Copyright © 2023 Computational Intelligence and Neuroscience. This is an open access article distributed under the Creative Commons Attribution License, which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

# Retracted: Generalized Zero-Adjusted Models to Predict Medical Expenditures

### Computational Intelligence and Neuroscience

Received 3 October 2023; Accepted 3 October 2023; Published 4 October 2023

Copyright © 2023 Computational Intelligence and Neuroscience. This is an open access article distributed under the Creative Commons Attribution License, which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Generally, there are large amounts of uncertain factors in the multi-attribute decision system. By using the gray relational degree and fuzzy gray relational degree, the weights of the comprehensive indexes are extracted. Then, a novel decision model is established based on the concept of relative similarity degree. Finally, comparative research is carried out taking the maritime safety engineering construction in Hunan Province, China, as an example to verify that the developed model is rather effective and practical for its high resolution and sensitivity in multi-attribute decision.

## 1. Introduction

Multi-attribute decision problems refer to selection of the ideal scheme from a limited number of alternative schemes after comprehensively comparing these attributes (indexes) and ranking them in the scheme set. Each attribute in a decision system generally has uncertainty to some extent. Aiming at the presence of these large amounts of uncertain factors, numerous researchers have conducted relevant research. The commonly used method is to extract the weights of indexes to serve the final decision by using the gray relational degree and fuzzy processing method [1, 2]. Literature [3–5] proposed a decision-making method based on possibility and satisfaction, which was improved in literature [6]. Literature [7, 8] gives an integrated method of multi-objective decision-making and extends this method. On this basis, literature [9–15] gives a multi-attribute decision-making method based on distance similarity measure. Literature [16–20] introduces the concept of uncertain fuzzy set and gives an improved method of multiobjective decision-making. Literature [21–23] proposed a new similarity weighted aggregation method.

While these methods can solve practical problems, the obtained decision results show low discreteness and tend to be normalized sometimes, which influences the resolution of

the results and the utilization of given information in the system. The above problem becomes more prominent in the comparison of schemes with similar levels, high fuzzy degree, and difficulty in selection. To solve the problem, the concept of relative similarity degree is introduced to construct a novel decision model, followed by comparative research based on a practical case. The research provides a reasonable and effective approach for the comprehensive evaluation of a project.

## 2. Problem Description

In decision-making problems, in order to ensure the accuracy and effectiveness of decision-making results, the similarity between language terms is a factor that cannot be ignored. In order to better express decision information, the following symbolic notation is used to represent the sets and quantities related to multi-attribute decision-making problems:

$X = \{x_1, x_2, \dots, x_m\}$  represents the set of  $m$  decision schemes

$S = \{s_1, s_2, \dots, s_n\}$  refers to the set of  $n$  attributes which are assumed to be independent

$\mathbf{A} = [a_{ij}]_{m \times n}$  represents the decision matrix, where  $a_{ij}$  is a result of an attribute  $s_j$  using a scheme  $x_i$  (i.e., the attribute value)

In general, attributes can be divided into benefit, cost, fixed, and interval types and different attributes possibly have different dimensions. Therefore, for the sake of convenient analysis and calculation, the decision matrix  $\mathbf{A}$  needs to be normalized, using the normalization formula in Reference [1] for instance. Suppose that the normalized decision matrix is  $\mathbf{B} = [b_{ij}]_{m \times n}$  and  $\bar{b}_i = (1/n) \cdot \sum_{j=1}^n b_{i,j}$  ( $i = 1, \dots, m$ ) is the expected value of the index.

Let  $\omega_k = (\omega_1, \omega_2, \dots, \omega_n)^T$ , where  $\omega_j \geq 0$  ( $j = 1, 2, \dots, n$ ), and  $\sum_{j=1}^n \omega_j = 1$  is the weight vector of an attribute and  $k$  denotes the different methods used for extracting the weight. The concepts of ideal point of multiobjective decision-making problem, negative ideal point of multiobjective decision-making problem, and objective vector corresponding to any feasible solution are introduced. It is extracted by gray correlation degree and fuzzy gray correlation degree operator,  $k = 1, 2$ .

$$r_{i,j} = \frac{\min_{i=1}^m |b_{i,j} - \bar{b}_i| + \zeta \max_{i=1}^m |b_{i,j} - \bar{b}_i|}{|b_{i,j} - \bar{b}_i| + \zeta \max_{i=1}^m |b_{i,j} - \bar{b}_i|} \quad (i = 1, \dots, m; j = 1, \dots, n), \quad (2)$$

is the average gray relational degree. The constant  $\zeta$  is the identification coefficient of gray relation. It is used to adjust the size of the comparative environment and generally let it be  $\zeta = 0.5$  in practical engineering applications.

**3.1.2. Operator of Fuzzy Gray Relation.** According to the theory of fuzzy system, the weight of the  $j$ th index is defined as follows:

$$\omega_j = \frac{\sum_{i=1}^m \tilde{r}_{i,j}}{\sum_{j=1}^n \sum_{i=1}^m \tilde{r}_{i,j}}, \quad (3)$$

where

$$\tilde{r}_{i,j} = \frac{\sum_{i=1}^m b_{i,j} \wedge \bar{b}_i}{\sum_{i=1}^m b_{i,j} \vee \bar{b}_i}. \quad (4)$$

**3.2. Determining the Relative Similarity Degree.** Because the relative closeness makes effective use of the distance information from the structural type scheme to the ideal scheme and the negative ideal scheme, the relative closeness method for multi-attribute decision-making can overcome the limitations brought by only using the Euclidean distance. Using the relative closeness between the objective scheme and the ideal point and the satisfaction of the objective function, an interactive multiobjective decision-making method based on relative closeness is proposed as follows:

- (1) Constructing the expanded normalized decision matrix  $\mathbf{C}$

### 3. Establishment of the Multiattribute Decision Model

**3.1. Extracting Weight  $\omega_j$  of the Index.** Reasonably and correctly extracting the weight of an index is of great significance for investment decision. Theoretically speaking, the larger the influence of an index on other indexes is, the greater the information contained by the index in the system; otherwise, the index has less information. Based on this, the weight of the index is extracted by using the relational operator.

**3.1.1. Operator of Gray Relation.** In accordance with the gray relational theory, the weight of the  $j$ th index is defined as follows:

$$\omega_j = \frac{\sum_{i=1}^m r_{i,j}}{\sum_{j=1}^n \sum_{i=1}^m r_{i,j}}, \quad (1)$$

where

Optimal and worst schemes are the possible ideal and least ideal schemes in a comprehensive evaluation problem.

Assume that the optimal and worst schemes are  $\bar{P} = \{p_1, p_2, \dots, p_n\}$  ( $p_j \geq 0$ ) and  $\bar{Q} = \{q_1, q_2, \dots, q_n\}$  ( $q_j \geq 0$ ), respectively.

After normalization of the index, the normalized decision matrix  $\mathbf{B} = [b_{ij}]_{m \times n}$  is obtained, in which  $0 \leq b_{ij} \leq 1$  and the larger the value of  $b_{ij}$  is, the better a scheme under the current index. Obviously, the optimal scheme in the decision matrix  $\mathbf{B}$  is when the values of all of the normalized indexes are 1, and the worst scheme is when the values of the normalized indexes are 0. While as a matter of fact, these two schemes are difficult to obtain. However, to extract the relative similarity degree, the optimal and worst schemes are also considered, that is, adding two rows (all indexes valuing 1 and 0, separately) in the matrix  $\mathbf{B}$ , thus obtaining the following expanded normalized decision matrix  $\mathbf{C}$ :

$$\mathbf{C} = \begin{bmatrix} c_{11} & c_{12} & \cdots & c_{1n} \\ c_{21} & c_{22} & \cdots & c_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ c_{m1} & c_{m2} & \cdots & c_{mn} \\ 1 & 1 & \cdots & 1 \\ 0 & 0 & \cdots & 0 \end{bmatrix}. \quad (5)$$

- (2) Weights are assigned to the expanded normalized decision matrix  $C$ , to attain the following weighted expanded normalized matrix  $D$ :

$$D = \begin{matrix} x_1 \\ x_2 \\ \dots \\ x_m \\ \bar{P} \\ \bar{Q} \end{matrix} \begin{bmatrix} d_{11} & d_{12} & \dots & d_{1n} \\ d_{21} & d_{22} & \dots & d_{2n} \\ \dots & \dots & \dots & \dots \\ d_{m1} & d_{m2} & \dots & d_{mn} \\ \omega_1 & \omega_2 & \dots & \omega_n \\ 0 & 0 & \dots & 0 \end{bmatrix} \quad (6)$$

$$= \begin{bmatrix} \omega_1 c_{11} & \omega_2 c_{12} & \dots & \omega_n c_{1n} \\ \omega_1 c_{21} & \omega_2 c_{22} & \dots & \omega_n c_{2n} \\ \dots & \dots & \dots & \dots \\ \omega_1 c_{m1} & \omega_2 c_{m2} & \dots & \omega_n c_{mn} \\ \omega_1 & \omega_2 & \dots & \omega_n \\ 0 & 0 & \dots & 0 \end{bmatrix}$$

- (3) Determining the ideal point  $E^+$  and the negative ideal point  $E^-$

$$\begin{aligned} E^+ &= \max_i \{d_{ij} | j = 1, 2, \dots, n\} \\ &= (E_1^+, E_2^+, \dots, E_n^+), \\ E^- &= \max_j \{d_{ij} | j = 1, 2, \dots, n\} \\ &= (E_1^-, E_2^-, \dots, E_n^-). \end{aligned} \quad (7)$$

It can be seen from the matrix  $D$  that  $E^+ = (\omega_1, \omega_2, \dots, \omega_n)$  and  $E^- = (0, 0, \dots, 0)$ .

- (4) Calculating the relative similarity degree of each scheme with the ideal point:

$$\frac{(E^+ - D_i)(E^+ - E^-)^T}{\|E^+ - E^-\|^2} = 1 - \frac{\sum_j \omega_j d_{ij}}{\sum_j \omega_j^2}, \quad i = 1, 2, \dots, m, \quad (8)$$

where  $D_i = (d_{i1}, d_{i2}, \dots, d_{in})$ .

The value of  $T_i$  reflects the similarity degree of a scheme with the ideal scheme and the disparity with the worst scheme, that is, the relative similarity degree with the ideal point. Apparently,  $T \in [0, 1]$ . The smaller the value of  $T_i$  is, the more similar a decision scheme with the ideal point and, correspondingly, the better the scheme; otherwise, the scheme is worst.

**3.3. Establishing the Decision Model.** In general conditions, the decision model for multi-attribute problems based on gray relation and fuzzy gray relation is as follows:

$$Y_i = \sum_j \omega_j \circ b_{ij}, \quad i = 1, 2, \dots, m, \quad (9)$$

where  $\circ$  represents a certain operation and  $Y_i$  is the array output from the decision results. The larger the value of  $Y_i$  is, the better the scheme.

According to the above analysis, the relative similarity degree based decision model is constructed as follows:

$$Y_i = 1 - \frac{\sum_j \omega_j d_{ij}}{\sum_j \omega_j^2}, \quad i = 1, 2, \dots, m, \quad (10)$$

where  $Y_i$  represents the output array of the decision results. The scheme with a smaller value of  $Y_i$  is more similar to the ideal point; that is, the scheme is better.

#### 4. Case Study

To verify the model established in the research, several decision models for the construction and planning of maritime safety engineering in Hunan Province, China, were compared based on the self-designed investment decision support system of maritime safety engineering construction. Taking the construction planning of Maritime Safety Engineering in Hunan Province as an example, the decision-making models of gray correlation degree, fuzzy gray correlation degree, and relative closeness degree are used for comparative research.

From the perspective of the optimal comprehensive benefit of the construction project of local maritime safety engineering, the index system (the RAW data were derived from the *Construction and Planning Report for the Maritime Safety Engineering in Cities of Hunan Province, China* (November, 1999)) for comprehensive evaluation is constructed (Table 1). The 17 technical and economic indexes (attributes) in the table involve multiple aspects including the technology, economy, environment, and society. By conducting a preliminary feasibility study and expert survey, most of these attributes are benefit-type except for the investment volume per unit length of river bank and the buildings demolished for building per unit length of river bank which are cost-type attributes.

At first, the range transformation method is used to normalize the indexes. Then, the weights  $\omega_1$  and  $\omega_2$  of the index based on gray relational degree and fuzzy gray relational degree are obtained by using (1) and (3), respectively [4].

$$\omega_1 = (0.0593 \ 0.0523 \ 0.0583 \ 0.0649 \ 0.0626 \ 0.0611 \ 0.0701 \ 0.0685 \ 0.0615 \ 0.0555 \ 0.0525 \ 0.0474 \ 0.0594 \ 0.0576 \ 0.0556 \ 0.0583 \ 0.055)^T$$

$$\omega_2 = (0.0531 \ 0.0342 \ 0.0514 \ 0.0794 \ 0.0618 \ 0.0694 \ 0.0862 \ 0.0805 \ 0.0744 \ 0.0579 \ 0.0614 \ 0.0175 \ 0.0546 \ 0.0569 \ 0.0423 \ 0.063 \ 0.056)^T$$

The decision results in Table 2 are obtained by using (9).

The decision results in Table 3 are acquired by using (10).

It can be seen from the above case study that the results obtained using different decision models are basically consistent; that is, Changsha applies the optimal scheme while Zhangjiajie uses the worst one. Using the decision-making methods of gray correlation degree and fuzzy gray correlation degree, a decision-making model of correlation degree is constructed based on the concepts of interval gray and fuzzy gray, but the correlation degree with the ideal scheme is not considered, so the scheme ranking may be

TABLE 1: Technical and economic indexes for the construction and planning of maritime safety engineering in cities of Hunan province.

City	Internal rate of return (%)	Net present value ( $1 \times 10^8$ yuan)	Benefit-cost ratio	Affected population (10,000 people)	Area of flooded cultivated land (10,000 hectares)	Direct economic loss ( $1 \times 10^8$ yuan)	Urban Population (10,000 people)	Urban construction area ( $\text{km}^2$ )	Gross fixed assets ( $1 \times 10^8$ yuan)

one-sided. The decision-making method of relative closeness degree integrates the relevance closeness degree and can comprehensively consider the relationship between each scheme and positive and negative ideal schemes, so that the decision-making will not deviate from the phenomenon and is more practical. It is not difficult to find from the analysis results and the decision results (Table 2) obtained using the method based on the relative similarity degree are more discrete and have more sensitive ranking, so it is more beneficial to the decision of the scheme, in comparison with the results (Table 3) attained using the other method. It indicates that the decision model based on the relative similarity degree is particularly suitable for situations with schemes of little discrepancies and requiring more elaborate and reliable decision.

## 5. Conclusions

Based on the developed investment decision support system of maritime safety engineering construction, the multi-attribute decision model based on the concept of relative similarity degree is used to carry out numerous case studies. The decision results obtained are objective, which verifies the effectiveness and rationality of the model. Compared with the existing gray relational decision-making model, this decision-making method can comprehensively consider the relationship between each scheme and positive and negative ideal schemes, so that the decision-making will not deviate. With clear concept and reasonable logic and making full use of the decision information of the system, the proposed model is capable of improving the sensitivity and resolution

The random and disordered configuration of expression package image, text, and context is in line with the emotional consumption trend of young groups, so it has become a kind of image symbol favored by young groups. How to integrate the text and images related to emoticons and carry out emotion analysis in a specific consumer environment is the focus of attention. In view of these needs and defects, this study uses the association rule algorithm in data mining technology to explore brand marketing targeting different consumers. Taking the nonverbal symbols on social media as the research object, this study collects and mines the download ranking and appreciation of the expression package of “WeChat expression open platform.” The persistence of users’ use of expression package has the characteristics of power distribution. When choosing, there are sprouting attributes and dynamic and serialized selection preferences. The advantages of emoticon package are used, brand communication and marketing are strengthened, and effective brand marketing analysis is implemented. The simulation results show that by taking advantage of the strong communication and appeal of the expression package, the brand will help to expand the contact surface of the marketing brand concept. Secondly, as a gathering community, expression packs are divided into different circle groups between and within groups, which helps brand marketing realize precision marketing based on “strong connection” with the help of expression packs and promote the occurrence of consumer behavior.

