processor APP library where OpenCV automatically loads some database during startup. After the anaconda environment is installed, the configured Anaconda Navigator has integrated various library files. OpenCV can use python as the programming language. After Anaconda Navigator installs the OpenCV library files, the call of OpenCV can be completed with anaconda built-in software. We open the anaconda built-in software Spyder or Jupyter Notebook (TensorFlow) and enter `import cv2 as cv`. No error code produced that the OpenCV installed successfully. Figure 13 is the Installed Anaconda Navigator interface diagram.

3.2. Programming Language—Python. The birth of Python language perfectly solves the deficiency of ABC language and also completes the function that ABC language does not have. It can be said that Python has developed from ABC, and countless ABC speakers have turned to the embrace of Python. Today, Python has developed into one of the most popular computer languages in the world. Even in some countries, Python language learning has joined the local primary school students, enough to show the popularity of Python. Using the Python has the following features:

- (i) Concise and readability
- (ii) Good scalability
- (iii) Completely free

3.3. Handwritten Number Recognition System

3.3.1. KNN Handwritten Number Recognition Method. KNN is an instance-based learning, or local approximation and delayed learning, delaying all computations into

classification. The K-nearest neighbor algorithm is one of the simplest machine learning algorithms.

3.3.2. CNN Handwritten Number Recognition Method. As a commonly used classical machine learning algorithm, CNN has been proposed and studied since forty years ago. Some experts have proposed the classical CNN architecture, demonstrated the potential of deep structure in feature extraction, and made major breakthroughs in image recognition tasks, setting off a wave of in-depth learning research boom. Convolutional neural network, as an existing deep structure with certain application cases, has also returned to people's vision for further research and application. Practice has proved that the accuracy of CNN network structure in handwriting digital recognition system is ideal and can basically meet the actual needs.

3.4. System Design and Implementation

3.4.1. System Construction. We install anaconda prompt in Anaconda Prompt, use Anaconda to create a virtual environment with Python version 3.6 by entering command line `conda create -n TensorFlow python=3.6`, and install CPU version TensorFlow 2.0.0 with command line `pip install TensorFlow 2.0.0`. We will import all the modules required to train the model, wait for them to download and install the corresponding library, and test the TensorFlow with the following code to verify that the installation of the TensorFlow is successful, as shown in Figure 14.

Computational results.

This means that the TensorFlow environment has been successfully built. Code running diagram is shown in Figure 15.

The programming software used is Spyder, a cross-platform, scientific computing integrated development environment using Python language. Writing code with this editor has many advantages, and it is convenient to import libraries. This is a digital recognition task. Thus, there are 10 numbers (0 to 9) or 10 categories to be predicted. The prediction error is reported using Python.

3.4.2. Sample Selection. The sample is a simple and practical computer vision dataset, MNIST dataset, which contains the image set of handwritten numbers as shown in Figure 16.

Implementation with
`"mnist = input_data.read_data_sets ('MNIST_data', one_hot = True)"` code.

A total of 60000 training data images in the MNIST dataset can be used to train the model, and 10000 test data images to test the recognition accuracy, each at $28 * 28$ pixel. Each pixel can be represented by a single grayscale value. The dataset was constructed from a number of scanned document datasets available from the National Institute of Standard Technology (NIST). This is where the dataset names originate, such as the modified NIST or MNIST datasets. Digital images are obtained from various scanned documents, standardized, and centered. This makes

it an excellent dataset for evaluating models, allowing developers to focus on machine learning with very little data cleaning or preparation. Each image is a square of $28 * 28$ pixel (total of 784 pixels). Standard partitioning of the dataset was used to evaluate and compare the models, where 60,000 images were used to train the model, while a separate set of 10,000 images was used to test the model.

3.4.3. Model Construction. KNN mode

The sample is a simple and practical computer vision dataset, MNIST dataset, which contains the image set of handwritten numbers:

- (i) Step 1. Load data.

- (ii) Step 2. Data preprocessing.
- (iii) Step 3. Calculate the distance between the test data and each training data.
- (iv) Step 4. Sort it by the increasing relationship of the distance.
- (v) Step 5. Select the K points with the smallest distance.
- (vi) Step 6. Determine the frequency of the previous K points.
- (vii) Step 7. The most frequent category among the first K points was returned as the predictive classification of the test data.

CNN model

The model is constructed based on the basic architecture of the convolutional neural network. The convolutional layer is responsible for extracting features, the sampling layer is responsible for feature selection, and the fully connected layer is responsible for classification.

- (i) Step 1. Load the data.
- (ii) Step 2. Data preprocessing: dimension adjustment.
- (iii) Step 3. Convolutional layer for convolution operation: the convolution kernel is generally initialized in the form of a random decimal matrix, and the convolution kernel will learn reasonable weights.
- (iv) Step 4. Pooling layer: a single pixel is used to replace the neighboring multiple pixels on the original image to maximum sample the data and retaining features while greatly simplifying the complexity of the model and reducing the parameters of the model.
- (v) Step 5. Full connection layer: we integrate the distributed features together and output them as a value, greatly reducing the impact of feature

location on classification. The fully connected data have its own weight, and the sum of their own weight product is the probability of the original image identification.

- (vi) Step 6. Start the training, find the error between the output value and the target value when the error is greater than the expected value, send the error back to the network, successively to obtain the error of the full connection layer, low sampling layer, and convolution layer. The error of each layer can be understood as the total error of the network, how much the network should bear; when the cycle iteration reaches the set cycle after the training.
- (vii) Step 7. Return the prediction results.

This chapter mainly introduces the library file OpenCV of image processing and then introduces Python, a language that can be invoked by OpenCV, and finally returns to the design requirements of this graduation design and describes the design and implementation of TensorFlow for the workflow of KNN and CNN.

4. Training Process and Results

4.1. *Deep Learning and Training Process.* KNN training process is shown in Figure 17.

KNN model first read test sample data, calculate the test data and the training data, sort the distance from small to large, select the smallest K points, determine the frequency of K point category, select the highest frequency category as prediction classification, and finally output classification results.

CNN training process is shown in Figure 18.

The CNN model first reads the test sample data; extracts the data features, updates the weight, convolutional layer, and pooling layer; and finally reaches the full connection layer. After judging the training cycle, it ends the training and finally outputs the classification results.

Training data for the CNN and KNN models are shown in Table 1.

Due to the low recognition rate of the convolutional and pooling layers, there are lag and crash phenomena due to the computer configuration problem. Therefore, in order to improve the recognition rate, it is decided to add a convolutional layer and a pooling layer into two convolutional layers and pooling layer. The training data are as shown in Table 3.

After adding a convolutional layer and a pooling layer, the program operation speed slowed down significantly. It took 20 minutes for cycle iteration and 30 cycles for cycle iteration for nearly two hours, but the recognition rate was significantly improved.

4.2. Realize the Whole Process

4.2.1. *Training and Preserving the Model.* After the convolutional neural network framework is built, the keeper saver is defined, and the trained model is saved with saver after the training completion.

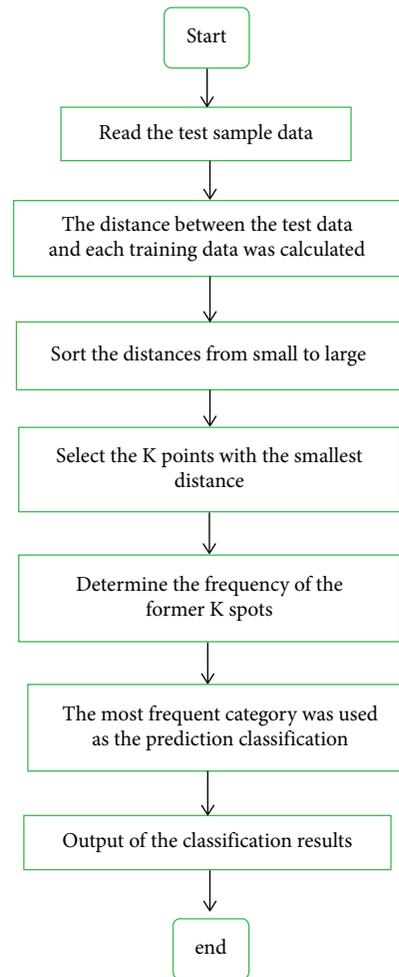

FIGURE 17: Flow chart of KNN algorithm training.

```

Definition:saver = tf.train.Saver()//saver.
saver.save(sess,'/home/XXX/learning_tensorflow/form/
model.ckpt')//Save the model/Fill the save address of the
model in quotes.
  
```

The model is obtained as shown in Figure 19.

4.2.2. Image Preprocessing.

- (1) Step 1. Select the image
- (2) Open the handwritten digital image of the computer, as shown in Figure 20.
- (3) It can be seen from the above that the handwritten digital pictures that can input the convolutional neural network requires that the pixels of these pictures are $28 * 28$, while the pictures to be identified are often greater than $28 * 28$ pixels and do not meet the requirements, so appropriately reduce the images to be processed into the same format as the MNIST dataset.
- (4) Step 2. Processing method

The `imread` function comes with grayscale image reading, and the `imread` function reads in grayscale image.

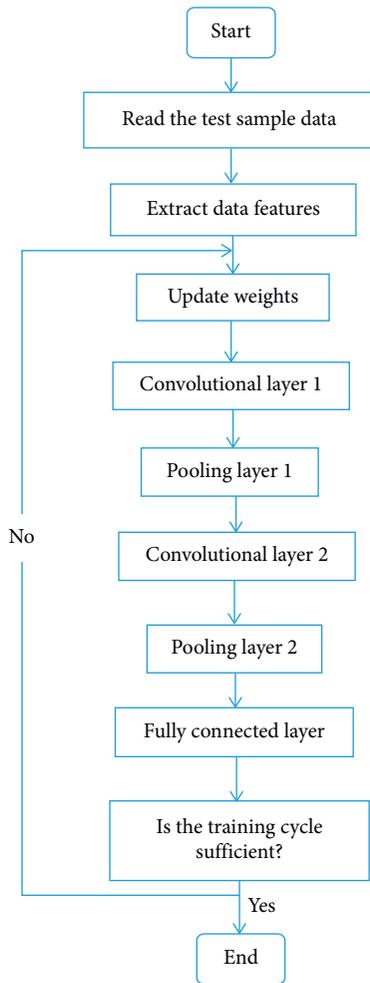

FIGURE 18: Flow chart of CNN algorithm training.

TABLE 1: Recognition rates at different K values and training set sizes.

K	2	3	4 (%)	5 (%)
5000 training images	89%	92%	88	92
10000 training images	91%	96%	94	94

The convolutional neural network training results with only one convolutional layer and one pooling layer are as shown in Table 2.

TABLE 2: Recognition rate at the different number of cycles of the CNN.

Cycle index	100 (%)	200 (%)
Discrimination	82	90

TABLE 3: Recognition rate at different cycles of CNN convolved by two layers.

Cycle index	5 (%)	30 (%)
Discrimination	88	99

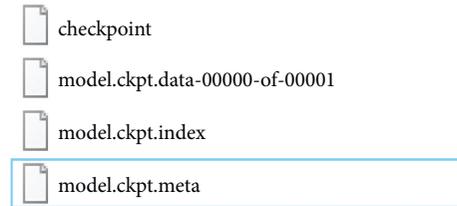

FIGURE 19: A well-trained model.

FIGURE 20: Images to be processed.

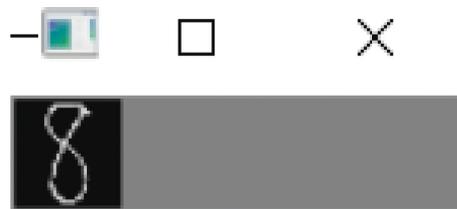

FIGURE 21: The processed image.

Counterphase grayscale diagram, reversing the black and white threshold with access pixel and processing pixel by pixel.

Using the threshold function, the reverse-phase binarization image is performed.

Use the rank scanning method to find out the digital border to determine the specific location of the number.

The filled pixels were resized to 28 * 28 pixels and finally processed into the same format as the images in the MNIST dataset, as shown in Figure 21.

(5) Step 3. Adjusted model

```
[saver.restore(sess,"C:/Users/Desktop/demo/model.ckpt")//Call the trained model].
```

We import the handwritten digital pictures processed by OpenCV into the neural network model, run the test.py program, and identify the results. All the test pictures are shown in Table 4.

TABLE 4: Identification results of the ten handwritten digit pictures

Handwritten digital pictures	The number identified by the program	Result
0	0	Correct
1	1	Correct
2	2	Correct
3	3	Correct
4	1	Error
5	5	Correct
6	6	Correct
7	7	Correct
8	8	Correct
9	9	Correct

After the analysis, it was found that only the picture “4” in the above table was wrong, and all the others were correct, so that the task of this graduation design was successfully completed.

5. Conclusion

This graduation innovation point includes the following three parts:

- (i) Part 1: The title of the graduation design is the handwritten digital picture research based on convolutional neural network, but the relatively simple KNN algorithm and CNN algorithm are easy to achieve, highlighting the advanced aspects of convolutional neural network. Learning deep learning from different angles can more intuitively understand the advantages of convolutional neural network in image recognition. Choosing KNN algorithm is to better understand the idea of K-nearest neighbor method. At the same time, several algorithms are also helpful to learn Python programming language.
- (ii) Part 2: It really realizes the recognition of handwritten digital pictures, not just an accuracy, but the real identification of a written digital picture, the more practical graduation design requirements, can make students interested, and the boring accuracy is not intuitive and too theoretical.
- (iii) Part 3: Really introduced OpenCV technology, with OpenCV to process pictures so that the measured pictures are not subject to $28 * 28$ pixels requirements, and any pictures after OpenCV processing can be imported into the built neural network framework [26].

Nowadays, the development of online college education is in full swing, and various online college education platforms have also sprung up. The development of technology has made these online platforms more and more powerful, escorting the continuous development of online education. Colleges and universities, as the main front for the cultivation of high-quality talents in my country, have already introduced large-scale online courses into education and teaching, enriching the teaching content, and expanding the teaching form. In the face of new technical means and abundant online education resources, the teaching quality of online classrooms in colleges and universities is so low, which deserves our further reflection. For a long time, the effect of online classroom teaching in colleges and universities has been closely concerned by the academic community, but most of them start from external factors, ignoring the internal relationship of online classrooms. Clarifying the complex relationships in the online classroom field of colleges and universities and clarifying the rules of habitus and capital operation in the online classroom field of colleges and universities are the intrinsic motivation and important source to stimulate the vitality of the online classroom field of colleges and universities and improve the quality of teaching. By grasping the essence of classroom teaching and analyzing the inherent characteristics of the online classroom field, this research intends to clarify the proper state of the online classroom field, and to explore the reasons why the current online classroom field function has not been fully realized, so as to find the depth of college education.

1. Related Introduction

The development of information technology has revolutionized the way and influence of information dissemination time and time again, and subsequently caused changes in social organization, management methods, economy, and industrial structure. These changes have a subtle impact on all aspects of people's lives. With the acceleration of the modernization of education, the application of online technology in the field of education has become more and more extensive. Colleges and universities are the main positions for talent training, and online classroom teaching has gradually become a new normal teaching method. However, many studies have shown that the teaching effect of online classrooms in colleges and universities is not satisfactory. There are still many problems. These series of

problems are not only external factors but also internal factors that cannot be ignored. Therefore, using the field theory to analyze the problems existing in the online classroom field of colleges and universities from the perspective of internal relations is of great value to improve the teaching effect of online classrooms in colleges and universities and the quality of online education in colleges and universities.

As an existing form of classroom, online classroom is mainly characterized by breaking the time and space constraints of classroom teaching. The research and analysis of it has certain limitations. But in the sense of space, in the process of classroom teaching, teachers and students are in different positions of power due to the difference in the mastery of cultural knowledge between teachers and students, thus forming a complex relationship network, which

is not in line with the field theory. In this relational network, there are specific logical rules that both teachers and students should abide by. This logical rule aims to promote the flow and reproduction of cultural capital between teachers and students, which is exactly what the online classroom should be.

Field is a relational theory that aims to study the relational workings between actors within the field. In the normalized classroom field, teachers and students are in the same physical field, and the connection in the field is very easy to construct. Teachers can control the power in the classroom by virtue of their own cultural capital. Students because of their culture, the relative weakness of capital can only agree with the rules within the classroom field. In the process of classroom teaching, teachers can timely and accurately observe students' learning status, communicate and interact with students, and adjust teaching content and methods so as to attract students to "enter," supervise their "presence," and avoid students' "absence." At the same time, according to the view of situationism, learning activities cannot be separated from learning situations, and different learning situations will have different degrees of influence on the effect of teaching. In the normalized classroom field, students are in the same physical space, and their behaviors will definitely be influenced by other students around them and be driven into learning activities, so that most students can abide by the rules of the field and participate in cultural capital. The constraints of time and space are broken, teachers and students are in an abstract social space, and it is difficult for teachers to grasp the learning status of students in a timely and accurate manner. In the context of collective learning, it is also difficult to integrate into classroom learning; on the other hand, due to the abundance of online course resources, students have more power in the choice of knowledge, teachers' power in the classroom is also weakened, and students have the ability to learn independently [1–10].

However, due to the fact that the relationship between teachers and students and their respective roles in the online classroom field of colleges and universities cannot be timely transformed from the normalized education field, the teaching methods of teachers and the learning methods of students still maintain the normalized classroom field habit in. The unclear relationship between teachers and students and the mismatch of habitus and other factors have caused various problems in the online classroom field of colleges and universities, and the field cannot function normally, resulting in low quality of online classroom teaching. How to clarify the internal relationship of the online classroom field of colleges and universities, form a healthy online classroom field of colleges and universities, and make the functions of the online classroom field of colleges and universities really play, is the main problem to be solved in this research.

2. Related Work

In today's increasingly popular online teaching, due to the change of teaching mode, the teaching behavior of teachers in online teaching has undergone great changes compared with traditional teaching. On the basis of comparative analysis of teachers' teaching behavior in traditional teaching and teachers' teaching behavior in network teaching, Liu Fanhua found that traditional classroom teaching is teacher-centered, and teachers' teaching is the main way for students to acquire knowledge. In the process of classroom teaching, teachers control the rhythm of the entire classroom, and teachers supervise students' learning behaviors to ensure that students carry out learning activities under the guidance of teachers; however, in online teaching, due to the openness of online platforms and learning resources, students can choose the content of learning by themselves, build knowledge in advance through the addition of interest, become the protagonist in the classroom, and the teacher becomes the facilitator in the classroom, which is more in line with the current student-based education and quality education requirements. Francescucci conducted an experimental study on two modes of online video teaching and class teaching in 2013 and 2018, respectively. In the 2013 experiment, because students did not understand the online video teaching mode, one-third of the students said they were unwilling to do so. Learning is carried out online, but in the 2018 experiment, it was found that the effect of online video teaching and class teaching was equivalent, and there was no significant difference between students' participation and final grades. Faulconer set up four modes in one course for experimentation, which are class teaching, online asynchronous, online synchronous, and remote video. The test results show that the teaching effect is not much different, but the dropout rate of asynchronous online classroom is slightly higher than that of the other three forms. Skylar explored the teaching effect and student satisfaction of online teaching and face-to-face teaching, and found that students' grades in face-to-face teaching were slightly higher than online teaching, and nearly four-thirds of students also expressed a preference for face-to-face teaching [11–14].

Most of the existing studies take the field as the theoretical perspective and use the field habitus to analyze the specific problems in the online classroom, such as the interaction between teachers and students in the field of online teaching in colleges and universities, and the learning field of management flipped classroom. By sorting out related research studies in the field of online education, this study found that the above research mainly takes the specific form of online classroom as the research object. By grasping the essence of classroom teaching and analyzing the inherent characteristics of the online classroom field, this research intends to clarify the proper state of the online classroom field, and to explore the reasons why the current online classroom field function has not been fully realized so as to find an optimization path.

3. Behavioral Scenarios of Online Classrooms and Analysis of College Students' Demand Behaviors

3.1. Behavioral Scene Construction of Online Classroom. As well as the theory of embodied cognition based on Merleau-Ponty's embodied phenomenology, the theoretical sources of these two aspects become the theoretical support for the research on the online classroom user behavior model in this study. Through "scenario construction" to restore the user's real use scene or simulate the user's mentality, then in the field construction, it is to connect the original realm of the experience and the user's present, and finally make the immersive experience and meaning happen [15].

The realm of the online classroom is to build a private space of one's own, in which class tasks and thinking activities can be effectively completed. The inspiration of this study from Heidegger's field theory is to return to the original classroom environment, allowing users to complete the construction of experience and meaning in a focused situation, under the synthesis of their own apperception or body schema. Therefore, the first step of construction is to help him move towards the realm and connect the immersive scene. The second step is to help him focus on the task flow of the target interface through sensory design. Figure 1 shows the framework of the classroom behavioral scene model research.

3.2. Construction of Fielded Embodied Behavior Model in Online Classroom. On the one hand, the fielding theory puts forward the hypothesis of the learning experience model of "formal display-practice-comprehension." On the other hand, learning experience is both a learning cycle process and an experience cycle process. Users recognize and learn from experience. According to the observation and interview of classroom learning, and derived from the theory of embodiment, the process model of the fielded embodied behavior in the online classroom is finally determined, which are physical participation, experience meaning, reflection (self-examination) [1], situational motivation (motivation) [2], physical participation [3], experience meaning [4], reflection (self-examination) [5], and cooperation [16].

3.3. The "SHDD" Positioning of Online Classroom Experience Based on the Phenomenological Perspective

3.3.1. Establishment of "SHDD" Positioning for Online Classroom Experience. "Outer experience" and "inner experience" together constitute "one experience." Dewey believed that "an experience" has no "dead center," that is, the "outer experience" and "inner experience" will not be suddenly interrupted. The user's combination of "external experience" and "internal experience" determines the quality of "one experience." This study proposes to use the ratio (qualitative) of "inner experience" to "outer experience" to

locate a student's experience. Internal experience: external experience ≥ 1 , indicating that the final experience is beyond expectations (full expectations); internal experience: external experience < 1 , indicating that the final experience is lower than expected (vacant expectations). On this basis, this study further proposes an experiential "SHDD" orientation. The two poles of the ordinate are "inner experience: outer experience ≥ 1 " and "inner experience: outer experience < 1 ." The abscissa is examined from the dimension of frequency, and the two poles are "Occasionally" and "Frequently," respectively. This results in four quadrants. When the user's internal experience: external experience ≥ 1 occurs for the first time, it brings a sense of surprise to the students and gains a trustworthy group of students. When the user's internal experience: external experience ≥ 1 often occurs, it brings students a sense of happiness and gains a loyal student group. When the user's internal experience: external experience < 1 occurs for the first time, it will bring students a sense of disappointment and gain a tired student group. When the user's internal experience: external experience < 1 often occurs, it brings students a sense of deception and gains a disgusting group of students. Trusting and loyal student groups will further lead to good teacher reviews, while bored and disgusting student groups may lead to bad teacher reviews, specifically as shown in Figure 2 [17].

3.3.2. Experience Containers in the Classroom. The simple process of predetermining a purpose-achieving a purpose does differentiate an "experience" from a piecemeal experience, but it is not a sufficient measure of the quality of purpose-completion, i.e., how good or bad it is. Taking "classing" as an example, the preset purpose of "classing" did not include key factors such as course content, whether to procrastinate in class, teacher attitude, etc., which led to the fact that although students completed the purpose of "classing," they felt this "one experience" is in short supply. In other words, there is no system for describing how good or bad "an experience" is. After all, the expected construction is multilayered, so it is necessary to re-examine "an experience" from the perspective of body metaphor. As "an experience" experience, like "substance" "event" "behavior" and "state" become the object of physical metaphor. Therefore, this study proposes to take experience as the object of body metaphor and construct a conceptual container with inner-outer orientation from the genetic level. This is an experience "container" with the behavior of entering the classroom as the turning point. The experience before entering the classroom is the experience outside the container, which is called the "external experience"; the experience after entering the classroom is the experience in the container, which is called the "internal experience" [18]. The "EEI model" divides the process of experience into three stages: expectation, event, and impact. It is essentially a time model that explores how the experience occurs in the time dimension and its follow-up. But all time models have their limitations. On the one hand, from the physical dimension, the time model cannot show the obscurity of the product or service to the user's final experience; on the other hand, from

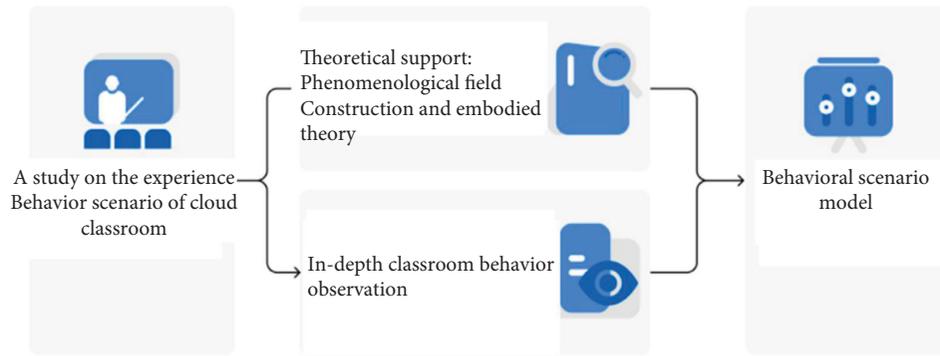

FIGURE 1: Research framework of classroom behavior scene model.

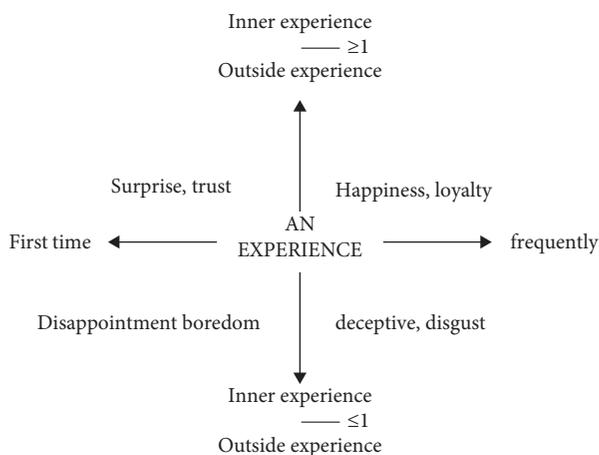

FIGURE 2: The “SHDD” orientation of a student’s experience.

the philosophical dimension, any experience occurs in time and time. In the intuitive form of space, the “experience container” proposed in this study is not only based on time but also emphasizes the shielding effect of the spatiality of experience on people’s intuition.

4. Design of Online Classroom Experience Based on Field Theory

4.1. Establishment of a Situation Description Swimlane Diagram. Swimlane diagram is a Unified Modeling Language (UML) activity diagram designed to show the activities of different characters at the same time. In 2007, Yvonne Shek of nForm Company modified the Unified Modeling Language activity and invented the Scenario Description Swimlanes [1]. Scenario description swimlane diagram describes the various behaviors of multiple participants (students, teachers, family members, etc.) in a series of activities in the online classroom, making the results more intuitive and clear, and this overall analysis is compared to the simple addition of each part better results. The swimlane diagram in the online classroom scenario includes storyboards, resources, user experience, target process, tool contact requirements, and pain points, as shown in Figure 3 [19].

According to the situation description swimlane diagram, the situation space of online classroom users is drawn, as shown in Figure 4.

4.2. Building a User Journey Map. The process of the traditional offline classroom is as follows: check the time and place of the class-on the way to the classroom-check in and punch in (or have)-find a seat-open textbooks, handouts and other school supplies-listen to the class-take notes-discuss with classmates between classes (or)-be called to answer questions (or yes)-record coursework-leave class-pack school supplies-leave the classroom. Among them, the classroom acts as a space medium that brings together teachers and students. For students and teachers, it is a temporary residence, and the bell of the get out of class will always ring. [20,21].

The class process of the existing online classroom products is as follows: the teacher notifies the class in the class group when the class will take place. When the time comes, the teacher will drop a Tencent conference meeting number or link to the group, or invite the whole class to join the live broadcast on the corporate WeChat. After the teacher entered the meeting, he shared his screen to explain the PPT for lesson preparation, and the students took notes while listening to the class. After the course is over, everyone will leave the conference live room. The students then communicate and collaborate with the classmates in the group on WeChat or other communication tools to complete the homework. This process is inconvenient. Everyone is distributed in different parts of the country. A collaborative tool group with online classrooms as the carrier becomes very necessary.

In the traditional service blueprint, the direct interface between products and services and users is called the operation interface. The interface not only refers to the human-computer interaction interface of the mobile phone screen or computer window in the narrow sense, but actually covers the direct or indirect contact between products and services and users. Mr. Dai Fuping proposed generalized interface and full-contact design thinking based on Husserl’s spatial intuition. That is to say, the contact is not only performed on the specified contacts, but also contacts outside the specified contacts. Non-contacts also become contacts through

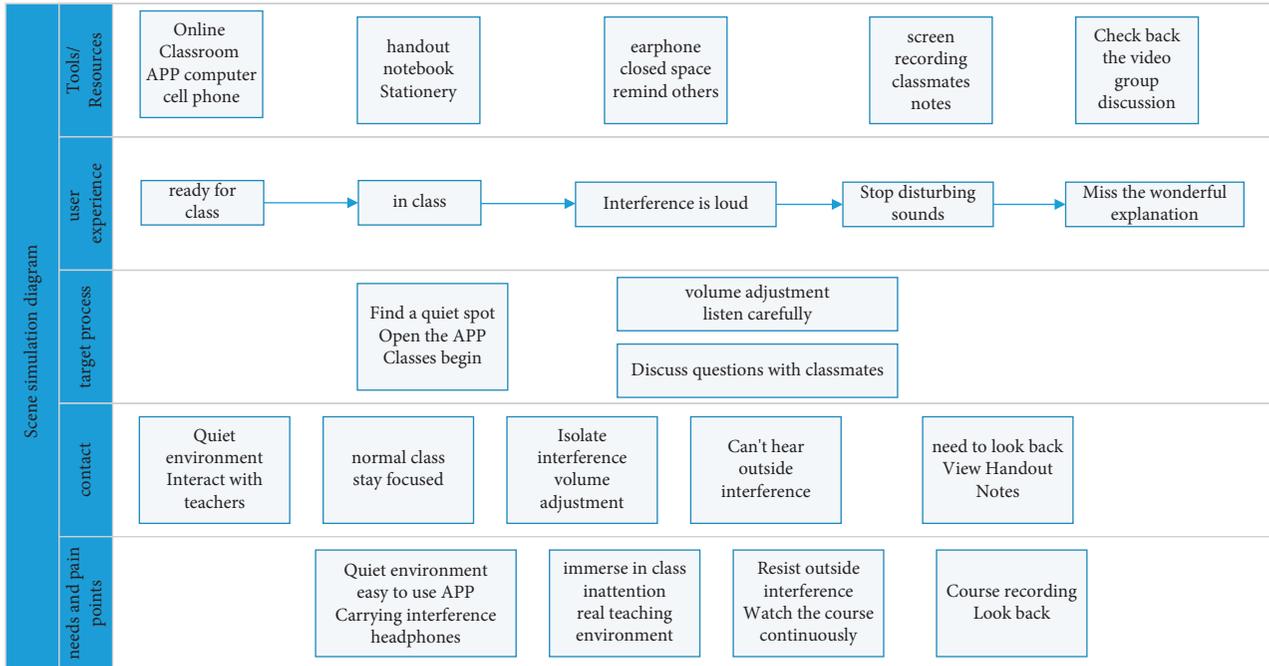

FIGURE 3: Scenario description swimlane diagram.

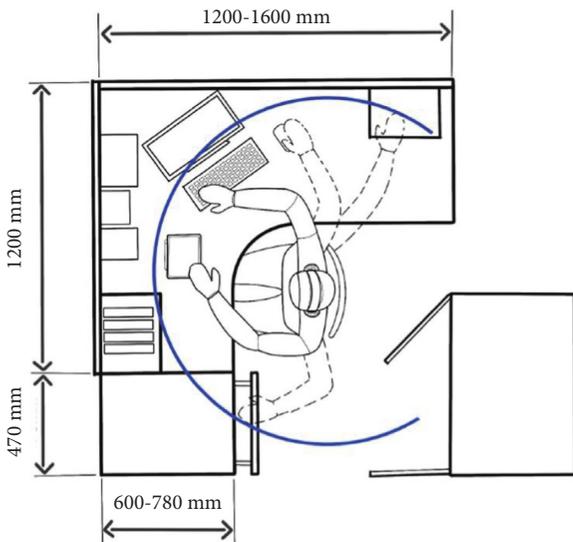

FIGURE 4: Online classroom user scenario space.

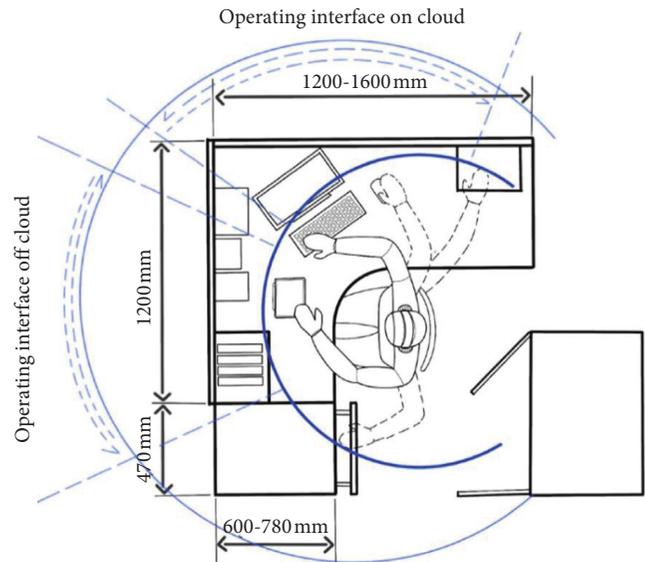

FIGURE 5: Online classroom user interface.

contact, so they are actually full contacts. This is actually because Mr. Dai Fuping took human freedom into consideration in the design at the philosophical level. The subjective initiative of human freedom cannot be ignored. Do not regard the user as a number or symbol in an equation, but consider that he is a person with essential intuitive ability. Therefore, in the apperception of this essential intuitive ability, non-contact points may also become contact points, as shown in Figure 5.

Restored to the specific online classroom scene, the apperception of this essential intuitive ability of people is reflected in the specific scene. The generalized interface includes not only the software interaction interface of the

class but also the interface background or background interface formed by the desks and chairs in the space where it is located. Not only that, the head-mounted hardware in this design is in contact with the user's scalp to form a body interface, and the touch panel is adjusted to form an interactive interface with fingers. These interfaces will be composed of a series of experience touch points, such as the elasticity of the head beam, the texture, and agility of touch.

4.3. Building an All-Touch User-Other Interface. Turning to the other (derAndere), that is, the subject of the full-contact and generalized interface with other people in this space is

replaced, such as the user's parents, friends, and even pets. What potential touchpoints will they have with the product or target user in this common field? These things that traditional designers choose to ignore can actually be taken into account, because we cannot design a person completely separated from his real-life scenes and characters. If the touch points of the people around the user can be taken into consideration, it will eventually bring about changes in the way people communicate with each other. The product as a carrier becomes a dual interface, which is the interface of "Möbius strip." Different people's interfaces can produce a meeting point, instead of connecting users with other people's space or resources through a product. Taken apart, this is an "onion" interface, as shown in Figure 6. The dual interface proposed in this study is to use the product as the medium to bring people in this space into the category of experience design. This is different from the previous contact points above, which are not only the contacts of a certain person, but the full-user, full-contact, or full-consciousness contact in the true sense. Improvements in the way people interact with each other in the spatial field can be achieved through this dual interface.

Under the guidance of the design thinking of all-consciousness and all-contact, this research integrates the potential interaction interface of family members and the target interaction interface of students into a system and at the same time as the object of experience design, forming a "student user as the main body of operation." "Online operation interface," "offline operation interface," and "other interface" with family members as the main body. In order to enable target users to obtain an immersive online and offline operating experience without being disturbed by others, it is necessary to study the behavioral scenarios of others and design the interface of others so that others can operate in this field. Get the feedback they should have, and then guide them to make the right behavior, as shown in Figure 7.

By establishing different behavioral scene models, the interface systems of different roles are not mechanically integrated so that the target users have an immersive class experience. According to the different types of touchpoints, this study divides the touchpoints into the following types: visual touchpoints, physical touchpoints, and interactive touchpoints. And incorporate different types of touchpoints into the appropriate interface.

4.4. Main Product Modules and Experience Service System

4.4.1. Class Module. The class module includes three scenarios: before class, during class, and after class. Before class, students can learn the specific information of this course by entering the course details page, including course name, instructor, course label, course outline, teaching objectives, homework and discussion, and related training plans, and can also recommend this course to your classmates. During class, after students enter the class, the system automatically turns off the students' microphones and cameras. Students can manually turn on

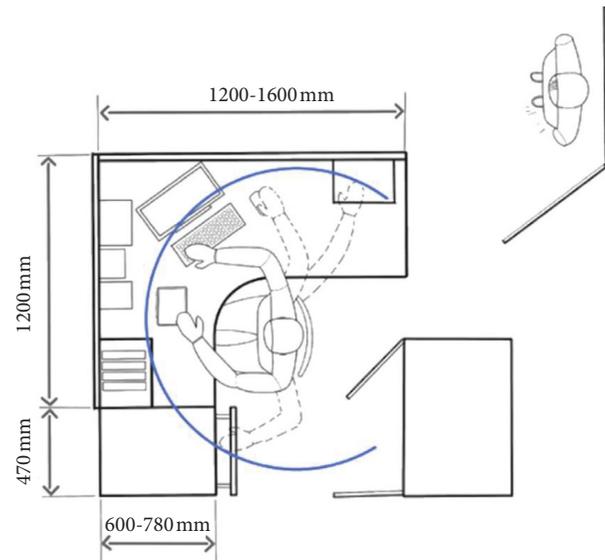

FIGURE 6: Family members in an online classroom scenario.

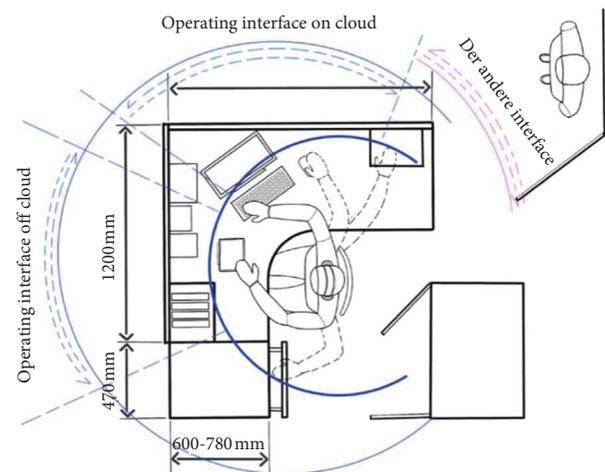

FIGURE 7: "Other interface" in online classroom space.

the microphone and camera, and can share the class ID to add classmates. In terms of hardware, students can enter the immersive classroom atmosphere by wearing professional online classroom headsets. The hardware has microvibration energy, and by taking a pat on the avatar, a private interaction is formed between students without affecting the classroom environment. There are class notes, drawing boards, and schedules in the classroom recording tool. You can cancel the acceptance of classmates' pats, and enable or disable the beauty function. One of the most distinctive designs on the student side is the curriculum. Clicking a course on the curriculum will jump to the course details page. If you are in class, you will directly jump to the class live page. The traditional curriculum only provides viewing; the curriculum designed in this study provides classroom entrance. Friends can view each other's class schedule and learn about each other's class time and common courses. After class, the

system will automatically generate class time for users, and a more detailed statistics will be formed every week, such as “You have completed 290 minutes of course study this week and participated in three courses, which is great!” which will push some short sentences about learning methods. The biggest difference between the class module on the teacher side and the student side is that the teacher can edit and design the course content, and has more authority to operate the classroom. For example, the “Take a pat” function can only allow the teacher to take pictures of the students, and the students cannot take pictures of the teacher.

4.4.2. Collaboration-Shared Modules. Compared with the traditional student work alone, the current student work advocates division of labor and cooperation. In this study, an online group module is designed on the student side of the online classroom, which is used for students to collaborate and discuss learning. The truth is always clearer and clearer, and the practice is always the best standard to verify the theory. This process is an effective supplement to the classroom time. Taking the design school where this institute is located as an example, all courses require teamwork to be completed, and design activities pay attention to team awareness and do not advocate fighting alone. In the existing online classroom products, there is a lack of collaborative design for college students. Interaction and vision overlapped for a period of time. At this time, visual students will first formulate visual specifications and components, and product students will also join the discussion. Group members can manage their own personal plans. Everyone’s personal plan can be synchronized to the online end in real time and shared with team members. Each individual plan involves other team members, forming a positive cycle of mutual promotion. The relationship between classmates is not only a collaborative relationship but also a relationship of friends. In order to avoid strong work attributes, this study added some interesting designs to the online group, such as today’s Whisper. This is an anonymous truth-talking area that can add a little fun to busy work and add some lubricant to task-driven and sometimes tense relationships, as shown in Figure 8.

4.4.3. Lesson Preparation and Preview Linkage Lesson Preparation Module. Existing mainstream online classroom products such as DingTalk, Enterprise WeChat, and Tencent Meetings do not have modules for teachers to prepare lessons. Their office attributes and tool attributes are relatively strong, and they attach importance to timely meeting capabilities in product design. In the design of online classes for college students, the teacher’s lesson preparation is very important, which is related to the quality of the class. This is also designed under the guidance of all-touch design thinking. In the previous investigation, this study found that most of the online classes during the COVID-19 epidemic did not have syllabuses and had a strong temporary nature. This results in students not knowing what to expect before class, and therefore not knowing how to prepare. Some

FIGURE 8: Usability test results.

FIGURE 9: Software and hardware interaction.

difficult and systematic courses, such as advanced mathematics and physics, lack of preclass preparation is very unfriendly to students. In traditional classrooms, teachers have difficulty in grasping the basic situation of students during lesson preparation, and often fall into misunderstandings. The online classroom lesson preparation module designed in this research solves this problem well. Taking advantage of the timeliness of online and online sharing, while teachers are preparing lessons, they can be shared with class groups in a timely manner to form positive interactions with students and get feedback on lesson preparation. Teachers can do questionnaires, voting, and other activities in the group, and design courses in a “personalized” style, realizing “personalized courses” that cannot be achieved in traditional classrooms.

4.4.4. Software and Hardware Interaction Module. The software and hardware interaction module is based on the online classroom software and hardware parts. Why introduce hardware? Professional hardware is to create an immersive classroom space, to separate students and teachers from their environment, and devote themselves to classroom learning and teaching. In traditional classrooms, each course will be completed in an independent classroom. The function of the classroom is to isolate the classroom

from other environments and form a closed and immersive teaching environment. First of all, as a specialized device, the hardware can only be used on the online classroom APP, specifically as shown in Figure 9. This research draws on several market-proven professional equipment, such as iFLYTEK's professional voice recorder and Bose's "Sleep Bean." The hardware extracts students from the home environment through noise reduction technology and then uses sound technology to simulate the immersion brought by the sound space of the offline classroom.

5. Conclusion

Under the process of education modernization, the development of online education has become an inevitable trend. As the main front of talent training and the key implementation object of education modernization development plans, the teaching effect of online classrooms in colleges and universities is a problem that is generally concerned by the current society. It is particularly necessary to improve the teaching effect of online classrooms in colleges and universities through investigation and research. Therefore, through Bourdieu's field theory, this study analyzes various relationships in the online classroom field of colleges and universities from a micro-perspective, aiming to clarify the ideal state of the online classroom field of colleges and universities so as to find an optimization path and improve colleges and universities. Combining the theoretical research of Heidegger and Merleau-Ponty, this study proposes a "field-based embodied behavior model"; through the research on the characteristics of cloud classroom experience and the investigation of actual needs, it proposes a "new positioning of cloud classroom learning experience." At the level of experience design strategy, combining the field-based embodied behavior model and the specific design practice form, the "experience design strategy under the embodied scFene" is proposed; based on the new positioning of cloud classroom learning experience, "experience design for experience unmasking" is proposed.."

This paper designs a three-dimensional display system for intangible cultural heritage based on generative adversarial networks. The system function is realized through four modules: input module, data processing module, 3D model generation module, and model output module. Two 3D model reconstruction methods are used to realize the transformation from 2D images to 3D models. In the low-resolution Nuo surface 3D construction, multiresidual dense blocks are introduced and applied to the deep image super-resolution network. The experimental comparison results show that the quadratic optimization multifusion 3D construction model proposed in this paper can achieve considerable improvement and can improve the reconstruction accuracy by about 6.3%. In the high-resolution 3D construction of the Nuo surface, a generative adversarial network model is used to improve the generator, discriminator, and loss function of the original SRGAN model. Experimental results show that this method can generate super-resolution images with more realistic and natural depth maps. In addition, when it is used for high-resolution 3D Nuo surface sculpting, it can also generate 3D voxel Nuo surfaces with more details.

1. Introduction

At present, the development status of intangible cultural heritage projects and the protection of intangible cultural heritage need to be improved. The modern production and way of life have undergone great changes, and traditional handicrafts and artworks have been gradually replaced by industrial products, resulting in certain difficulties in the status quo of intangible cultural heritage projects and the life status of intangible cultural heritage inheritors. The biggest problem facing intangible cultural heritage is the lack of intangible cultural heritage. On the one hand, the intangible cultural heritage is complicated and difficult to learn; on the other hand, some of the intangible cultural heritage is mostly oral, and there is no specific learning carrier. To solve the problem of the decline of national culture caused by the reduction in intangible cultural heritage, it is urgent to use

modern three-dimensional construction technology to reproduce the intangible cultural heritage.

The traditional 3D construction technology uses 3D reconstruction software to construct the target 3D, and the construction result has high accuracy, but the use of the software requires training of professionals and detailed data of the modeled objects. In addition, the multi-view geometric method can also be used for 3D construction [1, 2], using multiple views to complete the fusion of different information of the target, so as to complete the 3D construction of the target. However, the above methods are difficult to complete the three-dimensional reconstruction and display of intangible cultural heritage. Therefore, how to complete the 3D construction of a single RGB image quickly and with high quality is particularly important. With the deepening of deep learning research, deep learning models based on CAD databases have begun to be used for 3D

reconstruction of a single image. In 2015, Wu [3] started to propose the 3D ShapeNets model, which utilizes deep convolutional belief networks to learn the joint distribution of all 3D voxels in a data-driven manner. Their proposed model learns the distribution of complex 3D shapes across different object classes from raw CAD data, performing joint object recognition and shape reconstruction from 2.5D depth maps. Choy [4] proposed a new structure—3D recurrent reconstruction neural network in 2016, which avoids the prior matching problem existing in traditional methods, which is derived from a large number of A mapping of learning objects to their 3D shapes in synthetic data sets, using one or more images of real objects from any viewing angle as input and 3D voxels as output. In addition, taking advantage of the powerful ability of generative adversarial network in image generation [5–8], more and more scholars have begun to study the use of GAN for 3D model reconstruction. Generative adversarial networks proposed earlier use a game-like approach to generate images from random noise and refine them to approximate real images. Inspired by this, Wu et al. [9] extended the 2D generative adversarial network to 3D generative adversarial network in 2016. Gadelha et al. [10] proposed projective generative adversarial networks, which estimated the 3D shape and viewpoint, respectively, through the generator network to generate a binary projection image for the projection module and then used the discriminator network to judge true and false. Riegler et al. [11] proposed a learning-based deep fusion method, designed a 3D convolution model for octree network fusion, and used one or more depth maps as input to estimate the 3D space division, ranging from coarse to fine. The reconstruction resolution is increased to $128 \times 128 \times 128$ in three steps. The GAN-based idea uses the discriminator to judge the reconstructed high-resolution image and the ground truth image, which makes the generated high-resolution image closer to the real image as a whole, has more details, and is more in line with human visual perception.

Based on the 3D reconstruction technology of intangible cultural heritage based on generative adversarial network, this paper takes Guangxi Nuo surface as the research object and introduces in detail how to design the 3D display system of intangible cultural heritage. By establishing an intangible cultural heritage data set, a multifeature fusion method is used for low-resolution voxel 3D modeling, and a high-resolution 3D model of intangible cultural heritage is established based on a generative adversarial network.

2. Relevant Knowledge

2.1. Convolutional Neural Networks. A simple convolutional neural network is mainly composed of three types of network layers: convolutional layer with nonlinear activation function, pooling layer, and fully connected layer, and the basic structure is shown in Figure 1, where the small white box represents the size of the convolution kernel. Among them, the size of the convolution kernel can be any value smaller than the size of the input image, and the larger the convolution kernel, the larger the receptive field. Therefore,

the more picture information is seen, the better the features are obtained. However, using an excessively large convolution kernel will lead to a dramatic increase in model computation, which is not conducive to increasing the depth of the neural network. In Figure 1, the input layer takes the pixels of the image as the feature node as input. During the forward propagation process, the convolution kernel slides along the width and height of the image and calculates the convolution kernel and the dot multiplication between inputs. Finally, the response of the input to the convolution kernel at each spatial position is obtained, which is called a feature map. To make the neural network have nonlinear fitting ability, a nonlinear activation function is usually added to the convolutional layer. Since the increase in the feature map after the convolution operation will lead to too many parameters of the neural network, the pooling layer is often used to reduce the spatial dimension of the feature map. Finally, outputting the results through a fully connected layer can accomplish tasks similar to handwritten digit recognition.

2.1.1. Convolutional Layer. In different image processing tasks, the input image can be subjected to convolution operation to extract different features for processing. Different features can be extracted using different convolution kernels, such as edges and contours. It is well known that the depth of the neural network can improve the performance of the model more than the width. In the convolutional layer, due to the local connection and weight sharing of the convolutional layer, the parameters that the neural network needs to learn are greatly reduced, which is also conducive to designing a larger neural network to handle more complex tasks. In a convolutional neural network, for an input image X , its convolution is defined as follows:

$$s(i, j) = (X * W)(i, j) = \sum_m \sum_n X(i + m, j + n)W(m, n). \quad (1)$$

Among them, W is the convolution kernel, X and W are both two-dimensional matrices, (i, j) represents the two-dimensional matrix coordinates, and $W(m, n)$ represents the weight at the convolution kernel (m, n) . Figure 2 is a schematic diagram of a simple convolution. In Figure 2, the convolution kernel calculates the value of 9 pixels on the input image at a time, and then, the sliding step size moves one unit to the right or down, respectively. Finally, the convolution kernel traverses the entire input image to obtain a 2×2 output feature map.

2.1.2. Pooling Layer. The introduction of the pooling layer imitates the human visual system to reduce the dimension and abstract the input object, and the use of the pooling layer can retain the main features of the image and reduce the parameters of the model, which can also reduce the degree of overfitting of the model to a certain extent and improve the generalization ability of the model. In addition, the pooling layer can make the model pay more attention to a certain feature present in the image rather than the location of the feature.

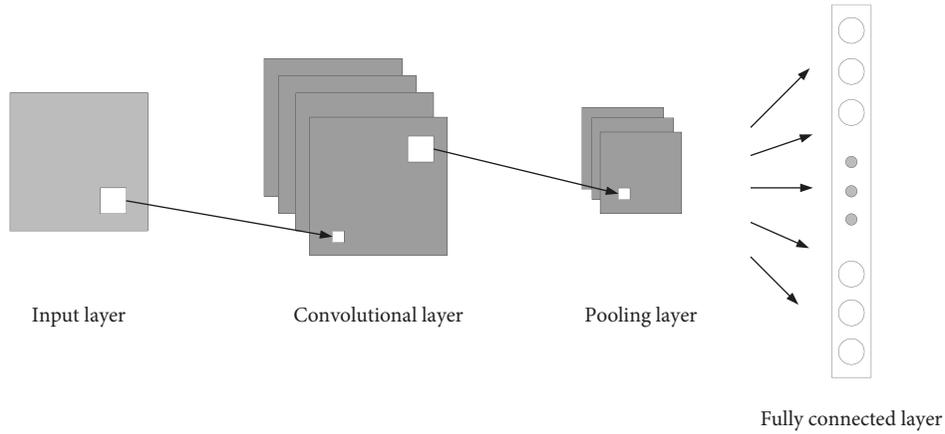

FIGURE 1: Basic structure of convolutional neural network.

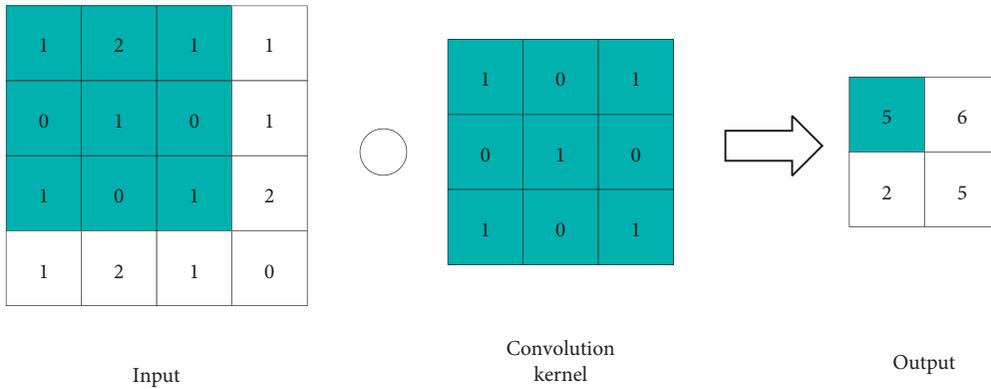

FIGURE 2: Two-dimensional convolution operation.

The max-pooling layer is one of the most commonly used nonlinear pooling functions. This pooling operation divides the input image pixels into multiple sub-pixel regions and then takes the maximum pixel value of each sub-pixel region as the output. Suppose the size of the convolution kernel W is $p \times q$, the stride is s , and the input x is an $m \times n$ matrix, and then, the maximum pooling layer is calculated as follows:

$$y(i, j) = \max[x(i \times s + r, j \times s + k)],$$

$$r = 0, 1, \dots, p - 1,$$

$$k = 0, 1, \dots, q - 1, \frac{i \leq (m - p)}{s}, \frac{j \leq (n - q)}{s}.$$

The pooling operation is shown in Figure 3. In Figure 3, max pooling is computed using a filter of size 2×2 with a stride of 2. Comparing the calculation results with the input image, it can be seen that the data are reduced by 75% after the max-pooling layer.

2.1.3. Fully Connected Layer. Each layer of the fully connected layer is composed of many neurons, and each neuron is connected with each neuron in the previous layer to integrate the previously extracted features. The essence of a fully

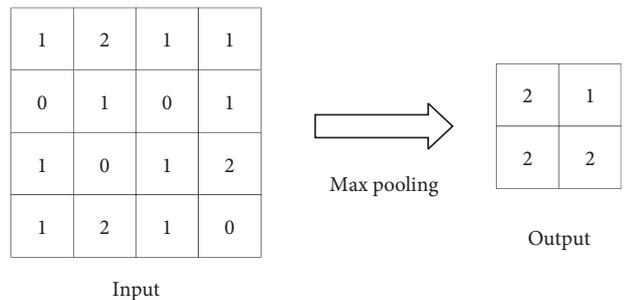

FIGURE 3: Max-pooling operation.

connected layer is to transform one feature space into another feature space. To improve the performance of the neural network, the fully connected layer uses a nonlinear activation function. Due to its own characteristics, the use of fully connected layers can lead to a dramatic increase in the parameters of the model. Therefore, the general convolutional neural network model uses one or more fully connected layers after the convolutional layer and the pooling layer.

2.1.4. Activation Function. In neural networks, activation functions usually refer to functions that can achieve non-linear mapping. The main function of the activation function

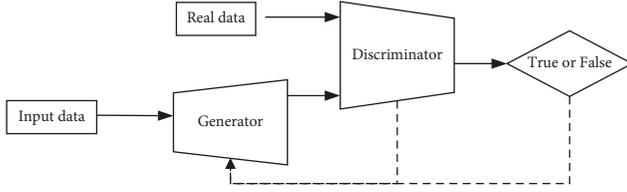

FIGURE 4: Basic model of generative adversarial network.

is to add nonlinear factors, so that the neural network can approximate any nonlinear function and solve the defect of insufficient expression ability of the linear model. Several commonly used nonlinear activation functions are as follows: sigmoid function, tanh function, ReLU function and its variants, and Swish function.

(1) *Sigmoid Function*. The sigmoid function is a common activation function, and its mathematical expression is as follows:

$$f(x) = \frac{1}{1 + e^{-x}}. \quad (3)$$

The sigmoid function can make the output smooth and continuously limited in the range of 0~1, which is close to linear in the region of the input near 0 and nonlinear in the region far from 0. The result tends to be 1 for large positive numbers and 0 for large negative numbers. It is precisely because of the existence of its saturation region that the gradient of the input at both ends of the function is almost 0, causing the gradient to disappear. In addition, because the output value of the sigmoid function is not centered at 0, the model convergence is prone to oscillation during back propagation.

(2) *ReLU Function*.

$$f(x) = \begin{cases} x, & x > 0 \\ 0, & x \leq 0 \end{cases}. \quad (4)$$

The ReLU function is equivalent to $f(x) = \max(0, x)$, the output below the threshold is 0, and the output above the threshold is linearly invariant. Experimental results show that the ReLU function converges 6 times faster than the tanh function [12]. However, ReLU may update the weights to positions that are never activated again due to excessive gradients during training. Also, setting the learning rate too high may cause most of the neurons in the network to not be activated. To solve the possible vanishing gradient of the model due to the negative value problem in ReLU, a series of variants are proposed, such as leaky ReLU [13]. When $x < 0$, the input is multiplied by 0.01 as the output, and the mathematical formula is as follows:

$$f(x) = \begin{cases} x, & x > 0 \\ 0.01x, & x \leq 0 \end{cases}. \quad (5)$$

2.2. Generative Adversarial Networks. Generative adversarial networks (GANs) were first proposed by Goodfellow et al. in 2014 [14]. The generative adversarial network is different from the traditional convolutional neural network. It uses

two neural networks to play a game to train the neural network. GAN consists of a generator and a discriminator. The basic model is shown in Figure 4. First, the generator network generates the corresponding target data from the input data. Then, the discriminant network judges whether the data from the generator network are real or fake after learning the knowledge of the real data. To generate more realistic target data to deceive the discriminator, the generation network needs to continuously optimize its generation ability. The generation network and the discriminant network optimize each other in the process of continuous confrontation and finally make the whole network reach the Nash equilibrium. As the discriminator network approaches the optimal solution, the generator network also approaches the minimum.

Currently, GANs are commonly used in image generation tasks and 3D object reconstruction tasks. The standard GAN objective function can be described as follows:

$$\min_G \max_D V(D, G) = E_{x \sim p_{\text{data}}(x)} [\log D(x)] + E_{z \sim p_z(z)} [\log(1 - D(G(z)))]. \quad (6)$$

2.3. 3D Construction Based on Voxel Representation. At present, in the three-dimensional construction model of the image, the encoding-decoding architecture is generally used. The encoding stage in this architecture can use different encoders, and similarly, the decoding part in the decoding stage can also use different neural network-based decoders. In the decoder stage, the voxel-based 3D decoder decodes the feature vector to generate a 3D shape represented by a voxel. Because of the regular 3D decoder, which needs to convolve each voxel position in the 3D volume, the network computation time and memory need to grow cubically as the resolution at which the 3D volume is generated increases, but the method is robust to input, enabling voxel-based 3D construction methods to reconstruct 3D shapes of arbitrary topologies. Deep learning is a type of representation learning, that is, generating useable representations from data. In the encoding-decoding architecture, the encoder can extract the main low-dimensional representation through learning, and the decoder can generate the required high-dimensional data through the low-dimensional representation. For the 3D construction model represented by voxels, it can be divided into a direct representation decoding model, an intermediate representation decoding model, and other decoding models. In this paper, the decoding model is directly represented, and the specific process is shown in Figure 5.

The network consists of a 2D encoder and a 3D decoder. In general, encoders use 2D convolutional neural networks, while decoders use 3D deconvolutional networks. In the encoding stage, the 2D encoder encodes the input 2D image into a low-dimensional latent vector for feature compression. This practice of compressing the input image from a high-dimensional space to a low-dimensional space is mainly to preserve the main features of the input image to a greater extent, which makes the model parameters

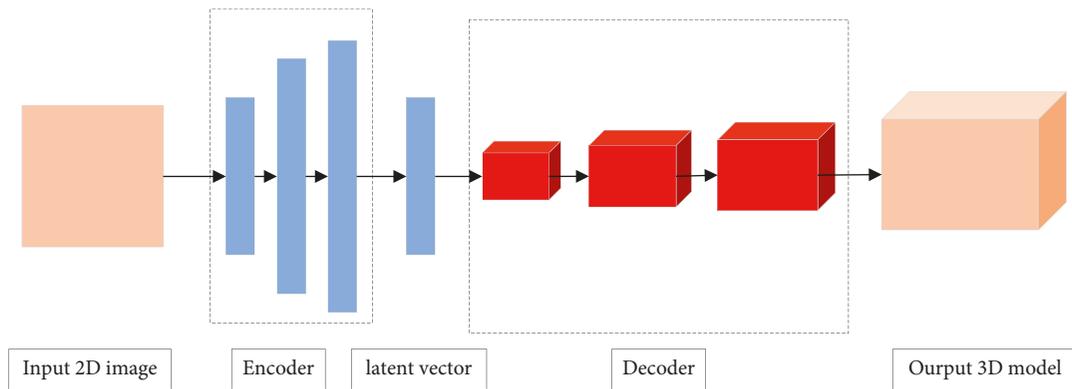

FIGURE 5: Direct representation decoding model.

significantly reduced to fit in the video memory. In the decoding stage, the decoder decodes the latent vectors to generate 3D shapes. Therefore, in short, the 3D construction process of this architecture is to design a 2D encoder to extract image features and then use a conventional voxel decoder to output a 3D shape.

3. System Design

To realize the 3D display system of intangible cultural heritage based on generative adversarial network, this section develops according to the development steps of software engineering standard. Firstly, a detailed demand analysis is carried out for the 3D display system, and then, according to the system design principle, the functional structure of the 3D display system is designed and analyzed, and finally, each functional module is designed in detail.

3.1. System Design Requirements. This paper aimed to complete the three-dimensional display of intangible cultural heritage and contribute to the inheritance and protection of intangible culture. In particular, it has the following significance.

- (1) **Digital Protection of Intangible Cultural Heritage.** In this study, the artistic features of intangible cultural heritage are preserved in the form of three-dimensional digitalization, and the digital protection of intangible cultural heritage is realized.
- (2) **Cultural Heritage Display Application Design Strategy.** There are many theoretical supports and research methods for the current research on client display applications, but these methods are usually generally applicable models. This study narrows the scope of the research and attempts to summarize the design strategies for cultural heritage display applications, for the purpose of this type of application. The design provides reasonable and scientific design ideas.
- (3) **Case Design of Three-Dimensional Display of Intangible Cultural Heritage.** For the purpose of education, the sample case of intangible cultural heritage display application is realized, aiming to achieve a better user

experience, users are enabled to have a systematic and comprehensive understanding of intangible cultural heritage, and users are allowed to have a stronger understanding of traditional cultural interest, to achieve better protection of traditional culture and improve the effect of cultural transmission.

3.2. System Design Principles. When designing the three-dimensional display system for intangible cultural heritage, we follow the following principles in system development.

The first is the abstract principle. Abstraction refers to the simplification of complex phenomena, which must be simplified to the extent that it is convenient for people to analyze and understand.

The second is the encapsulation principle. The encapsulation principle is a rule that developers must use when developing the system structure. Each individual program component needs to be encapsulated into a single and independent module, and the module's internal processing logic details are exposed as little as possible when defining a module. It is necessary to require that each module can be independently developed and tested, and the final complete program is assembled from a series of sub-module programs. The principle of encapsulation can greatly improve the modifiability, testability, and portability of the system.

The third principle is the principle of independence between modules. The independence between modules means that any relatively independent subsystem program is completed by an independent module, and the connection between this module and other modules must be achieved very simply. Two standards are commonly used in the industry to measure the independence between modules: cohesion and coupling. Cohesion is a measure of how closely each element is related to each other within each module. The coupling measures the degree of independence between each module, which mainly depends on the interface information type and interface complexity provided by each module and the way to call the module.

3.3. System Structure Design. The key to realizing the dance generation application based on generative adversarial network lies in the patch-based pixel generation in the

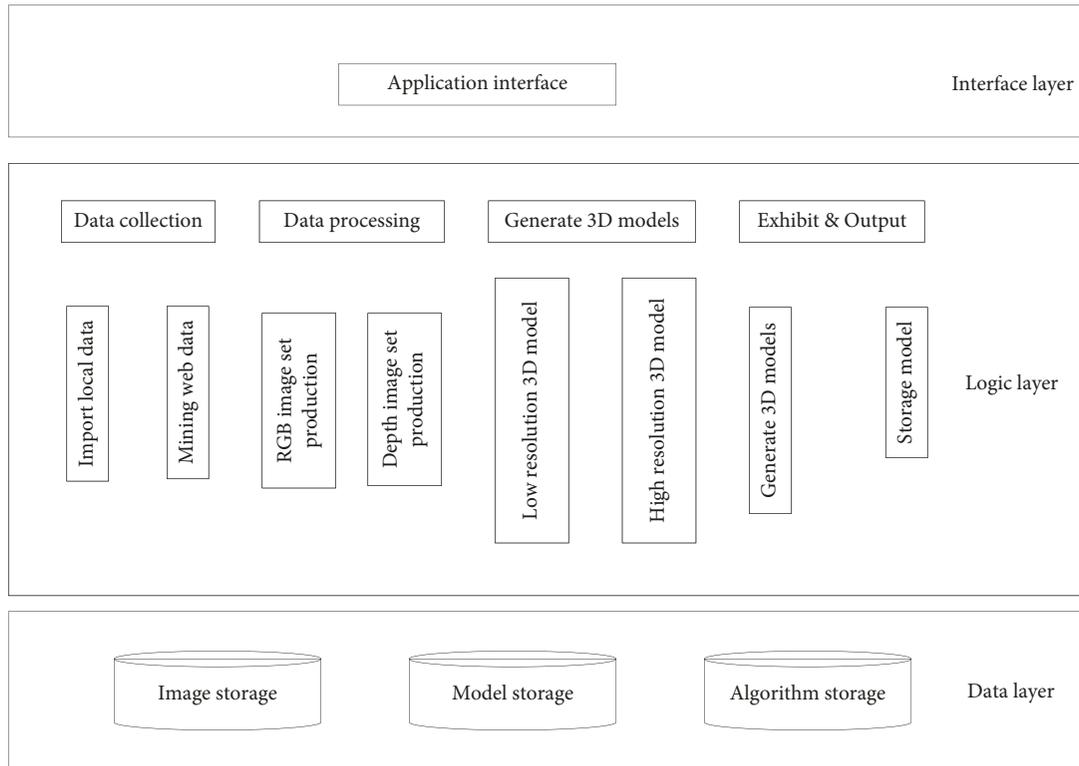

FIGURE 6: Overall structure of the three-dimensional display system of intangible cultural heritage.

generative network and the multiscale image discrimination in the discriminant network and the final loss function design. The overall structure of this application is shown in Figure 6.

3.3.1. Interface Layer. The interface layer is mainly used for the interaction between the user and the system, and all functions need to be as simple as possible. This application interface mainly includes various controls and view modules, such as select video button, display video view, generate dance button, and text prompt view. The application interface will directly display the original dance video and the generated dance video to the user, compare the synthesis effect, and generate corresponding indicator descriptions. Simple and elegant interface design will bring users a good user experience.

3.3.2. Logic Layer. The logic layer is often the core of the entire application system, including the realization of core functions and the connection between the upper and lower layers. The main functions include reading local images or mining data from Web pages. Collecting data are an essential function for generating models; in addition, the system needs to call other open-source projects to make RGB image sets and depth image sets; more importantly, inputting RGB images and depth images into the trained generative model to obtain the target 3D model is the core of the system application; finally, the system displays the generated 3D model to the user.

3.3.3. Data Layer. The data layer is mainly used to store and read data, including image storage, algorithm storage, and model storage.

3.4. System Function Design. This section mainly focuses on the module design of this application, including the overall module design of this application and the detailed design of each module. The functional structure diagram of the system is shown in Figure 7.

This application is mainly divided into four modules according to the system implementation framework, mainly including input module, data processing module, 3D model generation module, and model output module. This section focuses on the data processing module and the 3D model generation module.

3.4.1. Image Set Production Module. In the task of 3D reconstruction of images, one of the keys for deep learning to exert its powerful learning ability is to establish relevant data sets for training. The establishment of the data set is the basis for the 3D construction of the entire model. The data set in this paper mainly refers to the MVD method [15] in the production process. At present, there is no public 3D Nuo mask model of the Maonan people at home and abroad. The only way to solve the data set problem is to use a 3D scanner to collect scans in the field. A total of 36 Maonan Nuo masks were collected by visiting the Huanjiang Maonan Autonomous County Museum in Hechi, and a 3D voxel library and a 2D database were created by scanning.

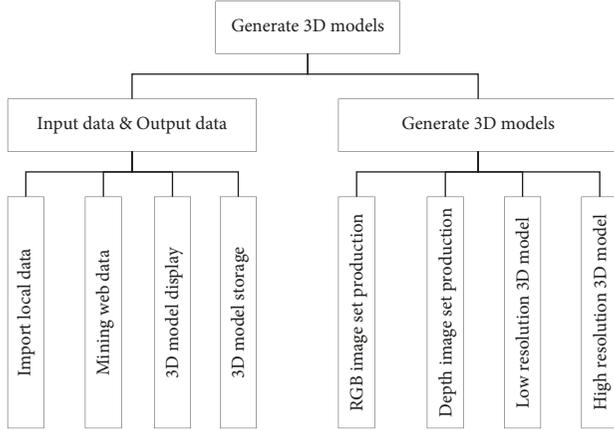

FIGURE 7: Functional module division.

3.4.2. Low-Resolution Reconstruction Module. This module adopts a multifeature fusion method, first generates a 3D model as the initial reconstruction result, and then optimizes the 3D encoding-decoding network to generate a low-resolution Nuo surface voxel 3D model.

- (1) 3D model construction
- (2) Loss function

To train the model to generate better 3D shapes, a suitable loss function is required. The loss function of the model is defined as the L_2 loss between the reconstructed 3D object and the real 3D object. The loss function can be defined as follows:

$$L_2 = \|\text{Pred}_x - GT_y\|_2^2. \quad (7)$$

- (3) Training method

This paper uses a 128×128 RGB image as input, and the final output resolution of the network is a voxelized 3D shape of $64 \times 64 \times 64$. This article implements a NVIDIA GTX 1080 with a Dell desktop as the hardware platform and 8G of GPU memory. In addition, the software platform installs TensorFlow on Ubuntu 16.04 and utilizes GPU acceleration to train the network. To fit into the GPU memory size, the training batch size of the single-shot network is 32. The training process uses the Adam optimizer with $\beta_1 = 0.5$ and $\beta_2 = 0.9$ in the optimization parameters. Meanwhile, the initial learning rate is set to 1×10^{-4} , and the network is trained for 300 epochs. Then, training is fine-tuned for another 50 epochs. For the secondary optimization multifusion reconstruction model, the pretrained model first generates a 3D volumetric surface with a resolution of $32 \times 32 \times 32$, and then, the network model parameters are fixed and sent to the 3D encoding-decoding network for secondary optimization. A 3D Nuo surface with a resolution of $64 \times 64 \times 64$ is allowed. Other training parameters remain the same as other network training parameters.

3.4.3. High-Resolution Reconstruction Module. This module uses a generative adversarial network to obtain a high-resolution Nuo surface voxel 3D model. The image super-resolution method based on the generative adversarial network can reconstruct a more natural super-resolution image, which is mainly due to the two networks adopting the idea of confrontation, that is, using the two opposing sides to play a game against each other. First, the low-resolution images are reconstructed into super-resolution images through a generator network. Then, the discriminator compares the input super-resolution image with true and false sexual judgments. Subsequently, the discriminated results are returned to the optimized generator network and discriminator network. Repeatedly, the final generator network and discriminator network complete self-optimization in mutual confrontation. Early SRGANs were implemented on the basis of standard generative adversarial networks (SGANs). The discriminator loss and generator loss of this network are as follows:

$$\begin{aligned} L_{\text{SGAN}_D} &= -\log(D(I^{HR})) - \log(1 - D(G(I^{LR}))), \\ L_{\text{SGAN}_G} &= -\log(D(I^{HR})). \end{aligned} \quad (8)$$

The binary cross-entropy loss function adopted by the SGAN model has the property of unstable training. How to balance the training of the generator and the discriminator is a problem. To this end, some research works try to improve SGAN [16] with other loss functions, for example, relative GAN loss function. Inspired by these works, we also try to improve its network structure and loss function based on SRGAN. Next, we introduce an improved generative adversarial network image super-resolution model.

- (1) Improved Generative Adversarial Network Super-Resolution Model. The improved generator network is shown in Figure 8. First, we replace the FEB in the feature extraction module (FEM) from the residual dense block of the SRGAN model to a multiresidual dense block. Through the improved multiresidual dense block, more features are reused in the image feature extraction stage and a deeper network is designed. After the features of the image are extracted, two sets of convolution and image sub-pixel convolution operations are performed to generate a fourfold super-resolution image. The multiresidual dense block with batch normalization layer is used.

The improved discriminator network is shown in Figure 9. Recent experiments [17] show that strided convolutional layers in the discriminator network lead to reduced resolution of the generated feature maps. Ultimately, this causes the super-resolution images generated by the model to lose details. Therefore, we adopt the same improvement and set the stride size to 1 for all strided convolutions. To make the model fit in memory for training, we change the number of output feature maps for each layer to the amount shown in Figure 9. The other

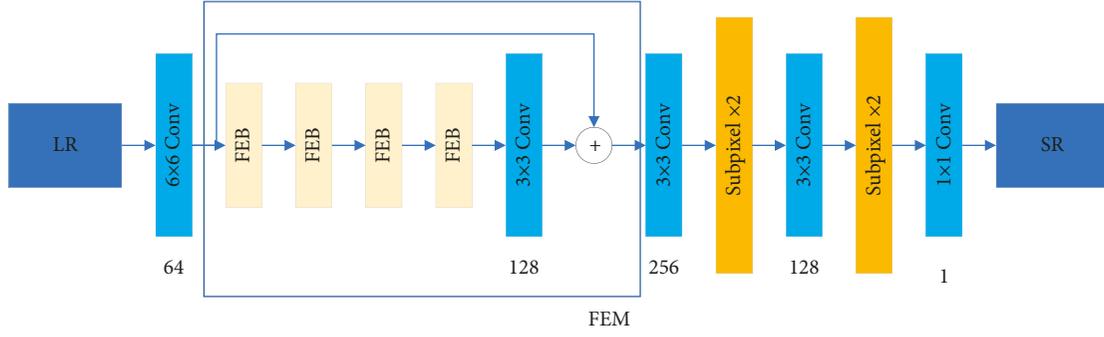

FIGURE 8: Improved generator network.

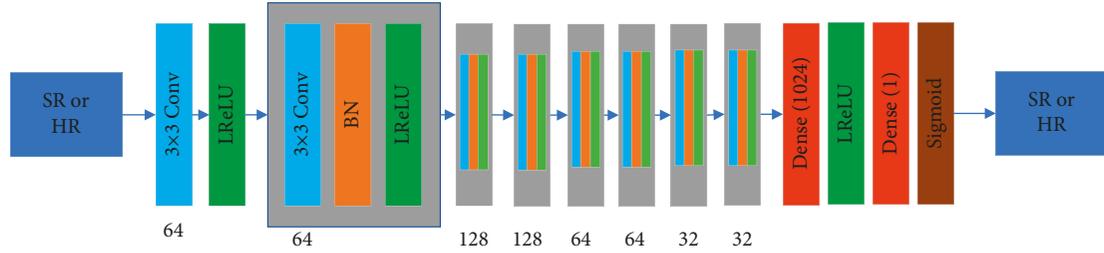

FIGURE 9: Improved discriminator network.

structures of the discriminator network remain unchanged from those in SRGAN.

(2) Loss function

The loss function of the generator consists of three parts: L_1 content loss, perceptual loss LVGG, and relative average adversarial loss LRa_G. The loss function can be expressed as follows:

$$L_G = \alpha L_1 + \beta L_{VGG} + \gamma L_{Ra-G}. \quad (9)$$

Among them, α , β , and γ represent the coefficients used to balance the overall loss, which are taken as 1, 10^{-3} , and 2×10^{-6} , respectively, in the experiment. LVGG calculates the loss in the feature space of super-resolution images and high-resolution images. To ensure that the reconstructed image is structurally similar to the real image, we use pixel-based L_1 content loss. The L_1 loss computes the 1-norm distance between the generated super-resolution image $G(I^{LR})$ and the true high-resolution image I^{HR} . This loss function can be expressed as follows:

$$L_1 = G(I^{LR}) - I_1^{HR}. \quad (10)$$

In the SGAN training process, when training the generator, the real data samples are not used in the loss function, which means that the optimization of the entire generator is entirely guided by the discriminator. In the relative GAN, the loss function of the generator uses real data samples as a reference. Furthermore, in SGAN, the model is forced to recognize real samples as real and fake samples as fake. In the relative GAN, the real and fake samples are mixed and the discriminator is used to judge the real and the fake. This method is more stable for GAN training to a certain extent. In addition, it also has a faster advantage in training speed.

The generator loss function and discriminator loss function relative to GAN are expressed as follows:

$$\begin{aligned} L_{G-Ra} &= -E_{I^{HR}} \left[\log(1 - D_{Ra}(I^{HR}, G(I^{LR}))) \right] \\ &\quad - E_{I^{HR}} \left[\log(D_{Ra}(G(I^{LR}), I^{HR})) \right], \\ L_{D-Ra} &= -E_{I^{HR}} \left[\log(D_{Ra}(I^{HR}, G(I^{LR}))) \right] \\ &\quad - E_{I^{LR}} \left[\log(1 - D_{Ra}(G(I^{LR}), I^{HR})) \right]. \end{aligned} \quad (11)$$

4. System Implementation and Testing

4.1. System Development Environment. The training and generation of this application are run on the server, and the runtime development environment configuration is shown in Table 1. For the core algorithm, a large amount of video memory is required. This time, 8 Tesla P100 GPUs are used for training, and the training time is 5×24 hours. Since the system model needs to be trained for a long time, the displayed samples are all models trained in advance.

4.2. System Application Test

4.2.1. Low-Resolution Nuo Surface Voxel 3D Construction Based on Multifeature Fusion. The training details between the traditional 3D reconstruction model, the multi-fusion 3D reconstruction model, and the quadratic optimization multi-fusion 3D reconstruction model are set according to Section 4. By comparing the parameter sizes of different models, we can know the degree of GPU memory required by different models, which can determine whether the model can meet the hardware conditions to a certain extent. In

TABLE 1: System development operating environment.

	Program language: Python 3 GUI: PyQt5

addition, the training time of different 3D reconstruction models is also an important indicator to measure the performance of a model. In Table 2, the single iteration time between different models and the parameter sizes of the models is listed. As can be seen from Table 2, the number of model parameters between the improved model and the traditional 3D reconstruction model is not much different, and the parameters of the multi-fusion feature fusion model are 0.1 M more. However, the multi-fusion 3D reconstruction model has greatly improved the single iteration time, and the speed is 1 time faster than that of the traditional 3D reconstruction model. The iteration time and model parameters of the secondary optimized multi-fusion 3D reconstruction model include the iteration time and model parameters of the pretrained multi-fusion 3D reconstruction model. The second optimization of the multi-fusion 3D reconstruction model in a single network training is not much different from other model parameters, but it is more time-consuming than other models in terms of iteration time. In the experiment, the traditional 3D reconstruction model takes 10 hours, while the improved multi-fusion 3D reconstruction model takes only a few hours. Using 3D deconvolution to generate a higher-resolution 3D object from a lower-resolution 3D object requires more computation time. However, rearranging multiple low-resolution 3D objects to form a higher-resolution 3D object will save computational overhead.

The rendered images in the test set are directly used as the input of the low-resolution Nuo surface 3D construction model, and a 3D Nuo surface with a resolution of $64 \times 64 \times 64$ is output. The 3D reconstruction results of different models are shown in Figure 10. Figure 10(b) is the low-resolution 3D shape generated by the traditional 3D reconstruction model, Figure 10(c) is the low-resolution 3D shape generated by the multifeature fusion 3D reconstruction model, and Figure 10(d) is the low-resolution 3D shape generated by the quadratic optimization of the multifeature fusion 3D reconstruction model. As can be seen

from Figure 10, the overall reconstruction results on the rendered image in Figure 10(b) compared with Figure 10(c) and Figure 10(d) are not much different. However, due to the low reconstruction resolution, these reconstruction results cannot show the required details, and only rough contours can be reconstructed. Comparing the reconstruction results of different models with the real 3D structure shown in Figure 10(d), there is not much difference in appearance. However, in terms of details, the improved models proposed in this paper can achieve better visual effects than the traditional 3D construction models. The experimental results show that the proposed 3D construction model can preliminarily complete the generation of corresponding 3D shapes from a single Nuo surface image.

Using IoU as an evaluation metric is used to measure the quality of the generative model. IoU measures the degree of overlap (intersection-over-union ratio) between the reconstructed model and the real model and takes a value from 0 to 1. The higher the IoU calculation result, the closer the reconstructed model is to the real model. The IoU value was calculated on the test results of each model. The IoU is calculated as follows:

$$IoU = \frac{\sum_{i,j,k} [I(x_{(i,j,k)} > t)I(y_{(i,j,k)})]}{\sum_{i,j,k} [I(x_{(i,j,k)} > t) + I(y_{(i,j,k)})]} \quad (12)$$

The results are shown in Table 3. The fully improved multifeature fusion 3D reconstruction model is better than the traditional 3D reconstruction model and can achieve better performance. From the perspective of model reconstruction accuracy, the quadratic optimization multi-fusion 3D construction model proposed in this paper can achieve considerable improvement and can increase the reconstruction accuracy rate by about 6.3%. Therefore, different comparative experiments show the superiority of the model proposed in this paper in 3D reconstruction of the Nuo surface.

4.2.2. 3D Construction of High-Resolution Nuo Surface Voxels Based on Generative Adversarial Networks.

Low-Resolution Results from the Previous Module. The network training period is set to 100, and other parameter settings of the network are the same as above. The generator is pretrained with pixel-based loss. The pretraining method can ensure that the generator can obtain images with better visual quality from the beginning. This way of pretraining avoids the need for the discriminator to discriminate on irrelevant generated images at the beginning, but allows the discriminator to focus on the details of the reconstructed image. The comparison results of the depth map super-resolution experiment based on the GAN method are shown in Figure 11. GAN-based image super-resolution methods do not look visually different from multiresidual dense methods. This may be due to the fact that the reconstructed image is a depth map, and the differences between each local depth image are subtle and not obvious on the reconstructed depth image. However, the calculation results on the PI score show that the improved GAN-based image super-resolution

TABLE 2: Comparison of the single iteration time and model parameters of the improved 3D.

Model	Iteration time (s)	Model parameters (M)
Traditional 3D reconstruction model	0.4	27.0

MFF + ESPCN-3D	0.736
MFF + ESPCN-3D_2	0.791

method can achieve lower perceptual scores. This shows that GAN-based methods are able to generate more realistic depth images overall. However, it also needs to be seen that there is still a big gap between the smaller details and the real depth image based on the GAN method.

Figure 12 shows the comparison results of the improved 3D Nuo surface high-resolution reconstruction results in this section and the quadratic optimization, multifusion, and multiresidual dense 3D Nuo surface high-resolution method proposed in Section 3. As can be seen in Figure 12, the GAN-based approach looks similar to the multiresidual dense approach overall. However, in terms of the local details of the generated Nuo surface depth map, the GAN-based method can reconstruct more Nuo surface details. In addition, it is also necessary to see that the multiresidual dense depth map super-resolution method adopts the mean square error loss function, and the depth map generated by this loss function is smooth on the whole. Therefore, the reconstructed 3D Nuo surface is smooth as a whole. However, the

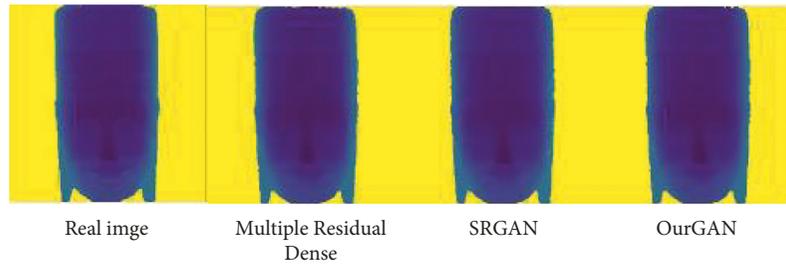

FIGURE 11: GAN-based image super-resolution comparison results. (a) Real image. (b) Multiple residual dense. (c) SRGAN. (d) OUR-GAN.

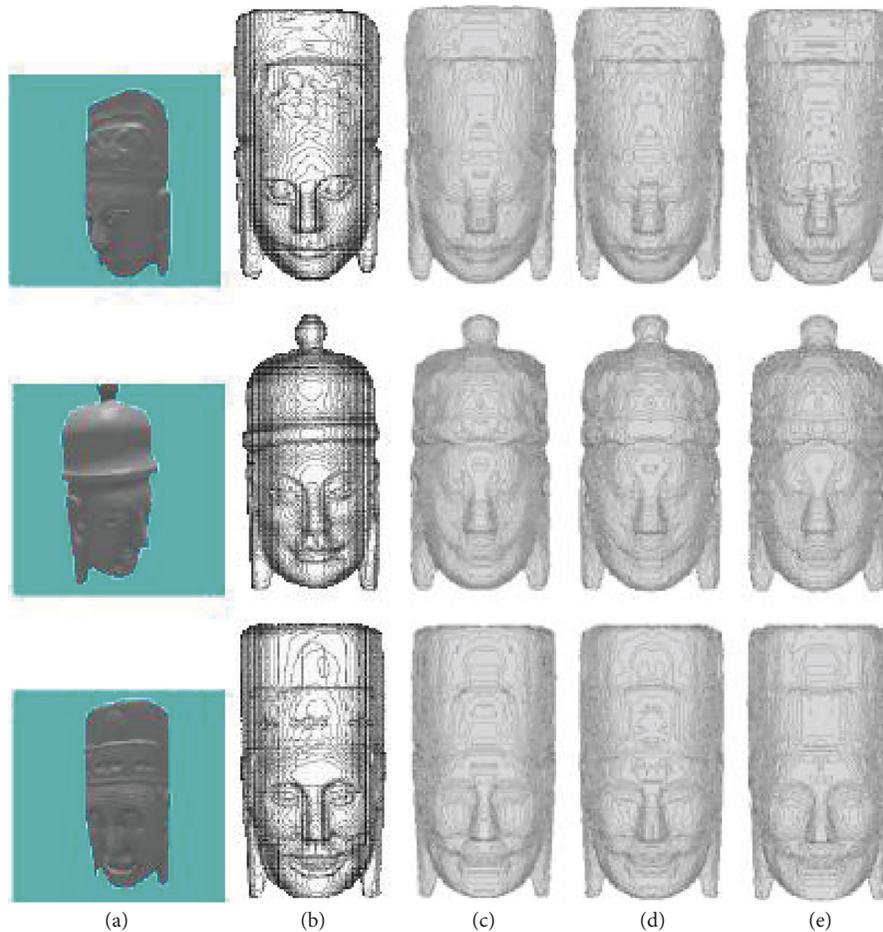

FIGURE 12: High-resolution comparison results of 3D Nuo masks based on GAN: (a) input; (b) real shape; (c) multiresidual dense method; (d) SRGAN method; (e) OUR-GAN method.

surface of the 3D Nuo surface generated by the GAN method is relatively rough, mainly because the super-resolution depth map generated by the GAN method is also prone to image artifacts when generating more realistic surface details.

5. Conclusion

The main research content of this paper is the design of a three-dimensional display system for intangible cultural

heritage based on generative adversarial networks. The system function is realized through four modules: input module, data processing module, 3D model generation module, and model output module. Through two 3D model reconstructions, the three-dimensional display of intangible cultural heritage is realized.

This paper takes the Nuo surface as the research object and tests the function of the system. In the low-resolution 3D construction of the Nuo surface, the reconstructed Nuo surface is relatively rough due to the low resolution. This

makes it difficult to show the details of the reconstructed 3D Nuo surface in appearance. Multiresidual dense blocks are introduced and applied to the depth image super-resolution network. At the same time, a perceptual loss function is applied, which combines the advantages of residual blocks and dense blocks to make the output depth image more realistic. The experimental comparison results show that our proposed multiresidual dense high-resolution Nuo surface voxel 3D construction model can achieve better performance. The quadratic optimization multi-fusion 3D construction model proposed in this paper can achieve considerable improvement and can improve the reconstruction accuracy by about 6.3%.

Inspired by the SRGAN model's ability to generate images with more high-frequency details, we also use generative adversarial networks for high-resolution Nuo surface voxel 3D construction. To be able to further improve the performance of GAN-based image super-resolution, we improve its generator, discriminator, and loss function on the original SRGAN. Experimental results show that this method can generate super-resolution images with more realistic and natural depth maps. In addition, when it is used for high-resolution 3D Nuo surface sculpting, it can also generate 3D voxel Nuo surfaces with more details.

Based on the medium-resolution Landsat TM and OLI satellite images in the study area, the deep learning ENVINet-5 model is adopted for vegetation coverage monitoring. By referring to the fusion image and Google Earth high-resolution satellite image, the training samples and verification samples are manually labeled, and the labels of four types of ground objects (desert, water body, cultivated land, and construction land) are made. Through the ENVI deep learning binary classification model, the labeled training samples are trained, and a large number of samples of desert, water, and cultivated land are extracted and transformed into corresponding label images. Then, a large number of training sample labels extracted from the model are combined with the manually made construction land sample labels and both of them are used as the training samples of the ENVI deep learning multiclassification model. According to the classification process of the deep learning model (creating label image, initializing training model, and training model and model classification), through the adjustment of various parameters, the four types of ground objects in the study area are finally classified. Finally, the classification results that meet the accuracy requirements are statistically analyzed. It is proved that the model classification results can meet the use requirements.

1. Introduction

Desertification is an important factor threatening human survival and sustainable development in the 21st century. How to effectively prevent and mitigate desertification is the focus and hotspot of current research [1–4]. Land desertification seriously reduces the carrying capacity of the ecological environment, and the area and degree of desertification land are rapidly expanding, which seriously restricts the sustainable development of society [5]. Monitoring vegetation coverage and rocky desertification and timely and accurate assessment of the current situation and changes in desertification will help to formulate global actions to prevent and eliminate desertification [6–8].

The traditional desertification research mainly adopts the artificial field mapping method, which has the disadvantages

of time-consuming, laborious, and low efficiency in the implementation process [7]. With the emergence of remote sensing technology [9–11] and vigorous development of information technology [12–18], its macro-, objective, and economic advantages make up for the shortcomings of traditional desertification research to a certain extent, so it can better deal with environmental change monitoring [16–18]. On the other hand, with the development of computer technology, the machine learning method [19–21] is widely used in the classification and extraction of remote sensing images. It can better extract the ground features in the image. Especially in recent years, the emergence of deep learning has greatly improved the technical means of image processing. Rapid and accurate feature classification of a large amount of data can better adapt to the development of society and meet the needs of human production and life.

As a complex form of machine learning, deep learning can make the system automatically discover the feature expression of data. Compared with other machine learning types, it can continuously improve the prediction accuracy without external guidance or intervention, and draw conclusions through multilayer learning in neural networks. For the processing of remote sensing images, deep learning attempts to discover and use the spatial, spectral, and statistical features of remote sensing images. In view of this, a vegetation coverage and rocky desertification monitoring method is proposed based on deep learning in this study, so as to provide a scientific basis and data basis for ecological environment monitoring and sandy vegetation restoration in desertification areas.

2. Methods

2.1. Deep Learning Model Architecture. The ENVINet-5 model is developed based on TensorFlow deep learning framework. The model architecture is based on the improvement of the U-NET neural network, which is similar to the U-NET architecture. It is a mask-based and encoder-decoder architecture. Combined with the powerful remote sensing image processing software ENVI, researchers can directly use the deep learning network to process remote sensing images.

This study uses the ENVINet-5 deep learning module to classify the ground objects in Landsat medium-resolution satellite images in the study area [22, 23]. The ENVINet-5 model architecture has 5 levels and 27 convolution layers, and each level represents different pixel resolutions in the model. We input the original image into the model, slice it, and then use a 3×3 convolution layer to convolute the slice, so as to increase the number of image features. We use a 2×2 pooling layer to reduce the size of the image, so as to reduce the operation and retain most of the features of the image. The sampling process is divided into upsampling process and downsampling process. We recognize and classify many features generated in the downsampling process, so as to achieve the purpose of feature classification.

After the remote sensing image is loaded into the deep learning network, the convolution operation will be carried out after slicing. Convolution is essentially to extract the features in the image and generate feature images with different dimensions, which are often composed of multiple convolution kernels of different sizes. The size of the commonly used convolution kernel is 3×3 and 5×5 . In this study, the convolution kernel size of a deep learning network is 3×3 . In addition, the function of activation function is indispensable in convolution operation. The activation function can better solve the gradient disappearance problem, simplify the computational complexity, speed up the training speed, and reduce the burden of computer operation. In convolution operation, the rule activation function is often used. As a nonlinear activation function, it can better solve the problem of overfitting in training.

After the convolution operation, a large number of feature images will be generated. If the convolution operation is carried out again, the amount of operation will be

greatly increased. Therefore, it is necessary to reduce the amount of computation and retain more feature information of the generated feature image. The appearance of the pooling layer solves this problem better. Common pooling methods include mean pooling and max pooling. In this study, max pooling is used, and the window size is 2×2 . It can not only extract the main features but also reduce the amount of computation. After pooling, the feature image size is reduced to half of the original size.

In addition, the loss function is introduced into the deep learning network, which can map values to non-negative space. When the value of the loss function is smaller, it means that it is closer to the real value. Therefore, the classification effect of the model can be quantitatively evaluated and optimized. The commonly used loss functions include root mean square error, cross-entropy loss, and so on.

2.2. Deep Learning Model Parameters

2.2.1. Epochs and Batches. In order to make the training model achieve better classification results, the number of training iterations (epochs) needs to be adjusted. In ENVI deep learning, the number of iterations (epochs) represents that the model intelligently extracts the number of slices (batches) from the label image. Because there is bias judgment when extracting slices, an epoch refers to the number of slices trained before bias judgment adjustment.

The determination of the number of epochs and the number of extracted slices has certain randomness, which depends on the diversity of learning feature sets. In ENVI deep learning, the number of iterations is generally set between 16 and 32. For the number of patches per epoch, the number of slices extracted by each epoch determines the training amount of the model, which is usually set between 200 and 1000.

The model will use multiple slices at the same time in an iterative training. Batch refers to a group of slices read in an iterative training. Batches run in an iterative training and stop after reaching or exceeding the total number of slices. The number of slices in a group needs to be set according to the size of GPU video memory.

2.2.2. Class Weight and Loss Weight. The ENVI deep learning network uses the statistical technology of inverse transform sampling to train the model based on slice deviation selection. By introducing a deviation, the model can see the slices of highlighted feature pixels more often. In inverse transform sampling, the samples introduced into the model are directly proportional to their contribution to the probability density function. The deviation is controlled by the class weight parameter in the Train TensorFlow Mask Model tool. The value range of the class weight parameter is 0 to 2 (when the maximum value is set for the sparse training set, the valid range of the maximum value is 0 to 6).

The loss weight parameter is used for the deviation loss function, focusing on the correct identification of characteristic pixels and reducing the identification of background

pixels. Parameters are useful when the distribution of feature targets is sparse. A value of 0 indicates that the model treats the feature and background pixels equally. Increasing the value of the loss weight parameter will bias the loss function to find the characteristic pixels. The valid range of parameter values is 0 to 3.

2.2.3. Solid Distance and Blur Distance. In the process of model training, in addition to the weight of features and background pixels, the size and edge of features must also be considered. The solid distance parameter is often used to expand the size of linear or point features. The parameter value size represents the number of pixels around the marked ROI, which forms the target feature together with the ROI.

In deep learning, the setting of blur distance helps the model to obtain the sharp edge of the target. By setting the fuzzy edge and gradually reducing the fuzzy value in the model training, the model is close to the sharp feature of the target. In the ENVINet-5 model, the value range of blur distance is 0 to 70.

2.3. Deep Learning Model Extraction Process. The ENVINet-5 is defined by basic neural network parameters. To extract target, it is necessary to create a label raster that can indicate the target and then use the label sample to train the model. The label image can be created jointly with the tools ROIs and Deep Learning/Build Label Raster from ROI, and then, the label sample is used to train the model. The trained model can find targets with similar features in other images. The extraction result is a class activation map/raster, in which the DN value represents the probability that the pixel belongs to a certain ground object target. The deep learning training model involves the adjustment of parameters and has a certain degree of randomness. Due to the convergence mode of the algorithm, different models will be obtained even if the parameters in the training are the same. The extraction process is shown in Figure 1.

2.3.1. Create Label Image. For target recognition, label rasters need to be created to train the model. Based on the original image to be classified, through field investigation, sample site selection or, combined with a high-resolution image as reference, we establish proprietary identification marks for different ground objects, so as to create label images. In order to generate high-quality label images, representative samples of typical areas should be selected.

First, we select the object of interest in the typical area to create ROI. The ROI drawn should contain a variety of surface features such as shape, color, and texture, which is conducive to improving the classification accuracy of the model.

Finally, we use the Deep Learning/Build Label Raster from ROI tool in the ENVI toolbox to create label images. The tag image contains the original band and mask band of the input image. Different DN values of the mask band represent different types of ground objects.

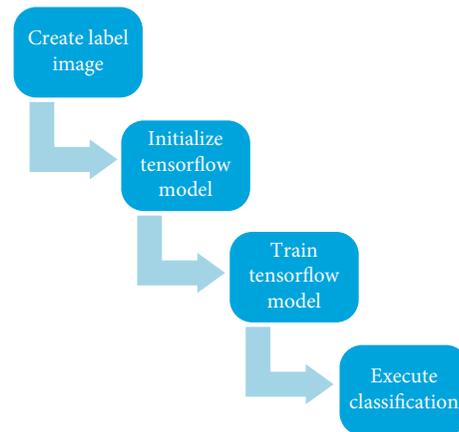

FIGURE 1: The extraction process.

2.3.2. Initialize TensorFlow Model. In ENVI, we select the Deep Learning/Train TensorFlow Mask Model tool. Before deep learning model training, it is needed to initialize or load a TensorFlow model. Model initialization needs to define model parameters, including patch size, number of bands used for training, and saving path.

2.3.3. Train TensorFlow Model. After model initialization, various parameters and weights need to be set in the train TensorFlow mask model to guide TensorFlow model to learn target features.

In the training process, the label image is repeatedly exposed to the model. The model learning converts the spectral and spatial information in the label image into a class activation gray image to highlight the extracted target. Through the loss function, the model can know the wrong random guess results. Through the adjustment of internal parameters or weights of the model, the model is more accurate. The trained TensorFlow model can find the same features in other images.

2.3.4. Execute Classification. We use the trained model to search for the same ground feature in other images and use TensorFlow Mask Classification tool to classify and extract remote sensing images.

2.4. Remote Sensing Monitoring of Vegetation Coverage. Vegetation coverage refers to the percentage of the vertical projection area of vegetation on the ground in the total area of the statistical area. It is of great practical significance to analyze and evaluate the regional ecological environment by obtaining the regional surface vegetation coverage and revealing the change and dynamic change trend of surface vegetation in the region. The vegetation index method has little dependence on surface measured data, has universal applicability, and can be extended to a wide range of areas. It is a reliable means to quantitatively monitor the change in vegetation cover.

The calculation formula for normalized vegetation index is as follows:

$$NDVI = \frac{(NIR - RED)}{(NIR + RED)}, \quad (1)$$

where NIR is the near-infrared reflectance of remote sensing image, and RED is the infrared reflectance of remote sensing image.

Vegetation coverage retrieved by normalized vegetation index is as follows:

$$VFC = \frac{(NDVI - NDVI_s)}{(NDVI_v - NDVI_s)}, \quad (2)$$

where $NDVI_s$ is the NDVI value of bare soil or non-vegetation coverage area, and $NDVI_v$ is the NDVI value of pure vegetation pixel.

$$NDVI_s = \frac{(VFC_{max} * NDVI_{min} - VFC_{min} * NDVI_{max})}{(VFC_{max} - VFC_{min})},$$

$$NDVI_v = \frac{((1 - VFC_{min}) * NDVI_{max} - (1 - VFC_{max}) * NDVI_{min})}{(VFC_{max} - VFC_{min})}, \quad (3)$$

where $NDVI_{max}$ and $NDVI_{min}$ are the maximum and minimum NDVI values in the study area. Because noise is inevitable, the value within a certain confidence interval is generally taken, and the confidence interval is determined according to the actual situation of the image.

Furthermore, it can be converted into the following:

$$VFC = \frac{(NDVI - NDVI_{min})}{(NDVI_{max} - NDVI_{min})}. \quad (4)$$

Therefore, the data of different vegetation coverage levels in each period of the study area can be obtained.

2.5. Deep Learning Model. Based on the U-shaped neural network structure, we use the means of jump connection to make the output UAV image features of each decoding layer in the decoder corresponding to the encoder (the image size is the same). Each decoding layer is an interworking structure, which makes full use of the image features extracted by all coding layers in the encoder. Compared with the traditional neural network deep learning model based on encoder-decoder, it can get more accurate results under a small amount of training data. The specific model framework is shown in Figure 2.

As can be seen from Figure 2, the encoder part of the model is designed with four coding layers and two convolution layers, and the decoder is composed of four decoding layers and one softmax layer, in which the activation function used by the model is ReLU function. The specific steps are as follows: input the remote sensing HD image data into the encoder, extract the features through the encoder, and output the feature images with the size of $I/2$, $I/4$, $I/8$, and $I/16$ (I represents the image size), with the numbers of 16, 32, 64, 128, and 256, respectively. Then, the feature images output by the encoder are analyzed by the decoder and the image segmentation results with the size of I are output, that is, the divided vegetation coverage area (the result output is white) and nonvegetation coverage area (the result output is black), so as to calculate the vegetation coverage of different typical sample plots.

3. Experiment and Analysis

This research mainly applies the computer to test. The computer system is Windows 1064 bit professional version, the processor model is Intel Core i7-9750h, the graphics card model is NVIDIA GeForce GTX 1050, the memory size of the solid-state disk is 512 g, and the memory size is 8 g. The computer is loaded with the remote sensing image processing software ENVI 5.5, in which the deep learning binary classification model and multiclassification model are installed for the binary classification and multiclassification of ground objects, respectively.

In the process of training model, the label image is needed to mark the training target so that the ground object categories can be distinguished in the neural network. We use the region of interest tool in ENVI to manually draw or import the existing vector data. At present, the deep learning two classification model supports single-class target extraction. In view of the need for a large number of training samples for deep learning, and according to the actual distribution of features in the study area, label images are made for deserts, water bodies, and cultivated land in the study area. After model extraction, a large number of samples can be provided for the deep learning multiclassification model.

The study selects the deep learning binary classification model in ENVI and uses ENVI Net-5 to extract desert, water, and cultivated land from some label samples. Due to the small area occupied by the construction land, it is manually selected with reference to the high-score image. Then, the extracted three types of features and construction land are made into multiclassification label samples as the training and verification samples of the deep learning multiclassification model. Figure 3 shows a partial screenshot of the desert, water, and cultivated land label images.

After the image label is made, the model needs to be initialized. We need to define model parameters, including patch size, the number of bands used in training, and output path. The slice size of this test is set to 300×300 pixels, which cannot be greater than the number of pixels with the minimum side length of the cropped subregion, and the number of bands is set to the number of bands of the original

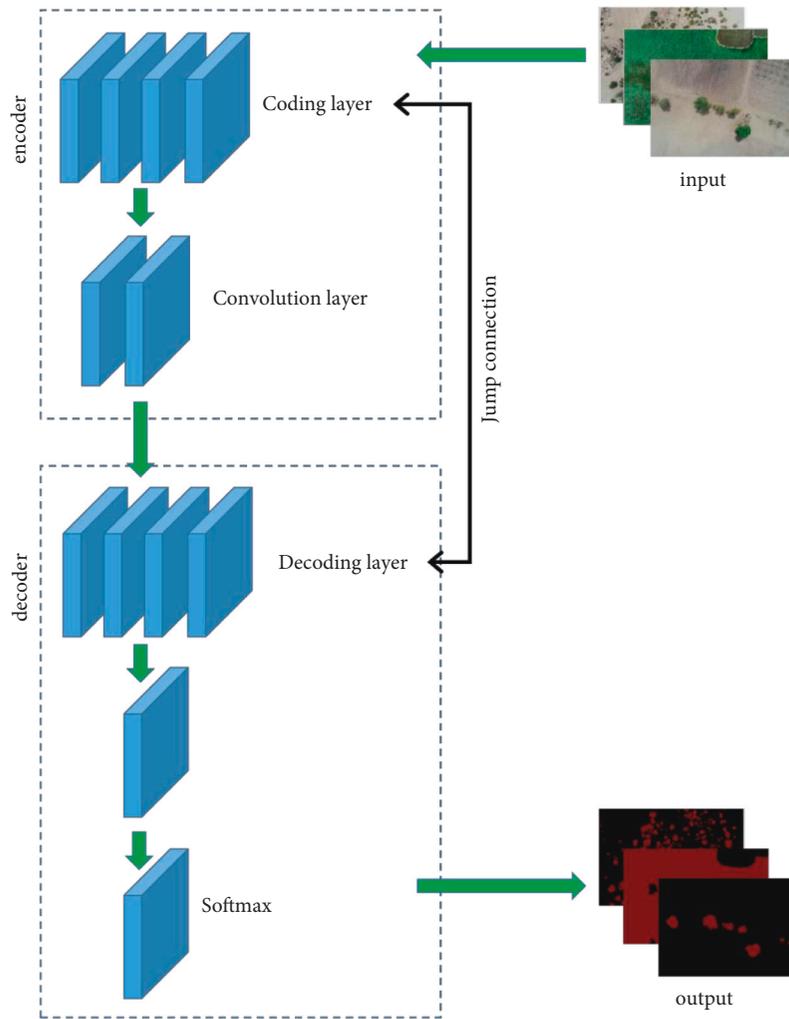

FIGURE 2: The deep learning model for vegetation coverage extraction.

FIGURE 3: A partial screenshot of the desert, water, and cultivated land label images.

image. After the initialization of the model, it is necessary to set the parameters of the training model (train TensorFlow mask model). For the number of iterations, we set the number of iterations to 30 according to the computing power of the computer processor and the size of GPU memory. The number of slices per epoch determines the training amount of the model. The number of slices is generally selected between 200 and 1000. We set the number of slices in iterative training to 300. The number of patches per batch is set to 4. The fixed distance and blur distance are mainly set according to the drawing of the label image. The

classification weight has a minimum value of 0 and a maximum value of 2, and the loss weight ranges from 0 to 3. We adjust it according to the actual training effect.

After parameter adjustment, the final parameter is set as 20 iterations, 300 training slices per iteration, 4 reading slices per batch of training, 0.8 classification weight, and 0.6 loss weight. Considering the features of the study area, we do not set the fixed distance and fuzzy distance. The image extraction results are shown in Figure 4.

The desert, water body, and cultivated land extracted by the binary classification model are used to make the region

FIGURE 4: The image extraction results.

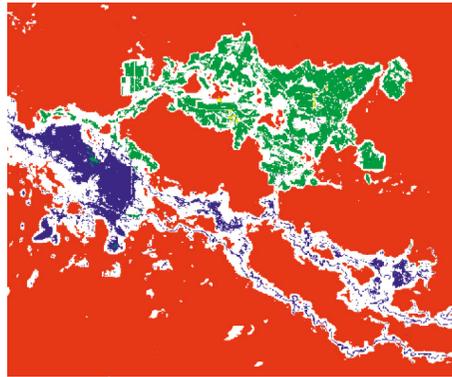

FIGURE 5: The area of interest.

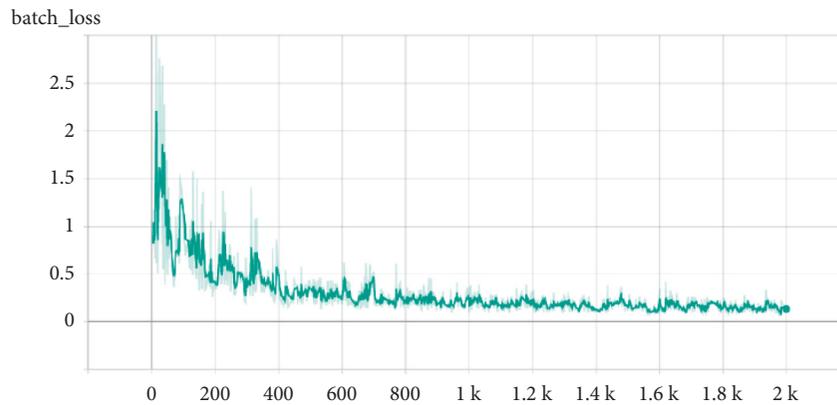

FIGURE 6: Loss function curve.

of interest based on the extraction results. Together with the manually drawn construction land, the area of interest is shown in Figure 5.

The training process of the multiclassification model is similar to that of the two classification models, with occasional differences. Only when initializing the output category of the training model, we can set it to 4 categories and set the number of slices to 304. The multiclassification depth model trained by samples is used to extract different features in the study area. The loss function curve and training accuracy curve in the training process are shown in Figures 6 and 7. The minimum loss value is 0.1483, and the maximum training accuracy is 0.9425.

After extraction, the classification map of desert, water body, cultivated land, and construction land is obtained, and then, the accuracy test is carried out in combination with the

verification points selected by field investigation, fusion image, and Google Earth high-score image. A total of 43646 validation samples (20055 deserts, 9169 water bodies, 9407 cultivated land, and 5015 construction land) were used to calculate the producer accuracy, overall classification accuracy, and kappa coefficient of feature classification in combination with the transfer matrix to carry out the comprehensive evaluation model. The overall classification accuracy is equal to the sum of correctly classified pixels divided by the total number of pixels. Kappa coefficient represents the proportion of error reduction in the evaluated classification compared with completely random classification. We output the classification results that meet the precision requirements. The test results are shown in Table 1.

Based on the verification accuracy of the extraction results, we can see that the overall classification accuracy is

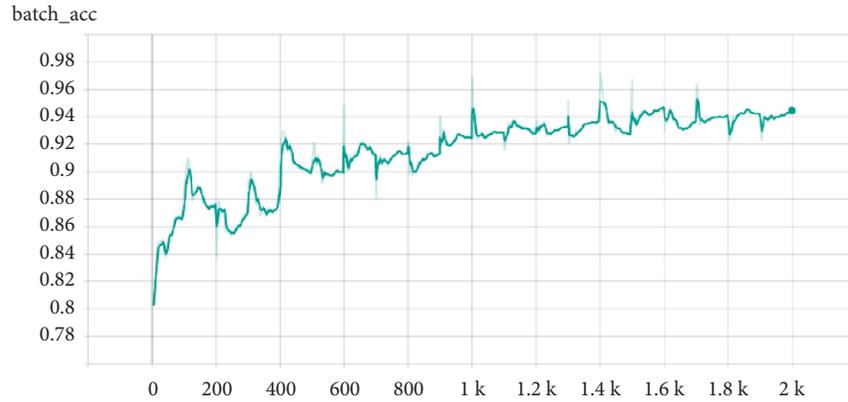

FIGURE 7: Training accuracy curve.

TABLE 1: The classification results.

	2000 year	2005 year	2010 year	2015 year	2018 year
Desert precision	87.11%	85.34%	85.04%	84.88%	86.87%
Water precision	86.23%	91.09%	88.02%	85.87%	85.66%
Cultivated land precision	85.66%	89.02%	90.11%	85.34%	90.00%
Construction land precision	88.19%	86.22%	92.22%	89.02%	89.02%
Overall precision	89.89%	85.88%	87.52%	87.76%	85.87%
Kappa coefficient	0.86	0.85	0.85	0.84	0.85

more than 85%, and the kappa coefficient is about 0.85. The model classification results can meet the use requirements.

4. Conclusions

In this study, we take the northwest region of China as the research area. Based on the Landsat medium-resolution remote sensing satellite images of five periods (2000, 2005, 2010, 2015, and 2018) in the study area, and based on ENVI 5.5, the remote sensing image software processing platform used for image preprocessing, the deep learning model is used to classify the features of desert, water body, construction land, and cultivated land in the study area in recent 19 years. The classification results satisfying the accuracy are obtained; furthermore, the annual change in desertification in the region is statistically analyzed by using the single land dynamic degree and land-use transfer matrix method, and the mutual transfer between desert and other features. Based on the above classification results, the desert area was extracted to obtain the normalized vegetation index (NDVI), and then, the vegetation coverage of the study area was obtained. Combined with the quantitative relationship between vegetation coverage and desertification, the classification results of desertification grades in different years in the study area were obtained, and the mutual transformation among severe, moderate, and mild desertification areas was analyzed by using the transfer matrix method. The results show that the main feature of the study area is the rocky desert, accounting for more than 80% of the area. In the past 19 years, it has reduced to 106.33 km², the average annual growth rate is -0.32%, and the rocky desertification continues to reverse. The results showed that the ecological

environment in different research periods developed well as a whole.

Compared with traditional machine learning classification methods, the deep learning method used in this study can automatically extract the features of remote sensing images, so it can effectively avoid the complex work of manual extraction and feature selection, and has high operability.

There are many influencing factors of desertification. Due to the limitations of data source, time, economy, and technology, this study still has many deficiencies. The Landsat series remote sensing data used in this study do not have a high spatial resolution, and one pixel may contain a variety of ground objects. It is not conducive to the establishment of a pure feature sample set, which has certain errors in the training and verification of the model. The high spatial resolution remote sensing data greatly increase the probability of pure pixels, which is conducive to the better learning of samples by the deep learning model. In the model training of deep learning, the adjustment of parameters is subjective and tentative. After meeting the classification results, further experimental research was stopped. In the next step, the scientific parameter adjustment method can be used to obtain better classification results.

Driven by artificial intelligence technology, the research of intangible cultural heritage innovative design is carried out. Firstly, the appearance modeling characteristics, decorative element characteristics, and composition form characteristics of typical intangible cultural heritage products are analyzed. According to the collected relevant data of intangible cultural heritage products and existing products, combined with the regional cultural characteristics of intangible cultural heritage products and other factors, the analysis Atlas of intangible cultural heritage product innovation design is constructed. Based on perceptual engineering, the elements of intangible cultural heritage product innovation design for user participation are determined according to the needs and perceptual images of users. The shape grammar is used to extract the elements of intangible cultural heritage products, deduce and deform them, and finally generate the preliminary design scheme.

1. Introduction

Intangible cultural heritage refers to various traditional cultural expressions handed down from generation to generation by people of all ethnic groups and regarded as an integral part of their cultural heritage, as well as physical objects and places related to traditional cultural expressions. Intangible cultural heritage is an important symbol of the historical and cultural achievements of a country and nation and an important part of Chinese excellent traditional culture. “Intangible cultural heritage” is opposite to “material cultural heritage,” which is collectively referred to as “cultural heritage.” To some extent, intangible culture is a nation’s unique cultural memory, and its inheritance value and application value are worthy of in-depth exploration. There are many kinds of intangible cultural heritage in China [1–6]. With the progress of domestic economic development and social development, many intangible cultural heritages began to appear in people’s vision, but there are still a large number of intangible cultural heritage facing the dilemma of no inheritance [7–10]. Intangible cultural heritage may integrate with other industries, explore its market value with

the help of the people, and regard it as an unattractive cultural element in the innovative design system, so as to lay a more solid foundation of traditional culture while promoting the progress of cultural design level. It is worth noting that the national cultural spirit behind the intangible cultural heritage can also become the power source to promote the progress of cultural and creative industries [11–14]. Modern innovative design can be based on material cultural heritage and traditional cultural spirit, fully reflect the important value of innovative thinking, and create cultural products that can better meet people’s diversified needs with the help of more diversified forms of expression.

Intangible cultural heritage is different from static cultural relics displayed in museums [13, 14]. It is the inheritance and accumulation of culture and the continuation of living civilization with vitality. However, the current situation of China’s intangible cultural heritage is not optimistic, as shown below.

- (1) Insufficient attention to intangible cultural heritage: at present, for many people, intangible cultural heritage is a vague concept. The first reason is the

lack of regulations and measures and rescue and protection funds; second, the inheritance and dating of some intangible cultural heritage. Due to the impact of industrialized mass production, most of the intangible cultural heritages of technology type have complex production processes. Young people's unintentional learning leads to no successors and abandoned technology, which directly leads to the loss of many materials; third, the concept of intangible cultural heritage protection is backward, the technology and means are single, and there is no connection with new technologies and methods.

- (2) A large number of intangible cultural heritage are disappearing. Intangible cultural heritage is a valuable spiritual wealth. It carries the cultural memory of national generations and is a cultural symbol of national diversity. However, these memories and symbols are easy to be ignored and forgotten over time, especially some oral cultural heritage. They will be trapped in remote and underdeveloped areas, which will make them more vulnerable and underdeveloped.

From the conceptual conception in the 1960s to the practical application today, artificial intelligence [15–19] has triggered three upsurges of development and application. Different from previous academic research, business demand is the primary factor leading this upsurge. The continuous expansion of application scope not only improves its application value and influence, but also realizes the organic integration of artificial intelligence technology and industrial chain. As the combination of human knowledge, skills, and aesthetic taste, traditional handicraft intangible cultural heritage belongs to an important part of the cultural industry. Artificial intelligence also brings new technical means and development space for its dissemination. As the continuation of human cognitive ability and emotional talent, the deep learning rate of artificial intelligence in the field of cognitive understanding is much higher than that of human beings. In the field of communication, artificial intelligence has strong practicability, such as natural language technology, real-time learning technology, cross screen recognition technology, and intelligent interaction technology. The embedding of digital technology makes virtual information coexist with tangible forms, and the accessibility and experience of intangible cultural heritage resources have been enhanced. Through technological empowerment, we can integrate the traditional intangible cultural form into the contemporary cultural ecology, make it survive and develop healthily, and continue to grow new cultural forms adapted to the times.

2. User Participatory Innovative Design

Under the development trend of experience economy, users are no longer satisfied with the ownership of a single commodity [20, 21]. On the basis of meeting the basic material needs, they begin to seek the creation of their own lifestyle and pursue their own products or services. User

participatory design is to integrate users into the design, in which the status and power of all participants are equal. The concept of participatory design originated from Nordic countries. Its original intention is to add the “voice” of the public to the decision-making of public affairs. At this time, the Nordic trade union movement made the new law give new rights to enterprise employees, and employees have the right to decide and speak to change their working environment. User participatory design mainly emphasizes the participation of users, which is less related to design. Later, it was developed into a design method by American enterprises.

User participatory design method is a modern design method that takes the user as the center, integrates the user into the design process, and cooperates with each other on the premise of respecting the user's background, ability, and ideas. It is also a modern design method to meet the diversified needs of users and ensure the equality of design. Compared with the traditional design method (the difference between them is shown in Table 1), user participatory design method is more flexible and open, allowing users to participate in the design process to the greatest extent and enable users to get the best interactive experience. At present, participatory design has been applied to many research fields.

With the rapid development of social and economic level, users' demand for products is not only satisfied with functionality and practicability, but also the pursuit of spiritual enjoyment. This study proposes the design concept of “user participation.” Its purpose is to open some design rights and production rights to users, so that nonrelic lovers, designers, and the general public can give full play to their advantages and characteristics and carry out independent innovation with the assistance of relevant personnel, truly participate in the design and production process of intangible cultural heritage innovative products, and improve users' participation and sense of experience, so as to better carry forward and inherit traditional culture.

User participation in design starts from user analysis and establishes user needs, such as interaction needs, self-realization needs, use needs, and cultural needs, by analyzing users' physiology, behavior, and psychology. Then, it analyzes user demand data, designs and develops product forms and decorative elements that meet users' needs, and allows users to give full play to their creativity through user participation in design. Finally, complete the product design and production. The user participation design process is shown in Figure 1.

The specific steps are as follows:

- (1) User analysis: it mainly analyzes the physiological, behavioral, and psychological needs of target users, which helps designers better understand users and obtain characteristic needs. Products can only be accepted by users on the premise of truly grasping the needs of users. In the whole design process, the user is the main body to help designers more accurately obtain the real needs of users, so as to find a solution satisfactory to users. User analysis is the first step of user participatory design. The commonly

TABLE 1: The difference between user participatory design method and traditional design method.

	User right	Inclusiveness	Main output	Value goal	Main demands	Technical advantages	Difficulties in modeling and decoration
Traditional design method	Right of choice	None	Products	Low production cost	Rapid and mass production	Low cost, short production cycle, and high efficiency	It is up to the designer
User participatory design method	Right of choice, right of creation, and right of design	Inclusiveness (no set goals)	Experience	Meet creative needs	Open and independent creation	High yield, novel, unique, and diversified	Determined by user's design ability

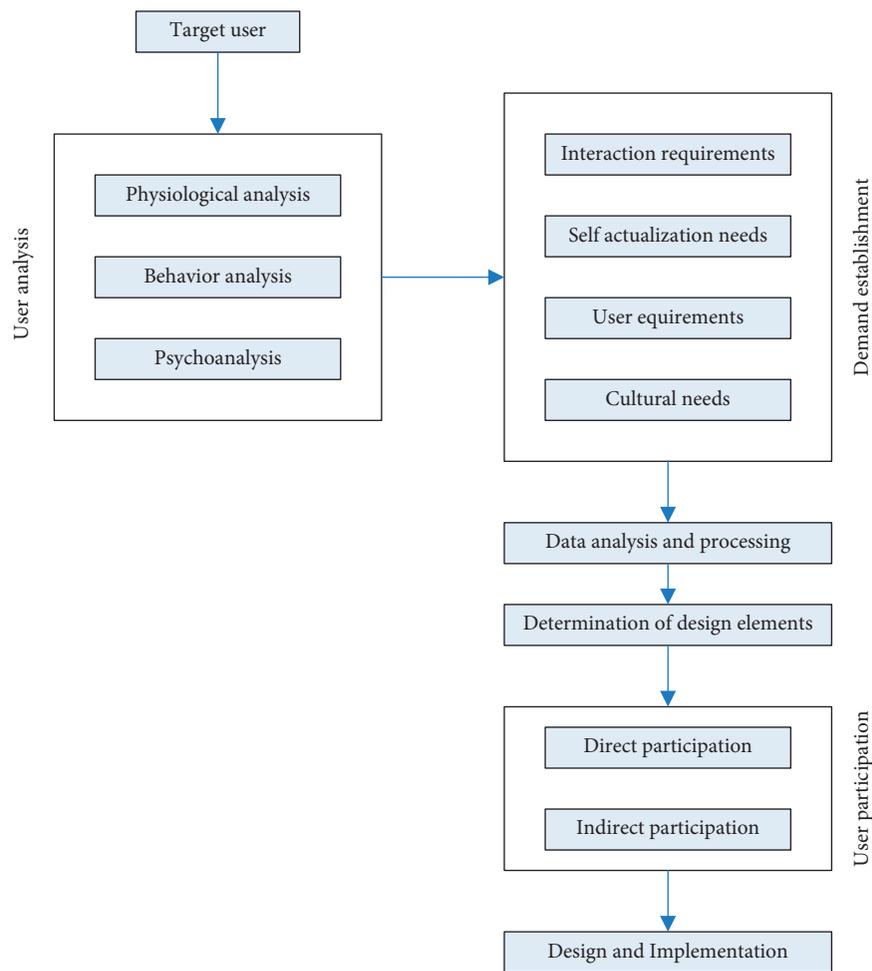

FIGURE 1: The user participation design process.

used methods include interview, accompanying observation and cultural analysis.

- (2) Requirements acquisition: through field research, user interview, accompanying observation and cultural analysis, we can understand the user's life situation, behavior habits, cultural concepts, and expectations, so as to further improve the information needed for the research and prepare for relevant data analysis. We gradually insight and analyze the role of stakeholders in nonlegacy cultural

and creative products and explore the service experience of users in the process of using products from multiple angles.

- (3) User demand analysis: we obtain the relevant data information of users through questionnaires and other methods and finally establish the user needs according to the distribution characteristics of the data.
- (4) Design element development and user participation: according to the needs of users, determine the shape,

decoration, and decorative style of products. Users can make their own choices and then directly or indirectly participate in the process of product design and production.

- (5) Design and implementation: users design and choose under the guidance of designers or traditional craftsmen and finally complete the production of products.

3. Extraction and Reconstruction of Innovative Design Elements of Intangible Cultural Heritage Driven by Artificial Intelligence

3.1. Design Element Extraction. The innovative design elements of intangible cultural heritage are mainly extracted from intangible cultural heritage products, including ancient products and existing products, from which the characteristic factors such as appearance modeling, decorative elements, composition form, and color application are extracted, respectively. The feature factor extraction model of intangible cultural heritage innovative design is shown in Figure 2.

Through consulting relevant documents, visiting museums, and field investigation of intangible cultural heritage product factories, we collected a large number of cultural relics, pictures, documents, and other materials containing intangible cultural heritage innovative design factors, screened and sorted out the collected materials, mainly divided into ancient products and existing products, formed the characteristic analysis table of intangible cultural heritage products, and constructed the analysis Atlas of design elements.

3.2. Selection and Reconstruction of Design Elements. The intangible cultural heritage innovative design for user participation is mainly divided into five parts: selection of design elements, reconstruction of design elements, generation of design scheme, evaluation of design scheme, and participation in the production experience. The specific process is shown in Figure 3.

- (1) Identify design elements. Based on perceptual engineering, collect relevant perceptual words according to the user's perceptual image, let the user score the sample, and determine the elements of intangible cultural heritage innovative design through the user's perceptual semantic word evaluation results and the target user's perceptual image words for intangible cultural heritage innovative design products.
- (2) Design element refactoring. The shape grammar is used to deduce and deform the design elements selected by the user, generate new design elements, and reconstruct the design elements.
- (3) Generate design scheme. According to the needs of users and the regenerated design elements, finally generate multiple sets of initial design schemes for users to choose and evaluate.

- (4) Design scheme evaluation. The fuzzy comprehensive evaluation method is used to evaluate and score the generated multiple sets of design schemes and finally select several groups of schemes with high scores for refinement.
- (5) Participate in the production experience. Users first choose their favorite product components through app, including the shape, decoration, style, and carcass of intangible cultural heritage innovative design products, and then participate in the post-production of products offline, under the guidance of relevant professionals, including carcass production, decoration, and polishing.

Perceptual engineering is guided by the needs of users and expresses perceptual problems qualitatively or quantitatively through mathematical analysis, so as to achieve the goal of guiding product design. We use perceptual engineering and shape grammar to guide the design of many similar modeling elements and decorative elements of intangible cultural heritage innovative products for users to choose independently. Firstly, through the comparative analysis of the characteristics of the collected intangible cultural heritage ancient products and existing products, such as appearance modeling, decorative elements, and composition forms, we can get the common design factors and select 10 typical samples from the collected samples of intangible cultural heritage products. We collect relevant perceptual words according to users' perceptual images, classify and sort out the collected semantic words, and finally get 63 semantic words. Then, we invite 30 typical users to rate the 63 perceptual semantic words collected, select words with similar semantics according to the score, and select "sharp-mellow," "complex-concise," "gorgeous-plain," "exaggerated-elegant," "simple-exquisite," "rough-smooth," "gorgeous-plain," and "dim-bright" 8 pairs of adjectives.

In order to further obtain the user's perception preference of intangible cultural heritage innovative design products, 10 samples were selected from the design element Atlas of intangible cultural heritage innovative products, and the perception survey was carried out by using the 7-order scale method. According to the semantic vocabulary correlation, they were divided into 7 levels: 3 points, -2 points, -1 point, 0 point, 1 point, 2 points, and 3 points, where "0" means consistent, "-2" and "2" mean average, and "-3" and "3" mean very high.

Finally, the distribution of users' perceptual semantic vocabulary evaluation results is obtained. By constructing a five-point psychological evaluation table and connecting the semantic vocabulary of each group of samples with broken lines, the semantic vocabulary description diagram of intangible cultural heritage innovation style features is obtained. According to the evaluation results and results of users' perceptual semantic words, the perceptual image words of target users for intangible cultural heritage innovative products are smooth, exquisite, mellow, elegant, bright, simple, and elegant.

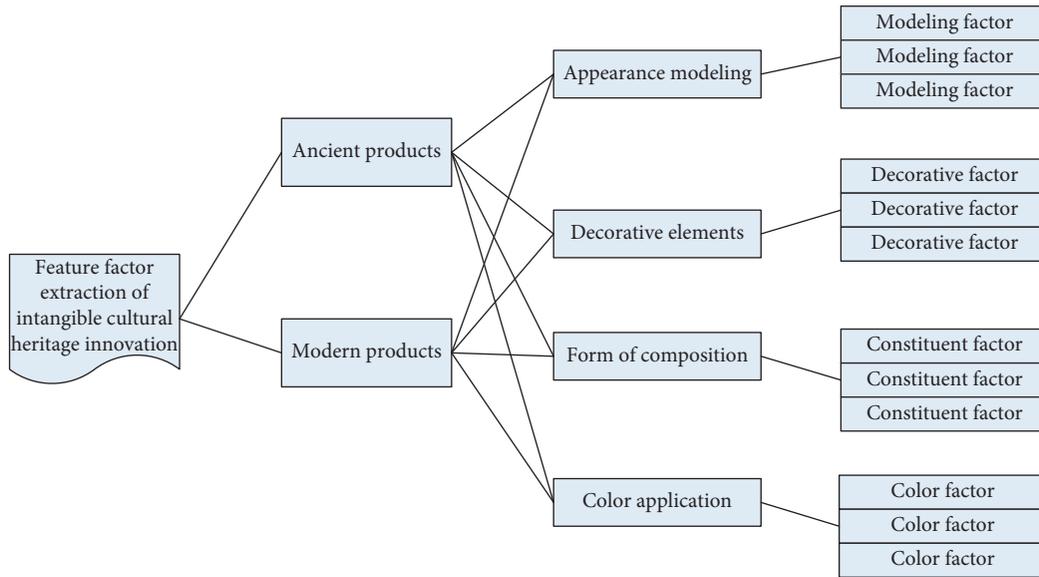

FIGURE 2: The feature factor extraction model of intangible cultural heritage innovative design.

According to the extraction method of design elements of intangible cultural heritage innovative products and based on the positioning needs of intangible cultural heritage innovative products, modeling elements, decorative elements, and color elements are selected, respectively. Based on the perceived image of the target user, determine the parent elements, and then determine the appearance modeling elements and color elements, so as to provide design element support for subsequent practice.

Based on the selected design elements of intangible cultural heritage innovative products, the shape grammar [22] is used to deduce and deform them, and finally new design elements are obtained. Shape grammar (SG) can be represented by

$$SG = (S, L, R, I), \quad (1)$$

where “SG” is the shape set derived from “s” through translation, scaling, deformation, and mirroring, “L” represents the marker set, “R” is the reasoning rule set, and “I” is the original shape. According to the morphological deduction rules in the shape grammar theory, the seven rules of shape grammar are used to properly deform the original intangible cultural heritage innovative product design elements and then form new intangible cultural heritage innovative product design elements that meet the aesthetic needs of users by means of random arrangement and combination, replacement, addition and deletion, scaling, and staggered cutting. In the choice of color, black is generally selected as the main color, and red and yellow are the auxiliary colors.

3.3. Design Scheme Generation. Through the shape grammar deduction rules, the elements are deformed and redesigned to obtain new design elements. According to the needs of users, 6 sets of initial design schemes are finally generated. The preliminary design schemes can meet the basic needs of users. In

order to further meet the diversified needs of users, this study selects the fuzzy comprehensive evaluation method [23–26] to evaluate the scheme generated by reasoning. With reference to the design elements of intangible cultural heritage innovative products, the evaluation index is set as

$$E = \{e_1, e_2, \dots, e_n\}, \quad (2)$$

where $n = 5$.

According to the needs and satisfaction of users, the evaluation weight of each evaluation index of intangible cultural heritage innovative product design is determined by scoring method.

$$W = \{0.3, 0.3, 0.2, 0.1, 0.1\}, \quad (3)$$

where the highest weight given is 0.3 and the lowest is 0.1. e_5 is regarded as the basic demand in the evaluation index. We invite 100 users to evaluate the scheme. The evaluation and test criteria are shown in Table 2.

Finally, three schemes with high scores are selected for design optimization. Taking scheme 1 as an example, the evaluation and test results are shown in Table 3.

The fuzzy judgment matrix D of the design optimization solution is obtained from Table 4.

Then, the comprehensive evaluation model B is

$$B = W \times D. \quad (4)$$

That is, $B = \{0.224, 0.139, 0.185, 0.191, 0.261\}$.

The comprehensive evaluation results of the final 100 users on the six initial design schemes are shown in Table 5.

According to the evaluation results, it can be seen that 22.4% think scheme 1 is very good, 8.8% think scheme 2 is very good, 31.8% think scheme 3 is very good, 24.6% think scheme 4 is very good, 27.4% think scheme 5 is very good, and 21.8% think scheme 6 is very good. The top schemes are scheme 3, scheme 5, and scheme 4 in turn. Therefore, this

6	0.218	0.057	0.123	0.380	0.222

study takes these three sets of schemes as the schemes for end users to participate in practice and carries out iterative optimization to get the final design scheme.

4. Conclusions

With the acceleration of market evolution, people's material life is becoming richer and richer, and their needs are becoming more and more diversified. The demand for products is no longer just functional, but also pays more attention to the feeling of spiritual level, and has higher requirements for the aesthetic value and cultural value of products themselves. This study comprehensively uses questionnaire survey, user interview, and user perception preference analysis to analyze and study the personal needs of users and the methods and processes of user participation in design. Finally, the theory is applied to practice to complete the research on the innovative design of artificial intelligence in intangible cultural heritage.

This study uses the Atlas analysis method to analyze and summarize the characteristics of intangible cultural heritage products, constructs the analysis Atlas of intangible cultural heritage products, determines the design elements of intangible cultural heritage innovative products according to the needs of users, deforms and reconstructs the design elements of intangible cultural heritage innovative products based on the shape grammar, deduces the deformation,

obtains new design elements that meet the aesthetic needs of users, and generates the initial design scheme. The fuzzy comprehensive evaluation method is used to score and evaluate the generated design scheme, and the scheme with the highest user satisfaction is selected for iterative optimization to obtain the final design scheme. Secondly, through a series of design practices, it provides users with independent creative space and platform to meet the diversified needs of users. Finally, the design of intangible cultural heritage is verified by user-oriented design.

The main innovations of this study are as follows: (1) by combining traditional handicrafts with modern design ideas, the market transformation channels of intangible cultural heritage innovative design products are increased, and a user-oriented intangible cultural heritage innovative design model is established. (2) In view of the difficulties faced by intangible cultural heritage art, explore the needs of different users for intangible cultural heritage innovative products, let users participate in the design process of intangible cultural heritage innovative products, enable users to obtain the creative dominance of products, and improve users' consumption experience. (3) According to the needs of users, this paper puts forward the design scheme of intangible cultural heritage innovative products to meet the needs of user groups and promote the wide dissemination of intangible cultural heritage culture.

High-dimensional data usually exist asymptotically in low-dimensional space. In this study, we mainly use tensor t-product as a tool to propose new algorithms in data clustering and recovery and verify them on classical data sets. This study defines the “singular values” of tensors, adopts a weighting strategy for the singular values, and proposes a tensor-weighted kernel norm minimization robust principal component analysis method, which is used to restore low-probability low-rank third-order tensor data. Experiments on synthetic data show that in the recovery of strictly low-rank data, the tensor method and weighting strategy can also obtain more accurate recovery when the rank is relatively large, which improves the volume of the rank. The proposed method combines the two and reflects its superiority through the restoration of 500 images under a small probability noise level.

1. Introduction

In recent years, the development of science and technology has been changing with each passing day, and at the same time, it has also brought complicated data [1–4]. With the development of the Internet and artificial intelligence [5–8], the data on education, medical treatment, e-commerce, transportation, and other industries show explosive growth. How to mine useful information from massive data has become a research hotspot. Due to the continuous improvement of people’s ability to obtain data, the scale of data is becoming larger and larger, and the structure is becoming more and more complex, such as millions of frames of video, texts, and web pages carrying hundreds of millions of information.

Data recovery and clustering are of great significance to the analysis of high-dimensional data [9–14]. Many high-dimensional data usually exist approximately in low-dimensional subspaces, and the low rank prior of data becomes the key to effective data recovery [15–18]. In cluster analysis, many data are usually modeled as coming from multiple cluster subspaces. Based on this, the data are clustered and a popular subspace clustering algorithm is formed.

Analyzing these high-dimensional data not only occupies memory and takes time but also because the useful

information of the data often only exists in the low-dimensional space, other redundant components will bring great interference to the analysis algorithm [19]. Noise or outliers due to the increase of information will also affect the performance of the algorithm. How to grasp and make use of the characteristics of data has become a breakthrough in the effective analysis of data. In the form of data processing, the traditional method of matrix decomposition usually needs to transform multi-level data samples into column vectors, which inevitably destroys the original structure of data and leads to information loss. While retaining the original form of the data, the tensor form will be used for decomposition. In recent years, in the field of practical application, the analysis of tensors has played an increasingly important role, so more and more scholars have paid attention to it. The forms of tensor operations are diversified with the in-depth exploration of the academic community.

2. Data Recovery of Low-Rank Third-Order Tensors under Small Probability Sparse Noise

Low rank exists widely in data. In algorithms applied to traditional matrix factorization, converting each multi-order data sample into a long column vector form is necessary

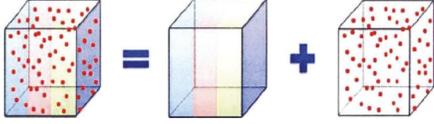

FIGURE 1: Schematic diagram of TRPCA decomposition.

[20]. A third-order tensor has a lower-rank structure than the corresponding matrix. Therefore, theoretically, from the perspective of low-rank recovery, the original structure of tensors has certain advantages.

Theorem 1. For any tensor:

$$\mathcal{A} \in \mathbb{R}^{n_1 \times n_2 \times n_3}. \quad (1)$$

We convert each of its side slice matrices into a column vector, the matrix \mathcal{A} is formed by these column vectors, which is unfold (\mathcal{A}).

Then the average rank of \mathcal{A} is less than or equal to the rank of \mathcal{A} , that is,

$$r_a(\mathcal{A}) \leq r(\text{unfold}(\mathcal{A})). \quad (2)$$

Prove:

$$\text{bcirc}(\mathcal{A}) = [I_{n_1 n_3}, P, P^2, \dots, P^{n_3-1}] \begin{bmatrix} A \\ A \\ \vdots \\ A \end{bmatrix}, \quad (3)$$

where P is the permutation matrix $\begin{bmatrix} O & \cdots & O & I_{n_1} \\ I_{n_1} & \cdots & O & O \\ \vdots & \ddots & \vdots & \vdots \\ O & \cdots & I_{n_1} & O \end{bmatrix} \in \mathbb{R}^{n_1 n_3 \times n_1 n_3}$.

Then,

$$r_a(\mathcal{A}) = \frac{1}{n_3} r(\text{bdiag}(\mathcal{A})) = \frac{1}{n_3} r(\text{bcirc}(\mathcal{A})). \quad (4)$$

So,

$$r_a(\mathcal{A}) \leq \frac{1}{n_3} r \left(\begin{bmatrix} A \\ A \\ \vdots \\ A \end{bmatrix} \right) = r(A). \quad (5)$$

2.1. Tensor Low-Rank Structure of RGB Images. An RGB image data itself is a third-order tensor, and the general image tensor has a low-rank structure, which will be explained from experiments in this section. Two-color pictures are randomly selected from the Berkeley Segmentation dataset [21], and the picture size is 321×481 . Each picture's data (RGB picture) can be regarded as a third-order tensor (set as $\mathcal{A} \in \mathbb{R}^{m \times n \times 3}$). We perform tensor singular

value decomposition for each image: $\mathcal{A} = \mathcal{U} * \mathcal{S} * \mathcal{V}^*$. Also, we calculate the singular value of $\text{bdiag}(\mathcal{A})$. It can be seen that the general RGB image itself has a tensor low-rank structure.

Tensor low-rank representation (TLRR) [22] and tensor robust principal component analysis (TRPCA) [23] use the tensor low-rank structure to remove the sparse noise of the image. The decomposition of TRPCA is shown in Figure 1.

2.2. Tensor-Weighted Nuclear Norm Minimization Robust Principal Component Analysis Method. Perform singular value decomposition on a matrix of approximately low rank; the larger singular value corresponds to the "main structure" information of the matrix, such as larger edges and smooth parts in the image matrix. The small noise does not interfere much with the main structure of the matrix; therefore, in the denoising algorithm based on singular value shrinkage, different singular values should be treated differently. Based on this prior, weighted nuclear norm minimization (WNNM) [24] and weighted nuclear norm minimization-robust principal component analysis (WNNM-RPCA) [25] give a small degree of shrinkage to large singular values based on nuclear norm minimization (NNM) and robust principal component analysis (RPCA), respectively, and greatly improve the denoising effect.

The singular value of any tensor \mathcal{A} is defined as the singular value of $\text{bdiag}(\mathcal{A})$; then, the above analysis is also valid for tensor singular value decomposition. Referring to the weighting strategy in literature [26], we set the weight of each singular value σ_i of the tensor as

$$w_i^{t+1} = \frac{C}{\sigma_i(\mathcal{A}^t) + \epsilon}. \quad (6)$$

In this equation, σ_i represents the i -th singular value of \mathcal{A} , t represents the number of iterations, C is a normal number, and ϵ is a minimal number to prevent the denominator from being 0.

The L_1 norm is often used to characterize random probability noise. For example, RPCA, etc. For the problem of removing small probability noises from third-order tensors, a tensor-weighted nuclear norm minimization robust principal component analysis method is proposed as

$$\min_{\mathcal{L}, \mathcal{E}} \|\mathcal{L}\|_{w,*} + \|\mathcal{E}\|_1, \text{ s.t. } \mathcal{X} = \mathcal{L} + \mathcal{E}. \quad (7)$$

To deal with the equality constraint problem, the augmented lagrange multiplier method is used, that is,

$$\min_{\mathcal{L}, \mathcal{E}} \|\mathcal{L}\|_{w,*} + \lambda \|\mathcal{E}\|_1 + \frac{\mu}{2} \|\mathcal{X} - \mathcal{L} - \mathcal{E}\|^2 + \langle y, \mathcal{X} - \mathcal{L} - \mathcal{E} \rangle. \quad (8)$$

We solve equation (8) by the alternating direction method of multipliers (ADMM) method. This is a supplementary explanation of the solution to the following model used to update \mathcal{L} .

Giving the tensor $Z \in \mathbb{R}^{n_1 \times n_2 \times n_3}$, the \mathcal{L} of the following function is solved as

$$\min_{\mathcal{L}} \|\mathcal{L}\|_{w,*} + \frac{\mu}{2} \|\mathcal{L} - \mathcal{X}\|^2. \quad (9)$$

This is equivalent to the following matrix model:

$$\min_{\mathcal{L}} \|\text{bdiag}(\mathcal{L})\|_{w,*} + \frac{\mu}{2} \|\text{bdiag}(\mathcal{L}) - \text{bdiag}(\mathcal{X})\|^2. \quad (10)$$

Let

$$\text{bdiag}(\mathcal{L}) = \begin{bmatrix} L_1 \\ L_2 \\ \vdots \\ L_{n_3} \end{bmatrix}, \quad (11)$$

$$\text{bdiag}(\mathcal{X}) = \begin{bmatrix} Z_1 \\ Z_2 \\ \vdots \\ Z_{n_3} \end{bmatrix},$$

where $L_i, Z_i \in \mathbb{R}^{n_1 \times n_2}$, $i = 1, \dots, n_3$.

Then, the model can be transformed into

$$\min_{L_i} L_{i,w,*} + \frac{\mu}{2} L_i - Z_i^2, \quad i = 1 \dots, n_3. \quad (12)$$

It can be solved by applying Theorem 2.

Theorem 2 ([see 25]). *Suppose $Y \in \mathbb{R}^{m \times n}$, for the wavelet neural network prediction (WNNP) problem of the reweighted strategy:*

$$\min_X \|X\|_{w,*} + \|Y - X\|^2, \quad (13)$$

where $w_i^t = C/\sigma_i(X^t) + \epsilon$, C is a positive constant, ϵ satisfies $\epsilon < \min(\sqrt{C}, C/\sigma_1(Y))$ and initializes $X^0 = Y$, then the problem has a closed-form solution.

We perform singular value decomposition on Y :

$$Y = U \sum V. \quad (14)$$

Then, the closed-form solution is

$$X^* = U \sum V^T, \quad (15)$$

where,

$$\sum = \begin{pmatrix} \text{diag}(\sigma_1(X^*), \widetilde{\sigma}_2(X^*), \dots, \sigma_n(X^*)) \\ 0 \end{pmatrix}, \quad (16)$$

$$\sigma_i(X^*) = \begin{cases} 0 & c_2 < 0, \\ \frac{c_1 + \sqrt{c_2}}{2} & c_2 \geq 0, \end{cases}$$

$$c_1 = \sigma_i(Y) - \epsilon, c_2 = (\sigma_i(Y) + \epsilon)^2 - 4C.$$

3. Experiments

It is assumed that the value range of each element in the low-rank tensor \mathcal{A} is $[a, b]$, and the element with frequency p in \mathcal{A} is disturbed by noise. This experiment mainly explores the accurate recovery of low-rank third-order tensor $\mathcal{A} \in \mathbb{R}^{n_1 \times n_2 \times n_3}$ under low-probability sparse noise by the proposed tensor-weighted nuclear norm minimization robust principal component analysis method.

The main comparison algorithms are RPCA [27], WNNM-RPCA [25], low-rank representation (LRR) [28], tensor robust principal component analysis (TRPCA) [23], and tensor low-rank representation (TLRR) [22]. Each positive slice matrix of the tensor is denoised separately when applying the matrix methods: WNNM-RPCA and LRR.

In addition to the parameters already set, set

$$C = 4p\sqrt{n_1 n_2}. \quad (17)$$

p value prior is needed here. Better results can be obtained without p prior value, but experiments show that setting the C value in this way is more effective.

3.1. Synthesis of Data. Firstly, the vector linearly produces a low-rank tensor. The steps of this experiment are:

(1) Generate a low-rank tensor:

$$\mathcal{A} = \text{fold}(\text{unfold}(\mathcal{B})C), \quad (18)$$

where $\mathcal{B} \in \mathbb{R}^{n_1 \times r \times n_3}$, $\mathcal{C} \in \mathbb{R}^{r \times n_2}$, all obey the normal distribution $\mathcal{N}(0, 1)$.

(2) Randomly select the element whose proportion frequency is p from \mathcal{A} and set it as a large random value in the range of $[a, b]$. $[a, b]$ is set as the value range $[\min(\mathcal{A}), \max(\mathcal{A})]$ of \mathcal{A} .

(3) Use the corresponding algorithm to process separately to get the recovery value \mathcal{A}^* .

(4) Comparing the relative error,

$$\text{RF} = \frac{\mathcal{A} - \mathcal{A}^*}{\|\mathcal{A}\|}. \quad (19)$$

The restoration fails if the error is greater than 0.2.

Then, we fix $n_1 = 300$, $n_2 = 300$, $n_3 = 5$, $p = 0.15$ unchanged, set r to 5, 10, 15, 20, 40, 60, 80, respectively. Each group of experiments generates 10 noise data recovered by different algorithms (each row in the error result table uses the same group of data), and the average results are taken. A comparison of recovery errors for low-rank tensors produced by vector linearity is shown in Table 1.

Then, tensors linearly generate low-rank tensors. This experiment is different from the first experiment only in the method of generating low-rank tensors in step 1, which is changed to

$$A = B * C, \quad (20)$$

TABLE 1: Comparison of recovery errors for low-rank tensors produced by vector linearity.

r	RPCA	WNNM-RPCA	TRPCA	TWRPCA
5	$5.58e-11$	$3.86e-08$	$1.23e-08$	$1.01e-08$

80	—	—	—	—

“—” indicates that recovery failed.

TABLE 2: Comparison of recovery errors for low-rank tensors produced by tensor linearity.

r	RPCA	WNNM-RPCA	TRPCA	TWRPCA
5	$5.39e-11$	$7.69e-08$	$8.51e-09$	$6.21e-09$
10	0.012	$1.31e-07$	$6.84e-09$	$6.72e-09$
15	—	—	$7.22e-09$	$5.78e-09$
20	—	—	$4.24e-09$	$3.92e-09$
40	—	—	$1.04e-08$	$4.70e-09$
60	—	—	0.12	$6.72e-09$
80	—	—	—	$9.62e-09$

“—” indicates that recovery failed.

where $\mathcal{B} \in \mathbb{R}^{n_1 \times r \times n_3}$, $\mathcal{C} \in \mathbb{R}^{r \times n_2 \times n_3}$, all obey the normal distribution: $\mathcal{N}(0, 1)$. The results are shown in Table 2.

From the above two experiments, we can draw the following conclusions: in the case of low-rank and low-noise level, the inpainting result of RPCA is the most accurate. This also verifies the theory described in [27]. From the perspective of “tolerance” to rank, both the tensor method and the weighting strategy make the original algorithm significantly improved. The improvement effect of the tensor method is particularly significant in the recovery of data generated by tensor linearity.

3.2. Image Restoration. This experiment uses 500 pictures from the Berkeley dataset [27–29] under different scenarios. For each test picture, the pixel value of $p = 3\% \sim 15\%$ is randomly selected and set to a random value of $[0, 255]$, and different algorithms are applied to repair. When applying the proposed tensor weighted nuclear norm minimization robust principal component analysis method, the experiments show that the denoising results need to be performed twice by the proposed tensor weighted nuclear norm minimization robust principal component analysis method for better results. Taking mean square error (MSE) and peak signal to noise ratio (PSNR) values as evaluation indicators:

$$\text{MSE} = \frac{\|\mathcal{L} - X\|^2}{n_1 n_2 n_3}, \quad (21)$$

$$\text{PSNR} = 10 \log_{10} \left(\frac{\|X\|_{\infty}^2}{\text{MSE}} \right),$$

where \mathcal{L} is the recovery result for $\mathcal{X} \in \mathbb{R}^{n_1 \times n_2 \times n_3}$.

Under the noise level of $p = 9\%$, each algorithm recovers the data of four example images. The average processing time of the four images is shown in Figure 2. MATLABR

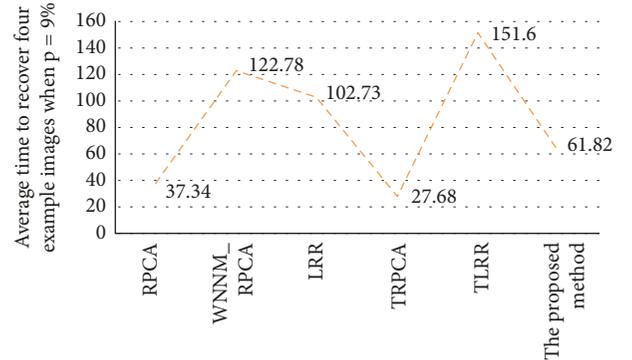

FIGURE 2: Average time to recover four example images when $p = 9\%$ (unit: seconds).

2020 is used in this experiment, the computer parameters are the operating system win10, CPU Inter(R) Core(TM) i5-3230M, CPU of 2.60 GHZ, and the memory of 8 GB.

Under different noise levels, each algorithm restores 500 images, and the average MSE and PSNR values are shown in Tables 3 and 4, respectively (the best results are shown in bold).

It can be seen from Tables 3 and 4 that the repair results of the tensor method are better than the repair results of the matrix method; WNNM-RPCA and TWRPCA obtained by the weighted strategy perform better in similar methods, and the lower the noise level, the more pronounced the advantage of the weighted strategy.

As mentioned above, the larger part of the singular value of the data represents the “main structure” of the data itself. At the same time, the low noise level has less influence on the main structure of the data, and the weighting strategy uses this prior. The experimental results further verified this hypothesis.

TABLE 3: Average MSE value recovered from 500 pictures.

	$p = 3\%$	$p = 6\%$	$p = 9\%$	$p = 12\%$	$p = 15\%$
RPCA	199.78	214.66	226.93	242.23	260.63

The proposed method	38.55	36.32	32.80	31.02	29.01

4. Conclusions

This study focuses on the data recovery of low-rank third-order tensors under small probability sparse noise. Tensor t-product is only one of many tensor operations. Although it has an excellent performance in some aspects, it can not achieve all aspects of transcendence. Tensor subspace has more “right shift” closeness than quantum space, but this property has not been further analyzed in combination with practice. In the face of practical problems, the theoretical analysis of this paper is relatively weak. It is hoped that there will be more in-depth theoretical research in the future, and there will be more perfect trade-off strategies for various forms of matrix or tensor operations.

In data recovery, although the tensor weighting strategy proposed in this paper has brought better results, the current experiments have only achieved better results under small probability noise. Relevant experiments show that the weighting parameters are also related to the image itself, and the image information should be taken into account when determining the weighting parameters. For example, images with more details (such as texture images) and smoother images should be treated differently; in addition, the RGB image itself is regarded as a third-order low-rank tensor, and the application of weighted low rank will make the image lose some detail information while denoising. We can use the prior of nonlocal approximation for reference to aggregate the similar blocks of the image to obtain a tensor with a lower rank, and then use the corresponding algorithm to denoise. However, because TRPCA, TLRR, TWRPCA, and other methods dealing with sparse noise do not have an explicit solution, it will consume memory and greatly increase the time cost. Therefore, it is hoped that there will be a denoising algorithm that considers the image information and can estimate the noise level in the future.

In the background of the information age of “Internet+,” the traditional teaching mode of business English has many drawbacks in terms of curriculum, teaching content, teaching methods, and teachers’ backgrounds and cannot adapt to the needs of the times. Therefore, business English teaching should actively follow the trend of “Internet+ education” and continue to innovate in a multimodal way. The multimodal teaching mode of “wireless network+ business English” is in line with the background of “Internet+,” optimizing teaching resources to the maximum extent and truly realizing the effective combination of Internet and business English teaching. The Internet-based multimodal innovation can be carried out in the four elements of business English teaching: environment, task, learner, and guide teaching. The specialization and modernization of business English teaching can be promoted through the optimization of O2O multisituational classroom, the application of multimodal tasks in three-dimensional teaching materials, the communication of diversified categories of students, and the configuration of multilevel teachers across fields.

1. Introduction

With the continuous innovation of information technology, we have entered the 2.0 era of Internet development [1]. On July 4, 2015, the State Council issued the “Guidance on actively promoting the ‘Internet+’ action.” According to the Guidance, the “Internet+” is “the deep integration of Internet innovations with all areas of the economy and society. As the infrastructure and innovation factor, the “Internet+” is instrumental in promoting technological progress, efficiency improvement, and organizational change, enhancing the innovation and productivity of the real economy. This also indicates that “Internet+” has been incorporated into national strategy and will become an important form of social innovation and development in the future [2]. The profound influence of modern information technology represented by the Internet on all aspects of education is also being gradually reflected. The “Internet+ education” is not a simple addition of the two but a kind of change and innovation, using information technology and the Internet

platform to integrate the Internet with education in depth so that the Internet thinking really penetrates the teaching design, teaching content, teaching evaluation, and other aspects of the teaching process, resulting in new teaching forms and models. In this environment, the reform of the teaching mode of business English courses in colleges and universities is in urgent need of strengthening the integration with information technology to co-construct and share high-quality and effective educational resources [3].

The new industry of “Internet+ traditional industry” provides new thinking and new opportunities for the innovative development of the education industry. With the development of wireless networks and smart terminals, multimodal communication methods, mainly pictures, text, audio, and video, are gradually replacing one-dimensional text and rapidly becoming the mainstream form of information transmission in education and communication activities. In multimodal information, language text and other hypertext social symbols such as images and videos jointly construct meaning and spread in real time through the

emerging mobile Internet media, greatly compensating for the disadvantages of traditional paper media, which are static and monotonous.

Business English, as an interdisciplinary cross-emerging major integrating business knowledge and skills and English language ability, still suffers from development problems such as lack of unified teaching objectives, weak teachers, lagging teaching methods, and single evaluation methods at this stage [4]. Therefore, starting from the four main elements of the teaching mode and using Internet thinking for the organic optimization and allocation of multimodal teaching resources, this paper focuses on analyzing how business English teaching can be multimodally innovated and updated at the level of environment, task, learner, and guide to promote the informational development of business English professional construction.

2. The Main Problems in Traditional Business English Teaching

With the development of global economic integration, the demand for business English professionals in China has been rising, especially the demand for talents with high quality, solid language foundation, and business knowledge. Therefore, many colleges and universities, especially those undergraduate colleges and universities in transition, have opened business English majors one after another [5]. However, due to the strong practicality and interdisciplinarity of business English, the traditional teaching mode in ordinary colleges and universities can no longer meet the requirements of society for business English talents, and its drawbacks are becoming more and more obvious. The shortcomings of the teaching mode are becoming more and more obvious.

2.1. The Curriculum Lacks Modernity. At present, the core courses of business English majors in colleges and universities are mainly set around traditional international trade activities, such as foreign trade correspondence, international marketing, business negotiation, and so on. However, with the vigorous development of information technology, the economic form has long been not only limited to a certain mode, such as the increasing growth of cross-border e-commerce with B2B and B2C as the main mode [6], which highlights the huge gap in the demand for related talents. But the corresponding business English talents in colleges and universities cannot really dovetail with each other, and the professional curriculum is obviously not forward-looking enough, without closely linking the business activities in the Internet era with the related teaching, and the related courses are very insufficient or even blank.

2.2. Lack of Practicality of Teaching Contents. Business English itself is a special-purpose English, and its practical teaching purpose is different from that of traditional English majors. However, due to the limitation of the speed of updating the teaching materials, when teachers teach business English courses, most of the teaching of

professional business knowledge stays at the level of books, and it is difficult to combine the new terms, new terminology, or new business environment that emerge rapidly nowadays. As a result, when students graduate, as long as they work in related industries, they will obviously feel that their professional knowledge is lacking, or their professional background is incompatible with the employment environment, and the gap is obvious [7]. This makes the profession, which should have strong practical value, lack real practicality, and thus face an awkward situation in the job market.

2.3. Lack of Diversity in Teaching Methods. In today's rapid development of information technology, the application of multimedia technology and the Internet are both very common. And diversified teaching modes are also inseparable from these. However, in business English teaching, the teaching methods in many colleges and universities are still very single, and most of them still follow the teaching mode of English majors; the teacher is still the main body in the classroom; most of the time the teacher teaches the knowledge points; the students learn more passively; there are few or no links of teacher-student interaction and student-student interaction; and there are few courses that allow students to really participate in practical operations effectively [8]. The teaching process is heavy on theory indoctrination and light on practical operation phenomenon abounds. If students do not have timely and complete practical training, it is difficult for them to apply what they have learned in the future, which is very unfavorable to the cultivation of high-quality and application-oriented business English talents.

2.4. Lack of Professionalism in Teachers' Background. In colleges and universities, business English is a young and emerging major compared with other majors, but many teachers are purely English education majors who are not very familiar with business practice, or even if they have studied related professional knowledge, most of them only stay at the level of books, lacking practical experience and social practice ability itself. As a result, they cannot really integrate business ideas and practical methods into teaching and cannot fully realize the cultivation of students' core competence and professionalism. In Business English, English is only a tool, and business knowledge is the pillar. If the teacher's knowledge framework focuses on language rather than business or if the teacher accumulates personal corpus during teaching but does not share relevant professional knowledge in time, the knowledge structure is old and not up-to-date [9] and lacks professionalism he or she should have or he or she will not be able to meet the training needs of business English talents. Therefore, in order to evaluate the relationship between the number of business English courses and the teaching effect of business thinking and practical methods, the researchers obtained the internal relationship between the number of business English classes and business thinking through the statistical data of many colleges and universities. The mathematical relationship is as

follows. Figure 1 shows the relationship between the quality of business English talents, business knowledge, and pure English teaching. As can be seen from the figure, in addition to the English language itself, business knowledge plays an important role in the quality of business English talents.

$$\begin{aligned}
 N &= \sum_{i=1}^n n_i, \\
 E_n &= \sum_{m=0}^{N-1} x_n^2(m), \\
 M_n &= \sum_{m=0}^{N-1} |x_n(m)|,
 \end{aligned} \tag{1}$$

where N is the number of business English courses, E_n is the teaching effect of business ideas and practical methods, and M_n is the teaching effect of pure English education.

3. Feasibility of “Wireless Network + Business English” Teaching Mode

3.1. Opportunity of “Internet+” for Teaching. The Internet has the largest amount of information and resources in the world today, and these huge amounts of information are interconnected in an intricate form, and the direct or indirect resources that can be served and shared for teaching are inexhaustible. The Internet supported by big data also makes information collection more convenient for each learner, making mobile devices the carriers of virtual communities and virtual classrooms. In other words, in the context of “Internet+,” the teaching mode is different from the traditional form, and the forms, channels, and media for teaching and learning have become more diversified and diverse. They can cut and reconstruct the knowledge system independently, and if they are truly integrated with the business English teaching process, they will make teaching more vivid, effective, and relevant, thus showing the humanity of teaching.

3.2. The Fit between Business English Teaching and Wireless Network. In the era of “Internet+,” the traditional education model of one school, one teacher, and one classroom is fading; a wireless network and one mobile terminal, millions of students, schools, and teachers of your choice are emerging as the new education model, which is the charm of “Internet+ education” [10]. The nature of the business English major determines that it is by no means only a simple language teaching but with the help of teaching English language knowledge to develop students’ intercultural business communication skills. This major requires a high level of practical ability, and the teaching of business English must be combined with information technology, which is in line with the background and diversity of the “Internet+” era. Therefore, it is feasible and inevitable to rely on network information, deeply integrate various high-quality teaching resources, and explore the construction of the “Internet + business English” teaching mode.

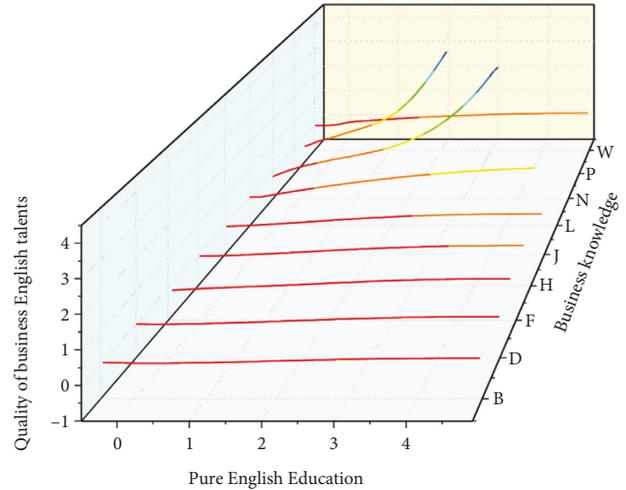

FIGURE 1: The relationship between the quality of business English talents, business knowledge, and pure English teaching.

4. The Construction of Multimodal Interactive Teaching Model of Business English

4.1. Analysis of Multimodal Interaction. Norris, a famous linguist, believes that multimodal interaction is universal [11]. Communication interaction forms social action through the mediation of various modalities. Norris points out that in communicative interaction, verbal and nonverbal modalities have different interactive effects depending on the context of interaction, and verbal modalities do not play a dominant role in all interactions. The choice of modality use needs to take into account the differences in communicative contexts. In addition, multimodal interaction should take into account the degree of interactional awareness and attention of the communicative subject and the participant and pay active attention to the feelings, thoughts, and feedback of the communicative subject and the participant and informed unity. Modal density and modal configuration are the key elements of multimodal interaction research. Modal density and modal intensity are proportional to each other, and the higher the modal intensity, the higher the modal density. Modal complexity refers to the number of modalities used in the construction of the action; the greater the number, the greater the modal complexity.

4.2. Multimodal Interactive Teaching Model. “Multimodality” refers to the inclusion of different symbolic modalities in a finished communication product or communication activity [12], as well as the various ways in which different symbolic resources are mobilized to construct meaning in a given text [13]. In the early twenty-first century, Stein proposed a multimodal pedagogy, which argues that course instruction and assessment should be centered on the modal characteristics of the learning environment centered on the development of all communicative activities in the classroom as multimodal [14]. As a pedagogical concept, multimodal teaching means that under the guidance of multimodal theory, teachers use a variety of teaching tools and diverse teaching channels, such as the

Internet, pictures, videos, and role-plays, to activate and engage learners' various senses, synergize, and construct them into the most effective way of meaningful expression and communication.

In the process of multimodal interactive teaching, learners' multiple abilities are stimulated and highlighted. The role of the teacher changes from "preaching, teaching, and solving" [15] to that of a collaborator, modality selector, and perceptual stimulator of students' learning, while the students perceive, decode, and store the multimodal input knowledge and then output it to form a positive interaction with the teacher and learners, thus realizing the deep transformation and internalization of knowledge. In business English teaching, teachers can make full use of the multimodal system to design teaching sessions, accumulate and build a multimodal corpus and curriculum resources with the help of multiple learning platforms on the Internet, activate students' sensory potential to the maximum extent, and provide a multimodal interactive teaching and learning environment for teachers and students, so as to collaborate students' multimodal understanding of relevant knowledge and complete their meaning construction [16]. Figure 2 shows the relationship between students' multimodal understanding of relevant knowledge and multimodal corpus, curriculum resources, and multimodal interactive teaching environment. As can be seen from the figure, there is a positive correlation between the three.

4.3. "Wireless Network + Business English" Teaching Mode. In the era of the "Internet+," the openness and sharing of knowledge have brought great changes to the language service industry and new requirements to traditional teaching. However, the integration of the two is not a patchwork that can be achieved overnight. In the teaching of business English, teachers should fully reform and improve the teaching concept, teaching content, and teaching methods, so as to maximize the allocation and optimization of teaching resources and truly realize the effective combination of Internet and business English teaching.

4.3.1. Change of Teaching Concept. Teaching is not only the transmission of knowledge but also the conversion process of learners' internalization of knowledge. Therefore, in business English teaching, teachers should update their teaching concept, deeply understand the essence of business English as special-purpose English, emphasize the cognitive subject role of learners, and practice the teaching concept of "student-centered" [17]. Therefore, teachers should design teaching sessions that meet learners' learning requirements and enhance their practical skills, and let students actively participate in various practical activities, cooperate with each other, and give full play to students' initiative and enthusiasm when teaching according to learners' characteristics and the features of "Internet+." Teachers are transformed into instructors and collaborators of students in

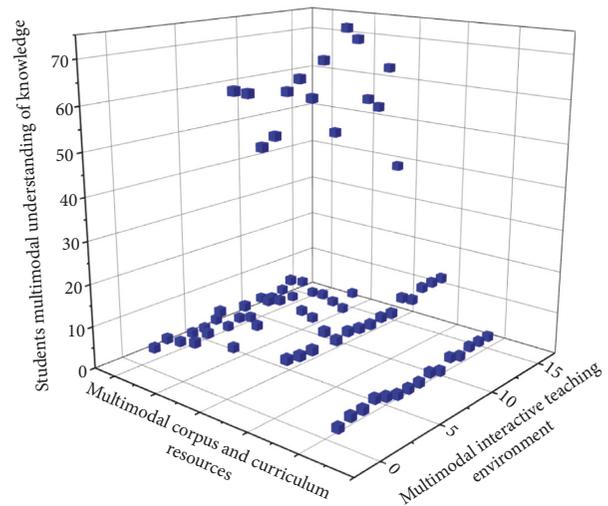

FIGURE 2: The relationship between students' multimodal understanding of relevant knowledge and multimodal corpus, curriculum resources, and multimodal interactive teaching environment.

constructing knowledge, while students become real participants and constructors of learning.

4.3.2. Update of Teaching Contents. In the teaching practice of "wireless network + business English," the change of teaching content is the most important. Business English itself is different from general language teaching, so teachers should comply with the requirements of the "Internet+" era and add more real-life corpus as the course content. In the course "Cross-cultural Business Communication" [18], for example, teachers should not only introduce basic business etiquette and cross-cultural knowledge but also add real cases of cross-cultural business communication through online platforms or shared corpora, select typical cases of successful or unsuccessful communication for learners to analyze and dig into, and then let students give feedback on the learning effect to assess the students' construction of new business communication. The students will then give feedback on the learning effect to assess the validity of their new knowledge. In the context of "Internet+," there is a constant flow of resources shared on relevant online platforms. Therefore, the resources provided by teachers (e.g., authentic business texts) do not necessarily have to be in one form but can be multimodal, such as videos, images, text, or a combination of both or all three.

Multimodal interactive teaching models emphasize multiple inputs, and business activities are evolving rapidly. While "Internet+" provides teachers with diversified teaching resources, teachers should also, according to the latest development in business communication, make use of the advantages of multimedia, effectively select the best and most practical cases, actively establish a dynamic network resource database, update the data content at any time, and improve the authenticity and timeliness of teaching content. The data content is updated at any time to enhance the authenticity and

timeliness of teaching content and improve students' learning ability. The number of dynamic network resource databases is closely related to the diversification of teaching materials and business teaching cases. Through the statistical analysis of a large number of network resources and business teaching cases, scholars and experts try to find out the internal relationship between the capacity of teaching resources and students' learning ability. Based on the results of statistical analysis, a correlation between them is obtained. In order to quantitatively evaluate the relationship between the capacity of dynamic network resource base based on diversified teaching resources and students' learning ability, the mathematical expression are as follows:

$$D(X, Y) = \sqrt{\sum_{i=1}^n (x_i - y_i)^2},$$

$$D^n = \sum_{i=1}^j \sum D(X, Y_i^{n-1}), \quad (2)$$

$$\delta^n = \frac{|D^{n-1} - D^n|}{D^n},$$

where D is the volume of the dynamic network resource library, D^n is the updated data volume of network the resource library, δ^n is students' learning ability based on diversified teaching resources, and X and Y represent diversified teaching resources and business practical cases, respectively.

4.3.3. Breakthrough of Teaching Methods. The multimodal interactive teaching mode of "wireless network + business English" is based on a personalized teaching mode on the one hand and emphasizes the spirit of cooperation on the other hand, that is, while respecting the different learning characteristics and habits of individuals, it can collaborate with each other in learning according to the metacognitive ability of learners so that students can have targeted fragmented knowledge points but also allows them to actively interact, build on their strengths, internalize their knowledge, and acquire the most needed business communication skills.

In the precourse self-study stage, students no longer rely on books to simply prestudy the text content but instead learn the knowledge points in a targeted manner based on the learning applications and system modules provided by the relevant online platforms and multimodal teaching resources [19]. Online teaching methods such as catechism and microlearning allow students to preview the important knowledge and background information of the course by watching videos at any time and any place, according to their own learning habits and pace. Take the "Business Negotiation" course as an example where students can learn the background knowledge and negotiation process of a certain negotiation case first and summarize and analyze it by themselves so that they can discuss it in class. At this stage,

"Internet+" teaching allows students to learn any knowledge point repeatedly without the limitation of time, place, and number of students, which breaks the traditional teaching method, makes full use of the time before class, and gives new vitality to the multimodal interactive teaching mode. In the classroom stage, the teacher-student relationship is a "two-way interaction" [20]. The role of the teacher has also changed dramatically. In the business English classroom, teachers should abandon the traditional teaching method of knowledge inculcation and carry out a flipped classroom based on the favorable resources of "Internet+" teaching. For example, in the course "Business English Translation," teachers can design a complete and clear teaching task, give a specific translation task online, and ask students to complete the translation practice in a project-oriented way. In this process, students can collaborate and discuss with each other in groups, while the teacher provides personalized guidance, observes and judges the teaching progress, and dynamically grasps the students' learning situation. The teacher is a facilitator and supervisor of student learning. In the flipped classroom, students complete the output of language knowledge and the internalization of business knowledge through the practice of real tasks or projects.

In the practical stage of teaching, we can strengthen the cooperation between schools and enterprises by means of "innovation and entrepreneurship" competitions, participation in projects, or internship in enterprises so that students can experience the foreign business process directly and effectively comprehend what they have learned in class so that they can apply what they have learned. For example, under the trend of "Internet+," the rise of cross-border e-commerce has completely overturned the traditional form of business transactions. To make students understand B2B and B2C business knowledge [21], teachers can use real cross-border e-commerce network platforms, such as sales, Amazon, eBay, or online virtual trading systems so that students can do practical work and find real problems. Teachers can realize teacher-student interaction online, help students solve problems in time, realize students' various business communication skills, and meet the urgent demand for high-quality applied business English talents in the "Internet+" era. In the business English talent market, it is often necessary to calculate the number of morning English talents to be accommodated according to the development of e-commerce platforms. The following formula can be used to evaluate the demand for business English talents on different e-commerce network platforms. And taking three cross-border e-commerce network platforms (Selling, Amazon, and eBay) as an example, Figure 3 shows the histogram of the proportion of business English talents in different cross-border e-commerce network platforms in different periods.

$$X = \{X_1, X_2, \dots, X_m\},$$

$$X_i = \{X_1, X_2, \dots, X_n\}, \quad (3)$$

where X is the demand for a cross-border e-commerce network platform for business English talents and X_i is the

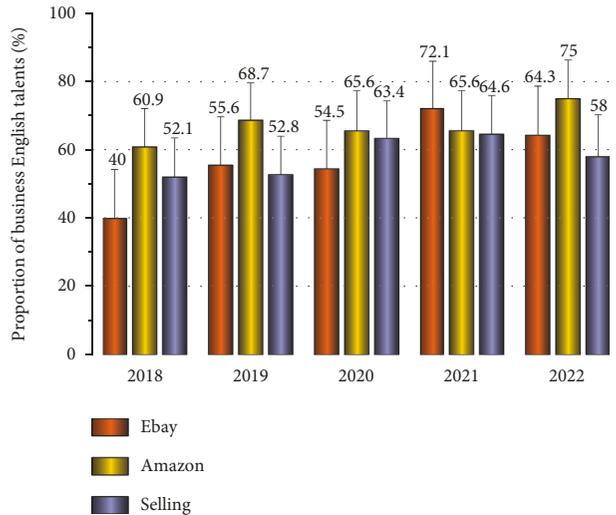

FIGURE 3: Histogram of the proportion of business English talents in different cross-border e-commerce network platforms in different periods.

demand for an e-commerce network platform for business English talents.

5. “Internet+” Multimodal Interactive Innovation from Four Elements of Teaching

5.1. Wireless Network + Environment: The Setting and Optimization of O2O Multisituational Classroom. The nature of the teaching environment is the decisive factor in the richness and density of teaching action modality. In the traditional business English teaching process, the environment mainly refers to the teaching classroom, where all teaching activities basically take place. The modalities used to construct interactive meanings in traditional classrooms are mainly visual modalities based on teacher-book-textbook and auditory modalities based on teacher lecture-student response. Students answer questions in a single form and limited content, and easy to form the inertia of students' participation motivation is not high, resulting in low teaching efficiency. The O2O (online-to-offline) business model in the new “Internet + economy” [22] has given profound inspiration to the education industry, thus giving rise to the emerging teaching model of the flipped classroom. The flipped classroom is a new form of “Internet + classroom” classroom, which greatly enriches the types of modalities and increases the complexity and intensity of modalities by adjusting the ratio of the number of modalities, thus enhancing the density of modalities and the construction of meaning in multimodal interactive behaviors.

With the development and popularity of smartphones and mobile networks, learners can download multimodal learning materials and conduct learning activities anytime and anywhere. Therefore, in the long run, schools need to consider updating the classroom format, including seat design and multimedia hardware equipment, to support and

ensure the smooth implementation of the flipped classroom. The typical flipped classroom does not highlight the practical nature of business English teaching, so it needs to be contextualized and optimized. At present, many universities already have business English practice courses, but they are basically separate from the relevant theory courses, which is not conducive to the comprehensive development of theory and practice. The business English flipped classroom can be optimized from online and offline to form a new form of O2O classroom (as shown in Figure 4).

In addition to various user-based learning platforms, the online environment can also be increased to varying degrees by adding a high-simulation model with a scene layout as the foreground.

In addition to various user-based learning platforms, the online environment can also be enhanced to varying degrees with a high level of simulation modeling training platform that foregrounds the layout of scenes and various new media platforms that attract the attention of communicative subjects, such as WeChat, Weibo, QQ, and Blue Ink Cloud Class. The offline environment can be composed of multiple scenarios such as activity classrooms, practical training bases, and public markets. The activity classroom can be used for business activities such as negotiation, forum, and seminar; the practical training base jointly organized by the school and enterprises can be used for realistic business training, such as entering the simultaneous interpretation box for business translation courses to feel the real atmosphere, which can help mobilize the real emotions of the learning subjects for experiential teaching; the public market includes banks, courts, science and technology parks, ports, and other real communication places related to business English communication situations. The public market includes banks, courts, science and technology parks, ports, and other real communicative places related to business English communication situations, which can be used to conduct situational multimodal tasks such as field surveys, industry research, and sample interviews. Learners improve their ability to solve practical problems through the flipped mode of online simulation and offline field restoration of Business English O2O classroom, which first trains virtually and then operates realistically and helps colleges and universities cultivate composite business English talents who meet market demand [23].

5.2. Wireless Network + Tasks: Design and Use of Multimodal Tasks for Stereoscopic Teaching Materials. The task is the interface between learners and the guide, and it is the medium for learners to reflect on their learning ability and the guide to check the teaching situation, which can be divided into two parts: classroom materials and after-class tasks (as shown in Figure 5).

On the one hand, the multimodal innovation of the new three-dimensional business English teaching materials is carried out. The new three-dimensional textbook responds to the learning characteristics of today's learners of “multiple information, communicative images, and short attention span” and realizes the real-time connection between paper

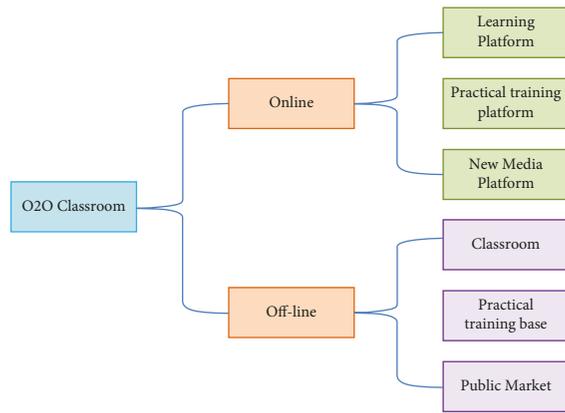

FIGURE 4: “Wireless network + environment”: O2O new form of the classroom.

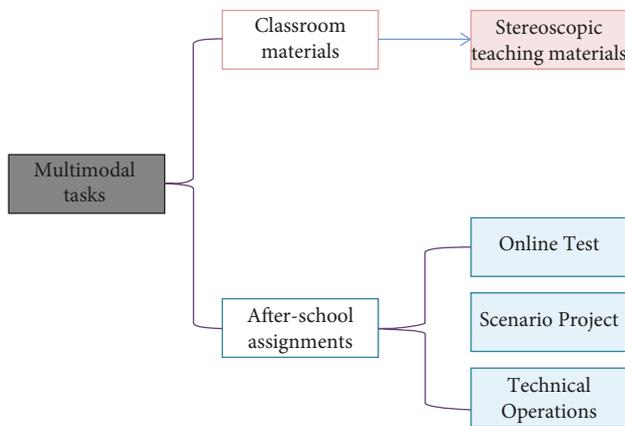

FIGURE 5: “Wireless network + tasks”: three-dimensional multimodal tasks.

textbooks and digital resources through QR code links, forming a new three-dimensional textbook of “paper book + digital course + tablet version of the digital textbook.” The new form of teaching material is three-dimensional and diverse. The use of new stereoscopic high-modal density and multimodal structured teaching materials that are based on the representational modality of print and supplemented by nonrepresentational modalities such as sound, video, and scene layout can increase students’ attention as interactive communicators, stimulate their sense of active participation, and realize language and business learning in multimodal interactive communication, which will greatly enhance the contextualized experience of learning and lasting and profound learning effects.

On the other hand, the multimodal after-school tasks that accompany the three-dimensional teaching materials should also be designed in an integrated way. The multimodal after-school tasks in the “Internet+” mode can be divided into three forms: online tests, scenario-based projects, and technical assignments [24].

The online test refers to the digital input of traditional homework based on multiple choices, judgments, links, and short answers to questions, which is distributed to learners for practice on the learning platform or online push in the

form of regular open test. Some of the objective questions in the digital online test can be reviewed and corrected in real time, which improves the interest and effectiveness of traditional practice.

Scenario-based projects are scenario-based integrated assignments implemented in specific real-life situations, such as market research, street interviews, and so on. The coordinated use of mobile Internet allows for real-time follow-up of project progress, tracking of respondents for dynamic feedback, and remote assignments from anywhere and anytime, enhancing the possibility and operability of scenario-based project implementation.

More novel is technical homework, which requires learners to have a high level of overall ability. It refers to learners’ electronic presentation of learning results through the use of modern information technology, including short video production such as microfilm, PowerPoint presentation, business platform project development, and online store operation, as well as other multimodal tasks integrating business skills and information technology. In the field of e-commerce, business platform companies and customers often need to collect business platform projects to measure the learning effectiveness of information technology. Therefore, in order to quantitatively describe the relationship between e-display of learning results and project development of the business platform, the mathematical equation is as follows. Figure 6 shows the popularity of modern information technology on different e-commerce platforms. Technology assignments can also be used as an alternative to traditional assignments. For example, traditional unimodal paper assignments on business translation can be presented in the form of multimodal videos to increase the interest in the learning process and learners’ sense of accomplishment. In addition, online tests, situational projects, and technical assignments can be personalized through new forms of teaching materials, and popular breakthrough models can be used to stimulate learners’ enthusiasm for active learning.

$$\sigma(x) = \frac{1}{1 + e^{-x}},$$

$$RE(x) = \max(0, x), \tag{4}$$

$$D = \frac{1}{a\sigma(x) + b},$$

where D represents an electronic display of learning achievements by modern information technology, x represents business platform project development, RE is the multimodal tasks, $\sigma(x)$ represents technical operation, and a and b are the relative parameters.

5.3. *Wireless Network + Learners: Combining and Communicating with Diverse Categories of Students.* Learners are the subject and the center of this communicative and interactive behavior of teaching activities, and they are the guide, the task, and the object of environmental services in the teaching process, and their learning and practice results are the only

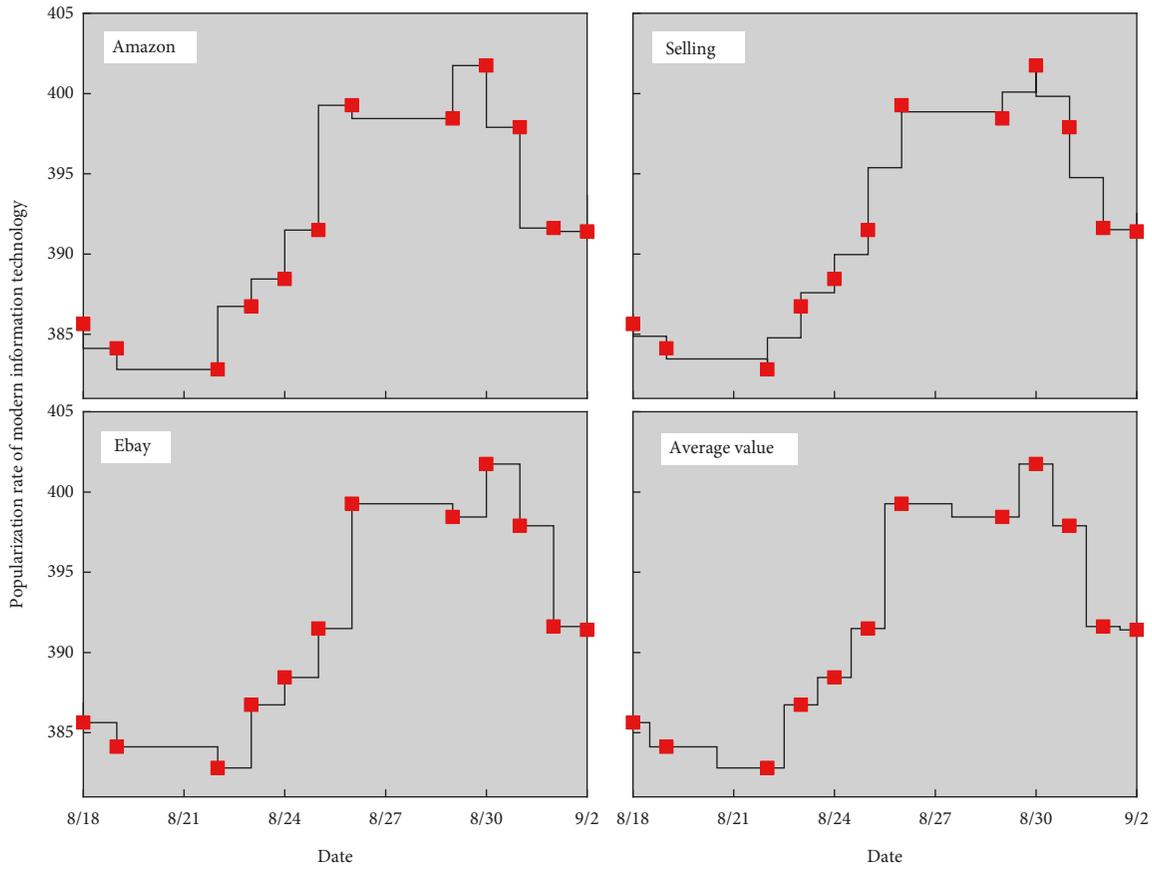

FIGURE 6: The popularity of modern information technology on different e-commerce platforms.

criteria to test the success of teaching activities [25]. Therefore, the multimodal interaction innovation of business English teaching should focus on the main role of learners, give full play to humanistic thinking, divide different types of learners according to their own and acquired learning characteristics, and selectively optimize the combination of learner groups according to different learning needs and teaching modes to achieve better learning interaction. According to the learners' innate environment, they can be divided into Chinese learners who are native Chinese speakers and foreign learners who are native English speakers or other foreign languages; according to the learners' habitual communication mode, they can be divided into traditional learners who are dominated by teachers' lectures and independent learners who are dominated by multichannel personalized learning resources; according to the learners' learning habits, they can be divided into unimodal learners who are text-based and multimodal learners who are dominated by pictures and videos. According to the learners' learning habits, they can be divided into text-based unimodal learners and picture-video-based multimodal learners; according to the learners' social status, they can be divided into student learners and social learners; according to the learners' geographical location, they can also be divided into learners from our school, learners from neighboring schools, learners from outside the province, learners from abroad, and so on (as shown in Figure 7). In teaching practice, if we can distinguish

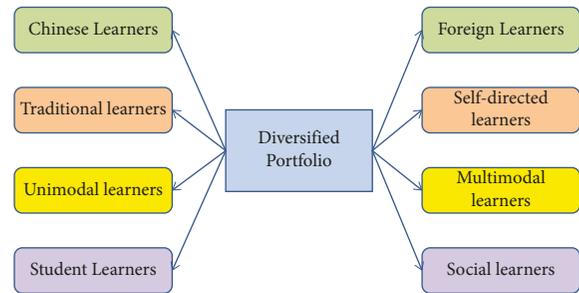

FIGURE 7: “Wireless network + learners”: Diverse student combinations.

different combinations of learners according to different classroom modules and teach them according to their needs, the teaching effect will have a great breakthrough.

