Computing intelligence is built on several learning and optimization techniques. Incorporating cutting-edge learning techniques to balance the interaction between exploitation and exploration is therefore an inspiring field, especially when it is combined with IoT. The reinforcement learning techniques created in recent years have largely focused on incorporating deep learning technology to improve the generalization skills of the algorithm while ignoring the issue of detecting and taking full advantage of the dilemma. To increase the effectiveness of exploration, a deep reinforcement algorithm based on computational intelligence is proposed in this study, using intelligent sensors and the Bayesian approach. In addition, the technique for computing the posterior distribution of parameters in Bayesian linear regression is expanded to nonlinear models such as artificial neural networks. The Bayesian Bootstrap Deep Q-Network (BBDQN) algorithm is created by combining the bootstrapped DQN with the recommended computing technique. Finally, tests in two scenarios demonstrate that, when faced with severe exploration problems, BBDQN outperforms DQN and bootstrapped DQN in terms of exploration efficiency.

1. Introduction

IoT analytics heavily relies on reinforcement learning techniques. Making decisions consecutively is the foundation of reinforcement learning. Simply said, every next input depends on the output of the previous input and the output depends on the state of the current input. Model-based techniques may identify a solution analytically without actually engaging with the environment and can generate the precise result of every state and action interaction in RL. Because the environment is frequently too complicated to create a model, the majority of real-world problems lack models. Second, model-free solutions in RL can only monitor the behavior of the environment through real interaction with it. Machine data are often fragmented and/or include a time aspect. Also, when we accept the data coming

from a certain device, gadgets can act differently depending on the context. Therefore, it is tricky to catch all instances for the data and the data cleaning phase of an algorithm. Continuous sensor data monitoring is also time-consuming and pricey. Reinforcement learning technologies embedded with IoT can help these hazards. These algorithms pick up new information on their own, freeing the programmer to focus on other important responsibilities rather than bothering about the training procedure and data collecting procedure. These developments in computational intelligence methodologies have the potential to greatly improve reliability in terms of latency and processing resources without sacrificing service quality. However, the explosive increase in the use of sensors and actuators for next-generation IoT systems generates enormous quantities of information that are processed all through the cloud, which can materially reduce processing efficiency. Sensor technology is evolving at a rate never witnessed before, driven by advances in materials' science and nanotechnology. As a result, it is becoming more accurate, smaller, and less expensive and capable of detecting things that were not imaginable before. In fact, in a few years, we will see a trillion new sensors deployed yearly since sensing technology is advancing so quickly. Actuator is a different kind of transducer that is used in many IoT systems. Simply said, an actuator works the opposite way from a sensor. It transforms an electrical input into physical movement. Actuators come in a variety of forms, such as electric motors, hydraulic systems, and pneumatic systems. In addition, IoT sensors and actuators can cooperate to provide automation on an industrial scale. Finally, over time, analysis of the data generated by these sensors and actuators might yield insightful business information. Furthermore, the traditional reinforcement learning methods may address exploration issues successfully, but there are certain constraints: the state space of a Markov decision process must be both discrete and constrained; however, in this case, it was not given sufficient attention or focus. Moreover, there are three main problems in the field of reinforcement learning [1]: (1) generalization, (2) how to balance the relationship between exploration and utilization, and (3) credit assignment problem. In recent years, the research hotspot is mainly focused on the generalization problem in large-scale state space, and there is a new research field named deep reinforcement learning [2]. The rise of this field began after the DeepMind team proposed the DQN (deep Q-network) algorithm [3]. The main contribution of the DQN algorithm is to combine deep learning [4] and reinforcement learning [5] and through experience playback (experience replay) and target network mechanism to solve some problems related to generalization [6]. Since then, many improved versions of the DQN algorithm have been proposed [7, 8]. These algorithms mainly focus on the generalization problem, and the main problem to be discussed in this paper is how to balance the relationship between exploration and utilization with the integration of IoT and reinforcement learning. A learning algorithm may be thought of as a stochastic mapping, or a channel in information theory, that takes training data as input and produces a hypothesis as output.

The generalization error is the difference between the output hypothesis' population risk and its empirical risk on the training data. It quantifies the degree to which the learnt hypothesis suffers from overfitting. The usual method of measuring generalization error is based on either specific complexity metrics of the hypothesis space. The reciprocal data between the collection of empirical hazards of the available hypotheses and the algorithm's final output may be utilized to efficiently assess and control bias in data analysis, which is analogous to generalization error in learning issues. The total variation data between a random instance in the dataset and the output hypothesis are used to calculate the generalization error in learning problems; however, the approach is limited to bounded loss functions. Another benefit of relating the generalization error to the input-output mutual information is that, unlike the VC dimension or the uniform consistency, which only depends on the hypothesis space or the learning algorithm, the latter quantity depends on all components of the learning problem, including the dispersion of the dataset, the hypothesis space, the learning algorithm itself, and possibly the loss function. The input-output mutual information may be more closely linked to the generalization error than typical generalization-guaranteeing parameters of interest since the generalization error might substantially depend on the input dataset.

IoT analytics heavily relies on deep learning techniques. Machine data are often sparse and/or contain a temporal component. Even when we believe the data coming from a certain device, gadgets might act differently depending on the environment. Therefore, it is challenging to capture all instances for the data preprocessing/training step of an algorithm. Continuous sensor data monitoring is also time-consuming and costly. Deep learning techniques can reduce these hazards. Deep learning algorithms pick up new information on their own, freeing the developer to focus on other important tasks rather than worrying about the training process. A machine learning method called reinforcement learning involves the agent interacting with its surroundings in an effort to optimize the financial reward. The human brain communicates with the outside world and makes use of that interaction to comprehend and survive in that world. Reinforcement learning compares learning about the environment to learning about the human brain and sensory processing system. It is a process where an agent must investigate every aspect of the system to comprehend it. It is not practical in many situations due to the length of time required to converge and obtain an optimal policy. The problem with traditional RL is its dimensionality. The number of factors that an RL agent must learn increases exponentially as the environment gets more complicated. Over the network, IoT links millions of devices. Because IoT devices are so dynamic, a complicated RL may constantly acquire new data to adapt to many advanced situations. Some IoT ecosystems are so complicated that modeling them is challenging. The effort needed to simulate and solve such a complicated environment is reduced by RL. Think of a challenging IoT case where we need to develop a model to address a challenge.

The hottest supervised learning algorithms in the field of machine learning can only learn relevant patterns from data

collected by humans, but what data need to be collected, or which data are important, is still up to humans to decide. However, IoT-based reinforcement learning can obtain different observation sequences by selecting different actions, and then learning-related patterns according to the obtained observation sequences. That is to say, within the scope of reinforcement learning, an algorithm is needed to decide whether to select the current optimal action (use) or choose an action (exploration) that has the potential to bring long-term benefits. However, algorithms such as DQN use a simple heuristic exploration strategy ε-greedy, which only randomly selects an action with the probability of ε ($0 \leq \varepsilon \leq 1$) to achieve the effect of exploration. However, such an exploration strategy is extremely inefficient. Although the DQN algorithm can reach or even exceed the human level in an Arcade Learning Environment [9], the time complexity of the algorithm is O (2N) when faced with deep exploration problems [4].

A good exploration strategy must consider the information gained brought by the selected action, and the information is mainly measured by the degree of uncertainty of the estimated value, then a good exploration strategy can be obtained only by introducing probabilistic thinking. As early as 1998, Dearden and other scholars proposed Bayesian Q-learning [10] to balance the relationship between exploration and utilization. Since then, other researchers have proposed reinforcement learning algorithms under the Bayesian framework [11, 12]. However, the computational processes of these algorithms are relatively complex and cannot be combined with deep learning techniques. The main problem with the combination of Bayesian reinforcement learning and deep learning is that it is intractable to obtain the posterior distribution of neural network parameters in high-dimensional state space.

The contribution of this paper is to propose a new calculation method that can generate samples of the posterior distribution of parameters, and the IoT-based deep reinforcement learning algorithms using this calculation method are collectively referred to as Bayesian deep reinforcement learning algorithms. Machine intelligence techniques govern computation, regulation, system lag, reliability, consistency, effectiveness, and energy efficiency at multiple elements in IoT ecosystems. These methodologies are in control of information gathering, linking devices to the Internet, data processing, and decision-making without interpersonal interactions. Currently, this calculation method is only applicable to value-based deep reinforcement by the combination of intelligent learning algorithms with policy-based deep reinforcement learning algorithms. Combining the bootstrapped DQN with this calculation method, a new algorithm BBDQN (Bayesian bootstrapped DQN) is obtained, and the exploration efficiency of the algorithm is verified through experiments in two environments, one of which is a lattice world with a deep exploration structure. Another experimental environment is the classic control problem Mountain Car, which does not have a deep exploration structure itself, slightly modify its reward function to make it have a deep exploration structure, and then conduct experiments on the modified Mountain Car.

The experimental results show that BBDQN can solve the deep exploration problem, and its exploration efficiency is better than the DQN algorithm using a random exploration strategy (i.e., ε-greedy) and the bootstrapped DQN algorithm. Through the use of randomized value functions, the straightforward algorithm bootstrapped DQN explores in a computational and statistically efficient way. Bootstrapped DQN engages in temporally extended (or deep) exploration as opposed to dithering tactics such as epsilon-greedy exploration; this can result in tenfold quicker learning. We illustrate these advantages in the expansive arcade learning environment and complicated stochastic MDPs. Bootstrapped DQN significantly reduces learning times and enhances performance in the majority of Atari games. In a traditional bootstrap, you simulate sampling your data from a population by collecting samples with substitutions from your data. This procedure is repeated K times to mimic drawing your sample several times, allowing you to assess the potential variability estimate of your statistic (a function) over various samples drawn from the same population (Xk). Consequently, we are emulating the statistic's "sampling distribution" (variability due to the sampling process). In the specified Bayesian bootstrap, you are estimating the posterior distribution of the estimates of the statistic ϕ (X) and the distribution of your data $X = \{x1, x2, \ldots, xN\}$. It is a nonparametric model in which your data points are assumed to have a categorical distribution (the likelihood).

Even though the DQN has already considerable success, it may still be enhanced with the aid of a variety of different methods, including a more precise approximation approach for the state action-value function and prioritized experience replay. Due to its capacity to balance exploration and exploitation in reinforcement learning, the exploration approach should be the most crucial of these strategies. The exploration strategy determines the course of action to pursue given the current situation and has the potential to affect how the process will ultimately develop in the future. Given its significance, several exploration tactics have been suggested. The strategy employed in the first DQNs and possibly the one that is utilized the most is the epsilon-greedy one. The greedy approach mostly selects the action that is thought to be the best, but it also randomly selects an action with little probability. An activity that has been proven to be a poor option may be repeatedly picked in the succeeding decision-making process since the activities are chosen entirely at random for investigation. To increase the effectiveness of exploration, add some Gaussian noise. For jobs with well-defined incentives, these heuristic strategies are enough.

A significant issue for reinforcement learning is still effective exploration in complicated situations. We suggest the bootstrapped DQN, a straightforward technique that uses randomized value functions to explore in a way that is both computationally and statistically efficient. The bootstrapped DQN engages in temporally extended (or deep) exploration as opposed to dithering tactics such as epsilon-greedy exploration; this can result in tenfold quicker learning. We illustrate these advantages in the expansive Arcade Learning Environment and complicated stochastic

MDPs. The bootstrapped DQN significantly reduces learning times and enhances performance in the majority of Atari games. The bootstrapped DQN builds many posterior estimates using the same original data. The random initialization of the weights for the heads is what causes the variety of approximate solutions. This implies that these heads first try random actions (due to varied random initials) but that some (but not all) of the heads will learn from it due to bootstrapping when some heads discover a favorable state and generalize to it. Other heads will eventually either discover additional excellent states or come to understand the greatest good states discovered by the other heads. Simply employing the bootstrapped DQN as an exploitative approach is quite good in and of itself, even better than the vanilla DQN. This is due to bootstrapped DQN's deep exploration capabilities, since it may employ the best states, it knows while simultaneously planning to try out states it does not know anything about. Even in the films, it is clear that the heads agree on all critical decisions but disagree on other, less significant actions.

2. Related Work

The exploration efficiency of the reinforcement learning algorithm directly affects the sample efficiency of the algorithm, and improving the exploration efficiency can reduce the number of time steps required to train the agent. The Bayes policy is a criterion for measuring the exploration efficiency of reinforcement learning algorithms; however, computation of Bayesian optimal policies is tricky because the computation time grows exponentially with the problem space (states and actions) [13]. There are many studies considering exploration efficiency, and Liu et al. [14] were the authors to propose it, and their work confirmed that polynomial-time reinforcement learning algorithms must use multiperiod exploration. Based on their work, a series of tabular reinforcement learning algorithms has been proposed [15–21]. The exploration methods mentioned in these papers are more efficient than ε-greedy and Boltzmann exploration, but these methods all cannot handle the curse of dimensionality. Deep reinforcement learning algorithms [3, 22, 23] are proposed in recent years to deal with large state spaces tend to use ε-greedy exploration. These algorithms can get good results in Atari arcade games and Go, but they do not have any practical applications; the inefficient exploration efficiency makes these algorithms only trained in simulated environments. By randomly selecting between exploration and exploitation, epsilon-greedy is a straightforward strategy for balancing exploration and exploitation. Epsilon refers to the likelihood of deciding to explore, and the epsilon-greedy, with a low probability of exploring, exploits most of the time. Theoretical computer science, optimization, machine learning, and decision theory all use exponential weighting schemes as basic tools. Exponential weighting systems, often known as Boltzmann, Gibbs, or softmax exploration strategies, are frequently employed in reinforcement learning to balance exploration and exploitation. The chance of selecting an arm in the most popular variant of

Boltzmann exploration is inversely related to an exponential function of the empirical mean of the reward for that arm.

For the exploration of large-scale state space, some researchers proposed a model learning algorithm [24]. The problem with this method is that it can only solve simple model problems. For complex models, the calculation of this method is also difficult. Some researchers have proposed a policy learning algorithm [25], which mainly solves the problem of continuous action space, such as robot control, but when the size of the policy space is exponential, this method cannot guarantee the efficiency of exploration. Another class of approaches encourages exploration by assigning rewards to infrequently visited states based on pseudocounts [26] or density models [27].

How to ensure the exploration efficiency, and generalization of the algorithm has always been a difficult problem in reinforcement learning, and some researchers have thought of using Bayesian thinking to deal with this problem, such as the Bayesian Q-learning algorithm [10], but this algorithm can only deal with state A limited number of problems; there is also the RLSVI (randomized least-square value iteration) algorithm proposed in this literature [28], which is only suitable for linear function approximates and cannot be combined with neural networks, a nonlinear function approximate; while the algorithm proposed in this literature [29] uses the neural network as the feature extractor that takes the input of the last layer of the network as a feature and then uses Bayesian linear regression to calculate the Q-value. RLSVI works similarly to least-squares value iteration (LSVI) and has many of the same principles as other closely related algorithms such as TD, LSTD, and SARSA. The difference between RLSVI and the alternatives is that the algorithm explores by randomly sampling statistically plausible value functions, whereas the alternatives are typically used in conjunction with action-dithering schemes such as Boltzmann or epsilon-greedy exploration, which results in highly inefficient learning. The randomized least-squares value iteration (RLSVI) technique rapidly investigates and generalizes value functions with linearly parameterized values. It is, however, reliant on hand-designed state representation, which necessitates engineering effort for each scenario.

Research in Bayesian neural networks has not been mainstreaming [30, 31]; however, there have been recent signs of a resurgence, with many concerns about quantifying the uncertainty of datasets. Methods [32] have been proposed, and the authors of this paper are inspired by these methods and propose a deep reinforcement learning algorithm that can efficiently compute Bayesian posteriors. Because they provide us with whole distribution across the regression parameters, Bayesian regression methods are known to be particularly powerful. Bayesian linear regression offers a built-in technique for calculating insufficient or unevenly distributed data. The coefficients can have a prior applied to them so that, in the absence of data, the prior can be used instead. In Bayesian linear regression, statistical analysis is carried out under Bayesian interface conditions. To create linear regression, we do not utilize

point estimates but rather probability distributions. An output is produced using a probability distribution rather than more traditional methods of regression. Bayesian linear regression seeks to identify posterior rather than model parameters.

3. Background Knowledge

A collection of potential world states S, a set of models, a set of potential actions A, a real-valued reward function $R(s, a)$, and a policy are all components of a Markov Decision Process (MDP) model. Each possible state for the agent is represented by a set of tokens called a state. A model, often known as a transition model, describes how an action changes a state. Specifically, the transition $T(S, a, S')$ describes a situation in which being in state S and performing an action "a" transports us to state S' (S and S' may be the same). All conceivable actions are included in an action A. The collection of actions that can be executed while in state S is defined as $A(s)$. A reward is a reward function with a real value. The reward for merely existing in the state S is denoted by $R(s)$. The reward for existing in a state S and doing an action "a" is indicated by the expression $R(S, a)$. The reward for being in a state S, doing an action "a," and then ending up in a state S' is denoted by the formula $R(S, a, S')$. The Markov Decision Process has a solution in the form of a policy. A mapping from S to a is a policy. It signifies that when in state S, action "a" should be conducted. Reinforcement learning problems are usually modeled as Markov Decision Processes. The Markov Decision Process used in this paper can be expressed as (S, A, T, R, γ), where S is the state space, A is the action space, and $A(s), s \in S$ is the action set available in state s; T is the state transition probability, $T(S_{t+1}|s_t, a_t)$ represents the probability of transitioning to state S_{t+1} after taking action at state s_t; R is reward functioned, $R_{s,a}$ denotes the mean value of the reward distribution obtained after taking action a in state s, and let r denote the immediate reward obtained after taking action a in state s (it can also be understood as a sample obtained from the reward distribution), and then there is $R_{s,a} = E[r|s_t = s, a_t = a]$; $\gamma \in [0, 1]$ as the discount parameter used to control the weight of future rewards.

The goal of reinforcement learning is to learn a policy that maximizes the discounted cumulative reward obtained by the agent. Let π denote the policy and $\pi(a|s)$ denote the probability of taking action a in state s. Then, introduce the concept of action-value function (Q function), the action-value function $Q_\pi(s, a)$ table under the policy π, and the agent can obtain the expected discounted cumulative reward after taking action states, namely,

$$Q_\pi(s, a) = E_\pi \left[\sum_{t=0}^{\infty} \gamma^t r_t | s_0 = s, a_0 = a \right]. \tag{1}$$

This equation can also be expressed recursively:

$$Q_\pi(s, a) = R_{s,a} + \gamma \sum_{s^t, a^t} \left(s'|s, a \right) \pi \left(a'|s' \right) Q_\pi \left(s', a' \right). \tag{2}$$

We denote the optimal policy by π^* and the optimal action-value function by Q^*. Since the optimal policy is the policy that obtains the maximum discounted cumulative reward, the Q^* function can be written as follows:

$$Q^*(s, a) = R_{s,a} + \sum_{s^t} T\left(s'|s, a \right) \max_{a'} Q^* \left(s', a' \right). \tag{3}$$

Equation (1) is also known as the Bellman optimality equation. For each pair of s, a, there is an equation. By combining all these equations, a system of equations is obtained, which can be solved by linear programming methods. This system of equations yields the optimal action-value function $Q*(s, a)$ for all s, a. The optimal action-value function can also be solved by dynamic programming methods such as policy iteration or value iteration. The optimal strategy can be expressed by the optimal action-value, that is, for all states s, select the action $a = \arg\max a\, Q*(s, a)$ that maximizes the optimal action-value function in this state; if there are multiple actions satisfying with this condition, one of these actions can be randomly selected. It can be seen from equation (1) that this method requires a known environment model—state transition probability T and reward the function R to be calculated. If the environment model is not known, other methods are needed to find the maximum value. Optimal strategies, such as Q-learning algorithms, are used to calculate the optimal action-value function, iteratively, and the update rule is

$$Q(s, a) \leftarrow Q(s, a) + \alpha \left[r + \gamma \max Q\left(s', a' \right) - Q(s, a) \right]. \tag{4}$$

Among them, α is the learning rate, and the reward r and the next state, s are both fed back to the agent by the environment. In the case of limited state space and action space, as long as the learning rate sequence satisfies the random approximation condition and all state-action pairs are in the case of continuous updates, the algorithm converges to the optimal value function Q^* [5] with probability 1.

In large-scale state spaces, the traditional reinforcement learning algorithm Q-learning is no longer applicable, but this problem can be solved by combining function approximation techniques. The combination of neural networks and reinforcement learning is a hot research topic in recent years, and the DQN algorithm is a model in this regard. When using a neural network, the action-value function can be expressed as $Q_\theta(s, a)$, where θ is a parameter of the neural network. We compute the target value from feedback from interacting with the environment:

$$y = r + \gamma \max Q_\theta \left(s', a' \right). \tag{5}$$

With the target value and the predicted value, the parameter θ of the neural network can be updated by the stochastic gradient descent algorithm. The update rule is

$$\theta \leftarrow \theta - \alpha \nabla_\theta \left[y - Q_\theta(s, a) \right]^2. \tag{6}$$

If you do this directly, the effect is not very good because the neural network is a supervised learning method, which requires that each training sample is independent of each other, and the samples collected by reinforcement learning are related to each other, and each update of the parameters will affect the target value, causing the target value to be unstable. As mentioned in the DQN algorithm, only two mechanisms are needed to alleviate this problem: experience replay and the target network. The experience replay mechanism is that, each time the agent interacts with the environment, the information (s, a, r, s') of the interaction is stored in the memory pool (replay buffer), and the agent randomly selects from the memory pool for each update. We take a certain number of samples and use these samples to update the parameters. The target network mechanism is that the agent maintains two Q networks, one network is used to select actions and update them in real time and the other network (target network) is used to calculate the target value and will not update in real-time the target value used in each update, and it can be expressed as

$$\gamma = r + \gamma \max Q^{\text{target}}\left(s', a'\right). \tag{7}$$

Among them, Q^{target} represents the target network, and only after the specified time step has passed, the parameters of the two networks will be synchronized once.

4. In-Depth Exploration of the Problem

The chain problem mentioned is a kind of deep exploration problem, and this paper will use this problem to analyze the exploration efficiency of the ε-greedy strategy and Boltzmann exploration. To simplify the calculation, some modifications have been made to the chain problem as discussed in the literature [10]. ε-greedy exploration is to randomly choose one of all available actions with probability ε, and choose the best action for the moment with probability $1 - \varepsilon$. The probability of selecting each action in Boltzmann's exploration is proportional to the estimate of the action-value function, which is calculated as

$$\pi\left(a|s\right) = \frac{e^{Q'(s,a)/t}}{\sum_i e^{Q'(s,a)/t}}. \tag{8}$$

Among them, Q is the estimation of the action-value function, t is the temperature parameter, the larger the value of t is, the closer the strategy is to the random strategy, and the smaller the value of t is, the closer it is to the greedy strategy. A chain problem is used to analyze the exploration efficiency of ε-greedy exploration and Boltzmann exploration. The state transition diagram of this problem is shown in Figure 1. Each arrow in the diagram corresponds to an action and reward. The starting state of the problem is 1, and the termination state is N. Suppose the length of each episode (episode) $H = N - 1$, and no matter in which state, the choice of action a will have, a probability of 0.2 failure (failure means that the selected action and the actual action are inconsistent) and action b is deterministic. The optimal strategy for this problem is to always choose action a, and the
Figure 1: Chain problem.

average reward that the optimal strategy can get in each cycle is the probability $(1 - 0.2)^{N-1}$ that the strategy successfully reaches N. Whether it is ε-greedy or Boltzmann exploration, since there is no reward before reaching the target state N (i.e., the reward is 0), the estimated values of action a and action b are equal in all states, and the action selection is completely random; in this case, the probability of reaching state N through exploration is $(1 - 0.2)^{N-1} \times 2^{-(N-1)}$, just take the reciprocal of this probability to get the average required amount of reaching state N through exploration. The number of cycles, with l representing the required number of cycles, the following relationship is established:

$$\text{the } E[l] = \frac{1}{(1 - 0.2)^{n-1}} 2^{N-1} > 2^{N-1}. \tag{9}$$

From this inequality, it can be determined that a reinforcement learning algorithm using an ε-greedy strategy or Boltzmann exploration has a time complexity of $O(2^N)$ when faced with a deep exploration problem such as the chain problem, where N represents the size of the problem.

The exploration efficiency of epsilon-greedy exploration and Boltzmann exploration is examined using a chain problem. Figure 1 depicts the state transition diagram for this problem. Each arrow in the graphics represents an activity and its associated reward. The problem's initial state is 1 and its final state is N. The described chain issue is a type of deep exploration problem, and this study will utilize it to compare the exploration efficiency of the epsilon-greedy method with Boltzmann exploration. Epsilon-greedy exploration is the process of randomly selecting one of all potential actions with probability, and then selecting the optimal action for the moment with probability. In Boltzmann's exploration, the likelihood of picking each action is proportional to the estimated action-value function.

5. Bayesian Deep Reinforcement Learning

The benefits of exploration can be estimated by the value of information. The so-called value of information refers to the degree to which the information obtained through exploration leads to the improvement of the quality of future decision-making, and how quantifying the information obtained through exploration is the key. According to information theory, the amount of information brought by the exploration can be calculated by the uncertainty of the estimated value of the action selected by the exploration. The quantitative treatment of the ideas, parameters, and regulations regulating message transmission through communication networks is known as information theory. It was established by Claude Shannon in the middle of the 20th

century and has since developed into a vibrant branch at the intersection of communication theory and mathematics, promoting the advancement of other scientific disciplines. Some people consider information theory to be a subset of probability theory since the methods utilized in it are probabilistic in nature. Whether an analog or digital communication technology is used, information is its source. Information theory is a mathematical method for studying information coding, as well as quantification, storage, and communication. In [10], a Bayesian method is proposed to maintain this information; however, in this paper, the number of state-action pairs of the problem discussed is limited, and all the obtained state-action pairs can be recorded by recording all the variance and then calculate the amount of information. When the number of state-action pairs is too large, reinforcement learning will consider combining generalization techniques to solve this problem. If a linear function approximator is used, it can be estimated according to the Bayesian linear regression mentioned in [33] value variance. However, in recent years, research related to deep learning has shown that the strong generalization ability of neural networks is much stronger than that of linear function approximators. Therefore, the combination of deep learning and reinforcement learning technology has become a major trend, and a new field of research is called deep reinforcement learning. Due to the complex structure of the neural network and the huge number of parameters, the variance of the estimate cannot be calculated by the calculation method mentioned in the literature [33], so this paper proposes a new calculation method. This method obtains a sample of the posterior distribution of the neural network parameters by calculation at each time step. Since the estimated variance of different actions is different, the action with high variance has a larger amount of information, and its sampling value may also be larger. Therefore, the probability of being selected is also higher. For example, there are two actions whose Q-value obeys a Gaussian distribution. Since action 1 is selected many times, its variance is smaller than that of action 2. Suppose that the variance of action 1 is 1, and the variance of action 2 is 10. In addition, the variance of action 1 is 1. Action 1 has a mean historical return of 3 and action 2 has a mean historical return of 1, so action 1 follows a Gaussian distribution with mean 3 and variance 1, while action 2 follows a Gaussian distribution with mean 1 and variance 10, resulting in action 2. Due to the large variance, the probability that its sampled value is greater than that of action 1 is also greater. The following sections describe in detail how to

apply Bayesian methods in deep reinforcement learning algorithms.

The input to a neural network can be a one-dimensional array, a two-dimensional matrix, or even a three-dimensional image. For the sake of clarity, $x \in \mathfrak{R}^d$ is used to represent the state feature, that is, the input value of the neural network, plus the target value y to form the training set, which is expressed as $D = \{(x_i y_i)\}_{i=1}^n$. The posterior distribution of the linear regression model $f_\theta(x_i) = \theta^T x_i$ parameters is calculated and later extended to the case of neural networks. The model parameters are expressed as $s \in \mathfrak{R}^d$, and the prior distribution of the parameters θ is assumed to be $N(\theta^-, \lambda I)$, and the observed target value has a certain noise, that is, $y_i = \theta^T x_i + w_i$, where $w_i \propto N(0, \sigma^2)$. For noise, the noise of each sample is independent of each other. According to Bayes' theorem, the posterior distribution of the parameter θ can be expressed as

$$p(\theta|D) = \frac{p(D|\theta)p(\theta)}{p(D)}. \tag{10}$$

In Bayesian theory, $p(D|\theta)$ is called the likelihood, $p(\theta)$ is called the prior, and $p(D)$ is called the evidence. According to the derivation of the literature [33], the posterior distribution of the parameter θ obeys the multivariate Gaussian distribution with the mean (12) and the covariance (13):

$$E[\theta|D] = \left(\frac{1}{\sigma^2}X^T X + \frac{1}{\lambda}I\right)^{-1}, \tag{11}$$

$$\text{cov}[\theta|D] = \left(\frac{1}{\sigma^2}X^T X + \frac{1}{\lambda}I\right)^{-1}. \tag{12}$$

Among them, $X \in \mathfrak{R}^{n \times d}$ is the matrix obtained by splicing n sample inputs $x_i i$ and $y \in \mathfrak{R}^n$ is the vector obtained by splicing n target values y_i. This posterior distribution can be inferred by methods such as Markov Chain Monte Carlo, but to extend to nonlinear model artificial neural networks, the posterior distribution is expressed in another form:

$$\theta' \leftarrow \left(\frac{1}{\sigma^2}X^T X + \frac{1}{\lambda}I\right)^{-1}\left(\frac{1}{\sigma^2}X^T(y+\delta) + \frac{1}{\lambda}\theta'\right). \tag{13}$$

Among them, $\delta \in \mathfrak{R}^n$ is a random vector, each component δ_i comes from the Gaussian distribution $(0, \sigma^2)$, and the sampling of each component is independent of each other, and θ comes from the parameter prior distribution $N(\theta', \lambda I)$. It can be shown that θ' and θ are equivalent because

$$E\left[\theta'|D\right] = \left(\frac{1}{\sigma^2}X^T X + \frac{1}{\lambda}I\right)^{-1} \cdot \left(\frac{1}{\sigma^2}X^T(y + E[\delta|D]) + \frac{1}{\lambda}E\left[\theta'|D\right]\right) = E[\theta|D]. \tag{14}$$

That is, the means of θ' and the mean of θ are equal, and there are

$$\text{cov}[\theta|D] = \left(\frac{1}{\sigma^2}X^TX + \frac{1}{\lambda}I\right)^{-1}.\left(\frac{1}{\sigma^4}X^TE[\delta\delta^T|D]X + \frac{1}{\lambda^2}E\left[\theta'\theta'^T|D\right]\right). \tag{15}$$

$((1/\sigma^2)X^TX + (1/\lambda)I)^{-1} = \text{cov}[\theta|D]$ and $E[\delta\delta^T|D] = \sigma^2 I$, $E[\theta'\theta'^T|D] = \lambda I$, that is, the covariance of θ' is equal to the covariance of θ. With θ', the posterior parameters can be directly calculated, which is the key to combine Bayesian methods and neural networks. Calculating θ' requires adding noise to the target value, which can be obtained by open delta number generation noise sample open δ_i for each sample (x_i, y_i). In addition, the reinforcement learning algorithm will continuously collect new data and modify its model parameters over time. Therefore, formula (15) is rewritten into an iterative calculation method to adapt it to the form of online learning. The update rules are as follows:

$$\theta' \leftarrow \theta' - \nabla_\theta L(f_\theta + f_\theta; D_{\text{noise}}). \tag{16}$$

Among them, $\nabla_\theta L(f_\theta + f_\theta; D_{\text{noise}})$ is the loss function and $f_{\theta'} + f_\theta$ indicates that the output of the prediction function is obtained by adding the outputs of two neural networks, one of which has the posterior parameter θ' and the other network has the prior. The parameter θ'; D_{noise} represents the dataset with added noise, i.e., $D_{\text{noise}} = \{(x_i y_i + \delta_i)\}_{i=1}^n$. Equation (16) is to update the posterior parameter θ', and the prior parameter θ will not change after it is determined in the initialization stage. We combine formula (16) for calculating the posterior parameters and the bootstrapped DQN method, since the DQN method adopts the experience replay mechanism, and the way of sampling samples from the memory pool in the experience replay mechanism is equivalent to inject Gaussian noise into the data [34], so there is no need to explicitly add noise; the dataset is represented by $D_{\text{sample}} = \{(x_i y_i + \delta_i)\}_{i=1}^n$, where n represents the number of samples drawn from the memory pool at each update, also known as the batch size. We denote the target network as $f_{\theta'}$, and then the loss function can be written as

$$\text{opensL}(f_{\theta'} + f_{\theta'}; D_{\text{sample}}) := \sum_{t \in D_{\text{sample}}} (y_i - (f_{\theta'} + f_{\theta'})(x_i)). \tag{17}$$

The method that combines the Bayesian method and bootstrapped DQN is called the BBDQN algorithm, see Algorithm1 for an overall description of the algorithm.

5.1. BBDQN Algorithm.

The Bayesian bootstrap, like other bootstrapping approaches, can enhance probabilistic forecasts by employing preprocessed data with replacement, which allows for distinguishing the output predictions. The Bayesian bootstrap in this research works analytically to obtain the posterior distributions of the QR model parameters, distinguishing itself from the classic bootstrap, which depends on random choices from the available input data. Because the observations are treated as fixed in Bayesian inference, this new perspective appears to be compatible with the Bayesian method. Indeed, the determination of the mean using the Bayesian bootstrap varies only in the weight distribution. However, from a conceptual viewpoint, the Bayesian bootstrap differs significantly from the frequentist form.

6. Experimental Analysis

6.1. Lattice World.

First, test the exploration efficiency of the BBDQN algorithm in the grid world shown in Figure 2. The white grid represents the scale of the grid world, and the gray grid is the terminal state. Due to space constraints, the grid world in Figure 2 has a scale of only 4×4, while the scale of the lattice world used in the experiment is 20×20, but this does not prevent the use of the small-scale lattice world of Figure 2 to describe its dynamic model. In Figure 2, the state S is the initial state, and the agent has always maintained a speed of moving to the right $+1$. The available actions in each state are up and down. If you choose up, then the next step will reach the upper right state of the current state, and if down is selected, the next step will reach the lower right state of the current state. If the agent is at the bottom of the grid world, the downward action can be understood as walking against the wall. At this time, the next state will be to the right of the current state. If you select the action up in the upper right corner of the white grid, you can reach the top of the gray grid. To get a reward of $+1$, there are no rewards in other states, so you must always choose the action up to get the reward, but the action up has a cost, and the cost is related to the size of the grid world. Assuming that the size of the grid world is $N \times N$, each selection action up will bring a reward of $-0.01/N$, while choosing action down has no cost, the reward is 0. In fact, this problem is a two-dimensional extended version of the chain problem mentioned in Paper 4. The input can be represented as a one-hot matrix $x_i \in \{0, 1\}^{N \times N}$, the position of the agent in the matrix is 1, and the other positions are all 0s. In this experiment, compared with the DQN using ε-greedy strategy and bootstrapped DQN, the hyperparameters used by BBDQN algorithm are shown in Table 1, where $0 \in \mathfrak{R}^d$ represents a vector with all 0 components.

In the grid world, simple is the norm. The left-bottom corner of your agent or robot serves as the "start" point, and it terminates at either $+1$ or -1, which corresponds to the associated reward. The agent has four alternative movements at each step, including up, down, left, and

(1) Input: di scount parameter γ, batch size n, number of learners K, parameter first
(2) Test mean $\bar{\theta}$, parameter prior variance λ, sampling interval T sample, target network more

right, while the black block is a wall that your agent cannot pass through. Our first solution assumes that each action is deterministic, i.e., the agent will move in the direction it desires to mov in order to simplify things. The wall, on the other hand, will stay in place if the agents run into it. This is where artificial intelligence comes into play, because our bot should be able to learn from the procedure and think like a person. Value iteration is the key to the magic. Once our agent discovers a path to reward +1, should it stick to it and always take that line (exploitation), or should it give other paths a shot (exploration) and expect a shorter path? In reality, we will balance exploitation and exploration in order to keep our agent from being stuck in the local optimum. Our agent will pick an action depending on the exploration rate.

The experimental results are shown in Figure 3, where the algorithm performance is measured with regret. Regret refers to the difference between the maximum cumulative reward and the actual cumulative reward. Because DQN has never found a rewarded area in the grid world, its cumulative reward is less than 0, and its regret is constantly growing. As can be seen from Figure 3, the BBDQN can learn the optimal policy in less than 2000 epochs, while the DQN does not learn a good policy after 10000 epochs. In fact, after 1 million cycles of experiments, the DQN still did not converge.

FIGURE 3: Algorithm performance over epochs for rewards gain.

TABLE 2: The number of episodes required to find rewards.

N	l
5	560
10	792
15	1663
20	1828
25	2657
30	7697

Among them, the parameter retains two decimal places. Therefore, when the BBDQN algorithm faces deep exploration problems, the time complexity of the algorithm is at the polynomial level, specifically $O(N^3)$, which is better than the random exploration strategy ε-greedy time complexity of $O(2^N)$.

6.2. Further Analysis on Lattice World. In Figure 3, there is no obvious difference between the DQN algorithm and the bootstrapped DQN algorithm, but this does not mean that the exploration efficiency of the two algorithms is the same. In fact, the bootstrapped DQN algorithm is more efficient than the DQN. To prove this conclusion, a series of experiments were carried out.

In the previous section, it was mentioned that the size of the lattice world is represented by $N \times N$, and the number of learners is represented by K. The performance of each algorithm is compared when K is fixed at 10 and N is 10, 20, and 30. In addition, the performance of each algorithm is compared when N is fixed at 20 and K is 10, 20, and 30. When the lattice size of the world becomes smaller, the superiority of the bootstrapped DQN over the DQN is reflected. As shown in Figure 4, when K is 10 and N is 10, the regret of the DQN algorithm keeps growing, while the bootstrapped DQN and BBDQN find the optimal policy within 1000 cycles. In addition, when the number of learners increases, the superiority of the bootstrapped DQN over the DQN can also be reflected. As shown in Figure 5, when K is 30 and N is 20, the bootstrapped DQN algorithm finds the optimal policy at around 2000 cycles.

The results of all experiments are shown in Table 3, where the bootstrapped DQN is denoted as the BDQN due to space constraints. In addition, the experimental results in Section 6.1 are the results shown in the table with $K = 10$ and $N = 20$. In Table 3, the algorithm can learn the optimal policy in 10,000 epochs.

Regrettably shown in bold, it can be seen that the DQN fails to find the optimal policy within 10,000 epochs in all experimental settings, while the bootstrapped DQN only works when $K = 10$, $N = 10$ (the size of the lattice world decreases), or $K = 30$ and $N = 20$ (the number of learners increases); the optimal policy can be learned in 10,000 epochs, while the BBDQN can learn the optimal policy in 10,000 epochs under all settings. It can also be seen from Table 3 that when the size of the lattice world is small ($N = 10$), the performance of the BBDQN algorithm and the bootstrapped DQN algorithm is not much different because the BBDQN adds a random initialization first.

The time complexity of the DQN algorithm using the ε-greedy strategy is $O(2N)$ when faced with deep exploration problems. This paper also tests the performance of the bootstrapped DQN algorithm. The action selection of this algorithm is not realized by ε-greedy, and the algorithm improves its exploration efficiency by adding ensemble technology on the basis of the DQN [10], but it cannot be used in solving this deep exploration problem in the short term. The regret of the bootstrapped DQN and DQN over 10 000 cycles has only a small difference, which is not visible in Figure 3 and must be zoomed in to see the difference. Specifically, the DQN has accumulated regrets of 9 over 10000 cycles.

Figure 3 is the performance curve of the algorithm when the grid world size is 20×20. It is possible to assume that the size of the lattice world is $N \times N$ and analyze the relationship between algorithm exploration efficiency and N. As in Paper 4, the number of cycles required for the algorithm to discover the reward for the first time is used as a measure of exploration efficiency, and 6 data samples are obtained through experiments, which are shown in Table 2, where l represents the first discovery of the reward by the algorithm. In order to express the relationship between the two, polynomial regression is used to fit these 6 points, which is expressed as follows:

$$l = b + w_1 N + w_2 N^2 + \ldots + w_m N^m. \tag{18}$$

Among them, $w_1, w_2, \ldots, w_m m$ are the parameters of the m degree polynomial, which can be obtained by the least-square method. We tested multiple m values and found that when m is 3, the mean square error is the smallest, that is, the relationship between the two can be approximated by a 3rd degree polynomial as follows:

$$l \approx -2.76 + 9.30N - 6.84N^2 + 1.63N^3. \tag{19}$$

Figure 4: Algorithm performance over epochs for rewards gain ($N = 10$ and $K = 10$).
Figure 5: Algorithm performance over epochs for rewards gain ($N = 20$ and $K = 20$).

Table 3: Cumulative regret of each algorithm in 10,000 episodes.

Variable settings		DQN	BDQN	BBDQN
	$N = 10$	9914.88	599.65	649.29
$K = 10$	$N = 20$	9922.02	9914.60	1590.03
	$N = 30$	9912.36	9910.96	5203.65
	$K = 10$	9922.02	9914.02	1590.03
$N = 20$	$K = 20$	9922.02	9912.13	1901.18
	$K = 30$	9922.02	1857.49	1784.71

The performance of the BBDQN is even slightly lower than the bootstrapped DQN, but when the scale of the grid world increases, the advantages of the BBDQN algorithm proposed in this paper become more obvious, which is also the embodiment of the BBDQN more suitable for solving deep exploration problems; in addition, BBDQN algorithm performance of the method does not increase with the number of learners, which means that the space requirement of the BBDQN is lower than that of the bootstrapped DQN because the more the number of learners, the more space is required to store each learned parameter, and these algorithms all use neural networks as function approximators, and the parameters of each network are in millions, and the BBDQN does not need to increase the number of learners like the bootstrapped DQN to improve algorithm performance (as shown in Table 3), so the space requirement of the BBDQN is lower than the bootstrapped DQN.

7. Conclusion

A variety of learning and optimization methods form the foundation of computational intelligence. Therefore, incorporating cutting-edge learning methods to balance the relationship between exploration and exploitation is an inspiring area, particularly when merging it with IOT. As a result, IoT collected the scattered data and screened the information out of it using computational algorithms, and reinforcement learning performed the deep exploration with the ultimate emphasis. While disregarding the issue of identifying and taking advantage of the dilemma, the reinforcement learning approaches developed in recent years have mostly concentrated on integrating deep learning technology to enhance the algorithm's generalization capabilities. In order to increase the effectiveness of exploration, a deep reinforcement algorithm based on computational intelligence is proposed in this study, using intelligent sensors and the Bayesian approach. In addition, the technique for computing the posterior distribution of parameters in Bayesian linear regression is expanded to nonlinear models such as artificial neural networks; also, this calculation method is combined with the bootstrapped DQN to obtain the BBDQN algorithm. The result of the experiments in two environments proves that the exploration efficiency of the BBDQN algorithm is better than the DQN algorithm using the ε-greedy strategy and the bootstrapped DQN algorithm.

The direction of further research is when the method of calculating the posterior distribution of the Q function parameter in this paper is used to calculate the posterior distribution of the policy function π_θ parameter in the policy gradient method, the policy gradient method can effectively improve the face of the policy gradient method and exploration efficiency when exploring problems in depth.

Retraction

Retracted: The Construction of Big Data Computational Intelligence System for E-Government in Cloud Computing Environment and Its Development Impact

Computational Intelligence and Neuroscience

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope

(2) Discrepancies in the description of the research reported

(3) Discrepancies between the availability of data and the research described

(4) Inappropriate citations

(5) Incoherent, meaningless and/or irrelevant content included in the article

(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Academic Editor: Akshi Kumar

An environment of physically linked, technologically networked things that can be found online is known as the "Internet of Things." With the use of various devices connected to a network that allows data transfer between these devices, this includes the creation of intelligent communications and computational environments, such as intelligent homes, smart transportation systems, and intelligent FinTech. A variety of learning and optimization methods form the foundation of computational intelligence. Therefore, including new learning techniques such as opposition-based learning, optimization strategies, and reinforcement learning is the key growing trend for the next generation of IoT applications. In this study, a collaborative control system based on multiagent reinforcement learning with intelligent sensors for variable-guidance sections at various junctions is proposed. In the future generation of Internet of Things (IoT) applications, this study provides a multi-intersection variable steering lane-appropriate control approach that uses intelligent sensors to reduce traffic congestion at many junctions. Since the multi-intersection scene's complicated traffic flow cannot be accommodated by the conventional variable steering lane management approach. The priority experience replay algorithm is also included to improve the efficiency of the transition sequence's use in the experience replay pool and speed up the algorithm's convergence for effective quality of service in the upcoming IoT applications. The experimental investigation demonstrates that the multi-intersection variable steering lane with intelligent sensors is an appropriate control mechanism, successfully reducing queue length and delay time. The effectiveness of waiting times and other indicators is superior to that of other control methods, which efficiently coordinate the strategy switching of variable steerable lanes and enhance the traffic capacity of the road network under multiple intersections for effective quality of service in the upcoming IoT applications.

1. Introduction

With the continuous increase in the number of motor vehicles in my country, the contradiction between the supply and demand of road traffic is increasingly intensifying. Especially in the intersection scene, the traffic flow of each

turn at the intersection presents an uneven distribution at different time periods, which easily leads to congestion and waste of lanes resources. In order to solve this problem, the variable steerable lane technology using intelligent sensors came into being, which uses the lane as a variable space resource and dynamically allocates it according to the needs

of each turning traffic flow on the basis of communications between the wireless sensors, so as to improve the utilization rate of road space resources. An intelligent sensor is a function that can sense and detect information from a specific item, as well as learn, judge, and receive signals, and has a new type of sensor with management and communication features. The intelligent sensor is capable of autonomously calibrating, compensating, and collecting data. The intelligent sensor's capabilities determine its high precision and resolution, stability and dependability, and flexibility. It provides a great performance-to-price ratio when compared to standard sensors. Smart sensors come in three varieties: those that can judge; those that can learn; and those that can be creative. Intelligent velocity sensors, intelligent acceleration sensors, intelligent flow sensors, intelligent position sensors, intelligent attitude sensors, intelligent displacement sensors, and intelligent dimension sensors are a few examples of intelligent sensor types.

Variable steerable lanes at a single intersection of the scene, the traditional control method can effectively alleviate the problem of unbalanced steering, but as the number of variable steering lanes increases, the traffic flow changes between multiple intersections become more complex, and the present ability of the traditional method is more difficult, and it is impossible to coordinately control multiple. Therefore, how to make the cooperation between the multi-intersection variable-guidance lanes more efficient becomes a new problem. Variable steering lane with many intersections is a technique for figuring out the length of a changeable guide lane for a signal control junction approach is disclosed in an invention in the field of road traffic sign marked lines. The process entails first obtaining traffic data information on the variable guide lane's steering in the desired direction, followed by translating the received traffic volume into an equal standard small vehicle traffic volume. Using a model in the theory of queuing, it is then possible to determine the number of vehicles queuing behind a stop line for the signal control intersection approach using a multipath queuing multichannel system and a combination of an approach lane queuing imbalance coefficient. Finally, the vehicle number is converted to a measurement of the span of the variable guide lane for the signal control intersection approach using the vehicle average queuing length in meters. The approach traffic efficiency may be increased by using the technique for estimating the length of the variable guide lane for the signal control intersection approach, which allows cars on the upper stream of the variable guide lane to enter the intersection approach smoothly.

The term "variable-guided vehicle route" describes a track where the travel direction is not totally set for left-hand rotation, right turns, or continuing straight ahead, but instead incorporates various turning functions depending on the time of day. The overall traffic efficiency in the crossing can be greatly increased thanks to the way this track is laid out. Since the entrance driveway to the signalized crossing is not suitable for widening or having many canalizations, the wagon flow lacks uniformity significantly and is not suitable for the condition under which a signal control device can solve the problem. Apply in places like Hangzhou, Wuxi,

Tangshan, and Yantai, China's equivalent of Shanghai. Variable lanes are now being installed at crossroads in several places in order to better use road resources and increase traffic capacity. The variable lane control method primarily employs manual observation of traffic conditions for switching, or switching is performed at a fixed-time based on statistics of historical data. The manual switching mode is inefficient, and the statistical technique does not accurately reflect current traffic conditions. However, the rapid development of artificial intelligence and vehicle-road cooperation technologies can supply more real-time and precise data for variable lane control. It is feasible to regulate the variable lane more efficiently by making proper use of these data.

In this paper, we present a collaborative control system for variable-guidance sections at various intersections based on multiagent reinforcement learning and intelligent sensors. This study proposes a multi-intersection variable steering lane-appropriate control strategy that leverages intelligent sensors to minimize traffic congestion at multiple junctions in the next generation of Internet of Things (IoT) applications. The priority experience replay algorithm is also incorporated to increase the efficiency of the transition sequence's utilization in the experience replay pool and accelerate the algorithm's convergence for effective quality of service in forthcoming IoT applications.

2. Related Work

The traffic flow at the intersection changes dynamically in time and space. For example, in the morning and evening rush hours, the traffic flow of each turn at the intersection shows obvious regular changes, and there is a serious imbalance in the queue length of vehicles in different guide lanes. In order to improve the traffic capacity of the intersection and solve the problem of urban road congestion, some traffic researchers have carried out research on the dynamic control method of variable steering lane steering, mainly focusing on three aspects: traditional control method, intelligent control method, and reinforcement learning method. Supervised learning is a machine learning term that refers to the approach of constructing a function independently by learning from a number of related samples. This is the method of learning a broad notion from a small number of examples that are comparable to others. Contrarily, reinforcement learning is a branch of machine learning that builds on the idea of behavioral psychology and focuses on interacting with the environment directly. It is an important part of the field of artificial intelligence. Regression and classification are the two major jobs in supervised learning, whereas exploitation or exploration, Markov's decision processes, policy learning, deep learning, and value learning are the diverse tasks in reinforcement learning. Basic reinforcement is specified in the model Markov's decision process in reinforcement learning, whereas supervised learning examines the training data and generates a generalized formula. Each example in supervised learning will have a pair of input objects and an output with the desired values, whereas, in reinforcement learning, the

agent interacts with the environment in discrete steps, making an observation for each time period "t," receiving a reward for each observation, and then attempting to accumulate as many rewards as possible in order to make more observations.

The formula to measure the queuing length of the lanes can be explained as we can demonstrate for the M/M/1 queue that $L_q = \rho2/1 - \rho$

We can demonstrate for the M/G/1 queue that

$$L_q = \frac{\lambda^2 \sigma_s^2 + \rho^2}{2(1 - \rho)}, \tag{1}$$

where L_q is the mean number of customers in the queue, the likelihood that it is busy, and the percentage of time it is busy are all represented by the formula $\rho = \lambda/(c\mu)$, $1/E$ [Inter-arrival-Time], where E stands for the expectation operator, represents the mean rate of arrival, and σ_s^2 variance of service time.

2.1. Traditional Control Method.

The traditional variable lane control method research uses the method based on experience or historical data to set the control plan in advance and design the rules for the steering of the variable steerable lane at the intersection. Literature [1] proposed a signal for lane optimization at the intersection based on experience with phase-integrated design. Literature [2, 3] proposed a steering control model for a variable-steering lane at an intersection based on the empirical rules for the setting conditions of the variable-steering lane. The change characteristics of traffic flow and the actual traffic steering demand are more closely matched in Literature [4] and comprehensively considered the real-time traffic factors at a single intersection, and evaluated the preimplementation plan.

The specific lane function and signal timing switching scheme are deployed, but the preplan must be repeatedly tested and the accuracy is not high. Literature [5, 6] carried out integer nonlinear programming according to multiple road constraints associated with the target intersection. The optimization of the model achieves the smallest critical flow ratio after the optimization of a single intersection. Literature [7, 8] integrated the road conditions of key intersections and downstream adjacent intersections to achieve an associated control model. The above-mentioned work only considers the key intersection to a single adjacent intersection impact but does not design a comprehensive optimization scheme for associated intersections. Literature [9] proposed a control method to coordinate the design of multiple intersection variable signs and corresponding signal groups based on the collected data rules to better reduce the average delay of vehicles.

The abovementioned method of presetting the steering rules for variable steering lanes through experience or summarizing historical data rules can adapt to the needs of regular traffic state changes to a certain extent, but it is difficult to dynamically adapt to road traffic conditions and sudden changes in supply and demand abnormal traffic flow.

2.2. Intelligent Control Method.

Research on intelligent control methods for variable steering lanes makes intelligent decisions based on various traffic flow data collected in real-time, and improves the adaptability to real-time traffic flow changes at intersections. Some works use the collected real-time traffic flow data on roads, such as the space of each turning lane, occupancy rate [10], traffic flow, speed, queue length, and other characteristics obtained through video detection [11], dynamic decision-making variable steering lane switching strategy, but its adaptability to subsequent traffic flow changes is not good when combined with real-time collected data. Literature [12] predicted each turning traffic flow as the basis for judging lane direction switching and minimized the average delay time at the intersection. Literature [13] used the least squares dynamic weighting and the short-term traffic flow prediction model with fusion algorithm as the core combined with the traffic state prediction model with fuzzy data theory and neural network system theory as the core to realize automatic control of variable steering lane steering. Literature [14] constructed a mixed integer and the two-layer programming model is solved by a particle swarm algorithm to achieve the goal of minimizing the total travel time of variable lanes based on the prediction model.

The above-related research work has two limitations: (1) it is mainly applied to intelligent control decision-making of variable-steering lane steering at a single intersection and (2) the prediction-based intelligent algorithm is mainly based on historical and real-time data, and cannot quickly update rules to adapt to the dynamics of traffic flow variety.

2.3. Reinforcement Learning Methods.

In recent years, reinforcement learning technology has developed rapidly. It has low requirements for prior knowledge of the environment and can achieve good learning optimization performance in complex nonlinear systems. Therefore, it is suitable for complex and changeable multi-intersection and variable-guided lane intelligent control scenarios. In the multi-intersection collaborative control problem, traffic signal optimization research has widely used the reinforcement learning method. Literature [15] combined deep reinforcement learning with the traffic signal control problem, respectively, defining the state, action space, and reward function, using DQN (Deep Q-Network) model, extensive experiments on synthetic and real datasets demonstrate the superiority of reinforcement learning methods. Literature [16] used multiagent reinforcement learning technology to define the joint Q-value as the weighted sum of local Q-values, by minimizing the weighted sum of individual Q-values and the global Q-value to ensure that a single agent can take into account the learning process of other agents and realize automatic control of large-scale traffic signals. Literature [17] proposed that different agents exchange strategies after each round of learning to achieve a zero-sum game. Based on this realize the signal control strategy of autonomous vehicles, and designed a rewarding method that combines individual efficiency with overall efficiency. In the multi-intersection collaborative control scenario, the traffic

signal optimizes the traffic situation in the time dimension, and the intelligent variable guide lane is used as the spatial dimension. The above-mentioned two directions are suitable for the use of reinforcement learning methods to carry out global optimization research.

3. Variable Steering Lane Cooperative Control Method Employing Intelligent Sensors

3.1. Overall Structure. This research proposes a multi-intersection variable-direction lane cooperative control algorithm using intelligent sensors based on multiagent reinforcement learning. The method mainly includes multiagent reinforcement learning model merged with intelligent sensors, a global reward decomposition algorithm, and a priority experience playback algorithm. The multiagent reinforcement learning model proposed is constructed based on the value function decomposition algorithm of the QMIX algorithm [18]. The QMIX algorithm adopts the strategy of centralized training and distributed execution and uses the global reward function to optimize joint actions during training with the aid of intelligent sensors. The value function can achieve the effect of multiagent cooperative control, and each agent constructs and extracts the corresponding local strategy from the joint action-value function, which can not only deal with the problems caused by environmental nonstationary through centralized training but also through joint action-value function backpropagation learns the local "best" policy for each agent, enabling multiagent decentralized execution. Through the provision of a more flexible version of the constraint, QMIX enhances the VDN algorithm. The constraint is described as follows:

$$\frac{\partial \, \text{Qtot}}{\partial \, \text{Qa}} \geq , \tag{2}$$

where Q_{tot} denotes the total value function and Q_a denotes the value function for each agent. The weights of each particular value function Q_a should be positive, according to an obvious explanation. If the weights of the individual value function Q_a are negative, the agent will be discouraged from cooperating since the greater Q_a, the lower the joint value Q_{tot}. For consistency between the centralized and decentralized rules, QMIX comprises agent networks that represent each Q_a and a mixing network that brings them together into Q_{tot} rather than just adding them up like in VDN. By requiring the mixed network to have positive weights, it also imposes constraints. Since QMIX's factored representation grows well with the number of agents, it is able to describe complicated centralized action-value functions and makes it simple to extract decentralized policies using individual argmax operations in linear time.

The global reward decomposition algorithm improves the global reward distribution method in the value function decomposition algorithm and imposes constraints between the global value function and the value function of a single agent. In some complex scenarios, the global optimal joint action may require the intelligent sensor to make some behaviors that sacrifice individual interests. Decomposition

techniques change a difficult problem into a simpler one. Only binary constraints, whose scopes form a directed acyclic graph, are present in the new problem. Each set of variables from the original problem is represented by a variable in the new problem. These sets encompass the set of the initial variables even if they are not necessarily disjoint. In relation to each set of variables, the translation uncovers all partial solutions. The interplay between local solutions is reflected in the translation problem. A decomposition approach creates a binary acyclic issue by definition; these problems may be solved in a time that is polynomial in their size. In response to this problem, this study decomposes the global reward into two parts, one part is the basic reward, and the specific distribution to different agents is realized through the QMIX hybrid network; the other part is the performance reward, according to the agent. The state hierarchically is assigned to each agent which is the IoT so that a single agent can maximize the global reward while taking into account its own reward, and realize the secondary distribution of the global reward. In RL, the agent receives a reward that is often a sum of many reward components, each designed to encode some aspect of the desired agent behavior. From this composite reward, it learns a single composite value function. Using value decomposition, an agent learns a component value function for each reward component. To perform policy optimization, the composite value function is recovered by taking a weighted sum of the component value functions. While prior work has proposed value decomposition methods for discrete-action Q-learning. The development of autonomous agents is frequently done via reinforcement learning. In the RL framework, the agent is permitted to behave in the environment and is rewarded numerically at each step rather than being explicitly programmed. The goal of RL algorithms is to discover a strategy that maximizes the overall predicted reward (or some related criterion). Therefore, the reward function implies that optimal behavior is described. In order to assess actions in terms of trade-offs among the kinds, the technique decomposes rewards into sums of semantically relevant reward categories. To concisely describe why one action is preferable over another in terms of the kinds, we particularly propose the idea of minimal adequate explanations.

In the priority experience replay algorithm, in view of the uneven quality of randomly sampled experience, resulting in low training efficiency and slow algorithm convergence speed, the joint value function in the value function decomposition algorithm is used to calculate the error, and combined with the number of extractions to calculate priority of samples to speed up algorithm convergence.

3.2. Multiagent Sensors Reinforcement Learning Models. The multiagent sensor reinforcement learning model based on value function decomposition is shown in Figure 1. Based on the value-decomposition networks (VDN) algorithm [19], the original linear mapping is replaced by a nonlinear mapping, and the super network is introduced to add additional global state information to the mapping process to improve the performance of the algorithm [20]. Using the
FIGURE 1: Multiagent reinforcement learning models.
FIGURE 2: Schematic diagram of vehicle location matrix.

current observation state of each agent which are the intelligent sensors that performs the action of the previous time step as input, a global action-value function is learned through the hybrid network by these intelligent agents, where τ is the global state, α is the global action. In the multi-intersection variable steering lane scenario, the involved elements such as state space, action space, and reward function are defined. In order to make the input state more realistic and richer, the queue length of the lanes in each direction is adopted as the average waiting time of vehicles, and the ratio of average delay time as indicators. In addition, in order to accurately describe the position distribution of vehicles, the variable steering lane area is discretized and encoded to obtain the vehicle mapping matrix, as shown in Figure 2. The lanes are divided into the same size the grid covers the entire road section. Each grid in grid represents the present state of a vehicle. A value of 1 means that the vehicle exists at the grid, and 0 means that the vehicle does not exists compared with the intersection image directly information as input, this method can compress the data dimension and remove redundant information, thereby speeding up the training practice speed.

In the multi-intersection scenario, the state space expression is defined as follows:

$$S(T) = (L_L, W_L, D_L, L_s, W_S, D_S, M), \tag{3}$$

where T is the number of signal cycles, L_L, W_L, D_L are the average queue length, average waiting time, and average delay time of the lane group in the left-turn direction, respectively, L_s, W_S, D_S is the average queue length, average waiting time, and average delay time of the lane group in the

straight direction, and M is the vehicle position mapping matrix.

In the variable steering lane scenario, the straight-left variable steering lane is mainly studied and applied, and the right turn direction is not considered, so the action space is left turn or straight.

The global reward function is defined as the weighted sum of the following metrics.

(1) The average queue length L of vehicles in all lanes

(2) The average delay time ratio D of vehicles in all lanes

The expression of the single lane delay time ratio D_i is as follows:

$$D_i = 1 - \frac{v_{lane}}{v_{max}}, \tag{4}$$

where v_{lane} is the average speed of vehicles on lane i, and v_{max} is the vehicle speed maximum speed limit for road i:

(3) The average waiting time W of vehicles in all lanes. When a vehicle starts to stop and wait, that is, when the speed is less than 0.1 m/s, the parking waiting time of this vehicle starts to accumulate;

(4) N is the average number of vehicles on all lanes that left the current lane after the previous action;

(5) V is the average speed of vehicles in all lanes leaving the current lane after the previous action. The expression of the average speed is given as follows:

$$V = \frac{1}{N} \sum_{j=1}^{N} v_j, \tag{5}$$

where v_j is the average speed of each vehicle.

Assign corresponding weights to the above-mentioned different traffic indicators, and finally calculate the global reward:

$$R = k_1 L + k_2 D + k_3 W + k_4 N + k_5 V. \tag{6}$$

In the formula, $k1, k2, k3, k4, k5$ are the weight parameters, and the effect of the final traffic condition optimization is set by analyzing the global reward results in 3200 experiments.

3.3. Global Reward Decomposition Algorithm.

The global reward R is decomposed into two parts, the basic reward R_b and the performance reward R_p based on the proportion, as shown in Figure 3 for the global reward decomposition algorithm structure. The performance reward is an additional reward that is used to distribute to the agents with larger contributions.

The global reward decomposition function is given as follows:

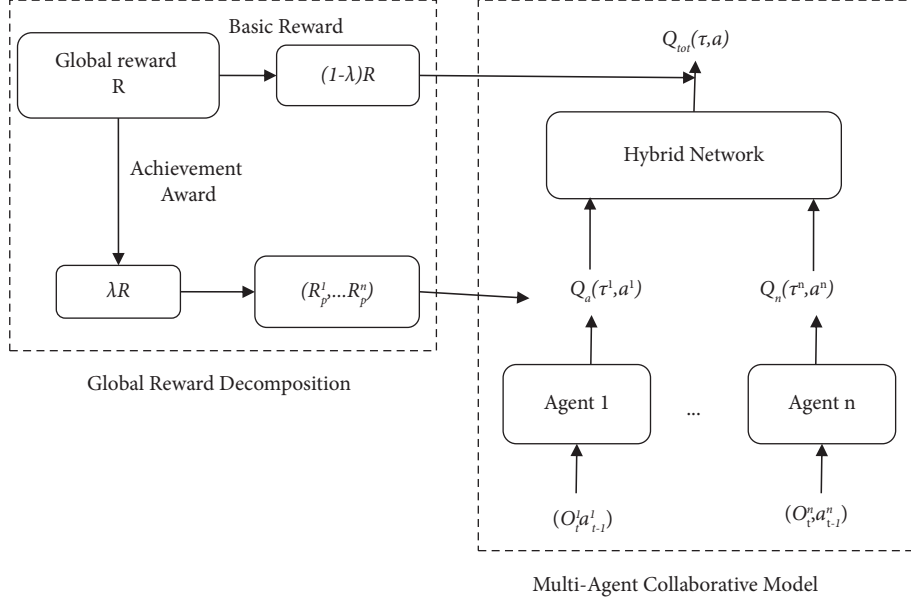
$$R = R_b + R_p,$$
$$R_b = (1 - \lambda)R, R_p = \lambda R; \lambda \in [0, 1.0]. \tag{7}$$


FIGURE 3: The global reward decomposition algorithm.

The traditional hybrid network method is used to distribute the basic rewards to each agent which are the intelligent sensors. The performance reward is used to motivate the agents that contribute more in the process of regional cooperative control. The expression of the performance reward obtained by each agent at the current time is given as follows:

Real-world situations like strategic conflict resolution, coordination between autonomous vehicles, and agent cooperation in defensive escort squads all include cooperative multiagent challenges. Such issues may be modeled as dual-interest situations, in which each agent simultaneously seeks to maximize its individual payout (local reward) and the team's performance as a whole (global reward). Two different forms of modern, state-of-the-art MARL algorithms exist. While algorithms like MADDPG and M3DDPG concentrate on optimizing local rewards without any explicit idea of coordination, algorithms like COMA and QMIX strive to maximize the global reward for the success of the group. We first define multiagent cooperation as a joint optimization on reward assignment and demonstrate that each agent has an approximately optimum strategy that decomposes into two parts: one that just depends on the agent's own state and the other that is connected to the states of adjacent agents. CollaQ decomposes each agent's Q-function into a self-term and an interacting term, using a multiagent reward attribution (MARA) loss to regularize training. CollaQ is tested on multiple StarCraft maps and surpasses existing state-of-the-art approaches (such as QMIX, QTRAN, and VDN) by increasing the win rate by 40% while using the same amount of samples.

$$
R_p^i = \begin{cases} \dfrac{1}{2L_T}\left(L_{S'} + L_{L'}\right)R_p, & L_{S'} < L_T, L_{L'} < L_T, \\[2mm] R_p, & other, \end{cases}
$$

$$
L_T = \frac{V_{out}}{V_{\max}},
$$

$$
L' = \frac{L}{\overline{L}}.
$$

(8)

In the formula, R_p^i is the performance reward obtained by the ith agent, L' is the ratio of the average queuing length of the lane group in a certain direction of the agent to the overall length of the lane, $\overline{L}$ is the average queuing length of the lane group during the execution of the previous decision, $L_{S'}$ is the overall length of the lane, and $L_{L'}$ is the ratio of the average queuing length of the straight lane group to the overall length of the lane, the ratio of the average queuing length of the left-turn lane group, L_T the threshold of the determination level of the lane, V_{out} the maximum traffic flow that can be driven out during the green light of the lane, and the capacity of the lane. $V_{\max}$ is the maximum traffic flow [21].

All agents are graded when the performance reward is allocated R_p, and the performance reward corresponding to each level is different [22, 23]. As shown in formula (8), when the $L_{L'}$ left turn and $L_{S'}$ straight lane group queue length ratio and are L_T less than the threshold when the traffic flow of the road section is determined to be small, $L_{L'}$ and $L_{s'}$ the performance reward is allocated by the ratio of

the average and the larger, more performance rewards should be allocated [24].

3.4. Priority Experience Replay Algorithm.

Deep learning uses target networks to increase the training's stability. The main training network and the target network are the two networks that the DQN method trains. The difference between the two networks, squared, is the loss the algorithm trains on (often replaced with Huber loss nowadays). The primary training network periodically replaces the target network's weights as training progresses. The target network predicts the optimum Q value from all actions that may be done from the next state in each data sample. This is the desired Q value. To train the Q network, the loss is computed using the predicted Q value, target Q value, and observed reward from the data sample. In single-agent reinforcement learning, in order to solve the problem of uneven quality of training samples extracted during the training process, a priority experience playback algorithm [25] was proposed, and the temporal-difference (TD) method was used to measure the importance of samples. The samples with larger errors are set as high priority, and the samples with high priority are extracted for training to improve learning efficiency. In the multiagent where agents are the intelligent sensors the reinforcement learning based on the value function decomposition algorithm, the joint value function can be used to calculate the TD error, and then use it for the calculation of the priority. In order to realize the priority experience playback algorithm, the target network loss L_n must be calculated:

$$
\begin{aligned}
L_n &= \left(y^{tot} - Q_{tot}\,(S, A) \right)^2, \\
y^{tot} &= R + \gamma Q_{tot}\,(S', A').
\end{aligned}
\tag{9}
$$

In the formula, S, A are the joint state and joint action of multiagent, γ is the attenuation coefficient, S', A' is the joint state and joint action of multiagent at the next moment. The larger the value, L_n the higher the corresponding experience sequence will be priority.

Using L_n as the only indicator to measure the importance of samples may cause some samples to be drawn less frequently due to their small size. Therefore, this study combines the target network loss and the number of times to be drawn N_{sam} as an indicator to measure the importance of samples. At the same time, considering different empirical the loss value of the target network has a large difference $f_{Top}(L_n)$, and it is converted into a dimensionless sorting amount, which is the position of the loss in the increasing sorting. The expression of the final priority PR_i is given as follows:

$$
\begin{aligned}
PR_i &= \frac{p_i}{\sum_{j=1}^M p_j + \epsilon p_i} \\
&= f_{Top}\left(f_{Top}\left(L_{ni}\right) + f_{Bot}\left(N_{sam}^i\right) \right).
\end{aligned}
\tag{10}
$$

In the formula, $f_{Bot}(N_{sam}^i)$ is the position of the number of extractions in descending order; $\varepsilon \in (0, 1.0)$ is the offset of the probability, which is used to correct the situation that the priority is too small to cause the probability of sample selection to be too low.

4. Experimental Results and Analysis

In order to verify the effectiveness of the cooperative control algorithm that employs intelligent sensors to alleviate the traffic congestion at multiple intersections methods for efficient quality of service in the next generation IoT applications using reinforcement learning. In the multi-intersection variable steerable lane scenario, the cooperative control BASE algorithm is combined with fixed-time control (FT) and traditional adaptive control algorithm for multi-intersection (MTAC), single-agent reinforcement learning adaptive algorithm (DQN), multiagent reinforcement learning adaptive algorithm (QMIX) and other methods, and analyze the performance of each algorithm in the data set, including algorithm-level reward value, traffic average queue length, average delay-to-time ratio, average waiting time, and average travel time metrics at the level. In cooperative multiagent systems, agents work together to complete tasks in exchange for a group reward as opposed to individual benefits. Credit assignment techniques are often used to differentiate the contributions of various agents in the absence of individual reward signals in order to promote successful cooperation. As credit assignment has recently been widely implemented using the value decomposition paradigm, QMIX has emerged as the leading technology. Robot swarms, autonomous vehicles, sensor networks, and cooperative multiagent reinforcement learning are just a few areas where this technique has found widespread use. In these activities, each agent must learn a decentralized policy through a shared team reward signal because individual incentives are not available. In order to achieve successful collaboration, agents must allocate credit in a discriminatory manner. Credit assignment techniques using cooperative multiagent reinforcement learning have made significant strides in recent years. Value-based approaches have among them demonstrated cutting-edge performance on difficult challenges. Value factorization, which is based on the centralized training with decentralized execution (CTDE) paradigm, has recently gained a lot of popularity. It specifically integrates separate value functions Q_i during centralized training to factorize the combined value function Q_{tot}. Decentralized policies may be easily determined during execution by greedily picking individual actions from the local value function Q_i. Because Q_i is learned by maximizing the overall temporal-difference error on a single global reward signal, an implicit multiagent credit assignment is accomplished.

4.1. Experimental Setup.

The experimental equipment configuration of this research is as follows: the CPU is AMD 2.10 GHz, the memory is 16 GB, and the operating system is Windows 10 (64 bit). Simulation experiments are carried out based on the microscopic traffic simulation platform SUMO v1.7.0. Interface to interact with the simulation

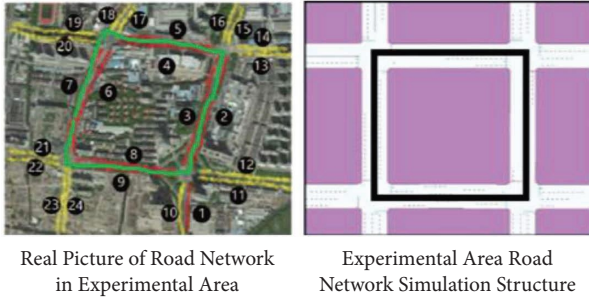
Real Picture of Road Network   Experimental Area Road
in Experimental Area   Network Simulation Structure


FIGURE 4: Structure diagram of the experimental road network area.

environment, obtain the traffic status in real-time and adaptively adjust the control strategy of the variable steering lane. As shown in Figure 4, the experimental environment includes 4 intersections and a total of 24 road sections, and the road sections are numbered 1~9. There are 9 variable steering lanes in total. The section with variable steering lanes consists of 5 lanes: fixed left turn, variable left turn/ straight, straight, straight, and right turn lanes. Section number 10~24 is a conventional road section, there are 15 in total, and the road section adopts a conventional fixed three-lane configuration. The signal cycle of each intersection is the same.

The experimental data set is collected from different traffic capture data of streets, roads, etc. such as upstream and downstream road section codes, capture time, lane number, and license plate number.

In this experiment, traffic flow data were collected at intersections in the urban area. The types of vehicles mainly included cars, station wagons, buses, and large passenger cars. The actual collected vehicle types and numbers were input into the simulation system, which were 24,17,592 cars, 156,008 station wagons, 91,089 buses, and 25,113 large passenger cars, accounting for 89.88%, 5.80%, 3.39%, and 0.93% of the total flow, respectively. In the calculation process of the simulation system, in order to standardize the vehicle position information at the intersection is converted into a discretized encoded vehicle position matrix, which is used as the quantitative input of the reinforcement learning model. In addition, the actual input vehicle type and quantity are converted into standard cars based on the conversion standard. The equivalent conversion coefficients of the models corresponding to standard cars are 1.2 for station wagons, 2.0 for buses, and large passenger cars. As is well known, traffic noise conversion and calculation used to be done using the prediction model in "Specifications for the Environmental Impact Assessment of Highways," whereas we now know that its levels or grades, as well as its equivalent conversion, can be calculated in a variety of ways using the equivalent conversion coefficient. The findings of the speed survey and their analysis allow us to conclude that the speed computation for all types of vehicles must follow the Gaussian distribution in free traffic flow, allowing us to suggest a speed discretization approach. The approach described above assists in converting various vehicles with varying speeds into car comparable numbers, while overall

traffic volume may be converted into that of passenger cars by evaluating themselves at the same noise levels.

In order to ensure the fairness of the comparison algorithm, the network structure and hyperparameter settings of the reinforcement learning algorithm are the same. The value of the discount factor is 0.95, the value of the learning rate is 0.001, the value of the greedy strategy ε is 0.05, and the size of the memory bank is 1000. The number of samples for each update is 32, and the model update step is 5 signal cycles. In order to improve the stability of the algorithm, the target network is updated with a delay. The weight replacement step of the target network is set to 30 signal cycles and RMS prop (root mean square prop) algorithm is the update algorithm.

In this study, the weight of global reward decomposition is set to $\lambda = 0.4$ in the BASE algorithm. Queuing length is used as an indicator to measure the efficiency of road traffic diversion under unbalanced traffic flow, and 32 combinations of weight values are set. In the process of training and testing, the accumulated vehicle queue length is calculated, 100 experiments are carried out for each scheme, and the average queue length is obtained by taking the average of the results. The smaller the average queue length the better the traffic diversion effect a total of 3,200 experiments were conducted using the numerous sensors. The results determine the weight of each influencing factor in the global reward function set in this experiment $k1, k2, k3, k4, k5$ are set to $-1.0, -0.5, -0.5, 0.5, 1.0$, respectively.

4.2. Experiment Analysis. Performance the test set is data of 6 periods, namely morning peak (periods 1, 2), evening peak (periods 3, 4), and flat peak (periods 5, 6). The performance of each control method is shown in Figures 5 and 6. In Figure 5, R is the reward index. In the data sets of multiple periods, the BASE algorithm performs better overall, followed by the QMIX algorithm, indicating that the multi-agent collaborative algorithm is still effective in real scenarios. The performance of BASE, QMIX, IQL, and MTAC is significantly better than that of the timing control scheme (FT), indicating that the adaptive algorithm can effectively adapt to the traffic flow changes in the real scene, and can make appropriate decisions according to the real-time traffic state.

Figure 5 and Table 1 show that the performance of the BASE algorithm in the datasets of multiple time periods is better than that of other algorithms, and the BASE algorithm has a significant lead in the morning and evening peak hours compared to the flat peak hours.

As shown in Figure 6 and Table 2, compared with other algorithms, the average queuing length index of the BASE algorithm in the morning and evening peak hours is reduced by 25.76% ~ 54.97%, and the index in the off-peak hours is reduced by 49.00% ~ 70.67%, indicating that the BASE algorithm is in the congestion scene. Compared with other algorithms, the average delay time of the BASE algorithm is reduced by 15.54%~55.09% as shown in Figure 7 and Table 3. In the test sets of 5 and 6 during the peak period, the road traffic in the network is small, the demand for the

function of the variable steering lane is weak, and the performance of each algorithm is close. The performance of the algorithm (BASE) in this study still maintains a slight lead. As shown in Figure 8 and Table 4, compared with other algorithms, in the BASE algorithm the average waiting time is reduced by 9.28%~42.39%, and in peak hours such as time period 3, the traffic state is more congested. The average waiting time of the IQL algorithm on this dataset is slightly better than that of the QMIX algorithm.

It can still maintain the leading performance, which further proves the effectiveness of the improved algorithm. As shown in Figure 9 and Table 5, the average travel time is reduced by 6.44%~29.93% compared with other algorithms, and the performance is stable under the test set of 6 periods, always has better performance.

Comparison results of each traffic index in the test set are shown in Figures 6 to 9.

The best performance of the algorithm in this study verifies the improvement of the multiagent collaborative algorithm for the multi-intersection variable-guidance lane scene: global reward decomposition, the proposed algorithm in this study can learn the policy better than the QMIX algorithm performance of the training process by comparing the BASE algorithm with the QMIX algorithm, the performance indicators of the training process are tested. The comparison of the average accumulated reward value index is shown in Figure – and Table 6. In Figure 10, E is the number of iterations.

The changes in traffic indicators during the training process are shown in Figure 8. Traffic indicators such as

average queue length, average delay time, average waiting time, and average travel time change with the training process of the algorithm model. The indicators are significantly reduced, the traffic state is gradually optimized, and the two multiagent collaborative algorithms can converge. At the same time, according to the downward trend of each traffic indicator in the training process and the final convergence state, it can be found that the global reward decomposition and priority experience playback are applied. The BASE algorithm of

algorithm has a faster convergence effect and better optimization performance, which can effectively adapt to the traffic flow of multi-intersection scenarios, and realize traffic state optimization of the local road network.

5. Conclusion

Computational intelligence is built on several learning and optimization techniques. Therefore, an emerging trend of major significance in the future generation of IoT applications is the integration of new learning methods, such as opposition-based learning, optimization approaches, and reinforcement learning. This research proposes a multiagent reinforcement learning-based collaborative control method employing intelligent sensors for variable-guidance lanes at multiple intersections. This method improves the performance in congested scenarios through a global reward decomposition algorithm and improves learning efficiency through a priority experience replay algorithm. Cooperative control of variable-guidance lanes at multiple intersections: compared with other control methods, this method has better effects in reducing the average queue length, average delay time, average travel time, etc., while convergent faster, and therefore, enhancing the quality of service in the next generation of IoT applications.

The follow-up work includes combining the algorithm with traffic signal control and performing joint optimization in the two dimensions of time and space to further improve the traffic capacity of multi-intersection scenarios.

Convolutional neural network (CNN) training often necessitates a considerable amount of computational resources. In recent years, several studies have proposed for CNN inference and training accelerators in which the FPGAs have previously demonstrated good performance and energy efficiency. To speed up the processing, CNN requires additional computational resources such as memory bandwidth, a FPGA platform resource usage, time, power consumption, and large datasets for training. They are constrained by the requirement for improved hardware acceleration to support scalability beyond existing data and model sizes. This paper proposes a procedure for energy efficient CNN training in collaboration with an FPGA-based accelerator. We employed optimizations such as quantization, which is a common model compression technique, to speed up the CNN training process. Additionally, a gradient accumulation buffer is used to ensure maximum operating efficiency while maintaining gradient descent of the learning algorithm. To validate the design, we implemented the AlexNet and VGG-16 models on an FPGA board and laptop CPU along side GPU. It achieves 203.75 GOPS on Terasic DE1 SoC with the AlexNet model and 196.50 GOPS with the VGG-16 model on Terasic DE-SoC. Our result also exhibits that the FPGA accelerators are more energy efficient than other platforms.

1. Introduction

In recent years, deep learning has shown their usefulness and effectiveness in finding an answer to many actual world problems. The DNN, notably the convolutional neural network, is at the root of this renaissance. The convolution neural network was shown to be a useful tool for a variety of functions, including image classification [1], image recognition [2], and object detection [3]. A CNN involves a massive number of computations that it could profit from acceleration using GPUs and FPGAs [4, 5]. Deep CNN hardware implementations are constrained by a memory bottleneck that need numerous convolutions and fully connected layers, which necessitate a considerable amount of communication for parallel processing [6].

A variety of accelerators, including graphics processing units (GPUs), Field Programmable Gate Arrays, and application specific integrated circuits, has been used to increase the efficiency of CNNs [7–9]. Among these accelerators, GPUs are the most commonly employed to enhance throughput and memory bandwidth [8], both in the training and the inference process of CNN; however, they use high power [1, 6, 10]. An alternatively, field programmable gate arrays (FPGAs) are a natural option for neural network deployment since computing, logic, and memory resources may be merged into a single device. Based on FPGAs (field programmable gate arrays), CNN accelerators provide significant benefits because of their reduced power consumption, high throughput, and design flexibility [11]. FPGAs also provide high parallelism and exploit the features of neural network processing [12]. However, CNN on FPGA

has a number of challenges such as requirements of memory storage, external memory bandwidth, and computational resource limitations. However, the FPGA restricted resources, such as the Stratix A7, have close effects to the midrange FPGA (Arria GX 10) citeli2017acceleration. The previous hardware accelerators for CNN have used different kernel for convolution and fully connected layers, which affect the FPGAs resource utilization [5, 13].

Intel's programmable solutions division has created a scalable convolutional neural network reference architecture for deep learning systems based on the OpenCL programming language. The OpenCL-based design tool is used to effectively accomplish the required accelerator design. This allows us to reuse the current code for Graphics Processing Units (GPUs) in FPGAs using OpenCL-based high-level synthesis tools [6, 14]. Developers may program the FPGAs in high-level languages like as C/C++ using high-level synthesis (HLS), which speeds up the development process. HLS techniques provide a developer with an extremely simple programming model as FPGA [12]. However, the CNNs are mostly solved using methods based on matrix-multiplication; this somehow requires the movement of huge volumes of data between compute units and external memory [5]. To speed up processing, the CNN requires more computational resources. Nonetheless, when processing CNNs, a memory bandwidth is often the bottleneck. Because of the high memory requirements of the fully connected (FC) layers, layer sections and the execution might be memory limited. The enormous number of weights held by these layers accounts for the high number of memory reads. If any of these accesses are to external memory, for instance, dynamic random access memory, throughput and energy power usage would be significantly impacted because dynamic random access memory accesses have far more latency and energy consumption than the compute itself.

However, memory storage, external memory bandwidth, and computing resource limits provide a number of challenges for CNN on FPGA.

The contributions of this work are as follows:

(1) It proposes single kernel for both convolutional and FC layers, which improve memory bandwidth and hardware resource utilization.

(2) Loop parallelization and single instruction multiple data (SIMD) have been applied.

(3) To get maximum throughput, we use design space exploration method that leverages resource usage and throughput and is able to find the optimal architecture configuration, for CNN on FPGA.

2. Background

This section explains the basic theoretical basis for solving image classification problems. As such, we explain how hardware accelerators are used for image classification by first giving brief description of the hardware platforms and convolution neural network.

2.1. FPGA Architecture. FPGAs (Field Programmable Gate Arrays) were first used nearly two and a half decades ago. FPGAs are semiconductor devices that are built around a grid of configurable logic blocks (CLBs) interlinked via programmable interconnects. The FPGAs are programmable devices that offer a versatile platform for developing unique hardware capabilities at a reduced development cost [15]. The modern FPGA has two main parts: programmable logic blocks (ALMs) and logic components [12]. Figure 1 shows that the FPGA has a different configurable logic block (CLB) as well as input and output ports. The configurable logic block (CLB) is the basic repeating logic resource on an FPGA, which contains smaller components, such as flip-flops, look-up tables (LUTs), and multiplexers. The FPGA resources that allow connecting the FPGA target to other devices are the input and output (I/O). Input and output are to change analog or digital signals to or from a digital value so that we can process the signals using an FPGA target. The FPGAs logic capacity has been greatly increased because of advancements in process technology, making them a feasible implementation option for bigger and more sophisticated designs. Generally, the FPGA nature of logic and resource usage affects the FPGA device's space, speed, and power efficiency [16].

2.2. Intel FPGA SDK for OpenCL. A high-level abstraction for FPGA programming is provided by the Intel OpenCL SDK as one of the HLS tools. A concurrent program is built to von Neumann fixed structure as shown in a series of instructions for hardware acceleration that each computation generally requires the retrieval of instructions as well as the moving of data between register data and also the memory [17]. The Intel OpenCL SDK solution, on the other hand, provides a highly effective solution. Inside this model, the platform resources are customized to the algorithm being run [17].

Global memory is arranged as external memory in the FPGA device for the memory system in the Intel OpenCL SDK, which could be DDR3 synchronous dynamic random access memory as well as other memory [18].

2.3. Convolutional Neural Networks. CNN is a type of deep neural network that is very useful for classification. It takes an input and predicts a class tag for it. CNN typically consists of many layers, such as convolutional layers, ReLU layers, pooling layers, normalization layers, and fully connected layers. So, every layer will have its own input and output, with the input mapped to either a linear or nonlinear transformation of the output. Below are listed a descriptions of the individual layers.

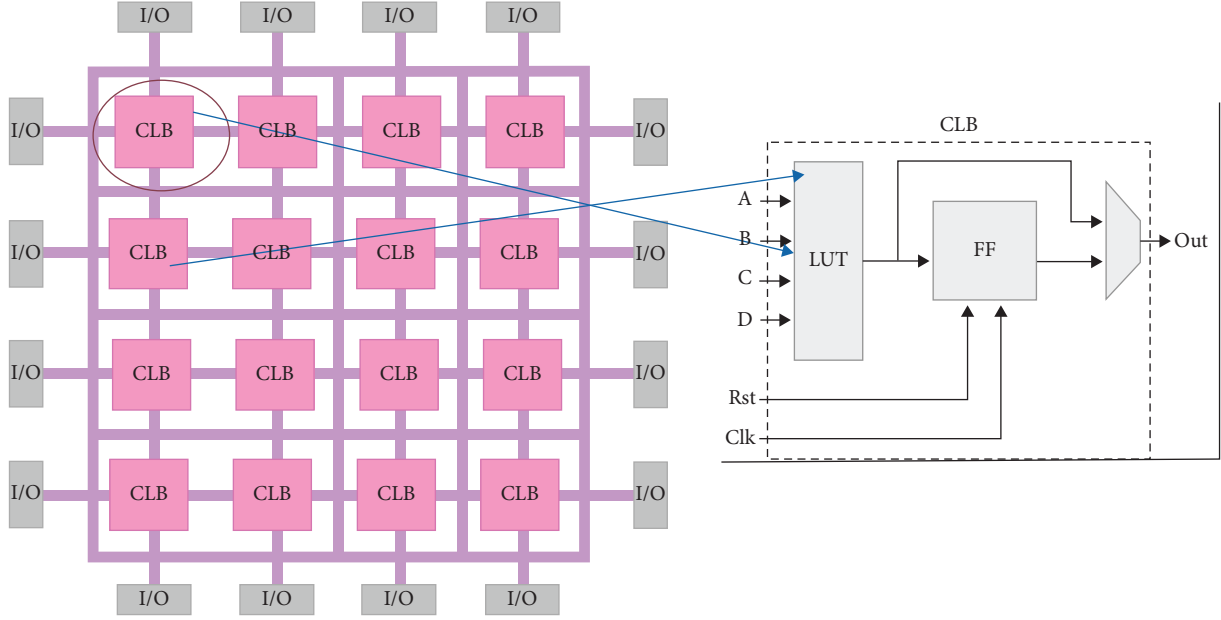
2.3.1. Convolutional Layer. The convolution layer parameters are made up of a series of learnable filters. Each filter has a small spatial footprint, but extending to the maximum depth of the input volume. CNN's most important layer is the convolutional layer. It is being used to retrieve the characteristics of the input image or the upper layer's feature


FIGURE 1: Overview of FPGA architecture, taken from [16].

map data [19]. The procedure is a three-dimensional convolution calculation based on input data and a huge variety convolution kernels, as well as the convolution operation is essentially a three dimensional multiply accumulate operation that could be described mathematically.

$$y_{out}(f_o, y, x) = \sum_{i_y=0}^{i-1} \sum_{i_x=0}^{i-1} w_l(f_o, i_y, i_x) \\ \times y_i(f_i, y + i_y, x + i_x) + b_i,$$

(1)

in which $y_i(f_i, y, x)$ as well as $y_{out}(f_o, y, x)$ refers neurons as input extracted feature f_i but also extracted feature f_o, respectively. $W_l(f_o, f_i, y, x)$ demonstrates the weights in the lth layer which is combined with f_i, as well as b_i would be a bias. The convolution filters are $i \times i$ in length.

2.3.2. Rectified Linear Unit Layer.

A recently proposed activation function in CNN is the Rectified Linear Unit (ReLU) that can be applied by thresholding a matrix at zero which is known to converge faster in training and has smaller computational complexity while the Sigmoid or tanh(x) activation functions involve expensive arithmetic operations [19]. The ReLU has become very popular in the last few years in convolutional neural network architecture. The equation of ReLU is very simple as follows:

$$f(x) = \max(0, x).$$

(2)

2.3.3. Pooling Layer.

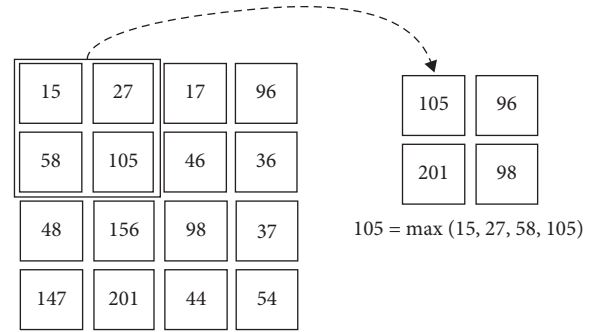
As shown in Figure 2, the pooling layer is known as the down sample layer; it reduces extracted feature redundancy as well a network computational cost by minimizing extracted feature dimensions but rather effectively prevents overfitting. Pooling is among the common operators inside a convolutional neural network. Convolved


FIGURE 2: Max pool, taken form [19].

extracted features are compressed in a pooling layer by a dataset obtained near the area feature values [20]. Because images have the regional property, this operation is possible. The spatial size of feature values is reduced after the pooling operation, resulting in fewer computational tasks to perform in the flowing layer. The pooling operator's most common options include max pooling as well as average pooling. The term "max pooling" refers to the following:

$$O(i, j) = \max[O(i_o, j_o): i < i_o < i + p, j < j_o < j + p], \quad (3)$$

in which p is the operator's length and (i, j) is the vertical and horizontal index.

2.3.4. Fully Connected Layer.

The fully connected layer is the classical component of a feed-forward neural network, wherein every element inside the max pooling is linked to every component in the output nodes. The extracted features of the convolutional as well as max pooling require the input image's distributed high-level attributes. The FC layers were designed to combine such extracted features in order to

categorize the input into several classes. The forward throw of the *lth* FC layer is calculated as follows:

$$O^{l+1} = f\left(b^l + f^l + w^l\right), \tag{4}$$

where O^{l+1} is the output at $l + 1$ layers, f is the activation function, b^l is the bias for l^{th} layers, f^l is the feature map in l th layers, and W^l is the weights at the lth layers.

By adjusting the filter size of the convolution controller, an FC layer could be easily translated to the convolutional layer, which would be especially useful in practice.

2.3.5. Backpropagation. Back propagation has performed two updates that are for the weights and the deltas [21]. We are looking to compute $\partial E/\partial w_{m,n}^l$ which can be translated as the measurement of how a single pixel alters $w_{m,n}$ in the weight affects the loss function E. During forward propagation, the convolution operation ensures that the pixel $w_{m,n}$ in the weight, between an element of the weight and the input feature map element that it overlaps; a contribution is made in all the products [20]. Convolution between the input feature map of dimension $H \times W$ and the weight of dimension $k_1 \times k_2$ produces an output feature map of size $(H - k_1 + 1)$ by $(W - k_2 + 1)$. By applying the chain rule in the following way, the gradient component for the individual weights can be obtained [9].

$$\frac{\partial E}{\partial w_{m,n}^l} = \sum_{i=0}^{H-k_1} \sum_{j=0}^{W-k_2} \delta_{i,j}^l \frac{\partial x_{i,j}^l}{\partial w_{m,n}^l}. \tag{5}$$

The summations represents a collection of all the gradients $\partial_{i,j}^l$ coming from all the outputs in layer *l*.

3. Literature Review

Recent FPGAs had also provided a significant design space for a convolutional neural network due to an increase throughout FPGA fabric density as well as reducing transistor scale. The work by Tapiador et al. [6] implemented a depth-wise separable convolution with a high rate of resources and also significantly increases bandwidth as well as accomplishes a complete pipeline through parameter tuning and through a streaming data interface and the on ping-pong. In the work by Kaiyoua et al. [22], CNN models and CNN-based implementations have been distinguished. The requirements for memory, computation, and system reliability for mapping CNN on embedded FPGAs were summarized. Requirement analysis: they proposed Angel-Eye, which is a programmable as well as configurable CNN hardware accelerator combined with quantization method, compilation tool, as well as a data quantization technique. The compilation tool converts a specific CNN model into the hardware configuration. They were tested on the Zynq XC7Z045 platform and outperformed; peer FPGAs on same network have same of performance as well as power efficiency by 6*x* and 5*x*, respectively. In the work by Naveen Suda et al. [5], FPGA throughput is optimized on large-scale CNN with 3D convolution as matrix-multiplication. Their work demonstrated that ImageNet classification on the P395-D8

board can achieve a peak performance of 136.5 GOPS for convolution operations and 117.8 GOPS for the entire VGG network.

In terms of the processing time, the FPGA implementation has almost the same performance as the GPU implementations although the FPGA's memory bandwidth is much smaller and has much high energy efficiency than the GPU's one. FPGAs will be advantageous in the high-performance computing scope for these reasons because they provide reprogrammable hardware as well as low power consumption, and FPGA implementation is a cost effective also fast [12] while OpenCL enhances the code portable as well as programmable of FPGA, which greatly reduces the time and complexity programming process and it comes at the best of performance [8].

4. Methodology

In this section, we would go over the architecture in general, including convolution, input max pooling, and backward and output kernels.

4.1. Accelerator Design. The overall system design flow as well as both host and device system section of the OpenCL kernels is created with the Intel FPGA SDK for the OpenCL enhanced version channel. The hardware accelerators design has five kernels, such as forward convolution, backward convolution, pooling, input, and output. The input and output kernels have been used to transfer extracted features as well as weight from and to the main memory, which brings some kernels with high-throughput sequencing data. The convolution kernel is designed to speed up the most parallelize computations in CNNs, which typically include the convolution operation and the FC layer [7].

The Max-pool part works to dwindle the dimension of the information by combining the outputs of neurons into a single within the another layer and undersampling operations specifically on the yield data stream of the convolutional part. The cascaded kernels shape a channel, which can operate the essential CNN operations without the requiremet of putting away interlayer information backmost to external memory. So, every convolution channel has a computing unit, and the kernel is made up of many computing units to do parallel convolution [9]. Both of input and output kernels are a most vital kernel which are utilized for a data movement and a kernel that is outlined to bring or store information from or to a main memory for the computing path. The input kernels begin with such a global work items in convolution configuration whereas the output kernel is operating in an NDRange unveiling with global work items. To enable concurrent work group processing, the work items have been organized up into multiple running in parallel work groups, also with a local work group length of (i, i). The convolution filters size is 3×3, which minimizes computational costs and weight sharing that to lower back-propagation weights. The number of pixels shifted over the input matrix is referred to as the stride, and we use the stride size as 2×2 to modify the amount of movement over the image.

4.2. Forward Convolution Kernel. The forward convolution kernel performs a convolution operation. The forward convolution kernel performs a convolution operation. At each position, the multiplication between each element of the kernel and the input feature map element is computed

and the results are summed up to obtain the output at that current location. The convolution operation is essentially a three-dimensional multiply accumulate (MAC) operation, which can be defined as

$$y_o(fe_o, y, x) = \sum_{fe_i=1}^{C_l} \sum_{i_y=0}^{i-1} \sum_{i_x=0}^{i-1} w_l(fe_O, i_y, i_x) \times y_i(fe_i, y + i_y, x + i_x) + b_i, \tag{6}$$

in which $y_i(fe_i, y, x)$ as well as $y_o(fe_o, y, x)$ refers neurons as input extracted feature f_i but also extracted feature fe_o, respectively. $W_l(fe_o, fe_i, y, x)$ demonstrates the weights in the lth layer which is combined with fe_i, as well as b_i would be a bias.

4.3. Input Kernel. The algorithm 1 shows that the input kernel is used for reading input extracted features and relates filters from memory, along with feeding weight into the local buffer and obtaining extracted features and caching them in the local buffer. Because an input extracted feature is recycled by numerous different filters, the input array is cached in local memory for access during data processing and to reduce the access of global memory.

(1) Get global and local index of work item

(2) Calculate location for input features and filters using index

(3) Bring input features into the local memory

(4) Bring filter into the local memory

(5) #progma unroll

(6) for each component i in both input feature and filter do

(7) Load weight into weight buffer

(8) Fetch the weight and bias by fetcher

(9) end for.

4.4. Pooling Kernel. The Pooling part performs to reduce the dimension of the weight by combining the outputs of neurons into a single within the another layer and undersampling operations specifically on the output data stream of the convolution kernel. The pooling layer reduces the convolutional outcomes while using the average or maximum value of elements in an area that is dependent on subsequent iterations. A shift registers with the depth that is developed for caching the accumulating data, similar to such convolutional layer. Then, depending on the pooling method, accumulating operations are performed on the shift register.

4.5. Output Kernel. The output kernel reads backproagation results from the accumulation channel and writes them back to global memory and then outputs to a local buffer, then extracts the data from the buffer, and copies it back to DDR.

This work makes use of batch processing to reduce the time it takes for filters to be reused in FC layers. As a result, in the FC layer output kernel, N batch sets of results must be collected and written. It processes one set of results for the additional layer. The kernel is constructed in an NDRange manner, executing with work items in parallel, so the output processing is entirely independent.

4.6. Backward Convolution Kernel. This kernel reads the result from the max pooling buffer channel as well as performs two functions: error δ calculation and partial derivatives ΔW and ΔE calculation, both of which are cross-correlation processes. The cross-correlation operation can be implemented by reversing the data in the convolution kernel. The difference in resource usage is that while calculating the derivatives, we require two input buffers for both δ^l and δ^{l-1}. Convolution between the input feature map of dimension $H \times W$ and the weight of dimension $k_1 \times k_2$ produces an output feature map of size $(H - k_1 + 1)$ by $(W - k_2 + 1)$. By applying the chain rule in the following way, the gradient component for the individual weights can be obtained [9].

$$\frac{\partial E}{\partial w_{m,n}^l} = \sum_{i=0}^{H-k_1} \sum_{j=0}^{W-k_2} \delta_{i,j}^l \frac{\partial x_{i,j}^l}{\partial w_{m,n}^l}. \tag{7}$$

5. Optimizations for Performance

In this section, we will discuss performance optimization techniques such as throughput maximizing, quantization, memory communication, parallelism in convolution neural networks, and converting fully connected layer to convolution layer.

5.1. Throughput. To keep moving forward, the accelerator's throughput, SIMD, and concurrent computing units are announced. The input kernel retrieves the SIMD and sends it to numerous computing units in the convolution. By adjusting the value of the SIMD as well as the number of computing units that is deployed, design could obtain scalable performance and hardware costs without requiring changes to the kernel code.

5.1.1. Computing Unit. The FPGA chip's resources are limited. If hardware resources are required for the optimization techniques, each kernel could have multiple compute units generated. This necessitates the creation of multiple copies of the various transmission lines. Even so, multiple computing units could not always improve throughput linearly since all computing units communicate over the global memory bandwidth. This causes memory access contention among computing units.

5.1.2. Single Instruction Multiple Data (SIMD). To increase the data processing performance of an OpenCL kernel by processing various work items can be accessed by a single instruction multiple data (SIMD) approach without annually vectorizing the kernel code. The largest amount of work items per workgroup that the Intel FPGA SDK for OpenCL compiler could execute SIMD or vectorized was determined. The work group size that could be used is defined by the compiler, and the local work size argument is used to clEnqueueNDRangeKernel. The workgroup length can be allowed to pass to clEnqueueNDRangeKernel as such local work length argument. The above enables the compiler to adequately enhance the generated kernel code.

5.1.3. Loop Unrolling. The several loop iterations in the device code could have an impact on the kernel performance. The loop unrolling method could assign the most hardware resources and minimize or even eliminate the loop queue, that is, increase the throughput in a linear manner. This approach supports memory coalescing as well that also reduces memory transaction cost.

5.2. Quantization Technique. In general, artificial neural deployments, including convolutional neural networks, make use of a 32-bit floating point. The circumstance, even so, has been transformed. Several more latest FPGA works on convolutional neural networks had also centered to use the fixed-point representation of the extremely narrow bit width, which now has accuracy reduction [23–25]. However, nevertheless, low-bit reduction-based designs demonstrate exceptional performance and energy efficiency; this indicates that extremely low-bit width is an useful solution for higher efficiency design [23, 26, 27].

[IL.FL], from which IL seems to be the total number of integer bits and FL has been the total number of fractional bits would be a fixed-point number structure. The overall number of bits is calculated as the sum of IL and FL as well as the fixed-point number has an exactness of 2^{-FL} and the scope could be described this way: $[-2^{IL-1}$ and $2^{IL-1} - 2^{-FL}]$ [23]. The fixed point is the hardware-friendly as well as enables so much logic resources on FPGAs, allowing for increased parallel computing [28]. This even decreases the chip's memory usage and bandwidth needs. Even so, as in fixed-point deployment, we would use a fixed-point which was with static configuration to create cost effective and much more precise hardware kernels [15]. In overall,

quantization is the most significant element in accelerating huge CNNs on the FPGA platform.

5.3. Memory Communication. Because several developments are limited by memory bandwidth, the other option is to use efficient memory access to reduce communication cost. Several developments are limited by memory bandwidth, the other option is to use efficient memory access to reduce communication costs.

5.3.1. Memory Alignment. Here, on host side, memory allocated would have to be at least 64-byte aligned. This significantly improves the transmission efficiency of DMA transmitting on the host-FPGA communication. The allocation can be executed in Linux using the POSIX mem-align function, which is supported by GCC, or Windows use that aligned malloc function, which is held by Microsoft.

5.3.2. The Local Memory Caching. Global memory, constant memory, local memory, and private memory are the four areas of the OpenCL memory model. Local memory, which would be executed in the on-chip Random access memory block, does have significantly decreased latency and high bandwidth than main memory. As a result, we can cache global memory which requires multiple accesses previous to computation using local memory. Those certain cached local memories have been viewable to everyone, work items in the same workgroup when data parallelism is enabled. By minimizing the memory access, the use of local memory would improve kernel performance.

5.4. Parallelism in Convolutional Neural Network. Those processing, which would include reading, convolving, pooling, and writing back, are data independent of varying extracted features. As a result, the entire output extracted feature can be vectorized along the N dimension, with each section processed on a different data path. This can be executed by a computing unit in OpenCL that would significantly enhance the proposed design throughput [10]. Furthermore, every convolution operation of an extracted feature unit consists of stage element-wise multiplication of input extracted feature and filters, followed by the accumulation of the product of these operations. [19]. In the first process, multiplication is completely independent and could be performed using a data parallelism technique.

5.5. Changing FC Layers to Convolution Layers. Fully connected layers and convolution layers have the same working order form, which entailed multiplying and adding. It should be noted that because the only difference between the fully connected and the convolution layer would be that the neurons in the convolution layer are only connected to a local region at the input and that many of the neurons in the convolution layer volume share parameters. The fully connected (FC) layer operates on a flattened input, with each input connected to all neurons. Dot products, on the other

hand, are always computed by neurons in both layers, so their functional form is similar. There are two approaches for changing FC layers to convolution layers. First, choose a convolution layer kernel filter with the same length also as input feature's map, and secondly, by using 1×1 convolutions with multiple channels.

6. Experimental Setup

The Terasic DE1 SoC Development Kit (DK) of FPGA board is used to implement the experiments. DE1 SoC would be a powerful hardware design platform based on Intel System-On-Chip (SoC) FPGA. The DE1 SoC board uses several features which enable designer to complete a broad range of designing circuits projects.

The terasic DE1 SoC board has M10K-10-kbit memory blocks including soft error correction code (ECC), as well as a 400 MHz/800 Mbps interface of an external memory and 64 MB of the SDRAM, 1 GB ($2 \times 256M \times 16$) of DDR3, and micro SD card port on Hard Processor System (HPS) memory [29]. The Intel cyclone V SoC 5CSEMA5F31C6 has 85K programmable logic elements, 4,450 Kbits of memory embedded, 6 fractional phase locked loops (PLLs), dual-core ARM Cortex-A9 (HPS), and 2 memory controllers based on TSMC's 28-nm low power (28LP) process technology. The architecture of a DE1 SoC includes two USB 2.0 Host ports (ULPI interface with USB type A connector) [29]. As communication ports, connectors, displays, switches, buttons, indicators, audio, and video inputs, G-Sensor on HPS and UART to USB (USB Mini-B connector), 10/100/1000 Ethernet, PS/2 mouse/keyboard, IR emitter/receiver, and I2C multiplexer are used. The accelerator boards communicate with the host through the use of an 8-lane PCI express link.

We use Intel SDK for OpenCL intelFPGA_Standard_18.1.0 build 625. The Intel FPGA SDK for OpenCL Standard Version includes programs, drivers, development kit library resources as well as files, and much more. The Intel SDK for OpenCL Standard_18.1.0 has logic components such as offline Compiler translates, a set of commands, host runtime providing the OpenCL host, and runtime API for the OpenCL host code. We used the Board Support Package (BSP) 18.1 version for de1soc board BSP from Terasic and Intel SDK for OpenCL the intelFPGA_Standard_18.1.0 with 625 buildings is used. Additionally, (Intel® CoreTM i5-4300) CPU and (AMD Radeon (TM) R5 M330) GPU are used.

7. Result and Discussion

In this section, we evaluate the performance of our proposed system with the different design specifications. The objective of this exercise is to learn the resource utilization and performance figures for combinations of design specifications. We employ two well-known CNN models for the possible combinations of convolutional neural network design specifications.

7.1. Design Performance and Analysis. We advanced to evaluate the accuracy of our design on the ImageNet ILSVRC-2012 data set, where it contains up to 1.2 million training and 50k validation instances. An AlexNet Caffe model, that has 61 million parameters as well as a top-1 accuracy of 57.2% and a maximum classification of top-5 accuracy of 80.3%, has been used as a reference model. On the same ILSVRC-2012 data set, we furthermore examined a larger, more latest network, VGG-16 [30]. The VGG-16 does have 138 million parameters and much more convolutional layers, but still only three fully connected layers at the moment [12]. The accuracy of our work was assessed with executing our models on 728K training and 50K validation samples from the ImageNet 2012 data set. The accuracy comparision for AlexNet model in Figure 3 and the accuracy comparision for VGG-16 model demonstrate the accuracy of various quantization compression rates.

Figure 3 and Figure 4 demonstrate the accuracy of various quantization compression rates. As shown, the model's accuracy starts to decline considerably while compressing below 8-bit data quantization of its base accuracy. The difference between the Caffe tool using AlexNet model with 32 bit floating point and the 32 bit floating point FPGA design on top-1 and top-5 accuracies is 0.5% and 0.59%, respectively. The difference between a 16-bit fixed point Caffe tool and FPGA design on top-1 accuracy is 0.59% and top-5 accuracy is 0.9% accuracy loss compared to the reference design. The accuracy difference between 8 bit Caffe and FPGGA implementation design on top-1 and top-5 accuracies is 0.77% and 0.5%, respectively. The accuracy difference between 4 bit Caffe tool and FPGGA implementation design on top-1 and top-5 accuracies is 2.05% and 1.19%, respectively. Therefore, the accuracy of our implementation is excellent. As a result, the exactness of our implementation is comparable to baseline.

7.2. Computation Throughput and Energy Efficiency. In this subsection, we will discuss the computation throughput as well as the energy efficiency of the system. Figures 5 and 6 show throughput, and Figures 7 and 8 depict energy efficiency.

7.3. Computation Throughput. In Figures 5 and 6, our experiments have show that with low-bit width quantization, we can achieve a high throughput in results. The low-bit width quantization techniques have significant benefits because it allows for high memory cache to be used as well as removes memory constraints in deep learning methods. This enables faster data movements and more efficient computation of the throughput in hardware acceleration. And it enables the device to do more operations per second, significantly speeding up workloads. Because of these advantages, low-bit width implementations are likely to become common in training and inference, particularly for convolutional neural networks.
FIGURE 3: The accuracy comparison for AlexNet model.
FIGURE 4: The accuracy comparison for VGG-16 model.

FIGURE 5: Throughout with difference data quantization with Caffe [CPU].
FIGURE 6: Throughput with difference data quantization on FPGA.
FIGURE 7: Energy efficiency with difference data quantization with Caffe [CPU].
FIGURE 8: Energy efficiency with difference data quantization on FPGA.

7.4. Computation Efficiency. Figures 7 and 8 demonstrate that the low-bit width quantizataion neural networks improve power efficiency. As we have discussed in the subsection of computation throughput, it reduces memory access costs by enabling high memory cache usage and increasing compute efficiency. Using low-bit quantization can reduce power consumption and save significant energy. Low-bit width quantization uses less energy and enhances compute efficiency, resulting in lower power consumption. Furthermore, decreasing the number of bits used to represent the neural network's parameters results in less memory storage.

Generally, among all the data quantization as observed from Figures 5 to 8, low-bit width-based designs demonstrate exceptionally good speed and energy efficiency. This indicates which extremely low-bit width is a likely answer for high performance. However, the extremely low-bit width has accuracy reduction.

7.5. Resource Utilization. Table 1 shows the trained CNN on FPGA resource usage. During training, CNN on FPGA consumes huge computational resources. We trained our models on the de1_SoC board before changing any parameters, and the resource usage is illustrated in Table 1.

Our design, as stated in section III, includes two major variables: the number of computing units and the number of SIMD. The replication of full data paths is the total number of computing units, that also controls the balance among both resource usage. Additionally, a compute unit may be composed one or more processing elements depending on our design choice. Having more processing elements per compute unit can significantly raise the data processing speed by allowing single instruction multiple data (SIMD) execution mode.

The number of SIMD processing elements is a design choice that also allows for contiguous memory retrieval which can enhance memory utilization efficiency. In the design, we were using a static configuration number of SIMD units, which allowed us to work with restricted on-board resources. We investigate how well the number of computing units and SIMD impact the De1 Soc-based board's resource utilization and throughput.

In order to achieve the maximum performance of our design, we configured the SMID as fixed as well as varied the number of computing units. When both parameters grow, there is also a growth in resource usage. Furthermore, with data path replication in the framework, the number of computing units does have a greater effect on resource utilization than that of the number of units. Whenever these variables are increased, it is simple to see even a linear improved performance in throughput. However, because of the limited resources on the DE1 SoC, the integration of computing is equal to sixteen as well as SMID sixteen results in successful synthesis both on fixed point and floating point.

7.6. Power Measurement. The power consumption is an important element in hardware accelerator performance. The power drain on one of the devices tells us how hard it is working and how power-intensive the design would be. This is especially essential for evaluating deep learning applications for hardware accelerators, where power consumption is a major consideration. We measure performance and power consumption by using the Perf performance analysis tool for Linux. The idle CPU-only system absorbs 50.70 W before the FPGA accelerator board is installed on the system. When using Caffe tools to run AlexNet and VGG-16 models, the average power utilization starts to rise to 109.2 W. Whenever a DE1 SoC-based FPGA board is properly configured, the idle power consumption rises to 63.40 W. Throughout CNN kernel implementation, the overall power usage of the hardware acceleration rises to 78.2 W by averages. Thereby, a power use for running a CNN framework on the a DE1 SoC-based board is (78.20–50.70) = 27.5 W.

7.7. Comparative Discussion on Previous Work and Other HPC Platform Design. In this section, we would first compare our implementations with previous FPGA research. The following is a comparison with similar designs focused on other high-performance computing platforms, such as CPUs and also GPUs.

7.7.1. FPGA-Based Design. We contrast the proposed models' efficiency to that of a number of other recent FPGA-based CNN design features. To determine the throughput, divide the total floating point numbers or fixed-point operations through the entire execution time and then use GOP/S as a unit for floating point as well as fixed-point operations in our implementation design. Zhang et al. [31] implemented a convolution layer which obtained 61.62 GOPS again for single precision floating point design. Similarly, the work by Yufei Ma et al. [13] reported 134.1 GOPS and 117.3 GOPS on a convolution layer for AlexNet and NIN model, respectively, while they achieved the overall performance 114.5 GOPS and 117.1 GOPS for AlexNet and NiN model, respectively. Our throughput from the 4-bit fixed point on DE1_SoC for AlexNet model 203.75 GOPS and also for VGG-16 model 196.50 GOPS on DE1_SoC. Our work gained 1.78x more throughput over the work by Naveen Suda et al. [5] with only using 85 DSP blocks. Furthermore, our design outperforms the RTL design in [13] by 1.51x on the different boards, demonstrating that OpenCL-based designs can compete with RTL designs. When compared to other designs, our DE1 SoC design has had the highest throughput, and there is still room for improvement.

7.7.2. Other HPC Platform-Based Design. We as well introduce energy consumption as both a measure for evaluation, which would be the ratio of throughput to power consumption (GOPS/Watt). In terms of throughput, the GPU is the best alternative, followed by one FPGA design, as shown in Table 2. Power usage, on the other hand, is an important measure to take into account in modern digital design. The GPU absorbs 3.709X so much energy than that of the FPGA, and the FPGA is 22.613x more efficient than the CPU.

TABLE 1: Resource usage CNN training.

Data quantization (bit)	ALUTs	DSP	FFS	M10 K
32	139913	85	172677	497
16	108313	76	144798	422
8	88712	64	126918	346
4	74511	52	91158	187

TABLE 2: Compare with other devices.

Platform	CPU Intel® Core i5-4300	GPU AMD Radeon (TM) R5 M330	FPGA DE1_SoC
Technology	22 nm	28 nm	28 nm
Power (Watt)	58.5	94.50	18.5
Throughput (GOPS)	28.50	280.60	203.75
Energy efficiency (GOPS/W)	0.487	2.969	11.013

8. Conclusion

In this work, we show a training and classification of a deep neural network that use the Intel, FPGA OpenCL SDK. To determine the best design requirements to speed up the CNN model for training while using constrained FPGA resources, we proposed a design space exploration methodology for energy efficiencies and resource utilization. We implemented CNN models such as AlexNet and VGG on the DE1 SoC FPGA board using the proposed approach as well as gained higher performance when compared to earlier work. As we compared with the other platform, the CNN training on FPGA consumes less power consumption and training time. Our findings indicated that FPGAs could obtain greater power or energy efficiency than GPUs, which typically restrict improvement only to power efficiency. We noted that it is mainly due to the huge difference in maximum compute performance as well as the external memory bandwidth between FPGAs and GPUs.

Generally, our designs achieve 203.75 GOPS on Terasic DE1 SoC with the AlexNet model and 196.50 GOPS with the VGG-16 model on Terasic DE-SoC. This, as far as we know, outperforms existing FPGA-based accelerators. Compared to the CPU and GPU, our design is 22.613X and 3.709X more energy efficient, respectively.

Data Availability

The source of the author's framework along with the datasets and analysis during the current study is already publicly available on https://image-net.org/challenges/LSVRC/2012/index php which is maintained by Princeton University and Stanford University. Quartus-18.1.0.625 software was used for processing and classification purposes during the author's research experiment.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

In this paper, the existing dynamic adaptive recommendation methods are studied, which combine the practical application scheme of transforming the actual dynamic adaptive recommendation problem into user microblog information. After that, a dynamic adaptive weight fusion method is proposed and based on experimental verification, a real-time dynamic adaptive recommendation system is finally designed. The speech recognition of the Internet of Things takes natural language problems as the research object for a long time and takes the sound signal as the research topic. This paper analyzes the application of dynamic adaptive recommendation and Internet of Things speech recognition in mass sports data monitoring. The simulation results show that the system in this paper is convenient for users to monitor the exercise indicators in real time through the mobile client, and at the same time query the exercise historical data and compare the exercise data through the network terminal, thereby improving the exercise method and exercise load. Users can access the motion monitoring module and see the past floating state of motion parameters more intuitively than graphs, contains queries for metrics such as heart rate, body temperature, kinetic energy, pulse, and weight. Due to the diversity and complexity of people's differences, personal characteristics and business environments, sports data monitoring systems also need to be designed according to the scope of use. This paper analyzes the requirements for a motion data monitoring system and provides the system architecture design and basic data for producing detailed information for the system.

1. Introduction

This paper mainly proposes a dynamic adaptive recommendation method that meets the user's interest, content, and site operator's authority [1]. Based on the rearrangement of the adaptive recommendation method, the characteristics of the dynamic adaptive recommendation method are integrated [2]. In order to prove its practicability, it was verified by coding. After proving the effect of the method, this paper designs and develops a personalized prototype system. The experimental environment of this article is (1) hardware configuration: Intel(R) I5-3110M3.2 GHz, 12G memory; (2) operating system: Win764 bit; (3) development environment: Eclipse, MySQL, Navicat, editolus R2012. At this stage, most of the Internet of Things speech recognition

technologies are based on statistical models. From the principle of speech generation, speech recognition can be roughly divided into two parts: speech layer and language layer [3]. The difficulty of current Internet speech recognition technology can be solved from the aspect of speech characteristics. Audio model is the most basic model that represents audio information, and it is also an important part of the system [4]. The type of training unit directly depends on the method of feature extraction. Feature extraction requires the extraction function not only to effectively reduce the data volume of the digital audio signal, but also to ensure the validity of all the original audio information [5]. However, due to the serious deficiencies in the development system of mass sports at this stage, the specific manifestations are incomplete basic facilities, imperfect

organizational structures, insufficient funds, lack of management talents, and lack of "work is sports" [6]. On this basis, we can take advantage of the favorable promotion of new construction to actively study the development path of mass sports in the field of construction, which has important significance in practical applications [7]. The sports data monitoring system server must provide real-time services for many sports users [8]. In order to realize real-time data monitoring, the system server provides stable and efficient features with low latency. At the same time, online operations are supported. By analyzing two traditional synchronization models, it is difficult for the traditional synchronization model to meet the scalability of complex network services [9]. The SEDA concurrency architecture model can flexibly adapt to system requirements and expansion, and combines the advantages of multithreading and event-driven that can maintain excellent performance in the environment. This will simplify the development of the system server, while also increasing the speed of the server, which contributes to the performance of the entire system [10]. Provides a strong foundation to optimize and promote server performance.

2. Related Work

The literature introduces the research content of the sports health evaluation model and explains the concept of sports health evaluation. Due to the complexity and randomness of the movement process, we can use the Markov statistical model for analysis. Next, the basic theory of the MARKP model is described, and the characteristics of the Markov model are analyzed [11]. Finally, for sports health assessment and various requirements of the group, an exercise model of health assessment is proposed. The literature introduces a real-time monitoring system for data collection hardware equipment, user equipment data, and sports data [12]. The data collection hardware equipment can be used to obtain real-time user data and display sports data. Among them, the data collection device uses 3D acceleration sensors to analyze the characteristics of people participating in the movement. These data are converted into a base station, and the base station sends specific data to the system communication service memory, combining the characteristics of the user's body and the energy consumption of the exercise, and finally sends the obtained data to the mobile monitoring terminal [13]. The literature introduces the operation time and energy consumption data obtained from the exercise data real-time monitoring system and proposes a health assessment model to explain the data consumption and personalized exercise to achieve the purpose of providing recommendations [14]. The literature analyzed the characteristics of energy consumption and individual height and weight during exercise, and proposed a health evaluation model for sports population [15]. The purpose is to eliminate the differences caused by individuals in sports, make an objective evaluation of the athletes, and give a reasonable evaluation effect to the sports team. The literature describes the basic principles of neural networks and the basic theories of audio signal processing [16]. First of all, based on the

principle of speech recognition, the speech recognition has been improved. Including digital sampling of audio signals and digital sound signal analysis, while spectrum analysis technology is suitable for signal content analysis and extraction. The literature introduces the back propagation network model and the deep belief network model, and gives some opinions and suggestions, many of which still need to be in-depth research and testing. In terms of speech processing, the samples used are collected in an ideal indoor environment. In practice, the samples may have obvious noise. Therefore, the influence of noise should be eliminated first in the experiment process to improve practicability.

3. Theoretical Basis of Dynamic Adaptive Recommendation and Internet of Things Speech Recognition

3.1. Dynamic Adaptive Recommendation. In this article, taking into account the degree of decline in the time value, it is divided into the following processes:

(1) Based on the original data, calculate sports popularity and time decay factors, and save them in their respective popularity databases and damping factor databases

(2) Use the neighborhood method to calculate the user motion similarity matrix and store it in the neighborhood method similarity database

(3) The loss function is defined by the matrix factorization method and stored in the loss function library of the matrix factorization method, and the processed data is used as the score value of the sports user

(4) The adjacent optimizer consolidates the similarity between flow motions in two stages to optimize the neighborhood method

(5) Fuse the loss function and the results of the 4 steps according to the initial ratio

(6) Combine the results of the time loss coefficient with the dynamic merge module to generate a list of suggestions

(7) Dynamically train the weighting factor according to the call of the recommendation result to find the best factor value

Figure 1 shows the recommendation system architecture of the dynamic adaptive fusion algorithm.

Through calculation and analysis, the square root of these types of exercise sample sizes can reduce missing data and improve the accuracy of recommendations. The improved popular formula is as follows:

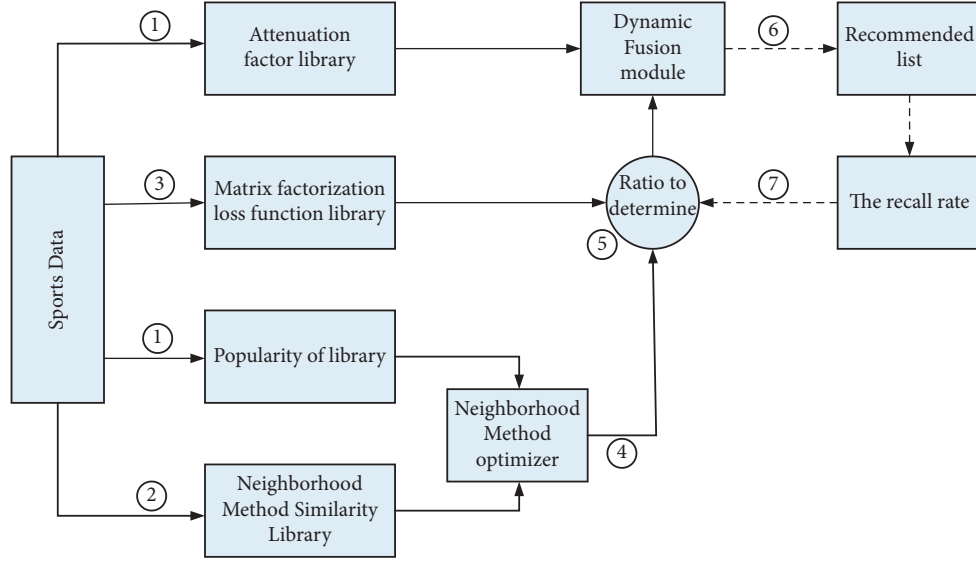
$$
\text{pop}_j = \begin{cases} \dfrac{|N(j)|}{\sum_{j \in pp} \|N(j)\|}, & \text{Popularity} \geqslant 200, \\[4mm] \dfrac{|N(j)|}{\sum_{j \in \text{pop} < 200} \sqrt{|N(j)|}}, & \text{Popularity} < 200. \end{cases} \tag{1}
$$


Figure 1: Dynamic adaptive fusion recommendation system framework.

All developments are time-sensitive, so this article introduces the concept of time fading. Suggestions for concave time decay function is as follows:

$$f(x) = \varphi^x. \tag{2}$$

Popular sports have long-term effects, while low-popular sports have temporary effects, so we first define the time frame function and use it as an exponential variable.

$$f_{ts} = -(T_c - T_0),$$
$$TD_j = e^{f_{ts}} \times \frac{1}{pop_j}. \tag{3}$$

The neighborhood method is used to calculate the similar relationship between users and sports according to formulas.

$$W_{ij} = \frac{|N(i) \cap N(j)|}{\sqrt{|N(i)\|N(j)|}}. \tag{4}$$

The matrix factorization technique uses the following formula to optimize the function of the power difference.

$$f_{loss} = \sum_{i=1}^{n} \sum_{j=1}^{m} \left(\mathbf{R} - \mathbf{u}_i^T \times \mathbf{v}_j \right)^2. \tag{5}$$

First, we define a similarity consistency function to ensure the consistency of the similarity matrix between users and sports obtained in the two calculations.

$$f_{smc-u} = \sum_{i=1}^{n} \left(\frac{\sum_{u_p \in KNN(u_i)} W_{ip} \times \mathbf{u}_p}{|KNN(\mathbf{u}_i)|} \right)^2,$$
$$f_{smc-v} = \sum_{j=1}^{m} \left(\mathbf{v}_j - \frac{\sum_{v_{jq}} \times \mathbf{v}_q}{|KNN(\mathbf{v}_j)|} \right)^2. \tag{6}$$

Whether users like sports and whether they are affected by popularity, so the optimization by multiplying the popular pop_j by the f_{smc-v} function is based on the proximity method.

$$f_{smc} = f_{smc-v} \times pop_j + f_{smc-u}. \tag{7}$$

Combining adaptive alpha weighting with time saving, used for time-based, adaptive f_{taf} mixing function, based on adjacent matrix transformation methods and techniques.

$$f_{taf} = (\gamma \times f_{smc} + (1 - \gamma) \times f_{loss}) \times TD_j. \tag{8}$$

Finally, we introduced a normalization function to prevent the dynamic adaptive recommendation algorithm from affecting the noisy data, so as to obtain the final objective function.

$$f_{MFDA} = f_{taf} + \lambda \times \left(\| u_i \|^2 + \| v_j \|^2 \right),$$
$$u_i = \frac{\text{Nei}(u) + (1 - \gamma) \times TD_j \times V \times R_i}{\gamma \times TD_j + (1 - \gamma) \times TD_j \times V \times V^T + \lambda},$$
$$v_j = \frac{\text{Nei}(v) \times pop_j + (1 - \gamma) \times TD_j \times U \times R_j}{\gamma \times TD_j \times pop_j + (1 - \gamma) \times TD_j \times U \times U^T + \lambda}. \tag{9}$$

Using the optimal solution of the alternating least square method, the prediction score matrix is finally obtained.

$$\text{Nei}(u) = \frac{\gamma \times TD_j \times W_{ip} \times u_p}{|KNN(u_i)|},$$
$$\text{Nei}(v) = \frac{\gamma \times TD_j \times W_{jq} \times v_q}{|KNN(v_j)|}. \tag{10}$$

In the simple addition fusion algorithm, the ratio of the neighbor method matrix decomposition method is 0.5. For comparison, the adaptive weighting factor of MFDA is fixed

TABLE 1: The relationship between times, weighting factors, and RMSE in different algorithms.

Index	10 to 29 years old		30 to 49 years old		50 to 69 years old	
	FSWA	MFDA	FSWA	MFDA	FSWA	MFDA
Training times weight factor RMSE	4	5	3	3	5	4
	0.4	0.15	0.2	0.34	0.7	0.74
	1.283	0.812	1.221	0.731	1.218	0.793

at 0.5. These three age records are applied to the FSWA and MFDA algorithms. The specific results are shown in Table 1.

3.2. Internet of Things Speech Recognition.

Sound waves are transmitted from the outer ear to the machine and converted into mechanical energy. When the last sogol (forged bone) in the cochlea moves, the flow of cochlear fluid generates traveling waves from the basement membrane. The impulse response of the cochlear basement membrane is represented by the function $\psi(t)$.

The response integral is zero.

$$\int_{-\infty}^{+\infty} \psi(t)dt = 0. \tag{11}$$

Mean square integrable or finite energy.

$$\int_{-\infty}^{+\infty} |\psi(t)|^2 dt < \infty. \tag{12}$$

Satisfy,

$$\int_{-\infty}^{+\infty} \frac{\Psi(\omega)|^2}{\omega} d\omega = C,$$

$$\Psi(\omega) = \int_{-\infty}^{+\infty} \psi(t)e^{-j\omega t}d\omega, \tag{13}$$

where $f(t)$ can all be mean square integral functions. The auditory conversion that converts the impulse response $\psi(t)$ of the base film to $f(t)$ is defined as follows:

$$T(a,b) = \int_{-\infty}^{+\infty} f(t)\frac{1}{\sqrt{a}}\psi\left(\frac{t-b}{a}\right)dt. \tag{14}$$

The above formula can also be written as follows:

$$T(a,b) = \int_{-\infty}^{+\infty} f(t)\psi_{a,b}dt,$$

$$\psi_{a,b}(t) = \frac{1}{\sqrt{a}}\psi\left(\frac{t-b}{a}\right). \tag{15}$$

This ensures that all values of α and b have the same energy.

$$\int_{-\infty}^{+\infty} \left|\psi_{a,b}(t)\right|^2 dt = \int_{-\infty}^{+\infty} |\psi(t)|^2 dt. \tag{16}$$

Definition formula of cochlear basilar membrane filter.

$$\psi_{a,b}(t) = \frac{1}{\sqrt{a}}\left(\frac{t-b}{a}\right)^\alpha \exp\left(-2\pi f_L\beta\left(\frac{t-b}{a}\right)\right)$$

$$\cos\left(2\pi f_L\left(\frac{t-b}{a}\right) + \theta\right)u(t). \tag{17}$$

The demand for inverse conversion comes from the reconstruction of decomposed signals such as music synthesis or noise reduction. Similarly, the original signal can be restored if it is inversely transformed.

$$f(t) = \frac{1}{C}\int_{a=0}^{+\infty}\int_{b=0}^{+\infty}\frac{1}{|a|^2}T(a,b)\psi_{a,b}(t)dadb. \tag{18}$$

Discrete-time auditory positive transformation.

$$T[a_i,b] = \sum_{n=0}^{N} f[n]\frac{1}{\sqrt{|a_i|}}\psi\left[\frac{n-b}{a_i}\right]. \tag{19}$$

Discrete-time inverse auditory transformation.

$$\widetilde{f}[n] = \frac{1}{C}\sum_{a_i=a_1}^{o_k}\sum_{b=1}^{N}\frac{1}{|a_i|}T[a_i,b]\psi\left[\frac{n-b}{a_i}\right], \tag{20}$$

$$h(a,b) = [T(a,b)]^2 \forall a,b.$$

In the next step, the output $S(i,j)$ of each hair cell represents the relevant neural spike in the center frequency response of the current filter.

$$S(i,j) = \frac{1}{d_i}\sum_{b=1}^{l+d_-1} h(i,b), \quad l = 1, L, 2L, \cdots; \forall i, j. \tag{21}$$

The output of hair cells is converted into energy-perceived loudness through a nonlinear cube root loudness function.

$$y(i,j) = [S(i,j)]^{1/3}. \tag{22}$$

Table 2 shows the frequency division under the Bark scale:

Assuming that the original ignition is $x(n)$, $0 < n < N$, the auditory conversion coefficients $T(a,b)$ of m channels and N points after auditory conversion are obtained. $1 \le a \le m$, $1 \le b \le N$, where α represents different channels corresponding to different center frequencies and b represents different positions at different times, depending on the audio signal processing result.

4. Design and Practical Application of Mass Sports Data Monitoring System

4.1. Demand Analysis of Mass Sports Data Monitoring System.

Before starting the topic, we determined that the system can meet the needs of three users and offline surveys. (1) We can

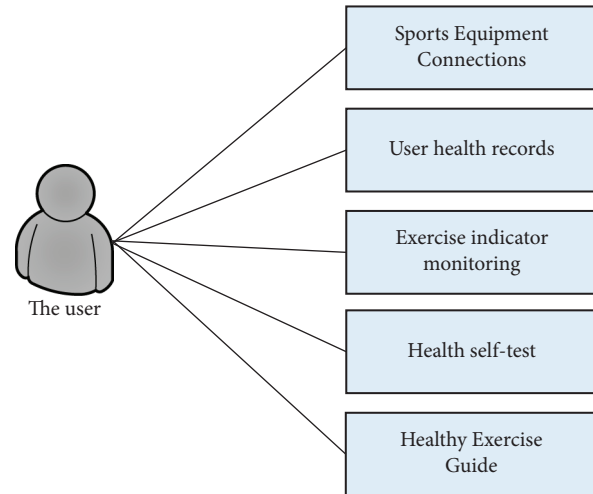
monitor the user's exercise index in real time. (2) The user's exercise index can be judged. (3) We can provide healthy exercise guidance according to the changes of users' exercise parameters.

The client mainly refers to the Android application. After the user registers with the client, if the login is successful, the APP will enter the basic interface of the function. The main interface of the APP is divided into five functional modules in the setting module: exercise equipment connection, exercise indicator monitoring, self-health assessment, healthy exercise guide, and user's health file.

(1) Connection of exercise equipment: to monitor the flow indicator, the user must connect the customer to a smart portable exercise monitoring device. The user clicks the "Connect Device" button to add a device, and the client's Bluetooth must be turned on before the device can be bound.

(2) Monitoring of exercise indicators: the functional exercise monitoring module is a module for real-time monitoring of user exercise data. This module mainly displays the flow data of the portable exercise monitor on the smart terminal and records the heart rate, body temperature, pulse, exercise speed, weight, and other exercise indicators. Users can monitor their movements in real-time anytime and anywhere, which is useful for accurately understanding their movements. Client use case diagram as shown in Figure 2.

When the user clicks "monitor exercise," the interface will take us to the "exercise data view" page. We can see the movement trend chart from the zero point of the week to the present. The data is updated every minute and the latest data is displayed in digital form in the upper left corner of the trend graph. And when we select an indicator, the indicator name will turn blue, and the trend chart corresponding to the indicator will be displayed. When you move the


mouse to a specific point on the trend graph, the data floating layer of the selected indicator at that point will be displayed. The system will provide personalized health exercise guidance based on exercise data. As shown in Figure 3.

(3) Self-health assessment: the functional module consists of three parts: basic information, health status, and exercise habits. The basic information module records the user's gender, age, weight, and other information; exercise habits: the user's exercise intensity, daily exercise time, etc. If the information recorded in the user's health file is different from the user's actual information, you can manually change it.

(4) Healthy exercise guide: the system provides a way to obtain multiple sets of self-health questionnaires from various aspects. The system will also identify users' anxiety and depression levels based on user problems and provide them with detailed health improvement plans.

(5) User's health file: daily articles on various healthy exercise guidelines, healthy diet guidelines, etc., will be published on the APP homepage. Improve users' health awareness, develop a healthy lifestyle, and prevent chronic diseases at the source.

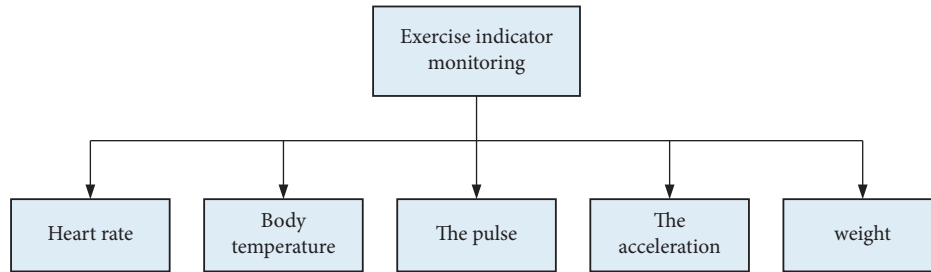
After the user completes the registration work from the mobile terminal, he can directly log in to the network terminal. If the user is not registered, the registration process must be completed, and the mobile terminal and the network terminal will synchronize user information. If the user is not logged in, he is not authorized to use some function modules. Users can input personal sports information through mobile devices or web devices to change their sports information. This information will be applied after the user clicks "Save," and the user's sports information on their mobile devices will be updated at the same time. If the practice data is different from the actual value, you can click the "Edit" or "Delete" button to perform the task.


FIGURE 3: Use case diagram of sports indicator monitoring.

When we click on "Sports Trends," the trend chart of the day the user selects the indicator will be displayed by default. The trend chart can display up to two indicators at the same time. When we move the mouse to a specific point in time, we will see the data drawing layer, and the indicator is now selected. According to the user's health report, the system uses a simple algorithm to obtain the user's health score, evaluate the health level, provide health notifications, and personalize the user based on the level, and we provide a reasonable recovery set plan.

Customers of this system are assigned to Android smartphones with different user groups. The display that can carry the human motion parameters is easy to display and does not require complicated work. The web-side motion parameter management cloud platform is almost distributed on every home computer. Users can monitor their movement anytime and anywhere, and if they find an abnormality, they can stop the movement. The system uses MySQL (a scalable relational database to store data) and uses HTTP communication for data communication between the client and the server to ensure data accuracy. The wearable motion parameter monitor and the client can use the Socket data communication method to synchronize the motion index data in real time and download it to the client. Scalability refers to the data transmission capacity of the system, and the coordination of single or system-wide functional modules can meet the conversion needs. The system uses the highly scalable Android platform and JavaEE Web platform, and the database uses the relational database of MySQL and SQLite, so the system can perform read-write isolation and data fragmentation processing, which can improve the overall throughput.

4.2. System Architecture Design.

The system is based on the Android platform and configures wearable health monitoring through various sensors to collect the person's heart rate, temperature, pulse, acceleration, and other exercise parameters, and performs exercise detection through the Bluetooth module. The Android client allows users to view and evaluate their health level through the Web health management cloud platform to monitor their exercise status in real time. The system consists of three parts: wireless sensor module, intelligent terminal module, and server module. Among them, the wireless sensor module is a smart module and a Bluetooth module, the smart terminal module is a mobile phone and an Android cloud platform, and the server module is a background server of the database. The sports health monitor collects data about the user's exercise, and the server receives the traffic data measured by the sports health monitor, analyzes it, and responds to mobile phone customers' requests. The Android client and the practice display communicate with data via Bluetooth. After activating the display, it is waiting to establish a Bluetooth connection with the Android phone. When two Bluetooth devices are connected to the same Bluetooth device RFCOMM channel, the mobile phone and the monitor normally establish a Bluetooth connection, the mobile phone obtains the motion monitor data, the server receives the connection request from the client, and then establishes the interactive thread data logic with the client. The whole system architecture is shown in Figure 4.

After the portable human motion monitor communicates with the Android phone through the Bluetooth module and is properly configured through AT commands, the Android smart phone will collect traffic information on the motion monitor. The built-in Bluetooth portable exercise parameter monitor for mobile phones can communicate data through Socket. After the Android mobile phone receives the exercise instruction data, it will analyze the data, save it, and display it in a certain format. It is a waveform diagram of the Android mobile APP interface.

Android XML development use layout files to design the interface, and each functional module uses activity classes to interact with users. The system is mainly divided into a motion parameter module and a maintenance module. The motion control module includes a heart rate module, a body temperature module, a kinetic energy module, and a heart rate module. There are four service modules: save practice data, process data, completeness warning, and manage practice information, and then click practice information.

4.3. Functional Module Design

4.3.1. The Layout of the Registration Page.

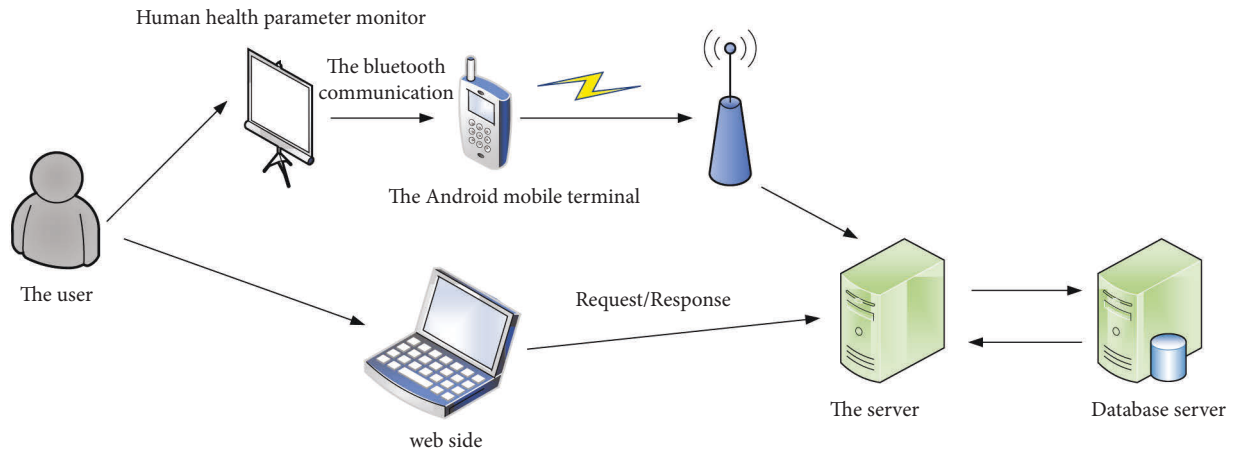
When the user uses the system application for the first time, user registration is required. When designing the UI interface of the "user registration" functional module, first create the layout file register.xml corresponding to the Activity, and then define the relative layout on the other side. EditText controls and buttons will be created in this layout. The EditText control is used to enter user information. Click the "Button" button to send the registration information entered by the external user. Then,


Figure 4: System overall architecture diagram.

generate another interface data.xml for receiving and sending data. The layout of the interface is relatively simple. Eight textViews have been added, and the registration form will display username, password, confirm password, gender, e-mail, and mobile phone. User information (such as b, Numbers, and real-time verification codes) will not be displayed in this interface of the application.

4.3.2. The Specific Realization of the Registration Function.

After creating the UI interface, create the RegisterActivity class inherited from the Activity class and implement the OnClickListener interface to cover onClick, where the getText method represents the registration information input by the user. Call the network interface class (requestapidat a) to create a getregistdata method, which interacts with the interface to create a user name, password, real name, gender, mobile phone number, e-mail, and other information entered by the user. Regardless of the login or registration function, it is very dangerous to send the password in plain text when connected to the network. The system uses the MD5 information digest algorithm combined with BASE64 to encrypt the password and calls the MD5 digest method to obtain a partial array of encrypted words.

This project is a network-side personal health exercise management that allows users to manage personal exercise parameters on various platforms (mobile and PC) to achieve personal health exercise management on multiple platforms. The system uses the open-source framework Spring, SpringMVC, and Mybatis to design a webchuk health exercise management cloud platform. The health exercise management cloud platform in the function module, registration module, and login module of the Weptuk system is divided into user health. The specific implementation of each functional module will be described in detail below.

If we are not familiar with the Webside health exercise management cloud platform, we need to register by clicking the register button at the top right of the homepage. When the user clicks the registration button, a registration mode dialog box will pop up, and the information that needs to be entered on the registration page includes user name,

password, gender, e-mail, and mobile phone number. The design of the registration interface mainly combines Spring mvc and JSP technology. In order to prevent unauthorized user input and malicious hacker attacks, the system introduces a verification mechanism, which regularly checks the information entered by the user on the register.jsp page. For example, when a user enters his mobile phone number on the registration page, if the input format or length does not match the regular expression format, the mobile phone number is entered incorrectly. At this time, a message will be displayed on the registration page showing the relevant mobile phone number and information that does not meet specifications. After entering the registered mobile phone number correctly, click "Get Confirmation Code," the page will display a 60-second countdown to start receiving the SMS verification code. The SMS verification function is an HTTP interface provided by the third party sendSms-ByHTTP. It is used to send Jixintong calls using the SMS platform Ali Da and sends the SMS template in the Ali-babaSmsUtils tool class, which sends short messages.

After the user successfully logs in, click "Healthy Sports File" to view past sports data. In this system, the exercise data of the health exercise management cloud platform is directly called from the database, and all these data are sent to the mobile client as exercise index data. The exercise index data is collected by the user using a wearable human exercise parameter monitor. The monitoring will be saved. The database uses paging technology to display a system generated from a large amount of relative exercise data measured at different time periods in a healthy exercise file.

4.4. Database Design.

The exercise data collected by the Android traffic monitor is retrieved via Bluetooth, and the exercise data is maintained locally and online to ensure that the data on the Android page is synchronized with the data on the server page. As shown in Table 3.

For Android, S'Lite is a lightweight database optimized for mobile devices. The system has developed an Android S'Lite database named joy Health, which contains five tables. (See Table 4)

TABLE 3: Mobile phone user information table (table name: user).

Field	Type of data	Field description
Id	Int	Data table auto-increment field
Username	Varchar	Registered user name
Password	Varchar	Password
Realname	Varchar	Actual name
Sex	Varchar	Gender
E-mail	Varchar	Register email
Phone	Varchar	Register mobile phone number
Date	Varchar	Registration time field
Is updated	Int	Whether to update to the server

TABLE 4: Heart rate measurement results of mobile phone users (table name: heart).

Heart_id	Int	Data table auto-increment field
Username	Varchar	Username field
Heart_value	Varchar	Weight measurement result field
Date	Varchar	Update time field
Is updated	Int	Whether to update to the server

5. Conclusion

In this course, we will design and implement a human health exercise management system based on Java Web and Android devices, and use cloud data processing technology to upload and save exercise parameters to the cloud. It is convenient for users to monitor exercise indicators in real time through the mobile client, and at the same time query exercise history data and compare exercise data through the network terminal, thereby improving exercise methods and exercise load, and avoiding physical discomfort caused by exercise. Scholars continue to study neural networks and audio signal processing. In this article, we use neural networks for speech recognition to conduct a more detailed study, so as to provide a preliminary exploration of the above problems. Deep learning is a new subfield of machine learning in the past few years, which focuses on NN model configuration and unsupervised learning using multiple layers of nodes. These detailed neural networks can better handle complex intelligence problems, and the way to process network model information is to imitate the human brain and can be used for speech recognition.

Fifth-generation (5G) cellular networks are state-of-the-art wireless technologies revolutionizing all wireless systems. The fundamental goals of 5G are to increase network capacity, improve data rates, and reduce end-to-end latency. Therefore, 5G can support many devices connected to the Internet and realize the Internet of Things (IoT) vision. Though 5 G provides significant features for mobile wireless networks, some challenges still need to be addressed. Although 5 G offers valuable capabilities for mobile wireless networks, specific issues still need to be resolved. This article thoroughly introduces 5G technology, detailing its needs, infrastructure, features, and difficulties. In addition, it summarizes all the requirements and specifications of the 5G network based on the 3rd Generation Partnership Project (3GPP) Releases 15–17. Finally, this study discusses the key specifications challenges of 5G wireless networks.

1. Introduction

The tremendous expansion in mobile connections and innovative applications has raised the demand for new wireless services. This expansion elevates the demands for network technical indicators to be more rigorous. According to Ref. [1], about 20.4 billion Internet of Things (IoT) devices will be connected via machine to machine (M2M) by 2020. According to Ericsson [2], the number of linked devices is predicted to reach 75.4–100 billion by 2025. Meanwhile, according to Huawei, the fifth-generation (5G) subscribers will reach 2.8 billion by 2025 [3].

Furthermore, the emerging 5G technology is the foundation for many future technologies and applications. As a result, the 5G mobile communication system has strengthened at a vital juncture in history to usher in an era of comprehensive information and give a superior user experience. Recently, the industry has been conducting extensive research on crucial 5G technologies, particularly with the emergence of Industry 4.0. As a result, the related inspection, assessment, and verification system must be established and upgraded. With the increasing demand for mobile traffic and the emergence of several technologies that require very high data rates, very low latency, and a broad spectrum, the next generation, 5G, is required to address these issues.

5G technology has eight innovative features such as ultrafast up to 10 Gbps, ultralow latency (1 ms), high capacity (large bandwidth), numerous connected devices, constant availability, and coverage everywhere designed to provide low energy consumption and long battery life [4].

IoT technology is one of the significant drivers of 5G technology. 5G provides innovative infrastructure for the IoT, and IoT use cases that are expected to grow significantly in the future. As a result, the IoT will also make a big difference in communication technology design. While 5 G will bring dramatic changes to cellular systems and the IoT, it faces some significant challenges [5].

The improved massive MIMO technique is another key technology employed in 5G [6]. Employing numerous antennas at the transmitter and/or receive in massive MIMO will considerably improve the wireless system's spectral and energy efficiency [7].

Another approach that allows the antenna to direct radio waves in a particular direction and the receiver is beamforming. Beamforming boosted spectrum efficiency and reduced interference while simultaneously transferring more data from more antennas [8, 9]. Furthermore, recently developed waveforms such as FBMC, UFMC, F-OFDM, and GFDM can overcome pulse shaping, filtering, and precoding issues to reduce the out-of-band (OOB) leakage of OFDM signals [10]. All of these technologies, as well as a few others, are regarded as critical enablers of 5G networks.

However, some issues need to be addressed to implement 5G technology. For example, 5G needs to enable device-to-device communication (D2D) and intelligent vehicle services, provide a reliable network, and ensure privacy and security. While D2D communication improves cellular reuse and interference with femtocells and microcells, and D2D communication can affect system performance because of sharing the same radio resources in the D2D network [11]. In addition, 5G needs to ensure network reliability and availability anytime and anywhere. Security and privacy are two critical challenges that 5G must address. 5G security and privacy challenges increase as the number of users and data exchange increases, increasing the number of threats [12]. In addition, 5G needs to deliver error-free, high-precision data transmission to meet its needs and vision. This is a significant challenge, especially regarding user mobility, which produces a doubly dispersive fading channel that needs complex equalization [13]. All these issues must be addressed efficiently to meet the demand and reach the specific goals of 5G technology.

Several survey papers on 5G technology have been conducted and published in peer-reviewed journals. A comprehensive assessment of the evolution of cellular networks toward 5G networks has been published [14]. The authors emphasized the new architectural paradigm change in radio network layout, air interfaces, smart antennas, cloud, and heterogeneous radio access network design (RAN). They have also detailed the core physical layer technology in detail. Recent research on 5G and IoT has been reviewed in Ref. [15]. They analyzed the new requirements for 5G-enabled IoT. Next, they explained the main methods of 5G IoT and analyzed future IoT issues and trends.

Meanwhile, a study of 5G energy-efficient systems was conducted in Ref. [16]. This paper explored new paradigms, including New Radio (NR), nonorthogonal multiple access (NOMA), machine learning, and cashable networks.

Another research study reports energy-efficient scenarios for green communications, such as D2D communications, spectrum sharing, UltraDense networks (UDNs), Massive MIMO, mmWave networks, and IoT [17].

This paper conducts comprehensive research focused on 5G technology. First, the paper outlines 5G networks, including the history of cellular networks, 5G cellular network architectures, 5G service-based architectures, NR 5G technologies, and standalone (SA) and nonstandalone (NSA) modes. Next, this paper will focus on the main requirements and specifications of 5G technology. This includes high data rates, low latency, wide bandwidth, many connected devices, network availability, coverage, low energy consumption, and long life. Finally, 5G specifications challenges such as frequency band completion, large amounts of data, MIMO technology, beamforming, D2D communication, ultralow latency, ultrareliable networks, security, and privacy will be outlined. This paper will help researchers and developers interested in 5G technology understand the challenges of the leading 5G requirements and specifications.

The rest of the paper is structured as follows. Section 2 provides an overview of the 5G system. We reviewed the fundamental requirements of 5G in Section 3, which included the eight 5G enabling critical criteria. Following that, Section 4 outlines the most pressing 5G standard challenges. Finally, Section 5 concludes the paper.

2. 5G System Overview

The 5G mobile system is the most recent mobile communication network technology that provides a new way to communicate, including widespread connectivity. Compared to the preceding 1st generation (1G) to the 4th generation (4G), 5G offers much higher performance. Furthermore, 5G should enable a new type of connectivity and applications such as smart vehicles, transport and car communications, and massive video downloads, as media is needed everywhere, a considerable increase in human, IoT interaction, and remote control with haptic feedback, all requires widespread connectivity, as shown in Figure 1.

At the same time, it has been designed to deliver a very low data rate to meet the needs of various applications, such as sensors and IoT applications [18]. In other words, it supports a wide range of applications, from those requiring a low data rate to those requiring a very high data rate with minimal latency. Even though the 5G network initially relied on legacy networks, the 5G cellular architecture is regarded as a heterogeneous network that must comprise macrocells, microcells, picocells, and relays. 5G speed tops out at 10 gigabits per second (Gbps), which is 10 to 100× faster than what you can get with 4G, as shown in Figure 2.

Furthermore, the mobile small cell system is an essential component of the 5G wireless cellular system, which includes both mobile relay and small cell systems.

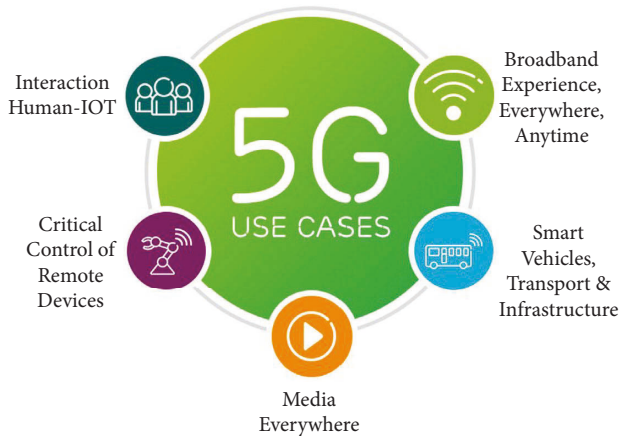
2.1. Architecture of the 5G Cellular Network. It is possible to notice from the existing 5G network that its multiple access methods remain stable, as evidenced by contemporary


Figure 1: 5G use cases.
Figure 2: Comparison between 3G, 4G, and 5G data rates.

technologies such as orthogonal frequency-division multiple access (OFDMA), which will most likely be used for the next 50 years [19]. In addition, there is no need to adjust wireless settings from 1G to 4G. However, additional implementation improvements can be made to the base network to meet user criteria [20]. As a result, after the commercial development of 4G is completed, package providers will migrate easily to the 5G network. To address the issues of 5G systems and meet users' needs, developing a 5G wireless cellular architecture requires rapid development. In Ref. [21], most wireless users spent about 80% of their time indoors and 20% outdoors. According to contemporary wireless cellular architecture, an outdoor base station at the cell's center supports outdoor and interior user contact. As a result, the signals would be transferred around the inside walls, allowing interaction between indoor and outdoor users. As a result, significant penetration loss occurs, resulting in a decline in performance due to a fall in spectrum effectiveness and the energy efficacy of wireless communications. To address this challenge, a new design method for building the 5G cellular architecture for various outdoor and indoor scenarios has been developed [22]. Massive MIMO technology [23], which allows for the geographical distribution of tens or hundreds of antenna units, is one of the design strategies that would limit penetration through interior walls. Instead of the conventional MIMO systems that use two or four antennas, massive MIMO systems use big array antenna components that provide significant capacity benefits. For indoor coverage, multiple technologies such as millimeter-wave communication [24], small cells, Wi-Fi,

ultrawideband [25], and visible light communication [26] are suitable for short-range, high data rate responses. However, visible light and millimeter-wave responses require the utilization of higher frequencies, which are not typically used in cellular responses. Notably, long-distance and external deployment of these high-frequency waves is not advised because the waves would not successfully penetrate dense materials.

On the other hand, these waves might be efficiently disseminated by flora, gases, and raindrops. Millimeter-wave and visible light responses have a wide bandwidth and can increase the data transmission rate of indoor setups [27]. In addition to the emergence of new spectra that are generally not used for radio interactions, another approach to solving the problem of spectrum shortages is to use cognitive radio (CR) networks to improve the spectral utilization of new radio spectra [28]. The heterogeneity of 5G cellular architectures requires the integration of relays, small cells, microcells, and macrocells.

In particular, the mobile small cell idea is a crucial component of the 5G wireless cellular network, which comprises small cell concepts and mobile relays [29]. This concept was developed to preserve users' connectivity with significant mobility in high-speed trains and vehicles. Furthermore, mobile small cells are installed inside moving vehicles to connect with users, while the massive MIMO unit is installed on the vehicle's exterior to communicate with the outdoor base station. From the user's point of view, the mobile small cell is identified as a regular base station, and the associated user is identified as a single entity with a base station, indicating the separation of indoor and outdoor construction. Furthermore, small mobile cell users employ high data rates for bandwidth-intensive services while reducing signaling overhead. The 5 G wireless cellular network design has two logical layers: network cloud and radio network [30].

Different elements with different functions make up a wireless network. The network functions virtualization (NFV) cloud comprises a control plane entity (CPE) and a user plane entity (UPE), with the more critical utility of the planes associated with the control plane and user plane, respectively.

Notably, the 5G cellular network architecture is critical in both the backhaul and front-end networks. Figure 3 shows a multilayer network with macrocells covered by D2D links, femtocells, picocells, and relays. Implementing multiple layers in a cellular network architecture results in the excellent management of interlayer and intralayer interference, resulting in improved overall power consumption, spectral efficiency, coverage, and capacity.

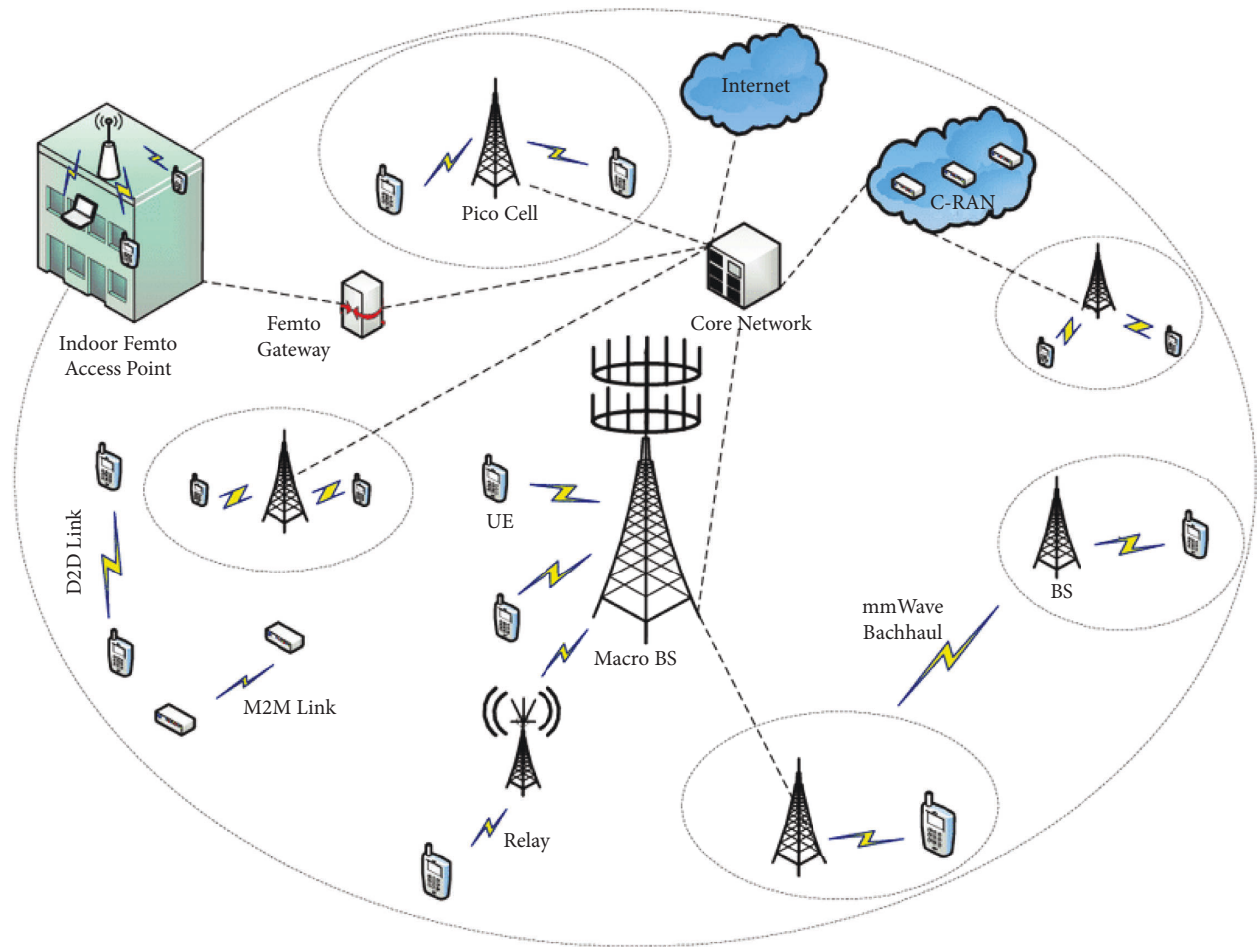
2.2. New Radio 5G Technology. The 3GPP is in the process of defining a new 5G radio interface known as NR [31]. Enhanced Mobile Broadband (eMBB) will remain substantial, driving demand for increased system capacity, enhanced coverage, and faster data rates. Nonetheless, the ambitions of 5G transcend beyond eMBB. For example, MMTC, often known as IoT, is concerned with enabling meager device


FIGURE 3: 5G cellular network architecture.

cost and energy consumption, offering extreme coverage, and handling a massive number of devices.

Another 5G goal is Ultra-Reliable Low-Latency Communication (URLLC), which provides data delivery with very low latency, for example, addressing critical industry applications. Furthermore, it is feasible that new and unexpected use cases will emerge during the life of NR. As a result, forward compatibility, which allows for the easy implementation of future optimizations, is a critical design requirement. Furthermore, improved network energy performance than the current systems is a key principle. Figure 4 depicts the several critical technologies that NR will support in 5G [32].

2.3. Standalone and Nonstandalone Mode. To improve 5G end-to-end performance, multiconnectivity is the optimal solution that combines long-term evolution (LTE) with reliable sub-6 GHz connections, such as simultaneous millimeter-wave connections. It can be used in the NSA mode with 5G NR [33]. This means that the 5G NR NSA mode means that the 4G network is used to connect to the control plane, and the 5G NR network is dedicated to the user plane. In contrast, in the standalone (SA) mode, both the control plane and the user plane use only the 5G NR leading network. Figure 5 shows both standalone and nonstandalone 5G NR systems. Technical work on NR began in the spring of 2016. The first release was part of Release 15 of 3GPP, and the NR specification was completed in late 2017. This initial release is limited to nonstandalone NR operations. NR devices rely on LTE for the initial access and mobility [34]. In addition, standalone NR operations are supported in the final release of 15 specifications available after June 2018 [35]. The difference between standalone and nonstandalone operations is primarily related to interface issues to the upper layers and core networks. The basic wireless technology is the same in both cases.

3. 5G Requirements

5G technology is driven by eight specification requirements, as shown in Figure 6:

(i) 100% coverage

(ii) Up to 10 Gbps data rate—>10 to 100x speed improvement over 4G and 4.5 G networks

(iii) one-millisecond latency

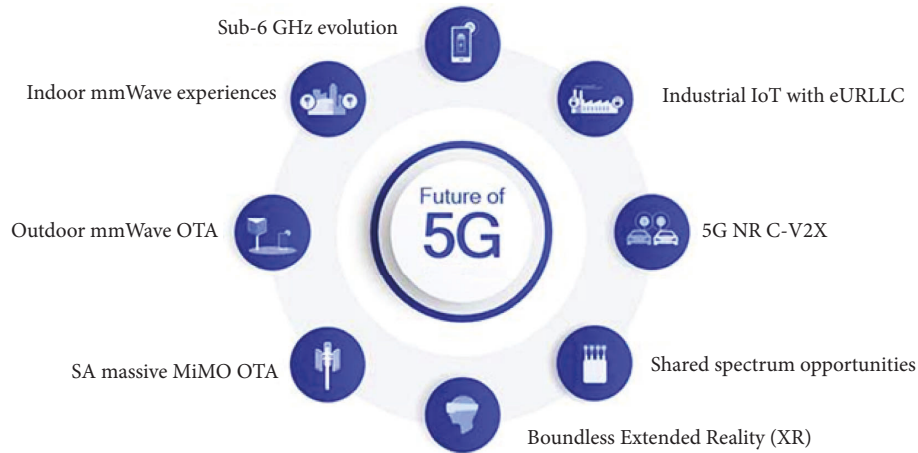
(iv) 1000 × bandwidth per unit area


FIGURE 4: Technologies supported by 5G NR.
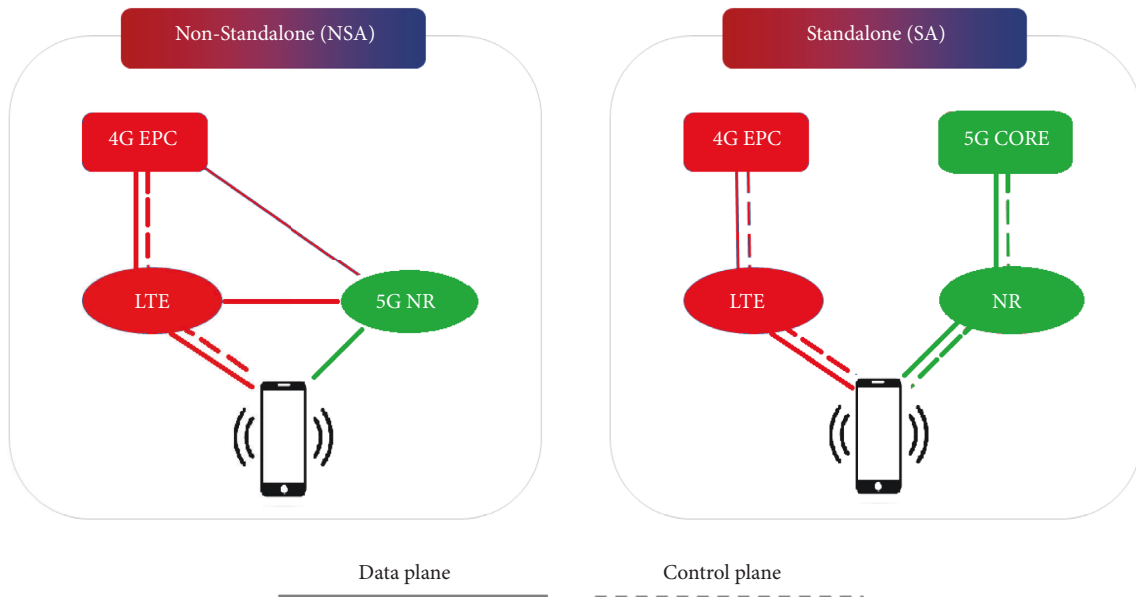

FIGURE 5: Nonstandalone 5G NR and standalone 5G NR.

(v) Up to 100x number of connected devices per unit area (compared with 4G LTE)

(vi) 99.999% availability

(vii) 90% reduction in network energy usage

(viii) Up to 10-year battery life for the low-power IoT device

3.1. High Coverage. Another issue for which 5G is looking for answers is coverage. 5G necessitates the perception of complete coverage [36]. By providing adequate coverage, technologies like IoT, D2D, and V2V can connect with the network from any location. Furthermore, because 5G enables network availability of up to 99.999 percent and coverage of nearly 100 percent, various services, including the technologies mentioned above, will be able to access the network at all times and from any location.

3.2. High Data Rate. The massive expansion in mobile connections over the last few years has increased the demand for large data volumes. This is the primary driving force behind the need for a high data rate in 5G technology. The 5G technology will support many services and applications that require high data rates. This system is designed to boost data rates up to 10 Gbps, a 10-fold improvement over the 4G network. Several advanced technical solutions, such as mmWave, massive MIMO, and various modulation and coding methods, enable 5G technology to achieve this goal [37].

3.3. Substantially Low Latency. One of the most significant needs that 5G focuses on is providing very low latency, where latency is the amount of time it takes for a request to complete an end-to-end round trip or the time it takes for the network to respond [38]. 5G latency will be significantly

1-millisecond latency

10 to 100x speed improvement over 4G

99.999% availability

1000x bandwidth per unit area

5G Technology

100% coverage

90% reduction in network energy usage

Up to 100x number of connected devices per unit area

10-year battery life for low power IoT device
Figure 6: Specification requirements for 5G technology.

reduced to 1 ms end-to-end round trip. The end-to-end round trip delay latency of a 5G network is ten times lower than that of a 4G network [39]. The low latency of 5G will enable various applications, such as AR, VR, self-driving cars, and remote surgery. [40].

3.4. Wider Bandwidth. Increasing capacity causes an increase in bandwidth. The traditional LTE network operates on a frequency band of 3 GHz. This property restricts 5 Gbps implementations and complicates the design difficulty [41]. A high bandwidth per unit space enables a large number of linked devices in a small area. This is possible using mmWave technology [42]. 5G technology will give 1000 times the bandwidth per unit area while increasing capacity by up to 10 Gbps [43].

3.5. Massive Number of Connected Devices. Another significant aim of the 5G system is dramatically expanding capacity and enabling a massive number of concurrently connected devices. Compared to legacy systems, 5G will support up to 10–100 times the number of concurrently connected devices [44]. Massive IoT devices and sensors will be connected to the 5G network because it is a crucial infrastructure network for IoT. However, the communication channels must also ensure a very high data throughput and minimal latency. Although connecting billions of devices and sensors to the network simultaneously is difficult, this goal can be realized by utilizing solutions like massive MIMO, D2D technology, and cloud RAN [45].

3.6. High Availability. Many of the services and applications enabled by the 5G network necessitate constant network connectivity. As a result, 5G promises to deliver a perception of 99.999 percent availability, implying that the network will always be operational. This functionality would enable users and devices to connect to and access the network at any time [46].

3.7. Enhanced Battery Life. The battery life in 5G is expected to be 10 years. This goal is attainable with the advancement of battery technology and power-consuming electronics. Increasing battery life is critical for devices with limited battery capacities, such as laptops, cellphones, and tablets [47].

3.8. Low Energy Usage. 5G will lower network energy consumption by up to 90%. This reduction in energy consumption by 5G must occur as it provides extraordinarily high speed [31, 48]. Even though 5G provides fast data rates, low latency and coverage, and 99.999 percent availability, it will increase energy consumption by allowing rapid switching between sleep and active modes.

4. 5G Specifications Challenges

Because of the high demand and complex features of 5G networks, various technological challenges must be addressed.

4.1. Wide Frequency Bands. Network traffic and required data rates will increase in the future. These developments require a higher frequency band than that used in LTE systems. Therefore, the current frequency band with a range below 4 GHz cannot support 5G requirements. Therefore, we need new technologies that can support high traffic and data rates anywhere, under any conditions. Millimeter-wave technology is the best way to meet such needs at the same time. This is because mmWave provides wider frequency bands supporting 5G network traffic data.

Moreover, using the mmWave with massive MIMO and beamforming techniques presents suitable 5G network implementation options. However, supporting high traffic and additional frequency bands increase system complexity and thus make the 5G network application challenging. More issues of wide frequency bands are coverage limitation and higher attenuation compared to the low-frequency bands [49].