## 1. Introduction

With the continuous progress of social economy, how to secure more market share in the emerging market is an essential indicator and a goal that many commodities chase after. Various brands have applied different promotional methods to enhance their brand awareness, such as developing different commodities for different age groups of users, engaging different celebrities for endorsement, and innovating various forms or methods of advertising. In fact, these methods have changed the traditional sales model and can improve the sales and develop certain markets to some extent [1, 2]. The development and enrichment of the new media technology have offered a new way of presenting the forms of pictures and texts and a new ideology of communication after reintegration. With regard to the emojis, or Internet expressions, as new text symbols and communication methods, a gradual evolution from colors, drawings,

to expression packs has been realized [3]. However, it should be noted that as the online culture is different from the traditional one, such online expressions may be a fusion between symbols or a fusion of texts and expressions, and this way tends to have the capacity of unlimited expansion in the form of conference codes. Hence, unique personality features can be presented based on specific expressions. On the other hand, emoji packs allow the random splicing and grafting of specific linguistic texts and images to express the specific meaning as needed.

From the aspect of cultural promotion, the emoji pack is a form and culture for the young generation. In a special consumerist contextual environment, the capital has completed penetration at a deeper level, while the value embodiment can be implemented among the youth groups at the consumption and market level according to the specific consumer groups, which ensures that this approach and means are direct, effective, and fast. As a specific visual

content, emoji packs can implement a specific youth-oriented cultural form through the completion of specific collocation of images and texts. Thus, it has become a symbol of communication and is highly popular in the youth network collective. The application of emojis in the brand marketing of commodities is in line with the features of the specific social media era, and it is also a fun way of marketing that can deeply engage the youth [4].

In the process of emoji marketing, a large amount of data are often generated, and it is extremely crucial to carry out effective mining of the information from these data. Mining and extracting the implied knowledge and information from a large amount of disordered data require effective methods and approaches of data mining [5]. Typical methods include data analysis, fusion, and knowledge discovery. The so-called data mining is not targeted at specific databases or simple query and retrieval, but at disordered data. No matter the data are at the micro-, meso-, or macro-scale, the relevant data knowledge can be extracted based on these methods and means [6].

For the purpose of addressing these deficiencies and demands, the business logic of brand marketing by means of emoji packs is first sorted out in this study based on the association rule algorithm in the data mining technology [7]. Secondly, brand recognition and consensus are expanded to promote and carry out marketing of the cosmetics and bath products for different consumer groups. Finally, the marketing word of mouth at different circles and levels is analyzed to implement effective brand marketing analysis by leveraging the advantages of emoji packs, aiming to improve the market share of the corresponding products [8, 9].

## 2. Methodology and Algorithm

In terms of the association rule, it is one of the technical directions of data mining, and its essence is to implement the correlation analysis of the relevance of the data sets by carrying out an effective analysis of the record set based on the given data set. This approach has important and extensive applications in finance, justice, business, and other fields.

In the process of using the specific association rule, the corresponding rule can be deemed in the form of “how the condition is considered to be is how the result will turn out.”

The specific association rule is represented by “A  $\rightarrow$  B,” which can be divided into two specific parts: A on the left side is the conditional part and B on the backside is the result part. The conditional part can contain one or more conditions. Under this premise, if the result is true, then the previous condition must be true.

A high coverage rate indicates that the rule is used frequently.

Association analysis can be described mathematically and formally as follows:

- (1) It contains a certain degree of support; that is, at least a certain number of data sets are included in the database

- (2) It contains a certain degree of confidence; that is, while  $X$  records are included in the database, the data set  $Y$  is also included

*2.1. Related Algorithms and Basic Principles.* The association rule is one of the main contents of the data mining algorithms. Based on the association rule, meaningful association information can be identified in a large amount of data; that is, information mining can be carried out based on the frequency of occurrence between the sets of items.

It is assumed that data set  $A$  contains  $n$  samples and  $L$  stands for the set of labels corresponding to the data set. Each sample in  $A$  is represented by a set of feature values (feature) and a label (label). Let  $F$  be the set of feature values in the data set. The specific formula for the category association rule is described as follows:

$$\text{feature} \Rightarrow \text{label}. \quad (1)$$

In the above equation, feature stands for a set of feature values,  $\text{feature} \subseteq F$ , and  $\text{label} \in L$ .

The two commonly used evaluation criteria for the association rules are support and confidence. The specific formula for their calculation is as follows:

$$\text{Support}(F \Rightarrow L) = \frac{|F \cup L|}{|A|}. \quad (2)$$

Support indicates the frequency of occurrence of a particular rule, which determines the frequency of occurrence of the item set  $|F \cup L|$ .

Confidence indicates the degree of trust of the corresponding rule. It is defined as  $\text{Conf}(F \Rightarrow L)$ , and its calculation formula is shown as follows:

$$\text{conf}(F \Rightarrow L) = \frac{\text{support}(F \cup L)}{\text{support}(F)} \times 100\%. \quad (3)$$

The basic structure of data mining for the association rules is shown in Figure 1.

The mining of frequent item sets is an essential but highly time-consuming process in the association analysis process. The FP-growth algorithm is often selected as the association rule analysis algorithm in the industry, which can avoid the generation of a large number of candidate frequent sets, and it is required to implement only two iterations of the database for the copper welding wire to complete the determination of the frequent item set. The FP-growth data mining process can be divided into two steps as follows: (i) construction of the FP-tree and (ii) frequent pattern mining based on the FP-tree, and subsequent mining of the constructed FP-tree to obtain all the frequent patterns. The construction process of FP-tree is described in Figure 2.

It can be observed from the construction process in Figure 2 that the basic conditional pattern is implemented from the most initial frequent items, and the corresponding conditional FP-tree is established on this basis to implement the filtering of frequent items that fail to comply with the corresponding threshold value. In addition, iterative recursive analysis and mining are carried out based on the

FIGURE 1: Basic structure of the association rules.

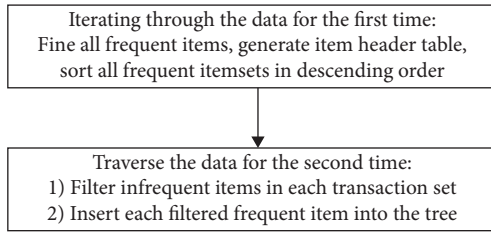

FIGURE 2: FP-tree construction flow.

specific conditional FP-tree until the final FP-tree is void. Subsequently, in the path analysis, the specific frequent items of the frequent item data set are obtained.

The smart grid dispatching technology support system adopts the Global Positioning System (GPS) and has the synchronous timing capability, which has implemented the unified spatial and temporal measurement of large power grids over a wide area. The accumulated wide-area spatial and temporal measurement information in the smart grid dispatching technology support system can be accumulated for a long period (days, months, and years), which can better reflect the spatial and temporal correlation features of the dispatching operation data and therefore have great practical value [10–13].

At present, China has formed a multilevel and hierarchical dispatching operation model at the national, regional, provincial, municipal, and county levels. Based on the scope of dispatch management, responsibilities, geographical location, voltage level, and features of power system, the dispatch functions and priorities at various levels can be different. The national dispatching focuses on UHV AC/DC transmission capacity and emergency guarantee capacity; the regional dispatching attaches more importance to the key contact sections of regional power grids; the provincial dispatching directly controls the output and load of key power plants in the region. At the same time, the security and stability of the power grid have also demonstrated typical regional features and spatial correlation. In this study, a multilevel correlation analysis model is established based on the safety and stability issues at the dispatching level. The details of the model are described in Figure 3. The hierarchical correlation analysis model is established based on empirical and historical data to derive the key factors that may affect the stability of the power grid at various levels and perform selective optimization of the combined input feature space.

Time correlation is the primary feature in the operation of the electric power system, and its correlation is mainly reflected in the following two aspects:

FIGURE 3: Multilevel correlation analysis model.

- (1) The changes in the operation mode of the power grid are closely related to time, and both the output curve and load curve present certain time regularity.
- (2) A large amount of operation data collected by the dispatching center, as well as the calculation data and result data, have a time scale. The data described above are the responses of various dynamic indicators of the power system at various moments, and they all have the corresponding time-series features [14, 15].

It is necessary to integrate the time-series features of the data closely when correlation analysis is carried out. In general, it is highly challenging to analyze the whole time series in data mining. In this study, the operating data are first divided into multiple subsegments according to the time-series features; subsequently, different features are established for each time-series segment, and the association analysis models are constructed separately to obtain the specific association rule models for various time-series segments.

**2.2. Data Mining Technology Association Rule Algorithm.** The essence of the Apriori algorithm is about the application of the database frequent item identification to implement the specific connection and pruning operation extraction, so as to achieve strong regular item set screening that complies with the threshold. The specific calculation formula is as follows:

$$S\% = Sup(X \longrightarrow Y) = P(XY) = \frac{\text{number}(X \cup Y)}{\text{num}(\text{all samples})} \quad (4)$$

The specific calculation of the confidence level is shown as follows:

$$C\% = Conf(X \longrightarrow Y) = P(Y|X) = \frac{P(XY)}{P(X)} \quad (5)$$

If an item set complies with the minimum support, it is referred to as a frequent item set; if it complies with both the minimum support and the minimum confidence, it is referred to as a strong association rule.

In general, the operation of the Apriori algorithm can be divided into 2 stages: (1) the candidate set 1 is generated, and the corresponding support degree is calculated. The unqualified item sets are pruned off according to the set threshold to obtain the frequent item set 1+. (2) The candidate set 2 item sets are generated for item set 1+ connection, and the item sets are further pruned according to the threshold value. Iteration is carried out repeatedly until the frequent item set is valid, and the algorithm is ended. This process is often inefficient due to the necessity to traverse the data set several times. In addition, there are usually a large number of duplicate and invalid misleading rules among the extracted rules. The lift can reflect the relevance of the antecedent and the consequent parts of a rule, while the interest degree indicates the interestingness of a rule [16]. Through the application of the lift, the interest formula can be established. In this way, a large number of invalid rules generated by the Apriori algorithm can be filtered out effectively. The lift is expressed as  $\text{Lift}(X \rightarrow Y)$ , and the interest is expressed as  $\text{Interest}(X \rightarrow Y)$ . Their specific calculation is shown as follows:

$$\text{Lift}(X \rightarrow Y) = \frac{P(X \cup Y)}{P(X)P(Y)}, \quad (6)$$

$$\text{Interest}(X \rightarrow Y) = \frac{\text{Lift}(X \rightarrow Y) - 1}{\text{Lift}(X \rightarrow Y) + 1}. \quad (7)$$

As a class of global optimization-seeking evolutionary algorithms, this feature of genetic algorithms from local to global can largely resolve the problem of inefficiency of the Apriori algorithm. However, it also has some problems. For example, it is easily limited to the local optimal solution, and its efficiency decreases gradually as the algorithm continues.

The ultimate goal of the association rule is to identify the interesting rules that comply with the min-sup and min-conf from a large set of transactions [17, 18]. For the purpose of screening out these interesting rules, the support degree is used to build the fitness function  $(X \rightarrow Y)_1$ ; at the same time, the confidence degree is used to construct the fitness function  $(X \rightarrow Y)_2$  so as to avoid the algorithm from repeated calculations leading to low efficiency, as shown in the following equations:

$$\text{Fitness}(X \rightarrow Y)_1 = \frac{\text{Sup}(X \rightarrow Y)}{\text{min} - \text{sup}}, \quad (8)$$

$$\text{Fitness}(X \rightarrow Y)_2 = \frac{\text{Conf}(X \rightarrow Y)}{\text{min} - \text{conf}}. \quad (9)$$

The selection operation is conducted to ensure the superiority of individuals in the population and to select the individuals with excellent environmental adaptability and pass them to the next generation. In general, the judgment condition of selection is determined according to the fitness function.

The crossover operator and genetic operator in the adaptive genetic algorithm (AGA) are changing in a dynamic manner, which has effectively solved the prematurity problem of the GA. However, the improved operator it has

put forward is highly unfavorable for the iteration of the initial population. On this basis, some scholars have further optimized an adaptive genetic algorithm; the formulas for the calculation of the specific crossover operator  $P_c$  and genetic operator  $P_m$  of this algorithm are shown as follows:

$$P_c = \begin{cases} P_{c1} - \frac{(P_{c1} - P_{c2})(f' - f_{avg})}{f_{max} - f_{avg}}, & f' \geq f_{avg}, \\ P_{c1}, & f' < f_{avg}, \end{cases} \quad (10)$$

$$P_m = \begin{cases} P_{m1} - \frac{(P_{m1} - P_{m2})(f' - f_{avg})}{f_{max} - f_{avg}}, & f' \geq f_{avg}, \\ P_{m1}, & f' < f_{avg}. \end{cases} \quad (11)$$

In this algorithm, the crossover probability and variation probability are improved. In this way, the algorithm will not fall into local solutions at the beginning of iteration. However, in the association rule mining problem, the change in  $(f' - f_{avg})/f_{max} - f_{avg}$  is actually not evident; the dynamic adjustment is not significant. As a result, it is impossible to seek the optimal solution properly. At the beginning of the iteration, it is often expected that the evolution can be accelerated. Hence, relatively high crossover probability and low variation probability are required [19, 20]. As the number of iterations increases, the similarity between individuals of the population will become higher, which can cause the genetic algorithm to fall into the local solution. Thus, it is expected that the genetic algorithm can jump out of the local solution with relatively low crossover probability and high variation probability. In the iterative process, if the crossover probability gradually becomes smaller and the variation probability gradually increases, the problem of premature and inefficient traditional genetic algorithm can be resolved properly. This variation trend is highly similar to the change in the sigmoid function. Hence, this function is combined with the number of iterations to improve the crossover operator  $P_c$  and genetic operator  $P_m$ . The specific calculation formula is as follows:

$$P_c = \begin{cases} P_{c2} + \frac{(P_{c1} - P_{c2})}{1 + e^{G/f_{max}}}, & f' \geq f_{avg}, \\ P_{c1}, & f' < f_{avg}, \end{cases} \quad (12)$$

$$P_m = \begin{cases} P_{m2} + \frac{(P_{m1} - P_{m2})}{1 + e^{G/f_{max}}}, & f' \geq f_{avg}, \\ P_{m1}, & f' < f_{avg}. \end{cases} \quad (13)$$

In the above equation,  $G = t_{max} - t/t_{max}$ ;  $t$  stands for the current number of iterations; and  $t_{max}$  stands for the set of maximum number of iterations.

The detailed steps of the association rule mining algorithm combined with the improved adaptive genetic algorithm and the Apriori algorithm are described as follows.

In Step 1, the database is traversed to generate frequent item sets, which are sorted accordingly. The set of populations is initialized, and each individual in the set of populations with individual bits is encoded, with each real number corresponding to the field of the database, respectively.

In Step 2, the value of each initial population set is calculated according to the corresponding formula.