In a multimodal and innovative business English teaching interaction, different types of learners can be combined according to different course requirements. For example, in an offline intercultural classroom, a combination of foreign and Chinese students with different cultural backgrounds can lead to more authentic and effective results in both classroom discussions and group role-playing experiences. High-intensity modalities such as language, posture, and eyes that are highlighted in the classroom can be amplified and used more frequently, and the modal

density and complexity of the classroom will be increased to deepen students' impressions. The "wireless network + learners" model can break through the geographical boundaries of learners, enabling more off-campus, off-province, foreign, and social learners to share learning resources with our learners and interact with business English in multiple modalities. Different learner combinations can also prompt hidden frozen actions and contextualized actions to rise to the surface and become mid-scene or even foregrounded actions; for example, classes with foreign learners will highlight hidden cultural differences such as arrival time points and other hidden frozen actions, strengthening the communicative subject's sense of participation and attention.

5.4. Wireless Network + Guide: Configuration and Selection of Multilevel Teachers across Fields. In the new era of "Internet+," the dominant position of the teacher in the traditional sense gradually diminishes and then retreats as the guide of teaching activities. As the guide of teaching activities, the allocation and selection of teachers has a pivotal role in the curriculum. Business English is an interdisciplinary subject, and its professional nature requires that teachers should be equipped with cross-disciplinary and dual-teacher talents. Generally speaking, business English teachers should have "good ideological quality, teaching ability (including the ability to organize teaching, use teaching methods and implement teaching evaluation), and professional knowledge (English language skills + business knowledge)." In addition, the new era of "Internet+" also requires business English teachers to pay more attention to the use of new media and other online platforms to search for relevant real-time materials for business teaching in terms of teaching ability and to highlight the application of business practical knowledge and skills in terms of professional knowledge.

At present, teachers of business English in local universities are generally divided into four types as follows:

- (1) Full-time teachers majoring in English linguistics and literature who serve after further study of relevant business courses
- (2) Full-time teachers majoring in commerce and business with better English
- (3) Part-time teachers who are elites from relevant enterprises or industries
- (4) A very small number of teachers who have graduated with a master's or doctoral degree in business English

The potential problems of these four types of business English teachers are as follows: first, solid language skills but insufficient business knowledge; second, rich business knowledge but poor language skills; third, proficient business skills but systematic business English theory needs to be improved; and fourth, comprehensive business English skills but lack of practical experience.

It can be seen that there is still a big problem in the construction of business English teachers' teams. As an emerging profession, the number of graduates with a master's degree or above is relatively small, and the possibility of employing teachers with the right profession in all aspects is small. Therefore, in order to ensure the joint development of business, language, and practical skills, the above four types of teachers are needed to form the Business English faculty in stages. For the basic courses in freshman and sophomore years, English majors can be used to teach; for the business courses in junior and senior years, business majors need to be guided by teachers on staff; for the practical courses in senior years, especially during an internship, part-time teachers from outside companies can be used to guide them. The "wireless network + guide" model makes the external part-time teachers of business courses break through the limitation of time and space to a certain extent, from local enterprises to the whole country or even abroad. In addition, the new form of flipped class courses can be divided into modules of a multiteacher distribution system to teach, learn from the strengths of others, really improve the quality and effectiveness of classroom teaching, and realize the school-enterprise linkage and collaborative education.

6. Conclusion

The wireless network-based multimodal teaching mode of business English fragments theoretical knowledge in a multimodal way for students to personalize their learning, realizing teacher-student and student-student interaction and improving learning efficiency. However, the implementation of "Internet+" teaching is constantly challenging and requires continuous improvement so that learners can form the awareness of "Internet+" and actively use the "Internet+" learning. The Internet + learning platform should be used for learning.

Thus, the construction of business English discipline should keep pace with the times by developing "wireless network + environment," "wireless network + task," "wireless network + learner," and the new era model reform of "wireless network + environment," "wireless network + task," "wireless network + learner," and "wireless network + guide," combined with the new era development requirements of the O2O multisituational classroom settings and optimization, three-dimensional teaching materials and multimodal task design and use, the combination and communication of diversified categories of students, cross-field multilevel teacher configuration and selection of multimodal interactive innovation, focusing on teaching activities in the main position of learners in teaching activities, the use of multimodal scenarios to stimulate learners' active emotional factors, and more effective implementation of business English teaching practices. Business English teachers should respond to the needs of the times in terms of teaching philosophy, teaching content, and teaching methods so that students can spontaneously and actively use the "wireless network + business English" teaching mode to engage in learning.

As an important data source of complex product design and manufacturing, 3D assembly model has accumulated a large number of 3D assembly models in various manufacturing industries under the background of widely used digital design technology. In order to make better use of reusable common structure information about 3D assembly model, reduce repetitive labor, and shorten product development cycles, a common structure mining method of 3D assembly models was proposed. Firstly, based on the attribute neighbourhood diagram of individual parts of the 3D assembly model, the information of the assembly feature attributes is maintained and the nonassembly feature attributes are simplified to form an attributed assembly feature neighbourhood diagram; then, based on the assembly relationship between the parts of the 3D assembly model, the attributed assembly feature neighbourhood diagrams of the parts are combined to form a 3D assembly model attribute neighbourhood diagram. Secondly, the common structure of the 3D assembly model is extracted by the frequent subgraph mining algorithm. Finally, a set of fixture models is used to verify the results, which show that this 3D assembly model common structure mining method can accurately and effectively explore the common structure information of the product and has good results.

1. Introduction

With the development of information science and technology, as well as the development of knowledge related to product modelling, CAD model has a qualitative leap in its ability to describe information in terms of connotation or denotation. The human being as an individual has certain three-dimensional characteristics in his or her visual senses in life, thus allowing him or her to perceive the three-dimensional model in life and its surroundings and to obtain more information.

The 3D assembly model contains many structures, functions, attributes, and other reusable information that reflect the design intent. This paper proposes a 3D assembly model common structure mining method with the 3D model as the object, as shown in Figure 1. The common parts of the graphs that are frequently found and meet the reuse requirements, namely, common structures, are then discovered. The study of the common structure discovery and

reuse method will provide a reference method for the designers to discover this valuable reuse information in the design and manufacture of products and provide a reference method for the analysis and reuse of 3D assembly models.

The representation of 3D assembly model information requires comprehensive expression of relevant information on 3D assembly model so as to provide information sources for subsequent related excavation and reuse work. Therefore, the representation of 3D assembly model information should include topological structure information that can express the structural resources related to the model, semantic information that can express the name, type and function as parts, and some characteristic information that can express the coordination relationship between parts.

Chakrabarty et al. [1] proposed the hierarchical structure model of 3D assembly model for complex 3D assembly model. Liu et al. [2] specifically divided product attributes, behaviours, and other information into product layer, feature layer, and other layers, and realized the connection

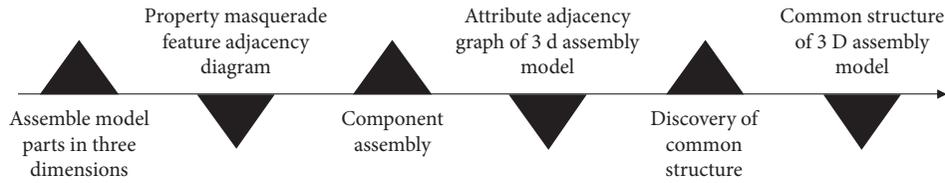

FIGURE 1: Schematic diagram of common structure method.

relationship between information layers on the basis of the hierarchical model. Based on the representation of hierarchical model, Mou [3] constructed human-machine collaborative quantification of the mutual assembly relations between parts of 3D assembly model so as to be used in assembly sequence planning of 3D assembly model. Li [4] constructed a reuse-oriented hierarchical model, such as the inclusion relationship of structural features and the morphological relationship of features, based on the correlation topological relationship and surface hierarchical division. Yang et al. [5] proposed a two-dimensional descriptor of process information oriented to 3D assembly instruction issuing, used an abstract matrix representation method to represent 3D process information, and established an assembly instruction issuing model.

Graph model representation is mainly composed of nodes and edges based on graph theory. Graph model can be used to describe the connection relation between structure and structure of 3D assembly model. The representation method of graph model is favoured by many scholars and applied in many research fields. Bourjault [6] expressed 3D assembly model based on graph structure. The model is a simple undirected graph, whose nodes correspond to the set of parts in the model, while edges correspond to the set of assembly relations between parts. On the basis of Bourjault's diagram model, Homem de Mello and Sanderson [7] added expressions of relevant functional attributes, thus establishing a graph model representation method of five-dimensional topology. Xiao et al. [8] proposed a single assembly interface 3D assembly model of information retrieval method: first, the preliminary model information retrieval is used, and then information is filtered according to the result of retrieval. Assembly model geometry retrieval can be converted to look for problems with the attribute adjacency graph. Finally, frequent subgraph mining algorithm is used with conjugate subgraph attribute adjacency graph search.

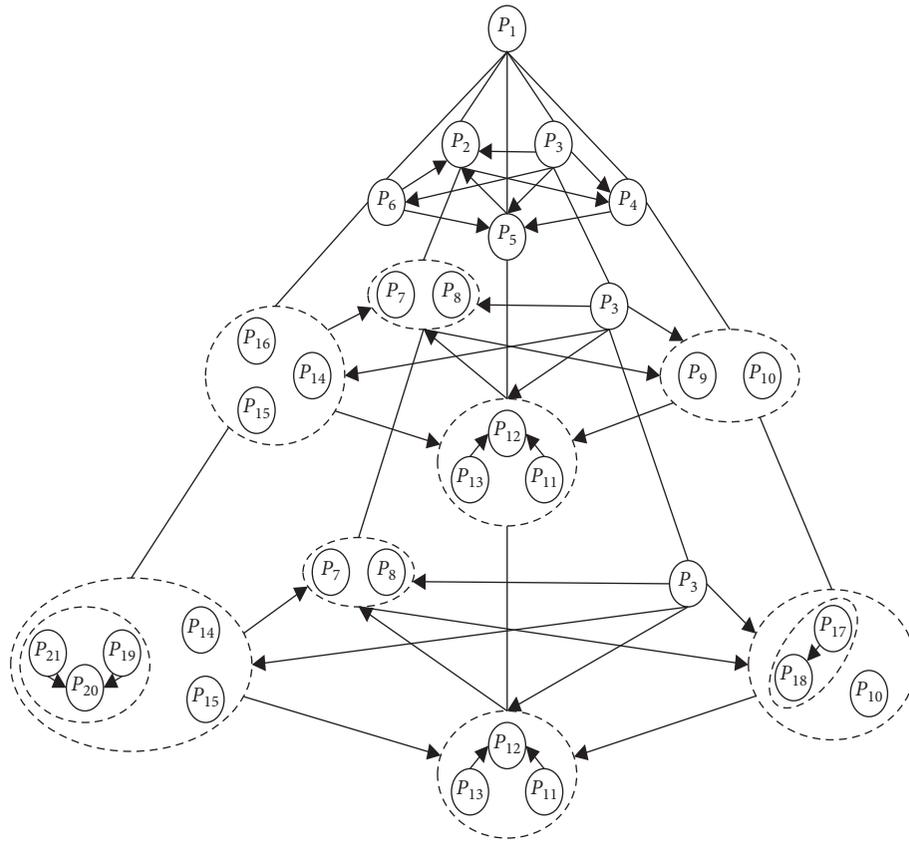

Zuo [9] took brake products as an example. First, the attribute connection graph expression specification is constructed, and then common design units are obtained based on clustering algorithm and frequent subgraph algorithm so as to realize assembly model information mining. Wu [10] took auto parts products as the research object, analysed the common information among products for objects at different levels, pointed out the key points to be dealt with in the reuse process, and proposed a reuse system suitable for products on this basis. Ma [11] expressed the assembly structure of products based on the number diagram of product structure and proposed the module division method of product cluster on the basis of frequent subgraph mining.

Zhou et al. [12] proposed a local structure similarity analysis method of 3D assembly model based on subgraph isomorphism and case matching. Firstly, based on the attribute adjacency graph, the assembly relations between parts in 3D assembly model are transformed into corresponding elements in the graph. Secondly, the classification rules and preprocessing rules of the connection relation were defined, and similar 3D assembly model structures were matched based on the correlation algorithm. Han et al. [13] proposed a method to identify key assembly structures in complex mechanical assembly. Firstly, the model was represented by complex network, and then the key assembly functional parts were obtained based on the evaluation model. Finally, the key assembly structures were identified by heuristic algorithm. Wang et al. [14] constructed graphic descriptors to express the geometric and topological information of 3D assembly models and combined clustering algorithm and frequent subgraph mining algorithm to realize the mining of reusable models.

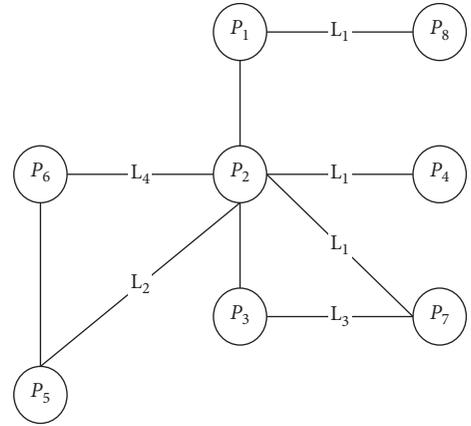

2. Materials and Methods

2.1. Representation of 3D Assembly Model Information. The representation of 3D assembly model information requires comprehensive expression of relevant information of 3D assembly model so as to provide information sources for subsequent related excavation and reuse work. Therefore, the representation of 3D assembly model information should include topological structure information that can express the structural resources related to the model, semantic information that can express the name, type, and function of parts, and some characteristic information that can express the coordination relationship between parts. In the representation of model information, attention should be paid to the accurate and comprehensive representation of model information. Secondly, the constructed method should be as simple, clear, and reasonable as possible, which can be applied to the subsequent related excavation and reuse work.

At present, attribute adjacency graph is used to build model, which has too much structure data and low application efficiency. Or take the whole part in the 3D assembly model as a single node and the connection relation between parts as the edge to construct the model attribute connection graph. Although these models have simple structure, they pay insufficient attention to the geometric shape information of the 3D assembly model itself. Therefore, in order to not only express important assembly information of 3D assembly model, but also improve application efficiency, this paper proposed a 3D assembly model information

(a)

(b)

FIGURE 2: Continued.

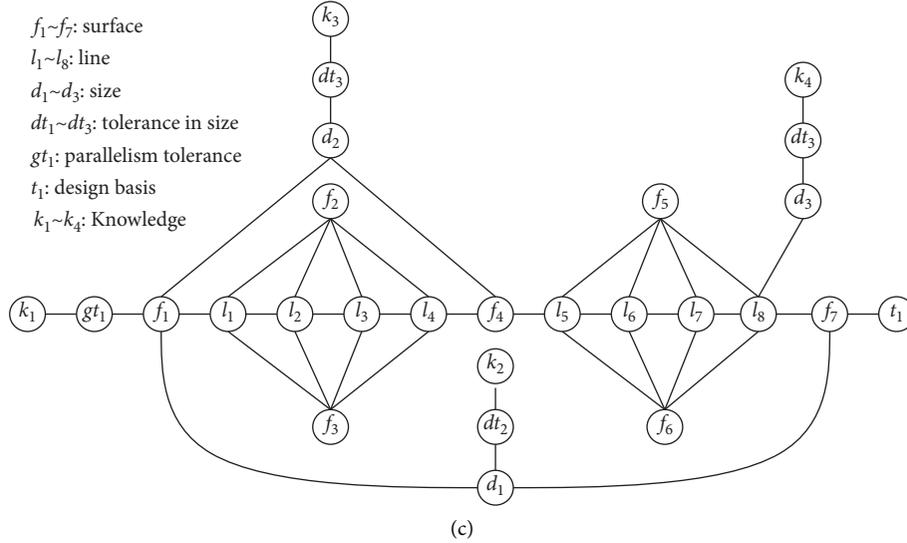

FIGURE 2: The model represents the sample diagram. (a) Hierarchical directed graphs represent sample graphs. (b) The property connection diagram represents the sample diagram. (c) Hybrid adjacency graphs represent sample graphs.

representation method based on assembly features. Firstly, on the basis of the attribute adjacency graph, the assembly features of each part in the 3D assembly model were retained, the nonassembly features were simplified, and the attribute assembly feature adjacency graph of the parts was constructed. Then, on this basis, the relationship between the parts in the 3D assembly model is analysed, and the assembly scheme is constructed based on this, and then the attribute adjacency graph of the 3D assembly model is established. Based on the above research, an effective way of information representation of 3D assembly model is presented.

2.1.1. The Definition of Attribute Adjacency Graph

Definition 1. Attribute adjacency graph: It is mainly a graph representation model in which the parts surface is the node and the adjacency relationship between the surfaces is the edge, so as $G = \{V, E, \alpha, \beta\}$ to express the topological relationship of the parts, where V represents the set of nodes, and any element v_i in the set meets the corresponding relationship with one side of the part; E represents the set of edges, is the adjacency relation of faces; any element in the set has a corresponding element, mainly including the geometric type of faces, the number of faces, and so on. β represents the set of attributes of an edge, and any element in the set has one element corresponding in E , mainly including the type of the edge and the position of the adjacent surface.

According to the current research, many scholars have proposed a variety of model representation methods. For example, shown in Figure 2(a) is the layered orientation graph model of [15] and shown in Figure 2(c) a mixture of adjacency graph model [16], respectively, the corresponding models of component assembly tolerance level, size, design, design standards, and other information in detail, and solve the problems of the corresponding field, but for the 3D

assembly model related to discover. The structure is multifarious, time-consuming, and of low retrieval efficiency and high cost. The attribute connection graph model [17] as shown in Figure 2(b) is simple in form, but it ignores the geometric shape information of the model itself, resulting in low accuracy of excavation results and large differences among models.

To sum up, this paper divides the shape features of the model into assembly features and nonassembly features. Assembly features include assembly information in parts and are used to construct the body shape of parts, which plays a decisive role in the assembly process of 3D assembly models. Nonassembly features are auxiliary features in parts, which are local modifications of part information and play little role in the assembly process of 3D assembly model. In this paper, based on the attribute adjacency graph of 3D model, the assembly feature information in the part model is preserved first, and then the semantic node is used to replace the other information in the model so as to construct the attribute assembly feature adjacency graph of the part. Its definition is as follows.

Definition 2. Property masquerade feature adjacency diagram: It is a graphical representation that focuses on assembly features in part models and is represented by $G = \{V, E, \alpha, \beta, V_0\}$, where V represents the set of nodes, and any element v_i in the set corresponds to one side f_i in the assembly features of parts; E represents the set of edges, in which any element e_j corresponds to the side formed by adjacent surfaces f_n and f_m in the assembly features of parts; and α represents the attribute set of the node, which mainly includes the geometric type of the face and the number of sides of the face. β represents the set of edge attributes, including the type of edge and the position relation of adjacent surfaces. $V_0 = \{I_N, I_F, I_C\}$ represents the semantic node of this part, which is the semantic expression

of other information except assembly features in this part, including the semantic information of part name (I_N), function (I_F), and category (I_C).

2.1.2. Construction of Attribute Adjacency Graph for 3D Assembly Model. The 3D assembly model is essentially a set of information set, that is, a collection of entities modelled by the designer in 3D space and the representation of their properties. For two parts in a 3D assembly model that are in contact with each other, two types are distinguished: contact connections and assembly connections, by determining whether they have assembly requirements. A contact connection is where two parts are in contact but there is no requirement for assembly. Conversely, where there is a requirement for assembly, the connection is an assembly connection. Secondly, assembly connections can be subdivided into welded, threaded, and pinned connections, depending on how the two parts are connected. In the process of discovering and reusing the common structure of a model, the assembly model requires special attention to the assembly relationships between parts as opposed to the part model. In this paper, the types of connection relation between parts and the contact types of mating surfaces are classified and coded, respectively, and the results are shown in Table 1 and Table 2. For example, the code “b1” means that the connection relation between two parts is “pin connection” and the contact type of the mating surface is “plane-cylinder contact.”

Taking the assembly process of the 3D assembly model shown (Figure 3) as an example, the 3D assembly model shown in Figure 3(c) is assembled by part A shown in (Figure 3(a)) and part B shown in (Figure 3(b)), respectively. By searching the assembly features corresponding to the model and related process documents, it can be obtained that the connection relation between parts is “threaded connection,” and the contact type of mating surface is “cylinder-cylindrical contact”

Based on the adjacency graph construction steps of attribute make-up features described above, corresponding graph representations are made for part A and part B, respectively. The results are shown in Figure 4(a) and Figure 4(b). The nodes marked with shadows in the graph

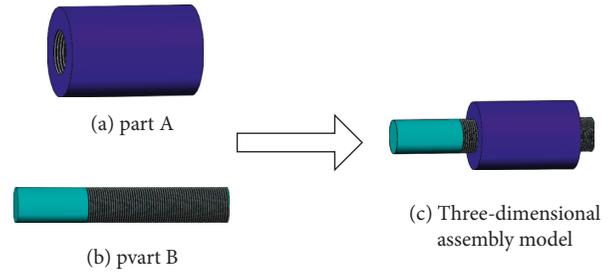

FIGURE 3: Assembly diagram of 3D assembly model. (a) Part A. (b) Part B. (c) Three-dimensional assembly model.

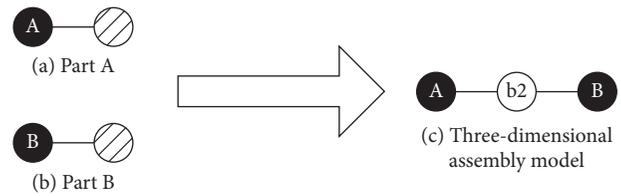

FIGURE 4: Schematic diagram of attribute adjacency graph construction of 3D assembly model. (a) Part A. (b) Part B. (c) Three-dimensional assembly model.

represent the mating surfaces of the parts. Then, based on the classification and coding specification of the connection relation, the mating surfaces are assembled into a node, which is named as the mating node, that is, the node marked with “B2” (“B” means thread connection; “2” means cylinder-cylindrical contact). Thus, the adjacency graph of model attributes is constructed, and the result is shown in Figure 4(c).

The structure of attribute adjacency graph constructed by this method is more concise, and the graph contains the related information of part name, category, function, and so on. The size of the constructed graph is much smaller than that of the traditional method. Compared with the traditional method, the graph size is too large due to too many parts, and the complexity of the attribute adjacency graph can be reduced to a large extent, and the effect is more obvious.

2.2. Common Structure Mining of 3D Assembly Model Based on Frequent Subgraph. The excavation of the common structure of 3D assembly model is not to discover the assembly model structure with identical structure, process, and function, but to find the model structure with similar structure and different local structure in the corresponding database. In fact, the process of discovering common structures is to integrate the design experience of similar model structures and accumulate relevant design advantages so as to effectively increase the reuse efficiency of 3D assembly models.

In this paper, simplified structural data information is used as input information to reduce the scale of attribute adjacency graph of 3D assembly model and reduce the complexity of common structure excavation. In addition, the semantic nodes and coordination nodes in the attribute adjacency graph of 3D assembly model are preprocessed to reduce the size of the attribute adjacency graph of 3D

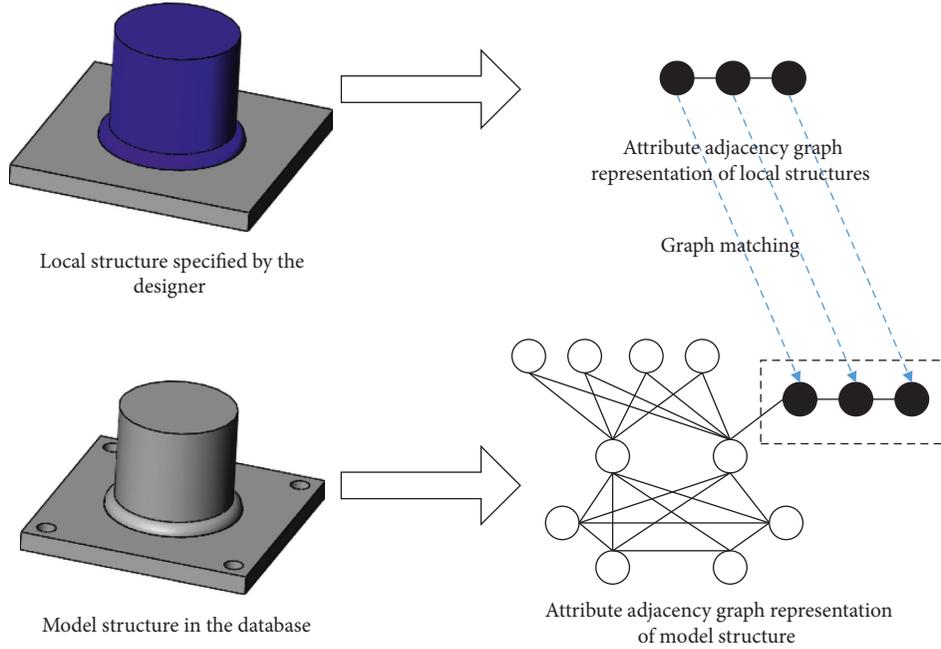

FIGURE 5: Isomorphism diagram of subgraph.

TABLE 3: Symbol definitions.

Symbol	Definition
V_0^a	Semantic node of part a
$V_{a,b}$	Mating nodes between parts a and b
Q	A collection of all attribute adjacency graphs
Q_p	All preprocessed Atlas
H^K	Set of K -order candidate frequent subgraphs
R^K	Set of frequent subgraphs of order K
T	Set of all frequent subgraphs, $T = \{R^1, R^2, \dots, R^m\}$
id	In H^K or R^K , the address number corresponding to the subgraph
F	All vertex properties corresponding to the subgraph
M	The adjacency matrix corresponding to the property adjacency graph
C_{id}	In the construction of $K+1$ candidate subgraph, it is necessary to connect two k -order frequent subgraphs containing the same $K-1$ -order frequent subgraph, C_{id} represents the address list of all $K-1$ -order frequent subgraphs, and C_{id} is usually obtained when the candidate subgraph is generated
S_{id}	If there is a subgraph isomorphism between a subgraph and a graph in Q , S_{id} is used to store the address number of the graph in Q , and S_{id} is usually obtained when frequent subgraphs are generated

assembly model, which is the first screening of the frequent subgraph mining process, before the common structure is mined through frequent subgraph. Through this process, the matching range is effectively reduced, and the overall mining efficiency is improved.

2.2.1. Related Concepts and Definitions

Definition 3. Graph isomorphism: Given graphs $G_A = (V_A, E_A)$ and $G_B = (V_B, E_B)$, G_A and G_B are isomorphic if there is a mapping between the two graphs $f: V_A \rightarrow V_B$ and $e_A = (v_A, v_A')$ is an edge in G_A , and if and only if $e_B = (v_B, v_B')$ is an edge in G_B .

Definition 4. Subgraph isomorphism: It is known that figures G_A and G_B and G_B' are a subgraph of G_B . If there are

isomorphic relationship in G_B' and G_A , the subgraphs G_A and G_B are isomorphic.

The subgraph isomorphism process shown in Figure 5 is the graph isomorphism process of a subgraph of a graph and another graph. The judgment of isomorphism relation between two graphs is essentially the judgment of mapping relation between nodes in the graph, and the mapping relation under node mapping relation also satisfies the corresponding mapping relation. Among them, the left side of the two charts, respectively, as the design requirements of the model structure and database structure, the blue part is the design personnel designated by the local structure (i.e., the subgraph), two figures on the right side are, respectively, corresponding to the attribute adjacency graph, said black nodes mapping relationship of vertices, said two figures of subgraph isomorphism; namely, the dotted line represents the mapping relationship between vertices.

Definition 5. Frequency We know that Atlas $Q = \{q_1, q_2, \dots, q_n\}$ and q are subgraphs. If q appears in q_i and $i \in n$, that is, q is isomorphic to q_i subgraph, then x_i is 1; otherwise, q is not isomorphic to any subgraph in q_i ; then, x_i is 0. Based on formula $\lambda = \sum_{i=1}^n x_i/n$, λ is obtained, and λ is frequency ($\sum_{i=1}^n x_i$ is the sum of the number of graphs with isomorphism).

Definition 6. Frequent subgraph: The minimum frequency λ_{\min} is known. If $\lambda_{\min} \leq \lambda$ exists, q is called its frequent subgraph in the Atlas Q .

Definition 7. Generic structure: Given a 3D assembly model database, $D = \{d_1, d_2, \dots, d_n\}$ represents its attribute adjacency graph set, d meets the condition of frequent subgraph and is the frequent subgraph of graph D . In the model database, the relevant structures of 3D assembly model corresponding to D are called common structures.

2.2.2. Discovery of Common Structure. Scholars at home and abroad often use frequent subgraph algorithm to solve common structure mining problems. Apriori algorithm has a strong influence on the mining of frequent subgraphs and is widely used [18–20]. This algorithm is a frequent item set algorithm [21, 22] that excavates and analyses association norms. The generation of frequent item sets mainly goes through the generation of candidate sets and candidate pruning and is solved through layer-by-layer search. In other words, it generates high-order item sets on the basis of low-order item sets. In addition, the generation and testing strategies are used to discover frequent item sets, and pruning operations are carried out according to the related properties of candidate pruning to obtain high-order candidate sets. Finally, the item sets that do not meet the minimum frequency are deleted through frequency judgment so as to generate high-order frequent item sets. Two classical frequent subgraph mining algorithms, AGM algorithm [23] and FSG algorithm [24], are evolved on the basis of Apriori algorithm. AGM algorithm is based on Apriori algorithm, which generates k -order candidate set by adding one node each time. Then, the graph isomorphism is used to judge whether there are identical $k - 1$ candidate sets in k -order candidate sets. The algorithm needs to traverse the data set repeatedly. When the graph size increases, the running time of the algorithm will increase and the efficiency of the algorithm will decrease. The FSG algorithm generates k -order candidate sets by adding edges one at a time. In the attribute adjacency graph, there are more edges than nodes, resulting in more candidate sets. In order to optimize the efficiency of the algorithm, the intersection of the TID (Transaction ID) lists of all k -order candidate sets is calculated for frequency counting and candidate pruning. To sum up, this paper takes graph nodes as the object, combines the advantages of the two algorithms and optimization methods such as preprocessing to improve the efficiency of the algorithm, and then achieves the purpose of discovering the common structure of the model.

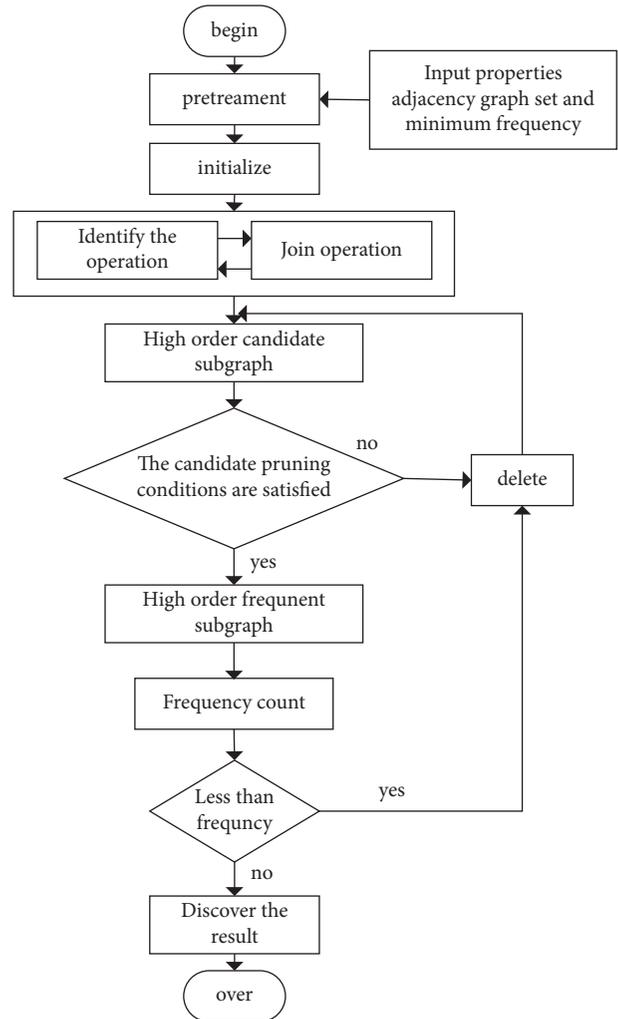

FIGURE 6: Flowchart of frequent subgraph algorithm.

To facilitate the description of the algorithm, the following symbols and data structures are defined, as shown in Table 3.

The algorithm steps are described as follows:

- Step 1.* Pretreatment.
- Step 2.* Initialize the first-order and second-order frequent subgraphs.
- Step 3.* Connect two K -order frequent subgraphs (including the same low-order frequent subgraphs) to form $K + 1$ -order candidate subgraphs.
- Step 4.* Prune the candidate subgraph of order.
- Step 5.* After $K + 1$ candidate subgraph is generated, frequency counting is performed.
- Step 6.* Find and delete redundant structures in the candidate subgraph set.
- Step 7.* Cycle until no new frequent subset can be formed.

As can be seen from the above algorithm steps, frequent subgraph algorithm mainly includes preprocessing, initialization, generation of candidate set, candidate pruning,

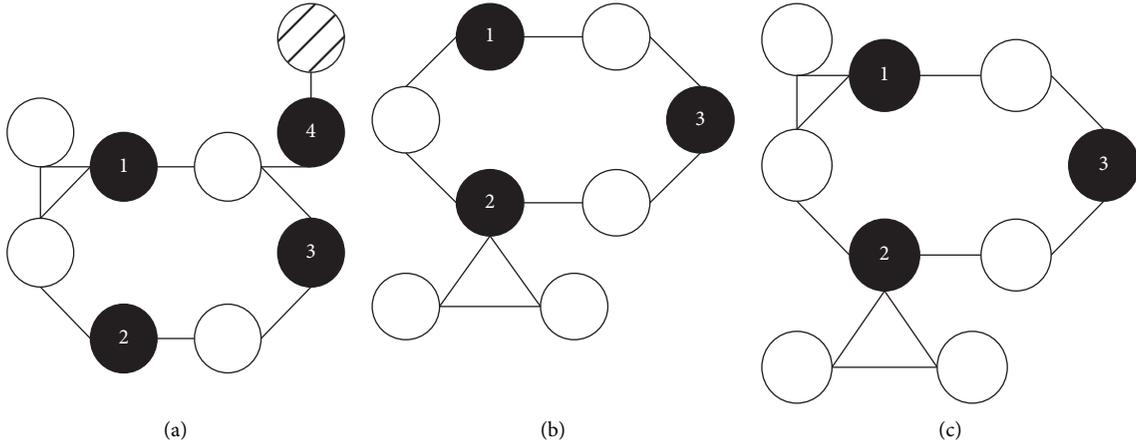

FIGURE 7: AAG of multi-assembly interface. (a) Property adjacency graph 1. (b) Property adjacency graph 2. (c) Property adjacency graph 3.

frequency counting, redundancy screening, and other common structure excavation processes shown in Figure 6, showing the flowchart of the algorithm. Since all elements in the attribute adjacency graph have corresponding attributes, the similarity of corresponding attributes should be judged during excavation. This paper refers to the similarity calculation method of for judgment so as to obtain more accurate excavation results.

(1) *Pretreatment.* The preprocessing is carried out before frequent subgraph mining, mainly by removing the semantic nodes that appear independently in each attribute adjacency graph of the graph set and the coordination nodes that are only connected with this node. That is, semantic nodes that

appear only in one graph and coordination nodes that are only connected to them do not appear in other graphs. The preprocessing process is the preliminary screening of common structure excavation so as to reduce the size of Atlas and the number of matching. The following definitions of semantic node frequency are given in this chapter.

Definition 8. Semantic node frequency: We have $Q = \{q_1, q_2, \dots, q_n\}$ and V_0^a . If V_0^a occurs in q_j and satisfies $V_0^a \in q_i$, $i \in n, j \in n, j \neq i$, then l_i is 1; otherwise, l_i is 0. The semantic node frequency ζ is obtained by the formula $\zeta = \sum_{i=1}^n l_i/n$.

In Figure 7, attribute adjacency graphs corresponding to a group of 3D assembly models are used to demonstrate the

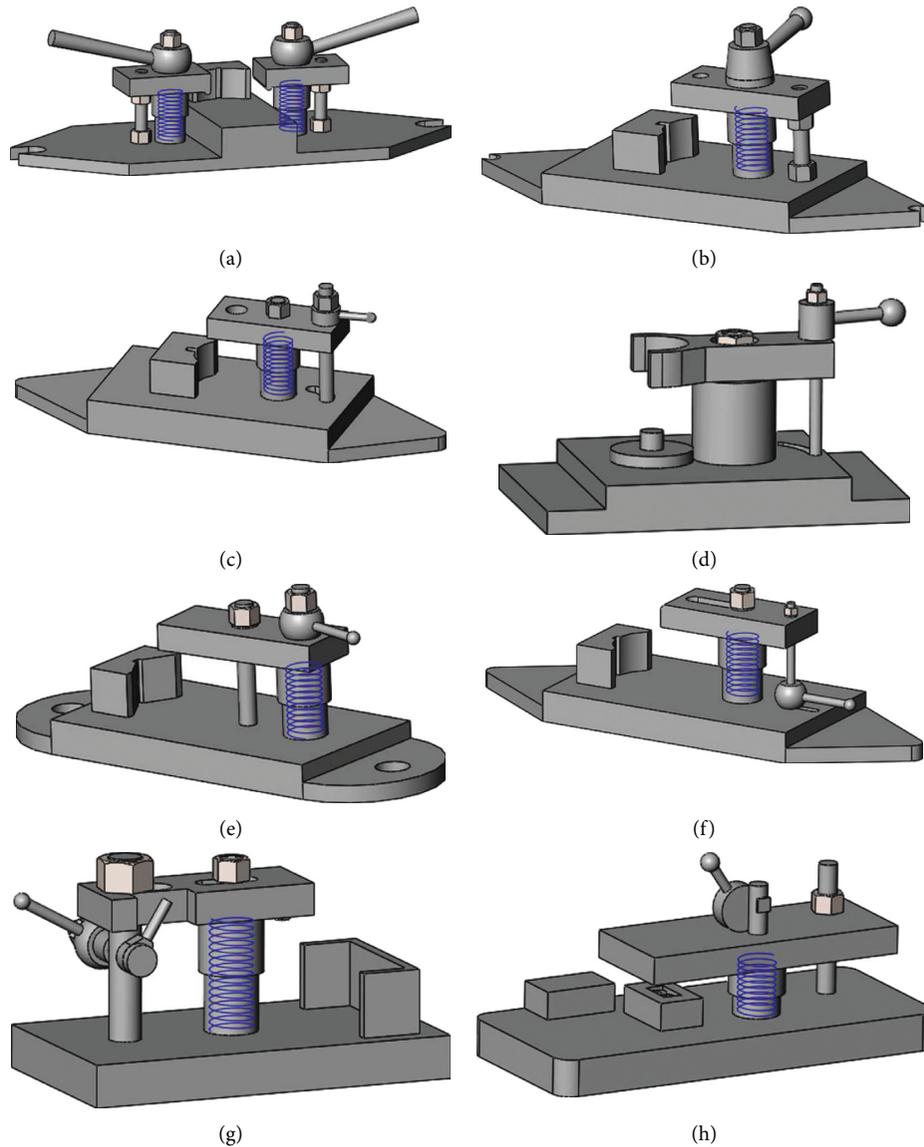

FIGURE 9: Three-dimensional assembly model of fixture. (a) Tongs 1, (b) tongs 2, (c) tongs 3, (d) tongs 4, (e) tongs 5, (f) tongs 6, (g) tongs 7, and (h) tongs 8.

pretreatment process. Black nodes are semantic nodes, and other nodes are coordination nodes. The preprocessing mainly traverses the adjacency graph of these 3D assembly model attributes. First, the semantic node is traversed. It can be observed from the figure that only the semantic node No. 4 in Figure 7(a) exists independently, and Figure 7(b) and Figure 7(c) do not contain the semantic node, so the semantic node will be deleted during the preprocessing. Then, the coordination nodes connected with the semantic node are judged. If a coordination node is only compatible with the semantic node, the coordination node will also be deleted in the preprocessing process, as shown in Figure 7(a), and the shaded part is the coordination node only connected with the semantic node. Until the traversal of all nodes is completed, the preprocessing process is finished, and the next step is entered.

In summary, the pseudocode describing the steps of the preprocessing Algorithm 1 is as follows.

Although the number of scanning Atlas increases in the pretreatment process, the number of scanning irrelevant nodes can be reduced to a large extent, the scan scale can be reduced, the matching loss can be reduced, and the excavation efficiency can be improved.

(2) *Initialize*. After preprocessing, the first-order frequent subgraph and second-order frequent subgraph need to be initialized. For the attribute adjacency graph of 3D assembly model, the first-order frequent subgraph can be easily obtained, which corresponds to nodes in the attribute adjacency graph, and connecting any two first-order frequent subgraphs is unique. The second-order frequent subgraph was obtained by traversing the attribute adjacency graph of

the 3D assembly model. In order to facilitate the later acquisition of high-order frequent subgraphs, the id, F, M, C_{id} , and S_{id} other data structures of second-order frequent subgraphs are stored accordingly.

(3) *Generation of Candidate Sets*. The core idea of candidate set generation is to generate high-order candidate subgraph on the basis of low-order frequent subgraph. That is to generate $K + 1$ -order candidate subgraph through K -order frequent subgraph. The generation of candidate set needs to go through two processes: (1) identification, judging whether two K -order frequent subgraphs contain the same $K - 1$ -order frequent subgraphs; (2) connection: two K -order frequent subgraphs that meet the recognition conditions are connected to form $K + 1$ -order candidate subgraphs.

The first step of candidate set generation is recognition; that is, in the corresponding two K -order frequent subgraphs (large graphs), judge whether the $K - 1$ -order frequent subgraphs (small graphs) are the same. If they are the same, the next step can be connected. Otherwise, the connection cannot be made.

The second step in candidate set generation is joining. After identifying two identical small graphs, it is necessary to connect the large graphs containing the small graphs to obtain $K + 1$ -order candidate subgraphs. The joining process can be understood as the joining process of adjacency matrix, namely, $(K \times K) + (K \times K) \Rightarrow (K + 1) \times (K + 1)$.

Suppose that the adjacency matrix of two identical small graphs is M_{K-1}^0 , then the adjacency matrix of the two large graphs is M_K^a and M_K^b , respectively, and the matrix form is shown in formulas (1) and (2). Connect the matrices M_K^a and M_K^b so as to obtain the corresponding candidate subgraph of $K + 1$ order, and its matrix form is shown in formula (3).

$$\mathbf{M}_{K+1}^a = \begin{bmatrix} \mathbf{M}_{K-1}^0 & a_1 \\ a_1^T & 0 \end{bmatrix}, \quad (1)$$

$$\mathbf{M}_{K+1}^b = \begin{bmatrix} \mathbf{M}_{K-1}^0 & b_1 \\ b_1^T & 0 \end{bmatrix}, \quad (2)$$

$$\mathbf{M}_{K+1}^c = \begin{bmatrix} \mathbf{M}_{K-1}^0 & a_1 & b_1 \\ a_1^T & 0 & c_{K,K+1} \\ b_1^T & c_{K+1,K} & 0 \end{bmatrix}, \quad (3)$$

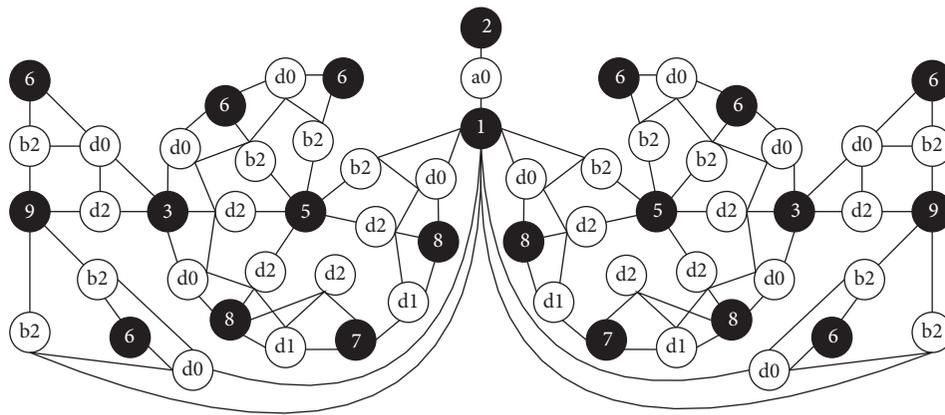

where a_1 and b_1 represent column vectors of dimension, respectively.

$c_{K,K+1}$ represents the adjacency between a_1 and b_1 . When the adjacency of a_1 and b_1 is different, the corresponding value of $c_{K,K+1}$ is also different.

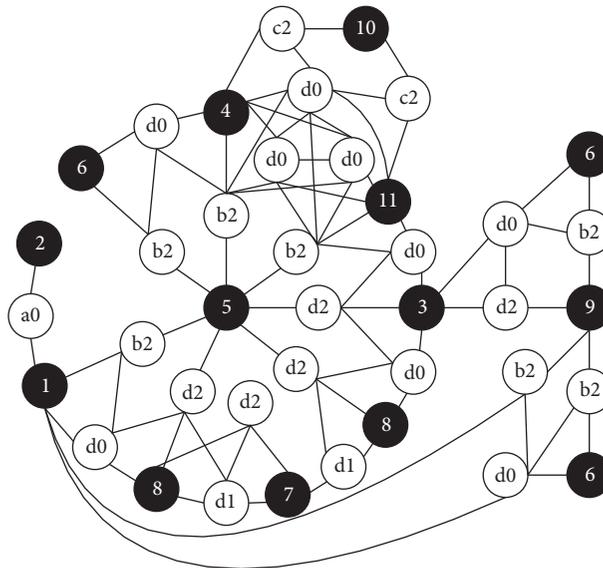

$$c_{K,K+1} = \begin{cases} 1, & a_1 \text{ and } b_1 \text{ have an adjacency,} \\ 0, & \text{there is no adjacency between } a_1 \text{ and } b_1. \end{cases} \quad (4)$$

The sample graph of candidate set generation is shown in Figure 8. The two attribute adjacency graphs shown in Figure 8(a) are mainly used to carry out corresponding subgraph recognition and connection process. The two attribute adjacency graphs shown in Figure 8(a) are composed of five different vertices, respectively. In order to connect them, the same low-order frequent subgraphs need to be identified first, and the result of subgraph recognition is shown in Figure 8(b). Based on the same low-order frequent subgraph after recognition, the two attribute adjacency graphs (Figure 8(a)) are connected to obtain the high-order candidate subgraph. The process of subgraph connection is shown in Figure 8(c), where the red line box is the same low-order frequent subgraph, and the dotted line is the adjacency relationship between vertices 5 and 6. If there is adjacency relationship between the two, the dotted line is transformed into a solid line. If no adjacency exists, delete the dotted line.

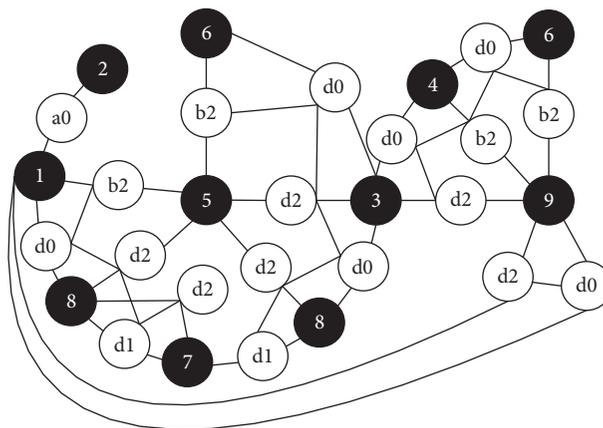

After the subgraph is connected, the generated $K + 1$ -order candidate frequent subgraph is compared with the existing graph in R^{K+1} . If there is no such $K + 1$ -order candidate frequent subgraph in R^{K+1} , it is added to R^{K+1} , and the low-order frequent subgraph id is added to C_{id} of the high-order candidate frequent subgraph C_{id} . Otherwise, the low-order frequent subgraph id is only added to C_{id} of the high-order candidate frequent subgraph, and then the repeated data is deleted.

(4) *The Candidate Pruning.* In the process of frequent subgraph mining, the following operations should be performed before the frequency counting of candidate subsets generated based on the generation of candidate sets:

- (1) For $K + 1$ -order candidate subgraphs, all of their K -order subgraphs are solved.
- (2) On the basis of graph isomorphism, judge whether K -order frequent subgraphs contain K -order subgraphs.
- (3) According to the related properties of candidate pruning, pruning was carried out. The related properties of candidate pruning are described as follows:

Given subgraph O , if O is frequent subgraph, then any subgraph $P (P \subseteq O)$ is frequent. If O is infrequent, then any subgraph $S (O \subseteq S)$ is infrequent.

Through the above operations, the number of candidate subgraphs with different structures and infrequent subgraphs is reduced, and the efficiency of frequency counting process is improved to a certain extent so as to improve the efficiency of frequent subgraph mining algorithm. However, once the number of isomorphic vertices increases, the corresponding retrieval efficiency will decrease. Therefore, this paper sets the number of frequent K -order subgraphs in C_{id} as a , and the number of all K -order subgraphs solved by $K + 1$ -order candidate subgraphs as b . By comparing a and b , it can determine whether they meet the candidate pruning-related properties, when

$$n \begin{cases} < \lambda_{\min}, & \text{Delete it and prune it,} \\ \geq \lambda_{\min}, & \text{Isomorphism judgment is made on the graph in the intersection with the graph.} \end{cases} \quad (5)$$

The above two cases do not require a lot of subgraph isomorphism judgment, which greatly reduces the complexity of frequent subgraph algorithm and improves the retrieval efficiency of the algorithm.

(5) *Redundancy Selection.* On the basis of the Apriori algorithm, frequent subgraphs are often mined, and redundant candidate subgraphs are often generated. Since the formation of frequent subgraphs is based on the recognition and connection operation of low-order frequent subgraphs to construct high-order candidate subgraphs, the phenomenon of high-order including low-order subgraphs may occur. Therefore, this paper adopts the union of C_{id} table to realize, check whether there is the same item in the union set, if there is, remove the same item, and delete the corresponding subgraph in the frequent subgraph set. This avoids scanning the whole Atlas, reduces the workload, and improves the efficiency of the algorithm.

In summary, the pseudocode describing the frequent subgraph mining Algorithm 2 is as follows:

Through the process of preprocessing, initialization, candidate set generation, candidate pruning, frequency counting, and redundancy screening, a large number of frequent subgraphs with different frequency were obtained. Any frequent subgraph corresponds to the local model structure frequently appearing in the model, namely, the common structure, which contains a lot of information, such as the attribute information of corresponding parts in the 3D assembly model and the assembly relationship between parts.

3. Discussion

In order to validate the 3D assembly model based on graph theory in common structure is found feasible, based on the laboratory model of long-term accumulation, in resources, select one series machine tool fixture for 3D assembly model

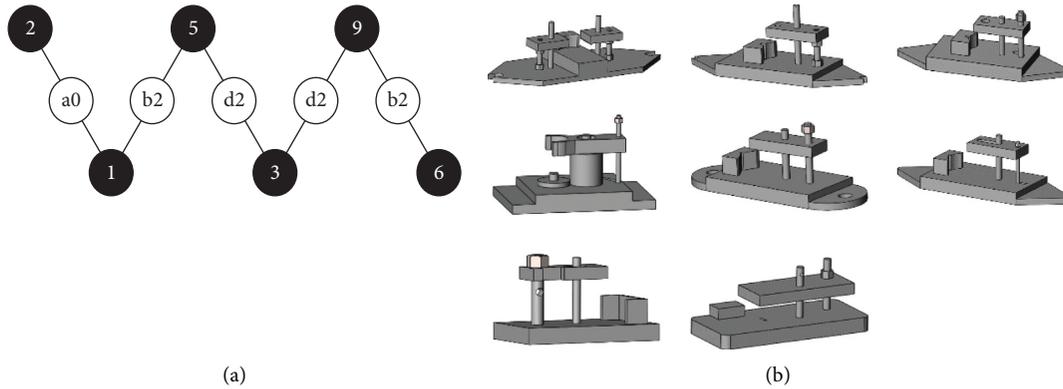

FIGURE 11: $\lambda_{\min} = 1$ corresponds to frequent subgraph and 3D assembly model. (a) Frequent subgraph. (b) Three-dimensional assembly model.

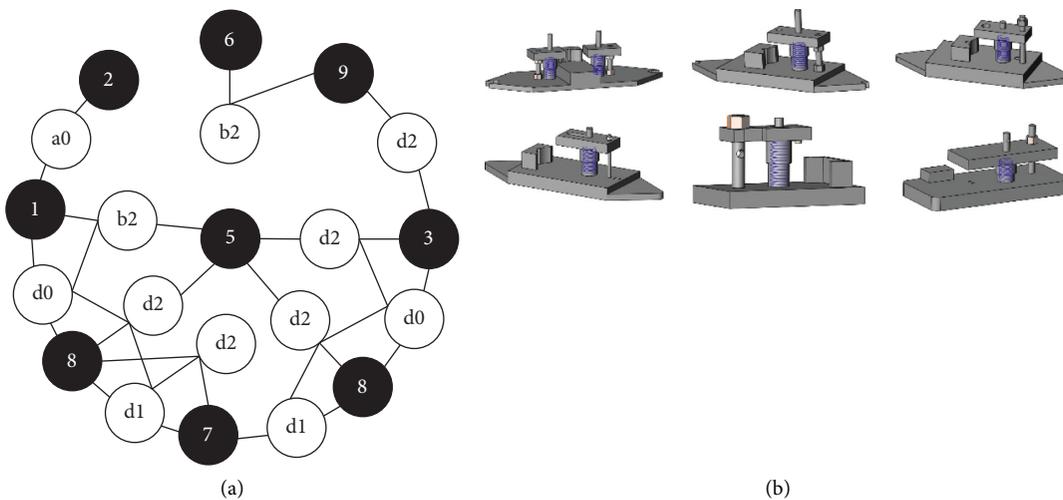

FIGURE 12: $\lambda_{\min} = 0.75$ corresponds to frequent subgraph and 3D assembly model. (a) Frequent subgraph. (b) Three-dimensional assembly model.

as the research object, and use the method in this paper to describe concrete step in detail and validate the rationality and feasibility of relevant methods.

The 3D assembly model of a certain series of machine tools and fixtures as shown in Figure 9 is taken as the verification object, and the detailed example verification process is carried out through the representation of model information described in Section 2 and the excavation of common structures based on frequent subgraphs.

3.1. 3D Assembly Model Information Representation. Establishing a reasonable and effective 3D assembly model information representation is the key to subsequent correlation analysis. Therefore, based on the model representation method described in Chapter 2, the 3D fixture assembly model in Figure 9 is represented by an attribute adjacency graph.

3.1.1. Construction of Adjacency Graph of Attribute Configuration Feature. Firstly, according to the method described in Section 2.1.2, the relevant information of

assembly features in the 3D assembly model is retained based on the attribute adjacency graph, and other information of parts is replaced by semantic nodes to construct the corresponding attribute assembly feature adjacency graph for all parts in the model. Fixture 2 as shown in Figure 9(b) is used in this paper for illustration. Relevant attribute information of parts can be obtained by searching for model structure tree, relevant design documents, national standards, industry standards, and other resources, and then the attribute assembly feature adjacency graph is expressed for all parts corresponding to Fixture 2. The results are shown in Table 4. In the table, the red part of the part model corresponds to the assembly feature part of the part. The black nodes in the attribute configuration adjacency graph correspond to the semantic nodes containing a lot of semantic information of the part.

3.1.2. Representation of 3D Assembly Model Information. Through the above steps, all parts in fixture 2 can get the corresponding attribute configuration feature adjacency diagram. Then, based on the attribute adjacency graph

```

input: Q and  $\lambda_{\min}$ 
Output: T
Step 1. Begin
Step 2. Pretreatment
Step 3. Initialization  $H^1, H^2, K = 2$ 
Step 4. While  $H^K \neq \emptyset$  do
Step 5.    $H^{K+1} \leftarrow \emptyset$ 
Step 6.    $R^{K+1} \leftarrow \text{candidate}(H^K)$  //form candidate subgraphs
Step 7.   For  $\forall q^{K+1} \in R^{K+1}$  do //candidate pruning and frequency count
Step 8.     If  $\lambda(q^{K+1}) < \lambda_{\min}$  then
Step 9.       remove  $q^{K+1}$  //remove subgraphs less than the frequency threshold
Step 10.    end if
Step 11.  end for
Step 12.   $K = K + 1$ 
Step 13. end while //higher order subgraphs are generated in turn until no new subgraphs can be formed
Step 14. redundancy screening //screening of redundancy
Step 15. return T //gets frequent subatlas
Step 16. end

```

ALGORITHM 2: The frequent subgraph mining algorithm.

construction method in Section 2.1.3 and the second jig's 3D assembly model shown in Figure 9(b), the assembly relations between parts are found by searching the corresponding features and relevant documents available of the jig model. Next, this section combines the assembly relations to build the corresponding 3D assembly model attribute adjacency graph. The results are shown in Figure 10(b).

Through the above steps, the 3D assembly model attribute adjacency diagram of fixture 2 is created. By using Figure 10(b), it can be visually observed that the attribute adjacency diagram contains information related to the assembly features of each part, as well as semantic nodes containing a lot of semantic information about the part, and that the diagram representation scale is greatly reduced, suggesting an information representation idea that can be used for related design and manufacturing work. Similarly, by using the same method of constructing the attribute adjacency diagram for the 3D assembly model of fixture 2, a corresponding model representation of the other machine tool fixture models in Figure 9 was made, and the results are shown in Figure 10.

3.2. The Discovery of Common Structure. Based on the attribute adjacency graph of the machine tool fixture constructed above, the method described in Section 2.2.2 is adopted to explore the common structure of the fixture model. The common structure of 3D assembly models to vary from set frequency threshold, and the excavation results from any threshold are corresponding to the corresponding common structure. In the process of verification, in order to reflect the corresponding common structure of under different thresholds, as well as the actual situation and requirements, the minimum frequency threshold (λ_{\min}) is set to 1 and 0.75, respectively, in this paper. The two sets of thresholds are used to illustrate the corresponding experimental results as shown below.

When the frequency threshold is minimum (i.e., the common structures obtained by excavation are corresponding to all fixture models in this group), the frequency subgraph obtained under this threshold and the corresponding model structure of this frequency subgraph are shown in Figure 11.

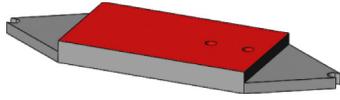

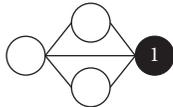

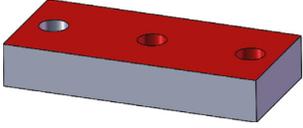

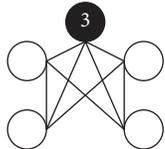

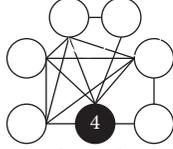

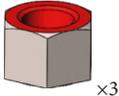

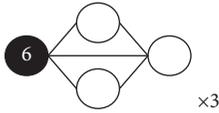

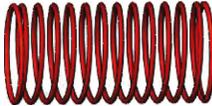

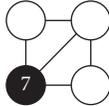

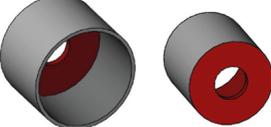

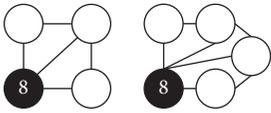

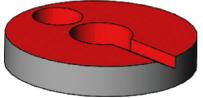

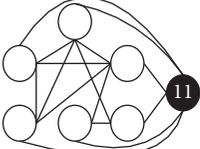

Through observation and analysis of Figure 11, the basic composition of fixture model components in the common structure corresponding to the minimum frequency threshold $\lambda_{\min} = 1$ can be obtained, and the model structure of this series of machine tool fixtures can be preliminarily recognized and understood. Corresponding to the examples given in this paper, the common structure of this group of fixture models under the threshold value should at least include the pressure plate, bottom plate, support parts, nuts, positioning blocks, and other components. Parts are connected by welding, thread connection, contact connection, and so on.

When the minimum frequency threshold is $\lambda_{\min} = 0.75$ (i.e., in this group of models, the common structures obtained through excavation correspond to at least 6 fixture models), the frequent subgraph obtained under this threshold and the corresponding model structure of the frequent subgraph are shown in Figure 12.

Through observation and analysis of Figure 12, the common structure corresponding to the minimum frequency threshold $\lambda_{\min} = 0.75$ of this group of fixture models can be obtained, which should at least include pressing plate, bottom plate, support parts, spring, spring protective sleeve, nut, positioning block, and other parts. Parts are connected by welding, thread connection, contact connection, and so on.

To sum up, taking the attribute information and the assembly relation between all parts, this method can obtain the common structures which frequently appear and support the reuse demand. This method has certain reference value for the assembly relationship and parts in 3D assembly model topology similar common structure discovery and reuse. In the design and manufacture of products, designers

TABLE 4: The adjacency diagram of the attributes of the components in fixture 2.

Serial number	Part name	Parts model	Property masquerade feature adjacency diagram
1	Baseboard		
2	Set piece		
3	Pressing plate		
4	Handle		
5	Strut member 1		
6	Screw nut		
7	Spring		
8	Spring sleeve		
9	Strut member 2		
10	Straight pin		
11	Rotating part		

can set the corresponding minimum frequency threshold according to the personalized requirements of products, and then obtain the common structure that fits the design intention.

4. Conclusions

In this paper, a method for mining common structures of 3D assembly models is proposed. Firstly, the relevant information of the 3D model is extracted and represented by the attribute make-up feature adjacency graph. Then, the relationship between components in the 3D assembly model was analysed, and the isolated attribute assembly feature adjacency graph was combined to form the attribute adjacency graph of the 3D assembly model. Finally, frequent subgraph

mining algorithm was used to discover the common structure of the 3D assembly model. The method can from 3D assembly model of product structure, the generality of the excavation support reuse to provide reference for related design work, improve the efficiency of product design and manufacture accuracy as well as design, increase the flexibility of the 3D assembly model information reuse, effectively improve product design and manufacturing enterprise of the reuse of exploring information resources.

4.1. Future Work

- (1) In the process of graphical representation of model information, this paper mainly highlights the assembly features of the model and unifies the

nonassembly features in the semantic node representation. However, certain nonassembly features also contain important information about the 3D assembly model. Therefore, how to screen the useful structural features in the 3D assembly model and create a suitable information representation is one of the focuses of the subsequent research.

- (2) In the design and manufacturing process of a product, there are many uncertainties in the many objective and subjective needs of designers for 3D assembly model information at different stages and under different conditions. Therefore, subsequent specific analysis of design intent can be carried out to summarise its composition characteristics and construct a more comprehensive and prominent semantic information expression standard for design personality, and this paper mainly focuses on similarity evaluation in design reuse, and the evaluation scope will be expanded subsequently.

This research focuses on the relationship between artificial intelligence technology and music performance in colleges and universities and explores the application of artificial intelligence technology in music teaching. At the same time, it explores the deficiencies of existing computer-assisted language learning software and systems through questionnaires and interviews and also proposes solutions, such as further understanding of theories, enhancing learners' confidence, and stimulating their interest in learning. The results of this research will help to improve the application of online intelligent human-computer systems in music teaching and provide dynamic support for improving the quality of music teaching and talent training in colleges and universities.

1. Introduction

The outstanding feature of the music performance major is performance. Whether students are studying vocal music or various instrumental music and dance, the core goal is to become a performer who can perform onstage. From the perspective of professional training goals and students' future career directions, the music performance major cultivates applied and compound talents. After graduation, students' main destination is social-cultural groups and relevant departments of enterprises and institutions. They are engaged in not only art performances but also the organization, guidance, planning, and implementation of art activities, which requires them to understand and be familiar with the characteristics, methods, procedures, details, etc., of music performances and related work, and also have the corresponding workability. Therefore, in the construction of the practical teaching system of this major, the first point is to firmly grasp the characteristics of the major and highlight the performative characteristics of practical teaching activities.

The fundamental purpose of music teaching in colleges and universities is to cultivate students' ability to perform

music, but the level of music performance that students actually master at present cannot achieve the desired effect. With the rapid development of Chinese society and the continuous enhancement of international exchanges, skilled music performance has become particularly important, which has brought great challenges to music teaching in colleges and universities. In today's British music teaching, traditional teaching methods can no longer meet the needs of contemporary society for comprehensive talent training. In recent years, the rapid development of artificial intelligence technology has brought new opportunities for the modernization of music teaching, which provides new opportunities for the creation of an intelligent music teaching environment. At present, a consensus has been reached on the importance of artificial intelligence technology applied to teaching systems. Guided by the integration of information technology and curriculum, it is of great practical significance to conduct research on the application of artificial intelligence technology in college music teaching. Based on the above background, this paper needs to solve the following three problems: (1) What problems exist in the current music teaching in colleges and universities? (2) The interactive relationship between artificial intelligence and

music teaching; and (3) the specific practice of artificial intelligence in music teaching in colleges and universities.

For the above three questions, some scholars and education experts have already conducted research. For the first question, Huang et al. have preliminarily studied the advantages, disadvantages, and innovations of various college music teaching models [1]; Rebecca et al studied the problems existing in the teaching of music performance in colleges and universities in our country [2]. For the second question, Guoliang studied the relationship between artificial intelligence and music teaching [3]. For the third question, Kun et al. studied the application of artificial intelligence in the field of music teaching. This paper mainly studies the relationship between artificial intelligence and music teaching by discussing the current problems in music teaching in colleges and universities and improves the application of artificial intelligence in music teaching. These misconceptions have been in the consciousness of students and some teachers for a long time. With the development of artificial intelligence, scholars have begun to study how to use artificial intelligence to solve the problems encountered in music teaching. The application of artificial intelligence technology in music teaching starts from artificial intelligence and the problems it intends to solve and explores the application of artificial intelligence technology in music teaching around the relationship between artificial intelligence and music teaching. However, there are also many problems with artificial intelligence in university music teaching. Based on the research of the above scholars, the author believes that artificial intelligence can effectively solve the problems in music teaching, but at the same time, there are also some problems in the application of artificial intelligence in music teaching. This paper mainly aims at the shortcomings of artificial intelligence in music teaching and proposes solutions to improve the confidence of learners to stimulate their learning confidence and further improve the application of artificial intelligence in music teaching.

2. Related Work

In nature, living things live according to the principle of “survival of the fittest.” In 1975, the random search algorithm proposed by Professor Holland from the United States used computers to solve intelligent analysis problems according to the survival law of nature which is the most effective method. The genetic algorithm (GA) was first proposed by John in the 1970s. The algorithm was designed and proposed according to the evolutionary laws of organisms in nature. It is a computational model of the biological evolution process that simulates the natural selection and genetic mechanism of Darwin’s theory of biological evolution. It is a method to search for the optimal solution by simulating the natural evolution process. The algorithm converts the process of solving the problem into a process similar to the crossover and mutation of chromosomal genes in biological evolution through mathematical methods and computer simulation operations. When solving more complex combinatorial optimization problems, better optimization results can usually be obtained

faster than some conventional optimization algorithms. Genetic algorithms have been widely used in combinatorial optimization, machine learning, signal processing, adaptive control, and artificial life. Each chromosome in the genetic algorithm corresponds to a solution of the genetic algorithm. Generally, we use the fitness function to measure the pros and cons of this solution. So the fitness from a genome to its solution forms a map. The process of the genetic algorithm can be regarded as a process of finding the optimal solution in a multivariate function. It can be imagined that there are countless “mountains” on this multidimensional surface, and these peaks correspond to the local optimal solution. And there will also be a “mountain” with the highest altitude, and then this is the global optimal solution. The task of the genetic algorithm is to try to climb to the highest peak, instead of falling into some small peaks. In addition, it is worth noting that the genetic algorithm does not have to find the “highest mountain.” If the fitness evaluation of the problem is as small as possible, then the global optimal solution is the minimum value of the function. Correspondingly, what the genetic algorithm is looking for is “the deepest valley.” The principle of the genetic algorithm is to express the set of problems to be solved as “groups.” Before solving the operation, some of the “groups” are assumed to be the solution sets to be sought, and these initially identified solution sets are placed in the environment of the problem. Through the principle of survival of the fittest, new groups are continuously generated through operations such as combination, exclusion, and mutation, and they evolve continuously until the obtained “group” meets the expected value, that is, the optimal solution to the problem. The solution of the genetic algorithm starts from the initialization and randomly selects a subset from the whole population as the initial population. During the running process of the algorithm, the size of the population does not change all the time. An individual is each specific element in a population. Fitness is the degree of adaptation of the individual to the external environment. In order to measure the individual, the function of measuring the fitness is called the fitness function. According to this function, the survival law of nature is reflected. Coding is because the algorithm cannot directly process the parameters of the problem space, and it needs to be converted into a space set that the computer can recognize according to certain rules. The workflow of its algorithm is shown in Figure 1.

Among them, selection, crossover, and mutation are the genetic operators of the algorithm. Selection is to keep the individuals with strong adaptability in the group and eliminate the individuals with low adaptability; crossover is to replace a part of the structure of the individuals according to certain rules and then obtain new individuals; variation is performing a specific operation on a gene value in an individual to generate a new individual which is the most important means to improve the global search ability of the genetic algorithm.

3. Basic Baseline for System Construction

The basic idea of the construction of the practical teaching system of the music performance major according to the

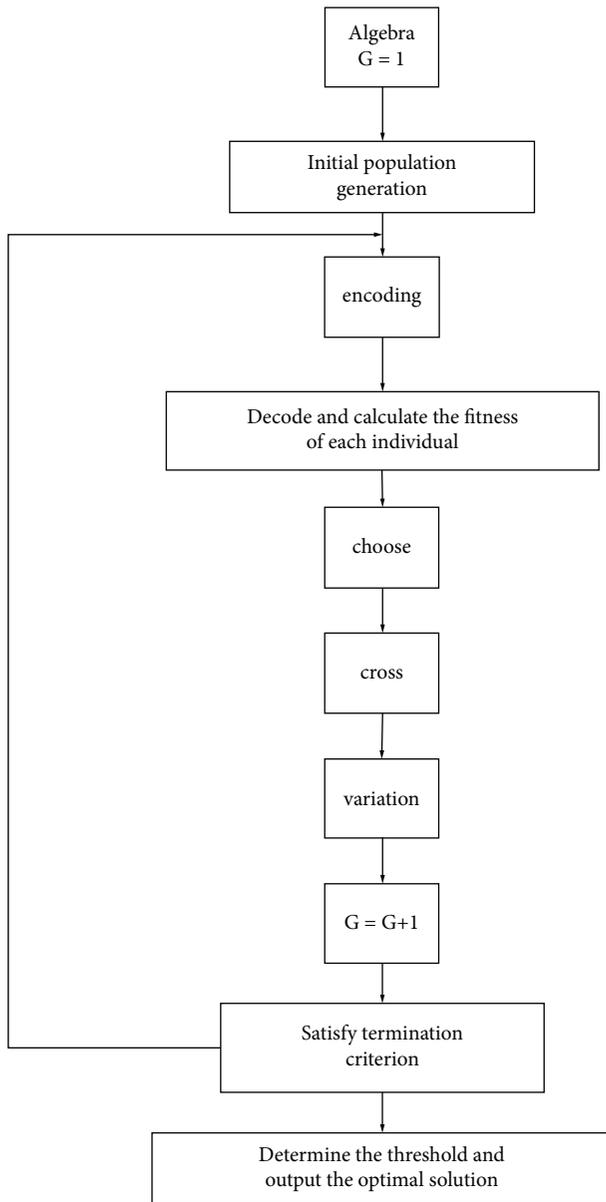

FIGURE 1: Steps of a genetic algorithm.

characteristics and training objectives of the music performance major, combined with the actual requirements of the society, the practical teaching system of this major should at least contain the following basic links:

- (1) The practical link in the basic course: the most basic course in the music performance professional curriculum system is the professional basic course. The basic curriculum settings of each college include music theory, solfeggio, harmony, polyphony, musical analysis, Chinese music history, foreign music history, and national folk music. The teaching objectives of the basic courses of music performance should be the trinity of basic knowledge, basic theory, and basic skills. That is to say, the teaching tasks of these courses should not only enable students to master the basic knowledge and basic theory

of music discipline but also carry out basic skills. Training and the organic combination of the three can lay a solid professional foundation for students. Among them, there is a flexible space for basic skills. From the perspective of the construction of the practical teaching system, these courses must become an integral part of the construction of the practical teaching system, and the development of the practical link should be strengthened in the curriculum planning. There are two main forms: one is exercise practice, that is, the relevant content in the course is repeatedly practiced through exercises so that students can form solid skills and skills on the basis of firmly grasping the relevant knowledge theory. For example, the music theory course, which involves the formation of intervals, mode tonal analysis, time value division, chord construction, etc., requires a large number of exercises to enable students to master relevant theories and knowledge and form basic skills for future music performance practice to lay the foundation. The second is the appreciation of works. Courses with a strong theoretical nature, such as Chinese music history and foreign music history, still need to expand the practical space. For example, some schools set the music history course as Chinese (foreign) music history and work appreciation, which is actually an organic combination of the practice of music appreciation in the teaching of music history courses. Even if the name of music appreciation is not clearly indicated in the course title, the practice of music appreciation should be combined with specific content in actual teaching.

- (2) The practical link in the skill and skill course: in the course system of the music performance major, the core course is the skill and skill course, such as Chinese and foreign instrumental music, vocal music, piano, dance, ensemble, chorus, and piano accompaniment. In such courses, it is a practice-oriented course in itself, and the basic goal of its teaching is to enable students to master relevant skills and skills to perform complete musical works [4, 5]. And if it is not enough to stay at this level, the ultimate goal of mastering and using the corresponding skills and techniques should be implemented onstage performances. The setting of practical skills and skill courses also needs to be developed from two aspects, one is the penetration and strengthening of performance factors in the teaching of traditional skills and skills courses, and the other is the appropriate expansion of other related auxiliary skills and skills courses [6, 7]. From the perspective of cultivating students' practical ability, the teaching of traditional skills and skill courses requires the penetration of performance elements first and also to ensure the development and improvement of students' artistic practical ability to meet the needs of stage performances. This

requires strengthening the design training of facial expression language, body language, and emotional expression in the teaching process so as to enhance the admirability of the works in the process of interpretation so that they can achieve the effect of both form and spirit, touching people's hearts [8]. Second, it is necessary to create opportunities for students to practice practical exercises, such as regular professional reports, final professional examinations, and second classroom activities for practical demonstrations. The expansion of other auxiliary skills and skills courses is mainly to add some elective courses according to actual needs, such as makeup, program hosting, recitation, and pronunciation [9]. On the one hand, the setting of such courses can expand students' professional ability and enhance the adaptability of social work. On the other hand, it can effectively assist the study of other professional courses, and to a certain extent, it can help students' personality development [10].

- (3) Independent practical links as practical teaching is getting more and more attention. Some schools generally set up independent practical teaching links in the process of formulating talent training programs for their majors, such as the second classroom activities of each semester, art practice weeks, professional apprenticeships, professional internships, and graduation reports (or graduation concerts). This link has a certain nature of comprehensive training, which plays a better role in cultivating students' professional practical ability [11–13]. The most critical part of this link is to strengthen the design and strengthen the implementation. The so-called strengthening design is to serialize, standardize, and even quantify the independent practice links. The second classroom activities should be carried out in close cooperation with the teaching of professional courses [14]. Art practice week should be arranged for at least one week per semester. They should run through the whole process of professional teaching, which requires overall planning and design to avoid randomness and randomness of activities. Low-level repetition ensures the scientific nature of practical training; the so-called strengthening implementation means strengthening the management and guidance of all practical teaching links and completing the corresponding practical training content according to plans and standards [15].
- (4) Practical links in comprehensive art activities The so-called comprehensive art activities mainly refer to practical activities characterized by actual stage performances, which require students to mobilize all professional knowledge and abilities, and exercise and improve on the real stage of the campus and society. It is a professional practice activity as well as a social practice activity, and it is a bridge for students to go from the campus to the society. This should be a stage performance-type three-level

practical activity system; that is, relying on the art stage, the three-level art practice activity system of professional basic practice, professional development practice, and professional improvement practice is unified. Professional basic practice art activities mainly refer to the art practice activities related to the teaching of professional courses [28]. For example, professional report concerts are held regularly, and professional examinations are held in the form of concerts every semester. The stage has become a platform for students to show their professional learning achievements, and the learning of single professional skills has become a comprehensive stage performance [16]. Using the skills and techniques learned in the classroom, we also need to carry out creative performance design, and preliminary stage practice accumulate corresponding stage experience and gradually improve stage adaptability. Professional development practice art activities mainly refer to the development of various types of practical performance activities [17–19]. This is an open stage space, which can carry out practical performance activities within the school, such as graduation concerts, large-scale comprehensive professional report concerts, and theatrical performances in major festivals or major events; it can also carry out interschool and even international art exchange activities. More importantly, we can vigorously carry out social art practice activities, such as performances in community culture construction, corporate culture construction, and performances in certain themed cultural activities carried out by local governments and local media. Such activities involve a wide range of activities, rich in content, high comprehensive level, and quality requirements, and truly achieve social integration, which is a comprehensive test and experience for students' professional level [20].

The artistic activities of professional improvement practice mainly refer to the practical activities of selecting some outstanding students to participate in high-level professional competitions. A unique advantage of the music performance major is that there are various art competitions in all walks of life every year, such as the annual national college student art exhibition activities, various art competitions held by the cultural department of the provincial education department, and media at all levels [21]. Professionally, it is a rare opportunity provided by the social stage for practical teaching work. It can be combined with such activities to carry out high-level artistic practice activities, such as holding trials.

The above are the basic construction ideas for the construction of the practical teaching system for the music performance major. The author tries to build a comprehensive and applicable professional practice teaching system through this design, which not only highlights the core professional characteristics of art performance but also includes other related work content; if the specific planning

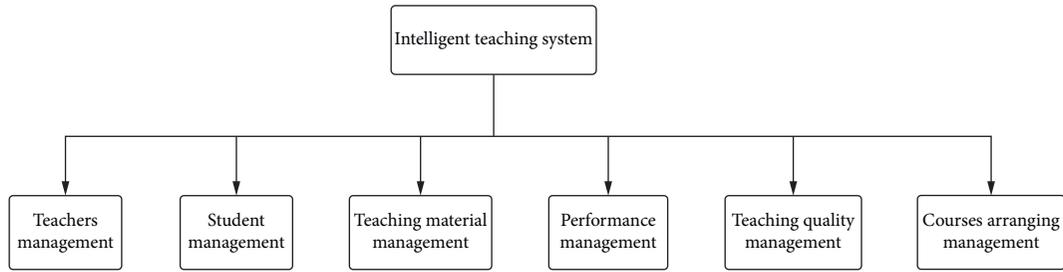

FIGURE 2: System functional structure diagram.

and implementation process can be scientifically designed and arranged reasonably and can fully mobilize the enthusiasm and initiative of students to carry out corresponding work in an all-round way and can strengthen management and assessment, then we will be able to achieve music. The performance major aims to cultivate applied and compound talents with a solid professional foundation, excellent basic skills, outstanding professional practical ability, and adapt to the needs of social and cultural development and construction [22].

4. System Design

4.1. *Design Principles.* The design of the teaching system should not only meet the needs of current school teaching but also be able to adapt to the needs of future development as the school expands over time.

- (1) *Scalability.* The school is the cradle of cultivating talents for the country. With the continuous development of my country’s economy and science and technology, society has put forward higher requirements for talents [23]. Therefore, schools have to keep changing with the needs of the society and put forward new requirements for the teaching system, which requires the teaching system to be continuously expanded in terms of functions to meet diverse needs.

- (2) *Security Teaching Is a Very Serious Matter.* Students’ teaching information, especially exam results, needs to be stored in student files, which raises higher requirements for the security of information storage and transmission in the teaching system.

4.2. *System Functions.* For the entire teaching system, teachers and students, teaching materials, classes, grades, and evaluation form a complete teaching management process [24]. Therefore, the teaching management system mainly focuses on several elements of the teaching process. The developed intelligent teaching system mainly has the following modules. The specific functional structure is shown in Figure 2.

Among them, teacher management is mainly to manage and maintain teachers’ basic information, scientific research, teaching, and other information; student management is to manage and maintain students’ basic information, rewards, punishments, etc.; at the same time manage the information

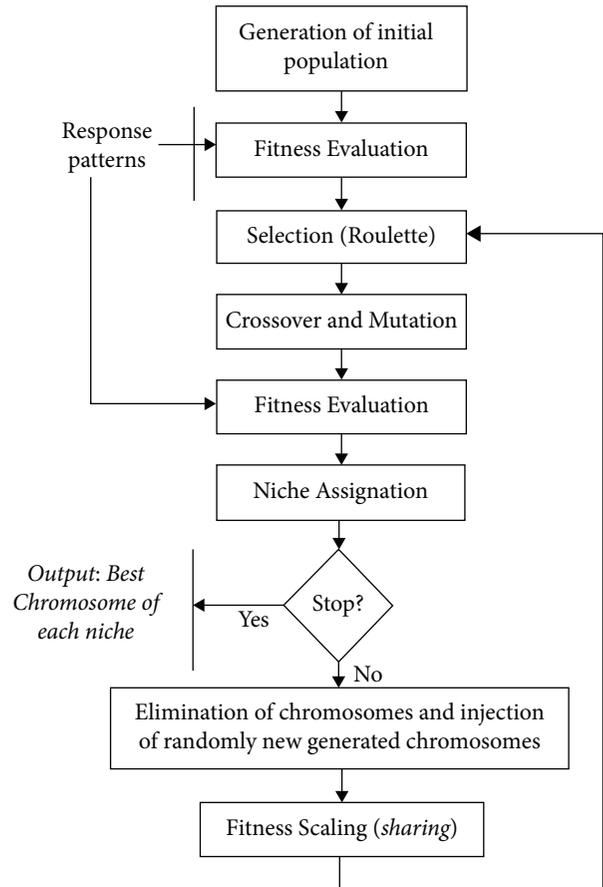

FIGURE 3: Diversity-enhanced genetic algorithm.

and maintenance [25]; performance management is the management and maintenance of students’ test scores, re-examination scores, and other information; teaching quality management is a quality evaluation management system formed based on students’ evaluations of teachers and expert evaluations; course management is that each teaching subject intelligently arranges courses according to its own teachers, students, teaching environment and other factors, so as to achieve the optimal allocation of teaching resources from the perspective of cultivating students’ practical ability, the teaching of traditional skills, and skills courses [23]. First of all, the penetration of performance elements is needed to ensure that students’ artistic practice ability can be developed and improved to meet the needs of stage performances. This

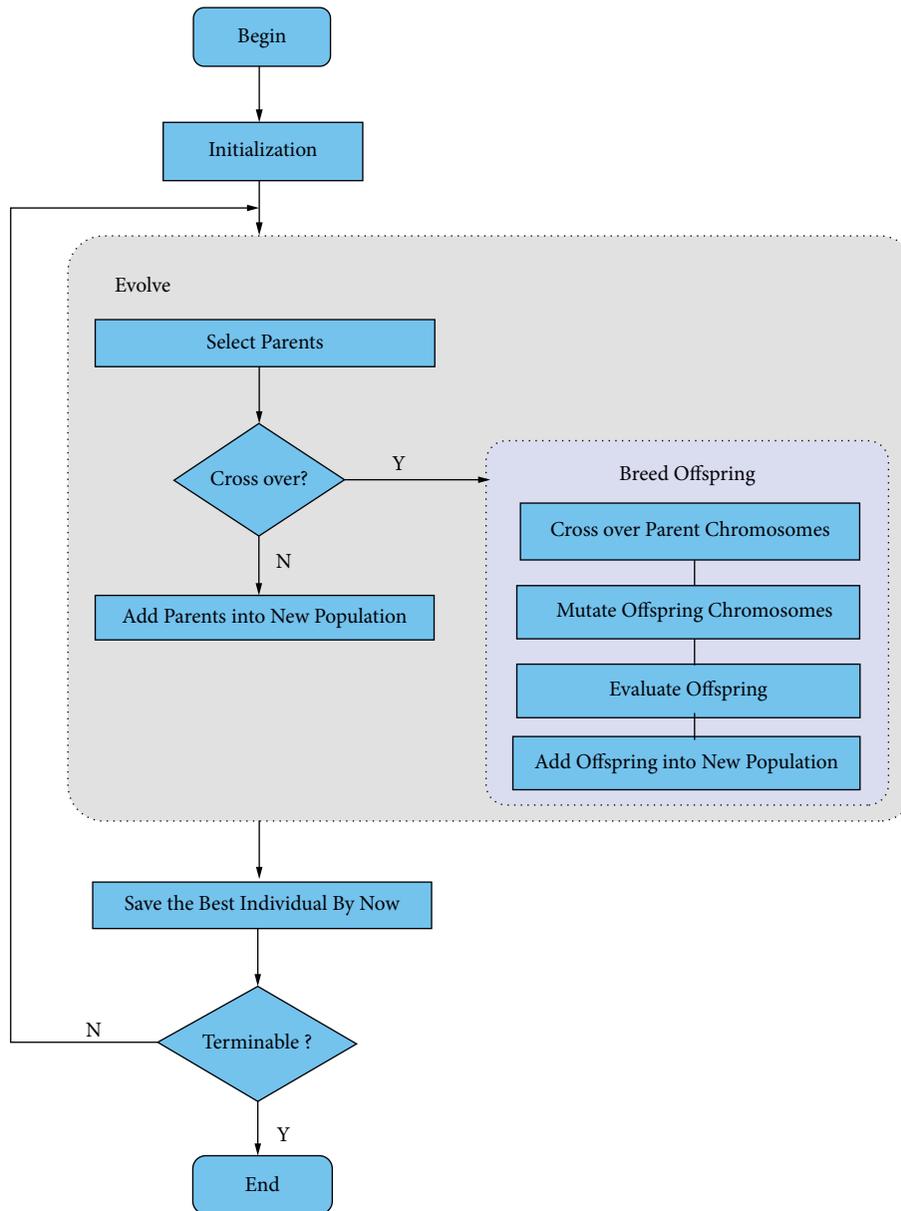

FIGURE 4: Simple genetic algorithm.

requires strengthening the design training of facial expression language, body language, emotional expression, etc. [26] in the teaching process, so as to enhance the admirability of the works in the process of interpretation, so that they can achieve the effect of both form and spirit and touch people's hearts. Second, it is necessary to create opportunities for students to practice practical exercises, such as regular professional reports, final professional examinations, and second classroom activities for practical demonstrations. The expansion of other auxiliary skills and skills courses is mainly to add some elective courses according to actual needs, such as makeup, program hosting, recitation, and pronunciation. On the one hand, the setting of such courses can expand students' professional ability and enhance the adaptability of social

work. On the other hand, it can effectively assist the study of other professional courses, and to a certain extent, it can help students' personality development [26, 27]. There are many genetic algorithms, including diversity-enhanced genetic algorithms (Figure 3), simple genetic algorithms (Figure 4), and multiobjective genetic algorithms (Figure 5).

4.3. Database. The teaching management database is mainly used to store basic information such as teachers, students, grades, and textbooks. Some information appears repeatedly in different tables. In order to maintain the integrity and stability of the data information, the data items of the data table are designed. The main data items of each data table are as follows:

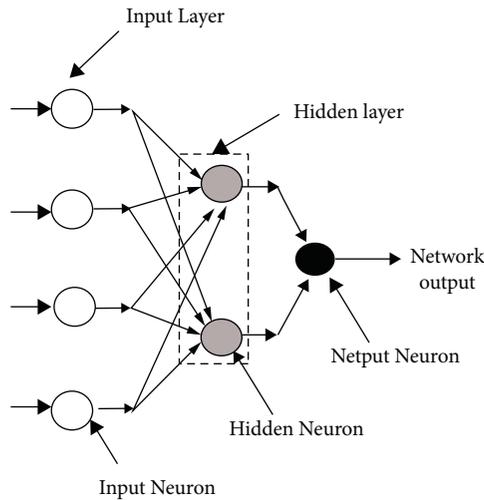

FIGURE 5: Multiobjective genetic algorithm.

- (1) User basic information table: it is used to store login information, and the main contents are user login name, password, user authority, etc.
- (2) Teacher information table: it is used to store the basic information of teachers. The main contents include the teacher's job number, name, gender, age, department title, telephone number, e-mail, QQ number, and home address.
- (3) Student information table: it is used to store the basic information of students, the main contents are student number, name, gender, age, date of birth, home address, telephone, e-mail, QQ number, department, class number, and other contents.
- (4) Classroom information table: it is used to store the information of different classrooms in the school. The main contents include classroom number, teaching building, classroom name, classroom capacity, classroom type, and so on. In addition to the above data tables, there are other data tables such as class basic information table, grade information table, course information table, teaching material information table, and class information table, which will not be described in detail here.

5. System Implementation

5.1. Course Scheduling Management. Class schedule is the top priority of a school. Schools should effectively integrate resources such as teachers, classrooms, classes, courses, and time to achieve the best configuration. The class schedule is to find the optimal combination problem under the condition of relatively limited resources. Regardless of the school, there are several constraints to avoid when scheduling classes.

- (1) A teacher can only take one course at a certain time.
- (2) A classroom can only arrange one course at a certain time.

- (3) A class can only take one course at a certain time.
- (4) The number of people in a certain class should be less than the capacity of the classroom. For the elements of class, course, classroom, time, and classroom, the mathematical formula is expressed as follows:

Class collection: $BJ = \{bj_1, bj_2, bj_3, \dots, bj_a\}$;

Course collection: $KC = (kc_1, kc_2, kc_3, \dots, kc_b)$

Classroom collection: $CR = \{(cr_1, cr_2, cr_3, \dots, cr_c)$

Time collection: $SJ = (sj_1, sj_2, sj_3, \dots, sj_d)$

Classroom collection: $JS = (js_1, js_2, js_3, \dots, jd_e)$

The problem with the class schedule is the Cartesian product of the above five elements, $PK = BJ * KC * CR * SJ * JS$. It is necessary to find a set that satisfies the constraints in PK, that is, the result of the class schedule. Here, a genetic algorithm is used to solve the problem of course scheduling, and each individual in the PK set is regarded as a course scheduling scheme. All the course scheduling schemes are taken as the initial population, and the population is operated to get the optimal results.

5.2. Teacher Management. For the teacher module, not only the basic information of teachers is maintained but also the statistics of teachers' information, statistics on the workload of teachers in the school, analysis of the proportion of teachers with different professional titles in the school, statistics on the number of teachers of all ages in the school, and information on teachers' scientific research details. The teacher management module can help the teaching management department to analyze the information of teachers and provide first-hand information for the school to carry out teaching, professional title evaluation, and introduction of talents.

6. Conclusion

Using artificial intelligence technology to design and study the teaching system, we explain in detail how to use the genetic algorithm to manage the course arrangement. Functionally, the teaching system can meet the teaching needs of various types of colleges and universities. This paper studies the application of artificial intelligence in college music teaching. Traditional teaching methods are very fundamental, so teachers often spend most of their time explaining basic music theory while students are often busy taking notes. Teachers do not release various tasks to attract students' learning, resulting in a small number of students who are not interested in learning and remain silent in the classroom. Therefore, in order to change this phenomenon, teaching should adopt new teaching methods. The task-based teaching process is task design, warm-up, pretasks, tasks, reporting, and assessment. These tasks are often accomplished through interaction between students. In doing so, students can put what they have learned into practice. Combined with the definition and basic characteristics of artificial intelligence, use teaching methods to combine artificial intelligence with music classroom teaching, explore the benign relationship between music teaching and artificial intelligence, and promote teaching and talent training. As

the integration of information technology and music courses continues to accelerate, artificial intelligence has brought new opportunities for music teaching. In order for students to learn music well, we need to create a free environment. Our music class cannot be limited to the ordinary class mode to complete the learning. A relaxed and active atmosphere must be created. Rooting information technology such as artificial intelligence in music teaching practice, and giving full play to its technical advantages and cutting-edge features, can promote the quality of teaching and improve the level of talent training while achieving better development of artificial intelligence technology.

The use of ion current signals generated during the combustion process of mixed gas as a function of initial mixture composition, temperature and pressure to detect cylinder combustion states is the most recent approach in the design, development, and optimisation of automotive engine combustion control. This paper aims to design predictive identification and computationally fast and accurate ion current models for obtaining combustion information in the engine cylinder in real time. To build a more comprehensive ion current calculation model, the effect of the flame ionisation process, the geometry of the spark plugs, and the combustion pressure and temperature are considered in the new building ion current model. The simulation ion current waveform, which has a double-peak structure, is in good agreement with the experiment values; thus, the ion current model has the potential to be used for real-time control and optimisation of engine cylinder combustion.

1. Introduction

In recent years, the energy crisis and its long-term problem, as well as the challenge of CO₂ emissions, have increased concern for the development and design of new energy engines with clean energy, high efficiency, and low emissions. Developing new electronic engine control systems can improve the efficiency of combustion engines, achieve online monitoring of the combustion process, and obtain timely information about the mixture combustion state, allowing for low-carbon and high-efficiency combustion, which has drawn the attention of many researchers and has become an active area of engine combustion diagnostics and optimisation.

The ion current signals produced in the flame combustion process carry rich information about the engine combustion process, and the spark plug as an ion current detecting probe is robust and inexpensive to manufacture; it can be installed in spark-ignition engines to obtain combustion information, such as misfire detection, peak pressure position and in-cylinder pressure, and the total combustion heat release. Given the close relationship between the combustion process and the ions produced, the study discovered that the ion current waveform can reflect

the characteristics of flame development, which has been divided into the ignition phase, the front phase, and the postflame phase. By analysing the ion current waveform's characteristic parameters, a researcher can gain a better understanding of the ion formation process in engines and develop a better control programme for engine performance and emissions [1–5].

In this paper, the new ion current computing model based on the combustion process is developed which considered the spark plug geometry, flame ionisation process, equivalence ratios, and engine model; the pressure model of the entire burning process is used in the simulation calculation, and the ignition energy is considered.

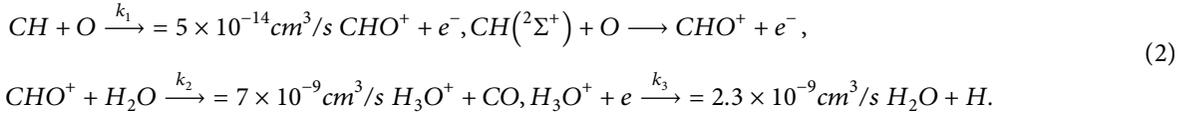

The objectives of this paper are to develop fast and robust tools for analysing the mixture gas combustion process in engine cylinders, which can aid in the design, analysis, and optimisation control of newer engine designs. The ion current comparison between model calculated values and experimental measured results validates the new building model. The ion current model may help in the rapid analysis of engine combustion performance and provide a new technology path for engine combustion performance optimisation control [4–7].

2. Flame Ion Current Theory and Formulation

2.1. *The Ion Current in the Front Flame Phase.* After the ignition system ignites the air-fuel mixture contained in the cylinder, the flame develops and ions are believed to be formed due to various chemical ionisation processes in the reaction zone of the propagating flame; the ion current is produced in one particular direction after the application of the electric field to ions. The reaction in equation (1) is considered a typical reaction in an internal combustion engine cylinder [8]:

There are various flame ionisation mechanisms proposed for ion generation during the flame burning process [9], as shown in a comprehensive discussion of the feasibility of these mechanisms [7], with the chemi-ionisation reaction in the front flame phase being the dominant initiation ionisation reaction. Equation (2) shows the main elementary reactions that create ions [8] are

In above set of reactions, it is experimentally found that H_3O^+ is truly the dominant positive ion in hydrocarbon flames [10, 11] and the H_3O^+ ions are produced by proton transfer from CHO^+ to H_2O , which mostly contribute to the formation of the ion current [7-12].

The ionisation reaction rates (k_1 , k_2 , and k_3) are shown in Equation (2), which are given in reference [12]. As the ion species produced in the above reactions reached a steady-state concentration, the ion concentrations can be expressed as follows:

$$\begin{aligned} [CHO^+] &= \frac{k_1 [CH][O]}{k_2 [H_2O]}, \\ [H_3O^+] &= \frac{k_2 [CHO^+][H_2O]}{k_3 [e^-]} = \frac{k_1 [CH][O]}{k_3 [e^-]_{\max}}. \end{aligned} \quad (3)$$

Based on the Saha equation, the local thermal equilibrium concentration is the function of temperature, as shown in the following equation:

$$\frac{n_i n_e}{n_{i-1}} = 2 \left(\frac{2\pi m_e kT}{h^2} \right)^{3/2} \frac{B_i}{B_0} \exp \left[-\frac{E_i}{kT} \right]. \quad (4)$$

In Equation (4), T is the absolute temperature, h is Planck's constant, k is Boltzmann's constant, the n_i and n_{i-1} are the number density of the ionised state i and $i-1$, respectively, n_e is the electron number density, m_e is the electron mass, E_i is the ionisation energy of the state I , and B_i is the internal partition function.

The electron drift velocity is a function of the mobility of electrons μ and the electrical field X , which is expressed as [10]

$$v_d = \mu X. \quad (5)$$

In classical physics, the particles mean free path length λ , the possibility of interaction between particles (which can be defined by their cross sections S), and the ion number density that passes through a volume can be expressed as follows:

$$\lambda = \frac{1}{n_{\text{tot}} S}, \quad (6)$$

$$n_{\text{tot}} = \sum_i x_i n_i, \quad (7)$$

where x_i is the species fraction and ρ_i is the number density of species, i .

The combustion temperature is the major contributor to the electron drift velocity in the combustion reaction, and the effect of the electrical field is relatively small [10]; the electron drift velocity expression is shown in the following equation:

$$\mu = \frac{e\lambda}{m_e v_T}, \quad (8)$$

$$v_T = \sqrt{\frac{8kT}{\pi m_e}}. \quad (9)$$

In the above equation, v_T is the mean random velocity of the electrons and m_e is the electron mass.

Since the combustion gas volume in the engine cylinder is cylindrical, the formula of the ion current can be expressed as follows:

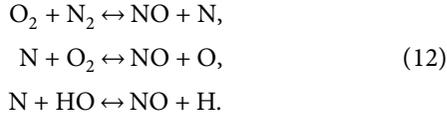

$$I_1 = U \frac{\pi r^2 e^2}{Sd} \left(\frac{\pi^3 x_i}{8m_e kT} \right)^{1/2} A, \quad (10)$$

$$A = \sqrt{\frac{(2(2\pi m_e kT)^{3/2}/h^3) B_i/B_0 \exp[-E_i/kT]}{n_{\text{tot}}}}. \quad (11)$$

In Equation (11), T is the combustion temperature, n_{tot} is the number density of total species, and x_i is the species fraction, where $n_{\text{tot}} = P/kT$ [6, 10].

2.2. *The Ion Current in the Postflame Phase.* The thermal NO formation mechanism is the so-called extended Zeldovich mechanism [10, 11], and the thermal NO formation

mechanisms consist of three elementary reactions in Equation (12) which were used for the estimation of the formation rate of NO from molecular nitrogen in near stoichiometric air-fuel mixtures.

The NO formation rate is much slower than the combustion rate, and most of the NO formation takes place in the postflame regions. The concentration [NO] is defined as follows:

$$\frac{d[\text{NO}]}{dt} = 6 \times 10^{16} T^{-1/2} \exp\left[-\frac{69090}{T}\right] (\text{O}_2)_{eq}^{1/2} (\text{N}_2)_{eq} \quad (13)$$

The eq subscript stands for equilibrated conditions and the unit is moles/cm³sec. In the equation, the temperature and the amount of O₂ are strongly dependent on the rate of NO formation in the postflame phase. This finding suggests that thermal ionisation is the source of the ion current in the postflame region, and NO⁺ dominating the ion current in the postflame region is consistent with much of the theory and experimental work in the thermal ionisation process [10, 11]. The ionisation ratio of NO is obtained from Saha's equation shown in Equation (4), and the electron drift velocity shown in Equation (5) can be calculated from basic gas kinetic theory. The result of the derivation, where the ion current is a function of temperature, has the following form:

$$I_2 = A \sqrt{\frac{\phi_s}{n_{tot}}} T^{1/4} \exp\left[-\frac{E_i}{2kT}\right]. \quad (14)$$

In the above formula, E_i is the ionisation energy of species s , n_{tot} is the total number density, and ϕ_s is the species fraction of species s . The symbol A is a constant which is shown in Equation (11).

So, because the total ion current includes the ion current produced by the chemical ionisation reaction as well as the ion current produced by the thermal ionisation reaction, the total ion current equation is as follows:

$$I_{tot} = I_1 + I_2. \quad (15)$$

2.3. Ion Current Measuring Circuit. The ion current in the combustion chamber is measured using a modified version of the spark plug inserted into the engine cylinder. The ion current measurement circuit is shown in Figure 1 [13, 14]. During the experiment, after the spark ignition is successful, the ion current generated during the combustion process is measured and the data are collected, and the combustion pressure data generated during the combustion process are collected using the ion current measurement circuit. The collection of the ion current data and combustion pressure data adopts the ADVANTECH 1710L data acquisition card, which holds an acquisition accuracy of $\pm 2.48\%$ [13, 14].

2.4. Engine Calculation Model. The engine geometry is taken into account in the calculation, and the relationship between

the rotation of crank and engine cylinder volume is as follows:

$$V(\theta) = V_c + \frac{\pi B^2}{4} \left(l + a - a \cos(\theta) - \sqrt{l^2 - (a \sin(\theta))^2} \right). \quad (16)$$

An analytic model for the combustion pressure is given in closed form, which is based on connection relations with components that are simple and convenient to measure and tune, and the model's advantage is that no ordinary differential equations must be numerically solved. The expression of the analytic model for the combustion pressure is

$$p(\theta) = \begin{cases} p_c(\theta) & \theta_{ivc} < \theta < \theta_{soc} \\ (1 - x_b)p_c(\theta) + x_b p_e(\theta) & \theta_{soc} < \theta < \theta_{evo} \end{cases} \quad (17)$$

The expression of the model is further decomposed as follows [4–6]:

$$\begin{aligned} p_c(\theta) &= p_{ivc} \left(\frac{V_{ivc}}{V(\theta)} \right)^{k_c}, \\ T_c(\theta) &= T_{ivc} \left(\frac{V_{ivc}}{V(\theta)} \right)^{k_c - 1}, \\ p_e(\theta) &= p_3 \left(\frac{V(\theta)}{V_3} \right)^{k_c}, \\ x_b(\theta) &= 1 - e^{-b(\theta - \theta_{soc}/\Delta\theta)^{m+1}}, \\ p_3 &= p_2 \frac{T_3}{T_2}, \end{aligned} \quad (18)$$

$$T_3 = T_2 + \Delta T_{\text{comb}},$$

$$\Delta T_{\text{comb}} = \frac{\eta_c Q_{LHV}}{c_v} \frac{1}{1 + A/F} x_b,$$

$$p_2 = p_c(\theta),$$

$$T_2 = T_c(\theta),$$

$$\theta_c = \Delta\theta_d + \frac{1}{2} \Delta\theta_b.$$

2.4.1. Intake Valve Close to Start of the Compression Process. Using a polytropic compression model, pressure and temperature are calculated during the compression stroke from IVC to SOC and displayed as a function of the crank angle and the coefficient $k_c = 1.3$.

$$p_c(\theta) = p_{ivc} \left(\frac{V_{ivc}}{V(\theta)} \right)^{k_c}, \quad (19)$$

$$T_c(\theta) = T_{ivc} \left(\frac{V_{ivc}}{V(\theta)} \right)^{k_c - 1}.$$

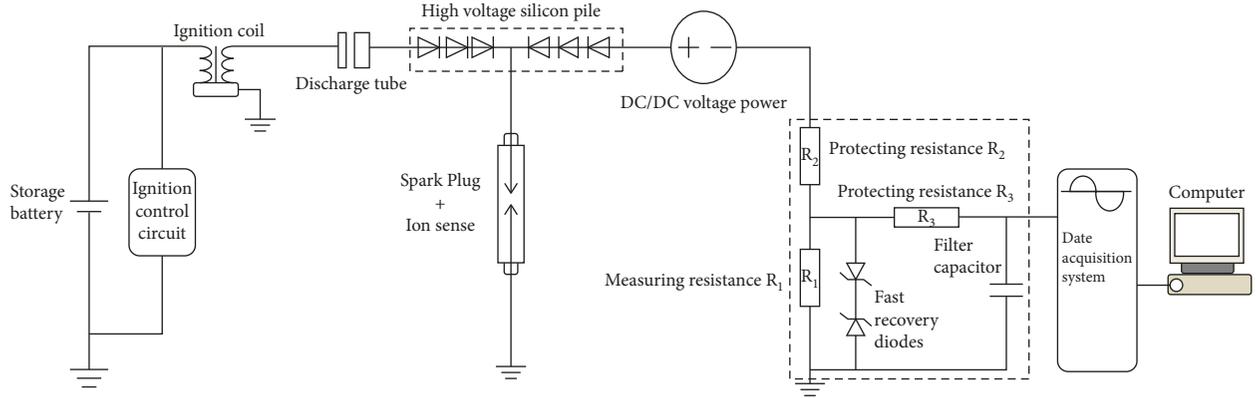

FIGURE 1: Ion current measuring circuit.

After to finish the compression stroke, the polytropic expansion stroke to begin, Equation (19) is performed to simulate the expansion stroke [4, 6, 8, 11, 12, 15].

2.4.2. Starting Combustion Process. After successful ignition, the combustion temperature rises in the cylinder due to the burning mixture, and the cylinder temperature is closely related to the LHV (low heating value) of the fuel, specific heat, A/F, and effective combustion efficiency.

$$T_3 = T_2 + \Delta T_{\text{comb}}, \quad (20)$$

$$\Delta T_{\text{comb}} = \frac{\eta_c Q_{LHV}}{c_v} \frac{1}{1 + A/F} x_b.$$

The burned fraction of the combustible mixture in the cylinder is described by the Wiebe function combustion model, which is as follows:

$$x_b(\theta) = 1 - e^{-b \left(\frac{\theta - \theta_{SOC}}{\Delta\theta} \right)^{m+1}}. \quad (21)$$

Where θ is the angle degree of crankshaft rotation, θ_{SOC} is the degree at the starting of combustion, $\Delta\theta$ is the duration degree of combustion, a and m are adjustable parameters of the Wiebe function which fitted to the values $b = 5$ and $m = 2$ to resemble actual mass fraction burned curves [4, 6, 11, 14–17].

2.4.3. Starting Expansion Process. After successful ignition, the combustion temperature rises in the cylinder due to the burning mixture.

During the expansion stroke (from SOC to EVO) process, the pressure and temperature are calculated using the polytropic expansion model, and the expression coefficient $k_c = 1.35$. The parameters of V_3 , p_3 , and T_3 in the following equation are related to the three-state in the ideal Otto cycle and described as follows [4, 6, 11, 16]:

$$T_c(\theta) = T_3 \left(\frac{V_3}{V(\theta)} \right)^{k_c-1},$$

$$p_c(\theta) = p_3 \left(\frac{V(\theta_c)}{V(\theta)} \right)^{k_c},$$

$$p_3 = p_2 \frac{T_3}{T_2},$$

$$p_2 = p_c(\theta),$$

$$T_2 = T_c(\theta).$$

(22)

Using the inverting the pressure ratio analysis (Matekunas, 1986, 1984, and 1983), the p_3 can be measured experimentally [17–20].

3. Simulation and Experimental Analysis

Based on the new building model, the ion current is calculated using the previously listed calculation formula, and the calculation parameters are shown in Table 1, 2, and 3.

The contribution of the major ionisation reaction and the species of charged ions to ion current generation are calculated. The parameters of several ion sources that dominate the ion current are as follows: the number of moles of H_2O is 0.125 and its ionisation energy $E_i = 12.6$ eV, the ionisation energy of CHO is $E_i = 9.88$ eV, the number of moles of N_2 is 0.75 and its ionisation energy $E_i = 15.5$ eV, and the ionisation energy of NO is $E_i = 9.27$ eV.

Figure 2 shows the calculated ion current results, the experiment measured ion current and the pressure change over the crank angle. Following a successful ignition, ion current signals are produced in the front flame during the chemi-ionisation process. The first peak of the ion current signal increases rapidly as the combustion reaction progresses; then, some of the generated ions are recombined quickly, and to produce more stabler new molecules, other ions have longer residential to the post-flame phase.

As shown in Figure 2, the calculated results and the experiment measured ion current signals have a double-peak structure, with the ion current decreasing after the first peak produced by the chemi-ionisation reaction until the second peak produced by the thermal ionisation.

Based on the chemi-ionisation theory and the derivation from formula (2) to (15), the first peak of the ion current

TABLE 1: The parameters of the model.

cv	Specific heat at the combustion
k_c	Polytropic coefficient for the compression pressure
k_e	Polytropic coefficient for the expansion pressure
Q_{LHV}	Heating value for the fuel
(A/F)	Stoichiometric air-fuel mass ratio
θ_{ivc}	Intake valve closing angle
θ_{evo}	Exhaust valve closing angle
p_{im}	Intake manifold pressure
T_{im}	Intake manifold temperature
$\Delta\theta_d$	Flame development angle

produced is mainly due to the concentration of the H^3O^+ ion increase with combustion temperature. CHO^+ ions are produced firstly in the chemi-ionisation reaction; then, some protons transfer from CHO^+ to H_2O , and H^3O^+ is produced. The concentration of H^3O^+ ions will reach the maximum value at the first peak of ion current waveform timing along with the combustion going on, so the first peak of the ion current is mostly constituted of H^3O^+ . Then, some CHO^+ are recombined quickly, and the ion current decreases. The pressure and temperature of the mixture combustion in the cylinder increase as the combustion reaction progresses; under high pressure and high-temperature conditions, NO^+ ions are the dominant ions generated by thermal ionisation reactions. When the ambient temperature is approximately 2000 K, the ionisation energy of the NO molecule is low: 9.26405 eV [21, 22]. At high temperatures, it easily ionises to NO^+ , resulting in an increase in the rate of NO^+ production. As a result, the amplitude of the thermal ion current reaches its maximum, and the second peak of the ion current appears in the postflame combustion phase.

Figure 2 shows the change in cylinder pressure and ion current as the crank angle changes. The ion current waveform exhibits a double-peak structure as the combustion pressure changes; the ion current reaches the first peak before the TDC (top dead center), but the pressure reaches the peak after the TDC, and the second peak position of the ion current is consistent with that of the pressure peak position. Based on the ideal $PV = nRT$, the cylinder temperature and pressure are closely related, and the ion current signals produced ionisation reaction that depends on combustion temperature and pressure, revealing that the ion current characteristic curve in the combustion reaction

TABLE 3: The input parameters and the valve.

U	Spark gap voltage	80 V
r	Radius of the measurement cylinder	1 mm
d	Length of the measurement cylinder	1 mm

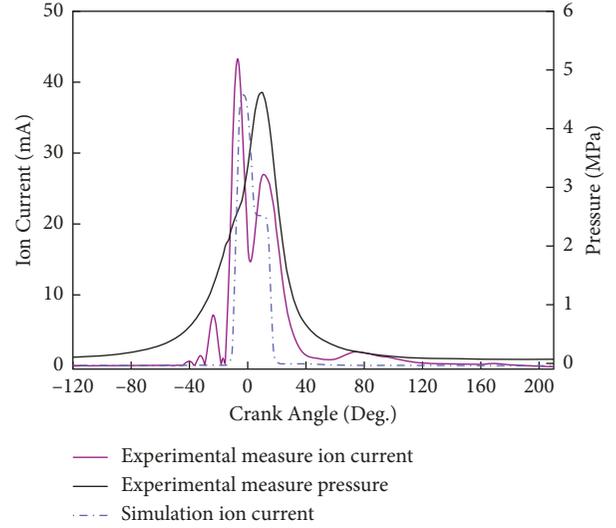

FIGURE 2: Ion current and the pressure variation versus the crank angle.

essentially reflects the intrinsic characteristics of the cylinder pressure and temperature during the combustion process.

Compared to the calculated and experimentally measured curve of the ion current in Figure 2, the calculated ion current follows the experimental ion current very closely; however, the peak and its width values of the calculated ion current are smaller than the experimental values, and the first peak timing are later than the experimental peak timing. The main cause of the above error is that the calculated model of the ion current primarily considers the predominant ionisation reaction mechanism and the predominant charged ions, resulting in calculated values of the ion current that are smaller and later than experimentally measured values.

4. Conclusion

This study developed the most recent model for predictive identification and computationally fast and accurate ion current for obtaining the combustion information in the engine cylinder in real time. The effect of the chemical ionisation and the thermal ionisation mechanisms, engine cylinder and spark plug geometry, and temperature and pressure of the entire combustion process are all considered in the model calculation formula to build a more comprehensive ion current calculation model. Because the

dominant function of the ionisation reaction mechanism and charged ion sources are emphatically considered in the calculations, the predicted peak value and the width of the ion current are smaller than the experimentally measured values. This model will be provided with a fast analytical method for considering the ion current as a function of the combustion flame ionisation reaction process, combustion pressure, and temperature; based on this model, a fast, robust tool for computing the ion current of the combustion process in the cylinder can greatly aid in the design, development, analysis, and control of new engine operating regimes.

With the continuous development of social economy, English learning plays an increasingly important role in daily communication. However, the update speed of English textbooks is far lower than the development speed of English. How to reconstruct the text of English textbooks in colleges and universities to improve the learning effect of college English has become an urgent problem to be solved. In order to solve this problem more effectively, this paper proposes a text reconstruction method for college English textbooks from the perspective of language images. First, this paper proposes a text reconstruction network model for college English textbooks, which includes two self-network models, namely, a text feature extraction network and an image feature extraction network. Second, text designs an English text feature reconstruction network to fuse image features and text features to guide the generation of new English texts according to the generated emotions. Finally, through a large number of experiments, it is proved that the text reconstruction method of college English textbooks from the perspective of language images can effectively generate new texts of college English textbooks, enhance the emotional color of college textbooks, and improve the effect of English learning.

1. Introduction

English plays an important role in the daily affairs of internationalization, but learning English [1, 2] is often a difficult problem. Usually, English learning requires teachers to reconcept and design the content of the text [3, 4], improve students' interest in learning in a reasonable way, turn boring learning into active learning, and deepen the understanding of the text content [5, 6]. The text reconstruction method of college English textbooks [7, 8] has gradually become an effective method to improve college students' English learning. Through the reconstruction of a variety of English knowledge in English textbooks and the use of diversified text forms, college students can improve the English learning methods and skills [9, 10] mastered by college students and deepen their understanding of the text content. The method of text reconstruction of English textbooks is widely used in various learning tasks such as English learning in primary and secondary schools, professional English training, and English reading teaching.

The teaching method of English textbooks is relatively simple. Traditional learning methods [11] often fail to stimulate students' desire to learn, limit students' imagination and comprehension ability, and cannot improve students' learning effect [12, 13]. Usually, teachers in colleges and universities will give a certain degree of guidance to study [14, 15] and reorganize [16, 17] the structure and content of college English textbooks, reconstruct the old-fashioned content in the text into lively cases, stimulate students' imagination, and improve students' learning effect. However, many teachers find some problems in the teaching process. First of all, each country has a certain degree of cultural difference [18, 19]. In order to improve students' ability to master English and improve their learning effect, students need to constantly feel the emotions [20, 21] and foreign cultures reflected in the text. Secondly, each teacher's teaching style [22, 23] is very different, and the understanding and reconstruction of the text content are very different. How to make students have a strong interest in the learning of English textbooks often requires teachers to pay a

lot of money, time, and energy [24, 25]. The difficulties in learning traditional college English textbooks are that the content of the text is relatively old-fashioned and lacks emotional color. College students will have a dull learning mood during learning, which will reduce the effect of learning.

With the continuous progress of science and technology, artificial intelligence methods represented by deep learning technology [26, 27] continue to solve the problems existing in real teaching. Deep learning technology is mainly divided into two aspects. One is the neural network method based on image processing [28, 29], which is mainly used to process image tasks and is widely used in vision-related tasks such as image recognition, image classification, and image segmentation. The second is the neural network method based on text processing [30, 31], which mainly deals with text tasks and is widely used in natural language processing tasks such as text emotion recognition, text emotion classification, and text prediction. In the task of text reconstruction of college English textbooks, it is mainly related to the content of the text and the images in the book. The text features and image features are extracted through neural networks, and new textbook texts with specific emotions can be generated by adding emotional factors and continuously improve students' learning interest and learning effect.

In order to allow college students to better master English and improve the effect of English learning, this paper proposes a text reconstruction method for college English textbooks from the perspective of language images. Firstly, this paper proposes a text feature extraction network based on college English textbooks. It mainly includes two sub-networks; the two sub-networks are the text feature extraction network and the image feature extraction network [32, 33]. Secondly, this paper designs an English text feature reconstruction network [34], which is mainly used to fuse image features and text features, reconstruct college English textbook texts according to the generated emotions, and generate texts with characteristic emotions. Finally, through a large number of experiments, it is proved that the text reconstruction method of college English textbooks based on the perspective of language images can effectively reconstruct the texts of college English textbooks, enhance the emotional color of college textbooks, and improve the English learning ability of college students' teaching burden. The main purpose of this paper is to solve the difficulty of learning English textbooks in colleges and universities, improve the learning effect of college students, and reduce the workload of teachers in schools.

2. Related Work

2.1. Image Feature Extraction. Image features exist widely in people's daily life and usually contain human emotional information, which is an effective way of emotional communication and communication between people. Human emotions are usually expressed through images, and this emotion representation method is widely used in intelligent monitoring, online learning, autonomous driving, and other fields.

Image emotional feature extraction is firstly to preprocess the input image, then use the convolutional neural network to extract the emotional information in the image, and then classify according to the extracted emotional information. Image emotion feature extraction is an indispensable link in neural network, and the effect of emotion feature extraction ultimately affects the effect of emotion classification. Convolutional neural networks can obtain higher-level and more abstract feature representations of images by directly extracting the features of images for learning, thus obtaining more essential features in images, and thus making deep learning features more accurate and general.

2.2. Text Feature Extraction. In recent years, text data has grown rapidly through the Internet, and a large amount of text data has been continuously accumulated. These massive data contain a lot of valuable information. Natural language processing is the main method to solve these pieces of text feature information. It uses the text to train a classifier model and then uses the trained network model to divide and supplement the new text.

Sentiment recognition of text content is also called sentiment analysis. It mainly divides the text into a variety of emotion types according to the meaning and emotional information expressed by the text, which is a multisentiment classification problem. By analyzing and researching these text data, important feature information is extracted, which can be used to analyze the public's attention to hot topics and emotional tendencies, which provides important research ideas for correctly guiding the direction of social public opinion.

With the continuous advancement and development of technology, multimodal data is still a very challenging task at present. In image and text multimodal data, the information contained in text and image is generally complementary. Compared with single-modal data of text or images, multimodal data contains more comprehensive information and can better display and explain the emotional characteristics used. First, the amount of information contained in data of different modalities is often different. Sentiment analysis of multimodal data requires effective understanding and extraction of emotional features of multimodal data. Compared with the traditional single-modal sentiment method, the multimodal sentiment analysis task needs to combine the effective information of multiple modalities to extract the feature interaction between the modal information and the multimodal information in a reasonable way.

2.3. English Text Reconstruction. It is often difficult to improve the English ability of college students through traditional English teaching methods, which are not conducive to students' good grasp of English syntax knowledge and enhance the effect of English learning. Therefore, on the basis of traditional college English textbook learning combined with English practical teaching activities, many teachers have proposed methods of text reconstruction of college English textbooks from the levels of syntactic

analysis, text sorting, title prediction, and textual analysis to improve English learning. The learning effect has a certain reference value.

English text prediction is a high-level idea of text reconstruction in English textbook learning. It requires readers to predict the unknown content of English textbooks based on existing information and personal understanding of textbook content. Mind map refers to presenting the text content in a more specific, vivid, and hierarchical organization based on the thematic events in English textbooks, using keywords, images, color changes, and other main branches. Based on the mind map of text content, it can help students have a deeper understanding of the content of English textbooks, splicing fragmentary knowledge, grasp the key points in learning, and understand English textbooks from a macrolevel. Reconstruction of text content is a common way of learning, which means that learners, from the perspective of the author, combine the knowledge and content they have learned and rewrite the text content, trends, trends, and so on on the basis of understanding and learning English textbooks. Reconstruction can deepen the understanding of the text content of the textbook and realize the process of learning, accumulating knowledge, and transforming the text content of college English textbooks. Text reconstruction can rearrange and understand the content of English textbooks, improve students' interest in learning, and deepen their understanding of the text in textbooks.

3. Methods of Text Reconstruction in College English Textbooks

In order to more effectively obtain the feature information of each modality and the interaction of feature information between modalities, this paper adopts a feature fusion model based on standard transformer structure to fuse the extracted image and text features and use it to generate emotional new text message in Figure 1. First, this paper proposes a text feature extraction network, which uses the LSTM network structure to encode temporally continuous text feature information, then uses the attention mechanism to obtain the text feature information that this paper pays more attention to, and finally generates text feature vectors for input into college English textbooks for text reconstruction in the network. Second, this paper proposes an image feature extraction network to input images from textbooks into the network structure. Its main function is to extract human emotional information through images, input the generated image feature vector into the text reconstruction network of college English textbooks, and add more emotional features to the newly generated text information. With two subnetworks and a backbone network, the text reconstruction method of college English textbooks proposed in this paper can generate new content with specific emotions through a generative method. Deep learning methods can generate various types of text reconstruction content, increase students' interest in learning, and greatly reduce the workload of school teachers.

3.1. Text Feature Extraction Network. The text feature extraction network proposed in this paper is improved on the basis of Att-CNN-BiGRU, which mainly consists of three aspects: text vectorization, text feature extraction, and feature vector generation, as shown in Figure 2. The first part is the vectorization of text features. The main function is to map each word in the input text to a vector representation, and the text vector is represented by the word vector.

Text vectorization is to map the text into a vector that can be recognized and processed by a computer. It is mainly to avoid the problems of one-hot encoding vector sparseness and dimension disaster. Generally speaking, text vectors are mainly composed of word vectors and position vectors. The word vector is to convert the words in the text into vectors that can express semantic information. Considering the meaning of the words and the influence between words, the semantic similarity of words is calculated. The position vector is to convert the position features of the words in the text into vectors and make it clear that the word in the sentence is the trigger word. The position feature is defined as the relative distance between the current word and the candidate word, which represents the relative position of the current word in the sentence.

$$\begin{aligned} S &= \{w_1, w_2, \dots, w_n\}, \\ X &= \{x_1, x_2, \dots, x_n\}, \\ x_i &= [e_i, pe_i], \quad d = d_w + d_p, \end{aligned} \quad (1)$$

where S represents the sentence, w_i represents the i -th value in the sentence, and n represents the length of the sentence. A similar method is used in this paper to map the word w_i to a real-valued vector x_i ; usually, a sentence consists of multiple values.

The text feature extraction network model proposed in this paper is used to extract text features. Text features are divided into lexical-level features and sentence-level features. The lexical-level feature is to extract the background knowledge of the word, including the word's part of speech, semantic information, emotional information, and classification information. Sentence-level features are the contextual information of the entire sentence in the text, such as grammatical features, degree of association, and emotional expression. Convolution operations are used to extract lexical features in text, and BiLSTM and attention mechanism are used to extract sentence-level features.

Convolutional neural networks can only extract local feature information within the convolution window and cannot perform feature extraction and association on textual context information. In order to fully consider the lexical-level features and sentence-level features of each word and enhance the degree of association between words, this paper introduces a self-attention mechanism to obtain lexical-level features more comprehensively while avoiding lexical position information in the pooling operation of loss.

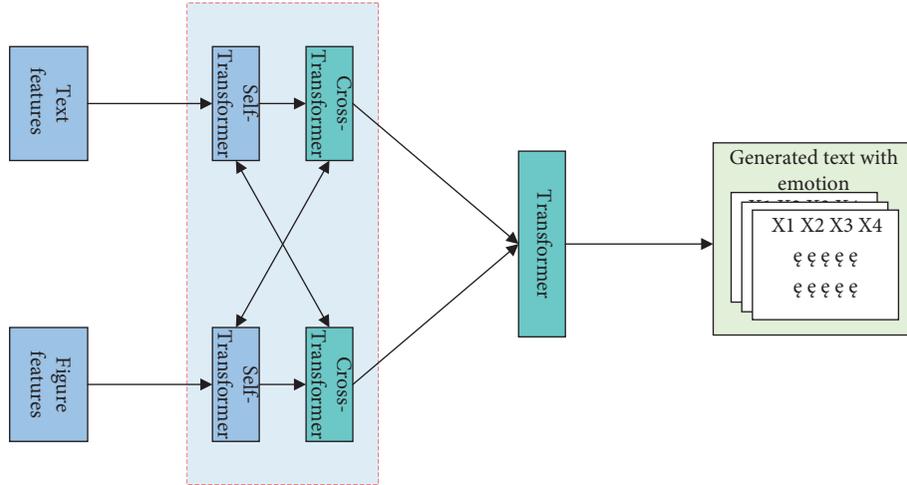

FIGURE 1: Structure diagram of the text reconstruction network of college English textbooks.

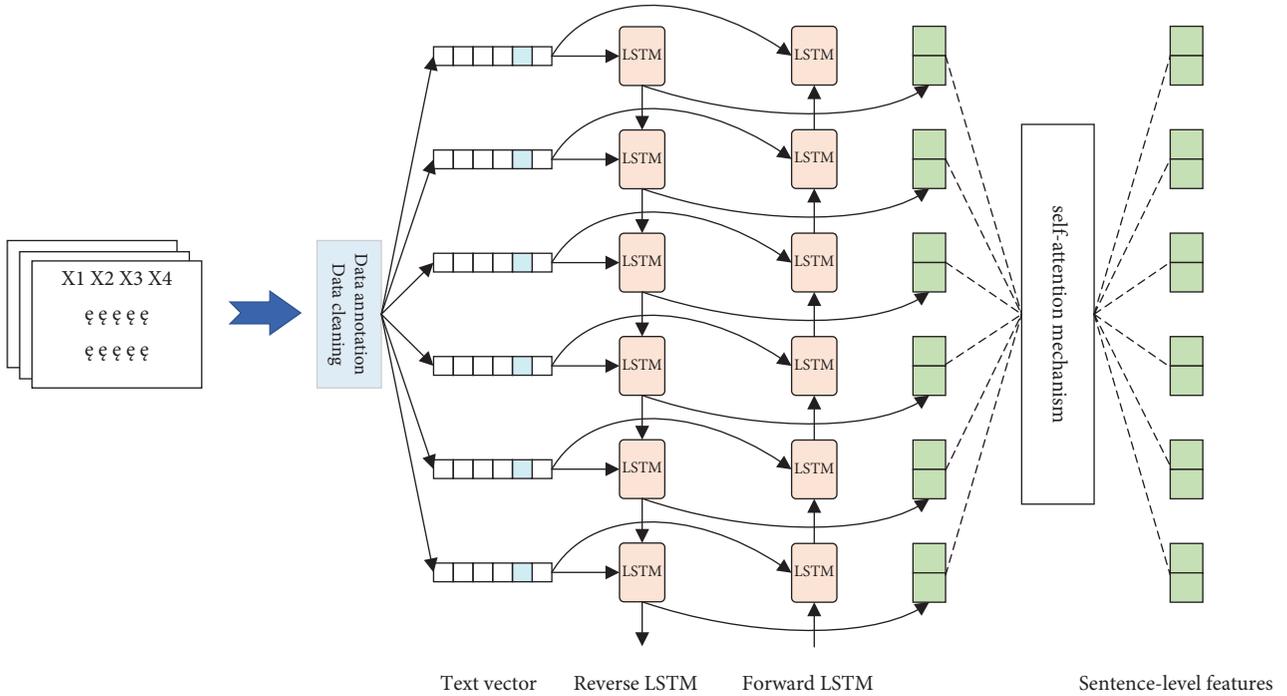

FIGURE 2: Network structure diagram of text feature extraction.

$$f_{att}(Q, K, V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V, \quad (2)$$

$$Q \in R^{n \times d_k}, \quad K \in R^{n \times d_k}, \quad V \in R^{n \times d_v},$$

where T represents the transpose operation of the matrix and dividing by $\sqrt{d_k}$ is to prevent the inner product result from being too large in the experiment. The self-attention mechanism essentially reencodes the input matrix into a new matrix after considering the global feature information through the convolution operation of the matrix. The self-attention mechanism assigns different weights to different vocabulary-level features and considers the global

information of the vocabulary and the relationship between related associations so as to obtain the corresponding vocabulary features or weights.

3.2. Image Feature Extraction Network. The AlexNet neural network is an 8-layer convolutional neural network with three hidden layers in Figure 3. Its basic structure includes an input layer, 5 convolutional layers, 3 pooling layers, 2 fully connected layers, and an output layer. The hidden layer consists of convolutional layers and pooling layers. Convolutional neural networks can obtain multidimensional features of images through convolution layers, and different

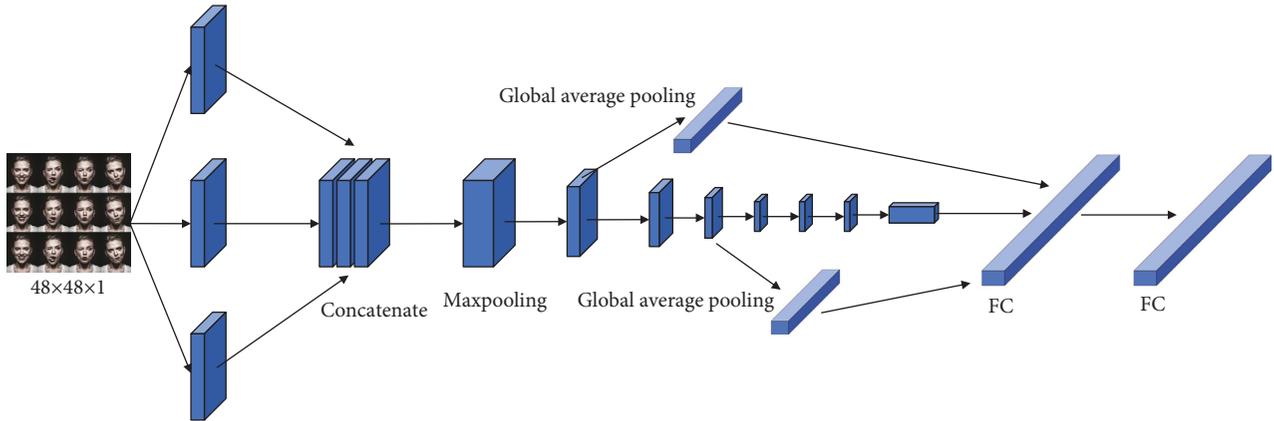

FIGURE 3: Network structure diagram of image feature extraction.

convolution kernels can extract different image features. For emotional images of faces, convolution kernels of different scales can be used for feature extraction, and feature information of different scales can be obtained. In this paper, various types of convolution kernels are used to obtain richer image features so that the feature information of the input data can be more accurately expressed.

The sizes of the multiscale convolution kernels in this paper are 1×1 , 3×3 , and 5×5 , which extract features from the input image data, respectively, and add a BN layer at the end of the convolution layer to improve the multiscale convolution network. Finally, the obtained multidimensional expression features are connected and fused. This feature connection method ensures the richness of features. Among them, the 1×1 convolution kernel can organize information across channels, improve the expressive ability of the network model, and greatly enhance the nonlinear features while keeping the feature scale unchanged. At the same time, the channel can also be adjusted, the pixels on different channels are linearly combined, and then the nonlinear operation is performed to reduce the dimension and the number of parameters.

After cross-layer information fusion, the edge information is also enhanced while retaining the rich high-dimensional features of the feature map. In this paper, the first and second pooling layers of the network are connected to the fully connected layer, and the low-level feature information and high-level feature information are fused as the input of the softmax layer. It can effectively express the feature information of input data, alleviate the problem of gradient disappearance and explosion, enhance the propagation of features in different dimensions, and effectively utilize multidimensional feature information. Cross-layer connection fuses low-level features and high-level features to more accurately describe the feature information of the input data. However, too many parameters are generated in this way, which will cause parameter explosion and overfitting. There are many redundant features, which will reduce the training speed of the network and affect the accuracy of recognition. Therefore, a global average pooling layer is added at the end of the network model to average each

feature map, and finally, the result is input to the softmax layer.

3.3. LSTM Neural Network. Because neural networks such as RNN retain previous data information when processing time-series-based data, the previous data will have less and less effect on the model with the subsequent data input; that is, there is a problem of long-distance dependence. In addition, some unimportant data will also be retained by neural network models such as RNN, resulting in data redundancy. In order to solve the above problems, this paper introduces the LSTM network structure. It has the characteristics of maintaining long-term memory and has good performance in processing time-series-based data. The network model structure is shown in Figure 4.

Equation (3) represents the forget gate of LSTM calculated from the input data and the hidden state. Equation (4) indicates that the input data and the weight of the forgetting gate are subjected to linear operation, and the output of the forgetting gate is obtained to represent the memory level of the long-term memory state. Equations (5) and (6) represent the input gate part of the LSTM.

$$C = \text{sigmoid}(W_1(x_{i-1}, h_{i-1}) + b_1), \quad (3)$$

$$C' = \text{sigmoid}(W_1(x_{i-1}, h_{i-1}) + b_1) \times c_i, \quad (4)$$

$$C_1'' = \text{sigmoid}(W_2(x_{i-1}, h_{i-1}) + b_2), \quad (5)$$

$$C_2'' = \text{sigmoid}(W_3(x_{i-1}, h_{i-1}) + b_3). \quad (6)$$

Through the calculation of the above formula, the LSTM network model can complete the update of the existing long-term memory elements, as shown in (7) and (8). Finally, the output gate, LSTM network model is improved. The LSTM network model comprehensively considers the influence of two aspects of the current long-term memory and the current input data elements in the output, as shown in formulas (9) and (10). Finally, the result of the long-term memory is activated by the tanh function, which finally represents the size and positive or negative of the actual output of the LSTM.

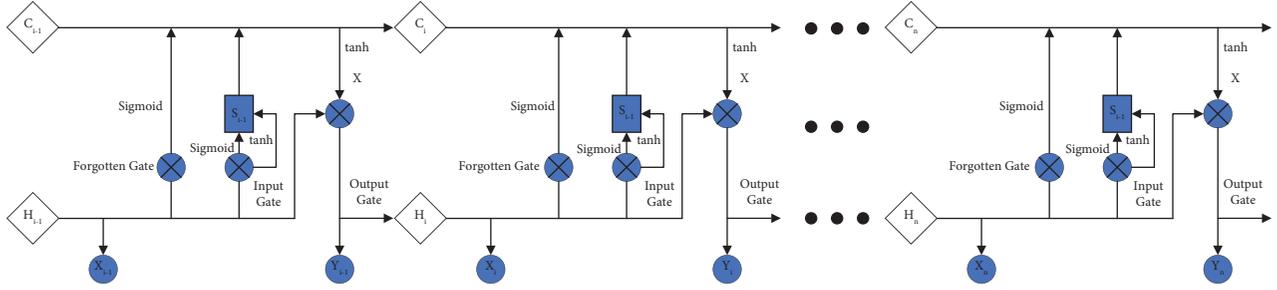

FIGURE 4: LSTM neural network structure diagram.

$$C'' = C_1'' \times C_2'' \quad (7)$$

$$c_i = C' \times C'' \quad (8)$$

$$y' = \text{sigmoid}(W_3(x_{i-1}, h_{i-1}) + b_3) \quad (9)$$

$$y_{i-1} = y' \times \tanh(c_i) \quad (10)$$

function value is often reduced to a very low level in order to obtain more ideal network model parameters. The loss function is an important reference index to measure the performance of the neural network. Usually, the smaller the loss function value in the test set, the better the function model. For the text reconstruction task of college English textbooks, we use the MSE mean square loss function as the loss function in this paper to fit the regression problem of the predicted value.

4. Experimental Results and Analysis

4.1. Experimental Setup. In terms of text feature extraction and processing, this paper uses the ACE2005 English prediction library as training data. It mainly annotates information such as event mentions, event trigger words, and event elements and is widely used in feature extraction tasks in English. It divides the dataset into training, validation, and test sets in a roughly 8:1:1 ratio. At the same time, the precision rate, recall rate, and F1 value are selected as important indicators for model performance evaluation.

In terms of image datasets, this paper uses the COCO large-scale dataset to train and test the network model. The main purpose of image training is to add emotional information to the newly generated text.

The text uses Adam optimizer to optimize the parameters of the neural network model. The initial learning rate is 10^{-3} , which is gradually reduced to 10^{-4} and 10^{-5} . By adjusting the learning rate, the loss function value of the network model is continuously reduced, and the prediction accuracy is continuously improved until a stable equilibrium state is reached.

There are many types of human emotions, and different datasets have different types. In order to prove the effectiveness of the proposed text reconstruction method for college English textbooks, this paper screened these emotion types. Both LSTM and GRU units are capable of processing sequences of events. In general, the LSTM prediction effect is better, and the GRU unit is actually more efficient. In this paper, more attention is paid to the generation effect of the text content, so the LSTM unit is adopted.

4.2. Evaluation Indicators. The loss function value is an important indicator for evaluating the actual performance of the model. When training a neural network, in order to improve the prediction effect of the network model, the loss

$$\text{MSE} = \frac{1}{n} \sum_{i=0}^n (\hat{y}_i - y_i)^2 \quad (11)$$

Text or images based on time series usually contain hidden relationships. Through the training of neural network models, latent features between continuous data can be discovered to realize data prediction. In this paper, the MSE loss function is used to continuously adjust the parameters of the network model in reverse to improve the prediction effect of the network model.

In addition, in order to evaluate the prediction effect of the network model, this paper also adopts the MAE mean absolute error as the evaluation index of the model. MAE represents the mean absolute value of the error between the predicted value and the true value. Compared with MSE, MAE can directly reflect the difference with the original data. The smaller the MAE of the network model test data, the better the prediction result of the model.

$$\text{MAE} = \frac{1}{n} \sum_{i=1}^n |\hat{y}_i - y_i| \quad (12)$$

4.3. Comparison and Analysis of Experimental Results. As shown in Figure 5, A–E represent the number of emotion categories in the image dataset in the subnetwork, which are angry, natural, fearful, happy, and sad, respectively. Correspondingly, the percentages in the figure represent the proportion of each type in the image dataset. From the figure, we can clearly see that the number of types B is the largest and the number of types E is the least. Natural and normal images make up the largest proportion of our dataset, and sad images make up the least. Image emotional feature extraction network is mainly trained on this dataset to extract emotional features in images.

Figure 6 shows the distribution of sentiment features in the text dataset. This paper mainly divides text sentiment features into two categories: one is positive sentiment, and

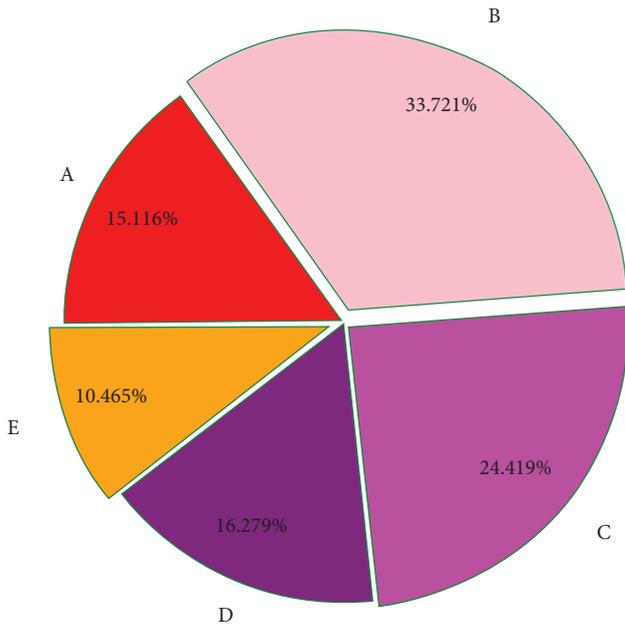

FIGURE 5: Proportion of emotion categories in image datasets.

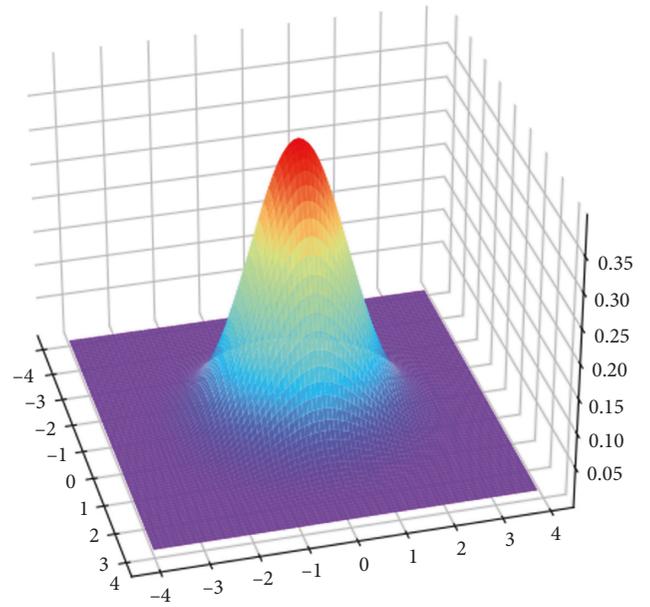

FIGURE 7: Network model optimization learning.

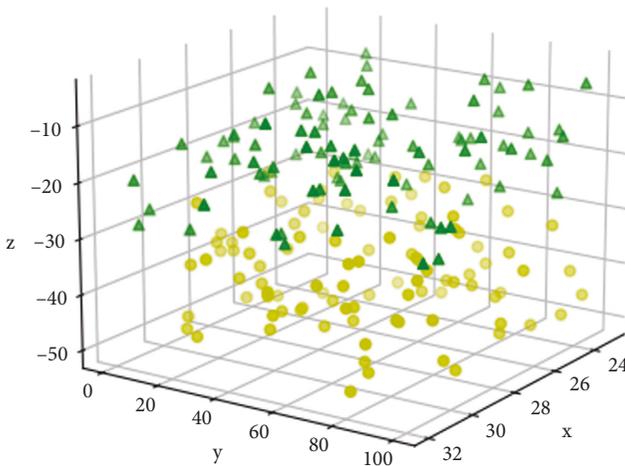

FIGURE 6: Sentiment dispersion in text datasets.

the other is negative sentiment. Positive emotions include joy, enthusiasm, and confidence, and negative emotions include anger, fear, and sadness. In the figure, we use green to represent positive sentiment in the text and yellow to represent negative sentiment in the text dataset. On the whole, the demarcation line between negative emotion and positive emotion is relatively clear, which is suitable for model training and testing.

Figure 7 shows the results of network model optimization learning. The two axes in the plane represent the model parameter settings of the image feature extraction and text feature extraction subnetworks. From the figure, we can see that the parameters of the network model can be optimized by setting some parameters in the image and text feature extraction subnetworks.

Figure 8 shows the learning effect of the image network model. The lighter the color value, the better the prediction effect of the model. From the above figure, we can clearly see

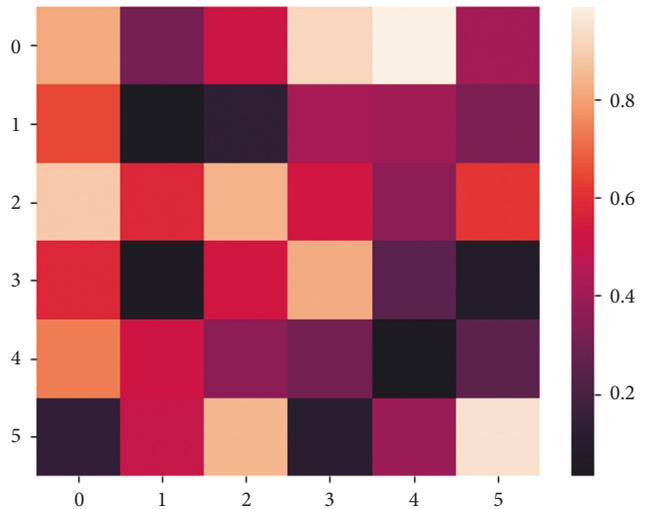

FIGURE 8: Confusion matrix for image network model learning.

that the network model in this paper has a certain accuracy in distinguishing emotion categories, which meets the requirements of image feature extraction.

Figure 9 shows the learning effect of the text feature extraction network. The deeper the red value of the color value, the worse the prediction effect, and the darker the blue value, the better the prediction effect. The text feature extraction network in this paper expands the category of emotion and has been able to classify 10 emotion types more accurately.

Figure 10 shows the learning effect of the backbone network model. The x -axis and y -axis, respectively, represent the number of iterations of the subnetwork model, which is the number of times of training in different data sets. The z -axis represents the effect of learning the backbone network model together with the two subnetwork models. From the

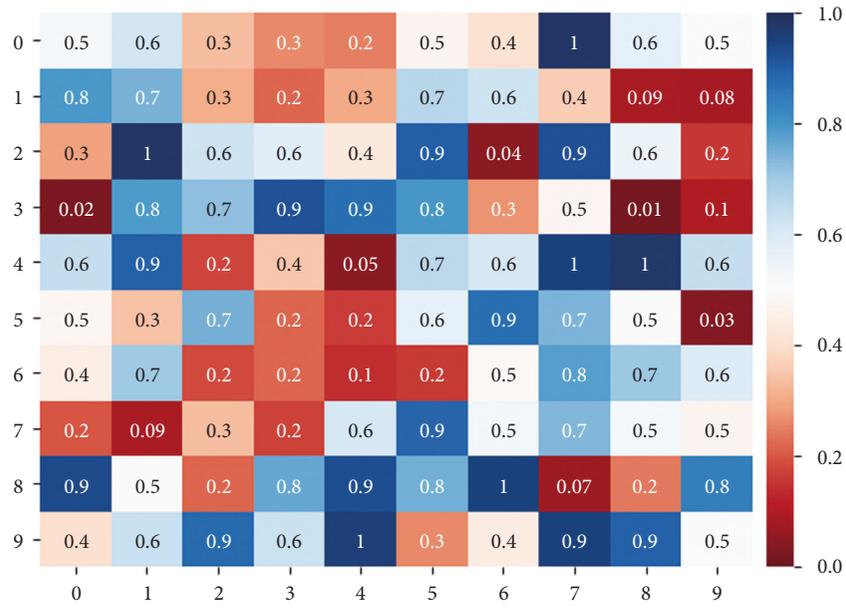

FIGURE 9: Prediction effect of text feature network model.

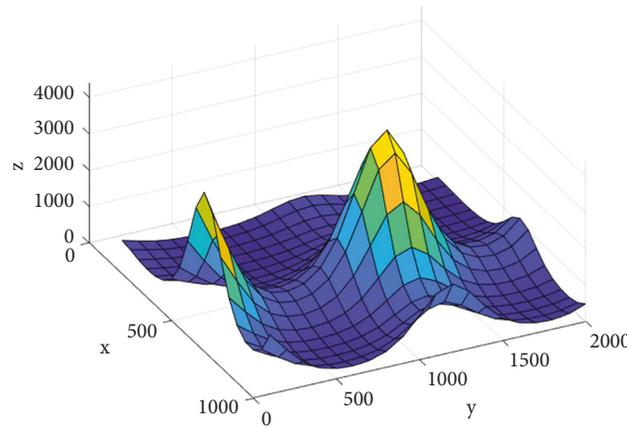

FIGURE 10: The learning effect of the backbone network model.

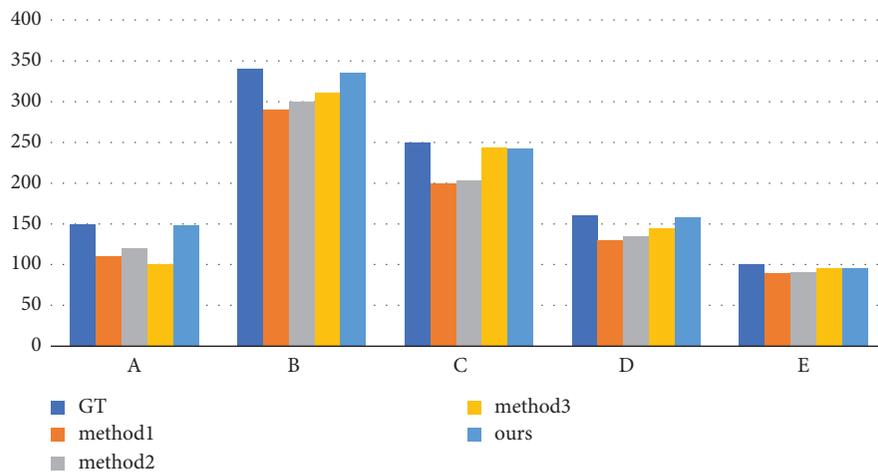

FIGURE 11: Comparison of various neural network models.

figure, we can see that multiple experiments and settings through multiple network models can effectively improve the generation effect of the entire network model.

This paper compares the methods of various neural network models, and the experimental results are shown in Figure 11. It should be noted that all experiments are trained and tested on the same test platform and only the structure of the network model is different. All experiments are trained from scratch with the same learning rate and optimizer. GT represents the real value of the data predicted by the network model, and other colors represent the experimental results obtained by CNN, RNN, transformer, and the method in this paper, respectively. From the data, we can clearly see that the method in this paper has a better prediction effect on the data and is closer to the true value.

5. Summary

In order to improve the learning effect of college English, this paper proposes a text reconstruction method for college English textbooks from the perspective of language images. In this paper, the text feature extraction network and image feature extraction network are used to obtain text features and image features, respectively. Then, this paper designs a multimodal feature fusion network and a college English text generation network, which mainly guides the reconstruction of new college English texts according to the emotional features in image texts, generates new texts of college English textbooks with emotions, and improves college English learning effect. Through a large number of experiments, it is proved that the reconstruction method of college English textbooks based on the perspective of language and images can improve the learning ability of college students and reduce the teaching burden of college teachers. The neural network model adopted by the text can handle multimodal data and can be extended to more data types in future work, such as audio data and video data.

As the development of my country's mobile Internet continues to advance in depth, its related industries have also continued to rise and especially, the short video industry has ushered in a period of rapid development. In the past, the research on short videos mostly started from the perspectives of communication, sociology, culture, etc., mainly based on the discussion of the content and communication characteristics of Douyin short videos and analyzed the origins behind its rapid development. The relevant research on moral education in colleges and universities is relatively weak. Based on the relevant sample data collected from questionnaires and interviews, this paper focuses on analyzing the impact of short videos on moral education in colleges and universities from the perspective of pedagogy. The rapid popularization and wide application of short video applications have had a huge impact on the study habits and living habits of college students. College students' moral education educators must make good use of the short video application as a carrier, create new ideas for work, and enhance the attractiveness and influence of moral education work.

1. Introduction

In the era of convergent media, short videos are developing rapidly in cyberspace due to their immediacy, vividness, and audio-visual characteristics and have a broad market space [1–3]. The 46th “Statistical Report on the Development of China's Internet” pointed out that as of June 2020, the number of short video users in my country reached 818 million, accounting for 87% of the total Internet users. In 2020, the online video industry will be further improved and developed [4–7]. The dissemination advantage of video clips has become a hot spot in the development of the industry. College students, who are susceptible to new things, have become the main force of short videos. Both the number of netizens and the penetration rate have increased significantly compared with 2018 [8–12]. Under the background of the era when short videos are favored by college students, “high importance is attached to the construction and innovation of communication means”, and choosing a discourse system and expression form that conforms to the characteristics of college students in the new era is an

inevitable requirement for the development of modern college moral education. How to use the development advantages of college moral education for solving development problems is an important issue facing the current development of moral education in colleges and universities [13–15].

With the progress of the times and the development of the society, my country's Internet-related industries have grown rapidly in recent years and the development of the mobile Internet has made great progress, which has profoundly affected the current social format [16–20]. Among them, Douyin short videos are widely disseminated and popular among young people and have a great impact on the values, behavioral education, patriotism, and psychological intervention in the ideological and political education of young people [21, 22]. At present, with the widespread use of smartphones and the continuous development of related technologies, the related applications of short videos have become an integral part of most people's daily lives. According to the statistical report, as of March 2020, the number of mobile Internet users in my country was 897

million, accounting for 99.3% of the total Internet users. The per capita online time per week was 30.8 hours, with an increase of 3.2 hours from the end of 2018. According to the report, most people in my country habitually choose to use smartphones to surf the Internet, and the use of mobile Internet access and online video (short video) has maintained rapid growth [23–25].

At present, college education is faced with some problems, such as the single teaching form, and the teaching style is the most traditional teaching form and the most commonly used method in college teaching. However, there are problems such as monotonous content and boring teaching. The penetration of education will be restricted and limited, and it will lose its attractiveness to students over time; secondly, the imbalance of teaching resources is restricted by the differences in the development of education in various places, and the distribution of educational and teaching resources is also uneven. In particular, audio and video resources are far from being able to meet the needs of increasingly diversified, convenient, and autonomous education in traditional classroom teaching. Finally, teachers lack media literacy. At present, teachers only give students some abstract concepts. The teaching thinking is closed and conservative, and they follow the old rules. In the era of all media, new media technology represented by videos has rapidly penetrated into all fields of teaching, which has had a huge impact on teaching methods. The use of new media to innovate teaching methods is an inevitable choice for college teachers, and it also puts forward new requirements for the media literacy ability of teachers.

The rapid popularization and wide application of short video applications have had a huge impact on the study habits and living habits of college students. College students' moral education educators must make good use of the short video application as a carrier, create new ideas for work, and enhance the attractiveness and influence of moral education work.

2. Research Status of Short Videos in Moral Education

2.1. Short Video Application Research. In the context of the great development of the mobile Internet, online videos (short videos) have achieved rapid development by virtue of its own advantages and the short video is even reshaping the ecological pattern of mobile phone networks. According to the latest statistical report, the number of users of online videos (including short videos) in my country has reached 850 million, an increase of 126 million compared with 2018. Among them, short video users reached 773 million, accounting for 85.6% of the total netizens. The scale of short video users in my country and their utilization rates are shown in Table 1.

Douyin short videos were officially released in September 2016, and they have achieved rapid development with their unique algorithm advantages and marketing promotion. According to the information disclosed by the data portal "DataReportal," the number of users of Douyin short video has exceeded 800 million in January 2020 and it

TABLE 1: Scale of short video users in my country and their utilization rate.

Time	The scale of short video users	Short video users (%)
2018.6	59320	74.5
2018.12	65008	79.2
2019.6	64748	75.7
2020.3	77362	85.9

is expected that its number of users will soon exceed 1 billion and its market share is still increasing. It is already a leading company in the short video industry.

In the research on short video content, a representative example is the Douyin Research Report jointly released by Miaozhen System and Haima Cloud Big Data in 2018. The report mainly divides short videos into four main types according to content creators: the first is actors and stars; the second is with a certain skill or expertise of the network red; the third is institutions and associations; the fourth is public hobbies. Deng Yongfang and Xie Jinpeng divided the video content on Douyin short videos into five main categories in "Seeing the Psychological Characteristics of Contemporary Young People from Popular Short Videos - Taking Douyin's App as an Example": handsome boys, beauties, cute babies, etc. The Yan Zhi group is represented by the Yan Zhi group; the creative group is represented by humor, dazzling skills, and eye-catching skills; the heart-moving group is represented by emotional expression; the intellectual group is represented by language teaching, skill teaching, makeup, food, etc. In the "Short Video Social Platform and Minor User Survey Report - Taking Douyin's Short Video as an Example," Hu Yuan divided its content into visual enjoyment, humor, knowledge popularization, creative skills, and talent show. There are six types of hot topics in current affairs.

2.2. Student Moral Education Research. In recent years, the user group of my country's mobile Internet has continued to expand from the middle to the two ends and the user group of Douyin short videos has extended to the lower age group especially. As shown in Figure 1, as of March 2020, the proportion of Internet users aged 10–19 years in my country reached an astonishing 19.3%. This age group is the scope of the vast majority of young people in my country.

Teenagers have strong self-awareness and curiosity and can easily accept new things. Douyin short videos on the mobile Internet are an important gathering place for current novelties. The improper use of Douyin short videos by teenagers can easily have an important impact on their values, patriotism, behavioral education, psychological intervention, etc. Similar cases also appear around us and in media reports from time to time. How to use short videos to spread positive information, effectively promote the ideological and political education of young people in my country, and prevent young people from being overly addicted.

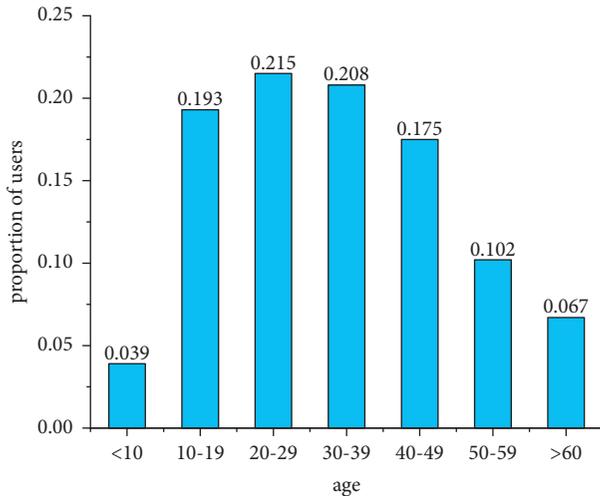

FIGURE 1: Age structure and proportion of netizens.

At present, there are few academic studies on the direct correlation between short videos and students' moral education. It is also a controversial topic whether the advantages outweigh the disadvantages or the disadvantages outweigh the advantages. Some scholars recognize its positive effects, some scholars have negative comments, and some scholars are neutral:

- (1) Short videos have a good role in promoting moral education of students. Some researchers believe that short videos on Douyin can better promote the ideological and political education of young people and advocate active promotion and application. On the advantages of Douyin short video on ideological and political education of teenagers, it is believed that the user portrait design of Douyin can better meet the psychological expectations of teenagers; the supervision system enables young people's online ideological and political education to promote strengths and avoid weaknesses; the appeal of visual experience makes Douyin a carrier of ideological and political education, and it advocates to make full use of Douyin to promote ideological and political education of young people. In "Research on the Promotion Effect of Internet Media on Ideological and Political Education of Teenagers - Taking Learning Power Platforms and Douyin's Short Videos as Examples," Zhang Hanghang believes that Internet video platforms have gradually become the main way for young people to obtain entertainment and information Liu Tongguo and Du Xiaoyan pointed out in the article "Strategies for Strengthening Ideological and Political Education of Teenagers under the Background of the Popular Development of Short Videos" that short videos have become a favorite entertainment and leisure method for teenagers. With its pertinence and timeliness, it can also be expanded as an important tool for contemporary ideological and political education. Some researchers believe that the short video of Douyin plays a

negative role in the ideological and political education of young people. A representative example is Lin Yirong's "Analysis of the Phenomenon of Moral Nihilism in Short Videos and Coping Strategies." It is observed that although short videos have a positive effect, at the same time, they contain a lot of moral nihilism. This phenomenon should be sorted out and criticized, to solve the problem of moral nihilism in short videos.

More researchers advocate a dialectical view of the role of Douyin short videos in students' moral education, and it is not appropriate to draw conclusions about the pros and cons. For example, Gao Pan analyzed the constantly developing short video platform and its impact on young people's thinking in the article "Thinking on the Ideological Education of Youth in the Short Video Era," focusing on the new changes in the ideological education environment for young people in the short video era. This article also proposes to optimize the platform environment of short videos to play a positive role in the ideological education of young people. In the article "Influence and Countermeasures of Mobile Short Videos on Teenagers' Moral Education," Hua Honglin analyzed the challenges brought by the tendency of pan-entertainment in mobile short videos to the moral education of adolescents and emphasized the use of mobile short videos to give full play to its role in moral education.

All in all, the research based on the dissemination of short videos and the psychological portraits of users has been relatively abundant, but the related research on the ideological and political education of young people, especially the ideological and political education of young people, encounters a relatively weak discussion of characteristics. Few studies have specifically focused on this special group of young people, based on ideological and political education, focusing on their self-presentation and self-description on the Douyin short video platform, and dialogue with society in a way they identify with. There is a lack of necessary intervention and guidance in the way young people contact new media such as Douyin short video, which makes it difficult to maintain the healthy growth of young people.

3. The Correlation between Short Videos and Moral Education in Colleges and Universities

3.1. Students Are an Important User Group for Short Videos. According to the latest statistical report of my country's CNNIC, as of March 2020, the number of short video users in my country was 773 million, accounting for 85.6% of the total number of netizens. The number of 19-year-old short video users is about 180 million. According to the results of my country's sixth census, it is not difficult to deduce the huge group of Douyin users of teenage. At the same time, according to the preliminary data of my country's seventh census, my country's population aged 0-14 is 253,383,938, accounting for 17.95% and the population aged 15-59 is 894,376,020, accounting for 63.35%. Compared with the sixth national census in 2010, the proportion of the population aged 0-14 increased by 1.35 percentage points.

TABLE 2: The weekly frequency of Douyin short videos used by teenagers.

Frequency	0 times	1–5 times	5–10 times	More than 10 times	Total
Dslbquantity	65	125	55	100	345
Proportion	18.8%	36.2%	15.9%	29.1%	100%

TABLE 3: The purpose of young people’s exposure to Douyin short videos.

Options	Entertainment and relaxation	Enhancing learning	Making friends	Transferring positive energy	Others
Quantity	315	70	30	145	55
Proportion	91.3%	17.4%	8.7%	42%	15%

Combined with the data of short video users, it is not difficult to judge that the vast majority of young people in my country are actively or passively using or contacting media types such as Douyin short video media.

3.2. Short Video Is an Important Tool for Students’ Moral Education. The development of the mobile Internet is the trend of the times, the short videos of Douyin are booming, and their social influence is obvious to all. Taking Chinese traditional culture as an example as an important part of contemporary youth ideological and political education, before relying on mobile short video dissemination, the education and promotion of excellent traditional culture have been in a tepid state and it has become more important in attracting the attention of young people. Unsatisfactorily, by incorporating Douyin short videos, breakthrough achievements have been made in its dissemination and influence. According to “Double Tradition: Research Report on Short Videos and Traditional Culture,” as of the beginning of May 2019, there were more than 65 million short videos related to traditional culture released on the Douyin platform, which were played more than 16.4 billion times and liked 4.4 billion times.

Promoting excellent traditional culture itself is an important part of ideological and political education for young people. Some of the above projects are aimed at young people as the main target group, guiding them to love traditional culture, carry forward the quintessence of the country, and improve their ideological and political literacy. Through the above research, according to the proportion and calculation of the user group data of the Douyin short video platform, it can be seen that young people should have participated in it extensively and the educational effect achieved is even far beyond the traditional teaching method. Douyin short videos have become an important part for the ideological and political education of young people. At the same time, judging from the inner aspirations of young people, it is basically impossible to break away from the novelty of Douyin short videos. It is better to give full play to the advantages of Douyin short videos in combination with the characteristics of young people, develop them into an important platform for ideological and political education of young people, and gather the strengths of schools, society, families, and other parties to jointly promote the achievement of educational goals.

4. The Application of Short Video Technology in Moral Education in Colleges and Universities

4.1. A Survey on the Status Quo of Short Videos Affecting Moral Education in Colleges and Universities. This questionnaire survey was chosen to be distributed and implemented among the freshmen of a university. Most of the entire questionnaire survey process was conducted in an anonymous form, and a combination of online and offline questionnaires was adopted. Later, some students were randomly selected as the in-depth interview objects, in order to correct the questionnaire results. The distribution and collection of the entire questionnaire lasted for about two weeks. In order to display the results of the questionnaire more vividly, the results of the questionnaire are shown in Tables 2 and 3.

According to the questionnaire feedback on the purpose of young people’s exposure to Douyin short videos, the vast majority of young people use Douyin short videos for entertainment, relaxation, and transmission of positive energy and a small number of young people said that it is to further strengthen their learning. From the perspective of the attractiveness of Douyin short videos, having nothing to do in free time and adding fun to life have become important factors for using Douyin short videos. At the same time, it is still not obvious that the youth group as the main body actively publishes short videos on Douyin. Most teenagers say that they have not done any publishing operations related to short videos of Douyin and more passively accept the relevant information on short videos of Douyin. Therefore, from the perspective of the time and behavioral characteristics of young people, it is feasible to use Douyin short videos to integrate the ideological and political education of young people, and young people themselves also have inherent demands in this regard.

4.2. The Positive Impact of Short Videos on Moral Education in Colleges and Universities

- (1) It can resonate with students and provide rich materials. First of all, the natural characteristics of Douyin short videos make it easy to connect with daily life, and their content is more likely to resonate with students. The so-called “life is the best teacher.” Traditional ideological and political education is

limited by various conditions, most of which are not closely related to life, so it is difficult for teachers to narrow the distance with students, and it is difficult to achieve learning in the environment. Douyin short videos are most closely related to daily life and even have a large amount of content based on daily life. For example, it can integrate relevant content of ideological and political education of young people in daily life and specific stories and match most of the boring theoretical knowledge. The music and scene effects are more likely to resonate with students, thus providing teachers with rich teaching materials.

Secondly, Douyin short videos can use modern Internet big data and other methods to provide rich materials for ideological and political education of young people. If teachers can reasonably use the short video content that is beneficial to the ideological and political education of young people in education, they can improve the effectiveness of ideological and political education for young people to a certain extent. The author has observed the relevant Douyin short videos of Zheng Qiang, a famous professor in my country. Professor Zheng Qiang combined his subject knowledge in many Douyin short videos to vigorously promote ideological and political education content such as patriotism. The playback volume of videos is often tens of millions, and it is obviously difficult for traditional teaching to achieve this effect.

In short, teachers can make good use of the advantages of Douyin short videos in all aspects to make them resonate with students in ideological and political education and enrich teaching materials. Judging from the relevant information observed and contacted by the author, this method has certain advantages in achieving educational effectiveness.

- (2) It can optimize the way of communication and provide a new interactive space. In recent years, with the rise of online educational videos, the influence of Douyin's online educational short videos has also continued to expand. According to the official data of the Douyin platform, as of June 2019, there have been more than 5.47 million online educational short videos on the platform, with nearly 14.9 billion likes, more than 850 million forwarding and sharing, and more than 475.2 billion views. . At the same time, in order to better promote the combination and development of youth education and Douyin short videos, a number of educational institutions such as China Education Television and the Coordination Center of Communication University of China jointly launched the "Green Pepper Plan," which aims to promote the active participation of young people in Douyin. Audio and video online education are developing. At present, a large number of online education institutions have used Douyin to carry out various online education, which provides certain objective conditions for optimizing the dissemination of ideological and political education. As an effective

supplement to after-school learning, online education is conducive to the optimization of the dissemination of ideological and political education for young people and provides a new interactive space.

- (3) It can break through the limitations of time and space and provide convenient learning. The traditional ideological and political education for teenagers adopts class-based teaching, and both educators and teenagers need to conduct ideological and political education and teaching according to fixed course schedules and requirements. After extracurricular activities, teenagers have so far had few options on how to adjust their learning progress according to their own schedule. To a certain extent, the application of Douyin short videos can play a complementary and filling role. Teenagers can use a lot of leisure time to complete their studies, and they can also play the videos repeatedly for difficult problems to strengthen and consolidate.

The traditional ideological and political education for young people is confined to closed classrooms, and the fixed space makes it impossible for young people to accept and adapt to more teaching content and methods. The use of Douyin short videos by young people outside school or after school is conducive to improving their ideological and political literacy, moral sentiment, etc., and is also conducive to breaking through the limitations of learning space. The place for ideological and political education for young people is no longer limited to specific locations. Space units such as families, scenic spots, and historic sites can all become educational places.

In general, in view of the huge influence of Douyin short videos on the youth group, the relevant functions endowed by its platform can be used to break through the limitations of traditional teaching of ideological and political education, and to a certain extent, it is difficult to change the traditional teaching, which is difficult for students to resonate, and there is lack of materials, poor interaction, time and space confinement, and other issues. If we can make full use of the extra-school environment or after-school time, combined with the relevant advantages and characteristics of Douyin short videos, it will undoubtedly be of great significance to achieve the goals of ideological and political education for young people.

4.3. The Negative Impact of Short Videos on Moral Education in Colleges and Universities. In terms of ideological and political education for young people, although Douyin short videos have an important positive role, their negative impact is also prominent and some even tend to intensify. Analyzing the negative impact of Douyin short videos on the ideological and political education of young people is conducive to finding effective coping strategies, limiting the spread of negative factors to the greatest extent, and creating a good Internet ecological environment:

- (1) Short videos impact the value judgment ability of young people. Value judgment is one of the important abilities of young people to understand and

judge the society. It is an integral part of the “Three Views” education and also affects the value orientation of young people’s future life. During this period, the physical and mental development of young people is not perfect, they cannot form correct and independent judgments about external things, and their value judgment ability is easily affected by the external environment.

As shown in Figure 2, the survey results show that 49.28% of teenagers think that the impact is moderate, 14.49% think that it has no effect, and only 10.14% of the teenagers think that the impact is relatively large. It can be seen that most teenagers cannot make a clear value judgment on the impact of Douyin short videos. The questionnaire also confirms from the side that most adolescents in this period are still in the process of forming and developing their physical, mental, and critical thinking abilities and it is difficult to make clear value judgments on issues such as right and wrong, good and evil, and value standards.

- (2) The pan-entertainment of short video dissemination increases the difficulty of ideological guidance. “Pan-entertainment” is a common phenomenon in today’s online media. In a sense, Douyin short video is the representative force of “pan-entertainment” in contemporary online media. Its content is mostly humorous, with music, fashion, Internet celebrity trends, etc. This way of entertainment attracts people, especially the youth group. Under the influence of the idea of pan-entertainment, Douyin pushes many contents indiscriminately to a certain extent, which objectively increases the difficulty of ideological guidance of young people. Taking media reports as an example, Douyin has repeatedly ridiculed or insulted revolutionary martyrs with comics, funny videos, and other entertainment methods, which has been criticized by all walks of life, which is an important aspect of pan-entertainment. The widespread dissemination of similar negative information can easily lead to misleading, which in turn increases the difficulty of guiding young people’s thoughts.

Taking the author’s questionnaire as an example, the proportion of teenagers who choose to play Douyin short videos for entertainment and relaxation has reached an astonishing 91.3%, which means that entertainment and leisure are the ideological and behavioral motives for the vast majority of teenagers to use Douyin. At the same time, it also proves that the current pan-entertainment phenomenon of Douyin short videos has an increasingly prominent impact on young people. For example, common entertainment stars directly affect the idol selection of some teenagers, which can be seen from the pursuit of “little fresh meat” from time to time in the society; fast-food cultural entertainment and fragmented reading make some teenagers’ cultural values superficial, lacking of the ability to speculate on cultural values; important historical “film and television tampering”

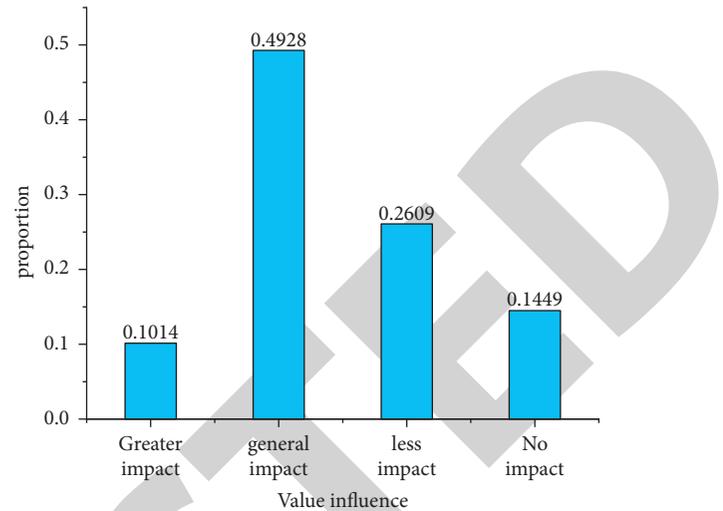

FIGURE 2: The impact of short videos on adolescents’ value judgments.

and ideological and moral “joking and scolding” seriously affect young people’s understanding of objective history and the improvement of ideological and moral quality. Similar pan-entertainment information is full of Douyin short videos, which cater to the public’s preferences but increase the difficulty of guiding ideological and political education for young people.

5. Conclusion

In the context of new media, the popularization of short video applications such as Douyin and Kuaishou has had a huge impact on the ideas of college students. This makes the moral education workers in colleges and universities face new opportunities and challenges. The majority of moral education educators in colleges and universities should recognize the characteristics and advantages of a short video application, use the short video application platform, use new media technology, innovate moral education work methods, and cultivate outstanding technical talents with both political integrity and ability for the society. We explore the impact of the Internet media represented by Douyin short video on moral education in colleges and universities and finally form a feasible and practical coping strategy. The ultimate goal is to better protect the youth group and promote it to form a good value judgment, media literacy, and safety awareness, etc. In terms of discussing and solving this problem, it is impossible to rely on one side’s efforts to solve it. It needs the concerted efforts of the government, society, schools, families, and other parties to promote it together for benign development. At the same time, it is impossible to achieve this overnight, and any method needs to be continuously verified by adolescents and social practice. Nowadays, with the progress and rapid changes in social science and technology, it is even more doomed that this is not a smooth road. However, in any case, we should not stop at the ideological and political education of young

After the implementation of the hybrid network-based English teaching system, a wide-ranging trial was carried out in schools. Although the trial time was not very long, according to the feedback given by the students, it is not difficult for us to find that the practicability of the English network teaching system is very strong, which is very suitable for current college students. The main goals of this research are the application development of the open source Moodle course management system and the practical design and realization of the English network teaching system based on in-depth research on the Moodle system and the secondary development technology. In view of the development of the existing English online teaching system in China and the current situation of domestic audio-visual information construction, it is planned that Moodle, an open source and free software system that fully complies with the CPL and GPL protocols, is used to teach the English language through in-depth research on the software support system. The software bottom layer supports the network teaching system and then uses PHP and web technology to expand and integrate system functions according to different needs and finally realize an English network teaching system suitable for college students at this stage.

1. Introduction

Blended learning is a relatively mature concept in the educational technology field, and it has been in a state of updating. In fact, in our previous teaching, blended teaching has been widely used, such as the combination of multiple teaching methods. The utilization of resources, the participation of various teaching media, etc. belong to blended teaching at a simple level. On the basis of traditional concepts, blended teaching in the information age includes online teaching and traditional classroom teaching. Online teaching is the usual teaching. The traditional classroom teaching is the teaching based on blackboard, chalk, and textbooks in the well-known real classroom. It is this advantage of blended teaching that makes higher education take a new direction. Traditional teaching can no longer meet the development needs of higher education. With the rise of the Internet, the combination of online teaching and

traditional teaching has become deeper and deeper, and blended teaching has emerged as the times require. It has become the direction of higher education reform. In hybrid teaching, in order to play its role and advantages, network teaching must offer reasonable and effective online courses. In addition to media technology factors, it is necessary to rely on effective and reasonable network resources to design a complete teaching system as network teaching. At the same time, the irreplaceability of classroom teaching should also be avoided, and students should not be allowed to learn at will because of online teaching. Online teaching is only a necessary teaching method, and it has great potential, but it will never replace traditional classroom teaching. In view of the above analysis, we can give full play to the dual advantages of online teaching and classroom teaching, properly handle the relationship between the two, and further improve teaching efficiency [1–10]. This research clarifies the importance and necessity of English online teaching through

the analysis of different English teaching methods and combines the existing advantages of the Moodle system to construct a network system for English teaching. So the traditional education method is no longer the only way of English teaching, and more efficient English teaching is carried out through the network, so as to achieve the purpose of cultivating students' learning ability and English application ability.

2. Related Works

With the rapid development of information technology in the world, online education and traditional education are no longer two distinct fields, but they gradually present a situation of "you have me, I have you" and tend to the realm of mutual integration. "A ruler is short, an inch is strong," and combining the advantages of online education and traditional education will maximize the strengths and avoid weaknesses to achieve the best results. Currently, "E-learning" is gradually becoming a "Moodle online teaching system" internationally. At the end of the last century, various countries have put forward successful cases of blended teaching. Based on the online teaching system, many online courses of blended teaching have been developed, and more blended teaching models have been designed, especially in the United States and European countries. At present, the network teaching systems that support blended teaching widely used abroad include WebCT of the University of British Columbia, Learning Space of IBM, Blackboard of the United States, and OpenCourseWare (MIT OCW) of the Massachusetts Institute of Technology. In traditional American campuses, teachers have begun to break through the complete face-to-face teaching, and many teachers have begun to adopt the innovative teaching mode of blended learning. In the weekly teaching tasks, they take part of the class time to arrange the Moodle online teaching system, so that students can access the Internet in the dormitory or library. These teachers proposed to add the Moodle network teaching system to the course, which has many benefits in cultivating students' ability to acquire knowledge, analyze, and solve problems. The Moodle network teaching system has been actively introduced into school education, organically combined with and complementing the advantages of traditional classroom teaching, which is the so-called blended teaching. In the blended teaching, the Moodle network teaching system can give full play to not only its own advantages in classroom teaching, but also the advantages of traditional teaching, such as the efficient and centralized classroom teaching, the leading role of teachers, and the main role of students [11–16]. There are many open source teaching systems. Most of the teaching systems are integrated by CMS and components to form a community-based teaching system. Among them, the Moodle network teaching system based on open source is particularly extensively researched. Foreign research on teaching systems has gone deep into the combination of teaching mode and teaching system, how to integrate the system structure with the teaching mode, etc. Therefore, there are many secondary development

technologies based on the Moodle system, through the integration of different plug-ins and modules, and addition and subtraction of functions to fit different teaching modes.

3. Related Theories and Technical Methods

3.1. Blended Teaching. Many scholars at home and abroad have different emphasis on the definition of the concept of blended teaching, and so far there is no more unified concept. Blended teaching can be divided into broad and narrow senses. In the broad sense, blended teaching includes teaching modes, teaching media, teaching resources, teaching theories, teaching methods, teaching evaluation, teaching space, teaching time, and other mixed senses. Blended teaching refers to a mix of offline and online teaching. In addition, because blended teaching and blended teaching are the most similar expressions, some scholars directly equate the concept of blended teaching with blended teaching. However, blended teaching and blended teaching are significantly different in focus and starting point. Blended teaching focuses on the main body of teaching—learning. Black believes that blended teaching combines face-to-face teaching and network-based teaching and then creates a teaching environment conducive to student teaching. Blended teaching starts from the dominant position of teachers and focuses on how to help students achieve optimal teaching results. Jennifer Hofmann proposed that blended teaching will use a concept as the basis. According to the characteristics of the teaching process, teachers can divide it into several stages. Professor G. Black defines "blended teaching" as a teaching form that combines the advantages of traditional teaching methods with the advantages of digital teaching or network teaching. Through the definition of blended teaching and the distinction between blended teaching and the concept of blended teaching, this study believes that blended teaching can be defined as a combination of traditional teaching methods and online teaching methods, giving full play to the role of teachers and students. The advantages of online and offline teaching methods are applied to teaching methods in blended teaching [17].

3.2. Moodle System

3.2.1. Moodle System Architecture. The Moodle system should have the following characteristics: it can run on a variety of systems; it is easy to install, learn, modify, upgrade, expand, integrate, etc. The architecture of the Moodle system is shown in Figure 1.

3.2.2. Moodle Business Logic Layer. As a perfect application of B/S mode, Moodle system should have a perfect business logic layer design, and some analysis of the core business logic in Moodle system is carried out here. In a general system, the first thing to pay attention to is the principle of authority allocation, so the judgment of authority is a core business logic in the Moodle system. The judgment of permissions in the Moodle system is done through a

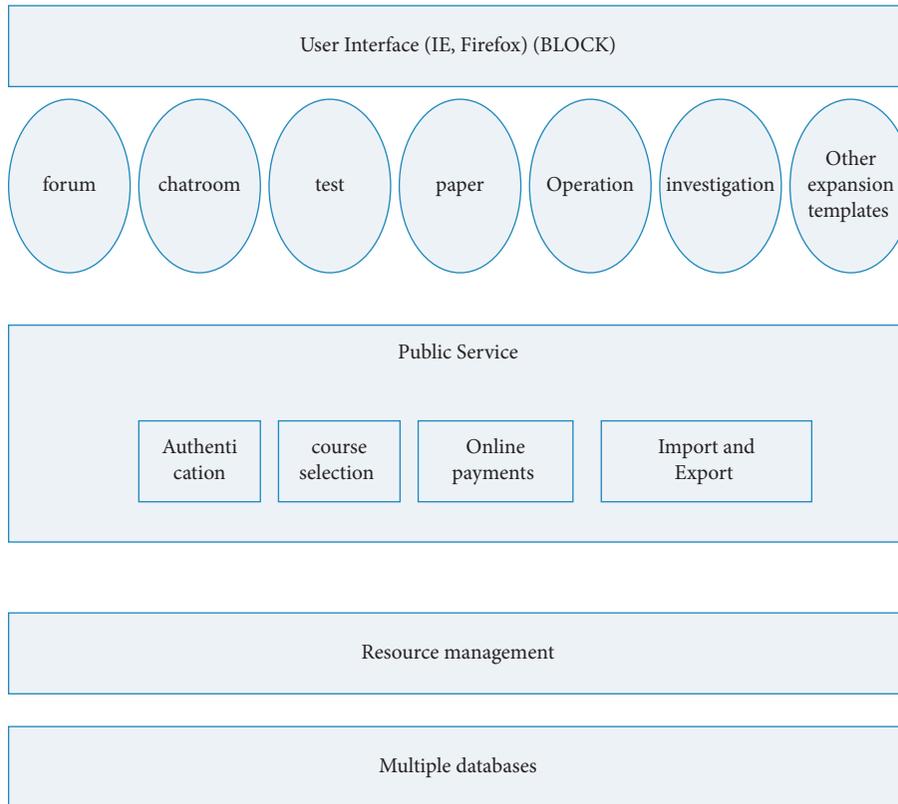

FIGURE 1: Moodle system architecture.

permission judgment function. In this function, the relevant permissions are judged through the acquisition of the context environment, and the code is shown as follows: [18].

```
$context = get_context_           instance
(CONTEXT_SYSTEM);
require_capability ('moodle/site:config',$ context);
```

For an application, in addition to permissions, it also uses a security code to maintain the security of the application environment. It uses “if(!empty (\$delete) and confirm_sesskey ()){}” to determine whether the logged in user is normal.