4.2. Huge Data Volume. Each year, the number of devices linked to the Internet grows considerably, as does the volume of data. The major challenge with 5G is the billions of gadgets and sensors connected to the Internet. According to Huawei and Information Handling Services (IHS) forecasts [50], the number of linked devices will reach 75–100 billion by 2025. As a result, 5G must be capable of handling vast amounts of data from an enormous number of connected devices and sensors and processing it concisely [51]. As data volume grows, it causes difficulty and complexity in securing, processing, regulating, and analyzing massive amounts of data [52].

4.3. Ultralow Latency. Providing an ultralow latency carrier is a severe situation confronted via way of means of 5G systems. Many crucial packages, including self-using and healthcare enterprise uses, require latencies of 1 ms. To offer an extensively low latency under 1 ms with huge statistics is a complicated challenge that 5G has to achieve. Besides that, machine-type communications (MTC) is a utility that 5G networks in all likelihood want to aid wherein the gadgets mechanically speak with every other possibility [53, 54]. For applications such as V2V communication, this type of communication requires very low latency. The METIS and METIS-II projects, which are European projects for traffic safety, and the "connected cars" use case addresses information exchange among vehicles and with the infrastructure to enable those as follows:

(i) A safer and more efficient transportation

(ii) Real-time remote computing for mobile terminals.

On the other hand, it has been proposed that traffic efficiency and safety be a typical application test case, with latency being critical in system evaluation. Intelligent traffic systems are a common scenario shown in METIS and METIS-II, in which cars require fast data sharing to avoid accidents. Low latency will also improve user experience in applications such as multiuser gaming. This reduction in latency necessitates technological innovation in waveform

design and flexible architecture in the network's higher layers, both of which can be met by wireless software-defined networking. [55, 56].

4.4. Ultrareliable Network. The accuracy of data transmission without errors is known as reliability. Several future applications and services will want highly dependable networks that will not tolerate failures. Operating at high frequencies using mmWave, 5G will make wireless technologies more vulnerable. As a result, 5G must address this difficulty by utilizing technologies such as beamforming, MIMO, and software-defined networking (SDN) [57].

4.5. Security and Privacy. In wireless communication systems, security and privacy are two of the most critical considerations. They are also the two most significant problems for the 5G system. 5G will accommodate many connected devices with fast data rates and massive capacity, raising security and privacy concerns. As a result, 5G must provide and guarantee end-to-end privacy and security for users. The vast number of connected devices to the 5G network with massive amounts of data and security and privacy concerns were two of the critical issues that 5G faced. To protect data and users' privacy, security and privacy must be considered [58, 59].

4.6. Smart Automobiles. Once 5G is built, self-driving automobiles and smart automobile technologies will be available. Smart cities are also projected to be launched to support this application. 5G will enable smart vehicles to connect and serve as a data transfer hub for communication with roadside infrastructure and other services [60]. Because of safety-critical use cases and rapidly changing vehicular network architecture, enabling smart automotive technologies necessitates networks with significantly reduced latency and exceptionally high dependability [13]. As a result, the 5G network must be designed to meet the rigorous QoS requirements of smart vehicle systems [54].

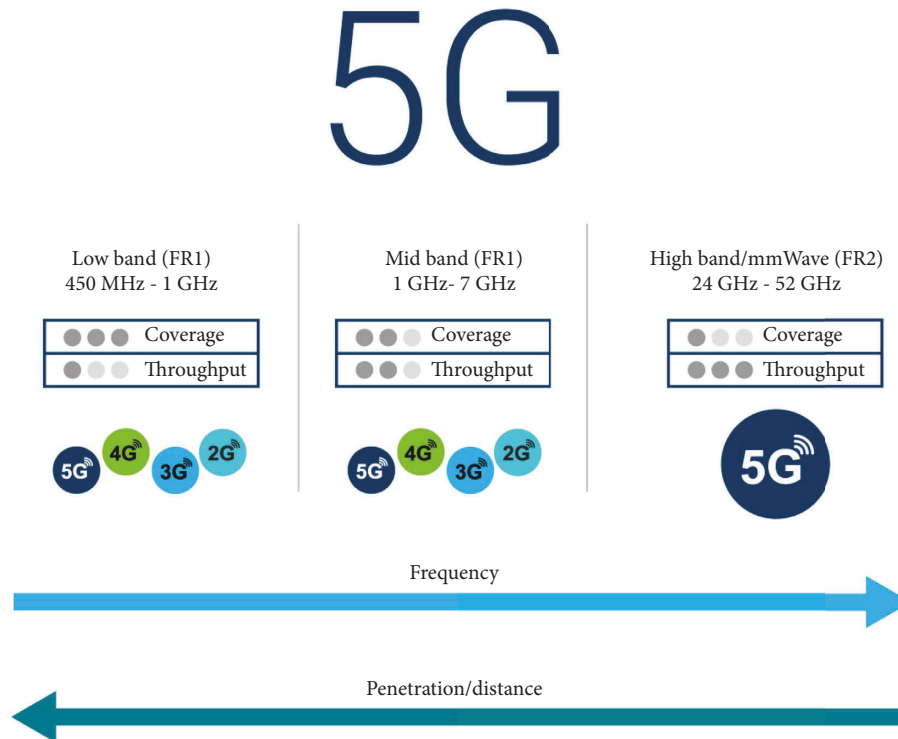
4.7. Spectrum Availability. The frequency spectrum is rare and is currently a supersaturated product. Therefore, it is important to evaluate the availability of the spectrum. Existing mobile technologies use frequencies ranging from 300 MHz to 3 GHz [61]. Regardless of this, new 5G frequency bands are being investigated. 5G uses low and high frequencies, as well as very high frequencies. Low frequencies (<1 GHz) and high frequencies (1–6 GHz) are commonly used for mobile communications. On the other hand, very high frequencies (30–300 GHz) represent a new spectral option for 5G. In Europe, Japan, South Korea, and the United States, intervals between 3.5 and 4.5, and also 28 GHz include targeted or allocated licensed and unlicensed bands. In addition, the 39 GHz band is typically used for 5G in the United States and Canada. The 39 GHz band can be helpful as this bandwidth is unsaturated and therefore is available for mobile communications. Figure 7 shows 5G radio frequency spectrum [62].


FIGURE 7: 5G radio frequency spectrum.

4.8. Air Interface. Due to the exacting requirements of 5G, a new air interface must be developed. Thus, new air interfaces, known as NR, are being created according to modulation schemes, which are being developed based on the scope of future mobile communication systems [63] since 5G using mmWaves technology, having small wavelengths, will require small antenna sizes. In other words, 5G uses a massive of small antennas. Exploiting beamforming technology directs the antenna's signals into a specific and desired direction, enhances the data rate, and increases the signal strengths with low interference [64]. However, 5G must overcome hardware design challenges, power consumption, directional accuracy, and analog-digital and digital-analog processes [65].

4.9. Special Protocols Adapt with 5G. Recent research is directed to apply particular protocols to improve the 5G wireless network specifications, such as the data rate, network congestion, and security. Applying network coding, co-operation networks, hybrid networks, etc. is an important technique to achieve the desired improvement.

Accordingly, applying network coding and co-operation networks resulted in what is called co-operation network coding (CoNC), which resulted in improving the data rate, network congestion, security, transmission packet error rate (PER), and bit error rate (BER) [66–69], where [51] the hybrid network was applied to improve the transmission range and to improve the PER. Moreover, improving the application over the physical layer was widely proposed

[70–72], and 5G applications more and more cover medical fields.

Future work is planned so as to focus on viewing an inclusive article that accumulates information for the medical applications that are suggested for 5G and B5G based on our published work in [73–77].

5. Conclusion

A complete survey of 5G technologies requirements and specifications challenges has been undertaken in this study. The survey describes the overall network architecture and essential requirements for the 5G network. Meanwhile, the paper introduced technologies that would make 5G a reality, including mmWave, massive MIMO, beamforming techniques, and other advanced technologies. Finally, the study outlined several essential difficulties that must be effectively solved before 5G technology can be globalized. This survey paper provides readers with a concise and in-depth review of 5G wireless networks.

Virtual reality and the Internet of Things have shown their capability in a variety of tasks. However, their availability in online learning remains an unresolved issue. To bridge this gap, we propose a virtual reality and Internet of Things-based pipeline for online music learning. The one graph network is used to generate an automated evaluation of learning performance which traditionally was given by the teachers. To be specific, a graph neural network-based algorithm is employed to identify the real-time status of each student within an online class. In the proposed algorithm, the characteristics of each student collected from the multisensors deployed on their bodies are taken as the input feature for each node in the presented graph neural network. With the adoption of convolutional layers and dense layers as well as the similarity between each pair of students, the proposed approach can predict the future circumstance of the entire class. To evaluate the performance of our work, comparison experiments between several state-of-the-art algorithms and the proposed algorithm were conducted. The result from the experiments demonstrated that the graph neural network-based algorithm achieved competitive performance (sensitivity 91.24%, specificity 93.58%, and accuracy 89.79%) over the state-of-the-art.

1. Introduction

Due to the global pandemic novel coronavirus [1], most of the pedagogical practices in all countries have to be carried out online, which significantly impacts or even hampers the expansion of teaching and learning activities [2]. Therefore, it is necessary to ensure the students concentrate on the content of courses during the process of learning. Meanwhile, the teachers also need to comprehend the dynamic changes of the entire online class. Both requirements have rendered the automatic identification of the status of the students become a thorny task.

In recent decades, virtual reality (VR) related techniques [3, 4] have been extensively exploited in a plethora of applications [5] ranging from industrial manufacturing [6], healthcare [7], entertainment [8, 9], and education [10, 11]. Meanwhile, different types of Internet of things (IoT) have also been deployed in practice [12], e.g., commercial and industrial scenarios [13, 14], medical assistance [15], and smart cities [16]. Both of them have shown their capacity and potential value in multidisciplinary tasks. However, online education especially music teaching remains a frontier domain that needs to be developed. Meanwhile, it requires an effective mechanism for measuring the students' academic performance since the adoption of the current evaluating manner might not be advisable.

Meanwhile, the deep learning-based models that emerged in the last years have been widely accepted as a powerful instrument in a plethora of domains and applications including but not limited to computer vision [17, 18], natural language processing [19], data mining [20], computer-aided diagnosis [21], recommendation system [22], and forecasting [23–26]. A variety of architectures were proposed in deep learning orientation, including the convolutional neural network (CNN) [27], recurrent neural network (RNN) [28], autoencoder [29], and generative adversarial network (GAN) [30]. It is worth noting that the deep learning-based algorithms focus on unveiling the inner

patterns hidden in Euclidean samples and they usually neglect the non-Euclidean data with complicated associations and interdependency, e.g., social networks. Therefore, these deep models suffer from applying the common computational operators used in the CNN, RNN, autoencoder, and GAN to the graph domain.

On the other hand, to cope with the non-Euclidean data, numerous graph neural networks (GNNs) were put forward with different patterns and have shown their satisfactory performance in the recent period. As the work of Goodfellow et al. [30] is taken as an early work of GNN, the recently emerged GNNs can be roughly divided into four categories, including convolutional GNNs [31, 32], recurrent GNNs [33, 34], graph autoencoders (GAEs) [35, 36], and spatial-temporal GNNs [37, 38].

Although, plenty of GNN-based algorithms have been presented to cope with various machine learning tasks, e.g., handwritten signature recognition [31, 37], document discrimination [32, 35], ranking [33], program verification [34], and human activity detection [38]. In recent 5 years, for instance, Zhang et al. [39], proposed a deep graph clustering framework. First, a feature transformation module is built up of both the node and graph topology. Second, a graph embedding and a self-supervised learning mechanism are introduced to constrain graph embedding by using the graph similarity and self-learning loss. To deal with the molecular graph generation issue for drug discovery, Shi et al. [40] presented a flow-based autoregressive model, which combines both the autoregressive and flow-based approaches. Zheng et al. [41] proposed a graph multiattention network to predict traffic conditions for temporal phases ahead at differentiated positions within a traffic network graph. Aiming at addressing the fact-checking problem in the text, Zhong et al. [42] proposed a method for reasoning about the semantic level structure of evidence by using semantic role labeling. These algorithms have shown their performance in various scenarios. However, most of the GNN-based methods ignore feature information for each node in the graph.

Bearing the abovementioned analysis in mind, this work fills a gap in the literature by introducing VR integrated with IoT into musical pedagogy. To the best of our knowledge, this is also an early work for the employment of VR and IoT in online education. First of all, the proposed music teaching platform exploits the VR techniques to offer a uniquely immersive service for each student to experience an actual scenario without any hefty cost. For instance, the students can virtually perform in front of a large audience without a real stage. Second, it can collect the real-time status of the students by using IoT sensors. Accordingly, the students' physiological status including the heart rate, respiratory rate, temperature, and facial appearance can be captured. Third, the GNN model can then be introduced to represent the integral circumstance of the students to form the whole feature vector space of the online class. The personal information of all students captured from the IoT sensors is denoted as the nodes in a graph. The subjective judgment of the students' performance (positive or negative) made by the teachers is used as the ground truth in the training samples.

Afterwards, a binary-class (positive and negative) graph neural network is trained over the manually labeled data samples. Accordingly, the subtle variation in this graph can be identified and predicted with high accuracy. The presented GNNs are then tested on the input samples and the practical condition of the students can be generated by updating the features embedded in the graph nodes. In general, the proposed network is supposed to alleviate the workload of the teacher in an online music class, while the network's output can unveil the status of each student revealed by the VR and IoT devices.

To evaluate the performance of the proposed framework, we conducted comparison experiments between state-of-the-art GNN models on the practical data samples collected from an online music class. Accordingly, the experimental results output from the proposed GNNs indicated that the GNN-based pipeline can come up with the practical engineering requirements.

In general, the contributions of this work consist of the following:

(1) To our best knowledge, this is an early work for using VR and IoT in an online music learning platform

(2) A semisupervised learning framework is proposed to recognize the students' status with GNNs. The situation of the entire class can be revealed prominently.

(3) The experimental results demonstrate the effectiveness and efficiency of the proposed framework

2. Materials and Methods

2.1. Online Music Learning Framework and Dataset.
An online music learning system (as shown in the left component of Figure 1) was built upon VR integrated with IoT sensors. This system consists of head-mounted VR display devices (Skyworth S801) and IoT sensors. The VR apparatus has $100°$ field of view and an optic lens. Before each class started, the students were instructed to wear both the VR apparatus and the wearable IoT sensors.

For each student, the data samples (heart rate, respiratory rate, temperature, and facial appearance) were collected and came into a feature vector at every 5 minutes. Then, three teachers labeled each sample as positive or negative separately by using a majority voting mechanism. In total, 6,104 recordings (3,020 positives and 3,084 negatives) from 16 students were collected in this study.

2.2. Graph Neural Network

2.2.1. Problem definition.
It is supposed that n subjects (i.e., the students as input samples) are available, denoted by $S = [S_1, S_2, ..., S_n]$. Each student then can be denoted by one matrix $Si \in R^{m \times ni}$, where m represents the total number of IoT sensors mounted on each student, n is the length of the feature derived from the corresponding IoT sensor, and $n_i \in \{0, 1\}$. The weighted graph used in the proposed GNN is denoted as a tuple $G = (V, E, W)$, where V is the set of m vertices, E represents the set of edges, and $W \in R^{m \times ni}$ is the
FIGURE 1: The pipeline from the online music learning platform with VR and IoT sensors to the non-Euclidean data structure.

adjacency matrix of the graph. Meanwhile, $W_{i,j}$ represents the weight of the edge from $v_i \in V$ to $v_j \in V$. In general, a global threshold is employed in the adjacency matrix to eliminate the irrelevant entries in the adjacent matrix or nodes in the graph. The space complexity of the proposed graph network is $O(n^2)$.

In general, the personal information of all students captured from the IoT sensors is denoted as the nodes in an undirected graph. Accordingly, the student's heart rate, respiratory rate, temperature, and facial appearance are integrated as a feature vector to represent the integral circumstance of the students. Meanwhile, the similarity between each pair of students is taken as the value of the edge between the two students denoted by two nodes. The edges with values lower than 0.4, which is set by conducting preliminary experiments, are eliminated from the graph.

In the proposed GNN model, the graph convolutional operator used can be considered as the spectral multiplication, which is equal to the convolution operator used in the temporal domain. Accordingly, the corresponding spectral filter can be realized by introducing the eigenfunctions of the normalized Laplacian into GNN.

$$L = I_m - D^{-1/2}WD^{-1/2}, \tag{1}$$

where D denotes the degree of the matrix and I_m is an identity matrix. Furthermore, the Laplacian matrix can be implemented by using Chebyshev polynomials [43]:

$$T_k(L) = 2LT_{k-1}(L) - T_{k-2}(L), \tag{2}$$

where $T_0(L) = 1$ and $T_1(L) = L$.

The K-ordered polynomial then yields unbiased K filters. Accordingly, the filtered outcome of the signal by K filters can be formulated as

$$o = g_\theta(L) * c = \sum_k 0_k \theta_k T_k(\bar{L})c, \tag{3}$$

where c denotes one IoT sensor mounted on a student, $L = 2/\lambda_{max}L - I_d$, and λmax is the maximal eigenvalue of the normalized Laplacian L. The output of the lth layer can then be expressed as

$$o_s^l = \sum_{i=1}^{F_{in}} g_{\theta_i^l}(L)c_{s,i}^l, \tag{4}$$

where F_{out} and F_{in} denote the output filter and input filter, respectively. $\theta_i^l \in R_K$ is the Chebyshev coefficient and $x_{s,i}^l$ is the input graph at layer l for student s.

A pooling layer is located at the end of the proposed GNN. In a fashion of semi-unsupervised learning, the feature map generated from the presented GNN can yield a pairwise association between the subjects. The intact GNN with the pooling operator is demonstrated in Figure 2.

2.2.2. Network Architecture. As described in Table 1, there are 3 pairs of convolutional layers integrated with the rectified linear unit (ReLU) as well as a pooling layer within the proposed GNN architecture. To guarantee the invariant scale for the graphs, the pooling is only incorporated at the end of the convolution operations. The dropout rate of every convolutional layer is 0.5.

In the initial stage, the training rate is set to 0.001 with fixed 500 iterations. Once the decrease in validation accuracy lasts for two consecutive iterations, then the learning rate is multiplied by 0.5. During the training process, 80% of the samples were used as the training set and the remaining 20% were taken as the testing set, and 100 of the training samples were used as the validation set. In total, there were less than 1,000 parameters in the proposed graph network. We trained the whole model by leveraging a back-propagating strategy and no overfitting was observed during training. Furthermore, the expected outcome of the proposed network is the binary status of each student (node in the graph) that is positive or negative.

3. Results and Discussion

3.1. Performance Evaluation Metrics. In this work, we used accuracy, sensitivity, and specificity in the experiments to measure the performance of the comparing methods.

(1) Sensitivity: the ratio between the number of true positives (TP, the samples are labeled as positive by the teachers; meanwhile, the method generates the correct result) and the number of all of the samples.

$$\text{Sensitivity} = \frac{TP}{TP + FN}, \tag{5}$$

where FN denotes the false negative (the outcome of one sample labeled as positive is negative).

(2) Specificity: the ratio between the number of true negatives (TN, the outcome of one sample labeled as negative is negative) and the number of all of the samples.

$$\text{Specificity} = \frac{TN}{TN + FP}, \tag{6}$$

where FP denotes the false positives (the outcome of one sample labeled as negative is positive).

(3) Accuracy: the ratio between the number of correctly identified subjects and the number of all of the samples.

$$\text{Accuracy} = \frac{TP + TN}{TP + FN + TN + FP}. \tag{7}$$

Figure 2: The structure of the proposed GNN.

Figure 3: The optimal threshold value set in the proposed GNN.

Second, we conducted the experiments on the 6,104 samples captured from 16 students by using the proposed approach. For each student, the corresponding number of samples ranged from 197 to 405. It is widely accepted that the quantity and quality of the training samples significantly relate to the performance of machine learning models, as well as the deep learning models.

Learning-based algorithms: accordingly, the sensitivity, specificity, and accuracy yielded from our model can rise or fall for different students in an online class, as shown in Figure 4.

As shown in Figure 4, the accuracy for all of the students is greater than 80% by using the proposed approach, while the accuracy of students 5, 12, and 13 is almost 100%. Moreover, we also examined the samples collected from student 6 whose accuracy is the lowest among the students. We found that student 6 contains the fewest samples (197) compared with the other students.

Generally, the proposed method can provide satisfactory sensitivity and specificity for most of the subjects. However, its performance relates to the quantity and quality of the input samples. By improving the data sample, the proposed GNN can be a potentially valuable instrument for online learning performance evaluation in practice.

Third, we conducted the comparison experiments between the state-of-the-art and the proposed framework on the entire dataset that was manually collected. Experimental results as shown in Figure 5 demonstrate that the current work achieved competing performance over the state-of-the-art techniques. Although the sensitivity produced by [37] is better than the proposed approach, this work outperformed the state-of-the-art methods [31, 37, 38] in both the specificity and accuracy of the whole data samples.

4. Discussion

The results of the experiments show that the proposed method can provide a favorable outcome for the issue that has an intrinsic graph structure, and it can be useful for other cases rendering similar characteristics. However, there are some limitations of the presented approach that need to be addressed before it is applied to those tasks. For instance, it does not take temporal information into consideration. Therefore, the relations between sequential samples might be

Table 1: Details of the proposed GNN architecture.

Layer	Conv	ReLU	Conv	ReLU	Conv	ReLU	Pooling	Class
Channels	16	N/A	32	N/A	64	N/A	N/A	2
K-order	9	N/A	9	N/A	9	N/A	N/A	N/A
Stride	1	N/A	1	N/A	1	N/A	N/A	N/A

3.2. Experimental Results. In this work, the proposed GNN was implemented with the TensorFlow 2.0 deep learning architecture with Python as the programming language.

The edge between each pair of students in the graph would affect the whole structure of the graph. A global threshold is expected to determine if one edge is preserved or not. Thus, we tested the effects of various threshold values to determine the optimal threshold. In the preliminary test, only 9 different numbers were leveraged (0.1, 0.2, ..., 0.9). Meanwhile, to decrease the computation complexity of calculating the optimal threshold value, only the subsamples were used during this stage. According to the outcome from the subsamples in Figure 3, 0.4 is chosen as the threshold value in the following experiments.
By leveraging it, personal information can be collected and formed into a non-Euclidean graph. Since it is difficult to employ the manners commonly adopted in an offline classroom, the identification and prediction of the students' real-time state deserve in-depth research for the online learning scenes. Bearing this in mind, we proposed a spatial-temporal GNN-based framework. Both the interdependent associations between the students and the corresponding development process can be unveiled from the presented GNN model.

To evaluate the performance of the proposed framework, comparison experiments were conducted between the state-of-the-art techniques and the proposed method. Experimental results demonstrated that the combination of VR and IoT, as well as GNN, should be taken as a potentially valuable instrument for online music learning.

In the future, the application of global average pooling (GAP) needs to be studied since it is supposed to decrease the number of parameters and eliminate overfitting and we will continue to delve into the online learning platforms and the applications of various machine learning-based algorithms into them.

Data Availability

The data used to support the findings of this study are available from the corresponding author upon request.

Disclosure

The funding sponsors had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript; and in the decision to publish the results.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Collaborative filtering (CF) techniques are used in recommender systems to provide users with specialised recommendations on social websites and in e-commerce. But they suffer from sparsity and cold start problems (CSP) and fail to interpret why they recommend a new item. A novel deep ranking weighted multihash recommender (DRWMR) system is designed to suppress sparsity and CSP. The proposed DRWMR system contains two stages: the neighbours' formation and recommendation phases. Initially, the data is fed to the deep convolutional neural network (CNN). The significant features are extracted from CNN. The CNN contains an additional layer; the hash code is generated by minimising pairwise ranking loss and classification loss. Therefore, a weight is assigned to different hash tables and hash bits for a recommendation. Then, the similarity between users is obtained based on the weighted hammering distance; the similarity between users helps to form the neighbourhood for the active user. Finally, the rating for unknown items can be obtained by taking the weighted average rating of the neighbourhood, and a list of the top n items can be produced. The effectiveness and accuracy of the proposed DRWMR system are tested on the MovieLens 100 K dataset and compared with the existing methods. Based on the evaluation results, the proposed DRWMR system gives precision (0.16), the root mean squared error (RMSE) of 0.73 and the recall (0.08), the mean absolute error (MAE) of 0.57, and the $F-1$ measure (0.101).

1. Introduction

Recommendation systems (RS) have recently become common on numerous websites, recommending movies, e-commerce, music, and television programs [1]. Based on the information provided by the user, the RS recommends items for purchase [2]. Several RS have been introduced to predict the behaviour of users and provide better recommendations [3, 4]. In general, RS recommends, based on the individual interests of the user and their previous usage history, finding items with the highest preference [5]. RS is a great machine learning system to increase product sales [6, 7]. Recommendation helps the user to speed up the search process and makes it simple for them to obtain content that is interesting to them, as well as provide them with offers they would not have searched for [8, 9]. Furthermore, companies may attract customers by showing movies and TV shows relevant to their profiles [10].

The approaches to recommendation may be categorised as collaborative filtering (CF), content-based (CB), and hybrid based on the type of data gathered and how it is used in the RS [11]. CB filtering is frequently used in the RS design, which uses items' content to select general characteristics and qualities that suit the user profiles [12]. Then, users compare items to previously liked items and recommend the best matching-items. The CF system works based on a user-item relationship. Hybrid systems utilise both forms of information to prevent issues that arise when only one type is used.

Although the recommendation system has demonstrated its usefulness in various fields, it faces some problems: sparsity and cold start problems (CSP). As the name implies, a sparsity problem develops when customers do not rate an item while purchasing online, resulting in a sparsity of available ratings. The CF method goes through this problem because it uses a rating matrix. A CSP arises when a new product is added to the recommendation system, and no past ratings for that product are available. As a result, an RS must provide options for new users, which makes the accuracy of the recommendations low. Several research groups are working to develop an efficient and well-organised RS algorithm. The methods like local sensitive hashing (LSH) [13], Bayesian personalized ranking (BPR) [14], Cofi Rank-maximum margin matrix factorization (CRMF) [15], etc. are used for removing sparsity and CSP. However, the existing methods fail to generate deep hashing by minimising classification loss, ranking pairwise, and high storage costs, motivating us to develop an efficient method for recommending items.

1.1. Contribution. The following are the research work's contributions:

   (i) The hash code is generated by reducing the classification and pairwise ranking loss, which can handle the users with cold start and sparsity problems.

   (ii) A weight is introduced to hash tables and hash bits according to their performance.

   (iii) The weighted Hamming distance is used to determine user similarity.

   (iv) Bit diversity and similarity preservation are utilised to calculate the hash bit's weight, and the MAP score is used to evaluate the weight-based table-wise.

   (v) The proposed DRWMR system performs better for the item recommendation.

The following is a summary of the paper's structure: Section 2 provides an overview of existing works. Our proposed DRWMR System is explained in Section 3. In Section 4, the proposed method is subjected to experimental analysis. Finally, the paper concludes in Section 5.

2. Literature Review

Da'u et al. [16] proposed a deep learning method that uses Aspect-based opinion mining (ABOM) in a recommendation system. This method contains two portions. They are rating predictions and ABOM. In the first portion, we utilised multichannel deep convolutional neural networks for extracting aspects. In the second portion, we add aspect-based ratings into a machine's tensor factorisation to predict overall ratings. This method increases the accuracy of the recommendation system, but the time consumption is more significant.

Ye and Liu [17] introduced Collaborative Topic Regression (CTR) and three novel granulation methods for the recommendation strategy. The three granulation methods are LDA-based, PMF-based, and CTR-based, based on building granular structures and conducting granulation. LDA-based and PMF-based methods are developed to extract granular features from content and feedback information. The CTR-based method is designed to be joined with LDA- and PFM-based methods to produce multilevel recommendation information and interpretable granular features. These methods were introduced to overcome the problem of time cost and decision cost. However, this method does not consider users' dynamic preferences.

Chen et al. [18] offered a Dynamic Decay CF (DDCF) recommendation method based on the user's interest. This method has four stages: clustering of items, identification of the interesting level, specification of the decay function, and preference prediction. In item clustering, similar items are grouped without any predefined parameters. Then, in the second stage, based on the number of ratings and time records in the cluster, we can identify the interesting level of users. In the third stage, decay functions describe the preference evolution at every level. Finally, the similarities between the users are calculated based on the decay rates, and future preferences are predicted. This method accurately predicts the user's interests, but the time consumption is high.

Beg et al. [19] introduced a chaotic based reversible data transform method (CRDTM) for preserving privacy in data mining for the recommendation system. This method will dynamically produce the values of RDT parameters during processing time, but it does not need the parameters during recovery. This method can substitute for the standard RDT algorithm, in which memory and bandwidth are considered significant factors. The RDT algorithm is used in the mobile app recommendation area. This method decreases the execution time, but accuracy is low.

Abbasi-Moud et al. [20] offered a context-aware recommendation system for tourism. It consists of three steps. 'Users' preferences are extracted from their reviews and comments in the first step. In the second step, tourist 'attractions' characteristics are extracted from the tourist reviews. In the third step, recommendations are given based on the 'user's preference and its similarity with the tourist attractions' characteristics and contextual information. The contextual information utilised in this method includes location, weather, user preferences, and time. This method gives high accuracy in tourism recommendation. However, the weather may change according to the season, so it's challenging to make a recommendation.

Zhang et al. [21] introduced a novel hybrid probabilistic matrix factorization method for distinguishing between items' attractiveness and users' preferences for a recommendation. It consists of two sub-divisions. One division attempts to predict the rating scores of users by extracting the user's personal preferences from auxiliary data. Another division attempts to model the textual interest of items for different users. These two sub-divisions are formed into a unified framework using a global objective function. This method gives high accuracy.

Choe et al. [22] offered a hierarchical model based on a recurrent neural network (HMRNN) for considering users' item usage histories in time series and sequences in a recommendation. This method contains two layers: a long-term (LT) and a short-term (ST). The ST sequences are handled by the ST layer, typically found in older ones. The LT layer recollects the data from the preceding ST sequences and distributes it to the lasting time. This method increases the amount of stored user history. However, it does not take the consideration of temporal properties.

3. DRWMR System

We propose a novel deep ranking weighted multihashing recommender (DRWMR) system to suppress sparsity and CSP by considering CSP and sparsity issues. This method has two stages: the neighbours' formation and recommendation phases. Initially, the user-item rating data of the user is fed into the neighbours' formation stage, and deep convolutional neural networks are used to extract text features. The deep neural network consists of an additional layer (hash table). The hash codes are produced by reducing the classification loss and pairwise ranking loss. The similarity preservation is preserved by pairwise ranking loss, and the prediction error is minimised by classification loss. Because each hash bit performs differently in the RS, it is not easy to treat them all equally. Therefore, a weight is assigned to different hash tables and hash bits for a recommendation. Then, the similarity between users is obtained based on the weighted Hamming distance—the similarity between users helps to get the neighbourhood formation for the active user. Finally, the rating for unknown items can be obtained by taking the weighted average rating of the neighbourhood and producing a list of the top n items. Figure 1 illustrates the architecture of the proposed DRWMR system.

3.1. Neighborhood Formation Phase.
The user-item rating data is given to the deep CNN, which is used to extract the features. Then, a hash code is generated by minimising classification loss and ranking pairwise loss. Therefore, a weight is assigned to different hash tables and hash bits. According to weighted Hamming distance, the most similar users are identified as active users.

3.1.1. Deep CNN.
The convolution and max pooling layers are used to extract the features. The demographic data of the user is fed to the convolution pooling layer. The convolution pooling layer is formed with the rectified linear activation function in the first three layers. The max pooling process is utilised in the initial convolution pooling layers, and the average pooling process is used in the final convolution pooling layers. They mostly use the original raw data to extract high-level representations. In the first three convolutional layers, we use 32, 32, and 64 with stride 1 for every convolution layer and a kernel size of 5×5. 3×3 is the size for pooling operations, while 2 is the stride for each pooling layer. The fully-connected layer uses a rectified linear activation function and a dropout layer with a 0.5 dropout ratio.

A tangent-like activation is used in the hash code layer to output hash codes. The softmax function is utilised as the activation function in the classification layers to preserve semantic similarity. The classification and hash code layers are sequentially learned in every training epoch. In the first fully-connected layer, the unit number is 500, the hash code's length is equal to the second fully-connected layer's output, and the number of classes is similar to the third fully-connected layer's output. A deep CNN architecture is constructed with this framework to learn the function of nonlinear transformation $\alpha(*)$ using the input as data. The hash bit is determined by using

$$a = \text{sign}(\alpha(K), \tag{1}$$

where K denotes the raw data, and sign (y) signifies the sign function.

The deep neural network consists of an additional layer (hash table). The hash codes are produced by reducing the classification loss and pairwise ranking loss. The similarity preservation is preserved by pairwise ranking loss, and the prediction error is minimised by classification loss. For a pair of users, the pairwise-loss function can be defined as follows:

$$S(a_i, a_j, I_{i,j}) = \frac{1}{2}(1 - I_{i,j})H_d(a_i, a_j) + \frac{1}{2}I_{i,j}\max(l - H_d(a_i, a_j), 0). \tag{2}$$

Such that $a_i, a_j \in \{+1, -1\}^h$,

where a denotes the user K's binary hash code, $H_d(a_i, a_j)$ signifies the Hamming distance between a_i, and a_j. The similarity between a_i and a_j is denoted by $I_{i,j}$, it is defined as

$$I_{i,j} = \begin{cases} 0 \text{ if } a_i, \text{ and } a_j \text{ are similar} \\ 1 \text{ if } a_i, \text{ and } a_j \text{ are dissimilar}. \end{cases} \tag{3}$$

The Hamming distance between the input user e_i, and its pairwise user is calculated to produce an arranged hamming list. The pairwise ranking loss for an input user e_i is defined in the following equation:.

$$P(a_i) = \sum_{j=1}^{M_i} P(S(a_i, a_j, I_{i,j})) = \sum_{j=1}^{M_i} S^2(a_i, a_j, I_{i,j}), \tag{4}$$

where M_i denotes the pairwise user's number for user e_i. Users similar to e_i should have short Hamming distances, therefore they seem at the top of the arranged Hamming list, whereas dissimilar data seem at the bottom. On the other hand, data at the improper positions of the Hamming list of e_i has substantial loss values. We aim to decrease the overall loss function for a training database with M user, which is given in the following equation:

$$P = \sum_{i=1}^{M} \sum_{j=1}^{M_i} P(a_i, a_j). \tag{5}$$

Such that $a_i, a_j \in \{+1, -1\}^h, i = 1, \dots \dots M$.

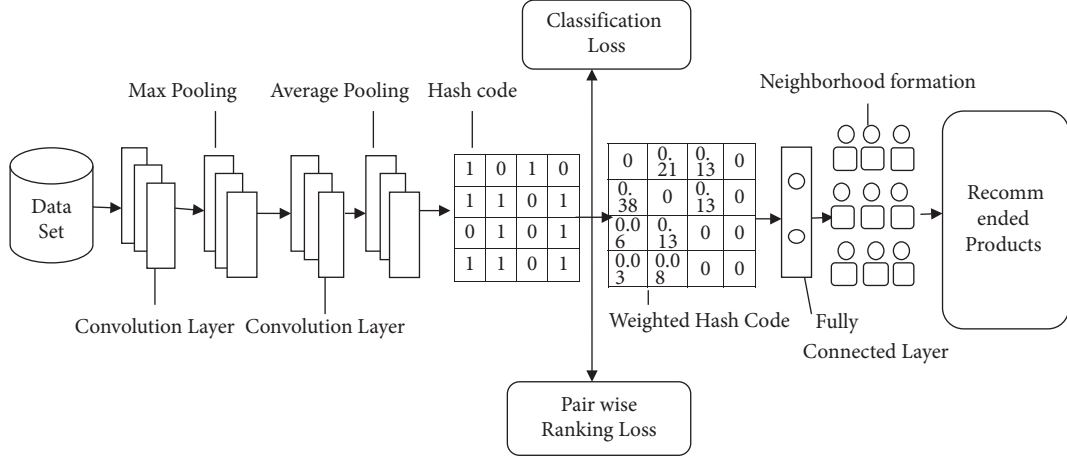
Since the hash codes are in binary, the fitness function is nondifferentiable. As a result, using the gradient descent approach is challenging for optimising the fitness function.


FIGURE 1: Architecture of the proposed DRWMR system.

Therefore, to overcome this problem, a tanh approximation function is used instead of the sign function. The tanh-like function can be used to estimate a_i's hash code, which is given as follows:

$$p_i(a_i) = \frac{e^{a_i} - e^{-a_i}}{e^{a_i} + e^{-a_i}}. \tag{6}$$

The Euclidean distance $E_d(p_i,)PJ$ between two users, can be further estimated as the Hamming distance $H(a_i, a_j)$ using the calculated hash codes determined in the following equation:

$$E_d(p_i, p_j) = \left\| a_i - a_j \right\|_2^2. \tag{7}$$

A regularisation term is included to reduce the quantisation loss. The final loss function is determined in the following equation:

$$P = \sum_{i=1}^{M} \sum_{j=1}^{M_i} \frac{1}{2} \left\{ \left(I_{i,j} E_d(p_i, p_j) + \frac{1}{2} I_{i,j} \max \left(l - E_d(p_i, p_j), 0 \right) \right)^2 \right\} + \sum_{i=1}^{m} \alpha \left\| p_i - a_i \right\|_2^2. \tag{8}$$

Such that $a_i, a_j \in \{+1, -1\}^h, i = 1, \ldots \ldots M,$

where α denotes the regularisation term's parameter coefficient. The classification layer outputs the recommendation for the category. As a recommendation function, the softmax function is used. The classification loss is determined in the following equation:

$$C_i = -\sum_{j=1}^{o} \hat{D}_{ij} \frac{e^{o_{X_{ij}}}}{\sum_{k=1}^{o} e^{o_{X_{ik}}}}. \tag{9}$$

Where o and o_x_{ij} signify the class's number and the recommended output of j's class for user e_i.

3.1.2. Weighted Multihashing.

A weighted multihash code is used based on the loss in the hamming distance. It multiplies the bitwise weight and table-wise weight to minimise loss. Each hash bit performs differently in the recommendation task, so it is not fair to treat them all the same. Therefore, a weight is assigned to different hash tables and hash bits. Bit diversity and similarity preservation are integrated for the bitwise weighting. The MAP value is utilised for each hash table to compute the weight-based table-wise. The weight-based table-wise and bitwise may change for dissimilar users. This method adjusts the two weights, and their

product determines the final weight. The bit b in table r final weight is defined as follows:.

$$WT_{b,r} = WT_{\text{bit}_b} \times WT_{\text{bit}_r}. \tag{10}$$

Similarity preservation (P) measures a hash bit's semantic similarity. The hash bit a_r''s similarity preservation (P) is calculated in the following equation:

$$Q(a_b) = \frac{1}{2} (a_b' I a_b - U), \tag{11}$$

where U signifies the training sample's number, and a_b' signifies the a_b's transpose.

The bit diversity is utilised to calculate the hash bit's performance. The difference between each user's hash bit is crucial for maintaining recommendation efficiency. Therefore, every hash bit must be independent. The correlation between two hash bits is used to determine bit diversity, which can be determined by the above formula.

Initially, a bitwise correlation metric $R = \left\{ r_{Q_{ij}} \mid i, j, \ldots \ldots h \right\} \in Z^{h \times h}$ can be generated by calculating $r_{Q_{ij}}$ for bit a_i and a_j pair. The bitwise correlation is measured using the Kappa value, which is determined in the following equation:

$$r_q = \frac{\varnothing_1 - \varnothing_2}{1 - \varnothing_2} \in [-1, 1], \tag{12}$$

where $\varnothing_1$, and $\varnothing_2$ denote the hash bit's probabilities. Eqn can determine the $_1$, and $\varnothing_2$ probabilities.

$$\varnothing_1 = \frac{w + z}{V}$$
$$\varnothing_2 = \frac{(w + x)(w + y) + (y + z)(x + z),}{v^2} \tag{13}$$

where w, x, y, and z denote the nonnegative variables indicating the sample's number that fulfills the relevant row and column requirements. The bit-correlated matrix $M = \{m_1, \ldots \ldots, m_h\} \in Z^{1 \times h}$ is formed by assigning the correlated coefficient for each bit. Finally, the bita_r's bit diversity weight is calculated by the following equation:

$$K(a_b) = \frac{1 - f_b}{2}, \tag{14}$$

where f_b signifies the bth bit's correlated coefficient. To generate a final bitwise weight WT_{bit_b}, the terms mentioned above are first adjusted and multiplied, which is determined in the following equation:

$$WT_{\text{bit}_b} = Q(a_b) \times K(a_b). \tag{15}$$

To combine multiple hash tables, table-wise weight (WT_{bit_r})for each hash table is determined using the mean average precision. It is specified in the following equation:

$$A = \frac{1}{P} \sum_{b=1}^{n} \frac{b}{P_b} \times \text{rel}_b, \tag{16}$$

where n signifies the size of the dataset, P denotes the similar user's number in the dataset that relates to the checking user, P_b denotes the similar user's number at the top of the dataset.

3.2. Recommendation Phase.
The neighbours obtained from the previous phase are used to generate a recommendation. This similarity between the active user and its neighbours is utilised to forecast the final rating for an unknown rating of item i. In this regard, the ultimate anticipated rating provided by user u for any item i is calculated as the following:

$$\text{Pre d}_{u,i}^U = \overline{r}_u + \frac{\sum_{u' \in N(u)} \text{sim}(u, u') \times (r_{u',i} - \overline{r}_{u'})}{\sum_{u' \in N(u)} \text{sim}(u, u')}, \tag{17}$$

where $N(u)$ is the user's neighbour, u and $\text{sim}(u, u')$ denote the similarity between two users.

The prediction value of each item can be sorted in descending order, and the top n items from this sorted list of items can be recommended to the user.

The similarity between the users can be obtained by the following equation:

$$\text{sim}(u, u') = \frac{\sum_{i \in I} (r_{u,i} - \overline{r}_u)(r_{u',i} - \overline{r}_{u'})}{\sqrt{\sum_{i \in I} (r_{u,i} - \overline{r}_u)^2} \sqrt{\sum_{i \in I} (r_{u',i} - \overline{r}_{u'})^2}} \tag{18}$$

where I is the set of items,$r_{u,i}$ rating of given to item $i$by user u, $\overline{r}_u$ average rating of user u.

4. Experimental Results and Analysis

This section contains the experimental setup and a description of the datasets for comparative analysis.

4.1. Dataset Description.
The movie Lens 100 K dataset contains numerous users' demographic data. There are 1682 movies in the dataset, with a total of 10,0000 ratings from 943 users. For this evaluation, data were gathered from the https://www.kaggle.com/prajitdatta/movielens-100k-dataset. It consists of the user's age, ID, occupation, and items provided. The datasets are used for 80% of the training, while the remaining 20% is used for testing.

4.2. Simulation Setup.
The proposed DRWMR system is implemented in python; the initial learning rate is 0.001, and after 1000 iterations, it lowers exponentially by 0.04. The batch size is 200, and the parameter coefficient is 0.01.

4.3. Evaluation Criteria.
The model's performance is evaluated using six metrics: recall, precision, F1-score, MAE, RMSE, and prediction accuracy.

(i) Recall:

It is the ratio of the total number of relevant recommendations to the actual or true number of relevant recommendations for a new user.

$$\text{RL} = \frac{F_r}{T_r} \tag{19}$$

where F_r denotes the recommendation related to the new user and T_r signifies the real amount of related recommendations.

(ii) Precision:

This metric indicates the precision of the process, i.e., whether the generated recommendations are appropriate for new users.

$$\text{PN} = \frac{F_r}{\text{tot}_r} \tag{20}$$

where F_r denotes the recommendation related to the new user and tot_r signifies the recommended item's total quantity.
FIGURE 2: RMSE analysis.

(iii) F1-score:

This score shows the experiment's accuracy based on the recall and precision measures and is calculated by the following equation:

$$F = \frac{2 \times RL \times PN}{PN + RL} \qquad (21)$$

(iv) RMSE:

It is measured by determining the difference between the predicted and observed values, which is given in the following equation:

$$R = \sqrt{\frac{1}{Q} \sum_{j=1}^{Q} \left(k_j - \hat{k}_j \right)^2}. \qquad (22)$$

(v) MAE:

The magnitude of the difference between the expected and observed values is computed to determine it, which is given in the following equation:

$$M = \frac{1}{Q} \sum_{j=1}^{Q} \left| k_j - \widehat{K_j} \right|, \qquad (23)$$

where Q signifies the user's total amount, $\widehat{K_j}$KJ denotes the predicted values, and KJ signifies the observed value.

4.4. Comparative Analysis with Existing Methods. The proposed DRWMR system is tested on the movie Lens 100 K dataset, and metrics such as recall, precision, RMSE, MAE, and F1-score are compared to existing approaches such as CTR [17], DDCF [18], CRDTM [19], and HMRNN [22].

4.4.1. Quantitative Analysis. Figure 2 illustrates the RMSE analysis of our proposed DRWMR system with existing methods such as CTR, DDCF, CRDTM, and HMRNN. Our research introduces a novel loss function that minimises the classification loss and ranks pairwise losses. It produces hash codes with high recommendation accuracy and more similar information. Therefore, our proposed DRWMR system reduces the error compared to the existing methods for the top 5, 10, and 15 recommendations. The proposed DRWMR system (0.73) has a low RMSE when compared with existing techniques such as CTR (0.87), DDCF (0.80), CRDTM (0.77), and HMRNN (0.75) for the top 10 recommendations.

Figure 3 shows the MAE analysis. The smallest Hamming distance between the users results in the recommendation to the new user. The weighted Hamming distance is used to determine how similar the users are. So, the errors can be reduced in the recommendation system. The MAE is low for the proposed DRWMR system (0.57) when compared with existing methods such as CTR (0.75), DDCF (0.72), CRDTM (0.705), and HMRNN (0.653) for the top 10 recommendations.

Figures 4 and 5 show the recall and precision analyses. In the proposed DRWMR system, a hash table is built as an additional layer. A table and bitwise weight method are presented based on the performance to attain a better recommendation performance. The proposed DRWMR system assigns weights to various hash bits and hash tables. Also, a hash code is generated based on minimising loss,
Figure 3: MAE analysis.
Figure 4: Precision analysis.

which can handle users with cold start and sparsity problems. This mechanism attains higher precision and recall. The precision is high for the proposed DRWMR system (0.16) when compared with existing methods such as CTR (0.10), DDCF (0.12), CRDTM (0.129), and HMRNN (0.14) for the top 10 recommendations. The recall is high for the proposed DRWMR system (0.08) when compared with existing methods such as CTR (0.04), DDCF (0.041), CRDTM (0.045), and HMRNN (0.06) for the top 10 recommendations.
Figure 5: Recall analysis.
Figure 6: *F*-measure analysis.

Figure 6 shows the $F-1$ measure analysis. The F-measure is high for the proposed DRWMR system (0.101), when compared with existing methods such as CTR (0.06), DDCF (0.064), CRDTM (0.077), and HMRNN (0.08) for the top 10 recommendations.

5. Conclusion

The RS has become vital to social networking and business apps such as Flipkart, Amazon, YouTube, and others. Therefore, we introduced the DRWMR system for an accurate recommendation initially. User-item rating data is fed into CNN to extract important features to reduce data sparsity. Then, the hash code is generated by minimising pairwise rank loss and classification loss. A weight is assigned to different hash tables and hash bits. According to weighted Hamming distance, the most similar users were obtained. Finally, the rating of unknown items can be obtained using the weighted average rating of similar users and active users. As a result, we have seen that our proposed DRWMR system performs better in recommending items. The proposed DRWMR system is quantitatively measured by precision (0.16), recall (0.08), RMSE (0.73), MAE (0.57), and F-measure (0.101). It shows better performance in the recommendation system.

Piano score recognition is one of the important research contents in the field of music information retrieval, and it plays an important role in information processing. In order to reduce the influence of vocals on the progress of piano notes and restore the harmonic information corresponding to piano notes, the article models the harmonic information and vocal information corresponding to piano notes in the frequency spectrum. We use the phase space reconstruction method to extract the nonlinear feature parameters in the note audio and use some of the parameters as the training set to construct the support vector machine (SVM) classifier and the other part as the test set to test the recognition effect. Therefore, the method of adaptive signal decomposition and SVM is introduced into the signal preprocessing link, and the corresponding recognition process is established. In order to improve the performance of the support vector machine, the article uses measurement learning method to obtain the measurement learning and uses the measurement learning to replace the Euclidean distance of the Gaussian kernel function of the support vector machine. The SVM method of adaptive signal decomposition and the SVM method of principal component analysis are introduced into the preprocessing process of the note signal, and then the preprocessed signal is reconstructed in phase space, and the corresponding recognition process is established. The method of directly reconstructing the phase space of the original signal has higher accuracy and can be applied to the note recognition of continuous music segments. The final experimental results show that, compared with the current popular piano score recognition algorithm, the recognition accuracy of the proposed piano score recognition algorithm is improved by 3.5% to 12.2%.

1. Introduction

With the development of digital information technology in the 21st century, many applications based on music signal analysis, such as automatic labeling of music, music score translation, and music retrieval, have higher requirements for analysis results [1]. However, due to the complex composition of music signals, even for fully digitized signals, there is still no more complete method to analyze them in detail [2]. Piano score recognition is one of the important research issues in music signal processing. It plays an important role in song cover recognition, audio matching, and music recommendation systems [3]. From a signal perspective, we are concerned about two characteristics of audio: time and frequency. Most of the audio signal

processing is also focused on the time-frequency analysis of music and frequency images and various statistical methods cannot achieve a good trade-off between time and frequency, so that audio processing has not been greatly improved [4]. The design of piano score notes feature and the selection of measurement learning models have always been the most active research content in the field of piano score note recognition. The content of piano music notes is not only an expression of the creator's emotions, but also an external representation of the music spectrum structure [5]. Therefore, the recognition of musical piano notes is inseparable from the knowledge of various aspects such as signal processing. According to the different processing domains, the single-tone estimation method can be divided into four categories: time domain method, frequency domain method,

time-frequency domain method, and cepstral domain method [6]. Among them, the short-time autocorrelation method, the harmonic peak method, the wavelet analysis method, and the cepstrum method have outstanding detection effects in each category. However, occasionally there will be situations where higher harmonic components are greater than the fundamental frequency components in music signals, which will make the detection error of the harmonic peak method [7].

Liu et al. [8] first compressed the signal spectrum energy to 12 musical scales based on music harmonic information and music theory knowledge and proposed to use 12-dimensional Pitch Class Profile (PCP) as the note feature of piano music scores. The piano score notes of the music are transcribed. Corpuz [9] proposed the Harmonic Pitch Class Profile (HPCP) feature and used it in the piano score recognition system. The experimental results show that the HPCP feature can effectively reduce the influence of the type of instrument on the notes of the piano score. Mello et al. [10] use the Enhanced Pitch Class Profile (EPCP) feature combined with the harmonic product spectrum and the PCP feature. EPCP superimposes and maps the harmonic energy by multiplication instead of summation, so that the distinction between simple chords is more obvious, and the effect of relatively complex piano notation patterns is poor, so it is rarely used. In addition to that, in recent years, scholars have further introduced ideas such as matrix analysis into the design of musical notes in piano scores. For example, Sun et al. [11] proposed a new type of NNLS-PCP feature based on Non-Negative Least Square (NNLS) solution. Before mapping the spectrum to the PCP vector, this feature obtains the frequency values corresponding to 84 notes through a priori knowledge and generates the dictionary based on this. Each element in the dictionary represents the fundamental frequency and its harmonic frequency corresponding to a note. Then they used the approximate x of the obtained spectrum and performed the mapping between the approximate spectrum and the PCP feature [12]. Through prior knowledge, this method can effectively solve the crosstalk of the fundamental frequency and harmonic frequency of the note during the mapping [13]. In order to enhance the robustness of the PCP feature to the notes of piano scores played by different timbre instruments, Liang et al. [14], based on the discrete cosine transform and the Mel frequency, proposed a Mel logarithmic PCP feature. A more practical type of multitone estimation method is the cyclic extraction method, which was first proposed by Patel and Chauhan [15]. Its idea is to regard the multitone signal as the superposition of multiple single-tone signals and then use a two-step loop to perform one by one estimate. In theory, it can deal with a mixture of countless single tones, and the detection result is particularly good for a mixture composed of random frequencies. But for music signals, the detection results are not satisfactory [16, 17]. In response to the existing problems, Noroozi et al. [18] also proposed an improved loop extraction method based on the principle of spectral smoothing. In this way, it is possible to avoid other harmonics that repeat the fundamental frequency and the detected fundamental frequency

from being removed from the signal after the current detection, which will affect the next detection. However, there is no universal standard for the principle of spectral smoothing, which reduces its applicability [19–21].

This article uses the method of measurement learning, according to the characteristics of the notes of the piano score, with supervised learning from the prior knowledge of the question itself to a measurement learning measurement matrix. Through this distance measurement, the original feature space is projected to a space with higher class discrimination, so that, in the projected feature space, the distribution of feature vectors with the same label is more compact, and the interval between feature vectors with different labels is larger. We further use measure learning to improve the Euclidean distance in the original SVM Gaussian kernel function, so that the improved measure learning-based SVM has better category discrimination. This article focuses on the aspect of frequency and on the basis of obtaining its accurate information, to the greatest extent to approximate the original signal. Through the processing of the approximation signal, the purpose of analyzing the original signal is achieved, and combined with the statistical measurement learning method, the single-tone signal is recognized. By collecting audio information from a single frequency level to obtain an accurate approximation of the signal, the approximation format is unified, the complex time-frequency analysis is transformed into a signal to matrix transformation, and the approximation format is detected with the measurement learning method, which improves the adaptability.

2. Construction of Piano Music Note Recognition Algorithm Model Based on Measure Learning Support Vector Machine

2.1. Support Vector Machine Hierarchical Spatial Distribution. Support Vector Machine (SVM) is a maximum boundary classifier, which has good robustness to outliers. SVM maps the feature vectors one by one into labeled outputs through strict mapping relationships. SVM is established on the basis of the dimension theory and the principle of structural risk minimization in the statistical learning theory. It is based on the limited sample information (training sample) in the model complexity and the learning ability to find the best compromise, so that it has the best generalization ability [22–24]. Figure 1 shows the hierarchical spatial distribution of support vector machines.

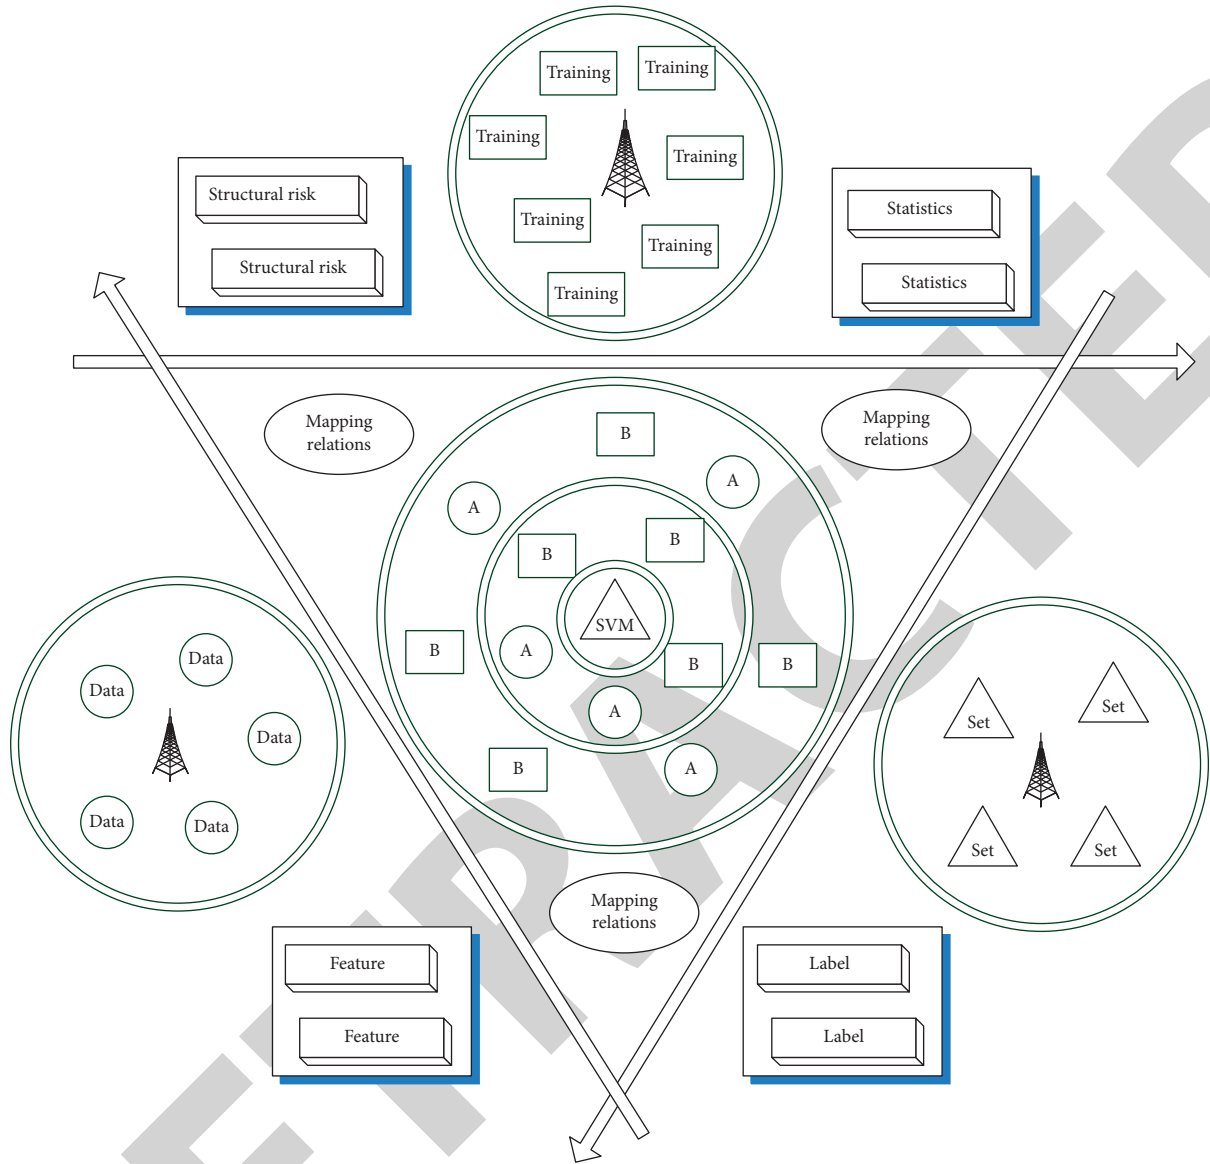
The key step of feature acquisition is to model the harmonic components corresponding to the piano score notes in the music signal spectrum and the nonharmonic components corresponding to the sparse and large noises and to obtain an optimization problem through augmented Lagrangian multiplication. The submethod is used to solve the problem, and finally the characteristic with better performance is obtained. This feature can remove large and sparse noise in the signal and reconstruct the harmonic information in the music signal, so that the feature contains more stable and pure harmonic information [25–27].


FIGURE 1: Hierarchical spatial distribution of support vector machines.

$$X[t|x(t)] = \{t \in R | x(1), x(2), \ldots, x(t)\},$$
$$y(n) = A \times X(n) - t \times x(n-1). \tag{1}$$

The signal preprocessing uses the empirical mode decomposition method. SVM is a smoothing process for a signal, and the result is to decompose the fluctuation or trend of different scales in the signal to produce a series of data series with different characteristic scales. Each series is called an intrinsic mode function.

$$h(x) = \begin{cases} \varepsilon(i,n) \times x(t), & 0 < t < 1, \\ \delta(i,n) \times x(t), & t > 1, \\ y(n) \times x(t), & t < 0. \end{cases} \tag{2}$$

After adding the signal preprocessing link, it is necessary to determine the number of characteristic subsignals after decomposition and determine the optimal phase space

reconstruction parameters corresponding to each characteristic subsignal. When the cumulative contribution rate of the current k-level principal components reaches 85%, it indicates that the previous k-level principal components basically contain all the information contained in the test data.

$$f(x+1) - f(x) = \partial \frac{y(x,n)}{\|d(n)\|^2} d(n). \tag{3}$$

In addition, because the feature vectors corresponding to some piano score types have a certain degree of similarity, the feature vectors corresponding to different piano score notes are likely to have a small Euclidean distance, which makes the classification accuracy of the support vector machine not high.

$$\overline{x^2}(k,n) - |x(k,n)|^2 - 2|\overline{x(k,n)}| \times \cos \alpha = 0. \tag{4}$$

We hope that the classification process is a process of measurement learning. In fact, there are many classifiers that meet the above requirements, and what we are looking for is an optimal classifier that satisfies the maximum separation of data points belonging to two different classes, so this hyperplane is called the maximum separation hyperplane.

$$\begin{cases} \dfrac{\alpha(x) - \alpha(x - 1)}{2\pi x} = 1, \\[2mm] \dfrac{\beta(x) - \beta(x - 1)}{2\pi x} = 1. \end{cases} \tag{5}$$

For a musical instrument, the sound it plays is of course caused by its vibration, but the strength and duration of the frequency vibration that constitutes the note must be measured by the amplitude.

$$g(x, k) = \frac{1}{n} \times \sum_{i=1}^{n} (1 - \alpha(x)) \times (1 - \beta(x)) \times x(t). \tag{6}$$

2.2. Measure Learning Recognition Algorithm.

In general, the adaptive signal decomposition of the music signal using the empirical mode decomposition method will generate a large number of subsignals, and most of the subsignals contain relatively little information. If all are determined as features in the case of subsignals, it will greatly increase the time required for the construction and recognition of the classifier and reduce the efficiency. Therefore, it is necessary to determine the signal containing more information as the characteristic subsignal from the decomposed subsignals.

$$W(x) = \begin{bmatrix} \dfrac{x(1)}{g(k,1)} & \dfrac{x(2)}{g(k,2)} & \cdots & \dfrac{x(n)}{g(k,n)} \\[2mm] 1 & 0 & \cdots & 0 \\[2mm] 0 & 1 & \cdots & 0 \\[2mm] 0 & 0 & \cdots & 1 \end{bmatrix}. \tag{7}$$

By observing the decomposed subsignal image and its corresponding spectrum image, it can be found that the first two subsignals after decomposition contain more information. Therefore, the first two subsignals after decomposition are determined as characteristic subsignals. After determining the number of characteristic subsignals, it is also necessary to determine the delay time and embedding dimension corresponding to each characteristic subsignal during phase space reconstruction.

Therefore, we cannot measure the gap between the selected hypothetical model and the real model. The spectrum before compression is called the original spectrum; then the compressed spectrum is compared with the original spectrum. For example, if the sampling coefficient is set to 2, then the first vertex in the original spectrum corresponds to the second vertex in the compressed spectrum. It corresponds to the third vertex in the compressed spectrum; when the

original frequency spectrum and all compressed frequency spectrums are correspondingly multiplied, the result can clearly show the position of the fundamental frequency.

Figure 2 shows a schematic diagram of the measure learning recognition algorithm. After obtaining a classifier, we can approximate the error with the real model with certain quantities we have already mastered. The most intuitive method is to use sample data to classify the sample data with the obtained classifier and compare the result with the real classification result (still sample data). The difference between them is called the empirical risk. Algorithmically, the real number frame is used in the approximation process to avoid the solution of the high-order band matrix. The recognition process uses the normalized vector principle to standardize the amplitude range, so that the features at any time have a standard representation, which is more conducive to training and recognition. Theoretically speaking, an audio signal generated by a monophonic melody, the amplitude matrix A, obtained after the frame is approximated, each row of which should contain only the amplitude of one note, that is, the basis of the note.

Table 1 shows the combination of musical note audio signal attributes. For a single-tone melody, it is composed of different notes, and after being played by a specific instrument, each note contains the unique overtone combination of this instrument, that is, the frequency combination. We can determine to construct the vector with the amplitude of the frequency as the feature and input it into the SVM as a training sample. From the knowledge of music theory, we also know that the different combinations of fundamental frequency and overtones are precisely the characteristics of the sound of the musical instrument, and it is the mark that distinguishes it from other musical instruments.

In theory, an audio signal is generated by a monophonic melody (only one note played at any time). Therefore, if we know the frequency composition of each note played by a certain musical instrument, then for the calculated row vector in A, the combination of its nonzero elements in turn corresponds to a note. After obtaining, we count the number of consecutive notes, so that the note and note duration of this audio signal can be obtained.

2.3. Weight Optimization of Piano Score Data.

The method of principal component analysis SVM is a statistical method to reduce the dimensionality of the variable space. This method uses the orthogonal projection method to transform the original data from the high-dimensional variable space to the low-dimensional feature variable space, reducing the dimensionality of the variable space under the premise of the characteristic information, and the original data is retained. In this way, the analysis of the high-dimensional original data with the correlation between the variables is transformed into a low-dimensional space, thereby reducing the difficulty of analysis. In the case of unknown rules, an effective tool for classification is SVM.

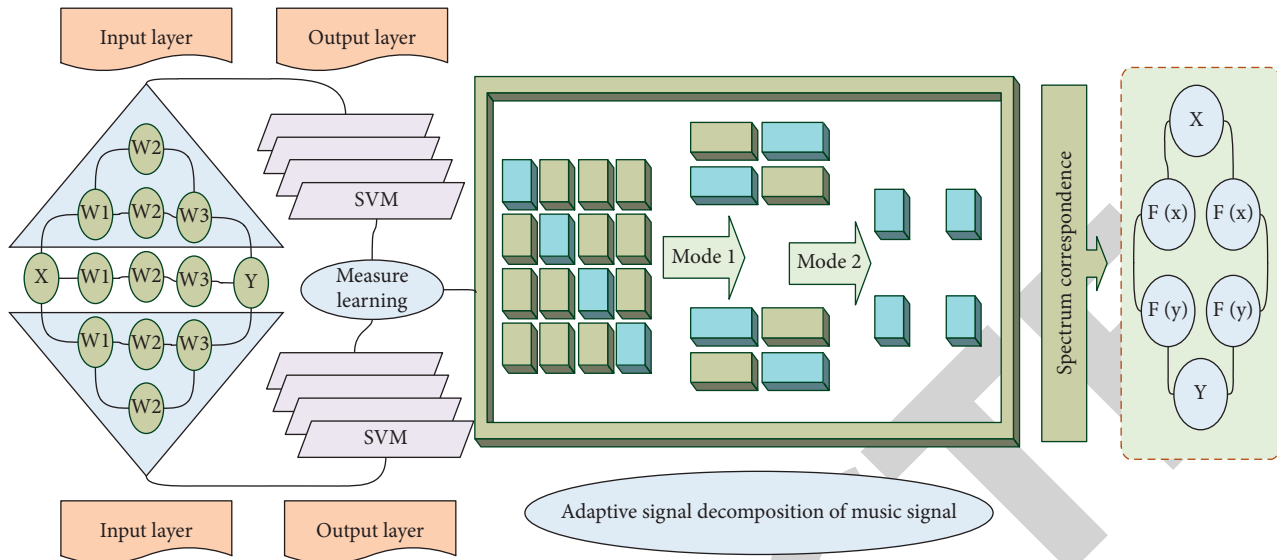
Autocorrelation is effective for detecting repetitive patterns in a signal, such as detecting the period of a periodic


FIGURE 2: Schematic diagram of measure learning recognition algorithm.

TABLE 1: Musical note audio signal attribute combination.

Node serial	Frequency (Hz)	Duration ratio (%)	Standard deviation
1	2000	87	1.81
2	4000	91	0.98
3	6000	79	2.02
4	8000	56	1.96
5	10000	54	0.59
6	12000	69	0.64
7	14000	88	0.77

FIGURE 3: Comparison of broken lines of detection error for different groups of note data.

signal covered by noise. In addition, the results of SVM analysis on other kinds of notes also show that the first four eigenvalues can represent the main components in the nonlinear matrix. Figure 3 shows the comparison chart of the detection error broken lines of different groups of note data. It can be seen that, in the process of node length from 100 sampling points to 700 sampling points, the error ratio is also reduced from 3.6% to 1.5% in the worst case, but relative to the influence of low sampling times, the length of node is helpful to the accuracy of pitch detection and the accuracy of pitch extraction, but the effect is not as great as the impact of low sampling.

Since the timbre characteristics of each instrument, that is, the composition of the frequency corresponding to the notes, are unknown, we need to build training data and input it into the SVM to build a classification model. First, the music signal is distributed to 9 nonoverlapping bands (nonoverlapping bands) through the filter group. Figure 4 shows the feature vector processing process of musical note data information. In each frequency band, we use the autocorrelation algorithm to find the pitch of its corresponding frequency band. In the final stage, the pitches obtained in all frequency bands are fitted, and the desired pitch of the music is synthesized. Each row vector containing frequency and amplitude in A is exactly a feature vector containing audio

information corresponding to the note, so it can be input into SVM for training.

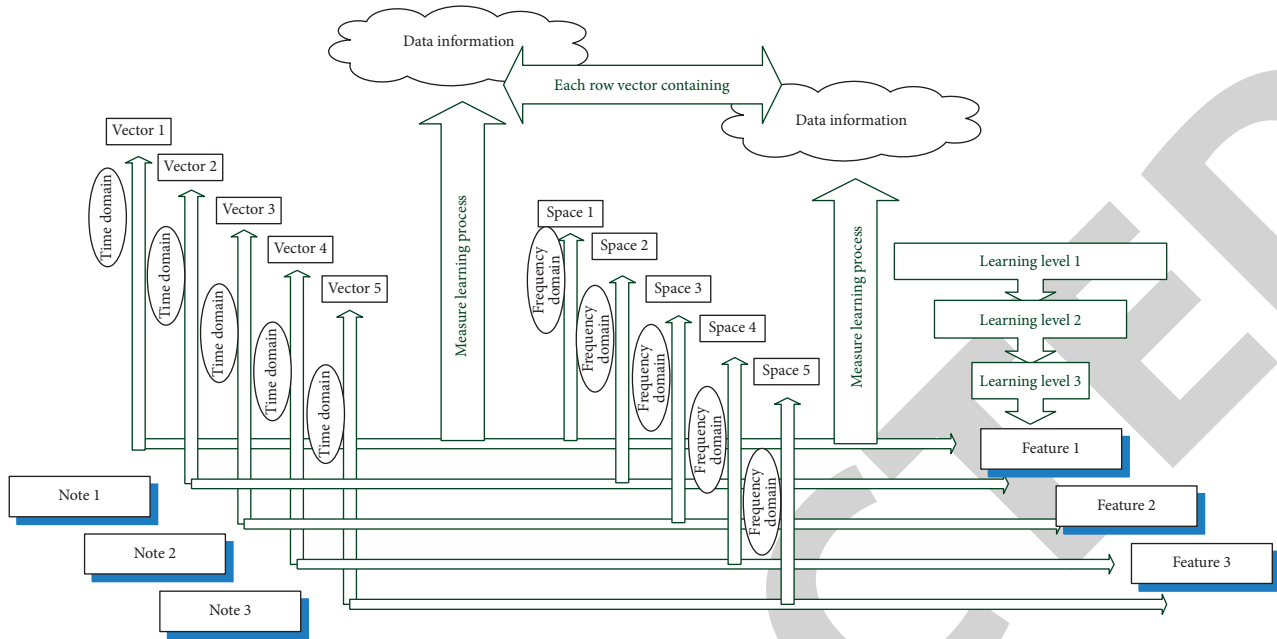
For the traditional short-term analysis method, if the window width is 50 ms, taking the wav file with the highest sampling accuracy as an example, only 2205 samples can be obtained. Both accuracy and breadth are far from meeting the requirements of audio signal analysis. If the window width is increased to 1 s, the frequency domain resolution can reach the minimum difference 1 for distinguishing music signals. For a song with a tempo of 200, the 32th note lasts only 37.5 ms, which obviously cannot be detected. This is the bottleneck of traditional short-time analysis, which is a trade-off between the resolution of the time domain and the frequency domain. Because the music itself has signal stability in a short period of time, it exhibits a certain period, so the autocorrelation method can be used to detect the period of the music, and of course the fundamental frequency of the signal can be detected. We trade off model complexity and learning ability based on small sample data, hoping to


Figure 4: Feature vector processing process of musical note data information.

achieve the best generalization ability measurement learning method. It can be found that the cumulative contribution rate of the first four eigenvalues can reach more than 90%.

3. Results and Analysis

3.1. Feature Extraction of Musical Notation Data. The masking of notes and missing notes during the performance of the music will have a certain impact on the recognition and transcription of the final piano score. Therefore, the extraction of robust PCP features is divided into two steps: reconstruction of the harmonic information in the signal spectrum and scale mapping. The frame method starts from the whole audio signal, first obtains accurate frequency information from a large window, and uses the known frequency to construct an approximation of the original signal. In this way, the main frequency information of the original signal is kept as close as possible to its time domain information, so as to achieve the analysis of the music signal.

The two-tone connection recognition results of common piano notes are given; that is, the first note starts at 0 s, the second note starts at 0.5 s, and the number of recognition samples is 44100. From the data, it can be seen that, for the two-tone case, the classification is completely correct and does not include nonaudio internal notes; in most cases, the first note gets more recognition results, and the error is completely caused by this. This process is generally about 10–15 ms. Although theoretically speaking, the second note starts playing at 0.5 s, but its effective time will have a lag of 10–15 ms. That is to say, when the frequency contained in the second note is large enough to be classified, there is a 10–15 ms lag from the theoretical time.

Table 2 shows the statistical classification of the recognition results of piano score data. For the reliability and convenience of category labeling, the songs in the test music library and their corresponding labels are all from the music library on the Internet. We have selected a total of 480 songs in 6 categories. In this experiment, all music songs are in mp3 format, and their sampling rate is adjusted to 11025 Hz, and the bit rate is 16 kbps. It provides a software package for reading mp3 format music through MATLAB software. In this experiment, the length of 1024 is used for each frame. In the octave critical frequency band filter, because the sampling frequency of the test data is 11024 Hz, when it is decomposed into the critical frequency band, only the first 7 frequency bands are included in the effective frequency band, because the upper limit of the effective frequency is 5513 Hz. When calculating the 44th and 60th frames, the experimental data are as follows.

Each row of the amplitude matrix A obtained after the frame approximation should only contain the amplitude of one note. The usual method for detecting the starting point of a note is to find the "transient" area in the music signal; there are many definitions for the transient area, such as energy mutation points, short-term changes in the signal spectrum, etc. The above reduces the size of the data volume but refers to the audio signal as the input of a highly low sampling detection function and the role of the detection function to show the "instantaneous" in the original signal.

In this experiment, only the first 120 seconds of each song are intercepted for training or testing. Therefore, the time length of most songs is 3–5 minutes, so the first 120 seconds can already contain the basic characteristics of the song. For songs up to 120 seconds, a loop sampling method is adopted; that is, the beginning part of the song is connected to the end of the song. Figure 5 shows the fan-shaped distribution diagram of the recognition accuracy of different sampling units. In the 120 seconds of each song, 2.6 seconds are used as a music segment; each music segment is further divided into smaller unit music frames. The sampling

TABLE 2: Statistical classification of piano score data recognition results.

Node number	Frame number	Resolution (Hz)	Time delay (ms)	Error (%)
1	10	3.60	15	3.10
2	20	3.50	17	2.70
3	30	2.90	18	3.30
4	40	2.70	16	3.10
5	50	3.10	19	2.90
FIGURE 5: Fan-shaped distribution diagram of recognition accuracy of different sampling units.

frequency occupied by each time period is 28.99%, 21.89%, 22.19%, 11.54%, and 15.38%, respectively. Each music segment is further divided into 64 music frames. Each music frame contains 512 sampling points, and adjacent frames overlap 64 sampling points.

That is, the amplitude of the fundamental frequency and the overtone constituting the note and the amplitude of the frequencies contained in the notes that are not sounded at that moment are all zero. At the same time, due to the natural attenuation of audio, when the original feature data is processed by SVM, the projection feature of 95% of the original feature information is retained. After the SVM projection processing, the final feature of the dataset is reduced to 13 dimensions, and the feature of the dataset is reduced to 8 dimensions. Then, the SVM algorithm based on each kernel function is used to classify the data after SVM dimensionality reduction. It can be seen that after the original feature data is processed by SVM, the classification accuracy of each SVM is improved. This is because the original feature data after SVM projection and dimensionality reduction can effectively reduce aliasing and redundant information, thereby improving the accuracy of the final classification.

3.2. Simulation of Measure Learning Recognition Model. Firstly, the music fragment is sampled and processed with a sampling rate of 11025 Hz, and an audio signal with a length of node is generated. For the audio signal mode of this length, we use the window function $W(n)$ to preprocess the audio signal, and the window shift length is 50% of the window width to obtain the windowed waiting. Then, we

multiply the signal matrix by the Fourier transform matrix, the force is an $N \times N$ square matrix, and the rows of the matrix are the orthonormal basis, so that the frequency spectrum matrix of the framed signal is obtained as M. In the experiment, phase space reconstruction is performed on the original note signal, the first subsignal, and the second subsignal, the SVM principal component is extracted, and then the nonlinear feature construction is carried out. The piano score data set adopts MIDI format digital score files that contain piano score information such as pitch, beat, time, chord, speed, and channel.

In order to obtain more features related to the difficulty of piano scores, this paper adopts the related features of difficulty as the feature space of this paper. Therefore, the feature space in this article includes all the difficulty and semantic features except the fingering complexity (which belongs to the information of the score labeling level, and MIDI scores does not contain this information), key signature (key signature is meta tag information); except for the fingering feature (also belongs to the label layer feature) all the features, a total of 22 features, form a 22-dimensional feature vector to represent the MIDI score. Given the recognition results of common triplet within 1 s, 50 samples are selected for recognition from the approximation data. Figure 6 shows a matchstick graph of the attenuation rate of the note data signal based on measurement learning. From the figure, we can see that there are still notes that will get more detection results. This is caused by the crossover of notes, especially when the sound is not deliberately muted during performance, so that each note is naturally attenuated and played.

Either from the audio waveform graph or from the approximate amplitude graph, it can be clearly found that the previous note still has a strong amplitude at the note boundary. After normalization, the note with a weaker amplitude will be detected. However, although reducing the sampling rate increases the error percentage, the statistically obtained duration does not change much, and it has no effect on the translation of the score.

In the experiment, the 20 samples of each note signal were taken as test signals for the identification experiment. Figure 7 shows the SVM-based note data recognition deviation box diagram. In addition, considering many situations in actual piano learning and teaching, music scores are divided into 4 difficulty levels, and a large number of music websites generally provide digital music scores with 4 difficulty levels (easy, beginning, intermediate, and advanced). The scalability of the algorithm in this paper is suitable for practical applications. We also collected 400 MIDI scores from the large music website to form a data set with 4 difficulty levels, each with 100 MIDI scores.
FIGURE 6: Match stick graph of attenuation rate of note data signal based on measurement learning.
FIGURE 7: Box diagram of note data recognition deviation based on SVM.

From the knowledge of music theory, we also know that the different combinations of fundamental frequency and overtones are precisely the characteristics of the sound of an instrument, and it is the mark that distinguishes it from other instruments. Among them, the delay time and embedding dimension of the original signal are determined as 5 and 9, the delay time and embedding dimension of the first subsignal are determined as 2 and 7, and the delay time and embedding dimension of the second subsignal are determined as 4 and 9. The nonlinear characteristics of the training signal are used for the construction of the SVM classifier, and the nonlinear characteristics of the test signal are used for the recognition experiment. According to the recognition results, after adding empirical mode decomposition and SVM preprocessing in the recognition process, the recognition accuracy rate is better than the method of directly using the phase space of the note signal to reconstruct the matrix, and the average accuracy rate is improved.

3.3. *Example Results and Analysis.* The algorithms in this paper are all implemented with MATLAB software, and the computer environment used is a 32-bit Windows 7 operating system, with a built-in Intel I5-4200M processor and 4 GB of memory. In the experiment, in order to better evaluate the classification performance and generalization ability of the ML-SVM algorithm proposed in this paper, the ML-SVM algorithm is combined with logistic regression and linear kernel function in two musical score data sets of 9 and 4 difficulty. Each experiment was repeated 5 times independently, and a fivefold cross-validation was used, and the average accuracy rate was taken as the final recognition accuracy rate. At the same time, in order to evaluate the performance of the recognition algorithm more comprehensively, the 90% confidence interval of each algorithm result is also given.

Figure 8 shows the histogram comparison of the SNR (signal-to-noise ratio) of note data with the same algorithm. We use the B-spline frame twice to approximate the signal and the Gaussian frame to approximate the acoustic guitar d
FIGURE 8: The comparison chart of SNR of note data of different algorithms.

1, and the error is measured. The characteristics of these three examples are clearly contrasted and can truly reflect the practical effects of the framework under various signal compositions. We see that, for signals with clear and clear frequencies, the result of frame approximation is very satisfactory.

In the actual playback of this signal, the error is very small, and human ears can hardly distinguish the difference. It can be seen that the error is larger at the beginning of the note and decreases with time. This is because plucked instruments are affected by factors such as plucking strength and angle, which will cause other strings at the beginning of the note. Resonance and the noise caused by flicking will therefore weaken over time.

Figure 9 shows the amplitude response curves of different note signal frequencies. In addition, when setting the music frequency, we only kept the 10 frequencies of the piano, with a maximum value of 1000 Hz. In actual recording, the effector will add harmony and simulation effects. These effects contain a lot of high-frequency signals, but these frequencies are discarded as noise. When the signal is actually played, the note restoration is highly recognizable, and the pitch and timbre information of the original signal is preserved, but it does not sound as bright and crisp as the original signal. This is precisely the result of discarding the high-frequency signal. We see that the response amplitude value is much lower than the previous two.

Therefore, if we know the frequency composition of a certain musical instrument playing each note, then for the calculated row vector in A, the combination of its nonzero elements in turn corresponds to a note. This is caused by the upgrade of signal complexity. Due to the influence of the sound of the instrument itself, the superimposition of notes is serious, and it is also affected by the recording environment and the structure of the piano itself. Environmental noise and high-frequency overtones are more and more complicated than the previous two examples. In actual playback, the approach signal retains the main frequency composition of the original signal, the note recognition is high, the energy feedback is obvious, and the beginning and end of the note can be clearly heard. However, part of the timbre information is lost, and the recognition of the instrument is reduced. This is related to the piano's own frequency response range. The threshold of the main frequency selection can be lowered to improve the approximation effect.

In order to improve the generalization ability, we perform multiparameter approximation on the training audio and obtain different frequency combinations of the same note by adjusting the Fourier transform threshold and the frame translation distance. Numerical experiments show that SVM can recognize single-tone melody very well, and every moment is correctly classified into the frequency that appears in the audio, and no nonaudio frequency is recognized, so the recognition rate of the note is 100%. However, due to the attenuation nature of the audio signal and the setting of the playing time, in the intersecting zone the previous note is about to stop and the next note has been played.

Figure 10 shows the line comparison chart of the recognition accuracy of musical note signal algorithms. It can be seen that, in the two data sets, among several algorithms, the final recognition accuracy of the algorithm proposed in this paper is higher than that in [19], in [20], and in [21], especially in the data set. The proposed algorithm obtains a recognition accuracy rate of 90.67%, which is greatly improved compared to the 85.63% literature algorithm. And a narrower confidence interval indicates that the result is more stable and significant. Compared with theoretical expectations, when the sampling rate is 1000, the duration error is between 0.5% and 1.6%. If the sampling rate is reduced, not only can the classification accuracy be improved, but also the real-time processing requirements for music within 200 tempos can be met.
FIGURE 9: Amplitude response curves of different note signal frequencies.
FIGURE 10: The comparison chart of the broken line of the recognition accuracy of the musical note signal algorithm.

4. Conclusion

The piano music note recognition system designed in this paper includes four main steps: audio input, spectrum preprocessing, feature calculation, and measurement learning support vector machine classification. Because the method of using fixed parameter values for different types of notes to extract the characteristic parameters will cause the loss of some nonlinear information of the notes and ultimately affect the recognition accuracy, this paper applies the method of adaptive signal decomposition to the signal preprocessing link. At the same time, in order to improve the recognition efficiency and reduce the time required for recognition, the paper also uses the SVM method to extract the principal components of the nonlinear features for the construction of the classifier and specific note recognition experiments. Then we propose a new method of

monophonic melody recognition based on frame approximation theory by using the accurate characteristics of the Fourier transform in the frequency domain, the frequency of energy concentration is detected in a large window, and then the idea of least squares is used to approximate the original signal, and on the basis of preserving the time-frequency characteristics of the original signal to the greatest extent, the audio is standardized and organized. Combining support vector machines based on statistical methods to recognize notes, it has the characteristics of supporting multiple frequencies and multiple notes, fast recognition, expandable models, and strong generalization capabilities. Among them, the spectrum preprocessing mainly uses the nuclear norm convex optimization technology to reconstruct the harmonic components in the original audio and adds a norm penalty term to enhance the robustness of the calculated spectrum against sparse noise; then the scale mapping is

The development of industry is inseparable from the support of steel materials, and the modern industry has increasingly high requirements for the quality of steel plates. But the process of steel plate production produces many types of defects, such as roll marks, scratches, and scars. These defects will directly affect the quality and performance of the steel plate, so it is necessary to effectively detect them. Steel plate surface defects are characterized by their types, shape, and size: the same defect can have different morphologies, and similarities can exist between different defects. In this paper, industrial steel plate surface defect samples are analyzed, and a sample set is established by screening the collected defect images. Then, annotation and classification are performed. A multilayer feature extraction framework is developed in experiments to train a neural network on the sample set of defects. To address the problems of low automation, slow detection speed, and low accuracy of the traditional defect detection methods, the attention graph convolution network (AGCN) is investigated in this paper. Firstly, faster R-CNN is used as the basic network model for defect detection, and the visual features are jointly refined by combining attention mechanism and graph convolution neural network. The latter network enriches the contextual information in the visual features of steel plates and explores the semantic association between vision and defect types for different kinds of defects using the attention mechanism to achieve intelligent detection of defects, thus enabling our method to meet the practical needs of steel plate production.

1. Introduction

Steel is widely used in daily life and industrial production in a very large number of application areas and is the basic material for many products. According to statistics, in people's daily use of metal, steel accounts for up to 90% and is involved in most common products (home appliances, cell phones, etc.). The use of steel is essential in many industries, such as petrochemical, vehicle engineering, aerospace, military defense, and other fields, and its excellent performances have an invaluable role [1]. China's steel production in 2019 was as high as 996 million tons, accounting for 53.31% of the world's total production, far ahead of any other country [2].

Steel is an important and indispensable material in the modern construction of the country, and it is used in various production fields, especially in automotive, construction, and bridges. The production of steel plate is an extremely long and complicated process, from the raw stone to the final plate. It undergoes several processing steps, so the finished steel plate will inevitably have defects, most of them in the form of iron oxide, holes, cracks, scrapes, scratches, etc., on its surface. These defects directly affect the compressibility, toughness, corrosion resistance, and plasticity of the steel plates, rendering the manufactured products unable to meet customer requirements and resulting in severe economic losses for manufacturers. Without a set of effective testing methods, unqualified steel plate products put into use can even endanger people's lives and safety. Although steel production is high and export volumes are large, China still suffers from a slight shortage of automation compared to some developed countries [3]. Surface quality is a very important performance indicator of steel products, but it has not received the attention it deserves. According to statistics,

because of surface quality problems, large steel industrial groups lose an average of about 6 million U.S. dollars a year because surface defects lead to the return of the products. According to the market response, the vast majority of companies are challenged by the presence of surface defects, causing huge economic losses and hindering the transformation and upgrading of enterprises. Hence, controlling steel surface defects at the source is a very effective measure. Therefore, steel plate manufacturers need to carry out effective quality inspection of their products, to screen the steel plates that do not meet the technical specifications and improve the yield rate of the delivered products. On the other hand, analyzing the causes of surface defects will provide a reliable basis for improving the steel plate production technology. However, it is difficult to detect surface defects on steel plates. Production is made in very harsh environments, so it is difficult to install and protect inspection equipment; furthermore, moisture and impurities increase the difficulty of inspection [4].

Many researchers have studied defect detection and proposed several effective methods, mostly based on manual visual inspection [5], magnetic particle detection, penetration detection, eddy current detection, ultrasonic detection, traditional machine vision detection and identification, and deep learning detection and identification methods. But the recent developments in artificial intelligence theory and technology [6], the emergence of high-speed, high-precision CCD and CMOS industrial cameras, and the tremendous increase of CPU and GPU computing power and distributed computing provide the theoretical basis and hardware conditions for high-speed high-precision detection of steel surface defects based on computer vision. Deep learning benefits from the recent progress in computing power and automation technologies. It is one of the most representative fields of artificial intelligence, with excellent performance in image classification, target detection, segmentation, and target tracking. Deep learning stands out in the field of related technologies with powerful memory capability, nonlinear mapping capability, self-learning capability, and robustness [7]. Training a deep learning network with a large amount of data enables the low-level network to automatically learn the detailed features in the data and the high-level network to automatically learn the abstract features. So far, deep learning techniques have been widely used in agriculture, medicine, automotive, and aviation. One of its important applications in industrial production is product quality estimation, where it efficiently overcomes the shortcomings of traditional defect detection methods, more sensitive to human and external environment interference. Deep learning-based methods can detect products defect more quickly and accurately.

The surface quality of a steel strip is an important indicator to evaluate the grade of steel. Surface defects not only affect its appearance, which is not conducive to sales and exports but also affect its mechanical properties and quality, decreasing its stiffness and strength and reducing its corrosion resistance. Defects may also be the cause of serious safety accidents. Analysis of the steel surface defects shows that there can be various kinds of defects on the steel surface,

such as cracks, scratches, patches, inclusions, pitting, and bonds in the oxide skin, etc. In this paper, we propose a novel steel surface defect detection method (called AGCN) based on the attention mechanism and graph convolution neural network. The main contributions include the following: (1) the use of faster R-CNN [8] as the basic network model for surface defect detection and the combination of attention mechanism and graph convolution neural network; (2) exploring the contextual information in the visual features of steel plates and enhancing the semantic association between visual features and defect types using the attention mechanism and graph convolution neural network. Extended experiments are conducted on the steel surface dataset, and the advanced performance and effectiveness of the proposed method are demonstrated by method comparison and ablation analysis.

2. Related Work

2.1. Steel Plate Surface Defect Detection. The detection of steel surface defects began to develop in the 1920s and can be roughly divided into three families of methods: manual inspection, traditional photoelectric detection, and machine vision detection.

Manual inspection method, also known as manual visual method, was the first to be used. At that time, with the backward production technology, slow production speed, and low demand for products, the speed and quality of product testing were not very demanding. However, with the improvement in the level of production, the increase in demand and the disappearance of the demographic dividend, the shortcomings related to low inspection efficiency, high labor intensity, and nonuniform inspection standards gradually appeared and the inspection methods were no longer suitable for the requirements of speed and accuracy and were gradually abandoned [9].

Traditional photoelectric detection with optical sensors has been gradually applied in many enterprises, which improved the detection speed, accuracy, and efficiency [10]. Other methods based on eddy current detection and Faraday's electromagnetic induction principles have been developed. Common practice is to apply an alternating current to the strip surface, generating an alternating magnetic field affecting the detection coil. Measuring the induction current and impedance changes enables to determine the presence of defects. The main disadvantages are (1) waste of resources and (2) the method is not suitable for the detection of small defects. Leakage detection methods are based on the principle that when the steel plate is magnetized by a strong magnetic field, the change in the cross-sectional area of the steel plate due to the defect affects the magnetic permeability and reluctance. A part of the magnetic field bypasses the defective part through the surrounding air, causing the deformation of the magnetic field, from a straight line to a curve. The corresponding sensor converts the change of magnetic field into an electrical signal, and the size of the defect on the surface of the steel plate can be estimated from the electrical signal size. Leakage detection technology is a very simple, highly reliable, and fast detection technology,

subject to small environmental interference factors. But at the same time, there are simple leakage signal characteristics, detection of defects, and a limited variety of disadvantages [11]. Infrared detection methods use the principle that any object continuously emits infrared waves depending on its temperature, according to Planck's law of radiation, Wien's displacement law, Stefan–Boltzmann's law, etc. Infrared detection is more functional and can be used for defect detection, stress and fatigue analysis, simulation, image processing and fault diagnosis, and some other functions. The detection device is made of three main parts: the excitation part (signal generator and excitation source), the infrared camera, and the PC terminal. The working process is roughly to apply the corresponding excitation source to the steel material to obtain its thermal phase diagram. Since the temperature of the defective and nondefective parts of the steel is not the same, this will form areas with different temperature levels on the steel surface and emit different infrared waves. However, this method can only detect a few defect types, so it cannot be widely used. Laser scanning detection uses a laser as the emitting light source. The laser beam is reflected on the surface of the strip towards a rotating reflector and finally through the optical system equipped with an electric multiplier tube which converts it into an electrical signal through the converter, so that it can ensure the detection of defects at a certain speed. Using upper and lower lasers, this method enables to scan simultaneously both sides of the strip and obtain two-sided data of the inspected material. The final image is then processed and analyzed by a computer. However, laser detection technology requires high environmental protection, allows only slow detection speed, continuous motion of the laser life and reliability is reduced, and the purchase and maintenance costs are high. The limitations are large, and it is difficult to make further breakthroughs. So many companies began to look for low cost, high detection efficiency, and easy maintenance detection equipment.

With the breakthrough of CCD (charge-coupled device) camera and related hardware, while computer technology gradually developed and gradually appeared in industries, online machine vision-based steel plate inspection became popular. Figure 1 shows the working process and the role of each part: the steel plate to be inspected moves below the light source which provides additional light to remove the influence of background light and provide clear images collected by the camera which transmits them to the computer [12]. The computer analyzes and processes the images in real time according to the existing model and framework to assess the grade or defect situation of the steel plate surface. The use of CCD image sensors and pattern recognition technology has greatly improved the efficiency of steel surface defect detection, while various industries have started to detect surface defects with the help of similar devices.

Deep learning-based machine vision algorithms are the core of machine vision surface inspection technology, which is the key technology of the whole inspection system and one of the most challenging problems in the whole machine vision field. For steel surface defect detection, it is a popular research direction today to study algorithm models that can be executed with high accuracy, quickly extract the image features, and accurately identify the defect's category and location in real-time using massive image data. Deep learning is an end-to-end feature extracting algorithm, in which the model is similar to a black box. The process involves entering an image that contains a defect into the black box of the deep learning model which provides the category and location of the defect. Compared with traditional manual feature extraction, deep learning-based feature extraction enables more complete and accurate understanding of sample defects and features, thus achieving precise identification. Foreign research in this field began relatively early, for rail surface defect detection. The study and experiments of deep learning network models have concluded that different regularization methods have a certain impact on the recognition rate of defects. Sun et al. [13] designed a device for the identification of casting defects based on the mask R-CNN target detection model. Domestically, Cai and Wei [14] improved the YOLO target detection model with an accuracy of 97.55% in steel surface defect detection. He et al. [15] gave a multilayer feature fusion network structure using region proposal net (RPN) to generate regions of interest (RoI) on feature maps and obtained up to 82.3% of mAP (mean average precision) value on the dataset of defect detection at Tohoku University. To address the problem of insufficient dataset, Cui et al. [16] in foreign countries enhanced and expanded the dataset by cropping the original image, applying horizontal flipping, mirror flipping, transparency, and other processes. Liu et al. [17] used GAN (generative adversarial networks) network models to generate new defective dataset sample by merging original defect samples and defect-free samples and expand the dataset and achieve the purpose of sample migration. From the above analysis, with the increase of steel production, the defect detection of steel surface has stepped into the era of intelligent detection.

2.2. Multilayer Feature Extraction.

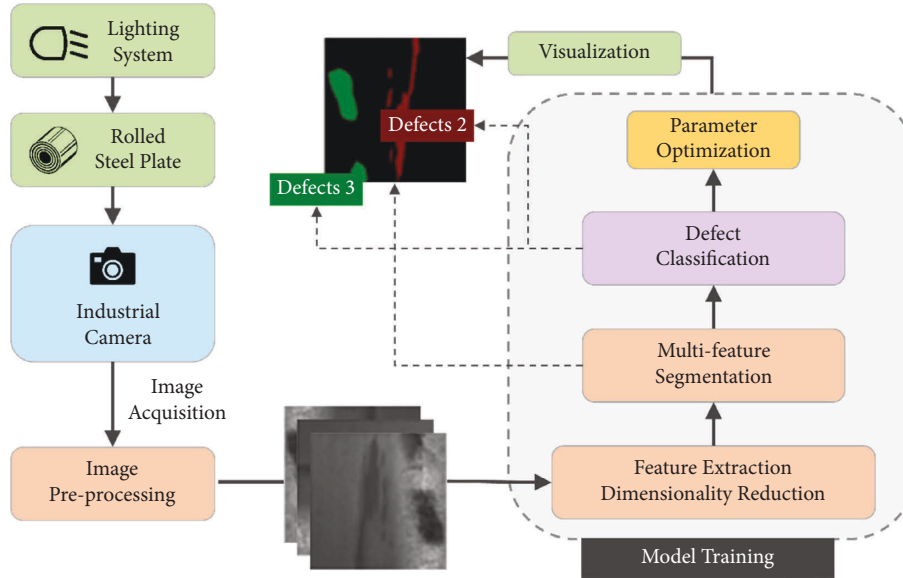
Convolutional neural networks (CNN) have developed rapidly and caught everyone's attention with their powerful modeling capabilities. Compared with traditional methods, the introduction of CNN has brought great improvements to areas such as image processing and natural language processing, for automatic translation, image, and speech recognition. However, traditional CNNs can only process Euclidean space data (e.g., images, text, and speech), which are translation invariant in these domains [18]. Translational invariance allows us to define convolution networks by defining globally shared convolution kernels in the input data space. Taking image data as an example, a picture can be represented as a set of regularly spaced pixels in the Euclidean space, and translation invariance means that a local structure of the same size can be obtained around any pixel [19]. Based on this, CNNs model local connectivity by learning convolution kernels shared at each pixel, which in turn create meaningful hidden layer representations for pictures. Although traditional CNNs bring enhancements in text and


FIGURE 1: Process of computer vision diagnosis of surface defects on steel plates.

image domains, they can only handle Euclidean space data. Meanwhile, non-Euclidean spatial data—graph data—are gradually gaining attention due to its ubiquity [20].

In defect segmentation, the model needs to extract sufficient and effective semantic information to describe the difference between foreground (refer to the defects) and background (refer to the noise). Mahendran and Vedaldi [21] considered that convolution network feature maps in different layers contain the characteristics of different context information abundance. As shown in Figure 2, low-level feature maps with high resolution have clearer edges more detail information, which can be used to describe specific texture feature, but it contains less context information. On the contrary, the context information of high-level features is more abstract, and the semantic information is more separable after multilayer convolution extraction, but the texture details cannot be extracted due to low resolution. For classification problems, most methods mainly focus on high-level features, resulting in poor defect segmentation results in complex backgrounds. Inspired by the multilayer feature fusion method [22], this paper introduces the boundary refinement module to retain the low-level texture information.

Besides, the segmentation models need to be non-deformable for various variations such as defect's shape, scale, and texture. Most CNN-based methods try to expand the receptive field to cover the entire defect for global perception. In the DeepLab model [23], the receptive field is extended in the last convolutional layer to enhance the recognition of feature changes, but this will lead to grid artifacts [24]. Zhao et al. [25] use pyramid models with different pooling cores to amplify local features to overcome intraclass differences. However, excessive pooling in feature fusion makes the model unable to capture a wider range of global information, resulting in missing parts when marking defect masks [26]. To solve the above problems, we propose a multilayer feature fusion method, which uses multiscale

convolution (receptive fields of different sizes) to weight the feature maps of all convolutional layers to obtain the context information. On the premise of fully exploiting defect features, grid artifacts and excessive pooling are avoided.

2.3. Graph Convolution Neural Network.

Graph data can naturally represent real-life data structures, such as traffic networks, World Wide Web, and social networks. Unlike image and text data, the local structure of each node in graph data varies, which makes translation invariance no longer satisfied. The lack of translation invariance poses a challenge to define CNN on graph data. In recent years, due to the prevalence of graph data, researchers have started to focus on how to construct deep learning models on graphs. With the ability of CNNs to model local structures and the prevalence of node dependencies on graphs, GCN (graph convolution neural) networks have become one of the most active and important research fields. Recently, several articles have been published to explore deep learning on graphs, but there is still a gap in the in-depth discussion and summary of the modeling methods and applications of the most important branch, graph CNNs. In this paper, we summarize the development of GCNs and their future trends [27].

The challenges faced in the construction of GCNs are mainly related to the following aspects: (1) graph data are non-Euclidean spatial data and do not satisfy translation invariance, i.e., each node has a different local structure. The basic operators in traditional CNNs (convolution and pooling) rely on the translation invariance of the data. At this point, it becomes a challenging task to define convolution and pooling operators on graph data. (2) A variety of real-life applications can be naturally represented by graphs, which give them diverse properties, such as directed connections of users in social networks, heterogeneous connections of authors and citations in citation

Low-level
Features

High-level
Features
Figure 2: Feature extraction from low level to high level.

networks, and positive and negative tendency band symbolic connections in political relationship networks. The various graph characteristics bring more information to the construction of GCNs, but the modeling of multiple characteristics also requires a more complex and detailed design of GCNs, which brings new challenges. (3) The scale of graph data is very large: in the era of big data, graphs in practical applications may be extremely large, with millions or even tens of millions of nodes, such as user commodity networks in recommendation systems and user networks in social networks. It is very challenging to build GCNs on large-scale graphs in an acceptable range of time and space [28].

In addition, researchers borrowed knowledge from graph theory, such as using eigenvalues and eigenvectors of Laplacian matrices for community analysis or population clustering. With the rise of deep learning, researchers started to consider introducing deep learning models into graph data, and the representative research work is called network embedding, i.e., learning fixed-length expressions for each node by constraining the proximity of nodes. This led to new methods such as Deep Walk, LINE, and node2vec. During this period, when solving specific application problems, researchers usually modeled them as two-stage problems [29]: taking node classification as an example, the first stage learns uniform-length expressions for each node, whereas the second stage uses node expressions as inputs to train classification models. In recent years, researchers have gradually shifted their focus from modeling graph data to how to migrate deep learning models to graphs for end-to-end modeling, and GCNs are one of the most active fields. In modeling graph convolution neural networks, researchers focus on how to build convolution operators on graphs. Zhang et al. [30] proposed the first graph convolution neural network in 2013, where they defined graph convolution in the spectral space based on graph theory using the convolution theorem. This branch was later developed as the spectral approach in the field of graph convolution. The initial spectral methods had the disadvantage of high spatio-temporal complexity, and Cheb-Net and GCN parametrized the convolution kernel in the spectral domain to greatly reduce the spatio-temporal complexity [31]. These two methods, although categorized as spectral methods, have started to define the weight matrix of nodes from a spatial perspective. Inspired by these two methods, spatial methods were applied and began to consider modeling the weights between nodes in the node domain with attention mechanisms, serialization models, etc. The graph convolution neural networks of this period did not take too much

account of the characteristics of graphs in the process of constructing convolution operators. With the gradual improvement of convolution operators, people began to consider various features of graphs, starting with a focus on how to model higher-order information on graphs, and fine-grained designs for graphs with features on edges, heterogeneous graphs, etc. In addition, the question of how to train more efficient GCNs has also received much attention. Researchers have started to train deeper GCNs to enhance generalization. In addition, the scalability of the models to large-scale graphs and the training speed are very focused research directions in GCN. The pooling operator, as the main component of CNNs, enables to expand the perceptual field and reduce the number of parameters. Recently, some research has also started to focus on the construction of on-graph pooling operators [32]. The on-graph pooling operator is mainly used in graph classification problems with the aim of learning the hierarchical structure of the graph. The broad application scenarios targeted by graph data modeling makes the tasks handled by graph data modeling diverse. We divide the downstream tasks into node-level tasks and graph-level tasks. Node-level tasks include node classification and link prediction, such as article classification in citation networks and inference of user preferences for products in recommendation systems. Graph-level tasks include graph generation and graph classification, such as drug network generation and protein classification in protein networks [33].

3. Method

3.1. Steel Plate Defect Analysis. Since the original size of each defect can vary greatly, we will apply scaling to achieve a uniform size. Figure 3 shows five common steel plate surface defects: their basic characteristics are as follows. (1) White iron scale: mainly in the form of strips of varying length, the color is generally white, mostly in patches of aggregated distribution, and the size of the defect varies. (2) Roll marks include three main types of features: defects for the lighter gray-white distribution of scattered microarcs, with low contrast to the background; defects for the dark gray arc-shaped microfolds; and a small number of defects for the continuous gray-black periodic straight band. (3) Scratches are generally gray-black, mainly in the width of the continuous periodic band. When the background color is dark, the defect looks like it and the contrast is low. (4) Scarring: mainly in the form of black dots or surfaces of different sizes, usually aggregated in patches, part of the distribution is more scattered. The background brightness may vary: as the

(a)   (b)   (c)   (d)   (e)
FIGURE 3: Types of defects in the collected data set. (a) White iron scale. (b) Roll printing. (c) Scratch. (d) Scarring. (e) Embroidery skin.

background gets darker, the contrast of features gradually decreases. (5) Rusty skin/embroidery skin. Mainly a certain width of short gray-black bands, features are more obvious, usually a single distribution or a very small number of clustered distributions. The above five kinds of defects are the ones that are the most studied.

The analysis of a large number of defect images shows that there are similarities between different types of defects (such as interrupted parts of rusty skin and scars, shallower, smaller scars, and white iron scales), and the same type of defects have a variety of forms and sizes (roll printing defects have three different forms and sizes). Traditional vision inspection methods have difficulty solving these problems, while GNN-based inspection algorithms can effectively detect these complex forms of defects.

3.2. Model Architecture. The proposed model is shown in Figure 4 and is made of three parts: (1) multilayer feature extraction network as backbone for steel plate defect detection, to extract visual features and spatial information of salient regions. (2) Graph CNN: to enrich the contextual information of visual features. (3) Attention mechanism: to explore the semantic association between visual features and fault categories.

3.3. Multilayer Feature Extraction. The multilayer feature extraction module is divided into 4 parts, which is feature extraction network, RPN (region proposal network) module, RoI pooling module, and R-CNN module [34]. It mainly generates candidate regions and performs preliminary classification and localization through RPN [35]. Then, it pools the acquired candidate regions and finally classifies and again improves the positions of the pooled defect features.

In this paper, firstly, we establish the global context attention mechanism into the adjacent resolution feature map. Secondly, the global context information is extracted from the low-resolution feature map. Thirdly, the high-resolution information is weighted to refine the spatial position of the category pixels, which can ensure the high-level features are not weakened and achieve a more accurate classification result without increasing the amount of calculation. Consider RPN network can map the generated region to the feature map generated by the convolution network through "anchors," realizing the connection

between the two and further improving the detection speed and accuracy [36]. To learn whether a defect is present in the input image, anchors (rectangular boxes with a certain size and aspect ratio) are placed on the image for each location on the output feature map from the RPN network. Then, the anchor is matched with the real defect, and the classification and fine-tuning of the defect location is performed. Figure 5 shows the computational flowchart of the multilayer extraction process, dividing the detection process in two steps and providing preliminary localization and classification (proposal). The more accurate the proposal is, the smaller the error of the later redetection. The RoI is obtained by screening a large number of proposals generated by the predicted anchor during training, and the proposal is directly used as the RoI during testing. RPN module mainly consists of five submodules:

(1) Anchor generation: RPN corresponds to nine anchors for each point on the generated feature map, and each anchor has three different area sizes and three different aspect ratios, corresponding to the original map covering possible defects.

(2) RPN convolution network: by employing a convolution network, each generated anchor is processed to obtain its prediction score and offset value.

(3) Calculate RPN loss: this part occurs only during the training process, matching the anchor with the labels to distinguish between positive and negative samples, obtaining the true values of classification and offset, and calculating the loss with the prediction score and offset values obtained in the previous step.

(4) Generate proposal: screen the anchor obtained by the RPN convolution network to get a better set of proposal for the subsequent network.

(5) Screening proposal to get RoI: screen the proposal obtained in the previous step to get the final RoI.

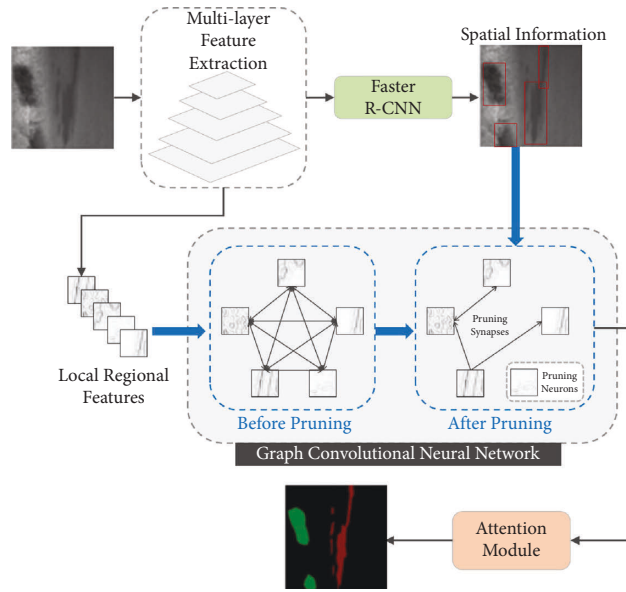
3.3.1. Feature Extraction Network. In order to obtain a better feature map if the image has a low contrast, a 13-layer convolution network similar to VGG16 is used to extract the defect features of the scaled image. The convolution layers use a small convolution kernel of size 3×3 with a small number of parameters, while the large number of layers gives it a better nonlinear capability to improve its learning


Figure 4: Model architecture.
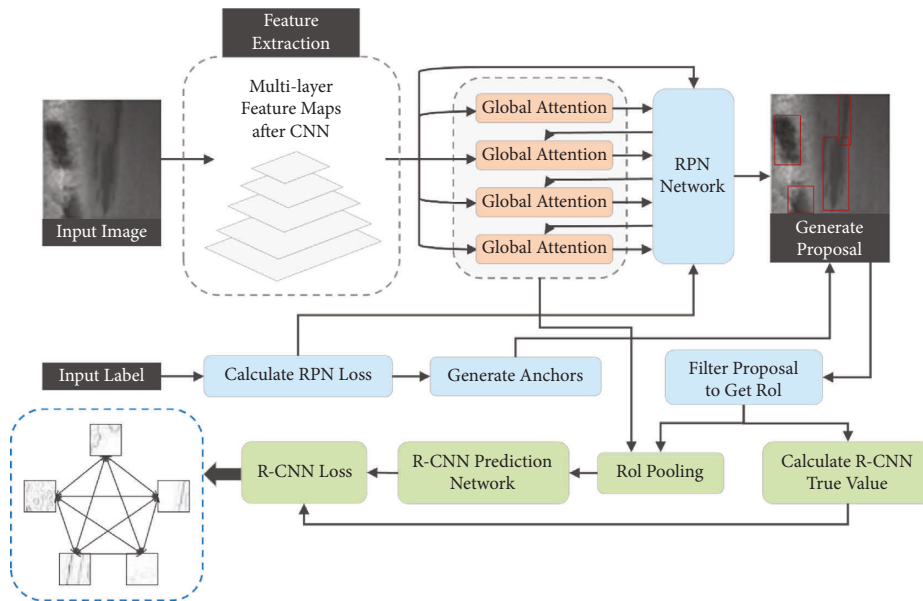

Figure 5: Schematic diagram of the multilayer feature extraction process.

capacity. This part includes five convolution modules, each outputting feature maps of 64, 128, 256, 512, and 512, respectively.

3.3.2. RPN Module.

Anchor generation is performed on the feature maps, the category score, and position offset value of each anchor are predicted, and the binary classification of defects (i.e., the presence or absence) and their preliminary location are performed according to the acquired proposals [37]. This module shares the convolution features of the whole map with the R-CNN detection network, saving time and providing high quality proposals to the R-CNN detection network, which improves the detection accuracy of the model. The number of output feature maps is 512, and 18 and 36 in the later classification and localization parts, respectively.

3.3.3. RoI Pooling Module.

Since the R-CNN module behind the faster R-CNN uses a fully connected layer, a uniform dimension is required before the defect feature subgraphs are input to the fully connected layer (the feature subgraph size in this paper is 7×7). Since the defect images of steel plates are of different sizes, their RoI corresponding feature map sizes are also different. RoI pooling is used to perform feature scale transformation to enable taking defect images of arbitrary sizes as input and output a fixed feature map size,

suitable for detecting the five different defects scales of this paper. The number of feature maps in this part is kept constant.

3.3.4. R-CNN Module.

The RoI feature subgraphs obtained from RoI pooling are mapped to the whole feature map and output to the fully connected network of the R-CNN module, which performs the defect class prediction and location regression. This part of the fully connected layer outputs 2048 feature maps. Faster R-CNN outputs the visual features of the i-th anchor point as $h = \{h_i\}_{i=0}^{m} \in R^{m \times 2048}$ and the spatial information as $S_i = [x_{i1}, y_{i1}, x_{i2}, y_{i2}]$, where m denotes the number of salient regions.

3.4. Graph Convolution Neural Network.

A first fully connected graph is constructed and further refined using the accurate contextual information between multiple salient regions, to obtain a spatial graph network. We use faster R-CNN to obtain the visual features and spatial information of saliency regions, as shown in Figure 6(a). Next, we introduce the construction of the fully connected graph by considering each object region in the image as a vertex, and by constructing a relationship graph, we obtain a fully connected indirect graph as shown in Figure 6(b), where each edge represents the relationship between two regions. The spatial information of the regions representing the position of the regions in the image is a four-dimensional spatial vector $S_i = [x_{i1}, y_{i1}, x_{i2}, y_{i2}]$, where (x_{i1}, y_{i1}) is the coordinate of the upper left corner of the bounding box and (x_{i2}, y_{i2}) is the coordinate of the lower right corner of the bounding box. The identification of the correlations between regions is done according to the following steps: (1) the visual features of the two regions are fed into the multilayer perceptron to obtain feature integration, and the corresponding elements of the two-feature embedding are multiplied to obtain a correlation score. (2) We determine whether there is a correlation between two regions based on the size of the overlap area. If two regions have a large overlapping area, it means there is a strong correlation between these two regions. If the two regions do not have any overlapping part, we consider that these two regions have weak correlation, which means there is no edge connecting these two nodes. In addition, we identified five different categories of region relationships, such as internal, overlay, and overlap. Based on the spatial relations, we removed some irrelevant region relations from the fully connected graph and obtained a relatively sparse graph as shown in Figure 6(c).

To enhance the contextual information in the visual features of each region, we use GCN to update the object representation. If the image contains m salient regions, considered as nodes, we use the $m \times m$ adjacency matrix A to represent the structure of the graph, with $A_{ij} = 1$ if there is an overlapping region between node i and node j; $A_{ij} = 0$ otherwise. Given the target node i and neighboring node $j \in N(i)$ in the image, where $N(i)$ is the set of nodes adjacent to node i, the visual feature representations of node i and node j are h_i and h_j, respectively. To obtain the correlation score s_{ij} between nodes i and j, by splicing the visual features of h_i and h_j, we first train a fully connected layer.

$$s_{ij} = w_a^T \sigma\left(W_a[h_i, h_j]\right), \quad (1)$$

where w_a and W_a are the learning parameters, σ is the nonlinear activation function, and $[h_i, h_j]$ denotes the concatenation operation. We apply the softmax function on the correlation score s_{ij} to obtain the weight α_{ij}, as shown in Figure 6(c).

$$\alpha_{ij} = \frac{\exp(sij)}{\sum_{j \in N(i)} \exp(sij)}. \quad (2)$$

For the graph convolution, the neighboring nodes of $h_j, j \in N(i)$ are first passed through a learned linear transformation W_b. These transformed representations are aggregated by the weights α_{ij}, and finally the updated node features h_{vi} are obtained by the activation function σ:

$$h_{vi} = \sigma\left(h_i + \sum_{j \in N(i)} A_{ij} \alpha i_j W_b h_j\right). \quad (3)$$

The output feature of the last layer node i in GCN is H_i, and the set of features of all nodes is H.

3.5. Attention Mechanism.

In order to enhance the higher-order semantic association between visual features and defect types, to refine and reduce the redundant information in visual features and highlight the key semantics, we designed the attention mechanism. First, for the regional visual representation H obtained by convolution of the graph neural network, each node's feature set is updated using the self-attention mechanism to obtain a new feature set $\tilde{H}$:

$$\tilde{H} = \mathrm{softmax}\left(\frac{HH^T}{\sqrt{d}}\right)H, \quad (4)$$

where H^T is the transpose of H and d is the dimension of H. To obtain the visual representation associated with the surface defect representation of the steel plate, we utilize the design learnable parameter matrices W_m. W_m is used as a guiding matrix to adjust the visual representation $\tilde{H}$. The similarity score between W_m and $\tilde{H}$ is calculated as follows:

$$r = \frac{W_m \tilde{H}^T}{\sqrt{d_m}}. \quad (5)$$

For the i-th region, a softmax function is used to normalize the score ri to obtain the defect diagnosis probability $\tilde{r}_i$.

$$\tilde{r} = [\tilde{r}_1, \tilde{r}_2 \ldots, \tilde{r}_i] = \frac{\exp(r_i)}{\sum_{j \in m} \exp(r_j)}. \quad (6)$$

3.6. Loss Function.

We deploy a multitask loss function that combines classification loss and edge localization regression loss for unified training and finally outputs the

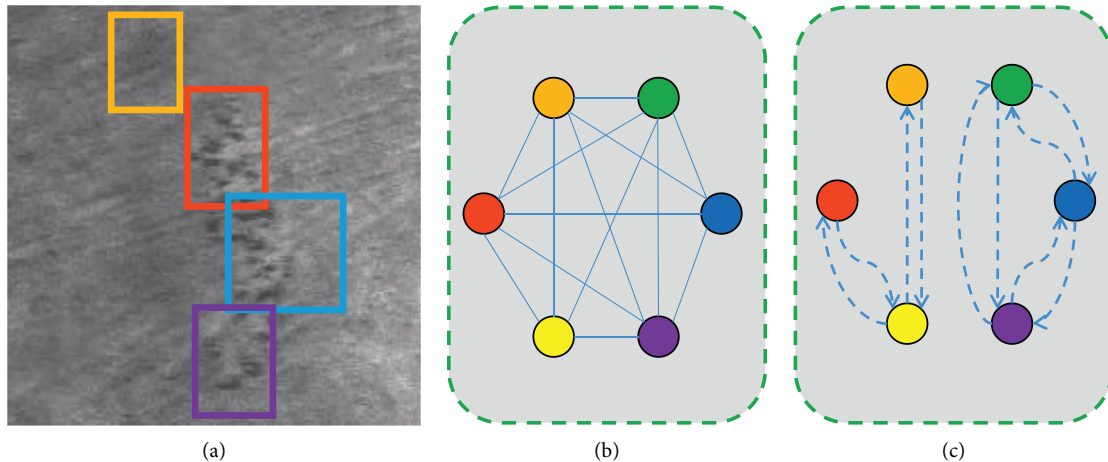
(a)　　　　　　　　　　(b)　　　　　　　　　　(c)


FIGURE 6: Graph generation.

corresponding classification and edge locations, which can improve the detection accuracy and is suitable for detecting small target defects:

$$L(\{\tilde{r}_i\}, \{S_i\}) = \frac{1}{N_{cls}} \sum_i L_{cls}(\tilde{r}_i, r_i^*)$$
$$+ \lambda \frac{1}{N_{reg}} \sum_i p_i^* L_{reg}(S_i, S_i^*), \tag{7}$$

where i is the index of the anchor; $\tilde{r}_i$ is the probability of anchor being predicted as a target; r_i^* is the category label, 1 when a target exists and 0 otherwise; S_i is the predicted value of location regression; S_i^* is the label value of location regression; λ is the weight balance value; N_{cls} and N_{reg} are the normalized values of classification loss L_{cls} and regression loss L_{reg}, respectively.

4. Experimentation and Evaluation

4.1. Datasets. We set up a test bench in a steel production factory and used a line-scan camera to acquire online images of steel plates and obtained a total of 5,000 defect samples after screening, 1,000 for each defect type, of which 4,000 were used as training samples and 1,000 were used as test samples. In the datasets of this paper, each defect image contains at least one defect, and some images contain multiple defects of different scales to ensure that the trained detection model can adapt to complex detection [38]. In this paper, the defect samples are labeled with defects using labeling software with rectangular boxes, where the label name is the first letter of the Chinese pinyin capitalization of each defect, such as TL for white iron scale, GY for roll marks, GH for scratches, JB for scars, and XP for rusty/embroidery skin.

4.2. Experimental Setup and Evaluation Metrics. The experiments were completed using the conditions shown in Table 1. To further demonstrate the effectiveness of the proposed method, 6 models and the AGCN were trained for

TABLE 1: Experiments conditions.

100 epochs (rounds) on the datasets of this paper. The training methods are as follows: the initial learning rate of the model is set to 0.0001; the Adam optimizer is used; the learning rate decay is performed once every 5 epochs, and its decay rate is 0.1; the batch size is set to 8 (the batch size is the number of samples selected for one training epoch; it is limited by the GPU of the device, and chosen to obtain the best optimization and highest training speed). The loss value plot of the proposed model trained on the dataset of this paper with 100 epochs is shown in Figure 7, where the vertical coordinate is the loss value (loss) and the horizontal coordinate is the number of training sessions. The loss values converge quickly during the training process and finally sets to about 0.18.

4.3. Performance Comparison. In this paper, the average accuracy mIoU (mean intersection over union) and frame rate are used as the actual metrics for defect detection, and the final saved optimal network model is taken for testing. The average detection accuracies of the five defects on the test set are shown in Table 2.

In order to avoid overfitting, this paper adopts 5-fold cross-validation. Compared with the original method (faster R-CNN) and recent advanced methods, our method has the highest average mIoU of 0.8580. Among the existing five categories of defect recognition, our methods are the most prominent in the 4 categories of defects. Compared with the most accurate RefineNet model, we are
FIGURE 7: Training loss convergence plot.

only 0.0092 behind in the defect detection of roll printing. It is proved that this method is effective for steel plate defect detection.

On the other hand, the recognition accuracy of each category of defects is different. Since embroidery skin is generally reflective which have large contrast with the background noise, its features are easy to be captured by the algorithm, and its recognition accuracy is generally higher than that of other categories. For roll printing, it typically appears as a long strip. However, the length of such defects varies in different images. One picture probably has more than one roll printing defects, which leads to low mIoU.

From Tables 2 and 3, it can be seen that faster R-CNN obtains a better detection accuracy than YOLOv4 on the test set; the defect detection accuracy of AGCN is better than that of faster R-CNN. AGCN improves the average detection accuracy of embroidery skin defects to 97.67%, which is 7.5% better compared with faster R-CNN. Compared with faster R-CNN and YOLOv4 model, the detection time of AGCN model is increased, but the impact is not significant, and our model can meet the practical requirements. The trained

model is tested on the test set and found to have issues such as false detection and missed detection. Defect characteristics vary greatly between classes, and when several types of defects have similarities, the accuracy is low. If a single "White iron scale" defect is present in a small area of an image, after multiple convolutions, the model losses the defect characteristics and cannot detect it. For "Roll marks" defects, when the color is light, bright or white, this type of defect can be misdiagnosed as "White iron scale"; because when the color is very similar to the background, the characteristics are not obvious and detection can be missed. When several small target defects are detected in an image, such as rusty/embroidery skin defects, the AGCN model has significantly higher average detection accuracy (The segmentation map are shown inFigure8).

4.4. Ablation Experiments. To verify the role of the proposed attention module and the graph convolutional neural network, we did some ablation experiments. The number of convolutional layers of the graph convolutional neural

network is varied to verify the effect of the model. We set the number of convolution layers as 1, 2, 3, and 4. The results are shown in Table 4. The model achieves the best results when the number of convolution layers is 3, which indicates that there are deep semantic associations between different salient regions in the images that require multilevel graph convolution. The effectiveness of the proposed graph convolutional neural network is demonstrated.

5. Conclusion

This paper introduces a AGCN detection method based on the multilayer feature. We analyze the features of the most common steel plate defects and the characteristics of the faster R-CNN network-based model as the visual multifeature encoder and propose to refine the visual features by combining the attention mechanism and the graph convolution neural network approaches. The graph convolution neural network enriches the contextual information in the visual features of steel plates and further explores the semantic association between vision and defect types using the attention mechanism to achieve intelligent defect detection. This method meets the practical needs of defect detection in steel plate production. In the future, we plan to explore the dynamic neural network-based steel plate defect detection.

Data Availability

The datasets used during the current study are available from the corresponding author on reasonable request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

Chi Zhang was the initiator of the subject and completed article writing and first revision, put forward the model framework, and finished the experimental verification. Jian Cui supplemented the experiment, improved the attention mechanism, and completed the second revision according to the opinions of reviewers. Wei Liu added comparative experiments and integrated the concept of multilayer fusion into the model. At the same time, she embellished the whole text to make the article more compact.

Retracted: IoT-Oriented Wireless Sensor Network and Sports Dance Movement Perception

Computational Intelligence and Neuroscience

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope

(2) Discrepancies in the description of the research reported

(3) Discrepancies between the availability of data and the research described

(4) Inappropriate citations

(5) Incoherent, meaningless and/or irrelevant content included in the article

(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

The Internet of Things needs to connect different types of sensors in accordance with the agreement, and different agreements can be used for information and information exchange systems, which can facilitate the identification and control of intelligent systems. In many scenarios, location service application data are very important for obtaining accurate location information about nodes. In this paper, a wrist motion sensing sensor based on the PVDF piezoelectric film is developed. To realize the monitoring of wrist motion signals, this paper designs and manufactures a series of PVDF noninvasive sensors for motion perception. The characteristics of sports dance movements are reflected in the coordination between men and women, and the dance posture and movements must be synchronized with the music according to the level of music rhythm structure. The transfer of center of gravity is the main driving force of sports, and the gait of athletes is related to the transfer of center of gravity. Posture stability is the basic element of sports dance training. Only on this basis can it be possible to develop specific motion function trajectories and technical action forms.

1. Introduction

The Internet of Things has certain development prospects in some broad fields, and each positioning information needs to be accurately found. In many scenarios, location service application data are very important for obtaining accurate location information about the site [1]. Therefore, the research on precise positioning of the Internet of Things has a great social and commercial significance; for individuals, it can also effectively improve the quality of life [2]. Based on the in-depth study on the research results of the positioning algorithm of the Internet of Things, the improvement of the positioning algorithm can further improve the positioning accuracy [3]. The Internet of Things expands based on the Internet [4], connecting people, people and things, and things with things [5]. With the continuous development of the Internet of Things, sensors have been applied more and more [6]. In some applications, location information is very important, and the data used can only be effective if it contains appropriate location information. Generally speaking, the

development of a high-precision, low-complexity wireless sensor network positioning algorithm has always been an urgent need in the field of wireless research [7]. Technical problems are solved. This article takes some equipment as a starting point and then starts with the design of each unit to realize the detection of each motion signal. Investigate and study some key issues in the PVDF sensor array developed [8]. The ultimate goal of this article is to detect motion signals, use gesture recognition algorithms to realize finger motion perception, design and manufacture a set of PVDF sensor array devices, and provide a new and convenient human-computer interaction device for man-machines [9, 10]. This article does not study the hand movements because according to the sports dance technique, the standard dance arm is a fixed frame type, and different dance movements are issued by the dance arm of the body, passing through the shoulder and foot bones to the terminal fingers and then become the most basic law of movement. The limitation of the quality of sports dance technical movements comes from the results of competitive attributes, evaluation standards, and music. The

environmental limitations of sports dance technical movements come from the rules of the competition and the competition venue. As a background venue for performing technical moves, athletes can fully participate so that referees can conduct objective and rational analysis. When the quality of a technical action can be observed, it is difficult to describe its parts individually. All the athletes' technical actions must have an "obvious" effect, and any rational analysis by the referee is based on a certain "phenomenon."

2. Related Works

According to the literature, sports dance training should not only solve the kinematics and dynamics of personal technical movements at any time but also cooperate with dance partners, music, and dance style and express emotions and show themselves [11]. Under many restrictive conditions, the above elements outside the human body are deeply combined with athletes' body movements and artistic expression to show the quality of technical movements, and the pursuit of perfect technical movement quality is the competition content and winning goal [12]. The literature points out that an important technical feature of sports dance and the important feature of human independence is to rely on movement. The beginning of sports dance is reflected in the cooperation between men and women, which is mainly divided into two aspects: gait and center of gravity displacement [13]. Literature review shows that the direct research on "technical movement quality of sports dance" is extremely limited, and there is no corresponding theoretical framework to follow. The literature shows that the famous manipulator and experts in the United States have created bionic technology and can control technology in the development and design of exoskeleton robots [14]. With the rapid development of data, exoskeleton robots have developed rapidly in various countries. However, due to the gap between technology and economic level, the development of robot exoskeleton technology also varies from country to country [15]. The literature briefly introduces the current development and research results of global exoskeleton robot technology. Compared with much foreign exoskeleton technology research, the research and development of foreign skeleton robots lags behind. With the support of technology development and policy environment, action recognition technology has been greatly improved [16].

3. Internet of Things Algorithms and Wireless Sensor Network Application

3.1. Internet of Things Algorithm. Based on the positioning algorithm to measure the nodes in some positions, the initial position starts to use the weighted least square method to calculate the estimated value of the problem. Different algorithms have different functions in the positioning of the nodes in the plane.

Different nodal coordinate formulas can be obtained by three-side measurement, such as formulas (1)–(3):

$$\left(x_{it} - u_{t_1}\right)^2 + \left(y_{it} - v_{t_1}\right)^2 = d_{i,t_1}^2, \tag{1}$$

$$\left(x_{it} - u_{t_2}\right)^2 + \left(y_{it} - v_{t_2}\right)^2 = d_{i,t_2}^2, \tag{2}$$

$$\left(x_{it} - u_{t_3}\right)^2 + \left(y_{it} - v_{t_3}\right)^2 = d_{i,t_3}^2. \tag{3}$$

In formulas (4) and (5), (b) minus (a) and (c) minus (b) is the equation set as follows:

$$2\left(u_{t_1} - u_{t_2}\right)x_{it} + 2\left(v_{t_1} - v_{t_2}\right)y_{it} \\ = d_{i,t_2}^2 - d_{i,t_1}^2 + u_{t_1}^2 + v_{t_1}^2 - u_{t_2}^2 - v_{t_2}^2, \tag{4}$$

$$2\left(u_2 - u_{t_3}\right)x_{it} + 2\left(v_{t_2} - v_{t_3}\right)y_{it} \\ = d_{i,t_3}^2 - d_{i,t_2}^2 + u_{t_2}^2 + v_{t_2}^2 - u_{t_3}^2 - v_{t_3}^2. \tag{5}$$

The T-th guess of the I-th unknown node is

$$\begin{bmatrix} x_{it} \\ y_{it} \end{bmatrix} = \begin{bmatrix} 2\left(u_{t_1} - u_{t_2}\right) & 2\left(v_{t_1} - v_{t_2}\right) \\ 2\left(u_{t_2} - u_{t_3}\right) & 2\left(v_{t_1} - v_{t_2}\right) \end{bmatrix}^{-1} \\ \times \begin{bmatrix} d_{i,t_2}^2 - d_{i,t_1}^2 + u_{t_1}^2 + v_{t_1}^2 - u_{t_2}^2 - v_{t_2}^2 \\ d_{i,t_3}^2 - d_{i,t_2}^2 + u_{t_2}^2 + v_{t_2}^2 - u_{t_3}^2 - v_{t_3}^2 \end{bmatrix}. \tag{6}$$

Taking each average value as the initial value of i position nodes and then we get the estimated value as

$$\begin{bmatrix} \widehat{x}_i \\ \widehat{y}_i \end{bmatrix} = \left[\sum_{t=1}^{N} x_{it} \sum_{t=1}^{N} y_{it} \overline{NN} \right]^T. \tag{7}$$

Different positioning models will be expanded to determine the initial value of the position based on the description of the node, the distance between the nodes, and the known information measured by the TOA sorting technology, such as

$$D = Q\Delta + E. \tag{8}$$

Using the weighted least square method to determine the position deviation, we get

$$\begin{bmatrix} \Delta x_1 \\ \Delta y_1 \\ \vdots \\ \Delta x_n \\ \Delta y_n \end{bmatrix} = \left(Q^T T^{-1} Q\right)^{-1} Q^T T^{-1} D. \tag{9}$$

According to the process of the algorithm, the time complexity of the algorithm is calculated. On the basis of the Taylor formula, the three-sided complexity of each measurement method is compared, and the value of the number of different nodes is n, and each improved three-sided complexity of the edge measurement algorithm is greater than that of other algorithms. The main reason is that the

TABLE 1: Comparison of time complexity.

Algorithm	Time complexity
Trilateral calculation	$O(nm^3)$
Three-sided calculation and traditional Taylor series expansion	$O(nm^3) + O(nm)$
Three-sided calculation and Taylor series expansion of multivariate variables	$O(nm^3) + O(n^4)$

distance of the unknown node increases, which leads to the expansion of the Taylor series, in exchange for higher positioning accuracy. The comparison of time complexity is shown in Table 1.

Constructing the Fisher information matrix can get formula:

$$F = \begin{bmatrix} F_{xx} & F_{xy} \\ F_{xy}^{T} & F_{yy} \end{bmatrix}. \tag{10}$$

Equation (11) finds the F matrix that satisfies the root mean square error of the positioning result as

$$E\big((\widehat{\varphi} - \varphi)(\widehat{\varphi} - \varphi)^{T}\big) \ge \mathrm{CRLB}(\widehat{\varphi}) = \mathrm{tr}\big(F^{-1}\big). \tag{11}$$

When different algorithms are used to verify the validity of knowledge, it is necessary to use simulation technology for simulation calculation, and then determine the positioning algorithm of the trilateration in the Taylor series. The modeling parameter is an area of $100\,\mathrm{m} \times 100\,\mathrm{m}$, 20 nodes are randomly and uniformly distributed, and simulated independently for 1000 times. Formula 12 can be obtained as

$$\mathrm{error} = \sqrt{E\left(\sum_{i=1}^{n} (\widetilde{x}_i - x_i)^2 + (\widetilde{y}_i - y_i)^2\right)}. \tag{12}$$

Based on the different initial values of the positioning algorithm, it is necessary to use the least square method to estimate each different position, and then obtain each environment suitable for the two-dimensional plane.

The specific steps to solve the positioning algorithm are as follows:

① Establish the distance square matrix, as

$$D = \begin{bmatrix} 0 & d_{1.2}^2 & \cdots & d_{1.(n+m)}^2 \\ d_{1.2}^2 & 0 & \cdots & d_{2.(n+m)}^2 \\ \vdots & \vdots & \ddots & \vdots \\ d_{1.(n+m)}^2 & d_{2.(n+m)}^2 & \cdots & 0 \end{bmatrix}. \tag{13}$$

② After each different center matrix is determined, multiply, then we get

$$J = E - (n+m)^{-1}.I. \tag{14}$$

The matrix H after double centralization has the form

$$H = -\frac{1}{2}JDJ. \tag{15}$$

After the determination of different initial positions, the position of the anchor node and the distance between the two are measured using TOA sorting technology. Different Taylor set formulas create different models between multivariate expansions, and then we get

$$D = Q\Delta + E. \tag{16}$$

Equation (17) uses the least square method to solve the position deviation:

$$\begin{bmatrix} \Delta x_1 \\ \Delta y_1 \\ \vdots \\ \Delta x_n \\ \Delta y_n \end{bmatrix} = \big(Q^{T}Q\big)^{-1} Q^{T}D. \tag{17}$$

Equation (18) is the estimated location of the unknown node:

$$\begin{bmatrix} \widetilde{x}_1 \\ \widetilde{y}_1 \\ \vdots \\ \widetilde{x}_n \\ \widetilde{y}_n \end{bmatrix} = \begin{bmatrix} \widehat{x}_1 + \Delta x_1 \\ \widehat{y}_1 + \Delta y_1 \\ \vdots \\ \widehat{x}_n + \Delta x_n \\ \widehat{y}_n + \Delta y_n \end{bmatrix}. \tag{18}$$

The output mode of CRLB needs to be based on a certain algorithm in each positioning algorithm, and then meet the error according to the positioning as

$$E\big((\widehat{\varphi} - \varphi)(\widehat{\varphi} - \varphi)^{T}\big) \ge \mathrm{CRLB}(\widehat{\varphi}) = \mathrm{tr}\big(F^{-1}\big). \tag{19}$$

When the measured error is zero, the variance can be determined as an estimate of performance, and the Gaussian distribution of the root mean square error can be determined. Looking for the positioning algorithm, we obtain

$$\mathrm{error} = \sqrt{E\left(\sum_{i=1}^{n} (\widetilde{x}_i - x_i)^2 + (\widetilde{y}_i - y_i)^2\right)}. \tag{20}$$

3.2. Wireless Sensor Network Application. Because some higher-dimensional two-dimensional spaces are more intuitive, you only need to consider the two-dimensional situation. In the two-dimensional situation, the position information of the wireless sensor node is represented by a column vector of coordinate elements as

$$v_{ij} = \begin{cases} 1, & \text{measurable situation}, \\ 0, & \text{other}. \end{cases} \tag{21}$$

The distance between all pairs of nodes is measured as

$$r_{ij} = \left\| p_i - p_j \right\| + n_{ij}, i = 1, \ldots, M, j = 1, \ldots, M, i < j. \tag{22}$$

One technique that can be used to reasonably estimate its positioning performance is the AM positioning error of all detected sensor nodes as

$$\text{a.m.s.locazation error} = \frac{1}{M_{\text{loesen}}} \sum_{m \in S} E\left\{ \left\| \widehat{p_m} - p_m \right\|^2 \right\}. \tag{23}$$

According to the CRLB of AMS, formula (24) can be obtained as

$$\text{CRLB}_e = \text{TR}\left\{ I_e^{-1} \right\}. \tag{24}$$

The probability density function associated with an independent model of Gaussian measurement error with zero mean and proportional variance is

$$f_p\left(r_{ij}, i = 1, \ldots, M, j = 1, \ldots M, i < j | p_m, m = 1, \ldots, M\right). \tag{25}$$

4. Sports Dance Movement Quality and Movement Perception

4.1. Research on the Quality of Sports Dance Movements. The quality of the technical movements of sports dance is not only related to different cognitions of technical knowledge but also related to the performance of body movements. Different sports activities combine different functions in terms of concepts and principles of movement control. In training, one of the movement techniques of each athlete is to include some trajectories, timing, and movement postures related to speed, strength, and rhythm. However, it turns out that time, speed, and rhythm are all part of the content of time, and strength is related to the use of body energy. At the biological level, the understanding of movement is not only from the perspective of movement control theory, but starting from the right phase of human beings, different body movements are connected with the activities of the brain. When each athlete pursues the goal of the competition, he must constantly feel, experience, and create a state of complete or even extreme mobilization and

activation of the nervous system. Human gait can be divided into standing period and swing period. The normal gait support in dance movements requires vertical force (floor reaction force) to resist gravity, support body weight, and generate horizontal friction to resist the support surface (to make the body move towards all directions). Need to move in direction. In addition, the posture control strategy needs to be adjusted to make it more flexible, and the speed change and direction also need to be changed. In the change of each support surface, the principle of motion control will complete a certain posture control so that different speed changes can be changed. The basic principle of movement is also based on the training and application of sports dance movement. The athlete's gait model needs new adaptation, especially facing various complex tasks and environmental conditions.

As a spatial component of the quality of technical movements, the most important function of trajectory and movement methods is to control the body and prepare for the victory of the game. It can reflect the beauty more than art sports and other competitive sports. Therefore, this article examines the relationship between the quality of technical movements and the athletes and space from the perspective of kinematics, and whether the form and trajectory of the movements are related to posture positioning. Technical actions are based on body anatomy and vertical body lines and movement in spherical space. Whether it is basic movements or the movements of standing, walking, running, jumping, turning, and bending, the control of balance is a complex sensation and movement technique. Always keep this in mind during training and take the initiative to adapt to various changes. It is necessary to know that "the space where the body is located will affect the perception of position stability and direction." Posture stability is the basic element of sports dance sports training. Only on this basis can it be possible to develop specific motor function trajectories and technical movements. Amplitude, acceleration, and speed are a special technical action mode, and they are the external effect components of "mass."

4.2. The Perception of Lower Limb Movement in Sports Dance. The movement of the lower limbs of the human body contains many aspects and types of data although the use of muscle electrical signals can directly reflect the advantages of the brain's muscular awareness of the human body's actions and quickly reflect a person's movement intention. In addition, due to the uncertainty of the environment, the surface EMG signal is also more susceptible to interference. Different surface area signals are used to determine changes in motion status and ensure the accuracy and reliability of body motion. Based on the above considerations, this article assists the inertia and inertia of the lower limbs. Foot pressure information perceives movement behavior and strives to rely on the combination
Figure 1: Low-pass filtering of plantar pressure.

of multiple sports information to make lower limb movement research more accurate and reliable, as shown in Figure 1.

Taking the lateral thigh muscles as an example, using the above-mentioned method of detecting the end point of the activity segment of the EMG signal can better identify the end point of the activity of the EMG signal, as shown in Figure 2.

After recording the acceleration characteristics, sEMG, and plantar pressure signals separately, some important characteristics can be obtained, but this also leads to an increase in the size of the elements, and the excess elements
FIGURE 2: Schematic diagram of active segment extraction.

are also different. Therefore, the preliminary merge function should be checked. This article uses a method to check the relevance and redundancy of the function, as shown in Figure 3.

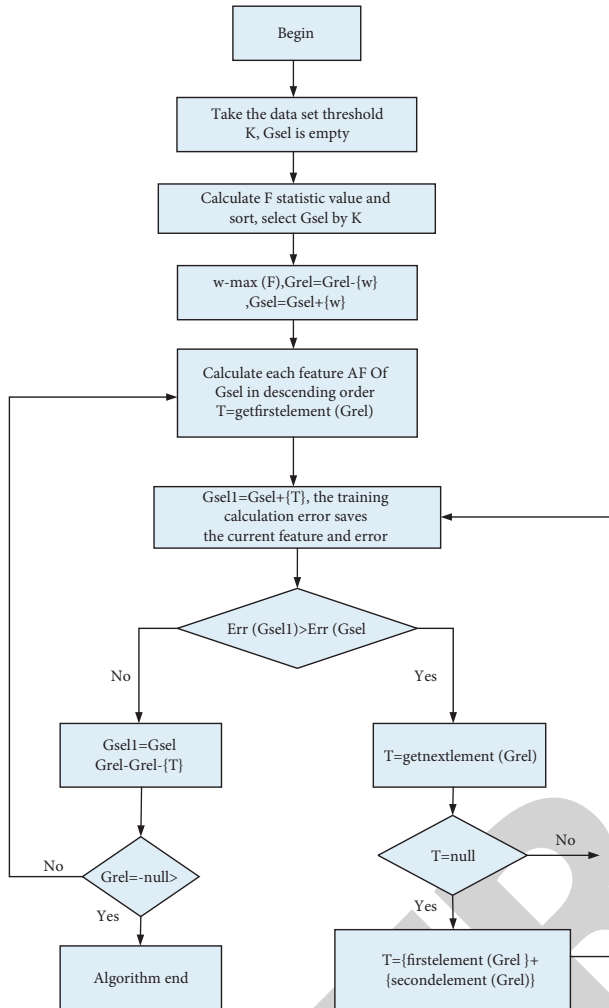
Table 2 shows the comparison and analysis results of the classification effect data. From the results obtained, the classification accuracy of the algorithm combining the three types of information functions is compared with the method of a single sensor function and compared with the previous method using the gait periodic function as the unit. Compared with the recognition method, the classification accuracy is higher, and at the same time, it has a great advantage in classification efficiency.


FIGURE 3: Flow chart of the forward search algorithm based on dynamic correlation and redundancy analysis.

TABLE 2: Comparison of three feature classification results.

	Walk (%)	Jump (%)	Raise leg (%)	Stretch (%)
Original period unit	90.12	89.10	92.50	89.98
sEMG	81.32	82.50	89.00	81.20
Acceleration	87.30	87.20	83.92	86.17
Plantar pressure	90.35	91.50	78.65	77.15
Fusion feature	88.93	93.80	91.32	91.56

5. Conclusion

This article aims to further reduce the influence of ranging error on positioning accuracy and improve the positioning accuracy of the algorithm. Based on the Taylor series expansion method, in each of the expansion positioning models, which are mostly Taylor series, each model proposes two brand new positioning algorithms, which combine the multilateral measurement methods, and then uses the MATLAB algorithm to model and test the algorithm. In order to be able to model and analyze the positioning algorithm more intuitively and conveniently, this paper also uses MATLAB to design and implement an IoT node positioning modeling platform. Different environmental monitoring has attracted widespread attention in areas such as intelligent transportation and technological battlefields. Different industrial production and life have gradually expanded to social life. However, as a continuously developing technology industry, it is still in application. As the core technology of WSNS, WSNS positioning technology has always been a research topic for scientific research institutes and enterprises at home and abroad. Different positioning algorithms emerge in endlessly, but no one positioning algorithm is omnipotent and suitable for all situations. Each algorithm has its own advantages and limitations in a given environment. Based on the analysis of the principles and performance of various positioning algorithms, this article assumes the basic requirements of low computing power and high practical feasibility of the product to develop a system that uses a small number of reference nodes. The practice of multiple scenarios requires in-depth research and positioning. Technology and algorithm goals apply part of the positioning information to the real wireless temperature monitoring system. It is the internal and external sum of technical knowledge and performance behavior concepts. It includes many factors, and only when the requirements of these factors are fully met as much as possible will it affect the quality of technical actions.

Overall prediction of oral cavity squamous cell carcinoma (OCSCC) remains inadequate, as more than half of patients with oral cavity cancer are detected at later stages. It is generally accepted that the differential diagnosis of OCSCC is usually difficult and requires expertise and experience. Diagnosis from biopsy tissue is a complex process, and it is slow, costly, and prone to human error. To overcome these problems, a computer-aided diagnosis (CAD) approach was proposed in this work. A dataset comprising two categories, normal epithelium of the oral cavity (NEOR) and squamous cell carcinoma of the oral cavity (OSCC), was used. Feature extraction was performed from this dataset using four deep learning (DL) models (VGG16, AlexNet, ResNet50, and Inception V3) to realize artificial intelligence of medial things (AIoMT). Binary Particle Swarm Optimization (BPSO) was used to select the best features. The effects of Reinhard stain normalization on performance were also investigated. After the best features were extracted and selected, they were classified using the XGBoost. The best classification accuracy of 96.3% was obtained when using Inception V3 with BPSO. This approach significantly contributes to improving the diagnostic efficiency of OCSCC patients using histopathological images while reducing diagnostic costs.

1. Introduction

Oral squamous cell carcinoma (OSCC) is a diverse collection of cancers that arise from the mucosal lining of the oral cavity [1, 2], accounting for more than 90% of all oral cancers [3]. It is a subtype of head and neck squamous cell carcinoma (HNSCC), which is the world's seventh most frequent cancer [4]. The World Health Organization estimates that 657,000 fresh cases are diagnosed annually, with over 330,000 fatalities globally. OSCC frequency rates were found to be massively greater in South Asian countries. India has the biggest number of cases (one-third of cases), whereas

Pakistan has the first and second most common cancers in males and females, respectively [5]. Drinking alcohol, smoking cigarettes, poor oral hygiene, human papillomavirus (HPV) exposure, genetic background, lifestyle, ethnicity, and geographical region are all risk factors.

The detection of OSCC in early stages is essential to achieve a successful therapy, increased chances for survival, and low mortality and morbidity rates [6]. With a 50% average cure rate, the OSCC has bad prognosis [7, 8]. Microscopy-based histopathological analysis of tissue samples is considered the standard method for diagnosing OSCC [9, 10]. This diagnostic pathology methodology depends on

histopathologists' interpretation, which is typically slow and error-prone, limiting its clinical utility [11]. As a result, it is critical to provide effective diagnostic tools to aid pathologists in the assessment and diagnosis of OSCC.

Lately, there have been a growing number of studies on applying artificial intelligence (AI) to improve medical diagnostics. Researchers have been able to examine AI applications in medical image analysis thanks to increasing the usage of diagnostic imaging. Deep learning (DL) [12], in particular, has shown outstanding success in solving a variety of medical image processing challenges [13], specifically in the diagnostics of pathological images [14, 15]. Computer-aided diagnosis (CAD) systems based on DL have been suggested and established on a large scale for a range of cancer sorts, such as breast cancer, prostate cancer, and lung cancer ([16, 17] and [18]). Nevertheless, the research shows that DL has been seldom used to diagnose OSCC from pathological images. To recognize keratin pearls in oral histopathology images, Dev et al. employed Convolutional Neural Network (CNN) and Random Forest. For keratin area segmentation, the CNN model achieved 98.05 percent accuracy, whereas the Random Forest model spotted keratin pearls with 96.88 percent accuracy [19]. Das et al. used DL to divide oral biopsy images into different classes according to Broder's histological grading system. CNN was also proposed, which had a 97.5 percent accuracy rate (N) [20].

Folmsbee et al. used CNN to classify oral cancer tissue into seven types using Active Learning (AL) and Random Learning (RL) (stroma, tumor, lymphocytes, mucosa, keratin pearls, adipose, and blood). The AL's accuracy was determined to be 3.26 percent higher than that of the RL [21]. Furthermore, Martino et al. applied multiple DL architectures, such as U-Net, SegNet, U-Net with VGG16 encoder, and U-Net with ResNet50 encoder, to segment oral lesion whole slide images (WSI) into three groups (carcinoma, noncarcinoma, and nontissue). A deeper network, such as U-Net upgraded with ResNet50 as encoder, was shown to be more accurate than the original U-Net [22]. Amin et al. recently used VGG16, Inception V3, and Resnet50 were fine-tuned individually and then used in concatenation as a feature extractor to perform binary classification on oral pathology images [23].

The categorization of oral histopathological images into normal and OSCC classes was enhanced in this research. The increase is achieved by employing the notion of transfer learning to extract features from pretrained CNN models (VGG16, AlexNet, ResNet50, and Inception V3). Then, using the Binary Particle Swarm Optimization (BPSO) approach, features were selected. Finally, three different classifiers, XGBoost, KNN, and ANN, were used to determine the detection performance of OSCC and normal oral histopathology images.

2. Research Contributions

The proposed research investigates the following:

   (a) Oral histopathological images introduced to extract the desired features to four various models of DL.

TABLE 1: Image categories with the related source.

Resolution	Class	Number of images
100× magnification	NEOR	89
	OSCC	439
400× magnification	NEOR	201
	OSCC	495
Total images	NEOR and OSCC	1224

   (b) Investigating the obtained features in "a" by applying the methods of metaheuristic feature selection.

   (c) The metaheuristic feature selection method is explored to enhance the performance of the classifiers.

   (d) Achieving the most recommended "hybrid" system that provides the highest accuracy in the stage of the making decision, which is obtained by comparing the highest performance of the proposed models for detecting OSCC.

   (e) The final stage of the proposed research is the effect evaluation for the stain normalization on images classification.

   (f) Based on "a" to "e," AIoMT platforms development [24–26] is regarded as the main goal of the introduced research in the medical and health field.

The rest of the paper is organized as follows: The literature study in Section 1 goes into detail on previous successful approaches. A discussion of the method and approaches used in this study can be found in Section 3. A breakdown of the findings from the study is given in Section 4. Finally, the outcome of the investigated study is described in Section 5 before concluding the paper in Section 6.

3. Materials and Methods

3.1. Materials. The histopathological images dataset is got from the online resource repository [27], and medical experts prepared and cataloged data from 230 individuals. These images were collected from two different locations in India: Dr. B. Borooah Cancer Research Institute and Ayursundra Healthcare Pvt. Ltd, Guwahati. Images are divided into two categories: normal epithelium of the oral cavity (NEOR) and OSCC. A Leica ICC50 HD microscope camera was used to get the images. Table 1 shows the histopathological image details in terms of class, resolutions, and quantity. Figure 1 shows a chosen selection of histopathological images and the related categories.

3.2. Proposed Model. Figure 2 depicts the proposed model. The model states that the input histopathology images were first preprocessed. In order to extract features from normalized histopathology images, four DL models were used. The transfer learning approach was used during the feature extraction procedure. To find the best probable features, Binary Particle Swarm Optimization was employed as a feature selection method. Finally, three machine learning

(a)

(b)
FIGURE 1: Different classes of histopathological images with (a) NEOR and (b) OSCC.

methods were used to classify abstract features, such as DL [28].

3.2.1. Image Enhancement.

To develop the classification process, some preprocessing work is regarded as essential. So, the processes performed in the preprocessing step are explained in the following.

(1) Image Resizing. As shown in Table 2, the size of the histopathology images was adjusted depending on the size of the input of each DL architecture. Losing local features in histopathological images when resized is offset by the preservation of global features.

(2) Image Normalization. The analysis of the histopathology images faces may challenges, such as producing robust models to the variations resulting from different labs and imaging systems [30], caused by raw materials, the response to various colors of the scanners' slide, protocols for staining, and manufacturing techniques [31]. The histopathology dataset was stain-normalized using the Reinhard method [32, 33]. The purpose of the Reinhard stain normalization approach is to bring these stains' appearances into line [34]. This method allows a target image to be shifted in the color domain to more closely match the template image, which is applied on each histopathology image pixel as shown in equations 1 to 3 [35, 36].

Step 1: Convert both the source image X and target image Y from RGB space to $l\alpha\beta$ space.

Step 2: Do the following transformation in $l\alpha\beta$ space:

$$l_2 = \mu_g(l_1) + [l - \mu_g(l)] * \left[\frac{\sigma_g(l_1)}{\sigma_g(l)}\right], \quad (1)$$

$$a_2 = \mu_g(a_1) + [a - \mu_g(a)] * \left[\frac{\sigma_g(a_1)}{\sigma_g(a)}\right], \quad (2)$$

$$b_2 = \mu_g(b_1) + [b - \mu_g(b)] * \left[\frac{\sigma_g(b_1)}{\sigma_g(b)}\right], \quad (3)$$

where $l_2, a_2,$ and b_2 are intensity variables of the processed image in $l\alpha\beta$ space. $l_1, a_1,$ and b_1 are intensity variables of target image in $l\alpha\beta$ space. $l, a,$ and b are intensity variables of source image. μ_g indicates the global mean of the image and σ_g represents the global standard deviation of the image.

Step 3: Convert back the processed image Z from $l\alpha\beta$ space to RGB space.

The intensity variation of the original image is preserved using this procedure. As a result, its structure is kept, while the contrast is altered to match that of the target.

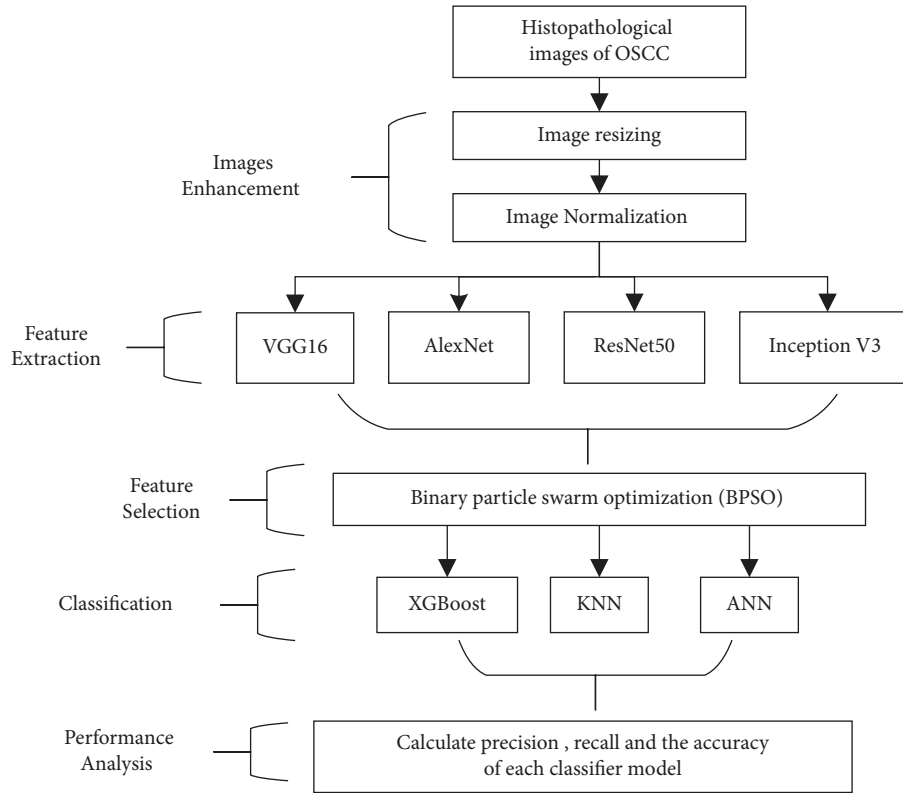
3.2.2. Features Extraction Using Deep Learning Models.


Figure 2: The proposed model for realizing AIoMT in medical systems.

Table 2: The input size for each DL architecture [29].

Model	Input size (pixels)
VGG16	224×224
AlexNet	227×227
ResNet50	224×224
Inception V3	299×299

In this work, four DL models were used for feature extraction, namely, VGG16, AlexNet, Inception V3, and ResNet50.

*(1) VGG*16. Maximum pooling and the convolution layers arrangement are followed by the VGG16 architecture [37] (Figure 3). Eventually, there are three FC layers: the first and the second are triggered by ReLU, while the third is triggered by Softmax. This design has 16 layers and 138 million parameters; the input layer can receive images with 224×224 pixels.

(2) AlexNet. The AlexNet [38] model contains 61 million parameters using an 8-layer CNN architecture. In the AlexNet architecture (Figure 4), there are five convolutional layers, where three of them are only used as linked layers. The fourth layer is the Softmax layer that requests a resolution of 227×227 pixels input image, and the last layer is the ReLU activation function, which performs the system convolutional and connected processes. Moreover, the FC-8 layer is linked to the Softmax layer via 39 neurons.

*(3) ResNet*50. The ResNet50 architecture [39] addressed the issues of several nonlinear layers, not learning identity mappings, and deterioration. Simply said, ResNet50 is a network made up of residual unit stacks (Figure 5). The network is built using residual units as building components. These units were built with convolution and pooling layers. The input histopathology images have a resolution of 224×224 pixels, and the design includes 3×3 filters.

*(4) Inception V*3. Convolutions, average pooling, maximum pooling, dropouts, and completely connected layers are among the asymmetrical and symmetrical building elements used in the model (Figure 6). The Softmax function is found in the last layer of the Inception V3 architecture [40], which comprises 42 levels, where the resolution of the received information by the input layer in pixels is 299×299.

3.2.3. Binary Particle Swarm Optimization for Feature Selection. In processing data, the selection of features is critical [41–43]. Longer training and overcompliance are challenges caused by the vast amount of data to be handled (Deif et al. [12, 44]). Unnecessary features should be removed from the data to avoid situations like this. For feature selection [7], BPSO is used, where BPSO is the binary form of PSO [45, 46]. The BPSO algorithm process was summarized in Figure 7 and described below:

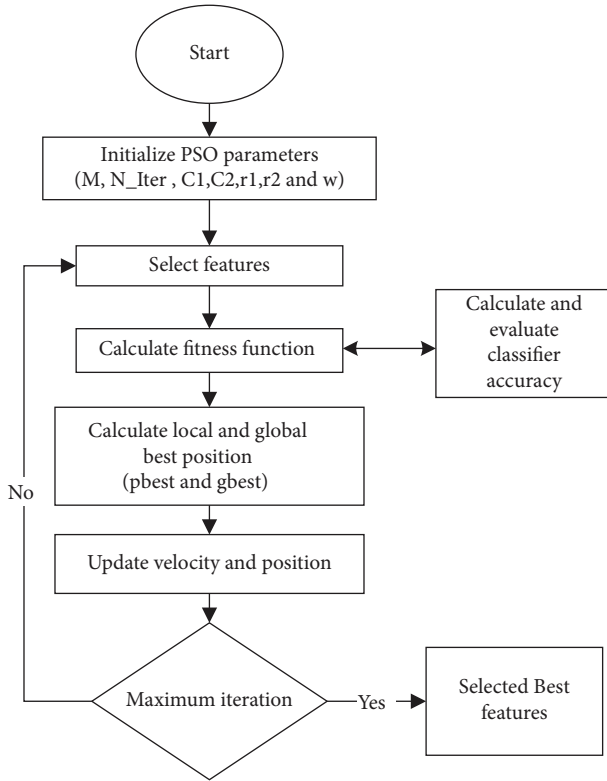
> Step (1): Equation (4) is used to update the particle velocity in the swarm.
Figure 3: Schematic illustration of VGG16 architecture.
Figure 4: Schematic illustration of AlexNet architecture.
Figure 5: Schematic illustration of ResNet50 architecture.
FIGURE 6: Inception V3 architecture schematic.


FIGURE 7: BPSO approach for feature selection.

$$v_i^d(t+1) = wv_i^d(t) + c_1 r_1 \left(pbest_i^d(t) - x_i^d(t) \right)$$
$$+ c_2 r_2 \left(pbest^d(t) - x_i^d(t) \right). \tag{4}$$

Step (2): Equations (5) and (6) are used to modify the particle's location.

$$S\left(v_i^d(t+1)\right) = \frac{1}{1 + \exp\left(-v_i^d(t+1)\right)}, \tag{5}$$

$$x_i^d(t+1) = \begin{cases} 1, & \text{if rand} < S\left(v_i^d(t+1)\right). \\ 0, & \text{otherwise.} \end{cases} \tag{6}$$

Each swarm particle represents a potential solution. A 0/1 (1x feature number) matrix is one conceivable option, with each column value produced at random. Selecting the column numbers in the feature matrix with 1 yields a workable solution (a particle). The fitness value of particles in a swarm was calculated using the kNN classifier error rate. The particle with the best objective function value in the swarm is considered as g_{best} in the first iteration.

Step (3): The particle with the highest aim function value is allocated in subsequent iterations (equation (7)).

$$Pbest \begin{cases} id(t+1) = xi(t+1), & if F\left(x_i(t+1)\right) < F\left(pbest_i(t)\right). \\ pbest_i(t), & \text{otherwise.} \end{cases} \tag{7}$$

If p_{best}'s aim function value is higher than g_{best}'s, p_{best} is assigned to G_{best} (equation (8)).

$$gbest(t+1) = \begin{cases} pbest_i, (t+1), & if F\left(pbest_i(t+1)\right) < F\left(gbest(t)\right), \\ gbest(t), & \text{otherwise,} \end{cases} \tag{8}$$

where x is the solution, p_{best} denotes the personal best, B_{best} denotes the global best, $F(.)$ denotes the fitness function, and t denotes the number of iterations.

This process is repeated for T iterations, and the algorithm returns the best global solution as output [7].

3.2.4. Classification Stage. Xtreme gradient boosting (XGBoost) achieves the classification model for distinguishing between histopathological images for NEOR and OSCC. The findings of XGBoost are compared to those of classic machine learning techniques like artificial neural networks (ANN) and Random Forest (RF) [47].

3.2.5. Assessment of the Suggested Methodology's Classification Performance. The suggested methodology is evaluated

(a)   (b)   (c)
Figure 8: Samples of original and normalized histopathological images: (a) original image; (b) target image; and (c) Reinhard normalized.

by calculating sensitivity, precision, and accuracy for classifiers. The following formula is used to calculate these terms:

$$\text{Sensitivity} = \frac{TP}{TP + FN} \times 100\%,$$

$$\text{Precision} = \frac{TP}{TP + FP} \times 100\%, \qquad (9)$$

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \times 100\%.$$

The number of correctly classified chest disease images in the normal and OSCC classes, respectively, is represented by TP (True Positive) and TN (True Negative). The numbers FN (False Negative) and FP (False Positive) in the normal and OSCC classes, respectively, show the number of misclassified histopathological images.

4. Experimental Setup and Setting

The layers of the all deep models would have been trainable true during the training phase. Softmax was used as the activation function of the final CNN layer, and MSE was used as a loss function. The early halting approach was employed, with patience set at 5 and the minimal loss change set to 0.0001. The SGD optimizer was employed in all deep models with a learning rate of 0.001. The size of the mini-batch is 32.

Histopathological images were divided into two groups in the classification stage: 80 percent for training the classifier models and 20 percent for testing, with 10-fold cross-validation. All experiments were run on Google Colab [48] with GPU support. The whole code was written in Python 3.10.1 [49] using Keras version 2.7.0 [50].

The algorithms implemented in this research are BPSO, XGBoost, ANN, and RF, taking into consideration the fact that these algorithms are varying in the hyperparameters, and the settings are shown in [51].

5. Results

In the first step, to better understand the impact of stain normalization approaches on classification performance, all

histopathology images in the dataset were stain-normalized using the Reinhard technique. The Reinhard stain normalization approach used in this study is illustrated in Figure 8. In this diagram, (a) represents the original histopathological image used for the Reinhard technique, (b) represents the target image to be transferred (the techniques aim to normalize the colors in the target images to those of the original), and (c) represents the result of using the Reinhard technique.

In addition, we employed the probability density function (PDF) to investigate the effect of the Reinhard normalization method on histopathological images by comparing the postnormalization image PDF with the prenormalization image PDF. Figure 9(a) is the original PDF. The resultant density functions of the pixels in 3-channel RGB show that the target image's distribution is substantially skewed to the left (Figure 9(b)). Figure 9(c) shows that, after normalization, the probability distribution of the three channels resembles that of the original image.

Then, four deep models were used to extract features from the images: VGG16, AlexNet, ResNet50, and Inception V3. Figure 10 shows the total number of features got from each deep model. It can be seen in Table 3 that the smallest number of extract features was from the AlexNet model and numerous extract features were got from the ResNet50 model. Meanwhile VGG16 and Inception V3 extracted the same number of features.

Two experiments were carried out to see if the proposed feature selection strategy could increase the classification model's accuracy. In the first experiment, to train the classifier, all features were used without applying the feature selection technique. The second experiment was performed by employing the proposed feature selection method, that is, BPSO, to eliminate the undesired redundant and unrelated features by looking for the best features used to train the classifier. The performance values obtained for the XGBoost classifier using all extracted features and selected features are given in Figure 11.

The findings of the experiments show that when using the selected technique on features extracted using VGG16 and Inception V3, the classification performance of the XGBoost model was reduced but not when applying the

(a)

(b)

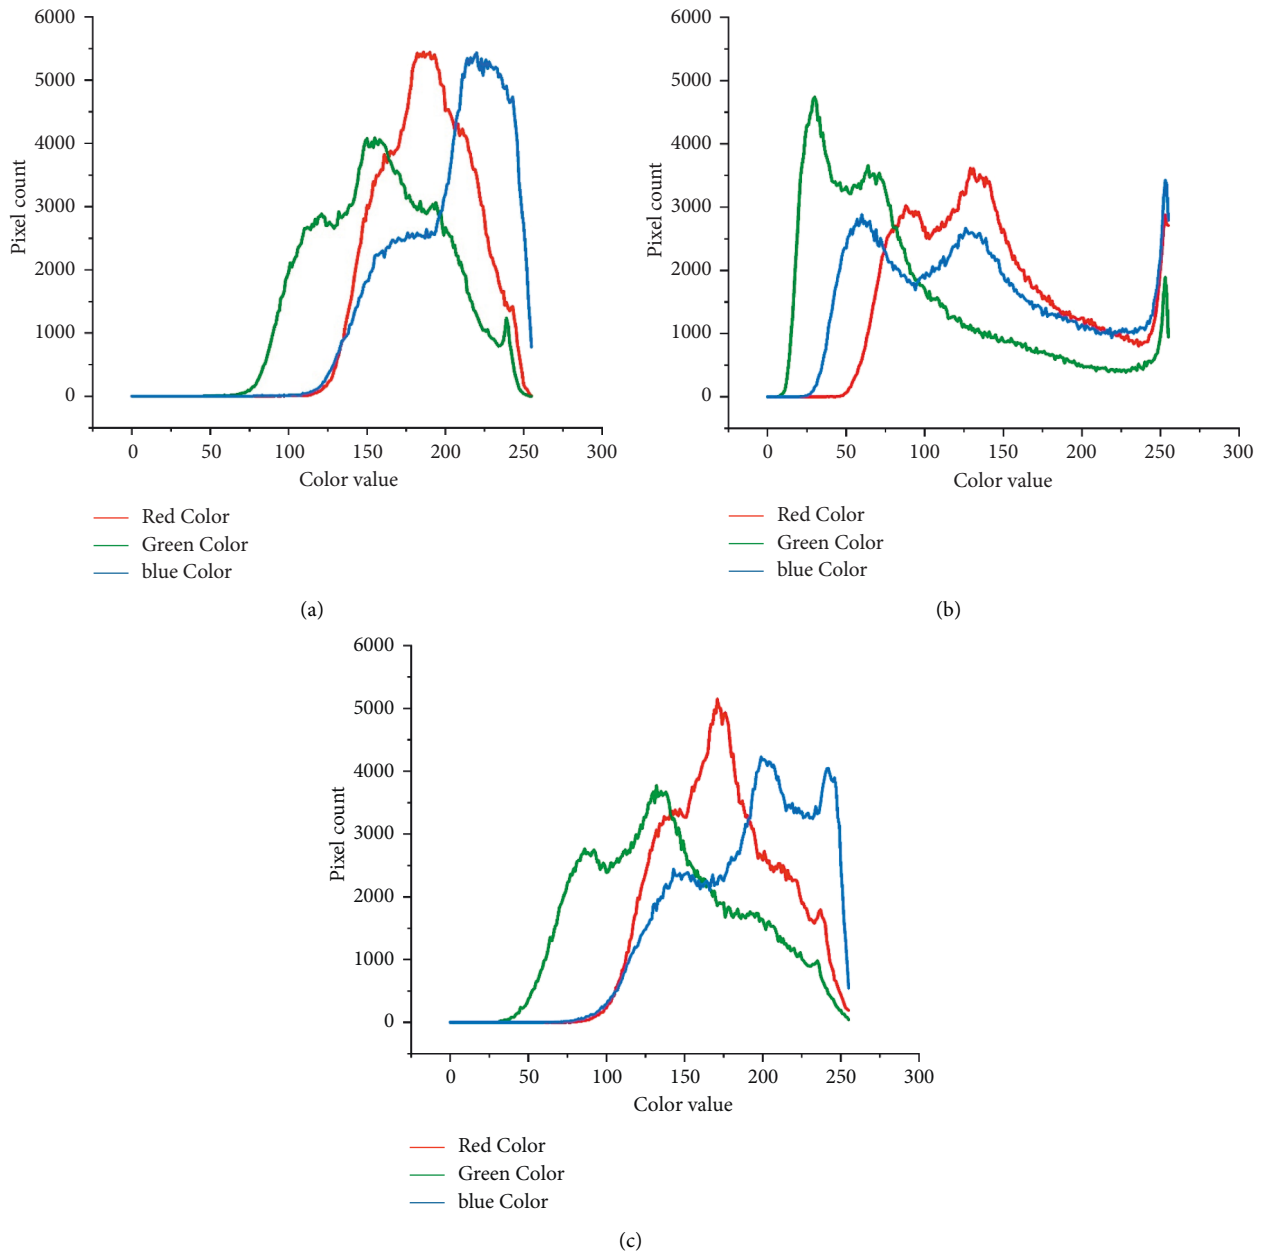
(c)


FIGURE 9: Samples of the probability density function (PDF) for (a) original histopathological image, (b) target histopathological image, and (c) Reinhard normalized.

selected approach on features derived using AlexNet. Meanwhile the XGBoost model delivered outstanding results when using the selected feature approach on features that were extracted using ResNet50.