In Step 3, the selection operation is performed. The specific function calculated value is passed down to the next generation to conduct the corresponding calculation; otherwise, the crossover operation is performed, and the number of specific individuals in the next generation is retained as  $m1$ .

In Step 4, crossover operation is conducted. Two different individuals are randomly selected, and the crossover operation is carried out according to the corresponding formula. The individuals after the crossover are put into the next population, and the number of individuals ( $m2$ ) that have been passed down to the next generation after this step is recorded.

In Step 5, the mutation operation is conducted. On the basis of Step 4, the specific individuals are selected, and the variation operation is conducted using the formula to change the specific number of mutations to implement the change in the next-generation population. As a result, the specific number of individuals in the next generation is expressed as  $m3$ .

In Step 6, statistics are carried out on the number of individuals entering the next generation  $m = m1 + m2 + m3$ . If the statistical result fails to meet the specified population scale,  $(n - m)$  individuals are randomly generated to supplement the next generation; then, Step 2 is proceeded to repeat the operation.

In Step 7, whether the condition for the end of the algorithm is met is determined, and the corresponding rule is output at the same time; otherwise, Step 2 is proceeded to continue the loop.

In Step 8, the association rule that complies with the minimum interest degree is output. The operation flow of the algorithm established on the basis of the above steps is shown in Figure 4.

The transaction database used in the algorithm is stored in the event-store, where the population size is life-count, and the termination condition of the algorithm is iteration-max (i.e., the maximum number of iterations). The current population and new-population are used to store the current population and the next generation of new populations, and the final output value is a strong association rule  $T$  that complies with the minimum interest (min-inte) [21, 22]. Thus, the pseudo-code of the algorithm can be described in Algorithm 1.

**2.3. Brand Marketing Leveraging the Creative Communication Advantages of Two-Dimensional IP.** The marketing of commodity brands by means of emoji packs allows the multilevel exposure of the commodity brands in an all-round way, which can enrich the connotation of the brands, facilitate the effective communication of the brands, and achieve the

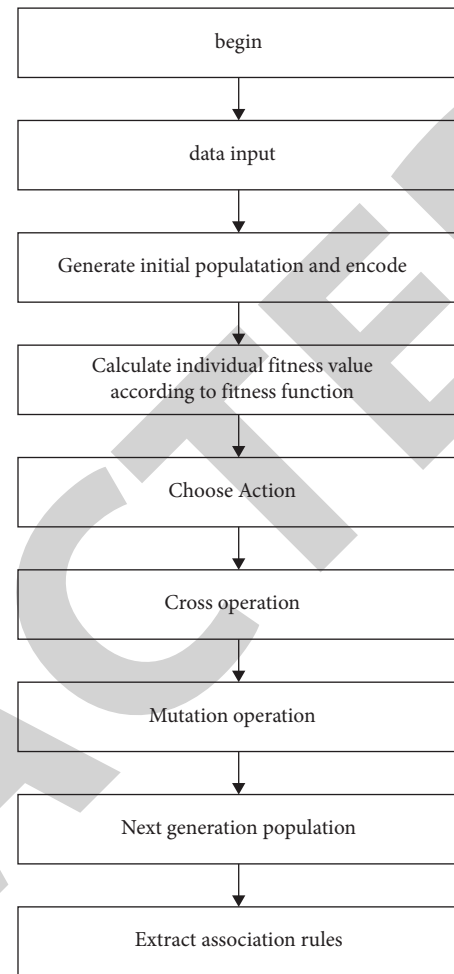

FIGURE 4: Algorithm flow chart.

tension and dimensional expressiveness of advertising creativity [15, 23]. Moreover, emoji packs often come with a certain core audience, which has clarified the specific user groups for the corresponding brands. In addition to the corresponding consumer screening and fixing links, the core value construction and image shaping of commodity brands can build a bridge between the products and consumers.

The rise of various new media application forms has weakened the channel advantages of traditional media; in the context of media decentralization, it is highly challenging to achieve the accurate dissemination of information by mass communication from the perspective of the traditional media. Hence, it is necessary to integrate various types of data to implement the integrated marketing communication of brand information.

Hence, brands can take the advantage of two-dimensional IP in their communication using the cross-media narrative concept. On the basis of traditional integrated marketing communication, advertisers can make use of the IP effect to integrate the discrete marketing mechanisms of each link into an integrated marketing system with a coherence, systemic, and laser-sharp focus.

“The purpose of the communication creative point is to communicate and share, which is the bridge that connects

ALGORITHM 1: Association Rules Mining Algorithms.

the brand touchpoints and core creative points. Through the integration of hot topics and consumer interests, consumers are ultimately guided to the core brand value. In this process, audience engagement is of crucial significance to the communication of the core value of a brand.”

From the aspect of the coverage of communication, the strong connection based on the community content will form word-of-mouth communication, which in turn will lead to multi-community information dissemination with human communication nodes. The reason is that individuals do not join a single community, but rather participate in the role-playing in a diverse community, which indicates that the individuals prefer to cruise among multiple communities.

The purpose of the core creative points is to create an emotional resonance and value recognition with consumers. As the two-dimensional space culture itself is spontaneously produced by youth groups, it is possible for brands to accomplish the communication of the core creative points smoothly by leveraging the advantages of two-dimensional IP [24, 25].

The value of commodities and services that are endowed with the thoughts of consumers goes beyond the consumption itself and has become a way to acquire self-identity through consumption, which is also the reason why consumers are more willing to pay for such commodities.

### 3. Simulation Experiment

According to the data, 74.19% of Chinese college students understand the application of expression pack in video/short video, and 67.74% of Chinese college students understand

the application of expression pack in comics; 62% of foreign students understand the application of expression pack in comics, and 60% of foreign students understand the application of expression pack in video/short video. However, only 48.39% of Chinese college students and 42% of foreign college students said they had understood the application of expression pack in advertising. It can be seen that the expression package has a high exposure in new media matrices such as short videos and comics, which makes a deep impression on college students. Relatively speaking, the expression package used for advertising scenes also has a certain degree of exposure, but it is relatively weak, indicating that the expression package used for advertising scenes has great market potential and broad market prospects, as shown in Figure 5.

The data mining technology association rule algorithm provides a guarantee for the complete protection of emoji pack, digital restoration and reproduction technology provides support for the effective inheritance of emoji pack, digital display and dissemination technology provides a platform for the widespread sharing of emoji packs, and virtual reality technology provides the space for the development and application of the expression packs. It is protected and implemented to market domestic emoji packs and facilitate the formulation of relevant policies. This study fully analyzes the problems in the inheritance and protection process of emoji pack and applies data mining technology association rule algorithm to the marketing process of emoticons, which provides a strong basis for the realization of emoji pack marketing. The accurate marketing of emoticons can be completed using the data mining technology

FIGURE 5: College students' understanding of the application of expression pack.

association rule algorithm. In addition, a marketing method of leveraging the advantage of brand emoji pack is also designed.

The data mining technology association rule algorithm is used to realize the marketing of Chinese painting, calligraphy emoji pack, and image package, to train various types of emoji pack suit, and to record the values of  $w_1$ ,  $w_2$ , and  $w_3$  when they reached the maximum value. Figures 6 and 7 show the weight changes, where “o” represents the weight change in smoothness, “—” represents the weight change in consistency, and “\*” represents the weight change in entropy. After training all emoji packs, the average of the two emoji pack values and the average of  $w_1$ ,  $w_2$ , and  $w_3$  are used to test the emoji pack with the average weight value, and the  $I$  value of the test emoji pack is obtained. The data shown in Table 1 (retaining only the integer part) are 10 data arbitrarily extracted from the experimental results. It can be seen from the table that the  $I$  value of the image is relatively small.

For the  $I$  value obtained from the test emoji, the difference measurement of the two emoji packs is carried out as follows:

$$S_i = |I_{\text{test}} - \bar{I}_i|, \quad (14)$$

where  $i = 1, 2$ ,  $\bar{I}_i$  is the average obtained for the two types of emoji packs, and  $I_{\text{test}}$  is the  $I$  value generated by the test emoji pack. In  $S_1 > S_2$ , the test emoji pack is set as the first category; otherwise, it is set as the second category. In  $S_1 = S_2$ , the emoji pack cannot be marketed.

The experimental results are shown in Table 2. The experimental results show that the three groups of experiments have achieved good results, realizing the marketing of Chinese painting, calligraphy emoji pack, and images (stick drawings, tables, function emoji packs). Experiments also fully proved the reliability of the method.

The data mining technology association rule algorithm provides guarantee for the complete protection of expression package, digital restoration and reproduction technology provides support for the effective inheritance of expression package, digital display and communication technology provides a platform for the wide sharing of expression

FIGURE 6: Three weight changes of 600 emoji packs.

FIGURE 7: Three weight changes of 600 images.

TABLE 1: Comparison of  $I$  values between emoji pack and images.

Emoji pack $I$ value	Image $I$ value	Emoji pack $I$ value	Image $I$ value

package, and virtual reality technology provides space for the development and utilization of expression package to market the expression package in China and facilitate the formulation, protection, and implementation of relevant policies. This study fully analyzes the problems existing in the inheritance and protection process of expression package and applies the association rule algorithm of data mining technology to the marketing process of expression package, which provides a strong basis for the realization of expression package marketing. Using data mining technology and association rule algorithm, we can complete the accurate marketing of expression package. In addition, we also design the marketing method of using brand expression package.

TABLE 2: Experimental results.

Experiment	Number of emoji packs	Emoji pack		Image		Accuracy rate (%)
		Right	Wrong	Right	Wrong	
1	21	19	0	0	2	90.02
2	15	1	0	13	1	92.87
3	17	8	0	8	1	93.74

FIGURE 8: Risk frequency chart.

Based on the classification of the specifically defined risk level, the frequency of risks accumulated by the samples over a period of five months is shown in Figure 8.

The sales operation samples on a certain day are divided into five stages according to the time correlation, and the actual sales network data are mined at different voltage levels of the hierarchical data by establishing a model to explore its patterns separately [26]. At the same time, taking into consideration the requirement to extract as much hazardous data as possible, the minimum confidence threshold is set to 35%. In the practical operation of the sales network, the occurrence frequency of severe overload cases is relatively low. Hence, the minimum support threshold of the model is set to 0.9%. Among them, rule 1 is applicable to the first stage; rule 2 is applicable to the second stage; and rule 3 is applicable to the third stage.

From the analysis above, it can be known that the algorithm constructed in this study is in line with the brand marketing by leveraging the advantages of emoji pack. In addition, it can also assist in the identification of some unknown and potential operation patterns in the sales network at the same time and provide a tool for decision-making in the future work of sales operations.

#### 4. Conclusions

By taking advantage of the strong communication and appeal of the expression package, the brand helps to expand the contact surface of the marketing brand concept. In this study, the data mining technology association rule algorithm excavates the association information with high confidence and support, reflects the complexity and interest of the data in the database, and then excavates the beneficial association between the expression package data, promotes the development of the expression package database information mining technology, and fully analyzes the impact of the advantages of the expression package on brand marketing.

The marketing hotspots of the brand for different users are expanded to enhance the reputation and identification points of the brand, and the brand marketing is effectively analyzed using the advantages of emoticon package. The simulation results show that the research on brand expression package under the association rule algorithm of data mining technology is in line with the marketing concept of taking consumers as the core. It can not only help to expand the brand contact points and strengthen the communication creative points using the word-of-mouth marketing of circle communication but also use the emotional consumption characteristics of expression package to stimulate the emotional resonance of the audience and realize the transmission of the core value of the brand. The advantages of emoticon package are fully used to provide support for the application of brand marketing.

Medical multiobjective image segmentation aims to group pixels to form multiple regions based on the different properties of the medical images. Segmenting the 3D cardiovascular magnetic resonance (CMR) images is still a challenging task owing to several reasons, including individual differences in heart shapes, varying signal intensities, and differences in data signal-to-noise ratios. This paper proposes a novel and efficient U-Net-based 3D sparse convolutional network named SparseVoxNet. In this network, there are direct connections between any two layers with the same feature-map size, and the number of connections is reduced. Therefore, the SparseVoxNet can effectively cope with the optimization problem of gradients vanishing when training a 3D deep neural network model on small sample data by significantly decreasing the network depth, and achieving better feature representation using a spatial self-attention mechanism finally. The proposed method in this paper has been thoroughly evaluated on the HVSMR 2016 dataset. Compared with other methods, the method achieves better performance.

## 1. Introduction

In multiobjective segmentation, medical image segmentation aims to segment the images into multiple regions and extract the parts of interest based on the similar characteristics or single attributes of the image, such as edge contour, structure, and shape, which is of great significance for medical image analysis, disease diagnosis, and clinical applications (e.g., 3D computed tomography (CT) and magnetic resonance image (MRI)). Accurate segmentation can not only help precise diagnosis and prediction of prognosis but also benefit surgical planning and intraoperative guidance.

For example, in diagnosing congenital heart disease, segmenting the blood pool and myocardium from 3D cardiovascular magnetic resonance (CMR) images is a prerequisite before creating patient-specific heart models for preprocedural planning of children with complex congenital heart disease (CHD).

One of the main applications of deep learning is medical field, including biomedicine and MRI analysis [1]. However, the level of doctors is uneven, and some departments are

labor-intensive, which has had a profound impact on the development of artificial intelligence in this field [2]. Currently, segmenting vital organs or structures from 3D medical images is an imperative preliminary action for a wide range of clinical treatments. The recognized standard segmentation results are obtained from experienced physicians and radiologists via visual inspection and manual delineations. On the one hand, there always are hundreds of images in an individual's cardiac MRI. It is tedious, time-consuming, and costly to annotate the 3D medical images in a slice-by-slice manner. On the other hand, the whole heart's manual labeling is subjective and suffers from low reproducibility. The results of the labeling could be seriously affected by the experience and knowledge of the observer. Consequently, automatic medical image segmentation with high accuracy is highly demanded. However, using deep learning for automatic medical image segmentation with high accuracy is also a huge challenge [3]. The reasons include (I) the missing borders or indefinite boundaries, with inadequate edge information, and (II) the too low quality of the cardiac images.

There are many deep learning models applied to image segmentation [4]. Convolutional neural network (CNN) based deep learning strategies especially achieved remarkable success in medical image segmentation methods. U-Net [5] is a semantic segmentation network based on fully convolutional networks (FCN) [6], which mainly applied CNN structure for the heart segmentation. U-Net can be quickly trained on small sample data in medical segmentation by data augmentation and achieve outstanding segmentation results. Different from the FCN structure, there is not any encoder or decoder in the U-Net. U-Net contains two paths, the downsampling contraction path, which extracts the high-level abstract features of pixels, and the extended upsampling path, which can reconstruct pixel information lost during downsampling. In the process adopted above, the parts from the comprehensive upsampling approach and the features extracted by downsampling are stitched to maximize the retention of low-level feature information lost by the pooling and convolution operations. Compared with FCN, U-Net can run more efficiently because there is no fully connected layer in the structure. The paper on DenseNet [7] was voted the best paper of CVPR in 2017, which has the same basic idea as ResNet [8]. However, it establishes the dense connection between all the previous layers and the latter layers. The dense block in the DenseNet is a densely connected network model between layers. In each dense block, the input of each layer is the union of the outputs of all the previous layers. DenseNet enhances feature representation with skip connections. However, the feature maps in DenseNet are relatively large, resulting in a large amount of computation in the convolution process, which affects the overall performance of the network.