“print_error (‘ courserequestdisabled ’);” is generally used to terminate the execution. Once an error occurs, the system will stop executing the remaining statements, and its function is similar to the exit statement.

3.3. Key Technologies of Secondary Development Based on Moodle System. This research aims to design and implement an English network teaching system based on Moodle. The system is aimed at college students who have preliminary teaching ability. In the process of systematic education, they have formed dependence on traditional education methods, and they have initially connected to and used the system. To implement teaching, we set up the English network teaching system on the Internet, based on the very popular B/S structure today, so that it can be promoted on a large scale and reduce the entry threshold. Because the secondary development of some modules is carried out on the basis of

the original system, the system foundation should be the same. Although there are many systems that Moodle can set up, we chose the simple and cheap LAMP system: Linux, Apache, MySQL, and PHP. The four open source software components constitute the LAMP system that we are familiar with, and this basic development system is also a core key technology for secondary development. Using the object-oriented method in software engineering in the development process can make the system have the advantages of easy maintenance, high quality, high efficiency, and easy expansion.

3.3.1. Three-Tier B/S Architecture. B/S architecture is the structure of browser plus server, where B is the browser and S is the server. It is a supplement and improvement to the C/S structure. The biggest difference between it and the C/S structure is that the B/S structure does not need to install the client. The client’s request will be sent through the browser, and the web server will receive the request after corresponding data processing is performed. During this period, the web server will also exchange data with the background server. Finally, the web server will send the processed data results back to the browser. In this structure, all the user interface is implemented through the browser, only a relatively small amount of transaction logic will be implemented in the front section, and most of the transaction logic will be implemented in the server side, which is the so-called three-tier structure. [19–21].

In the B/S three-tier structure system, because the server processes and implements almost all transaction logic, it has

the advantages of easy maintenance and upgrade. The software of the B/S architecture only needs to manage the server. No matter what modifications are made to the system, they can be modified at one point on the server side. The browser is just a tool for presenting the results of things. In this case, the usability of the system is further improved. However, because of this feature, the B/S architecture has some inevitable disadvantages. With the continuous upgrading of software and the continuous increase in the amount of information, the server will become more and more bloated, and the load on the server will also increase. It will become heavier and heavier, which is also a major test for the server on the server side and also increases the burden on the background maintenance personnel. However, with the development of science and technology, hardware devices are becoming more and more powerful, their processing capabilities are getting better and better, and most units using this architecture also have database storage servers for separate data backup, so B/S architecture is used. The construction and promotion of software are also an inevitable trend.

3.3.2. *Ubuntu*. In the design and implementation of the English online teaching system, the Linux system we use is Ubuntu. Although the Moodle system documentation recommends Unix as the best operating system, most of the Unix systems are not free. At the same time, the architecture of WAMP under the Windows system will be prone to instability, the system is overburdened, and the memory allocation is not enough, in addition to other various problems, which will eventually lead to system crashes. The operating system that is widely used in small companies has high stability, fast connection speed, and reasonable content distribution. Therefore, in the initial construction, considering the purpose of system stability and cost saving, the GNU/GPL-compliant Ubuntu was selected as the operating system.

3.3.3. *Apache2*. Apache is the abbreviation of Apache HTTP Server. It is one of the most popular web servers in the world. It is an open source software project belonging to the Apache Software Foundation. Apache has an absolute advantage over all kinds of existing web server software, far ahead of the second-place Microsoft IIS. Apache has various characteristics such as simplicity, fast speed, and stable performance, and it can run on almost all operating systems. The installation and configuration process of Apache is also very simple, and it is also very suitable for new developers. Its installation methods can be simply divided into two types: source code installation and binary package installation. These two installation methods have their own characteristics and are suitable for different user options. Since the Ubuntu system is used as the basic system in this study, we use the binary package installation method to install it. Just execute the following command in the terminal to automatically complete all the download and installation process: `sudo apt-get install apache2`. After the installation is complete, Apache2 will start automatically. If necessary, you can

stop it by executing the command “`sudo/etc/init.d/Apache2 stop`” in the terminal; finally enter the command “`sudo/etc/init.d/apache2 start`”; and then start the Apache service once. There is an “`apache2.conf`” file in the “`etc/Apache2`” directory; we can modify Apache2 by modifying it. For example, modifying the “`ports.conf`” file can redirect the port and redirect the default port 80 to other nonconflicting ports, so that multiple sites can be established on one server, which is convenient for unified management. Under normal circumstances, the files that Apache2 will publish will be located in the “`var/www`” directory, which is the default value of Apache2. We can also modify the document root in the main configuration file to complete the redirection.

4. Design of a Hybrid English Teaching System Based on In-Depth Multi-intelligence

4.1. *Development Tools and Environment*. The English network teaching system is developed on the basis of the Moodle system. Therefore, the first step in the realization of the English network teaching system is to construct the operating environment and development environment of the whole system. Although PHP can be run without editing, the requirements for development software are not high. It can be developed using general web page editing software or even simple text editors such as Notepad. To improve the development speed and the accuracy of code writing, select PDT (Eclipse PHP development tools) as the preferred development environment. Eclipse can be used in several mainstream operating systems such as Windows, Linux, and macOS. It also belongs to an open source development system, so there is no need to pay extra fees to use it for program development. Although Eclipse is mainly developed for Java, among the many plug-ins of Eclipse, there are two specially developed for PHP. These customized plug-ins are Eclipse foundation and PHPEclipse, which are also open source software. After installing PDT in the large open source environment of LAMP, the corresponding PHP development can be carried out. At the same time, the official website of the Moodle system, which is also open source software, also recommends Eclipse in its development software, because its use is completely free without any additional development costs. After completing the installation of the operating system, you only need to enter the following command in the terminal of Ubuntu: `sudo apt-get install Apache2 mysql-server-5.1 mysql-client-5.1 php5 libapache2-mod-php5phpmyadmin`. You can set some accounts and other information during the installation process according to the prompts. When the LAMP environment is installed, it can be installed using Eclipse downloaded from the Eclipse official website. After everything is completed, the basic development environment construction of the English online teaching system is completed.

4.2. *Implementation of System Database*. There are many choices of databases, but due to the cost and the choice of the system construction environment made before, we choose MySQL as the database of the whole system. In the whole system, MySQL, as the underlying data support, can store all

user information, system parameters, login information, etc., to ensure that the system program can call data quickly and effectively. Code 1 of the student information database table establishment part is as follows:

4.3. Main Function Module Code and Implementation

4.3.1. Flowchart of the Overall Function of the System.

The overall function flowchart of the system describes the general function realization process of the entire English network teaching system, which is particularly important for the entire English network teaching system. The identification of the user's identity and the subsequent behavior process are included in the overall function flowchart of the entire system, and the responses that should be made to operations in general are also included in the overall system function flowchart, as shown in Figure 2.

The overall function variables of the entire system can be set in the "config.php" file, and the different user-level key variables involved in the system can be set by controlling the same file and then detailed through the corresponding files. The source code of the "config.php" file is as follows:

4.3.2. Implementation of System Common Modules.

There are many public modules in the English online teaching system, such as the login module and logout module. In these public modules, the corresponding process needs to be managed. We will take the login module as an example to understand how to realize it in the public module. In the login module, it is necessary to first judge the user's access situation and limit the user's login time. For example, within the valid time limit, you can log in by reading the session file to enter the account and password; otherwise, go back to the main login page to verify the user's account and password, which can ensure that the user does not need to repeatedly perform identity verification during the use process, and can also perform the role of identity confidentiality to a certain extent. After the user completes the identity verification, it will immediately return to the user's personal page. The interface is shown in Figure 3.

4.3.3. *Course Content Management.* In the English network teaching system, the course management should have a certain mode, which can enable all teachers to manage the course without special training. Course management must ensure the basic management functions while making the entire management process simple and easy to operate. For example, the basic adding and editing functions should be similar to or the same as Word document operations, so that teachers can adapt to the course content management functions faster. In the course content management page, the teaching content can also be classified and managed for the teaching of different skills in English listening, speaking, reading, writing, and translation. There are courses such as short reading comprehension and long reading, as well as composition training courses specially designed to exercise writing ability. Figure 4 is the interface diagram of the course management function.

In the course management function of the Moodle system itself, there is no function to time and manage the user's online time. In this study, related functions have been added for the first-years who have just entered the university. Since PHP is a scripting language, it will not be used in the long term. There are many problems in executing certain statements at the same time. Therefore, there is no perfect solution for using PHP to determine the user's online time. This study uses the method of inserting the user's exit time into the database and comparing it with the recorded user's login time. In order to improve the accurate timing online, the function of online timing is realized by formulating a program on the system server.

4.3.4. *User Management.* The user management function mainly exists for the unified management of all users in the English online teaching system by the administrator. Therefore, the following functions must be included in the user management function. First, there should be an individual user information management function. Each user in the English online teaching system can be managed individually with functions such as information, permissions, classes, and groups, followed by the batch user management function. The administrator should be able to manage a large number of users. Figure 5 shows the main interface of the user management function.

4.3.5. *Job Management.* In the English network teaching system, students' homework is submitted by uploading personal homework content or files. In the English online teaching system, students are the individual main unit, but students are put together to form a class, and the final homework will be stored in the database in a class as a unit. Students and teachers can log in to the English online teaching system for homework viewing, correction, etc. For example, students plan to get writing ability training after completing the corresponding course teaching. Students can click on the corresponding writing ability training course to enter the homework content. At that time, they can check and operate the homework they have completed again, such as downloading the voice for listening correction and so on. They can also view the specific content and requirements of the writing ability training they selected before, and after completion, they can upload the operation to complete the assignment submission. And they can view all their own homework in the student homework management process, in addition to performing download, upload, and other operations. Figure 6 shows the job management interface.

5. System Test

5.1. *Interface Test.* The interface plays the role of directly interacting with the user, and the user's first impression of the software basically depends on the interface. At the same time, whether the design of the interface is good also affects the user's ease of use of the software. The interface can help and guide the user to a certain extent. In the interface test, various windows existing in the interface should be tested. We conduct

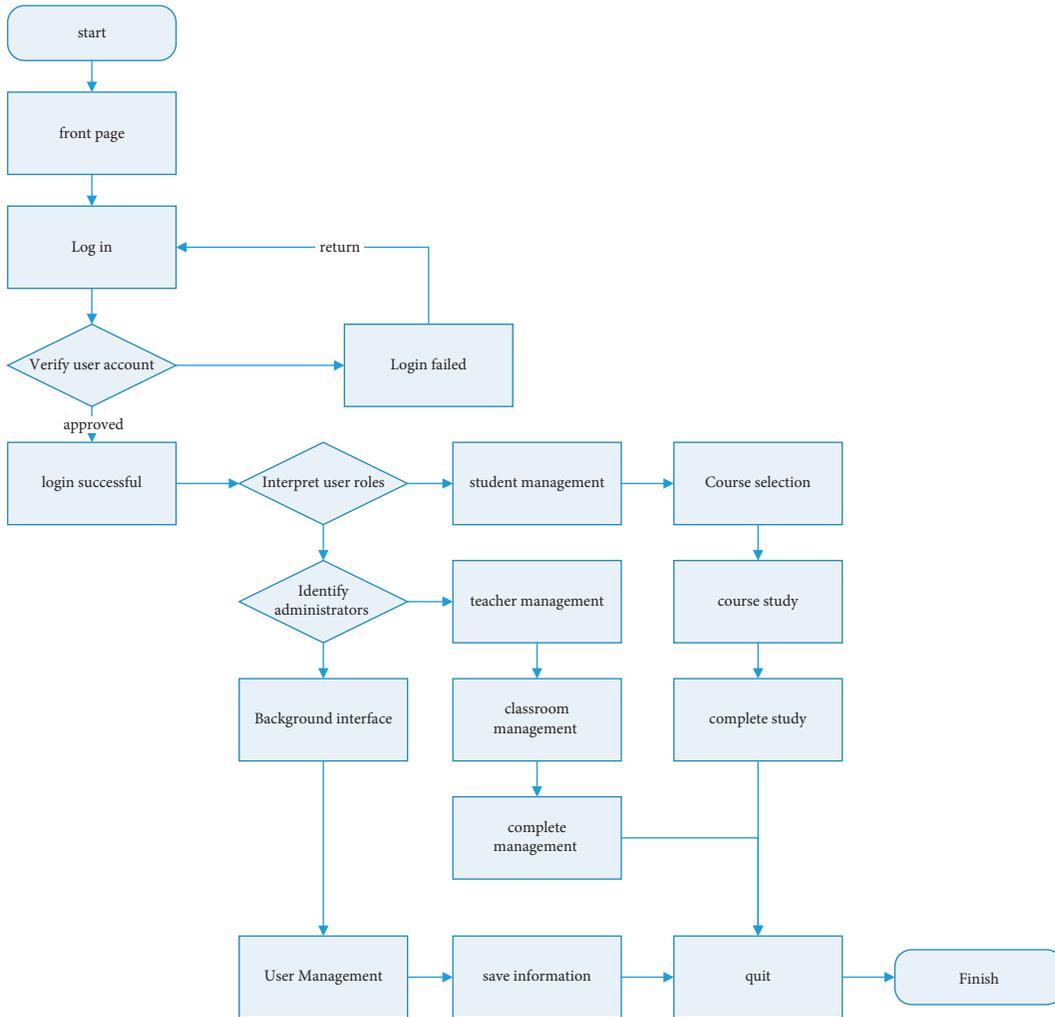

FIGURE 2: The overall function flowchart of the system.

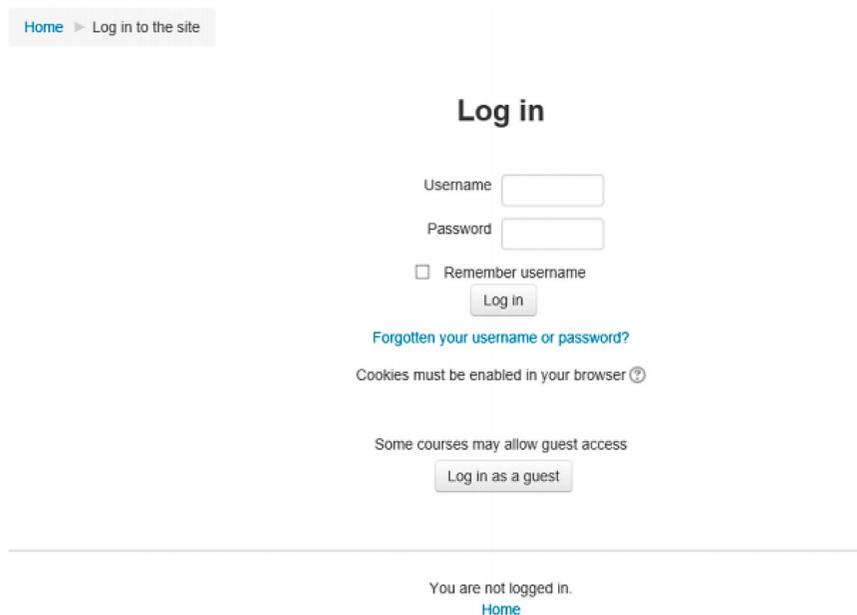

FIGURE 3: User login main interface.

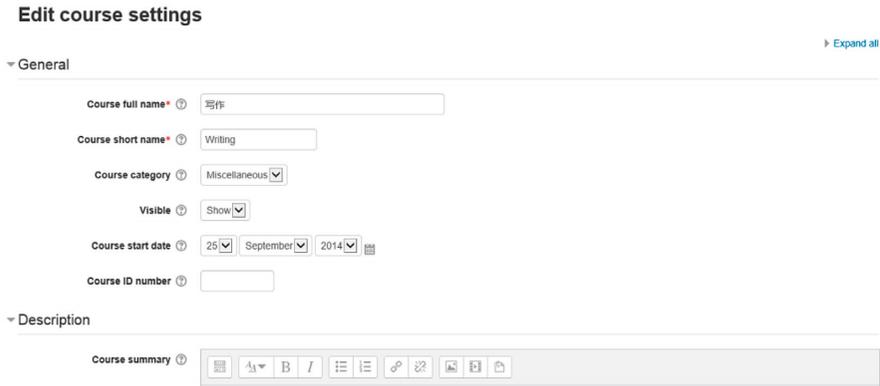

FIGURE 4: Course management function interface diagram.

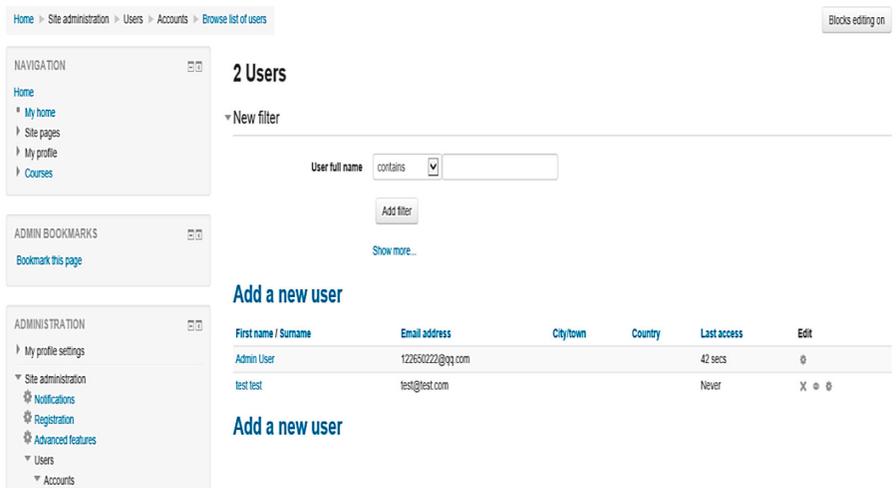

FIGURE 5: User management function diagram.

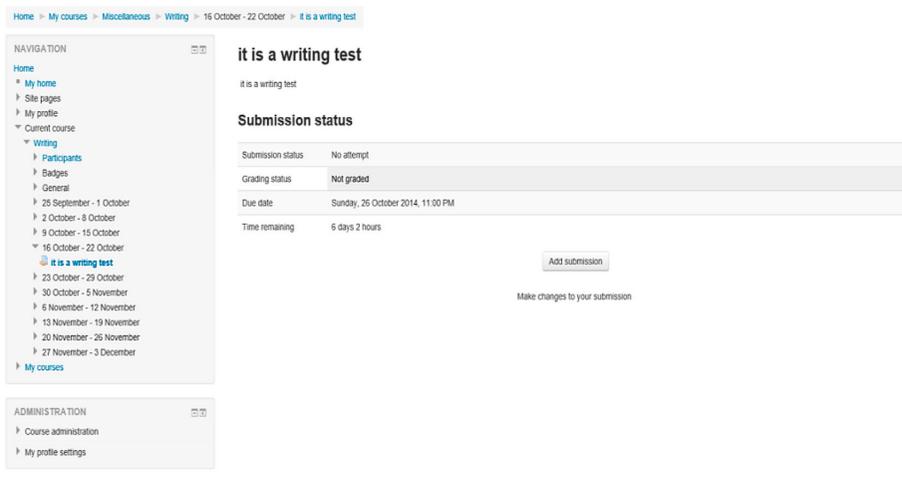

FIGURE 6: Job management interface.

individual tests to see if each UI meets the general usage expectations and whether the window objects and features conform to the standard. Because the English online teaching

system is mainly used in the environment of domestic universities, it is inevitable that there will be a lot of Chinese and English content mixed in the interface, so the encoding of

TABLE 1: Test proportion distribution.

	Distributed type				Total
	Interface testing	Function testing	Security testing	Performance testing	
System test content	12	34	4	7	57
The proportion (%)	22	57	7	13	100

Chinese and English is particularly important. Errors will lead to garbled characters. At the same time, the typesetting methods of Chinese and English are different. If the same method is used for typesetting, this can easily cause irregularities in the interface, which will affect the cleanliness and beauty of the interface. Tests should also address both text encoding and typography.

5.2. Functional Testing. Functional testing can also be called black box testing. The testing method is to test the software according to the specifications and other documentation of the developed software. This testing method generally does not involve the working principle of the software content, so it is like a correct test for the tester. In functional testing, testers should observe the various output results of each function of the software from the perspective of ordinary users through various methods such as input and use, so as to discover the functional defects of the software.

5.3. Security Testing. The software responds to behaviors such as unauthorized user access or malicious damage by other users. In the security test, the testers use different identities of authorized users and non-authorized users to enforce different permission requirements of the system to test whether the permissions are normal and whether the data is normal.

5.4. Performance Test. The performance test is generally used to verify whether the performance of the software meets the requirements in the software demand environment and, at the same time, to confirm whether the repeated use can still meet the performance indicators. A total of 57 test cases were designed in this test, which involved interface testing, functional testing, security testing, and performance testing. The use case content distribution is shown in Table 1.

5.5. Analysis of Test Results

5.5.1. Interface Test Results. In addition to the necessary aesthetics, the interface of the English online teaching system should pay more attention to whether the function of the page is correct. All the functions of the software system based on the existence of the network rely on the existence of hyperlinks, so whether the hyperlinks are displayed correctly in the interface is particularly important, and each functional module should be expressed in a suitable size and clear way. The test results of this link are shown in Table 2.

5.5.2. Safety Test Results. After completing the basic functional test, corresponding security tests should be carried out for some common security vulnerabilities, including common functional modules that different user levels choose not to have, forced access to the corresponding content through the browser, and testing through the browser. The test results are shown in Table 3.

5.5.3. Performance Test Results. At the beginning of the design of the English network teaching system, it was hoped that it could be promoted on a large scale, so that more college students could enter the teaching mode of English teaching. Therefore, the system needs to handle a large number of users, and the performance should be tested in all aspects including concurrency and stability. User concurrency testing is the most important part of performance testing, including the process of load testing and stress testing. It mainly aims to gradually increase the number of users to increase the system burden until an unacceptable performance point or bottleneck occurs. Generally, it is necessary to test the concurrency of a normal number of users and the concurrency of users under a limit number.

Function: Users access the website from different regions at the same time to ensure that the website can be accessed normally.

Purpose: To test whether it is normal for 200 users to access the English online teaching system from different regions at the same time.

Method: Use the Apache bench test website that comes with the WAMP environment to access the website concurrently, test the usual time and bandwidth required for the visit, and analyze the website operation through the test data. The concurrent test results are as follows in Table 4:

Server performance testing is an important part of testing, including the process of load testing and stress testing. Mainly by simulating multiple users to use the system at the same time, until the system has insufficient performance or bottleneck, generally test the normal use and extreme use.

Function: Users use various functions to ensure normal functions.

Purpose: To test the ability of 200 users to simultaneously access the entire English online teaching system from different regions.

Is there a normal page?

TABLE 2: Interface test results.

Serial number	Test function	Testing method	Test results
1	Home navigation location	Client browser browsing	Normal
2	Interface function location	Browser	Correct
3	Content layout of the navigation bar	Browser	Correct
4	Interface text display	Browser	Normal
5	Interface being garbled	Browser	None
6	Interface text size	Browser	Normal
7	Interface text position	Browser	Normal
8	Hyperlink display method	Browser	Correct
9	Page layout	Browser	Normal
10	Browser compatibility	Browser	Normal

TABLE 3: Safety test results.

Serial number	Test function	Testing method	Test results
1	Wrong choice function	Selecting high-privilege user functions with low-level privilege users	This feature is not available
2	Forcing entry to content via URL	Directly entering the permission in the browser address bar without the content RUL address	Prompt for login information
3	Injection vulnerability	Using common injection vulnerabilities to gain advanced privileges	Cannot be injected

TABLE 4: Concurrency test results.

Number of concurrent clients	10	50	100	200
Average response time (s)	0.037	0.863	2.152	5.741
Denial of service rate (%)	0	0	1.3	2.9

TABLE 5: Server performance test results.

Number of concurrent clients	10	200	500	1000
Network utilization (%)	5	18	37	54
Average memory usage (%)	21	27	34	39
CPU usage (%)	7	15	39	57

Method: Use anychat to conduct high concurrent access to the website, test the CPU occupancy rate and memory occupancy rate of the server during the visit, and analyze the operation of the website through the test data. The concurrency test results are shown in Table 5.

6. Conclusion

Information-based teaching methods are developing through the efforts of a large number of educational practitioners, and the development and use of networked teaching systems are also an inevitable trend. For university teachers and students, the Internet has always been around, and the teaching classroom has also become an online classroom. The cramming method of knowledge instillation has gradually become rationalized, and it has become a teaching method in which students completely master the teaching subject. The English network teaching system is the connecting link in this key reform, and it is also the technical key for all ideas to become reality. The Moodle-based English

online teaching system has finally realized the core functions of English online teaching, such as user login, teaching timing, course content management, user management, and homework management. From the operation situation and the feedback information of students, we can know that English online teaching is very suitable for today's college students. This teaching method effectively liberates students' teaching time and improves students' learning.

The English online teaching system is based on the secondary development of the Moodle system. Therefore, there are still many deficiencies in the localization customization of the Moodle system and the software compatibility of secondary development. In the future, we will continue to further develop the software and improve the English network teaching system, so as to improve the quality of the entire software teaching.

3D model retrieval is increasingly becoming a hot topic in today's research. The existing model retrieval methods are limited to the retrieval between similar models, while the matching retrieval for models with assembly relationships is neglected. They cannot realize the prediction of the virtual assembly and make the assemblers to spend extensive time detecting when there are assembly errors in the model. This work proposes a 3D assembly model retrieval method for multiassembly interface, which can retrieve the parts or subassemblies that can be assembled with the input model. In this work, a method for the reuse of the 3D assembly mode is also provided. The method here involves a series of steps, which includes an attribute adjacency graph to express the 3D assembly models, followed by the definition of a conjugated subgraph, and the serialization of the vertices of the graph for the Atlas of the assembly model. Finally, the frequent subgraph mining method is improved, and the 3D assembly model that satisfies the multiassembly interface is extracted. The article claims through the obtained results that this method not only allows the performance of the 3D assembly model retrieval of multiassembly interfaces but also the extraction of the 3D model required by designers, improving, at the same time, the product design efficiency.

1. Introduction

In today's digital design and manufacturing, most manufacturing enterprises modify existing products in the actual production process, and products designed from scratch almost do not exist [1–3]. The reuse of this model is particularly important. Especially in the aerospace, automotive, shipbuilding, and other fields produced more and more three-dimensional CAD models, and product design is based on the existing model above modification. The existing 3D model retrieval is more focused on the retrieval of parts themselves, and the technology is relatively mature, but in the practical application of enterprises, 3D CAD model mainly exists in the form of assembly, especially in manufacturing enterprises to achieve automatic workshop. This makes part model retrieval that cannot meet the actual needs of industry [4].

At present, the existing 3D model retrieval technology is based on model similarity retrieval. Firstly, the characteristic information of the model itself is marked, and then, the

similarity retrieval is carried out in the model library. This method does not consider the topology structure of the assembly model, assembly connection, and other information, leading to the difficulty in the development of 3D model retrieval method. Although the intelligent retrieval of models can realize the retrieval of similar parts among models, it cannot realize the retrieval of models with matching relationship. In actual enterprise manufacturing, model retrieval is not limited to the retrieval between similar parts, but is more applied to the virtual assembly process of products. What users need is not the retrieval of a single similar model, but the matching model with the input model.

Most of the existing 3D model retrieval methods, such as 3D CAD model semantic retrieval based on sketch [5] and 3D model retrieval based on multilevel feature extraction [6], are based on assembly model granularity as the basis of reuse to retrieve the similarity of key semantic or geometric features. Most of these methods extract the features of 3D models, then compare the similarity based on the features, and finally achieve a purpose of retrieval.

In terms of part retrieval, Qin et al. [7] proposed a 3D CAD model retrieval approach that considers the speed, accuracy, and ease of use at the same time based on sketches and unsupervised learning. Hojooon and Lee [8] abstracted the features of the model as nodes and then calculated their similarity to finalize the retrieval. Zhou et al. [9] completed 3D model retrieval based on 2D image features. Li et al. [10] proposed a multiview diagram matching method for 3D model retrieval, which aimed at breaking down and integrating the complex multiview diagram similarity degree measurement into several single view diagram similarity degree measurement. Mcwherter et al. [11] carried out 3D model retrieval based on invariant topological vector (ITV) and composed vector by multiple topological invariants in entity connection graph as feature descriptor of entity model. The effectiveness of invariant topological vector in 3D model retrieval is verified by comparing with many feature descriptors. Bspalov et al. [12] proposed a model retrieval method based on scale-space decomposition in view of the difficulty in local feature extraction and matching of 3D models. Based on parametric decomposition, the network of 3D model is decomposed into several local engineering surfaces. Then, according to the correlation features between local surfaces, a binary tree containing the correlation features is constructed, and the adjacency graph of feature attributes is established. Finally, the similarity between 3D models is calculated based on the attribute adjacency graph. McWherter et al. [13, 14] proposed a 3D model retrieval method based on attribute adjacency graph, in which the vertices of attribute adjacency graph represent different faces of 3D model, and adjacent faces are connected by edges. Edges represent surface properties such as size and concavity. The attribute adjacency graph of the 3D model is shown in the figure below.

In terms of assembly retrieval, Dong and Xu [15] endowed the surface of assembly parts with the double attributes of function and structure and divided the surface into functional and nonfunctional surfaces so that it can account for the similarity of the part's shape and functional properties. Zhang et al. [16] used the similarity of 3D assembly model attributes to propose a method of discovering common design units to find reusable information in the model. Zhou et al. [17] analyzed the similarity of the local structure of the assembly on the basis of the subgraph isomorphism and matching of the items and provided a theoretical basis for the retrieval of the 3D assembly model. Wang et al. [18] used random walk and optimal matching theories to analyze the topological relations and comparative attribute characteristics of each part so that it can obtain the similarity of the assembly as a whole. Wu and Gao [19] proposed a 3D assembly model retrieval method based on the similarity of spatial structure, where the similarity of the assembly can be obtained by the attribute feature similarity of the product model and the similarity of the part's spatial position. Qiao et al. [20] proposed a single assembly interface 3D assembly model of information retrieval method, first using the preliminary model information retrieval, and then filtered according to the result of retrieval; assembly model geometry retrieval can be converted to look for problems with the attribute

adjacency graph, finally using frequent subgraph mining algorithm with conjugate subgraph attribute adjacency graph search. In this paper, a three-dimensional assembly model with multiple assembly interfaces is studied.

However, the retrieval target models of these methods are similar to the input models and do not consider the retrieval of part or subassemblies that can be assembled with the input model. By contrast, the 3D assembly model is connected through the geometric interface between the parts. The geometric interface can be a single connection or be connected through multiple interfaces, which increase the difficulty for the 3D assembly model retrieval.

Considering the above problems, we take a multiassembly interface 3D assembly model as the object and study the 3D assembly model retrieval method. First, this method uses the attribute adjacency graph to express the graph of the 3D assembly model and builds the Atlas of the assembly model to establish the Atlas library. This method introduces the conjugated concept to define the conjugated subgraph between assembly parts. Then, the vertices of the graph are serialized for the Atlas of the assembly model, and the traversal times during the vertex matching process are reduced. On this basis, model retrieval is performed through the attribute adjacency graphs of parts, and it uses an improved frequent subgraph mining method to extract a 3D assembly model that satisfies multiple assembly interfaces. This article proposes a 3D assembly model retrieval method for the multiassembly interface, which can retrieve the parts or subassemblies that can be assembled with the input model, and it provides a method for the reuse of the 3D assembly model.

2. Materials and Methods

2.1. Representation of the 3D Assembly Model Based on Attribute Adjacency Graph and Definition of Conjugate Subgraph. There are many ways to represent the CAD model. Among them, the B-Rep model can easily obtain the geometric element information, topological relations, and attribute information of the model, so it is used by most commercial CAD systems. In the process of 3D model retrieval, the similarity degree of B-Rep model information needs to be compared, and how to express this information becomes the primary problem. The B-Rep can describe the modelled object more accurately. The B-Rep model not only describes the geometric information of all the geometric elements that constitute the modelling object but also describes the topological information of the object in detail. The topology information of a target object refers to the connections among all vertices, edges, and faces on the target. It can effectively improve the level of automation in the modelling process.

Attributed adjacency graph (AAG) [18] can express the geometric element information, topological relations, and attribute information of the model, and it is widely used.

2.1.1. Method for the Representation 3D Assembly Model Based on AAG. A 3D assembly model contains the relationship between parts, and its essence is a collection of information.

The points, lines, and surfaces contained in the part and the topological relationship between parts can be effectively expressed by the AAG's nodes and their attributes and edges. The AAG of CAD model is represented by $G(V, E, \alpha(V), \beta(E))$:

- (1) (V, E) is an undirected simple graph (without loops or heavy edges), V is the vertex set in the corresponding figure of the part, and $V = \{v_1, v_2, \dots, v_i\}$, V_i represents the i th face of the part.
- (2) E is the edge set in the corresponding figure of the part, and $E = \{e_1, e_2, \dots, e_j\}$, E_j is the edge connecting the vertices v_a and v_b .
- (3) $\alpha(V)$ represents the attribute set of the model's vertex and is used to represent the properties of the model surface, including the geometric information of the model surface and the number of edges of the surface;
- (4) $\beta(E)$ represents the attribute set of the model's edge, including the type of edge, information on the concavity and convexity, and the positional relationship between the faces of the model. This study focuses on 3D assembly retrieval, focusing on the concavity and convexity of the side.

The cooperation relationship between the 3D assembly model parts can be converted into a certain attribute relationship between AAGs of part. A certain attribute relationship refers to the connection relationship and the type of contact surface between parts. The 3D assembly model can be represented by AAG's Atlas, expressed as $A = \{G, S, P\}$,

- (1) $G = \{G_1, G_2, G_3, \dots, G_i\}$ represents the AAG set of the assembly model part, and G_i represents the AAG of the i th part.
- (2) $S = \{S_1, S_2, S_3, \dots, S_m\}$ represents the set of part's connection type. The connection type can be divided into three categories, including threaded connection (screw connection, stud connection, nut connection, and special thread connection), keyway connection (round head flat key connection, flat head flat key connection, semicircular key connection, wedge key connection, and tangential key connection), and shaft hole connection (interference fit, clearance fit, and transition fit). m is the number of connections.
- (3) $P = \{P_1, P_2, P_3, \dots, P_n\}$ represents the set of a part's contact surface types. The contact surface types are plane and plane constraints (parallel on both sides, angled on both sides), plane and surface constraints (plane and cylinder tangent, and plane and sphere tangent), and surface and surface constraints, and coaxial constraints. n is the number of contact surfaces.

According to the above method of representation, an Atlas library of a 3D assembly model can be constructed. The Atlas contains the AAG of the part, the connection between the parts, and the type of contact surface between the parts. Different atlases have different attribute tags. When it retrieves a 3D assembly model, the computer can find the

corresponding Atlas from the Atlas library according to the attribute tag.

2.1.2. Definition of Conjugated Subgraph. The assembly parts are connected by a geometric interface, and the conjugated relationship exists in the matching part of the geometric interface. That is, the topological connection of the mating parts is the same, but the concavity and convexity are opposite [21]. Therefore, through the AAG of the part, the 3D assembly model search can be transformed to find the AAG that satisfies the conjugate subgraph, to find the parts or subassemblies that can be assembled with the input model.

Definition 1. Conjugated subgraph: for the two AAGs to which the matching parts (assembly features) of the assembly parts correspond, their topological connection forms are the same, but their concavity and convexity are opposite, and they are called a conjugate subgraph. The conjugate subgraph features of assembly parts include the following: (1) the structure of the conjugate subgraph is the same; (2) the conjugate subgraph corresponds to the same vertex properties, the matching face has the opposite of the loss vector, and the matching area and radius of curvature are the same (nonessential conditions); and (3) the edge properties that the conjugate subgraph correspond to are the opposite.

For 3D assembly model retrieval of multiassembly interface, the input model has the features of multiple geometric interfaces, and its corresponding output model should also have multiple conjugate interfaces. As shown in Figure 1, the input model has two geometric interfaces, and the subassemblies that can be assembled with the input model also have two corresponding conjugate interfaces. The portion marked with a red circle in the figure is a conjugated subgraph with a matching relationship. They have the same topological structure, but the concavity and convexity are opposite.

2.2. Serialization of AAG. The model retrieval is based on AAG, which needs to perform judgment of subgraph isomorphism, and the definition of graph isomorphism and subgraph isomorphism are as follows:

Definition 2. Graph isomorphism: there are two graphs, $G_i = (V_i, E_i)$ and $G_j = (V_j, E_j)$. If there is a mapping relationship between them, $f: V_i \rightarrow V_j$, and $e_i = (v_i, v'_i)$ is one edge in G_i . If and only if $e_j = (v_j, v'_j)$ is an edge of G_j , then G_i and G_j are isomorphic.

Definition 3. Subgraph isomorphism: for a given symbol graph G_i and G_j , if there is a G'_j , then it is the subgraph of G_j and G'_j , and if G_i are isomorphic, then G_i and G_j have subgraph isomorphism.

Subgraph isomorphism is a typical NP problem, which requires repeated traversal of the vertices of the graph. However, the vertices of the graph are unordered, which leads to a very large amount of computation for isomorphism judgment. In addition, the 3D assembly model retrieval of multiassembly interface extracts atlases, from the

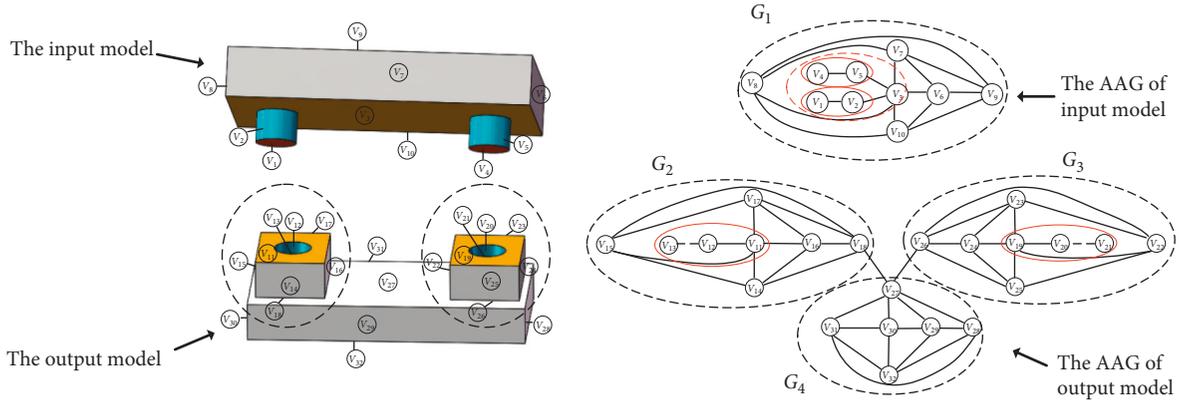

FIGURE 1: AAG of multiassembly interface.

Atlas library, that are similar to attribute information and topology of the input model. Then, it performs the judgment of isomorphism for each graph in the Atlas. There are multiple graphs in the Atlas, which also makes the calculation of graph isomorphism more difficult. Therefore, a method is needed to establish a unique sequence of vertices of graphs so that the judgment of graph isomorphism can reduce the amount of calculation.

Document [14] proposed that the sequence of the vertices of the AAG is determined according to the adjacency matrix M , and the adjacent vertices after serialization have adjacent edges in the graph. It defines the vector u as a sequence of vertex sets and satisfies

$$g(u) = \sum_{i=1}^{|V|-1} \sum_{k=1}^{|V|} (L(i, k) + L(i+1, k)) u_k^2, \quad (1)$$

where u_k is the k -th term of u and represents the sequence value of the k -th vertex of vertex set V . When u is the eigenvector corresponding to the largest eigenvalue of the adjacency matrix L , $g(u)$ can obtain the maximum value. In this study, after serializing vertices, the same type of vertices is guaranteed to have adjacent edges in the graph and satisfy the maximum aggregation of vertices of the same type. The specific steps of serialization are as follows:

The flow chart of the algorithm is shown in Figure 2.

Step 1. Define the linked list W . The starting point has the largest sequence value in the AAG, $W_0 = V_i$, $V_i = \max(u)$.

Step 2. Find W_{i-1} neighbors in AAG, $N_{W_{i-1}} = \{i | (W_0, V_i) \in E\}$.

Step 3. The i th point in the linked list W , $W_i = \{V_i | \max(u) \cap V \in N_{W_{i-1}}\}$.

Step 4. Get the serial number of the linked list W_i is $\max(u) - i$, and perform k -step iteration on the linked list and repeat step 2~step 3. The list length is $k + 1$.

Step 5. Judge $k + 1 = n$, n is the number of vertices of AAG, if equal, the algorithm ends and the output is serialized. If not, it goes to the next step.

Step 6. Find the complement of vertex sets $C = \{i | V_i \notin W \cap V_i \in V\}$, and order AAG's new vertex set $V=C$. Then, go to step 2.

After all vertices of the AAG are accessed, the sorting result of the output is shown in Figure 3. The assembly interface can be summarized as “planar-plane,” “square rib-groove,” “circular pin-hole,” “curved surface-curved surface,” “dovetail rib-groove,” and “square pin-hole” [20]. When these assembly interfaces are represented by AAG, the vertices of them always have the largest sequence value in AAG, and the vertices corresponding assembly interfaces are independent of other vertices. Therefore, the conjugate subgraph does not disappear owing to serialization.

The significance of serialization is to improve the computational efficiency of the algorithm. The 3D assembly model retrieval of multiassembly interface extracts atlases that are similar to the attribute information and topology relationship of input model from the Atlas library, and then, it performs a judgment of isomorphism on each graph in Atlas. There are multiple graphs in an Atlas, which increases the calculation of graph isomorphism judgment. This makes the entire algorithm more efficient.

2.3. 3D Assembly Model Retrieval Method. The output model of this paper's retrieval method is a part or the subassembly that can be assembled with the input model, and it has multiple geometric interfaces. The retrieval method needs to perform multiple isomorphism judgments of AAGs conforming to the conjugate subgraph; only when the conjugate subgraph of the target is greater than or equal to the input model, the corresponding Atlas can be selected, and then, the corresponding 3D assembly model can be extracted. On the basis of graph serialization, first, a method of efficient graph isomorphism judgment is used to judge the isomorphism of AAG that conforms to conjugate subgraph; then, on the basis of the method of graph isomorphism, the Atlas containing multiple conjugate subgraphs is selected by using the improved frequent subgraph mining algorithm so that the corresponding 3D assembly model is extracted. The overall algorithm flow is shown in Figure 4.

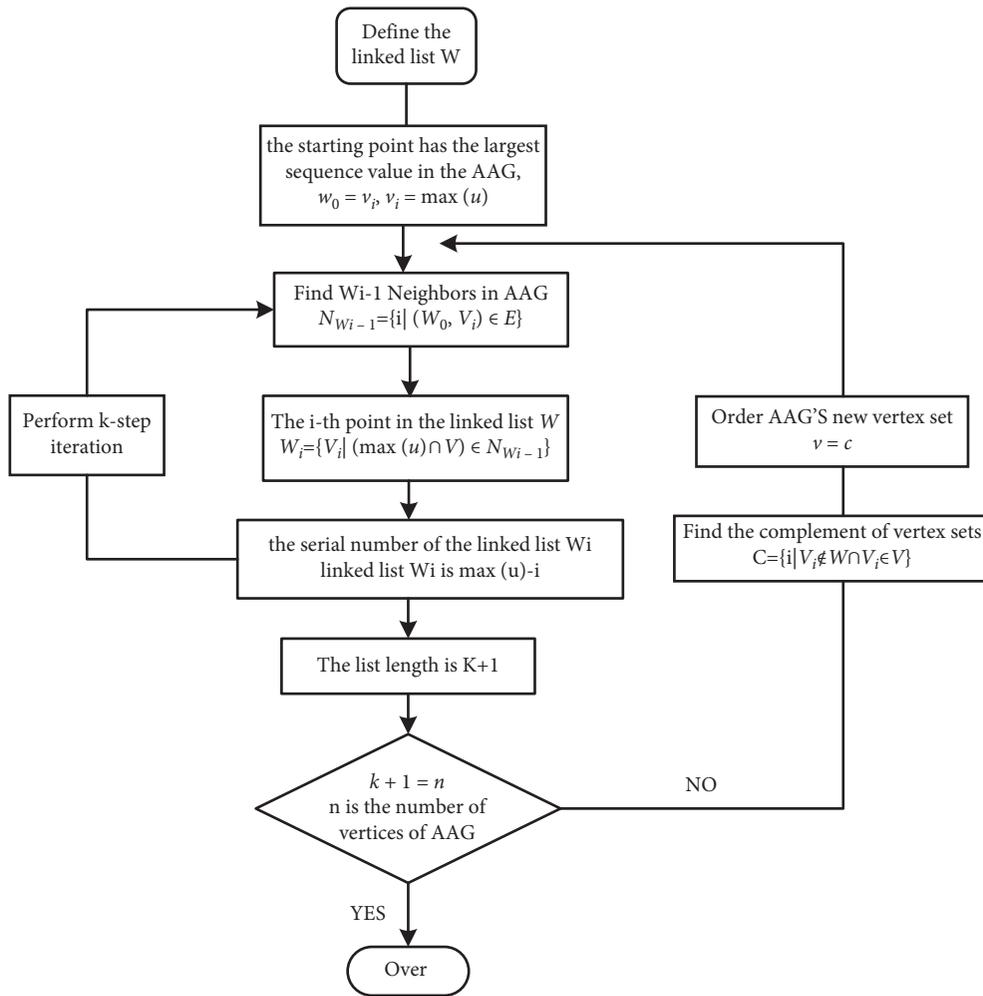

FIGURE 2: Serialization of AAG.

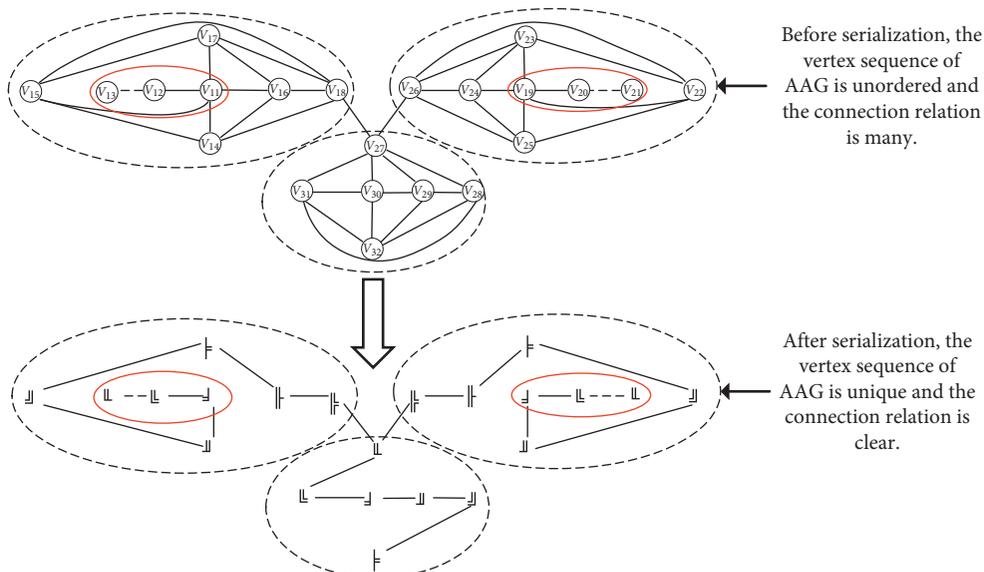

FIGURE 3: Result of AAG's serialization.

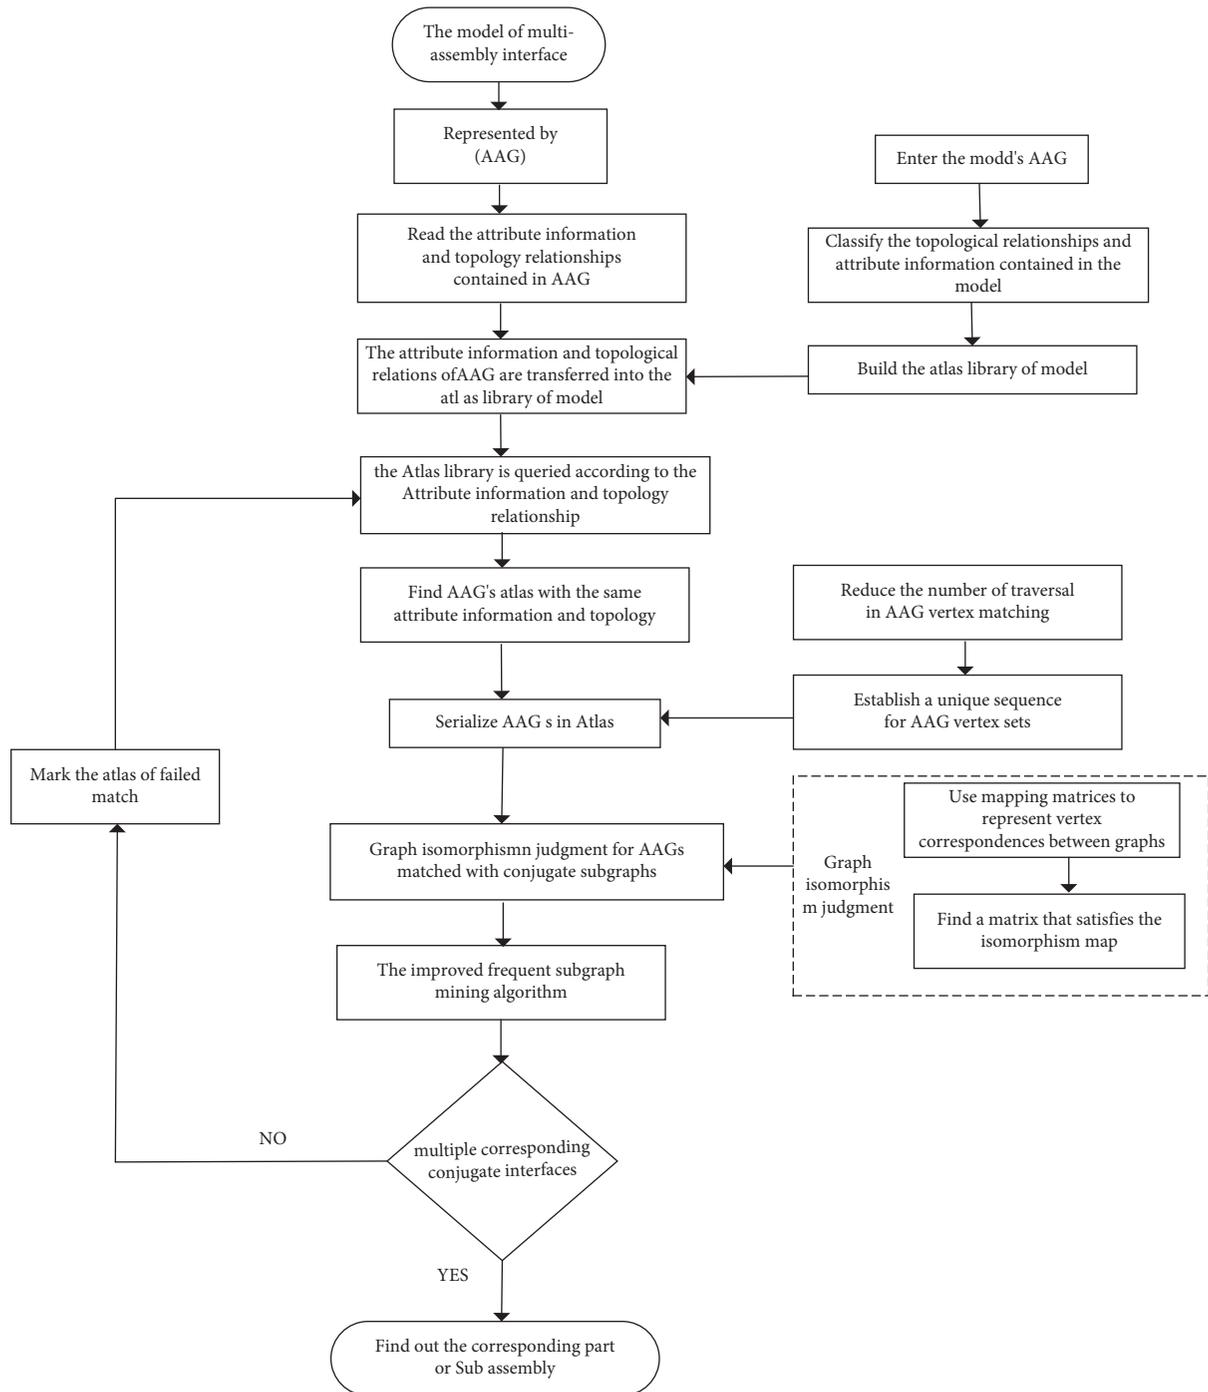

FIGURE 4: 3D assembly model retrieval method for multi-assembly interface.

2.3.1. Method of Judgment of Graph Isomorphism. The 3D assembly model retrieval method based on AAG transforms the similarity analysis of the assembly parts model into the similarity analysis of the AAG with the conjugate subgraph. The graph similarity judgment is accomplished using the graph isomorphism judgment to determine whether two graphs are isomorphic; that is, it assesses whether there is a mapping relationship between two graph vertices. The mapping relationship between two graph vertices can infer the mapping relationship between two graph edges.

The computational complexity of subgraph isomorphism determination is an NP-complete problem. In this study, an efficient graph isomorphism determination method is used. We assume that we have G_1 and G_2 , where G_1 is the target graph, and G_2 is the graph to be retrieved. The number of vertices of the vertex set V_1 of the graph G_1 is a , the number of vertices of the vertex set V_2 of the graph G_2 is b , and $a < b$. The mapping relationship of the vertices between the graphs G_1 and G_2 is represented by an $a \times b$ mapping matrix $M_{a \times b}$. m_{ij} is the i -row and j -column element in the mapping matrix M . If

V_1 and V_2 are related, then $m_{ij} = 1$; otherwise, $m_{ij} = 0$. For matrix $M_{a \times b}$, if there is a map with only one 1 per row and no more than one 1 per column, the matrix $M_{a \times b}$ represents the isomorphic mapping between G_1 and G_2 .

The steps of the graph isomorphism matching algorithm are as follows:

Step 1. Initialize the mapping matrix M and set two empty sets V_1 and V_2 . Use these sets to hold the vertices that have been matched by the two graphs during the retrieval.

Step 2. Retrieve from the first row of matrix M and look for columns with a value of 1 from left to right. For any i th row, if the value of the j th column is 1, and if the column is not occupied, it means that a possible vertex association is found.

Step 3. Add the two vertices of the previous step to sets V_1 and V_2 .

Step 4. Determine whether the newly added vertices in V_1 and V_2 correspond to the matching vertex pairs in the final isomorphism graph.

If the newly added vertices in V_1 and V_2 correspond to the matching vertex pairs in the final isomorphism graph, the subgraphs that are composed of the set of vertices V_1 matched in G_1 and the set of vertices V_2 matched in G_2 are isomorphic. Thus, it can be judged that the subgraph formed by V_1 and the subgraph formed by V_2 are isomorphic.

2.3.2. Improved Frequent Subgraph Mining Algorithm.

On the basis of the method of graph isomorphism matching, the frequent subgraph mining algorithm is improved. Frequent subgraph mining is actually a graph isomorphism matching process, which is used to judge the Atlas extracted from the Atlas library. From this, it can be concluded whether the Atlas contains conjugate subgraphs that conform to the features of the assembly interface, and the number of conjugate subgraphs can be determined. If the number of conjugate subgraphs in the graph set is greater than or equal to the number of geometric interfaces of the input model, then the corresponding 3D assembly model of the Atlas is extracted. Otherwise, the Atlas is marked as a failure.

The related definitions of frequent subgraph mining algorithms are as follows:

Definition 4. Frequency: there is a graph database $B = \{b_0, b_1, \dots, b_n\}$ for subgraph b such that

$$\phi(b, b_i) = \begin{cases} 1, & \text{if } b \text{ and the subgraph of } b_i \text{ are isomorphic} \\ 0, & \text{if } b \text{ and the subgraph of } b_i \text{ are not isomorphic} \end{cases},$$

$$S = \frac{\sum \phi(b, b_i)}{|B|}, \quad (2)$$

$|B|$ represents the base of Atlas B , $\sum \phi(b, b_i)$ represents the total number of isomorphism of b and b_i , $b_i \in B$, and S is the frequency.

TABLE 1: Symbolic meaning.

Symbol	Meaning
C^K	K -order candidate frequent subgraph sets
F^K	K -order frequent subgraph sets
F^F	All frequent subgraph sets, $FF = \{F^1, F^2, \dots, F^n\}$

Definition 5. Frequency subgraph: for a given minimum frequency S_{\min} , if there is a subgraph b that satisfies $S \geq S_{\min}$, then b is called a frequent subgraph of the Atlas database B .

The simple steps of the frequent subgraph mining algorithm are as follows:

- (1) Connect the K -order frequent subgraphs to generate $K+1$ candidate subgraphs;
- (2) Clip the candidate $K+1$ order subgraph Atlas, and delete all $K+1$ -order candidate subgraphs containing K -order infrequent subgraphs;
- (3) Calculate the frequency of all subgraphs in the $K+1$ -order candidate subgraph set;
- (4) Delete candidate subgraphs with frequencies less than S_{\min} in the $K+1$ -order candidate subgraphs.

By solving the loop from $k=0$ until it cannot generate higher-order frequent subgraphs, frequent subgraph mining is completed. Calculating the frequency of subgraphs is the process of graph isomorphism judgment. In extracting AAGs with conjugate subgraphs, the process needs to define some symbols to describe the algorithm. Table 1 lists some of these meanings.

The frequent subgraph Atlas generation algorithms are shown below. We start with Atlas B and frequency S_{\min} , and the output is the set F^K of the K -order frequent subgraph.

Frequent subgraph generation algorithm: (Algorithm 1)

Starting from $K=0$, the above algorithm is cyclically named, and the set of all frequent subgraphs is obtained as $FF = \{F^1, F^2, \dots, F^n\}$.

The algorithm is based on the K -order frequent subgraphs to build $K+1$ candidate subgraphs. The $K+1$ -order frequent subgraphs are obtained by using two K -order frequent subgraphs containing the same frequent subgraph of $K-1$ order. The two most important steps in this process are identifying two identical $K-1$ -order subgraphs and connecting two K -order frequent subgraphs.

The recognition of two identical $K-1$ -order subgraphs can record the IDs of all $K-1$ -order frequent subgraphs in the K -order frequent subgraph properties. The same $K-1$ -order frequent subgraph is obtained by the intersection of the two K -order frequent subgraph attribute values to avoid the judgment of subgraph isomorphism. The connection of two K -order frequent subgraphs can be seen as the process of generating the $(K+1) \times (K+1)$ adjacency matrix by combining two $(K \times K)$ adjacency matrices.

The importance of the retrieval method proposed in this paper lies in the following:

- (1) The retrieval of assembly information improves the semantic consistency of the model's retrieval results from the perspective of assembly design intent.
- (2) The search of the geometric structure adopts an efficient graph isomorphism decision method that is combined

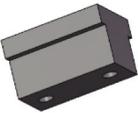

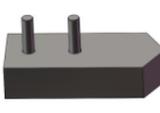

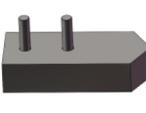

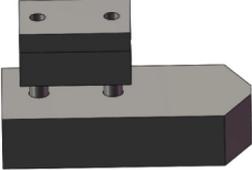

```

(1) Begin
(2)  $F^{k+1} \leftarrow \emptyset, C^{k+1} \leftarrow \text{Candidate}(F^k)$ //generate candidate subgraphs.
(3) For  $\forall b^{k+1} \in C^{k+1}$  do//candidate sets downsizing and frequent count.
(4) If  $\sigma(b^{k+1}) \geq S_{\min}$  then.
(5)  $F^{k+1} \leftarrow F^{k+1} \cup \{b^{k+1}\}$ 
(6) End if
(7) End for
(8) Return  $F^k$ 
(9) End

```

with frequent cartographic mining algorithms, thus improving the retrieval accuracy and retrieval efficiency.

The significance of the retrieval method proposed in this paper lies in the following: the graph that is extracted satisfies the conjugate subgraph with the features of the assembly interface and satisfies the set frequency. It can be used to judge the graph in the Atlas, resulting in a 3D assembly model with multiple conjugate interfaces.

3. Discussion

To verify the validity of this method, a CAD model library for machine tool fixtures and accessories was established. An experiment of 3D assembly model retrieval of multiassembly interface is performed using MATLAB software. The computer used was an Intel Core I7-8700K CPU with 4 GB of memory.

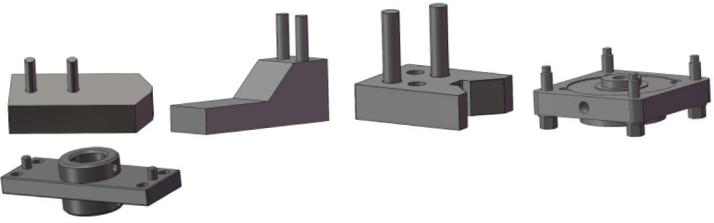

It takes the machine's jaws as the input model, which has two fixing holes. It needs to extract models that have conjugate features with the fixed holes in the model library, and there are two or more conjugate features.

In the retrieval process, first, the system reads the attribute information and topology of the input model. Then, it passes the reading input model information to the Atlas library of models, queries the Atlas library based on this information, and extracts the atlases whose attribute information and topology are similar to the input model. The corresponding 3D models of the retrieved atlases are listed in Table 2.

According to the table, the corresponding models of the Atlas are single assembly parts, and some are subassemblies. They all have the features of axial hole connection, plane and surface contact, or plane and plane contact.

After extracting the Atlas that is similar to the input model's attribute information and topology, the judgment of

TABLE 3: Retrieval of judgment of graph isomorphism.

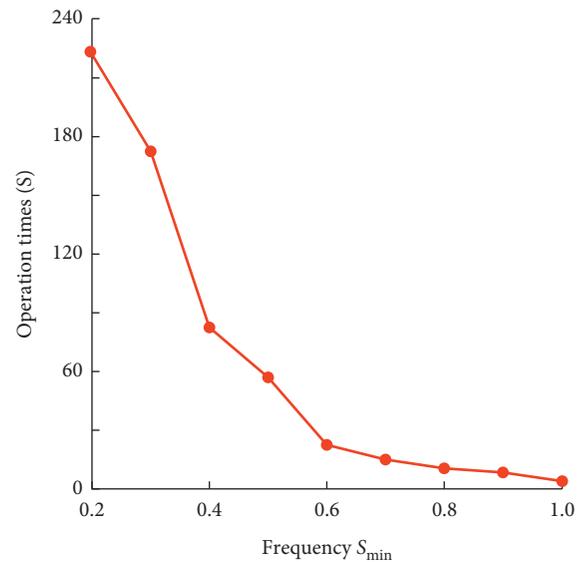

S_{min} value	Retrieval result
$S_{min}=1.00$	
$S_{min}=0.60$	

graph isomorphism is performed on the AAG of the Atlas. It judges whether the AAG in the Atlas contains conjugate subgraphs, and its number must be greater than or equal to the number of conjugate subgraphs of the input model. To verify the search conditions in the case of S_{min} with different frequency, experiments were performed with $S_{min} = 1.00$ and $S_{min} = 0.60$, respectively. The results of the retrieval are listed in Table 3.

After graph isomorphism judgment, the atlases of AAGs that do not conform to conjugate subgraphs are eliminated. Moreover, because the frequent subgraph mining algorithm is based on the idea of layer-by-layer iteration, the number of extracted atlases is reduced as the S_{min} increases. The meaning of changing S_{min} is that the scope of the output model can be set according to the designer's needs. When the design intent is clear, S_{min} can be increased to accurately output the model; when the design intent is ambiguous, S_{min} can be reduced to extend the range of the output model, which gives the designer more choices.

From Table 3, it can be seen that the retrieval method of judgment of graph isomorphism can accurately match the assembly interface of the 3D model. The Atlas of the model has similar attribute information and topological relations. Using the advantages that the AAG can express the topological structure of the 3D model, the model is retrieved from the shape structure, and the conjugate subgraph can retrieve the matching structure of the two models with the assembly relationship. Therefore, the matching 3D model of the assembly interface can be extracted through the judgment of graph isomorphism, which significantly improves the accuracy of model retrieval results.

Although the vertices of AAG are serialized and the number of vertices traversing in the judgment of graph isomorphism decreases, the calculation amount of judgment of AAG isomorphism in the Atlas is still large. Therefore, in

FIGURE 5: Operation of different S_{min} .

order to verify the time efficiency of retrieval algorithm, the execution time of the algorithm under different S_{min} is verified. Experiments show that the larger S_{min} is, the shorter the execution time of the algorithm is. This is the result of the algorithm's iterative idea. The experimental results are shown Figure 5.

4. Conclusions

In this paper, a 3D assembly model retrieval method for multiassembly interface is proposed. First, the 3D assembly model is represented by an attribute adjacency graph, and the definition of the conjugate subgraph is given according to the coordination relation between the assembly interfaces.

Then, the graph in the Atlas is serialized so that the vertex of the attribute adjacency graph has a unique sequence. Finally, through the method of efficient graph isomorphism judgment and the improvement of frequent subgraph mining algorithm, the attribute adjacency graph that conforms best to the assembly conjugate subgraph is judged in the Atlas, to extract the 3D assembly model of the multiassembly interface. Experimental results show that the method proposed in this paper can retrieve the parts or subassemblies that match the input model, and it provides a method to reuse the 3D assembly model.

4.1. Future Work. This paper proposes a 3D assembly model retrieval method incorporating assembly semantics, which is based on the existing 3D models of the subject group, whose semantic information has already been marked up, and the model information reflected is not perfect. In order to achieve a better 3D model retrieval system, further research can be done in terms of semantic annotation specification, similarity metric method, and 3D assembly model information subnetwork acquisition and pushing method.

- (1) According to the different needs and influences of designers on 3D assembly model information in the early, middle, and late stages of design, the components of design intent in the time dimension are summarized and the semantic annotation specification of 3D assembly model information reflecting design intent is constructed.
- (2) A design intent semantic information association mapping specification is constructed, and design intent information subnetworks of different sizes are formed according to different granularity of design intent. The similarity measure between the design intent information subnetwork and the subnetwork in the 3D assembly model information network is investigated, and the best matching subnetwork is searched for in the 3D assembly model information network.

To assess students' learning efficiency under different teaching modes, we used students' facial expressions in the classroom as a study point. An enhanced generative adversarial network is presented. We designed a generator as an automatic coding-decoding combination in a cascade structure with a discriminator configuration. It can retain different expression intensity features to the maximum extent. We also added a new auxiliary classifier, which can classify different intensity features and improve the model's recognition of detailed features of similar expressions, thus improving the comprehensive facial expression recognition accuracy. Our approach has a great advantage over the other facial expression recognition approaches on public datasets. Finally, we conduct experimental validation on the self-made student facial expression dataset in all cases. The experimental findings showed that our approach's recognition accuracy is superior to that of other methods, demonstrating the method's efficacy.

1. Introduction

In classroom teaching, what the teacher explains and what the students understand is not visually represented in the current assistive teaching systems. It is also a topic of debate which teaching style students would prefer between the traditional classroom teaching style and the modern smart classroom teaching style. The literature [1] then mentions that smart teaching and intelligent learning environments can give full play to students' cognitive abilities, greatly increase their interactivity, and provide better mastery of new knowledge. In terms of the current investigation, there is no intuitive system to measure students' acceptance of different teaching methods. For this reason, we will concentrate on this problem, we set out to identify facial expressions, and by obtaining the emotional expressions of the teacher and the facial expressions between students and then performing facial expression analysis, we can determine the students' acceptance and satisfaction with the teaching method. Our research, to some extent, provides some reference value for the quality of teaching and can respond to the effectiveness of teaching at the biotechnical level.

In human communication, facial expression is an important communication tool. It often adds different emotional factors to nonverbal communication, and it is crucial in the process of comprehending one another's emotional expression. With the advancement of biotechnology and computer science, facial expressions are used in various industries. The most common application area is privacy and security, which is most directly demonstrated by the face unlocking feature on cell phones and computers. Second, in the field of transportation, driver fatigue and drunken driving detection are also predicted by capturing facial expressions. Also, facial expression recognition technology is also frequently integrated into the fields of virtual reality, medical care, and service robotics [2–4]. Of course, the facial expression recognition technology is not so simple, and there are several technical difficulties to be broken. Different countries have different language and cultural backgrounds, and their meanings conveyed by facial expressions are more or less different. In addition, the results of facial expression recognition are not sufficient due to the objective influence of nonstructural conditions, such as occlusion, illumination, and focus problems. Recently, many researches have arisen

in the field of facial recognition to address these technical challenges, but the technological breakthroughs are all relatively limited [5].

The process of recording real-life student emotions is known as facial expression recognition, and the inner feelings can be mapped side by side from the fluctuations of emotions. The process is mainly based on video dynamic frames and still image sequences as the main recognition subject, and based on face recognition, it rises to a level to synthesize the linkage reaction among five senses, thus predicting facial expressions. The literature [3] starts the study from the simplest basic facial expressions, mainly the expressions of joy and sadness series. The authors, in order to obtain facial expressions accurately, first remove the noise from the images by preprocessing operations, followed by face detection to delineate the range of facial expression features. Then feature fusion is performed jointly with the linkage between the eyes, eyebrows, mouth, and cheeks, and finally, facial expressions are predicted by matching with the training feature library.

To address the difficulties in facial expression recognition research, related researchers have made unremitting efforts. Some researchers have focused their research on manual features. For example, literature [6] proposed the use of Gabor filters to optimize manual features, and literature [7] proposed local binary patterns to break the limitations of manual features. The literature [8] proposed a gradient histogram method to extract features, which further enriched the artificial feature set. Some researchers put their research focus on deep neural networks. For example, the literature [9] innovatively improved the network structure in the approach using neural networks, and the authors picked to fine-tune the two-stage training algorithm to adapt the feature linkage between the five senses and enhance the expression recognition. The literature [10] both adopted generative adversarial networks, which further explored the intrinsic features of the face and eliminated the interference of nonsubjective factors. The literature [11], on the other hand, performed adaptive optimization on the constraint function and proposed island loss to determine the attribution problem between features by learning the connection between different expressions. The literature [12] places the research focus on the attention mechanism and proposes an adaptive regional attention network and validates the high efficiency of the network on the available dataset, and results proved that integrating the learnt model can increase the model's robustness.

However, facial emotion detection is not a simple work, so the previously mentioned studies ignore the direct connection between facial attributes and emotions, and the main reason for the poor recognition results is the inability to positively map the way of distortion among the five facial nodes, and the changes between specific locations cannot be responded. Some researchers have proposed setting up standard lines on the face for facial node calibration, and the literature [13] also mentions that using this approach can decrease the data variance and improve the stability of the model. The literature [14] also proposed model-aware flags for the automatic perception of facial position, and

experiments demonstrated that this method not only reduces the workload but also preserves the robustness of the model. In the literature [15], it was unexpectedly found in the experiments that additional flagging of facial positions by predetermined trajectories could increase the recognition speed of the model without affecting the accuracy. All the above methods take an end-to-end form, and such methods also have certain limitations. Its recognition effect is limited by the quality of facial markers, and when facial expression features are captured, they can easily be incorporated into shallow features in a nonmaximal suppression operation.

To counteract the drawbacks of deep learning approaches, the literature [16] used a multitask learning strategy in neural network construction to enhance the primary task by shifting the learning number of different tasks. In addition, the literature [17, 18] added facial detection flags in the feature design of the facial action structure unit, which can aid in improving facial emotion recognition accuracy. In terms of multitask parameters, most of the previous studies launched optimization based on hard parameter sharing, but this approach limited the recognition efficiency of facial expressions to some extent. Nowadays, more soft parameters have started to be developed for sharing, such as the multitask convolutional partial sharing strategy in the literature [19] and the cross-stitch network proposed in the literature [20], which successfully break the efficiency limitation.

In our study, we consider various models comprehensively. We finally choose a generative adversarial network as the base method. To obtain the intensity features of different expressions hierarchically, we added a new auxiliary classifier and optimized the network structure. Finally, the effectiveness of our approach is demonstrated on both public and self-made datasets.

The rest of the study is arranged as follows. Section 2 presents the work related to different facial expression recognition methods. Section 3 introduces our adaptive improvement strategy and implementation process for generative adversarial networks. Section 4 presents the comparison of experimental databases and experimental methods. Finally, Section 5 presents research prospects and improvement directions.

2. Related Work

Traditional facial expression recognition research mainly relies on extracting geometric features, texture features, and hybrid features of the face as the basis [21]. The active shape model is the mostly used in facial expression recognition work and is the geometric feature method, which mainly uses facial feature points as a reference to construct geometric features and then localizes them. In practical application, the method is affected by lighting and occlusion and does not achieve better recognition results. The facial action unit is also a typical example of the geometric feature method. This method first divides the face into units and then compares them with the facial reference points by calculating the relative distance between units. However, this method requires intensive training in advance and has a very

high computational complexity at the time level [22]. Texture feature-based facial expression recognition methods are more common and usually have faster computational speed, but they are not effective for motion scenes such as Gabor filter and local orientation pattern methods. In the face of occlusion, the most effective method is the scale-invariant feature variation, which can automatically find the spatial extrema and extract their position, scale, and rotation invariants and can circumvent the effect of occlusion by local mapping, but this method is not effective for the target smoothed by edges.

In facial expression recognition work, the input video frames or image information are subjected to preprocessing operations and then input to convolutional layers of different scales for feature extraction, and then the facial features are transformed into independent vectors, and finally, the classification is completed by fully connected layers [23]. Different application scenarios have different structural requirements for convolutional neural networks [24], and to address the influence of nonstructural environmental factors, facial expression recognition work often requires specific preprocessing operations, such as the HOG feature method [25], the LBP method [26, 27], and the ROI method [28–30]. Different features have different extraction stages, resulting in multiple features in different dimensions, which cannot be unified at the time level and affect the convergence efficiency of neural networks. Besides, convolutional neural networks are often used by researchers as a basic network. According to different requirements for different tasks, convolutional neural networks are optimized and upgraded accordingly to the increase in the adaptability and performance of deep networks. Some researchers have designed cascade networks to enhance the efficiency of the localization of facial nodes [31]. Some researchers tried to add auxiliary modules to improve the robustness of the model [32]. Some researchers divided the network into parallel or tandem networks of small modules to achieve the inclusion of features at the decision level [33, 34]. All of the above research methods aim to improve the depth and parameter tuning of the network, which invariably increases the number of parameters. Considering the computational cost, some researchers have proposed recurrent neural networks [15], capsule networks [35], deep belief networks [36, 37], and so on.

For deep learning methods, the recognition accuracy is proportional to the volume of training data, and the richer the dataset, the higher the recognition accuracy. For facial emotion detection, building a database of facial expressions is undoubtedly a difficult and long-lasting task. The features of facial expressions are deeply related to different background cultures, and the process of data annotation usually requires the annotators to have a certain understanding of national culture and background. In addition, the optimization process of neural networks is often not transparent enough, and most researchers rely on constant repetition of experiments and experience to verify the optimal parameter sizes [38]. Therefore, the period and computational cost factors of the project need to be considered before adopting a deep learning approach. To circumvent complex parameter

tuning strategies, the literature [39] proposed the multi-granularity cascade forest method, an integrated neural network structure inspired by the cascade forest classification rule and the random forest rule. Compared with pure deep learning methods, this method has a smaller number of parameters and sets hidden layer hyperparameters to reduce the computational cost.

3. Method

3.1. Pipeline Overview. Researchers usually take an unsupervised approach to train the adversarial model, which belongs to the same deep neural network model and is divided into two parts in the phased design of the network. The generator part belongs to the front-end of the network and the discriminator belongs to the back-end. The generative adversarial network principle is simulated training at the neural network level, where different samples are iterated and generated in a random mode. The original samples are input at the input side, and the generator generates pseudosamples based on the original samples, and the usability of the generated samples is judged by comparing the difference between the original samples and the generated samples within a specified threshold of the pseudosamples. If the generated sample does not meet the standard value, by iterating this method, the pseudosamples can be approximated to the eigenvalues of the true samples in terms of eigenvalues. The structure of the generative adversarial network is shown in Figure 1.

In our study, face recognition systems can be made more robust by combining facial expression recognition with adversarial generating networks. Generative adversarial networks essentially play the facial expression details against each other by repeatedly updating iterations until the best facial expression features are obtained and then output to the terminal. Considering the facial expression details feature refinement, we define the classification of facial expressions to prevent the problem of increasing errors with different expression strengths.

3.2. Generator. The generator is in the front part of the adversarial network and its input is the real sample. After the real samples are input, the generator parses the real samples, divides the real samples into different feature nodes, and finally simulates the feature nodes to generate pseudosamples. The working process of the generator is shown in Figure 2.

We refer to the literature [40, 41] for an enhanced method to generative adversarial networks, where the generator is meant to work as an encoder and decoder in the tandem, which is a creative design. After several experimental verifications, we also apply the nested combination of encoding and decoding to the generator network. The encoder of the generator acquires different intensity facial expression features I^{low} by downsampling. Researchers in the literature [42] added a residual structure to the generator optimization to improve the efficiency of the generator encoding. We also verified the effectiveness of the method

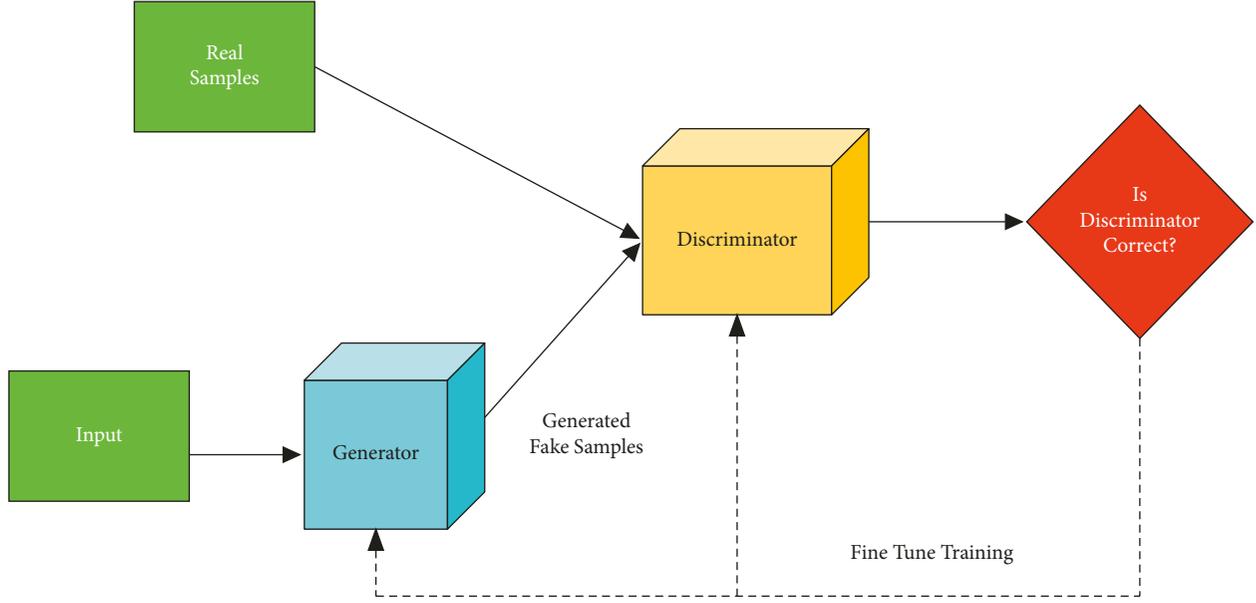

FIGURE 1: Generative adversarial network architecture.

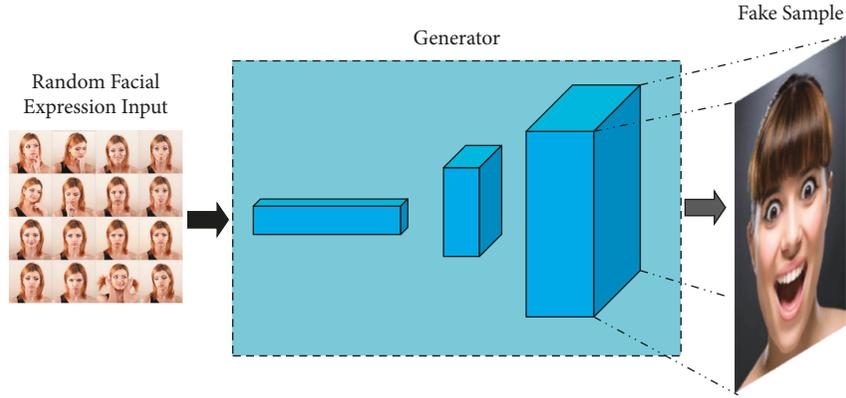

FIGURE 2: Facial expression generator process.

experimentally. In the decoder network layer, we use upsampling to transform the intensity features of facial expressions and then implement nonlinear activation by RELU. According to the decoder network optimization method in the literature [43], we implemented facial expression intensity figuration using the X-conv operator. Assuming the expression K input point (p_1, p_2, \dots, p_k) , where K denotes the result of a multilayer perceptron of real samples, in a transformation matrix $X = MLP(p_1, p_2, \dots, p_K)$ of dimension $K \times K$ is computed, and the summation between feature elements can be simplified to the commonly used convolution operator. When X is performing the computation of the transformation matrix, different facial expression nodes have different effects, and we define the mathematical equation of the X-conv operator as follows:

$$\begin{aligned}
 F_p &= X_conv(K, p, P, F), \\
 X_Conv(K, p, P, F) &= Conv(K, MLP(P - p) \times [MLP_\delta(P - p), F]),
 \end{aligned}
 \tag{1}$$

where p represents the facial expression feature node, K represents the facial expression traversal function, $P = (p_1, p_2, \dots, p_k)^T$ represents the nodes within the neighborhood expression feature node with K nodes, and $F = (f_1, f_2, \dots, f_K)$ represents the expression feature nodes in different domains. In the nonlinear connection of the X-conv operator, facial expressions of different intensities will have different feature expressions in the generator, and the details of the X-conv operator at each level are shown in Figure 3.

3.3. Discriminator. The discriminator network consists of a combination of fully connected and deconvolutional layers. The discriminator is at the output port of the generator. In the discriminator, different threshold ranges are set and the pseudosamples are marked as invalid if they are below the threshold range. The feature information of the invalid sample will be fed back to the generator with the simulation side of the real sample. All the feedback methods will pass the correct feature values in this back propagation way, and

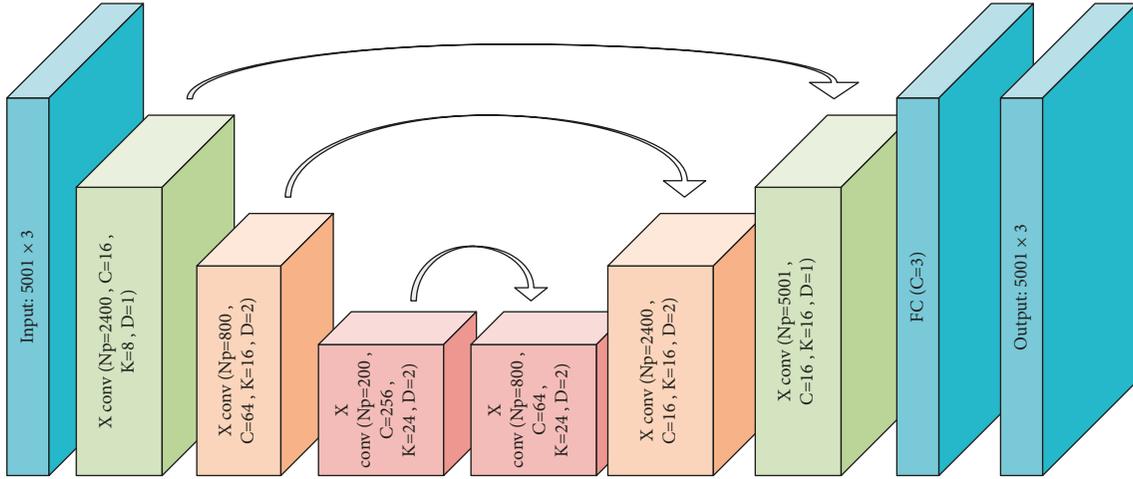

FIGURE 3: Detailed hierarchy of generators.

the generator will automatically correct the newly generated expression features based on the feedback feature values. The discriminator principle is shown in Figure 4.

The intensity of facial expression features was not consistent according to the differences in facial expression types. Low-intensity expression features are less demanding on the generator and only need to filter the facial contour data density. For high-intensity expression features, it is necessary to first decompose the high-intensity expression features and then convert them into low-intensity feature combinations. Researchers in the literature [44] will have used an alternating training model to optimize the discriminator with threshold discretization detection of pseudosamples. We define min-max as follows:

$$\min_{Gen} \max_{Dis} = E_I^{high} \log(Dis(I^{high})) + E_I^{low} \log(1 - Dis(Gen(I^{low}))), \quad (2)$$

where Gen denotes the twin sample of the generator and real sample and Dis denotes the threshold discrete detection of the discriminator and pseudosample. $\{I^{low}, I^{high}\}$ represents the feature intensity grading corresponding to facial expressions, and the generator Gen and discriminator Dis are distributed in a certain linear function, and the mathematical expression is as follows:

$$\begin{aligned} L_{G_adv} &= -\frac{1}{N} \sum_{n=1}^N \log(Dis(Gen(I_n^{low}))), \\ L_{D_adv} &= -\frac{1}{N} \sum_{n=1}^N \{\log(Dis(I_n^{high})) + \log(1 - Dis(Gen(I_n^{low})))\}, \end{aligned} \quad (3)$$

where N represents the expression feature intensity. During the intensity feature convergence process, the pseudosample features can be ranked with respect to the degree of threshold discretization under the detection of the discriminator. The generator fine-tunes the new features at a later stage based on the feature discretization values fed by the discriminator. The different levels of discriminator network layers we constructed are shown in Figure 5.

3.4. Auxiliary Classifier and Loss Function. The intensity of facial expression features can cause feature loss in the middle transition layer of the network layer. For this reason, we add auxiliary classifiers in the middle layer, which can retain the facial expression feature information under different intensities. In the actual course scenario, facial expressions will have different levels of facial muscle expressions. In order to maintain a stable mapping relationship between expression changes and feature intensities, the adversarial loss function is utilized to guide the feature decomposition of real expressions. Adaptive linear fitting function is added to the auxiliary classifier network layer, and all samples are configured with low intensity features combined with low intensity features by default during the production of classifier pseudosamples. It prevents the problem of feature intensity confusion in the process of expression feature perception. The mathematical equations of feature perception added in the auxiliary classifier are shown below:

$$L_{perceptual} = \frac{1}{N} \sum_{n=1}^N \|\phi(G(I_n^{low})) - \phi(I_n^{high})\|, \quad (4)$$

where ϕ represents the expression feature intensity perceptron. In refining the pixel feature representation of 2-dimensional images of facial expressions, the high-intensity facial expression feature I^{high} and the linked expression feature $Gen(I^{low})$ generated by the generator take advantage of the point-by-point loss optimization to overcome the feature refinement and loss problems arising from the high-intensity feature decomposition. Researchers in the literature [45] performed experimental validation on the algorithm of point-by-point loss optimization, and the authors found that the L2 loss function is more stable. The mathematic functions are calculated as follows:

$$L_{pixel} = \frac{1}{N_{pixel}} \sum_{i=1}^{N_{pixel}} \|Gen(I^{low})_i - I_i^{high}\|, \quad (5)$$

where N_{pixel} denotes the intensity expression of the facial expression at the two-dimensional level. According to the

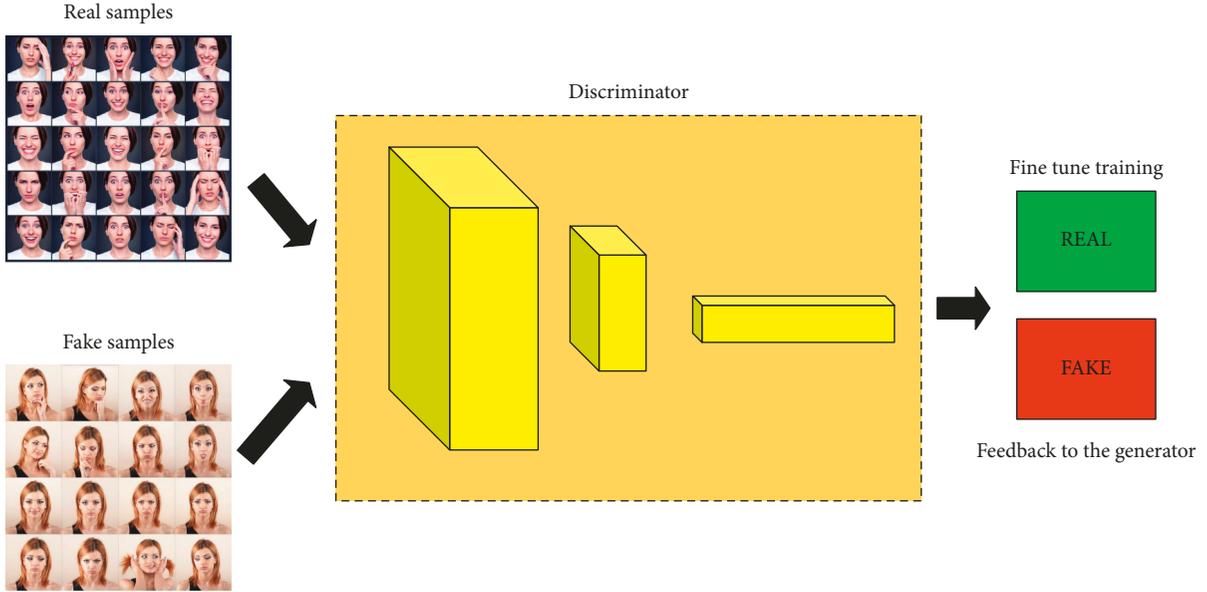

FIGURE 4: Facial expression discriminator process.

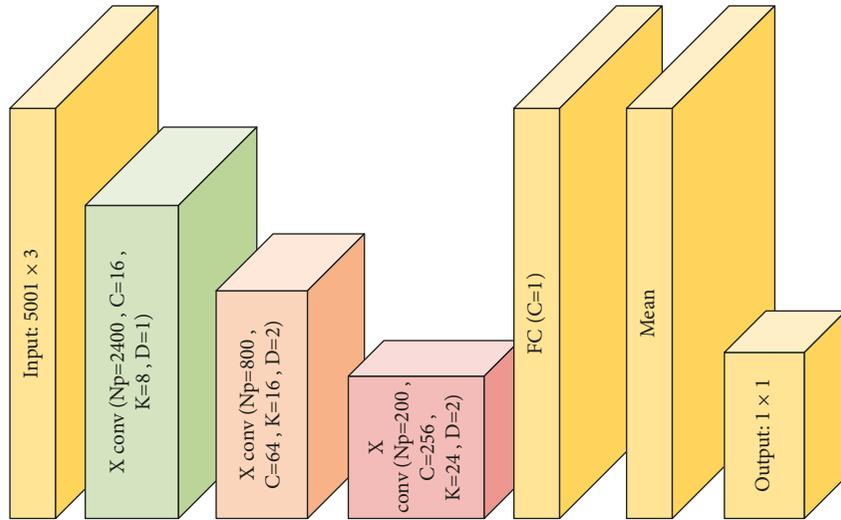

FIGURE 5: Detailed hierarchy of discriminator.

constraint effect of the loss function, we designed the new loss function has the following mathematical expression:

$$L = \omega_1 L_{G_adv} + \omega_2 L_{pixel} + \omega_3 L_{perceptual}, \quad (6)$$

where ω_1 , ω_2 , and ω_3 denote the expression intensity feature weighting coefficients.

3.5. Improved Generative Adversarial Networks. In our study, to assess students' learning efficiency at the level of their facial expressions in the classroom, we present an enhanced generative adversarial network strategy for improving the accuracy of facial expression recognition models while also separating comparable expressions using feature intensity classification. The auxiliary classifier can provide feature generation guidelines and pseudosample feature

discrimination to the generator and discriminator. At the pixel level, the auxiliary classifier middle layer neural network uses the X-conv operator to assist in synthesizing independent facial expression pseudofeatures, which are fed back in parallel with the generator in the joint output. The back propagation information from the discriminator will act as a filter in the auxiliary classifier to extract the feedback that aids in enhancing the effectiveness of the pseudofeatures into the real sample perception network. The facial expression detection network is shown in Figure 6.

4. Experiment

4.1. Datasets. We chose the well-known contemporary public facial expression datasets Oulu-CASIA (OC), Cohn-Kanade (CK+), and Facial multiview expression

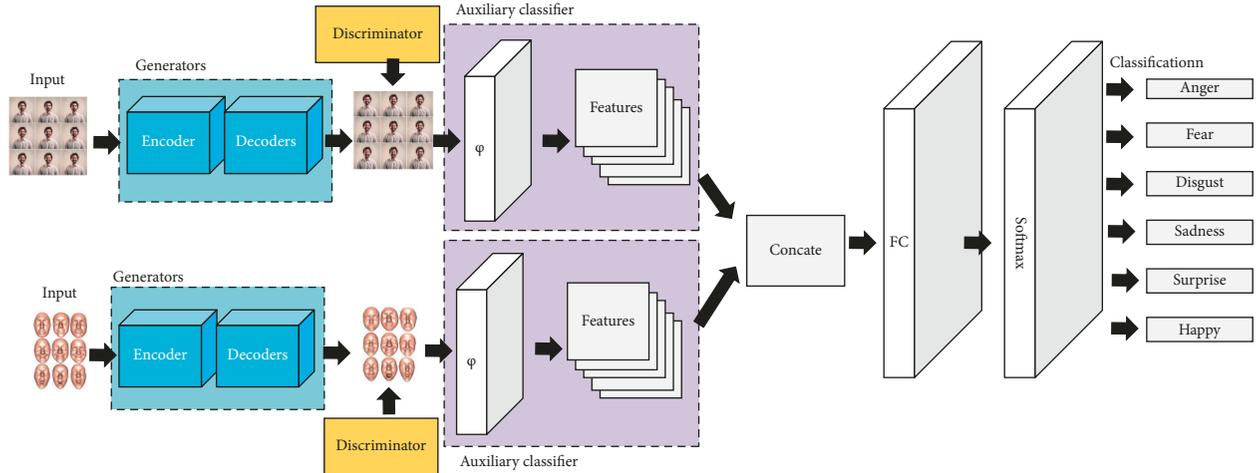

FIGURE 6: The structure of improved generative adversarial networks.

dataset with occlusion (FMEO) for the experimental test. Before performing expression classification operations on the above datasets, we collaborated with medical schools to manually standardize clear boundaries between expressions, and then we preprocessed all data to segment the images to specified sizes, with differences in the testing approach we took for different sizes of data.

The Oulu-CASIA dataset [46] contains a total of 2880 samples from the expression acquisition of 80 volunteers, which were captured using video recording and divided into visible light (VIS) series and near infrared (NIR) series according to the imaging system. Three different illumination methods were selected for the acquisition process to analyze the effect of detection methods on the structural environment. There are 480 videos of normal illumination samples, 60 videos of low illumination samples, and 15 videos of dark scenes. For the selection of the training set, we chose all the normal illumination video frame samples. The details of expression classification are shown in Table 1.

The Cohn-Kanade(CK+) dataset [47] contains a total of 593 video samples of facial expressions captured from 118 volunteers. Each piece of video is divided into 20–50 frames, and all video frame sequences are captured using a facial action coding system, which automatically classifies the expressions and labels them accordingly after the capture is completed. Its detailed facial expression classification information is shown in Table 2.

To evaluate the effectiveness of our strategy in complex situations such as occlusion, we chose FMEO to do the validation test. The dataset contains a total of 690 samples of data from 10 young volunteers, who were used in the experiment to collect facial expression samples by masking their faces with props, such as hats, glasses, and masks. The detailed classification of facial expressions in this dataset is shown in Table 3.

4.2. Experimental Settings. We trained the two-dimensional samples separately from the three-dimensional samples. The detailed parameter settings are shown in Table 4. In the

validation process, we adopted the method mentioned in the literature [11]. For multitask learning training, to fairly compare random input expressions, we utilized a random search strategy with hyperparameter tuning.

4.3. Experimental Results. In the facial emotion detection work, we mainly analyze three metrics, such as accuracy (Acc), F1 score, and recall (R). To ensure that our method is effective, we conducted a test, and we choose traditional facial emotion detection approaches and a neural network series of facial emotion detection methods as control group experiments. We compared three methods, LBP_SVM, CNN, and LSTM. During the training and tuning phase, each network was trained independently without the recognition module to confirm the accuracy of each technique. The experimental results are shown in Table 5.

Table 5 proves the facial emotion detection effectiveness of our strategy. Considering the results of the experiments, CNN is the more commonly used method; however, it falls short of the LSTM approach in terms of facial expression recognition accuracy. This is mostly owing to the benefits provided by the LSTM's unique network topology, which can achieve local perception and maximize memory information fusion. Our method uses generative adversarial networks with a new CNN-based auxiliary classifier, which can recognize similar expressions hierarchically starting from the expression feature strength, further improving the accuracy of facial expression recognition while obtaining better robustness.

The experimental results show that the datasets OC and FEMO perform the best. Due to the computational cost, we mainly use the experimental results of datasets OC and FEMO as the main judging criteria. To test the efficiency of our approach for facial expression recognition in the classroom, we conducted experimental validation by self-made datasets. We collected classroom expression video data of 300 college students and manually labeled the homemade dataset according to the OC dataset labeling rules, and then tested it with the trained model. The results are shown in Table 6.

In the students’ facial expression recognition experiments, our improved generative adversarial network outperforms the others, and it further proves the effectiveness of our approach.

5. Conclusion

We offer a method for recognizing facial expressions based on an upgraded generative adversarial network. The method belongs to the deep training model, we divide the network into three stages. The front end of the network is the generator network layer, which relies on real sample features to generate pseudosamples. The middle of the network is the auxiliary classifier, which assists the generator in generating pseudosamples that are closer to the real samples. The end of the network is the discriminator network layer, which determines whether the pseudosamples satisfy the output conditions according to the degree of threshold discretization, and the pseudosamples that do not satisfy the conditions are fed back to the front layer for reconstruction. During the experiment, we test the efficiency of the strategy on the open-source datasets. In addition, we also test on the homemade student datasets. The experimental results prove that the facial expression detection accuracy of our method stays above 92%. Comprehensive performance of the model outperforms other methods.

Facial expressions are a very complex task to capture, and there are thousands of facial expressions in different scenes. In this paper, we tentatively select facial expressions with more prominent features as the study points. However, for many obscure expressions, our method still does not perform well. In further research, we are going to use a dual RNN framework to perceive the 3D features of facial expressions, and enhance the model’s tolerance of high-intensity feature expressions.

The power head is the key part of the rock breaking work of the raise boring machine. Because the power head cannot adjust speed in time with the change in complex rock stratum, it leads to high failure rate, low work efficiency, and even accidents, so it is urgent to improve the controllability of the power head. In this paper, the electrohydraulic coupling mathematical model of the power head is established using the characteristic equations of dynamics and hydraulic components, and the control strategy of the fractional electrohydraulic drive system of the power head is proposed; genetic algorithm (GA), particle swarm optimization (PSO), and whale optimization algorithm (WOA) are used to adjust the parameters of FOPID, so as to improve the control effect of electrohydraulic system. The results show that the step response of WOA-FOPID control strategy is also better than that of genetic algorithm (GA) and particle swarm optimization (PSO). It can reach a stable state in 0.02 seconds, and the overshoot is only 0.12137%. The test verifies the correctness of the adaptive control and simulation results of the power head, which can effectively improve the adaptability of the power head to complex coal seams.

1. Introduction

Due to the advantages of the high safety, relatively low cost, and ensuring the safety of operators to the greatest extent, the reverse well drilling rig is widely used in underground roadway space, mine development, subway tunnel, and other projects, and the drilling technology is also a fundamental change technology for well hole drilling. In recent years, with the improvement of intelligent control technology of the drive system of the reverse well drilling rig, it has not only accelerated the speed of excavation but also greatly alleviated the labor intensity.

The power head is the key component of the reverse well drilling rig, and its control method and effect directly affect the safety and stability of the reverse well drilling rig in construction. At the same time, the intelligent control of the power head also has a positive role in promoting the

intelligent construction of coal mines nationwide. Therefore, the intelligent control strategy of the electrohydraulic drive system of the power head has attracted the attention of the majority of scientific researchers at home and abroad. For example, Wang and Yang [1], and others studied the relationship between the four parameters of drill pipe tension, torque, rotational speed, and drilling speed in the power head control system. Shen and Liu [2] formulated the mathematical modeling and robust integral adaptive controller of the power head valve-controlled hydraulic motor based on Padde's theorem and the reverse step derivation method, which improved the accuracy and tracking speed of the system control. Yang [3] proposed a fuzzy PID control algorithm based on the problem of synchronization of four hydraulic motors in the power head device, which improved the synchronization accuracy of the motor. Cheng [4] used Amesim and MATLAB-Simulink to construct a joint

simulation model of the test bench drilling simulation system, and Cheng Lilin designed a fuzzy adaptive PID controller to analyze the control performance of the power head system. Zhang [5] used the method of co-simulation between Amesim and MATLAB-Simulink, the adaptability of different control algorithms of traditional PID fuzzy and feedback linear synovial membrane structure to the position tracking control of valve-controlled asymmetrical hydraulic cylinders is analyzed, and the problems of nonlinearity and low control accuracy of the electrohydraulic control system of the power head are solved. Foreign hydraulically driven reverse well drilling rig, power head drive using electrohydraulic proportional PID control technology, control unit using PLC or engineering controller [6–9], due to the introduction of computer control technology, and a variety of more complex control logic and PID control algorithms can be realized. The above literature research has made certain contributions to the intelligent control of the electrohydraulic drive system of the power head of the reverse well drilling rig and laid a certain foundation for the intelligent control algorithm of the power head. However, the research in the above articles is based on the traditional PID control algorithm. Especially in downhole operation, complex uncertainties such as surrounding rock parameters and downhole force of the drill will make the driving head of the drill unable to adjust the control parameters in time, resulting in low drilling efficiency, short service life of rock breaking hob, and even damage to the drill bit, sticking, etc. Under special working conditions, the traditional PID control effect is not ideal, even if the PID is re-parameter tuned, it still cannot achieve a good control effect, and it is essentially impossible to overcome the shortcomings of traditional PID control technology. Therefore, the complex system has a low control accuracy, reflecting the poor sensitivity and other issues, and it is difficult to explore the intelligent control principle of the electrohydraulic drive system of the power head from a deep level, and the parameter selection of the PID controller has a great impact on the control effect, the traditional parameter tuning method is still based on experience, and it is difficult to find a set of parameters with good control effect in a short period of time.

The fractional order FOPID controller has 5-bit adjustable parameters. Compared with other control laws, it has better dynamic performance, parameter adjustment flexibility, and control accuracy [10–12], and there is a great vacancy in the research and application of fractional order FOPID in the research of electrohydraulic system control method of raising boring. Based on the internal control principle of the reaming operation of the power head of the reverse well drilling rig, if the control effect is required to have good timeliness and reliability, the parameter adjustment research of the intelligent control algorithm is also indispensable, such as the particle swarm algorithm [13–15], the genetic algorithm [16], the gravity search algorithm [17], the neural network algorithm [18], the ILMI algorithm [19], and the whale optimization algorithm [20], which are all applied in the PID controller, improving the control effect of the traditional PID controller. The method of parameter tuning that relies on experience is got ridden.

Based on this, this paper establishes the electrohydraulic coupling model of the power head of raise boring machine from the dynamic principle, electrohydraulic coupling properties, and the characteristic equation of hydraulic components and puts forward the control method of the power head electrohydraulic drive system based on fractional FOPID. To further improve the control effect of the system, the genetic algorithm (GA), particle swarm algorithm (PSO), whale optimization algorithm (WOA), three groups of intelligent optimization algorithms are used to adjust the FOPID and PID controller parameters, and the influence of the above different combination algorithms on the control system is evaluated, to provide theoretical guidance for the reliability of the reaming operation of the reverse well drilling rig [21–24]. Finally, field experiments were conducted in Liuqiao Town, Suixi County, Anhui Province, to prove the effectiveness of WOA-FOPID control strategy in electrohydraulic drive control system. It further provides new theoretical guidance for the intelligent control strategy of the electrohydraulic drive system of the power head.

2. Mathematical Modeling

This article takes a deep well lane full-section test drilling rig (raising boring) as an example to study, which is the most widely used [25] and belongs to the lower lead upward expansion type. In order to apply intelligent drilling technology to raise boring machine, taking the power head as the research object, PLC and HMI are used to design the rock breaking control system. Four variable displacement piston pumps a11vlo130lrd are connected in series into two groups, which are driven by 132 kw motors to drive four mcr15a1500w80z32a0m2l4 2S 506u two-speed radial piston motors, and the hydraulic motor also controls the rotation of the power head [26, 27]. The overall idea of the structure composition, construction process, and control scheme of the reverse well drilling rig and the power head is shown in Figure 1.

To facilitate the theoretical modeling and analysis, the basic assumptions of hydraulic motor modeling are made. On this basis, the proportional amplifier, electrohydraulic proportional control valve, power head electrohydraulic coupling model, and the transfer function of power head hydraulic motor speed are established, respectively. The signal output by the controller is a voltage signal or a current signal, which is a component that amplifies its input signal and simplifies this model to a proportional link because of its input and output characteristics. Its transfer function is as follows:

$$G_i = \frac{I(s)}{U_i(s)} = K_b, \quad (1)$$

where K_b is the gain of the proportional amplifier.

The current signal output by the proportional link is based on dynamics and electromagnetic induction to drive the proportional solenoid movement, and then, the valve spool generates motion, thereby controlling the size of the

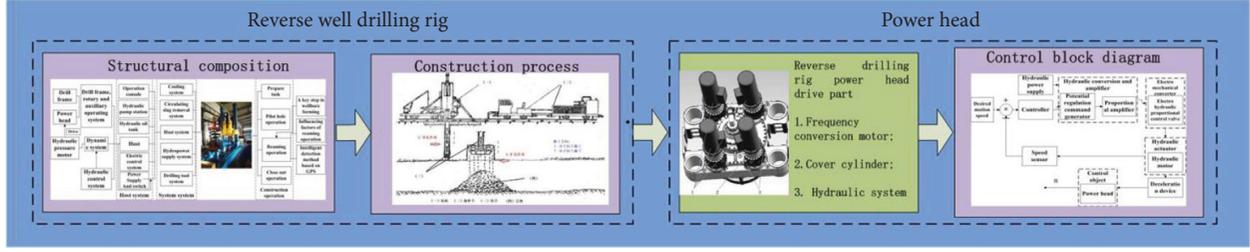

FIGURE 1: Overall train of thought block diagram.

valve opening and the direction of the liquid in and out. The working principle of the electrohydraulic proportional control valve is established, and the following expressions are established for the relationship between the coil current in the electromagnet, the driving force of the electromagnet, and the displacement of the valve core:

$$\begin{cases} u = L \frac{di}{dt} + (R_c + r_\rho)i, \\ F_d(t) = K_I U(t), \\ F_M(t) = m \frac{d^2x}{dt^2} + c \frac{dx}{dt} + k_s x. \end{cases} \quad (2)$$

The transfer function obtained by pulling the change of (2) is as follows:

$$G_2 = \frac{X(s)}{I(s)} = \frac{K_{xi}}{s^2 + 2\omega_n \xi s + \omega_n^2}. \quad (3)$$

In the formula, ω_n is the natural frequency of the spool, ξ is the damping ratio of the spool, and K_{xi} is the gain of the electrohydraulic proportional valve.

The electrohydraulic coupling model of the power head is composed of the hydraulic motor connected to the power head through the deceleration device, so the following relationship is established according to the flow continuity of the hydraulic motor valve, the static characteristic equation, the dynamic balance equation of the shaft, and C_d :

$$\begin{cases} q_L = C_d A x \sqrt{\frac{1}{\rho} (p_s - p_L)}, \\ q_L = D_m \frac{d\theta_m}{dt} + C_{tm} p_L + \frac{V_t}{4\beta_e} \frac{dp_L}{dt}, \\ T = D_m P_L = J \frac{d^2\theta_m}{dt^2} + B_m \frac{d\theta_m}{dt} + G\theta_m + T_f, \\ T_f = \frac{J_e s \omega_d(s) + B_e \omega_d(s) + T_d(s)}{i}. \end{cases} \quad (4)$$

As can be seen from Figure 1, the hydraulic motor and the power head are connected through the deceleration device, and the angular velocity exists: \vec{r} . A pull transform on equation (4) is performed to get the following equation:

$$\begin{aligned} T &= D_m P_L(s), \\ &= (iJ_1 + J_e) s \omega_d(s) + (iB_m + B_e) \omega_d + \frac{T_d(s)}{i}. \end{aligned} \quad (5)$$

From (5), it can be known that the equivalent inertia of the power head $J_d = iJ_1 + J_e$ is equivalent to viscous damping coefficient $B_d = iB_m + B_e$. The transfer function of the electrohydraulic coupling power head model under no-load state is sorted out:

$$G_{d1}(s) = \frac{\omega_d(s)}{U_i(s)} = \frac{K_d}{(s^2 + 2\omega_n \xi s + \omega_n^2)(s^2/\omega_d^2 + 2\xi_d/\omega_d s + 1)}, \quad (6)$$

where $K_d = K_a K_{xi} K_q D_m / i D_m^2 + B_d (C_{tm} + K_c)$, $\omega_d = \sqrt{\beta_e [i D_m^2 + B_d (C_{tm} + K_c)] / V_t J_d}$, and $\xi_d = J_d \beta_e (C_{tm} + K_c) + B_d V / 2 \sqrt{\beta_e} V_t J_d [i D_m^2 + B_d (C_{tm} + K_c)]$.

Proportional amplifier, electrohydraulic proportional valve, and hydraulic motor-related parts of the parameters are as follows: the inertia of the motor shaft J is $67 \text{ kg}\cdot\text{m}^2$, \vec{r} is $0.4755 \text{ kg}\cdot\text{m}^2$, the total volume V_t of the connecting pipe is $3 \times 10^{-4} \text{ m}^3$, the elastic modulus of the system is $6.9 \times 10^8 \text{ N/m}^2$, the flow gain K_q is $2.42 \text{ m}^2/\text{s}$, the motor displacement is $2.39 \times 10^{-4} \text{ m}^3/\text{rad}$, the gear ratio of the reducer is i of 6.817, and the open-loop transmission function of the power displacement signal by calculating the angular velocity of the power head is as follows:

$$\begin{aligned} G_{d1}(s) &= \frac{\omega_d(s)}{U_i(s)} = \frac{K_d}{(s^2 + 2\omega_n \xi s + \omega_n^2)(s^2/\omega_d^2 + 2\xi_d/\omega_d s + 1)}, \\ &= \frac{8.476 \times 10^4}{5.487 \times 10^{-5} s^4 + 0.0252 s^3 + 2.85 s^2 + 432.59 s + 10000}. \end{aligned} \quad (7)$$

By (7), we obtain the system without interference and control Bode diagram as shown in Figure 2.

From Figure 2, it can be seen that when the amplitude-frequency characteristics reach zero decibels, the phase-frequency characteristics are below -180° line, and the phase lag point has a negative stability margin at the 180° point, so there is a stability problem in the system, but due to the stability of the system itself and the dynamic characteristics, to make the system have a stable margin, it is necessary to add a controller to adjust to meet the stability requirements.

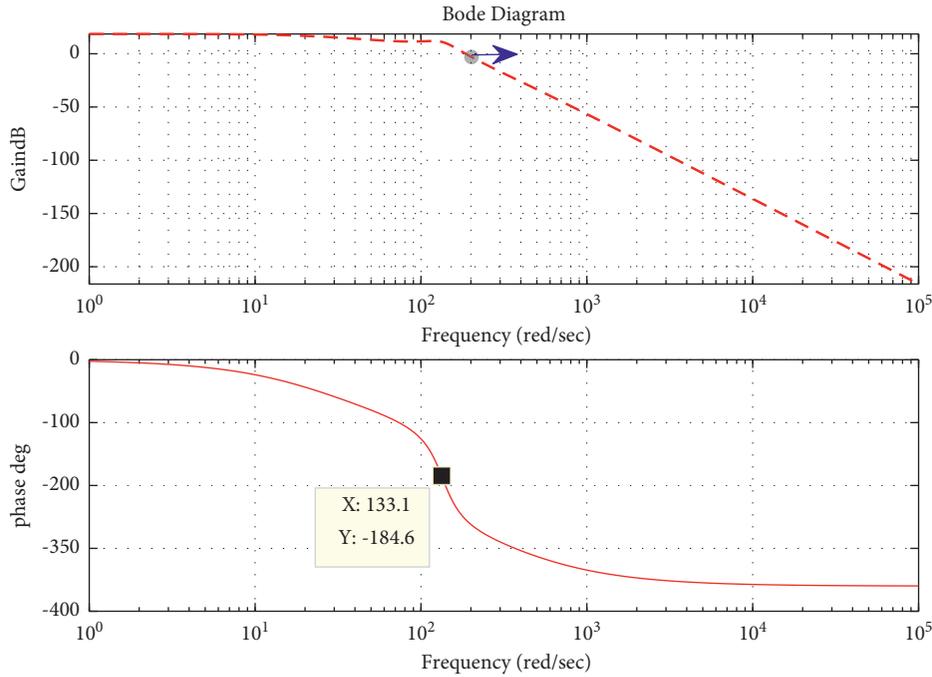

FIGURE 2: Open-loop Bode diagram of the system without interference and control.

3. Fractional Order FOPID Controller Design

As a branch of the control field, fractional order (FOPID) control has many advantages such as flexible and precise parameter adjustment, large system stability margin, and strong system robustness and has been widely used in different types of controller design [28–30]. Fractional order $PI^\lambda D^\mu$ control was first proposed by Igor Podlubny, and its superiority over traditional PID control was demonstrated through response analysis [28–30], [31–36]. Fractional order $PI^\lambda D^\mu$ controller of the order of parameters λ and μ can take any real number, in the $P-I-D$ plane, according to the different controller parameters to take the value; FOPID control system structure is shown in Figure 3. Compared with traditional PID control, fractional $PI^\lambda D^\mu$ control can more subtly reflect the transition process from proportional control to integral control and differential control, to achieve a control effect with higher accuracy, better stability, and stronger anti-interference ability.

The mathematical expression for the FOPID controller is as follows:

$$C(s) = \frac{U(s)}{R(s)} = K_p + \frac{K_i}{s^\lambda} + K_d s^\mu, \quad (8)$$

where K_p is the proportional gain, K_i is the integral gain, K_d is the differential gain, and λ and μ are the fractional and integral orders, respectively.

4. Whale Optimization Algorithm

Based on the advantages of fractional order PID control algorithm, this paper proposes a control strategy based on WOA-FOPID algorithm. There are many kinds of parameter tuning methods for FOPID. According to the regulation

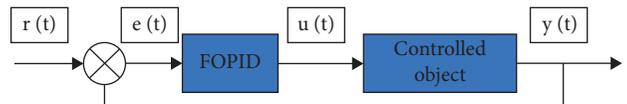

FIGURE 3: Structure of the FOPID control system.

characteristics of the algorithm itself, it is mainly divided into traditional method tuning and intelligent optimization algorithm tuning, and the intelligent optimization algorithm is widely used because of its self-adaptability. In this paper, genetic algorithm (GA), particle swarm optimization (PSO), and whale optimization algorithm (WOA) are combined with FOPID control theory, respectively, and the above three intelligent optimization algorithms are used to set FOPID control parameters. The structure of intelligent control algorithm FOPID control system is shown in Figure 4.

To fully explore the advantages of genetic algorithm (GA), particle swarm optimization (PSO), and whale optimization algorithm (WOA), three intelligent optimization algorithms are combined with PID and FOPID, respectively, and the speed control effect of power motor is further analyzed through different control strategies. The flow chart of setting FOPID parameters by the developed intelligent optimization algorithm is shown in Figure 5.

5. Parameter Setting and Optimization Process of Real Analysis and Optimization Flow Simulation Analysis

There are many kinds of parameter tuning methods for FOPID. With the development of intelligent and control technology, according to the regulation characteristics of the algorithm itself, it is mainly divided into traditional method

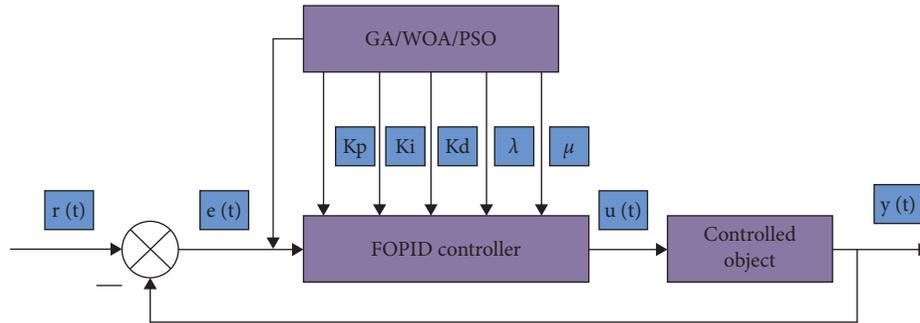

FIGURE 4: Structure diagram of the intelligent control algorithm FOPID control system.

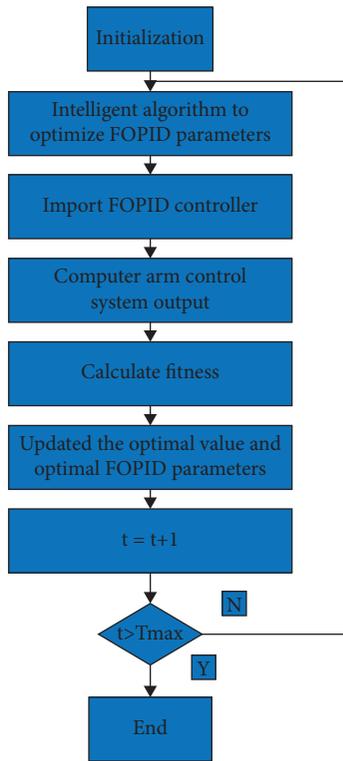

FIGURE 5: Flow chart of intelligent optimization algorithm for tuning FOPID parameters.

and intelligent optimization algorithm. The intelligent optimization algorithm is widely used because of its self-adaptability. The whale optimization algorithm (WOA) has been widely used because of its simple optimization mechanism and fast solution speed. The algorithm searches for the optimal solution by simulating the predation behavior of humpback whales [37–39] and solves the D-dimensional optimization problem in which $f(x)$ is the optimization objective function:

$$\text{Min } f(x), \text{ s.t. } 1 \leq x \leq u. \quad (9)$$

In servo control, the ITAE performance index weights the error so that the error signal converges to zero as soon as possible. The optimization objective function generates the objective function of control parameter optimization under the ITAE index, which is defined as follows:

$$f_y = \sum_{t=0}^N L(t)|e(t)|. \quad (10)$$

Here, N is the number of search targets; $L(t)$ is the time series; and $e(t)$ is the error signal between the response frequency and the reference frequency. The smaller the f_y , the better the effect of dynamic response. As shown in Figure 6, the contents and steps of WOA are summarized.

In this paper, genetic algorithm (GA), particle swarm optimization (PSO), and whale optimization algorithm (WOA) are combined with PID and FOPID, respectively. Through different combined control strategies, the control effect of raising boring power head is further analyzed and compared. The specific parameter settings of each algorithm are shown in Table 1.

It can be seen in Table 2 for comparison of different combination strategies and control indicators, the dynamic response curve comparison diagram of each combination strategy of the regulation system is shown in Figure 7. Figure 7(a) is the step response diagram of each intelligent optimization algorithm and PID combination strategy, and Figure 7(b) is the step response diagram of each intelligent optimization algorithm and FOPID combination strategy; the comparison of PID and FOPID combined control strategies based on WOA is shown in Figure 8.

As can be seen in Figure 7, after adding PID and FOPID controllers, the system can quickly tend to a stable state. Comparing Figure 7(a) with Figure 7(b), in the control based on the same algorithm, the FOPID control is significantly better than the PID control in terms of response time and dynamic response; in Figure 7(a), the step response of WOA-FOPID control strategy is obviously better than the control strategy based on GA and PSO algorithm, and the overshoot is 8.35%, only 0.5%. Stable state is reached in 1 s; in Figure 7(b), the step response of WOA-FOPID control strategy is also better than the control strategy based on GA and PSO algorithm, at 0.5%. It reaches a stable state within 0.2 s, and the overshoot is only 0.5% 12137%. The simulation results in Figures 7(a) and 7(b) show that in the PID/FOPID combination strategy, the whale optimization algorithm (WOA) has more advantages than the genetic algorithm (GA) and particle swarm optimization algorithm (PSO) in the process of intelligent parameter adjustment.

Figure 8 compares the two controllers based on WOA. The results show that WOA-FOPID is more dominant, which further verifies the superiority of FOPID controller. In

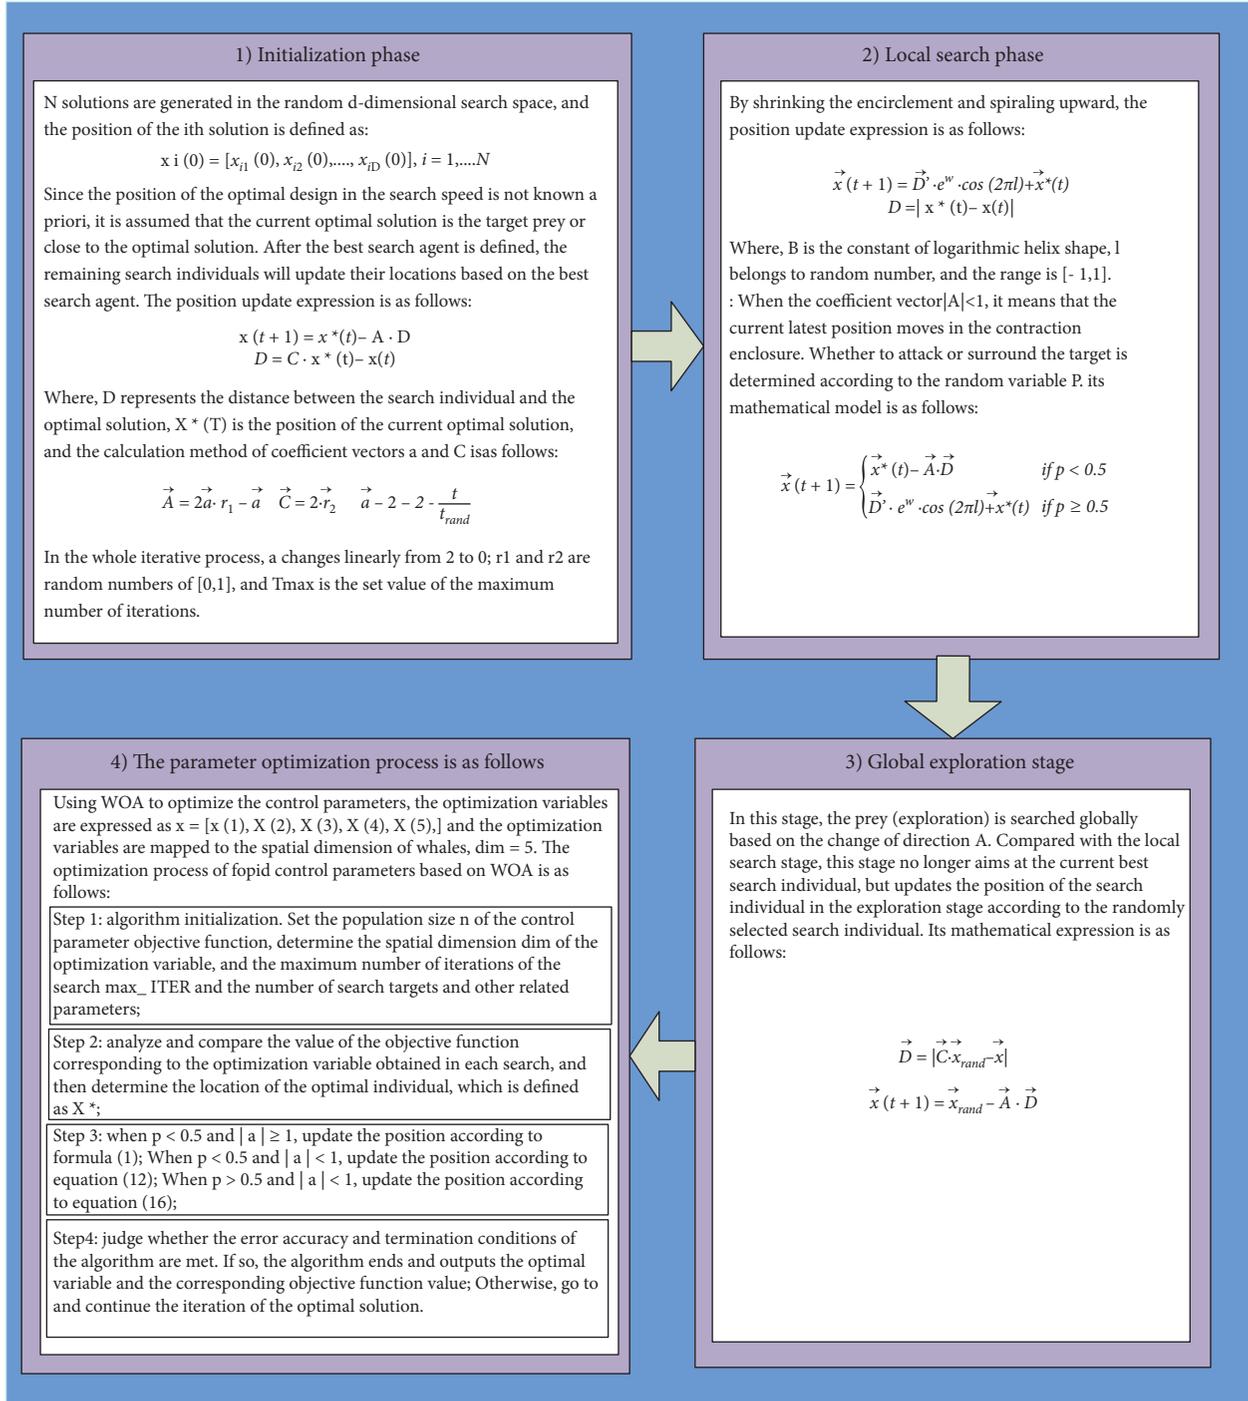

FIGURE 6: WOA steps and contents.

these combination strategies, it is concluded that the optimal controller is the FOPID controller based on WOA, and the parameters of the controller are as follows:

$$Gc = 15.2654 + 20s^{-1.0039} + 9.5963s^{1.1118}. \quad (11)$$

6. Experiment

To verify the correctness and effectiveness of WOA-FOPID control strategy in the electrohydraulic drive control system

of the power head of raise boring machine, the performance test of the power head of raise boring machine was carried out in Liuqiao Town, Suixi County, Anhui Province. The on-site commissioning layout is shown in Figure 9.

To meet the normal operation of the rock breaking test rig, the rock breaking control system mainly adopts Siemens S7-1200 series PLC and its expansion module, combined with the control system designed by HMI to realize the start/stop action of the pump station motor, the forward/reverse action of the power head motor, the stepless speed regulation

of the power head output shaft, the lifting/lowering action of the thrust cylinder, the pressure, displacement, stroke, constant pressure/constant torque drilling mode switching precise control of temperature control, and automatic operation of pump station. At the same time, the rock breaking control system is equipped with a remote control function to facilitate remote operation. S7-1200 series PLC and large screen display form the control core in the control cabinet, and each working condition monitoring and input/output drive unit cooperates with each other to ensure the stable operation of various control functions of the system. The

general scheme of electric control system of raise boring machine is shown in Figure 10.

6.1. Power Head Speed Control Scheme. Power head speed regulation control model in the process of power head speed adjustment potentiometer from minimum to maximum adjusts the displacement of variable pump from 0 to 145 ml/R and variable motor from 215 to 65 ml/R in turn. That is, in the first half of the speed regulation process, the displacement of the motor remains unchanged, and only the

displacement of the variable pump is adjusted to meet the requirements of speed adjustment. In the second half, the maximum displacement output of the variable pump is maintained, and only the displacement of the variable motor is adjusted to meet the requirements of speed adjustment. In this way, no matter at any speed, the output torque is the maximum torque corresponding to the speed:

- (1) *Remote Control and Valve Group Control of Hydraulic Pump Station.* Before the remote control of hydraulic pump station operates the control system, the pump station motor must be started first to make the pump station in working state. To avoid starting the pump station in another place, the system adds

signal drives the corresponding solenoid valve action through the relay to realize the corresponding functions.

- (2) The power head is driven by 160 ml/R variable pump and variable motor. To realize the adjustable steering and speed, the system designs a three-position knob to control the action of the electromagnetic directional valve, so as to realize the steering control of the power head. At the same time, the potentiometer is designed to input 0~5 V analog signal, and then, through the calculation of PLC speed regulation model, the first conductive signal of 0~10 V driving proportional amplifier is output, the proportional amplifier to output 200~600 mA current is controlled, and then the speed of power head is controlled.

Forward/Reverse Control Scheme of Power Head. Forward/reverse switching control is realized through three-position four-way solenoid directional valve. That is, the control of the electromagnetic directional valve is realized through the console knob or the remote controller knob, to realize the control of the forward/reverse switching function. Control flow is shown in Figure 13.

Stepless Speed Regulation Control Scheme of Power Head Output Shaft. The flow is adjusted by controlling the swing angle of variable pump, to realize the function of stepless speed regulation of power head output shaft. That is, the proportional electromagnet is controlled by the knob potentiometer, and then, the swing angle of the variable pump is

controlled to realize the function of stepless speed regulation of the output shaft of the power head. Control flow is shown in Figure 14.

6.2. Implementation Plan. Field commissioning stage: This stage involves speed regulation of power head under shunt state. The experimental parameters are shown in Tables 3–5:

- (1) Stage I: the displacement of the power head motor is kept unchanged, and the displacement of the hydraulic pump is adjusted from 0 ~ 145 (ml/r). At this time, the driving current of the power head motor is about 43 mA (the corresponding digital quantity is 2000). According to the driving characteristic curve, the maximum displacement of the power head motor is 216.5 ml/r.
- (2) Stage II: the displacement of the power head motor is kept unchanged, the discharge of the hydraulic pump is adjusted to the maximum value of 145 ml/r (theoretical value), the actual control driving current is about 586 mA (corresponding to the digital quantity of 27000), and the flow of the corresponding pump is 140 ml/r. At this time, the displacement of the power head motor remains at the maximum value of 216.5 ml/r.
- (3) Stage III: the maximum displacement of the hydraulic pump is kept unchanged at 145 ml/r, and the displacement of the power head motor is adjusted from 216.5 ml/r to V_g min. When the software controls the minimum displacement of the power head motor, the corresponding driving current is

about 526 mA, $V_{g\min}$ is 0.185 times, and $V_{g\max} = 216.5 \text{ ml/r} \times 0.185 = 40.0525 \text{ ml/r}$.

- (4) Stage IV: the rotating speed of the power head is the maximum, and the Baote remains unchanged.

6.3. Empirical Conclusion

- ① Compared with “the power head parameter table of enhanced TD2000 drilling rig under shunting state and turning into working condition,” there is an error in the maximum displacement control of hydraulic pump station, with an error of about 5 ml/r. There is still a little room for optimization, which can be optimized on-site.
- ② Compared with “the power head parameter table of enhanced TD2000 drilling rig under shunting condition and turning into working condition,” the minimum displacement control of power head motor has error, and the error is about 2 ml/r, so the optimization needs to be careful (during plant commissioning, when the speed regulation exceeds a certain position, the speed of power head decreases instead).
- ③ In the whole speed regulation process, the trend is basically consistent with the table of power head parameters under shunting condition of enhanced TD2000 drilling rig, but there is a little error at the two end points. The error is as described in points ① and ② above. The position number described in the table is included in the whole speed regulation process and does not need to be corrected separately. Only the corresponding speed identification needs to

be carried out on-site. The corresponding position is marked.

7. Conclusion

Aiming at the problem of whether the power head of raise boring machine can be driven in complex environment during reaming operation, using the fine-tuning characteristics of FOPID control to apply to the nonlinear control object, a method of adjusting FOPID control parameters based on whale optimization algorithm (WOA) is proposed. Through the establishment of the electrohydraulic coupling model of the power head of the raise boring machine and the simulation analysis in MATLAB software, the following conclusions are obtained (Table 6):

- (1) From the simulation results of six different combined control strategies, it can be seen that the overall control effect of FOPID is much better than PID control in the overshoot and response time in the frequency response curve. In PID control, the overshoot is at least 8.35%, while the overshoot of FOPID control is at most 6.9309%. The results show that FOPID is more suitable for the electrohydraulic control of raising boring than PID, and the overall response time is shorter. It can adjust the angular speed of the power head in time and then control the fast and slow switching of the power head, which shows that FOPID control has a better application prospect in the electrohydraulic drive control of raising boring.
- (2) Among the six combined control strategies, the combined strategy based on WOA has obvious

advantages in each control method. The overshoot of WOA-PID control strategy in PID control is at least 8.35% and takes 0.1 s; the overshoot of WOA-FOPID control strategy in FOPID control is at least 0.12137%, with a time of 0.02 s. From the numerical iteration process of WOA objective function, it can be found that WOA has good optimization ability and convergence performance, which verifies the excellent performance of WOA in control parameter tuning. The experimental data show that the WOA-FOPID combined control strategy studied in this paper can respond to the input in time, and the FOPID parameters are adjusted through WOA, which has a good effect on the optimization of control parameters and can effectively improve the control accuracy of FOPID.

- (3) After the design of the control system is completed, it is debugged and applied on the raise boring rig. The control system realizes various functions including remote pump station start and stop control and single/double drive motor switching control and meets the requirements of process operation. Experiments show that the WOA-FOPID control strategy is effective in the electrohydraulic drive control system. The control strategy can make the electrohydraulic drive control have good real time, accuracy, and rapidity and can realize fast power head. Slow switching and high-precision control can be used as the exclusive control system of raise boring rig.

This study specifically designed an eye-tracking supported scientific problem-solving assessment: hands-on manipulation task system to explore the differences in visual attention and cognitive processes between high and low science achievement groups. Thirteen students with high science achievement and fourteen students with low science achievement participated. Students needed to complete the hands-on manipulation assessment, consisting of three modules, including selecting experimental equipment, experimental design, and building the experimental model. Behavioral and eye movement data were collected during the process. The results showed that the high science achievement group allocated more visual attention to the hands-on manipulation task, acquired more information through visual fixation, and assigned more attention to the key area. In module three of the hands-on manipulation task, the high science achievement group transformed from a visual channel to a tactile channel, and they generated more hands-on behaviors depending on the experimental area. Furthermore, the results showed a high correlation between students' eye movement behavior and the performance of scientific problem-solving assessments. Eye movement behavior could predict students' performance in scientific problem-solving. The average fixation duration and the average fixation duration of the interest area were two significant determining parameters. The implications of the experimental results for front-line science education, curriculum designers, and science assessment were also discussed.

1. Introduction

China's educational reform in recent years emphasized the importance of cultivating students' ability to solve scientific problems. According to the Primary School Science Curriculum Standards issued by the Ministry of Education in 2017, primary school students should master the necessary scientific knowledge and scientific research methods, develop the ability to handle practical scientific problems, and participate in public affairs. In the face of increasingly complex scientific problems, the ability to quickly retrieve and integrate essential information to form practical scientific problems solving paths and take actions along a practical path is crucial [1]. In PCAP scientific academic assessment content framework, three

competencies in students' continuous knowledge learning were mentioned: scientific inquiry, scientific reasoning, and problem-solving. Thinking skills that students need include creativity, critical thinking, problem-solving, and metacognition [2]. Problem-solving is the cognitive processing of transforming a known state into a goal state when the problem solver has no obvious solution [3]. Newell and Simon [4] believed that problem-solving began with information retrieval to construct the mental representation of external problems in well-structured problems. By comparing the difference between the target state and the known state, effective operations are performed to successfully transform the given state of the system into the target state. The OECD [1] proposed the framework for problem-solving that involves four main

processes: “exploration and understanding,” “representing and formulating,” “planning and executing,” and “monitoring and reflecting.” Traditional assessment measures like standardized tests are unsuitable for assessing multiple core competencies such as problem-solving competence. The following four methods are suggested for assessment: project assessment, performance assessment, group assessment, and portfolio assessment [5]. The reasoning could be strengthened when the relevant behavior is observed multiple times in multiple environments, and its performance takes into account cognitive, motivational, ethical, and emotional aspects [6]. Therefore, it is necessary to integrate evidence from various assessment sources. Redecke [7] stressed that, according to the core literacy to determine different evaluation ways, computer-based testing, online testing, simplified game, and electronic portfolio played a crucial role in the core literacy assessment. Meanwhile, the school curriculum evaluation should strengthen the technical development and application of authentic situation assessment. The Program for International Student Assessment (PISA) emphasized three characteristics of the problem-solving definition: “authentic situation” rather than the abstract problem. The “nonobvious” of scientific problem-solving reflected the nonroutine of problem solutions. The “interdisciplinary assessment” draws on a wide range of problem-solving knowledge [1].

The level description of problem-solving is not based on the specific thought process. It focuses on situational complexity, authenticity, and strategies. Authentic situation tasks require presenting situations that reflect real challenges in an individual’s life and work, where students use scientific knowledge and skills, independent judgment, and creative collaboration to solve problems. The design of problem-solving tasks in [8] had carried out the computer management and human-computer interactive evaluation based on. An interactive task was added in which participants were designed to manipulate variables to determine the impact on the results [1]. NAEP has added interactive computer tasks and hands-on task sections since 2009. In hands-on tasks, students have to design scientific inquiry by themselves, select materials, and conduct an inquiry to solve problems and explain scientific phenomena [9]. Adopted the human-computer interaction mode, and the computer dynamically collected students’ data to complete authentic situation tasks. However, as PISA tried to avoid repetition with other literacy evaluations when designing the assessment of problem-solving ability, thus such questions rarely involve the subject background knowledge, which restricted the practical application of problem-solving competency assessment. The “authenticity assessment” is always associated with performance assessment. The competency to use knowledge can only be assessed when completing a job in response to a specific task by using our knowledge and skills. This evaluation method can fully reflect students’ competency, learning achievements, and extensive knowledge understanding [10]. According to the “authenticity evaluation” model, Chang [10] designed three different question forms to investigate students’ scientific cognition level when

studying ninth-grade students’ scientific literacy. These studies found that the “authenticity evaluation” model with different question forms was an effective method to evaluate students’ scientific literacy, among which “hands-on manipulation” significantly influences students’ evaluation results. However, cultivating students’ hands-on manipulation competency is often neglected due to time problems. Therefore, educators can improve their understanding of complex concepts by designing authentic situation models to reduce the gap between students’ knowledge learning and real life.

The development of big data and information technology [11–14] provides a reliable supporting tool for this research. Many studies have found that some eye movement parameters [15–17], such as fixation duration, fixation duration percentage, fixation frequency, regression frequency, and average pupil diameter, provided critical evidence to explore the psychological process of students. Tai [18] compared the eye movement differences in problem-solving behaviors of participants with different professional backgrounds in scientific evaluation and found that the eye movement differences were related to the participant’s professional level on a specific topic. Tsai et al. [19] investigated the eye movement differences of students with different professional backgrounds in PISA online assessment, and the study found that students majoring in science allocated more attention to critical areas and conducted deeper processing. Hu et al. [20] studied the information processing strategies of students in solving PISA interactive and analytical questions, which required self-discovery of information or provided a large amount of information in the questions. Students with good performance had a longer fixation duration in both questions. They tended to apply their previously constructed problem patterns to solve current problems, meanwhile adopting plan-driven forward reasoning to obtain more effective actions. Underperforming students switched their gaze points frequently between areas of interest and adopted “goal-result” backward reasoning, which required constant searching to reduce the difference between the current state and the target state. Krstić et al. [21] explored the students’ eye movement patterns in PISA reading evaluation and found that students with high scores paid more attention to relevant information in texts and pictures, while students with low scores lingered in texts and pictures instead of extracting essential information. Kaller et al. [22] found evidence to distinguish the processes using eye-tracking technology. The study showed that the initial fixation change and fixation duration did not change with the problem structure, suggested that the early eye movements generate mental representations of the starting state and the target state, and compared the two states to determine structural differences. The problem structure did not affect the initial fixation change. The final gaze shifted before the problem structure affected the execution phase, suggesting that fine processing was related to the final fixation change. In recent studies, Mobile Eye Tracker (MET) has been conducted to compare the visual attention characteristics widely, people’s cognitive process in authentic situation tasks allows participants to move their heads freely,

and their behaviors are not strictly restricted. For instance, participants can walk in the park [23] and complete the experimental task [24]. The applications of MET meet the needs of different topic formats in the evaluation, especially the hands-on evaluation format. In educational evaluation, using MET to study problem-solving helps reveal participants' strategies for acquiring information, making it possible for procedural evaluation. Bryan et al. [25] applied MET to the International Adult Competency Assessment (PIAAC). The study selected a computer-based technology assessment containing literacy, numeracy, and problem-solving modules, where participants may use a pen or calculator and interact verbally with the researcher. Off-screen eye movements were captured with MET to see how participants read and recognized information during problem-solving. In the experiment of physical concept learning, Chien et al. [24] proposed that hands-on manipulation was essential for laboratory learning. The previous studies showed the following: (1) More professional people showed more refined visual behaviors when performing tasks, paid more attention to areas related to actual tasks, and paid less attention to redundant areas [26]. (2) Studies on grouping participants according to their performance found that participants with higher achievement could not only effectively use previous knowledge [27] and identify task-related areas but also adopt more effective analysis strategies to gain relevant information [20]. (3) Eye movement indicators could predict students' evaluation performance. Studies have shown that successful problem solvers had smaller pupils on easy problems while larger pupils on complex problems [28]. Other studies have found that average fixation duration was the best predictor; students with longer average fixation duration showed deeper cognitive processing [27].

2. Purpose

This study designed a set of scientific problem-solving evaluation tasks in the authentic situation, including the paper evaluation and hands-on manipulation assessment. After completing the scientific knowledge task module presented on the computer, participants were required to complete three scientific problem-solving hands-on manipulation tasks. According to their scientific knowledge concept evaluation and previous comprehensive scores, the participants were divided into high and low groups. The differences in eye movement and cognitive process among different groups were explored. Eye movement tracking technology was used to record and collect the eye movement behavior of each participant, such as their average fixation time, fixation time percentage, average pupil diameter, fixation times in each task module, and the average fixation time and fixation time percentage in different areas of interest in each task module. The following research questions can be used as guidelines in pursuing this goal:

- (1) Would the high science achievement group perform better than the low science achievement group in the hands-on manipulation assessment?

- (2) When performing the hands-on manipulation assessment, would the high science achievement group allocate more visual attention than the low science achievement group?
- (3) What is the relationship between students' scientific problem-solving performance and eye movement behavior?
- (4) Could the eye movement behavior be used to predict students' performance in scientific problem-solving?

3. Methods

3.1. Participants. In this study, thirty-nine students from grade seven in Taicang No. 1 Middle School, Jiangsu Province, China, were randomly selected. The number of participants in the preliminary experiment was 7. The number of valid participants in the formal experiment was 27, and 5 were invalid participants, who were rejected because the rate of eye movement data did not reach 90%. There was no significant difference in age between the high and low science achievement groups ($n = 27$; between ages 12 and 13; $M = 12.66$; $SD = 1.09$; 15 males and 12 females). The students who participated in the assessment have studied the core science concepts covered. The scores of students' entrance science examination and core concept evaluation were weighted as the basis for grouping. The average score of 27 students was 56.78, and there was an extremely significant difference in the weighted average score between the two groups of students, $t_{(1, 25)} = 5.97$, $p < 0.001$. Twenty-seven students were divided into high and low science achievement groups based on their weighted average scores. There were 13 students in the high science achievement group but 14 students in the low science achievement group.

3.2. Design of Scientific Problem-Solving: Hands-On Manipulation Assessment. This study developed a science problem-solving assessment, "Energy Efficient House," to evaluate students' core science concept of "heat absorption and heat dissipation." Participants were required to make experimental hypotheses, build experimental platforms, obtain measured data, and form preliminary conclusions according to the experimental result. The hands-on manipulation assessment consisted of three task modules, which correspond to the problem-solving framework "exploration and understanding," "representing and formulating," and "planning and execution" proposed by OECD [1]. Students were required to read computer materials, learn assistance manuals, and operate experimental instruments.

Module one was the selection of experimental equipment, in which participants chose experimental equipment suitable according to the various equipment provided by the laboratory. Module two was the experimental design. Participants made the experimental hypothesis of the "relationship between color and heat absorption ability" and designed the experimental scheme based on the problem-solving orientation. Module three was to build the experimental model; after completing the preliminary

experimental design and equipment selection, participants needed to use experimental materials, sensors, and computer software to build an experimental model and then verify the hypothesis of “the relationship between object’s color and heat absorption ability” by using the measured data.

The assessment was designed based on the ECD (Evidenced-Centered Design) model and explored the students’ grasp of “heat energy” as the specific form of energy and conversion principle. Authoritative international science problem-solving assessments such as PISA, TIMSS, and NAP are based on paper or online text formats, while our research attempted to study hands-on science problem-solving processes.

The evaluation information presented on the computer was in well-constructed mixed text and composed of written web pages with paragraphs, tables, charts, and graphs organized in a mutually supportive and coherent manner. The computer was also equipped with experimental software adapted to the heat sensor, which was convenient for reading data from the sensor.

The experimental materials included a heating lamp, three metal heat absorption rods of the same material in different colors, an iron rack, a clamp, three-hole support, a pen, and a heat sensor. The usage of experimental equipment and sensors was described in the auxiliary manual, which was convenient for students to read. A team of four science education designers, consisting of two science teachers with master’s degrees in science education, a science education researcher with a doctoral degree, and a science education professor, was responsible for designing the overall science problem-solving assessment.

The online scientific problem-solving evaluation assessment platform runs on the Linux server. The core of the scientific problem-solving evaluation system was programmed in PHP and MySQL to process large data sets and analytical programs efficiently.

3.3. The Encoding Process. The response of all participants in the scientific problem-solving assessment was recorded in the database for analysis. Meanwhile, the experimenter recorded participants’ performance in the hands-on assessment for analysis. Three experimenters were all graduate students majoring in “educational technology” and “applied psychology.” The experts’ team developed a standard coding system and experimenter manual.

The coding system carried out detailed coding guidelines for the evaluation criteria of each question, such as how the principal tester scores the answers of each item and examples of answers that middle school students may have. Coding guidelines were developed according to the content of each module to ensure reliability and coding quality between encoders.

3.4. Eye Movement Analysis. Eye-tracking glasses 2 W were the instrument for participants to operate flexibly in computer-based scientific problem-solving assessment. The mobile tracking device designed and manufactured by the German company SMI recorded each student’s eye

movements at a 60 Hz sampling rate. It was a noninvasive system, as a standard pair of glasses weight 68 grams, with less impact on the psychological and physical burden of the students. The device was specially designed for the study of dynamic eye movement, and it provided maximum peripheral perception and binocular visual positioning to capture the natural gaze behavior of the students during the hands-on manipulation assessment. A standard three-point calibration and validation procedures were completed before the formal assessment. The following eye movement parameters were further analyzed from the original data to record participants’ completion duration, total fixation duration (TFD), average fixation duration (AFD), fixation duration percentage (FDP), and Z score of pupil diameter (PDZ). BeGaze™ software was used to analyze further each student’s eye movement parameters in scientific problem-solving assessment. Division of AOI in hands-on manipulation assessment is shown in Figure 1.

4. Results

4.1. Different Hands-On Assessment Performance between High and Low Science Achievement Groups. The independent sample *t*-test result for the high and low groups of students showed that the high science achievement group students significantly outperformed the low science achievement group in the total score of the hands-on task, $t_{(1, 25)} = 5.97$, $p < 0.001$, the first module, $t_{(1, 25)} = 3.34$, $p < 0.01$, and the second module, $t_{(1, 25)} = 4.36$, $p < 0.001$. However, there was no significant difference in the score of the third module, $t_{(1, 25)} = 1.25$, $p > 0.05$.

4.2. Differences in Eye Movement Behavior between High and Low Science Achievement Groups in Hands-On Manipulation Assessment. Two-factor repeated measure ANOVA results among three modules in the assessment and the eye movement indexes furthermore conducted the simple effect analysis of the three modules and different scientific achievements, as shown in Tables 1–3. Tests of within-subjects effects on the module are shown in Table 1, and tests of between-subjects effects on group are shown in Table 2. The results of the simple effect analysis of different group students on FDP, AFD, and PDZ are shown in Table 3.

The main effect of the three modules on the FDP was highly significant, $F_{(2, 50)} = 11.11$, $p < 0.001$, $\eta^2 = 0.31$. The main effect of scientific literacy on FDP was significant, $F_{(1, 25)} = 7.95$, $p < 0.01$, $\eta^2 = 0.24$. The edge of interaction between scientific literacy level and hands-on assessment was significant, $F_{(2, 50)} = 2.53$, $p = 0.090$, $\eta^2 = 0.09$. During three modules of hands-on manipulation assessment, the result revealed that the high science achievement group allocated more visual attention to the task and more access to information through visual gaze than the low scientific achievement group, including FDP_{module1} , $F_{(1, 25)} = 1.87$, $p > 0.05$, AFD_{module1} , $F_{(1, 25)} = 1.32$, $p > 0.05$, PDZ_{module1} , $F_{(1, 25)} = 8.21$, $p < 0.01$, FDP_{module2} , $F_{(1, 25)} = 6.42$, $p < 0.05$, AFD_{module2} , $F_{(1, 25)} = 5.10$, $p < 0.05$, PDZ_{module2} , $F_{(1, 25)} = 6.99$, $p < 0.05$, FDP_{module3} , $F_{(1, 25)} = 6.92$, $p < 0.05$,

$AFD_{module3}$, $F_{(1, 25)} = 4.96$, $p < 0.05$, and $PDZ_{module3}$, $F_{(1, 25)} = 1.89$, $p > 0.05$.

4.3. Differences of AOI in Eye Movement Behavior between High and Low Science Achievement Groups in Hands-On Manipulation Assessment. The two-factor repeated

measurement ANOVA and multiple comparison test conducted on the FDP of AOI between the high and low groups and the key areas of each module were shown in Table 4. In module one, the FDP of the high group was significantly higher than the low group on the key auxiliary manual area, $F_{(1, 25)} = 10.02$, $p < 0.01$. In module two, the FDP of the high group was significantly higher than the low group on the key

TABLE 4: The key area of each module in hands-on manipulation assessment.

Stage of module	Auxiliary manual area	Worksheet area	Experimental area
Module one: Selection of experimental equipment	+		
Module two: Experimental design		+	
Module three: Build the experimental model			+

worksheet area, $F_{(1, 25)} = 7.40$, $p < 0.05$. In module three, the FDP of the high group was significantly higher than the low group on the key experimental area, $F_{(1, 25)} = 8.73$, $p < 0.01$.

4.4. The Correlation and Regression Analysis of Students' Eye Movement Behaviors and Scientific Problem-Solving Performance. The results of the Pearson correlation analysis, which was conducted to explore the correlation between students' eye movement behavior and scientific problem-solving performance, indicated that students' scientific problem-solving performance was highly correlated with their eye movement behavior, including cFDP ($r = 0.56$, $p < 0.01$), aAFD ($r = 0.77$, $p < 0.001$), cAFD ($r = 0.86$, $p < 0.001$), and bPDZ ($r = -0.97$, $p < 0.001$). In addition, a stepwise multiple regression analysis was used to assess which eye movement indicators could best predict students' scientific problem-solving performance. The results showed that aAFD and bAFD were the most significant predictors of eye movement when participants completed the scientific problem-solving task, as shown in Table 5, $T = -2.43$, $p < 0.05$, $\beta = -0.66$; $T = 2.31$, $p < 0.05$, $\beta = 0.48$.

The regression equation of Model one was

$$Y = 16.78 - 21.75aPDZ + 37.62cPDZ - 0.22aAFD + 0.05bAFD + 0.07cAFD. \quad (1)$$

The study compared the prediction result with students' hands-on manipulation performance; the prediction success rate for high science achievement students was 84.6%, but 78.6% for low science achievement students, and the total prediction success rate was 81.5%. In conclusion, the AFD and PDZ in the three modules of hands-on manipulation assessment could better predict the students' scientific performance. What is more, if the AFD of students was lower in module one but higher in module two, the student's scientific performance may be better.

4.5. The Correlation and Regression Analysis of AOI Index and Scientific Problem-Solving Performance of Students. The results of Pearson correlation analysis showed that students' AOI was highly correlated with their scientific problem-solving performance, including a2AFD ($r = 0.81$, $p < 0.001$), b1AFD ($r = 0.62$, $p < 0.001$), b3AFD ($r = 0.63$, $p < 0.001$), and c3AFD ($r = 0.7$, $p < 0.001$), as shown in Table 6. In addition, a stepwise multiple regression analysis was used to assess which AOI indicators could best predict students' science problem-solving performance. The results showed that b1AFD and c2AFD were the most significant predictors of AOI when participants completed the scientific problem-solving task, $T = 2.92$, $p < 0.01$, $\beta = 0.75$; $T = -2.60$, $p < 0.05$, $\beta = -0.60$.

TABLE 5: Standard multiple regression for eye movement indexes on scientific achievements.

Parameter	B	SE	β	T	Tolerance	VIF
Constant	16.78	37.60		0.45		
aPDZ	-21.75	13.20	-0.43	-1.65	0.40	2.52
cPDZ	37.62	26.73	0.37	1.41	0.40	2.47
aAFD	-0.22	0.09	-0.66	-2.43*	0.36	2.75
bAFD	0.05	0.02	0.48	2.31*	0.64	1.56
cAFD	0.07	0.04	0.43	1.70	0.43	2.32

*a stands for module 1, b stands for module 2, and c stands for module 3.

TABLE 6: Standard multiple regression for AOI on scientific achievements.

Parameter	B	SE	β	T	Tolerance	VIF
Constant	82.36	18.60		4.43 * * *		
a1AFD	-0.08	0.05	-0.49	-1.68	0.27	3.67
a2AFD	-0.09	0.13	-0.23	-0.66	0.18	5.49
a3AFD	0	0.02	0	0.01	0.72	1.39
b1AFD	0.04	0.02	0.75	2.92* *	0.35	2.88
b2AFD	0.01	0.02	0.09	0.42	0.49	2.06
b3AFD	0.03	0.03	0.19	0.88	0.48	2.09
c1AFD	-0.01	0.02	-0.07	-0.37	0.59	1.70
c2AFD	-0.10	0.04	-0.60	-2.60*	0.43	2.35
c3AFD	0.05	0.03	0.38	1.54	0.38	2.66

*a1 stands for the auxiliary manual area in module 1, a2 stands for the worksheet area in module 1, a3 stands for the experimental area in module 1, and so on.

The regression equation of Model two was

$$Y = 82.36 - 0.08a1AFD - 0.09a2AFD + 0.04b1AFD + 0.01b2AFD + 0.03b3AFD - 0.01c1AFD - 0.10c2AFD + 0.05c3AFD. \quad (2)$$

The study compared the prediction results with students' hands-on manipulation performance; the prediction success rate of Model two for high science achievement students was 69.2%, but 92.9% for low science achievement students, and the total prediction success rate was 81.5%. Model two could explain 61% of the variability in student performance during the same overall success rate as Model one. Therefore, Model two could better predict the students' scientific performance. According to the significance index, if the AFD on the worksheet was higher in module two experimental design, while the AFD on the auxiliary manual was lower in module two experimental model building, the students' scientific performance may be better.

5. Discussion

The comparison of eye movement behavior between the high and low science achievement groups.

The study showed that the high science achievement group performed better than the low science achievement group in the hands-on manipulation performance, while eye movement behavior also showed that FDP and AFD were higher in the high science achievement group. One possible explanation was that high science achievement students allocated more visual attention in the hands-on manipulation assessment, more concentrated, and acquired information through visual gaze to a greater extent, while low science achievement students were more distracted by external factors when completing the task. Goldhammer et al. [29] pointed out that, in problem-solving tasks, the more time students spend on the task, the better they perform. In addition, they found the effect of time depended on the difficulty and intensity of the task, especially in the more difficult tasks; investing time in cognitive activities had a positive predictive effect on the successful completion of the task. The result of this study was consistent with previous studies that high science achievement students had higher fixation duration and were more concentrated.

The total fixation counts of high scientific achievement students were lower in module two experimental design and module three experimental model building. High science achievement students allocated more fixation duration and average fixation duration and fewer fixation counts in the cognitive processing, which were consistent with previous studies that students with longer average fixation duration tend to show deeper cognitive processing and better learning results. Students with high science achievement were more likely to be aware of the tasks' difficulties, especially representation, refinement, and execution. Thus, they took longer to think profoundly and achieve higher accuracy. These findings provided great support to several previous studies suggesting that high-level problem-solving students had deeper cognitive processing of task-related areas. They tended to apply their previously constructed mental models to solve problems, while low-level problem-solving students have not established a correct mental model due to their shallow cognitive processing of the critical areas in a problem-solving task. Thus, they reevaluated the consistency of the established model with the problem task by using the visual information of the auxiliary areas [30].

In the hands-on manipulation assessment, the high science achievement group had a higher PDZ than the low science achievement group, consistent with previous studies that individuals showed more significant pupil dilation when handling complex tasks [31]. Pupil dilation reflected individuals' continuous information processing, and challenging tasks would elicit more cognitive effort. In this study, the average pupil diameter of students was maximized in module three, which was the most challenging module. However, our results indicated no statistically significant difference between the high and low science achievement

groups in module three, and one possible explanation was that students in both groups made more cognitive efforts in module three.

5.1. Comparison of AOI between High and Low Science Achievement Groups. The results showed that students with high science achievement assigned more visual attention to the auxiliary manual in module one, which was the key area of this module. Meanwhile, they allocated more attention to the key experimental area in module three, consistent with previous research that high-level students paid more attention to the task-related areas. In the hands-on manipulation assessment, the worksheet area and auxiliary manual area belong to the visual mode information of text or pictures, while the experimental area belongs to the tactile channel mode. The comparison between the two groups revealed that the high science achievement students had a statistically significant change in the problem-solving process from relying on visual channel mode to tactile channel mode. Particularly in module three, high science achievement students relied more on experimental areas and produced more hands-on behaviors.

The fixation sequence of the AOI revealed that high science achievement students showed more continuous cognitive processing in the key areas. In module three, the low scientific achievement students' gaze of interaction frequently switched between the key experimental area and auxiliary areas. The eye movement index reflected that the low science achievement students allocated more fixation duration in auxiliary manual area, which meant they could have recognition difficulty in experimental model building. The findings of students' cognitive processing were consistent with previous studies, and high-level problem solvers could deeper conduct cognitive processing of task-related areas [32].

5.2. Eye Movement Behavior Predicted Students' Scientific Problem-Solving Performance. The regression prediction model showed that the AFD and the AFD of AOI were the best indicators to predict students' performance in scientific problem-solving performance assessment. The finding added to previous evidence that eye movement was highly correlated with mental effort, reading processes, computer-based assessment of performance, and the construction of mental models. Students may perform better if they engage in deeper cognitive processing on relatively difficult tasks. In solving systematic experimental problems, if students could think profoundly and construct psychological models gradually, their evaluation performance may be better. These findings have implications for how eye-tracking-supported hands-on manipulation science problem-solving assessment could be used to improve science learning in junior high school students. In order to cultivate and improve students' scientific literacy, educators should pay more attention to students' cognitive process and deep thinking in science teaching and design high-level cognitive activities to achieve this goal. For instance, to establish a complete practice, encourage students to explore learning. The practice should

be set up as realistic as possible, regarded as solving problems in real life. When designing the practiced mask, we could start from the eight links of “asking questions, making assumptions, making plans, collecting evidence, processing information, drawing conclusions, expressing and communicating, and reflecting and evaluating.”

In the practice of student inquiry, educators could use prominent hints to guide students to think deeply about key information and difficult problems rather than repeatedly thinking superficially. The guidance and intervention in practice would shape students’ thinking and behavior patterns, relieve their anxiety when meeting practical problems, and improve students’ problem-solving ability. However, solving practical problems depends not only on the ideas and skills of the problem solver but also on the difficulty of the problem itself. Therefore, the significance of setting up practical exploration lies in improving students’ problem-solving ability on the one hand and guiding students to see the boundaries and limitations of problem-solving and recognize the future development direction of a specific field on the other hand, which has more excellent value in improving students’ cognitive level and scientific literacy.

6. Conclusions

This study specifically designed an eye-tracking supported problem-solving assessment hands-on manipulation task system to further explore the differences in visual attention and cognitive progress between high and low science achievement groups in the scientific problem-solving process. The research combined synchronous computer and pupil 60 Hz tracking system technology with a hands-on manipulation assessment system to explore the students’ cognitive processes in hands-on operation. The system included static concept evaluation problems and dynamic hands-on problems instead of being limited to reading and solving cognitive model exploration in static problems. These results are also very encouraging as they demonstrate some important findings. (1) Students in the high science achievement group performed better than those in the low science achievement group in solving scientific problems assessment, consistent with their eye movement behavior. (2) The results of ANOVA in eye movement indicator showed that, in the three modules of hands-on manipulation assessment, students with high science achievement had more fixation and concentration on the task and acquired more information through visual fixation. In contrast, students with low science achievement were more likely to be distracted by external factors when finishing the assessment. (3) ANOVA results in the AOI index showed that students with high science achievement paid more attention in key areas during different modules. In addition, students with high science achievement had a more noticeable change from relying on visual channel mode to relying on tactile channel mode in the problem-solving process. Particularly in module three, the execution phase of problem-solving, students with high science achievement paid more attention to the experimental area, which produced more operation behavior. These results were consistent with their eye

movement behavior. (4) Eye movement behavior was highly correlated with scientific problem-solving performance. (5) Eye movement behavior could predict students’ performance in scientific problem-solving. The AFD and the AFD of AOI were significant determining parameters.

The highlights of this work are summarized as follows:

- (1) This study specifically designed an eye-tracking supported scientific problem-solving assessment: hands-on manipulation task system to explore the differences in visual attention and cognitive processes between high and low science achievement groups.
- (2) The result showed that the high science achievement group allocated more visual attention to the hands-on manipulation task, acquired more information through visual fixation, and assigned more attention to the key area than the low science achievement groups.
- (3) The study also found that the average fixation duration and the average fixation duration of the AOI were two significant determining parameters for predicting students’ performance in scientific problem-solving. [33–39]

The equipment information in the regional energy system is difficult to retrieve and the amount of data is too large to realize intelligent application. In order to solve the problem, this paper proposes a regional energy visualization research method based on knowledge graph. Firstly, the collected regional energy information is classified. Secondly, the framework is defined for the unstructured data, which is difficult to be recognized by computer, and the hidden Markov model is used for word segmentation and labeling. Finally, the regional energy equipment information data are processed to construct the knowledge graph, the regional energy map structure information is represented by the ternary group graph structure, and the regional energy retrieval system is designed. The system can efficiently process and retrieve a large amount of natural language information in regional energy and realize the intelligence of regional energy equipment. It provides a strong guarantee for the efficient and stable operation of regional energy-related equipment and has a wide range of practical application and research value.

1. Introduction

District energy systems are local energy networks through which it is used to supply hot water, steam (district heating), cold water (district cooling), electricity (often called microgrids), or integrated supply to complex buildings. In the daily construction and operation of regional energy system, a large number of equipment parameters and operation data are accumulated, but the corresponding information is often idle in the system, which affects the data value discovery of regional energy system. With the increase of equipment information, how to retrieve equipment information efficiently is of great significance to the staff of regional energy system. However, the complexity of regional energy system equipment makes it difficult to accurately retrieve equipment information [1].

- (1) The primary equipment information of the regional energy system is described in the form of natural language, which increases the difficulty for the computer to understand the equipment information,

and the complexity of the equipment information causes great difficulties for the accurate retrieval of the information;

- (2) The intelligence degree of the primary equipment information management is not enough and it cannot select useful information to utilization from a large number of monitoring data and historical data.

The continuous development of artificial intelligence technology, the Internet of Things, and other technologies provides a new direction for the intelligent management of regional energy system equipment information [2]. Natural language processing (NLP) is an intelligent and efficient text processing technology that can systematically analyze, understand, and extract key information from text data. As for the equipment information corpus of regional energy system, literature [3, 4] expresses the text by establishing semantic framework, but the semantic framework is difficult to adapt to the complex information situation of power equipment [5], and the framework relies on the definition of expert experience, so it is difficult to comprehensively

consider the complex expression mode of equipment of regional energy system. Literature [6, 7] uses machine learning algorithm to mine rules in corpus to represent features of corpus. However, the features selected by machine learning methods are basically limited to the occurrence of keywords [8] or the occurrence frequency of words [9]. These statistical features do not fully consider the internal logic of keywords in sentences, although they have certain regularity, they are easily limited to the textual features of defect records, which is not enough to explain. With the continuous development of intelligent regional energy system strategy, the equipment information of regional energy system increases exponentially, and the requirements for information storage and retrieval are higher and higher. As a kind of efficient database, knowledge graph can manage regional energy system equipment information effectively and provides a new way for regional energy equipment information management. Different from the traditional literature review [10–13], the literature knowledge graph can extract and screen structured knowledge sequences from a large number of literature data, then show the evolution process of research hotspots and map the cross-interaction between knowledge groups, so as to realize the mining of hot spots and emerging trends. At present, common mapping tools include CiteSpace [14], etc., which provides an efficient, repeatable, and rapidly applied analysis method for scholars and has application prospects in various fields.

Therefore, this paper tries to apply the knowledge graph method to the primary equipment information management of intelligent area energy system. Firstly, the data collected by the intelligent regional energy system information collection platform are classified. Secondly, considering that the unstructured data are difficult to be accurately recognized by the computer, the unstructured data extraction framework is defined, and the hidden Markov model is used to classify and annotate the collected data, providing data support for the construction of the primary equipment information knowledge map of the regional energy system. Finally, the knowledge graph of regional energy system is constructed on this basis, the regional energy system information is represented in the form of ternary group graph structure, and the primary equipment information retrieval system of regional energy system is designed. The system can effectively improve the retrieval efficiency of regional energy system equipment information and improve the intelligence level of regional energy system.

2. Regional Energy Data

2.1. Data Sources for Regional Energy Systems. Data sources of regional energy system mainly include original data, internal data of each automation system in the regional energy system, fault error recording information, and data obtained from monitoring of the surrounding environment [15]. The primary equipment of the regional energy system is directly connected to the high voltage grid of the power system and participates in the transformation, transmission, and distribution of power energy. There are many

kinds of primary equipment in regional energy system, including transformer, circuit breaker, disconnecting switch, and other related equipment. Transformer is the main equipment for the conversion of AC power energy in the power system. It can realize the conversion of power energy between different voltage levels, so as to facilitate the connection of the power system and optimize the transmission of power energy. Transformer data not only include voltage, current, active power, reactive power, phase, and other data, but also include transformer online monitoring data, chromatographic data information, and also include the proportion of dissolved gas in power transformer insulation oil and gas production data information [16]. These data parameters constitute the main components of power transformer data.

The circuit breaker is an important piece of equipment to connect or disconnect the equipment of the power system. It is equipped with relatively perfect arc extinguishing device and has the ability to disconnect the current of the power system. The circuit breaker can change the connection relation of the power system and adjust the power flow according to the demand when the system is running normally. In the event of a system failure, a circuit breaker can disconnect the fault current and cut off the electrical connection between the faulty device and the system. The operation information of circuit breaker is important reference data for daily operation and management of regional energy system.

Switching equipment in regional energy system has the characteristics of high air tightness and good sensitivity, and many parameters such as moisture content and contact temperature of gas-insulated composite electrical equipment are important parameters that need to be monitored online. The GIS online monitoring system mainly monitors two types of data, one is the density of sulfur hexafluoride gas, the other is the water content generated when a small amount of water enters the monitoring system as SF₆. The partial discharge monitoring system the of GIS online monitoring system can monitor the defects such as conducting small particles and some alien substances, conducting current, internal air gap, and blocked grounding brought into the equipment during manufacturing, installation, and maintenance. GIS real-time system can determine the location of hidden danger by collecting different location information. By using sensors to collect temperature information inside the equipment, GIS high-speed optical fiber temperature measuring instrument can quickly and accurately obtain the temperature information inside the equipment. The data generated by the common primary equipment in the area energy system, such as isolation switch, grounding switch, capacitor, reactor, and transformer, plays an important role in the maintenance and fault diagnosis of the area energy system.

Environmental monitoring data are also of great significance to intelligent regional energy system data. The micrometeorological monitoring system of the intelligent regional energy system can regularly collect environmental data around the intelligent regional energy system, including air humidity, haze information, and other data.

2.2. Regional Energy System Data Classification. In order to facilitate the operation of data collection and processing, it is necessary to classify and process the data of the smart district energy system. Among them, the data volume of primary equipment is huge and diverse, and the related similar data can be roughly divided into five types for cluster analysis, namely, basic data, online monitoring data, operation data, test data, and accident data.

- (1) Basic data: basic data refer to the ledger and design parameters of the primary equipment. The data are usually complete and accurate. Including the basic parameters of power equipment information, such as rating, power, size, manufacturer, and date of production. These data are permanently stored in the power equipment database and the other data are the flow data of the equipment.
- (2) Online monitoring data: online monitoring data are the continuous or periodic automatic monitoring and detection of regional energy system equipment. It has the characteristics of high monitoring frequency and large data volume and can reflect the electrical, mechanical, and chemical characteristics of related equipment, such as the insulation oil chromatographic analysis of transformers and dielectric loss of capacitance bushing.
- (3) Operating data: operating data refer to written or electronic records obtained after a device is inspected according to the specified check content and period during a device running. Operation data reflect the specific operation of electrical equipment, such as current, voltage, active power, reactive power, and circuit breaker operation times.
- (4) Test data: test data can reflect the electrical, mechanical, chemical, and other properties of the equipment data and their specific value through the use of professional instrument test. Usually, equipment test data are obtained by the experiment after equipment power outage, such as DC resistance and insulation resistance, but it also includes in the case of equipment without power outage, far away from the equipment body data test, such as oil pressure value.
- (5) Accident data: when a fault occurs in the regional energy system, the accident data mainly refers to the data of the related equipment when the short-circuit accident occurs, such as the effective value and peak value of the short-circuit current and the waveform of the short-circuit current.

3. Regional Energy Information Processing Based on HMM Model

Vector representation of regional energy information is required before regional energy information processing. The common method is to use vector group form composed of 0 and 1 to represent regional energy information, but there are problems of dimensional disaster and data sparsity, and

association information in the same statement cannot be represented, which lead to word isolation [17].

In order to effectively vectorizing the associated relationship among fault information, word vector representation based on deep learning is adopted in this paper. The word vector is determined by calculating the distance between words, and the model is shown in Figure 1.

This method introduces word vector to construct probability model, and the formula is as follows:

$$\begin{aligned} p(s) &= p(\omega) \\ &= p(\omega_1, \omega_2, \dots, \omega_T) \\ &= \prod_{t=1}^T p(\omega_t | \text{context}). \end{aligned} \quad (1)$$

The words above are used to predict the words that may appear in the following paragraphs, and the hidden layer is used for nonlinear processing of the results. Finally, the corresponding probability value is obtained, and the maximum likelihood estimation is trained to obtain the word vector ω_t .

Variable regional energy information contains a large number of power system vocabularies but lacks the annotated corpus. Hidden Markov model (HMM) is used to process regional energy information. Each word in regional energy information has its own lexeme label. There are four kinds of morpheme labels in a sentence. B is the initial tag of the noun, M is the middle tag of the name, E is the end tag of the noun, and S is the single word tag. Each extracted information in the regional energy information record constitutes a corpus to be processed, and each word is labeled with lexeme. The word segmentation of regional energy information is summarized as A labeling problem. The word bit probability $\lambda = (\pi, A, B)$ of each word is obtained by HMM model, and the optimal labeling sequence is obtained by the Viterbi algorithm.

- (1) State transition probability matrix: state probability of regional energy information word sequence.

Here, B, M, E, and S are the sequence of input words, and P is the probability of conversion between each state.

$$A = \begin{bmatrix} 0 & P\left(\frac{M}{B}\right) & P\left(\frac{E}{B}\right) & 0 \\ 0 & P\left(\frac{M}{M}\right) & P\left(\frac{E}{M}\right) & 0 \\ P\left(\frac{B}{E}\right) & 0 & 0 & P\left(\frac{S}{E}\right) \\ P\left(\frac{B}{S}\right) & 0 & 0 & P\left(\frac{S}{S}\right) \end{bmatrix}. \quad (2)$$

- (2) Observation probability matrix: the probability of obtaining each observation value according to the current state.

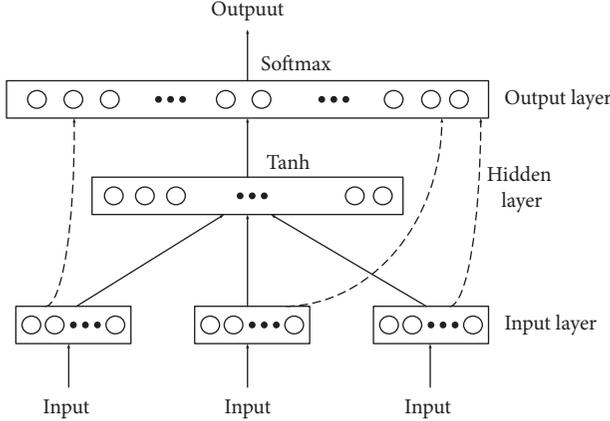

FIGURE 1: Word vector model.

Here, $P(o_n/Z)$ is the probability of the observed value, and o_n is the observed value.

$$B = \begin{bmatrix} P(o_1/B) & P(o_2/B) & \dots & P(o_n/B) \\ P\left(\frac{o_1}{M}\right) & P\left(\frac{o_2}{M}\right) & \dots & P\left(\frac{o_n}{M}\right) \\ P\left(\frac{o_1}{E}\right) & P\left(\frac{o_2}{E}\right) & \dots & P\left(\frac{o_n}{E}\right) \\ P\left(\frac{o_1}{S}\right) & P\left(\frac{o_2}{S}\right) & \dots & P\left(\frac{o_n}{S}\right) \end{bmatrix}. \quad (3)$$

- (3) State transition matrix: the probability of model transitions between states.

$$\begin{cases} S_t(i) = \max_{1 \leq j \leq N} [S_{t-1}(j)a_{ij}]b_i(O_t), \\ \phi_t(i) = \arg \max_{1 \leq j \leq N} [S_{t-1}(j)a_{ij}]. \end{cases} \quad (4)$$

- (4) Optimal state sequence of energy information in the output region.

$$\begin{aligned} i_t^* &= \phi_{t+1}(i_{t+1}^*), \\ I^* &= (i_1^*, i_2^*, \dots, i_T^*). \end{aligned} \quad (5)$$

i_t^* represents the shortest path of regional energy information sequence, and I^* represents the optimal state sequence of regional energy information vocabulary.

4. Construction of Regional Energy Knowledge Map

Regional energy information has the characteristics of multidomain cross fusion and complexity. Knowledge graph is a structured semantic knowledge base, which extracts knowledge from text data in a structured way and forms the network knowledge structure of visual graph by connecting with each other [18]. Graph databases provide a unique perspective by focusing on the relational relationships between data. They

can examine proprietary data from different perspectives and even connect it to external data resources to further reveal the underlying relationships. Using the node parallel mechanism of graph database can improve computing performance and, at the same time, storing data and knowledge in graph database to build knowledge map, which can help answer the data knowledge and query questions raised by people in natural language communication. In addition, semantic network is used to organically connect all the original regional energy data from different sources for deep mining, which can find the neglected or difficult to detect connections between different data [19].

The Neo4j graph database uses a high-performance engine to realize the visualization function, which can map entity-relationship-attribute to knowledge graph. This paper analyzes and stores the regional energy information through Neo4j graph database, finds the internal correlation of the information, and realizes the connection of equipment information.

The construction process of regional energy knowledge map is as follows:

- (1) To identify and define the professional field according to the characteristics of the electric power field to build the main power.
- (2) The regional energy corpus is processed by word segmentation. The security risk information is extracted and processed by word segmentation method. Then, the word segmentation results are tagged with part-of-speech tagging, and then the entities and attributes of each part are identified by naming. Due to the specialty and particularity of the words in the electric power field, the professional dictionary of the electric power industry is imported into the database as an auxiliary word segmentation tool. If the extracted entities and attributes match the words in the dictionary, the entities and attributes will be determined. In the specific field of regional energy, the knowledge graph of safety hazards belongs to the closed graph, so the entity disambiguation step is not required.
- (3) Knowledge processing: it mainly extracts the basic elements of the knowledge graph contained in the regional energy data, namely entities, relations and attributes, and the inherent hazards of hidden dangers of power equipment. Besides the entity-entity and entity-attribute relationships, it also needs to extract attribute-attribute relationships. Through the dependency syntax analysis of "subject-verb-object," "definite form complement" and other dependency relations among entities and attributes, and through the manual selection of labeling types of safety risk relations, the terms related to electric power safety regulations are divided in detail in order to form a corpus of safety risk relations. After the extraction of relationships, to avoid redundancy, semantic similarity calculation is used to screen redundant relationships [7] to improve processing performance.

- (4) Knowledge fusion: use Neo4j graph database [20, 21] to integrate the processed data, import entity-attribute-relation triplet of regional energy and load corpus, create relations and attribute matching among entities, form knowledge map of regional energy, and realize global index. Figure 2 shows the example of generating knowledge atlas of substation security risks. Then, the basic elements of the knowledge map are integrated, and the regional energy knowledge map is shown in Figure 3.
- (5) Knowledge update: with the continuous advancement of power system construction and the continuous operation of power system, the knowledge map of regional energy should be updated and amended to ensure the accuracy and effectiveness of retrieval based on the accumulation of fault information. The construction process of the regional energy knowledge map is shown in Figure 4.

The architecture design of regional energy knowledge atlas search engine is shown in Figure 5, which is mainly composed of data warehouse, service module, and application module. Data warehouse includes distributed management of elastic-block hidden metadata, Chinese word segmentation, index management, and logstash batch file import. After processing, the hidden data are submitted to the service module, where the elastic search service provides all sorting and read access, the data-offer service provides new data entries, and the security service provides permission control and security management. Then, the application modules are introduced, including hidden danger information input, retrieval display, and regional energy knowledge map display. The process of regional energy visualization system based on knowledge graph search engine is shown in Figure 2. The design steps of the regional energy knowledge map engine are as follows:

- (1) Build Django background processing framework, which is mainly used for page request forwarding and processing, as well as creating elastic search engine service module and HMM-VA word segmentation service module.
- (2) A front-end display platform based on vue.js is built, which is mainly used for the front-end display of background processing content, including regional energy retrieval information display, regional energy knowledge map generation, and statistical analysis functions.
- (3) Environment module is deployed on Ali Cloud. On CentOS system, Docker is used to deploy Django background, HMM-VA word segmentation service module, elastic search, Vue front end, and other requests, configure relevant parameters, and use them jointly.

According to the above steps, by inputting regional energy information and adding specific key information fields, such as “66 kV,” “substation,” “rainy day,” and other keywords, the 66 kV regional energy knowledge map can be

personalized and dynamically generated. The association search of the atlas can be used to analyze the types and causes of hidden dangers faced by all kinds of equipment, hazards after untreated results, possible treatment methods, violation of rules and regulations, prevention and control measures, etc.

5. Analysis of Experimental Examples

In this paper, regional energy data in recent three years are used as a data set to verify the effectiveness and practicability of the proposed method. The dataset contains information 1655 criteria. The hidden danger information is stored in the knowledge graph search engine by manual input and batch import. The proposed HMM word segmentation model is used for word segmentation processing of security hidden danger text. The validity of the proposed method is verified by the following four examples: comparison of regional energy data entity word segmentation methods; search engine information retrieval performance comparison; analysis of regional energy data cause knowledge atlas; and statistical analysis and prediction of regional energy data.

5.1. Comparison of Entity Segmentation Methods for Regional Energy Data. In this paper, the HMM model word segmentation steps, include corpus training, test set prediction, and word segmentation results. The power dictionary and regional energy data standard corpus of state grid corporation were used for pretraining, with a total of 150,000 words. The initial parameter information $\lambda=(\pi, A, B)$ was obtained by training the corpus in a supervised way instead of setting it as a fixed numerical parameter. The frequency of speech parts of energy data in each region was counted. The probability π can be calculated for the number of parts of speech and hidden speech of each region energy data and the corresponding words of the region energy data, and then the state transition probability matrix A and observation probability matrix B can be calculated.

Precision (P), recall (R), and F value, which are commonly used in entity word segmentation, were used as evaluation indexes to evaluate the word segmentation effect of regional energy data. Precision refers to the proportion of positive samples predicted by the model to positive samples in practice. The accuracy allows the classifier not to label negative sample errors as positive samples. Precision (P) is calculated in the following formula:

$$\text{precision} = \frac{TP}{TP + FP}, \quad (6)$$

where TP represents the number of entities in the test sample whose predicted category is positive and whose real category is positive. FP represents the number of entities whose prediction category is positive and real category is negative.

Recall rate refers to the proportion of positive samples that are predicted to be positive to positive samples that are actually positive. Recall rate can represent the ability of the

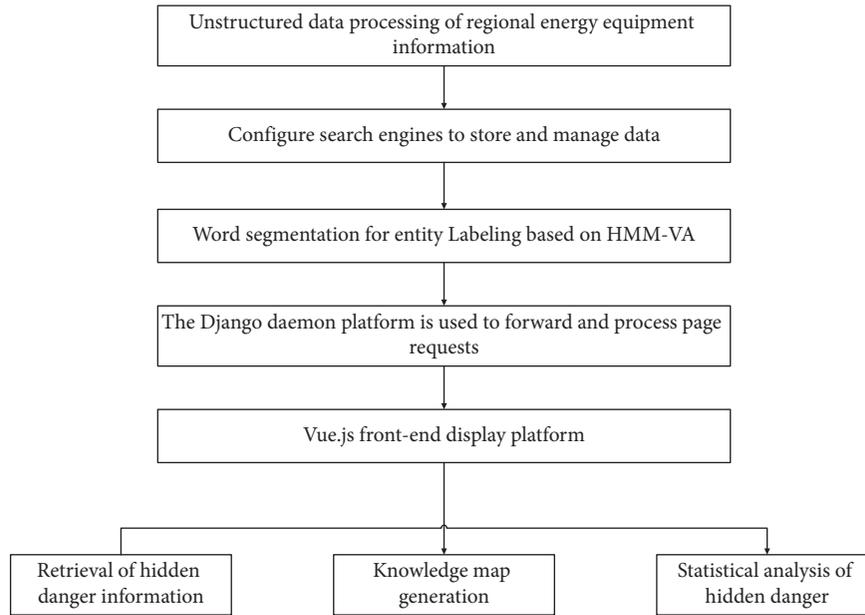

FIGURE 2: The process of regional energy visualization system based on knowledge graph search engine.

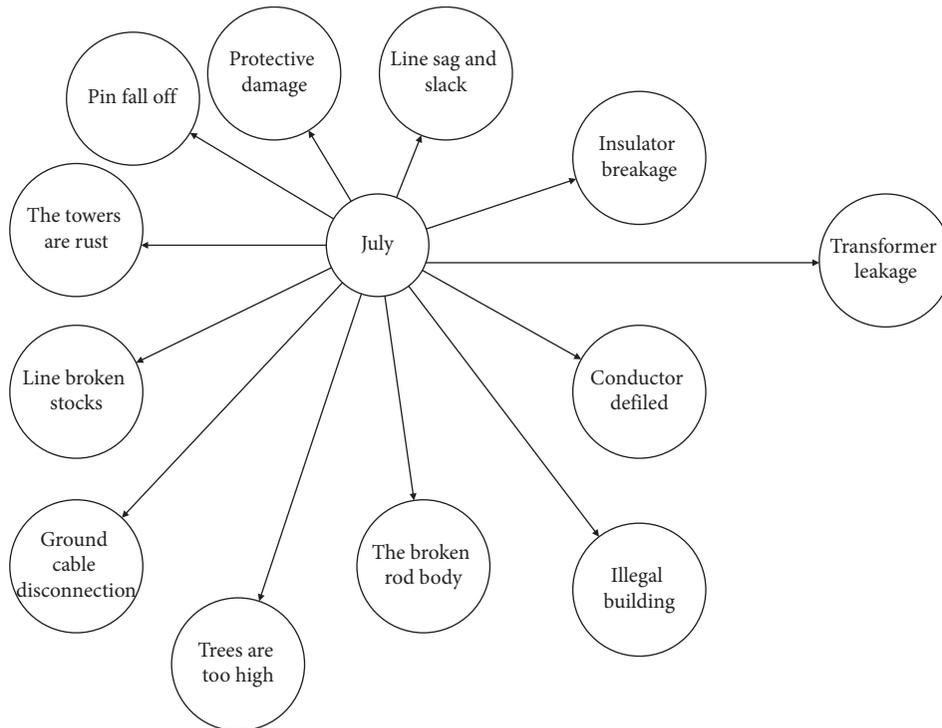

FIGURE 3: Knowledge Atlas of transformer Hidden dangers.

classifier to find all positive samples. The calculation of recall (R) is shown in the following formula:

$$\text{recall} = \frac{TP}{TP + FN} \quad (7)$$

where FN is the number of entities whose prediction category is negative and real category is positive.