To interpret the performance of XGBoost when using the features selection technique, Figure 12 was developed to illustrate the relation between the numbers of extracted features from all deep models; the number of features was selected using BPSO and Delta value (δ) that indicates difference between classification accuracies for XGBoost before and after applying BPSO.

It is seen that the highest extracted number belongs to the ResNet50 model, while VGG16 and Inception V3 have about half extracted number compared to the ResNet50 model. The lowest extracted number was got from AlexNet.

It is concluded that there is a relationship between the number of features extracted and the feature selection approach, where numerous features increase the ability of BPSO to select the best features and then select from fewer features. Therefore, we can interpret that the accuracy of XGBoost increased ($\delta = 11\%$) when applying BPSO on features that were extracted from ResNet50 because the BPSO selects the best features from numerous features (4099) compared to features extracted from VGG16 (2051) and Inception V3 (2069), while the XGBoost accuracy has not changed ($\delta = 0$).
FIGURE 10: The features got in the study and all execution times.

FIGURE 12: Comparison between the number of extracted features from all deep models, number of selected features, and Delta value (δ).

TABLE 3: Performance comparison for XGBoost classifier with another state-of-the-art traditional machine learning algorithm.

Classifier name	Overall accuracy (%)	Sensitivity (%)	Precision (%)
XGBoost	96.3	98.9	96.3
RF	93.1	97.8	93.3
ANN	94.1	97.8	94.7

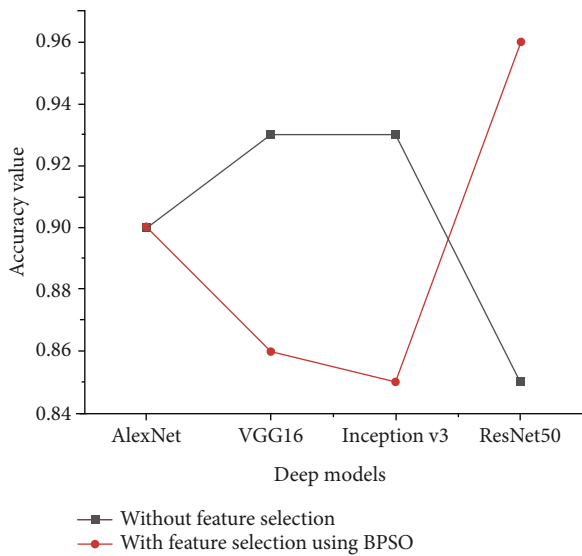
FIGURE 13: Fitness values of BPSO for different extracted features.


FIGURE 11: Accuracy performance for the XGBoost classifier using all extracted features and selected features.

Figure 13 illustrates a comparison of the BPSO convergence curves algorithm at the feature selection stage. It is important to note that the fitness is the average of 20 runs. The greater the performance, the lower the values of the best fitness, worst fitness, and mean fitness. It is observed that the features obtained from VGG16 and Inception V3 models achieved the lowest fitness value for BPSO, while the best performance is given by the feature group obtained by using ResNet50.

Because the XGBoost classifier's histopathological image classification results with each features extraction method are the average accuracy got from 20 independent runs, a two-sample t-test with a 95 percent confidence level was used to see if the classification performance of the proposed ResNet50 with BPSO was significantly better (p value <0.05) than those of the other methods on histopathological images.

To assess the XGBoost classifier's classification performance, artificial neural network (ANN) and Random Forest are two more traditional machine learning techniques that are compared to the outcomes (RF). The classifier models were trained using features taken from the ResNet50 model and then fed to the classifier by best-selected features using BPSO, based on previous results. A confusion matrix for all classifiers is shown in Figure 14.

It is clear from the confusion matrix that the highest TP results were got from the XGBoost classifier, where 184 of

(a)

(b)

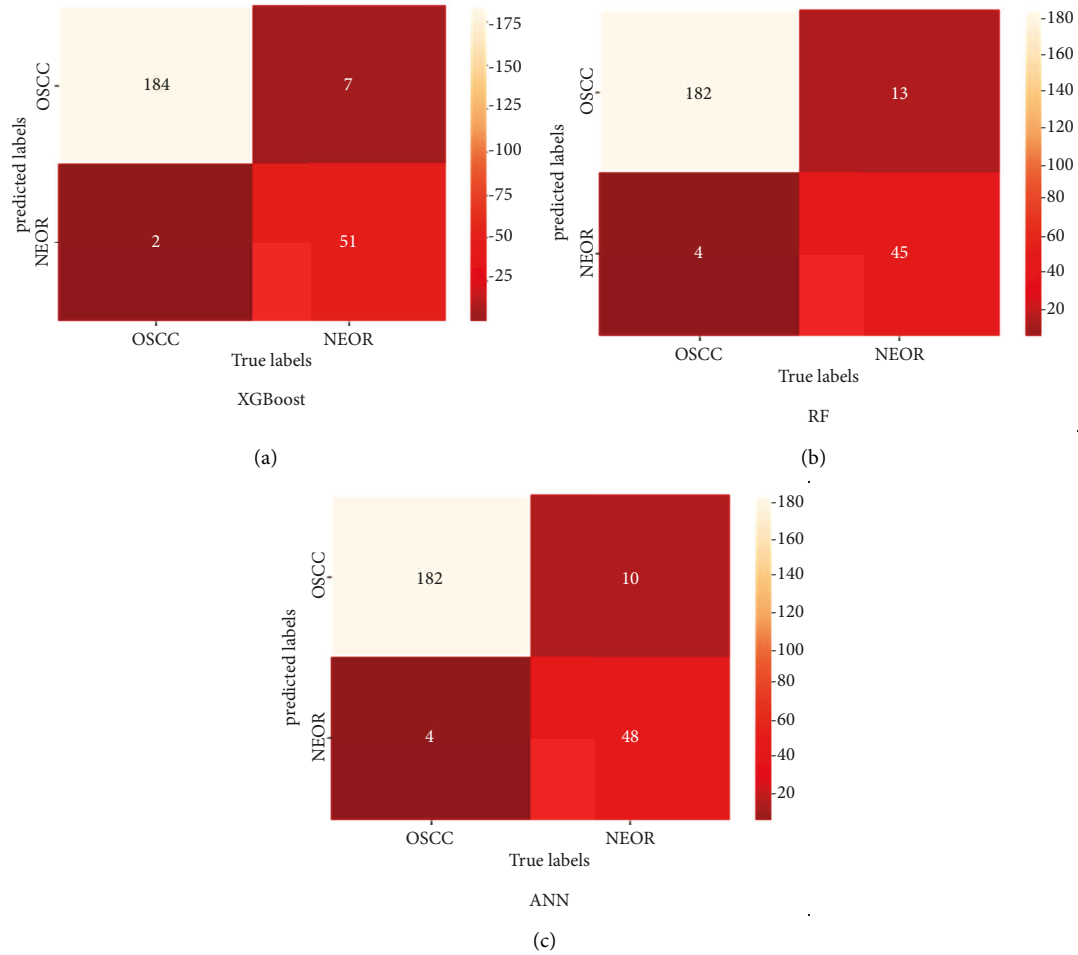
(c)


FIGURE 14: Confusion matrix of classification results for all classifiers.

TABLE 4: Accuracy performance for the classifier with non-stain-normalized image and stain-normalized image

Classifier name	Without stain normalization (%)	With stain normalization (%)
XGBoost	95.1	96.3
RF	91.3	93.1
ANN	94.2	94.1

186 histopathological images with OSCC were detected correctly, while two were diagnosed as NEOR. On other hand, the classifier had 7 histopathological images with NEOR. The XGBoost classifier has misclassified 7 normal histopathological images, which is the lowest number of FP compared to other classifiers.

According to the results shown in the confusion matrix, overall accuracy, sensitivity, and precision were calculated, as shown in Table 3. The XGBoost model delivered outstanding results compared to the other classifiers. It has consistently high accuracy, sensitivity, and precision (96.3%, 98.9%, and 96.3% respectively) across all models. This shows that this model was the most successful in learning and extracting essential features from the training data.

Finally, the proposed work investigates whether data normalization techniques can improve the accuracy of classification models or not, where all models were trained on nonnormalized histopathological images and the classification performance is illustrated in Table 4. It is seen that the accuracy was decreased when using histopathological images without applying the Reinhard approach. These effective results show that Reinhard stain normalization can improve the classifier performance and can produce satisfactory results.

For further evaluation of the proposed approach, it was compared with several previous research works shown in Table 5, which shows that the proposed method achieves the highest accuracy of 96.3% to classify different classes of histopathological images.

TABLE 5: Comparison of previous research works with the proposed method.

Authors	Algorithm architecture	The objective of the study	No. of images	Accuracy
Uthoff et al. [52]	CNN	Early detection of precancerous and cancerous lesions	170	86.88%
Jeyaraj et al. [53]	CNN	Develop an automated computer-aided oral cancer-detecting system	100	91.4%
Jubair et al. [54]	CNN	CNN using EfficientNet-B0 transfer model CNN for binary classication of oral lesions into benign and malignant	716	85.0%
Sunny et al. [55]	ANN	Early detection of oral potentially malignant/malignant lesion	82	86%
Rathod et al. [56]	CNN	Classify different stages of oral cancer	Not mentioned	90.68%
Alabi et al. [57]	ANNs	Predicting risk of recurrence of oral tongue squamous cell carcinoma (OTSCC)	311	81%
Alhazmi et al. [58]	ANNs	Predicting risk of developing oral cancer	73	78.95%
Chu et al. [59]	CNN	Evaluate the ability of supervised machine learning models to predict disease outcome	467	70.59%
Karadaghy et al. [60]	DT	Develop a prediction DT model using machine learning for 5-year overall survival among patients with OCSCC	33, 065	71%
Proposed method	CNN and BPSO	The features were extracted with Inception V3 and selected with BPSO to improve the classification performance of patients with OCSCC	1224	96.3%

6. Conclusion

In this study, traditional classification algorithms are used by extracting features from the four CNN models (VGG16, AlexNet, ResNet50, and Inception V3) and selecting the best features using the BPSO algorithm. The features extracted with Inception V3 and selected with BPSO improved the classification performance and contributed positively to the results. In addition, the effects of stain normalization procedures were investigated and compared with nonnormalized histological images. The results showed that the XGBoost model performed better when the Reinhard technique was used. This breakthrough achievement has the potential to be a precious and rapid diagnostic tool that might save many people who die each year because of delayed or incorrect diagnoses.

In order to better solve the problem of product logistics supply chains with short life cycles, a solution optimization of short life cycle product logistics supply chains based on support vector machines is proposed. This method recommends key technical problems and solutions through information represented by support vector machines and explore the research of short life cycle products to realize logistics supply chains. The research shows that, whether it is a retail channel or a network channel, the RMSE value of the effect index predicted by SVM is smaller than the RMSE value of the improved Bass. It can be seen that the SVM demand forecasting model constructed by considering multiple input factors can obtain a more accurate forecasting effect. The accuracy of the demand forecasting model based on SVM is verified.

1. Introduction

In recent years, the rapid development of the e-commerce industry not only drives the rapid development of the traditional consumption field but also gradually forms the dual-channel supply chain mode of coexistence of the traditional industry and the e-commerce platform. The rapid development of e-commerce directly promotes the rapid development of the traditional logistics industry. In addition, the continuous progress of science and technology, the transformation and rise of personalized demand of market consumer groups have virtually promoted the upgrading of products, and at the same time, the life cycle of products is constantly shortened; that is, short life cycle products have begun to appear. The market demand of this kind for product is too uncertain and time-sensitive, which virtually increases the difficulty of the supply chain management of enterprises. Enterprise supply chain management requires the mutual activities of different entities and related functions to gradually achieve a high degree of coordination, and on the basis of a high degree of coordination and cooperation, gradually achieve the purpose of a more flexible and low-cost corresponding consumer market [1, 2]. Therefore, the product supply chain with a short life cycle must be

further optimized. On this basis, a model prediction algorithm based on support vector machine and random inventory control adjustment and an optimization strategy based on TOC dynamic buffer management advantage are proposed, and this model is applied to the short life cycle product logistics supply chain to optimize the supply chain scheme [3]. Due to the fashion, seasonality, and depreciation characteristics of short life cycle products, it is particularly important to accurately predict logistics supply chain information and quickly respond to market changes. Traditional time series and other forecasting methods need to find out the law of historical data changing with time to predict market demand, but this method lacks consideration of short product life cycles and lacks historical data. Some scholars take into account the characteristics of short life cycle products and use the Bass model family to achieve prediction, but there is a lack of research on the different characteristics of traditional and network channels. The support vector machine (SVM) method has significant advantages in solving the problem of small sample and nonlinear high-latitude model construction, and can improve the generalization ability of the model. Therefore, the use of SVM for forecasting has lower requirements on the amount of data, and is suitable for demand forecasting of

products with short life cycles. Combining the characteristics of short life cycle product supply chain dual-channel sales cycle and less historical sales data, this paper discusses a short life cycle product demand forecast model based on Bass model that only considers the single factor of sales historical data; analyzes service and purchase intentions Bass improvement model under two factors. Based on this, the SVM algorithm is applied to the demand forecast of short life cycle products under dual-channel, considering the influence of price, season, promotion, industry status, historical sales data, and channel type of the short life cycle products in dual-channel sales. Combining the forecast correction value of the Bass model family with various influencing factors such as channels, a demand forecast model based on SVM is constructed, and simulation analysis shows that this method can improve the effect of short life cycle product dual-channel supply chain demand forecasting.

2. Related Works

Due to the rapid change in the market environment and various internal problems in the supply chain, the supply chain system must deal with various possible uncertainties in supply and demand in an appropriate way. At the same time, due to the inventory in the supply chain system, between the link between the medium and the buffer role. Therefore, good supply chain inventory management can effectively reduce the impact of various uncertainties on the overall supply chain system [4]. At the same time, in supply chain inventory management, a better management strategy and method should be able to ensure a higher level of customer service it can also maintain reasonable and effective control over the overall inventory level of the supply chain system, and increase the overall effective output of the system as much as possible, and further improve the comprehensive competitiveness of enterprises in the supply chain [5, 6]. Therefore, inventory management has always been one of the important issues in traditional supply chain research, and related research has been continuously developing. The existing inventory theory research can be roughly divided into deterministic inventory models, stochastic inventory models, multilevel inventory model, infinite cycle inventory models, and various inventory contract models which are currently in the research hotspot. For the deterministic inventory model, its main parameters, including the specific order quantity of each batch, order cost, and unit inventory cost, remain unchanged while the demand for related products is determined. In the research of this model framework, we generally conduct in-depth analysis and research from the perspectives of product quantity discount setting, replenishment lead time setting, and how to compensate for out-of-stock. In reality, there are many conditions, such as uncertain lead time, random demand, and variable ordering costs, and out-of-stock allowance. Therefore, the research on the stochastic inventory models has more practical significance [7].

Short life cycle products are commodities with a relatively short and fixed sales time, such as newspapers and magazines, fashion, all kinds of decorations, and increasingly electronic consumer goods [8]. For these short life products, distributors typically place orders well in advance of the selling season. It is also difficult for distributors to obtain particularly accurate demand information before placing orders. Therefore, only after calculating the expected revenue brought by all kinds of possible situations, such as shortage or overstocking, can it formulate the optimal ordering strategy by way of prediction according to the actual situation.

Considering that manufacturers' channel selection, channel competition, and contract coordination are the main factors affecting supply chain performance, some scholars put forward that perishable manufacturers' sales channel selection under the Internet environment will be affected by product price, the freshness of perishable products, and product price and quality of competitive channels. It is found that the increase of e-commerce channels is beneficial to the profit increase of the whole supply chain system. In the case of high distribution cost, the low wholesale price, and market demand fluctuation, it is more advantageous to choose two sales channels than a single channel. Considering the convenience factor of the channel, the pricing problem of the two sales channels is studied after the manufacturer adds the e-commerce channel to the two-layer supply chain system. The optimal coordinated price strategy of a dual-source supply chain is studied from the perspective of whether demand information is shared. The influence of service competition on channel pricing and profit distribution in the dual-channel supply chain is studied. From the perspective of consumers' sensitivity to service quality and price, different coordination modes of supply chain dual-source channels are studied. This article studies the win-win problem of supply chain channels achieved by manufacturers through quantity discount contracts in a mixed channel supply chain systems [9, 10].

3. Methods

3.1. Support Vector Machine Classification Algorithm. In the case of linear separability, a support vector machine is proposed based on the optimal classification hyperplane of a binary classification problem [11]. For example, if we look at two separate classes of problems on a two-dimensional plane, the basic idea can be expressed as a two-dimensional planar graph (see Figure 1). It is easy to observe that the two categories are divided into many possible boundaries, and each boundary has a related edge. If we choose the one with the maximum interval, there is little possibility of mistakes in the classification of unknown items in the future. Support vector machines map samples from input space to higher dimensional space by the kernel function. In this way, the samples on both sides of the dividing boundary can be accurately split, and the optimal classification plane can be found to maximize the classification distance between the two categories [12]. The empirical risk $\text{Remp}(w) = 0$ and the confidence range $\varphi(h/n)$ is minimized, so that the real risk $R(w)$ is minimized.
FIGURE 1: Optimal classification surface.

Assume that the given sample set is shown in:

$$\{(x_1, y_1), (x_2, y_2), \ldots, (x_n, y_n)\},$$
$$x \in R^d, \quad (1)$$
$$y \in \{1, -1\}.$$

The two types of samples in the figure above are represented by hollow points and solid points, respectively. $H2$ is the classification line, i.e. there is no boundary line separating the two types incorrectly, and the width of $H2$ and $H3$ lines is the classification interval [13]. 。 The normalized processing, equation $w \cdot x + b = 0$ for the equation of classification line, in high dimensional feature space, can be calculated by the equation $H2$, $H3$ classification interval is $2/\|w\|$. According to the theory in the previous section, in order to obtain the maximum interval hyperplane of a linearly separable problem, constraints should be satisfied as shown in equation:

$$y_i (w \cdot x_i + b) \geq 1. \quad (2)$$

To maximize the interval $\triangle$ under the precondition of satisfying the above conditions, it is equivalent to the following optimization problem as shown in equations (3) and (4):

$$\min_{wh} \frac{1}{2} \|w\| s.t, \quad (3)$$

$$y_i (w \cdot x_i + b) \geq 1, i = 1, \ldots, l. \quad (4)$$

The above equation is a typical linear constrained convex quadratic programming problem, which determines the unique maximum interval classification hyperplane. Its Lagrange function is shown in the following equation:

$$L(w, b, \alpha) = \frac{1}{2} \|w\|^2 - l \sum \alpha_i (y_i (w \cdot x_i + b) - 1). \quad (5)$$

The variable α_i is the Lagrange multiplier. The saddle-point control optimization problem of the Lagrange function $L(w, b, \alpha)$, which differentiates with respect to b and w. $L(w, b, \alpha)$ solved the differential equations of w and b respectively and made the results zero. Two optimization conditions could be obtained, as shown in equations (6) and (7):

$$\text{Condition1:} \frac{\partial L(w, b, \alpha)}{\partial w} = 0, \quad (6)$$

$$\text{Condition2:} \frac{\partial L(w, b, \alpha)}{\partial b} = 0. \quad (7)$$

Equation (8) can be obtained from condition 1:

$$w = \sum_{i=1}^{l} \alpha_i y_i x_i. \quad (8)$$

That is, the linear combination of training sample vectors is the weight vector of the optimal hyperplane. According to condition 2, the following equation can be obtained:

$$\sum_{i=1}^{l} \alpha_i y_i = 0. \quad (9)$$

Equation (8) problem can be transformed into a simpler "dual" problem by equation (9), as shown in the following equation:

$$W(\alpha) = \sum_{i=1}^{l} \alpha_i - \frac{1}{2} \sum_{i,j=1}^{l} \alpha_i \alpha_j y_i y_j (x_i, x_j). \quad (10)$$

Equation (10) is the extremum problem of quadratic functions with inequality constraints. According to the optimality condition—Karush-Kühn-Tucke condition, the solution of the optimization problem of equation (10) must satisfy:

$$\alpha_i \{[(w \cdot x_i) + b] y_i - 1\} = 0, i = 1, \ldots, l. \quad (11)$$

After solving the above quadratic programming problem, the classified decision function can be expressed asfollows:

$$f(x) = \text{sgn}\left(n \sum \alpha_i * y_i (x_i \cdot x) + b^*\right). \quad (12)$$

When the training sample set is linear and not time-sharing, nonnegative relaxation variables can be introduced, as shown in:

$$\xi_i, i = 1, 2, \ldots, l. \quad (13)$$

The optimal problem of classified hyperplane is shown in:

$$\min_{w, b, \xi_i} \frac{1}{2} \|w\|^2 + C \sum_{i=1}^{1} \xi_i. \quad (14)$$

Solving the maximum value of the following function for α is its duality problem, as shown in equations (15)– and (17):

$$\sum_{i=1}^{l} \alpha_i - \frac{1}{2} \sum_{i,j=1}^{l} \alpha_i \alpha_j y_i y_j (x_i, x_j), \quad (15)$$

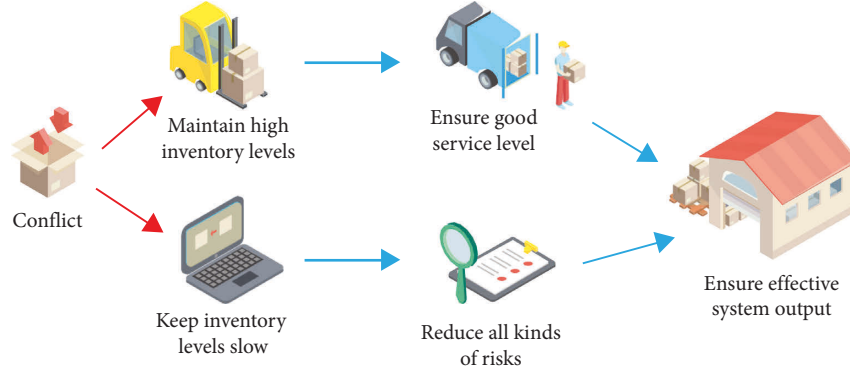
$$y_i (w \cdot x_i + b) \geq 1 - \xi_i, i = 1, \ldots, l, \quad (16)$$


Figure 2: Inventory control system conflict diagram.

$$\sum_{i=1}^{l} y_i \alpha_i = 0,$$
$$0 \le \alpha_i \le C, \qquad (17)$$
$$\xi_i \ge 0, \quad i = 1, \ldots, l.$$

The performance of SVM is largely determined by the choice of penalty parameters and kernel parameters. In recent years, many scholars have focused on how to determine the parameters of kernel function to obtain the optimal generalization ability of SVM. At present, the simplest method is to first set the interval, range of each parameter, and search exhaustively within the defined step interval, and test one by one to get the parameter with the best performance on the learning object. In the application of the SVM model, the determination of the SVM model is determined by the determination of the kernel function. Therefore, the selection of kernel parameters is a very key step in the establishment of the SVM model. Although there is no universally accepted the best guideline for kernel selection, the Gaussian radial basis (RBF) kernel is the most commonly used kernel in many experiments and studies. Similarly, the radial basis kernel function (RBF) was selected as the kernel function of SVM. By analyzing the influence of radial basis parameters on the regression performance of the SVM model, the decision basis for the optimization of the SVM algorithm can be provided [14, 15].

3.2. Inventory Buffer Control Method in Supply Chain Coordination

3.2.1. Questions Raised. With the increasingly fierce market competition, customer preferences for short life cycle product supply chains are constantly changing. The increasing variety of commodities, the shorter life cycle of products, the frequent fluctuation of demand, and many other factors make the demand of each link of the whole supply chain show strong uncertainty and nonstability, and the uncertainty of demand greatly increases the difficulty of inventory control and management. According to the characteristics of short life cycle product supply chain, TOC puts forward methods and suggestions to establish a corresponding coordination system. The first is to take the VMI

inventory system as the "link" between all the links in the supply chain, and apply the buffer management strategy in TOC, and then take this as the basis and main way of information transmission between each link. Therefore, in fact, in this supply chain system, the inventory system determines the overall "strength" of the supply chain system, so the setting of the inventory control system is particularly important for the short life cycle product supply chain based on the TOC system to be studied [16, 17]. The main contradictions commonly existing in various supply chain inventory control systems are shown in Figure 2.

3.2.2. Problem Analysis. On the one hand, in order to ensure a good service level for the downstream links and reduce possible delivery delays or shortages, it is necessary to maintain a high inventory level of raw material parts or finished products in the supply chain system. On the other hand, upstream supply chain enterprises also need to reduce the backlog of raw material parts inventory or finished products, the occupation of capital and all kinds of risks brought by inventory. Therefore, it is necessary to keep a small inventory [18]. At the same time, it should be noted that in the case of nonstationary demand, the contradiction between inventory cost and production satisfaction rate is often more difficult to balance because the fluctuation of demand is difficult to be described by probability model. In order to ensure the effective output of the whole supply chain system, it is necessary to ensure the better service level of each link of the system and reduce the various risks faced by the supply chain system. The assumption of the upper part of the conflict diagram is that if the overall inventory of the supply chain keeps a high inventory level, good service level of the supply chain system can be guaranteed [19]. However, the current reality is that the coexistence of high inventory level and a low service level often leads to the shortage of urgently needed products in the market and the high inventory level of products with poor sales. Therefore, a higher inventory level cannot guarantee a good service level in the supply chain system. The assumptions therein are not tenable similarly, for the lower half of the conflict graph; it is assumed that if the overall inventory of the supply chain keeps a low inventory level, various risks caused by inventory can be reduced in the supply chain system [20].

Especially in the supply chain of fashion products, the demand volatility is often very large, especially in some seasonal peak demand; too low inventory level will make the supply chain system unable to meet the market demand, and then, have to face the risk of more severe market competition. Therefore, a low inventory level cannot completely reduce various risks in the supply chain system, and its hypothesis is also not valid. Based on the above analysis, in fact, the core problem of inventory control is still caused by the uncertainty of demand. If the inventory level is maintained at the appropriate time, the core conflict will be resolved, so the supply chain coordination needs a set of inventory control systems that can dynamically adjust the inventory level.

3.2.3. Problem Solving. In order to carry out effective inventory control in supply chain coordination and solve the contradiction between inventory cost and customer service level, the following measures can be taken: first, improve the accuracy of demand prediction, make full use of historical demand data and expert knowledge provided by decision makers to make an effective prediction. Second, the inventory control strategy should have strong flexibility. When demand changes suddenly or seasonal demand comes, inventory control parameters can be flexibly adjusted according to historical information.

3.3. Construction of an Improved Bass Demand Forecast Model Based on Sales Records. The demand forecasting method, usually based on historical sales records, is to scientifically fit the past sales through a large number of historical sales records of products to find their demand trends. Due to the short sales period of short life cycle products, it is difficult to obtain a large number of historical sales records for a long period of time, usually only one year or even a few months of sales records. In response to this situation, this paper regards market sales as a process of continuous diffusion and penetration. That is, first, dealers attract a small number of consumers with a certain sense of innovation through product promotion or trial, and these consumers drive subsequent consumers, and so on. While a realistic diffusion process involves a large number of factors and their relationships, this complexity can be modeled and studied by the improved Bass diffusion model. Considering that the improved Bass model family has better applicability, the improved Bass model is firstly used to discuss the demand forecasting problem of short life cycle products, considering only the historical sales record as a single factor. The Improved Bass model is a model used to predict the sales of consumer goods. The improved Bass model can analyze the decision time of consumers to purchase products. It believes that the buyers of a product are influenced by external or internal factors, and thus, divides potential buyers of products into two categories: (1) innovation groups, which are susceptible to external influences, that is, mass media; (2) imitation groups, which class groups are susceptible to internal influence, that is, word-of-mouth influence. The core idea of the model is that the purchasing decision of the
Figure 3: E-commerce dual-channel supply chain system.

innovation group is independent of the purchasing behavior of other members of the social system, and the time when the imitation group purchases products is affected by the social system, and this influence increases with the increase of the number of buyers, thus, imitating the purchasing decision of the group. Time is influenced by members of the social system. According to the Bass thought above, let $f(t)$ be the time density function of adopters in period t, indicating the possibility of purchasing in period t; $f(t)$ is the proportion of cumulative adopters to all buyers in period t; ρ is the innovation group coefficient, indicating the external influence of the attributes of the communication product that can be easily verified, such as price, function, and media $\rho \in (0, 1)$; The propaganda function of potential users, such as products, disseminates some characteristics of products that require long-term experience to discover, $q \in (0, 1)$; m is the potential purchase amount; $n(t)$ is the cumulative purchase amount in the t period; $n(t)$ is the noncumulative purchase amount in period t; $X(i)$ is the product demand.

3.4. Optimization Model of Short Life Cycle Product Logistics Supply Chain Scheme Based on Support Vector Machine. The demand forecasting method based on historical sales records only focuses on the sales records of products, so it has certain limitations. The demand forecasting method based on service-purchase intention takes into account the market behavior characteristics of participants in addition to the sales record data, and has made certain progress. However, these two schemes can only distinguish the two channels by their different historical sales record values, but ignore the unique characteristics of the two channels. To this end, this paper considers the dual-channel demand forecast for short life cycle products under multiple influencing factors. Multiinfluencing factors refer to the dual-channel market demand that is affected by multiple factors. For retail channels, it is mainly affected by product price, seasonal index, promotion level index, industry status quo, the number of people entering the store, and historical sales data; for online channels, it mainly considers product price, seasonal index, and promotion level index, industry status, credit index and historical sales data and other influencing factors. Considering that SVM can effectively analyze multiple small samples and multiple input factors, the SVM method is combined with the improved Bass diffusion model, and the product price, seasonal index, promotion degree index, industry status quo, number of shoppers, credit index, and historical sales are introduced. Data and other market-influencing factors are used, and the sales value predicted by the improved Bass model is used as the

input vector to establish a dual-channel short life cycle product demand forecasting model under multiple influencing factors.

3.4.1. Establish a Demand Forecasting Model Based on Support Vector Machine.

According to the basic idea of SVM regression, through a nonlinear mapping Φ, the sample data (x_i, y_i) is mapped to the high-latitude feature space F, and linear regression is performed in this space:

$$f(x) = \left(\alpha^T \Phi(x)\right) + b, \Phi: R^n \longrightarrow F, \alpha \in F. \quad (18)$$

The support vector machine regression can be expressed as the following constrained optimization problem, that is, the quadratic programming form of the objective function is

$$s, t. R^T \begin{bmatrix} \alpha \\ \alpha^* \end{bmatrix} = 0, 0 \le \alpha_i, \alpha_i \le C. \quad (19)$$

In the formula: $i = 1, 2, \ldots, m$; α is the weight vector, $\alpha \in F$; Q and P are the two specified vector groups. When $i = 1, 2, \ldots, l$, $r_i = 1$; then, $i = l + 1, l + 2, \ldots, 2l$, $r_i = -1$. Among them, $x_i (i = 1, 2, \cdots, l)$ is the input of the ith training sample, $y_i (i = 1, 2, \ldots, l)$ is the output of the ith training sample, write a program according to the above process, that is, get the regression decision function of the SVM demand forecasting model:

$$f(x) = \sum_{i=1}^{l} \left(\overline{\alpha}_i, \overline{\alpha}_i^*\right) K(x, x_i) + \overline{b}. \quad (20)$$

3.4.2. Determining SVM Optimization Parameters.

The most commonly used method for SVM parameter optimization is to make the minimum penalty parameter c and the reciprocal g of the number of attributes in the input data that can achieve the highest verification classification accuracy take values within a certain range. For a certain set of c and g, the K-CV method is used to obtain the training set verification classification accuracy under the set of c and g, and finally, the set of c and g with the highest training set verification classification accuracy is selected as the best. Parameters. After the regression decision function is obtained, the normalized forecast sample is substituted into the regression decision equation, that is, the value y of the demand forecast between $(0, 1)$ can be obtained, which can be converted into the actual forecast value by using the formula (20):

$$y = \widehat{y}(y_{\max} - y_{\min}) + y_{\min}. \quad (21)$$

In the above forecasting process, the fitted values, historical record values, and other market characteristics of the improved Bass model are substituted into the model in the form of input vectors, and the optimal parameters and demand forecast values can be determined through model simulation.

3.5. Dual-Channel Supply Chain Coupling Model for Short Life Cycle Products

3.5.1. Supply Chain Model of Different Economic Forms

(1) Supply Chain Model of Different Economic Forms Based on Customer Order Separation Point (CODP). For manufacturers, generally speaking, their internal supply chain operation is separated from customer orders, and there is a combination of design process, manufacturing process, assembly process, delivery process, and after-sales service process in the customer order completion process. Among them, the activity on the left of the customer order separation point is push type, and the activity on the right of the customer order separation point is a pull type. Therefore, it divides the supply chain into two parts: one is to respond directly to the needs of the end customer, and the other is to cushion the change of supply chain demand with planning and strategic inventory. The decoupling point is also the turning point of enterprise production activities from forecasted inventory production to customized production in response to customer demand. The equation and optimization of plans at this point is no longer based on prediction but on customer orders and resource allocation of the enterprise itself.

(a) *Engineer to Order (ETO).* The needs of each consumer are different. Production can only be organized by designing products according to the needs of consumers when they receive orders, which requires a long time to prepare production technology. In this type of production, products are largely designed to meet the requirements of a particular consumer. To be designed to support consumerization is an important function and component of the production process. In this type of production, the production batches of products are small, but the design work and the final product are often very complex. In the production process, each job has to be specially handled so that the various subparts of a large product or project can be precisely matched at the final stage so that the different subparts produced by different people and different places can be combined into a complex product or project. Very advanced configuration systems are required for overall coordination and management control.

(b) *Make to Order (MTO).* It purchases raw materials in advance according to product demand characteristics and forecast, and starts production after consumer demand is determined. The enterprise starts the manufacturing process after the order arrives, and the customer provides the design data, and the enterprise carries out personalized production according to the design requirements. Because customer orders trigger production, the finished product is rarely kept.

(c) *Assemble to Order (ATO).* A product is a sequence of optional parts or prefinished components that users can select according to their individual needs.

TABLE 1: Operation characteristics of lean supply chain and agile supply chain.

	Lean supply chain	Agile supply chain
Product design strategy	Achieve maximum performance with the lowest product cost	Provide solutions for customers, use a large number of common parts, and delay customer differentiation
The pricing strategy	The margin is low and price is the main factor to attract customers	Price is not the main attraction for customers
Production strategy	Reduce costs by increasing the utilization of equipment and personnel	Maintain production flexibility and try to meet uncertain demand
Inventory strategy	Realize the minimum inventory to array low-cost	Maintain safety inventory to meet uncertain demand
Lead-time strategy	On the basis of not increasing the cost, reduce the supply cycle	Maintain safety stock. To satisfy the uncertainty of demand
Supply strategy	Balance costs and service levels	Water in speed, elasticity, and service. Balance up
Transport strategy	More reliance on low-cost means of transportation	Rely more on block agility

Manufacturers produce semifinished products or components, assemble them according to customer orders, and reduce lead times by producing standardized modules and assembling customized products to order. It also reduces the risk of early production. For example, computer production and assembly manufacturers cannot assemble a computer without receiving an order. However, in order to improve the response speed to consumers, they can produce some standard components in advance according to the market forecast and conduct rapid assembly when the orders arrive to meet the personalized needs of consumers.

(d) *Make to Stock (MTS)*. Consumers basically have no suggestions or requirements for the determination of final product specifications, and they have little input. Manufacturers do not make products tailored to any particular consumer. The products of the enterprise are manufactured before the order arrives, and the customer needs are satisfied through the inventory. The MTS production plan is based on a market forecast; such products should have relatively accurate forecast accuracy.

(e) *Physical Distribution on Stock (PDS)*. The demand for production comes from distributors. The product is standardized, and the manufacturer does not know who the final consumer is during the production process but predicts demand information based on historical sales data. This is generally a mass-consumer product, and management focuses on forecasting and inventory control.

(2) Lean-Agile Supply Chain Coupling Based on Customer Order Separation Point (CODP). CODP is a certain point in the manufacturing process as well as a certain point in the supply chain, which is closely related to the enterprise supply chain. If the customer order separation point (CODP) of each link in a manufacturing enterprise is extended to a multistage supply chain, it involves suppliers, manufacturers, distributors, consumers, and other links. And for a supply chain system, its response time refers to the sum of
FIGURE 4: MRP material procurement model.

time accumulated in all stages of the whole process, from the supply chain detecting the demand of the end customer and receiving the order to the delivery of the product/service to the end customer. Obviously, the response process of the supply chain to the final customer is actually the completion process, of the customer order, and its length depends on the point at which the customer order customization begins. In general, the part of direct response to consumer demand has strong demand correlation and autocorrelation, and it is easy to complete its relatively accurate prediction with a scientific algorithm through traditional forecasting methods and adopt the supply chain operation mode of MTS. The other part needs to use demand-side supply chain predictive management and adopt the supply chain operation mode of MTO. The dual-channel supply chain system of e-commerce is shown in Figure 3.

3.5.2. The Delay Strategy is Coupled to the MTO/MTS Supply Chain

(1) MTO/MTS supply chain coupling model from the perspective of flexible low-cost response. Lean supply chain management originates from lean production management and its bigger foothold lies in the reduction of supply chain costs. It refers to a series of supply chain planning, implementation, and control processes that optimize and transform the whole chain, including the upstream and downstream chains, to eliminate unnecessary steps, delays, waiting, and consumption, eliminate waste in
FIGURE 5: Delayed manufacturing model.

TABLE 3: Comparison of forecast—driven and order—pulled production economics.

Project	Predict to promote	Order pull
Starting point	Reduce purchasing and production cost as much as possible with accurate forecast	Be flexible and responsive to customer needs and changes
Location	Vendor-coupling point	Coupling point—consumer
Material characteristics	Long procurement cycle, variety, and centralized procurement to reduce unit price and production into components	Species is less
Processing requirements	Specialized equipment and skilled workers are generally required	Low requirements for equipment and workers
Supplier selection	Cost and quality	Speed, elasticity, and mass
Implementation method	Standardization, process, and modular	Customized
Economic benefits	Low cost operation	The pursuit of fast response can lead to higher costs
Advantages	Material versatility	Targeted, to meet the needs of customization
Disadvantages	Response period length	Need an inventory to be a buffer

enterprises, minimize costs, and meet consumer needs to the greatest extent. Lean supply chain management requires upstream and downstream efforts to reduce costs and waste throughout the process. See Table 1.

The competition of consumer demand response has developed from the simple quick delivery to the stage where enterprises unconditionally accept the increase, decrease, change or even cancel the demand put forward by consumers at any time. Enterprise cost management has also developed from the reduction of procurement, production, storage, transportation, and other physical costs to the total cost competition stage, including physical costs and market response costs, including out-of-sale costs and inventory holding costs. The above new supply chain competition stage generates a new supply chain development model—a flexible low-cost response model.

Combined with the above analysis and flexible low-cost response model, there is a coupling mechanism between lean supply chain and agile supply chain in enterprise operation. The advantages, disadvantages and complementarities of MTS-oriented supply chain strategy design in lean supply chain and MTO-oriented supply chain strategy design in agile supply chain are considered, and the factors and requirements of MTS supply chain in cost reduction and MTO supply chain in flexible response are combined.

(2) MTO/MTS supply chain coupling model based on two-stage supply system. Generally speaking, manufacturing enterprises issue material purchase orders based on MRP operations and require all materials to be delivered at the same time specified. Material quantity conforms to BOM structure ratio of production product. In order to facilitate the study, this section selects a simple material procurement model consisting of only four raw materials and only one supplier for each raw material, is shown in Figure 4.

In operation, the materials required for production are often not all in accordance with BOM requirements. When the delivery time of products is tight, the manufacturer will start production activities based on all the materials in stock when the delivery time of the missing materials is relatively clear. This is not only the practice of advance production but also the concrete implementation of delayed production, as shown in Figure 5.

Through the second-order supply system, manufacturers can divide a wide variety of raw materials with different lead periods into multiple components or materials (raw materials) with strong generality, relatively easy demand

TABLE 2: Supply chain based on time dimension Decoupling Points.

Supply chain structure	Flow of the supply chain	Process involved in each link
Manufacturers	Product design	(1) Modular design of components (2) BOM design
	Purchasing supply	(1) Material procurement process in different cycles (2) Different material procurement and inventory strategies
	Order processing	(1) Order acceptance and review (2) Production planning and control
	Production and processing	(1) Production process route
Dealers	Shipment delivery	(1) Order priority
	Order processing	(1) Order acceptance and review
	Shipment delivery	(1) Order priority
Consumers	Demand forecasting	(1) Prediction based on historical requirements (2) Requirement change
	Purchase order	(1) Regular or quantitative ordering plan
	Warehouse inventory	(1) Daily inventory strategy and level (2) Product acceptance and storage management

prediction, and a long production cycle according to the process characteristics, and it adopts an MTS type supply chain to compress the order response speed of this part of component modules or materials, and it purchases and manufactures costs to start final product assembly after receiving consumer orders, which not only meets the rapid demand of consumers but also reduces the cost of the supply chain

The MTO/MTS supply chain coupling model of the above two-stage supply system is based on one premise. That is, before all kinds of materials arrive, part of the material has the technological basis of advanced production. Similarly, the quantity and type of each order are not consumed in the first place, which provides a management basis for the manufacturer's batch delivery

3.5.3. MTO/MTS Supply Chain Coupling Model

(1) *Supply Chain Coupling Model Based on Customer Order Separation Point.* Time-dimension Customer Order Decoupling Point (TCODP) is used to describe the Time course from the Customer's Order to the customized product delivered to the end customer. It divides the whole supply chain into two parts: the order pull chain contributes (S2 chain), and the inventory push chain contributes (S1). This section takes the MTO/MTS supply chain with a short life cycle order as the research object, and adopts the link analysis method to decompose the supply chain into a process consisting of a series of five interactive links, including order processing, product design, procurement/supply, production and processing, and product distribution. See Table 2.

(2) *MTO/MTS Supply Chain Coupling Model Considering Economic Value.* Decoupling Point (DP) refers to the demarcation Point in the MTO/MTS supply chain. The choice of Decoupling Point plays a key role in the rapid response of consumer demand and the reduction of supply chain costs. According to the analysis in the MTO/MTS supply chain
FIGURE 6: Classification of products (broken lines).
FIGURE 7: MTO/MTS supply chain coupling for product matching.

coupling model from the perspective of flexible and low-cost response, the left side of the decoupling point is the push production mode based on prediction, and the right side is the pull production mode based on order. This point is likely to become

the point of delayed manufacturing and order separation, and also the supply chain inventory control point. The economic comparison between forecast-driven and order-driven production is shown in Table 3:

(3) Economic Value Analysis Dimension Analysis. This section will analyze the influencing factors of Decoupling Point from three dimensions: material versatility, customer demand diversity, and delivery time. Material versatility: refers to the extent to which materials can be used for different purposes and by different users, depending on the practicability of the product and the position of the Decoupling Point. When the material can meet the needs of multiple types of customers or when there is no market segmentation, its versatility is high; with the further processing of materials from raw materials to components (semifinished products) and then, to finished products, the universality of materials is gradually reduced.
FIGURE 8: Data of SVM model retail channel sales.

FIGURE 9: Data diagram of SVM model network channel sales fitting.

(4) *MTO/MTS Supply Chain Coupling Model Based on Short Life Cycle Products*. By jumping out of the limitations of traditional functional products and innovative products and just comparing different products, the classification of the same product under different demand-deterministic environments is expanded and expanded; the nature of the product is similar to functional products when its demand is determined and innovative products when its demand is uncertain. See Figure 6.

Mass procurement production and agile response are both designed to meet the different needs of consumers.

FIGURE 10: Sales forecast data diagram of SVM model retail channel.

They both produce customized products in the mode of flexible and low-cost response but adopt different technical routes. The maximum profit model of the supply chain is used to explain the response. They are the best choice to meet consumer demand under certain constraints. See Figure 7.

4. Results Analysis

Suppose a manufacturer sells a class of fashionable electronic products with a high replacement rate through dual channels. Among them, one channel is the traditional retail channel, and the other channel is to directly conduct transactions with end customers through its own e-commerce outlets. The sales volume and influencing factor indicators of retail channels and online channels are shown in Tables 4 and 5.

According to the basic Bass model constructed in Section 2 and the programming of the improved Bass model, combined with the optimization method, Matlab2010 is used to perform nonlinear fitting to improve the goodness of fit. First, the 14-month sales data of the retail channel are fitted, and the parameter values of the fitting curve equation can be obtained, as shown in Table 6.

As can be seen from Table 6, compared with the basic model of retail channels, the potential purchase volume of retail channels under the improved Bass model decreases slightly, and the coefficient of innovation group and imitation group increase slightly, which more accurately reflects the market demand of retail channels.

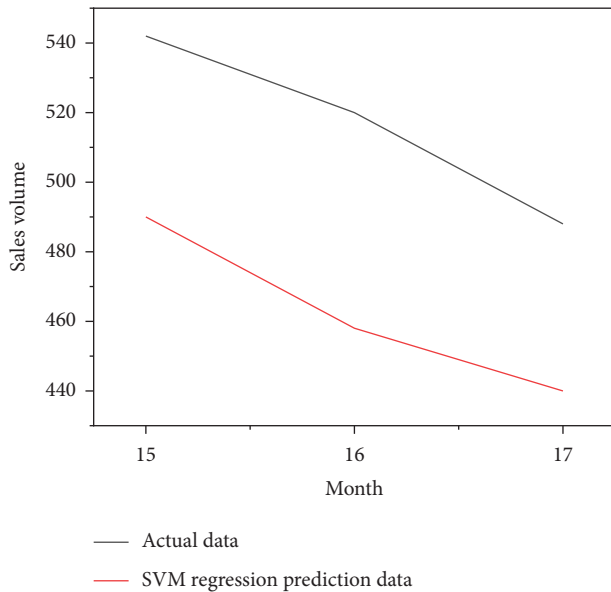
Put the data of the training group of retail channels and network channels into the SVM model for calculation, and put the data of the test group into the SVM model for prediction, and you get the comparison chart of the simulated sales volume and the actual sales volume of the SVM model for the first 14-months of retail channels and network


FIGURE 11: Sales forecast data of SVM model.

channels, as shown in Figures 8 and 9, as well as the forecast sales and actual sales in the next three months, as shown in Figures 10 and 11.

Table 7 further compress the prediction effect index RMSE, that is, the regression root mean square, or the fitting standard deviation of the regression system. It can be seen from the table that, whether it is a retail channel or a network channel, the RMSE value of the effect index predicted by SVM is smaller than the RMSE value of the improved Bass. It can be seen that the SVM demand forecasting model constructed by comprehensively considering multiple input factors can obtain a more accurate forecasting effect.

According to the definition of dual channels mentioned above, whether it is traditional retail channels or online channels, the short life cycle products sold originate from manufacturers and ultimately flow to end customers. Obviously, the total market demand forecast is composed of the superposition of demand forecasts of two channels, that is, the forecasted sales volume from the dual-channel system.

5. Conclusions

Based on the work practice and literature research and according to the double channel supply chain ordering mode and the characteristics of short life cycle products, a comprehensive ordering optimization method and system are proposed. This method system can not only effectively solve the existing problems of short life cycle products in dual-channel supply chain ordering, but also enrich the content of dual-channel supply chain theory. The demand forecasting model is optimized and the demand forecasting model under the dual-channel supply chain is proposed. Traditional demand forecasting methods, such as quantitative forecasting method, the time series method, and causal analysis, assume that the law of demand in the past will remain unchanged in the future. With the rapid iteration of products with a short life cycle and the rapid change of

consumer demand in the e-commerce environment, the accuracy of demand prediction is difficult to guarantee by traditional forecasting methods. In the existing literature, some scholars reduce the impact of demand uncertainty and improve the accuracy of demand prediction from the perspectives of repeated purchase, demand diffusion, increased order times, and demand renewal, respectively. However, the above studies did not consider the demand impact factors of products with short life cycle and the demand overlap and conflict brought by e-commerce dual channels. To this end, the article puts forward the characteristics of considering the influencing factors of product demand, the increase of demand information channels of dual-channel supply chain, the superposition effect of O_2O demand interference and conflict, the change of O2O demand alone or coupled change, and deduces the demand prediction model of optimization of product demand factors and the O2O demand prediction model of dual-channel supply chain. At the same time, products are classified from the perspective of demand certainty, which provides a theoretical basis for the study of the MTO/MTS coupling orders.

In this paper, we proposed an assessment system of forest environmental carrying capacity from many aspects and comprehensively evaluated and predicted the forest environmental carrying capacity of 40 cities in the Yangtze River Delta of China by using the proposed deep learning-based model. In addition, the proposed model is used to dynamically evaluate the comprehensive scores of forest environmental carrying capacity of 34 provinces and cities in China between 2015 and 2020. This paper also has the following contributions: (1) a deeply integrated unidirectional bidirectional LSTM considering the correlation of time series is proposed. The bidirectional LSTM network is used to deal with the backward dependence of input data to prevent the omission of some useful information, which is beneficial to the prediction results. (2) In terms of missing data processing, the Mask layer is added to subtly skip the processing of missing data, which will help to enhance the evaluation results.

1. Background

The decline of ecological environment quality directly threatens the quality of life and health of human beings [1, 2]. The term "health," which was first used in medicine to describe the life state and behavior of organic individuals, was adopted and developed by ecologists and environmentalists in their respective fields. For example, several concepts have been proposed by some scholars: environmental health, environmental medicine, forest ecosystem health, wetland ecosystem health, watershed health, landscape health, etc. [3]. Forest ecosystem health has been accepted and used more and more by ecologists, forestry, and natural resource management scholars, and "forest health" has been regarded as the standard and goal of forest status evaluation and forest resource management, and the assessment of forest ecosystem health has been put forward. After the 1990s, a series of monitoring programs have been initiated around the world [4] such as EMAP (environmental monitoring and assessment program) and FHM (forest health monitoring). It is used to understand forest state and assess forest ecosystem health, opening up a

research approach to explore sustainable research, development, and utilization of forest resources.

Ecological carrying capacity is an important basis for evaluating regional sustainable development, as well as an important indicator to measure the degree of human social and economic activities on the utilization and interference of natural resources [5]. As a component of the terrestrial ecosystem with the largest area and highest biomass, forest carrying capacity will directly affect global ecosystem security and human survival and development [6]. Therefore, the study of forest ecological carrying capacity is of great significance for coordinating the relationship between regional forest resources and sustainable economic and social development.

Since American scholars, Parker and Burgess, first defined carrying capacity as the maximum number of an individual living creature in a specific environment in 1921 [7], many foreign scholars have discussed the connotation and research methods of carrying capacity. Meadows from MIT constructed the famous "World Model" [8] by using the system dynamics model in The Limits to Growth, making carrying capacity research the core hot issue in this field for the first time. Then, Slesser began to apply the ECCO model

to the system dynamics model [9]. Daily and Ehlrich [10] focused on the relationship between population and Earth carrying capacity. Saveriades [11] proposed the concept of tourism carrying capacity for the first time in their study of ecological carrying capacity on the east coast of Cyprus.

Zhang et al. [12] believed that carrying capacity theory is a philosophical issue related to the future fate of mankind and will always be a hot and difficult issue in ecological research. Liu and Zhu [13] discussed the comprehensive, regional, and human-land relationship of geography in the application of resource and environmental carrying capacity. By definition, Gu [14] thinks that ecological carrying capacity is to point to in a certain time, within the scope of a certain space, the ecological system under the action of self-adjusting and positive human healthy and orderly development, and the ecological system can support the resource consumption and environmental pollution degree, the intensity of social and economic development, and the population of a certain level of consumption. Huang and Ren [15] studied the relationship between ecological carrying capacity and ecological security. In terms of research content, Yang and Yang [16] and Fu et al. [17] have evaluated the natural resources and environmental carrying capacity of Gansu province and Hainan Province from the provincial perspective, respectively. Jiao et al. [18], and Yu and Sun [19] studied water ecological carrying capacity and land ecological carrying capacity, respectively, from the perspective of resource types. In terms of research methods, Li et al. [20] conducted a comprehensive evaluation of Marine ecological carrying capacity in Shandong Province by using the artificial neural network method. Ma and Wang [21] used system dynamics to simulate and predict the ecological carrying capacity of Dalian city. Tian et al. [22] studied the ecological carrying capacity of Hubei Province by using the ecological footprint model.

2. Index System of Forest Ecosystem Health Assessment

Forest ecosystem health evaluation is mainly based on the stability and sustainability of forest ecosystem and the completeness (integration) of ecosystem structure and function. The stability, sustainability, and integration of ecosystem are the foundation of ecosystem health and the standard of forest ecosystem health evaluation. Only when the structure of an ecosystem is complete and the system is relatively stable, can it fully realize its ecological process and ecological function, and maintain the sustainability of the system, such an ecosystem is a healthy ecosystem. Evaluation factors include ecosystem vitality, organizational structure, resistance, and resilience.

Vigor refers to the energy input and nutrient cycling capacity of ecosystem, and its specific indicators are primary productivity and material cycling of ecosystem. Resilience refers to a system's ability to overcome stress and bounce back when the stress is gone. Organization refers to the complexity of the system, which will change and function with the secondary succession of the ecosystem.

The forest vigor can be measured by net primary productivity (NPP) of forests, biomass, and metabolism. NPP is

mainly measured by experiment and investigation, biomass is mainly calculated by investigation and model, and metabolism can be measured by biological methods.

Organizational structure refers to the species composition structure of the system and the relationship between species, reflecting the complexity of ecosystem structure. The organizational structure of ecosystem includes two meanings: one is the species diversity of ecosystem, and the other is the complexity of ecosystem. The meaning of species diversity includes both the number of existing species and the relative abundance of species.

Forest adaptation includes resilience, which refers to the system's ability to gradually recover in the absence of external stress, and resistance, which refers to the system's ability to resist external disturbance. It is difficult to measure resilience and resistance directly.

The resistance and resilience of forests are generally measured by indirect means. In forest health evaluation, the degree of forest pests and diseases in the study area or forest fire risk level can be selected to measure.

3. Determination of Biomass

Table 1 shows the evaluation index system in this article, and the following section in section 3 will introduce those indicators for details.

3.1. Sample Wood Standard. The standard tree in the ground for each wood inspection chooses the most close to the average diameter of the DBH 1 tree as a sample wood, and the selection of sample wood should avoid the following conditions: trunk serious bending, trunk section serious deformation, double branches, no roof, disease rot, the main shoot, or large branch dead.

3.2. Determination of Tree Layer Biomass. On the basis of standard field investigation, the relative growth method is adopted to calculate the biomass of tree layer. The relative growth method is the use of DBH square by tree height (D^2H) as the independent variable of fitting model, it can more truly reflect the biomass with diameter at breast height (D) and the change trend of height (H), and the calculating formula is $W = a(D^2H)^b$ or $LnW = Lna + bLn(D^2H)$, so through the survey of standards of D and H, we can work out standard ground biomass, and then calculating the biomass per hectare.

In standard plots, DBH (D) and height (H) of tree species were measured and recorded. The selected sample wood should be measured tree height, DBH, and crown; marked at 1.3 m on the ground; and marked on the trunk of the north and south orientation. After finishing the retest, we cut down the sample wood and measure the height of the live branch and the diameter of the trunk at that height immediately. We measure the height and azimuth of branches one by one from bottom to top and number them one by one. All branches were sawed together to separate branches and trunks, and then, the biomass of trunks, branches, leaves, and roots was measured, respectively.

TABLE 1: The evaluation index system.

		Sample wood standard
		Biomass of trunk
		Biomass of branch
	Determination of tree layer biomass	Determination of leaf biomass
Determination of biomass		Biomass of root
	Determination of biomass of shrub layer	
	Determination of biomass of herbaceous layer	
	Determination of plant diversity index	
	Classification of forest fire risk levels	

(1) Biomass of trunk: after removing the trunk of the branch, the disc was cut in sections from the trunk base to the top tip, with specific heights of 0 m, 1 m, 1.3 m, 3 m, 5 m, and 7 m. The last tip of the old tip should be reserved and weighed. The sample tree number, the disk number, the height of the section, and the north-south orientation were marked on the nonworking surface. Then, the diameters of each ring on the disk section were measured in the north-south and east-west vertical directions according to the requirements of the tree science. The volume of wood and bark in each section was calculated according to the skin diameter, peeling diameter, and dividing section length. Then, the bark and wood were separated, and their volumes were measured, respectively. After being dried in an oven at 85°C for 48 h, the bark was taken out and weighed to calculate the volume weight of wood and bark. Then, according to the volume of wood and bark in the segment and their volume weight, the dry matter weight of wood and bark in the segment was obtained. The total dry matter weight of wood and bark per tree was obtained by accumulative values of each section of the same sample tree.

(2) Biomass of branch: base diameter (D_0) and branch length (L) of all branches of the whole tree were measured branch by branch. Ten branches with different sizes were selected as samples, and the samples were marked. The length of the segment was determined according to the diameter and length of branches. Cut branches in each segment to distinguish the segment of the disc. The dry matter weight of wood and bark of sample branches was measured and calculated by the method of trunk. Add the wood and bark together to get the total weight of dry matter (W). Taking D_0^2L of the sample branch as independent variable and dry matter weight (W) of the branch as dependent variable, the regression analysis was conducted according to $W = a(D_0^2L)b$, and parameters a and b were obtained to establish the regression equation of the branch biomass. The D_0 and L of all branches of a single sample tree were substituted into the regression equation one by one to calculate the biomass of all single branches, and the biomass of sample wood was obtained by summing them up.

(3) Determination of leaf biomass: the sampled branches were selected to pick the leaves and weigh the fresh weight, and a small number of leaves were selected as samples. The fresh weight of the extracted leaf samples should be immediately weighed, and the leaf samples should be put into a drying oven immediately after being brought back indoors, and dried at a constant temperature of 85°C for 24 h. The dry matter ratio of leaves was calculated, and the dry matter weight of leaves per branch was further calculated. Then, with the dry matter weight of leaf as the dependent variable, the regression equation between the dry matter weight of leaf and D_0^2L was established by using the same method as the biomass of branches, and the dry matter weight of the whole plant was calculated by the relative growth method.

(4) Biomass of root: dig out all the root piles and roots of the sample wood as far as possible, and classify them according to their coarseness. Weigh the fresh children of root piles and roots of each coarseness and take samples to weigh their fresh weight. After drying for 48 h, the drying weight of the sample was weighed, and the dry matter ratio of each component and the dry matter weight of each root were calculated. We total the dry matter weight of root pile and root of all levels, namely, root biomass of the sample wood.

3.2.1. Determination of Biomass of Shrub Layer. Two to five representative quadrats were selected to dig out all shrubs with roots, separate branches, and roots, and weigh the fresh weight of stems, branches, leaves, and roots by species. Meanwhile, the wet weight and drying weight of different parts of each species were sampled to calculate the dry matter rate, and the biomass of each species and the total biomass of shrub layer in the quadrat were further calculated, and the total biomass of shrub layer per hectare was converted.

3.2.2. Determination of Biomass of Herbaceous Layer. Two to five representative quadrants were selected, and all herbaceous plants were cut down to the ground and weighed for fresh weight. A 0.5 m × 0.5 m quadrant was set in one corner of the quadrant, and the roots of all herbaceous plants

in the quadrant were dug out and weighed for fresh weight after the soil was removed. At the same time of weighing fresh weight, the aboveground part and root system were, respectively, weighed. After drying, the drying weight was weighed, and dry matter rate was calculated. Finally, biomass and biomass per hectare were calculated.

3.2.3. Calculation of Total Biomass.

The biomass of the whole community can be obtained by summarizing the biomass of each layer of tree, irrigation, and grass per unit area, and then, the subfunction relationship between the total biomass and DBH (D) and height (H) can be established by using formula $W = a(D^2L)b$. In this way, the biomass of the sample plot can be calculated by investigating D and H of the sample plot, and then, the biomass of each hectare can be calculated.

3.3. Determination of Plant Diversity Index.

The following factors should be considered in the selection of forest plant diversity indicators:

(1) The selected plant diversity index is simple and easy to operate.

(2) The selected index must be a standard quantity at a certain spatial scale, which should not only quantitatively represent the relative size of plant diversity in a specific community but also be comparable in analyzing the relative size of plant diversity among forest communities.

(3) The selected plant diversity index should reflect the differentiation of plant diversity of selected community species and each structural community as much as possible, and reflect the spatial differentiation characteristics of plant diversity quantity in the community to a certain extent.

(4) The characteristics of specific community data should be considered, which should not only meet the variable requirements in the diversity index formula but also have clear ecological significance.

According to the above principles, research needs, and collected data, the Simpson diversity index was selected in this study to represent the forest plant diversity. Simpson diversity index, as an analysis index, reflects the plant diversity of the community. This diversity index can basically be employed to handle the spatial distribution and change characteristics of the plant diversity of the forest community, and its calculation formula is as follows:

$$S = \frac{N(N-1)}{\sum_{i=1}^{m} n_i (n_i - 1)}, \tag{1}$$

where S is Simpson diversity index of the overall species in the forest community, N is the total number of individuals, n_i is the number of individuals of the ith species, and m is the number of species.

3.4. Classification of Forest Fire Risk Levels.

Forest fire is the natural enemy of forest, and it is a natural disaster with wide occurrence, great harm, strong timeliness, and difficult disposal and rescue in the world. The basic principle of forest fire risk classification is based on the "National Forest Fire Classification" as the standard, but it is different from the national classification. For forest fire danger division using clustering method, the influence of many factors, forest fire selection effect on fire bigger height, crown density and management measures, the distance from the distance from the tourist spots, advantage tree species, forest-road six factors as factor analysis, clustering to area, and 40 small class as a unit, the cluster factors of each cluster unit were investigated and assigned according to the actual survey data. Then, according to the actual experience, the SPSS statistical software was used for cluster analysis, and the threshold value was 0.8. The Forest Farm was divided into three fire risk levels:

Level I Danger Zone. The distribution area is characterized by large population density, large population mobility, close distance to the forest road, convenient transportation, railway line, and road through different site conditions of forest types of combustible materials accounted for a large proportion, which are the area of high fire risk, in the forest health evaluation value of 0.4.

Level II Danger Zone. The distribution area is characterized by close proximity to tourist spots and roads, and its stand also has obvious characteristics. The stand structure is complex, with more shrubs and dead objects in the forest, and the proportion of combustible objects in different site types is large. The value of this area in forest health evaluation is 0.4.

Level III Danger Zone. Located in the southwest corner of Forest Farm, the distribution area is characterized by relatively concentrated small classes, far from tourist spots, mostly natural broadleaved mixed forest, steep slope, high altitude, and little human interference. The value of this area in forest health evaluation is 0.8.

4. The Comprehensive Evaluation Model Construction for Forest Carrying Capacity

4.1. Recurrent Neural Network.

Cyclic neural network can well process sequence information and learn effective features from it, and is applied to image [23], speech recognition, and other fields in the early stage [24]. In recent years, RNN has also achieved good performance on tasks in the field of NLP. Lin et al. [25] used hierarchical RNN to model documents and proposed a two-step training method, which achieved good results in sentence ordering task and oral translation task. Liu et al. [26] proposed a multi-time-scale LSTM model extracts sentence and document representation. Experimental results on four data sets indicate that this model is superior to other neural network models. Zhou

et al. [27] constructed a bidirectional LSTM network based on an attention mechanism to learn features from sentences for relational classification, only considering the word vector of sentences, without considering other lexical or syntactic features generated by NLP tools. In document-level emotion classification tasks, researchers generally construct hierarchical neural network models to learn document feature representation. For example, Tang et al. [28] first used the LSTM network to learn sentence vector representation from word vector and then used bidirectional threshold RNN (gated RNN) to learn document vector representation from sentence vector. Chen et al. [29] constructed a two-layer LSTM network and considered the attention mechanism of users and products.

RNN can not only learn the information in the sentence but also learn useful feature representation from the syntax tree path. Roth and Lapata [30] used the LSTM network to extract features of dependency paths for semantic role labeling. In terms of the task of relation classification, Xu et al. [31] adopted multichannel LSTM network and considered four dependency paths of words, parts of speech, dependency relation, and hypernym among entities. Cai et al. [32] proposed a RNN network, which contains bidirectional two-channel LSTM network, learning word path, and dependency path are two characteristic representations of dependency path. Similarly, the proposed model includes a bidirectional LSTM network for learning valid features from syntactic paths.

4.2. LSTM Network Structure. The LSTM network structure was first proposed by Hochreiter and Schmidhuber in 1997 [33]. Figure 1 shows the structure diagram of an LSTM basic unit. Like RNN, LSTM elements have layer input x_t and layer output h_t at each iteration. The complex unit also takes into account the unit input state $\widetilde{C}_t$, the unit output state C_t, and the previous unit output state C_{t-1} when training and updating parameters.

In LSTM network, the basic structure of the hidden layer is a storage unit, and the structure shown in Figure 2 is an LSTM cell structure unit. It contains one or more memory cells and a pair of adaptive, multiplicative connectivity cells that connect inputs and outputs to all cells in the block. At the core of each memory cell, it is a circular self-connecting linear cell, commonly known as "constant error transmission," and the activation of this cell is called "cell state," which is the key to LSTM. The constant error transmission of a unit is shown in the dotted box in Figure 2.

Constant error transmission solves the vanishing error problem: in the absence of new input or error signals, the local error return of constant error transmission remains unchanged, neither growing nor decaying. However, if only constant error conveyor belt, LSTM structure is unable to realize the addition and deletion of information flow. Therefore, a similar gating structure is proposed to realize the screening in the process of information transmission. As shown in Figure 3, the gated structure cleverly filters the information, mainly through a neural layer of sigmoid function and a point-by-point multiplication operation.
Figure 1: The architecture of LSTM.
Figure 2: Constant error transmission structure.
Figure 3: Gate control structure.

Through the sigmoid layer structure, an output value between 0 and 1 can be obtained. These output values imply a weight assignment of passing information (e.g., 0 means that no information is allowed to pass through the structure, and 1 means that all input information can pass through the structure).

In summary, LSTM unit includes 3-gate structures. These gated structures, especially forgetting gates, help LSTM become an efficient and extensible model for solving several learning problems related to sequential data. For the t th time step, the forgetting gate, input gate, and output gate are expressed as f_t, i_t, and o_t, respectively.

The first step we need to consider in the LSTM network unit is what redundant information the network structure wants to discard that we do not care about. This decision requires the forgetting gate structure to operate. The forgetting gate will receive the input x_t of this unit and the output h_{t-1} of the hidden layer of the previous time step as the input of the cell unit at this moment, and learn according to the following formula (2). It learns a real value between 0 and 1 for each item in C_{t-1}, so as to control the degree of forgetting of the state of the previous unit:

$$f_t = \sigma_g\big(W_f x_t + U_f h_{t-1} + b_f\big), \tag{2}$$

where W_f is the weight matrix that maps the hidden layer input to the forgetting gate, U_f is the weight matrix that connects the output state of the previous unit to the forgetting gate, and b_f is the bias vector. σ_g is the gate activation function. Usually, the hyperbolic tangent function (tanh) is used as the activation function in LSTM structures.

The next step is to decide how much new information to add to the cellular state. An input gate and a hyperbolic tangent function (tanh) control what new information is added. Then, according to the output f_t of the forgetting gate obtained previously, it is used to control the extent to which the information of the previous unit is forgotten, and the output i_t of the input gate is used to control how much new information is used. Then, we can update the unit state of the memory unit according to the following formulas:

$$i_t = \sigma_g\big(W_i x_t + U_i h_{t-1} + b_i\big), \tag{3}$$

$$\tilde{C}_t = \tanh\big(W_C x_t + U_C h_{t-1} + b_C\big). \tag{4}$$

Similarly, W_i and W_C are weight matrices that map hidden layer input to legacy input gate and input unit state, respectively, while U_i and U_C are weight matrices that connect previous unit output state to input gate and input unit state, respectively. b_i and b_C are bias vectors.

Finally, we need to make sure that our network produces the desired output, which will be based on our cell state. The output gate is employed to consider how much information the network needs for further learning. Similar to the updating of the two parts of the input gate, the final output content of the output gate is also determined by activation function, as shown in the formula (4). The tanh function is then used to process the content of cell state (formula (5)). Each computed Ct value may not be within the range of -1 to 1, so it needs to be adjusted. We multiply these two pieces and get the part that we want to output.

$$o_t = \sigma_g\big(W_o x_t + U_o h_{t-1} + b_o\big), \tag{5}$$

$$h_t = o_t * \tanh\ (C_t). \tag{6}$$

Similarly, W_o is the weight matrix that maps the hidden layer input to the output gate, while U_o is the weight matrix that connects the output state of the previous unit to the output gate. b_o is the bias vector. According to the results of the four equations above, during each iteration, unit output state C_t and layer output h_t can be calculated as follows:

$$C_t = f_t * C_{t-1} + i_t * \tilde{C}_t. \tag{7}$$

Finally, the C_t obtained is the cell state of the hidden layer unit.

The final output of the LSTM layer should be a vector of all outputs, represented by $Y_T = [h_{T-n}, \cdots, h_{T-1}]$.

4.3. Two-Way LSTM Network Prediction Model.
Bidirectional propagation LSTM network (Bi-LSTM) is also a deformation of bidirectional cyclic network structure. So, let us first introduce bidirectional cyclic networks (BiRNN).

4.3.1. BiRNN Network. Since the classical RNN usually include the time step lag among the input and the target when handling the sequence problem, some context information can be given to the network; that is, the future information of T step time step can be added to obtain the output together. Theoretically, T can be very large to capture all future available information, but in fact, it is found that if T is too large, the accuracy of prediction results may decline. This is because the network concentrates on learning and memorizing a large amount of input information and does not reasonably learn the input information, which leads to the decline of the joint modeling ability of the prediction model.

BiRNN can be modeled by processing forward and backward data propagation. Such bidirectional transmission not only provides historical knowledge for each neuron node in the network but also imperceptibly learns the trend of subsequent changes.

In the forward propagation layer, a forward hidden layer output h_t^f is obtained through a nonlinear transformation of input data according to the formula (8). In the backward propagation layer, a nonlinear transformation is performed on the input data according to the formula (8) to obtain a backward hidden layer output h_t^b.

$$h_t^f = \sigma\big(W_{hh}^f h_{t-1}^f + W_{xh}^f x_t + b_f\big), \tag{8}$$

$$h_t^b = \sigma\big(W_{hh}^b h_{t+1}^b + W_{xh}^b x_t + b_b\big). \tag{9}$$

Two recurrent neural network (RNN) hidden layers are trained, and the two independent hidden layers pass through a connection layer. According to the formula (10), the output of forward transfer layer and the output of reverse transfer layer are combined into the same output layer.

$$h_t = W^f h_t^f + W^b h_t^b + b_h. \tag{10}$$

4.4. Structural Optimization of the Prediction Model.
For the network framework we have built, we need to refine our predictions. Predecessors have tried a variety of methods to optimize the model as a whole. In our article, the dropout and early-stop algorithms are employed to optimize the proposed framework to promote the Acc of the proposed method.

TABLE 2: Forest health grade division criterion.

Health grade	I	II	III	IV	V
Network output value	0	1	2	3	4
Health condition	Healthy	General healthy	Sub-healthy	Unhealthy	Other lands

TABLE 3: Forest health condition of the cities.

Health condition	Small class number
Healthy	7, 37
General healthy	1, 3, 9, 12, 28, 33, 40, 41, 4, 5, 8, 10, 13, 14, 16, 22, 23, 25,
Subhealthy	26, 27, 30, 32, 35, 38, 39
Unhealthy	11, 18, 19, 20, 36
Other lands	21, 29

4.5. Dropout Principle. Hinton proposed a method called dropout, which can effectively reduce the occurrence of overfitting, which is equivalent to adding a regularization constraint to the model. This method will be employed in this paper.

5. Experiment and Result Obtained

In order to unify standards and ensure the reliability of experimental results, it is generally necessary to preprocess the original data before modeling, which is commonly referred to as standardized data processing. We need to transform the original data into dimensionless standardized values to eliminate the influence caused by different attributes among different indicators, so as to make the results more comparable. Otherwise, the accuracy of experimental results may be affected to some extent.

$$X' = \frac{X - X_{\max}}{X_{\max} - X_{\min}}, \tag{11}$$

$$X = 2 * X' - 1. \tag{12}$$

$X_{\max}$ is the maximum value in the sample instance, and $X_{\min}$ is the minimum value in the sample instance. The normalized sample data X' are scaled to a value between -1 and 1 through the formula (12).

5.1. Standardization of Factors. As the evaluation factors of the evaluation index system come from different aspects, it is difficult to directly evaluate them, because the dimensionality between the coefficients is not unified, so there is no comparison. Even for the same parameters, although their impact on health can be judged according to the size of their measured values, there is still a lack of a comparable environmental standard to accurately reflect their contribution to health. Therefore, the evaluation factors must be quantified and the incomparability of parameters can be solved by standardized methods. The standardization method is as follows:

$$X_j = \frac{X_i}{Y_{\max}}, \tag{13}$$

where X_j is standardized index value; X_i is the value of the selected index; and $Y_{\max}$ the highest value in a class of indexes.

5.2. Forest Ecosystem Health Result

5.2.1. Classification of Forest Health Status. In the process of forest health evaluation, this paper chooses BP neural network model to evaluate the forest farm. According to its evaluation method and selected index system, on the basis of systematic analysis and integration of existing research results at home and abroad, the forest ecosystem health evaluation method based on Bi-LSTM is constructed. The grading standards of health are indicated in Table 2.

5.2.2. Prediction of Forest Carrying Capacity. This paper takes 40 urban forests in the Yangtze River Delta of China as research samples. Table 3 shows the forest health condition of the cities.

As can be seen from Table 3, there are 7 subhealth areas in carrying capacity, accounting for 17% of the total number of major areas. There are 18 districts, or 45 per cent of the main districts, with average health. There were 5 undesirable areas, accounting for 12.5% of the total number of major areas. Only two districts, or 5 percent of the total, are healthy.

5.2.3. Forest Carrying Capacity in Yangtze River Delta from 2015 to 2020. Figures 4 and 5 show the Local Moran scatter diagram of high-quality forest development of urban agglomerations in the Yangtze River Delta in 2015 and 2020 under the adjacency matrix. It could be found from the figure that Moran's I index is positive and most cities are concentrated in the first and third quadrant, namely, high and low agglomeration areas, indicating that the forest development level of cities in the Yangtze River Delta has a positive spatial correlation.

5.2.4. Forest Carrying Capacity in China (Part of the Area) from 2015 to 2020. According to Figures 6 and 7, the comprehensive evaluation scores of forest environmental carrying capacity of 34 provinces and cities in China
Figure 4: Standardized value of forest development level in 2015.
Figure 5: Standardized value of forest development level in 2020.

changed from 2015 to 2020. It can be found that: (1) the forest environmental carrying capacity of Tibet, Xinjiang, and Inner Mongolia has always maintained a high level; (2) compared with 2015, the forest environmental carrying capacity of almost all cities in 2020 has been improved, which indicates that the intensity of environmental protection and forest protection in China has been increasing.

6. Conclusion

The improvements and contributions of this study mainly focus on the following aspects: (1) a deeply integrated unidirectional bidirectional LSTM considering the correlation of time series is proposed. The bidirectional LSTM network is used to deal with the backward dependence of input data to prevent the omission of some useful information, which is beneficial to the prediction results. (2) In terms of missing data processing, the Mask layer is added to subtly skip the processing of missing data. The results indicate that the proposed method in this paper could predict and evaluate the comprehensive index of forest environmental carrying capacity well. On the basis of this study, further improvement and expansion can be made. A neural network based on graph structure can be added to the model to learn and interpret spatial features.

With the gradual development of digital information and software computing capabilities, the use of computers in dance-assisted choreography is becoming more and more widespread. But although the level of computers is now in rapid development, the technical level of using computers in dance choreography is not yet very mature, technical support is not in place, dance-assisted choreography is not effective, and the existing technical level is not yet able to meet the new needs of dance choreography. In order to improve the dance-assisted choreography technology and provide a more complete educational user interface for dance-assisted choreography, the content similarity algorithm of user clustering has a wide range of operations and a strong ability to calculate the amount of data, combined with the computer to apply the content similarity algorithm of user clustering in dance-assisted choreography technology to build a dance-assisted choreography system based on user clustering. The article proposes three major methods based on collaborative filtering algorithm of user clustering, collaborative filtering algorithm based on similarity class and user preference, and fuzzy cluster analysis of users and analyses their principles. In the experimental part, the performance of IBCF algorithm and collaborative filtering algorithm in dance-assisted choreography system is compared and analysed to observe the change of MAE value under the change of user similarity with number under different k values of cluster classes. The experimental results found that the MAE values of the IBCF algorithm and the collaborative filtering algorithm in the system were at 0.84 and 0.76, respectively, with a difference of about 8% between the two MAE values. The smaller the MAE value, the higher the effectiveness in the dance-assisted choreography technique. Applying the clustering algorithm to the system to make local adjustments and analysis of dance movement paths, it can grasp the choreography rules more precisely and innovate the choreography techniques.

1. Introduction

With the development of science and technology, the use of computers has become more widespread and the development trend of combining computing technology for dance choreography is getting better and better. In the process of dance-assisted choreography, how to meet the different needs of different people for dance choreography under the development of the times, improve the dance-assisted choreography system, analyse the movements for the given movement fragments, and apply the analysis in the new

dance-assisted choreography technology has become a problem that more and more people need to pay attention to. This paper investigates the effect of the content similarity algorithm in the development of a dance-assisted choreography system by combining it with user clustering. Experimental analysis is conducted for the proposed algorithm, and the experimental results find that the collaborative filtering algorithm has obvious advantages in the dance-assisted choreography system, its overall MAE value is smaller than that of the IBCF algorithm, and the MAE of the IBCF algorithm and the collaborative filtering algorithm is

0.84 and 0.76, respectively, when the analysis data set is selected at 40, with a difference of about 8% between the two MAE values; as the number of k values increases, the values on the recommendation results as well as the accuracy and recall of the collaborative filtering algorithm increased, confirming the high effectiveness of the collaborative filtering algorithm in the dance-assisted choreography system; compared to the traditional dance-assisted choreography system, the results of the analysis of the index of each factor of the dance-assisted choreography system under the user clustering algorithm found that the effectiveness of the dance choreography rose by 15%. The dance-assisted choreography system with various user clustering algorithms was found to be more effective in capturing human movement to some extent.

The analysis of user clustering-based content similarity algorithms in dance-assisted choreography technology can be developed to meet the different needs of dance-assisted choreography, and with the support of the algorithms, the dance-assisted choreography system is made better and more adaptable to the current development of the web. With algorithms such as content similarity for user clustering, dance movements can be analysed in depth to improve the movement path of movement data, master the essence of dance-assisted choreography, and facilitate the improvement of dance technology.

Driven by social developments, the use of cluster analysis is becoming more and more widespread. Virmani et al. [1] aimed to analyze the role of relational clustering behind group interactions in social networks. Clustering enhances the predictability between users and the ability to discover like-mindedness. They use integrated K-means clustering to extract entities and their corresponding interests based on skills and location by aggregating user profiles across multiple online social networks. The proposed integrated clustering utilises known K-means algorithms to improve the results of aggregating user profiles across multiple social networks. It turns out that good integrated clusters can be generated to envision the discoverability of users for specific interests [1]. Bouras and Tsogkas [2] propose a new approach to personalised recommendations that combines user and text clustering with other information retrieval (IR) techniques based on the algorithm they developed, W-k-means, in order to provide users with articles that match their profiles. Experimental results show that by aggregating items and user clustering using multiple IR techniques (e.g., classification and summarisation), the recommender generates better results than when using each or both of these techniques but without applying clustering [2]. Chandler et al. [3] used statistical cluster analysis algorithms to identify natural groupings based on AE profiles in a data-driven exploratory analysis. Clusters were clinically assessed to identify clusters associated with current safety issues. Using proportional reporting rates, headache and dizziness combined with fatigue or syncope were more common in HPV vaccine reports compared to non-HPV vaccine reports in women aged 9–25 years. Cluster analysis revealed additional reports of AE following HPV vaccination that were severe in nature, describing symptoms that overlapped with those reported in recent safety signals (POTS, CRP, and CFS) but without a clear diagnosis. Although the causal relationship between HPV vaccination and these adverse events remains uncertain, a more extensive analysis of spontaneous reports could better identify relevant case series for a thorough signal assessment [3]. Ilmarinen et al. [4] used data from baseline (diagnosis) and 12-year follow-up to determine the phenotype of asthma exacerbations in adults. K-mean cluster analysis was performed to identify phenotypes using variables from 171 patients at baseline examination and follow-up. Five clusters were identified. At follow-up, these patients were on the lowest dose of ICS, but 56% were well controlled. The results of the study can be used to predict the prognosis of adult asthma patients and contribute to the development of personalised treatment [4].

Enache [5] argues that the essence of spiritual and cultural life is the artistic integration of the performer-audience division, which goes hand in hand with the subdivision of "dance" into work and play. Language is expressed in formulas, and gestures and dance are rhythmic. It is worth noting that the extent to which dance as an organic necessity can be further developed into a closed structure still needs to be analysed and studied by researchers in the field [5]. These frames offer the experience of viewing the solo from multiple perspectives. It interweaves the individual with the voices of other artists, scholars, and students to discover that they all have the ability to articulate some of the most subtle, practical, and logical aspects of their experiences in creating new works [6]. Poutanen et al. [7] report on a study that used two visions created by Microsoft as a starting point for describing a user-centred design approach that extends the ideas of the dance method to interaction design and demonstrates how micro-motion analysis can be carried out in practice. They use the structural reorganisation of the movement continuum initially presented in the video to personalise the description of the dance for the first time as a way of understanding the kinesthetic quality and potential of the implied dance. The approach emphasises the impact of interaction design on the moving and experiencing body, and the potential of the moving and experiencing body for interaction design [7]. The above analysis of the clustering algorithm and the development of the choreography is relatively clear and provides informativeness for the following depiction.

2. User Clustering-Based Content Similarity Algorithm in Dance-Assisted Choreography Research and Development Method

2.1. Collaborative Filtering Algorithm Based on User Clustering

2.1.1. User Similarity Measure. Collaborative filtering algorithms based on user clustering first use statistical search methods to find similar users in a user group, and then evaluate specific users based on the results of similar users' evaluations of specific entries. If some users rate some items similarly, they rate other items similarly, a condition that must be met for the user-based collaborative filtering

algorithm to hold. The method based on collaborative user filtering is widely used in existing recommendation systems because of its low computational effort and high accuracy. The key to this approach is to identify the neighbourhood users of the target user based on the similarity of the item scores and to feed their predicted score results back to the user. The principle of the collaborative filtering algorithm based on user clustering is shown in Figure 1.

User-based collaborative filtering algorithms have the advantage of being simple to compute and highly accurate. Collaborative filtering algorithms based on users generally include several major steps such as user similarity metrics, finding nearest neighbour users and predicting the ratings of target users. Currently, three methods, namely, cosine similarity measure, modified cosine similarity measure method, and association similarity measure method, are commonly used as user similarity measures [8].

Cosine similarity: the users' ratings of items in the user-item matrix are regarded as vectors on a multidimensional space, with the rating value set to zero at the position of the default rating, and the similarity between users can be obtained from the cosine angle of their rating vectors of items [9]. Assuming that there are two different users, a and $\underline{b}$, whose corresponding vectors in the space vector are $\vec{a}$ and $\vec{b}$, then the similarity between users a and b can be calculated as follows:

$$sim_{ab} = \cos{(\vec{a}, \vec{b})} = \frac{\vec{a}, \vec{b}}{\|\vec{a}\|\|\vec{b}\|}. \tag{1}$$

Modified cosine similarity: this is ignored in the cosine similarity measure because different users have different evaluation criteria. The average ratings $\overline{K}_a$ and $\overline{K}_b$ for users a and b can be known from the ratings, and finally, the similarity between user a and user b is calculated, giving

$$sim_{ab} = \frac{\sum_{g \in h_{ab}} (K_{a\varphi} - \overline{K}_a)(K_{b\varphi} - \overline{K}_b)}{\sqrt{\sum_{g \in h_a} (K_{a\varphi} - \overline{K}_a)^2} \sqrt{\sum_{g \in h_b} (K_{b\varphi} - \overline{K}_b)^2}}. \tag{2}$$

The correlation similarity is based on an improvement of the idea of the Pearson correlation coefficient (PCC), which, like the modified cosine similarity measure, corrects for the problem of the scale on which items are rated by users. The formula for calculating the similarity of users using correlated similarity is

$$sim_{ab} = \frac{\sum_{g \in h_{ab}} (K_{a,g} - \overline{K}_a)(K_{b\varphi} - \overline{K}_b)}{\sqrt{\sum_{g \in h_{ab}} (K_{a,g} - \overline{K}_a)^2} \sqrt{\sum_{g \in h_{ab}} (K_{b,g} - \overline{K}_b)^2}}. \tag{3}$$

Once the similarity between users is obtained through the similarity metric, the top k nearest neighbours of the current user can be obtained and the item recommendation can be made [10]. However, in the similarity calculation, it can not only help users improve their personal experience to improve the user proximity of the website, but also shorten the user's product selection time to improve the user's purchasing efficiency, but the following shortcomings are common in the existing collaborative filtering algorithms.
Figure 1: Recommendation principle of collaborative filtering algorithm based on user clustering.

Cold start problem: The cold start problem consists of two situations: firstly, for a new user, the system does not have any information about the user and cannot recommend any items for him/her, and secondly, for a new item, there is no information about the user's rating of the item and the system cannot recommend it to the user.

Data sparsity problem: The collaborative filtering algorithm relies on user ratings of items to make recommendations, but in most cases the user ratings are small compared to the total number of users and items. It tends to result in sparse user and item scoring matrix data with many unscored null values. In this case, it is difficult to obtain a similar set of users to the target user and to generate suitable recommendations for the target user.

Scalability issues: The collaborative filtering algorithm has to perform the work of finding nearest neighbour users after performing the similarity measure; however, when the number of users in the system is particularly large in order of magnitude, the efficiency of finding neighbour users decreases and the scalability of the algorithm is not high [11].

2.1.2. K-Means Algorithm. *K*-means is the process of dividing a collection of *m* data into specified *k* classes, where the similarity between objects is calculated using the Euclidean distance as the criterion, and the clustering is based on the principle of least squared error [12]. The operation is repeated in the clustering process to derive the optimal clusters corresponding to the initial cluster centre distribution. The final number of clusters, *k*, is specified from the given *m* data samples, and the corresponding number of cluster centroids is selected. The distance from each data object in the data set to these *k* centres is calculated, and the data are classified into clusters accordingly. After the classification is complete, the centroids of the clusters are redetermined once again, and this completes the calculation in one iteration. The better centroid is selected again in the

first classification result, the division of the data is calculated from this centroid, and the clustering of the data is divided through several iterations until the criterion function converges. Figure 2 shows the data partitioning diagram after the national porcelain iteration.

The formula for the criterion function using *K*-means is

$$R = \sum_{i=1}^{h} \sum_{j \in g_h} \left(k_j - \beta_i\right)^2. \tag{4}$$

The contour coefficients are generally used to analyse the classification effect of the *K*-means algorithm, expressed by the formula as follows:

$$M(i) = \frac{n_i - m_i}{\max(m_i, n_i)}. \tag{5}$$

When the value of the contour coefficient is closer to 1, it means that this clustering is good and the clustering is reasonable; when the contour coefficient is close to −1, it means that similar samples do not belong to this class of clusters. When the contour coefficient is close to 0, it means that the similar samples are on the boundary of the two cluster classes.

It is indicated that the contour coefficient of a class is the mean of the corresponding values through all the points in it, expressed by the formula as follows:

$$MN = \frac{\sum_{i=1}^{k} \left(k_j - \beta_i\right)^2}{k}, \tag{6}$$

where SC is the contour coefficient of the whole data set; the larger the SC value, the more appropriate the number of clusters *k* value; *m* indicates the number of objects in the data set.

2.1.3. Recommendation Results Generated by User Clustering.
The improved query method for the target user's neighbourhood set points out that the correct neighbourhood set has a significant impact on the accuracy of the recommendation results [13]. The interests and preference tendencies of the target user can be more accurately predicted by finding the neighbourhoods closest to the target user, which are closer to the target user's interests and preferences. The improved method finds the set of neighbours most similar to itself in a smaller user class cluster space when the system searches for neighbouring users. Preprocessing of users is done by clustering using *K*-means to generate *k* clusters of user classes. The user rating information is processed into a user rating matrix, from which *k* initial cluster centroids are selected, and the distance from the user to the cluster class centre is recorded according to the different ratings of each user. The method for dividing the centroids of the cluster classes is

$$H = \sum_{i=1}^{G} \sqrt{\left(k_{1i} - k_{2i}\right)^2}. \tag{7}$$

Next, the set of neighbours is filtered in the space of class clusters to which the target user belongs, using the previous
Figure 2: *K*-means algorithm after several iterations of data division.

improved research method, and the possible ratings given by the user for content not visited in that system are derived [14]. From these predicted ratings, the top rated items are selected to be recommended for the target user.

2.2. Collaborative Filtering Algorithm Based on Similar Classes and User Preferences.
In order to facilitate the subsequent selection of services based on preferences, users need to have an accurate description of their preferences in order to select the service they are most satisfied with. Due to the problem of data sparsity, it is difficult to obtain similar user sets of the target user to generate suitable item recommendations for the target user. How to overcome the sparsity problem of data in the rating matrix and accurately grasp the user's interest preferences in this limited information becomes the main concern of the recommendation system [15]. By exploring user authenticity, user preferences, and user access frequency, it recommends products that are similar to user preferences, thereby improving user ratings. The collaborative filtering algorithm based on similarity classes and user preferences focuses more on the high ratings given by users when mining their real interests, not only considering the number of visits by the user but also corresponding the user's rating information to the feature matrix of the item class.

For user preference dance moves selection, the set of similar classes and the user's preference weights are first input, and the candidate dance moves in each similar class are normalised and calculated to produce a dance move for each similar class. Firstly, the user's interest preference is initially determined from the frequency of the user's access to the feature. The feature classes belonging to the items that have been rated by the user's visits are collated and extracted, and then the user's ratings of the items are mapped to the user's ratings of the corresponding features. The number of visits to a feature category is used to determine the level of interest in that category; i.e., the ratio of the number of visits to a category to the total number of items visited by the user is the user's preference for that feature category. The initial interest of the user in the feature class in terms of the frequency of access is calculated using the formula as follows:

$$W_{a,b} = \frac{c_{a,b}}{|H_a|}. \tag{8}$$

However, the number of visits to a feature category is not sufficient to determine a user's preference for that feature category; the true preference is determined by the user's subjective rating of the feature category. It is therefore important to analyse users based on their access characteristics, so that their interest preferences are more realistic, and to calculate their true interest preferences in terms of subjective ratings.

$$Q_{a,b} = \frac{m_{a,b}}{c_{a,b}}. \tag{9}$$

Finally, the similarity of users' true preferences for feature categories is calculated based on the frequency with which they visit the feature category and the number of high ratings the user has in the feature category.

$$F_{a,b} = W_{a,b} \times Q_{a,b}. \tag{10}$$

2.3. User Fuzzy Clustering.
The user fuzzy clustering process first uses the data recorded by the computer to construct a fuzzy matrix of human motion, which is then normalised and then calibrated to produce a fuzzy similarity matrix of human motion, which is clustered and output [16]. Fuzzy clustering algorithms provide more reasonable clustering results compared to hard clustering algorithms, but increase in time complexity. In general, the methods for performing fuzzy clustering analysis are broadly divided into normalisation of sample data, calibration of the fuzzy similarity matrix, and clustering. In practice, a suitable classification should satisfy three conditions: self-reflexivity, symmetry, and transferability, and satisfying the above conditions is an equivalence relation, so fuzzy clustering analysis is based on equivalence relations. A diagram of the process of fuzzy clustering is shown in Figure 3.

2.3.1. Data Standardisation.
In fuzzy clustering analysis, the sample data should first be preprocessed. Data normalisation is the unification of each indicator value within a certain range of numerical characteristics for various numbers and orders of indicators, thus eliminating the influence of differences in units of characteristic indices and different orders of magnitude [17]. Currently, there are two common methods of data normalisation: mean-variance normalisation and great-minimum normalisation.

Given a sample set, mean-variance normalisation is calculated and the formula is expressed as

$$k_{ab}' = \frac{k_{ab} - \overline{k}_a}{s_a} \ (1 \le b \le k). \tag{11}$$

Very large and very small standardisation:

$$k_{ab}' = \frac{k_{ab} - \min\{k_{ab}\}}{\max\{k_{ab}\} - \min\{k_{ab}\}}. \tag{12}$$

2.3.2. Establishing a Fuzzy Similarity Matrix.
Calibration is to measure the degree of similarity between the classified objects, which is generally expressed by the similarity coefficient. There are many methods commonly used to calibrate similarity coefficients in fuzzy similarity matrices, such as the similarity coefficient method, the angle cosine method, the maximum-minimum method, and the arithmetic mean-minimum method. The algorithms for several calibration methods are described next.

Correlation coefficient method:

$$r_{ab} = \frac{\sum_{h=1}^n (k_{bh} - \overline{k}_b)}{\sqrt{\sum_{h=1}^n (k_{ah} - k_b)^2}\sqrt{\sum_{h=1}^n (k_{ah} - k_a)^2}}. \tag{13}$$

Clipped cosine method:

$$r_{ab} = \frac{\sum_{h=1}^n k_{ah} \cdot k_{bh}}{\sqrt{\left(\sum_h^n k_{ah}^2\right)^2 \left(\sum_h^n k_{ah}^2\right)}}. \tag{14}$$

Maximum-minimum method:

$$r_{ab} = \frac{\sum_{h=1}^n \min(k_{ah}, k_{bh})}{\sum_h^n (k_{ah} + k_{bh})}. \tag{15}$$

Arithmetic mean-minimum method:

$$r_{ab} = \frac{\sum_{h=1}^n h = 1}{1/2 \sum_{h=1}^n (k_{ah}, k_{bh})}. \tag{16}$$

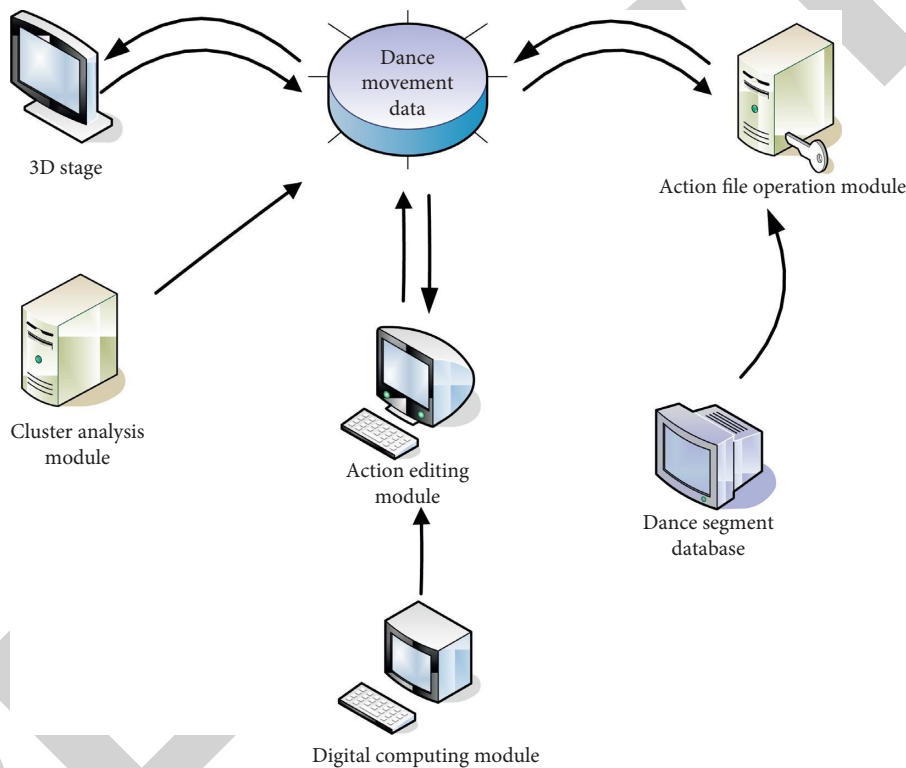
2.4. User Clustering-Based Dance-Assisted Choreography System.
User clustering is applied to dance choreography to build a dance-assisted choreography system based on user clustering features. This system can capture the motion information in the data file with the support of clustering algorithms, display the captured 3D animation effect, and then provide dance path editing based on the settled animation [18]. In this system, dance movement segments and local movements and paths can be edited, and physical adjustment drills are provided so that the resulting performance movements are realistic and conform to physical laws. The choreography assumes that the performer is travelling along a straight path, meaning that the performer's path of movement is abstracted into a straight line, and editing the path of movement allows for further reuse of movement data. The implementation of the system is therefore divided into six modules: a movement file manipulation module, a 3D movement display module, a movement editing module, a user clustering module, a mathematical calculation module, and a dance clip database module [19]. A user clustering-based dance-assisted
Figure 3: Fuzzy clustering composition.


Figure 4: User clustering-based choreography system.

choreography system is shown in Figure 4. This system has an important role to play in improving and refining dance-assisted choreography techniques.

In the movement editing module, since the movement data itself only include information on the spatial position of the joints and do not contain information on the mass distribution of the body, there is also a need to focus on the impact of the physical parameters of the body on the choreography [20]. In biomechanics, the body's central nervous system automatically adjusts the angular momentum of the centre of mass to a minimum during movement, so that the centre of mass remains translational to enhance dynamic balance [21]. In the human movement system, ZMP is an important basis for determining dynamic equilibrium, when the body is in dynamic equilibrium, and

the centre of pressure of the supporting polygon is coincident. During the human balance adjustment process, the frames of the performance segments are divided into touchdown and nontouchdown categories in order to reduce the huge data calculation and to correct the human motion according to the variation of the force on the human body [22].

Touchdown frame equilibrium is when the body touches the ground and the external forces acting on it are ground support and friction in addition to gravity. After rotational filtering of the performance segment to be optimised, for each touchdown frame in that performance segment, the human pose is adjusted according to the classification of the skeletal segment set in each step, so that the adjusted ZMPs fall within the support polygon and the human body is

dynamically balanced. Nontouchdown frame equilibrium is when the body does not touch the ground and the only external force acting on it is gravity, so its centre of mass must follow a parabolic trajectory and the total angular momentum must be conserved [23]. This can be expressed in the mathematical formulation of the physical constraint as

$$\text{COM}(f) = \frac{\sum iw_f e_i(f)}{\sum iw_i},$$

$$d_{\text{COM}} = F, \tag{17}$$

where COM represents the body centre of mass position and d_{COM} represents the angular momentum of the centre of mass.

The division of the angular momentum of the centre of mass into two components can be expressed by the equation as follows:

$$d_{\text{COM}} = d_{\text{COM}}^A + d_{\text{COM}}^B. \tag{18}$$

When translations and rotations of the centre of mass of the individual limb segments of the human body take place, it is possible to obtain

$$d_{\text{COM}}^A = \sum_i g_i (e_i - COM) \times D_i,$$

$$d_{\text{COM}}^B = \sum_i K_i f_i = \sum_i K_i F_c^B \beta^i, \tag{19}$$

where F_c^B denotes the matrix in the limb section, the unit vector of the line connecting the joint points at both ends in section i.

According to the six modules in the system, the dance movements can be captured and optimised based on user clustering similarity [24]. For the captured motion, data are a collection of 3D spatial coordinates of the individual joints in the human body model over time. Think of the human body model as a tree, with the waist joint as the root node, and as the parent node moves, the child joints follow. The effect of the performance clip after optimisation is shown in Figure 5.

3. Development of a Content Similarity Algorithm Based on User Clustering in Dance-Assisted Choreography Technology

3.1. Experiments on the Application of Collaborative Filtering Algorithm in Dance-Assisted Choreography Technology. The accuracy of the algorithm for scoring predicted items is assessed by the value of the mean absolute error (MAE); the smaller the value of MAE, the better the result. As the user clustering algorithm helps to improve the quality of system recommendations, in the dance choreography system, it is assumed that there are k clusters of user dance feature classes in the system. According to the similarity calculation method, the similarity of human movements is calculated, the accuracy of the similarity algorithm is firstly experimented, and then the experimental results are used to analyse whether the class clusters can be included in the
Figure 5: Analysis of dance movement segments after user clustering similarity optimisation.

dance-assisted choreography technology. To confirm the collaborative filtering algorithm, the article analyses the IBCF algorithm and the collaborative filtering algorithm under the same data situation, as shown in Figure 6 which shows the change of MAE value under the change of user similarity with number for different k values of cluster classes.

As shown in the figure, under the same conditions, the collaborative filtering algorithm proposed in the article has more obvious advantages than the IBCF algorithm, and its overall MAE value is smaller than the IBCF algorithm. When the number of actions is selected to be 40, the MAE value of the IBCF algorithm is about 0.84, and the MAE value of the collaborative filtering algorithm is about 0.76. The MAE value of the two differs by about 8%, and the collaborative filtering algorithm is used after the number of human bodies is 40. The MAE value tends to be stable, so the collaborative filtering algorithm is more effective than the IBCF algorithm.

In order to verify the effectiveness of the collaborative filtering algorithm in dance-assisted choreography and the diversity of similarity calculation, the length of the recommendation list is set to 20 in the experiment; that is, 20 items are recommended for the target user, and the collaborative filtering under different k values is analysed. The precision and recall of the recommendation list results given by the filtering algorithm are shown in Table 1.

The corresponding graph is shown in Figure 7.

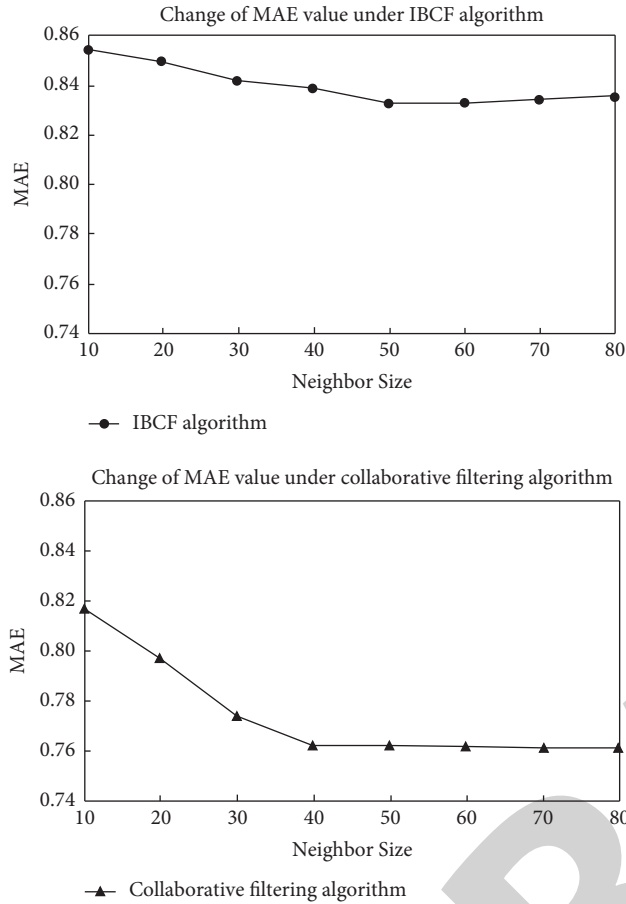
The precision rate and recall rate are greater than 0.3, indicating that the algorithm recommendation quality is good. As shown in the figure, as the number of k values increases, the accuracy and recall of the recommended results of the collaborative filtering algorithm are improving. Therefore, it can be judged that the recommendation quality of the collaborative filtering algorithm is constantly improving. When the number of k values is between 10 and 50, the precision rate and recall rate increase rapidly, the two k values are above 40, and the precision rate and recall rate are both greater than 0.3. The more the number, the higher the precision rate and recall rate. The accuracy and recall rate of the recommended number after 50 tend to be stable,


Figure 6: Comparison of MAE changes under IBCF algorithm and collaborative filtering algorithm.

Table 1: Precision and recall with different numbers of neighbours.

Characteristic class cluster k	Accuracy	Recall
10	0.1923	0.2105
20	0.2355	0.2216
30	0.3640	0.2821
40	0.4311	0.3346
50	0.4321	0.4213
60	0.4356	0.4407
70	0.4386	0.4532
80	0.4399	0.4511

indicating that the collaborative filtering algorithm is highly effective in dance-assisted choreography.

3.2. Application Experiment of User Fuzzy Clustering in Dance-Assisted Choreography Technology. Under the user fuzzy clustering analysis, for all the page sequences visited by users within a period of time, because the preprocessing part cannot get the page paths that the user is really interested in, according to the algorithm idea of this paper, the user interest matrix is intercepted with a threshold value to extract the user's sense of interest. The user fuzzy clustering analysis is applied to the dance assistant choreography system, and the speed of human movements is systematically analysed by

comparing the IBCF algorithm and the user fuzzy clustering algorithm. Judge the help of user fuzzy clustering to dance-assisted choreography technology. Figure 8 shows the time consumption of the two algorithms under the same amount of data.

Because the IBCF algorithm is more suitable for analysing objects with a small amount of data, the response to operations with a large amount of data is slow and the efficiency is low. It can be seen from the figure that as the amount of data increases, the clustering time of the two algorithms increases, the amount of data increases, and the sides become longer. In the experiment, when the maximum amount of data is 60, the time used by the IBCF algorithm is 50 s, the time used by the user fuzzy clustering algorithm is 38, and the time difference between the two algorithms is 12 s. Compared with the user fuzzy clustering algorithm, the running time of the IBCF algorithm is longer, and the user clustering effect is more obvious under the user fuzzy clustering algorithm. Under the effective clustering, over time, the dance assistant choreography system can easily adapt to user preferences, perform choreography in a targeted manner, and improve choreography techniques.

Compared with the traditional dance assistant choreography system and the index analysis of each factor of the dance assistant choreography system under the user clustering algorithm, the data information in Table 2 is obtained.

By analysing Table 2, it can be seen that in the choreography system optimised by the user clustering algorithm, the technical level of dance choreography has increased from 77% to 84%, the choreography effect has increased from 67% to 82%, the quality of choreography has increased from the original 76% to 85%, and the satisfaction with choreography has risen from 72% to 83%. The choreography effect has increased by 15%, and the room for improvement is the largest. Under the user clustering similarity algorithm, each reference factor in the dance choreography system has been improved to a certain extent.

4. Discussion

This paper researches, develops, and analyses the content similarity algorithm based on user clustering in dance-assisted choreography technology. In view of the problems and shortcomings encountered by the existing dance choreography technology, this paper uses the content similarity algorithm of user clustering. This paper proposes three methods: collaborative filtering algorithm based on user clustering, collaborative filtering algorithm based on similarity class, and user preference and user fuzzy clustering analysis. It is found that the collaborative filtering algorithm is higher than the IBCF algorithm in terms of accuracy and recall. In the application experiment of fuzzy clustering in dance assistant choreography, comparing the time consumption of IBCF algorithm and user fuzzy clustering algorithm in data analysis, it is found that user fuzzy clustering algorithm consumes less time and has better clustering effect; compared with traditional dance assistant, the index changes of each factor of the choreography system and the

choreography system after clustering optimisation found that each reference factor was improved to a certain extent.

5. Conclusions

This paper takes user clustering as a premise and integrates several user clustering similarity algorithms to analyse dance-assisted choreography techniques. The paper proposes a collaborative filtering algorithm based on user clustering, a collaborative filtering algorithm based on similarity classes and user preferences, and a user fuzzy clustering analysis. In the collaborative filtering algorithm based on user clustering, the user similarity measure, the K-means algorithm, and the recommendation results generated by user clustering are analysed, and for the problem of data sparsity in the collaborative filtering algorithm based on user clustering, the collaborative filtering algorithm of similar classes and user preferences is proposed to mine the authenticity of household interest preferences; then, the data are standardised and a fuzzy matrix is established to the fuzzy clustering of users then generalised through data normalisation and establishment of fuzzy matrices. In the experimental part, the collaborative filtering algorithm in dance-assisted choreography technology application and user fuzzy clustering in dance-assisted choreography technology application are analysed. After the experiments, it is

Research on the Performance of Network Propagation by Using the Machine Learning and Internet-of-Things Technology Integrating Model

Feng Chen [ID]

College of Artificial Intelligence, Zhejiang College of Security Technology, Wenzhou 325016, Zhejiang, China

Correspondence should be addressed to Feng Chen; chenfeng@zjcst.edu.cn

We combine machine learning with Internet of Things technology to study the performance of network propagation model. This paper first introduces the construction environment of the business push system and then realizes user clustering and active business push by using the experimental data. Experimental results show that the active service push system constructed in this paper is feasible and effective. The experiment also compares and analyzes the influence of different clustering methods on the accuracy of service push. The results show that the clustering effect of the multi-Markov chain model (m-MCM) method is superior to that of the *K*-means method, a commonly used machine learning method, and the accuracy of user-service push obtained by the m-MCM method is superior to that obtained by the *K*-means method. Finally, on the basis of the existing experimental results, the shortcomings of the service push system are summarized, the future improvement direction and specific implementation measures are proposed, and new requirements for the future update of the service push system are put forward.

1. Introduction

The industrial Internet of Things is the product of the deep integration of the Internet of Things, big data, cloud computing, and other new-generation information technologies into the manufacturing industry. It is the main starting point for the digital transformation of the manufacturing industry and has become a key support for the fourth industrial revolution. Germany, the United States, Japan, and other major developed countries have established promotion agencies for the industrial Internet of Things and formulated strategic plans for the development of advanced manufacturing industries, including the industrial Internet of Things, so as to realize the transformation and upgrading of traditional manufacturing industries and reshape their competitive advantages. China has also formulated the "Made in China 2025" policy to accelerate the in-depth integration of the new generation of information technology and manufacturing as the main line and to promote intelligent manufacturing as the main direction.

2. Related Works

The research on the industrial Internet of Things started earlier in the world, and the research from the perspective of economics mainly focuses on business model, innovation model, enterprise organization, and other fields. First, regarding research on the business model, Arnold et al. [1] divided the business model of the industrial Internet of Things into cloud-based business model, service-oriented business model, and process-oriented business model according to different service objects. Gierej [2] believes that the emergence of the industrial Internet of Things on the one hand heralds the prospect of the development of industrial intelligence and on the other hand marks the transformation of the traditional manufacturing industry to "Outcome Economy," that is, the product and service delivery mode with customer demand as the core. Montori et al. [3] proposed that the industrial Internet of Things has spawned a new business model, which is due to the fundamental change of consumer behavior and the entry of competitors

from outside the manufacturing industry (such as technology enterprises and information technology enterprises). In order to cope with the drastic change of market environment and the increasingly fierce competition, manufacturing enterprises must adjust their original product-centered business model to evolve into the business model of "integration of product and service" [4, 5]. Second, regarding research on the innovation model, Kazuyuki [6] analyzed the relationship between the utilization status, scope, and innovation of big data of Japanese B2B and B2C large enterprises based on questionnaire survey data and pointed out that the application of Internet of Things and big data can on the one hand improve enterprise productivity and on the other hand change enterprise production mode and work content, and the society needs to cope with and adapt to this change. Third, regarding enterprise organization research, Iivari et al. [7] pointed out that the key issues that industrial IoT enterprises need to consider are not only the technical level but also the organizational level so as to achieve the balance and adaptation of enterprise organization, human resources, and industrial IoT technology. This requires the corresponding adjustment of the organizational structure of the enterprise, such as the development and integration of industrial Internet technology, the reconstruction of the core business of the enterprise, and the new mode of production and employee incentive system. Since the beginning of the twenty-first century, academic research on platform enterprises has increased dramatically. The references research path is as follows [8, 9]: since 2000, bilateral market research [10, 11], platform architecture research [9], open innovation research [12], and business ecosystem research have transferred to user innovation research [8, 13], it has formed the research trend of platform strategy under the interdisciplinary background. As soon as the concept of cloud manufacturing was put forward, it became an emerging topic and was warmly welcomed by many scientific researchers. Based on cloud computing, Internet of Things, and other contemporary information technologies, cloud manufacturing extends the concept of "software as a service," an emerging concept in the field of cloud computing, and is introduced into the manufacturing industry.

The research significance of information push technology is mainly reflected in three aspects. First of all, for service providers, a fast and accurate personalized service push system can improve the service quality, provide convenient and high-quality service content for service demanders smoothly, improve their competitiveness in the market, and promote the long-term development of enterprises. Secondly, for the service demand side, the intelligent service push technology saves users' time and energy and improves users' sense of pleasure in experience, and the efficient information push technology can realize the sharing value of information so that the majority of users can quickly find their service needs through this technology. Finally, for manufacturing production form, the development of information push technology accelerates the upgrade of the traditional manufacturing industry and makes manufacturing better integrated into the global economic

development in order to improve the utilization rate of resources, reduce the manufacturing cost, promote the wisdom of the worldwide manufacturing model, and provide strong technical support [14].

From passive search to active screening and elimination, active service push technology has changed greatly the people's lifestyle. With the acceleration of social development, people hope to obtain more convenient and satisfying services through active service push technology. Information push is an active, intelligent, and perceptive information service form. According to the needs of users, the technology combines various advanced information technologies such as big data, artificial intelligence, and other technologies to timely and actively transfer information to the needs of users. This technology is widely used in e-commerce, social networks, information science, user personalized knowledge services, and other fields [15].

Active service push technology combined with automatic system recognition and analysis technology analyzes the potential interest preference of push objects. It helps manufacturing enterprises find potential service objects among a large number of users, realize real-time push operation of personalized service, and improve the accuracy and satisfaction of push service. Active push service is widely used in a web browser and e-commerce platform. For example, Baidu platform analyzes the frequency of browsing and length of stay according to the types of web pages frequently browsed by users and recommends news content that may be of interest to users according to the specific ranking order, thus eliminating the user input keywords or related website.

There are two characteristics of the active service push technology. (1) Active service push refers to the fact that the system automatically obtains the information of the web page browsing by users and uses various advanced data analysis technologies to push the content that users may be interested in. In the past, the demand analysis of services was initiated by users. (2) Cloud platforms are built through service virtualization. It is a gathering place of services and resources, realizing the sharing of services and resources, providing products and services needed by the market efficiently, and delivering them to users timely and accurately. Platform system 24 hours uninterrupted background operation.

Research institutions have done a lot of research on the combination of information push with business processes such as enterprise design and manufacturing. The existing research is mainly reflected in the application of knowledge push in specific fields [16]. In terms of active push of cloud services, Palmisano [17] explored the blank field of online e-retail system and designed and built a recommendation system based on environment awareness. Tosi [18] proposed a method of knowledge push based on user content after identifying the user's interest characteristics. Kobayashi et al. [19] proposed a search engine method based on user interest characteristics in the face of information flooding in the current network environment.

There is a lot of networked manufacturing service information in the cloud manufacturing service platform. This

paper takes the data maintenance disaster caused by big data as the research background, analyzes the historical browsing data of users, and speculates users' preferences, tastes, and needs from the perspective of operators. A machine learning method based on the Markov chain model is proposed to aggregate users with the same interest characteristics, and then a collaborative filtering recommendation algorithm is used to analyze browsing logs, interaction logs, and transaction logs of users with the same interest characteristics. Finally, according to users' ratings, recommend some novel service information that users have not contacted before or may be interested in.

3. Construction of Network Propagation Model

This section introduces the peripheral architecture of the network propagation and how to use machine learning to realize the active push process of service.

3.1. The Peripheral Architecture of Network Propagation. As shown in Figure 1, the peripheral architecture of the push system is composed of four modules, which are data capture, data preprocessing, user clustering analysis with similar interest preferences, and service push module.

The main functions of each module in the push system are as follows.

3.1.1. Data Capture Module. This module provides important user data resources for simulation experiments. The data acquisition of this module mainly includes two processes: (1) web crawler technology to simulate logging into a social manufacturing network to obtain interested topic database information; (2) web crawler technology combined with a website API interface to capture the information of many ordinary users in the platform. After a month of data collection, the web crawler helped obtain personal and browsing information from unauthorized users, eventually collecting 830 users and more than 200,000 text messages. In order to reduce potential errors, this paper divides the data set into 20% as test set and 80% as training set according to the rule of 2 : 8.

3.1.2. Data Preprocessing Module. The module mainly refines and analyzes the obtained text information and converts the obtained text information into numerical information to enable computer recognition. This module mainly includes two processes. (1) Transform the interest topic library information into a standard user interest eigenvalue vector. (2) With the standard user interest eigenvalue vector as the reference, the text information of each user is transformed into the eigenvalue vector as the input parameter of machine learning.

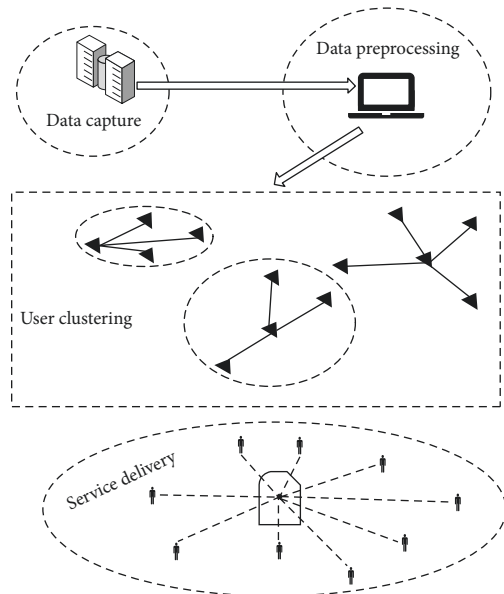
3.1.3. User Clustering Module with Similar Interest. This module mainly gathers a class of users with the same interest and hobbies together through the Markov chain model in machine learning, reduces the scope of user collaborative


Figure 1: The peripheral framework of the push system.

filtering calculation, and reduces the workload of the working platform. This module takes the user interest eigenvalue vector obtained in the data preprocessing module as the relevant parameters of the multi-Markov model. In the multi-Markov model, the eigenvalue vector of each user can be regarded as a Markov chain, so the set of users becomes the set of Markov chains. In the set of Markov chains, clustering and merging Markov chains with the same or similar characteristics can realize the aggregation of a class of users with the same interests.

3.1.4. Service Push Module. This module is based on user clustering module with similar interests. Through the clustering module, a class of users with the same interest characteristics are gathered together. By analyzing the transaction record information obtained by the data acquisition module, the user-based collaborative filtering recommendation method is used to realize the active push of the service.

3.2. Overall Framework Design of Push System. Section 3.1 outlines the peripheral architecture of the push system, and this section will analyze the main contents of the push system module one by one. Figure 2 describes the main contents of the system in detail. Data acquisition module and data preprocessing module mainly include data acquisition, interest topic database data, and data processing of ordinary users. User clustering module mainly includes transforming user's eigenvalue vector into Markov chain and similar Markov chain clustering operation; service push module mainly includes service evaluation and active push operation of user transaction records. This section will introduce the main contents of user clustering module and service push module in detail.
FIGURE 2: Push system internal details.

3.3. Markov Chain Model

3.3.1. Single Markov Chain Model (s-MCM). According to the characteristics of the Markov chain, the interest characteristic value vector of each ordinary user is transformed into the corresponding parameters in the single Markov chain model to predict the user's interest orientation and interest category. However, if you want to use the single Markov chain model to judge the user interest category, you must make the following assumptions about the user browsing process on the website.

Assumption l. (Markov hypothesis) Assuming that the browsing process is a random process, users can be regarded as homogeneous discrete Markov chain. Therefore, a user's browsing record on the website is translated into a sequence of random variables X, which satisfies Markov property.

Under assumption 1, we establish a single Markov chain model (s-MCM).

Definition 1. s-MCM is represented by triple $MC = \langle X, A, \lambda \rangle$ [20]. X represents the discrete random variable, its value range is $\{x_1, \ldots, x_i, \ldots, x_n\}$, and x_i is one state of the model, representing that the user stays in the state of interest. A represents state transition probability matrix, which is also named transition matrix. In the transition matrix, the probability of transition from state x_i to state x_j can be calculated by the formula $P_{ij} = P(X_t = x_j / X_{t-1} = x_i)$, and the transition process can be simplified and written as a state pair (x_i, x_j). λ represents

the initial state distribution, where each term $P_i = P(X_{t=0} = x_i)$. In summary, the transfer matrix A is

$$A = (p_{ij}) = \begin{bmatrix} P_{11} & P_{12} & \cdots & P_{1j} & \cdots & P_{1n} \\ P_{21} & P_{22} & \cdots & P_{2j} & \cdots & P_{2n} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ P_{i1} & P_{i2} & \cdots & P_{ij} & \cdots & P_{in} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ P_{n1} & P_{n2} & \cdots & P_{nj} & \cdots & P_{nn} \end{bmatrix}, \quad (1)$$

$$R = \begin{matrix} u_1 \\ u_2 \\ u_3 \\ u_4 \\ u_5 \end{matrix} \begin{bmatrix} 4 & 0 & 0 & 5 & 0 \\ 5 & 5 & 0 & 5 & 4 \\ 0 & 5 & 4 & 0 & 3 \\ 5 & 3 & 5 & 5 & 4 \\ 4 & 0 & 4 & 3 & 0 \end{bmatrix}. \quad (2)$$

At the same time, the initial state distribution is as follows:

$$\lambda = (p_i) = (P_1, P_2, \ldots, P_n). \quad (3)$$

According to the definition of the single Markov chain model, a user's interest eigenvalue sequence X_i is essentially a collection of all pages x_i visited by the user. By counting the number of visits that the user clicks on different pages x_i, the vector of the user's number of visits to different pages is obtained, that is, the interest eigenvalue vector X_i. All the data recorded in the process is denoted d_1. By analogy, the

data recorded by the m th user is d_m, so the data set obtained by all users is $D = \{d_1, d_2, \ldots, d_m\}$.

Thus, the parameters P_{ij} and P_i in the single Markov chain model based on all user data can be estimated by the data set D and the maximum likelihood estimation method; namely,

$$p_{ij} = \frac{s_{ij}}{\sum_{j=1}^n s_{ij}}, \tag{4}$$

$$p_i = \frac{\sum_{j=1}^n s_{ij}}{\sum_{i=1}^n \sum_{j=1}^n s_{ij}}. \tag{5}$$

In (4) and (5), s_{ij} represents the number of occurrences of state pairs (x_i, x_j) in all user text information. When the parameters p_{ij} and p_i are calculated, substituted into (2) and (3), the triple parameters $\langle X, A, \lambda \rangle$ of the single Markov chain model can be obtained based on all user data.

3.3.2. Multi-Markov Chain Model. As described in the summary of Section 3.3.1, it is inaccurate to describe all users' interest characteristics and categories only by establishing a single Markov chain model based on all users' data. In order to improve the accuracy of predicting user interest characteristics, this paper introduces the concept of multi-Markov chain model based on the single Markov chain model, which aims to obtain higher accuracy. The reason why the multi-Markov chain model is more suitable for the modeling of this topic is that the user's interest preference is affected by the user's own manufacturing environment, manufacturing capacity, and other factors. It is an uncertain complex sequence affected by multiple external factors. Therefore, the same category of users with the same or similar interest features is more suitable to be described by the same model; on the contrary, it is more reasonable to describe different types of users with different or not similar interest characteristics by different models. Based on this idea, a multi-Markov chain model based on all user data is established to describe the interest characteristics of all users. The premise is that the user's browsing process needs to meet the following two assumptions.

Assumption 2. (User Classification Hypothesis) Let all users have K categories, and then $C = \{c_1, c_2, \ldots, c_k\}$ denotes the category set of users, and $P(C = c_k)$ denotes the probability that any user belongs to category c_k.

$$\sum_{k=1}^K P(C = c_k) = 1. \tag{6}$$

Assumption 3. (Markov-like chain hypothesis) Let the same category of users have the same or similar interest features, and the sequence of these features is a unique random process. The multi-Markov chain model is defined under Assumptions 1 and 2.

Definition 2. m-MCM is represented by four tuples $\langle X, K, P(C), MC \rangle$. X is a discrete random variable in the range of $\{x_1, \ldots, x_i, \ldots, x_n\}$, and x_i is a state of the model, representing the user interest eigenvalues. K is a preset value in the model, representing the number of user classifications. $C = \{c_1, c_2, \ldots, c_k\}$ denotes the category of users, and the probability distribution of different types of users is represented by the distribution function $P(C)$. Element mc_k represents the Markov chain composed of the same user c_k with the same interest type. If the element mc_k is set together, we obtain the class Markov set $MC = \{mc_1, mc_2, \ldots, mc_k\}$, which represents the set of Markov chains of all categories of users.

In the multi-Markov chain model, the state transition matrix A_k of the class k is

$$A_k = (p_{kij}) = \begin{bmatrix} P_{k11} & P_{k12} & \cdots & P_{k1j} & \cdots & P_{k1n} \\ P_{k21} & P_{k22} & \cdots & P_{k2j} & \cdots & P_{k2n} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ P_{ki1} & P_{ki2} & \cdots & P_{kij} & \cdots & P_{kin} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ P_{kn1} & P_{kn2} & \cdots & P_{knj} & \cdots & P_{knn} \end{bmatrix}. \tag{7}$$

And the initial distribution of class k is

$$\lambda_k = (p_{ki}) = (P_{k1}, P_{k2}, \ldots, P_{kn}). \tag{8}$$

In (7) and (8), the unknown parameters p_{kij} and p_{ki} can be obtained according to the definition of the multi-Markov chain. Because any user has its own unique interest characteristics in the initial state and can be regarded as a class of users alone, the parameters p_{kij} and p_{ki} can be obtained by a calculation method similar to the single Markov chain; namely,

$$P_{kij} = \frac{S_{kij} + a_{kij}}{\sum_{j=1}^n (S_{kij} + a_{kij})}, \tag{9}$$

$$p_{ki} = \frac{\sum_{j=1}^n (S_{kij} + \alpha_{kij})}{\sum_{i=1}^n \sum_{j=1}^n (S_{kij} + \alpha_{kij})}. \tag{10}$$

In (9) and (10), S_{kij} represents the number of state pairs (x_i, x_j) appearing in the class k user text information. α_{kij} is the superparameter. And the superparameter α_{kij} can be calculated by assuming that all state pairs (x_i, x_j) have the same number of occurrences, that is, Bayes assumption, and then α_{kij} can be obtained by (11) approximation:

$$\alpha_{kij} = \frac{\beta}{n \times n}. \tag{11}$$

In (11), constant β is often replaced by the size n of the problem domain space. In summary, when the parameters p_{kij} and p_{ki} are calculated, substituted into (7) and (8), we obtain the four-tuple parameters of the m-like Markov chain mode $\langle X, K, P(C), MC \rangle$. It is worth declaring that there are m users in the whole process, and the users are divided into m categories; each class Markov chain calculated represents a sequence of user interest eigenvalues.

3.4. Fusion of Interest Feature Vector and Multi-Markov Chain Model. The user's interest eigenvalue vector has been calculated in Section 3. This section will focus on how to use the known interest eigenvalue vector to calculate the parameters in the multi-Markov chain model.

The core idea is summarized as follows. Firstly, $K = m$ is set to generate a quasi-Markov chain, and the practical significance of this step is to regard each user as an independent category, so the sequence of interest characteristic values of m users is correspondingly transformed into m Markov chains. Then, according to the one-to-one correspondence between m users and m Markov chains, the clustering operation of these Markov chains is carried out to realize the clustering of m users. The specific Markov-like chain generation process is as follows.

The initial state is regarded as a multi-Markov chain model under special circumstances; that is, a user's interest eigenvalue sequence is a category ($K = m$), and then the data set $D = \{d_1, d_2, \ldots, d_m\}$ composed of m user's interest eigenvalue is divided into K categories: $D_1, D_2, \ldots, D_k$. Therefore, each user category c_k is essentially a single Markov chain model based on learning data D_k. Therefore, the parameters p_{kij} and p_{ki} can be obtained by (9) and (10), and then the state transition matrix A_k and the initial state λ_k are obtained.

At this point, the interest eigenvalue vector of m users is transformed into a Markov-like chain of m users. Then, the clustering of similar or similar users is actually the clustering of similar or similar user class Markov chain.

3.5. Markov Chain Clustering. Section 3.4 has introduced in detail how the text data of m users are transformed into a Markov chain like m users; that is, the collected user data is transformed into a Markov chain set. The user clustering is actually the clustering of Markov chains, so the similarity evaluation criteria of two Markov chains must be defined in advance.

According to the definition, the dynamic characteristics of the Markov chain are represented by its state transition matrix, so the similarity between Markov chains mc_k and mc_l can be defined by mining the relationship between the two state transition matrices. The definition process of similarity is as follows. Let mc_k and mc_l be any two Markov chains, and their state transition matrices are A_k and A_l, respectively. The i th row p_{ki} parameter in the state transition matrix A_l is $P_{kij} | j = 1, 2, \ldots, n$. And the i th row p_{li} parameter in the state transition matrix A_k is $P_{lij} | j = 1, 2, \ldots, n$.

The parameters of both rows represent the distribution of variables $[t]$ under a given condition $X[t-1] = x_t$, that is, $P(X_t | X_{t-1} = x_t)$, whose approximation can be represented by their cross-entropy. The parameters of the two lines P_{ki} and P_{li} both represent the distribution of the variable $[t]$ under the given $X[t-1] = x_t$ condition, that is, $P(X_t | X_{t-1} = x_t)$, whose approximation can be represented by their cross-entropy:

$$CE(P_{ki}, P_{li}) = \sum_{j=1}^{n} P_{kij} \log \frac{P_{kij}}{P_{lij}}. \tag{12}$$

Therefore, the approximate degree of state transition matrices A_k and A_l can be expressed by the mean of cross-entropy of all row distributions; namely,

$$Similarity(A_k, A_l) = \frac{\sum_{i=1}^{n} CE(P_{ki}, P_{li})}{n}. \tag{13}$$

However, if (4)–(16) is directly used to evaluate the similarity between state transition matrices A_k and A_l; there will be two defects:

(1) First, the cross-entropy (12) is directional, so (13) does not meet the symmetric property; that is, $Similarity(A_k, A_l) \neq Similarity(A_l, A_k)$.

(2) Equation (13) reflects that the more similar the dynamic characteristics of two Markov chains are, the smaller the similarity value of the two Markov chains is, which does not conform to the definition of similarity semantics.

Therefore, to avoid the above two defects, we define the similarity of mc_k and mc_l of two Markov chains as

$$Similarity(mc_k, mc_l) = \frac{2}{Similarity(A_k, A_l) + Similarity(A_l, A_k)}. \tag{14}$$

Note: if the $Similarity(A_k, A_l) + Similarity(A_l, A_k) = 0$, $2/0 = \infty$. The analysis (14) shows that the more similar the dynamic characteristics of two Markov chains are, the greater the similarity value is, which meets the requirement of similarity semantics.

3.6. Multi-Markov Chain Model Clustering Method. Based on the above steps, we give a user clustering method based on the multi-Markov chain model.

(i) User clustering steps:

(ii) Input: user learning data $D = \{d_1, d_2, \ldots, d_m\}$.

(iii) Output: User clustering result.

(iv) Process:

(v) Step l: Use (9) and (10) to map the learning data D into M Markov chains.

(vi) Step 2: Use (11) to (14) to calculate the similarity degree between two Markov chains and arrange them according to the similarity value obtained by calculation from large to small.

(vii) Step 3: According to the preset number of classifications and similarity values, cluster m Markov chains.

(viii) Step 4: According to the corresponding relationship between m Markov chains and m users, output the clustering result.

3.7. Design of Active Service Push Algorithm. The service push system can be vividly described by a black box. The basic data resources of the pushed object are processed by the black box to obtain the push list, and they will receive service

recommendations from the platform at a certain point offline.

In the existing service push system, the system that can achieve accurate push has not emerged because each push method only uses a small part of the system information. To achieve the goal of pushing more accurate, higher quality, and higher satisfaction services for service push objects, this paper adopts multilevel and all-round analysis methods to deal with the information acquired in the system, that is, the cluster-service collaborative filtering and mixed push method. Through the clustering analysis of users in the platform, users with the same interest category are classified into one class. Then, the collaborative filtering recommendation algorithm is used to push services to users with the same interest category. Because the evaluation model of "user-service" for users of the same type is similar, there will not be too many nonevaluation services, which makes the evaluation matrix sparse. This can improve the accuracy of service push. The user clustering analysis method in the mixed push method has been introduced in detail in the previous sections, and the user-based collaborative filtering method will be explained in detail in the following.

3.8. User-Based Collaborative Filtering Recommendation Method.
Through user clustering, a class of nearest neighbor user sets with similar interest characteristics can be obtained. The services in user sets are all closely related to users. Although the massive service types and quantity at the beginning of push have been reduced through clustering operation, service demanders will still be at a loss when facing a series of untargeted push services if these services are sent to service push objects in no order. In order to reduce the time spent by service demanders to understand each service, the nearest neighbor user set is substituted into the "user-service" evaluation model, which aims to generate a ranking list of services that users may like through this model. Finally, the service push object will receive the push information offline and in some way.

3.9. Establishment of "User-Service Evaluation Model".
"User-service evaluation model" is shown as follows. Assuming that there are m users in the nearest neighbor user set and s corresponding service sets, the "user-service" evaluation matrix R is

$$R = \begin{matrix} & \begin{matrix} r_1 & \cdots & r_j & \cdots & r_s \end{matrix} \\ \begin{matrix} u_1 \\ \vdots \\ u_i \\ \vdots \\ u_m \end{matrix} & \begin{bmatrix} R_{11} & \cdots & R_{1j} & \cdots & R_s \\ \vdots & & & & \vdots \\ R_{i1} & \cdots & R_{ij} & \cdots & R_{is} \\ \vdots & & & & \vdots \\ R_{m1} & \cdots & R_{mj} & \cdots & R_{ms} \end{bmatrix} \end{matrix}. \quad (15)$$

In (15), UI represents the i th user, Rj represents the j th service, and Rij represents the score of the i th user on the j th service.

Rij is a real number ranging from 1 to 5. The higher the value of Rij is, the higher the user satisfaction is. If the user UI does not evaluate the service Rj, the value of Rij is defined as 0. The real-value scoring method is widely spread among service platforms because this scoring mode is more reasonable and detailed, which can greatly reduce the sparsity of "user-service" evaluation matrix R so as to improve the accuracy and satisfaction of service push to the greatest extent.

3.10. Similarity between Computing Services.
When the "user-service" evaluation matrix R is used to calculate the list of push score values of similar services, cosine similarity value and Person similarity value between services can generally be calculated. However, the Person similarity calculation method is more delicate, and the average operation of subtracting the score value from the overall service score value is used to reduce the impact of different evaluation values on the same service with the same evaluation. The calculation results are more reliable and convincing, so the Person similarity measurement is adopted in this paper.

3.11. Person Similarity Measurement Calculation Method.
Assuming that I_{pq} is the set of users who have commented on service r_p and r_q together in the nearest user set and $\overline{R_p}$ and $\overline{R_q}$ are the average ratings of users on service r_p and r_q, respectively, then the similarity $\delta(r_p, r_q)$ is shown in (16):

$$\delta(r_p, r_q) = \frac{\sum_{i \in I_{pq}} (R_{ip} - \overline{R_p})(R_{iq} - \overline{R_q})}{\sqrt{\sum_{i \in I_{pq}} (R_{ip} - \overline{R_p})^2} \sqrt{\sum_{i \in I_{pq}} (R_{iq} - \overline{R_q})^2}}. \quad (16)$$

3.12. The Calculation Example of Service Actively Pushes.
Calculation example 1: assume that users $u_0, u_1, u_2, u_3, u_4, u_5$ are a small group of nearest neighbor users after a clustering, and its user-service evaluation matrix is

$$R = \begin{matrix} & \begin{matrix} r_1 & r_2 & r_3 & r_4 & r_5 \end{matrix} \\ \begin{matrix} u_0 \\ u_1 \\ u_2 \\ u_3 \\ u_4 \\ u_5 \end{matrix} & \begin{bmatrix} 4 & 0 & 0 & 5 & 0 \\ 5 & 5 & 0 & 5 & 4 \\ 0 & 5 & 4 & 0 & 3 \\ 5 & 3 & 5 & 5 & 4 \\ 4 & 0 & 4 & 3 & 0 \end{bmatrix} \end{matrix}. \quad (17)$$

Among them, $\overline{R_1} = 3.67, \overline{R_2} = 2.83, \overline{R_3} = 2.67, \overline{R_4} = 3.0, \overline{R_5} = 1.83$. The users who jointly commented on service 1 and service 2 are u_1, u_2, u_4, so $\delta(r_1, r_2)$ can be calculated by the following formula:

$$\delta(r_1, r_2) = \frac{\sum_{i \in I_{12}} (R_{i1} - \overline{R_1})(R_{i2} - \overline{R_2})}{\sqrt{\sum_{i \in I_{12}} (R_{i1} - \overline{R}_1)^2} \sqrt{\sum_{i \in I_{12}} (R_{i2} - \overline{R}_2)^2}}$$

$$= \frac{(5 - 3.67) \times (5 - 2.83) + (4 - 3.67) \times (4 - 2.83) + (5 - 3.67) \times (3 - 2.83)}{\sqrt{(5 - 3.67)^2 + (4 - 3.67)^2 + (5 - 3.67)^2} \times \sqrt{(5 - 2.83)^2 + (4 - 2.83)^2 + (3 - 2.83)^2}} \tag{18}$$

$$= 0.7413.$$

Furthermore, the calculation process of $\delta(r_1, r_3), \delta(r_1, r_4)$, and $\delta(r_1, r_5)$ is as follows:

$$\delta(r_1, r_3) = \frac{(4 - 3.67)(4 - 2.67) + (5 - 3.67)(5 - 2.67) + (4 - 3.67)(4 - 2.67)}{\sqrt{(4 - 3.67)^2 + (5 - 3.67)^2 + (4 - 3.67)^2} \times \sqrt{(4 - 2.67)^2 + (5 - 2.67)^2 + (4 - 2.67)^2}} = 0.9422,$$

$$\delta(r_1, r_4) = \frac{(4 - 3.67) \times (5 - 3) + (5 - 3.67) \times (5 - 3) + (5 - 3.67) \times (5 - 3) + (4 - 3.67) \times (3 - 3)}{\sqrt{(4 - 3.67)^2 + (5 - 3.67)^2 + (v)^2 + (4 - 3.67)^2} \times \sqrt{(5 - 3)^2 + (5 - 3)^2 + (5 - 3)^2 + 0}} = 0.8908, \tag{19}$$

$$\delta(r_1, r_5) = \frac{(5 - 3.67) \times (4 - 1.83) + (4 - 3.67) \times (3 - 1.83) + (5 - 3.67) \times (4 - 1.83)}{\sqrt{(5 - 3.67)^2 + (4 - 3.67)^2 + (5 - 3.67)^2} \times \sqrt{(4 - 1.83)^2 + (3 - 1.83)^2 + (4 - 1.83)^2}} = 0.9819,$$

where $\delta(r_1, r_5) > \delta(r_1, r_3) > \delta(r_1, r_4)\delta(r_1, r_2)$ is sorted according to the service similarity value. And the active service push list is shown in Table 1.

Therefore, according to the service push data in Table 1, if user u_0 is the active service push object, service 5 and service 3 will be pushed preferentially.

4. Experimental Analysis

4.1. Experimental Environment and Data. Experimental data set is a user data resource, which is obtained through the API interface provided by the official platform of China Machinery Network. In this paper, the web crawler software developed by myself crawls more than ten official users selected initially and extends other user data according to these users, realizing layer-by-layer crawler and deep mining. By the time of simulation analysis, about 830 users had been mined and recorded, who posted more than 200,000 SMS messages. In the face of such a large data set involving all aspects of society, it is crucial to correctly identify valid and invalid data. First, the distribution of the amount of text information published by these users is graphically described as follows.

As shown in Figure 3, the number of SMS messages sent by users is close to 248, and the number of similar users in this range is 478. When fewer than 200 messages were posted, the number of received messages dropped sharply, with the lowest users posting only about six messages. For example, the more detailed the user's information, the more accurate the classification of the user's interest characteristics, and vice versa. Therefore, in subsequent experimental tests, users with less information need to be

filtered to improve the accuracy of user interest feature classification.

4.2. Experimental Evaluation Method. After the implementation of user clustering and service active push operation, this paper adopts the classic mean absolute error (MAE) as the measurement index to evaluate the accuracy of the recommendation system to verify its accuracy. MAE is an effective measure to evaluate the difference between the predicted score and the real score. Its basic idea is to calculate the difference between the predicted score and the real score and absolute value. After the absolute value operation, the evaluation indexes are all positive numbers, which avoids the offset between positive and negative values so as to reflect the deviation of predicted value error from the real score value to the greatest extent. The mathematical formula of MAE is defined as follows:

$$\text{MAE} = \frac{1}{N} \sum |P_{ij} - R_{ij}|. \tag{20}$$

In (17), N represents the sum of the scores predicted by the test, P_{ij} represents the predicted score value of user i for service j, R_{ij} represents the real score of user i for service j. According to (17), the smaller the MAE value is, the smaller the predicted value error is and the higher the accuracy of recommendation is, and vice versa.

4.3. Experimental Analysis

4.3.1. Data Dimension Reduction. Section 3.2 introduces the processing method of interest subject database information

Table 1: Active service push list.

Push sequence sort	Service type	Service evaluation
1	r_5 (service 5)	0.9819
2	r_3 (service 3)	0.9422
3	r_4 (service 4)	0.8908
4	r_2 (service 2)	0.7413

and user text information in detail, and we obtain the interest eigenvalue vector of each user. In Section 4.3.2, the multi-Markov chain model is established to convert the eigenvalue vector of each user's interest into a unique corresponding state transition matrix, whose dimension is 624×624. Because each user has a unique Markov chain state transition matrix and the matrix dimension is 624×624, the clustering calculation will produce repeated data calculation and data dimension disaster, which will greatly affect the calculation efficiency. To sum up, in order to reduce the server load and improve the efficiency of calculation, this paper needs before the user clustering for all users of the Markov chain state transition matrix PCA (Principal Component Analysis) dimensionality reduction. The advantages of PCA dimension reduction are as follows: (1) data dimension reduction can alleviate dimensional disasters; (2) data dimension reduction can minimize information loss while compressing data; (3) the structure of data after dimensionality reduction is easier to understand through visualization. In short, the operation essence of PCA is to map the original data to the low-latitude numerical space through a series of numerical linear transformations under the premise that the characteristics and attributes of the original data are not damaged as much as possible. Figure 4 is the Pareto figure of user state transition matrix.

4.3.2. User Clustering.

As described in Section 4.2, the accuracy of the user clustering effect in the early stage is directly related to the accuracy of user-service active push in the later stage. The clustering of users with the same or similar interest characteristics can increase the accuracy of the later service's active push. Therefore, this section mainly discusses the user clustering effects of the two methods. This paper adopts two methods to realize user clustering: (1) enhanced learning method in machine learning to realize user clustering, namely, multi-Markov chain model clustering method introduced in Section 3 (m-MCM clustering); (2) the unsupervised learning method in machine learning that realizes the clustering of users, namely, the classical K-means clustering method, the implementation of which is provided by Weka software. After user data processing, user clustering results are shown in Table 2.

As can be seen from Table 2, different clustering methods can obtain different clustering results; that is, there will be some deviation in the amount of clustering for each type of user. However, it is difficult to judge which clustering method has a better clustering effect only based on the data in Table 2. Therefore, Figures 5 and 6 are used to show the clustering situation of the K-means method and the

user, a group of users with the same or similar characteristics of interest.

By observing Figures 5 and 6, it can be found that the scattered noise points in the two images make the clustering effect picture very messy, and it is difficult to clearly distinguish the distribution of clustering users. These noise points are caused by the users with less published information mentioned in Section 3.10. Because the data of these users are less, it is difficult to accurately identify their interests, so they become noise points in the clustering effect figure. Because of these scattered noise points, it is difficult to distinguish the clustering of users accurately. At the same time, noise points will greatly reduce the accuracy of user clustering and affect the clustering effect. Therefore, noise point denoising is also adopted in this paper; that is, users with less data are deleted in advance. The user clustering effect figure after denoising is shown in Figures 7 and 8.

After denoising, Figures 7 and 8 show an obvious improvement in user clustering effect compared with Figures 5 and 6 without denoising. Although there are still noise points in Figures 7 and 8, the clustering of users can be distinguished, so the existence of some noise points is acceptable and within the error range. However, through observation, it can be found that there are significant differences in the user clustering effect in Figures 7 and 8. These differences come from the following: (1) In Figures 7 and 8, the clearance between cluster and the cluster is bigger, and it shows that other users have been spun off the accurate

segmentation. On the contrary, in Figure 7, the gap between clusters is very small, and some clusters are even closely connected, which makes it difficult for us to determine which cluster these points close to the boundary belong to. Therefore, the m-MCM method has a better user clustering effect than the *K*-means method in the gap comparison between clusters and families. (2) As shown in Figure 8, within each family, the distance between points is mostly compact. On the contrary, in Figure 7, the distance between points inside each cluster is too scattered, which makes it difficult for us to distinguish some close clusters and determine whether this cluster is an aggregation of one category cluster or multiple category clusters. Therefore, the m-MCM method has a better user clustering effect than the K-means method in terms of gap comparison within clusters. (3) According to the clustering distribution in Figure 8, we can accurately divide the distribution of 20 types of user interest characteristics. On the contrary, according to the clustering effect in Figure 7, we can only roughly distinguish the user clustering distribution of 18 categories, which is a little deviation from the 20 categories of interest subject database that we set in advance.

In addition, Figure 9 lists the comparison figure of clustering time consuming of *K*-means method and m-MCM method. The figure shows that the clustering time
FIGURE 9: Comparison of clustering time between *K*-means method and m-MCM method.

No clustering method

K-means method clustering

M-mcm method clustering
FIGURE 10: MAE under different clustering methods.

of the m-MCM method is 3416 seconds, while that of the *K*-means method is 1431 seconds; that is, the clustering time required by the m-MCM method is about two times that of the *K*-means method. The m-MCM method is not dominant in the time consumed by clustering because the m-MCM method needs to repeatedly calculate the similarity between two Markov chains corresponding to 830 users in clustering. Therefore, although m-MCM clustering has a good clustering effect, it takes a huge amount of time.

To sum up, the m-MCM method is better than the *K*-means method in the user clustering effect. The m-MCM method can relatively accurately determine the interest category to which users belong and accurately define the boundary between classification and class, but it takes more

time. If the m-MCM method is applied to the active push of user service, the accuracy of push can be greatly improved.

4.4. Verification of Collaborative Filtering Recommendation Method Based on User Score Clustering. In order to verify the conjecture that the clustering operation in the early stage has a significant impact on the collaborative recommendation in the later stage, a series of simulation experiments are conducted to compare and evaluate the correctness of the conjecture based on the experimental results. Before the beginning of the experiment, the evaluation method of the experiment, data sources, and preprocessing methods should be explained in advance: (1) The evaluation method

of the experiment is measured by MAE in Section 4.2. The smaller the MAE is, the higher the accuracy of the recommendation is. (2) The experimental evaluation results were measured according to the MAE value of each category. (3) The actual score in the experiment comes from the user's "user-service" evaluation matrix, while the predicted score is the service score calculated by the "user-service" evaluation model. (4) The scoring data of the experiment is about 160,000 service scoring data of 830 users in the social manufacturing platform. (5) The extended service set shall be considered after user clustering. If the original user does not have this service, the score of the extended service shall be set as 0. If the original user has a score for this service score, it will be added to the "user-service" evaluation matrix according to the original service score. As described in the previous chapter, the better and more accurate the user clustering effect in the early stage, the higher the accuracy of user-service push in the later stage. Therefore, three small experiments are designed in this section to verify this assumption: (1) without user clustering, collaborative filtering recommendation is carried out directly for users; (2) cluster users by K-means method, and then make collaborative filtering recommendation; (3) cluster users using the m-MCM method, and then make collaborative filtering recommendation. Experimental evaluation results are shown in Figure 10.

Through the analysis of Figure 10, the following conclusions can be drawn: (1) MAE value obtained by the nonclustering method is much larger than the MAE value obtained by the clustering method; that is, the accuracy of service push can be greatly improved by clustering users first and then actively pushing service to users. (2) The MAE value obtained by clustering with the m-MCM method is smaller than that obtained by clustering with the K-means method. In other words, different methods of clustering users will result in different accuracy of service push. At the same time, the better the clustering effect, the higher the accuracy of service push. (3) In comparison with MAE values of certain categories, the MAE values obtained by K-means clustering are smaller than those obtained by m-MCM clustering, which indicates that K-means clustering is also advantageous in some fields. If different clustering methods can be reasonably used in different fields to actively push users' services, in this way, a more precise and active service push effect can be achieved, which also provides a new research idea for future research. (4) As mentioned above, the user clustering takes a quantity, and the m-MCM method of clustering is not dominant. However, the time spent by M-MCM method is almost twice that of K-means method, but in return, the service push accuracy of M-MCM method is also close to twice that of K-means, and higher accuracy of service push will also consume more time. Therefore, these costs are acceptable in terms of time.

5. Summary and Discussion

The experiment in Section 4.2 implements user clustering and active service push. On this basis, the experiment also compares the clustering effect of the K-means method and the m-MCM method, as well as the accuracy of active service push. The experiment draws the following conclusions: (1) Cluster analysis of users before collaborative filtering can greatly improve the accuracy of active service push. (2) Different user clustering methods lead to different active service push. If the user clustering effect is better, the accuracy of the service push will be higher. Through experimental verification, this paper concludes that the clustering effect of the m-MCM method is better than that of the K-means method, and the accuracy of the clustering effect of the m-MCM method is better than the accuracy of service push after K-means method clustering. (3) In the early stage, spending more time on user clustering can improve the accuracy of the cluster, which is of great help to the later active service push. Since this paper constructed the active service push system for the first time, the experiment in Section 4.2 only preliminarily completed the basic architecture of active service push. In the future, the push system should be further updated and improved in the following aspects: (1) Reduce the clustering analysis time in the early stage of the push system and improve the clustering accuracy without reducing the user clustering effect. (2) A combination of multiple clustering methods is adopted to conduct cluster analysis on users so as to improve the speed and accuracy of cluster analysis and lay a good foundation for later service push. (3) The establishment of a more perfect "user-service" evaluation model can more accurately realize personalized service recommendation for users, thus improving the accuracy of service push by users.

Retracted: Application of Improved DEA Algorithm in Public Management Problem Classification

Computational Intelligence and Neuroscience

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

1. Discrepancies in scope
2. Discrepancies in the description of the research reported
3. Discrepancies between the availability of data and the research described
4. Inappropriate citations
5. Incoherent, meaningless and/or irrelevant content included in the article
6. Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

In order to effectively solve the related problems in the process of public management, this research proposes an improved algorithm technology based on Data Envelopment Analysis (DEA) and classification algorithm. With the help of lever management, this paper further solves and overcomes the problem of DEA algorithm itself and the defect of "relative effectiveness." At the same time, in order to avoid the impact on the input and output indicators, with the help of principal component analysis, taking the performance evaluation of public management departments as the research direction, this paper makes an empirical analysis on the performance evaluation of public management departments. The evaluation results of the index system show that the correlation coefficient between the efficiency value of the initial index system and the efficiency value of optimization 2 is 0.977759, and the correlation coefficient is less than 0.7. The evaluation results are more reasonable than those before the improvement.

1. Introduction

In recent years, with the continuous development of the market economy, the social governance structure has been continuously improved, and the pace of social governance has been gradually accelerated. As an important part of the process of social governance, the importance of public management is becoming more and more obvious. The so-called public management is the scientific management of public affairs, which includes the management of the government, administrative management, urban management, and other aspects. With the continuous deepening and development of public management in China, some major contradictions and problems begin to appear [1]. Such problems as insufficient practical operation means, insufficient governance ability, poor organizational personnel quality, and public management personnel training have seriously affected the improvement of the quality of public management [2–4]. This study is based on these issues, through the integration of Improved DEA algorithm to further improve the public management evaluation system.

On the basis of summarizing the above, foreign scholars elaborated the interaction between the transformation of government functions and the implementation of cultural policies. Xue put forward that only by adopting the overall governance mode, crossing over the administrative settings of each department, and realizing "horizontal" cross departmental cooperation can cultural services be truly implemented; otherwise, it will only be "a piece of empty talk" [5]; Zhao believes that the characteristic of cultural output is that with the growth of the national economy, the wage rate of the government's cultural department develops with other departments. However, due to the labor-intensive output, it is difficult for the productivity to keep pace with the wage growth rate, resulting in an increase in the cost of cultural input, which eventually leads to a doubling of public cultural expenditure [6]; Chen proposed that through the joint investment of the government and local cultural institutions, public cultural services can achieve twice the result with half the effort, and cause the domino effect, bringing more investment to cultural undertakings; joint investment requires both sides to express their own views and reach unity through consultation based on the principle

of mutual cooperation and communication. Such a model is conducive to the diversity and innovation of public cultural development [7]; Ma European cultural identity, which involves ethnic and regional identity in a broader sense, is a model of self-understanding through which individuals, groups, and societies define themselves and their relationships with others. This changing relationship, in turn, will affect the change of self-understanding, that is, the difference in government system and environment will lead to the change of cultural identity [8].

In general, the lack of specialized research on the state of foreign service culture also means that research on the development of China's cultural service needs to be improved renewed in thought and action.

In China, DEA has been applied in many fields. National cotton mills, industryers, and smelters use the DEA method to evaluate the performance of companies and deliver the results to the actual department, which has been praised by stakeholders affected. The National Academic Association approached the DEA to evaluate its effectiveness, which was favored by many. The DEA is a great way to learn about the human resources and potential of coal production in China. Some scholars use the DEA method to determine that "finance is the most important factor affecting the performance of China's high-tech industry and human technology" [9]. He hoped that China's high-tech industry will continue to benefit from the application of science and technology of human resources in the field of performance measurement, innovation baking, and financial management. Some researchers have used the best data shell model to measure the performance of listed companies in the coal industry and estimate the market share and product shortages in the decision-making. They believe that the production efficiency

of most listed coal enterprises is acceptable, but there are great individual differences. Many enterprises still have great room for improvement and put forward suggestions to the administrative departments [10].

2. Improved DEA Algorithm and Classification Algorithm

2.1. Improved DEA Algorithm and Its Application. There are designated decision-making units (DMUs) and design solutions (SU). Their sampling units and components have the same M input and output characteristics, and the input parameters and output parameters are as follows:

$$x_p = \left(x_{1p}, x_{2p}, \ldots, x_{mp}\right)^T, \tag{1}$$

$$y_p = \left(y_{1p}, y_{2p}, \ldots, y_{sp}\right)^T, \tag{2}$$

$$x_j = \left(x_{1j}, x_{2j}, \ldots, \overline{x}_{mj}\right)^T, \tag{3}$$

$$y_j = \left(y_{1j}, y_{2j}, \ldots, \overline{y}_{sj}\right)^T, \tag{4}$$

where equation (1) represents the value of the determination p, which includes the value of the measure; equation (2) represents the value of the p-order, resulting in the measured value; equation (3) represents the value of the jth cell at the input index value; equation (4) represents the value of the jth model unit of the output index value [11].

First, the production possibility set $T(1)$ determined by the sample unit set is expressed as follows under the condition that the axiom system of the production possibility set of the sample unit and the decision-making unit is satisfied:

$$T(1) = \left\{(x, y) \mid x \geq \sum_{j=1}^{\overline{n}} \overline{x}_j \lambda_j, y \leq \sum_{j=1}^{\overline{n}} \overline{y}_j \lambda_j, \delta \sum_{j=1}^{\overline{n}} \lambda_j = \delta, \lambda = \left(\lambda_1, \ldots, \lambda_{\overline{n}}\right) \geq 0\right\}, \tag{5}$$

where $(\overline{x}_j, \overline{y}_j)$ indicates the input and output status in the sample cell set. The input indicator reflects the consumed resources and is also the input data. The output indicator reflects the effectiveness and is the output data. According to the construction method of production frontier, the effective frontier of sample production possibility set $T(1)$ is as follows:

Assumption 1

$$\overline{\omega}, \overline{\mu}, \overline{\mu}_0 \text{ meet } \overline{\omega} > 0, \overline{\mu} > 0. \tag{6}$$

Hyperplane composed simultaneously:

$$L = \left\{(x, y) \mid \omega^{-T} x - \mu^{-T} y - \delta \overline{\mu}_0 = 0\right\}. \tag{7}$$

Meet the following set:

$$T(1) \subset \left\{(x, y) \mid \widehat{\omega}^T x - \widehat{\mu}^T y - \delta \widehat{\mu}_0 \geq 0\right\}, L \cap T(1) \neq \varphi, \tag{8}$$

Then, the set represented by L is the effective surface of the sample possibility set $T(1)$, and the intersection $L \cap T(1)$ is the effective frontier of the sample possibility set $T(1)$.

There are now n decision-making units (DMUs) to be evaluated and n sample units selected. Both DMU and sample units have m input and s output indicators, which are expressed as follows:

$$x_p = \left(x_{1p}, x_{2p}, \ldots, x_{mp}\right)^T > 0, \tag{9}$$

$$y_p = \left(y_{1p}, y_{2p}, \ldots, y_{sp}\right)^T > 0, \tag{10}$$

$$x_j = \left(x_{1j}, x_{2j}, \ldots, \overline{x}_{mj}\right)^T > 0, \tag{11}$$

$$y_j = \left(y_{1j}, y_{2j}, \ldots, \overline{y}_{sj}\right)^T > 0, \tag{12}$$

Here, equation (9) represents the value of the input index and p is the unit value of the decision; formula (10) represents the output value and the unit value determined by p; formula (11) represents the value of the input index and the cell value of model j; formula (12) represents the output value and the j-type cell value [12].

The generalized CCR model for decision unit p is as follows:

$$\left(G - C^2R\right) \begin{cases} \text{Maximize } \mu^T y_p = V(d), \\[1ex] s.t\ \omega^T \overline{x}_j - \mu^T \mathrm{d}\overline{y}_j \geq 0, j = 1, \ldots, \overline{m}, \\[1ex] \omega^T x_p = 1, \\[1ex] \mu, \omega \geq 0, r = 1, \ldots, s; i = 1, \ldots, m, \end{cases} \quad (13)$$

where

$$\omega = (\omega_1, \omega_2, \ldots, \omega_m)^T, \quad (14)$$

$$\mu = (\mu_1, \mu_2, \ldots, \mu_s)^T. \quad (15)$$

Equation (14) represents the input index weight of the selected sample unit, equation (15) represents the output index weight of the selected sample unit, and D is a moving factor greater than 0.

The dual problem model of the generalized model can be expressed as follows:

$$\left(DG - C^2R\right) \begin{cases} \min \theta = D(d), \\[1ex] s.t \sum_{j=1}^{\overline{n}} \overline{x}_j \lambda_j \leq \theta x_p, \\[1ex] \sum_{j=1}^{\overline{n}} d\overline{y}_j \lambda_j \geq y_p, \\[1ex] \lambda_j \geq 0, j = 1, 2, \ldots, \overline{n}. \end{cases} \quad (16)$$

The above formula can prove that $(G - C^2R)$ has an optimal solution.

2.2. Linear Separable Support Vector Classifier. Firstly, Lagrange function is introduced.

$$L(w, b, \alpha) = \frac{1}{2}\|w\|^2 - \sum_{i=1}^{l} \alpha_i \left(y_i\left((w \cdot x_i) + b\right) - 1\right), \quad (17)$$

where

$$\alpha = (\alpha_1, \ldots, \alpha_l)^T \in R_+^l. \quad (18)$$

The above formula is Lagrange multiplier. From the definition of duality, we can know that the minimum value of Lagrange function with respect to w, b must be obtained first. By extreme condition,

$$\Delta_b L(w, b, \alpha) = 0, \Delta_w L(w, b, \alpha) = 0. \quad (19)$$

This leads to

$$\sum_{i=1}^{l} y_i \alpha_i = 0. \quad (20)$$

$$w = \sum_{i=1}^{l} y_i \alpha_i x_i. \quad (21)$$

Bring equation (20) into equation (17) and use equation (21) to know that the dual problem of the original optimization problem can be expressed as

$$\max_{\alpha} -\frac{1}{2} \sum_{i=1}^{l} \sum_{j=1}^{l} y_i y_j \alpha_i \alpha_j \left(x_i \cdot x_j\right) + \sum_{j=1}^{l} \alpha_j. \quad (22)$$

$$s.t. \sum_{i=1}^{l} y_i \alpha_i = 0\ \alpha_i \geq 0, i = 1, \ldots, l. \quad (23)$$

The algorithm we want can be obtained by converting the objective function into minimization.

3. Performance Evaluation of Public Management Cultural Service Classification Based on Improved DEA Algorithm

3.1. Construction of Index System. We check the impact of indicators on museum performance evaluation according to the commonality of specific indicators. The greater the degree of commonality, the greater the degree of common dependence of the index on the common factor, that is, it is relatively effective to use this common factor to explain the index. Correlation analysis is required before analysis [13]. Generally, the higher the correlation coefficient, the closer the relationship between the two index items. Generally speaking, above 0.7 can be understood as relatively high. By taking the data of 31 provinces in China from 2018 to 2021 as the sample data (124 sample data), after standardized processing, Spss21.0 was run to calculate the common factor, and the following results (Tables 1 to 4) were obtained [14].

The analysis results of gravel diagram are shown in Figure 1.

Sample data passed KMO test. The higher the KMO value, the greater the significance of the changes and the greater the need for analysis. The chart shows that the KMO value is 0.879, indicating that the index is appropriate for analysis. In general, it is shown in Figure 1. Three indicators have been omitted due to differences in three indicators returned this year: cultural monuments, important artifacts, and the number of patents are less than 0.3. Go back to another measurement to get a performance measurement in time. Based on collaborations and releases, 10 museum performance measures were performed as shown in Table 5 [15].

It is scientific and innovative to use factor analysis to select the evaluation indicators of museums. Factor analysis is used to enhance the accuracy and objectivity of the index system [16]. In the actual operation of the museum, there are

many and complex achievement indicators, but too many indicators are easy to form mutual interference between indicators, and it is difficult to find more accurate original data. Factor analysis method is used to eliminate some unnecessary and redundant indicators to achieve the purpose of simplification and optimization.

3.2. Performance Evaluation of Public Cultural Services Based on Methods

3.2.1. Optimization of Input and Output Indexes Based on DEA Method. DEA method is based on known data sets, so the evaluation results directly depend on the selection of input and output indicators. In the chapter, the index system is constructed theoretically and scientifically, but the principle of the method itself on the data is not fully considered. Therefore, the index system should be analyzed from the perspective before performance evaluation. From the perspective of DEA application, the selection of DEA indicators should follow the following basic principles:

Objective measurement. When selecting a measuring device, whether the measurement objective can be achieved, i.e., the choice of the measuring device, the output measurement should be consistent with the functional and objective measurement. Objective assessment requires a variety of materials and tools to describe the whole process [17].

Number of events. Determine the number of units of measurement. Numerous input and output parameters can increase the number of positives, thereby reducing the effectiveness of the DEA method. Measurements should be

kept as simple as possible at the target location. Some researchers believe that all input and output measures should not exceed 1/3 of the scoring sequence [18].

Relevance. Considering the relationship between input indicators and output indicators, the inputs and outputs of DMU are often not isolated [19]. When there is a strong linear correlation between an input indicator and other input indicators, it can be considered that the information of the indicator has been included by other indicators to a large extent, so it can be considered to exclude the input indicator. The same is true for output indicators. This will also lead to more DEA-effective units and affect the evaluation results.

Diversity. Since the core work of the method is "evaluation," there are generally different aspects under a large evaluation objective. The diversity of input and output indicator systems should be considered [20]. Then, on the premise of determining the evaluation objective, multiple input and output indicator systems should be designed, such as from multiple indicators to fewer indicators, to observe which indicators have the greatest impact on the effectiveness value or design similar but different index systems to reflect different aspects of the evaluation.

	Number of visitors
	Number of completed projects
	Minor visitors

The specific process is as follows: calculate the effective value of each decision-making unit through the practice index system and then calculate the effective value of each decision-making unit through the optimization index system that specifically reflects the evaluation purpose. Finally, the correlation coefficients of the two sets of effective values are calculated. If there is no significant correlation between the effective values calculated by the

two index systems, it can be considered that the optimization index system is not comprehensive. On the contrary, if the correlation is significant, it indicates that the optimized index system can replace the previous index system for performance evaluation analysis [21]. The steps are as follows:

Step 1: determine the practice index system and preliminarily evaluate each decision-making unit; Step 2: optimize the index system based on principles and criteria and conduct preliminary evaluation on each decision-making unit; Step 3: calculate the correlation of the effectiveness values of the two sets of index systems obtained by the method and use the above criteria to judge the comprehensiveness and equivalence of the two sets of index systems so as to form a relatively accurate index system.

3.2.2. Principle of Determining Index Weight

(1) The principle of system optimization. In the evaluation index system, each index has its role and contribution to the system and has its importance to the system. Therefore, the determination of index weight should not only start from a certain index but should consider comprehensively, deal with the relationship between the evaluation indexes, and reasonably allocate their weights. We should follow the principle of system optimization and take the overall optimization as the starting point and goal. Under the guidance of this principle, analyze and compare each evaluation index in the evaluation index system, weigh their respective roles and effects on the whole, and then judge their relative importance. Determine their respective weights, that is, they cannot be evenly distributed, nor can they unilaterally emphasize the optimization of a certain index or a single index while ignoring the development of other aspects. In practice, each indicator should play its due role.

(2) The principle of combining the subjective intention of the evaluator with the objective situation. The weight of the evaluation index reflects the guiding intention and values of the evaluator and the organization. When they feel that a certain indicator is very important and need to highlight its role, they must use a larger weight for each indicator. However, the actual situation is often not completely consistent with people's subjective will. For example, when determining the weight, we should consider the following issues: historical indicators and realistic indicators, recognized by the society and the particularity of the enterprise, and balance between the same industry and the same type of work. Therefore, we must consider the reality at the same time and combine the guiding intention with the reality. As mentioned earlier, economic and social benefits should be considered simultaneously in evaluating the performance of public cultural services.

(3) The principle of combining democracy with centralism. Weight is people's understanding of the importance of evaluation indicators, is the quantification of qualitative judgment, and is often affected by personal subjective factors. Different people have their own views on the same thing, and they are often different, in which there are reasonable elements. Of course, there are also prejudices caused by personal values, abilities, and attitudes. This requires the implementation of the principle of group decision-making, integrating the opinions of relevant personnel to complement each other and form a unified plan. This process has the following advantages: considering problems comprehensively, making the weight distribution more reasonable, and preventing individuals from understanding and dealing with problems unilaterally. It objectively coordinates the contradictions of different opinions among the evaluation parties. The scheme determined through discussion, consultation, and investigation of various specific situations is very persuasive and eliminates many unnecessary disputes in advance. This is a mode of participating in management. During the discussion of the scheme, all parties put forward their own opinions and have further experience and understanding of the evaluation objectives and system objectives. In daily work, they can better work according to the original objectives [22].

The standard values of qualitative indicators are different from those of quantitative indicators, which are easy to collect. They are generally obtained through the following methods:

(1) Expert experience. Expert experience refers to the experience of experts in judging the performance of the public resource supply based on their own experience, combining the political and economic development situation at that time, as well as the economic and social benefits generated by similar projects, units, or departments using similar funds in previous years, and combining certain domestic and foreign experience.

The questionnaire test establishes qualitative standards through public judgment for some indicators related to public satisfaction and expenditure targets to be achieved.

(2) Horizontal comparison. Make a comprehensive comparison of the results achieved by the supply performance of similar public goods at home and abroad. Of course, with the continuous progress of science and technology in human society, new technologies and methods will continue to emerge, and some qualitative indicators that are difficult to quantify will be gradually quantified or accurately grasped.

3.2.3. Performance Evaluation Method System of Public Cultural Services. When engaging in any work, we must understand the methods. As the resource input of public cultural services depends on the government and financial input, the output mainly depends on the public's awareness and satisfaction with culture. As a result, the competition mechanism in the whole field is not strong, and public cultural services are difficult to quantify. In particular, the public cultural services studied in this paper are

difficult to measure by market means. In addition, the authenticity and comparability of data in the field of cultural public services and the difficulty in quantifying most of the achievements of cultural services make it difficult to measure the performance of the public sector. Despite this, people still try to apply various advanced methods to the performance evaluation of public cultural services. The main methods are as follows:

(1) Performance evaluation table method. The performance evaluation table method, also known as the scoring table method, should be said to be an early method. It mainly uses the relevant performance factors formulated by the government to evaluate the performance of the work (such as the number of annual visitors to the museum and the number of books lent out). Compare and score the work performance with the relevant factors one by one and then get the overall results of the work performance. According to the results, it is classified into four levels: excellent, good, qualified, and unqualified.

(2) Management by objectives. It is the most typical result-oriented performance evaluation method. At that time, the objective management method was widely used. The evaluation object of the objective management method was mainly the work performance of employees, that is, focusing on the completion of objectives. Through this method, employees could be promoted to work towards objectives to a certain extent.

(3) Key performance indicator method. The theoretical basis of the process of measuring performance is based on the "February 8 principle" stated by Italian scientist Pareto. In the process of establishing the business value, it is believed that 80% of the work of each department and staff do 20% of the simple behavior, and this 20% capture will understand all. Along with these concepts, key indicators such as feedback and benefits of the organization's internal processes are identified, modeled, accounted for, evaluated, and implemented, and goals of the industry have exploded. This way, it is possible to clearly identify the key roles of responsibility to the director of the company and to develop standards of performance for the employees in the department.

(4) Data envelopment analysis method. Data envelopment analysis (DEA) is developed on the basis of the theory of "relative efficiency evaluation." Its core idea is to estimate the frontier of effective production by observing a group of values about input and output. It is applicable to the effectiveness evaluation of multiple decision-making units with the same type of multiple inputs and outputs. DEA has obvious advantages in efficiency evaluation: first, in the process of evaluation, only input indicators and output indicators need to be determined, without constructing specific production functions or models; secondly, it is suitable for complex objective evaluation with multiple inputs and outputs; then, this method does not require the dimension of the indicators. As long as a specific indicator of the decision-making unit uses the same dimension, the original data can be directly analyzed. The above advantages of DEA method can just meet the requirements of efficiency evaluation of public cultural services. First of all, the government's human, financial, and material inputs in various branches of public cultural services are eventually transformed into various specific public goods and services. Generally, we can only determine which outputs are related to inputs. As for the transformation relationship behind it, it is difficult to quantify and measure in reality; secondly, public cultural services cover a wide range, which belongs to a typical multi-input and multi-output situation.; Moreover, it is inconvenient or impossible to measure the input and output of public cultural service supply in terms of money or some other specific dimension in many cases, and DEA can just avoid this point. Therefore, the DEA method will have a broad application prospect in evaluating the efficiency of government supply of public goods. This paper is also based on this discussion.

3.2.4. Classification Performance Evaluation of Public Cultural Services Based on C^2R Model. First of all, according to the important position of museums, public libraries, and mass art centers in public cultural services, the practice index system has been established according to the fifth chapter. Then, according to the optimization idea of input and output indicators based on DEA method, the practice indicator system is optimized to form a new indicator system, and the performance structure model diagram of public cultural services is constructed as shown in Figure 2.