This paper proposes a novel and efficient 3D sparse convolutional network named SparseVoxNet to comprehensively address these challenges, which can effectively carry out voxel-to-voxel learning and infer 3D medical images. Specifically, we develop a sparse convolutional network that aims to contribute the following ideas:

(1) The sparse network can eliminate redundant computation, reduce model parameters, and decrease the risk of overfitting small sample training data. (2) The full skip connection mechanism in the module can effectively solve the problem of gradient disappearance in 3D deep model training, accelerate the convergence speed, and improve recognition ability. (3) The self-attention mechanism is added to optimize the expression ability of feature maps and capture the long-range dependency between features better.

## 2. Related Work

Multiobjective image segmentation can be divided into supervised and unsupervised methods. Pham et al. [9] proposed a multiobjective optimization approach to segment the brain MRI using fuzzy entropy clustering and region-based active contour methods. Hongwei et al. [10] proposed a multiobjective clustering and toroidal model-guided tracking method to distinguish vascular structures from complicated structures in background regions. In

recent years, deep learning has been successfully applied to medical image segmentation. Çiçek et al. [11] proposed a 3D U-Net network structure to realize the 3D image segmentation. Habijan et al. [12] proposed a framework consisting of two 3D U-Nets. In this framework, the first network was used for localizing the bounding box encompassing the heart, and the second network was employed to segment the different substructures. Ding et al. [13] incorporated attention mechanism within the gradient expanding process to enhance the coarse segmentation information with less computation expense. Furthermore, they extended the network's gradient flow and used the low-resolution feature information. Jeevakala et al. [14] proposed a Mask R-CNN approach driven with U-Net to detect and segment the Internal Auditory Canal (IAC) and its nerves. In this method, the U-Net segmented the structure related information of IAC and its nerves by learning its features.

However, the variants' structure of U-Net suffers from redundant information. More and more network structures have been proposed and applied to image analysis [15].

Fisher and Koltun [16] proposed a new convolutional network module which used dilated convolutions. This module could aggregate multiscale contextual information systematically without losing resolution. Recently, dilated convolution is increasingly applied to medical images. Wolterink et al. [17] proposed a method to segment the myocardium and blood automatically in CMR of patient who has CHD by CNN. In the same year, Fisher et al. [18] developed a convolutional network module specifically for intensive prediction which used extended convolution to systematically aggregate multiscale context information without loss of resolution. Residual network (ResNet) was proposed in 2016, which added skip connections to each convolution layer for 2D image classification tasks. In addition, this architecture has been extended to 3D volumetric segmentation [19–21]. Huang et al. proposed the DenseNet with  $L(L+1)/2$  direct connections, which improved ResNet. It can strengthen feature propagation and reuse all features. After this improvement, Jégou [22] proposed a 2D fully convolutional DenseNet for semantic segmentation. In the same year, Yu et al. [23] proposed the DenseVoxNet; this network extended the deep residual learning in 2D image recognition tasks into 3D, which could simplify network training, reduce the parameters, and add auxiliary paths to enhance gradient propagation. However, there were no direct connections between the dense blocks and the final prediction layer. DenseVoxNet may not be able to appropriately capture multiscale contextual information useful for accurate segmentation. The correlation of adjacent images or frames should be effectively exploited for improving the accuracy of the target tasks which involves 3D volumetric data. Therefore, more and more methods have been proposed to use 3D features for biomedical volumetric data [24–29]; for example, Hosseini-Asl et al. [30] proposed a deep supervised adaptive 3D CNN, which could automatically extract and recognize the characteristics of Alzheimer's disease and capture the changes caused by Alzheimer's disease, such as the size of ventricle, the shape of the hippocampus, and the thickness of cortex. Dou et al. [31]

proposed a 3D fully convolutional network, called 3D Deeply Supervised Network (DSN), equipped with a deep supervision mechanism. This method has obtained good results in two tasks: liver segmentation of 3D CT scan, and whole heart and large blood vessels segmentation of 3D MRI. Previous CNN expresses dependencies between different image regions through convolution. Convolution operators have local receptive fields, so processing long-range dependencies goes through multiple convolutional layers, which may prevent learning about long-term dependencies. While it is possible to increase the representational capacity of the network by increasing the size of the convolutional kernels, the computational and statistical efficiency gained by using local convolutional structures are lost. However, self-attention [32–34] can exhibit a better balance between the ability to model long-range dependencies and computational efficiency. However, it is still a challenging task for CNNs to segment the important organs from 3D medical images due to the complexity of 3D structures, the difficulty of voxelized grid optimization, and the insufficiency in training samples.

Dou et al. [35] proposed Pnp-AdaNet using the method of adversarial learning, which could adapt to medical images of different modalities through plug-and-play modules. In another experiment, Dou et al. [36] constructed a domain adaptation module (DAM) to map the target region to features that were spatially aligned with the source domain region. The domain critic module (DCM) was responsible for distinguishing the feature spaces of the two domains. Then these two modules were optimized via an adversarial loss without using any target domain label. They trained the network using MRI, used it to segment CT images, and finally achieved certain results. The experiments done by Schlemper et al. [37] showed that using a grid-like attention mechanism in CT images might achieve better results. Shi et al. [38] proposed Bayesian VoxDRN for segmenting the entire heart from 3D MRI. Bayesian VoxDRN could predict voxel class labels by measuring the uncertainty of the model. During the test, it was realized by sampling based on Monte Carlo to generate a posteriori distribution of voxel labels. The attention mechanism was first applied to the text field. When the improved attention mechanism was applied to image processing, very good results were achieved. Liu et al. [39] proposed a novel medical image super-resolution method based on dense neural network and blended attention mechanism to address the problem that medical image would suffer from severe blurring caused by the lack of high-frequency details in the process of image super-resolution reconstruction. Kaul et al. [40] joined the attention tool to CNNs using feature maps generated by a separate convolutional autoencoder. This attention architecture was well suited for incorporation into deep convolutional networks. The results showed that this attention architecture was better than U-Net and residual variant.

### 3. Methods

**3.1. The Architecture of SparseVoxNet.** The architecture of SparseVoxNet proposed in this paper is shown in Figure 1. It improves U-Net which includes upsampling and

downsampling processes to implement end-to-end training. The padding is used for keeping the feature-map sizes constant in every sparse block, because the sparse block is not applicable when the feature maps have different sizes. Therefore, in each sparse block, the first 4 layers use ordinary convolutions, and the last 3 layers use dilated convolutions. The hole sizes are 2, 3, and 5. The spatial self-attention mechanism is added after the original feature map of data to strengthen the more important features in the original feature map. In the final deconvolution layer, instead of using a fully connected layer, three  $1 \times 1 \times 1$  convolution layers and softmax layer are used to obtain the segmented final label map. A dropout layer with a coefficient of 0.2 is added after each convolution layer to enhance the generalization ability of network.

Inspired by DenseNet, the black dotted line in SparseVoxNet in Figure 1 represents a skip connection. The image is segmented once by deconvolution on the skip connection. The network will converge faster and the accuracy rate will be higher due to the skip connection. The first segmented image will perform better on edge segmentation, because the shallow neural network loses less information through convolution and gets more edge information. The result is a fine grained segmentation. The result of the second segmented image is better in overall segmentation, which is coarse grained segmentation. Deep neural network features are high-level abstract features, which is really helpful when extracting the segmented central area of the entire tissue. The final segmentation result is determined by the voting of multiple segmentation results of different cropped input data on a single voxel point. The downsampling process of U-Net is replaced with sparse blocks, and the two deconvolutions are equivalent to the upsampling process.

Furthermore, we calculate the number of parameters for each layer in the SparseVoxNet shown in Table 1. Table 1 shows the parameters of 4 convolution layers, 2 deconvolution layers, 2 sparse blocks, a spatial attention mechanism layer, and a skip connection layer. Among them, the 4 convolution layers are represented by Conv\_n, the 2 deconvolution layers are represented by Deconv\_n, and the 2 sparse blocks are represented by Sparse Block\_n. We also show the convolution kernel and stride of each layer in Table 1. Note that each row in Table 1 corresponds to each layer in Figure 1.

**3.2. Sparse Block.** DenseNet has denser connections compared to ResNet, which makes the consumption of hardware resources very high. Therefore, we propose a sparse network structure to change the way of feature reuse while keeping feature reuse and skip connection characteristics unchanged. The sparse block which we propose reduces the number of connections, just having direct connections between any two layers with the same feature-map size, referred to as full skip connection, but the effect of sparse block is similar to dense block. The input of transition layer is as follows:

$$[T_0, T_1, T_2, T_3, T_4] = [T_0, H_1(T_0), H_2(T_1), H_3(T_2), H_4(T_3)]. \quad (1)$$

FIGURE 1: An overview of the proposed SparseVoxNet, with intermediate feature volumes. The light blue and dark blue areas of the slice represent the blood pool and myocardium. The dark blue and black areas belong to the background. The blue, yellow, and dark purple of segmented result represent the myocardium, blood pool, and background, respectively. There are two sparse blocks in this network. The black dotted line at the bottom right represents a skip connection.

TABLE 1: Our 3D convolutional model.

where the input of  $H_1$  is  $T_0$ , the input of  $H_2$  is  $T_0 + T_1$ , and so on.

The feature maps of different receptive fields are referred to as different scales. It is found that the nonlinear combination of the features of different scales is not better than the linear combination. Inspired by the U-Net network structure, composite expression features are constructed by directly stacking feature maps of different scales.

DeletedUnlike U-Net, the improved network structure uses deconvolution to replace the upsampling process, which reduces the loss of information during the conversion process. In DenseNet, the network connections of the previous layer and the latter layer are too dense, which can easily cause overfitting. The sparse network can solve this problem. The network's feature expression ability is greatly enhanced, and there is no vanishing gradient.

**3.3. 3D Dilated Convolution.** Dilated convolution has one more hyperparameter than traditional convolution, called dilation rate. Dilated convolution adds holes to the standard convolution kernel. In this paper, we extend the dilated convolution to 3D data, and mix the traditional convolution and dilated convolution. Referring to the DenseVoxNet, we use 4 layers of  $3 \times 3 \times 3$  traditional convolution and 3 layers

of dilated convolution with 2, 3, and 5 holes. The 4 layers of traditional convolution can extract the local features of the image, and the 3 layers of dilated convolution expand the reception field of the feature exponentially to capture the potential relationship between long distance features. We only use 7-layer convolution to make the reception field reach  $26 \times 26 \times 26$ .

**3.4. Spatial Self-Attention Mechanism.** In both the computer vision tasks and the natural language processing tasks, the dependencies between long distance features are difficult to capture. In serialization tasks, recurrent and recursive neural networks are major means to capture long-range dependencies. In convolutional neural networks, large reception fields are formed by superposing multiple convolution operations. Currently, there are no specific methods to capture long-range features. Convolution and cyclic operators have the following disadvantages: (1) being too inefficient, (2) easily producing gradient disappearance, (3) difficulty of passing information back and forth between long ranges.

Inspired by the nonlocal mean filtering for images, Wang et al. [41] proposed nonlocal block for capturing long-range dependencies, which is a self-attention mechanism.

Nonlocal block ignores the Euclidean distance and calculates the relationship between two positions directly. Actually, it calculates the generalized autocorrelation matrix of features. However, the calculation efficiency is relatively high. Because after adding nonlocal operators, it is not necessary to stack too deep convolution operations for achieving the network's fitting ability. Furthermore, it does not change the size of input data and can be easily embedded in the network, so the spatial self-attention model is added in front of the first sparse block. We apply the self-attention mechanism, proposed by Zhang et al. [42], in this paper. The nonlocal block is embedded in the 3D network, which is defined as follows:

$$y_i = \frac{1}{C(x)} \sum_{\forall j} f(x_i, x_j)g(x_j), \quad (2)$$

where  $i$  is a 3D coordinate meaning the position index of input data,  $j$  is the index of all possible positions,  $x$  is the input data,  $f$  is an autocorrelation calculation function, which can calculate the correlation between  $i$ -th position and  $j$ -th position, and  $g$  is a unary mapping function. The  $1 \times 1 \times 1$  convolution is used for ascending dimension and fusing the multichannel feature in the experiments, and finally  $C(x)$  is used for normalization. Using multiple  $1 \times 1 \times 1$  convolution kernels in the attention model can not only achieve cross-channel interaction and information integration, but also reduce or increase the number of channels. People begin to pay attention to the  $1 \times 1 \times 1$  convolution because of the network structure proposed by Lin [43]; this convolution connects two full connection layers for fusing the features linearly. After that, in Google's Inception-v4 [44] network structure,  $1 \times 1 \times 1$  convolution is used in the inception module for dimensionality reduction or ascending dimension. Inspired by this advantage, in this paper, the  $1 \times 1 \times 1$  convolution kernel is used to reduce the original input data dimensionality, calculate the spatial autocorrelation relationship, and then ascend the dimension of data. The different weights calculated are added back to the original data and then regularized to describe the influence on features of voxel points in different spatial positions.

## 4. Experiments and Results

**4.1. Dataset.** Radiobiological images mainly have six data formats. The NIFTI (Neuroimaging Informatics Technology Initiative) is one of them. The data format used in this paper is NIFTI. This format contains two affine coordinates, so that it can associate the physical index of voxels with its actual spatial location. The HVSMR 2016 dataset is used to evaluate the algorithm and network structure. HVSMR 2016 has a total of 10 cardiac magnetic resonance 3D scans for training and 10 scans for testing. All training sets of cardiac MRIs are from patients with CHD, including annotations of myocardium and large blood vessels.

Due to the large difference in intensity between different images, the cardiac MR images are all normalized. After normalization, the mean and unit variance are 0. To leverage

the limited training data, simple data augmentation was employed to enlarge the training data. The augmentation operations include the rotation and cropping. The original training set is divided into three parts, namely, the training set, the validation set, and the testing set. The cross-validation method is used for parameter training. We use 70% of the images for training and 30% for testing. Then, we compare and briefly discuss the experimental results.

**4.2. Evaluation Metrics.** Medical image segmentation is an important step of medical image processing. However, it is difficult to select accurate evaluation index to evaluate the quality of segmentation by comparing segmented medical images. The following three metrics are used in this paper for measuring the results of segmentation.

**4.2.1. Dice Coefficient.** Dice coefficient is widely used for verifying the effect of 3D medical image segmentation. The core idea is to ensure a high recall and precision. Compared with the evaluation method of directly computing the difference between the automatic segmentation results and the original data labels, using Dice coefficient can better characterize the segmentation effect. Dice coefficient is defined as follows:

$$\text{Dice} = \frac{2|G \cap R|}{|R| + |G|} = \frac{2\text{TP}}{2\text{TP} + \text{FP} + \text{FN}}, \quad (3)$$

where  $G$  is the segmentation result of ground truth, which is the labeled testing data.  $R$  is the automatic segmentation result of testing data. TP, FP, and FN represent true positives, false positives, and false negatives, respectively, for each class. Ideally, the template of segmentation result and the template of label data completely overlap, which means  $R = G$ , and the absolute value of the Dice coefficient is 1.

**4.2.2. Average Symmetric Surface Distance.** Average symmetric surface distance (ADB) is defined as follows: for a single voxel point, if one or more voxel points within its 18-neighborhood are not elements of the object, they are regarded as surface voxel points. For each surface voxel point in the  $R$ , we calculate the Euclidean distance between it and the nearest surface voxel point of the real label  $G$ . Similarly, perform the same calculation for each surface voxel point in the  $G$ .  $S(R)$  represents the surface voxel point set of  $R$ . The distance from any voxel point  $v$  to  $S(R)$  is defined as  $d(v, S(R)) = \min_{s_R \in S(R)} \|v - s_R\|$ . Based on this formula, the average symmetrical surface distance is defined as follows:

$$\text{ADB} = \frac{1}{|S(G)| + |S(R)|} \times \left[ \sum_{s_R \in S(R)} d(s_R, S(G)) + \sum_{s_G \in S(G)} d(s_G, S(R)) \right]. \quad (4)$$

Many segmentation boundary evaluation metrics are constructed based on this distance formula, which measures the boundary difference between the segmentation result and the ground truth by calculating the voxel surface distance. The larger the value of ADB, the more dissimilar the segmentation boundary is. When the boundary of the segmentation result matches the ground truth exactly, the value of ADB is 0.