The harmonic mean of accuracy and recall is the F score. The specific calculation of F value is shown in the following formula:

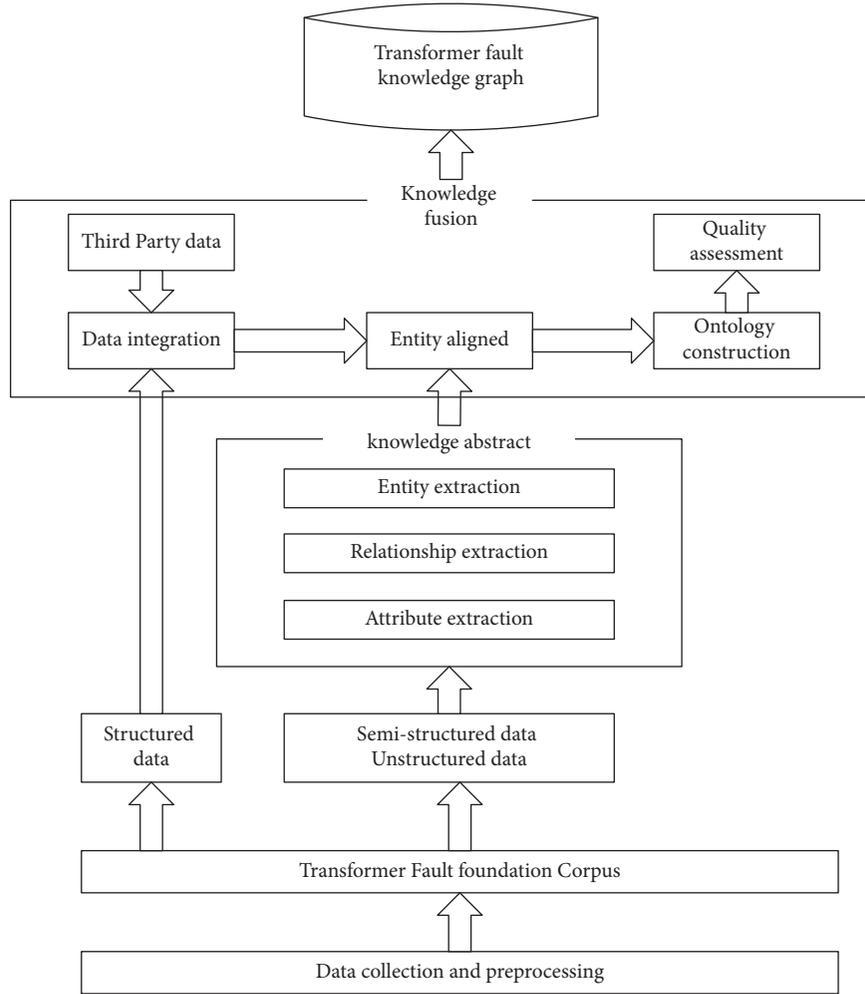

FIGURE 4: Knowledge graph construction process.

$$F = \frac{2 * \text{precision} * \text{recall}}{\text{precision} + \text{recall}}. \quad (8)$$

The comparison of different named entity word segmentation models is considered to verify the word segmentation effect of the proposed model. Models involved in the experiment include BM matching model [22], N-Gram word segmentation model [23], Jieba model [24], and HMM-VA model proposed in this paper. The above models were all carried out on the same training set and test set. Table 1 shows the comparison results of the test set in different named entity recognition models.

As can be seen from the experimental results in Table 1, the average performance of the HMM-VA regional energy data segmentation model proposed in this paper is 85.93%. Higher than Jieba model 5.81%, N-gram model 10.8%, and BM model 15.42%, respectively, and better than the other three entity word segmentation models in terms of accuracy, recall rate, and F value.

5.2. Information Retrieval Performance Comparison of Search Engines. The index performance of the system is measured by testing the index speed of standalone index [25], which is a

standalone search engine using the default configuration of elastic search, and distributed index, which is a 12-node distributed search engine designed and configured for the system. The test results for index performance are shown in Table 2.

As shown in Table 2, the elastic distributed search engine designed and configured in this paper is obviously superior to the standalone search engine in index efficiency indexes, such as average data rate, central processing unit (CPU) occupancy, memory occupancy (mem), and read/write rate (Io) and load rate, indicating that the proposed method can effectively improve the real-time performance of regional energy data index. It also meets the requirements of quick disposal efficiency in the investigation of hidden dangers in actual substations.

As shown in Table 3, for the search of the four test keywords, the average response time of the single machine is 1295.05 ms, and the average response time of the search proposed in this paper is 110.75 ms, indicating that the response time of the engine is significantly lower than that of the original single machine, which fully proves the advantages of the search engine in this paper. In addition, with the increasing of data volume, the processing advantage of the search engine for regional energy data is very significant.

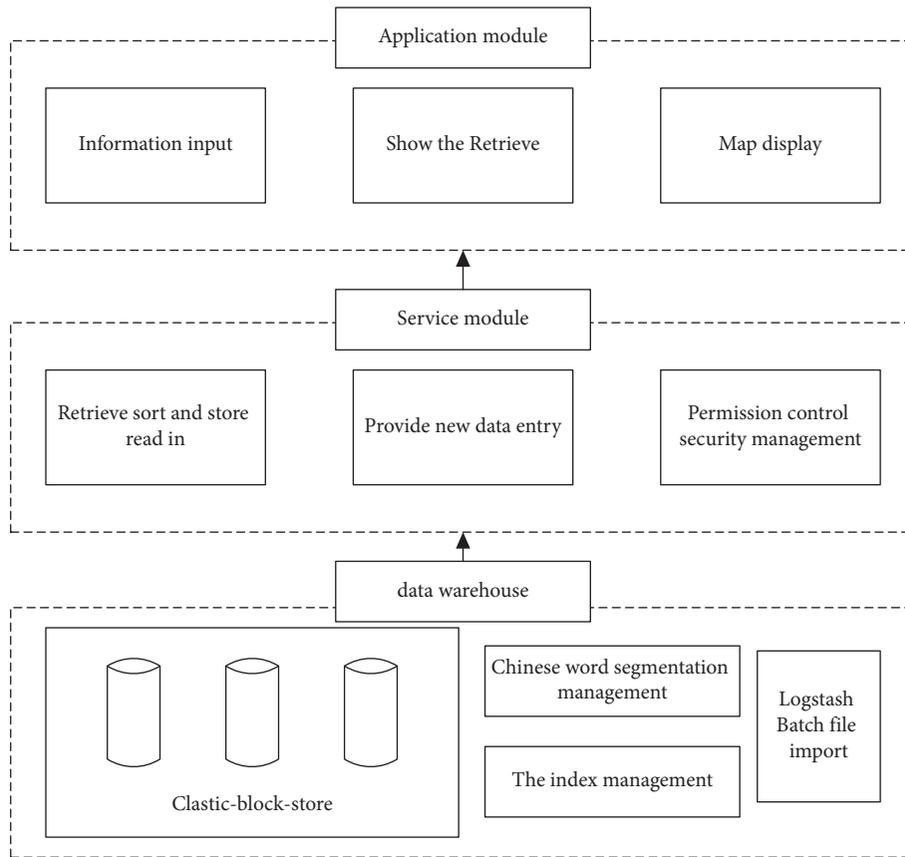

FIGURE 5: The architectural design of regional energy knowledge atlas search engine.

TABLE 1: Effect comparison of named entity recognition model.

Model	Precision (P) (%)	Recall (R) (%)	F score (F) (%)
BM matching	70.01	69.84	71.68
N-Gram word segmentation	76.77	74.27	74.35
Jieba model	81.52	80.31	78.54
HMM-VA	86.73	85.69	85.44

TABLE 2: Index test results.

	The average rate (thousand /SEC)	CPU (%)	Mem (%)	Io (%)	Load (%)
Single engine	6	57	63.6	90	43.1
The engine	39	14	16.5	41	18.7

TABLE 3: Search time test results.

Test key	Standalone search engine time (ms)	The system search response time (ms)
Substation	876	97
Rainy day	1438	161
Transformer	1389	84
Protection regulations	1479	101

6. Conclusion

This paper introduced technical knowledge map and flexible distributed search engine technology, this paper proposes a dynamic analysis method of regional energy data, through the research of regional energy data, distributed storage security hidden danger, to build knowledge map and analysis, has realized the knowledge map visualization display of search engine, and the safe hidden trouble efficiently retrieve and correlation analysis. It has good practical application value and promotion value. In the following research, more corpus features will be extracted in the relational extraction step to improve the accuracy of knowledge graph construction, so as to improve the analysis effect of regional energy data.

With the comprehensive coverage of the Internet in China, the online learning space can basically cover the whole country, but in terms of the use of online learning space in education, it has not been fully used. The basic application mode of the school, namely, autonomous learning, flipped classroom learning, collaborative learning, exchange, and discussion learning, and personalized learning mode, based on flipped classroom learning and relying on network learning space, design the corresponding English teaching process based on network learning space, according to the teaching process, the specific design of the platform, content, organization, implementation, and evaluation. From the research results, the students in the experimental class are more active and active in class than in the control class, their work scores are generally higher than those in the control class, and their interest in English has been significantly improved. The ability has also been significantly improved. After long-term practical research, it has been shown that the performance of the experimental class students in the online learning space has also been significantly improved. Therefore, it can be shown that the English course based on the network learning space has a certain positive influence and promotion effect on the teaching effect.

1. Introduction

With the continuous addition of new educational concepts and technologies, how to use modern information technology to provide services for learning and teaching has become the current focus. The continuous informatization and networking of high-quality resources has gradually increased the use of online teaching resources to assist teaching in junior high school English teaching. Rooted in the characteristics of junior high school English teaching, the use of online learning space in junior high school English teaching helps classroom teaching to show the superiority of modern educational methods. During the “Thirteenth Five-Year Plan” period, efforts will be made to promote the informatization of education, use modern information technology to complete the sharing of high-quality resources, focus on the breadth and depth of the application of online learning space, and gradually complete the concept of having a space for life and unique space for life. By 2022, the

system will fully popularize the online learning space, integrate the use of information technology to solve practical puzzles in education and teaching, and complete the teaching application, management, and governance supported by the space, making it the norm. It will continuously promote teachers' use of online learning spaces, workshops, training communities, and other tools, use online resources, integrate offline discussions, complete the creation of “technological innovation classrooms,” improve the use of information technology to analyze learning conditions, improve teaching, design, guidance on learning methods, and evaluation of academic performance and other diverse abilities and qualities, resolve difficulties in education and teaching, meet children's individual development needs, and help the school to carry out teaching innovation. From the perspective of teaching application, the deep integration of online learning space and English subject teaching has changed the traditional teaching mode. The use of online learning space in school education and home-school

coeducation helps to train talents' information literacy and promote educational information. To move forward, it is essential to strengthen and improve basic education informatization in junior high school English teaching and optimize its process. Therefore, with the support of online learning space, teachers and students have the opportunity to have a personalized online environment. Applying the online learning space to the real English subject teaching not only shows the idea of combining information technology with the subject but also becomes one of the important guides for applied research in the future [1–8]. This study takes English as the subject background. Through the analysis of the online learning space and the exploration of the online learning platform, it comprehensively considers how to integrate the diversified functions of the online learning space with the English teaching of junior high school and selects the appropriate teaching content. The junior high school English teaching based on the main functions of the online learning space is designed and implemented in the classroom. After that, interviews are conducted with students and teachers, and the results of the application are compared and analyzed according to the students' pre- and posttest scores in the experimental class in order to optimize the application of the online learning space in junior high school English teaching and provide support for its follow-up implementation in H Middle School, so that it can truly exert its advantages, effectively improve the quality of English education and teaching, and further promote the sharing of high-quality resources.

2. Related Works

There are foreign studies on the existence of online learning space to analyze. Regarding the current research situation abroad, in 2005, the design scheme of learning space and its technical configuration mentioned by American scholar Brown is very representative. Brown agrees that, compared with traditional learners, new learners pay more attention to interactivity and participation in experience. He encourages the design of corresponding learning modes and learning spaces based on the characteristics of learners themselves, and the design of the learning space and the configuration of technology should be considered according to the characteristics of new learners. After summarizing the relevant research on new learners, Brown proposed that they have characteristics such as “group activity tendency, goal and achievement orientation, multitask orientation, and high dependence on the network.” Taking these characteristics as a reference, they provide a variety of corresponding learning. In 2010NETP (National Educational Technology Program), the United States mentioned the learning model assisted by technology support and the learners who use it. Having the construction paradigm existing in the personalized online learning space, which provides the information management, communication, and knowledge construction tools that learners need and integrates every learning participant into the space to form an online learning community, the University of Minnesota created an active classroom for the first time; in 2008, the British Joint Information Systems

Committee issued the “21st Century Learning Space Design Guidelines” and said: “In order to meet the needs of two different teaching methods, teacher-centered and student-centered, building a technology-rich learning environment is an important research trend in learning space, and learning space must also be the focus of future research.” In 2008, this framework focuses on how the virtual learning space supported by information technology plays a special role in teaching method reform and improving teaching efficiency. The first idea was proposed by the Norwegian University of Science and Technology; based on the problem-based learning model, Cindy divides the learning space into two types: problem space and related concept space. However, the above literature on learning spaces focuses on physical space design. The research on online learning space in foreign countries is gradually growing on the online learning platform, and the foreign online learning platform has become a universal and mature learning resource; especially in the United States, most schools have installed official learning websites, these websites can cover the whole school, and students and teachers within the school can learn through the network platform anytime, anywhere. [9–17].

3. Related Theories and Technical Methods

3.1. Vue.js Framework. Vue.js technology framework is a very convenient and powerful framework for front-end web design and development, and its essence is the JavaScript MVVM library. Vue.js is a lightweight front-end framework, Vue. The performance of js is very high, with fast data rendering speed. In addition, Vue.js technical framework provides many simple instructions and APIs for users to learn the front-end framework and can also efficiently build a relatively complete front-end page. Vue uses a simpler template for data rendering, which is closer to the native code mode. The development mode is also relatively simple and convenient, and it also provides tools for rapid development of projects, which is conducive to the analysis and analysis of later development personnel. Code maintenance and updates: the ViewModel of Vue is responsible for the two-way data binding and data monitoring of the database and the real DOM. The real DOM monitors the data at the ViewModel layer and transmits it to the database, and the data of the database monitors the monitored data in the view. The model layer performs two-way binding of data, passes it to the virtual DOM, and then obtains the real DOM to form a closed loop of DOM rendering [18]. The rendering process is shown in Figure 1.

In addition, the two-way data binding of Vue.js also plays an important role in the development of our project platform. Generally speaking, the data binding process of Vue.js is that the user enters data in the view interface. The view layer can bind data to both the view model layer and the model layer. After binding, the data is paired at the model layer. Data is bound to each other. This feature of Vue.js makes it easier for developers to run and maintain the system later, making the management of data state changes very simple and convenient [19]. The two-way data binding process is shown in Figure 2.

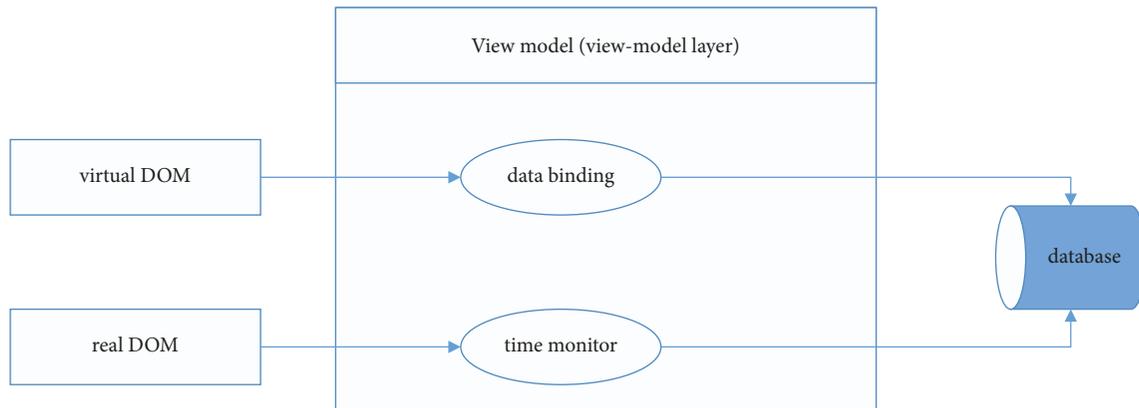

FIGURE 1: Rendering process.

The most prominent feature of Vue.js is that it has easy-to-manipulate components, and it is also the most used feature of the Vue.js framework. It can not only extend HTML but also encapsulate and reuse code to improve software development efficiency. Vue.js components come in four flavors, including global components, local components, nested components, and single components. Generally speaking, we most often use the form of global components. All global components in Vue can be used in all js instances, and the life cycle of use is relatively long. You can reuse the developed source code, develop new projects, expand the use of code, save development time, improve development efficiency, and save development costs.

3.2. Markdown Language. Markdown is a lightweight markup language that can easily and quickly write documents in various formats. Markdown is now a markup language commonly used by many international editors and writers. Compared with the HTML markup language, its language syntax is very simple, easy to learn, and the easiest to use. Editing various documents with markdown notation allows for very elegant and immersive recording. It pays more attention to the content, not the typography, because the editor or the platform can render the final typography of the article through markdown markup. The resulting effect is very simple and clear. On the other hand, the cost of learning markdown is not very high. As long as you understand this grammar rule, you can achieve the effect once and for all. It can also be used to write documents, which are saved in the software directory, and the file name is "README.md." In the English core literacy platform, we need to take notes or mark the chapters we read during the reading process. During the reading process, if you have any questions that you do not understand, you can leave a message to the teacher or ask questions on the forum. This process is inseparable from the language markdown. Markdown was originally primarily used for web writing. Later, after a series of development of the Internet, now markdown has been applied to more fields, and many extended grammars have also been generated. These grammars are based on the basic grammar. Functions such as tables, character lists, and fence

codes are added. Another notable feature of markdown is that it has good compatibility. You can quickly open multiple editors, allowing you to write in one place and use it in many places. It works in any scenario where you can write. This is the solution for writing. This problem has been solved perfectly [20]. Markdown workflow is shown in Figure 3.

3.3. SQL Database. Structured Query Language, referred to as SQL, is a language in the database world. It uses query statements to query and modify data in the database. SQL is a relational database system in database classification and has all the features of relational databases. Databases can store large amounts of data, which are processed by computers to efficiently access collections of data. Structured Query Language can nest query data. Relational databases are managed by a database management system. Two-dimensional tables called database tables are used to manage data in relational databases. A database table consists of a column of data items and a row of data and is read and written in units of records. The most common system structure of relational database management system (RDBMS) is client/server type (C/S type), as shown in Figure 4 [21].

In the structure diagram of the relational database, the server is used to process requests from other programs. The client uses the SQL query statement of the program in the database to send a request to the server. The server receives the query statement and reads the data program to the database. The database performs logical judgment processing on the data request and responds to the requested program. The server responds to the received processed data to the client, and the user can get the processed data. It can also be sent to the relational database management system through SQL statements to change and obtain data.

4. Teaching Design of English Courses Based on Network Learning Space

4.1. Teaching Application Mode in Online Learning Space. For teaching based on the network learning space, this study proposes five basic modes suitable for teaching, namely, autonomous learning mode, collaborative learning mode,

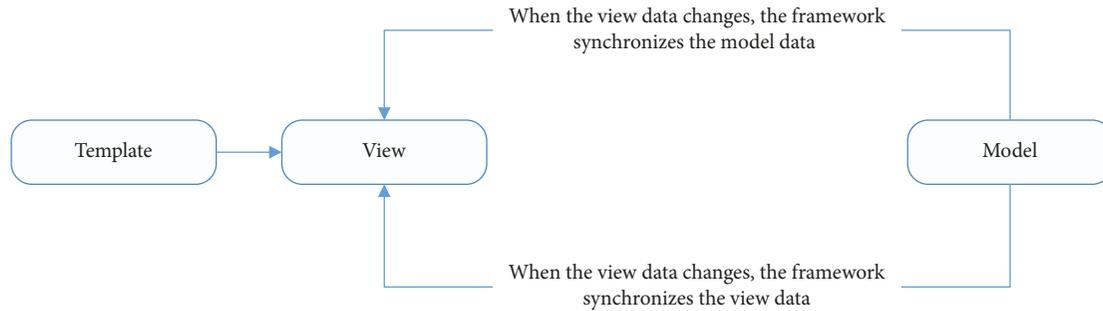

FIGURE 2: Two-way data binding.

FIGURE 3: Markdown workflow.

flipped classroom, communication and discussion mode, and personalized learning mode. One of the characteristics of the online learning space is that the students' autonomous learning ability can be developed. Therefore, the autonomous learning mode under the online learning space is one of the basic modes of the online learning space. The specific process is shown in Figure 5.

Students obtain tasks through the online learning space, then determine the learning goals, then conduct independent learning, and answer questions through self-learning methods such as searching for materials, viewing resources, and online communication learning and finally through self-examination to find insufficient and continue to learn mistakes. Collaborative learning mode under the network learning space collaborative learning is also one of the characteristics of the network learning space, so the collaborative learning mode under the network learning space is of great significance. The specific process is shown in Figure 6.

Collaborative learning is also one of the teaching methods commonly used by teachers. Collaborative learning in the online learning space has injected new vitality into teachers' classrooms, enabling collaborative groups to clarify learning goals and conduct targeted learning. The teaching process mainly takes place in the classroom. The teacher explains in the classroom, and the students practice after the class. The flipped classroom is the opposite. Students obtain teaching resources for learning before class, ask and solve problems in the classroom, and conduct summary evaluation and reflection after class. It can be seen that the flipped classroom mainly includes preclass learning and classroom inquiry. The flipped classroom learning mode in the online learning space is shown in Figure 7.

Communication and discussion mode in the online learning space mostly refers to the communication and discussion between students and students, and it is an important mode of informal learning to answer questions and solve doubts through discussions between classmates. The details are shown in Figure 8.

The communication and discussion mode in the online learning space breaks the traditional boundaries of time and space. Students' communication and discussion do not only happen in the classroom. A good online learning space creates an environment for students to communicate and discuss.

4.2. Teaching Process Based on Teaching Mode. According to the learning mode in the network learning space proposed above, this research constructs a teaching process based on the teaching mode, as shown in Figure 10.

From Figure 9, the teaching process based on the network learning space is mainly divided into three parts: before class, during class, and after class. Based on the flipped classroom, self-learning is carried out before class, and relevant knowledge is previewed; knowledge and skills are consolidated and strengthened through exchanges and discussions after class.

4.3. Teaching Design Based on Network Learning Space

4.3.1. Platform Selection Design. Teaching based on the network learning space requires the support of a specific teaching platform, and the teaching platform needs to include student space and teacher space. According to the research on each platform, this research chooses the "cloud class" education platform for teaching process practice. Cloud class has all the characteristics of online learning space, can share resources and communicate, can realize independent learning and collaborative learning, can track and give feedback on students' learning situation in time, and so on. It is a good online learning space.

4.3.2. Content Design. When choosing the teaching content of the online learning space, it is also necessary to consider the characteristics of its content:

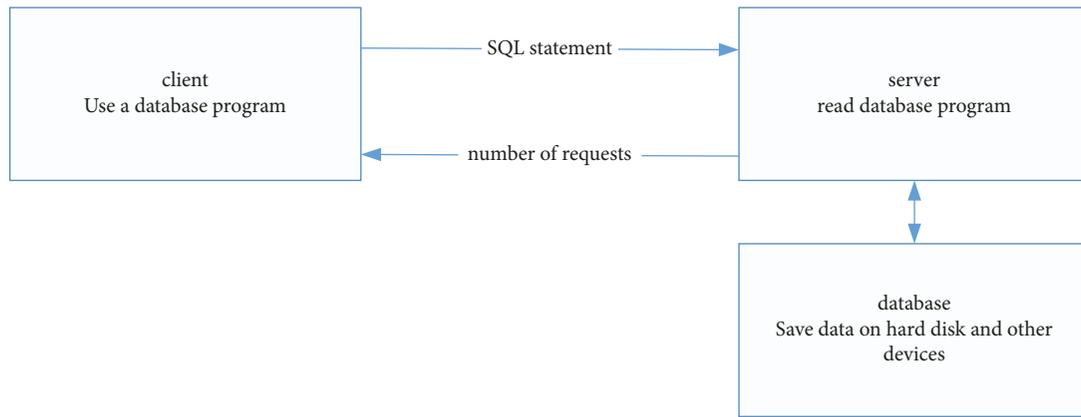

FIGURE 4: System structure of relational database.

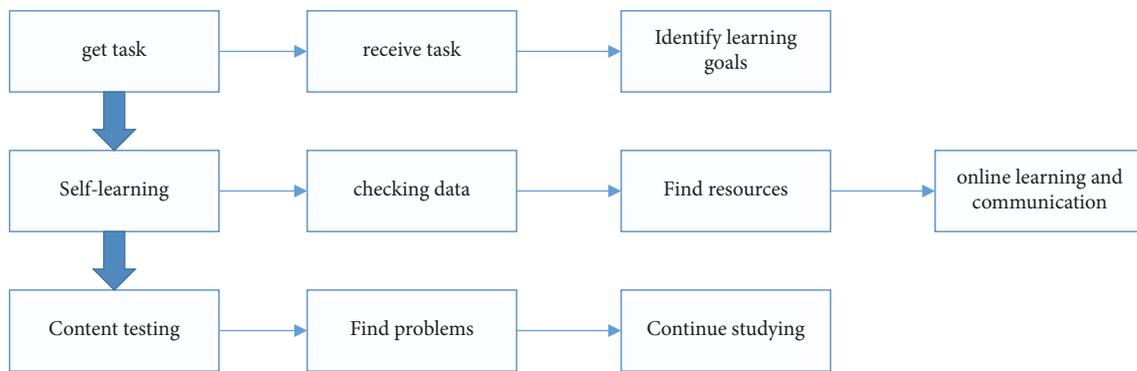

FIGURE 5: Self-directed learning mode in online learning space.

- (1) *Challenging*. Generally, it refers to the degree of difficulty of learning content in the learning process. For students, the content of learning can neither be too easy nor too difficult. Students have basically mastered the simple content, and it is difficult to have the desire to communicate and discuss the content; too difficult learning content exceeds the students' own learning cognition and ability, which will also affect the effect of students' communication and cooperation.
- (2) *Openness*. It generally means that there is no fixed answer to the content of learning, and the answer can be varied. In the process of students' learning, students get the best answer through mutual exchange and discussion and finally report according to the discussion process. Such learning content can further stimulate the enthusiasm of students to learn and communicate, obtain more different answers, and improve the learning effect.
- (3) *Exploratory*. It generally means that students can learn knowledge independently in the process of inquiry and can use it to deal with practical problems at the same time. This type of learning content focuses on mobilizing students' autonomous learning, encouraging students to express their ideas bravely,

and forming consensus answers among group members in group communication and discussion.

4.3.3. Implementation Design. The implementation design is a very important stage. It is mainly for teachers and students to cooperate with each other to carry out learning. In the implementation design stage, the first step, the teacher can introduce the problems of this class through some media, such as stories, audio, or video materials, to set up relevant scenarios so that students can understand the learning goals of this class through the platform. At the same time, you can also ask some questions so that students have some thinking before the class.

5. Application and Analysis of English Course Teaching Based on Network Learning Space

5.1. Design of the Experimental Study. For the purpose of the experiment, this research puts forward the following hypotheses. Hypothesis 1: using the English course teaching based on the network learning space, compared with the traditional teaching method, students can better grasp the relevant course knowledge, which is conducive to improving students' learning effect and level of learning. Verification method: after the experiment is over, professional information technology teachers are invited to

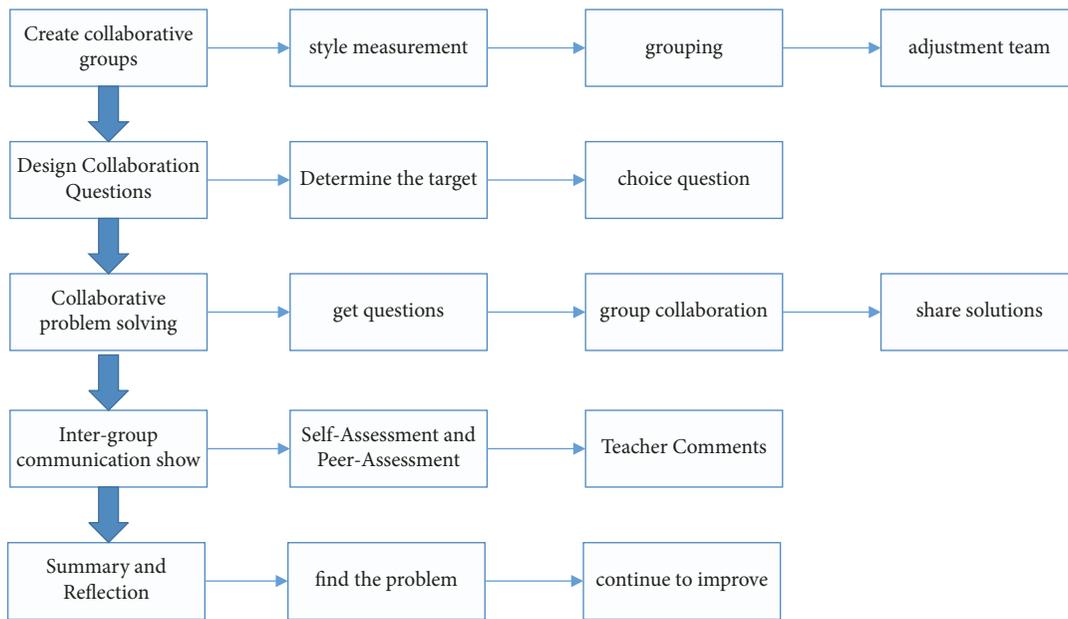

FIGURE 6: Collaborative learning mode in the online learning space.

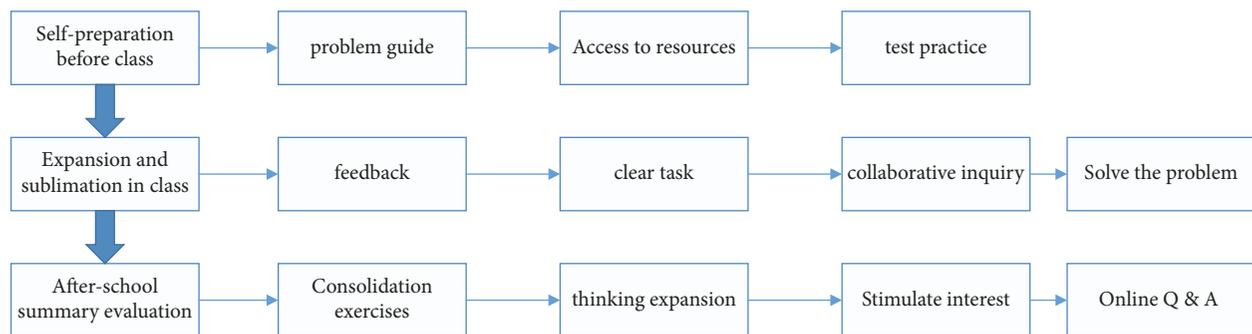

FIGURE 7: The flipped classroom learning mode in the online learning space.

make a score based on the classroom performance and the comparison of the works of the experimental class and the control class. Hypothesis 1 holds if the quality of the experimental class is better than that of the control class. Hypothesis 2: applying the teaching of English courses based on network learning space, students' collaborative learning ability and autonomous learning ability are improved. Verification method: after the experiment, verification is carried out through interviews and measurement methods. The students in the two classes were measured with the independent learning ability measurement table and the collaborative learning ability measurement table, and the independent sample t -test was carried out on the experimental data. If the measured data of the experimental class and the control class are significantly different and the scores of the experimental class are higher than those of the control class, then hypothesis 2 is established.

5.2. Experimental Procedure. During the experiment, students in the experimental class and the control class were observed in class. The experimental class adopted the

English course teaching method based on the network learning space, and the control class adopted the traditional information technology classroom teaching mode. Through classroom observation, it is found that the students in the experimental class are more active in the classroom, have a higher degree of participation in the questions raised by teachers, and have more active discussions among group members and between groups. They can ask their own questions and take the initiative. If you ask your classmates and teachers for advice, the classroom has a good learning atmosphere, which is conducive to the cultivation and development of students' interests. Compared with the experimental class, the students in the control class were not active enough in class. Most of the students lacked interest in classroom activities. Only a few students could raise their hands to answer the teacher's questions. Practice time for things is not related to classroom learning. Moreover, the students in the control class were rarely able to ask questions to the teachers and classmates and solve the problems. There was less discussion time between the students and the teachers and students, and they basically practiced alone. Therefore, in terms of classroom activity and students'

Question	Very much in line (%)	Meet (%)	Basically meet (%)	Incompatible (%)	Very inconsistent (%)
1. You are using the online learning space because of a teacher's request	40	17.5	22.5	12.5	7.5
2. You are using the online learning space for your learning needs	10	15	25	35	15
3. Do you think the online learning space has made the course more interesting	75	15	7.5	2.5	0
4. Do you think the course resources in the online learning space are helpful for the learning of information technology courses	75	17.5	7.5	0	0
5. Your willingness to continue using the online learning space in the future	55	25	7.5	7.5	0

enthusiasm, the students in the experimental class performed better than those in the control class.

5.2.1. Analysis of Teaching Effect. This section mainly starts from the analysis of the results of the comparative experiment, compares the classroom performance, works, and achievements of the control class and the experimental class, and analyzes the teaching effect of English course teaching and traditional teaching based on the network learning space. Finally, the collaborative ability results are obtained.

After analyzing the experiment of this research, the collaborative learning ability of the two classes was measured again to find out whether there was a difference in the level of collaborative learning ability between the two classes after the experiment [1]. Analysis of the independent sample *t*-test results of "collaborative attitude" is shown in Tables 1 and 2.

From Table 1, it can be seen that the average value of the experimental class is 34.45, and the average value of the control class is 33.12. It can be seen that the average value of the experimental class is 1.325 higher than that of the control class. It can be seen from Table 2 that $p = 0.001$ and $p < 0.05$, indicating that the two classes cooperated after the experiment. Attitudes differ markedly. From the data level, it can be considered that the teaching process of this experimental study can improve the collaborative attitude of students.

5.2.2. Analysis of Learning Situation in Network Learning Space. The students' learning effect in the experimental class is investigated to understand the students' evaluation of the

learning effect and the degree of satisfaction with the online learning space after the experiment. In order to understand the learning situation of students in the online learning space, this research made a scale based on excellent master's and doctoral dissertations. After filling in the data, the students imported the data into SPSS software and obtained an Alpha coefficient of $0.857 > 0.8$, with good reliability. The questionnaire divides the survey of the learning situation of the online learning space into two parts, namely, the survey and analysis of the application attitude and the application effect. (1) Results and analysis of application attitude for students' attitude towards the application of online learning space: this study set five questions, designed from the attitude and importance of online learning space, and the questionnaire design adopted a five-point Likert scale form from the data level to analyze the students' application attitude. The specific structure is shown in Table 3. According to the data obtained in Table 3, most of the students (80%) use the online learning space because of the teacher's request in the early stage of learning. This is in line with the current education situation in China. Students' cognition of learning comes from multiple sources. Due to the guidance of teachers and the fact that students in junior high school do not have the ability to find online learning spaces by themselves, teachers need to guide in the early stage of teaching; after the teaching practice based on online learning spaces, 90% of students believe that online learning spaces become more interesting, and interesting classes help attract students' attention; more than 90% of students believe that this way of teaching is helpful for course learning and can

improve classroom efficiency; 80% of classmates said that, in the future days, they will continue to use the online learning space. After teaching practice, students have a preliminary understanding of the online learning space, most students believe that the online learning space has a positive impact on their own learning, and most of the students have also recognized the importance of the online learning space and expressed that the online learning space will continue to be used in subsequent studies. (2) Application effect results and analysis: for the application effect of students on the online learning space, this study set five questions to analyze the learning effect of students in the online learning space. The specific investigation results are shown in Table 3.

6. Conclusion

Through the experimental data obtained from the experimental research of English course teaching based on the network learning space, the data is analyzed, processed, and summarized, and the following conclusions are initially obtained in this research. The teaching of English courses based on the network learning space can improve students' interest in learning to a certain extent and stimulate their passion for learning English courses, which can be reflected from the students' performance. The teaching based on the network learning space has the interest that the traditional classroom does not have. After the teaching method is changed, the autonomy of the students is improved, and the open network learning space provides a stage for the personalized development of the students. Through the classroom performance of the experimental class and the control class, the students in the experimental class are active in class and raise their hands positively, and the final performance evaluation is also better than that of the control class.

A software construction detection algorithm based on improved CNN model is proposed. Firstly, extract the vulnerability characteristics of the software, extract the characteristics from the static code by using the program slicing technology, establish the vulnerability library, standardize the vulnerability language, and vectorize it as the input data. Gru model is used to optimize CNN neural network. The organic combination of the two can quickly process the feature data and retain the calling relationship between the codes. Compared with single CNN and RNN model, it has stronger vulnerability detection ability and higher detection accuracy. In contrast, the software algorithm of the improved CNN model has strong vulnerability detection ability and higher detection accuracy. In terms of training loss rate, the DNN + Gru model is 17.2% lower than the single RNN model, 10.5% lower than the single CNN model, and 7% lower than the VulDeePecker model.

1. Introduction

Software systems are widely used in various production and life fields. The primary issue to be considered in the development process is security. Software vulnerabilities will not only cause unnecessary consumption of resources, but also seriously damage the economic property of the application industry. Traditional vulnerability analysis is divided into three methods: static analysis, dynamic analysis, and combined dynamic and static analysis [1]. Xia [2] compared the static analysis method with other program analysis methods and found that the static analysis method has a higher degree of automation and faster speed in detecting software vulnerabilities, but the static analysis method generally has the problem of high false positive rate. Lu [3] proposes a vulnerability detection technology based on dynamic taint analysis, which realizes the taint propagation process based on control flow and data flow, but frequent taint mark detection takes up a lot of memory and reduces system performance. Pan and Zhou [4] propose a method of combining static code analysis of pollution propagation

model and dynamic detection of purification units to discover vulnerabilities in web applications, but this method is only used for cross-site scripting attacks and is used to detect other vulnerabilities, such as poor ability. Perl et al. [5] proposed a tool VccFinder that uses SVM classifier to mark suspicious codes. Although this tool reduces the false positive rate, it needs to reextract features and perform model training every time when detecting codes in different languages. Li et al. [6] developed the VulPecker tool, which has a very low false positive rate when detecting vulnerabilities in code clones, but is not suitable for dealing with other types of vulnerabilities.

With the continuous development of the deep learning discipline, the use of machine learning to achieve software vulnerability detection has gradually emerged. A deep learning-based Android malicious application detection is proposed, and a recurrent neural network is used to detect Smali static code, but this method is only aimed at malicious application attack problems and cannot find vulnerabilities in the code itself [7]. Li et al. [8] proposed an improved long short-term memory network (LSTM) model, which is

applied to the vulnerability detection problem of open source code, but this model is only for C/C++ source code problems and can only handle API and library function calls question.

On the basis of the above method, this paper proposes a software vulnerability detection method of deformable convolutional neural network, relying on the activation function and residual unit to improve the stability of the training gradient, because the convolution kernel can be shared in the convolutional neural network, and the network depth determines the length of the back propagation path, so it can greatly reduce the algorithm's time when detecting software vulnerabilities memory consumption.

2. Software Code Feature Extraction

Feature extraction of software code is the key to vulnerability detection. Firstly, program slicing is performed with key points in the vulnerability library as entry points, and code fragments containing vulnerability features are extracted from open source code, and these code fragments are called "code unit sets" [7]. Secondly, the set of code units containing vulnerabilities is vectorized, and the features are represented in a vector form that can be processed by the deep learning model. The feature processing flow of open source code is shown in Figure 1.

2.1. Establish a Vulnerability Library. In order to ensure that the slicing tool can accurately locate the code part containing the vulnerability features, a vulnerability library needs to be designed, and the key points of program slicing are defined in the vulnerability library. Taking API misuse as an example, the calling function of the API in the program is the key point of API misuse in the vulnerability library. Using the calling function as the entry point, the parameters, statements, and expressions related to the key points in the code are extracted. Therefore, the design of open source software vulnerability library is an indispensable link in static code vulnerability detection.

The open source software vulnerability library designed in this paper is mainly based on the CVE vulnerability database. CVE is compatible with 28 communities and institutions and contains about 6,500 entries. It is currently the authoritative standard vulnerability library for vulnerability scanning and evaluation. In addition, this paper also combines other large vulnerability information bases, such as CWE, NVD, and CNNVD. Through comparative analysis, the vulnerability library is roughly divided into seven categories: input validation, buffer overflow, memory management, API misuse, error handling, information leakage, and cross-site scripting [9]. Some key points are shown in Table 1.

2.2. Program Slicing. Program slicing is used to implement static code vulnerability feature extraction and process static code into a code unit set containing features. In the slicing process, the key points in the vulnerability library are used as entry points, and the control flow graph and data flow graph

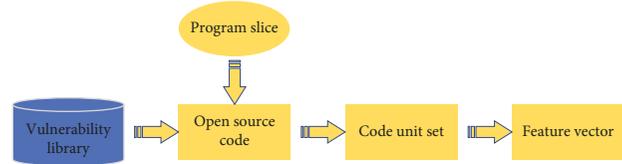

FIGURE 1: Feature code feature processing flow.

are constructed according to the order of mutual calls in the program and the flow of data parameters, so as to extract the expressions related to the key points. Formulas and statements and code statements and comments that are not related to features are removed [10]. There are many algorithms and tools related to program slicing. This paper uses LLVM to complete static code slicing.

2.3. Feature Vectorized Expression. After the program is sliced, a code unit set containing vulnerability features is obtained. The code unit set cannot be directly used as the input of the deep learning model and needs to be quantized into a fixed-length vector. In this paper, the word vectorization model word2vec is used to complete the vectorization of features. The word2vec model processes the code unit set by constructing a multilayer neural network. During the processing, the parameters of the neural network are continuously corrected and a series of linear and nonlinear operations are performed. Finally, we get the required word vectors. Before vectorizing the code unit set, the code unit set should be regularized, and the user-defined variables and function names in the code should be replaced with standard symbolic names in one-to-one correspondence. In this paper, the static analysis tool cppcheck is used to traverse line by line code and completes the substitution of user-defined variables and standardized names.

3. Improve the CNN Vulnerability Detection Model

3.1. CNN Model. The basic structure of CNN consists of an input layer, a convolution layer, a pooling layer, a fully connected layer, and an output layer. Generally, several convolution layers and pooling layers are used, and the convolution layers and pooling layers are alternately set; that is, one convolutional layer is connected to a pooling layer and so on. Since each neuron of the output feature surface in the convolutional layer is locally connected to its input, and the corresponding connection weights and local inputs are weighted and summed together with the bias value to get the input value of the neuron, this process is equivalent to the convolution process.

The convolution layer consists of multiple feature surfaces, each feature surface consists of multiple neurons, and each neuron is connected to the local area of the feature surface of the previous layer through a convolution kernel, which is a weight matrix (such as for two-dimensional avatars, it can be a 3×3 or 5×5 matrix) [11], the convolutional layer of CNN extracts input features through convolution operations, the first convolutional layer extracts

TABLE 1: Program vulnerabilities and key points.

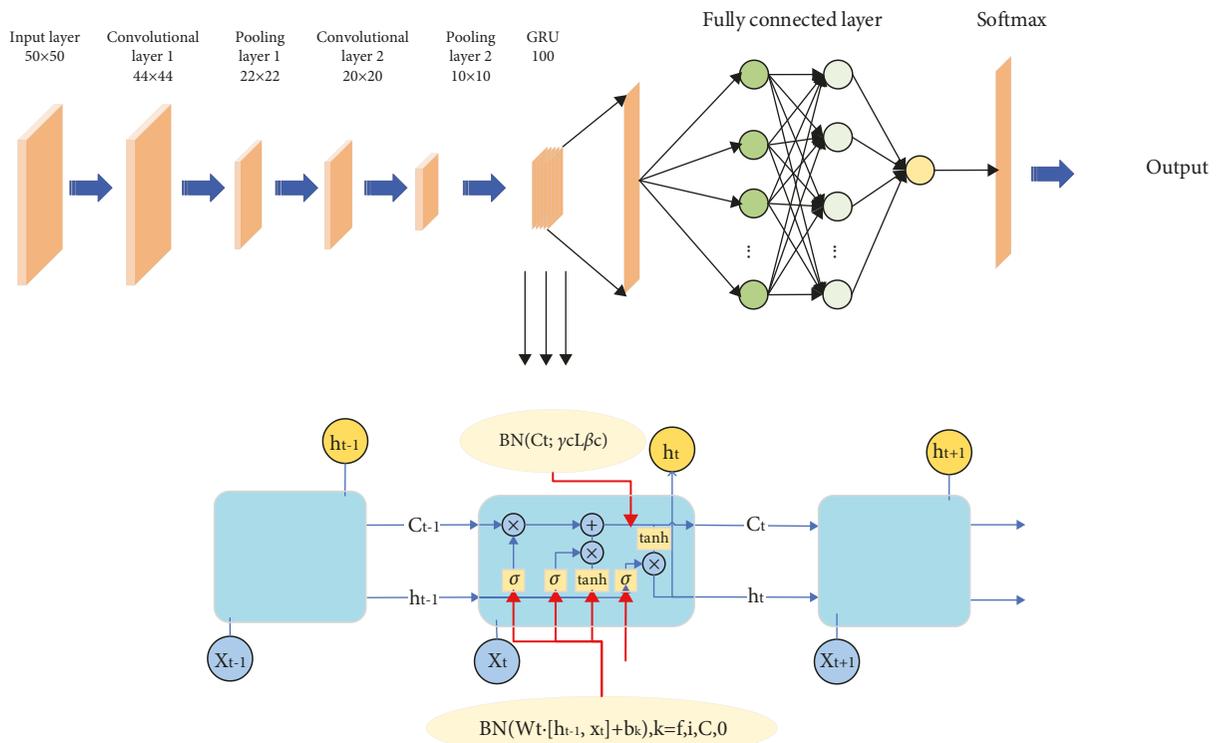

FIGURE 2: DNN + GRU model structure diagram.

low-level features, and the convolutional layer of higher layers extract higher-level features. Figure 2 shows a schematic diagram of the convolutional layer and pooling layer structure of a one-dimensional CNN.

The pooling layer follows the convolutional layer and is also composed of multiple feature surfaces, each of which uniquely corresponds to a feature surface of the previous layer and does not change the number of feature surfaces. As shown in Figure 2, the convolutional layer is the input layer of the pooling layer. A feature surface of the convolutional layer uniquely corresponds to a feature surface in the pooling layer, the neurons of the pooling layer are also connected to the local receptive field of the input layer, and the local receptive fields of different neurons do not overlap. The pooling layer aims to obtain spatially invariant features by reducing the resolution of feature surfaces [12].

The pooling layer plays the role of secondary feature extraction, and each neuron performs a pooling operation on the local receptive field. In the CNN structure, one or more fully connected layers are connected after multiple convolutional layers and pooling layers. Each neuron in the fully connected layer is fully connected to all neurons in the previous layer. The fully connected layer can integrate the class-discriminative local information in the convolutional layer or the pooling layer [13].

It can be seen from Figure 3 that the neurons of the convolution layer are tissue into each feature, and each neuron is connected to the local region of the upper layer, that is, the gland in the convolution layer. The feature in the input layer performs local connection [14]. The local connection weighted and passed to a nonlinear function such as the RELU function to obtain an output value of each neuron

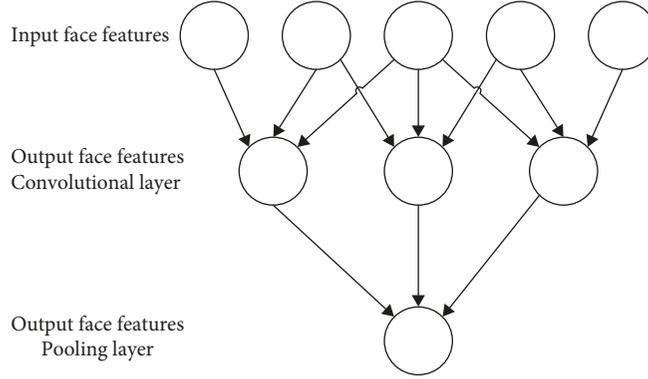

FIGURE 3: Schematic diagram of convolutional layer and pooling layer.

in the convolution layer. In the same input feature and the same output feature, the weight sharing of the CNN can reduce the model complexity by weight sharing, making the network easier to train.

3.2. CNN + GRU Model. Although CNN has good classification ability in vulnerability detection, it cannot well preserve the contextual relationship between code statements, and the overly complex neural network structure will have the problem of gradient disappearance as the number of layers increases [15]. RNN is often used to deal with time series problems and can better express the contextual calling relationship between codes, but RNN also has the problem of gradient disappearance. GRU is an effective variant of LSTM network. It has simpler structure and better effect than LSTM network. Therefore, it is also a very manifold network at present. Since Gru is a variant of LSTM, it can also solve the long dependency problem in RNN networks [16]. GRU introduces three gate functions into LSTM: input gate, forgetting gate, and output gate to control input value, memory value, and output value. In GRU model, there are only two doors: update door and reset door.

This paper proposes to combine CNN and GRU, organically integrate the advantages of the two models, and build a new model that is more suitable for open source software vulnerability detection. The CNN is used as the interface for interacting with the feature vector, and the GRU is used as the gating mechanism to deal with the relationship between the code statements, which constitutes the CNN + GRU model. The efficiency of CNN in processing data is higher and faster than GRU, and the automatic learning ability of convolution kernel is also stronger than GRU [17], and GRU model not only solves the problem of gradient disappearance in CNN, but also captures CNN Call information between code functions is ignored. The structure of the CNN + GRU model is shown in Figure 4.

In Figure 2, the first is the convolution and pooling processing of CNN. CNN can quickly process high-dimensional data and ensure the invariance of feature data to the greatest extent during dimensionality reduction [18]. Second, the GRU is embedded between the pooling layer and the fully connected layer, and the GRU is used to preserve the up-down calling

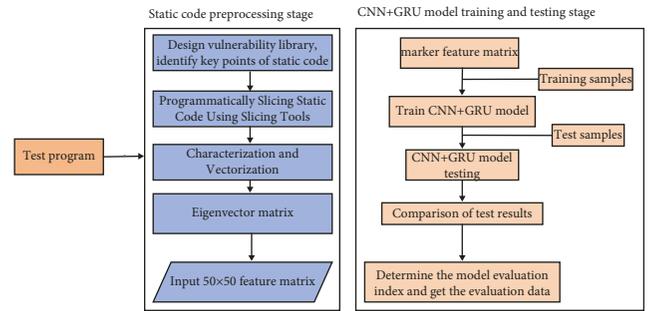

FIGURE 4: The process of CNN + GRU model detecting software vulnerabilities.

relationship between code data. Finally, the fully connected layer is used to complete the normalization process, and the processed output value is sent to the SoftMax classifier for classification and detection, and the classification result is obtained [19].

The input layer is a preprocessed 50×50 -dimensional feature matrix. The red square in the figure represents the convolution kernel with a size of 7×7 . The convolution kernel is the weight matrix in the perception field. The scan pitch for input data is set to 1. There may be out-of-bounds phenomenon when scanning to the boundary, the boundary needs to be expanded, and the value of the out-of-bounds part is set to 0. The input of the convolutional layer is the 50×50 feature matrix in the input layer, and the output matrix dimension is determined by

$$\begin{cases} \text{height}_{\text{out}} = \frac{\text{height}_{\text{in}} - \text{height}_{\text{kemel}} + 2 \times \text{padding}}{\text{stride}} + 1, \\ \text{width}_{\text{out}} = \frac{\text{width}_{\text{in}} - \text{width}_{\text{kemel}} + 2 \times \text{padding}}{\text{stride}} + 1. \end{cases} \quad (1)$$

In formula (1), height and width represent the length and width of the matrix, padding is the padding mode, and stride is the step size. To be precise, each convolution kernel also contains a bias parameter, but the formula omits bias. In the CNN + GRU model, padding is 0, stride is 1, and the length and width of the output matrix are $(50 - 7 + 2)/1 + 1 = 44$; that is, the input matrix of pooling layer 1 is 44×44

dimensions. The pooling layer is mainly to compress and reduce features and prevent overfitting. In pooling layer 1, a filter of size 2×2 is used, and the stride is chosen to be 2. It can be concluded that the output of pooling layer 1 is 22×22 . The processing of convolutional layer 2 and pooling layer 2 is similar to convolutional layer 1 and pooling layer 1.

GRU is embedded between the pooling layer and the fully connected layer. Since CNN uses filters and windows of different sizes to process data, it often loses the up-down calling and transfer relationship between these code data. In addition, too many neural network layers will also have the problem of gradient disappearance, so it is necessary that GRU acts as a storage timing information and control gate in the whole model. In the GRU structure diagram, x is the input, h is the output, f_i is the forgotten part of the input information, and r_i is the memorized part of the input information. The calculation in GRU is shown in

$$\begin{cases} r_t = \sigma(W_r \times [h_{t-1}, x_t]), \\ f_t = \sigma(W_f \times [h_{t-1}, x_t]), \\ \tilde{h}_t = \text{Relu}(W \times [f_t \times h_{t-1}, x_t]), \\ h_t = (1 - r_t) \times h_{t-1} + r_t \times \tilde{h}_t. \end{cases} \quad (2)$$

In formula (2), w represents the weight, and relu is the activation function. In order to make CNN+GRU have nonlinear modeling ability, an activation function is added to GRU. The relu function, which is faster to calculate and can alleviate gradient disappearance, is selected as the activation function, as shown in

$$f(x) = \max(0, x), \quad (3)$$

where x is the input, $f(x)$ is the output, and relu can keep the gradient from decaying when $x > 0$, alleviating the problem of gradient disappearance.

The problem of program vulnerability detection is actually a two-category problem, with or without loopholes. So you need to add a fully connected layer and a SoftMax layer at the end of the model. The fully connected layer is responsible for further dimensionality reduction and purification of the features, and the classifier is responsible for whether the final sample contains vulnerabilities. Through filters (also called convolution kernels), the fully connected layer connects the input and output together, and the fully connected part is shown in

$$W * x + b = z. \quad (4)$$

Among them, $x = [x_0, x_1, x_2, \dots, x_n]_T$ is the input vector; $y = [y_0, y_1, y_2, \dots, y_n]_T$ is the output vector, then the filter part is a matrix of size $m \times n$, and b is a partial set of the term, $b = [b_0, b_1, b_2, \dots, b_n]_T$.

SoftMax classifiers are widely used to solve multi-classification problems in various domains. The input feature of the SoftMax function is set to x , and the probability value is $p(y = j|x)$, assuming the function is as follows:

$$h_\theta(x) = \begin{bmatrix} p(y^{(i)} = 1|x^{(i)}; \theta) \\ p(y^{(i)} = 2|x^{(i)}; \theta) \\ \vdots \\ p(y^{(i)} = k|x^{(i)}; \theta) \end{bmatrix} = \frac{1}{\sum_{j=1}^k e^{\theta_j^T x^{(i)}}} \begin{bmatrix} e^{\theta_1^T x^{(i)}} \\ e^{\theta_2^T x^{(i)}} \\ \vdots \\ e^{\theta_k^T x^{(i)}} \end{bmatrix}. \quad (5)$$

The parameter θ is obtained through training, the setting of θ needs to minimize the regression cost function, k is the dimension of the vector, and the regression cost function of SoftMax is

$$J(\theta) = -\frac{1}{m} \left[\sum_{i=1}^m \sum_{j=1}^k 1\{y^{(i)} = j\} \ln \frac{e^{\theta_j^T x^{(i)}}}{\sum_{i=1}^k e^{\theta_j^T x^{(i)}}} \right] + \frac{\lambda}{2} \sum_{i=1}^k \sum_{j=0}^n \theta_{ij}^2. \quad (6)$$

$(\lambda/2) (\sum_{i=1}^k \sum_{j=0}^n \theta_{ij}^2)$ is the weight failure; in order to minimize the value of $J(\theta)$, use iterative optimal algorithm. By seeking, gradient formulas can be obtained:

$$\nabla_{\theta_j} J(\theta) = -\frac{1}{m} \sum_{i=1}^m [1\{x_i; (y_i = j)\} - p(y_i = j|x_i; \theta)] + \lambda \theta_j. \quad (7)$$

$\nabla_{\theta_j} J(\theta)$ represents a vector, and a SoftMax model can be implemented by minimizing $J(\theta)$.

3.3. Model Assessment Indicator. Before training and testing models, you need to give an evaluation indicator of the vulnerability detection model, the accuracy (ACC), and the loss rate (LOSS), which is often used.

Refer to the mainstream assessment index system, according to the difference between the prediction results and the real results, divided into the following four cases [20]:

TP: the prediction result is positive and the real results are positive.

FP: the prediction result is positive, and the real results are negative.

FN: the forecast results are negative, and the real results are positive.

TN: the forecast results are negative, and the real results are negative. The calculation of the accuracy ACC is as shown in

$$\text{ACC} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{FP} + \text{FN} + \text{TN}}. \quad (8)$$

The loss rate of the CNN+GRU model is calculated by the cross-entropy loss function and reflects the gap between the prediction results and the real results by calculating the cross entropy. The collection of predicted results is used to represent the collection of real results, and the cross-entropy of the two sets can be defined as follows:

TABLE 2: Simulation experiment environment.

Name	Parameter
RAM	16 GB
HD	512 GB
CPU	Intel® Core™ i5-3515M
OS	64-bit Win10 physical machine
Python	3.7.1

$$H(p, r) = E_p[-\log r] = H(p) + D_{KL}(pr). \quad (9)$$

$H(p)$ represents the entropy of P , and $D_{KL}(pr)$ is KL distance to measure the distance of two collections.

4. Simulation Experiment

When using the software vulnerability detection algorithm of the CNN model, the corresponding indicators are mainly the accuracy rate of training and the loss rate of training as the main basis for judging the detection of software vulnerabilities of the CNN model.

4.1. Experimental Environment. The training and testing environment of the vulnerability detection model is 16 GB memory, and the processor is Intel® Core™ i5-3515M, 64-bit Win10 physical machine. Open source data often have class imbalance problems; that is, most of the data are positive samples (samples without vulnerabilities), while the number of negative samples is low (samples with vulnerabilities). Such imbalance problems will affect the vulnerability detection model performance, causing vulnerability cases in the standard library. This dataset is preprocessed, including feature extraction, normalization, and vectorization of features. Finally, more than 300 samples were formed as experimental data (171 positive samples and 144 negative samples), and 215 samples were taken as training data (117 positive samples and 98 negative samples). The remaining 100 samples are used as test samples, 54 positive samples, and 46 negative samples, which are used to verify the vulnerability detection ability of the CNN + GRU model as shown in Table 2.

4.2. Detection Process. The vulnerability detection process can be divided into two stages: the static code preprocessing stage and the vulnerability detection model training and testing stage [21].

In the static code preprocessing stage, first of all, refer to the real vulnerability cases in CVE, extract the API functions with specific errors in the cases, divide the API functions into 7 categories to construct the open source software vulnerability library of this article, and use the API functions in the vulnerability library. It is the key point and the entry point of the program slice. Second, collect the data set, use LLVM to slice the data set program, extract key points from the data set code, and construct the control flow chart of the key point function. In the control flow graph, each node is a basic block. The variables and operations related to the key point function are found through each branch of the basic block.

Finally, all the basic blocks related to the key point function are intercepted to form more than 300 code unit sets. In addition, it is necessary to standardize and vectorize the code unit set and use word2vec to vectorize more than 300 code unit sets in batches to obtain training samples. Use the same method to obtain test samples. Finally, normalize all the feature vectors, and process the feature vectors into a 50×50 -dimensional feature matrix according to the size of the sample. The size of the ordinate is the dimension of the word vector, and the abscissa is the number of word vectors. If the word vector is less than 50, it is filled with 0. In the training and testing phases of the vulnerability detection model, the training model and the testing model need to be written, and the entire compilation process uses the python language. Add a label to the test sample, set the label of the sample containing the vulnerability to "0," and set the label of the sample without the vulnerability to "1." 215 samples were taken as training data. In the experiment, batch extraction was used to extract a fixed number of samples from the test samples each time, and the model was trained through multiple iterations. In the testing phase, use the trained CNN + GRU model for testing, compare whether the model test results are the same as the actual results, and test the detection ability of the CNN + GRU model. The overall process of the entire static code vulnerability detection is shown in Figure 4.

4.3. Analysis of Experimental Results. In the training phase, iterate 3000 training cycles, and use the minibatch gradient descent algorithm (MBGD) for batch extraction. Every 10 iterations, the current training accuracy rate (training ACC) and training loss rate (training loss) are output, and save the model document. The model document saves the weights that are adjusted and set when training the neural network, so that the model document can run directly. The detection results of part of the model during the training process are shown in Table 3.

During the training process, the accuracy and loss rate after 500 iterations are stable at 0.903 3 and 0.154 1. The weight values of the model at this time are saved in the ckft model document, and the parameters in the document are in the testing phase parameter to use. The changes in the accuracy and loss rates during training are shown in Figure 5.

As can be seen from Figure 5, when the number of iterations is less than 500, the accuracy of the whole curve is significantly improved; when the number of iterations is more than 500, the accuracy curve tends to be stable and remains at about 0.9. When the number of iterations is less than 500, the whole curve shows an obvious downward trend. When the number of iterations is greater than 500, the curve also tends to be stable and remains at about 0.15. After the model training is completed, the test samples are tested. By loading the model documents saved during the training, the model can be directly restored to the state at the end of the training. 100 samples are randomly selected from 315 test samples each time for 5 times. See Table 4 for test accuracy (test ACC) and test loss rate (test loss).

In order to further prove that the CNN + GRU model has high vulnerability detection ability, the CNN + GRU model

TABLE 3: CNN + GPU model training results.

Number of iterations	Training ACC	Training loss
10	0.3706	0.6635
20	0.6225	0.3782
30	0.8742	0.2375
60	0.9017	0.1581
90	0.9032	0.1543
120	0.9033	0.1541
150	0.9033	0.1541

TABLE 4: CNN + GRU Model test results.

Sample	Test ACC	Test loss
1	0.8800	0.1617
2	0.8700	0.1674
3	0.8700	0.1707
4	0.8600	0.1972
5	0.8700	0.1591

TABLE 5: Data comparison of deep learning models.

Model	Training ACC	Training loss	Test ACC	Test loss
RNN	0.8372	0.1819	0.8000	0.2068
CNN	0.8810	0.1702	0.8400	0.1918
VulDeePecker	0.8791	0.1613	0.8300	0.1844
CNN + GPU	0.9033	0.1541	0.8700	0.1713

is compared with a single CNN, RNN, and the existing vulnerability detection model VulDeePecker [22]. The CNN, RNN, and VulDeePecker models were trained and tested using the same dataset, and the experimental results of the four models were compared. The specific results are shown in Table 5. The information in the table is the average of the training data and test data of the four models. It can be seen that the experimental results of CNN + GRU are the best.

The experimental results show that it is feasible to nest GRU into the pooling layer and fully connected layer of

CNN. The CNN + GRU model proposed in this paper can not only ensure the invariance of feature vectors to the greatest extent during dimension reduction, but also preserve the invariance between codes. Call relationship has stronger vulnerability detection ability, and compared with CNN, RNN, and VulDeePecker models, CNN + GRU has higher accuracy and lower loss rate.

5. Conclusion

This paper proposes a software building detection algorithm based on an improved CNN model. Firstly, extract the vulnerability features of the software, use program slicing technology to extract features from static code, establish a vulnerability library, and standardize and vectorize the vulnerability library as input data. GRU model is used to optimize CNN neural network. The organic combination of the two can quickly process the feature data and retain the calling relationship between the codes. The improved CNN model is better than the single CNN and RNN model in vulnerability detection ability and detection accuracy. Compared with single CNN model and VulDeePecker model, the training loss rate is 4.25% higher. On the contrary, compared with single RNN model and VulDeePecker model, the training loss rate is 17.2% and 7% lower, respectively.

Compared with other single algorithms, the improved CNN algorithm has relatively high requirements for data and needs to be further optimized in the future.

Data Availability

The dataset can be accessed upon request.

Aiming at the related problems existing in the field of leisure sports computing, in order to study the behavior recognition of leisure sports by deep residual network, based on the deep residual neural network theory, the behavior recognition algorithm and the corresponding robust model are used to analyze the leisure sports related samples, and the correlation model is used to predict and analyze the leisure sports related content. The results show that the change curves of Sig and Tanh functions can be divided into slow increasing stage, linear increasing stage, and stable stage. The y value corresponding to ReLU curve shows a linear change trend with the increase of x value. The Leaky function's corresponding curve can be divided into two stages. The function coincides with the ReLU function in the first quadrant and remains linear in the third quadrant. The activation function curves corresponding to layers 56 and 20 have a relatively large variation range, and both of them show an overall trend of gradual decline. On the whole, the curve value corresponding to layer 56 is higher than that corresponding to layer 20, indicating that the method of layer 20 is relatively good and the corresponding training error is relatively low. It can be seen from the robustness recognition rate of various methods under different training samples that F_1 has the highest overall data recognition rate while S_c has relatively poor stability. However, the recognition rate of IDCC and DCC shows a relatively flat trend, indicating that these two methods have certain advantages in describing the robust recognition rate. The research results can provide theoretical support for the application of deep residual neural networks in other fields.

1. Introduction

Deep residual neural network has been widely applied in different fields: Aiming at the problems in the field of handwriting, a method based on deep residual network has been established, which can achieve higher accuracy [1]. In view of the problems existing in the accurate recognition of cancer lesions, deep learning technology can play a certain role in performing natural image segmentation, and this model has reasonable scale invariance and the ability to detect even small differences [2]. In view of the problems existing in the operation process of short-term load, a deep residual network short-term load prediction method based on adaptive method is proposed [3]. The accuracy and timeliness of neural network are considered in this method. A method using deep residual network to enhance image resolution was proposed. The method used behavior

recognition algorithm and robustness analysis to calculate data and samples, and the results showed that the model could better reflect and describe images [4]. In order to better analyze and describe the characteristics of radar, an optimization model based on deep residual network is proposed. This model can not only analyze and verify the relevant data of radar, but also carry out predictive analysis of radar samples within a certain range, and the accuracy of this model has been verified by experiments [5]. The evaluation index of image quality is very important for image processing. Aiming at a series of problems existing in image research, an image evaluation model based on deep residual network and behavior algorithm is established. The model extracts relevant data for analysis, thus obtaining the corresponding model results, and the accuracy of the model has been verified through experiments [6]. Deep fuzzy neural network cannot well explain the behavior of nonlinear

dynamics. A new architecture based on deep residual neural network theory is established. In order to verify the superiority of the model, a large amount of data were used for verification, and the structure showed the accuracy of the model [7].

The above studies mainly analyzed the application of deep residual network in aspects other than leisure sports. Therefore, in order to better study related behavior recognition algorithms and other problems existing in leisure sports, deep residual neural network theory is adopted. Leisure sports are monitored and analyzed based on behavior recognition algorithm, and the correlation model is used to predict and analyze the sample data of leisure sports. The research results can provide support for the application of deep residual neural networks in other fields.

The scale of leisure sports is shown in Figure 1. From the scale of leisure sports, we can see that with the passage of time, the scale of sports shows a trend of gradual increase [8–10]. The scale of leisure sports increased by 5.7 times from 129 in 2011 to 731 in 2021, indicating that the scale of leisure sports is gradually increasing. In order to quantitatively analyze the change rule of leisure sports scale over time, the increment percentage of leisure sports scale at different times was plotted. It can be seen from the figure that the corresponding increment also shows a trend of gradual increase. In addition, it can be seen from the way of linear fitting that this law conforms to the quadratic function distribution. Through the above analysis, we can draw relevant conclusions: The scale of leisure sports increases gradually with the increase of time, and the increment proportion also shows an increasing trend. However, from 2019 to 2021, it can be seen that the increment of the size of leisure sports decreased, indicating that there are some problems in the development process of leisure sports scale, which has restricted the development of leisure sports scale to some extent.

2. Basic Theory of Deep Residual Networks

2.1. Convolutional Neural Network. Convolutional neural network (CNN) is the most representative deep learning algorithm, which has achieved great success in the field of computer vision [11, 12]. Compared with traditional fully connected neural networks, CNN has fewer training parameters and more flexible training methods and can deepen model layers through network optimization methods. When the network model trains image data, the original image to be processed or the preprocessed fuzzy image is first put into the input layer, and then the convolutional layer and pooling layer process the image of the input layer. The feature information is extracted to form the feature map, and then the activation layer performs nonlinear operation on the feature map to enlarge the image and reconstruct the final result. CNN uses convolution computation to propagate feedforward signals, and the corresponding fully connected neural network is shown in Figure 2.

Through the whole neural network diagram, we can see that neural network can be divided into three parts according to its different functions: input layer, hidden layer,

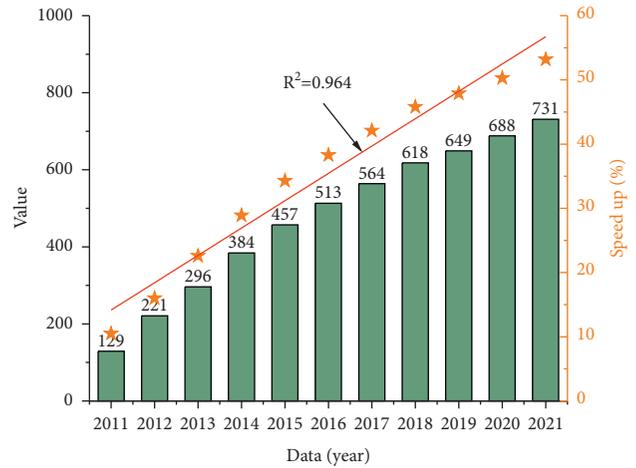

FIGURE 1: Leisure sports scale map.

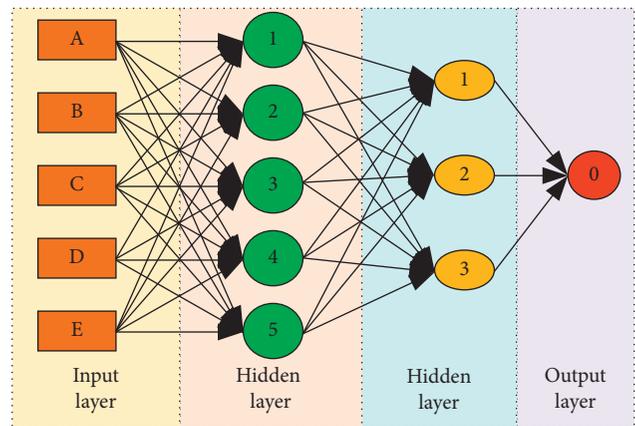

FIGURE 2: Fully connected neural network diagram.

and output layer. The specific data processing process is as follows: Firstly, the verification samples and data are imported into the input layer; the data is analyzed through the algorithm in the input layer; and then the analyzed data is imported into hidden layer 1. Further analysis and validation of the input data are carried out through the five units and modules in hidden layer 1, and the corresponding data is then exported. The data of the map is imported into hidden layer 2 again. In hidden layer 2, there are three variable elements that can verify the input data. After the above hidden layer analysis, the obtained data is output, so as to realize the description of the neural network.

In order to better analyze the computation process of convolutional neural network, an introduction neural network structure diagram is drawn, as shown in Figure 3. As can be seen from the convolutional neural network flow chart, convolutional neural network can be divided into five parts: convolution unit, upsampling, convolution, downsampling, and full connection. Firstly, the sample data is imported into the convolution part to extract the relevant features of the data. Then, the feature data is imported into the upsampling for further analysis, through a series of operations such as copying and pasting the data. Then, the pasted data is imported into the new convolution part again

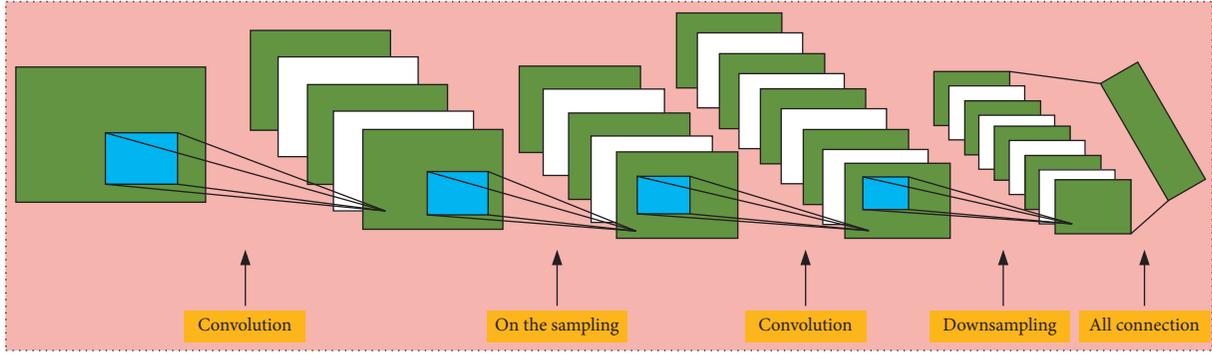

FIGURE 3: Convolutional neural network diagram.

for calculation. The newly obtained data is imported into the lower sampling for a new round of more accurate copy-and-paste operations. In this way, the obtained new data can be imported into the full connection operation. Through the full connection operation, the data sample can be analyzed and modified, and finally the relevant data can be exported.

Convolutional neural network mainly includes convolutional layer and corresponding activation function.

2.1.1. Convolutional Layer. The convolutional layer is the foundation of convolutional neural network and the most core component of the network. Through the combination analysis of the obtained local feature information, the global feature information is formed. The corresponding operation mode is as follows:

$$\text{CONV}_{(ij)} = \sum_i^{m-1} \sum_j^{n-1} u_{ij} \times w + b, \quad (1)$$

$$(i = 1, 2 \dots m - 1; j = 1, 2 \dots n - 1),$$

where u_{ij} is the input image, m and n are the size of the input image, w is the size of the convolution kernel, and b is the bias constant of the convolution kernel. $\text{CONV}(ij)$ is the characteristic graph output after convolution operation.

2.1.2. Activation Function. CNN adds an activation function layer to the network and analyzes the model better by adopting the feature mapping method of nonlinear function. The full name of ReLU function is modified linear unit. The function is one of the commonly used activation functions, which is characterized by low computational complexity and no exponential operation. The ReLU function can be expressed as follows:

$$f(x) = \max(0, x),$$

$$= \begin{cases} x, & (x \geq 0), \\ 0, & (x < 0). \end{cases} \quad (2)$$

However, it is worth explaining that ReLU function has certain defects in the calculation process. When the data passes through the negative range of ReLU function, the output value is equal to 0. Under certain conditions, some neurons in the data network will no longer update

parameters, thus reducing the expression ability of the network model. Based on the above problems, a Leaky-ReLU function is proposed to correct and optimize the ReLU function, which makes the output value not equal to 0 when the data passes through the negative range of the function. The Leaky-ReLU function can be expressed as follows:

$$f(x) = \begin{cases} x, & (x \geq 0), \\ ax, & (x < 0). \end{cases} \quad (3)$$

The corresponding equations of Sig and Tanh are as follows:

$$\begin{cases} \text{sig}(x) = \frac{1}{1 + \exp(-x)}, \\ \text{tanh}(x) = \frac{\exp(x) - \exp(-x)}{\exp(x) + \exp(-x)}. \end{cases} \quad (4)$$

The graph of activation function corresponding to the above functions is shown in Figure 4. The y value of Sig function increases gradually with the increase of x , which can be divided into three parts: The first part belongs to the stable stage. In this stage, with the increase of x value, the corresponding y value shows a constant trend of change, and the value is near zero. In the next stage, with the increase of x value, y value shows the trend of the curve increasing in the last step, and the slope corresponding to the curve at this stage is approximately constant, indicating that the linear characteristics of the curve are obvious. After the second part, as the x value increases, and the curve recovers again, showing an approximately constant trend of change. However, compared with the first part, the y value corresponding to the constant phase in this part is relatively large. From the change curve of Tanh, this curve is basically consistent with the change trend of Sig curve, except that the corresponding y value is in a negative state in the stable stage of the first part. In the second stage, the curve still shows a linear trend of change, but compared with the Sig function, the slope of Tanh function in this stage is relatively larger. As the value of x increases further, the curve reaches the third stage and coincides with the corresponding curve of the Sig function at this stage.

From the ReLU curve, the corresponding y value shows a linear change trend with the increase of x value, and the

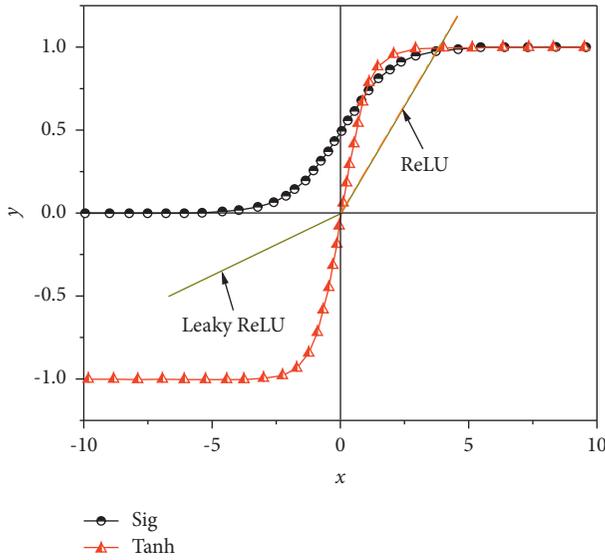

FIGURE 4: Activation function under convolutional neural network.

slope of this linear curve is constant. In addition, the slope of ReLU curve is basically consistent with that of Sig function in the second stage. And, the curve corresponding to Leaky function can be divided into two stages, indicating that Leaky function belongs to a segmented function, which coincides with the curve of ReLU function in the first quadrant. In the third quadrant, it still shows a linear change rule, but the slope is relatively smaller than that in the first quadrant.

2.2. Basis of Residual Neural Network. Deep residual network has a good application effect in image classification, location task, and semantic segmentation and can effectively alleviate the related problems caused by the disappearance of gradient [13–15]. CNN convolution layer has the characteristics of local perception and weight sharing. Local perception means that the convolution layer only extracts local features during operation and then combines all local features into global features after operation. Weight sharing means that the weight parameters between the convolution kernels are shared and the features extracted by the convolution kernels with shared weight parameters are the same in any region of the neural network. These two characteristics enable CNN to have faster training speed and better network performance compared with traditional fully connected neural network. In order to better analyze the relevant calculation content of residual neural network, the structure diagram of different types of residual neural network is summarized, as shown in Figure 5.

In order to explore the structure differences of different residual neural networks, they can be divided into three structures according to the difference of their operation processes: ResNet structure, VDSR structure, and DRRN structure. It can be seen from the structure comparison diagram that the three structures are consistent in the initial data input and final data export, while there are great differences in the concrete computing part in the middle. The

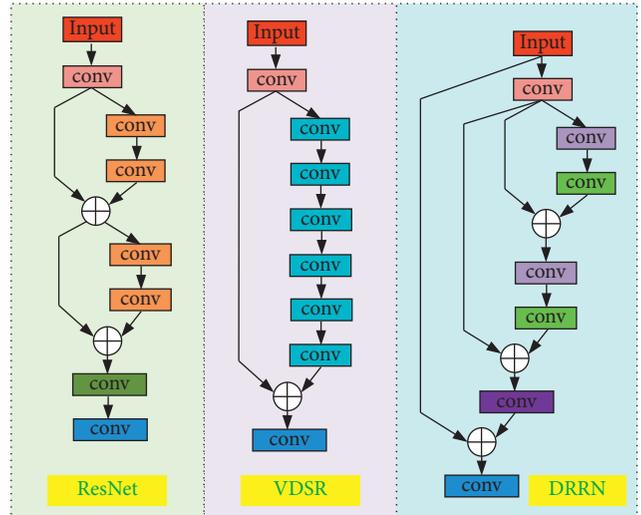

FIGURE 5: Comparison of several residual network structures.

intermediate operation part of ResNet structure can include two identical data loop chains, which can make the data better for iteration and analysis and make the calculation results more targeted. In the VDSR structure, the data operation part is directly carried out without any cycle, which can ensure the fluency and authenticity of the data and make the data results more comparative. The running part in the middle of the DRRN structure belongs to the multi-iterative loop, and multiple iterative loops can make the analysis of experimental data more accurate thus making the derived structure more general.

The structure characteristics of several common residual neural networks are shown as follows [16–18]:

- (1) VDSR: VDSR model is a new network structure that will add residual module into the deep neural network. Compared with SRCNN and other traditional super-resolution network models, the VDSR model has a faster training speed, and it can be found through calculation that the model can train image data of different sizes.
- (2) DRRN: It adopts a deeper network structure, which makes better use of the residual network module. Each residual unit has two convolution layers, and the parameters at the corresponding positions between the convolution layers are shared. DRRN has faster computing speed and higher accuracy during training and can reconstruct higher-quality high-resolution images with less memory resources.
- (3) ResNet: It refers to VGG19 network and is modified on its basis. Residual unit is added through short-circuit mechanism. The changes are mainly reflected in ResNet directly using convolutional samples for downsampling. In order to better analyze the influence of different layers on the training error of ResNet, the calculation results of ResNet under different layers are summarized, as shown in Figure 6.

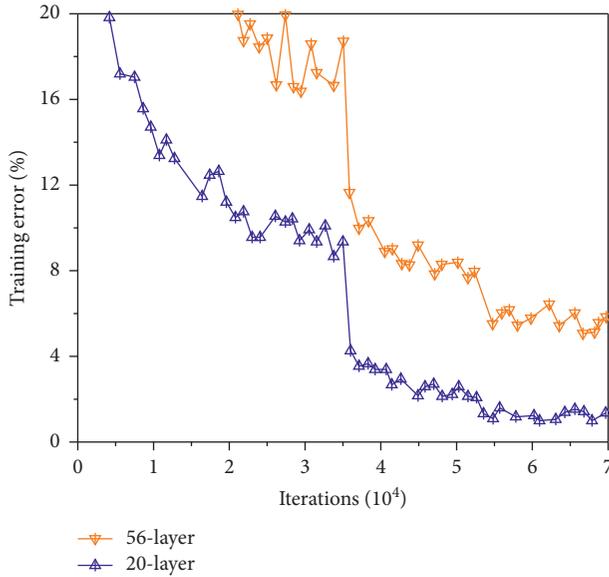

FIGURE 6: Activation function under residual neural network.

The two activation functions of different types are shown in Figure 6. It can be seen from the figure that the curves corresponding to the 56th and 20th floors change in a relatively large range, and both of them show a trend of gradual decline on the whole. However, their different trends can be divided into two parts: In the first part, with the increase of the number of iterations, the two curves first show a trend of gradual decline, but in the process of change, there are still certain fluctuations in the data. This indicates that the training error corresponding to the activation function has a certain jump. When the number of iterations reaches 3.5×10^4 , the curve suddenly drops rapidly and enters the second stage. The main reason for the rapid decline of the curve in this stage is that there is a certain jump in the relevant data, which leads to the rapid decline of the training error. In the second stage, the curve still shows an overall trend of gradual decline, but the corresponding data still have certain fluctuations. Compared with the first stage, the changes of the two curves are relatively small. On the whole, the curve value corresponding to the 56th layer is higher than that corresponding to the 20th layer, indicating that the training error corresponding to the 56th layer is higher than that of the 20th layer. At the same time, this also shows that the 20-layer method is relatively good and the corresponding training error is relatively low, which can better reflect the relevant properties of the activation function.

In order to better analyze the influence of structures corresponding to different residual neural networks on the calculation results, the calculation results of residual neural network structures of different types are summarized, as shown in Figure 7. As can be seen from the figure, different data structures show a trend of gradual decline on the whole. Their different trends can be divided into three stages on the whole: In the first stage, the residual neural network shows a trend of rapid decline and then slow decline. In the process of this change, the data of relevant structures fluctuated to some extent, indicating that the value of this data changed with the increase of the number of iterations. The overall

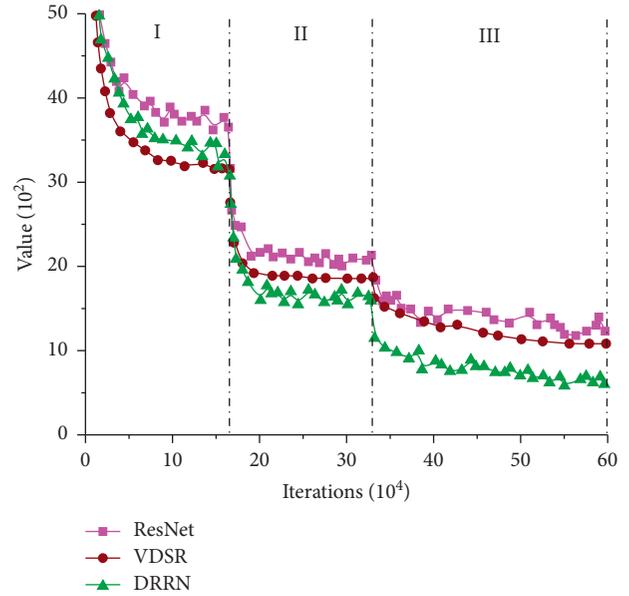

FIGURE 7: Comparison diagram of different residual network data.

performance is a certain degree of decline. With the further increase of the number of iterations, the data curve drops sharply, thus entering the second stage. At this stage, the data tended to be stable after experiencing a short rapid decline and remained stable all the time, indicating that the curve had good stability on the whole at this stage. As the number of iterations further increases, the data enters the third stage, and the curve shows a slow downward trend. The slope of the corresponding curve gradually approaches zero, indicating that the data has good stability after the first and second stages, and the data can be derived. The curves of different structures are basically the same. It can be seen that the curve values corresponding to ResNet structure are the largest. The values corresponding to the VDSR curve are the smallest in the first part, but only second to the ResNet structure in the second and third parts. The values of the corresponding DRRN structure are second only to ResNet in the first part, but lowest in the second and third parts, indicating that the stability of VDSR and DRRN structure is poor, while the stability of ResNet structure is relatively good.

2.3. Evaluation of Residual Networks. In order to better analyze the calculation results of the residual neural network, different analysis methods are adopted to analyze the deep residual network [19, 20]. The different evaluation indexes can be divided into subjective indexes and objective indexes.

2.3.1. Subjective Evaluation. Mean Opinion Score (MOS) is a subjective evaluation standard for residual network quality evaluation, and its definition is as follows:

$$MOS = \sum_{i=1}^n X_i, \quad (5)$$

where i represents the i -th sample to evaluate the residual network, and X_i is the score of the i -th sample to evaluate the residual network. MOS did not establish a rigorous mathematical model in the process of residual network quality evaluation. Considering the particularity of structural calculation, MOS was not used as the evaluation standard of residual network quality after reconstruction in this paper. The evaluation method of MOS is relatively fair and reasonable and is often used as an indicator of evaluation model algorithm. However, the results of MOS are also subject to subjective influence of participants. Different evaluators will have different views and opinions when comparing the same model, so there is a big gap in the evaluation results, leading to many uncertain factors.

The index of subjective evaluation is the range of scores, which is generally between 1 and 5: 5 means “very good evaluation,” 4 means “good evaluation,” 3 means “medium evaluation,” 2 means “poor evaluation,” and 1 means “poor evaluation.”

3.2.2. Objective Evaluation. The principle of Mean-Square Error (MSE) is to evaluate the quality of the reconstructed network by analyzing the difference between the reconstructed residual network and the original neural network. It can be expressed as follows:

$$\text{MSE} = \frac{1}{mn} \sum_{i=0}^{m-1} \sum_{j=0}^{n-1} (X_{ij} - Y_{ij})^2, \quad (6)$$

where X_{ij} represents the reconstructed residual network with length and width of $m-1$ and $n-1$, and Y_{ij} represents the original neural network with length and width of $m-1$ and $n-1$.

Since the neural network will cause data changes in the process of computation and compression, it is more rigorous to use the Peak Signal-to-Noise Ratio (PSNR) to evaluate the quality of the reconstructed residual neural network.

The function of PSNR is to use data to reflect the advantages and disadvantages of each neural network algorithm, and its specific expression form is as follows:

$$\text{PSNR} = 10 \times \log_{10} \left(\frac{mn \times (\text{Max})^2}{\sum_{i=0}^{m-1} \sum_{j=0}^{n-1} (X_{ij} - Y_{ij})^2} \right). \quad (7)$$

Max is the peak value of the model, which is 255 in general. If it is 1, it indicates that the model has been linearly normalized. Structural similarity is used to evaluate the similarity of residual neural network from the three aspects of contrast, brightness, and structure and is an index to measure the similarity of residual neural network. The evaluation method is more accurate and has a wider range than PSNR. The definition of structural similarity is as follows:

$$\text{SSIM} = \frac{(2u_x u_{x_1} + C_1)(2\delta_{xx_1} + C_2)}{(u_x^2 + u_{x_1}^2 + C_1)(\delta_x^2 + \delta_{x_1}^2 + C_2)}, \quad (8)$$

where u_x represents the gray mean of the original neural network, δ_x represents the variance of the original neural network, u_{x_1} represents the gray mean of the neural network after reconstruction, δ_{x_1} represents the variance of the residual neural network after reconstruction, δ_{xx_1} represents the covariance between x and x_1 , and C_1 and C_2 are constants. Generally speaking, the closer SSIM is to 1, the higher the similarity is, and the better the computational quality of the model is. SSIM can evaluate the quality of models from three different aspects, better meeting the requirements of perceptual evaluation, so it is widely used in the field of super-resolution.

3. Behavior Recognition Algorithm

In order to better analyze the behavior recognition algorithm, a behavior recognition flow chart is drawn, as shown in Figure 8. As can be seen from Figure 8, the behavior recognition algorithm mainly includes acquisition end, information processing, feature extraction and behavior recognition. The specific calculation process is as follows: Firstly, the target and sample to be identified are imported to the collection end of the behavior recognition algorithm, and the samples are analyzed by feature extraction and behavior extraction in the collection end. Then, the parameters after feature extraction are input into the information processing module, corresponding to the extraction of morphological features and behavioral features. In order to better analyze the extracted data, the external morphological and behavioral features of the sample are fused through the feature extraction data plate. In this way, the corresponding analysis can be carried out by comprehensively considering the behavior of samples. Finally, the data are compared and verified with the data in the database of the corresponding object’s morphological characteristics, so as to explain the relevant problems.

3.1. Basic Theory of Model. The path of behavior recognition algorithm is divided into two-stream recognition network model and class activation model [21–23].

3.1.1. Two-Flow Network Model. Image sequence and optical flow diagram can be regarded as two different modes of information, and the sampling sequence of each mode can be expressed as follows:

$$m_i = (m_{i1}, m_{i2}, \dots, m_{iT}), \quad (9)$$

where T is the total number of video frames.

In the model corresponding to the behavior recognition algorithm, the modal features of the image sequence and the modal features of the light flow are average-pooled, and then the channel splicing and feature fusion are carried out, so that the final classification and prediction result of the network for the operation behavior in the video can be expressed as follows:

$$y = h(G(f_1(m_1)), G(f_2(m_2))), \quad (10)$$

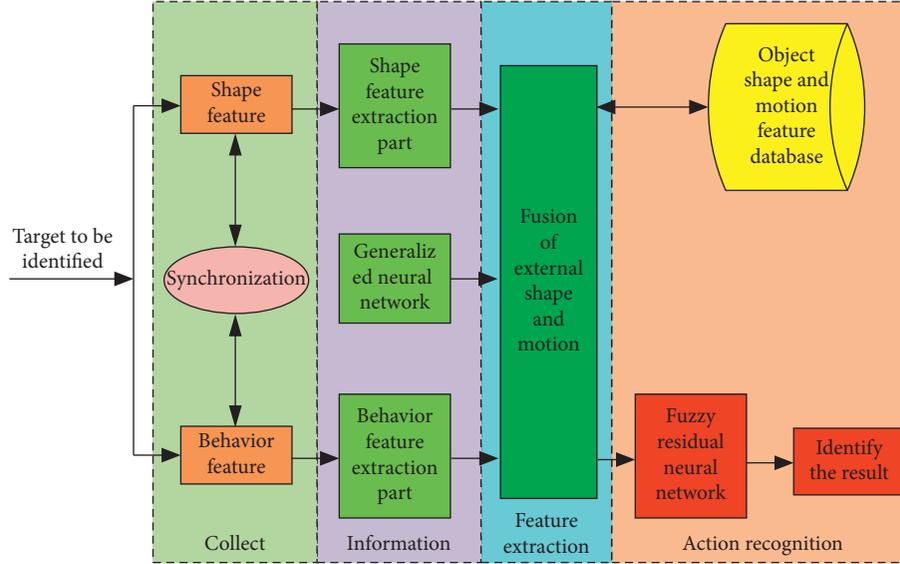

FIGURE 8: Behavior recognition flow chart.

where f_1 and f_2 are feature extractors of each mode, G is time aggregation function, h is multimode fusion function, and y is the predicted output of video.

3.1.2. Class Activation Model. Class activation model (CAM) is a salient feature model that generates specific categories using average-pooling layer in modern deep CNN network [24, 25]. The principle formula of CAM is derived as follows:

$$F_l = \sum_t f_l(i), \quad (11)$$

where $f_l(i)$ is set as the activation value of unit l at the spatial position i of the last convolutional layer of the network, and CNN network operation is performed on unit l to obtain F_l .

Softmax input for category c is as follows:

$$S_c = \sum_t w_l^c F_l, \quad (12)$$

where w_l^c is the weight.

Softmax output for category c is as follows:

$$P_c = \frac{\exp(S_c)}{\sum_t \exp(S_c)}. \quad (13)$$

For a given category c , its CAM can be expressed as follows:

$$M_c(i) = \sum_t w_l^c f_l(i). \quad (14)$$

Using the CAM generated by M_c , we can identify the image region considered by CNN when it classifies the image as class c . Therefore, if we use the highest probability categories corresponding to the results output by the Softmax function, the generated CAM will provide a saliency feature map of the image. Since the operation behavior in the first view focuses on the object being operated by the first person,

CAM can be used to make the network focus on the area of the operation object in the image, so as to realize the spatial positioning of the operation object under weak supervision. In view of the differences among different algorithms in the class activation model, the calculation results of relevant parameters under different algorithms are summarized, as shown in Figure 9:

In order to better analyze the differences and connections of various methods under different training samples, their recognition rates are drawn, as shown in the figure. It can be seen from the figure that, with the gradual increase in the number of iterations, the training samples show different trends. Among them, the recognition rate of F_l data is the highest, and the overall variation range is between 80 and 90. The curve is relatively flat, indicating that the training method is relatively stable. The data of S_c curve was second only to that of F_l , which also showed relatively stable changes, with the overall change ranging from 70 to 89. On the other hand, the data of the corresponding identification methods P_c and M_c are relatively close on the whole, except that the number of iterations is relatively minimum when it is 10, and the range of other changes remains around 80. From the above analysis, we can see that the F_l and S_c methods have relatively high recognition rate, while the P_c and M_c methods have relatively low recognition rate.

3.2. Robust Analysis. Multiple samples are selected as robustness test data for the above algorithm [26–28]. Relevant studies show that the robustness recognition rate of class activation model is higher than that of other methods under different number of training samples [29–31].

Specifically, for each frame of the input image, CAM is firstly calculated using the category with the highest probability output by CNN network, and then Softmax operation is applied along the spatial dimension. The obtained CAM is transformed into a probability graph, which is a spatial attention diagram. Finally, it is multiplied by the output of

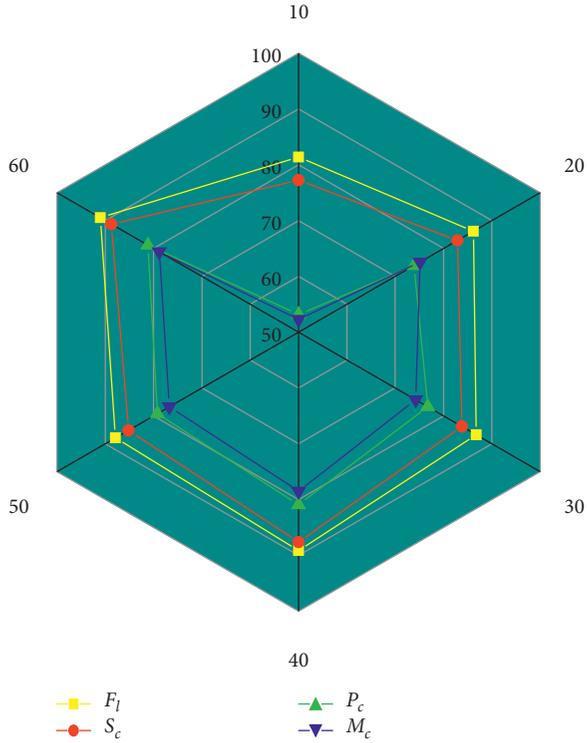

FIGURE 9: The recognition rates of various methods under different training samples.

the last convolutional layer of CNN network to obtain a new image feature with spatial attention. For each image input frame, the class of CAMs with the highest probability needs to be output using the network. Firstly, the data are applied Softmax operations along the spatial dimension to transform the resulting CAMs into probability maps, and then the last layer of convolution is multiplied with the CNN network output to obtain new image features with spatial attention. The corresponding formula is as follows:

$$f_{SA}(i) = f(i) \frac{\exp(M_c(i))}{\sum_t \exp(M_c(i))}, \quad (15)$$

where f_i is the feature graph output by the convolution layer at the spatial position i , $M_c(i)$ is the CAM obtained using the category c with the highest probability output by CNN network, $f_{SA}(i)$ is the image feature obtained using spatial attention, and \odot is the product of the corresponding elements.

The above methods have certain errors in the recognition of training samples. In order to better study the robustness recognition rates of various methods under different training samples, robustness analysis method is adopted to calculate the data, as shown in Figure 10. As can be seen from the figure, the overall recognition rate of F_l data is the highest, showing a trend of slow decline at first and then a gentle change. The identification trend corresponding to S_c identification method increases rapidly at first, then decreases slowly, and finally increases rapidly, indicating that the stability of this identification method is relatively poor. However, the recognition rate of IDCC and DCC shows a

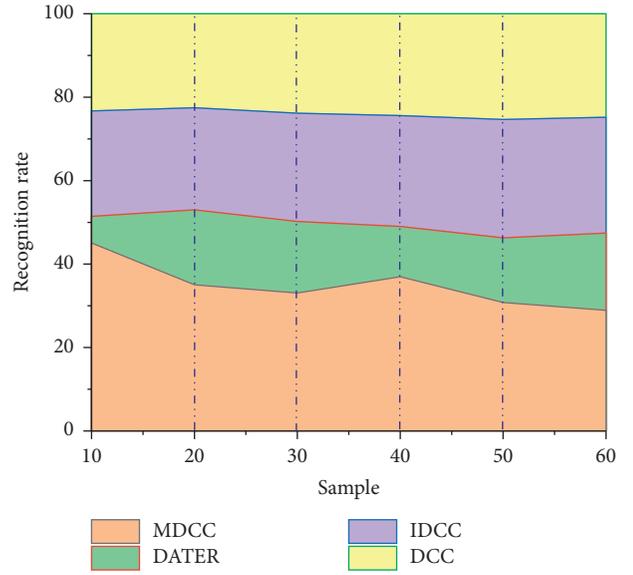

FIGURE 10: The robustness recognition rates of various methods under different training samples.

gentle trend of change on the whole, and the corresponding recognition rate is basically the same, indicating that these two methods have certain advantages in describing the robust recognition rate. Therefore, under different training methods, the order of the robustness recognition rate is F_l , P_c , M_c and S_c .

4. Analysis of Leisure Sports Behavior Recognition Algorithm

4.1. Introduction to Leisure Sports. Leisure sports require people to choose their favorite sports to exercise after work, in order to achieve the goal of physical exercise and relaxation. Compared with traditional sports, leisure sports take fitness and entertainment as the main goals, assuming that all participants can participate in sports in a relaxed state of mind and body. In addition, recreational sports are not necessarily winners like traditional sports, but emphasize that all participants can get a sense of physical and mental pleasure and improve their physical quality, and play a certain role in enriching their spare time.

With the continuous development of the times, leisure sports have become an indispensable part of people's daily life. Leisure sports, as a new form of sports, are characterized by freedom, culture, nonutility, enthusiasm, and initiative. In order to better analyze the influence of different factors on leisure sports, the proportion chart of leisure sports under different impression factors is summarized, as shown in Figure 11. From the proportion of different factors, it can be seen that enthusiasm, as the most important influencing factor in leisure sports, accounts for 33.33% of the total. The proportion of nonutilitarian factors in leisure sports is about 23.33%. Culture, as an important influencing factor, accounts for about 20% of leisure sports. Free activities are one of the leisure sports pursued by people in today's environment, accounting for about 13.33. The lowest proportion

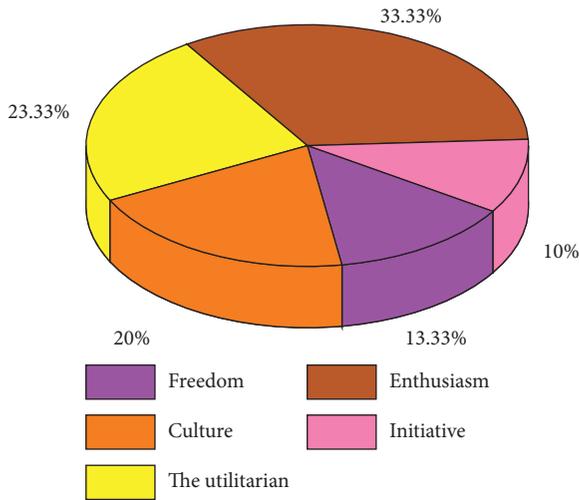

FIGURE 11: Proportion of main characteristics of leisure sports.

is that of the initiative factor, which is only 10%, indicating that initiative has the least influence on leisure sports.

4.2. Analysis of Leisure Sports Behavior Algorithm. On the basis of the above research, in order to better analyze and study the relevant content of leisure sports, based on the theory of deep residual neural network, behavior recognition algorithm is used to analyze the relevant data of leisure sports, so as to obtain the corresponding recognition algorithm of leisure sports. In order to more accurately describe the variation rule of the samples of the behavioral motion algorithm, the calculation results of different samples under the behavior recognition algorithm are summarized, as shown in Figure 12.

By using the above method to identify leisure sports under different samples, the corresponding sample analysis graph was obtained. It can be seen from the graph that, with the gradual increase of samples, the corresponding value showed a relatively fluctuating trend of change, which remained at about 40 on the whole. The variation trend is a series of fluctuation changes, which first slowly decreases, then gradually increases with the increase of samples, then slowly decreases, and finally slowly increases again. The values are relatively high when the sample size reaches about 52–56. Specifically, when the sample number was 54, the highest sample value (278) was reached.

In order to better analyze the impact of different models on leisure sports, different models are used to analyze relevant data, and the prediction curves of leisure sports under different models are obtained through iterative calculation, as shown in Figure 13. It can be seen from the figure that the calculated data of different models show different changing curve trends, which can be divided into three stages. From the perspective of the dual-flow model, the curve shows a rapid downward trend in the first stage, with a large drop range, indicating that the stability of the curve in this stage is poor. As the number of iterations increases, the curve enters the second stage. The overall performance of the curve is relatively flat, and the variation range is small, indicating that

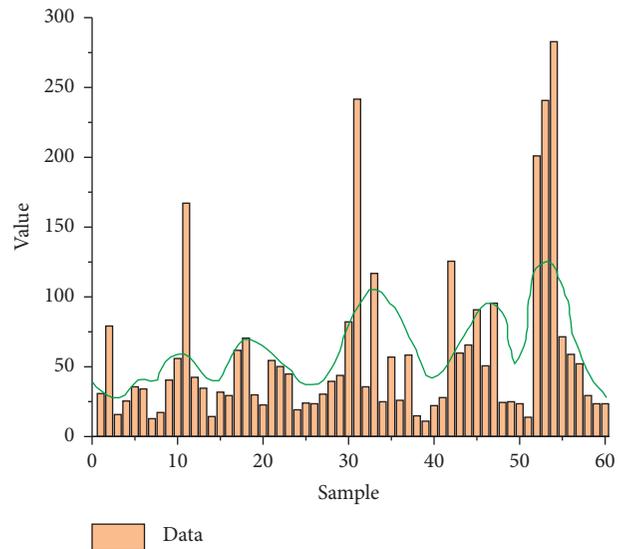

FIGURE 12: Sample diagram.

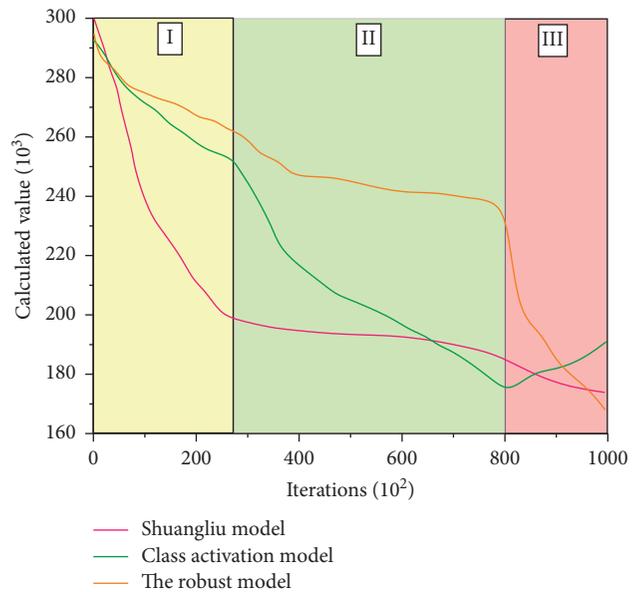

FIGURE 13: Prediction curves of leisure sports under different schemes.

the stability of the curve in this stage is relatively high. Finally, the curve enters the third stage, showing a slow downward trend. In the quasi-activation model, the curve shows a rapid downward trend in both the first and second stages, but the downward trend in the second stage is higher than that in the first stage. In the third stage, the curve shows an upward trend, indicating that the model increases to a certain extent when the number of iterations is high. In the robustness model, the curve drops slowly in the first stage, shows an approximately constant change trend when it reaches the second stage, and drops rapidly in the third stage. On the whole, the three models have basically the same overall range of variation. The robustness model has good stability in the first and second stages, while the dual-flow model has good stability in the third stage.

5. Conclusion

- (1) As time goes by, the scale of sports shows a trend of gradual increase. The scale of leisure sports increases from 129 in 2011 to 731 in 2021, an increase of about 5.7 times. The scale of leisure sports increases gradually with the increase of time, and the increment proportion also shows an increasing trend.
- (2) Activation curves of residual neural networks with different structures are basically the same, and the curve values corresponding to ResNet structure are the largest. The values corresponding to the VDSR curve are the smallest in the first part. The DRRN structure values are second only to ResNet in the first part, but lowest in the second and third parts. This indicates that the stability of VDSR and DRRN structures is poor, while the stability of ResNet structures is relatively good.
- (3) The overall variation range of F_l data recognition rate is between 80 and 90, and the curve is relatively flat, indicating that the training method is relatively stable. The data of S_c curve was second only to F_l curve, which also showed relatively stable changes. However, the data of the corresponding P_c and M_c identification methods are relatively close, indicating that the recognition rates of P_c and M_c methods are relatively low.
- (4) The calculated data of different models show different changing curve trends, which can be divided into three stages. On the whole, the three models have basically the same overall range of variation. The robustness model has good stability in the first and second stages, while the dual-flow model has good stability in the third stage.

Digital multimedia resources have become an important part of people's daily cultural life. Automatic scene classification of a large number of dance art videos is the basis for scene semantic based video content retrieval. In order to improve the accuracy of scene classification, the videos are identified using a deep convolutional neural network based on differential evolution for dance art videos. First, the Canny operator is used in YCbCr colour space to detect the human silhouette in the key frames of the video. Then, the AdaBoost algorithm based on cascade structure is used to implement human target tracking and labelling, and the construction and updating of weak classifiers are analysed. Next, a differential evolution algorithm is used to optimise the structural parameters of the convolutional neural network, and an adaptive strategy is adopted for the scaling factor of the differential evolution algorithm to improve the optimisation solution accuracy. Finally, the improved deep convolutional neural network is used to train the classification of the labelled videos in order to obtain stable scene classification results. The experimental results show that by reasonably setting the crossover rate of differential evolution and the convolutional kernel size of the convolutional neural network, high scene classification performance can be obtained. The high accuracy and low root-mean-square error validate the applicability of the proposed method in dance art scene classification.

1. Introduction

Due to the accelerated pace of life today, many people are busy with work, resulting in not having enough time to rest. People want to enrich their spare time activities more in their leisure time, such as dancing. However, as dance learning usually requires attending professional classes offline, resulting in many people not having much time to learn. Therefore, it has become a trend to learn dance by searching and watching online videos [1–7]. The main means of expression in the art of dance is the flexible footwork and graceful movement of the human body. Dance expresses feelings and reflects social life through this art form. As society continues to develop, people's demand for quality of life continues to increase. The traditional offline dance learning method is no longer able to meet people's needs, and is still very limited. As more and more people want to learn dance, which creates the problem of limited resources in teaching dance teachers, the original face-to-

face teaching method can no longer meet the actual needs. Online teaching has become more and more accepted and has become a new mode of teaching.

The online teaching and learning process requires students to access the knowledge they learn through the computer network. As online teaching not only maximises the sharing of information resources, it can also generate multiple forms of teaching and learning, helping to improve teaching efficiency and achieve sharing of teaching resources. At present, there is an explosive growth in the use of digital multimedia video. Along with the popularity of the Internet, massive amounts of dance art video data have appeared on various online media [8–10]. According to relevant statistical reports, online media around the world generate about tens of T of video data every day, which contains video data of movies, music and dance.

With so much dance video data available, only a fraction of it is of interest to each individual. So, how can one find the data one needs from this dance video data? This requires

effective scene classification of this dance video data. Classifying scenes from a large number of dance videos can be a very difficult task. The traditional method is to annotate and classify these videos manually, thus, forming a database of dance videos that can be indexed by keywords. However, with the huge amount of dance video data, it would take a lot of human resources, money, and time to use the manual annotation method [11–13]. This manual approach requires staff to face a large amount of dance video data every day, which is prone to visual errors, thus, leading to errors in video annotation and classification. Therefore, this traditional method has major drawbacks [14]. An alternative approach is to use computers to analyse these massive amounts of video data and eventually achieve an automated dance video scene classification system. In using computer technology to annotate, classify, and retrieve dance videos, an efficient algorithm needs to be designed to process them [15]. In recent years, the issues of video annotation, video scene classification, and video retrieval have become a hot research topic in the multimedia field. Numerous scholars and research institutions have conducted in-depth research on this problem.

Traditional video scene classification methods generally use manually designed features for modelling. Wei et al. [16] proposed a motion human tracking algorithm based on region segmentation contours with more accurate and stable performance in complex occlusion situations. Suganya et al. [17] proposed an AdaBoost-STC and random forest based human eye tracking and localisation algorithm. Wang et al. [18] proposed a target tracker based on likelihood graph and real-time AdaBoost cascade. Both methods are effective in improving tracking speed without degrading tracking accuracy. Ibrahim et al. [19] conducted a video classification study using video saliency features. They divided the RGB colour channel of each frame into three images, and then combined the grey-scale images to arrange these three images in temporal order to obtain three spatio-temporal container models. These spatio-temporal containers were then subjected to pyramidal degradation and the regions of significance in the containers were divided using mean clustering. Finally, a support vector machine is used to classify the video scenes. This algorithm has a more complex process and is not effective in video scene classification. Calvin et al. [20] mapped motion vectors into the unit circle and divided it into 8 regions. Each motion vector is mapped to the coordinate axes of the corresponding region, and the corresponding matrix is derived as features for the data on the axes. Finally, the SVM is used to classify the video. However, this method can only detect the corresponding moments taken as features, and finally, the video is classified using SVM. However, this method can only detect some motion patterns in the video, such as jumping, running, swimming, and some other specific events, and cannot determine the scene classification of the video. Lu et al. [21] classify the video by taking the comparative values of luminance between regions in the video as featured, and by using Hidden Markov Model (HMM). This method is able to eliminate the influence of factors such as illumination on the video, but can only perform the classification of different

categories of videos, such as news, movie, and animation videos. In addition, the calculation of the parameters of the HMM requires a large number of videos for training, and the whole process is more complicated.

Semantic-based information processing has developed rapidly in recent years with the development of artificial intelligence and data mining techniques. Many researchers are conducting research in mapping from the underlying features of the video to the semantic information of the video. By mining the semantic information of videos and forming semantic rules according to certain algorithms, scene classification of video data can be achieved. Therefore, the use of semantic information to classify video is also a future trend in video classification. Deep learning abandons the complex operation process of the underlying features in the traditional algorithm, so it can effectively achieve the task of video semantic information mining based on computer vision. Convolutional neural network (CNN) [22–24], which emerged in the field of deep learning, first achieved great success in image recognition and image segmentation. Then, breakthroughs in typical network structures continued, such as recurrent neural network (RNN) [25, 26], deep belief network (DBN) [27], generative adversarial networks (GAN) [28], and other types of network structures. These network structures are capable of enhancing the feature extraction capability of models in a supervised learning manner. Compared to traditional machine learning methods, deep neural networks perform feature extraction at different scales on images, combining gradients to explore better strategies, and saving the tedious manual feature extraction process. As a result, deep neural networks only require a well-designed network structure. With the excellent image feature representation capability, deep neural networks have good robustness in dealing with scene classification problems of sports, news, and other videos. However, dance art videos are more diverse and involve human target tracking and labelling problems, so, the various types of network structures available in deep learning do not perform well enough for the scene classification task of dance videos.

The aim of this study is to automatically classify scenes from dance videos using deep convolutional neural networks and to further improve the accuracy of the model through structural parameter optimisation. The proposed method helps to implement a video content retrieval task based on scene semantics.

Key innovations and contributions to the video include the following:

- (1) Both the contour model and the AdaBoost algorithm show some advantages in terms of robustness and accuracy of video target tracking. Therefore, a combination of both is proposed to solve the person tracking problem in dance art videos.
- (2) A deep CNN based on differential evolution (DE) [29] was proposed to address the problem of unsatisfactory classification efficiency and stability of the traditional CNN structure in processing the classification of dance video scenes based on

$$D_i = D_i e^{\alpha_t |h_t(x_i - y_i)|}. \quad (8)$$

3.2. Description of the Algorithm Flow. The AdaBoost algorithm is an iterative algorithm. AdaBoost can aggregate multiple weak classifiers from the same training set to form a strong classifier. The main steps of the AdaBoost algorithm are shown as follows:

Step 1. Set the input be $\{(x_1, y_1), (x_2, y_2) \dots (x_n, y_n)\}$ where, $x_i \in X, y_i \in \{-1, 1\}$ and the data set be X . Initialize the weights $D_1(i)$ is shown as follows:

$$D_1(i) = \frac{1}{n}, \quad (9)$$

$$i = 1, 2 \dots n.t$$

Step 2. Find the weak classifier $h_t: X \rightarrow \{-1, 1\}$, when $t = 1, 2 \dots T$ and train a weak classifier h_j with each feature f_j , which gives a weighted error rate.

$$\epsilon_j = \sum_{t=1}^n D_t, h_t(x_i) \neq y_i. \quad (10)$$

Step 3. The classifier h_t with the smallest weighted error rate ϵ_j is selected and its smallest weighted error rate value is noted as ϵ_t . The weights of the weak classifier are then calculated as follows:

$$\alpha_t = \frac{1}{2} \ln \left(\frac{1 - \epsilon_t}{\epsilon_t} \right). \quad (11)$$

Step 4. The actual method used to update the sample weights is shown as follows:

$$D_{t+1}(i) = \frac{D_t(i) \exp[-\alpha_t y_i h_t(x_i)]}{Z_t}. \quad (12)$$

where Z_t denotes the normalisation parameter.

Step 5. Construct the final strong classifier using the following approach.

$$H(x) = \text{sign} \left(\sum_{t=1}^T \alpha_t y_t h_t(x) \right). \quad (13)$$

4. DE-CNN Based Dance Video Scene Classification

4.1. Adaptive DE Algorithm. Let the population size be N , the attribute dimension be D , the differential scaling factor be F , the crossover rate be CR , and the value of each individual be $[U_{\min}, U_{\max}]$, then the j dimensional attribute [31] of the i -th individual can be shown as follows:

$$x_{ij} = U_{\min} + \text{rand} \times (U_{\max} - U_{\min}), \quad (14)$$

where $i = 1, 2, \dots, N, j = 1, 2, \dots, D$, rand are random numbers in $(0, 1)$.

Individuals $x_i^G, (i = 1, 2, \dots, N)$ of the G generation can obtain the $G + 1$ generation using the mutation operation.

$$v_i^{G+1} = x_{r_1}^G + F \times (x_{r_2}^G - x_{r_3}^G), \quad (15)$$

where r_1, r_2 , and r_3 are three random individuals from the G generation. A common range of F values is $[0, 2]$.

The individual crossover method is shown as follows:

$$u_{ij}^{G+1} = \begin{cases} v_{ij}^{G+1}, & \text{rand}(0, 1) \leq CR, \\ x_{ij}^G, & \text{otherwise.} \end{cases} \quad (16)$$

Compare x_i^G with u_i^{G+1} and find the fitness value of each individual. Select the individual with the higher fitness value for the subsequent evolutionary process.

$$x_i^{G+1} = \begin{cases} u_i^{G+1}, & f(u_i^{G+1}) > f(x_i^G), \\ x_i^G, & f(u_i^{G+1}) \leq f(x_i^G), \end{cases} \quad (17)$$

where f represents the fitness function. The DE algorithm stops, when the maximum number of generations G_{\max} is reached.

A common range of F values is $[0, 2]$. The optimisation process for DE is closely related to the F value. A wrong choice of F value will result in unsatisfactory optimisation performance of the differential evolution algorithm. Therefore, adaptive F values are introduced in the calculation. The value range of F_{\min} and F_{\max} is $[0, 2]$.

$$F = F_{\min} + (F_{\max} - F_{\min}) \times e^{1 - G_{\max}/G_{\max} - G + 1}. \quad (18)$$

The F value becomes progressively smaller as the evolutionary generation G changes. Early evolution pursues population diversification, while late evolution focuses on search ability, so that the DE algorithm is more likely to obtain optimal individuals.

4.2. CNN Model Design. Machine learning has played a huge role in computer vision processing techniques. Most of the traditional machine learning methods use shallow structures that deal with limited data operations. A large number of experiments have proven that the feature expressions learned from shallow structures, when dealing with complex classification problems, are difficult to meet the practical needs. In recent years, computer performance has continued to improve, providing a powerful support for deep learning. New deep learning models are constantly being proposed and successfully incorporated into application areas such as image recognition, speech recognition, and natural language processing.

Common deep learning models in image recognition include deep belief network (DBN), recurrent neural network (RNN), generative adversarial network (GAN), capsule network (CapsNet), restricted boltzmann machines (RBMs), and convolutional neural network (CNN). Based on the deep

convolution neural network, this paper selects the most representative dance video as the recognition object.

Originally designed, specifically to handle image recognition tasks, CNNs are multilayer neural networks and are currently the most classical and commonly used computational structure in the field of computer vision. The basic structure of a CNN consists of an input layer, an implicit layer and an output layer. The implicit layer is the core part of the convolutional neural network, which contains the convolutional layer, the pooling layer (also known as the downsampling layer), and the fully connected layer, as shown in Figure 2.

Pooling layers generally reduce the dimensionality of the input feature map between successive convolutional layers. The pooling layer effectively reduces the output feature vector of the convolution layer. This process uses a partially contiguous region of the image as the pooling region and translates the sliding window matrix of the pooling function within the region. The pooling size and step size control the sliding window size and translation rule respectively, as shown in Figure 3.

Let the set of dance video samples be $\mathbf{X} = (x_1, x_2, \dots, x_N)$. The m video attribute features are convolved through the l layer.

$$x_{lj} = f \left(\sum_{j \in m} x_{l-1} * k_{lj} + b_{lj} \right), \quad (19)$$

where k_{lj} and b_{lj} represent the weights and biases assigned to the features j by the l layer, respectively, and $*$ is the convolution.

$$f(z) = \frac{1}{1 + e^{-z}}. \quad (20)$$

Convolution of m features is from N samples. Convolution kernel size $h \times w$:

$$g(x) = \max_{1 \leq k \leq h \times w} (x_k). \quad (21)$$

Assuming $M = N/(h \times w)$, then the original sample $\mathbf{X} = (x_1, x_2, \dots, x_N)$ is reconstructed after convolution pooling as $\mathbf{X}' = (x_1, x_2, \dots, x_M)$. The conversion operation is then performed on \mathbf{X}' .

$$x_j^l = f \left(\sum_{i=1}^M a_{ij} (x_i^{l-1} * k_i^l) + b_j^l \right). \quad (22)$$

The restrictions are $\sum a_{ij} = 1, 0 \leq a_{ij} \leq 1$.

After obtaining all the connected layers of the CNN, the classifier is selected to predict the sample class. Let the training output and the actual value of the k -th node be y_k and d_k , respectively, and the error term be δ_k .

$$\delta_k = (d_k - y_k) y_k (1 - y_k). \quad (23)$$

Assuming that the l and $l + 1$ layers contain L and P nodes, respectively, the error of node j in the l layer is δ_j .

$$\delta_j = h_j (1 - h_j) \sum_{k=1}^P \delta_k W_{jk}, \quad (24)$$

where h_j is the output and W_{jk} is the weight of the neuron j to the neuron k in the $l + 1$ layer. The weights are updated as shown follows:

$$\Delta w_{jk}(n) = \frac{\eta}{1 + N} (\Delta w_{jk}(n-1) + 1) \delta_k h_j, \quad (25)$$

where η is the learning rate.

The bias $\Delta b_k(n)$ is updated as follows:

$$\Delta b_k(n) = \frac{\alpha}{1 + N} (\Delta b_k(n-1) + 1) \delta_k, \quad (26)$$

where α is the bias update step, typically $\alpha = 1$. The adjusted weights are shown as follows:

$$w_{jk}(n+1) = w_{jk}(n) + \Delta w_{jk}(n). \quad (27)$$

The adjusted offsets are shown as follows:

$$b_k(n+1) = b_k(n) + \Delta b_k(n). \quad (28)$$

The error for all nodes E is shown as follows:

$$E = \frac{1}{2} \sum_{k=1}^M (d_k - y_k)^2. \quad (29)$$

When E meets the set threshold, the iteration stops and a stable CNN model is obtained.

4.3. Classification Process Based on DE-CNN Model. Before the CNN can be applied to classify a video, the sample data to be classified first needs to be transformed, which is mainly to address the vectorisation process of the video attributes. The converted Skip-gram facilitates efficient input to the CNN. After the CNN video classification model is established, the random weights and biases are optimally solved by the DE algorithm. An adaptation function is established based on the video classification accuracy function. The optimal individuals of weights and biases are obtained by multigeneration evolution of DE. Finally, the video classification results are obtained using CNN for classification training, as shown in Figure 4.

5. Experimental Results and Analysis

5.1. Experimental Setup. In order to validate the performance of the DE-CNN model in dance video scene classification, simulation experiments were conducted on dance video sequences (resolution 640×480), with the length of 400 frames. Firstly, the performance of human target tracking was verified. Secondly, the performance was verified for different DE algorithm parameters. Then, the performance was verified for different convolutional kernel sizes. Finally, the performance of the DE-CNN model is compared with commonly used video scene classification algorithms.

The data sources for the video classification experiment were 11 large video websites. All videos were in MP4 format, and seven categories of dance videos were selected for the classification test: classical dance, ballet, folk dance, modern dance, tap dance, jazz dance, and Latin dance. The number of videos in each category is 500, so there are 3500 dance video sequences in the experimental video dataset. The

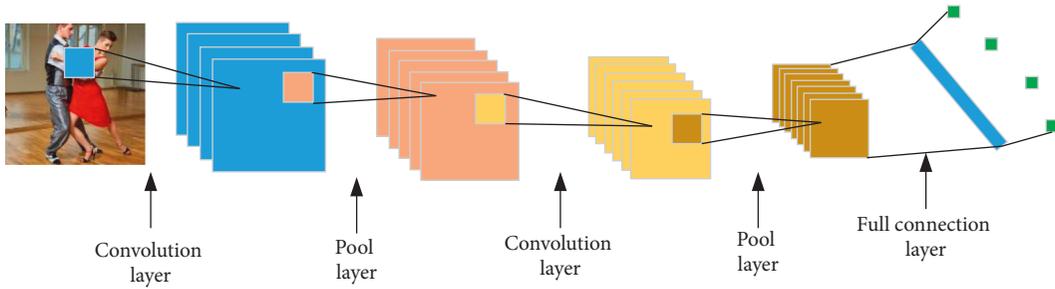

FIGURE 2: CNN network structure.

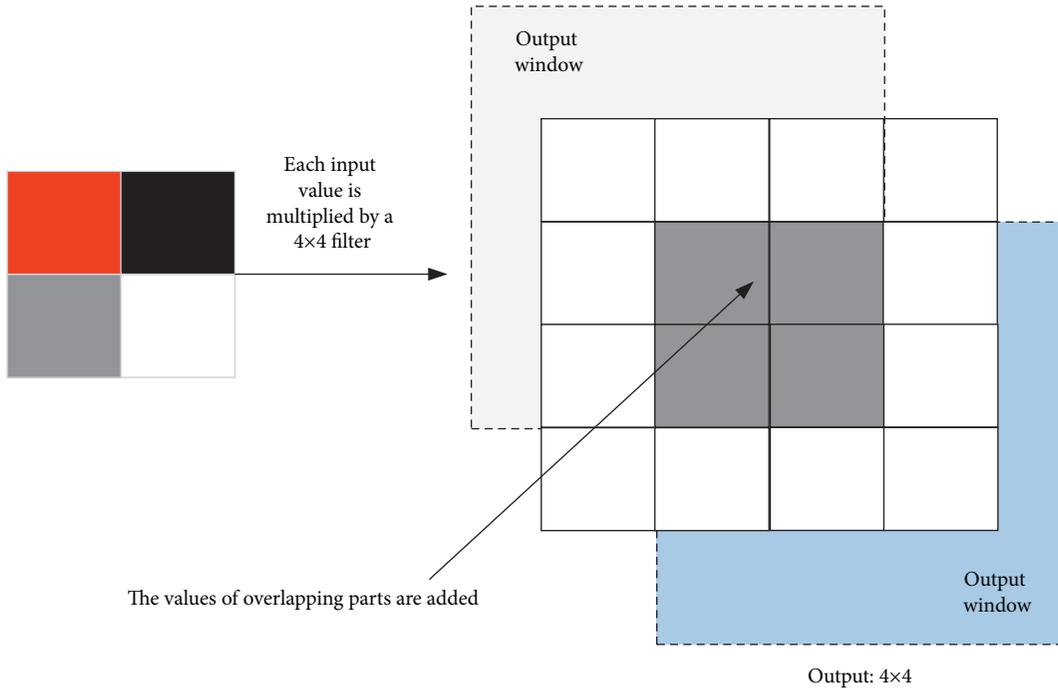

FIGURE 3: Pooling feature diagram.

length of each video sequence was 400 frames and the duration was 5 min. Some of the data of the dance video samples are shown in Figure 5.

The proposed method classifies the dance videos so that automatic scene recognition can be achieved. Information on the experimental video dataset is shown in Table 1.

The video from Table 1 was transformed using the Skipgram structure, thus completing the video-to-attribute vector mapping. This allowed the video samples to be trained for CNN classification. During the experiments, the entire dance video sample set was trained and tested in a 7 : 3 ratio respectively. The experimental hardware environment is: CPU i7 3770 (3.4 Hz), 8 G RAM. The experimental software environment is: Windows 10 operating system, Matlab 7.0 simulation software. The initial values of DE algorithm settings are $F_{\min} = 0.2$, $F_{\max} = 0.9$, $CR = 0.1$, and $G_{\max} = 100$. CNN convolutional kernels are $2 * 2$ by default.

5.2. Human Target Tracking Performance. The effect of human target detection was first quantified in order to assess

its robustness. The panning errors for human detection are shown in Figure 6. As can be seen from Figure 6, the human detection is good in the panning case with an average error of less than 10 pixels.

In addition, in order to quantitatively compare the tracking performance, the comparison experiments of the same video sequences are conducted by using hybrid algorithm, AdaBoost-STC algorithm, and adaptive EKF algorithm.

$$d = \sqrt{\sum_{i=1}^N (x_i - y_i)^2} \quad (30)$$

where x_i is the centre of the trace result and y_i is the centre of the baseline result.

After repeating the experiment 100 times and taking statistical averages, the human tracking results for the three different algorithms on a 400-frame video sequence are shown in Figure 7.

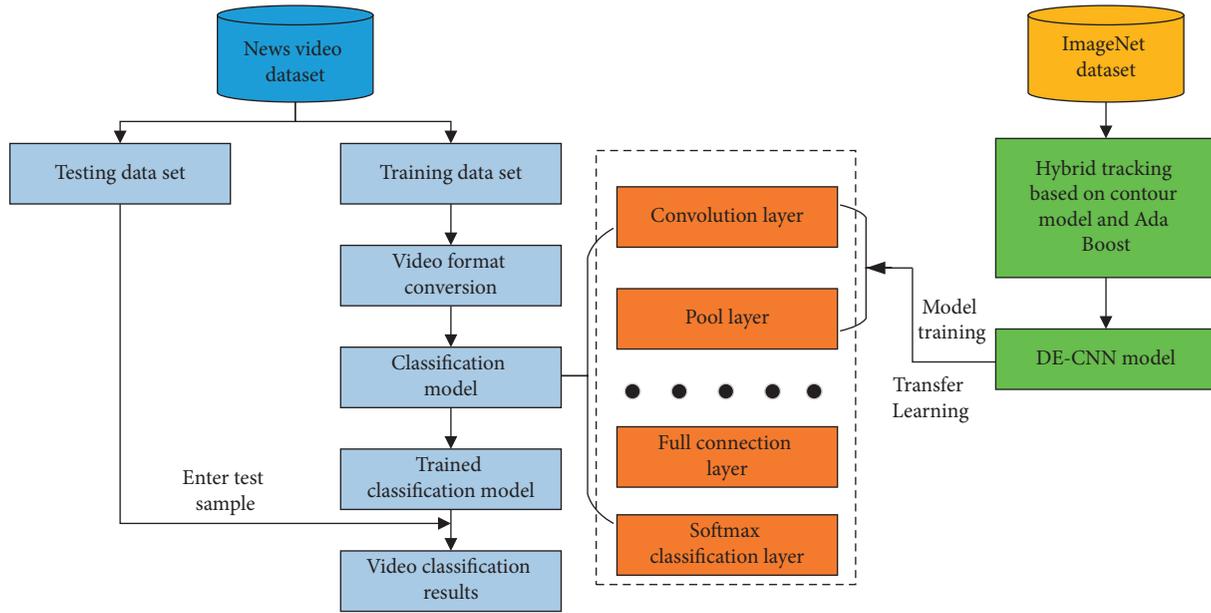

FIGURE 4: Flow of dance video scene classification based on DE-CNN model.

As can be seen in Figure 7, the difference in centroid pixel error between the three different algorithms is not very significant until 250 frames. However, as the tracking time increases, the hybrid tracking algorithm based on the contour model and AdaBoost shows a stronger advantage when it exceeds 250 frames. In other words, the hybrid tracking algorithms based on the contour model and AdaBoost are better in terms of stability and robustness under the same conditions.

5.3. Video Classification Performance with Different Convolution Sizes. CNN structures with different kernel sizes were used to test the experimental samples separately, and the results are shown in Table 2.

From Table 2, the best results were obtained when the convolutional kernel size of 3×3 was chosen, and the classification accuracy of the dance video data samples came to 92.16%. When the size increases, the classification accuracy and standard deviation are decreasing. This is because the convolution size is too large, resulting in a larger convolutional granularity, which reduces the opportunity for the important attributes of the samples to participate in the convolution and transformation operations. The temporal performance of the DE-CNN algorithm on the dance video dataset, when the convolutional kernel size is 3×3 is shown in Figure 8.

As can be seen from Figure 8, the classification time of the DE-CNN model was about 55 s at a convolutional kernel size of 3×3 . Ultimately, the classification accuracy of the DE-CNN model at convergence was all over 0.9.

5.4. Optimisation Performance of the DE Algorithm. In order to verify the optimisation performance of the DE algorithm for CNN, the performance of the test samples was simulated

using the CNN algorithm and the DE-CNN algorithm, respectively.

As can be seen from Table 3, the DE-CNN algorithm showed better performance in the classification of dance video scenes. All three metrics of DE-CNN video classification exceeded 0.9. The maximum classification accuracy of DE-CNN was 93.18%, while the maximum classification accuracy of CNN was only 88.96%, so the accuracy of DE-CNN was significantly improved. This is mainly due to the fact that after weight optimisation by DE, the CNN obtains better weights and bias initial values, resulting in a more accurate video classification performance. The comparison of the convergence performance of the two algorithms will be continued below, as shown in Figure 9.

It can be seen that the convergence performance of DE-CNN is significantly superior compared to CNN. In the classification of dance video data samples, DE-CNN converges with an RMSE of about 0.18, while CNN converges with an RMSE value of about 2.5. Therefore, the DE-CNN algorithm has better classification stability compared to the CNN algorithm. In terms of convergence time, the CNN converges in about 5 s less than the DE-CNN. This may be due to the longer time taken by the DE algorithm to solve for the optimal weights and biases. However, in terms of the overall DE-CNN classification time, the DE algorithm consumes a small percentage of the time and has less impact on the video classification time.

5.5. Video Classification Performance of Different Algorithms. The commonly used plain Bayesian (NB) [32], BP neural network [33], LSTM neural network [34], and DE-CNN were used to compare and analyse the test dataset respectively, as shown in Figure 10.

In terms of classification accuracy of the videos, DE-CNN and LSTM algorithms have the highest classification accuracies. In terms of classification time, the LSTM

FIGURE 5: Partial data presentation of the dance video sample. (a) Classical dance. (b) Ballet dance. (c) Folk dance. (d) Tap dance. (e) Jazz dance. (f) Latin dance.

TABLE 1: Information on the experimental video dataset.

Dance video category	Number	Video sources
Classical dance	500	Google videos, Baidu videos
Ballet	500	CCTV, movies, Microblog, Facebook
Folk dance	500	Youku App, Twitter, MetaCafe
Contemporary dance	500	Netflix, LiveLeak
Tap dance	500	Microblog, Google videos
Jazz dance	500	Facebook, LiveLeak
Latin dance	500	CCTV, Baidu videos, Twitter

algorithm consumes the longest time, followed by the DE-CNN algorithm, and the NB algorithm the least time.

The following continues to test the stability of the 4 algorithms in video scene classification. The RMSE performance of the 4 algorithms was verified and is shown in Figure 11.

It can be seen that the DE-CNN algorithm has the best RMSE values and the NB performs the worst. This also indicates that the classification RMSE values are more sensitive to the number of video categories. In summary, for scene classification of 3500 dance video sequences, the DE-CNN model still achieves good classification time and

6. Conclusion

In this paper, a differential evolutionary convolutional neural network model is applied to scene classification of dance videos. A contour model-based detection approach is used to achieve human target detection, which effectively improves the robustness of human detection. The AdaBoost algorithm based on cascade structure is used to achieve human target tracking. The weight optimisation solution advantage of the differential evolution algorithm is used to improve the applicability of the convolutional neural network model in video scene classification. The following conclusions are drawn.

- (1) The average error in human motion detection is less than 10 pixels, which indicates higher robustness.
- (2) The proposed method has a smaller pixel error in the centroid of human movement than other methods and is suitable for a long tracking process.
- (3) Compared with commonly used video classification algorithms, the proposed DE-CNN model has significant advantages in terms of classification accuracy and RMSE performance. Subsequent studies will further tune the differential evolution parameters to improve the video scene classification time performance.

The progress of big data technology has promoted the development of intelligent marketing for education companies. The online course selection system on the official website of the education company can provide users with online course selection and purchase services. The early marketing conversion rate remained below 0.09% throughout the year. After the analysis of the marketing department, it is found that there are some problems on the official website, such as a low marketing conversion rate. To improve the marketing conversion rate of the official website, the marketing department puts forward business needs. The experiential marketing strategy has been formulated, and it is planned to implement experiential course purchase and secondary marketing on the official website. The IT R & D department has established a big data marketing intelligent recommendation system project to meet the business needs put forward by the marketing department. Firstly, use the big data real-time computing technology to collect the user behavior information of users screening courses on the official website. Real time analysis of user behavior information can predict the courses given to users, which is conducive to the purchase of courses. Then, use the big data machine learning technology to integrate the marketing activity opportunity data in each marketing activity opportunity management system and establish a user portrait. For users who have participated in online or offline marketing activities but have not purchased courses, offline predict the courses and classes that can be recommended to users to carry out secondary marketing for them. Finally, the information of recommendable courses and classes predicted in real time and offline is displayed in the display area of the official website, which makes the marketing conversion rate of the official website reach 0.20%, which is 125% higher than that of the original official website.

1. Introduction

In the era of big data, information overload is serious, and a large amount of information is generated on the internet all the time [1–4]. A large amount of information is presented in front of the users. It is more difficult for users to filter out the information that meets their wishes. At the same time, a large amount of information has great business value for enterprises. How to transform this information to help the operation and development of enterprises has also been a problem perplexing enterprises. It is difficult for users to find information that meets their wishes, and enterprises are trying to push the information beneficial to the operation of enterprises to users. The intelligent recommendation system has built an information bridge between users and

enterprises. Users search or browse information on the enterprise website, which records the behavior of the users searching or browsing information. The intelligent recommendation system constructs the user portrait based on the above user behavior recorded on the website, analyzes the user preference information based on the data of the user portrait, and recommends the information that conforms to the user's search intention and the enterprise's marketing strategy to the user in combination with the enterprise's marketing strategy [5–8].

The internet e-commerce industry has rich practical experience in using the intelligent recommendation system to help enterprises operate, such as Amazon, Taobao, etc. The internet e-commerce industry recommends users to search or browse similar products according to the products

selected by users and in combination with the industry attributes of e-commerce enterprises, such as commodity inventory location, merchant advertising investment, etc. Each industry has its own industry-specific attributes. In the process of studying the implementation of the intelligent recommendation system in its own industry, it will be combined with its own industry-specific marketing attributes, and the education industry is no exception. In the field of education, the research and practice of big data intelligent recommendation are mostly in the fields of intelligent evaluation, educational law discovery, educational management and decision-making, online learning, and adaptive learning. As the basic theoretical and technical support of big data landing research in the field of education, the recommendation system selects user learning behavior data, such as courses, learning processes, and test evaluation. Combined with the relevant research of education big data, build the relevant big data intelligent recommendation application with the business nature of the education industry. Learning from the practical experience of the internet e-commerce industry recommendation system and combined with the unique business attributes of the education industry, various educational institutions are exploring and studying to build a unique recommendation system for the education industry [9, 10].

This paper takes the big data marketing intelligent recommendation system of Education Company H as the research object, which provides a reference for educational enterprises on how to use the big data intelligent recommendation system to realize user experience class purchase. Since its establishment, Education Company H has gradually developed into an institution with foreign language training and basic education as the core. Its teaching products span a wide range, covering various educational stages, such as preschool education, middle school education, university education, and overseas consultation. The campus covers many provinces in China and has many users, however, the company has many problems in its daily channel business activities. The online course selection system on the official website of Education Company H provides users with online course selection and purchase services. The online course selection system on the official website has more than 600,000 classes of thousands of courses for users to select and purchase courses online. User screening courses consume a lot of time and energy. The online course selection system on the official website does not integrate the business opportunity information of various marketing activities. It is still unknown which marketing activities promote users to buy courses, and it has lost the opportunity to carry out secondary marketing to users on the online course selection system on the official website. In response to the above problems, Education Company H investigated the successful big data intelligent recommendation system cases at home and abroad, referred to relevant technical and academic literature, and learned from the intelligent recommendation system models of well-known internet and e-commerce companies at home and abroad, such as Amazon predictive shopping and Taobao intelligent recommendation. Combined with the relevant theories of market research and

prediction [11–13], consumer behavior [13–15], and user information behavior [16–18], the marketing department proposes to implement user experience course purchase in the online course selection system on the official website.

The IT R & D department has established a big data marketing intelligent recommendation system project to meet the business needs of the online course selection system on the official website to implement the user experience course purchase. Firstly, the big data marketing intelligent recommendation system uses the big data real-time computing technology to analyze the user behavior and predict the courses and classes that can be recommended to users by collecting the user's behavior of viewing the detailed information of courses and classes on the online course selection system on the official website. Then, the big data marketing intelligent recommendation system uses the big data machine learning technology [19–22] to integrate the marketing activity business opportunity data in each marketing activity business opportunity management system and mine the causal law between user behavior and user class purchase offline. Using the mining causal law, offline predict the recommended courses and classes for users who have participated in marketing activities but have not purchased courses. Finally, the online real-time predicted recommendable course class information and the offline big data predicted recommendable course class information are displayed in the “guess what you like” display area on the website of the online course selection system of the official website, which supports the online course selection system of the official website to implement the user experience course purchase and realize secondary marketing to users, and it improves the marketing conversion rate of the online course selection system of the official website.

Education Company H uses big data technology to enhance the enterprise's marketing ability, and it also provides a reference for relevant enterprises in the domestic education industry on how to apply big data technology to help enterprise operation. Although the field of big data recommendation in the field of internet e-commerce has been relatively mature, the education industry has many unique attributes in the field of education. It cannot fully learn from the big data application mode in the field of e-commerce. It can only develop a big data marketing recommendation system suitable for its own industry attributes in the field of education on the basis of reference. It is the application of domestic educational institutions in the field of big data, lack of relevant practice in the field of channel marketing, and lack of reference for successful practice cases.

2. Current Situation of Big Data Intelligent Recommendation System at Home and Abroad

The big data intelligent recommendation system originated from internet e-commerce. The most well-known foreign company that develops and applies the recommendation system is Amazon. Amazon applied predictive shopping

recommendations on its global e-commerce website in 2013. Amazon applies the famous item-to-item collaborative filtering recommendation algorithm [23–27] in predictive shopping. This algorithm records the user behavior data generated by users on the Amazon e-commerce platform, such as browsing goods, staying on the goods page, putting products into the shopping cart, and purchasing goods. Amazon uses the big data intelligent recommendation algorithm to calculate the goods users likes. It also predicts the goods that users may buy in the next stage.

The commodity recommendation ideas and rules of the internet e-commerce industry are not only applied to Amazon but also to Facebook, Walmart, and other companies. The application of big data personalized recommendation in the field of internet e-commerce greatly reduces the work of users screening goods, enhances users' shopping experience, and promotes the popularization of intelligent recommendation mode in various industries, including the education industry. The foreign education industry has widely used the big data intelligent recommendation technology in adaptive learning and other fields. The well-known product is the Knewton platform. The behavior of each student and the response to each content item can not only improve the system's understanding of a single learner and a single content item but also improve the understanding of all the contents in the system and all online students. At Arizona State University, more than 2000 students participated in the experiment of Knewton products in a two-semester course. The experimental results show that after students use the Knewton platform, the dropout rate of students decreased by 56%, and the passing rate of students increased from 64% to 75%. At the same time, 45% of students can complete the course four weeks in advance.

The Smartbook product is a personalized recommendation platform that supports thousands of McGraw-Hill courses, and it calculates the courses and fields that students should pay attention to based on their previous user behavior. Scootpad products identify the weaknesses of each student through diagnostic exercises to ensure that they receive personalized learning courses. At the same time, teachers can guide specific students by creating targeted homework. The successmaker product provides reading and mathematics software and personalized learning paths for students aged K-12. It was launched at Stanford in the 1960s as a joint project with IBM and Dr. Patrick supplies, a computer learning expert. The product mainly provides adaptive mathematics and reading guidance for primary school students. The perfect combination of the internet big data technology and education has promoted the development of educational science. The application of big data intelligent recommendation technology in the foreign education industry is worth learning from. The application of big data technology in the domestic education industry has just sprung up in recent years. While learning from the experience of internet e-commerce and big data in the foreign education industry, educational institutions have also made some breakthroughs in the field of big data application.

3. Business Requirements of Marketing Platform

3.1. Current Situation of Online Course Selection System on Official Website. The online course selection system on the official website of Education Company H provides users with online course selection and purchase services. The online course selection system on the official website has a low marketing conversion rate, which is maintained below 0.09% throughout the year. The marketing department sorted out the current situation of the online course selection system on the official website to find the reasons affecting the low marketing conversion rate of the official website.

3.1.1. Show the Course Screening Results from the Perspective of Community Characteristics. The online course selection system on the official website has more than 600,000 classes of thousands of courses for users to select and purchase courses online. The online course selection system on the official website provides the function of course screening, which is realized by keyword full-text retrieval technology (similar to Baidu search technology). In the process of course selection and purchase, the user selects and combines the screening course conditions to screen the course class information that meets the user's own purchase needs. The keywords for screening courses include the course subject, school, campus, class time, course class price range, etc. The course class information that meets the screening conditions is presented to the user in the form of a list. The information in the list can be sorted according to the course class price and class opening time. The results of course screening are displayed to users from the perspective of community characteristics, i.e., when the screening conditions of selection and combination are the same. We can see that the course class information after course screening is the same, the content and the sequence of content are unchanged, and the results sorted by price or class opening time are the same. The information of the displayed courses and classes is not differentiated, and there is a lack of content display of individual trait differentiation.

3.1.2. Business Opportunity Information of Various Marketing Activities to be Integrated. The online course selection system on the official website has not integrated the business opportunity information of various marketing activities, and it is unknown which marketing activities promote users to buy courses. In all kinds of marketing activities, Education Company H will collect the marketing activity opportunity information of users' purchase intention. The business opportunity information of marketing activities is stored in the business opportunity management system of various marketing activities. The marketing activity business opportunity management system refers to the marketing auxiliary IT system that provides users with consulting, evaluation, and participation in offline marketing activities and other services before users buy courses, such as offline customer service consulting business opportunity management system, CRM telephone customer service business

opportunity management system, OTS online evaluation business opportunity management system, offline marketing activity business opportunity management system, etc. Users who have the intention to purchase courses finally need to enter the online course selection system on the official website for online course selection and purchase. As the online course selection system on the official website does not integrate the marketing activity business opportunity data in the business opportunity management system of various marketing activities, it is not known which marketing activities promote users to buy courses.

3.2. Problems of Online Course Selection System on Official Website. After sorting out the current situation of the online course selection system on the official website, the marketing department found two problems affecting the conversion rate of the online course selection system on the official website.

3.2.1. Lack of Display of Individual Trait Differentiation Content. In the process of screening courses on the online course selection system on the official website, users select and combine the conditional keywords of the screening courses to screen the courses and classes that meet the users' needs for the course purchase. The filtering function realized by the keyword full-text retrieval technology cannot fully reflect the user's demand for course purchase in the user's behavior, push the course class information that does not meet the user's own demand for course purchase, and affect the user's experience of course selection and purchase. Learn from the relevant theories of market research and prediction and big data marketing theory, investigate and collect the user behavior-related data and information in the process of user screening courses, analyze the user behavior-related data and information from the perspective of individual characteristics, predict the courses that meet the user's purchase needs, recommend the courses that meet the user's purchase needs to users on the online course selection system on the official website, enable users to quickly find courses and classes that meet their own purchase intention, and promote users to purchase courses and improve the marketing conversion rate.

3.2.2. Lack of Secondary Marketing to Users. The online course selection system on the official website did not integrate, mine, and use the marketing activity business opportunity information of various marketing activities, and it lost the opportunity of secondary marketing to users. For example, the user calls the CRM call center and inquires about IELTS-related courses. Then, when the user enters the online course selection system on the official website, the system shows users IELTS-related courses for the first time. On the one hand, the user can no longer screen the courses. On the other hand, the user can conduct secondary marketing IELTS courses, which will certainly promote the improvement of the conversion rate of the official website. The user's intelligent behavior in the user information

behavior theory points out that the user's behavior is related to a specific goal. Integrate, mine, and use the marketing activity business opportunity information of each marketing activity to analyze the relationship between users' participation in marketing activities and users' purchase of courses, and predict the courses that users may buy to carry out secondary marketing to users.

3.3. Practical Experience of User Experience Shopping in Internet E-Commerce Industry. The marketing department, after discovering the problems of Chu duo in the online course selection system on the official website, actively looked for ways to solve the problems. In the process of finding solutions to the problems, the marketing department found that the practical experience of the internet e-commerce industry in implementing user experience shopping on e-commerce websites and e-commerce apps is worth learning from. The marketing department summarized the practical experience of experiential shopping in the e-commerce industry as follows: (1) in the internet e-commerce industry, add commodity recommendation information to the page of the e-commerce website or e-commerce mobile app to recommend the same kind of commodity to users who have just viewed the commodity. For example, if users view commodity A on Taobao, Taobao will display the same kind of commodity to users in the "you may still like" commodity display area. (2) In the internet e-commerce industry, various information systems of e-commerce have realized the sharing of user behavior data. The user has viewed commodity A on the e-commerce website. When the user enters the e-commerce mobile app, he can see the recommendation information of commodities similar to commodity A. Similarly, the user has viewed product A on the e-commerce mobile app. When the user enters the e-commerce website, he can also see the recommendation information of products similar to product A. The second user of user marketing is thus realized.

3.4. Online Implementation of Experiential Marketing Business Needs on the Official Website. To solve the problems existing in the online course selection system on the official website and learn from the practical experience of user experiential shopping in the e-commerce industry, the marketing department plans to implement experiential course purchase in the online course selection system on the official website to promote the improvement of the conversion rate of the official website.

3.4.1. Online Real-Time Experiential Course Purchase Business Requirements. The online course selection system on the official website realizes the intelligent recommendation of online real-time marketing, recommends courses similar to the courses viewed by online users on the official website, and realizes the business needs of experiential course purchase. The specific business needs are as follows: (1) the display method of recommendation results: learn from the user experiential shopping practice method of the internet

e-commerce industry, and add the “guess you like” display area on the web page of the online course selection system on the official website. It is used to highlight the course class information recommended to users. (2) The formulation of online real-time marketing intelligent recommendation strategy: from the perspective of individual characteristics of users, the marketing department formulates the online real-time marketing intelligent recommendation strategy on the official website, which is used to clarify the business rules of online real-time recommending courses and classes to users on the official website. (3) Build an online real-time user portrait: investigate and collect the user behavior information of the course filtered and viewed by the user on the online course selection system on the official website, analyze the user behavior, and predict the course classes preferred by the user in real time. (4) The construction of the algorithm model and prediction: using an online real-time intelligent recommendation-related technologies, combined with user preferences and online real-time marketing intelligent recommendation strategy on the official website, calculate and obtain the course classes recommended to users and display the course class information recommended to users in real time in the “guess what you like” display area. Figure 1 presents the online real-time experiential course purchase business requirements.

3.4.2. Demand for Secondary Marketing Business of Offline Big Data. The online course selection system on the official website realizes the intelligent recommendation of offline big data marketing. Analyze the relationship between users’ participation in marketing activities and users’ purchase of courses using the business opportunity data of various marketing activities (business opportunity data, i.e., the information of users’ intention to purchase courses collected in marketing activities). Predict the courses and classes that users may buy offline, and recommend the courses and classes predicted offline to users online on the official website to realize the business demand of secondary marketing for users. The specific business requirements are as follows: (1) build offline big data user portrait: investigate, collect, and integrate the marketing activity opportunity data in each marketing activity opportunity management system to build an offline big data user portrait. The marketing activity business opportunity management system is as follows: offline customer service consulting business opportunity management system, CRM telephone customer service business opportunity management system, OTS online evaluation business opportunity management system, and offline marketing activity business opportunity management system. (2) Build the algorithm model and prediction: based on the offline big data user portrait data, mine the causal law between users’ participation in marketing activities and users’ purchase of courses offline, and build an offline recommendation algorithm model. The offline recommendation algorithm model is used to predict the courses that may be purchased by users who have participated in online and offline activities but have not purchased courses on the official website. When users enter the official website, the

courses that may be purchased by users predicted offline will be recommended to users on the official website. (3) The formulation of an intelligent recommendation strategy for offline big data marketing: the marketing department, based on the relevant theories of user behavior information, formulates an intelligent recommendation strategy for offline big data marketing, which is used to clarify the business rules of courses and classes that recommend offline prediction to users online on the official website. (4) Only provide offline big data marketing intelligent recommendation service to registered users: only provide offline big data marketing intelligent recommendation service to registered users who log in to the online course selection system on the official website with their mobile phone number, and do not provide offline big data marketing intelligent recommendation service to unregistered browsing users. Figure 2 presents the demand for secondary marketing business of offline big data.

4. Marketing Business Needs to Realize the Overall Design of IT System Architecture

4.1. Origin of Big Data Marketing Intelligent Recommendation System Project of Education Company H. The online course selection system on the official website of Education Company H has been in operation for many years. The online course selection system on the official website is now implemented with the B/s technology architecture. The R & D and realization of the user experiential course purchase business requirements of the online course selection system on the official website requires the use of the internet technology and big data technology. It greatly changes the technical architecture of the original online course selection system on the official website. After discussion between the IT R & D department and the marketing department, it was decided to establish a big data marketing intelligent recommendation system project in the form of a subsystem of the online course selection system on the official website to meet the business requirements related to the user experience course purchase of the online course selection system on the official website. The big data marketing intelligent recommendation system and the online course selection system on the official website work together to realize the user experience course purchase. The specific collaborative work content is shown in the figure below.

Figure 3 shows the collaborative work between the big data marketing intelligent recommendation system and the online course selection system on the official website. The description is as follows: (1) the online course selection system on the official website collects user behavior information and sends the user behavior information to the big data marketing intelligent recommendation system. (2) The big data marketing intelligent recommendation system realizes the user experience class purchase business requirements proposed by the marketing department, calculates the online real-time marketing intelligent recommendation and offline big data marketing intelligent recommendation, and stores the calculated recommendation results in the recommendation result information index of the ES search engine. (3) The big data marketing intelligent recommendation system provides

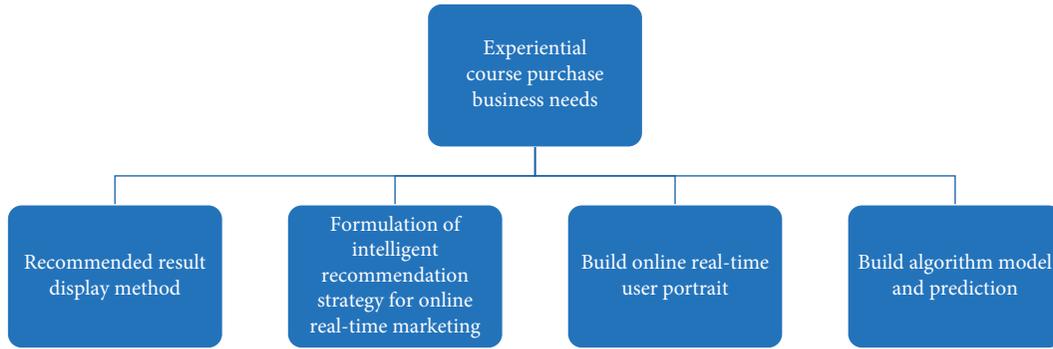

FIGURE 1: Online real-time experiential course purchase business requirements.

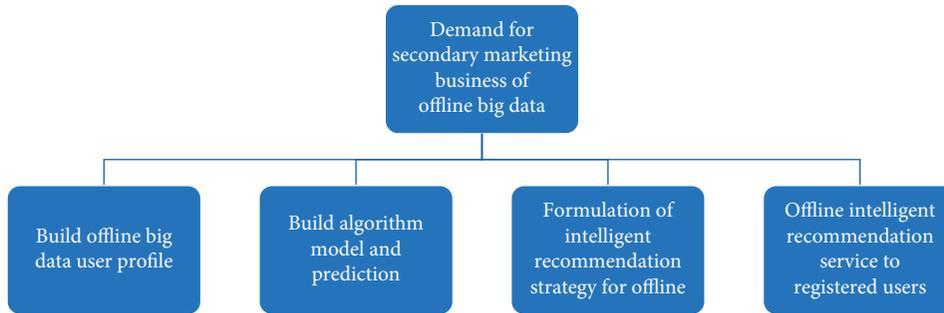

FIGURE 2: Demand for secondary marketing business of offline big data.

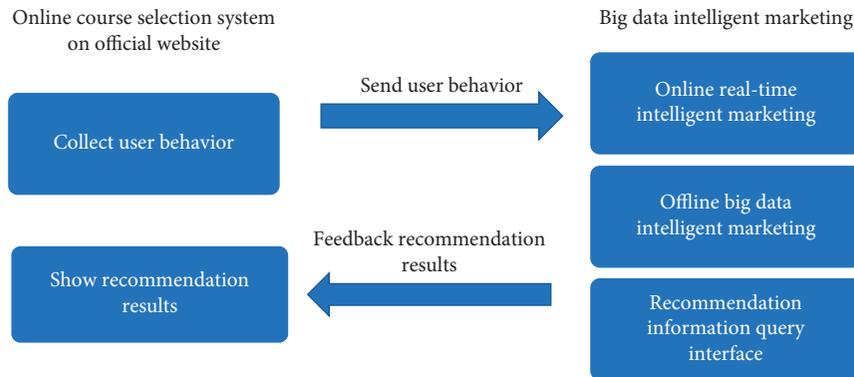

FIGURE 3: Collaborative work between big data marketing intelligent recommendation system and online course selection system on official website.

a recommendation information query service interface and recommendation information query service for the online course selection system on the official website. (4) The “guess what you like” display area is added to the web page of the online course selection system on the official website. When the “guess you like” display area of the online course selection system on the official website is displayed in the browser, call the recommendation information query service interface provided by the big data marketing intelligent recommendation system to obtain the recommendation information, and display the course information recommended for online users on the official website in the “guess you like” display area.

In the big data marketing intelligent recommendation system, to use IT technology to realize the marketing

business needs, we first need to divide the functional modules to realize the business needs and specify the IT technology required by the functional modules. At the same time, we need to design and explain how each functional module cooperates with each other to complete the business needs, which is the problem to be solved in the overall design stage of IT system architecture.

4.2. Overall Design of Big Data Marketing Intelligent Recommendation System Architecture of Education Company H.

The marketing business requirements of the online course selection system on the official website are mainly composed of the following two core business requirements: online real-time marketing intelligent recommendation and offline big

data marketing intelligent recommendation. The IT R & D department established the big data marketing intelligent recommendation system project after analyzing the feasibility of the demand realization of the marketing business demand of the online course selection system on the official website. Recommend courses on the official website and use the intelligent data system to recommend courses and provide users with big data service. The IT R & D department has carried out the overall design of the IT architecture of the big data marketing intelligent recommendation system.

According to the requirements of the online marketing recommendation system, the intelligent computing module can realize the two core functions of the online marketing recommendation system: (1) according to the requirements of the online marketing recommendation strategy, the intelligent computing module can realize the two core functions of the online marketing recommendation system and realize the real-time prediction of the business needs of online user preference courses. (2) Offline big data marketing intelligent recommendation calculation unit: according to the requirements of offline big data marketing intelligent recommendation strategy specification, excavate the causal law between user behavior and user course purchase in marketing activity business opportunities, and use this causal law to predict the courses that users who have participated in marketing activities but have not purchased courses may buy. At the same time, there are several functional modules to assist in the realization of marketing business needs, such as the following: each marketing activity business opportunity management system database, data extraction and synchronization program, ES data search engine, big data buffer middle layer, internet web service interface, etc. Online real-time marketing intelligent recommendation calculation unit, offline big data marketing intelligent recommendation calculation unit, and other functional modules are combined to form the overall architecture of big data marketing intelligent recommendation system, and they work together to meet the needs of marketing business. The following is a brief description of the functional design of each functional module cooperating with each other to realize business requirements. Table 1 presents the overall design of the big data marketing intelligent recommendation system architecture of Education Company H.

4.2.1. Design of Intelligent Recommendation Function for Online Real-Time Marketing. Online real-time marketing intelligent recommendation solves the business problem of recommending user-preferred courses and classes for online users on the official website in real time. In the overall architecture design of the big data marketing intelligent recommendation system, several functional modules are divided to realize the business requirements of online real-time marketing intelligent recommendation. The divided functional modules and how to cooperate with each other to complete the functional design of business requirements are briefly described as follows: (1) the official website online user behavior information receiving service

interface: is used to receive the user behavior information sent by the official website online users to view the course details and forward the user behavior information directly to the “big data buffer layer.” The user behavior information receiving service interface is implemented by the spring-cloud microservice technology. (2) Big data buffer layer: it is used to receive the online user behavior information on the official website forwarded by the “user behavior information receiving service interface,” cache the user behavior information and wait for the “online real-time marketing intelligent recommendation computing unit” to read. The significance of the big data buffer layer is to smoothly transfer the user behavior data to the “online real-time marketing intelligent recommendation computing unit” during the peak access of the official website to prevent the computing unit from a system crash because of an excessive amount of calculation. The big data buffer layer is implemented by the flume and Ka & a technology. (3) Online marketing intelligent recommendation calculation unit: read the user behavior information in the “big data buffer layer,” analyze the online user behavior, calculate and obtain the course classes and recommended scores recommended to online users according to the recommendation rules in the “online real-time marketing intelligent recommendation strategy specification,” and store the calculated recommendation results and recommended scores in the “ES search engine.” The online marketing intelligent recommendation computing unit is implemented by the storm real-time computing framework. (4) ES search engine: mainly used to store online real-time recommendation result information. The ES search engine is implemented by the Elasticsearch search framework. The use of Elasticsearch search engine technology to provide the storage and query of recommendation results is mainly because Elasticsearch has very fast and stable data writing and data query characteristics, which can solve the performance problems of a large number of recommendation result information data writing and data query during the peak of official website access.

4.2.2. Design of Intelligent Recommendation Function for Offline Big Data Marketing. The business problem of offline big data marketing intelligent recommendation is to mine the causal law between users’ participation in marketing activities and users’ purchase of courses and use this causal law to offline predict the courses that users who have participated in online or offline marketing activities but have not purchased courses may buy. In the overall architecture design of the big data marketing intelligent recommendation system, several functional modules are divided to realize the business requirements of offline big data marketing intelligent recommendation. The divided functional modules and how to cooperate with each other to complete the functional design of business requirements are briefly described as follows: mining the causal law of users’ participation in marketing activities and users’ purchase of courses in the business opportunity data of marketing activities. When the user enters the official website, recommend the courses that

TABLE 1: The overall design of the big data marketing intelligent recommendation system architecture.

The overall design of intelligent recommendation system architecture
Design of intelligent recommendation function for online real-time marketing
Design of intelligent recommendation function for offline big data marketing
Function design of replacing offline recommended courses with similar courses on the official website

may be purchased by the user predicted offline to the user on the official website. (1) Collect and extract marketing activity opportunity data from each marketing activity opportunity management system database. The marketing activity business opportunity management system database includes the following: CRM telephone customer service business opportunity management system database, OTS online evaluation business opportunity management system database, offline customer service consulting business opportunity management system database, offline marketing activity business opportunity management system database, course product database, and order database of online course selection system on the official website. The purpose of collecting and extracting marketing activity data is to analyze the causal law between user behavior and the user class purchase. Hence, data collection is divided into two steps: collecting “cause” data and collecting “result” data, which is as follows: the first step is to collect “cause” data. Extract the marketing activity business opportunity data from the CRM telephone customer service business opportunity management system database, OTS online evaluation business opportunity management system database, offline customer service consulting business opportunity management system database, and offline marketing activity business opportunity management system database. There is information about the user’s intention to purchase courses in the business opportunity data of marketing activities, such as the user’s call to the CRM call center, telephone consultation regarding IELTS-related courses, leaving information about the user’s intention to purchase IELTS courses, etc. The second step is to collect “fruit” data. Extract the user’s historical order information from the course purchase order database of the online course selection system on the official website. In the first and second steps above, the business opportunity data of marketing activities collected and extracted will be stored in the “big data storage system.” At the same time, the time of data collection and extraction is 2 a.m. every day, because the business is relatively idle at this time. (2) Big data storage system: used to store the original marketing activity opportunity data in the collected marketing activity opportunity management system. (3) Big data user portrait: it consists of two types of user portraits: user portraits of purchased courses and user portraits of nonpurchased courses. Use Spark SQL and hive technology to extract, clean, and convert the original marketing activity business opportunity data stored in the big data storage system, and build the user portraits of purchased courses and nonpurchased courses. Analyze the data of user portraits of purchased courses, and use the big data machine learning algorithm to find the causal law between the user behavior and user purchase courses. This causal law is used to predict the course classes that users in

the user portrait of nonpurchased courses may buy. (4) User preference course recommendation: it uses big data machine learning technology to predict the course products that users may buy. Using big data machine learning technology, train the algorithm model on the data of the user portraits of the purchased courses and find out the causal law between the user behavior and user purchase courses. The trained algorithm model is used to predict which courses and classes the users in the user portrait of nonpurchased courses may buy and the probability of possible purchase. If the course classes in the recommendation results of offline prediction have expired in the online course selection system on the official website and are no longer sold, replace the expired course classes with the similar course classes being sold in the online course selection system on the official website.

4.2.3. Function Design of Replacing Offline Recommended Courses with Online Similar Courses on the Official Website.

The result of online real-time marketing intelligent recommendation is calculated based on the class data of the courses being sold. The results of offline big data marketing intelligent recommendation are calculated based on the historical business opportunity data of marketing activities and the historical data of the user course purchase. Therefore, the course classes in the offline big data recommendation results may have expired and will not be sold in the online course selection system on the official website. Therefore, before recommending offline predicted recommendation results to online users on the official website, it is necessary to replace the courses in the recommendation results with similar courses on the official website. By simulating the user behavior of the official website, convert the course class information in the offline big data recommendation results into user behavior information, take the converted user behavior information as the request parameter of the service interface, and call the online user behavior information receiving service interface of the official website to hand over the replacement of similar courses to the online real-time marketing intelligent recommendation module. The online real-time marketing intelligent recommendation module will convert the offline recommended course classes into similar course classes being sold online on the official website, and store the recommendation results after replacing the course class information in the ES search engine.

5. Conclusion and Prospect

With the advent of the internet big data era, information technology is developing by leaps and bounds, and the traditional enterprise operation and marketing mode is also

changing. The traditional market survey and prediction model has been replaced by information technology. By collecting user behavior and other information on Web pages or apps, we can understand users better than through questionnaires and interviews. The traditional commodity sales model gradually changes from the mode of users looking for commodities to the mode of products looking for users. It uses big data machine learning technology to predict users' preferred commodities and timely recommends commodities to users. The internet and big data are rapidly and quietly changing the world, the marketing mode of modern enterprises, and people's lifestyle. Education Company H, moving with the times and keeping up with the pace of the internet big data era, has developed a big data marketing intelligent recommendation system using the internet big data technology to support the online course selection system on the official website and realized user experience course purchase. After analysis and research, the conclusions drawn are as follows: (1) use the big data real-time computing technology to recommend user-preferred courses to users in real time to reduce the workload of user course screening. Firstly, collect the user behavior of users viewing the detailed information of courses and classes on the official website. Then, analyze the user behavior and predict the course class of user preference. Finally, the online real-time recommendation of the predicted user preference courses and classes to users improves the online marketing conversion rate of the official website. (2) Use the big data machine learning technology to integrate the business opportunity data of various marketing activities and realize secondary marketing on the official website. Firstly, collect the business opportunity data of various marketing activities from the business opportunity management database of various marketing activities. Then, use the big data machine learning technology to analyze the causal law between users' participation in marketing activities and users' purchase of courses. Finally, using the causal law obtained from the analysis, for users who have participated in marketing activities but have not purchased courses, offline predict the courses and classes that users may buy. When users log in to the official website, the system will recommend courses and courses that can be predicted offline to users at the first time. This way can realize the secondary marketing to users and improve the online marketing conversion rate of the official website.

In the future, more recommendation algorithm models will be implemented to improve the recommendation business and improve the accuracy of recommendation. The big data marketing intelligent recommendation system delivered in phase I realizes the real-time marketing recommendation strategy, which is mixed with the decision-making information from the perspective of enterprise marketing, such as recommended accommodation classes and VIP classes. It has not been able to completely solve the real purchase needs of users from the perspective of users' individual characteristics. In essence, the big data marketing intelligent recommendation system should look at and solve problems from the perspective of users' individual characteristics and provide users with courses that they really want

to buy, and the marketing mode has shifted from traditional marketing products to marketing users. At present, only the decision tree algorithm is used for offline recommendation business. There are many similar algorithms in the field of machine learning, which can be used together to select the best algorithm model most suitable for business and improve the accuracy of recommendation. In the future, collaborative filtering or classification-related machine learning algorithms will be used to classify similar populations and recommend similar courses to similar populations; In the future, association rules and related algorithms will be used to analyze the historical data of course purchase, find the associated courses that are often purchased together, recommend the associated courses to users, and so on.

Data Availability

The dataset can be accessed upon request.

Conflicts of Interest

The author declares that there are no conflicts of interest.

This research mainly analyzes the influence of foreign investment in the era of big data on China's economic growth, in the process of analyzing the impact of foreign investment on the national economy, based on the analysis of the current situation of foreign investment and error-correction model, etc., through the correlation coefficient matrix to determine the variables data needed to fit the model; after fitting the model, the residual model is extracted, and the stationarity of the residual sequence is tested. On the basis of the above, this paper analyzes the difference of foreign direct investment in different regions, combined with the coastal areas and central region model and actual situation analysis, analyzes the two foreign direct investment (FDI) development speeds, base development speed, and average development speed, at the same time for the two regions in 2017; the specific direction of FDI do a detailed analysis. Finally, a series of conclusions are obtained.

1. Introduction

For China, since the reform and opening up in 1978, the economy of the eastern coastal areas has shown a trend of rapid development, while the economic development of the central and western regions is relatively slow compared with the coastal areas [1–5]. The impact of foreign direct investment on China is very far-reaching, but due to China's large and vast territory, the impact of foreign direct investment on different regions is different [6, 7]. For example, Jiangsu is located in the eastern coastal areas of China, and it has the advantage of the eastern coastal areas. From 1978 to 2017, Jiangsu's foreign direct investment quota was from \$639915 million to \$2513541 million; located in the central of Henan; foreign direct investment increased from \$495.27 million to \$1722428 million. Only from the surface data observation, we can find the foreign direct investment quota in the two regions [8–11]. This research is devoted to the analysis model design of the impact of foreign investment on China's economic growth, so as to provide decision support for the formulation of

macroeconomic policies and the management and control of microeconomic operation.

2. Analysis of the Impact of Foreign Investment on the National Economy

2.1. Current Utilization of Foreign Investment in China. Since the reform and opening up, the level of China's export-oriented economy has been continuously improved, the scale of introducing and utilizing foreign capital has been continuously expanding, the level has been continuously improved, and the number of domestic foreign-invested enterprises has also been continuously increasing [9–12]. Next, the statistical analysis of foreign direct investment will be conducted from the change of foreign investment quota, capital source, and industrial investment.

2.1.1. Current Situation of Foreign Direct Investment in Recent Years. Data on the actual utilization of foreign direct

investment and foreign investment from 2009 to 2018 and 1999 to 2018 are processed in Figures 1 and 2.

From Figure 1, we can see that in the decade from 2009 to 2018, both actual utilized foreign direct investment and actual utilized foreign capital showed an upward trend, but the growth trend of actual utilized foreign investment and actual utilized foreign investment between 2012 and 2018 is slower than before. The actual use of foreign investment includes two parts, one is large foreign direct investment and the other is another foreign investment. From Figure 2, we can see the actual use of foreign direct investment and the actual use of foreign investment during the 20 years from 1999–2018 [13]. This shows that in the actual use of foreign investment, the actual use of foreign investment proportion gradually decreased, reduced to 0 in recent years. For example, in 2015, the actual utilization of foreign investment and the actual utilized foreign direct investment were the US \$1,26,267 million, in 2016, both were US \$12,6001 million, in 2017, both were US \$13,1035 million, and in 2018, both were US \$13,49,666 million, indicating that the actual utilization of other foreign investment in recent years was 0.

2.1.2. Analysis of the Source Structure of Foreign Direct Investment. Under the background of the era of economic globalization, WTO was established on January 1, 1995, a total of 162 members, including a large part of the countries and regions in the world, can say the world economy roughly forms a whole, and the arrival of the electronic information age and transportation more and more convenient, our country and superior geographical location, rich resources attract all over the world to invest in our country [14–16]. China's foreign direct investment sources more areas, spread across five continents. Table 1 is the general situation of the sources of foreign direct investment in China from 2016 to 2018.

As can be seen from Table 1, China's foreign direct investment mainly comes from Asia, accounting for about 80%, while Hong Kong is the main source of foreign direct investment in China [17]. From the data, it can be concluded that more than half of China's foreign direct investment in China comes from Hong Kong, accounting for more than 60%. Among the five continents in the world, China's foreign direct investment from Africa is the least, which is less than 1%, which is directly related to the economic situation of Africa. Compared with Asia, the proportion of foreign direct investment from Europe, Oceania, and Latin America is also relatively small. From the above results, we can find that the source of a foreign direct investment structure is not reasonable, mainly foreign direct investment from Hong Kong. This phenomenon is related to the relationship between the mainland and Hong Kong; the transportation between China and Hong Kong region is very convenient, and for Hong Kong, the mainland also has various preferential policies. In addition, foreign direct investment is also directly related to the distance.

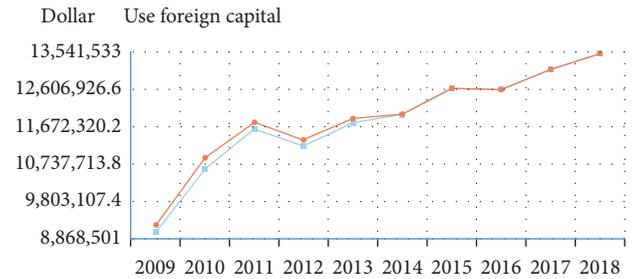

FIGURE 1: Actual use of foreign direct investment.

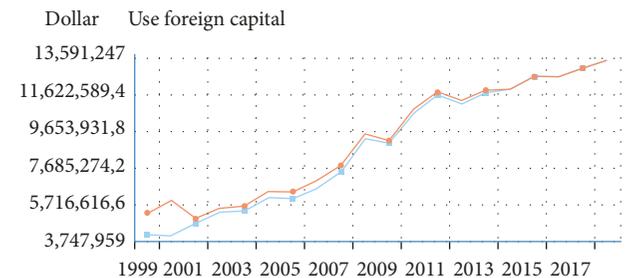

FIGURE 2: Data on the actual utilization of foreign capital.

2.1.3. The General Situation of Foreign Direct Investment by Industry in China. This summary adopts the data of foreign direct investment in China in 2018 collected by the National Bureau of Statistics. Table 2 shows China's foreign direct investment in 2018 is roughly divided by industry (ten thousand dollars).

Taking out the largest amount of several industries from Table 2 into the pie chart, it is more convenient to see the specific direction of FDI in China (Figure 3).

It can be seen that China's foreign direct investment is mainly concentrated in the manufacturing, real estate, leasing, and business service industries, which account for about 62%. However, the FDI used for education, public management, and social organizations is particularly small, which shows that the introduction of FDI in China is extremely unbalanced in China, and the proportion of FDI varies greatly among various industries, which is also related to the main development of manufacturing and real estate industry in China.

2.2. Model Construction

2.2.1. Determination and Cointegration Test of the Sample Data. First of all, after inquiring about the database of the National Bureau of Statistics, the variables related to foreign direct investment (X_1) include the number of contractual utilization of foreign investment projects (X_2), the total import and export of foreign-invested enterprises (million US dollars) (X_3) net foreign direct investment (X_4), and the actual use of foreign direct investment (X_5) [18–20]. Collect and collate data from 2009 to 2018 (incomplete data, so only 11 years). The correlation coefficient matrices were calculated between all the variables, such as in Table 3.

TABLE 1: Source structure of FDI in China (ten thousand dollars).

National	2016		2017		2018	
	Actual investment	Proportion	Actual investment	Proportion	Actual investment	Proportion
Summation	12600100	100%	13103500	100%	13496600	100%
Asia	9883103	78.44%	10919387	83.33%	10701310	79.29%
Hongkong	8146508	64.65%	9450901	72.13%	8991724	66.62%
Taiwan	196280	1.56%	177247	1.35%	139136	1.03%
Japan	309585	2.46%	326100	2.49%	379780	2.81%
Singapore	604668	4.80%	476318	3.64%	521021	3.86%
Korea	475112	3.77%	367253	2.80%	466688	3.46%
Africa	112720	0.89%	65746	0.50%	61042	0.45%
Europe	943439	7.49%	883619	6.74%	1119350	8.29%
Latin America	1221618	9.70%	636273	4.86%	902646	6.69%
North America	310421	2.46%	428552	3.27%	514789	3.81%
Oceania	126794	1.01%	160950	1.29%	190904	1.41%

TABLE 2: China’s foreign direct investment in 2018 is roughly divided by industry (ten thousand dollars).

Index	Sum
Actual utilized amount of foreign direct investment	13496589
The amount of foreign direct investment actually utilized in agriculture, forestry, animal husbandry, and fishery	80131
The actual amount of foreign direct investment utilized in the mining industry	122841
The actual amount of foreign direct investment in the manufacturing industry	4117421
Actual utilization amount of foreign direct investment in the production and supply of electricity, gas, and water	442390
The amount of foreign direct investment actually utilized in the construction industry	148809
The actual amount of foreign direct investment in transportation, storage, and postal services	472737
Actual utilization amount of foreign direct investment in information transmission, computer services, and software industry	1166127
Actual utilization amount of foreign direct investment in the wholesale and retail industry	976689
The amount of foreign direct investment is actually utilized in the accommodation and catering industry	90107
The actual amount of foreign direct investment is utilized in the financial industry	870366
The actual amount of foreign direct investment is utilized in the real estate industry	2246740
The actual amount of foreign direct investment in leasing and business services	1887459
The amount of foreign direct investment actually utilized in scientific research, technical services, and the geological exploration industry	681298
The amount of foreign direct investment actually utilized by the water conservancy, environment, and public facilities management industry	47408
The amount of foreign direct investment actually utilized in residential services and other service industries	56166
The actual amount of foreign direct investment utilized in education	7420
The amount of foreign direct investment actually used in the health, social security, and social welfare industry	30178

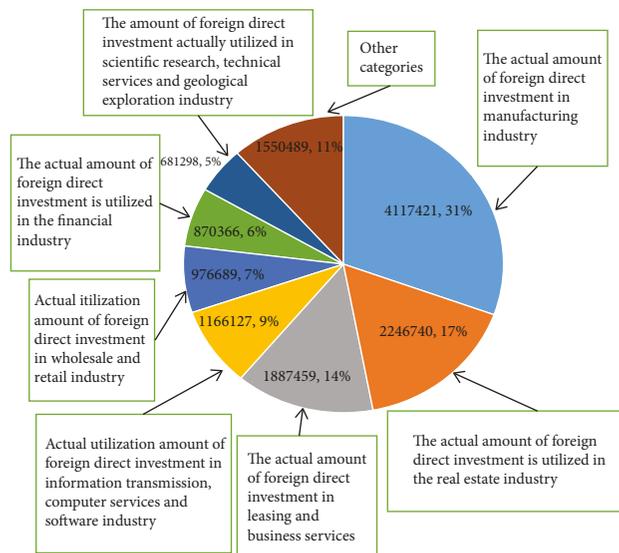

FIGURE 3: The proportion of FDI in various industries in China.

TABLE 3: Correlation coefficient matrix between the individual variables.

Covariance correlation	X1	X2	X3	X4	X5	Y
X1	1.57E + 12 1.000000					
X2	7.92E + 09 0.588991	1.15E + 08 1.000000				
X3	2.10E + 11 0.765397	7.21E + 08 0.306813	4.79E + 10 1.000000			
X4	4.41E + 12 0.825655	1.56E + 10 0.340532	3.75E + 11 0.401326	1.82E + 13 1.000000		
X5	1.47E + 12 0.998509	7.51E + 09 0.595392	1.99E + 11 0.775343	4.04E + 12 0.805613	1.38E + 12 1.000000	
Y	2.03E + 11 0.941857	129E + 09 0.696803	2.31E + 10 0.612225	6.32E + 11 0.860660	1.88E + 11 0.929698	2.97E + 10 1.000000

Table 3 shows that from 2009 to 2018, the correlation coefficient between FDI and actual FDI was 0.998509, indicating that the correlation between FDI and FDI is very high, and in the statistical Yearbook, some provinces have no data for FDI, so we can use foreign investment to measure FDI, and the correlation coefficient matrix can provide a theoretical basis for this. For the five variables with FDI, the correlation coefficient between foreign direct investment (X1) and the explained variables is the largest, indicating the strongest correlation between the two sets of data can be used as analyzed sample data.

Secondly, use Eviews to make a scatter map of China's GDP and foreign direct investment, as shown in Figure 4.

It can be seen from the figure that almost all points are evenly distributed on both sides of the line. GDP (Y) and FDI of foreign direct investment I (X1) present a positive trend; combined with the correlation coefficient matrix, we can determine the two sets of time series as the analysis of the required data: economic growth is measured by GDP, recorded as Y: foreign direct investment with the actual use of foreign investment measured as an explanatory variable, recorded as FDI [21].

Next, the GDP (Y) and actual FDI from 2000 to 2019 will be taken as the sample data to analyze the problems. Table 4 shows China's GDP and FDI and its development speed.

Since both sets of GDP and actual FDI are time series, and the time-series data are often nonstable, the stability of GDPs and actual FDI is tested before analyzing the relationship between the two so as to prevent the phenomenon of false regression. After the first-order difference operation between GDP and actual foreign direct investment can pass the stability test of 95% confidence, so Y and FDI are the first-order single integral sequence, which belongs to the same order single integral variable, and may have a long-term stability relationship [22, 23]. Table 5 shows the unit root test results.

2.2.2. *Sample Data Were Fitted.* We take the GDP as the explanatory variable and the actual foreign direct investment as the explanatory variable. The model is set as follows:

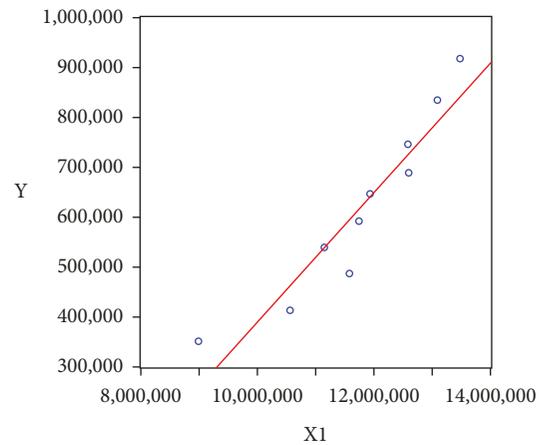

FIGURE 4: Scatter chart of China's GDP and foreign direct investment.

$$Y_t = C + \beta FDI_t + \mu_t. \tag{1}$$

The model is established by the least-squares method, and the results of the estimated parameters are shown in Table 6.

$$Y_t = -331994 + 0.082954 FDI_t + \mu_t, \tag{2}$$

$$R^2 = 0.916579 \quad F = 197.7735.$$

Extract residuals:

$$\mu_t = Y_t + 331994 - 0.082954 FDI_t. \tag{3}$$

The residual stability (ADF) test is shown in Table 7.

The results show that the residual sequence is a nonsmooth sequence, which shows that there is no long-term stable relationship between Y and FDI, contradictory to the previous conclusion. Considering that the GDP unit is billions, and the actual foreign direct investment is dollars, the unit difference is particularly large, so the result may be the difference of units. So, the two groups of sample data measurement to eliminate the effect of the dimension take the logarithm of Y and FDI in Eviews 8.0. For the newly obtained data, Table 8 shows the stationarity test after taking the logarithm.

TABLE 4: China’s GDP and FDI and its development speed.

Set the model after eliminating the dimension to the following:

$$\ln Y_t = C + \alpha \ln FDI_t + \mu_t. \tag{4}$$

Then, Table 9 shows the results of the regression of $\ln Y$ versus $\ln FDI$.

TABLE 7: An ADF test for the extracted residuals.