Finally, two sets of index systems are input through model C^2R for operation to form the corresponding performance evaluation result analysis. The flow chart of public cultural service classification performance evaluation based on C^2R model is shown in Figure 3.

4. Performance Evaluation of Public Cultural Service Classification Based on C^2R Model

4.1. Determination of Input and Output Indicators. The indicator system constructed according to the above is shown in Table 6.

According to the optimization of input and output indicators of the above DEA method, since the employees' indicators already include the indicators of senior employees, the senior employees are eliminated from the perspective of simplification. Similarly, the actual use of the housing area index already includes the exhibition room index, so the exhibition room is excluded. In the output indicators, the number of visits by minors has been reflected in the number of visitors, so the number of minor visits is excluded. The index system after comprehensive optimization is shown in Table 7.

C^2R model is used to calculate the data of the two groups of index systems, and the efficiency value is obtained as shown in Table 8.

	Number of completed projects

It cannot be found from the table that the optimized index system has a great impact on some regions, in which the effective value of Beijing is reduced from relatively effective 1 to 0.48, which indicates that the index items subject to subdivision have a great impact on the performance value [23]. The correlation coefficient obtained from the correlation test of the effective values corresponding to the two groups of index systems is 0.644816.

30	Ningxia Hui autonomous region	0.568312	0.561783341
31	Xinjiang Uygur autonomous region	0.795216	0.703376021

We believe that if the correlation coefficient is greater than 0.7, then our optimized index system cannot replace the original index system. Therefore, it is necessary to further optimize the practice performance evaluation indicators, find out which indicator system has a greater impact, and conduct correlation analysis on the original indicator system as shown in Table 9.

The removed senior staff and exhibition rooms are highly correlated, and the correlation value between the number of collections and other indicators is mostly below 0.7. Therefore, the optimization indicators are re-optimized as shown in Table 10.

C^2R model is used to calculate the data of the two groups of indicator systems, and the effective values obtained are shown in Table 11. The correlation coefficient obtained from the correlation test of the effective values corresponding to the two groups of index systems is 0.903433. We believe that if the correlation coefficient is greater than 0.7, then our secondary optimized index system cannot replace the original index system. Through the optimization of indicators, the indicators after the secondary optimization of museum performance evaluation can relatively comprehensively represent the

indicators of museum performance evaluation. The following analysis is also based on the indicators after the secondary optimization.

4.2. Performance Evaluation Analysis. In the previous section, the efficiency values of provinces are calculated according to the evaluation secondary optimization indicators. After processing, see Figure 4.

The overall service efficiency of national museums will be moderate in 2020. The efficiency level of the national evaluation is 0.870559, and the overall efficiency is moderate. This has something to do with the country's great investment in public cultural undertakings in recent years. However, there are some regions with low efficiency and relatively poor efficiency in Xinjiang and Ningxia. The projection analysis is shown in Table 12, and the investment needs to be adjusted. Through the above index adjustment, we can also find that the number of collections is a very important index item for museums. In the future construction and development of museums, museums should devote more energy to how to enrich the number of collections in museums.

31	Xinjiang Uygur autonomous region	0.795516	0.703376061

The regional characteristics of museum performance evaluation are obvious. Among the 31 provinces, autonomous regions, and municipalities directly under the central government in the mainland of China, 14 regions' museum performance is efficient compared with other regions, including Beijing, Tianjin, Shanghai, Hubei, and Anhui. Liaoning, Ningxia Hui autonomous region, Shaanxi, and Gansu have relatively low-efficiency values. The results show obvious regional characteristics.

The low number of collections is the main reason for the low efficiency in some areas, which has been fully reflected in the process of index optimization. Therefore, to improve the efficiency of museums, on the one hand, it is necessary to increase the number of collections, exhibitions, and other measures, on the other hand, it is necessary to make reasonable allocation in terms of employees, financial allocation, and the actual use of housing area.
Figure 4: Line chart of museum performance evaluation.

5. Conclusion

Based on the improved DEA algorithm, this research puts forward the theoretical framework of public cultural service performance evaluation system. The theoretical framework of performance evaluation system is the key to the government supply of public cultural services. The construction of the public cultural service performance evaluation index system needs to have a clear target, be good at using scientific analysis methods, scientifically measure the validity and reliability of the index system, and design the public cultural service performance evaluation index system according to the objectives, performance dimensions, performance orientation, and other ideas of performance evaluation. C^2R model and superefficiency model in DEA algorithm are innovatively and comprehensively applied to the performance evaluation of government supply of public cultural services. DEA method has many advantages. It determines the attribution of the index system by fitting the path coefficients of each factor in the model through objective data and automatically generates weights. It is suitable for analyzing the performance evaluation of public cultural services. On the basis of collecting a large number of statistical sample data, taking into account the large differences between different types of public cultural services, this paper makes an empirical analysis on the performance appraisal of public management departments with the help of principal component analysis and taking the performance appraisal of public management departments as the research direction. The evaluation results of the index system show that the correlation coefficient between the efficiency value of the initial index system and the efficiency value of optimization 2 is 0.977759, and the correlation coefficient is less than 0.7. The evaluation results are more reasonable than those before

Research Article

Cultural Heritage Resource Development and Industrial Transformation Resource Value Assessment Based on BP Neural Network

Mining and utilizing cultural heritage resources and creating and developing creative and cultural industries have become the priority direction of economic development, setting off a wave of cultural heritage resource development, and industrial transformation. Which cultural heritage resources can have the high value of industrial transformation has become one of the research topics that have attracted much attention. In view of this problem, research is of great significance to the development of cultural heritage resources and the field of industrial transformation. With the in-depth research on resource development and industrial transformation, the research on artificial neural network (ANN) in cultural industry transformation is gradually carried out, and its performance advantages are of great significance to solve the problem of value evaluation. This paper aims to study the application of the value assessment method based on the BP neural network (BPNN) in the development of cultural heritage resources and industrial transformation. Through the analysis and research of BPNN and cultural heritage resource development and industrial transformation, it can be applied to the construction of resource value assessment methods to solve the problem of improving the value level of cultural heritage resource development and industry. This paper analyzes BPNN, cultural heritage, and value evaluation methods, conducts experimental analysis on the performance of the algorithm, and uses related theoretical formulas to explain. The results show that the evaluation method has passed the random consistency test, and the results are valid. The obtained index popularity weight value is 0.134, the economic benefit weight value is 0.093, and the resource correlation degree weight value is 0.074, which can be used as the key criteria for resource value evaluation. The classification of resources through resource value assessment can provide theoretical support for the development and industrialization of cultural heritage and can meet the needs of improving the value and quality of cultural heritage development and industrial transformation, and the development level and satisfaction have been greatly improved.

1. Introduction

Under the upsurge of cultural resources and heritage protection, developers have carried out development and industrial transformation of traditional cultural heritage. In the past, the development of most of the cultural heritage was too blind, and the value generated by the transformation industry was uneven, and it could not meet the increasing demands of people in terms of economic development and artistic aesthetics. Resource value assessment is an evaluation method to assist decision-making to quantify the value of the assessment object, which can solve the problem of comparing the value of different types of resources. Due to its advantages in comparison, it has been applied to various fields to successfully solve various decision-making problems. It quantifies the value of several different types of resources according to the set indicators according to the purpose of evaluation and judges the value of a certain

resource by sorting the calculated values to assist decision-making. In the development of cultural heritage, its content exists in various forms, and how to identify the development value of a large number of cultural heritage resources has far-reaching significance for its development and industrial transformation. ANN is an operation model, which is composed of a large number of nodes connected to each other. However, ANN has a better effect on the value evaluation problem to be solved and has less restriction, so its application range is very wide. In recent years, scholars have used ANN for cultural resource evaluation, but the application and research of BPNN in this area are relatively few. Therefore, it is of great significance to apply BPNN in this paper to solve the research on resource value evaluation in the development of cultural heritage resources and industrial transformation.

At present, with the continuous advancement of the development of cultural heritage, more and more scholars have explored the development and industrial transformation of cultural heritage resources. Among them, in order to solve the problems of insufficient resource integration and serious destruction of cultural heritage, Pang et al. used the geographic information system platform to establish a basic database of historical heritage [1]. Rouhani introduced the protection and development of cultural heritage in peace-building and economic development and put forward his own views on the path of protection of cultural heritage resources in the future [2]. Yi et al. focused on the latest progress of China's national cultural information resource sharing project to understand people's expectations and requirements for cultural heritage development projects [3]. In order to better develop cultural heritage resources, Heitman et al. studied an extensive and centralized repository of cultural heritage information, providing opportunities for research and facilitating the cocreation of a cultural heritage information exchange community [4]. In order to develop smart cultural tourism services, Ruzic identified and sorted cultural heritage resources that appeared on social media and marked them [5]. However, these are not good for the development of the transformation industry of cultural heritage resources.

BPNN can be used in the value assessment of cultural heritage resources, and it has a good effect on the processing speed of the assessment data and the accuracy of the assessment results. Among them, cultural heritage resources can arouse heated discussions on social platforms. Ding and Tian proposed an algorithm called PRABP to predict the number of retweets in cultural heritage [6]. In order to analyze the tourism volume of cultural tourism resources, Li et al. proposed an effective model based on the Baidu index to predict tourism volume [7]. Zhang et al. proposed a method based on the improved artificial fish swarm algorithm neural network algorithm to improve the prediction accuracy of the audience's preferences for cultural heritage [8]. In order to improve the efficiency of resource value evaluation, Zhang et al. developed a simulator using BPNN to predict the exploitability of cultural heritage resources [9]. These methods improve the efficiency of resource value evaluation to a certain extent, but the accuracy is not high.

In order to solve the problem of the above-mentioned low level of cultural heritage resource development and industrial transformation, this paper uses BPNN to analyze the development of cultural heritage resources and evaluates various indicators to find high-value cultural heritage resources. The innovation of this paper is using BPNN and cultural heritage development and industrial transformation to analyze how BPNN, cultural heritage resources, and value assessment methods play a role in the research on cultural heritage resource development and industrial transformation resource value assessment based on BP neural network. This paper expounds the proposed resource evaluation method. Through the evaluation, this paper finds that this method can improve the accuracy of cultural heritage resource value evaluation and improve the level of industrial transformation.

2. Method of Cultural Heritage Resource Development and Industrial Transformation Resource Value Assessment

The 21st century is an era of cultural and economic integration. The cultural industry and modern technology have become the driving force of economic growth, but the quality of the emerging cultural heritage development projects is uneven, and there are many problems, such as the low actual industrial value of the project and resource damage caused by excessive development. Therefore, it is very important to study the development of cultural heritage resources and the evaluation of the value of industrial transformation resources [10]. The cultural heritage resources are shown in Figure 1: Figure 1(a) is the Fujian Tulou, and Figure 1(b) is the mural of Huashan Mountain.

Through the investigation, it is found that the current research on cultural heritage resource development and industrial transformation resource value assessment based on BP neural network is not complete, and most of the research focuses on the theoretical analysis of cultural resource development strategies or phenomena, so this paper proposes a research on the value assessment of cultural heritage resources using BP neural network [11, 12]. This paper analyzes the related methods of BPNN, cultural heritage resource development, and resource value evaluation and proposes an evaluation method for cultural heritage development and industrialization resource value. Through experimental analysis, it is found that cultural resource value assessment can promote the development of cultural heritage and the better development of industrialization.

This paper mainly introduces the research background of cultural heritage resource development and industrial transformation resource value assessment based on the BP neural network, draws out the problems to be solved to illustrate the purpose and significance of this paper, then makes a general analysis of the research status of cultural heritage resources development and industrialization and the application of BPNN, and explains the content and innovation of this paper. At the same time, the organization structure and method of this paper are described, and the

(a)   (b)

Figure 1: Cultural heritage resources: (a) Fujian Tulou; (b) Huashan Murals.

related methods of BPNN, cultural heritage resource development, and industrialization and resource value assessment are analyzed and described; then, the data source of this paper is explained in detail; after arranging the data, this paper analyzes the development trend of heritage resource development and industrial transformation, the preference of cultural heritage types, the satisfaction of former cultural heritage development projects, and the results of the comparison of various levels within the evaluation index system and different cultural heritage resource projects and draws conclusions; finally, the full text is summarized.

2.1. BPNN Method.

BPNN is an inverse operation of error, which optimizes and repairs the weights of each neuron by sending out information until the independent error of each neuron is obtained and the expected result is obtained. The algorithm has two main processes, one is forward propagation of data, and the other is reverse propagation. When the sample data enter the test program, the final result is sent to the output layer by computing each hidden neuron. The error between the result and the expected result cannot be ignored, and the program enters the antimissile step. The process of this process is mainly to amortize the errors of the output layer to the front through hidden neurons to provide data. On the basis of adjustment and modification, obtaining data according to the output result, and run the program for many times to finally obtain the desired output result. Such resource value calculation will take the influence of each factor into account more comprehensively, as the weights between the various factors need to be modified several times to obtain valid procedural results [13].

The neural network is developed under the inspiration of the neurons of the human brain, and it forms its own processing method by systematically and abstractly processing the data. A neuron is the smallest unit of structure in BPNN [14]. Its structure is shown in Figure 2.

The input of data can be expressed as a stimulus to neurons, and the output of data can be expressed as simple responses of neurons [15]. The relationship between them is shown in the following formulas:
Figure 2: Neuron structure.

$$R_j \sum_{j=1}^{n} q_{ij} z_j - \alpha_j, \tag{1}$$

$$o_i = h(R_i). \tag{2}$$

Among them, z_j is the input variable; α_j is the threshold; q_{ij} is the weight of adjacent neurons; $h(R_i)$ is the transfer function.

BPNN means a multilayer feed-forward network that only propagates the signal from the back to the front [16]. BPNN supports N-to-N multipoint input and multipoint output mapping with a very high degree of nonlinearity. Its basic structure is shown in Figure 3.

As shown in Figure 3, the neural network training is mainly carried out in the data processing process. Through the forward feedback of the network, the model automatically processes the operation to reduce the error and change the weight between the model layer and each node. Stop training if the threshold feedback errors for the layers and the model's control variables are within the desired accuracy [17, 18]. In practical applications, various training methods can be used to shorten the time of model training, optimize the effect of model training, and further improve the convergence speed of model training. The most commonly used method to improve model training efficiency is gradient descent. It is a first-order optimization algorithm, which iteratively searches for the specified step distance point in the opposite direction of the gradient corresponding to the current point on the function to find the minimum value.
FIGURE 3: Network structure.

The neurons of BPNN learn general linear functions by default as basic functions. Its expression is shown in the following formula:

$$u = \sum_{j=1}^{n} q_j z_j - \alpha = z' q - \alpha. \tag{3}$$

In order to meet the requirements of increasing partial differential equations and monotonicity for specific intervals, the Sigmund function can be used as the output function of the BPNN. The expression is shown in the following formula:

$$h(z) = \left(1 + e^{-\beta z}\right)^{-1}. \tag{4}$$

Then, the derivative function expression is obtained as shown in the following formula:

$$h'(x) = h(z)(1 - h(z)). \tag{5}$$

The forward propagation of data information is analyzed as follows.

The data input from the first-layer network will be processed by the first-layer and second-layer network connection functions, and the process is shown in the following formulas:

$$nt_j = \sum_{i=0}^{n} r_{ij} z_i \, (j = 1, 2 \cdots m), \tag{6}$$

$$u_j = h(nt_j) \, (j = 1, 2 \cdots m). \tag{7}$$

The processed information is then output through the connectivity between the second- and third-layer networks to complete the simple forward propagation of data information. The process is shown in the following formulas:

$$nt_k = \sum_{j=0}^{m} r_{ik} u_j \, (k = 1, 2 \cdots l), \tag{8}$$

$$o_k = h(nt_k) \, (k = 1, 2 \cdots l). \tag{9}$$

The error back-propagation processing of data information is analyzed as follows.

Assuming the sample is obtained as shown in the following formula:

$$Y^d = \frac{1}{2} \sum_{K=1}^{L} \left(a_k^d - o_k^d\right)^2. \tag{10}$$

Substituting it into the calculation formula of the second to third layers to obtain the following formula:

$$Y = \frac{1}{2} \sum_{K=1}^{L} \left(a_k - h\left(\sum_{j=0}^{m} q_{jk} u_j\right)\right)^2. \tag{11}$$

Among them, q_{ij} is the weight of each layer, that is, the error, which can be changed by adjusting the weight.

In general, it is hoped that the weight value should be proportional to the negative gradient of the error, and this is due to the continuous reduction of the error in the learning process, so it is obtained as shown in the following formulas:

$$\Delta q_{jk} = -\delta \frac{\varepsilon Y}{\varepsilon q_{jk}} \, (j = 0, 1, 2, \cdots, m; k = 1, 2, \cdots, l), \tag{12}$$

$$\Delta r_{ij} = -\delta \frac{\varepsilon Y}{\varepsilon r_{ij}} \, (i = 0, 1, 2, \cdots, n; j = 1, 2, \cdots, m). \tag{13}$$

Among them, δ is the learning rate.

Therefore, for the output layer, the formula (14) is obtained as

$$\Delta q_{jk} = \delta \varphi_{jk} u_j. \tag{14}$$

Among them, φ_{jk} is the error signal. The error signal is shown in the following formula:

$$\varphi_{jk} = (a_k - o_k) o_k (1 - o_k). \tag{15}$$

Then, the hidden layer is obtained as shown in the following formula:

$$\Delta r_{ij} = \delta \sum_{k=1}^{l} \varphi_{jk} q_{jk} u_j (1 - u_j) Z_i = \delta \varphi_{jk} z_i. \tag{16}$$

The error signal is then corrected as shown in the following formula:

$$\varphi_{ij} = \sum_{k=1}^{b} \varphi_{jk} q_{jk} u_j (1 - u_j). \tag{17}$$

Through the above formula, the error adjustment of the second and third layers of the sample can be calculated as shown in the following formulas:

Cultural and radio
facilities

Ancient artifacts

Cultural Resources

Intangible cultural
heritage

Celebrities

FIGURE 4: Types of cultural resources.

$$q_{jk}(b+1) = q_{jk}(b) + \delta \sum_{d=1}^{D} \varphi_{ij} u_j, \tag{18}$$

$$r_{ij}(b+1) = r_{jk}(b) + \varnothing \sum_{d=1}^{D} \varphi_{ij} u_j. \tag{19}$$

Since the construction of the BPNN model, many fields have been using it for different degrees of research and development, and the applicability of BPNN in resource value evaluation has been enhanced. When using BPNN to deal with complex resource information, regardless of economic, legal, or technical aspects, no matter how large the dependence between the data is, it can make the model predicted value closer to the function of the real value. So, this paper applies it to the value assessment of cultural heritage resources.

2.2. Cultural Heritage Development and Industrialization Resource Value Assessment. Cultural resources are the first link in the evolution of cultural forms in the production process of cultural industries and are the basis for creativity. Therefore, evaluating the value of local cultural resources is the first step in the development of local cultural industries. Based on the inherent spiritual and material dual attributes of cultural resources, evaluating and measuring their value has a dual meaning. There are many kinds of cultural resources, and their classification is shown in Figure 4.

As shown in Figure 4, the correct classification of cultural resources is an important prerequisite for the development of cultural resources statistics, and research and cultural industry development strategies. According to the definition of cultural resources, avoid using too empty concepts such as material cultural resources, spiritual cultural resources, and intangible cultural resources.

To evaluate the value of cultural resources, we must first clarify the principles of evaluation. Evaluation should strictly adhere to the principle of objectivity, avoid subjective preference guessing, and adopt one-sided methods when evaluating the value of cultural resources and should combine the mainstream value orientation of the historical development of the cultural industry and use scientific methods. Cultural resources should be measured from a realistic perspective, so as to reflect the real value of cultural resources; evaluation should adhere to local principles, and an important task of cultural resource evaluation is to investigate the heritability of dominant factors in regional cultural contexts. Therefore, it is necessary to pay attention to the discovery of core value resources and the thorough discovery of value when evaluating; the evaluation should be based on qualitative and quantitative principles, cultural resource evaluation is based on the weighted design problem commonly used in systems engineering technology. "Analytic Hierarchy Process" can solve multipurpose system evaluation and decision-making problems caused by multipurpose, inclusive, uncertain, complex, and other characteristics. The overall principle should be followed in the assessment. Cultural resources share their own unique cultural

ecological environment. In the industrialization and development of cultural resources, the influence of these cultural and ecological factors needs to be considered. Therefore, assessing the value of cultural resources is not a simple scoring of individual resources but requires looking at it from a holistic point of view.

For the method of resource value evaluation, the first step is to determine the evaluation index of cultural resources and form a set of intuitive evaluation system of cultural resources. Combined with BPNN data analysis, a set of "cultural resources value evaluation index system" is established, and finally, a basic evaluation model is established through the analytic hierarchy process, and this method is used to count and evaluate cultural resources. Through BPNN, the indicators of each layer of the evaluation model are compared and analyzed, and the weight of each indicator is obtained. The weight comparison adopts a top-down approach, determining the weight of upper-level indicators according to the characteristics of cultural resources in industrial development, comparing the weights of lower-level indicators, and refining the top-level indicators to obtain the bottom-level indicators and overall importance. After weighting the indicators of the evaluation model, comprehensively evaluate and analyze the cultural resources of the objects selected in the above-mentioned cultural resources statistics.

3. Data Sources for Cultural Heritage Resource Development and Industrial Transformation Resource Value Assessment

This paper conducts an online questionnaire survey on the types of cultural heritage favored by netizens and their satisfaction with the current industrial transformation, and a total of 348 valid questionnaires are obtained. The specific data results of the survey content are shown in Table 1.

Among them, the content information contained in the questionnaire includes the respondents' gender, age, favorite type of cultural heritage, and their satisfaction with the current cultural heritage resource development project. For the satisfaction evaluation part of the questionnaire, 4 options were set, namely very dissatisfied, general, relatively satisfied, and very satisfied, corresponding to numbers 1, 2, 3, and 4, respectively. According to these data, the needs of cultural heritage resource development and industrial transformation resource value assessment can be analyzed.

At the same time, by taking 10 different types of cultural resource development projects as examples, this paper evaluates the resource value of them and classifies them according to the score of the evaluation value. The cultural resource development project data used for the experiment were obtained through Internet search, and the detailed information data are shown in Table 2.

The content of the table includes the label, project name, province, and time of cultural resource development projects used for value assessment.

Table 1: Partial data of the content of the questionnaire.

Project	Netizen 1	Netizen 2	Netizen 3
Gender	Male	Female	Male
Age	19	41	27
Type of preference	Cultural relics	Ruins	Immaterial
Satisfaction level	1	3	2

4. Results and Discussion of Cultural Heritage Resource Development and Industrial Transformation Resource Value Assessment

4.1. Resource Value Assessment Needs. This paper analyzes the development trend of cultural heritage resource development and industrial transformation from 2012 to 2021 through the data of cultural resource development projects collected by data mining; and through the distribution of online questionnaires, this paper collects the satisfaction evaluation of netizens according to the current development of cultural heritage resources and industrial transformation. After sorting and analyzing the data, the results are obtained. The development trend of cultural heritage resource development and transformation is shown in Figure 5.

Figure 5 shows the proportion of cultural heritage resource development projects from 2012 to 2021. It can be seen that the overall trend is increasing year by year. Figure 5(a) shows that the overall number of projects in the development of cultural heritage resources increased from 2011 to 2016, but the growth rate was slow; Figure 5(b) sees an explosive growth in the number of projects for cultural heritage resource development from 2017 to 2021, with a faster growth rate. This is because people gradually realize the value of the development of cultural resources and heritage and advocate their development and industrialization, setting off a wave of upsurge. It can be seen that in the huge number of cultural heritage development projects, the identification of its development value is particularly important for the effective use of limited resources.

Through the questionnaire survey, netizens were collected about their preferences for cultural heritage types and their satisfaction with the current cultural heritage development projects. The specific results after data collection and arrangement are shown in Figure 6.

Figure 6 shows the results of an online questionnaire survey on the types of cultural heritage favored by netizens and their satisfaction with the current industrial transformation. From Figure 6(a), we can see the distribution of netizens' preferences for the type of resources. Netizens who like cultural relics accounted for 24.4%, those who like ancient buildings accounted for 11.4%, and those who liked sites accounted for 16.4%, and netizens who liked nonmaterial types accounted for 47.8%. It can be seen that the intangible cultural heritage resources are the most popular among the many types of cultural heritage resource development. Figure 6(b) shows the degree of satisfaction of netizens with the current cultural resource development project, among which 23.4% of netizens said they were very dissatisfied, 44.6% said they were average, 21.4% said they were relatively satisfied, and

TABLE 2: Ten different types of cultural resource development projects.

Serial number	Project name	Province	Time
X1	Huangzhong embroidery	Qinghai	2008.6.7
X2	Wudu mountain opera	Gansu	2012.8.7
X3	Emei martial arts	Sichuan	2009.4.12
X4	Painting of Tibetan colored sand mandala	Tibet	2013.2.4
X5	Rice cultivation customs in Wannian County	Jiangxi	2020.4.6
X6	Gansu gaolan shilan ancient pear garden	Gansu	2016.3.14
X7	Traditional incense-making techniques	Guangdong	2019.6.7
X8	Evenki clothing	Inner Mongolia	2014.3.6
X9	Lightning protection project of the fourth detachment of the new fourth army in Shu	Shandong	2020.8.6
X10	Ancient Jujube Garden in Jiaxian County, Shaanxi Province	Shaanxi	2018.5.14
FIGURE 5: Development trend of cultural heritage resource development projects from 2012 to 2021. (a) 2012–2016, (b) 2017–2021.

10.6% said they were very satisfied, the proportion of netizens who expressed dissatisfaction reached 68%. It can be seen that the quality of the current numerous cultural resource development projects is uneven, and netizens are generally not satisfied with them. Therefore, it is necessary to evaluate the value of the cultural resources to be developed before the project development to improve the quality of the project and improve satisfaction.

4.2. Comparison of Various Levels within the Evaluation Index System. This paper calculates the weights of indicators at various levels of cultural resource value evaluation, organizes and analyzes the data, and finally obtains the results shown in Figure 7.

Figure 7 shows the weights of different levels of indicators for the evaluation of cultural resource development value. Figure 7(a) shows that in the criterion layer, the weight of historical heritage value is 0.35, the weight of economic development value is 0.3, the weight of scientific,

educational, and cultural value is 0.25, and the weight of artistic aesthetic value is 0.1. It can be seen that the historical heritage value of the resource has the greatest impact on the evaluation score, and the artistic aesthetic value has the least impact on the result. Figure 7(b) shows the top 6 weight indicators that have a great influence in the project layer, among which the popularity is 0.134, the education and scientific examination is 0.116, the economic benefit is 0.093, the brand effect is 0.083, the ancient degree is 0.098, and the resource correlation degree is 0.074. It can be seen that focusing on the above six indicators in the development and industrialization of cultural resources can improve the actual quality of the project.

4.3. Comparison of Different Cultural Heritage Resource Projects. This paper evaluates the industrialization development value of a total of 10 cultural heritage resource development projects from X1–X10, and the total evaluation results are shown in Figure 8.

(a)

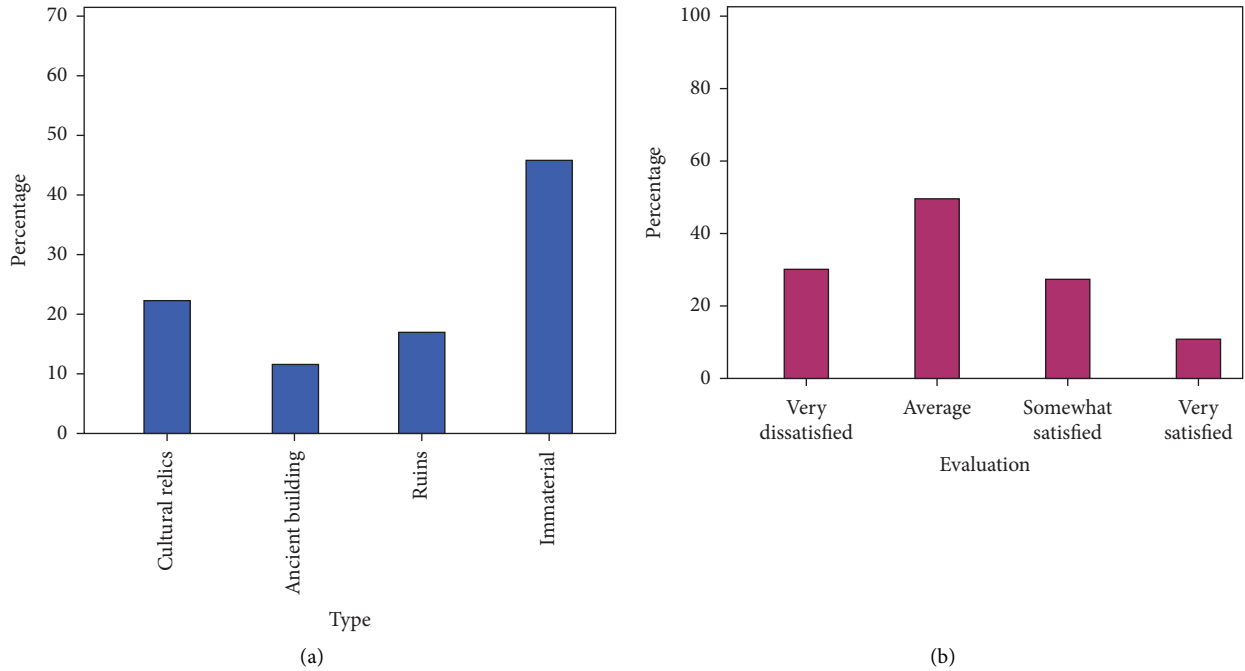
(b)


FIGURE 6: Questionnaire survey results. (a) Type preference distribution. (b) Satisfaction survey.

(a)

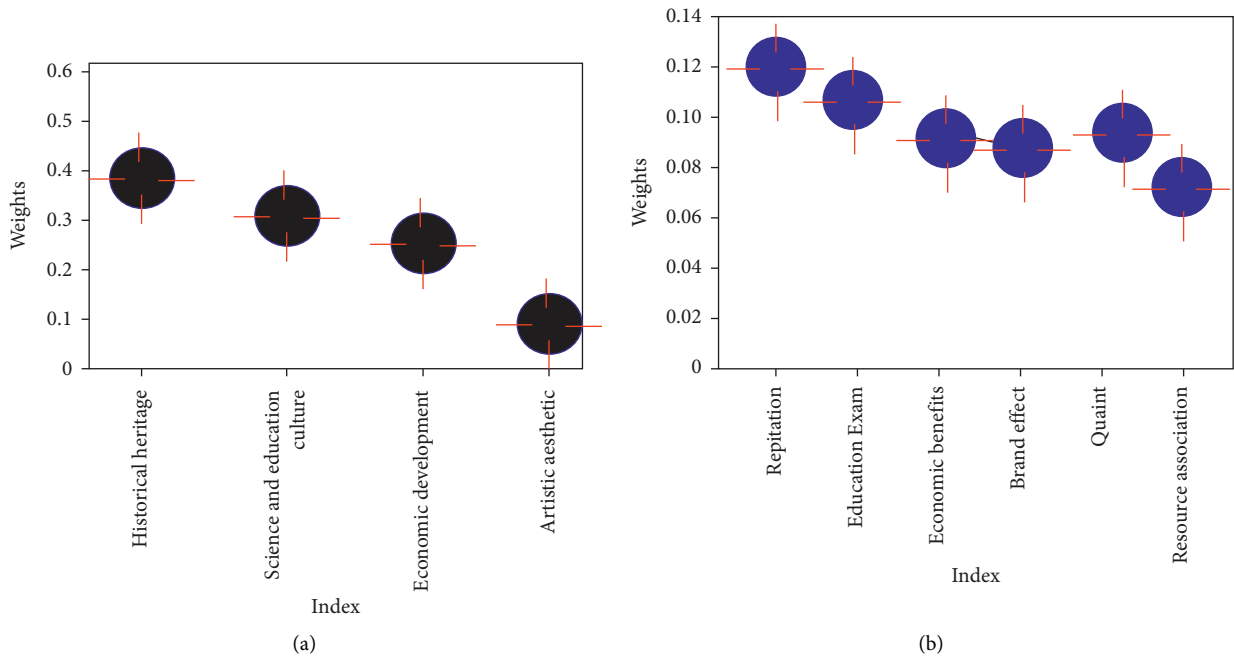
(b)


FIGURE 7: Indicator weights at each level. (a) Criterion layer. (b) Project layer.

As shown in Figure 8, on the whole, it can be seen that the value evaluation results of different types of cultural heritage resource development projects are still quite different. Most of the items were scored between 50 and 70 points, with the highest overall score for the assessment of item X7 being 73.2 points and the lowest overall score for the assessment of item X5 being 42.3 points.

According to the results of evaluation and scoring, they can be divided into three categories: semidevelopment

category (1), pending development category (2), and key protection category (3), as shown in Table 3.

Category 1 in Table 3 is a semideveloped category, and the score range for this category is >70 points. This category is a cultural resource project that is in the development stage and has already achieved certain results. It includes Huangzhong embroidery project, Wudu Mountain Opera project, and traditional incense technology, which are high-industrial value projects. Category 2 is the category to be
Figure 8: Value assessment results.

Table 3: Classification of the value assessment of the industrialization development of cultural heritage resource projects.

Serial number	Project name	Category
X1	Huangzhong embroidery	1
X2	Wudu Mountain Opera	1
X3	Emei martial arts	3
X4	Painting of Tibetan colored sand mandala	2
X5	Rice cultivation customs in Wannian County	3
X6	Gansu Gaolan Shilan Ancient Pear Garden	2
X7	Traditional incense making techniques	1
X8	Evenki clothing	2
X9	Lightning protection project of the fourth detachment of the new fourth army in Shu	2
X10	Ancient Jujube Garden in Jiaxian County, Shaanxi Province	2

developed, and the score range for this category is 50–70 points. This category is a cultural resource project that can be developed but has not been industrialized for some reasons, or has just started. It includes the Tibetan Caisha Mandala Painting Project, the Ewenki Clothing Project, the New Fourth Army Shu Four Detachment Lightning Protection Project Site Project, the Shaanxi Jiaxian Ancient Jujube Garden Project, and the Gansu Gaolan Shilan Ancient Pear Garden Project, which are projects of medium industrialization value. Category 3 is the protection category, and the score range for this category is <50 points. Compared with the first two types, this category is a cultural resource with lower economic benefits and more serious damage. It includes Emei Wushu Project and Wannian County Rice Farming Custom Project, which are projects of low industrial value but in urgent need of protection.

5. Conclusions

Cultural heritage resources are the treasures of human material and spiritual civilization, and people's requirements for cultural resource development projects are getting higher and higher. The development of cultural heritage resources industrialization is inseparable from the contribution of BPNN. BPNN has been applied in the value evaluation of cultural resources industry development because of its powerful data processing advantages. It can be seen from the comprehensive experimental test that the accurate evaluation of resource value can better promote and improve the quality level of cultural resource industrialization. Through the analysis of the needs of cultural resource value evaluation, it is found that due to the continuous development of the cultural economy industry, a large number of industrialization projects for the development of cultural resources have emerged, so it is particularly important to screen the resource value of these projects. At the same time, in the face of a large number of projects, the quality is uneven. This paper investigates the satisfaction of netizens with the project through a questionnaire survey. Netizens are not satisfied with the current cultural resource development, 68% of netizens expressed dissatisfaction. It can be seen that evaluating the cultural resource value of development projects to improve project quality is also very important to improve satisfaction. By comparing the internal levels of the evaluation index system, it is found that the weight of the influence index on the value of the popularity is 0.134, the education and scientific examination is 0.116, the economic benefit is 0.093, the brand effect is 0.083, the ancient degree is 0.098, and the resource correlation degree is 0.074, and these 6 indicators will be the focus of evaluating the value of resources. By comparing different cultural heritage resource projects, 10 different heritage resource projects are divided into 3 categories according to their scores. Among them, Huangzhong embroidery project,

Wudu Mountain Opera project, and traditional incense technology belong to the development category, with a score range of >70 minute. This type of project has a high degree of resource relationship, significant cultural characteristics, strong economic benefits, and high mass participation, and it is relatively easy to form a brand, and the feasibility of industrialization is very high. Tibet Caisha Mandala Painting Project, Ewenki Clothing Project, New Fourth Army Shu Four Detachment Lightning Protection Project Site Project, Shaanxi Jiaxian Ancient Jujube Garden Project, and Gansu Gaolan Shilan Ancient Pear Garden Project belong to the category to be developed, with a score range of 50–70 minute. This type of project has the same advantages as the previous type of project but needs to be properly developed on the basis of better protection and inheritance. Emei Wushu Project and Wannian County Rice Farming Custom Project belong to the protection category, with a score range of <50 points. Due to the special nature of low economic benefits or due to the large degree of damage suffered by such projects, rescue and protection are more necessary than industrial development. It can be seen that the evaluation of the development value of the cultural heritage resources industry provides a basis for guiding the industrialization development and can effectively promote the development of cultural resources. In future research, the focus of follow-up research will focus on how to adapt to the regional conditions of industrial development, what kind of heritage protection mechanism to adopt, how to balance protection and development, and the impact of industrial development.

Blockchain technology is now regarded as one of the most interesting and possibly innovative technologies. It enables information to be stored and exchanged securely and transparently without the need for a centralized authority to regulate it. Some of the primary benefits of this technology are the atomicity of the stored data. Given its features, this technology has the potential to provide answers to challenges encountered in a very sensitive sector, namely, Internet of Vehicles (IoV). In IoV, vehicles and service providers autonomously capture and produce data without human intervention. This exchanged data must meet certain criteria such as decentralization, automation, security, and stakeholder trust management. To overcome these challenges, the integration of blockchain technology and multi-agent systems is a key solution. Based on smart contracts, the proposed solution consists of exploiting role-based access control (RBAC) and attribute-based access control (ABAC) techniques. This solution removes the central authority (CA) to reduce maintenance costs and eliminate legacy threats from centralized systems. The results, obtained from consumption costs, show that the developed platform is characterized by security, availability, and privacy.

1. Introduction

With its evolution, the Internet of Things (IoT) is included in various sectors: healthcare, agriculture, energy, industry, and intelligent transportation systems [1]. It allows communication between different types of objects at any time and in real-time. In 2021, the number of connected objects was estimated at 35.82 billion and will exceed 75.44 billion by 2025 [2]. Included in Vehicular Ad-Hoc Networks (VANET), the vehicle becomes the connected object par excellence, forming a new paradigm called the Internet of Vehicles (IoV). In the IoV, vehicles become capable of establishing interactions with themselves and with other connected surrounding objects. This interaction is ensured thanks to the permanent Internet connectivity offered by the IoV. The vehicles will enable consumers to become familiar

with the Internet of Things through new services that bring more comfort, precision, and efficiency. Indeed, road safety and traffic fluidity as existing applications can be improved by this new concept. Other new services such as vehicle maintenance, parking access, fuel stations, and tolls are developed. As a result, vehicles and service providers autonomously capture and generate data without human intervention [3]. This exchanged data must meet certain criteria. The high connectivity of vehicles and connected objects in the IoV network facilitates malicious attacks. Therefore, the different parties involved in the communication process must interact in a secure and confidential manner. Let us also not forget that the centralized architecture of intelligent vehicle communication models can lead to an interruption of the IoV network if the central server fails. Therefore, decentralization of the system is a very

important challenge. To overcome these challenges of decentralization, automation, security, and stakeholder trust management in IoV, the fusion of blockchain technology and multi-agent system is a key solution.

Distributed ledger technology is often known as blockchain technology. In this peer-to-peer network, data is manipulated in an immutable, decentralized, and confidential manner. These characteristics increase the demand for the use of blockchain technology in various sectors. Included in the supply chain, the blockchain is involved in terms of data security and traceability [4]. Ethereum blockchain and the ERC20 interface are the basis of the proposed system. This system allows automating P2P exchanges, reducing the cost for a trusted third party by ensuring interoperability. Therefore, it guarantees the reliability and trust of information access. Combined with IoT, an extensive study exposed by Saxena et al. [5] and Bhushan et al. [6]. The developed IoT applications are characterized by privacy, confidentiality, and security of managed data. The authors in their article [7], with the same objective of ensuring security and privacy, have outlined the contribution of this technology in the design and development of the smart city. The integration of blockchain technology in IoV and health is the subject of several review articles [8–10].

Any real or abstract entity that can communicate with other entities in its environment is defined as an agent. The set of autonomous agents thus forms a multi-agent system (MAS). The collaboration between the components of the system allows for solving a predefined problem [11]. The MAS allows automating the interactions between the agents forming a fully decentralized system. Indeed, the MAS consolidate the efficiency and the confidence of the human/ machine or machine/machine communication. It also ensures the security of the agents. The authors [12] have exploited the multi-agent system and propose a trust management system between agents by using the technique of identification of agents via private and public keys. In the same context, ensuring security and trust in the multi-agent system shows relevant and reliable results in energy exploitation in a smart home, in logistics, and in an industry [13, 14].

Several researchers have combined the multi-agent system with blockchain technology to take advantage of its security and privacy features. Among the applications developed are carpooling systems, energy consumption, as well as food supply chain monitoring, and electronic voting [15].

Applied in the IoV, our proposed solution consists in designing a decentralized communication system between vehicles and vehicular service providers such as automatic fueling stations using both technologies: multi-agent system and blockchain. The main objective is to ensure security and trust between the agents of the system by establishing automated communication without human intervention via smart contracts. The focal contributions of this work are summarized as follows:

(1) We propose an autonomous agent-to-agent communication system.

(2) To reduce operating and maintenance cost and eliminate legacy threats from a centralized system, we combine the MAS technology with the blockchain technology.

(3) We propose a smart contract-based distributed and dynamic access control mechanism that enables system agents to share data securely.

(4) We implement our scheme on Ethereum blockchain. The performance evaluation, experimental results, and security analysis clearly prove the systems' efficient.

The rest of this paper is organized as follows: The second section is devoted to the study of existing works regarding the application of blockchain technology in IoV. The proposed system architecture is introduced in detail in Section 3. While Section 4 describes the simulation platform and the obtained results. The analysis and performance of the system is included in Section 5. Finally, Section 6 concludes this paper and gives some hints for further research.

2. Related Works

The IoV concept is based on vehicular communication. Vehicles are thus intelligent objects that share and exchange information with each other and/or with other connected objects. Vehicle-to-object (V2X) communication enables the creation of a multitude services for the intelligent transport ecosystem [16]. In V2X, security and trust are two essential elements because the manipulated data can be subject to attacks. To overcome this problem, many scientists have recently become interested in using blockchain technology in vehicular networks. Its integration with data trading makes it possible to facilitate P2P exchanges. Table 1 summarizes the several works presented in this section.

In this context, Chen et al. [17] proposed a framework based on a consortium blockchain that allows the exchange of data that is both secure and efficient between buyers and sellers. The developed solution is an iterative double auction method. It aims to maximize the welfare of the society while preserving the privacy of buyers and sellers so that more users are encouraged to take part in data trading. In addition, the cost of data transmission is also considered to improve the stability of the system. This system is composed of 3 entities, namely, vehicles, edge layer, and blockchain layer. Vehicles interact with each other to exchange data. To access specific types of data, any car in the system must pay a virtual token. Depending on its current state and data needs, the purpose of each node may change. Data brokers are edge servers in the edge layer of the IoV framework. Each car communicates its data needs to the nearest data broker, which then informs local providers. Blockchain, smart contracts, and miners are the three main mechanisms in the blockchain layer. The blockchain is used to ensure high credibility and security, smart contracts allow for a variety of user-designed algorithms, and mining ads to the resilience of the system. The edge layer and the blockchain layer can work together in two ways. For ledger storage and consensus, the edge layer provides significant storage and computational

resources. To create trust and ensure security, the blockchain layer enables an edge layer.

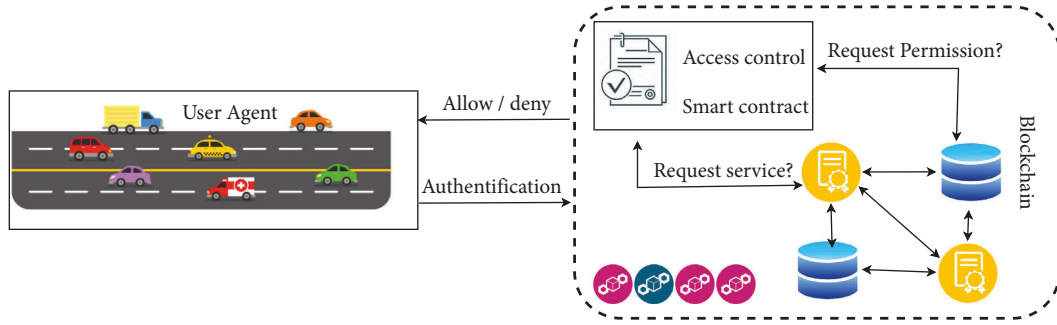
Using blockchain technology, the authors in [18] offer a secure and decentralized IoV exchange system. This system uses an incentive-based investment and pricing structure, enabling car lending. By promising to pay interest and an incentive, a vehicle with a loan request can borrow from a group of cars. To optimize the payoffs for borrowers and lenders, a two-stage Stackelberg game is established. The perfect subgame equilibrium at each stage is analyzed by inverse induction. Furthermore, for secure data exchange and peer-to-peer financing services, the authors exploited the consortium blockchain, smart contracts as well as the proof of work as a consensus mechanism. The numerical results show that both the suggested independent and uniform pricing systems are effective.

Yang et al. [19] develop a blockchain-based decentralized trust management approach in vehicle networks. The Bayesian inference model is used by cars in this system to verify the signals received from nearby vehicles. They use the combination of proof-of-work (PoW) and proof-of-stake (PoS) consensus method. Through this fusion, all RSUs work together to keep the trust blockchain up to date, reliable, and consistent.

The study in [20] proposes a vehicle-to-vehicle (V2V) energy exchange mechanism to solve the driving resistance problem of electric vehicles. In the distributed BIoV with imperfect information sharing, Bayesian pricing is used. The proposed approach has several advantages over a static set with all available data. Electricity transactions are more

trustworthy, secure, and reliable using blockchain technology. For starters, the public/private key pair and digital signature are used with blockchain to address the security concerns of vehicle users. Second, the pricing method is incorporated into the smart contract for electric transactions, which not only reduces the dependency on the middleman, but also ensures that the transaction is fair.

Javaid et al. [21] address the problem of trust in the IoV network. They rely on blockchain technology to overcome this challenge by developing a trust protocol. The proposed solution uses both smart contracts and dynamic proof of work (dPoW) as consensus algorithm as well as certificates and nonclonable physical functions. These 4 mechanisms work together to ensure security and trust in vehicle registration. The resulting solution is characterized by throughput scalability, decentralization, low latency, and vehicle privacy protection. Similarly, to solve the problem of security during the transmission of messages between vehicles in the IoV network, a protocol named IoV-SMAP is implemented. This protocol makes it possible to overcome security flaws while guaranteeing the confidentiality and authentication mechanisms of the users.

In their paper [22], the authors propose a protocol for vehicle accident detection and notification in an ITS environment using a new authentication method called BCAS-VADN. They use blockchain technology to store the information generated by this method. In addition, BCAS-VADN offers end-to-end encryption and the ability to store a cryptographic hash signature of the interactions included in the blocks of the blockchain, thus providing a method of


validating the integrity of transactions. The proposed system is composed of 4 phases: registration of all entities in the system, their authentication, verification, and addition to the blockchain and the dynamic addition of new nodes to the network. The use of blockchain technology and the Practical Byzantine FaultTolerance consensus mechanism reinforce the security since it is impossible to delete or modify the data exchanged in the network.

PSEV [23] is a framework based on blockchain technology that allows the creation of payments and secure communications between the different participants of the IoV system. This solution ensures the automation of data exchange processes using smart contracts. To validate the proposed solution, the authors use the Ethereum blockchain to develop a decentralized real-time parking reservation and payment application. The designed system is characterized by a low cost and a reduced execution time compared to existing systems. It also ensures integrity, immutability, and confidentiality.

Singh et al. [24] proposed a mechanism for trust management in the IoV system. The studied approach is to overcome the scalability problem by exploiting blockchain technology. The decentralized feature is ensured by using smart contracts and Proof of Work as a consensus mechanism. For validation, the authors resort to the use of the Ethereum blockchain platform that allows examining the performance of the system considering the average throughput and execution time. For the same purpose, Zhao et al. [25] also addressed the problem of trust management in the IoV system. They developed a protocol that bundles the practical Byzantine fault-tolerance consensus mechanism with the proof-of-work. This linkage ensures the anonymity of vehicles via identity-based group signature.

3. System Design and Architecture

The proposed system is a platform allowing the communication between autonomous agents by integrating the blockchain technology and the multi-agent system (MAS). The architecture of the system is composed of 2 main parts: a MAS that allows communication between agents and a public blockchain network (BC) that allows to store all transactions and smart contracts.

Blockchain technology, namely, smart contracts, allows agents to engage more quickly, automate business

procedures, and transmit orders across them. The data generated by multi-agent modeling can be kept in the blockchain. Agents are critical in IoV systems, and with blockchain, they may provide even more value to the ecosystem, increase its dependability, and facilitate its expansion.

3.1. System Design. Our system's model is depicted in Figure 1. Connected automobiles can communicate with a variety of items. They are also linked to the Internet through the provision of intelligent services. The most important feature is the decentralized exchange of information between different entities. The proposed model is composed of two actors or two agents: service providers and vehicles. All agents have their blockchain address. The blockchain records the transactions between the actors, as well as information about the vehicle and services. The smart contract ensures these transactions automatically validated by consensus mechanisms. The proposed model is based on 3 main concepts as follows:

3.1.1. Smart Contract. Smart contracts are the most important component of any blockchain framework as they fulfill basic functions. For the design of our framework, the first step is the deployment of different smart contracts either for system stakeholder's enrollment or for authentication to benefit from a service and pay the provider.

3.1.2. Authentication. Access to the system requires user authentication through Ethereum addresses for each agent. After authentication, the vehicle agent can consult and communicate with the service provider agent.

3.1.3. Access Control. Access control is a process that allows only authorized entities to manage information and controls this information. In our case, to use a service, the vehicle agent sends an access request via the smart contract that verifies the identity of the requester and authorizes him to send a request to the service provider.

3.2. Blockchain and Agent Communication Process. The communication process between our system's agents is divided into five stages: agent enrollment, agent registration,

Symbol	Description
A_X	Stakeholders agent in the communication process
VA	Vehicle agent
GSA	Gas station agent
S_L	Station localization
R_D	Remaining distance
M2M	Machine-to-machine

agent authentication, request service, and payment. The registration and communication process between agents based on the smart contract is explained by Algorithms 1–3 as described below. For convenient reference, Table 2 lists the various symbols and acronyms used in this subject.

3.2.1. Agent Enrollment. In this step, the system administrator assigns to each Ethereum address an agent type or a role. This designation is recorded in a hash table via a smart contract. The added role is then used when adding an agent or in the handling of transactions in the communication process. However, the deployment of different smart contracts required by our system was the object of this step.

3.2.2. Agent Registration. The registration step consists of adding the agents to the system. After verifying the account address, the agent can add its information to the Agent_DB through a smart contract. In this phase, the smart contract saves the characteristics or attributes of each agent, especially the identifier and its account in token. Upon successful registration, agents are allowed to join the blockchain.

3.2.3. Agent Authentication. To communicate and benefit from a service, the registered agents authenticate themselves. Two types of access control are used: Role-Based Access Control and Attribute-Based Access Control. The use of the "msg.sender" variable of the OpenZeppelin library allows for identifying and validating the agent's address. On the other hand, during the payment phase, it is necessary to control the access to the data of the agents such as the balance account.

3.2.4. Request Service. Once enrolled, the vehicle agent sends a request to the system to consult the list of available service providers. Then it chooses the appropriate provider. In this step, a smart contract is established between the stakeholders. This contract contains all the necessary criteria to use a service such as the minimum amount that must be in the applicant's portfolio.

3.2.5. Payment. After having exploited the desired service, a request is sent to the blockchain to complete the payment phase. The request containing the amount to be paid is managed automatically by a smart contract. This smart contract accesses the account of the stakeholder in this process and settles what is due.

3.3. Smart Contract Design. The suggested smart contract design comprises of three contracts: Registration_Contract, VA_SA_Contract, and Access_Contract.

3.3.1. Registration_Contract. It is designed to add Vehicle_Agent and Service_Agent in the system. The information provided by each agent is then stored in Vehicle_Agent_DB and Service_Agent_DB. These two registration tables represent a distributed database containing all registered agents. The authentication and authorization of agents are also controlled by the logging database.

3.3.2. VA_SA_Contract. It is a binding agreement between the vehicle agent and the service agent. It includes the system's stakeholder ID as well as the service charge.

3.3.3. Access_Contract. It maintains access control among system agents. When sending a service request from the vehicle agent to the service agent, this contract controls the access of this request. This contract is also involved in the payment phase. When access to the service is finished, using ABAC, it deposits the requested amount from the vehicle wallet to the service wallet.

4. System Implementation and Analysis

Figure 2 presents the system operation as well as the simulation tools used, which will be discussed later. The proposed platform consists of two agents: VA and GSA. The latter two form an autonomous system allowing the automation of "M2M communication" processes. First, VA, when it reaches a fuel threshold, will choose a GSA from a list of stations registered in the blockchain. This list provides information about the location of the station and its rates and its availability. The loading process requires the authentication of the vehicle requesting the service and the provider station. This is done via decentralized application interface (Dapp). BC is used to eliminate the middleman for authentication, payment, and automation of the service via smart contracts. After choosing the station, a smart contract is established between the two parties for the loading. The vehicle pays the loading amount which depends on the loaded quantity, type, and price, but the money is kept in the blockchain. When the loading process is completed, the smart contract automatically pays the agreed amount of money to the station account.

4.1. Simulation Platform. The agents of our system are modeled by the Netlogo Framework through which two types of communication are implemented between the different agents: the request and the reception of a transaction. The conversation between the agents is ensured by an agent communication language (ACL). To facilitate the communication between Netlogo, the Dapps, and the blockchain network, the Maven extension is used.

Each agent has an account in the Ethereum blockchain. To access this account, we use the web3.js library through an
FIGURE 2: Proposed system diagram.

the Ethereum account information and make the transaction payment. Any changes submitted to the transactions are recorded on the blockchain network (see Figure 3).

Table 3 provides a list of the technologies used to implement the system and a brief description of each.

4.2. Results and Performance Evaluation. In this section, we will present the results of smart contracts deployment of our system as well as the consumption cost and transaction cost.

4.2.1. Smart Contracts Deployment. Figure 4 depict the compilation and migration of smart contracts to the blockchain ganache. Five smart contracts are compiled and deployed in the "development" blockchain: "Gas-StationAgent.sol," "Registration.sol," "Auth.sol," "VehicleAgent.sol," and "VehicleGasStation.sol." The entire cost of this transaction as shown by the migration result, is 0.003796388 ether, which is the equivalent of £ 13.21. This conversion is done on March 28th, 2022.

Figure 5 represents the execution costs of the different smart contracts in our system. We notice that the cost of the vehicle gas station contract is higher than the other contracts. This contract contains the main functions of the system, such as communication between the different agents as well as the access control functions ABAC and RBAC. While registration contract consumes less gas since it just assigns a role to the agents in a table containing the accounts and roles. Vehicle agent and gas station agent contracts take care of adding the relevant information to each agent. Their gas consumption costs are nearby.

Following the transfer of our smart contract, we will build a local virtual server containing the client-side application using the truffle framework. To join to our blockchain network, we need to connect to our Metamask portfolio as shown in Figure 6.

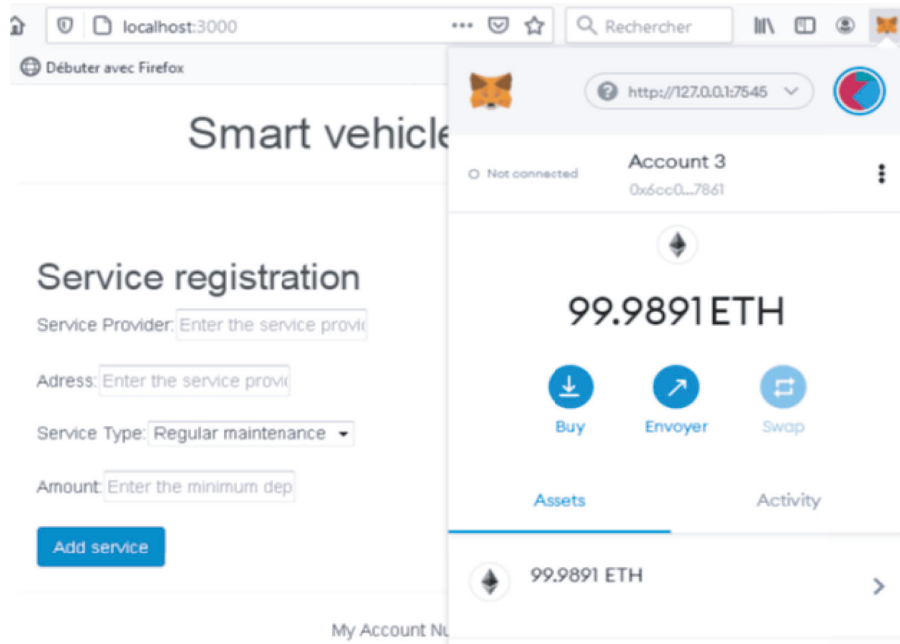
4.2.2. Consumption and Transaction Cost. The system's cost of consumption is calculated in terms of the number of gas units utilized by smart contracts. Gas is a unit of


FIGURE 6: Vehicle registration data screen.

ALGORITHM 2: Upload agent information

measurement that estimates the processing power required for transaction execution. Gas units are transformed into ether value in Ethereum. To calculate the gas fees for each transaction in our system, we apply the following equation:

$$\text{Transaction Fee} = \text{gasUsed} \times \text{gasPrice}. \tag{1}$$

where gas used is defined depending on the storage and processing quantity for each transaction and gas price denotes the amount of Gwei necessary for the transaction. Let us take the example of the agent enrolment function which allows assigning to each agent a role and account. The gas used of this is 112883 and gas price is 20 Gwei. So,

$$\text{Transaction Fee} = 112883 \times 20 = 2257660$$
$$\text{Gwei} = 0.000225766 \, \text{Ether}. \tag{2}$$

We have calculated the transaction costs for the different smart contracts. Table 4 shows the gas consumed. Note that

the transaction cost for reading data from the blockchain, such as the "getVehicleAgent," "getAllGasStation" and "readMessage" functions, is null. Since mining is not required while getting messages from blocks, and no changes are required for the smart contract, this function does not incur any extra costs.

Figure 7 shows the gas consumed by each function in our system. The functions of the agent communication subsystem consume more gas with 0.000470134 Eth, 0.000297561 Eth and 0.000244863 Eth for the respective requestService, payment, and sendMessage functions. This high cost is due to the operations and the data they manipulate. On the other hand, the functions that manage the addition of agents: addVehicleAgent and addGasStationAgent consume about 0.0003.

4.3. Comparison. Table 5 compares the proposed method to other works in the field in terms of performance parameters

TABLE 3: Technologies used for the realization of the system.

Technologies		Description
Blockchain	Ganache	A personal blockchain for local development. It allows to deploy smart contracts, develop applications, and run tests. Ganache provides 10 Ethereum accounts with a balance of 100 ether for each account, as well as a graphical interface to examine everything that happens in this blockchain.
	Truffle	A framework that provides a suite of tools for developing Ethereum smart contracts and a client-side interface, testing and deploying smart contracts in any Ethereum network.
	Ethereum	A distributed computing platform based on a public blockchain that can support advanced custom smart contracts using the turing-complete programming language.
	Smart contract: solidity	An object-oriented programming language dedicated to writing smart contracts. It is used to implement smart contracts on various blockchains, including Ethereum
Web server	Meta mask	A plugin allows to transform a web browser into a blockchain browser. It also allows the management of blockchain accounts, as well as ether funds to pay transactions
	Web3.js	A collection of libraries allowing interaction with a local or remote Ethereum node, using an HTTP or IPC connection in JSON RPC format.
Multi-agent system	Netlogo	A well-known and widely used cross-platform modeling and simulation environment for complex systems of simultaneously interacting agents, written on top of the Java virtual machine. Netlogo offers a wide range of generic features and operators to its users. In addition, to compensate for missing functionality, Netlogo is compatible with other platforms and libraries. Conversely, Netlogo can also be called and controlled by other programs. For this purpose, Netlogo provides a Java API.
	Maven extension	A program construction management system developed by the Apache foundation. It is based on the definition and use of POM (project object model) files containing all the instructions guiding the correct construction of the program.

Table 4: Function cost.

System	Function	Transaction cost (eth)	Price ($)
	Deploy contracts	0.003796388	13.21

and used technologies. As previously stated, we were unable to locate a paper that shared our concerns. As a result, several works implemented a solution based on blockchain technology and smart contracts, but they did not use multi-agents' system. It is important to note that in the related works, we only focused on papers that are more relevant to our use-case and chose from them; as a result, some papers are not related to alternative access control methods.

4.3.1. Security. The use of the RBAC and ABAC mechanisms ensures the security of our proposed framework. So, no third party is allowed to access the system. Let us not forget also that blockchain is protected with mechanisms and protocols. Therefore, agent data can be handled reliably and confidentially. Only trustworthy persons have access to these data. The system denies access to any untrusted third party attempting to access the system.

4.3.2. Availability. The use of the public blockchain allows the system to be accessible to anyone who need a gas station service.

4.3.3. Trustfulness. Trust is maintained with access control via user registration as well as restricting access to the data of our system stakeholders.

5. Conclusions

In this study, we propose a smart contract-based distributed and dynamic access control mechanism that ensures an autonomous agent-to-agent communication system. As a result, blockchain technology is combined with multi-agent

systems and access control in order to guarantee security and trustfulness. To ensure that these features are implemented, various smart contracts are strategically placed. Vehicle Agent and Gas Station Agent are dedicated to the management of the agents' data. The smart contract vehicle Gas Station allows the exchange of data between vehicles and service providers and payment. The search for a neighboring service is handled by the multi-agent system. To evaluate the performance of the proposed system, the calculation of the costs of the different smart contracts and the costs of the functions that they contain is performed. The results obtained show that the developed platform is characterized by security, availability, and privacy.

In the proposed system, several data are manipulated and need to be stored securely so their storage is a challenge to consider when implementing a real system. So as a perspective cloud storage is considered. In this case, the data of the different agents as well as the smart contracts are stored in the cloud and the blockchain just contains their URL. Another perspective is the implementation of an access control mechanism for the access to the cloud.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The authors declare no conflicts of interest.

This article is aimed at studying the features of the control systems development for a small-sized Computer Numerical Control (CNC) portative laser engraver. The CNC is implemented in mobile maintenance and repair platforms for remote sensing of the environment where the wild environment may not allow us to access the animals and places. The proposed work in this paper is based on recent research, which shows that applying the automated CNC speeds up the processes of repair, modernizes the equipment size, and significantly reduces the economic costs; accordingly, the authors developed a block diagram of a portable CNC laser engraver. The choice of the hardware was also made, taking into account the possibility of quick replacement in the field, which reduces the repair time and the cost of the developed layout. A control system based on the selected modules was synthesized, and a stability check was carried out using MatLab tools. To check the correctness of the developed control system, the authors developed and assembled an experimental layout to illustrate the results of engraving on such a layout. Finally, the stability and sensitivity of the proposed system have been obtained and proved that the system works in a comfortable zone of stability. The obtained results show that the proposed CNC laser engraver has achieved the expected improvements (high speed, small size, short production and repairing time, minimum human influence factor, and achieving a better outcome).

1. Introduction

The introduction of modern progressive technologies in all spheres of human activity was presented in the concept of the fourth industrial revolution (Industry 4.0) [1–5]; resulting in making it possible to apply and integrate modern information technologies such as Artificial Intelligence (AI) [6, 7], Big Data (BD) [8, 9], and Internet of Things (IoT) with hardware solutions based on Microcontroller Unit (MCU) [10–14]. Accordingly, it becomes possible to automate the production process through the introduction of new control systems such as Computer Numerical Control (CNC) machines or Programmable Logic Controller (PLC) [15–17]. The implementation of CNC and PLC provides a wide

opportunity to optimize the production process, improve the adaptation flexibility and customization for the release of new products, and minimize the influence of the human factor at the production stage. When combining the Computer-Aided Technologies (CAx) with CNC and PLC, the resulted symbiosis technique enables the implementation of the following solutions on the basis of CNC [18]:

(i) Additive 3D printing (plastic or metal)

(ii) Industrial milling (metals, plastic, or wood)

(iii) Laser engraving (metal, plastic, wood, etc.)

All of the above-mentioned solutions are regarded as an integral part of the Cyber-Physical Manufacturing Systems

(CPPS) that are used in enterprises with flexible production cycles.

During the analysis of the CNC machines' performance, the authors gave good attention to the NATO reference book and the Logistics Handbook, mainly for Logistics in the Maintenance and Repair sections. Indeed, understanding the repairing field is regarded as a set of measures to restore the suitability of the material part for the operation in the shortest possible time [19]. Armament Repair Shop Set (ARSS) is a one-sided sliding shelter of a repair shop that contains small-sized portable CNC machines, on the basis of which you can quickly repair or upgrade the equipment without sending it to manufacturers [20, 21]. Similar portable machines can also be useful for field work and small workshops. At the same time, it should be noted that most of the CNC machines that are mainly designed for industrial applications have large overall dimensions and cannot be used in ARSS systems [22].

Thus, the development of a small-sized portative CNC laser engraver with high engraving accuracy is an actual and promising research area. Accordingly, to conduct such a study, it is necessary to solve the following tasks:

(i) Conduct research and analysis of the vectors of input parameters for a laser engraver to obtain a good description

(ii) Establish the relationship between the input and output parameters for control system implementations

(iii) Develop a structural control system for laser engraver

(iv) Select hardware modules for the control system and executing devices, which rely on the selected hardware modules and synthesize the control system and the stability check that applies the theories of automatic control

(v) Assemble an experimental portable model of a laser engraver and conduct trial engravings based on the developed control system to confirm the main theoretical provisions of the proposed work and the performance of a portable laser engraver model

2. System Design and Implementation

Matching the selected CNC and the laser machine equipment's hardware is regarded as the backbone of the proposed work.

2.1. Match Selection of CNC Laser Machine Control Key Parameters and the Equipment's Hardware. The brightness of images taken with the help of a laser vestal from the CPC is directly deposited according to the cob parameters that are set at the input of the control system. Among the main parameters that directly affect the quality of engraving, as a rule, the following parameters should be distinguished [23]:

The number (density) of engraving lines, which depends on the quality of the original image;
Figure 1: CNC laser machine as an object of control.

Laser power, which determines the choice of material for engraving and the maximum engraving depth;

The speed of the laser moving along the engraving surface and the engraving step determined by the type of Stepper Motors (SM) and the resolution of the laser beam, which depends on the type of the selected laser module, resulting in the need to configure the laser machine with CNC to ensure the quality of the image, represented as a "gray" box [24], with a vector of input parameters $x_1, x_2, x_3, x_4,$ and x_5, and the vector of output parameters $y_1, y_2,$ and y_3, as shown in Figure 1.

The vector of input parameters includes the number of image lines (lines/mm), power and speed of the laser (Watt), engraving step (mm), and laser beam resolution (dpi):

$$X = \{L, S, V, N, F\}, \tag{1}$$

where L is the number of lines (lines/mm), S is the laser power (Watt), V is the laser speed (m/s), N is the engraving step (mm), and F is the laser beam resolution (dpi). Depending on the requirements for the material on which the engraving is to be performed, the parameters F and S can be changed by installing a more powerful laser module. All other parameters can be changed programmatically through the CNC machine control system.

The vector of output parameters includes the line density per mm, the image engraving time, and the burn depth as shown in the equation as follows:

$$X = \{q, t, h, k\}, \tag{2}$$

where q is the line density (line/mm), t is the time (s), h is the burn depth (mm), and k is the image contrast. Note that the image contrast k depends on the movement speed of the laser module, which implements SMs, and the accuracy of the model position, which serves as the basis for choosing the type of SM.

The analysis of the relationship between input and output parameters of the control object allows drawing the following conclusions in the presented work:

(i) Number of lines L allows to achieve high-quality images by passing the laser a specified number of times

(ii) The laser power S sets its range of work associated with the speed of movement to simulate the color of the image, i.e., the depth of burning h

(iii) The laser movement speed V depends on the hardware of the engraver, which affects the time of engraving the image t
FIGURE 2: The structure of the control system of the CNC machine.
(a)   (b)

FIGURE 3: (a) Control board is Arduino Mega 2560-M16U [26]. (b) A4988 SM driver [27].

(iv) The image contrast k depends on the speed of the laser V

(v) The engraving step N depends on the density of the obtained lines q, that is, the fill density of the image

(vi) The detailed level of the received image, i.e., the quality of execution of an engraving, depends on the resolution of a laser beam

To create more control through CNC machines, it is necessary to select components such as control boards, SMs, temperature sensor, laser, and actuator (lead screws).

Based on the analysis of the relationship between the input and output parameters of the portable laser engraver developed, the authors propose the following structure of the cutting system with a laser engraver based on a CPC, as shown in Figure 2.

The input parameters are denoted by $x(t)$, which is a file in Bitmap Picture format (∗.bmp). The file ∗.bmp formatted file can be loaded into the control system, such as in microcontroller ATmega2560 [25], installed CNC Shield v.3.0 [26], and A4988 drivers [27], where 3-SMs are also connected to the board. SM 1 is responsible for moving along the X axis (Axis X), and SM 2 and 3 are responsible for moving along the Y axis (Axis Y). The use of two SMs allows ensuring the accuracy of moving the laser module along the

machine frame without using a more expensive SM with two shafts, resulting in reducing the cost of the experimental layout. The proposed solution allows moving the laser in Cartesian coordinates and controlling the engraving working area using the feedback through the Sensor as shown in Figure 2.

Figure 2 illustrates the way to select the elements of the machine control system with CNC, namely the microcontroller, SMs, actuators, and laser.

The selected control board in the proposed work is Arduino Mega 2560-M16U as shown in Figure 3(a), which has a low cost, simple instruction, and easy to provide a good interface and compatibility with operating systems, such as Windows, Macintosh OSX, and Linux, taking into consideration that most of the operating systems are focused only on Windows [28].

The selection of the Arduino Mega 2560 control board requires choosing an expansion board that reduces the number of wires and facilitates the installation. Drivers for the SMs are installed on the expansion board as in Figure 3(b), where jumpers for dividing the motor pitch are installed, which further affects the image clarity parameter.

CNC Shield v3.0 [26] was chosen as the expansion board, which is a specialized board for working with CNC machines as shown in Figure 4(a).

(a)   (b)
Figure 4: (a) CNC shield extension board v3.0 [26]. (b) Stepper mottor nema 17 [29].

(a)   (b)
Figure 5: Focusable 500 mw diode laser and driver board [31]. (a) Low-power diode laser; (b) laser driver board.

Given that this small-bore portable laser engraver is being developed to be used in ARSS, the main condition is high maintainability and availability. Based on this, the authors believe that in the field, if one of the elements of the control system fails, it is possible to make an emergency replacement in the PnP (Plug and Play) mode. Therefore, the proposed hardware modules for the implementation of the control system are the best solution, in contrast to all the hardware elements of the control system integrated into one board.

Next, the SM is chosen, which converts electrical voltage pulses of the control voltage into discrete angular or linear movements of the rotor with its potential fixation in the desired positions. SM allows moving the functional tool throughout the working area of the machine with CNC. The functional tool is regarded as one of the main parts of the machine because it is responsible for the main operation, and where the CNC is intended for the surface treatment of the workpiece, or other operation. The hybrid Stepper Mottor Nema 17 (17HS4401), which is shown in Figure 4(b), is used for the control task of X and Y axis movement [29].

Powerful lasers are used on industrial CNC machines, the most common of which are CO_2 lasers and fiber lasers [30]. Such lasers require expensive maintenance. To decrease the maintenance cost, a low-power diode laser shown in Figure 5(a) and a laser driver board shown in Figure 5(b) [31] were chosen in the proposed work because it is easy to operate and has relatively high performance characteristics. Moreover, on the laser driver board, there is a TTL channel that monitors the power, where the laser is tuned off (zero power) at 5 V and tuned on (full power) at 0 V. TTL enables controlling a few parameters as the shades of gray, power of the laser module 1.6 W, wavelength 445–450 nm, color blue, supply voltage DC 12 V, and Frequency TTL from 0–20 kHz.

Comparisons of the studied laser parameters for small machines are presented in Table 1.

As can be seen from Table 1, the selected laser at an output power of 500 mW has different wavelengths and prices. Considering that a laser is a module with a life cycle of 3,000 to 8,000 hours of operation, the authors of the experimental machine with CNC under development chose the Focusable 500 mW, laser model.

TABLE 1: Comparison of the parameters of the studied lasers.

Laser model	Wave-length (nM)	Output power (mW)	Laser shape	Reverse polarity protection	Warm-up time	Price ($)
Focusable 500 mw [31]	808	500	Dot (rectangular or oval)	+	0	26
405MD-500 [32]	405	500	Dot (oval)	+	0	42
SRBI FB04-500 [33]	405	500	Dot (rectangular or oval)	+	0	41
FB03-500 [34]	405	500	Dot (oval)	+	0	62

2.2. *The CNC Machine Control System and the Generalized Main Parameters.* According to the selected control system elements of the CNC machine and the developed block diagram proposed in Figure 2, it is further necessary to synthesize the control system for each element. To do so, it is proposed to use the theory of automated control, where all the selected elements in the form of transfer functions are presented in this paper. The transfer function is one of the ways to mathematically describe a dynamic system. In automatic control theory, the transfer function of a continuous system is the ratio of the Laplace transform of the output signal to the Laplace transform of the input signal at zero initial conditions [35]. Accordingly, the developed control block diagram of the workbench with the CPC is described mathematically for each element through the transfer function [36].

The transmitter transfer function equation is

$$W_{\text{sen}} = \frac{0.4412}{0.02s^2 + s}. \tag{3}$$

The transfer function of the first engine equation is

$$W_{d1} = \frac{1}{0.1s + 1}. \tag{4}$$

The transfer function of the second engine equation is

$$W_{d2} = \frac{1}{4.49s + 1}. \tag{5}$$

The transfer function of the third engine equation is

$$W_{d3} = \frac{31.62}{0.4732s + 1}. \tag{6}$$

The transfer function of the laser module equation is

$$W_l = \frac{4.49s + 1}{0.000398s^2 + 0.01995s + 1}. \tag{7}$$

The transfer function of the first shaft equation is

$$W_{sh1} = 0.0335s + 1. \tag{8}$$

The transfer function of the second shaft equation is

$$W_{sh2} = 0.01s + 1. \tag{9}$$

Based on the developed structure presented in Figure 2 and the transfer functions shown in equations (3)–(9), the control system can be represented as the structure of the transfer functions, as illustrated in Figure 6.

The next step is to calculate the transfer function of the open and closed loop system [36, 37]:

The transfer function of the open loop system is given in the following equation:

$$W_p(s) = W_{mk}(s) \times ((W_{d2}(s) + W_{d3}(s)) \times W_{sh2}(s)$$
$$+ W_{d1}(s) \times W_{sh1}(s)) \times W_l(s) \times W_{\text{sen}}(s). \tag{10}$$

The transfer function of the closed-loop system is given in the following equation:

$$W_3(s) = \frac{W_{mk}(s) \times ((W_{d2}(s) + W_{d3}(s)) \times W_{sh2}(s) + W_{d1}(s) \times W_{sh1}(s)) \times W_l(s)}{1 + W_{mk}(s) \times ((W_{d2}(s) + W_{d3}(s)) \times W_{sh2}(s) + W_{d1}(s) \times W_{sh1}(s)) \times W_l(s) \times W_{\text{sen}}(s)}. \tag{11}$$

Making the substitution equations (1)–(7) into equations (8) and (9), the overall transfer function of the open loop system becomes the following equation:

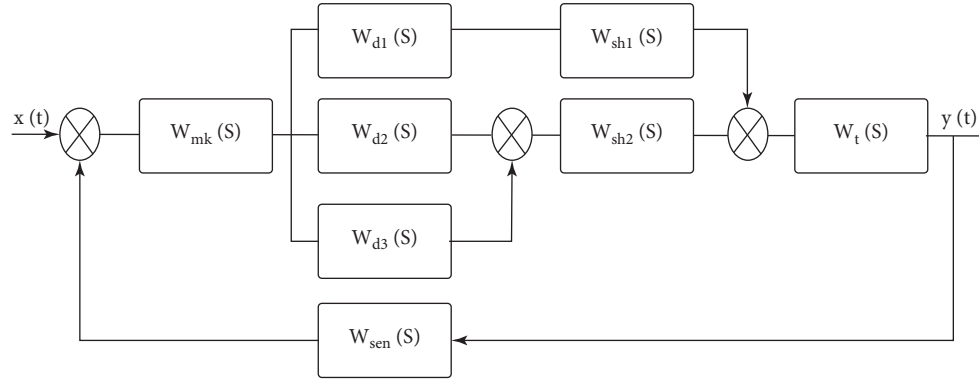
$$W_p = \frac{2.098s^3 + 27.72s^2 + 68.71s + 13.95}{1.691 \times 10^{-6}s^7 + 0.0001902s^6 + 0.01062s^5 + +0.3212s^4 + 2.821s^3 + 5.103s^2 + s}, \tag{12}$$


FIGURE 6: Structure of the automated control system of the CNC machine.

and of the closed loop system equation as follows:

$$W_3(s) = \frac{2.098s^3 + 27.72s^2 + 68.71s + 13.95}{1.691 \times 10^{-6}s^7 + 0.0001902s^6 + 0.01062s^5 + 0.3212s^4 + +4.922s^3 + 32.82s^2 + 69.71s + 13.95}. \tag{13}$$

The next step is to assess the stability of the open loop system at the roots of the characteristic equation. To do so, it is necessary for the transfer function of a closed loop system (13) to select the denominator in the form of a characteristic equation (14) and find its roots equation (15). If all roots of the characteristic equation have the same sign (either all negative or all positive), then the system will be stable. Otherwise, the system will not be stable.

$$1.691 \times 10^{-6}\lambda^7 + 0.0001902\lambda^6 + 0.01062\lambda^5 + 0.3212\lambda^4$$
$$+ 4.922\lambda^3 + 32.82\lambda^2 + 69.71\lambda + 13.95 = 0, \tag{14}$$

$$\begin{cases} \lambda_1 = -25.3646 + 34.9229\,i; \\ \lambda_2 = -25.3646 - 34.9229\,i; \\ \lambda_3 = -24.0819 + 3.6019\,i; \\ \lambda_4 = -24.0819 - 3.6019\,i; \\ \lambda_5 = -10; \\ \lambda_6 = -3.3537; \\ \lambda_7 = -0.2227. \end{cases} \tag{15}$$

Equation (15) shows that the sign of all roots are the same (negative), which means that the system is stable. To plot the location on the complex plane of the roots of the characteristic level equation (15), a package of applications is used to solve the technical calculation challenges by MatLab. Based on the stability conditions for linear automatic control systems, which can be formulated as follows: the system is regarded as stable when all the roots of its characteristic equation are located on the left side of the axis, i.e., all the real parts of the roots are negative, taking into consideration that it is enough to have one real part of any root in the right side of the axis to make the system unstable. As can be seen in Figure 7, the location of characteristic polynomial roots

on the complex plane is along the axis y, where y is the imaginary part, and along the axis x, where x is the real part. Accordingly, all roots are located on the left side of the axis. Therefore, the system is regarded as stable.

As a result, it is possible to assume that the closed loop system is stable; however, it is required to estimate the stability of the closed-loop system by Mikhailov's criterion to fully evaluate the proposed system, where the Mikhailov criterion is described as follows.

Mikhailov curve vector $D(jw)$ tests the system's stability by increasing the frequency from 0 to ∞, ∞, where the system is considered stable when it starts moving on a real positive semiaxis and rotates only counterclockwise, passing sequentially n quadrants of the coordinate plane, where n is the degree of the characteristic polynomial, i.e., the number of the roots of the characteristic polynomial [38].

The Mikhailov curve for stable systems is characterized by having a smooth spiral shape, and its end goes to infinity in that quadrant of the coordinate plane. If, as a result of the calculation, the control system of a portable laser engraver is stable, then the system becomes stable from external disturbances and will return to a state of rest.

Using MatLab, the Mikhailov curve was constructed, which is shown in Figure 8.

Though Figure 8 shows that the Mikhailov curve consistently covers 7 quadrants, to obtain clearer curves, the range of the coordinate axes can be changed as shown in Figures 9(a) and 10(b).

The graphs of Figures 9(a) and 10(b) show that the Mikhailov curve consistently covers 7 quadrants, which is equal to the degree of the characteristic polynomial without intersecting the origin, and fully meets the requirements of the Mikhailov criterion. Consequently, the closed loop system is regarded as stable.
FIGURE 7: Location of the characteristic equation roots.
FIGURE 8: Mikhailov curve for the proposed system with 7 roots of the characteristic polynomial.

To define direct indicators of system's quality, the graph of the transient characteristic of the system is obtained and shown in Figure 11.

From Figure 11, the time of the system's regulation is determined, which is equal to $t_p = 0.805s$, and the value of over-regulation is calculated in the equation as follows:

$$\sigma = \frac{h_{max} - h_\infty}{h_\infty} \times 100\% = \frac{1.06 - 1.01}{1.01} \times 100\% = 4.95\%. \quad (16)$$

Under the operating conditions, the parameters of the control system vestal with CNC may vary within certain limits (wear, temperature fluctuations, friction, surface angle, etc.), where these fluctuations in parameters can lead to a loss of stability of the system mainly when operates close to the stability limit. Therefore, the designed ACS for CNC should work far from the limit of sustainability. In addition, it is necessary to determine the stability margins of the Westat control system with CNC by the values of the phase and amplitude margins; accordingly, a decibel log frequency characteristic (DLFC) and Logarithmic amplitude-phase frequency response (AFPFR) are obtained and shown in Figure 10.

Figure 10 identifies the following indicators of stability:

(i) The amplitude stability margin (ΔA) = 8.73 dB

(ii) The phase margin of stability ($\Delta\phi$) = 130°

The obtained values of stability indicate that the value of the margin of stability in the amplitude falls in the range of 6–20 dB, whereas the values of the margin of the phase fall in the range of 30°–600°, which indicates that the developed system is normally damped system. Based on the study of the stability of the developed control system of the CNC machine, the quality indicators and the stability margins, it is concluded that the selected elements of the system and its structure meet all the conditions of the design of such systems.

2.3. Optimization of CNC Machine Tool Control System.
CNC laser machine is a complex multidimensional object, and the values of its adjustable and outrageous parameters are dynamic. There are some difficulties in developing a management system for such facilities. For example, in the transfer function of the laser power control area that is applied to obtain the desired color intensity, which is calculated according to known methods of setting standard regulators for this class of objects, accordingly, corrections and, in many cases, nonstationary noise and perturbations acting on objects are required, resulting in considering the automatically

(a)

(b)
Figure 9: Mikhailov curve at the approximation range. (a) Range one. (b) Range two.
Figure 10: DLFC and AFPFR of CNC control systems.

adjustment of the control settings or selecting the optimal settings as an urgent task. For such a task, modeling is carried out by firstly building a model of the CNC machine control system with PID controller, as shown in Figure 12.

Determining the optimal parameters of the controller is an iterative process, which consists of 21 iterations, in which the parameters of the PID controller were selected and tested experimentally. At the same time, it is noted that the number of iterations depends on the requirements of the laser engraver control system (quality, reliability, accuracy, est.). The results of the optimization are the calculated optimal parameters of the PID controller that is shown in Figure 12.

Moreover, the graphs of the calculated transient characteristics are shown in Figure 13.

The obtained results shown in Figures 13 and 14 are not optimal because the parameters of the laser machine system controller are optimized according to certain parameters. To obtain optimal results for the system according to the operation parameters, a block diagram of the model based on Figure 12 is built, and the "Saturation" block is added, which is a nonlinear device that acts as an ideal limiter.

The saturation block keeps changing the output signal till it becomes equal to the input signal, which is the adjusted threshold for the upper and lower bounds. When reaching

the adjusted thresholds, the output signal stops changing, resulting in improving the PID controller. Figure 15 shows the block diagram of the optimized model of the PID controller in MatLab.

Based on the simulation results, the PID controller parameters were optimized, and the optimal PID controller coefficients were obtained, which are presented in Figure 16.

The following coefficients were selected for the developed CNC workbench control system: coefficient of integral component = 87.32; coefficient of differential component = 79.6, and the coefficient of the proportional component = −4.

The transition graphs with optimized controller parameters are shown in Figure 17.

3. Development of the Structure and Prototype of the Laser Workbench Model with CNC

The full model structure contains hardware structure, parameters setting, and the operating software.

3.1. Hardware and Setting Development. Based on the proposed block diagram of the machine with CNC (Figure 2)

and the selected hardware modules (Figures 3–5), a block diagram was developed, which is presented in Figure 18.

Accuracy is important for CNC, so the design with the use of profile and rails allows for achieving the highest possible accuracy, which determines the scope of the application. The surface of the rail is pretreated and carefully sanded to avoid the slightest corrosion and dents. Due to the presence of side recesses in the form of a holder for balls, the carriage moves along the beam. Unlike a round shaft, the collision area is not a point but a line. This creates certain advantages, such as increasing the wear resistance of the rail, increasing the accuracy of the machine, increasing the load capacity, and improving the ability to withstand loads. Accordingly, the minimum backlash or its complete absence is provided. To achieve maximum accuracy in the developed model of the CNC machine, it is proposed to use rail linear guides as shown in Figure 19 [39].

A SM is attached to the aluminum so that its shaft is inside the profile, and the guide is fixed from above by the cut hole from the corner that will fasten the portal with the Y axis. The portal is mounted on the carriage, the operation is symmetrical, and the belt is fastened inside the profile. Figure 20 shows the mounting of the portal with the Y axis.

After that, the design is fastened on the chipboard, the power is supplied, and hence the laser is fastened on a portal carriage. Figure 21 shows a side view.

All electronic parts are placed in the rear and covered with a piece of chipboard resulting in building the body as shown in Figure 22, which shows the model of the assembled CNC laser machine.
FIGURE 17: Transition process of CNC control system with optimized parameters UNDER the regulator.
FIGURE 18: Block diagram of a CNC laser machine.
FIGURE 19: Rail linear guide [39].
FIGURE 20: Attaching the portal to the Y axis.

the machine with CNC, getting rid of missing SM steps, and reducing the heat of the SM or driver.

To calculate the voltage on the A4988 driver board, the following formula is used [40]:

$$V_{\text{ref}} = I_{\max} \times 8 \times R_s, \qquad (17)$$

where V_{ref} is the voltage on the driver board (v), $I_{\max}$ is the rated motor current (A), and R_s is the resistance of the resistor on the board A4988 ($0.1 \, \Omega$).

After assembling the prototype of the layout, the voltage on the driver board A4988 is adjusted for CD, and finally, the value of the step (Step) of the belt drive is calculated.

The correct current setting for the SM affects the following characteristics: noise reduction from the operation of

FIGURE 21: View of the CNC machine from the side.
FIGURE 22: The assembled layout prototype of the Laser machine with CNC.

FIGURE 23: The variable resistor on the A4988 board.

TABLE 2: Step settings on the A4988 driver.

MS0	MS1	MS2	Step resolution
Low	Low	Low	Full step
High	Low	Low	1/2
Low	High	Low	1/4
High	High	Low	1/8
High	High	High	1/16

Due to the fact that the operating current of the motor is equal to 70% of the holding current, the obtained value of 1.36 V (from cutout 15) must be multiplied by 0.7. Otherwise, the temperature of SM in the hold mode increases resulting in heating the SM. Accordingly, equation (17) is modified as shown in the following equation:

$$V_{ref} = 1.36 \times 0.7 = 0.952. \tag{18}$$

The result of 0.952 V should be adjusted on the board by adjusting the variable resistor shown in Figure 23.

To "fine tune" the A4988 driver, you need a 5 V voltage source (Arduino Nano controller). You will also need a voltmeter and a small screwdriver. First, we connect the common wire of the Arduino Nano to the common driver and +5 V to the power output of the driver logic called VDD. We power the Arduino Nano and use a voltmeter to measure the voltage between the common wire and the trimmer motor (in the green circle in Figure 23). Next, twisting the construction resistor with a screwdriver, we achieve the calculated voltage of 0.952 V on the voltmeter. The specifics of setting the A4988 driver is that during the setting, it is necessary to carry out without contact of the hand to the metal part of the screwdriver since the hand can act on the measured electrical circuit. This, accordingly, can introduce errors into the settings and, consequently, into the quality of the image obtained by laser engraving. If the voltage does not change when the resistor slider rotates, then the A4988 driver chip is out of order.

To calculate the value of the step (Step) for the belt drive, it is required at first to determine the number of the needed steps to enable the engine's shaft to generate one full revolution, i.e., 360°, so, to obtain 200 steps for example, the single step adjusted to rotate the shaft by 1.8° according to the following formula:

$$N_d = \frac{360}{1.8} = 200, \tag{19}$$

where N_d is the number of the steps needed to obtain one full rotation for the shaft.

Therefore, it takes 200 steps (pulses) to make a full shaft rotation. Moreover, the A4988 driver enables increasing the number of engine steps by controlling the intermediate steps, which increases the accuracy of the CNC machine by reducing torque. To adjust the step on this driver, applying the voltage to certain foams according to Table 2 is required.

Choose the largest division of step 1/16 and install jumpers on the expansion board CNC Shield v3.0 where the A4988 driver board is located.

For example, calculating the number of steps at the full rotation of the motor shaft with the division of step 1/16 can be obtained according to equations (19) and (20):

$$N_d = \frac{360}{1.8 \times 1.6} = 3200. \tag{20}$$

Based on the results of the calculation, it is possible to determine the value of the step for the belt drive according to the formula as follows:

$$N = \frac{(N_d/n)}{N_{step}}, \tag{21}$$

where N is the number of the step for the belt drive, n is the number of gear teeth (GT2 toothed belt with 2 mm pitch installed), and N_{step} is the gear pitch frequency. For the developed layout, the value of the step for the belt drive is 80 ($N = 80$).

3.2. Firmware and Configuration of the CNC SHIELD V3.0 Workbench Software.

Based on the selected hardware modules (Figures 3–5) of the developed laser workbench with CNC and block diagrams (Figure 18), the next step is to develop an information model of software relationships. Figure 24 shows the aggregation of the information model of the relationship between the software and the hardware modules of the workbench with CNC.

In the first step, download Marlin 2.0 Firmware as the most optimized for CNC machines [41]. Open the file X:\∗∗∗\Marlin-2.0.x\Marlin.ino in the Arduino IDE. Reconfigure the configuration.h file. For work with the developed laser machine with CNC. First of all, adjusting the speed of the Serial Port to work with the Arduino Mega 2560-M16U is required, which does not need to change:

 # define BAUDRATE 250000 на *# define BAUDRATE 115200*.

Next, the board to which the laser control module is connected is required to be specified, which depends on the used foam. In the proposed work, the following was specified:

```
# ifndef MOTHERBOARD
# define MOTHERBOARD BOARD_RAMPS_14_EFB
# endif
```

The next step is to specify the used laser, where it is not necessary to specify the same settings:

```
# define EXTRUDERS 1
```

After that, it is necessary to adjust the operation of thermistors used to measure the table and extruder. As the proposed work is for a laser engraver, the firmware must indicate their absence (Appendix A).

Adjustment of the PID controller is carried out in the following parts of the firmware, where it is needed to specify the calculated values:

```
# define DEFAULT_bedKp 79.6
# define DEFAULT_bedKi 87.32
# define DEFAULT_bedKd-4
```

Next, it is needed to spend the mood of the limbs, in the form of maximum and minimum position, and in which direction they should park, which is very important because it depends on the grid of the CNC laser machine.

```
# define USE_XMIN_PLUG
# define USE_YMIN_PLUG
# define USE_ZMIN_PLUG
```

The next step is to specify the logic of the suns, normally open or normally closed. This is done in the following lines of code (Appendix B).

Next, it must be indicated which drivers of SMs are used in the assembled machine:

```
# define X_DRIVER_TYPE A4988
# define Y_DRIVER_TYPE A4988
# define Z_DRIVER_TYPE A4988
```

Now it is necessary to adjust the "steps," i.e., how far the carriage of the laser engraver will travel along the axis. The distance depends on the belt, the driver of the soft engine, the engine itself, or the nut screw. To calculate the steppes according to (18-19).

```
#define DEFAULT_AXIS_STEPS_PER_UNIT {80, 80, 400, 500}
```

Then the speed and acceleration are set, as shown in Appendix C:

The next step is to adjust the direction of SMs rotation, if they work properly, except for the second motor, so it must be inverted:

```
define INVERT_X_DIR false
# define INVERT_Y_DIR true
# define INVERT_Z_DIR false
```

The last step is to specify the direction of parking and the size of the work area, as shown in Appendix D.

After configuring the laser engraver firmware, it is needed to save the Marlin 2.0 Firmware and compile it for testing.

4. Examples of Trial Engraving as Confirmation of the Performance of the Laser Engraver Layout

To verify the accuracy of the decisions made, which hardware and software were made for trial engraving on the developed model of the laser engraver.

In Figures 25 and 26, sample drawings for engraving are illustrated for two different engraving surface materials.

Figure 26 shows the results of engraving of Figure 25 on the engraving surface of plywood 4 mm, where the engraving time is 2 hours 30 minutes. The obtained results of the proposed first example show that the accuracy of the resulting image is regarded as high.

Figure 26 shows the results of engraving, where the high engraving precision is clear. However, despite the high accuracy of engraving for the example in Figure 26, it should be noted that for a more detailed assessment of the quality and accuracy of engraving, it is necessary to conduct a number of test experiments, taking into consideration that such experiments and their full description are beyond the scope of this article, moreover, implementing the deep learning technique can lead to much clearer results such as implementing the deep learning in [42]; however, this is regarded as the future work.

It is important to note that the layout of the laser engraver presented in this work showed its fundamental capabilities for engraving on different media, overall performance, compliance with the theoretical foundations, and practical implementation of the laser engraver proposed in the experimental sample. The conducted experiments confirm that the developed control system based on the PID controller allows high-quality engraving on leather, plywood, and wood. In this aspect, the key is the choice of optimal control parameters for controlling the operation of a laser engraver.

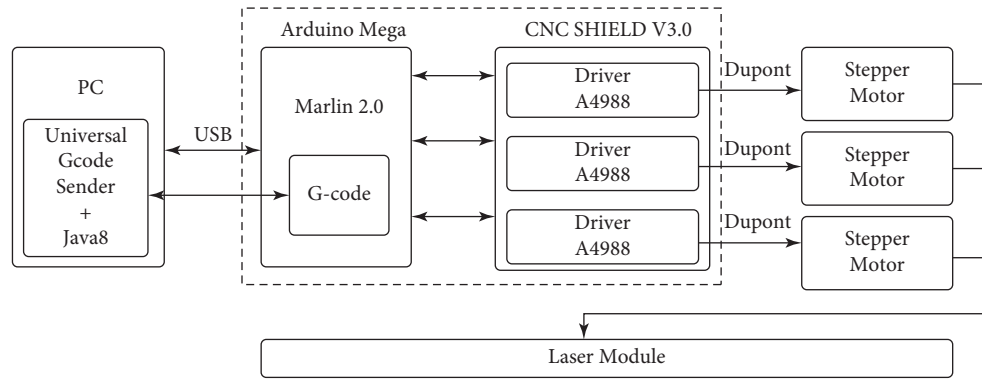
Based on the above, the main goal of this study has been achieved, and an experimental portable laser engraver has


FIGURE 24: Consolidation of the information model of the relationship of the software and the hardware modules of the workbench with CNC.

FIGURE 25: Test image.

FIGURE 26: Results of test image (Figure 25).

been developed and assembled, which has shown its performance and engraving quality.

5. Conclusions

The proposed work in this article is focused on designing and implementing a laser engraving system based on modern industrial Computer Numerical Control (CNC), based machines which shows the great complexity of their application in Armament Repair Shop Set (ARSS) systems. This is due to the large overall dimensions, limited mobility, and the complexity of repairs in the field. The authors made an assumption about the development of small-sized portable laser engravers based on CNC. There is also the possibility of future mobile adaptation to a CNC milling machine by replacing the working body,

which is expected to save a lot of space for other equipment. Based on this solution, the authors set a number of tasks, during the solution of which an analysis was made of the relationship between the input and output parameters of the control object vectors. To comply with these relationships, the authors proposed a block diagram of small-sized portable CNC-based laser engravers. Moreover, the authors developed and mathematically described the control system for selected modules, which applies the theories of automated control. The construction and synthesis of the designed system in MatLab were carried out, and it was proved that the developed system is stable. To ensure the quality and accuracy of laser engraving, the authors optimized the developed system by including a PID controller in it. To check the correctness of the decisions made and the mathematical conclusions, the authors developed an experimental prototype of a small-sized portable CNC-based laser engraver.

In the course of the study, the authors optimized the synthesized control system by using a PID controller in it. By means of mathematical modeling, the indicators of the PID controller were obtained, which accordingly increased the stability of the control system to the occurrence of external vibrations and parasitic factors that could adversely affect the quality of laser engraving.

Finally, the authors applied the proposed model to several actual images, and the obtained results are regarded as high in quality, though just 2 hours and 30 minutes were required to finish the whole laser engraving process in such a small area on different types of surfaces, which practically proves the validity and efficiency of the proposed mode.

The future work is planned to conduct a detailed assessment of the quality and accuracy of engraving based on the developed layout. It is also planned to modify the structures to develop a universal CNC machine with a replaceable working body laser engraver/CNC milling machine.

With the continuous development of network technology, the production and lifestyle of human beings are also quietly changing. People find that the network makes life faster and more convenient and also makes our life more "transparent." The openness, sharing, and convenience of the network make it easier to infringe on the privacy rights of others, bringing an unprecedented impact on traditional privacy protection. This paper studied information security assurance-related algorithms and built an information security assurance model. Through this model, some privacy violation events existing in the network today were analyzed. Then, a corresponding questionnaire was constructed according to some of the problems of these events. The questionnaire is mainly used for research on people of all age groups, mainly to study their understanding of relevant legal knowledge and their views on the law. A total of 188 valid questionnaires were collected in this survey. Only 37.23% people knew a lot about the law. Most of them learned it from the Internet, and they rarely learned about it from relevant books. About 70% people believe that the law plays a big role in privacy protection, and they will choose legal help if they encounter privacy violations. However, this is inconsistent with some data obtained from the information security assurance model. Through analysis, it can be seen that although they want legal help, they lack the relevant knowledge of the law, and they do not know whether the privacy of individuals has been violated. Therefore, it is necessary to strengthen personal knowledge of privacy protection laws and improve the personal information legal protection and fair use system.

1. Introduction

Infringement of personal information is concealed, and information users are good at covering up their own behavior with the help of various information technologies, which make it difficult to define and obtain evidence of their behavior. At the same time, the absence of relevant legal systems, insufficient government supervision, and vague industry rules make it difficult to achieve effective legal protection. On the other hand, the lack of protection leads to abuse, and excessive protection pressure will hinder the development of the personal information industry. The inherent conflict between protection and use makes this a tricky one. The invasion of personal privacy in the Internet age has become a hidden worry and trouble for many netizens, and the security of Internet privacy has become a

difficult problem. It can be said that the protection and use of personal information is a relatively new problem in the world. Many experts, scholars, and staff from various countries and regions are struggling to be on the front line of solving this problem. Therefore, how to successfully deal with information security issues to ensure the security of development is of great practical significance to many countries. The more common or deadly information security issues become, the more critical it is to have effective security assurance.

In order to protect the privacy of individuals, researchers have conducted research on the legal aspects of privacy protection. Among them, Mohamed and Chen [1] examined the potential relationship between the existence of a national data protection framework and its impact on e-health. They researched how college students share and

use personal information through online media. The findings will be used to discuss and suggest improvements needed for the current iteration of Malaysia's data privacy laws [1]. Zapadka [2] studied the selected aspects of statistical secrecy, determining the extent to which the data collection and storage processes provided by the Public Statistics Act constitute justified legal interference with the constitutional rights and freedoms of natural people [2]. Danilovic [3] discussed Serbian employees' right to privacy at work in the early twenty-first century and its relationship to international regulations and practices. He proposed the establishment of an internal privacy policy with full respect for data protection regulations, which can provide a feasible and reasonable expectation of privacy at work [3]. Baruh et al. [4] investigated privacy concerns and literacy as predictors of online service and social networking site usage, information sharing, and adoption of privacy-preserving measures. However, their method has not been practically applied.

In order to further strengthen the protection of personal privacy, scholars have begun to study information security algorithms to analyze the network. Among them, Beebeejaun [5] studied the challenges posed by current laws, which are based on assessing the legal framework for the rapid growth of fintech [5]. Dan [6] examined the role of information assurance in managing data security by analyzing the formulation and introduction of the General Data Protection Regulation in May 2018 [6]. Saranya et al. [7] analyzed different types of cloud security issues and used a variety of information security assurance algorithms to generate keys and signatures to provide efficient security [7]. Nabi et al. [8] studied the application logic-related component risk, representing "the process of unifying security assurance properties" to deal with logic vulnerabilities in the system [8]. Alexander [9] investigated whether the AHP model can be effectively applied to the prioritization of information assurance defense-in-depth measures. Findings showed that AHP does not affect the relationship between information technology analysts' prioritization of the five defense-depth dependent variables and independent variables such as cost, ease of use, and effectiveness in protecting an organization's devices from attack [9]. However, the practicality of their algorithm is not great.

This paper established a model of an information security assurance system by studying information security assurance algorithms. Using this model to analyze the current network and then combining it with the questionnaire to study a large number of people, it is found that there are a large number of privacy violations on the network. However, these groups have a lack of legal knowledge about privacy protection, which further exacerbates the lack of privacy. Therefore, new strategies need to be developed to protect personal privacy. The innovation of this paper is as follows: based on the original information security assurance algorithm, it built a more comprehensive information security assurance system model and optimized the algorithm of the model.

2. Information Security Assurance Algorithms and Privacy Protection

2.1. Information Security. The concept of information security has been continuously expanded and deepened with the development of information technology. Initial information security mainly refers to communication security. The current concept of information security refers to information security assurance that comprehensively protects information infrastructure, application services, and information content [10, 11]. The connotation of information security has been extended to the confidentiality, integrity, authenticity, controllability of information, availability of information infrastructure, and nonrepudiation of interactive behavior, and it also includes active defense in information operation conditions. The relationship between information security, information assurance, and information confrontation is shown in Figure 1.

The research content of information security includes two themes: data security and network security. Closely related to this research topic are the security and reliability of computer mainframes and network environments. There are various measures taken for the security and reliability of the computer host and network environment, such as virus prevention, network firewall, and access control [12].

Data security means that the user's data information is not destroyed, the read and write can be consistent, and unauthorized access can be rejected. It is the most fundamental research content of information security. There are many measures to ensure data security, including physical measures, such as strict control of important computer rooms, strict management of hosts, and data backup. It also includes technical measures, such as data consistency check, data redundancy, and network security. In the network environment, network security is an important fundamental measure to ensure data security.

Network security refers to the use of network management control methods and technical measures to ensure the confidentiality, integrity, and availability of data and information in the network environment [13]. The main goal of network security is to ensure that information transmitted over the network and data on network hosts are not added, altered, lost, or illegally read, and host systems in the network are not illegally exploited. These levels are divided into physical security, host system security, and network security detection.

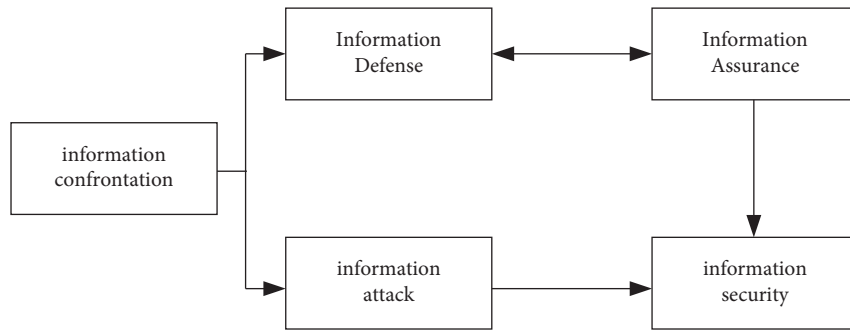
The information security model is an important basis for describing and characterizing the system and information security features, and it is also the foundation of security thinking and technology. The highest-level security system requires formal design and correctness proof [14]. Information assurance is an interdisciplinary subject involving many fields, including not only information security technology but also security management technology, the technical framework of security protection, and the life cycle process of information assurance. Figure 2 shows the "section" of the extended McCumber model in the time dimension. The multidimensional model fully describes the


FIGURE 1: Relationship diagram of information security, information assurance, and information confrontation.
FIGURE 2: Time section of the information assurance model.

FIGURE 3: Basic elements of the network information security system.

various elements contained in information assurance in detail and also reflects the connections and relationships between various elements. The four dimensions included in the information assurance model are information states, security services, security countermeasures, and time.

In order to realize the security of network information, users should establish the capabilities of information collection, protection, and coordination in the information domain. Then, based on this ability, they put themselves in a more favorable position relative to the attacker's information. In this way, the ability to establish, generate, and share high-quality attitude perceptions, jointly understand defense intentions, and self-synchronization of defense processes in the cognitive domain is further realized. As a state of network information security, the network should have the following three specific capabilities: (1) immunity to external damage; (2) to ensure the normal and effective performance of its functions and to maintain its openness and scalability; (3) to protect its integrity and stability [15]. Network information security should include three elements, as shown in Figure 3.

Based on the above analysis, it can be seen that an effective and complete network information security system should have three mechanisms: protection, detection, and response. Based on this, a complete network information security assurance system should include four systems:

protection capability, monitoring capability, management mechanism, and emergency mechanism, as shown in Figure 4.

An intrusion is any attempt to compromise the integrity, confidentiality, and availability of computer system resources or to override the security mechanisms of a computer or network. Intrusion behaviors include the following two aspects: (1) maliciously obtaining system control rights beyond the legal scope; (2) behaviors that cause certain harm to the network system through system vulnerabilities. Intrusion detection is a technique used to detect intrusions in computer networks that violate security policies [16]. By collecting and analyzing key information in the network and host systems in real time, it timely detects and reports the abuse of resources by illegal users and legitimate users in the system and makes appropriate responses. The schematic diagram of intrusion detection and its relationship with other technologies are shown in Figure 5.

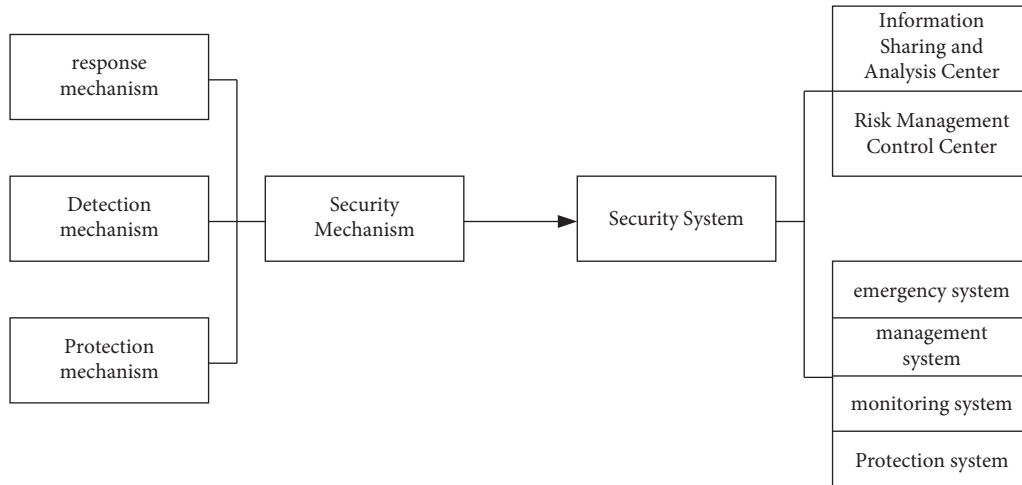
From Figure 5(a), it can be seen that the intrusion detection is placed behind the firewall, and its monitoring or


FIGURE 4: Composition model of the network information security assurance system.
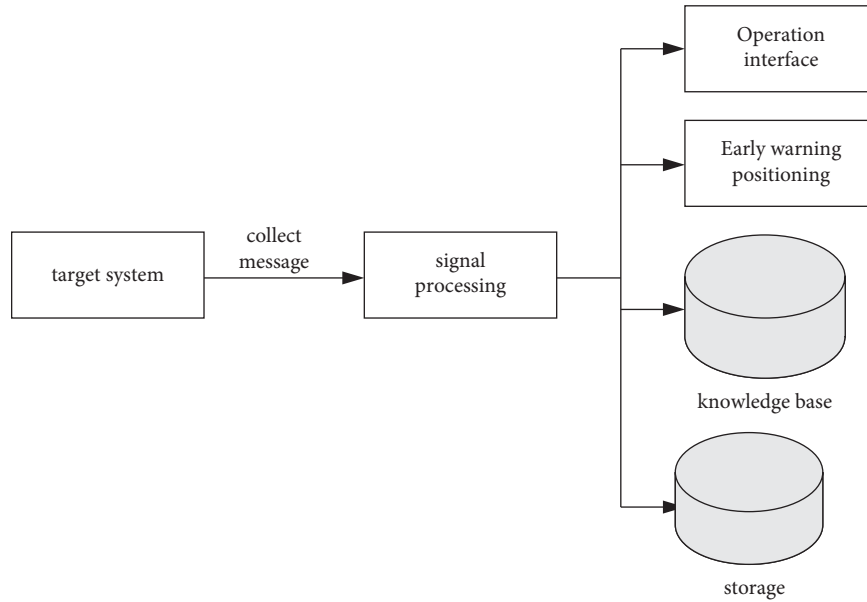

(a)
(b)

FIGURE 5: Intrusion Detection. (a) Principle of the intrusion detection system. (b) The relationship between intrusion detection and other security technologies.

information processing of the network generally does not affect the performance of the system. It provides real-time protection against internal and external attacks and more. It can be seen from Figure 5(b) that in the overall security system of a network, intrusion detection systems, firewalls, vulnerability scanning, and antivirus software work together to describe the role of IDS in the network security system [17, 18]. The main role and function of IDS should be reflected in the following points: (1) subjecting the activities of users and systems to its monitoring and analysis; (2) configuration and weaknesses of audit systems; (3) assessing the integrity of critical system data files.

At present, the most widely used intrusion detection systems are mainly expert systems and statistical analysis techniques. The expert system is currently the most widely used technology in abuse detection systems. It uses domain-expert knowledge and reasoning mechanisms and has certain intelligence. It is mainly used for the abuse detection system. The main method of this technology is to set the domain expert knowledge as an intrusion detection rule and judge the legitimacy of the behavior by detecting whether the user's behavior is consistent with the detection rule.

A statistical survey is one of the earliest technologies used in intrusion detection technology, and many commercial versions of intrusion detection products still use this technology [19]. The system assumes that the user's behavioral habits are regular and then builds an auditor of the system by analyzing and modelling the user's historical behavior or collecting early evidence of the system. The auditor judges the intrusion by checking whether the user's behavior conforms to the normal behavior model. Their schematics are shown in Figure 6.

Figure 6(a) shows the schematic diagram of the intrusion detection of the expert system. It can be seen from the figure that the key technologies in the expert system are as follows: (1) The detection knowledge base stores the knowledge of intrusion detection rules. It is operated by experts in the security field and can add detection rules at any time. (2) The inference engine simulates the reasoning ability of the human brain and judges whether the network behavior is legal or not according to the intrusion rules and the rules of the comprehensive knowledge base. (3) The comprehensive knowledge base stores data of various networks and hosts, intermediate inference results, and final results. The system has a high detection efficiency for known intrusion behaviors but does not have the ability to detect unknown intrusion behaviors. The acquisition of intrusion detection rules requires human intervention, and the ability to automatically acquire knowledge is low.

Figure 6(b) shows the schematic diagram of the intrusion detection system based on statistical analysis. It can be seen from the figure that the detection method of the detection system uses some statistical variables to describe the behavior of users or systems. The main functions of the system include selecting appropriate statistics, statistical data analysis and intrusion judgment, and adaptive update of statistical models. Intrusion detection systems based on

statistical analysis have a certain learning ability and adjust the model data of the auditor by continuously analyzing the historical behavior of users or systems. However, it also has a fatal disadvantage that illegal users can train intrusion detectors through a large number of abnormal behaviors to achieve "legitimate" purposes. In addition, the real-time performance of the system is poor.

2.2. Information Security Assurance Algorithm. By means of information security assurance, the risk of information and information systems can be reduced. Considering the differences in the degree of informatization between different countries and the gap in information technology, this paper puts forward the idea of building an information security assurance system based on risk management, highlighting the importance of risk management in an information security system. The information security assurance model is shown in Figure 7.

Through the risk analysis, the security threats existing in the information environment and the vulnerability analysis of the system are given. According to the context of information security assurance and the system vulnerability obtained by the risk analysis, appropriate security control measures are selected. At the same time, the cost of safeguard measures and the value of information assets are analyzed in order to obtain the optimal risk management scheme [20].

The BP neural network is the most widely used network at present, which is usually composed of an input layer, several hidden layers, and an output layer. The BP algorithm is a supervised learning algorithm. Its main idea is to use gradient search technology for known learning sample pairs, in order to minimize the mean square error between the actual output value of the network and the expected output value. If the expected output cannot be obtained in the output layer, it is transferred to backpropagation, and the error of the output signal is returned along the original connection path. The weight of each layer of neurons is modified to minimize the error. The basic evaluation process is as follows:

Network state initialization: assigning a random number between the connection weight w_{ij}, v_{jt} and the threshold θ_j, γ_t endow and $(-1, 1)$.

Entering the first learning sample pair.

Calculating the input u_j and output h_j of each neuron in the middle layer, namely,

$$
\begin{aligned}
u_j &= \sum_{i=1}^n w_{ij} x_i - \theta_j, \\
h_j &= f\left(u_j\right).
\end{aligned}
\tag{1}
$$

Among them, f adopts the sigmoid function, i.e.,

$$
f(u) = \frac{1}{\exp(-u) + 1}.
\tag{2}
$$

Calculating the input l_t and output y_t of each neuron in the output layer, namely,

(a)

(b)
FIGURE 6: Intrusion detection system. (a) The schematic diagram of expert system intrusion detection. (b) Principle of the intrusion detection system based on statistical analysis.
FIGURE 7: Information security assurance model based on risk management.

$$l_t = \sum v_{jt} h_j - \gamma_t,$$

$$y_t = f(l_t) = \frac{1}{\exp(l_t) + 1}. \tag{3}$$

Calculating the weight error δ_t connected to the output layer unit t, which is as follows:

$$\delta_t = (c_t - y_t) y_t (1 - y_t). \tag{4}$$

Among them, c_t in the above formula is the expected value of the sample.

Calculating the weight error σ_t connected to the intermediate layer unit j, as shown in the following equation:

$$\sigma_t = \sum_{t=1}^{q} \delta_t v_{jt} h_j (1 - h_j). \tag{5}$$

Updating the connection weight v_{jt} and the threshold γ_t, i.e.,

$$v_{jt}(N+1) = v_{jt}(N) + \alpha \sigma_t h_j,$$

$$\gamma_t(N+1) = \gamma_t(N) - \beta \delta_t. \tag{6}$$

Updating the connection weight w_{ij} and the threshold θ_j, i.e.,

$$w_{ij}(N+1) = w_{ij}(N) + \alpha \sigma_j x_i,$$

$$\theta_j(N+1) = \theta_j(N) - \beta \sigma_j. \tag{7}$$

Enter the next learning sample pair and return to step 3 until all z pattern pairs are trained.

Starting a new round of learning and training until the following conditions are met:

$$\left| \sum_{k=1}^{z} E_k \right| \leq \varepsilon. \tag{8}$$

Among them, ε is the preset accuracy and E_k is the mean square error, i.e.,

$$E_k = \frac{1}{2} \sum_{t=1}^{q} (c_t - y_t)^2. \tag{9}$$

There are more than 100 original data features in the network, which belong to multifeature, high-noise, and nonlinear datasets. If such high-dimensional data are directly used for classification, the computational load of the classifier will be very large. In particular, there will also be a large number of features irrelevant to data classification in the features, which are more likely to reduce the classification accuracy of the classifier. Therefore, before data classification, it is necessary to perform feature selection on the original network data, that is, data dimensionality reduction. The features that are most conducive to data classification are selected from them, thereby reducing the computational complexity of the classifier and improving the accuracy of classification.

The essence of feature selection is a process of optimizing computation, and pattern recognition is still one of the typical solutions. That is to say, it is necessary to find a criterion and express it with a formula, so that the formula reaches the extreme value in the calculation process [21]. In the process of feature evaluation, the evaluation methods are roughly divided into two categories. One is the distance-based separability criterion, that is, the criterion is based on calculating the dispersion degree of the sample in the feature space; the other is based on the probability density distribution as the basis for judgment.

Supposing the feature candidate set $X = [x_1, ..., x_n]$, in its defined n-dimensional feature space, $d = (x_{ik}, x_{jt})$ is used to represent the distance metric between the k-th sample in the i-th class and the l-th sample in the j-th class. Then, the distance metric value can be defined as per the Euclidean formula and other calculations. Considering the computational complexity of the formula, it is converted into the corresponding overall matrix to measure and calculate, and the overall distribution matrix calculation formula is as follows:

The i-th mean vector can be expressed as follows:

$$\overline{X}^{w_i} = \frac{1}{N} \sum_{x \in w_i} X. \tag{10}$$

The mean vector of the sample aggregate can be expressed as follows:

$$\overline{X} = \frac{1}{N} \sum_{i=1}^{M} p(w_i) \overline{X}^{w_i}. \tag{11}$$

Type i covariance can be expressed as follows:

$$\sum_i = \frac{1}{N_i - 1} \sum_{X \in w_i} (X - \overline{X}^{w_i})(X - \overline{X}^{w_i})^T. \tag{12}$$

The total covariance of the sample can be expressed as follows:

$$\sum = \frac{1}{N - 1} \sum (X - \overline{X})(X - \overline{X})^T. \tag{13}$$

The intraclass scatter matrix for the i-th class can be expressed as follows:

$$S_i = E \left| (X - \overline{X}^{w_i})(X - \overline{X}^{w_i})^T \right|. \tag{14}$$

The population within the class scatter matrix can be expressed as follows:

$$S_w = \sum_{i=1}^{M} p(w_i) S_i. \tag{15}$$

The population between the class scatter matrix can be expressed as follows:

$$S_B = \sum_{i=1}^{M} p(w_i)(\overline{X}^{w_i} - \overline{X})(\overline{X}^{w_i} - \overline{X})^T. \tag{16}$$

The population scatter matrix can be expressed as follows:

$$S_T = E \left| (X - \overline{X})(X - \overline{X})^T \right|. \tag{17}$$

S_T and S_B, S_w have the following relationship:

$$S_T = (S_B + S_w). \tag{18}$$

The intraclass scatter matrix represents the scatter of each sample point around its mean. The interclass scatter feature represents the distance distribution between classes, which depends on the sample category attributes and division. The overall scatter matrix has nothing to do with the sample division and attributes.

2.3. Privacy Protection. The essence of privacy mainly includes three parts, namely, private space, information, and activities that are not disturbed by the outside world. It also has the premise that is harmless to society and others. The privacy right is the right of citizens to make their own decisions about their personal life and information and has nothing to do with the public interest.

Privacy protection is mainly performed through the method of government legislation to formulate relevant legal regulations. The basic principles and specific systems for the protection of online privacy rights are legally established, and corresponding judicial or administrative remedies are established on this basis. The use of information makes the traditional closed society transition to transparent society. Personal information should not be locked in a "coffer" but should be put into the "big warehouse" of society to give full play to its value. The legal protection of personal information

should not only protect individuals but also affirm the legality of the use of personal information by information users such as governments and commercial organizations. The purpose of legal protection is to seek coordination between the development and utilization of information resources and the protection of personality rights to reasonable use of personal information.

3. Experiments of Privacy Protection Law

3.1. Questionnaire of Privacy Protection Laws. This questionnaire set up a survey on different groups of people on privacy protection laws and conducted a survey on people of different age groups, as shown in Table 1. A total of 200 questionnaires were distributed in this survey, and 188 valid questionnaires were recovered, with a recovery rate of 94%.

It can be seen from Table 1 that in this questionnaire survey on privacy protection legal issues, the majority of people gave positive responses. Among them, 54.26% were teenagers aged 18–25, which were mainly students, followed by workers aged 25–40, accounting for 28.19% of the total questionnaires. The rest of the questionnaires were mainly attributed to minors under the age of 18 and people over 40. Because they mainly had little contact with the Internet, the ratio is relatively small, accounting for 9.57% and 7.98%, respectively.

In response to the concept of privacy and privacy rights, this questionnaire surveyed and found that they mainly understood privacy and privacy rights in a relatively simple way. They simply believed that it was their own personal information, and privacy rights also stayed in personal information. Only a few people have a comprehensive understanding of privacy and privacy rights, and the survey results are shown in Table 2.

From Table 2, it can be seen that only 57 people have learned about privacy and privacy rights, and the other 131 people have not seriously understood privacy and privacy rights. Thirty of the 53 people aged 25 to 40 have seriously understood it. It shows that more than half of people in this age group will learn about privacy protection laws, which are closely related to their work experience. It makes them more concerned about their personal information. Only 21 out of 102 aged 18 to 25have learned about privacy and privacy rights, which may also include students who majored in law. It shows that contemporary teenagers do not pay much attention to privacy concerns, thinking that these have nothing to do with themselves. However, in fact, privacy and privacy rights are closely related to our daily lives. As for minors, they are less concerned about privacy and privacy rights.

In order to further understand people's understanding of privacy protection laws, this questionnaire also raised a number of legal questions. Among them, about the two questions "How did you learn about privacy protection laws?" and "Do you know more or less about privacy laws?," the received questionnaires have been organized, and the questionnaire data are shown in Figure 8.

From Figure 8(a), it can be seen that people in the age group of 18–40 mainly learn about privacy protection laws

TABLE 1: Survey distribution by age groups.

Age	Number of people	Proportion (%)
<18	18	9.57
18 ∼ 25	102	54.26
25 ∼ 40	53	28.19
>40	15	7.98

TABLE 2: Whether people know about privacy and privacy rights.

Age	Yes (number of people)	No (number of people)
<18	1	17
18 ∼ 25	21	81
25 ∼ 40	30	23
>40	5	10

through the Internet, while those who are underage mainly learn about privacy protection laws through schools and books. For people over 40 years old, because they have little contact with schools and little use of the Internet, their information about privacy protection laws mainly comes from books. For one of them from the school, it may be because he is a school teacher. In Figure 8(b), it can be seen that there are significantly more people who know little about privacy protection laws than those who know a lot about privacy protection laws. This shows that contemporary people do not have a clear understanding of the importance of privacy protection laws, and most people have the mentality that privacy violations will not fall on their heads. However, privacy violations happen to us all the time.

In order to understand contemporary views of today's privacy protection laws, this questionnaire asked the two questions "How effective do you think the laws are in protecting privacy today?" and "Would you seek legal aid if your privacy was violated?." The data are shown in Figure 9.

It can be seen from Figure 9(a) that the vast majority of people agree with the current law and believe that the law can protect privacy. A large part of the population will choose to seek legal protection, but some people do not choose to seek legal help, as shown in Figure 9. Although there are not many people, it further illustrates that the current privacy protection laws may not fully protect privacy. There are still some problems, which make some people not want to seek legal help.

In addition, this questionnaire also conducted a questionnaire survey on the lack of legal knowledge among the population. The questionnaire questions were as follows: "Do you have legal popularization in your area?" and "Do you think the impact of legal knowledge on daily life?." The questionnaire data are shown in Figure 10.

From Figure 10(a), it can be seen that most of the people in the area have no legal publicity, which leads them to not understand legal knowledge, especially some people aged 18–40. From Figure 10(b), most people think that legal knowledge has no effect on daily life, while a very small number of people think that legal knowledge has a deep impact on daily life, especially people aged 25–40. Most of this group of people have married and started a business, so they will be more concerned about the daily life of the family.

(a)

(b)
FIGURE 8: Knowledge of privacy protection laws. (a) Access to privacy shield laws. (b) Knowledge of privacy shield laws.

(a)

(b)
FIGURE 9: Views on privacy protection laws. (a) How effective the law is for privacy protection. (b) Whether they will seek legal aid.

In order to find out whether people are interested in legal knowledge, the questionnaire was surveyed on legal videos. The question was "What would you do if you swiped a short video about the law?," and the data from all the questionnaires were analyzed, and the results are shown in Table 3.

As can be seen from Table 3, the number of people who will watch short videos related to the law is not very large, and most of them will watch for a few seconds or skip them directly. Especially for teenagers in the age group of 18–25, the ratio of being able to watch a complete short video about the law is even less. 28 people will choose to watch it. This is because of the development of technology and the diversity of short videos. Many young people aged 18–25 pursue some funny and celebrity videos and other videos that are not

useful in life, so they will choose to skip short legal videos when they see them. The same is true for other age groups, and the biggest aspect may be the different pursuit of short videos. However, about one-third of people over the age of 40 choose to watch a short video about the law when they swipe it, because this age group has a general awareness of how to make life better.

Combining all data analysis, most people now lack legal knowledge, especially regarding privacy protection laws. Although they know that laws are important, they do not have a detailed understanding of the nature of the relevant laws, which leads them to further ignore the importance of laws. As a result, when their privacy may be violated, they will not choose the law to protect themselves.

(a)

(b)
FIGURE 10: Reasons for lack of legal knowledge. (a) Whether there is any publicity about law. (b) Degree of influence of legal knowledge on daily life.

Age	See it all	Watch it for a few seconds	Skip straight through
<18	2	5	11
18 ∼ 25	28	36	38
25 ∼ 40	11	24	18
>40	5	4	6

3.2. Suggestion. The first point is to improve the legal system. The first is to confirm the right to personal information and to define the subject and object of protection. The struggle for division makes the objects of legal protection have the right to maintain. Second, it is recommended that we distinguish personal information into private information and general information. The unreasonable use of private information is far more harmful to its subjects than that of general information. The protection of the former should be strengthened by the law, and the constraints on the use of the latter should be weakened.

The second point is to build a government supervision system to implement the legal protection of personal information and guide users to use it reasonably. Specifically, through the use of the licensing system, the entry threshold for the personal information industry is raised, and those commercial institutions that do not have the ability to use security measures and regulatory systems are excluded, and the work of the regulatory agency is focused. At the same time, the reward and punishment measures are clearly stipulated to play an exemplary role. Rewards are used to subsidize the efforts of enterprises in the process of reasonable use, whereas punishment is used to prevent abuse of illegal profits.

The third point is to respond to the legal protection of personal information from the perspective of industry autonomy. Through self-management, self-requirement, and self-promotion in the form of industry associations and industry codes, they should do a good job in the self-discipline of the industry and also participate in the balance of protection and use.

The fourth point is from an individual point of view. It is suggested that we improve the liability system and introduce a representative litigation model. The unequal proof capacity and response level should be balanced between information rights and information users to reduce the cost of the former rights of the protection process and increase the amount of damages so as to protect personal information, dispel the speculation of information users, and use personal information rationally.

4. Conclusion

This paper investigated and researched people of all age groups by means of questionnaires, mainly to explore the citizens' understanding of privacy protection laws and other laws. From all the data analysis of the questionnaire, it can be seen that people of all age groups have a serious lack of legal knowledge and little knowledge about privacy protection. As an intangible property, personal information plays an increasingly important role in the development of society. Therefore, it is necessary to strengthen citizens' knowledge of the law so that more citizens can use legal knowledge to protect themselves when they encounter privacy violations. People believe that with the gradual improvement of the country's legislation on privacy protection, the popularization of privacy protection education, and the protection of privacy rights, technological means will change with each passing day.

Data Availability

The datasets generated during and/or analyzed during the current study are not publicly available due to sensitivity and data use agreement.

Appropriate business models are very important for enterprises. With the advent of the new century, the rapid development and application of technologies such as the Internet of Things and big data have become more and more widely used, which provides great convenience for people's daily life. With the rise and development of the Internet of Things and big data technology, human work and life have become easier and easier, and it has also greatly changed human production and development. Under the fierce market competition, enterprises pay more and more attention to the independent research and development capabilities of their own brand products. With the rapid development of the Internet age, the status of brands in the improvement of business models is also increasing. The brand business model design must not only meet the ever-changing market consumer demand but also conform to the ever-changing fashion trends. The article briefly analyzed the development and application of the Internet of Things and big data technology and optimized the design method of the brand business model by using big data technology in design of the brand business model. On this basis, a decision support method for a brand business model based on a data warehouse was proposed to achieve scientific, efficient, and accurate brand product development. In order to understand consumers' consumption habits and awareness of brands, the article randomly selected 400 people to conduct a survey. It was found that 45% of male respondents preferred commercials with simple and elegant colors; 38% of female respondents preferred commercials with minimalist styles. Modern consumers are mainly pragmatic, and the design of brand business models should be developed in this regard.

1. Introduction

With the advent of the era of big data, human society has entered the digital era. The massive increase and penetration of data and information have driven tremendous changes in people's living and production levels, as well as changes in people's consumption needs. It is driven by the continuous development and progress of high-tech such as information technology, network technology, and social media technology, business trends are rapidly changing and changing, presenting a variety of popular information. The intersection of computer networks, e-commerce, information technology, and other fields has resulted in an ever-increasing amount of massive data. In this case, as soon as the concept of big data appeared, it has received extensive attention from scholars, experts, and managers from all over the world. The reason why big data is "big" is not because it is too numerous, but because it has too many types, such as web page scanning, location information services, online and offline consumption, and so on. Under the background of fierce market competition and economic globalization and competition integration, localization, and homogeneity, more and more enterprises pay attention to corporate image, strengthen the core competitiveness, and improve brand awareness. At the same time, they also recognizes the importance of design to the enterprise.

Economic globalization has made it possible for companies from all countries to participate in world competitions and share the world's advanced development achievements. At this crossroads, which is both an opportunity and a challenge, almost all companies have thought of the importance of brands. Lee and Soon's purpose was to

explore the Apple iPhone jailbreak phenomenon, a new scenario in which a company actively suppresses and discourages loyal consumers from cocreating value and customizing its products. Lee and Soon provided a comprehensive conceptual model to show how different theories of consumer behavior are synthesized in this new phenomenon. Compared to previous work, consumer activists were committed to the brands and products they boycott. Instead of switching to other brands, these jailbreakers and hackers stay loyal to the product and really try to help the brand [1]. Although there is a lot of research on Perceived Brand Globalization (PBG), the concept itself is far from clear and more in-depth research is needed. Mandler aimed to contribute to the global brand literature by proposing a scalable PBG concept and examining the impact of traditional versus global brands in practice. Clearly, the impact of international brands was not all positive. The result provided a clearer perspective on the rise and fall of managers' awareness of brand globalization and called for future research on global brands to be included in all levels beyond the brand, so as to fully grasp this phenomenon, but it's not very practical [2]. Huaman-Ramirez et al. aimed to expand the comprehension of how digital platforms actively impact brand trust by presenting two new variables mediated by brand affection and brand creativity, and by testing the modifying role of consumer e-centrism in these associations. Research had shown that brand globalization was positively correlated with brand sentiment, which in turn was positively correlated with brand trust, which suggested a weaker relationship between brand globalization and brand sentiment for ethnocentric consumers. Brand globalization was positively correlated with brand innovation, which in turn was positively correlated with brand trust, which was a weaker relationship between brand globalization and brand innovation for ethnocentric consumers. This research presented new opportunities for managers concerned with optimizing global brand management. First, the findings suggested that managers were interested in increasing the emotional and emotional aspects of their global brands, making them more trustworthy. Secondly, it was important for brand executives to also highlight the innovative sides of their global brands. Indeed, it was important for practitioners not only to constantly come up with new and exciting propositions for citizens but as well as to keep up with the recent trends in the market. The better managers offered new and helpful resolutions to meet consumer needs, the more consumers would trust these global brands [3]. The results of the study indicated that Sarkar et al. aims to find previous research work on brand cocreation and the role of different stakeholders in brand cocreation and to propose a conceptual tool that can be empirically validated. The results of the study showed that the history of literature presented two main stakeholders, namely, consumers and organizations. The importance of the third important stakeholder, the supplier, had been mostly ignored. However, previous studies had shown that properly managed supplier involvement could reduce the time and cost of product and brand development, and it could provide newer technologies and better quality.

Therefore, the importance of suppliers for the creation of a successful brand together cannot be forgotten. In addition to studying the incentives and results of brand cocreation from the standpoint of consumers and organizations, the aim was to examine the supplier's point of view of the brand cocreation framework. This was the first review of the scholarly literature on brand cocreation from the point of view of three key stakeholders: consumers, organizations, and suppliers [4].

The circular economy (CE) is gaining significance, partly due to the rarity of existing natural assets useable in the context of the environment and changes in collective consumer actions. Cutting-edge technologies such as Big Data and the Internet of Things (IoT) have the possibility to pry the concept of CE from being introduced in organizations and societies and becoming more present in everyday life. Nobre and Tavares conducted a content and social network analysis by using the "R" statistical tool and then made comparisons with a number of current industry initiatives. The results showed that China and the United States were the countries most interested in this area and revealed a context with significant research opportunities [5]. Advances in wireless technologies, computing, and sensing devices, as well as the decreasing cost of these technologies, were driving and accelerating the development of cyber-physical systems. These systems used the IoT model to provide various types of services, such as monitoring, weather monitoring, vehicle traffic management, and controls of production activities. The development and adoption of these systems still face various challenges. On the one hand, the development challenges are primarily related to security, robustness, availability, adequate performance, and optimization of energy savings. On the other hand, the use of these systems generates large amounts of fine-grained data that need to be processed and correlated, commonly through big data analyses to extract useful knowledge that can be used by the software services that control them. Ochoa et al. presented a novel contribution to the design, implementation, and use of these systems as part of a special issue on cyber-physical systems, the Internet of Things, and big data [6]. In addition to the functions of self-monitoring, self-diagnosis, and self-protection, intelligent electrical equipment also has the functions of digitally monitoring electrical parameters, implementing judgments, and intelligently controlling and protecting the monitored objects. Jianhua et al. believed that it was reasonable to analyze and judge the status of in-service power equipment, and to use the method of life cycle management for predictive maintenance, thereby improving the reliability and safety of the entire electrical system. It has become an irreversible trend to use big data-related technologies to process the online monitoring parameters of power equipment, so as to realize the full life cycle management of power equipment. In the future, power equipment manufacturers should provide comprehensive and in-depth services to their customers, that is, become service providers, not just physical products of power equipment. The operating parameters of power equipment are obtained through the Internet of Things, and their life status is analyzed based on big data technology [7].

These studies provided a detailed analysis of brand design and IoT big data technologies. It was undeniable that these studies had greatly contributed to the development of the corresponding fields, and a lot of experience could be learned from methods and data analysis. However, the research on brand business model design based on big data and Internet of Things technology was relatively few and not thorough enough, and it was necessary to fully apply these technologies to the research in this field.

In the research of commercial brand design combined with big data and Internet of Things technology, it was found that the business model of the e-commerce platform has developed by leaps and bounds. Among them, the transaction scale structure of the B2C sales model had increased year by year, accounting for 64% in 2018. In the survey of consumers' consumption habits and brand awareness, it was found that 82% of consumers liked to travel and other outdoor activities and more than 75% of consumers were used to buying goods at special counters in department stores or shopping malls, and about 40% of consumers preferred brand commercials with simple colors and simple style.

2. Design Method of Brand Business Model Based on Big Data and Internet of Things Technology Application

The business model is to combine internal and external factors to form an efficient operation system with unique core competitiveness, so as to achieve the best interests of customers. The rapid development of business models has an important relationship with the advancement of technology, the rise of the Internet, and the rise of e-commerce [8]. The speed and tolerance of consumers accepting new things make many companies adjust their corporate and brand strategies at any time, trying to continuously meet the sales hot spots in the market through efficient design and operation of management activities.

The early marketing methods of enterprises were relatively simple. Generally, enterprises made a series of marketing plans through market research, and finally made decisions and sold products through written data. The whole process was one-way. This one-way information research method had no practical significance to the marketing strategy of enterprises. Enterprises still cannot have a deep understanding of customers, and there was no way to connect the relationship between enterprises and customers, so they could not provide better services for customers [9]. Although some companies further used the method of telephone return visits to customers to improve customers' loyalty to the brand, this kind of telephone consultation service method was very unpopular. This method was not only extremely inefficient but also unsatisfactory [10]. After that, many companies also discovered the limitations of the telephone return visit method, so some companies pushed the promotion activities of the merchants through SMS to attract customers. However, the time for this passive marketing method to benefit was very short. On the one hand,

customers were easily numb or even annoyed by this behavior. On the other hand, because there was no way for enterprises to screen according to the needs of customers, and could not convey effective information to customers who really need it, the effectiveness of the marketing method of SMS push was obvious [11].

With the development of science and technology, the Internet has gradually become known to people. By building official brand websites, companies allow customers to understand corporate and brand information more quickly. Enterprises have established the most direct contact information with customers. Customers can find out about enterprises at any time by searching for enterprises and brands on the Internet platform, and can quickly obtain the contact information of enterprises. Although this method of network construction can let people know about enterprises and brands in a faster and more convenient way, this method of publicity is still single information dissemination, and enterprises are still unable to actively provide timely services to customers in need until the mobile internet appeared [12]. If an enterprise does not have Internet thinking and does not know how to apply the large platform of the Internet, it cannot become bigger and stronger if it is limited to traditional store sales. Under the background of the popularity and history of today's mobile Internet, enterprises not only have to have Internet thinking to reasonably apply network platforms for strategic marketing but also need to follow the current trend of technology—WeChat marketing thinking [13]. As an indispensable communication method in people's daily life, WeChat is used as an important means of information acquisition, and WeChat brings customers together. Through WeChat, a well-known communication platform, the communication method between the enterprise and the customer is close to zero distance like relatives or friends. By following the company's WeChat public account, customers can learn about the company's dynamics and brand culture, and obtain information on the latest research and development products and activities. And enterprises can manage more effectively for different customer groups by establishing a complete customer information database. This not only facilitates timely communication and effective interaction between enterprises and customers but also pushes the latest product and activity information developed by the company to customers. It can also answer all customer questions and receive feedback and suggestions from customers through intelligent replies and artificial real-time [14]. Many commodities, like the previous products, are aimed at primary consumers. They are directly sold to the market without packaging and have no inherent brand image. Most of the target groups are grassroots working people as the main consumers. With the rapid development of the Internet industry and the continuous expansion of the market, the positioning of the original commodities makes them face the bottleneck of sales, which increases the unnecessary waste of most commodities [15]. The current sales situation is gradually declining. In other words, in order to change the current low development situation, it is necessary to change the positioning of the products. It is necessary to ensure the intimacy

of products from nature, and it is necessary to meet the sales concept that products come from pure nature without additives, so as to meet people's emotional and psychological needs, make the product itself have a human touch, and stimulate consumers' desire to buy. It is also necessary to build people's loyalty to the brand [16]. Brands not only represent the main products and services in the exchange process but also reflect consumers' deepening psychological feelings and acceptance of commodity value. However, with the changes in the consumption behavior of consumer groups and the turning of their habits, in the face of the rapid changes in people's consumption behavior, some well-known brands with a long history of precipitation cannot fully meet the needs of all consumers. Therefore, the products of the e-commerce platform are resegmented again, and the target market positioning is refined again. The repositioning of consumer groups makes the brand younger, and establishes an internal connection between the brand and this normal consumer group, as shown in Figure 1 [17].

In today's era, the brand not only represents the image of an enterprise, but also a symbol of the enterprise's management strength and innovation ability. The number of world-famous brands also symbolizes the strength of the country's comprehensive competitiveness. The material composition of the value of the brand business model is mainly reflected in the technical level of the product, the design quality of the product, and the manufacturing quality of the product. One of the key points involved in the brand concept is the establishment of brand image, which is based on the perception subject—consumer usage and perception experience—and then it forms the psychological association to the brand. In terms of expression, it includes two aspects (1) Tangible content (external): the functional content of the brand, which is the functional needs of consumers that the products and services of the brand can satisfy; that is, the external intuitive features of products, logos, packaging, etc., which can be directly contacted and seen by consumers, and the intuitive feeling of brand image on the basis of material [18]; (2) Intangible content (intrinsic): the charming characteristics of the brand, that is, the personality characteristics that the entrepreneur endows the brand and is perceived by consumers. It usually includes the brand's cultural connotation, entrepreneurial spirit, and other internal characteristics, which are the key factors to determine the success of the brand [19], as shown in Figure 2.

The derivation of brand value is nothing more than accompanying the growth of customer demand. The promotion of brand value and the creation of customers are inseparable and complementary, and they together constitute the cornerstone of the sustainable development of enterprises [20]. Generally speaking, brand value is mainly composed of brand premium, satisfaction, loyalty, perceived quality, leadership, perceived value, brand personality, organizational association, brand recognition, market share, price, distribution index, etc. [21]. Almost most of them are customer value-oriented factors, so a customer value model based on brand equity is used to illustrate it vividly, as shown in Figure 3. And brand maintenance is particularly important as an inherent requirement for corporate image and

large-scale long-term development. Brand maintenance includes standardized management and testing of product quality, operating technology, and related equipment. More importantly, it is necessary to continuously improve and implement corporate culture and promote the overall improvement of corporate management.

Internet of Things (IoT) is a system that connects people to people, things to things, and people to things for information exchange through various proprietary networks, such as communication networks, sensor networks, and industry-specific networks. Currently, with the development of an increasing number of sensing technologies, such as infrared and 4G, IoT is defined as a network where all objects are connected to the Internet for communication through sensing devices. The current IoT architecture is usually considered to contain three layers: sensing layer, network layer, and application layer, as shown in Figure 4.

With the development of science and technology, people have entered the era of "big data," and big data is becoming the core competitiveness of business competition in this era. The generation, development, and application of big data pose challenges to traditional business models and provide opportunities for continuous innovation of business models. From the previous summary and analysis, it can be seen that big data has an important impact on the content of the four elements of business model innovation. The realization of business model innovation or transformation from the perspective of these four elements is an important condition for enterprises to realize business model innovation. Therefore, this paper constructed a model of the impact of big data on business model innovation, as shown in Figure 5.

Along with the speedy progress and application of information technology, computer technology, and Internet technology, human society has rapidly moved into a modern digital era. With the development of the network, the continuous development of the Internet, mobile, social networking, and other fields, the application scope of network information technology has been greatly expanded. As a positive factor, "data" is constantly eroding people's lives, and the explosion of information has led to a large amount of data. The continuous increase in the amount of information has led to qualitative changes in people's thinking and behavior, which also heralds the advent of the era of big data.

It is supposed there are N customers with K brands to choose from, or they can choose not to buy, that is: customer n ($n = 1, 2, \ldots, N$) has $K + 1$ kinds of products to choose from, $k = 0, 1, \ldots, K$, respectively. For the i-th customer facing $K + 1$ choices, it is supposed the utility of choosing k is

$$U_{nk} = X_n' \beta_k + \varepsilon_{nk}, n = 0, 1, \ldots, K. \tag{1}$$

Among them, X_n' is a vector representing the intrinsic features of the customer, β_k is also a vector representing the parameters for the intrinsic features of the correspondent customer when the k-th good is selected, and ε_{nk} is a random term that is separate and obeys.

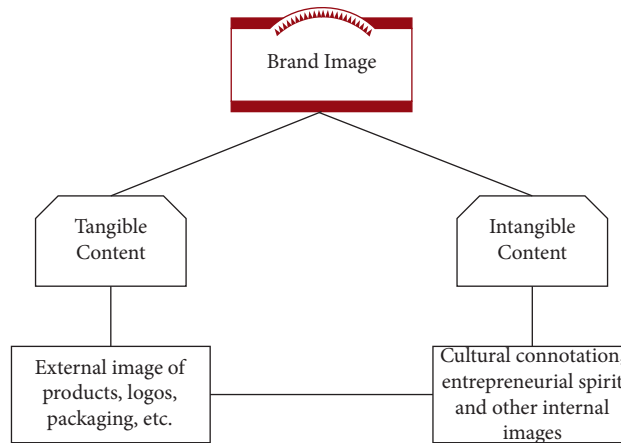
$$\varepsilon_{nk} \sim N(0, 1). \tag{2}$$
Figure 1: Requirements for brand design in the existing consumer market.


Figure 2: Brand image content.
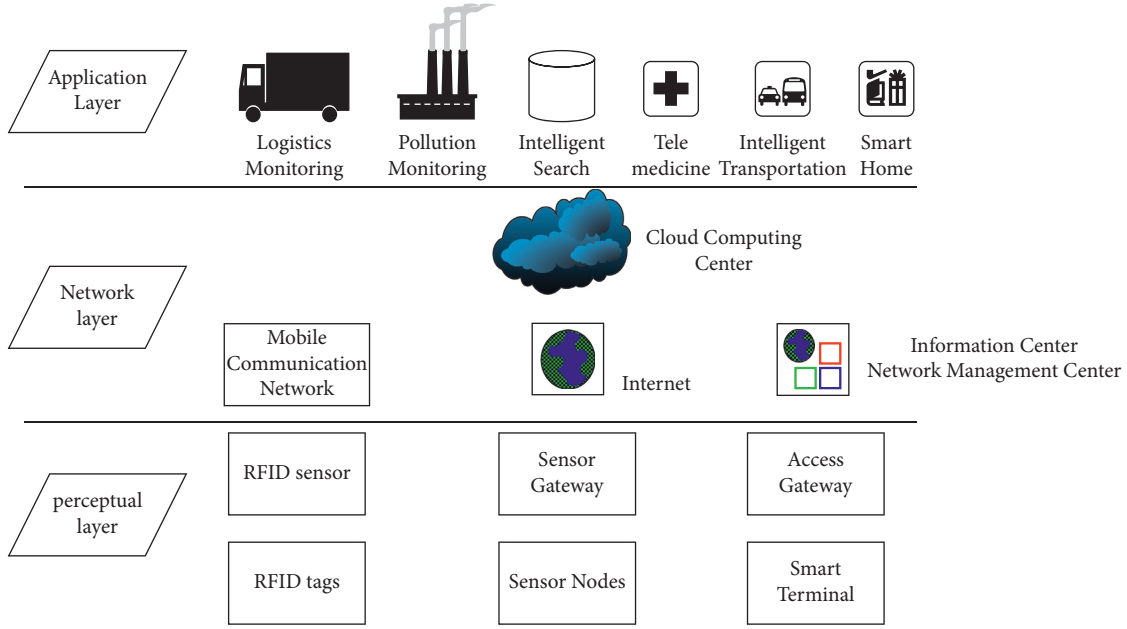
Figure 3: Customer value model based on brand equity.


FIGURE 4: Schematic diagram of IoT architecture.
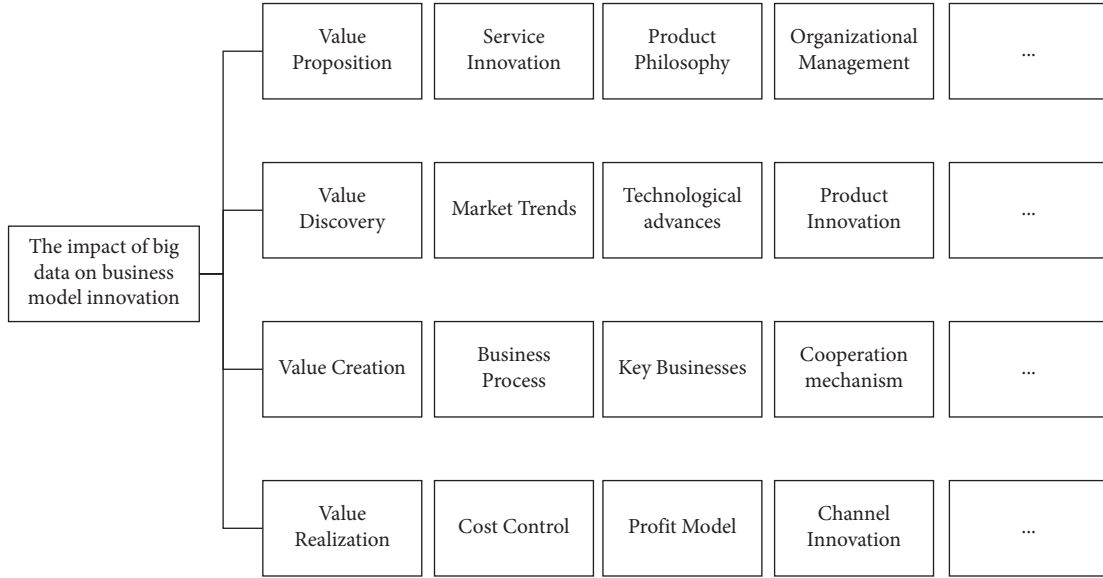

FIGURE 5: Model of the impact of big data on business model innovation.

p_{nk} is to express the possibility of customer n choosing brand k. Then based on the principles of utility maximization, the probability of a customer n choosing brand k can be obtained as follows:

$$p_{nk} = P\left(U_{nk} > U_{nj}, j \neq k\right). \tag{3}$$

The density function for the unobserved utility function is

$$\mathrm{f}\left(\varepsilon_{nk}\right) = \mathrm{e}^{-\varepsilon_{nk}} \mathrm{e}^{-\mathrm{e}^{-\varepsilon_{nk}}}. \tag{4}$$

After integration, the cumulative distribution function is obtained as follows:

$$\mathrm{F}\left(\varepsilon_{nk}\right) = \exp\left(-\mathrm{e}^{-\varepsilon_{nk}}\right). \tag{5}$$

From the random utility part, it can be known that the probability of a customer n choosing option i is

$$\begin{aligned} p_{ni} &= P\left(C_{ni} + \varepsilon_{ni} > C_{nk} + \varepsilon_{nk}, \forall k \neq i\right) \\ &= P\left(\varepsilon_{nj} < \varepsilon_{ni} + C_{ni} - C_{nk}, \forall k \neq i\right). \end{aligned} \tag{6}$$

If ε_{ni} is given, this expression is the cumulative distribution function of every ε_{nk} on $\varepsilon_{ni} + C_{ni} - C_{nj}$, which can be expressed as $\exp\left(\exp\left(\varepsilon_{ni} + C_{ni} - C_{nj}\right)\right)$ by formula (5). Since ε_{nj} is independent, this cumulative distribution is the result of multiplying a single cumulative distribution for all $k \neq i$;

that is, in the presence of random interference, the conditional probability that customer n chooses i is as follows:

$$p_{ni}|\varepsilon_{ni} = \prod_{k \neq i} e^{-e^{-(\varepsilon_{ni}+C_{ni}-C_{nk})}}. \tag{7}$$

Formula (7) is substituted into the distribution to solve p_{ni}

$$p_{ni} = \int (p_{ni} \mid \varepsilon_{ni}) d\varepsilon_{ni}. \tag{8}$$

It can get

$$\begin{aligned} \% \quad p_{ni} &= \int_{\varepsilon_{ni}=-\infty}^{+\infty} \exp\left(-e^{-\varepsilon_{ni}} \sum_k \exp\left(-(C_{ni}-C_{nk})\right)\right) e^{-\varepsilon_{ni}} d_{\varepsilon_{ni}} t \\ &= e^{-\varepsilon_{ni}}. \end{aligned} \tag{9}$$

The formula (9) is substituted to get

$$\begin{aligned} p_{ni} &= \int_{t=\infty}^{0} \exp\left(t \sum_k \exp\left(-(C_{ni}-C_{nk})\right)\right) dt \\ &= \frac{\exp\left(t \sum_k \exp\left(-(C_{ni}-C_{nk})\right)\right)\Big|^{0}}{\sum_k \exp\left(-(C_{ni}-C_{nk})\right)}\Bigg|_{\infty} p_{ni} \\ &= \frac{1}{\sum_k e^{-(C_{ni}-C_{nk})}} = \frac{e^{C_{ni}}}{\sum_k e^{C_{ni}}}. \end{aligned} \tag{10}$$

And from formula (1), it can get

$$p_{ni} = \frac{e^{x_n \prime \beta_i}}{\sum_{k=0}^{K} e^{x_n \prime \beta_i}}. \tag{11}$$

If $\beta_j^* = \beta_j + m$ is defined for any vector m, and then the probabilities defined in formula (11) are recalculated using β_j^* instead of β_j, the result is the same as using β_j, because the terms containing m are eliminated. That is, adding any customer attribute variable m has no effect on the results, so it can be concluded that customer attributes, such as gender and occupation., have no effect on the results. For this purpose, $\beta_0 = 0$ can be normalized. (Because the probabilities sum to 1, only K parameter vectors are needed to determine $K+1$ probabilities) so the probabilities are

$$p_{ni} = \frac{e^{x_n \prime \beta_i}}{1 + \sum_{k=1}^{K} e^{x_n \prime \beta_k}}. \tag{12}$$

By formula (12), the K log odds ratios can be calculated as follows:

$$\ln\left(\frac{p_{ni}}{p_{nk}}\right) = \ln \frac{e^{x_n \prime \beta_i}/1 + \sum_{k=1}^{K} e^{x_n \prime \beta_k}}{e^{x_n \prime \beta_k}/1 + \sum_{k=1}^{K} e^{x_n \prime \beta_K}} = x_n \prime (\beta_i - \beta_j), j \neq i. \tag{13}$$

If the model has $K+1$ categories, it can be expressed as follows:

$$\begin{aligned} \ln\left(\frac{p_{n0}}{p_{nK}}\right) &= x_n \prime (\beta_0 - \beta_K), \\ \ln\left(\frac{p_{n1}}{p_{nK}}\right) &= x_n \prime (\beta_1 - \beta_K), \\ \ln\left(\frac{p_{n(K-1)}}{p_{nK}}\right) &= x_n \prime (\beta_{K-1} - \beta_K). \end{aligned} \tag{14}$$

Among them, K is the reference category, that is, k is the standard to compare with other options.

In product development, the use of big data resources—mainly consumer input and the objective grasp of popular information—this open and innovative way can enhance the specific operation in the design work and reduce the cost of research and development, so as to achieve the ability to respond quickly to consumer and market changes. At the same time, it also plays a key role in realizing the practicability, science, and value of product design.

Through the theory of value sharing, enterprises, customers, and other stakeholders must establish sufficient connections, maintain continuous interaction, and form effective aggregation, so as to promote the overall value creation of the enterprise system. Based on the brand community, it can be divided into three business models as follows: (1) take the enterprise as the center, strengthen the company's functions, and improve the customer's products and services; (2) taking the customer as the center, create customer experience shaping with a special experience for customers; (3) focus on stakeholders, and build a broad set of values for members of society by strengthening the connection of various stakeholders, as shown in Table 1.

3. Experiment Preparation for Brand Business Model Design Based on Big Data and Internet of Things Technology Applications

Successful brands usually have a strong brand identity with concise expressions, diverse forms, and distinct personality traits. A representative brand image will show the essential characteristics of the company and show it in a specific way, allowing customers to have a visual impact, thereby improving the recognition of the product and distinguishing it from other products. As a corporate brand design, there should be distinct differences to facilitate the understanding of customers; at the same time, elements that best reflect the company's characteristics should be incorporated into the design.

In today's increasingly abundant information resources, massive information resources will become an important part of the development of human society. The use of information technology to assist product development has become a new development trend. In the process of information technology guiding product design, obtaining consumers' input and contributions through a large number of consumer information resources is an important means to

TABLE 1: Types of business model innovations based on brand communities.

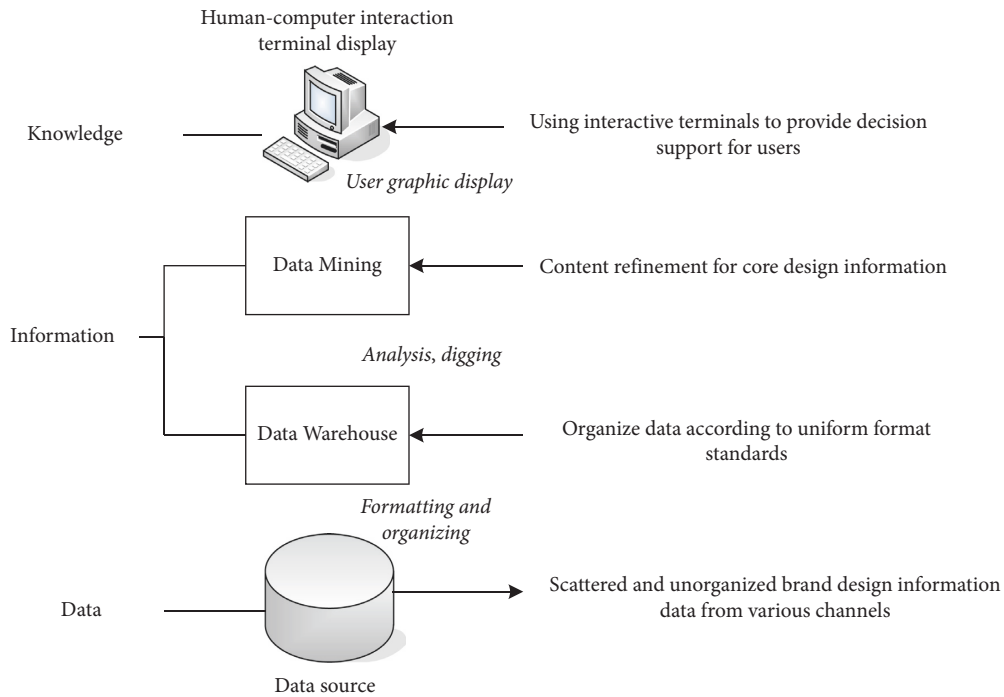
Name	Objectives	Functions	Community characteristics
Corporate function enhancement	Strengthen the business	Enhance corporate functions	Company-led community result-oriented
Customer experience shaping	Strengthen customers	Focus on a lifestyle theme and unique lifestyle	The natural integration of brand value proposition and lifestyle brand community and corporate business activities are moderately divided by customer-led brand community
Cross-border platform integration	Strengthen stakeholder connections	Stakeholders form connections to generate value	Enterprise has brand appeal


FIGURE 6: Basic process of brand design decision support system based on a data warehouse.

complete product development. Numerous good companies have begun trying to mine and quantify consumer opinions and preferences from traditional data sources, including point-of-sale data and customer feedback. They distill key information to aid product design from new data sources including consumer reviews on social media and third-party platforms, and sensor data describing actual product usage. The decision support method for brand product design based on data warehouse is shown in Figure 6.

At the end of the data collection phase, the company has a complete set of data collection and archiving tools and can either sell the collected data to larger companies that can analyze it, or provide data collection and archiving services to companies without data collection systems. Once data analysis is complete, the company is again fully capable of data extraction and can connect data extraction activities. Once the analysis and statistical reporting are complete, the company can sell the net data mining business.

Once the data application phase is complete, companies are no longer limited to data sales policies. Selling data has

no commercial value for the company's core business, but can adjust and design business around the relationship between data, and effectively implement data-driven business.

The terminal is at the end of the supply chain and is the place where consumers have the closest contact with the brand, so the image of the terminal directly affects the image of the brand in the minds of consumers to a certain extent. And the brand is generally independent, there are franchise chains, there are entrusted companies, and the standard franchise image is uniformly designed. Some brands have high franchise fees and need an optimal location. Classic business districts do not allow returns, and these strict conditions cannot be returned. These strict franchise conditions can control the expansion speed of the brand, and also ensure the relevant service quality of the store to a certain extent. In order to understand consumers' consumption habits and awareness of brands, 400 consumers in area A were randomly surveyed. The basic information of the respondents is shown in Tables 2 and 3.

TABLE 2: Basic information of respondents.

Test items		Number of people	Proportion (%)
	18–25	69	17.25
	26–35	136	34
Age	35–45	156	39
	45–60	19	4.75
	> 60	20	5.0

4. Brand Business Model Design Data

In recent years, the development of e-commerce has been very fast, and the types of advertising campaigns will also change at different times, so many sales models will gradually shift from physical stores to e-commerce platforms. In this way, e-commerce can not only expand development in popular industries but also reduce costs for the business itself. This improves the display of products in the sales process, it will be more efficient to face these channels, and the development of e-commerce will be more efficient. Today, when the current monopoly model is changing, in order to meet the needs of customers, future product sales will move in the direction of "digitization, channelization, and platformization." For most consumers, what they like is the traditional handmade products they make or the deep cultural heritage they have. The current e-commerce

platform sales model has become a major sales method, especially since the B2C transaction scale is increasing every year, and by 2018, it has reached 64%, as shown in Figure 7, this sales model has been affected by favored by many young people. If the development model of the e-commerce platform cannot be well grasped, the sales model of professional brick-and-mortar stores will face difficulties and bottlenecks in development.

Figures 8 and 9 are the statistical results of the respondents' brand tendencies.

It can be seen from Figure 8 that the highest proportion of respondents' hobbies is travel, accounting for 82%, followed by music 64%, sports 42%, drama 28%, and art 26%.

As can be seen from Figure 9, 81% of consumers are accustomed to buying things on department store counters, and 78% like to buy things in shopping mall specialty stores. More than 40% of consumers shop through trend
FIGURE 8: Respondents' occupations and hobbies.

information provided by the Internet, fashion magazines,
FIGURE 9: Channels for purchasing goods and channels for obtaining fashion information.
FIGURE 10: Top aspects consumers pay attention to when purchasing a product.

and major brands. Other avenues include friend recommendations, movies, outdoor advertising, and fashion shows.

For the brand business marketing style, there is a large gender difference in the style that the respondents prefer, as shown in Figure 10. The majority of male respondents prefer commercials with simple and elegant colors, accounting for 45%; the majority of female respondents prefer simple-style commercials, accounting for 38%. Regarding the aspects that consumers pay attention to when purchasing products, male customers pay the most attention to the quality of products, and female customers pay the most attention to brands, accounting for 45% and 36%, respectively.

In general, with the development of the times, modern consumers are mainly pragmatic. Consumers have little influence on the company's culture, service concept, store design and layout, and the influence of people around them, as well as advertisements and celebrity endorsements.

5. Conclusions

In today's 21st century, with the continuous development of technologies and applications such as computer networks, mobile Internet, and social networks, computer technology is gradually integrated into people's daily lives, and "data" is also constantly infiltrating people's lives. The promotion of brand value is of great significance to enterprises. On this basis, a decision support system for brand design based on a data warehouse was proposed. Data mining technology was used to obtain design element information, decision support for brand design was provided through human-computer interaction tools, and information sharing, communication, and application were realized. The system not only provided an objective and scientific thinking method and theory for brand design but also filled the gap of research theory using information technology theory to assist brand design work. It organically integrated various information technologies and brand design theories to form an efficient, scientific, and accurate brand design method, and refined design information from the brand design information data from multichannel sources. In the era of big data, a brand design must conduct in-depth research on the social environment, transform design thinking, and use information technology to adapt to current consumption and trends.

Automated human fall detection is an essential area of research due to its health implications in day-to-day life. Detecting and timely reporting of human falls may lead to saving human life. In this paper, fall detection has been targeted using machine-learning-based approaches from two perspectives regarding data sources, that is, contact-based and noncontact-based sensors. In both of these cases, various methods based on deep learning and machine learning techniques have been attempted, and their performances were compared. The approaches analyze data in fixed time windows and extract features in the time domain or spatial domain which obtain relative information between consecutive data samples. After experimentation, it was found that the proposed noncontact-based sensor techniques outperformed the contact-based sensor techniques by a margin of 1.82%. After this, it was also found that the noncontact-based sensor techniques outperformed the state of the art of noncontact-based sensor results by a margin of 3.15%. To better suit these techniques for real-world applications, embedded board implementation and privacy preservation of subject by using advanced methods such as compressive sensing and feature encoding need to be attempted.

1. Introduction

The falls are widespread among elderly individuals due to the weakening of body parts which occurs due to aging [1]. Sudden falls can affect not only the elderly but also people of all age groups. Falls can cause injuries ranging from fractures to concussions and, in extreme cases, even death. Due to this, falls have recently been an extensively researched topic, and various automation methods are being studied to detect and analyze them. Thus, there is a growing need to use the latest techniques for the automated detection of falls.

Falls can occur in various different ways. Oneill et al., in their study, classified fall into forward, sideward, and backward [2]. Out of this, it was observed that forward fall was the most prominent fall, with 56.33% of all the falls, with 17.60% of falls being backward and 23.23% of falls being sideward.

Also, the chances of falls increase with increasing age varying from about 26% of people suffering falls at least once

a year in the age group of 65 to 74 to 36.5% in the age group above 85 [3]. Thus, detecting falls among the elderly is more critical due to increased chances of falls and slow recovery rates. The reasons for falls among the elderly can be many, and the consequences can be severe if not detected in time. Unconsciousness resulting from the fall can delay the treatment process; thus, an automated fall detection system can help the concerned people know about the fall quickly. For this purpose, falls can be detected through either contact-based or noncontact-based sensors. Both methods are equally important in different ways.

There are many methods through which fall detection can be approached depending on which sensors are used, like accelerometers, gyroscopes, cameras, and others. In this paper, we have discussed some ways to detect falls using vision-based tools and contact-based sensors. Cameras are becoming very prominent in everyday environments and can be found in various environments such as railways and airports. At the same time, accelerometers are the devices

used for capturing acceleration. When fitted to a body part, they provide information on the acceleration of the body parts. Using the information from data captured on acceleration and the change in acceleration, detection algorithms can be designed and trained to perform automatic fall detection. Thus, these two cases provide very different approaches to fall detection.

Neural networks are becoming very popular in the areas of fall detection due to increased efficiency in the detection process. Convolution neural network (CNN) is the method that specializes in analyzing sequential and visual data [4]. CNNs have been used for tasks such as image classification, natural language processing, and human activity classification. Thus, in this paper, many proposed approaches are designed based on neural networks architectures.

This work has contributed towards (1) detecting falls based on cameras and (2) detecting falls based on smartphone sensors. Various approaches are applied and tested in both cases. Then comparisons of these approaches are presented. Some techniques are also introduced to help reduce computation time and efficiency.

The paper first provides related works in the field and the description of the detection dataset used (UP-Fall). Then, the approaches used for contact-based and noncontact-based fall detection are discussed, followed by the results and analysis. Then, finally, conclusions are drawn.

2. Related Works

Recently, in the field of human activity recognition, many research studies are being done as this is an essential aspect and has a wide variety of use-cases such as healthcare, sports, and elderly care. Of the research works done, many utilized a variety of ways to detect falls, like using classical ML models, which include Support Vector Machine (SVM), K-nearest neighbors, and Random Forest, and neural networks based model. Recently deep learning models have become very popular due to their promising results.

The falls systems were mainly based on contact-based and vision-based sensors. Thakur [5], in his research, analyzed various recent fall detection systems using contact-based, ambiance-based, and vision-based sensors. Many datasets are also increasingly becoming available in both aspects. The two following domains were analyzed for the work being done in automated human fall detection.

2.1. Machine-Learning-Based Fall Detection Using Contact Sensors. This type of sensor relies on sensors being fitted on the subject to detect any sudden motion indicating a fall. They include using sensors such as accelerometers and gyroscopes. These sensors are generally fitted on the watch or mobile phone. These sensors record acceleration of the body parts on which they are fitted. The change in acceleration due to change in the activity changes acceleration is utilized for fall detection.

Many different approaches in this domain have been applied and researched utilizing different aspects. Khojasteh et al. [6], in their research, proposed a fall detection system based on wearable devices like smart wristbands where they utilized a threshold-based solution for this purpose in which if any change in acceleration crossed a certain threshold, then fall signal was generated. Kwolek [7] utilized a similar method based on threshold-based detection on accelerometers. He proposed an innovative solution based on a fuzzy-based system to authenticate the fall event. Şengül et al. [8] used a quaternion algorithm to detect falls and send a signal to the concerned people with the patient location. More recently, fall detection using convolutional neural networks has become popular due to these networks' ability to learn features without any data processing and their robustness and flexibility. Santos et al. [9], in their research, utilized CNN-based models on the accelerometers-based dataset.

2.2. Machine-Learning-Based Fall Detection Using Noncontact Vision Sensors. The major advantage of this type of fall detection is that the user is not required to wear any type of sensor. However, the user is required to be always inside the region of operation of the camera. Also, detecting falls on the border is difficult in these cases [10]. They include the detection of falls using video camera recordings, I.R. sensors, bioradars, and others.

Many different approaches have been attempted in this case utilizing machine learning and deep learning techniques, as well as using different preprocessing techniques like optical flow images, image lightning, and others. Rougier et al. [11], in their study for detecting fall events using a video surveillance camera, used the shape deformation of humans in the video frames during the fall for the detection. Furthermore, shape analysis models were used for training. Capturing human deformation during the fall is a good technique as it is very much noticeable in the fall video frames. Anishchenko et al. [12], in their research, showed the advantages of using bioradar's systems to detect human falls. The research used wavelet transform and neural networks for fall detection. At the same time, Miao et al. [13] utilized CNN-based models to detect human-based activity and further modified them for detecting falls. In a similar approach, the CNN model using 3D ConvNets was approached in this case as well. More recently, latent feature polling was used for detecting falls effectively in ADLs (activities of daily living) [14].

3. Dataset Description

For this research, we have chosen a publicly available dataset, the UP-Fall detection dataset [15], after analyzing the various fall detection datasets [16–20]. Due to variability in subjects, activities, and different lighting conditions, this dataset provided real-life conditions for training and testing. Of all the datasets, the UP-Fall dataset provided more variability in terms of subjects, activities, frontal and lateral views, a greater number of trials, and so forth, and it contained a larger number of videos enough for effectively training the network. Besides that, it also provided data from contact-based sensors like accelerometers, gyroscopes, and

others, which can also be used for trying other approaches to fall detection. The dataset and features are publicly available [21]. The dataset consists of 11 activities performed by 17 young, healthy individuals (8 females and 9 males) in the age group of 18–24 years. Out of the 11 activities performed, 6 consisted of daily human activities, which are lying, jumping, picking up an object, sitting, standing, and walking, and 5 consisted of fall activities, out of which two consisted of falling forward using a hand and knees, two consisted of falling sideways and backward, and one consisted of falling sitting on a chair. Figure 1 describes the positions of some of the contact-based and noncontact-based sensors that were used in the UP-Fall dataset.

For the purpose of the experiment, we have used data recorded at 18 FPS from the two cameras and Inertial Measurement Unit (IMU) sensors fitted on the wrist and right pocket of the subject. We aim to implement a system to distinguish between fall and nonfall activities using data from contact-based sensors such as accelerometers as well as noncontact-based sensors such as cameras.

4. Methodology and Implementation

Human fall detection can be captured through a variety of methods. The analyzed methods were chosen such that they are not much affected by the environmental factors and can be applied to any general setting (not requiring any special arrangements). The following section describes the methods and the architectures that were implemented for contact-based and noncontact-based fall detection (Figure 2).

4.1. Detection Using Contact-Based Sensors. Data from the triaxial accelerometer was utilized in this case for fall and nonfall prediction. Two 3-axial accelerometer sensors were fitted on the subjects in the right pocket and on the right wrist simulating the wristwatch and cell phone, respectively. Since the accelerometers are kept very close to the subject, predicting the fall using them is very institutive for automated detection. Machine learning architectures and a 1D CNN-based approach were deployed for this purpose.