**4.2.3. Hausdorff Distance.** Based on the ADB, when using the maximum symmetric distance, the metric is known as Hausdorff distance, which is defined as follows:

$$\text{hausdorff}(R, G) = \max_{r \in R} \left\{ \min_{g \in G} \{d(r, g)\} \right\}, \quad (5)$$

where  $d(r, g)$  represents the distance between points  $r$  and  $g$ ; that is, the set consists of the shortest distance (usually expressed in Euclidean distance) from all points in the predicted segmentation set  $R$  to any point in the real label set  $G$ , and the maximum distance is selected from this set as the Hausdorff distance between the two sets  $R$  and  $G$ . This distance and the symmetrical surface distance both describe the similarity of the contour. The larger the absolute value, the less similar the segmentation.

**4.3. Training.** In the experiments, all weights are randomly initialized by the Gaussian distribution with  $\mu = 0$ ,  $\theta = 0.01$ , and the stochastic gradient descent optimization algorithm is used. Batch size is set to 8. In order to reduce the model overfitting and speed up the convergence rate, the weight attenuation is 0.0005, and the momentum is set to 0.9, which is often used to speed up training, while making it easier to jump out of extreme points and avoid getting stuck in local optimal solutions. The drop rate is 0.2, and the initial learning rate is set to 0.01. If the learning rate is too low, the training period is too long, and the high learning rate will cause the model to be unstable and never converge. Our algorithms were trained and tested on the Dual RTX 2080 Ti GPU.

The polynomial decaying learning rate is used for ensuring the rapid convergence of the model during the initial training period and the stability of the model parameters in the later period. The initial learning rate is set relatively large, and the learning rate is reinitialized and decayed every 5000 steps. The attenuation coefficient of the learning rate is  $\delta = (1 - \text{iter}/\text{max\_iter})^{\text{power}}$ . After testing, the model stabilizes after 8000 iterations. The input data of SparseVoxNet consists of 8 groups of  $64 \times 64 \times 64$  heart MRIs, which are cropped randomly in the same axis direction.

Multiple sets of comparative experiments and ablation experiments are designed to verify the effect of the improved method on segmentation. In the experiments, we compared our method with the traditional methods and other deep learning methods, and also compared the network only with the mixed dilated convolution and the network only with the attention mechanism and DenseVoxNet.

**4.3.1. Ablation Study.** We conduct ablation experiments to verify the importance of 3D dilated convolution and spatial self-attention mechanism in exploiting multiscale features. The results are presented in Table 2.

When we just add the mixed 3D dilated convolution to the model, we define this model as SparseVoxNet-D. The Dice coefficient of myocardium and blood pool gets the best results, 82.4% and 91.6%, respectively. It verifies our conjecture: dilated convolutions can exponentially expand receptive fields to obtain multiscale information without losing resolution or coverage, especially for structures with a small size or irregular boundary, such as the cardiac myocardium structures. Since the receptive field expansion speed of the dilated convolution depends on the number of holes in the dilated convolution, although the more holes will contribute a larger receptive field, the pixels in the large receptive field are not necessarily related to the current convolution. In other words, the larger receptive field is not the better. Local perception can better capture local features. Global perception can better capture the relationship characteristics of pixels at different locations. Hence, we mix the 4 layers of traditional convolution and 3 layers of dilated convolution and define the different dilation rates of dilated convolutions to better capture features.

When we just add the spatial self-attention mechanism to the model, we define this model as SparseVoxNet-S. It can be seen that ADB and Hausdorff distance of blood pool and myocardium achieve better performance than DenseVoxNet, the Hausdorff distance of myocardium outperforms DenseVoxNet by around 3.0%, and the Hausdorff distance of blood pool outperforms DenseVoxNet by around 4.8%. This indicates that with the spatial self-attention mechanism, the segmented images have been brought closer to the target domain successfully, because the self-attention in our model is complementary to the convolution for capturing long-range, global-level dependencies occurring in cardiac structure. The advantages of the attention mechanism are as follows: (a) few parameters; (b) fast calculation; (c) capturing long-range features. The problem applied in this paper is a small sample training process, so when the spatial self-attention mechanism is removed, the segmentation result is not ideal, which means the long-range features cannot be extracted efficiently. We use both dilated convolution and spatial self-attention mechanism to capture long-range features, because the method based on dilated convolution obtains information from a small number of surrounding points and cannot form dense context information. The spatial self-attention mechanism makes a single feature in any location perceive the features of all other locations, and can produce more powerful pixel-level representation capabilities. These observations demonstrate that the 3D dilated convolution and the spatial self-attention indeed play a meaningful role in exploiting multiscale features.

**4.4. Results.** There are segmentation results on three training images shown in Figure 2. These three slices come from different patients. The data whose indexes are 60 in the

FIGURE 2: Segmentation results on three training images.

sample dataset have the same coronal plane view in the same dimension. The light blue and dark blue areas of the image in the first line represent the blood pool and myocardium; the dark blue and black areas belong to the background. The images in the second line are labeled, corresponding to the myocardium and blood pool in the first line of images. The third line is the results of automatic segmentation by the method proposed in this paper, where blue, yellow, and dark purple represent the myocardium, blood pool, and background, respectively. It can be seen from Figure 2 that although the cardiac structure of different patients in the training set is quite different, the method we proposed can still successfully calibrate the myocardium and blood pool from low contrast cardiac MRI, which proves that this method has a good enough fitting ability to the original data. However, there are still some disadvantages. In the first auto-segmentation result, the myocardium in the lower left corner is partially divided. In the second result, the background appeared in the myocardium. In the third result, there is extra myocardium in the upper right corner, which shows that deep learning has the ability to perceive most data features, but it does not have reasonable logical reasoning

capabilities. Human segmentation will not produce these subtle logical errors.

Figure 3 shows segmentation results on three testing images. The data extraction method is the same as above. By observing the results, we can see that the method proposed in this paper also has good generalization effect on unlabeled data. However, when using the gradient descent algorithm, it is easy to fall into the local optimum and cause overfitting, because of the huge number of parameters.

*4.5. Discussion.* The comparison of the results between the method we proposed and other six methods is shown in Figure 4. They are mainly ranked according to the Dice coefficient. The figure also shows the auxiliary reference indexes, such as ADB and symmetric Hausdorff distance. The first three are traditional methods, such as manually extracting features and using hidden Markov random fields, and the other deep learning methods are on the HVSMR 2016 Challenge dataset. According to Figure 4, the Dice coefficient of blood pool in all methods is higher than that of myocardium, suggesting that the segmentation of blood pool is

FIGURE 3: Segmentation results on three testing images: The three slices in the first line come from different patients. Images in the second line are the results of automatic segmentation by the method proposed in this paper.

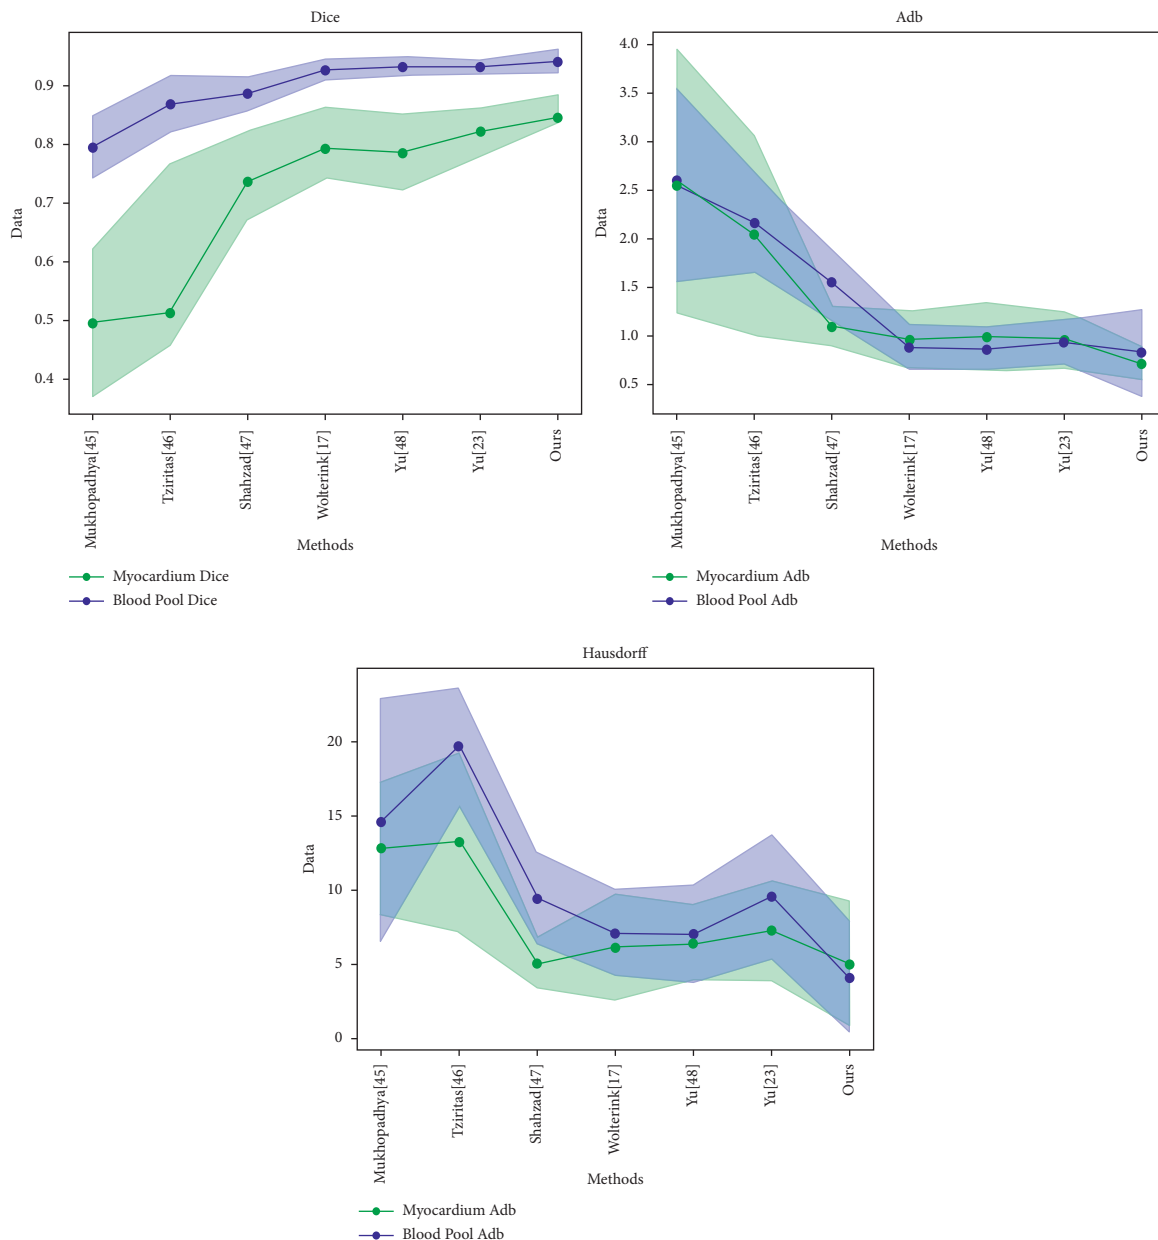

FIGURE 4: Comparison of experimental results between the improved method and other methods.

TABLE 3: Comparison of experimental results between the improved method and the 3D methods. Bold results are the best ones.

Method	Myocardium			Blood pool		
	Dice (%)	ADB	Haus.	Dice (%)	ADB	Haus.
3D U-Net [11]	69.4	2.596	12.796	79.4	2.550	14.634
V-Net [26]	70.3	2.367	10.624	81.9	2.435	12.539
VoxResNet [19]	77.4	2.041	13.199	86.7	2.157	19.723
DenseVoxNet [23]	79.2	0.943	7.175	89.48	0.955	9.608
Ours	<b>84.5</b>	<b>0.721</b>	<b>5.027</b>	<b>94.0</b>	<b>0.831</b>	<b>4.102</b>

relatively easier due to the ambiguous borders of the myocardium in the low-resolution MRIs. Regarding the segmentation of myocardium, the method we proposed achieves the best performance with the Dice; i.e., the ranking metric in the challenge,  $0.861 \pm 0.024$ , outperforms the second one by around 4%. The best result also has been achieved in blood pool segmentation with Dice; the ranking metric in the challenge,  $0.94 \pm 0.016$ , demonstrates that our sparse connected network has the capability to tackle hard cardiovascular segmentation problem. The ADB and Hausdorff distance of our method also achieved the best performance.

The results of other 3D MRI segmentation methods are mainly shown in Table 3. Firstly, the experimental parameters are compared, and the method proposed in this paper needs the least parameters. The sparse block and dilated convolution can achieve a good fitting effect with the participation of such a small number of parameters, thanks to the introduction of the attention model. The feature expression ability of sparse block will not be better than dense block in many cases, but the problem applied in this paper is medical segmentation and a small sample training process, so the sparse block can fit and generalize the data well with a small number of parameters, and the exponentially increasing receptive field provided by the dilated convolution reduces the convolution operations. The attention mechanism can well capture the features to strengthen the generalization ability of the network. Because of the small number of parameters, the amount of calculation is reduced, and the model's convergence rate is also fast.

Comparing the cross-entropy loss of DenseVoxNet and SparseVoxNet with sparse block and dilated convolution, we can find that the network only using the mixed dilated convolution can converge faster and reach lower loss values, which proves that the improved sparsely connected network structure can reduce the calculation amount and improve the efficiency and that the method of extracting long-range features by hybrid 3D dilated convolution is suitable for medical images. It has better ability to represent features and fit data.

The comparison shows that the time of one iteration of DenseVoxNet (forward and backward propagation of the network) is 0.113 s, the time of SparseVoxNet-D is 0.045 s, and the time of SparseVoxNet is 0.049 s. The proposed method has a great improvement in efficiency.

## 5. Conclusion

In this paper, we propose a novel and efficient 3D sparse convolutional network to segment blood pool and myocardium from 3D cardiac magnetic resonance images. This

method can eliminate redundant calculations and reduce model parameters and the risk of overfitting training data on small samples. The spatial self-attention mechanism can optimize the expression ability of feature maps, and the sparse blocks can reduce the convolutional network depth. The work in this paper is an accurate pixel-level classification. Moreover, we achieve competitive results in comparison with existing methods. The proposed method can provide comprehensive information for doctors to make diagnoses of CHD.

As an extension of intuitionistic fuzzy sets (IFSs), picture fuzzy sets (PFSs) can better model and represent the hesitancy and uncertainty of decision makers' preference information. In this study, we propose a multicriteria group decision making (MCGMD) method based on picture fuzzy sets. We first define some basic picture Einstein operations with closed properties among PFSs on the basis of the Einstein  $t$ -norms and  $t$ -conorms. Then, utilizing the hybrid-weighted operator and the developed picture Einstein operations laws, we put forward a picture fuzzy Einstein hybrid-weighted aggregation operator for aggregating PFSs and discuss its several important properties. Furthermore, we present a new MCGMD method based on the proposed picture fuzzy Einstein hybrid-weighted aggregation operator. Finally, an example is conducted to validate the effectiveness of the proposed MCGMD method.