Augmented dickey-fuller test statistic	-0.321640	0.9035
Test critical values:	1% level -3.857386	
	5% level -3.040391	
	10% level -2.660551	

The results of the Granger causality test [9] show that the F value of $Y=0.53843 < 0.80041$, which shows that gross domestic product (Y) is not the reason for FDI, and similarly, FDI is the reason for gross domestic product (Y).

2.3. Establishment of the Error-Correction Model.

According to Granger’s theorem, the error-correction model can be established with the cointegration relationship between the nonstationary variables, so we can establish the error-correction model between the above two variables. Table 10 shows the cointegration regression results of GDP and FDI.

The resulting error-correction model is as follows:

TABLE 8: The stationarity test after taking the logarithm.

Variable quantity	ADF	Type of inspection (c, t,n)	Critical value			Whether smooth
			1%	5%	10%	
lnY	-1.917836	(c, 0,1)	-3.857386	-3.040391	-2.660551	No

S.E.of regression	0.033125	Akaike info criterion		0.043980-3.800180 -3.658570-3.801689
Sum squared resid	0.013167	Schwarz criterion		1.077134
Log-likelihood	31.50135	Hannan-Quinn criteria		
G-Statistic	6.339296	Durbin-Watson stat		
Prob (F-statistic)	0.013218			

$$\Delta \ln \hat{Y}_t = 0.095734 + 0.457138 \Delta \ln FDI_t + 0.034950 e_{t-1},$$

$$R^2 = 0.513749 DW = 1.077134. \tag{5}$$

The error-correction model $R^2 = 0.513749$ is relatively bad, but P is far less than 0.05, so the model can be adopted.

2.4. *Empirical Results Analysis.* The empirical results show two aspects: (1) In the short term, FDI has a significant influence on GDP (i. e., economic growth). (2) In the long run, significant impact of FDI on GDP (i. e., economic growth). One percentage point change of FDI will cause a 0.46 percentage point change, and the large introduction of FDI will cause rapid growth of GDP.

2.5. *Chapter Conclusion.* In this section, the variable data needed to fit the model was first determined by the correlation coefficient matrix. After fitting the model, the residue

is extracted, and the stationarity of the residue sequence is tested. Granger causality tests the model to find that FDI is the cause of Y. Finally, the model is corrected for error-correction and empirical analysis.

3. The Impact of Foreign Direct Investment on the Economy of Different Regions

3.1. *Model Construction.* When analyzing the impact of foreign direct investment on the economy of different regions, the factors with great impact on economic growth, such as consumption level, net export and labor force level (L), and domestic direct investment, should be combined [24, 25]. The sample data required for the analysis of the economic growth (Y) by FDI, consumption level (CPI), net export (NE), labor (L), (L), domestic investment (K), after the elimination of magnitude, the model can be set as follows:

$$\ln Y_t = \alpha_1 \ln FDI_t + \alpha_2 \ln NE_t + \alpha_3 \ln K_t + \alpha_4 \ln L_t + \alpha_5 \ln CPI_t + \mu_t. \tag{6}$$

3.1.1. *Economic Growth Model of Coastal Areas (Jiangsu Province as an Example)*. Consumption level is measured by per capita consumption (CPI), labor (L) is employed, NE is expressed by the difference between exports and imports, and domestic investment (K) is measured by social fixed asset investment. Data of each variable in Jiangsu Province are collected as shown in Table 11.

Due to the inconsistent dimensions of each index, the influence of log-eliminating the dimensions and the sample data are all time-series data, so the stability needs to be tested. According to the results in Table 11, the first-order difference sequence is stationary [26–35], indicating a long-term relationship between these variables. Table 12 shows the test of the stationarity of the sample data.

The model can therefore be set to the following:

$$\ln Y_t = \alpha_1 \ln FDI_t + \alpha_2 \ln NE_t + \alpha_3 \ln K_t + \alpha_4 \ln L_t + \alpha_5 \ln CPI_t + \mu_t. \quad (7)$$

The results of fitting these variables at Eviews 8.0 are shown in Table 13.

The resulting fitted model is as follows:

$$\begin{aligned} \ln Y_t &= 0.063049 \ln FDI_t \\ &+ 0.045071 \ln NE_t + 0.490681 \ln K_t \\ &+ 0.223155 \ln L_t + 0.268569 \ln CPI_t + \mu_t, \quad (8) \\ R^2 &= 0.999152. \end{aligned}$$

Table 14 shows the Stationarity test of the residuals. It can be seen that the fitting effect is good, and then the residuals of the model are proposed as follows:

$$\begin{aligned} \mu_t &= \ln Y_t - 0.063049 \ln FDI_t - 0.04507 \ln NE_t \\ &- 0.490681 \ln K_t - 0.223155 \ln L_t \\ &- 0.268569 \ln CPI_t. \quad (9) \end{aligned}$$

The results in Table 13 show that at the 5% significance level, the value of the t -test statistic is -3.629831, less than the cut-off of -3.052169, rejecting the null hypothesis that the residual root from the model and the residual sequence are a stationary sequence, and the long-term relationship between the explanatory variables and the explained variables can be learned.

3.1.2. *Economic Growth Model of the Central Region (Henan Province as an Example)*. Data was collected first according to the coastal area operation method. The results obtained are as shown in Table 15.

All the data in Table 15 are done as in the previous section, and Table 16 shows the test of the stationarity of the sample data.

The model-fitting results are as follows:

$$\begin{aligned} \ln Y_t &= 0.044262 \ln FDI_t + 0.042003 \ln NE_t \\ &+ 0.526400 \ln K_t + 0.523185 \ln L_t \\ &- 0.040786 \ln CPI_t + \mu_t, \quad (10) \\ R^2 &= 0.998457. \end{aligned}$$

Extract residuals:

$$\begin{aligned} \mu_t &= \ln Y_t - 0.044262 \ln FDI_t - 0.042003 \ln NE_t \\ &- 0.526400 \ln K_t - 0.523185 \ln L_t \\ &+ 0.040786 \ln CPI_t. \quad (11) \end{aligned}$$

Table 17 is the Residual stationarity test. The results in Table 17 show that at the 5% significance level, the value of the t -test statistic is -3.748439, less than the cut-off of -3.052169. Thus, it rejects the null hypothesis that the residual roots from the model and the residual sequence are stationary sequences, and the long-term relationship between the explanatory variables and the explained variables can be learned.

3.2. The Differences Were Analyzed by Combining the Two Regional Models and the Actual Situation

3.2.1. *Analysis of the Speed of FDI in the Two Regions*. Taking the quota of foreign direct investment from 1999 to 2017 as the research object, the sequential development rate, fixed base development rate, and average development rate are calculated as shown in Table 18.

It can be seen from the calculation results in Table 18 that the month-on-month development rate of foreign direct investment in Jiangsu Province is basically stable between 0.84 and 1.15, while the floating range of the month-on-month development rate in Henan Province is between 0.66 and 1.67, which is slightly larger than that of Jiangsu Province.

The average development speed of FDI in Henan province and Jiangsu Province is calculated as follows:

$$\bar{x}_G = \sqrt[n]{x_1 x_2 \cdots x_n} = \sqrt[n]{R}. \quad (12)$$

According to the formula, the average development rate of FDI in Henan province is 1.20537, while the average development rate of FDI in Jiangsu Province is 1.07466. It can be seen that the average development rate of FDI in Henan province is higher than that of Jiangsu Province, but because its base is far smaller than that of Jiangsu Province, although it has grown too fast in the past 20 years, it is much different from Jiangsu Province.

3.2.2. *Analysis of the Industrial Structure of Foreign Direct Investment in the Two Regions*. The general situation of FDI by industry is as follows: the total foreign direct investment in 2017 was \$2513541 million, of which FDI of manufacturing was \$1118072 million, real estate \$346007 million, leasing and business services \$223912 million, electricity, heat, gas, and water production and supply \$578.78 million, construction \$2276.35 million, and other industries accumulated \$540.34 million, as shown in Figure 5.

In 2017, FDI in Henan province showed a total FDI of \$1722428 million, including manufacturing utilization FDI of \$1034835 million, electricity, heat, gas, and water \$2311.5 million, leasing and business services \$8788.44 million, real estate \$187056 million, construction \$27.56 million, and \$178,7.87 million in other industries. Figure 6 shows the portion of FDI industries in Henan Province.

TABLE 11: Data of each variable in Jiangsu Province.

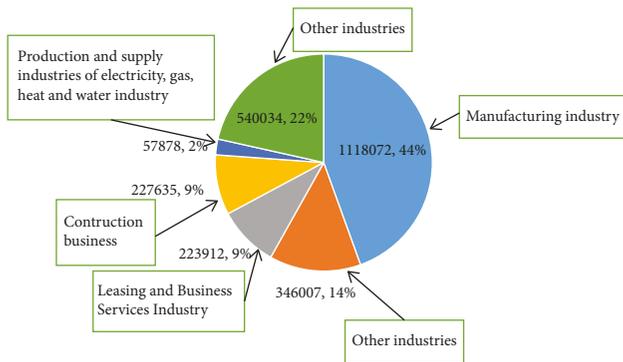

FIGURE 5: The portion of FDI industries in Jiangsu Province.

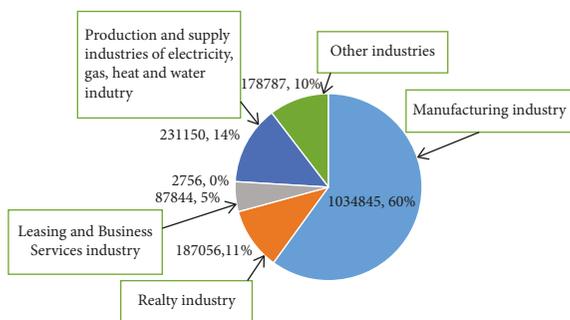

FIGURE 6: The portion of FDI industries in Henan Province.

The economic growth model of Jiangsu Province is as follows:

$$\ln Y_t = 0.063049 \ln FDI_t + 0.045071 \ln NE_t + 0.490681 \ln K_t + 0.223155 \ln L_t + 0.268569 \ln CPI_t + \mu_t \quad (14)$$

It can be seen that when other variables remain unchanged, for every 1 percentage point of FDI growth, the GDP of Henan Province increased by 0.044262 percentage points, while Jiangsu Province increased by 0.063049 percentage points, and the difference between the two regions was 0.018787 percentage points. There are many reasons for this difference. From the analysis of this chapter, we can find some reasons: First of all, the distribution of FDI in Henan province is relatively uneven. FDI has been invested too much in the manufacturing industry, as high as 60%, while the manufacturing industry in Jiangsu Province is 44%, which is also due to the inconsistency between the leading industries in the two regions. Secondly, the construction industry is an important industry in promoting economic development. However, in terms of the construction industry, the FDI utilization in Jiangsu Province accounts for 9%, while the FDI introduced in the construction industry is only 0.0016%. Finally, although the growth rate of FDI introduced in Henan Province is very fast, its amount is far less than that of Jiangsu Province. Jiangsu Province has formed a relatively mature foreign joint venture, while the foreign investment in Henan Province is in the growth period, and the number of foreign direct investment cooperative enterprises is small.

4. Conclusion

Through the analysis of this paper, the study can obtain the following conclusions: First, China's FDI is mainly derived from the Hong Kong region. Second, foreign direct investment has a positive role in promoting China's economic growth but also increases China's domestic employment opportunities. Third, the distribution of foreign direct investment in various industries is very uneven, showing a situation dominated by manufacturing, leasing, and business services, and the real estate industry also accounts for a large proportion but relatively little foreign investment in education, public management, health, and social security. Fourth, in different regions, due to the regional economic law, development level is inconsistent, the introduction of FDI value is very different, and the introduction of the FDI economic benefits (i.e., GDP) because of different leading industries, so each industry introduced FDI also has different, but in each region are manufacturing most FDI. Manufacturing, leasing and business services and real estate are a large part of the FDI. These three major industries have contributed to economic growth after the introduction of FDI.

Obtaining the learning behavior of terminal learners solves the problem of inability to understand students' concentration in class. When learners learn English, they can obtain learning concentration to understand learners' concentration, in order to analyze the influence coefficient of various learning behavior data on learning concentration. This paper will design and implement a terminal data acquisition tool to collect the device perception information in the learning environment of learners, and capture the learner's touch screen operation data based on the virtual simulation experiment, and then use the improved neural network to process the collected terminal sensor data for learning behavior. We identify and obtain the learner's learning activity state, and finally fit the learner's behavioral data weight through a linear regression equation, monitor the learner's learning state, and explore the influencing factors of learning concentration.

1. Introduction

In recent years, with the rapid changes in the era of intelligent information and the rapid development of the technological society, the trend of intelligentization has accelerated, and people's demand for intelligent life has gradually increased. Automated driving technology has entered the field of transportation, intelligent voice robots have entered the service industry, and intelligent sweeping robots have entered the field of home furnishing. In the context of education, it is on the agenda to develop intelligent applications suitable for English classroom education.

Concentration, also known as concentration, refers to the continuous and persistent listening state in the classroom and refers to the psychological state of a person when he is concentrating on a certain thing or activity. Due to their young age, primary and secondary school students do not have a strong sense of self-management, and their energy is easily dispersed by other things, resulting in insufficient energy invested in a relatively important thing. For example, when students are listening to a class, part of the time will be

in a "slippage" state, which leads to many students' knowledge breakpoints, which directly affects the quality of the classroom. In addition, when the number of students in the class is large, it is difficult for English teachers to make real-time judgments on everyone's concentration while focusing on lectures. The low concentration of students leads to poor completion of homework after class, which will greatly increase the need for English teachers after class workload, and it is impossible to truly teach students in accordance with their aptitude. Therefore, the monitoring of students' concentration in English classroom is one of the most needed research directions. The traditional English classroom quality analysis is carried out by arranging lectures in the classroom, after-class questionnaires, etc., which is highly subjective, exposing the shortcomings of classroom real-time monitoring and analysis, and cannot meet people's expectations for high-quality English classroom teaching requirements and expectations. Therefore, it is most important to introduce intelligent education into the classroom, assist teachers in intelligent classroom management, and understand the listening status of each student anytime

and anywhere, so as to supervise English classrooms in a timely manner, and customize personalized English teaching plans in a timely manner after class one of the tasks. Research on a concentration monitoring and analysis system that can be applied to English classrooms has strong practicability and market space, and can also promote the development of English education in the direction of intelligence, comprehensiveness, and diversification, and has broad application prospects [1–10].

2. Related Work

Most scholars have done a lot of research on one aspect of mindfulness, attention, and put forward many insightful points, which provide a lot of thought reference for this research. To sum up, the relevant research on concentration is mainly carried out from the following three aspects: the first is the role of attention. It mainly conducts in-depth research on the phenomenon of inattentiveness in children, adolescents, athletes, etc.; the second is the research on the detection methods and evaluation standards of attention; and the third is the research on the cultivation of attention. The research on attention has a complete set of detection methods and evaluation standards. Although it is only a part of attention, it also provides many valuable references for the study of attention. Then, with the improvement of attention, the level of information technology, the research on the intelligent management, concentration monitoring, and analysis system of primary and middle school students' classrooms are moving toward the intelligent mode. In the 1850s, foreign scholar Aryamov made a statistical analysis of the attention of primary school students through the method of observation and recording, and believed that the attention span of primary school students aged 7–10 was about 20 minutes. This method does not have very good objectivity, has a strong subjective color, and also requires the observer to have the relevant ability. Later, the classroom teaching evaluation method appeared mainly by arranging different teachers to randomly listen to the class and record the lecture notes. This method cannot specifically reflect the concentration of each student during class. In recent years, the methods of monitoring students' classroom concentration have been studied in a more objective and convenient direction. The main methods of concentration monitoring include facial microexpression recognition; recognition and analysis of head posture information; and collection of physiological data such as brain waves (EEG), manual filling of questionnaires, and behavioral recognition of video images. However, the above methods have some problems more or less. Although the classroom expression evaluation system can identify most expressions of students in class, there will be certain errors due to the insufficient amount of existing data. A relatively complete classroom expression database is needed to train the model, and there is no such classroom expression database in the public libraries at home and abroad, and it cannot be completed in a short time if the collection is carried out. The above research shows that relying on a single dimension to monitor students' classroom concentration and analyze the results obtained is not

accurate enough and unreliable. The advent of the era of intelligence has prompted the development of traditional classroom management in the direction of technology and informatization, and manual collection methods have gradually been replaced by automated operations. And at this stage, there is not much research on the concentration monitoring and analysis system of primary and secondary school classrooms that combines deep learning and multimodal integration, and there is a big gap, which is worth studying [11–16].

3. Relevant Theories and Technical Methods

3.1. Learning Behavior. Nowadays, with the widespread application of Internet devices such as networks and mobile terminals in all aspects of modern people's daily life, online learning has a positive impact on the progress of education in the field of higher education in my country. It not only breaks through the traditional teaching method and classroom model but also considered as a creative innovation of educational science and technology. By collecting and obtaining data about learners' learning behavior during online learning, it is possible to better understand and effectively optimize learning and the place where it occurs, discover information rules in learning behavior data, and apply them to realize its value. The process of learning behavior data acquisition includes the following three aspects, namely, data collection, data processing, and data analysis and presentation. The content of learning behavior data acquisition is shown in Figure 1 [17].

3.2. English Education Learning Behavior Concentration Recognition Technology

3.2.1. Classroom Attention Behavior Recognition Based on Long Short-Term Memory Network Model. Recurrent neural network (RNN) is a type of directed graph that combines the data connections between each neural node in the order of a corresponding time point, and RNN can be widely used in real-time processing. The input data of the corresponding spatial time series are extracted, and the network structure of the corresponding time-sequential objects of the output data with time-dependent characteristics is extracted. In the recurrent neural network, each node is connected to the next layer of neuron nodes through a one-way connection. During the network iteration process, each neuron contains its own previous information, and its output is affected by the previous neuron. Impact on its expanded unit is shown in Figure 2.

The structure of the RNN unit and its open structure in time are shown in Figure 2. In the figure, $x = (x_0, x_1, x_2, \dots, x_t)$ represents the input sequence of the recurrent neural network, and $y = (y_0, y_1, y_2, \dots, y_t)$ represents the output sequence of the recurrent neural network, and $h = (h_0, h_1, h_2, \dots, h_t)$ represents the hidden state sequence of the recurrent neural network. The output state of each hidden layer of the recurrent neural network depends not only on the sequence t and x of the previous hidden input and output state layer of the current input neuron but also on the

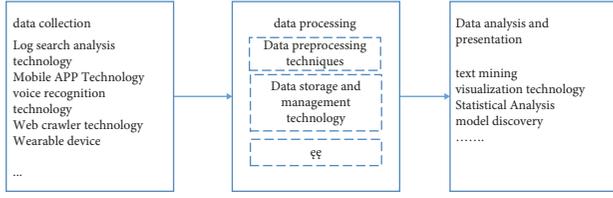

FIGURE 1: Learning behavior data acquisition process.

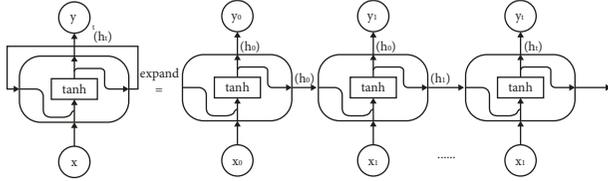

FIGURE 2: RNN unit expansion structure.

sequence of each hidden output state layer of the input neuron at the current moment h , and the expression of the calculation formula of the output layer at time t is as follows:

$$\begin{aligned} h_t &= \tanh(w_{xh}x_t + w_{hh}h_{t-1} + b_h), \\ y_t &= w_{hy}h_t + b_y. \end{aligned} \quad (1)$$

Due to the limited amount of sequence historical data information that can be saved by samples in the hidden state of the recurrent neural network, problems such as gradient explosion or gradient disappearance may occur in the process of processing this long-term sequence of samples. Problems such as gradient explosion and disappearance will cause the recurrent neural network to be unstable and unable to converge to the optimal result, so the long short-term memory network (LSTM) with a strong feedback mechanism effectively solves the drawbacks of long-term dependence in the recurrent neural network. As a variant of the recurrent neural network, LSTM is composed of a self-connected memory data storage unit and three “gates” used to control the memory data information storage. The internal structure of the LSTM unit is shown in Figure 3 [18].

3.2.2. Recognition of English Education Learning Behavior Based on Convolutional Neural Network Model. A convolutional neural network system includes several layers of convolution, pooling, and fully connected layers. There is a huge technical difference between the point-to-layer structure of a convolutional neural network and the point-to-layer structure of a fully connected neural network. Each layer of neurons in a fully connected neural network must be arranged in a one-dimensional order, while each layer of a convolutional neural network must be arranged in a three-dimensional order. Compared with the fully connected neural network, the convolutional neural network has many basic characteristics such as multilayer local data connection, weight data sharing, and next-layer sampling. Local connection means that each neuron is no longer connected to all neurons in the previous layer, and weight sharing means that a group of neurons can share weights at the same

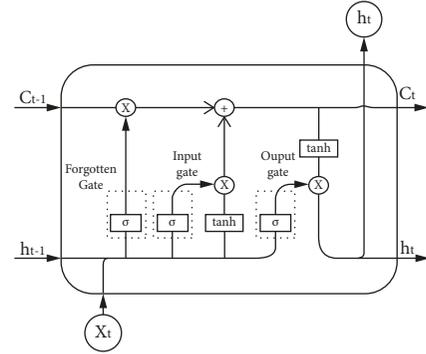

FIGURE 3: LSTM unit internal structure diagram.

position, not each connected neuron has its own positional weights. The downsampling method can greatly reduce the number of samples between each layer through the pooling layer, further greatly reduce the number of each parameter, and also greatly improve the robustness of the model. A schematic diagram of a convolutional neural network is shown in Figure 4.

The convolutional layer has the characteristics of realizing weight distribution and local links through the convolutional neural network. The convolutional layer performs feature extraction on the original input. The calculation formula is as follows:

$$a_{i,j} = f\left(\sum_{m=0}^2 \sum_{n=0}^2 w_{m,n}x_{i+m,j+n} + w_b\right). \quad (2)$$

In Formula 2 $w_{m,n}$ represents the weights of the functions in rows m and n , while $x_{i,j}$ -th row represents the elements of rows i, j . The element of row j th column w_b represents the bias term; $f()$ represents the activation function; usually, the model construction selects the ReLU function as the activation function, and the definition of the ReLU function is as follows:

$$f(x) = \max(0, x). \quad (3)$$

Compared with the training process of the fully connected neural network, although the whole training method of the convolutional neural network is more complicated, the main workload and principle of the whole training are the same, mainly using a chain algorithm to obtain the derivation method, to recalculate the partial derivative coefficient of the weight function to the weight of each unit, and then update each weight according to the principle of reverse descent of the weight gradient. The process of training this algorithm requires a reverse weight propagation algorithm.

4. Establishment of Experimental Model of English Education Learning Concentration and Analysis of Experimental Results

4.1. Data Collection

4.1.1. Terminal Data Acquisition Framework. In the whole system, the design of the mobile terminal frame is very

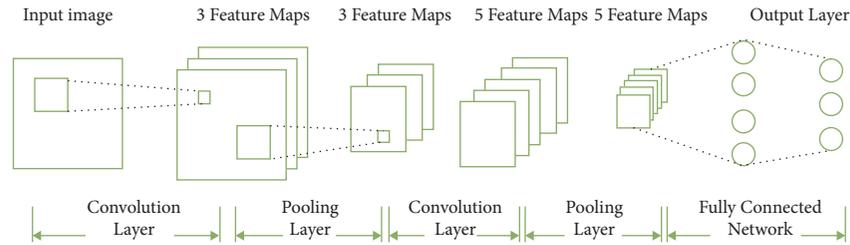

FIGURE 4: CNN neural network architecture.

important, and it is the cornerstone of the whole system. The functions completed in this design are shown in Figure 5. The terminal data, network data, and user usage data of learners' English learning behavior are collected, stored, and uploaded, and the sensor data collected in real time are packaged in API and provided to the focus. Force recognition module is shown in Figure 6.

- (1) Learner behavior data collection module. This module collects learning behavior data of a single terminal learner. The terminal data, network data, and user usage data of mobile terminal learners are collected to facilitate the calling and storage of other modules. The collected data are formed into a unified format "key-value" method in which the key is used as the unique identifier in the system, and the corresponding value saves the learner's learning behavior data in the form of a string.
- (2) Local data storage module. This module receives and stores the collected mobile terminal learning behavior data. The collected data will be directly stored in the local server in the form of a database, providing sample data for subsequent model training.
- (3) API calling module. This module provides the collected mobile terminal learning behavior data to the model in a standard format as sample data or to other models for calling. API (application programming interface) is an interface provided to the application program. After the system call is obtained, the API and the system call jointly complete the data access in the user mode and the kernel mode.
- (4) Terminal behavior data upload module. This module stores the collected learning behavior data of English classroom teaching learners, uploads it, and sends it to the network side. The network side generates summary information according to the data uploaded by the terminal and sends the summary information to the terminal to visualize the results of the collected data.
- (5) Learning concentration recognition module. This module is a research on learning concentration behavior recognition based on sensor data collected on terminal equipment. By building a model based on the LSTM model and integrating the convolutional neural network to improve the low-level processing unit to obtain the local saliency of the time series and the high-level processing unit to obtain the hidden

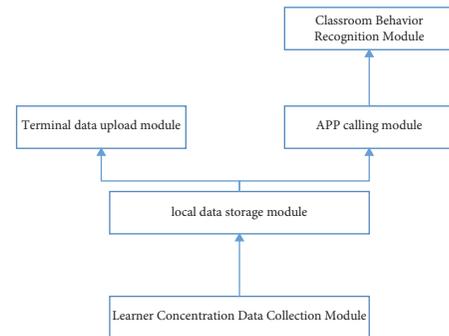

FIGURE 5: Logic diagram of terminal data acquisition framework.

feature of the time series, the classification of the learner's learning behavior and activity state are realized identify. When the terminal data acquisition system performs the startup operation, the application program is initialized, and the data for monitoring the terminal operation of the learner are set. We acquire terminal data information and network data information and return the data to the system; collect user usage data when the learner operation occurs, the corresponding device perception information is successfully captured by the system acquisition module; and store the acquired data in a standard format. We upload the acquired data to the server, and the operation flow of the terminal data acquisition framework is shown in Figure 6.

4.1.2. Terminal Data Acquisition Development Platform and Tools. In this study, the Android system was selected as the development platform, and a set of learner terminal data acquisition system was implemented. Based on common technology architecture (MVC), Android Studio is used as the main development tool. Android Studio is an application editor developed by Google and specially developed for Android developers. The Android Studio development tool supports the flexible construction of the operating system based on Gradle and supports the automatic construction of multiple versions and the simultaneous generation of multiple APK files. Based on the above advantages, this paper uses Android Studio to develop and design the learner terminal data acquisition system.

4.1.3. Realization of Terminal Data Acquisition. The terminal data acquisition system frame includes three parts,

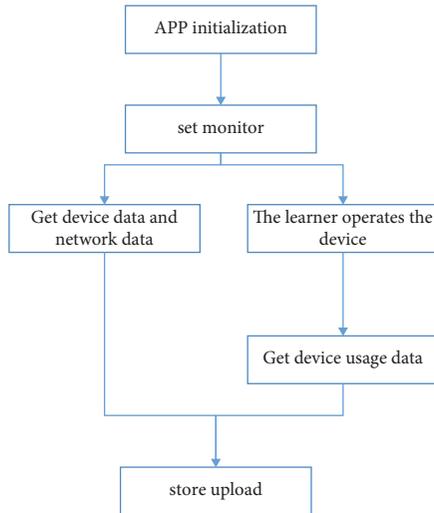

FIGURE 6: Operation flow chart of terminal data acquisition framework.

namely, terminal data, network data, and user usage data acquisition. The framework takes the sense controller class as the core, which combines the contents of device data (terminal data), network data (network data), and equipment usage data (user usage data) to work together. The core control class structure is shown in Figure 7.

- (1) The realization of terminal equipment information acquisition is shown in Figure 7. The terminal device information acquisition is based on the digital serial number and DEVICE_ID dialing provided by the Android system to the mobile phone developer for acquiring the designated mobile terminal device name symbol.
- (2) The realization of terminal power information acquisition, an information module about mobile phone power supply, is designed, and the mobile phone power supply is obtained in this way so that the learning behavior of learners on the mobile terminal can be better monitored and analyzed.
- (3) As shown in Figure 8, the application “data-Acquisition,” “rediobutton,” “qqttest,” and “Phone” are displayed as the list of APP usage in the virtual machine. The purpose of obtaining the usage of the APP is to obtain whether the learner has switched to other applications during English learning. During the learning process, multitasking is performed in parallel, which affects the concentration of learning.
- (4) The realization of unlocking the screen event acquisition is shown in Figure 9. The purpose of acquiring the unlocking screen event is to analyze the behaviors of the English learners during the learning process. By analyzing the unlocking screen state, the learner-related learning information is obtained.

4.2. Human Behavior Recognition. In this study, a new neural network is designed: a two-layer convolutional neural

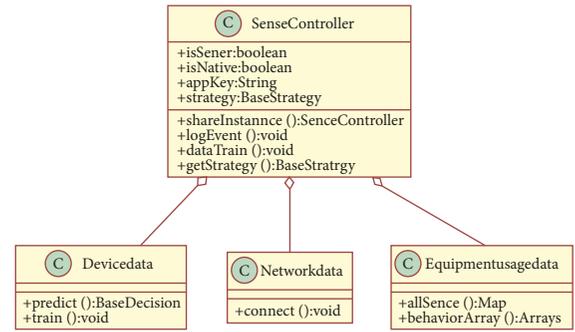

FIGURE 7: Core control class structure diagram.

network is integrated into the long short-term memory network. It only needs to send the preprocessed data to the network for training and does not need to manually extract the feature set.

The convolutional neural network plays a great role in identifying the concentration of English education learners. The low-level processing unit can obtain the local saliency of the time series, and the high-level processing unit can obtain the hidden features of the time series. In the face of time-series sensor data, convolutional neural networks need to perform convolution and pooling calculations along the time dimension, stack time-series sensor data into three-dimensional arrays, and extract time-series feature sets through convolution pooling. The long short-term memory network is a recurrent network that simulates the temporal correlation in time series problems through memory units, which can effectively obtain the temporal dependence of features.

4.2.1. Data Collection and Preprocessing. In order to obtain a form that is more conducive to learner feature extraction, the data should be preprocessed before feature extraction and model recognition. In order to fully mine the focus state information of English education learners, the data standardization is carried out by using the standard descriptive method, and the data are preprocessed by the sliding window technology of the sensor, and the data collected every second are used as a sample; that is, the sensor samples the learning behavior of the learner at a frequency of 50 Hz. When it is completed, all the collected data are sampled in a certain time dimension. When dividing, every 128 consecutive samples are taken as 1 sample. The distance between each sample and the starting position is 64 samples as a point, and each active window is described by 561 features. This study uses two-dimensional convolution operation to process time series, obtains the local dependency of sensor data time dimension, uses two-dimensional convolution to capture the spatial characteristics of English education learning behaviors, and obtains the two-dimensional matrix of learning action input according to the operation size, and the calculation formula of its dimension N is as follows:

$$N = \sqrt{m * 2 + \text{cell}(\sqrt{m})^2}, \quad (4)$$

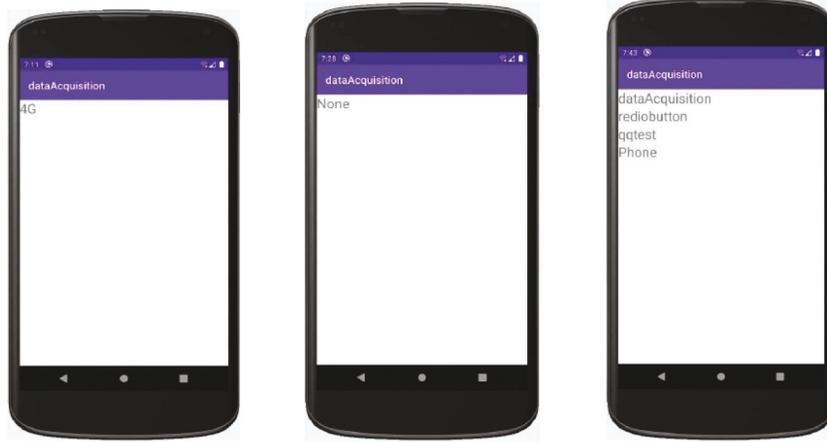

FIGURE 8: Access network type data.

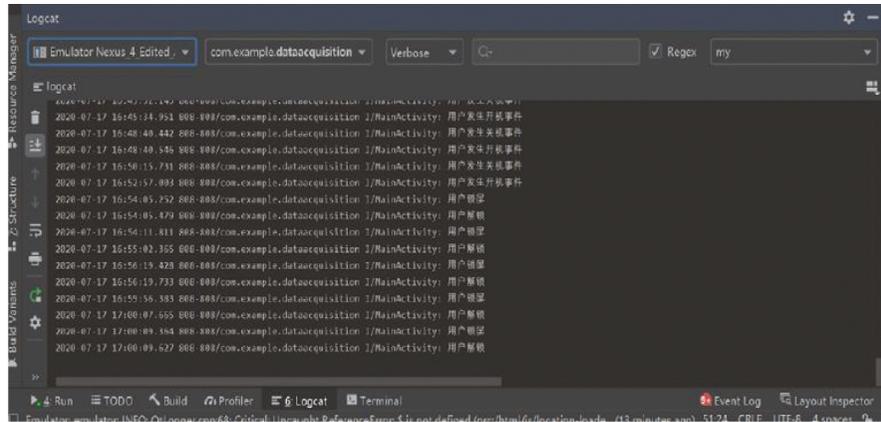

FIGURE 9: English learner learning behavior data.

where m is the number of collected data samples, and $\text{cell}()$ is rounded up. The processed time-series data are input into the neural network for training, and the algorithm model is obtained. The output layer in the model is the softmax layer, and its output is a probability distribution, so the labels of the sample data also need to appear in the form of probability distributions.

4.2.2. Learner Learning Concentration Recognition Model.

In this paper, the method of learner focus recognition is mainly based on the segmentation of various learning behaviors, and each learning behavior has a unique and refined action and category label.

Attention learning behavior recognition model takes human behavior, that is, multi-action sequence information as the input of the model, in which the multi-action output is used to predict the human behavior category of the model. The model mainly uses convolutional neural network and long short-term memory. The combined form of the network is used for human behavior recognition. The model is defined as the sequential Keras model, and a CNN model is defined with the Keras deep learning library. The network structure framework is shown in Figure 10. It mainly includes two one-dimensional convolutional layers, a dropout

layer and a pooling layer. The training of the convolutional neural network model is very fast in which the dropout layer can slow down the learning process and make the final model better, and the pooling layer shortens the learned features to $1/4$, so that it retains the most important elements. To better enable the model to learn features from the input data, we wrap the entire CNN model in a time distributed layer, allowing the same CNN model to be read in each of the four subsequences of the window. After the convolutional and pooling layers, the learned features are unrolled into a long vector, the extracted features are flattened and fed to the single-hidden layer LSTM model for reading, and the CNN-LSTM model will be in chunks. We read subsequences of the main sequence, allow the LSTM to interpret and extract features from each block, define dropout layers to reduce the model's overfitting to the training data, extract its own features before final classification of the activity, and finally, in turn, classify through fully connected layers and softmax layers.

4.2.3. Learning Behavior Recognition Model Training. In the process of fitting the CNN-LSTM model, no shuffle operation is performed on the sequence data, but the window of the input data is randomly adjusted during training, so the

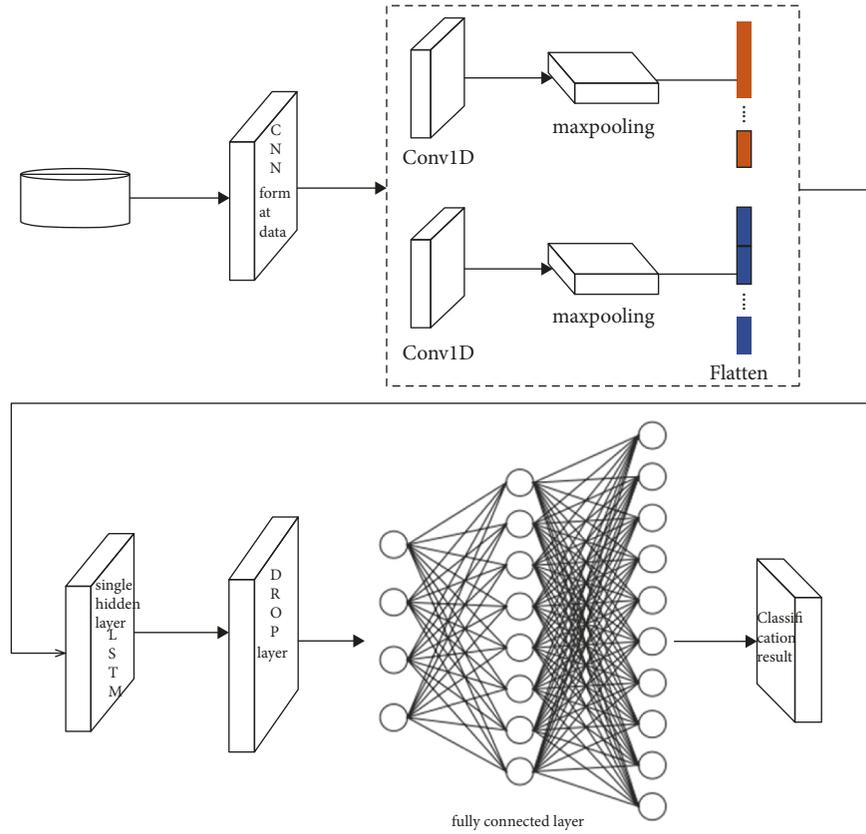

FIGURE 10: Building a neural network structure framework.

log information is not output to the standard output stream during model training. The number of iterations of the training model is 15, and the learning efficiency of the model is set to 0.1 to improve the generalization ability of the model. The Adam optimizer is used as the stochastic gradient descent algorithm to iteratively update the network weights for training data, providing a sparse stochastic gradient weight descent optimization algorithm that can effectively deal with the problem of network noise reduction. In the process of training the model, the optimization objective is set as the cross-entropy categorical_crossentropy to describe the accuracy of the model for human action recognition. Cross-entropy is defined as follows:

$$H_{y'} y = - \sum_{i=1}^N y'_i \log y_i. \quad (5)$$

Among them, y'_i and y_i represent the i -th ground-truth sample labels and the i -th predicted sample labels are the number of identified categories. After the weight matrix calculates the cross-entropy loss function, the weight matrix and the offset are corrected in turn. The neural network uses the gradient descent method to solve the minimum value of the loss function, which is defined as follows:

$$x_{\text{new}} = x_{\text{old}} - \varphi \frac{\partial f(x)}{\partial(x)}. \quad (6)$$

Among them, x_{new} and x_{old} represent the modified weight matrix and the uncorrected weight matrix,

respectively, and $f(x)$ represent the learning rate, which is a hyperparameter of the neural network. The data features and labels of the test set are input into the evaluation function run_experiment respectively, and the accuracy of the model used for the test set data is calculated. By creating and evaluating models, debug information and a sample score are printed for each model.

4.2.4. Experimental Results and Analysis. The experimental results mainly compare and analyze the improved CNN-LSTM model proposed in this paper with the machine learning hierarchical hidden Markov model, machine learning algorithm, and LSTM model algorithm, in order to verify the accuracy of the model. First, some data sets used in the experiment, experimental environment, and parameter configuration in other experiments are briefly introduced, and then, the corresponding experiments are designed according to the needs and analyzed with the comparison results.

The data of the experiment come from the machine learning knowledge base of the public website UCI. The HAR data set collects sensor data on smartphones. The data set is recorded from 30 students, who collect six learning behaviors while wearing smartphones around their waists activity. They are dictation, reading, answering, discussion, thinking, and classroom practice. After the sampling work results are detected, all samples and data are divided according to the time dimension. The analysis results are

TABLE 1: UCI data sample distribution table.

	Dictation	Read	Answer	Discuss	Think	Classroom exercises	
Training set	1253	1307	1359	1355	1086	992	7352
Test set	491	537	532	496	471	420	2947
Total	1744	1844	1891	1851	1557	1412	10299

TABLE 2: Experimental parameter settings.

Parameter name	Parameter value
Length of time sample	128
Number of times to train the model	25
Number of batches per training	64
Time step	32
The number of neurons in the hidden layer	100
Learning rate	0.1
Dropout ratio	0.5

2.56 seconds and a 50% overlapping fixed window for sampling. The segmentation of various learning behaviors is that every 128 consecutive samples are taken as a new sample, each sample data are 64 sampling points apart at its start and end positions, and each active window is described by 561 feature methods, and these data are analyzed. After normalization, the data values are between $[-1, 1]$. The entire sample set was redivided and split into two groups, with the behavioral data of 21 students as the training set and the behavioral data of 9 students as the test set. The entire UCI data set has a total of 10,299 data samples, and the specific sample distribution is shown in Table 1 [19–23].

Through the analysis of the data set, this paper continuously adjusts and tests the parameters, and obtains the optimal relevant parameters for the current training. The experiment is defined as a shallow-level CNN that extracts features from the input data, flattens the feature vector into a single-hidden-layer LSTM model, and adds a dropout layer that reduces the model's overfitting to the training data, and a dropout layer for classification. Softmax layer uses a fully connected layer to interpret the features extracted by the CNN-LSTM hidden layers before using the output layer for prediction. In the practice process of training the model, the method of stochastic gradient descent is used for training, and the optimization objective is set as the cross-entropy categorical_crossentropy to describe the accuracy of the model for classifying human actions. When performing the training operation iteratively, only a small part of the data is used for stochastic gradient descent each time, and 64 items are randomly selected from the training set as mini_batch; that is, the batch size is set to 64, and 64 data windows are inputs into the model before updating the model weights. In the CNN-LSTM model, the settings of parameters and matrix size are learned through model training, so 30% of the data set is selected as the training set to train the model to obtain the optimal parameters, and the remaining data are used as the test set to evaluate the performance of the model. The specific experimental parameter settings are shown in Table 2.

This experiment is a training test of the neural network model built based on the public data set of sensor

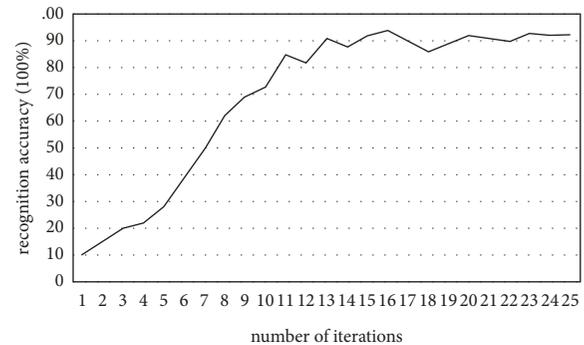

FIGURE 11: Variation curve of recognition accuracy of CNN-LSTM model training set.

data. In order to make the experimental results more accurate, the experiments are carried out under the weight parameter that obtains the highest accurate value, and the experimental results are compared with the hierarchical hidden Markov model, machine learning algorithm, and LSTM model. The recognition accuracy is used as an evaluation index for experimental comparison. The higher the accuracy, the better the performance of the model classifier.

When experimenting with the CNN-LSTM model, we set the experimental parameters. Figure 11 shows the change process of the recognition accuracy of the experimental training set based on the CNN-LSTM model. It can be seen that with the increase of the number of iterations, the recognition accuracy rate rises rapidly and remains above 0.92; the standard deviation is 0.373; and the recognition accuracy is accurate. The rate is about 92.499%.

Through the above experiments, the operation results based on the hierarchical hidden Markov model, machine learning algorithm, LSTM model, and CNN-LSTM model are obtained. The comprehensive recognition accuracy of the above experiments is summarized in Table 3. Compared with the existing research, it is found that the hierarchical hidden Markov model structure saves the storage space of the mobile phone and reduces the computational complexity, but the space complexity is expensive and the data overfitting phenomenon that may occur in the experimental classification process is not carried out. Processing. In the experiment based on machine learning algorithm, the data features selected manually after dimensionality reduction of the data by principal component analysis are still insufficient; when recognizing students' concentration behavior based on the LSTM model, the single-layer LSTM structure is used to process long-term sequences. There is a problem of taking too long to sample. Compared with the above three

TABLE 3: Comparison of experimental results.

Method	Recognition accuracy (%)
Hierarchical hidden Markov model	72.5
Machine learning algorithms	78.2
LSTM model	89.1
CNN-LSTM model	92.5

methods of human behavior recognition, the recognition accuracy of the CNN-LSTM model has increased, which indicates that the model has a higher accuracy rate and better effect in recognizing concentration behaviors in English classroom teaching.

By integrating the convolutional neural network on the basis of the LSTM model, the local saliency of the time series obtained by the low-level processing unit and the hidden features of the time series obtained by the high-level processing unit are improved. On the one hand, the model does not require manual feature extraction, which leads to deviations in the experimental results; on the other hand, the combination of convolutional neural network and long short-term memory network can make the model better learn features from the input data and achieve more effective results. *English learning concentration activity recognition*. Finally, the model is compared with the hierarchical hidden Markov model, machine learning algorithm, and LSTM model, and the models improve the recognition accuracy by nearly 19.99%, 14.29%, and 2.79%, respectively, thus verifying the effectiveness of the model.

5. Conclusion

This paper obtains learning behavior data based on the application scenario of mobile terminal learning, obtains the learning status device perception information of the learner by implementing a terminal data acquisition tool, captures the touch screen operation of the learner experiment based on the virtual simulation experiment, and then improves the CNN-LSTM by improving the CNN-LSTM. The collected terminal acceleration sensor data are processed for human behavior recognition, and the learning activity status of the learner is obtained. Finally, the influence of the learning behavior of the learner's mobile terminal on the learning concentration is analyzed by fitting the weights of various types of learner behavior data. The acquisition of learning behavior data of mobile terminal learners is the premise of analyzing the influence of learners' online learning concentration factors. The acquisition of learner behavior data provides experimental data sets for subsequent research modules such as intelligent learning guidance and personalized diagnosis.

With the development of educational informatization, the educational data of each school is increasing day by day. How to rationally use the existing information to make scientific teaching decisions is a problem that every educator is closely concerned about. This paper proposes a correlation analysis method for college art courses based on data mining technology. Through the study of association rules in data mining, the Apriori algorithm based on three-dimensional matrix is used to quickly mine student performance data, so as to obtain some reasonable and reliable courses. The results show that the method in this paper can find valuable information for curriculum setting from the actual teaching data, so as to reasonably optimize the curriculum, provide a decision-making basis for the revision of the art curriculum and syllabus in colleges and universities, and further improve the teaching effect and the quality of personnel training.

1. Introduction

With the development of various undertakings in the country, the society is required to cultivate more high-quality talents. As one of the most important talent training bases, the school has a long way to go. As far as the professional development of educational technology is concerned, there are common shortcomings in the school's professional construction, such as lack of characteristics, broad curriculum, and severe employment situation [1–5]. The school's curriculum setting directly affects the quality of teaching and the level of personnel training. The report shows that the factors restricting employment also include improper curriculum. Curriculum setting is not only related to the quality of talent training and student employment but also closely related to the development of disciplines. Therefore, it is particularly important to use existing data to reasonably set up courses in colleges and universities [6, 7].

In the course setting, the knowledge correlation of the course content itself is usually analyzed, and the course is set according to these correlations. This kind of correlation analysis based on course content and learning objectives solves problems such as course level and setting order,

content connection, and credit hour allocation [8–11]. However, the curriculum is set simply by considering the relevance of the curriculum content without considering the actual situation of students' learning after the school offers such a course with valuable information [10, 12–14]. With the help of data to reflect the internal connection of courses and further research, we can set up courses more scientifically and reasonably, better optimize teaching management, and improve teaching quality [15].

With the vigorous development of education informatization, the data stored in the educational administration system, student employment system, and enrollment system of various schools is increasing rapidly. Faced with these massive data, how to extract effective information from it is a problem that every educator must think about. At this stage, the use of students' grade data in the educational administration system is only for query, statistics, and simple analysis, and no other information hidden behind the grades has been found in depth [16–19]. Data mining technology can analyze and process complex data. Using data mining technology, we can find the internal relationship between grades and find useful information, which is beneficial to improve the teaching management level and teaching quality

of colleges and universities. Therefore, the curriculum setting should not only consider the relevant course names on the surface of each course or the simple content of the courses, but should start more from the actual learning of students to find the learning effect that reflects the actual situation of the school curriculum [9, 20, 21].

Data mining technology is used to analyze the actual teaching data to find out the curriculum relevance reflected in it, but the relevance of the curriculum is not completely consistent with the relevance of the course content itself, and not only be obtained through a simple analysis of the course content, but it also reflects the actual situation of the school curriculum, the learning effect of the course, and the difference between the course setting, so how to use the real data generated in the actual teaching to more accurately find the existence of the course? Objective correlation is the problem to be solved in this study. In the above background and meaning, with the help of data mining technology, we can quantitatively analyze the course performance data in teaching practice, find the correlation between courses, and realize from the actual learning situation of students in our school to find the data reflected in the actual teaching. It can further optimize the curriculum construction and provide reference information for students' course selection, early warning of students' performance, and the formulation of training programs, thereby improving the quality of teaching. However, the use of data mining technology for course correlation analysis needs further research [14, 22]. Generally, researchers use the correlation between the academic performance of various subjects to reflect the correlation between courses, and the application of correlation analysis between courses is mainly reflected in three aspects: curriculum setting, grade warning, and student course selection. Sima Birong obtained the dependence relationship and degree of dependence between each course from the analysis results of students' course grades and could predict students' academic grades in subsequent courses; Ji Shunning used association rules and hierarchical association rules to analyze students' performance in school and the degree of dependence. Graduation data obtained the correlation between courses, core courses, and important skills and then constructed the curriculum system based on the project-based teaching mode of the major; Sun Yuehao used the association rule algorithm to analyze the course performance data of a major and found the curriculum and enterprise needs. Wang Hua et al. used the improved Apriori algorithm to analyze the learning effect of students to find the correlation between courses and used to early warning students' performance; Wu Haifeng et al. mainly focused on using data mining technology to build early warning models, respectively. Data statistics are used for low-level early warning, cluster analysis is used for landslide early warning, the correlation between courses is found through association rule analysis, and the association rule base is used to search to predict potential crises in the next semester's study and achieve the potential effect of early warning.

Therefore, this paper will use the three-dimensional matrix-based Apriori algorithm to mine the test scores of the four majors of painting, art design, photography, and

animation in colleges and universities and find the dependencies and connections between the courses. The teaching reform provides scientific and reliable decision-making guidance.

2. Course Relevance Analysis

2.1. Correlation Analysis Overview. In the existing course setting, due to the mutual connection between the contents of each course, the content and arrangement of one course will have an impact on the learning of another course. The effect is called curriculum relevance in this study. Generally speaking, curriculum relevance includes the following two dimensions: one is the content dimension: that is, there are certain associations and connections between different curriculum contents; the other is the time dimension: that is, the temporal relevance of different courses and the different curriculum contents topic relevance when presented.

When there is not only a quantitative relationship between the things under study, but not a definite, stable, and one-to-one corresponding value like a functional relationship, this relationship is called a correlation relationship. Correlation is mainly used to describe the relationship between variables that cannot be represented by a functional relationship, but there is a dependent relationship. It uses appropriate statistical indicators to represent the strength and direction of the correlation between variables. Correlation is mainly used to study the covariant relationship between things and cannot directly reveal the internal causal relationship of things. Therefore, if it is necessary to judge whether the things that are related have a causal relationship at the same time, further analysis should be carried out according to the existing knowledge and experience.

Generally, r is used to represent the correlation coefficient, which reflects the change in direction and closeness of the correlation between things. Its value range is $0 \leq |r| \leq 1$, where the symbol of r indicates the direction of change between variables, and the "+" sign indicates that the changing trend between variables is consistent, increasing or decreasing, that is, positive correlation, "-" sign indicates that the direction of change is opposite, that is, negative correlation. The absolute value of r indicates the closeness of the connection between things. According to previous studies, several different degrees of correlation can be obtained according to the size of the correlation coefficient: $|r| \geq 0.8$, two variables are highly correlated, $0.5 \leq |r| < 0.8$, two variables are significantly correlated, $0.3 \leq |r| < 0.5$, the two variables are highly correlated, and $|r| < 0.3$, the two variables are not correlated. In practical problems, in addition to calculating the degree of correlation, a significance test must be completed, thereby reducing the random risk of sample data.

2.2. Quantitative Analysis of Course Relevance. Usually, the relevance of courses can be reflected in the categories, purposes, requirements, content, and types of hours of courses, etc., but the relevance of course purposes, requirements, and content is mostly qualitative analysis, and it is difficult to quantify it. Many researchers have begun to use

quantitative analysis of course performance to explore correlations between courses. For example, Gao Minghai et al. used the method of multiple linear regression to analyze the grade data and obtained the statistical relationship and rules between courses by constructing a data model; Liu Peng et al. used the correlation between a certain course and subsequent courses; Ji Lianen et al. obtained the correlation between courses by calculating the Pearson correlation coefficient of course performance data and combined interactive technology to design a multisubject-oriented student achievement visualization system; Yao Shuangliang used the improved Apriori algorithm after analyzing the students' grades in each course, and the association rules between courses were obtained; Li Ludan also used the simple correlation analysis method to calculate the correlation of the course grade data and then used the results of the course correlation to obtain the course setting optimization strategy.

Combining other researchers' analyses of the relevance of courses, this study also obtained the internal connection between courses by means of quantitative analysis of learning effect data. If the courses are highly relevant, further research on related courses can improve teaching to provide reference for the improvement of teaching quality. This study mainly takes an art major in a university as an example and explores the correlation between courses by mining the scores of each course in the teaching empirical data.

2.3. Curriculum Relevance Analysis Method

2.3.1. Simple Correlation Analysis. Simple correlation analysis is a method of analyzing the correlation between two variables. In course analysis, it is mainly used to analyze the correlation between different courses under the same type of course.

2.3.2. Canonical Correlation Analysis. Canonical correlation analysis is a method of analyzing the correlation between one set of data ($X_1, X_2, X_3, \dots, X_m$) and another set of data ($Y_1, Y_2, Y_3, \dots, Y_n$). In the course analysis, it is mainly used to analyze the overall correlation between different types of courses. The essence is to screen out several typical courses to comprehensively describe the relationship between the two types of courses.

2.3.3. Association Rule Analysis. Association rule analysis is used to find valuable associations in a large amount of data and obtain the association rules that describe the relationship between transactions, such as "if the antecedent is what, then what is the consequent" information to infer information about another transaction. In course analysis, it is mainly used to analyze the degree of mutual influence between courses.

3. Data Mining Algorithms

Data mining (DM) technology is an emerging technology that has emerged with the development of artificial

intelligence and database technology in recent years. It is to screen out hidden, credible, novel, and effective data from a large amount of data. Association rules, also known as association patterns, were proposed by Agrawal et al. of BIM (Almaden research center) in 1993. Association rules refer to interesting associations or correlations between item sets in a large amount of data. The object discovered by association rules is mainly the transaction database, which is a knowledge model that describes the laws that are between items in a transaction at the same time. At present, there are many algorithms for association rules, and the Apriori algorithm is the most influential algorithm for mining frequent item sets of Boolean association rules. The algorithm uses an iterative method called layer-by-layer search. Its candidate generation-checking method significantly reduces the size of the candidate item set and leads to good performance. However, it has two disadvantages: one is that it may need to generate a large number of candidate item sets; the other is that it needs to scan the database repeatedly and check a large candidate set through pattern matching. Therefore, we use the improved Apriori algorithm based on the three-dimensional matrix to study art teaching in colleges and universities.

3.1. Algorithm Description

3.1.1. Related Definitions. Each transaction t used in mining association rules is stored in the data warehouse D , denoted as

$$D = \{t_1, t_2, \dots, t_M\}. \quad (1)$$

In formula (1), each transaction t is composed of various attributes i , which can be expressed as

$$i = \{i_1, i_2, \dots, i_N\}. \quad (2)$$

Define the association rule between attributes X and Y as $X \Rightarrow Y$. The support of the association rule support is equal to the ratio of the number of transactions with attributes X and Y at the same time to the total number of transactions, which can be expressed as

$$\text{support}(X \Rightarrow Y) = \frac{\text{count}(X \cup Y)}{M}. \quad (3)$$

In formula (3), M is the total number of transactions and $\text{count}(X \cup Y)$ is the number of transactions, where attribute X and attribute Y appear at the same time. Confidence of the association rule is equal to the ratio of the support of the rule to the support of the attribute X itself, which can be expressed as

$$\text{confidence}(X \Rightarrow Y) = \frac{\text{support}(X \Rightarrow Y)}{\text{support}(X)}. \quad (4)$$

In formula (4), $\text{support}(X)$ is the number of occurrences of attribute X . Data mining controls the minimum requirements that the resulting association rules need to meet by setting the minimum support and minimum confidence.

3.1.2. Algorithm Process. The traditional Apriori algorithm will generate a large number of candidate item sets when the amount of data is large and the analysis categories are many, especially when generating binomial sets and tri-item sets. And every time a higher level of frequent item sets are generated, the database needs to be rescanned, which will generate a lot of computational redundancy and low efficiency. Based on the Apriori algorithm, improvements are made to address these shortcomings of the traditional algorithm. The improved algorithm idea is as follows:

- (1) First scan the database, and abstract the database into a two-dimensional matrix based on the attributes contained in all its transactions, which are used to store all the information in the database.
- (2) Traverse each attribute of each transaction in the two-dimensional matrix. By reading two different attributes in the same transaction each time without repeating reading, the three-dimensional upper triangular attribute matrix Matrix (i, j, k) is established, and the coordinates are established according to the corresponding attributes. The coordinate intervals in the three dimensions are all $[1, N]$ (N is the largest attribute type). During the scanning process, each time the coordinates are repeated, the corresponding weight is increased by one, and the matrix can be expressed as

$$\text{Matrix}(i, j, k) = \text{Matrix}(i, j, k) + 1. \quad (5)$$

- (3) Second, by reading the three-dimensional attribute matrix, we can directly obtain the frequent item set, frequent binomial set, and frequent tri-item set. The space diagonal of the first hexagram limit of the three-dimensional matrix is the support of frequent item sets. The coordinates (i, j, j) on the corresponding plane are the support of frequent binomial sets, and the coordinates (i, j, k) are the support degree of the corresponding three-item set.
- (4) Because in transactions where the number of attributes is less than k , there must be no possibility of containing k item sets. Therefore, after getting the frequent three-item set, scan the database and delete the matters that contain no more than four attributes to simplify the database.
- (5) Through the frequent three-item sets that have been obtained, the standard Apriori algorithm is used for subsequent calculations. The specific algorithm flow is shown in Figure 1.

3.2. Algorithm Time Complexity Analysis. Suppose the number of transactions in the database is M , the average number of attributes of transactions is n , and the proportion of transactions with attributes less than 4 is b . The time complexity of the traditional Apriori algorithm is analyzed, and the time complexity of the two algorithms is compared. The time complexity is denoted by O . After the Apriori algorithm forms the frequent item set L_1 , the time

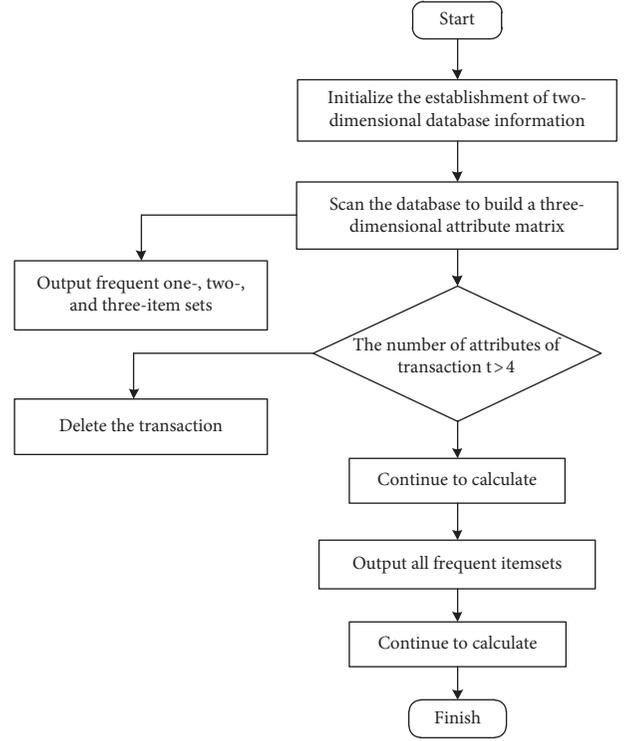

FIGURE 1: Three-dimensional matrix algorithm flow.

complexity of obtaining the candidate binomial set through the branch is expressed as

$$O\left[\frac{L_1(L_1 - 1)}{2}\right]. \quad (6)$$

Then, by scanning the database and calculating the support degree, the time complexity of frequent binomial set L_2 is expressed as

$$O\left[\frac{L_1(L_1 - 1)}{2} Mn\right]. \quad (7)$$

To obtain the frequent binomial set L_2 in the form of a three-dimensional matrix, it is only necessary to read the support of the corresponding coordinates (i, j, j) in the matrix one by one according to each candidate set (i, j) in the candidate binomial set. Candidate binomial sets are obtained from frequent one-item sets without pruning. The number of candidate binomial sets is $L_1 L_1 - 1/2$. The time complexity of this process can be expressed as

$$O\left[\frac{L_1(L_1 - 1)}{2}\right]. \quad (8)$$

It can be seen that the complexity expressed by equation (8) is the same as that of equation (6), so in the process of calculating the frequent binomial set L_2 , the time saved by the data mining algorithm based on the three-dimensional matrix is equation (6) + equation (7) – equation (8) = equation (7). It can be seen that the time saved in the process of calculating frequent binomial sets is related to M , n , and L_1 , which can effectively save calculation time in larger data samples.

According to the frequent binomial set L_2 , the time complexity of the candidate three-item set is obtained by linking and pruning, which can be expressed as

$$O[L_2(L_2 - 1)]. \quad (9)$$

Then, by scanning the database, the support degree is calculated to obtain the time complexity of the frequent three-item set C_3 , which can be expressed as

$$O(C_3Mn). \quad (10)$$

Using the form of a three-dimensional matrix to obtain frequent trinomials, you only need to read the support of the corresponding coordinates in the matrix one by one according to each candidate set (i, j, k) in the candidate trilemma, and you can obtain the frequent tri-lemma. Its time complexity can be expressed as

$$O(C_3). \quad (11)$$

Then, the process of calculating frequent triplets, the data mining algorithm based on the three-dimensional matrix can save time as formula (9) + formula (10) – formula (11), which can be expressed as

$$O[L_2(L_2 - 1) + C_3(Mn - 1)]. \quad (12)$$

Obviously, equation (12) is far greater than 0, and the time saved is related to M , n , L_2 , and C_3 . It can save a lot of calculation time when mining association rules with larger data sets. Before performing subsequent calculations, transactions with attributes less than 4 will be deleted. Therefore, each time the database is scanned, the maximum time complexity that can be reduced is

$$O(bM3). \quad (13)$$

The minimum time complexity that can be reduced is

$$O(bM). \quad (14)$$

The comparative analysis shows that the improved algorithm reduces the time complexity and improves the calculation efficiency compared with the traditional Apriori algorithm.

4. Relevance Mining of Art Classrooms in Colleges and Universities Based on Apriori Algorithm

4.1. Data Preprocessing. The nature of the four art undergraduate majors of the college is mainly divided into two categories: “compulsory” and “optional.” Since the “compulsory” courses cover basic subjects and professional courses, the composition of the courses is relatively stable and the number of students in the required courses. At most, the level of grades can reflect the learning status of students to a greater extent, so choose the grades of “compulsory” courses for mining. The score assessment is mainly divided into usual scores + test scores and usual scores + work design. The usual results are subjective and unstable, so only the test results and work design are used

for the results. Art courses have different assessment methods in different periods. Some grades use a 100-point system, and some grades use a grade system (excellent, good, medium, pass, and fail). The following methods are used to discretize the score system: 90 points or more (including 90 points) are rated as “excellent,” represented by “A”; between 80 and 89 points are rated as “good,” represented by “B”; 60 ~ A score of 79 is rated as “medium,” represented by a “C”; a score of 60 is a pass, and a score of 60 or less is a “failed,” and it is represented by an “E.”

4.2. Transaction Representation. The Apriori algorithm requires the transaction database to adopt a horizontal structure, so it is necessary to convert the vertical structure of Table 1 (course information) to a horizontal structure with each student as a transaction, which includes the student’s ID number and the score of each required course. We reorganize the data in Table 1 to obtain a data table structure that can be used for data mining, as shown in Table 2.

Each record in Table 2 represents student affairs. The student ID attribute can be regarded as the transaction identifier TID. The content of the latter attribute can indicate the item set of the transaction, that is, the grade of a certain professional course.

4.3. Mining Results. Table 3 lists some of the strong rules obtained by mining using the Apriori algorithm (only consider the course scores of students whose grades are A after discretization).

From the mining results in Table 3, it can be found that the probability that the color composition and photography exposure scores of the college’s photography students are A is 27.5% and the probability that the color composition scores are A is 70.2%. It can be seen that the results of enhancing the color composition can significantly provide the results of photographic exposure. For art majors, the probability that both color and landscape sketching scores are A is 37.2%. It can be seen that the two courses have many similarities in the sense of color, and the students with a color score of A have the scores of landscape sketching. The probability of being A is as high as 78.3%, which further confirms the fact that strengthening the study of color courses can bring significant effects to the improvement of later landscape sketching. Based on the above results, it can be seen that the curriculum of the art major of the college is basically reasonable. Strengthening and consolidating the students’ professional basic courses can bring significant teaching effects to the later professional courses. When revising the syllabus, it is necessary to ensure that the professional basic courses are included in the majors studied. The proportion of teachers who strengthen and consolidate students’ professional basic courses in teaching can achieve a multiplier effect with half the effort.

TABLE 1: Course information of longitudinal structure.

Course no.	Course title	Course nature
2379	Art overview	Compulsory
2298	Color D	Compulsory
2247	Structure sketch	Compulsory
2317	Visual identity design	Compulsory
2137	Two-dimensional animation production	Compulsory
2161	Landscape sketch B	Compulsory

TABLE 2: The horizontal structure of student affairs transcripts.

Student ID	2379	2298	2247...	2161
2018003564		A B B A...	A	
2018003572		A A A B...	A	
2018003578		B A C A...	B

2018003812		A A B A...	C	

TABLE 3: Some strong rules obtained by association mining.

Rule precursor	Rule successor	Support	Confidence
...
Color composition A	Photographic exposure A	27.5	70.2
Plane composition A	Landscape photography A	31.2	66.9
Perspective principle A	Animated perspective A	25.4	71.3
Human anatomy A	Sketch human body A	21.8	69.6
Color A	Landscape sketch A	37.2	78.3
...

5. Conclusion

With the increasing number of students' information, how to use the existing information reasonably to improve the quality of personnel training is a problem that every educator is closely concerned about. Using data mining technology in the education industry, it is possible to find meaningful information from a large amount of data to provide decision support for educators. This paper mainly takes a large number of students' course data as the starting point, and with the help of data mining technology, it proposes a correlation analysis method for college art courses based on data mining technology. The examination results of each course of students majoring in painting, art design, photography, and animation in colleges and universities were quickly mined, and some reasonable and reliable course correlation rules were obtained. Valuable information, so as to rationally optimize the curriculum, provides a decision-making basis for the revision of the art curriculum and syllabus in colleges and universities, to further improve the teaching effect and improve the quality of personnel training. There are still some problems in this research, which is also the direction of future efforts [16]:

- (1) Further research on the data mining algorithm, and by improving the algorithm, we can obtain a data score that is more suitable for our school's curriculum.
- (2) Collect more extensive course-related data, and conduct further research on the laws to be studied as proposed in this paper.
- (3) Introduce more data related to courses and students, and analyze the relevance of courses at a deeper level to more valuable information.

Vocational education is an important means to promote the development of the national manufacturing industry. To correctly grasp the relationship between vocational education and the labor market, we start with the quality of vocational education and employment rate and study the interconnection between them. To this end, we propose a vocational education employment rate prediction method based on a big data model and build a vocational education quality assessment and employment rate prediction system. We draw on the big data cross-learning model to improve the model hyperparameters by using generalized intersection sets on the joint loss function to compensate for the shortcomings of dense vocational education datasets. We use the GSA algorithm to enhance the local features of different vocational education quality assessment index data series. To scientifically assess the recognition of vocational education, we evaluate the vocational education assessment indexes at the student level and the parent level to verify the reliability of the experiment. The experimental results prove that our method performs best in the prediction accuracy of vocational education quality assessment indicators, and the prediction accuracy rate stays above 91%. In the prediction of vocational education employment rate, the difference between the predicted and actual values of our method is the smallest, and the difference stays within 1%. Compared with other big data models, our method has higher prediction accuracy and better robustness.

1. Introduction

Vocational education is a powerful driver of manufacturing and plays an important role in the country's economic development. The integration of vocational education with secondary education can solve the contradiction of a single form of secondary school and provide more options for young people of school age. Diversified vocational education can not only improve the pressure for further education in the general education system but also address the pressure on employment rates in higher education [1, 2]. The more developed a city is, the more importance it places on vocational education, and the spread of vocational education can help rationalize the distribution of urban economies, can reduce youth unemployment, and is a necessary tool to guarantee skill acquisition for school-age youth [3]. For the general education system, vocational education offers multiple options for young students. Students with insufficient academic abilities can make voluntary choices about

their future development according to their situation, fully guaranteeing their willingness to learn skills and advance to higher education [4].

Despite the important role of vocational education in socioeconomic mediation, the association between vocational education and employment rates is not supported by data. The feedback period of vocational education is long, and the linear correlation between economic feedback and the cost-effectiveness of vocational education is not strong enough for enterprises. After a large number of vocational education employment rate data analyses in which the employment rate of vocational education does not match the actual employment rate, the vocational education employment rate is in urgent need of a predictive model to enhance the economic benefits of vocational education [5]. The poor feedback on the economic benefits of vocational education has led society as a whole to hold a high and low opinion of vocational education. However, it is worth affirming that vocational education is by no means the only way out for

working-class people. Most studies on vocational education have discussed this issue, and the level of individual ability has a dominant role in the future development of students, followed by the financial background of the family. Statistics show that most students with strong family financial backgrounds do not choose vocational education because it is the immediate choice for students whose families do not have enough financial resources, and they do not represent a continuous low labor output after choosing vocational education. In fact, the vocational education system also provides reasonable promotion channels for students in the vocational job promotion system to prevent the occurrence of class differentiation problems [6, 7].

For capable vocational education students, they can also be promoted to engineering positions through their practical efforts, which is a reflection of the advantages of diversified vocational education [8, 9]. Vocational teaching was created as a powerful measure to balance the large differences in general learning in the financial background of families and to prevent class differentiation. Although the current economic feedback benefits of vocational education are influenced by several complex factors, students trained in vocational education occupy a significant employment advantage in terms of age, given the reduced labor market advantage due to aging [10, 11]. Some developed countries investigating the impact of vocational education have focused on the way the vocational education system is organized, for example, with a clearer division of labor and a specific vocational training model for different types of occupations. Vocational teaching schools will provide basic vocational theoretical and practical training in school and will also provide factory internships for corresponding jobs with one-on-one training and assessment by skilled workers in which those who pass the assessment can choose a variety of jobs [12, 13]. In addition, vocational education is based on the student development model in terms of curriculum, teaching mode, and teacher expertise. Although some studies have shown that there is some variation in the link between vocational education preparation models and the labor market, most studies can use data analysis and computer science methods to compensate for this variation.

Considering the differences between the vocational education system and the labor market, we refer to studies related to vocational education and find a compensatory relationship between selectivity bias, age effectiveness, and vocational education training model. Compared to the employment rate of general education students, the employment rate of vocational education students is oriented to different recruitment demands. However, according to the available data, the demand for vocational education jobs is much greater than the demand for jobs of general college graduates, which is a great advantage of the vocational education system. Depending on the length of the work cycle, vocational education students have a wider range of choices, with short-term company training, medium- and long-term factory practical work, and a long-term promotion system for engineers, giving vocational education students more room for development [14].

The rest of the paper is organized as follows. Section 2 presents the history and research results of vocational education quality research. Section 3 introduces the relevant principles and implementation details of the LSSVR-based vocational education quality and employment rate prediction model. Section 4 shows the experimental datasets and the analysis of the experimental results. Finally, Section 5 summarizes our research and reveals some further research work.

2. Related Work

Vocational education, which directly corresponds to manufacturing production jobs, can facilitate the renewal iteration of manufacturing and also maintain a steady increase in manufacturing output. Despite the poor feedback benefits of vocational education employment, the relationship between vocational education systems and socio-economics is only a temporary mismatch in terms of macroeconomics [15–17]. The data on employment rates in vocational education are only temporarily inadequate, and with the intervention of scientific management and job planning tools, the vocational education system will become more relevant to students' situations in career training planning, employment rates will be more accurately predicted, and cooperation between companies and vocational education schools will increase substantially. Most economists, when considering the role of vocational education in the socioeconomy, give priority to the ability and substitutability between the vocational teaching system and manufacturing production jobs. The desired outcome of vocational education is the training of a pool of directly applicable skilled people for each skilled workplace, and the quality of vocational education training is indirectly reflected by the assessment of the competencies of skilled people at the firm level [18, 19]. The higher the quality of vocational education, the higher the economic benefits it generates for the company, which will indirectly increase the future employment rate of vocational education. This model of assessment in cooperation with companies tends to bring a more substantial employment rate increase than that of general higher education. In addition, researchers in the literature [20] argue that vocational education is an important measure to increase national manufacturing productivity, reduce youth unemployment, and reduce poverty. The literature [21, 22] in studies on vocational education found that vocational education is an important tool for national transformation and can achieve a smooth transition from developing to developed countries. Developing countries strongly advocate the training of industrialized and skilled personnel in vocational education to improve the vocational education system and promote the transformation of industrialized countries.

In labor market projections, some researchers have compared vocational education with general education in a hierarchical manner, taking into account the ability weights, cognitive weights, the ability to learn new knowledge among students, and other factors. However, in the data comparison of hands-on practical scores and efficiency of enterprise

rotations, vocational education students performed more superiorly. To equalize the differences in learning and cognitive abilities of vocational education students, some scholars have developed vocational education student development systems that aim to balance learning ability differences through skill acquisition for student ability prediction in employment rates [23, 24]. There are also researchers who have developed studies from students' family backgrounds, which provide great value for vocational education development based on students' family social status, family financial resources, family education, and family cohesion [25]. In addition, the development of students from different family backgrounds in the vocational education system strictly limits the development of student's abilities and indirectly predicts their future employment and development potential [26]. Some researchers started with the quality of vocational education, studied the distribution of vocational courses in different vocational schools, the strength of teachers, the arrangement of enterprise practice, and other key factors, and then established a prediction model for vocational education development system, which can effectively predict the development of students in different vocational education systems, providing a solid basis for the prediction of vocational education employment rate and providing detailed vocational training for enterprises that choose to cooperate with rules [27, 28].

Different countries have different planning systems and development orientations for vocational education. Compared to general higher education, the curriculum and delivery methods of the vocational education system are determined by the country's basic industrial model. Most industrially developed countries use a dual vocational education training system. For students who choose vocational education, vocational classroom studies and on-the-job training in companies are alternatives to compulsory education, which is similar to the academic guidance courses offered by an academic education. In this case, researchers, to assess the educational quality and employment rate of vocational education, mostly use deep neural network models to capture the key influences from the multiple vocational education systems. The learning model of neural networks is used to integrate a large amount of vocational education data to effectively predict the trends of quality and employment rates of vocational education. For agricultural developing countries, which advocate vocational education similar to developed countries, but considering the weak industrial base due, the focus of vocational education training is more on theoretical education of vocational courses. In this case, to assess the quality and employment rate of vocational education, researchers mostly use data analysis and machine learning models due to the inability to capture a large amount of information on vocational education and employment rates in real time [29–31]. The data is limited, the trend of employment rate data can only be predicted by data analysis, and then machine learning is used to complete the learning of vocational education quality factors. The vocational education employment rate prediction results obtained in this way are less accurate and less preferable for the overall socioeconomic prediction.

3. Method

3.1. Mainstream Model. The demand for vocational education is closely related to employment rate and economic development, and we innovatively use vocational education employment rate and economic indicators as transition variables. We investigated the literature related to vocational education employment rate prediction research methods, among which the least square support vector regression (LSSVR) model performed the best in the research of employment rate prediction; therefore, we chose this model as our base network. To improve the employment rate prediction accuracy of the vocational education model, we proposed the gravitational search algorithm (GSA) to optimize the LSSVR model. The model contains three parts, as shown in Figure 1; the data preparation part represents the data input from various aspects of vocational education. The GSA part represents the additional part with the model parameters adjustment and the model structure optimization. LSSVR represents the backbone network of the vocational education employment rate prediction model.

3.2. LSSVR Mathematical Principles. In the literature research, it was found that the literature [32] proposed the support vector machine approach, which the authors applied to structural risk optimization with the main principle of statistical planning learning theory. In planning learning of large-scale data samples, the support vector machine causes the model to take a long time to process the data due to its complex structure. To solve the time-consuming problem, we take inspiration from the literature [33], and we use a nonlinear function $\varphi(y_t)$ based on the LSSVR model, assuming that the original data is y_t , and we try to map the original data into the high-level feature map by the nonlinear function. The linear regression is then performed on the mapping results, and the mathematical function relationship is shown as follows:

$$\bar{y}_t = w^T \varphi(y_t) + b, \quad (1)$$

where w represents the vocational education parameter weights and b represents the employment rate forecast bias. The values of these two parameters represent the prediction estimates with the least structural risk. The mathematics is calculated as follows:

$$\text{Min} \frac{(w^T w)}{2} + \frac{(\gamma \sum_{t=1}^T e_t^2)}{2}, \quad (2)$$

$$\text{s.t. } \bar{y}_t = w^T \varphi(y_t) + b + e_t, \quad (t = 1, 2, \dots, T),$$

where γ represents the weight parameter and e_t represents the estimation error in time t . Based on the above solution equation function, to obtain the optimal solution to the optimization problem, we used the following mathematical equation to obtain the solution:

$$\bar{y} = \sum_{t=1}^T \alpha_t K(y, y_t) + b, \quad (3)$$

where $K(y, y_t) = \exp(-\|y - y_t\|^2/\sigma^2)$ is a kernel function with a Gaussian operator.

In the design of the network structure of LSSVR, we tried to set the parameter values of hyperparameters γ and σ^2 in advance by migration learning. After experimental tests, it was found that the parameter settings of migration learning could not reach the optimal values of data simulation, and for this reason, to enhance the similarity of data simulation, we borrowed the heuristic optimization algorithm proposed in the literature [34], and the GSA algorithm can achieve the optimization of large-scale data simulation with the assistance of the heuristic optimization algorithm, which takes the simulation of universal gravity as the main principle. The GSA algorithm is based on the main principle of simulating gravity, treating the search particles as a set of relative numbers in the universal gravity, and learning the gravitational optimal distance under the action of universal gravity by simulating the trajectory of this set of particles in space. The mutual attraction between particles follows the laws of dynamics, and the attraction between the host particles is positively related to their mass.

3.3. Model Optimization Principle. Assuming that there are N_a impact factors in the vocational education system, the data dimension of the i -th impact factor is defined as follows:

$$X_i = (x_i^1, \dots, x_i^d, \dots, x_i^n), \quad (4)$$

where n represents the dimensionality of the i -th vocational education quality factor and x_i^d represents the data mapping performance of the i -th vocational education quality factor in the d -th dimension, $i = 1, 2, \dots, N_a$. The mathematical definition between the vocational education quality factors i and j in the d -th dimension at time t is as follows:

$$F_{ij}^d(t) = G(t) \frac{M_{pi}(t) \times M_{aj}(t)}{R_{ij}(t) + \varepsilon} (x_j^d(t) - x_i^d(t)), \quad (5)$$

where, at time t , $G(t)$ denotes the vocational education quality constant, $M_{pi}(t)$ denotes the i -th passive quality factor variable, $M_{aj}(t)$ denotes the j -th active quality factor variable, ε denotes a constant, and $R_{ij}(t)$ denotes the Euclidean distance between two employment rate variable factors i and j . The mathematical expressions are as follows:

$$R_{ij}(t) = \|X_i(t), X_j(t)\|_2. \quad (6)$$

The i -th employment rate variable factor in dimension d is defined as

$$F_i^d(t) = \sum_{j=1, j \neq i}^{N_a} \text{rand}_j F_{ij}^d(t), \quad (7)$$

where rand_j denotes a random variable whose data series are uniformly distributed within the ideal interval. Then, according to the gravitational acceleration formula of gravity, we migrate its mathematical expression to the vocational education employment rate prediction model. It is shown as follows:

$$a_i^d(t) = \frac{F_i^d(t)}{M_{ii}(t)}, \quad (8)$$

where $M_{ii}(t)$ denotes the i -th employment rate inertia quantity. Suppose $M_{ai}(t) = M_{pi}(t) = M_{ii}(t) = M_i(t)$. The mathematical expression of the i -th employment rate variable for the vocational education curriculum and practice factors at time t is as follows:

$$m_i(t) = \frac{\text{fit}_i(t) - \text{worst}(t)}{\text{best}(t) - \text{worst}(t)}, \quad (9)$$

$$M_i(t) = \frac{m_i(t)}{\sum_{j=1}^{N_a} m_j(t)},$$

where $\text{fit}_i(t)$ denotes the fitness value of the i -th employment rate variable factor at time t . To optimize the hyperparameters of the LSSVR model, we introduced the GSA algorithm, and to facilitate the experimental validation of hyperparameter ablation, we adopted a cross-validation grid search method for hyperparameter introduction.

3.4. Optimization Model. The GSA algorithm is mainly used to filter the best solution from the mixed trajectory by predefined data mixture search. To be able to get the best learning result, the algorithm is set up to automatically loop iteratively through the vocational education assessment range system, and the best predictor of employment rate is obtained by clustering algorithm during the iteration process. The main steps of GSA are shown in Figure 2.

The LSSVR model is used in the prediction of static samples of large data, the pretraining dataset is mainly used to determine the initial parameters of the predefined model in one stage, and the formal model training is performed after the initial parameters are determined. Finally, a test dataset is used for model evaluation.

To compare the predictive performance of the models, we used three metric items at the performance evaluation level. The root means square error (RMSE) is mainly used to measure the deviation between the predicted and true values and is more sensitive to outliers in the data. Mean absolute percentage error (MAPE) represents the relative error metric, which avoids positive and negative errors from canceling each other by absolute values. The Willmott's Index of Agreement (WIA) rated the accuracy and predictive power of the regression formulas, and the regression formulas for each parameter had good generalizability.

$$\text{RMSE} = \sqrt{\sum_{t=1}^N \frac{(y_t - \bar{y}_t)^2}{N}},$$

$$\text{MAPE} = 100 \times \sum_{t=1}^N \frac{|1 - (\bar{y}_t/y_t)|}{N}, \quad (10)$$

$$\text{WIA} = 1 - \frac{\sum_{t=1}^N (\bar{y}_t - \bar{y})^2}{\sum_{t=1}^N (|\bar{y} - \bar{y}| + |y_t - \bar{y}|)^2},$$

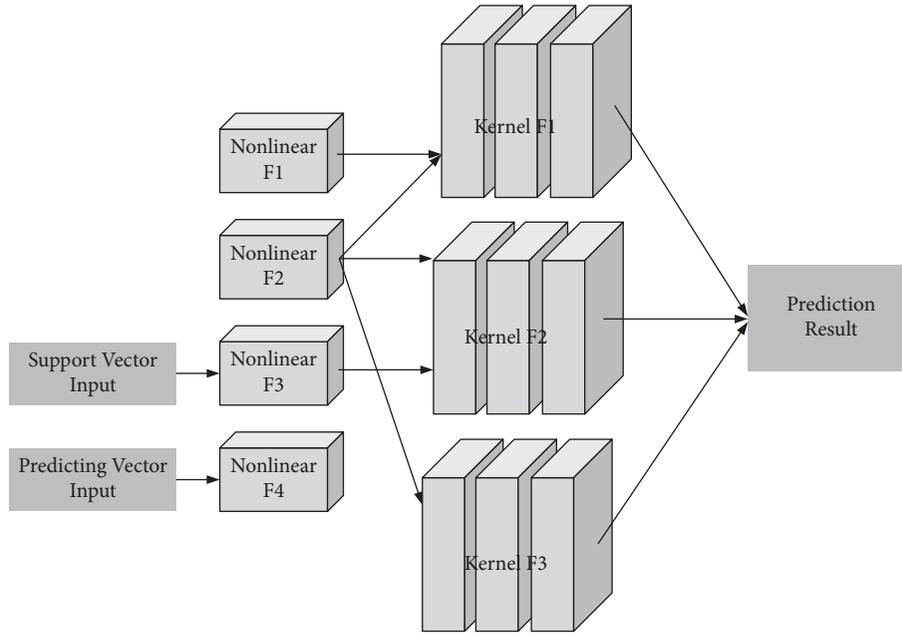

FIGURE 1: LSSVR model structural.

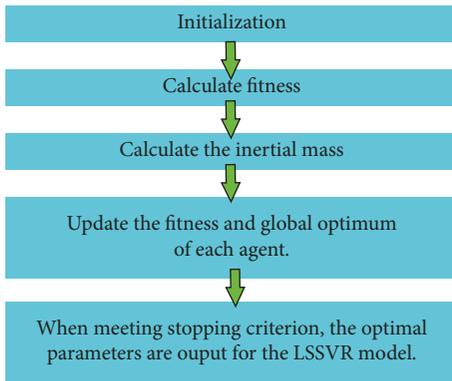

FIGURE 2: The main steps of GSA.

where N denotes the employment rate detection factor in the test set. In the assessment of vocational education employment rate prediction performance, RMSE and MAPE are used to predict the test accuracy. WIA is used to measure the peripheral prediction ability of the vocational education employment rate prediction model, so WIA is used to assess the generalization ability of the model. The Improved LSSVR for vocational education quality assessment and prediction system is shown in Figure 3.

4. Experiment

4.1. Data Preparation. Vocational education data collection was carried out with the support of professional data analysts. In the work of vocational education data collection, we referred to the data keyword collection methods mentioned in the literature [35–37]. We obtained data on vocational education in terms of curriculum data, faculty strength, training mode, and enterprise cooperation methods through keyword search on educational websites. For all the acquired

data, we performed uniform preprocessing operations to integrate the data differences between mobile and PC to prevent the problem of training inapplicability due to data format mismatch during the model training. The data preprocessing process is shown in Figure 4.

To unify the orders of different types of vocational education data, we use the keyword of lag order l ($l = 0, 1, \dots, L$) to encode x , where the number of interrelationships between the vocational education quality series and the employment rate series y is calculated as follows:

$$r_l = \frac{\sum_{t=1}^{T-l} (x_t - \bar{x})(y_{t+l} - \bar{y})}{\sqrt{\sum_{t=1}^{T-l} (x_t - \bar{x})^2 \sum_{t=1}^{T-l} (y_{t+l} - \bar{y})^2}}, \quad (11)$$

$$\bar{x} = \sum_{t=1}^{T-l} \frac{x_t}{(T-l)}, \bar{y} = \sum_{t=1}^{T-l} \frac{y_{t+l}}{(T-l)},$$

where $l < T$. We set the number of interrelationships in the keyword search process to prevent the search from exceeding the bounded range and causing the problem of data inflation. After data collection, we added data cleaning and transformation work to match keywords as word labels relative to economic indicators and to build a vocational education database. The data details are shown in Table 1.

4.2. Preexperimental Evaluation. With the Ministry of Education’s strong support for vocational education, the number of vocational teaching schools is increasing year by year, as shown in Figure 5. According to a large number of vocational education needs, the Ministry of Education sets up assessment norms for other types of vocational education by assessing successful vocational education models.

In the process of developing student training programs, vocational education usually refines the assessment

	Train	Test	Total
Curriculum data	2981	1363	4344
Faculty strength	3635	2653	6288
Training mode	3453	1941	5394
Enterprise cooperation	3530	1696	5226

indicators to the purpose of vocational education (PVE), school enrollment (SE), professional settings (PS), education costs (EC), and employment rates (ER). To investigate the views of students and parents on the assessment indicators, we randomly interviewed 4 parents and 4 students, and each assessment indicator was evaluated with a score out of 100. The results of the survey are shown in Table 2. The quality construction of each assessment index helps to improve the employment rate of vocational education, which is a key aspect of vocational school construction.

From the above table, it can be seen that students and parents are more concerned about the details of the cost of vocational education among the assessment indicators stipulated by the Ministry of Education for vocational education. In the preliminary research, it was found that most of the students who choose vocational education have insufficient family financial resources; therefore, parents and students always rank first in terms of cost consideration for vocational education, and the cost-performance comparison between vocational education and general higher education is the key point to determine the enrollment volume. Besides, students and parents are most concerned about the employment rate of vocational education. The employment rate determines the stability of students' jobs after

graduation, and for most students, the ultimate goal of choosing vocational education is to find a stable job. Employment rate data can directly reflect the economic benefits of vocational education in social development, and the higher the employment rate, the better the enrollment situation. The professional setting of vocational education is also the assessment index that students are more concerned about. The professional setting of vocational schools directly connects with social production, and different professional choices determine different employment positions. Therefore, for vocational schools, the broader the specialties set, the more choices students have, and the better their employment quality is.

4.3. Experimental Results. To verify the effectiveness of our vocational education employment rate forecasting system, we compared three different big data forecasting models. The autoregressive integrated moving average model (ARIMA) [38] is a well-known time series forecasting method, the main principle of which is to obtain a random series through time-lapse and then use a mathematical model to achieve an approximate description of this data series. The method is more widely used in a variety of economic segments and has a better effect on the prediction of economic trends. Backpropagation neural network (BPNN) [39] is based on a neural network and uses the principle of error backpropagation to apply supervised learning to batch data and finally generates a prediction model for trend prediction of characteristics among data. The BPNN model performs better in the prediction of economic risk control. The radial basis function (RBF) [40]

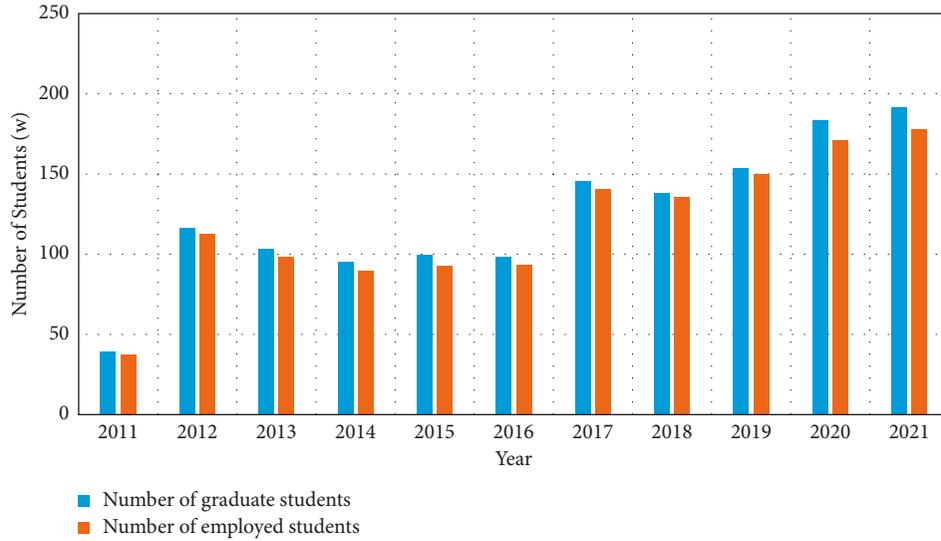

FIGURE 5: Number of graduates and employment over the years.

TABLE 2: Students and parents' evaluation of vocational education assessment indicators.

		PVE	SE	PS	EC	ER
Students	1	72	70	86	96	99
	2	76	74	85	94	98
	3	77	73	88	96	99
	4	71	71	89	93	99
Parents	1	78	72	85	98	96
	2	79	73	89	97	97
	3	75	72	90	92	96
	4	76	71	91	95	99

model works on the principle of mapping interoperability between low-dimensional data features in the hidden space and high-dimensional data features. The model is more commonly used in studies of predicting serial trajectories and data trends. To ensure independent validation relationships between the methods, five sets of experiments were conducted during the training process, and each set of methods was independently validated for different vocational education assessment indicators. The test results of each method were directly input to the statistical calculation part of the dataset, and the final evaluation results were obtained by balancing the total number and quality factors of the dataset. In the first stage of the experiment, we validated all vocational education quality feedback datasets and compared the efficiency of our methods with those of other methods. The experimental results are shown in Table 3.

From the experimental results in the above table, it can be seen that the ARIMA model does not perform well in the vocational education quality assessment index. Since the model is more suitable for predicting the trend direction of data in data prediction by hyperparameter addition, it is slightly insufficient in the accurate prediction of vocational education quality assessment indexes. The performance of BPNN and RBF models in the prediction accuracy of

TABLE 3: Comparison of vocational education quality assessment of different methods.

Indicators	ARIMA (%)	BPNN (%)	RBF (%)	Ours (%)
Curriculum data	75	81	86	91
Faculty strength	73	83	85	92
Training mode	69	85	87	95
Enterprise cooperation	78	86	82	94

vocational education quality assessment indexes is not very different, maintaining around 85%. The overall prediction accuracy of our method stays above 90%, which is significantly better than other methods and proves the effectiveness of our method.

In the employment rate prediction experiment, we verified the proportion of different vocational education quality assessment indicators in the employment rate separately and subdivided the association between each vocational education quality assessment indicator and the employment rate. Before the start of the experiment, we performed preprocessing operations on vocational education feedback data to standardize the input format and sampling frequency of assessment index data to prevent the influence of data discrepancies on the experimental results. The results of the second phase of the experiment are shown in Table 4.

From the table above, we predict the employment rate of vocational education in the past five years and compare it with the actual employment rate. The experimental results found that the ARIMA model has a larger gap between the employment rate prediction and the actual employment rate. The BPNN model employment rate prediction is lower than the actual employment rate, but the difference between the predicted and actual values stays within 5%. The RBF model employment rate prediction is higher than the actual value because the mapping relationship between its implicit

TABLE 4: Comparison of predicted results of vocational education employment rates.

Years	Actual rate (%)	ARIMA (%)	BPNN (%)	RBF (%)	Ours (%)
2017	75	65	70	80	74
2018	86	78	80	88	85
2019	85	79	79	88	85
2020	70	63	66	75	71
2021	73	66	79	78	74

functions leads to a better match between the assessment indicators, so the predicted value is higher than the actual value, but the difference between both of them stays within 5%. The predicted employment rate of our model is closer to the actual value, and the difference between the predicted and actual values remains within 1%. This shows that our method is superior in vocational education employment rate prediction compared with other methods, which proves the effectiveness of our method.

5. Conclusion

In this paper, we propose a vocational education employment rate prediction method based on a big data model and build a vocational education quality assessment and employment rate prediction system. We draw on the big data cross-learning model to improve the model hyper-parameters by using generalized intersection sets on the joint loss function to compensate for the shortcomings of dense vocational education datasets. We use the GSA algorithm to enhance the local features of different vocational education quality assessment index data series. In addition, we use the minimum outer matrix algorithm to extract the features of assessment index sequences of different dimensions to improve the accuracy of the model for vocational education quality index assessment. To scientifically assess the recognition of vocational education, we evaluate the vocational education assessment indexes at the student level and the parent level to verify the reliability of the experiment. The experimental results prove that our method performs best in the prediction accuracy of vocational education quality assessment indicators, and the prediction accuracy rate stays above 91%. In the prediction of vocational education employment rate, the difference between the predicted and actual values of our method is the smallest, and the difference stays within 1%. It proves that our method performs well in both vocational education quality assessment and employment rate prediction. Compared with other big data models, our method has higher prediction accuracy and better stability.

Although our method performs well in vocational education quality assessment and employment rate prediction, the number of assessment indicators of vocational education quality is huge, and only five assessment indicators are covered in our study. In our future research, we will try to add generative adversarial neural networks to the adversarial network as an auxiliary classification, optimize the reasonable segmentation of data sequences of different

dimensions, and improve the model's inclusiveness of more vocational education quality assessment indexes.

Constructing a scientific evaluation system of curriculum education quality is an important content to improve the effectiveness of curriculum ideological and political education. Starting from the practical significance of exploring the effectiveness evaluation system of curriculum ideological and political education, supported by analytic hierarchy process, this paper constructs the evaluation model of curriculum educational quality through the five dimensions of curriculum design, teaching staff, student cognition, development evaluation, and system design, clarifies the hierarchical relationship between the implementation elements of curriculum ideological and political education from the micro level, and defines the basic responsibilities, in order to provide reference for curriculum teaching reform and educational quality evaluation.

1. Introduction

For a long time, there has been a phenomenon of “two skins” between ideological and political education and professional teaching in colleges and universities. Professional teachers “only teach but not educate people,” and ideological and political education teachers (counselors) still fight alone. At the same time, according to the spirit of the National Conference on Ideological and Political Work in Colleges and Universities, classroom teaching, as the main channel and position for colleges and universities to carry out education, is the basic element and important carrier to implement the fundamental mission of “building morality and cultivating people.” Therefore, in the curriculum reform, we should not only pay attention to the cultivation of students’ professional knowledge and ability but also do a good job in shaping students’ ideological guidance and values, so as to enhance knowledge in value guidance and strengthen value guidance in knowledge teaching.

At the National Conference on Ideological and Political Work in Colleges and universities, General Secretary Xi stressed that we should adhere to building morality and cultivating people as the central link, run the ideological and political work through the whole process of education and

teaching, and realize the whole process and all-round education. However, for a long time, in terms of educational concept, we cannot correctly understand the relationship between knowledge transfer and value guidance, and the “whole curriculum education concept” has not been fully established. In terms of curriculum, we cannot correctly deal with the relationship between explicit curriculum and implicit curriculum. In terms of team building, the relationship between talent cultivation ability and moral cultivation ability cannot be handled as a whole. The reason is that, on the one hand, the evaluation system standard still stays in the traditional evaluation with knowledge, skills, and literacy as the core in the early years, and there is no reasonable design evaluation standard in the process of promoting the transformation of ideological and political curriculum to the three-dimensional education of curriculum ideological and political education [1]. On the other hand, in the current education and teaching reform of higher vocational colleges, it is rarely considered from the micro level such as classroom teaching. In the process of promoting the three-dimensional education of “curriculum thinking and politics,” classroom teaching is a necessary place. How do teachers organize the curriculum teaching of “classroom thinking and politics” [2–5] and how to arouse and stimulate students’ interest in

learning and how to improve the quality and efficiency of curriculum teaching are the key issues. Therefore, it is very necessary to carry out the monitoring, evaluation, and optimization of higher vocational classroom teaching quality under the background of “curriculum ideological and political” reform, optimize the methods of improvement, integrate the concept of “whole process and all-round education” into teaching evaluation and supervision, improve the evaluation criteria, and establish a richer teaching supervision team to diversify the evaluation personnel. It is timely to carry out the research on the quantitative evaluation of classroom teaching quality under the background of “curriculum ideological and political reform.” The significance of the research lies in the following: First, it is conducive to the implementation of national education policies, the implementation of education and teaching laws and regulations, and the implementation of semester teaching plans. Ideological and political work is run through the whole process of education and teaching. Second, it is conducive to timely discover and summarize the deficiencies and advanced experience of classroom teaching under the background of “classroom ideological and political” reform and the quality of classroom teaching can be timely improved. Third, it is conducive to improve the scientificity, comprehensiveness, and timeliness of classroom teaching quality evaluation, increase the objectivity and fairness of evaluation effect, and stimulate teachers’ enthusiasm to continuously improve classroom teaching quality.

2. Practical Significance of Curriculum Ideological and Political Evaluation

The effectiveness of curriculum refers to the degree to which educational activities achieve their preset goals. To evaluate the effectiveness of curriculum ideological and political education is to judge the actual or potential value of the implementation process and results of curriculum teaching as shown in Figure 1.

2.1. The Need of Innovation Theory Research Perspective.

In recent years, many colleges and universities have made some positive explorations in the reform of curriculum ideological and political education and formed representative courses. In particular, the “Shanghai experience” first implemented and summarized by colleges and universities in Shanghai has become the standard bearer leading the teaching reform of ideological and political education in domestic higher education courses. Some scholars discussed the basic idea, connotation and composition of curriculum ideological politics, and curriculum ideological politics from different levels and summarized and analyzed the implementation path and logical relationship. Some scholars put forward good suggestions on the construction of evaluation indicators for the effectiveness of curriculum ideological and political education from the macro level [6–8]. It can be seen that scholars have made some achievements in the research of curriculum ideological and political effectiveness, but there is still a lack of technical research on the effectiveness

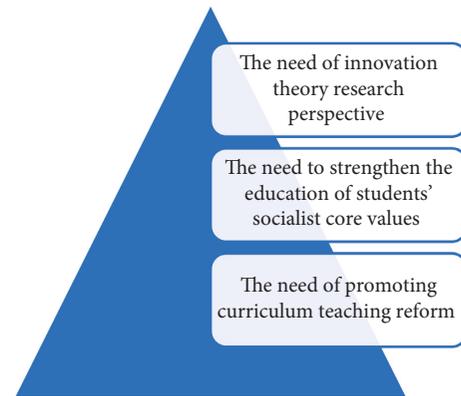

FIGURE 1: Practical significance of curriculum ideological and political evaluation.

evaluation system of curriculum ideological and political effectiveness, and there is also a lack of qualitative evaluation models and methods. Therefore, through qualitative analysis, this paper attempts to apply the analytic hierarchy process to the research on the quality evaluation of curriculum ideological and political education, build a multi-level and multifactor analysis model, and put forward the observation points of multidimensional evaluation from the micro level, so as to provide a theoretical basis for the research on educational evaluation of specific courses in the future.

2.2. The Need to Strengthen the Education of Students’ Socialist Core Values.

In the open information age, under the complex background of multiple social values and the interweaving and infiltration of a variety of social thoughts, the limitations of relying solely or excessively on ideological and political theory courses to guide the value of college students have become increasingly prominent. At the same time, with the promotion and implementation of the teaching reform of the credit system in domestic colleges and universities, in order to meet the personalized development needs of students, the school advocates more respect for the subject status of students, pays attention to the hierarchical and classified training of students, emphasizes the credit acquisition of students, and weakens the education follow-up and constraints on students in ethics, physical and mental health, professional quality, and so on. Students will also pay more attention to the pursuit of credits to meet the graduation requirements, pay attention to the improvement of their own knowledge and skills and the design of career development path, and despise the important value of Marxist basic principles and methodology and despise the study of socialist core values and the cultivation of ideological and moral character, which is easy to lead to weak personal ideals and beliefs and low political literacy. Therefore, by establishing the evaluation system of the effectiveness of curriculum ideological and political education, it is very necessary to urge all departments of the school to perform their basic responsibilities in promoting curriculum education from a multidimensional perspective.

2.3. The Need of Promoting Curriculum Teaching Reform. University courses are arranged based on the training objectives of various majors to a certain extent. The purposes of imparting curriculum knowledge are to promote students to better understand and love relevant majors (industries) or culture, constantly innovate knowledge through learning, promote the inheritance and promotion of industries or culture with practical actions, actively serve social development, and promote social progress and harmony. Promoting curriculum reform, starting the ideological and political mode of curriculum education, giving full play to the role of classroom teaching as the main channel and position of educating people, and realizing the collaborative education of various courses are the specific practice of implementing ideological and political education into the whole process of education and teaching. Scientifically construct the evaluation index system of curriculum education quality, clarify the evaluation dimensions and elements, guide the direction of curriculum ideological and political reform from the aspects of theory, action, and serving students' development, fully tap the ideological and political factors contained in relevant knowledge in the design of curriculum content, scientifically apply moral education means in the teaching process, and track and supervise the fixed-point and qualitative teaching process and make the teaching of ideological and political education theories and methods consistent with students' physical and mental health and personality development, in line with the national education policy and the development needs of the times.

3. Literature Review

In western countries, mainly represented by the United States and Britain, the evaluation of teaching quality of higher education has been very mature. The typical feature is the comprehensive evaluation of students' learning process and learning results. Different countries have different national conditions, and the evaluation methods cannot be completely copied. The early evaluation of higher education quality in China, which began in the 1980s, is essentially equivalent to the evaluation of classroom teachers' teaching quality. Teachers, as the object of evaluation, are generally students, experts, or peers and teaching supervisors. The common practice is to design indicators including "teaching attitude," "teaching method," and "teaching content" to quantitatively evaluate teaching attitude and the role of teaching contents and methods in improving teaching quality [9–11].

With the deepening of the research on the evaluation of teaching quality in colleges and universities, more and more scholars believe that the traditional evaluation of teaching quality (effect) is simplified to evaluate teachers' teaching activities. The main problems are as follows: paying attention to students' evaluation of teachers and neglecting teachers' self-evaluation, paying attention to summative evaluation and despising process evaluation, and attaching importance to the evaluation of teachers' teaching and despising the evaluation of students' learning. In recent years, the evaluation methods of some colleges and universities have been

quietly changing from teachers to students. The research confirms that learning input has a significant positive correlation with learning harvest. It is suggested to promote the emotional connection between teachers and students through method guidance and value guidance, stimulate the internal driving force of students' learning, and comprehensively improve the learning quality [12–14]. In addition, researchers believe that students' autonomous learning is the main motivation to improve teaching quality and emphasize the stimulating effect of learning motivation and learning behavior on students' autonomous learning [15–17].

In addition to the "teaching" of teachers and the "learning" of students, such as the construction of school study style and examination style, school management and teaching guarantee play a vital role in mobilizing students' learning enthusiasm. The research shows that students' learning input is significantly positively correlated with curriculum requirements, college requirements, and support [18–20]. Some studies emphasize the influence of teaching media (such as teaching facilities) on improving classroom teaching effect. In addition to focusing on teachers and students, the improvement of teaching quality in colleges and universities is a comprehensive system, which needs the joint efforts of teachers, students, school leaders, families, society, alumni, and employers.

Indeed, the key place to improve the teaching quality of colleges and universities is in the classroom, and the key subject to improve the effect of classroom teaching is students. In the teaching process of teachers, this study mainly draws lessons from the indicators commonly used in the academic circles to reflect the teaching attitude, teaching content, and teaching methods. Different from previous studies, under the teaching requirements of "curriculum thinking and politics," the author believes the following: First, classroom teaching activities are a two-way interactive activity between teachers and students. The characteristics of teachers' appearance, personality, morality, professional quality, and behavior play a direct or indirect guiding role in students' values, outlook on life, and world outlook and ultimately affect the teaching effect. Second, the school's serious study style and examination style, strict teaching management and orderly teaching guarantee, and other logistics services also play a very important role in mobilizing students' learning enthusiasm. Third, the quality of classroom teaching includes not only the acquisition of theoretical knowledge but also the improvement of practical ability. With high-quality classroom teaching, students can not only thoroughly master theoretical knowledge and practical ability but also stimulate their interest in continuous learning and get happiness from autonomous learning. Such students can generally make career planning in advance and develop rapidly after graduation.

4. Construction of Analytic Hierarchy Process Model for Evaluation of Ideological and Political Effectiveness of Curriculum

4.1. Analytic Hierarchy Process. In recent years, with the development of data mining and deep learning, data analysis

technology has been developing in many fields [21–26]. Analytic hierarchy process (AHP), as a typical method of data analysis [27], was formally proposed in the mid-1970s. Analytic hierarchy process is a decision-making method that decomposes the elements always related to decision-making into objectives, criteria, schemes, and other levels and carries out qualitative and quantitative analysis on this basis. It is a comprehensive evaluation method of multiple attributes and multiple indexes. It is widely used in various fields related to decision-making. It is suitable for the target system with hierarchical and staggered evaluation indexes, and the target value is difficult to describe quantitatively. It is also one of the mainstream research directions of evaluation methods.

Curriculum education is a systematic activity. At the same time, it is affected by many factors, such as educational policy, professional environment, curriculum content, and teaching staff, which leads to many eigenvalues and complex levels of the effectiveness evaluation of curriculum ideological and political implementation. The analytic hierarchy process can provide a combination of qualitative and quantitative decision-making analysis methods to solve this problem by constructing the judgment matrix between factors. On the research path, we can form a scientific evaluation system by layering the educational factors involved in the process of curriculum education and teaching. For a specific course (major), the weight value of the evaluation index can be calculated and sorted in combination with the survey data. Finally, the fuzzy comprehensive evaluation method is used to obtain the comprehensive analysis data to complete the effectiveness evaluation of curriculum education.

4.2. Analytic Hierarchy Process Model. The quality evaluation model of effective ideological and political education in curriculum consists of three levels. According to the hierarchical construction method proposed by Professor Thomas SETI, since this stage considers the construction of evaluation system and does not involve decision-making, the scheme level is not described here. However, due to many index factors and complex relationships in the criterion layer, the criterion layer is further subdivided into sub-criterion layers. First is the target level, that is, the evaluation results of scientific and effective curriculum education. Second is the criterion layer. Combined with the teaching characteristics and practical laws of ideological and political education, the criterion level is set as five dimensions: curriculum design, teaching staff, students' cognition, development evaluation, and system design.

4.3. Construction of Judgment Matrix. The judgment matrix is a key link in the application of analytic hierarchy process, which can show the relative importance of each index of the current level relative to a certain index of the previous level in the quality evaluation hierarchy model of Ideological and political education. According to the constructed curriculum education quality evaluation model, when evaluating the education effect of specific courses, the obtained evaluation data can be used to establish the judgment matrix of

indicators at all levels, and then the appropriate calculation method can be used to calculate the relative weight of each element for a certain criterion level, conduct consistency test, and finally obtain effective evaluation data. Figure 2 presents the whole pipeline.

5. Hierarchical Relationship and Responsibilities among Various Executive Elements

Due to the many links and factors involved in the implementation of curriculum ideological and political education, if the responsibilities of various executive units or groups in colleges and universities are not fulfilled enough, this will lead to the lack of motivation for curriculum teaching reform, the uneven teaching effect, the different evaluation of students' recognition and sense of acquisition of the curriculum, and so on. Therefore, we sort out the implementation elements and responsibilities involved in the implementation process according to the established evaluation model.

5.1. The School Is a Top Designer. The school party committee should earnestly fulfill the main responsibility, put forward the overall requirements and objectives of curriculum ideological and political construction from the perspective of the national education development planning strategy, clarify the educational functions of each curriculum and the educational responsibilities of all teachers, issue the assessment and evaluation mechanism, and do a good job in supervision and implementation. All functional departments should jointly establish a curriculum evaluation and incentive mechanism guided by the effect of education and take the results of teachers' education as an important factor for teachers' post and grade determination. Through joint training with local schools and enterprises, we will build a collaborative and shared platform for ideological and political education resources.

5.2. College (Department) Is the Basic Executive Department. Colleges (departments) are the basic educational units of universities. First, we should do a good job in the selection of courses and teachers. Second, we should build a "great ideological and political" and "great coordination" education pattern, strengthen the exchanges between ideological and political discipline teachers and professional course teachers, front-line teachers, and ideological and political work team personnel, and do a good job in teacher education training. Third, we should introduce the specific implementation plan of curriculum ideological and political education, carry out the satisfaction evaluation of students' career development, and do a good job in the collection of evaluation data and result analysis. Fourth, we should do a good job in case summary, tap excellent teaching plans and educational models, and do a good job in experience promotion and case exchange.

5.3. Discipline (Curriculum Group) Is the Core Organization. Discipline (curriculum group) is the grass-roots organization to implement curriculum education. Disciplines such as

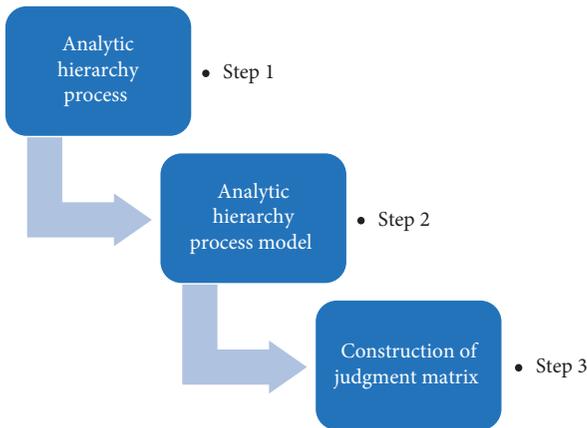

FIGURE 2: The whole steps of the experiment.

ideological and political education theory should actively assist teachers of other disciplines in the excavation of ideological and political education resources and the integration of teaching plans and actively advocate the all-round development of moral education. Other disciplines or curriculum groups should be driven by the students' curriculum selection and knowledge needs in the context of the new era, deeply explore the ideological and political education resources of various courses, and design the curriculum system and teaching scheme that can meet the students' personality characteristics and growth needs in the new era according to the training objectives and educational objectives of different majors, combined with the industry talent standards and learning from the OBE concept.

5.4. Teachers Are the Key Group to Implement Tasks. Teachers should really study curriculum thought and politics as a knowledge that can shape students' hearts and accurately locate the value orientation and teaching purpose of the curriculum in combination with the professional training objectives. First of all, we should establish the awareness of "interdisciplinary," do a good job in the excavation and introduction of ideological and political elements systematically and scientifically, and establish a multidimensional blending relationship between knowledge and life and social responsibility. Secondly, in the teaching process, pay attention to the attention and observation of students' ideological status, timely correct the inappropriate thoughts, views, and attitudes among students, and realize the organic combination of ideological and political education and professional course content. Thirdly, adhere to the unity of teaching by speech and teaching by example, take the lead in setting an example, become a mirror for students to behave and work, and become a banner for students to study and ask questions.

As the main way to implement the "three complete educations," curriculum education is a detailed and systematic project. In order to give full play to the role of the classroom as the main channel in educating people, colleges and universities must always adhere to the guidance of Marxist theory, promote the curriculum education reform

with high standards and strict requirements, determine the direction and content of the curriculum reform, and clarify the main responsibilities and mutual relations of various implementation elements in the process of curriculum reform and education and teaching, so as to obtain a good evaluation path and effect of curriculum education quality and comprehensively form a vivid situation of collaborative education.

6. Suggestions on Classroom Teaching Quality

The main task of colleges and universities is to cultivate students into talents that play an important role in the society, and the evaluation of classroom teaching quality is an important aspect that directly reflects the quality of talents in colleges and universities. Under the guidance of the thought of "curriculum thought and politics," this paper puts forward targeted optimization strategies. Table 1 lists the suggestions on classroom teaching quality.

6.1. Change the Concept of Evaluation Purpose and Evaluation Content

6.1.1. Changing the Purpose Concept of Classroom Teaching Quality Evaluation. There is an inseparable relationship among education, society, and people. Classroom teaching is bound to be affected by various factors at the social level, especially the current social, economic, and cultural impact on college classrooms. Therefore, the evaluation of classroom quality also needs to be improved. Therefore, classroom teaching evaluation should change the traditional evaluation concept, abandon the traditional evaluation means and methods, and be under the guidance of curriculum ideology and politics, in line with the concept of modern talent training. Talents who meet social needs are important. Through the multidirectional evaluation of teachers' "teaching" and students' "learning" in classroom teaching evaluation, we need to pay attention not only to the results of classroom evaluation teaching but also to the evaluation of classroom teaching process, encourage teachers to actively participate in teaching evaluation, and finally improve teachers' teaching ability and the overall quality of teachers.

6.1.2. Enrich the Content of Classroom Teaching Quality Evaluation. The education of students in higher education mainly includes ideological education, skill training, scientific research, and social services, of which the most important are the ideological education and skill training of talents. Classroom teaching is the most important, direct, and fundamental way for colleges and universities to cultivate talents. Traditional classroom teaching activities only guide students to master scientific cultural knowledge according to teaching objectives, and this cultural knowledge is only a simple presentation of teaching materials, which restricts teachers' ability from being stimulated to a great extent. Under the traditional concept of teaching evaluation, the evaluation of classroom teaching mainly focuses on the selection of teachers' teaching methods and relevant

TABLE 1: The suggestions on classroom teaching quality.

Suggestion
Change the concept of evaluation purpose and evaluation content
Build a diversified evaluation subject
Establish effective feedback mechanism
Other recommendations

teaching materials, ignoring whether the curriculum content in teaching evaluation is in line with the current ideological development of college students and whether the curriculum content setting is reasonable. Therefore, the evaluation of classroom teaching quality changes the traditional evaluation concept of teachers' teaching behavior and teachers' curriculum setting. First is scientific and reasonable teaching content. According to the teaching objectives and teaching contents, teachers reasonably determine the role of teaching materials, determine the key points and difficulties of teaching contents, and guide students to effectively stimulate students' interest in learning while learning basic knowledge and skills, cultivate independent learning ability, enterprising innovation spirit and ability to solve practical problems, let alone ignore the cultivation of college students' humanistic quality, and actively study ideological courses. Second is implementing effective teaching methods. Teachers should be good at actively guiding students to participate in classroom teaching activities, actively play their due role in the classroom, and let students realize that they are the main body of the classroom. At the same time, teachers should pay attention to cultivating students' innovative spirit, cooperative spirit, and self-consciousness in the teaching process, which can not only cultivate students' ability to adapt to the society but also have the creative ability of independent thinking.

6.2. Building a Diversified Evaluation Subject. The traditional classroom evaluation in colleges and universities is mainly based on student evaluation, supplemented by peer evaluation, teaching supervision, and leading cadre evaluation, but, in practice, it gives great weight to student evaluation and ignores the importance of other evaluations. Therefore, we should build a diversified evaluation subject that encourages teachers to actively participate in evaluation and form a student evaluation and teacher self-evaluation as the main body, supplemented by peer evaluation and leading cadre evaluation.

6.2.1. Mainly Student Evaluation and Teacher Self-Evaluation. We should learn from the advanced experience of classroom teaching quality evaluation, combine the concept of advanced curriculum ideas and developmental teaching evaluation contents, and timely adjust the evaluation methods of teachers, which can help teachers constantly reflect on their teaching activities and teaching behaviors and make a comprehensive and intuitive evaluation of the teaching activities carried out in the classroom from multiple angles, levels, and directions, as well as helping teachers improve the quality of classroom teaching.

At the same time, the evaluation subject can have diversified ways, which also means different evaluation methods. These evaluation methods can improve the process of classroom teaching and carry out comprehensive supervision and management.

6.2.2. Supplemented by Peer Evaluation and Evaluation of Leading Cadres. Classroom activities in colleges and universities are highly professional and different, so the classroom evaluation standards of different disciplines cannot use a unified way to judge the value. Compared with other evaluation subjects, peer evaluation has two advantages. The first advantage is that teachers with the same discipline background are very familiar with the teaching objectives, teaching contents, teaching structure, and teaching process of this discipline, so they can make very professional evaluation. The second advantage is that peers can conduct mutual evaluation after class and put forward problems and solve them, so as to comprehensively improve the quality of classroom teaching. The evaluation of leading cadres is generally divided into two levels: school and branch. More attention should be paid to the evaluation of leading cadres, while branch leaders are more familiar with professional courses, and the classroom teaching evaluation of all teachers in the middle and end of the period is checked, so as to promote the mutual communication of teaching methods among teachers.

6.3. Establish Effective Feedback Mechanism. Whether the results of classroom teaching quality evaluation are reasonable and effective and the use of evaluation results are the key to determine whether the whole evaluation process is effective. Reasonable evaluation can promote the improvement of classroom teaching quality; on the contrary, it is a mere formality. Establishing a perfect and effective feedback mechanism is an important measure to ensure that the evaluation results can be used in time. By establishing diversified and timely feedback forms, the evaluation results can be used more scientifically.

6.3.1. Timely and Diverse forms of Feedback. Improving the feedback mechanism is an effective bridge, which can timely and accurately deliver the evaluation results to teachers, help teachers improve their teaching behavior, and improve teachers' teaching level. However, the current feedback is unified feedback to teachers after counting the evaluation results of students, peers, and leading cadres through the teaching management part, which is not conducive to the timely improvement of teachers' teaching behavior in terms of time. Corresponding feedback forms should be set between the evaluation subjects, and the evaluation information of teaching supervisors and leaders on teachers should be delivered to teachers in time after the class. Teachers know the advantages and disadvantages in the teaching process through scoring results and personal opinions. Students' evaluation opinions should be delivered to teachers in time after collecting and sorting students'

information, The evaluation among peers should be released through the regular exchange seminars organized by the college. The person in charge of the branch specially organizes and requires each teacher to summarize their experience, make effective use of the evaluation results, and timely deliver the evaluation results to teachers after the classroom teaching quality evaluation, so as to effectively improve the efficiency of classroom teaching.

6.3.2. Effective Use of Evaluation Results. How to effectively summarize and apply the evaluation results and take them as an important basis to improve the teaching quality and the management department in charge of teaching in colleges and universities should change the traditional evaluation results, sort out the developmental teaching evaluation concept, and make an in-depth, detailed, and comprehensive analysis of the evaluation results. The Education department of colleges and universities should distribute the evaluation results to each department, timely urge the teaching secretary of the branch department to organize the evaluated teachers to discuss the evaluation results, and help teachers adjust the teaching contents and teaching methods in combination with the contents of the evaluation. At the same time, teachers should take the initiative to combine the new educational ideas and learn relevant professional knowledge, overcome many difficulties, constantly improve the classroom teaching behavior, constantly summarize, absorb, and improve the good evaluation results, pay attention to the poor evaluation results, maintain a good attitude, and make continuous improvement.

6.4. Other Recommendations. Teachers' teaching attitude and teaching content, teaching methods and professional quality, study style, examination style, and teaching guarantee have a common impact on students' knowledge acquisition and skill improvement. Students' own learning attitude is very important, which is basically consistent with the research conclusions of other scholars. Whether and how students learn plays a vital role in students' knowledge acquisition and skill improvement. Teachers' teaching attitude and teaching content cannot directly affect students' knowledge acquisition and skill improvement but can only play a small role in promoting through the school's study style, examination style, and teaching guarantee. Teachers' teaching methods and professional quality have the greatest impact on students' knowledge acquisition and skill improvement. They can not only promote directly but also have an indirect impact through the school's study style, examination style, and teaching guarantee. Therefore, under the background of "curriculum thinking and politics," the evaluation of classroom teaching quality in colleges and universities should go hand in hand with "teaching" and "learning" and "management."

6.4.1. Clarify the Learning Purpose and Correct the Learning Attitude. In the university, especially in the undergraduate stage, the courses learned are to a large extent to lay the

foundation for future study and work. With the rapid development of science and technology and the accelerated replacement of new and old jobs, most people may have to engage in multiple types of work before retirement. Changing jobs is a very common and frequent thing. In the short term, a course seems to be of little help to one's postgraduate entrance examination and employment. It may come in handy when one changes his next job. It is necessary to urge students to take seriously the study of each course in the undergraduate stage with a long-term view, so as to meet the needs in the future.

6.4.2. Strengthen the Reform of Teaching Methods and Improve Teachers' Professional Quality. There is a close relationship between teaching methods and teaching contents. Teaching methods include both general teaching methods suitable for general courses and specific teaching methods according to the characteristics of specific courses. The teaching method to be adopted needs to be determined according to the specific courses and even the teaching objects of different majors. Experienced teachers focus on teaching methods and selected cases when they treat students of different majors in the same course, which puts forward higher requirements for teachers. Teachers' professional quality will also be fully demonstrated in the process of classroom teaching. Teachers with excellent professional quality are more attractive in classroom teaching, can stimulate students' learning potential, and significantly improve learning effect.

6.4.3. Strictly Enforce the Style of Study and Examination and Improve the Guarantee of Teaching. To sum up, if teachers' teaching attitude, teaching content, teaching methods, and professional quality can maximize the promotion of students' knowledge acquisition and skill improvement, the school's study style, examination style, and teaching guarantee play an important media role. Imagine that if the style of study and examination is not strict, students who usually do not study hard may get high scores by cheating, which will directly attack the enthusiasm of students who study hard. Through the construction of strict study style and examination style, maintain a fair examination environment and force students to study hard. Only in this way can teachers' teaching attitude, teaching content, teaching methods, and professional quality play a greater role in promoting students' learning knowledge and improving skills. Through the structural equation model, the author studies the influence of college teachers' teaching and professional quality, school style of study, examination style, and teaching guarantee on students' knowledge acquisition and skill improvement. There are far more factors affecting the effect of classroom teaching in colleges and universities; for example, how the social environment and employers affect the teaching effect needs further research.

7. Conclusion

The evaluation of classroom teaching quality is an important link in the teaching process. It is the key to measure the

quality of the whole teaching and plays a very important role in promoting and improving the teaching quality. The purpose of classroom teaching evaluation is to improve the improvement of classroom education quality and help teachers find the deficiencies in classroom teaching in time, as well as the mode of classroom teaching quality evaluation in colleges and universities. Methods and ideas need to be scientific, reasonable, and perfect in the future research and practice, so as to promote the reform of teaching classroom in colleges and universities. Our method is a general evaluation method, which can be applied to other fields in the future.

With the rise of social network platforms such as WeChat, Weibo, and TikTok, social networks have developed from simple social networks to complex social networks. Researchers have gradually found that the traditional data sampling methods can no longer meet the development needs of the complex social network structure. In order to save network resources, various methods of social relationship prediction have been proposed. In this paper, we propose a BTCS algorithm based on low sampling rate under cognitive model and conduct several sets of comparison experiments under different networks and different sampling rates, and the results show that the BTCS algorithm improves the prediction accuracy and reduces the prediction time under low sampling rate. To address the problems of poor stability and slow prediction speed of random sampling prediction methods, this paper proposes a CCS algorithm in colleges and universities using the characteristics of high awareness among nodes within the same college. It can effectively combine the cognitive characteristics of the nodes with the college attributes and apply them to the relationship prediction to realize the college-oriented relationship prediction. The simulation results show that the CCS algorithm is more stable than other random sampling prediction methods. The results make full use of the cognitive characteristics and college attributes of nodes in social networks; reduce the influence of multiple factors such as response time, data packet loss, and individual behavior on relationship prediction; and improve the efficiency of college student group relationship prediction, which has certain theoretical significance and application prospects.

1. Introduction

With the rapid development of information technology, e-commerce and social networking sites have become inseparable from people's daily life, coupled with the increasing networkedness and various data resources, the network has received wide attention as a new perspective for information analysis and management research. [1–6] Especially since entering the twenty-first century, Internet technology has been rapidly developed and people have rapidly entered the era of online Internet. With the rise of various social networking sites and communication software such as Weibo, WeChat, TikTok, Alipay, and QQ, they provide people with direct and quick platforms for online

friendships and online shopping. [7–10] Network group is a collective form by individuals in the network with mobile devices or computers as the communication medium and information as the link. Its purpose is mainly study, interest, communication, or need, while college students' network group is an aggregation formed by college students on the network. The activities of college students on the Internet are not individual activities, but more interactive activities with others. Therefore, the communication behaviors of college students' netizens in the virtual space of the network constitute the group network of college students. The complex and changeable network environment brings abundant resources to college students and satisfies their pursuit of material and spiritual culture. However, the virtual network

world also changes the way of psychological activities of college students, making them show a variety of abnormal thinking or action in the network world. The popularity of these social networks and communication tools has revealed that data processing based on the attributes of the entities themselves ignores the information connections between entities and that such data processing methods cannot meet the needs of big data analysis and research. Therefore, in response to the ever-complex internode relationships, researchers have proposed a novel network, that is, social networks. In fact, social network not only refers to the scope of sociology but also includes various information networks, technology networks, and bio-information networks. [11–14] Of course, the most common social networks in daily life are social networks. For most online social networks, they often have thousands and tens of thousands of nodes, and the relationships between nodes are complex and may change in real time. Therefore, they have the same various properties of complex networks. These social networks with a large number of network nodes and complex relationships between nodes are called complex social networks, which is an important branch of complex networks. In recent years, due to the continuous improvement of the mathematical model of social networks, researchers have been studying complex social networks more and more deeply. [15–18] However, in the analysis of complex social networks, researchers have found that there are always nodes that cannot be directly sampled, and this part of node information plays an extremely important role in the overall study of the network. Therefore, the study of prediction methods for internode relationships in complex social networks is an important element of social network research. [19–21]

Social relationship prediction methods can solve the problem of difficult node information collection in interactive networks. In different social networks, they use different network models, so data collection under different models can have mutual effects. Social relationship prediction can provide a unified mechanism to predict out the relationship between nodes, which can realize the data analysis among interactive networks. College student group relationship prediction methods can achieve accurate prediction of internode relationships at low sampling rates. In the analysis of some specific networks, the sampling rate is often limited due to the influence of node response time and the properties of the nodes themselves. However, lower sampling rates can significantly reduce the accuracy of various analyses of social networks. It then needs to predict the topology of the network at low sampling rates. For the needs of these specific networks, the social relationship prediction method can accurately predict the topology of the overall network based on the information of the sampled nodes under the condition of sampling a small number of nodes, which plays an important role in the analysis of social networks at low sampling rates. The group relationship prediction method for college students has important practical applications. In practical applications, if researchers can make full use of the available data information, build accurate model structures, plan experiments rationally,

and analyze and predict hidden relational information, then relational prediction methods will save time, improve efficiency, and produce accurate and valuable results for people. In social networking sites, friend recommendation is realized based on the information of friends' circle; in shopping sites, interest product recommendation is realized based on the kind of goods users browse; in biological information network, hidden species relationship is predicted based on experimental results, etc. [22–25] As an important tool of social network analysis, college student group relationship prediction plays an important role in the research of all fields of social networks. In recent years, researchers began to pay more and more attention to the study of social relationship prediction and proposed various college student group relationship prediction algorithms; especially, since the twenty-first century, researchers have combined college student group relationship prediction with the theoretical findings of psychology and searched for a new perspective on the integration of network structure prediction and individual perception: the social network cognitive model. [26]

The social network cognitive model is a network structure model that emphasizes the importance of network node perception on network structure prediction. It is an emerging mathematical model of social networks, whose core idea is to analyze the network structure by using the cognitive determination of individual nodes on the relationship between nodes of the whole network. As the field of network perception continues to develop, researchers have found that node perception capabilities can help node relationship prediction. Social relationship perception prediction has also gradually received the attention of social network researchers. Therefore, this paper addresses the research of social relationship prediction methods under the social network perception model with very significant scientific and practical significance.

2. BTCS Prediction Algorithm

2.1. Algorithm Improvement. In the prediction of relationships in complex social networks, most researchers find that network data collection is very difficult, especially in interactive networks, which can be affected by multiple factors such as response time, data packet loss, and individual behavior, resulting in unavailability of node information. However, traditional relational prediction methods are highly dependent on the sampling rate and response rate of nodes, and will directly affect the measurement results if the node information is lost or inaccessible. The flow chart of the traditional prediction method is shown in Figure 1. As can be seen from Figure 1, the sampling process of the traditional prediction method requires sampling all nodes in the network to obtain the internode relationship matrix. Then, according to the node relationship matrix, the senders and receivers in the network relationship are accessed and merged two by two. The network relationship exists only when both sender and receiver acknowledge the existence of the network relationship. If one party decides that the relationship does not exist, then the network relationship does not exist. Finally, the network topology matrix is obtained

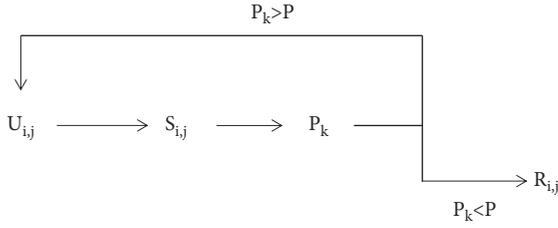

FIGURE 1: BTCS algorithm flow.

based on the merged results. However, in the traditional relational prediction method, it is affected by response time and sampling error, and data packet loss occurs. Therefore, the error analysis of the traditional method requires multiple repetitions of sampling. In the prediction of high-precision networks, the traditional method needs to complete multiple repetitions of sampling, which is very inefficient.

The BTCS algorithm achieves accurate prediction of social relationships at low sampling rates. The flow chart of the improved BTCS prediction algorithm is shown in Figure 2. Compared with traditional prediction methods, the BTCS algorithm is a randomized, low-sampling-rate relationship prediction method. It only needs to sample a small number of network nodes and obtain the cognitive determination information of the sampled nodes on the relationships among all nodes in the network, and then predict the social relationships among nodes based on the cognitive determination information without sampling all nodes. It adopts a threshold control method to adaptively control the node sampling error and avoid the duplicate sampling of data. Therefore, the BTCS algorithm can reduce the effects of response time, data packet loss, and individual behavior on node sampling and relationship prediction, and improve the efficiency of relationship prediction.

The BTCS prediction algorithm is a cognitive model-based relational prediction method, which is divided into three main steps: sampling, matrix merging, and fault-tolerant control process, as shown in the flow chart of the algorithm. The following section will introduce the specific process of each of the three steps of the BTCS algorithm.

2.2. Sampling Design. The data sampling process of BTCS prediction algorithm is different from the traditional relationship prediction method. In the traditional relationship prediction method, it needs to sample most of the network nodes and investigate to obtain the social relationships among the sampled members, while in the BTCS algorithm, it just samples a small number of nodes randomly, obtains the cognitive information of the sampled nodes on the social relationships among all network members, and records it in the form of a kind of three-dimensional 0–1 cognitive matrix set.

In the following example of the network (A, B, C, D , and E), Figure 3 represents the five cognitive matrices of members A, B, C, D , and E in the network (A, B, C, D , and E) in order. In each cognitive matrix, it records 20 social relationships among the members. In the sampling, the BTCS algorithm is randomly sampled in the sampling space n . In the network (A, B, C, D , and E), three nodes (A, D , and E) were randomly sampled

when the sampling space n was 3, and the node sampling set m and the cognitive matrix set $R_{i,j,k}$ were obtained, where $m = (1, 4, 5)$.

2.3. Matrix Design. There are three methods of matrix merging under the cognitive model: the cognitive slice method, the local summary structure method, and consistency structure dispel. Since these three methods merge the known and cognitive relationships of the sampled nodes equally in cognitive matrix merging, a new matrix merging method is proposed. According to the cognitive information of sampled nodes is divided into two categories of self-knowledge relationships and cognitive relationships, this paper divides the merging process into three cases: (1) merging self-knowledge relationships between sampled nodes; (2) merging cognitive relationship between sampled nodes; (3) merging known and cognitive relationship between sampled nodes. Merging rules are set according to these three cases.

We combine the known relationships between the sample nodes. In this paper, we use the merging local aggregation method, as in the following equation:

$$R_{i,j} = \{R_{i,j,i} \cap R_{i,j,j}\}, \quad (1)$$

where $R_{i,j,i}$ and $R_{i,j,j}$ represent the known relationships in the cognitive matrix of sampled nodes i and j , respectively, and $R_{i,j}$ denotes the group relationship between node i and j . When both $R_{i,j,i}$ and $R_{i,j,j}$ are 1 and both the sender and receiver of the relationship determine that the relationship exists, then the relationship i to j is judged to exist and $R_{i,j}$ is 1.

Cognitive relationship merging between sampled nodes is as follows:

$$R_{i,j} = \begin{cases} 1, & \sum_m R_{i,j,m} \geq K, \\ 0, & \end{cases} \quad (2)$$

where $\sum_m R_{i,j,m}$ denotes the individual cognitive summary of all sampled nodes for the social relationship between i and j . K is a set threshold valve. When both sender i and receiver j of the relationship are not sampled, the summary value of cognitive information of the relationship is referred to all sampled nodes, and if the summary value is greater than or equal to K , then the relationship $R_{i,j}$ is determined to exist.

The known and perceived relationships between sampled nodes are merged.

$$R_{i,j} = \begin{cases} 1, & R_{i,j} = 1 \text{ \& } \sum_m R_{i,j,m} \geq K, \\ 0, & \end{cases} \quad (3)$$

where $R_{i,j} = 1 \& \sum_m R_{i,j,m} \geq K$ denotes that when only one side of both sender i and receiver j of the relationship is sampled, then the known relationship of the sampled node is first considered to be 1. If the known relationship of the sampled node is 1 and the aggregated value is greater than or equal to K , then the relationship $R_{i,j}$ is determined to exist.

The final result θ is obtained by combining the three cases, $\theta = \alpha + \beta + \gamma$.

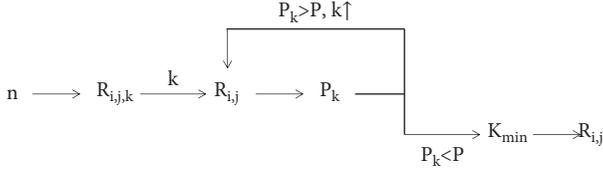

FIGURE 2: Upgraded BTCS algorithm flow.

Taking the network (A , B , C , D , and E) in Figure 3 as an example, the nodes (A , D , and E) are randomly sampled to obtain the sampling set (1, 4, and 5) and the cognitive matrix of A , D , and E . Then, the matrix merging is completed when the threshold value is 2, and the merging process and the merging results are obtained as shown in Figure 4. In Figure 4, α , β , and γ are the matrices obtained by merging in the first, second, and third cases, respectively; θ is the final result to obtain the real network matrix. The social relationship between the sampled nodes (A , D , and E) is obtained in α . For example, when analyzing the social relationship from E to D , by accessing the self-knowledge relationship of the cognitive matrix of D and E , we get $R_{E,D,D}$ and $R_{E,D,E}$ as 1. Then, we can decide that the social relationship from E to D exists, so we get $R_{E,D}=1$ in α .

The social relationships between the unsampled nodes (B and C) are obtained in β . For example, in the analysis of the social relationships from B to C , the cognitive relationships of all sampled nodes are accessed and $\sum_m R_{B,C,m} = 2$, which is equal to the threshold K , so we get $R_{B,C}$ in β as 1. The social relationships between sampled nodes (A , D , and E) and unsampled nodes (B and C) are obtained in γ . For example, when analyzing the social relationship from A to C , the known information of the cognitive matrix of A is accessed first, and R_a is obtained as 1. Then, the cognitive relationships of all sampled nodes are accessed, and $\sum_m R_{A,C,m} = 2$, so $R_{A,C,A}$ is obtained in γ , and $R_{A,C}$ is 1.

The nodal relationship matrix θ is predicted by introducing the K -value merged 3D matrix $R_{i,j,m}$, and different prediction results θ are obtained under different K -values. The random partial sampling method under the social relationship cognitive model is a fast and efficient measurement method, and the prediction results are subject to error, which requires us to control the error within a tolerable range, so the error-tolerant control of the algorithm is important. Therefore, an error-tolerant control process with a threshold value is designed to adaptively regulate the value of K so that the prediction result θ is closest to the true result.

Firstly, we analyze the relationship between the sampling error rate and the threshold value as a function of P_k . These errors are divided into two categories: the first type of relationship error refers to the relationship does not exist in the real network, while the cognitive relationship is judged to exist; the second type of relationship error P_2 is the relationship exists in the real network, while the cognitive relationship is judged not to exist. In the dichotomous threshold algorithm, the threshold K is compared with the network recognition to determine whether the relationship holds, and the recognition is

influenced by P_1 , so P_1 is the main factor affecting the threshold reduction result, while P_2 will be gradually reduced in the reduction operation.

In Figure 4, the first type of error is generated by merging the cognitive matrices of sampled nodes A and D , which determine the nonexistence of the relationship A to D , while the cognitive determination exists in the cognitive matrix of E . In complex networks, P_1 increases as the network data increase, and the error P_1 can represent the network error rate P_k . Therefore, we need to analyze the relationship between the error P_1 and the threshold K . Therefore, this section analyzes the effect of the threshold K on θ by comparing the merged matrix θ and the cognitive matrix $R_{i,j,m}$ of the sampled nodes, and obtains the relationship between the value of K and the sampling error rate P_k .

$$P_k = \frac{V}{Q}, \quad (4)$$

where V is the number of errors present in the sampled nodes and Q is the number of possible errors in the sampled nodes.

Setting the fault-tolerance control condition. In this section, based on the maximum tolerable sampling error rate P' (0.1, 0.15, 0.2), an error-tolerant control process is established to find the smallest K_{\min} value such that $P_k < P'$, and the matrix merging result is obtained when the output threshold K is K_{\min} , which is the closest to the real network. The prediction result is the closest to the real network.

An error-tolerant control process is designed. Through the above analysis, the relationship P_k between the error rate P and the threshold K is obtained. Therefore, according to the control theory and method, and the fault tolerance range, it can adaptively adjust the threshold K and control the error rate P_k within the fault tolerance rate P' . In words, in BTCS algorithm, fault-tolerant control process is an important part of the algorithm. Too large or too small K value will directly affect the accuracy of prediction results. BTCS algorithm mainly analyzes the direct relationship between K value and network sampling error, and designs the fault-tolerant control process of threshold value, which can adaptively control K value, find the best K value, minimize prediction error, and improve prediction accuracy.

2.4. Mathematical Model. The mathematical model of BTCS algorithm is divided into two parts: matrix dimension reduction model and fault-tolerant control model. In the matrix dimensionality reduction model, it combines the cognitive matrix according to the dimensionality reduction rules under the set K value. In the fault-tolerant control model, it analyzes the sampling error rate of the combined matrix, controls the error rate within the fault-tolerant range, and obtains the best threshold. Therefore, the mathematical model of BTCS algorithm is established step by step according to the matrix dimensionality reduction model and error-tolerant control model.

According to the matrix dimensionality reduction rules designed in the BTCS algorithm description, this subsection

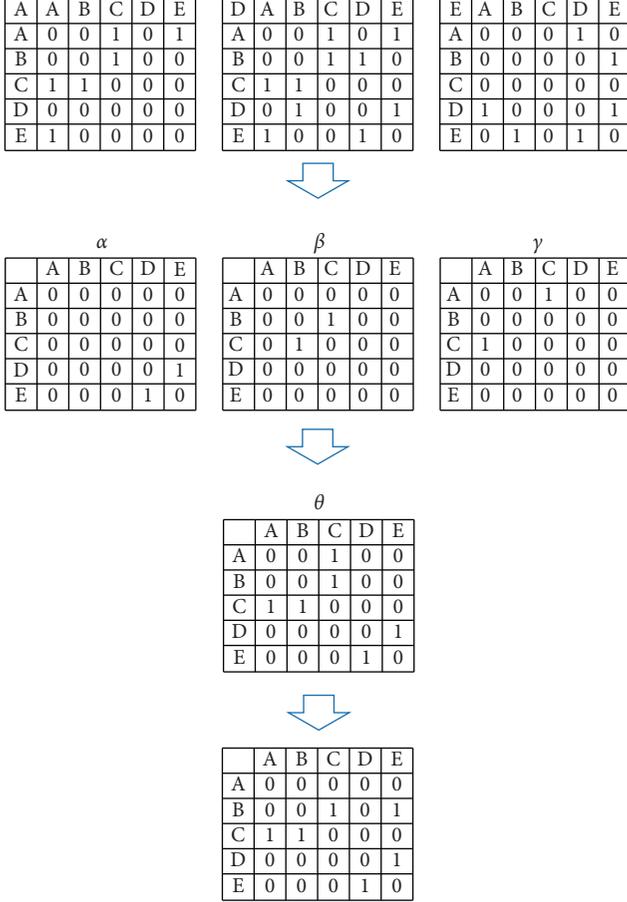

FIGURE 4: Merge matrix process.

first obtains the sampling set m , the cognitive matrix Y_i , and the set threshold K . Then, the valid information in the cognitive matrix is extracted in steps, and the mathematical matrix operations are obtained as follows:

- (1) separate the cognitive matrix Y_i to obtain the known relationship matrix $Y_{Z,i}$, and the cognitive relationship matrix $Y_{R,i}$.

Known relationship matrix:

$$Y_{Z,i} = i * Y. \quad (5)$$

Cognitive relationship matrix:

$$Y_{Z,i} = -i * Y_i. \quad (6)$$

Cognitive matrix:

$$Y_i = Y_{z,i} + Y_{R,i}. \quad (7)$$

Sampling node matrix and Z:

$$Z = \sum_{i=m} Y_{Z,i}. \quad (8)$$

Sampling node matrix and R:

$$R = \sum_{i=m} Y_{R,i}. \quad (9)$$

- (2) The topological information among the sampled nodes is extracted from the cognitive relationship Z to obtain the matrix α .

Extraction matrix:

$$T = m, \quad \alpha = S_1(T * Z). \quad (10)$$

- (3) extract the topological information of the cognitive relationship judgment to obtain $\beta + \gamma$.

2.5. Extraction Matrix

$$W = -m. \quad (11)$$

Cognitive information

$$P_1 = W * Z, \quad P_2 = W * R, \quad (12)$$

$$\beta + \gamma = S_k(P_1 + P_2).$$

The three cases are summed to obtain the reduced-dimensional merged matrix θ .

$$\theta = \alpha + \beta + \gamma. \quad (13)$$

2.6. Error-Tolerant Control Mathematical Model Implementation. According to the error-tolerant control process described by the BTCS algorithm, the sampling error rate P_k of the merged matrix under the set threshold K is analyzed and the mathematical model operation is obtained as follows:

- (1) Calculate the number of errors W present in the sampled nodes.

$$W = S_k(T * R). \quad (14)$$

- (2) Calculate the number of possible errors Q in the sampling nodes.

$$Q = T - \alpha. \quad (15)$$

- (3) Sampling error rate P_k .

$$P_k = \frac{W}{Q}. \quad (16)$$

Finally, the sampling error rate P_k under the control of threshold K is obtained, and the dichotomous iteration method is used to find the optimal threshold value K that satisfies the fault tolerance condition.

3. CCS Relationship Prediction Method within Colleges and Universities

3.1. CCS Algorithm. In the social relationship cognitive model, the overall network random sampling prediction method ignores the different cognitive characteristics among nodes and ignores the high cognitive characteristics of nodes within the same college. Therefore, the stability of this relationship prediction method is poor. To address the shortcomings of the overall network random sampling prediction method, a relationship prediction method with random sampling in colleges and universities is proposed as the CCS prediction algorithm. [27] The CCS algorithm is applicable to networks where all college information is known and the college structures do not overlap. When a node belongs to more than one college at the same time, it is grouped into the college with the higher number of relationships among nodes.

The CCS algorithm takes advantage of the characteristics of high cognitive degree among nodes within the same college; firstly, the CCS algorithm assigns the sampled nodes to each college proportionally; then, the CCS algorithm completes the random sampling within the college according to the sampling space of each community to obtain the cognitive matrix of sampled nodes; finally, for the characteristics of high cognitive degree of nodes within the college, the CCS algorithm designs the matrix merging rules based on the college to get the final prediction results. Compared with other relationship prediction methods, the CCS prediction algorithm effectively combines the cognitive characteristics of nodes and college attributes.

The CCS prediction algorithm is a relationship prediction method in colleges and universities based on a social cognitive model. Figure 5 shows the flow chart of CCS prediction algorithm; in general, it is divided into three main steps: community-based sampling, intracollege node relationship merging, and inter-GA node relationship merging.

The community-based sampling is mainly to reasonably allocate the sampling nodes according to the network community structure and sampling space to obtain the sampling node cognitive matrix. In the community-based cognitive matrix merging, the sampled node cognitive matrix relationships are first classified into intracommunity

FIGURE 5: Flow chart of CCS prediction algorithm.

node relationships and intercommunity node relationships; then, the nodes are merged in steps according to the different intracommunity and intercommunity nodes to obtain the prediction results. In this section, four parts of community-based sampling process design, community-based node relationship classification, intracommunity node merging design, and intercommunity node merging design are introduced, respectively.

3.2. Sampling Process Design. In the data sampling process, the CCS prediction algorithm implements a community-based cognitive matrix data sampling, which combines cognitive information with college information. The community-based sampling characteristics of the CCS prediction algorithm are mainly reflected in the following three aspects.

The CCS prediction algorithm is a data sampling process based on a cognitive model. Like other relationship prediction methods under the cognitive model, the data obtained after sampling by the CCS prediction algorithm are also a kind of three-dimensional 0–1 cognitive matrix set $R_{i,j,k}$, where i represents the sender of the social relationship, j represents the receiver, and $R_{i,j,k}$ represents the observer of the social relationship between i and j . If K observes that the relationship from i to j exists, then $R_{i,j,k}$ indicates that it does not exist.

The CCS prediction algorithm is a data sampling process based on the node community structure. Based on the network community structure (C1, C2, ... CN), the CCS algorithm will allocate the sampling space to each community proportionally so that the sampling ratio within each community is the same. For communities with more nodes, the CCS algorithm allocates a correspondingly larger number of sampled nodes; while for communities with fewer nodes, the number of samples is correspondingly lowered to ensure an even number of sampled nodes within each community.

The CCS prediction algorithm is a data sampling process based on random sampling within communities. For each community, under the condition that the number of sampled nodes is determined, the CCS algorithm uses a random sampling method in which each node has the same probability of being sampled.

3.3. Stability Analysis. In this subsection, this paper analyzes the stability of the prediction algorithm under random sampling conditions. In order to analyze the stability of the prediction algorithm, multiple sets of experimental predictions were performed in this paper for different node sampling results under the same sampling space using the CCS algorithm, the Central Graph algorithm, and the LAS algorithm. In each set of experiments, 1000 random samples are performed for the same sampling space and 1000 prediction results are obtained, and the confidence interval (CI)

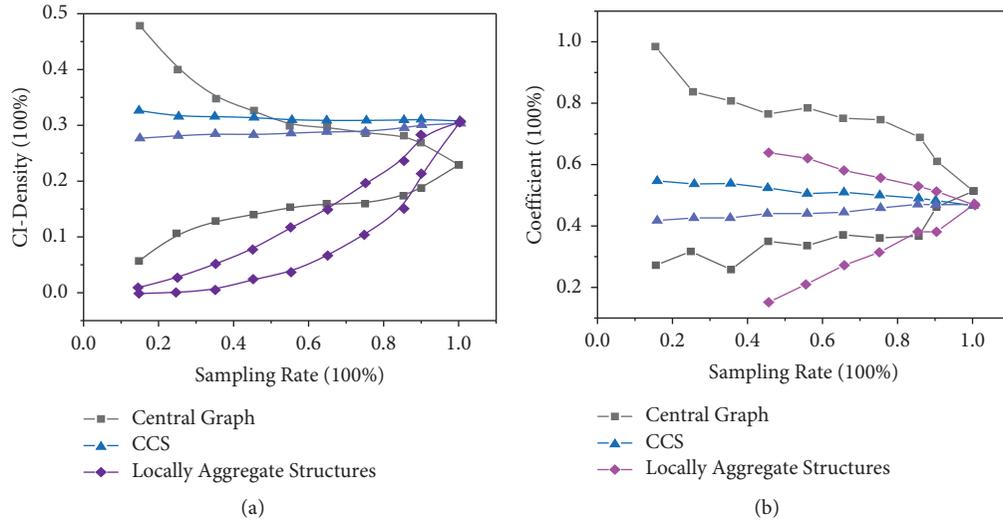

FIGURE 6: Density CI distribution (a) and clustering coefficient CI distribution (b).

numerical processing method is used to analyze the 1000 results.

In the confidence interval processing, this paper first ranks the performance parameters of 1000 prediction network results and then removes the first 2.5% and the last 2.5% to get the distribution curve of the performance parameters, and finally, this paper compares the confidence distribution of the performance parameters of the obtained prediction network results with the performance parameters of the real network results to analyze the stability of the algorithm under the random sampling conditions.

Figures 6(a) and Figure 6(b) show the density CI distribution curves and clustering coefficient CI distribution curves of the CCS algorithm, Central Graph algorithm, and LAS algorithm under different meter sample nodes at the same meter sample rate, respectively; where the horizontal coordinates indicate the sampling rate, the vertical coordinates indicate the network density values and clustering coefficient values of the predicted results, and the dashed lines indicate the performance parameters of the real network. From the analysis in Figures 6(a) and 6(b), it can be obtained that (1) the network density distribution and the clustering coefficient distribution of 1000 measurements at different sampling rates are within the confined curve range. (2) When the sampling space is small, the network density confidence interval distributions and the clustering coefficient confidence interval distributions of the 1000 random sampling prediction results of the CCS algorithm are smaller than those of the LAS algorithm and the Central Graph algorithm, and both are close to the performance parameters of the real network. (3) As the sampling rate increases, the network density confidence interval distribution and the clustering coefficient confidence interval distribution of the prediction results of the three prediction algorithms show convergence and gradually become smaller. However, compared with the other two algorithms, the network density confidence interval distribution and the clustering coefficient confidence interval distribution of the CCS algorithm are closer to the performance parameters of the real

network. (4) When the sampling rate is larger, the CCS prediction algorithm outperforms the LAS algorithm and the Central Graph algorithm, and the CCS prediction algorithm predicts results that are close to the real network density. Therefore, the CCS algorithm is more stable than the other two algorithms, it is less volatile by the different sampling nodes and the stability of the algorithm is higher.

3.4. Prediction Accuracy Analysis. In terms of accuracy analysis of the prediction results, the mean square error of the three algorithms under different sampling rates is compared. In this paper, the CCS algorithm is compared with the Central Graph algorithm and the LAS (locally aggregates structures) algorithm.

To analyze the prediction accuracy of the CCS algorithm in communities, multiple sets of prediction experiments were conducted in the cognitive social network data package using the CCS algorithm with the Central Graph algorithm and the LAS algorithm, respectively, and network density MSE curves and average clustering coefficient MSE curves were obtained, as shown in Figures 7(a) and 7(b), where the horizontal coordinates denote the sampling rate, and the vertical coordinates indicate the MSE values of network density and clustering coefficients. From Figures 7(a) and 7(b), we can get that (1) the MSE values of CCS prediction algorithm fluctuate less than Central Graph algorithm and LAS algorithm at different sampling rates, and the prediction results of both CCS algorithms are very close to the real network. (2) When the sampling rate is small, the MSE values of Central Graph algorithm and LAS algorithm are larger, while the MSE values of CCS algorithm are smaller, and the prediction accuracy of CCS algorithm is still very high. (3) When the sampling rate is larger, the error value of the LAS algorithm gradually decreases and approaches the real network results, while the CCS algorithm still has a certain smaller error when the sampling rate is 1. Because in the sampling process of the CCS algorithm, it makes full use of the network community information and subcommunity

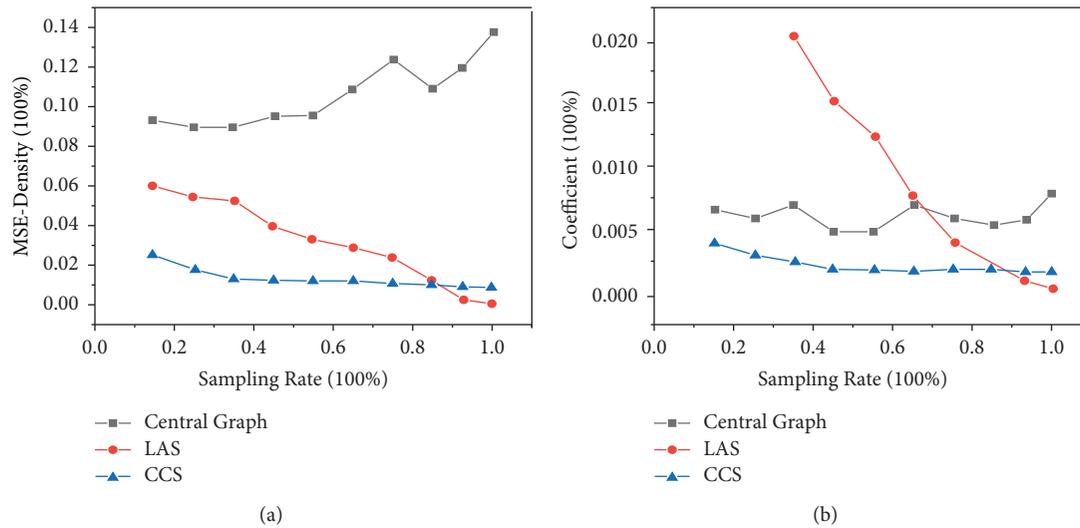

FIGURE 7: MSE of network density at different sampling rates (a) and MSE of clustering coefficients at different sampling rates (b).

random sampling to ensure the balance of the overall network cognition of the sampled nodes, it can always maintain a high prediction accuracy. When the sampling rate is 1, the community merging rule of CCS algorithm relies on the overall cognition of the community to complete the relationship determination instead of directly accessing the relationship sender and receiver, and thus, there is a small error even if all nodes are sampled.

The CCS prediction algorithm in the community is more stable, more accurate, and faster than other relationship prediction algorithms under cognitive models.

4. Conclusion

This paper addresses the relationship prediction method under the social network cognitive model. Based on the relationship prediction method under the cognitive model, a relationship prediction method under the cognitive model of college student group is proposed, that is, BTCS prediction algorithm. The cognitive nature of the nodes in the network is exploited, and the cognitive model of social relationships is combined with the relationship prediction technique to design a new method of cognitive matrix merging under the cognitive model of university student groups, which achieves the relationship prediction of complex social networks with low sampling rate and reduces the sampling time; secondly, two methods of threshold control and dichotomous lookup are introduced, and the interrelationship between threshold and network topological relationship error is analyzed, and the dichotomous lookup is used to optimize the measurement process. The method of dichotomous lookup is used to optimize the measurement process and improve the efficiency of threshold control. Based on the characteristics of high node awareness within the same college, a method for predicting college student group relationships in colleges and universities is proposed, that is, the CCS prediction algorithm. In social networks, network nodes not only have cognitive properties but also have social attributes. Due to the different social attributes among

nodes, the closeness and cognitive degree among nodes are different. The group relationship prediction method for college students with random sampling under the cognitive model exploits the node cognitive characteristics to reduce the effects of response time, data packet loss, and individual behavior. Experimental results show that the CCS prediction algorithm in colleges and universities is more stable, more accurate, and faster than other group relationship prediction algorithms for college students under cognitive models.

This paper applies the CenterNet target detection algorithm to the foreign object detection of coal conveying belts in coal mines. Given the fast running speed of coal conveying belts and the influence of background and light sources on the objects to be inspected, an improved algorithm of CenterNet is proposed. First, the depth separable volume is introduced. The product replaces the standard convolution, which improves the detection efficiency. At the same time, the normalization method is optimized to reduce the consumption of computer memory. Finally, the weighted feature fusion method is added so that the features of each layer are fully utilized, and the detection accuracy is improved. The experimental results show that the improved algorithm has improved speed and accuracy compared with the original CenterNet algorithm. The foreign object detection algorithm proposed in this paper mainly detects coal gangue and can also detect iron tools such as bolts, drill bits, and channel steel. In the experimental environment, the average detection rate is about 20fps, which can meet the needs of real-time detection.

1. Introduction

As the main artery of coal mining and transportation, the working state of coal transportation belt directly affects the mining and transportation volume of coal. Foreign matters on the belt, such as large gangue and anchor bolt, are easy to cause problems such as scratch and tear of the belt and coal stacking and blocking at the coal chute during the high-speed operation of the belt. Therefore, the detection of large blocks, anchor bolts, and other foreign matters on the transportation belt can effectively ensure the safe production of the coal mine [1, 2].

Both target detection and image classification technology can realize the classification and recognition of belt foreign objects. However, target detection needs to locate the foreign object in the image before recognition, which increases the amount of calculation of the network to a certain extent, while image classification technology can directly identify the foreign object without locating the foreign object, and more computing resources can be used in fast foreign object recognition.

The complex environment of the mine makes the application of the existing image classification methods in the classification of foreign objects in coal conveying belt very challenging. Many scholars introduce machine vision technology into the image classification of foreign objects in the mine. Wang et al. [3] identified large foreign bodies of belt conveyor based on interframe difference method, threshold classification, and select-shape operator. He et al. [4] used the classification method of support vector machine to classify foreign objects in combination with the texture and gray features of foreign objects. Zhang [5] used multifeature fusion, combined with k-nearest neighbor algorithm and support vector machine for foreign object recognition. The above methods have achieved good results, but the image processing method combining feature extraction and classification algorithm has some problems, such as poor robustness and easy to be affected by illumination [6–9].

Convolution neural network uses convolution method for feature extraction, which has strong robustness and has

been widely used in many fields [10–13]. Some scholars also study the image classification network of mine foreign bodies. Pu et al. [14] established a foreign object recognition model based on vgg16 network and the idea of transfer learning, but the sample set was small, only 240 pieces. Su et al. [15] designed an improved LeNet-5 network and trained 20000 foreign object pictures in nonproduction environment, with a recognition rate of 95.88%. Ma [16], based on MobileNet network, optimized the network structure, improved the loss function, and further improved the recognition rate according to the characteristics of foreign object image. At this stage, the shortcomings of image classification of mine foreign bodies are as follows: (1). The sample collection is ideal without considering the actual working environment. (2). The network model has high complexity, large amount of parameters, low accuracy, and poor real-time performance.

Based on convolution neural network, in order to improve the adaptability of the algorithm for the detection of foreign matters in coal conveying belt under coal mine, this paper puts forward the corresponding improved method. In view of the low image quality caused by dark and uneven illumination in the underground, firstly, the dataset is preprocessed. Aiming at the problem of complex background of foreign object and large interference by coal block, the training data is correctly marked, the backbone network with good effect is adopted, and the weighted feature fusion of feature layers with different scales is introduced, which speeds up the convergence speed and reduces the amount of parameter calculation. Under the condition of ensuring the detection speed, the detection accuracy has been greatly improved.

2. Methods

2.1. Target Detection Algorithm. The CenterNet target detection method was proposed at the 2019 CVPR (Computer Vision and Pattern Recognition) conference [17–21]. The core idea of the algorithm is to regard the object to be detected as a point, that is, the center point of the target frame. Then, the center is found through the heat map and other attributes of the target object, such as the size information and pose information of the thing. The network structure of the CenterNet algorithm adopts ResNet-18, DLA-34, and Hourglass-104, three backbone networks for design and experiment. The three networks are complete encoding-decoding networks. The resolution of the final output feature map is subsampled 4 times compared to the original image, so that it can adapt to the detection of objects of various scales without multiscale design. The algorithm is based on anchor-free, so there is no need to set anchor boxes in advance, thereby avoiding the selection of related hyperparameters and eliminating the postprocessing process of NMS, which significantly reduces the computational load and training time of the network. The CenterNet object detection algorithm consists of three independent head structures: the center point prediction, the center point offset, and the target box's size, as shown in Figure 1.

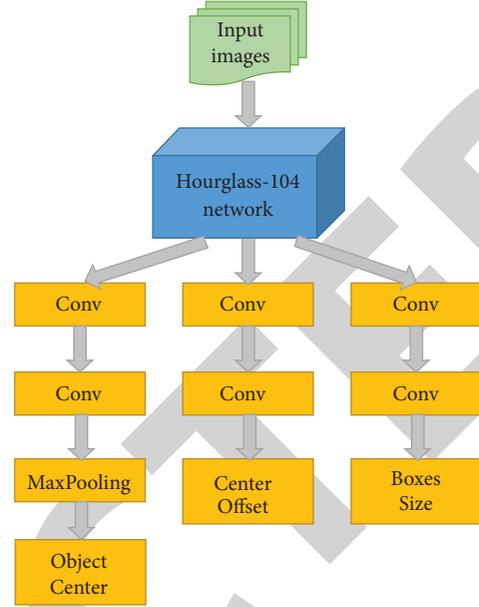

FIGURE 1: Algorithm structure.

Assuming that $I \in R^{W \times H \times 3}$ is the input image, where W and H represent the width and height of the image, respectively. After it is sent to the backbone network, a heat map containing the key will be generated.

$$Y \in [0, 1]^{(W/R) \times (H/R) \times C}, \quad (1)$$

where R is the subsampled factor and C is the number of classes in the detection target.

If class c is detected at the position (x_i, y_i) of the heat map, $\hat{Y}_{x_i, y_i, c} = 1$; on the contrary, if there is no target object at the point, $\hat{Y}_{x_i, y_i, c} = 0$.

In the training phase, for an object, assuming that the coordinates of its real frame in the input image are $(x_1, y_1, x_2, \text{ and } y_2)$, the center point of the object can be expressed as $p = (x_1 + x_2)/2, (y_1 + y_2)/2$. After subsampled, the coordinates of the point are mapped to the heat map as $\tilde{p} = \lfloor p/R \rfloor$ and mapped it to the heat map $Y \in [0, 1]^{(W/R) \times (H/R) \times C}$ through the Gaussian kernel transformation of the following formula:

$$y_{x_i y_i} = \exp\left(-\frac{(x - \tilde{p}_x)^2 + (y - \tilde{p}_y)^2}{2\sigma_p^2}\right). \quad (2)$$

where σ_p is the standard deviation of the object size adaptation if the Gaussian kernels of two objects of the same category overlap, taking the one with the most value.

In the prediction stage, the most considerable eight-neighborhood value is first screened on the heat map, which is equivalent to performing an entire pooling operation with a kernel size of 3 on the heat map, and a total of 100 such values are selected. Assuming that P_c is the detected point, the coordinate of the i -th key point is (x_i, y_i) and using this point to regress, the calibration frame is

$$\left(x_i + \delta x_i - \frac{w_i}{2}, y_i + \delta y_i - \frac{h_i}{2}, x_i + \delta x_i + \frac{w_i}{2}, y_i + \delta y_i + \frac{h_i}{2}\right)s. \quad (3)$$

where $(\hat{x}_i, \hat{y}_i) = \hat{O}_{\hat{x}_i, \hat{y}_i}$ is the offset of the point in the heat map relative to the original image during the subsampled process and $(\hat{w}_i, \hat{h}_i) = \hat{S}_{\hat{x}_i, \hat{y}_i}$ is the length and width of the target corresponding to the current point measured.

$\hat{Y}_{x,y,c} = 0$ is used to represent the confidence of the point, that is, the probability of the existence of an object at the current center point. In this paper, the screening threshold is set to 0.3. For the 100 values selected above, it will be reserved as the final result if the predicted probability is greater than the threshold.

The Loss function of the CenterNet algorithm consists of three parts: the category loss function L_{cls} , the regression loss function L_{size} , and the bias loss function L_{off} , which are linear combinations of the three.

$$L_{det} = L_{cls} + \lambda_{reg} L_{reg} + \lambda_{off} L_{off}. \quad (4)$$

The category loss function is the Focal Loss function.

$$L_{cls} = -\frac{1}{N} \begin{cases} (1 - \hat{Y}_{xyc}) \log(\hat{Y}_{xyc}) Y_{xyc} = 1, \\ (1 - Y_{xyc})^\beta (\hat{Y}_{xyc})^\alpha \log(1 - \hat{Y}_{xyc}) \text{ other.} \end{cases} \quad (5)$$

The target center bias loss function is

$$L_{off} = \frac{1}{N} \sum_p \left| \hat{O}_p - \left(\frac{p}{R} - \tilde{p} \right) \right|. \quad (6)$$

The regression loss function is

$$L_{reg} = \frac{1}{N} \sum_{k=1}^N |s_{pk} - s_k|. \quad (7)$$

The relevant hyperparameters are chosen as $\lambda_{reg} = 0.1$, $\lambda_{off} = 0.1$, $\alpha = 2$, and $\beta = 4$.

2.2. Hourglass Network Improvements. In this paper, the Hourglass-104 network [22] is selected as the backbone network of the CenterNet algorithm to extract features and generate heat maps. The network consists of two Hourglass modules stacked, as shown in Figure 2.

For the first-order module shown in Figure 3, the network adopts a fully convolutional neural network structure in the form of encoding-decoding. The repeated use of bottom-up and top-down supervision mechanisms combined with intermediate results has achieved good results in keypoint detection.

The most basic network unit in the Hourglass-104 network is the residual module, as shown in Figure 4. Almost all the network computation is consumed in the convolution operation of the residual module. For the detection task in this paper, since the datasets are directly derived from video surveillance, the image resolution is vast, the training time is also very long, and the consumption of computer hardware facilities is also relatively high.

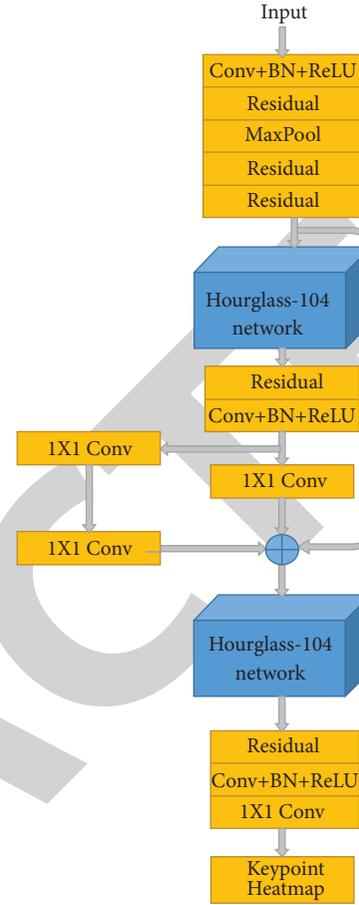

FIGURE 2: The structure of Hourglass-104 network.

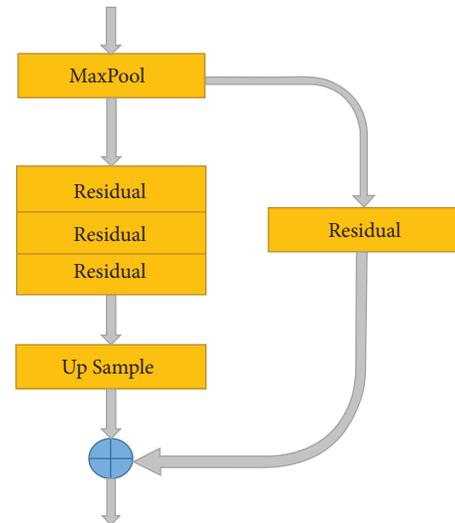

FIGURE 3: The first-order module.

To solve this problem, depthwise separable convolution (DSC) module is introduced. The DSC module is a lightweight network. In the processing process, the depthwise convolution of spatial relationship mapping is performed first, and then the point-by-point convolution of channel relationship mapping is performed. In the process of network

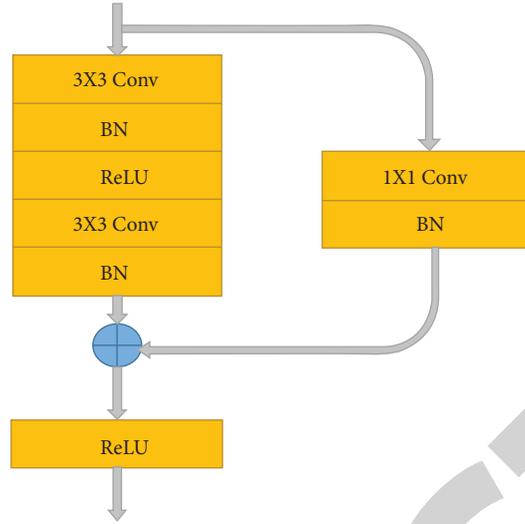

FIGURE 4: The residual module in the Hourglass-104 network.

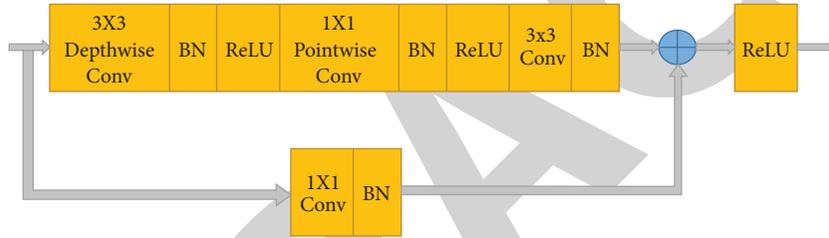

FIGURE 5: The residual module after introducing DSC.

training and detection, the calculation of parameters can be significantly reduced, which dramatically improves the network's work efficiency. The structure diagram of the residual module after introducing DSC is shown in Figure 5.

Assume that the input is (B, C, W, H) data, where $B, C, W,$ and H are the size of the feature image batch size, the number of channels, width, and height, respectively. The convolution operation of 3×3 is performed, and the calculation of standard convolution is as follows:

$$stc = B \times C \times W \times H \times 3 \times 3. \quad (8)$$

Depthwise separable convolution for calculation is used first, and then the depthwise convolution operation is performed, the calculation of the amount is as follows:

$$dw = C \times H \times W \times 3 \times 3. \quad (9)$$

Then, the pointwise convolution operation is performed, and the calculation of the amount is as follows:

$$pw = B \times C \times W \times H. \quad (10)$$

The total computational cost of depthwise separable convolution is the sum of the two.

$$dsc = dw + pw = (B + 3 \times 3) \times C \times W \times H. \quad (11)$$

The computational cost ratio of the standard convolution operation and the depthwise separable convolution operation is as follows:

$$\frac{dsc}{stc} = \frac{(B + 3 \times 3) \times C \times W \times H}{B \times C \times W \times H \times 3 \times 3} = \frac{1}{B} + \frac{1}{3 \times 3}. \quad (12)$$

When a lot of data are processed, the difference between the two calculation methods is more prominent.

2.3. Group Normalization Method. The calculation result of the BN layer depends on the data of the current batch. When the batch size is small, the mean and variance of the batch data are less representative, so the final result is also greatly affected. As shown in Figure 4, as the batch size becomes smaller and smaller, the reliability of the statistical information calculated by the BN layer becomes worse and worse, which will quickly lead to an increase in the final error rate. However, when the batch size is more significant, there is no noticeable difference. In target detection, segmentation, and video-related algorithms, the batch size is generally set relatively small due to large input images, diverse dimensions, and computer performance reasons. To weaken the influence of small-batch training on the detection results and make the CenterNet algorithm more flexibly applied to different hardware configuration environments, this paper improves the BN (batching normalization) in the backbone network to GN (grouping normalization).

Unlike BN, which normalizes channel by channel, GN groups channels and normalizes them in groups. First, the C channels are divided into G groups, and $S_k = \{c | [(c/G) = k], c = 0, 1, \dots, C\}$ is the channel number set composed of the

channel numbers that fall into the k -th channel group, where $k \in \{0, 1, \dots, G-1\}$, let the i -th feature of the j -th sample of the current mini-batch sample set in the c -th channel be $x_i^{(j,c)}$, the result after normalization is $y_i^{(j,c)}$, and the corresponding calculation formula is as follows:

$$x_i^{(j,c)} = \frac{1}{\sigma_i^{(k)}} (x_i^{(j,c)} - \mu_i^{(k)}) \quad (13)$$

$$y_i^{(j,c)} = a\hat{x}_i^{(j,c)} + b, \quad (14)$$

where sum is the mean and standard deviation of the i -th feature of each feature map of the k -th channel, respectively,

$$\mu_i^{(k)} = \frac{1}{m \cdot |S_k|} \sum_{j=1}^m \sum_{c \in S_k} x_i^{(j,c)} \quad \text{and} \quad (15)$$

$$\sigma_i^{(k)} = \sqrt{\frac{1}{m \cdot |S_k|} \sum_{j=1}^m \sum_{c \in S_k} (x_i^{(j,c)} - \mu_i^{(k)})^2 + \varepsilon}. \quad (16)$$

The group-based normalization groups the feature map channels, making each channel's mean and standard deviation more stable, effectively weakening the influence of the number of samples in the small-batch sample set on the feature normalization, and at the same time, the learning efficiency of the model based on the gradient descent method under low memory capacity is improved.

2.4. Weighted Feature Map Fusion. In the CenterNet network structure, the input image is input into the Hourglass-104 network after being subsampled 4 times. After 8 times, 16 times, 32 times, 64 times, and 128 times of subsampled in turn, and then 2 times of upsampling in turn, only one feature map is output. The output feature map size is subsampled 4 times from the input image. It can be seen that only using the most extensive feature map for target detection will inevitably lose some features of the image.

To make full use of the feature map generated after the convolution operation, improve the detection ability of small-sized targets, and reduce the algorithm's complexity. In this paper, the input image is subsampled 2 times, and then sent to Hourglass, and then subsampled 2 times, 4 times, 8 times, and 16 times in a turn, and output four feature maps, namely, P_1 , P_2 , P_3 , and P_4 , each feature's layer resolution is $(1/2^{i+1})$ times the input image, and multiple output feature maps are fused. Since each feature map contributes differently to the final fusion output, feature fusion cannot be performed directly. This paper uses a weighted method to fuse the features of each feature map; that is, when the feature map is fused, a learnable weight is assigned to each input feature map. During training, the network can learn to change the fusion weight of each feature map to change the importance of each feature map to the final detection result. To reduce the number of parameters and computation, the improved model directly uses short-circuit connections in the bypass convolution and instantly removes the convolution operation. The schematic diagram of feature fusion is

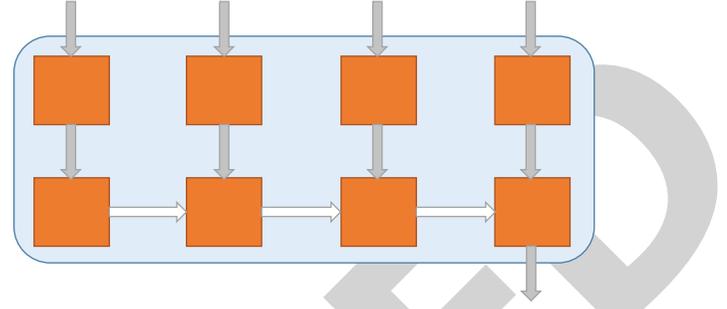

FIGURE 6: Feature fusion.

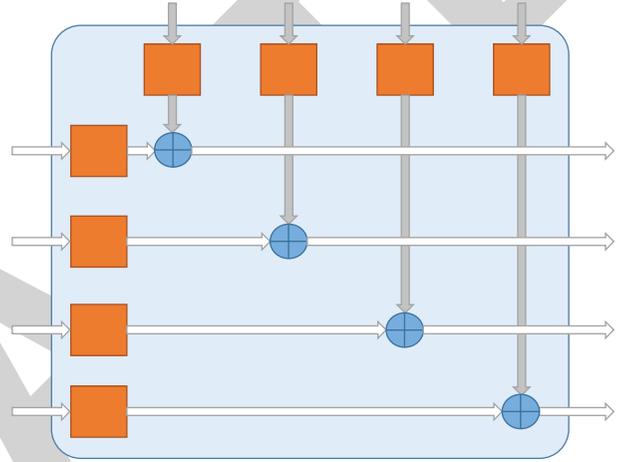

FIGURE 7: Weight fusion.

shown in Figure 6. The feature maps from high-level to low-level are obtained after upsampling, and then added, and the final output has only one fused feature map P_{out} .

The calculation formula of feature fusion is

$$O = \sum_i \frac{\omega_i}{\varepsilon + \sum_j \omega_j} \cdot I_i, \quad (17)$$

where I_i is the input feature map, the fused feature map, and ω_i , $\omega_i \in [0, 1]$ is the corresponding weight. A minimum value $\varepsilon = 1e-4$ is set to avoid the situation where the denominator in the above formula is 0.

The fast normalized fusion method is also used for weight fusion of the feature maps output by the two Hourglasses, and the calculation formula is

$$P_{out} = \frac{\sum \omega_{ij} \cdot P_{ij}}{\sum \omega_{ij} + \varepsilon}. \quad (18)$$

The schematic diagram of weight fusion is shown in Figure 7.

The final improved CenterNet (Improve-CN) algorithm network structure is shown in Figure 8.

3. Experiments and Analysis

3.1. Data Preprocessing and Labeling. The dataset images in this paper include two types of gangue and iron. The gangue is mainly coal road gangue and washing gangue, and the iron

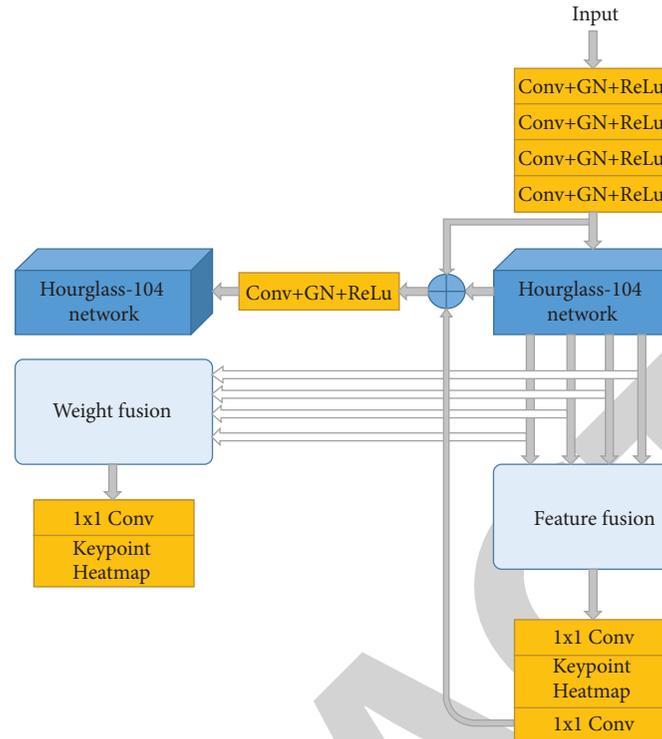

FIGURE 8: Improved CenterNet (Improve-CN) algorithm network structure.

includes bolts, drills, steel bars, and channel steel. The data is obtained through industrial infrared surveillance cameras. The foreign bodies obtained with this mounting type have the largest geometry. Detecting the foreign object early in entering the belt, effectively reducing the missed detection rate. There is no additional light source in the experiment, only the underground lighting source, and the possible miner's head-mounted lamp.

Due to low brightness in the coal mine and the uneven illumination caused by the irritating light source, the image quality obtained is poor. It is necessary to preprocess the directly acquired coal mine images to solve this problem. There is a lot of underground impulse noise in coal mines, so median filtering is performed first to eliminate the influence of noise and slight jitter. Although the effect of noise is eliminated, the contrast of the denoised image is still not high, and it is not easy to distinguish the foreground and background accurately. Therefore, the image continues to be enhanced. The method used is adaptive histogram equalization (AHE). AHE achieves the purpose of adjusting the image contrast by calculating the local histogram of the image and redistributing the brightness. The AHE algorithm improves the local contrast of the original image, makes the dark image brighter, suppresses the overbright area, and obtains more detailed information, which enhances the quality of the image.

Figure 9 compares the original image and the image after median filtering and adaptive histogram equalization.

The dataset in this paper is mainly composed of two classes, namely, "gangue" and "iron" (including channel steel, anchor rod, drill bit, and I-beam), which are marked

with label software. After an image is observed, a file with the suffix "json" will be generated in the directory, which contains the name and ID of the marked image, the category label of the significant object, and the coordinates of the object frame. The coordinates are marked as the coordinates of the upper left corner and the lower right corner of the box. A total of 5,605 images of two types were collected in the dataset of this paper. Since the foreign objects in the coal conveyor belt are mainly gangue, the majority of gangue images are 3,421, and there are a total of 2,184 iron images. The pictures are divided in the dataset, 70% of which are used as the train set, 20% are used as a validation set, and the remaining 10% are used as the test set. The distribution of the datasets is shown in Table 1.

3.2. Network Training. Since the collected dataset pictures are few and cannot meet the training requirements of deep learning, the dataset needs to be augmented. In this paper, the dataset is augmented by random cropping, flipping, rotation, translation, and scaling. There are five types of scaling factors in augmentation (0.5, 0.8, 1, 1.2, and 1.5). During training, Batch size is set to 8, an epoch is 140, and the initial learning rate is 5×10^{-5} . At 90 rounds and 120 rounds, respectively, it is attenuated 10 times, and SGD is used for network optimization. The weight decay rate and momentum factor are designed to be 10^{-4} and 0.9, respectively, and the input image is uniformly scaled to 512×512 sizes. The experiments are all completed on Ubuntu18.04, Nvidia GTX1060 graphics card, E5-2650 v2 CPU, CUDA10.1, cudnn7.6.5, Pytorch1.2.0, and the

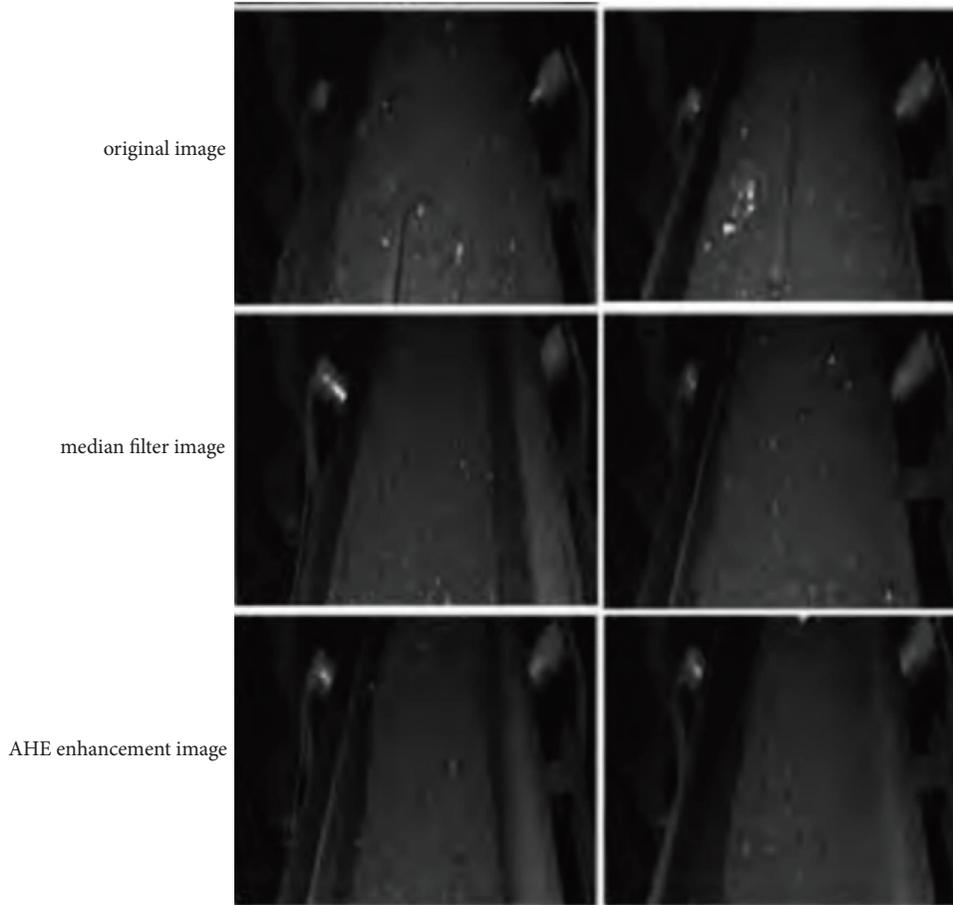

FIGURE 9: Comparison of the three images.