Firstly, the 3-axial data received from the accelerometers was trimmed to 3 seconds in order to capture the fall and nonfall parts effectively. To standardize the dataset, the data points were subtracted from the mean and divided by the standard deviation. Afterward, continuous 1.5 seconds of fixed arrays were drawn from the normalized data, which were then appended one after the other in 3rd dimension order. The obtained flow stacks were passed through the classifier (ML models and 1D CNN) to predict the fall event. The overall process outline can be seen in Figure 3. For the experiments, the dataset was divided into 70% for training and 30% for testing.

4.1.1. Machine Learning Methods. In this paper, the following machine learning classification methods were implemented for the detection:

(1) Support Vector Machine (SVM): This method differentiates between the classes by creating a hyperplane and mapping the inputs on it. The hyperplane is further optimized by training and then acts as a decision boundary for prediction. The target of the algorithm is to maximize the gap between the data points and the hyperplane. SVM is a very popular ML algorithm and is used extensively in fall detection systems [22].

(2) Random Forest (RF): This method is a widely used machine learning algorithm that works on the principle of ensemble learning. It works by creating an ensemble of decision trees through which the input is passed, and, on the basis of the mode of the responses received, the output of the algorithm is computed. The greater number of trees leads to better accuracy and reduces risks of overfitting [23].

(3) Multilayer Perceptron (MLP): This method is a feedforward method passing inputs through the multiple layers before computing the final output. Each node has a neuron that utilizes a nonlinear activation function. It uses the back-propagation technique for the training of the model [24].

The parameters used for the machine learning architecture used are described in Table 1.

4.1.2. 1D CNN Network. CNN is very good for classifying sequential data. Thus the data from the 3-axial accelerometers is a good match for applying CNN-related methods. Lee et al. [25], in their research, analyzed the benefits of using the 1D CNN process for fall detection. In the research, 1D CNN was shown to be better than most of the traditional ML methods when using time-sequential data.

The convolutional and pooling layers used in 1D CNN are one-dimensional with height and width of 1. The algorithm that was used for this purpose is described in Figure 4. It is a simple convolution method with 1st layer being convolutional followed by max pooling and then one more convolutional layer followed by a softmax activation function for calculating probabilities. The network was trained for 500 epochs.

4.2. Detection Using Noncontact-Based Sensors. RGB camera recordings captured from the frontal and the lateral side of the subject were utilized in this method for predicting the fall and nonfall events. Additionally, the RGB images were also converted to optical flow images. Optical flow images are useful in removing the background noises as they only capture the motion between the consecutive frames, as shown in Figure 5. Both RGB and optical flow images were attempted for the detection. Figure 6 describes the stepwise procedure that was used for training the dataset. Overall, it consisted of 5 steps which were dataset collection, segmentation, feature extraction, training of the model, and classification. These steps are explained in the following sections.
FIGURE 1: Position of the sensors. (a) Contact-based sensors located on the human body. (b) Video camera location layout for the lateral and frontal views.
FIGURE 2: Overview of the methods and architecture used in the paper.
FIGURE 3: The process outline used for fall detection using contact-based sensors: 3-axial data input from accelerometers is processed and then passed through the classifier, which identifies whether there is a fall or not.

4.2.1. Dataset Used. Camera recordings from the UP-Fall detection dataset were used as the data input. Videos were captured from the frontal and lateral sides of the subject at 18 FPS. It comprised 17 subjects performing 11 activities in three trials, as shown in Table 2. Out of the 11 activities, 5 were classified into fall and 6 into nonfall category.

To keep the computational costs low, the resolution of the images was reduced to 224×224 from 640×480. Moreover, the recordings were trimmed to 50 frames each,

given that 50 frames are sufficient for identifying any fall or nonfall event. The dataset was further divided into training set and testing set in an $80:20$ ratio.

4.2.2. Segmentation. As observed from the dataset, detecting any fall event does not require more than 20 frames. Using this observation, the sliding window segmentation technique was attempted to capture video frames containing only the

TABLE 1: Parameters used for ML methods.

Architecture used	Parameters
SVM method	Kernel = "radial basis function"

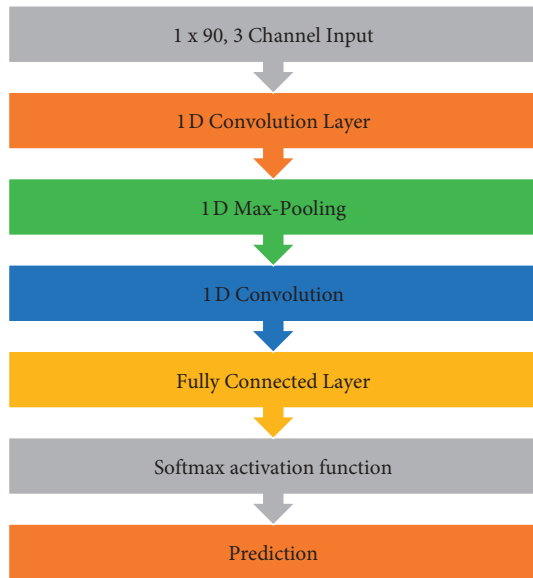
	Epsilon (numerical stability measure) = $10-8$


FIGURE 4: Architecture used in case of 1D CNN for sensor-based training of the model.

fall event, if present. So, out of the N frames, if L is the length of the window used, then using a sliding window of 1 frame, $N - L + 1$ windows were captured, as shown in Figure 7.

4.2.3. Feature Extraction.
The target of this step is to get the most important features that are relevant to the experiment. This part involves removing the noise from the data and capturing the part that is most relevant to the training of the architecture. The noise can be any repetitive data or unwanted data points that can affect the convergence of the model.

For vision-based approaches, the optical flow method delivers good information for clear movements between the images and removing any background noises [26]. Thus, for capturing the motion and removing the background noises, the effect on the model by converting the RGB images to optical flow images was analyzed. For this purpose, out of 50 frames, the difference in the intensity of consecutive frames was taken. Thus, starting from the 1st frame, the difference between the 1st and 2nd was taken, followed by that between the 2nd and 3rd, and so on till the 49th and 50th frame. Thus, in this way, we obtained 49 optical images representing the activity. Figure 6 describes the effect of converting an RGB image to an optical flow image in the case of the UP-Fall dataset.

4.2.4. Model and Training.
For training the model with video recordings as the input, 3D convolutional neural networks offer the capability to capture spatial information in time by stacking consecutive video frames. Tran et al. [27], in their study, analyzed the benefits of using 3D ConvNets when using video datasets for training. By using stacks of consecutive frames as the input, they allow capturing the features that take the spatial video frame data and motion between the frames into account. Due to this edge offered in the case of 3D ConvNets, they are increasingly becoming important in the field of human activity recognition. Thus, in this paper, 3D ConvNets were utilized for training the models in the case of noncontact-based sensors.

The training steps used for building the network are as follows:

(I) The model was trained on the ImageNet dataset [28]. ImageNet is an extensive image dataset that comprises more than 14 million images and 1000 classes such as animals, sports, and daily human activities. This helped the model to learn basic generic characteristics about the RGB images, such as identifying border, texture, and color.

(II) From the CNN model trained on the ImageNet dataset, the input layers were modified to take the input as $224 \times 224 \times 20$, where 224×224 is the size of the image and 20 is the stack size. Then the model was fine-tuned on the UCF101 fall dataset [20], which comprises 13,320 videos of 101 different human activities. It helped the model to learn the features of generic human actions. To avoid biasing errors, the fall video frames were reduced in order to contain falls only. 3D ConvNet was used here for training the models.

(III) In the final step, the obtained model was fine-tuned over the UP-Fall dataset.

The following experiments were done to decide the configuration to be used for the training phase.

(1) Learning Rate. It is a very important hyperparameter that decides how the model weights are updated during the training. Deciding on a proper learning rate is very important as very small learning rates can make the training too slow, and higher values can make it too fast to converge the model optimally. It was observed from a series of

RGB Images

Optical Flow Images
FIGURE 5: RGB and its optical flow image equivalent. Optical flow images help in removing background noises and capture only the motion.
FIGURE 6: Process pipeline used for fall detection using contact-based sensor.

TABLE 2: Duration of activities and their classification [15].

Sr. no.	Description	Duration (in seconds)	Classification
1.	Falling forward with knees	10	Fall
2.	Falling backward	10	Fall
3.	Falling forward using hands	10	Fall
4.	Falling sideward	10	Fall
5.	Falling sitting on a chair	10	Fall
6.	Standing	60	Nonfall
7.	Walking	60	Nonfall
8.	Sitting	60	Nonfall
9.	Jumping	30	Nonfall
10.	Laying	60	Nonfall
11.	Picking	10	Nonfall

experiments that the network provided the best results when the learning rate was between 10^{-3} and 10^{-4}. Choosing higher or lower values affected the accuracy, as lower learning made the system too slow and higher learning made too big steps which made it far away from achieving proper optimization in those cases.

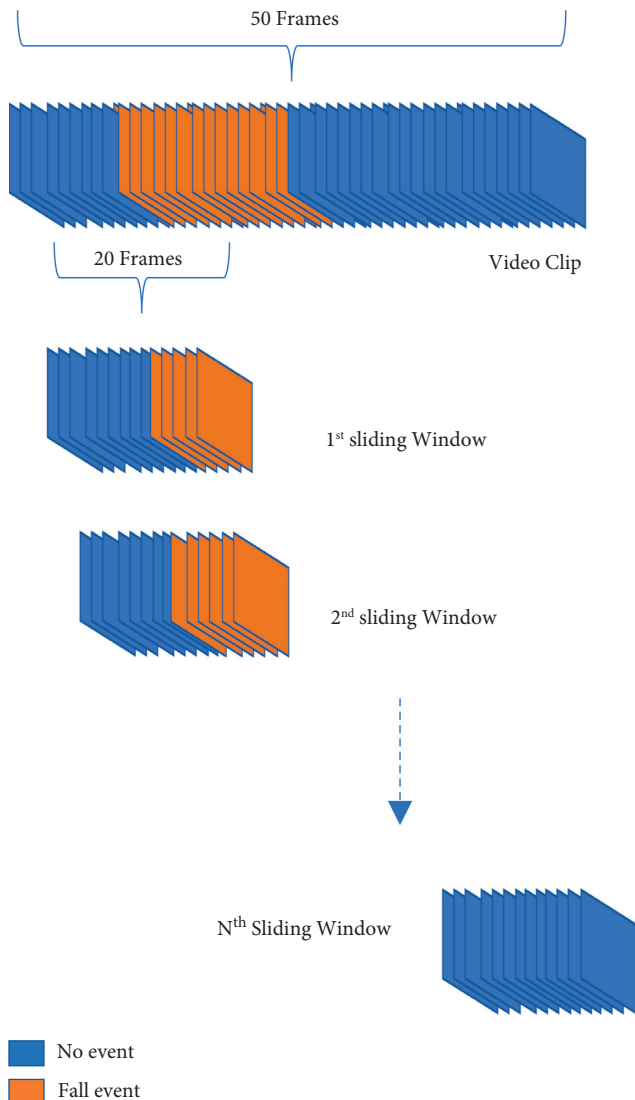
(2) Minibatch Size. Li et al. [29], in their study, showed that using minibatch size properly with proper experimentation yields better results than the standard gradient descent. Minibatch gradient is used to split the dataset into batches, and then the training of the network is done in batches; that is, model weights are updated in the batches. Due to a greater


FIGURE 7: Sliding window technique used to capture stacks of consecutive frames. Here frames in orange color are the ones that contain events important for the detection.

number of updates done using minibatch, a good convergence is obtained by using minibatch gradient descent. We tried batch sizes in powers of 2. It was observed through a series of an experiment that a batch size of 1024 was giving the best results.

(3) Number of Epochs. Epoch is the number of times the algorithm passes through the training dataset. It is an important parameter for balancing between the time taken for training (with greater number of epochs, higher computation is required) and the saturation obtained. The number of epochs used was 500 in all the experiments, as proper saturation was seen to be obtained within the 500 epochs.

One more important step in the training process is batch normalization. Ioffe et al. [30], in their research, explained that making the batch normalization method part of the minibatch training process can make the training process much faster. It was further shown that it eliminates the need for using dropout rates to a great extent. The activation function ReLU (Rectified Linear Unit) was used in the experiments with batch normalization to avoid overfitting and faster training.

After fixing the hyperparameters, three different architectures backbones experimented with the 3D ConvNet to fine-tune on UP-Fall dataset. These three were chosen to consider the different types of diverse combinations. In two phases, the training of the model was done. Firstly, RGB images were trained on the architectures in two parts, initially on the frontal view and then on the lateral view. The optical flow images were trained similarly. The architecture used was as follows:

(1) VGG-16 [31]. It is a very popular CNN architecture that is widely used for classification purposes. It consists of 16 layers for training. It uses 3×3 convolutional kernels and 2×2 pooling kernels. The consistent arrangement of these layers is followed throughout the architecture. The input shape of 224×224 was used in the architecture. Figure 8 describes the layers of the VGG-16 architecture used.

(2) Xception [32]. Xception is a CNN architecture that is 71 layers deep. With modified depth-wise separable convolution, it is a modification of Inception v3 with a parameter that is almost equal to Inception v3. Figure 9 gives an overview of the Xception architecture implemented by showing some of the layers presented.

(3) DenseNet [33]. DenseNet is a CNN architecture in which the layers are densely concentrated, which makes its training time somewhat more than other architectures, but, at the same time, it leads to better convergence of the model. There are many different versions of DenseNet, which vary by the difference in the layer depth. In the experimentation, DenseNet201 with 201 layers was used. The major advantage of using DenseNet as compared to other architectures is that it is more efficient than the other models in capturing low-level features of the images. The overview of the DenseNet architecture can be seen in Figure 10.

5. Results and Analysis

For evaluating the performance of models, developed accuracy, sensitivity, specificity, precision, and $F1$-Score were used. Accuracy defines the correctness of the classification model. Sensitivity and specificity define the ability of the system to detect the falls and nonfall events, respectively. Precision predicts the rate of happening of positive events. $F1$-Score is another measure of accuracy focusing on precision and sensitivity.

Equations (1)–(5) define the formulas used to calculate them. Here, F.P. denotes False Positive, F.N. denotes False Negative, T.P. denotes True Positive, and T.N. denotes True Negative. These values are defined as follows:
FIGURE 8: VGG-16 architecture: padding layers in brown, convolution layer in blue, pooling layers in green, and dense layers in orange.
FIGURE 9: Overview of the Xception architecture implemented. Due to large number of layers present, some of the layers from the start and end are shown here.
FIGURE 10: Overview of the DenseNet architecture. T.B. is transition block, and A.P. is average pooling and connected block.

$$\text{Accuracy} = \frac{(T.P + T.N)}{T.P. + T.N. + F.P. + F.N}, \tag{1}$$

$$\text{Sensitivity} = \frac{T.P.}{(T.P. + F.N.)}, \tag{2}$$

$$\text{Specificity} = \frac{T.N.}{(T.N. + F.P)}, \tag{3}$$

$$\text{Precision} = \frac{T.P.}{(T.P. + F.P)}, \tag{4}$$

$$F1 - \text{Score} = 2.\frac{(\text{Precision.Sensitivity})}{(\text{Precision} + \text{Sensitivity})}. \tag{5}$$

The models trained on similar datasets were compared based on these parameters. All the experiments related to CNN architectures were performed on Python v3.7.3 with Keras v2.2 [34] framework using TensorFlow as backend, and ML methods were trained using sklearn library [35]. The hardware used for the experimentation includes 2 Nvidia GTX 1080 Ti graphic cards with 32 GB physical RAM and Intel i7 3.6 GHz processor.

5.1. Using Contact-Based Sensors

5.1.1. Using ML Methods. The 3-axial data obtained from the accelerometer fitted on the right wrist of the subject was used for training the model on 3 machine learning methods, which were Support Vector Machine, Random Forest, and Multilayer Perceptron. The data obtained from accelerometers captured acceleration along the x-axis, y-axis, and z-axis in continuous time frames. The data was further divided into training set and test set in the ratio of $70 : 30$.

The results obtained from the three algorithms are summarized in Table 3. It can be seen that the RF method performed the best among all the machine learning methods on all the performance metrics. The results also suggest that ML methods can provide significant efficiency on the sequential data stream provided by the accelerometers. To improve on the performance, we further tried the 1D CNN method.

5.1.2. Using 1D CNN Method. Convolutional neural network methods are very good at training sequential streams of data; here 1D CNN-based method was implemented. In 1D CNN, data streams are passed after converting them into 1D arrays and passing them through multiple 1-dimensional layers for training. The training was performed for 500 epochs, with a decent gradient optimizer with a learning rate of 10^{-4}.

Here the descent gradient optimizer was used with a negative log-likelihood cost function, as shown in the following equation:

$$\text{Loss}(x) = -\log(x). \tag{6}$$

Figure 11 shows the accuracy/loss plots obtained in this case. An accuracy of 98.07% was obtained, shown in Table 3. Thus, it was observed to be better than the other implemented ML algorithms.

5.2. Using Noncontact-Based Sensors. The model's training was done in two phases through RGB images and optical flow images. RGB images included the frames obtained directly from the camera, while optical flow images were obtained to capture the motion between the consecutive frames. Then, in both cases, the dataset was divided into training set, 80%, and test set, 20%.

The K cross-validation approach was used to remove the biasing effect, where K refers to the number of different types of groups the data was split into. It is a beneficial technique as it helps get the models variety of combination training and testing datasets. The value of K was chosen to be 5 as selecting a higher value of K leads to overfitting, and a lower value of K is not high enough to remove the biasing effect, so the value of 5 seemed optimal.

5.2.1. Using RGB Cameras. In this experiment, three architectures were trained, namely, VGG-16, Xception, and DenseNet, on lateral and frontal views of the subject. The learning rate was set at 10^{-6}, with batch normalization with ReLU as an activation function. The network was then trained for 500 epochs.

Tables 4 and 5 show the summary of the performances of all the three architectures in lateral and front views, respectively. Figures 12 and 13 highlight the accuracy/loss plots for lateral and frontal views, respectively.

The frontal view was seen to be slightly better than the lateral view; this is because the subject occupies more part of the image in the former case. It can be observed that DenseNet outperformed other architectures with an accuracy of 98.41% in the case of lateral camera recordings and with an accuracy of 99.85% in the case of frontal camera recordings. So, it can be concluded that DenseNet has better performance than the other architectures in the case of fall detection.

When compared with the other vision-based fall detection methods reported in the literature [14, 36], which also implemented CNN-type architectures on UP-Fall detection dataset, as shown in Table 6, it can be seen that the proposed methodology produced results that are comparable with the state-of-the-art methods.

TABLE 3: Summary of results of ML methods implemented.

Architecture used	Accuracy (%)	Precision (%)	Sensitivity (%)	Specificity (%)	F1-Score (%)
SVM method	94.00	93.54	93.00	94.00	93.26

Architecture used	Accuracy (%)	Precision (%)	Sensitivity (%)	Specificity (%)	F1-Score (%)
VGG-16	92.625	95.46	89.50	95.75	92.38
Xception	93.625	96.28	90.75	96.50	93.43
DenseNet	96.00	96.46	95.50	96.50	95.97

5.2.2. Using Optical Flow Images. Optical flow images are constructed based on the information between the consecutive frames. They capture the motion, if any, between the continuous frames and remove background noises. Tables 7 and 8 show the performances of the architectures in the case of optical flow images of lateral and frontal side views, respectively. They compare the architectures in both the lateral and frontal views based on accuracy, precision, sensitivity, specificity, and F1-Score.

The learning rate was kept at 10^{-6}, batch normalization with ReLU as activation function was used, and again it was observed and concluded that the DenseNet architecture gave better performance than the other architectures in both the lateral and frontal views. Also, it was observed that the frontal view was giving better performance when compared to the lateral view due to the subject occupying more space in the former case.

In Figures 14 and 15, training accuracy/loss plots are shown for all three architectures in the case of lateral and frontal views, respectively.

Overall, two approaches based on the contact- and noncontact-based sensors data were attempted to detect falls. Analysis of the results suggests that the 1D CNN method, with an accuracy of 98.07%, outperformed the traditional machine learning methods in the case of contact-based sensors.

It can also be seen that dataset preprocessing steps, which include segmentation and feature extraction, are very important steps for improving the performance of the models by leading to better convergence. Similarly, with an accuracy as high as 99.85% in the case of noncontact sensors, DenseNet outperformed the other architectures and it is shown that very good predictions can be made using camera recordings as well.

The two methods using contact- and noncontact-based sensors discussed above were totally independent. The key advantages of the approaches are discussed here. First, user privacy is a very important concern when going for fall detection based on video recordings. To tackle this, the previous recording can be discarded immediately from the system after processing. In sensor-based detection, only data from the accelerometer is required, so there are not many issues of personal privacy there. For further improving privacy through video camera recording, an optical flow camera-based approach was also discussed, which allows only relevant information. Thus, in both approaches, privacy of an individual can be preserved. Second, in sensor-based fall detection using 1D CNN, the proposed architecture is very efficient in terms of high efficiency at a very low computation cost due to the simplicity of the architecture.

The architectures were implemented on the UP-Fall detection dataset, which includes 17 individuals performing 11 activities. Out of 11 activities, 5 activities were classified as fall, and the other 6 were classified as nonfall. The actors in the dataset were aged 18–24 years. Since the fall activity is only composed of motion, the approaches can be easily transferred to people of all age groups. So, we think these approaches can be extended to apply to real-life conditions as well.

It is also very important to discuss the limitations of the proposed approaches. There are many activities that can be classified into falls. Detecting different falls happening for a very short period can be difficult. For achieving very good efficiency in the case of camera-based detection, the computation cost of the system required will be very high. For real-time fall detection, the system processing speed would be required to be on par with the model processing time as there should not be lag; otherwise, that lag would keep on accumulating to create a huge difference in time and memory requirements.

One important difference between the two approaches is that fall using noncontact-based sensors has low computation cost, and the user has the flexibility of movement. Meanwhile, through camera-based fall detection, the user is required to be inside the frame of the recording. Even falls happening on the edges could be difficult to recognize.

6. Conclusions

In this paper, we presented two approaches for fall detection which were using video camera recordings and accelerometer sensors that are commonly found in smartphones. These were done using machine learning and deep learning methods. In the case of contact-based sensors, 1D CNN and machine learning methods were studied. Then, in the case of noncontact-based sensors, 3D ConvNets were implemented utilizing 3 different CNN-based architectures: VGG-16, Xception, and DenseNet.

From the conducted experiments, various things can be concluded. In the case of vision-based sensors, from the three different architectures attempted for implementation, VGG-16 was found to be computationally faster (due to only 16 layers) with good accuracy and comparable with the literature. For further improving on the accuracy, DenseNet is suggested, which performed best among the architectures, but this was obtained at the cost of increasing computation due to a greater number of densely connected layers. In the case of contact-based Sensors, the proposed 1D CNN architectures were shown to outperform ML methods. Both methods have their particular advantages in various conditions. Particularly, sensor-based detection showed various advantages, which include user privacy, no restricted area for movement, and simple architecture.

As can be seen from Table 6, our proposed methodology outperforms the existing architectures with an accuracy of 99.85% as compared to 96.70% of the current state-of-the-art methods. Further improvements in this research should be directed towards embedded board implementation and privacy preservation of the subject by using advanced methods such as compressive sensing and feature encoding.

Data Availability

The UP-Fall detection data used to support the findings of this study have been deposited in the UP-Fall repository (https://sites.google.com/up.edu.mx/har-up/).

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Eliminating Data Duplication in CQA Platforms Using Deep Neural Model

Seema Rani [ID], Avadhesh Kumar, and Naresh Kumar

School of Computing Science & Engineering Galgotias University, Greater Noida, Uttar Pradesh, India

Correspondence should be addressed to Seema Rani; seemanandal011@gmail.com

Primary research to detect duplicate question pairs within community-based question answering systems is based on datasets made of English questions only. This research put forward a solution to the problem of duplicate question detection by matching semantically identical questions in transliterated bilingual data. Deep learning has been implemented to analyze informal languages like Hinglish which is a bilingual mix of Hindi and English on Community Question Answering (CQA) platforms to identify duplicacy in questions. The proposed model works in two sequential modules. First module is a language transliteration module which converts input questions into a mono-language text. The next module takes the transliterated text where a hybrid deep learning model which is implemented using multiple layers is used to detect duplicate questions in the mono-lingual data. The similarity between the question pairs is done utilizing this hybrid model combining a Siamese neural network with identical capsule network as the subnetworks and a decision tree classifier. Manhattan distance function is used with the Siamese network for computing the similarity between questions. The proposed model has been validated on 150 pairs of questions which were scrapped from various social media platforms, such as Tripadvisor and Quora which achieves accuracy of 87.0885% and AUC-ROC value of 0.86.

1. Introduction

With the wireless access to the Internet becoming pervasive, recent years have seen an incessant advancement in Web usage with new user-centric applications and media-rich services. Social media has become an integral and indispensable part of our lives. Social networks make sharing of information, communication, and collaboration straightforward and opportune. The social media websites have grown significantly popular over the past decade as open-source platforms for information and knowledge sharing. Social media has become a primary source of the big data. Formally, big social data are the voluminous and varied data with high-velocity that is generated from technology-mediated social interactions and actions in online realm, and which can be scrapped and mined to comprehend social interactions and behavior. Undeniably, big data and social business intelligence are the key components for reaping full ROI.

Social media has been developing momentously and has changed the dynamics of the sharing and learning ecosystem. Social media news feeds and question answering sites are increasingly becoming popular valuable resource material for enriching knowledge base. The emerging role of social media in teaching-learning process cannot be ignored. Community Question Answering (CQA) [1] as a crowd-sourced service has emerged as a collective intelligence social system which facilitates participation of volunteers to express their knowledge and clear their uncertainties regarding some topics. It allows collaborative user participation where some users ask questions and the others provide answers to them. The number of participating users and the volume of questions and answers of different varieties characterize the popularity of CQAs.

Though these sites have high informational value while on the other hand in order to filter out the relevant information in the form of best answers, or answers by experts for reliable information and user satisfaction, it requires time

and labor. Some of the challenges associated with these platforms include ambiguity in user preference, duplicity in the questions, fuzziness, and imprecision among the huge and speckled answers [2]. The regular influx of new questions and getting answers to questions requires detecting semantic equivalence of questions. The problem of detecting semantic equivalence of multiple sentences is prevalent in natural language processing tasks. The problem further extends if there exists multilingual text or text using mash-up of varied languages like Hinglish.

Numerous CQA sites provide forum which contains answers to existing questions, and users are recommended to search the forum before posting their questions but it may not work as a same question may be rephrased in different ways and languages. There exist duplicate detection policies in some platforms, but these are limited to exact duplicate questions as well as near-exact duplicates. However, some of the challenges associated with analyzing questions for semantic equivalence detection are as follows:

(i) There are multiple ways to rephrase a same question

(ii) There may exist same solution to different questions

(iii) A question may be phrased in a mash-up of two languages

(iv) Merging of question threads is required after duplicate questions have been answered

(v) There exist volumes of historical questions

The first two cases define the issue where questions are in an asymmetrical domain. The examples in Figure 1 expound the first three cases.

Maximum number of primary studies on duplicate question detection deals with English-only CQAs. The cultural diversities, country-specific trending topics—hashtags on social media, and availability of native language keyboards add to the user-generated content in multiple languages contributing the linguistic challenges [3]. Linguistic anglicization of a language which is defined as to make a language sound or appear in English is a commonly observed phenomenon where one language/script word is transcribed into a source language so as to preserve source phonetics. For example, the question "Kya roz exercise krna zruri hai?" is a transliterated on the basis of pronunciation of bilingual mix of Hindi and English called Hinglish. The transliteration is not based on meaning. Instinctively, the question semantically becomes similar to the mono-lingual English question "Is daily exercise important?"

With recent upsurge in transliterated bilingual posts on CQAs which are restricted by their mono-lingual abilities and lack of collective part-of-speech taggers, it is essential to explore techniques that extend the cognitive capabilities of machines to interpret, comprehend, and learn features for semantic matching in multilingual (bilingual/trilingual) data. This research put forward a solution to resolve the problem of detection of semantic equivalent questions for duplicate detection in transliterated bilingual data. The proposed model examines the semantic similarity for input questions of varied languages using deep learning-based Siamese neural networks. In recent studies, evidences exist

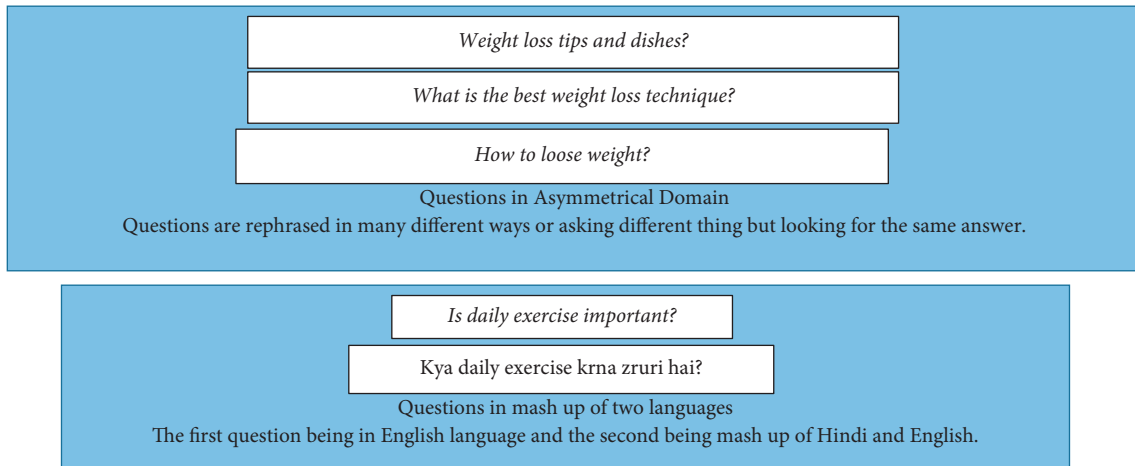
where deep learning techniques are achieving advanced results on specific natural language processing-based problems as these possess hierarchical learning capabilities and are capable of generalizations [4, 5]. Siamese neural network is a deep learning-based technique comprising more than one identical subnetworks having same configuration (parameters and weights) [2, 6, 7]. The subnetworks of Siamese neural network are built on various categories of neural networks including convolutional neural networks and capsule networks. Semantic matching using Siamese neural network is performed by transforming the input sentences at each subnetwork into vectors and using a Manhattan distance function.

Thus, the proposed framework comprises two submodules first being the language transformation module and the second being the semantic matching module. As a first step, the input text containing questions is converted into a mono-language using language transliteration and translation tools. Further, a hybrid deep learning model is used for identification of duplicate questions in mono-language. Similarity detection between question pairs is carried out using a hybrid model using Siamese neural network combining with decision tree (DT) classifier. The Siamese neural network is built up of two identical capsule networks [8, 9] with same configuration, and Manhattan function is used as a distance measure for evaluating the similarity among questions. Further, DT classifier is used at the output layer which produces whether a question pair is duplicate or not. A dataset of 150 question pairs has been used to validate the proposed. The questions have been scrapped from multiple CQA forums like Tripadvisor and Quora.

The manuscript is structured as follows: Section 2 explores the literature review related to the domain of the study, Section 3 explains the proposed methodology, Section 4 presents the results, and Section 5 concludes the study.

2. Related Work

The growing number of Internet users in around interactive networking sites has increased researchers' interest to intelligently mine the user-generated online content. The utilization of machine learning and deep learning techniques for providing solutions to various problems of natural language processing tasks with user-generated online data has been evident to give accurate results. The potential of analyzing user-generated online content with intelligent data analysis techniques has provided solutions to various natural language processing problems which include sentiment analysis [4, 10], sarcasm detection [3, 11], rumor detection [12, 13], etc.

The large data generated by users each day on CQAs make it necessary to filter relevant data by discarding duplicate data. First step to achieve this is to analyze the data in order to detect duplicate questions by semantically matching the text. Multiple researchers have attempted to detect semantically equivalent sentences. Dey et al. [14] employed support vector machine (SVM) for identification of semantically equality in blogs using the SemEval-2015 dataset. Siamese neural network which encodes two input sentences


encoding those using same neural networks has been used recently to detect semantic equivalence of sentences and has shown accurate results [6, 7, 15]. In studies [16, 17], dataset of Quora has been analyzed for duplicate detection utilizing various connection networks. Rodrigues et al. [18] present performances of efficient experiments on detection of duplicity in questions using the established approaches and proposing a novel method. Chen et al. [19] attempt to solve duplicate question detection problem on Quora by a feature engineering and a neural-network-based model. Zhang et al. [20] propose a novel model named DupPredictor in order to recognize possible duplicates of an original question on stack overflow. In another study [21], the authors propose a model utilizing classification algorithms for duplicate question detection on stack overflow. They named their model as Dupe. Reproduction of DupPredictor as DupPredictorRep and Dupe as DupeRep has also been executed by Silva et al. [22] conducting advanced experiments. The use of Siamese neural network for resolving problem of duplicacy in CQA has also been seen in recent studies. Kumar [2] proposes a Siamese neural network model with attention-based bidirectional long short-term memory as subnetworks for detection of duplicate questions in medical CQAs.

The existing studies in the domain of matching of duplicate questions are done with English questions only as the current CQA forums provide facilities to post in one language only, mainly English only. Existing studies deal with question only in English language and deal with other language questions as noise. In a recent study [23], authors explored a code-mixed Q&A platform for Indian languages including Tamil and Hindi, their mash-up with English.

3. The Proposed Siamese Capsule Network with Manhattan Similarity

The proposed model comprises two modules. First one is the language transformation module, and second one is the semantic matching module (Figure 2).

The following sections describe the working of each module of the proposed framework in detail.

3.1. Language Transformation. The tokens of Hinglish are decoded in this module using transliteration into Hindi, and subsequently the Hindi words into English language are translated. "Transliteration is the process of converting a text in one language to text in another language on the basis of its pronunciation (maintaining it to greatest possible extent) without the change in grammar" [24]. Transliteration is different from translation in a manner that it is based on the pronunciation in the aimed language, while translation is based on the meaning in the target language (Figure 3). For instance, for the Hindi phrase "किस उम्र में बच्चों को इंटरनेट यूज़ करने देना चाहिए?" its translation in English would be "At what age should children be allowed to use the Internet?" and "Kis umar mein bachon ko Internet use karne dena chahiye?" is the transliterated Hindi. In this work, the Google Transliteration–Translator toolkit (Google Input Tools: https://www.google.co.in/inputtools/try/) has been used for the task of transliteration of code-mixed text into English in this module. The purpose of using a two-step transformation is imperative to capture the right textual interpretation. Using the Google Translate independently may not always output the correct meaning (Figure 3).

The correct interpretation for the example in Figure 3 would be "Should chocolate be eaten in depression?" and therefore, to improve the meaningfulness of transliterated text, the language transformation follows these steps (Figure 4):

(i) Word-level transliteration is done to convert Hinglish text to Hindi

(ii) Sentence-level translation is done to translate Hindi to English

This translated English question is then input to the Siamese network to match the semantics with the English-only input. The next section discusses the details about the semantic matching module.

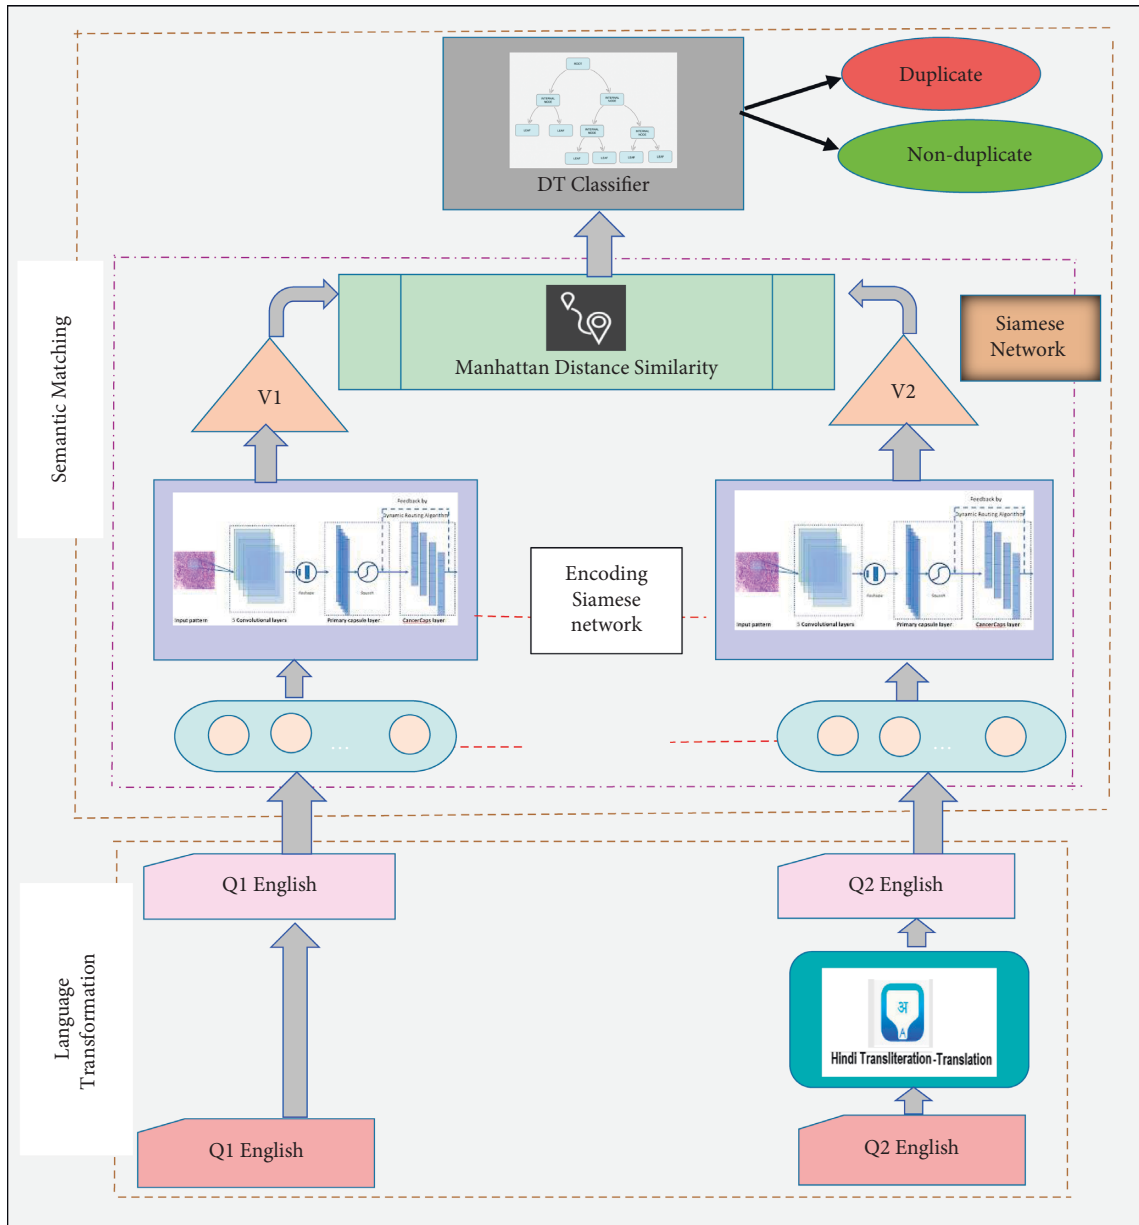
3.2. Semantic Matching. Semantic matching of question pairs is done using a Siamese capsule network. Siamese neural network is made up of two neural networks of same


FIGURE 2: The proposed model.

configuration (parameters and weights) each taking different inputs. An energy function which compares feature representations of highest level on each side of the network by assessing a metric is used to join these two neural networks. Similarity among the two inputs (questions) is evaluated by transforming the inputs into representation vectors and using a distance function. We use Manhattan distance function for calculation of the similarity between all question pairs. The vector representations from the encoder are fed to the DT model together with their distance for binary classification.

3.2.1. Input Layer. This layer accepts questions as inputs into each subnetwork of the Siamese model. The question pair is further passed to the embedding layer.

3.2.2. Embedding Layer. In this study, GloVe [25] which is a count-based model is used for word embeddings in the embedding layer. In this layer, the input textual format is converted into vector table of words using GloVe. A real-valued vector of words is built as pretrained word embedding. Each question's embedding matrix is sent into the next layer.

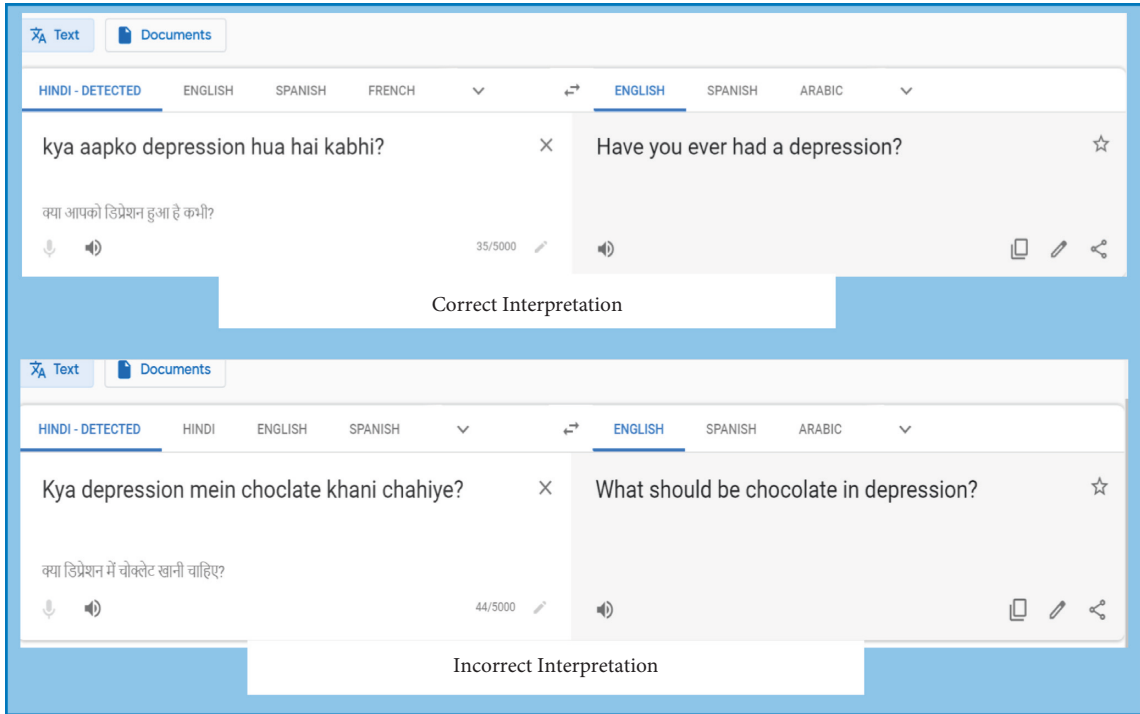
3.2.3. Encoding Layer: Siamese Capsule Network. In this layer, the output of GloVe (word matrix) is converted into a one-dimensional feature vector. In this work, the encoding layer is employed using capsule network [8, 9]. The capsule network is composed of capsules which are groups of neurons. These groups are locally invariant groups with the capability of recognizing visual entities


FIGURE 3: Sample independent use of Google translation.
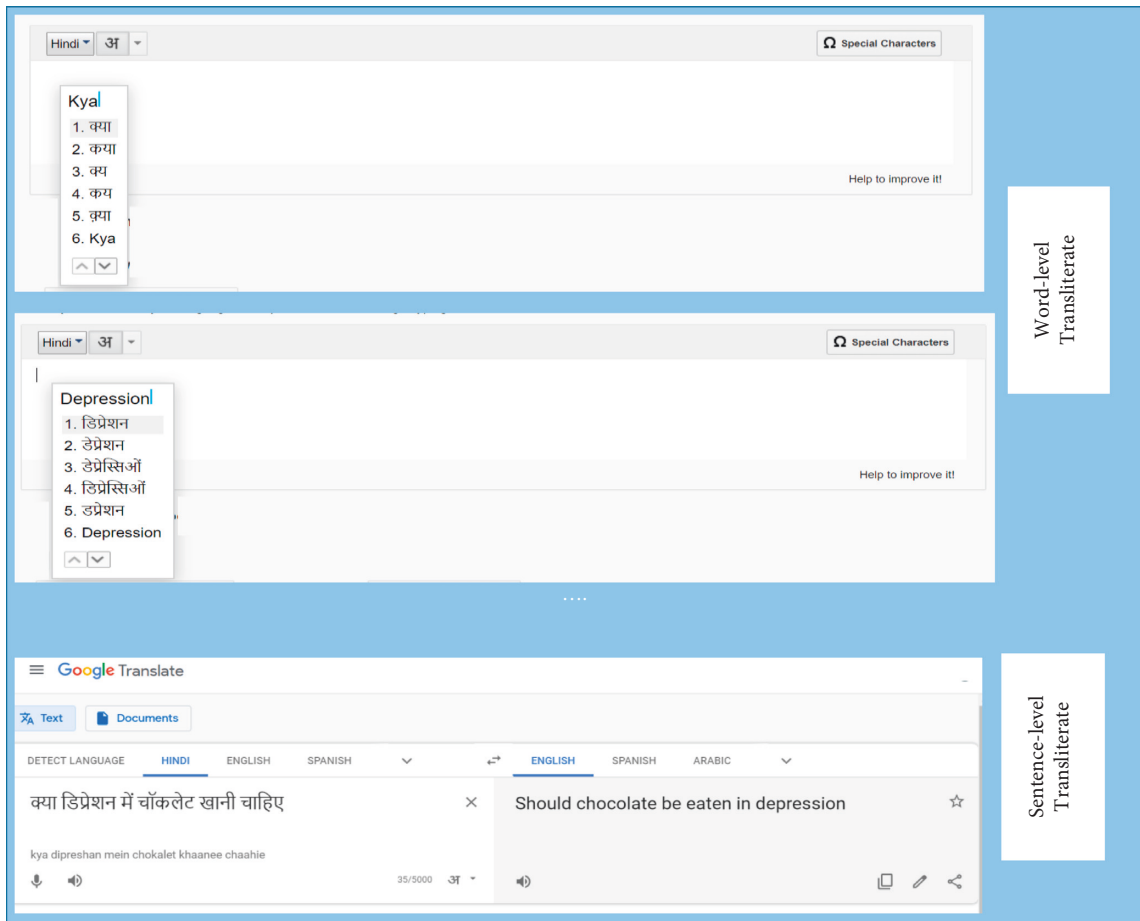

FIGURE 4: Transliteration: Hinglish to Hindi and translation: Hindi to English.

and encoding their features into vectors [26]. A capsule network comprises three layers including convolutional layer, primary capsule layer, and class capsule layer. Each layer provides a unique functionality given in following sections.

(1) Convolutional Layer. The vector representation of the text is provided to the filtration layer of the convolution having 128 filters of 8 size each, after applying a randomized function over the vectors. These filtered feature vectors are given as an input to a nonlinear function that acts as a linear function and uses stochastic gradient descent to train the model and to avoid the saturation problem of other activation functions. The rectified linear activation function has used the third layer of CNN, so named as ReLU activation layer. In each convolutional layer, the output from ith feature map, given by y_i^l, after the convolution operator is calculated as given in

$$y_i^l = b_i^l + \sum_{j=i}^{m} f_{i,j}^l * y_j^{l-1}, \tag{1}$$

where l is the layer having m filters, $f_{i,j}^l$ is the convolution filter, y_j^{l-1} is the output obtained from the previous layer, and b_i^l denotes the bias matrix.

(2) Primary Capsule Layer. The scalar inputs from the lower convolution layers are passed onto the first capsule layer. Here, these inputs are converted into vector outputs which are called capsules. Capsules intend to preserve the instantiate parameters including the syntactic or semantic representations of word and their local order. The features produced by the lower convolutional layers are further produced as combinations of features grouped into capsules in this layer, and a routing algorithm is implemented for communications with the upper layer. A capsule in the upper layer is activated if numerous lower layer capsules vote for that capsule. Results from lower level capsules are broadcasted to that activated upper level capsule. A cluster of capsules coming from lower layer is created at this activated capsule and a high probability of observation that an entity is present and a high-dimensional pose is produced as an output at the higher-level capsule.

For semantic matching of two sentences, it is difficult to say that two sentences are different because the order of the sentences is different. Hence, in this work we use the capsule network with routing algorithm as static routing algorithm.

Let u_i be the output of a single capsule, then the equation for static routing is as follows:

$$s_j = \sum_i W_{ij} u_i. \tag{2}$$

Here, capsule "i" is in the primary capsule layer which is the current layer, capsule "j" is a capsule in the higher level, and W_{ij} is translation matrix.

v_j is the output vector limited to [0, 1] as the result of applying squashing function to s_j as given below:

$$\mathbf{v}_j = \frac{\left|s_j\right|^2}{1 + \left|s_j\right|^2} \frac{s_j}{\left|s_j\right|}. \tag{3}$$

(3) Class Capsule Layer. This layer is the capsule network's final capsule layer which takes inputs from the lower layer through a static routing algorithm, also called the routing by agreement.

(4) Similarity Measure. This study utilizes the exponential function on the negative value of distance measured by Manhattan distance function to find the similarity distance between the vector representations. This is represented in

$$\exp\left(-\|v1 - v2\|\right) \in [0, 1], \tag{4}$$

where v_1 and v_2 represent the outputs of subnetworks.

3.2.4. Output Layer. Decision tree (DT) classifier is implemented at the output layer to make the final prediction. DT is a tree-based model which comprises a root, branches, and leaf nodes where the dataset information is broken down into smaller subsets till an associated decision tree is built. The input attributes are allied with the nonleaf nodes, and the classes are represented by the leaf nodes. The output of Siamese network is sent to DT classifier which models the interaction between the two questions. The output of Siamese encoder is fed to DT generating a hybrid Siamese neural network and DT classifier which models the interaction between the two questions. The concatenation of the representations of questions with their distance, $c = [f(q1); f(q2); d(q1, q2)]$, is given as input to DT, and the probability of a match between them is produced as output.

4. Results

Section 4.1 discusses the dataset used in this study to validate the proposed model, and Section 4.2 discusses performance of the proposed hybrid model. Section 4.3 describes the performance analysis of various question types, and Section 4.4 compares the Manhattan distance measure with various other distance measures. Lastly, Section 4.5 shows the comparison of the accuracy of the proposed hybrid model with different variants of Siamese subnetworks.

4.1. Dataset. The data are prepared by extracting 150 pairs of questions from CQA forums including Tripadvisor and Quora. It consists of pairs of questions each having one question in English, and one is in Hinglish script. The dataset is labeled with "duplicate" and "nonduplicate" for each question pair. Table 1 presents a sample snapshot of the data.

4.2. Performance of Proposed Framework. The performance of the proposed Manhattan hybrid Siamese neural network model with DT classifier for similarity matching is evaluated in terms of accuracy and AUC-ROC. "Accuracy is defined as the proportion of correct predictions to the total number of

TABLE 1: Snapshot of dataset.

English question	Hinglish question	Is duplicate?

predictions." "ROC curve (receiver operating characteristic curve) is a graph measuring the performance of a classification model by plotting true-positive rate against false-positive rate." "AUC stands for area under the ROC curve which measures the entire two-dimensional area underneath the entire ROC curve." Optimal selection of parameters is imperative to achieve superlative performance results. The hyper-parameters are tuned using the validation data in order to obtain accurate results. GloVe is implemented with dimensions of 300 and a batch size of 60 and 0.5 drop-out.

The confusion matrix and ROC graph plots for the same are given (Figures 5 and 6). The confusion matrix is a plot of true positive, false positive, false negative, and true negative. The model attains an accuracy of 87.0885%. The results show that it is predicting accurate results in identifying correct and incorrect answers. The value of the precision column indicates low false-positive rate. It does not identify wrong answers as correct answers. Higher recall value suggests that our system makes less mistakes in classifying the answers of a question. It can correctly predict that is the answer right or wrong. Because the recall value is high, there are fewer forecasts when the actual answer is true but the system predicted incorrectly.

Finally, $F1$ score is basically the average of two quantities that is the precision and the recall in which we consider the false positives and the false negatives. Higher $F1$ score establishes that our system makes less mistakes.

4.3. Performance on Different Question Types.
The accuracy of the proposed hybrid framework has been evaluated for various question types such as "what," "who," "why," "when," "where," "which," "are," "is," "should," and "how" using the exact match measure which is represented in Figure 7.

It can be seen that the best predictions can be made for questions of type "when." The next best predictions are made for the questions beginning with "who" and "how," whereas least accuracy was achieved with the "why"-type questions.

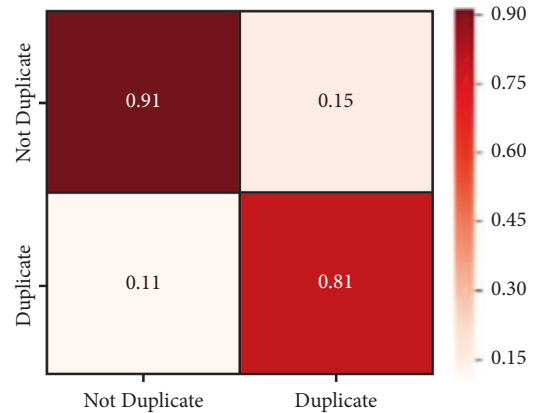
4.4. Comparison of Various Similarity Measures.
The performance of the model using the Manhattan distance has been compared with the models using Euclidean and cosine distances as similarity measures. The results are shown in Figure 8.


FIGURE 5: Confusion matrix.
FIGURE 6: ROC curve.

The model using Manhattan distance performs best, and the model using cosine distance gives the worst performance.

4.5. Assessment of Other Subnetworks.
The accuracy of the proposed hybrid model has also been compared with Siamese models having different neural network architectures at the subnetworks. The other models which have been evaluated for the detection of duplicate question pairs in transliterated bilingual data are as follows:

Performance based on Types of questions
Figure 7: Accuracy obtained on different question types.

	Manhattan Distance	Euclidean Distance	Cosine Distance
Accuracy	87.08	80.65	76.42
Figure 8: Comparative performance using varied distance functions.
Figure 9: Performance of various subnetworks.

(i) Siamese MLP network

(ii) Siamese LSTM network

(iii) Siamese CNN

Manhattan distance for similarity measure and the same dataset has been used in all the models. The comparative performances are given in Figure 9 where the y-axis denotes the accuracy percentage plotted for each model on the x-axis.

As seen in the figure, the proposed methodology utilizing hybrid Siamese capsule network with DT classifier and Manhattan similarity outperforms the other Siamese neural network models' semantic similarity matching in transliterated bilingual data.

5. Conclusion

The large volume big data generated through the communications through social networks makes it imperative analysis for data-driven decision making. But adversarial IR (targeting, probing, spam traps), multilingual, and duplicate content are the key issues that challenge the performance of a typical CQA. This study proposes a hybrid model combining a Siamese neural network with capsule network as a subnetwork and a decision tree classifier to detect duplicate pairs of questions. For the problem of semantic question matching for duplicate detection in transliterated bilingual data on CQA, the input questions are transformed into a single language using language transliteration and translation tools. Manhattan distance similarity measure is used with the deep learning model for similarity match between the question pairs. The proposed hybrid model achieves an accuracy of 87.0885%. The limitation of the work includes lack of benchmark datasets. In future, we intend to build a language-independent framework for identifying semantic similarity which could comprehend duplicates in bilingual or trilingual data. The model can also be trained and tested for visual question answering. Further studies on types of mash-up including code-mix and code-switch input types can also be done.

Traditional healthcare services have changed into modern ones in which doctors can diagnose patients from a distance. All stakeholders, including patients, ward boy, life insurance agents, physicians, and others, have easy access to patients' medical records due to cloud computing. The cloud's services are very cost-effective and scalable, and provide various mobile access options for a patient's electronic health records (EHRs). EHR privacy and security are critical concerns despite the many benefits of the cloud. Patient health information is extremely sensitive and important, and sending it over an unencrypted wireless media raises a number of security hazards. This study suggests an innovative and secure access system for cloud-based electronic healthcare services storing patient health records in a third-party cloud service provider. The research considers the remote healthcare requirements for maintaining patient information integrity, confidentiality, and security. There will be fewer attacks on e-healthcare records now that stakeholders will have a safe interface and data on the cloud will not be accessible to them. End-to-end encryption is ensured by using multiple keys generated by the key conclusion function (KCF), and access to cloud services is granted based on a person's identity and the relationship between the parties involved, which protects their personal information that is the methodology used in the proposed scheme. The proposed scheme is best suited for cloud-based e-healthcare services because of its simplicity and robustness. Using different Amazon EC2 hosting options, we examine how well our cloud-based web application service works when the number of requests linearly increases. The performance of our web application service that runs in the cloud is based on how many requests it can handle per second while keeping its response time constant. The proposed secure access scheme for cloud-based web applications was compared to the Ethereum blockchain platform, which uses internet of things (IoT) devices in terms of execution time, throughput, and latency.

1. Introduction

In the recent past, data volumes are exponentially increased each passing day due to affordable and easy access to internet-enabled connected devices [1, 2]. The healthcare systems are under constant strain to deal with a high volume of healthcare data with the expectation to predict the results in a reasonable time duration. Systems and algorithms are developed to deal with the high velocity of the healthcare data for efficient prediction. However, most of such systems are subject to data security risk and face attacks such as denial of service (Dos), snooping, and traffic analysis [3]. In addition, the recent coronavirus pandemic has forced the hospitals to run at overcapacity making it difficult to keep

patient records secure. The conventional method of manual handwritten paper-based information storage is not viable and makes it difficult to efficiently retrieve the data. Moreover, traditional methods make it challenging to find a patient's individual medical and data that are subject to be lost or destroyed [4]. Using blockchain and Interplanetary File System (IPFS), the author [5] proposes an architecture that aims to offer quicker retrieval and consistent personal health record availability. The findings demonstrate that an ideal node is chosen among all potential adjacent nodes in each iteration.

The internet of things (IoT) technology enables the storage of health records in digital format [6, 7]. Because e-healthcare security includes the patient's confidential health information, it is more essential to be in a secured form. To carry out attacks, attackers can take advantage of the vulnerabilities in open wireless channels [8–11]. These attacks have the potential to harm the e-healthcare system in various ways. An example of this would be a patient who has been treated and then sent home from a hospital in a place other than his own. The patient later becomes ill and is hospitalized nearby, but it does not have all of the data or the records from his previous hospitalization. Due to a lack of information, his therapy may be delayed or fatal. However, if the patient's data are already stored on cloud-connected devices, retrieving the patient's data takes only seconds, allowing the new hospital personnel to begin treatment earliest possible [12].

Using high-security cryptography techniques, the healthcare department can keep encrypted data in the cloud, limiting access to only those who have been granted permission. The cloud comprises servers that run various software and databases and can be accessed via the internet. Cloud servers can be found worldwide to store and access data from any place, anywhere. Because of cloud computing, the healthcare departments and insurance companies do not need to make use of any physical servers or any software programs [13]. The capacity to quickly and securely transfer massive volumes of data, such as patient medical records, is one of the many advantages of cloud computing [14]. Healthcare providers should use digital solutions in hospitals to ensure that their infrastructure is well managed and that they have adequate opportunities to engage themselves with IT service providers [15, 16]. Cost-effectiveness, collaborative resource sharing, scalability, and agility enhancement are some of the other advantages of mobile and cloud computing [17].

Electronic health data (EHD), personal health record (PHR), and electronic medical record (EMR) are all types of digital medical records [18]. Healthcare professionals keep EMR and EHR, whereas the patients or their relatives own PHR. Man-in-the-middle attack, denial of service (DOS), eavesdropping, and so on are all threats to wireless communication among physicians and patients, and between the cloud and the systems.

Healthcare providers and patients can benefit from the cloud's ability to store, process, and update information without spending a lot of money and its ability to make things more efficient and of better quality. Since this information is stored on more than one server, it can be easily accessed from many different places. E-health systems guarantee on-demand, quick, and consistent access to health records, and fewer medical errors and higher-quality treatment. But they also leave patient privacy open to misuse of EHR data and improper authorization. So, security and privacy are very important when multiple people share or look at patient data. Figure 1 gives an overview of the architecture of e-health.

Although cloud services offer enormous benefits, they still face numerous security risks. The cloud service provider, for example, has a vast amount of data that users do not know about [19]. A lack of transparency makes it impossible to know how data are handled and where. Because of this, it is harder to have faith in the service provider, and data loss may result. Figure 1 shows the vulnerability of untrusted servers to assaults from both internal and external adversaries because they lack privacy-preserving safeguards.

The CP-ABE systems with multiple authorities and threshold secret sharing (t, n) can be integrated; this research [20] presents an improved security and performance for public cloud storage by addressing the single-point bottleneck problem, which enhances both security and performance. Using an auditing technique, a solitary bottleneck issue for the most existent CP-ABE systems can be alleviated, according to the author [21]. E-health cannot benefit from these advanced access control schemes [20, 21] despite the fact that the central authority and many attribute authorities cannot ensure protection from insider attacks, even though they are advanced access control schemes with excellent security measures. Water-based CP-ABE (cyphertext-policy attribute-based encryption) system deniable on attribute-based encryption (ABE) technique is a particular encryption approach that allows cloud storage providers to build fake user identities using preserved cyphertext in order to safeguard data from external attackers [22].

By encrypting data belonging to many patients who share the same access policy mentioned by [23], the author's system offers multiprivileged access control for personal health records (PHRs). For disease prediction, author [24] uses the single-layer perceptron learning algorithm. Using encrypted prediction models developed by this model, the cloud leverages encrypted symptom data supplied by patients to diagnose their illness without jeopardizing patient privacy. Health records cannot benefit from these procedures because of their high level of data privacy and computational complexity and scalability concerns [23, 24]. A CP-ABE with the disguised access control mechanism policy and permitted access control was proposed in another study, [25].

A new identity-based encryption (IBE) method based on revocable storage presented by the author [26] protects cyphertext in both the forward and backward directions. There is currently no dynamic user management among the most secure provenance cloud storage systems, which results in considerable performance overhead and poor access control. An attribute-based, provenance-assured cloud storage system is presented in this paper [27], which offers an answer to the issue. As efficient as ABE schemes are, it is
FIGURE 1: Cloud-based electronic health data architecture.

still not possible to implement them on EHRs. This is despite the fact that ABE schemes provide perfectly alright, well-formed access to health records [25, 27]. There are several reasons for this, including high computing costs, the difficulty of managing keys, and the inability to effectively administer access control regulations [22]. A policy that offers approved access control with a constant key length increases as the number of attributes in the access structure increases [25].

The e-healthcare technology should also protect patient's data, even if the healthcare department argues that personnel are responsible for doing so. Our study suggests a system in which only authorized personnel have access to patient information. The doctor has read and wrote access to the data, whereas others can only read it but not edit it. To guarantee the protection of sensitive data from beginning to end, the suggested technique outlines how an administrator generates subkeys with help of the master key. Confidentiality, authenticity, and protection from known critical attacks were all included in our study of healthcare system security [28, 29].

1.1. Motivation and Contribution.
There are not enough privacy protection systems in place to guarantee complete safety in the cloud for e-health data. Health records kept on cloud servers face the greatest risk from insider assaults, such as those by database administrators or key managers, rather than outsiders as it is contrary to popular opinion. Furthermore, cloud access could expose potentially sensitive information to malicious users if not secured. Risks to patient's lives increase as a result of its medical usage. The malicious user may also use the information to harm the hospital's reputation. Future solutions to these cyberattacks and criminal individuals may include the adoption of secure access control technologies. However, due to asset user

devices and insecure wireless channels, it is challenging to build such protocols. As a result, lightweight security mechanisms with excessive reliability should be developed to protect sensitive patient data over the third-party cloud service provider.

(i) We created a single cloud-based web application used to store and provide secure access to e-health records from anywhere. The web application is hosted on the AWS (Amazon Web Services) cloud platform by launching multiple instances. We also investigated the performance of our web application in terms of specific requests per second. Performance is evaluated by looking at resource provisioning, CPU utilization, throughput, and response time.

(ii) We compared the performance evolution of a secure access scheme for a cloud-based web application for patient health records with the Ethereum blockchain platform using IoT devices.

(iii) We propose a bold and secure method of entry for e-healthcare services in the cloud-based scheme.

(iv) In accordance with the recommended security protocols, only legitimate users can use cloud services, which confirm the user's identification in cloud-based e-health application (patient, doctor, and ward boy).

(v) The proposed protocol protects networks from message modification, replay, and man-in-the-middle attacks while ensuring data confidentiality, message freshness, and other security features.

The rest of this paper is organized as follows. Section 2 discusses the literature review, Section 3 describes the system design and adversary prototype, Section 4 explains the proposed scheme for secure access, Section 5 presents the

experimental setup with results and discussion, Section 6 discusses experimental design, and Section 7 ends with the conclusion.

2. Literature Review

According to a study [30], a new web-based solution that allows doctors, ward boys, and pharmacists to access patients' medical records has been developed. It stores the patient's information on the local cloud. The data can be accessed and updated from a distance. To collaborate on treatments, records must be provided to other doctors. The disadvantage in the method is it prevents patients from accessing their medical records.

The researchers of [31] proposed a healthcare framework based on the cloud for effective collaboration among caregivers and the healthcare providers, which might fully change hospital's handwritten record systems. The records can be accessed by healthcare providers and patients from any location utilizing the system. The authorization management service, part of the framework, could only be accessed by a genuine healthcare practitioner or patient. In contrast to patients, healthcare professionals are allowed to write, read, and alter the data. There are two portions to a patient's health record; one is locally stored in a healthcare facility, while another is stored on a cloud database server. The biggest issue with this approach is that the cloud server stores all data when a hospital or healthcare facility does not have a local EHR system.

In paper [32], experts examined, studied, and evaluated several papers and found that several issues need to be addressed to preserve e-healthcare records (EHR). EHR security, EHR cloud architecture, and EHR privacy are only a few. The authors also state that there are still many studies to be performed in the field of EHR security. Author [33] proposes a solution to the problem of managing user access control to a complex universe of user data while maintaining confidentiality while storing medical records in the cloud. Author [34] described an authentication method for an EHR system with a hybrid cloud structure, allowing us to handle different types of users with varying access privileges.

The authors [35] propose a simple and effective method for securing healthcare institution collaboration. They present secure multiparty computation (SMC) methods to assure compliance with data protection regulations. When outsourcing computations to the public cloud, the authors employ the Paillier scheme to safeguard medical data from unauthorized access. Another advantage of this technique is its ability to execute arithmetic operations on encrypted data without access to the original data. Using Shamir's secret sharing, the author proposes a novel cloud storage system for EHRs that ensures data privacy in its entirety. In this system, a healthcare facility divides an EHR into multiple segments, which are then distributed to numerous cloud servers. When retrieving EHRs, the healthcare facility extracts segments from partial cloud servers and reconstructs EHRs [36].

The suggested method listed in paper [37] is based on the FHE (fully homomorphic encryption) algorithm with key delegation to ensure data privacy, authentication, integrity,

and availability in a hierarchical structure with multiple levels. This will give the healthcare provider the freedom to use or not use any access rule in any order, which is especially important in a medical research setting. Still, there is more work to be done to make FHE really useful. Flow-enabled distributed mobility anchoring (FDMA) was proposed by the author to reduce signaling overhead cost (SOC) and packet tunneling cost (PTC) [38].

The researcher in paper [39] presents the experimental investigation of cryptographic algorithms to classify encryption algorithm types such as symmetric and asymmetric. It provides a comprehensive analysis of advanced encryption standards (AES), data encryption standards (DES), 3DES, RSA, and Blowfish in terms of timing complexity, file size, encryption, and decryption performance. The speed of encryption and decryption of the selected encryption algorithms has been evaluated utilizing a simulation-based methodology. The research [40] proposes using the distributed fog computing architecture that uses the elliptic curve Diffie–Hellman ephemeral (ECDHE) key exchange algorithm with the preshared key (PSK) as an authentication method that is both lightweight and safe. As an alternative to the static PSK technique, the ephemeral preshared key used by the ECDHE-PSK authentication system provides perfect forward secrecy (PFS). Literature [41] provides a lightweight, reliable encryption scheme for healthcare image encryption.

The purpose of paper [42] is to discuss data security and authentication in the healthcare industry. Author [43] has proposed a blockchain-based, public-key cryptography-based secure framework. The authors of [43] suggest a model in which medical pictures from the Digital Imaging and Communications in Medicine (DICOM) standard, which contains data on disease and may be applied in real time to the healthcare system, are shared. Due to the blockchain-based decentralized storage model, the framework keeps the immutability, privacy, and availability of information. They also discussed how peers inside the blockchain network could access information via consensus, which they explained in detail. To solve the problem of scalability, the author [44] suggests an improved version of the Bell–LaPadula model and divides peers and transactions into groups with different levels of clearance and security. Due to the clearance level, the peers do not have to keep track of every transaction made. Using smart contracts, author set up dynamic access control policies in the network to keep data safe. Author uses a blockchain-based healthcare network to test their model [44].

Today, this large amount of medical data made by IoMT (internet of medical things) is kept in a centralized storage system. However, centralizing all of a patient's private information raises questions about security and privacy. To deal with these problems, author suggests a consortium blockchain network that can handle smart contracts. In the initial stage of patient and medical device authentication, the author built an integrated interplanetary file system cluster node that is an interplanetary file system using smart contracts. In order to safely transfer device-generated data throughout the consortium blockchain, it is proposed that the same cluster layer has been used as a distributed data storage layer [45].

After the study of various comparative literature review of cryptographic and noncryptographic methods, decentralized EHR of patient for legitimate users with centralized management of patient data security is one of the most challenging problems when using cloud systems. It is one of the main reasons why many organizations in e-healthcare avoid using cloud services. The issue is how cloud systems for integrating decentralized information systems must be constructed in terms of technology and organization so that cloud user privacy laws may be guaranteed. Our paper proposes a secure scheme implemented in a cloud-based e-health application in which only authorized personnel can access patient data. Those outside of the doctor's office can only view the data, but they are unable to change or add to the information. The proposed scheme implemented in cloud-based e-health application is designed for decentralized EHR with centralized management. Moreover, in the industrial IoT, there is a growing demand for a privacy-preserving secured framework. In [46], a deep blockchain-based trustworthy privacy-preserving secured framework in the industrial internet of things systems is proposed.

Patient EHRs are decentralized in terms of providing selected rights to third parties (doctors, ward boys, relatives, and hospitals) with access to critical resources (information, applications, EHR, and reports) to enable more effective operations in application. The "Storage Cloud" cloud computing technology is suitable for the technological implementation because it facilitates the simple incorporation of user data storage into the system. Data administration and authoritative authority are delegated to a centralized service provider that does not store user data. The user acquires a greater degree of responsibility and authority as a result of the breakdown of trust. A guarantee of data availability is essential for the provision of high-quality services. Applications containing EHR are run in a decentralized manner but are centrally managed.

2.1. Comparative Analysis of Proposed Scheme. Table 1 provides a clear comparison of the security features of the existing and new protocols. The suggested approach achieves all of the significant security features, for example, secrecy, integrity, authorization, anonymity, and authentication, as shown in the first row of Table 1. On the other hand, traditional approaches cannot achieve all of them, as evidenced by all except the first row of the table. The failure of any standard system to accomplish all basic security features indicates potential weaknesses and high attack possibilities.

Table 2 compares and contrasts the different protocols on e-healthcare security. Table 2 details that many risks attackers can use to launch cyberattacks against different medical devices. Table 2 includes the level of complexity required to successfully hack into medical devices and the level of awareness that stakeholders must have in order to successfully hack into them. The strategies in some of the research paper presented here in literature review do not provide perfect security regarding authenticity, anonymity of one's identity, communication integrity, and secrecy. Because traditional schemes lack these security features, they

are unsuitable for sensitive e-healthcare applications. Adversaries can invade and obtain unlawful resources due to flaws in the structure of existing methods. Furthermore, traditional systems have high processing and transmission costs, depriving tiny, intelligent nodes of valuable resources. E-healthcare apps require a sophisticated, authenticated vital agreement method to safeguard the network against unauthorized misuse.

The proposed scheme's advantages and disadvantages are as follows:

(1) Resilient against repeated attacks.

(2) Protected against "man-in-the-middle" (MITM) attacks.

(3) Protected from attacks that modify the data.

(4) The proposed method protects the confidentiality of the data.

(5) The proposed scheme demonstrates authorization from legally responsible different stakeholders

However, the disadvantage is when used with low-power wide area networks, the proposed scheme does not result in cost saving when using a local database. This is the possibility for the scheme's future development to turn into a more affordable low-power wide area network solution. As a result of the investigation, the proposed system is seen to be superior to the traditional schemes.

3. System Design and Adversary Prototype

3.1. System Design. The admin, gateway (G_T), patient, ward boy, and doctor relationships are described in the system design. Figure 2 illustrates how stakeholders could access cloud-based health records via gateway.

3.2. Central Administrator. A hospital's IT director serves as the central administrator and registers the facility in the cloud. The administrator securely interacts with the cloud by way of the gateway using the public key of that cloud. The cloud calculates the hospital's master key and returns it to

the administrator upon registration. Subsequently, the administrator uses KCF (key conclusion function) to produce numerous subkeys from the master key. The administrator also registers the doctor, ward boy, and patient's devices offline and assigns subkeys to them.

3.3. Doctor.
A doctor is responsible for treating the patients who have been assigned to him. The patient's data should only be accessible to the doctor who is related to the patient. Comparing the cloud-based patient ID here to the patient ID provided by the doctor is how it is accomplished, and if a match is found, the request is approved; otherwise, the request is denied. Access to editing/writing of a patients' medical record is available to the doctor based on his treatment. The doctor uses encryption, hashing, and subkeying to save all of the patient's data on the cloud. The information can only be read by those who have been granted access. The doctor provides the administrator with two unique identifiers, ID_{UG} and ID_{UH}. They are kept in the cloud by the administrator. Cloud generates a one-of-a-kind DR_{ID} number. To connect securely with the gateway, a doctor uses the confidential subkey issued by the admin.

3.4. Patient.
The hospitalized person for a diagnosis or examination is referred to as the patient. A specific ward boy and doctor are allocated to care for patient in the hospital based on patient diagnosis. The patient additionally gives the administrator two unique identifiers supplied by the government (ID_{UG}) and by the hospital (ID_{UH}). The administrator gets both identifiers and keeps them in the cloud. The administrator receives the unique patient identifier (PT_{ID}) from the cloud. A patient must have the administrator's secret subkey to safely communicate with the gateway. We can assume that the devices of the stakeholders are resource constrained.

3.5. Ward Boy.
After the doctor has left, the patient is cared for by a ward boy. Ward boy gets the data from the cloud through a gateway using his subkey K_S. The ward boy supplies her government-issued unique identity number (ID_{UG}) and the hospital's address when registering offline (ID_{UH}). The ward boy receives the administrator's secret subkey K_S and the cloud's NS_{ID} (ward boy ID). A ward boy can only see the information about the patients who have been allocated to him through the healthcare department.

The patient's EHR does not allow a ward boy to update or write information in it; thus, he is only able to view the data rather than alter it. Ward boy uses his private subkey issued by the administrator to securely interact with gateway, and it is considered that user's devices have limited resources.

3.6. Relative. Relative is role which patient from its dashboard can assign. Patient can give specific access rights of its e-healthcare records stored on cloud environment from its dashboard. If patients are in critical condition or cannot share their health records from a third-party cloud, relative can access their health records and consult a doctor.

3.7. Gateway. When a user wants to access the cloud, they can do so through a gateway. The gateway is resource-unrestricted in the present system paradigm, centered on the hospital's applications. The gateway creates a secure interface for the doctor, ward boy, and patient that too view their cloud records after receiving their complete security credentials from the administration. The gateway obtains the master key K_M, and subkeys K_S and HP_{ID} through the administrator during offline registration. The doctor, ward boy, and patient communicate with the gateway via distinct subkeys while the gateway and cloud communicate via the master key (K_M); the gateway uses encryption to protect their communications.

3.8. Adversary Prototype. To disrupt normal network and service operations, hostile nodes are employed. This new protocol's ability to withstand hostile operations was evaluated using the Dolev–Yao adversary model (DY model). Messages transmitted between a gateway, a user, and the cloud can be intercepted by an adversary, according to the DY model. A hacker can intercept and replay user authentication messages en route to the cloud to illegally access cloud services. Intercepted communications may reveal secret credentials that the adversary can use for attacks like man-in-the-middle or known key emulation. An opponent can also launch a DoS attack by repeatedly bombarding the cloud.

4. Proposed Scheme for Secure Access

For any hospital, keeping track of patients and their data is a major concern for the staff; therefore, they have to multitask at all times. The solution we provided was for medical records to be stored in the cloud, saving hospital staff time and effort by eliminating the need to manually enter data. We consider the following assumptions in order to run the proposed methodology:

    (i) Although the user's device has limited computational and storage resources, the cloud and gateway are well-known entities with enormous compute and storage capacities.

    (ii) The user device, cloud, and the gateway can perform cryptographic functions.

    (iii) Data can only be accessed by a user who has been authenticated in the cloud.

The key conclusion function (KCF) is a cryptographic function for generating more than one secret keys using a master key (KCF). KCF can be used to stretch keys to make them longer or to get the keys in the desired format. The key derivation function, in this case, KCF, serves as good example of pseudorandom function. In this case, the derived key is D_K and the key conclusion function is KCF. The suggested approach comprises four stages: registration for hospital, data retrieval, data storage, and offline registration.

4.1. Registration for Hospital. The notations used all over the paper are listed in Table 3. Figure 3 depicts the administration's cloud registration process with the hospital via gateway. The nonce (N_{CC1}) is generated by administrator, who concatenates these values $RR_N \| RP_N \| HP_{ID} \| N_{CC1}$ for formation of ε. The message ε is encrypted with CK_{PU} forming v, and the resulting message (M_{01}) is forwarded to the gateway. The message v is received by the gateway, by which the nonce is generated N_{CC2}, which gets encrypted using CK_{PU} to create ι. The encrypted message gets in series with v to α, and subsequently, the generated message M_{02} is delivered to the cloud. The message received gets decrypted with CK_{PR} for computing β, and then, N_{CC2} is generated. The cloud checks the nonce N_{CC2}'s freshness. The procedure is continued if N_{CC2} is fresh; otherwise, it is aborted. To compute F, the cloud uses CK_{PR} to decrypt the message v. Cloud also checks the nonce N_{CC1} for freshness; if it is, the process is continued; otherwise, it is cancelled. The cloud checks $RR_N \| RP_N \| HP_{ID}$ and aborts the procedure if they are not found to be true. The master key K_M and nonce N_{CC3} and N_{CC4} are now generated by the cloud. To compute G, all values are concatenated $HP_{ID} \| K_M \| N_{CC3}$. By concatenating and hashing, H_S ($RR_N \| RP_N \| HP_{ID} \| N_{CC1}$), cloud additionally computes KY_{AT} at this point. A key, KY_{AT}, is used to encrypt the computed value G. $KY_{GT} = H_S$ is obtained by using hash function (N_{CC2}). To construct L, the gained key, KY_{GT}, is used for the encryption of the nonce N_{CC4}. The messages L and K are concatenated and then stored in M. The gateway receives the message M. The KY_{GT} gets calculated by the gateway using the hash of N_{CC2}. KY_{GT} is used to decrypt the message L, resulting in R. The purity of N_{CC4} is tested, and if it is found to be true, the process is restarted; otherwise, it is stopped. The value K is sent to the admin as a message M_{04} by the gateway. To construct KY_{AT}, administrator evaluates the hash value of $DR_{ID} \| PT_{ID} \| D_{RQ} \| N_{CC4}$. To create Y, the received message K is decrypted with KY_{AT}. The purity of nonce N_{CC3} is tested at this point, and if it is determined to be pure, the procedure is resumed. Finally, the administrator can successfully obtain the master key (K_M). This master key is a secure communication between the gateway and the cloud through the secret key.

4.2. Offline Registration. Registration method of offline device registration is shown in Figure 4. The administrator keeps track of each stakeholder's unique identifying

Table 3: Description of annotations.

Annotations	Description
$\|$	Concatenation operation
KY_{GT}	Temporary key of gateway
KY_{AT}	Temporary key of administration
H_S	Hash
S_{NO}	Serial number

information, such as ID_{UG} and ID_{UH}. As identifying data, the gateway provides the administrator with the MAC address and serial number S_{NO}. After recording the data, the administrator uploads it to the cloud, which produces the K_M and unique identifiers for the doctor $(DR_{I\,D})$, patient $(PT_{I\,D})$, and ward boy $(NS_{I\,D})$ and sends them to the admin. KCF is used by the administrator to generate several subkeys (K_S) for the secure communication between the gateway and other organizations. Users (patient, doctor, etc.) receive identification details and unique secret subkeys from the administrator, while the gateway gets the K_M, K_S,

$DR_{I\,D}$, $PT_{I\,D}$, $NS_{I\,D}$, and $HP_{I\,D}$. The unique IDs assist the administrator in ensuring the privacy of the patient's records during the offline registration phase. Only those ward boys and doctors treating that patient are given access to the patient by the administrator. The suggested approach allows the administrator to pick which stakeholders can access the cloud-based information. Table 4 shows the administrator's default settings, which include granting access and storage privileges to doctors treating the patient. On the other hand, other stakeholders have merely been provided access to the information.

4.3. Data Retrieval Phase. It is shown in Figure 5 that the doctor visits the gateway to express interest in communicating with a cloud-based service. The nonce N_{CC1} is generated by the doctor's device, and it is concatenated with DR_{ID} and PT_{ID} to compute γ. For computing Γ, the resulting message γ is encrypted (K_S, γ). $H_S(DR_{ID})$ has been calculated and saved in O using the hash function. Γ is combined with the message O for producing A. The gateway receives the message $S1$ from the user, which contains the value A. The gateway retrieves DR_{ID} from the database, calculates its hash value, and saves it in Z. To determine the right subkey for decryption, the gateway compares Z with O $(Z == O)$ using the subkey K_S, to form δ, and Γ is decrypted. The gateway examines the nonce N_{CC1} for freshness; if it is fresh, then the procedure is restarted; otherwise, it is aborted. The nonce N_{CC2} is generated by the gateway and is concatenated with some other values $HP_{ID}\|DR_{ID}\|PT_{ID}\|N_{\text{CC2}}$ and form ζ. Subsequently, M_K is used for the encryption of ζ in order to form η. The gateway has now sent message $S2$ to the cloud. Cloud decrypts the message η using M_K after receiving it to give ϑ. The procedure is continued if N_{CC2} is fresh; otherwise, it is aborted. The variables HP_{ID}, PT_{ID}, and DR_{ID} are checked, and if they are determined to be false, the procedure is aborted. It is checked to see whether PT_{ID} belongs to DR_{ID}, and if it does, the procedure is continued. Nonce (N_{CC3}) and requested data (D_R) are generated after successful verification and are concatenated with other values $HP_{ID}\|PT_{ID}\|DR_{ID}\|D_R\|N_{\text{CC3}}$ to form Θ. To generate κ, the Θ calculated is encrypted with M_K. The gateway receives message $S3$ from the cloud. When gateway receives a message, it decrypts it using $D_{\text{YP}}(K_M, \kappa)$ to form μ. When N_{CC3} is checked, if it is found to be fresh, the operation is continued; otherwise, it is paused. The gateway now verifies HP_{ID} and generates N_{CC4} as a nonce. Subsequently, $\varnothing$ is calculated by concatenating all of the values $DR_{ID}\|PT_{ID}\|D_{RQ}\|N_{\text{CC4}}$, and then, $\varnothing$ is encrypted using K_S to form $\varnothing$. The doctor receives the message $S4$ from the gateway and decrypts the message $\varnothing$ using K_S and computes

TABLE 4: Access rights distribution.

Device	Read	Write
Patient	Yes	No
Doctor	Yes	Yes
Ward boy	Yes	No

ρ. Only if nonce N_{CC4} is still alive, the operation is continued further. The doctor can successfully retrieve the requested data, D_{RQ}, after verifying the freshness.

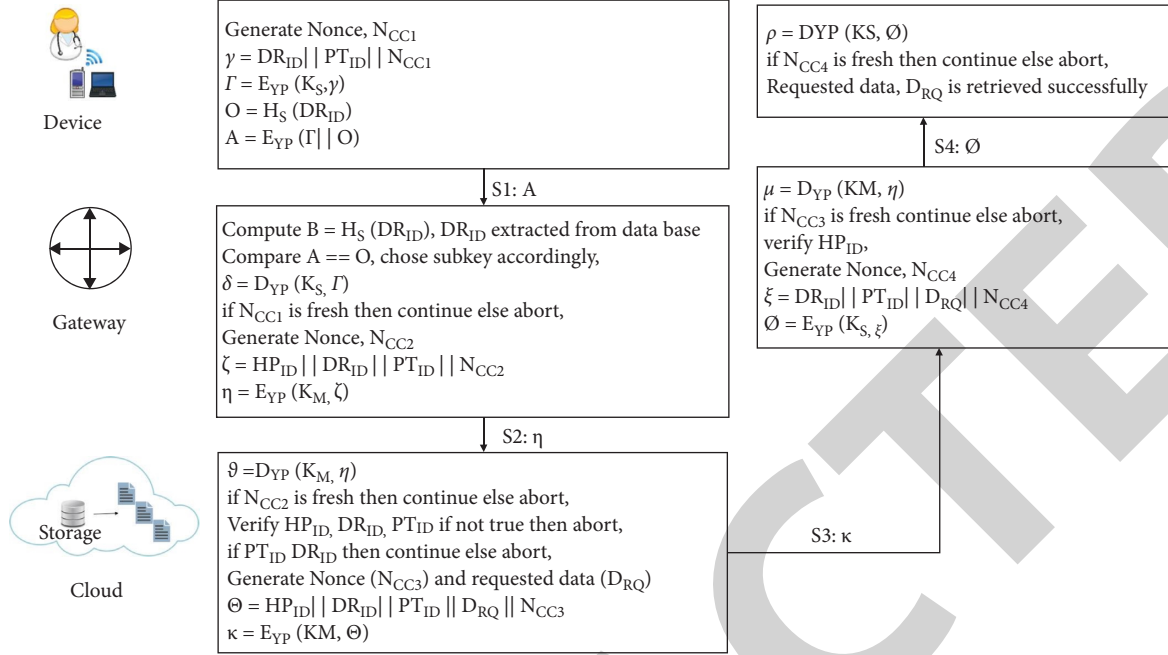
4.4. Data Storage Phase. It is shown in Figure 5 that the doctor visits the gateway to engage in communicating with a cloud-based service. The nonce N_{CC1} is generated by the doctor's device, and it is concatenated with DR_{ID} and PT_{ID} to compute γ. For computing Γ, the message resulting γ is then encrypted (K_S, γ). $H_S(DR_{ID})$ has been calculated and saved in O using the hash function. Γ is merged with the message O to produce A. The gateway receives message $S1$ from the user, which contains the value A. The gateway extracts DR_{ID} through the database for calculating and storing its hash value in Z. To determine the right subkey for decryption, the gateway compares Z with O $(Z == O)$. The gateway examines the nonce N_{CC1} for freshness; if it is fresh, the procedure is restarted; otherwise, it is aborted. The nonce N_{CC2} is generated by the gateway and is concatenated with some other values $HP_{ID}\|DR_{ID}\|PT_{ID}\|N_{\text{CC2}}$ and form ζ. Subsequently, M_K has been used to encrypt ζ for formation of η. The message $S2$ is now sent to the cloud by the gateway. Cloud decrypts the message η using M_K after receiving it to give ϑ. The procedure is continued if N_{CC2} is fresh; otherwise, it is aborted. The variables HP_{ID}, PT_{ID}, and DR_{ID} are checked, and if they are determined to be false, the procedure is aborted. It is checked to see whether PT_{ID} belongs to DR_{ID}, and if it does, the procedure is continued. Nonce (N_{CC3}) and requested


Figure 5: Retrieval phase for data.

data (D_R) are generated after successful verification and are concatenated with other values $HP_{ID}\|PT_{ID}\|DR_{ID}\|D_R\|N_{CC3}$ to form Θ. To generate κ, the Θ calculated is encrypted with M_K. The gateway receives message S3 from the cloud. When gateway receives a message, it decrypts it using $D_{YP}(K_M, \kappa)$ to form μ. When N_{CC3} is checked, if it is found to be fresh, the operation is continued; otherwise, it is paused. The gateway now verifies HP_{ID} and generates N_{CC4} as a nonce. Subsequently, $\varnothing$ is calculated by concatenating all of the values $DR_{ID}\|PT_{ID}\|D_{RQ}\|N_{CC4}$, and then, $\varnothing$ is encrypted using K_S to form $\varnothing$. The doctor receives the message S4 from the gateway after that. The doctor decrypts message $\varnothing$ using K_S and computes ρ. Only if nonce N_{CC4} is still alive, the operation is continued further. After verifying the freshness, the doctor can successfully retrieve the requested data, D_{RQ}.

5. Experimental Setup

We have developed a cloud-based web application hosted on third-party AWS cloud infrastructure. Web application is developed using PHP version 7.3. The main aim of this web application is to store and protect the e-healthcare records of the patient over a third-party cloud. The web application uses a dynamic access control scheme for sharing and uploading e-healthcare data over the cloud. Our web application service was hosted and tested on Elastic Compute Cloud (EC2) instances provided on Amazon Web Services (AWS). On the cloud platform, the virtual environment is provided by an instance of Amazon's Elastic Compute Cloud (EC2). We used EC2 instances to conduct experiments in our experimental evaluation, as shown in Table 5.

6. Experimental Design

We ran three sets of experiments to assess the web application's performance. When we conduct an experiment, we use a preallocated Amazon EC2 instance to run an artificial workload to measure the throughput (requests per second) and average web application response time. For artificial workload generation, we have used [63] for web application service performance measurement. It is possible to create an artificial user session to mimic the process of searching for an existing patient and adding a new patient record to the system. It is possible to simultaneously add a new patient to the system while conducting a patient search that returns a significant number of results from the database. The details of all the three experiments are described in Table 6.

6.1. Experiment 1: An EC2 Medium Instance with a Predetermined Allocation.
As part of experiment 1, EC2 instances assigned to the web and database tiers are shown in the following Figures 6–8 which show throughput with average response time and CPU use for the EC2 instances. The figure shows that by the 15th minute of the study, the throughput has stopped rising linearly, significantly increasing the application's response time. An obvious constraint has been discovered in the web server tiers that CPU use approaches 100%, indicating a bottleneck. After 29th minutes, the web server tier instance has stopped responding, and we cannot receive throughput and response time measures after that point in time. Howsoever, we can still monitor both instances of CPU consumption with the Amazon CloudWatch. This experiment achieved a maximum throughput of 934 requests per second.

Table 5: Resource allocation and cost.

Type of instances	vCPU (core)	RAM	Storage	Cost in (USD/hour)
m3.medium	1	3.12	4	0.071
m3.large	2	7.35	32	0.137
m3.xlarge	4	16	600	0.476

Table 6: Details on the experiment.

Number	Experiment	Description
1	Using the EC2 medium instance for a fixed amount of storage	Preallocated EC2 instances of type m3.medium and m3.2xlarge are preallocated in the web service layer and the database layer, respectively
2	Statically allocating resources with an Amazon EC2 large instance	We have preallocated two EC2 instances, one for web services and the other for databases, both of which are of type m3.2xlarge
3	EC2 xlarge instance for static allocation	Preallocated EC2 instances of type m3.2xlarge for the database and one of type m3.2xlarge for the web service tier
Figure 6: Throughput (requests per second).
Figure 7: Avg. response time.
FIGURE 8: Web server and database tier instances' CPU utilization.

6.2. Experiment 2: An EC2 Large Instance with a Pre-determined Allocation. Figures 9–11 illustrate throughput, average response time, and CPU consumption for EC2 instances assigned to the web and database tiers in Experiment 2. The throughput stops increasing linearly by the 21th minute of the experiment, and there was no significant increase in response time throughout this experiment. As of this writing, the typical response time remains under around 45 milliseconds. There has been no discernible increase in CPU use in the web server with database tier replicas. This experiment gained a maximum throughput of 1051 requests per/second. Because bandwidth became a big issue at the 21th minute of the experiment and the web server instance is using 245 MB/seconds and 486 MB/second on an average for network input and output, ideally throughput should have continued to rise throughout the experiment.

6.3. Experiment 3: An EC2 xlarge Instance with a Pre-determined Allocation. Data from Experiment 3's EC2 instances are shown in Figure 12 for the throughput, average response time, and CPU utilization of the web and database tiers of EC2 instances, respectively, as depicted in Figures 13 and 14. In this experiment, there is no hint of a significant rise in response time at the point where throughput stops rising linearly at 21th minute. As of this writing, the typical response time is around 45 milliseconds. A lack of CPU saturation has been found within web and database tiers of the application. In this experiment, we achieved a maximum throughput of 1150 requests/per second. Because we see the identical bandwidth constraint in this experiment as we did in Experiment 2, the results are very similar. The conclusion is clear: increasing the web tier instance's resources does nothing to alleviate bandwidth constraints.

6.4. Comparing Cloud-Based Web Application with Block-chain Platform. EHR and EMR interoperability and security issues have been addressed by blockchain technology, which

has seen tremendous growth in the healthcare industry. Before blockchain can realize its full potential and be used in medical care, it must overcome various barriers. In this section, in terms of latency, throughput, and execution time, we test and compare the performance of the blockchain platform and web application hosted on the third-party cloud platform AWS using a secure scheme implemented for patient health records in the cloud environment. To evaluate our cloud-based web application with the Ethereum blockchain platform, we compared execution time, throughput, and latency of paper [64]. Paper [64] deployed Ethereum smart contracts using IoT devices. The purpose of paper [64] is to evaluate, store, and access transactions. We compare our patient's records, which are stored and accessed from a third-party cloud with paper [64]. The main focuses for comparing cloud-based web application with Ethereum blockchain platform are as follows:

(1) Ethereum and cloud-based web application comparison analysis.

(2) Performance matrices based on latency, throughput, and execution time are used to analyze the number of user transactions.

JMeter tools are being used in an experiment to protect patient e-health records hosted on third-party cloud providers' AWS. We then examined paper [64] Ethereum performance. We assessed latency, execution time, and throughput by different loads, such as the number of queries fired by the user on Amazon AWS cloud, for the performance evolution of cloud and blockchain technologies. The system configuration is shown in Table 7 for comparing blockchain platforms and third-party cloud platform AWS. For comparing the cloud-based web application system, we store and access e-health records of a patient analyzed with store and access transaction of Ethereum blockchain platform using IoT devices. Figures 15–19 show analysis Figures 20 of latency, execution time, and throughput of store and access transaction of third-party cloud AWS and Ethereum with IoT devices. We can see as per Figures 15 and
Figure 9: Throughput (requests per second).

EXECUTE TIME COMPARISION OF STORE TRANSACTION
Figure 18: Execute time comparison of store transaction.
Figure 19: Throughput comparison of access transaction.
Figure 20: Throughput comparison of store transaction.

16 the latency of access and store transaction comparison. As the dataset rises in size, so does the latency of both platforms, which can be seen in the graph. As transaction gets increases latency performance of the third-party cloud-based platform is less compared to the Ethereum blockchain platform, increasing the number of transactions prompts us to look into the impact on transaction execution time variances that might exist. On both systems, as the number of transactions in the dataset grows, Figures 17 and 18 execution times are longer. Finally, the number of completed transactions per second, starting with the first deployment time, is used to determine throughput. Here, in Figures 19 and 20, it is shown that when the number of transactions is varied, the throughput remains relatively constant as the number of transactions increases; the throughput of access transactions is greater than that of store transactions in both the platforms. As transaction increases, the throughput performance of a third-party cloud-based platform is greater compared to the Ethereum blockchain platform. Secured and reliable dynamic access control scheme of patient e-healthcare records implemented in third-party cloud-based e-health application performs better in cloud environment compared to Ethereum blockchain platform using IoT devices. Finally, based on JMeter tool results, we can deduce that a cloud-based web application hosted on AWS for secure sharing of patient health records over a third-party cloud platform has the edge over the Ethereum blockchain platform.

7. Conclusions

To demonstrate the performance of our web application service, we used Amazon EC2 instances of various sizes to simulate growing workloads. We believe this study will assist web application service providers in utilizing proper cloud resources to provide response time guarantees while minimizing operational costs. Patient medical records can be easily accessed from anywhere with cloud-based e-healthcare services. Since cloud service providers offer cost-effective solutions, cloud-based e-health care has become possible. Despite the many benefits, the cloud storage and retrieval framework are particularly sensitive to wireless channels. Patient data can only be stored and accessed by those who have been granted permission (such as the patient, ward boys, doctors, and close family members). The hospital's responsibility for keeping records of patients is reduced, and access to storage of health records is improved. The proposed scheme's reliability against numerous significant attacks such as message alteration, MITMA, and replay, among others, was revealed by security analysis. The method has enormous potential for cloud-based solutions. The proposed secure access methodology for storing and accessing patient's e-health records over third-party clouds is compared to the performance evaluation of two natural traffic flow, store, and access transactions proposed using the Ethereum blockchain platform with IoT device. It can be seen that, despite having a standard system configuration, the cloud platform performs significantly better than Ethereum in relation to execution time, throughput, and

latency. Eventually, in future work, we want to test newer versions of Hyperledger Fabric with a cloud-based solution and look into different scenarios like how having numerous functions in the network affects the network's overall performance of both platforms. Furthermore, we want to compare the performance of cloud-based e-health solutions for the patient with different public blockchain technology for a higher number of transactions. Other analyses related to data security and privacy are on our agenda for the near future, particularly in the context of external access to e-healthcare data transferred through various networks over the cloud.

Data Availability

No data were used to support the findings of the study.

Presently, technological advancements in the healthcare sector pose a challenging problem relevant to the security and privacy of health-related applications. Medical images can be considered significant and sensitive data in the medical informatics system. In order to transmit medical images in an open medium, the design of secure encryption algorithms becomes essential. Encryption can be considered one of the effective solutions for accomplishing security. Although numerous models have existed in the literature, they could not adaptable to the rising number of medicinal images in the health sector. At the same time, the optimal key generation process acts as a vital part in defining the performance of the encryption techniques. Therefore, this article presents a Pigeon Inspired Optimization with Encryption-based Secure Medical Image Management (PIOE-SMIM) technique. The proposed PIOE-SMIM approach majorly concentrates on the development of secret share creation (SSC) and the encryption process. At the initial stage, the medical images are converted into a collection of 12 shares using the SSC approach. In addition, an elliptic curve cryptography (ECC) scheme is employed for the encryption process. In order to optimum key creation procedure in the ECC model, the PIO technique is exploited with the aim of maximizing PSNR. Finally, on the receiver side, the decryption and share reconstruction processes are performed to construct the original images. The PIOE-SMIM model displayed an enhanced PSNR of 59.37 dB in image 1. Improved PSNR of 59.53 dB is given for image 5 using the PIOE-SMIM model. For demonstrating an enhanced performance of the PIOE-SMIM method, a widespread experimental study is made and the results highlighted the supremacy of the PIOE-SMIM model over other techniques.

1. Introduction

Most healthcare providers in recent times have implemented any procedure of electronic mode of medical record system [1]. For reducing the cost of medical imaging (MI) structures by means of front-end ownership and IT maintenance cost burdens, many health practices have changed to outsource options and save MI data from the centralization databases on a third-party cloud which is not completely trustworthy and could be probably presented at remote areas. Though, if

the MI data is saved on a third-party cloud and probably distrusted cloud, security, and secrecy in relation to the safeguarding of data and data access become critical problems [2, 3]. Security and secrecy problems of the healthcare cloud emerge primarily from the inherent property of cloud computing (CC), namely heterogeneity and service composition and consolidation, multitenancy, and dynamic resources [4].

Initially, if the medical activities deploy the cloud memory services to save their MI data on a remote cloud [5],

these medical practices activities needed to encounter the actual risk that their MI data are being widely open to the cloud service provider by which unlawful accesses for invading the secrecy and confidentiality of the saved medicinal data [6]. Second, the medicinal data from various medicinal practices are frequently held in a similar memory cloud for data accessing and processing [7]. Confirming the security purpose and secrecy of patients and other private information is an ongoing research area. Hence, we definitely needed an encryption structure that delivers a very effective method for controlling data accessibility on the basis of user attributes (or privileges), relatively more than their identities. The healthcare cloud is a mission-critical cloud service system that needs the strongest security and secrecy guarantees for medicinal practices with reference to both data as well as access [8, 9]. First, for the sake of preventing information leakages from the saved data, all health data saved on the healthcare cloud must be encoded [10]. Pigeons are simple and intelligent birds that can fly long distances in search of food and then return home without becoming disoriented. This move encouraged researchers, who concluded that pigeons navigate by using the Earth's magnetic field, differences in sun altitude, and memory of a few landmarks. The success of any algorithm is guaranteed when the algorithm can explore and exploit the problem domain globally. Probing PIO on multiple applications allows us to gain a deeper understanding of the method. Pigeons are known to travel large distances in quest of food. They can fly through a forest as well as 759 International Journal of Engineering and Technology through wide space. Another intriguing feature is that the pigeons can find their way back to their home by sensing the Earth's magnetic field, the sun's height, and visual cues such as landmarks. Leading pigeons in the flock communicate with the rest of the flock and navigate by keeping a close flocking distance. A pigeon's leadership is defined by the number of times a specific bird speaks with the other pigeons in a given random population.

The researchers in [11] examined the safety of medicinal images in the IoT environment through the advanced cryptographic method with metaheuristic optimizer-based approaches. For growing the security level of encrypting as well as decrypting procedures, the optimum key would be selected via hybrid swarm optimization, viz., GSO, and PSO in elliptic curve cryptography. In [12], the dual encryption process is exploited for encrypting medicinal images. At first, Blowfish Encryption is taken into account and signcryption procedure is employed to authorize the encryption method. Next, the Opposition-based Flower Pollination (OFP) is exploited to upgrade the public and private keys. Blowfish algorithm encrypts data and expands keys. P–array and S–boxes are used at the beginning of key expansion with numerous subkeys, requiring precomputation before encryption or decryption. P–array has 18 32-bit subkeys, P1 to P18. This section converts 448-bit keys into 4168-byte subkey arrays—The second stage of the Blowfish algorithm encrypts data, starting with a 64-bit plaintext block and ending with a 64-bit ciphertext. First, identical 64-bit segments 39. Second, the exclusive or–operation (XOR) between the initial 32-bit block termed left (L) and the first

P-array. The 32-bit data from Step 2 is passed to the F function, which permutes it into a 32-bit block segment and XORs it with the right (R) 32-bit block of the main 64-bit plaintext. After XOR, L and R segments are exchanged for Blowfish iterations. P1 through P18 are utilized in reverse order for decryption. An opposition-based flower pollination algorithm, also known as an OBFPA, has been used to solve problems involving the optimization of functions and the construction of structures in engineering. The enhancement is accomplished through the utilization of two primary optimization methodologies. The local self-adaptive greedy approach promotes the population's ability to exploit its resources, while the global opposition-based learning of the elite population increases the population's genetic variation. The 18 benchmark functions and two structure engineering design issues are used to validate an elite opposition-based flower pollination method.

This study devises a Pigeon Inspired Optimization with Encryption-based Secure Medical Image Management (PIOE-SMIM) technique. The proposed PIOE-SMIM technique intends in the design of secret share creation (SSC) and the encryption process. At the initial stage, the medical images are converted into a collection of 12 shares using the SSC approach. In addition, an elliptic curve cryptography (ECC) scheme is employed for the encryption process. In order to produce optimum keys involved in the ECC model, the PIO algorithm is exploited with the aim of maximizing the peak signal-to-noise ratio (PSNR). Finally, on the receiver side, the decryption and share reconstruction processes are performed to construct the original images. For demonstrating an enhanced performance of the PIOE-SMIM model, a comprehensive simulation study is made. In summary, the study's contributions are given in the following.

(i) To introduce a new PIOE-SMIM model for a secure image management system in the healthcare sector

(ii) To employ the ECC-based encryption technique to securely transmit the medical images

(iii) To design a PIO algorithm to optimally generate the keys for enhanced secure medical image transmission.

(iv) To validate the performance of the proposed model against a benchmark medical dataset and examine the results interms of different measures.

The rest of the study is planned as follows. Section 3 presents the proposed PIOE-SMIM model and Section 4 elaborates the result analysis. Finally, the concluding remarks are drawn in Section 5.

2. Literature Survey

Sambit et al. [13] examined secure medicinal images with a pair of subkeys, first a pair of subkeys are provided through the tent and chaotic logistic maps. Adoptive GSO with PSNR and correlation coefficient fitness function has been presented for choosing the optimum public and secret keys amongst the arbitrary number.

Hasan et al. [14] introduced an effective, lightweight encryption model to design a secured image coding approach for the medical sector. The presented method applies two permutation approaches for securing medicinal images. The presented method is evaluated, analyzed, and compared with the encrypted one in security and implementation time. In [15], DNA-based cryptography, as well as dual hyperchaotic map methods, are suggested to offer higher-level security for the medicinal image. The digital medicinal image is larger in size and requires computation time. Song et al. [16] proposed a rapid and real-time cryptosystem by the means of chaotic encryption and parallel computing. The concept is based on a "permutation-substitution" structure of a chaotic encryption system. During the substitution phase, encryption over adjacent images through an expanded cipher-blockchain (CBC) model ensures desired diffusion in the entire image set. During the permutation phase, the batch image is classified into different groups. Then, multi-thread generates permutation coordinates simultaneously in every group to save time, from which more than one image is shuffled at one go.

The researchers in [17] employ the chaotic tent map and SCAN concept for medicinal image encryption. It comprises of pixel rearranging stage, diffusion operation, and bit plane decomposition. The amount of data in the images is divided into eight binary planes with differing proportions. Low and high four-bit planes undergo shuffling by diagonal and spiral SCAN patterns. In [18], an Improved Chaos Encryption (ICE) is employed for improving the secrecy using arbitrary nature. The overall energy is computed on the image and a comparison is made with adaptive thresholds for segmenting the Lorenz module employed in the chaotic technique for improving the security approach.

In [19], the authors presented a V-net convolution neural networks (CNNs) model relying on the 4D hyperchaotic method to encode medicinal images. At first, the plaintext medicinal image deal with 4D hyperchaotic sequence image, including pseudorandom sequence generation, image segmentation, and chaotic system processing. Next, the V-net CNN model is utilized for training chaotic sequences to remove the periodicity of chaotic sequences. At last, the chaotic sequence image undergoes diffusion for changing actual image pixels for realizing the encryption process. Masood et al. [20] a light-weighted cryptosystem based on Chen's chaotic, Henon chaotic map, and Brownian motion system is proposed for encrypting the healthcare images with higher security. The experiment result shows that the presented system is a lightweight technique that could accomplish the anticipated security level to encrypt secure image-based patient datasets.

Block-based image processing and hyper-image encryption techniques were used in this study to secure images. A transformation algorithm reorganized the original image into the transformed image and then encrypted the encrypted image using the Blowfish algorithm, or hyperimage encryption techniques. According to the results, the correlation between image elements has been much reduced. A lower correlation and higher entropy were also found when the number of blocks was increased by using smaller block sizes. There is not a key generator in this algorithm. In order to protect the image, a hyper-image encryption method was utilized. IJSER International Journal of Scientific and Engineering Research, Volume 7, Issue 1, January-2016 96 ISSN 2229–5518 is unable to process this volume's enormous amount of data. International Journal of Science and Engineering Research Multimedia data may not be acceptable for text-based algorithms. The degree of correlation between different aspects of an image was greatly reduced using this approach.

In Matlab 2013, Blowfish Algorithm is used to encrypt and decrypt images. In this study, a secret-key block cypher named 64 bits Blowfish was proposed for picture encryption and decryption, to improve both security and performance. This algorithm is used to generate keys with a range of sizes ranging from 32 bits to 448 bits. A Feistel network is used, which repeats a simple function sixteen times. There are no known vulnerabilities in the blowfish algorithm. It also outperforms the current industry standard in terms of speed and efficiency MATLAB is used to develop and implement the proposed algorithm. As a result, the blowfish algorithm becomes more robust when the number of rounds is increased. Blowfish is an effective standard encryption algorithm because it has no known security flaws.

3. The Proposed Model

In this article, a new PIOE-SMIM model has been developed for accomplishing a secure image transmission system. The proposed PIOE-SMIM technique mainly focuses on the design of SSC and the encryption process. At the initial stage, the medical images are converted into a collection of 12 shares using the SSC approach. In addition, the ECC scheme is employed for the encryption process. In order to optimize the key generation procedure in the ECC model, the PIO technique is exploited to maximize PSNR.

3.1. Share Creation Process. Generally, an image is comprised of overlapping shares, from which the human optical system finds private images without primitive technology. At last, the count of shares is widely distributed. The homogenous model contains sensor hubs that are similar because it is farther from dimensions namely battery power and the devices are extremely complex to construct. Hence, an image generates "N" shares for the security system. E-Secret picture distribution is a fine talent and skill that concerns itself with the security of significant color photographs by dividing the secret into numerous copies. This is done in order to ensure the integrity of the image. The core idea behind the technique is to convert the color image into a number of different unreadable format type shares. This will ensure that the information contained inside the image will remain hidden until it is once again combined with some sort of mathematical computation. Security, reconstruction precision, computation complexity, and storage requirements are the four conditions that can be used to evaluate a Secret Sharing Scheme's performance.

Encryption is the process of transforming information into a code that is only known to a select few, hence concealing the information's actual meaning. The process of encrypting and decrypting information is referred to as cryptography, which is a scientific discipline. In computers, data that has not been encrypted is referred to as plaintext, and data that has been encrypted is referred to as ciphertext. Decryption is the process of converting data that has been encrypted back into its original form. In most cases, decryption is simply the process of encryption done backward. It takes the encrypted information and decodes it so that only a user with the appropriate authorization may decrypt the data. This is because decryption requires a secret key or password. Encryption is the process of transforming a message that can be read into one that cannot be read, to prevent third parties who are not authorized from accessing the information. The process of turning an encrypted message back to its original format (which can be read by humans) is referred to as decryption. The communication in its original form is referred to as the plaintext message. At the initial stage, the medical images are converted into a collection of 12 shares using the SSC approach. The pixel values of images were determined and the RGB values get described by matrix (R_m, G_m, B_m). The size of the matrix is equal to input image size ($P * Q$). It is described by the following equation:

$$\text{Pixel} = \sum R + G + B, \tag{1}$$

whereas pixel denotes the overall R_m, G_m, and B_m pixel values. All the pixels present in the input images undergo n transformed way named shares. The RGB shares are depending upon the pixel value that exists in the RGB image. The shares for RGB are symbolized by R_s, G_s, and B_s.

$$R_s = \int_1^k \frac{\lim}{k \longrightarrow 1\text{ton}} R_{ab},$$

$$G_s = \int_1^k \frac{\lim}{k \longrightarrow 1\text{ton}} G_{ab}, \tag{2}$$

$$B_s = \int_1^k \frac{\lim}{k \longrightarrow 1\text{ton}} B_{ab},$$

whereas a and b shows the location of the matrices, (R_s, G_s and B_s) signifies the RGB share, (R_{ab}, G_{ab} and B_{ab}) represents the component of the image pixel. In previous to share formation, the elementary matrix is required to be derivative according to the number of shares to be produced that is fixed by the user. Here, the elementary matrix amount is 2 and the share amount is 4. Next, the elementary matrix is acquired by the abovementioned process and is characterized by B_{M1} and B_{M2} correspondingly. In previous to making share, the succeeding process is implemented on the matrices XR_1 and XR_2.

$$XR_1 = 128 - B_{M1},$$
$$XR_2 = B_{M2}. \tag{3}$$

The red band share is generated by XOR operation among the basic matrix and key matrix as shown in the following.

$$Rs1 = XR_1 \oplus K_M,$$
$$Rs2 = XR_2 \oplus XR_1,$$
$$Rs3 = XR_2 \oplus Rs_1, \tag{4}$$
$$Rs4 = Rs1 \oplus R.$$

In the reconstruction process, multiple shares are incorporated to generate the original images that are shown below:

$$R = Rs1 \oplus Rs2 \oplus Rs3 \oplus Rs4 \oplus Rs4 \oplus K_M,$$
$$G = Gs1 \oplus Gs2 \oplus Gs3 \oplus Gs4 \oplus Gs4 \oplus K_M, \tag{5}$$
$$B = Bs1 \oplus Bs2 \oplus Bs3 \oplus Bs4 \oplus Bs4 \oplus K_M.$$

When the share is recreated, the encryption and decryption method with the ECC approach is exploited on each color band of the recreated share. All the band images are separated into blocks previous to encryption and decryption procedures. The block is divided into the size of $4 * 4$. From the abovementioned process, the share is produced and an encryption procedure is employed.

3.2. ECC Based Encryption.

Once the shares are generated, the ECC scheme is employed for the encryption process. ECC is a public key cryptographic method relying on the algebraic architecture of elliptical curves through finite fields. It includes a small key through the non-EC cryptography for offering similar safety. Figure 1 displays the working process of the ECC. At the ECC, the prime value is elected as n_p and the private key is preferred as H [21]. Next, it can be expressed in the following:

$$E = p(i)^3 + u * p(i) + v, \tag{6}$$

where u and v denote the constant value $u = v = 2$. Once the state $X = Y$ is satisfied, the optimum points are selected for the ECC. Next, X and Y aredetermined as

$$X = \text{mod}(E, n_p),$$
$$Y = \text{mod}(p(j)^2, n_p). \tag{7}$$

Now, $p(i, j)$ denotes the point of the elliptic curve. n_p describes a prime number. The doubling technique is exploited for defining the X and Y values. The optimum point $P_e(k, l)$ and P_f indicates public key as given below:

$$P_f = H * P_e. \tag{8}$$

In the encryption procedure, each share comprises a block and all the blocks are comprised of encrypted sections. The total number of blocks is indicated by $b(i, j)$ whereas i and j indicates the row along with the column of the blocks. At this point, all the portions of information are delivered as an input to encrypt data. Data $D_x(i, j)$ and $D_y(i + 1, j)$ along with the point can be described as follows [22]:

$$C_1 = H * P_e,$$
$$C_2 = (D_x, D_y) + C_1. \tag{9}$$
FIGURE 1: Process in ECC.

In decryption procedure, the private key (H) is employed for communication decryption whereas the point C_{11} is exploited to decrypt pixels.

$$C_{11} = H * C_1,$$
$$C_{ij} = C_2 - C_{11}. \quad (10)$$

The C_{ij} shows the final result of the decryption procedure. From the outcomes of C_{ij}, pixel values of IR and original color bands (RGB) are uniquely saved. Eventually, it can be expressed as follows:

$$F_{\text{image}} = R + G + B. \quad (11)$$

Now, the keys exploited into encrypting and decrypting data are produced through the MRFO process that is deliberated in the succeeding subsection.

3.3. Optimal Key Generation. To generate ECC keys optimally, the PIO algorithm is exploited to maximize PSNR. The POA has three operators: the compass, landmark, and map operators. During the map and compass operators, pigeons sense the geomagnetic field for the procedure the mapping to home [23]. In this recently developed technique, the map and compass operator model is presented based on the magnetic field and the sun, whereas the landmark operator model is presented based on the landmarks themselves. Map and compass operator: The birds would orient themselves by using the magnetic field of the Earth (also known as the CMT), which would also enable them to take over in the event that the environmental conditions no longer permitted optical orientation. This phenomenon is known as magnetoreception. Landmark operator: Pigeons rely on the neighboring landmarks in order to find their way as they go closer and closer to their destination. If they are familiar with the locations, they will bypass the intermediate stops and go straight to their destination. They will follow the pigeons that are familiar with the landmarks in the event that they are a considerable distance from the goal and do not know where the landmarks are located. Consider that searching space is N dimensional, and i^{th} pigeon of swarms is represented as N dimensional vectors $X_i = (X_{i,1}, X_{i,2}, \ldots, X_{i,N})$. The velocity of pigeons

signifies the altered place of pigeons and is demonstrated as other N dimensional vectors AC. The previous visited place of ith pigeons are signified as $P_i = (P_{i,1}, P_{i,2}, \ldots, P_{i,N})$. The global optimum place of swarms is presented as $(g_1, g_2, \ldots, g_N)$. Every pigeon was flying dependent upon equations (12) and (13):

$$V_i(t+1) = V_i(t) \times e^{-Rt} + rand \times \left(X_g - X_i(t)\right), \quad (12)$$

$$X_i(t+1) = X_i(t) + V_i(t+1), \quad (13)$$

where R implies the map and compass factors, whereas r and refers to the arbitrary value in the range of [0, 1], X_g represents the global optimum solutions, $X_i(t)$ signifies the present place of pigeons at the time t, and $V_i(t)$ indicates the existing velocity of pigeon at iterations t. During the landmark operator, each pigeon is ranked dependent on its fitness values. During every group, the amount of pigeons is upgraded by equation (14), whereas the number of pigeons were taken into account for evaluating the chosen place of centered pigeons, whereas each other pigeon changes its terminus as follows [24].

$$N_p(t+1) = \frac{N_p(t)}{2}, \quad (14)$$

where N_p signifies the number of pigeons from the existing iteration t. The place of the chosen terminus was measured by equation (1), whereas each other pigeon upgrades its place nearby equation (16).

$$X_c(t+1) = \frac{\sum X_i(t+1) \times \text{Fitnes}\left(X_i(t+1)\right)}{N_p \sum \text{Fitness}\left(X_i(t+1)\right)}, \quad (15)$$

$$X_i(t+1) = X_i(t) + rand \times \left(X_c(t+1) \times X_i(t)\right), \quad (16)$$

where X_c signifies the place of centered pigeons. Figure 2 demonstrates the flowchart of the PIO approach.

Optimization based on pigeons as seen in the images above, bio-inspired Swarm Intelligence Optimizer (SIO) is presented for the classification of satellite images [25–29]. Scientists have found that pigeons' orientation is primarily based on two operators that appear to utilizing particular rules. The pigeon's natural behavior, according to estimates, is that they travel long distances in search of food.
FIGURE 2: Flowchart of PIO technique.

They are equally adept at flying in dense woodland as they are at soaring through an open field. The pigeons' capacity to perceive the Earth's magnetic field, the sun's height, and visual cues like landmarks is another intriguing characteristic. Leading birds communicate and navigate with the remainder of the flock by flying side-by-side with each other. Researchers have shown that pigeons' amazing directing abilities are nearly entirely dependent on small magnetic particles in their beaks. Pigeons, in particular, have iron crystals in their beaks that give them a sense of direction. The trigeminal nerve appears to transmit messages from the nose to the brain via magnetite particles, according to research [30–33]. The pigeon's ability to detect the difference in height between the sun at the base and at the time of release has been regarded as evidence that the sun also plays a role in the pigeon's navigation. There is new evidence that pigeons can follow major highways, railroads, and waterways instead of flying straight to their destination, according to studies on the birds' behaviors. An optimum key selective method assumes that 'fitness function' is the maximal key using PSNR for scrambling and unscrambling data in the medicinal images in IOT. The procedure was generated by the model of hybrid optimized for assessment. It can be demonstrated in the subsequent condition.

$$\text{fitness} = \text{maximum } \{\text{PSNR}\}. \tag{17}$$

4. Experimental Validation

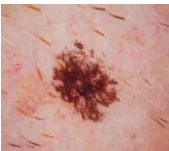
The experimental validation of the PIOE-SMIM model is tested using three medical datasets namely DR [25], dermoscopic [26], and lung [27] datasets. Figure 3 demonstrates a sample test image.

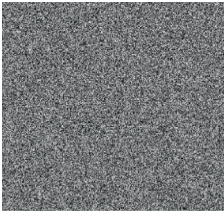
To comprehend the share conception, a group of four shares (R, G, and B band) created to perform dermoscopic images is depicted in Table 1. The three rows from the table represent the shares of the RGB band correspondingly. As the shares outperformed in the table, it can be clear that the shares are not meaningful.

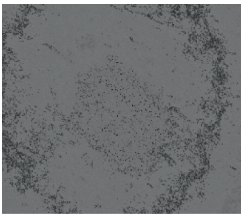
For understanding the share conception, a group of four shares (R, G, and B band) created to execute the DR image is exposed in Table 2. The three rows from the table signify the shares of the RGB band correspondingly. As demonstrated in the table, it can be clear that the shares do not convey any meaning.

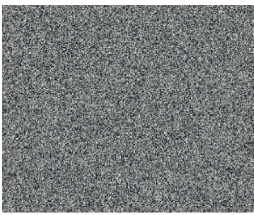
Table 3 provides a brief result examination of the PIOE-SMIM model under distinct test images. Figure 4 highlights a brief PSNR investigation of the PIOE-SMIM model under a distinct number of test images. The figure indicated that the PIOE-SMIM model has resulted in increased values of PSNR. For instance, with image 1, the PIOE-SMIM model has provided a PSNR of 59.37 dB. Moreover, with image 2, the PIOE-SMIM model has provided a PSNR of 59.99 dB. Similarly, with image 3, the PIOE-SMIM model has offered a PSNR of 58.82 dB. Moreover, with image 4, the PIOE-SMIM model has resulted in a PSNR of 60.28 dB. At last, with image 5, the PIOE-SMIM model has accomplished a PSNR of 59.53 dB.

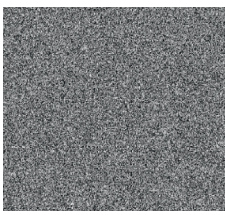
Figure 5 demonstrates a detailed SSIM and CC study of the PIOE-SMIM model under a distinct number of test images. The figure designated that the PIOE-SMIM model has resulted in enlarged values of SSIM and CC. For instance, with image 1, the PIOE-SMIM model has offered SSIM and CC of 99.90 and 99.95. Also, with image 2, the PIOE-SMIM model has provided SSIM and CC of 99.99 and 99.91. Equally, with image 3, the PIOE-SMIM model has offered SSIM and CC of 99.90 and 99.97. Furthermore, with image 4, the PIOE-SMIM model has resulted in SSIM and CC of 99.94 and 99.91. Finally, with image 5, the PIOE-SMIM model has led to SSIM and CC of 99.90 and 99.96.

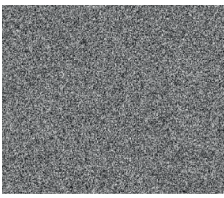
A detailed PSNR and MSE comparison study of the PIOE-SMIM model with other models is provided in Table 4 and Figure 6. The outcomes implied that the PIOE-SMIM model has accomplished enhanced values of PSNR and reduced values of MSE. For instance, with image 1, the PIOE-SMIM model has provided the least MSE of 0.0751 whereas the OSC-MI, hybrid, GWOE-SCO, and SC-ECC models have accomplished increased MSE of 0.1050, 0.1254, 0.1521, and 1.4460, respectively. At the same time, with image 5, the PIOE-SMIM model has offered a reduced MSE


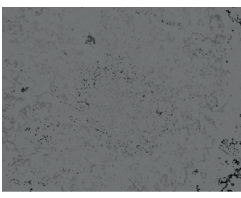


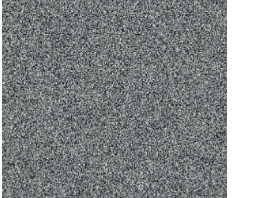


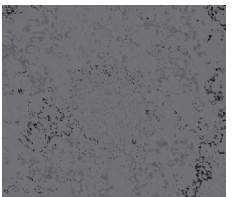


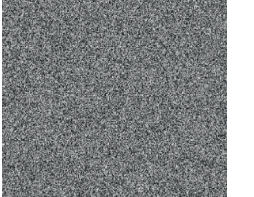












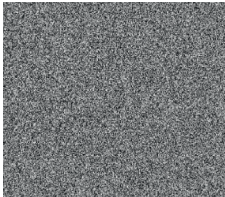


FIGURE 3: Sample medical images.

TABLE 1: Visualization of multi-share creation scheme image 1.

Test image	Share 1	Share 2	Share 3	Share 4

of 0.0725 whereas the OSC-MI, hybrid, GWOE-SCO, and SC-ECC models have gained improved MSE of 0.0812, 0.1280, 0.1542, and 2.1652, respectively.

A thorough CC comparison study of the PIOE-SMIM model with other models is provided in Table 5 and Figure 7. The outcomes portrayed that the PIOE-SMIM model has resulted in improved values of CC.

For instance, with image 1, the PIOE-SMIM model has provided a maximum CC of 99.95 whereas the OSC-MI, hybrid, GWOE-SCO, and SC-ECC models have accomplished minimum CC of 99.71, 98.03, 98.11,Similarly, with image and 97.68 respectively. In line with image 5, the PIOE-SMIM technique has offered superior CC of 99.96 whereas the OSC-MI, hybrid, GWOE-SCO, and SC-ECC models

have gained decreased CC of 99.27, 98.51, 97.24, and 97.06, correspondingly [34].

Table 6 reports a detailed study of the PIOE-SMIM model with recent models under the existence and non-existence of attacks. Figure 8 showcases the PSNR examination of the PIOE-SMIM model with other models under the existence of attacks. The results indicated that the PIOE-SMIM model has gained effectual outcomes with increased PSNR. For instance, with image 1, the

PIOE-SMIM model has showcased an increased PSNR of 58.43 dB whereas the OSC-MI, hybrid, GWOE-SCO, and SC-ECC models have depicted reduced PSNR of 56.93 dB, 55.91 dB, 55.39 dB, and 45.53 dB respectively [35]. Similarly, with image 5, the PIOE-SMIM model has reported an improved PSNR of 58.52 dB whereas the OSC-MI, hybrid, GWOE-SCO, and SC-ECC models have exhibited lower PSNR of 57.96 dB, 55.68 dB, 54.76 dB, and 43.40 dB, respectively.
FIGURE 8: PSNR analysis of PIOE-SMIM technique with attacks.
FIGURE 9: PSNR analysis of PIOE-SMIM technique without attacks.

Figure 9 illustrates the PSNR inspection of the PIOE-SMIM model with other models without attacks (WOA). The results designated that the PIOE-SMIM model has expanded capable outcomes with amplified PSNR. For instance, with image 1, the PIOE-SMIM model has showcased an improved PSNR of 59.37 dB whereas the OSC-MI, hybrid, GWOE-SCO, and SC-ECC models have portrayed compact PSNR of 57.92 dB, 57.15 dB, 56.31 dB, and 46.53 dB, respectively. Likewise, with image 5, the PIOE-SMIM model has stated enhanced PSNR of 59.53 dB whereas the OSC-MI, hybrid, GWOE-SCO, and SC-ECC models have displayed inferior PSNR of 59.04 dB, 57.06 dB, 56.25 dB, and 44.78 dB, respectively.

The abovementioned tables and figures implied that the proposed PIOE-SSIM model has accomplished enhanced security in medical image transmission. Therefore, the proposed PIOE-SSIM model can be employed in the real-time hospitals and healthcare institutions to securely transmit medical images.

5. Conclusion

In this article, a new PIOE-SMIM model has been developed for accomplishing a secure image transmission system. The proposed PIOE-SMIM technique mainly focuses on the design of SSC and the encryption process. At the initial stage, the medical images are converted into a collection of 12 shares using the SSC approach. In addition, the ECC scheme is employed for the encryption process. In order to optimize key generation process in the ECC model, the PIO algorithm is exploited to maximize PSNR. Finally, on the receiver side, the decryption and share reconstruction processes are performed to construct the original images. For demonstrating an enhanced performance of the PIOE-SMIM technique, a comprehensive simulation study is made and the results highlighted the supremacy of the PIOE-SMIM model over other techniques. In the future, blockchain technology can be applied to improve security in the healthcare sector. Blockchain is applied in healthcare and other industries. In healthcare, a Blockchain network stores and shares patient data among hospitals, labs, pharmacies, and clinicians. Blockchain can detect deadly medical blunders. This could improve medical data sharing's performance, security, and transparency. This tech analyses medical records. Blockchain can improve healthcare and other industries. Blockchain can uncover hazardous medical errors. Blockchain avoids dishonesty to enhance clinical trial results.

Data Availability

The manuscript contains all of the data.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Retracted: Ageing Design of Urban Park Landscape Based on Computer Virtual Simulation Technology

Computational Intelligence and Neuroscience

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope

(2) Discrepancies in the description of the research reported

(3) Discrepancies between the availability of data and the research described

(4) Inappropriate citations

(5) Incoherent, meaningless and/or irrelevant content included in the article

(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Greenery are the parks in the urban areas and it becomes progressively most significant as cities grow more crowded. In the end, urban parks contribute to the population's healthiness and welfare by providing opportunities intended for physical and social activity, leisure, and relaxation. In order to construct "Digital Land," computer and system software and hardware were used. Computer simulations are used to examine the value of a city garden's landscape design. Digital models and multimedia performances are being built using computer-aided design (CAD), this underlines the need for digitizing data for landscape design. A region's landscapes can only be accurately assessed if sufficient information is available on the elements that influence the people's awareness of landscape quality, as well as the kind, method, and effective rate of each of them. We use an LVQANN (artificial neural network) to forecast the landscape aesthetic assessment of urban parks and priorities the model's significant factors in this research. User viewpoint and artificial neural network modelling were utilized in conjunction to assess the aesthetic quality of the urban park's environment. This was done for two reasons. The design of urban parks decision support system is known as MATLAB software's multilayer perceptions model, which gives the ability to anticipate landscape visual significance in innovative parks. In this study, the ANN LVQ model is used to execute an ageing design of an urban park landscape based on a computer virtual simulation application. An example land is selected as input and area linked to sunny spot, top view, and so on is fixed. The ANN tool box is used to develop this application in MATLAB 2018b software. The following approach is used to create the ideal urban park landscape model. An accuracy of 89.23 percent, a sensitivity of 87.34 percent, and a recall of 78.93 percent were achieved, outperforming the approach and competing with the current model.

1. Introduction

For inhabitants, urban parks provide low-cost chances to connect with nature in their everyday lives, while also improving the aesthetics of the city. In order to accurately analyze a region's landscapes, it is necessary to know the kind, method, and effect rate of each of the influential aspects, as well as how they affect the user's sense of landscape quality. Environmental, biological, social, cultural, and physiological aspects all have a role in landscape's aesthetic value. For the majority of individuals, landscape variety, kind of landscape, and people's taste and ideals all play a role in aesthetic choice.

Designing Tehran's urban parks now adheres to the guidelines outlined in Vice President for Strategic Planning

and Supervision publication No. 203, with some minor modifications. This has resulted in a dramatic decrease in the park's landscape structure's aesthetic value, and there is no specific framework for increasing landscape quality. Which landscape aspects are most appealing to users and which are the most important variables in influencing their view of the environment? How can we forecast the aesthetic worth of urban parks in the eyes of observers by constructing the most suitable structure? 'The factors that affect the aesthetic quality of natural surroundings were found to be the viewpoint, land slope, and landform. Researchers feel that assessing the visual excellence of a land and its ecosystem requires paying close attention to the physical conditions of the landscape (which is illustrated in Figure 1).

Figure 1: Urban park landscape.

This has looked at the role that water plays in enhancing the aesthetics of the park and drawing in more visitors. Water features like ponds, pools, runnels, fountains, etc., should be included into landscape design, says one researcher, in order to provide park visitors with more diversity and enjoyment. For the evaluation of urban green space, Jahani and Mohammadi Fazel employed CNN modelling to determine characteristics and indications such as bared surfaces, architectural features, water, trees and shrubs, sports equipment, and mountain vistas as beneficial landscape beautifying aspects. Landscapes are classed as high-quality if they offer access to water, leisure, and sports equipment, according to studies. In addition to trees and plants, architecturally appealing buildings, and mountain vistas, urban green space has a better landscape quality. With the introduction of a multilayer perception model, the diversity of tree species and pure natural regions devoid of human interventions such as buildings, paths, and park equipment were given a boost in the landscape quality of natural areas. It is possible to utilize any of the design concepts outlined in these studies as indications of the current research as shown in Figure 1.

The contribution of the work is as follows:

(i) To execute an ageing design of an urban park landscape by using the ANN LVQ model based on a computer virtual simulation application.

(ii) To select the example land and taking it as an input and area linked to sunny spot, top view, and so on is fixed and perform evaluation.

1.1. Literature Survey. Jo and Jeon consider the relevance of human components; we determined that designs are required to encourage an adequate degree of park-goers to boost their overall contentment with the surroundings. An urban park setting may be made more enjoyable by using this study's results as design recommendations and supporting data [1].

Yu et al. As a result of using ArcGIS 3-D analysis, we want to present a novel study viewpoint and a service that provides techniques for creating layouts of such places that are beneficial for the elderly in order to better assure urban sustainability civilization [2].

Li and Xu Moreover, the research study and effectiveness test results show that the realized distribution rationality technology is better than the competition. This method might serve as a scientific reference and basis for the present landscape gardening industry to include 3-D images and other cutting-edge technologies [3].

Van Vliet et al. In an urban park, the natural components and a wide range of floral species are vital while the services provided vary widely in value among various sectors of the public Research like this might help park planners and legislators make better choices. As a result, it shows the value of establishing a virtual park in environmental preference study. Check out the full-length article [4].

Luo and Liu. As the rehabilitation environment evolves, this study examines present empirical research methodologies from the perspectives of subject and object, pointing out their flaws, forecasting their future development trends, and ultimately proposing future empirical research. The study should be more rigorous and methodical, with a better knowledge of what the research is about, and the establishment of an assessment system with the most practical significance possible should be encouraged [5].

Yang The urban parks landscape design and analysis of city parks significance may be improved by using computer simulation. More and more people are realising how important digitising information is to creating digital models and multimedia performances in computer-aided design (CAD), particularly when it comes to the landscape design process [6].

Ma et al. Analyzing the garden's rational distribution is based on a new three-dimensional picture. Virtual reality technology was used to build a three-dimensional simulation of the distribution landscape's efficacy. Finally, the garden, rational medication delivery methods, case studies, benefits, and results of performance tests will be discussed [7].

Irvine et al. To better understand the challenges of combining multidisciplinary visioning and modelling of green space design and performance evaluation in the Thai town of Cha Am, we interviewed students from three universities: Thammasat University, Mahidol University, and AIT. Examples from Phnom Penh illustrate how 3D visualisation and modelling might help people better comprehend the benefits of green space. For urban green space design to be successful, we believe that a decision support system that is easy to use is essential [8].

Bishop and Rohrmann findings from the study suggest that the most meticulous and time-consuming computer simulations may not always reflect actual-world behaviour. However, the realism evaluations of the viewers were largely positive, and the contrasts between day and night circumstances in the simulated environment are almost identical to those in the actual world. The results reveal areas in need of improvement and reassessment [9].

Jeon and Hong. Various human activities in parks have been shown to have a significant effect in influencing soundscape perception. There was also a strong link between how people perceived soundscapes and the aesthetic quality, simplicity, and feeling of enclosure provided by a given environment. As a consequence of this study, soundscapes in urban parks might benefit from the findings, even if they are only applicable to Seoul's specific settings [10].

Daniel and Meitner. Each degree of realism–abstraction was used to portray the identical woodland landscape images in this investigation. One similar set of forest landscape images was given to various groups of observers, and each group was asked to score the perceived scenic quality of the scenes. Computer-generated landscape visualisations may not be accurate representations of the landscape since correlations between judgments of the same landscapes in various visualisation situations were very low [11].

Lange. This investigation focuses on the subject of whether, how, and to what extent virtual landscapes can be used to accurately reproduce genuine landscapes seen in images. The settlements of Schwyz and Ingenbohl–Brunnen, located on the shores of Lake Lucerne in Central Switzerland, are the focus of this research [12].

Bishop and Lange. The field of visualisation technology has a lot to offer, and notable developers discuss the latest advancements in hardware, software, and display technology. Concerns about the legitimacy and ethics of the use of visual simulations are raised. Authors from forestry, agriculture, mining, energy, and urban planning have contributed cutting-edge applications. Finally, a look at what's to come in terms of augmented reality and public engagement is included in the volume's last chapter [13].

Bishop. The view analysis of Two-Dimensional GIS's approach is ineffective in circumstances when significant 3D aspects are present. For landscape visual interpretation, a new standard is required due to an increase in agent-based modelling. Both GIS-based visual modelling and 3D-based visual modelling are examined in this paper [14].

Thompson It is suggested that open space be defined and used in a more flexible manner, taking into account 'loosefit' landscapes that provide possibilities for the socially marginalised and environmentally moving within a dynamic context of urban structures and networks [15].

Wergles and Muhar. Visualizations, on the other hand, were more effective in conveying particular features of the design because of their capacity to draw the viewer's attention to focal points. As a means of conveying design concepts, visual representations may work well, but they must be tailored to the audience in order to be effective [16].

Sheppard Ethical and scientific validity may be improved by providing direction and assistance to visualisation practitioners, according to a suggested framework. An preliminary code of ethics is offered for evaluation, testing, and change by other researchers and users until more thorough results are gathered from the vast amount of study required on this topic. Such a code should incorporate general principles and guidelines for ethical behaviour in the creation, presentation, and analysis of visualisations, as well as the analysis of user comments [17].
Figure 2: Proposed block.

Appleton and Lovett. According to the data, it seems that certain characteristics are more significant than others when it comes to realism. Ratings were significantly influenced by foreground vegetation and the general appearance of the ground surface, despite a large variation in ratings across the three situations evaluated [18].

Kort et al. On four measures, researchers discovered substantial variations. Environment and plants, on the other hand, did not seem to interact in a major way. Virtual environments have many characteristics with actual ones, but there are also significant distinctions. As a result, we believe that this is an important and fascinating topic for environmental psychology [19].

Orland et al. Using virtual reality (VR) technology to aid with environmental decision-making is the focus of this article. Human-computer interfaces are discussed and categorized, and then we examine how VR's qualities match up with landscape representation demands [20].

The drawback of the existing approaches is as follows, expensive direct observations, it requires numerous employs for monitoring the extended periods and restricted information only provided.

2. Methodology

In this section, urban park landscape-based analysis was performed using LVQ ANN technology. For multiclass classification, LVQ (learning vector quantization) is a prominent class of adaptable nearest prototypes classifiers. However, learning algorithms from this family have been developed on heuristic grounds so far. LVQ (Learning Vector Quantization) classifiers are reviewed in this article. A suggested taxonomy incorporates the most significant LVQ techniques to date. The fundamental elements of contemporary LVQ techniques are outlined in this article. 11- LVQ extractors are compared by means of a real-world dataset and 2 fake areas shown in Figure 2.

$$y = \{y(t)|t = o, 1, 2, \ldots d - 1\}. \tag{1}$$

Here, the quantity of Urban park area [5] for time. t, d: length of network traffic duration.

The domain represents a discrete-time series of finite length *according* to ANN theory. So,

$$x(n) = y(t), n = t, n = 0, 1, \ldots, d - 1. \tag{2}$$

This discrete series $x(n)$ represents the set given below,

$$\{x(0) = y(1), x(1) = y(2), \ldots .x(d - 1) = y(z)\}. \tag{3}$$

The ANN $x(n)$ with finite length d is considered as a sequence of periodic nature. Subsequently, with the theory of ANN.

$$X(k) = \sum_{n=0}^{d-1} \left(x(n) e^{-j(2\pi/d)nk} \right), \quad 0 \le k \le d-1. \tag{4}$$

Consequently, $x(n)$ is expanded as the equation given below:

$$x(n) = \frac{1}{z} \sum_{k=0}^{z-1} \left(Y(k) e^{j(2\pi/d)nk} \right), \quad 0 \le n \le d-1. \tag{5}$$

From (2) and (5), the value of $y(t)$ at time t is obtained as follows:

$$\bar{y}(t) = y(n) = \frac{1}{z} \sum_{k=0}^{z-1} \left(Y(k) e^{j(2\pi/d)nk} \right), t = n, 0 \le n \le d-1. \tag{6}$$

(a)

(b)

(c)

(d)

FIGURE 4: Top view for selected urban park landscape.

Since the network traffic considers $x(t) \geq 0$, the equation below is attained for accessing traffic in network.

$$\begin{cases} \tilde{y}(t) = \dfrac{1}{z} \sum_{k=0}^{z-1} \left(Y(k) e^{j(2\pi/d)nk} \right), & 0 \leq n \leq d-1, \\ \\ \tilde{y}(t) \geq 0. \end{cases} \tag{7}$$

Equation (7) represents that the traffic across network is extended to Fourier series with the duration length d as well as network traffic correlation at $d-1$ time points. The Fourier series expansion matrix is given by the following:

$$\hat{y} = \begin{bmatrix} \hat{y}_{0,0} & \hat{y}_{0,1} \cdots & \hat{y}_{0,d-1} \\ \hat{y}_{1,0} & \hat{y}_{1,1} \cdots & \hat{y}_{1,d-1} \\ \hat{y}_{d-1,0} & \hat{y}_{d-1,1} \cdots & \hat{y}_{d-1,d-1} \end{bmatrix}. \tag{8}$$

Hence, we get the following:

$$\hat{y} = \left(\hat{y}_0, \hat{y}_1, \ldots \hat{y}_{d-1} \right)^T. \tag{9}$$

Here, T: matrix transposition operation

$$\text{Consequently, } \hat{y}_i = \left(\hat{y}_{i,0}, \ldots \hat{y}_{i,d-1} \right). \tag{10}$$

In which, $i = 0, 1, \ldots \ldots, d-1$
From (7),

$$\hat{y}_{i,k} = X(k) e^{j(2\pi/d)ik}, \tag{11}$$

where. $i, k = 0, 1, \ldots, d-1$

Here, (8) captures the relation within the network traffic effectively. Subsequently,

$$\hat{y} = UDV^T, U, V, D \text{ and } V \text{ are } d \times d \text{ matrices.} \tag{12}$$

D and V represent the network traffic features and equation (12) captures the area dimensions features.

$$K(d) = \frac{p_0}{2} + \sum_{k=1}^{d} \left(p_k \cos kx + q_k \sin kx \right). \tag{13}$$

The authentication key for the time duration $d+1$ is given by,

(a)

(b)

(c)

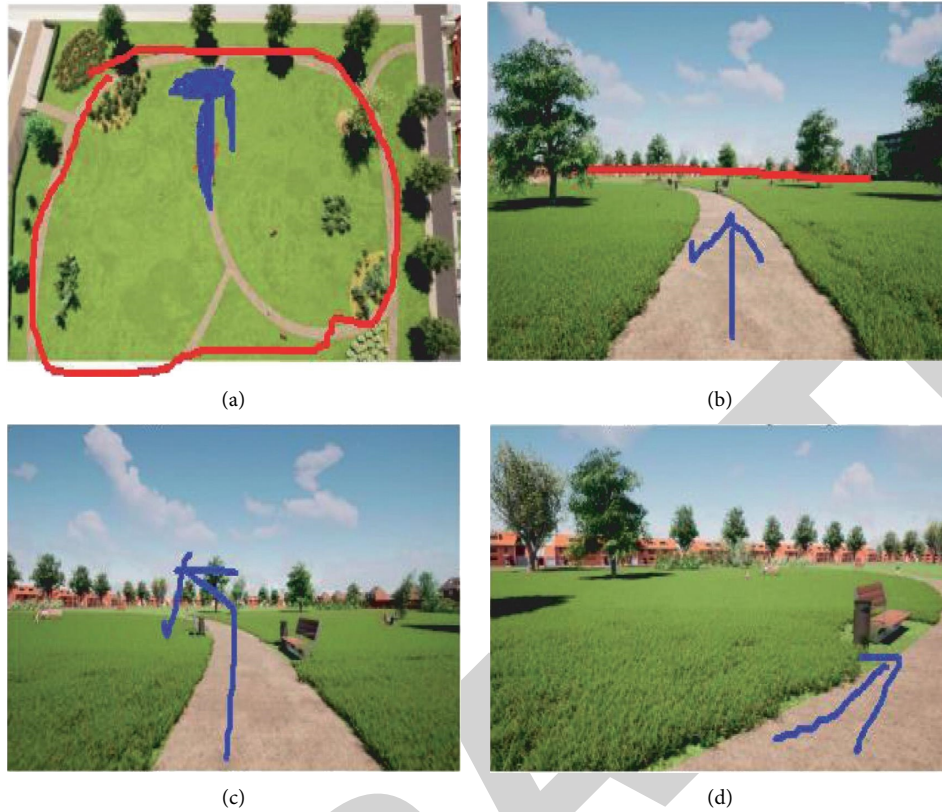
(d)


Figure 5: Computer level design with ANN.
Figure 6: Inner layout.

$$K(d+1) = \frac{p_0}{2} + \sum_{k=1}^{d+1} \left(p_k \cos kx + q_k \sin kx \right), \tag{14}$$

$$= K(d) + \left(p_{d+1} \cos (d+1)x + q_{d+1} \sin (d+1)x \right). \tag{15}$$

The authentication key $K(d+1)$ for time period $d+1$ is calculated by $K(d)$ as well as the Fourier series coefficients p_{d+1} and q_{d+1}.

In statistical classification and prediction, LVQ (Learning Vector Quantization) is a family of methods that try to learn prototypes (codebook vectors) that represent class areas. Voronoi partitions are used to

define the class areas as hyperplanes between prototypes. Late in the '80s, Teuvo Kohonen came up with LVQ1 an algorithm that has since been used in many different ways. There has been a small but dedicated group of researchers studying LVQ algorithms since their introduction. "Learning Vector Quantization" or "LVQ" appeared in the titles or abstracts of 665 academic articles that were indexed by the ISI Web of Science in November 2013. This article presents a survey of recent developments in the subject.

In order to achieve competitive learning's, LVQ algorithms are similar to SOMs and c-means. During training, the winner-takes-all learning rule and variations based on iterative URBAN PARK _SCAPE_002ates to just selected components or neighborhoods are used to create competitive learning algorithms. Class-labeled prototypes are obtained via supervised learning in the original LVQ technique and most recent extensions (classifiers). Unsupervised learning may also be used to train LVQ for clustering without labels. We will exclusively cover LVQ classifiers in this work.

Data are supposed to have a Gaussian mixture probability density function (URBAN PARK _SCAPE_002f). Logarithmically maximizing the difference between the proper class's and erroneous class 'URBAN PARK _SCAPE_002f ratios is a cost function given a data point.

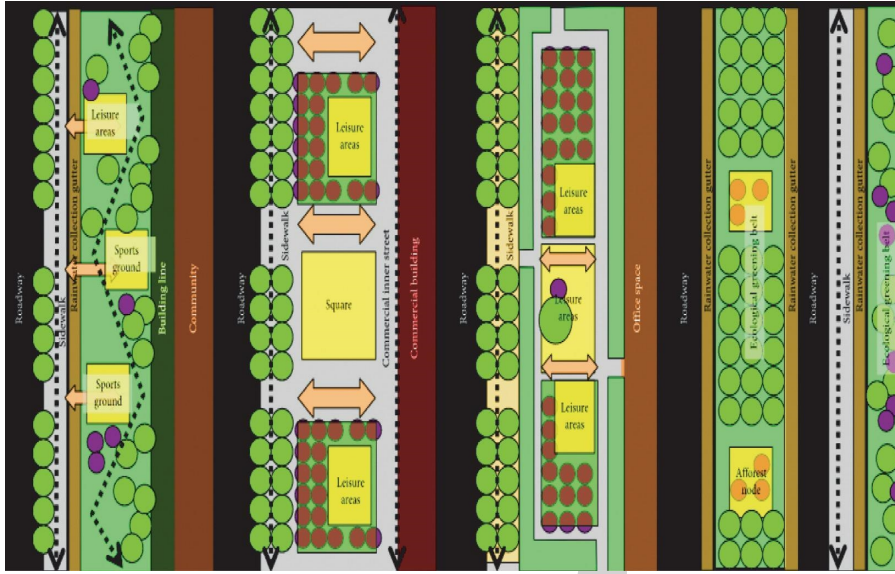
In addition, GLVQ and the original LVQ algorithms have been improved in terms of their initialization sensitivity [15].


Figure 7: Final layout.

Table 2: Results comparison.

Models		LVQ [5]	ANN [6]	Deep ML [7]	Deep GA [7]	EST [30]	ANN_LVQ proposed
MATLAB	Accuracy	77.877	83.8687	87.6	84.3035	87.77	88.386
	Specificity	77.7373	83.743	83.7	83.8737	87.37	85.37
	Sensitivity	57.6473	74.43	87.77	87.3456	87.57	88.37
Theory	Accuracy	87.3374	83.76	83.45	83.6433	87.737	88.43
	Specificity	83.7378	83.56	83.7	83.874	85.74	86.37
	Sensitivity	87.6557	87.7	87.3	83	86.84	87.33

For example, LVQ may be used in image and signal processing, the biomedical area, and medicine and industry, just to mention a few examples of its many uses There is a vast collection of bibliographic data accessible in the system.

In this study, we give a thorough overview of the most significant supervised LVQ algorithms since Teuvo Kohonen's initial work. Our taxonomy and techniques for LVQ classification are presented here. A total of eleven different LVQ algorithms are tested on a variety of simulated and real-world datasets. Depending on the kind of datasets, we explore the benefits and drawbacks of each strategy.

Assuming that the input space contains a number of reference vectors Wk. Typically; a class is allocated a number of reference vectors. This means that input vector x has been assigned a classification based on the closest reference vector. We may think of Wk (t) as the discrete-time representation of Wk sequences. In this part, we will concentrate on LVQ2.1, which has been offered before. This is how LVQ2.1 URBAN PARK_SCAPE_002ates your reference vectors from a set of correctly specified beginning values.

$$\min\left(\frac{d_i}{d_j}, \frac{d_j}{d_i}\right) > S. \tag{16}$$

As in, di = Ix−WD and d_i = Ix−WD + wjl.

Based on the notion of pushing decision boundaries toward Bayesian bounds by applying attractive and repulsive pressures from x, LVQ2.1 implements an algorithmic approach (shown in Figure 3). As a result, the reference vectors diverge in the long term since no consideration is paid to the Wk location. Referencing the class distributions using multiple reference vectors has been suggested as a way of preventing reference vector divergence. However, LVQ3 has the same properties as the earlier LVQ2.1 and so does not address the issue of reference vector divergence.

3. Results and Discussion

In this section, a brief discussion of urban park landscapes are finding via the MATLAB-based ANN computer vision model.

The parameter estimation is shown in Table 1:

Figure 4 clearly explains about the top view model of a proposed design estimating image; in this, using ANN LVQ model attains proper landscape architecture.

Figure 5 clearly explains about different views of selected urban area, in this proposed green roof initiatives have been used to enhance climatic conditions, conserve and develop plant, encourage outdoor activities and active lifestyles, stimulate social connection and exchange, and create healthy urban circumstances for cognitive and emotional well-being.

Figure 6 clearly explains about the inner layout of urban park landscape analysis, in this all-road maps and paths are added accordingly.
RESULTS

FIGURE 8: Comparison of results.

Given the limited extent of these green spaces, design standards must be simple: trees, bushes, and grass areas must be placed in such a manner that shaded and sunny places alternate; paved areas must also be given, with areas for playing and relaxing shown in Figure 7.

The results' comparison is shown in Table 2:

Figure 8 clearly explains about different comparison of results of proposed model, in this proposed ANN_LVQ model attains more improvement. Functionality variation arises in the process of simulation, this system compares the sensitivity of the system with random variations and this results in the decrease of computational speed.

4. Conclusion

In this research work, ageing design of urban park landscape based on computer virtual simulation application is implemented using ANN LVQ model. The visual quality of 100 urban park settings was assessed using citizen perception. A total of 15 landscape characteristics impacted the visual quality of the scene. According to the findings, the multi-layer perceptions model 15-8-1 with a configuration of 15-8-1 (15 input variables, 8 hidden layer neurons, and 1 output variable) has the best structure optimization performance. Three data sets were obtained with R2 values of 0.97, 0.88, and 0.90: training (validation), test, and (test). The visual quality of urban park landscapes is most affected by land slope and vegetation/building/hard surface ratios with model sensitivity values of 0, 24, 0, 7, and 0. In this an example land is selecting as input and fixing area related to sunny place, top view etc. This application is implemented on MATLAB 2018b software using ANN tool box. The

perfect urban park landscape model is designed using following technique. The measures like accuracy 89.23%, sensitivity 87.34% and recall 78.93% had been attained those are out performance the methodology and compete with present model.

Data Availability

No data were used to support this study.

Conflicts of Interest

The authors declare that there are no conflicts of interest regarding the publication of this article.

We offer a neural network-based control method to control the vibration of the engineering mechanical arm and the trajectory in order to solve the problem of large errors in tracking the path when the engineering mechanical arm is unstable and under the influence of the outside world. A mechanical arm network is used to perform tasks related to learning the unknown dynamic properties of a engineering mechanical arms keyboard without the need for prior learning. Given the dynamic equations of the engineering mechanical arm, the dynamic properties of the mechanical arm were studied using a positive feedback network. The adaptive neural network management system was developed, and the stability and integrity of the closed-loop system were proved by Lyapunov's function. Engineering mechanical arm motion trajectory control errors were modeled and validated in the Matlab/Simulink environment. The simulation results show that the management of the adaptive neural network is able to better control the desired path of the engineering mechanical arm in the presence of external interference, and the fluctuation range of input torque is small. The PID control has a large error in the expected trajectory tracking of the engineering mechanical arm, the fluctuation range of the input torque is as high as 20, and the jitter phenomenon is more serious. The use of detailed comparisons and adaptive neural network monitoring can perform well in manipulating the trajectory of the engineering mechanical arm. The engineering mechanical arm uses an adaptive neural network control method, in which the control precision of engineering mechanical arm motion trajectory can be improved and the out-of-control phenomenon of mechanical arm motion can be reduced.

1. Introduction

With the development of science and technology, machine technology is more and more applied in various fields of national life, which puts forward higher requirements for the dynamic performance of machine control system. Machine modeling and control is the main content of machine research and plays a decisive role in the development and application of machines. The machine control object has one or more multi-joint mechanical arms. Its static and dynamic models are extremely complex, with multiple inputs and outputs, which are combined with each other. The system is also closely related to its kinematics and dynamics and is

highly nonlinear [1]. During the operation of the machine control system, the system load changes greatly with time and has strong time variability. This kind of complex control system has high requirements on the model of the control object. How to improve the accuracy of modeling is the focus of current research. Many emerging modeling strategies are introduced, which provide a good foundation for improving control performance. Modern industry and engineering construction have higher and higher requirements for mechanical arms, which are reflected in the working speed and precision of the machine [2]. Its appearance makes it inevitable to apply more advanced modern control theory to the field of machine control to solve the problem of

nonlinear severe disaster control. Typical advanced modern control theories and technologies include rational control, adaptive control, neural network control, sliding mode variable structure control, and so on. Track control plays an important role in mechanical arm traffic control. In the actual use of the mechanical arm, the system must not only have perfect functions but also have good performance. The first means that the machine must work within a relatively wide range, and the last means that the machine must meet human needs. As a typical representative of engineering machines, mechanical arms have the kinematics and dynamics of general machines, that is, multi-variable, time-varying, random, and extremely nonlinear. The existence of uncertain factors significantly affects the performance of the mechanical arm control system, which is inevitable. Traditional object-based control methods are increasingly difficult to meet the control requirements of mechanical arm trajectory [3, 4].

The development of intelligent management theory makes neural network technology an effective way to solve optimal problems. The reason why the neural network can solve the strong nonlinear mapping problem is determined by its self-organization and self-learning ability. Neural networks can approximate any nonlinear function and have good adaptability to data mapping, which cannot be satisfied by traditional numerical calculation methods [5]. Neural networks are widely used in various areas of automatic control, especially system recognition, nonlinear system control, fault diagnosis, and fault tolerance monitoring, and play a very important role. Nerve networks play a strong role in the recognition of nonlinear systems. As a model for recognizing nonlinear systems, it provides a general model for recognizing neural networks. Therefore, it is the physical realization of the actual system and is suitable for online control. RBFNN based on RBF (radial basis function) is a typical transmission network. It is based on function approximation theory. Network learning is basically to find the optimal plane for data alignment to meet the requirements of multi-dimensional information training space. Any basis function contained in this best-fit plane consists of the latent layer neuron transfer function of the RBFNN. The complexity of mechanical arm kinematics and dynamics makes neural networks very useful and highly applicable in the field of mechanical arm control. The application of neural network technology in mechanical arm control can solve the problem of real-time online control of mechanical arms. On the one hand, by learning the sample data during the actual operation of the mechanical arm, the neural network can obtain the nonlinear relationship between the kinematics or dynamics input and output of the mechanical arm, which is usually represented by a nonlinear expression. The obtained nonlinear relationship can make the system immune to the influence of parameter uncertainty on the control because its establishment process does not directly depend on the actual parameters of the mechanical arm. On the other hand, the neural network control system is robust, which reduces its sensitivity to the system characteristics or parameter distortion of the mechanical arm, making the mechanical arm more intelligent, so as to achieve the purpose of real-time

control of the mechanical arm. Neural network is a relatively systematic and accurate control method in the trajectory tracking control of mechanical arm, which provides an effective way to study the modeling and control of mechanical arm. It can ensure that the position and velocity tracking errors of the end effector of the mechanical arm gradually converge to zero [6, 7]. Aiming at the problems of closed-chain structure, unknown dynamic parameters, and strong coupling in coordinated multi-mechanical arm systems, a position-force hybrid control strategy was designed based on fuzzy neural network. The whole system is modeled dynamically in the task space, and the idea of position-force hybrid control is adopted. The controllers are designed in the position space and the force space, respectively. By introducing the coordinated control amount into the position controller, the engineering mechanical arm is reduced in size.

2. Related Works

Neural network originated in the early 1940s and has experienced nearly 20 years of development. It was not until the late 1950s that the neural network theory was initially formed. For the problem of mechanical arm modeling and control, many researchers have done a lot of research and successfully verified it in experiments or practice. Schwartz-Leyzac and others proposed an online identification method of mechanical arm dynamic model based on RBFNN and achieved good results on 6-DOF industrial mechanical arm [8]. RBF and MLP (multi-layer perceptron) have been successfully used in 6-DOF series mechanical arms, offering a mechanical armic reverse kinematic solution based on a combination of neural networks [9]. Carney and others studied a new method of adaptive control of neural networks that has been studied and successfully used to control the movement of the PUMA560 mechanical arm [10]. Hsu and others offered a hybrid learning algorithm that combines neural network-based Kalman filters and BP algorithms, combined neural networks with traditional PID control used in mechanical armic adaptive control systems, and explored effective heuristic learning algorithms [11]. Abbas and others made efforts in the study of manipulative neural network management, and a model of adaptive neural network management of mechanical arms based on dynamic return networks was proposed [12]. A stable mechanical armic neural network controller was studied, and a control circuit consisting of a neural network management and control controller was proposed [13]. Patocka and others put forward an adaptive neural slip mode control method to track the path of uncertain mechanical arms, which effectively performs rapid control of the mechanical arm's path under system uncertainty [14]. Liu and others proposed a kinematic model of a mechanical arm that effectively solves the problem of mechanical arm control by offering a dynamic repetitive neural network with state delay input [15]. Blacker and others proposed a solution method of forward and inverse kinematics of mechanical arm based on RBFNN from the perspective of geometry and mathematics, which effectively avoided the tediousness of traditional mechanical

arm kinematics solution methods and provided convenience for the research of mechanical arm dynamics control [16]. Fu and others recommended RBFNN-based iteration training controller, which effectively solves the problem of low wristband speed when using iterative training control to control the mechanical arm track [17]. Liu and others put forward a hybrid controller consisting of an adaptive RBFNN and a PD controller, which effectively solves the powerful control problem of controlling the path of an unknown mechanical arm in the event of an external failure [18].

Based on this research, the invention provides a vibration and trajectory control engineering manipulator based on neural network. Starting from the kinematics and dynamics of engineering mechanical arm, this paper studies the RBFNN learning algorithm based on EC-RBF, applies it to the mechanical arm motion control algorithm, realizes the neural network solution of the inverse kinematics of mechanical arm, and designs the mechanical arm NNMARC based on the learning algorithm. The neural network learning method combining offline learning and online adjustment is used to identify the dynamic model of the mechanical arm. Finally, the control of the engineering mechanical arm track is realized.

3. Research Methods

3.1. Dynamic Characteristics of Engineering Mechanical Arm. The engineering mechanical arm is a multi-link mechanism with an open chain, the main body is fixed on the construction machinery, and an actuator is installed at the free end to suit the needs of the work. The two joints are connected by a rotating joint or a moving joint, and the interaction of the joints involves the movement of the joint and the movement of the mechanical arm to reach a different position. The kinematic equation of the engineering mechanical arm is the conversion of the mechanical arm end effect between the joint space and the working space. The dynamic equation represents the nonlinear relationship between the torque applied to each joint of the engineering mechanical arm and the angular displacement and angular velocity of each joint, that is, the movement of the engineering mechanical arm is controlled by controlling the torque. In order to achieve the goal of real-time monitoring, it is necessary to create a dynamic model of the mechanical arm and effectively monitor it. The main content of the study of the kinematics of the engineering mechanical arm is the creation of a coordinate system of the coordinates of the position of each link, the direction, and the relationship between the transitions between the different coordinates. The kinematics of a engineering mechanical arm has two problems, one is the forward kinematic problem and the other is the reverse kinematic problem, called reverse kinematics. The forward kinematics of the mechanical arm depends on the spatial position and orientation of the mechanical arm, taking into account each of the joint variables of the engineering mechanical arm. Reverse kinematics is the solution of each joint variable according to the spatial position and orientation of the engineering

mechanical arm. Both the front kinematic policy of the mechanical arm and the problem of reverse kinematics can be considered as problems of nonlinear mapping of the engineering mechanical arm between the joint distance and the work area [19].

For the engineering mechanical arm with n degrees of freedom, the connection position variable is represented by $q = [q_1, q_2, \ldots, q_n]^T$. It is assumed that the research object can be represented by m variables $x = [x_1, x_2, \ldots, x_m]^T$ $(m < n)$, and $x = f(q)$, where f is the forward kinematics equation. After the quadratic differentiation of X, we can get

$$x'' = J'(q)q' + J(q)q'', \tag{1}$$

where $J(q) = \partial f(q)/\partial q$ and $J(q) \in R^{m \times n}$ represents the Jacobian matrix of the mechanical arm.

The pseudo-inverse matrix (represented by $\overset{+}{J}(q)$) of the Jacobian matrix (JQ) of the mechanical arm is defined as follows:

$$\overset{+}{J} = \overset{T}{J}(J\overset{T}{J})^{-1}, \tag{2}$$

where $\overset{+}{JJ} = I_m$ and $I_m \in R^{m \times n}$ is the identity matrix.

For the engineering mechanical arm with n connecting pairs, the rotation direct drive can be expressed by the following relationship:

$$M(q)q'' + V_m(q, q') + G(q) + F(q') = \tau, \tag{3}$$

where $M(q) \in R^{n \times n}$ is the inertia matrix; $V_m(q, q')$ is the centripetal Coriolis force matrix; $G(q) \in R^n$ is the gravity matrix; $E(q')$ is the friction matrix; and $\tau \in R^n$ is the torque input vector.

Engineering mechanical arm dynamics refer to the study of the relationship between the driving force of each joint and the motion of the joint. The engineering mechanical arm is composed of multiple joints and multiple connecting rods.

Each degree of freedom is driven by a separate actuator. From the control point of view, the engineering mechanical arm control system itself is an automatic control system, which has the characteristics of multi-input and multi-output, nonlinearity, redundancy, and combination. The combination of dynamics is reflected in the relationship between the joint motion of the engineering mechanical arm and the torque applied to each joint. Therefore, the motion control task of the engineering mechanical arm is essentially a dynamic task. There is a strong combination between them, and the parameters are time-varying, and the model is also uncertain. The purpose of studying the dynamics of engineering mechanical arm is to control. In order to realize the accurate control of the motion of the mechanical arm, its dynamic model must be established. Dynamic model identification is one of the most basic but relatively difficult problems in the research of engineering mechanical arm control. There are two main methods to analyze the dynamic model of engineering mechanical arm.

3.1.1. Newton–Euler Equation. This method is based on the dynamic balance method of force, which can eliminate the internal force between joints while obtaining the motion

speed of the mechanical arm. This method can be used to analyze the general simple engineering mechanical arm system. For more complex systems, this method will appear extremely complex, so it is not applicable.

3.1.2. Lagrange Equation. It is the main equation of Lagrangian mechanics, which can be used to describe the motion of objects, especially for the study of theoretical physics. The Lagrange equation is functionally equivalent to Newton's second law in Newtonian mechanics. This method is based on Lagrange function balance method. In the establishment process, it is not necessary to obtain the internal force between the joints of the mechanical arm. The derivation is simple and clear, and the physical meaning of the parameters is clear. It is a method with strong applicability. This section will focus on the establishment of the dynamic model of the engineering mechanical arm based on this method.

3.2. Feedforward Neural Network. The neural network is the simplest type of neural network. Each neuron is located in a layer, and each neuron communicates only with neurons in the previous layer. The output of the previous layer is received and passed to the next layer without feedback between the layers. It is one of the most widely used and fastest growing neural networks. Research began in the 1960s and reached a very high level of theoretical research and practical application. The feedforward neural network (FNN) is a type of artificial neural network called the feeder network. The transmission neural network uses a unilateral multi-layer structure. Each layer contains several neurons. In this type of neural network, each neuron can receive signals from nerve cells in the previous layer and output them to the next layer. Layer 0 is called the input layer, the last layer is called the output layer, and the other intermediate layer is called the hidden layer. The hidden layer can be a single layer. It can also be a multi-layer conductive neural network with n input units, m output units, and N latent level units, as shown in Figure 1.

The output vector Z can be determined by the input vector X through the following formula:

$$z_i = \sum_{j=1}^{N} \left[\omega_{ij} \sigma \left(\sum_{k=1}^{n} v_{jk} y_k + \theta_{vj} \right) + \theta_{\omega i} \right], \quad i = 1, 2, \ldots, m,$$

$$(4)$$

where $\sigma(.)$ is the hidden layer neuron activation function, $\sigma(y) = 1/(1 + e^{-y})$; v_{jk} is the input layer to hidden layer interconnection weight; ω_{ij} is the weight of the connection between the hidden layer and the output layer; and θ_{vj}, $\theta_{\omega i}$ represent deviation weight.

By substituting the neural network weight values v_{jk} and ω_{ij} into the weight matrices V^T and W^T, respectively, the corresponding vectors of the neural network equation can be obtained as follows:

$$z = W^T \sigma (V^T y),$$

$$(5)$$
FIGURE 1: Feedforward neural network.

where $\sigma(x) = [\sigma(x_1), \sigma(x_2), \ldots, \sigma(x_n)]^T$ is the activation function vector, $x \in R^n$.

The deviation weight value is used as the first column parameter of the weight matrix. In order to accommodate the deviation weight value, the vectors y and $\sigma(.)$ need to be expanded accordingly.

Property 1. Set the smoothing function from R^n to R^m to be h(y) and $U_y \subseteq R^n$. Then, under the condition of $y \in U_y$ and $\varepsilon > 0$, there are N hidden layer neurons and weight matrices W and V, and the relationship is $h(y) = W^T \sigma(VTy) + \varepsilon$. Then, the estimation of the smoothing function $h(y)$ can be expressed as $\hat{h}(y) = \hat{W}^T \sigma(\hat{V}^T y)$, and $\hat{W}$ and $\hat{V}$ are the estimation matrices of ideal neuron weights obtained by the online weight adjustment algorithm.

3.3. Engineering Mechanical Arm Neural Network Control

3.3.1. Neural Network Control. NNC (neural network control), also known as artificial neural network control system, neural network-based control, or neural control for short, refers to the use of neural network to realize the modeling, control, and optimization calculation of complex nonlinear objects. Such a control system is called neural network control system. The main system form of neural network control system is negative feedback regulation. The basic structure of the system is divided into open loop and closed loop. Its general structure is shown in Figure 2. The controller, identifier, and feedback link in the figure can be composed of neural network. Neural network uses binary logic, which is a digital network. Neural control is digital control, which uses digital quantity to control the controlled object. The neural network control system is a kind of digital control system, which has the general characteristics of the digital control system. Like the general microcomputer control system, it also has two parts: hardware and software. Neural network control has fundamentally changed the design idea of the traditional control system and has become a control method without mathematical model of controlled image [20].

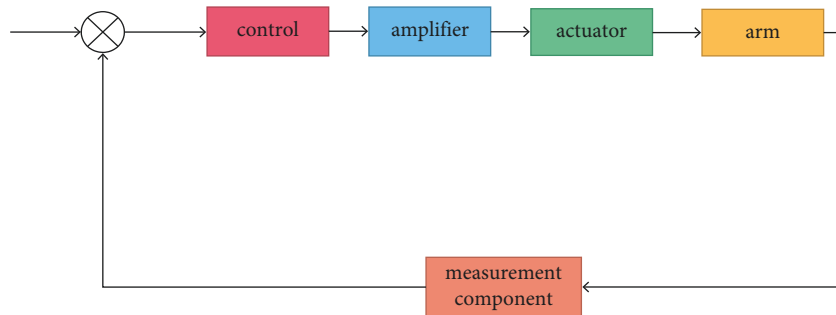
In the control system, the neural network functions either as a controller or as an identifier. Neural controller has intelligent performance, so the neural network control system, as an intelligent control system, is a system with learning ability, also known as learning control system. The
FIGURE 2: General structure of neural network control system R (T).


FIGURE 3: Control structure of mechanical arm.

learning process is a process of training and memorizing the training results. Compared with classical controller and modern controller, neural controller has obvious advantages and disadvantages. The biggest advantage is that the design of neural controller has nothing to do with the mathematical model of the controlled object, which is the fundamental reason why neural network can stand in automatic control. The disadvantage is that the neural network needs to carry out learning and training online or offline and use the training results to design the system. This kind of training largely depends on the accuracy of training samples, and the selection of training samples still has human factors. Neural identifier is used to identify the nonlinearity and uncertainty of the controlled object.

3.3.2. Neural Network Control Method of Engineering Mechanical Arm. The basic control of the mechanical arm includes position control, torque control, and force/position hybrid control. Most engineering mechanical arms adopt the control structure based on joint space. Firstly, the joint variables are obtained through inverse kinematics, and then the servo control is realized with the expectation of joint displacement, velocity, and acceleration. The control structure is shown in Figure 3.

In this paper, the research of engineering mechanical arm control starts from position control. Position control mainly refers to the method of the control system when the engineering mechanical arm tracks and controls the trajectory. These include control systems based mainly on switching variables and position-based control systems. The former is studied in joint space

and the latter is in operation space. Among them, the control system with shutdown variable is widely used.

In the control system based on joint variables, $q_d = [q_{d1}, q_{d2}, \ldots, q_{dn}]$ is the expected joint position vector, $\dot{q}_d$ and $\ddot{q}_d$ are the expected joint velocity and acceleration, u_1 and u_2 are control quantities, and $f = [f_1, f_2, \ldots, f_n]$ is the driving torque vector of the joint. The function of the control system is to find the appropriate control quantity to determine the driving torque required by the driving joint, so as to achieve the purpose of tracking the desired trajectory [21]. The above control process is based on the dynamics of the mechanical arm, so the control problem turns to the dynamics control of the mechanical arm. The traditional dynamics control structure is shown in Figure 4.

In Figure 5, q, $\dot{q}$ represent the joint position and speed of the engineering mechanical arm. As can be seen from the figure, the engineering mechanical arm controller includes a transmitter controller and a feedback controller, the most important part of which is the design of the transmitter controller. How the controller is designed to support the operation of the control system depends largely on the dynamic design of the engineering mechanical arm. If the model is clearly known, the traditional methods such as moment calculation method and accurate linearization method can meet the requirements. However, when the model is unknown, the control system actually becomes the traditional PID control. Obviously, such a control system is difficult to obtain good control performance. Using certain methods to eliminate or reduce the influence of the uncertainty of the engineering mechanical arm dynamic model on the control system, so as to improve the performance of
FIGURE 4: Dynamic control structure of mechanical arm.