## 1. Introduction

Multicriteria group decision making (MCGDM) is one of the most important human activities [1–6]. Due to the complexity and vagueness of information in group decision making, however, it is usually difficult for decision makers to evaluate the alternatives by crisp numerical values [7, 8]. In some occasions, it can be more reasonable to give uncertain or fuzzy evaluation information represented by fuzzy numbers [9, 10], intuitionistic fuzzy sets (IFS) [11–15], neutrosophic set (NS) [16–18], Pythagorean fuzzy sets [19, 20], Fermatean fuzzy sets [21, 22], hesitant fuzzy sets [23–25], and so on. Based on the concept of fuzzy sets (FSs), Atanassov [26] first introduced the concept of IFS, which is an extension of Zadeh's FSs. Different from FSs, it does not require that the sum of the degrees of membership and non-membership of an element to be equal to one. IFSs have been successfully applied to multicriteria group decision making. However, there are some scenarios that cannot be represented by IFSs in some real-life group decision-making problems, such as the option of hesitation or remaining neutral. To overcome this drawback, Smarandache [27] proposed the concept of the NS, which has the degrees of

truth, falsity, and indeterminacy, respectively. Considering that it is difficult to utilize NSs to solve real-life scientific and engineering problems, Zhang and Sunderraman [28] proposed the concept of the single-valued neutrosophic set (SVNS). In this paper, Boran and Akay [11] also developed some set-theoretic operators and discussed their various properties. Compared with NS, it is assumed in a SVNS that each type of membership degree can take its values in the interval  $[0, 1]$ , and the sum of its truth-membership degree, indeterminacy-membership degree, and false-membership degree is less than or equal to 3. This hypothesis implies that its three types of membership degrees do not satisfy probabilistic independence. This non-restriction leads to dialetheist and paraconsistent information in real-life decision-making problems represented as SVNSs. In order to overcome these drawbacks of IFSs and NSs, Cuong and Kreinovich [29] proposed the concept of the picture fuzzy set (PFS) to address a fact such that human opinions involve several types of answers such as yes, abstain, no, or refusal and so on. The PFS is characterized by a positive membership function, a negative membership function, and a neutral membership function, and the sum of its three membership degrees is less than or equal to 1. Different from

NS, there is a restriction on the sum of the three types of membership degrees in PFS, which implies that they are dependent on each other.

The PFS is an extension of FS and IFS [30]. The core of PFS is its picture fuzzy value (PFV), which is composed of the degree of positive, negative, and neutral memberships. Similar to an intuitionistic fuzzy value (IFV) and NS, PFV is also a very effective tool to express inherent uncertainty or imprecision of decision makers' preference information in human decision-making processes. Recently, PFS has been successfully applied to a lot of areas. For example, Zhang et al. [23] introduced the concept of generalized picture distance measure and applied it to pattern recognition. Based on the correlation measure of Atanassov's IFSs, Singh [31] also proposed the concept of correlation for PFSs to solve bidirectional approximate reasoning systems problems. By combining picture composite cardinality with PSO, Thong and Son [32] proposed a novel automatic picture fuzzy clustering method for pattern recognition and knowledge discovery.

In the course of MCGMD with IFS, hesitant fuzzy set, and NS, the aggregation operators play a very important role [33]. Many scholars have introduced various aggregation operators for IFS, hesitant fuzzy set, and NS, such as intuitionistic fuzzy aggregation operators [34], hesitant fuzzy aggregation operators [35], interval-valued intuitionistic fuzzy aggregation operators [36], the neutrosophic fuzzy aggregation operators [37, 38] picture fuzzy aggregation operators [39–41], and so on. Note that most of the abovementioned aggregation operators were developed based on the triangular t-norm and t-conorm for the following reasons. For IFSs, they only involve membership degree and non-membership degree such that their sum is less than or equal to 1. Thus, triangular t-norms and t-conorms are appropriate in developing the intuitionistic fuzzy aggregation operators. As for SVNS, the sum of its truth-membership degree, indeterminacy-membership degree, and false-membership degree is less than or equal to 3. Hence, triangular t-norm or t-conorm could be directly used to synthesize separate NSs into a collective one. Although NSs and PFSs both have three kinds of membership functions, their property regarding membership functions is different from each other. This means that the neutrosophic aggregation operators cannot be directly used to aggregate PFSs. For example, let  $A_1 = (0, 1, 0)$  and  $A_2 = (0, 0, 1)$  be two PFSs. According to the generalized union of SVNSs defined in [32], we have  $A_1 \otimes A_2 = (0, 1, 1)$ . This result does not satisfy the condition required by PFV that the sum of its membership degrees is less than or equal to 1.

The algebraic product and algebraic sum are usually used to develop the aggregation operators for FSs [42], IFSs [43], and NSs [44, 45]. There are also other operational rules that can be used in this respect. For example, Einstein t-norms and Einstein t-conorms are two typical classes of strict Archimedean t-norms and t-conorms for aggregating a collection of intuitionistic fuzzy values (IFVs). In this direction, Wang and Liu [46] introduced the intuitionistic fuzzy aggregation operators by using Einstein operations and developed some intuitionistic fuzzy Einstein aggregation operators. Wang and

Liu [47] furthermore developed some new intuitionistic fuzzy geometric Einstein aggregation operators. Recently, Einstein t-norms and t-conorms have also been used to aggregate neutrosophic sets and neutrosophic hesitant fuzzy sets, such as the neutrosophic number-generalized weighted power averaging operator [48], and the interval neutrosophic hesitant fuzzy generalized weighted average operator [49]. Among these Einstein aggregation operators; however, some only weight the fuzzy values and others only weight the ordered positions of the fuzzy values similar to the ordered weighted averaging (OWA) operator. To overcome this drawback, Zhao and Wei [50] proposed some new intuitionistic fuzzy Einstein hybrid aggregation operators to aggregate IFVs by combining the weighted average and the OWA operator, such as the intuitionistic fuzzy Einstein hybrid averaging operator and intuitionistic fuzzy Einstein hybrid geometric averaging operator. They weight not only the given arguments but also their ordered positions. However, all of them do not satisfy the desired properties for aggregation operators such as boundedness and idempotency. Recently, some new picture fuzzy aggregation operators are proposed to apply to multicriteria group decision making, such as picture fuzzy Einstein aggregation operators, picture fuzzy-weighted average operators, picture fuzzy-weighted geometric operators, and picture fuzzy Dombi aggregation operators, etc. Although the approaches of MCGMD based on fuzzy aggregation operators have been widely investigated, the existing aggregation operators have the following shortcomings in the aggregation process:

- (1) IFS cannot well describe inconsistent, hesitation, and indeterminate information, and it does not address the influence of hesitation or neutral fuzzy information on aggregating results in the aggregation process. Thus, the MCGMD method based on intuitionistic fuzzy aggregation operators has the drawback that it may lead to unreasonable decision-making in some situations.
- (2) The neutrosophic fuzzy hybrid aggregation operators have no occasion to prove that they must satisfy the probabilistic property of the tri-membership function. In some situations, if hybrid aggregation operators are applied in specific NSs, such as intuitionistic neutrosophic sets (INSs) whose sum of tri-membership degrees is required to be less than to 1, the aggregating set is no longer an INS. For example, let  $A = (0, 0.9, 0)$  and  $B = (0, 0, 0.9)$  be two INSs. According to the inner product operation defined in [51], we obtain  $A \otimes B = (0, 0.9, 0.9)$ , which implies that the aggregating set is no longer an INS. Thus, it is important to develop new neutrosophic fuzzy hybrid aggregation operators which are suitable to all types of NSs.
- (3) Picture fuzzy multicriteria group decision making problem will be a new direction for group decision making. However, the existing Einstein aggregation operators for NSs cannot be directly applied in picture fuzzy environments. Moreover, most of these

existing neutrosophic Einstein hybrid aggregation operators do not satisfy some properties such as boundedness and idempotency for picture fuzzy sets. It is, therefore, necessary to extend the existing neutrosophic Einstein aggregation operators to picture fuzzy environments and to propose some new Einstein aggregation operators for aggregating picture fuzzy information. To the best of our knowledge, however, there are no researches on the combination between the PFSs and MCMGD, and how to aggregate PFSs is still an open problem, which is the focus of this paper.

According to the above discussions, we can see that it is better to consider both the operations rules and aggregation operators for PFSs. The main contribution of this work is as follows:

- (1) We present some picture fuzzy Einstein operational laws based on Einstein t-norms and t-conorms and discuss their desirable properties.
- (2) We introduce a new picture fuzzy Einstein hybrid-weighted aggregation (PFIEHWA) operator to aggregate PFSs. Based on the proposed aggregation operator, we develop a MAGDM method and validate its effectiveness.

The remaining sections of this paper is organized as follows. In the next section, we introduce some basic concepts related to PFSs and Einstein operations. In Section 3, by extending the Einstein t-conorm and t-norm, we develop several new Einstein operations laws for PFVs, such as generalized intersection and union, and then we discuss their desirable properties. In Section 4, we develop a picture fuzzy Einstein hybrid aggregation operator for PFVs and discuss their desirable properties. In Section 5, we apply the picture fuzzy Einstein hybrid-weighted aggregation operator to a MCGMD problem. Some numerical examples are given to verify the developed approach and to demonstrate its practicality and effectiveness. Section 6 concludes the paper.

## 2. Preliminaries

In this section, we present some basic definitions and results for IFS and PFS.

*Definition 1 [18].* An intuitionistic fuzzy set (IFS)  $A$  in a finite set  $X$  can be written as follows:

$$A = \{ \langle x, \mu_A(x), \nu_A(x), \gamma_A(x) \rangle, x \in X \}, \quad (1)$$

where  $\mu_A(x)$  and  $\nu_A(x)$ :  $X \rightarrow [0, 1]$  are, respectively, the degrees of membership and non-membership such that  $0 \leq \mu_A(x) + \nu_A(x) \leq 1$ . For each IFS  $A$  in a finite set  $X$ , the hesitancy degree of an IFS  $A$  can be expressed as  $\pi_A(x) = 1 - \mu_A(x) - \nu_A(x)$ ,  $x \in X$ . Also, we have  $0 \leq \pi_A(x) \leq 1$ , for all  $x \in X$ .

*Definition 2 [5].* A picture fuzzy set (PFS)  $A$  in a finite set  $X$  is defined as follows:

$$A = \{ \langle x, \mu_A(x), \nu_A(x), \gamma_A(x) \rangle, x \in X \}, \quad (2)$$

where  $\mu_A(x)$ ,  $\nu_A(x)$ , and  $\gamma_A(x)$  represent the positive-membership function, negative-membership function, and neutral-membership function of  $x$  to set  $A$ , respectively. For each element  $x$  in  $X$ , we have  $\mu_A(x), \nu_A(x), \gamma_A(x) \rightarrow [0, 1]$  and  $0 \leq \mu_A(x) + \nu_A(x) + \gamma_A(x) \leq 1$ .

Similar to the IFS,  $\pi_A(x) = 1 - (\mu_A(x) + \nu_A(x) + \gamma_A(x))$  could be called the refusal-membership degree of  $x$  in  $A$ . For convenience, we can use  $x = (\mu_A, \nu_A, \gamma_A)$  to represent an element in PFSs.

*Definition 3 [52].* Let  $\alpha = (\mu_\alpha, \nu_\alpha, \gamma_\alpha)$  be a PFV, and its score function  $S_\alpha$  and accuracy function  $V_\alpha$  are, respectively, defined as follows:

$$\begin{aligned} S_\alpha &= \mu_\alpha - \nu_\alpha, \\ V_\alpha &= \mu_\alpha + \nu_\alpha + \gamma_\alpha. \end{aligned} \quad (3)$$

**Theorem 1 [53].** Let  $\alpha_1$  and  $\alpha_2$  be two PFVs, and the ranking rules between them are given as follows:

- (1) If  $S(\alpha_1) > S(\alpha_2)$ , then  $\alpha_1 > \alpha_2$
- (2) If  $S(\alpha_1) < S(\alpha_2)$ , then  $\alpha_1 < \alpha_2$
- (3) If  $S(\alpha_1) = S(\alpha_2)$ , then
  - (1) If  $V(\alpha_1) = V(\alpha_2)$ , then  $\alpha_1 = \alpha_2$
  - (2) If  $V(\alpha_1) > V(\alpha_2)$ , then  $\alpha_1 > \alpha_2$

*Definition 4.* Let  $PFS(X)$  denote the set of all the PFSs in a finite set  $X$ . Given any two PFSs  $A$  and  $B$ , their inclusion, union, intersection, and complement are defined as follows:

- (1)  $A \subseteq B$  if  $\forall x \in X$ ,  $\mu_A(x) \leq \mu_B(x)$ ,  $\nu_A(x) \geq \nu_B(x)$ ,  $\gamma_A(x) \geq \gamma_B(x)$
- (2)  $A = B$  if  $\forall x \in X$ ,  $A \subseteq B$  and  $A \supseteq B$
- (3)  $A \cup B = \{x, (\max(\mu_A(x), \mu_B(x)), \min(\nu_A(x), \nu_B(x)), \min(\gamma_A(x), \gamma_B(x)))\}$
- (4)  $A \cap B = \{x, (\min(\mu_A(x), \mu_B(x)), \max(\nu_A(x), \nu_B(x)), \max(\gamma_A(x), \gamma_B(x)))\}$
- (5)  $coA = A^c = \{ \langle x, \nu_A(x), \mu_A(x), \gamma_A(x) \rangle, x \in X \}$

## 3. Picture Fuzzy Einstein Operational Laws

Triangular t-norms and t-conorms play a prominent role for aggregating fuzzy sets in group decision making. Roychowdhury and Wang [53] gave some definitions and conditions for the triangular t-norm and t-conorm, which satisfy the requirements of both conjunction and disjunction operators. The set-theoretical properties of these operators for IFSs generally hold for IFS. In the following section, triangular t-norms and t-conorms are defined as given below:

*Definition 5 [54].* A function  $T: [0, 1]^2 \rightarrow [0, 1]$  is called a t-norm if it satisfies the following four conditions:

- (1)  $T(1, x) = x, \forall x \in [0, 1]$

- (2)  $T(x, y) = T(y, x), \forall (x, y) \in [0, 1]^2$
- (3)  $T(x, T(y, z)) = T(T(x, y), z), \forall (x, y, z) \in [0, 1]^3$
- (4) If  $x \leq x'$  and  $y \leq y'$ , then  $T(x, y) \leq T(x', y')$ ,  $\forall (x, y, x', y') \in [0, 1]^4$

*Definition 6* [54]. A function  $S: [0, 1]^2 \rightarrow [0, 1]$  is called as a t-conorm if it satisfies the following four conditions:

- (1)  $S(x, 0) = 0, \forall x \in [0, 1]$
- (2)  $S(x, y) = S(y, x), \forall (x, y) \in [0, 1]^2$
- (3)  $S(x, S(y, z)) = S(S(x, y), z), \forall (x, y, z) \in [0, 1]^3$
- (4) If  $x \leq x'$  and  $y \leq y'$ , then  $S(x, y) \leq S(x', y')$ ,  $\forall (x, y, x', y') \in [0, 1]^4$

Analogous operators on fuzzy sets have also been defined on IFs. For example, the inclusion of two IFs can be defined by using the algebraic t-norm for their membership degrees and the algebraic t-conorm for their non-membership degrees, and their inclusion is still an intuitionistic fuzzy set. This is because they are related by the De Morgan duality, *i.e.*, the t-conorm  $S$  can be defined as  $S(x, y) = 1 - T(1 - x, 1 - y), \forall (x, y) \in [0, 1]^2$ . In recent years, triangular t-norms and t-conorms have also been used to define the operation laws for NSs [55]. Although PFV is a generalization of NS, their properties regarding membership functions are different from each other. This means that the operational laws for NSs cannot be directly used to aggregate PFVs. For example, with algebraic t-norm and t-conorm, the union operation for NSs is defined as  $A \cup B = (T_1 T_2, I_1 + I_2 - I_1 I_2, F_1 + F_2 - F_1 F_2)$ . However, if they are extended to PFVs, there are some limitations. For instance, let  $A = (x, 1, 0, 0)$  and  $B = (x, 0, 1, 0)$  be two PFVs. It is clear that  $B$  is the smallest one among all PFVs. According to the generalized union operation mentioned above, we obtain  $A \cup_{S,T} B = (x, 0, 1, 0)$ . This means that the aggregating result is also the smallest PFV. Therefore, the

operation “union” cannot be accepted because it is against our intuition. Furthermore, let  $C = (x, 0, 1, 0)$  and  $D = (x, 0, 0, 1)$  be two PFVs, we also have  $\mu_{C \cup D} + \nu_{C \cup D} + \gamma_{C \cup D} = 2 > 1$ , and this result does not satisfy the condition required by a PFV that the sum of its membership degrees is less than or equal to 1. Thus, it is important to develop the operational rules for PFVs. Motivated by Definition 5 and Definition 6, we first propose a generalized intersection and union for PFVs based on triangular t-norm and t-conorm.