TABLE 1: Foreign object dataset in the coal belt.

Datasets	Gangue/piece	Iron/piece
Train set	2388	1545
Validation set	676	423
Test set	355	223

hyperparameters selection of each algorithm is completely consistent.

3.3. *Experimental Results and Analysis.* After about 100 rounds of training, the network converges. The loss function comparison between the improved algorithm and the original standard CenterNet algorithm is shown in Figures 10–13. The four figures are in order of total loss function curve, center point prediction loss function curve, target box regression loss function curve, and center point bias loss function curve. The abscissa is the number of training rounds, and the ordinate is loss change value. The blue line in the comparison image is the loss curve of the standard CenterNet algorithm and the orange line is the loss curve of the improved algorithm. It can be seen that the loss of the enhanced algorithm is reduced by about 0.3 compared with the original algorithm, and the original algorithm converges in about 120 rounds, that is, the improved

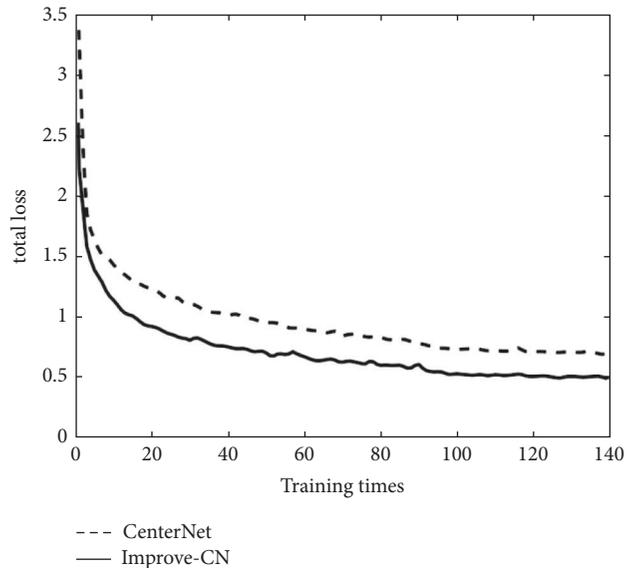

FIGURE 10: Total loss function curve.

algorithm speeds up the convergence speed. It can be seen from the loss function comparison curve that the improved algorithm has a smaller loss value than the original algorithm.

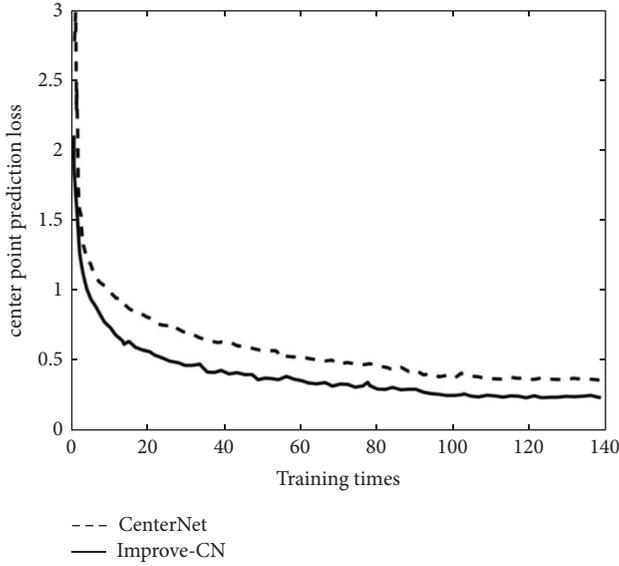

FIGURE 11: Center point prediction loss function curve.

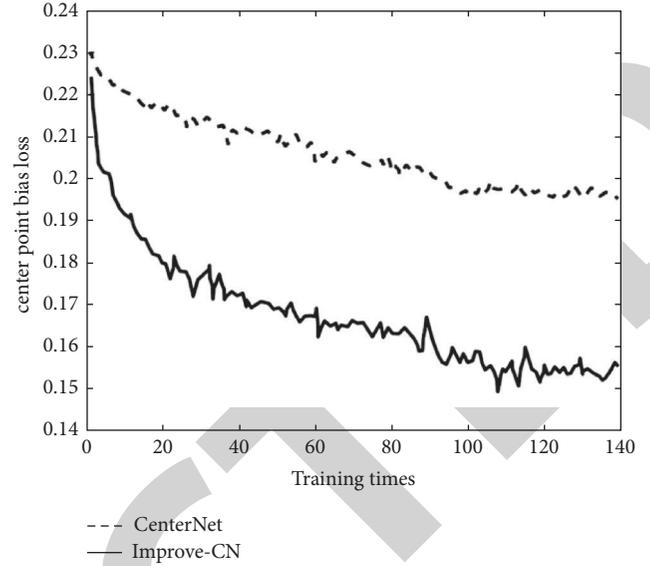

FIGURE 13: Center point bias loss function curve.

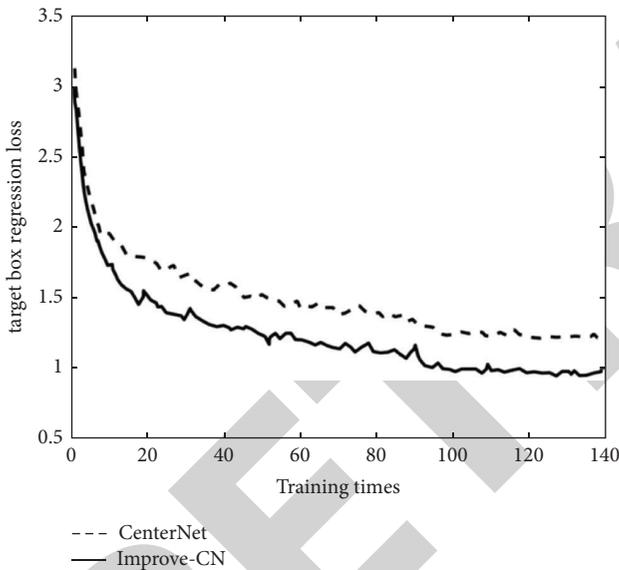

FIGURE 12: Target box regression loss function curve.

The quantitative comparison results of the two algorithms on the test set at 140 rounds are shown in Table 2. The main test indicators are average precision (AP) and average recall (AR), AP reflects the algorithm's accuracy and AR reflects the false detection level of the algorithm. The larger these two indicators are, the better the algorithm's performance is. AP_{50} and AP_{75} in Table 2 are the average accuracy rates when they are $IOU \geq 0.5$ and $IOU \geq 0.75$, respectively. AP_S , AP_M , and AP_L are the average accuracy indicators for small targets, medium targets, and large targets, respectively, and the AR indicators are marked in the same way.

It can be seen from Table 2 that the improved algorithm has a significant improvement in accuracy compared to the original algorithm, and the improved algorithm has

improved target accuracy and recalls for various scales, which is related to feature weighted fusion. By fusing the features at multiple scales, on the one hand, the rich semantic information of the high level can be fully utilized. On the other hand, the spatial location information of the low level can be obtained, which significantly improves the accuracy of the target detection.

Four test images are randomly selected from the test set and tested with the algorithm designed in this paper. The detection results are shown in Figure 14. It can be seen that the proposed algorithm can accurately detect targets of various scales, and the improved algorithm can also accurately detect slender "iron objects," especially those close to the edge of the conveyor belt and along with the movement direction distribution target.

Table 3 compares the detection results of different target detection algorithms in the test set after training under the same dataset. It can be seen that nearly 130 ms reduces the average detection time of the improved algorithm compared with the original algorithm, and the overall accuracy rate is improved by 6.9% or so. Compared with the two-stage faster R-CNN algorithm [23–26], the algorithm before and after the improvement significantly shortens the detection time, but the accuracy rate decreases because the improved algorithm only needs to predict the target's center point compared to the anchor frame. The computational complexity is significantly reduced, so the speed is improved. Still, many anchor boxes provide a greater possibility of correctly detecting the target, so the accuracy rate is higher, and the application can be used to monitor the same transmission belt through multiple cameras to offset this shortcoming. Compared with the one-stage detection algorithm YOLOv3, the detection speed and accuracy of the improved algorithm have been improved. The results show that the enhanced algorithm achieves a good balance between detection speed and accuracy.

Improve-CN	0.0508	0.5521

4. Conclusion

As fixed-point monitoring by network cameras is gradually replacing manual inspection and becoming an essential underground monitoring method for coal mining enterprises, the proposed foreign object detection method can be directly deployed on this basis. As long as the host computer that meets the hardware requirements is configured, the noncoal foreign matter can be detected at the early stage when it enters the coal conveying belt, and an alarm response can be made. In the later stage, the robot can automatically sort the detected foreign objects to realize the integration of foreign object detection and grasping, which can improve work efficiency while protecting personal safety and further reducing potential safety hazards.

Fault diagnosis technology is the science of identifying the operating state of a machine or unit, and it studies the response of the change in the operating state of the machine or unit in the diagnostic information. It can give an early warning to the failure state of the machine and stop the machine before a major failure occurs so as to protect the life safety of the on-site staff and avoid huge economic losses to the enterprise. For mechanical equipment, fault diagnosis consists of three main links: fault detection; fault identification; and fault classification. Aiming at the problems that need to be solved in the fault diagnosis of industrial robots, this paper adopts a data-driven intelligent diagnosis method to establish a fault diagnosis model of industrial robots based on Deep Belief Network (DBN) and DSMT theory. Firstly, based on wavelet transform and information energy entropy correlation theory, the vibration signal of industrial robot is extracted, and the energy entropy normalized eigenvector is established. Then, the energy entropy normalized feature vector is divided into training set and test set to complete the creation of DBN network model. Finally, using DSMT theory to carry out decision-making fusion, a fault diagnosis model for industrial robots is established, and experiments are carried out on the K-R-R540 robot to verify the applicability of the established fault diagnosis model. It is proved by experiments that the industrial robot fault diagnosis model based on the deep belief network can meet the requirements of the recognition accuracy of robot faults, and the model will perform poorly when the faults coexist with multiple faults.

1. Introduction

The efficient production of industrial robots is the key to ensure the whole product production system of the enterprise. Therefore, enterprises and researchers pay attention to keeping industrial robots in an efficient working state. For enterprises, once the system of industrial robots breaks down, it will lead to the stagnation of the whole production line. If the faulty robot cannot be repaired in time, the robot fault may evolve into a huge production accident, and even threaten the life safety of enterprise staff. After the industrial robot is put into use, its application is under the artificial inspection and maintenance mechanism under strict regulations. The enterprise needs to invest a lot of human resources to complete the daily, weekly, and monthly inspection and maintenance of the industrial robot, and according to the inspection and maintenance record, the itinerary of the final equipment working state, and take this

as the basis to form the equipment maintenance manual of the industrial robot and summarize the equipment parameters of the industrial robot in the fault state. After data analysis, the failure frequency of each equipment, as well as the failure law and failure cause, is obtained so as to accumulate practical experience for dealing with the failure in the future. This traditional industrial robot fault diagnosis has obvious disadvantages. It needs to consume a lot of human and material resources to complete, which is unbearable for ordinary small enterprises. Because they do not have a professional enterprise maintenance team to ensure production safety, they are finally banned in the fierce market competition. Moreover, with the continuous progress of production and the uncertainty and randomness of industrial robot fault itself, it is still unable to achieve timely early warning and fault isolation for unexplained faults, which is difficult to meet the efficient and safe requirements of industrial production.

Fault diagnosis is to identify and judge the early fault characteristics of the equipment through various monitoring methods based on the operation status of the equipment so as to formulate relevant maintenance plans. Based on the above research background, this paper will take industrial robot as the research object, based on signal processing knowledge and deep learning theory, and with the help of industrial robot fault simulation platform, study the application of deep confidence network in industrial robot fault diagnosis. From the perspective of practical considerations, when the industrial robot has faults or potential faults, the research in this paper can accurately identify the fault type and judge the fault degree, provide the basis for subsequent maintenance decisions, greatly reduce the downtime, and reduce the direct and indirect economic losses. From the perspective of theoretical research, it can enrich the content of industrial robot fault diagnosis methods and provide a certain theoretical reference and basis for the development of related research work [1–10].

2. Related Work

The widespread use of industrial robots requires researchers to monitor and evaluate their working status in real time. In order to achieve this goal, domestic and foreign scholars and experts have done a lot of research. Freeman et al. proposed that, by analyzing the robustness of the fault cause, the corresponding filter can be designed to eliminate strong interference, and the fault diagnosis of the underwater robot can be realized by calculating the residual error of the model. Saleh Ahmad et al. established a fault diagnosis system based on a reconfigurable robot model by applying additional force and torque sensors at the joints of the robot. This method requires additional sensors to be added to the structure of the robot, resulting in the failure of the robot hardware. *Additional Charges*. Hashimoto et al. established a fault diagnosis model based on Bayesian time series by analyzing the failure causes of the robot under working conditions, which can quickly identify the occurrence of robot faults and isolate them. This method requires a large number of system parameters of robot faults as prior conditions to guarantee the accuracy of the model. Verma et al. established a robot fault diagnosis method based on discrete-time observer by designing an observer method and completed the fault diagnosis of robot joints through the cooperation of detection and diagnosis observers. This method requires a large amount of joint sensor information. Jaber et al. analyzed the fault signals of the robot under various working conditions by collecting the vibration signal of the working state of the robot, using wavelet transform, time-frequency domain analysis, and other methods to realize the fault diagnosis of the robot. Ferreira et al. used the synovial observer to establish a robot fault diagnosis model and applied it to the fault diagnosis of the COMAU robot. The experiment proved that this method can achieve accurate diagnosis for a single fault, but it does not perform well in the diagnosis of robot fault states with multiple faults coexisting. The safe operation of industrial robots requires maintenance personnel to complete the processing of the

faults that have occurred or will occur in time. The traditional fault diagnosis methods have been unable to adapt to the current production mode of enterprises. The establishment of a fault diagnosis model suitable for industrial robots is to solve this problem. Due to the complex structure of industrial robots, concurrent failures often occur. It is precisely because of the existence of this problem that a fault diagnosis method for industrial robots based on analytical thinking logic has been proposed. By using the idea of deep learning, it is possible to explore and identify the intrinsic relationship between various types of faults in industrial robots. So that when the robot fails, it can easily solve the failure problem in the operation of the industrial robot [11–15].

3. Related Theoretical Methods

3.1. Failure Analysis of Industrial Robots. The failure forms of industrial robots usually manifest as control system failures and drive system failures. Therefore, industrial robot failures can be divided into two categories: logical failures and physical failures. Logical faults are mainly caused by the failure of the industrial robot control system, and the robot cannot complete tasks according to the instructions, which is mainly manifested in the decline of performance indicators; physical faults are mainly due to the robot shutdown caused by the hardware failure of the industrial robot, including circuit aging or damage, motor failure, bearing wear, and reducer failure. Table 1 shows several common failure forms, failure characterizations, and failure causes of industrial robots. It can be seen from Table 1 that there is not a simple one-to-one correspondence between the failure forms of industrial robots, the failure representations, and the failure causes. Some more complex failure forms and failure representations correspond to multiple failure causes, and some failure causes will also occur. There are many different forms of failure characterization. Since the failure of industrial robots will be accompanied by changes in vibration signals, and it is precisely because of this unique feature, the easiest way to evaluate the current working state of industrial robots is to judge the vibration signals of industrial robots. According to the basis, as well as having good applicability, using vibration signal as the fault of industrial robot is also used as a main research method to study the fault of industrial robot [16].

3.2. Deep Belief Networks

3.2.1. Restricted Boltzmann Machines. Ordinary Boltzmann Machine (BM) is the predecessor of RBM. Each BM structure consists of two layers of networks, which are defined as the visible layer v and the hidden layer h , respectively. Figure 1 shows the BM structure. It can be found that the network structure of BM is fully connected by random neurons, so it has a strong ability to learn specific rules from complex data in an unsupervised form, but at the same time its disadvantages are also obvious. The fully connected structure makes the network. The training time is long, and the computational cost is high. The emergence of

TABLE 1: Several common failure forms, failure characterizations, and failure causes of industrial robots.

Failure form	Fault characterization	Cause of issue
Power system failure	The robot cannot be powered on	Power circuit failure
	Robot cannot move	Power chip failure
	The host computer restarts	Short circuited
Control system failure	Controller cannot be powered	Damaged control chip
	The control port is unstable	Control chip soldering
		Controller failure
	Robot out of control	Control program run away
		Damaged control chip
Drive joint failure		Motor stuck
	Motor failure	Driver chip failure
		Motor overcurrent protection
		Bearing wear
	Bearing fracture	
	Reducer failure	Damaged reducer
		Coupling loose

RBM is to improve the defects of BM network structure; it is a new unsupervised learning network structure model based on greedy learning. Except for the undirected nature of the interlayer connection, there is no difference from the general BM principle in terms of network definition of each layer, neuron output and representation, and neuron state value rules. Figure 2 shows the RBM structure organization. The energy model of RBM can be intuitively understood as follows: a small ball with a rough surface and an irregular shape is placed anywhere in a large bowl with a very rough surface. Affected by gravitational potential energy, generally speaking, when the state is stable, the probability of the ball staying at the bottom of the bowl is the greatest, and of course there is a certain possibility that it will stay at other positions in the bowl. In the theory of the energy model, the final stable stop position of the ball is defined as a state, each state corresponds to an energy, and this energy can be represented by an energy function. So, in a sense, the probability that the ball is in a certain state can be expressed by the energy of the ball in the current state [17].

3.2.2. *Basic Structure of Deep Belief Network.* RBM is an important foundation of DBN. From the macroscopic point of view, the network structure of DBN is mainly composed of several RBM stacks and a labeled classifier, as shown in Figure 3. As can be seen from Figure 3, this deep DBN network has four layers of hidden units, the input of the network is the sample data that meets the requirements, and the top is the label information corresponding to the input data. First, the prepared input sample data is assigned to each neuron in the visual layer of the first layer one by one, after a series of iterative training and learning (i.e., forward greedy learning and backward fine-tuning; the specific process will be introduced later), the weight matrix between each layer and the bias value of each neuron will reach a certain stable state, which can fit the training samples to the maximum extent. After the training is completed, when a test data sample is input, the trained network will automatically analyze and process the data and assign the possibility of each category according to the calculation

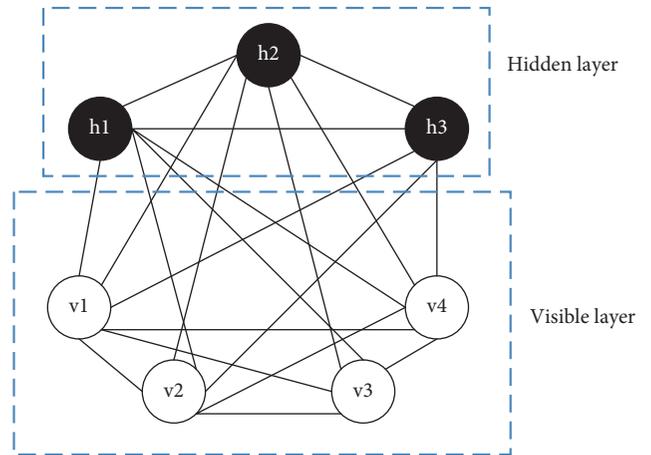

FIGURE 1: Schematic diagram of BM structure.

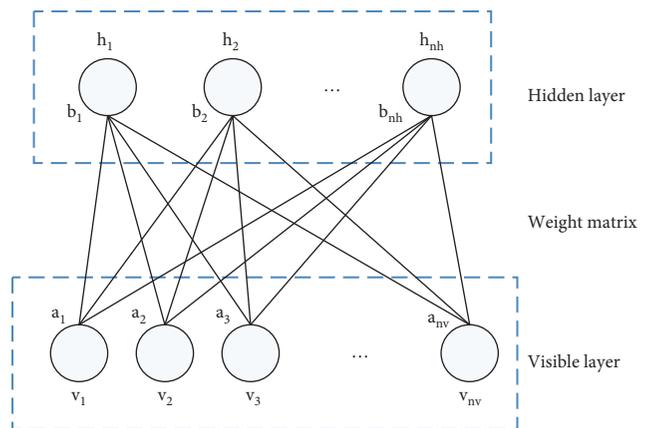

FIGURE 2: Basic structure of RBM.

result, and the sample will be included in the corresponding category with the highest probability. Inside the network, all feature data can share the entire network information together. This sharing mode makes it more convenient to extract the deep features of the data and can significantly enhance the memory capacity of the entire network. The

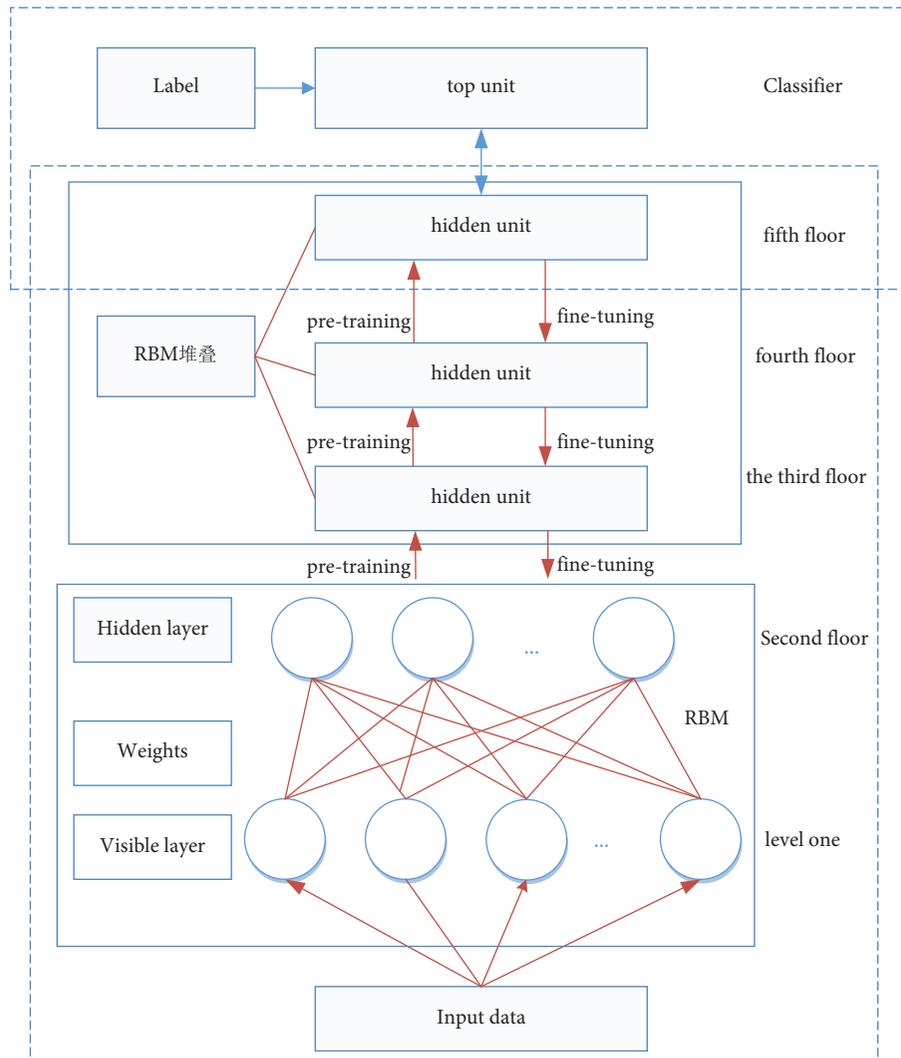

FIGURE 3: Schematic diagram of DBN network structure.

training process of DBN mainly includes two processes: forward greedy learning and backward fine-tuning. The greedy learning process of RBM is mainly to extract and mine the feature information of the input data layer by layer, and the backward fine-tuning process is to fine-tune the structural parameters of the entire DBN network through the known labels so as to adjust the parameters in the deep layer containing multiple hidden layer parameter vectors [18]. Through the neuron of the deep belief network and the ability to extract and mine the feature information of the input data layer by layer, it has a good application performance in industrial robot diagnosis.

3.2.3. Forward Greedy Learning. The forward greedy learning process is also called stacked RBM pretraining. In the whole process, the algorithm itself learns the data without the participation of label information, which belongs to a category of unsupervised learning. Before the DBN algorithm was proposed, one of the main bottlenecks encountered by the BP neural network was that when the number of network layers

was too large, the problem of gradient dispersion would occur during the training process, resulting in a poor learning effect of the entire model. The proposed unsupervised greedy learning method solves this problem, it divides the deep network into multiple shallow network structures and restricts model training and parameter adjustment to this shallow networks, good training results for the entire model can be achieved. The forward greedy learning process is shown in Figure 4. As can be seen from Figure 4, the training in each step is completed within a certain RBM. In the first step, the input data is assigned to the neurons of the visual layer, the data of the visual layer v is mapped to the hidden layer h_1 through greedy learning, and then the hidden layer h_1 is reconstructed through the CD-k algorithm to return to the hidden layer. View layer, and adjust the internal weights and biases after calculating the reconstruction error. On the basis of the first step, use the fully trained parameter vector to solve the hidden layer h_1 , and use it as the input of the second RBM structure, and train the subsequent RBM structure in the same way until the training of the entire DBN network is completed [19–21].

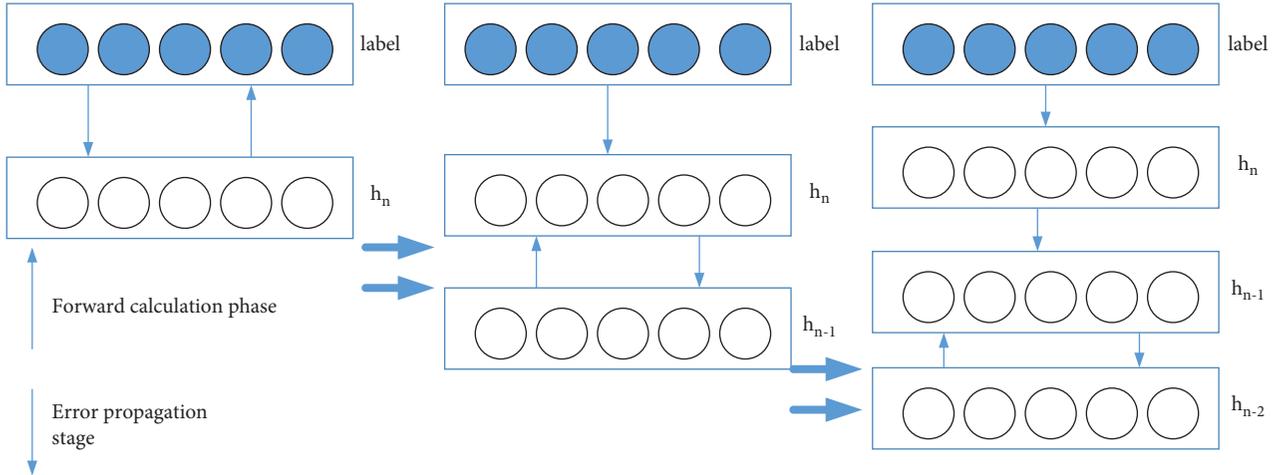

FIGURE 5: Background fine-tuning process.

and joint 6 is close, it is only at the end. Three acceleration sensors are applied to the actuator, corresponding to sensor 6, and no acceleration sensor is added to joint 6. Figure 6 shows the schematic diagram of the experimental platform. The vibration data is transmitted to the data acquisition and storage system through the single acceleration sensor applied to the robot joint and the three acceleration sensors of the end effector, and the subsequent analysis is performed by the computer.

4.2. Experiment Content and Data Collection

4.2.1. Experiment Content. Due to the interference of the motion frequency and resonance frequency of the robot, there is a large error in the original signal of the sensor. The range of the motion frequency and resonance frequency of the robot is obtained through the modal analysis experiment, and the signal is filtered by designing a filter. The time length is divided into experimental samples to obtain experimental data sets. In order to realize the creation of the robot fault diagnosis model, it is necessary to design experiments to collect the response joint vibration signals. Due to the limitation of technology and cost, the robot failure state used in this section is described as the robot's end pose deviation, which is not within the allowable range. The fault is a fault at the joint, and the fault is in the form of a simulated fault. The vibration exciter is set to continuously excite and interfere with the joint motion of the robot, resulting in the deviation of the robot's end pose beyond the allowable range. Set the robot running trajectory as a straight line in space. As shown in Figure 7, the vibration exciter interferes with the movement trajectory of the robot end effector before and after joint 1. In Figure 7(a), the movement trajectory of the robot end effector is in normal state; Figure 7(b) is the motion trajectory of the robot end effector after the vibration exciter interference (the point where the maximum deviation is intercepted is enlarged and displayed, and the different colors in the figure represent the repetitive motion trajectory of the robot). Since the error range of the robot's end effector is $[0, 0.35 \text{ mm}]$, comparing Figures 7(a)

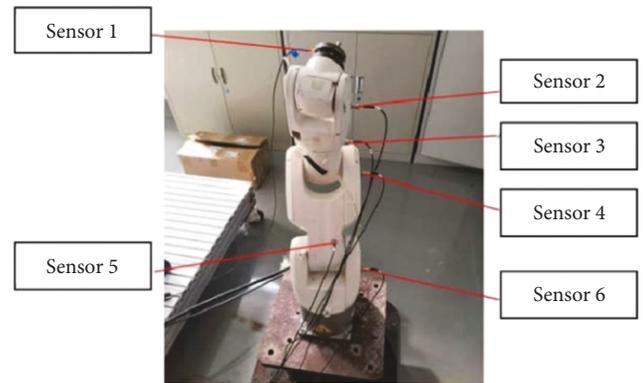

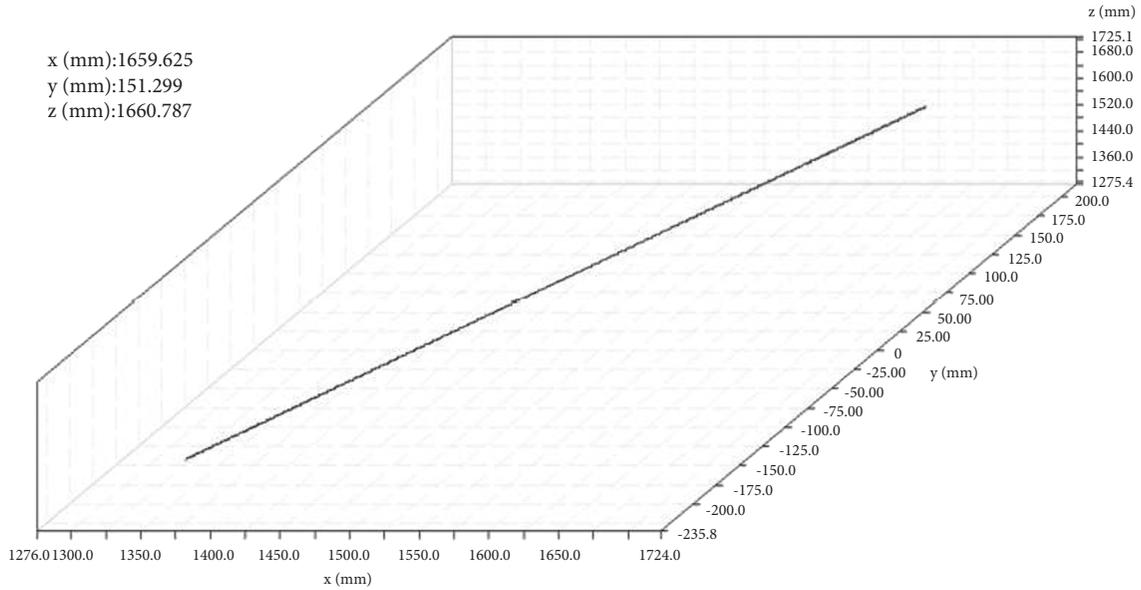

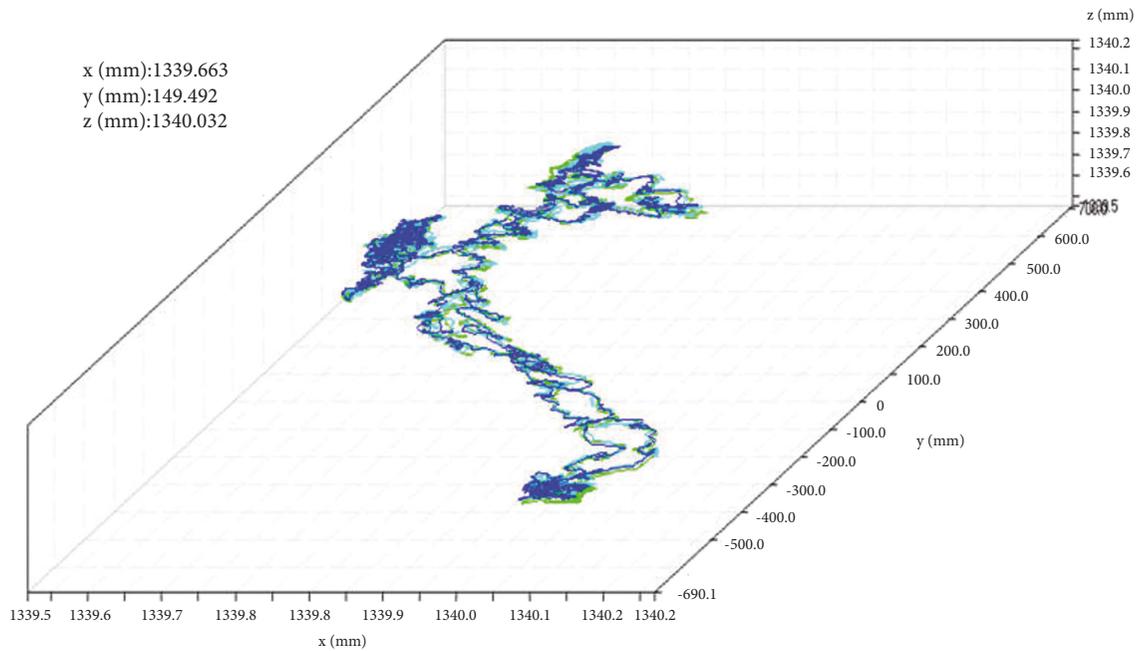

FIGURE 6: KR-3-R540 robot sensor layout.

and 7(b), it can be concluded that the pose accuracy of the robot's end effector is accurate after applying continuous excitation with the exciter. Serious deviation occurs. At this time, the robot state is regarded as a fault, and the specific fault is the fault at joint 1.

The specific content of the experiment includes the following steps: (1) Using the KR-3-R540 robot teach pendant, randomly set 10 closed-loop motion trajectories for the robot, and let the robot run at 30%, 50%, and 70% of the maximum speed. Complete the command movement, and the movement time is 20 s. (2) According to the above, set the robot joint fault; the fault status is divided into five categories; the first type of fault is expressed as no fault, the second type of fault is expressed as a joint fault, and the third type of fault is expressed as two joint faults, the fourth type of fault is represented as three joint faults, and the fifth type of fault is represented as four joint faults; the fault locations are set as joint 1, joint 2, joint 3, and joint 4. The detailed description of the fault is shown in Table 2. (3) Acceleration sensors are used to collect vibration signals of joints and end effectors in all working states of the robot. The sensors at the joints are single-term sensors, and the end-effectors are three-term sensors.

(a)

(b)

FIGURE 7: Comparison of the movement trajectories of the robot end effector before and after the exciter interference. (a) The motion trajectory of the robot end effector under normal conditions. (b) The exciter interferes with the movement trajectory of the robot end effector of joint 1.

4.2.2. *Experimental Data.* The joint vibration data of the robot is used to complete a series of steps to establish a fault diagnosis model suitable for the robot. Due to the limitation of technology and operation space, the acceleration sensor cannot be set inside the robot, but the sensor can only be set on the robot shell, which will inevitably collect the motion vibration signal and the robot resonance signal generated by the robot during the movement process. Filters need to be designed to eliminate these two interference signals. According to the modal analysis results, it can be known that

the motion frequency of the robot is about 100 Hz; the resonance frequency is about 2200 Hz.

In this study, the vibration data acquisition system under the LabVIEW platform was designed, and experiments were carried out on the gear fault simulation test bench, and the gear fault diagnosis data set under different working conditions was obtained. After the vibration signal is collected under all working states of the industrial robot, the corresponding experimental data are obtained, and a total of 150 sets of different experimental source data are

TABLE 2: Robot fault description.

Fault description	Type 1 fault	Type 2 fault	Type 3 fault	Type 4 fault	Type 5 fault
Joint 1	0	1	1	1	1
Joint 2	0	0	1	1	1
Joint 3	0	0	0	1	1
Joint 4	0	0	0	0	1

Note. "0" means there is no fault at the joint; "1" means there is a fault at the joint.

obtained. Each group includes the vibration signals of each joint and the end effector, a total of 1200 sets of sensor source data. First, filter the source data, and set the filter parameters as follows: the low-pass filter frequency is 100 Hz, and the high-pass filter frequency is 2200 Hz. Then, 1200 sets of source data are divided with 0.1s as the sample length, and 240000 experimental samples are obtained, of which the number of experimental samples in normal state is 48000, and the number of experimental samples in all five fault states is 192000. The vibration signal dataset of the robot is shown in Table 3.

5. Fault Diagnosis of Industrial Robot Based on Deep Belief Network

5.1. Creation Process of Fault Diagnosis Model. This section creates an industrial robot fault diagnosis model based on a deep belief network (DBN). First, the wavelet transform is used to decompose and reconstruct the vibration signal of the industrial robot joint and the end effector. Then, the energy entropy normalized eigenvector of the wavelet reconstructed signal is constructed using the information energy entropy and normalization theory. Finally, the normalized feature vector is divided into a training set and a test set. The training set is used for forward layer-by-layer training and reverse fine-tuning of the basic parameters of the fault diagnosis model. The test set is used to test the accuracy of the fault diagnosis model.

5.2. Initialize DBN Network Parameters. In the process of establishing a fault diagnosis model, it is necessary to initialize the basic parameters of the DBN network, including the number of layers of the DBN network model, the dimension of the underlying input sample, the dimension of the upper output label, and the forward unsupervised layer-by-layer training learning rate, inverse fine-tuning learning rate, number of iterations, momentum factor, and weight matrix and bias. Among these basic parameters, the number of model layers and the number of iterations can be set according to experience, mainly based on model training time and model accuracy; the underlying input sample dimension is determined by the number of elements of the energy entropy normalized feature vector. The label dimension is determined by the fault category labels contained in the sample data; the weight matrix, bias, learning rate, and momentum factor can be determined according to the following rules. (1) Initial setting of the weight matrix and bias: the initial setting of the weight matrix directly affects the training speed of the model. If the initial setting of the

connection weight is too large, the fault classification result will not meet the requirements, and the setting value is too small. This can lead to severely slow model training, neither of which is desirable. Usually, the initial setting of the weight should be a normal distribution conforming to $N(0, 0.01)$, and the initial setting of the bias between the visible layer and the hidden layer can be 0. Because in the process of DBN network training, the weight matrix and bias will be continuously updated according to the update criterion, which can be initialized according to the empirical formula. The empirical formula is expressed as follows:

$$\begin{aligned} w &= 0.1 \times \text{randn}(n, m), \\ a &= \text{zeros}(1, n), \\ b &= \text{zeros}(1, m). \end{aligned} \quad (1)$$

In the formula, n is the number of input layer neuron units and m is the number of output layer neuron units.

(2) Initial setting of learning rate: the learning rate is a key parameter of the gradient descent algorithm, an important basic algorithm in the DBN network training process, which determines the gradient descent distance each time the algorithm is executed. If the initial set value of the learning rate is relatively small, it will cause the model to step too slowly towards the minimum loss function value, which will take extra time to complete the model training; if the initial set value is large, it will lead to DBN. The reconstruction error of the network is too large, which will seriously cause model training failure. The initial setting of the forward unsupervised layer-by-layer training learning rate of the DBN model is generally 0.1, and the initial setting of the reverse fine-tuning learning rate is generally 0.01.

(3) Initialization of momentum factor: the main role of momentum factor in DBN model training is to improve the antioscillation performance of the training process by introducing the estimated gradient value after the previous iteration into the algorithm so that the algorithm can converge quickly and stably to the allowable range.

$$\begin{aligned} \theta_{t+1} &= \theta_t + \Delta\theta_t, \\ \Delta\theta_t &= m_b \Delta\theta_{t-1} + \varepsilon \times \frac{\partial \ln L}{\partial \ln \theta}. \end{aligned} \quad (2)$$

In the formula, m_b is momentum factor; ε is learning rate; and $\partial \ln L / \partial \ln \theta$ is sample gradient.

The formula is the parameter update formula of the DBN network after adding the momentum factor. After the momentum factor is introduced, the update value of the DBN network parameter is calculated by the sample gradient

TABLE 3: Robot vibration signal dataset.

Running speed	Type 1 fault	Type 2 fault	Type 3 fault	Type 4 fault	Type 5 fault
30%	16000	16000	16000	16000	80000
50%	16000	16000	16000	16000	80000
70%	16000	16000	16000	16000	80000
Total	48000	48000	48000	48000	24000

and the correction value after the last iteration. The initial value of the momentum factor is generally set to $[0.5, 0.9]$.

5.3. Model Accuracy Analysis. According to the analysis, it can be determined that the number of wavelet envelopes is 7. Figure 8 shows the energy entropy normalized eigenvectors corresponding to different wavelet base numbers. The abscissa is the wavelet packet decomposition node, and the ordinate is the element value in the energy entropy normalized eigenvector. It can be seen from the comparison in the figure that when the wavelet base is db1, there are still obvious differences after the 96th node, and the signal information is relatively complete; when the wavelet base is greater than db1, especially when the wavelet base is above db4, at 96. The normalized energy entropy of all nodes after the node is close to 0, the difference between the nodes is very small, and the signal information is seriously lost. In order to make the normalized energy entropy feature vector have a good representation and meet the requirements of the underlying input of the DBN model, the wavelet base is selected as db1 in this paper.

The software used in this section is MATLAB 2019b, the operating system is Windows 10, the CPU is Intel Core i7, the graphics card is NVIDIA 930 M, and the running memory is 8 G. Divide the sample data into training set and test set according to the ratio of 4:1. The training set includes 192,000 experimental samples (38,400 normal experimental samples and 38,400 each of 4 types of fault experimental samples); the test set contains 48,000 experimental samples (9,600 normal experimental samples and 9,600 each of 4 types of fault experimental samples). According to the decomposition level of 7 and the wavelet base of db1, the wavelet packet is decomposed and normalized. Each experimental sample can construct an energy entropy normalized feature vector containing 128 elements. The training set of the DBN network model is 192,000 input samples, and the test set is 48,000 input samples. The input layer item of the DBN network model is 128, the output layer is represented as the sample fault label, and the output layer item is 6. The basic parameters of the DBN model are shown in Table 4, and the sample labels corresponding to the output layer are shown in Table 5. The number of iterations of the

Sample description	Sample label					
Class I failure	0	0	0	0	0	0
Type II fault	1	0	0	0	0	0
Three types of faults	1	1	0	0	0	0
Four types of faults	1	1	1	0	0	0
Five types of faults	1	1	1	1	0	0

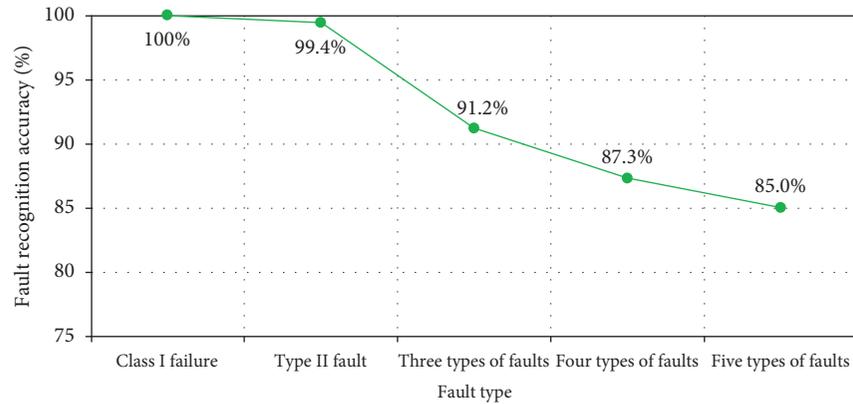

FIGURE 9: The fault identification accuracy of the fault diagnosis model based on DBN network when dealing with different fault states.

DBN model is set to 100, the number of inverse tuning times is preset to 100 and multiplied to 1000, and the learning rate and momentum factors are set to 0.1 and 0.9, respectively. Figure 9 shows the fault identification accuracy under different tuning times. It can be seen from Figure 9 that when the number of iterations reaches more than 900, the fault identification accuracy tends to a fixed value of 99.4%. It can be seen that the number of forward iterations of the DBN model used in this paper is 100 times, and the number of reverse tuning times is 100 times, should not be less than 900 times.

Figure 10 shows the fault identification accuracy of the fault diagnosis model based on DBN network when dealing with different fault states. It can be seen from the figure that the fault identification accuracy of the fault diagnosis model based on the DBN network can reach 99.4% when dealing with a single fault, and with the increase of the number of faults, the fault identification accuracy of the model also begins to decline, especially when dealing with the first fault. When there are five types of faults, the fault recognition accuracy is only about 85%. It is concluded that the fault

diagnosis model based on DBN network used in this chapter is not good in dealing with the fault diagnosis of multiple faults coexisting, and the model needs to be further improved.

6. Conclusion

The status of industrial robots in industrial production is getting higher and higher, and its normal operation is directly related to production safety, and it is also particularly important for the fault diagnosis of industrial robots. In order to improve the fault recognition accuracy of the industrial robot fault diagnosis model, this paper is based on the DSMT theory, and the results of the DBN network model diagnosis are fused at the decision level to achieve the purpose of improving the fault recognition accuracy of the model. Taking the output layer of the fault diagnosis model of the DBN network as the fault evidence, the conflict between the pieces of evidence is analyzed, the fusion rules and decision rules of DSMT are selected, and the fault diagnosis model based on DBN and DSMT is established. According to the requirements of the model for the experimental sample data, an experimental platform is built, the basic

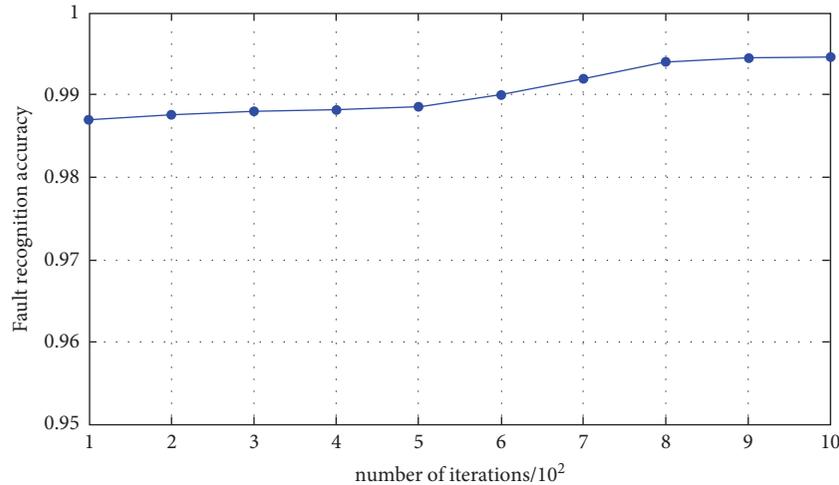

FIGURE 10: Fault recognition rate under different tuning times.

parameters of the DBN fault diagnosis model are determined through MATLAB programming, and a fault diagnosis model suitable for robots is established; finally, the fault diagnosis used in this experiment is verified by design experiments. The applicability of the model: It can be seen that the fault recognition accuracy of the industrial robot fault diagnosis model based on the DBN network can reach 99.4% when dealing with a single industrial robot fault. With the increase of the number of industrial robot faults, the industrial robot fault recognition accuracy of the model also begins to decline. Especially when dealing with the fifth type of fault, the accuracy of industrial robot fault recognition is only about 85%.

Public cultural services for the elderly are part of the government-led public services for society in order to meet the needs of people's spiritual and cultural life. As the global problem of ageing becomes increasingly serious, the problem of balancing the supply and demand of public cultural services for the elderly has become increasingly serious. How to realize a public cultural service system for the elderly with wide coverage and effective integration of resources has become a pressing problem to be solved. In order to solve the above problems, this article designs a public cultural service system for the elderly based on intelligent computing. Firstly, the problems that lead to the inefficient use of public cultural resources for the elderly are analyzed. Secondly, it attempts to introduce an advanced intelligent computing technology (Cuckoo Search) to build a three-dimensional public cultural resource sharing system for the elderly. Then, the standard Cuckoo algorithm is improved by using chaotic mapping and dynamic step size for the characteristics of public cultural services in order to improve the convergence speed and the accuracy of the search. The experimental results show that the designed system can effectively integrate the grassroots resources of cultural institutions such as libraries, cultural centres, and cultural service centres, verifying its effectiveness and feasibility.

1. Introduction

The right to culture is one of the fundamental rights of citizens. It is an important duty of governments to attach importance to and protect the basic public cultural rights of citizens. With the rapid development of the economy, the people have begun to pursue spiritual satisfaction after satisfying their material needs. People's demand for public cultural services is growing rapidly and is characterised by multilevel, differentiation and personalization. The ageing of the population is a major social issue in the twenty-first century and a major feature of human development in the twenty-first century. With the development of the country's economy and the improvement of people's living standards, the number of elderly people is increasing at an unprecedented rate [1–3]. Under the premise that material living conditions are basically satisfied, the spiritual and cultural needs of the elderly are receiving more and more attention.

The cultural industry for the elderly is an ageing business that aims to meet the spiritual and cultural needs of the elderly. The content of social security is divided into three levels: economic security, service security, and spiritual security [4–7]. Social security for the elderly is an important element of social security. Maslow's Hierarchy of Needs theory gives an incisive overview of the hierarchy of human needs. It is of great significance at this stage to organically combine public cultural services with the cause of the elderly so as to drive up the level of elderly services for the whole society. The construction and management of public cultural services is a process of gradual rise and improvement. Public cultural resources for the elderly are an important support to meet the growing cultural needs of the general public. In this context, it is of great practical importance to make a scientific analysis of the problems in using public cultural resources and to explore new ways of integrating resources.

With the growing differentiation in demand for public cultural services, a single cultural resource is no longer able

to meet the cultural needs of the majority of older people, and the integration of public cultural resources has begun to attract the attention of academics. Due to different research perspectives and local practices, researchers have conducted different studies on the integration of public cultural resources. After summarising, current research mainly discusses the integration of public cultural digital resources, the integration of public cultural resources, and the integration of public cultural resource paths [8–11]. The comprehensive use of various current advanced management methods and technologies to optimise the allocation of resources and to develop a reasonable integration plan are key elements in the design of public cultural service systems for the elderly. Currently, most of the public cultural resources management methods and integration schemes are still only in the original fixed manual mode. The low level of automation and informatization has resulted in a public cultural service system that is unable to meet the changing needs of older people. In other words, the existing public cultural service system for older people does not meet the time-sensitive requirements of changing needs. Therefore, the main objective of the design of public cultural services for older people is to optimise the allocation and path of the main resources according to the changing needs in real time.

At present, researchers have applied integer programming, linear programming, dynamic programming, and objective programming methods in operations research to solve a part of representative public cultural resources integration and optimisation problems. However, most of the public cultural resources integration and optimisation problems are NP-Hard problems, so the existing solution methods and strategies are not yet effective in solving the allocation of public cultural resources in real life. For example, the optimal solution algorithm can find the optimal solution to the scheduling problem in polynomial time for a specific optimisation objective, including the branch-and-bound method, mathematical planning method, and dynamic planning method. Kolpakov [12] used the branch-and-bound method to find the optimal solution to the small-scale problem with this objective based on the actual situation of production management with the objective of minimising time cost. For the feasible boundary problem along the positive direction of the gradient, Okon [13] proposed a multiobjective optimal solution for linear programming. Although the optimal solution algorithm can obtain an optimal solution, it requires an infinite exhaustion of the solution space of the problem and is therefore computationally too costly in terms of time. Based on knowledge and experience in solving scheduling problems, heuristic algorithms can obtain suboptimal solutions in a short time, such as goal tracking methods, linear relaxation methods, and domain search algorithms. For example, Güney [14] proposed a linear programming relaxation method for solving sequencing problems, implementing a 2-approximation algorithm based on three certainties. Although heuristic algorithms can construct problem solutions quickly, the quality of the solutions is poor. Heuristic algorithms often require a large number of iterative operations, and the solution efficiency and quality are greatly

influenced by the structure of the algorithm and the choice of parameters.

Intelligent computing is a new type of algorithm developed by simulating natural organisms, with features such as self-organization, self-learning, and self-adaptation. The collective movement of groups of animals in nature is a very interesting phenomenon. Each member of a group of animals is an individual, yet all the individuals are able to form a whole. Intelligent computing mainly includes genetic algorithms, forbidden search algorithms, simulated annealing algorithms, particle swarm algorithms, and ant colony algorithms. Intelligent computing is easier than general heuristic algorithms to find suboptimal solutions close to the optimal solution of a problem. Gong et al. [15] proposed an ensemble genetic algorithm for solving interval multi-objective optimisation problems and demonstrated that intelligent computing has faster solution speed and better solution accuracy. Pan et al. [16] proposed a caching strategy for ethnic traditional sports video resources based on intelligent computing. Experimental results show that the ant colony simulated annealing algorithm can improve the hit rate of the content on mobile edge computing servers.

The most important issue in the design of public cultural services for older people is the optimisation of resource allocation and pathways. However, when the number of individual older people is large, the traditional method of manual resource integration consumes a lot of time and effort. In addition, the lack of adaptiveness of the traditional manual resource integration method leads to public cultural resources being restricted to a fixed path, which is inflexible and cannot meet the timeliness in real life. Therefore, in order to solve the above problems, this article proposes introducing intelligent computing [17–20] into the design of public cultural services for the elderly. By simulating the movement behaviour of a large-scale group of elderly people in real time, the optimal location and path of cultural resources can be planned. The Cuckoo Search (CS) algorithm [21–24] is an emerging type of group intelligence algorithm that can imitate the movement behaviour of a flock of birds searching for the best nest location, with strong local and global search capability and convergence speed. Therefore, the CS algorithm is used in this article to simulate the movement behaviour of groups of elderly people.

The main innovations and contributions of this article include the following:

- (1) This article introduces advanced intelligent computing technology (Cuckoo Search) to build a three-dimensional system for sharing public cultural resources for the elderly.
- (2) The standard CS algorithm is improved for the limited range of optional spaces in public cultural services using chaotic mapping and dynamic step size in order to improve the convergence speed and optimisation finding accuracy.

The rest of the article is organized as follows: in Section 2, the problems in the existing public cultural services system for older people are studied in detail, while Section 3

provides the problem statement and research ideas. Section 4 provides the public cultural service system for the elderly based on an improved CS algorithm. Section 5 provides the simulation results and analysis. Finally, the article is concluded in Section 6.

2. Problems in the Existing Public Cultural Services System for the Elderly

2.1. Inadequate Supply of Public Cultural Resources. Older people use public cultural facilities through cultural institutions such as libraries, cultural centres, and cultural service centres. A statistical survey was conducted on the public cultural resources for older people in a provincial capital city in China, for example. It was found that the service effectiveness of cultural institutions was unevenly distributed in most areas. For example, cultural service centres are too small and not well equipped. In addition, the number of mass cultural and sports activities organized by cultural institutions was less than 10 per year. Although public libraries and cultural centres at all levels have public electronic reading rooms and provide free access to the Internet, the speed of access to the Internet is unsatisfactory, and the facilities are not well equipped. However, the speed of access to the Internet is not satisfactory, and the resources available are very limited.

2.2. Public Cultural Resources Are Too Dispersed. For a long time, public cultural resources for the elderly have been scattered across a number of grassroots departments. Each department uses the public cultural resources it has in its own area to provide public cultural services for the elderly population. The constraints of the administrative system have created a situation where grassroots public cultural resources are too scattered to be effectively integrated, which is not conducive to the full utilisation of grassroots public cultural resources. In particular, the layout of grassroots public cultural facilities is unreasonable.

Firstly, the government deliberately pursues the agglomeration effect of public cultural facilities, resulting in many public facilities being concentrated around local administrative centres. This type of layout planning ignores the service radius of public cultural facilities, which makes it very inconvenient for the public to use public cultural facilities. Due to the rapid development of urbanisation, local administrative centres are located far away from the city centre. Secondly, due to the constraints of construction land conditions, many cultural centres or cultural service centres are built in the corners of cities, towns, and villages. Such a layout is also very unreasonable. It is not convenient for the masses to participate in activities, resulting in the marginalisation of cultural service institutions. In the long run, grassroots cultural service facilities have become ornamental, resulting in a great waste of cultural resources. Finally, the lack of communication and coordination between departments results in a poor layout. The lack of communication between the planning and construction departments of public cultural facilities and their users has

led to deviations between the completed public cultural facilities and the needs of the public. This standardised construction planning ignores the actual needs of the users and, to a certain extent, also results in a waste of resources.

2.3. There Is Structural Waste in the Supply of Public Cultural Resources. The structural waste in the supply of grassroots public cultural resources refers, on the one hand, to the lack of coordinated planning resulting in the duplication of the construction of grassroots public cultural facilities; on the other hand, it refers to the inability to effectively match the supply of grassroots public cultural resources with the needs of the grassroots. Both of these aspects lead to low utilisation of grassroots public cultural resources, resulting in a waste of resources. Due to the administrative system, each department is responsible for the construction of public cultural facilities within its own area. This approach to resource planning is a “compartmentalised” construction model. The lack of coordination among all parties involved in the provision of public cultural services has led to the duplication of public cultural facilities and, to a certain extent, to a waste of resources. The imbalance between supply and demand leads to low utilisation of public cultural resources at the grassroots level. Public cultural resources are supplied in a single way, and there is a lack of feedback mechanisms on the needs of the public. The allocation of resources in public cultural institutions does not meet the needs of the public, which ultimately leads to low utilisation of public cultural resources at the grassroots level.

3. Problem Statement and Research Ideas

The group behaviour of animals shows consistency as a whole, but each member of the group is independent, i.e., having a certain freedom of behaviour. The behavioural trajectory of each individual is different. Therefore, due to this specificity of group behaviour, each individual’s motor control is required to have certain random properties in order to make the final simulated group behaviour more natural.

The basic principle of the group intelligence algorithm is to simulate animal evolution and natural competitive behaviour, and it has strong advantages in solving process arrangement and route planning problems. The Cuckoo Search (CS) algorithm is an emerging kind of group intelligence algorithm [25–27] with strong local and global search ability and convergence speed. Therefore, in order to solve the most important problems of resource allocation optimisation in the design of public cultural services for the elderly, this article proposes introducing intelligent computing into the design of public cultural services for the elderly. By simulating the movement behaviour of a large-scale group of elderly people in real time, the optimal location of cultural resource subjects is planned. Collision detection is introduced in the generation of individual movement paths in order to solve the problem of collision between individuals. In addition, the standard CS algorithm is improved with chaotic mapping and dynamic step size in

order to increase the spatial range of group behaviour options and smoothly adjust the trajectory curve in order to improve the convergence speed and optimisation accuracy.

4. A Public Cultural Service System for the Elderly Based on an Improved CS Algorithm

4.1. Modelling of Individual Goals for Older People. The system designed simulates the public cultural services as a bird's nest and each individual elderly person as a cuckoo. By simulating the natural behavioural changes of the elderly population, the final birdhouse location is generated that best matches the actual needs. In order to provide a comprehensive view of the individual behaviour of the elderly, an RGB colour space model is used to represent the individual target characteristics of the group. The entropy of the individual image is first analyzed by RGB information $H(U)$.

$$H(U) = E[\log p_i] = -E p_i \log p_i, \quad (1)$$

where p_i represents the probability of a single letter pixel occurring. The logarithm in the above equation generally takes the value of 2.

The colour degrees are calculated as follows:

$$\frac{1}{|\Omega|} \sum_{p \in \Omega} |R_p - G_p| + |G_p - b_p| + |B_p - R_p|, \quad (2)$$

where $|\Omega|$ is the individual size. R_p , G_p , and B_p are the RGB colour components.

The gradient distribution of individual targets in the population is then represented by a gradient histogram $g(p)$, which is calculated as follows:

$$g(p) = \min(\max(R_p, G_p, B_p), 1.1), \quad (3)$$

where 1.1 is the curve truncation value.

Finally, the texture features of individual targets in the population are represented using a grey-scale cooccurrence matrix $P(i, j)$, which is calculated as follows:

$$P(i, j) = \#\{(x_1, y_1), (x_2, y_2) \in M \times N | f(x_1, y_1) = i, f(x_2, y_2) = j\}, \quad (4)$$

where $f(x, y)$ represents the input population target of size $M \times N$ and $\#(x)$ represents the number of individuals in set x . i and j represent two different grey-scale values.

4.2. Basic CS Algorithm. A new global search algorithm, called the Cuckoo Search (CS) algorithm, was proposed in 2009 by modelling the behaviour of cuckoos searching for nests to lay their eggs [28]. In nature, cuckoos search for suitable nest locations to lay their eggs in a random way. To simulate the behaviour of the cuckoo in its nest search, first, three ideal states are set as follows:

- (1) Each cuckoo lays one egg at a time and chooses a nest at random to incubate it.
- (2) In a random selection process of nests, the best nest selected will be retained for the next generation.

- (3) The number of available nests n is fixed and the probability of discovery by the nest owner is $p_a \in [0, 1]$.

Based on the three ideal states mentioned above, the updated formula for the optimal path and location of the bird's nest is shown as follows:

$$x_i^{t+1} = x_i^t + \alpha \oplus L(\lambda) \quad (i = 1, 2, \dots, n), \quad (5)$$

where x_i^t denotes the position of the nest of the i -th cuckoo in the t -th iteration and α denotes the step parameter. S denotes the random walk step length. To facilitate the implementation of the algorithm, S in this article uses the vegetable dimensional flight formulation [29]:

$$S = \frac{\mu}{|v|^{(1/\beta)}}, \quad (6)$$

where the flight parameters μ and v follow a normal distribution.

$$\mu N(0, \sigma_\mu^2), v N(0, \sigma_v^2), \quad (7)$$

$$\sigma_\mu = \left\{ \frac{\Gamma(1 + \beta) \sin(\pi\beta/2)}{\Gamma[(1 + \beta)/2] 2^{(\beta-1)/2} \beta} \right\}^{(1/\beta)}, \quad (8)$$

$$\sigma_v = 1.$$

4.3. Improved CS Algorithm. Chaotic mapping [30–32] is the inherent characteristic of nonlinear dynamical system, which is a kind of random process with the certainty of the regular expression. Therefore, it is often used to improve the performance of intelligent algorithms to find the best performance. Therefore, in this paper, the standard CS algorithm will be improved using chaotic mappings. The logistic formulation of the standard chaotic mapping system is shown as follows:

$$y_{n+1} = 4y_n(1 - y_n), \quad (9)$$

where $n = 1, 2, \dots$ is the state, y_n denotes a chaotic variable, and $y_n \in [0, 1]$.

In order to increase the range of optional spaces for group behaviour and improve global optimisation performance, the current optimal position of the bird's nest in the CS algorithm x_{best} is chaotically optimised:

$$y_1^k = \frac{x_{\text{best}} - x_{\min}^k}{x_{\max}^k - x_{\min}^k}. \quad (10)$$

The above equation is the process of mapping x_{best} to the defined interval $[0, 1]$ of y_{n+1}^k . The chaotic sequence $y^k = (y_1^k, y_2^k, \dots, y_T^k)$ is generated by performing T iterations on y_1^k according to equation (10):

$$y_{n+1}^k = 4y_n^k(1 - y_n^k). \quad (11)$$

Next, the chaotic sequence $y^k = (y_1^k, y_2^k, \dots, y_T^k)$ is mapped back to the original space by the inverse of equation (11):

$$x_{\text{best},m}^{*k} = x_{\text{min}}^k + (x_{\text{max}}^k - x_{\text{min}}^k) y_m^k, \quad m = 1, 2, \dots, T. \quad (12)$$

At each iteration, the adaptation value for each nest is calculated and the best location $x_{\text{best},m}^{*k}$ in each iteration will be selected. The best location $x_{\text{best},m}^{*k}$ is then used to replace a randomly selected nest location in the nest.

In the basic CS algorithm, Levy flight is used to generate a random step size. However, the variation of this step size is very unstable. During the search process, the larger the step size is, the easier it is for the CS algorithm to search for the global optimal solution; however, it reduces the search accuracy and even sometimes oscillates. The smaller the step size, the lower the search speed of the CS algorithm, but the local search ability is enhanced, which improves the solution accuracy. Therefore, the use of Levy flight to generate step size, although random, lacks adaptivity. To address this problem, the step size needs to be dynamically adjusted adaptively according to the search results at different stages, and the relationship between the global search ability and the search accuracy needs to be properly handled.

$$d_i = \frac{\|x_i^k - x_{\text{best},m}^k\|}{d_{\text{max}}}, \quad (13)$$

where x_i^k is the location of the nest i at the iteration k and d_{max} is the maximum distance between the best nest location and the other nest locations in the group.

The specific dynamic step adjustment method is as follows:

$$\text{step}_i = \text{step}_{\text{min}} + (\text{step}_{\text{max}} - \text{step}_{\text{min}}) d_i, \quad (14)$$

where step_{max} is the maximum step size and step_{min} is the minimum step size. Equations (13) and (14) allow for the automatic adjustment of the dynamic step size.

4.4. Collision Detection Based on NURBS Modelling. In order to prevent collisions between different individuals in a group, a group model was constructed by means of NURBS modelling and collision detection was introduced in order to solve the problem of collisions between individuals. The NURBS model is defined as follows:

$$C(t) = \frac{\sum_{i=0}^n \omega_i P_i N_{i,k}(t)}{\sum_{i=0}^n \omega_i N_{i,k}(t)}, \quad (15)$$

where P_i represents the position of the surface vertices of the target model, $N_{i,k}(t)$ represents the basis function of the nonuniform rational B spline curve, and ω_i represents the control adjustment weights. The method for collision detection is shown as follows:

$$\text{vel}j = \left[\sum_{i=1, i \neq j}^n \frac{1}{\text{dist}(i, j) \cdot n} \cdot \text{vel}j \right] \cdot S + \text{vel}j \cdot (1 - S), \quad (16)$$

where $\text{vel}j$ indicates the current speed of movement of the detected individual j and $S \in [0, 1]$ indicates the weight that

controls the degree of aggregation of the group. $\text{dist}(i, j)$ denotes the distance between different individuals.

In order to keep the direction of each individual in the group consistent with that of other individuals, equation (16) only selects the average direction of the neighbouring individuals of the target individual.

$$\text{vel}j = \left[\sum_{i=1, i \neq j}^n \frac{1}{n} \cdot \text{vel}j \right] \cdot S + \text{vel}j \cdot (1 - S). \quad (17)$$

Finally, to complete the aggregation behaviour, to bring all individuals closer to the centre of the whole cluster, the final calculation of $\text{vel}j$ is shown as follows:

$$\text{vel}j = \left[\left(\sum_{i=1, i \neq j}^n \frac{\text{pos}i}{n} \right) - \text{pos}i \right] \cdot S + \text{vel}j \cdot (1 - S), \quad (18)$$

where $\text{pos}i$ represents the vector of cluster centres.

4.5. Steps for Planning the Best Cultural Resource Subject.

An improved CS algorithm is used to simulate the movement behaviour of large groups of elderly people in real time so as to obtain the best locations for cultural resources. The aim of the planning is to obtain the best locations for cultural institutions, including libraries, cultural centres, and cultural service centres, so as to improve the coverage and utilisation rate of elderly public cultural service resources. The steps for the simulation of movement behaviour of elderly groups based on the improved cuckoo algorithm are as follows:

Step 1: set the number of individuals in the group, the nest location, the initial adaptation value, the maximum step size step_{max} , and the maximum step size step_{min} .

Step 2: calculate the fitness function value for each nest in order to obtain the current optimal nest location and optimal value. The individual fitness values fitness are calculated as follows:

$$\text{fitness} = \sqrt{(x - g_x)^2 + (y - g_y)^2 + (z - g_z)^2} - \text{rand}(t), \quad (19)$$

where (x, y, z) is the current position of the individual, (g_x, g_y, g_z) is the 3D coordinate of the cluster target location and $\text{rand}(t)$ is the threshold value. This threshold is needed for distance spacing because the individuals in the group cannot all gather to the final target point but rather surround it.

Step 3: perform chaotic mapping of the current optimal nest and a nest update process using equation (14) to produce a new generation of nest locations, such as cultural service centres.

Step 4: determine whether the stopping condition is met; if so, output the optimal location (e.g., cultural centres) and the optimal fitness value; otherwise, repeat step 3.

Step 5: after obtaining the optimal solution (the central position of the entire cluster, e.g., the library), the individuals in the population are collision detected with all other individuals, and if a collision occurs, then skip back to step 3 until no collision occurs.

5. Simulation Results and Analysis

5.1. Experimental Configuration Parameters. The experiments in this article are divided into two parts: (1) standard function testing and (2) simulation of the planning of public cultural resources. The environment used for the experiments is MATLAB R2016a, PC configuration of Intel 2.4 GHz, 8G RAM, Window 10 operating system. The basic parameters of the improved CS algorithm were set as follows: maximum step size is 1, minimum step size is 10^{-4} , variation probability is 0.5, crossover probability is 0.9, probability of the bird's egg being found by the host is 0.25, and population size is 50. The experiment was conducted to simulate the movement behaviour of a large group of elderly people in real time by the improved CS algorithm so as to obtain the best location and path of the cultural resource subject. The aim of the experiment is to obtain the best locations of cultural institutions, including libraries, cultural centres, and cultural service centres, so as to improve the coverage and utilisation of elderly public cultural service resources.

5.2. Standard Function Tests. The optimal solution performance of the improved CS algorithm was tested using six classical test functions, and the results obtained were compared with typical CS, ASCS [33], and DECS [34]. The maximum number of iterations in the tests was 1000, with 20 runs of each function and a dimension of 30. The variables of the six test functions took values in the range $[-5.12, 5.12]$. The six classical test functions were defined as follows:

(1) Sphere function:

$$f_1(x) = \sum_{i=1}^n x_i^2. \quad (20)$$

(2) Schwefel function:

$$f_2(x) = \sum_{i=1}^n |x_i| + \prod_{i=1}^n |x_i|. \quad (21)$$

(3) Rastrigin function:

$$f_3(x) = \sum_{i=1}^n [x_i^2 - 10 \cos(2\pi x_i) + 10]. \quad (22)$$

(4) Griewank function:

$$f_4(x) = 1 + \frac{1}{4000} \sum_{i=1}^n x_i^2 - \prod_{i=1}^n \cos\left(\frac{x_i}{\sqrt{i}}\right). \quad (23)$$

(5) Ackley function:

$$f_5(x) = -20 \exp\left(-0.2 \sqrt{\frac{1}{n} \sum_{i=1}^n x_i^2}\right) - \exp\left(\frac{1}{n} \sum_{i=1}^n \cos(2\pi x_i)\right) + 20 + e. \quad (24)$$

(6) Quartic (noise) function:

$$f_6(x) = \sum_{i=1}^n i x_i^4 + \text{random}[0, 1), \quad (25)$$

where both $f_1(x)$ and $f_2(x)$ are a single-peaked function. The global optimal solution of $f_3(x)$ is within a steep canyon. $f_4(x)$ has numerous local optimum points. $f_5(x)$ and $f_6(x)$ are both complex multi-peaked functions with a large number of local minima. The minimum, maximum, mean, and standard variance of each run were obtained. The results of the comparison of the six test functions are shown in Table 1.

As can be seen from Table 1, when the number of iterations is the same, the improved CS algorithm proposed in this article obtains results that are closer to the global optimal solution when solving for six functions than the other five algorithms. The average fitness value of the improved CS algorithm is improved by 10 orders of magnitude, and the variance is significantly reduced. In particular, for functions f_4 with an infinite number of local optima, both the minimum and average fitness values of the improved CS algorithm reach the theoretical optimum, while the CS algorithm falls into the local optimum. The Schwefel function is a complex single-peaked function and the Rastrigin function is a complex multi-peaked function, and other existing algorithms are prone to produce local optimum solutions. The algorithm in this article enters the chaotic mapping and uses its ephemeral nature to improve the search range and accuracy.

In order to directly observe the optimisation-seeking effect of the improved CS algorithm and the typical CS algorithm on the six test functions, the evolutionary curves of the optimal fitness values of the two were compared, as shown in Figures 1–6. It can be seen that the improved CS algorithm has higher optimisation accuracy and faster convergence. In summary, the improved CS algorithm has improved in terms of convergence accuracy and convergence speed compared to CS. This is due to the use of a dynamic step size adjustment method, compared to a typical cuckoo algorithm with random step sizes, thus enhancing the search speed while ensuring global optimisation-seeking capability.

5.3. Modelling the Movement Behaviour of Large Groups of Older People. MATLAB programming was used to implement the improved CS algorithm based elderly group movement behaviour control, and the obtained path data was imported into NURBS software to simulate the crowd animation. The simulation of the elderly gathering group

movement behaviour based on the improved CS algorithm is shown in Figure 7, which verifies its feasibility.

5.4. Examples of Public Cultural Resources Planning. The essence of planning the public cultural resources is the Traveling Salesman Problem (TSP). This is the most basic route problem and a classical combinatorial optimisation problem. The feasible solution to the problem is the full permutation of all vertices. As the number of vertices

increases, the corresponding number of feasible solutions increases accordingly. Therefore, public cultural resource planning is an NP-Hard problem. As shown above, the improved CS algorithm is very effective in finding the optimal solution to the continuous function problem. Next, the effectiveness of the improved CS algorithm in public cultural resource planning will be tested. The designed system modelled the public cultural service institution as a bird's

FIGURE 3: Iteration curve of function f_3 .FIGURE 5: Iteration curve of function f_5 .FIGURE 4: Iteration curve of function f_4 .FIGURE 6: Iteration curve of function f_6 .

nest and each individual elderly person as a cuckoo. The natural behavioural changes of the elderly population are simulated to ultimately produce the bird's nest location that best meets the actual needs. The location of the bird's nest location is the location of cultural institutions such as libraries, cultural centres, and cultural service centres.

The typical CS, ASCS, DECS, and improved CS algorithms were used to simulate the planning of public cultural resources for the elderly in each of the four cities, and a comparison of the simulation results is shown in Table 2. In City A, there are only 10 public cultural resources for the elderly. In City B, there are 30 public cultural resources for the elderly. In City C, there are 50 public cultural resources for the elderly. In City D, there are only 75 public cultural resources for the elderly.

As can be seen from Table 2, for the very-small-scale problem with 10 public cultural resources, all four algorithms can find the optimal solution. For the problem with 30 public cultural resources, the improved CS algorithm can find the optimal solution. For problems with 50 and 75 resources, the improved CS algorithm obtains optimal values that are closer to the optimal solutions compared to the other algorithms. It can be seen that the improved CS algorithm has better optimality finding accuracy. Finally, the coverage rate and utilisation rate of public cultural service resources for the elderly after using the designed system were counted in City D, and the results are shown in Figure 8.

As can be seen from Figure 8, the coverage and utilisation rate of public cultural service resources for the elderly in City D increased over time after using the designed

system. At 160 days, both the coverage and utilisation rates reached their highest values of 74.8% and 79.8%, respectively, verifying the effectiveness of the improved CS algorithm in the planning of public cultural resources for the elderly.

6. Conclusion

This article designs an intelligent computing-based public cultural service system for the elderly. Intelligent computing is introduced into the design of public cultural services for the elderly, thus solving the most important resource planning problem in the planning of public cultural services for the elderly. The CS algorithm is used to simulate the movement behaviour of large groups of elderly people in real time to plan the best location and path for cultural resource subjects. Collision detection is introduced in the generation of individual movement paths in order to solve the problem of collision between individuals. In addition, the standard CS algorithm is improved with chaotic mapping and dynamic step size in order to increase the spatial range of group behaviour options and to smoothly adjust the trajectory profile in order to improve the convergence speed and optimisation accuracy. Experimental results from six standard function tests show that the improved CS algorithm is very effective in finding the best for continuous function problems. The experimental results of the simulation with the planning of public cultural resources show that the coverage and utilisation rate of public cultural service resources for the elderly have been increasing with the improved CS algorithm, reaching 74.8% and 79.8%, respectively.

The “pursuit of deep learning” is mentioned among the recent trends driving the key trends driving educational technology in schools. “Deep learning” is widely used as a term, and classroom teaching has begun to focus more and more on deep learning. The heuristic teaching method is gradually accepted and used by educators all over the world with its scientific teaching mode and novel teaching methods. In today's children's physical education classroom, the heuristic teaching method has achieved certain results and effects, but in the process of trying, there is still room for development and improvement. Based on the deep learning model, this research will improve the existing heuristic teaching methods, through the experimental research on children's physical education classroom, observe the data results obtained by the deep learning-based children's physical education heuristic teaching, and analyze according to the results, so as to achieve the effect of heuristic teaching. A multilabel classification model ALSTM-LSTM is proposed according to the algorithm adaptation method in the multi-label learning method. The experimental results obtained an accuracy of 95.1%, which is higher than other deep learning models, and also reached the best in the evaluation indicators of precision, recall, and *F1* score.

1. Introduction

With the continuous development of science and technology and the progress of society, the future society needs talents who can create high technology and new resources. Based on such a situation, it is urgent to deepen the reform of education. In the educational reform, heuristic teaching is a key point of the reform. Heuristic teaching emphasizes the combination of educators' follow-up guidance and students' thinking expansion, so that a class should not only learn the content of knowledge but also open up a new way of thinking for students, that is, independent inquiry learning. As the main body of education, students should actively participate in the curriculum and the process of knowledge exploration, so as to achieve the purpose of integrating knowledge. Educators should also respect students, fully mobilize students' interest in the inquiry

process, care for students, not criticize students' wrong answers in class, give correct guidance, and encourage students to think. It can also improve students' self-confidence in mathematics learning. The multi-label analysis of posture in rope skipping refers to the use of the constructed deep learning model to judge which limb posture meets the standard and which limb posture needs to be corrected in the process of rope skipping. In artificial intelligence science, the multi-label limb posture analysis problem in children's physical education heuristic teaching can be transformed into multi-label learning problem. Based on the principle of deep learning, through the combination of multi-label limb posture analysis in children's sports heuristic teaching, this paper designs a heuristic teaching algorithm for children's sports, so as to solve the problems in the process of children's sports heuristic teaching [1–10].

2. Related Work

With the rapid development of Internet of Things technology, the combination of sports industry and emerging industries has become closer and closer. The first extension is based on reducing the subspace and swimming style information of possible posture configuration. The researchers have developed a class of label coding with spatial redundancy, which allows the network to learn the specific filter of swimming style. This principle is applicable to any form of activity information. The second extension focuses on the time of swimming video and proposes a two-step method, in which the initial pose estimation is refined in a fixed length sequence by an independent CNN module, and the experimental results show that the LSVM has reached the best first extension based on reduction possible. The second extension focuses on the time of swimming video, which proposes a two-step method in which the initial posture estimate is refined by a separate CNN module in a fixed length sequence. The experimental results show that the method has the ability to predict and improve the posture, which clearly improves the baseline CPM architecture, which provides help to attitude analysis during the player swimming. Extract human appearance characteristics and motion characteristics by using the OpenPose network model. Use supervisory machine learning to identify four activities categories, including sitting, standing, walking, and falling. The results show that the activity recognition method based on two-dimensional bone data can obtain better matching results as compared with the method based on three-dimensional bone data. Classification of KNN classifier is found by comparing the performance of K-nearest neighbor (KNN), support vector machine, Naive Bayes, linear discriminating formula (LDA), and feedforward reverse neural network (BPNN). The effect is best, and the overall accuracy is 98%. The robustness of the method also tests in two multi-camera view scenarios, and the results show that the CNN has better classification effect than other classifiers, and the classification results are 100%. From the current development of intelligent sports in the world, it has been gradually realized. This paper realizes the principle of intelligent sports in the heuristic teaching of children's sports, which involves many contents, mainly including the collection and processing of sports data and sports characteristics, the extraction of sports network model, the research on the development of the rope skipping action analysis system, etc., and the heuristic teaching experience research based on rope skipping in sports [11–15].

3. Related Theoretical Methods

3.1. Circulating Neural Network Model. The time series is a series of data accumulated in the time dimension, and many applications are analyzed in time series data. Assuming $1 = \{x_1, \dots, x_n\}$, X_n is a time series of a length N , $X = \{X^1, \dots, X^M\}$ consists of M different single-dimensional time series, and for each $1 \leq i \leq M$, the length of the time sequence is n . On the classification problem of the time series, the format of the data is usually as follows: dataset $D = \{(x_1, y_1), (x_2, y_2), \dots,$

$(x_N, y_N)\}$ indicating the time series and corresponding label, y_i is achieved by one-hot coding, and the length k indicates that there is K category. From a whole, in a network model based on a time series, the input is the corresponding classification probability of the continuous learning of the neural network in the middle of the time series. Because time data are complex and unstable, the depth learning method is not assumed to assume the basic mode of the data, which is more robust to noise, so the depth learning model is the preferred method in time series data analysis. Circulating neural networks are complex depth learning networks that can be remembered, so they are widely used in the processing of sequence data. The RNN unit is the backbone of the circulation network, and there are two incoming connections and two outgoing connections in the RNN. LSTM can select an input sequence area that contributes to class tags in the context vector by attention. Note that mechanisms are often used in natural language processing. In the machine translation, a set of context vectors C is conditioned in the target sequence y , and the context vector C_i depends on the annotation sequence (h_1, \dots, h_{T_x}) that maps the input sequence to the encoder. In each comment, H_i contains information about the entire input sequence, and the model will focus on the part around the i -th word of the input sequence where c_i is weighted and calculated by h_i [16]:

$$c_i = \sum_{j=1}^{T_x} a_{ij} h_j. \quad (1)$$

Each comment a_{ij} 's weight h_j is calculated as follows:

$$a_{ij} = \frac{\exp(e_{ij})}{\sum_{k=1}^{T_x} \exp(e_{ik})}, \quad (2)$$

where $e_{ij} = a(s_{i-1}, h_j)$ is the alignment model, which scores the matching degree of the input around the j position with the output at the i position. Bahdanau et al. parameterized the alignment model as a feedforward neural network that is co-trained with all other parts of the model, computing the soft alignment directly during the computation of the alignment model [17].

3.2. Heuristic Teaching Network Structure Based on OpenPose.

In preschool physical education, OpenPose, an open source library for real-time multi-person pose estimation based on deep learning, is introduced. It can accurately estimate the pose of each person in the image in physical education teaching in real time, so as to realize the extraction of face, trunk, limbs, and hand bone points. It takes into account real-time performance and accuracy and has strong robustness. The core of this method is a bottom-up human pose estimation algorithm based on part affinity fields (PAFs), that is, to detect key points before acquiring the skeleton, which avoids the long calculation time in multi-person scenarios [18].

3.2.1. OpenPose Network Structure. Figure 1 shows the multi-level prediction network structure designed by

OpenPose. The framework is based on the VGG19 network model and converts the input image into image features F , $L(p)$, and $S(p)$ by stage prediction. $L(p)$ is the affinity vector field PAFs, and $S(p)$ represents the confidence of the key points in the skeleton. The structure divides the prediction into 6 stages, the first 4 stages predict the affinity vector field, and the last 2 stages predict the confidence. At each subsequent stage, the predictions from the previous stage are concatenated with the original image features as input to generate more refined predictions. After obtaining the confidence and affinity of the key points, the Hungarian algorithm is used to optimally match the adjacent key points to obtain the skeleton information of each person. OpenPose has good real-time performance and has designed a variety of model architectures to be compatible with different hardware configurations. It uses a monocular camera for reliable key point information without the need for a dedicated depth camera like Kinect. Parts that can be estimated are eyes, ears, nose, neck, shoulders, elbows, wrists, hips, knees, and ankles [19].

3.2.2. Confidence Map. In the human body pose estimation based on OpenPose, in order to obtain the coordinate information of the key points of the human body, the Gaussian modeling method is used to obtain the confidence map of the position of the key points, and the confidence map is used to represent the key points, wherein the value in the confidence map is expressed as a certain probability of key point locations. The confidence map of key point locations can be expressed as [20]

$$c_{j,k} = \exp\left(-\frac{\|p - x_{j,k}\|_2^2}{\delta^2}\right), \quad (3)$$

$$c_j(p) = \max_k S_k^{j,k}(p),$$

where j represents the joint point of the human body, k represents the k th target person in the image.

4. Action Analysis Algorithm in Heuristic Teaching Sports Scenario

Computer vision-based motion analysis during exercise is a complex problem, especially when analyzing vigorous sports. In order to achieve a detailed description of the body movements during the movement process, this paper uses deep learning to build a model of the network.

4.1. Problem Definition. The content of this paper is an implementation method of intelligent sports in the rope skipping motion analysis system, which involves many fields, including data collection and processing, feature extraction, data transmission, network model design, system implementation, etc. According to the flowchart, it can be clearly seen that the analysis of the swaying and jumping action mainly includes two modules: one module is used to obtain the key point information of the human body, and the

other module is used to mathematically model the obtained key point information and build a multi-label classification network model [21].

The problem can be defined as given m groups of rope skipping records, preprocess m groups of sequence data to obtain a data sequence $D = (r1, r2, \dots, rm)$, where r_j , $i = 1, \dots, m$ represent m sequence data, where the label set $L = (l1, l2, \dots, ln)$, l_j , $j = 1, \dots, n$ represent the limb labels during the rope skipping process, and each record in D is associated with multiple labels in L . Multi-label pose analysis can be represented by a tuple (r_i, Y_i) , where Y_i is contained in L . Our goal is to design and implement a label classification model that judges the limb labels Y_i during rope skipping based on the new pose dataset ri' [22–24].

4.2. Network Framework Design

4.2.1. MobileNetV2 Framework. Convolutional neural networks have made breakthroughs one after another in the field of computer vision, but the application of deep learning models on the mobile terminal is not wide enough. At present, the recognition effect of the lightweight network on the ImageNet dataset is based on top-1, which is improved compared with ResNet-34 and VGG19, and its accuracy is slightly lower than that of ResNet-50, which is lightweight. The high-level network model has a certain balance in real-time performance and accuracy. In order to train and apply the model in an environment with few resources and low hardware support, a lightweight network model is more needed in real scenarios. When obtaining the human body pose, the OpenPose network model first sends the image frame to VGG19 to obtain the set of image feature maps $F = (F1, F2, \dots, Fx)$, where x represents the number of feature maps. However, VGG19 consumes more computing resources and will generate a lot of parameters during the training process, which will take up more memory. In view of the high performance and efficiency of MobileNetV2, this paper modified the original OpenPose method when extracting image feature maps.

The MobileNetV2 network is an improved version based on the MobileNet network. Its innovation is that an inverted residual structure is added to MobileNetV2. The inverted residual structure is different from the original residual structure.

4.2.2. ALSTM-LSTM Network Framework. In this paper, the human posture analysis problem in rope skipping obtained in physical education teaching is transformed into a multi-label classification problem according to the time order relationship. Because LSTM can play a role in global processing and storage unit, it can maintain good performance in time series. Attention mechanism is a global approach to processing. Applying attention mechanism to LSTM can improve the performance of LSTM. Therefore, inspired by LSTM and attention mechanism, this paper creatively proposes a method of applying attention mechanism in LSTM and combining a single LSTM for multi-label

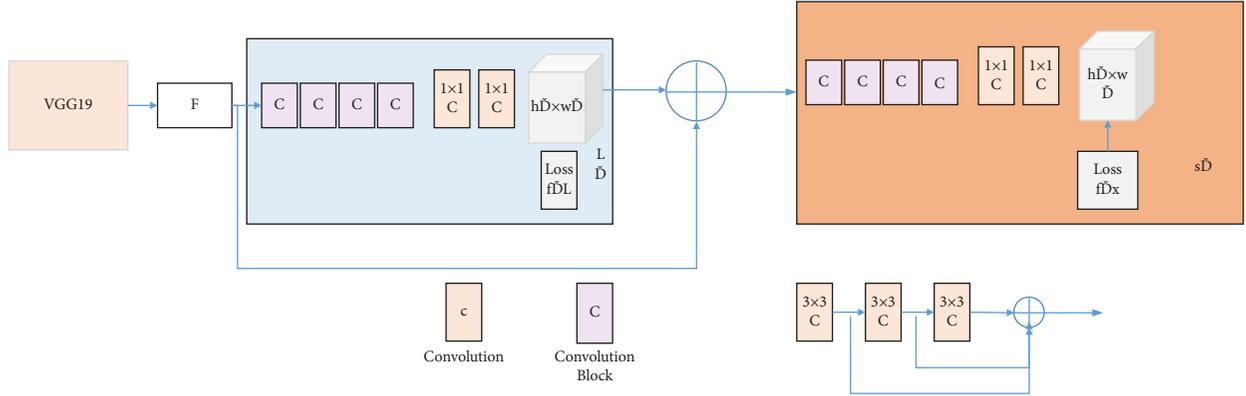

FIGURE 1: OpenPose network structure diagram.

classification. The network framework of ALSTM-LSTM is shown in Figure 2.

The most typical example in the breakthrough of the algorithm is the proposed batch normalization (Batch-Norm) method. BatchNorm smoothes the solution space of related optimization problems, thereby ensuring more predictable gradients, which in turn allows the use of a wider range of learning rates for faster network convergence. This study demonstrates that adding a BatchNorm layer to a deep learning network model greatly improves the Lipschitzness of the loss function and gradient in the model. So, this article adds a BatchNormalization layer before using the LSTM and ALSTM layers. In addition, since this paper studies a multi-label classification problem, according to the multi-label algorithm transformation method, the activation function of the ALSTM-LSTM model in the last layer is set to the sigmoid activation function, and the loss function selects the binary cross-entropy loss function.

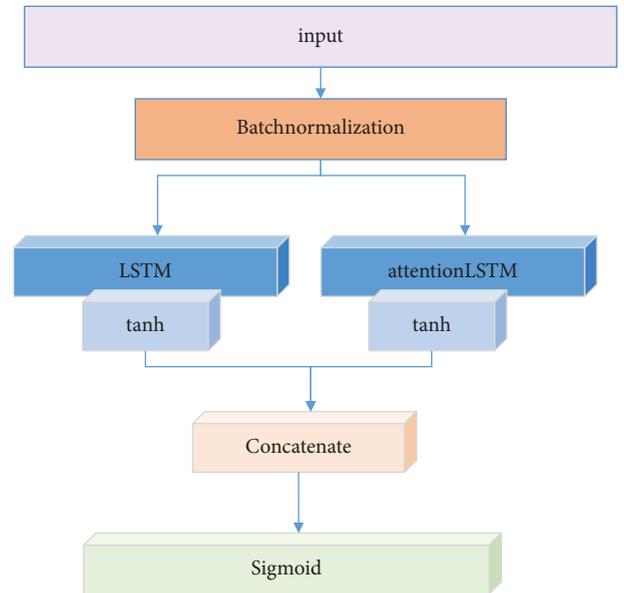

FIGURE 2: ALSTM-LSTM network framework.

4.3. Attitude Estimation Optimization Algorithm. In the two branches of OpenPose, one branch is used to predict the confidence map (S) of the key point, that is, the probability value of this key point, and the other branch is used to predict the affinity field PAFs between the two key points (L).

$$f_s^t = \sum_{j=1}^j \sum_p w(p) \cdot \|S_j^t(p) - S_j^*(p)\|_2^2, \quad (4)$$

$$f_L^t = \sum_{j=1}^C \sum_p w(p) \cdot \|L_j^t(p) - L_j^*(p)\|_2^2.$$

The overall loss is the loss sum of each stage:

$$f = \sum_{t=1}^T \sum_p (f_s^t + f_L^t). \quad (5)$$

In order to further improve the generalization ability of the pose estimation algorithm and improve the accuracy of the algorithm, this paper introduces two weights and a penalty term into the total loss function:

$$f = \sum_{t=1}^T (\alpha f_s^t + \beta f_L^t + \theta). \quad (6)$$

By introducing weights, we analyze how much the losses in the two branches affect the results.

5. Design and Implementation of Heuristic Physical Education Teaching System

5.1. Overall Design of the System. The overall design of children's physical education teaching system determines which functions the system should realize according to the analysis of children's physical education teaching needs and generally explains how the system is realized. The overall design of children's physical education teaching is to introduce the functions of each module and the relationship between each other. The overall design of children's physical education teaching system includes the design of system function module and database table.

5.1.1. Functional Module Design. The function module design is to divide the smart rope skipping teaching system into several subsystems and then divide the subsystems into different modules according to their functions. The division of project modules can help developers simplify complex problems. The design of functional modules is a further refinement of the requirements. The appropriate division of functional modules can provide a detailed understanding of each function of the system, reduce the time for developers in the development process, and enhance the maintainability of the system. In this design, the Android-based smart rope skipping teaching system APP is implemented on the server side using the SSM framework and MySQL database. The SSM framework is a combination of three frameworks, namely, Spring Framework, SpringMVC, and MyBatis. At present, the SSM framework has been widely used in the development of websites and has become more and more popular in the development of commercial software. The APP client of this system adopts the basic mode of the current popular MVP (model view presenter), which is mainly composed of three major components: view, model, and presenter. The view is responsible for displaying the page, the model is responsible for providing data support for business processing, and the presenter is responsible for processing business logic. The entire system architecture is shown in Figure 3. The user transmits data through the mobile phone camera, the MySQL database is responsible for storing the data, and the server accepts the user's data request, processes, and feeds the result back to the user.

5.1.2. Database Table Design. The design of infant physical education teaching database table further describes the infant physical education teaching data by relying on the conceptual structure design of infant physical education teaching database. The early childhood physical education teaching system includes four basic tables: personnel basic information table person, video information table video, information message table news, and rope skipping analysis results. The database table is established according to the relational schema as follows:

- (1) User table: the user table is used to store the basic information of the user, including the user's id, user name, user's password, and user's authority. According to the user's authority, users can be divided into administrators and ordinary users. The structure of the user table is shown in Table 1.
- (2) User video table: the user video table is used to store the id of the video uploaded by the user and the storage path of the video. The structure of the user video table is shown in Table 2.
- (3) Message table: the message table is used to store the information and consultation related to the rope skipping test issued by the administrator, as well as some rope skipping skills. The message table contains the id of the message, the title of the message, and the content of the message. The structure of the message table is shown in Table 3.

- (4) Analysis result table: analysis result table mainly stores the contents of the results of the analysis and analysis results. The analysis result surface structure is shown in Table 4.

5.2. Detailed Design and Implementation of the System

5.2.1. Environment Introduction. The development of the APP is carried out on the Android Studio platform. It is an Android integrated development environment that only supports Android development. It is a plug-in focused on Android development that Google excludes other functions from the IntelliJ IDEA Community Edition. It is equivalent to a weakened version of the IntelliJ IDEA which is different however. Before using Android Studio, you need to download Java JDK first. During use, Android Studio's prompt tool supports ProGuard and application signature. Android Studio's powerful layout editor can directly drag UI controls and preview the effect. There is also an Android emulator on Android Studio, which makes it easy to debug during the development of the APP. During the development of the software, the Android emulator was used and several models of mobile phones were used in the testing phase. On the server side, we use HUAWEI CLOUD server as data storage and model invocation and build the deep learning model on HUAWEI CLOUD server. The training process of deep learning is implemented through Python language, and SpringMVC is used to realize the controller layer of the server side. At the same time, it also realizes the communication interface between the server and the APP. Table 5 describes the environment used for the development of this system.

5.2.2. System Function Test. The goal of functional testing is to test each functional module of the system, determine whether each functional module is optimal, and make subsequent improvements based on the test results. According to demand analysis, the system is mainly divided into seven modules: system login registration module, model upload module, user management module, message release module, data upload module, and analysis report viewing module. According to the test, you can check whether each function can be carried out smoothly and optimize the interface according to the user experience. Test for each functional module is shown in Table 6. The purpose of the system registration login module test is to detect whether the user can jump normally when logging in, and whether the registered information is encrypted in the database.

The purpose of the model upload function test is to check whether the administrator can upload the newly trained model to the location specified by the server and ensure that the model can be called correctly, as shown in Table 7.

The purpose of the analysis report viewing function module test is to detect whether the server can return the results normally after the user uploads the one-minute rope skipping dataset to the server and correctly display it on the mobile phone page, as shown in Table 8.

6. Conclusion

Traditional teaching methods can play a certain role and effect in imparting knowledge and skills. It has the advantage of being able to popularize educational knowledge quickly, imparting knowledge to students under the circumstance of limited teaching environment, single teaching method, and tight teaching time. Combined with the literature, we can see that traditional teaching is derived from class-based teaching under specific social conditions. However, in the classroom of traditional teaching method, the shortcomings of this teaching method can be clearly found, including the lack of subjective initiative of students in learning, low learning interest, less interaction between teachers and students, and depressed classroom atmosphere. With the development of the times, predecessors have conducted more research on heuristic teaching, which has laid a solid foundation for the

popularization of heuristic teaching in primary and secondary schools. Teaching research is rarely involved, and a set of elementary school basketball heuristic teaching experimental program has not been formed. Therefore, heuristic teaching is a new type of teaching method at present, which can be improved according to the inner development and actual needs of young children and is in line with the development needs of the current new era. In view of the current research hotspots for human behavior detection and recognition, this paper seldom studies the recognition of continuous actions in actual scenes, focusing on the improvement of the recognition rate and accuracy of motion actions, and is committed to solving traditional sports training equipment to realize the scientific, standardized, and unified management of children's sports training.

In recent years, the interdisciplinary exploration of combining traditional visual communication design with somatosensory interaction technology has become a new form of artistic expression. In order to explore the feasibility of somatosensory interaction technology in visual communication design, this study proposes a 2D dynamic graphic generation method based on somatosensory interaction parameterisation and uses traditional Chinese elements as an example for specific applications in visual communication design. Firstly, the motion parameters recognised using the Kinect somatosensory interaction device are bound to the function variables used to generate the images in the development environment, thus enabling human somatosensory interaction with different characters in the scene. Secondly, a linear discriminant analysis based on kernel functions is used to reduce the dimensionality of the vector space, thus solving the problem of real-time and accurate capture of human movements. Then, using the skeletal parameter binding technique, the association between the motion parameters of the somatosensory interaction and the two-dimensional dynamic graphics is achieved. The experimental results show that the visual communication technique based on somatosensory interaction has a high recognition accuracy. Distinguished from traditional digital video, the proposed method can greatly enrich the visual representation of traditional Chinese elements.

1. Introduction

In recent years, there have been many points of convergence between the rapidly developing digital economy and the cultural industries. Science and art are beginning to merge in terms of technology and form. In today's cultural communication application scenarios, audiences increasingly need a good live experience. However, in the current presentation of design content, spatial interpretation is still usually done by means of printed posters or by showing offline videos [1–5]. As the design content itself is independent, the audience cannot communicate with the design content. To achieve real-time interaction between the design content and the audience, a fundamental change in the design approach is required. The interdisciplinary exploration of traditional

visual communication design in combination with somatosensory interaction is a new solution to these problems.

In the landscape of museum exhibitions and tourism developments, designers prefer to use immersive interactive experiences to attract foot traffic. Unlike traditional interface interaction, somatosensory interaction emphasises the use of body movement responses to communicate with the product [6–8]. As a representative of Human-Computer Nature Interaction (HCI), somatosensory interaction is a new stage of technological development. With good immersion, low learning cost, and good user experience, somatosensory interaction has won wide application prospects and has received attention from scholars in various fields at home and abroad [9–12]. More advanced somatosensory interaction first appeared in 2007. During this period, Nintendo

combined somatosensory with gaming and introduced the concept of “health gaming.” In 2010, Microsoft launched Kinect v1.0, which was released with the X-BOX console and won high reputation and sales. At this stage, Kinect v1.0 began to be used in the medical, fitness, and retail industries, with various leading-edge applications being attempted. As a noncontact means of interaction, somatosensory interaction has a natural advantage for scenario applications on immersive and large digital spaces. Currently, rapid advances in science and art are leading to increasing demands for spatial visual applications. The use of interactively updated visual information to improve spatial functionality is a future area for joint development across media.

In order to explore the feasibility of somatosensory interaction technology in visual communication design, this study proposes a 2D dynamic graphics generation method based on somatosensory interaction parameterisation and uses traditional Chinese elements as an example for specific applications in visual communication design. It is important to note that somatosensory interaction technology requires real-time and accurate capture and recognition of human movements. Therefore, this paper employs the latest Kinect v2.0 device and designs a method for action parameter feature extraction based on linear discriminant analysis.

2. Related Studies

Humans sometimes do not always speak the truth, but body language often expresses their truest emotions. Therefore, the recognition of human body movements has been an important research direction in the field of computer image recognition [13–16]. Currently, popular algorithms for body movement recognition include BP neural networks, decision trees, and Support Vector Machine (SVM), among others.

At this stage, the most commonly used hardware device for body movement recognition is the Kinect body sensor. For example, Ying et al. [17] proposed a human motion recognition method using the Kinect body sensor. Lai et al. [18] proposed a DSP-based portable human gesture action recognition system in real time, using a combination of spectral analysis and linear discriminant analysis (LDA) strategy. Although these two methods improve the accuracy and efficiency of action recognition, respectively, there are more types of actions in practical applications. At the same time, human actions are more complex in Kinect-based somatosensory interaction, resulting in real-time and high-dimensional action data, so the dimensionality of the vector space must be reduced as much as possible in order to recognise more action types in real time.

The main objective of this research is to visualise 2D motion graphics using the Kinect v2.0 device and apply it to visual communication design. When the body posture data obtained from the Kinect v2.0 device is used as a “parameter” in the 2D motion graphics, changes in body posture can trigger changes in the 2D motion graphics, creating an interaction between somatosensory and traditional Chinese elements. When a person walks across the screen, the Kinect sensor recognises the person’s x -coordinates and maps them to the computer, which then projects the motion parameters

FIGURE 1: Kinect v2.0.

onto the screen via a projector, causing the traditional Chinese elements in the 2D graphics to change dynamically by panning. The experimental results validate the effectiveness and accuracy of the proposed method.

The main innovations and contributions include the following: (1) This paper proposes an LDA-based feature extraction method for motion parameters in order to improve the recognition accuracy of the Kinect v2.0 device. (2) Using the binding technique of skeletal parameters, the association between somatosensory interaction motion parameters and 2D dynamic graphics is achieved.

3. Kinect v2.0-Based Parameterisation of Somatosensory Interaction

3.1. Key Technologies. Microsoft first announced Kinect in June 2009 [19, 20] with the hope that the hardware would merge motion with communication. The device was officially launched in November 2010, and in May 2013, Microsoft demonstrated the next generation Kinect v2.0, which allows developers to design based on the voice, gesture, and player sensory information sensed by Kinect v2.0, bringing users an unprecedented interactive experience. In this paper, we decided to use the Kinect 2.0 device as the base hardware for development.

The colour resolution of Kinect v2.0 has been dramatically increased from 640×480 to 1920×1080 , enabling very beautiful images to be acquired. Kinect v2.0 can bone bind all 6 of the maximum number of identified users and identify 25 keys. The Kinect V2.0 will be able to bone bind all 6 users and identify 25 key nodes. Also, because of the increased resolution of the depth sensor, the user data can be separated from the person with a simple cut, and the detection range has been increased from 0.8–4 m to 0.5–4.5 m. It is important to note that the infrared sensor does not require light, i.e., it can still be used in dark or dark environments.

Kinect consists of a colour camera, an IR camera, and an IR projector with a microphone array underneath [21–23] as shown in Figure 1. The IR camera and IR projector work together to achieve the depth image function. The main hardware features of Kinect v2.0 are shown in Table 1.

The colour image is based on the data stream acquired by the colour camera on the far left of Kinect v2.0. The colour camera sensor is shown in Figure 2.

Depth image and skeleton tracking technology is the dominant technology in the Kinect device and is somewhat representative. It contains information about the distance of the current object from the camera’s point of view in addition to the grey scale value. Each pixel has its own information, and when there are enough of them, they can form a point cloud that recreates the geometry of the object

TABLE 1: Kinect v2.0 key hardware features.

No.	Kinect key modules	Brief description of functions
1	Colour camera	Colour data streams are available and essentially all the functions of a normal camera can be achieved
2	IR projector	Emits infrared light into the external environment. Infrared light waves are picked up by the IR camera through scattering and provide a source of thermal energy
3	IR camera	Receives scattered infrared light and performs depth processing of the information to draw a depth image of the Kinect
4	Microphone array	Sound is collected from multiple microphones, filtered for ambient noise, complementary to the user's sound source, and can determine the user's location

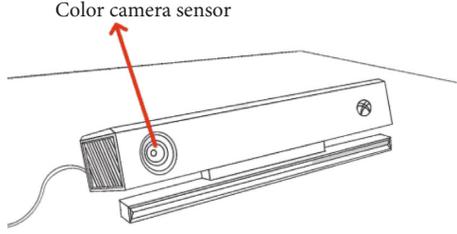

FIGURE 2: Colour camera sensor.

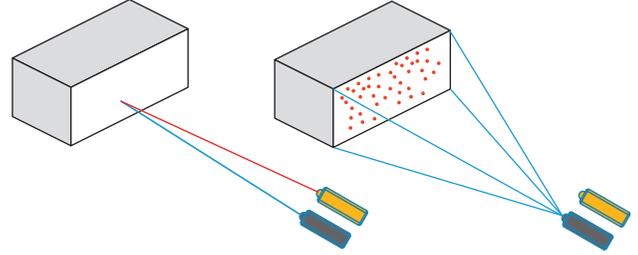

FIGURE 3: Imaging principle of TOF technology.

as well as its position and distance. The closer the object is, the darker the colour in the depth image, while the more distant the object is, the more white it tends to be. The TOF technique allows infrared light to be emitted and the attenuation of the light to be offset by phase detection, as shown in Figure 3.

The pixel information obtained from the depth image contains two parts, where the higher order 13 bits of information is the detected object pixel distance depth information. The Kinect sensor can detect the target human depth information in the valid range of 0.6 m to 4.5 m. The depth image pixel information is shown in Figure 4.

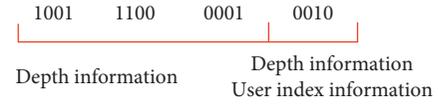

FIGURE 4: Depth image pixel information.

3.2. Feature Extraction and Recognition of Action Parameters.

The motion data captured in Kinect-based somatosensory interaction is complex. In particular, when the types of actions to be recognised are large and variable, the action data can contain a large number of high-dimensional nonlinear features. Therefore, this paper uses linear discriminant analysis based on kernel functions to reduce the dimensionality of the vector space and thus solve the problem of capturing human actions accurately and in real time.

Due to the complexity and variability of human actions in VR scenes, it is not possible to extract some important high-dimensional nonlinear feature information hidden in the action data. Therefore, this paper introduces the kernel function in the LDA algorithm for nonlinear projection to extract the expression features.

In the Kinect captured human movement dataset, let \mathbf{A} be the action matrix and \mathbf{A} be the full rank matrix with class labels in the LDA algorithm [24, 25].

$$\mathbf{A} = [a_1 \dots a_n] = [B_1 \dots B_k] \in \mathbf{R}^{m \times n}, \quad (1)$$

where each a_i ($1 \leq i \leq n$) is a data point in an m -dimensional space. Each block matrix $B_i \in \mathbf{R}^{m \times n}$ ($1 \leq i \leq k$) is the set of

data items in class i . n_i is the size of class i , and the total number of data items in the data set \mathbf{A} is n . Let N_i denote the index of the columns belonging to class i . The global centre c of \mathbf{A} and the local centre c_i of each class \mathbf{A}_i are denoted, respectively, as follows:

$$c = \frac{1}{n} \mathbf{A}e, \quad (2)$$

$$C_i = \frac{1}{n_i} B_i e_i, \quad i = 1, \dots, k.$$

Suppose that the following settings are met:

$$\begin{aligned} S_b &= \sum_{i=1}^k n_i (c_i - c)(c_i - c)^T, \\ S_w &= \sum_{i=1}^k \sum_{j \in N_i} (a_j - c)(a_j - c)^T, \\ S_t &= \sum_{j=1}^n (a_j - c)(a_j - c)^T, \end{aligned} \quad (3)$$

where S_b , S_w , and S_t are referred to as the interclass scatter matrix, intraclass scatter matrix, and total scatter matrix, respectively.

$$S_t = S_b + S_w. \quad (4)$$

The standard LDA objective function can be shown as follows:

$$G = \arg \max_{G \in \mathbf{R}^{m \times 1}} \text{trace} \left(\left(G^T S_t G \right)^{-1} \left(G^T S_b G \right) \right). \quad (5)$$

As the standard LDA algorithm uses a linear computational principle, it leads to less effective results in dealing with nonlinear problems and has a singularity problem. Therefore, kernel function-based LDA is used to reduce the dimensionality of the vector space and thus effectively extract the nonlinear features in human action data.

Set the kernel matrix is $\mathbf{K} = \phi(X)^T \phi(X) = [k_1^1, \dots, k_i^j, \dots, k_C^{N_C}]$, where $k_i^j = \phi(X)^T \phi(x_i^j)$. The Fisher criterion functions in H can be expressed as follows [26]:

$$J(w) = \frac{w^T \mathbf{S}_b^\phi w}{w^T \mathbf{S}_t^\phi w}, \quad (6)$$

where, w is the kernel space projection vector.

$$\begin{aligned} \mathbf{S}_w^\phi &= \sum_{i=1}^C \sum_{j=1}^{N_i} (\phi(x_i^j) - u_i) - (\phi(x_i^j) - u_i)^T, \\ \mathbf{S}_b^\phi &= \sum_{i=1}^C N_i (u_i - u)(u_i - u)^T, \end{aligned} \quad (7)$$

where u_i is the mean of the i th sample in H , u is the overall mean, and \mathbf{S}_w^ϕ is the intraclass scatter matrix w . This can be expressed as follows:

$$\mathbf{w} = \phi(X)\mathbf{a}, \quad (8)$$

where $\mathbf{a} = [\mathbf{a}_1, \dots, \mathbf{a}_N]^T$. Equation (6) can be expressed as follows:

$$J(\mathbf{a}) = \frac{\mathbf{a}^T \mathbf{K}_b \mathbf{a}}{\mathbf{a}^T \mathbf{K}_t \mathbf{a}}, \quad (9)$$

where \mathbf{K}_t denotes the overall scatter matrix of kernels and \mathbf{K}_b denotes the scatter matrix between kernel classes [27].

$$\begin{aligned} \mathbf{K}_w &= \sum_{i=1}^C \sum_{j=1}^{N_i} (\mathbf{k}_i^j - \mathbf{m}_i)(\mathbf{k}_i^j - \mathbf{m}_i)^T, \\ \mathbf{K}_b &= \sum_{i=1}^C N_i (\mathbf{m}_i - \mathbf{m})(\mathbf{m}_i - \mathbf{m})^T, \\ \mathbf{K}_t &= \mathbf{K}_w + \mathbf{K}_b, \\ \mathbf{m}_i &= \frac{1}{N_i} \sum_{j=1}^{N_i} \mathbf{k}_i^j, \\ \mathbf{m} &= \frac{1}{N} \sum_{i=1}^C \sum_{j=1}^{N_i} \mathbf{k}_i^j, \end{aligned} \quad (10)$$

where \mathbf{K}_w is a kernel intraclass scattering matrix. For any collected human action data point x , let \mathbf{A}_{opt} denote a set of feature vectors of the optimal solution; then, we obtain the kernel space projection matrix [28, 29].

FIGURE 5: Live physical interaction in the Cleveland Museum of Art.

$$\begin{aligned} \mathbf{W}_{\text{opt}} &= \phi(X)\mathbf{A}_{\text{opt}}, \\ \mathbf{z} &= \mathbf{W}_{\text{opt}}^T \phi(x) = \mathbf{A}_{\text{opt}}^T \phi(X)\phi(x). \end{aligned} \quad (11)$$

Finally, an SVM classifier is used to implement the recognition of human actions. Combined with a SVM classifier, complex action classification recognition is finally achieved.

4. Two-Dimensional Motion Graphics in Visual Communication

4.1. Association of Movement Parameters with Two-Dimensional Dynamic Chinese Traditional Elements. Somatosensory is the perception of body posture, which can be achieved through a variety of sensors. Sensors can capture changes in our body posture, including the position of our head and individual joints, the speed and direction of movement, and even facial expressions, joint flexion of the hands, gestures, and so on. Essentially, these changes in body posture are changes in some data. Changes in the parameters of the posture data then cause changes in the generated graphics. When the body posture data obtained from somatosensory is used as a “parameter” in 2D dynamic graphics, changes in body posture can naturally lead to changes in 2D dynamic graphics. This creates an interaction between body sensing and 2D motion graphics, enabling the association of body sensing with 2D motion graphics. From a design and user experience perspective, this enables the user’s behaviour to be involved in the design, resulting in a better user experience.

As shown in Figure 5, the Cleveland Museum of Art has developed a somatosensory interaction installation in Ohio, USA. In this installation, when a person approaches the screen, the image unfolds to form a Dunhuang fresco containing traditional Chinese elements. The Kinect body sensing device captures the movement signals of the audience and maps the recognised movement parameters to the traditional Chinese Figs on the mural. This interactive approach allows the audience to control the movement of a character in the image.

The motion of the character’s arms, head, body, and legs in the motion graphics are motion-bound to the viewer’s captured bone points, allowing the viewer to directly manipulate the character on-screen. This type of interaction

USB interface	USB 3.0

used to generate the images in the development environment, human interaction with the different characters in the murals can be achieved. The person can sense the motion graphics in different screens when they are in different areas.

4.2. Binding of Skeletal Parameters. The most resource-intensive part of the Kinect hardware is the bone tracking technology. The bone coordinate system is the most important part of the Kinect hardware, accounting for 50% of the resources of the entire Kinect system. Using this technology, 2D motion graphics applications based on somatosensory human-computer interaction can be developed. Kinect v2.0 can simultaneously identify the position information of six people and bind the user's pose to the coordinate information of key bone points. Bone data is also one of the most commonly utilised parts of action recognition based on Kinect hardware. The correspondence between the human skeleton recognised by Kinect and the character's bones in the mural is shown in Figure 6.

Each bone point is represented by a Joint. In Kinect v2.0, 5 new bone points have been added, as well as 20 bone points

allows for a more fluid experience. The characters in the Dunhuang murals can be synchronised with the viewer's movements. By binding the motion parameters recognised by the Kinect interaction device to the function variables

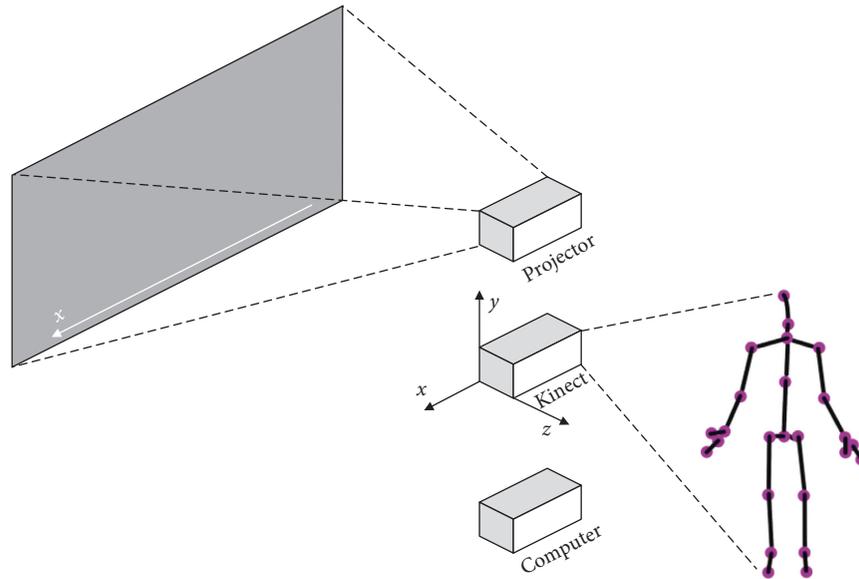

FIGURE 7: Experimental environment for somatosensory interaction.

in the previous version, all of which have corresponding names in the JointType, as shown in Table 2.

5. Experimental Results and Analysis

5.1. Experimental Setup. In order to implement the interactive features offered by the somatosensory device Kinect, the Kinect Development Kit needs to be installed before running the device. The main development software currently available is the official Microsoft SDK, which manages the colour images and depth information obtained by the Kinect camera through the SDK 2.0, sharing it with Unity 3D and writing language functions to control it. In the development environment configuration, the Kinect for Windows SDK 2.0 tool needs to be applied. The Kinect v2.0 device has a resolution of 1980×1080 and an FPS value of 30. The experiments were carried out using the official Kinect wrapper plugin. The experimental hardware configuration is shown in Table 3.

During the experiment, when a person walks across the screen, the Kinect sensor recognises the person's x-coordinates and maps them to the computer through arithmetic. The computer then projects the motion parameters onto the screen through a projector, causing the two-dimensional graphics in the mural to change dynamically in translation. The experimental environment for somatosensory interaction is shown in Figure 7.

5.2. Visual Communication Effects Based on Somatosensory Interaction. The Kinect recognition range is: 0.5–4.5 m, without special circumstances the whole body bone is generally selected for recognition and the full body sensory interaction is selected through subsequent program control. Kinect v2.0 device eliminates the generation of motors and the capture angle needs to be set manually. Therefore, after the capture angle has been determined, a horizontal plane

TABLE 4: Interaction range test.

Distance (m)	Number of tests	Number of times lost
0.5–0.55	30	4
0.55–1.0	30	0
1.0–1.5	30	0
1.5–2.0	30	0
2.0–2.5	30	0
2.5–3.0	30	0
3.0–3.5	30	0
3.5–4.0	30	0
4.0–4.05	30	0
4.05–4.5	30	0

distance conversion is performed for the farthest interaction distance threshold. The closest distance threshold is the horizontal plane distance at which the colour image just fully accommodates the user's entire body. In the absence of special requirements, the threshold can be contracted by 10% to ensure tracking stability. After the interaction range was set for the real environment, interaction capture detection was performed and the experimental results are shown in Table 4.

Using the test data recognised by Kinect, the results and statistical analysis of the nine human movements were derived as shown in Figures 8 and 9 respectively.

As can be seen in Figures 8 and 9, the visual communication technology based on somatosensory interaction achieved 92.1% and 92.2% on the precision and accuracy metric averages, respectively. This indicates that the technology exhibits excellent performance across the nine action types. Unlike traditional digital video that does not have an interactive experience, somatosensory interaction associates a relationship between the person and the digital landscape. The viewer can assume that they are in the space depicted in the mural and can move freely. This allows the viewer and the digital work to break out of the binary spatial relationship

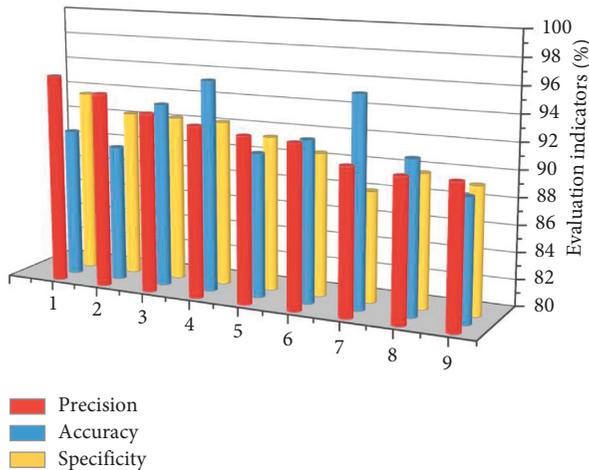

FIGURE 8: Experimental results of motion recognition.

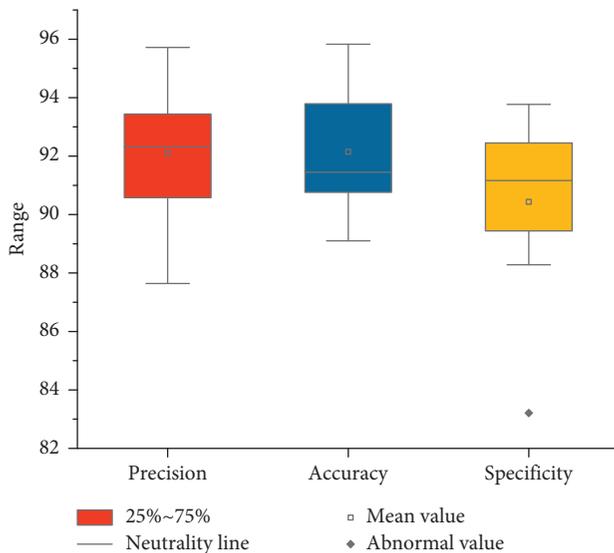

FIGURE 9: Statistical analysis.

and achieve a more multi-dimensional spatial expansion. The application of somatosensory interaction to the visualisation of two-dimensional motion graphics can greatly enrich the visual representation of traditional Chinese elements.

6. Conclusion

In order to explore the feasibility of somatosensory interaction technology in visual communication design, this study proposes a 2D motion graphics generation method based on somatosensory interaction parameterisation and uses traditional Chinese elements as an example for specific applications in visual communication design. The latest Kinect v2.0 device is used and an LDA-based feature extraction method for action parameters is designed in order to improve the recognition accuracy of the Kinect v2.0 device. Using the skeletal parameter binding technique between the human body and the characters in the graphics, the association between physical interaction action parameters and 2D

dynamic graphics is realised, thus greatly enriching the visual representation of traditional Chinese elements.

This study adheres to the principle of combining empirical analysis and normative analysis and establishes an analytical framework according to the research ideas from theoretical analysis to empirical analysis to countermeasures. Suggestions for high-quality economic growth in my country and paths for promoting coordinated regional development were made. This study will take the data from 1993 to 2020 as a unit, taking into account factors such as education, consumption, investment, and labor costs and using SAR model, SEM model, and spatial panel data model to measure the degree of economic complexity in my country. For the research on the difference of regional economic growth in my country, this study is refined to the county level to measure the degree of regional economic development and compare and analyze the regional development differences, and we strive to use empirical evidence to scientifically analyze the degree of economic complexity and regional development differences, using the spatial panel model, SAR model, and SEM model to comprehensively consider the impact of my country's economic complexity on regional economic growth differences; finally, combined with theoretical analysis and empirical test results, based on the perspective of economic complexity, coordinated development provides countermeasures and provides corresponding suggestions for the high-quality development of my country's economy, the continuous optimization of industrial structure, and the establishment of regional cooperation mechanisms.

1. Related Introduction

The continuous upgrading of industrial structure, diversification of industrial types, and increasing economic complexity enable enterprises to formulate a reasonable development direction according to social needs. Finally, China encourages enterprises to take the path of green development, strengthen the content of science and technology, reduce resource consumption, actively realize the transformation of industrial structure, and make China's industrial structure scientific and reasonable. All this means that the stability of China's economic growth has been enhanced, and the diversity and complexity of the economy are also improving. With the continuous upgrading and optimization of industrial structure, industrial diversification, and the improvement of economic complexity, higher

requirements are put forward for the measurement of economic development efficiency. More comprehensive, more specific, and more complex measurement indicators are indispensable for China's economic development in the construction of modern economic system. All regions pay more and more attention to the healthy development of market economy, actively explore regional cooperation and regional mutual assistance mechanisms, and pay more and more attention to the relationship between government and market. The current situation of China's regional economic development still has the problems of large regional economic differences and unbalanced regional social and economic development. In recent decades, most of the work of quantifying the complexity of socioeconomic systems and financial markets has been done by physicists. They help promote economic research by introducing Physics related

research methods and models into economic research. Although scholars have conducted a series of studies on economic development, international economic complexity, regional development balance, and other issues, under the background of China's economic growth from high speed to medium high speed, from high speed to high quality, based on the perspective of economic complexity, there is a lack of research on the level of economic development and regional development differences in China [1–10].

This study adopts a relatively novel nonmonetary index-economic complexity index as the measurement index of China's economic development and analyzes the differences of regional economic growth in China by subdividing counties. SEM model analyzes the impact of China's economic complexity on regional economic growth differences and improves the relevant theoretical research. Finally, based on a series of research evidence, this study attempts to put forward the countermeasures to control the dynamic and coordinated development of regional economy from the perspective of economic complexity, so as to provide some reference for broadening the research field of economic complexity and regional economy and growth differences.

2. Related Research Methods and Measurement Models

2.1. Theil Index. Theil entropy standard index calculates the inequality degree of regional or individual indicators through entropy, which is abbreviated as TL index in the article. The value of the TL index ranges from 0 to 1, with a coefficient approaching 0 indicating a small amount of difference, and a coefficient approaching 1 indicating a large developmental difference in the subject variable. And the Theil index has a decomposition property, which has a fine-grained role in the analysis of the difference properties of the measured subjects. The main formula of Theil index is as follows [11–15]:

$$T = \frac{1}{n} \sum_{i=1}^n \frac{y_i}{\bar{y}} \ln \left(\frac{y_i}{\bar{y}} \right). \quad (1)$$

The following formula is the application formula after data grouping:

$$T = \sum_{k=1}^k w_k \ln \left(\frac{w_k}{e_k} \right). \quad (2)$$

The good decomposability of the index can refine the research on the differences of the subjects and, more specifically, measure the degree of inequality of the measurement subjects. When the number of subject samples is large, it can be regarded as multiple group samples, and the disassembly of the main expression of Theil formula can analyze the contribution of the gap between sample groups and the gap within the group to the total gap specifically as follows:

$$T = T_b + T_w = \sum_{k=1}^k y_k \ln \left(\frac{y_k}{n_k/n} \right) + \sum_{k=1}^k y_k \ln \left(\sum_{i \in g_k} \frac{y_i}{y_k} \ln \frac{y_i y_k}{1/n_k} \right). \quad (3)$$

The difference between groups T_b is expressed as

$$T = \sum_{k=1}^k y_k \ln \left(\frac{y_k}{n_k/n} \right). \quad (4)$$

The intragroup gap T_w is expressed as follows:

$$T_w = \sum_{k=1}^k y_k \left(\sum_{i \in g_k} \frac{y_i}{y_k} \ln \frac{y_i y_k}{1/n_k} \right). \quad (5)$$

T is the Theil index to measure inequality; k is the grouping sample value; y_i is the value of the individual; y_k is the variable value of the k group; e_k is the population proportion; n_k is the number of individuals in the k group g_k ; w_k is the proportion of k groups of values to the total value. The sum of the within-group gaps of each group constitutes the within-group gap term, and the specific calculation methods are not very different.

2.2. Moran's I. Combine spatial data and variable data to analyze the characteristics of spatial data. The highlight of spatial measurement is that relatively common panel data or cross-sectional data take into account the effect of mutual distance to take into account the spatial effects and spatial dependencies between variables. Before constructing a spatial econometric model, it is necessary to consider the spatial relationship between regions and construct a spatial weighting matrix. In this paper, a geographic weight matrix W is constructed based on the geographic adjacency relationship. W contains the regional distance spatial matrix of 31 provinces and cities in my country (excluding Hong Kong, Macao, and Taiwan). Ordinary time series are only unidirectionally correlated, while spatial series have multi-directional correlations of variables, and there is the possibility of mutual influence. Before constructing a related spatial model, it is necessary to test the dependence and correlation of geographic space. For example, if Moran's I passes the test, a spatial econometric model can be used for analysis, and a spatial econometric model can be constructed for analysis. The correlation test shows that there is no spatial correlation in the tested area, so the time series model of Putin is suitable for analysis. Moran's I is actually the coefficient between the observed variable and the spatial lag, and the equation is expressed as

$$\text{Moran's I} = \frac{\sum_{i=1}^n \sum_{j=1}^n W_{ij} (x_i - \bar{x})(x_j - \bar{x})}{S^2 \sum_{i=1}^n \sum_{j=1}^n W_{ij}}. \quad (6)$$

The construction of Moran's index is based on the establishment of the spatial weight matrix W , i and j are expressed as the distance between regions, and S^2 is the sample variance, expressed as

$$S^2 = \frac{\sum_{i=1}^n (x_i - \bar{x})^2}{n}. \quad (7)$$

2.3. Spatial Lag Model (SAR). Spatial lag model SAR is a kind of spatial econometric model. The spatial lag model is also known as the spatial autoregressive model. The model lag process is an autoregressive process. There are many complex classifications of spatial econometric models, and there are higher-order and more complex situation settings in order. In view of the difficulty in estimating the spatial weight problem in the model, the current spatial econometric models are mostly based on the first-order model. The first-order autoregressive model and the first-order average moving model are set based on adding spatial weights to consider. The spatial lag model SAR reflects whether the correlation of the dependent variable affects the nearby area through a spatial mechanism. Formally, the space lag model is related to the ordinary time lag model, and there are similarities between the two, but the space lag model adds space factors to consider, and the multidirectionality of the space correlation makes the calculation of the space effect necessary. The expression of the spatial lag model SAR is as follows [16]: SAR model has a negative impact on my country's economic complexity and poor regional economic growth. Comprehensive consideration of the impact of different

$$y = \lambda W_y + X\beta + \varepsilon. \quad (8)$$

W is the established spatial matrix. There are various types of matrix, including geospatial weight matrix, economic distance spatial weight matrix or traffic weight matrix, etc. X is the data matrix, and λ is the spatial autoregressive coefficient, that is, the parameter of the lag term, the measurement. The significance of the influence of the spatial lag matrix on y is to measure the spatial multidirectional effect of each observation variable introduced into the model, β is the correlation coefficient, and ε is the white noise interference term.

2.4. Spatial Error Model (SEM). The spatial dependence of variables can also be represented by the error term. This model form reflects the effect that the regional spillover is a random outflow and is called the spatial error model SEM. The spatial error model expression is as follows:

$$y = X\beta + \mu = X\beta + (PM\mu + \varepsilon), \quad \varepsilon \sim N(0, \sigma^2 I_n). \quad (9)$$

μ is the disturbance error term, and the regression value residual vector has spatial dependence; M is the spatial weight matrix; p is the autoregressive parameter, which means to measure the influence scale and degree of the variables in the local area on the surrounding area, etc. Spatial dependence: ε is the white noise interference term.

This model is suitable for the measurement of the spatial relationship between the spatial dependence value and the variable due to the difference of the geographical relative position of the region in the presence of the spatial effect.

3. Spatial Econometric Analysis of the Impact of Economic Complexity on Regional Economic Growth Differences

3.1. Data Sources. In this experiment, the basic data of 31 provinces and cities in my country from 1993 to 2020 were selected for analysis. The reason why the study area does not include Hong Kong, Macao, and Taiwan is because the differences in the basic conditions of listing in various regions may lead to errors in model setting and parameter calculation. The data of this study come from "China Statistical Yearbook," "China County Statistical Yearbook," "China Financial Yearbook," "China Fixed Asset Investment Statistical Yearbook," "China Labor Statistics Yearbook," "China Science and Technology Statistical Yearbook," "China Education Statistical Yearbook," China Education Expenses Statistical Yearbook, China Price and Urban Residents Income and Expenditure Survey Statistical Yearbook, and provincial (municipal and autonomous region) statistical yearbooks and social statistical bulletins. The listed company data used to measure economic complexity in my country comes from the reset financial database. The selected dataset mainly uses the basic registration information and financial information of all listed companies on the Shanghai Stock Exchange and Beijing Stock Exchange since 1993 to 2020. The relevant experimental data in [17] can be viewed from the public official website, the data is authentic and reliable, and it has a certain representative significance. The relevant experimental data can be accessed from the public official website, and the data is authentic and reliable and has certain representative significance.

3.2. Spatial Autocorrelation Test of Regional Economic Growth Differences in My Country. The most common method to measure the spatial sequence and the spatial autocorrelation is Moran's I. Correlation: the Moran index I is between -1 and 0 ; that is, the measurement high-value area is adjacent to the low-value area. First of all, the article sets the spatial matrix of the 31 provinces and cities observed, and the 0-1 spatial weight matrix of 31×31 is used here. Table 1 shows the results of the global autocorrelation bilateral test on the Theil index of the explanatory variables in 31 provinces and cities. The global spatial autocorrelation index of my country's regional economic disparities, the Moran index, is all greater than 0 , indicating that regional economic disparities have spatial correlations (Table 1). Except from 1993 to 1997 and 2004, the rest of the years passed the P test at the 5% level, and the test results are true and valid as a whole. This proves that the differences in regional economic growth in my country from 1993 to 2020 are spatially correlated, and the differences in economic growth between provinces and cities are interrelated and affect each other, rather than being single and independent [18].

TABLE 1: Spatial correlation test of regional economic differences from 1993 to 2020.

Years	Moran I	Z value	P value	Years	Moran I	Z value	P value
1993	0.039	2.07	0.07	2007	0.272	2.90	0.00
1994	0.039	3.07	0.07	2008	0.531	1.26	0.01
1995	0.001	2.33	0.07	2009	0.371	1.93	0.03
1996	0.039	2.06	0.07	2010	0.128	1.50	0.07
1997	0.007	3.37	0.06	2011	0.309	3.16	0.00
1998	0.038	3.06	0.05	2012	0.192	2.13	0.02
1999	0.055	3.81	0.02	2013	0.199	2.07	0.02
2000	0.055	2.20	0.04	2014	0.199	2.15	0.02
2001	0.061	2.86	0.02	2015	0.233	2.61	0.00
2002	0.064	2.91	0.02	2016	0.352	3.30	0.04
2003	0.028	1.57	0.03	2017	0.298	-2.86	0.02
2004	0.121	1.43	0.08	2018	0.179	1.99	0.02
2005	0.161	1.80	0.03	2019	0.228	3.48	0.02
2006	0.105	1.30	0.04	2020	0.164	1.93	0.03

According to the trend chart of Moran index drawn in Table 1, it can be found that, with the continuous development of the economy, the spatial relationship of regional economic growth differences in my country has shown a trend of fluctuation as a whole (Figure 1). The spatial correlation curve has been fluctuating and rising since 1993, reaching a peak in 2009, and then decreasing slightly. The curve change is relatively stable. This is because with the continuous development of social economy and the continuous improvement of transportation and communication construction, the connection in regional space has become closer, and the spatial correlation has been continuously strengthened. The economic development of a certain area will directly affect the economic situation radiating to the surrounding areas, coupled with population mobility and policy influence, resulting in a positive spatial correlation of economic growth differences.

3.3. The Spatial Impact of My Country's Economic Complexity on Regional Economic Growth Differences

3.3.1. Construction and Selection of the Spatial Econometric Model. In order to better construct a spatial econometric model and choose whether there is a spatial effect between the variables to be diagnosed. In order to conduct a more accurate spatial econometric analysis of my country's economic growth differences, it is necessary to perform a Lagrange multiplier test (LM test for short) on the estimated results of the spatial model to select a better spatial econometric model. After the spatial weight matrix is set, the reference items need to be tested for Spatial error and Spatial lag. The spatial effect test is set based on the ordinary linear model OLS test. Before the spatial effect test, it is assumed that there is no spatial autocorrelation in the level of economic growth differences between 31 provinces and cities in my country from 1993 to 2020. As can be seen from Table 2, among the three tests on spatial error, Moran's index, LM test, and RL test all rejected the hypothesis that there is no spatial autocorrelation in my country's economic development level, and the P values were all significant at the level of 0.05, and the statistical RL test was passed, and the LM test

results were relatively good in the two tests after the space, and the above results all rejected that there is no space for the differences in economic growth levels of 31 provinces and cities in China from 1993 to 2020. The relevant null hypothesis shows that spatial econometric analysis is needed to measure the influencing factors of the differences in the level of economic development in my country (Table 2) [19, 20].

In the spatial econometric model, the spatial lag model (SAR) and the spatial error model (SEM) play an important role. Both of them take into account the spatial multidirectional effects between the variables in the model. The biggest difference between the two is the disturbance term constitute. The SAR model pays more attention to spatial dependence, and the key error items in the spatial error model are the product of the dependent variable and the corresponding spatial weight matrix. The SEM reflects the spatial dependence between variables through the error term. The components of the spatial lag item are the product of the corresponding spatial weight matrix and the error term. The SEM model lag term interprets the error term rather than the dependent variable of the model reference. In order to better explain the impact of my country's economic complexity on regional economic growth differences, the SAR model and the SEM model are now constructed to measure and analyze it.

3.3.2. Analysis of the Impact of My Country's Economic Complexity on Regional Economic Differences. In order to more accurately measure and evaluate the differences in my country's economic growth, it is necessary to conduct a comprehensive analysis of the geographic space of our city's Theil index. This paper divides my country's geographical space into eastern, central, western, and northeastern regions and analyzes the economic development and economic growth differences of cities located in different geographical locations. Specifically, each region has its own local economic characteristics, so the selected regions include both the eastern and central regions, as well as the western and northeastern regions.

The difference in economic growth in the eastern region of my country is generally high. As an important region for

FIGURE 1: Spatial correlation test of regional economic differences from 1993 to 2020 (Moran I index).

TABLE 2: Spatial effect test of factors influencing my country’s economic growth differences.

	Statistic	df	P
Moran’s I (spatial error)	6.403	1	0.02
Lagrange multiplier (error)	6.099	1	0.03
Robust Lagrange (error)	9.811	1	0.01
Lagrange multiplier (lag)	4.521	1	0.05
Robust Lagrange (lag)	7.233	1	0.02

my country’s reform and opening up, the economic development level of the eastern region ranks high. In addition, the establishment of special economic zones has greatly promoted the social and economic development of the eastern region. As shown in Figure 2, Shijiazhuang, Shanghai, Fuzhou, Quanzhou, Huizhou, Shenzhen, Wenzhou, and other cities have relatively high Theil indices. These cities are the representatives of my country’s economic and trade development and the development of the tertiary industry. Due to the successful transformation of foreign trade and some industries, the economic situation of some people in the city is good. At the same time, the social and economic developed areas are attractive to talents. Such areas are easy for most people to flow, and the quality and quantity of labor force are improved. It will counteract the development of the regional economy, strengthen the development of local industries, and add icing on the cake for the regional economy. The development of transportation and roads in such areas is convenient for the development of trade and the improvement of the economic level, but the rapid growth of economic development will accelerate the silence and elimination of other industries, causing outdated and technologically backward industries to stop developing and accelerate their elimination. However, the development of regions without excellent enterprises and convenient transportation is easy to be ignored, so that the economic growth rate of some regions is slow, and the economic development is lagging. Compared with some regions with ultra-high economic growth, the Theil coefficient increases, and the level of interregional economic development appears different. Compared with Shanghai and Shenzhen, the

difference in economic growth in Beijing is not very high, first, because Beijing occupies a relatively small area in terms of geographical location; secondly, Beijing is the capital of my country, and its political significance is greater than its economic significance; Beijing pays attention to the grasp of macro-control. The eastern region is an important economic development region in my country and has made outstanding contributions to the high-quality social and economic development and industrial optimization and upgrading in China. Therefore, when formulating regional development strategies, it is more important to adjust measures to local conditions and formulate scientific development policies.

The economic growth differences in the western regions of my country are generally large, and the Theil index of some cities is more prominent. As can be seen in Figure 3, Lhasa, Nyingchi, Shigatse, Shannan, Yushu Tibetan Autonomous Prefecture, Xilingol League, Yulin, Zunyi, and other regions are regions with relatively unbalanced economic development and large differences in economic growth. There are many cities with unbalanced economic development in Tibet, Gansu, and Inner Mongolia, and there are some common reasons for the high Theil index in the western region: first, the provinces and cities in western my country generally have problems of being deep in the inland and difficult to build traffic roads; secondly, due to the geographical characteristics and development mode of the west, it is difficult to optimize and upgrade industries in some areas, and the backward productive forces cannot promote the improvement of social and economic levels; finally, due to the lack of education and the loss of talents, the

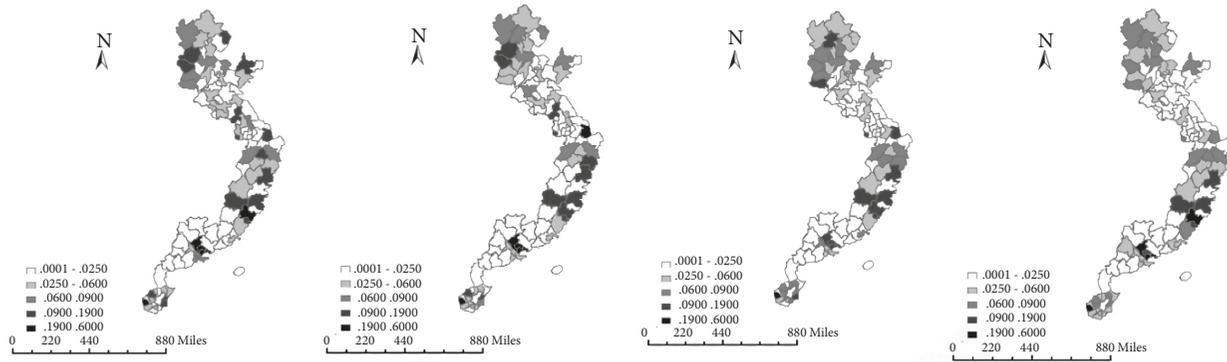

FIGURE 2: Differences in economic growth among cities in eastern region in 1993, 2002, 2011, and 2020.

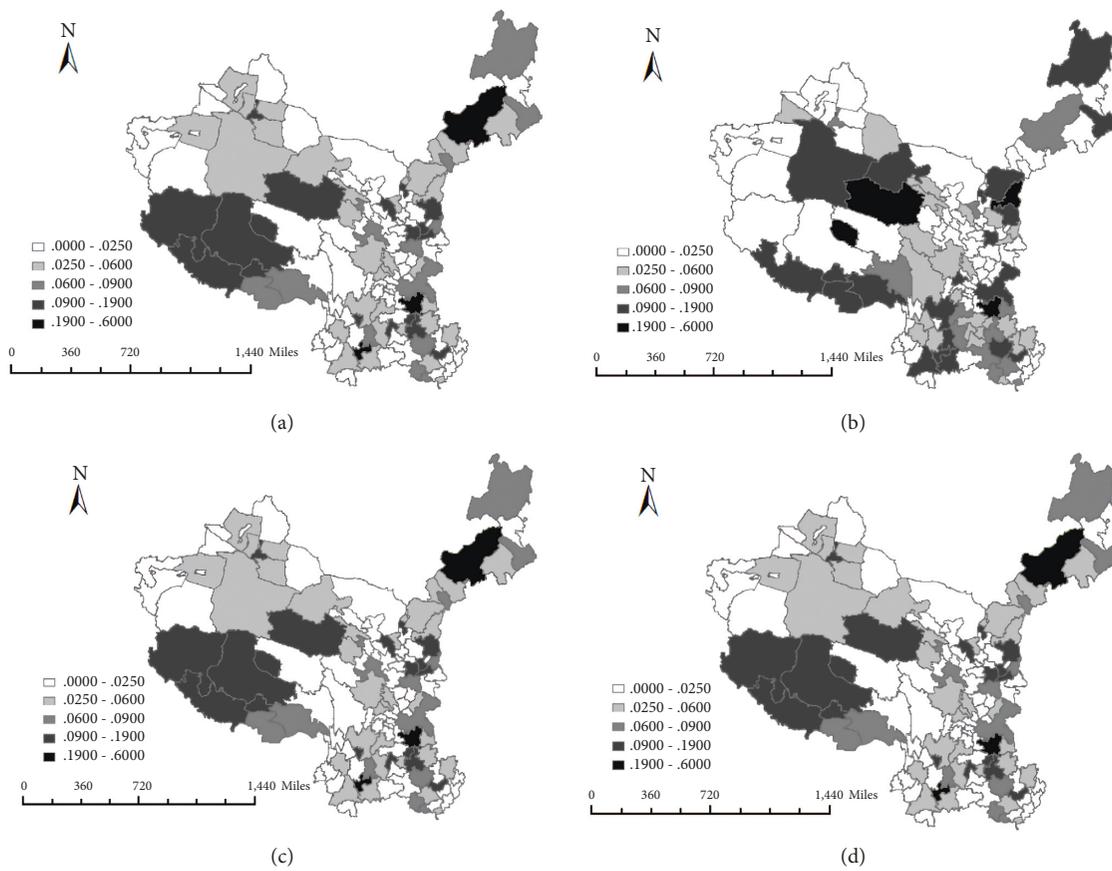

FIGURE 3: Differences in regional economic growth in western my country in 1993 (a), 2002 (b), 2011 (c), and 2020 (d).

speed of economic development is not easy to improve. There is a general problem in the west that productivity restricts the development of talent education, and the lack of high-quality labor will lead to a decline in social productivity. The western region has a wide geographical coverage, and the ecological environment in some regions is relatively fragile, which means that if the production mode of other regions is copied, the blind development of the primary and secondary industries will increase ecological pressure and pose a threat to green development. Within the western region, Xinjiang, Chongqing, and Guangxi do not have

particularly prominent differences in economic growth among cities. Xinjiang, Inner Mongolia, Guangxi, and other regions are vast and sparsely populated, and their economic level is relatively average. Chongqing, as a municipality directly under the Central Government, has made some achievements in economic development, constantly strengthening foreign exchanges and industrial upgrading, and its social development level and per capita income are relatively considerable. The western region has a large area, uneven levels of economic development, a large number of poor people and regions, and an obvious gap between the

rich and the poor. This poses challenges and requirements for the government's scientific regulation and control policies. In formulating development strategies and economic development guidance, it is even more necessary. Adjust measures to local conditions and strengthen the grasp of regional economic and geographical features.

Compared with other regions, the difference in social and economic growth in the central region of my country is relatively small. Except for some provincial capital cities and transportation hub cities, the Theil index of other cities has little difference (Figure 4). Hefei, Nanchang, Changsha, and Wuhan, as provincial capitals, have a significantly higher degree of difference in economic growth compared with surrounding cities. This is due to the fact that such cities are the economic and political concentration points of a province, and the diversification of industries and scientific development of technology is more convenient. Provincial capital cities are more attractive to talents and labor, and at the same time, the infrastructure is more complete. As an important area connecting the north, south, and east of my country, the central provinces play an important role in transportation development. This is also the central urban area. We also explained one of the reasons for the relatively low Theil index. Jiujiang City, Yichang City, Zhuzhou City, Shiyan City, and other cities due to their excellent geographical location and traffic conditions have led to an increase in the economic development speed of some counties, and the difference in economic growth with the surrounding regions has increased, which shows that the city's Theil index is relatively high. The central region is linked to the whole country in terms of geographical location and has a vast territory; in terms of transportation development, water, land, and air transportation have huge innate development advantages, and the flat terrain and developed river channels can help speed up regional economic development; in terms of labor force, Henan, as the most populous province in my country, provides high-quality labor for regional development. Generally speaking, the development potential of the central region is huge. With the continuous construction of infrastructure and the continuous increase of investment, the economic development of the central region will continue to improve. However, in the process of development, it is still necessary to pay attention to the development caused by regional natural and human factors. With the steady improvement of the social economy, the economic growth differences between regions are continuously narrowed, and the social and economic development model is optimized.

Observing the differences in economic growth in Northeast China from 1993 to 2020 through Figure 5, it can be found that, except for Changchun City, Dalian City, Shenyang City, Daqing City, Anshan City, Yanbian Korean Autonomous Prefecture, and other cities, the economic growth of other regions as well as the growth differential is relatively stable, and the Theil index is on the small side. However, these regions with high Theil indices and large differences in economic growth often have their own characteristics and reasons for the differences in economic development levels.

Through a series of verification and consideration of the model, this study chooses to construct spatial lag model (SAR) and spatial error model (SEM) to analyze the spatial impact of China's economic complexity on the level of regional economic growth difference. Through the study of Table 3, it can be found that, in the spatial lag model, China's economic complexity is negatively correlated with the difference of regional economic growth, and the coefficient is -0.069 . It shows that the improvement of China's economic complexity plays a catalytic role in narrowing the difference of regional economic growth. The economic complexity index can explain China's economic development. In the spatial lag model for studying the impact of China's economic complexity on regional economy, the Z value is -1.29 , and the results pass the P test, which is significant at the level of 5%, indicating that the SAR coefficient is effective in the model results. The estimated value Rho of spatial autoregressive coefficient is 0.054 , and the estimated value shows significant results at the level of 1%, indicating that there is a spatial effect on the impact of China's economic complexity on regional economic differences, and the model result is more significant. From the perspective of spatial measurement, Moran I index proves that there is spatial correlation between provinces and cities in China in terms of regional economic growth differences. The degree of regional economic growth difference in China does not exist independently but is closely related to the surrounding areas. Adding economic complexity to measure, through the spatial lag model, it can be concluded that if the economic complexity index of a province and city changes, the degree of economic growth difference between adjacent regions will also change, which is reflected in the good economic development and the improvement of economic complexity index, which will not only reduce the difference of regional economic growth, but also reduce the difference of economic growth in surrounding regions, and vice versa. This influence is bidirectional, even multidirectional. The result of the model means that when formulating the regional development strategy, the government needs to consider not only the actual development of the region, but also the policy implementation of surrounding provinces and cities and the actual situation of the region, so as to formulate strategies in line with the actual situation of the region. Science policy: by comparing the results of OLS panel regression test with those of SAR spatial lag model, it can be found that there are differences in variable regression coefficients between the two. The spatial error model is used to analyze the spatial characteristics of the impact of China's economic complexity on regional economic growth differences. Looking at Table 3, it can be found that the regression coefficient of SEM error term of spatial error model λ is shown as 0.049 , and the regression coefficient is significant at the level of 1%. This shows that the spatial error model is reasonable, and the model results are true and effective. In the spatial error model, the spatial impact value of economic complexity index ECI on regional economic growth difference TL is -0.061 , which is significant at the level of 5%. The Z value is -1.93 , and the standard error is 0.05328 . This result also verifies that there is a negative correlation between China's

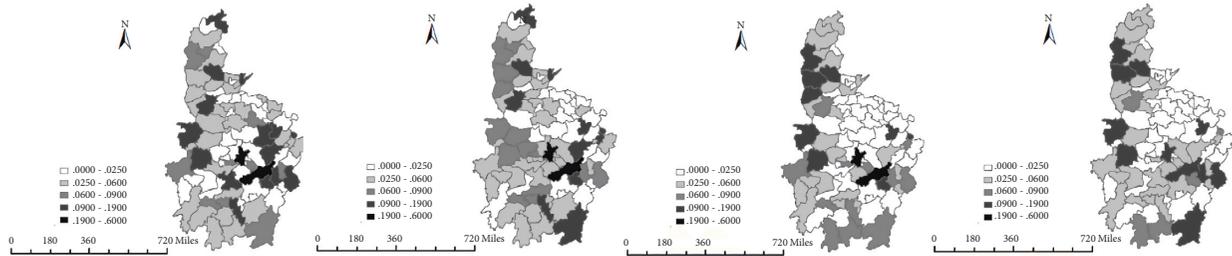

FIGURE 4: Differences in regional economic growth in central my country in 1993, 2002, 2011, and 2020.

economic complexity index and regional economic growth differences. Improving the regional economic complexity index can reduce the difference of economic growth level, accelerate the balanced development of China’s economy, promote the coordinated development of industrial development, and accelerate industrial transformation and upgrading.

3.4. Spatial Econometric Analysis of Other Factors Affecting My Country’s Regional Economic Growth Differences. The differences in my country’s economic development are not caused by a single reason, but different types of reasons of different natures lead to the differences in my country’s economic development. In addition to my country’s economic complexity index, the paper also adds other variables to measure and evaluates the impact of different factors on my country’s regional economic growth differences through

model analysis. The specific analysis results are shown in Table 4.

3.4.1. Analysis of the Impact of Investment Levels on Regional Economic Growth Differences. By observing the data of the IIFA terms in the SAM model, it can be found that the coefficients of IIFA are significant at the 1% level (Table 4). The investment level is represented by fixed asset investment here. The data shows that the improvement of the investment level has a reducing effect on the difference of regional economic growth in my country. If the regional investment is insufficient, it will lead to insufficient vitality of regional economic development and increase the difference of economic growth. At the same time, due to the correlation between different economic growth factors among different regions, the backward investment level will also lead to the slow development of the regional economy in the surrounding areas, which has an adverse effect on reducing the imbalance of regional economic development. Comparing the investment level parameters in the SEM model, the IIFA term coefficient in the SAM model is also significant at the 1% level (Table 4). The coefficient value in the SEM model is slightly higher than that of the investment level in the SAM model, but it also shows that the difference in my country’s regional economic growth is affected by the investment level, and the improvement of the regional investment level is conducive to reducing the economic growth in the region and surrounding areas difference. This result shows that regional governments and enterprises should pay attention to the grasp of investment level and investment intensity

when formulating development strategies, strengthen the setting of scientific investment policies, and improve the high-quality development of regional economy through the introduction of investment [21–23].

3.4.2. Analysis of the Influence of Consumption Factors on Regional Economic Growth Differences. From the perspective of spatial measurement, with the continuous development of scientific and technological information and the continuous improvement of transportation facilities, the communication between populations in different regions has been enhanced, and the changes in people's lifestyles and consumption habits have led to the consumption level and consumption patterns in our country. The impact of social and economic development continues to increase. The consumption habits of the masses in a certain area will directly affect the economic growth difference index between this area and the surrounding areas. If the consumption level in this area declines, or there are differences in consumption patterns, it will directly lead to the expansion of the economic growth difference between this area and surrounding areas, and it is not conducive to regional economic development, and the opposite will have an impact on people's lives. The government should actively observe the characteristics of the market in a timely manner, guide the masses

to develop healthy consumption habits, and continuously improve the consumption level of the people through the development of the social economy, and the improvement of the consumption level of the people will also promote the stable development of the social economy.

3.4.3. Analysis of the Impact of Educational Factors on Regional Economic Growth Differences. By analyzing the educational factors in Table 4, the results of the model show that the educational factors have a positive effect on the differences in regional economic growth in my country. Excessive cultural differences may cause regional economic growth differences to increase. In addition, there is a certain mobility of regional talents. Influenced by the treatment of regional talents, the impact of educational factors on the differences in my country's regional economy has spatial characteristics. Differences in education level and education level lead to differences in regional economic growth. The gathering of high-level talents will lead to the peak gathering of regional economies. However, if basic education is weak, regional economic differences will increase. The impact of educational factors on my country's economic differences is obvious. My country should pay attention to the development of education and the allocation of educational resources. It should not only pay attention to the development

of higher education, but also should not relax the construction of basic education. The development of education in areas with relatively weak economic development and the balanced development of education will play a role in reducing the gap in economic growth in my country [24, 25].

3.4.4. Analysis of the Impact of Human Capital on Regional Economic Growth Differences. This study measures the impact of human capital factors on regional economic growth differences and finds that the level of human capital has an impact on regional economic growth differences, but the impact is weaker than other factors. The level of economic development in the region and surrounding areas is rising; if the level of human capital declines, the difference in economic growth in this region will also be narrowed. It will have an impact on the level of human capital and regional economic development in the surrounding areas and will drive the level of human capital in the surrounding areas to decline and reduce the difference in regional economic growth. It should be noted that the representation vector of the level of human capital in the article is the proportion of the government's investment in education in GDP. It is necessary for my country to change from a country with a large population to a country with excellent human capital, but it also takes a certain amount of time. The improvement of the total amount of human resources, the rational distribution of human resources, and the rationalization of the structure of human resources can promote the continuous high-quality development of my country's economy. The continuous improvement of the human resources system is an issue that the society and enterprises have always paid attention to, only the continuous optimization and upgrading of human resources in order to better promote the economic and social benefits of enterprises.

3.4.5. Analysis of the Impact of Technological Innovation on Regional Economic Growth Differences. Whether it is the SAR model or the SEM model, the coefficient of technological innovation factor is the highest among all evaluation factors, which proves that, compared with other evaluation factors, the level of technological innovation in this model has the highest impact on the difference in economic growth in my country. And the level of technological innovation IB has a positive impact on the regional economic growth difference TL. Both the spatial lag model and the spatial error model show that, with the continuous increase of scientific and technological innovation in some regions, the economic value created by science and technology will increase significantly, which will cause the economic growth difference between the region and the surrounding regions to increase. Although regions with a low level of technological innovation can reduce the difference in economic growth between the region and surrounding regions, there may be a general lack of economic development momentum, which will affect the high-quality social and economic development. At the present stage, my country is in the historical intersection of industrial transformation and technological innovation revolution affecting the

transformation of my country's economic development mode. The government and enterprises need to better grasp and control the technological innovation mode in a scientific way. While promoting the continuous development of industrial informatization and intelligence, we should also pay attention to the coordination of regional characteristics and different technological innovations, develop technological innovations according to local conditions, steadily improve my country's technological innovation capabilities, and drive new models of industrial systems with technological and intelligent production models. The construction of social production capacity and comprehensive national strength will be the key to narrowing the gap in economic growth in my country.

By analyzing the basic statistical data of 31 provinces and cities in my country from 1993 to 2020, the following conclusions are drawn:

First, the development of industries in my country is diverse, and there are regional differences in the diversity of industries. According to the measurement of industry indicators, the development of my country's regional economic industries can be divided into four types of regions, namely, regions with high industry diversity and low industry ubiquity, regions with low industry diversity and high industry ubiquity, and regions with low industry diversity and low industry ubiquity. Industry Prevalence Regions, High Industry Diversity, and High Industry Prevalence Regions.

Second, the time dimension of economic complexity in my country is not very different, but the economic complexity of regional spatial locations varies greatly. The economic complexity index is higher in the eastern region, such as Shanghai, Beijing, Tianjin, Guangdong, Fujian, and other regions. In the early stage of the western region, the economic complexity index was relatively low. In the later stage, due to the continuous development of the economy, the strengthening of the government's macro-control, and the construction of regional infrastructure, the types of industries in the region continued to increase, and the industry was upgraded. The index keeps rising.

Third, not only does the regional economic complexity index have a spatial impact on regional economic development, but also the levels of investment, household consumption, education, human capital, and technological innovation in the SAR model and SEM model also show that they are closely related to the regional economy. There is a spatial correlation of growth differences. The improvement of investment level has a reducing effect on the difference of regional economic growth in my country. If the regional investment is insufficient, it will lead to insufficient vitality of regional economic development and lead to the increase of the difference in economic growth.

4. Conclusion

This study combines my country's economic complexity with regional economic growth differences, puts the relevant basic data from 1993 to 2020 into a panel model for research, and uses the method of spatial econometrics to

comprehensively analyze my country's economic complexity and other factors. The impact of regional economic development was measured. The research highlights of the article lie in the nonmonetary indicators—the calculation of economic complexity, the measurement of regional economic growth differences refined to the county level, and the combination of economic complexity and regional economic growth differences. In general, the observation time span is long, the observation sample size is relatively abundant, and the results of each model are significant.

Aiming at the problems of low building segmentation accuracy and blurred edges in high-resolution remote sensing images, an improved fully convolutional neural network is proposed based on the SegNet network. First, GELU, which performs well in deep learning tasks, is selected as the activation function to avoid neuron deactivation. Second, the improved residual bottleneck structure is used in the encoding network to extract more building features. Then, skip connections are used to fuse images. The low-level and high-level semantic features are used to assist image reconstruction. Finally, an improved edge correction module is connected at the end of the decoding network to further correct the edge details of the building and improve the edge integrity of the building. Experiments are carried out on the Massachusetts building dataset, and the precision rate, recall rate, and *F1* value reach 93.5%, 79.3%, and 81.9%, respectively, and the comprehensive evaluation index *F1* value is improved by about 5% compared with the basic network.

1. Introduction

With the development of remote sensing technology, massive high-resolution remote sensing images provide data guarantee for research in the field of remote sensing [1, 2]. As the most important part of the national basic geographic database, buildings have very important research value in the fields of urban planning, change detection, and geographic information system construction. Building segmentation using high-resolution remote sensing images has always been the focus and difficulty of remote sensing research [3–5]. Traditional building segmentation methods are mostly based on traditional remote sensing image classification technology, but this method cannot achieve high-precision and fully automated segmentation. With the development of deep learning in the field of computer vision, Shao and Cai [6] proposed Fully Convolutional Networks (FCN) for image segmentation tasks, which overcome the shortcomings of traditional image segmentation methods and become the mainstream mode in image segmentation tasks. Subsequently, researchers have successively proposed

image segmentation networks such as U-Net [7, 8] and SegNet [9, 10] on the basis of FCN. In order to improve the segmentation effect of buildings, many researchers in the field of remote sensing have made improvements on the basis of U-Net and SegNet networks. These methods either improve the feature extraction part of the network or compare the basic network with the classical structures in other networks. Combined, the segmentation accuracy of buildings is improved, but there is still the problem of edge blur caused by loss of details [11–13].

Therefore, based on the SegNet network, this paper designs a residual bottleneck structure that can extract multiscale features in parallel by modifying the activation function. Combined with the skip connection operation and the improved edge correction module, an improved deep semantic segmentation network RsBR-SegNet (Residual + Boundary Refinement-SegNet) is used to improve the accuracy and edge integrity of high-resolution remote sensing image building segmentation and provide a reference for the practical application of remote sensing image building segmentation.

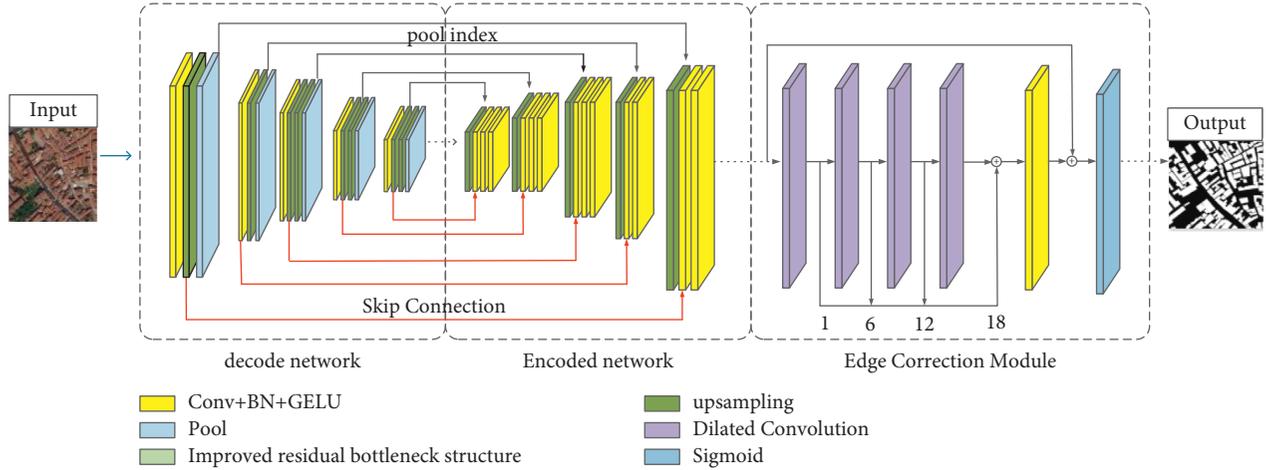

FIGURE 1: RsBR-SegNet model structure diagram.

2. Experimental Data

2.1. Introduction to Datasets. In order to verify the effectiveness and practicability of RsBR-SegNet in the task of building segmentation, experiments were carried out successively on the “Satellite dataset I (global cities)” [14] and the aerial remote sensing image dataset “Massachusetts Buildings Dataset” [15]. The “Satellite dataset I (global cities)” dataset contains 204 satellite remote sensing images of 512×512 pixels, with resolutions ranging from 0.3 m to 2.5 m. The “Massachusetts Buildings Dataset” dataset consists of 151 aerial remote sensing images in the Boston area, each image is 1500×1500 pixels in size, and the data are divided into 137 training sets, 10 testing sets, and 4 validation sets, with a resolution of 1 m.

2.2. Dataset Preprocessing and Expansion. In this paper, the “Satellite dataset I (global cities)” dataset is divided into the training set and test set according to 4:1, without any transformation, only to verify the effectiveness of the model in the task of building segmentation. Then, in order to prove the practicability of the network model in the field of remote sensing image building segmentation and considering the limited computing power of the computer, the “Massachusetts Buildings Dataset” dataset was cropped and expanded. First, each 1500×1500 image in the original training set is cropped into 9 images of 512×512 size, and then the training set is expanded to 12330 images through a series of data augmentation operations such as translation, mirroring, rotation, and random combination. We are required to crop the test set only and expand it to 90 images of size 512×512 .

3. The Working Principle of the RsBR-SegNet Network Model

In order to improve the segmentation effect of buildings at the edges and details, this paper improves the SegNet network structure and builds a fully convolutional neural

network RsBR-SegNet for building segmentation in remote sensing images. Its structure is shown in Figure 1. RsBR-SegNet preserves the upsampling way of the original SegNet, using GELU [16]. As an activation function, we are required to avoid neuron necrosis; retain the first layer of standard convolution in each convolution group in the encoding network to undertake the maximum pooling operation, and use the improved residual bottleneck structure to replace the remaining volumes in the encoding network. Layers are stacked to further extract image features, deepen the network depth, and improve the segmentation accuracy of buildings; use skip connections between the encoding network and the decoding network to fuse low-level features and high-level features between image channels to further retain the original detail information of buildings; the end of the decoding network is connected to an improved edge correction module to refine the edges of buildings and improve the integrity of building segmentation. The input of the network is a three-channel (red, green, and blue) remote sensing image of buildings, and the output is a single-channel segmentation result map, where the white pixels are the segmented buildings, and the black pixels are the background.

3.1. Activation Function. The original SegNet network uses ReLU (Rectified Linear Units) [17] as the activation function, but when the input value of the function is negative, the neuron will appear necrotic, which is an unavoidable defect of the ReLU function. For this reason, this paper selects GELU (Gaussian Error Linear Units, Gaussian Error Linear Units), which performs well in deep learning tasks, as the activation function in the RsBR-SegNet network because it is derivable at the origin and introduces the idea of random regularity. Therefore, the final activation transformation will establish a random connection with the input, avoiding the phenomenon of neuron necrosis and improving the speed and accuracy of learning. The function image is shown in Figure 2.

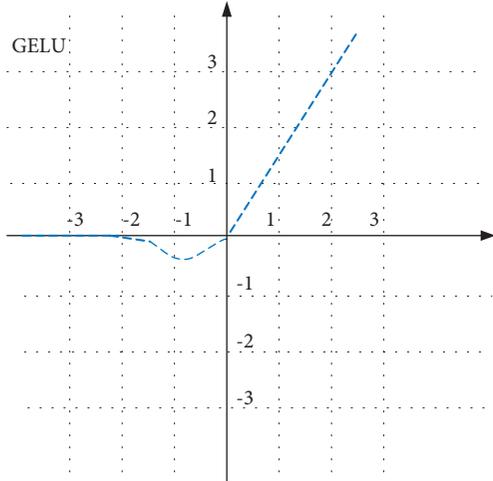

FIGURE 2: GELU activation function image.

3.2. Improve the Residual Bottleneck Structure. By increasing the network depth, the model can learn more complex detailed features, but the increase of the network depth will lead to problems such as gradient instability and network degradation during the training process. The residual bottleneck structure proposed in the ResNet network can alleviate this phenomenon. The MobileNetV2 network proposed by Guillermo et al. [18] is based on the original residual bottleneck structure and proposes a reverse residual bottleneck structure, which reverses the original channel dimension and uses depth-wise separable convolution for feature extraction, which improves segmentation speed and accuracy.

Although the depth-wise separable convolution used in the literature significantly reduces the number of weights, there is still room for improvement in segmentation performance. For this reason, this paper proposes an improved residual bottleneck structure to obtain more feature map information and improve the accuracy of building segmentation. First, in the improved residual bottleneck structure, the first layer adopts the convolution kernels of 5×5 , 3×3 , 2×2 , and 1×1 for parallel calculation of channel-by-channel convolution, receives the feature maps of different receptive fields, concatenates the feature maps of each path together to obtain more features, and then uses point-by-point convolution to reduce the number of channels to the original input size, so that the improved residual bottleneck structure can effectively reduce the number of weights and improve segmentation performance. At the same time, the ReLU activation function will cause information loss due to neuron inactivation in low-dimensional input. GELU can effectively alleviate this phenomenon and improve performance. Therefore, GELU is also used as the activation function after the channel-by-channel convolution and the point-by-point convolution. After reducing the nonlinear transformation, the improved residual bottleneck structure is shown in Figure 3.

The improved residual bottleneck structure is influenced by the idea of the reverse residual bottleneck structure. In this structure, the channel dimension is also expanded and then contracted. By stacking depth-wise separable

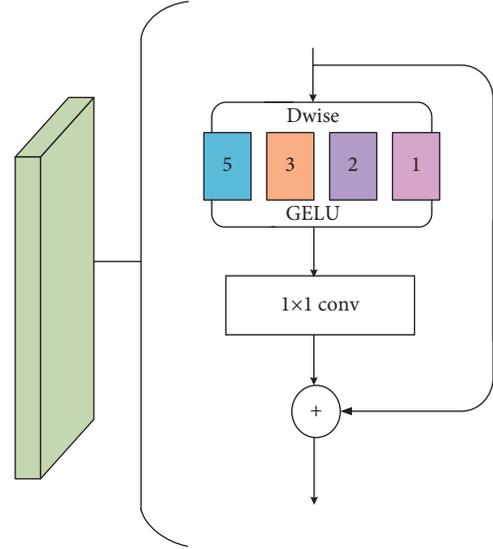

FIGURE 3: Improved residual bottleneck structure diagram.

convolutions of different sizes, global features are further obtained and features improved. Extracting ability and reducing the occupation of running memory, the number of parameters is shown in equation (1). The number of parameters of the reverse residual bottleneck structure in the MobileNetV2 network is shown in equation (2).

$$P = [5 \times 5 + 3 \times 3 + 2 \times 2 + 1 \times 1] \times M + 4 \times M \times 1 \times 1 \times N \quad (1)$$

$$= (39 + 4 \times N - N) \cdot M,$$

$$P = M \times 1 \times 1 \times 6 \times -M + 6 \times -M \times -3 \times -3$$

$$+ 6 \cdot \cdot M \cdot 1 \times 1 \times -N = (54 + 6 \times N + 6 \times M) \times M. \quad (2)$$

In the above formula, P represents the number of parameters, M represents the number of input channels, and N represents the number of output channels.

The number of input channels of the residual bottleneck structure in the RsBR-SegNet network is equal to the number of output channels, so the number of parameters of the improved residual bottleneck structure is less than the number of parameters for the inverse residual bottleneck structure in the MobileNetV2 network.

3.3. Improve the Edge Correction Module. At present, most of the deep learning-based remote sensing image building segmentation methods generate building segmentation results in one step and do not make further corrections to the results. There is a large difference between the segmentation results and the ground truth [19–21]. In order to further correct the segmentation results, this paper proposes an improved edge correction module, which takes the single-channel probability map output by the model as input, automatically learns the residual between the input image and the corresponding real result during the training process, and further refines the input. Image for more accurate segmentation results. The original

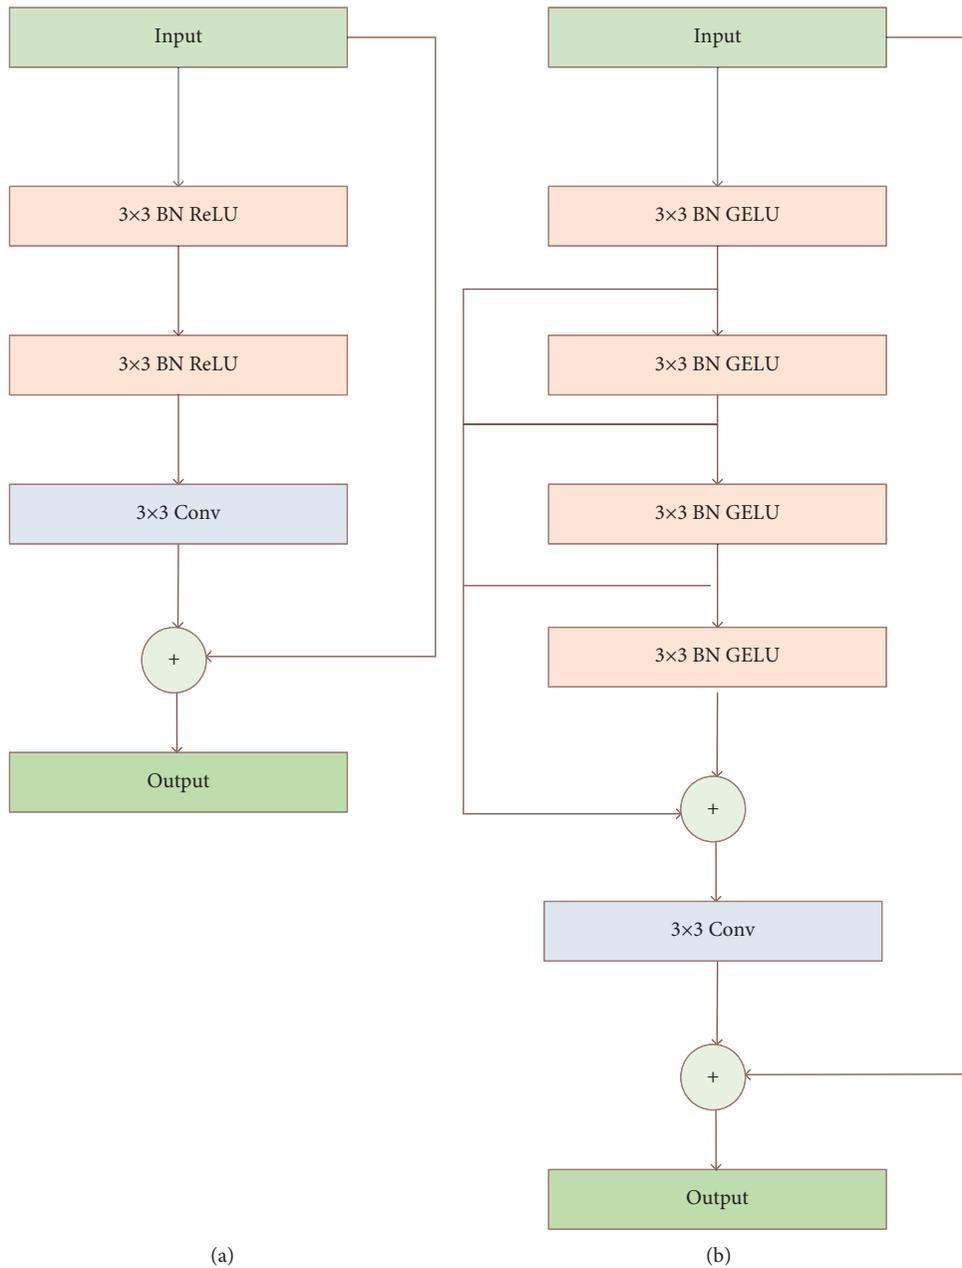

FIGURE 4: Comparison (a) of edge (b) correction modules.

edge correction module was originally proposed by Song et al. [22] to further refine the boundary information, and the structure is shown in Figure 4(a). Although this structure improves the segmentation accuracy of the boundary to a certain extent, due to the small number of network layers, the deeper features of the input image cannot be extracted. Therefore, an improved edge correction module is proposed, which corrects the original edge. On the basis of the module, the depth of the network layer and more receptive fields are increased, and its structure is shown in Figure 4(b).

In the improved edge correction module, four holes convolutions with expansion rates of 1, 6, 12, and 18 are used to extract image features, and then the extracted feature maps are superimposed. After each convolution operation,

normalization, and in the activation operation, in order to avoid the phenomenon of neuron necrosis in ReLU [23–28], GELU is selected as the activation function, and then the standard convolution of 3×3 is used to convert the number of feature map channels to 1, and then the obtained feature map is compared with the input image of this module. Fusion is performed to obtain the preliminary information of the prediction module, and finally, the fused feature map is classified by the Sigmoid function to obtain the final segmentation result map [29–33]. Compared with the original module, the improved edge correction module proposed in this paper has a deeper structure, and the extracted image features are richer. At the same time, the dilated convolution with different expansion rates can also

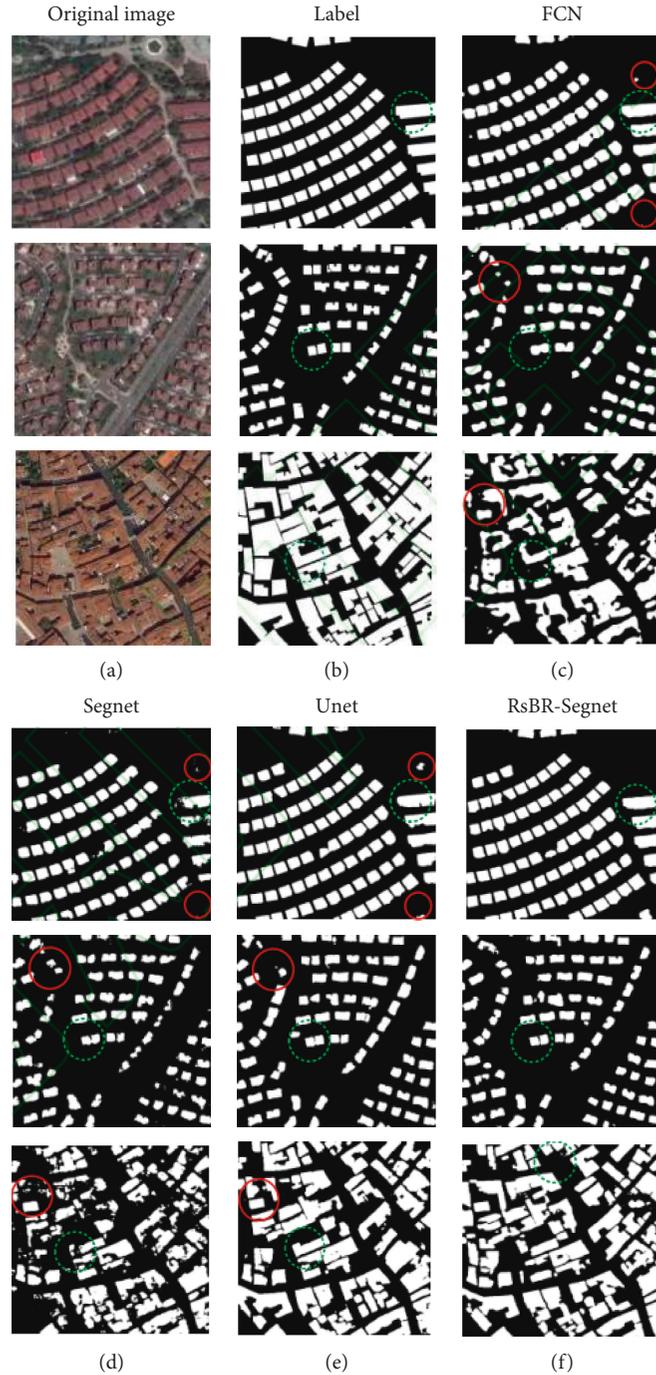

FIGURE 5: Comparison of segmentation results of satellite dataset I (global cities).

obtain more global information, which makes the final segmentation result of the building more accurate and complete.

4. Experimental Results and Analysis

The computer hardware configuration in this experiment is Intel Xeon(R) Gold 5215@2.5 GHz, 64 G memory, NVIDIA GeForce RTX 2080 Ti GPU. The operating system is 64-bit Ubuntu18.04, Cuda10.0 + Cudnn7.5, and the code is based on the PyTorch framework.

4.1. Evaluation Indicators. We use precision rate, recall rate, F1-score, and intersection over union (IoU) to evaluate and analyze the segmentation effect of remote sensing image buildings. The calculation formula is as follows:

$$\text{precision} = \frac{\sum tp}{\sum tp + \sum fp}, \quad (3)$$

$$\text{recall} = \frac{\sum tp}{\sum tp + \sum fn}, \quad (4)$$

TABLE 1: Evaluation of satellite dataset I (global cities).

Network name	Accuracy	Recall	F1 value	Cross-over
FCN	0.86315	0.69252	0.72543	0.57586
SegNet	0.83997	0.62044	0.66617	0.50669
U-net	0.86616	0.73194	0.73196	0.59867
RsBR-SegNet	0.87526	0.75458	0.75907	0.61834

$$F1 = \frac{2(\text{precision} * \text{recall})}{\text{precision} + \text{recall}}, \quad (5)$$

$$IoU = \frac{\sum tp}{\sum tp + \sum fp + \sum fn}. \quad (6)$$

Among them, tp indicates the pixels that correctly segment the building, fp represents the pixels that are wrongly classified as buildings, and fn represents the pixels that are buildings but not correctly segmented. The precision rate is used to measure the probability that the correctly predicted building samples account for all the predicted building samples in the prediction result. The larger the value, the more accurate the building segmentation is; the ratio is actual building samples, the larger the value, the more complete the segmentation of the buildings in the sample; the $F1$ value is used to integrate the two evaluation indicators of precision and recall, and the larger the value, the better the network model. The segmentation is more effective; IoU is used to evaluate the similarity between the identified building area and the ground truth area, and in IoU, a higher value indicates a higher correlation between the identified buildings and the ground truth.

4.2. Evaluation of Segmentation Results. In order to prove the effectiveness of the network in this paper, the classical semantic segmentation networks FCN, U-Net, SegNet, and the network in this paper are tested on the small sample dataset “Satellite dataset I (global cities),” and the experimental results are shown in Figure 5. Here, (a) is the original image, (b) is the label corresponding to the building in the original image, (c) is the segmentation result of the FCN network, (d) is the segmentation result of the SegNet network, (e) is the segmentation results of the U-Net network, and (f) is the segmentation result of the network RsBR-SegNet. In this paper, the area surrounded by the dotted frame is the comparison of segmentation details, and the area surrounded by the solid frame is the misclassification and omission in the segmentation results. It can be seen from the segmentation results that compared with other networks, the image scale change has less impact on the network in this paper, and there are fewer misclassifications and missed classifications in the segmentation results, and it performs better in the segmentation of small buildings. Edge recovery is also more complete. It can be seen from the first line of segmentation results that compared with other networks, RsBR-SegNet can effectively overcome the misclassification of buildings. From the second line of segmentation results, it

can be seen that U-Net has a better segmentation effect on buildings than FCN and SegNet. RsBR-SegNet can further identify small buildings that U-Net misses and loses detailed information. The phenomenon has been effectively alleviated. The third row of segmentation results shows that for buildings interfered by vegetation and road shadows, RsBR-SegNet has a certain antiinterference ability, and the integrity of the building edge is higher.

Table 1 records the test results of each network model on the “Satellite dataset I (global cities)” dataset. As can be seen from the data in the table, compared with SegNet, the improved network has an increase of 3.5%, 13.4%, and 9.3% in evaluation indicators such as precision rate, recall rate, and $F1$ value, and an increase of 11.2% in IoU. It can be seen from the index comparison results that compared with SegNet and FCN, the improved network RsBR-SegNet achieves a significant improvement in the segmentation performance of buildings, and it also has certain improvement advantages compared with the U-Net network. A good segmentation effect can also be achieved on the dataset.

In order to prove the practicability of the network in this paper in the task of building segmentation, each network is tested on the expanded Massachusetts building dataset. The experimental results are shown in Figure 6. The meaning and legend of each column are consistent with Figure 5.

It can be seen from the segmentation results that the improved network has more advantages in the intensive small building segmentation task. The first line of segmentation results shows that compared with other networks, RsBR-SegNet has fewer misclassifications and missed classifications, and the edges of buildings are restored more completely. It can be seen from the segmentation results of the following lines that for small buildings that cannot be recognized by other networks in the figure, the improved network can still identify them effectively, and the overall segmentation effect of RsBR-SegNet is better than other comparison networks.

They are tested on the expanded Massachusetts building dataset. Table 2 records the index evaluation results of each network. From the data in the table, it can be seen that in the large sample data set, the indicators of all networks have improved. Compared with SegNet, the improved network is improved by 1.7%, 6.1%, 5.0%, 6.7% in precision, recall, $F1$ value, and IoU, respectively. Compared with other classical semantic segmentation networks, the RsBR-SegNet network has improved various evaluation indicators, the accuracy rate reaches 93.503%, and the IoU reaches 69.746%, which fully proves the practicability of the improved network in the task of remote sensing image building segmentation.