—— PID tracks the trajectory

FIGURE 6: Movement track of engineering mechanical arm 3 (without external interference).

the control system, has become a problem that researchers need to solve. Thus, the adaptive method is effectively applied to it. Adaptive control can effectively overcome the structural uncertainty, compensate the influence of nonlinear and uncertain factors on the system, and can significantly improve the performance of the engineering mechanical arm. However, adaptive control is not effective for nonstructural engineering manipulator. In order to solve this problem, researchers have made a lot of exploration and opened up a new idea of control with the help of neural network. Neural network can become a powerful tool for engineering mechanical arm control, which is determined by its strong nonlinear mapping ability, self-learning ability, and adaptive ability [22, 23].

4. Result Discussion

The established schematic diagram of the engineering mechanical arm model is simulated and verified, as shown in Figure 5.

The tracking error of the engineering mechanical arm movement trajectory was modeled in the Matlab/Simulink environment to test the tracking effect of the mechanical arm motion trajectory controlled by the adaptive neural network. The simulation results of motion track tracking error of engineering mechanical arm 3 are obtained. The simulation

results of mechanical arm 1 and mechanical arm 2 are similar to those of mechanical arm 3, so simulation verification is not performed here. The simulation parameters are set as follows: the expected trajectory of mechanical arm 3 is $\theta_3 = 0.4 \cos(2\pi t)$, the initial condition is $\theta(0) = [000]^T$, the control parameter $k = \text{diag}(40, 40, 40)$, the interference parameter $\tau' = 20 \cos(\pi t)$, and the mechanical arm link parameters are $L1 = 0.62$ M, $L2 = 0.41$ m, $L3 = 0.34$ M, $M1 = 3.5$, $M2 = 2.5$ kg, $m3 = 2.0$ kg, $g = 9.82$ m/s^2, and $t = 2$ S. Under the condition of no external interference, the simulation results of motion trajectory tracking of engineering mechanical arm 3 are shown in Figure 6, and the simulation results of input torque of engineering mechanical arm 3 are shown in Figure 7. In the case of external interference, the trajectory tracking simulation results of engineering mechanical arm 3 are shown in Figure 8. The simulation results of input torque of engineering mechanical arm 3 are shown in Figure 9.

It can be seen from Figures 6 and 7 that under the condition of no external interference, both adaptive neural
Figure 7: Torque control of engineering mechanical arm 3 (no external interference).
Figure 9: Torque control of engineering mechanical arm 3 (with external interference).
Figure 8: Movement track of engineering mechanical arm 3 (with external interference).

network control and PID control can effectively track the desired trajectory of the engineering mechanical arm. Using PID control, the input torque fluctuates greatly and the jitter phenomenon is serious. Therefore, the adaptive neural network control method is better. It can be seen from Figures 8 and 9 that under the condition of external interference, the adaptive neural network control can better track the desired trajectory of the engineering mechanical arm, and the fluctuation range of input torque is small. However, the PID control has a very large tracking error in the expected trajectory path of the engineering

mechanical arm, the range of input torque fluctuations is up to 20, and the jitter phenomenon is more serious. Adaptive neural network monitoring can be used to control the trajectory of engineering manipulator.

5. Conclusion

The modeling and control of a nonlinear dynamic system based on neural network is a frontier subject of nonlinear discipline, which is of great significance in many fields, especially for the multi-variable and strong disaster uncertain nonlinear object such as mechanical arm. This article examines the control of the neural network to control the trajectory of the engineering mechanical arm. The neural network controller can effectively control the pathway of the end effector and control the subtask of the program. Given the dynamic equations of the engineering mechanical arm, the dynamic properties of the engineering mechanical arm were studied using a positive feedback network. The adaptive neural network management system was developed, and the stability and integrity of the closed-loop system were proved by Lyapunov's function. We created a schematic diagram of the engineering mechanical arm model and simulated the dynamic parameters of the engineering mechanical arm using the Matlab/Simulink program. In addition, the PID control system simulation results are compared and analyzed. The simulation results show that in the case of external interference, the adaptive neural network control method can not only accurately realize the trajectory tracking task of the mechanical arm but also effectively weaken the jitter of the engineering mechanical arm.

SI is a relatively recent technology that was inspired by observations of natural social insects and artificial systems. This system comprises multiple individual agents who rely on collective behavior in decentralized and self-organized networks. One of the biggest difficulties for existing computer techniques is learning from such large datasets, which is addressed utilizing big data. Big data-based categorization refers to the challenge of determining which set of classifications a new discovery belongs to. This classification is based on a training set of data that comprises observations that have been assigned to a certain category. In this paper, CIN-big data value calculation based on particle swarm optimization (BD-PSO) algorithm is proposed by operating in local optima and to improve the operating efficiency. The convergence speed of the particle swarm optimization (PSO), which operates in the local optima, is improved by big data-based particle swarm optimization (BD-PSO). It improves computing efficiency by improving the method, resulting in a reduction in calculation time. The performance of the BD-PSO is tested on four benchmark dataset, which is taken from the UCI. The datasets used for evaluation are wine, iris, blood transfusion, and zoo. SVM and CG-CNB are the two existing methods used for the comparison of BD-PSO. It achieves 92% of accuracy, 92% of precision, 92% of recall, and 1.34 of F1 measure, and time taken for execution is 149 ms, which in turn outperforms the existing approaches. It achieves robust solutions and identifies appropriate intelligent technique related to the optimization problem.

1. Introduction

In this day and age, the development of high-throughput technologies has resulted in exponential increase in harvested information [1]. This exponential growth termed as "big data" (BD) is in terms of both dimensionality and sample size. Nowadays, efficient and effective management of these big data is increasingly challenging. Traditional management techniques of these become impractical [2]. Therefore, data mining (DM), machine learning (ML), and metaheuristic techniques are developed to automatically discover knowledge and recognize patterns from these big data [3, 4].

The categorization of big data (BD) is an essential procedure that aids in the effective study of enormous

datasets [5]. For effective BD classification, highly parallelized learning algorithms must be designed. Many relevant data features, such as a high-dimensional dataset, a large number of data kinds (classes), high-speed data processing, and unstructured data, make up the complexity parameter of big data [6]. Machine learning approaches will be used to solve the complexity parameter, and the certain difficulties it causes are hard to handle. However, upgrading present learning algorithms to deal with massive data categorization challenges and needs remains a difficulty [7]. The process of big data is given in Figure 1.

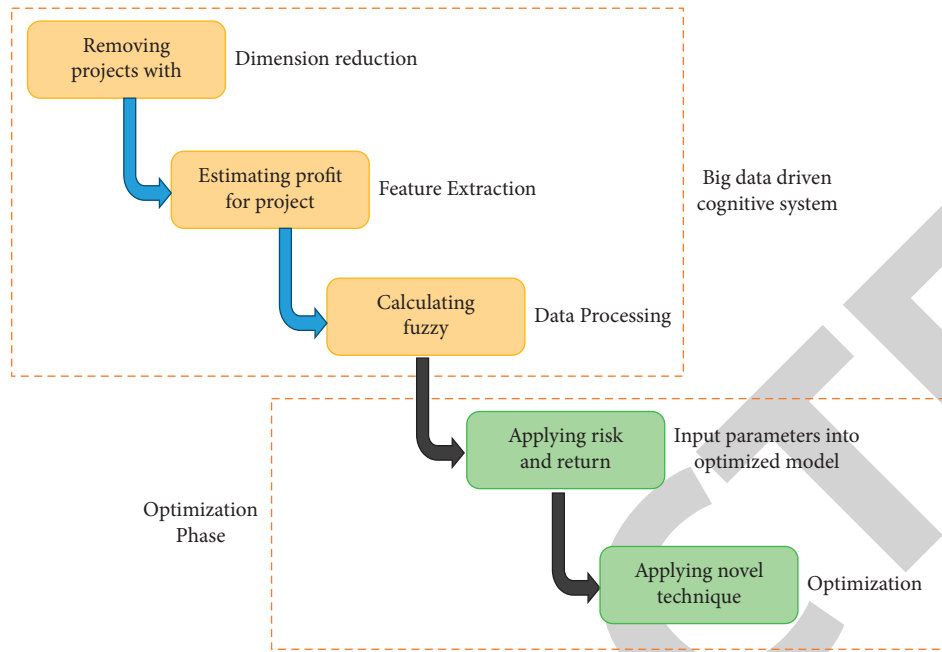
Evolutionary computation (EC) approaches have been applied to scheduling difficulties, resulting in the


Figure 1: Methodology of big data.

evolutionary scheduling (ES) study field. EC is a rapidly expanding artificial intelligence (AI) study topic [8, 9]. Natural selection and genetic inheritance are examples of EC approaches that draw concepts and inspiration from natural evolution/adaptation. Evolutionary algorithm (EA) and structural inference (SI) are the two basic categories of EC. The SI is a new field of research for EC [10, 11]. It is a novel computational and behavioral paradigm for addressing scheduling issues that was identified via simplified social behaviors of insects and other animals. It is inspired by the collective intelligence of swarms of biological populations [12].

Most of the optimization algorithms suffer due to the exploitation and exploration problem, since the identification of target entirely depends on the initial solution of the optimization algorithm [13, 14]. The same issue appears in PSO and some other optimization search algorithm also. These two optimization algorithms are more advantageous than other existing optimization algorithms. In PSO, there will be no adaptive variation or random solution so that the generation of fresh solution takes place around the initial solution [15].

The exploration issue entails condensing a large number of implausible answers into a single group and selecting the best among them. The exploitation of the problem, on the other hand, is concerned with finding the best solution among the many possibilities [16]. PSO algorithm also has some advantages, which can generate optimized results. One of the significant advantages of PSO is that the new solution generated is based on the local best and global best. This will deliver the new solution by considering the best solution of current and whole iterations, so that fresh solution can travel to the target in a smoother way [17].

This paper is motivated to calculate CIN-big data value based on particle swarm optimization (BD-PSO) algorithm operating in local optima and to improve the operating efficiency.

The remainder of the research article is systemized as follows: recent works in big data classification are given in Section 2, the proposed methodology is discussed in Section 3, the outcome is compared and contrasted in Section 4, and the article is concluded in Section 5.

2. Related Works

The supervised machine learning-based classification approaches to train the data for effective classification problems. In the quantum computer, a binary classifier approach for optimization issues is introduced; that is, support vector machine and the complexity of the computation are reduced. The matrix inversion approach is used in training the matrix, and exponentiation of nonsparse matrix is the core concept of the quantum big data approach [18]. The intrusion in the network traffic is minimized by the continuous collection and processing of collected data. The continuous collection of data results in the growth huge volume of data, and the machine learning approach is used in processing and formulating the significant inference from the data [19].

The processing and maintaining of big data necessitate the robust technique where the shortcomings of the traditional approaches are rectified by the training and learning approaches [20]. Big data is an eminent research and application field, whereby the extraction of significant insight with high scalability is a complicated process. The issue of scalability is rectified by MapReduce, and it utilizes the divide and conquer method. The scalability of the big

data is rectified by the MapReduce framework [21]. The ensembles of particle swarm optimization (PSO) and support vector machine (SVM) are considered to classify the big data, and significant insights are acquired from the classified data [22].

In the problem of classification, the feature selection approach is incorporated with the optimization approach to attain an effective solution. The cat swarm optimization (CSO) is developed from the food searching behavior of the cat, and it is modified to classify the big data [23]. Big data has shown its progression in diverse industry and application domains, whereas the growth of data necessitated a strong approach to process those data. Cuckoo-grey wolf-based correlative Naive Bayes (CG-CNB) classifier is framed by altering the CNB classifier with a developed optimization approach that is cuckoo-grey wolf-based optimization (CGWO).

The CGCNB-MRM method executes the process of classification for every data sample based on the posterior probability of the data and the probability index table [24]. The scale-free particle swarm optimization (SF-PSO) is developed for the selection of features in the high-dimensional datasets. The multi-class support vector machine (MC-SVM) is incorporated as a machine learning classifier and acquired the best result. The big data classification approaches have numerous drawbacks that are rectified with the incorporation of optimization and the deep learning-based approach.

The extreme learning machine (ELM) and particle swarm optimization (PSO) were integrated in [25] to select features and to determine the hidden node's count. The classification of sleep stages was used for predicting the proportion of sleep stages. Support vector machine (SVM) is used for comparing ELM methods that are lesser than the ELM and PSO integration. In [26], PSO algorithm was presented for performing a global search for the optimal weights/biases of the ANN method selected. This method is represented as PSO-ANN. A performance metric's variety was utilized for assessing the training procedure quality, and also the performance of model in the testing dataset. The results exposed that the representations established and GCV was determined accurately and rapidly.

3. Big Data-Based Particle Swarm Optimization Algorithm

The appliance of PSO is developed from the complex social behavior which is exposed by the natural species. For a D-dimensional search space, the position of the ith particle is denoted as $X_i = (x_{i1}, x_{i2}, \ldots \ldots x_{iD})$. Each particle upholds a memory of its previous best position $P_i = (p_{i1}, P_{i2}, \ldots, \ldots p_{iD})$ and a velocity $V_i = (v_{i1}, v_{i2}, \ldots v_{iD})$ along each dimension. The P vector of the particle with the best fitness in the immediate neighborhood is nominated as g at each iteration. The current particle's P vector is merged to change the velocity along each dimension, and the particle's new location is computed using the adjusted velocity. The conventional PSO Algorithm 1 pseudo-code is shown below.

PSO is a population-based stochastic search algorithm inspired by the social behavior of a flock of birds. This method has a population of particles, each of which represents a possible solution to the issue. A swarm in the context of PSO indicates to a group of potential results to an optimization issue, and every outcome can be indicated as a particle. The PSO's main purpose is to locate the particle location that yields the best assessment of a fitness function. Every particle indicates a location in N_d-dimensional space, and it is flown across this multi-dimensional search space, altering its position in relation to both other particles until the optimal position is identified. Each particle I is responsible for maintaining the subsequent data.

xc_i: Particle's exact position.

ve_i: Particle's exact velocity.

yp_i: Particle's best position (personal).

By utilizing the above notation, a particle's incidence is altered by

$$ve_i, k(t+1) = wve_i + k(t)c_1 r_{1.k}(t)\left(p_{i,k}(t) - xc_{i,k}(t)\right)$$
$$+ c_2 r_{2.k}(t)\left(p_{k,g}(t) - xc_{i,k}(t)\right) \tag{1}$$
$$xc_i(t+1) = xc_i(t) + ve_i(t+1),$$

where the inertia is indicated by ω, acceleration constants are indicated as c_1 and c_2, $r1.(t)$, $r2.kt \sim U(0.1)$, and $k = 1, \ldots, Nd$.

The velocity is thus computed based on the three influences which are described below.

(i) A fraction of the former velocity.

(ii) The cognitive module, which is considered as a function of the distance of the particle from its private best position.

(iii) The social component, which is determined by the particle's distance from the best particle identified thus far.

The pbest$_i$ value is presented as the best previously visited position of the ith particle. It is signified as $pi = (pi1, pi2, \ldots, pi D)$. The $g$best is the global best position of the all individual $p$best$i$ values. It is represented as the $g = (g1, g2, \ldots, g D)$. The position of the ith particle is denoted by $(x_{il}, x_{i2}, \ldots, x_{i d})$, $x \in (x_{\min}, x_{\max}).D$, and its velocity is indicated by $vi = (vi1, vi2, \ldots vi D)$ $v \in (v\min, v\max).D$.

$$v_{\text{id}}^{\text{new}} = w * v_{\text{id}}^{\text{old}} + c_1 * r_1 * \left(pbest_{\text{id}} - x_{\text{id}}^{\text{old}}\right)$$
$$+ c_2 * r_2 * \left(pbest_{\text{id}} - x_{\text{id}}^{\text{old}}\right) \tag{2}$$
$$x_{\text{id}}^{\text{new}} = x_{\text{id}}^{\text{old}} + v_{\text{id}}^{\text{new}},$$

where r_1 and r_2 represent the random count among (0, 1); c_1 and c_2 control how far a particle will move in one's generation; and $v_{\text{id}}^{\text{new}}$ and $v_{\text{id}}^{\text{old}}$ denote the old and new particle, respectively. The existing particle position is $x_{\text{id}}^{\text{old}}$, while the revised particle position is $x_{\text{id}}^{\text{new}}$. The inertia weight w

ALGORITHM 1: Procedure for PSO.

regulates the effect of a particle's prior velocity on its current velocity. w is intended to exchange V_{max} and alter the optimization process's influence of prior particle velocities. An acceptable compromise between exploration and exploitation is critical for high-performance issues. How to optimally stabilize the swarm's search skills is one of the most important issues in PSO because maintaining a good mix search during the whole run is complex to PSO's performance. Throughout the search process, the inertia weight decreases linearly from 0.9 to 0.4, and the specific equation may be expressed as follows:

$$W_{LDW} = (w_{max} - w_{min}) * \frac{\text{iteration}_{max} - \text{iteration}_i}{\text{iteration}_{max}} + w_{min}, \tag{3}$$

where w_{max} is 0.9, w_{min} is 0.4, and Iteration$_{max}$ is the maximal count of permitted iterations.

Contrarily, these computation tasks consume more time. Therefore, in between, optimal scheduling of tasks to the nodes is performed by utilizing the same optimization algorithms. This helps in determining allocation of the tasks efficiently to the corresponding nodes using a random approach, thus reducing the overall computation time. All these processes are employed using the MR programming model, for parallelization purpose. This is one of the most popular distributed processing systems implemented within the Hadoop environment. It provides a design pattern that advises algorithms to be represented in two fundamental functions, known as "Map" and "Reduce" to ease enormous simultaneous processing of large datasets. "Map" is used for per-record calculation in the first phase, which means that the input data are handled by this function to provide some intermediate results. The intermediate outputs are then passed into a second phase known as the "Reduce" function, which combines the output from the Map phase and applies a specific function to get the final results.

4. Result and Discussion

In this research work, big data-based calculation is done by using a particle swarm optimization (PSO). This approach is implemented and tested using MATLAB. The performance of this algorithm is evaluated using different datasets and compared with the outcome acquired by utilizing various existing optimization algorithms. The datasets used for evaluation are wine, iris, blood transfusion, and zoo. The performance of the BD-PSO is tested on four benchmark datasets, which are taken from the UCI. The number of iterations taken to attain the best fitness value is 10. In the wine dataset, 178 samples are formed into three subclasses by applying the BD-PSO clustering algorithm.

4.1. True Positive. The proportion of correct forecasts in positive class predictions is known as the true-positive rate (TPR). The true-positive rate is given as

$$TP = \frac{TP}{TP + FN}. \tag{4}$$

4.2. True Negative. A true-negative test outcome in a study of diagnostic test accuracy indicates that the test being assessed accurately showed that a participant did not have the particular goals, according to the reference standardized score where individual did not have the negative condition. The true-negative rate is given as

$$TN = \frac{TN}{TN + FP}. \tag{5}$$

4.3. False Positive. The false-positive rate (FPR) is a statistic for assessing the accuracy of a test, being it an inquiry, a machine learning approach, or something else. In technical terms, the FPR refers to the chance of mistakenly rejecting the null hypothesis. The false-positive rate is calculated as follows:

$$FP = \frac{FP}{TN + FP}. \tag{6}$$

4.4. False Negative. A "false alarm" is a term for a false positive. When you suggest something is untrue when it is actually the truth, you are using a false negative. The false-negative rate is given as

Table 1: Comparison of accuracy.

File name	SVM	CG-CNB	BD-PSO
Wine	73.18	81.87	92.03
Iris	74.61	82.98	92.65
Blood transfusion	74.96	81.26	89.25
Zoo	76.36	82.86	91.94

$$FN = \frac{FN}{TP + FN}. \tag{7}$$

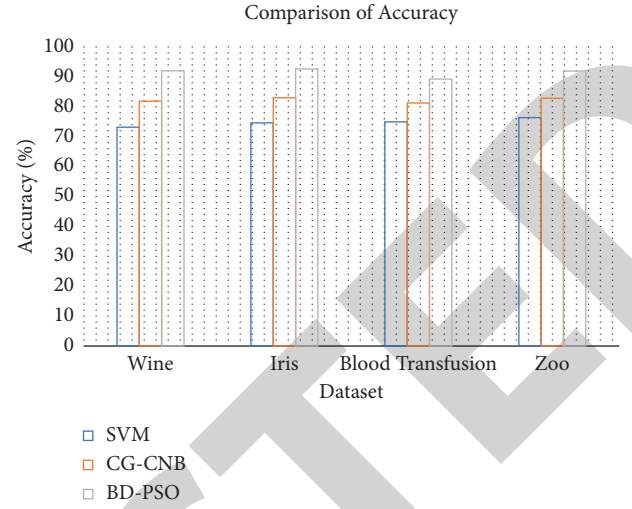
4.5. Accuracy. The classification accuracy of the instance is estimated by dividing the count of appropriate negative instance identifications by the total count of instance. The competency of the classification model is determined by the accuracy value. The accuracy is measured using true-positive (TP) and true-negative (TN) values generated from instance-based classes. Comparison of accuracy is given in Table 1 and Figure 2. The most accurate classification method is known as an effective classification algorithm. An estimate of the accuracy value is as follows:

Figure 2: Comparison of accuracy.

$$Accuracy = \frac{True\ Positive\,(TP) + True\ Negative\,(TN)}{True\ Positive\,(TP) + True\ Negative\,(TN) + False\ Positive\,(FP) + False\ Negative\,(FN)}. \tag{8}$$

4.6. Precision. The quantitative rate with positive results, also known as precision, reflects the reliability of the prediction and the relevance of the feature found. The frequency of arbitrary mistakes is expressed as precision, which is expressed using statistical variables. Accuracy and precision are the same concepts for received feature values. Typically, binary or decimal digits are used to represent the accuracy of a data. True-positive (TP) and false-positive (FP) rates are used to calculate it. The fraction of positive values in the whole fake profile determines the precision value. The count of genuine positive attributes is the accuracy count for a certain issue in the categorization process (i.e., the count of the item relevantly labeled as positive classes of instances). The application's high precision shows a resulting value that achieves more desired data than the incorrect data. Comparison of precision is given in Table 2 and Figure 3. It is equated as

$$Precision = \frac{True\ Positive}{True\ Positive + False\ Positive}. \tag{9}$$

4.7. Recall. The associated fake profiles among the substantially retrieved occurrences make up the rate of recall. The estimated measure of recall is effective in predicting rate, and recall is the count of associated events. In the fake profiles, recall is calculated as the count of accurately


detected values divided by the count of TP and FP data. The difference in the negative instance recognition at TP and FN rates is used to assess precision. Comparison of recall is given in Table 3 and Figure 4. It is calculated as

$$Recall = \frac{TP}{TP + FN}. \tag{10}$$

4.8. F-Measure. The accuracy of the examination of the categorization problem is indicated by the *F*-measure or *F*-score. The method achieves the optimum *F*-measure value by achieving the highest accuracy and recall value. The *F*-measure value improves the extraction of essential information from characteristics and provides an accurate representation of the computation performance. Comparison of *F*-measure is given in Table 4 and Figure 5. It is computed as

$$F - measure = \frac{2\Delta\ Precision\ \Delta\ Recall}{Precision + Recall}. \tag{11}$$

4.9. Execution Time. The time taken to complete the classification process is determined as execution time, and the algorithm with minimal execution time is the effective algorithm. The values of proposed and existing approach are given in Table 5 that is illustrated in Figure 6.

The numerical outcome of the proposed approach is given in above tables and figures. The results are compared for different files, and the outcome of the proposed approach

outperforms the existing approaches. The performance of the BD-PSO is tested on four benchmark datasets, which are taken from the UCI. The datasets used for evaluation are wine, iris, blood transfusion, and zoo. SVM and CG-CNB are the two existing methods used for the comparison of BD-PSO. It achieves 92% of accuracy, 92% of precision, 92% of

recall, and 1.34 of F1 measure, and time taken for execution is 149 ms, which in turn outperforms the existing approaches. However, the results obtained do not provide optimal solution.

5. Conclusion

Swarm intelligence (SI) is a relatively new technology derived from observations of natural social insects and artificial systems. In decentralized and self-organized systems, this system consists of several individual agents who rely on collective behavior. Learning from such big datasets is one of the major issues for the current computational algorithms, whereby the drawback is rectified using big data. The difficulty of identifying to which set of classes a new discovery belongs is known as big data-based categorization. This identification is based on a training set of data that encompasses interpretations with identified class membership. BD-PSO enhanced the speed of convergence in the PSO, which runs in the local optima. The performance of the BD-PSO is tested on four benchmark datasets, which are taken from the UCI. The datasets used for evaluation are wine, iris, blood transfusion, and zoo. SVM and CG-CNB are the two existing methods used for the comparison of BD-PSO. It achieves 92% of accuracy, 92% of precision, 92% of recall, and 1.34 of F1 measure, and time taken for execution is 149 ms, which in turn outperforms the existing approaches. It thereby increases the computational efficiency by optimizing the algorithm, thus reducing the computational time. It achieves robust solutions and identifies appropriate intelligent technique related to the optimization problem. In the future, the multi-objective big data based on hybrid optimization algorithm can be used for achieving optimal results.

Data Availability

No data were used to support this study.

Conflicts of Interest

The authors declare that there are no conflicts of interest with any financial organizations regarding the material reported in this manuscript.

According to OWASP 2021, cross-site scripting (XSS) attacks are increasing through specially crafted XML documents. The attacker injects a malicious payload with a new pattern and combination of scripts, functions, and tags that deceits the existing security mechanisms in web services. This paper proposes an approach, GeneMiner, encompassing GeneMiner-E to extract new features and GeneMiner-C for classification of input payloads as malicious and nonmalicious. The proposed approach evolves itself to the changing patterns of attack payloads and identifies adversarial XSS attacks. The experiments have been conducted by collecting data from open source and generating various combinations of scripts, functions, and tags using an incremental genetic algorithm. The experimental results show that the proposed approach effectively detects newly crafted malicious XSS payloads with an accuracy of 98.5%, which is better than the existing classification techniques. The approach learns variations in the existing attack sample space and identifies the new attack payloads with reduced efforts.

1. Introduction

Web services provide a solution for information exchange over web applications developed on varied platforms [1, 2] and facilitate integration and interoperability among heterogeneous software applications using XML (eXtensible Markup Language) [3, 4]. Many available protocols and standards provide security to web services, but attacks on web services are continuously increasing [1]. According to OWASP [5], 94% of web applications are tested for one or more forms of injection attacks. The number of cross-site script (XSS) injection attacks has increased from 470 in 2011 to 22,000 in April 2022 [6], as shown in Figure 1. The injection attacks occur due to the attacker's insertion of malicious characters and strings in XML documents [1, 7]. The attacker crafts the payload in such a manner to bypass the existing filters. The injection attacks have caused disclosure, distortion, disruption, and destruction of sensitive information and defacement of websites [1]. The impact of injection attacks is scored 7.25 on an average on a scale of 10 in terms of severity [8].

Adversarial attack payload refers to a newer combination of malicious characters, strings, tags, and scripts. Attackers deceive the available security standards, mitigation approaches, security testing, filters and firewalls, intrusion detection, and prevention systems by injecting a malicious adversarial payload. Suppose an algorithm is trained to detect payloads consisting of a script and alert tags. In that case, malicious attack payloads easily deceive the trained algorithm by using newer functions and obfuscation techniques. For example, techniques trained for detecting the payload <script> alert("XSS") </script> are easily deceived by newer payload onload = alert(/hacked/) by using *onload* and obfuscation of *alert*.

Machine learning (ML) [9–13] and neural network (NN) [14–17] techniques have recently been used to detect XSS vulnerability in source code. Genetic algorithms and fuzzy inference are combined with ML and NN to generate a large number of permutations and combinations of payloads using the existing datasets to mitigate the newer adversarial attacks [18–21]. Existing algorithms are limited by training on a fixed number of features and datasets. Further, the authors observed the following issues in the existing techniques and approaches:

(1) Existing models are nonadaptive and do not fit into a dynamic and ever-changing real-world environment

where attackers generate malicious payloads, each with a different combination and unique enough to escape the filters. The malicious attack payloads have a mix of encoded characters, case mixtures, recursively nested keywords, blank spaces, and tags to bypass filters.

(2) With the ever-changing diversity in injection payloads and increase in feature set, the training algorithm becomes multidimensional, increasing the computational complexity manifolds.

In this paper, the authors propose an approach, Gene-Miner, that identifies known XSS attacks and can detect the unknown and newer attack patterns. The proposed approach has utilized the properties of the incremental genetic algorithm to detect the ever-evolving heterogeneous and changing XSS payloads. The key contributions and innovations of the paper are as follows:

(1) The proposed approach evolves to detect the adversarial malicious payloads consisting of newer functions, features, combinations, encoded characters, and obfuscation techniques.

(2) The approach is optimized to search in the large multidimensional repositories by reducing it to single-dimensional search space.

(3) The approach will learn variations in the existing attack sample space and evolve to the new attack environment consisting of a newer feature set with reduced efforts.

(4) The authors conducted experiments with 1,60,264 records for performance evaluation of the newly added feature including comparison with other widely used machine learning and neural network models.

The rest of the paper is organized as follows. In Section 2, related work is discussed. Section 3 contains the preliminaries to understand the proposed approach. In Section 4, the proposed XSS attack detection model—GeneMiner—is explained. The results of the experiments and their discussions are given in Section 5. In Section 6, conclusions and future work are discussed.

2. Related Work

NVD [8], Common Weakness Enumeration [22], and Common Attack Pattern Enumeration Catalog [23] enlisted that the most common attacks are XSS attacks via crafted XML documents [8]. XML cross-site scripting attack is carried out by manipulating the logic of XML-based web services. Hyper Text Markup Language (HTML) tags, JavaScript functions, and other characters are injected into XML messages to create an XSS attack. XSS attacks are also made by injecting parts of the attack vector in two or more input fields such that it bypasses the filter [24]. These XSS attacks on web services are capable of triggering phishing attacks, cookie theft, denial of service (DoS) attacks, distributed denial of service (DDoS) attacks, XSS worms, and browser screenshot theft.
Figure 1: Increasing trend of XSS attacks.

2.1. Detection of XSS Attacks Using Neural Network.
Fang et al. [14] and Lei et al. [15] extracted six categories of features using word2vec and trained the model using LSTM recurrent neural network. The method DeepXSS [14] included a decoder to detect obfuscated malicious payloads. The network detection model proposed by [15] was based on long short-term memory (LSTM) to extract abstract features of XSS attacks. Lei et al. [15] added a hidden layer of the attention mechanism to extract more relevant information to improve the classification using the recurrent neural network.

Melicher et al. [17] trained deep neural network using taint tracking methods to predict the vulnerability of payloads by analyzing JavaScript functions. Liu et al. proposed an approach GraphXSS, for the detection of XSS attacks, which converted an XSS payload into a graph of interconnected words and characters. Fang et al. [20] combined the techniques of the deep neural network with reinforcement learning to detect the adversarial samples of XSS attacks. The detection approach generates adversarial samples and retrains the model to optimize the classification of XSS attacks.

Liu et al. [25] expressed the relationship between words and characters using the word2vec tool released by Google [26]. Liu et al. trained the model using a 2-layer and 6-layer graph convolutional network to detect XSS attacks and showed that accuracy increased with the number of layers in the detection model.

Wang et al. [27] performed experiments on 27000 samples of malicious JavaScript code and trained them using one hidden layer of stacked denoised auto-encoders forming a neural network. The accuracy of detection was 94.82%. However, the approach took longer time for training using the neural network technique. Mokbal et al. [28] designed three models for detecting XSS attacks. Raw data were collected using the first model [28] of random crawling. The second model, built on a neural network, extracted the features from raw data [28]. The third model used artificial neural network (ANN)-based multilayer perceptron (MLP) to classify and predict malicious XSS payloads [28].

2.2. Detection of XSS Attacks Using Machine Learning Algorithms.
Krishnaveni and Sathiyakumari [10] conducted experiments of 500 Uniform Resource Locators (URLs) by extracting script, applet, and DOM features to classify XSS attack payload using Naïve Bayes, decision tree, and

multilayer perceptron techniques. Vishnu and Jevitha [11] extracted 12 features from URL and JavaScript from 43,579 URL instances and classified XSS attack payload using support vector machine (SVM), Naïve Bayes, and decision tree algorithms.

Rathore et al. [29] extracted HTML and URL features from social network services and applied ten machine learning classifiers to detect an XSS attack on webpages of social network sites. The machine learning classifiers were applied on a dataset of 1000 webpages containing 400 malicious and 600 benign webpages collected from XSSed, Alexa, and Elgg sources.

Zhang et al. [30] extracted features from XSS payloads using word2vec and trained the dataset using two unsupervised clustering techniques, Gaussian mixture models (GMMs). Zhang et al. [30] built two GMMs for detecting XSS in web request and web response packets. The XSS payloads are distinguished as two clusters with two different Gaussian functions characterized by the mean and covariance of the data points in a dataset. Any addition of payloads with different feature sets will require retraining to calculate the mean and covariance of all data points again.

2.3. Detection of XSS Attacks Using Genetic Algorithm.

Khan and Motwani [31] proposed a signature-based intrusion detection of XSS attacks using a genetic algorithm with binary-coded eleven-bit chromosomes. The approach considered the count of suspicious HTML characters and words in the first three bits and the presence of encoded characters in the fifth bit, the following three bits stored the count of suspicious script characters, and the last four bits specified the class of XSS attack.

Suleman and Awan [32] applied genetic algorithm to optimize the machine learning algorithms by reducing the features selected and showed that the accuracy rate of detection of Naïve Bayes, ID3, K-nearest neighbor (KNN), decision tree, and random forest algorithms increased from 76% to 94.99% by applying genetic algorithm for feature selection. Suleman and Awan [32] selected two to eight best features out of 15 features by applying genetic algorithms to detect XSS attacks and optimized detection rate.

Tariq et al. [33] used 30 features proposed by Zhou and Wang [16] and applied a basic genetic algorithm to detect malicious XSS payloads. The model proposed trained dataset on the number of features occurring in the training dataset, and the accuracy rate was as low as 5.78% for a feature "confirm" to 69.60% for feature "script." Tariq et al. [33] added the reward policy of reinforcement learning to the detection model by updating the novel payloads to the training data to improve the accuracy rate.

2.4. Security Testing and Static Code Analysis for XSS Attacks.

Gupta and Gupta [7] proposed XSS SAFE, an automated framework for detecting and mitigating XSS attacks. The JavaScript functions were repeatedly injected into the sanitization modules of the source code, and rules were generated to mitigate the attacks. The JavaScript functions and characters were encoded using different encoding techniques and injected to generate detection rules. Gupta and Gupta [7] tested the framework on five Java Server Pages and reported a zero false-positive rate.

Hydara et al. [18] converted the source code of web applications built on Java into control flow graphs and detected the hidden vulnerabilities in control flow paths using genetic algorithms. Taint analysis was done to discover the paths of data insertion through users in five Java-based web applications with 3000 to 80000 lines of code. A genetic algorithm was then used to pass generated XSS input data to identify paths vulnerable to XSS attacks through the input points.

Ahmad and Ali [19] generated XSS test cases using a genetic algorithm and performed dynamic security testing by identifying multiple execution paths in the static code. Ahmad and Ali tested for three types of XSS vulnerability in three small web applications written in PHP. The genetic algorithm's fitness function is minimized to ensure no node is missed in a path testing of a program.

Zhang et al. [21] generated adversarial XSS attacks using the MCTS algorithm and constructed a generative adversarial network (GAN) to detect many XSS payloads.

Jan et al. [24] proposed an automated testing methodology for identifying XML injection attacks. The method randomly generates test data by using five mutation operators. The mutation operators are designed to add randomly selected XML meta-characters, remove quotes from randomly selected attributes, add a closing tag, replicate element, and replace a random element. The method showed that 78.86% of test cases generated bypassed the XML gateway filters.

Duchene et al. [34] detected only reflected XSS (type 1) attacks in web applications by generating malicious input loads using fuzzy inference and genetic algorithms. Duchene et al. [34] considered seven attributes for detecting XSS injection, namely, HTML spaces, attribute delimiter, tag limiter, JavaScript code, URL, and regular text. In their later work, Duchene et al. [35]and Kameleon Fuzz detected and tested for stored XSS attacks (type 2) by generating malicious payloads using fuzzing and genetic algorithm.

Salas and Martins [36] combined penetration testing and fault injection methods to detect XSS vulnerabilities in SOAP UI and XML messages. Salas and Martins [36] showed that the impact of XSS attacks on web services is reduced from 42% to 36% through web service security tokens.

Sahu and Tomar [37] developed a static code analysis tool for assisting web developers in writing secure code. The tool detected hidden code vulnerabilities based on three defensive programming principles. The tool ensures that all unexpected conditions are handled, external data are properly sanitized, and error messages containing technical information are disabled after development.

Liu et al. [38] introduced randomness in the initial payload and the generated high-quality vector using fuzzy inference and operators of genetic algorithm to detect XSS vulnerability in webpages. The attack payloads were generated by replacing and inserting sensitive words, characters, events, functions, blank characters, comments, tags, confusing code, and changing case structure at different location of the XSS attack payload.

2.5. Recent Surveys for XSS Attack Process, Detection, and Mitigation in Web Services. In the literature, several techniques are available that perform security testing and detection of input payloads for identifying the existence of unwanted strings and characters in the XML message packet that trigger an XSS attack. Research and review articles about various techniques for security testing and detection of XSS attacks on web services, XML messages, and web applications from the year 2010 to 2022 are studied. Gupta and Gupta [7] presented a survey of ten detection and protection techniques for XSS attacks on the server and browser sides. Gupta and Gupta [7] compared the techniques on five parameters: location of the exploit—server or browser; discovery site; technology for detection; type of XSS attack detected; and modification site—browser, server, or code. Chen et al. [13] discussed the advantages of using machine learning techniques to detect XSS attack. Chen et al. [13] discussed the limitations of whitelisting approach in detection of XSS attack. The library of filtering rule in whitelisting approach is difficult to update with the fast changing nature of XSS attack payload.

The taxonomy of XSS attacks and worms is given by Liu et al. [39]. The authors presented a state-of-the-art process to detect whether a webpage is vulnerable to XSS attack or not. Liu et al. [39] categorized defensive techniques to prevent XSS attacks into black-whitelisting, string injection, static analysis, taint flow analysis, and machine learning [39].

Mishra and Gupta [40] surveyed eleven techniques for detection and mitigation of XSS attacks including the attack via cookie theft. The authors [40] also presented an approach using cryptography techniques to prevent cookie theft through XSS payloads in web services.

Rodriguez et al. [41] analyzed more than fifty review and research articles to analyze various detection and mitigation techniques of XSS attacks. Mitigation techniques for XSS attacks include laboratory activity emulation, simulation, honeypots, IDS Snort, content analysis, rule filters, cache test, text filter, content security policy, string and URL analysis, XML, input validation, filtering patterns, attack modeling, web scanner, black box testing, defensive programming, concolic test, proxy coding of alphabets, cookies analysis, and session authentication [41].

The security of web services, SOAP UI, and XML messages can be validated through testing in the static and dynamic phases [36]. The static phase of fault detection uses code inspection, static vulnerability analysis, or theorem proof without running the system. The dynamic phase of testing searches for vulnerabilities by sending attack payloads in the request or response message. Other forms of commercial and open-source vulnerability scanners (VS) (like HP Web Inspect, BIXSAN, PathCutter, FLAX, SWAP, IBM Rational AppScan, WSDigger, WebScarab) have limited low coverage of existing vulnerabilities and a high percentage of false positives [36, 41].

Sarmah et al. [42] analyzed several XSS filters, e.g., XSS Auditor, XSS Filter, NoScript, IE8, XSS-immune, XBuster, and Rule-Based, in different web browsers. These filters use the techniques of exact or approximate string matching, string comparison, or regular expressions. However, newer and sophisticated XSS payloads and worms like the Facebook XSS worm bypass such filters. Moreover, most ML techniques for detecting malicious XSS payloads cannot detect DOM-based attacks [42].

2.6. Comparative Analysis of Recent XSS Detection Approaches. Web applications and other detection techniques undergo frequent changes with increased dependencies in the source code as the newer attack pattern is detected. These frequent changes made in the web application and security mechanisms incorporate new challenges for testing and removing the bugs [43–45]. The existing techniques in the literature require a complete restructuring of the algorithm, changing the source code [46] and retraining of the training dataset [47]. Moreover, with an increase in the size of web applications, usage of code confusion, and dynamic code generation, the various static, dynamic, and hybrid techniques of detection of XSS attacks also become more complicated [39]. The efforts required to detect changing XSS attack payloads increase exponentially. Table 1 summarizes the techniques and approaches available in the literature.

The available approaches for detecting and classifying cross-site script attacks on web services are deceived with a newer combination of malicious characters, strings, tags, and scripts commonly referred to as adversarial attacks. A fixed number of features limit existing techniques. Further, these techniques perform with lower accuracy and higher complexity as many identifying features in the dataset are added. These models also do not update the dataset with the values of newly discovered features, thereby increasing data with missing values. The problem of missing values in the existing data leads to loss of information, biased learning, and reduced statistical power.

3. Preliminaries and Terminologies

In this section, preliminaries and terminologies necessary to understand the proposed approach have been discussed.

The incremental genetic algorithm (IGA) simulates the evolving nature of attack payloads by incorporating mutation and crossover operations in the feature set [47, 48]. Newly discovered features are added in descending order of their classification accuracy to the existing feature set. The payload population with the newly added feature is then evolved using mutation and crossover. The process of mutation and crossover provides an incremental and recursive learning environment that is highly efficient and adaptable to a training set with a large dimensional space with an improved classification rate. The algorithm projects the problem of searching for a solution in a large multidimensional space by projecting it into a single-dimensional space. The algorithm reduces the cost and effort of deriving classification rules.

The IGA consists of a population with a set of chromosomes which in turn are composed of genes. The algorithm works by computing a fitness function, selection of parents, formation of the child using operations of crossover

TABLE 1: Summarized limitation of recent XSS detection and testing approaches.

Reference	Number of features	Type of XSS attack detected	Number of malicious instances in dataset	Approach	Limitations
[10]	04	R,S,D	500	ML	The dataset tested is very low in number.
[11]	12	R,S,D	43,579	ML	URL and script features were extracted. Polyglots and other complex features were not considered. Decoding of URLs was not considered
[14]	07	R,S,D	33,426	LSTM, DL	XSS attacks due to polyglots, angular JS, and CSS-style tags could not be detected. The detection algorithm lacks optimization as the number of features increases
[15]	07	R,S,D	32,168	LSTM, RNN	
[20]	07	Adversarial	33,426	LSTM, DNN, RL	
[28]	41	R, S	38,569	MLP	
[29]	25	R, S	400	ML	
[30]	10	R	35,884	GMM	DoM and stored XSS attacks were not explored
[16]	30	R,S,D	16,151	Bayesian network and EL	Attacks due to polyglots, JS, file upload, and CSS could not be detected
[17]	10	D	1,80,000	DNN	Reflected and stored XSS was not detected
[25]	07	R, S	5000	GCN	DOM type of XSS attack could not be detected
[31]	02	R,S,D	—	Signature and entropy	The detection is based on several script and URL features present in the payload. The exact pattern, sequence, and combination are not considered
[32]	15	R	11054	GA for feature selection and ML for detection	Only URL-based features were selected to detect website phishing attacks
[33]	30	R,S,D	50540	GA and RL for increasing accuracy	Polyglots and other complex XSS payloads could not be detected. Benign payloads in the dataset are considered devoid of all 30 features, while in the actual scenario, an input payload may have a few features but still not malicious. The accuracy was as low as 76% using GA, which increased after applying RL
[34, 35]	08	R, S	—	FL and GA	Attack grammar requires manual updating of the feature set. Very few attack grammar rules are generated, limiting fault detection
[27]	15	R, S	14783	Stacked denoised auto-encoder DNN	Only script tags and functions triggering XSS attacks were considered. Long training time is another limitation
[42]	21	R, S	289	ML	DOM-based XSS attack could not be detected. The training set consists of a low number of malicious instances

R: reflected XSS; S: stored XSS; D: document object model XSS; DL: deep learning; ML: machine learning; FL: fuzzy logic; RL: reinforcement learning; GA: genetic algorithm; RNN: recurrent neural network; MLP: multilayer perceptron; DNN: deep neural network; EL: ensemble learning.

and mutation, eliminating the least fit individual, and including the more fit individual. The process is repeated in a continuously evolving population until a condition is met that terminates the process.

Gene: A gene is a feature that characterizes an attack payload. A set of genes is combined into a string to form a chromosome. A vector $g = \{g_1 g_2 g_3, \ldots, g_n\}$ is a one-dimensional row vector consisting of all features identifying an injection attack payload.

Chromosomes: A chromosome, often called a "genotype," is a collection of features or attributes that provide a solution to a problem being solved through a genetic algorithm. A vector $c = \{c_1 c_2 c_3, \ldots, c_n\}$ is a one-dimensional row vector that consists of feature value identifying an injection attack payload. The value of a feature may be continuous real values or binary values.

For an attack payload, A, $c = \{c_1 c_2 c_3, \ldots, c_n\}$ is a chromosome such that

$$\forall g_i \in g,$$
$$c_i = x \text{ where } x, \text{ where } R \text{ is a set of real values,} \quad (1)$$
$$c_i = 0, \quad \text{otherwise.}$$

Population: A population is an array of chromosomes or individuals. As the new features are added, mutation and crossover are performed, and the initial population gets updated and converges to a solution recursively.

$$\text{Population } P = \begin{matrix} c_{11} & c_{12} & \ldots & c_{1n} \\ c_{21} & c_{22} & \ldots & c_{2n} \\ \ldots & \ldots & \ldots & \ldots \\ c_{i1} & c_{i2} & \ldots & c_{in} \end{matrix}. \quad (2)$$

Mutation: The small deviation in the feature value is termed as "mutation" in the chromosome. The mutation is

done by changing the value of one or more features within a chromosome. For an attack payload, A,

$$\text{original chromosome } cx = \{c_1 c_2 c_3, \ldots, c_n\},$$

$$\text{mutated chromosome } cy = \{c_1' c_2' c_3', \ldots, c_n'\}, \quad (3)$$

where c' represents changed value for a gene g_i,

Crossover: The crossover is an operation where features of two-parent chromosomes are swapped to form new child chromosomes. The swapping of features may be done at a single point and multiple points, or in a random manner. The process of crossover generates a new set of child chromosomes.

$$\text{Parent1 chromosome } cx = \{c_1 c_2 c_3 c_4, \ldots, c_n\},$$

$$\text{Parent2 chromosome } cy = \{c_1' c_2' c_3' c_4', \ldots, c_n'\},$$

$$\text{After crossover at position 2,} \quad (4)$$

$$\text{Child 1 chromosome } cx' = \{c_1 c_2 c_3' c_4', \ldots, c_n'\},$$

$$\text{Child 2 chromosome } cy' = \{c_1' c_2' c_3 c_4, \ldots, c_n\}.$$

Adapting to new features: The IGA used for classifying the injection attack vector consists of the formation of the initial population, integration of old and new features, and incremental evolution of new features. The current features are retained in the population, and the newer features are added to the current chromosomes. For more than one feature discovered, the accuracy rate of each of the newly discovered features is calculated and arranged in descending order. The newly discovered features are then appended to the old chromosome ruleset to update the population. A gene set $g = \{g_1 g_2 g_3 g_4, \ldots, g_n\}$, with two newer features g_{n+1}, g_{n+2}, is integrated into the gene set such that $g' = \{g_1 g_2 g_3 g_4, \ldots, g_{in} g_{n+1}, g_{n+2}\}$ and integrated chromosome $c' = \{c_1 c_2 c_3 c_4, \ldots, c_{in} c_{n+1} c_{n+2}\}$ where c_{n+1} and c_{n+2} represent the values for the new feature $g_{n+1,}$ and g_{n+2}.

Fitness Function: The fitness of a chromosome is calculated by the percentage of payloads correctly classified by the ruleset of the chromosome [47]. The global fitness of a chromosome is defined in the whole search space. While adding the new features to form a more fit chromosome, the local fitness function considers the newer payload patterns in a local region of search space. The chromosome that correctly classifies highest number of payloads in a dataset is selected for defining the rules. Such chromosomes have highest fitness function value.

$$\text{Global Fitness function f} - \text{global: } \frac{\text{Number of Correctly classified payloads}}{\text{Total Number of payloads in the dataset}}$$

$$\quad (5)$$

$$\text{Local Fitness function f} - \text{local: } \frac{\text{Number of Correctly classified newer payloads}}{\text{Total Number of newer payloads}}.$$

Termination Criteria: The evolution process is stopped if any one of the following four criteria is reached:

(i) Maximum generation limit of the population is attained.

(ii) The best fitness of the chromosome is obtained.

(iii) There is no improvement in the accuracy and fitness of the best chromosome after a specified number of generations.

(iv) Performance of validating the data is less than 10% for the last 20 generations.

Classification Mechanism: The IGA is a rule-based classification technique that assigns each instance of a payload to a class by identifying relationships among features in it. The rules are represented in the form of IF (Condition 1) & (Condition 2) &.... Condition n-THEN (Class A_i). Each rule has one or more conditions as the antecedent, and a class is identified as the consequent. The conditions are represented as if-then rules, and the values of the set of features are represented in binary form. A ruleset contains several rules, providing a solution for a classification problem. A rule defining a class is represented as follows:

$$R_i: If\left(V_{1\_\min} \leq x_1 \leq V_{1_{\max}}\right) \land If\left(V_{2\_\min} \leq x_2 \leq V_{2\_\max}\right) \ldots \land If\left(V_{n\_\min} \leq x_n \leq V_{n_{\max}}\right)$$

$$\text{THEN } y \in C, \quad (6)$$

where R_i is a rule label, n is the number of features, $x_1 x_2, \ldots, x_n$ is the feature set, C is a class identified for payload y, and $V_{i\_\min}$ and $V_{i\_\max}$ are the minimum and maximum bounds of the feature x_i, respectively [47, 48].

4. Research Methodology

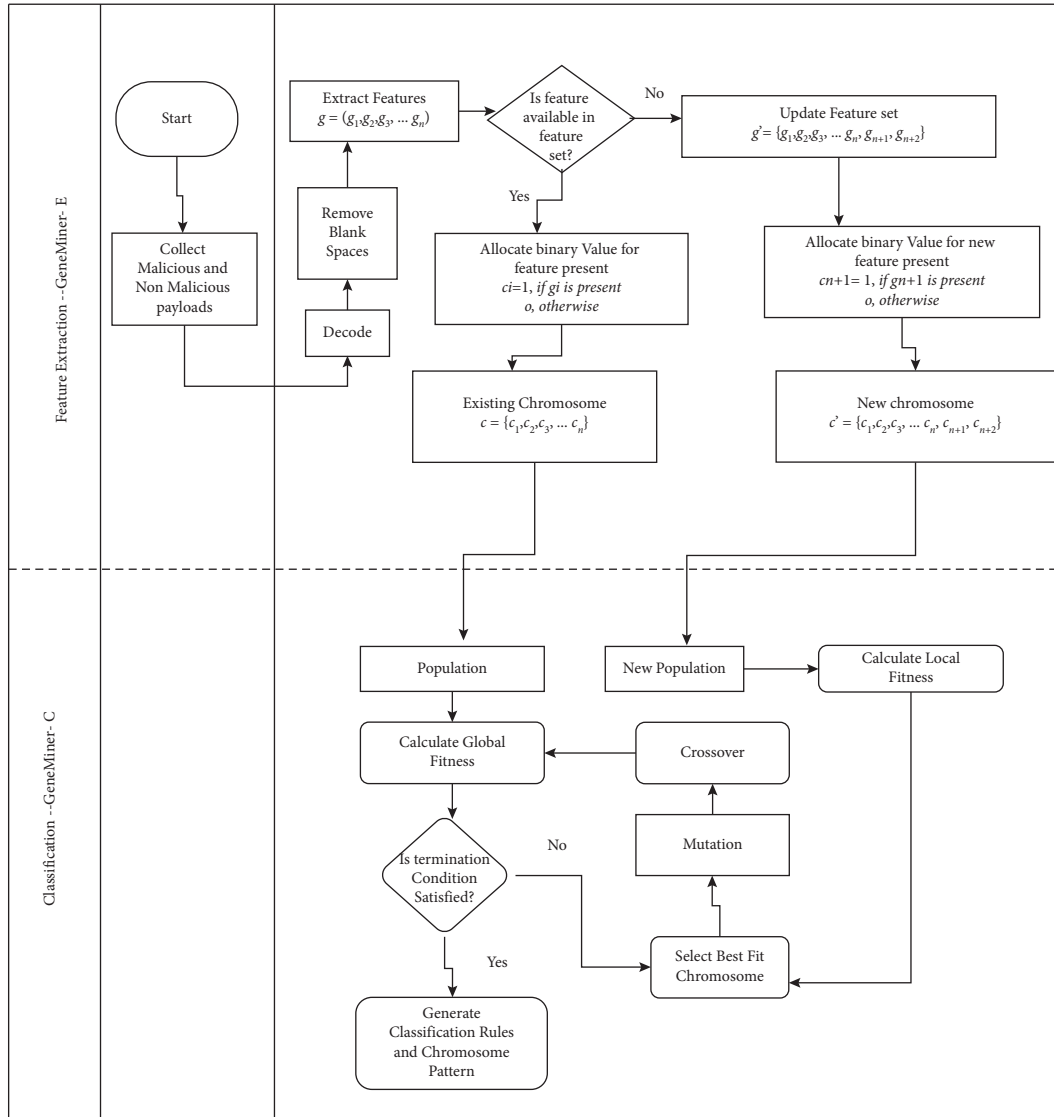
This section discusses the proposed GeneMiner approach to detect malicious payloads triggering XSS attacks, as shown in Figure 2. The authors have collected the XSS payloads


FIGURE 2: Proposed approach GeneMiner for detection of XSS attacks.

from various open-source repositories to conduct the experiments. The payload data are preprocessed, features are extracted, and the existence of a feature in the attack vector is populated in a database using the GeneMiner-E extraction model. The experiments are conducted to classify the payload as malicious or nonmalicious using the GeneMiner-C classification model.

4.1. Dataset Collection.

The authors collected the payloads from various sources for conducting the experiments to detect XSS vulnerability. The dataset contains the 6606 malicious records collected from https://github.com/payloadbox/xss-payload-list/, and 18,151 malicious and 1,35,507 nonmalicious records from https://github.com/duoergun0729/1book/tree/master/data. In total, training dataset contains 160, 264 URLs with payloads that may trigger an XSS attack. The testing dataset in the experiment is gathered from GitHub sources and security forums, which

consists of 3497 malicious and 6503 nonmalicious URLs provided by Zhou and Wang [16].

4.2. GeneMiner-E: Data Preprocessing, Decoding, and Feature Extraction.

For preprocessing of the data and extraction of features from the data, an approach, GeneMiner-E, has been proposed. The GeneMiner-E anonymizes the data by removing the domain part of the URLs and websites. Then, it decodes the encoded characters available in the payloads and cleans the data by removing blank spaces. For normalizing the data, the approach extracts the features from the payloads and prepares the final dataset by marking the feature set available in the attack vector as one and zero for the nonavailable feature.

The XSS payloads have common features of the same sensitive words and characters but differ in triggering XSS attacks. The payloads also contain characters obfuscated using encoding mechanisms such as URL encoding, ASCII

encoding, Unicode escaping, and hexadecimal encoding. These characters are decoded to original characters. For example, an attack payload may have a left-angle bracket < in hexadecimal code as %3C. The attack payload with characters 'al
er &emsp bypassed through filters as the keyword "alert" has been modified by inserting a break tag (
 and variants of blank space, namely, single space ( ), double-space ( ), four space ( ).

A payload from client to server or server to the client is classified into two classes: vulnerable and nonvulnerable. An attacker may modify the payload by injecting malicious characters, words, scripts, tags, or codes. All such malformed payloads capable of triggering an XSS attack on a webpage are labeled as malicious payloads, while the payloads that do not trigger an XSS attack are nonmalicious.

XSS payloads are identified by sensitive charact'al
er &emsp, keywords, HTML tags, scripts, redirection links, and unusual lengths of data [16, 33]. A few sensitive words and characters are alert, prompt, script, angle brackets, parenthesis, and onmouseover. The decoder module of GeneMiner also identifies the obfuscated URL modified through various encoding mechanisms, Unicode escape, inserting blank spaces, inserting invalid characters, case mixture, and other forms of malicious attack payloads [21]. The existence of these words and characters in a payload is considered a feature as it defines the characteristic nature of malicious payloads. For conducting experiments, 40 features are identified in the dataset of 1,64,204 records. Table 2 shows the list of 40 features extracted from the collected XSS payloads using GeneMiner.

4.3. GeneMiner-C: Classification Model. The training set of malicious and nonmalicious XSS payload data forms the initial population in the proposed approach. The dataset contains unique features and independent variables, while the class identified is the dependent variable. The authors constructed two datasets: one training and another testing dataset. The classification model is constructed using an incremental genetic algorithm on the training dataset and validated using the testing dataset.

The population is a binary matrix of order $m \times n$, where m is the number of URLs and n is the number of features called genes extracted from the dataset. Every row of the population matrix consists of chromosomes representing the payload as defined in

$$
\begin{aligned}
&c = \{c_1 c_2 c_3 \ldots . c_n\} \text{ is a chromosome such that} \\
&\forall g_i \in \text{gene}, g, \\
&c_i = 1 \text{ if } g_i \text{ exists in } P \text{ and,} \\
&c_i = 0, \text{otherwise.}
\end{aligned}
\tag{7}
$$

The combinations of attack payloads are generated by using a single-point crossover. The vertical dotted line in Figure 3 represents a single-point crossover. The process of mutation and crossover generates a unique

and large number of attack payloads that provides a solution to classify the payload as vulnerable or nonvulnerable.

On identifying a newer attack payload, the newly discovered features are appended to the chromosomes of the population matrix. For example, consider a payload city = test%3Cscript%3Eale%20rt%28/42873/%29%3 C/script %3E. The features extracted from the payload using the proposed GeneMiner-E are "script, left-angle-bracket, alert, open-parenthesis, close-parenthesis, right-angle-bracket." Initially, there are six features, and the chromosome corresponding to the payload will have these features marked as "1." With the addition of the new attack payload with the new feature "prompt," the number of features is increased from 06 to 07. Similarly, with the discovery of two new features, "onload" and "onmouseover," in the attack payload, the chromosome is modified by integrating the newly discovered features, as shown in Table 3. The absence of the new feature in the old payload is given a binary value of 0, and new features are appended to the modified chromosome with a value of 1.

The process of mutation and crossover continues till the termination condition is reached. A threshold of the number of generations and rules is set as a termination condition. A classification rule is obtained for each generation that classifies a certain number of chromosomes. For each classification rule, the local fitness and global fitness are calculated. The rule with the highest fitness function value, correctly classified instances, is further used in the training model to classify attack payloads. For evaluating the proposed GeneMiner, the threshold for termination condition of the proposed classification scheme has been kept at 200 generations and 100 rules by mutating one gene and single-point crossover for maximum classification rate [48].

5. Experiments and Results

The experimental environment used in this paper was run under Windows 11 operating system, equipped with a 2.6 GHz 6-core Intel Core-i7 processor and 16 GB RAM. In the experiments, the effect of adding new features and a new adversarial attack vector on the classification efficiency is analyzed on the proposed GeneMiner approach. Initially, the training dataset consists of twenty features with 44000 malicious and nonmalicious records. Newly discovered payloads are added to the initial training set in a newly discovered five feature batches. The classification accuracy of the proposed approach is compared with the popular classification techniques, i.e., Naïve Bayes (NB), random forest (RF), logistic regression (LR), support vector machine (SVM), AdaBoost, and multilayer perceptron (MLP). The results obtained are presented in Table 4.

The performance of the proposed GeneMiner is further evaluated using the accuracy, sensitivity, specificity, precision, and *F*-score metrics as defined in equations (8)–(12). The results obtained for the feature set are reported in Table 5.

$$\text{Sensitivity} = \frac{TP}{TP + FN} \times 100, \quad (9)$$

$$\text{Specificity} = \frac{TN}{FP + TN} \times 100, \quad (10)$$

$$\text{Precision} = \frac{TP}{TP + FP} \times 100, \quad (11)$$

$$F - \text{Score} = 2 \times \frac{\text{Precision} \times \text{Sensitivity}}{\text{Precision} + \text{Sensitivity}} \times 100, \quad (12)$$

where TP, TN, FP, and FN are the number of true positives, true negatives, false positives, and false negatives, respectively.

The set of experiments conducted shows that the addition of a new feature improves the accuracy of detection of XSS attack payload using the proposed GeneMiner approach. The proposed approach has an accuracy of 98.07%, while other classifiers have accuracy as low as 69.49 for the

TABLE 5: Comparison of classification accuracy of GeneMiner with other approaches on the addition of newer attack payloads.

Approach	Accuracy	Sensitivity	Specificity	Precision	F-Score
Naïve Bayes	89.05	96.44	85.3	76.88	82.52

GeneMiner proposed	GAN [21]	EL [16]	RL [20]	RF [29]	DL [27]	CNN [49]	NB [16]	SVM [16]	LR [16]	RF [16]
98.5	94.59	97.78	91.7	97.2	94.82	90.2	84.44	85.76	85.82	85.76

GAN: generative adversarial network; EL: ensemble learning; RL: reinforced learning; DL: deep learning; CNN: convolution deep neural network; NB: Naïve Bayes; SVM: support vector machine; LR: logistic regression; RF: random forest.

random forest, 89.05 for Naïve Bayes, and 93.7 for logistic regression. Logistic regression and Naïve Bayes approaches are unbalanced in classifying one class. These approaches classify negative classes more accurately with higher sensitivity, but positive classes are identified with lower accuracy. The accuracy, specificity, sensitivity, and F-Score of the proposed GeneMiner approach are high, signifying the accurate and balanced classification of vulnerable and nonvulnerable classes.

6. Empirical Evaluation with Existing Approaches

The proposed approach for the classification of payloads triggering an XSS attack is compared with the existing approaches available in the literature. The authors of [18, 19, 21, 34, 35] performed security testing using fuzzy evolutionary inference to identify XSS attacks in web applications. Khan and Motwani [31] and Suleman and Awan [32] applied a genetic algorithm for feature selection during the XSS detection methodology. Fang et al. [14, 20] performed decoding of XSS payloads and applied neural network techniques to identify malicious XSS payloads. Lei et al. [15] used the LSTM model for XSS detection, and Melicher et al. [17] applied deep neural network for detecting DOM-based XSS attacks. Liu et al. [25] applied graph convolution networks, and Abimov and Bianchi [49] used convolutional deep neural network (CNN) for the detection of XSS attacks. Zhou et al. [21, 30] applied machine learning techniques, [33] applied a genetic algorithm along with reinforcement learning to detect XSS attacks, and [50] detected reflected XSS attacks using reinforced learning. It is observed that only 06 out of 16 articles focused on evolutionary algorithms for the detection of XSS attacks, while only 01 focused on XML injection [51, 52].

The existing approaches of [14, 21, 33, 42] detect XSS payload by extracting script tags, special characters, eval function, features from URLs, and cookies but do not consider CSS style, dangling markups, and polygons. It is observed by [53] that the escape rate of XSS payloads from various detection models of machine learning and deep learning has reached 85%, and such techniques are less efficient for the detection of adversarial attacks. The proposed GeneMiner approach has extended the feature set by incorporating CSS style, dangling markups, encoded characters, and polyglots to detect malicious XSS payloads in XML messages. Table 6 shows the classification accuracy using the proposed approach and the existing approaches.

The existing approaches of XSS attack detection using generative adversarial network [30] have an accuracy rate of 94.59%, and enforcement learning [21] reaches an accuracy up to 97.78, using deep neural network [20] (with an accuracy of 91.7%). Other machine learning techniques detect XSS payloads with less than 90% accuracy. The proposed GeneMiner approach has reached the accuracy of 98.5 with 40 features detecting varied, changing, and evolving malicious XSS payloads. The existing approaches available in the literature do not evolve to changing nature and addition of newer features of XSS in attack payloads. Due to computational complexity, these approaches are also not suitable with higher dimensional feature sets. The proposed GeneMiner approach evolves itself to the modifying nature of XSS attack payloads and updates the training set incrementally with the addition of newer features. The proposed GeneMiner approach also optimizes the search space by reducing it to single-dimensional search space.

7. Conclusion and Future Work

The ever-increasing and varying nature of XSS attack payloads bypasses the filtering mechanisms of existing techniques. The XSS attack results in defacing websites, destruction of data, disruption of services, and disclosure of confidential data in web applications. This paper proposes a GeneMiner approach to detect XSS attacks in XML documents. The proposed approach evolves itself to detect malicious payloads consisting of newer functions, features, combinations, encoded characters, and obfuscation techniques. The experiments were conducted by collecting open-

source payloads and training them to detect XSS attack payloads. The proposed approach works in two steps. In the first step, the features that define the XSS attack are extracted from many payloads using the GeneMiner-E model. The newer features identified in newer malicious payloads are appended to the existing feature set. In the second step, the GeneMiner-C creates a single-dimensional ruleset to classify attack payloads. The experimental results showed that the proposed approach identifies the new adversarial attack payloads and gives a higher accuracy of 98.5%, which is better than the existing classification approaches. In the future, the authors intend to extend the proposed approach for detecting other forms of injection attacks on web services.

Data Availability

The dataset contains the 6606 malicious records collected from (1) https://github.com/payloadbox/xss-payload-list/, and 18,151 malicious and 1,35,507 nonmalicious records from (2) https://github.com/duoergun0729/1book/tree/master/data. The testing dataset in the experiment is gathered from GitHub sources and security forums, which consists of 3497 malicious and 6503 nonmalicious URLs provided by the authors of [16] Zhou, Y., amp; Wang, P. (2019).

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Legal judgment prediction (LJP) and decision support aim to enable machines to predict the verdict of legal cases after reading the description of facts, which is an application of artificial intelligence in the legal field. This paper proposes a legal judgment prediction model based on process supervision for the sequential dependence of each subtask in the legal judgment prediction task. Experimental results verify the effectiveness of the model framework and process monitoring mechanism adopted in this model. First, the convolutional neural network (CNN) algorithm was used to extract text features, and the principal component analysis (PCA) algorithm was used to reduce the dimension of data features. Next, the prediction model based on process supervision is proposed for the first time. When modeling the dependency relationship between sequential sub-data sets, process supervision is introduced to ensure the accuracy of the obtained dependency information, and genetic algorithm (GA) is introduced to optimize the parameters so as to improve the final prediction performance. Compared to our benchmark method, our algorithm achieved the best results on four different legal open data sets (CAIL2018_Small, CAIL2018_Large, CAIL2019_Small, and CAIL2019_Large). The realization of automatic prediction of legal judgment can not only assist judges, lawyers, and other professionals to make more efficient legal judgment but also provide legal aid for people who lack legal expertise.

1. Introduction

In traditional judicial cases, the results can be obtained only after the analysis and interpretation of relevant people, and the complexity and professionalism of legal documents are insurmountable barriers for ordinary people. In early studies, relevant people build expert systems in the judicial field to solve the problems encountered by people, but in the construction process of expert systems, legal people often need to provide a lot of rules and definitions, and the later maintenance of the system will consume a lot of time and energy. With the maturity of deep learning technology, a large number of excellent deep neural network models have been proposed, which lays a solid foundation for intelligent judicial research. Article prediction is an important subtask in intelligent justice. The article prediction task can assist judges to deal with cases; predict the law involved in the trial process, provide the basis for the judicial decision of charges, prison terms, fines, and so on; and greatly improve the

efficiency of judges to deal with cases. Legal judgment prediction (LJP) tends to enable machines to forecast the verdict of legal cases after reading the description of facts, which is an application of AI in the legal field. The realization of automatic prediction of legal judgment can not only assist judges, lawyers, and other professionals to make more efficient legal judgment but also provide legal aid for people who lack legal expertise. Recently, with the development of machine learning and natural language processing (NLP) technology, the research on the prediction of legal decisions has attracted more and more scholars' attention.

LJP research began decades ago [1–5]. At present, the legal judgment task is regarded as text classification task. Researchers have carried out researches on this task and proposed many landmark methods [6–13], mainly including the traditional machine learning method and deep neural network-based legal judgment prediction method. Most of the legal judgment methods [9, 10] based on traditional machine learning methods mark features manually based on

specific case types, which are difficult to be applied to other types of cases and have poor adaptability to scenarios. The legal judgment prediction method [11, 12] based on the deep neural network no longer relies on the manual carefully designed template but captures the context information through the convolutional neural network or cyclic neural network and makes feature representation according to the description of the case facts so as to achieve judgment prediction. Although the existing methods have achieved good prediction effect, the accuracy is still difficult to be greatly improved, mainly because the legal judgment prediction task still faces the following challenges:

(1) There are topological dependencies among legal decision sub-data sets. An LJP usually consists of detailed and complex clauses, like the relevant legal provisions involved, the crime committed by the offender, and the level of punishment (fine, prison term, etc.). Therefore, the prediction of each subtask in a legal judgment should be a whole prediction, and there is interdependence among each task [13]. Zhong et al. [13] pointed out that for human judges, there is a strict order between the sub-data sets of legal decisions.

(2) Sentence prediction based only on case description lacks prior knowledge. Compared with other sub-data sets, sentence prediction based on factual description is more challenging. In the real scene, when determining the sentence of a case, the judge will be influenced by many factors, including not only the age of the defendant described according to the facts of the case, the number of cases, but also the crime involved and other factors such as prior knowledge. Therefore, how to obtain the prior knowledge of sentence prediction under the supervision of the sub-data set information it depends on plays an important role in improving the final prediction performance. However, the existing sentence prediction task only makes prediction based on the fact description part of the case [14–16] or only considers the intermediate features of the sub-data sets it depends on in the training process as the prior knowledge of sentence prediction but lacks the process supervision of these prior knowledge [7, 9, 17].

To solve the above problems, this paper proposes a legal judgment prediction model (PS-LJP) based on process supervision. By considering the sequential topological dependence among various tasks, the prediction of relevant articles, crimes, and sentences in legal judgments is regarded as a sequential LJP problem. The process supervision information of each sub-data set is added in the training process so as to ensure the accuracy of the obtained information of the first task and then realize the effective prediction of the subsequent sub-data set. The model in this paper is based on the end-to-end recurrent neural network LJP framework. The supervision information of sub-data set labels is added to the LJP framework, and task-related features are expressed through the self-attention mechanism. The features of the prior task are taken as prior information and integrated with the features of subsequent tasks, and the result is used as the input of the subsequent prediction task to realize the decision prediction of sequential LJP.

2. Related Works

2.1. Prediction of Legal Decisions. Research on the prediction of legal judgments began many decades ago. Early studies were mostly limited by the limitations of public cases, and statistical-based methods achieved statistics for a small number of judgments rather than truly predicted [13, 18].

With the development of ML methods and NLP techniques, the legal judgment prediction task is regarded as a text classification task. Therefore, most legal judgment prediction tasks are specific to specific tasks, exploring how to extract more effective text features, which in turn achieve better crime prediction based on machine learning methods [9, 10, 17, 19, 20]. However, these traditional methods rely on hand-crafted shallow text features, with significant labor costs and poor domain adaptation, making it difficult to migrate to other scenarios.

Recently, DNN has been widely employed to [21] in the NLP field. Inspired by this, researchers try to integrate the deep neural network framework of legal knowledge for legal judgment prediction [7, 8, 13, 18, 22, 23]. For example, Luo et al. [12] adopted an NN method with attention mechanism to achieve the joint task of crime forecasting and related document extraction. Hu et al. [1–5] achieved the prediction of small sample and confusing crimes by defining 10 discriminative legal attributes. Ye et al. [6] use a sequence-to-sequence model to generate legal documents and realize crime prediction in civil cases. Zhong et al. [13] proposed the TOPJUDGE model, the first defining legal decision prediction as an LJP problem and proposed a topological LJP learning framework. However, without adding process supervision information, it is difficult to guarantee the accuracy of dependent features. Yang et al. [18] proposed an LJP learning framework that can encode multiple perspectives and multiple feedback on the dependencies and verification relationship between judgment sub-data sets, but this method is difficult to achieve end-to-end prediction and requires external auxiliary information.

2.2. Research Status of Text Classification. Traditional text classification methods are composed of feature engineering and classifier, in which feature engineering is used to extract feature information from text, and the classifier can obtain the probability distribution of each text category based on feature information. In the early text classification, bag of words, N-grams, and TF-IDF are usually used to extract features from the text, and then, support vector machine, naive Bayes, linear model, and K-nearest neighbor algorithms are combined to complete the text classification task. Word2vec tool is subsequently used to train the word vector. Each word in the text is represented as the word vector and

used as the feature vector of the text. Different machine learning algorithms are used to achieve classification prediction. The text representation obtained by traditional text classification methods is usually high-latitude sparse vector, which cannot understand the deep semantic information in the text. Deep learning text classification method uses end-to-end training neural network model and can automatically extract semantic feature information from text. Experimental results show that text classification based on deep learning is generally better than the machine learning method. Joulin [24] proposed a fast and efficient text classification model (FastText), which uses the word bag (Bow) method to represent the whole sentence and constructs the relationship between text features and text categories by linear model. FastText is not only able to achieve the accuracy of other deep learning models but also significantly faster in training tests. Yoon et al. [25] proposed text classification model (TextCNN) based on convolutional network, which includes embedding layer, convolution layer, pooling layer, and full connection layer. Word vector has two modes: static and nonstatic. By using different sizes of filter layer and pooling layer, convolution text feature extracting method will reduce the dimension of the feature vector to make it more representative. The connection layer will effectively extract the text by giving the influence of different parameters on features according to the weight of classification features. Xiang et al. [26] constructed a character-based convolutional neural network model, which takes characters as the basic unit of sentence formation and does not require word segmentation in the text classification task based on the Chinese corpus, so as to avoid the situation of poor training model due to inaccurate word segmentation. Pengfei et al. [27] coded and represented texts with recurrent neural networks, trained multiple tasks simultaneously with an LJP learning framework, and modeled different text tasks using three different information-sharing mechanisms. Zichao et al.'s [28] multilevel attention model (HAN, hierarchical attention networks) adopts the bidirectional LSTM network in the words and sentences on the two levels to form different attention mechanism at the same time and has the ability to assign large weights to important words and sentences when constructing document representations. Siwei et al. [29] proposed a recursive convolutional neural network text classification model, using recursive structure to capture context information, and the maximum pooling layer in the convolutional neural network to determine which words play a key role in text classification so as to capture key elements in the text. Conneau et al. [30] paid attention to the influence of layers of the convolutional neural network on the classification effect, and the experimental results showed that increasing the number of convolutional layers was conducive to the extraction of more comprehensive text features.

2.3. Review of Similar Case-Matching Research.

Similar case matching mainly compares the text similarity of two legal documents and selects the most similar one from the two candidate documents, which is a text similarity task in essence. However, due to the general description framework of legal documents and the professional words in the documents, higher requirements are put forward for similar case matching method. At present, most of the research on similar case matching is based on text similarity task, and the method is optimized according to the specific situation of the task. We then introduce the study of text similarity.

2.4. Review of Text Similarity Research.

Text similarity is an important task in the field of natural language processing and has very important practical significance for other tasks, such as information retrieval, reading comprehension, and abstract generation. Early researchers proposed string-based methods by analyzing literal surface information in text. Representative methods include longest common substring, edit distance, and Jaccard. These methods simply consider the composition of characters or words and can generally be used for simple text similarity calculation tasks. Salton et al. [31] proposed a vector space model (VSM), and employed it to choose an optimum indexing vocabulary for a collection of documents. The evaluation results indicate the usefulness of the model. However, the document information of different words was counted and expressed in vector form by term frequency and inverse document frequency (TF-IDF); the disadvantage of this method is that the constructed text vector is usually high dimensional and sparse. The calculation efficiency is low. Landauer et al. [32] proposed the latent semantic analysis method (LSA), whose basic idea is to reduce the dimension of the high-dimensional sparse matrix represented by text by using singular value decomposition technology, so that the data finally obtained do not have high-dimensional sparsity and can better represent text information. Hofmann [33] improved the PLSA model based on LSA, and the model used maximum expectation algorithm to calculate text topic in LSA. Blei et al. [34] proposed an LDA topic model, whose basic idea is to use three different levels of the Bayesian model to model text topic, get text topic distribution through layer upon layer traversal, and calculate text similarity value by using this distribution. In recent years, deep learning techniques have been widely used in text similarity tasks. Mikolov et al. [35] proposed the Word2Vec word vector model tool. Word2Vec contains two different modes, CBOW or CSkip, to train the language model through shallow neural networks. Each word is represented as word embedding with general semantic information. On the basis of the word vector, each word in the text is represented as a fixed dimension vector, and the similarity of the text is calculated by calculating the similarity between the word vectors. Mikolov subsequently proposed the Doc2vec method [36], which is similar to the word vector representation method trained by Word2vec. Compared with word vector representation trained by Word2vec for a single word, Doc2vec can train word vector representation for the whole document. Doc2vec can avoid semantic deviation of the whole document caused by some inaccurate word vectors, so it has more advantages in the semantic representation of the whole document. Mueller et al. [37] proposed Siamse LSTM based on twin structure, which consists of two subrecurrent neural networks. Each

recurrent neural network uses LSTM to encode and represent each text, and each text is represented as a vector of the same dimension. Finally, cosine similarity is used to calculate the similarity of two texts. Yin et al. [38] proposed a convolutional neural network (ABCNN) based on twin structure, which is used for sentence pair matching task. The model contains two subconvolutional neural networks, and an attention mechanism is added to the input layer and the convolutional layer of the convolutional neural network to better construct the semantic representation of text. Recently, Google researcher Devlin [39] proposed a pre-training model (Bert) based on bidirectional transformer encoder, which has the function of calculating the similarity of two texts. The training process includes pretraining and fine-tuning. Firstly, pretraining is carried out on large-scale unsupervised data so that the pretraining model has general semantic information. Secondly, the model is fine-tuned according to the specific task so that the model has the semantics of the specific task. The model has achieved breakthrough results in many natural language processing tasks.

This paper proposes a sequential LJP legal decision prediction model based on process supervision for end-to-end legal decision prediction. Different from the traditional LJP learning study on how to realize parameter sharing, the model in this paper not only models the sequential dependencies among various sub-data sets but also introduces a process supervision mechanism so as to realize the prediction of legal decisions by integrating prior information.

3. Data Processing

3.1. Feature Extraction Processing. Convolution neural network is one of the representative methods of deep learning technology, the convolutional neural network first began in the 1980s, and with the rise of artificial intelligence and machine computing power to ascend and the convolution neural network to get fast development, the different structures of convolution neural network are applied in computer vision, image processing, and other fields. A simple convolution neural network usually contains the input layer, convolution meter calculate layer, and pooling layer. The convolution meter calculation is the core of the CNN, which is used to extract local features of image or text information.

Researchers mainly mine text semantic features by constructing feature engineering and emotion dictionary, but they need to spend a lot of manpower on feature selection and design. In deep learning, the one-dimensional convolutional neural network CNN can obtain the local main semantic information of the text. Therefore, we used CNN network to extract features from the data in this paper. The structure of the CNN model includes three hidden layers in this paper as shown in Figure 1.

3.2. Dimension Reduction Processing. In the process of processing high-dimensional data in the model, important independent variables can be obtained by using variable selection, which can reduce the complexity of the model and ensure that the screened independent variables have a strong interpretation of the dependent variables. This method makes the model have the excellent performance of low-dimensional ideal model, so it has become a common method of scholars in various fields. The starting point of the variable selection method is summarized. First, the independent variable level is studied to test whether each independent variable can enter the model by establishing appropriate rules. These studies have formed traditional model selection algorithms based on AIC criterion, BIC criterion, RIC criterion, and so on. However, in the case of high dimensions, this kind of thinking is likely to fall into the dilemma of difficult calculation, that is, the frequently mentioned "dimension disaster" problem. PCA algorithm was proposed and widely used in various fields [40]. In our model, we will use the PCA algorithm to reduce the dimension of feature data.

4. A Computational Intelligence Model for Legal Prediction and Decision Support

In this paper, a sequential legal decision prediction model (PS-LJP) based on process supervision is proposed. The framework of the cyclic neural network which introduces process supervision is introduced.

4.1. Sequential Legal Decision Prediction Model (PS-LJP) Based on Process Supervision. This article proposes a sequence decision prediction framework based on process supervision, which consists of three layers: shared fact description coding layer, process supervision layer based on self-attention mechanism, and output prediction layer.

4.1.1. Shared Fact Description Coding Layer. In the prediction framework adopted in this paper, the fact description coding layer is the shared layer of the prediction. For the description of facts, this paper adopts BiLSTM to encode the description of facts. To input, the LSTM unit calculates through the input gate, forgettable gate, update gate, and output gate and carries out characteristic coding on the input.

At each time step $t \in [1, n]$, the LSTM unit takes x_t as the input, recalculates the storage unit c_t, and outputs the new hidden state h_t as shown in the following equations:

$$f_t = \sigma\big(W_f[x_t; h_{t-1}] + b_f\big). \tag{1}$$

$$i_t = \sigma\big(W_i[x_t; h_{t-1}] + b_i\big). \tag{2}$$

$$o_t = \sigma\big(W_o[x_t; h_{t-1}] + b_o\big). \tag{3}$$

$$\widehat{c}_t = \tanh\big(W_c[x_t; h_{t-1}] + b_c\big). \tag{4}$$

$$c_t = f_t \cdot c_{t-1} + i_t \cdot \widehat{c}_t. \tag{5}$$
FIGURE 1: The structure of CNN model.

$$h_t = o_t \cdot \tanh(c_{t-1}). \tag{6}$$

In the BiLSTM coding process, the forward LSTM network can obtain the left-to-right feature representation of the fact description, and the backward LSTM network can encode and fuse the semantics of subsequent features. Therefore, two hidden layer feature representation sequences $\{\overrightarrow{h}_1, \overrightarrow{h}_2, \cdots \overrightarrow{h}_n\}$ and $\{\overleftarrow{h}_1, \overleftarrow{h}_2, \cdots \overleftarrow{h}_n\}$ and the two implicit states of each word are spliced together to obtain the implicit state representation $h_j = \overrightarrow{h}_j; \overleftarrow{h}_j$ and finally obtain the following equation:

$$h = BiLSTM(x, \phi). \tag{7}$$

In other words, the input vector x obtains high-level semantic output h through the coding of the BiLSTM network. Here, the dimension of the forward and backward implicit state is set as $d/2$, and the dimension of implicit state after splicing is set as d, and ϕ is the parameter involved in the above coding process.

4.1.2. Process Supervision Layer Based on Self-Attention Mechanism. The process supervision layer based on the self-attention mechanism mainly introduces process supervision to obtain effective prior task-related dependency information, thus providing an important feature guarantee for subsequent sequential LJP dependency information fusion layer extraction. In the monitoring layer of the LJP process, the BiLSTM network based on the self-attention mechanism is adopted to obtain the fact description features of each sub-data set by using sub-data set label information to supervise.

Input the output h of the shared fact description coding layer into the BiLSTM network of $|T|$ sub-data sets, respectively, and obtain the high-level semantic representation of each task:

$$h^i = BiLSTM(x, \phi_i), i = 1, 2, \cdots, |T|, \tag{8}$$

where ϕ_i is the parameter of BiLSTM corresponding to the $i - th$ sub-data set. To better capture the relevant characteristics of each task, we introduce the attention mechanism

by entering h^i into a full connection layer and mapping it between [0,1] using the softmax function.

$$a^i = softmax(W_i^p h^i + b_{ai}). \tag{9}$$

Then, the feature representation for each sub-data set classification is obtained by weighted sum based on self-attention weight.

$$\widehat{h}^i = h^i \cdot a^i. \tag{10}$$

In order to ensure that each sub-data set can obtain its related feature representation from the fact description feature in modeling, category labels of each sub-data set are added for process supervision during this part of training, namely,

$$\widehat{y}_{pi} = \text{soft max}\left(W_i^p \widehat{h}^i + b_i^p\right). \tag{11}$$

Based on the obtained prediction result $\widehat{y}_{pi}$, the minimum cross-entropy between $\widehat{y}_{pi}$ and y_{pi} is adopted.

$$L_{pi}(\widehat{y}_{pi}, y_{pi}) = -\sum_{k=1}^{|Y_i|} y_{pi,k} \log(\widehat{y}_{pi,k}). \tag{12}$$

Process supervision is introduced to ensure that it can obtain effective sub-data set-oriented feature representation, which can guarantee the accuracy of sequential LJP prediction based on the dependency feature.

4.1.3. Output Prediction Layer. Based on the feature representation h_{dj} of fusing dependent task information, it is linearly transformed and the final prediction of the task containing dependent information is realized by the softmax function so as to minimize the cross-entropy of the task containing dependent information.

$$\widehat{y}_{dj} = \text{soft max}\left(W_j^d \widehat{h}^j + b_j^d\right),$$

$$L_{dj}(\widehat{y}_{dj}, y_{dj}) = -\sum_{k=1}^{|Y_i|} y_{dj,k} \log(\widehat{y}_{dj,k}). \tag{13}$$

4.1.4. Training. For all prediction tasks, we weighted the sum of the process-supervised cross-entropy loss of each sub-data set and the final cross-entropy of the task containing dependent information so as to obtain the final loss function.

$$L = \sum_{i=1}^{|T|} \alpha_{i \cdot pi}\left(\widehat{y}_{pi}, y_{pi}\right) + \sum_{j=1}^{|T|} \beta_{j \cdot dj}\left(\widehat{y}_{dj}, y_{dj}\right), \tag{14}$$

where α_i is the weight coefficient of each sub-data set in the process of process supervision and β_j is the weight coefficient of each sub-data set in the training process containing dependent information. In practice, we keep the weight of the loss function of process supervision and the weight of the sub-data set containing dependent information consistent. We only need to obtain the weight proportion of the two parts. Here, GA is used for parameter optimization.

5. Experiment

5.1. Data Set. The law prediction task uses the China Judicial AI Challenge data set CAIL2018, which is the first large-scale Chinese data set for predicting legal decisions. The data come from real criminal cases published by the Supreme People's Court. Each sample is judged by the factual description of the case and the corresponding outcome. In actual cases, many involve more than one defendant, which will greatly increase the difficulty of legal forecasting. Therefore, this paper only retains the sample of cases composed of a single defendant. According to statistics, the distribution of law categories in CAIL2018 is quite unbalanced. Some common crimes, such as theft and intentional injury, account for a large proportion. The data of the ten laws with the highest frequency account for 79.0% of the total data, while the data of the ten laws with the lowest frequency only account for 0.12% of the total data. The imbalance of data classes in CAIL2018 is a great challenge for the prediction of low frequency and obfuscation laws. The CAIL2018 data set consists of Small_CAIL2018 and Large_CAIL2018 data sets. Small_2018 contains 196,000 instrument samples, and Large_2018 contains 1.5 million instrument samples. The division of the two data sets in the experiment is shown in Table 1. In addition, we supplemented the CAIL2019 database to further verify the validity of our proposed model.

We use accuracy (Acc.), macro average precision (MP), macro average recall rate (MR), and macro average F1 value (F1) as evaluation indexes, where the macro average indicator refers to the average of all categories of indicators.

5.2. Experimental Results and Analysis. This article evaluates the prediction effect of four sub-data sets of legal judgment prediction: CAIL2018_Small, CAIL2018_Large, CAIL2019_Small, and CAIL2019_Large. To compare the experimental results, the following three models were used as the baseline models (each baseline system was trained under the LJP frame, and the best experimental results were compared):

Table 1: Statistic information of CAIL2018 data sets.

Data sets	Small	Large
Training	150000	1450000
Test	30000	30000
Valid	16000	20000

Table 2: Prediction results of CAIL2019_Large.

Methods	Data set	CAIL2019_Large			
		Acc.	MP	MR	F1
Baselines	CNN	0.8219	0.8543	0.8836	0.8176
	HLSTM	0.8443	0.878	0.8082	0.8418
	TOPJUDGE	0.8444	0.8892	0.8015	0.8433
Ours	LJP	0.8453	0.884	0.8064	0.8436
	PS-LJP	0.8568	0.878	0.8368	0.57
	PCA-PS-LJP	0.8791	0.8786	0.8726	0.8682

(1) *CNN*. In the text, the CNN model [15] containing multiple filter lengths is used to characterize and classify the fact description

(2) *HSLTM*. Referring to the hierarchical neural network structure adopted by Yang et al. [41] in the emotion classification task, this paper adopts LSTM to encode sentence features and another LSTM to encode document features described by facts

(3) *TOPJUDGE*. Zhong et al. [13] proposed a legal decision prediction model considering topological dependency among various sub-data sets, in which the representation of fact description features was obtained by LSTM coding

Tables 2–4 list the experimental results of the pretest for the four sub-data sets. The experimental results show that the PS-LJP model adopted in this paper outperforms the baseline system in four classification indexes of four data sets, which demonstrates the effectiveness of the model presented in this paper. Tables 2–5 list the experimental results.

It can be seen from Tables 2–5 that, (1) in the four data sets, all the models perform better in the Small data set than in the Large data set, which indicates that the size of the data set will directly affect the prediction accuracy of our method; (2) in the benchmark model and our proposed model, our model outperforms the benchmark model in the four data sets. This shows that our proposed model is better than some classical benchmark models for predicting legal decisions; (3) in general, compared with the single LJP, the PS-LJP model proposed by us has better performance in four different indicators on four data sets; (4) compared with the PS-LJP model without feature data preprocessing, the PS-LJP model based on principal component analysis proposed by us achieved better results in our four data sets.

More importantly, we found that the PCA-PS-LJP model we proposed achieved the best prediction results among all the models, which will prove that the method we proposed is very effective.

TABLE 3: Results of CAIL2019_Small.

6. Conclusion

As an important subtask of intelligent justice, the study of law prediction is of great value. It can not only help legal personnel to deal with cases and improve work efficiency but also help ordinary people to understand cases and make them have certain psychological expectations for the outcome of cases. Based on the research of law prediction in intelligent justice, this paper analyzes the problems from the judicial perspective and converts them into text processing tasks. It adopts the deep learning technology to construct different neural network models and conducts training and testing on the basis of real legal data sets. In the law prediction task in this article, convolutional neural network (CNN) algorithm was used to extract text features, and the principal component analysis (PCA) algorithm was used to reduce the dimension of data features. Next, the prediction model based on process supervision is proposed for the first time. When modeling the dependency relationship between sequential sub-data sets, process supervision is introduced to ensure the accuracy of the obtained dependency information, genetic algorithm (GA) is introduced to optimize the parameters so as to improve the final prediction performance. Compared to our benchmark method, our algorithm achieved the best results on four different legal open data sets (CAIL2018_Small, CAIL2018_Large, CAIL2019_Small, and CAIL2019_Large).

In recent years, the Internet of Things (IoT) has been industrializing in various real-world applications, including smart industry and smart grids, to make human existence more reliable. An overwhelming volume of sensing data is produced from numerous sensor devices as the Industrial IoT (IIoT) becomes more industrialized. Artificial Intelligence (AI) plays a vital part in big data analyses as a powerful analytic tool that provides flexible and reliable information insights in real-time. However, there are some difficulties in designing and developing a useful big data analysis tool using machine learning, such as a centralized approach, security, privacy, resource limitations, and a lack of sufficient training data. On the other hand, Blockchain promotes a decentralized architecture for IIoT applications. It encourages the secure data exchange and resources among the various nodes of the IoT network, removing centralized control and overcoming the industry's current challenges. Our proposed approach goal is to design and implement a consensus mechanism that incorporates Blockchain and AI to allow successful big data analysis. This work presents an improved Delegated Proof of Stake (DPoS) algorithm-based IIoT network that combines Blockchain and AI for real-time data transmission. To accelerate IIoT block generation, nodes use an improved DPoS to reach a consensus for selecting delegates and store block information in the trading node. The proposed approach is evaluated regarding energy consumption and transaction efficiency compared with the exciting consensus mechanism. The evaluation results reveal that the proposed consensus algorithm reduces energy consumption and addresses current security issues.

1. Introduction

The digitization transition gives expressive possibilities for the industry to grow creative and changing economic models and complex circular distribution networks. However, the information technology and transmission sector have a small impact on the environment; such a conversion has significant consequences for sustainability.

It is vital to supply solutions in a resilient and comprehensive manner throughout their entire life cycle to meet the milestones set forth by the industrial revolution for sustainable development [1] and achieve the circular economy's goals. Three fundamental innovative models enable the long-term digitization of a smart circular economy: industrial IoT, edge-based computing, and artificial intelligence (AI).

The introduction of the context of big data and two dominant digital innovations, such as machine learning and the Internet of Things, has recently been experienced around the world. Whereas the Internet of Things establishes a network of interlinked systems, machine learning (AI) allows machines to mimic cognitive abilities. AI and the IoT can work together to allow a new potential technology called Artificial Intelligence of Things (AIoT). In general, AIoT intends to make IoT production effective, increase human-machine interactions, and improve data gathering and analysis capabilities. These innovative techniques are developed through intelligent system advances in hardware (e.g. edge devices and accelerators) and software (e.g. RTOS, digital twin, deep learning architecture); AIoT is becoming the real-time application. In recent times, AIoT has been adopted in many application areas such as smart home automation [2], industry automation, and smart cities [3].

AIoT, as an AI-enabled framework, follows the standard training and inference approach [4] depicted in Figure 1. In the first stage, AI models utilise various machine learning techniques for training the data set. In the deployment of AIoT, training data have frequently gathered various data from IoT devices. Models are developed in the second step to arrive at conclusions from specific information. The two processes are commonly referred to as model development and Inferencing. A fundamental difficulty in AIoT is that the development of the model algorithm stage necessitates a large quantity of data and processing capabilities to produce the best AI models [5]. Yet, most IoT devices lack the necessary storage resources due to different constraints.

With the development of smart sensor technologies to integrate AI-based systems deployed in real-time applications, all data start from the era of the Industry 4.0 revolution [6]. Smart sensors are a topic that contributes to the enhancement of production and increased turnover in a variety of industries [7]. These advantages have been proven, especially when the technology available on the market is used effectively. However, AI applications can be harmful in some situations, causing major problems for the company in question. Furthermore, sensors can respond differently in different environments. They may give data of varying quality, which might misidentify the model decision and result in categorization failures if the model is not sufficiently stable. A significant effort and high costs are associated with an AI-based system developed to solve a single classification challenge, and a single misclassification scenario is costly.

The disadvantages of misclassification differ from one area to the next, based on a specific domain. On the one side, in the medical field, when a computerized diagnosis suggests that a person is sick, but in reality his health is not that poor [8]. Later, a doctor can verify and discover that the patient is, in fact, healthy. In the opposite situation, failing to recognize a sick patient and allowing him or her to continue without treatment is extremely harmful. Human safety is taken into account here; hence, high classification accuracy of greater than 99.99 per cent is essential. On the other hand, we permit marginally greater categorization errors for most industrial settings that do not endanger people's safety.
FIGURE 1: Artificial Intelligence two-stage process.

Based on various research studies in the agricultural field, the work of Xiong et al. [9], as well as Wossen et al. [10], validated that the cost of a misclassification error varies based on whether it is a false-negative or false-positive error in terms of financial and material loss. Various fault prediction approaches have been developed in the literature [11] to achieve low classification error rates. Other Support Vector Machine (SVM)-based approaches for minimizing misclassification situations have been proposed [12]. These approaches require a significant amount of training data, that is, data that contain classified information. This step is still challenging and time-consuming, particularly when working on new software programs that lack previous defect data.

Furthermore, time is a critical issue because these received much attention in the post-evaluation of the classification stage. Achieving a low classification error rate with the lowest possible risks is essential. Even more model re-training must be conducted after the prediction of the misclassification impact based on reference data, as demonstrated by Xiong, Y. and Zuo and Xiong in their paper [13], where they investigate the effect of misclassification errors to train a cost-effective neural network with different expense proportions. This method is time-consuming and requires an online training variable change despite the positive findings. There are also additional types of studies interested in evaluating sensor data online. In their study [14], Song and Deng use proof theory and intuitionistic fuzzy to continuously assess the trustworthiness of sensor data. As a result, the system can assign a fair dependability factor to sensors that give contradictory data. On the other hand, the proposed system design is extremely sophisticated and necessitates a good mathematics background.

Combining data from several sources yields significant benefits for decision-making and framework management, primarily in terms of increased trust and better-resolved system information. However, deciding on appropriate sensors to integrate for a specific task is difficult. Time and money are generally spent on respectful considerations. Instead, we present a clever AI-based solution to advanced sensor fusion that determines multiple sensor data streams based on the individual requirements, situations, and tasks. We recommend using AI automation as a pre-evaluation method in particular. This AI-based sensor assessment and clever fusion using interpretable frameworks technique can be easily applied to a wide range of sensor fusion systems.

As a result, the model's interoperability allows the candidate to follow the decision-making activity. In

addition, the suggested method can deny a request if the model is unsure about a decision. We demonstrate how to create a bi-functional system that incorporates both aspects. We concentrate on both the dynamic and static pre-evaluation of the system. A dynamic pre-evaluation evaluates sensor inputs during the classifier training phase. In contrast, a static pre-evaluation is done offline after the classifiers have been taught but before they are used in manufacturing lines. The developed system enables the evaluation of each sensor in terms of its data contribution to a predetermined categorization assignment and the hardiness of this information based on various external conditions.

Artificial intelligence (AI) has been hailed as a cure for a slew of problems in various industries [15]. It can upend old business models by opening new ones [16–18]. AI applications in the industrial business promise unique services in addition to efficiency improvements [19]. Enhancing goods with data-driven solutions is a crucial revenue generator in marketplaces with shrinking margins. It allows companies to stand out from competitors, especially in environments with ubiquitous nondata-driven services [20]. As discussed in this research [21], AI technologies are particularly valuable for commercial comprehensive supplier marketing strategies. Full-service providers (FSPs) retain ownership of intellectual products (e.g., industrial systems) and offer their use as a service in the manufacturing sector. FSP customers gain from converting procurement expenses into usage- or time-based costs, as well as the elimination of operational costs and the transfer of property control risks to the FSP. The FSP, on the other hand, gains from improved client loyalty [22] and additional revenue streams by embracing innovative payment formats. AI applications have the potential to boost the profitability of FSP marketing strategies by lowering maintenance costs and improving the availability of products or durability [23].

On the other hand, most AI applications use statistical approaches to training as part based on information [24]. These predictions allow for categorization that helps with various industrial applications and services. Cost-effective predictive maintenance (PM) and computerized predictive quality assurance (PQ) are two examples of such applications. As a result, the categorization algorithms that FSPs use must add value to consumers–i.e., service recipients (SRs)– while still being profitable.

Although most machine learning techniques are designed to turn even complicated cognitive issues into a binary classification [25], we look into classification techniques. Furthermore, the statistical structure of today's AI applications renders classifications inaccurate; nonetheless, studies show that up to 30% of decision-makers lack a basic knowledge of AI. Firms wanting to reinvent data-driven solutions based on categorization techniques must account for this imperfection in the construction of service-level agreements (SLAs) to obtain the promised benefits. As a result of the poor predictive power (PP), misclassifications resulted in breakdowns and decreased service levels. The FSP, for example, may be required to pay the SR for a lesser service level, resulting in additional costs.

Similarly, fluctuating service standards could impact an FSP's revenue. The revenue fluctuates regarding the payment system according to the PP-dependent quality of service. Low PP has little effect on a subscriber payment schedule, which provides FSPs with consistent revenue. On the other hand, a high PP allows FSPs to grow income by increasing service levels in utilization payment models. On the other hand, Low PP reduces the level of services provided and, consequently, income. The interaction of PP and different payment arrangements might positively or negatively impact the FSP's estimated net present value (NPV) [26]. As a result, FSPs must use an economic calculus to weigh the risks and benefits of using classification algorithms to pick payment arrangements.

1.1. Contribution. In Industrial automation applications, integrating blockchain, artificial intelligence, and big data constitutes the core technologies that allow dynamic data transmission. Moreover, integrating these technologies provides many features in addressing the challenges related to security, such as transparency, privacy, ensuring ownership rights, decentralization, and so on [27]. The integration of blockchain and artificial intelligence, on the other side, is still being investigated. More research studies have recommended artificial intelligence adoption using a simplified distributed system, with a focus on decentralized authentication. These research studies have failed to develop an artificial intelligence-based big data security model. Furthermore, the blockchain is not employed for big data analytics to overcome the risk of handing dynamic data into the system [28]. Instead, researchers implemented a blockchain model incorporated with distributed ledger for secure transaction processes in the industries.

In this manuscript, we introduce an improved DPoS-based consensus algorithm to increase the data transaction speed, decentralized control, and data security for IIoT networks. The novelty of developed consensus mechanism for industrial applications is as follows:

(i) To resolve the centralized security problems of IIoT, we proposed an improved DPoS consensus algorithm based on honor delegates for real-time applications.

(ii) To accelerate IoT block creation, nodes use an improved DPoS to reach a consensus for selecting delegates and store block information in the trading node.

(iii) Due to the demanding needs of enabling technologies in industrial applications, the data transmission and energy consumption are challenging tasks. To overcome these issues, we introduce delegates and honor delegate nodes–based consensus algorithm for AI-enabled IIoT.

2. Related Work

In this section, we describe the basic mechanism of artificial intelligence, big data, and blockchain for industrial application and how consensus mechanism-based AI change

industrial IoT. Blockchain, data science, and AI are the enabling technologies for industrial applications. Blockchain is mainly focused on the distributed ledge and decentralized framework for real-time applications. At the same time, data science is used for providing dynamic information and AI is employed for analyzing and classifying the sensor data in IoT applications. These innovative techniques are allowing machines to make decision and provide intelligent services. Figure 2 shows the IoT node interconnection for industrial applications.

2.1. Artificial Intelligence and Big Data Overview. Big data has been one of the most prominent research topics in recent years. Because of its huge volume, rapid velocity, and heterogeneous diversity, it differs from regular data. These traits of volume, velocity, and variety are known as the 3 Vs of big data. Later, the list was expanded to include two more Vs: value and veracity. As a result, all data that are of substantial quantity (volume), generated at a high rate (velocity), and diverse in nature (organized, semi-organized, or unorganized) are referred to as big data (variety). The value of big data analytics is that it incorporates the fourth V (value) into its qualities, making it a valuable asset to the company.

Big data analytics is a technique for analyzing large amounts of data and turning it into useful information by employing cutting-edge statistical, analytical, logistic, or artificial intelligence methods. The 3 Vs of big data, on the other hand, introduce a new set of obstacles, such as collecting, storing, exchanging, organizing, processing, analyzing, and visualizing such large amounts of data at rapid speeds [29]. Various frameworks have been built to manage large data for successful analytics in various applications for this purpose.

The digital reproduction of three primary cognitive abilities: training, thinking, and self-correction, is known as artificial intelligence (AI). Digital learning is a set of principles applied as a predictive algorithm that transforms real-world historical data into useful information [30]. The purpose of digital reasoning is to select the best rules for achieving a specific goal. Digital self-correction, on the other hand, is the continuous process of accepting the results of reinforcement learning. This approach is followed by every AI model in order to create a smart technology that can accomplish a task that would ordinarily consume a lot of time.

Machine learning, deep learning, data analysis, and principle techniques are used in the majority of intelligent systems, while reasoning and experience and understanding methods are used in others [31]. Machine learning and deep learning are two AI methods that are commonly employed nowadays. The distinctions among artificial intelligence, machine learning, and deep learning methods are frequently misunderstood.

Machine learning is a type of artificial intelligence (AI) that looks for certain trends in past data to help with decision-making. The more data we gather, the more precise is the learning process (eliminate the term big data). Machine learning can be classified into three types based on the
Figure 2: Graph-based IoT node generation for industrial applications.

decision process. First, supervised learning, wherein sets of data containing labelled outputs are accepted in required amounts to practice a model for categorization or future projections. Second, unsupervised learning is a type of machine learning that works with unstructured sets of data which are used for clustering and sorting. Finally, reinforcement learning collects data recordings with no labels but delivers response to the intelligent agent once specified actions take place. Linear regression, decision tree, and SVMs are the examples of supervised machine learning algorithms [32]. *K*-means and hierarchical cluster analysis fall under the unsupervised learning [33]. Lastly, Monte Carlo learning and Q-learning comes in the categories of reinforcement learning techniques [34]. Deep learning is a data mining technique inspired by the biological neural network and utilising one or more hidden units of artificial neurons. The historical data are handled repeatedly by several layers during the learning process, creating links and continuously weighting the neuron inputs for best results.

2.2. Relationship between Artificial Intelligence, Big Data, and IIoT. Real-time surveillance of physical equipment, indoor asset management, and outdoor asset management are just a few of the novel opportunities enabled by new smart sensors and IoT deployments in industrial ecosystems [35]. By integrating the physical environment to its virtual picture, IoT devices promote the real-time data gathering required for the production of a digital model of the physical component and permit the enhancement and servicing of the physical component (using smart devices). Because the IoT data indicated above is large in size, big data analytics can be useful in the building of an effective technology.

The reason for this is that industrial activities are extremely complicated, making early detection of possible issues difficult using conventional methods. Such issues, on the other side, may be easily retrieved from collected data, bringing productivity and expertise to industrial applications. However, in the industrial and technological realms, handling this massive volume of data necessitates complex approaches, structures, platforms, technologies, and algorithms. In a digital twin setting, for example, Zhang et al. [36] suggested a big data analytic system for smart account

auditing and maintenance. The relationship between AI, big data, and IIoT is depicted in Figure 3.

Cloud technology is frequently the perfect platform for processing and analyzing large amounts of data [37]. Furthermore, only by using AI technologies on the obtained data how would an intelligent digital system be created. In a nutshell, the IoT is used to collect large amounts of data from the physical world. The data are then placed into an AI model to create a digital twin. The developed digital system can then be used to improve other industrial processes.

2.3. Research Challenges and Security Issues.

The growing acceptance and accessibility of blockchain, as well as the use of IoT, data science, and AI innovations, has broadened the research problems of blockchain. These difficulties are divided into four categories.

2.3.1. Data Collection.

Data collecting from a physical device, data combining, and data exchanging with the associated blockchain are all made easier by the IoT. This procedure has the potential to be rather costly. It is possible that the digital ledger will be more expensive than the asset itself, in which case it will not be worthwhile to build the digital system. The acquired data, on the other hand, is huge, fragmented, unorganized, and noisy. As a result, more data processing is necessary to guarantee its optimal usage.

We need to use data cleaning procedures, as well as organize, rearrange, and homogenize the data. Furthermore, keeping such a massive volume of data under control is a huge task. Furthermore, the fundamental machine learning techniques require a specific quantity of data for training reasons in order to enhance the reliability of the blockchain model.

2.3.2. Challenges in Big Data.

The rapid use of IoT technology in the industries has resulted in massive volumes of monitoring (sensor) data being generated. To this goal, improved infrastructures, foundations, platforms, techniques, and strategies are needed to represent, preserve, share, analyze, and evaluate the raw data in big data and analytics. Edge and cloud services platforms could also be used to handle digital twin related data. Edge computing, in particular, allows for dispersed computation at the network's edge, with collective analysis taking place in the cloud. However, data processing on the cloud may result in a longer response time.

2.3.3. Analysis of Raw Data.

As described in the literature, artificial intelligence–based techniques for big data played an important role in industry for decision-making. However, choosing a certain model from hundreds of machine learning with unique settings is difficult. To various applications and data sources, each intelligence has various levels of accuracy and efficiency. On the other hand, accuracy might have a negative impact on efficiency. As a result, choosing the proper optimization algorithm and functionalities is difficult depending on the motivation and
FIGURE 3: AI enabled IIoT network integration.

implementation of industry automation. Furthermore, there are less realistic deployments of intelligence for industry 4.0 revolution in the literature, which adds to the difficulties.

2.3.4. Challenges in Privacy and Security.

Some manufacturing sectors, such as sensor data, product-related information, and human management ledger are deemed sensitive and may demand strict security and privacy guarantees. First, because IoT devices are involved in digital twinning, the privacy of the fundamental communication systems must be prioritized. Furthermore, the enormous amount of asset-related data must be securely held to avoid data theft from both inside and outside attacks.

2.4. Need of Blockchain Technology in IIoT.

In recent times, there has been a lot of studies into the privacy and security of interaction among IoT devices. Blockchain technology is a new use in IIoT networks, and its effective deployment has been the focus of much research. The IIoT benefits from the blockchain's decentralization, data integrity, cryptography privacy, fault tolerance, data security and identification, and consensus mechanism [38]. Several research studies compared popular blockchain platforms, including cryptocurrency, Ethereum [39], Hyperledger-Fabric [40], and IOTA [41], and discussed the advancement of smart contracts and its practicability in the industry, IOTA offers free transactions designed specifically for device to device communication, but it lacks the maturity of Ethereum and Public blockchain.

Blockchain technology has clearly evolved in people's perception as scientific research and innovations have progressed, and it has become a topic of studies by scholars and researchers. Industry and academics are paying growing attention to it. People have recognised the one-of-a-kind extraordinary development that distributed ledger may

bring about and have committed in the development on business elements such as banking, healthcare, and traceability. The distributed system is speeding up the maturity and industrial adoption of blockchain technology. Presently, China is creating its own blockchain technology; the competitive market structure and the separate copyright system are being developed [42].

At the same time, relevant techniques and developed ecology are integrating sectors, such as energy, healthcare, and agriculture. The decentralized security is a new kind of innovative platform in that digital information such as random data blocks are used to authenticate user and provide the data privacy through consensus algorithm. The blockchain technology is implemented to ensure the security and privacy of data transmission between nodes.

2.5. Consensus Algorithm for Industrial Applications. A consensus algorithm is a collection of rules governing how a decentralized network is supposed to work. These principles outline the basic roles of various parts, how they interact, and the criteria that must be met in order for them to function correctly. A consensus algorithm specifies the rules that must be followed in order to establish an agreement, as well as the procedures that should be done under what situations. The proof of work (POW) technique states that as long as such a node could generate a block which adheres to the desired value, the entire network can verify it [43]. In a distributed system, a consensus algorithm is a technique for resolving data synchronisation between nodes that do not trust each other.

PoX (proof-of-X) decision techniques for blockchain systems without authorities have recently emerged and developed, with all techniques focusing on network transactions [43]. However, because there is no agreement, transaction verification is delayed, which is incompatible with most dynamic IIoT devices that demand real-time validation. The Equihash method [45] is a proof-of-work (PoW) agreement technique based on the generalised birthday dilemma in which a fundamental cryptography implementation is difficult. This is a memory-dependent consensus technique that sets the burden based on the nodes' storage sizes. It requires a lot of storage to provide evidence, but it can achieve quick confirmation. Although this design enhances the cost-effectiveness of ASIC devices, the application's security has yet to be validated.

The Ouroboros techniques deployed in Ref. [46] is a distributed system-based proof of stake (PoS) consensus model. The techniques develop a tight security guarantee consensus procedure and push the PoS consensus process via a reward system. This reward is to confirm that non-malicious devices maintain a nash equilibrium and also prevent security breaches affected by selfish block creation. Da Xu and Viriyasitavat [47] combined the PoW and PoS consensus concepts for security transactions. The PoW method is utilised for the acquisition of tickets in the early stages of the process. When the blockchain system has acquired sufficient assets, the PoS algorithm is utilised to ensure the network's long-term safety. The PoS algorithm

provides direct correlation between coin age and time that is converted to an exponentially decaying rate. This approach helps the rate of growth of coin age to reach zero over the period of time and prohibits the accumulation of money. However, the approach increases computation time and necessitates a large amount of network memory size.

Based on the original Paxos algorithmic concept, Moraru et al. [48] created EPaxos consensus method. Creating the dependency, accepting the request, and completing the phase are the three stages of the method. Each proposition has characteristics, such as gathering and pattern numbering, in addition to the intrinsic data. To establish the execution order of competing proposals, the ideas of a quick stream, slow stream, and dependency graph are presented. Only implementation situations with few or no conflicts are acceptable for the technique.

For the distributed ledgers, Sousa et al. [49] introduced the Byzantine fault-tolerant consensus protocol. To model the continuity of Byzantium fault-tolerance, this protocol employs a probability remuneration network. Although the protocol offers some benefits in terms of transmission capacity and faster transaction time, the execution flow could be improved. On the basis of credit, Yeow et al. [50] suggested an enhanced practical Byzantine fault-tolerant (PBFT) consensus protocol. The consensus protocol was enhanced, credit assessment predicated on a coalition chain was created, and the system was brought into a feedback loop by including a lightweight integrity method. The checkpoints protocol was changed to allow devices to enter and depart the network on demand, increasing the platform's adaptability.

Lin et al. [51] developed a ring signature-based modified PBFT consensus technique. The PBFT technique, the ElGamal cryptographic signature encryption method, and the ring signature concept were all presented. The efficiency and secrecy of a ring signature technique based on the ElGamal technique were then investigated. The ring signature strategy was optimized to enhance the PBFT computation signature and validation procedure, allowing nodes to enter and depart the network continuously. The suggested solution surpassed the original PBFT computation fault-tolerant percentage.

Delegated Proof of Stake (DPoS) was created by Larimer and deployed initially for the BitShares project [52]. The DPoS consensus process is separated into two parts: the first is the election of witnesses (block creators), and the second is the generation of blocks. Witnesses are simply authorized for confirming the transactions, validating the signature, and timestamping it; they are not allowed to trade. They each produce one block every three seconds, and if a witness fails to perform the task within the time limit, it is ignored and substituted by the next one. Each network node has the ability to vote for its own dedicated witness, and the more smart contract stakes he or she has, the more likely he or she is to be a witness. However, because of the core method whereby each witness node generates blocks in succession, the identification of the witness is already established and stable, making the distributed ledger network more open to fraud assaults.

Furthermore, achieving fairness by solely employing DPoS is challenging, as it will only allow those with more resources to become voters. In addition, while employing the PoW alone, the block period is around 10 minutes, wasting a significant amount of computer and energy resources. For this third issue, this paper proposes an honor mechanism akin to that used in reputation to select the delegate node that causes the consensus to be harmed and replace them.

There are two types of nodes in the consensus algorithm, according to our findings. The delegate node, for example, is a node that creates or validates transactions and contributes in the consensus mechanism. The honor delegate node, on the other hand, serves as a contender for the delegate node and is used to replace it if it fails. These two types of nodes are termed as delegate nodes for conforming consensus mechanism.

2.6. Proposed Blockchain-Based Consensus Mechanism for AI-Enabled IIoT. To resolve the security and privacy issues of AI and enable IIoT, considering the distributed ledge of sensor information, we proposed an improved DPoS consensus mechanism based on honor voting system for industrial application. We construct a consensus mechanism–based ledger for sensor data storage in IoT device system solutions for smart industrial automation because of the transparency and data integrity of blockchain. Data cannot be changed by distant attackers wanting to quickly get into the device for harmful modification. Since IoT sensor data, such as identification, password protection, application settings, and behavioral records, may be safely kept in distributed ledger, in this paper, we employed an improved DPoS algorithm to create a consensus for producing blocks including sensor information, which speeds up block generation.

2.7. Improved DPoS Consensus Algorithm. The most appropriate delegates cannot be picked for block formation due to the inaccuracy of voting choices and the inaccuracy of vote calculation. An improved DPoS algorithm is introduced in this manuscript to be more effective, versatile, and precise in choosing suitable delegates. Improved DPoS algorithm is made up of three parts. The first is an honor voting system, which yields a collection of delegates phrases for each voting node. The second step is to create an improved voting function that will be used to determine each node's value. The highest number of honor voting, the better the node's chances of becoming a delegate. To complete the voting process, the final step is to determine the divergence level.

2.8. The Basic Concept of Improved DPoS Algorithm. According to the literature, the major drawbacks of the public blockchain consensus mechanism are that the distributed ledge techniques are more permissioned and insecure, and its difficulty in creating blocks is considered as a critical limitation to our technological needs. To overcome these issues, the DPoS-based consensus algorithm can solve the security problems because the DPoS algorithm can

greatly enhance the authentication and also reduce energy consumption. On the other side, the PoW mechanism greatly reduces the energy consumption because every node has the right to create blocks.

However, achieving fairness by solely employing DPoS is challenging, as it will only allow those with more money to become voters. Furthermore, while employing the PoW alone, the block interval is around 10 minutes, wasting a significant amount of computing power sources. For the power consumption issue, this paper proposes an honor voting mechanism akin to that used in the modern system to reduce the latency of the voting node that causes the consensus to be harmed and replace them. We have considered that there are two types of nodes in the consensus algorithm. The one is the voting node, which creates blocks and takes part in the authentication process. The second node is termed as a honor voting node, and it has special voting privilege. With the special voting privilege, the honor voting node can replace the node when it fails to perform. And, these kinds of proposed nodes are generally considered as the consensus nodes.

2.9. The Development of Consensus Mechanism. We separate the consensus procedure into two parts. To begin with, utilise the PoW concept to select a set number of suitable nodes from the entire network, and employ stake voting to select consensus nodes. In this network, the top 101 nodes serve as delegate nodes and the remainder nodes serve as honor delegates. The delegate nodes then record the transactions in a block and disseminate it to all consensus nodes for consensus in the second phase. The block will be added to the blockchain if it is successfully verified by more than half of the consensus nodes. The process steps of an honor delegate node selection based on improved DPoS algorithm is shown in Figure 4.

As immediately as the malicious node is discovered, we implement an honor voting method to regenerate it. When a delegate node is discovered to be malicious, it is added to the honor delegates' nodes set, and the rank of all existing delegate nodes is reduced by one. The node in the set of honor delegate nodes with sequence number is moved to the delegate nodes set and ranked last in the delegate nodes set. The malicious node is sorted at the end of the collection of honor delegate nodes, while the identifiers of all the remaining honor nodes are decremented by one. Algorithm 1 describes the proposed mechanism for honor node selection in the IoT network.

The N number of nodes with the maximum votes can be selected as delegate nodes in improved DPoS, and the shortlist of delegates nodes will be updated every 20 hours, just like in DPoS. The delegate node's reputation and witness identification will be revoked if someone is discovered to have a poor rate of creating blocks or to be engaging in harmful activities.

The module for choosing consensus networks: all nodes in the public ledger are successfully prepared in order to allocate various tasks to different types of nodes, which are primarily separated into consensus nodes (such as delegate

nodes and honor nodes) and transaction network. Trading nodes are responsible for generating transactions, while consensus nodes are responsible for generating and verifying blocks. Figure 5 shows the delegate node selection using the graph method. The consensus module is responsible for executing the entire process from block creation to block confirmation. The module for degrading malicious nodes is as follows: When a malicious node is discovered, the improved DPoS algorithm switches to a module that replaces honor node and sorts the delegate nodes.

The decentralized network ecosystem is described as a peer-to-peer network made up of all branches in the architecture, with consensus nodes and trade nodes being the two types of nodes in this network. The consensus network is a sub-network ecosystem made up of delegate nodes that will change when the voting number in the improved DPoS algorithm updates. Conversely, the trading sub-network is the network architecture comprising of trading nodes which is not static. The trading nodes update them after each round of selecting the delegate node.

Only during the time between the formation of the current delegate nodes and the beginning of another round of honor node selection will the trading networks be secure.

As previously stated, the nodes that participate in the consensus process rather than generating transactions are divided into two categories: delegate node and honor nodes. The trade nodes are accountable for the production, transmitting, and storage of distributed ledger, while the witness nodes take turns recording trades into a block and transmitting it to the other delegate nodes for validation.

3. Result Evaluation and Discussion

In this section, we describe the performance assessment of the blockchain-based consensus mechanism for AI-enabled IIoT network. We present the comparison result of the proposed work with existing mechanism such as PoS, PoW, and DPoS in terms of important parameters which includes block creation approach, block generation time, and energy resources. To carry out security performance, we include existing consensus mechanism. Each work represents the artificial intelligence–based big data analysis at the IoT device with decentralized control. The proposed blockchain-based consensus mechanism provides distributed architecture to enhance security and privacy at the IoT device.
FIGURE 5: Graph-based delegate nodes selection in consensus mechanism.

TABLE 1: Performance of various consensus algorithm.

Consensus mechanism	Proof-of-work (PoW)	Proof-of-stack (PoS)	Improved delegate PoS (DPoS)
Mechanism for block generation	Computing power	Stake	Stake votes
Security issues	Constant power	Inactive nodes	Malicious nodes
Energy consumption	Very high	High	Low
Average block generation time	10 min	65 sec	5 sec
Reliability	High	Low	Low
Robustness	High	High	High
FIGURE 6: Transaction data rate of various consensus mechanisms.

The distributed consensus mechanism–based AI-enabled IoT architecture resolved the real-time security issues and also reduced the energy consumption. An improved DPoS algorithm suggested AI-based decentralized IoT network for big data analysis in real-time, and it will overcome the issue of data storage. The proposed mechanism introduces the trading node in which the actual block information is stored. The implementation of big data analytic is developed on the IIoT blocks to evaluate the scalability and robustness of improved DPoS. We presented the performance of the proposed method with existing consensus algorithm research shown in Table 1. According to the security metric, the proposed algorithm provides better results compared with PoS and PoW in terms of energy consumption.
FIGURE 7: Energy consumption comparison of various consensus mechanisms.

To analyze the data transaction rate of improved DPoS algorithm, we investigate the performance with existing methods such as a PoW, PoS, and DPoS mechanism [43]. The transaction rate of PoW is very low because of its computation time. In PoW, blocks are verified based on the computing power. In the same way, in the case of PoS the blocks are verified through stake methods and it will require more transaction time. In order to reduce the transaction time, DPoS is proposed based on the stake voting mechanism.

Likewise, our proposed algorithm verified through honor delegates which required less time for verification. Therefore, compared with other three mechanisms, our improved DPoS increases the transaction rate.

Figure 6 clearly shows that our improved DPoS algorithm has more TPS than other mechanisms. To reduce the energy resource of the blockchain-based consensus mechanism, we developed an improved DPoS algorithm for IIoT devices. In order to overcome the computing resources problems in the PoW and PoS mechanism of decentralized ledger-based industrialized IoT devices, we propose to combine artificial intelligence and blockchain technology. In the decentralized improved DPoS consensus algorithm implemented to enhance the data privacy and reduce energy resources for big data analysis, the main reason to introduce delegates and honor nodes-based consensus mechanism for IIoT devices is to reduce overall energy consumption, as it will verify the blocks in the idea of stake voting mechanism and also replace malicious nodes through honor delegates. To develop smart contracts between nodes, we used DPoS-based stake voting mechanism, which is denoted as delegates nodes.

Figure 7 represents the energy consumption analysis of the proposed algorithm and other two existing models. In the PoW mechanism, if the number of blocks increases, the energy consumption also increases because in this algorithm the blocks are created based on the computing power of the particular system. Therefore, the PoW model required more resources than other models. In the case of the proposed algorithm, the blocks are created through stake vote which will be part of the IoT network, as the energy consumption is very less compared to the PoW model.

Finally, the different performance evaluations of the developed blockchain-based AI-enabled IIoT network conforms that an improved DPoS consensus algorithm increases data transaction rate per seconds and reduces the energy resources. Overall, the proposed consensus mechanism is most applicable for AI-based IIoT applications in order to analyze data in a secure manner with less energy resources.

4. Conclusion

A combined blockchain and artificial intelligence–based consensus algorithm for big data analysis in IoT applications are introduced in this manuscript. This work aims to develop efficient and reliable IoT data transactions at the industrial level. The suggested DPoS consensus algorithm performance was evaluated using security and energy consumption metrics. An improved DPoS was implemented to blockchain-based AI for decentralized control in IIoT. The experimental analysis is presented to evaluate the performance of the suggested consensus mechanism AI-enabled IIoT applications with distributed and secure big data analytics. In terms of reliability, speed, privacy, and security, the experimental results show the efficiency of the proposed algorithm compared with existing mechanisms. According to the TPS results, the integration of blockchain with artificial intelligence successfully addresses the issues of getting

high accuracy, security, and low latency through a decentralized network. The proposed consensus algorithm successfully overcomes the difficulties of accuracy, latency, and security by combining blockchain and artificial intelligence and also addresses the energy consumption issue [44].

As a result of the ease with which the internet and cell phones can be accessed, online social networks (OSN) and social media have seen a significant increase in popularity in recent years. Security and privacy, on the other hand, are the key concerns in online social networks and other social media platforms. On the other hand, cyberbullying (CB) is a serious problem that needs to be addressed on social media platforms. Known as cyberbullying (CB), it is defined as a repetitive, purposeful, and aggressive reaction performed by individuals through the use of information and communication technology (ICT) platforms such as social media platforms, the internet, and cell phones. It is made up of hate messages that are sent by e-mail, chat rooms, and social media platforms, which are accessed through computers and mobile phones. The detection and categorization of CB using deep learning (DL) models in social networks are, therefore, crucial in order to combat this trend. Feature subset selection with deep learning-based CB detection and categorization (FSSDL-CBDC) is a novel approach for social networks that combines deep learning with feature subset selection. The suggested FSSDL-CBDC technique consists of a number of phases, including preprocessing, feature selection, and classification, among others. Additionally, a binary coyote optimization (BCO)-based feature subset selection (BCO-FSS) technique is employed to select a subset of features that will increase classification performance by using the BCO algorithm. Additionally, the salp swarm algorithm (SSA) is used in conjunction with a deep belief network (DBN), which is known to as the SSA-DBN model, to detect and characterize cyberbullying in social media networks and other online environments. The development of the BCO-FSS and SSA-DBN models for the detection and classification of cyberbullying highlights the originality of the research. A large number of simulations were carried out to illustrate the superior classification performance of the proposed FSSDL-CBDC technique. The SSA-DBN model has exhibited superior accuracy to the other algorithms, with a 99.983 % accuracy rate. Overall, the experimental results revealed that the FSSDL-CBDC technique beats the other strategies in a number of different aspects.

1. Introduction

In recent years, people utilize virtual meeting platforms in their daily lives using global online social network (OSN) to facilitate communication. This network helps users for finding new friends and increases their connections around

the world. Furthermore, sharing of data and opinions is the significant features of OSN [1–3]. In recent years, the rate of utilizing OSN has rapidly increased. With OSNs such as Facebook, Google+, LinkedIn, Twitter, VKontakte, Mixi, and Sina Weibo, a Japanese social network turned into the desired manner of transmission for billions of everyday

active users. A user consumes maximal time for updating their content, interacting with primary user, and browsing others' account for finding particular data that are the major implication of social network website. OSN could remove the economical and geographical barriers among the users for sharing information and communication. In addition, OSN is highly beneficial to attain the objectives like amusement, education, search for jobs, etc. The popularity of OSN leads to high risks of an attack on the OSN users. Several OSN users expose their private data and that act as a proposal for the attacker to perform specific malicious activities [4, 5].

The current extensive nature of cyberbullying (CB) has enlarged the significance of its recognition. As per the survey, nearly 43% of the teenagers in the US alone have been stated to be the targets of CB at a certain point. CB is deliberated as a novel or electric method of conventional bullying. CB is determined as an aggressive, repeated, and intended response determined by an individual/group toward other individuals/groups, which is created using information and communication technology (ICT) methods like the internet, mobile phones, and social media [6]. The whole CB events are executed in internet broadcasting instead of in a physical system. The CB contains hate letters transferred by e-mails, social networking, and so on, via public/private computers/using private mobile phones. It is raised as a severe threat among the states. Current research displays the ratio as improved to be about 59% in the US. CB has a similar, when it is not a better, negative impact on the victim against conventional bullying, since the predators generally attack a victim on the aspect that an individual could not alter (viz., ethnicity, physical appearance, skin color, and religion), which leaves a deep and long-lasting effect on the victim. Occasionally, the related humiliations are sufficient for pushing the victim to self-infliction of suicide/harm.

A study in [7] displayed that suicide thoughts tend to rise among teenagers because of the disclosure of various types of CB. Although precautions are occupied, the redevelopment of victims of CB cases is challenging for society and families. Self-hate, dominance, isolation, and reaction to the socializing procedure lead to troubled and unhappy adults. Furthermore, this mental imbalance could alone make upcoming bullies. Among many problems, which create the recognition of CB in OSN is highly complicated, current advanced solution for detecting CB does not determine the possibility of bullying types in their detection method [8]. We specified the different kinds of CB, which could arise on the web, and it is not possible for assuming that a similar detection method would be effective in finding all types of bullying.

The main limitation present in the current detection system using CB study is the absence of input data. This study is traditionally executed on an available dataset/surveyed data, while the victim's/perpetrators are permitted for reporting the impression. Another issue with automatic CB identification is determining the most appropriate operation on CB material that takes into account the available studies in the CB detection region in order to achieve the goal of automatic detection accurately recognizing CB actions, which is another issue with automatic CB identification. It becomes more difficult to determine the actions as a result of this, and well-developed tools for combining the information via an autonomous decision technique are necessary [9]. To achieve the goal of automatic detection to precisely recognize CB actions, a CB detection zone was created. The automated decision-making is the process of making decisions without human intervention. Inferred data or digitally developed profiles can also be used to make these decisions. A preprogrammed algorithm and criteria may be used in an online loan decision or a recruitment aptitude examination. Administration heavily relies on automation. Automated systems can increase administrative decision-making consistency, correctness, and transparency, and enable new service delivery choices in the relevant areas and with suitable supervision. According to the findings of this study, machine learning was utilized to detect artificial CB material based on a number of psychological and common characteristics. The CB detection rate of this intelligent system has been reported to be lower, and it has been found to be mostly confined to a person writing a comment in the text [10]. The present research has stated that the consumption of user context in the event includes the history and features of user comments for improving the efficiency of CB classification or detection [11]. SSA with the DBN algorithm was used. Salp swarm algorithm (SSA) with deep belief network (DBN) is called as the SSA-DBN model. The SSA-DBN model is employed to detect and classify cyberbullying in social networks. For identifying suspicious attacks in a social, a salp swarm algorithm-based deep belief network is presented. As a result, the suggested chronological salp swarm algorithm-based deep belief network is constructed by fusing the chronological and salp swarm concepts. The fitness function, which accepts the minimal error vale as the optimal solution, reveals the optimal solution for detecting the incursion. The suggested approach tunes the weights appropriately in this case to produce an effective and optimal solution for identifying intruders.

This study presents a novel feature subset selection with DL-based CB detection and classification (FSSDL-CBDC) model on social networks. In addition, a binary coyote optimization-based feature subset selection (BCO-FSS) technique is applied to choose a set of features for enhanced classification efficiency. Moreover, the salp swarm algorithm (SSA) with deep belief network (DBN), called the SSA-DBN model, is working to detect and classify CB in social networks. Deep belief networks (DBNs) were created as a response to the issues that classic neural networks have with deep layered networks' training, such as slow learning, becoming stuck in local minima owing to poor parameter selection, and requiring much training datasets. The greedy algorithm is used to precondition deep belief networks—the design of the BCO-FSS and SSA-DBN models for CB detection and categorization procedure. To choose a set of features for improved classification efficiency, the binary coyote optimization-based feature subset selection (BCO-FSS) technique is used. To detect and classify CB in social networks, we combine the salp swarm algorithm (SSA) with

a deep belief network (DBN) and dubbed the SSA-DBN model. BCO-FSS and SSA-DBN model development for CB detection and classification process demonstrates the effort's inventiveness. Furthermore, the utilization of the SSA to fine-tune the hyperparameter of the DBN model resulted in enhanced outcomes over the traditional DBN model. The BCO technique is applied to choose a set of features for enhanced classification efficiency, and the SSA is employed to detect and classify cyberbullying in social networks. For the exploratory better detection presentation of the proposed FSSDL-CBDC method, a comprehensive range of simulations was performed on a benchmark dataset.

2. Related Works

This section reviews the recently developed automated CB classification models on social networks. Yuvaraj et al. [12] integrate the classification and feature extraction engine. The classification engine utilizing ANN categorizes the result, and it is given by a calculation scheme that either penalizes/rewards the categorized output. DRL performs the calculations, which increases the efficiency of classification. In their study, Mahbub et al. [13] investigate the impact of predatory approach words on CB detection and present a method for generating a vocabulary of predatory approach phrases. This study brings together findings from investigations of convicted criminals' chat logs in order to develop a lexicon of sexual approach terms for use in the future. Through the examination of data from a variety of social networks, the research establishes the relevance of this dictionary of approach terms in detecting online predatory behavior via machine learning methodologies. The variety of contents available on different social media sites are demonstrated by this example.

Talpur and O'Sullivan [14] created a supervised machine learning strategy for detecting CB and categorizing its severity on Twitter, which they published in Nature. The text classification engine created by Yuvaraj et al. [15] that preprocesses tweets, eliminates noisy data and other background information, extracts the desired features, and categorizes without overfitting the data is described in detail below. This research advances a novel DDT strategy that processes input components by utilizing the DNN hidden layer as tree nodes, as demonstrated in previous research. Chia et al. [16] use feature engineering and machine learning approaches to explore the use of irony and sarcasm on social media platforms. To begin, they define and assess the definitions of sarcasm and irony by looking at a large number of research studies that are focused on the contexts in which they are used. Subsequently, a comparison of numerous classification approaches with a few widely used classification schemes for the text classification process is carried out following the initial research. A variety of methods of data preprocessing were examined and compared in the following research.

In Murnion et al. [17], an automated data collection scheme is proposed that always gathers game chat data from the common online multiple player games. The data have been combined and collected using other data regarding the companies from the presented connected data service. It presented a scoring system for enabling the detection of CB depending upon this study. The organization of the gathered data was executed by humble feature recognition with SQL database enquiries and related with classifications from the AI-based sentimentality text analysis services, which have currently turned into presented and automatically classified data utilizing custom-built classification user.

Bu and Cho [18] proposed an ensemble technique of the 2 DL methods: first is character-level CNN that takes lower-level syntactic data from the series of characters and strong to the noise by the TL method. Next is word-level LRCN that takes higher-level semantic data from the series of words, accompanying the CNN module. Kumari and Singh [19] extract integrated features of text and images for identifying distinct events of CB. They utilize a pretrained VGG-16 network and CNN for extracting the features from text and images, correspondingly. These features are additionally improved by GA for increasing the performance of the entire system. Al-Garadi et al. conducted an in-depth research on cyberbullying prediction models on social media and identified several unresolved issues, including the prediction of cyberbullying intensity, human data features, and language dynamics. Numerous studies examine various machine learning options for detecting cyberbullying. Hosseinmardi et al. investigate the detection of cyberbullying episodes on the social media platform Instagram. They employ naive Bayes and SVM classifiers, the latter of which achieves the highest performance by combining multimodal text and image information, and media session data. Several other studies concentrate on the characteristics believed to be associated with cyberbullying, such as analyzing the social network structure of users, combining text and picture analysis techniques, profanity features, sentiment analysis, or geographical features, among others.

3. The Proposed Model

As illustrated in Figure 1, the operating principle of the FSSDL-CBDC approach is described. Several steps are required for the proposed FSSDL-CBDC technique to be effective, including preprocessing, feature selection using BCO-FSS, and classification using SSA-DBN. The FSSDL-CBDC technique was used. A variety of simulations were run to demonstrate the proposed FSSDL-CBDC technique's improved classification performance. Cyberbullying is a pernicious form of online abuse of authority that has malicious consequences. It takes on a variety of formats, and in the majority of social media platforms, it is in textual format. Intelligent systems are required to automatically detect such situations. Deep learning-based models have made their way into the detection of cyberbullying occurrences, claiming to be able to overcome the limits of conventional models and significantly enhance detection performance. The activities of these processes are described in greater detail in the following sections.
Figure 1: Working process of the FSSDL-CBDC model.

3.1. Preprocessing. During preprocessing, a lexical normalization technique is employed, which makes use of different elements for cleaning the input data. It also transforms the numerical parameters to the corresponding textual data. In addition, a spell corrector tool is used to eradicate the outbound vocabulary words. In addition, the repetitive or missing parameters are removed involving spelling mistakes, incorrect punctuation marks, and so on.

3.2. Design of the BCO-FSS Technique. Once the input social network data are preprocessed, they are fed into the BCO-FSS technique. The COA is a strong populace-based method projected lately by Juliano and Leandro [20]. This method draws stimulation from the common behaviors of *Canis latrans* species that live mostly in the NA. Because of its exclusive form, the COA could be categorized as evolutionary heuristics and swarm intelligence (SI). The coyote's population is separated to N_p packs, and N_c coyotes for each pack. The amount of coyotes in apiece pack is thought to be constant and equal. As a result, the populace size may be calculated by multiplying N_p and N_c. Every coyote's social status denotes a potential solution $\overrightarrow{x}$ to the optimization issue. In this case, the communal situation of cth coyote in p^{th} packet at t^{th} time may be described as follows:

$$soc_c^{p,t} = \overrightarrow{x} = (x_1, x_2, \ldots, x_D), \quad (1)$$

where D represents the amount of dimension in the search space. Initially, a population of $N_p \times N_c$ coyote is arbitrarily initiated within the predetermined search space as follows:

$$soc_{cj}^{p,t} = lb_j + r_j \cdot (ub_j - lb_j), \quad (2)$$

where lb and ub denote lower and upper bounds of jth decision variable, correspondingly. r_j represents real number arbitrarily created among zero and one, succeeding

uniform distributions. Then, the adaption of coyotes to their corresponding social condition is estimated by the following:

$$fit_c^{p,t} = f(soc_c^{p,t}). \quad (3)$$

As mentioned, the coyotes tend to leave their present pack for leading a lonely life or join other packs. The exclusion of coyote from its pack shadows a likelihood P_e, which differs based on the pack size as follows:

$$P_e = 0.005 \cdot N_c^2. \quad (4)$$

This method improves population range by stimulating a global interchange of data between the coyote packs. As P_e goes beyond one for $N_c \geq \sqrt{200}$, the COA limits the maximal amount of coyotes for each pack to fourteen [21]. In every pack, the coyote is optimally familiarized with the atmosphere and is allocated as alpha. For the minimization problem, the alpha is given as

$$alpha^{p,t} = \left\{ soc_c^{p,t} | arg_c = \{1, 2, \ldots, N_c\} \min f(soc_c^{p,t}) \right\}. \quad (5)$$

With the consideration of clear indications of the SI in coyotes, the COA assumes all the coyotes' share their social condition with the remaining packs for improving the pack's survivability. Regarding this, the traditional tendency of a pack is determined according to the data given its member, ciz.,

$$cult_j^{p,t} = \begin{cases} O_{(Nc+1)/2}^{p,t} & N_c \text{ is odd} \\ \dfrac{O_{(Nc/2),j}^{p,t} + O_{(Nc+1)/2,j}^{p,t}}{2} & \text{otherwise} \end{cases}, \quad (6)$$

where $O^{p,t}$ represents hierarchical communal condition of the prairie wolf within p^{th} pack at t^{th} time, for $j = 1, 2, \ldots, D$. In this method, the traditional propensity of every pack is calculated as the middle of the combined communal condition within the carton. For modeling the two main organic proceedings of the coyote, namely, birth and death, the ages of every coyote are deliberated, age $\in$ N. The birth of novel coyotes is defined by the combination among the communal circumstances of the two arbitrary parental coyotes from similar packs, and the effect of the environmental factor R_j,

$$pup_j^{p,t} = \begin{cases} soc_{r1,j}^{p,t}, & r \text{ and } j < P_a \text{ or } j = j_1 \\ soc_{r2,j}^{p,t}, & r \text{ and } < P_s + P_a \text{ or } j = j_2, \\ R_j, & \text{otherwise} \end{cases} \quad (7)$$

where $soc_{r1,j}^{p,t}$ and $soc_{r2,j}^{p,t}$ denote arbitrary coyote from the pth pack, and j_1 and j_2 denote two arbitrary dimensions of the search space. Alternatively, P_s and P_a denote scatter and relationship likelihoods, correspondingly. R_j denotes arbitrarily created vector within the bounds of jth dimension, and r and $_j$ denotes uniformly arbitrary amounts in zero and one. The scatter and relationship likelihoods have a substantial impact on the composition and diversity of the coyote's pack. It is given by the following:

$$P_s = \frac{1}{D},$$

$$P_a = \frac{(1 - P_s)}{2}. \tag{8}$$

Based on this, the coyote's pup has around 10% chance of death at birth. Moreover, the death risk of every coyote increases with age. Thus, the COA designs the coyote's survivability depending upon a simple method, whereas ω and φ denote set of coyotes fewer adapted to the atmosphere (viz. worst fitness value) compared to pup and size of the groups, correspondingly.

Additionally, the COA represents the traditional communication among the coyotes in the pack using δ_1 and δ_2. The previous denotes the effect of alpha on an arbitrary coyote cr_1, where the later indicates the effect of the traditional tendency of the pack on other arbitrary coyotes cr_2. The cr_1 and cr_2 are chosen after a uniformly distributed likelihood. Therefore, δ_1 and δ_2 are given by

$$\delta_1 = \text{alpha}^{p,t} - \text{soc}_{cr1}^{p,t}, \tag{9}$$

$$\delta_2 = \text{cult}^{p,t} - \text{soc}_{cr2}^{p,t}. \tag{10}$$

The social condition of the coyote is inclined by the alpha, and other members of the pack will be upgraded using

$$\text{new soc}_c^{p,t} = \text{soc}_c^{p,t} + r_1 \cdot \delta_1 + r_2 \cdot \delta_2, \tag{11}$$

where r_1 and r_2 are random values. The coyotes of new social conditions are assessed using

$$\text{new fit}_c^{p,t} = f\left(\text{new} - \text{soc}_c^{p,t}\right). \tag{12}$$

The coyotes' general fitness will either increase or remain the same, but it will never deteriorate.

$$\text{soc}_c^{p,t+1} = \begin{cases} \text{new\_soc}_c^{p,t} & \text{if new} - \text{fit}_c^{p,t} < \text{fit}_c^{p,t} \\ \text{soc}_c^{p,t} & \text{otherwise} \end{cases}. \tag{13}$$

Additional features could inhibit the learning procedure. The FS could authenticate the significance of the features, which create a dataset, and removing these does not assist in a positive manner. The selected features using an FS method could be denoted as N-sized vector, whereas N denotes the overall number of features in a dataset, whereas every position of the vector could consider the values as zero/one, whereas zero denotes features that were not chosen as also one signifies features that were chosen. The transfer purpose technique determines the likelihood of altering a position vector component from zero to one and conversely in an efficient and simple manner, and hence, the binarization method is the utilized most, particularly for the FS problem [22]. Based on this, a transfer function considerably affects the efficiency of the FS methods in seeking an optimal set of features, concerning the local optimal prevention and the balance between exploitation and exploration, and thus, it is a significant role in the binary version of metaheuristics. In the BCOA, the constraint of the social conditions of coyotes

for the binary values by a V-shaped transfer function is defined by equation (14) as follows:

$$V\left(\text{new\_soc}_c^{p,t}\right) = \left| \frac{\text{new\_soc}_c^{p,t}}{\sqrt{1 + \left(\text{new\_soc}_c^{p,t}\right)^2}} \right|, \tag{14}$$

where $\text{new\_soc}_c^{p,t}$ relates to the upgraded social condition vector existing, considering continuous values.

3.3. Algorithmic Design of the SSA-DBN Technique. Once the subsets have been feature-reduced, they are fed into the SSA-DBN model, which is then utilized to complete the classification assignment. This is accomplished through the use of the DBN model, which generates feature vectors that are then classified using the softmax layer. By picking hyperparameter values in the most optimal method, the SSA is used to improve the detection performance of a DBN model, whereas the SSA is used to improve its detection performance.

3.3.1. Architecture of DBN. Since DBN contains multiple hidden levels and countless hidden units within each of those layers, it is considered a member of the DNN family. The standard DBN technique is similar to the RBM technique in that it includes an output layer. Additionally, the DBN achieves its outcomes using a strong, greedy unsupervised learning technique to train RMB, and a supervised fine-tuning mechanism that adjusts the scheme using labeled data. The RBM is composed of two types of layers: visible and buried layers coupled with undirected weights. When RBMs are stacked in DBN, the RBM's hidden layer is chosen to be the visible layer of the subsequent RBM. This is because the RBM's hidden layer provides information about the subsequent RBM. RMB's variable sets are defined as $= (w, b, a)$, where w ij is the weight difference between v I and h j. The bias layers b I and a j must be identified.

Figure 2 displays the framework of DBN. The RBM defines equivalent energy as described as follows:

$$E(v, h \mid \theta) = -\sum_i b_i v_i - \sum_j a_j h_j - \sum_i \sum_j w_{ij} v_i h_j. \tag{15}$$

The joint likelihood distribution of v and h is defined below as follows:

$$p(v, h \mid \theta) = \frac{\exp(-E(v, h \mid \theta))}{\sum_{v,h} \exp(-E(v, h \mid \theta))}. \tag{16}$$

Here, the marginal likelihood distribution of v is established by

$$p(v \mid \theta) = \frac{\sum_h \exp(-E(v, h \mid \theta))}{\sum_{v,h} \exp(-E(v, h \mid \theta))}. \tag{17}$$

To gain an optimum θ value for a solitary data vector v, the incline of log probability approximation is evaluated by [23] the following:
Figure 2: DBN structure.

$$\frac{\partial \log\ p(v\,|\,\theta)}{\partial w_{ij}} = v_i h_{j\,\text{data}} - v_i h_{j\,\text{model}},$$

$$\frac{\partial \log\ p(v\,|\,\theta)}{\partial a_j} = h_{j\,\text{data}} - h_{j\,\text{model}}, \qquad (18)$$

$$\frac{\partial \log\ p(v\,|\,\theta)}{\partial b_i} = v_{i\,\text{data}} - v_{i\,\text{model}}.$$

Here, $\langle\bullet\rangle$ denotes expectation using the delivery of a specific subscript. Because of the lack of influences between units within the same layer, $\langle\bullet\rangle$ _data suggests that it may be obtained by measuring the conditional likelihood distribution by measuring the provisional likelihood delivery by

$$p\left(h_j\,|\,v,\,\theta\right) = \frac{1}{1 + \exp\left(-\sum_j w_{ij} v_i - a_j\right)},$$

$$p\left(v_i\,|\,h,\,\theta\right) = \frac{1}{1 + \exp\left(-\sum_j w_{ij} h_j - b_i\right)}. \qquad (19)$$

Due to the shape of the activation function, it is referred to as a sigmoid function. Contrastive divergence can be regarded of as a learning technique that approximates maximum likelihood. It calculates the divergence/differences between the positive phase (energy of first encoding) and the negative phase (energy of second encoding) (energy of the last encoding). To reduce the variation of two Kullback-Leibler divergences through renovation, the contrastive divergence (CD) learning module is used in the case of _model (KL). To begin, the CD learning is more efficient than Gibbs sampling in real-world applications and requires less processing time. Thus, weights in the DBN layer are taught using unlabeled data by unsupervised algorithms that are both fast and greedy in their information search. For predictions, the DBN uses the supervised layer to fine-tune the learned features using labeled data from the training set. The fully connected (FC) layer

is now the top layer, and the layers beneath it are activated using the sigmoid activation function.

3.3.2. Overview of SSA. The SSA is a novel SI method, which was established lately by [24]. The main concept behindhand in the SSA operator is that they simulate the swarming behavior of salp in deep oceans. Salp belonged to the species of Salpidae and contain transparent barrel-shaped bodies. They are related to jellyfishes in their tissue and motion. Moreover, they shift as the water is driven by the body as a force to move onward. The salp provides a novel 160 forms of swarm called a slapping chain while directing in the ocean. The salp chain behavior was numerically modeled by separating the population into groups depending upon leader and follower. The front of the chain is deliberated as the led 1 when the remaining salps are called as followers. The leader's part is to direct the swarm of salp, and all the followers follow the previous one. Related to the other SI techniques, the procedure of SSA imitates by initiating an arbitrary population of salp and later evaluates the fitness for every salp [25]. The slap with an optimal best fitness value is represented as a front-runner salp, whereas an additional slap is symbolized as a follower. The salp swarm algorithm (SSA) is a new stochastic algorithm inspired by salps' navigational and foraging abilities. However, higher dimension problems show a poor convergence rate for classical SSA. The SSA lacks exploration and exploitation, resulting in inefficient convergence. A salp's best fitness is found by exploring and exploiting the search space. The leader's salp location is modified based on the distance between the salp and food supply. The optimal performing slaps are represented as a food source to be chased using a salp chain. For updating the location of the slap chain, two major stages are determined: leader and follower phases.

The location of the leader is upgraded by equation (20) as follows:

$$X_j^1 = \begin{cases} X_{\text{Best}_j} + c_1\left(\left(ub_j - lb_j\right)c_2 + lb_j\right) \text{if } c_3 \geq 0.5, \\ X_{\text{Best}_j} - c_1\left(\left(ub_j - lb_j\right)c_2 + lb_j\right)\text{else}, \end{cases} \qquad (20)$$

where X_j^1 and X_{Best_j} represent novel location of leader and food source in *jth* dimension, and ub_j and lb_j represent upper and lower bounds of jth dimension, correspondingly. c_2 and c_3 denote arbitrarily created amounts in the range zero and one . The variable c_1 presents an important aspect in the SSA that controls the balance between exploration and exploitation. Moreover, c_1 gradually decreases by iteration as displayed in the following equation (21):

$$c_1 = 2e^{-(4t/T)^2}, \qquad (21)$$

where t specifies present iteration, and T denotes maximal amount of 152 iterations. Figure 3 exemplifies the flowchart of the SSA. For updating the location of follower, novel idea
Figure 3: Flowchart of SSA.

is presented where 185 is depending upon Newton's law of movement as in equation (22).

$$X_j^i = \frac{1}{2} g t^2 + w_0 t, \ i \geq 2, \tag{22}$$

where X_j^i denotes location of ith follower salp in j^{th} dimension. In the optimization procedure, the time t corresponds to the present iteration, 188, whereas g and w_0 indicate velocity and acceleration, correspondingly. In equation (22), the early speed w_0 is set to zero and the inconsistency is set 190 to one ($\triangle t = 1$); thus, the upgrading procedure of follower is equated in 191 equation (23).

$$X_j^i j = \frac{1}{2} \left(X_j^i + X_j^{i-1} \right). \tag{23}$$

3.3.3. Parameter Optimization of DBN Using SSA. For optimally regulating the hyperparameters of the DBN model, the SSA is used and the detailed working is provided in the following. The training process of the DBN model takes place using a fitness function [26–30]. In addition, 10-fold cross-validation (CV) process is utilized to evaluate the FF. Under 10-fold CV, the training dataset is randomly subdivided into a collection of ten equally exclusive subsets of nearly equal sizes, where nine subsets are used to train the data, and the remaining one is applied to test the data. These processes are repeated for a set of 10 iterations in such a way that each subset can be used to test the model. The FF is denoted as 1-$CA_{\text{validation}}$ of the 10-fold CV model in the training data, as defined in equation (24). Also, a solution with maximum $CA_{\text{validation}}$ leads to minimal fitness value [31–33].

$$\text{Fitness} = 1 - CA_{\text{validation}},$$

$$CA_{\text{validation}} = 1 - \frac{1}{10} \sum_{i=1}^{10} \left| \frac{y_c}{y_c + y_f} \right| \times 100, \tag{24}$$

where y_c and y_f indicate the true and false organization count. Finally, the hyperparameter involved in the DBN model is optimally picked up by the SSA, and also, the performance of classification gets improved.

4. Performance Evaluation

In this section, we validate the proposed model performance under several aspects. Table 1 investigates the performance of the feature selection techniques in terms of classification accuracy under different sets of training data and varying number of residuals [34, 35]. Figure 4 examines the result analysis of different feature selection techniques in terms of classification accuracy on 60% of training data. From the figure, it is depicted that the BCO-FSS model is found to be an effective method and it leads to maximum classification accuracy. For instance, under 200 residuals, the proposed BCO-FSS technique has accomplished a higher classification accuracy of 28.61%, whereas Pearson's correlation, chi-squared, and information gain techniques have resulted in a lower classification accuracy of 28.61%, 27.10%, and 25.18%, respectively.

Moreover, under 1000 residuals, the BCO-FSS technique has obtained an increased classification accuracy of 37.80%, whereas Pearson's correlation, chi-squared, and information gain techniques have attained a decreased classification accuracy of 34.78%, 32.68%, and 29.46%, respectively.

Figure 5 inspects the outcome analysis of different feature selection approaches with respect to classification accuracy on 75% of training data. From the figure, it can show that the BCO-FSS method is found to be an effective technique and it leads to maximal classification accuracy. For instance, under 200 residuals, the presented BCO-FSS manner has accomplished a higher classification accuracy of 43.24%, whereas Pearson's correlation, chi-squared, and information gain methods have resulted in a lesser classification accuracy of 40.39%, 36.26%, and 34.65%, correspondingly. Furthermore, under 1000 residuals, the BCO-FSS technique has gained an improved classification accuracy of 66.26%, whereas Pearson's correlation, chi-squared, and information gain techniques have achieved a reduced classification accuracy of 60.07%, 55.47%, and 52.19%, correspondingly.

Figure 6 investigates the result analysis of different feature selection methods in terms of classification accuracy on 90% of training data. From the figure, it can be stated that the BCO-FSS manner is initiated to be an effective approach and it leads to higher classification accuracy. For sample, under 200 residuals, the projected BCO-FSS method has talented a larger classification accuracy of 47.44%, while Pearson's correlation, chi-squared, and information gain techniques have resulted in a lower classification accuracy 43.88%, 39.55%, and

TABLE 1: Consequences of existing with future feature assortment methods on various training data size.

Classification accuracy on 60% training data			
Residuals	BCO-FSS	Pearson correlation	Chi-squared	Information gain
200	28.61	27.10	25.18	23.21
400	31.87	30.47	28.26	26.54
600	33.09	31.23	29.43	27.41

FIGURE 6: Classification accuracy analysis of the BCO-FSS model on 90% of training data.

33.29%, correspondingly. Also, under 1000 residuals, the BCO-FSS technique has attained a maximum classification accuracy of 74.18%, whereas Pearson's correlation, chi-squared, and information gain techniques have gained a lesser classification accuracy of 69.60%, 64.51%, and 59.61%, correspondingly.

If fewer than 60% of the training data are available, the suggested SSA-DBN model is compared to existing techniques in Table 2. Figure 7 displays an overview of the SSA-DBN model's sensitivity and specificity studies, which were conducted using the comparable methodologies. The LR model performed worse than the LR model, as seen in the figure, with a sensitivity of 74.335 % and a specificity of 75.025 %, respectively. It was expected that the RF model would produce a little better result, with a sensitivity of

TABLE 2: Results of existing with the proposed SSA-DBN on predicting cyberbullying with 60% training data.

Measures	NB	LR	RF	SVM	ANN	ANN-DRL	SSA-DBN
Accuracy	61.821	69.023	71.814	77.236	80.897	85.369	88.473
F-measure	72.674	72.965	73.045	73.325	77.876	83.588	86.901
G-mean	73.115	73.065	74.895	76.856	79.427	82.008	84.371
Sensitivity	80.657	74.335	74.825	76.506	76.976	83.598	85.728
Specificity	73.475	75.025	78.196	83.708	84.719	85.129	88.728
FIGURE 7: Sensitivity and specificity analysis of the SSA-DBN model on 60% training data.
FIGURE 8: Comparative analysis of the SSA-DBN model on 60% training data.

74.825 % and a specificity of 78.196 %, and the RF model did so. Furthermore, the SVM model displayed significantly improved performance, with a sensitivity of 76.506 % and a specificity of 83.708 %, respectively, compared to the baseline model. The ANN model also generated moderate results, with a sensitivity of 76.976 % and a specificity of 84.719 %, respectively, for the sensitivity and specificity tests. Aside from that, the NB model provided a tolerable outcome, as evidenced by its sensitivity of 80.657 % and specificity of 73.475 %, among other statistics. Additionally, the ANN-DRL model must yield competitive outcomes with 83.598 percent% sensitivity and 85.129 % specificity in order to be considered successful. But the proposed SSA-DBN model outperformed the competition, with sensitivity and specificity values of 85.728 % and 88.728 %, respectively, in the study.

Figure 8 offers a comparative analysis of the SSA-DBN with other classifiers in terms of accuracy, F-measure, and G-mean. The obtained results illustrated that the NB and LR models have attained a lower accuracy of 61.821 and 69.023, respectively. Next, the RF and SVM models have showcased moderately closer presentation with the correctness of 71.814% and 77.236%, respectively. In addition, the ANN and ANN-DRL techniques have showcased reasonable consequences with the correctness of 80.897% and 85.369%, correspondingly. However, the SSA-DBN perfect has outperformed the other methods with a maximum accuracy of 88.473%.
FIGURE 9: Sensitivity and specificity analysis of the SSA-DBN model on 75% training data.

On the following page, you will find a quick comparison of the given SSA-DBN approach to alternative strategies that use less than 75 % of the training data. Figure 9 displays a detailed sensitivity and specificity evaluation of the SSA-

TABLE 3: Results of existing with proposed SSA-DNN on predicting the cyberbullying with 75% training data.

Measures	NB	LR	RF	SVM	ANN	ANN-DRL	SSA-DBN
Accuracy	96.743	97.063	96.993	97.003	97.553	97.313	98.362
F-measure	61.281	62.901	63.491	63.891	65.242	65.552	70.466
G-mean	82.238	82.498	83.388	83.468	84.499	85.189	88.471
Sensitivity	68.593	69.583	70.074	70.394	72.614	73.315	79.063
Specificity	98.093	98.583	98.513	98.663	98.553	98.353	98.976
FIGURE 10: Comparative analysis of the SSA-DBN model on 75% training data.

DBN model, which was carried out utilizing comparative methodology. In this study, we discovered that the NB approach had lower sensitivity than the other methods (68.593 %) but greater specificity than the other methods (98.093 %). Additionally, the LR strategy produced somewhat better outcomes, with a sensitivity of 69.583 % and a specificity of 98.583 %, respectively, compared to the LR approach. Afterward, the RF algorithm displayed significantly improved performance, with a sensitivity of 70.074 % and a specificity of 98.513 %, respectively, compared to the baseline algorithm. The SVM model also performed well in terms of sensitivity and specificity, scoring 70.394 % and 98.663 %, respectively, for mild outcomes in the study. As an additional benefit of using the artificial neural network model, a tolerable outcome was achieved with a sensitivity of 72.614 % and a specificity of 98.553 %. At the same time, the ANN-DRL model aimed to exhibit competitive outcomes with 73.315 % compassion and 98.353 % specificity while also attempting to demonstrate competitive outcomes. However, the accessible SSA-DBN practice obtained optimal performance, with a compassion rate of 79.063 % and a specificity rate of 98.976 %, respectively, compared to the other practices tested in Table 3.

Figure 10 provides a comparative analysis of the SSA-DBN with other classifiers with respect to accuracy, F-measure, and G-mean. The attained outcomes showcased that the NB and RF methods have attained a lower accuracy of 96.743 and 96.993, correspondingly. Next, the SVM and LR techniques have depicted moderately closer performance

with the accuracy of 97.003% and 97.063%, correspondingly. Also, the ANN and ANN-DRL techniques have exhibited reasonable consequences with the correctness of 97.553% and 97.313%, respectively. However, the SSA-DBN perfect has outperformed the other techniques with a maximal accuracy of 98.362%.

With less than 90 % of the training data, the anticipated SSA-DBN model's performance is compared to the performance of other techniques, which is presented in detail in Table 4. According to the comparison methodologies used in this work, the SSA-DBN model's sensitivity and specificity were briefly evaluated (Figure 11). In the figure, it can be seen that the LR technique fared poorer than the other approaches, with a sensitivity of 92.766 % and a specificity of 99.583 %. Although the NB technique produced a little better results than expected (sensitivity 92.796 % and specificity 99.673 %), it did so in a more consistent manner. A similar improvement in performance was seen in the RF model, which had a sensitivity of 93.537 % and a specificity of 99.773 % when compared to the baseline model. The SVM model also showed moderate results, with a sensitivity of 93.697 % and a specificity of 99.803 %, respectively, according to the results of the study. In addition, the ANN model provided a tolerable outcome, with a sensitivity of 94.387 % and a specificity of 99.733 %, according to the results. As part of this effort, the ANN-DRL approach aimed to simultaneously exhibit competitive outcomes. The method's sensitivity and specificity were both 99.873 %, indicating that it was successful in demonstrating competitive outcomes. The new

TABLE 4: Results of existing with the proposed SSA-DNN on predicting cyberbullying with 90% of training data.

Measures	NB	LR	RF	SVM	ANN	ANN-DRL	SSA-DBN
Accuracy	99.503	99.633	99.623	99.673	99.563	99.703	99.983

G-mean	96.299	96.269	96.530	96.640	97.030	97.000	98.361
Sensitivity	92.796	92.766	93.537	93.697	94.387	94.418	96.037
Specificity	99.673	99.583	99.773	99.803	99.733	99.873	99.997
FIGURE 11: Compassion and specificity analysis of the SSA-DBN model on 90% of training data.
FIGURE 12: Comparative analysis of the SSA-DBN model on 90% training data.

SSA-DBN model, on the other hand, outperformed the prior model, with sensitivity and specificity values of 96.037 and 99.997 %, respectively, in comparison.

Figure 12 gives a comparative analysis of the SSA-DBN with other classifiers in terms of accuracy, F-measure, and G-mean. The attained results demonstrated that the NB and RF approaches have attained a lower accuracy of 99.503 and 99.623, respectively. In addition, the LR and SVM copies have showcased abstemiously closer presentation with the correctness of 99.633% and 99.673%, correspondingly. At the same time, the ANN and ANN-DRL manners have showcased reasonable consequences with the correctness of 99.563% and 99.703%, congruently. However, the SSA-DBN perfect has demonstrated the other algorithms with a higher accuracy of 99.983%.

5. Conclusions

In this post, we will describe a novel FSSDL-CBDC technique for detecting and classifying cyberbullying in social media, and how to apply it. The suggested FSSDL-CBDC technique consists of a number of phases, including preprocessing, feature selection, and classification, among others. Additionally, by creating the BCO-FSS approach to choose the optimal collection of features from the preprocessed data, the overall classification results are significantly enhanced. Figure 1 shows the BCO-FSS technique design. The SSA-DBN model receives and classifies the feature-reduced subset in the same time frame as the other models. When compared to the classic DBN model, the usage of the SSA to fine-tune the DBN model's hyperparameter resulted in improved outcomes when using the SSA. A large number of simulations on a benchmark dataset were carried out in order to assess the increased detection performance of the proposed FSSDL-CBDC technique, which was found to be effective. When compared to other state-of-the-art approaches, the simulation results revealed that the FSSDL-CBDC strategy performed significantly better in classification than the others. In the future, the performance of the FSSDL-CBDC technique may be enhanced by including outlier identification and feature reduction techniques in the algorithm. Unsupervised feature selection (FS) for outlier detection (OD) in streaming data (SD) for fields such as intrusion detection and network security, which are increasingly challenged with large amounts of high-dimensional data that must be analyzed in near real time.

With the rapid advancement of information technology, online information has been exponentially growing day by day, especially in the form of text documents such as news events, company reports, reviews on products, stocks-related reports, medical reports, tweets, and so on. Due to this, online monitoring and text mining has become a prominent task. During the past decade, significant efforts have been made on mining text documents using machine and deep learning models such as supervised, semisupervised, and unsupervised. Our area of the discussion covers state-of-the-art learning models for text mining or solving various challenging NLP (natural language processing) problems using the classification of texts. This paper summarizes several machine learning and deep learning algorithms used in text classification with their advantages and shortcomings. This paper would also help the readers understand various subtasks, along with old and recent literature, required during the process of text classification. We believe that readers would be able to find scope for further improvements in the area of text classification or to propose new techniques of text classification applicable in any domain of their interest.

1. Introduction

In recent years, we have seen a growth in the amount of digital textual data available, which has generated new perspectives and so created new areas of research. With the emergence of information technology, the monitoring of such digital textual data is of great importance in many areas such as the stock market: gathering data from news sources to forecast the movement of underlying asset volatility [1], forecasting the stock prices of green firms in emerging markets [2], understanding the impact of tone of communications on stock prices [3], and determining indicators for

stock prices volatility [4]; healthcare: disease surveillance [5, 6]; politics: developing a probabilistic framework on politics using short text classification [7]; education: understanding pedagogical aspects of the learners [8]; tourism: analyzing travelers sentiments [9]; and e-commerce: predicting success by evaluating users' reviews [10].

News is widely available in electronic format on the World Wide Web these days, and it has proven to be a valuable data source [11]. The volume of news, on the other hand, is enormous, and it is unclear how to use it most efficiently for domain-specific research. Therefore, a framework or architecture is required for a domain-specific

news monitoring system, as well as a classification mechanism for classifying relevant online news into distinct subject groups automatically [5]. News monitoring is a type of oversight system that monitors and ensures the quality of each news instance generated, used, and retained for a purpose. Processes for assessing news to guarantee its completeness, consistency, and correctness, as well as security and validity, are included in these methods. There is always a need for a methodology that can extract meaningful information from a pool of textual documents belonging to distinct subject groups intended for certain research as shown in Figure 1.

Indeed, the majority of the digital data are available in the form of text, but this is usually unstructured or semistructured [12]. Thus, to make data useful for decision-making, structuring this textual data became a necessity [13, 14]. However, because of the high volume of data, it is quite impossible to process the data manually. Text classification has evolved due to this challenge. It is defined as assigning the text documents to one or more categories (called labels) according to their content and semantics. Traditionally, the majority of classification tasks were used solved manually, but it was expensive to scale. Classification can be thought of as writing rules for assigning a class to similar text documents. These rules include some related information that identifies a class. Handwritten rules can be performed well, but creating and maintaining them over time requires much manpower. A technical expert can frame rules by writing regular expressions that could maximize the accuracy of the classifier. The existing studies have proposed various techniques to automatically classify text documents using machine learning [15, 16]. In this approach, the set of rules or criteria for selecting a classifier is learned automatically from the training data. Under each class, it requires a lot of training documents and expertise to label the documents. The labeling is a process of assigning each document to its associated class. The labeling process was easier than writing handcrafted rules. Moreover, there exist variously supervised and semisupervised learning techniques that can even reduce the burden of manual labeling [17, 18]. This can be performed using automatic labeling. Automated text classification methods can be divided into three groups: rule-based methods, data-driven methods, and hybrid methods.

Using a set of predefined rules, rule-based techniques classify text into various categories as shown in Figure 2. For example, the "fruit" label is applied to any document with the words "apple," "grapes," or "orange." These techniques require a thorough knowledge of the domain, and it is difficult to maintain the systems. Data-driven methods, on the other hand, learn to make classifications based on previous data values. A machine learning algorithm can learn the inherent associations between pieces of text and their labels using prelabeled examples as training data. It can detect hidden patterns in the data, is more flexible, and can be applied to different tasks. As the title indicates, hybrid approaches use a mixture of rule-based and machine learning methods (data-driven) for making predictions.
Figure 1: Monitoring and downloading relevant text documents to subject groups.
Figure 2: Labeling text documents with appropriate predefined classes or labels during the process of text classification.

In recent decades, models of machine learning have attracted a lot of interest [19, 20]. Most conventional models based on machine learning follow the common two-step method, where certain features are extracted from the text documents in the first step, and those features are fed to a classifier in the second step to make a prediction. The popular feature representation models are BOW (bag-of-words), TF-IDF (term frequency-inverse document frequency), and so on. And the common classifiers are naïve Bayes, KNN, SVM, decision trees, random forests, and so on. These models are discussed in detail in the following sections. Deep learning models have been applied to a wide variety of tasks in NLP, improving language modeling for more extended context [21–23]. These models are attempting, in an end-to-end fashion, to learn the feature representations and perform classification. They not only have the potential to uncover latent trends in data but also are far more transferable from one project to another. Quite significantly, in recent years, these models have become the mainstream paradigm for the various tasks of text classification. The following are some of the natural language challenges solved with the text classification.

Topic modeling is widely used to extract semantic information from text data. An unsupervised method of topic modeling learns the collection of underlying themes for a batch of documents as well as the affinities of each document to these topics.

News classification: online news reporting is one of the most significant sources of information. The task of finding and deriving structured information about news events in any text and assigning the relevant label is referred to as news classification.

Sentiment classification is an automatic technique of discovering views in text and classifying them as negative, positive, or neutral based on the emotions expressed in text. Sentiment classification, which uses NLP to evaluate subjective data, can help understand how people think about company's products or services.

Question answering has rapidly evolved as an NLP challenge that promises to deliver more intuitive means of knowledge acquisition. In contrast to the typical information retrieval approach of creating queries and perusing results, a question answering system simply takes user information requests stated in ordinary language and returns with a brief answer.

Language translation models have been attempting to translate a statement from one language to another resulting in perplexing and offensively inaccurate results. NLP algorithms through text classification may be trained on texts in a variety of languages, allowing them to create the equivalent meaning in another language. This approach is even applicable to languages such as Russian and Chinese, which have historically been more difficult to translate due to differences in alphabet structure and the use of characters rather than letters, respectively.

Nevertheless, it is observed that most text classification literature studies for solving NLP challenges are limited to showcasing the results of text classification using standard or state-of-the-art methods and focusing on specific research domains. For example, the authors mention the application of text analytics in the industry, but the task of monitoring and collecting text data was not detailed, and the scope of the proposed models appeared limited to particular domains [24]. In another study, the authors discuss the information extraction from tweets for monitoring trucks fleets to model truck trips, but it does not cover the feature selection or extraction methods to achieve information extraction [25]. Other studies [26, 27] focus on text classification for domain-specific search engine based on rule-based annotated data; however, it does not cover the semisupervised or unsupervised approaches of labeling data to achieve text classification [28]. Moreover, these works do not reveal the latest techniques being used in the area of natural language processing. The deep learning-based pretrained language representation model can be explored in information extraction and classification. These studies also lack in detailing the subtasks require to initiate the research in text classification, that is, data collection, data preprocessing, and semisupervised or unsupervised data labeling for training machine learning models. To the best of our knowledge, there are no similar

review studies available that cover in-depth presentations of various subtasks of text classification.

In this paper, we focus to overcome the above-mentioned issues. We put a lot of effort to create qualitative research for text classification to help us understand its subtasks or elements. Moreover, this paper presents the old and latest techniques used in each subtask of text classification as shown in Figure 3 along with their benefits and limitations. It also presents the research gap in the area of text classification by examining various existing studies. The key contribution of the study is mentioned below:

(i) Discussing the subtasks of text classification

(ii) Presenting the most recent and former techniques used in each subtask

(iii) Presenting benefits and limitations of various models used in the process of text classification

(iv) Presenting the research scope for further improvements in existing techniques and proposing new techniques with their application in different domains

Section 2 presents the process of text classification along with the comprehensive literature on each subtask; Section 3 presents the evaluation methods of classification techniques; Section 4 presents the comparison of approaches or models used in the subtasks of the text classification system mentioning their benefits and limitations; Section 5 presents the research gap and further scope for research; and Section 6 concludes the existing studies.