*Definition 7.* Let  $\alpha_j = (\mu_j, \nu_j, \gamma_j), (j = 1, 2)$  be two PFVs. The generalized intersection and union between  $\alpha_1$  and  $\alpha_2$  are, respectively, defined as follows:

$$\begin{aligned} \alpha_1 \oplus_{S,T} \alpha_2 &= (S(\mu_1, \mu_2), T(\nu_1, \nu_2), T(\gamma_1, \gamma_2)), \\ \alpha_1 \otimes_{S,T} \alpha_2 &= (T(\mu_1, \mu_2), S(\nu_1, \nu_2), T(\gamma_1, \gamma_2)). \end{aligned} \quad (4)$$

There are lots of operators based on the algebraic operation which are one of the general concepts of the t-norms and t-conorms. Einstein operation, including the Einstein product and the Einstein sum, also belongs to the t-norms and t-conorms families. Let additive generator  $N(x) = 1 - x$ , then Einstein product  $\otimes_\varepsilon$  and Einstein sum  $\oplus_\varepsilon$  are defined as follows [36]:

- (1)  $\alpha \otimes_\varepsilon \beta = \alpha\beta / (1 + (1 - \alpha)(1 - \beta)), \forall (\alpha, \beta) \in [0, 1]$
- (2)  $\alpha \oplus_\varepsilon \beta = (\alpha + \beta) / (1 + \alpha\beta), \forall (\alpha, \beta) \in [0, 1]$

With the abovementioned analysis, the operations laws for PFVs based on Einstein t-norms and t-conorms can be defined as follows:

*Definition 8.* Let  $\alpha = (\mu, \nu, \gamma)$  and  $\alpha_j = (\mu_j, \nu_j, \gamma_j), j = 1, 2$ , be PFVs, and  $\lambda$  is a positive real number. Let additive generator  $N(x) = 1 - x$ , then we have the following operations laws:

$$\alpha_1 \oplus_\varepsilon \alpha_2 = \left( \frac{\mu_1 + \mu_2}{1 + \mu_1 \mu_2}, \frac{\nu_1 \nu_2}{1 + (1 - \nu_1)(1 - \nu_2)}, \frac{\gamma_1 \gamma_2}{1 + (1 - \gamma_1)(1 - \gamma_2)} \right), \quad (5)$$

$$\alpha_1 \otimes_\varepsilon \alpha_2 = \left( \frac{\mu_1 \mu_2}{1 + (1 - \mu_1)(1 - \mu_2)}, \frac{\nu_1 + \nu_2}{1 + \nu_1 \nu_2}, \frac{\gamma_1 \gamma_2}{1 + (1 - \gamma_1)(1 - \gamma_2)} \right), \quad (6)$$

$$\lambda \cdot_\varepsilon \alpha = \left( \frac{(1 + \mu)^\lambda - (1 - \mu)^\lambda}{(1 + \mu)^\lambda + (1 - \mu)^\lambda}, \frac{2\nu^\lambda}{(2 - \nu)^\lambda + \nu^\lambda}, \frac{2\gamma^\lambda}{(2 - \gamma)^\lambda + \gamma^\lambda} \right), \quad (7)$$

$$\alpha^\lambda = \left( \frac{2\mu^\lambda}{(2 - \mu)^\lambda + \mu^\lambda}, \frac{(1 + \nu)^\lambda - (1 - \nu)^\lambda}{(1 + \nu)^\lambda + (1 - \nu)^\lambda}, \frac{2\gamma^\lambda}{(2 - \gamma)^\lambda + \gamma^\lambda} \right). \quad (8)$$

**Theorem 2.** Let  $\alpha_j = (\mu_j, \nu_j, \gamma_j), j = 1, 2$ , and  $\alpha = (\mu, \nu, \gamma)$  be PFVs,  $\lambda$  is a positive real number. Then,  $\alpha_1 \oplus_\varepsilon \alpha_2, \alpha_1 \otimes_\varepsilon \alpha_2, \lambda \cdot_\varepsilon \alpha$ , and  $\alpha^\lambda$  are also a PFV.

*Proof:* See Appendix A. □

**Theorem 3.** Let  $\lambda_j \in [0, 1]$ ,  $i = 1, 2, 3$ , and  $\alpha = (\mu, \nu, \gamma)$  be PFVs, and  $\lambda_1, \lambda_2$  and  $\lambda$  are positive real numbers, then we have the following properties:

$$\alpha_1 \oplus_\varepsilon \alpha_2 = \alpha_2 \oplus_\varepsilon \alpha_1, \quad (9)$$

$$\alpha_1 \otimes_\varepsilon \alpha_2 = \alpha_2 \otimes_\varepsilon \alpha_1, \quad (10)$$

$$(\alpha_1 \oplus_\varepsilon \alpha_2) \oplus_\varepsilon \alpha_3 = \alpha_1 \oplus_\varepsilon (\alpha_2 \oplus_\varepsilon \alpha_3), \quad (11)$$

$$\lambda(\alpha_1 \oplus_\varepsilon \alpha_2) = \lambda \alpha_1 \oplus_\varepsilon \lambda \alpha_2, \quad (12)$$

$$(\alpha_1 \otimes_\varepsilon \alpha_2)^\lambda = \alpha_1^\lambda \otimes_\varepsilon \alpha_2^\lambda, \quad (13)$$

$$\lambda_1 \cdot_\varepsilon \alpha \oplus_\varepsilon \lambda_2 \cdot_\varepsilon \alpha = (\lambda_1 + \lambda_2) \cdot_\varepsilon \alpha, \quad (14)$$

$$\alpha^{\lambda_1} \otimes_\varepsilon \alpha^{\lambda_2} = \alpha^{(\lambda_1 + \lambda_2)}. \quad (15)$$

Note that the proofs of these theorems are straightforward and thus omitted here for the sake of brevity.

In the next section, we investigate an Einstein hybrid aggregation operator under the picture fuzzy environment based on Einstein operations.

#### 4. Picture Fuzzy Einstein Hybrid-Weighted Aggregation Operator

In this section, we propose the picture fuzzy Einstein hybrid-weighted average (PFEHWA) operator based on the proposed Einstein operations laws on picture fuzzy values.

**Definition 9.** Let  $\alpha_j = (\mu_{\alpha_j}, \nu_{\alpha_j}, \gamma_{\alpha_j})$ , ( $j = 1, 2, \dots, n$ ) be a collection of PFVs. The picture fuzzy Einstein hybrid-weighted average (PFIEHWA) operator is a mapping  $\text{PFIEHWA}: \Omega^n \rightarrow \Omega$ , with an aggregation-associated weighting vector  $\omega = (\omega_1, \omega_2, \dots, \omega_n)^T$ ,  $\omega_j \in [0, 1]$  and  $\sum_{j=1}^n \omega_j = 1$ , such that

$$\text{PFIEHWA}_{\omega, \lambda}(A_1, A_2, \dots, A_n) = \frac{\oplus_{\varepsilon, j=1}^n (\omega_{\varepsilon(j)} \lambda_j A_j)}{\sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j}, \quad (16)$$

where  $\varepsilon: (j) \rightarrow (1, 2, \dots, n)$  is a permutation such that  $\alpha_j$  is the  $\varepsilon(j)$ <sup>th</sup> largest element of the collection of PFVs and  $\lambda = (\lambda_1, \lambda_2, \dots, \lambda_n)^T$  is the weighting vector of  $\alpha_j$ , with  $\lambda_j \in [0, 1]$  and  $\sum_{j=1}^n \lambda_j = 1$ .

**Theorem 4.** For a collection of PFVs  $\omega_j \in [0, 1]$ ,  $j = 1, 2, \dots, n$ , their aggregated value by using the PFIEHWA operator is also a PFV, and

$$\begin{aligned} & \text{PFIEHWA}_{\omega, \lambda}(\alpha_1, \alpha_2, \dots, \alpha_n) \\ &= \left( \frac{\prod_{j=1}^n (1 + \mu_{\alpha_j})^{(\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j)} - \prod_{j=1}^n (1 - \mu_{\alpha_j})^{(\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j)}}{\prod_{j=1}^n (1 + \mu_{\alpha_j})^{(\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j)} + \prod_{j=1}^n (1 - \mu_{\alpha_j})^{(\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j)}} \right. \\ & \quad \left. \frac{2 \prod_{j=1}^n (\nu_{\alpha_j})^{(\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j)}}{\prod_{j=1}^n (2 - (\nu_{\alpha_j}))^{(\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j)} + \prod_{j=1}^n (\nu_{\alpha_j})^{(\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j)}} \right. \\ & \quad \left. \frac{2 \prod_{j=1}^n (\gamma_{\alpha_j})^{(\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j)}}{\prod_{j=1}^n (2 - (\gamma_{\alpha_j}))^{(\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j)} + \prod_{j=1}^n (\gamma_{\alpha_j})^{(\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j)}} \right). \end{aligned} \quad (17)$$

*Proof:* See Appendix B.  $\square$

**Theorem 5.** The PFIEHWA operator satisfies the following properties:

(1) (Idempotency): If  $\alpha_j = (\mu_{\alpha_j}, \nu_{\alpha_j}, \gamma_{\alpha_j})$ ,  $j = 1, 2, \dots, n$  are all equal, that is,  $\alpha_j = \alpha$ , for all  $j = 1, 2, \dots, n$ . Then,

$$\text{PFIEHWA}_{\omega, \lambda}(\alpha_1, \alpha_2, \dots, \alpha_n) = \alpha. \quad (18)$$

(2) (Boundedness): Let  $\alpha_{\min} = (\min_{1 \leq j \leq n} \mu_{\alpha_j}, \max_{1 \leq j \leq n} \nu_{\alpha_j}, \max_{1 \leq j \leq n} \gamma_{\alpha_j})$  and  $\alpha_{\max} = (\max_{1 \leq j \leq n} \mu_{\alpha_j}, \min_{1 \leq j \leq n} \nu_{\alpha_j}, \min_{1 \leq j \leq n} \gamma_{\alpha_j})$ , then

$$\alpha_{\min} \leq \text{PFIEHWA}_{\omega, \lambda}(\alpha_1, \alpha_2, \dots, \alpha_n) \leq \alpha_{\max}. \quad (19)$$

(3) (Monotonicity): Let  $\alpha_j^1 = (\mu_{\alpha_j^1}, \nu_{\alpha_j^1}, \gamma_{\alpha_j^1})$ ,  $j = 1, 2, \dots, n$  and  $\alpha_j^2 = (\mu_{\alpha_j^2}, \nu_{\alpha_j^2}, \gamma_{\alpha_j^2})$ ,  $j = 1, 2, \dots, n$ , be two collections of PFVs, if  $\mu_{\alpha_j^1} \leq \mu_{\alpha_j^2}$ ,  $\nu_{\alpha_j^1} \geq \nu_{\alpha_j^2}$ , and  $\gamma_{\alpha_j^1} \geq \gamma_{\alpha_j^2}$ . Then,

$$\text{PFIEHWA}_{\omega, \lambda}(\alpha_1^1, \alpha_2^1, \dots, \alpha_n^1) \leq \text{PFIEHWA}_{\omega, \lambda}(\alpha_1^2, \alpha_2^2, \dots, \alpha_n^2). \quad (20)$$

*Proof:* See Appendix C.  $\square$

## 5. Application of Picture Einstein Fuzzy Hybrid Aggregation Operator

In this section, we investigate the application of the picture Einstein fuzzy hybrid aggregation operator in group decision making with picture fuzzy information.

### 5.1. MAGDM Method Based on the PFIEHWA Operator.

For a MCGMD problem under the picture fuzzy environment, let  $D = (d_1, d_2, \dots, d_l)$  be a set of decision makers,  $C = (C_1, C_2, \dots, C_n)$  be a set of criteria, and  $X = (X_1, X_2, \dots, X_m)$  be a set of alternatives to be evaluated. Let  $\tilde{D}^{(k)} = (\tilde{\alpha}_{ij}^{(k)})_{m \times n}$  be a picture fuzzy decision matrix, where  $\tilde{\alpha}_{ij}^{(k)} = (\mu_{\alpha_{ij}}^{(k)}, \nu_{\alpha_{ij}}^{(k)}, \gamma_{\alpha_{ij}}^{(k)})$  is a PFV for alternative  $X_i$  with respect to criteria  $C_j$  provided by decision maker  $d_k$ , such that  $0 \leq \mu_{\alpha_{ij}}^{(k)} \leq 1$ ,  $0 \leq \nu_{\alpha_{ij}}^{(k)} \leq 1$ ,  $0 \leq \gamma_{\alpha_{ij}}^{(k)} \leq 1$ ,  $0 \leq \mu_{\alpha_{ij}}^{(k)} + \nu_{\alpha_{ij}}^{(k)} + \gamma_{\alpha_{ij}}^{(k)} \leq 1$ ,  $k = 1, 2, \dots, l$ ,  $i = 1, 2, \dots, m$  and  $j = 1, 2, \dots, n$ . The expert committee gives the weighting vector  $\lambda = (\lambda^{(1)}, \lambda^{(2)}, \dots, \lambda^{(l)})^T$  for the decision makers, where  $\lambda^{(k)} \in [0, 1]$  and  $\sum_{k=1}^l \lambda^{(k)} = 1$ . Considering that different decision makers are familiar with differentiated fields, the expert committee also determines the ordering weights vector  $\omega = (\omega^{(1)}, \omega^{(2)}, \dots, \omega^{(l)})^T$  for the decision makers, where  $\omega^{(k)} \in [0, 1]$  and  $\sum_{k=1}^l \omega^{(k)} = 1$ . After that, the picture fuzzy decision matrixes  $\tilde{D}^{(k)} = (\tilde{\alpha}_{ij}^{(k)})_{m \times n}$  will be aggregated into a collective picture fuzzy decision matrix  $\tilde{D} = (\tilde{\alpha}_{ij})_{m \times n}$ . Then, the expert committee assigns the weighting vector  $\eta = (\eta_1, \eta_2, \dots, \eta_n)^T$  for the criteria according to their relative importance in decision making, where  $\eta_j \in [0, 1]$  and  $\sum_{j=1}^n \eta_j = 1$ . Meanwhile, considering the fact that diverse alternatives may have differentiated focuses and advantages, the expert committee also gives the aggregation-associated weights vector  $\xi = (\xi_1, \xi_2, \dots, \xi_n)^T$  for different criteria, where  $\xi_j \in [0, 1]$  and  $\sum_{j=1}^n \xi_j = 1$ .