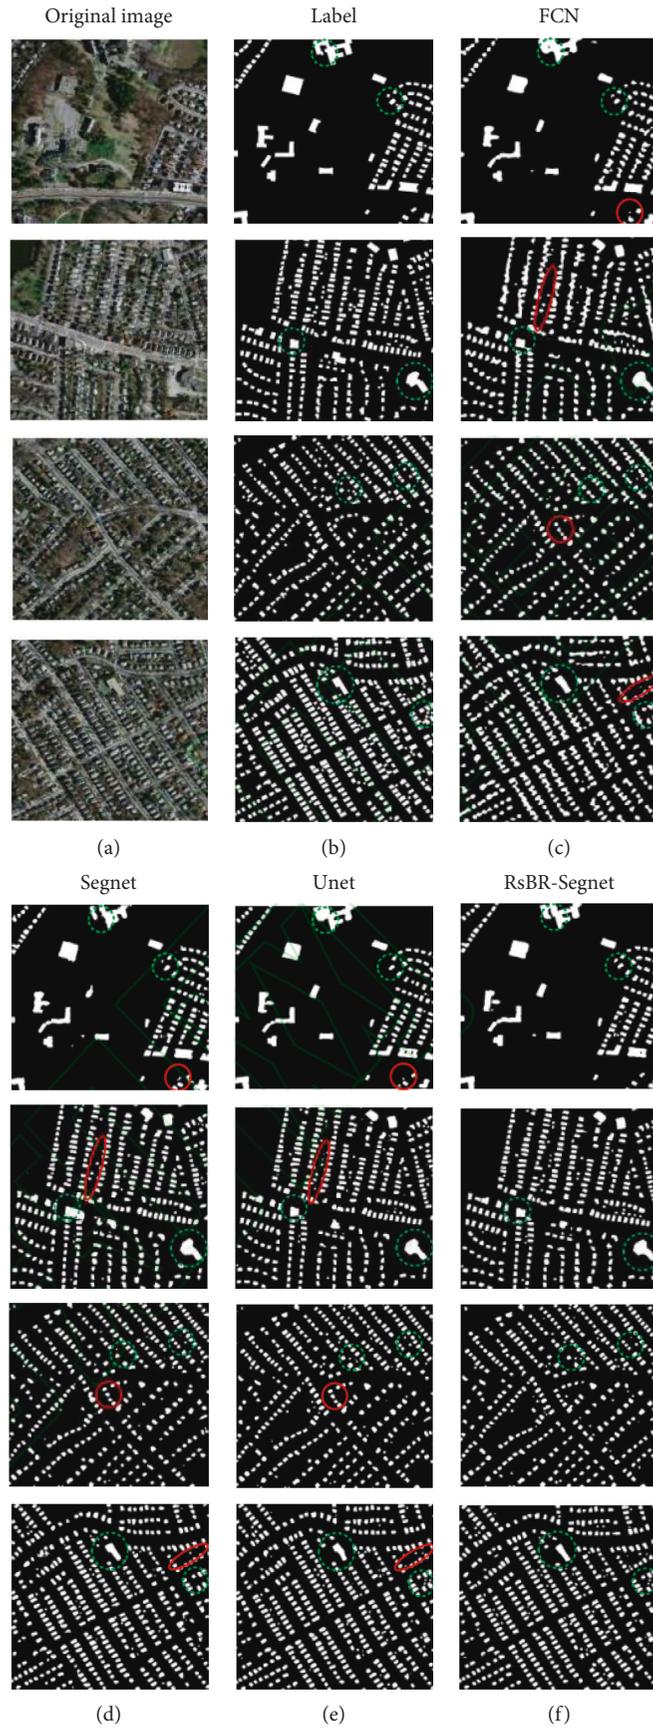

FIGURE 6: Comparison of Massachusetts building dataset segmentation results.

TABLE 2: Massachusetts building dataset evaluation.

Network name	Accuracy	Recall	F1 value	Cross-over
FCN	0.91789	0.73896	0.77118	0.63075
SegNet	0.91844	0.73145	0.77000	0.62998
U-net	0.92345	0.75802	0.79303	0.67429
RsBR - SegNet	0.93503	0.79288	0.81915	0.69746

5. Conclusion

This paper proposes a fully convolutional neural network RsBR-SegNet suitable for building segmentation. CELU as the activation function in the network has to be used to improve the learning ability of neurons, skip connections have to be used to fuse the low-level semantic features and high-level semantic features of the image, the phenomenon of loss of details needs to be alleviated, and the improved residual bottleneck structure and edge correction module are to be used to extract more buildings. It can improve the segmentation accuracy and edge integrity of buildings. Experiments are carried out on satellite and aerial remote sensing image datasets, respectively, and the results show that the RsBR-SegNet network has more accurate segmentation results than the classical segmentation networks FCN, U-Net, and SegNet and effectively overcomes the edge blurring phenomenon. Compared with the evaluation indicators such as precision rate, recall rate, F1 value, and IoU, RsBR-SegNet has achieved the highest value, which is more suitable for remote sensing image building segmentation tasks.

English teaching in general higher education is faced with great challenges. English teachers have to face a group of students from different regions, who have received different English teaching methods during middle school, and their English proficiency is uneven. At present, the teaching methods of most colleges and universities are backward, unable to make full use of modern information technology, and students have low interest in learning, poor independent learning ability, and low learning effect, especially in English. In order to comprehensively improve students' English level, English teaching methods in colleges and universities should be completely different from the traditional teaching methods in middle schools. This paper sorts out trial research, questionnaire survey, and data analysis method and combines some problems existing in college English teaching and the characteristics of microvideo, such as short, concise, sound, and text, to apply microvideo as a teaching resource in college English grammar teaching. A trial group was set up to study the effectiveness of microvideo teaching. No students in the trial group disliked the microvideo teaching and the average score of students in the trial group was 8.992 points higher than the average score of students in the traditional group. The results show that microvideo teaching can not only increase students' interest in learning English but also improve their English language skills.

1. Introduction

In recent years, with the continuous development of the network and modern education technology, the traditional teaching methods need to change correspondingly, and the teaching mode of microvideo has gradually entered the teaching stage. The integration of microvideo into English classroom teaching allows students to freely enter the situation created by the microvideo to learn independently, making the originally boring teaching process vivid and interesting. [1–5] Through rigorous design, microvideo can give students a large amount of information in a short time, which is suitable for students' cognitive characteristics such as short attention span. Microvideo can give different students different learning needs and meet their learning needs. In the case of intuitiveness and interest, students can complete their learning tasks more effectively and improve their self-confidence. [6, 7].

Through the application of microvideo in English classroom teaching, students can use microvideo to arrange

and control their own learning according to their own situation in the English classroom, which can be carried out in a relaxed atmosphere, breaking the form of teacher singing a solo show in the original classroom. [8–12] Students can watch videos at their own pace, rather than closely following the pace of the teacher. What you have learned can be fast-forwarded, what you have not learned can be watched over and over again, or you can stop to think carefully or practice. In addition, you can also learn through group cooperation or with the help of the teacher. The teaching reform that combines microvideo with English classroom teaching truly focuses on learners, regards students as the main body of the teaching process, and respects students' individual differences and personalized needs. In China, in the present stage of higher education, the teaching of English subject is often valued as skills training, teaching form does not have novelty, could not keep up with the pace of The Times development, and English teachers are still in accordance with the "speak, play, and practice," the traditional teaching method of teaching, not giving full play to students'

various aspects and abilities. It is not conducive to the cultivation of information literacy. [13–16].

In the traditional teaching mode, there is less exploration in bring learners into the corresponding learning situation, which is generally explained step by step based on the examination content, which is insufficient to mobilize students' interest in learning. Based on constructivism theory, microlearning theory, situational teaching theory, and knowledge visualization theory, this paper deepens the unique advantages of microvideo teaching resources and applies them to English grammar teaching in colleges and universities through the integrated application of relevant theoretical concepts, in order to obtain better teaching effects and gradually form a teaching model, so as to enrich the theoretical research results of the application of microvideo in English grammar teaching. [17–21].

Microvideo teaching is helpful to enhance students' interest in Learning English and cultivating their independent learning ability. In order to change the monotonous and boring characteristics of traditional teaching and enhance students' interest and enthusiasm in learning English grammar, microvideo teaching should be applied in English grammar teaching in a timely and appropriate way to create a real and vivid language teaching situation. Meanwhile, with the help of microvideo, students can play the video unlimited times, anytime and anywhere, so that they can not only check and fill in the gaps of knowledge that they do not know but also review the old and learn the new, so as to cultivate students' ability of independent inquiry and learning. Microvideo can help teachers change teaching methods and improve classroom efficiency. Microvideo teaching is a new teaching method. In English grammar teaching, teachers can effectively integrate excellent microvideos and share resources, which can not only reduce the burden of teachers but also enable students to actively learn grammar knowledge, which is convenient to improve classroom efficiency and maximize classroom teaching. [22–25] Exploring the application of microvideo teaching in actual English grammar teaching, the microvideo teaching resources are applied to judge the ultimate impact of this teaching method on students' academic performance and to break through the key and difficult points. Based on the application of English grammar in colleges and universities, it is extended to all aspects of English listening, speaking, reading, and writing. [25–27].

Taking college English classroom teaching as an example, this paper analyzes the application ideas and status quo of conventional English teaching. According to the actual situation of college English classroom teaching, this paper tries to combine microvideo with classroom teaching to carry out classroom teaching reform, such as reasonable use of classroom time and improving teaching effect and efficiency.

2. Microvideo Theory

2.1. Microlearning Theory. The biggest characteristics of microvideo are short, fast, fine, and mass participation. Compared with traditional teaching resources, microvideo

teaching resources have vivid images, stimulates the senses, make abstract knowledge interesting, short time, precise content, simplifies the classroom, improves classroom efficiency, and student participation.

Grammar is the basis of learning language subjects well. Languages are governed systems, and such rules are grammatical rules. Mastering grammar rules is the key to improve the language skills of listening, speaking, reading, and writing. Students not only need to master a variety of advanced vocabulary but also must master a variety of sentence patterns and tenses, which shows how difficult it is for college students to learn English grammar well. English grammar microvideo in higher education refers to the production of English grammar knowledge into short and concise video resources in accordance with English curriculum standards and students' cognition skills with the help of modern tools, so as to facilitate students' understanding and learning of grammar. We summarize the grammar contained in the textbook, download or record short videos of relevant grammar knowledge, and create a vivid and interesting micro-video teaching situation, thus causing a strong visual feast for students and motivating them. Meanwhile, we summarize and categorise the relevant grammar, simplify and systematise it in a piecemeal manner, so as to help students structure their grammar knowledge and build up their self-confidence in learning. The clear and convenient grammar tutorials provided by the grammar microvideo can meet the aim of some students to learn grammar when they want, where they want, and to consolidate their grammar knowledge whenever and wherever they want.

The concept of microlearning theory was first introduced in the early years of the 21st century and refers to learning activities that deal with relatively small learning units and focus on short periods of time. Microlearning also refers to “learning activities that break down knowledge into smaller learning units and that people can do in their daily communication and work”, emphasising the convenience of microlearning. Microlearning is a learning activity supported by information technology with micromedia, microprocesses, and microresources based on the concept of ubiquity, connectivity, ecology, and uniqueness. Micromedia emphasise learning activities that involve learning to master smaller pieces of knowledge in a limited amount of time. Learners can learn whenever and wherever they need to, and the content knowledge learned is generally brief. The media provide many preprocessed knowledge modules or knowledge points, which are usually both interlinked and independent of each other.

2.2. Knowledge Visualization. Knowledge visualization is a new teaching idea and an important means to acquire knowledge in the era of graphic existence. Visual representation is the most effective form of knowledge visualization, including knowledge presentation, transmission, and acquisition. Knowledge visualization emphasizes the visualization of learning content and knowledge, and improves students' learning ability and knowledge construction ability

through visual organs. Knowledge visualization is a new requirement of teaching reform and development in the era of graphic survival. Knowledge visualization can not only externalize the tacit knowledge but also visualize, animate, and simplify the explicit knowledge, which can promote the dissemination and innovation of knowledge among groups. However, both visual design and visual application of knowledge are closely related to visual representation, which is an indispensable part of teaching. Therefore, visual representation is a crucial form to realize the value of knowledge visualization. In addition, based on graphic design and cognitive science, knowledge “transmission” and “innovation” can be promoted, such as concept map, mind map, and knowledge animation. Under the condition of information technology, numerous video websites have massive video resources, which provide great convenience for teaching. Figure 1 represents the transformation of dry knowledge into an easy-to-remember picture or video.

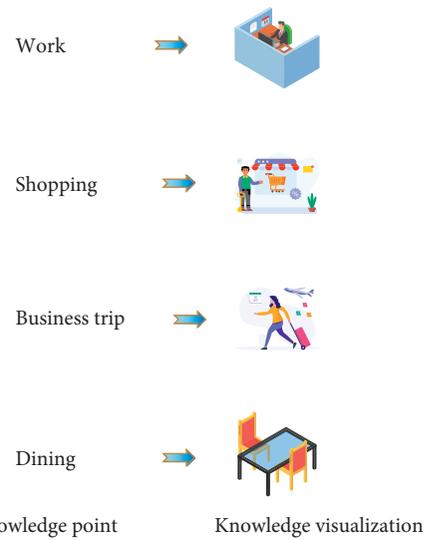

FIGURE 1: Visual transformation of knowledge points.

2.3. Immersion Teaching. Situational teaching is a kind of teaching mode which sets out from the angle of feeling and environment, feeling and speech, feeling and reason, and feeling and all-round development that creates the situation which is beneficial to students’ study, stimulates students’ interest, and combines emotional activities with cognitive activities. Video teaching in the foreign language classroom extends the teaching content by creating contexts, creating realistic and vivid language situations to arouse students’ response to English, increase their enthusiasm for learning English, build their confidence in learning English, develop their ability to learn independently, form a good sense of English and intonation, and lay the foundation for them to communicate in English in their daily lives. The visualization process of teaching English increases the extent to which students remember points (Figure 2).

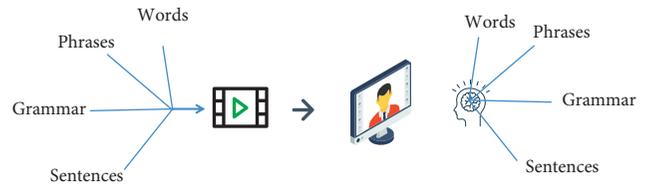

FIGURE 2: Visualizing the process of teaching English.

3. Feasibility of Microvideo Implementation

3.1. Features of English Language Teaching. Grammar is a combination of common patterns, types, and rules summarized from many complex grammar groups. Grammar has strong abstractness and generality. Grammar is a kind of language rules and is the key to master the language. Therefore, to learn a language, we must first understand its grammar rules, which is also true for English learning. English grammar is the expression of English language rules, which can be divided into five levels: sentence, clause, phrase, word, and morpheme. A good command of English grammar is very important for an English learner. The knowledge of English grammar includes not only verbs, adverbs, numerals, and other basic parts of speech but also difficult tenses, such as past continuous, present continuous, present perfect, and past perfect. English grammar content is such a large and complex collection, and it is scattered in English textbooks. In addition, the boring characteristics of grammar content itself make it even more difficult for non-native English learners to learn grammar well. However, after careful summarization, it is found that English

grammar knowledge has potential stability and regularity. For the majority of college students, learning grammar is the most important thing to learn English well in the future. The short and concise feature of microvideo is combined with the systematic feature of English grammar. With the feature of both pictures and videos, students can better understand abstract grammar knowledge, master the rules of English grammar weaving, learn English language better, and improve English communication ability. Figure 3 shows the structure of the language.

3.2. Characteristics of English Teaching. In college, many students come from different regions and receive different education methods, so their learning ability and acceptance ability are at different levels. The traditional way of education is to teach according to one standard, which is difficult to meet the learning requirements of all people. At the same time, college students have more freedom in extracurricular activities, and it is more difficult to spend a lot of time previewing and reviewing lessons after class. Therefore, students must master more knowledge and memorize more knowledge points in class. At the same time, the use of more advanced teaching methods to increase students’ independent learning ability, increase their personal interest. In teaching, teachers should grasp these characteristics of college students, timely and appropriate use of various teaching means, using new things to stimulate students’ interest in learning. Only when students are full of fun and

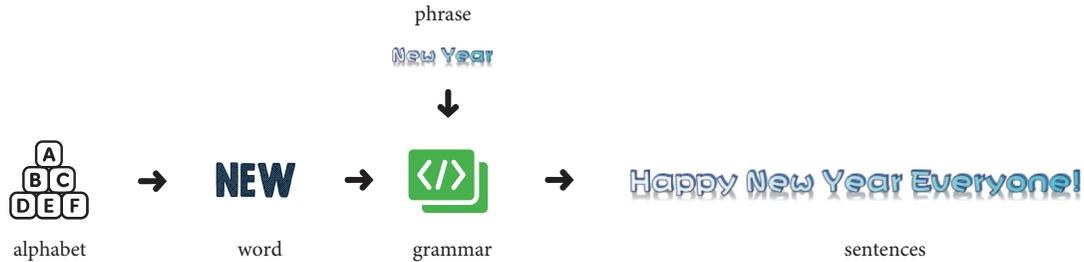

FIGURE 3: The structure of the language.

enthusiasm can they improve their learning efficiency and achieve twice the result with half the effort.

Microvideo teaching resources are generally set for a certain knowledge point or teaching link, and the length of time is generally limited to about five to eight minutes. Compared with traditional English grammar teaching, microvideos are more flexible and targeted, with clear themes and graphic features, which are more in line with the daily learning habits of college students. Combined with the characteristics of English textbooks and students' learning characteristics, the advantages of microvideo teaching resources in grammar teaching are found. Combining the "short and concise" characteristics of microvideo with the scattered and boring characteristics of language grammar, a microvideo teaching mode suitable for college students to learn English is created, which is conducive to students' mastering of grammar knowledge and improving their ability to use grammar, so as to study English more carefully and intently, and improve their English scores.

In traditional classroom teaching, teachers generally focus on the content of the books, with teachers talking and indoctrinating while students mechanically receive. The dryness and abstractness of English itself, as well as the teaching conditions and the characteristics of students, make it much harder for students to learn English well. The advantages of microvideo illustrations, short and concise, and the traditional classroom complement each other, making it possible to improve the quality of English teaching. The teaching context that the microvideo can create is more in line with students' cognitive needs and allows them to focus more on their English learning, thus stimulating their interest in learning English. The use of microvideo teaching in English language teaching is appropriate to create a language situation associated with the teaching content, so as to change the traditional teaching of a single boring mode and enhance students' interest and enthusiasm, and motivate them in learning English. Meanwhile, students can make use of the feature that microvideo can be played anytime and anywhere without restriction, so that they can not only check the content of knowledge that they do not understand but also learn new things from the past, thus developing students' ability and habit of independent inquiry into English language knowledge. Microvideo teaching is a new type of teaching method. By using the characteristics of storable and replayable microvideo teaching resources, teachers can effectively integrate and share resources of excellent

microvideos in English teaching, which can not only reduce the burden of teachers but also make students actively participate in English classroom learning in order to improve the classroom efficiency of English learning. Therefore, the use of microvideos in English grammar learning is not only convenient for students but also for the teachers.

4. Implementation of Microvideo Teaching

4.1. Contrast Test Setup. In this trial, new students were divided into two groups of 100 each randomly assigned. The two groups were randomly selected. None of them had studied college English. One group followed the traditional teaching mode, while the other group adopted microvideo assistance in the normal teaching process. The trial lasted for a semester, and the effect of the trial was tested by comparing the scores at the end of the semester. At the same time, questionnaires were used to understand the application effect of microvideo in English teaching.

Design of the two groups of courses according to the first lesson of college English I, A New Start. The trial design is shown in Table 1.

4.1.1. Teaching Application Examples. Course: A New Start. Course focus analysis: this part of the course is the first lesson in the university and is about introducing people to each other and starting a new life. By watching a microvideo in which people are introduced to each other, it introduces what we are about to learn in this topic: A New Start. Students are able to recognise key vocabulary, key phrases, and important grammatical structures through the dialogue in the video. These points are then applied to the self-presentation through student interaction, and they are memorised without realising it. Figure 4 shows multiple scenarios of self-presentation.

The relevant microvideo is copied onto the electronic whiteboard in the trial class before the lesson and students are divided into established groups and assigned pre-watching tasks, which are completed through discussion and analysis among the group members. The exercises are then tested, explored, and summarized in class to further consolidate students' mastery of the new curriculum. This lesson uses microvideos to supplement the teaching of English and uses group competition and cooperation to complete the exercises, increasing students' motivation to participate.

TABLE 1: Trial design.

Teaching link	Microvideo teaching group	Traditional teaching group
1	Carry out microvideo guidance course	Learn according to books
2	Microvideo introduces new lessons, explains, and summarizes knowledge points	The teacher enters the new curriculum according to the textbook and summarizes the knowledge points orally
3	Microvideo consolidation exercises	Practice according to the exercises after class

FIGURE 4: Self-introduction microvideo.

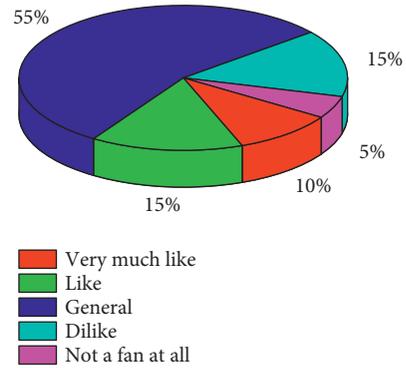

FIGURE 5: Level of enjoyment of the subject of English.

4.2. *Effectiveness of Microvideo Teaching.* The main purpose of this questionnaire is to find out students' attitudes and feelings towards the use of microvideo for English grammar teaching, feedback on its effectiveness, and whether they are willing to continue using it. The students' attitudes towards microvideo-assisted English teaching involved three main questions: Do you like English as a subject? Which aspect of English do you feel is the most difficult? In classroom teaching, do you like the teacher's use of microvideo for English teaching? The questionnaire was used to get a true picture of students' attitudes towards English as a subject, the difficulties in learning English, and how students really feel about the use of microvideo for English-assisted teaching in the classroom.

According to Figure 5, when it comes to whether students like English as a subject, 10% said they liked it a lot, 15% said they liked it, 55% said they liked it generally, 15% said they did not like it, and 5% said they did not like it at all. The above figures show that only 25% of the class enjoyed English. At the same time, 55% of the students expressed a general preference for English, which indicates that learning English is a major barrier to learning for most students. Therefore, it is imperative to increase the class participation rate and student enjoyment.

Figure 6 shows the results of the questionnaire survey on the most difficult part of English. As can be seen from Figure 6, 30% regard listening as the most difficult, 40% regard speaking as the most difficult, 10% regard reading as the most difficult, and 20% regard writing as the most difficult. As can be seen from the above data, oral English is considered the most difficult to learn by students. It can be seen that the output of English is the most difficult part of learning, and repeated input is needed to break through English learning. Repeated learning at difficult points can comprehensively improve oral English learning.

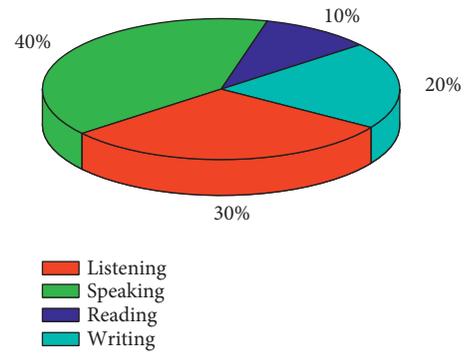

FIGURE 6: Most difficult part of English.

Figure 7 is a survey of students' liking for microvideo teaching. Figure 7 shows that 60% of the students like microvideos very much, 30% like them, and 10% like them generally. There is no student who does not like this teaching method. It can be seen from the data that all students can accept microvideo teaching, and 90% of students like teachers to use microvideo assisted teaching in English class. This shows that the microvideo teaching method is widely welcomed by students and is a successful attempt.

Figure 8 shows the research on how microvideo teaching helps English learning. As can be seen from Fig. 8, 21% of students think microvideo teaching is very helpful for English learning, 49% think it is helpful, 17% think it is a little helpful, and 13% think it is not helpful. It is worth noting that none of the students thought that microvideo teaching was useless for English learning. This shows that microvideo teaching can stimulate students' interest and enthusiasm in learning and make them like learning English more.

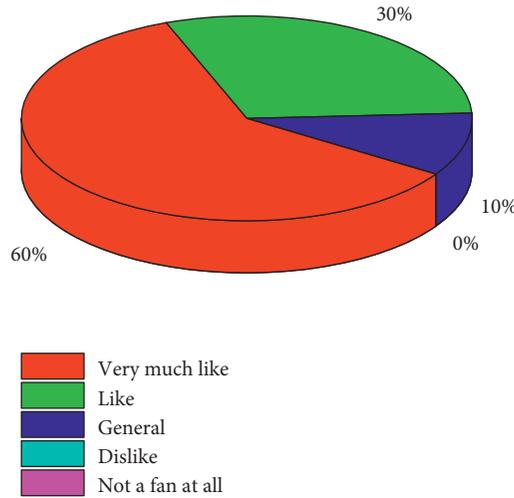

FIGURE 7: Level of liking microvideo.

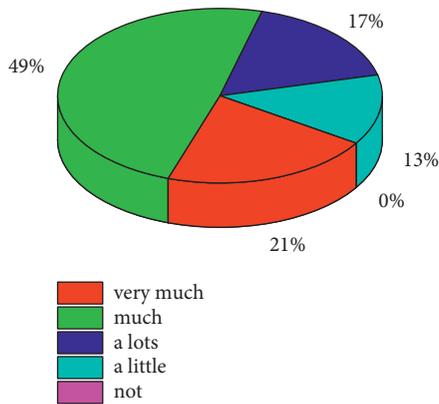

FIGURE 8: Results of microvideo teaching on the usefulness of learning.

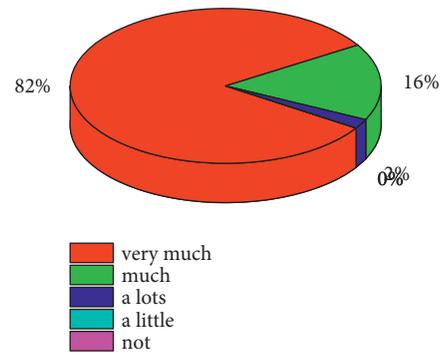

FIGURE 9: Results of the survey on whether students want to continue microvideo teaching.

The research in response to whether to continue with microvideo teaching is shown in Figure 9. As can be seen from Fig. 9, 82% of the students very much wanted to continue microvideo-assisted English teaching, 16% wanted to continue microvideo teaching, only 2% of the students generally wanted to continue microvideo teaching, and no students did not want to continue microvideo teaching. This reveals that all students hope to continue microvideo teaching, which is students' recognition of this teaching method.

4.3. Test Result Inspection. In this study, final tests were conducted on the trial group and the general group, and the results of the two groups were analyzed by sample Student-test, and the results obtained are shown in Table 2.

As can be seen from Table 2, the average score of the final exam of the trial group is 52.263, and that of the traditional group is 43.271. The average score of the trial group was 8.992 points higher than that of the traditional group, with a large gap between the two groups. The standard deviation of

TABLE 2: Student-test analysis results of other grades of the two test groups.

Group	Sample size	Average	Standard deviation	Standard error
Microvideo	100	52.263	10.564	3.594
Traditional	100	43.271	13.018	4.171

the final exam results of the trial group is 10.564, while that of the traditional group is 13.018, indicating that the distribution of the results of the traditional group was more discrete than that of the trial group, and there was a large difference among the students in the traditional group.

As shown in Table 3, the P value of the independent sample test of scores was equal to $0.027 < 0.05$, indicating that the scores of the two groups were significantly different, and it was obvious that the scores of the trial group were higher than those of the traditional group.

Microvideo teaching resources are more in line with the preferences of contemporary university students than text and images. The classroom teaching involving microvideo

TABLE 3: Independent sample test form.

	Variance isotropy test				Mean isotropy student-test				
	F	Single tail significance	t	Degrees of freedom	Two-tailed significance	Average difference	Standard error difference	95% confidence upper bound	95% confidence lower bound
Assumed isovariance	1.825	0.257	1.951	97.534	0.027	6.578	3.952	-0.655	14.256
Nonassumed isovariance			1.951	94.554	0.027	6.578	3.952	-0.662	14.356

simplifies and vivifies students' English learning through dynamic pictures, lively situations, and brightly colored scenes, which has been praised by the majority of students. In English class, the introduction of microvideo English teaching timely and appropriately can not only attract students' attention but also mobilize students' enthusiasm in Learning English to a great extent and stimulate their enthusiasm for learning. Based on the above analysis of student questionnaire and performance test of microvideo English teaching, the teaching design of microvideo in the new English teaching in this study has injected vitality into classroom teaching to a certain extent. The vivid and lively scenes created by microvideos can well attract students' attention in class, improve students' motivation to learn or want to learn English, and improve classroom efficiency and English teaching effect.

5. Conclusion

In this paper, microvideo technology is applied to college English teaching. In the classroom teaching involving microvideo, students' English grammar learning is simplified and vivid through dynamic pictures, lively situations, and brightly colored scenes, which is highly praised by the majority of students. The success of microvideo in English teaching not only increases students' interest in English learning but also improves the level of college English teaching. The application of microvideo technology can well solve the problems of college English teaching and make students from different regions receive more appropriate teaching methods.

With the continuous development of China's economy and society and the gradual reform of various industries, the modern folk opera performance art has received more and more attention, and through the excavation of features in the folk opera performance art, the modern folk opera performance level can be promoted. This paper proposes a generalised principal component analysis (PCA) feature extraction method, which first reorganizes the image matrix, constructs the overall scatter matrix based on the reorganized image matrix, and then finds the best projection vector for feature extraction. The proposed method is a further extension of the 2DPCA module, which can build a scatter matrix of arbitrary dimensions and obtain a projection vector of arbitrary dimensions. The results show that the best feature extraction is achieved by optimising the SVM with a principal component contribution of 50% and using the grid search algorithm. The smaller the dimension of the scatter matrix, the stronger the feature extraction ability of the generalised principal component analysis and the faster the feature extraction speed.

1. Introduction

1.1. Current Development of Modern Folk Opera Performing Arts. The analysis of the basic content and relevance of our vocal singing is of a certain systematic and complex nature. At the current stage of the world opera scene, all the operatic content of vocal singing is divided into two concepts: broad and narrow. Opera in the broadest sense of the word primarily means that there is no limit to the feelings expressed in opera and the way in which they are expressed. Opera performers who express relevant emotions in the course of their stage interpretations that are appropriate to the situation are singing opera in the broadest sense. Opera singing in the narrower sense, on the other hand, is primarily about the use of the stage performer's own characteristics. At the same time, playing to stage performers' own strengths in terms of speed or structure, they give a relatively delicate expression to the inner emotions of operatic characters, grasping their own emotions for operatic performances based on the understanding of the script and the actual situation of the characters. Such a vocal performance is called an operatic vocal performance in a relatively narrow sense.

Through comparison and analysis, we can see that both the broad sense of performance and the narrow sense of vocal performance in opera are closely related to the writer's creative state at the time. In the process of creating an opera, the writer's own state of mind and movements held at the time affect the overall opera and its expression. Considered in terms of scope, opera falls within the scope of the current phase of opera. At the same time, as opera continues to develop and grow, it has been able to inherit most of the commonalities and characteristics of the operatic form of expression and has become an art form rich in connotations. In the process of continuous development, opera mainly includes various forms of expression such as opera story, plot contradiction, and conflict.

However, the art of stage opera in China has expanded and developed rapidly since the founding of New China. During the past two decades, the art of opera in China has gained a great degree of enrichment, mainly in the form of folk opera. The main content of stage opera at this stage basically consisted of actors performing the roles of the main characters and singing on this basis, with the voice style possessing the characteristics of diversity and ethnicity. The

development of stage opera at this stage was mainly operatic in the narrower sense, mainly in the form of large lyrics sung by professional actors through their own unique accents and relatively specialized methods of expression. Generally in the performance of a stage opera, the singer can perform through different parts of the tone and characteristic tempo changes, thus creating a contrasting effect in the stage opera and thus reflecting the distinctive role of the main character and the emotional changes.

Through in-depth comparison and research and analysis, we can find that this stage of China's stage opera creation has made development and progress. The way in which different passages are sung in stage operas can already be contrasted in many ways in terms of content. However, it cannot be ignored that there are still some flaws and shortcomings in this stage of stage opera composition. The inability to compare partial passages or stanzas in minute detail has prevented a very strong sense of contrast in the artistic expression of opera during this period, a conclusion that can be drawn from a comparison of many classical cantatas. It is also clear from this analysis that a large part of the reason for remembering the classics is that the large passages are very significant and expressive, allowing for good expression in terms of pitch, quality, and timbre, but the operatic nature is not fully reflected.

There are two main reasons why the development of stage opera in China has struggled to reflect operaticism. The first is that the stage opera art form needs to rely on musical expression, but the attention of professional composers is often focused between passages and the comparative analysis of the levels of utterance rarely has an emotional element. The second is because the singing ability of professional actors in stage opera can have an impact on the artistic expression of stage opera, which requires professional actors to perform the main character's role freely.

However, through research and analysis, we can find that there is a large gap between the actors' own quality and the actual demands of role interpretation at this stage. After a certain degree of professional training, the performers may be able to sing with a certain degree of competence. At this stage, however, many folk opera programmes require a unique singing voice or talent, but many singers have a single tone or no contrasting characteristics in their interpretation. The operatic nature of vocal singing in folk opera performance art needs to be taken seriously.

1.2. Status of Research on Feature Extraction by PCA. Pattern recognition has long been a hot issue in research. Various methods have been proposed to extract the most effective discriminative features from patterns for pattern classification. PCA [1, 2], considered as a classical feature extraction [3] and data dimensionality reduction method, has been widely applied in the field of pattern recognition and computer vision. Sirovich and Kirby [4, 5] first used PCA to process face images and introduced the concept of eigenimages. Based on this, Turk and Pentland proposed an eigenface approach based on PCA [6]. Since then, PCA has been studied in depth and some new algorithms related to

PCA have been proposed, such as ICA (Independent Component Analysis) and KPCA (Kernel Principal Component Analysis) [7].

Recently, Yang Jian et al. proposed 2DPCA [8] as a feature extraction method. On the basis of this, many scholars have conducted research [9, 10] and applications [11, 12], and the PCA method is applicable to the development of various industries [13]. Zhang et al. [14] proposed DPCA (Diagonal Principal Component Analysis). The module 2DPCA is the deformation and extension of 2DPCA, which is better than 2DPCA in terms of feature extraction performance.

By further extending the modular 2DPCA, a generalised PCA feature extraction method is proposed, which can be computed by building a scatter matrix of arbitrary dimensions when solving for the optimal projection vector, simplifying the operation process. The experimental results show that as the dimensionality of the scattering matrix decreases, the generalised PCA will have better feature extraction capability and faster processing speed. In this paper, a generalised PCA feature extraction method is proposed by applying the PCA method to modern folk opera performance art features extraction, in order to analyse the problems affecting the development of opera performance through the data and promote the improvement of modern folk opera performance.

2. PCA Theory

In order to fully reflect the information contained in modern folk opera performing arts images, multiple feature values need to be extracted for analysis. However, too many feature values can add to the burden of classification testing and have an impact on the analysis, so it is necessary to find the feature values that best reflect the differences in the images among the multidimensional feature values and reduce the multidimensional feature space to a lower dimensional feature space.

The basic idea of PCA is to reorganize the original data to obtain a new set of unrelated and independent data, in order to achieve the purpose of representing the information of the original data characteristics with less data [15, 16]. For a group of data with N indicator, after PCA, the new combination form is used to characterize the original data combination, and the combination with the largest variance $V_{ar}(N)$ among all linear combinations is called the first principal component, which is recorded as Q_1 . When the principal component Q_1 is not enough to characterize the original data information, a new combination form is selected to complement the information of the original data, which is called the second principal component Q_2 , and Q_2 should not overlap with the information of Q_1 , Q_1 and Q_2 satisfy $COV(Q_1, Q_2) = 0$, and so on until the number of principal components characterizes the original information feature. The steps of PCA are as follows:

- (1) Suppose there is a set of samples noted as K . Firstly, the samples are standardized to obtain the standardized sample matrix R :

$$\mathbf{R}_{ij} = \frac{K_{ij} - (1/m) \sum_{m=1}^{i=1} K_{ij}}{\sqrt{1/m - 1 \sum_{m=1}^{i=1} (K_{ij} - 1/m \sum_{m=1}^{i=1} K_{ij})^2}}, \quad (1)$$

where $i = 1, 2, \dots, m; j = 1, 2, \dots, n$.

- (2) Calculate the correlation coefficient matrix for the standardized sample B :

$$B = \frac{1}{m} \mathbf{R}^T \mathbf{R}. \quad (2)$$

- (3) Let the eigenvalue be λ , then the characteristic equation of the correlation coefficient matrix B can be calculated, from which m characteristic roots can be obtained:

$$|B - \lambda I_m| = 0. \quad (3)$$

Based on the calculated eigenvalue $\lambda_i (i = 1, 2, 3, \dots, m)$, the unit eigenvector $P_1, P_2, P_3, \dots, P_m$ can be obtained.

The number of principal components, determined from the cumulative contribution of the principal components, is used to derive the covariance matrix and its eigenvalues for the data matrix and its matrix transpose matrix determined for each combination of principal components. The contribution of the principal components, the cumulative contribution can be determined from the following equations:

$$A_i = \frac{\lambda_i}{\sum_{m=1}^{i=1} \lambda_i}, \quad (4)$$

$$C_{(m)} = \frac{\sum_{p=1}^{i=1} \lambda_i}{\sum_{m=1}^{i=1} \lambda_i}, \quad (5)$$

where p is the number of eigenvalues to be determined.

- (4) When the cumulative contribution of the principal components is greater than 90%, the first p combination of principal components can be considered here to include most of the characteristic information of the original data. The corresponding P is the first p principal components [17].

The flowchart of modern folk opera performing arts feature extraction using PCA in this paper is shown in Figure 1.

3. Principle of Feature Extraction

3.1. Image Recombination. Let I_1, \dots, I_N be a training set consisting of N n -dimensional image vectors, where $I_i = (I_1^i, \dots, I_n^i)$. Each training sample is partitioned into one subvector of dimension k according to the same rules a_j^i and arranged according to equation (6) to form a new matrix sample A_i of size $1 \times k$. The number of vectors is $l = \text{ceil}(n/k)$, and if the last vector has less than k dimensions, it is padded with zeros:

$$A_i = \begin{bmatrix} a_1^i \\ \dots \\ i \\ a_1^i \end{bmatrix}. \quad (6)$$

3.2. Projection Vectors. Calculate the scatter matrix of the matrix sample A_1, A_2, \dots, A_N , denoted as S_T :

$$S_T = \sum_N^{i=1} (A_i - \bar{A})^T (A_i - \bar{A}). \quad (7)$$

Here, $\bar{A} = 1/N \sum_N^{i=1} A_i$, and since matrix S_T is a symmetric matrix, there must exist an orthogonal matrix $\Phi = (\varphi_1, \dots, \varphi_n)$ such that S_T is diagonalised:

$$\begin{cases} \varphi_i^T \varphi_j = 1, & (i = j, i, j = 1, \dots, n), \\ \varphi_i^T \varphi_j = 0, & (i \neq j, i, j = 1, \dots, n). \end{cases} \quad (8)$$

The vector $\varphi_1, \dots, \varphi_d$ corresponding to the first d largest eigenvalues of S_T is taken as the projection vector.

3.3. Feature Extraction. The sample F_i is divided into l subvectors b_j^i of dimension k according to the same partitioning rules and arranged according to the rules of equation (6) to form a matrix sample of size $1 \times k$, denoted as B_i . The number of vectors $l = \text{ceil}(n/k)$, when the last vector is less than k , is also filled with zeros. The matrix sample B_i is projected with the projection vector $\varphi_1, \dots, \varphi_d$, and the eigenvalue matrix Y_i is extracted from B_i , and the elements of Y_i are the eigenvalues of the sample F_i to be tested:

$$Y_i = B_i (\varphi_1, \dots, \varphi_d). \quad (9)$$

If sample I_i of eigenvalues needs to be extracted, then we have the following:

- (1) When $k = m' \times n', l = 1$, the A_i obtained from image I_i is a vector of $1 \times m' \times n'$, which is the classical PCA feature extraction method.
- (2) When $k = n', l = m'$ A_i is a matrix of $m' \times n'$, this is the 2DPCA feature extraction method.
- (3) When $k = n'/z, l = zm'$ A_i is a matrix of $zm' \times n'/z$. This is the module 2DPCA feature extraction method. In fact, in the module 2DPCA algorithm, the dimensionality and specific values of the eigenvectors of the scattering matrix only vary with the chunking pattern in the row direction, independent of the chunking pattern in the column direction.

It can be seen that the generalised PCA feature extraction method proposed in this paper covers classical PCA, 2DPCA, and module 2DPCA. In addition, for images with a resolution of $m' \times n'$, k can be taken as an integer value in the range of $1 \leq k \leq m' n'$, which makes the algorithm more general and flexible.

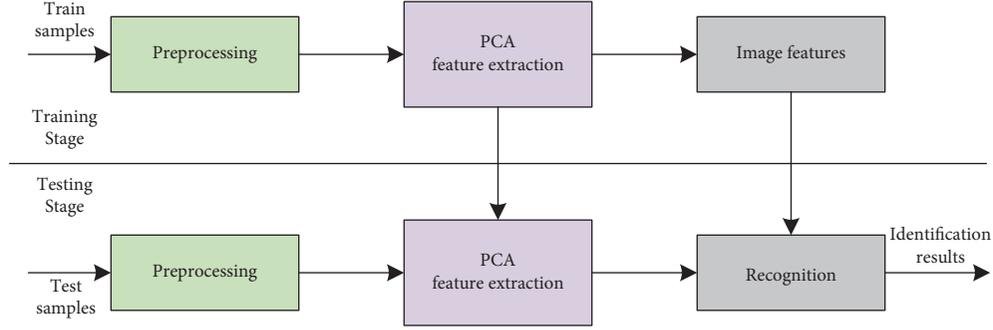

FIGURE 1: Flowchart of feature extraction by PCA.

3.4. Properties of the Algorithm. The generalised PCA feature extraction method has the following two important properties, which are the rationale behind the proposed generalised PCA:

- (1) The scatter value of the sample set scatter matrix does not change depending on the dimensionality of the subvectors into which the samples are partitioned.

Let a vector sample I_i of dimension n be partitioned into a matrix sample A_i of dimension $1 \times k$ and the number of samples is N :

$$A_i = \begin{pmatrix} I_1^i & \cdots & I_k^i \\ \cdots & \cdots & \cdots \\ I_{(l-1)k+1}^i & \cdots & I_n^i \end{pmatrix}, \quad (10)$$

$$S_T = \sum_{i=1}^N (A_i - \bar{A})^T (A_i - \bar{A}).$$

The scatter between samples $tr(S_T)$ is then

$$\begin{aligned} tr(S_T) &= tr \sum_{i=1}^N (A_i - \bar{A})^T (A_i - \bar{A}) \\ &= tr \left(\sum_{i=1}^N (A_i - \bar{A}) (A_i - \bar{A})^T \right) \\ &= \sum_{i=1}^N \sum_{j=1}^k \sum_{d=1}^k (I_{(n-1)k+j}^i - I_{(n-1)k+j}^j)^2 \\ &= \sum_{i=1}^N \sum_{d=1}^k (I_j^i - I_j^j)^2. \end{aligned} \quad (11)$$

The final transformation of the scatter $\sum_{i=1}^N \sum_{d=1}^k (I_j^i - I_j^j)^2$ is independent of parameters k and l , which proves that the scatter between samples remains the same no matter how many dimensions the matrix is partitioned into and that the above conclusion holds true for $k = n$.

- (2) The Euclidean distance between sample eigenvectors is equal to the Euclidean distance between the original sample vectors, regardless of the dimensionality of the vector sample split into matrix samples.

Let F_1 and F_2 any two samples, which can be represented as l matrix samples B_1 and B_2 of dimension k :

$$B_i = \begin{pmatrix} F_1^i & \cdots & F_k^i \\ \cdots & \cdots & \cdots \\ F_{(l-1)k+1}^i & \cdots & F_n^i \end{pmatrix}. \quad (12)$$

Let the eigenvectors of F_1 be $B_1\Phi$, the eigenvectors of F_2 be $B_2\Phi$, and $\Phi = [\phi_1, \dots, \phi_k]$ be the matrix consisting of all eigenvectors of the scattering matrix.

Similarly, the Euclidean distance $\text{Dis}(B_1\Phi, B_2\Phi)$ between the eigenvectors of samples B_1 and B_2 of the split matrix is equal to the Euclidean distance $\text{Dis}(F_1, F_2)$ between samples F_1 and F_2 , and the same conclusion holds when $k = n$.

4. Experimental Results and Analysis

4.1. Experimental Data. The data set used in this paper was collected from the works of 40 modern folk opera artists, each consisting of 10 images with a resolution of 112×92 . Some of the images were taken in different periods, with different degrees of variation in facial expressions and body movements. Among the 10 image samples of each person, the best ratio was selected according to the training model. Seven images from each person were randomly selected as the training set and the remaining three images as the test set, with the ratio of the total number of training and test samples for all people being 7 to 3. Each set of experiments was conducted five times, and the average of the five experiments was chosen as the final result.

4.2. Experiment 1. Each image is viewed as a 10,304-dimensional vector with a subvector dimension of k , taking a range of different values. The eigenvectors corresponding to the first seven largest eigenvalues of the scatter matrix are used as projection vectors to extract eigenvalues for classification with the nearest neighbour classifier, and the experimental data are shown in Table 1.

The comparison of recognition rate and time at different values of subvector dimension is shown in Figure 2. It can be seen that the recognition accuracy decreases as the subvector dimension increases, but the recognition time increases

TABLE 1: Experimental data for different values of subvector dimensions.

Subvector dimension k	12	23	46	92	184	368	736	1472
Recognition (%)	85	85	84	82	81.5	81.5	81	81.5
Time (s)	2.23	11.89	21.78	31.83	42.87	51.94	60.08	82.92

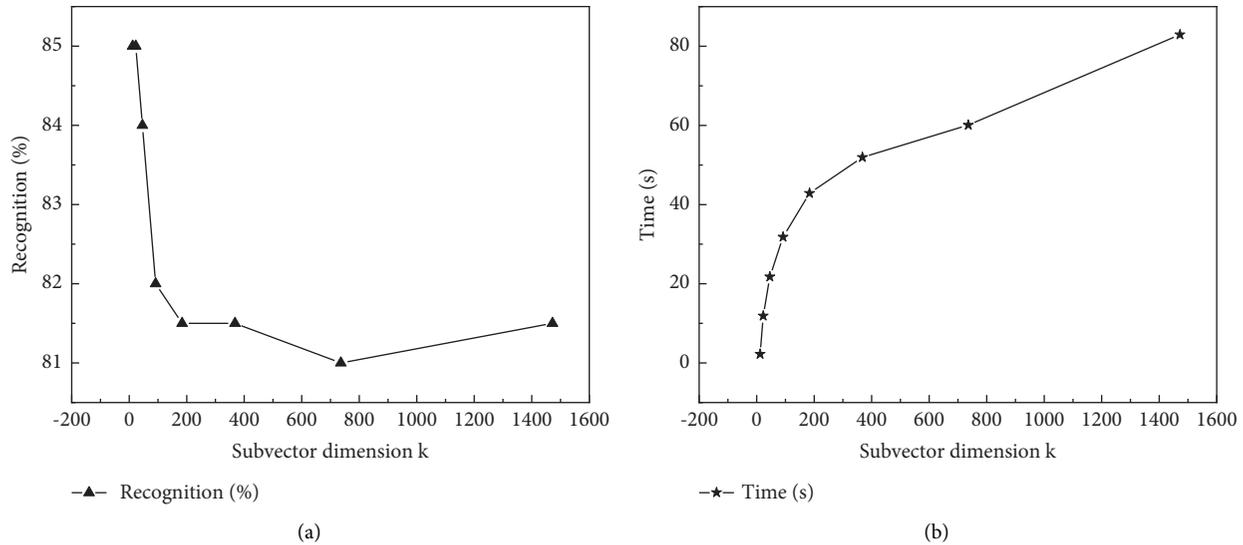

FIGURE 2: Comparison of data for different values of subvector dimensions: (a) recognition and (b) time.

gradually, which shows that the lower the subvector dimension, the better the experimental results.

The 2,240 eigenvalues were extracted from each image, and as the subvector dimension k increased, the number of projection vectors d was increased as the number of rows l of the matrix sample decreased, and vice versa, always making $l \times d = 2240$. The classification was performed with the nearest neighbour splitter, and the recognition rates are shown in Table 2.

The comparison between the recognition rate and the number of projection vectors d for the number of eigenvalues of 2240 is shown in Figure 3. From the figure, it can be seen that the recognition rate at different subvector dimensions is not very different, and the best recognition rate is achieved at dimension 23, and the number of projection vectors shows a positive proportional relationship with the number of projection vectors.

4.3. Experiment 2. In order to identify the influence of gender in the extraction of features in modern folk opera performance art, this study is then conducted. Twenty-two images of female opera artists were selected, and 11 colour images of 480×640 resolution each were used as experimental data. Due to the large size of the images, the images were converted to 120×160 grey scale before the experiment. Each image was considered as a 19 200-dimensional vector, and the first 5 images of each person were used as the training set, while the remaining 6 images were used as the test set. From each image, 1,200 feature values, i.e., $l \times d = 1200$, were extracted and classified using the nearest

neighbour classifier, and Table 3 shows the experimental data.

The data comparison results for the projection vector d , recognition rate, and time consumed in this experiment are shown in Figure 4.

From Figure 3, it can be seen that the change in recognition rate is not very different, but the recognition time gradually becomes longer as the number of dimensions increases, and the projection dimension d also becomes larger as the number of k increases.

4.4. Experiment Comparison. The results of Experiment 1 and Experiment 2 show that the maximum recognition rate occurs when the number of projection vectors is the same or the number of extracted features is the same, but the value of k is smaller. The analysis shows that when the value of k is small, the scattering matrix is smaller and it is easier to extract the local features of the image. This is the real reason why 2DPCA is superior to PCA, and 2DPCA is superior to 2DPCA. Therefore, in practice, a smaller value of k is beneficial for the recognition rate.

The data in Tables 1 and 3 show that feature extraction takes less time when the value of k is small. Because the scatter matrix is small when the value of k is small, it takes less time to find the scatter matrix and projection vector, so the feature extraction of the image is faster. Therefore, in terms of speed, a smaller value of k is more effective in practice.

The number of image features in both experiments varies with the dimension of the subvector k as shown in Table 4.

TABLE 2: Comparison of recognition rates for a feature value of 2,240.

Subvector dimension k	23	46	92	184	368	736	1472
Number of projection vectors d	5	10	20	40	80	160	320
Number of image feature values	448 * 5	224 * 40	112 * 20	56 * 40	28 * 80	14 * 160	7 * 320
Recognition (%)	85	85	84.5	84.5	84.5	83.5	83

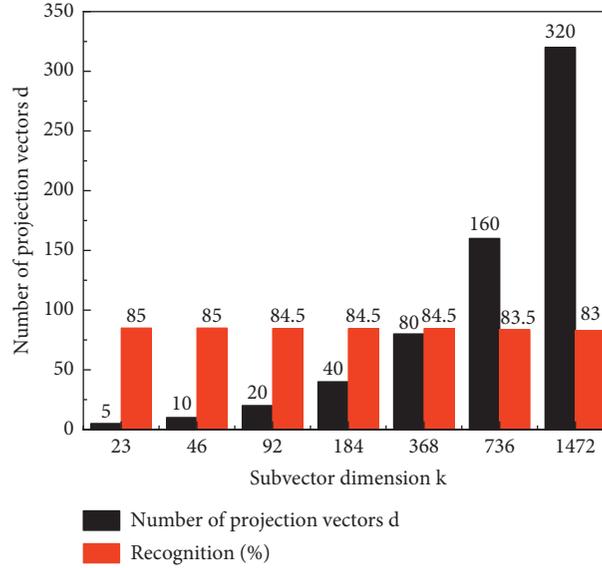

FIGURE 3: Comparison of data with an eigenvalue of 2240.

TABLE 3: Basic data set of Experiment 2.

Subvector dimension k	40	80	160	320	640	1280
Number of projection vectors d	2	4	8	16	32	64
Number of image feature values	480 * 2	240 * 4	120 * 8	60 * 16	30 * 32	15 * 64
Recognition (%)	78.8	77.3	76.5	76.5	76.2	76
Time (s)	1.95	12.38	23.16	38.31	42.85	85.26

A visual comparison of the number of image eigenvalues for the two experiments as a function of subvector dimension k is shown in Figure 5.

The larger the value of $k \times k$ and k , the larger the storage space required. When the value of k is taken as $m' \times n'$, the size of the scatter matrix is $10\,304 \times 10\,304$, which is difficult to achieve on a normal machine, while a smaller value of k is beneficial for saving storage space.

In summary, when k is taken as a small value, it is beneficial for the recognition rate, feature extraction speed, and storage space saving. Therefore, when the dimensionality of the vector sample is high, it is more beneficial to use a generalised PCA feature extraction method with a smaller value of k .

After fixing the value of k , the effect of the classifier on the effect of PCA on feature extraction is next considered. The experiments were conducted using the nearest neighbour classifier, followed by a support vector machine (SVM) [18, 19] to test the effect on feature extraction in modern folk opera performance art and to compare the experimental results with different principal component contribution

rates, and finally, a grid search algorithm (GS) [20] is used to optimise the support vector machine parameters and thus improve the classification results.

The experiments are conducted on two datasets, Experiment 1 and Experiment 2, using the support vector machine instead of the nearest neighbour classifier, and each set of experiments is conducted five times, and the recognition results are shown in Table 5.

Comparing the data in Tables 1 and 3, it can be seen that the recognition results under SVM are higher than the nearest neighbour classifier in both experiments, which shows that SVM is more suitable for modern folk opera performing arts feature extraction. The visual comparison effect of the two experimental results is shown in Figure 6.

The data were dimensioned down using PCA to test the feature recognition results and classification time under different principal component contribution rates, as shown in Tables 6 and 7, and the comparison results are shown in Figure 7.

When using SVM for classification prediction, the relevant parameters (penalty parameter C and kernel function

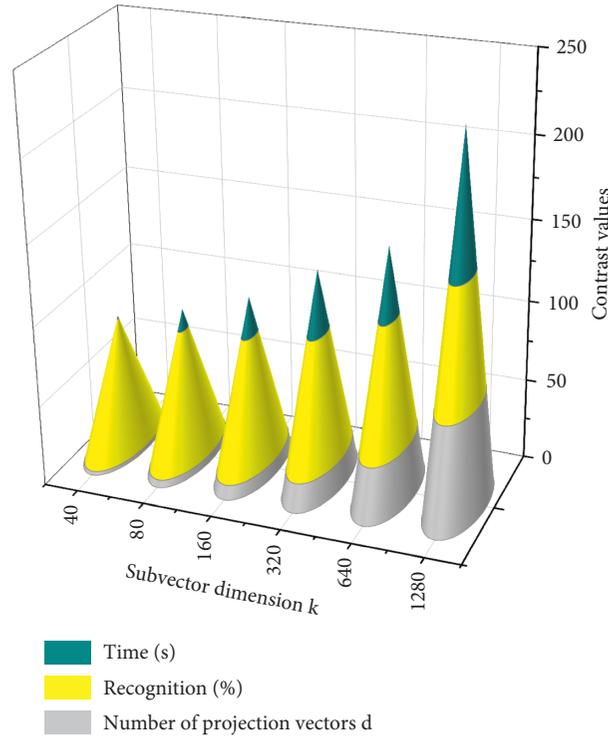

FIGURE 4: Comparison of data information from Experiment 2.

TABLE 4: Variation of the number of image features with subvector dimension k .

Subvector dimension k	12	23	46	92	184	368	736	1472
Experiment 1	4480	2240	1120	560	280	140	70	35
Experiment 2	960	960	960	960	960	960	960	960

parameter g) need to be adjusted to obtain the desired recognition accuracy. In this paper, a grid search algorithm is used to obtain the optimal model parameters. The grid search algorithm is an exhaustive search algorithm that finds the optimal hyperparameters of the model by combining all

possible values of the parameters in a permutation by cross-validation. The combinations are then used for SVM training and the performance is evaluated using cross-validation to find the largest combination of parameters for the scoring pair and then returned to the model for training.

TABLE 5: Recognition results of the support vector machine.

Category	1 (%)	2 (%)	3 (%)	4 (%)	5 (%)
Experiment 1	86.5	87	86.5	87.5	87
Experiment 2	80	80.5	79.5	81	80.5

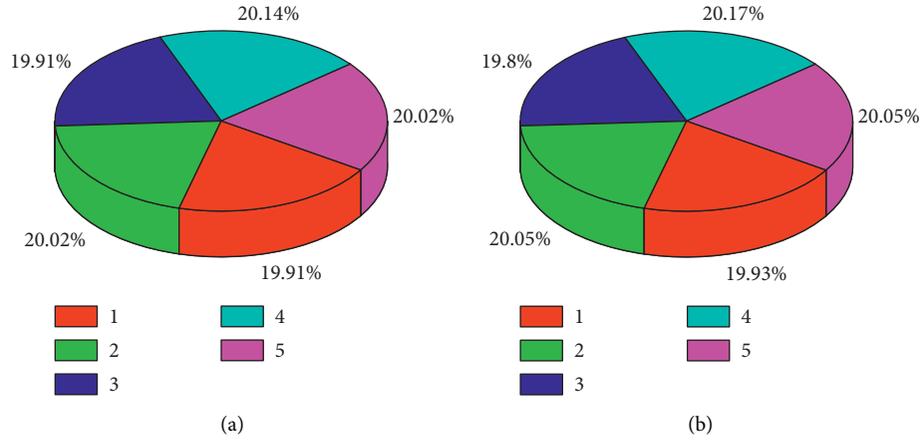

FIGURE 6: Pie chart of recognition results of support vector machine under two experiments: (a) Experiment 1 and (b) Experiment 2.

TABLE 6: Feature recognition results under different principal component contribution rates.

PCA	Recognition (%)		
	Contribution of principal components		
Data	25%	50%	75%
Experiment 1	84	87	85
Experiment 2	78	81	80.5

TABLE 7: Feature identification time with different principal component contribution rates.

PCA	Time (s)		
	Contribution of principal components		
Data	25%	50%	75%
Experiment 1	2.03	2.12	2.23
Experiment 2	1.81	1.89	1.95

As can be seen from Tables 6 and 7, feature identification results and time were improved when the principal component contribution was 50%, demonstrating the importance of the PCA method in feature extraction. Finally, the GS optimisation parameters were used and the classifier was noted as GS-SVM. When the k value was fixed and the principal component contribution was 50%, the experimental results for both classifiers are shown in Table 8.

A comparison of the accuracy of the recognition results of the two classifiers is shown in Figure 8.

From Figure 8, it can be seen that the recognition rate has improved significantly after using GS-optimised SVM, which shows that the feature extraction of modern folk opera performing arts is feasible after parameter optimisation. In summary, when the value of k is fixed and its value is small, the 2DPCA principal component contribution rate is 50%

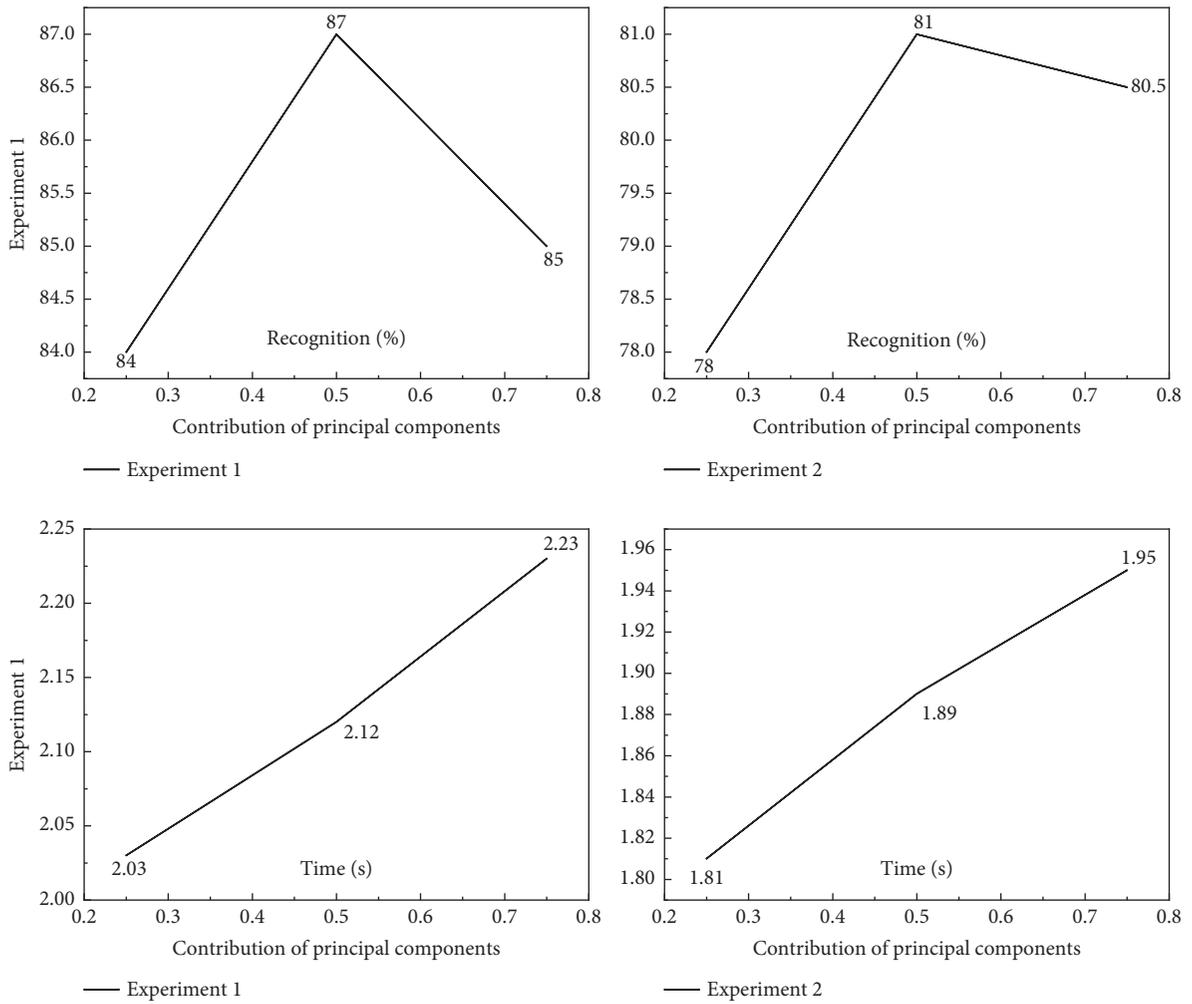

FIGURE 7: Comparison of feature identification results and classification time data for Experiment 1 and Experiment 2 with different principal component contribution rates.

TABLE 8: Grid search algorithm optimised recognition rate results.

Number of experiments	SVM (%)	GS-SVM (%)

and the feature extraction effect using GS-SVM is the best, and the classification time reaches the shortest at this time.

5. Conclusion

In this paper, a generalised PCA feature extraction method is proposed for modern folk opera performing arts. The method consists of reorganising the image matrix, thereby reducing the dimensionality of the scatter matrix and improving the feature extraction capability of PCA, which incorporates classical PCA, 2DPCA, and module 2DPCA feature extraction methods. Experiments on both types of image data show that when subvector dimension k is small, the scatter matrix becomes smaller, requiring less storage space and less time, while the extracted feature values are more efficient and the recognition rate is higher. By comparing the effect of the nearest neighbour classifier and SVM on feature extraction, the experimental results show that the best feature extraction is achieved with a principal component contribution of 50% and the use of GS-optimised SVM, which improves the recognition rate by about 2%, demonstrating the important value of the proposed method. However, further research is needed to find out whether there is a specific rule when the dimension k of the subvectors in the image is taken as the best result.

Over the past 30 years of reform and opening up, China has undergone tremendous changes. With the continuous growth of China's economy, the core competitiveness of Chinese enterprises is also increasing day by day. After China joined the WTO in 2001, economic globalization hit Chinese enterprises. Under such circumstances, a large number of foreign multinational companies have entered China to establish factories, which has caused huge pressure on Chinese companies. Facing this unprecedented pressure, Chinese enterprises need to fundamentally improve management and operation problems. Companies need to change aggressively to respond to the shock of foreign companies. The development of multisensor technology has brought great changes to enterprise human resource management. The real-time changes in this technology allow the continuous optimization of human resource management. Human resource management technology also needs to adapt to the modern social environment and constantly improve and quickly existing enterprise employee management methods and methods. These technical contents need to be optimized, and the working methods need to be improved. At the current stage, enterprise human resource management has not fully understood multisensor technology. Enterprises have poor adaptability in the application of this technology, and have not carried out comprehensive planning and clear optimization of detailed rules from the macro level. On this basis, the company has also failed to establish a relatively excellent team of professional management talents. There are three issues involved in talent team management. This article firstly analyzes the effect of human resource management in contemporary enterprises based on multisensor technology. Enterprises need to improve their awareness and application of sensor technology. It also needs to establish the overall strategy of human resource management and specific means of implementation. Through the in-depth application of these technologies, enterprises can enhance the comprehensive capabilities of human resource management teams. The application of this technology also provides practical and effective help for modern enterprise human resource management.

1. Introduction

The key to improving the core competitiveness of an enterprise is to improve the ability of human resource management. The competition among enterprises in the 21st century is the competition among enterprise talents. For high-tech enterprises, the number of technical talents has become a symbol of enterprise strength. In this context, how to improve human resource management has become a topic of the times. Existing studies have carried out many new tentative studies on human resource management from the perspective of information. These studies combine

human resource management with information to explore the efficiency and effect of strengthening human resource management in high-tech enterprises [1–3]. The existing research has conducted in-depth research on the basic theory of human resource management and information, and further summarized the general practice process of information management. Existing studies have systematically summarized the great changes brought about by information to human resource management. Many enterprises have gone through the process of transforming from manual human resource management to information-based human resource management. This method improves

the management efficiency of enterprises and realizes the management connection between Chinese enterprises and foreign enterprises [4–6]. This article systematically sorts out the existing relevant theories and optimizes the human resource management model of enterprises in the current environment. It also analyzes the combination of information technology and enterprise human resource management. Multisensor technology and enterprise human resource management: in the era of multisensor technology, the human resource management model of enterprises has also undergone tremendous changes, especially for the design of human resource management mode under multisensor technology. Enterprises need to improve the efficiency of enterprise management and human resource management from a more refined perspective. On this basis, from the perspective of high-tech enterprises, this article expounds the importance of knowledge workers and technical talents to high-tech enterprises. This article further sorts out the specific role of the e-HR software system in improving employee satisfaction and enthusiasm. It further analyzes the impact of mobile devices on human resource information. The purpose of this article is to improve the competitiveness of Chinese high-tech enterprises through the e-HR system. Through the improvement of its own competitiveness, the enterprise makes its own management more modern [7–10].

On this basis, this thesis analyzes the theory of human resource management information. The text analyzes the necessity of implementing human resource management information in high-tech enterprises. This article focuses on expounding the process of implementing human resource information in enterprises [11–13]. With the global economic integration and the arrival of the information age, human resources have become more important resources than material, financial, and information resources. Information resources are regarded as strategic resources for enterprises to gain a competitive advantage. In view of the problems such as insufficient effectiveness of the current enterprise human resources informatization construction, this study believes that enterprises need to adhere to the multisensor technology as the carrier to establish a perfect human resource management module. Enterprises need to provide a carrier platform for upgrading human resource management capabilities. On the one hand, enterprises adopt multisensor technology and can design a technical model suitable for business modules. The development and management of human resources in enterprises have gradually shifted from traditional personnel management to strategic human resource management. With the continuous optimization of enterprise functions, the management concepts and methods of enterprises need to make breakthroughs. Human resource management in China is still at the basic stage [14–16]. Chinese enterprises need to cope with the transformation of human resource management functions. The management concepts and methods of enterprises need to be broken through. However, China's human resource management work is far behind the world level in terms of theory and practice. This article systematically sorts out the domestic human resource management

work. This article puts forward the specific content of enterprise human resources information management through systematic analysis. On this basis, through human resource information management, this article gives a specific method to quickly improve the operation efficiency of the enterprise. This article further analyzes and summarizes the methods commonly used in daily human resource management work in American and Japanese companies [17–19].

Through the positive and negative experiences and lessons, this article further analyzes and draws the main points of human resource management work. Guided by comprehensive strategy and corporate culture, this article ensures the correctness of the direction of human resource management work through a reasonable corporate development strategy. Enterprises can find the design of human resource management module that multisensor technology can be applied to the whole process of data resource collection, integration, and analysis. The technology can provide a scientific basis for the management of the human resources of enterprises. At the same time, enterprises also need to realize scientific planning of human resources under the guidance of multisensor technology. On this basis, this article promotes the continuous improvement of enterprise operation efficiency through systematic cultural management methods. In this article, the multisensor technology analysis method is adopted to make the management method of the enterprise continuously updated and optimized. In the specific research, this article subdivides the work of human resource management information. The specific information work is divided into the technical level and management level. Combined with the relevant research of existing scholars, this article believes that human resource information pays more attention to the management level [20]. This article further puts forward the specific ideas and measures for the development of enterprise human resources at different management levels. This technology can improve the management efficiency of human resources. Therefore, multisensor technology is of great help to the module design of enterprise human resource management. Different modules of an enterprise differ in their choice of strategy and corporate culture. Different enterprise development strategies produce different enterprise development ideas and practice models. At the technical level, companies focus on two issues. First, companies need to make forward-looking recommendations on the technical analysis of human resource management [21]. This technical analysis method can ensure that enterprises will not be eliminated for a long period. The choice of specific functions must be able to contribute to the realization of its own strategy. The development of an enterprise needs to match its own positioning and development needs. The flowchart of enterprise information management based on multisensor technology is shown in Figure 1.

2. The Research Progress on Information Management of Enterprise Human Resources

Enterprises need to deeply study the combination of information technology and human resource management.

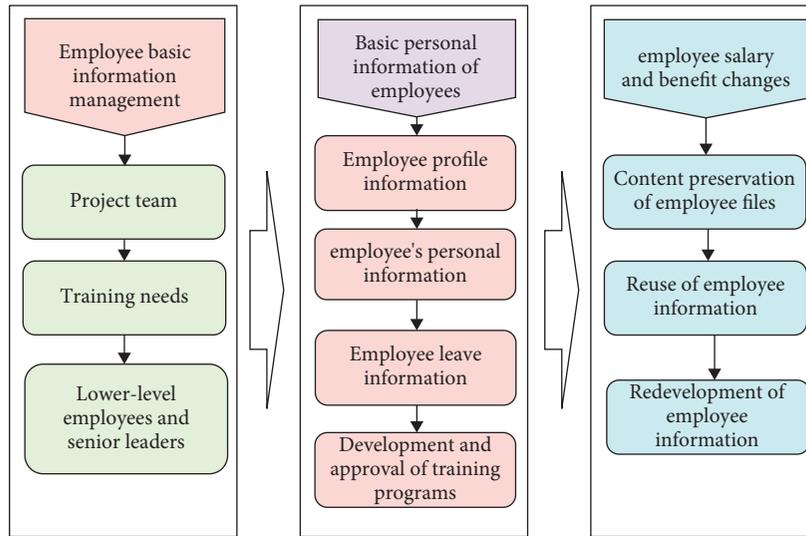

FIGURE 1: The flowchart of enterprise employee information management based on multisensor technology.

Information has become a new pillar supporting the development of our national economy. The information development of enterprises is also a new economic growth point worthy of our attention. The information industry has also received the attention of national leaders and governments. Under the background of economic globalization, information technology plays a very important role in the competition between enterprises.

2.1. The Main Achievements of Information Management of Enterprise Human Resources. The wave of information has a relatively large impact on traditional human resource management data. This kind of influence requires enterprises to abandon the original traditional concepts and take the initiative to add more information-based concepts. In the current environment, the network-based information environment has formed, and human resource management should change itself accordingly. In this case, the development of China's human resources information has entered a new era. The rapid development of information conforms to the needs of enterprise human resource management. Multisensor technology and human resource planning work: in the application of multisensor technology, the planning mode of human resources has changed. This technology provides a strong guarantee for the long-term and strategic nature of enterprise planning. In the process of continuous updating of multisensor technology, enterprise human resource management pays more attention to the actual situation. The 21st century is the era of the combination of knowledge and network, and the role of the knowledge economy is very important. In the environment of the knowledge economy, high-tech talents have become the main body of knowledge. People-oriented, knowledge-based, networked, and information-based developments are becoming more and more important. When enterprise management integrates information, human resources, as the most important factor, play a key role as a bridge. Traditional human resource management methods are often

outdated, mainly sorting out resource data in a purely manual form. The method of personnel management is generally subjective, and the enterprise managers themselves mainly determine the standard of judgment.

The standards of performance appraisal of enterprises are generally relatively subjective. However, this relatively subjective performance appraisal model is inconsistent with the development demands of enterprises. With the advent of networking and information, computer and Internet technologies have been widely popularized in society. We must make full use of the convenience brought by information technology to our work and make human resource management more scientific. The human resources department is an ordinary department of an enterprise. In the overall development of the enterprise, it has not been deliberately elevated to a strategic level. The companies do not pay attention to human resources. Businesses only see people as tools to achieve business performance. In the information age, human resources have become an important resource for enterprises. Therefore, enterprises need to raise human resources to a strategic level. In this context, human resource management is very important. Enterprises need to abandon the traditional personnel management methods and make full use of information methods for human resource management. The organizational structure of the human resource planning function module based on multisensor technology is shown in Figure 2.

2.2. The Main Problems of Information Management of Enterprise Human Resources. In more than 30 years of reform and opening up, China's information technology has developed and changed faster and faster. It can be said that without information, there will be no modernization in China. Information technology is crucial to the development of China's economy, politics, and culture. In the process of China's transition from a planned economy to a socialist market economy, the market has also paid more and more attention to the management of human resources. Human

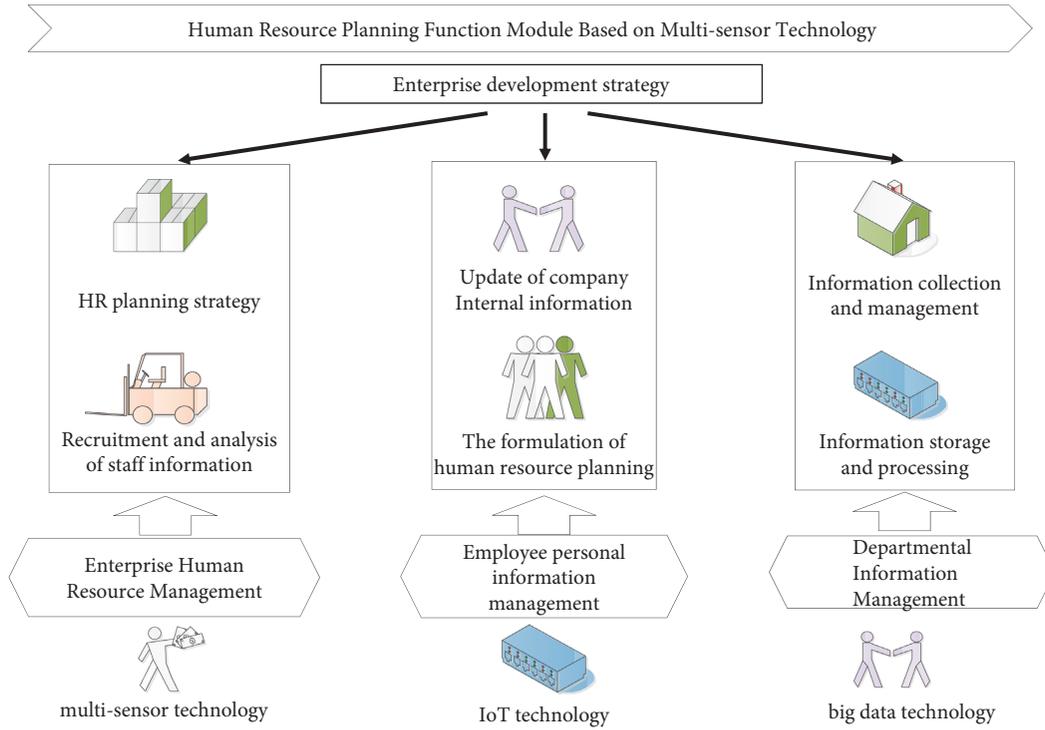

FIGURE 2: The organizational structure of the human resource planning function module based on multisensor technology.

resources have become an important resource and wealth of society. The management mode of human resources is in line with the country’s people-oriented development concept. In the context of the rapid development of information technology, the combination of human resources and information has become an important part of enterprise development. The development of information technology can provide the high-speed operation of enterprises. Data integration and application in human resource management are key concerns of enterprises. The calculation formula for the information entropy of each node is as follows.

The calculation principle of local consistency is relatively simple, mainly using the Kendal Concorde coefficient, and the specific calculation formula is as follows:

$$W = \frac{\sum (R_i)^2 - n(\bar{R})^2}{1/12K^2(n^3 - n)}. \quad (1)$$

The calculation formula of single-sample statistics is as follows:

$$t = \frac{\bar{X} - \mu}{\delta_x / \sqrt{n - 1}} \quad (2)$$

The calculation of the statistics of the hypothesis of the single-body sample is as follows:

$$t = \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{(n_1 - 1)S_1^2 + (n_2 - 1)S_2^2/n_1 + n_2 - 2(1/n_1 - 1/n_2)}} \quad (3)$$

2.3. *The Significance of Information Management of Enterprise Human Resources.* This technology can be widely used in many industries. This technology has played a very important role in the management and operation of enterprises. Enterprise human resource management is a very practical technology. With the continuous development and update of multisensor technology, traditional human resource management methods are also facing a huge impact. With the innovation of technical methods, multisensor technology has also brought more opportunities for the development of enterprises. Human resource management plays an important role in the development of enterprises. The value of human resources reflects the comprehensive competitiveness of enterprises. A good human resource management method can build an optimistic and progressive work environment within the enterprise. The application of new technology can improve the enthusiasm and sense of responsibility of the company’s employees. The specific calculation formulas are as follows.

Set two random sequences X and Y , the Pearson correlation coefficient between the two sequences is r , then

$$r = \frac{\text{cov}(X, Y)}{\sqrt{\sigma_x^2} \sqrt{\sigma_y^2}} = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2} \sqrt{\sum_{i=1}^n (y_i - \bar{y})^2}} \quad (4)$$

To ensure the accuracy of the results, this article uses two evaluation indexes, mean absolute error and root mean square error, to evaluate the optimization effect of the model. The specific calculation formulas are as follows:

$$\text{MAE} = \frac{1}{s} \sum_{i=1}^s |\hat{y}_i - y_i|, \quad (5)$$

$$\text{RMSE} = \sqrt{\frac{1}{s} \sum_{i=1}^s [\hat{y}_i - y_i]^2}, \quad (6)$$

$$J = \sum_{i=1}^{N_p} \left\| y(k+i) - y_{ref}(k+i) \right\|_Q^2 + \sum_{i=1}^{N_p} \|U(k+i)\|_R^2 + \sum_{i=1}^{N_p} \|\Delta U(k+i)\|_R^2. \quad (7)$$

Considering the influence of the target vehicle's speed and penalty function on obstacle avoidance, the following obstacle avoidance function is selected:

$$J_{\text{obs},i} = \frac{S_{\text{obs}} v_i}{(x_i - x_o)^2 + (y_i - y_o)^2 + \zeta}. \quad (8)$$

This technology helps to enhance the creativity of employees on the job. This technology can lay the foundation for the long-term and efficient development of the company. In the era of continuous innovation of multisensor technology, enterprise human resource management must be properly process optimized. Through refined human resource management, the enterprise guarantees the scientific validity of human resource planning. First, the enterprise adopts multisensor technology and builds a human resources multisensor technology library. This process optimization method can guide the reform and innovation of human resource management. This article needs to further strengthen the information construction of human resource management and uses multisensor technology to build a human resource management system with high accuracy, good predictability, and strong real time.

We treat each of the monomials as m input models in the original structure of the modeling network:

$$v_1 = a_0, v_2 = a_1 x_1, v_3 = a_2 x_2, \dots, v_6 = a_5 x_1 x_2. \quad (9)$$

The final information $i_t \times C'_t$ is expressed as the value that can be obtained C_t from the output information of the joint forgetting gate:

$$C_t = f_t * C_{t-1} + i_t * C'_t. \quad (10)$$

The calculation method is:

$$O_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o), \quad (11)$$

$$h_t = o_t * \tanh(C_C). \quad (12)$$

The use of this technology can effectively promote the long-term stable development of the company. On this basis, this article focuses on analyzing the impact of multisensor technology on enterprise human resource management. This article points out the dilemma faced by human resource management at this stage and proposes corresponding management methods. The conclusion of this article can

effectively improve the effect of enterprise human resource management. The modular application framework of the e-HR system based on multisensing technology is shown in Figure 3.

3. The Influence of Multisensor Technology on Enterprise Human Resource Management

With the advent of the information age, multisensor technology has been widely used. Many enterprises have completed the analysis and integration of information through multisensor technology. Enterprises extract useful information from large-scale data, and integrate, analyze, and use it. The application of new technology promotes the close integration of enterprise management and information technology. Human resource management is an indispensable part of many management tasks of enterprises. Multisensor technology can reform and innovate the existing human resource management methods. This technology library facilitates accurate, granular analysis of multisensor technology. This technology helps to improve the planning efficiency of human resources to meet the data analysis needs of different types of structures. Then, human resource planning focuses on the systematic nature of resource management. Through this new technology and new method, the purpose, timeliness, and precision of human resource management can be strengthened. This new method can continuously improve the effect of enterprise human resource management and promote the development of enterprises in the direction of standardization and refinement. In the era of multisensor technology, enterprise human resource management is bound to closely link with information technology. Therefore, the human resources management personnel of enterprises need to have the professional ability and master certain information technology.

3.1. The Application Status of Multisensor Technology in Enterprise Human Resource Management. These enterprises need to gradually build a human resource management team with a high professional level and high level of information. In carrying out multisensor technology mining work, companies need to focus on strengthening their own level of innovation. Enterprises need to use the characteristics and advantages of multisensor technology to continuously improve and innovate the methods and paths of human resource management. Companies need to use multisensor technology to set a strategic direction for themselves. Businesses need to take advantage of multisensor technology for management. This technology can effectively promote the popularization of human resource management information. Enterprises need to build a system platform for human resource management with the support of multisensor technology. In the application of multisensor technology, enterprises need to continuously improve the management efficiency of human resources. The application of new technology provides a scientific basis for the scientific planning of human resources. In addition, the information work of enterprise human resources needs to establish a

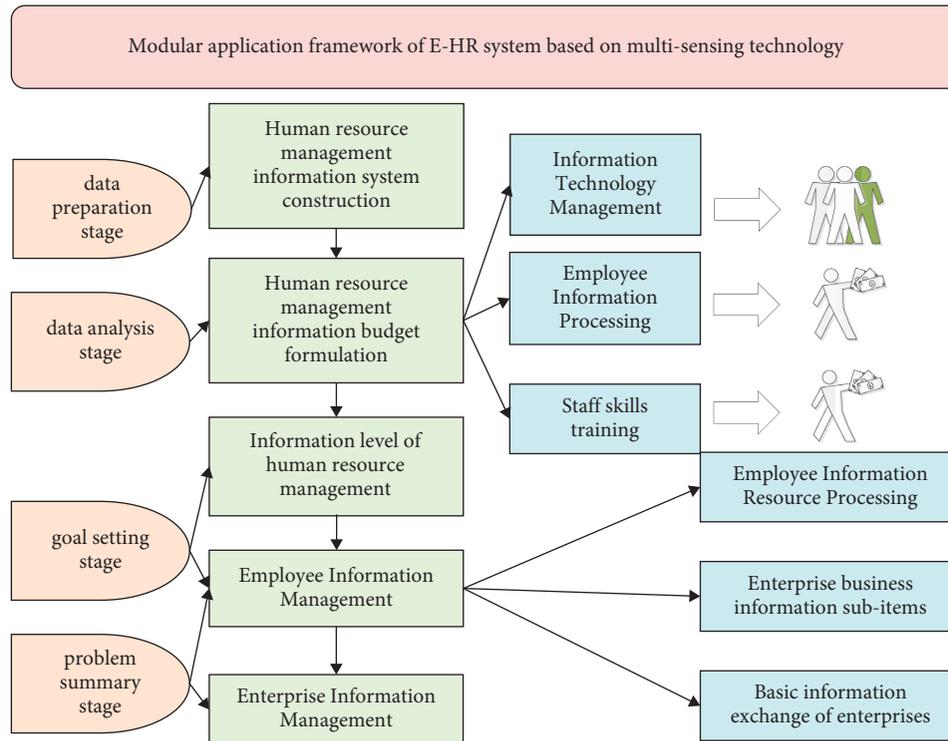

FIGURE 3: The modular application framework of the e-HR system based on multisensing technology.

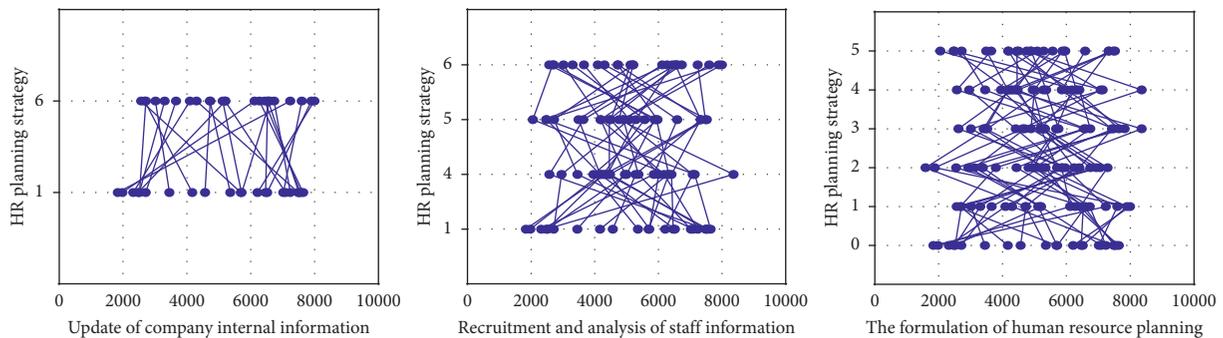

FIGURE 4: The comparison of different technologies applied in human resource management system construction.

good awareness of information confidentiality. This is because the personal information of employees, corporate information, and other contents are easily leaked on Internet data. Once the information is stolen, it will bring great loss to companies and individuals. This threatens the company's market position. Multi-sensor technology offers significant convenience. Enterprises will generate many data resources in the process of human resource management. Therefore, these massive data resources need reasonable extraction and analysis by human resource managers. These human resource managers need to identify the results of data analysis. This information can help managers obtain valuable data from a large amount of data and can also provide data support for the specific direction of human resource management. The comparison of different technologies applied in human resource management system construction is shown in Figure 4.

3.2. *Enterprises Fail to Understand the Advantages of Multi-sensor Technology.* Companies are less able to use new technologies in human resource management. The scientific nature of human resource management directly affects the long-term development of an enterprise. This situation also affects the making of important decisions within the enterprise such as multisensor technology and talent recruitment management. In the Internet era, enterprises need to use online recruitment technology as the main way to recruit talents. Through multisensor technology analysis, enterprises can understand and classify the basic data of applicants. Through basic data screening, enterprises realize the first-level check of talent recruitment. As the application of multisensor technology in enterprise human resource management continues to deepen, the influence of multi-sensor technology on human resource management is gradually increasing. This new technology has gradually

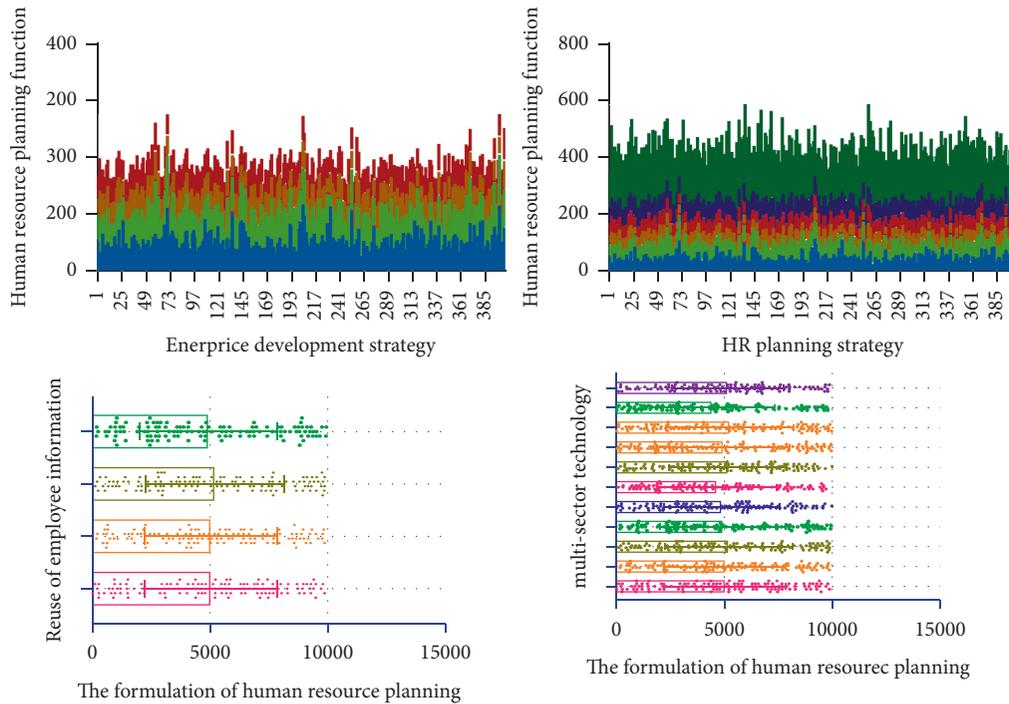

FIGURE 5: The comparison of human resource information construction in different scenarios.

applied to all aspects of human resource management. However, judging from the status quo of human resource management at this stage, the responsible personnel and managers of the enterprise have not been able to establish a scientific understanding of multisensor technology. Managers of enterprises have an insufficient understanding of the connotation of multisensor technology. Enterprises still lack attention to the innovation of human resource management systems. In addition, enterprises need to conduct directional analysis of capability data and development potential data. On this basis, the company compares the work experience, innovation, and development ability of the recruits and other information. Enterprises analyze employee information through multisensor technology. At present, the application of information technology by enterprises is still on the surface, and it cannot give full play to the advantages of information technology. In the process of human resource management, enterprises have not applied multisensor technology to manage decision-making. Enterprises are still stuck in the traditional thinking mode of human resource management. In addition, due to the long application time of traditional management concepts and methods, enterprise managers cannot give full play to the advantages of multisensor technology in practical work. Enterprise management lacks a long-term vision for the reform and development of the human resource management system. This lack of vision causes the human resource management system of enterprises still use traditional methods. The lack of application of this new technology affects the reform and development of the human resource management model. The comparison of human resource information construction in different scenarios are shown in Figure 5.

3.3. *The Enterprise Did Not Carry Out Comprehensive Planning and Clarify the Optimization Rules.* The improvement and optimization of enterprise human resource management should focus on the overall strategy of the enterprise. Enterprise managers need to clarify the direction and implementation plan of enterprise reform. In the era of continuous updating of multisensor technology, human resource managers of some enterprises do not consider enterprise development from the perspective of the overall strategy. Corporate managers themselves have not formulated detailed reform methods. At the same time, the strategic layout of many enterprises mainly continues the previous development model. These enterprises are neither connected to Internet technology nor fully integrated with multisensor technology. This situation has caused enterprises to encounter various difficulties in the process of the human resource management system. Enterprises have not established incentive systems and guarantee systems, and many reform measures cannot be implemented. The reform of the management system of human resources still needs to consider this from many aspects. In addition, the scope of work of human resource management is concentrated within the enterprise. Business leaders have not fully realized the importance of human resource management. This situation leads to difficulties in enterprise human resource management and personnel management. Enterprises cannot establish a comprehensive understanding of multisensor technology and cannot correctly predict the development direction of multisensor technology. Therefore, enterprises cannot formulate their own human resource management reform plans in combination with multisensor technology. The reform work of enterprises cannot be effectively implemented and the formalism is serious. The

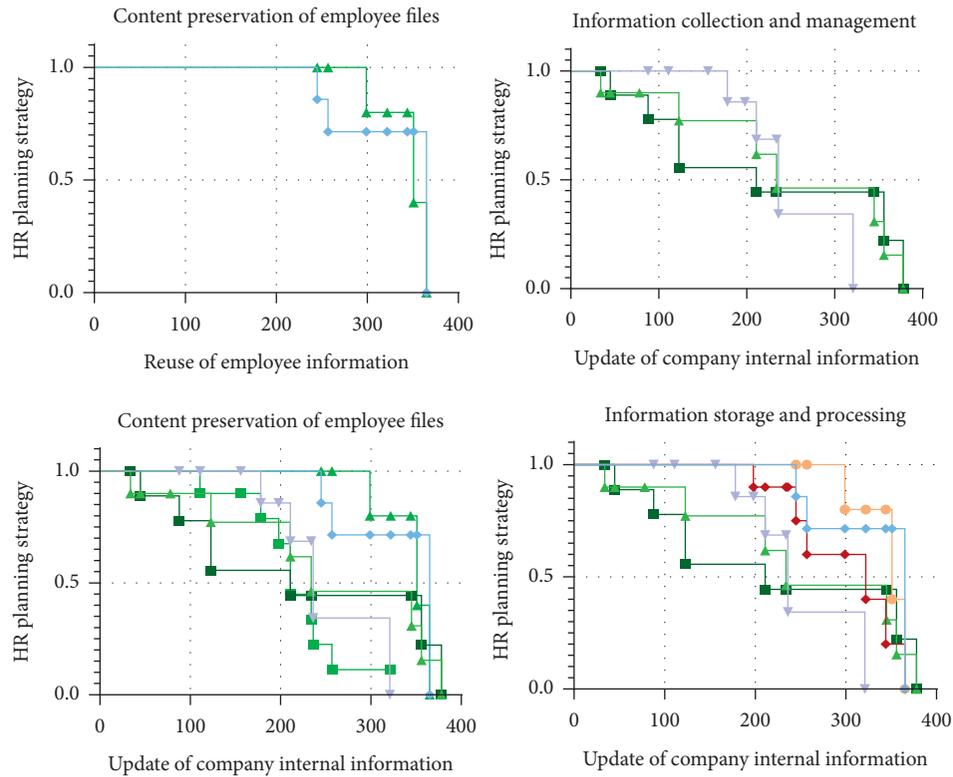

FIGURE 6: The comparison of the effect of information management within the enterprise among different departments.

comparison of the effect of information management within the enterprise among different departments is shown in Figure 6.

3.4. The Company Has Not Been Able to Build an Excellent Team of Professionals. China is in the era of the knowledge economy, and enterprises need to give full play to the value of talents. The value of talents is of great significance to the development of enterprises. In the era of multisensor technology, to achieve good results in human resource management, an excellent team of professionals must be established. Enterprises need to improve the comprehensive business level of the talent team. This analysis method can better meet the needs of the position and recruit talents that meet the needs of the enterprise. At the same time, enterprises also need to protect the value created by talents at work. Therefore, enterprises need actively carry out the application combination of multisensor technology and talent recruitment management. However, at this stage, the integration of human resource management and multisensor technology in most enterprises is not close enough. This integration is still in its infancy. In the composition of the human resource management team, only a very small number of workers have systematically learned too many sensor technologies and can flexibly use them. Enterprises need to analyze data of different characteristics, recruit high-quality talents for enterprises, and then achieve mutual benefit and win-win results. When carrying out the training of human resource managers, enterprises mainly conduct training in the traditional way. Enterprises rarely involve the

knowledge points of multisensor technology in the training process. Even if the development of enterprises incorporates multi-sensor technical knowledge, it only stays on the surface. The application of technology by enterprises is mainly based on simple and common sense knowledge. Businesses cannot really improve managers' awareness of multi-sensor technology. This situation results in multi-sensor technology that cannot be fully integrated into the management of human resources. At the same time, the company did not pay attention to the introduction of management talents and did not formulate a reasonable salary system and incentive system. This situation also leads to a more serious brain drain, and enterprises cannot establish a comprehensive human resource management team.

4. The Introduction Strategy of Multisensor Technology in Enterprise Human Resource Management

4.1. Enterprises Need to Improve Their Awareness of Multi-sensor Technology. At the current stage, with the rapid development of the Internet and computer technology, the application scope of multisensor technology is becoming more and more extensive. Technology has had a major impact on various industry sectors. Enterprises pay more attention to the application of multisensor technology to human resource management. The application of new technology has become an important direction of the current reform of enterprise human resources management. Therefore, business leaders and human resource managers

must fully understand multisensor technology. Enterprises need to pay attention to the application of new technologies and continuously improve their business scenarios using multisensor technology. Multi-sensor technology and human resource development work. In the modern management system, the development of human resources is the core content of resource management. This kind of work is related to the important foundation of the strategic development of human resources of enterprises. In “multisensor technology,” companies need to carry out multisensor technology analysis. Specifically, enterprises can work from the following two aspects. First, human resource managers should pay attention to the application of multisensor technology from an ideological point of view. Managers need to understand the important role of multisensor technology in human resource management. Managers need to change their management thinking and methods and understand multisensor technology as the focus of promoting human resource management reform. Enterprises need fully integrate multisensor technology in management methods, management concepts, and workflows. Businesses need to take advantage of multisensor technology.

Second, enterprises should combine multisensor technology to build a new human resource management platform. Enterprises need to further improve the actual effect of human resource management. The enterprise management department needs to further separate the work content of human resource management and personnel management. Enterprises need to gradually establish a human resource management method based on computer data. According to the characteristics of different employees, enterprises need to carry out a comparative analysis of multisensor technology. Enterprises carry out precise development of human resources according to the strengths and abilities of employees. At the same time, enterprises need to establish a comprehensive human resource management database according to their own conditions. Enterprises need to disclose the database within the company to realize the sharing and circulation of data information. Through this database, enterprises can better improve the efficiency of enterprise human resource management. Through this database, enterprises can keep an eye on the latest developments of employees at all levels. By establishing an information resource database, enterprises lay the foundation for future human resource management.

4.2. Enterprises Need to Clarify the Means of Implementing Human Resource Management. In the era of multisensor technology, the market environment has undergone tremendous changes. Changes in this market environment require constant innovation in human resource management. Enterprise management should constantly be reformed according to the external environment. Enterprises need to formulate a scientific human resource management strategy. At the same time, to ensure that the new management system can be fully implemented; enterprises also need to build a corresponding security system. In this way, we can improve the scientific and foresight of enterprise

human resource management. Specifically, companies need to work from the following two aspects. First, enterprises should pay full attention to the application of multisensor technology in the process of human resource management. Enterprises need better tap the advantages of multisensor technology. Companies need to use multisensor technology accurately analyze their strategic goals.

On this basis, enterprises need to formulate a clear reform direction, implementation path, and ultimate goal; need to start from every detail to improve the recognition of organizational leaders and employees for human resource management. Enterprises need to change the traditional human resource development model and need to put more emphasis on the analysis of multisensor technology. It needs to scientifically realize the human resource development efficiency of “making the best use of their talents.” Then, it should make full use of the advantages of multisensor technology and mobilize every employee to participate in human resource management. Enterprises need to divide the overall strategic layout into several branches according to their actual conditions. On this basis, let each employee undertake corresponding branch tasks. On the one hand, this management method can effectively stimulate the enthusiasm of employees, mobilize their subjective initiative of employees, and make employees feel their sense of responsibility and honor. On the other hand, this management method is also conducive to changing the main body of enterprise human resource management. Enterprises can rely on multisensor technology further extract valuable information in human resource management. Enterprises need to further share useful information internally to ensure the orderly progress of enterprise human resource management reform. The application comparison of multisensor technology in enterprise human resource management is shown in Figure 7.

4.3. Enterprises Need to Improve the Comprehensive Ability of Human Resource Management. Under the background of the modern knowledge economy, the stable development of enterprises cannot be separated from the support of excellent teams. Similarly, in enterprise human resource management work, an excellent team with strong professional ability is also very important. An excellent team is a carrier that promotes the continuous reform and innovation of human resource management. Therefore, enterprise leaders need correctly understand the important role of human resource management in enterprise development. Enterprises need to invest a certain amount of money to improve the comprehensive level of the human resource management team. In addition, enterprises need to carry out training courses and seminars on human resource management on a regular basis. In the process of learning, managers should improve their professional knowledge and skills in human resource management on the one hand. On the other hand, managers also need to learn more multisensor technology knowledge. Enterprises need to cultivate a team of compound talents with professional knowledge and multisensor technology knowledge. With the popularization

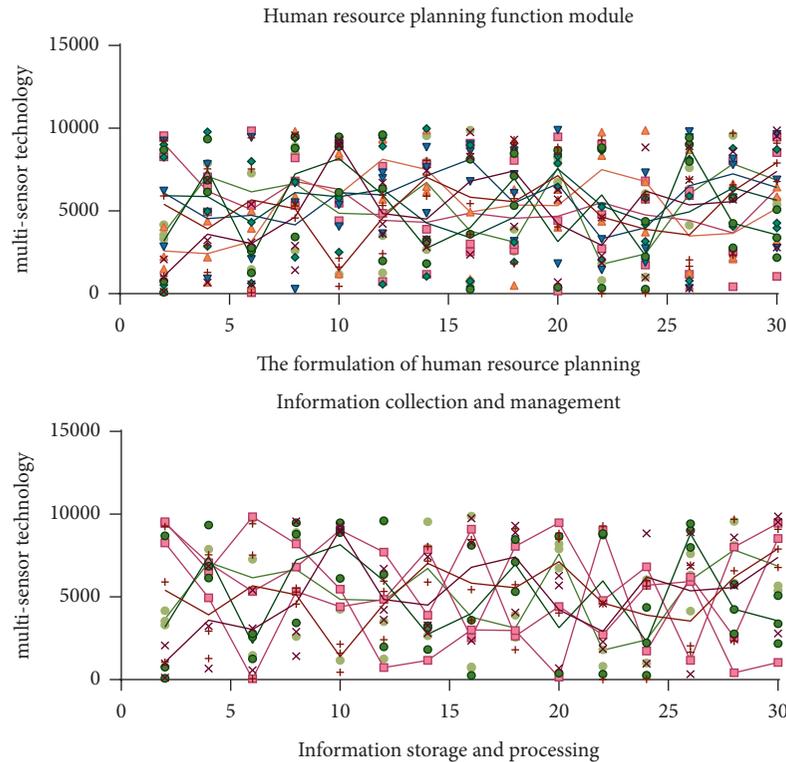

FIGURE 7: The application comparison of multisensor technology in enterprise human resource management.

of multisensor technology in human resource management, this technology will inevitably lead to changes in the human resource management system. At the same time, enterprises need simultaneously carry out reforms and innovations in talent incentives and salary management. Enterprises need to strengthen the introduction of talents in multisensor technology. Establish strategic cooperative relations with institutions of higher learning, scientific research institutions, and other institutions through the school-enterprise cooperation model. Enterprises need to introduce more multisensor technology professionals in human resource management. It needs to improve the deficiencies in human resource management work and promote the improvement of human resource management efficiency and quality.

5. Industrial Distribution of Human Resources

5.1. Personnel Configuration Module Design. In the existing human resources management system, though some daily personnel management work needed information input, register, statistics, and daily tasks, such as function modules, but all of these works are directly on the existing data processing, on the basis of no in-depth integrated use of the data mining analysis function. In particular, there are still some deficiencies in the design of human resource allocation based on data mining information.

By building a human resource allocation data mining analysis module in the system, combining indicator data of different description types, and using K-Means clustering algorithm for classification and analysis research, a unique human resource allocation analysis indicator system is

proposed, which provides a method to improve the system's comprehensive human resource allocation analysis function.

5.2. Human Resource Allocation Needs. Before the design of the human resource allocation data mining function, we must first conduct a requirement analysis to clarify what basic functions need to be achieved by the mining function, which steps are necessary, the indicators that may be used, and the program language or program algorithm that needs to be used to achieve the function, etc., and then, we can carry out the specific function implementation program design.

According to the concept of modern human resources "personnel quality concept," human resources allocation is not simply a matter of increasing or decreasing the number of personnel, but more importantly, considering the comprehensive quality, work ability, work efficiency, work attitude, health condition and other factors of the personnel in the workforce. At present, before conducting staffing, human resource management departments usually give priority to the job responsibilities of each division, business characteristics, annual workload, and the number of personnel required to complete the tasks, according to the importance procedures of various factors, and conduct a comprehensive study to determine the staffing plan of the division according to whether the age structure, knowledge structure, gender structure, and ability of the existing personnel of the division can meet the needs of completing the tasks. Therefore, the analysis and study of human resource allocation tasks should not only analyze the issue of staffing

quantit but also analyze the structure and quality of the staffing of different divisions according to whether the divisional staffing is reasonable. In the past, when the human resource management department analyzed the basic quality configuration of the staff in the division, it was usually based on perceptual understanding, and there was a lack of in-depth data mining analysis tools and corresponding data analysis conclusions to support whether the configuration plan was reasonable, whether it could not meet the different needs of different divisions, and how to allocate human resources in a balanced manner when the number of existing staff structure could not be changed quickly.

This paper attempts to use the existing basic human resources data to cluster and analyze the basic quality of personnel, and visualize the basic quality of divisional personnel allocation through visual display so as to facilitate a more convenient judgment of whether the staffing is reasonable and provide a decision basis for the next human resources allocation adjustment.

5.3. Human Resource Allocation Data Mining Analysis Main Functions. Human resource allocation data mining is a new functional module in the original HR management system. According to the design plan of data mining analysis process and the need of data mining analysis task, this function module should have the following main functions: selection of data analysis index, entry display of data index, cleaning and modification of original data, construction of new data index, integration processing of data, selection of data mining algorithm, parameter setting and adjustment of data mining algorithm, realization of data mining algorithm, display of data mining, the display of results, backfill of data mining results, and graphical display of staffing situation. The functional design of the module combines some existing functional modules in the existing software, and at the same time extends it with the analysis needs. Among them, the selection and re-integration of analysis indicators can be done by using the original functions of the system, while the implementation of data mining algorithms and the presentation of results need to be redesigned to be realized.

5.4. Human Resource Allocation Module Data Mining Analysis Process. The general idea of the data mining process design of human resource allocation module is to use some basic functions of the existing human resource management information system and add algorithm analysis function and graphic display function; the main steps are as follows:

(1) Analysis of the data mining task. The initial analysis of the data mining task is carried out to clarify the main purpose of the mining task, the specific steps to be implemented, the main indicators involved, the overall effect you want to achieve, etc.

(2) Selection and construction of basic analysis index items. Based on the analysis results, the basic index items required for analysis are selected from the human resource information system, and a preliminary judgment is made as to whether the basic index items are complete. When there

are incomplete indicator items, they are constructed by building new subtables and new indicator items as needed.

(3) Improvement of data of basic index items. The data of the basic index items are adjusted and improved; especially, the important data needed for analysis must be added and completed.

(4) Construction of personalized index items. Without changing the data of basic index items, new process index items are constructed through the system function, and the process index items are mainly processed in various forms such as merging, calculating, format converting, and intelligent fetching of basic index items to create personalized index items for data mining analysis in the next step.

(5) Human resource allocation analysis. Through the interface of human resource allocation analysis function module, K-Means clustering algorithm is used to cluster personnel. When analyzing, you need to select the analysis index items, set the number of clusters, the number of iterations, select the initial clustering center, and then cluster the personnel by K-Means clustering algorithm. After the clustering is finished, the clustering effect is judged whether it meets the expectation, if it meets the expectation, the result of clustering is backfilled into the basic index item; if it does not meet the expectation, the clustering is reclustered by adjusting the clustering parameters, initial centroid, or adjusting the clustering index until the clustering effect meets the expectation.

(6) Visualization display. According to the clustering results of backfill outputting the two-dimensional point diagram of divisional staff quality analysis, study and judge whether the staffing structure is reasonable, if it meets the task requirements, then end; if it does not meet the task requirements, then make appropriate staff adjustment, and then output the two-dimensional point diagram of divisional staff quality analysis to study whether it is reasonable.

Based on the analysis results and intuitive graphic display, management can more easily study and judge whether the staffing of each office is balanced and reasonable, and provide a basis for decision making on the staffing adjustment of the office at a later stage.

6. Conclusion

The theoretical significance of this study mainly includes the following aspects. First, the application of information technology has brought systematic innovation to the theory of human resource management. Information technology plays an important role in innovation and management practice. The combination of information technology and human resources fully meets the requirements of system management. This article takes high-tech enterprises as the research object and studies the information construction of human resource management. The article further sorts out and clarifies the specific solutions of human resource management. This study has practical significance in two aspects. On the one hand, the application of information technology can support enterprises in the comprehensive management of human resources. Information technology is very helpful for enterprises to carry out the information

construction of human management. Specifically, it can be reflected in management processes, functional design, training and compensation, and external consultation. On the other hand, information technology can provide relevant experience for other management work.

Especially for the management work related to human resources, the tools of information technology can bring good results. The application of information technology can provide a reference for the theoretical innovation of human resource management. In today's rapid development of the global economy, the competition between enterprises is the competition of talents. The importance of human resources has been valued by more and more enterprises. Under the background of rapid information iteration, enterprises need to make better use of talents to create a performance. The rapid development of enterprises also requires more professional talents and intellectual services. Enterprises need to use a variety of new technologies and new methods to efficiently manage talents. High-tech enterprises are the vanguards of enterprise reform and possess more knowledge-based talents. The management mode of human resources information of high-tech enterprises is also provided to other related industries for reference. The results of this study can drive the rapid development of Chinese enterprises as a whole. This article systematically sorts out the information problems of enterprise human resources, which helps to reduce enterprise human capital and improve enterprise management efficiency. The research in this article will help Chinese enterprises to develop as a whole and improve their international competitiveness. Therefore, this article has important practical significance to study the information work of enterprise human resources.

Under the background of the development of multi-sensor technology, enterprise leaders and managers must fully realize the application prospect of multisensor technology. In the work of human resource management, enterprises need to focus on strengthening the reform and innovation of human resource management technology. Enterprises need to improve the cognition and application level of multisensor technology and establish a strategic layout of human resource management. At the same time, enterprises need to set up an excellent compound human resource management team to lay the foundation for continuously improving the effect of enterprise human resource management.

With computer technology rapidly growing in recent years, there is a significant trend that virtual reality technologies turn into the public. The paper found that VR has a high potential to improve reading efficiency. The research discussed various figures, which is the key element for data visualization in digital publications. Furthermore, the research analyzes the characteristic of VR. The research divides the data into three types: Static Data, Dynamic Data, and Interactive Data. The research designs the framework to transfer the data into VR platforms. In order to evaluate the performance efficiency of the framework, we conducted performance evaluations and a user study with 20 participants. Compared with traditional 2D figures, the experimental results show that the 3D framework can be used as an effective visual tool for reading on VR platforms. The paper indicates the possible future view based on the design study.

1. Introduction

In recent years, virtual reality (VR) technology has developed rapidly in the entertainment, media, education, and medical industries [1]. Developers can use VR devices to integrate virtual content with natural scenes to combine various interaction methodologies. VR technologies mainly use headsets to interact with the virtual world using controllers or hand recognition [2, 3].

VR technology has two significant advantages as a communication medium. The first one is 'simulation' [4, 5]. The VR technologies can build a highly simulated environment [4, 5]. The second advantage is 'immersive' [4, 5]. The users explore the simulated environment with various interactive methodologies [4, 5].

Numerous studies show that the VR has a high potential to improve reading efficiency, considering the VR advantages. Baceviciute summarizes that reading in VR is found to be more cognitively effortful and less time-efficient by his user experiments [6]. Significantly, the reading is transferring from nonimmersive to immersive media [6, 7].

HTC Vive has released Vivepaper with VR digital publication in 2016 [8]. Vivepaper brings lives of pictures, videos, audio, and 3D models. Users can watch and listen to multimedia content in an innovative way by pointing fingers [8, 9]. However, Vivepaper only covers the tourism and fashion journey without a detailed content description. Besides, most VR digital publications only display the content in 2D panels in the 3D environment without considering redesigning its 3D User Interface (UI) layout [6, 10, 11].

We should consider how to use VR technologies as the carrier of digital publications in the era of digitization. The study aims to design a 3D data visualization framework in reading and optimize the VR reading user experience.

There are various types of publications globally. It is necessary to narrow the research scope into a specific aspect and analyze its related UI structure and design framework.

The social science publications include different figures and tables to illustrate the social research output to the public [12]. The figures provide convenience in reading and assist the reader in understanding the content. Suppose the

figures remain in 2D modes in VR platforms. In that case, it is significant that the 2D panel cannot improve the VR reading efficiency without applying VR features. Millais' research shows that 3D data visualization can lower the reading barrier and improve reading efficiency [13]. The research focuses on social sciences publications to build the initial design data visualization principle with fundamental VR characteristics. The research tries to provide a general and interactive UI framework to assist the social science publication transfer into the VR Reading field.

In this project, the research aims to design a general interactive data visualization framework. It covers various data figures from our research. It can improve the user experiences in VR reading. The proposed principle is based on VR interaction methodologies. The characteristics are as follows:

- (1) The research uses the VR interaction features to build the data visualization principle and provide users with immersive exploratory experiences.
- (2) The research balances the reading and VR characteristics. The research refers to 20 social science publications to conclude the general figure types. Meanwhile, 3D layout and gesture interaction are integrated with data visualization to enhance the user's immersive experiences.
- (3) The research evaluates the performance efficiency of the framework. We conducted performance evaluations and a user study.

2. Related Works

The session investigates the related publication knowledge and describes how to build up the data visualization principles. The research designs a general 3D data visualization concept by dividing various figures.

The research uses Unreal 4(UE4) UX development tools to design data visualization prototypes based on VR devices. The research uses different publications' data to testify to the possibility of the principles. The prototype can display how the concept plan adapts to the VR environment and the existing social science publications.

2.1. Data Elements in Social Science Publications. Before designing the general data visualization framework, it is necessary to discuss the existing general data figure elements in social publications. The study uses 20 articles from various open-access social science journals including Sage Open, Sustainability, and Agribusiness. We use the articles as case study samples to investigate the general data elements. We summarize the data elements and analyze how the elements achieve usage in data visualization. With critical analysis, we believe that the study can help us better discuss the overall data visualization concept and build the framework.

Through the investigation, the histogram is the most general data element. 75% of articles have used column charts. The line chart occupies the second position which number is 65%. Some articles only use line charts and

histograms [14, 15]. The flow chart is in the third position which number is 55%. The pie chart is in the fourth position with 30%. There are other specific charts with mixed types that occupy 20%. Besides, tables have appeared in 60% of articles.

By analyzing the above-given statistic, we can summarize the general data elements: column chart, line chart, flow chart, and pie chart. We should consider transforming them in the VR platforms.

2.2. Design Concept. The data and figure cannot directly transfer to VR platforms. Therefore, the digital publication should contain the data file and the VR system can read the data file when displaying the selected figure. The data visualization framework includes two significant functions: data loading and display, as shown in Figure 1. It is necessary to discuss how to load the data and display the data with immersive experiences.

In data loading, the study requires considering how to transfer the data from various data files to VR platforms. Therefore, it is necessary to customize the function library. The study uses Direct Excel, the plug-in to allow UE4 to load the data files from a specified path [16]. The study builds a customized function library to make reading the data more convenient through the functions provided by the plug-in. The customized function library can read the data of the table more flexibly. The library can read the specific data range and compare it with other ranges. It is beneficial to simplify the data visualization working process and improve efficiency [17–20].

Besides the loading, the framework should provide a suitable visualization in displaying the data. The study divides the data into three types: static data, dynamic data, and interactive data (Table 1).

The static data are the fundamental data visualization element. After loading the data, the static data display as a 3D layout without interaction and animation. Dynamic data does not only include the 3D perspective but also has an animation effect to display how the data transform and straightly to display the comparison trend. Interactive data can use most VR features, including 3D layout, animation, and gesture interaction. The data allows users to modify the data with gesture interaction and display the simulated result in a 3D environment.

3. Framework Overview

The framework [21, 22] contains three major sections: Static Data, Dynamic Data, and Interactive Data. The study sorts out different figures in these sessions and explains the working flow in the principles.

3.1. Static Data. Static Data displays the data in the 3D layout and provides the move manipulation with hand controllers. Static Data supposes to illustrate the data which is hard to use animation to display. By analyzing various figures, single-column charts, pie charts, and line charts can

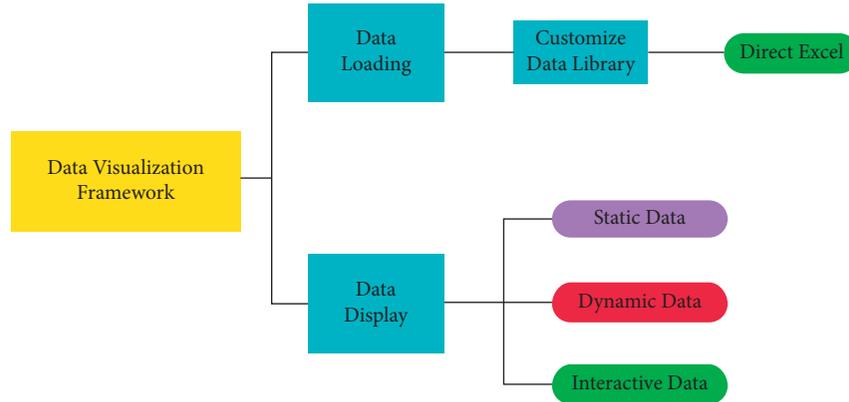

FIGURE 1: Framework overall structure.

TABLE 1: Data category.

	3D layout	Animation	Gesture interaction
Static Data	√	×	×
Dynamic Data	√	√	×
Interactive Data	√	√	√

be included with Static Data. The study aims to design the basic 3D visual effect to improve the above-given data figure.

We design the static column chart 3D layout plan as shown in Figure 2. The single-column chart has limited data and is clear to see the data, and the study uses the blue and red colors to highlight both sessions (Figure 2(a)). The single stacked column chart is the extended version of the single-column chart. The framework uses random colors with high contrast to highlight the data (Figure 2(b)). Both static column charts display the detailed percentage number in each session.

The static pie chart displays the pie in a 2D panel with 45-degree angles (Figure 3). The angles can provide the 3D perspective and the percentage number is beside each pie.

The 3D environment offers the line chart display with a three-axis (Figure 4). The line chart can straightly illustrate the trending in 3D mode and the position can display in the 3D environment.

3.2. Dynamic Data. Dynamic Data do not only provide the 3D layout but also allow us to play the trending with animation. The study aims to provide the convenience for users to analyze the dynamics trend. The study summarizes the chart which is suitable for animation. Dynamic Data includes regular column chart, pie chart, and line chart with a limited interaction in playing the animation.

Figure 5 displays the dynamic column chart 3D layout animation plan. The regular column chart has more data than the single-column chart. It usually contains data from multiple groups.

Using the animation can assist the user in contrasting the difference in groups (Figure 5(b)) and analyzing the growing trend (Figure 5(a)). The framework provides the horizontal and vertical columns in Figure 5.

Compared to the static pie chart, the dynamic pie chart uses the growing animation to represent the percentage (Figure 6). Each pie has a different height even though they have the same values. The percentage number is on the top of each pie. Different heights can assist the user in distinguishing the data belongs.

The dynamic line chart uses animation to represent the trend (Figure 7). The framework provides the key point highlight function. When the user marks the highlight option in the Excel file. It can display the key point value when the animation reaches the point.

3.3. Interactive Data. Compared to Dynamic Data, Interactive Data moves further, which focuses on interaction, animation, and 3D layout. The study aims to use interaction to lead the user to analyze the process and compare different groups’ data conveniently. Therefore, “comparison” and “controlling” are the key features of Interactive Data.

Comparison figures usually compare different groups’ data. Compared to regular column charts, the multiseries column chart has more information by lining different groups. Therefore, multiseries column charts should belong to the “comparison” group. However, different groups are usually hard to distinguish due to too many columns. Therefore, using interaction to display different states can improve the distinguishing result. The study designs the comparison interaction panel as shown in Figure 8. The panel provides the button to switch different groups. It also allows both groups are visible to compare. The user can easily distinguish the advantages of different groups.

A flow chart usually describes a complex working flow. A complex working flow has different conditions and results. It is hard to read due to various information and images. Therefore, it is necessary to provide the control flow

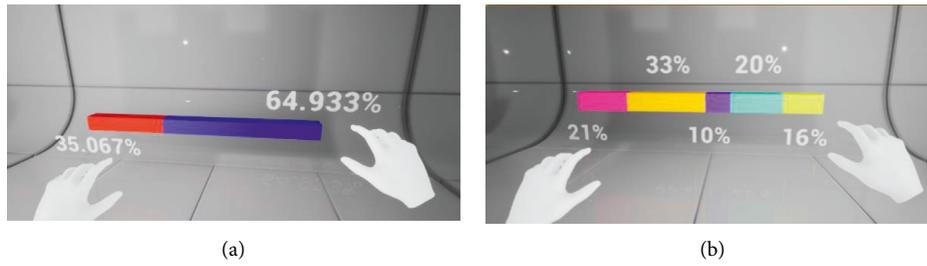

FIGURE 2: Static Column Chart Overview in VR platform. (a) Single Column Chart; (b) single Stacked Column Chart.

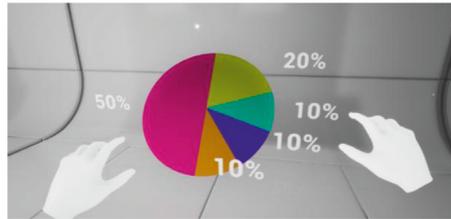

FIGURE 3: Static Pie Chart in VR platform.

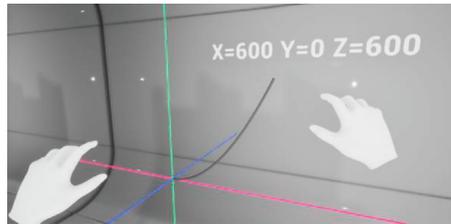

FIGURE 4: Static Line Chart in VR platform.

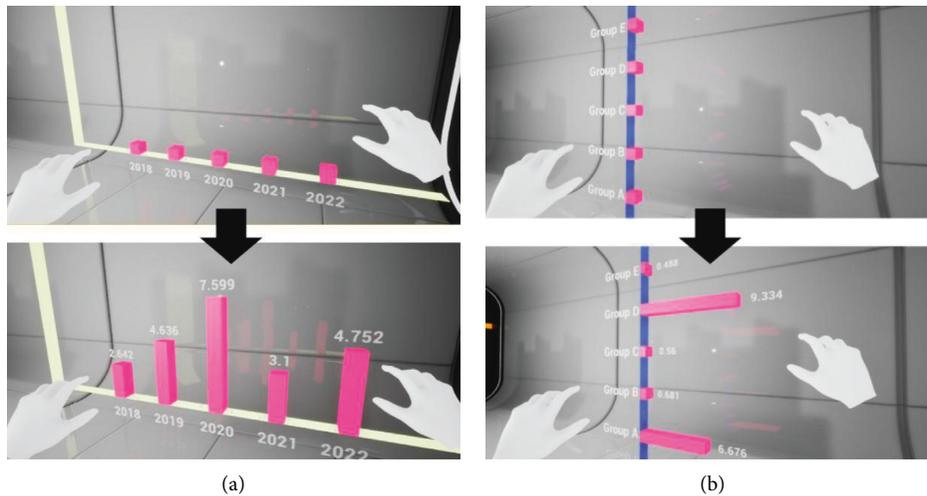

FIGURE 5: Dynamic Column Chart Overview in VR platform. (a) Horizontal Column Chart; (b) Vertical Column Chart.

function. The ‘controlling’ can efficiently assist the user in checking different statuses.

Figure 9 displays the flow chart in Interactive Data. The interactive panel is in front of the chart. The user can select different statuses (previous and next) and results. The switching interaction can help the user to see how the research moves to the specific result by reducing other result information. Meanwhile, the user can check other statuses by switching the panel.

4. Evaluation

We conducted user studies to investigate the user experience in the VR reading through a questionnaire [23–26]. Formally, we have the following hypotheses: (1) our framework helps the users improve their reading efficiency in checking the figures. (2) Our framework helps increase users’ immersive experience and engagement of the reading.

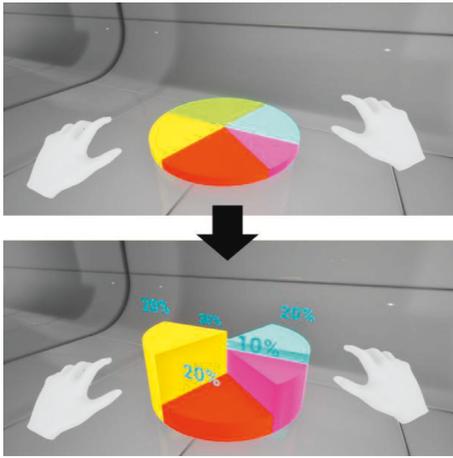

FIGURE 6: Dynamic Pie Chart in VR platform.

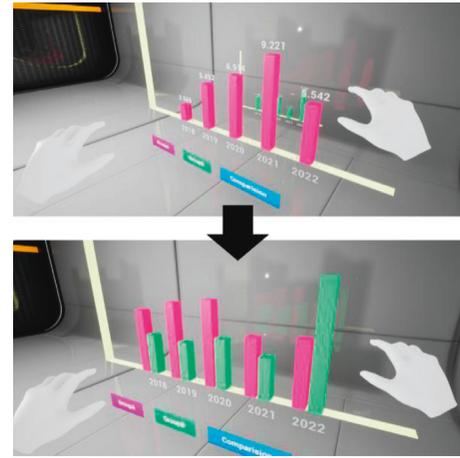

FIGURE 8: Multiseries column chart switching states in VR platform.

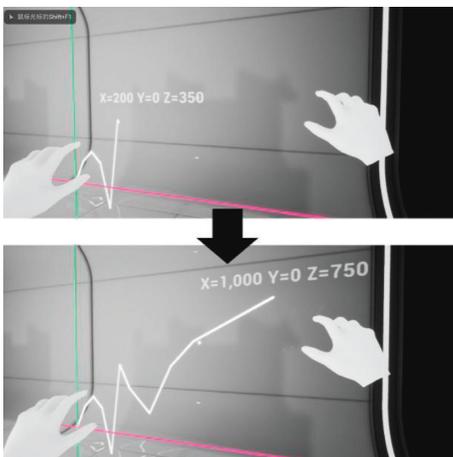

FIGURE 7: Dynamic Line Chart in VR platform.

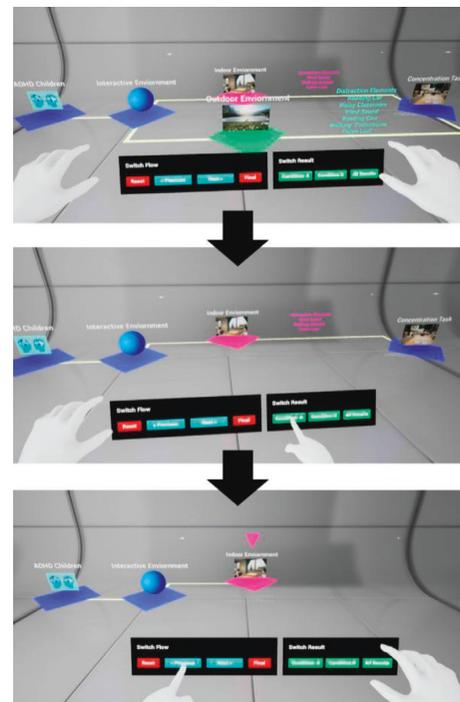

FIGURE 9: Interactive flow chart in VR platform.

4.1. *Participants.* Twenty participants (10 men, 10 women, aged 20–22 years old, $M=21$) were recruited from Guangdong University of Finance to take part in this study. The study divides them into Group A and B. Group A and B are the experiment group. Group A uses VR devices (HoloLens (2) to interact with the 3D figures under our framework designed. Group B uses desktops to check the same data with traditional 2D reading mode.

4.2. *Procedure.* Group A participants took part in the interactive experiment. Figure 10 shows that the participants used HoloLens 2 to interact with the framework. Group B participants used desktops to explore the figures. Group A/B has 20 minutes time limitation to check 10 figures.

Table 2 displays the figures’ distribution detail. All of Group B’s figures are using the traditional 2D display. After the reading, participants were required to complete a brief questionnaire regarding the data information they watched. The questionnaire section includes five single choices and five judgments. The questionnaire covers the data information overview. The questionnaire asks for exact numbers

such as maximum and minimum numbers. For instance, a question judges the trend in a dynamic line chart.

5. Results

The research collects the user score in two groups from questionnaire data. Figure 11 displays the user score distribution in each group. The research calculates the average and median score as shown in Table 3. For the data visualization framework, three trends are obtained as follows:

- (1) It is encouraging that Group A has better performance in average and median score than Group B. But the superiority is very small which is only 3.07%.

FIGURE 10: Group a user test.

TABLE 2: User test Figures Distribution.

		Question numbers
<i>Static Data</i>	Static single column chart	1
	Static single stacked column chart	1
	Static pie chart	1
	Static line chart	1
<i>Dynamic Data</i>	Dynamic horizontal column chart	1
	Dynamic vertical column chart	1
	Dynamic pie chart	1
	Dynamic line chart	1
<i>Interactive Data</i>	Interactive flow chart	1
	Interactive column chart	1

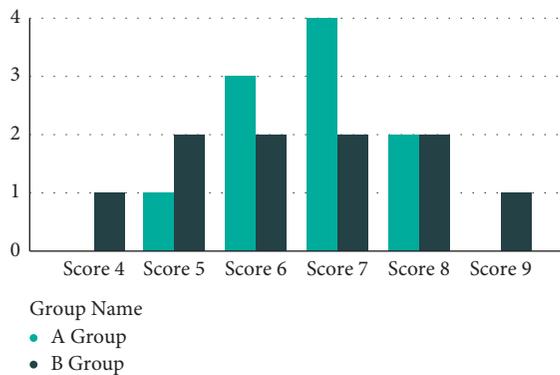

FIGURE 11: Group score distribution.

TABLE 3: User test score data.

	Group A (average score)	Group B (average score)
Static Data	2.4	2.7
Dynamic Data	2.8	2.9
Interactive Data	1.5	0.9
Total	6.7	6.5
	7	6

- (2) Group A has worse performance in Static Data. The average score is number is 11% lower than Group B.
- (3) Group A has limited worse performance in Dynamic Data. The average score is number is 3.04% lower than Group B.
- (4) Group A has better performance in Interactive Data. The average score is number is 66.67% higher than Group B.

Considering the above-given data, the data visualization framework can significantly improve performance efficiency, especially in Interactive Data. We conclude that the interaction can engage the user participant and remember the data. At the same time, the multiple-column chart and flow chart has more information than the Static and Dynamic Date Group. Therefore, it is significant that the VR interaction can assist with more complicated figures and information. The animation method can also provide similar experiences to the 2D reading. However, there are some existing issues. Significantly, the 3D figure without animation and interaction (Static Data) is worse than the traditional reading. We analysed that the Static Data contains simple figures which are easy to read. If we use the 3D display that may bring distraction due to the 3D environment and receive a negative effect. Therefore, we should consider that the simple figures do not fit with 3D reading.

Future research should optimize the Interactive and Dynamic Data. Furthermore, the controlling difficulty is another challenge for the users not familiar with VR applications. Therefore, the framework should provide more tutorial elements to decrease the difficulty. The study will consider the above data carefully and put forward the optimizing solution. The framework will continue to be optimized and contribute to the VR reading field.

6. Conclusion

In order to improve the reading user experience in VR platforms, the research aims to design a data visualization framework with VR characteristics. The paper finds that VR has a high potential to improve reading efficiency. The research discusses various figures, which is the key element for data visualization in social publications. A 3D data visualization framework is proposed to provide an immersive, explorative, and readable user experience. The framework divides data into three types: Static Data, Dynamic Data, and Interactive Data. The framework follows the VR features to provide a 3D visual effect and immersive interactive experiences. The research runs a comparative user test with 20 participants. The result shows that the framework is more attractive and efficient than reading the traditional 2D figures in VR platforms. Based on these evaluations, we believe that the proposed framework can be used as an effective reading tool for social science publications. The proposed

framework can improve user experience in the VR reading fields. Our research contains the VR reading field and uses VR interactive technology to improve user experiences. Future work continues to discuss data visualization and move to the VR text reading. We will use various statistical analysis methodologies such as mixed-ANOVA to measure the user experience after using the framework with pretest and post-test.

Data Availability

The data used to support the findings of this study are available from the corresponding author upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

With the gradual deepening of the combination of 3D printing technology and the furniture manufacturing industry, the production of 3D printed furniture has begun to transition from experimental single furniture production to small batch furniture production, which will profoundly affect the manufacturing mode change of the furniture manufacturing industry in the future. This paper conducts a detailed study on the complex molding links, product development links, parts production links, and product body forming links of 3D printing technology in the furniture manufacturing industry. The design and printing process can provide practical reference for the manufacture of furniture products.

1. Introduction

In the context of the development of high-tech technologies, 3D printing technology has emerged as the times evolve. 3D printing technology has the advantages of digital and intelligent development and can be customized for specific products. 3D printing technology is a transformative digital additive manufacturing technology that manufactures three-dimensional objects through layer-by-layer superposition of materials influence. In recent years, with the development of this technology becoming more and more advanced, 3D printing technology has been widely used in aviation, transportation, manufacturing, and other fields [1–5]. 3D printing technology plays an important role in promoting the transformation of our country's manufacturing industry from the “Made in China” model at the low end of the industrial chain to the “Made in China” model, assisting the overall development of the manufacturing industry to upgrade from the downstream processing and assembly links to the upstream design and development links [6–8]. While the 3D printing technology continues to progress, promoting the combination of technology and specific industries is the only way to promote its long-term development [9, 10].

While the impact of 3D printing technology on the manufacturing industry has been deepening, the competition in our country's furniture manufacturing industry has become increasingly fierce [11–13]. How to correctly grasp the future development direction is a problem that most furniture manufacturers continue to explore. At present, in the overall development of the furniture manufacturing industry, enterprises continue to integrate, the market is constantly subdivided, and the professional division of labor is more clear. However, there are still serious product homogeneity, slow update speed, waste of resources, and serious pollution in the manufacturing process of furniture. It is difficult to meet consumers' needs for originality, diversity, and environmental protection of furniture products. Furniture manufacturing enterprises have an increasingly strong demand for the improvement of furniture manufacturing process and furniture modeling structure [14–17]. In addition, the intelligent upgrading of furniture products in the context of the development of intelligent manufacturing is also a gradually improved field in the furniture manufacturing industry. In recent years, the development of intelligent furniture has accelerated significantly [18–20]. In this situation of rapid changes in the furniture manufacturing industry, the rapid prototyping

characteristics of 3D printing technology and the superiority of solving complex technological processes have brought it into constant contact with the furniture manufacturing industry, and in the process of furniture production, technology plays an important role in the development of the industry. Increasingly, the mass customization trend of 3D printed furniture is taking shape. From the perspective of the development of 3D printing technology and the background of the furniture manufacturing industry, the application of 3D printing technology in the furniture manufacturing industry is an inevitable product for the continuous interaction between technological progress and market demands [2, 21–23].

With the advancement of 3D printing technology and the continuous decline of material manufacturing costs, the development of its technology research and equipment manufacturing has accelerated significantly, but the corresponding industrial applications are still facing a huge bottleneck period. Some domestic researchers in the field of 3D printing technology do not know enough about the specific industry needs, and there is a lack of specific industry support for research on 3D printing technology and materials, while the insiders in the furniture manufacturing industry also have less contact with 3D printing technology and have little understanding of new technologies. The lack of broad awareness of application methods and advantages has seriously hindered the further promotion of 3D printing technology in the furniture manufacturing industry. In the urgent need to open the communication channel of technological progress and industrial market, the research purpose of this paper is to analyze the application status of 3D printing technology in the furniture manufacturing industry and provide solutions to problems in the furniture manufacturing process through the application research of 3D printing technology.

2. 3D Printing Technology

3D printing technology is accurate in physical replication, and combined with scanning technology, more accurate replication effects can be obtained; there are various materials, and 3D printing technology can be used to print different materials to meet the needs of various fields; the printing speed is fast, which is comparable to traditional manufacturing. Compared with the process, it saves a variety of complex processing and improves the efficiency; the manufacturing cost is low, and compared with the traditional machine tool processing, it saves the cost of manufacturing materials and transportation, which can effectively reduce the cost; the degree of personalization can meet a variety of demands, wide range of manufacture, and fast delivery time. The emergence of new technologies has both advantages and disadvantages. 3D printing technology consumes a lot, which is more than 10 times that of the traditional manufacturing processes. Therefore, under the current social background that promotes green energy, 3D printing needs to be transformed to reduce the existing energy consumption; the combination of 3D printing technology and biotechnology will bring certain security

risks to the society. If there is no restriction, there will be contradictions that are inconsistent with the development of technology; the emergence of 3D printing technology provides convenience for lawbreakers, and it is easy to cause certain threats to public security; at the same time, there are certain restrictions on the selection of material varieties. Today, with the rapid development of computer technology, it is easy to copy and transfer relying on 3D technology; equipment is expensive, and if it is to be widely promoted and applied, certain difficulties will be faced.

2.1. Basic Concepts of 3D Printing. The 3D printing technology is also known as rapid prototyping technology or additive manufacturing technology. 3D printing is based on three-dimensional models, using materials such as wires, powders, and liquids that can be melted and bonded by heating and layer-by-layer superimposition. However, the modern society is increasingly pursuing personalized customization, which is consistent with the advantages of 3D printing, such as short production cycles, small batch production, and convenient product shape change, so it brings space for 3D printing development.

2.2. Basic Types of 3D Printing

- (1) Fused deposition type: this printing type of FDM is the most basic and elementary type of 3D printing. It mainly uses plastic filaments (ABS, PLA, nylon, etc.) to be heated and melted by the nozzle of the printer, and then, the materials are layered layer by layer. Extruded onto the printing platform, according to the slicing of the 3D model, the multilayer accumulation is carried out and finally the shaping of the solid model is completed. The overall process is similar to squeezing toothpaste, so this technology does not have high requirements on the printing environment and consumables and is relatively easy to use and control. It is generally used as an introduction to 3D printing and teaching.
- (2) Selective laser sintering type: this printing type of SLS mainly uses powder (metal, ceramic, wax powder, plastic powder, etc.) as the material and is performed by sintering and bonding. During processing, the powder is first preheated to a temperature slightly below its melting point and then flattened under the action of a leveling stick; the laser beam is selectively sintered according to the layered cross section information under computer control. The molding method has the characteristics of simple manufacturing process, high flexibility, wide range of material selection, low material price, low cost, high material utilization rate, and fast molding speed. According to the above characteristics, the SLS method is mainly used in the foundry industry and can be used directly to make quick stencils.
- (3) Light-curing three-dimensional molding: this printing type of SLA mainly uses liquid photosensitive resin and is cured by light. Light-curing

molding is the most widely used due to its high degree of automation in the molding process, good surface quality of prototypes, high dimensional accuracy, and the ability to achieve relatively fine dimensional molding.

2.3. Research Status of 3D Printing Technology. The time from theoretical research to practical application of foreign 3D printing technology is relatively early, and most of the fields involved are at the forefront of the development of the times, from 3D printing automobiles, aerospace parts, high-end medical models, and new concept architectural design to manufacturing and other applications. The 3D printing technology has also achieved leapfrog development in the field of foreign art design. Art design-related industries have made various cross-border attempts combined with the advantages of 3D printing technology. 3D printed shoes, clothes, accessories, etc., have appeared in world-class fashion for many times shows and art exhibitions. The new era has brought new opportunities for the application of 3D printing technology in indoor home furnishing. Foreign developed countries have carried out a lot of research and application in indoor interface modeling design and interior decoration construction. For example, in interior decoration products, Nervous System, a design firm from the United States, used generative algorithms to create the latest lamps made of nylon material. Nervous System is shown in Figure 1.

When the Nervous System light is turned on, the light will penetrate the hollow and divergent branch and leaf shells and project into the indoor space, making people feel like they are in a dream forest. In terms of interior furniture products, Dutch designer Drik Vander Kooij has designed “Endless Flowing” furniture, as shown in Figure 2.

By observing the chair, people will not realize that the Endless Flowing” chair is made of 3D printing. This is because Kooij uses a unique technology in 3D printing: Kooij 3D prints the chair, unlike most 3D printed furniture. When printing, the printer only moves back and forth. Instead, he allows his 3D printer to print in multiple directions to create a unique appearance.

Domestic research on 3D printing technology started relatively late, and there is insufficient research on 3D printing technology methods. Although there are individual units or individuals with advanced awareness about the use of 3D printing technology in China, they are not in-depth enough. The traditional domestic products in the home furnishing industry are relatively simple in shape and function, and the actual products manufactured cannot meet the original intention perfectly due to the limitations of craftsmanship. The application of domestic 3D printing technology is mainly at the architectural level and design level, and some cutting-edge technologies still have to be imported from abroad. Since most companies do not have a strong awareness of the application of 3D printing technology, they have not dig deeper or are skeptical of it and still design and manufacture household products in accordance with traditional concepts and processes. Facing the reform of new production methods and the “re-industrialization

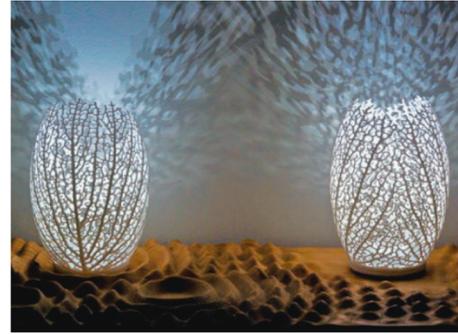

FIGURE 1: Vein lamps designed by Nervous System.

FIGURE 2: “Endless Flowing” furniture.

strategy” vigorously promoted by developed countries, the country attaches great importance to the R&D and industrialization of new digital manufacturing technologies such as 3D printing and intensifies personnel training, market cultivation, and application promotion. An example of the latest domestic experimental interior decoration works is the experimental villa of Shanghai Yingchuang Company’s integrated printing of interior and exterior decoration and architecture, as shown in Figure 3.

With the development of the times, the new term “cross-border design” came into being. The innovative integration of craftsmanship is an important component of cross-border, and due to the requirements of new crafts and personalized design, 3D printing has become a tool that can concretize various personal tastes and materialized arts. The cooperation between interior decoration and 3D technology and convergence has become the inevitability of the times. The increasingly developed trend of 3D printing technology has greatly responded to people’s claims of consumption and opened up a broader space for indoor home design. In the future, the application potential of 3D printing technology in indoor homes is huge, and it will better meet people’s needs for personalized customization and modern smart home environment [15–17].

3. The Application of 3D Printing in Furniture Manufacturing

At present, the application scope of 3D printing technology in the furniture manufacturing industry is expanding, from

FIGURE 3: The world's tallest 3D printed building.

experimental single-piece furniture production to mold manufacturing, product development, parts production, and other manufacturing links. Its application mainly focuses on solving various complex problems such as shape complexity, material complexity, hierarchical complexity, and functional complexity in the production process. The 3D printing technology is closely related to the traditional furniture manufacturing process. The combination of new technology and traditional technology can cooperate to solve the problems of long R&D and production cycle and slow product update speed in the furniture manufacturing industry.

3.1. Application of 3D Printing Technology in Complex Furniture Molding. The application of 3D printing technology has promoted the current furniture manufacturing industry, which is firstly reflected in the simplification of the complex mold manufacturing process, which is used to solve the mold opening problem of some irregularly shaped furniture. In the prototype stage of furniture production such as upholstered furniture, metal furniture, and injection-molded furniture, some furniture or components need to be processed by plastic molding or metal casting and the furniture production is highly dependent on mold manufacturing.

Compared with traditional mold-opening methods, 3D printing technology is applied to the complex mold-making process of furniture products and its advantages are mainly reflected in the following aspects: first, it solves the rapid prototyping of complex shapes of molds and second, it saves the cost of furniture molding links. In the field of mold manufacturing, the application of 3D printing technology is also known as rapid mold manufacturing technology. This technology is used in conjunction with CNC machining centers, engraving machines, vacuum laminating machines, and other equipment to jointly provide rapid prototyping services for furniture molding. At present, the 3D printing technologies applied in the mold manufacturing process mainly include photocuring molding technology and selective laser sintering technology. The available printing materials include metal, plastic, ceramics, recycled paper, etc. When making molds with 3D printing technology, the shape of the mold is directly generated from computer graphics data, which can be adjusted at any time in the virtual model-making stage before the mold is printed.

3.2. The Application of 3D Printing Technology in the Research and Development of Furniture Products. At this stage, the application of 3D printing technology in the furniture manufacturing industry mainly focuses on the research and development of new furniture products and the printed furniture product prototypes are used for the appearance and structure verification of new products. The research and development stage of traditional furniture manufacturing usually requires multiple repeated communication processes such as product prototype design, mold making, and re-improving the prototype design. The one-time molding feature of 3D printing technology turns the repeated communication between furniture product design and mold production into direct printing of product prototypes, thereby simplifying the development process of furniture products as “furniture design-3D printing product prototypes-modifying product prototypes-reprinting and functional verification-final mold opening” process.

Specifically, the intervention of 3D printing technology is mainly to reduce the repeatability in the product development process through the following means:

- (1) The performance of furniture products is pretested in the 3D model stage, and the process of determining the rationality of the design will be more concentrated in the stage of virtual model making and modification.
- (2) The application of new technologies makes the design of furniture products take into account the satisfaction of product functions. The integrated molding of furniture products enables designers to obtain the prototype of furniture products more intuitively, better grasp the appearance and structure of furniture products, and improve the modeling accuracy. In the process of furniture design and modification, a variety of product prototypes can also be quickly printed, so that furniture product development can be upgraded from simple prototype trial production to conceptual model derivation, ergonomic analysis, visual analysis, form coordination and function testing, engineering comprehensive analysis of furniture products such as evaluation tests.
- (3) We can concentrate on the product design department for mold making and small-scale trial production and reduce the time for docking with mold manufacturing enterprises, communication between company internal personnel, and product flow.

3.3. The Application of 3D Printing Technology in the Production of Furniture Parts. Since furniture products have high requirements on the structural strength and material adaptability of the connecting parts, the production of furniture parts mainly relies on standardized means to restrict the production of parts. In the assembly of traditional standardized connectors, the connectors are usually commissioned by furniture companies to produce parts manufacturers and complete the assembly in the furniture

assembly workshop. Although the standardized parts production process can meet the needs of various furniture connections, complex structural assembly processes are still required at the connections and furniture products exhibit obvious assembly characteristics. Therefore, furniture products are prone to wear and deformation of parts during use, and the service life is greatly affected by the firmness of the parts.

The application advantages of 3D printing technology in the production of furniture parts are as follows:

- (1) The connectors are integrally formed by modular means, which reduces the use of screws and connecting hinges for furniture products, improves the degree of fit, and reduces the difficulty of parts production and assembly.
- (2) In the mold-opening stage of traditional parts, a more concise mold shape is formed, so that the shape of the manufactured metal or plastic parts is more simplified, the structure is more reasonable, and it is beneficial to realize the simplified processing of complex structural parts.
- (3) In addition to the initial process of applying 3D printing technology to furniture production, it can also exert its technical advantages in the process of secondary recycling of furniture, realize the processing of existing furniture incomplete parts, prolong the service life of furniture products, and obtain better quality products at a high environmental value.

3.4. The Application of 3D Printing Technology in the Molding of Furniture Main Body. In addition to the application in the auxiliary links of furniture production, the current industrial-grade 3D printers are mostly aimed at directly manufacturing molded products. The large-scale 3D printing equipment produced by some printer manufacturers specifically provides services for directly printing furniture products.

In the furniture main body forming process, the application advantages of 3D printing technology mainly include the following:

- (1) 3D printing technology can reduce the time for auxiliary mold opening, parts production, assembly and splicing, and material consumption in furniture production, so that furniture products have the appearance characteristics of integral molding. 3D printing technology has successfully produced single furniture or small batch of furniture many times in the furniture manufacturing industry, and the products are mostly used for the manufacture and reproduction of high-end art furniture such as European-style or Chinese-style furniture.
- (2) 3D printing technology can realize the one-time molding of the self-occlusal structure and cavity structure of the furniture. The printing of key parts of the furniture can remove the visual barriers of

cumbersome mechanical parts and achieve a qualitative leap in functional innovation. The designer's consideration of the functionality of the work can be subtly realized through the modeling capabilities of computer modeling and 3D printing equipment. These structural features and plastic arts are usually difficult to achieve seamless assembly when they are made by cutting, molding, and other means.

- (3) Manufacturers of 3D printing materials and equipment can conduct product research and development on nylon, wood-plastic, metal, resin, and other printing materials to obtain different textures of printing materials. These new printing materials realize the structural remodeling of traditional materials through the structural design of virtual three-dimensional models and provide new material choices for furniture production.

4. 3D Printing Furniture Product Model Practice

When the 3D printing equipment prints a single piece of furniture, its generalized manufacturing process consists of the following three parts: first, the acquisition of virtual 3D model data and format conversion are performed; second, the furniture is printed on the machine; finally, the post-processing after printing is performed.

4.1. Acquisition and Format Conversion of Virtual 3D Model Data. In the acquisition and format conversion of virtual 3D model data, there are mainly two steps as follows: first, acquisition of virtual 3D model data; second, model sorting and STL format conversion.

4.1.1. Acquisition of Virtual 3D Model Data. There are three main ways to obtain the virtual 3D data model of the furniture or parts to be printed: one is to establish 3D model data by means of traditional computer modeling software. The virtual 3D data modeling software that can be applied to 3D printing technology includes AutoCAD, Maya, 3DS MAX, Rhino3D, and other common commercial design software, and there are also relatively low-difficulty design software packages such as Blender, Sketch Up, and Tinkercad. At present, this method is the more commonly used modeling method. Through short-term learning, we can quickly grasp the modeling requirements of 3D printing furniture; the second is to establish 3D model data through parametric design software. Among the commonly used parametric design software, the mainstream application software is Pro/Engineer, UGNX, CATIA, and Solidworks. The modeling method of parametric design software can enable furniture products to establish various constraint relationships based on the parametric models, realize more intelligent programming design, and obtain the systematic and growing model effects so that furniture products can be standardized according to user requirements. With rapid customized modeling on the basis of products, this way of

building 3D data models is more in line with digital modeling thinking, so it can better utilize the advantages of 3D printing technology; the third is to obtain 3D models of existing furniture by using scanners and tactile devices. After the furniture data is scanned by the 3D scanner, it needs to be converted into a triangular mesh model by a software. The advantage of this method is that it can realize the function of quickly copying the existing furniture products.

4.1.2. Model Sorting and STL Format Conversion. After acquiring the virtual 3D model data, it is necessary to scale and repair the model to adapt it to the size, model, and resolution of the printer used and then convert the data format of the furniture model after adjustment. After these virtual 3D models obtained by modeling or scanning are established, they need to be uniformly converted into a file format that can be read by the driver software of the 3D printer, usually into a printable multilateral network file, that is, a file in STL format. STL is one of the commonly used file formats for 3D printing. Specifically, small triangular patches in a large number of spaces are used to approximate the solid model, and the solid object is cut into digital cross sections or layers by software and divided into equal thicknesses along the Z axis. Slicing creates a two-dimensional image, which is transmitted to the machine according to the image information. Different materials are bonded and stacked layer by layer to form a three-dimensional entity, and then, the necessary code that can control the 3D printer hardware to construct the object is generated, which is stored in the database for future modification and use.

4.2. Printing Furniture on the Machine. After completing the processing of the 3D data model of the virtual space, the printing enters the specific manufacturing stage. When printing furniture, you need to choose a 3D printer that meets dimensional accuracy and structural strength to maintain continuous print jobs. The process steps are as follows.

4.2.1. Performing Layering and Support Settings. At present, the professional layering software mainly includes SLICER and SFACT. After the layering is completed, the generated GCODE file is transferred to the 3D printer. The thickness of each thin layer can be appropriately adjusted according to the type of printer and printing accuracy, generally in between tens to hundreds of microns. It is worth noting that the reasonable and accurate handling of complex models largely determines the success or failure of the printed product. The processed model needs to ensure that there are no overlapping triangles, and if there are overlaps and holes, the transcribed 3D model may break or the file may not be printed after transfer to the printer. For the problems of material consumption and printing time in large-volume solid virtual models, under the premise of ensuring the structural strength, the structure can be simplified and hollowed out to form a hollow shell-like object. This process needs to consider the following aspects: Firstly, the

minimum wall thickness of the printing material needs to be met. Secondly, if it is a liquid printer, it is necessary to leave a minimum overflow hole when printing the model and finally set the width and height requirements of convex or concave detailed structures (such as yin and yang engraved characters) question.

4.2.2. Importing the Printer Program to Complete Printing. After finishing the previous link, the generated GCODE file is sent to the 3D printer for identification and printing, thus completing the acquisition and format conversion of the virtual 3D model data. In specific applications, printers of different molding methods and models are slightly different in receiving print data, which is embodied in differences in transmission speed, storage, and instruction set.

4.3. Postprocessing after Printing. After the main body of 3D printing furniture is completed, the key application difficulty is the postprocessing link. Like the furniture produced by the standardized production line, after the main body printing process of the furniture is completed, a series of post-processing procedures such as grinding, polishing, and coloring of the furniture can be performed according to the requirements for the fineness of the molding surface and we can complete inspection and packaging of furniture products and finally complete furniture production.

At present, the postprocessing methods that can be used for 3D printing furniture mainly include the following: plastic, nylon, glass, and other parts. These are postprocessed by component splicing, sandpaper grinding, manual polishing, coloring, and steam smoothing; metal parts are processed by electroplating, oxidation, chemical conversion coating treatment, thermal processing, and other means for posttreatment. From the perspective of the entire production process, according to the structural characteristics and actual use of the product, various manufacturing modes such as printing first, processing after printing, processing while printing, and no processing after printing can be formed to complete large-scale, high-density, and high-quality products in a flexible and efficient way manufacturing of precision, complex products.

5. Conclusion

With the gradual deepening of the combination of 3D printing technology and the furniture manufacturing industry, the production of 3D printed furniture has begun to transition from experimental single furniture production to small batch furniture production, which will profoundly affect the manufacturing mode change of the furniture manufacturing industry in the future. This paper conducts a detailed study on the complex molding links, product development links, parts production links, and product main body forming links of 3D printing technology in the furniture manufacturing industry, as well as its general characteristics when using 3D printing equipment to print furniture products. The molding process, in the actual application process, needs to choose the appropriate printing

method according to the furniture production requirements and the characteristics of the printing equipment.

The application of 3D printing technology in the furniture manufacturing industry is a newborn calf compared to the current relatively mature furniture production technology. With the gradual expansion of the application depth in recent years, the state's support for this technology has also been unprecedentedly high. However, it is undeniable that due to the few examples of technology industry applications, the authors are still lacking in the ability to write papers and the research may be biased and not in-depth, such as statistical sorting of 3D printing technology data and specific cases in the argument. Analysis is not thorough enough. These reasons lead to the data legacy and some deficiencies in the research in this paper. These unresolved problems are also the key to the future development and application of 3D printing technology in the field of furniture manufacturing.

The art of piano playing has been continuously entering into people's life. However, with the continuous improvement of science and technology and living standards, the traditional teaching mode can no longer meet the piano teaching mode. The teaching of piano is different from traditional subjects, such as Chinese and mathematics. It requires students to experience the artistic characteristics and the live atmosphere of the players brought by the piano. This study integrates video and image teaching methods with piano teaching. Videos and images can more intuitively show the live atmosphere brought by piano players and musical artistic features brought by the piano. At the same time, this study uses the convolutional neural network (CNN) method to study the relevant features of videos and images of piano teaching. These features are mainly the characteristics of piano music, the behavior of players, and the basic knowledge of a piano. The research results show that the clustering method can effectively classify the features of videos and images in piano teaching, and the maximum classification error is only 1.89%. The CNN method also has high performance in predicting the relevant features of piano teaching videos and images. *Accuracy*. The largest prediction error is only 2.23%, and the linear correlation coefficient also exceeds 0.95. This set of the piano teaching mode that combines videos and images is beneficial to both teachers and students.

1. Introduction

The traditional teaching method is to use the blackboard or PPT to impart knowledge. With the continuous progress of computer-aided teaching methods and hardware equipment, the teaching mode has also undergone great changes [1]. Computers can help people with some tedious tasks. It can also display teaching content in the form of pictures or flow charts. It more intuitively shows teaching knowledge to the students. This is different from the traditional teaching mode. The piano teaching mode is different from the traditional methods of mathematics and Chinese subjects. Mathematics and Chinese teaching modes are knowledge and methods that need to be taught in textbooks. However, a piano is a teaching mode that needs to be understood [2, 3]. Piano art not only embodies the meaning of music itself but also embodies the humanistic feelings of the connotation of music. Therefore, the piano teaching mode is not a simple superposition of knowledge, it also requires students to

experience the connotation of piano art. This requires the teaching mode of piano art to be improved. Traditional teaching methods can only allow students to learn the basics of piano, such as musical notation, musical notes, etc. It does not allow students to appreciate the humanities in it [4, 5]. The PPT method can allow students to learn piano knowledge in the form of pictures, but this method is far from enough. A piano is an artistic method that combines musical instruments and music, and it is also closely related to the emotional performance of the audience. The piano teaching classroom also requires students to combine the music scene and the form of the piano performance to carry out effective learning. The video method can record the ambient atmosphere, music atmosphere, and the content of the piano performance at the music scene, and it can effectively record the performance of the audience and the performer. Piano learners can learn more knowledge from piano-playing videos [6, 7]. The image can effectively record the key piano performance, it can capture the mood and

performance content of the piano player very well. However, the content of videos and images needs to be grasped and captured efficiently by the pianist, which requires big data technology to capture the key content of videos and images and relevant knowledge. This study intends to design a piano teaching mode by combining videos and images, which will better capture the content of the piano performance and the atmosphere of the scene. The research on the relationship between the content of videos and images and the content of the piano performance requires big data technology to analyze.

A convolutional neural network (CNN) can better extract the spatial features of data and it can also better map the relationship between input and output [8]. It has been widely used in many fields, such as image recognition and feature extraction. CNN can have higher efficiency and computing power than manual methods, so it can handle the relationship between large amounts of data very well. Video methods will contain many image features, and CNN can have better feature extraction capabilities in both videos and images [9, 10]. This research integrates videos and images to design a piano teaching mode, which mainly designs feature extraction. It also does not involve temporal features, so the CNN method was chosen in this study. The CNN method is also an intelligent algorithm that has developed rapidly in recent years, and many research objects have complex mapping relationships. However, there is relatively strong nonlinear correlation between these complex data. It is difficult for manual methods to deal with these problems with experience or professional knowledge. CNN methods can use these complex data to find correlations between data. At present, big data technology has produced algorithms related to spatial feature extraction or temporal feature extraction [11, 12]. There are relatively few temporal features involved in piano teaching videos and images recognition. Therefore, this study only selects the spatial features of piano teaching videos and images. CNN has relatively high requirements on computers and hardware devices. With the continuous advancement of science and technology, there will be huge amounts of data in every field. The larger the magnitude of the data, which requires deeper CNN to complete the feature extraction task [13, 14]. The birth of GPU technology makes it possible for CNN to develop to a deeper level. The computing power of GPU technology will be many orders of magnitude superior to the computing power of CPU. The piano video technology has more image features, and the GPU technology provides more technical support for the feature extraction of the video method.

This research will solve the shortcomings of the traditional piano teaching mode, it uses video and image methods to design a new teaching method for piano teaching. At the same time, CNN technology is used to extract spatial features existing in piano video and image teaching, and it can also be used to complete the extraction of nonlinear relationships. This set of an intelligent piano video and image teaching mode will not only effectively extract the piano player's behavior information and music and art content embodied by the piano but also improve students' learning

efficiency and interest. Compared with the teaching mode of the blackboard or PPT, the teaching mode of videos and images will attract more students' attention. When students' learning attention and learning interest are improved, piano learners will gain more piano teaching knowledge.

In this study, a new piano teaching mode was designed using the form of videos and images. At the same time, this study uses the CNN method to extract the relevant features of piano video and image teaching. This study will be introduced from five aspects. Section 1 introduces and analyzes the defects of the piano teaching mode and the research significance of the CNN method in piano teaching. The research status of the mode of piano teaching is introduced in Section 2. The piano teaching mode and the CNN method combining videos and images are introduced in Section 3. Section 4 analyzes the feasibility and accuracy of CNN for feature extraction of videos and images in piano teaching mode, which is the core part of this research. Section 5 summarizes the full text.

2. Related Work

The piano is an art form that can reflect the art of music and humanistic feelings, and it can also integrate the audience and the performer into an art form. There is a big difference between piano teaching and the teaching mode of traditional subjects. Many researchers have conducted a lot of research on the teaching mode of a piano. Cui [15] uses augmented virtual reality technology AR to study the relevant skills of piano teaching. This study mainly proposes an online piano teaching mode. It selected a number of college students in Heilongjiang to study the relevant situation of the piano, which mainly includes the learners' subjective attitudes and personal learning progress. The results of the study found that 89% of students had a significant improvement in the learning of musical terminology, which was mainly in reading sheet music and using music materials. This online piano teaching mode provides a new teaching mode and development direction for piano teaching. Pi [16] believed that piano education can alleviate teaching fatigue and improve the teachers' happiness index. This study discusses the relationship between work fatigue and piano education. It mainly uses qualitative and quantitative methods to study the relationship between piano education and the teachers' happiness index. The results of the study show that piano teaching can improve work motivation and efficiency. At the same time, it found that the happiness index of most teachers in piano teaching is at a low level, and this research will help to improve the happiness index of piano teachers. Liu [17] has found that the current piano teaching mode lacks comprehensiveness and scientificity, and it has been unable to use the development of the piano teaching mode. This study uses BP neural network technology to establish a mode of the music signal and the piano teaching performance score. It selects well-known piano works as the test set to verify the effect of the mode. The research results show that this method can effectively verify the working level of the piano. It can accurately

provide players with a certain scoring reference. This method can not only improve the musical level of piano performance but it can also help to improve the talent of a piano. Xue and Jia [18] found that information technology has brought about tremendous changes in the development of all areas of life. However, the teaching and learning of music and musical instruments is a huge challenge for teachers and students in remote areas, and this artistic discipline is extremely disadvantageous to teachers and students in remote areas. This study uses the multi-information classification (MSC) algorithm of artificial intelligence technology to study the piano teaching mode in remote areas. This algorithm will be spread through the wireless network, it can effectively spread the teaching knowledge of a piano. This teaching mode can efficiently classify the piano information data. The research results show that this piano teaching mode is beneficial to teachers and students in remote areas. Li [19] found that deep learning technology and artificial intelligence technology will provide more technical support for the improvement of modern piano teaching quality. It studies note detection methods for piano teaching using convolutional neural networks. The input to the CNN neural network is the music signal for piano teaching. The results of the study show that the intelligent piano teaching method can improve students' interest in learning piano. This method will improve children's interest and efficiency in learning piano. Huang and Ding [20] proposed a back-propagation neural network piano teaching evaluation system. This can solve the problem that traditional note recognition methods are easily affected by noise. It used the optimized BPNN algorithm to accurately measure the pitch of the note and the time value of the note. The research results show that this mode can effectively correct the pitch problem in the piano teaching process, which is 5.21% higher than the traditional method. The optimized BPNN algorithm can significantly improve the error correction accuracy of the player's note and pitch, which is beneficial to improve the teaching quality of piano teaching. Guo et al. [21] used wireless network technology to realize the intelligent piano teaching mode. It uses the regression fitting algorithm and the Relief F weight algorithm to extract the characteristics of the piano teaching process. The results of the study found that the use of intelligent algorithms can quantitatively analyze the relevant characteristics of the piano teaching process. This is conducive to the reform of the piano teaching mode. Through the above literature review, it can be found that artificial intelligence technology has been applied in the process of piano teaching, and it is mainly used to identify signal features, such as notes. This study mainly uses CNN to identify the features in the teaching process of piano videos and images. This is an innovative study. Most of the studies mainly use neural network methods to study the timbre and note characteristics of piano teaching. However, this study utilizes the CNN method to perform feature extraction on videos and images of piano teaching.

3. Piano Video and Image Teaching Program, Design, and Algorithm Introduction

3.1. The Significance of the CNN Method for Piano Teaching. In order to solve the shortcomings of the traditional piano teaching mode, this research introduces video and image methods into the piano teaching classroom, which realizes a new piano teaching scheme. The CNN method will assist in the recognition of video and image features. There are huge data features in the videos and images in the piano teaching plan, and these features have relatively large correlation with the musical features of the piano and the behavioral features of players. It is difficult to teach these characteristics only by relying on teachers' professional knowledge and teaching experience. CNN methods can efficiently and accurately identify and extract these features. Then, the CNN method can also realize the mapping of piano teaching features to video and image information. These relevant information can be transmitted to piano learners through computer-aided systems. If the CNN method is not used to extract piano-related features in the piano teaching classroom plan, this will limit the display of piano features. Some music or player characteristics cannot be visually displayed through video and image methods. In short, the CNN method is more important for the piano teaching system, especially it involves the relevant information of the videos and images of the piano.

3.2. The Design and CNN of Piano Teaching Scheme Integrating Videos and Images. The goal of this research is to integrate video and image methods into a piano teaching method, and then it utilizes a CNN method to identify the relevant features of piano videos and images. The identified features will be visually displayed to the students or teachers through the computer-aided system. This will improve the learning interest and learning efficiency of piano learners. Figure 1 shows the piano teaching scheme and workflow that integrates videos and images. First, the features of the piano videos and images are processed into data between 0 and 255. These data will then be normalized to be between 0 and 1. It needs to feed piano-related video and image data into the CNN algorithm in the form of an input layer. However, these data need to be classified by a classification algorithm before being input into CNN, which is beneficial to improve the accuracy of prediction. The classification algorithm will perform effective classification processing according to set classification criteria. This research needs to map the feature relationships between piano videos, images and piano music features, player behavior features, and piano connotations. After these three features are processed, it will be visually displayed to teachers and students through a computer-aided system. Although this piano teaching method seems to be more complicated. However, once this teaching scheme is trained, it only takes a few seconds to achieve the mapping of relevant features. In an actual piano teaching session, this only takes a few seconds. This is also an efficient and accurate

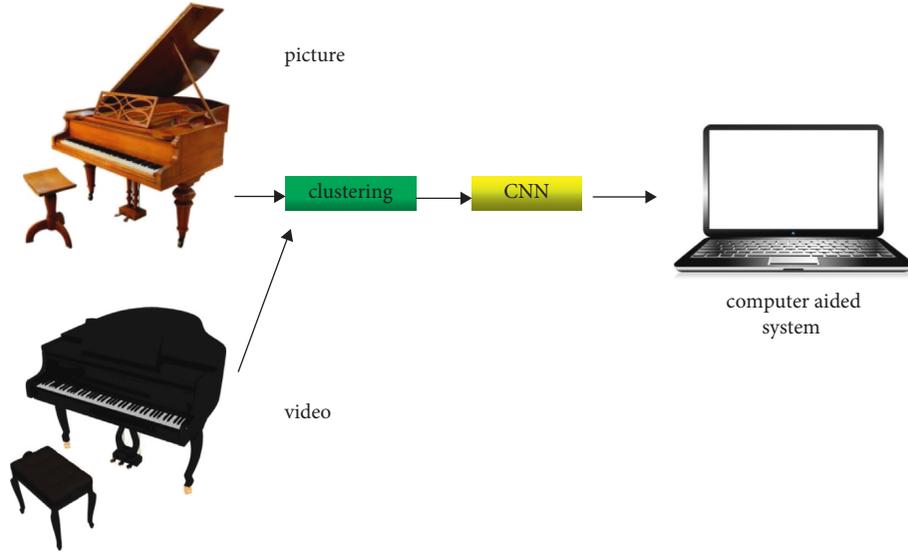

FIGURE 1: System design of piano teaching scheme integrating videos and images.

way from a time perspective. The computer-aided system will display the piano teaching features extracted by CNN to the students or teachers. Videos or images of piano teaching are also displayed to students or teachers through computer-aided systems.

The CNN method has great advantages in feature extraction and data mapping. It is also good at processing huge amounts of data and features. There is also a huge amount of data and associated features in the videos and images in piano teaching classes. These advantages of the CNN method are precisely to deal with the characteristics in piano teaching. Figure 2 shows the workflow of the CNN method. The CNN method has certain similarities with the fully connected neural network, which also utilizes the mechanism of forward propagation and back propagation. At the same time, its gradient descent is also carried out by means of derivation. However, it is more efficient than the fully connected neural network because it has a certain weight sharing mechanism. The weights of each layer are not connected to each other, it is selectively connected, which reduces the amount of parameter calculation. CNN can generally extract features with strong correlations. It will selectively filter features with weak correlation. CNN generally consists of multiple layers of convolutional layers, pooling layers, and activation functions. The process of feature filtering in CNN is carried out through the filters and strides of the convolutional layers. The output layer of CNN will perform error operation with the label data of piano teaching. The gradient descent method will calculate derivation based on the error between the predicted value and the actual value of the piano teaching. The step size used in this study is 1, and the number of filters is set to 64, which is a relatively common numerical range. Meanwhile, in order to fully exploit the features of piano videos and images, the learning rate is set to 0.0001.

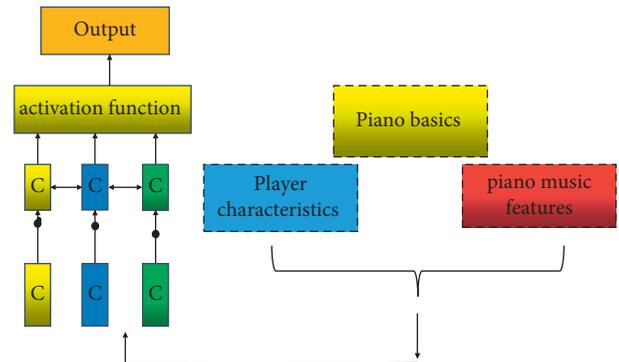

FIGURE 2: The workflow of the CNN method.

The difference between CNN and the fully connected neural network mainly reflects the existence of more hyperparameters, which are the source of feature selection and feature filtering. Different hyperparameter combinations will affect the accuracy and convergence of calculation results. Equation (1) shows the computational relationship that is satisfied between the hyperparameters. s represents the step size of feature selection. p represents the padding step size of the matrix. k represents the number of CNN filters.

$$w' = \frac{(w + 2p - k)}{s} + 1. \quad (1)$$

CNN is similar to other neural networks. It also has forward propagation mechanism and back propagation mechanism. These weights and biases are derived using automatic differentiation techniques. Equations (2) and (3) show the unfolded shape of weight derivative calculation at each layer. This is also the expanded form of loss function calculation.

$$E = \frac{1}{2} \sum_{k=1}^m [d_k - f(\text{net}w_k)]^2 \quad (2)$$

$$= \frac{1}{2} \sum_{k=1}^m \left[d_k - f \left(\sum_{j=0}^n \omega_{jk} y_j \right) \right]^2,$$

$$E = \frac{1}{2} \sum_{k=1}^m [d_k - f(\text{net}w_k)]^2 \quad (3)$$

$$= \frac{1}{2} \sum_{k=1}^m \left[d_k - f \left(\sum_{j=0}^n \omega_{jk} y_j \right) \right]^2$$

$$= \frac{1}{2} \sum_{k=1}^m \left[d_k - f \left[\left(\sum_{j=0}^n \omega_{jk} f \left(\sum_{i=0}^q u_{ij} \chi_i \right) \right) \right] \right]^2.$$

The derivation operation is a method to find optimal weights and optimal biases. Equations (4) and (5) show the calculation methods for the derivation of weights and biases. It can be seen that the gradient descent method is used here. Equation (6) shows the computation between each convolutional layer.

$$\Delta u_{ij} = -\eta \frac{\partial E \partial}{\partial u_{ij}}, \quad (4)$$

$$\Delta \omega_{ji} = -\eta \frac{\partial E}{\partial \omega_{ji}}, \quad (5)$$

$$\frac{\partial E}{\partial k_{ij}^{\zeta}} = \sum_{u,v} (\delta_j^{\zeta})_{uv} (p_i^{\zeta-1})_{uv}. \quad (6)$$

3.3. Introduction to Piano Feature Data Classification Algorithm. The video and image data in piano teaching differ greatly in magnitude and numerical size. If these data are fed into the CNN network layer together, this will lead to the problem of uneven weight distribution. The uneven distribution of weights leads to large errors in the results. Therefore, before feeding the video and image data of piano teaching into CNN, this data needs to be classified. The purpose of classification processing is to effectively classify different features. This allows the same type of features to have the same data distribution. Figure 3 shows the computational flow of the classification algorithm. It can be seen from Figure 3 that the classification algorithm can classify data with the same distribution characteristics together, and it can also separate different characteristics. In this study, the classification method of clustering was selected, which grouped the data of the same category into one category and processed different data separately. This classification method is processed according to the distance of data features.

When processing the data of piano teaching videos and images, the clustering method is mainly based on the distance of the data. Equation (7) shows the expression for the Euclidean distance, one of the commonly used distance

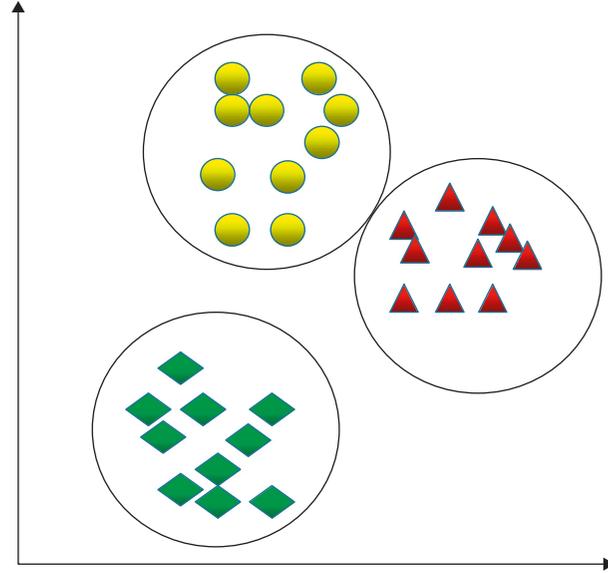

FIGURE 3: Clustering methods classification methods and principles.

measurements. Euclidean distance measures the distance between two points.

$$\text{dict}_{ed} = \sum_{k=1}^m (x_{ik} - x_{jk})^2. \quad (7)$$

Equation (8) shows the Chebyshev distance measurement method. It measures the difference in distance between the coordinate values of points in space. Equation (9) shows the Minkowski's distance measurement method. This is also a variant of the Euclidean and Chebyshev distances. There is a p -value here, and when p takes different values, it represents a different distance measurement method.

$$\text{dict}_{cd} = \lim_{t \rightarrow \infty} \left(\sum_{k=1}^m |x_{jk} - y_{ik}|^t \right)^{1/t}, \quad (8)$$

$$\text{dict}_{\min d} = \sqrt[p]{\sum_{k=1}^m |x_{ik} - y_{jk}|^p}. \quad (9)$$

Equation (10) shows the evaluation index of the external performance of classification. Among them, a , b , c , d represent different features of piano instruction videos and images. Equation (11) shows the Rand statistic, where P is the precision and R is the recall.

$$R = \frac{a + d}{a + b + c + d} \quad (10)$$

$$F = \frac{(\beta^2 + 1)PR}{\beta^2 P + R}. \quad (11)$$

4. Result Analysis and Discussion

4.1. Classification and Prediction Error Analysis of Piano Videos and Images. The goal of this research is to use the

classification algorithm and the CNN algorithm to study the video and image features in the piano teaching process. In this study, video and image information of piano art courses in many colleges and universities in Hangzhou was selected as the research dataset. It will be divided into training set and test set. The test set is also a dataset derived from a college piano art course. This will ensure the reliability of algorithm verification.

In the piano teaching system integrating videos and images, the first step is to use the clustering algorithm to classify the related features of videos and images. The classification accuracy will affect the prediction accuracy of the CNN algorithm for videos and images in piano teaching. Figure 4 shows the classification errors of three features for videos and images of pianos. It can be seen from Figure 4 that the classification errors of the three related features of the piano are all within an acceptable range, and all the classification errors are within 2%. This is acceptable enough for teaching content with videos and images of the piano. The largest classification error is only 1.89%, and this part of the error mainly comes from the classification of the characteristics of piano players. The smallest classification error is only 1.23%, and this part of the error mainly comes from the classification of piano music features. This is mainly because there is a relatively large mutation in the characteristics of piano players. For the classification of the piano music feature method, this part of the error is only 1.52%. The classification errors of these three main features are all within 2%. This is a reliable error for both teachers and students of piano teaching.

After the three features of the piano videos and images are effectively classified, the CNN algorithm is required to predict the three features. This is a critical step for the piano teaching mode that combines videos and images. The video and image features of the piano predicted by CNN will be intuitively displayed to teachers and piano learners. The accuracy of the CNN algorithm in the piano teaching mode is also the key to the success of the fusion video and image piano teaching system. Figure 5 shows the prediction errors for three video and image features in the piano teaching mode. Overall, the CNN method has high feasibility and accuracy in predicting the characteristics of piano videos and images. This has high credibility for both teachers and students of piano lessons. All forecast errors are within 2.5%. The largest prediction error is only 2.23%, which mainly comes from the prediction of the characteristics of piano players. The characteristics of the pianist have a great relationship with the scene of the piano performance, and there is a great mutation in this part of characteristics. It is not just about the basics of the piano itself, so this part of the error is the biggest. Although this part of the error is the largest, it is also within a reasonable and acceptable range. The smallest error is also from the characteristics of piano music, and this part of the error is only 1.54%. The characteristics of piano music are closely related to the notes and spectrum of the piano. However, the mutation of this part of the characteristics is relatively small. This is because knowledge of the musical aspects of the piano is also less abrupt. The prediction error of CNN mainly comes from the

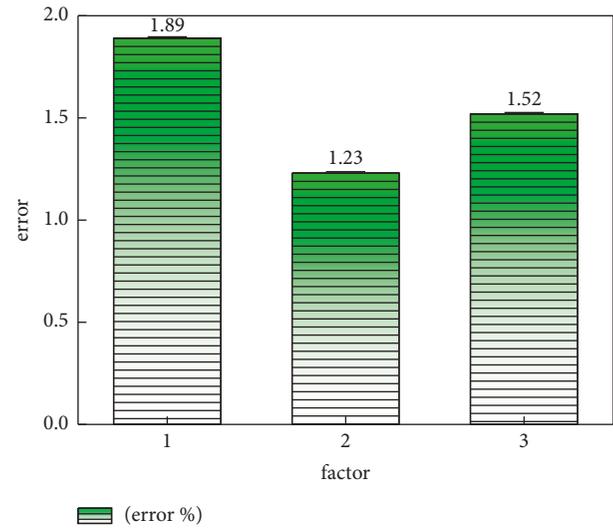

FIGURE 4: The classification errors of piano videos and images using clustering methods.

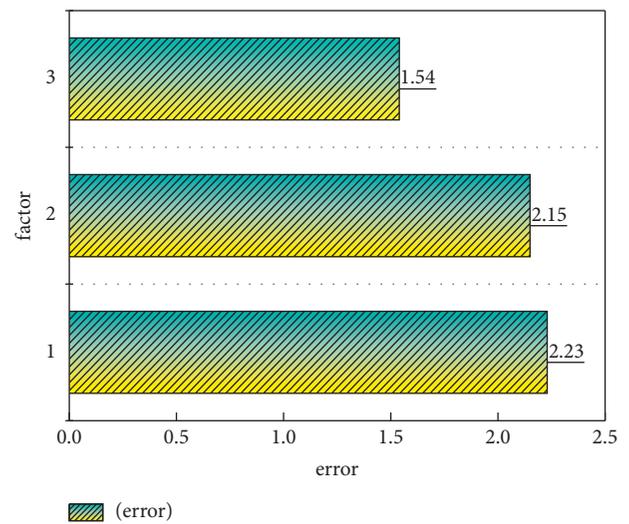

FIGURE 5: Three feature prediction errors of piano teaching mode using the CNN method.

error of the model and the error of the data. The reason for the relatively large error in this part is also that there is a certain cumulative error in the data when using the clustering method. In general, the CNN method can better complete the video and image prediction tasks in the piano teaching course.

4.2. Analysis of Three Characteristics of Piano Teaching Videos and Images. In this section, we discuss the piano music features, player behavior features, and basic piano features involved in videos and images in piano teaching. We selected 30 different sets of data to verify the accuracy and feasibility of CNN in predicting three features of piano teaching fusing videos and images. Figure 6 shows the distribution of predicted and actual values of musical features for piano teaching. In Figure 6, the green area represents the error of

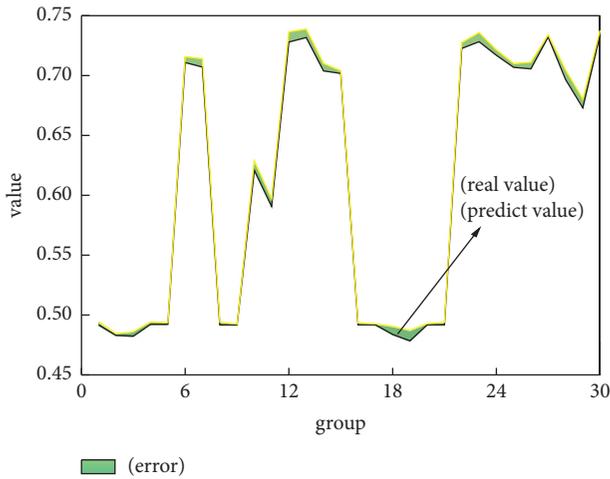

FIGURE 6: The predictive distribution of musical features in piano teaching.

the predicted value of music features in piano teaching. The black lines represent the predicted values of the musical features of piano teaching. The yellow lines represent actual piano music characteristic values. In general, CNN can better capture the peaks and trends between different sets of data. Although there are many peaks and troughs in different groups of piano music characteristics, CNN can still capture the characteristics of these data as well. The green area represents the error between the predicted value and the actual value. It can be seen that the distribution of prediction errors for the musical characteristics of the piano is relatively small, and these prediction errors are relatively small. This further illustrates the feasibility and accuracy of CNN in predicting the characteristics of piano teaching music.

The linear correlation coefficient can further demonstrate the accuracy of CNN in predicting the characteristics of piano teaching music. If the linear correlation coefficient is closer to 1, it means that CNN has good performance in predicting the musical features of piano teaching. If the linear correlation coefficient is closer to both sides of the function $y = x$, it means that the linear correlation coefficient is closer to 1. Figure 7 shows the linear correlation coefficient distribution of the musical features of the piano teaching mode fused with videos and images. In general, all data points are relatively close to the linear function $y = x$, which means that the linear correlation coefficient exceeds 0.95. It can also indicate that the predicted value of the musical characteristics of piano teaching is relatively close to the actual value. In other words, the CNN method has been shown to be accurate in predicting the musical features of piano teaching fusing videos and images. This is an algorithm and the teaching system that students or teachers can trust.

The player's behavioral characteristics are also an important indicator in piano teaching. The player's behavioral characteristics can only be shown in the form of videos. It is difficult for traditional teaching models to capture the behavioral characteristics of performers. This shows that the piano teaching mode integrating videos and images designed

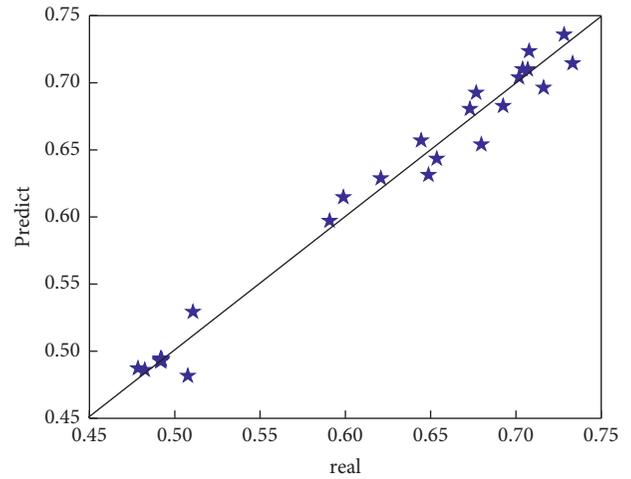

FIGURE 7: The correlation distribution of music feature prediction in piano teaching.