2. Text Classification: Framework

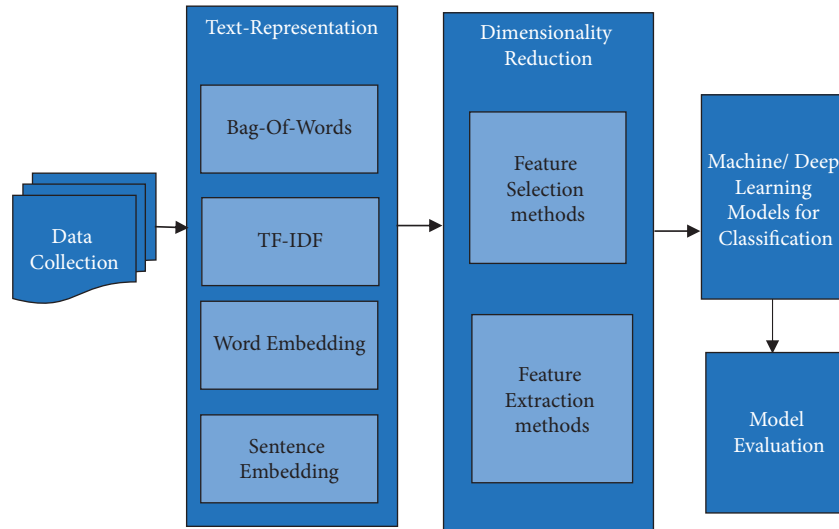
Text classification is a problem formulated as a learning process where a classifier is used to train to differentiate between predefined classes based on features extracted from the collection of text documents [29]. The accuracy of the classifier depends upon the classification granularity and how well separated are the training documents among classes [30, 31]. In text classification, a set of labels or classes are given, and we need to evaluate which class/label a particular text document relates to. Usually, a class or label is a general topic such as sports or business. But it may be significantly more difficult to distinguish between documents that are about more similar classes such as networks and the internet of things. Certain features represent the potential overlap between classes; the learning task would be simplified by removing such overlapping features. If the gap between classes could be increased, the classification performance would increase. This can be achieved through features weighting and selecting valuable features. Text classification has been studied and applied by many researchers in real-world scenarios such as sentiment classification of stock market news and its impact [31], news classification for syndromic surveillance [5], microblog topic classification [32], domain adaptation for sentiment classification [33, 34], and brand promotion based on social media sentiments [35, 36].


FIGURE 3: Subtasks of the text classification process cover state-of-the-art data collection, text representation, dimensionality reduction, and machine learning models for classifying text documents to an associated predefined class/label.

The text classification process is described as classifying a set of N documents; first, we build a classifier T. There is a collection of text documents D, and every text document is given a class/label by an expert. Secondly, we need to train a classifier for each class/label by giving input as a corresponding set of documents in D. Now we need to apply trained classifier C to classify N documents. We will get each document in N assigned to a predefined class/label by C. Text classification is a comprehensive process that includes not just model training but also several other steps including data preprocessing, transformation, and dimensionality reduction. The process starts with the collection of textual content from various sources. The textual content may be belonging to a domain(s) representing some events, business processes, or public information. Then these text documents require preprocessing to generate appropriate text representation for the learning model. This is done in two phases: in phase 1, the features are extracted from the processed text using any feature extraction algorithm, and in phase 2, the features are reduced by applying feature selection techniques. This reduction of features tends to decrease the dimensions of data required for the learning method. After these phases, the learning algorithms are chosen to train on data to generate the best classifier for recognizing a target category or class. This text data required to train a classifier is known as training data. The data is divided into two sets: the majority of data are taken for the training model, and the rest part of the data is taken for testing the classifier, known as testing data. Similarly, the model is trained to recognize each target class representing its data available in the associated text documents. During the testing phase, when a classification method is developed, it is executed on test data to define the target class of input text, and the result is produced in the form of weights or probabilities. Finally, the result is evaluated for its accuracy, of text classifier, using evaluation techniques. These are the main phases or subtasks of the text classification process, also shown in Figure 4. The

different approaches have been used in each phase of text classification discussed in the next subsections of the study.

2.1. Data Collection. The initial stage in text classification is to acquire text data from different sources as per the research domain. There are several online open data sets available, for example, various newsgroups (Bloomberg, Reuters, Financial Express), Kaggle, and WebKB for solving a classification problem. Researchers have used such database architecture for their research purposes [37–39]. The corpus can also be built with data that could be anything from emails, language articles, company's financial reports, medical reports, to news events. In the study, the authors have created a fine-grained sentiment analysis corpus for annotating product reviews. However, they faced the most challenging tasks that had not been targeted in applications such as sentiment analysis, target-aspect pair extraction, and implicit polarity recognition, for recognizing aspects and searching polarity with nonsentiment sentences [40].

2.2. Text Document Representation: Features Construction and Weighting. Text classification is the most demanding area of machine learning for understanding texts written in any natural language. One of the most essential tasks that must be completed before any classification process is text representation. Moreover, the texts cannot be provided as input to the machine learning models because almost all algorithms take input in numbers as feature vectors with a predefined size instead of the textual data with variable length. To resolve this issue, first textual data need to be transformed to document vectors. This can be done in two different ways in general. The first is a context-independent approach in which a document is represented as a set of terms with their corresponding frequency in the document, but they are independent of the sequence of terms in the collection. The second approach is to represent text as strings, with each
FIGURE 4: A text classification framework. Note: Black connecting lines represent training and blue connecting lines represent the testing phase.

document consisting of a sequence of terms. The following subtopic covers the various representations in natural language processing from the early days to the latest state-of-the-art models.

2.2.1. Context-Independent Approaches. The bag-of-words [41] is the most commonly used model in document transformation that considers every word in the text document as a token/feature although words' order and their context are ignored. Each word, sometimes tens or hundreds of dimensions, is represented by a real-valued vector called a one-hot representation [42]. The feature vector has the same length as the vocabulary size, and only one dimension is on as shown in Figure 5. However, the one-hot representation of a word suffers from data sparsity. On the other hand, the words with very high frequency may cause biases and dominate results in the model [44]. To overcome the weaknesses of BOW, the text documents are represented with weighted frequencies, a document-term matrix, where a column signifies a token and a row signifies a document. This scheme of assigning weights to token frequencies in the form of a matrix is called TF-IDF (term frequency-inverse document frequency). During the implementation of this model using a matrix, the value w_{ij} in each cell corresponds to the weight of t_j in d_i that is calculated as $tf\ \square t_j, d_i\ |\ n_{d_i}\square$, where $tf\ \square t_j, d_i\square$ represents the count of token t_j in text document and d_i and n_{d_i} represents the total quantity of token t_j in document d_i. Due to the simplicity of the model, this is preferably used in natural language processing. The improved features subset using this approach has been taken together with the characteristics of term frequency and document frequency [45–47]. However, even a small collection of

documents may consist of a large number of meaningful words that leads to the problem of scalability or high dimensionality. This offers opportunities to find effective ways to decrease running time or reduce high dimensionality in the case of a large number of documents.

The primary alternative has emerged in the form of statistical language modeling for modeling complex text classification or other natural language tasks. In its beginning, however, it used to struggle with the curse of dimensionality when studying typical probability functions of language models [48]. This led to the inspiration to learn distributed representations of low-dimensional space terms. The distributed representations describe a co-occurrence matrix of terms × terms that considers the frequency of each term that appears in the context of another term, with a window size of k [49]. The singular value decomposition was used for text representation, where the matrix decomposition technique was used for reducing a given matrix to its constituent matrices via an extension of the polar decomposition with the idea of making subsequent matrix calculations simpler. It gives the top rank-k constituent parts of the original data. The singular value decomposition will break this into best rank approximation capturing information from most relevant to least relevant ones [49].

The big popularization of word embedding was possibly due to the continuous bag-of-words (CBOW) paradigm to create high-quality distributed vector representations effectively. A solution is designed to counter the curse of dimensionality where a distributed representation for each word is concurrently studied along with the probability distribution for word sequences represented in terms of such representations [21]. The continuous bag-of-words is a prediction-based model that directly learns word

representation as shown in Figure 6(a). The distributed representations of context (or surrounding words) are combined in the CBOW model to predict the word in the middle. The CBOW has reshaped the word embedding [51]. The continuous bag of representation is applied with a neural network model to achieve improved accuracy in classification [52, 53]. Another model is designed called skip-gram that further reshaped the word embedding [54]; its architecture works in reverse of what the continuous bag-of-words model does. The model predicts each context word from the target word as shown in Figure 6(b). It iterates on the words of each sentence in the given corpus and uses the current word to predict its neighbors (its context); thus, the model is called "skip-gram" (local context window) [55].

Weighted words calculate document similarity directly from the word-count space, which takes longer to compute for large vocabularies. While counts of unique words give independent evidence of similarity, semantic similarities between words are not taken into consideration. Word embedding techniques solve this problem, but they are constrained by the need for a large corpus of text data sets for training. The word embedding algorithms were developed using the word and its closest neighbor. There was an approach suggested by authors for generating a word embedding GloVe (global vector, combines count- and predict-based methods) model for distributed word representation. The unsupervised learning algorithm, where a model is trained on overall statistics of word-word co-occurrence that how often it appears in a corpus, and the result obtains the vector representation of words with linear substructures of the word vector space [56]. GloVe's solution is to count how many times a term i (context word) in another term j (target word) occurs. The purpose is to establish a meaning for the word i and word j as to whether the two words occur close to N-word apart or not. The encoding vector includes the ratio of two words specifically recognized as a count-based system

of co-occurrence probabilities. The prediction-based approach receives popularity, but GloVe's authors claim that the count-based methodology incorporates the global statistics and may be more effective because it outperforms word representation testing on word comparison, term similarity, and called entity recognition tasks.

The enhanced text document representation system was developed to work on the issues of traditional feature-based extraction techniques that included only nouns and nouns phrases to represent the important events called event detection techniques [57]. This technique has used fewer tokens or features than bag-of-words to handle the problem of scalability or high dimensionality of documents. Furthermore, this technique has led to another representation based on named entities. The authors have presented the classification of tweets using named entity recognition to filter out noiseless required information [30, 58]. It works by finding proper nouns in the documents that belong to predefined categories. This process involves systematically assigning categories to each term or entity while developing a corpus or labeling process. But this corpus-based representation was unable to represent some domain-specific words that are infrequent during training. The authors have proposed techniques to deal with infrequent or unseen words during labeling [59].

Previous representations were not considering the morphological relation of words to disambiguate the unseen words. Many studies have presented methods that automatically extract features from the documents. These have used infrequent words that produce a high variety of low anticipated relations between the text documents. This kind of information once aggregated provides potentially less obvious and hidden relations in the text documents. Using less-frequent words with lexical constraints has reduced the associated cost of knowledge re-engineering, and it was able to process many documents from a large number of domains [59, 60]. These methods help for better representations of text documents especially handling unseen or less-frequent words. And the problem of scalability was also controlled and associated with word's semantical approach. There is another approach that was proven most efficient in a domain-specific text representation, *proper nouns*, an intermediate solution between noun phrases and named entities. This technique has reduced the ambiguity that occurred due to particular associated nouns with more than one named entity category [31]. Recent approaches are concentrating on capturing context beyond the word level to produce performance by giving a more structured and semantic notion of text [61].

2.2.2. Context-Aware Approaches. Context-aware classification approaches essentially find and employ term association information to increase classification effectiveness. They allow the presence or absence of a term to impact how it contributes to a classification outcome. Context is a concise term referring to high-level semantics. It may be taken in several ways and used in a variety of dimensions. We categorize context-based classification systems according to how
FIGURE 6: The word2vec algorithm uses two alternative methods: (a) continuous bag of words (CBoW) and (b) skip-gram (SG) [50].

the context was understood and what features were used to determine it.

The authors have come up with improved embedding for texts, such as *word2vec*, which transforms a word into an *n*-dimensional vector. To map the words into an Euclidean space, we can go through an approach to creating sequence embedding that brings a sequence into an Euclidean space. One of the sequential data function learning problems is called sequence embedding [62], where the aim is to convert a sequence into a fixed-length embedding. This approach is a highly strong tool for identifying correlations in text corpora as well as word similarity. However, it falls limited when it comes to capturing out-of-vocabulary words from a corpus. *RNN*-based models interpret the text as a sequence of words and are intended for text classification to capture word dependencies and text structures [63]. By adding a memory cell to remember values over arbitrary time intervals and three gates (input gate, output gate, and forget gate) to control the flow of information into and out of the cell, *LSTM* addresses gradient vanishing or exploding problems experienced by the RNNs. In a recursive method, the authors expand the chain-structured LSTM to tree structures, using a memory cell to store the background of multiple child cells or multiple descendants. They claim that the new model offers a realistic way to understand contact between hierarchies between long distances, for example, language parse structures [64]. To capture text features, the authors also incorporate a *bidirectional-LSTM* (Bi-LSTM) model with two-dimensional max-pooling [65]. The seq2seq model is used in various NLP applications [66, 67]. Most real-world problems have a data set with a substantial number of unusual words. The embeddings learned from these data sets are unable to produce the correct representation of the word. To do this, the data set needs to have a large vocabulary. Words that appear frequently help you create a large vocabulary. Second, when learning embeddings from scratch, the number of trainable parameters grows. As a result, the training process is slowed. Learning embeddings from scratch may also leave you confused about how the words are represented [68].

Pretrained word embeddings are the solution to all of the above difficulties. The studies have consistently shown the importance of transfer learning by pretraining a neural network model on an established problem in the field of computer vision and then doing fine-tuning utilizing the learned neural network as the foundation for a new purpose-specific model. It is demonstrated in recent years that a related approach may be effective in several tasks relating to natural language. This is another kind of word embedding; the classification algorithms provide a greater sense of learning the features of such embeddings. Yet such embeddings do not take the word order or the word meaning of each sentence into consideration. This is where *ELMo* (embedding from models of language) comes into action. ELMo is a contextual embedding that takes into consideration the terms that surround it. It models word use characteristics such as morphology and how it is used in different contexts. The term vectors are learned features of a deep bidirectional language model (biLM) internal state that is pretrained on a broad text corpus. The authors have demonstrated that these representations can be readily applied to current frameworks and greatly strengthen the state-of-the-art NLP issues such as addressing queries, textual entailment, and interpretation of emotions [62]. A Transformer [69] is another solution to working with long dependencies such as LSTM. LSTM is long short-term memory, a sort of neural network that has a "memory unit" capable of maintaining knowledge in memory over strong periods helping it to learn longer-term dependencies [22]. The Transformer is based through the encoder and decoder on an attention process as shown in Figure 7. The Transformer allows the use of this method to store knowledge about the specific meaning of a given term in its word vector.

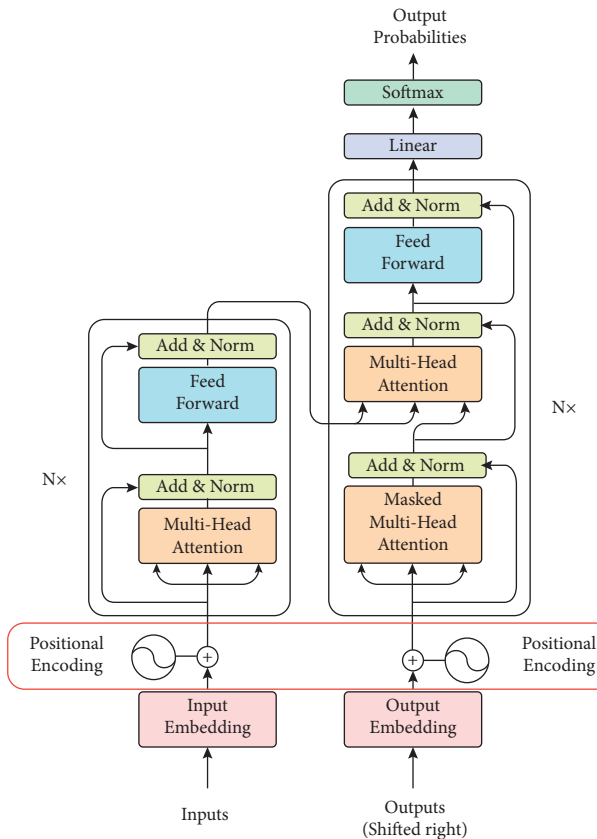
Unlike past deep contextualized language representation studies [62] that take into account the backward model as in the ELMo bidirectional LSTM, the authors proposed a new type of language representation named *BERT*, which stands for bidirectional transformer encoder representations. BERT uses a Transformer, a mechanism of *attention* that learns


Figure 7: The transformer architecture.

contextual connections between words (or subwords) in a document. The authors have argued that conventional technologies limit the power of the pretrained representations, especially for the approaches to fine-tuning [70]. The main constraint is the unidirectional existence of modern language models, which restricts the range of frameworks that can be used during pretraining. BERT is structured to pretrain profound bidirectional representations from unlabeled text documents by jointly conditioning across both layers in both the left and right contexts [71]. In setting language modeling, transformers can acquire longer-term dependence but are constrained by a fixed-length context. The authors suggested a novel Transformer-XL neural architecture that allows learning dependence to interrupt temporal coherence beyond a fixed length. It consists of a recurrence function at the segment level and a novel positional encoding scheme [69]. Learning regarding the inductive transfer has significantly impacted computer vision, but current techniques in NLP also need complex task modifications and preparation from scratch. The authors suggested universal language model fine-tuning (ULMFIT), an important transfer learning approach that can be extended to any NLP task, and implemented techniques that are essential to fine-tuning a model of language [72].

A total of 15% of the words in every sequence are substituted with a mask token before feeding word sequences into BERT. The model then tries to determine the actual context of the masked words in the list, based on the

context given by the other, unmasked, words. The BERT loss function only considers the estimation of the masked terms and excludes the estimation of the unmasked phrases. As a result, the model converges slower than directional ones, a feature offset by its enhanced understanding of the context. Centered on BERT's masking technique [71], the authors developed a novel language representation model enhanced by knowledge-masking technique named *ERNIE* (enhanced representation by knowledge integration) [73], which involves masking at the entity level and masking at the phrase level. Strategy at the entity level covers entities that typically consist of several terms. The phrase-level technique covers the whole phrase consisting of many words that serve as a cohesive entity together. Their experimental findings indicate that ERNIE outperforms other standard approaches by obtaining modern state-of-the-art outcomes on natural language processing activities, including natural language inference, conceptual similarity, named-entity identification, emotion analysis, and question answering. DistilBERT, a technique for pretraining a smaller general-purpose language representation model that can later be fine-tuned with high performance on a wide range of tasks like its bigger equivalents, is created. While most previous research focused on using distillation to build task-specific models [74, 75], this study uses knowledge distillation during the pretraining phase and demonstrates that it is possible to reduce the size of a BERT model by 40% while retaining 97% of its language understanding capabilities and being 60% faster [76].

The Transformer paradigm is generally popular in several tasks relating to natural language processing. Using a transformer is therefore also an expensive operation since it requires the method of self-attention. The Transformer employs an encoder-decoder design that includes stacked encoder and decoder layers. Two sublayers comprise encoder layers: self-attention and a positionwise feed-forward layer. Self-attention, encoder-decoder attention, and a positionwise feed-forward layer are the three sublayers that comprise decoder layers. Self-attention assumes we are conducting the task of attention on the sentence itself, as compared to two separate sentences. Self-attention allows defining the connection in a single sentence between the words. It is the function of self-attention that adds to the expense of utilizing a transformer. The quadratic structure of self-attention, however, constrains its operation on long text. Attention is described using the (query, key, and value) model. A query Q is a "context," and in previous equations, the prior concealed state is employed as the query context. Based on what we already know, we want to know what happens next. The value represents the features of the input. The phrase "key" is just an encoding of the word "value." To attract attention, the query's relevancy to the keys is established. The associated values that are unrelated to the query are then hidden. The authors follow a method of fine to coarse attention on multi-scale spans by binary partitioning (BP); they suggest *BP-Transformer*. BP-Transformer has a strong balance between the complexity of computations and the capability of models. The authors performed a series of experiments on text classification and language

processing, showing that BP-Transformer performs superior to previous self-attention models for long text [77]. The Binary-Partitioning Transformer attempts to boost the self-attention mechanism's usefulness by considering the transformer as a graph neural network. Any node in this graph represents an input token.

Another research suggests a variant of the Neural Attentive Bag-of-Entities, which is a neural network algorithm that uses entities in a knowledge base to conduct text classification. Entities include unambiguous and specific syntactic and semantic signs that are useful for catching semantics in documents. The authors put together easy high-recall dictionary-based entity recognition, with a neural attention system that helps the model concentrate on a limited number of unambiguous and specific entities in a text [78]. The model first identifies entities to whom this name might be addressed (e.g., Ap Inc., Apple (food)) and then describes the entity using the weighted average of all entities' embedding. The weights are measured using a modern method of neural attention that helps the model concentrate on a specific subset of entities that are less ambiguous in context and more important to the document.

It is the time for NLP when the transition started as we listed the unsupervised pretrained language models that had made breakthroughs in different tasks of understanding the natural language, such as named-entity identification, emotion interpretation, and question-answer records for art performance beginning one after another in that short period. These NLP models indicate that a lot more is yet to come, and the authors look forward to researching and implementing them. However, the authors proved that a single pretrained language model may be applied as "a zero-shot task transfer" to execute basic NLP tasks without the requirement for fine-tuning on a training example data set. While this was an encouraging proof of concept, the best case performance only equaled certain supervised baselines on a single data set. Performance on most tasks was still well behind even simple supervised baselines. Across one order of magnitude of scaling, the study found generally consistent log-linear trends in performance on both transfer tasks and language modeling loss. GPT-3 performs well on NLP tasks in the zero- and one-shot settings and, in the few-shot setting, is sometimes comparable with, and occasionally surpasses, the state of the art (although the state-of-the-art is held by fine-tuned models). This might imply that bigger models are better meta-learners [79].

GPT-3 approaches the performance of a fine-tuned RoBERT as a baseline on the "Challenge" version of the data set, which has been filtered to questions (multiple-choice questions on common sense reasoning collected from 3rd to 9th-grade science examinations) that standard statistical or information retrieval algorithms are unable to accurately answer. GPT-3 marginally outperforms the same fine-tuned RoBERT baseline on the "Easy" version of the data set. However, both of these findings are much inferior to MBART's overall SOTAs.

2.3. Data Preprocessing: Data Cleaning. There are a lot of text data available today, and data are being grown daily in

structured, semiunstructured, or fully unstructured forms. To perform the text classification task, it is always required to process the raw corpus data. There are many steps involved in data processing; generally, data cleaning, that is, organizing the data as per the structure and removal of unneeded subtexts; tokenization, that is, breaking up text into words; normalization, that is, converting all texts into the same case, removing punctuation (stemming leaves out root forms of the verb and lemmatization); and substitution, that is, identifying candidate words for translation, performing word sense disambiguation [80]. In one of the studies [81], the researchers have also focused on how machine learning techniques are needed to design to recognize similar texts when text data are downloaded from multiple and heterogeneous resources. In the labeling task, the text documents are labeled with two commonly used approaches; one is to label each part of the text individually, and the second is to label the group of texts. The first approach includes different supervised learning methods, and the second is called multi-instance learning [82, 83].

2.4. Data Preprocessing: Dimensionality Reduction. Dimensionality reduction is a crucial approach in data preprocessing for preparing data for text classification. It is done to reduce the classifier's memory requirements and execution time, hence increasing the learning model's efficiency and efficacy. The dimensions of data are increasing as the volume of data grows. To map large dimensions to space with low dimensions, it becomes necessary to reduce the dimensions of the data [84, 85]. The purpose of decreasing high-dimensional space is to find a subdimensional space that is less complex and can adjust the learning model to the greatest extent possible. In some cases, several researchers have noticed that the number of features in samples is substantially larger than the number of samples. This leads to a problem known as overfitting [86]. As a result, dimensionality reduction becomes necessary to avoid overfitting. Feature selection and feature extraction are two significant subtasks in lowering dimensionality. The process of supplying the part of the original attributes that are necessary for the task is known as feature selection. Feature extraction is a technique for changing space with many dimensions into a new space with few dimensions, to increase data variance [87].

2.4.1. Standard Feature Selection Methods. The following are the goals of the feature selection method:

(i) To improve the predictability of the classifiers

(ii) To create a cost-effective classifier while also speeding up the process

(iii) To improve the clarity of the data-gathering approach

The approach of finding a portion of the original attributes that are significant for the training set is known as feature selection. It is used to create an effective classifier while keeping important lexical properties in vocabulary [88]. It removes the noisy attributes that tend to reduce

accuracy [89]. The goal of feature selection is to decrease the feature space by picking a subset of Kay attributes and minimizing overfitting while maintaining text classification performance [90]. For instance, a feature or attribute set $X = \{X_1, X_2, \ldots, X_N\}$

When N is a group of feature sets, $2N$ feature subsets are created, each of which is represented by a vector of size N. The methods identify a feature subset of size K, $K < N$ without losing the accuracy of the full feature set. It has been the subject of investigation, and the writers have so far provided many techniques. Filter, wrapper, and embedded are the three types of approaches available [91, 92]. Filter-based feature selection offers several ways to evaluate the information value of each feature. The filter approach picks the top-N features based on the results of various statistical tests to identify a connection with the target label or to establish which attributes are more predictive of the target label, and it is independent of any learning algorithms. Because this technique ignores feature dependencies, it is computationally efficient. The wrapper technique evaluates a subset of features based on their utility to a given class. It uses a learning model to assess the subset of features based on their predictive power, but it is significantly very costly owing to repetitive learning and cross-validation. Embedded techniques are analogous to wrapper methods, except that they include feature selection during the training phase [93].

(1) Filter methods

Univariate Feature Selection. To determine the link between the features and the target variable, univariate feature selection evaluates each feature independently. Because they pertain to linear classifiers created using single variables, the following univariate feature selection methods are linear.

The filter approach chooses attributes without focusing on the core goal of improving any classifier's performance. To score the attributes, it uses the data's most important attributes. If d features or attributes are identified as S, the goal of a filter-based approach is to pick a subset of $m < d$ features, T, which maximizes some function F:

$$\tau^* = \operatorname{argmax}_{\tau \subseteq S} F(\tau), \text{s.t.} |\tau| = m. \tag{1}$$

It finally settles on the top-m rated features with the highest scores. This number is known as joint mutual information, and maximizing it is an NP-hard optimization problem since the number of potential feature combinations rises exponentially.

The following are the often used linear univariate filter techniques in text classification:

The *information gain* approach selects features based on the item's frequency concerning the class/label prediction. Researchers have demonstrated that by removing superfluous features without modifying the features, the approach may lower the vector dimensionality of text and enhance classification results [94]. It adds the most value when the text corresponds to a

certain label or class, and the word is also present in the document. It can be written as follows:

$$IG(t) = -\sum_{i=1}^{m} P(C_i) \log p(C_i) + p(t) \sum_{i=1}^{m} P(C_i \mid t) \log p(C_i \mid t)$$

$$+ p(\bar{t}) \sum_{i=1}^{m} P(C_i \mid \bar{t}) \log p(C_i \mid \bar{t}). \tag{2}$$

The utility of feature t in the classification is measured by this formula. If *IG* is higher than the prior value without the feature t, the current feature t is more relevant for classification. In other words, the discriminating power of the term t increases as the value of the information gain *IG* increases. Here, *IG* stands for information gain; C_i is the i-th class; $P(C_i)$ is the probability of an i-th class; and m is several target classes. $P(t)$ is the probability the feature t appears in the documents and the probability $P(\bar{t})$ for feature; t does not appear in the document. $P(C_i|t)$ is the conditional probability of the feature t appearing in i-th class. $P(C_i \mid \bar{t})$ is the conditional probability of the feature t that does not appear in i-th class.

The *Chi-square test* is a statistical strategy for assessing the relationship between a set of categorical features using their frequency distribution and determining how much the findings differ from the predicted output [95, 96]. This may be determined given events A and B, which are considered to be independent if

$$p(AB) = p(A)p(B). \tag{3}$$

The occurrence of the term and the occurrence of the class are the two events in feature selection. The terms are then ranked according to the following value. Chi-square can be calculated from the following equation:

$$\text{CHI}^2(t, C) = \sum_{t \in \{0,1\}} \cdot \sum_{C \in \{0,1\}} \frac{\left(N_{t,C} - E_{t,C}\right)^2}{E_{tC}}, \tag{4}$$

where t denotes the feature, C denotes the specific class, $N_{t,C}$ is the frequency of feature t and class C occurring together, and $E_{t,C}$ is the frequency of feature t occurring without class C. The chi-square between each feature and class is computed, and the features with the highest chi scores are chosen.

Fisher score calculates the variance of the predicted value from the actual value to get the information score or how much knowledge one variable has about the unknown parameter on which the variable depends, and when the variance is the smallest, the information score is the highest. For a support-vector-based feature ranking model, researchers employed Fisher's linear discriminant [97–99].

For instance, let μ_j^k and σ_j^k be the mean and standard deviation of the k-th class, concerning the j-th feature.

Let μ^j and σ^j represents the mean and standard deviation of the entire training data concerning the j-th feature. The Fisher equation for determining the j-th feature's score is stated as follows:

$$F\left(x^j\right) = \frac{\sum_{k=1}^{c} n_k \left(\mu_k^j - \mu^j\right)^2}{\sigma_j^2}, \tag{5}$$

where σ_j^2 is computed as $\sum_{k=1}^{c} n_k (\sigma_k^j)^2$. Top-$m$ features with higher fisher scores are chosen by the algorithms.

Pearson's correlation coefficient is used to measure linear dependency between two continuous variables by dividing their co-variance by the product of their standard deviation, and its value ranges from -1 to $+1$. In two variables, a–1 value signifies a negative correlation; a +1 value shows a positive correlation; and a 0 value represents no linear association [93].

Using vectors, Pearson's coefficient r can be computed as follows:

$$r = \frac{\left(x_1 - \overline{x}_1 L\right)\left(x_2 - \overline{x}_2 L\right)}{\left(|x_1||x_2|\right)}, \tag{6}$$

where $\overline{x}_1$ is the mean of the vector x_1 and similarly for x_2, L is the vector of 1s, and $|x|$ is the magnitude of vector x.

Variance threshold is a technique for reducing vector dimensionality by deleting all low-variance features. Features that have a lower training-set variance than the threshold will be deleted [100, 101].

$$s = \frac{\sqrt{\sum \left(x_i - \overline{x}\right)^2}}{(n-1)}. \tag{7}$$

The equation may be used to find features that have a variation below a given threshold. When the feature does not vary much within itself, it is seen to have low predictive potential.

Multi-Variate Filter Methods. During the assessment of the multi-variate filter selection approach, the interdependencies of features are also taken into account to choose relevant features.

It is based on mutual information that discovers the features in a feature set with the highest dependency with the target label. However, it is not appropriate for use when the goal is to achieve high accuracy with a small number of features.

Alternatively, it may utilize max relevance, which detects features with a dependency by averaging all mutual information values between all features x_i and target label c. S refers to features, and I represents mutual information; in the following equation, it is calculated between feature i and class c:

$$\max D\left(S, c\right), D = \frac{1}{|S|} \sum_{x_i \in S} \left(I\left(x_i; c\right)\right). \tag{8}$$

However, this results in a high level of redundancy, that is, a higher level of a dependency across features. As a result, to locate mutually exclusive features, minimum redundancy can be used [102].

$$\min R\left(S\right), R = \frac{1}{|S|^2} \sum_{x_i, x_j \in S} I\left(x_i, x_j\right), \tag{9}$$

where $I(x_i, x_j)$ is the mutual information between feature i and j.

Multi-Variate Relative Discriminative Criterion. The author offers a multi-variate selection strategy that takes into account both feature relevance and redundancy in the selection process. The RDC is used to assess the relevance, whereas Pearson's correlation is used to assess redundancy between features [103]. This measure boosts the rankings of terms that are exclusively found in one class or whose term counts in one class are much higher than in the other.

$$\mathrm{RDC}\left(w_i, tc_j(w_i)\right) = \frac{\left(\left|df_{\mathrm{pos}}(w_i) - df_{\mathrm{neg}}(w_i)\right|\right)}{\min\left(df_{\mathrm{pos}}(w_i), df_{\mathrm{neg}}(w_i)\right) * tc_j(w_i)}, \tag{10}$$

where $df_{\mathrm{pos}}(w_i), df_{\mathrm{neg}}(w_i)$ are the collection of positive and negative text documents, respectively, in which the term w_i is occurred. The word may be repeated several times in specific documents and represented by $tc_j(w_i)$. Instead of adding together RDC values for all term counts of a term, the area under the curve (AUC) for a difference graph is treated as term rank.

Researchers have been looking for novel approaches to increase classification accuracy while also reducing processing time. The author has provided a differentiate feature selector, a filter-based strategy that has picked unique features that have term properties while eliminating uninformative ones [92]. It provided efficiency by reducing processing time and improving classification accuracy.

(2) Wrapper Methods. Wrappers' approaches are bound to a certain classifier; the methods choose a subset of features based on their influence on the classifier by assessing the prediction performance of all potential feature subsets in a given space. It signifies that the features subset will be assessed by interacting with the classifier, which will improve the classification technique's accuracy. As the feature space expands, the computing efficiency suffers as a result of this method. Wrappers are used to choose features for other models as filters. The procedure may be accomplished in three ways: the first methodology employs a best-first search technique; the second methodology employs a stochastic approach such as random selection; and the third

methodology use heuristics such as forward and backward passes to include and omit features.

Multi-Variate Feature Selection. Univariate feature selection approaches are computationally efficient, but they eliminate features owing to a lack of interaction between features that, when combined, may have offered important information regarding classification [104, 105]. When evaluating the performance of features, multi-variate takes into account the interdependencies between them. "Linear multi-variate" employs linear classifiers made up of a subset of features, with the score of feature subsets being calculated based on classification performance. Nonlinear multi-variate, on the other hand, use nonlinear classifiers to complete the task.

The following are the most often used *linear multi-variate wrapper* approaches in in-text classification:

Recursive Feature Elimination. It is a recursive strategy that ranks features according to a key measure. During each cycle, the significance of features is assessed, and less relevant features are removed. To design ranking, the opposite process is utilized, in which features are rejected. From this rating, this technique extracts the top-N features [106]. This is a greedy optimization that seeks the highest performing feature subset.

Forward/Backward Stepwise Selection. It is an iterative procedure that begins with the examination of each feature and picks the one that produces the best performing model, based on some predetermined criteria (like prediction accuracy). The next step is to examine every potential combination of that selected feature and the following feature, and if it improves the model, the second feature is chosen. The model continuously appends the list of features that best improve the model's performance in each iteration until the requisite features subset is picked. In the backward feature selection approach, the method starts with the whole collection of features and discards the least relevant feature in each iteration, improving the method's speed. This method is repeated until no improvement is shown when features are removed, and the best subset of features is found. In comparison to other techniques, the researcher developed a rapid forward selection methodology for picking the optimal subset of features that required less computing work [107].

The *Genetic Algorithm* uses a feature set to generate a better subset of features that are free of noise. At each step, a new subset is formed by picking individual features in the correct sequence and merging those using natural genetics procedures. The result is cross-validated variance divided by the percentage of right predictions. The end outcome may be mutated. This procedure aids in the creation of a feature set of individual features that are more appropriate for the model than the initial feature set. The chaotic genetic algorithm was designed to simplify the feature

selection procedure and improve the classification technique's accuracy [108, 109].

The commonly preferred *nonlinear multi-variate wrapper* methods in the text classification are discussed as follows:

Nonlinear kernel multiplicative updates entail iteratively training a classifier and rescaling the feature set by multiplying it by a scaling factor that lowers the value of less impacted features. Nonlinear techniques can outperform linear algorithms by selecting a subset of features [110].

Relief is based on instance-based learning. Each feature receives a value ranging from −1 to +1 based on how well it matches the desired label. The algorithm's scope is binary-classification-compatible [111, 112].

(3) Embedded Methods. In terms of computing, "embedded methods" outperform wrappers, but they conduct selection features as a subpart of the learning methodology, which is primarily exclusive to the learning model and may not function with any other classifier.

The commonly preferred embedded methods in the text classification are discussed as follows:

In social sciences, the *LASSO* method is generally used [113]. To alleviate the dimensionality problem, it penalizes features with large coefficients by inserting a penalty during the log-likelihood maximization procedure. By picking a correct weight and reducing dimensionality, LASSO assigns zero to some coefficients. When there is a strong correlation between some features, it creates a difficulty [114].

Ridge Regression lowers the complexity of a model by reducing coefficients while keeping all of its features. The issue with ridge regression is that features are retained. If the feature collection is huge, the problem remains complicated [115].

Elastic Net calculates a penalty that is a mix of LASSO and ridge penalties. The elastic net penalty may be readily handled to give LASSO or ridge penalties extra power. It has a grouping effect, with high correlation features tending to be in or out of the feature subset. It incorporates both L1 and L2 regularization techniques (LASSO and ridge). By fine-tuning the settings, it aids in the implementation of both strategies [116].

2.4.2. Text Feature Extraction Methods. After selecting the features and representing N documents by d-dimensional features *vectors* $\{X_1, X_2, \ldots, X_N\}$. Sometimes original terms in the form of features may not be optimal dimensions for text document representation. The text feature extraction methods try to solve these problems by creating new feature space Y or artificial terms [117]. It requires (a) a method to convert old terms to new terms and (b) a method to convert document representation from old to new. A popular example commonly used for this purpose is principal component analysis (PCA) in which a feature set Yi is selected in a manner that the variance of the original feature vectors is maximized in the direction of new feature vectors. This is

done by computing eigenvectors of the covariance matrix of the original vectors. The drawback of the PCA is the time it takes to evaluate eigenvalue decomposition to compute the principal component for each class/label when applied to a large data set. This is overcome by the researcher by using the power factorization method (PFM) to find a fixed quantity of eigenvectors from a data set [118]. Another commonly preferred method for feature extraction is latent semantic indexing (LSI) that uses singular value decomposition of the term correlation matrix computed from a large collection of text documents. This technique is used to address the problem of deriving from the use of synonymous and polysemous words as dimensions of the text document representation. But the disadvantage is to compute the correct number of latent components that proves computationally expensive. Another method that helps for optimal discrimination of data is linear discriminant analysis (LDA) [99]. It identifies the linear collection of features that best explain the data. It tries to find the model that can explicitly differentiate between the classes of data. Latent Dirichlet allocation is another method that explains that each text document is a mixture of latent topics and each word in that document is attributable to one of the topics of that document. This is most preferred for topic modeling [119]. This is a generative probabilistic model.

A newer approach is a simplified version of stochastic neighbor embedding that creates much better visuals by eliminating the potential to cluster points together in the map's centers known as t-SNE. It visualizes high-dimensional data by assigning a two- or three-dimensional map to each data point. When it comes to constructing a single map that displays structures of several sizes, t-SNE outperforms previous approaches. On almost all of the data sets, the analysis shows that t-SNE produces visuals that are much superior to those produced by the other approaches [120]. Furthermore, the authors provide a technique UMAP (uniform manifold approximation and projection) that is comparable to t-SNE in terms of visualization quality and, in certain ways, retains more of the global structure while providing better run time efficiency [121]. It is based on Laplacian eigenmaps as a mathematical foundation. Umap can scale to far bigger data sets than t-SNE. It is a general-purpose dimension reduction strategy for machine learning since it has no computational constraints on embedding dimensions. The approach is used in the study to evaluate the uniqueness of subjects, important phrases and features, information dissemination speed, and network behaviors for COVID-19 tweets and analysis [122]. To increase the detection of relevant themes in the corpus and analyze the quality of created topics, they use UMAP, which finds distinctive clustering behavior of separate topics [120]. Another study used UMAP to depict the matching word vector spaces of a pretrained language model using LaTeX mathematical formulations. In the LaTeX formula domain, they develop a state-of-the-art BERT-based text classification model augmented by unlabeled data (UL-BERT) [123].

2.5. Classifiers for Classification Task.

The classifier is trained based on the selected features from the text documents. The selection of appropriate features in feature space decides the performance of learning models. Machines understand numbers more easily than texts as input. So texts as tokens are required to be converted into numbers (vectorization) for most of the learning algorithms. Vectors are combined to originate vector space to apply statistical methods for checking document relatedness. Each algorithm offers a different document representation for text classification. Researchers offer several classification methods that work on the vector representation of texts. The basic assumption for vector representation of texts is known as the contiguity hypothesis. It states that text documents belonging to the same class develop a contiguous region and regions of different classes do not overlap. The relatedness of the documents can be evaluated on 2D space based on cosine similarity or Euclidean distance.

The authors have presented naïve Bayes, a linear classifier, approach to vectorize the text documents according to probability distribution with two commonly used models: multi-variate Bernoulli event and multi-nomial event; the features with the highest probability were chosen to reduce the dimensionality [124].

$$PC_k|d_i = Pd_i|C_k * \frac{P(C_k)}{P(d_i)}. \quad (11)$$

The output of the classifier is the probability of the text document d_i is belonging to each class C_k, and it is a vector of C elements. In a way of text classification scenario, we could compute $Pd_i|C_k$ using bag-of-words as follows:

$$Pd_i|C_k = P(BoW(d_i)|C_k) = Pw_{1,i}w_{2,i},,,w_{|V|,t}|C_k. \quad (12)$$

The problem can be reduced to compute the probability of each word $w_{j,i}$ in class C_k as follows:

$$Pd_i|C_k = \prod_j^{|V|} Pw_{j,i}|C_k. \quad (13)$$

The naïve Bayes has a high bias for a nonlinear problem because it can model one type of class, that is, a linear hyperplane. The bias is the statistical method of evaluating the performance of a classifier that how accurately a classifier classifies the texts into the correct class with less error. The learning task is the last activity in classification, but reducing the feature dimensions is more concerned with the efficiency of the classifier model. The possibility of salient feature reduction caused by using classifiers can be overcome by using the model SVM that identifies the best decision-boundary between feature vectors of the document with their categories [125]. The SVM entails an optimal classifier that guarantees the lowest classification error. The SVM computes a hyperplane that falls between the positive and negative example of the training set.

$$D = \left\{ (x_i, y_i) \middle| x_i \in R^D, y_i \in \{-1, 1\} \middle| \right\} i =_i^n, \quad (14)$$

where the minus sign represents the negative hyperplane, the positive sign points to the positive hyperplane, i ranges from 1 to L (training examples), (x_i, y_i) represents feature vectors of each document, R^D is a vector space having a dimension of D. and D is evaluated to +1 and −1 for positive and negative hyperplanes, respectively.

The naïve Bayes itself results in the best classification model if it is trained on a high volume of data. However, feature reduction remains an issue. So naïve Bayes is used as a prestep to SVM that converts text documents into vectors before the classification task starts. This resulted in improving the whole system while spending quite an appropriate classification time by reducing to low-dimensional space. But, in certain cases, the majority of features are redundant with each other; the author has presented a divergence-based feature selection method without relying on a complex dependence model where the maximum marginal relevance-based feature selection was outperformed by the SVM [126]. The paper has suggested the need for novel criteria to measure the relevance and novelty of features separately and provided the linear combination as the metric.

The studies have mentioned the KNN, a nonlinear classifier, where the algorithm classifies the document by moving through all the training documents that are like that document. The KNN model frames the documents in the Euclidean space as points so that the distance between two-point u and v can be calculated as follows:

$$D(u, v)^2 = u - v^2 = (u - v)^T (u - v) = \sum_{i-1}^{d} (u_{i-} v_i)^2. \quad (15)$$

The classifier finds the K-value that is the factor that represents a collection of documents from all the documents closest to the selected document in that space [127]. If there are too many features, KNN may not operate effectively. As a result, dimensionality reduction techniques such as feature selection and principal component analysis may be used.

$$\hat{y}(x) = y_{n^*} \quad \text{where} \quad n^* = \arg \min_{n \in D} \text{dist}(x, x_n). \quad (16)$$

The study mentions that using KNN increases the overhead to calculate the K-value of all the documents with all other training documents with the largest similarity or closet to the selected document. Also, the variation in the number of training sample documents in different categories leads to a decline in accuracy. Due to the high variance and complex regions between classes, it becomes sensitive to noise documents. Sometimes, the document tends to misclassify if it occurs very relevant to a noise document in the training set and sometimes accurately classified if there is no presence of noise documents in the training set close to them. This ends up in high variance from the training set to the training set. High variance leads to overfitting. The goal of finding a good learning classifier is to decrease the learning error. Learning error is calculated from bias and variance or bias-variance trade-off. The traditional algorithms possess some limitations that attract the researchers to improve the efficiency by (a) reducing the computational overheads by establishing low-dimensional space, (b) speeding up the computational capacity of finding nearest neighbors in KNN or locating decision boundaries in SVM, and (c) increasing efficiency by not compromising accuracy [128]. The model is chosen that optimizes the fit to the training data.

$$H^* = \arg \max_{H} \text{fit}(H|D). \quad (17)$$

The supervised learning classification algorithms such as naïve Bayes, SVM, and KNN use a bag of words to design a classifier. None of these methods take the order of words into consideration that can lead to the loss of some valuable information. In natural-language-based problems, the order of the words, for example, multi-words, has a meaning (like names of organization or person) that is not considered by the learning models trained on individual words of the texts. The algorithm n-grams consider the sequence of n-adjacent words from the selected text phrases. The n-grams behave like the individual word's representation as feature vectors. The value of n may range from 1 to the upper value [129]. This proves very beneficial in short text documents where the number of n-grams is less in number [89]. The author proposes another representation for character n-grams to introduce the enhancement of the skip-gram model, which considers subword into account. It considers the word morphology while training the model, and words are represented by the sum of its character n-gram [55].

Many researchers have used a decision-tree-based algorithm (decision support tool) that represents a tree-structure-based graph of decisions [130]. The commonly used decision tree algorithms are ID3, C4.5, and C5. The algorithm presents each intermediate node (labeled as terms and branches represent weight) that can split into subtrees and ends at leaf nodes (represents the class/label/outcome of the problem). Decision tree structures are rule-based solutions. A rule can be designed by forming a conjunct of every test that occurs on the path between the root node and the leaf node of the tree. The rules are formed after traversing every path from a root to the leaf node. Once the decision tree and rule are framed, it helps assign the class/label for a new case [129, 131]. It was evaluated in the study that decision trees result better than naïve Bayes in terms of accuracy but a little worse than KNN methods [132]. As a result, the authors introduce the boosting data classification approach. The boosting algorithm is a method for combining many "poor" classifiers into a single, powerful classifier. The boosting technique is used on decision trees in the study, and the boosted decision tree performs better than an artificial neural network [133]. It is expected to find widespread use in a variety of fields, particularly text classification. Gradient tree boosting is another boosting strategy that builds an additive regression model using decision trees as the weak learner. Trees in stochastic gradient boosting are trained on a randomly selected portion of the training data and are less prone to overfitting than shallow decision trees [134].

Neural networks or deep learning systems use several processing layers to learn hierarchical data representations and have reached state-of-the-art outcomes in most domains. In the sense of natural language processing (NLP), several model designs and approaches have recently

progressed. In areas such as computer vision and pattern recognition, deep learning architectures and algorithms have also made remarkable progress. Recent NLP research is now primarily focused on the application of new deep learning approaches, continuing this development. In areas such as computer vision and pattern recognition, deep learning architectures and algorithms have also made remarkable progress. Recent NLP research is now primarily focused on the application of new deep learning approaches, continuing this development. The performance of word embedding and deep learning strategies referred to in the following section is driving this development.

In the late 90s, the researcher found an application of nonlinear neural networks to text classification or topic modeling [135]. In this model, a three-layered neural network was designed to learn a nonlinear mapping from training documents to each class/label. Later on, the researcher proposes convolutional neural network (CNN) for text classification by considering the order of words in the phrases, and this outperforms SVM in terms of error rate [136]. CNN uses the vector representation of text data considering the order of words. Each word is considered a pixel, and the document is treated as an image. Then the image is taken into $|D| \times 1$ pixels, and each pixel represent a word as a $|V|$ dimensional vector. For instance, vocabulary $V = \{$"classification", "course", "I", "love," "NLP'," "text"$\}$, and words are taken as a dimension of vectors in alphabetical order. And document $D = $ "I love NLP course". Then the document vector would be $X = [0010000 \mid 000100 \mid 00001 \mid 010000]$.

The researcher mentions that to reduce the dimensionality of vector space, the vocabulary size must be kept low. Also, the n-gram algorithm ignores the fact that some n-grams share the constituent words; this is overcome by CNN that learns the embedding of text regions by providing CNN with the constituent words as input, and this technique provides higher accuracy. To construct an informative latent semantic representation of the sentence for downstream activities, CNNs have the potential to extract salient n-gram features from the input sentence. The author proposes a three-way enhanced CNN for classification for sentiment analysis, where decisions are divided into three parts accept, reject, and delay. The instances in boundary regions that are neither in accept nor reject are reclassified by another classification model. This guarantees the enhancement in CNN to deal with boundary regions in a better way, resulting in model 3W–CNN [137]. Another study has shown the application of CNN in document modeling for personality detection based on text in the context of sentiment analysis [34]. Overall, in contextual windows, CNNs are highly successful in mining semantic hints. They are very data-heavy models, though. They have a huge range of parameters that are trainable and need tremendous training data. This raises a concern as data shortage happens. Another unresolved concern with CNNs is their failure to model contextual long-distance data and maintain sequential order in their representations [138].

Deep neural networks are difficult to train on data; it requires a lot of resources to get high performance. The feed-forward neural network commonly known as multi-layer perceptron (MLP) is the most preferred technique in

classification problems. In a feed-forward neural network, the information travels in one direction from the input layer to hidden layers and then followed by the output layer. They have no memory of the input received previously so lack in predicting what comes next. To overcome this, RNN (recurrent neural network) is preferred where information moves through the loop. In this paragraph, we discuss the fundamental characteristics that have favored the popularization of RNNs in a variety of NLP tasks. Since an RNN performs sequential processing in sequence by modeling units, it may have the ability to generate the intrinsic sequential structure present in language, where characters, words, or even phrases are units. Based on the previous words in the sentence, words in a language establish their semantic meaning. The disparity in interpretation between "computer" and "computer vision" is a clear example that states this. RNNs are perfect for language and related sequence modeling activities to predict certain context dependencies, which turned out to be a clear incentive for researchers to use RNNs over CNNs in these fields.

RNNs were originally three-layer networks in the NLP sense [139]. While deciding on the current input layer, it considers what it has learned from the previous inputs. Basically, in the architecture of simple RNN, the hidden units create internal representations for the input patterns and recode these patterns in feed-forward networks using hidden units and a learning algorithm in a way that allows the network to generate the appropriate output for a given input. Typically, the hidden state of the RNN is assumed to be the most important feature. It can be regarded as the memory portion of the network that accumulates data from other steps.

The formula of the current state in RNN can be written as mentioned below. A nonlinear transformation such as tanh, or ReLU, is taken to be the function f.

$$h_t = f\left(h_{t-1}, x_t\right), \tag{18}$$

where h_t is the new state, h_{t-1} is the previous state, and X_t is the input at time t.

The tanh function is commonly used as an activation function. The weights can be defined as the matrix W_{hh}, and input is defined by the matrix W_{xh}:

$$h_t = \tan h\left(W_{hh}h_{t-1} + W_{xh}X_t\right). \tag{19}$$

The output can be calculated during test time as follows:

$$y_t = W_{hy}h_t. \tag{20}$$

The output is then compared to the actual output, and then the error value is computed. The network learns by backpropagating the error through the network to update the weights. But usual RNN has a short-term memory. These basic RNN networks suffer from the issue of vanishing gradient, which makes it very difficult to understand and adjust the parameters of the previous layers in the network. It is used in combination with LSTM, which has long-term memory, and it gives an extension to the memory of the usual RNN. Over the basic RNN, LSTM has additional "forget" gates, allowing the error to backpropagate over an

infinite amount of time steps. Comprising three gates: input, forget, and output gates, taking a combination of these three gates, it determines the hidden state [22]. The applications based on RNN and LSTM have been used in solving many NLP problems due to their capacity of capturing complex patterns within the text [140]. It has also been used in sequence labeling tasks in POS (part of speech) activity. It is preferably used in topic modeling for fake news [141, 142], sentiment analysis [143, 144], and negative speech detection on social media. More recently, authors have suggested another type of recurrent unit, which they refer to as a gated recurrent unit (GRU) [145]. It has been shown that RNNs employing any of these recurrent units perform well in tasks (such as machine translation, speech recognition, or depending parsing in text documents for NER) requiring long-term dependency capture. The application of gated RNN is not limited to the mentioned tasks, but it can be applied to different NLP challenges [146]. GRU is a form of recurrent neural network (RNN) that can process sequential data using its recurrent architecture. The fundamental issue in text classification is how to improve classification accuracy, and the sparsity of data, as well as semantics sensitivity to context, frequently impedes text classification performance. The study introduces a unified framework to evaluate the impacts of word embedding and the gated recurrent unit (GRU) for text classification to overcome the flaw [147].

Recurrent neural networks, in particular long short-term memory [22], and gated recurrent neural networks [62] are firmly known as state-of-the-art approaches in sequence modeling. Within training examples, the inherently sequential nature of recurring models prevents parallelization, which becomes important at longer sequence lengths, as memory limitations restrict batching through examples. Recent work, through factorization tricks [148] and conditional computation [149], has achieved substantial improvements in computational efficiency while also improving model output in the case of the latter. The authors have presented two simple ways of reducing the number of parameters and speeding up the training of large long short-term memory networks: the first is the "matrix factorization by design" of the LSTM matrix into two smaller matrices, and the second is the division into separate classes of the LSTM matrix, its inputs, and its states. However, the essential restriction of sequential computation persists.

Attention mechanisms have become an integral part of sequence modeling in different applications, allowing dependencies to be modeled regardless of their gap in the input or output sequences. The following paragraph examines some of the most prominent models of attention that have created new state-of-the-art tasks for text classification. The study's conclusion was largely focused on text classification experiments that could not be extended to many other NLP tasks [150]. The authors mentioned that attention offers a reliable explanation for model predictions, expecting these properties to hold (a) attention weights should align with feature-relevant measurements (e.g., gradient-based measurements) and (b) alternative (or counterfactual) weight configurations should result in corresponding prediction changes. They stated that in the sense of text classification,

neither property is consistently observed by a Bi-LSTM with a standard attention mechanism. The layers of attention specifically weigh the representations of the input elements; it is also often believed that attention can be used to classify information that was considered relevant by models. In another study, the authors evaluate if that assumption holds by modifying weights of attention in already trained text classification methods and examining the resulting variations in their predictions. Although experimenting with text classification, the authors note several cases in which higher attention weights correlate with a greater impact on model predictions, they also notice several cases this does not hold, that is, where gradient-based attention weight rankings predict their effects better than their magnitudes [151]. In contrast to the current work on interpretability, the authors in another research reported that they examined the attention mechanism on a more diverse set of NLP tasks that included text classification, pairwise text classification, and tasks for generating text such as neural machine translation [152].

Although the hidden vectors represented by an attention model through encoding can be interpreted as internal memory entries for the model, memory-augmented networks integrate neural networks with an external memory type that the model could learn from it and respond to. For text classification, the study proposes a memory-augmented neural network called the neural semantic encoder [153]. In another research, the authors introduce neural network architecture, the dynamic memory network (DMN), which processes input sequences and questions, shapes episodic memories, and generates appropriate responses. The model possesses an iterative mechanism of attention that allows the model to condition its attention on the inputs and outcomes of previous iterations. In a hierarchical recurrent sequence model, these outcomes are then reasoned over to produce answers [154]. The authors also stated that it is possible to train the DMN end-to-end and obtain state-of-the-art text classification results using the Stanford Sentiment Treebank data collection.

Sequential processing of text is one of the system inefficiencies experienced by RNNs. Transformers address this constraint by applying self-attention to measure an "attention ranking" in parallel for each word in a phrase or document to model the impact each word has on another. Because of this feature, Transformers allow for far more parallelization than CNNs and RNNs, allowing very large models to be efficiently trained on large quantities of data on GPU stacks [155]. The Transformer architecture is especially suitable for pretraining large text corpus, leading to significant accuracy improvements in downstream tasks, including text classification [69]. They propose a novel Transformer-XL neural architecture that allows learning dependence to interrupt temporal coherence beyond a fixed length. We have seen the emergence of several large-scale transformer-based pretrained language models in the current scenario. As stated in Section 2.2.2, these Transformers are pretrained to learn contextual text representations in much greater volumes of text corpora by predicting terms that are trained on their context. These pretrained models

were fine-tuned using task-specific tags and in many subsequent NLP tasks, especially text classification produced new state-of-the-art. Fine-tuning is supervised learning, while pretraining is unsupervised.

The authors design the largest model, OpenGPT, 1.5 B parameter Transformer that ensures state-of-the-art results and comprises 12 layers of Transformer frames, each composed of a masked multi-head attention unit, followed by a standardization layer and a forward feed layer in place. With the addition of task-specific linear classifiers and fine-tuning with task-specific tags, OpenGPT can be extended to the text classification. Unlike OpenGPT that predicts words based on previous predictions, there is another model that comes into use, that is, BERT, intended to pretrain deep bidirectional representations from the unlabeled text by conditioning in all layers on both the left and right context together [71]. For text classification, BERT variants have been fine-tuned [156]. ALBERT decreases memory usage and improves BERT's training speed [157]. Another variant of BERT, SpanBERT [158], is a pretraining method designed to accurately represent and forecast spans of text. It improves BERT by (1) masking consecutive random spans, rather than random tokens, and (2) training the span boundary representations to estimate the entire content of the masked span without relying on the individual token representations within it. Deep learning provides a way to manage massive volumes of processing and data with next to no engineering by hand [23]. Unsupervised learning has had a catalytic impact on the growing interest in deep learning, but the contributions of solely supervised learning have since been overshadowed. In the longer term, we expect unsupervised learning to become even more significant.

3. Evaluation

We have discussed several supervised and unsupervised text classification methods based on machine and deep learning models so far; however, the shortage of uniform data collection procedures is a big issue when testing text classification techniques. Even if there is a standard collection method available, it can generate differences in model results by simply selecting different training and test sets [146]. Moreover, to compare various performance measures used during separate tests, there may be another difficulty related to process evaluation. In general, performance metrics assess attributes of the performance of the classification task and therefore do not necessarily present similar information. Although the underlying mechanics of various measurement metrics vary, it is important to consider precisely what each of these metrics describes and what kind of data they are attempting to express for comparability. Some examples of such performance measures include precision, recall, accuracy, microaverage, macroaverage, and F-measure. These calculations are based on a "confusion matrix" composed of true positive, false positive, false negative, and true negative [47]. Accuracy is considered the fraction of accurate predictions in overall predictions. The fraction of known positives accurately estimated is referred to as recall. The fraction of positives accurately estimated for all positives is called precision.

Another technique for evaluating how well our machine learning models perform on unknown data is cross-validation. If we expose the model to entirely new, previously unknown data, it may not be as accurate in predicting and may fail to generalize over the new data. Overfitting is the term for this issue. Because it is unable to discover patterns, the model does not always train effectively on the training set. It would not do well on the test set in this situation. Underfitting is the term for this issue. We employ cross-validation to solve overfitting issues. A cross-validation is a resampling approach in which the data set is split into two parts: training data and test data. The model is trained using training data, and the model is predicted using test data that has yet to be observed. If the model performs well on the test data and has a high level of accuracy, it has not overfitted the training data and may be used to forecast. K-fold cross-validation is the most basic type of cross-validation. Other types of cross-validation include variations on k-fold cross-validation or entail repeating k-fold cross-validation rounds. The data is initially partitioned into k equally sized segments or folds in k-fold cross-validation. Following that, k iterations of training and validation are undertaken, with each iteration holding out a different fold of the data for validation and the remaining k-1 folds being employed for learning [147]. For each of the k "folds", the following approach is used:

(i) The folds are used as training data to train a model

(ii) The generated model is validated using the remaining data (i.e., it is used as a test set to compute a performance measure such as accuracy)

In cases where there is uncertainty, entropy is especially appealing as a predictor of classification quality. It denotes how well the class membership probabilities are distributed throughout the specified classes. Its usefulness as a predictor of classification accuracy is predicated on the notion that in an accurate classification, each sentence has a high likelihood of belonging to just one class [159]. Cross-entropy loss is a key indicator for evaluating the performance of a classification issue. The prediction is a probability vector, which means that it reflects the anticipated probabilities of all classes, which add up to one. In a neural network, this is commonly accomplished by activating the final layer with a softmax function, but anything goes, it just has to be a probability vector. Maximum entropy is used in our text classification scenario to estimate the conditional distribution of a class label given a document. A collection of word-count characteristics represents a document. On a class-by-class basis, the labeled training data is utilized to estimate the anticipated value of these word counts. Iterative scaling is improved to obtain a text classifier with an exponential shape that is compatible with the limitations of the labeled data [160].

4. Comparative Analysis

The following section summarizes the benefits and limitations of feature extraction, feature selection methods, and supervised and unsupervised machine and deep learning models used for a text classification task.

TABLE 1: Benefits and limitations of text representation or feature extraction methods.

Method	Benefits	Limitations
Bag-of-words	Works well with unseen words and is easy to implement as it is based on the most frequent terms in a document	Does not cover the syntactic and semantic relation of the words, common words impact classification
TF-IDF	In like bag-of-words approach, common words are excluded due to IDF so does not impact the result	Does not cover the syntactic and semantic relation of the words
Word2vec	Covers the syntactic and semantic relation of the words in the text	Does not cover the words' polysemy
GloVe	As the same as word2vec but performs better, eliminates common words, trained on a large corpus	Does not cover the words' polysemy and does not work well for unseen words
Context-aware representation	Covers the context or meaning of the words in the text	Huge memory is required for storage and does not work well for unseen words

TABLE 2: Benefits and limitations of feature selection methods.

Method		Benefits	Limitations
Univariate filter method	Information gain	Results into the relevance of an attribute or feature	Biased towards multi-valued attributes and overfitting
	Chi-square	Reduces training time and avoids overfitting	Highly sensitive to sample size
	Fishers' score	Evaluates features individually to reduce the feature set	Does not handle features redundancy
	Pearson's correlation coefficient	Is simplest and fast and measures the linear correlation between features	It is only sensitive to a linear relationship
	Variance threshold	Removes features with variance below a certain cutoff	Does not consider the relationship with the target variable
Multi-variate filter method	mRMR (minimal redundancy maximum relevance)	Measures the nonlinear relationship between feature and target variable and provides low error accuracies	Features may be mutually as dissimilar to each other as possible
	Multi-variate relative discriminative criterion	Best determines the contribution of individual features to the underlying dimensions	Does not fit for a small sample size
Linear multi-variate wrapper method	Recursive feature elimination	Considers high-quality top-N features and removes weakest features	Computationally expensive and correlation of features not considered
	Forward/backward stepwise selection	Is computationally efficient and greedy optimization	Sometimes impossible to find features with no correlation between them
	Genetic algorithm	Accommodates data set with a large number of features and knowledge about a problem not required	Stochastic nature and computationally expensive
Nonlinear multi-variate wrapper methods	Nonlinear kernel multiplicative	De-emphasizes the least useful features by multiplying features with a scaling factor	The complexity of kernel computation and multiplication
	Relief	Is feasible for binary classification, based on nearest neighbor instance pairs and is noise-tolerant	Does not evaluate boundaries between redundant features, not suitable for the low number of training data sets
Embedded methods	LASSO	L1 regularization reduces overfitting, and it can be applied when features are even more than the data	Random selection when features are highly correlated
	Ridge regression	L2 regularization is preferred over L1 when features are highly correlated	Reduction of features is a challenge
	Elastic net	Is better than L1 and L2 for dealing with highly correlated features, is flexible, and solves optimization problems	High computational cost

4.1. Comparative Analysis of Standard Text Representation or Feature Extraction Methods. The two major feature extraction methods are highlighted: weighted words and embedding of words. By considering their frequency and co-occurrence details, word embedding approaches learn through sequences of words. These strategies are also unsupervised models to create word vectors. In comparison, the properties of weighted terms are based on counting words in documents and can be used as a basic word representation ranking scheme. Each approach poses specific constraints. Weighted words explicitly quantify text similarities from the word-count space, which enhances the computational time for large vocabulary. Although counting unique terms offers

TABLE 3: Benefits and limitations of the machine and deep learning model.

Model	Benefits	Limitations
Naïve Bayes	It needs less training data; probabilistic approach handles continuous and discrete data; and it is not sensitive to irrelevant features, easily updatable	Data scarcity can lead to loss of accuracy because it is based on assumption that any two features are independent given the output class.
SVM	It is possible to apply to unstructured data also such as text, images, and so on; kernel provides strength to the algorithm and can work for high-dimensional data	It needs long training time on large data sets and is difficult to choose good kernel function, and choosing key parameters varies from problem to problem.
KNN	It can be implemented for classification and regression problems and produces the best results if large training data is available or even noisy training data, preferred for multi-class problems	Cost is high for computing distance for each instance; finding attributes for distance-based learning is quite a difficult task; imbalanced data causes problems; and no treatment is required for missing value.
Decision tree	It reduces ambiguity in decision-making; implicitly performs feature selection, easy representation, and interpretation; and requires fewer efforts for data preparation	It is unstable due to the effect of changes in data requires changes in the whole structure, is not suitable for continuous values, and causes overfitting problem.
Boosted decision tree	It is highly interpretable and prediction accuracy is improved. It can model feature interactions and execute feature selection on its own. Gradient boosted trees are less prone to overfitting since they are trained on a randomly selected subset of the training data.	These are computationally expensive and frequently need a large number of trees (>1,000), which can take a long time and consume a lot of memory.
Random forest	In contrast to other methods, clusters of decision trees are very easy to train, and the preparation and preprocessing of the input data do not require.	More trees in random forests increase the time complexity in the prediction stage, and high chances of overfitting occur.
CNN	It provides fast predictions, is best suited for a large volume of data, and requires no human efforts for feature design.	Computationally expensive requires a large data set for training.
RNN	It implements feedback model so considers best for time series problems and makes accurate predictions than other ANN models.	Training of model is difficult and takes a long time to find nonlinearity in data, and gradient vanishing problem occurs.
LSTM, Bi-LSTM	Adds short- and long-term memory components into RNN so it considers best for applications that have a sequence and uses for solving NLP problems such as text classification and text generation, and computing speed is high. Bi-LSTM solves the issue of predicting fixed sequence to sequence.	It is expensive and complex due to the backpropagation model, increases the dimensionality of the problem, and makes it harder to find the optimal solution. Since Bi-LSTM has double LSTM cells so it is expensive to implement.
Gated RNN (GRU)	In natural language processing, GRUs learn quicker and perform better than LSTMs on less training data. As it requires fewer training parameters. GRUs are simpler and hence easier to modify and do not need memory units, such as by adding extra gates if the network requires more input.	Slow convergence and limited learning efficiency are still issues with GRU.
Transformer with an attention mechanism	The issue with RNNs and CNNs is that when sentences are too long, they are not able to keep up with context and content. By paying attention to the word that is currently being operated on this limitation was resolved, the attention strategy is an effort to selectively concentrate on a few important items while avoiding those in deep neural networks to execute the same operation, enabling much more parallelization than RNNs and thus reduces training times.	At inference time, it is strongly compute-intensive.

independent confirmation of similarity, semantic comparisons between words are not taken into consideration [148]. Word embedding techniques solve this challenge but are constrained by the need for a large corpus of text data sets to train [21]. Therefore, researchers tend to use vectors with pretrained word embedding [149]. Table 1 presents the advantages and limitations of each technique of text representation or feature extraction.

4.2. Comparative Analysis of Standard Feature Selection Methods. Some studies have preferred Fisher's linear discriminant for the support-vector-based feature ranking model [99, 100]. The author has mentioned that the filter-based method provides distinguish feature selector that has further selected distinctive features that possess term characteristics during the elimination of uninformative ones [92]. It offered performance by decreasing processing time and

increasing classification accuracy. Another technique in the wrapper method has gained popularity fast forward selection technique for selecting the best subset of a feature that demanded less computational effort as compared to other methods [107]. In the genetic algorithmic approach, a chaos genetic algorithm was proposed to simplify the feature selection method and obtained higher accuracy of classification technique [108, 109, 161]. Embedded methods were preferred over wrappers in many studies. Researchers mentioned that embedded methods have performed better than wrapper computationally, but these algorithms perform selection features as a subpart of the learning technique. Furthermore, these were followed by hybrid feature selection approaches where both filter and wrapper methods were combined, and these approaches were proven more computationally effective than the performance of a single selection technique. It was observed by the researchers that sometimes original features may not be optimal dimensions for text document representation. They provided text feature extraction methods to solve the problem by creating new feature space or artificial terms [117]. Table 2 presents the benefits and limitations of feature selection methods.

4.3. Comparison of State-of-the-Art Machine and Deep Learning Models for Text Classification. The performance of the classifier depends on the selection of feature selection and extraction method. The supervised and unsupervised machine learning techniques have offered a variety of classifiers that performed well in a variety of domain-specific classification problems. The following Table 3 presents their pros and cons. Recent studies have focused on deep learning or neural network-based classifiers such as CNN, RNN, and RNN with LSTM that have shown better results than conventional algorithms such as SVM and KNN in solving a different range of problems. RNN and LSTM have been used in many NLP applications due to their capacity of capturing complex patterns within the text [151]. It has also been used in sequence labeling tasks in POS (part of speech) activity. But it has offered a lot of future scope in resolving complexities involved in the backpropagation technique used in RNN and making the learning model cheaper and faster [104].

5. Research Gap and Future Direction

From this review of existing studies, we identified that there exist certain gaps, which we can plan to fill in the future. While labeling unstructured text data manually, it takes a lot of time to understand the data to categorize it. Also, it needs specialists for understanding domain-specific data. In such scenarios, the machine learning algorithms do not produce the expected accuracy [12]. Extraction of meaning or finding semantic relations between words of unstructured data is a complex task, which has been tried by several authors using NLP techniques for years [24, 162]. However, these methods prove inefficient when pursuing building a high-quality classification system. It offers opportunities to design semisupervised machine learning models to label some parts

of training data manually, and the rest data can be trained using machine learning algorithms [163].

Apart from conventional methods used for representing data sets for extracting patterns from the text data using vector representation based on word-embedding and paragraph-embedding [38, 58], the authors have presented deep neural network models for NLP-based applications using character-embedding [164], unsupervised techniques based on transfer learning, Bert, with fine-tuning with domain-specific data [156]. However, these representations and globally available representations cannot be generalized to unseen texts, which are very specific to a particular domain [59]. It offers opportunities to design methodology for extending the vocabulary of existing representations for specific domains.

The deep learning algorithms are proven good in decision-making for NLP-based applications, and these models cannot handle symbols directly [165]. Also, the computational cost of training such algorithms is very high. It offers scope for designing deep neural network-based architecture, which can be inputted with linguistic knowledge, lexical knowledge, and word knowledge from different domains.

6. Conclusions

In this paper, we have provided a detailed review of the complete process of the text classification system. This paper covered various algorithms or methods used in subtasks of classification. It has presented the techniques for data collection from several online sources. The documents were represented with basic techniques and followed by recent research in document representation for different areas of machine learning and natural language processing. To provide suitable and fast classifiers the higher dimensional space of data was reduced to a lower space using feature selection and feature extraction methods. Different algorithms perform differently depending on the domain-specific data collections and to train machine learning text classifiers. The authors have used these algorithms based on the problem statement, and none of the algorithms has proven perfect for all types of problems and data dimensionality.

It is observed that in recent years, some studies focused on new applications of text classification such as multi-label classification [166, 167], and hierarchical classification [168, 169] in the field of natural language processing or machine translation and medical sciences, respectively. The neural network-based algorithms are commonly used in NLP-based problems [136, 137, 142]. However, these algorithms mainly focus on generic data. Moreover, CNN is preferably used for image processing, and RNN with LSTM is preferred for time-series problems. Initially, these algorithms were not applied to text data, but in recent years, CNN with character-embedding is being used for document representation and feature selection in text documents [58]. The transformers-based unsupervised models also overcome the issue of RNN and LSTM, but these techniques are proven computationally expensive. With the advancement of deep neural networks, we may find in the future that these deep

neural networks will be applied efficiently in the automatic monitoring of web-based text data and classifying unseen data into automated labels [7].

Data Availability

The data used in this study are publicly available.

Conflicts of Interest

The authors declare that there are no conflicts of interest.

The bivariate or multivariate distribution can be used to account for the dependence structure between different failure modes. This paper considers two dependent competing failure modes from Gompertz distribution, and the dependence structure of these two failure modes is handled by the Marshall–Olkin bivariate distribution. We obtain the maximum likelihood estimates (MLEs) based on classical likelihood theory and the associated bootstrap confidence intervals (CIs). The posterior density function based on the conjugate prior and noninformative (Jeffreys and Reference) priors are studied; we obtain the Bayesian estimates in explicit forms and construct the associated highest posterior density (HPD) CIs. The performance of the proposed methods is assessed by numerical illustration.

1. Introduction

It is extremely common that the failure of a product or a system contains several competing failure modes in reliability engineering; any failure mode will lead to the failure result. Competing risks' data contain the failure time and the corresponding failure mode, which can be modeled by the competing risks' model and has been commonly performed in many research fields, such as engineering and medical statistics. Previous studies have mostly assumed the competing failure modes to be independent; Wang et al. [1], Ren and Gui [2], and Qin and Gui [3] focused on the independent competing risks' model under progressively hybrid censoring from Weibull and Burr-XII distributions. Objective Bayesian analysis for the competing risks' model with Wiener degradation phenomena and catastrophic failures was studied by Guan et al. [4]. In practice, the independency relationship between different failure modes is a very special case; a more common situation is dependency. That is, the failure mechanisms are interactive and interdependent; the occurrence of one failure mode will affect the occurrence of other failure modes. For example, a ship fixed carbon dioxide fire extinguishing system can fail due to pressure gauge, distribution value, cylinder group, and so on; these failure modes are dependent because they all are related to the storage environment. Therefore, it is more reasonable to assume dependency among different competing failure modes. The competing risks' model considers the product or system with multiple dependent competing failure modes, any one of which will cause the occurrence of failure. The dependent competing risks' model has been extensively studied. Zhang et al. [5] and Zhang et al. [6] studied the dependent competing risks' model under accelerated life testing (ALT) by copula function to measure the dependence between different competing failure modes; the results indicate the copula construction method has good accuracy

and universality. Wang and Yan [7] and Wu et al. [8] also studied this model under ALT and progressively hybrid-censoring scheme using Clayton copula and Gumbel copula, respectively. For other related works, see the works of Lo and Wike [9] and Fang et al. [10].

In addition to using copula function to handle the relationship between different competing failure modes, the bivariate or multivariate distribution also can be used to account for the correlation between different failure modes. The Marshall–Olkin distribution [11], which has many good properties, is the best-known bivariate distribution and has been discussed extensively; it has a parameter to describe the dependence structure. Li et al. [12], Kundu and Gupta [13], and Bai et al. [14] provided reviews on Marshall-l–Olkin–Weibull distribution; Kundu and Gupta [13] obtained the explicit forms of the unknown parameters when the shape parameter is known; when the shape parameter is unknown, they used the importance sampling to compute the Bayesian estimates of the unknown parameters. Bai et al. [14] discussed the statistical analysis for the accelerated dependent competing risks' model under Type-II hybrid censoring schemes. Guan et al. [15] studied objective Bayesian analysis for the Marshall–Olkin exponential distribution based on reference priors; they also found that some of the reference priors are also matching priors and the posterior distributions based on these priors are proper.

The Gompertz distribution is a widely used growth model which has been studied extensively; Ismail [16] studied the Bayesian analysis of Gompertz distribution parameters and acceleration factor in the case of partially accelerated life testing under Type-I censoring scheme. Ghitany et al. [17] considered a progressively censored sample from Gompertz distribution; they discussed the existence and uniqueness of the MLEs of the unknown parameters. The Gompertz distribution plays an important role in fitting clinical trials' data in medical science and can be used to the theory of extreme-order statistics. In this paper, we will study the dependent competing risks' model from the Marshall–Olkin bivariate Gompertz (MOGP) distribution, which is a bivariate distribution with Gompertz marginal distributions. We focus our attention on the

statistical analysis of the model parameters, including classical likelihood inference, Bayesian analysis, and objective Bayesian analysis. Because the Bayesian analysis based on conjugate prior is sensitive to the hyperparameters, inappropriate choice of it will cause bad priors. Based on this reason, we propose the objective Bayesian analysis based on noninformative priors for comparison. The objective Bayesian inference has been studied by Guan et al. [14], Bernardo [18], and Berger and Bernardo [19] based on Reference and Jeffreys priors.

In the rest of this paper, we will present the model description and some properties. Section 3 presents the MLEs and associated bootstrap CIs. In Section 4, Bayesian estimates and associated HPD CIs based on conjugate prior, Jeffreys prior [20], and reference priors [18] are obtained, and these priors lead to proper posteriors which are proved. Section 5 presents some results obtained from simulation study and illustrative analysis. Section 6 gives some final concluding remarks.

2. Model Description

Suppose that $f(t; \lambda, \theta)$ is a Gompertz distribution; the density function and reliability function of it are

$$f(t; \lambda, \theta) = \theta e^{(\lambda t - \theta(e^{\lambda t} - 1)/\lambda)}, \ \lambda, \ \theta > 0, \ t > 0,$$
$$S(t; \lambda, \theta) = e^{(-\theta(e^{\lambda t} - 1)/\lambda)}, \ \lambda, \ \theta > 0, \ t > 0, \tag{1}$$

where λ is shape parameter and θ is scale parameter.

Suppose U_0, U_1, and U_2 are three independent Gompertz variables with different scale parameters, that is, $U_0 \sim GP(\lambda, \theta_0)$, $U_1 \sim GP(\lambda, \theta_1)$, and $U_2 \sim GP(\lambda, \theta_2)$. Let $T_1 = \min(U_0, U_1)$ and $T_2 = \min(U_0, U_2)$; we obtain $T_1 \sim GP(\lambda, \theta_0 + \theta_1)$ and $T_2 \sim GP(\lambda, \theta_0 + \theta_2)$. Then, the pair of variables (T_1, T_2) follows the MOGP distribution denoted by $(T_1, T_2) \sim MOGP(\lambda, \theta_0, \theta_1, \theta_2)$. When $\theta_0 = 0$, the two variables T_1 and T_2 are independent and T_1 and T_2 will be dependent when $\theta_0 > 0$; hence, θ_0 can be regarded as a correlation coefficient between T_1 and T_2.

The joint PDF of (T_1, T_2) can be written as

$$f_{T_1, T_2}(t_1, t_2; \lambda, \theta_0, \theta_1, \theta_2) = \begin{cases} f(t_1; \lambda, \theta_0 + \theta_1) f(t_2; \lambda, \theta_2) & t_1 > t_2 \\ \\ f(t_1; \lambda, \theta_1) f(t_2; \lambda, \theta_0 + \theta_2) & t_1 < t_2. \\ \\ \left(\dfrac{\theta_0}{(\theta_0 + \theta_1 + \theta_2)} \right) f(t; \lambda, \theta_0 + \theta_1 + \theta_2) & t_1 = t_2 = t \end{cases} \tag{2}$$

The surface plots of $f_{T_1, T_2}(t_1, t_2; \lambda, \theta_0, \theta_1, \theta_2)$ are presented in Figure 1. From Figure 1, we can see that $f_{T_1, T_2}(t_1, t_2; \lambda, \theta_0, \theta_1, \theta_2)$ is a unimodal function.

Put n identical products into test, and each product has two dependent failure modes with lifetimes T_1, T_2,

$(T_1, T_2) \sim MOGP(\lambda, \theta_0, \theta_1, \theta_2)$. Then, the system lifetime is $X = \min(T_1, T_2) \sim MOGP(\lambda, \theta_0 + \theta_1 + \theta_2)$. Let $\delta_{0l} = I(T_{1l} = T_{2l})$, $\delta_{1l} = I(T_{1l} < T_{2l})$, and $\delta_{2l} = I(T_{1l} > T_{2l})$, for $l = 1, \cdots, n$, where $I(\cdot)$ is an indicator function. Then, we can compute $n_0 = \sum_l \delta_{0l}$, $n_1 = \sum_l \delta_{1l}$, $n_2 = \sum_l \delta_{2l}$, and $n = n_0 + n_1 + n_2$.
FIGURE 1: Surface plot of $f_{T_1,T_2}(t_1,t_2;\lambda,\theta_0,\theta_1,\theta_2)$ with different values of $\lambda, \theta_0, \theta_1, \theta_2$. (a) $(\lambda, \theta_0, \theta_1, \theta_2) = (3, 0.5, 2, 1)$. (b) $(\lambda, \theta_0, \theta_1, \theta_2) = (3, 1.5, 0.5, 2)$. (c) $(\lambda, \theta_0, \theta_1, \theta_2) = (1, 0.5, 0.5, 0.5)$. (d) $(\lambda, \theta_0, \theta_1, \theta_2) = (1, 0.2, 0.8, 0.6)$.

Theorem 1. *For* $l = 1, \cdots, n,$ $\delta_{0l} = I(T_{1l} = T_{2l}),$ $\delta_{1l} = I(T_{1l} < T_{2l}),$ *and* $\delta_{2l} = I(T_{1l} > T_{2l}),$ *We have*

$$(\delta_{0l}, \delta_{1l}, \delta_{2l}) \sim \text{Multinomial}\left(1; \frac{\theta_0}{\theta_0 + \theta_1 + \theta_2}, \frac{\theta_1}{\theta_0 + \theta_1 + \theta_2}, \frac{\theta_2}{\theta_0 + \theta_1 + \theta_2}\right), l = 1, \cdots, n. \quad (3)$$

Proof. For $l = 1, \cdots, n$, we have $\delta_{0l} + \delta_{1l} + \delta_{2l} = 1$,

$$P(T_1 < T_2) = \int_0^\infty \int_0^{t_2} f(t_1; \lambda, \theta_1) f(t_2; \lambda, \theta_0 + \theta_2) dt_1 dt_2 = \frac{\theta_1}{\theta_0 + \theta_1 + \theta_2},$$

$$P(T_1 > T_2) = \int_0^\infty \int_0^{t_1} f(t_1; \lambda, \theta_0 + \theta_1) f(t_2; \lambda, \theta_2) dt_2 dt_1 = \frac{\theta_2}{\theta_0 + \theta_1 + \theta_2}, \quad (4)$$

$$P(T_1 = T_2) = 1 - \frac{\theta_1}{\theta_0 + \theta_1 + \theta_2} - \frac{\theta_2}{\theta_0 + \theta_1 + \theta_2} = \frac{\theta_0}{\theta_0 + \theta_1 + \theta_2}.$$

Therefore, $(\delta_{0l}, \delta_{1l}, \delta_{2l}) \sim \text{Multinomial}(1; \theta_0/(\theta_0 + \theta_1 + \theta_2), \theta_1/(\theta_0 + \theta_1 + \theta_2), \theta_2/(\theta_0 + \theta_1 + \theta_2))$.

The likelihood function is

$$L(\lambda, \theta_0, \theta_1, \theta_2) = \prod_l \left[f_{T_1, T_2}(x_l, x_l; \lambda, \theta_0, \theta_1, \theta_2)\right]^{\delta_{0l}} \left[-\frac{\partial S_{T_1, T_2}(t_1, t_2; \lambda, \theta_0, \theta_1, \theta_2)}{\partial t_1}\Big|_{(x_l, x_l)}\right]^{\delta_{1l}},$$

$$\times \left[-\frac{\partial S_{T_1, T_2}(t_1, t_2; \lambda, \theta_0, \theta_1, \theta_2)}{\partial t_2}\Big|_{(x_l, x_l)}\right]^{\delta_{2l}}, \quad (5)$$

where

$$f_{T_1, T_2}(x_l, x_l; \lambda, \theta_0, \theta_1, \theta_2) = \frac{\theta_0}{\theta_0 + \theta_1 + \theta_2} f(t; \lambda, \theta_0 + \theta_1 + \theta_2),$$

$$= \theta_0 \exp\left\{\lambda x_l - \frac{\theta_0 + \theta_1 + \theta_2}{\lambda}\left(e^{\lambda x_l} - 1\right)\right\},$$

$$-\frac{\partial S_{T_1, T_2}(t_1, t_2; \lambda, \theta_0, \theta_1, \theta_2)}{\partial t_1}\Big|_{(x_l, x_l)},$$

$$= \theta_1 \exp\left\{\lambda x_l - \frac{\theta_0 + \theta_1 + \theta_2}{\lambda}\left(e^{\lambda x_l} - 1\right)\right\},\tag{6}$$

$$-\frac{\partial S_{T_1, T_2}(t_1, t_2; \lambda, \theta_0, \theta_1, \theta_2)}{\partial t_2}\Big|_{(x_l, x_l)},$$

$$= \theta_2 \exp\left\{\lambda x_l - \frac{\theta_0 + \theta_1 + \theta_2}{\lambda}\left(e^{\lambda x_l} - 1\right)\right\}.$$

Then, we obtain

$$L(x; \lambda, \theta_0, \theta_1, \theta_2) = \theta_0^{n_0}\theta_1^{n_1}\theta_2^{n_2} \exp\left\{\lambda \sum_l x_l - \frac{\theta_0 + \theta_1 + \theta_2}{\lambda}\left[\sum_l\left(e^{\lambda x_l} - 1\right)\right]\right\}.\tag{7}$$

□

3. Classical Inference

3.1. Maximum Likelihood Estimates (MLEs). The MLEs of θ_0, θ_1, θ_2, and λ can be obtained by maximizing the logarithm of $L(x; \lambda, \theta_0, \theta_1, \theta_2)$. Set the first partial derivation of $\log L(x; \lambda, \theta_0, \theta_1, \theta_2)$ about θ_0, θ_1, θ_2, λ to 0, i.e.,

$$\frac{\partial \log L(x; \lambda, \theta_0, \theta_1, \theta_2)}{\partial \lambda} = \sum_l x_l + \frac{\theta_0 + \theta_1 + \theta_2}{\lambda^2}\left[\sum_l\left(e^{\lambda x_l} - 1\right)\right] - \frac{\theta_0 + \theta_1 + \theta_2}{\lambda}\left(\sum_l x_l e^{\lambda x_l}\right) = 0,$$

$$\frac{\partial \log L(x; \lambda, \theta_0, \theta_1, \theta_2)}{\partial \theta_j} = \frac{n_j}{\theta_j} - \frac{1}{\lambda}\left[\sum_l\left(e^{\lambda x_l} - 1\right)\right] = 0, \quad j = 0, 1, 2.\tag{8}$$

From (8), we get the MLEs of θ_0, θ_1, and θ_2 as

$$\widehat{\theta}_j(\lambda) = \frac{n_j \lambda}{\left[\sum_l\left(e^{\lambda x_l} - 1\right)\right]}, \quad j = 0, 1, 2.\tag{9}$$

Substituting $\widehat{\theta}_j(\lambda)$ into $\log L(x; \lambda, \theta_0, \theta_1, \theta_2)$, we obtain

$$h(\lambda) = \lambda \sum_l x_l + \sum_{j=0}^{2} \ln\left(\frac{n_j \lambda}{\sum_l\left(e^{\lambda x_l} - 1\right)}\right)^{n_j},\tag{10}$$

which is the profile logarithm likelihood function of λ.

We can show that $\partial^2 h(\lambda)/\partial \lambda^2 < 0$, which implies that $h(\lambda)$ is concave. Some iterative schemes can be used to find the MLE for λ, such as Newton–Raphson algorithm.

3.2. Bootstrap Confidence Intervals (CIs). Since it is hard to construct the exact CIs for the unknown parameters, we consider the Bootstrap method to construct CIs for parameters θ_0, θ_1, θ_2, and λ. The Bootstrap method is a resampling method to estimate some statistical characteristics for the unknown parameters by taking samples from

the original samples repeatedly; the obtained samples are called Bootstrap samples. This method has a great practical value since it does not need to assume the overall distribution or construct the pivot quantity. We generate the Bootstrap sample by the following three steps:

Step 1: for the fixed value of n and observed data $(x_1, x_2, \cdots, x_n)$, we get the estimates $\widehat{\lambda}$, $\widehat{\theta}_0$, $\widehat{\theta}_1$, and $\widehat{\theta}_2$ based on the maximum likelihood method.

Step 2: for the values of n, $\widehat{\lambda}$, $\widehat{\theta}_0$, $\widehat{\theta}_1$, and $\widehat{\theta}_2$, we generate the sample $(x_1^*, x_2^*, \cdots, x_n^*)$. Then, get the MLEs $\widehat{\lambda}'$, $\widehat{\theta}_0'$, $\widehat{\theta}_1'$, and $\widehat{\theta}_2'$.

Step 3: repeat Step 2 M times to obtain M sets of the values $\widehat{\lambda}'$, $\widehat{\theta}_0'$, $\widehat{\theta}_1'$, and $\widehat{\theta}_2'$. Arrange them as follows to get the Bootstrap sample:

$$\left\{ \widehat{\theta}_{0[1]}' < \cdots < \widehat{\theta}_{0[M]}', \widehat{\theta}_{1[1]}' < \cdots < \widehat{\theta}_{1[M]}', \widehat{\theta}_{2[1]}' < \cdots < \widehat{\theta}_{2[M]}', \widehat{\lambda}_{[1]}' < \cdots < \widehat{\lambda}_{[M]}' \right\}. \tag{11}$$

Based on the Bootstrap sample and by percentile Bootstrap (Boot-P) method, we construct the Boot-P CIs for θ_0, θ_1, θ_2, λ at $1 - \gamma$ confidence level as

$$\left(\widehat{\theta}_{0[M\gamma/2]}'', \widehat{\theta}_{0[M(1-\gamma/2)]}'' \right), \left(\widehat{\theta}_{1[M\gamma/2]}'', \widehat{\theta}_{1[M(1-\gamma/2)]}'' \right), \left(\widehat{\theta}_{2[M\gamma/2]}'', \widehat{\theta}_{2[M(1-\gamma/2)]}'' \right), \left(\lambda_{[M\gamma/2]}'', \lambda_{[M(1-\gamma/2)]}'' \right). \tag{12}$$

4. Bayesian Inference and HPD CIs

4.1. Conjugate Prior.
In this section, we suppose the shape parameter λ is known. Denote $\theta = \theta_0 + \theta_1 + \theta_2$, which has a Gamma prior with hyperparameters a and b as

$$\pi(\theta) = \left(\frac{b^a}{\Gamma(a)} \right) \theta^{a-1} e^{-b\theta}, \tag{13}$$

$$a > 0, b > 0, \theta > 0.$$

Due to $\theta_0/\theta + \theta_1/\theta + \theta_2/\theta = 1$, so given θ, $(\theta_1/\theta, \theta_2/\theta)$ follows a Dirichlet prior with hyper parameters c_0, c_1, and c_2, that is,

$$\pi_D\left(\frac{\theta_1}{\theta}, \frac{\theta_2}{\theta} \Big| \theta \right) = \frac{\Gamma\left(\sum_{i=0}^2 c_i \right)}{\prod_{i=0}^2 \Gamma(c_i)} \prod_{i=0}^2 \left(\frac{\theta_i}{\theta} \right)^{c_i - 1}, \quad \theta_i > 0, c_i > 0, i = 0, 1, 2. \tag{14}$$

Therefore, the joint prior of θ_0, θ_1, and θ_2 becomes

$$\pi_1(\theta_0, \theta_1, \theta_2; a, b, c_0, c_1, c_2) = \frac{\Gamma(c)}{\Gamma(a)} (b\theta)^{a-c} \prod_{i=0}^2 \frac{b^{c_i}}{\Gamma(c_i)} \theta_i^{c_i - 1} \exp(-b\theta_i), \tag{15}$$

where $c = c_0 + c_1 + c_2$.

4.2. Jeffreys Prior.
According to Jeffreys [20], Jeffreys prior is proportional to the square root of the determinant of the Fisher information matrix. From (7), we obtain the Fisher information matrix of $(\theta_0, \theta_1, \theta_2)$ as

$$I = I(\theta_0, \theta_1, \theta_2) = \begin{pmatrix} \dfrac{n_0}{\theta_0^2} & 0 & 0 \\ 0 & \dfrac{n_1}{\theta_1^2} & 0 \\ 0 & 0 & \dfrac{n_2}{\theta_2^2} \end{pmatrix}. \tag{16}$$

From Theorem 1, we have $n_i = n \cdot \theta_i/(\theta_0 + \theta_1 + \theta_2)$, $i = 0, 1, 2$, so $I(\theta_0, \theta_1, \theta_2)$ can be written as

$$I = n \begin{pmatrix} \dfrac{1}{(\theta_0 \theta)} & 0 & 0 \\[2ex] 0 & \dfrac{1}{(\theta_1 \theta)} & 0 \\[3ex] 0 & 0 & \dfrac{1}{(\theta_2 \theta)} \end{pmatrix}. \tag{17}$$

Thus, the Jeffreys prior is given by

$$\pi_2(\theta_0, \theta_1, \theta_2) \propto \sqrt{\frac{1}{\theta_0 \theta_1 \theta_2 \theta^3}}. \tag{18}$$

Theorem 2. *Based on the Jeffreys prior $\pi_2(\theta_0, \theta_1, \theta_2)$, the joint posterior distribution of $(\theta_0, \theta_1, \theta_2)$ is proper.*

Proof. From (6) and (7), we obtain the joint posterior distribution of $(\theta_0, \theta_1, \theta_2)$ based on $\pi_2(\theta_0, \theta_1, \theta_2)$ as

$$\pi_2(\theta_0, \theta_1, \theta_2 | x) = \frac{L(x; \lambda, \theta_0, \theta_1, \theta_2) \pi_2(\theta_0, \theta_1, \theta_2)}{\int_0^\infty \int_0^\infty \int_0^\infty L(x; \lambda, \theta_0, \theta_1, \theta_2) \pi_2(\theta_0, \theta_1, \theta_2) d\theta_0 d\theta_1 d\theta_2},$$

$$\propto \theta^{(-3/2)} \theta_0^{(n_0 - 1/2)} \theta_1^{(n_1 - 1/2)} \theta_2^{(n_2 - 1/2)} e^{(-A\theta/\lambda)}. \tag{19}$$

Integrating $\pi_2(\theta_0, \theta_1, \theta_2 | x)$ with respect to θ_0, θ_1, and θ_2, we obtain

$$\int_0^\infty \int_0^\infty \int_0^\infty \theta^{-3/2} \theta_0^{n_0 - 1/2} \theta_1^{n_1 - 1/2} \theta_2^{n_2 - 1/2} e^{(-A\theta/\lambda)} d\theta_0 d\theta_1 d\theta_2,$$

$$= \int_0^\infty \int_0^\infty \int_0^\infty \left(\frac{\theta_0}{\theta}\right)^{n_0 - 1/2} \left(\frac{\theta_1}{\theta}\right)^{n_1 - 1/2} \left(\frac{\theta_2}{\theta}\right)^{n_2 - 1/2} \theta^{n-3} \exp\left\{-\left(\frac{A}{\lambda}\right)\theta\right\} d\theta_0 d\theta_1 d\theta_2,$$

$$= \int_{0 < \theta_0/\theta + \theta_1/\theta < 1} \prod_{i=0}^1 \left(\frac{\theta_i}{\theta}\right)^{n_i - 1/2} \left(1 - \sum_{i=0}^1 \frac{\theta_i}{\theta}\right)^{n_2 - 1/2} d\frac{\theta_0}{\theta} d\frac{\theta_1}{\theta} \cdot \int_0^\infty \theta^{n-1} \exp\left\{-\frac{A}{\lambda}\theta\right\} d\theta, \tag{20}$$

$$= B\left(n_0 + \frac{1}{2}, n_1 + n_2 + 1\right) B\left(n_1 + \frac{1}{2}, n_2 + \frac{1}{2}\right) \frac{\Gamma(n)}{(A/\lambda)^n} < \infty,$$

where $A = \sum_{i=1}^n (e^{\lambda x_i} - 1)$ and $B(\cdot, \cdot)$ is a beta function.

Thus, the joint posterior distribution of $(\theta_0, \theta_1, \theta_2)$ based on $\pi_2(\theta_0, \theta_1, \theta_2)$ is proper. □

4.3. Reference Priors. Bernardo [18] and Berger and Bernardo [19] proposed the reference prior which plays a vital role in the objective Bayesian inference. We set $\mu_0 \equiv \theta = \theta_0 + \theta_1 + \theta_2$, $\mu_1 = \theta_0/\theta$, and $\mu_2 = \theta_1/\theta$; the transformation from $(\theta_0, \theta_1, \theta_2)$ to (μ_0, μ_1, μ_2) is one-to-one with the inverse transformation $\theta_0 = \mu_0 \mu_1$, $\theta_1 = \mu_0 \mu_2$, and

$\theta_2 = \mu_0(1 - \mu_1 - \mu_2)$. The Jacobian matrix of the transformation has the form

$$J = \begin{pmatrix} \mu_1 & \mu_0 & 0 \\ \mu_2 & 0 & \mu_0 \\ 1 - \mu_1 - \mu_2 & -\mu_0 & -\mu_0 \end{pmatrix}, 0 < \mu_0 < \infty, 0 < \mu_1 + \mu_2 < 1. \tag{21}$$

The likelihood function (3) becomes

$$L(x; \lambda, \mu_0, \mu_1, \mu_2) = \mu_1^{n_0} \mu_2^{n_1} (1 - \mu_1 - \mu_2)^{n_2} \mu_0^n \exp\left\{\lambda \sum_l x_l - \left(\frac{\mu_0}{\lambda}\right)\left[\sum_l (e^{\lambda x_l} - 1)\right]\right\}. \tag{22}$$

The Fisher information matrix of (μ_0, μ_1, μ_2) can be written as

$$I_1 = J'IJ = n \begin{pmatrix} 1/\mu_0^2 & 0 & 0 \\ & & \\ 0 & \dfrac{1}{\mu_1} + \dfrac{1}{(1-\mu_1-\mu_2)} & \dfrac{1}{(1-\mu_1-\mu_2)} \\ & & \\ 0 & \dfrac{1}{(1-\mu_1-\mu_2)} & \dfrac{1}{\mu_2} + \dfrac{1}{(1-\mu_1-\mu_2)} \end{pmatrix}. \tag{23}$$

Theorem 3.

(i) *Under the ordering groups* $\{\mu_0, (\mu_1, \mu_2)\}$ *and* $\{(\mu_1, \mu_2), \mu_0\}$, *the reference priors are the same, which is given by* $\omega_{R_1}(\mu_0, \mu_1, \mu_2) = \sqrt{1/\mu_0^2\mu_1\mu_2(1-\mu_1-\mu_2)}$; *the corresponding reference prior for* $(\theta_0, \theta_1, \theta_2)$ *is* $\pi_2(\theta_0, \theta_1, \theta_2) = \sqrt{1/\theta_0\theta_1\theta_2\theta^3}$

(ii) *Under the ordering groups* $\{\mu_0, \mu_1, \mu_2\}$, $\{\mu_0, \mu_2, \mu_1\}$, $\{\mu_1, \mu_0, \mu_2\}$, *and* $\{\mu_1, \mu_2, \mu_0\}$, *the reference priors are the same, which is given by* $\omega_{R_2}(\mu_0, \mu_1, \mu_2) = \sqrt{1/\mu_0^2\mu_1\mu_2(1-\mu_1-\mu_2)(1-\mu_1)}$; *the corresponding reference prior for* $(\theta_0, \theta_1, \theta_2)$ *is* $\pi_3(\theta_0, \theta_1, \theta_2) = \sqrt{1/\theta^2\theta_0\theta_1\theta_2(\theta_1+\theta_2)}$

(iii) *Under the ordering groups* $\{\mu_2, \mu_0, \mu_1\}$ *and* $\{\mu_2, \mu_1, \mu_0\}$, *the reference priors are the same, which is given by* $\omega_{R_3}(\mu_0, \mu_1, \mu_2) = \sqrt{1/\mu_0^2\mu_1\mu_2(1-\mu_1-\mu_2)(1-\mu_2)}$; *the corresponding reference prior for* $(\theta_0, \theta_1, \theta_2)$ *is* $\pi_4(\theta_0, \theta_1, \theta_2)) = \sqrt{1/\theta^2\theta_0\theta_1\theta_2(\theta_0+\theta_2)}$

Proof.

(i) The Fisher information matrix of (μ_0, μ_1, μ_2) is

$$I_1 = \begin{pmatrix} \sum_{11} & 0 \\ 0 & \sum_{22} \end{pmatrix}, \tag{24}$$

where $\sum_{11} = n/\mu_0^2$ and $\sum_{22} = n$ $\begin{pmatrix} 1/\mu_1 + 1/(1-\mu_1-\mu_2) & 1/(1-\mu_1-\mu_2) \\ 1/(1-\mu_1-\mu_2) & 1/\mu_2 + 1/(1-\mu_1-\mu_2) \end{pmatrix}$.
The reference prior for the ordering groups $\{\mu_0, (\mu_1, \mu_2)\}$ and $\{(\mu_1, \mu_2), \mu_0\}$ is the same as in [21], which is given by

$$\omega_{R_1}(\mu_0, \mu_1, \mu_2) \propto \left|\sum_{11}\right|^{1/2} \left|\sum_{22}\right|^{1/2} \propto \sqrt{\dfrac{1}{\mu_0^2\mu_1\mu_2(1-\mu_1-\mu_2)}}. \tag{25}$$

(ii) The inverse of I_1 is

$$H = \dfrac{1}{n} \begin{pmatrix} \mu_0^2 & 0 & 0 \\ 0 & \mu_1(1-\mu_1) & -\mu_1\mu_2 \\ 0 & -\mu_1\mu_2 & \mu_2(1-\mu_2) \end{pmatrix}. \tag{26}$$

(iii) According the notations in [18], we obtain $h_1 = 1/\mu_0^2$, $h_2 = 1/\mu_1(1-\mu_1)$, and $h_3 = (1-\mu_1)/(\mu_2(1-\mu_1-\mu_2))$.

Choose the compact sets $\Omega_k = \{(\mu_0, \mu_1, \mu_2)| a_{0k} < \mu_0 < b_{0k}, a_{1k} < \mu_1, a_{2k} < \mu_2, \mu_1 + \mu_2 < d_k\}$, such that $a_{0k}, a_{1k}, a_{2k} \longrightarrow 0$, $b_{0k} \longrightarrow \infty$, and $d_k \longrightarrow 1$, as $k \longrightarrow \infty$. Then, we have

$$\pi^k(\mu_0, \mu_1, \mu_2) = \dfrac{\sqrt{|h_1|}\sqrt{|h_2|}\sqrt{|h_3|}}{\int_{a_{0k}}^{b_{0k}} \sqrt{|h_1|}d\mu_0 \cdot \int_{a_{1k}}^{d_k-\mu_2^0} \sqrt{|h_2|}d\mu_1 \cdot \int_{a_{2k}}^{d_k-\mu_1} \sqrt{|h_3|}d\mu_2} I_{\Omega_k}(\mu_0, \mu_1, \mu_2), \tag{27}$$

where $\int_{a_{0k}}^{b_{0k}} \sqrt{|h_1|}d\mu_0 = \int_{a_{0k}}^{b_{0k}} 1/\mu_0 d\mu_0 = \log b_{0k} - \log a_{0k}$:

$$\int_{a_{1k}}^{d_k-\mu_2^0} \sqrt{|h_2|}d\mu_1 = \int_{a_{1k}}^{d_k-\mu_2^0} \sqrt{\dfrac{1}{\mu_1(1-\mu_1)}}d\mu_1 = -\arcsin\left(1 - 2(d_k - \mu_2^0)\right) + \arcsin(1 - 2a_{1k}),$$

$$\int_{a_{2k}}^{d_k-\mu_1} \sqrt{|h_3|}d\mu_2 = \int_{a_{2k}}^{d_k-\mu_1} \sqrt{\dfrac{1-\mu_1}{\mu_2(1-\mu_1-\mu_2)}}d\mu_2, \tag{28}$$

$$= (1-\mu_1)^{1/2}\left(-\arcsin\left(\dfrac{1-\mu_1-2(d_k-\mu_1)}{1-\mu_1}\right) + \arcsin\left(\dfrac{1-\mu_1-2a_{2k}}{1-\mu_1}\right)\right).$$

Then, we get the reference prior as

$$\omega_{R_2}(\mu_0, \mu_1, \mu_2) = \lim_{k \to \infty} \frac{\pi^k(\mu_0, \mu_1, \mu_2)}{\pi^k(\mu_0^*, \mu_1^*, \mu_2^*)} \propto \sqrt{\frac{1}{\mu_0^2 \mu_1 \mu_2 (1 - \mu_1 - \mu_2)(1 - \mu_1)}}, \tag{29}$$

where $(\mu_0^*, \mu_1^*, \mu_2^*)$ is an inner point of Ω_k.

Similarly, under the ordering group $\{\mu_0, \mu_2, \mu_1\}$, the reference prior is $\omega_{R_2}(\mu_0, \mu_1, \mu_2)$.

The Fisher information matrix of $\{\mu_1, \mu_0, \mu_2\}$ is

$$I_2 = n \begin{pmatrix} \dfrac{1}{\mu_1} + \dfrac{1}{(1 - \mu_1 - \mu_2)} & 0 & \dfrac{1}{(1 - \mu_1 - \mu_2)} \\ 0 & \dfrac{1}{\mu_0^2} & 0 \\ \dfrac{1}{(1 - \mu_1 - \mu_2)} & 0 & \dfrac{1}{\mu_2} + \dfrac{1}{(1 - \mu_1 - \mu_2)} \end{pmatrix}. \tag{30}$$

The inverse of I_2 is

$$H_1 = \frac{1}{n} \begin{pmatrix} \mu_1 (1 - \mu_1) & 0 & -\mu_1 \mu_2 \\ 0 & \mu_0^2 & 0 \\ -\mu_1 \mu_2 & 0 & \mu_2 (1 - \mu_2) \end{pmatrix}. \tag{31}$$

Similarly, we obtain $h_1 = 1/\mu_1 (1 - \mu_1)$, $h_2 = 1/\mu_0^2$, and $h_3 = (1 - \mu_1)/(\mu_2 (1 - \mu_1 - \mu_2))$.

Choose the compact sets $\Omega_k = \{(\mu_1, \mu_0, \mu_2) \mid a_{0k} < \mu_1, \ a_{1k} < \mu_0 < b_{1k}, a_{2k} < \mu_2, \mu_1 + \mu_2 < d_k\}$, such that $a_{0k}, a_{1k}, a_{2k} \to 0$, $b_{1k} \to \infty$, and $d_k \to 1$, as $k \to \infty$. Then, we have

$$\pi^k(\mu_1, \mu_0, \mu_2) = \frac{\sqrt{|h_1|}\sqrt{|h_2|}\sqrt{|h_3|}}{\int_{a_{0k}}^{d_k - u_2^0} \sqrt{|h_1|} d\mu_1 \cdot \int_{a_{1k}}^{b_{1k}} \sqrt{|h_2|} d\mu_0 \cdot \int_{a_{2k}}^{d_k - \mu_1} \sqrt{|h_3|} d\mu_2} I_{\Omega_k}(\mu_1, \mu_0, \mu_2), \tag{32}$$

where $\int_{a_{0k}}^{d_k - u_2^0} \sqrt{|h_1|} d\mu_1 = \int_{a_{0k}}^{d_k - u_2^0} \sqrt{1/\mu_1 (1 - \mu_1)} d\mu_1 = -\arcsin(1 - 2(d_k - u_2^0)) + \arcsin(1 - 2a_{0k})$,

$$\int_{a_{1k}}^{b_{1k}} \sqrt{|h_2|} d\mu_0 = \int_{a_{1k}}^{b_{1k}} \frac{1}{\mu_0} d\mu_0 = \log b_{1k} - \log a_{1k},$$

$$\int_{a_{2k}}^{d_k - \mu_1} \sqrt{|h_3|} d\mu_2 = \int_{a_{2k}}^{d_k - \mu_1} \sqrt{\frac{1 - \mu_1}{\mu_2 (1 - \mu_1 - \mu_2)}} d\mu_2,$$

$$= (1 - \mu_1)^{1/2} \left(-\arcsin\left(\frac{1 - \mu_1 - 2(d_k - u_1)}{1 - \mu_1}\right) + \arcsin\left(\frac{1 - \mu_1 - 2a_{2k}}{1 - \mu_1}\right) \right). \tag{33}$$

Let $(\mu_1^*, \mu_0^*, \mu_2^*)$ be an inner point of Ω_k; we get the reference prior as

$$\omega_{R_2}(\mu_0, \mu_1, \mu_2) = \lim_{k \to \infty} \frac{\pi^k(\mu_1, \mu_0, \mu_2)}{\pi^k(\mu_1^*, \mu_0^*, \mu_2^*)} \propto \sqrt{\frac{1}{\mu_0^2 \mu_1 \mu_2 (1 - \mu_1 - \mu_2)(1 - \mu_1)}}. \tag{34}$$

Similarly, under the ordering group $\{\mu_1, \mu_2, \mu_0\}$, the reference prior is $\omega_{R_2}(\mu_0, \mu_1, \mu_2)$.

(v) The Fisher information matrix of $\{\mu_2, \mu_1, \mu_0\}$ is

$$
I_3 = n \begin{pmatrix} \dfrac{1}{\mu_2} + \dfrac{1}{(1 - \mu_1 - \mu_2)} & \dfrac{1}{(1 - \mu_1 - \mu_2)} & 0 \\[3mm] \dfrac{1}{(1 - \mu_1 - \mu_2)} & \dfrac{1}{\mu_1} + \dfrac{1}{(1 - \mu_1 - \mu_2)} & 0 \\[3mm] 0 & 0 & \dfrac{1}{\mu_0^2} \end{pmatrix}. \tag{35}
$$

The inverse of I_3 is

$$
H_2 = \frac{1}{n} \begin{pmatrix} \mu_2(1 - \mu_2) & -\mu_1\mu_2 & 0 \\[2mm] -\mu_1\mu_2 & \mu_1(1 - \mu_1) & 0 \\[2mm] 0 & 0 & \mu_0^2 \end{pmatrix}. \tag{36}
$$

Then, we obtain $h_1 = 1/\mu_2(1 - \mu_2)$, $h_2 = (1 - \mu_2)/(\mu_1(1 - \mu_1 - \mu_2))$, and $h_3 = 1/\mu_0^2$.

Choose the compact sets $\Omega_k = \{(\mu_2, \mu_1, \mu_0) | a_{0k} < \mu_2, a_{1k} < \mu_1, \mu_2 + \mu_1 < d_k, a_{2k} < \mu_0 < b_{2k}\}$, such that $a_{0k}, a_{1k}, a_{2k} \longrightarrow 0$, $b_{2k} \longrightarrow \infty$, and $d_k \longrightarrow 1$, as $k \longrightarrow \infty$. Then, we have

$$
\pi^k(\mu_2, \mu_1, \mu_0) = \frac{\sqrt{|h_1|}\sqrt{|h_2|}\sqrt{|h_3|}}{\int_{a_{0k}}^{d_k - u_1^0} \sqrt{|h_1|}d\mu_2 \cdot \int_{a_{1k}}^{d_k - \mu_2} \sqrt{|h_2|}d\mu_1 \cdot \int_{a_{2k}}^{b_{2k}} \sqrt{|h_3|}d\mu_0} I_{\Omega_k}(\mu_2, \mu_1, \mu_0), \tag{37}
$$

where $\int_{a_{0k}}^{d_k - u_1^0} \sqrt{|h_1|}d\mu_2 = \int_{a_{0k}}^{d_k - u_1^0} \sqrt{1/\mu_2(1 - \mu_2)}d\mu_2 = -\arcsin(1 - 2(d_k - u_1^0)) + \arcsin(1 - 2a_{0k})$,

$$
\int_{a_{1k}}^{d_k - \mu_2} \sqrt{|h_2|}d\mu_1 = \int_{a_{1k}}^{d_k - \mu_2} \sqrt{\frac{1 - \mu_2}{\mu_1(1 - \mu_1 - \mu_2)}}d\mu_1,
$$

$$
= (1 - \mu_2)^{1/2} \left(-\arcsin\left(\frac{1 - \mu_2 - 2(d_k - \mu_2)}{1 - \mu_2}\right) + \arcsin\left(\frac{1 - \mu_2 - 2a_{1k}}{1 - \mu_2}\right) \right), \tag{38}
$$

$$
\int_{a_{2k}}^{b_{2k}} \sqrt{|h_3|}d\mu_0 = \int_{a_{2k}}^{b_{2k}} \frac{1}{\mu_0}d\mu_0 = \log b_{2k} - \log a_{2k}.
$$

Let $(\mu_2^*, \mu_1^*, \mu_0^*)$ be an inner point of Ω_k, we obtain the reference prior as

$$
\omega_{R_3}(\mu_0, \mu_1, \mu_2) = \lim_{k \longrightarrow \infty} \frac{\pi^k(\mu_2, \mu_1, \mu_0)}{\pi^k(\mu_2^*, \mu_1^*, \mu_0^*)} \propto \sqrt{\frac{1}{\mu_0^2 \mu_1 \mu_2 (1 - \mu_1 - \mu_2)(1 - \mu_2)}}. \tag{39}
$$

Similarly, under the ordering group $\{\mu_2, \mu_0, \mu_1\}$, the reference prior is $\omega_{R_3}(\mu_0, \mu_1, \mu_2)$. According to the one-to-one transformation from (μ_0, μ_1, μ_2) to $(\theta_0, \theta_1, \theta_2)$, we can obtain the reference priors $\pi_2(\mu_0, \mu_1, \mu_2)$, $\pi_3(\mu_0, \mu_1, \mu_2)$, $\pi_4(\mu_0, \mu_1, \mu_2)$ from ω_{R_1}, ω_{R_2}, and ω_{R_3}, respectively. □

Theorem 4. *Based on the reference priors $\pi_3(\theta_0, \theta_1, \theta_2)$ and $\pi_4(\theta_0, \theta_1, \theta_2)$, the posterior distributions of $(\theta_0, \theta_1, \theta_2)$ are proper.*

Proof. The joint posterior distributions of $(\theta_0, \theta_1, \theta_2)$ based on reference prior $\pi_3(\theta_0, \theta_1, \theta_2)$ and $\pi_4(\theta_0, \theta_1, \theta_2)$ are, respectively, as

$$\pi_3\left(\theta_0,\theta_1,\theta_2|x\right) = \frac{L\left(x;\lambda,\theta_0,\theta_1,\theta_2\right)\pi_3\left(\theta_0,\theta_1,\theta_2\right)}{\int_0^\infty \int_0^\infty \int_0^\infty L\left(x;\lambda,\theta_0,\theta_1,\theta_2\right)\pi_3\left(\theta_0,\theta_1,\theta_2\right)d\theta_0 d\theta_1 d\theta_2},$$

$$\propto \theta^{-1}\theta_0^{n_0-1/2}\theta_1^{n_1-1/2}\theta_2^{n_2-1/2}\left(\theta_1+\theta_2\right)^{-1/2}\exp\left\{-\frac{A\theta}{\lambda}\right\},$$

$$\pi_4\left(\theta_0,\theta_1,\theta_2|x\right) = \frac{L\left(x;\lambda,\theta_0,\theta_1,\theta_2\right)\pi_4\left(\theta_0,\theta_1,\theta_2\right)}{\int_0^\infty \int_0^\infty \int_0^\infty L\left(x;\lambda,\theta_0,\theta_1,\theta_2\right)\pi_4\left(\theta_0,\theta_1,\theta_2\right)d\theta_0 d\theta_1 d\theta_2},$$

$$\propto \theta^{-1}\theta_0^{n_0-1/2}\theta_1^{n_1-1/2}\theta_2^{n_2-1/2}\left(\theta_0+\theta_2\right)^{-1/2}\exp\left\{-\frac{A\theta}{\lambda}\right\}.$$

$$(40)$$

Integrating $\pi_3\left(\theta_0,\theta_1,\theta_2|x\right)$ and $\pi_4\left(\theta_0,\theta_1,\theta_2|x\right)$ with respect to $\theta_0,\theta_1,$ and θ_2, respectively, we obtain

$$\int_0^\infty \int_0^\infty \int_0^\infty \theta^{-1}\theta_0^{n_0-1/2}\theta_1^{n_1-1/2}\theta_2^{n_2-1/2}\left(\theta_1+\theta_2\right)^{-1/2}\exp\left\{-\frac{A\theta}{\lambda}\right\}d\theta_0 d\theta_1 d\theta_2,$$

$$= B\left(n_0+\frac{1}{2},n_1+n_2+\frac{1}{2}\right)B\left(n_1+\frac{1}{2},n_2+\frac{1}{2}\right)\frac{\Gamma(n)}{(A/\lambda)^n}<\infty,$$

$$\int_0^\infty \int_0^\infty \int_0^\infty \theta^{-1}\theta_0^{n_0-1/2}\theta_1^{n_1-1/2}\theta_2^{n_2-1/2}\left(\theta_0+\theta_2\right)^{-1/2}\exp\left\{-\frac{A\theta}{\lambda}\right\}d\theta_0 d\theta_1 d\theta_2,$$

$$= B\left(n_1+\frac{1}{2},n_0+n_2+\frac{1}{2}\right)B\left(n_0+\frac{1}{2},n_2+\frac{1}{2}\right)\frac{\Gamma(n)}{(A/\lambda)^n}<\infty.$$

$$(41)$$

Thus, the posterior distributions of $(\theta_0,\theta_1,\theta_2)$ based on $\pi_3\left(\theta_0,\theta_1,\theta_2\right)$ and $\pi_4\left(\theta_0,\theta_1,\theta_2\right)$ are proper.   □

4.4. Bayesian Estimates. The joint posterior distributions of $(\theta_0,\theta_1,\theta_2)$ based on $\pi_1,\pi_2,\pi_3,$ and π_4 are, respectively, as

$$\pi_1\left(\theta_0,\theta_1,\theta_2|x\right) = \frac{L\left(x;\lambda,\theta_0,\theta_1,\theta_2\right)\pi_1\left(\theta_0,\theta_1,\theta_2\right)}{\int_0^\infty \int_0^\infty \int_0^\infty L\left(x;\lambda,\theta_0,\theta_1,\theta_2\right)\pi_1\left(\theta_0,\theta_1,\theta_2\right)d\theta_0 d\theta_1 d\theta_2},$$

$$(42)$$

where

$$\int_0^\infty \int_0^\infty \int_0^\infty L\left(x;\lambda,\theta_0,\theta_1,\theta_2\right)\pi_1\left(\theta_0,\theta_1,\theta_2\right)d\theta_0 d\theta_1 d\theta_2$$

$$= w_1 w_2 \exp\left\{\lambda\sum_l x_l\right\}\int_{0<\theta_0/\theta+\theta_1/\theta<1}\prod_{i=0}^1\left(\frac{\theta_i}{\theta}\right)^{n_i+c_i-1}\left(1-\sum_{i=0}^1\frac{\theta_i}{\theta}\right)^{n_2+c_2-1}d\frac{\theta_0}{\theta}d\frac{\theta_1}{\theta},\int_0^\infty \theta^{n+a+1}e^{-(A/\lambda+b)\theta}d\theta$$

$$= w_1 w_2 \exp\left\{\lambda\sum_l x_l\right\}B\left(n_0+c_0,n_1+c_1+n_2+c_2\right)B\left(n_1+c_1,n_2+c_2\right)\frac{\Gamma(n+a+2)}{(A/\lambda+b)^{n+a+2}},$$

$$(43)$$

where $w_1 = \Gamma\left(\sum_{i=0}^{2} c_i\right) b^{a-c_0-c_1-c_2}/\Gamma(a)$ and $w_2 = \prod_{i=0}^{2} b^{c_i}/\Gamma(c_i)$.   Thus, we obtain

$$\pi_1\left(\theta_0, \theta_1, \theta_2 | x\right) = \frac{\theta^{a-c_0-c_1-c_2}\theta_0^{n_0+c_0-1}\theta_1^{n_1+c_1-1}\theta_2^{n_2+c_2-1} \exp\{-(A/\lambda + b)\theta\}}{B\left(n_0 + c_0, n_1 + c_1 + n_2 + c_2\right)B\left(n_1 + c_1, n_2 + c_2\right)\Gamma(n+a)/\left(A/\lambda + b\right)^{n+a}}. \tag{44}$$

Similarly,

$$\pi_2\left(\theta_0, \theta_1, \theta_2 | x\right) = \frac{L\left(x; \lambda, \theta_0, \theta_1, \theta_2\right)\pi_2\left(\theta_0, \theta_1, \theta_2\right)}{\int_0^\infty \int_0^\infty \int_0^\infty L\left(x; \lambda, \theta_0, \theta_1, \theta_2\right)\pi_2\left(\theta_0, \theta_1, \theta_2\right)d\theta_0 d\theta_1 d\theta_2}, \tag{45}$$

where

$$\int_0^\infty \int_0^\infty \int_0^\infty L\left(x; \lambda, \theta_0, \theta_1, \theta_2\right)\pi_2\left(\theta_0, \theta_1, \theta_2\right)d\theta_0 d\theta_1 d\theta_2,$$

$$= \int_0^\infty \int_0^\infty \int_0^\infty \theta^{-3/2}\theta_0^{n_0-1/2}\theta_1^{n_1-1/2}\theta_2^{n_2-1/2} \exp\left\{\lambda \sum_l x_l - \frac{A}{\lambda}\theta\right\}d\theta_0 d\theta_1 d\theta_2, \tag{46}$$

$$= \exp\left\{\lambda \sum_l x_l\right\}B\left(n_0 + \frac{1}{2}, n_1 + n_2 + 1\right)B\left(n_1 + \frac{1}{2}, n_2 + \frac{1}{2}\right)\frac{\Gamma(n)}{(A/\lambda)^n}.$$

We obtain

$$\pi_2\left(\theta_0, \theta_1, \theta_2 | x\right) = \frac{\theta^{-3/2}\theta_0^{n_0-1/2}\theta_1^{n_1-1/2}\theta_2^{n_2-1/2} \exp\{-A\theta/\lambda\}}{B\left(n_0 + 1/2, n_1 + n_2 + 1\right)B\left(n_1 + 1/2, n_2 + 1/2\right)\Gamma(n)/\left(A/\lambda\right)^n},$$

$$\pi_3\left(\theta_0, \theta_1, \theta_2 | x\right) = \frac{L\left(x; \lambda, \theta_0, \theta_1, \theta_2\right)\pi_3\left(\theta_0, \theta_1, \theta_2\right)}{\int_0^\infty \int_0^\infty \int_0^\infty L\left(x; \lambda, \theta_0, \theta_1, \theta_2\right)\pi_3\left(\theta_0, \theta_1, \theta_2\right)d\theta_0 d\theta_1 d\theta_2}, \tag{47}$$

where

$$\int_0^\infty \int_0^\infty \int_0^\infty L\left(x; \lambda, \theta_0, \theta_1, \theta_2\right)\pi_3\left(\theta_0, \theta_1, \theta_2\right)d\theta_0 d\theta_1 d\theta_2,$$

$$= \int_0^\infty \int_0^\infty \int_0^\infty \theta^{-1}\theta_0^{n_0-1/2}\theta_1^{n_1-1/2}\theta_2^{n_2-1/2}\left(\theta_1 + \theta_2\right)^{-1/2} \exp\left\{\lambda \sum_l x_l - \frac{A\theta}{\lambda}\right\}d\theta_0 d\theta_1 d\theta_2, \tag{48}$$

$$= \exp\left\{\lambda \sum_l x_l\right\}B\left(n_0 + \frac{1}{2}, n_1 + n_2 + \frac{1}{2}\right)B\left(n_1 + \frac{1}{2}, n_2 + \frac{1}{2}\right)\frac{\Gamma(n)}{(A/\lambda)^n}.$$

We obtain

$$\pi_3\left(\theta_0, \theta_1, \theta_2 | x\right) = \frac{\theta^{-1} \theta_0^{n_0 - 1/2} \theta_1^{n_1 - 1/2} \theta_2^{n_2 - 1/2} \left(\theta_1 + \theta_2\right)^{-1/2} \exp\{-A\theta/\lambda\}}{B\left(n_0 + 1/2, n_1 + n_2 + 1/2\right) B\left(n_1 + 1/2, n_2 + 1/2\right) \Gamma(n) / (A/\lambda)^n},$$

$$\pi_4\left(\theta_0, \theta_1, \theta_2 | x\right) = \frac{L\left(x; \lambda, \theta_0, \theta_1, \theta_2\right) \pi_4\left(\theta_0, \theta_1, \theta_2\right)}{\int_0^\infty \int_0^\infty \int_0^\infty L\left(x; \lambda, \theta_0, \theta_1, \theta_2\right) \pi_4\left(\theta_0, \theta_1, \theta_2\right) d\theta_0 d\theta_1 d\theta_2},$$

(49)

where

$$\int_0^\infty \int_0^\infty \int_0^\infty L\left(x; \lambda, \theta_0, \theta_1, \theta_2\right) \pi_4\left(\theta_0, \theta_1, \theta_2\right) d\theta_0 d\theta_1 d\theta_2,$$

$$= \int_0^\infty \int_0^\infty \int_0^\infty \theta^{-1} \theta_0^{n_0 - 1/2} \theta_1^{n_1 - 1/2} \theta_2^{n_2 - 1/2} \left(\theta_0 + \theta_2\right)^{-1/2} \exp\left\{\lambda \sum_l x_l - \frac{A\theta}{\lambda}\right\} d\theta_0 d\theta_1 d\theta_2,$$

$$= \exp\left\{\lambda \sum_l x_l\right\} B\left(n_1 + \frac{1}{2}, n_0 + n_2 + \frac{1}{2}\right) B\left(n_0 + \frac{1}{2}, n_2 + \frac{1}{2}\right) \frac{\Gamma(n)}{(A/\lambda)^n}.$$

(50)

Then, we have

$$\pi_4\left(\theta_0, \theta_1, \theta_2 | x\right) = \frac{\theta^{-1} \theta_0^{n_0 - 1/2} \theta_1^{n_1 - 1/2} \theta_2^{n_2 - 1/2} \left(\theta_0 + \theta_2\right)^{-1/2} \exp\{-A\theta/\lambda\}}{B\left(n_1 + 1/2, n_0 + n_2 + 1/2\right) B\left(n_0 + 1/2, n_2 + 1/2\right) \Gamma(n) / (A/\lambda)^n}.$$

(51)

From (9)–(12), we get the Bayesian estimates of parameters θ_0, θ_1, θ_2, and θ against squared error loss function based on π_1, π_2, π_3, and π_4, respectively, which are listed in Table 1.

4.5. HPD Credible Intervals. The HPD credible intervals of parameters θ_0, θ_1, θ_2, and θ can be constructed by the Monte Carlo method studied by Chen and Shao [22].

Step 1: given the value of n and the observed data $(x_1, x_2, \cdots, x_n)$, compute the Bayesian estimates of $\widehat{\theta}_0$, $\widehat{\theta}_1$, $\widehat{\theta}_2$, and $\widehat{\theta}$ based on π_1, π_2, π_3, and π_4, respectively.

Step 2: repeat Step 1 M times; we obtain M sets of the values $\widehat{\theta}_0$, $\widehat{\theta}_1$, $\widehat{\theta}_2$, and $\widehat{\theta}$ based on π_1, π_2, π_3, and π_4, respectively. Arrange them in the ascending order, we obtain

$$\widehat{\theta}_{0\pi_k[1]} < \cdots < \widehat{\theta}_{0\pi_k[M]}, \widehat{\theta}_{1\pi_k[1]} < \cdots < \widehat{\theta}_{1\pi_k[M]}, \widehat{\theta}_{2\pi_k[1]} < \cdots < \widehat{\theta}_{2\pi_k[M]}, \widehat{\theta}_{\pi_k[1]} < \cdots < \widehat{\theta}_{\pi_k[M]}, k = 1, 2, 3, 4.$$

(52)

Step 3: compute the CIs at $1 - \gamma$ confidence level as

$$\left(\widehat{\theta}_{\nu\pi_k[w]}, \widehat{\theta}_{\nu\pi_k[w+(1-\gamma)M]}\right), \left(\widehat{\theta}_{\pi_k[w]}, \widehat{\theta}_{\pi_k[w+(1-\gamma)M]}\right), \nu = 0, 1, 2; w = 1, 2, \cdots, M - (1-\gamma)M; k = 1, 2, 3, 4.$$

(53)

Step 4: the HPD CIs for θ_ν, $\nu = 0, 1, 2$, and θ are the shortest intervals among $\left(\widehat{\theta}_{\nu\pi_k[w]}, \widehat{\theta}_{\nu\pi_k[w+(1-\gamma)M]}\right)$, $\left(\widehat{\theta}_{\pi_k[w]}, \widehat{\theta}_{\pi_k[w+(1-\gamma)M]}\right)$, and $w = 1, 2, \cdots, M - (1-\gamma)M$, respectively.

Table 1: Bayesian estimates of parameters based on different priors.

Prior	θ_0	θ_1	θ_2	θ
π_1	$\lambda(n_0 + c_0)(n + a)/(n + c_0 + c_1 + c_2)(A + b\lambda)$	$\lambda(n_1 + c_1)(n + a)/(n + c_0 + c_1 + c_2)(A + b\lambda)$	$\lambda(n_2 + c_2)(n + a)/(n + c_0 + c_1 + c_2)(b\lambda + A)$	$(n + a)\lambda/A + b\lambda$
π_2	$n\lambda(2n_0 + 1)/A(2n + 3)$	$n\lambda(2n_1 + 1)/A(2n + 3)$	$n\lambda(2n_2 + 1)/A(2n + 3)$	$n\lambda/A$
π_3	$n\lambda(2n_0 + 1)/2A(n + 1)$	$n\lambda(2n_1 + 1)/2A(n + 1)$	$n\lambda(2n_1 + 2n_2 + 1)(2n_2 + 1)/4A(n + 1)(n_1 + n_2 + 1)$	$n\lambda/A$
π_4	$n\lambda(2n_0 + 2n_2 + 1)(2n_0 + 1)/4A(n + 1)(n_0 + n_2 + 1)$	$n\lambda(2n_1 + 2n_2 + 1)(2n_1 + 1)/4A(n + 1)(n_1 + n_2 + 1)$	$n\lambda(2n_0 + 2n_2 + 1)(2n_2 + 1)/2A(n + 1)(n_0 + n_2 + 1)$	$n\lambda/A$

5. Numerical Simulation and Illustrative Example

5.1. Simulation.

Suppose the common shape parameter λ is known. The initial values for parameters $(\lambda, \theta_0, \theta_1, \theta_2)$ are $(3, 1, 2, 1)$. The initial values for the hyperparameters a, b, c_0, c_1, and c_2 are all 0.001. Take the sample size $n = 10$, 20, 30, and 50. Generate the random samples $(x_1, x_2, \cdots, x_n)$ from $MOGP(\lambda, \theta_0, \theta_1, \theta_2)$ by the following steps:

Step 1: for a fixed value n, generate n samples $u_{01}, u_{02}, \cdots, u_{0n}$ from $GP(\lambda, \theta_0)$, $u_{11}, u_{12}, \cdots, u_{1n}$ from $GP(\lambda, \theta_1)$, and $u_{21}, u_{22}, \cdots, u_{2n}$ from $GP(\lambda, \theta_2)$. Then, we obtain $T_{1l} = \min(u_{0l}, u_{1l})$ and $T_{2l} = \min(u_{0l}, u_{2l})$, $l = 1, 2, \cdots, n$.

Step 2: compute $(x_l, \delta_{0l}, \delta_{1l}, \delta_{2l})$, $l = 1, 2, \cdots, n$, where $x_l = \min(T_{1l}, T_{2l})$, $\delta_{0l} = I(T_{1l} = T_{2l})$, $\delta_{1l} = I(T_{1l} < T_{2l})$, and $\delta_{2l} = I(T_{1l} > T_{2l})$.

Repeat the procedures 10,000 times; we get the values of the mean squared errors (MSEs) of the MLEs, the average lengths (ALs), and coverage probabilities (CPs) of the 95% Boot-P CIs, and the MSEs of the Bayesian estimates, the ALs, and CPs of the 95% HPD CIs, which are shown in Table 2–5. From the results in Table 2–5, we can make the following conclusions.

The MSEs of MLEs and Bayesian estimates decrease as the sample size increases. For given sample size n, the Bayesian estimates based on π_1, π_2, and π_4 are smaller than the MSEs of MLEs. The MSEs of Bayesian estimates of

θ_0 and θ_2 based on π_4 are smaller than that based on π_1, π_2, and π_3. The MSEs of Bayesian estimates of θ_1 based on π_3 are smaller than that based on π_1, π_2, and π_4. The MSEs of Bayesian estimates of θ based on π_1 are smaller than that based on π_2, π_3, and π_4.

The CPs of Boot-P and HPD CIs are all close to 0.95. The ALs of Boot-P and HPD CIs decrease; the associated CPs increase when the sample size increases. The CPs of HPD CIs based on Bayesian estimates are larger than the CPs of Boot-P CIs based on MLEs.

5.2. Illustrative Analysis

5.2.1. Simulated Data.

For illustrative purposes, with initial value for parameters $(\lambda, \theta_0, \theta_1, \theta_2)$ as $(3, 1, 2, 1)$, we use the procedures mentioned above to generate U_0, U_1, and U_2 from $GP(3, 1)$, $GP(3, 2)$, and $GP(3, 1)$, respectively. We then get $T_1 = \min(U_0, U_1)$ and $T_2 = \min(U_0, U_2)$; the latent lifetime of the system is $\min(T_1, T_2)$. The simulated data are listed in Table 6. The MLEs, Bayesian estimates, and associated 95% CIs for parameters θ_0, θ_1, θ_2, and θ are shown in Table 7. From Table 7, all the MLEs and Bayesian estimates of $(\theta_0, \theta_1, \theta_2, \theta)$ are close to the true value.

5.2.2. Real Data.

Use the procedures mentioned above to a real dataset. Kundu and Gupta [13] analyzed the football data of UEFA Champions' League data which are presented in Table 1. From the data, T_1 and T_2 can be regarded as two

dependent failure modes, and $n_0 = 7$, $n_1 = 17$, and $n_2 = 13$. This data have been fitted by Marshall–Olkin bivariate Gompertz distribution (see Wang et al. [23]).

The MLEs, Bayesian estimates, and associated 95% CIs for parameters θ_0, θ_1, θ_2, and θ are shown in Table 8. From Tables 7 and 8, Bayesian estimates under different priors are close to MLEs, and the lengths of 95% Boot-p CIs associated to MLEs are longer than the lengths of 95% HPD CIs associated to Bayesian estimates.

6. Conclusion

This paper discussed the point estimates and CIs for the parameters of the dependent competing risks' model from MOGP distribution. We studied the appropriateness of the posteriors based on conjugate prior and Jeffreys and Reference priors, obtained the Bayesian estimates in closed forms, and constructed the associated HPD CIs. From the simulations results, the use of the Bayesian method can be recommended if the priors are available. The results of the illustrative analysis show that the proposed methods work well; from the lengths of CIs, we can conclude the Bayesian estimates are better than MLEs in general.

Data Availability

The data used to support the findings of the study are available within the article.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

In the application of classical graph theory, there always are various indeterministic factors. This study studies the indeterministic factors in the connected graph by employing the uncertainty theory. First, this study puts forward two concepts: generalized uncertain graph and its connectivity index. Second, it presents a new algorithm to compute the connectivity index of an uncertain graph and generalized uncertain graph and verify this algorithm with typical examples. In addition, it proposes the definition and algorithm of α-connectivity index of generalized uncertain graph and verifies the stability and efficiency of this new algorithm by employing numerical experiments.

1. Introduction

In graph theory, the connectivity graph is a fundamental concept. Many phenomena in the real life can be conveniently described as the graphical problems, which are formed by the "points" and the "lines." For example, a roadmap can be interpreted as a graph, the vertices are the junctions, and an edge is the stretch of road from one junction to the next [1]. Graph theory is an important branch of operation research, and it is a young but rapidly maturing subject. Graph theory originated in the eighteenth century. Euler solved the first real problem (seven bridges of Königsberg) using graph theory in 1736 [2, 3], which thereby made him a founder of graph theory.

The information of edges and vertices is completely deterministic in traditional graph theory. However, in applications, due to the complexity of the system, uncertain factors in the graph may appear and produce a new situation. For example, the optimal objective cannot be easily formulated if the weight of the edges is uncertain in some shortest path problems [4], and the classical algorithms fail to solve shortest path problems. Whether two vertices are connected by an edge cannot be accurately determined in real life, which results in the failure of proving the properties of uncertain graph by the classical method. To cope with the

above situation, the concept of uncertain graph was proposed in 2011 in a reference [5].

Sometimes, whether some vertices exist cannot be completely determined and the information of edges cannot be completely determined. For example, in cloud computing networks, the vertices could represent data centers, with edges representing that the two data centers participate in the calculation at the same time. The vertices and the edges in cloud computing networks both have indeterminacy. As a result, it cannot be fully determined whether the graph is connected.

Generally, when we apply probability theory, the exact probability distribution has to be known. However, the probability distribution does not exist in some observational data of small samples. In this case, we must predict the data based on the experience of experts. To properly use empirical data, Professor Liu proposed the uncertainty theory [6] and revised in [7]. In an uncertain environment, the uncertainty theory is a very powerful tool to solve the situations in which only empirical data can be employed.

Based on the work of [8], this study attempts to deal with the situation where the existence of vertices and edges cannot be completely determined. Reference [8] first presented the concepts of generalized uncertain graph and its connectivity index. The study is mainly to compute the

connectivity index of the generalized uncertainty graph. This study puts forward a new algorithm to compute the connectivity index by the uncertainty theory.

There are five sections in the study. Section 1 is the introduction of this study. Section 2 introduces the relevant concepts and relevant properties of the uncertainty theory and graph theory. Section 3 briefly introduces an uncertain graph and puts forward a new algorithm to compute the connectivity index of uncertain graph and then verifies this algorithm with typical examples. Section 4 proposes a new algorithm of connectivity index of generalized uncertain graph based on the concepts of generalized uncertain graph and connectivity index and employs numerical experiments to verify the correctness of this new algorithm. Section 5 is the conclusion of the study.

2. Preliminaries

2.1. Main Theorem in Uncertainty Theory.
Professor Liu Baoding established the uncertainty theory system [9] in 2007, which was revised and improved in 2010 [7]. Today, the uncertainty theory is a very important branch of mathematics.

This study will shortly present the main developments of uncertainty theory in multiple fields. Reference [10] presented the uncertainty process and defined the uncertainty differential equation. Reference [11] proposed uncertain programming. Reference [4] explored the shortest path problem that the weight of the edges is uncertain in 2011. Reference [12] explored the connectivity index of uncertain
FIGURE 1: A 4-order graph.

graph in 2013. In the next few years, Gao has discussed the cycle index [13, 14], regularity index [8], tree index [15], and α-connectivity index [16] of uncertain graph. Reference [17] discussed some properties of uncertain relations on a finite set in 2014. Reference [18] discussed the distribution function of the diameter in uncertain graph in 2014. There are four main axioms in the uncertainty theory: normality, duality, subadditivity, and product axiom [6, 9]. References [6] and [9, 19] give the concepts and conclusions about the uncertainty theory used in the study.

Theorem 1 (see [19]). *The events $\zeta_1, \zeta_2, \ldots, \zeta_n$ are independent Boolean uncertain variables, i.e.,*

$$\zeta_i = \begin{cases} 1 & \text{if its uncertain measure is } \delta_i, \\ 0 & \text{if its uncertain measure is } 1 - \delta_i, \end{cases} \tag{1}$$

for $i = 1, 2, \ldots, n$, respectively. When g is a Boolean function, $\zeta = g(\zeta_1, \zeta_2, \ldots, \zeta_n)$ is a Boolean uncertain variable such that:

$$M\{\zeta = 1\} = \begin{cases} \sup_{g(\zeta_1, \zeta_2, \ldots, \zeta_n)=1} \min_{1 \le i \le n} v_i(y_i), & \text{if } \sup_{g(\zeta_1, \zeta_2, \ldots, \zeta_n)=1} \min_{1 \le i \le n} v_i(y_i) < 0.5, \\ 1 - \sup_{g(\zeta_1, \zeta_2, \cdots, \zeta_n)=0} \min_{1 \le i \le n} v_i(y_i), & \text{if } \sup_{g(\zeta_1, \zeta_2, \cdots, \zeta_n)=1} \min_{1 \le i \le n} v_i(y_i) \ge 0.5, \end{cases} \tag{2}$$

where y_i is the real number either 0 or 1, and v_i is defined as follows:

$$v_i(y_i) = \begin{cases} \delta_i & \text{if } y_i = 1, \\ 1 - \delta_i & \text{if } y_i = 0, \end{cases} \tag{3}$$

for $i = 1, 2, \ldots, n$, respectively.

2.2. Main Concepts and Terminologies of Classical Graph.
This part will introduce the definition of graph and some main concepts of classical graph theory. At the same time, it will discuss the main theorems about graphs with some examples. The following basic terminology and concepts are from [17].

A graph G means a finite nonempty 2-element set, which consists of a set of vertices and a set of edges. The numbers of vertices of G are called the order, and the numbers of edges of G are called the size. A path is an alternating sequence of vertices and edges if no vertices are repeated. Two vertices are said to be connected if there exists a path between the two

vertices in the graph. A connected graph G means that there exists one path between any two vertices.

Definition 1 (see[17]). *Let G be an n-order and m-size graph, $V(G) = \{v_1, v_2, \ldots, v_n\}$ be its vertices' set, and $E(G) = \{e_1, e_2, \ldots, e_m\}$ be its edges. The symplectic $n \times n$ matrix is the adjacency matrix of G:*

$$A_G = \begin{pmatrix} \delta_{11} & \delta_{12} & \cdots & \delta_{1n} \\ \delta_{21} & \delta_{22} & \cdots & \delta_{2n} \\ \vdots & \vdots & \cdots & \vdots \\ \delta_{n1} & \delta_{n2} & \cdots & \delta_{nn} \end{pmatrix}, \tag{4}$$

where $\delta_{ij} = \begin{cases} 1 & \text{if } v_i v_j \in E(G), \\ 0 & \text{if } v_i v_j \notin E(G). \end{cases}$

Example 1. Figure 1 is a 4-order graph.
The adjacency matrix of Figure 1 is as follows:
Figure 2: An uncertain 4-order graph.

$$\begin{pmatrix} 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 0 \end{pmatrix}. \tag{5}$$

There is a very important theorem in the classical graph theory, and it is a sufficient and necessary condition to verify whether the graph is a connected graph.

Theorem 2. *If G is a n-order graph and its symplectic adjacency matrix is the A_G, let R be the $n \times n$ matrix, where*

$$R = I + A_G + A_G^2 + A_G^3 + \cdots + A_G^{n-1}. \tag{6}$$

Then, G is a connected graph if and only if $R > 0$.

To analyze graphs and their properties with uncertainty factors, the fundamental concepts are given as follows.

Definition 2. If a symplectic adjacency matrix of the n-order graph is A_G, the connectivity function of G is the following function:

$$C(A_G) = \begin{cases} 1, & \text{if } I + A_G + A_G^2 + A_G^3 + \cdots + A_G^{n-1} > 0, \\ 0, & \text{otherwise.} \end{cases} \tag{7}$$

3. Uncertainty Graphs

3.1. Basic Concepts. Every vertex and edge of a graph is wholly determined. That is to say, the vertex and the edge either exist or do not exist in the classical graph theory. An n-order graph may be defined as a $n \times n$ symplectic adjacency matrix, and its elements are either 1 or 0. At the same time, the indeterminacy factor will absolutely occur in practical applications. To study this problem, [12] gave the concept of uncertain graph, which means all edges are independent and exist with uncertain measure. That is, the elements are no longer 1 or 0 in adjacency matrix, but a number in [0,1]. For instance, $\delta_{ij} = 0.65$ represents that the uncertain measure is 0.65 about the edge existing between the two vertices, and the uncertain measure is 0.35 about the edge not existing between the two vertices.

Definition 3 (see [12]). The n-order graph G is called an uncertain graph if its symplectic adjacency matrix is as follows:

$$A_G = \begin{pmatrix} \delta_{11} & \delta_{12} & \cdots & \delta_{1n} \\ \delta_{21} & \delta_{22} & \cdots & \delta_{2n} \\ \vdots & \vdots & \cdots & \vdots \\ \delta_{n1} & \delta_{n2} & \cdots & \delta_{nn} \end{pmatrix}, \tag{8}$$

where δ_{ij} means the uncertain measure of the edge between vertexes i and j, for $i, j = 1, 2, \ldots, n$, respectively.

It should be noted that $\delta_{ii} = 0 \, (i = 1, 2, \ldots, n)$ in the uncertain adjacency matrix. Besides, an uncertain adjacency matrix is symmetric if the uncertain graph is undirected; i e., $\delta_{ij} = \delta_{ji}$ for any i and j. Evidently, all the information of an uncertain graph may be contained in the symmetric adjacency matrix.

Example 2. An uncertain 4-order graph is as the following in Figure 2.

The symmetric adjacency matrix of Figure 2 is as follows:

$$\begin{pmatrix} 0 & 0.8 & 0.6 & 0.2 \\ 0.8 & 0 & 0.4 & 0.7 \\ 0.6 & 0.4 & 0 & 0.3 \\ 0.2 & 0.7 & 0.3 & 0 \end{pmatrix}. \tag{9}$$

We may know that the edge set of G is an uncertain Boolean variable set according to the definition of uncertain graph.

$$E(G) = \left\{\zeta_{12}, \zeta_{13}, \ldots, \zeta_{1n}, \zeta_{23}, \ldots, \zeta_{2n}, \zeta_{34}, \ldots, \zeta_{3n}, \ldots, \zeta_{(n-1)n}\right\}, \tag{10}$$

where $M\{\zeta_{ij} = 1\} = \delta_{ij}$, for any $1 \le i < j \le n$. For the sake of simplicity, we remove these edges ζ_{ij} satisfying $M\{\zeta_{ij} = 1\} = 0$ and denote as $E(G) = \{\zeta_1, \zeta_2, \ldots, \zeta_m\}$.

Definition 4 (see [12]). Let G be an uncertain graph and $E(G) = \{\zeta_1, \zeta_2, \ldots, \zeta_m\}$ be its edge set, and then, connectivity function of G may be denoted as follows:

$$\mathbb{C}(G) = \begin{cases} 1, & \text{if } G \text{ is } a \text{ connected graph,} \\ 0, & \text{otherwise.} \end{cases} \tag{11}$$

Evidently, $\mathbb{C}(G)$ is a Boolean function. We define connectivity index of an uncertain graph G with $E(G) = \{\zeta_1, \zeta_2, \ldots, \zeta_m\}$ as follows:

$$\partial(G) = M\{\mathbb{C}(G) = 1\}. \tag{12}$$

In other words, the connectivity index is the uncertain measure of the connected graph.

The key is how to obtain the connectivity index in a given uncertain graph. A theorem is proposed to deal with this problem.

Theorem 3. *Let G be an n-order uncertain graph with a symmetric adjacency matrix as follows:*

$$A_G = \begin{pmatrix} \delta_{11} & \delta_{12} & \cdots & \delta_{1n} \\ \delta_{21} & \delta_{22} & \cdots & \delta_{2n} \\ \vdots & \vdots & \cdots & \vdots \\ \delta_{n1} & \delta_{n2} & \cdots & \delta_{nn} \end{pmatrix}. \tag{13}$$

The connectivity index of G is the formula (14) if all edges are independent.

$$\partial(G) = \begin{cases} \sup\limits_{\mathbb{C}(Y)=1} \min\limits_{1 \le i < j \le n} v_{ij}(y_{ij}), & \text{if } \sup\limits_{\mathbb{C}(Y)=1} \min\limits_{1 \le i < j \le n} v_{ij}(y_{ij}) < 0.5, \\ 1 - \sup\limits_{\mathbb{C}(Y)=0} \min\limits_{1 \le i < j \le n} v_{ij}(y_{ij}), & \text{if } \sup\limits_{\mathbb{C}(Y)=1} \min\limits_{1 \le i < j \le n} v_{ij}(y_{ij}) \ge 0.5, \end{cases} \tag{14}$$

where Y is an uncertain symmetric matrix and its diagonal entries are zero, and Y is denoted as follows:

$$Y = \begin{pmatrix} y_{11} & y_{12} & \cdots & y_{1n} \\ y_{21} & y_{22} & \cdots & y_{2n} \\ \vdots & \vdots & \vdots & \vdots \\ y_{n1} & y_{n2} & \cdots & y_{nn} \end{pmatrix}, \tag{15}$$

and $y_{ij} = y_{ji}$ is equal to either 0 or 1 and $y_{ii} = 0$, and v_{ij} is denoted as follows:

$$v_{ij}(y_{ij}) = \begin{cases} \delta_{ij}, & \text{when } y_{ij} = 1, \\ 1 - \delta_{ij}, & \text{when } y_{ij} = 0, \end{cases} \tag{16}$$

for $i = 1, 2, \ldots, n$; $j = 1, 2, \ldots, n$, respectively, and

$$\mathbb{C}(Y) = \begin{cases} 1, & \text{if } I + Y + Y^2 + Y^3 + \ldots + Y^{n-1} > 0, \\ 0, & \text{otherwise.} \end{cases} \tag{17}$$

Proof. Since y_{ij} is independent Boolean uncertain variables for any i and j, Y is the Boolean symmetric uncertain matrix. Therefore, we may get that the function $\mathbb{C}(Y)$ is a Boolean function based on Definition 3. Therefore, according to Theorem 1, we have the following:

$$M\{\mathbb{C}(Y) = 1\} = \begin{cases} \sup\limits_{\mathbb{C}(Y)=1} \min\limits_{1 \le i < j \le n} v_{ij}(y_{ij}), & \text{if } \sup\limits_{\mathbb{C}(Y)=1} \min\limits_{1 \le i < j \le n} v_{ij}(y_{ij}) < 0.5, \\ 1 - \sup\limits_{\mathbb{C}(Y)=0} \min\limits_{1 \le i < j \le n} v_{ij}(y_{ij}), & \text{if } \sup\limits_{\mathbb{C}(Y)=1} \min\limits_{1 \le i < j \le n} v_{ij}(y_{ij}) \ge 0.5, \end{cases} \tag{18}$$

where Y is the symmetric uncertain matrix as follows:

$$Y = \begin{pmatrix} y_{11} & y_{12} & \cdots & y_{1n} \\ y_{21} & y_{22} & \cdots & y_{2n} \\ \vdots & \vdots & \vdots & \vdots \\ y_{n1} & y_{n2} & \cdots & y_{nn} \end{pmatrix}, \tag{19}$$

and $y_{ij} = y_{ji}$ is equal to either 0 or 1 and $y_{ij} = y_{ji}$, and v_{ij} is defined as follows:

$$v_{ij}(y_{ij}) = \begin{cases} \delta_{ij}, & \text{when } y_{ij} = 1, \\ 1 - \delta_{ij}, & \text{when } y_{ij} = 0, \end{cases} \tag{20}$$

for any i, j. The connectivity index of an uncertain graph is the uncertain measure of connected graph according to Definition 4. Therefore, Theorem 2 has been proved.

However, the connectivity index is difficult to obtain from Theorem 1 as to other more complex graphs. A new theorem to compute the connectivity index will be given. First, some new definitions will be introduced in the following. □

Definition 5. Assume $A = (a_{ij})$ and $B = (b_{ij})$ be all the $m \times n$ matrices. Then, the logic sum $A \oplus B$ is defined as follows:

$$A \oplus B = (c_{ij}), \tag{21}$$

where $c_{ij} = a_{ij} \vee b_{ij} = \max\{a_{ij}, b_{ij}\}$.

Definition 6. Assume $A = (a_{ij})$ be $m \times k$ matrix and $B = (b_{ij})$ be $k \times n$ matrix. Then, the logic product $A \circ B$ is defined as follows:

$$A \circ B = (c_{ij}), \tag{22}$$

where $c_{ij} = \vee_{p=1}^{k} (a_{ip} \wedge b_{pj}) = \max\limits_{1 \le p \le k}\{\min\{a_{ip}, b_{pj}\}\}$.

Definition 7. Assume $A = (a_{ij})$ be the $n \times n$ matrix. Then, the logic power $A^{(k)}$ is defined as follows:

$$A^{(k)} = A^{(k-1)} \circ A, \tag{23}$$

where I be the $n \times n$ unit matrix, $A^{(1)} = A$ and $A^{(0)} = I$.

Definition 8. Let G be an n-order uncertain graph and its symmetric adjacency matrix be as follows:

$$A_G = \begin{pmatrix} \delta_{11} & \delta_{12} & \cdots & \delta_{1n} \\ \delta_{21} & \delta_{22} & \cdots & \delta_{2n} \\ \vdots & \vdots & \cdots & \vdots \\ \delta_{n1} & \delta_{n2} & \cdots & \delta_{nn} \end{pmatrix}. \tag{24}$$

Then, the reachable measure matrix P of uncertain graph G is defined as follows:

$$P = I \oplus A_G \oplus A_G^{(2)} \oplus A_G^{(3)} \oplus \ldots \oplus A_G^{(n-1)}. \tag{25}$$

Theorem 4. *Let G be an n-order uncertain graph and its uncertain symmetric adjacency matrix be A_G, and its reachable measure matrix be P, and then, the connectivity index of G is the smallest number in the reachable measure matrix P.*

Proof. Since connectivity index of an uncertain graph is the uncertain measure of the connected graph based on Definition 4, a connected graph G is that any two vertices are connected in the graph G. That is, there exists at least a path between any two vertices in the graph G. Thus, we only need to prove that the element $\delta_{ij}^{(k)}$ in $A_G^{(k)}$ is the uncertain measure that there exists at least a path whose length is k from the vertexes i to j in the graph G. In a n-order graph, the

length of a path at most is $n-1$. Then, we can know that Theorem 4 is the right according to the previous theorem and definition.

Now, we begin to prove the conclusion that the element $\delta_{ij}^{(k)}$ in $A_G^{(k)}$ is the uncertain measure that there exists at least a path whose length is k from the vertexes i to j in the graph G using mathematical induction.

Obviously, the conclusion is correct when $k = 0$ or 1.

If $k = 2$, based on Definition 6 and Definition 7, we have the following:

$$\delta_{ij}^{(2)} = \bigvee_{l=1}^{n} \left(\delta_{il} \wedge \delta_{lj} \right), \tag{26}$$

where δ_{il} represents that the edge e_{il} between vertexes i and l exists with uncertain measure δ_{il}, and δ_{lj} represents that the edge e_{lj} between vertexes l and j exists with uncertain measure δ_{lj}, and $\delta_{il} \wedge \delta_{lj}$ represents the uncertain measure that the two edges e_{il} and e_{lj} exist at the same time; i.e., $\delta_{il} \wedge \delta_{lj}$ represents the uncertain measure of the path whose length is 2 from the vertexes i to j via vertex l. So, $\bigvee_{l=1}^{n} (\delta_{il} \wedge \delta_{lj})$ represents the uncertain measure that there exists at least a path whose length is 2 from the vertexes i to j.

According to the above discussion, the conclusion is correct when $k = 2$.

Assume the conclusion is correct when $k = p$, and then, when $k = p + 1$, we have the following:

$$\delta_{ij}^{(p+1)} = \bigvee_{l=1}^{n} \left(\delta_{il}^{(p)} \wedge \delta_{lj} \right), \tag{27}$$

where $\delta_{il}^{(p)}$ represents the uncertain measure that there exists at least a path whose length is p from the vertexes i to l in the graph G, and δ_{lj} represents that the edge e_{lj} between vertexes l and j exists with uncertain measure δ_{lj}, and $\delta_{il}^{(p)} \wedge \delta_{lj}$ represents the uncertain measure that the path whose length is p from the vertexes i to l and edge e_{lj} exists at same time; i.e., $\delta_{il}^{(p)} \wedge \delta_{lj}$ represents the uncertain measure of the path whose length is $p + 1$ from the vertexes i to j via vertex l. So, $\bigvee_{l=1}^{n} (\delta_{il}^{(p)} \wedge \delta_{lj})$ represents the uncertain measure that there exists at least a path whose length is $p + 1$ from the vertexes i to j. Thus, the conclusion is correct when $k = p + 1$.

From what has been discussed above, the conclusion is correct, for $k = 0, 1, 2, \ldots, n-1$, respectively. Therefore, Theorem 3 has been proved. □

Example 3. Figure 2 illustrates the uncertain 4-order graph, and its symmetric adjacency matrix is as follows:

$$A_G = \begin{pmatrix} 0 & 0.8 & 0.6 & 0.2 \\ 0.8 & 0 & 0.4 & 0.7 \\ 0.6 & 0.4 & 0 & 0.3 \\ 0.2 & 0.7 & 0.3 & 0 \end{pmatrix}. \tag{28}$$

Now, we compute its connectivity index according to Theorem 3.

$$A_G^{(1)} = A_G,$$

$$A_G^{(2)} = \begin{pmatrix} 0 & 0.8 & 0.6 & 0.2 \\ 0.8 & 0 & 0.4 & 0.7 \\ 0.6 & 0.4 & 0 & 0.3 \\ 0.2 & 0.7 & 0.3 & 0 \end{pmatrix} \circ \begin{pmatrix} 0 & 0.8 & 0.6 & 0.2 \\ 0.8 & 0 & 0.4 & 0.7 \\ 0.6 & 0.4 & 0 & 0.3 \\ 0.2 & 0.7 & 0.3 & 0 \end{pmatrix}$$

$$= \begin{pmatrix} 0.8 & 0.4 & 0.4 & 0.7 \\ 0.4 & 0.8 & 0.6 & 0.3 \\ 0.4 & 0.6 & 0.6 & 0.4 \\ 0.7 & 0.3 & 0.4 & 0.7 \end{pmatrix},$$

$$A_G^{(3)} = \begin{pmatrix} 0.8 & 0.4 & 0.4 & 0.7 \\ 0.4 & 0.8 & 0.6 & 0.3 \\ 0.4 & 0.6 & 0.6 & 0.4 \\ 0.7 & 0.3 & 0.4 & 0.7 \end{pmatrix} \circ \begin{pmatrix} 0 & 0.8 & 0.6 & 0.2 \\ 0.8 & 0 & 0.4 & 0.7 \\ 0.6 & 0.4 & 0 & 0.3 \\ 0.2 & 0.7 & 0.3 & 0 \end{pmatrix}$$

$$= \begin{pmatrix} 0.4 & 0.8 & 0.6 & 0.4 \\ 0.8 & 0.4 & 0.4 & 0.7 \\ 0.6 & 0.4 & 0.4 & 0.6 \\ 0.4 & 0.7 & 0.6 & 0.3 \end{pmatrix}, \tag{29}$$

$$P = I \oplus A_G^{(1)} \oplus A_G^{(2)} \oplus A_G^{(3)},$$

$$= \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \oplus \begin{pmatrix} 0 & 0.8 & 0.6 & 0.2 \\ 0.8 & 0 & 0.4 & 0.7 \\ 0.6 & 0.4 & 0 & 0.3 \\ 0.2 & 0.7 & 0.3 & 0 \end{pmatrix}$$

$$\oplus \begin{pmatrix} 0.8 & 0.4 & 0.4 & 0.7 \\ 0.4 & 0.8 & 0.6 & 0.3 \\ 0.4 & 0.6 & 0.6 & 0.4 \\ 0.7 & 0.3 & 0.4 & 0.7 \end{pmatrix} \oplus \begin{pmatrix} 0.4 & 0.8 & 0.6 & 0.4 \\ 0.8 & 0.4 & 0.4 & 0.7 \\ 0.6 & 0.4 & 0.4 & 0.6 \\ 0.4 & 0.7 & 0.6 & 0.3 \end{pmatrix}$$

$$= \begin{pmatrix} 1 & 0.8 & 0.6 & 0.7 \\ 0.8 & 1 & 0.6 & 0.7 \\ 0.6 & 0.6 & 1 & 0.6 \\ 0.7 & 0.7 & 0.6 & 1 \end{pmatrix}.$$

So, we can know that the connectivity index of the uncertain graph in Figure 2 is 0.6 according to Theorem 3.

In 2014, the distribution function of the diameter of uncertain graph is discussed in reference [18]. The diameter is an uncertain variable in uncertain graph since the existence of each edge is uncertain. The diameter is a fundamental concept in the graph theory, which means the maximal distance between any two vertices; that is, the diameter in determinate graph $G = (V, E)$ is $\text{diam}(G) = \max_{v_i, v_j \in V} d(v_i, v_j)$. Based on Theorem 3, the following conclusion can calculate the distribution function of the diameter in an uncertain graph.
FIGURE 3: A generalized uncertain 4-order graph.

Corollary 1. *Let G be an uncertain n-order graph and its uncertain symmetric adjacency matrix be A_G. Let the matrix D be described as follows:*

$$D = I \oplus A_G \oplus A_G^{(2)} \oplus A_G^{(3)} \oplus \ldots \oplus A_G^{(k)}. \tag{30}$$

Then, the uncertainty distribution of the diameter in the graph *G* is as follows:

$$M\{\text{diam}(G) \le k\} = \min_{1 \le i,j \le n}\{d_{ij}\}, \tag{31}$$

where k ($k \le n-1$) is a positive integer and d_{ij} is the element in *D*.

In the next section, the connectivity of generalized uncertain graph is investigated and analyzed.

4. Generalized Uncertainty Graphs

4.1. Basic Concepts and Algorithms. Not only whether an edge exists between two vertices cannot be completely determined but also whether some vertices exist cannot be completely determined in applications of traditional graph theory. In the study, the indeterministic factors are that whether vertices and edges exist is uncertain. If there are no historical data or experimental data, a random variable cannot be employed to describe this indeterministic factor. Often, we may consult experts and ask them to give a belief degree that the edge exists. The experience data are precisely the research category of uncertainty theory. Therefore, uncertain variable is employed to describe the indeterministic factor in this study.

Definition 9. A n-order graph is called a generalized uncertain graph if its symmetric adjacency matrix is as follows:

$$A_G = \begin{pmatrix} 0 & \delta_{12} & \cdots & \delta_{1n} & \delta_1 \\ \delta_{21} & 0 & \cdots & \delta_{2n} & \delta_2 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \delta_{n1} & \delta_{n2} & \cdots & 0 & \delta_n \\ \delta_1 & \delta_2 & \cdots & \delta_n & 0 \end{pmatrix}, \tag{32}$$

where δ_{ij} represents the uncertain measure of edges and δ_k represents the uncertain measure of vertex.

It should be noted that there always are $\delta_{ii} = 0$ in the generalized uncertain adjacency matrix.

From the above, we know that all the information of a generalized uncertain graph is contained in the adjacency matrix.
FIGURE 4: Basic graph of Figure 3.

Example 4. Figure 3 is a generalized uncertain 4-order graph as follows.

The adjacency matrix of Figure 3 is as follows:

$$\begin{pmatrix} 0 & 0.85 & 0.65 & 0.15 & 0.95 \\ 0.85 & 0 & 0.45 & 0.75 & 0.35 \\ 0.65 & 0.45 & 0 & 0.35 & 0.75 \\ 0.15 & 0.75 & 0.35 & 0 & 0.65 \\ 0.95 & 0.35 & 0.75 & 0.65 & 0 \end{pmatrix}. \tag{33}$$

Definition 10. Suppose *G* is a generalized uncertain n-order graph, and its adjacency matrix is as follows:

$$A_G = \begin{pmatrix} 0 & \delta_{12} & \cdots & \delta_{1n} & \delta_1 \\ \delta_{21} & 0 & \cdots & \delta_{2n} & \delta_2 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \delta_{n1} & \delta_{n2} & \cdots & 0 & \delta_n \\ \delta_1 & \delta_2 & \cdots & \delta_n & 0 \end{pmatrix}, \tag{34}$$

where δ_{ij} represents the uncertain measure of edges between two vertexes and δ_k represents the uncertain measure of vertex. The basic graph $\overline{G}$ of generalized uncertain graph *G* is defined as an uncertain graph with the following adjacency matrix:

$$B_G = \begin{pmatrix} \lambda_{11} & \lambda_{12} & \cdots & \lambda_{1n} \\ \lambda_{21} & \lambda_{22} & \cdots & \lambda_{2n} \\ \vdots & \vdots & \vdots & \vdots \\ \lambda_{n1} & \lambda_{n2} & \cdots & \lambda_{nn} \end{pmatrix}, \tag{35}$$

where $\lambda_{ij} = \min\{\delta_{ij}, \delta_i, \delta_j\}$.

Example 5. Figure 4 is the basic graph of Figure 3.

The symmetric adjacency matrix of Figure 4 is as follows:

$$\begin{pmatrix} 0 & 0.35 & 0.65 & 0.15 \\ 0.35 & 0 & 0.35 & 0.35 \\ 0.65 & 0.35 & 0 & 0.35 \\ 0.15 & 0.35 & 0.35 & 0 \end{pmatrix}. \tag{36}$$

Definition 11. Suppose that *G* is a generalized uncertain graph with a symmetric adjacency matrix as follows:

$$A_G = \begin{pmatrix} 0 & \delta_{12} & \cdots & \delta_{1n} & \delta_1 \\ \delta_{21} & 0 & \cdots & \delta_{2n} & \delta_2 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \delta_{n1} & \delta_{n2} & \cdots & 0 & \delta_n \\ \delta_1 & \delta_2 & \cdots & \delta_n & 0 \end{pmatrix}. \tag{37}$$

The connectivity function of G is expressed as follows:

$$\mathbb{C}(G) = \begin{cases} 1, & \text{if graph } G \text{ is connected}, \\ 0, & \text{otherwise}. \end{cases} \tag{38}$$

From the above, we can know that $\mathbb{C}(G)$ is a Boolean function. Thus, in a generalized uncertain graph G the connectivity index may be denoted as follows:

$$\partial(G) = M\{\mathbb{C}(G) = 1\}. \tag{39}$$

Namely, the connectivity index is the uncertain measure to which the generalized uncertain graph is connected.

Obviously, the connectivity index of a generalized uncertain graph is exactly equal to the connectivity index of its basic graph.

Based on some of the ideas that we have discussed above, we may know the connectivity index of a generalized uncertain graph, and then, we may compute the connectivity index of a generalized uncertain graph as follows.

Step 1. To write out the adjacency matrix of the generalized uncertain graph G.

Step 2. To compute the adjacency matrix of the basic graph $\overline{G}$ of the generalized uncertain graph G.

Step 3. To compute the connectivity index of the basic graph $\overline{G}$ of the generalized uncertain graph G according to Theorem 3, and thus, the connectivity index of generalized uncertain graph is obtained.

4.2. Examples. In this part, two examples are given to compute the connectivity index of a generalized uncertain graph.

Example 6. Figure 5 is a 2-order generalized uncertain graph G and the uncertain measure of edge is a, and the uncertain measure of vertices is α and β respectively.

In Figure 5, the connectivity index of G is the smallest number of α, β, and a.

Example 7. Figure 6 illustrates a 3-order uncertain graph G, and the uncertain measure of edges is 0.8, 0.7, and 0.6, respectively, and uncertain measure of vertices is 0.75, 0.9, and 0.8, respectively.

As Figure 6 illustrates a 3-order generalized uncertain graph (G), its basic graph is shown in Figure 7. In Figure 6, the connectivity index of (G) is 0.7 by Theorem 1.
FIGURE 5: A 2-order generalized uncertain graph.
FIGURE 6: A 3-order generalized uncertain graph.
FIGURE 7: Basic graph of the generalized uncertain graph (G) in Figure 6.

Example 8. Figure 3 illustrates a 4-order generalized uncertain graph G, and the uncertain measure of its edges is 0.8, 0.7, 0.6, 0.4, 0.3, and 0.1, respectively, and the uncertain variables of its vertices are 0.9, 0.3, 0.7, and 0.6, respectively.

Because Figure 3 is a 4-order generalized uncertain graph, its basic graph is Figure 4, and the connectivity index of G in Figure 3 is 0.3 by Theorem 3.

4.3. α-Connectivity of Generalized Uncertain Graph

Definition 12. Let G be a generalized uncertain graph with a confidence level α. If the uncertain measure of an edge or vertex in G is not smaller than the confidence level α, the uncertain measure is mapped as 1, or the uncertain measure is replaced by 0. Thus, a sample subgraph of G can be obtained and the sample subgraph is referred to as fundamental subgraph about the confidence level α.

Definition 13. A generalized uncertain graph G is called α-connected if its fundamental subgraph about the confidence level α is connected.

According to the above two definitions, we may easily get an algorithm for how to verify the α-connectivity of a generalized uncertain graph as follows.

Step 1. According to the pre-given confidence level α, write out the fundamental subgraph of the generalized uncertain graph G about the confidence level α.

Step 2. Write down the adjacency matrix $\overline{A_G}$ of the fundamental subgraph of the generalized uncertain graph G about the confidence level α.

Step 3. Calculate the value $\overline{R} = I + \overline{A_G} + \overline{A_G^2} + \overline{A_G^3} + \ldots + \overline{A_G^{k-1}}$, in which k is the order number of the fundamental subgraph of the generalized uncertain graph G about the confidence level α.

Step 4. According to Theorem 1, we can easily know that the generalized uncertain graph G is α-connected if $\overline{R} > 0$; otherwise, it is not α-connected.

Example 9. Figure 8 illustrates a 7-order generalized uncertain graph, and the uncertain measure of its every edge is 0.75, 0.64, 0.69, 0.5, 0.3, 0.2, 0.89, 0.85, 0.55, 0.62, 0.26, 0.9, 0.7, and 0.28, respectively, and the uncertain measure of its any vertex is 0.6, 0.9, 0.65, 0.79, 0.95, 0.8, and 0.86, respectively.

Figure 9 presents the fundamental subgraph of G, and its confidence level is 0.5 when the confidence level α is 0.5. Obviously, it is connected, so the generalized uncertain graph G is 0.5-connected. Figure 10 shows the fundamental subgraph of G, and its confidence level is 0.65 when α is 0.65. Obviously, the graph in Figure 10 is non-connected. Thus, the generalized uncertain graph G is non-connected under the confidence level of 0.65. In the following, we let α be 0.8, we can get a connected fundamental subgraph of G, and its confidence level is 0.8, as shown in Figure 11. Thus, the generalized uncertain graph G is 0.8-connected, but its order is 4.

A major application of α-connectivity of generalized uncertain graph is that the user can determine the size of the graph and the reliability measure according to different requirements.

Definition 14. α-connectivity index of generalized uncertain graph G is defined as follows:

$$\mu(G) = \sup_{\alpha}\{\text{the graph } G \text{ is } \alpha - \text{connected}\}. \tag{40}$$

According to the above discussion, we can easily know the relationship between the α-connectivity index and the connectedness index of a generalized uncertain graph.

Assume G is a generalized uncertain graph, the α-connectivity index of G is equal to its connectivity index.

4.4. Experimental Verification Analysis. We verify the implementation stability and efficiency of the algorithm about the connectivity index of generalized uncertain graph using a large number of experiments. Without a trusted query algorithm according to the reliability index, conditional connectivity query, and so on, the paper only studies the main query methods in different data set scales and the efficiency of different constraint conditions.

The experimental data are implemented in the operating system of Windows 7, the processor of 1.8GHZ, and the memory of 8G condition, using the artificial simulation in the programming environment of Visual C++ 6.0.

In the experiment, we generate randomly some uncertain networks. Table 1 shows the numbers of vertices and edges in these networks. These edges in every uncertain network are randomly created between the two vertices. The reliability of each uncertain edge is randomly created among the real numbers in [0,1], and the reliability of each
FIGURE 8: Generalized uncertain graph (G) of order 7.
FIGURE 9: An confidence level is 0.5 of fundamental subgraph in Figure 8.

uncertain vertex is randomly created among the real numbers in [0,1].

There are two parts in the experiment. In the following part, we will test the credibility of algorithm of connectivity index generalized uncertain graph if there is no limitation. In Experiment 1, we test the change in algorithm performing required time based on the different scales of edges and vertices. We test the time variation of the algorithm execution under the same number of edges in Experiment 2.

Experiment 1. Figure 12 shows the results of the query results. The execution time of the algorithm has a similar distribution to the change in the number of vertices and edges in the uncertain network.
Figure 10: An confidence level is 0.65 of fundamental subgraph in Figure 8.
Figure 11: The confidence level is 0.8 of fundamental subgraph in Figure 8.

Table 1: Artificial simulation data of uncertain network.