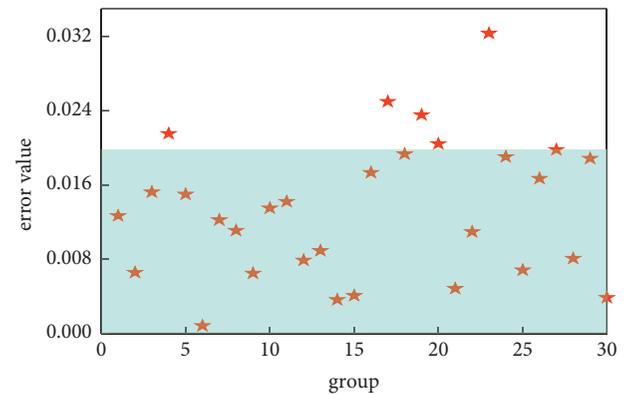

FIGURE 8: Scatter plot of player characteristics distribution in piano teaching.

in this study is innovative to a certain extent. Figure 8 shows the distribution of the prediction errors of the player's behavioral characteristics in the piano teaching mode. In Figure 8, the blue area represents data with prediction errors within 2%, a range where prediction effects can be distinguished. Overall, CNNs also have high reliability in predicting player behavior. Although the player's behavior information in the piano teaching mode has great volatility, it also has a great correlation with the piano performance scene. However, CNN has high reliability in predicting player behavior information for piano teaching. Most forecast errors are distributed within 2%. Only a small number of prediction errors exceed 3%. Basic knowledge of piano is also an important part of piano teaching. Figure 9 shows the distribution box plot of predicted and actual values for the basic knowledge of piano teaching. For the box plot, if the size of the box plot of the predicted value and the distribution of values are consistent with actual values, this indicates that the mode has a strong predictive ability. In general, the predicted value is basically the same as the actual value of the box, whether it is the size of the box or the distribution of the data. Basic knowledge of piano is

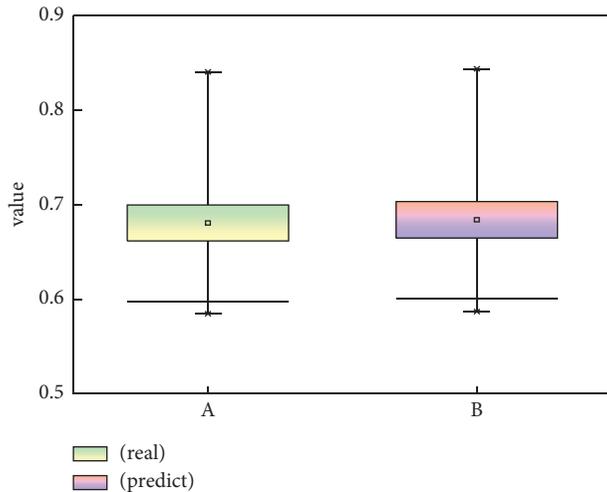

FIGURE 9: Predicted box distribution for the basics of piano teaching.

relatively easy to predict compared to the other two characteristics of piano teaching. CNN has basically reached a trustworthy level in predicting the basic knowledge of piano teaching.

5. Conclusion

With the advancement of technology and the improvement of living standards, the traditional teaching mode has limited the development of piano teaching. Piano teaching is a mode that is different from traditional subjects. It requires learners to experience the artistic information brought by piano. The player's on-the-spot performance will also have a certain impact on piano teaching.

This research introduces the teaching mode of videos and images into the teaching of piano, and it also uses CNN to predict the characteristics of piano music, player's behavior, and basic knowledge of piano in the piano teaching mode. Before using CNN prediction, this study also uses clustering methods to achieve the classification of piano video and image data. In terms of clustering, it shows certain feasibility in classifying relevant data of videos and images of piano teaching. The largest classification error is only 1.89%, and this part of the error comes from the relevant characteristic data of piano players. CNN also shows high accuracy in predicting the piano teaching features that fuse videos and images. The highest prediction error is only 2.23%, and this part of the prediction error also comes from the behavior characteristics of piano players. However, this part of the linear correlation coefficient exceeds 0.95. Overall, the design of this research is that the piano teaching mode that integrates videos and images will improve students' learning interest and efficiency, and CNN and clustering methods also show high accuracy in processing related features of piano videos and images.

As the most important strategic resource of enterprises, big data has become the basic background of business model innovation. From the perspective of psychological contract, this paper discusses the mechanism of psychological contract in customer value proposition driven business model innovation and puts forward four research hypotheses. This paper adopts the confirmatory factor analysis method of structural equation to verify these four hypotheses. It is concluded that there is a significant positive relationship between customer value proposition and psychological contract; there is a significant positive correlation between psychological contract and business model innovation; and psychological contract has intermediary effect between value proposition and business model innovation. Furthermore, value proposition has a significant positive correlation with business model innovation, which has not been verified.

1. Introduction

Emerging information technologies and their applications have brought rapid growth in the amount of data, and the era of “big data” has come [1]. Big data is deeply affecting our life, work, and thinking [2, 3]. Big data has become the most important strategic resource for enterprises. Enterprises improve their competitiveness through the acquisition, cleaning, management, and processing of big data. Naturally, big data has also become an important driving force for business model innovation. Big data is affecting the business ecology of enterprises in various ways. It has become the basic background of business model innovation [4].

Big data represents a new way of life, which changes the demand content, demand structure, and demand mode of consumers [5–7]. Big data provides a new resource and capability and provides a new foundation and path for enterprises to discover value, create value, and solve problems. Big data is a new technology that provides basic

conditions for the operation of the whole society. Big data is a way of thinking, which leads to the reconstruction of traditional concepts such as resources, value, structure, relationship, and boundary. Big data has the potential to be infinitely close to consumers and can provide accurate value proposition for enterprises [3, 8–10]. The application of big data technology helps us understand the real needs of consumers, accurately segment consumers, and then provide real-time and accurate products. As basic technical conditions and tools, big data resources have the energy to release and amplify the value of other resources. The key business and process innovation based on big data is the big data of enterprise business activities. The whole business process can be reengineered based on big data facilities and technology and data information flow. Big data is changing the resource environment, technology environment, and demand environment on which enterprises rely. Enterprises need to rethink the issues involved in the business model, such as who creates value, what value to be created, how to create value, and how to realize value.

In the era of big data, business enterprises have greatly increased their dependence on data. On the one hand, this will make the business model innovation based on data more convenient. On the other hand, this will also stifle the potential business model innovation without data support and greatly reduce the business model innovation not based on data. It can be seen that big data will bring changes in management rules and business model, thus bringing competitive advantages to enterprises. Big data has the potential to creatively destroy the business model [11].

Big data has become one of the driving forces of enterprise business model innovation. At the enterprise level, big data is used in many aspects of the business model, including customer value proposition innovation, key business and process innovation, revenue model innovation, external relationship network, and value network reconstruction [4]. Big data has the potential of creative destruction and promotes the transformation of the constituent elements and structure of the business model [12]. It is common to analyze the business model from the perspective of constituent elements and their relationship, which is also recognized by most researchers. Osterwalder et al. [13] proposed that enterprises can carry out business model innovation by changing the constituent elements in the business model system. Lindgadt et al. [14] proposed that there are two top-level elements of business model, namely, value proposition and operation mode, and believed that enterprises can choose one or several sub-elements to carry out innovation activities. Value proposition is an important component of business model and the starting point of business model innovation. It runs through the whole process of business model innovation and plays an important guiding role. It is very important to find a unique customer value proposition. In order to provide and realize customer value, enterprises must produce products or services with the help of corresponding resource capabilities and value networks, then transfer them to target customers, and obtain certain benefits. As Jiang and Liu [15] pointed out, business model includes value proposition, value creation, and value acquisition, which is the general framework of business model. This framework is systematic and dynamic.

In the context of big data, with the help of big data technology, enterprises can have in-depth insight into customer needs, timely respond to changes in customer needs, adjust the positioning of products or services, reduce transaction costs, reduce information asymmetry, enhance the emotional cognition between enterprises and customers and stakeholders, build psychological contracts, enhance trust relations, cultivate customer loyalty, and realize value creation and acquisition.

Since business model innovation is a systematic and dynamic work, it is a nonlinear process full of uncertainty from the proposition of customer value to the acquisition of customer value and enterprise value. The relationship between business model innovators, innovation teams, and business organizations; the relationship between stakeholders and business organizations; their psychological expectations and disappointments; and the relationship

between rights and obligations are also constantly adjusted with the changes of business model innovation cycle. During this period, the formation, violation, and reconstruction of psychological contract will have a lot of impact on the effectiveness of business model innovation. However, there is a lack of research in this area.

Based on the above analysis, this paper intends to explore the intermediary role of psychological contract from the perspective of the general framework of customer value proposition driven business model innovation. Theoretically, it enriches the influence mechanism of psychological contract on business model innovation. In practice, it provides a reference for enterprises to implement business model innovation against the background of big data.

2. Conceptual Background

2.1. Business Model Innovation. Most scholars agree that changing the core elements of the business model or changing the relationship between the elements can realize the innovation of the original business model. Weill and Vitale [16] put forward the concept of atomic business model and believed that changing the combination mode of atomic business model can form a new business model. Yongbo [17] believes that business model innovation is the innovation of business model constituent elements and their combination, especially the innovation of the relationship between core value elements. Value proposition model innovation, value creation model innovation, value transmission model innovation, and value network model innovation are the main aspects of business model innovation. These four aspects play a role, leading to the continuous improvement of enterprise competitive advantage. In order to seek competitive advantage and fully explore the potential value of technological innovation or nontechnical service innovation, a set of continuous and dynamic logic to better realize the value proposition of consumers can be regarded as business model innovation [18].

Based on the above analysis, this paper believes that the business model innovation follows the construction logic, and the source of innovation is the customer value proposition. By establishing relations with different stakeholders, we can reach cognitive agreement and form a psychological contract, so as to obtain resources to create, transfer, and realize value.

2.2. Value Proposition. In the Internet era, against the background of big data, the internal and external environment change too fast, and the nonlinearity, uncertainty, and difficulty of prediction are becoming more and more obvious. Enterprises should constantly put forward new value propositions, constantly reflect, constantly improve, and innovate. The more complex it is, the more it is necessary to clarify the logic of development and find the pain points of customers. Among the components of business model innovation, the core element is customer value proposition. Business model innovation is a creative activity. From conception to formation, it is a continuous trial and

error exploration process. It is also the process from putting forward customer value proposition, perfecting customer value proposition, and implementing customer value proposition to realizing customer value proposition. All ideas and actions should focus on value proposition, constantly meet customer needs, and gradually cultivate customer loyalty. Customer value proposition is the core element of business model [19], the source of business model innovation, and the main line running through business model innovation.

Especially since 2000, with the advent of the Internet era, the development environment faced by enterprises has become more complex and full of uncertainty. The linear hypothesis is not tenable, product upgrading is accelerated, information transmission is convenient, big data plays a huge role, information exchange is almost cost-free, communication between manufacturers and customers is closer, and it is more common for customers to participate in enterprise design, interaction, and innovation. Business model innovation ushered in a new scene.

The emergence of a new customer value proposition is no longer a unilateral act of enterprises. Consumers have become “producers and consumers.” Xiaomi mobile phone has created impressive performance. It is not so much product innovation as customer participation model innovation. It is the innovation of business model against the background of large data. It is a typical example of customer driven business model innovation, but also the deep participation of customers in the formation of customer value proposition, innovation of development, and perfection. Innovative customer value proposition drives the changes of other elements of the business model and changes the combination mode of the relationship between the elements of the business model. In a sense, it is an innovation in the construction of the relationship between the elements of the business model. The premise assumption of traditional value chain theory is that “industry” or “environment” factors are unchanged. However, this assumption obviously fails today. Modern business model innovation is to be good at changing value proposition, so as to reconstruct a microenvironment conducive to itself and create cross-border relationship combination [20]. Business model innovation is to reconstruct a new rule relationship [21]. The essence of business model is to continuously build a relationship combination across enterprise boundaries.

Building a new rule relationship is actually the shaping process of the new business model, which is a process of continuous trial and error, fault tolerance, and iteration. From the blueprint stage of customer value proposition to the conclusion of various cross-border relationships, it involves the cognitive problems of consumers, industries, and stakeholders, which is a process of psychological contract formation, violation, and reconstruction.

2.3. Psychological Contract. Psychological contract, which is also known as psychological contract, is a concept of social psychology. Its predecessor can be traced back to the interpersonal relationship theory in

the early 1930s. In 1960, Chris Argyris, a famous American organizational psychologist, published understanding organizational behavior, in which psychological contract was first introduced into the field of management research from the field of social psychology, and the informal expectation relationship between factory employees and foremen was expressed as psychological work contract, which was considered to be the pioneer of psychological contract research in the field of management [22].

Robinson et al. [23] believe that psychological contract is the understanding of mutual obligations between employers and employees in the context of employment relationship, that is, employees’ perception of the exchange relationship between explicit and implicit employee contributions and organizational incentives.

Early scholars tend to regard psychological contract as an invisible contract between organizations and individuals. There are two schools: unilateral psychological contract school and bilateral psychological contract school. The unilateral psychological contract school began in the 1980s, and its research focus is the individual level of the formation of psychological contract. Scholars who hold this view believe that psychological contract is essentially a subjective belief of reciprocal exchange and connection between individuals and organizations. This belief is based on the subjective understanding of commitment, but it is not necessarily realized by the organization or its agents [24].

There are many psychological contract schools on both sides: One is to define psychological contract as the sum of implicit and unwritten mutual expectations existing in the relationship between employees and employers. One view is that the cooperation mechanism exists between personal dedication and the acquisition of organizational desire. However, in essence, it is the mutual expectation relationship between employers and employees. It is the subjective feelings of both parties on each other’s responsibilities and obligations, mainly including two levels: one is the employees’ perception of mutual responsibility; the other is the perception of mutual responsibility, which is also known as the psychological contract school.

This paper holds that psychological contract is the perception of mutual responsibility between the organization and employees, including the stakeholders of employees and the organization. This is because, in the context of big data, the information asymmetry has been reduced unprecedentedly, the dynamic change process between psychological expectation and satisfaction will be more transparent, and the two-way nature of rights, responsibilities, and interests will be more obvious. Secondly, in the Internet era, the boundary of enterprises is blurred, the scope of organizations and employees participating in innovation activities is expanded, and even the organization is only a natural person and employees are not only employees of incumbent enterprises. As long as they contribute to innovation activities, they should be considered.

Li et al. [25] believe that psychological contract is mainly composed of three dimensions: transactional psychological contract, relational psychological contract, and management psychological contract.

Referring to the research of Robinson & Morrison, this paper divides psychological contract into three types: transaction contract, development contract, and relationship contract and discusses its relationship with business model innovation based on cognitive theory.

The formation of business model is a process of trial and error, and it is also a process of rule relationship. In this process, the change of the psychological contract of the business model innovation team is also dynamic, which needs to be transformed through formation, deconstruction, and reconstruction. In the initial stage of team formation there is mistrust and uncertainty between the members and the team. The psychological contract of cooperation tends to be short-term and limited one. At this time, the model of psychological contract is economical. With the increase of cooperation time and cooperation opportunities among members of the team members expect to have a good space for their own development. The team also hopes to obtain better output benefits with less human and material resources. Therefore, both the team and members have the motivation to promote the transformation of psychological contract to a developmental model. On this basis, the results of win-win cooperation will strengthen this sense of gain. This situation will gradually change to an open and collaborative mode, the organizational relationship will be more harmonious, the employees' sense of trust in the organization will be enhanced, and the team will have good output benefits. Employees also get a good space for their own development. At this time, a relatively stable relational psychological contract will be formed.

3. Research Hypothesis

Customer value proposition is a clear statement made by the enterprise on who to transfer benefits and what benefits to transfer [26]. Customer value proposition has strong trend and guidance, plays a good role in promoting the development of business model, and is the source of all business model innovation. The value orientation, value creation, and value acquisition in the value chain are realized through the value proposition of customers. For the characteristics of business model, it is an outward looking and creative exploration process, and all designs are based on customer value proposition. Johnson [27] pointed out that enterprises help target customers complete important tasks by providing a product or a service to meet their needs or solve problems. Target customers, supplies, and tasks to be completed are the three elements of value proposition. This concept emphasizes paying attention to the needs of target customers and the problem-solving degree of target customers, so as to provide products or services based on this. It is also the connotation of providing customers with value or service portfolio in the business model. Customer value proposition is the basis and source, the most active factor, and the soul of business model innovation [27, 28]. Reasonable value proposition is the premise of promoting business model innovation and creating value, which is the key for enterprises to obtaining competitiveness.

Based on the above analysis, this paper puts forward the first hypothesis.

Hypothesis 1. There is a significant positive correlation between customer value proposition and business model innovation.

Customer value proposition is the basis for customers to realize the delivered value and the starting point of enterprises' commitment to customers. Kotler [29] expounded customer value from the perspective of customer delivered value and believed that customer delivered value is the difference between total customer value and total customer cost. Gale Bradley [30] believes that customer value is the relative perceived quality of customers after the price of a product changes in the market. Holbrook [31] believes that customer value is created by goods through the process of customer experience. Whether the products or services provided by enterprises meet their needs or not, customers should perceive and evaluate the degree of satisfaction they have obtained. After comparing the expectation of the products provided by the manufacturer with the real gain, trust and satisfaction are generated, forming a psychological contract. It can be seen that customer value proposition is the basis for the formation of psychological contract between manufacturers and customers, and there is a positive correlation between them. Accordingly, this paper puts forward Hypothesis 2.

Hypothesis 2. There is a significant positive relationship between customer value proposition and psychological contract.

Most scholars believe that business model can be regarded as a structural template [32]. It can even be regarded as a configuration of measurement relationship [33]. Osterwalder [19] expressed the relationship in the business model as an abstract cooperative relationship between enterprises and stakeholders. Zott et al. [32] pointed out that the relationship between focus enterprises and stakeholders plays an important role in business model value creation. Due to the heterogeneity and dynamics of stakeholder relations and the diversity of value creation structure of business model, it will lead to the differentiation of value creation process and mechanism and the uncertainty of value creation results. However, in essence, the stakeholder relationship in the business model is also the subjective perception and comprehensive evaluation of stakeholders. Starting from the basic requirement of depicting the key and core characteristics of subjective perception, satisfaction, trust, and commitment can still be used as the basic dimensions of psychological contract between stakeholders [34]. Accordingly, this paper puts forward Hypothesis 3.

Hypothesis 3. There is a significant positive correlation between psychological contract and business model innovation.

The business model gradually realizes its logic of discovering, creating, transmitting, and obtaining value. In the logic of value creation, it involves the key business processes

of enterprises and the correlation mechanism between processes, including the operation mode of enterprises, consumers, upstream suppliers, potential entrants, and substitutes to create value in the competition. In the Internet era, new elements of business model are gradually taking shape. With the help of big data technology, the interaction between people becomes closer, and knowledge spillover and emotional communication become more frequent. The exchange of information between people and between people and organizations makes it easier to form psychological contracts, which promotes the continuous innovation of business models and the acceleration of the replacement of business models. This is also conducive to the effective coordination of value creation and business resources [32].

In this process of value creation, the psychological contract relationship between the individual members and the team in the organization implementing business model innovation reflects the unwritten mutual expectations between individuals and organizations and reflects the commitment and reciprocity of rights and obligations. If the content of organizational commitments and actions made by incumbent enterprises can stimulate the innovation spirit and team cohesion, the psychological contract relationship will be formed. Otherwise, there will be violation of the psychological contract relationship, degradation of innovation spirit, and lax team cohesion, which will inevitably affect the effectiveness of business model innovation. To stimulate the effectiveness of psychological contract in the context of big data, we should pay attention to the collective innovation, cognitive sharing, risk sharing, and cultivation of cooperative and enterprising awareness of business model innovation. Accordingly, this paper puts forward Hypothesis 4.

Hypothesis 4. Psychological contract has intermediary effect between value proposition and business model innovation.

4. Research Methods

4.1. Structural Equation Research Method. Social phenomena are complex, not as simple as natural phenomena. People and people, people and things, things and things are complex. Compared with general regression models, structural equation models are better for describing or fitting complex relationships and can be closer to objective reality. Structural equation model is mainly used to analyze and study the structural relationship between potential variables. Because potential variables cannot be measured directly, some measurable indicators are needed to reflect potential variables. These variables can be expressed in linear equations. This linear equation system is called structural equation modeling (SEM). SEM is suitable for the analysis of large samples. Generally speaking, the number of samples shall not be less than 100; otherwise, the software analysis is unstable.

SEM deals with the comparison of the overall model, so the indexes referred to mainly consider not a single parameter, but the coefficient of integration. At this time,

whether individual indexes have specific statistical significance is not the focus of SEM analysis [35].

4.2. Questionnaire Design and Reliability Analysis

4.2.1. Questionnaire Design. Due to the fierce competition among enterprises, most enterprises pay attention to the confidentiality of their enterprise management information, especially the technological innovation and business know-how. It is difficult to conduct quantitative analysis in terms of business decision-making, partners, cooperation effect, and social benefits. Therefore, Likert quantitative scoring is often adopted in the study of enterprise business model. Ketokivi and Schroeder's research found that "although random errors and systematic deviations will cause some variation of measurement items, the perceived measurement of performance can still meet the requirements of reliability and validity." Whether from theoretical circles or business circles, people recognize the credibility of insiders' perception of the organization. Even without consulting financial data, they can have a basic judgment or even profound insight into the operation of the organization.

Based on the above considerations, the questionnaire is designed by Likert quantitative scoring. In order to design a high-quality questionnaire, the first draft of the questionnaire was completed on the basis of a large number of relevant references. After the first draft is completed, I invited colleagues and classmates with vice senior titles and doctorate degrees to help review and put forward suggestions. In addition, I also widely solicited the opinions of middle and senior managers of enterprises with whom I have contacts. In short, the questionnaire design widely mobilized contacts, solicited the opinions of experts and enterprise managers, and generated an open discussion at an academic seminar. Finally, these valuable opinions were classified and analyzed as an important reference for revision. The final questionnaire is targeted, readable, indirect, logical, and operable. In order to make the questionnaire conform to the reality and the purpose of the survey, at the beginning of the survey, the research team also interacted and modified based on the interview and the on-the-spot answers. Once there are questions about the meaning and measurement understanding, they will have in-depth communication and discuss how to improve the presentation together, so as to ensure the accuracy and clarity of the questionnaire. The questionnaire has been implemented for one year. The research team distributed it purposefully, even taking advantage of various opportunities such as business trips and family visits to distribute questionnaires. Through various channels such as training lectures for middle and senior managers of the enterprise, various seminars on economic management, on-site distribution, and interviews in the enterprise, a total of 160 questionnaires were distributed, and 155 were recovered, with a recovery rate of 96%. Excluding incomplete answers and similar and other unreliable questionnaires, the number of effective questionnaires was 150.

The final scale consists of 22 questions. Each option has five numbers: 1, 2, 3, 4, and 5. 1 means "very low," 2 means

TABLE 1: Corresponding table of model variables.

Latent variable	Connotation and item design basis	Measurable variable
Customer value proposition	Customer value proposition is to clearly state the interest combination to be provided to stakeholders, which should be attractive, differentiated, superior, and difficult for competitors to imitate [27, 36]	Q1 What is the social awareness of your products (services)?
		Q2 What is the degree of uniqueness of your products (services) relative to your competitors?
		Q3 Compared with peers and competitors, do you think your business model is different?
Psychological contract	Psychological contract is formed between employees and organizations as a variety of beliefs about each other's responsibilities and obligations [37]; the success of an enterprise requires teamwork [38]; consumer psychological contract is essentially a relationship of rights and obligations between enterprises and customers [39]	Q4 How satisfied are the partners with your business model?
		Q5 What is the degree of win-win benefits among the main partners of your business model?
		Q6 How stable is the relationship between your business model partners?
		Q7 How much knowledge is shared among your business model partners?
		Q8 How supportive are your business model partners?
Business model innovation	Whether it is a good business model depends on whether its performance exceeds the average level of the industry and whether it is sustainable, profitable, and expandable [40, 41]	Q9 What is the ability of your business model to attract key resources?
		Q10 How do you recognize the current market performance level of the enterprise?
		Q11 How confident are you that the current business model will shape the market performance of the enterprise in the next three years?
		Q12 How attractive is your business model to potential participants?

TABLE 2: Reliability test of latent variables.

Latent variable	Number of measurable variables	Cronbach's alpha
Customer value proposition	3	0.674
Psychological contract	5	0.884
Business model innovation	4	0.769
Total amount	12	0.916

“low,” 3 means “general,” 4 means “high,” and 5 means “very high.” The higher the score, the higher the recognition of the respondent for this option.

4.2.2. Setting of Latent and Measurable Variables of the Structural Equation Model (Table 1).

4.2.3. *Reliability Analysis.* Reliability is the degree of consistency or stability of measured data. Using SPSS version 22, Cronbach's test is carried out, and the coefficients obtained are shown in Table 2.

Generally speaking, the consistency of items is related to the measurement content. The larger the Cronbach α coefficient, the stronger the internal consistency. Previous studies have suggested that if Cronbach's α coefficient is greater than 0.7, it can be considered that the consistency between items is good.

Cronbach's coefficient value of Q1–Q3 items measuring customer value proposition in this study is 0.674, slightly lower than 0.7, and the values of the other items are more than 0.7, indicating that the corresponding items have high internal consistency. The overall Cronbach α coefficient value for the 12 items is 0.916, which has high consistency.

4.2.4. *Model Design.* The structural equation model shows [42–44] the standardized model (as shown in Figure 1). See Table 3 for the estimation results and test of business model innovation parameters by psychological contract, and Table 4 for the estimation results of standardization coefficient.

It can be seen from Table 3 that the CR values of all factor loads are much greater than 2. The probability that the parameters in the right column may be 0 P. Three asterisks, , indicate that the probability of 0 is less than 0.01. Therefore, all load coefficients are significantly nonzero at the significance level of 0.01. As can be seen from Table 4, the CR values of all variances are much greater than 2, so all variances are greater than 0.01 at the significance level of 0.01. It can be seen that the model estimation effect of psychological contract on the mechanism of business model innovation is good except BMI<---CVP.

4.2.5. *Model Matching Analysis.* It can be seen from Table 5 that the indexes meet the requirements when rounded, and the model fits well, indicating that the data matches the designed model. There is a significant positive correlation between value proposition and business model innovation, and Hypothesis 1 has not been verified.

TABLE 5: Fitting index.

Index name		Evaluation criterion	Index of this model
Absolute fitting index	CMIN/DF	<3	1.993
	GFI	>0.9	0.893
	RMR	<0.05	0.043
	RMSEA	<0.08	0.082
Relative fitting index	NFI	>0.9	0.892
	TLI	>0.9	0.925
	CFI	>0.9	0.942
Information index	AIC	The smaller, the better	155.644
	CAIC	The smaller, the better	155.644

TABLE 6: Standardized direct effects.

	Customer value proposition	Psychological contract	Business model innovation
Psychological contract	0.885	0.000	0.000
Business model innovation	0.182	0.784	0.000

Business model innovation \leftarrow value proposition, $P = 0.472 > 0.05$.

Hypotheses 2 and 3 are verified. There is a significant positive relationship between customer value proposition and psychological contract. There is also a significant positive correlation between psychological contract and business model innovation.

The following is to analyze the intermediary role of psychological contract in customer value proposition and promoting business model innovation (see Table 6). The total utility is $0.182 + 0.885 * 0.784 = 0.876$. The intermediary effect is $0.885 * 0.784 = 0.694$. The proportion of intermediary utility in the total utility is $0.694/0.876 = 0.79$.

It can be seen that psychological contract plays a relatively large intermediary role in customer value proposition and promoting business model innovation, accounting for 79%. Hypothesis 4 is verified.

5. Conclusion and Discussion

Only three latent variables are selected in this paper, although there are many factors affecting business model innovation, which is a limitation of this research. In addition, there are only 150 samples, which is also a few number. In the future, in the context of big data, we should take external big data as a latent variable for in-depth research and discuss the impact of big data capability on psychological contract.

The policy enlightenment is that in the context of Internet big data, the implementation of business model innovation should pay attention to the role of relationship change and the research of psychological contract. In practice, we should strengthen the management of the psychological contract of employees and stakeholders; pay attention to the construction of system, culture, commitment, and trust; and constantly build a mood environment.

Under the background of energy conservation and emission reduction and large-scale promotion of electric energy substitution, fully exploring the complementary potential of various energy systems and realizing the optimization of comprehensive energy utilization are the most critical development goals of the current energy system. The key to achieving this goal is the investment potential analysis of integrated energy projects. In order to effectively solve the problems of difficult scientific determination of evaluation index weight and low accuracy of evaluation results in the analysis of investment potential of integrated energy projects, an investment potential analysis model of integrated energy project based on deep learning neural network is designed. The design process of the integrated energy project is summarized. The RBF-BP neural network model is established to obtain the correlation between the factors of the evaluation unit, further analyze and process the training results, and calculate the weight of the evaluation index. The obtained weight is substituted into the TOPSIS comprehensive evaluation model for the investment potential analysis of integrated energy projects. According to the investment potential analysis results, the investment potential analysis value of energy performance contracting (EPC) mode is 0.9122, which is the best operation mode. The results show that the analysis results reflect the investment potential of integrated energy projects more objectively and scientifically.

1. Introduction

Integrated energy system includes the production, use, and transmission of different types of energy, including many conventional energy subsystems, such as natural gas system and traditional power system, as well as new energy generation systems, such as geothermal power generation and wind power generation [1–5]. The integrated energy system can realize the comprehensive utilization of different types of energy, reduce the problems in energy supply, reduce the number of energy conversion, and reduce environmental pollution. It can not only meet people's demand for electricity, but also realize many other services, such as refrigeration and heating, so as to realize the cascade use of energy; improve energy efficiency; and promote the sustainable development of society, market economy, and

energy [4]. However, there are many subsystems in the integrated energy system, and the operation mode and functional characteristics of these subsystems are also very different. The integrated energy system has rich levels, diversified structures, and nonlinear and multiple space-time characteristics, in which there are many problems to be solved. It is difficult to solve the problems only by using the traditional operation mode, control technology, and modeling and simulation technology [5].

The premise of investment potential analysis of integrated energy system is to realize system integration and optimization [6, 7]. The feasibility study, design, and operation mode optimization of integrated energy project need to be carried out on the basis of investment potential analysis. Therefore, the importance of investment potential analysis of integrated energy projects is extraordinary.

With the development of information technology [7–11], artificial intelligence technology has been gradually applied in various industries [12–16]. Because BP neural network [17–19] has strong learning ability and nonlinear fitting ability; it has been empirically applied to the field of investment potential analysis of integrated energy projects. In this paper, RBF-BP neural network is proposed and used to calculate the weight of investment potential evaluation index of integrated energy project. The example shows that this method not only makes full use of the advantages of fast approximation speed of RBF neural network, but also has the ability of BP neural network to better predict unknown samples and improve the evaluation accuracy.

The rest of this article is organized as follows. Section 1 introduces the engineering design of integrated energy project. The principle and algorithm design of RBF-BP neural network are described in Section 2. In Section 3, construction of index system and evaluation index weight solution based on RBF-BP neural network model are applied in a case, and finally the investment potential analysis result is obtained. The main contributions of this study are summarized and analyzed in Section 4.

2. Engineering Design of Integrated Energy Project

According to different energy demands, integrated energy projects can be divided into solar energy and heat pump collaborative heating scheme; solar energy and low valley electric heat storage collaborative heating scheme; heat pump and low valley electric heat storage collaborative heating scheme; solar energy, heat pump, and low valley electric heat storage collaborative heating scheme. The collaborative controller is used to realize the collaborative regulation of different technologies. The standard of collaborative control is generally that the heat pump supplies the basic heat load. In the area with sufficient light, the solar heat collection is large, and the heat pump load is appropriately reduced. In areas with preferential valley price, electric boilers can be used to store heat in the valley to reduce the load of heat pump. Through the analysis and comparison of the investment potential of different technical schemes, the project technical scheme suitable for the industrial park is selected.

As shown in Figure 1, the technical scheme design process of integrated energy projects is divided into five steps:

- (1) Requirement analysis: heating load demand of users in heating season, including design heat load, average heat load, and minimum heat load; annual heat load continuation diagram and analysis; hourly heat load calculation; annual average heat load simulation calculation and analysis, etc.
- (2) Site investigation: understand the building system characteristics, energy structure around the building, climate resources, and other conditions in detail, and judge the applicable technology on site.

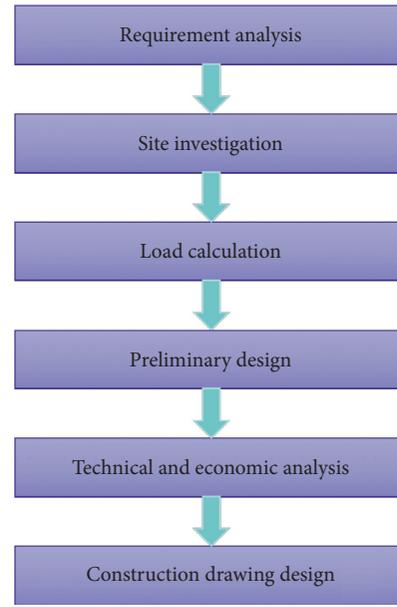

FIGURE 1: Technical scheme design process of integrated energy projects.

- (3) Preliminary design: according to the analysis of users' heat load characteristics, determine the proportion and supply period of solar hot water heating. Combined with the heating load borne by solar energy and its time period, analyze whether it has the spatial and economic conditions for the implementation of electric heat storage. Comparative analysis of heat pump collaborative heating schemes is applied, especially for users with large-scale and stable needs of heating and refrigeration.
- (4) Technical and economic analysis: determine the technical scheme and conduct technical and economic review on the scheme.
- (5) Construction drawing design: issue detailed construction drawing design, and provide the list of materials, equipment, and project budget.

The main functions of the integrated energy project include the following:

- (1) *Energy Monitoring*. From the perspective of the safe and stable operation of the energy network, the production and operation of energy subsystems such as electricity, cold/hot water, hot water, important energy production equipment in the park, and the energy consumption of buildings in the park are monitored through the three-dimensional visualization platform, so as to ensure the stable and safe operation of the park.
- (2) *Energy Regulation*. With the help of a variety of technologies to complete the interaction between user load demand and energy production, such as optimizing the ratio, different energy amounts can be fully utilized.

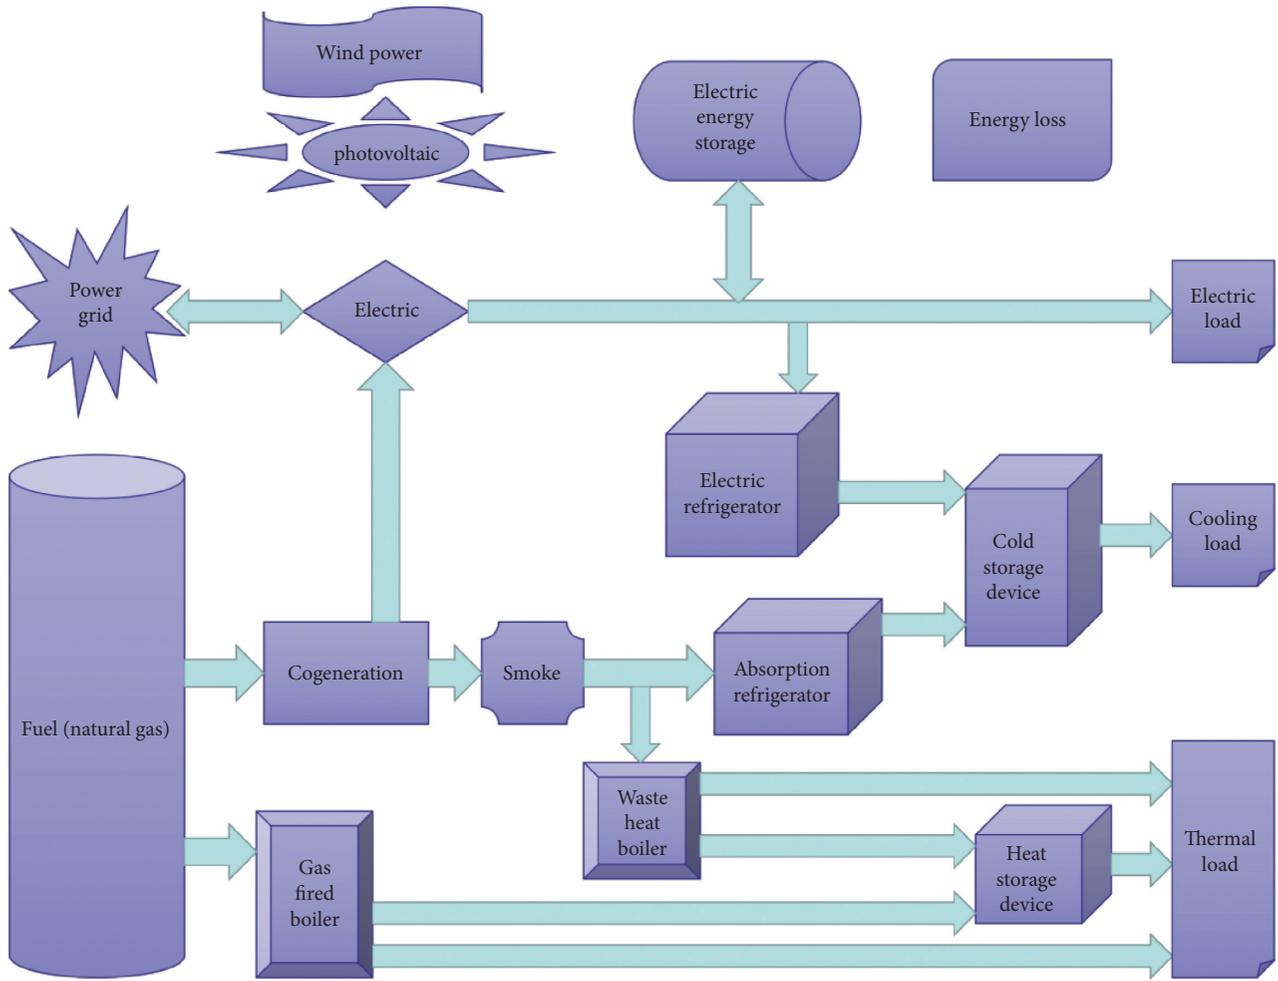

FIGURE 2: The energy flow of the integrated energy project.

- (3) *Energy Analysis.* The interactive analysis of the power grid structure and the improvement of the power grid structure will provide the interactive support for the power grid decision-makers from the perspective of the visualization of the power grid structure and safety.
- (4) *Asset Operation and Maintenance Management.* Through the management business of the whole life cycle of equipment in the park, intelligent patrol inspection business, digital maintenance business, and process three-line operation and maintenance business, realize the structured management, process standardization of the park, and provide information support for the information management of equipment inspection and maintenance in the park.

The energy flow of the integrated energy project is shown in Figure 2.

3. RBF-BP Neural Network Model

3.1. *RBF and BP Neural Network Structure.* BP neural network and RBF neural network are two commonly used

neural network algorithms [20, 21]. As a global approximation network, BP neural network is a stable and reliable nonlinear function approximation method. However, it has the disadvantages of slow convergence speed and easy-to-trap local minimum, although the system is unstable and difficult to ensure that the learning result can reach the global minimum of mean square error. However, the system has good generalization performance. RBF neural network is a kind of optimal approximation network. If there are enough neurons in the hidden layer, it can approximate any continuous nonlinear function with arbitrary precision. RBF neural network has the advantages of simple training and fast learning convergence, overcoming local minimum problem, but having poor generalization ability. RBF-BP neural network combines the advantages of RBF neural network and BP neural network [20–26]. It consists of RBF subnet and BP subnet. Among them, a 4-layer neural network system includes input layer, two hidden layers, and output layer. The model structure is shown in Figure 3.

n , j , k , and m represent the number of neurons in input layer, first hidden layer, second hidden layer, and output layer, respectively. σ_j is the Gauss function width matrix. $C_{n,j}$ is the central vector matrix. $w_{k,j}$ is the weight matrix

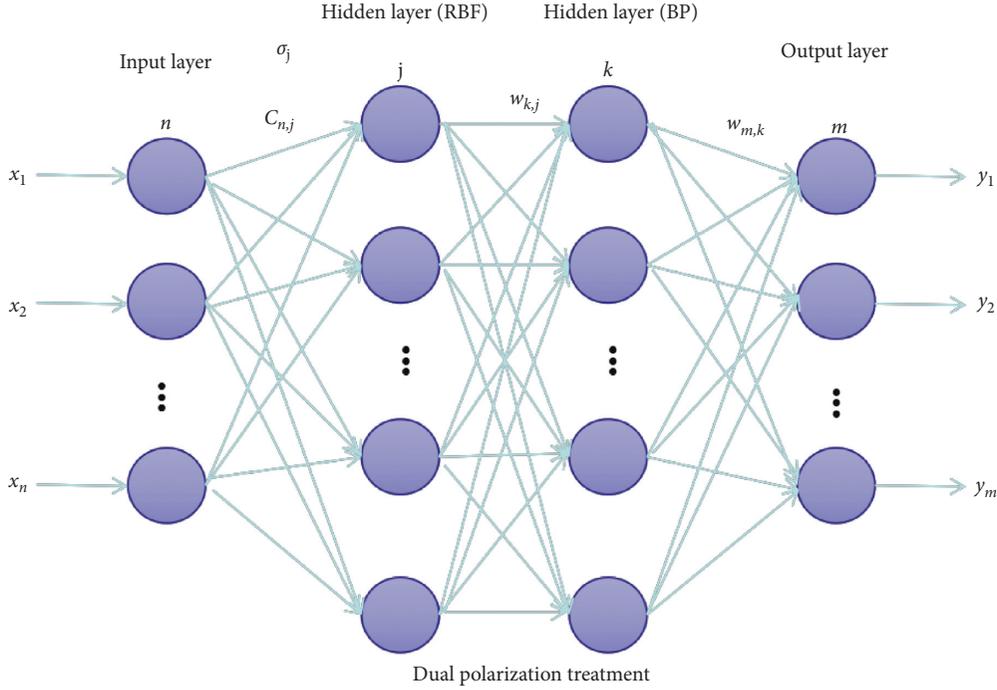

FIGURE 3: RBF-BP neural network structure.

between the second hidden layer and the second hidden layer. $w_{m,k}$ is the weight matrix between the second hidden layer and the output layer. The activation function of neurons in the first hidden layer is Gauss-type function. The activation function of neurons in the second hidden layer is Sigmoid-type function.

3.2. RBF and BP Neural Network Algorithm Design. According to the input training samples, through the RBF subnet preliminary training. After kernel mapping of the input sample by the hidden layer node of RBF subnet, the kernel mapping value needs to be double-polarized before it can be used as the input of BP network. The formula for $\varphi_j(x)$ dual polarization treatment is

$$\varphi_j(x) = 2\cdot\varphi_j(x) - 1. \quad (1)$$

First the output of the hidden layer (i.e., input of BPNN) is as follows:

$$h_i = \sum_{j=1}^{N_2} w_{ij}\varphi_j(x), \quad i = 1, 2, \dots, N_3, \quad (2)$$

where N_3 is the number of nodes of the second hidden layer (BP) and w_{ij} is the weight between the two hidden layers.

Then, the output of RBF subnet is used as the input of BP subnet for strengthening training. Finally, BP subnet training results are obtained. It identifies and outputs results quantitatively. The algorithm flow is shown in Figure 4.

RBF and BP algorithm to realize the detailed steps are as follows.

Step 1. Initialize the weights and widths of each layer. Randomly set to the smaller number between [0,1]. Set parameters such as maximum training times, target accuracy, and learning rate.

Step 2. Calculate the center vector. Set the transfer function of RBF subnet hidden layer to Gauss function. It has the following form:

$$\varphi_j(x) = \exp\left(-\frac{x - C_j^2}{2b_j^2}\right), \quad j = 1, 2, \dots, N_3, \quad (3)$$

where φ is the output of RBF hidden layer node. N_2 is the number of nodes in the hidden layer. X is the input sample vector. C_j represents the center vector of the Gaussian kernel function. b_j represents the Gaussian kernel width of the JTH neuron ($b = d_{\max}/\sqrt{2N_2}$, d_{\max} is the maximum value of each cluster center). $x - C_j$ is the Euclidean distance between x and C_j .

Step 3. Set the transfer function of BP subnet hidden layer as Sigmoid-type function:

$$F(h_i) = \frac{1}{1 + \exp(-h_i)}, \quad i = 1, 2, \dots, N_3. \quad (4)$$

Step 4. Calculate the output value of node M at the output layer. Linear transfer function is adopted, which is expressed as

$$y(m) = \sum_{l=1}^{N_3} w_{lm}F(h_l), \quad m = 1, 2, \dots, N_4, \quad (5)$$

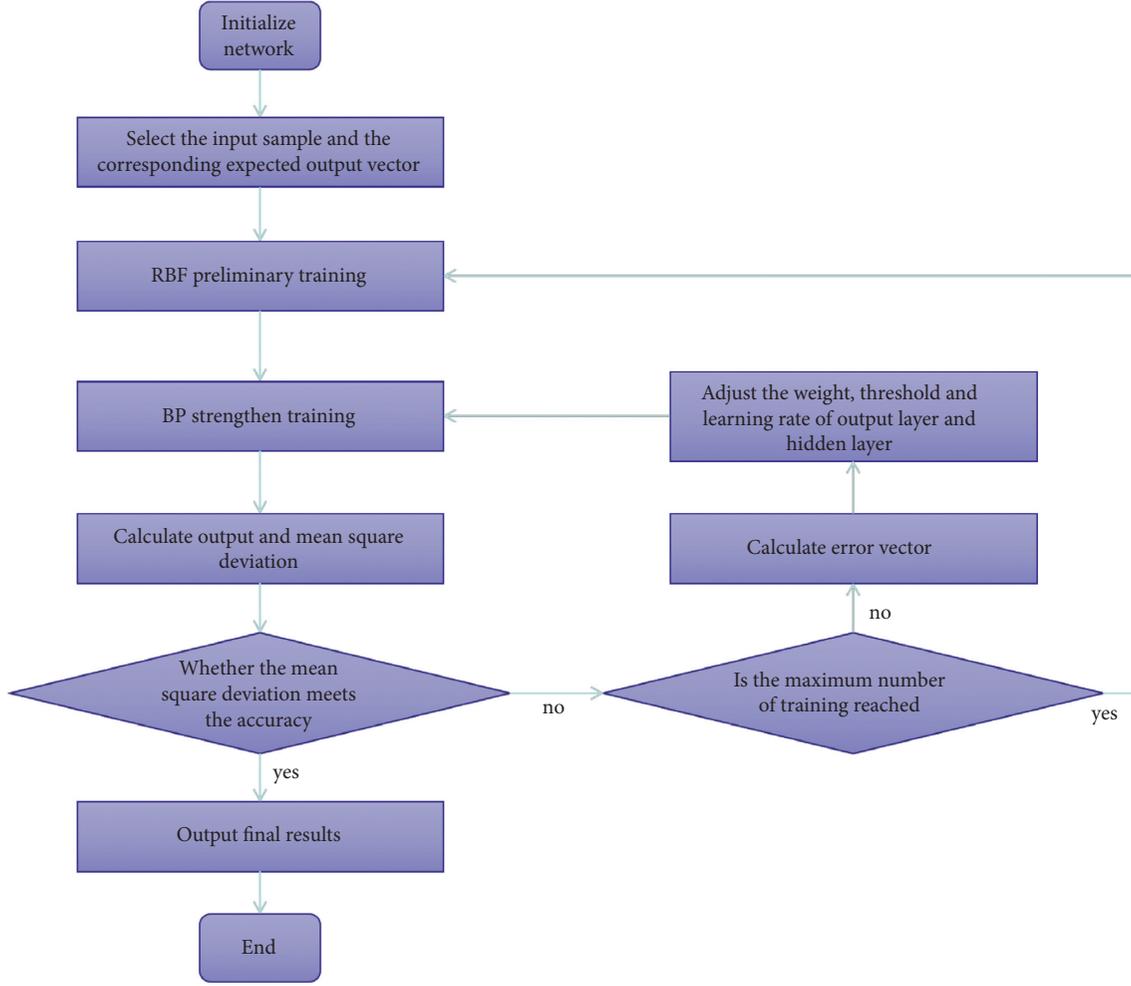

FIGURE 4: Algorithm flow.

where $y(m)$ is the output value of the m -th node in the output layer. N_4 indicates the number of output layers. w_{lm} represents the connection weight between neuron l of the full hidden layer and neuron m of the output layer.

$$E = \sum_{k=1}^{N_4} [d_k - y(m)]^2, \quad (6)$$

where d_k is the expected output value.

Step 6. Calculate the error vector of each neuron in the output layer:

$$\text{ERR}_m = y(m)[1 - y(m)][d_k - y(m)]^2. \quad (7)$$

Step 7. Adjust the weight of each layer, rich value vector.

The weight coefficient w is adjusted according to the difference between the known output data d_j and the output data $y(j)$ calculated by formula (5). The formula of adjustment quantity is

$$\Delta w_{ij} = \eta \delta_j x_j, \quad (8)$$

where η is the learning rate (proportional coefficient) that can be adjusted adaptively. It is set to a value between $[0,1]$ in the calculation. In network training, the value can be gradually increased until the satisfactory training speed can be achieved if the oscillation cannot be caused and the high precision can be ensured. x_j at the hidden node is the input of the whole network. In the output node, it is the output of the lower level (hidden layer) node ($j = 1, 2, \dots, N_4$). δ_j is a value associated with output bias. For the output node,

$$\delta_j = \eta(1 - y(j))(d_j - y(j)). \quad (9)$$

For hidden layer nodes, the outputs are not comparable. Therefore, after reverse calculation, there are

$$\delta_j = x_j(1 - x_j) \sum_k \delta_k w_{jk}, \quad (10)$$

where k refers to traversing the upper (output layer) node. Error δ_j is calculated from the output layer backward layer by layer.

Each layer neuron weight is adjusted for

$$w_{ij}(t) = w_{ij}(t-1) + \Delta w_{ij}, \quad (11)$$

where t is the learning times. Each layer neuron weight is adjusted for

$$\theta_j = \theta_j + \eta \cdot \text{ERR}_j, \quad (12)$$

where η represents the learning rate.

In the process of running the program, when the training error of RBF-BP neural network is less than the set target accuracy, the training ends. At this point, it is converging. If the number of training selection times is greater than the maximum number of training times, it has not reached the target precision and the network structure does not converge. It returns to Step 2 and continues executing the program until the process converges.

4. Case Study

According to the field investigation and cooperation negotiation, there are three operation modes that can be applied to the comprehensive energy project in an industrial park: EPC mode, construction operation transfer (BOT) mode, and public-private partnership (PPP) mode. This section will build a comprehensive evaluation index system of investment potential of comprehensive energy department projects, use the model in Section 2 to solve the index weight, analyze the investment potential, and select the most suitable operation mode.

4.1. Construction of Index System. The key to the optimal planning and design of integrated energy service system is to determine the type and composition of equipment with long-term economy, energy conservation, and environmental protection according to the total cold, heat, and power demand of regional users and build a high-energy efficiency system. The construction of integrated evaluation index system is shown in Table 1.

4.2. Evaluation Index Weight Solution Based on the RBF-BP Neural Network Model

4.2.1. Comprehensive Evaluation Model. In order to explain the investment potential level of an integrated energy project, the contribution and influence of the single factors in the above studies on the investment potential of integrated energy project are different. The contribution degree of each evaluation factor to the investment potential of integrated energy project in an industrial park was calculated by RBF-BP neural network. The calculation is as follows:

$$CI_i = \sum_{j=1}^n I_j w_{ij}, \quad (13)$$

where I_j is the j -th evaluation factor and w_{ij} is the weight of the j -th evaluation factor.

4.2.2. RBF and BP Neural Network Model Structure Determination. In order to obtain the weight of each evaluation index, it is necessary to standardize the value of the evaluation index. The reverse index and moderate index

TABLE 1: Integrated evaluation index system.

Index type	Index name
Economy feature	Annual comprehensive energy efficiency
Economy feature	Electricity charge savings
Energy saving feature	Total primary energy consumption
Energy saving feature	Annual electric energy substitution
Environmental protection feature	CO ₂ emission reduction
Environmental protection feature	SO ₂ emission reduction
Environmental protection feature	NO _x emission reduction

also need to do forward processing. This makes the values of all evaluation indicators between [0,1]. Positive indicators are standardized by maximum effect method (equation (14)). The minimum effect method is adopted to realize standardization of backward indicators (equation (15)). Moderate indicators are standardized by central effect method (equation (16)):

$$x'_i = 100 \times \frac{x_i - x_{\min}}{x_{\max} - x_{\min}}, \quad (14)$$

$$x'_i = 100 \times \frac{x_{\max} - x_i}{x_{\max} - x_{\min}}, \quad (15)$$

$$x'_i = \begin{cases} 100 \times \frac{x_i - x_{\min}}{k - x_{\min}}, & x_i < k, \\ 100 \times \frac{x_{\max} - x_i}{x_{\max} - k}, & x_i > k, \end{cases} \quad (16)$$

where x_i represents the actual value of the i -th lattice of this indicator. x'_i represents the forward normalized value. k is the most moderate value of this factor.

After standardized treatment, there is no difference in dimension, order of magnitude, and degree of variation among factors. Then, RBF-BP neural network model was used to solve the weight of each single factor.

Firstly, the number of neurons in each layer of RBF-BP neural network was determined, since the weight of four individual indicators was required in this study. Then, the number of input layer and output neural unit is set to 4. Forty groups of data were selected as training samples of neural network. Ten groups of data were used as test samples. Through continuous debugging, if the number of input layer neurons < the number of neurons in the hidden layer ≤ the principle of number of neurons in input layer + number of neurons in output layer, the number of neurons in the first hidden layer and the second hidden layer is set to 5. The network structure is shown in Figure 5.

The activation function of the first hidden layer adopts radbas () function. The activation function of the second hidden layer is tangent S-type transfer function tansig (). The neuron transfer function of the output layer adopts the linear transfer function purelin (). Network training algorithm uses

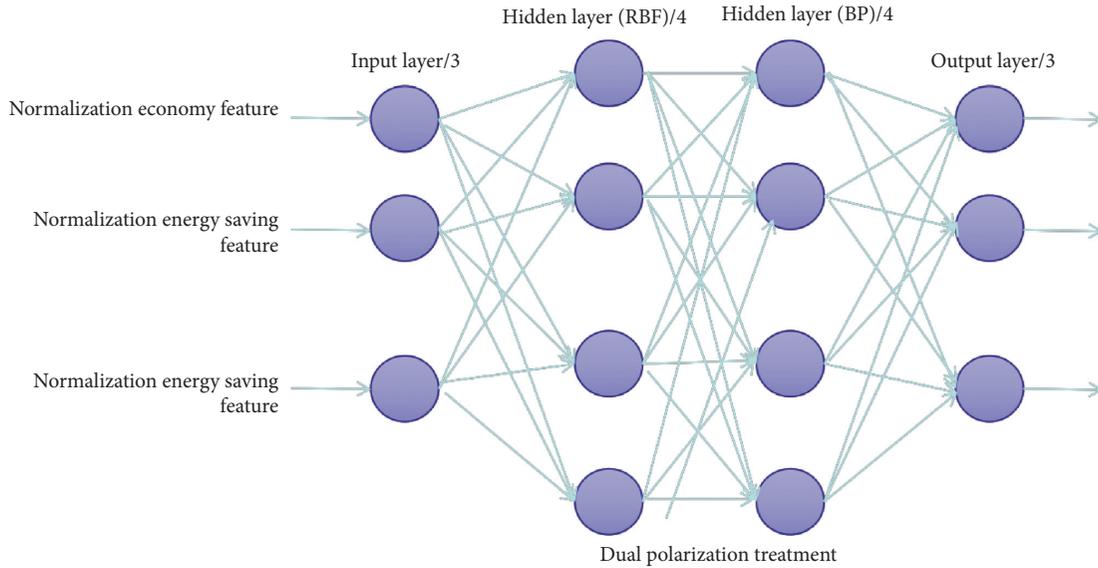

FIGURE 5: Network structure.

LM algorithm `trainlm()`. Learning function uses gradient descent momentum learning function `Learngdm()`.

We apply `newff()` to construct rBF-BP network: `Net = newff(minmax(C), [S, 4, 4], {'radbas', 'tansig', 'logsig'}, 'trainlm')`.

4.2.3. Network Training. According to the algorithm flow in Figure 4, the initial network training times were set as 100 times in parameter setting. The margin of error is set to 0.00001. The learning rate is set to 0.3. The simulated annealing algorithm was used to adjust the generation selection.

After the network is established, appropriate samples are determined according to the specific application and network size to train and learn network signals. This study establishes the characteristics and value range of evaluation indicators. 1500 samples were selected. After the normalization of the attribute values of each indicator. Partial data obtained are shown in Table 2.

MATLAB was used to select 40 groups of samples in the sample set for network training. The maximum number of training cycles is 150. Then, the entire sample is tested. After repeated network training, it is found that the network tends to converge when the number of selected generations reaches about 30 times. The convergence effect is shown in Figure 6. The final error is 0.7461×10^{-5} .

4.2.4. Model Training Results. The RBF-BP neural network model is used to train the normalized data of three evaluation factors (economy feature, energy saving feature, and environmental protection feature). The curve of mean square deviation is shown in Figure 7.

As can be seen from Figure 7, BP neural network achieves convergence after about 54 times of iterations. However, RBF-BP neural network model needs about 28 times to achieve convergence. It can be seen that RBF-BP

TABLE 2: Sample data (part).

15	0.8794	0.8135	0.8826

neural network improves the convergence speed and the mean square error is always lower than BP neural network, indicating that RBF-BP neural network can improve the accuracy of the model.

Figure 8 shows that although BP has a high evaluation accuracy (always higher than 80%), the evaluation accuracy of RBF-BP neural network is better than that of BP neural network. Statistical results show that in 40 groups of test data, the accuracy of training results of RBF-BP neural network model is greater than 90% and the accuracy of 22 groups was greater than 92%. This shows that the model has high approximation accuracy.

4.2.5. Solution of Index Weight. The results of neural network training only reflect the correlation between each neuron in the neural network. If it wants to get the weight of

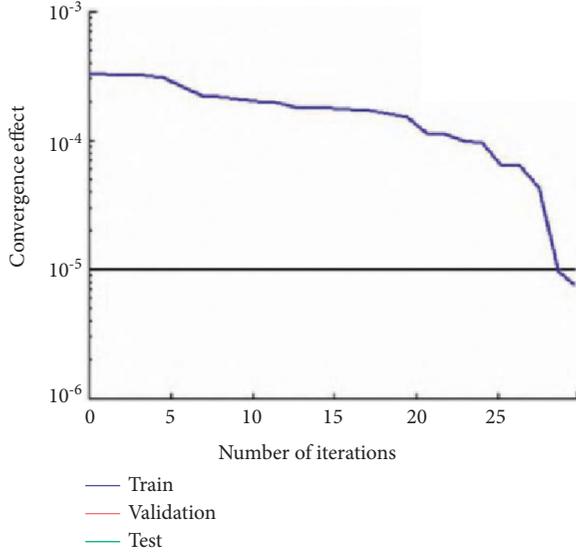

FIGURE 6: Network convergence.

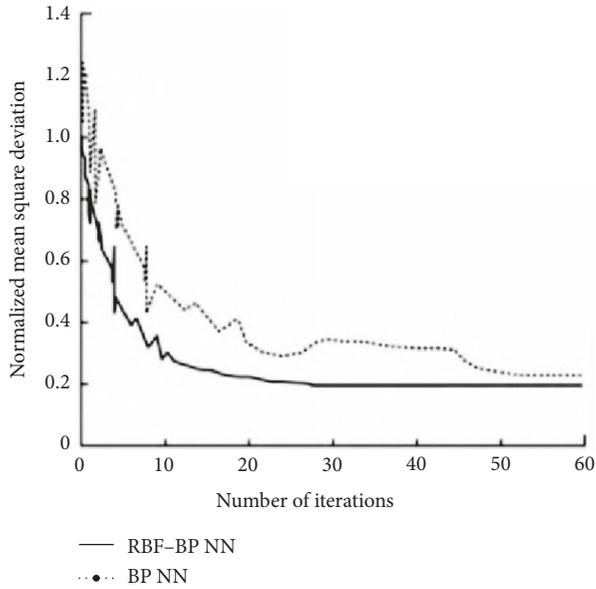

FIGURE 7: Normalized mean square deviation. The training accuracy of 40 groups of test samples is shown in Figure 8.

input factor to output factor, it needs to further analyze and process the weight of each neuron. In this paper, the following coefficients and indices are used to describe the relationship between input factor and output factor.

The relevant significant coefficient is

$$r_{ij} = \sum_{k=i}^p w_{ki} \frac{(1 - e^{-x})}{(1 + e^{-x})}, \quad (17)$$

$$x = W_{jk}, \quad (18)$$

The relevant index is

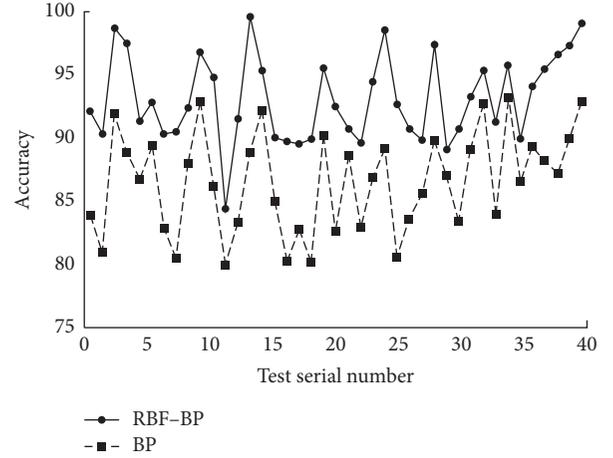

FIGURE 8: Training accuracy.

TABLE 3: Evaluation factor weight.

Evaluation factor	Weight
Economy feature	0.3082
Energy saving feature	0.3761
Environmental protection feature	0.3157

$$R_{ij} = \left| \frac{(1 - e^{-y})}{(1 + e^{-y})} \right|, \quad (19)$$

$$y = r_{ij}. \quad (20)$$

The absolute influence coefficient is

$$S_{ij} = \frac{R_{ij}}{\sum_{i=1}^m R_{ij}}, \quad (21)$$

where i is the RBF-BP neural network input unit, $i = 1, \dots, m$. K is the hidden unit of neural network, $k = 1, \dots, p$. J is the output unit of neural network, $j = 1, \dots, n$. w_{ki} is the weight between input layer neuron I and hidden layer neuron K . w_{jk} is the same weight of output layer neuron and hidden layer neuron k .

Among the above three correlation coefficients, the absolute influence coefficient s_{ij} represents the weight of input layer neuron I to output layer neuron J .

Using equations (17)–(21), the weight of each evaluation index is concluded, as shown in Table 3.

4.2.6. Construction and Application of the Investment Potential Model. We will use TOPSIS method to comprehensively evaluate the investment potential of different operation modes. By substituting the index data into TOPSIS model for calculation, the Euclidean distance and investment potential analysis values of different operation modes can be obtained, as shown in Table 4.

According to the investment potential analysis results, the investment potential analysis value of EPC mode is 0.9122, which is the best operation mode, and the investment potential analysis value of BOT mode is 0.8076, which is second only to EPC mode. The comprehensive benefit value of PPP mode is the lowest, 0.4231.

TABLE 4: The Euclidean distance and investment potential analysis values of different operation modes.

	Euclidean distance to the best point	Euclidean distance to the worst point	Investment potential analysis value
EPC	0.1250	0.0143	0.9122
BOT	0.0944	0.0243	0.8076
PPP	0.0882	0.1451	0.4231

5. Conclusions

The integrated energy project can realize the organic integration and collaborative optimization among electricity, heat, gas, water, and other energy sources, mainly by using the coupling and complementarity of various energy sources in time and space. It can coordinate the energy supply and demand, effectively improve the utilization rate of renewable energy, and reduce the use of fossil energy as much as possible. It can also achieve the cascade use of energy and improve the comprehensive energy efficiency on the user side and supply side. Under the background of energy conservation and emission reduction and large-scale promotion of electric energy substitution, fully exploring the complementary potential of various energy systems and realizing the optimization of comprehensive energy utilization are the most critical development goals of the current energy system. The key means to achieve the above objectives is to improve environmental benefits, energy consumption, economic cost, and other factors through an integrated energy project.

An investment potential analysis model of integrated energy project based on deep learning neural network is designed. The case study results show that the analysis results are roughly consistent with the actual conditions. At the same time, it also shows that the model has high yield, fast learning speed, high fitting accuracy, and stronger generalization ability and can accurately and scientifically analyze the investment potential of integrated energy projects. RBF-BP neural network can combine the fast convergence speed and good stability of RBFNN with the strong reverse self-study ability and generalization ability of BPNN. The correlation training model of each factor based on RBF-BP neural network algorithm reflects the complex nonlinear relationship of each factor in the comprehensive evaluation results in the investment potential analysis of integrated energy projects. It can automatically adjust the correlation weight according to the influence of each index on the investment potential, abandon the subjective influence caused by artificial weight, and have good generalization ability. RBF-BP neural network can carry out nonlinear mapping of any continuous function and more accurately reflect the relationship between evaluation indexes and evaluation results.

With the development of tourism, rural tourism as an industry with great development potential is gradually attracting urban consumers. Considering the differences between different types of rural tourism, I refine it at the visitor level to balance the differences in visitor groups of different types of rural tourism. I propose an improved LSTM framework for rural tourism theme feature extraction. I chose a deep neural network approach to decompose the diverse rural tourism word of mouth into different tourism themes. Then, through tourist feedback data preprocessing, destination theme detection, rural tourism type classification, and word-of-mouth management prediction network, I finally achieve an accurate grasp of rural tourism word-of-mouth features and develop corresponding tourism management strategies. To test the performance of our method, I established different types of rural tourism databases through field surveys for experimental validation. The experimental results show that our method achieves over 90% accuracy in review sentiment detection.

1. Introduction

With the dramatic expansion of the urban economy, urban space is constantly being compressed, and people's recreational space and park areas are decreasing. Along with the industrial development, the air quality within the city is decreasing, and more and more people are planning to travel to the countryside. Every holiday season, most people who work in the city choose to leave the city and travel to a distinctive countryside or town to experience the beauty, food, and culture of the countryside. Villages in different regions have different characteristics. Villages in coastal cities are themed around fishing villages, creating an all-around atmosphere of fishermen's life and allowing visitors to experience the fun of fishing. The villages in the inner mountainous areas are themed around hunting, with livestock kept in captivity in the mountain forests for visitors to simulate hunting, in addition to creating a paradise atmosphere for visitors to enjoy the tranquility of the countryside away from the hustle and bustle of the city [1, 2]. The countryside in the inland plains is dominated by herdsmen, creating original herdsmen's life projects to attract tourists

to experience the details of herdsmen's life and make tourists have a different experience with the grassland culture being the cultural background. I cannot deny the siphon effect of big cities and tourist attractions. But, with the development of tourism, the demand for rural tourism has gradually increased. Different regions of rural tourism with a characteristic cultural background need to have a reasonable management model. From the deep level of the local cultural background, a reasonable strategic plan for rural tourism is formulated, together with computer-aided technology, to form a closed-loop system for rural tourism management [3–5].

To allow tourists to intuitively understand the cultural context of rural tourism, a weighting model with historical and cultural and landscape features should be built during the construction of tourism culture. In rural tourism destination selection, researchers in the literature [6] proposed five key points: destination image, life cycle, tourism experience, condition value, and destination quality. Of these, the destination image is the foundation of rural tourism, and a good destination image can add more appeal to the other key points and increase tourism expectations in the minds of

tourists. Researchers in the literature [7] have again demonstrated in a large number of studies that destination image is a decisive influence in tourism postmanagement and marketing. The destination image requires to be as simple and dynamic as possible. It gives more functionality to tourism activities in the process of building tourism culture and enhances tourists' sense of game experience and activity participation. Some tourism experts point out that tourists' image of the destination generates tourism word-of-mouth benefits, and excellent tourism word of mouth can enhance the chances of tourists' choice of tourist destinations and improve the value attributes of tourist destinations in tourists' minds [8]. In addition, good tourism word of mouth can bring a huge economic effect to rural tourism from souvenirs to food series.

The image of a tourism destination is directly proportional to the tourism word of mouth, so the image enhancement of rural tourism destinations is a key task in tourism management. The image of rural tourism is designed to convey the content, culture, and sense of the experience of rural tourism to the tourists. The tourists' understanding of the image of rural tourism needs to be combined with the actual tourism experience [9, 10]. Visitors' opinions and comments on rural tourism are the most important part of rural tourism word of mouth. Researchers in the literature [11, 12] have attempted to develop a mapping model between tourists' tourism experiences and tourism concepts for judging the conceptual differences in images between tourist destinations. The experimental results proved that heterogeneity exists between tourism purposes in terms of tourism word-of-mouth measures. Researchers in the literature [13] found that rural destinations with the tourism objective of discovering culture and history were more advantageous in the image assessment of rural destinations across geographic regions and that these rural destinations achieved an automatic closed-loop flow in terms of supply and demand pressure, which greatly reduced tourism development costs. Researchers in the literature [14] found that computer vision-based presentation of multidimensionality of tourism destination images can form a new concept for tourists and enhance the attractiveness of tourism destinations to tourists in terms of tourist numbers, cultural tourism definition, and tourist emotional variables for tourism word-of-mouth construction.

To enhance the impact of rural tourism, rural tourism uses optimal scheduling algorithms that play an active role in the rational allocation of resources [15, 16]. Diversification of rural tourism models is the most efficient means of enhancing the competitiveness of rural tourism. With the assistance of tourism agencies, rural tourism has introduced diversified experiences such as farmhouses, traditional culture experience villages, fishing villages, hunting grounds, and cultural and creative product villages. To save the development cost of rural tourism, the literature [17] proposes the construction and sharing of rural facilitation infrastructure and proposes a rural tourism organization to develop various comfort resources to revitalize citizens' rural tourism. In addition, rural tourism cultural product development and event planning are also important

management tools for rural tourism to enhance the attractiveness of rural tourism to tourists and increase the network reputation of rural tourism. Researchers in the literature [18, 19] point out in the data analysis of rural tourism and the establishment of rural basic amenities that rural tourism, while preserving the local characteristics of resources, should take the construction of tourism culture as the main. In the analysis of data on rural tourism and the establishment of rural infrastructure facilities, the researchers pointed out that rural tourism, while preserving local resources, should focus on the construction of tourism culture as the main task and optimize tourism facilities by scientific means to reduce the uneven distribution of tourism resources such as vehicle congestion and accommodation shortage during the peak season. Reasonable expansion of tourist destinations to neighboring villages under the reasonable scope of tourism support construction not only can ease the pressure of tourism but also can create more economic benefits. The use of computer means for simulation and optimization is considered in the rational allocation of tourism resources to enhance the stability and sustainability of rural tourism [20].

The remainder of this paper is laid out as follows. Section 2 describes research related to rural tourism. Section 3 details the principles and implementation process related to the improved LSTM rural tourism word-of-mouth prediction network. Section 4 presents the relevant experimental datasets and an analysis of the results. Finally, Section 5 reviews our findings and reveals some additional research.

2. Related Work

The construction of rural tourism word-of-mouth should be judged on tourists' real experiences and tangible emotions, and the literature [21–24] has proposed a method of rational, and emotions were conceptually fused using images, and a cognitive evaluation method was proposed, which focused on testing three aspects of tourists' virtual impressions, real perceptions, and cultural knowledge of the tourist destination. Under the experimental conditions set by the authors, tourists' feelings are linearly correlated with the perceptions and perceptions of tourist destination images. The attributes of tourism word of mouth consist of tourism resources, tourism facilities construction, and tourism package completeness of the tourist destination, which also determine the relative excellence of the destination. Researchers in the literature [25] argue that different tourism cultures should have different assessment rules; therefore, the authors classify tourism destinations into four categories: natural landscapes, historical landscapes, cultural landscapes, and artificial parks. There are independent tourism word-of-mouth assessment models for different tourism destination categories, which make the construction of tourism word of mouth more balanced, detailed, and complete.

Researchers in the literature [26] have attempted to extract personal assessment opinions of tourist destinations from a list of representative attributes, using interval vectors with ordinal coding for automatic measurement of image

cognitive components. In addition, researchers in the literature [27] used a multidimensional scale's array mapping model, which was able to effectively discriminate polar emotions in the reviews of tourist destinations, and the efficiency of this array mapping model was experimentally demonstrated. Researchers in the literature [28] proposed a dyadic analysis applying nominal scales, where the authors compare the heterogeneity between different tourist destinations to obtain the values of tourism word-of-mouth attributes. Researchers in the literature [29] used an open-ended question model in the data processing of tourist feedback, starting from adjective and noun suggestions of tourist responses, to develop a tourism word-of-mouth assessment in a preliminary model.

Many researchers have attributed the influences of tourism word of mouth to tourists' intuitive feelings and emotional reactions to the destination. Researchers have assessed strategic images through tourists' feelings and emotions, and there are some tourists' opinions that contain the real situation of the destination, some tourists' opinions that are filled with a lot of subjective factors, and some tourists' opinions that contain a lot of constructible suggestions. The current tourism word-of-mouth assessment model does not correctly classify the mixed tourist opinions [30]. Although sentiment and word of mouth are directly related, it would certainly be unfair to travel platforms if they cannot screen out malicious comments from tourists. Tourism word of mouth is an objective opinion and emotion conveyed by tourists after they have personally experienced a tourist attraction, and the emotional dimension of tourism destination image should be based on tourists' objective feelings. Some researchers have proposed a Russel-based structure of tourists' emotional perceptions, which is mainly developed with a two-dimensional structure of emotional variables and a bipolar structure. Based on this, subsequent studies have gradually subdivided tourist feedback emotions such as boredom, pleasure, relaxation, depression, and so on. All emotions were coded in the same dimension on an interval scale, and the method was experimentally shown to be efficient in distinguishing tourists' polar emotions.

Several researchers have computer-modeled tourist destination images covering both the perceptual part and the affective image part. The data were then summarized in terms of image images, where the perceptual part images consisted of tourist cognitive data and the affective images consisted of tourist emotional data. There is a fixed linear relationship between cognition, emotion, and the overall image of the tourist destination. The emotional component can directly affect the overall image of the tourist destination, and the cognitive component affects one-fifth of the overall image of the tourist destination, but the cognitive component and the emotional component can be transformed under certain conditions [31]. For example, tourists' reasons for choosing a tourist destination, tourists' characteristics, tourists' travel habits, tourists' sources of tourist information, and so on are all part of the cognitive component. Such a linear relationship has been transformed into a destination image assessment model in later studies and has been widely used in many studies.

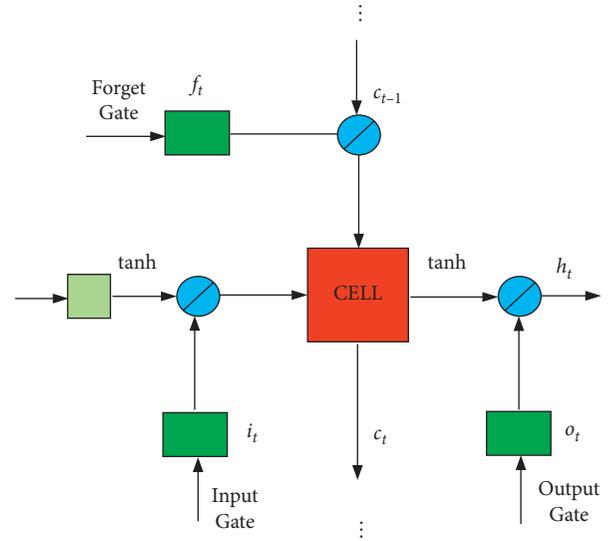

FIGURE 1: LSTM network.

3. Method

3.1. Travel Word-of-Mouth Feature Extraction Network. In the deep learning neural network model of traveler's word of mouth, I found that the long short-term memory network (LSTM) has extremely strong local perception ability in natural language processing, can learn traveler's word-of-mouth features with superhigh efficiency, and can store the relevant features in the short-term network to prevent the problem of information feature omission when learning new features subsequently. I found that some researchers also choose to use LSTM networks to parse tourist attraction text features and achieve good results. The structure of the LSTM network is shown in Figure 1. In this paper, I choose LSTM networks as the basic framework for rural tourism word-of-mouth feature extraction.

The semantic features of rural tourism word of mouth are input at the input side of the LSTM network, and all word-of-mouth semantic features form a feature sequence M before moving to the next stage with the following mathematical expressions:

$$M = [m_1, m_2, \dots, m_t], \quad (1)$$

where t represents the length of the feature sequence M . Natural language processing was initially dominated by recurrent neural networks (RNN), and as natural language processing requirements became more stringent, RNNs were unable to provide complete features for global information due to the omission and loss of textual information due to the framework architecture. Therefore, the LSTM framework was formed based on the optimization of RNN, and the emergence of this method solves the problem of the sequential mapping of text features and also provides local features for global information continuously. The LSTM network has a total of four gates and one memory unit, which are an input gate i_t , forgetting gate f_t , output gate o_t , and a memory unit c_t for updating the hidden state h_t , as follows:

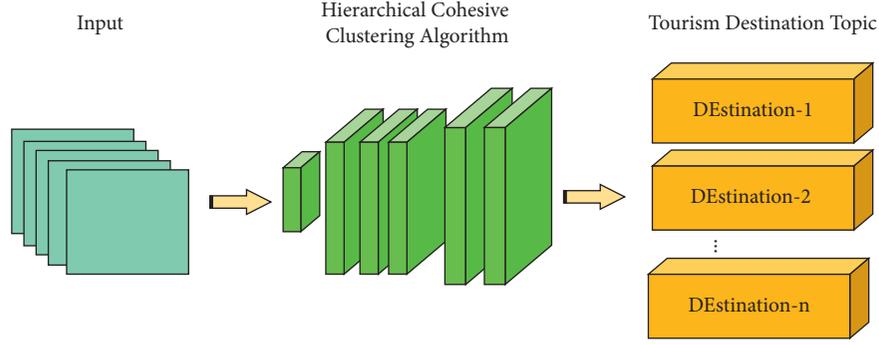

FIGURE 2: Tourism destination image topic detection network.

$$\begin{aligned}
 i_t &= \sigma(W_i x_t + V_i h_{t-1} + b_i), \\
 f_t &= \sigma(W_f x_t + V_f h_{t-1} + b_f), \\
 o_t &= \sigma(W_o x_t + V_o h_{t-1} + b_o), \\
 c_t &= f_t \odot c_{t-1} + i_t \odot \tanh(W_c x_t + V_c h_{t-1} + b_c), \\
 h_t &= o_t \odot \tanh(c_t),
 \end{aligned} \tag{2}$$

where \odot is a function similar to a multiplicative operation, V denotes the matrix associated with the weights, and b denotes the learning vector. In the process of natural language text information processing, LSTM needs to be trained in advance on the forgetting gate side of the semantic elements to obtain deeper text features and implicit features. Forward and reverse bidirectional semantic training allows for travel word-of-mouth character features to be completed ahead of feature replication and stored in hidden memory cells in a tandem combination before being passed to the next layer.

3.2. Tourism Destination Topic Detection. Tourism destination image theme detection is a fusion between text features and sentiment features, and character features between lexemes, words, sentences, and paragraphs can be fully mentioned in the text feature detection phase. To map each character feature to the set of sentiment features, I use a tagging approach. In the data preprocessing phase, I reset all text data sets to be trained and classify all text features in layers with the support of professional linguists. I classify text at four levels: lexemes, words, sentences, and paragraphs, and at each level, I manually annotate using different sentiment tags. Manual annotation is a huge project, and to reduce the workload and improve efficiency, I use the word root dispersion method, where I encode the same word roots and their similar texts predefined to the computer, to achieve automatic annotation of text data. Finally, this is used as the textual theme of the tourism destination image.

In the stage of tourism destination image theme assignment, I adopt the rule of sameness, that is, different text units share the same; tourism theme, which will not affect their tourism theme labels in the subsequent text decomplication. In special cases, I also follow the specified coding units, such as the annotation of keywords, technical terms, and new vocabulary, and I redesign the annotation process

according to the actual situation. The details of tourism destination image theme detection are shown in Figure 2. In our design, each lexeme, word, sentence, and paragraph have a unique label, but this does not affect sentence-to-lexeme disassembly either. The disassembled labels change only at the text level, but their labels correspond to the text level and do not affect the labels at their next level.

To ensure the requirements of rural tourism destination management, I finally chose the hierarchical intraclustering clustering algorithm through extensive experimental validation [32]. I first segmented the text for tourism topics and then filtered the tourism features of word positions by different thresholds. The text clustering similarity was then used to determine the degree of matching between character features and textual tourism features by setting a criterion line and then adjusting the similarity of the extreme data according to the criterion line. The clustering of lexical positions and words can be done at once, while the clustering of sentences and paragraphs requires two to three cycles to satisfy the clustering requirements. The literature [33] proposes two evaluation metrics to determine the effectiveness of text tourism topic clustering in the same context. The mean value of word-level similarity discriminates whether the character features at the word level satisfy the feature mapping condition. The mean value of the maximum similarity between graphemes determines whether the mapping between grapheme features and tourism theme features is within the specified threshold. The mathematical equation of the above evaluation index is expressed as follows:

$$\text{sim}(T_1, T_2) = \frac{1}{2} \left(\frac{\sum_{w \in \{T_1\}} (\text{maxsim}(w, T_2) * \text{idf}(w))}{\sum_{w \in \{T_1\}} \text{idf}(w)} + \frac{\sum_{w \in \{T_2\}} (\text{maxsim}(w, T_1) * \text{idf}(w))}{\sum_{w \in \{T_2\}} \text{idf}(w)} \right), \tag{3}$$

where T_i represents a sentence and w represents a word contained in the sentence T_i . Considering that sentence- and paragraph-level clustering requires circular disambiguation and fairness of same-level clustering for bitwise N -dimensional character vectors, I additionally add cosine similarity as a weight.

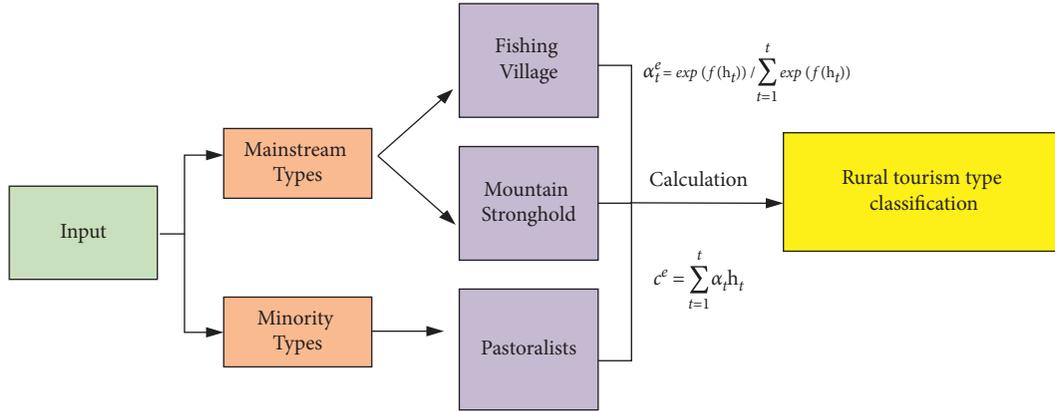

FIGURE 3: The rural tourism type classification network.

3.3. *Rural Tourism Type Classification.* Rural tourism type classification incorporates criteria of tourism themes and emotional characteristics of tourists. I need to classify the character hidden tourism theme features of lexemes, words, sentences, and paragraphs. Different character levels of hidden tourism theme features will have different responses. Considering the requirement of asynchronous homogeneity, I introduce an attention mechanism to monitor the abnormal states of different sequences and perform task control by classifier pointers so that the improved LSTM network can learn more character-level tourist sentiment features and improve the model's recognition accuracy of text sentiment features. Meanwhile, I add character sentiment tourism feature sharing in the improved LSTM network, and the weighted representation of the relevant feature sequences is $h_t = \sigma([\vec{h}_t, h_t])$. Character sentiment features of different travel types correspond to different feature encoders, and I assume that the sequence of shared travel type features is $h_t = (h_1, h_2, \dots, h_t)$, where t denotes the length of the sequence. I add an attention mechanism to the modified LSTM network to traverse the features α_t^e of the time sequence t . Each travel type corresponds to a weight h_t . The detailed mathematical expression is given below:

$$\alpha_t^e = \frac{\exp(f(h_t))}{\sum_{t=1}^t \exp(f(h_t))}, \quad (4)$$

where $f(h) = W^T h$, W represents the parameters that can be trained. c^e represents the weighted sum of the output sequences of the attention mechanism, and its weighting equation is as follows:

$$c^e = \sum_{t=1}^t \alpha_t h_t. \quad (5)$$

The travel type ordinary and hidden layers are interconnected, and the travel topic features are input to the next layer in the form of high-level semantic features c^e . The travel topic features are then classified. The rural tourism theme covers several categories of features, and to distinguish different tourism type features, I use a multimodal theme classifier. The rural tourism type classification network is shown in Figure 3. In this classifier, a total of 128

nodes are set in the fully connected layer based on the tourism features in the word element layer, and the activation function is chosen as ReLU for nonlinear activation. Before outputting to the next layer, I added a random deactivation layer to prevent the activation function from causing overfitting of the travel features. In the final output layer, I use softmax to activate the tourism theme features and then filter them according to the weights to get the text corresponding to the countryside tourism theme category.

3.4. *Rural Tourism Word-of-Mouth Management Prediction Network.* I developed the extraction of rural tourism word-of-mouth features via distributed vectors at the word position level using LSTM network processing in the initial stage. To complete the classification of multiple tourism theme features fed back by tourists, I manually constructed a rural tourism theme type database for detailed polar sentiment for each tourism category. Each character vector contains a set of tourism theme features, and all the character vectors are stacked to form a character vector matrix, and the matching of tourism theme features is obtained by mapping the unknown vectors to the categories in both directions. In the retrieval process, the index of tourism categories can be tracked in the projection layer by the rural tourism theme labels, and the tourism theme features are linked to the corresponding classification tables.

Considering that a large amount of tourist data is needed to support the pretraining of the rural tourism word-of-mouth prediction model. I pre-process tourist data from the restaurant, hotel, bar, and amusement park industries as data input for model pretraining. Considering the specificity of the embedding stage of tourism theme features, I split all tourism text features into characters for embedding, provided that such splitting does not affect the integrity of the text tourism type analysis. The detailed implementation network is shown in Figure 4. All the inputs are in the form of characters, starting from the left, and the thematic features of different tourism types are projected to the next layer through the bidirectional propagation and feedback of the network. The LSTM network can keep the number of features consistent in the process of text feature segmentation. I also used the CRFs method to ensure that the neighboring

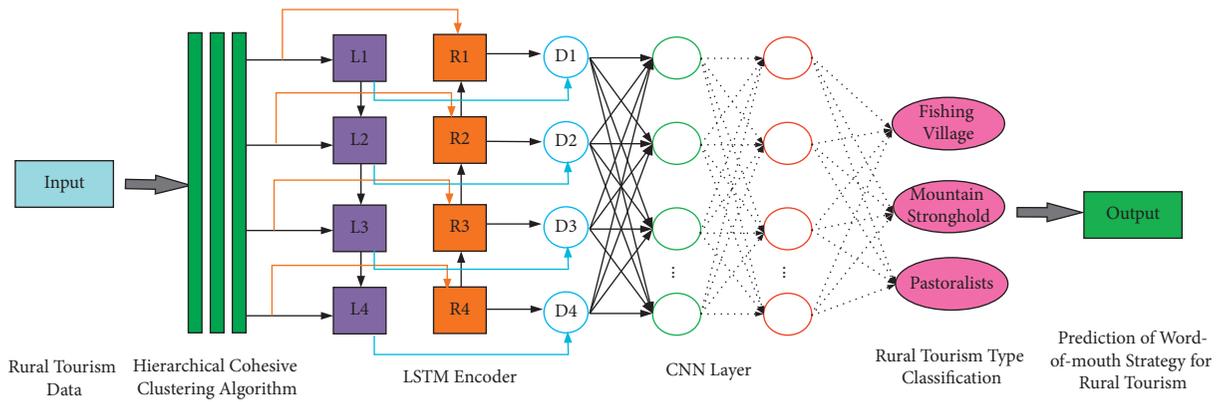

FIGURE 4: Rural tourism word-of-mouth management prediction network.

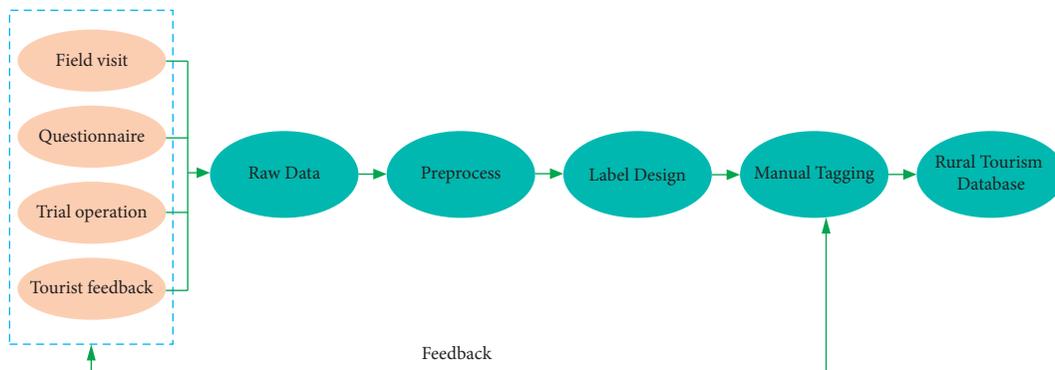

FIGURE 5: Rural tourism review data production process.

labels of each travel type do not affect the final predicted values. To refine the local information in long sentences, I added a CNN layer at the end to recursively feed the tour word-of-mouth features to ensure that the large-scale word-of-mouth features are fully controlled.

4. Experiment

4.1. Data Sets. Rural tourism is an emerging business in the tourism industry, with limited data on the same type of tourism industry, and there is no publicly available dataset on the Ib for rural tourism management. To validate the effectiveness of our method in rural tourism word-of-mouth management, I first collected feedback from rural tourism planning and trial operations in recent years on tourism websites and then visited some successful rural tourism cases in the field and recorded tourist satisfaction data of rural tourism. I used a splitting tool to preprocess each visitor's feedback data. Then I used the anomalous data detection system to screen out the anomalous data and obtained the preliminary polarity training set and test set by manual calibration. The data processing process is shown in Figure 5.

For different types of rural tourism, I categorized and outlined in the visitor feedback data so that rural tourism of the same type and scale is comparable, and rural tourism of different types and scales is only informative. For this purpose, I categorized different types of rural tourism data from field visits and finally obtained a homemade rural

TABLE 1: The detail of data sets.

tourism dataset with details shown in Table 1. In the subsequent efficiency evaluation methods, I still use precision, recall, and $F1$ score to evaluate the effectiveness of rural tourism word-of-mouth prediction.

4.2. Experimental Results. To compare the efficiency of our approach in rural tourism word-of-mouth management, I

TABLE 3: Experimental reliability analysis results.

	Fishing village		Pastoralists		Mountain stronghold	
	Prediction	Actual	Prediction	Actual	Prediction	Actual
RF	0.94	0.88	0.91	0.85	0.96	0.88
RNN	0.95	0.91	0.92	0.88	0.95	0.90
Ours	0.94	0.93	0.94	0.93	0.95	0.95

conducted experiments based on three major rural tourism categories. I selected the random forest method (RF) and recurrent neural network (RNN) as the comparison algorithms. Each model maintains an independent running process during the training process. For the training parameter set, I used the migration learning method to reduce the computational cost. The experimental results are shown in Table 2.

As shown in Table 2, the accuracy of word-of-mouth prediction for different types of rural tourism industry remains above 90% for all categories of our method. Compared with the random forest method, the prediction accuracy is improved by up to 50 percentage points. This is at most 19 percentage points higher than the recurrent neural network method. The random forest method does not perform well in word-of-mouth prediction of rural tourism in the fishing village category. The random forest method, as a traditional machine learning method, relies too much on the construction and labeling of manual tourism text databases and is slow in processing when facing a large amount of tourist data. For unfamiliar tourist feedback, it is easy to generate misleading problems. This also leads to the poor word-of-mouth management results of the random forest method in our experiments. From the data, I can find that the accuracy of word-of-mouth detection of pastoralists is generally lower than in other categories of rural tourism. This is because pastoralists deal with a small base of tourists, and it is difficult to incorporate more tourism word-of-mouth feature vectors at the data learning level. Since fishing village and mountain stronghold are more sought after by tourists, more tourism word-of-mouth factors can be analyzed, and then the activation function is used to highlight their features, which improves the word-of-mouth prediction accuracy. Therefore, the word-of-mouth prediction accuracy of pastoralists is lower overall. To verify the credibility of our experiments, I supplemented the credibility verification experiments, in which I mainly compared the word-of-mouth prediction results with the actual results. The experimental results are shown in Table 3.

From the reliability analysis experiments in the table above, it is clear that the random forest method has the largest difference between the predicted and actual values, with a difference of about 0.06. Our method has the highest reliability, with only a 0.01 difference between the predicted and actual values. This shows the superiority of our method. To verify the effectiveness of our method in more detail, I conducted a comprehensive validation in terms of three metrics: recall (R), $F1$ score, and precision (P). Based on our preliminary study, I found that different types of rural tourism have different impacts on their word-of-mouth

TABLE 4: Comparison of prediction results of rural tourism word-of-mouth strategy.

	Fishing village			Pastoralists			Mountain stronghold		
	P	R	$F1$	P	R	$F1$	P	R	$F1$
RF	0.79	0.75	0.79	0.78	0.77	0.81	0.79	0.79	0.77
RNN	0.85	0.86	0.88	0.86	0.88	0.89	0.87	0.85	0.87
Ours	0.92	0.93	0.95	0.92	0.93	0.91	0.94	0.93	0.92

predictions due to different levels of popularity among tourists. Therefore, in the next experiments, I will analyze the categorized feedback data of tourists. Based on our previous work on the refinement of rural tourism themes, I again conducted a refinement of visitor categories. The experimental results are shown in Table 4.

From the experimental results in the table above, it can be seen that our method performs better after visitor type refinement, as seen in the independent classification validation of different types of rural tourism. The experimental results are more objective and reliable and more responsive to the real feedback of the same type of tourists on rural tourism. From the accuracy and recall data, I can see that our method performs well. Our method can give word-of-mouth data management predictions for different types of rural tourism, and a weighted balance of this tourism theme features according to professional word-of-mouth evaluation agencies. Finally, rural tourism management strategies are developed based on the word-of-mouth prediction results. Such rural tourism word-of-mouth prediction results give tourists a detailed travel reference.

5. Conclusion

In this paper, I analyze the development and prospects of rural tourism and then discuss the links between rural tourism management and conventional tourism. Considering the differences between the different types of rural tourism, I refine them at the visitor level and balance the differences in the visitor base between the different types of rural tourism. Comparing various development factors of rural tourism, I propose an improved LSTM framework for rural tourism theme feature extraction. I discarded the traditional machine learning method and chose a deep neural network approach to decompose the diverse rural tourism word-of-mouth into different tourism themes for classification. Then, through visitor data preprocessing, destination theme detection, rural tourism type classification, and word-of-mouth management prediction network, I finally achieve an accurate grasp of rural tourism word-of-mouth features. To test the performance of our method, I built a database of different types of rural tourism through a field survey for experimental validation. The experimental results show that our method maintains over 90% accuracy in review sentiment detection, which is significantly better than other methods.

Since rural tourism is a new industry, the volume of data is too small. The performance of the deep neural network

model is proportional to the amount of training data. The amount of data I have is far from sufficient for the later study. For the optimization of the network, I will consider using bidirectional recurrent neural networks to process the feature sequences of different types of rural tourism word-of-mouth to achieve better accuracy of word-of-mouth prediction.

With the comprehensive development of information technology, the continuous optimization of products can make enterprises stand in the market. Various industries are involved in the upsurge of computer-enabling products; computer-aided (CAD) technology has also been rapid development. CAD technology is composed of problem analysis, innovative method, problem transformation and problem-solving invention principle, standard solution, and so on. In this paper, the theoretical system, basic scheme, and solving algorithm of CAD technology are described in detail. Meanwhile, the content of value evaluation and root cause analysis is analyzed and solved to further illustrate the application process of CAD technology optimization products and gradually form a more perfect application method of CAD innovation technology so that its solution process is more scientific, operable, and universal.

1. Introduction

With the increasing development of the market economy and technology, all companies around the world are competing in the market, and the new products that are developed and successfully brought to market each year are the key to all companies' success in the competition [1, 2]. New products are the result of continuous technological innovation. An important part of product innovation is the creation of new concepts with marketability and realization possibilities that arise during the product concept design phase, a process that requires the support of knowledge. There are many problems that need to be solved in each stage of product innovation. Some of them can be solved according to experience, but they cannot solve difficult problems or invention problems, which form obstacles to product or process innovation. Inventing problem-solving theory can help corporate developers solve difficult problems, thereby removing obstacles [3–6]. The popularization and application in Chinese enterprises are of great significance to improve the independent innovation ability and market competitiveness. Since 2000, the former Soviet Union invention expert Akishule and a group of

researchers, after years of efforts, put forward and create theory of the solution of inventive problems. The theory is proposed based on the analysis of a large number of high-level patents in the world. The core of the theory is to answer the problems of the process of invention problem-solving and support tools. Designers or problem solvers can solve current problems efficiently and conveniently on the basis of previous knowledge and experience in different fields of innovation. Achishuler argues that only patents are original, while the rest take advantage of existing ideas or concepts, plus novel methods. He firmly believed that the basic principles of solving invention problems existed objectively and could be organized into a complete theoretical system, which could be used to improve the success rate of invention, shorten the invention cycle, and make the solution of invention problems predictable [7–11]. After more than half a century of development and rapid explosive popularization and application in the past ten years, it has become an effective tool in the field of engineering technology to creatively solve the problems of product design and manufacturing process and has helped many well-known companies to achieve significant economic and social benefits [12].

The technology in the early stage of computer-aided innovation is only the application platform of electronic invention problem-solving theory. Due to the limited application scope of the early theory, it has high requirements on the user's knowledge level, thus greatly hindering the spread and promotion of technology [13]. Modern technology integrates innovation theory, innovation technology, and technology, and theory is no longer just a tool for experts to innovate, which greatly reduces the use of technology and promotes the spread and application of theory. With the rapid development of science and technology in recent decades, technology has become an important basic technology in the development of new industrial products. At present, computer-aided technology software is a powerful tool for designers to break the thinking pattern and broaden the ideas in the conceptual design stage of products in different fields and put forward effective design schemes with high quality [14–17]. Throughout the characteristics of these types of software, rich innovation knowledge base as important support, with the advantages of large storage, fast speed, stability, and reliability of the computer, reduces accidental factors and one-sidedness in the design process, so technology is more effective than conventional solutions in solving existing problems and innovation problems of products [18–22]. It should be emphasized that software relies on an innovation knowledge database and innovation problem-solving process to provide feasible ideas for design innovation, and the complete final scheme needs designers to refine and expand these ideas concretely. The development trend of software is to gradually integrate different innovation principles and thinking methods into software to strengthen its ability to assist designers in innovative ideas. Compared with the traditional innovation methods such as trial and error method and brainstorming method, it has distinct characteristics and advantages [23, 24]. It successfully reveals the inherent laws and principles of creation and invention and is committed to clarifying and emphasizing the contradictions existing in the system, rather than avoiding them. Its goal is to completely solve the contradictions and obtain the final ideal solution, rather than compromise. It studies the whole process of product design and development on the basis of the law of technological development and evolution so that innovative design is no longer a random behavior [25–27]. Computer-aided innovation systematically analysis problems can help the designers quickly find out the nature of the problem or contradiction, accurately position problem of direction, and break the conventional mode of thinking, in a different way of looking at problems and analysis, according to the law of evolution in technology to predict the future development trend and accelerate the process of the social innovation and high-quality products [28].

After years of development, it has become a knowledge-based, human-oriented systematic method for solving invention problems. Technology is a new and high technology integrating theory, ontology, modern design methodology, semantic processing technology, and computer software technology, providing natural language query technology based on semantic processing technology. Analyze the

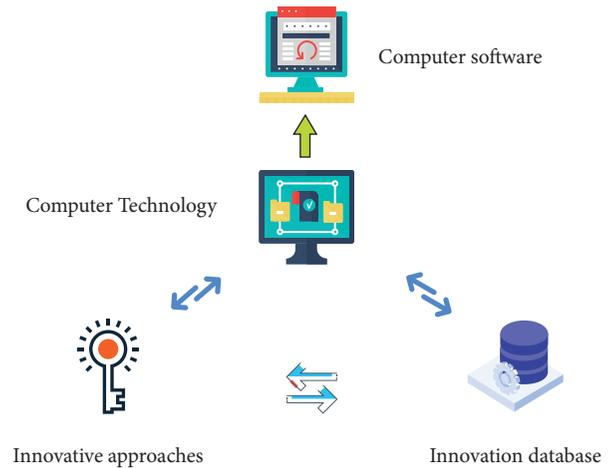

FIGURE 1: Computer-aided technology components.

problem situation systematically, find the essence of the problem, and define the problem and conflict accurately to provide more reasonable solutions to innovative technical problems and technical contradictions. It can predict the future development trend based on the law of technological system evolution, which opens the way for making decisions and developing innovative products, and can effectively save the innovation results for future use.

2. Computer-Aided Technology

Computer-aided technology integrates modern design methods, invention and creation methods, knowledge of various engineering disciplines, and computer software technology and integrates scientific knowledge of multiple fields. Its system composition is shown in Figure 1. Technology provides technical support to designers at the stages of requirements analysis, concept design, solution design, and solution evaluation of new product development, assisting designers in broadening their thinking, guiding them to apply knowledge from various disciplines in an integrated and effective manner, gaining ground-breaking innovative thinking, and providing a constant stream of creative solutions for product design.

Analyzing the characteristics of innovative product design and the functional modules of the commonly used software mentioned in the previous section, the main functional modules of the current better software include project navigation, problem-solving tools such as innovation principles, technology forecasting, patent searching, solution evaluation, and knowledge management to help designers correctly analyze problems in technical systems, predict possible problems in the design phase, and explore the direction of innovative product development. Reasonable assessment of conceptual design options will reduce the probability of errors at this stage.

As can be seen in Figure 2, the designer can effectively use the built-in software in the field of multidisciplinary knowledge and the wisdom of predecessors, follow the rules of innovation, try to find the problems existing in the technical system, find innovative solutions to build their

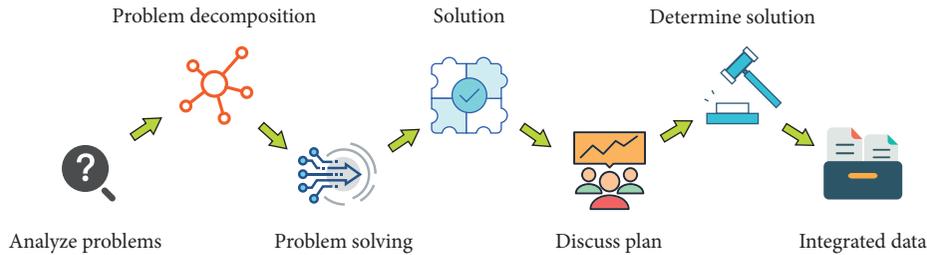

FIGURE 2: The logic of computer innovation technology.

own core technology and knowledge base, and help enterprises to effectively avoid the existing patent competition, into independent intellectual property rights.

2.1. Computer-Aided Innovative Design Platform.

Pro/Innovator is a new generation of computer-aided innovative design tools combining TRIZ, ontology, modern design methodology, natural language processing technology, and computer software technology. With its powerful comprehensive analysis tools and innovative solution library created from the world's outstanding patents, technicians in different engineering fields can break the stereotype and broaden their thinking when facing each technical problem, analyze the problem with a new perspective and thinking, and quickly obtain operational and efficient solutions. Pro/Innovator problem-solving steps are divided into four stages: problem analysis, problem-solving, solution generation, and knowledge management.

2.1.1. Analyze Problems. The problem analysis stage consists of three modules: project navigation module, system analysis module, and problem decomposition module. Innovative design processes include project description, navigation module supporting project initiation, initial conditions and switching of each module, problem solution evaluation process, patent generation and project report generation. The system analysis module includes two parts: building component model and analyzing component value. Building component model mainly includes the interrelationship between functional analysis, role definition, flow analysis, and so on to help technical personnel from the perspective of system fully understand the problem system and its causation of the items constituting the system and subsystem effectively reveal the internal and external problems existing in the system and the weak link, so that the follow-up can be more accurate to describe the contradiction problem. The general improvement direction of the system model is further determined, which can also provide some reference for the subsequent system function evolution. After the completion of the system function analysis, the value analysis of each component of the system, first, determine the functional contribution value, problem, and cost allocation of each component. Then automatically calculate the ideal degree of each component of the system index, comprehensive analysis of each component of the initial problem of the degree of impact, and its contribution to the

main function of the system value, and in order to locate the weak link in the system, clear system improvement direction. Component value analysis is based on the theory of value analysis in value engineering. The main idea of value analysis is to make certain product or certain operation have appropriate value at the lowest cost by analyzing the function and cost of the selected research object, that is, to realize the necessary function it has and improve the value of the object.

The problem decomposition module is a tool for the decomposition of surface problems, supporting the decomposition of initial problems and problems generated from the system analysis module. When describing the initial problem of a system, the root cause of the problem is often not found because the initial problem is not clearly and fully expressed at the beginning. Therefore, in order to dig out deeper causes, it is necessary to carry out a layer-by-layer analysis of the initial problem and its subproblems. The working principle of the problem analysis module is to use the triaxial analysis method to redefine the initial problems along the three axes of causality axis, operation axis, and subsystem axis and transform each subproblem into a triaxial diagram for analysis so that the root cause of the initial problems gradually emerges. In the process of problem decomposition, the causality of the problem is graphically expressed. In this process, other available resources in the system may be mined to analyze the actual causes of the existing resources.

The main working principle of problem decomposition module is based on the theory of root cause analysis and nine-screen method. The nine-screen method is one of the methods of system thinking, which can help people comprehensively and systematically analyze problems from multiple dimensions, such as structure, time, and causality, and find new ideas and solutions according to existing resources. Root cause analysis, also known as root cause analysis, is a process of analyzing problems in depth and finding out the mechanism or cause of failure. It is a simple and practical analysis tool for finding problems and locating causes. It helps to understand and explore the detailed causes behind the problems so that appropriate improvement and preventive measures can be taken. The root cause is determined and problem is fixed step by step. Root cause analysis is a systematic process of dealing with problems, including identifying and analyzing the causes of problems, finding solutions, and developing preventive measures.

2.1.2. Solve Problems. The tools in the problem-solving stage include the solution module, innovation principle module, and patent inquiry module. These three modules have their own knowledge base support, and appropriate modules can be selected according to the types of problems obtained in the previous step.

The solution module has a rich knowledge base of technical solutions, covering most engineering fields of manufacturing industry. The content of technical solutions is structured, refined, and supplemented by vivid, accurate, and professional animation demonstration and contains predefined solutions based on application examples of patent and innovation principles, as well as a library of technical solutions based on past experience of individuals or enterprises. It has a query tool based on ontology relationship, including functional query, structured query, and keyword query, and supports further expansion of query-related patents.

In the application of innovation principle module, the contradiction matrix is the basis of the tool, which supports the whole process of contradiction analysis and solution in the process of innovation problem-solving. It contains three ways to define contradictions: contradiction parameters, contradiction matrix, and contradiction definition wizard. After contradiction definition, the module will automatically give corresponding innovation principles to solve contradiction problems. Each innovation principle contains detailed subprinciples and is accompanied by animation demonstration to help users understand the connotation of innovation principles. The innovative thinking or breakthrough ideas obtained can be used as a reference to solve similar contradictory problems.

The patent query module contains multiple international patent databases and supports access to patent databases in China, the United States, Japan, and Europe. Patent query mode is an automatic extension function based on ontology relationship and function query. The module also has the ability to preview patent content through a web browser.

2.1.3. Form a Solution. In the process of solving contradictory problems, predefined solutions, alternatives, or analogical alternatives are generated based on some illuminating ideas. In order to obtain the best solution, these preliminary solutions need to be evaluated, and the final solution best suited to the initial problem can be selected based on the comprehensive evaluation results. The program evaluation module includes subjective evaluation and objective evaluation. Subjective evaluation includes a single expert program and a multiexpert program. The module provides an evaluation model and can also customize the evaluation model to set the weight of each expert according to the experience, background, or other factors of each expert. Objective evaluation refers to the evaluation based on the citation index of parametric patents. The evaluation results will be displayed in percentage format or bar chart format, and the predefined schemes or alternative schemes participating in the evaluation will also be ranked according to the comprehensive evaluation value.

2.1.4. Data Management. To improve the utilization rate and acquisition efficiency of knowledge, knowledge can be accumulated and shared by sorting out, summarizing, or adding knowledge to the user's knowledge base, and knowledge exchange and mutual learning between relevant personnel can be promoted. Knowledge management tools include project report generation, patent generation module, and knowledge sharing module. Software also has components, which can manage existing knowledge, obtain solutions to problems, and add them to the knowledge effect database of individuals or enterprises, so as to form a reference for similar problems that may occur in the future.

2.2. Value Analysis. Value analysis is a kind of thinking method and management technology to improve the value of the object of analysis. It is a thinking method and management technology to improve the value of the object of study by systematically analyzing the function and cost of the object of study through the cooperation of various related fields and constantly innovating. From the point of view of the purpose of carrying out value engineering activities, value engineering is through the analysis of the function and cost of the object of analysis, with the lowest life cycle cost of the object to reliably realize the necessary functions of the object of analysis, in order to obtain the best social and economic benefits. For products, it is necessary to improve their functions and reduce their life cycle costs through various means.

The main idea of value analysis is to make a product or an operation have appropriate value at the lowest cost by analyzing the function and cost of the selected research object, that is, to realize or create the necessary function it has and improve the value of the object. Value is the ratio of function and cost, which is inversely proportional to cost and directly proportional to function. That is, the higher the function, the lower the cost and the greater the value. Thus, the principle of value analysis is to improve product value to improve economic benefits by comparing product functions and costs.

In terms of the control scope of the product cost, value analysis considers product life cycle cost. Value analysis is to seek the lowest life cycle cost and to achieve the necessary function of the product as the goal and is committed to the study of the mutual interest between function and cost to overcome the one-sided consideration of a single aspect of blind practice. Value analysis is centered on function analysis. It is difficult to define product function accurately because there are many influencing factors, it is not easy to quantify abstract indicators, and people's evaluation methods of product function are different. Therefore, the analysis of product function can be considered the core of value analysis. Value analysis is an organized activity. Because the value analysis process runs through the whole life cycle of the product and involves a wide range of areas, it needs the cooperation of all units, departments, and professionals involved in the production of the product to accurately measure the cost of the product, function evaluation, and achieve the purpose of improving the efficiency of the unit cost of the product. Value analysis can reduce

product cost to the greatest extent. It can combine technology and economic problems organically and overcome the disjointed phenomenon of economy and technology in product design and manufacturing. Value analysis is a creative activity based on information. Value analysis is based on product cost, functional index, market demand, and other related information data, looking for the best solution for product innovation. In terms of the time spent on a product analysis, value analysis is carried out before product design and manufacture. Therefore, information is the basis of value analysis, and product innovation is the ultimate goal of value analysis.

2.2.1. Content of Value Analysis. The content of value engineering is the process of raising, analyzing, and solving problems according to the function and cost of products. The general working procedure of value engineering can be carried out in five stages: preparation stage, analysis stage, comprehensive stage, evaluation stage, and implementation stage. The specific working steps are shown in Figure 3.

The selection of value analysis object is the key step of value evaluation. The selection of objects mainly includes value coefficient analysis, cost proportion analysis, function evaluation coefficient analysis, and cost proportion analysis. The value coefficient is used to analyze the relationship between component function and cost, and the component whose cost does not adapt to function is taken as the key analysis object and the target of improvement. Value coefficient is determined by function coefficient and cost coefficient. Function importance coefficient refers to the proportion of part function to total product function, and cost coefficient refers to the proportion of part cost to total part cost.

$$\begin{aligned} \text{Value coefficient} &= \frac{\text{Function coefficient}}{\text{Cos coefficient}}, \\ \text{Cost coefficient} &= \frac{\text{Cost of spare parts}}{\text{Total product cost}}, \\ \text{Function coefficient} &= \frac{\text{Function of parts}}{\text{Product functions}}. \end{aligned} \quad (1)$$

The function coefficient of each component relative to the product is calculated according to the importance of the component in the whole component. A high value of the function coefficient indicates that the component has a great influence on the function of the component.

Cost-specific proportion analysis (ABC analysis method), a creation of Pareto, an Italian economist, is now widely used, especially in material cost analysis. It is a method that preferentially selects parts, processes, or other elements that account for a significant cost ratio as the object of value analysis.

Class A parts: the number of parts accounted for 10~20% of the total number of products, and the cost accounted for 70~80% of the total cost of products. Class C parts: the number of parts accounted for 70~80% of the total number of parts of the product, and the cost accounted for 10~20% of the total cost of products. Class B parts: the rest of the parts are called Class B, and the number of parts is proportional to

the cost of the product. Using this classification method, we can find out the Class A parts which have the greatest impact on product cost as the main object of analysis and cost reduction. In practical application, the value coefficient analysis method is often combined with the ABC analysis method. Because A product often has many parts, it is relatively complicated to use the value coefficient analysis method for all parts. Generally, the ABC analysis method is adopted to select key parts, and then the value coefficient analysis method is applied to select specific objects based on the selected A or B categories.

Functional evaluation coefficient analysis method will queue up parts according to the size of functional requirements and preferentially select those with large functional coefficient as the value analysis object. And the cost proportion analysis method makes statistical analysis of various costs, and the largest one is the object of value analysis.

3. Root Cause Analysis

Root cause analysis is an analysis process of in-depth analysis of problems and finding out the mechanism or inducement of failure. It is a simple and practical analysis tool to find problems and locate causes, which can help to understand and dig out the detailed causes behind problems so as to take appropriate improvement and prevention measures. Root cause analysis is a systematic process to deal with problems, including identifying and analyzing the causes of problems, finding solutions, and developing preventive measures.

3.1. Root Cause Analysis Tool. The 5W2H method refers to the use of the five words "WHAT," "HOW," "WHY," "WHEN," "WHERE," "WHO," and "HOW MUCH" to ask questions in order to discover clues to solve problems, find ideas for inventions, and design ideas, so as to arrive at a comprehensive analysis of problems and ideas for solutions. The 5W2H method is shown in Figure 4.

In Figure 4, the process of asking and answering questions in the above seven areas provides some insight into the problematic events to be addressed and thus gets to the heart of the matter. The areas of the answers that are not at the desired level can then be improved in a more targeted way.

The system diagram lists the problems according to the order of occurrence and searches for all possible causes for each problem so as to get the root cause of the most likely problems. This is a way of describing an effect and all the possible causes that might affect it.

It can be seen from Figure 5 that the object of the tree diagram is a system, which is the relationship between a certain quality problem and its components. The graphic features are "layer-by-layer inclusive," just like a big tree. Therefore, a certain problem can be systematically decomposed into many components, and the logical and sequential relationship between them can be displayed. Through the description of the system, show the appearance of things to explore the most appropriate method to achieve the goal.

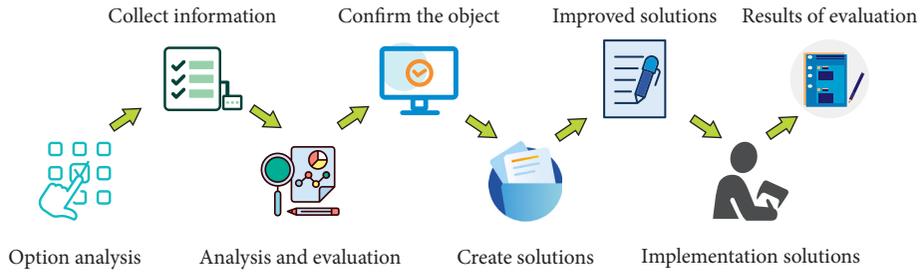

FIGURE 3: Process of value evaluation.

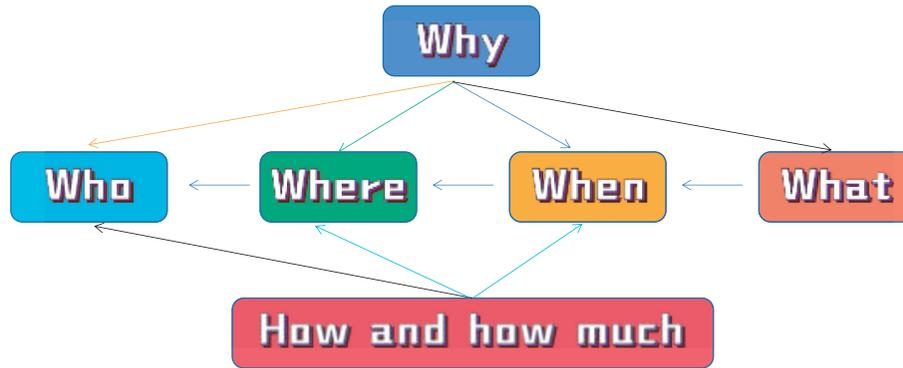

FIGURE 4: 5W2H method.

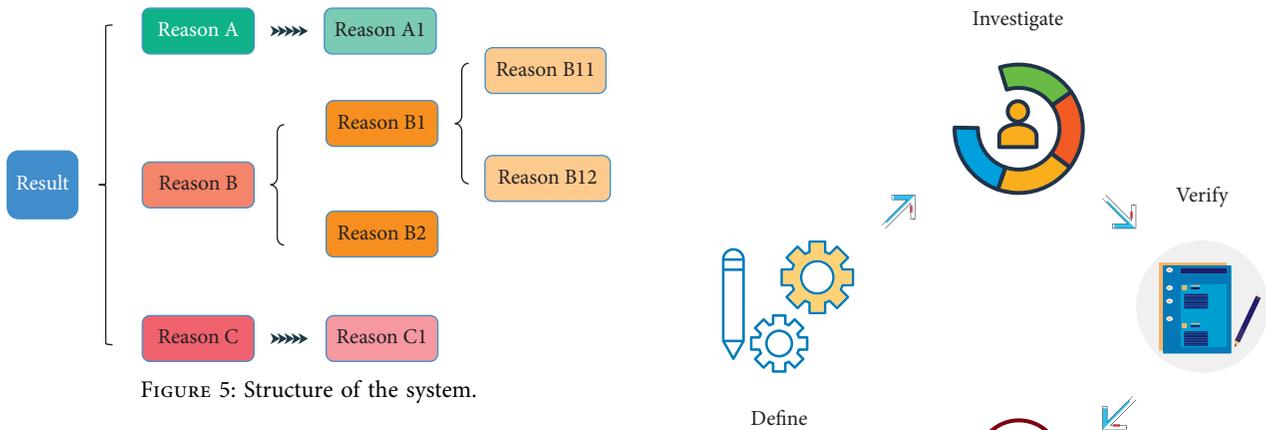

FIGURE 5: Structure of the system.

3.2. *Application of Root Cause Analysis.* The implementation of root cause analysis includes a series of logical processes, and its four key elements in solving problems are Define, Investigate, Verify, and Ensure. Based on the idea of Define, Investigate, Verify, and Ensure problem-solving tool, according to the characteristics of root cause analysis and the use of problem-oriented innovation strategy, the appropriate analysis method is selected and supported by a relevant knowledge base, and the prototype system structure is constructed, as shown in Figure 6.

The purpose of defining the problem phase is to set goals for improvement or solving the problem. Identify the conditions that are relevant to the problem and identify which factors may and may not be relevant to a particular problem. The purpose of the problem investigation stage is to find out the root and true cause of the problem. Through the analysis process, the basic situation of the problem is

FIGURE 6: Root analysis process.

sorted out to lay a foundation for cause analysis and evaluation. It can be divided into two situations: when analyzing the problems of simplicity and inferiority, the “5 Why” analysis method can be given priority to gradually explore the root cause of the results through signs and find the root cause of the problem. In the analysis of complex problems, system diagram, and so on, in the design of manufacturing products, problems need to be analyzed from the machine, method, material, personnel, measurement, and environment in order to find the root cause of the problem. The

purpose of the problem identification and evaluation stage is to verify the validity of the root cause analysis. Analyze each cause with background information and data. The assessment identifies one or more most likely root causes. Verify and identify the cause of the problem through field tests or process descriptions that provide valid information to pinpoint the true cause. The stage of determining the best solution is to solve the root cause of the above three stages, use the invention of problem-solving-related tools and other methods to produce solutions, and then consider the feasibility of the solution from the perspective of time, cost, and resource utilization. Then the solutions are sorted out, the weight of each factor is set according to the existing common rules of the industry, the feasibility of the above schemes is evaluated by selecting appropriate evaluation criteria, and the best scheme is selected according to the comprehensive evaluation results. Finally, the effectiveness, reliability, and environmental adaptability of the scheme are verified by experiments.

In the problem decomposition module of Pro/Innovator, the subproblems of the initial problem were decomposed along the three axes of the causality axis, operation axis, and subhypersystem axis, and the subproblems were transformed into a three-axis diagram. The causal axis reflects the causal relationship between events that precede or follow the occurrence of the initial problem. This axis can be used to reveal the root cause and possible outcome of a problem, and the name of the causal axis node is Define Cause and Define Result. The action axis reflects the sequence of actions that represent all the actions experienced by the object in question. The hierarchy axis reflects how a subsystem or supersystem interacts with the technical system under consideration. The causality axis is the most commonly used and important decomposition axis for Pro/Innovator to solve problems. The layer-by-layer analysis of initial problems and subproblems along the causality axis by the problem decomposition module is actually the process of root analysis. Through the continuous decomposition of problems at the upper layer, the root causes of problems are gradually discovered. The graphical expression is similar to tree diagram or fishbone diagram. Pro/Innovator can automatically add analysis results to the project navigation and integrate them with subsequent problem-solving modules. When the problem decomposition module analysis does not reach ideal results, the solution process of root cause analysis can be used for deeper analysis.

The purpose of root cause analysis is to try to identify the contributing factors to a problem and analyze all the causes by repeatedly asking multiple whys and gradually digging deeper into the problem until the root cause is found. When exploring the root cause, try to evaluate each identified cause and try to give a solution, which will contribute to the overall improvement and improvement of the original problem. It should also be added that root cause analysis, as a general term, is not limited to the application process proposed in this chapter, but there are different structured approaches for solving specific problems.

4. Conclusion

CAD technology is an important auxiliary tool in the field of engineering. It benefits from the development of innovative methods and theories and the continuous integration with computer technology. The integration of technology innovation theory, value analysis, root analysis, and other theories makes the computer-aided innovation technology perfect day by day and consolidates its solid theoretical foundation. Computer-aided innovation technology supplements the limitations of traditional innovative design and technical improvement, and the integration of a variety of innovative methods can effectively help designers improve the efficiency of solving engineering design problems.

College ideological and political education has always been the primary content of national spiritual civilization construction. The current teaching methods are more flexible, resulting in the quality of ideological and political teaching not being reasonably assessed. To address this problem, we propose a method for assessing the quality of ideological and political teaching based on the gated recurrent unit (GRU) network and construct an automatic assessment system for ideological and political teaching. We draw on the migration learning model to improve the loss function by using the generalized intersection set over the joint loss function to compensate for the shortcoming of the small number of ideological and political teaching datasets. We use a masking algorithm to enhance the local features of teaching data sequences for different classes of ideological and political teaching quality assessment metrics. In addition, we use the minimum outer matrix algorithm to extract the sequence features of different assessment dimensions to improve the accuracy of the model for the quality assessment of ideological and political teaching. To meet the quality assessment conditions of ideological and political teaching, we compiled and produced ideological and political teaching datasets according to the teaching data coverage. The experimental results proved that our method performed best in comprehensive quality assessment accuracy in ideological and political teaching, with the assessment accuracy rate above 90%. Compared with traditional machine learning methods and deep learning methods, our method has higher accuracy and better robustness.

1. Introduction

College ideological and political education has always been the primary content of national spiritual civilization construction. In the process of cultivating talents in colleges and universities, cultivating talents requires not only professional skills but also noble ideological and moral cultivation. We advocate personality education as the foundation and ideological and political education as the bricks and mortar. Personality is the stable psychological foundation for the formation of life values, and the role of ideological and political education is to regulate bad moral habits and establish correct values. At present, colleges and universities have opened courses in ideological politics for college students. In addition to a positive theoretical explanation from the classroom level, school teachers also deepen ideological and political work from the psychological perspective of students, so that ideological and political education is

implicitly integrated into the life values of college students [1]. Civic education is in full swing, but the quality of civic education is an unknown quantity. To study the quality of civic education, we referred to a large body of literature in the field of educational effectiveness research and drew on its educational quality validation methods [2–4]. One of the most mainstream educational validity testing methods is meta-analysis, and related research has shown that meta-analysis can extract student benefit factors at the student level, which can be converted into educational validity weights. Changes in student achievement, changes in life habits, and changes in learning attitudes can all be introduced into a multilevel statistical model. Some studies have directly matched the weights of classroom, school, student, and teacher to obtain different levels of educational grading, and the link between educational grading and learning outcomes can be used as a reference for educational effectiveness. For effective ideological and political education,

more perfect classroom performance in ideological and political courses, more enthusiastic teachers, more motivated students, and more interactive classrooms directly impact the quality of ideological and political education [5–7]. It has also been found that students' classroom performance also has a significant impact on the quality of ideological and political instruction, and the results of student thought quality tests administered during different academic years show that students' self-awareness in ideological and political courses has an indirect impact on the quality of ideological and political instruction [8, 9]. Currently, most researchers on the quality of ideological and political teaching and learning attempt to suggest a multi-dimensional assessment model that disperses assessment elements across the classroom and life, aiming to highlight the role of other influences on ideological and political teaching and learning in addition to mainstream civics.

In studies assessing the quality of ideological and political teaching, a large number of studies have attributed the factors that have the greatest impact on the quality of ideological and political teaching to the teachers themselves [10–12]. Some studies have indicated that teachers' teaching experience, educational height, and personality development all leave different impressions on students in the course, and the extent to which subject knowledge is imparted changes with students' impressions of the teacher. The degree of subject matter knowledge imparted also varies with students' impression of the teacher. In addition, students' learning methods and teachers' teaching methods have an indirect effect on the quality of teaching civics. This also reflects most of the classroom management problems of ideological and political teaching, teachers' teaching objectives development, and course structure planning reference. Issues such as students' performance in the classroom, the positive level of answering questions, the degree of completing assignments after class, and students' classroom feedback can reflect the quality of ideological and political teaching. The meta-analysis can synthesize teachers' teaching data to generate teachers' teaching effectiveness [13, 14]. For students, meta-analysis can also generate corresponding learning outcomes. Students' learning outcomes and teachers' teaching effectiveness are an important set of data for teaching quality assessment, and the results of a meta-analysis can provide feedback on the overall trend of teaching quality. The influencing factors of teaching quality evaluation are shown in Figure 1.

Teaching quality assessment is an important way to identify the effectiveness of education, and a variety of teaching quality assessment models have been studied in the field of educational effectiveness research, mainly using meta-analysis when it comes to teaching data analysis. All of these models cover multiple aspects of teaching and learning, including not only the interaction between students and teachers in the classroom, but also the teacher's preparation for the course, the teacher's mastery of the course, the student's completion of assignments at the end of the class, and the students' feedback on the course. Although different methods of assessing teaching quality use different data survey instruments, all teaching quality assessment

models follow the following characteristics. Within the multivariate teaching quality framework, priority is given to the conceptual model of teaching quality, which also has limitations and is not comprehensive in its scope [15, 16]. Connections are established between scholars to integrate feedback on teaching quality with opinions among scholars to obtain recommendations on teaching quality weights.

The rest of the paper is organized as follows. Section 2 presents the history and research findings of teaching quality assessment research. Section 3 introduces the relevant principles and implementation details of the GRU-based ideological and political teaching quality assessment network. Section 4 shows the experimental datasets and the analysis of the experimental results. Finally, Section 5 summarizes our research and reveals some further research work.

2. Related Work

According to teaching effectiveness research, it was found that the model for assessing teaching quality is determined by multiple influencing factors. Researchers in the literature [17] have identified six inter-influential factors of teaching quality in teaching role assignment, which are course orientation, course structuring, classroom questioning, instructional modeling, instructional case application, and time management. The researchers also noted that the role of the teacher's teaching experience in the classroom directly influences the classroom learning environment and is a key indicator of classroom performance assessment. In the assessment of teaching quality in skill-based learning courses, the literature [18] suggests a more direct approach to assessing teaching effectiveness, such as structuring course instructional tests and theorizing skills assessment. Researchers in the literature [19] focused mainly on the degree of influence of the teaching model, and the authors framed the model for assessing teaching quality in terms of the ability of the teacher and students to interact and cooperate in the classroom. At the same time, the authors argue the interaction between different students and teachers in the same classroom as interrelated in terms of its contribution to the quality of teaching and learning in the whole course. To test this idea, researchers in the literature [20] adopted a control variable approach to verify the former idea based on the former. The experimental results showed that teaching quality was linearly associated with course instructional factors in stages and that efficient interaction between teachers and students during the effective teaching stage promotes the level of students' understanding of course knowledge.

Some researchers have defined five key indicators of instructional quality effectiveness: frequency, quality, stage, focus, and differentiation. These five indicators are derived from student feedback data from instructional assessments, teacher self-assessment data, and school ratings of classroom performance. Each of the five indicators corresponds to five dimensions of instructional effectiveness assessment, and each dimension can describe the function of an influencing factor in detail. For the quantitative characteristics

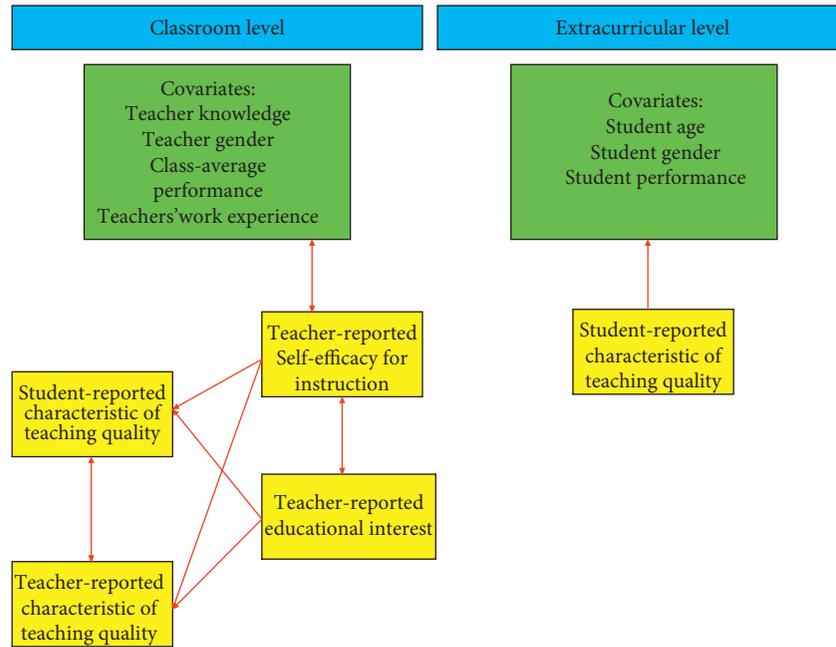

FIGURE 1: The influencing factors of teaching quality evaluation.

dimension, the authors chose frequency as the frequency of association between instructional effectiveness factors, thus achieving a quantitative role for each of the instructional effectiveness factors [21]. In matching individual instructional quality factors with the number of activities, it was found that cases of application of new knowledge were able to materialize the pedagogical theory and students were better able to understand this pedagogical approach. Such an approach can have a positive impact on the effectiveness of instructional quality. If too much time is spent on teaching examples of applications, it can create an illusion of a shift in the focus of learning for the students. That is why teachers need to structure the teaching phases. While grasping the course schedule, the course teaching methods should be reasonably arranged, and the centralized course model that pursues the course schedule should be avoided as much as possible, which will, on the contrary, produce negative effects on the classroom learning efficiency [22].

Most researchers have chosen the deep learning approach to evaluate teaching quality effectiveness research after comparing machine learning and deep learning approaches. Dynamic neural network models should be chosen as much as possible in the assessment models of teaching quality effectiveness, and dynamic neural network models can weigh the qualitative and nonqualitative characteristics of teaching quality factors. Researchers in the literature [23] found that for each neural network dimension of the instructional quality factors correspond to independent mathematical functional relationships, and for mapping associations between neural network dimensions and theories, dynamic neural network models can achieve single or multiple feature correspondences simultaneously. If all teaching quality assessment activities need to be completed according to expectations, the dynamic neural network model can generate corresponding teaching quality

dimension assessment indicators at each stage, and according to the specific indicators, different neural network dimensions can be independently parameterized to obtain the expected values. Some researchers point out that the teaching quality assessment indexes of each neural network dimension are derived from a comprehensive functional assessment report, the index factors of each neural network dimension are independent of each other, the factors between dimensions do not influence each other, and the teaching quality factors of each neural network dimension will collaboratively govern the assessment trend of teaching quality according to the weight ratio when the overall teaching quality is assessed [24–26]. Each instructional quality assessment factor has a certain expectation of purpose fulfillment, and if an expectation corresponds to more than one purpose in an instructional course activity, the fulfillment rate of that expectation will decrease and the instructional quality assessment factor will be negatively affected [27, 28].

3. Method

3.1. Initial Structure. In the study of quality assessment of teaching of college and university civics, we conducted experiments between the machine learning model and the deep learning model, and the experimental results proved that the deep learning model was superior, so we finally chose the deep neural network model. We studied many neural network algorithms and conducted experimental validation, and finally we chose gated recurrent unit (GRU) as the network foundation. GRU is an upgrade of the RNN. GRU belongs to the algorithm of processing serial data, and in the quality assessment of college ideological and political teaching, GRU can obtain validity features from teaching data, also segment instances from the meta-analysis of

classroom performance and student feedback, and mask the target features with different thresholds. The GRU algorithm is a two-layer algorithm: the first layer is to scan the instructional sample data to generate the weight factors, and the second layer is to output the instructional validity factor mask on the recurrent neural network branch. In the mask decoding process, we adopt the separation method to decode each instructional validity factor independently and cover all instructional validity dimensions accurately.

The GRU algorithm is obtained by optimizing based on the recurrent neural network, which aims to mine more feature information from instructional data sequences, and the authors use instructional effectiveness factor feature regions to replace the sequential traversal of data sequences. To prevent over-stacking the network, the GRU network borrows from the VGG network proposed by Google, and the authors propose a local memory unit network based on the VGG network with adaptive improvements to the GRU network. The biggest advantage of this network is that it uses a series of short-term memory units instead of the iterations of long- and short-term memory networks. The structure of the GRU network is shown in Figure 2.

3.2. Mathematical Principles. RNN is a kind of feedforward neural network, which retains the advantages of a feedforward neural network and adds local feature processing network to efficiently identify data sequences of different lengths. Given a set of data sequences $x = (x_1, x_2, \dots, x_T)$, the relationship between the front and back layers of the hidden layer state of the RNN has the following mathematical equation.

$$h_t = \begin{cases} 0, & t = 0, \\ \phi(h_{t-1}, x_t), & \text{otherwise,} \end{cases} \quad (1)$$

where ϕ denotes a nonlinear function. In the above mathematical equation, we use a combination of logistic sigmoid and affine transform to calculate ϕ , avoiding the problem of forwarding transmission difficulties due to data redundancy. Furthermore, assuming that the output of RNN is $y = (y_1, y_2, \dots, y_T)$, and the length of this data sequence is also varied according to the input data sequence, then h_t has the following mathematical expression.

$$h_t = g(Wx_t + Uh_{t-1}), \quad (2)$$

where g represents the smoothed bounded function, and in the actual calculation, we adopt the hyperbolic tangent function as the bounded function. Assume that at the specified state h_t , the recurrent neural network outputs a new set of elements of the data sequence, the probability distribution of the elements can be represented according to the special symbols inside the model, the special symbols inside the model can be mapped to feature sequences at different lengths, and the matched sequence probabilities in the mapping have the following mathematical expressions.

$$p(x_1, \dots, x_T) = p(x_1)p(x_2|x_1)p(x_3|x_1, x_2) \cdots p(x_T|x_1, \dots, x_{T-1}). \quad (3)$$

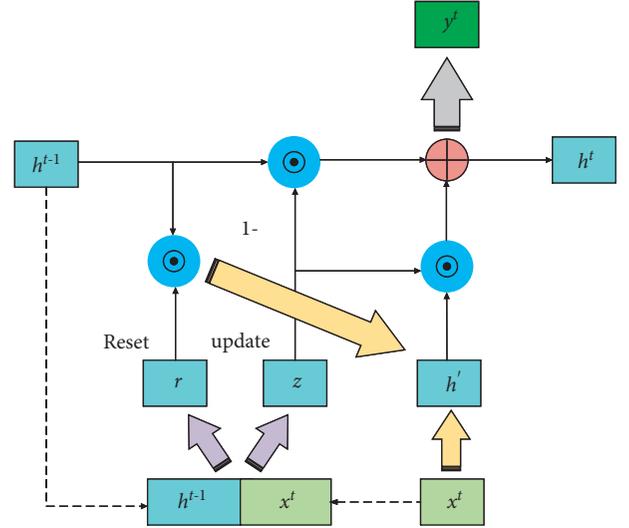

FIGURE 2: GRU network.

Each instructional effectiveness factor is modeled using a conditional probability distribution, where the final instructional effectiveness factor depends on the length of the sequence, and different sequence lengths correspond to different conditional probability distributions. The mathematical expression is as follows.

$$p(x_t|x_1, \dots, x_{t-1}) = g(h_t). \quad (4)$$

In the literature [29], it was found during experiments that recurrent neural networks are prone to long-term dependencies in the process of training data sequences. Due to the specificity of the recurrent neural network structure, the problem of gradient disappearance often occurs during the training process, which makes the method less variable in gradient amplitude changes and more difficult to optimize the network structure. For data with a long sequence length, its long-term dependence on exponentially smaller is not conducive to the learning of new sequence features at a later stage. To solve this problem, some researchers try stochastic gradient descent to reduce the dependence on a gradient. Other researchers have used the gradient cropping method to circumvent the gradient disappearance problem. Some researchers have also used the second-order method to normalize the gradient vector to prevent the occurrence of gradient explosion and reduce the sensitivity of the network structure to the gradient method by using the same growth pattern of the second-order derivative as the first-order derivative [30]. The GRU algorithm is similar to the LSTM algorithm, but the structure of the two is significantly different, as shown in Figure 3.

An efficient activation function has been found in the approach of sequence feature capture optimization of recurrent neural networks. Researchers found a nonlinear implementation of affine transform and gated units that take local recurrent units or activation functions in an independent direction, called gated recurrent units. All gated cyclic units do not cause long-term dependencies when extracting features in sequences of variable length. In

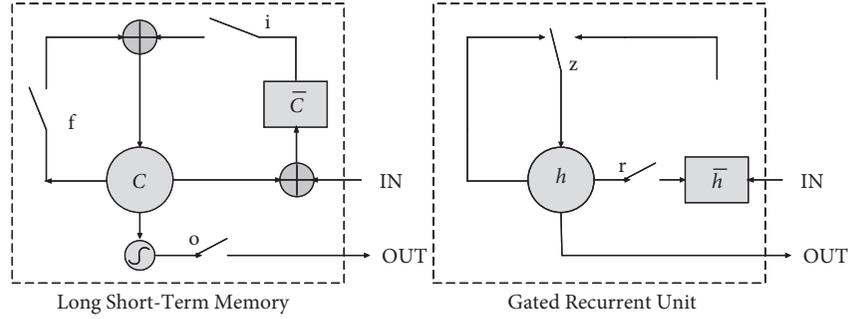

FIGURE 3: Structural differences between LSTM and GRU.

addition, GRU algorithms are often used in machine translation and speech recognition studies in addition to being able to process data sequences [31, 32].

3.3. Gated Recurrent Unit. Gated recurrent units (GRUs) were originally proposed by researchers in the literature [33]. The authors argued that each independent recurrent unit can correlate the dependencies between data sequences at different time scales during data sequence processing. Each cyclic unit is gated, and the gating method can regulate the flow of information within the unit on demand, and all gated units share a storage unit but do not share local feature information. During the processing of a whole data sequence, each gating unit acquires a segment of independent local sequence features, which will not overwrite the previous sequence features when new features are input, and the new features will be stored in the gating unit in parallel with the previous features. Suppose the GRU activation function is h_t^j at time t . The activation function of the previous layer is h_{t-1}^j , and the candidate activation layer is \bar{h}_t^j .

$$h_t^j = (1 - z_t^j)h_{t-1}^j + z_t^j\bar{h}_t^j, \quad (5)$$

where z_t^j represents an update gating unit that is capable of maintaining a superposition of activation function updates and stored sequences within the gating unit. The expression of the mathematical equation of the update gate is as follows.

$$z_t^j = \sigma(W_z x_t + U_z h_{t-1}^j). \quad (6)$$

The processing means between the current state and the computed state of the new sequence is a linear summation operation, which is similar to the computation of the gating unit of the LSTM. All gating units in the GRU algorithm are in the visible state, and there is no unit controlling the hidden layer feature extraction in this algorithm structure, so the whole sequence processing is in the exposed state in this GRU algorithm unit. The mathematical principle between the features of the teaching data sequence is shown in Figure 4.

The expression of the \bar{h}_t^j function for the candidate activation layer is shown below.

$$\bar{h}_t^j = \tanh(W x_t + U (r_t \odot h_{t-1}^j)), \quad (7)$$

where r_t denotes the reset gate and \odot represents a multiplication operation. When the reset gate is closed, r_t^j is close

to 0. The reset gate generates a special symbol for each sequence as it processes the sequence, and in addition, the reset gate is special in that the gating unit internally allows the previous sequence characteristics to be forgotten and new sequence characteristics to be stored. The mathematical expression of the reset gate r_t^j is shown below.

$$r_t^j = \sigma(W_r x_t + U_r h_{t-1}^j). \quad (8)$$

3.4. Teaching Quality Assessment System. Referring to a large number of teaching quality effectiveness studies, we choose the GRU network as the base network. We introduced the GIOU loss function to enhance the generalized feature extraction ability of the model for teaching quality effectiveness factors, and we also chose Compute Unified Device Architecture to accelerate the computational power of the model. To improve the teaching quality assessment system, we added a classroom data recording tool as the data source for later teaching quality classroom assessments. Data preprocessing is performed on the teacher-side, student-side, and school-side teaching data samples, then the local gating unit feature layer is obtained by convolutional transportation, then-candidate regions are extracted on the feature layer, and the candidate regions are pooled and convolved to extract features. We introduce the GIOU loss function after the pooling layer and set 3 threshold criteria for the GIOU loss function, which is trained iteratively by teaching quality feature update and CUDA model acceleration. Finally, we obtain the grade features, grade matching features, and classroom teaching effect feedback features for teaching quality assessment.

Traditional machine learning methods in teaching quality effectiveness research are limited to the differences in available teaching feedback data, and no distinction can be made between staged and final teaching outcomes. This leads to a biased teaching quality assessment system, with the final teaching effectiveness accounting for the largest impact. To overcome this problem, we adopted a GRU gated unit-based recurrent neural network framework, which uses a masked gating structure that can reinforce the sequence features at the edges and can capture the local features of the sequences more comprehensively before storing them in each gating unit. Each sequence processing is divided into one stage, and the sequence features of each stage are stored in segments to avoid the loss of previous sequence features during the input

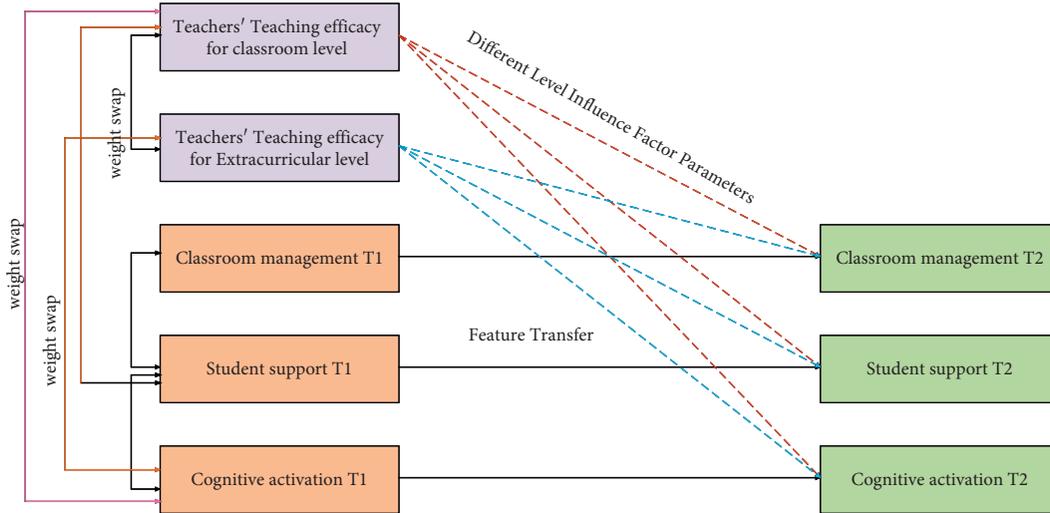

FIGURE 4: Structural differences between LSTM and GRU.

of new sequences. We also used the minimum external moment algorithm to accurately extract the sequence feature information of the teaching quality factor for independent segments. The detailed structure of the teaching quality assessment system is shown in Figure 5.

4. Experiment

4.1. Dataset. Current teaching effectiveness research does not have a systematic public dataset of teaching feedback. To validate our teaching quality assessment methods, we produced teaching quality feedback datasets supported by three dimensions: teacher, school, and student. To standardize the categories of teaching effectiveness assessment, we set up five main teaching quality assessment items in the early stage of teaching quality feedback dataset production, namely, teacher effectiveness (TE), student satisfaction (SS), classroom feedback (CF), course research (CR), and course size (CS). The detailed data preprocessing process is shown in Figure 6.

Teacher efficacy is the teacher's mastery of the course, the overall organization of the course, and the efficiency of the teacher's delivery, among other factors. Student satisfaction is only the level of satisfaction of the students who chose the course with the course and the instructor after taking the class. Classroom feedback refers to feedback and suggestions from students or the school about the problems of the course. Course research refers to the understanding and preparation of the course by the instructor before the course begins. Course size refers to the number of people who choose the course, which is often a direct indicator of the course's popularity and effectiveness. Different teaching effectiveness datasets were created according to the categories of teaching quality assessment indicators. Detailed information on the datasets is shown in Table 1.

4.2. Experimental Setting. To ensure the independence and stability of the ideological and political teaching quality assessment system, we configured an independent upper

computer for the system, and all integrated systems were developed on the upper computer as the platform. In our experiments, we mainly configured the experimental environment of the Anaconda system. Considering the different requirements of the programming environment for the classroom interactive visual system and the teaching quality independent learning system, we configured multiple programming environments on the upper computer to suit different needs. In the construction of the ideological and political Teaching Quality Prediction Neural Network, we mainly use TensorFlow as the main framework. With the support of the powerful software community module, our teaching quality prediction network can be successfully built. The detailed training parameters are shown in Table 2.

4.3. Analysis of Experimental Results. To verify the effectiveness of our ideological and political teaching quality assessment system, we compared machine learning methods and deep learning methods. Among the machine learning methods, we chose the RF [34] algorithm, and among the deep learning algorithms, we chose the RNN algorithm [35] and the LSTM [36] algorithm. To ensure the independent validation relationship between methods, we conducted five sets of experiments during the training process and independently validated each group of methods for different teaching efficiency assessment metrics. The test results of each method were directly input into the statistical calculation part of the dataset, and the final evaluation results were obtained by balancing the total number and quality of the dataset. In the first phase of the experiment, we validated all teaching quality feedback datasets and compared the efficiency of our methods with those of other methods. For method testing efficiency metrics, we chose recall (R) and precision (P) as general evaluation metrics, where X_{TP} denotes the correctly assessed teaching quality data, X_{FN} denotes the teaching quality data without any features acquired, and X_{FP} denotes the incorrectly assessed teaching quality data. The experimental results are shown in Table 3.

TABLE 2: Experimental parameter settings.

Parameter	Value
Learning rate	0.001
Decay rate	0.001
Momentum	0.8
Epoch	130
Iterations	1000
Dropout rate	0.5

The X_{TP} in the experiment indicates the readiness rate for qualitative assessment per 500 samples of instructional feedback data. The experimental results in Table 3 show that the RF method has the highest number of instructional validity misclassifications, accounting for one-fifth of the total. The recall rate is only 64.1%, which is not very accurate.

The efficiency of teaching quality assessment is slightly better than RNN and LSTM methods, but there is still room for optimization. Our method has only five teaching effectiveness misclassification data, and the accuracy of teaching quality assessment reaches 98.5%. This is superior to other methods, which shows the superiority of our method in the first phase of experimental validation. In the second phase of the experiment, we verified the details of each teacher's teaching data separately. The highest student feedback score was 100, the highest expert rating was 10, and the highest workload was 25. Education represents the teacher's academic background, with higher scores representing higher education. Before the start of the experiment, we performed a preprocessing operation on the teaching quality feedback data to standardize the input format and sampling frequency of teaching quality data to prevent the influence of data

TABLE 4: Comparison of teaching quality data for teachers with different experiences.

Teacher (experience)	Workload	Leadership (%)	Student feedback	Expert score	Education
1(2)	8	72.3	85	7	8
2(4)	12	81.2	89	7	8
3(5)	14	89.8	91	8	7
4(8)	20	93.5	96	9	4

TABLE 5: Comparison of the accuracy of ideological and political teaching quality assessment by different methods.

	Classroom part (%)	Extracurricular part (%)
RF	64	71
RNN	73	75
LSTM	74	84
Ours	89	93

discrepancies on the experimental results. The results of the second phase of the experiment are shown in Table 4.

The results of the second phase of the experiment showed that teachers with more teaching experience had a heavier workload, and teachers with more years of experience held more positions in the school and had more work issues. At the leadership level, teachers with more years of work experience had stronger leadership skills, performed better in their courses, and had higher student feedback scores for their teachers. At the expert rating level, teachers with more work experience scored higher on the teaching quality assessment, and despite a less academic background, work experience became a major factor in improving teaching quality.

In the third stage of the experiment, the accuracy of the Civic Education Teaching Quality Assessment System is verified in assessing teachers' civic education performance and work assessment performance. We divided the ideological and political education into two categories: the classroom part and the extracurricular part, where the classroom part includes teaching progress and students' ideological and political performance, and the extracurricular part includes students' after-class homework. The experimental results are shown in Table 5.

The experimental results from the third stage show that all methods have higher assessment accuracy in the extracurricular part of ideological and political teaching than in the classroom part. The accuracy of the extracurricular part is higher than that of the classroom part because many assessment details cannot be implemented in the extracurricular part, so the highest scores are taken in many aspects. The RNN and LSTM methods still need to be improved in the work of meta-analysis of data outside the classroom. Our method performs best in the quality assessment of ideological and political teaching and learning, outperforming RNN and LSTM methods.

5. Conclusion

In this paper, we propose a method for assessing the quality of ideological and political teaching based on the gated recurrent unit (GRU) network and construct an automatic

ideological and political teaching assessment system. We draw on the migration learning model to improve the loss function by using the generalized intersection set over the joint loss function to compensate for the shortcoming of the small number of ideological and political teaching datasets. We use a masking algorithm to enhance the local features of teaching data sequences for different classes of ideological and political teaching quality assessment metrics. In addition, we use the minimum outer matrix algorithm to extract the sequence features of different assessment dimensions to improve the accuracy of the model for the quality assessment of ideological and political teaching. To meet the quality assessment conditions of ideological and political teaching, with the support of ideological and political teachers, students, and school administration teachers, we compiled and produced ideological and political teaching datasets based on the teaching data coverage. The experimental results proved that our method performed best in comprehensive quality assessment accuracy in ideological and political teaching, with the assessment accuracy rate above 90%. The assessment accuracy rate is the best performance in teaching outside of class. It proves that our method performs well both inside and outside the ideological and political teaching classroom. Compared with traditional machine learning methods and deep learning methods, our method has higher assessment accuracy and better stability.

Although our method performs best in experiments inside and outside the ideological and political classroom, there is still much room for improvement in the accuracy of ideological and political teaching quality assessment. In future research, we will try to add generative adversarial neural networks to the adversarial network as an auxiliary classification to optimize the reasonable segmentation of teaching data sequences of different dimensions and improve the robustness and generalization of the network.

An artificial intelligence integrated application model of supply chain financial risk assessment is constructed. Based on the financial data and supply chain data of listed companies in China's new energy electric vehicle industry, the supply chain financial credit risk evaluation index system is constructed. The data samples are preprocessed by PCA as the input data of the support vector machine, which effectively solves the problem of high-dimensional data in supply chain finance. By improving the inertia weight of particle swarm optimization and introducing mutation operation, a dynamic mutation particle swarm optimization algorithm is proposed to avoid the problem of particles falling into a local minimum in the process of optimization. Finally, the improved optimization algorithm is used to optimize the parameters of SVM and input AdaBoost integration as a weak classifier to build an integrated model with good performance in many aspects. The model has been successfully applied to the credit risk assessment of China's new energy vehicle supply chain finance. The comparison with other models shows that the constructed model has certain advantages in performance.

1. Introduction

Supply chain finance has become an emerging model to carry out comprehensive financial services for small and medium-sized enterprises [1–3]. The operation of the supply chain finance mode depends on the supply chain management activities of enterprises. Financial institutions provide financing design for the capital demander after an overall consideration of the capital flow, logistics, and information flow of the whole supply chain of the enterprise with financing demand. Supply chain finance is based on the good credit evaluation of core enterprises with a strong financial background in the supply chain [4–7]. At first, the financing model of supply chain finance appeared to solve the financing difficulties of small and medium-sized enterprises in the supply chain. Small and medium-sized enterprises operate on a small scale, and their assets and management capacity are limited. Moreover, small and medium-sized enterprises are generally in the situation of poor credit status, low degree of

financial transparency, less or even no asset mortgage and guarantee. These factors lead to banks and other financial institutions unwilling to bear too many risks and inspection costs and provide loans for small and medium-sized enterprises, and the financing cost of small and medium-sized enterprises is often much higher than that of large enterprises. With the business exchanges between core enterprises and small and medium-sized enterprises, it improves their own commercial credit for small and medium-sized enterprises, making it easier for small and medium-sized enterprises to obtain loans from banks and other financial institutions.

Even after years of development, although supply chain finance is well known by more and more people, there are still many problems in practical operation, which need us to conduct more in-depth discussion and exploration [8–13]. Especially in terms of risk management and control, the risk management problems in supply chain finance deserve special attention. Risk management in supply chain finance emphasizes the antirisk ability of the

whole supply chain. Compared with the previous traditional financing model, the access scope of financial participants in the supply chain is extended to the whole supply chain, and the inspection standard is not limited to the financial indicators of an enterprise. Financial institutions implement closed credit to enterprises in the whole supply chain according to the real trade background and upstream and downstream credit strength of the enterprise, mainly based on the sales revenue of the enterprise or the determined future cash flow generated by trade. This is the advantage of supply chain finance. However, there are some risks in supply chain finance. There are many participating enterprises in a supply chain, and the mode of the supply chain will be different. This diversity and complexity may lead to the emergence of enterprises in a supply chain in the financing process with financial institutions. In order to obtain their own interests and maximize their own interests, it may threaten the interests of other cooperative enterprises in the supply chain to be damaged.

To study the risk problem in supply chain finance, for banks, from the uncontrollable risk of financing individual enterprises in the past to the controllable risk of financing enterprises as a whole in the supply chain, and by obtaining different information from each enterprise in the supply chain, firmly grasp the possible risks, keep them at the lowest level, and protect their own interests. For each subject in the supply chain, being able to control the risk of supply chain finance can not only ensure the stable operation of the supply chain system but also improve the efficiency and cooperation of the supply chain.

The vigorous development of information technology [14–17] has brought new opportunities to the financial risk assessment of the supply chain. Various advanced artificial intelligence methods, such as support vector machine (SVM) [18, 19], particle swarm optimization (PSO) algorithm [20, 21], and AdaBoost algorithm [22, 23], have been gradually applied in this field. This study is carried out under this background.

2. Credit Risk Evaluation Index System

Under the traditional financing model, there is a severe information asymmetry between the bank and the small and medium-sized enterprises applying for financing. It is difficult to make those small-scale, unsound financial systems, and their small and medium-sized enterprises that meet the requirements of bank guarantees or pledged assets are granted credit. Under the supply chain finance model, the evaluation indicators should consider the relationship between small and medium-sized enterprises and core enterprises and the overall situation of the entire supply chain to more comprehensively and accurately grasp the credit situation of financing enterprises. Therefore, based on the supply chain perspective, this paper considers the financial and nonfinancial status of

financing enterprises and core enterprises and the overall operation status of the supply chain. The combination of qualitative and quantitative indicators has redesigned the credit risk evaluation index system to reflect the risk level of the whole chain, as shown in Figure 1.

3. Algorithm

Assuming a training sample set of n samples $\{(x_i, y_i), (i = 1, 2, \dots, n)\}$, x_i is the first sample, $y_i \in \{1, -1\}$ is the classification hyperplane equation is $wx + b = 0$ (w is the normal vector of the hyperplane, b is the bias). It is assumed that the classification hyperplane can correctly classify samples into two categories, and the samples of the same category are placed on the same side of the hyperplane, that is, satisfying

$$\begin{cases} wx_i + b \geq 1, & y_i = 1 \\ wx_i + b \leq -1, & y_i = -1 \end{cases}, \quad (i = 1, 2, \dots, n). \quad (1)$$

Then, we can get $y_i(w_i + b) \geq 1$.

The geometric distance between the sample point x_i and the classification hyperplane is $d_i = wx_i + b/\|w\|$, and then, the distance between the two types of samples is $2wx_i + b/\|w\|$, set $|wx_i + b| = 1, 2|wx_i + b|/\|w\| = 2/\|w\|$. The optimal hyperplane should maximize $2/\|w\|$, that is, minimize $\|w\|^2/2$. Adding penalty factor A and slack variable B to the above problem can be transformed into

$$\begin{cases} m \frac{\|w\|^2}{2} + C \sum_{i=1}^n \xi_i, \\ s.t. y_i(w \cdot x_i + b) \geq 1 - \xi_i, i = 1, 2, \dots, n. \end{cases} \quad (2)$$

Lagrange function is built as

$$L(w, \xi, b, \alpha, \beta) = \frac{\|w\|^2}{2} + C \sum_{i=1}^n \xi_i - \sum_{i=1}^n \alpha_i [y_i(w \cdot x + b) - 1 + \xi_i] - \sum_{i=1}^n \beta_i \xi_i. \quad (3)$$

Due to the high-dimensional, nonlinear, and dynamic characteristics of supply chain financial evaluation indicators, SVM needs to introduce a kernel function $K(x_i, x_j) = \Phi(x_i)^T \cdot \Phi(x_j)$ to calculate the nonlinearity in high-dimensional space. The classification problem is transformed. Compared with several other SVM kernel functions, the radial basis (RBF) kernel function performs better in both linear and nonlinear data sets. Therefore, the radial basis kernel function is selected in this paper: $(x, x_i) = \exp(-\gamma\|x - x_i\|^2)$, $\gamma > 0$, is input to SVM.

According to equations (2) and (3), the original problem is transformed into a Lagrange dual problem:

$$\begin{aligned}
f(x) &= \text{sgn}[w^* \Phi(x) + b^*] = \text{sgn} \left[\sum_{i=1}^n \alpha_i^* y_i \Phi(x_i)^T \Phi(x) + b^* \right] \\
&= \text{sgn} \left[\sum_{i=1}^n \alpha_i^* y_i K(x_i, x) + b^* \right].
\end{aligned} \tag{5}$$

In the standard particle swarm optimization algorithm, the inertia weight ω is usually set to a fixed value, which is challenging to meet the dynamic requirements of the global search capability in the early stage of the algorithm iteration and the local search capability in the later stage. Based on the basic principles of particle swarm optimization, this paper considers the convergence accuracy and convergence speed of the algorithm. It uses the dynamic variation particle swarm optimization (DPSO) to optimize the parameters of the SVM, and the dynamic weights are as follows

$$\omega = \begin{cases} \omega_{\min} + \frac{(\omega_{\max} - \omega_{\min}) \times (f_i - f_{\min})}{f_{\text{avg}} - f_{\min}}, & f_i \leq f_{\text{avg}}, \\ \omega_{\max}, & f_i > f_{\text{avg}}, \end{cases} \tag{6}$$

where $f_{\text{avg}} = 1/n \sum_{i=1}^n f_i$ represents the average fitness value of the particle.

ω_{\max} and ω_{\min} are the maximum and minimum weights, f_i is the fitness value of the current particle, f_{avg} and f_{\min} represent the average fitness value and minimum fitness value of the particle $t - 1$ generation, respectively.

For the particle with $f_i > f_{\text{avg}}$, its ω value is ω_{\max} . For the particle with $f_i \leq f_{\text{avg}}$, when the particle fitness is the same, the ω value becomes larger. Otherwise, it becomes smaller. Drawing on the idea of genetic algorithm mutation, the mutation operation is introduced into the particle swarm algorithm. The particles jump out of the original area and enter other new areas to search to find a new group extreme value and cycle the mutation operation until the global optimum is found. The solution, the specific method is as follows.

Let the population fitness variance of the particle swarm be

$$\sigma^2 = \frac{1}{N} \sum_{i=1}^n \left(\frac{f_i - f_{\text{avg}}}{f} \right)^2, \tag{7}$$

where n is the number of particles in the particle swarm, and σ^2 represents the particle's degree of convergence. As σ^2 becomes smaller, the particle swarm gradually converges from a random search state. f represents the normalized scaling factor, and its values are as follows:

$$f = \begin{cases} m(|f_i - f_{\text{avg}}|), & \max |f_i - f_{\text{avg}}| > 1, \\ 1, & \text{else.} \end{cases} \tag{8}$$

Let the aggregation degree of particles be α , and the calculation formula of t generation α is as follows:

$$\alpha = 1 - \frac{\sqrt{1/N \sum_{i=1}^N (f_i^c - f_{\text{avg}}^t)^2} - \sigma_{\min}}{\sigma_{\max} - \sigma_{\min}}. \tag{9}$$

σ_{\max} and σ_{\min} represent the maximum and minimum fitness values of the standard deviation of all particles, respectively. According to the definition of population aggregation degree, the formula for the mutation probability of t generation particles is set as follows:

$$P_{t+1} = \frac{\lambda \cdot \alpha}{\ln(N \cdot m)}. \tag{10}$$

P_{t+1} is proportional to the particle aggregation degree α , $\lambda \in [3, 5]$ is a fixed constant proportional gain, N represents the size of the population, and m represents the dimension of the optimization problem. The algorithm flow is shown in Figure 2.

AdaBoost (adaptive boosting) is an ensemble learning algorithm that strengthens weak learners by iterating over the weights of training samples. In this paper, AdaBoost is used to train the DPSO-SVM learner. The algorithm implementation steps are as follows:

Step 1. Input N initial learning and training sample sets:

$$D = \{(x_i, y_i)\}_{i=1}^N, \tag{11}$$

where x_i is the sample feature of the sample space, y_i is the category symbol of the category space.

Set the weight matrix of the initial training samples:

$$W_1 = (\omega_{11}, \omega_{12}, \dots, \omega_{1i}, \dots, \omega_{1N}). \tag{12}$$

Assuming that the weights of each training sample are equal; namely, $\omega_i = 1/N$, ($i = 1, 2, \dots, N$).

Step 2. Use $W_t = (\omega_{t1}, \omega_{t2}, \dots, \omega_{ti}, \dots, \omega_{tN})$, training set data with weight distribution to learn, using DPSO-SVM as the base classifier

$$h_t(x_i): x_i \longrightarrow \{-1, 1\}. \tag{13}$$

Step 3. Calculate the classification error of the base learner:

$$\varepsilon_t = \sum_{i=1}^N \omega_t(i) I[y_t \neq h_t(x_i)]. \tag{14}$$

If $|\varepsilon_t|$ is greater than the error setting value, go to Step 4; otherwise, the iteration is terminated.

Step 4. Calculate the weight of the DPSO-SVM classifier. Set

$$\alpha_t = \frac{\{\ln[(1 - \varepsilon_t)/\varepsilon_t]\}}{2}. \tag{15}$$

Update the weight of the training sample $\omega_{t+1}(i) = \omega_t(i) \exp\{-\alpha_t y_i h_t\} / C_t$, C_t , C_t is the normalization factor. Then,

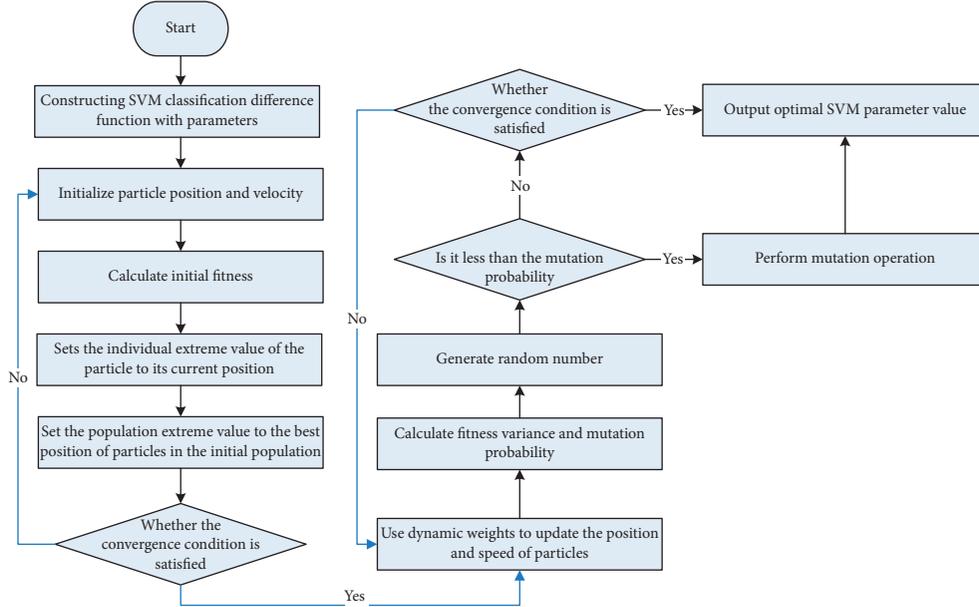

FIGURE 2: Algorithm flow.

$$C_t = \sum_{i=1}^N \omega_t(i) \exp\{-\alpha_t y_i h_t\}. \quad (16)$$

Return to Step 2 iteration.

Step 5. Combine each DPSO-SVM weak classifier:

$$f(x) = \sum_{t=1}^T \alpha_t h_t(x). \quad (17)$$

The final strong classifier model is obtained as

$$G(x) = \text{sign}[f(x)] = \text{sign}\left[\sum_{t=1}^T \alpha_t h_t(x)\right]. \quad (18)$$

4. Experiment

We select the relatively mature new energy vehicle supply chain in China's supply chain finance business as the research object. The financial and other relevant data of 60 domestic listed companies in the upstream and downstream of the chain in the past 5 years from 2016 to 2020, a total of 320 samples, excluding 52 samples with abnormal data, and the remaining 268 available samples, and released according to the annual 38 samples with "bad credit" were compared and screened out, and 230 samples with "good credit" were used as initial data.

Since the established evaluation index system has many variables and there is a certain correlation between each index, to simplify the data input to the model on the premise of ensuring the least loss of data information, principal component analysis (PCA) [24–26] is used to reduce the dimensionality of the collected data. Table 1 shows the eigenvalues and contribution rates of the principal components. It can be seen from Table 1 that the

cumulative contribution rate of the first 12 principal components is 86.6680%, so the first 12 principal components are extracted.

Table 2 shows the 12 linearly independent principal components extracted after the principal component attribute reduction of the 46 supply chain financial risk evaluation indicators of the 268 original data samples. Inputting the dimensionality-reduced data into the evaluation model can significantly improve computational efficiency; it also avoids the problem that the support vector machine RBF kernel function is not good at dealing with dimensionally nonuniform datasets.

Taking the extracted 12 principal components as the input variables of the support vector machine, set 200 samples in the training set, 68 samples in the test set, the class label of bad samples is 1, and the class label of good samples is 0.

The improved particle swarm algorithm optimizes the penalty coefficient C and parameter g of the radial basis (RBF) kernel function. The parameters $C_1 = 1.5$, $C_2 = 1.7$, the population size is 30, and the maximum number of iterations is set to 300, the value range of SVM penalty coefficient C and kernel parameter g is set to $[0.001, 10]$, particle position $X_i \in [-6, 6]$, particle velocity $V \in [-10, 10]$.

After optimal selection, the parameters of the SVM kernel function are screened to obtain $C = 2.8284$, $g = 0.087936$, which is used as the basic parameter of the model.

Taking DP-SO-SVM as the base classifier, using AdaBoost to integrate DP-SO-SVM, the obtained classification results are compared with the single classifier SVM, PSO-SVM, and BP-AdaBoost. Table 3 compares classification results between different indicators of each model.

Accuracy reflects the ability of the classifier to classify and discriminate the overall samples, that is, the ability of the model to identify good and bad samples correctly. An

enterprise with good credit is evaluated as an enterprise with poor credit in the credit evaluation. For the credit institution, it is only the customer's future loan interest loss. Default risk of credit institutions will lead to irrecoverable loss of principal and interest of credit institutions. Therefore, compared with the Recall indicator, which represents the prediction accuracy rate in instances labeled as positive samples, this paper pays more attention to the size of the specificity indicator, which reflects the prediction accuracy rate in instances labeled as negative samples. Due to the specific sample data, the predicted value of the support vector machine for the test set is a single value, and the ROC curve is degraded. At this time, the AUC index cannot fully reflect the classifier's performance, so this paper uses F_1 -Score, G -means, accuracy, and other indicators were used as the primary evaluation indicators. AUC was used as the auxiliary evaluation indicator.

The results in Table 3 show that all models can effectively classify the data collected in this paper, with the lowest classification accuracy of 87.21%. At the same time, it can be

seen that the recognition error of negative samples is always higher than that of positive samples, so, in future research, more attention should be paid to the misclassification rate of bad samples.

Comparing different models, the performance of the PSO-SVM model is significantly improved based on SVM. Using an adaptive mutation particle swarm algorithm to optimize SVM, DPSO-SVM has a better classification effect than standard PSO-SVM. The accuracy of the test set samples is improved from 92.34% to 93.57%. The AdaBoost-DPSO-SVM model integrated with the AdaBoost algorithm has a significant improvement in various indicators, and the model accuracy reaches the highest, 96.13%. Compared with the BP-AdaBoost model, its classification performance is better.

The specificity index of the AdaBoost-DPSO-SVM model is the highest among the five models, indicating that it has the lowest error rate in identifying bad credit companies as good credit companies. The G -means and F_1 -score index values that comprehensively reflect the output effect of the

model are the highest, 97.63% and 97.62%, respectively, indicating that the AdaBoost-DPSO-SVM model proposed in this paper can be better applied to the assessment of supply chain financial credit risk.

5. Conclusions

The research on credit risk first appeared in the field of finance. It is one of the main risk types faced by credit subjects such as enterprises and financial institutions. Many domestic and foreign scholars study credit risk from different perspectives. In our research, we pay more attention to the evaluation of supply chain financial credit risk. The diffusion of credit risk among many subjects is the result of the joint action of internal and external factors such as the psychological and behavioral factors of credit risk holders, the network composed of credit risk holders as nodes, and the behavior of market regulators. The artificial intelligence integrated application model of supply chain financial risk assessment constructed in this paper provides a new perspective for accelerating the supply side structural reform in China's financial field, making finance better serve the real economy, and realizing high-quality economic development.

Chinese character fonts not only carry the long history of Chinese civilization, but also burst out modern design art elements with distinctive Chinese characteristics. This article first analyzes the origin and writing form of several ancient Chinese characters and draws out the influence of the historical evolution of ancient Chinese characters on Chinese culture. In the basic theoretical structure of font design, traditional art elements and modern font design are integrated, and specific design cases are analyzed. A Chinese character packaging quality detection method combining machine vision and a lightweight convolutional neural network is proposed. First, the method based on threshold segmentation and affine transformation in machine vision is used to perform threshold processing on the image to be tested, and the Chinese character region is tilted and cropped; then, the network structure of the classification algorithm is designed according to the requirements of image features and defect recognition. The field images are produced, a dataset of Chinese character packaging defects is established, and then the proposed Chinese character packaging defect recognition network is verified and deployed to test the accuracy and detection speed of the algorithm deployed on the Jetson Nano embedded platform. Combined with theoretical research and case analysis, the design of packaging design series is practiced with the idea of combining Chinese character art design and classical culture.

1. Introduction

The birth of the written word symbolizes the progress of human society, and the culture of Chinese characters, which has undergone millennia of baptism, is the only ancient script that has survived and is still in use today [1, 2]. The study of the visual arts of Chinese characters has gradually become an important part of the design and is widely used in modern graphic design, such as poster design, packaging decoration and product description, book layout design, and media advertising communication. Packaging plays an increasingly important role in modern design trends, and more and more industries require product packaging design. For example, material products and other series of physical packaging belong to the traditional packaging design category, whereas film and media, advertising, and corporate image belong to the new modern packaging [3, 4].

Regardless of the modern and traditional packaging, all put words in the first place of design, and Chinese characters are an important member of font design. The design of Chinese characters in packaging design not only expresses the excellent Chinese civilization, but is also an outstanding representative of modern Chinese design. Through the study of the artistic expression of Chinese characters, it is possible to gain a deep understanding of the ideology and aesthetic flavour of Chinese civilization, to lay a good foundation for modern type design, to further explore the relationship between tradition and modernity, to promote a better breakthrough in the international development environment of modern art design of Chinese characters, and thus to better express the national spirit and Chinese style of packaging design. National cultural values and traditional art forms are the artistic sources of Chinese character font design. Especially in packaging design, the Chinese character

art form, with the modern design concept as the medium of packaging materials, conveys the connotation of Chinese character culture from the perspective of visual art, which has very important research significance and artistic value [5–7].

Chinese characters contain the long cultural history of our country and at the same time have a rich cultural heritage. It is not only a character, a language, but also a spirit, a heritage. Chinese characters have a wide variety of expressions, whether they are pictographs or morphological characters, and they have a unique charm that is much loved by Chinese children and even by people from overseas. Because of their plasticity, Chinese characters can have a strong visual effect in terms of shape, size, font, and meaning, conveying a message or even an aesthetic effect [8]. This feature of Chinese characters was discovered and explored by businessmen, so Chinese fonts began to appear in the design of product packaging, and this new form soon came to be noticed and loved by the public, and many businesses began to compete to imitate it, in order to give full play to the promotional role of Chinese fonts and to express the efficacy of the product vividly. Here we look at the linguistic expression of Chinese fonts in product packaging, and see the visual effect it plays [9].

The application of Chinese character font epigraphic decoration design in product packaging, from the text pen shape: the structure of Chinese characters is actually complex, different Chinese characters are composed of different strokes that make up the shape of the text, which is often referred to as the text pen shape. The brush shape is a type of Chinese character decoration and is used more often in product packaging [10].

The structural shape of the characters: different characters have different artistic shapes and are suitable for different product packaging designs. And some Chinese characters have a vivid image, which can give a good visual impact to a certain extent. We have just analyzed the characters from the perspective of strokes, and now we are talking about how to do a good job of decorating the characters from the point of view of the overall shape and the overall structure of the characters. Some Chinese characters have fewer strokes and the overall structure is simple and easy to understand, giving people a sense of simplicity and generosity. Such a Chinese character structure is combined with some novel and fun patterns, and then the text is processed through computer technology to enrich the image. Of course, different products have different packaging concepts and there is a great deal to be said for the choice of Chinese characters, which is something that packaging professionals should be aware of when they are working on the packaging [11, 12].

This article proposes a method for detecting the quality of Chinese character packaging by combining machine vision and lightweight convolutional neural networks. Firstly, a method based on threshold segmentation and affine transformation in machine vision is used for shareholding, skew correction, and cropping of the Chinese character region of the image to be measured; then, the network structure of the classification algorithm is designed

according to the image characteristics and defect recognition requirements; finally, the production site images are collected to build a Chinese character packaging defect dataset, after which the proposed Chinese character packaging defect recognition network is validated and tested for the accuracy and speed of the algorithm deployed on the Jetson Nano embedded platform [13]. The accuracy and detection speed of the algorithm deployed on the Jetson Nano embedded platform was tested. Combining theoretical research and case studies, the design of the packaging design series is practiced with the idea of integrating Chinese character art design and classical culture. To sum up, we have a certain understanding of the visual language effect of Chinese character font design in product packaging. From the appearance, imagery, and overall calligraphy structure of Chinese characters, we explore how to integrate Chinese character fonts into packaging design, which can not only promote product promotion and the effect of sales, but also to meet people's aesthetic psychology. By analyzing the application of Chinese fonts in packaging design, the development of Chinese packaging is promoted.

2. Related Works

The study of Chinese fonts in packaging design, first of all, should cut into the subject from the perspective of philology, the process of development and evolution of Chinese fonts in the textual dimension is the mainstream academic argument of current textual research, by knowing the origin of civilization and the development of philology, to establish a theoretical basis for subsequent design practice [14].

Domestic research into the basic theory of packaging design is currently at a rapid stage of development, where the combination of theoretical literature and excellent design practice work has led to packaging having the role of an industry vane in the discipline of graphic design. Firstly, regarding the current status of the basic theory of packaging design, [15] makes a clear study of the relationship between packaging development and economic culture and provides a detailed overview of the essential functions of packaging, integrating the study of new materials and new design concepts into innovative design practice. In [16], the principles of visual communication design are systematically and clearly outlined, from conceptual theory to physiological activity, and sublimated through the study of visual perception into a perceptual account of visual art. In [17], a series of theories of packaging design is elaborated, including a complete theoretical study of the functional nature, cultural values, market positioning, design elements, and printing and manufacturing.

With the development of modern thinking of fashion and nationalism, packaging design is more dependent on the decoration of visual art design based on theoretical research, breaking through the traditional packaging forms and rules of design, which is the goal of the pursuit of market value. In [18], the visual language of packaging design such as text, colour, and graphics is studied separately to pursue a more suitable visual symbol design for the product, which is applied to design practice according to theoretical research.

In [19], the chronological evolution of packaging design is systematically studied, from the mid-19th century to the 1980s, a period of about 150 years of packaging design cases, with Europe and the United States as the main objects of study, revealing the history of economic culture and packaging design processes in developed Western countries or regions, allowing an intuitive understanding of the evolution and development of advanced design concepts abroad. It has a certain reference value for the innovation of modern packaging art and design forms in China. Reference [20] describes the rise of Japanese design after World War II and analyzes, from the perspective of reason and sensibility, the different senses of modern design for society, human beings, and nature, which is useful for the study of packaging design and consumer psychological appeal.

The packaging of Chinese characters is the final step in the process of testing the quality of Chinese characters before they are used as packaging to go to market. Compared to manual inspection, machine vision has great advantages in terms of speed and accuracy. Reference [21] used Blob Analysis on a smart camera to detect missing bottles and breaks in the packaging of specific colour Chinese characters; [22] used Speeded Up Robust Feature (SURF) with a support vector machine (SVM) to detect defects.

3. The Imagery of Chinese Fonts

The connotations of Chinese characters are rich and varied, and in addition to the use of representational decoration of Chinese characters as we have described earlier, the imagery of Chinese fonts can also be applied to the design of product packaging. What is the imagery of Chinese characters? The imagery of Chinese characters refers to the unique connotation of Chinese characters, combining this connotation with the essential features and practical functions of the product, enriching the expression of Chinese characters by implying meaning in form [23]. The imagery of Chinese characters can be divided into the morphological expression of the characters and the meaning of the characters. The morphological expression means finding the commonalities between the characters and the product and combining them with the meaning of the words in a comprehensive graphic art, which will produce unexpected design effects. The meaning of the word is to find the appearance or properties of the product and design the world by incorporating creative elements into the word, which can sometimes achieve a very good mood.

Whether we are talking about representations or imagery, in the end, it comes back to the calligraphic script and stylistic structure of the Chinese characters. The content of the text is important, as it introduces the product name, but if we focus on the content and structure of the art, the effect of the packaging will be doubled. The requirements for packaging are getting higher and higher, and the forms of packaging are becoming more and more diverse, with a series of new forms of expression such as images being discovered all the time. To continue to play the role of Chinese fonts in packaging design, we need to give more thought to the artistic and decorative quality of Chinese characters [24].

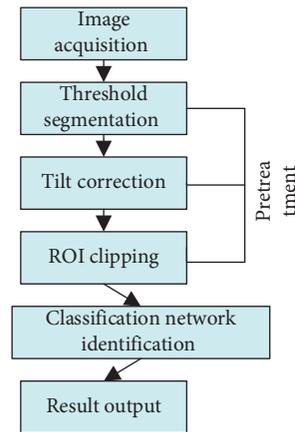

FIGURE 1: Flow of Chinese character packaging quality detection algorithm.

To sum up, we have a certain understanding of the visual language effect of Chinese character font design in product packaging, from the appearance, imagery, and overall calligraphic structure of Chinese characters to explore how to integrate Chinese fonts in packaging design, both to play the effect of product promotion and sales and to meet people's aesthetic psychology. Through the analysis of the use of Chinese fonts in packaging design, we will promote the development of Chinese packaging.

4. Programme of This Article

In order to meet the detection task of this article and to achieve low-cost deployment and improve production efficiency in a production environment, this article combines traditional image processing methods and designs a Chinese character packaging defect detection algorithm with reference to the Mobile Net series network structure. The first step is image acquisition, followed by preprocessing (threshold segmentation, tilt correction, ROI cropping) and recognition by the classification network, and finally the results are outputted. First, the original image captured by the industrial camera is preprocessed, including threshold segmentation, position correction, and region of interest (ROI) cropping [25], to obtain a single Chinese character region image; then the single Chinese character region images are fed into the packaging defect classification network in turn; finally, the category of each Chinese character region image is outputted (see Figure 1).

5. Image Preprocessing

The colour image was first grey-headed, that is each pixel in the image had equal component values in all three RGB channels. After grey-scale processing, the original image was cropped according to ROI based on the external trigger used by the camera and the relatively stable region of the Chinese character blister pallets in the image to reduce computational effort, and the region of interest image $f(x, y)$ was obtained, as shown in Figure 2(a). The blister tray in the grey-scale image is close to the grey value of a part of the

FIGURE 2: Image threshold process.

block in the background, and direct use of global shareholding cannot effectively separate out the tray. Figure 2(b) shows the result of the direct use of the maximum inter-class difference method (Otsu). Observing the ROI image shows that the edge distinction of the blister tray box background is obvious, so the edge information can be used to assist Otsu in shareholding [26].

In this article, the ROI image is first smoothed using a Gaussian filter, then the image edges are calculated using the Laplace operator [27], and then the Laplace image is thresholded using 99% of the absolute value of the Laplace image to specify a threshold non-negative T to obtain a sparse set of pixels $g_t(x, y)$, and the process can be expressed as:

$$g_t(x, y) = \begin{cases} 1, & |R(x, y)| \geq T, \\ 0, & \text{otherwise} \end{cases} \quad (1)$$

where $R(x, y)$ is the response of the filter template at the centre of its coverage area. The ROI image $f(x, y)$ is then multiplied by $g_t(x, y)$ to obtain $g(x, y)$:

$$g(x, y) = f(x, y) \times g_t(x, y). \quad (2)$$

Based on the histogram of non-zero pixels, the ROI image was minimized using the Otsu method [28], and the results are shown in Figure 2(c). Although a part of the

interference region with similar grey scale is also segmented, the addition of edge information makes the blister tray and the interference region in the fruit segmented into mutually independent regions, and the threshold result is subjected to the connected domain operation, and then the regional area filtering is performed to obtain the complete blister tray segmentation image $I(x, y)$, as shown in Figure 2(d).

5.1. Chinese Character Packaging Defect Recognition Network.

In this study, we use the Mobile Net series of networks as the basis for improvement. In the Chinese character packaging defect detection task, the image content of the Chinese character region after cropping and segmentation is relatively single, and there are few image categories, so there is no need for an overly deep network to extract features, and hence we can appropriately reduce the number of network layers and use continuous down sampling. The original MobileNetv2 network uses global average pooling after the last layer of convolution, but since the network in this article is a rectangular image input, the last layer of convolution produces a rectangular feature map, so the pooling layer is changed to adaptive average pooling [13].

The specific structure of the network is shown in Figure 3: two fully convolutional (FC) layers, five convolutional

blocks, an adaptive average pooling layer, a fully connected layer, and a Softmax classification function.