Name	Vertices	Edges
G1	145	9100
G2	135	7100
G3	125	5100
G4	115	5100
G5	105	4600
G6	95	3600
G7	85	3100
G8	75	2100
G9	65	1800
G10	45	650

Experiment 2. To test the validity of the experiment based on the query algorithm under the user specified the number of edges and vertices in uncertain network. Figure 13 shows
Figure 12: Algorithm execution time versus number of edges and vertices.
Figure 13: Algorithm execution time versus number of edges and vertices with the reliability constraints ($\alpha = 0.5$).

the query results. Figure 13 shows that it is a similar distribution of the algorithm performing required time, and the change corresponds to a change in the number of edges and vertices in uncertain network.

5. Conclusion

A connected graph is the most basic property in classic graph theory. However, in certain actual applications, different uncertain factors are frequently encountered and must be solved. This study puts forward a definition of generalized uncertain graphs and connectivity index and α-connectivity of generalized uncertain graphs based on the uncertainty theory and proposes an algorithm for connectivity index and α-connectivity by symplectic adjacency matrix of a generalized uncertain graph. This study presents the definition of α-connectivity index of generalized uncertain graphs and obtains the relationship between the α-connectivity index and the connectivity index of a generalized uncertain graph. In the end, the study employs numerical experiments to verify the correctness of this new algorithm.

As the continous innovation of new media technology, the media environment of the entire society has undergone profound changes. Digital technology has had a profound impact on the way news is disseminated. It has made a significant impact on the collecting, creation, and distribution of news, as well as the way viewers receive it. As a result, the news media's operation and management style is continually modified. However, in the process of news dissemination, the situations involved are complex and changeable, which leads to different digital technology applications. Aiming at different complex situations in news dissemination under the vision of new media art, this work designs a neural network to optimize the distribution for the required digital technology application schemes. The main work of this paper has the following two points. First, it systematically investigates the current research status of news communication based on digital technology and analyzes the research trends of digital technology and news communication in complex contexts under the vision of new media art. Second, a new neural network is proposed for the optimal application of digital technology for news propagation in different complex situations. This neural network uses an improved particle swarm optimization algorithm and an improved network training strategy to improve the BP network, which can effectively solve the shortcomings of the BP network. A large number of experiments have proved the effectiveness and correctness of this method.

1. Introduction

Digital technology and information science are at the heart of new media. On the basis of the philosophy of mass communication and the creative techniques of modern art, its various domains, including science and art, business and education, culture and the arts, and management, are all integrated through the application of information technology's all-encompassing capabilities. A wide range of media forms are included in new media. New media art's distinguishing features are its communication medium and the digitalization of its disseminating content. Digitization fulfills the creative needs of new media artists by facilitating the collection, access, processing, and sharing of data. It has become a new information carrier in the post-language era, after text and electronic technology. During this period, researchers began to use computer technology for image processing and creation of sound works. At this time, the

forms of digital art showed diversified forms, from static to dynamic interactive works, from creating a virtual world to reflect the initiative of the real world. The development of digital technology makes new media art challenge traditional concepts. Therefore, new media art is a comprehensive media art and performance art that allows the audience to participate [1–5].

News dissemination refers to mass dissemination activities carried out through the news media. It includes not only news gathering, editing, transmission, and reception activities organized by traditional mass media, but also news dissemination activities through the Internet and mobile phones and other digital new media. Books, video games, CD/VCD/DVD, MP3/MP4 music, and other communication methods in the mass media are temporarily not included in the category of news media, because they have nothing to do with the dissemination of real-time news information. Auxiliary news media such as news agencies

and photo agencies will not discuss them temporarily, because they do not directly address a broad audience [6–10].

News communication has always been closely related to development of technology; communication technology is the first driving force for the development of communication, because it determines the renewal of the media, promotes the transformation of communication methods, and leads to the evolution of communication concepts and the development of high-energy journalists. Everywhere we go in the history of news reporting we see the traces of technical progress. Modern electronic technology has made it possible for news dissemination to outpace text delivery in terms of speed and efficiency. This has entered a new field of sound and image dissemination, further expanding the geographical scope and number of audiences of news dissemination. There has been a dramatic shift in the way news is disseminated since the introduction of digital technologies and the subsequent advancement of computer, multimedia, communication, and network technologies. The digitization and networking of news dissemination have changed the existence of news dissemination, the transmission content, and the temporal and spatial relationship of human activities and will create a broader space for news dissemination [11–15].

With the complexity of news dissemination situation, the digital technology required in the dissemination process is also different. For different communication situations, how to design the optimal digital technology application program is an important and novel topic in the process of news communication. With the development for computer science, neural networks can efficiently model this task. Therefore, this article designs a neural network based on computer neural network technology. It can optimize and customize digital technology application schemes for the complex situations of news dissemination under the vision of new media art.

The contributions of this article are as follows: (1) this article applies neural network to the complex situation of news dissemination, which is used to customize the optimal digital technology application scheme in this situation. (2) For the customization of digital technology application schemes, this paper designs an artificial neural network. This network combines the improved particle swarm algorithm with BP network and optimizes the training strategy of BP network accordingly. This can effectively improve the customization performance of digital technology applications.

2. Related Work

Foreign research in this area had been carried out relatively early. Sociologists and technical experts began to study this issue and achieved some results. Literatures [16–19] discussed the application of digital technology and outlined a rough outline for the future information society. Since the development of digital technology was still in its infancy at that time, these works had very little to do with the application of digital technology in news dissemination. It was not until the next few years that the literature [20] clearly put forward the argument that "the world of media has changed." And in the book, the concepts of digital TV, multimedia, virtual reality, and so on were mentioned. Other countries with rapid development of digital technology had also produced a number of research results on emerging online media. It mainly included literatures [21–23] and so on.

Before the mid-1990s, related research in my country was progressing slowly. After the mid-1990s, with the gradual advancement of my country's digitalization process, related foreign academic works had been translated and published successively, such as the related documents mentioned above. Some domestic scholars had begun to get involved in this research field and had achieved great research results. This was mainly manifested in the following: (1) related works and papers continued to emerge. Literature [24] analyzed the content of papers published in Journalism and Communication Research, International Journalism, and Journalism University from 1996 to the end of the 20th century. It found that articles related to media technical analysis showed an overall increasing trend, increasing from the previous single-digit percentage to more than 25%. A large number of relevant research articles had been published on the online platform "China Journalism and Communication Review" jointly established by Sina.com, Zhejiang Online, and the School of Journalism and Communication of Zhejiang University. (2) Among the papers presented at large-scale academic conferences held by the journalism and communication circles in my country, the proportion of papers related to the research on new technologies of journalism and communication had risen sharply. The School of Journalism and Communication of Tsinghua University held a seminar with the theme of "Media Reform in the Digital Background." The central issue discussed in this seminar was the impact of digital technology on media. The participating experts discussed the latest development trends of digital media, the behavior and characteristics of people using new media, and various issues related to this. (3) The National Social Science Fund was also very concerned about this field. Since 1996, related topics had been established almost every year, such as the 1996 project "Multimedia Technology and News Dissemination," the 1998 project "Research Report on the New Development of Network Communication and Its Countermeasures," and "Analysis and Development Forecast of the Digital Status Quo of News Dissemination Means." The 8 projects established in 2000 included "Research on the Influence of the Internet on Information Dissemination and People's Spiritual and Cultural Life" [25, 26]. Among relevant domestic researches, the more influential works included literatures [27–30] and so on.

In the era of digital information, news dissemination tools had achieved a high degree of uniformity, and computers and networks had become important tools for processing and transmitting news information. In the digital age, traditional writing tools and transportation tools were no longer needed for the processing and transmission of information. Computers and networks had completely replaced them. Moreover, the information carrier of news dissemination had also

been completely unified. Any information object, whether it was numbers, words, or symbols, or sounds, graphics, or images, only needed to be carried by bits. At the same time, digital information for news dissemination on the Internet is open, and people's acceptance and consumption of information had also shifted from a passive state in the materialized information age to a more active and interactive state. Therefore, it could be said that digital technology had brought a new stage of news dissemination. At this stage, the essence of news dissemination had not changed, and the function of news dissemination in monitoring the environment, coordinating society, and transmitting cultural heritage had not changed much. But the way and content of news dissemination were constantly changing. Literature [31] believed that the content of one communication tool was often another communication tool. The content of writing was speech, just as handwriting was the content of printing, and printing was the content of telegram. Literature [32] pointed out that when technology used symbolic signs or found a place in a special social structure, it became a medium, a social and intellectual resource created by a machine.

3. Method

This article uses neural networks to specify the best digital technology solutions for different news dissemination scenarios called DTPDN. For example, when the content of news dissemination is sound, and the media is broadcasting, voice signal processing is the most suitable digital technology. When the content of news dissemination is video, and the transmission medium is TV, video processing technology is the most suitable digital technology. In short, this article is to use neural network to model these attribute parameters through the parameter attributes of various complex situations under the vision of new media art and finally output the most optimized digital technology solution. The model used in this article is BP neural network, and it is improved by PSO and training optimization strategy. This can make the neural network more accurate in the formulation of digital technology solutions. The structure is illustrated in Figure 1.

3.1. Improved PSO. The classic BP network model's ability to forecast outcomes is not perfect. There is a reason for this: the BP network algorithm's initial threshold and weight parameters are often arbitrarily set. A local minimum state of the BP network is easy to enter, which results in low model prediction accuracy. This chapter uses an improved particle swarm optimization approach to optimize the initial parameters of the BP neural network model, which successfully increases the model's accuracy.

3.1.1. Particle Swarm Optimization Algorithm. For population assumed by particle swarm optimization, each particle is abstracted as an individual that can move independently and has a certain speed. In the objective function's solution space, each particle is a solution that is constantly

moving. The initial speed and initial direction of the particle flight can be randomly generated as the initial state of each individual. And based on the overall flight experience in the population and the individual's own flight experience to jointly determine the flight plan and status of the next iteration, in the actual problem to be solved by the PSO algorithm, it is necessary to determine the optimized objective function, also called the fitness function. Each individual particle judges and evaluates its own flight search effect according to the value of the fitness function. During the flight search process, the point where each individual encounters the optimal fitness function value is the optimal solution pBest. In the same way, by comparing the individual optimal pBest found by all the individual particles, the global optimal gBest can be compared. In the continuous iterative operation of PSO, each individual particle dynamically adjusts its flight search plan based on individual optimal pBest and global optimal gBest. Such a process is actually similar to the evolutionary process of species. Because each iteration produces a better population, PSO algorithm is also called evolutionary algorithm. The basis of PSO is to use the collective wisdom of the population to conduct a global search and compare local optimal solutions according to the fitness function. These processes do not need to derive the objective function, nor do they need to have too many assumptions and conventions.

The population is composed of some abstract individual particles. Each individual has no mass or volume, and the number of individuals is the dimension of the population. Assume that the dimension for a certain group is n, the position of the i-th particle in the group is a vector $X_i = [x_1, x_2, \ldots, x_n]$, and the flying speed of the particle is a vector $V_i = [v_1, v_2, \ldots, v_n]$. In PSO, each individual particle maintains the optimal value of the individual searched by itself. Then, in the process of individual particle flight search, it is necessary to compare with the global optimal value to judge and update its position. Its essence is to exchange global search result information, which is also the global search capability of particle swarm algorithm:

$$
\begin{aligned}
v(t+1) = v(t) &+ a_1 r(\,)(\text{pbest}(t) - p(t)) \\
&+ a_2 r(\,)(\text{gbest}(t) - p(t)),
\end{aligned} \tag{1}
$$
$$
p(t+1) = p(t) + v(t+1),
$$

where $r(\,)$ is a random function, $v(t)$ is the velocity expression of the particle, and a_1 and a_2 represent the learning speed of particles.

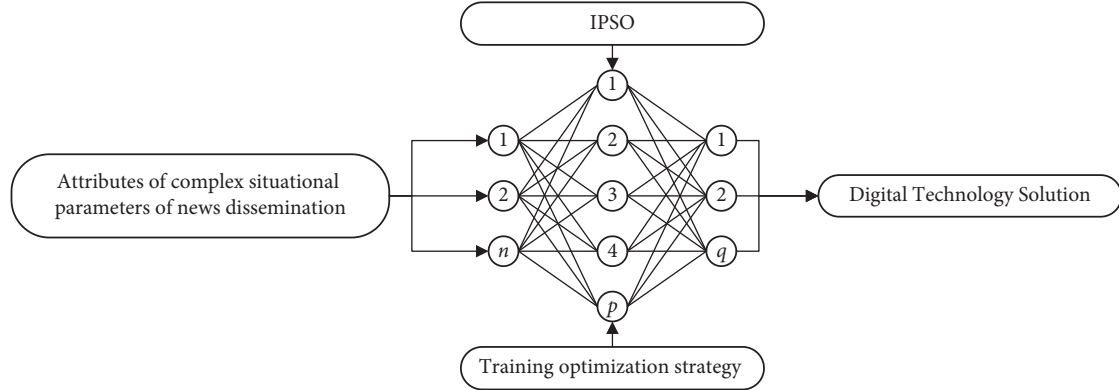
In actual optimization applications, it is often hoped that the particles can have a larger acceleration when the standard particle swarm optimization method is just started, thereby improving the global search ability. When the population obtains certain information, the search space is quickly converged to a smaller range. Then, reduce the particle's movement speed, so that the particle can be searched finely in the local area. Therefore, a nonnegative inertia weight is added to the particle's velocity term to control the speed of the current particle's velocity transformation:


Figure 1: The structure of DTPTN.

$$v(t + 1) = wv(t) + a_1 r(\,)(\text{pbest}(t) - p(t))$$
$$+ a_2 r(\,)(\text{gbest}(t) - p(t)), \tag{2}$$

where w is the inertia weight. The larger the inertia weight, the greater the potential for global optimization, and the lesser the ability for local optimization. The lower the value, the weaker the ability of global optimization, and the better the ability of local optimization. Dynamically changing the inertia weight can obtain better optimization ability than that of the fixed inertia weight. The inertia weight can change linearly during the particle swarm search process, or it can be dynamically changed according to a certain measurement function of the particle swarm performance. At present, the linearly decreasing weight strategy is widely used:

$$w = \frac{(w_s - w_e)(G_k - g)}{G_k} + w_e, \tag{3}$$

where G_k is the maximum number of iterations, w_s is the initial value of the inertia factor, and w_e is value of the inertia factor when the population is iterated to the maximum number of evolutions.

The advantages of particle swarm optimization algorithm are extremely significant. (1) The superiority of the idea of swarm intelligence is that it is not easy to fall into a local optimization, and it has the ability to search and optimize globally. (2) The population converges to the global optimum fast. (3) The search of each particle is parallel, except when exchanging information; the movement between the particles can be regarded as unrelated to each other, and they are all moving on the path they think is correct. (4) There are no special assumptions and restrictions on the input data, which makes the particle swarm optimization algorithm suitable for solving almost all optimization problems. (5) There is almost no need to modify any parameters; you can input into the model. (6) The standard particle swarm algorithm has a simple idea and does not have high requirements on the input data itself. The computational time complexity of PSO is much lower than that of the genetic algorithm.

3.1.2. Improvement Strategy. The standard particle swarm optimization algorithm converges to a local extremum and

cannot escape when it is calculated and solved. Because every time the population exchanges information, the search scope is narrowed. At this time, it is possible that the particle has not searched all the regions, or it is too late to find the optimal solution. The search area is narrowed down by the population, resulting in the optimal solution being excluded from the search range, and it can only converge to a local extremum. Many documents have studied this problem, but the nature of the problem has not changed, and the scope of the global search has been narrowed down. Therefore, this article attempts to improve this problem. When each particle searches for its own extreme value, it is compared with the extreme value found by population. If the extremum searched by the population is better than the extremum searched by the particle itself, the standard particle swarm method strategy is to update position and coordinate vector of the particle to the position and coordinates of the extreme point found by the population. At this time, the search range of the population will be narrowed down to the vicinity of the extreme point. However, the strategy adopted in this paper is to add random variation factors after the population finds the extreme points. After the particle position and coordinates are updated, the global search range is still maintained. It avoids the global optimal solution being excluded from the search area. At the same time, modify the adaptive function and modify the conditions for the particles to end the search, so that the particles can finally exit the iteration. The improved PSO in this paper can expand the search range of particles in the solution space, so that the particles have a certain random distribution in the global search range. This makes the algorithm converge to the optimal solution faster, while also ensuring that it will not converge locally.

To overcome the premature convergence, it is easy to fall local optimum. After the optimal information is exchanged, a dynamic position change is added when narrowing the search range. This allows the particles to have different random search capabilities at different stages. At the same time, some checking mechanisms are added to determine whether the particles have a tendency to locally converge. This can adjust the movement speed and position of the particles in time, so that the entire particle swarm can continue to maintain a faster convergence rate. This will not

sacrifice the global optimization capability of PSO itself. The specific design is as follows.

The variation factor of the particle is a binary random function with respect to the number of iterations and time. Use the number of iterations to consider, and add time as an independent variable. When the population is initialized, time t is 0 at this time. And within a certain period of time, no mutation occurs. Therefore, the significance of the independent variable of time is to control the timing of mutation. At the same time, the consideration of the number of iterations is that if iterations reached a certain value, the population still does not converge, and then mutation is turned on. This allows the particles to have a global search range.

But the fitness converges to a certain value, and the number of times of convergence reaches a certain number of times. At this time, it may be converged to the local optimum, and mutation is turned on at this time. This can help particles escape from local extreme points.

When the position of the particle is always in a certain area, and it is difficult to escape, it is considered that the population has the possibility of converging to the local optimum, and mutation can be turned on. The specific mutation factor operation is to modify the position of the particles with formula of standard PSO:

$$p(t + 1) = P \times r() \times p(t), \tag{4}$$

where P is the core probability factor, which determines the intensity of variation in the next iteration of the particle.

According to the improved ideas and design of PSO, the specific implementation steps of improved PSO (IPSO) are as follows: (1) initialize particle swarm and initialize dimension of the population. The initial velocity, initial position, and velocity extremes of individual particles are initialized to the optimal value of each individual particle. Set the fitness function and the maximum iterations to ensure that the algorithm can finally end. (2) According to global optimal value and individual optimal value, update the speed and position of each individual in the population, and judge whether the speed of each particle is out of bounds. If the boundary is exceeded, the velocity threshold is used to limit the velocity of the particles. (3) Update the global optimal value of the population based on the individual optimal value of all individuals in the population. (4) According to the differences in speed and location of the population before and after evolution, if the population has the possibility of converging to a local optimum, compare the iterations with the number for convergences to the local. According to the dynamic variation formula, the position of the particles is adjusted dynamically and has a certain uniform distribution in the whole world. (5) If the end condition is not reached, then go to step 2. (6) The algorithm operation ends. The final judgment condition is that the fitness of the particles meets the expected error range or the algorithm encounters an abnormality. This adaptive mutation will be called when the position update and speed update of the particles in the population are used to increase diversity of population and also maintain a better convergence speed.

3.2. Training Optimization Strategy.

The training of BP uses error backpropagation method. The change direction of the weight threshold depends on the change direction of the error function. This method begins to decline rapidly, but when the error function enters a flatter curve, it changes slowly and falls into a local extreme. Aiming at this defect, this paper proposes an improved BP method and designs an improved additional momentum algorithm and an improved adaptive learning rate adjustment method.

3.2.1. Improved Additional Momentum Algorithm.

The standard BP algorithm only relies on a simple static optimization method to modify the weight and does not consider the gradient direction at the previous time. As a result, the network converges slowly and oscillates during the learning process. Literature [33] proposed a BP learning algorithm to increase the momentum term. The weight change in this method is obtained by summing the appropriate ratio of the current negative gradient change of the error surface and the weight change used in the previous iteration correction. The weight adjustment formula of the additional momentum term is

$$\Delta w_{ij}(n + 1) = -(1 - \alpha)\beta \frac{\partial E}{\partial w_{ij}} + \alpha \Delta w_{ij}(n),$$

$$\Delta b_{ij}(n + 1) = -(1 - \alpha)\beta \frac{\partial E}{\partial b_{ij}} + \alpha \Delta b_{ij}(n), \tag{5}$$

where α is the momentum factor.

In order to increase learning speed, the momentum term can store the value of a change in the weight of the link at the previous time. Additionally, the added momentum component acts as a buffer and smoother function. During training, the inertial effect can be used to reduce the occurrence of oscillations. It is also advantageous for escaping the flat terrain because of the additional momentum period. If the training has entered the flat area of error surface, then $w(n + 1) = \Delta w(n)$, thus preventing the situation of $\Delta w(n + 1) = 0$, making the model jump out of the local minimum. To put it simply, the momentum component added in the additional momentum term technique is essentially a damping term that can help buffer and smooth out the learning process, minimizing the oscillation trend and therefore enhancing the network's converged performance. The addition of a momentum term can effectively reduce the network's susceptibility to local error surface features. It can also be effectively controlled when the network falls into a local minimum. However, when the error surface becomes steeper, it becomes difficult to select the learning rate. To solve this problem, many works have conducted research and proposed some solutions, for example, the adaptive learning rate adjustment method. Although this method improves the difficulty of learning rate selection to a certain extent, it still has the problem of slow learning rate update. In order to update the additional momentum in time, the judgment conditions of the improved use weight correction formula designed in this paper are

$$\alpha = \begin{cases} 0, & E(n+1)^3 > 1.04E(n)^3, \\ 0.95, & E(n+1)^3 < E(n)^3, \\ \alpha, & \text{others.} \end{cases} \quad (6)$$

Judging by this condition, the value of additional momentum is updated. To follow up on the change of the error in time, adjust the direction of the change of the weight threshold.

3.2.2. Improved Adaptive Learning Rate. It is impossible to change the conventional BP algorithm's learning rate after it has been established. BP neural network learning process is slowed down by this issue. The selection of the learning rate should not be too wide-ranging. The network may not be able to converge if the learning rate is set too high and oscillates throughout the training period. In other words, if the rate of learning is too low, the convergence speed cannot be guaranteed. It is difficult to make major modifications in a reasonably flat error surface, because some sections of the BP network error surface are uneven. Even if the adjustment amount of the weight is increased, it is difficult to reduce the error quickly. In this case, a larger learning rate is required. The gradient of the error changes very rapidly in a relatively steep area, and a smaller learning rate needs to be selected at this time.

This paper proposes an improved method of adaptively adjusting the learning rate. As a result, the normal BP algorithm's convergence characteristics are improved by this algorithm's ability to adaptively adjust its learning rate to manage the BP neural network's gradient descent speed in learning. It is vital to maintain a large learning rate in order to provide stability in the learning process, which is based on particular principles. The learning rate adaptive adjustment formula is

$$\beta(n+1) = \begin{cases} 1.05\beta(n), & E(n+1)^3 < E(n)^3, \\ 0.7\beta(n), & E(n+1)^3 > 1.04E(n)^3, \\ \beta(n), & \text{others.} \end{cases} \quad (7)$$

The learning rate is automatically adjusted based on error. When the error becomes a certain multiple compared with the previous error, the learning rate will become smaller. Otherwise, the learning rate remains unchanged. If the error becomes smaller, increase the learning rate. This method can keep the learning rate at the maximum acceptable value throughout the training process. The learning rate is updated quickly to ensure that the network is always trained at the maximum acceptable learning rate. This method can dynamically process the network, and it can make the learning rate reasonable, so as to speed up convergence speed. This can ensure the stability of BP network and the convergence of BP algorithm.

4. Experiments and Discussion

4.1. Dataset. This article uses a self-built dataset for experimentation. The input of this dataset contains four first-level indicators of news dissemination situation, and each first-level indicator contains several second-level indicators. The specific indicator is illustrated in Table 1.

TABLE 1: Parameter index of news dissemination situation.

First-level	Second-level
News dissemination subject	Government
	Organization/institution
	Individual
News dissemination medium	Radio
	Television
	Internet
News dissemination content	Sound
	Image
	Video
News dissemination audience	Old people
	Middle-aged people
	Young people

This article quantifies these indicators as the input of network, and the output is the corresponding digital technology application program, such as voice processing technology and video processing technology. The self-made dataset in this article contains a total of 16,392 pieces of data, of which 80% is training set and 20% is testing set. The evaluation indexes applied in this work are precision, recall, and F1 score.

4.2. Evaluation on Training Convergence. The convergence of network and performance of the convergence are two critical performance measures in the neural network. Studying training loss and precision is used to determine if this is a contributing element. Results are illustrated in Figure 2.

The training loss lowers, and the training precision increases as the network training advances. Network convergence occurs when the number of iterations exceeds 100. Network reliability and robustness may be ensured by achieving convergent network training with our proposed algorithm.

4.3. Comparison with Additional Methods. In order to determine the success of our deigned method, we compare this model to other methods such as logistic regression (LR), decision tree (DT), random forest (RF), and support vector machine (SVM). Precision, recall, and the F1 score are some of the comparison metrics. The experimental result is illustrated in Table 2.

It is not difficult to see that, compared to other similar methods, our method can obtain the highest performance on the three evaluation indicators. Specifically, 0.928 precision, 0.904 recall, and 0.915 F1 score can be obtained, respectively. Compared with the best method listed in the table, our method can obtain 2.5% precision gain, 2.7% recall gain, and 2.2% F1 score gain. This shows that our method is able to formulate accurate digital technology application plans for various complex communication environments under the new media art perspective. These data illustrate the effectiveness and reliability of our method.
Figure 2: Training loss and training accuracy.

Table 2: Comparison with additional methods.

Method	Precision	Recall	F1
LR	0.827	0.808	8.811
DT	0.852	0.843	0.847
RF	0.886	0.859	0.864
SVM	0.903	0.877	0.893
DTPDN (ours)	0.928	0.904	0.915
Figure 3: Evaluation on IPSO.

4.4. Evaluation on IPSO. As mentioned earlier, this paper designs an IPSO algorithm for the problem that BP networks tend to fall local optimal solutions to assign values to the initial weights and thresholds for networks. To verify the effectiveness, this work will compare the performance of not using genetic optimization algorithm, using traditional PSO, and using IPSO. The experimental results are shown in Figure 3.

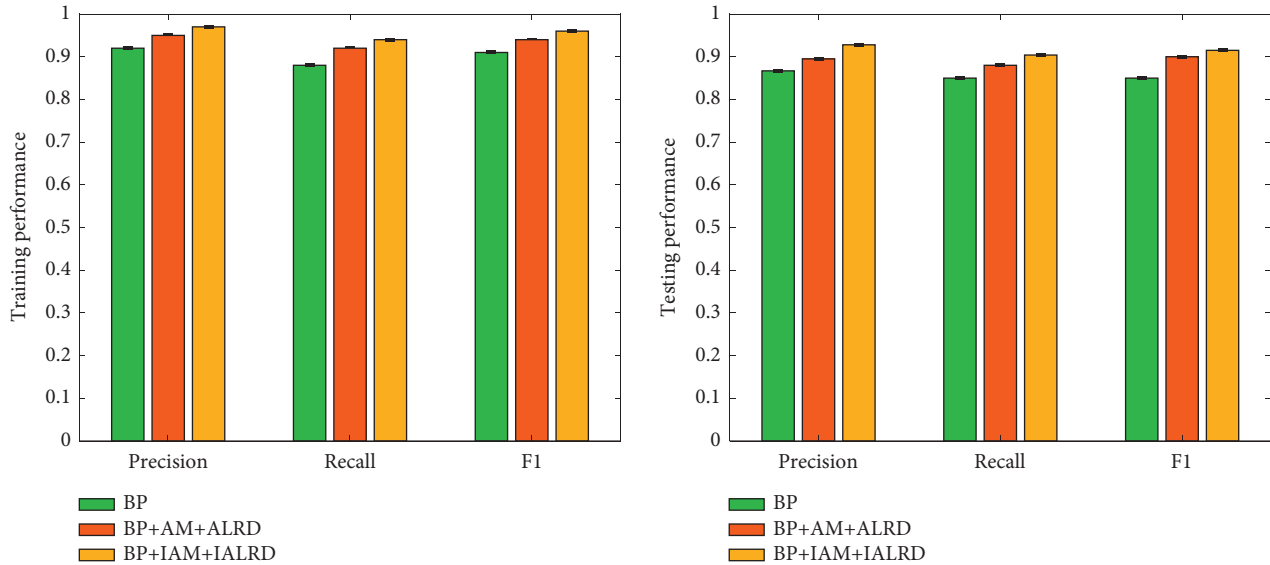
Obviously, whether it is during network training or testing, the performance of the traditional BP network is the lowest. But when the PSO algorithm is used, the performance of the network has been improved to a certain extent, and the improvement is limited. If the PSO algorithm is improved, the IPSO algorithm is constructed. After combining it with the BP network, a further performance improvement can be obtained. Compared with the traditional


Figure 4: Evaluation on training optimization strategy.

PSO algorithm, the testing performance can be improved by 4.3%, 3.4%, and 2.5%. This proves the correctness and effectiveness of IPSO and can improve the accuracy of the formulation of the optimal digital technology application program in the news dissemination of complex situations.

4.5. Evaluation on Training Optimization Strategy. As mentioned earlier, the training of BP neural network usually adopts the error backpropagation method. The change direction of the weight threshold depends on the change direction of the error function. In this method, the loss drops rapidly when the network is first trained, but when the error function enters a flatter curve, the change is slow. Aiming at this defect, this paper proposes an improved BP algorithm and designs an improved additional momentum (IAM) algorithm and an improved adaptive learning (IALRD) rate adjustment method. To verify the effectiveness of this method, this work will compare the performance of not using training optimization strategy, using traditional additional momentum (AM) algorithm with adaptive learning (ALRD) rate adjustment method, and using improved additional momentum (IAM) algorithm with improved adaptive learning (IALRD) rate adjustment method. The experimental results are illustrated in Figure 4.

Obviously, whether it is during network training or testing, the performance of the traditional BP network is the lowest. But when the training optimization strategy with improvement is used, the performance of the network has been improved. But the improvement is limited. If the training optimization strategy is improved, after combining it with the BP network, a further performance improvement can be obtained. Compared to traditional optimization, the testing performance can be improved by 3.2%, 2.3%, and 2.5%. This proves the correctness and effectiveness of the designed training optimization strategy in this paper and can improve accuracy of formulation of optimal digital

technology application program in the news dissemination of complex situations.

5. Conclusion

With the changes in society and new media art technology, the contemporary media environment has undergone profound changes. Moreover, the development and application of digital technology have brought tremendous changes to news dissemination under the vision of new media art. It has greatly improved every aspect of news dissemination and the way the audience accepts it. This factor keeps the development model of news media updated. In the process of news dissemination, the situations involved are complex and changeable, which directly leads to different applications of digital technology. In view of the different complex situations in news dissemination from the perspective of new media art, this paper proposes an improved artificial neural network to formulate the required digital technology application program. First, this article systematically examines the status quo of digital technology in news dissemination from the perspective of new media art. It also analyzes the research trend of digital technology and news communication in the complex context under the new media art vision. Secondly, this article proposes a new type of neural network to optimize the application of digital technology in news dissemination in different complex situations. The neural network uses an improved particle swarm optimization algorithm and an improved network training strategy to improve the BP network, which can effectively solve the shortcomings of the BP network. Massive experiments have proved the effectiveness and correctness of this method.

The aim of this study is to probe the possible molecular mechanisms underlying the effects of propofol on HT22 cells. HT22 cells treated with different concentrations were sequenced, and then the results of the sequencing were analyzed for dynamic trends. Expression pattern clustering analysis was performed to demonstrate the expression of genes in the significant trend modules in each group of samples. We first chose the genes related to the trend module for WGCNA analysis, then constructed the PPI network of module genes related to propofol treatment group, and screened the key genes. Finally, GSEA analysis was performed on the key genes. Overall, 2,506 genes showed a decreasing trend with increasing propofol concentration, and 1,871 genes showed an increasing trend with increasing propofol concentration. WGCNA analysis showed that among them, turquoise panel genes were negatively correlated with propofol treatment, and genes with Cor R >0.9 in the turquoise panel were selected for PPI network construction. The MCC algorithm screened a total of five key genes (CD86, IL10RA, PTPRC, SPI1, and ITGAM). GSEA analysis showed that CD86, IL10RA, PTPRC, SPI1, and ITGAM are involved in the PRION_DISEASES pathway. Our study showed that propofol sedation can affect mRNA expression in the hippocampus, providing new ideas to identify treatment of nerve injury induced by propofol anesthesia.

1. Introduction

Propofol is one of the intravenous hypnotic medicines used to induce and maintain sedation and general anesthesia. It exerts its action through potentiation of the inhibitory neurotransmitter γ-aminobutyric acid at the GABA-A receptor [1, 2]. It is highly lipophilic and thus can rapidly cross the blood-brain barrier, leading to early onset of action. The characteristics of propofol are well known. It has fast metabolism and short recovery time, regardless of the depth or length of sedation time [3]. In addition to being used as an anesthetic, researchers also found that propofol is also related to many cancer-related pathophysiological processes and can play an important role in cancer by regulating the expression of a variety of downstream molecules, long-chain noncoding RNA, microRNA, and signal pathways [4]. Propofol upregulates miR-195, and then JAK/stat and NF-κB pathway is inactivated to inhibit the proliferation, migration, and invasion of gastric carcinoma MKN45 cells [5].

Although propofol can play an excellent role in maintaining sedation and general anesthesia, studies have also focused on changes in regional cerebral blood flow or neuronal activity during propofol sedation. Only one study showed that as the depth of propofol sedation increased, the activity in the area corresponding to the stimulus applied during propofol sedation decreased. In addition, they found that propofol sedation impaired the function of basal ganglia circuits and thalamocortical connections [6]. It is
FIGURE 1: CCK8 shows the processing effect.

understood that learning and memory occur mainly in the hippocampus, and propofol may cause hippocampal neurotoxicity [7, 8]. General anesthetics may induce developmental neurotoxicity, including subsequent long-term memory, acute extensive nerve cell death, and abnormal learning behavior [9]. Although many researchers have figured out that propofol induced neurotoxicity in the brains of developing animals, its exact mechanism of action remains largely unknown. Then, this manuscript, on the other hand, was conducted to observe the potential biological processes and signaling pathways that may play an important role during propofol sedation through the biology information analysis of genes with different expression patterns.

2. Methods

2.1. Cell Processing and Sequencing.
The HT22 hippocampal cell line used in the present study was purchased from Shanghai Yaji Biotechnology Co. (Shanghai, China). The cells were fostered in DMEM containing 10% FBC, $100 \mu/\text{mL}$ penicillin, 100ng/mL streptomycin at 37°C, and 5% CO_2. When the cell density reached 60–70%, the HT22 cells were exposed to propofol at concentrations of $25 \mu\text{g/ml}$, $50 \mu\text{g/ml}$, $75 \mu\text{g/ml}$, and $100 \mu\text{g/ml}$ for 1 day. The experiment was repeated three times. The cDNA/DNA/Small RNA was sequenced on the Illumina sequencing platform by Genednovo Biotechnology (Guangzhou, China). The libraries were sequenced.

2.2. Effects of Treatment on CCK-8.
Cells were inoculated in 96-well plates at $1 \times 10\ 3$ cells per well. Cell Counting Kit-8 (CCK-8; Beyotime Biotechnology, Shanghai, China) assays were performed daily. Briefly, the cells were incubated in a $100 \mu\text{L}$ medium containing $10 \mu\text{L}$ of CCK-8 (0.5mg/mL) reagent at 37°C for one to four hours. Absorbance was measured at 450 nm by an enzyme-labeled assay (Figure 1). The experiment was performed at least three times in three replicate wells.

2.3. Trend Analysis.
The results obtained from sequencing were subjected to follow-up experiments. The expression of each gene was grouped according to different concentration

points, and then a dynamic trend analysis was completed using OmicShare Tools. A P value <0.05 would show a significant difference.

2.4. Protein-Protein Interaction (PPI) Network Construction.
All associations got from STRING were provided with a confidence score and imported into Cytoscape software. Modules of the PPI network were screened using the Molecular Complex Detection plugin in Cytoscape. A P value <0.05 would show a significant difference.

2.5. Gene Ontology (GO) Function.
Gene ontology annotations and KEGG pathway enrichment analyses were performed using the Enrichr database GO terms consisting of the following three components: biological process (BP), cellular component (CC), and molecular function (MF).

2.6. WGCNA Analysis.
Co-expression networks were constructed using the WGCNA data bank in R software. Paired Pearson correlations were first used to evaluate the weighted co-expression relationships between all subjects in the dataset in the adjacency matrix. The matrices were then converted to TOMs using the topological overlap matrix (TOM) similarity function, and the resulting TOMs were used to measure co-expression relationships between genes based on biologically meaningful genetic similarity.

2.7. GSEA Analysis.
The genes were classified into high and low-expression parts, and then GSEA V3.0 software was used to analyze the enrichment results for the genes. A nominal P value of <0.05 and false discovery rate (FDR) of <25% were selected as cut-off criteria. We selected the top two ranked analysis results.

3. Results

3.1. Trend Analysis.
We first subjected the expression data obtained from sequencing to trend analysis to observe the genes whose expression continued to increase or decrease with increasing propofol concentration. The results of the trend analysis showed that genes concentrated in module 0 decreased in expression with increasing propofol concentration, and genes concentrated in module 19 increased in expression with increasing propofol concentration; both panels were differentially significant. There were 2,506 genes in module 0 and 1,871 genes in module 19 (see Figure 2).

3.2. Heat Map Showing the Expression of Each Gene in Each Sample.
Subsequently, we selected statistically significant modules for expression pattern clustering analysis. The heat map shows the expression of each trend module gene in each group of samples (see Figure 3).

3.3. WGCNA Analysis.
We selected module 0, in which gene expression was downregulated with propofol concentration, and module 19, in which gene expression increased with

propofol concentration; we collected genes from both modules for WGCNA analysis. The analysis identified a total of two panels, in which the turquoise panel genes were negatively correlated with the treatment of propofol (see Figure 4).

3.4. PPI Network Construction.
We selected the genes with Cor R >0.9 in the turquoise panel, a total of 1,698 genes, to construct the PPI network. Subsequently, the top 5 key genes, i.e., CD86, IL10RA, PTPRC, SPI1, and ITGAM, were screened using the MCC algorithm (see Figure 5).

3.5. GSEA Analysis.
We grouped the samples as high and low parts, while GSEA analysis was performed on single genes afterward. The analysis figured out that the low expression of CD86, IL10RA, PTPRC, SPI1, and ITGAM all have important roles in the PRION_DISEASES pathway, and CD86, PTPRC, SPI1, and ITGAM are also all involved in the NUCLEOTIDE_EXCISION_REPAIR signaling pathway. Furthermore, IL10RA is involved in the CIRCA-DIAN_RHYTHM_MAMMAL signaling pathway (see Figure 6).

4. Discussion

Propofol causes fewer anesthetic side effects and facilitates faster recovery compared to other intravenous anesthetics. The benefits of propofol include the rapid onset of anesthesia, short recovery time, and neuroprotective effects in pathogenic situations [8, 10]. Hence, concerns have been raised about the possible effects of the widespread use of propofol on the central nervous system. Propofol does have neurotoxic effects on children. It affects brain development by inhibiting neuronal activation of hippocampal neurons, which may lead to the reduction of neurocognitive function [11]. Animal experiments have shown that exposure to subanesthetic doses of isoproterenol alters the long non-coding RNA profile in the hippocampus of immature mice and leads to disruption of hippocampal circuits, while

exposure to high doses of isoproterenol inhibits long-term potentiation in the CA1 region of the adult hippocampus [12]. Previous studies have suggested that this may be because propofol is the most potent drug for activating the GABA-A currents in the immature hypothalamus [13]. To date, the specific molecular mechanisms involved in propofol affecting the hippocampal neuronal cells still remain unclear. To find the potential mechanisms by which propofol may affect hippocampal neuronal cells, we performed a trend analysis of the results obtained from sequencing. We found that 2,506 genes may decrease in expression with increasing propofol concentrations, and 1,871 genes may increase in expression with increasing propofol concentrations. We then subjected these 4,377 genes to WGCNA analysis and found that the turquoise plate genes were significantly and negatively correlated with the propofol in your treatment group. We then selected the genes in this panel with correlation coefficients greater than 0.9 for PPI network construction and screened five key genes: CD86, IL10RA, PTPRC, SPI1, and ITGAM.

CD86 is a type I transmembrane protein associated with T-cell activation in the immune system [14]. CD86 may act as a key regulator of the immune response to disease through a T cell-mediated mechanism, and thus it has great potential to become a new target for immunotherapy [15]. IL10RA consists mainly of a heterotetramer of the anti-inflammatory cytokine IL10 receptor and belongs to class II cytokines [16, 17]. IL10RA is usually located as a cell surface receptor upstream of STAT3, and it can bind IL-10 together with IL10RB to mediate downstream signaling via STAT3 [18]. PTPRC is expressed on all nucleated cells of the hematopoietic system. It expresses several isoforms specific to a certain cell type and cell development or activation state [19]. PTPRC also plays an important role in autoimmune diseases and cancers, as well as in infectious diseases; its deficiency may lead to T and B lymphocyte dysfunction, manifesting as severe combined immunodeficiency [20].

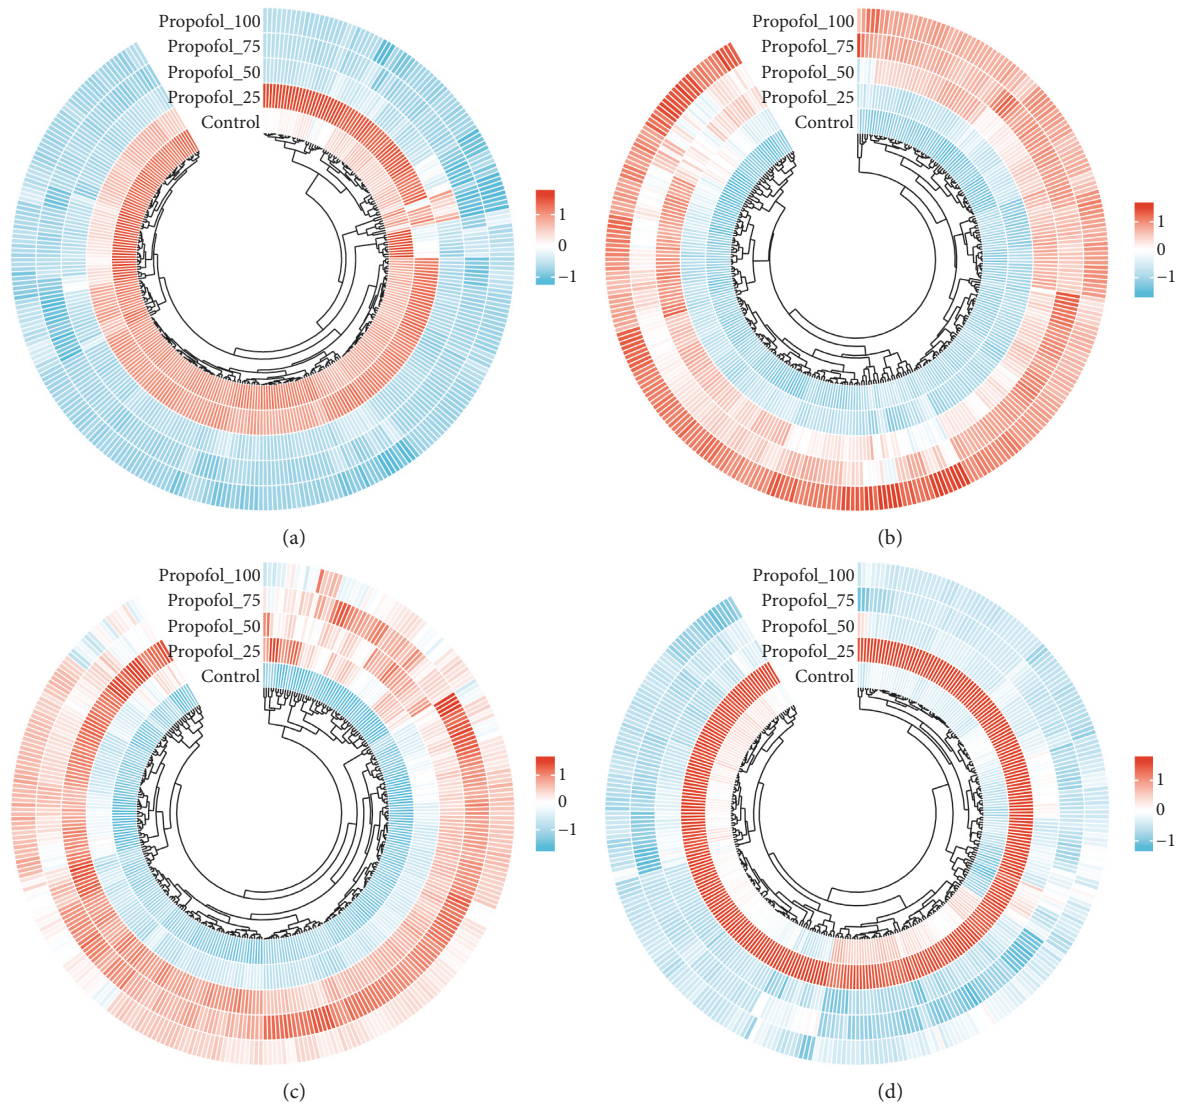
Spi1 is a major regulator of hematopoiesis because it is involved in the self-renewal of hematopoietic stem and progenitor cells, as well as in the stereotyping and


FIGURE 3: Heat map showing the expression of each gene in each sample. (a) Heatmap of module 0 gene expression in each sample. (b) Heatmap of module 19 gene expression in each sample. (c) Heatmap of module 18 gene expression in each sample. (d) Heatmap of module 12 gene expression in each sample.

maturation of the myeloid and B-lymphatic lineages. In-appropriate Spi1 expression is oncogenic. However, the molecular mechanisms mediating the oncogenic function of Spi1 are complex and not yet fully understood [21]. In addition, Spi1 transcription factors are important in regulating macrophage and neutrophil development [22]. ITGAM is expressed by a variety of myeloid cell types, which can form heterodimers with CD18 and mediate adhesion between cell types in the immune system [23, 24]. ITGAM deficiency may enhance disease progression and inflammation in multiple autoimmune models, including lupus [25]. The above then could show that CD86, IL10RA, PTPRC, SPI1, and ITGAM all play important roles in immune response. Inflammation is a response triggered by damage to living tissue. It can be beneficial or may lead to tissue destruction. Inflammation is particularly dangerous when the nervous system is involved (so-called

"neuroinflammation"), whether acute or chronic [26]. In turn, neuroinflammation can cause reversible and irre-versible neurological sequelae, including cognitive impair-ment [27]. However, by modulating inflammation, it is also possible to improve peripheral nerve repair [28]. It has been suggested that the abnormal expression of CD86, IL10RA, PTPRC, SPI1, and ITGAM may trigger an immune-in-flammatory response and thus lead to neurological damage.

In the present experiment, we performed GSEA analyses of individual genes separately and showed that CD86, IL10RA, PTPRC, SPI1, and ITGAM are involved in the PRION_DISEASES pathway. Prion diseases can make the prion protein (PrP Sc) in the central nervous system itch. In the early stages, microglia respond to the deposition of PrP Sc, thereby increasing their phagocytic capacity to clear PrP Sc. However, this phagocytosis is not sufficient and can have detrimental effects on the brain [29]. This is further evidence

that CD86, IL10RA, PTPRC, SPI1, and ITGAM have an important relationship in neurological impairment of the brain. This could also suggest that propofol may lead to neurological impairment by affecting the abnormal expression of CD86, IL10RA, PTPRC, SPI1, and ITGAM; thus, the exact mechanism remains to be investigated.

5. Conclusion

In conclusion, CD86, IL10RA, PTPRC, SPI1, and ITGAM may play an important role in propofol affecting mouse hippocampal neuronal cells. Propofol may affect mouse hippocampal neurons by affecting the expression of PTPRC, CD86, il10ra, spi1il10ra and ITGAM. Thereby, these findings may imply potential new targets for the treatment of

patients with propofol anesthesia-induced neurological injury.

This paper provides an in-depth study and analysis of the approach to digital media content creation using IoT technology. This study first investigates both WSN and NB-IoT technologies separately and then combines them to investigate the networking structure based on NB-IoT and WSN as well as the related technologies based on fusion. Then, the coverage method of the node redeployment of the traditional network of wireless sensors is elaborated. For the traditional method, a series of problems such as poor node connectivity and low coverage caused by not conducting a local search of subgroup nodes are proposed, and the node redeployment method of wireless sensor network based on the frog hopping algorithm is proposed, introducing the frog hopping algorithm, combining local search of subgroup and global information exchange, and proposing that for wireless sensor network nodes. We propose initializing the nodes of the wireless sensor network, combining the global information exchange with the subgroup, determining the range of the detectable area of the wireless sensor, and solving the calculus method for the irregular area to get the optimal network nodes so that the nodes of the wireless sensor network can be redeployed. In terms of system, this design abandons the CIS structure, which is more used in the current IoT and uses B/S structure and Java-web technology to design a web-based system. SSH (Struts + Spring + Hibernate) framework, AJAX asynchronous request technology, and JXLL/ JFreechart technology are fully applied to improve the practicality and comfort of the system, reduce development and maintenance costs, and facilitate popularization. After the system design was completed, the modules were tested with the existing experimental conditions. The experimental results show that the system is designed to be reliable and can operate normally with high stability and practical significance.

1. Introduction

The Internet of Things (IoT) is an extension and expansion of the Internet and communication networks, which mainly identifies the physical world through intelligent devices and sensing technologies, and carries out knowledge mining, processing, and computing based on network transmission and interconnection, to achieve the goal of seamless linkage and information exchange between things and things, and things and people, and thus accurately manage and control the physical world in real time based on scientific decision-making [1]. Since then, the Internet of Things (IoT) has received increasing attention from countries around the world, and the current consensus is that IoT belongs to another round of information technology achievements after mobile communication networks, the Internet, and

computer, which is extremely disruptive and revolutionary [2]. Former US President and the first black president Barack Obama responded to the "Smart Planet" strategy (proposed by IBM) as early as 2009, and during his term of office, the IoT strategy was fully integrated into the US national development strategy. The EU IoT Action Plan is the world's first IoT development strategy, which was officially released by the EU in 2009 and describes the trends in IoT technology development and application as its basic content [3]. Advances in science and technology have created new platforms and spaces for artists, greatly enriching the forms of artistic creation and promoting the development of art [4]. The rapid development of technology and media has led to a surprising collision between digital media technology and art in the era of mobile intelligence, and art creation has since had more new forms of expression and development

platforms, while the reading needs of the general audience have given art unlimited creative impetus and inspiration [4]. It is widely used in various exhibition halls, digital display, 3D virtual display, interactive display, guide system design, and other aspects of the use of digital media art. In recent years, digital media art has progressed particularly fast in display design activities, and the use of digital TV, digital broadcasting, digital advertising, virtual reality technology, laser light, heat-sensing equipment, etc. has become more widespread, which plays a vital role in improving the visual effect of the display, creating atmosphere, and promoting publicity [5].

The significance of this paper is to use the performance and planning of IoT-NB coverage as a basis to lay a solid foundation for future studies on coverage in other frequency bands, and to serve as a reserve for both coverage enhancement and interference prevention in the future. IoT-NB can be considered as a simplified LTE network, which is characterized by wide coverage area and large connections, and it plays a key role in the analysis and evaluation of IoT-NB IoT coverage and the planning of network capacity and scale [6]. The simulation and calibration of the model in this paper can be used as a guide for the subsequent planning, which is very important in the process of building the network. Today, global digitization is becoming more evident, and under this premise, the need for mobile communications is relatively high, and the efficiency and capability of communications are being enhanced [7]. 5G is a technology characterized by high reliability, low latency, and low power loss, which is no longer possible with simple wireless access technologies, which means that most of the new wireless access technologies need to be integrated to provide a combined solution. Combining new wireless access technologies can provide a joint solution.

2. Related Works

Contemporary digital media technology is formed based on digital information technology. Since the process of informatization of Western society started earlier, the digitization of media forms was earlier, Western scholars began to explore digital media technology from various fields and angles, and formed relatively comprehensive and in-depth theoretical research results [8]. From the macro perspective of digital media technology, many scholars have explored the impact of new digital media on the times and society. Marshall McLuhan proposed the concepts of "media as the message" and "media as human extension" in "Understanding Media—On Human Extension," revealing the significance of media technology in changing human culture and life, and in the age of electronic media, the limits of time and space will be broken through, and the distance between people in time and space will shrink, thus forming a "global village" [9]. With its precise analysis and prediction, this work has become an enlightening theoretical foundation in the field of digital media. In "Virtual Art: From Illusion to Immersion," I distinguish immersion in the digital media age from earlier forms of illusion art, draw on the actual works of contemporary artists and groups in the analysis, and summarize how to use 3D, IMAX, virtual reality, and other technologies. The

means create immersive illusions and outline the impact of virtual reality on contemporary art perceptions [10]. In "Digital Survival," it is described that in the world of the information age "information" is rapidly replacing material and becoming the basic exchange of society, and it explains that digital media technology based on the Internet and digital technology has an impact on human learning and work. In addition to the influence of entertainment and other lifestyle, it also has an important impact on the discussion and research on digital media technology [11].

The concept of the Internet of Things (IoT) was first proposed by Bill Gates, the president of Microsoft, but it was not given much attention at the strategic level because the development of the Internet was still in the rapid development stage and the related technology of IoT was not fully mature. Samie F took the transmission of radius sequence as the fundamental basis to express the distribution and heuristic algorithm of ant colony optimization, and then through the actual location of nodes [12]. The deployment is calculated in real-time to get the best node communication radius. This algorithm is heuristic, and although it can converge quickly to a more reasonable result, there is no way to ensure a continuous extension of the network lifetime because the nodes are the closest to the most correct solution and the algorithm is relatively difficult and costly. Many terminals, a small amount of data transmission, and low latency requirements are the characteristics of the current model of the Internet of Things. In terms of theoretical research, experts, and scholars such as Qiu et al. discussed the definition of IoT, technical directions, and the current development status of the IoT industry in China and worldwide and make a key analysis in each link of IoT industry chain and applications. The development status of the IoT application industry is also analyzed [13]. The Department of Technology and Economic Research of the Development Research Center of the State Council (2011) published a study on the development mechanism of China's IoT industry. The book presents the current situation of China's application of IoT technology and its problems in the sensor, cloud computing, smart grid, intelligent transportation, and electronic medical record industries [14]. The EPC field sees it as a mega-network covering everything in the world through next-generation information technology on the Internet. Any item in the network can interact with each other with data. In essence, it is the goal of information sharing by making objects automatically identify and transmit data through the Internet as a platform.

In summary, in terms of IoT technology, the promotion of the information age background has led to detailed and in-depth research both from a macro perspective and from a micro perspective of technology in the field of display, and on this solid foundation, there is still much room for improvement in research and practice regarding the use of technology in digital media content creation.

3. IoT-Based Digital Media Content Creation

3.1. IoT Model Design. The popularity and application of IoT technology have broken the traditional way of relying on a single information transfer between people. At the same

time, the information transmission of IoT technology still needs to rely on information sensing equipment to achieve, with the help of equipment and processing [15]. The Internet of Things is essentially an extension and expansion of the Internet and communication networks. It mainly recognizes the physical world through intelligent devices and sensing technology and carries out knowledge mining, processing, and calculation based on network transmission and interconnection.

The roles and functions of each structure of IoT technology are also different. The perception layer is mainly used for information perception, such as information collection and identification; the network layer is mainly used for transmission of various information, while the application layer mainly presents the results of the final identification information in front of human beings to further promote the intelligent management of something by human beings, as shown in Figure 1.

As the basic unit of the neural network, the single neuron has self-learning and self-adaptive capability and has a simple structure and fast response time. The combination of single neuron and traditional PID controller to form a single neuron adaptive PID controller, to a certain extent, solves the traditional PID controller and is not easy to adjust parameters online in real-time; it is difficult to effectively control complex processes and time-varying system parameters and other problems. Neural networks are characterized by learning, and the basic means of learning is learning rules. The connection weights are changed utilizing learning so that the adaptive function of the single neuron controller is realized. The learning algorithm is the core of the whole controller and w_i is the rule that adjusts the connection weights and reflects its ability to learn. The goal of seamless linking and information exchange between them is to accurately manage and control the physical world in real-time based on scientific decision-making. The learning algorithm is as follows:

$$w_i(k) = w_i(\kappa + 1)^2 - \lambda \lin(\kappa). \tag{1}$$

NB-IoT is an important branch of IoT technology, which has obvious differences from the traditional model in terms of voice service model and user distribution model. In traditional 2G, 3G, and 4G, the number of user accesses in base stations is controlled around 1000 and 400 in densely populated areas to ensure latency. However, NB-IoT does not require high latency, and it is dormant most of the time when there is no data interaction and activates the connection again when there is data exchange, which greatly improves the number of connections [16]. In terms of core network architecture, NB-IoT optimizes the EPC core network architecture, which can be known according to 3GPP's R13 protocol, and the principle of core network architecture is shown in Figure 2. Although there are certain differences in the way and focus of information transmission between the Internet and the Internet of Things, the ultimate purpose to be achieved is the same, which is to promote information transmission and communication between things and people. For the Internet of Things, this project the

birth of technology has laid a solid foundation for the further improvement and development of Internet technology. The user-level management of network airports is performed in FDD mode, and the process is implemented by first accessing the NB RAN with airports and then accessing the C-SGN (Cellular IoT Service Gateway) network at the S1 interface. The core capabilities are shared to third-party platforms using standard API interfaces. The core capabilities mainly include contract data management and location update management (HSS), terminal SMS function interoperability (SMS-GMSC/IWMSC/SMS ROUTER), and service capability development platform (SCEF), etc.

Using the HOP-DV algorithm to introduce multiple mobile anchor points, since each WSN contagion has its self-assembled graph, they can use neighboring nodes to transmit data to the aggregation node, so the most economical way is to distribute a mobile access point per cluster; this access point acts as the aggregation node and mobile anchor point. The mobile anchor point can obtain its location arbitrarily, and after receiving the information from all nodes in the cluster, it feeds back the number of hops and the shortest path, moves to other locations in turn, and repeats the above communication process. The coverage of all nodes in the cluster and the nodes are limited by the communication distance, and the distance moved by the mobile anchor point cannot be too small at each time of generating the movement but must be evenly distributed within the cluster. NB-IoT does not require high latency. When there is no data interaction, it is in a dormant state most of the time, and the connection is activated again when there is data exchange. This design greatly increases the number of connections.

$$C = \frac{\sum_{i \neq j} \max(h_{ik} + h_{jk})}{\sum_{i \neq j} \sqrt{(x_i + y_i) - (x_j - y_j)^2}}. \tag{2}$$

In the formula, h_{ik} and h_{jk} represent the number of hops from any position k nodes to anchor points i and j, respectively, and the maximum value of the sum of the number of hops from all position nodes to 2 anchor points is obtained and taken as the reference value of the number of hops between 2 anchor positions. This solution solves the estimation method of the average hop distance C, but the accuracy is equivalent to the classical DV-HOP algorithm, because the positioning accuracy is low, and locating the unknown node position will produce a large error rate.

$$\Delta S \leq \gamma \frac{\Delta L}{kL}. \tag{3}$$

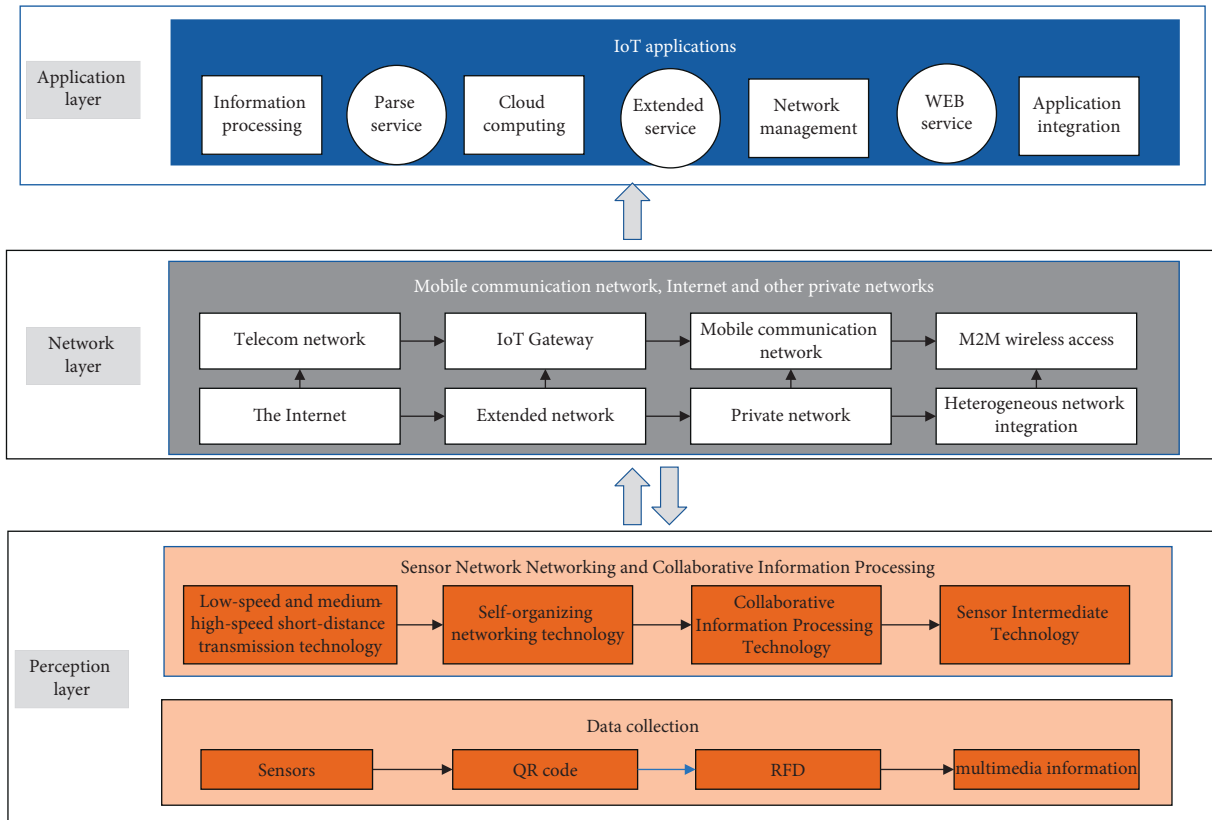
The cloud computing approach has many distinctive features with the development of the times and is widely used in various fields, with several main forms: processing, backup, multi-point storage, and large-scale centralized storage. This computing approach has a high value of use, can be used across platforms, and can be configured with servers, databases and core software, and other resources to meet the actual needs of applications. Based on the above advantages of cloud computing technology, cloud


FIGURE 1: IoT network architecture diagram.
FIGURE 2: NB-IoT core network architecture diagram.

computing can provide stable and scalable basic services for storing and processing large-capacity WSN data. Contemporary society is the era of the Internet of Things; privacy issues are particularly important with the changing habits and learning paths of human life. From film, television, camera to video art, multimedia art, digital art, all are the

progress of science and technology that inspired the birth of new art. The progress of science and technology has created new platforms and spaces for artists, which has greatly enriched the forms of artistic creation and promoted the development of art. In a questionnaire on "What should we worry about with the development of the Internet of

Things," personal privacy is the most important concern for contemporary people, followed by security. In addition to these two reasons, the following issues are operating system, application vulnerability, unauthorized access, identity impersonation, etc. The detailed statistics are shown in Figure 3. For WSN with IoT-NB technology, the sensing nodes have a huge amount, high data redundancy, simplicity, weak computing power, security issues, and drawbacks in the case of relying only on cloud computing has a huge impact and threat.

3.2. Digital Media Content Creation Model Construction. Digital Media is not simply a superimposition of digital technology and traditional media, but full integration of digital media and communication content. Digital media is more commonly referred to as "New Media" in the discourse of Western researchers. The difference between "new media" and "old media" is that, on the one hand, the plural form of the word "media" means that "new media" is no longer seen as a single media organization or media structure (e.g., print media, radio, and television media, etc.), but as a collective concept that divides all forms of digital media into one [17]. On the other hand, the "new media" integrates the content and characteristics of all existing media forms and adds digital, interactive, two-way communication characteristics to them. The application of this new form of digital media and novel technology in art has a broad development prospect and market appeal. It is widely used in various exhibition halls, and digital media art is used in digital display, 3D virtual display, interactive display, and way-finding system design. Digital media can be seen as a system that covers digital media organizations, products, technologies, contents, networks, and terminals and is led by government departments, enterprises, and individuals, with the means of computer technology and network information technology; digital media art contents are disseminated through the Internet, mobile communication networks and digital TV networks, on computers, mobile personal terminals, wearable devices, etc. On the digital terminal, it presents various websites, multimedia, computer animation, electronic games, interactive novels, interactive images, interactive devices, and virtual reality products.

As information technology continues to evolve in the digital age, traditional media have subsequently taken on their digital new forms. Web-based communication methods are becoming increasingly popular, personal digital terminals are gradually entering people's lives, and the distance between digital media and human beings is gradually being brought closer. As Negroponte said in "Digital Survival," "the development of information technology will bring revolutionary changes to our way of life." Information will no longer be "sold" to "consumers," but humans will carry information provided by "digital handymen" and participate in the interaction process, and the mass media will gradually evolve into a two-way communication media with personal characteristics [18]. The mass media has gradually evolved into a two-way communication media with personalized characteristics.
Figure 3: IoT security worry statistics results graph.

Chinese users have gradually shifted from traditional media to digital media and are spending more time on digital media than ever before. According to a statistic by Ariadne, from 2016 to 2021, the average daily use of digital media per capita in China increased from 1.78 hours to 3.08 hours, and the proportion increased from 35.8% to 50.4%, while the average daily exposure to traditional media per capita did not change significantly, as shown in Figure 4.

oT-NB can be called a simplified LTE network. It is characterized by wide coverage and large connections. It plays a very important role in the analysis and evaluation of IoT-NB IoT coverage and the planning of network capacity and scale effect. In the past, the exhibits on display were mainly in the form of physical objects. Due to their preciousness and state of conservation, these objects are not allowed to be touched by the public at close range, and there are restrictions on the time and place of their display. When the public goes to museums, they often encounter gaps in the content of the exhibits due to their condition or loans to other museums, which greatly affects visitors' interest and their desire to explore further in the exhibition activities [19]. With the addition of digital media technology, the exhibits start to develop from materialization to dematerialization and are presented in digital form in front of the visitors. Not only are the digital exhibits not easily damaged, is the display environment not restricted, and can the audience interact with them at zero distance, but also the same content can be displayed in multiple places at the same time, forming the sharing of resources. In addition, the digital exhibits will be a dynamic interpretation of static physical exhibits, making the exhibit content more vivid and comprehensive, stimulating the interest of the audience, thus improving the dissemination efficiency of museum display content.

A direct display scheme to solve the equations would make the algorithm less efficient, and therefore an acceleration of the algorithm is needed. The additive splitting algorithm (AOS) algorithm is a semi-implicit scheme for
FIGURE 4: 2016–2021 average daily time and timeshare of people using each mainstream media.

solving the nonlinear diffusion equation, where the image data of the kth + 1st iteration is not directly generated from the data of the kth iteration but is given indirectly through a matrix-vector equation. Since the stability of this semi-implicit scheme is not affected by the iteration step, a larger time step can be set to obtain a faster update speed. The rows and columns of the image are first diffused in one dimension using the semi-implicit scheme.

$$I_{\kappa+1} = \sum_{d=1}^{2} \left(A_d + 2\tau I_\kappa \right) \cdot I_{\kappa+1},$$

$$C_l = \frac{2L_{\min}}{L_{\max} - L_{\min}}.$$

$$(4)$$

With the continuous progress of technology, people's information concept is also constantly updated. People hope to meet the needs of information acquisition through various dynamic image information display channels and have a variety of sensory experience. This is something that cannot be given by traditional exhibition activities. In the era of digital media technology, the popularity and development of digital media technology have overturned the form of media and formed a unique form of information dissemination, and the exhibition activities have also changed significantly with the intervention of digital media technology. The purpose of immersive experience is to make the audience be completely submerged in the virtual scene displayed by digital media technology [20]. It is revealed that media technology is of great significance to the change of human culture and life, and it has made an in-depth interpretation of media technology in various eras. It is believed that in the era of electronic media the time and space limitations will be broken, and the space and time distance between people will continue to shrink and form a "global village." If some parts of the space itself distract the viewer's attention, it means that the viewer is not fully engaged in the

virtual scene during the visit, which results in a weakened sense of psychological immersion. In the evaluation of the importance of each element, it can be found that the elements that highlight the image of the space itself are no longer considered important to enhance the experience of digital display, while the physical environment with low presence has become a new demand for visitors, as shown in the Figure 5.

Therefore, the principle of virtualization guides architects to weaken people's sense of place in physical space when designing space. On the one hand, they can achieve indirect blurring of material space at the visual level using special interface materials, environmental illumination, or environmental color treatment, so that people cannot judge the boundaries and environment of space in space, nor can they clarify orientation and direction. On the other hand, digital photoelectric technology can be used to create virtual boundaries, which can directly realize the materiality of some elements in the physical space from a technical perspective.

4. Analysis of Results

4.1. IoT Model Results. Wireless sensor network technology is a distributed sensor network technology that senses and checks external world sensors. Its communication is achieved mainly by wireless means, with a very flexible network setup that can be changed at will, as well as by using wireless or wired connections to the Internet. Wireless connectivity is a multi-hop organizational network model that combines tens of thousands of sensing nodes freely to form a network. The technology is characterized by its large scale, self-organization, and dynamic form, making it useful for a wide range of applications, such as medical, military, and environmental monitoring. However, the traditional wireless sensor network node deployment method has problems such as low coverage and long and unstable mobile steps. This study proposes a wireless sensor network node redeployment method based on frog hopping algorithm, simulating the way of frog flock foraging, classifying the subpopulation of network nodes, realizing the whole process of information transfer combined with global information exchange, mixing all the frogs within the subpopulation, then classifying the subpopulation, collecting a certain place in the network coverage, using the nearest node to collect relevant data information, reducing the repetitive collection situation occurs, calculating the deployment of wireless network nodes, within the scope of the network area, divided into small areas of equal size, where the nodes can cover the area, that is, the area being monitored, the need for special monitoring, to complete the wireless sensor network node redeployment. This algorithm is heuristic, although it can quickly converge to a more reasonable result, but because the node is the closest to the most correct solution, and the algorithm is relatively difficult and the cost is relatively high, there is no way to ensure a continuous extension of the network service life.

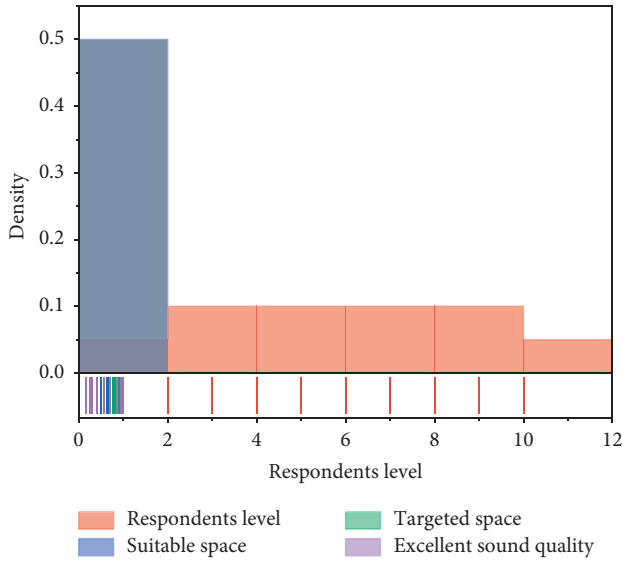
The coverage degree is an important parameter to measure the node deployment of the sensing network, i.e.,


FIGURE 5: Respondents' level of need for a sense of presence in the space itself.

the area covered by all nodes and the total ratio of the target area. Therefore, node redeployment starts with the calculation of the coverage of the optimal solution node, and the node redeployment is achieved by searching the coverage area through the coverage rate. If a certain area is to be focused on monitoring within the detected area, the calculation method at this time is to be calculated using different weights. If only one of these areas is needed for special monitoring, this node coverage area is expressed by the following formula:

$$S_{\text{all}} = S_{\text{area}} - (w + 1) \times S_i. \tag{5}$$

The above equation represents the area of the key monitoring area and represents the weight, which can be changed according to different specialty areas. The random forest (RF) algorithm, first proposed by Tin Kam in 1995 and studied in more depth by Breiman, enables pattern classification and regression prediction of the data to be input. RF successfully implements a combination of bootstrap strategies and random subspace methods. Since the decision tree is built very fast, the training of the decision tree is much faster than training an artificial neural network. To implement the random forest-based greenhouse temperature prediction, three environmental factors, namely, air temperature, air humidity, and light intensity in the greenhouse, are selected as model inputs to build the random forest prediction model. In this paper, the number of random forest decision trees is 500, which helps to enhance the generalization ability of the model calculation process. The roles and functions of each structure of the Internet of Things technology are also different. The perception layer is mainly used for information perception, such as information collection, identification, etc.; the network layer is mainly used for the transmission of various information, and the application layer is mainly used for information. The 2000 sets of data are selected as the training set and 400 sets as the

prediction set. As shown in Figure 6, the comparison between the predicted output and the actual output shows that the predicted output is very close to the actual output, and the calculated RMSE is 0.0183, which shows that the prediction accuracy of the random forest model is good from the intuitive point of view.

From the above experimental results, the random forest prediction model has a low error in the prediction experiments of greenhouse temperature, which is a key factor for tomato growth, and its root mean square error of prediction is about 0.0183, which is a low prediction error and a more accurate prediction of greenhouse temperature trends. Coverage is a measure of test integrity, reflecting the energy consumed by the network coverage area, and the degree of node redundancy. The higher the coverage is, the less redundant the network nodes are, while the opposite is true for the redundancy of the network nodes.

During the process of recording the single-hop or multi-hop information sent at each position where all nodes stay, the minimum number of node hops is sent, that is, the shortest path. And the initial node communication radius R is 6 m. The simulation results show that the error rate is lower compared with the HOP-DV (random deployment) and the improved DVHOP-NBIOT (uniform deployment at the boundary) under the condition that the number of unknowns (12) is equal, the communication radius (6) is fixed, and the number of unknown nodes (31–13) is unequal. The accuracy of the unknown node localization is greatly improved. A comparison of the effect of different mobile anchor deployment methods on the error rate is shown in Figure 7.

The deployment method of mobile anchor locations has a direct impact on the localization accuracy of unknown nodes. The DVHOP-NBIOT optimized localization algorithm, from the perspective of the localization error, produces lower results using several deployment methods such as center uniform, square, and cross than the boundary average deployment method. The center-uniform deployment method gives the best results with an average error rate of 18.66%. In the HOP-DV classical algorithm, irregular location deployment always occurs, which leads to unstable and large differences in the localization accuracy between the anchor nodes to be located and the unknown nodes. The result of the final identification information is presented to humans, which further promotes the intelligent management of something by humans. In summary, the DVHOP-NBIOT optimization algorithm makes the best use of the self-localization capability of NB-IoT, the background computing capability, and further combines the deployment optimization of the original location of anchor points to calculate the unknown node positioning, and a comparative analysis based on the original DV-HOP method finds that the error rate is reduced to a great extent.

5. Digital Media Content Creation Simulation Experiment

The digital display is based on the theoretical knowledge of display design and digital theory, based on modern information technology and other related fields (such as

FIGURE 6: Schematic diagram of predicted and actual output distribution.

FIGURE 7: Comparison of the effect of different anchor deployment methods on the error rate.

activity of the audience, so visual is the main way for people to get information. On the one hand, the visual experience alone will affect people's sense of visiting experience and the degree of memory of information. Through the experiment, it was found that 94% of the information received came from visual, 11% from auditory, and 6% from the smell, touch, and taste perception, which indicates that visual and auditory are still the two main ways for people to obtain information, but the role of other senses also assists people in receiving information. In addition, the study also found that people's memory of information through reading accounted for 10% of the total, the memory of hearing for 20%, the memory of visual for 30%, the memory of listening while watching for 50%, the memory of telling by oneself for 70%, and memory of combining and acting on various ways for 90%, which indicates that the more perceptions involved in information acquisition, the stronger people's memory of information will be.

This section firstly introduces the basic concept of a variational method for image processing, the variational principle, and Euler's equation in detail and investigates the principle of a variational method for image restoration by introducing the variational problem in image restoration; i.e., the problem is transformed into a generalized function on the extremum problem to find the minimum value of the problem. The results show that the TV model has the strongest denoising ability, the P-M model has the strongest edge-holding ability, and the linear model is in the middle of the range, with a slightly weaker denoising ability than the TV model and weaker edge-holding than the P-M model. Finally, Chen's coupled PDE model is studied, which lays the foundation for multi-physics field coupling denoising. The system performance results are obtained by testing three sets of experimental data, as shown in Figure 8.

According to the consumption ratio, the consumption of lookup tables and flip-flops in the project is 38.02% and 14.89% respectively, both below 70%. The clock management MMCM and phase-locked loop PLL use 3 and 1, respectively, and there are still scalable parts of the clock. The global buffer BUFG uses 10 units, and the remaining 22 units can be used to reduce the signal transmission delay and increase the signal transmission frequency. In summary, the FPGA chip is fully capable of implementing this system project. Cloud computing methods mainly include processing, backup, multi-point storage, and large-scale centralized storage. This computing method has high use value, can be used across platforms, and can be configured with servers, databases, core software, and other resources to meet the actual needs of applications. As shown in Figure 9, due to the large error at the beginning, the single-neuron network adjusts the three PID parameters online quickly with a large amount of adjustment, so that it can compensate for the temperature error quickly and track the input signal as soon as possible; when the error becomes smaller, the single neuron adjusts the three PID parameters with a small amount, so that it can track the input signal stably and maintain the stability of the control.

This section presents the systematic implementation of the algorithm by modularizing the system and summarizing the design structure and design methodology of each module in the system in each subsection. Simulation of several

museums and exhibitions, etc.) to achieve the purpose of display for the public. Nowadays, digital image technology is maturing and has been popularized in China. Contemporary exhibition halls are also gradually adopting this new display technology, changing from static display to dynamic display, and a certain part of the halls even takes digital image technology to the extreme, developing into a multi-sensory interactive display mode. The growing maturity of digital technology has brought a revolution to the exhibition industry and brought a deeper impression and more vivid experience to the public. Digital display design will open a new chapter for this modern exhibition industry.

Traditional display activities are mainly in the form of static physical display, and browsing panels and exhibits are the main

FIGURE 8: System performance test results.

FIGURE 9: System parameter self-tuning curve.

module of the whole system, collects the sensors of each environmental factor at the terminal, sends the collected data to the remote server through the NB-IoT network, stores them in the database, and realizes the web page of B/S structure with Java technology. The administrator can log in to the web page through a PC or mobile terminal to realize intelligent management. In terms of control, the design adopts a fuzzy control algorithm to realize the regulation of external environmental factors and establishes the ARIMA model to predict the future environmental change trend and provide data support for intelligent management. There are still many shortcomings in the theoretical and practical research results in this paper. The topic of how to promote the development of the new media industry by promoting the development of digital media advertising is a grand and long-term topic that needs to be studied continuously. In the future research process, the author will conduct richer and more in-depth theoretical research to supplement and sublimate the research of this paper.

important modules, such as data storage and data processing modules, is also carried out and compared with the software implementation to highlight the advantages of the hardware implementation of the algorithm. Finally, the system is implemented on the board to complete the whole algorithm from design to implementation, which proves that the algorithm hardware implementation has the algorithm enhanced image function and meets the algorithm real-time requirements.

6. Conclusion

This paper designs a digital media content creation method based on NB-IoT IoT technology by studying the current stage of IoT technology, new energy technology, database technology, Web technology, and fuzzy control technology in the digital media field. The system abandons the traditional wireless communication technologies such as ZigBee and Wi-Fi, which are widely used, and chooses NB-IoT narrow-bandwidth IoT technology as the communication

Retracted: English Speech Recognition System Model Based on Computer-Aided Function and Neural Network Algorithm

Computational Intelligence and Neuroscience

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope

(2) Discrepancies in the description of the research reported

(3) Discrepancies between the availability of data and the research described

(4) Inappropriate citations

(5) Incoherent, meaningless and/or irrelevant content included in the article

(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

With the economic globalization continuous growth of China's socioeconomic level tends to be internationalized, China's attention to English has been significantly improved. However, the domestic English teaching level is limited, so it is impossible to correct students' English pronunciation and make a reasonable evaluation at all times so that oral training has certain disadvantages. However, the computer-aided language learning system at home and abroad focuses on the practice of words and grammar, and the evaluation indicators are less and not comprehensive. In view of the complexity of English pronunciation changes, traditional speech recognition is difficult to recognize speech speed and improve its accuracy. Furthermore, to strengthen the English pronunciation of domestic students, a nonlinear network structure is studied in depth to simulate the human brain to analyze a model of speech recognition is established Mel frequency cepstrum characteristic parameters of human ear model and deep belief network. In this paper, the traditional computer pronunciation evaluation method is improved in an all-round way, and a set of high-quality speech recognition system of speech recognition method is constructed. Aiming at the above problems, it takes the students as the research, which proves that the method adopted in this paper can give the learners accurate pronunciation quality analysis report and guidance and correct their intonation and improve the learning effect, and the experimental data verify that the improved speech recognition system model recognition ability is higher than the traditional model.

1. Introduction

With the increase of globalization and China's internationalization, the Chinese people's demand for learning English is also easy to grow. However, because the Chinese vocal characteristics are different from those of the British, China does not have an English learning environment and lacks excellent English teachers. Due to the influence of time, location, and other factors, traditional classroom teaching can no longer meet the needs of English learning. At present, there are still great problems in English teaching; for example, teachers' descriptions are too general, and students' subjective initiative in learning cannot be fully brought into play, and learning English has become one of the research hotspots in the field of education. With the development of computer, the progress of language teaching methods, computer-aided language learning [1] provides the possibility to solve this problem. This technology allows learners to study in no time or area, can give learners timely and sharp evaluation and guidance, and can also help learners to find differences and standard pronunciation in different ways. Allowing learners to listen repeatedly, compare and correct pronunciation errors, and improve language learning efficiency.

The research goal of the call is to combine computer technology, especially speech recognition and evaluation technology, with the current language teaching methods to further establish a call system. Some famous international university research institutions are carrying out relevant research, such as Carnegie Mellon University in the United States, Tokyo University in Japan, and Cambridge University in the United Kingdom. MIT and Cambridge are working together to develop the oral communicative language learning project (SCILL), which aims to develop a conversational system to provide learners with conversational practice. WebGrader developed by Stanford University uses a speech recognition

engine [2] and scoring technology to score pronunciation exercises for second language learners. This conversational system allows students to practice spoken English online and promotes communication in English learning. In the research of speech quality evaluation in China, the Institute of automation, Tsinghua University, Microsoft Asia Research Institute, and other institutions are carrying out relevant content research and have achieved good results. The core of call is high-precision speech recognition is the important foundation of speech evaluation. DTW, HMM, and ANN are the classical mainstream methods, each with its advantages and disadvantages.

In recent years, the development of DL [3], BD [4], and CCT [5] and quality assessment technology have made rapid progress. DL originated from the field of ML [6], which aims to establish and simulate the deep neural network (DNN) of the human brain for analysis and learning. DNN can multilayer deep transmission of data by human brain neurons. Therefore, the study of English SRT based on DL can greatly improve the ability of voice aspect, improve access to information, and improve the user experience.

At present, with the rise of the international market, the training of spoken English in colleges and universities has been continuously strengthened. Therefore, the following problems are encountered in the study of spoken: Most people still choose language transponder and MP3 player, to learn oral English. However, none of these methods can carry out speech recognition, and they are limited to voice query and tracking functions. In addition, limited by technological factors, some call systems at home and abroad mainly concentrate on the learning of words and so on. Evaluation indicators are used as the evaluation, which can give an accurate score. Limited by their own level is not enough, and it is hard for them to find their mistakes and correct them with a total score of one point. In terms of oral test evaluation, the current oral test is still based on strong subjective will, different standards, and slow manual scoring. Due to the different experiences of scoring experts, and the different status of the same expert, the evaluation of the same voice will be biased. The English speech recognition system model constructed in this paper mainly uses the deep neural network to make the speech recognition can automatically recognize speech.

In order to solve those shortcomings, the DL application is selected, and a speech recognition model based on DBN is constructed [7]. Speech quality has been improved, and a reasonable speech quality evaluation model has been established considering the multiparameter indexes and their weights such as voice tone, voice speed, rhythm, and voice tone. The original achievement of the research can be applied to the study and training of human-computer interaction oral English. It can give learners more intuitive and useful evaluation, give advice, and give wrong pronunciation. It can quickly guide and motivate learners to learn English. The results are helpful to solve the problems in oral English teaching. In addition, English STR can improve the articulation of speech in the aspect of speech transmission, and the collection of causes is also more clear. The pronunciation of each syllable in English can be clearly collected, and the sound quality and timbre of speech can be guaranteed in the process of transmission.

2. Speech Signal Preprocessing and Feature Extraction

2.1. Basic Principles of SRT. SRT is one of the most popular text captions because its simple specification makes it easy to create and modify. The purpose of SR [8] is to decode the feature stream M of speech recognition and get the corresponding word sequence N, that is, to find $M = \text{argmax}_M p(N/M)$. It includes the following key modules: feature extraction, acoustic model, speech dictionary, language model. In general, it is difficult to search the optimal word sequence directly through features, so the transformation is based on Bayesian criteria.

$$P(M/N) = \frac{P(M/N)P(M)}{P(N)}, \quad (1)$$

where $p(M/N)$ is the generating acoustic feature M for a given word sequence N, which is the probability that the acoustic model needs to estimate. In the recognition model, if the speech features need to be recognized and extracted, the recognition program needs to be input into the system to complete the feature extraction. P (N) is the observed word sequence, which is the problem to be solved by the language model, and the construction of the speech recognition system is transformed into modular acoustic modeling, language modeling, word sequence decoding, and so on. The traditional speech recognition framework is shown in Figure 1.

(1) SSP and AFE: SSP [9] needs to preprocess and extract feature parameters. Generally speaking, the process of feature extraction is independent of the training of the recognition model and the testing of the system. According to the previous research experience, the feature parameter extraction of speech can be completed through a series of mathematical processes. The common speech feature parameters are linear prediction cepstrum coefficient and MFCC. MFCC parameters simulate the auditory characteristics of human ears. In most cases, MFCC is the most commonly used.

(2) Acoustic model [10]: HMM is a very popular acoustic model in speech recognition. The state jump model is consistent with the short-term stability of speech signals, so HMM can model continuous speech signals. In the GMM-HMM model, the probability of observation sequence is output by GMM, then the likelihood degree of observation sequence is obtained by HMM, and then, the optimal sequence path is obtained by decoding algorithm. With the continuous in-depth study of researchers, we also use DNN and HMM as acoustic models, in which DNN replaces GMM to generate the probability of observation traits, and HMM is used to describe the dynamic characteristics of speech signals. The model has been proved to be feasible and widely used in the speech recognition system.

(3) Language model [11]: M-Gram is most commonly used in speech recognition research. Language model based on RNN language model RNNLM is
FIGURE 1: Structure of traditional speech recognition.

gradually introduced into speech recognition. This model can model long history information and has a better performance compared with n-gram. However, in large vocabulary speech recognition tasks, replacing n-gram with RNNLM will increase, and because of the calculation time, the recognition efficiency of the whole system will decrease.

(4) Decoding search: After the score of the acoustic model is obtained through the acoustic model, the language model is combined with the relevant algorithm to get the final recognition sequence. For example, the dimension bit algorithm is used to decode the HMM system, and some other models also use clustering search to obtain the optimal sequence.

2.2. Speech Signal Preprocessing.

Before speech signal pre-processing, it must be preweighted, framing, windowing, and endpoint detection. This is done to eliminate the influence of harmonics on the quality of speech signal, which is caused by human speech organs. SP affects the effect of speech, but a smoother speech signal can provide better parameters. Improving voice quality can solve coverage problems by reducing interference factors and improving the quality of the hardware.

2.3. Recognition of Speech Characteristic Parameters.

Speech recognition is the technology or function that enables a program or system to process human speech. It is mainly used to convert spoken language into computer text. The purpose of speech recognition is to make the machine finally understand the oral nature of human language and the form of a voice in the digital signal of the computer. It is obvious that the digital signal directly understood by the computer will make the whole model calculation huge. The voice signal is converted into the dimension that can reduce the characteristic parameters of speech and, at the same time, ensure the maximum retention of useful information. Speech features have better recognition characteristics, which is convenient for the modeling of speech recognition system and has the certain anti-interference ability to the environment. MFCC [12] is a cepstrum feature parameter extracted based on the critical frequency band effect of the human ear. In many researches, MFCC parameters and their differences are usually used to model speech recognition tasks.

Figure 2 describes the extraction structure of MFCC feature parameters. A complete speech is divided into equal length and adjacent frames by framing. In order to make the overlapped part of the adjacent frame signal smooth transition, Hamming window function is used to window the signal. Then, the fast Fourier transform is used to transform. Then, the Mel triangle filter is used to calculate the signal, and then, the logarithm is taken to get the Mel spectrum of the signal. Finally, MFCC parameters are obtained by DCT. MFCC parameters reflect the static characteristics of speech. Usually, after getting the parameters of MFCC, the dynamic change of speech is described by calculating the difference, and the recognition performance of the system is improved by combining the static and dynamic methods. For example, MFCC can obtain the time length of speech and then divide it into N speech segments for recognition according to the length of the speech.

3. Research on Speech Recognition Model

3.1. Concept of NN.

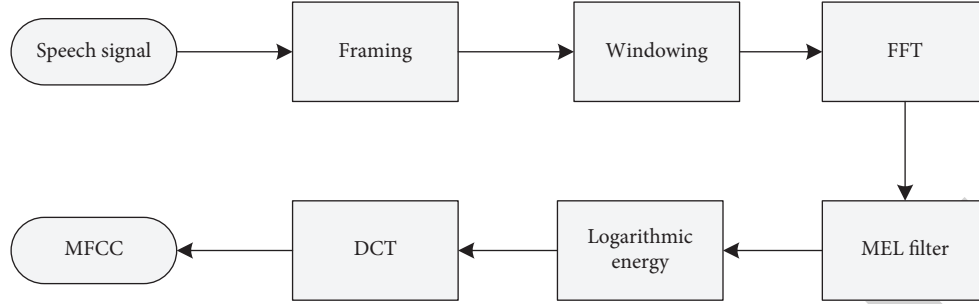
NN [13] can be regarded as bionic because the neural network is designed according to the


Figure 2: MFCC parameter extraction process.

human brain nerve and have the function of calculation and decision-making. The neural network is mainly used in classifiers. The NN calculates layer by layer according to the input characteristic quantity and finally outputs the identified signal. The NN itself has the function of learning. In the training stage, it can learn the unique characteristics of different samples according to the training samples and carry out memory; in the test samples, when encountering similar samples, it can distinguish the type of samples according to "memory," so the NN needs a large number of complete samples, and can correctly identify new samples through continuous learning and memory. It can ameliorate the generalization of NN. In the process of learning, if the training samples are not enough, it will lead to underfitting, and the actual classification effect will be very poor. If the training samples are single or overtrained, there will be overfitting. The overfitting network has a high recognition rate in training samples, excellent performance, and low recognition rate in test samples.

Different types of neural networks have different application scenarios. Common neural networks include BP NN [14], convolution neural network [15], wavelet NN [16], radial basis network [17], and self-organizing NN [18], among which BP NN is mainly for classification; convolution NN is mainly used for image recognition. Although the neural network is widely used in engineering, such as fingerprint recognition, face recognition, and biological body recognition, it is still unable to discuss the specific learning logic in theory, such as how to learn and remember the weight or value according to a certain function change and how to improve the number of hidden layers of the NN. In engineering, the parameters of the neural network are mainly adjusted, and the best is determined by the method according to the results of identification. With the increase of engineering complexity, there will be more and more related parameters, and the task of related parameter adjustment will gradually increase.

The artificial neuron [19] can be expressed by the following formula:

$$\begin{cases} a = \sum_{i=1}^{r} \omega_i x_i \\ b = f(a + \theta) \end{cases} . \tag{2}$$

Here, $x_1, x_2, \ldots, x_r$ represents the r input of the neuron; ω_i represents the connection strength (connection weight) of the ith input; θ is the bias of the neuron; b is the neuron. Therefore, the artificial neuron is a multi-input single-output nonlinear structure.

3.2. BP Neural Network.
Artificial NN, also known as NN, is a data processing model based on biological NN to each other for calculation and changes its structure according to external information, mainly through adjusting the weight of the network training input data and model, so that it has the ability to finally solve practical problems.

At present, a variety of neural network models have been put forward in the academic field, including radial basis function network [20], Hopfield network [21], CMAC cerebellum model [22], and BP NN. This paper studies BP NN. BP NN is usually multilayer, and another related concept is MLP, which has multiple hidden layers. MLP emphasizes the structure of NN, while BP NN uses the BP algorithm to adjust the network weight on the premise of a multilayer network. In most cases, they usually refer to the same network.

3.3. Deep Learning NN.
Deep NN is defined as a perceptron (MLP) with multiple layers that is usually greater than 2. Figure 3 depicts a NN with one input layer, one output layer, and three hidden layers. Neurons between adjacent layers are connected by weight. Through the input v_1, weight W_1, and deviation b_1 of this layer, the input of the next layer can be obtained by using the activation function.

$$v^{l+1} = f(v^l W^l + b^1). \tag{3}$$

Error backpropagation (BP) method is the deep NN. By calculating the partial derivative of each weight and the deviation of the loss function, the descent gradient of each parameter is obtained, and then, the parameter is updated by the gradient.

The depth NN can be represented in many different ways by different structures of hidden layer elements and different connection ways between adjacent layers. In speech recognition tasks, RNN and its variant CBLSTM have achieved good results and have been widely used.

The RNN connects the hidden layer elements of the feedforward neural network. When calculating the output of the hidden layer node, its calculation result depends on the calculation result of the previous node. Figure 3 depicts the RNN structure:
Figure 3: Depth neural network model.

The hidden layer of RNN is self-connected to expand the hidden layer. U, V, and W are connection output layer and hidden layer, respectively. The connection weights of all nodes are shared. x_t is the input of the current node, that is, the characteristic parameter vector obtained from the current voice frame signal, and the calculation formula of the hidden layer s_t and the output o_t are as follows:

$$s_t = \tan h(x_t U + x_{t-1} W + b_s),$$
$$o_t = s_t V. \tag{4}$$

The advantage of RNN hidden layer self-connection is that by extending it, the network of any length in the sequence can be obtained. In addition, different speech lengths are inconsistent. It provides a very flexible input model for speech signal by using the hidden layer self-connection of RNN.

3.4. Research on Speech Recognition Based on DBN. The core of the deep belief network is a layer greedy learning algorithm and then uses the backpropagation algorithm to fine-tune the network to get a better performance network model. Experiments show that the weight initialization of the multilayer perceptron corresponds to this network model.

Deep Boltzmann machines (DBMs) can be obtained by using an unsupervised greedy layer-by-layer approach. As shown in Figure 4 (i.e., the Bayesian belief network does not connect the layers between nodes) to approach the visual layer, layer by layer error propagation, and contain the farthest part used from the visual layer, we can obtain the deep belief network speech recognition model (DBN). In essence, RBM training can obtain the global optimal initial parameters, so as to improve the network performance [23, 24].

3.5. Content of Speech Recognition. As shown in Figure 5 first of all, the voice analog signal is digitized, and the voice signal is collected by the sound card of PC. According to Nyquist sampling theorem, in the process of analog/digital signal conversion, when the sampling frequency f_{s_max} is greater than twice the highest frequency of F_{max} in the signal, the following formula is obtained:

$$f_{s\_max} \geq 2 * F_{max}. \tag{5}$$

The sampled digital signal can fully express the information in the speech. The normal speech is generally 50~5000 Hz, and this paper sets the sampling as B kHz including preweighting and window. Preprocessed speech signal was collected. The speech features that can be recognized by the recognition model include auditory features, because the ultimate purpose of speech is to be listened to by human beings, and speech also has specific timbre features. Finally, the selected speech feature is recognized by the speech recognition model designed in this paper.

4. Evaluation of Multiparameter Pronunciation Quality

4.1. Process for Assessing Pronunciation Quality. The judge of voice quality is divided into subjective evaluation and objective evaluation, as shown in Figure 6.

Objective evaluation is the prediction and estimation of subjective evaluation, so the accuracy of subjective evaluation directly affects the performance of objective evaluation. Only when the experts evaluate the speech quality of the test speech truly and reliably and, on this basis, carry out machine evaluation, the objective evaluation is more meaningful. In order to get a real and reliable expert score, it is necessary to establish an appropriate voice quality evaluation standard according to the application requirements.

According to different situations, this paper uses two objective scoring methods to calculate scores.

(1) Quadratic curve fitting method is mainly used for the verification of single speech feature experiment. The specific process is as follows: the target distance between the training samples and the reference speech is calculated by using the training samples in the language library, and then, the parameters of the quadratic fitting curve are calculated by using the curve fitting method according to the principle of minimum variance. According to the parameters of the quadratic fitting curve, the subjective and objective mapping test is carried out, and the corresponding relationship between the objective distortion measurement $D(k)$ and the subjective estimation MOS is obtained.

$$M = a \cdot D^2(k) + b \cdot D(k) + C \quad 1 < k \leq K, \tag{6}$$

where *a, b, C* are the parameters of the quadratic fitting curve obtained by training, M is the target distance value, $D(k)$ is the objective estimate of MOS subjective score obtained by the quadratic fitting curve, and K is the total number of distortion conditions.

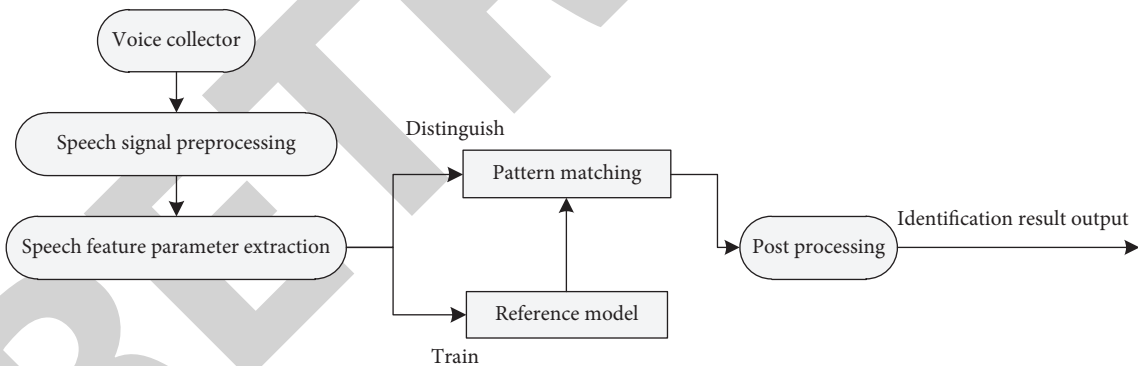
(2) BP scoring method mainly aims at the overall evaluation system of this paper, that is, using the BP algorithm to calculate the objective score of test speech.
Figure 4: DBN voice model.


Figure 5: Content of speech recognition.

4.2. Quality Evaluation Index. In recent years, Chinese English learners have made a great breakthrough in the overall level of pronunciation, especially in the pronunciation of monosyllabics (vowel-consonant), such as vowels in the back and change. This is largely due to the country's investment in educational resources and the enthusiasm of English learners. Therefore, for most English learners, they can better master the pronunciation of English words. But in real life, the rhythm of sentences is the key to English fluency. Many learners encounter a bottleneck after mastering the pronunciation of a single sound because they find that they can pronounce each sound very standard but still can express English with the strong Chinese flavor. This group

includes not only beginners but also many intermediate-level learners, English majors, and even some people who use English for a long time. In a sentence, prosody is a very important factor. Every language has its own prosody.

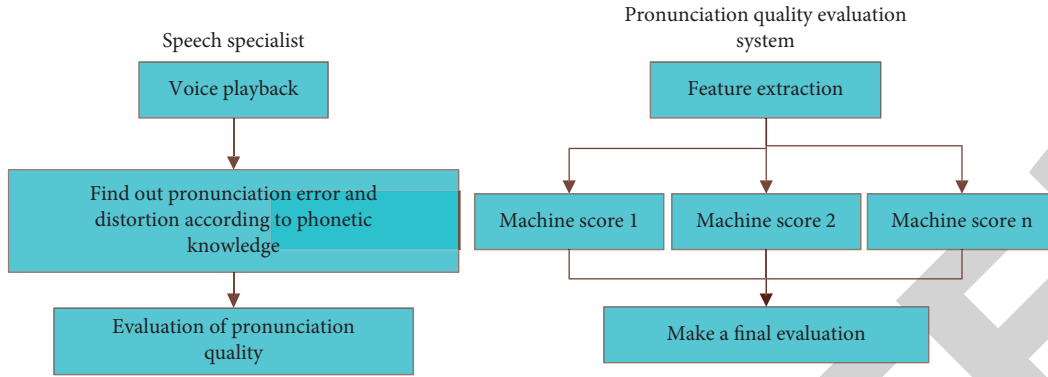
The evaluation of voice quality mainly includes voice tone, voice length, and voice rhythm. In the process of evaluation, phonemes and words are mainly evaluated by intonation. Sentences and paragraphs should not only check the content of the pronunciation itself but also determine the true meaning of the sentence to a large extent. When evaluating the pronunciation quality of sentences and paragraphs, we need to consider the prosody information comprehensively, such as whether the speaker can grasp the


FIGURE 6: A comparison between subjective and objective assessment of pronunciation quality.

key information of the sentence more accurately, whether the sentence is not so important, and whether the length of the voice is appropriate. In other words, when evaluating the voice quality of English sentences, good voice quality not only requires complete, no pronunciation errors but also needs speaking speed, accent, and accuracy. Therefore, this paper uses intonation and prosody to evaluate the quality of speech.

From the perspective of linguistics, prosody, also known as rhythm, refers to the organization of phonemes higher than the level of segments. It is a systematic organization that organizes various language units into discourse or related chunks in discourse. The realization of prosody can not only convey linguistic information but also paralinguistic and nonverbal information (including emphasis, emphasis, phrase grouping), as well as emotion, attitude, vocabulary discrimination, and other functions. Therefore, the quality of English pronunciation is closely related to its rhythm.

Prosodic features, also known as suprasegmental features, mainly refer to speed, rhythm, and intonation composed of dynamic modes such as pitch, intensity, and duration. This paper uses speech speed evaluation and paired variation basic frequency intonation to evaluate and guide English speech quality.

4.3. Evaluation Model of Multiparameter Pronunciation Quality. Different groups (such as college students and business people) have different requirements for learning oral English. Based on the evaluation of voice tone, speed, rhythm, intonation, and other quality indicators achieved by taking oral English of college students as the research object, a comprehensive analysis of various indicators is made. In the comprehensive quality evaluation, the relationship between the weight of each index should be considered, and a multiparameter evaluation model and method of college students' English pronunciation quality should be established to evaluate the pronunciation quality reasonably and objectively.

4.4. Speech Evaluation Experiment. The purpose of the speech evaluation experiment is to verify the performance of the English speech quality evaluation model and method

proposed in this paper. In this paper, consistency rate and PCC are used to express the manual evaluation.

The consistency ratio refers to the ratio of sample size, which is consistent with machine evaluation and nonautomatic evaluation. The specific calculation method is as follows:

$$A_{\text{Same rate}} = \frac{\text{Evaluate the same number of samples}}{\text{Total sample size}}. \quad (7)$$

The adjacent consistency rate is the ratio between the manual evaluation and the sum of adjacent samples and total samples, in which "adjacent" is defined as one level difference between machine evaluation and manual evaluation. The specific calculation method is as follows:

$$A_{\text{Adjacent consistency rate}} = \frac{\text{Same number of samples + adjacent samples}}{\text{Total sample size}}. \quad (8)$$

The two variables, which is expressed by r, are the linear correlation between two variables, and the value range is $-1 \sim +1$. The greater the absolute value, the stronger the correlation. Generally, $0 < R < 0.2$ indicates very weak correlation, $0.2 < R < 0.4$ indicates very weak correlation, $0.4 < R < 0.6$ indicates medium correlation, $0.6 < R < 0.8$ indicates very strong correlation, and $0.8 < R < 1$ indicates very strong correlation. The specific calculation method is as follows:

$$r = \frac{N \sum x_i y_i - \sum x_i \sum y_i}{\sqrt{N \sum x_i^2 - \left(\sum x_i\right)^2} \sqrt{N \sum y_i^2 - \left(\sum y_i\right)^2}}. \quad (9)$$

5. Experimental Simulation Results and Analysis

5.1. Reliability Analysis of Human-Computer Evaluation of Pronunciation Quality. It can be seen from Figure 7 that the deviation of a sample number of manual rating and machine rating of the test set in each score segment is kept in a reasonable range. As a whole, this distribution pattern of rating sample conforms to the performance distribution characteristics of general tests, and from the data distribution and data amount, the machine rating meets

the general requirements of test rating. However, from the micro point of view, manual rating and machine rating still show differences. The score of manual rating is relatively high, and the machine rating will be "stricter."

5.2. Analysis of Speech Recognition Experiment Results.
Compared with that of other models, this paper uses the Spanish Arabic digital, which includes 8800 Arabic digital voice data (88 people pronounce 10 Arabic digital voice, and each digit repeats 10 times). 6600 pronunciations of the first 66 subjects were used as training sets, and 2200 pronunciations of the last 22 subjects were used as test sets. The experimental software is matlab82013a.

For the same UCI machine learning knowledge base, Arabic spoken digital data set, Nacereddine Hammami, a new model of pattern tree distribution (TDA–GTS) based on tree structure and a new model of pattern tree distribution (TDA–MWST) based on regenerating tree structure are proposed. Compared with the traditional CDHMM and the CDHMM, the recognition effect is improved. Huang Wentao proposed a minimum KASWT weight value, and compared with the BP_Adaboost algorithm, its recognition effect is significantly improved.

As can be seen from Figure 8, the recognition rate of the DBN model is 97.32%, which is better than the above model. Therefore, the DBN established in this paper is reasonable and effective, which can be further used for speech quality evaluation.

5.3. Artificial Evaluation Experiment.
In order to facilitate the calculation, according to the method described, after obtaining the scores of 240 statements out of 10 sentences of 24 students, the scores are compared with manual evaluation as shown in Table 1 and Figure 9.

A total of 210 samples were obtained, including 34 first-level samples, 2 second-level samples, and 0 third-level samples. The results show that the coincidence rate of machine and artificial pitch is 87.63%, and the adjacent coincidence rate is 99.79%.

In the aspect of speech rate evaluation, there are 185 samples of ME and manual evaluation, 48 samples of the first grade not same, and no samples of the second- or third-grade difference; it shows that the consistency rate of machine and manual speech rate evaluation is 83.21%, the adjacent consistency rate is as high as 99.99%, and the Pearson coefficient is 0.527, which shows that the speech rate EM in this paper is credible.

In the aspect of result, there are 212 samples in the same level, 31 samples in the first level, 4 samples in the second level, and no difference in the third level. The results show that the consistency rate of machine and artificial RE is 86.89%, the adjacent consistency rate is 98.63%, and the Pearson coefficient is 0.556.

In terms of intonation, there are 184 samples with the same level of ME and manual evaluation, 39 samples with the first level are not the same, only 3 samples with the second level are not the same, and no samples with the third level are not the same. It shows that the consistency rate of
Figure 7: Distribution chart of human-machine rating.
Figure 8: Comparison of recognition rates of different methods.

machine and manual intonation evaluation is 81.36%, and the adjacent consistency rate is as high as 99.12%. The results show that the intonation evaluation method is very important.

To sum up, the assessment methods of intonation, rhythm, and intonation adopted in this paper are reliable and can be further applied to the construction of the English speech quality assessment model.

5.4. Test Results of Evaluation Model.
This paper evaluates 250 sentences out of 11 sentences of 25 students. The experimental results are shown in Figure 10. There are 200 samples for machine evaluation and manual evaluation of the same level, 28 samples for level 1, and no

TABLE 1: Sample number of experimental results of evaluation index.

Index/sample number	Consistency rate (%)	Adjacent consistency rate (%)	Pearson
Intonation	88.98	100	0.833

difference between level 2 and level 3 (see Table 2) for specific data.

According to Table 2, intonation is the most important, followed by rhythm and intonation, and speed is the least important. After obtaining the above experimental results, we communicated with the pronunciation experts to further discuss the reliability of the proposed multiparameter speech quality evaluation model. Experts believe that intonation is the most important index to evaluate the quality of English pronunciation, which requires accurate content, and pronunciation errors mainly show the emotional color of the speaker, enhance the melody of the voice, and make the voice closer to the reality of life.

6. Conclusion

Based on the globalization of China's economy, English has become a popular language in China. However, due to the Chinese accent, English is regarded as "Chinglish." However, the traditional speech recognition algorithms DTW, HMM, and ANN are not comprehensive enough, because these speech recognition models ignore that speech quality will be damaged during transmission. Because most of the computer-aided language learning systems at home and abroad focus on the accumulation of grammar and words, the importance of pronunciation is ignored, lack of evaluation indicators in pronunciation as the basis for evaluation,

so as to better correct students' pronunciation and improve oral skills. In addition, the traditional oral test has a strong subjective will, which is only based on manual scoring, so it cannot be fair. In view of the various problems, this paper strengthens the traditional speech recognition technology to consider many factors such as intonation, intonation, speed, and rhythm and further refines the defects of traditional speech recognition technology. From the tables in this paper, it can be clearly concluded that multiparameter pronunciation quality evaluation can be considered, which can give students accurate, effective, and objective evaluation and guidance, improve learners' oral English learning effect, and achieve a qualitative leap [25].

With the deepening of reform and opening up, great changes have taken place in the university financial management system. The role of financial analysis in university activities is becoming more and more obvious. In the new environment, especially in university financial reporting, we must establish effective reasonable and scientific financial analysis index system and quality evaluation team. In order to reflect the financial situation of colleges and universities, the university financial analysis indicators in this field have important theoretical and practical significance, such as finance, budget implementation, effective utilization of funds, risk prevention, and the formulation and application of such indicators. The financial management level of colleges and universities is improved, and the scientific development of colleges and universities is promoted. In this paper, we introduce the dynamic model of neurons, design a learning algorithm, and apply it to the quality evaluation of financial reports in colleges and universities. Through this research, a single-layer feedback network capable of fast learning and learning is established. This is not only helpful for universities to evaluate the quality of financial accounting business. However, enriching the significance of financial management in higher education has theoretical value.

1. Introduction

Financial analysis of colleges and universities is an important means to improve the efficiency of capital use and management level, an important indicator to promote the school to improve the financial risk tolerance, and an important basis for the school leaders to understand the current situation and make decisions for the future, so it has put forward higher and more requirements for the financial analysis of college system, and it has become vital to actively explore the way to optimize the financial analysis of colleges and universities [1–3]. The connotation of financial analysis of college system refers to the systematic analysis, comparison, and research of business activities of colleges and universities within a certain period of time by using special methods based on and starting from business plans, accounting statements, and other relevant information and summarizing and evaluating the experience of financial management, revealing the existing problems, gradually understanding and grasping the laws of economic activities

and business development status of schools, improving the financial management work, and enhancing the financial management level. The importance of studying the optimization measures of financial analysis of colleges and universities is an important part of financial management of colleges and universities. Studying the optimization measures of financial analysis of colleges and universities can provide a more correct and comprehensive understanding of the financial management activities of colleges and universities, grasp the input and use of various resources such as human, material, and financial resources of colleges and universities, analyze the deficiencies in the financial management of colleges and universities, use financial funds more efficiently, and improve the financial management level. In addition, the study of financial analysis optimization measures of colleges and universities can better help financial departments, external investors of colleges and universities, and leaders of colleges and universities understand the financial situation and development trend of colleges and universities and provide factual basis for

scientific [4, 5] decision-making. The current situation and problems of financial analysis in college system include the current situation of financial analysis awareness, the current situation of financial analysis content, the current situation of financial analysis methods, the current situation of financial analysis indexes, etc. With the current situation of financial analysis awareness and existing problems, the leaders do not pay enough attention to it, and the focus of attention is not on the financial analysis work on the one hand, most of the school leaders are education connoisseurs but not financial experts, they know about financial knowledge but not expertise, and they do not know enough about financial analysis and do not pay enough attention to it. On the other hand, the financial leaders of colleges and universities focus on the finance department's work of frequent reimbursement (accounting), tuition collection, budgeting, and declaration of spending and lack the initiative and enthusiasm for financial analysis. In the eyes of most school leaders, financial analysis is to analyze and integrate the data in the financial statements, calculate the relevant ratios and related indicators and, at most, summarize the financial situation with textual explanations. The leaders of colleges and universities do not pay enough attention to it, so it leads to the fact that there are few special financial analysis positions in the financial department of colleges and universities to focus on financial analysis, and it is a common phenomenon that financial staffs write down financial reports part-time every year and make simple and rough analysis and integration according to the report data, which does not achieve the real effect of financial analysis and makes the truthfulness and value of accounting information quality of majesty greatly reduced. The quality of financial analysts is not high on the one hand; the focus of the daily work of the financial personnel in colleges and universities lies in bookkeeping, accounting, and reporting, etc. A lot of energy is put into daily reimbursement work and little financial analysis of the economic activities of colleges and universities, and the focus of the financial personnel themselves is not on financial analysis. On the other hand, financial analysts should not only master down-to-earth professional skills, but also have certain management knowledge and understand statistics [6], probability theory, computer, network, and other aspects of information, and of course, they should be very familiar with the situation of this unit, which puts forward high requirements on the quality of financial personnel. The influence of mutual competition among colleges and universities is fierce. In order to stand out in the competition, schools have to develop continuously, expand the scale of enrollment, and build administrative buildings, teaching buildings, canteens, dormitories, gymnasiums, and other infrastructures, which is not enough only by financial funds and income from educational undertakings. In order to promote the rapid development of the school, attract external investors to invest in the infrastructure construction of the university, and obtain financing in many aspects, the financial analysis of the university system becomes very important. The structure of the index system at all levels of financial risk management assessment of universities is shown in Figure 1.

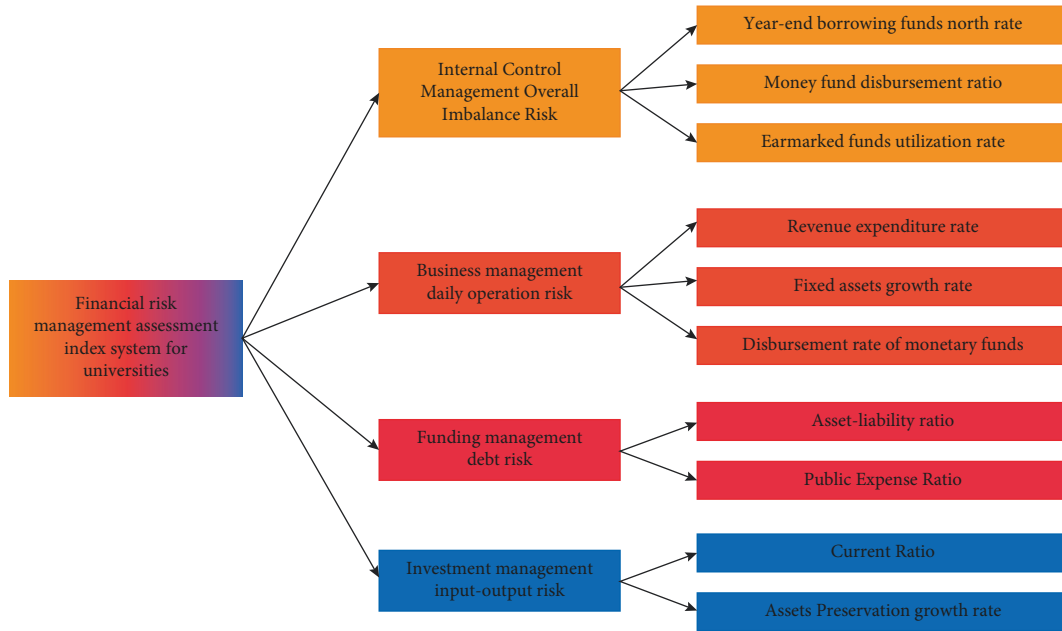
With the in-depth development of China's university system reform, universities gradually rely on financial analysis in behavioral decision-making, and financial management gradually changes from accounting management to analysis management, and financial analysis plays an increasingly prominent and important role in university management [7–9]. However, in the practical application, there are still many problems in the establishment of indicators and quality of analysis in the financial analysis of universities, which need to be improved continuously. Therefore, it is important to find out the problems in financial management through financial analysis, grasp the law of economic operation, and judge the risk level scientifically, so as to improve the financial management level of universities and promote their scientific development. In this paper, we analyze the design and application of financial analysis indexes of colleges and universities under the new situation, establish a scientific and reasonable financial analysis system, and apply it in order to improve the financial management level of colleges and universities and promote the long-term and rapid development of colleges and universities. Currently, under the influence of planned economic management mode, financial analysis has not attracted enough attention in the financial management of colleges and universities in China, and the management concept of financial analysis is not strong. In financial management, colleges and universities still generally focus on the process of nuclear management and supervision, while lacking postevent analysis and forecast. Even if quarterly or annual analysis is done, it is only an after-the-fact analysis. The financial analysis index system is not sound and perfect, and most colleges and universities do not extend the financial analysis index to the design process, not to mention establishing an efficient analysis model and using special analysis tools, thus failing to provide effective financial information for college behavior decision, not to mention adapting to the needs of rapid development of colleges and universities. At present, there are mainly the following problems in the application of financial indexes in colleges and universities: only simple data listing, lack of systematic analysis and scientific methods; the analysis index system is not comprehensive, and the comparability of relevant data is poor; the design of analysis system is not scientific and lacks accuracy, cannot be quantitative analysis, and is not strong in prediction. Therefore, with the deepening of university reform, China has developed higher education as an industry [10]. Under the new situation, it is especially necessary to carry out scientific design of financial analysis indexes and apply them reasonably. The scientific nature should fully consider the characteristics and nature of the management object and its movement law when designing the financial analysis indexes. The indicators are accurate and complete, neither duplicated nor omitted, independent of each other, and complementary to each other. The purpose of effective financial management is to maximize the economic and social benefits of funds by strengthening management. Financial analysis is for the service of financial management, so the design of financial analysis indexes should be centered on improving efficiency.


FIGURE 1: Financial accounting work system in colleges and universities.

Practicality the financial analysis index system of universities is a complex system with many contents and complicated relationships. When designing the analysis indexes, we should focus on each of them according to the evaluation objectives and tasks, so that the evaluation results of these indexes have practicality. The financial indicators established by comparability should focus on the interconnection, comprehensive, and developmental view and comparability and avoid one-sidedness, so as to draw correct analysis conclusions. Dynamic accounting and education management are constantly changing with the economic situation, and the design of financial analysis index system should also be updatable. If we do not consider from the dynamic nature, we cannot eliminate the influence of chance factors and lose the meaning of analysis and evaluation [10]. Reasonable determination of the weight of each financial analysis index and its ratio of colleges and universities makes the weight and ratio of each index according to the relevant requirements of the department and combined with the actual situation or according to the needs of their own management and development. The standard ratio of financial indicators of universities in recent years can be calculated by referring to other institutions to determine the specific weighting ratio of our indicators or by using arithmetic average. Reasonably determine the upper and lower limits of each single index score. Relevant authorities or universities should make reference to the weight and standard ratio in the financial analysis index system of universities to set the upper and lower limits according to their own situation when formulating analysis indexes, and universities should not be lower or higher than the upper limit when conducting financial evaluation. Reasonable determination of financial analysis standards of colleges and universities is carried out through reasonable analysis after the standards are formulated, and after the analysis,

excellent, good, qualified, and unqualified are derived, and the results of financial evaluation of colleges and universities can be obtained by substituting them into the relevant score intervals, which are clear and operable.

Dynamic neuron is an optimization method developed in recent years. It adopts the basic idea and structure of dynamic programming and draws on the achievements and methods of artificial neural networks, computer simulation, artificial intelligence, and other fields to optimize the system itself and improve the performance of the system through the simulation of the actual system. It adopts computer simulation and function approximation [11], which can effectively solve the long-standing "dimensional crisis" and has a broad application prospect in manufacturing, communication, logistics, and control engineering fields. Dynamic neuron is a novel artificial neuron model, whose supervised learning aims at stimulating a string of dynamic neurons that express specific information through precise temporal coding, hence the term dynamic neuron learning. The existing dynamic neuron learning methods are reviewed and compared for the significant application value of single-neuron dynamic neuron learning, various theoretical bases, and many influencing factors. The basic concepts of dynamic neuron model and dynamic neuron learning are first introduced; then the typical dynamic neuron learning methods are introduced in detail, and the theoretical basis and synaptic weight adjustment of each method are pointed out; finally, the performance of these learning methods is compared experimentally, and the characteristics of each method are summarized systematically. The results of this study contribute to the comprehensive application of dynamic neuron learning methods [12].

At present, most universities' financial risk identification mainly relies on managers' experience judgment, which is highly subjective and the accuracy varies from person to

person, and it is not easy to discover potential financial risk problems, and it also encounters bottlenecks in promoting the use and publicizing the identification results. Therefore, it is necessary to study a set of financial risk identification models for universities. At present, domestic and foreign scholars have established four main models in financial risk identification: univariate model, multivariate linear discriminant analysis, logistic regression model, and artificial neural network model, which still have shortcomings [13]. The dynamic neuron model has become a hot spot for research because it has no hypothesis requirement for samples and the model has strong fault tolerance, learning ability, and error correction ability, especially in the field of financial risk early warning of listed companies, which has made great progress. However, the research on the quality assessment method of financial accounting work of universities with dynamic neuron model is still in the initial stage. Therefore, this study tries to establish a set of index system for the quality assessment of financial accounting work in colleges and universities from the characteristics of colleges and universities and construct a financial risk identification model for colleges and universities based on dynamic neuron method to achieve the purpose of monitoring and assessment of financial risks in colleges and universities. The main contributions of the model proposed in this paper are as follows:

(1) Starting from the characteristics of colleges, this paper establishes a set of quality evaluation index system of financial accounting in colleges and universities

(2) This paper constructs a university financial risk identification model based on dynamic neuron method, which has a higher recognition rate than traditional machine learning algorithm and static neural network method

(3) The experimental results show that this model can monitor and evaluate the financial risk of colleges and universities, which lays a foundation for relevant research

2. Related Work

2.1. Financial Accounting in Higher Education. Financial analysis is a quantitative reflection of financial data, often only the amount of revenue, expenditure, budget execution rate, and other data, but with the lack of consideration of the impact of changes in revenue, resulting in low budget execution rate, the "quality" of economic operation is not enough to explore the connotation of this emphasis on quantity. This kind of analysis that emphasizes "quantity" but not "quality" inevitably leads to a lack of foresight and guidance in financial work. The financial analysis is not only to conduct microanalysis of our internal finance, but also to conduct horizontal comparison with other institutions of the same level and carry out macroanalysis. The financial analysis of many institutions is based on the description of accounting statement data, the data description of the basic situation of income and expenditure, and the lack of

comparison with the direction, amount, and magnitude of the increase or decrease of the relevant indicators of schools of the same scale of operation or schools with similar operation characteristics, the lack of understanding of the financial situation of the school and the trend of teaching changes, and the lack of reasonable evaluation of their competitive advantages [14]. Neglect of predictive analysis of the results of colleges and universities at the end of economic activities and then regularly has seriously restricted the development of colleges and universities. Colleges and universities should pay more attention to the prior analysis to avoid the drawbacks in the previous work. Otherwise, with the deepening of the reform of college running system, it is difficult for the colleges and universities with unreasonable allocation of educational resources and unsharp professional characteristics to transform into application-oriented universities. Under the new situation, the financial information required for the survival and development of colleges and universities must rely on financial analysis to provide in advance and reduce the competitive pressure of colleges and universities. Neglecting risk factor analysis: Although colleges and universities are nonprofit organizations, they are also in the market economy environment, where the risks and opportunities of running schools coexist and the inputs and benefits go together. Therefore, the financial analysis of colleges and universities only stays on the analysis of some deterministic factors, which has significant hidden dangers. Therefore, colleges and universities should strengthen financial management and strengthen financial risk analysis to prevent major decision-making mistakes from occurring. With lack of cost accounting analysis at present, the economic operation of colleges and universities mainly relies on the income and expenditure standards stipulated in the budget to control the economic activities of each department, so that each department can make full use of educational resources while achieving the set goals. Although the budget control makes the cost expenditure strictly restrained, it ignores the actual situation of various consumptions in economic activities. Therefore, colleges and universities should collect and allocate all kinds of consumptions that occurred in the process of education and teaching, so that the budget and cost can be effectively connected. At the same time, it should also implement the responsibility system for the value preservation and appreciation of state-owned assets and economic cost efficiency indicators and try out the economic responsibility system in a planned way. However, the cost accounting control of colleges and universities is not perfect, the consumption of common resources cannot be measured, teaching work or nonteaching work is costed according to uniform standards, resulting in the lack of authenticity of cost accounting, the educational resources cannot be optimally allocated, and it is difficult to control the phenomenon of occupying and idling resources. Paying attention to the analysis of financial development potential, as a nonprofit institution, the budgeting principles of universities are to balance income and expenditure, keep expenditure within the limits of revenues, and strictly prohibit overspending. The preparation and execution of school budget should be

carried out under this principle, and the red line of "operating in debt" and "deficit budget" should not be touched. Under the situation, it is one of the important indexes in the financial performance assessment of colleges and universities to measure the ability of colleges and universities to bear liabilities and risks and to comprehensively assess and evaluate the financial development potential [14]. The specific contents of the appraisal should include the following aspects: the status of accumulated external liabilities of colleges and universities and the ratio of liabilities, the ratio of annual total income and expenditure of schools, the net balance of deposits at the end of the year, the size of lending and temporary payments and their proportion, the assessment of business risks of school-run industries and the ratio of assets and liabilities, etc. In the new era, the essential task of colleges and universities is to cultivate application-oriented talents, meanwhile, strengthen scientific research and transformation of scientific research achievements, and adapt to the development trend of integration of production, learning, research, and application. Therefore, the performance appraisal of colleges and universities cannot be simply equated with the simple economic benefit appraisal but needs to be combined with various achievement appraisals after quantifying the work of colleges and universities as well as the simple economic benefit appraisal of less investment and more production, replacing the simple benefit appraisal with performance appraisal, and summarizing and analyzing the social and economic benefits with performance indexes. The analysis of university running efficiency is a comprehensive work with the characteristics of science and complexity. When analyzing and evaluating based on the above-mentioned indicators, the staff must integrate relevant statistics, funding arrangements, financial plans, fixed indicators, operations, and other relevant information, carefully sort out, compare, and study and analyze all economic activities and achievements of the university, and follow the principle of comparability and make precise calculations for each analysis indicator of the relevant year. Based on this, we compare and analyze the efficiency indicators between different years to reflect the dynamic changes of the efficiency of the university. Improvement of budget expenditure execution analysis of the expenditure budget of colleges and universities includes the expenditure for carrying out teaching, scientific research, management, and other activities in the year. From a macroperspective, the expenditure budget of colleges and universities can be divided into basic expenditure budget and project expenditure budget. If further subdivided, the basic expenditure budget, for example, can be further divided into the budget for personnel expenses and the budget for daily utility expenses. Among them, the budget of personnel expenses can be further divided into salary and welfare expenses, subsidies to individuals and families, including basic salary, allowance, social security contribution, performance salary, and other salary and welfare expenses; the budget of daily public expenses includes office expenses, printing expenses, consulting expenses, utilities, post and telecommunications, heating expenses, and property management expenses. If the university has implemented the

operation mode of "group management," the above detailed item budget can be further subdivided, and the detailed unit budget can be listed by responsible unit. Analyzing the budget execution rate of each department and preparing the analysis table of expenditure budget execution is an effective way to analyze the execution of university expenditure budget. Taking into account the characteristics and actual situation of colleges and universities, when analyzing the budget execution of each expenditure, it is necessary to analyze and evaluate both the absolute number of overspending or saving of each item and the relative number of the degree of budget execution of each funding item. For the budget execution of each expense item, the university should analyze and evaluate the above two aspects comprehensively to get an objective and fair analysis and evaluation result. At the same time, when analyzing the budget execution of expenditure, we should pay attention to the following contents: the data analysis from the budget execution rate is one-sided, not because the budget execution rate is low, the work of saving and use of funds is good, the budget execution rate is high or the expenditure exceeding the budget is the bad work of saving, which will cause the inaccurate results of budget execution of expenditure, and universities need to evaluate the overspending or saving of each item of funds according to the actual situation of using funds. The financial system of the university is shown in Figure 2. The universities need to evaluate the overspending or saving situation of each expense item according to the actual situation of expense use [15].

Colleges and universities usually use the comparative method and ratio method to analyze and compare the income and expenditure structure of each year, so as to compare the similar indicators with those of institutions with the same scale or similar structure in the same period, compare the differences of indicators, and explore the influencing factors that cause the differences, and make objective and scientific financial analysis. Among them, there are three kinds of comparative analysis methods mainly used by colleges and universities: using expenditure budget as the base, comparing the actual expenditure of funds with the budget, and preparing the corresponding budget expenditure execution table; comparing the current period with the same indicators of the previous period, or comparing the current year with the indicators of the same period of the previous year; level comparison, comparing and measuring the same indicators against similar institutions, and finding out the gaps through comparison and comprehensive thinking. To analyze the trend of financial appropriation income and expenditure of colleges and universities, we use the values of various indicators of financial income and expenditure of a certain period as a fixed base period and compare and analyze the data of financial income and expenditure of other periods or other years with them. Through the analysis of the trend of increase/decrease and magnitude change of the indicators in each period compared with the base period, we can trace the reasons for the fluctuation of the indicators, check the financial accounts, judge the financial situation, determine the economic operation and development trend, and predict the
FIGURE 2: University financial system.

possible development results. The indicators with large fluctuations are one of the situations that the trend analysis method focuses on; i.e., it focuses on strengthening the changes of the indicators of special and key parts. By analyzing the trends of the indicators, it is possible to make a general evaluation of the financial income and expenditure and provide a basis for the management to make decisions. The dynamic analysis method takes the quantitative characteristics revealed by the income and expenditure of colleges and universities as the standard, takes the rate of change of economic variables in the process of change in the time series as the basis of analysis, considers the process of change of economic operation from the process of continuous time points, recognizes the law of economic activities, explores the trend of change of economic variables, and judges whether it meets the requirements of strategic development of the university. The fundamental purpose of overall analysis method of financial management is to make limited funds produce greater social and economic benefits. Therefore, when applying the overall analysis method of university finance, it is necessary to follow objective laws, grasp the principle of overall optimization, and pay attention to timeliness, efficiency, and comparability. In this process, colleges and universities should clarify the purpose and take "maximizing efficiency" as the purpose of school economic construction.

2.2. Dynamic Neuron Model. Dynamic neural networks are known as the third generation of neural networks, which operate in a manner closer to real neurons and have stronger performance than traditional neural networks. With pulse excitation time as input and output, dynamic neurons can better simulate biological neurons and thus can be the basis for more effective simulation of artificial intelligence [16]. In the research of artificial neural networks, supervised learning theory has been a central part of the research. Since the physiological basis of various cognitive activities is the sequence of impulses excited by neurons in the human brain, supervised learning of dynamic neurons and networks has

an important application and has become an extremely important part of its research field. Among them, supervised learning with temporal encoding of the excitation of impulses has become a key research direction for researchers to focus on. The supervised learning methods based on temporal encoding of dynamic neural networks can be broadly classified into single-pulse learning and multipulse learning methods according to the number of pulses excited. Obviously, multipulse learning is more in line with the characteristics of biological neuron operation and also has stronger application performance. Supervised learning methods for dynamic neural networks can be classified into single-neuron learning and network learning methods according to the applicable network structure. A general rule for supervised learning methods in terms of network structure and number of pulses is that single-neuron learning methods are generally more capable of learning multiple pulses and can control more pulse excitation moments through learning, while multilayer network learning methods generally control a smaller number of output pulses. A few definitions of the concepts are introduced here first. Supervised learning of dynamic neural networks refers to learning that causes the output neurons to excite a specific sequence of desired output pulses. Time-coded supervised learning of a dynamic neural network means that the output neurons are learned to excite pulses exactly at the specified moment during a period of operation. Time-coded multipulse supervised learning of single dynamic neuron (hereafter referred to as single-neuron learning) refers to a single dynamic neuron with multiple input synapses that is learned to excite multiple pulses at the desired moment, i.e., a sequence of pulses, so it is also referred to as pulse sequence learning in [16]. Dynamic neurons are the basic units that constitute dynamic neural networks, and supervised learning of single dynamic neurons is of great importance as it can better draw on the well-defined synaptic tuning mechanisms of biological neurons, as well as being the basis for implementing supervised learning of more complex neural networks. The process of single-neuron pulse sequence learning is affected by many factors, including the length of the input and output pulse sequences, the excitation rate, and the number of neuronal synapses. The longer the sequence and the higher the excitation rate, the more difficult the learning process; however, many factors also make the pulse sequence learning more flexible with the available information for weight adjustment. Several single-neuron learning methods have been proposed by different researchers. Among them, one class has been proposed based on stochastic models, and such nondeterministic methods are difficult to analyze and compare their learning ability for complex target sequences [17–19]. An impulse sequence learning method is given using a linear algebraic approach, but the theory of this method is too much detached from dynamic neurons and therefore has received less attention from researchers. Also, there has been a review literature on learning methods for dynamic neural networks, but these studies have been presented more broadly and have not specifically focused on impulse sequence learning methods or conducted

experiments to compare the sequence learning ability of different methods. Sequence learning ability is the core performance of pulse sequence learning methods, while methods with stronger learning ability for longer and more complex pulse sequences will have stronger applications and better reflect the characteristics of dynamic neurons.

3. Methods

This section describes in detail the quality evaluation method of university financial accounting based on dynamic neuron model. Firstly, it introduces the specific evaluation indexes of university financial evaluation and then introduces the basic principle of dynamic neural network and how to apply it to university financial evaluation.

3.1. Evaluation Metrics. The index design of financial status analysis of colleges and universities is the performance status of assets, liabilities, and their equity of colleges and universities at a certain point in time. The main indicators are (1) Net asset growth rate = Net asset growth of the current year/Net asset amount of the previous year * 100%. It reflects the efficiency of the university's expenditure and the ability to preserve and increase the value of assets. (2) Ratio of fixed assets formation in current year's expenditure = total capital expenditure in current year/amount of credit incurred in current year's fixed fund * 100%, reflecting the capacity of fixed assets and the ability to preserve the value of fixed assets. (3) Growth rate of fixed assets = Current year's fixed fund growth/Prior year's fixed fund balance * 100%, reflecting the growth of fixed assets. Design of budget execution analysis indicators: Budget execution analysis indicators mainly include the difference between final income and expenditure and budget income and expenditure and income and expenditure structure analysis indicators, etc. (1) Revenue budget completion rate = total final school revenue/total budget revenue * 100%. This indicator reflects the difference between final income and budgeted income, which facilitates the comprehensive and scientific budget management of universities through analysis. (2) Completion rate of expenditure budget = total final expenditure of the university/total budgeted income * 100%. This indicator reflects the difference between final expenditures and budgeted expenditures of colleges and universities. Financial risk situation analysis index designs: The design of financial risk aspect indexes is mainly for risk avoidance. The main ones are as follows: (1) Asset-liability ratio = total liabilities/total assets * 100%. This indicator reflects the ability of universities to repay their debts. The funding source of colleges and universities is mainly financial allocation, and the asset-liability ratio should be controlled at a small ratio. (2) Current ratio = current assets/current liabilities * 100%. This indicator reflects the ability of current assets of colleges and universities to repay current liabilities when they are due. It is more appropriate to keep the ratio at 200%. (3) Cash ratio = Money capital/current liabilities * 100%. This indicator shows the ability of cash to repay current liabilities. (4) Other receivables to current assets ratio = Other

receivables/Current assets ending balance * 100%. Other receivables that have not been collected for more than three years will increase the financial risk of universities. (5) Other payables to current assets ratio = other payables/current assets ending balance * 100%. Take care to avoid financial risk when operating with debt. (6) Loan risk factor = outstanding loan balance (/unrestricted net income * 50% + general fund * 25%): 0.8-1.0 high risk; 0.8-0.6 higher risk; 0.6-0.4 medium risk; 0.4-0.2 low risk; 0.2-0 no risk. Design of indicators for fund utilization analysis: (1) Increase/decrease rate of per capita business expenditure = increase of per capita business expenditure of the current year/per capita business expenditure of the previous year * 100%. This indicator mainly reflects the cost of per capita expenditure of universities. (2) Self-sufficiency rate = (education income + operation income + other income) (/education expenditure + operation expenditure) * 100%. This index reflects the income capacity and the degree of recurrent expenditure of colleges and universities. (3) Growth rate of scientific research funds = the increase of scientific research funds in this year/scientific research funds in the previous year * 100%. This index reflects the ability of universities to serve the society. The evaluation factors of the financial work of colleges and universities are shown in Figure 3.

3.2. Dynamic Neuronal Network. The starting point of artificial neural network research is to mimic the information processing mechanism of biological neural networks. As neurophysiological research continues to advance, it is recognized that biological neural systems have dynamic properties, which are manifested in the delayed nature of synaptic connections, transmission of impulses, and stimulated excitation of cell membranes. In order to simulate dynamic functions such as learning, adaption, memory, and recall, and thus to better reflect the dynamic properties of biological neurons, it is necessary to introduce a feedback link in the mathematical modeling of biological neurons.

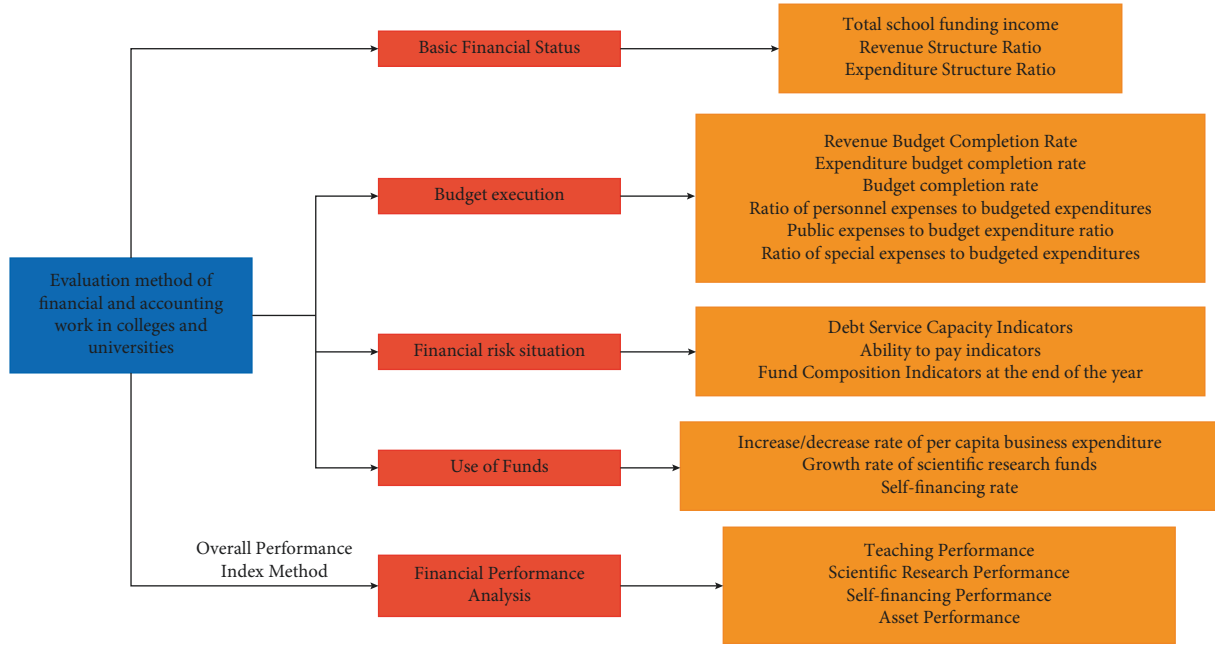
Most of the current popular deep networks have the same static reasoning paradigm: once the training is completed, the structure and parameters of the network remain unchanged in the test stage, which limits the representation ability, reasoning efficiency, and interpretability of the model to a certain extent. The dynamic network can adaptively adjust its structure and parameters according to the input samples in the reasoning stage, so it has many good characteristics that the static network cannot enjoy. The dynamic neural unit (DNU) model has both feedforward and feedback weights and then generates output values through the action of nonlinear excitation functions, whose characteristics and structure are different from the traditional static neuron model. The DNU model is shown in Figure 4, where $X_i(k)$ $(i = 1, 2, \cdots, n) \in R^n$ is the input quantity; W_i $(i = 1, 2, \cdots, n) \in R^n$ are the weights; $T \in R^1$ is the threshold; $S(k) \in K^1$ is the input of the linear dynamic system; $a_{ff} = [a_0, a_1, a_2]^T$ is the feedforward weight and $b_{fl} = [b_1, b_2]^T$ is the feedback weight; $V_1(k) \in K^{(-1)}$ is the output of the linear dynamic system; gs is the slope of the


FIGURE 3: Evaluation indicators.

Sigmoid-type nonlinear excitation function curve; $V(k) \in R^1$ is the input variable of the Sigmoid-type nonlinear excitation function; $Y^*(k) \in R^*$ is the output value; k denotes a ...rst moment. The linear dynamic system part of the DNU model is essentially a two-order IIR (Infinite Impulse Response) system, which simulates the reverse circuit in the biological nervous system.

The transfer function of the IIR dynamic system part of the DNU model can be expressed as

$$(k, a\_ff, b\_fb) = \frac{(V\_1(k))}{(S(k)) = [a\_0 + a\_1.\hat{Z}(-1) + a\_2.\hat{Z}(-2)]/[1 + b\_1.Z(-1) + b\_2.\hat{Z}(-2)]}. \tag{1}$$

Equation (1) can also be equivalently expressed in terms of the difference equation as

$$V\_1(k) = -b\_1.V\_1(k-1) - b\_2.V\_1(k-2) + a\_0.S(k) + a\_1.S(k-1) + a\_2.S(k-2) \ (2). \tag{2}$$

From Figure 4, the DNU model treats W_i ($i = 1, 2, \cdots,$ n), T,a_i ($i = 0, 1, 2$), b_i ($i = 1, 2$), g_s as adjustable parameters and modifies their values by learning. The learning algorithm can be optimized by using gradient descent method. Since the DNU model treats the feedback weights as adjustable parameters and modifies their values by learning, this inevitably brings the problem of dynamic stability of the model. In this paper, an improved dynamic neuron model, the CIIRDNU (Constricted Infinite Impulse Response Dynamic Neural Unit) model, is proposed. This model limits the feedback weights b_i ($i = 1, 2$)"," W_i ($i = 1, 2, \cdots,$ n), T, a_i ($i = 1, 2$), g_s as adjustable parameters to modify their values by learning. The learning algorithm is optimized using the gradient descent method. Since the feedback link

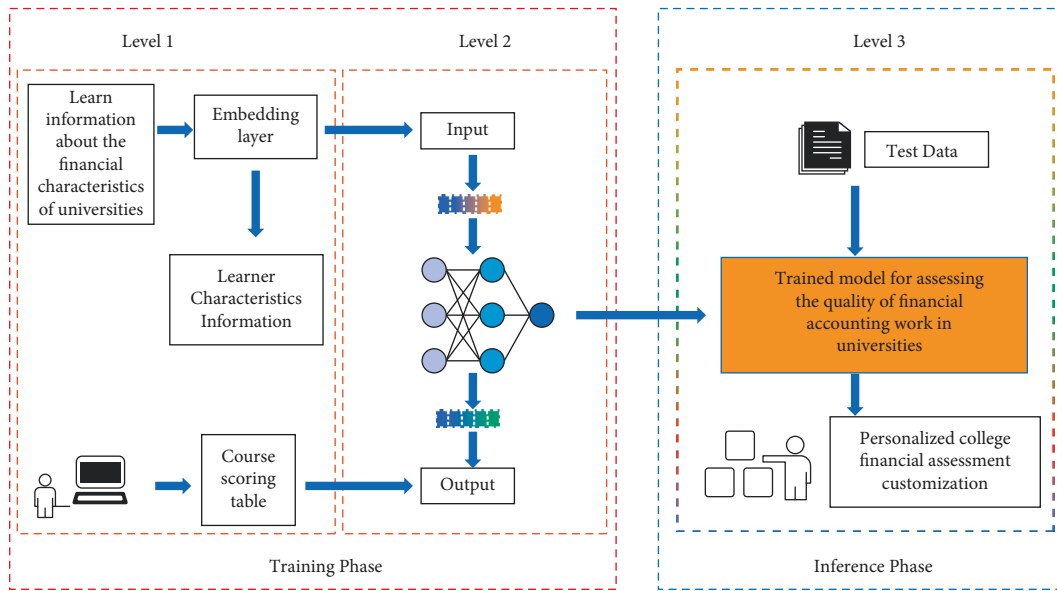
variables $b(i = 1, 2)$ are not modified as adjustable parameters in the model, the stability of the model can be ensured with proper initial settings. If $b1 = b2 = 0$, then according to the stability analysis of discrete linear system, $P1 = P2 = 0$, the linear dynamic system part of the model becomes FIR system, which can solve the stability problem of IIRDNU model, that is, another improved dynamic neuron model: FIR-DNU (Finite Impulse Response Dynamic Neural Unit) model. In this paper, traditional pattern recognition methods are combined with neural networks to realize the mapping from sample feature pattern space to pattern category space using feedforward networks of dynamic neuron models. The nonlinear excitation function in the dynamic neuron model is taken as
FIGURE 4: Dynamic neuron model.


FIGURE 5: Model architecture diagram.

$$Y(k) = \psi[V(k)] = \frac{1}{(1 + \widehat{e} - (V(k)))}. \quad (3)$$

From equation (3), the node output will be equal to 0 or 1 only when $V(k) \longrightarrow \pm\infty$. Therefore, for the binarized target output, the learning goal is considered to be reached as long as the output reaches values close to 0 and 1 at the time of learning. The overall architecture of the proposed model is shown in Figure 5.

4. Results

4.1. Dataset. The financial data of 16 universities (SH1-SH16) in 2018 were collected to construct neural network models, and the BP neural network data mining method was applied to analyze the financial situation of 2 of them (SH15 and SH16) in 2018 for early warning.

4.2. Experimental Setup. The experimental environment configuration information is shown in Table 1.

TABLE 1: Software and hardware configuration information.

Project	Configuration
CPU	Intel Core i7 7700
Memory	128G
GPU	NVIDIA GeForce GTX 2080ti
Operating system	Windows 10
Cuda	Cuda_9.0.176_384.81 with cudnn9.0
Language environment	*Python* 3.6

The number of neurons in the input and output layers of a BP network is determined by the number of dimensions of the input and output vectors. The dimension of the input vector is also the number of influencing factors. Through the analysis of factors affecting the financial status of universities, the article selects three primary indicators such as solvency, operation capacity, and development capacity and 15 secondary indicators such as asset-liability ratio, so the number of neurons in the input layer is 15. In order to refine the financial risk level, the risk level is divided into five levels: giant alarm, heavy alarm, medium alarm, light alarm, and no

TABLE 2: Model output results with actual value.

Colleges and universities	Year	Actual warning value	Network output
SH15	2018	(01000)	(0.1635 1.0000 0.0002 0.0004 0.0064)
SH16	2018	(00010)	(0.0000 0.0003 0.0043 0.9634 0.0051)

TABLE 3: Financial risk identification results.

	Group 1	Group 2	Group 3
Actual output value	1.2457	2.0121	3.2807
Ideal output value	1.0000	2.0000	3.0000
Relative recognition error	25%	1%	9%
Average recognition error		12%	

TABLE 4: Comparison of experimental results.

	Static neural network (%)	SVM (%)	Our model (%)
Recognition accuracy	89	85	98

alarm, so the target output patterns are (00001), (00010), (00100), (01000), and (10000), which are giant alarm, heavy alarm, medium alarm, light alarm, and no alarm, respectively [2, 5]. This gives the number of neurons in the output layer as 5.

Once the network structure is determined, the sample data is used to train through learning rules to improve the network's adaptive capacity. The learning rate determines the amount of change in the weight Figure Neural Network Modeling data stream values in each cycle and is an important factor in the training process. It is generally preferred to choose a smaller learning rate to ensure the stability of learning, and the learning rate is taken as 0.05 in this paper. The article collects the financial data of 16 universities (SH1-SH16) in 2018 as the research sample, and a total of 14 sets of financial indicators of the first 14 universities (SH1-SH14) in 2018 data and financial risk levels as network training samples, and the financial data of the last 2 universities (SH15 and SH16) in 2018 as prediction samples to apply BP neural network for early warning analysis of university financial risks.

4.3. Experimental Results. The results from the network output show that the network achieves the error requirement after 13 training sessions. The network output and the actual risk level of the university are shown in Table 2.

The results of the study show that the BP neural network model has a prediction accuracy of 98%, and the more the important variables for the model, the better the training effect. This shows that the BP neural network successfully forecasts the financial situation of 2 universities (SH15 and SH16) in 2018. The financial risk identification results are shown in Table 3.

4.4. Comparative Experiment. Then, the model in this paper is compared with static neural network and SVM classification algorithm. The experimental method is the same as the previous text. The experimental results are shown in

Table 4. It can be seen that the recognition accuracy of static neural network and SVM algorithm is 89% and 85%, respectively, which are lower than 98% of the accuracy of this model, which verifies the effectiveness of this model.

5. Conclusion

The financial management situation is more a combination of nonfinancial indicators and financial indicators, which can reflect the main measures and effectiveness in terms of budget management, internal control management, asset management, performance management, and talent team building. The description of nonfinancial indicators is an important reference factor to assist financial indicators for trend analysis, which not only is helpful for internal managers to make financial decisions, but also provides important reference information to external supervisors.

Under the new situation, the management system of China's colleges and universities has undergone great changes, and the role of financial analysis in financial management has become increasingly prominent. This paper is practical and valuable for university management by establishing and practically applying the financial index analysis system of universities, and it has certain reference and meaning for other universities to study. However, the financial analysis index system is a dynamic process, which keeps changing with the development of universities. Therefore, the research on the financial analysis index system of universities also needs to be adjusted continuously to meet the development of universities.

In this paper, we will assess the quality of financial accounting work in colleges and universities based on dynamic neuron model. It is studied that feedforward neural network can better reflect the neural computation ability, as long as the appropriate dynamic neuron model is selected (i.e., set the appropriate order n), the single-layer feedforward network established on this basis can solve the problem, and the learning training speed is fast and good. The future research direction is to improve the dynamic

neural network from the perspective of structure and cognitive mechanism, so that it can not only maintain high recognition accuracy, but also adapt to complex and unknown data and have stronger robustness. The dynamic neuron model has the potential for applications that are worthy of further research and development. The assessment results are generally consistent with the actual financial situation of the school, indicating that the financial risk assessment index system has a certain degree of reliability and validity [20].

Large-scale sports events with high-level competition as the main content will have a great impact on the host city whether from the economic level or from the social level. With the improvement of human civilization, people realize that the holding of large-scale sports events not only has a positive impact on the economy and society but also brings some negative effects, such as waste of resources and environmental pollution, which have attracted the attention of the government and investors. Therefore, how to scientifically, comprehensively, and reasonably evaluate large-scale sports events, especially the accurate evaluation of their economic and social effects, has become the focus of attention. The evaluation of large-scale sports events mainly includes two levels: economic and social. Through the specific analysis of the evaluation content and the weight calculation of the evaluation index, the overall optimization of the evaluation of large-scale sports events is realized, and the reference experience is provided for the holding and evaluation of large-scale sports events in the future. Based on this, this article proposes a sports event evaluation and classification method based on the deep neural network. Firstly, on the basis of literature review and field investigation, the evaluation index system of sports events is established. Deep learning models have strong fitting power and robustness and have been applied to many real-world tasks. Then the deep neural network is used to evaluate the holding effect of sports events. The experimental results show that the model has high evaluation accuracy and is of great significance to the supervision and guidance of sports events.

1. Introduction

Sports, as an important part of the social subsystem, has penetrated into every aspect of society. The reemergence of the modern Olympic Movement and the formation of the Olympic economy make large-scale sports events closely related to other social elements such as economy, politics, and culture and play a positive role in the modernization of the city [1]. Since the mid-1980s, the world's major cities have been racing to bid for the large-scale sports event; the main reason is that the city authorities see a big sporting event as an opportunity to exercise and promote the government or the host country or the host city government's administrative ruling ability, thus improving the status and prestige of the host city, expanding urban visibility [2]. For example, Atlanta is known as the world sports center city

because of its advanced sports facilities. Shanghai is also speeding up the pace of building the first-class sports center city in Asia [3].

The holding of large-scale sports events not only improves the political influence of the city but also directly brings great economic effect to the host city and establishes a good self-renewal mechanism and a perfect internal coordination mechanism. The economic driving effect of large-scale sports events on host cities is mainly reflected in stimulating investment, expanding consumption, increasing employment, and optimizing economic structure [4]. Especially in the tertiary industry, tourism, catering, social services, media, and communication industry, the tertiary industry has gradually been in line with the international standards in terms of marketing methods, service technologies, and management concepts. Especially since the

successful holding of the 23rd Los Angeles Olympic Games in 1984, the commercial operation of sports events has brought rich economic returns to the host cities. From the 23rd Olympic Games to the 27th Olympic Games, the direct revenue generated was $227 million, $470 million, $400 million, $100 million, and $450 million, respectively [5]. In addition, competitive sports events can provide more job opportunities for local residents, strengthen the construction of urban infrastructure, and expand economic cooperation and exchanges with various cities.

More and more attention has been paid to the economic and social benefits of sports events by society. The administrative departments of the state and city have been expecting the social and economic benefits of organized sports events while trying to make the society give support to sports events [6]. However, the two sides of things are unavoidable for sports events, and the holding of large-scale sports events will also have a negative impact on the host city. For example, in 1976, Montreal spent a huge amount of money to hold the Olympic Games, which did not bring ideal economic benefits but made it fall into the "Montreal trap." On August 28, 2004, the French newspaper La Tribune revealed that the Greek government had taken on 4 billion euros in debt for the Olympics. For example, during the Sydney Olympic Games, visitors and spectators in the Olympic Village consumed 10,000 cups of beer, 70,000 cups of cola, 3,000 bottles of mineral water, 2,000 pizzas, and 3,000 hot dogs every day [7]. A large number of spectators will leave a lot of waste and garbage for the stadium and the city, which will bring great pressure to the protection of the hosting environment. The combination of declining environmental conditions and a sudden increase in population density has increased the incidence of certain diseases [8].

It can be seen that the impact of large-scale sports events also has positive and negative aspects. Therefore, it is not enough to investigate the economic impetus that sports events bring to the host city. In order to consider the whole process of sports events as the end of a project group, it is necessary to pay attention to the evaluation of society, environment, culture, and other aspects in addition to the evaluation of economic benefits [9]. Therefore, only a comprehensive evaluation of sports events can provide a certain degree of reference for the host region or the host unit and accumulate experience for the holding of subsequent events. The main contributions of this article are as follows: (1) we propose a deep neural network-based evaluation and classification method for sports events; (2) we established a sports event evaluation index system based on the query of related literature and field survey; (3) a deep neural network is used to evaluate the effect of holding sports events; (4) experimental results show that the model has high evaluation accuracy, which is important for the supervision and guidance of sports events.

2. Related Work

The development of project management and evaluation is a result of engineering and project management practice, which mainly originated in the construction industry in the 1930s. With the progress of society and the development of modern technology, the application of related theories of project management and evaluation is also expanding. It can be said that the project management evaluation has gone through a long process from experience to science, which has roughly experienced four stages: subconscious project management evaluation, traditional project management evaluation, project management evaluation dissemination and modernization, and modern project management evaluation [10].

2.1. Status of International Research on Evaluation of Sports Events. At present, all countries in the world are very particular about project evaluation in various fields and the application of various periods; the initial project evaluation in foreign countries is just used in aerospace, defense, and chemical fields; as the subject mutual infiltration and the wide application of computer technology, the project of evaluation also gradually developed into an independent discipline [11]. Some developed countries in the world of international financial organizations in the process of domestic and foreign investment found that traditional project financial analysis methods have been unable to the decision-making of the project in order to guarantee the safety and profitability of its investments, project evaluation also from pure financial analysis to focus on the analysis of the economic development of the economy as a whole system [12].

In the process of project evaluation, some countries in Europe and Asia pay attention to economic benefit evaluation and advocate social evaluation of investment projects, including social equity evaluation, social justice evaluation, evaluation of mutual adaptability between projects and the region where they are located and evaluation of sustainable development [13]. Project social evaluation can be roughly divided into four stages: the first is the project financial evaluation stage. It only existed before the 1950s, characterized by the pursuit of profit maximization. The second is the SCBA evaluation stage. Under the influence of Keynesian economic theory, western economists gradually formed a social cost-benefit analysis method suitable for evaluating public projects [14]. It is from the perspective of the national economy, standing in the national standpoint of the evaluation: the third is the project environmental evaluation stage. Since the 1970s, the theories and methods of environmental assessment of investment projects have been formed and developed gradually. The "material-centered" economic evaluation does not reflect the distribution effect and cannot guarantee the optimal choice of the project [15]. Environmental assessment often ignores the assessment of social and economic impacts. Although it can alleviate the major adverse impacts of some projects, it is insufficient in guiding public participation and reducing negative social impacts. The general steps of sports event evaluation are shown in Figure 1.

As a social project, large-scale sports events have become a bright spot in the field of sports. After the commercial operation of the 1984 Los Angeles Olympic Games, the evaluation of sports events was also elevated to a higher
FIGURE 1: The general steps of sports event evaluation.

status [16]. Therefore, the related theories and methods of project evaluation have been widely used in the field of sports, but a professional system has not yet been formed. Judging from the development of the Olympic Games, after the end of the 2001 Sydney Olympic Games, the Sydney Olympic Organizing Committee submitted to the IOC an evaluation report on the overall impact of the Olympic Games on Sydney, which involved about 30 evaluation indicators [17].

2.2. Status of Research on Evaluation of Sports Events in China. At present, in China, project evaluation is widely used in various fields, mainly including public facilities construction project evaluation (highway construction project, urban transportation construction project, etc.), risk management project evaluation, development project evaluation of tourism resources, and project evaluation of ecological environment. The evaluation method is to select the corresponding index in a project and generally adopt a mathematical statistics method to deal with logarithmic excavation or determine the weight of the index, so as to put forward the evaluation system of the project or build the evaluation model of the project [18].

China's sports industry started late until the 1990s to develop. After several decades of development, China's sports industry has already taken shape, and various advanced theories, including project management and evaluation, have also been applied in the sports industry. With the success of Beijing's bid for the 2008 Olympic Games, the evaluation research of large-scale sports events has been pushed to a new height under the background of the Olympic economy [19]. In June 2003, Beijing Organizing Committee for the Olympic Games selected the Renmin University of China as the leader of this project. According to Fang Fu-Qian, a renowned professor at The National People's Congress of China, the overall impact defined by OGGI includes three parts: environmental impact, economic impact, and sociocultural impact [20]. A research team from the Renmin University of China analyzed the 159 indicators suggested by the IOC, and after revising them, the IOC finally confirmed 171 indicators.

The IOC also said individual indicators could be further negotiated. With the start of the 2008 Beijing Olympic Games, the International Olympic Committee requires each Olympic Committee to accurately and comprehensively analyze and study the overall impact of the Olympic Games on the host city or country's social culture, environmental conditions, and economic development and provides about 160 evaluation indicators as a framework [21]. This is the complete evaluation system for the overall effect of large-scale sports events. In the initial 159 indicators provided by the International Olympic Committee, there are 42 items related to environmental evaluation, including the reserve and utilization of water resources, the sewage discharge of Olympic venues, the disposal of household garbage, and the utilization of land. There are 57 indexes involved in economic evaluation, including direct economic benefit and indirect economic benefit. 6.0 items related to social and cultural influence, including public participation consultation, education, social moral construction, and other aspects [22].

2.3. Research Status of Deep Neural Network. Modern convolutional neural network, as one of the most important and active research directions in deep learning, has undergone a long historical development. From the proposal of cybernetics in the 1940s to the development of connectionism in the 1980s, the artificial neural network has been gradually improved. Deep learning was proposed in 2006, which promoted the capability of convolutional neural networks with deep network structure to a new level. For deep learning, one of the most well-known features is that it is inspired by the neural structure of the human brain [23], which is also the historical origin of the term artificial neural network. With this flexible and adaptive structure, mathematicians have built a powerful tool. LeNet, proposed by Lecun in an article published in 1998, is of great significance to modern convolutional neural networks [24], and the basic design of convolutional neural networks in the article is still widely used for reference today. Then in 2006, Geoffrey-Hinton, a professor at the University of Toronto, Canada, published a relevant article in science, marking the rapid development of deep neural network structure [25].

Domestic scholars have also made an attempt to apply deep learning to classification and recognition. Changxin and Gong [26] used the depth confidence network to set the target group layer and scene layer on the basis of the target layer to improve the target detection accuracy through the constraints of the context between the target and the target and the scene context. There is an interaction among the target layer, target group layer, and scene layer to form a supervised network. The network guides the learning of the whole model, adjusts the depth network parameters, and improves the target detection performance. Qi et al. [27] proposed a classification method based on the deep trust networks (DBN) model. Experiments show that compared with support vector machine and traditional neural network methods, the method based on the DBN model can achieve a better classification effect.

3. Establishment of Evaluation and Classification Model

This section describes the sports event evaluation and classification method based on a deep neural network in detail. Firstly, it introduces the determination method of sports event evaluation index weight and then introduces the

basic principle of deep neural network and how to use a deep neural network to evaluate and classify sports events.

3.1. Determine the Weight of Sports Event Evaluation Index.

After the evaluation indicator system is determined, because each indicator has different effects and influences compared with other indicators at the same level, different weights must be determined according to their importance. The weight of the index reflects the relative importance of the whole indicator system. Therefore, the determination of index weight is the most basic evaluation index method. In this study, the analytic hierarchy process was used to determine the weight of each index. According to the analysis of the factors of sports event evaluation, the evaluation criteria of each index are determined, and the evaluation analysis model of a sports event is constructed. The structure analysis model of sports event evaluation is shown in Figure 2.

Pairwise comparison is a method based on comparing two possible combinations of factors to determine the weight value of factors to first-level indicators. According to the principle of analytic hierarchy process (AHP), the importance index of the second round of expert consultation is compared in pairs by using the method of a 9-level grading system, and then all expert opinions are averaged to get a judgment matrix to judge their consistency. Then calculate the relative importance ranking of the index at the same level, namely, the weight of the index in the upper level.

3.2. Basic Principle of Deep Neural Network.

A batch standardization network layer is added to the convolutional neural network after the fusion of the first convolution block and the second convolution block and the feature images extracted from the third, fourth, and fifth convolution blocks [24]. The existence of the BN layer can improve the generalization ability of the convolutional neural network, make the loss function smooth, do not rely heavily on weight initialization, make the network parameters can be randomly initialized, and speed up the network training speed [25]. In the process of neural network training, input values before activation between layers will change in the distribution with the continuous training of the network, and the variation difference of input will accumulate with the deepening of network layers [26], which will cause the gradient disappearing in the process of network deepening. For the gradient descent method used in model training, parameter selection plays an important role in the training process [27]. After the BN layer is added, activation values can be automatically pulled back to normal distribution without deliberately adjusting parameters.

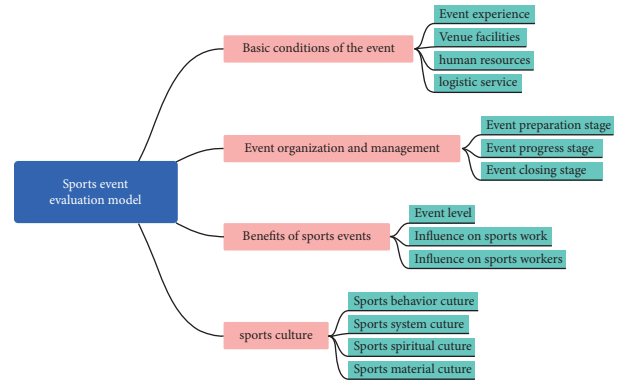
After the third convolution block, the fourth convolution block, and the fifth convolution block pass through the maximum pooling layer, three branches are connected, respectively, and each branch is connected to a global average pooling layer. The features extracted from three convolution blocks are fused together to form fused features for classification, which are connected together to enrich the extracted feature information. The fifth convolution block


Figure 2: The structure analysis model of sports event evaluation.

extracts the features of the whole band. Finally, the three convolution extracted features are fused together, and the fused features are input into the full connection layer. The fused feature map further highlights each type of feature. The structure of the convolutional neural network is shown in Figure 3.

Average pooling is above the characteristic figure of the extract, similar to the process of convolution, taking the average characteristic figure for dimension reduction results, but the global average pooling layer corresponds to the average of each characteristic in the unit, namely, each characteristic graph output a value, it sets the figure characteristics of the space information and does not require the adjustment of the parameters, reducing fitting. After feature extraction is completed, the extracted features need to be classified and processed, which is the function of the full connection layer, which is located in the last layers of the convolutional neural network. As neurons of the full connection layer need to be fully connected with all neurons of the previous layer, the data volume of the full connection layer is the largest, similar to the BP (backpropagation) algorithm.

When the training set is too small and the feedforward neural network is relatively complex, it is easy for the neural network to overlearn a certain type of data and affect the accuracy, which will lead to overfitting. The basic idea of the Dropout method is to make some neurons in the hidden layer stop working at a certain probability during network training. During the implementation process, the neuron activation function can be reduced to zero at the desired probability. When the Dropout value is set to 0.5, it means that 50 of the 100 neurons in this layer will be set to 0 after the Dropout processing. The neurons randomly set to 0 cannot be the same every time in each iteration update, so the whole process is equivalent to taking the average value of different neural networks. Different random processes produce different overfitting situations so that the overfitting situation is optimized on average. The connection mode of dropout strategy neurons is shown in Figure 4.

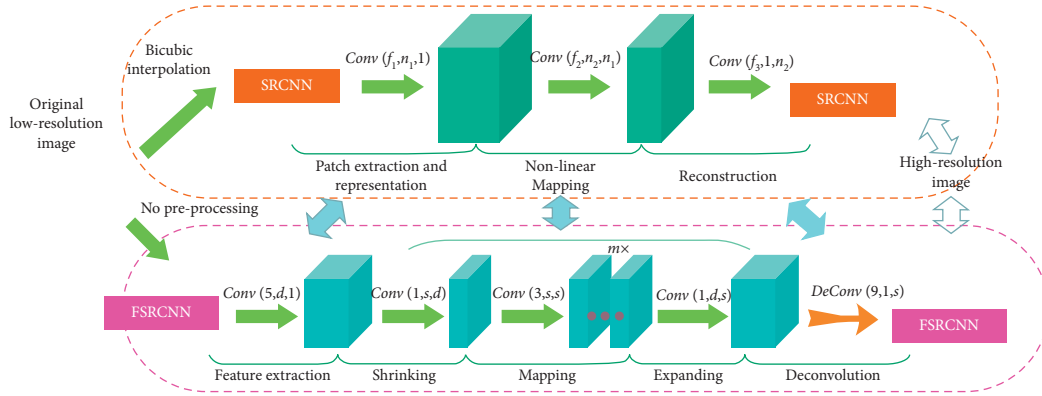
In the network, most training parameters are mainly in the full connection layer. By changing the last and second full connection layer of the original neural network to the Dropout layer, the number of parameters can be greatly reduced and overfitting can be reduced. The neural network


FIGURE 3: The structure of the convolutional neural network.
FIGURE 4: The connection mode of dropout strategy neurons.

added different network layers to reduce the original network parameters and reduce overfitting, fused the features of different convolution blocks together to enrich the feature semantics, and optimized the model to improve the accuracy of heartbeat learning for each category of arrhythmias. In the training process of the deep learning classification model, the main purpose is to reduce the error between the actual value and predicted value, that is, to reduce the loss function. The loss function is reduced mainly by adjusting neuron parameters, and the gradient descent algorithm is used to update neuron parameters and reduce the loss function.

A gradient is the derivative of the function at the current position. If a function $f(\theta)$ is convex and θ is an independent variable, then the gradient descent algorithm can be used for optimization, as shown in the following formula:

$$\theta = \theta_0 - \eta \cdot \nabla f(\theta_0), \qquad (1)$$

where θ_0 is the independent variable parameter, η is the learning rate, θ is the updated θ_0, and ∇ is the derivative of this point. The learning rate determines the speed of the network training process and generally takes a small value to avoid missing the global minimum value in the process of gradient update. The learning rate will constantly adjust its own value in actual network training so that training parameters can be updated more quickly.

Backpropagation, including forward process and backward process, after the forward propagation from the input layer to the output layer, and using the prediction results and the real worth to loss function values, to spread after using the loss function values obtained from the front, from the output layer to input layer, network parameter gradient, twice before and after the process, is complete parameter iteration process at a time. The basic principle comes from the basic chain rule of calculus:

$$\frac{dz}{ds} = \frac{\partial z}{\partial x}\frac{dx}{ds} + \frac{\partial z}{\partial y}\frac{dy}{ds}. \qquad (2)$$

The constant updating of model parameters is realized by reducing the loss function continuously through these two algorithms. Generally, n samples are selected as a batch sample during the training of the model, and the error between the predicted value and the real value is obtained through forward propagation operation, and then the parameter is updated by the gradient descent method. The classification of this model is shown in Figure 5.

All samples of different batches were trained according to the principle of no return, and all samples were studied to become an epoch. Gradient propagates backward, updating parameters layer by layer from back to front, which is a batch process. The network output can be fully utilized and the accuracy of network identification can be improved.

3.3. Gradient Optimization of Neural Network. As mentioned in the convolution neural network, a simple introduction of stochastic gradient descent has been proposed and a widely used optimization algorithm has made great progress; in this article's method study phase, the contrast experiment and the analysis of several kinds of the optimization algorithm are conducted. One of the biggest problems of gradient optimization in feature space in the early stage of deep learning is that it falls into local minimum value during the optimization process, and the problem of gradient noise in SGD training also largely reflects the training speed and effect. Hessian matrix and random gradient variance are difficult to control. The formula is as follows:

Euclidean Metric   Mahalanobis Metric
FIGURE 5: The classification of the model.

$$v = \alpha v - \varepsilon \Delta \theta \left(\frac{1}{m} \sum_{i=1}^{m} L\left(f\left(x^{(i)}; \theta \right), y^{(i)} \right) \right),$$

$$\theta = \theta + v,$$

(3)

where v is the velocity term, α is the momentum hyperparameter controlling the gradient decay rate, and its value is between [0,1]. Obviously, the momentum algorithm adds the idea of energy term to the gradient optimization algorithm by introducing the velocity term for gradient update. In the algorithm, the degree can be understood as the exponential decay average value of the negative gradient. According to classical mechanics, the negative gradient is the force acting on a particle moving at a certain speed. The point is assumed to be a unit mass in the feature space so this energy equation can be understood as the momentum of gradient optimization in the feature space. On this point, this article then makes a comparative experiment on such gradient optimization algorithms combined with data. The specific algorithms are as follows:

$$g = \frac{1}{m} \Delta \theta \sum_{i} L\left(f\left(x^{(i)}; \theta \right), y^{(i)} \right),$$