The complete procedure for multicriteria group decision making based on the proposed picture fuzzy Einstein hybrid-weighted aggregation operator can be summarized as follows:

*Step 1.* In order to eliminate the impact of different types of criteria values (i.e., benefit criteria or cost criteria), we will transform the criteria values of cost type into those of the benefit type i.e., transform  $\tilde{D}^{(k)} = (\tilde{\alpha}_{ij}^{(k)})_{m \times n}$  into a normalized picture fuzzy decision matrix  $\tilde{R}^{(k)} = (\tilde{r}_{ij}^{(k)})_{m \times n}$ , where

$$\tilde{r}_{ij}^{(k)} = \begin{cases} \alpha_{ij}^k & \text{for benefit criteria} \\ (\alpha_{ij}^k)^c & \text{for cost criteria} \end{cases}, \quad (21)$$

where  $(\alpha_{ij}^k)^c$  is the complement of  $\alpha_{ij}^k$  such that  $(\alpha_{ij}^k)^c = (\nu_{ij}^{(k)}, \mu_{ij}^{(k)}, \gamma_{ij}^{(k)})$ .

*Step 2.* Utilizing the PFIEHWA operator to aggregate picture fuzzy decision matrixes  $\tilde{R}^{(k)} = (\tilde{r}_{ij}^{(k)})_{m \times n}$  into a collective picture fuzzy decision matrix  $\tilde{R} = (\tilde{r}_i^{(k)})_{m \times k}$ .

$$\tilde{r}_i^{(k)} = \text{PFIEHWA}_{\omega, \lambda}(\tilde{r}_{i1}^{(k)}, \tilde{r}_{i2}^{(k)}, \dots, \tilde{r}_{in}^{(k)}) = \oplus_{\varepsilon=j=1}^n \frac{(\xi_{\varepsilon(ij)}^{(k)} \lambda_j \tilde{r}_{ij}^{(k)})}{\sum_{k=1}^l \xi_{\varepsilon(ij)}^{(k)} \lambda_j}. \quad (22)$$

*Step 3.* Utilizing the PFIEHWA  $\tilde{r}_i$  to aggregate all the evaluation values  $\tilde{r}_i^{(k)}$  into a collective evaluation value  $\tilde{r}_i$  for alternative  $X_i$ .

$$\tilde{r}_i = \text{PFIEHWA}_{\xi, \eta}(\tilde{r}_i^{(1)}, \tilde{r}_i^{(2)}, \tilde{r}_i^{(3)}, \dots, \tilde{r}_i^{(l)}) = \oplus_{\varepsilon=k=1}^l \frac{(\omega_{\varepsilon(ik)} \eta_k \tilde{r}_i^{(k)})}{\sum_{k=1}^l \omega_{\varepsilon(ik)} \eta_k}. \quad (23)$$

*Step 4.* Ranking  $\tilde{r}_i$  by using the ranking method described in Section 2 and select the best one.

*5.2. Illustrative Example.* In this section, we use an example presented in [49] to illustrate the proposed method.

*Example 1 [49].* Suppose a company wants to develop a new career, where there are three alternatives:  $X_1, X_2$ , and  $X_3$  to be selected.  $X_1$  is the real estate industry,  $X_2$  is the food industry, and  $X_3$  is the education industry. After preliminary screening, three experts  $d_1, d_2$ , and  $d_3$  are asked to evaluate the alternatives. Four criteria are determined: the ability to compete ( $C_1$ ), the ability to grow ( $C_2$ ), the influence of the surrounding environment ( $C_3$ ), and the influence of social politics ( $C_4$ ). Assume that the subjective importance degree of each decision maker is  $\lambda = (0.2, 0.4, 0.4)^T$ . Simultaneously, considering that some decision makers could be more familiar with career management, the aggregation-associated weighting vector of decision maker  $d_k$  is  $\omega = (0.3, 0.3, 0.4)^T$ . Furthermore, suppose the weight vector and aggregation-associated weight vector for the four criteria are  $\eta = (0.2, 0.3, 0.3, 0.2)^T$  and  $\xi = (0.2, 0.1, 0.3, 0.4)^T$ , respectively. The picture fuzzy decision matrices are given as follows:

$$\begin{aligned}
 \tilde{D}^{(1)} &= \begin{bmatrix} (0.1, 0.3, 0.5) & (0.5, 0.2, 0.3) & (0.2, 0.2, 0.1) & (0.3, 0.1, 0.2) \\ (0.2, 0.2, 0.3) & (0.1, 0.2, 0.4) & (0.2, 0.1, 0.3) & (0.1, 0.2, 0.3) \\ (0.1, 0.3, 0.5) & (0.3, 0.1, 0.2) & (0.3, 0.2, 0.1) & (0.2, 0.3, 0.2) \end{bmatrix}, \\
 \tilde{D}^{(2)} &= \begin{bmatrix} (0.3, 0.1, 0.2) & (0.3, 0.1, 0.2) & (0.3, 0.1, 0.2) & (0.2, 0.2, 0.3) \\ (0.1, 0.3, 0.2) & (0.2, 0.1, 0.3) & (0.3, 0.3, 0.2) & (0.3, 0.1, 0.1) \\ (0.2, 0.3, 0.1) & (0.2, 0.1, 0.3) & (0.4, 0.1, 0.3) & (0.2, 0.1, 0.3) \end{bmatrix}, \\
 \tilde{D}^{(3)} &= \begin{bmatrix} (0.5, 0.1, 0.1) & (0.5, 0.2, 0.1) & (0.2, 0.4, 0.1) & (0.3, 0.1, 0.1) \\ (0.4, 0.1, 0.2) & (0.3, 0.2, 0.4) & (0.2, 0.1, 0.4) & (0.5, 0.2, 0.1) \\ (0.4, 0.2, 0.2) & (0.4, 0.2, 0.1) & (0.5, 0.2, 0.3) & (0.3, 0.2, 0.3) \end{bmatrix}.
 \end{aligned} \tag{24}$$

Step 1. Considering the criteria are all the benefit criteria, there is no need to transform them into benefits ones. Thus we have  $\tilde{D}^{(k)} = \tilde{R}^{(k)}$

Step 2. Utilizing the PFIEHWA operator to aggregate all individual picture fuzzy decision matrix  $\tilde{R}^{(k)}$  into a collective picture fuzzy decision matrix  $\tilde{R}$

$$(1 - \mu_{A_j}^1) / (1 - \mu_{A_j}^1) \leq (1 + \mu_{A_j}^2) / (1 + \mu_{A_j}^2)$$

Let us illustrate this step by using  $\tilde{r}_{11}$  as an example. Since  $\tilde{r}_{11}^{(1)} = (0.1, 0.3, 0.5)$ ,  $\tilde{r}_{12}^{(1)} = (0.5, 0.2, 0.3)$ ,  $\tilde{r}_{13}^{(1)} = (0.2, 0.2, 0.1)$ ,  $\tilde{r}_{14}^{(4)} = (0.3, 0.2, 0.1)$ ,  $\eta = (0.2, 0.3, 0.3, 0.2)^T$ , and  $\xi = (0.2, 0.1, 0.3, 0.4)^T$ , we have  $S(\tilde{r}_{11}^{(1)}) = -0.2$ ,  $S(\tilde{r}_{12}^{(1)}) = 0.3$ ,  $S(\tilde{r}_{13}^{(1)}) = 0$ , and  $S(\tilde{r}_{14}^{(1)}) = 0.1$  by using the ranking function given in Theorem 1. Thus, we can obtain  $S(\tilde{r}_{11}^{(1)}) < S(\tilde{r}_{13}^{(1)}) < S(\tilde{r}_{14}^{(1)}) < S(\tilde{r}_{12}^{(1)})$ , which implies that  $\tilde{r}_{11}^{(1)} < \tilde{r}_{13}^{(1)} < \tilde{r}_{14}^{(1)} < \tilde{r}_{12}^{(1)}$ . Hence, we have  $\varepsilon_{11}(1) = 4$ ,  $\varepsilon_{12}(1) = 3$ ,  $\varepsilon_{13}(1) = 2$ , and  $\varepsilon_{14}(1) = 1$ . Then,

$$\begin{aligned}
 \frac{\xi_{\varepsilon_{11}(1)} \eta_1^{(1)}}{\sum_{j=1}^4 \xi_{\varepsilon_{1j}} \eta_1^{(1)}} &= \frac{0.2 \times 0.4}{0.2 \times 0.4 + 0.3 \times 0.3 + 0.3 \times 0.1 + 0.2 \times 0.2} = 0.3333, \\
 \frac{\xi_{\varepsilon_{12}(1)} \eta_2^{(1)}}{\sum_{j=1}^4 \xi_{\varepsilon_{1j}} \eta_2^{(1)}} &= \frac{0.3 \times 0.3}{0.2 \times 0.4 + 0.3 \times 0.3 + 0.3 \times 0.1 + 0.2 \times 0.2} = 0.3750, \\
 \frac{\xi_{\varepsilon_{13}(1)} \eta_3^{(1)}}{\sum_{j=1}^4 \xi_{\varepsilon_{1j}} \eta_3^{(1)}} &= \frac{0.3 \times 0.1}{0.2 \times 0.4 + 0.3 \times 0.3 + 0.3 \times 0.1 + 0.2 \times 0.2} = 0.1250, \\
 \frac{\xi_{\varepsilon_{14}(1)} \eta_4^{(1)}}{\sum_{j=1}^4 \xi_{\varepsilon_{1j}} \eta_4^{(1)}} &= \frac{0.2 \times 0.2}{0.2 \times 0.4 + 0.3 \times 0.3 + 0.3 \times 0.1 + 0.2 \times 0.2} = 0.1667.
 \end{aligned} \tag{25}$$

Finally, we have  $PFIEHWA_{\xi, \eta}(\tilde{r}_{11}^{(1)}, \tilde{r}_{12}^{(1)}, \tilde{r}_{13}^{(1)}, \tilde{r}_{14}^{(1)}) = (0.1720, 0.2054, 0.2958)$  by using (21). Similarly, we can derive the collective evaluation matrix given in Table 1.

Step 3. Utilizing the PFIEHWA operator to aggregate all  $\tilde{r}_i^{(k)}$ ,  $k = 1, 2, 3$ , into a collective PFV  $\tilde{r}_i$  for alternative  $X_i$  over all the experts. According to Theorem 1, we have

TABLE 1: Collective picture fuzzy decision matrix.

	$D_1$	$D_2$	$D_3$
$X_1$	(0.1720, 0.2054, 0.2958)	(0.1355, 0.1265, 0.2296)	(0.1728, 0.1879, 0.100)
$X_2$	(0.0700, 0.1700, 0.3334)	(0.1057, 0.1679, 0.2090)	(0.1655, 0.1219, 0.2764)
$X_3$	(0.1109, 0.1485, 0.2575)	(0.1174, 0.1210, 0.2522)	(0.2007, 0.2000, 0.1753)

$S(\tilde{r}_1^{(1)}) = -0.0334$ ,  $S(\tilde{r}_1^{(2)}) = -0.1$  and  $S(\tilde{r}_1^{(3)}) = -0.0376$ . Thus,  $S(\tilde{r}_1^{(3)}) < S(\tilde{r}_1^{(1)}) < S(\tilde{r}_1^{(2)})$ , which means that  $\tilde{r}_1^{(3)} < \tilde{r}_1^{(1)} < \tilde{r}_1^{(2)}$ . Hence,  $\delta_{11} = 2$ ,  $\delta_{12} = 3$  and  $\delta_{13} = 1$ . Then, we have as follows:

$$\begin{aligned}\omega_{\varepsilon(11)} \frac{\lambda_1}{\sum_{k=1}^3 \omega_{\varepsilon(1k)} \lambda_k} &= \frac{(0.2 \times 0.3)}{(0.2 \times 0.3 + 0.4 \times 0.3 + 0.4 \times 0.4)} = 0.1765, \\ \omega_{\varepsilon(12)} \frac{\lambda_2}{\sum_{k=1}^3 \omega_{\varepsilon(1k)} \lambda_k} &= \frac{(0.4 \times 0.3)}{(0.2 \times 0.3 + 0.4 \times 0.3 + 0.4 \times 0.4)} = 0.3529, \\ \omega_{\varepsilon(13)} \frac{\lambda_3}{\sum_{k=1}^3 \omega_{\varepsilon(1k)} \lambda_k} &= \frac{(0.4 \times 0.4)}{(0.2 \times 0.3 + 0.4 \times 0.3 + 0.4 \times 0.4)} = 0.4706.\end{aligned}\quad (26)$$

Thus, we can derive the following result:

$$\tilde{r}_1 = \text{PFIEHWA}_{\omega, \lambda}(\tilde{r}_1^{(1)}, \tilde{r}_2^{(1)}, \tilde{r}_3^{(1)}, \tilde{r}_4^{(1)}) = (0.1129, 0.1650, 0.2894). \quad (27)$$

Similarly, we can obtain the following results:

$$\begin{aligned}\tilde{r}_2 &= \text{PFIEHWA}_{\omega, \lambda}(\tilde{r}_1^{(2)}, \tilde{r}_2^{(2)}, \tilde{r}_3^{(2)}, \tilde{r}_4^{(2)}) = (0.1156, 0.1424, 0.2271), \\ \tilde{r}_3 &= \text{PFIEHWA}_{\omega, \lambda}(\tilde{r}_1^{(3)}, \tilde{r}_2^{(3)}, \tilde{r}_3^{(3)}, \tilde{r}_4^{(3)}) = (0.1812, 0.1639, 0.1821).\end{aligned}\quad (28)$$

*Step 4.* Computing the ranking values  $R(\tilde{r}_i)$  for  $A_i$ , for all  $k=1, 2$ , and  $3$ . By using Theorem 1, we have  $S(\tilde{r}_1) = -0.0521$ ,  $S(\tilde{r}_2) = -0.0268$ , and  $S(\tilde{r}_3) = 0.0173$ . Since  $S(\tilde{r}_1) < S(\tilde{r}_2) < S(\tilde{r}_3)$ , we obtain  $X_1 < X_2 < X_3$ , which implies that  $X_3$  is the most desirable career alternative. This order is the same as the method proposed by Liu and Shi's work.

**5.3. Comparative Analysis.** In this section, we compare the proposed method based on the *PFEHWA* operator with the method given by Zhang [44], Peng [56], and Liu [48] using the following example in [44]. In the method proposed by Zhang [44], a quasi-intuitionistic fuzzy Einstein hybrid-weighted averaging (*QIFEHWA*) operator and intuitionistic fuzzy Einstein weighted averaging (*IFEWA*) operator were utilized, which does not consider hesitation or neutral information in the aggregation process, whereas the method given by Peng [56], Liu [48], and the proposed method considers hesitation or neutral information. In the method of Peng [56] and Liu [48], NS was used to develop some single-valued Neutrosophic fuzzy-weighted averaging operators, such as the Einstein single-valued neutrosophic

number-weighted averaging (*ESVNNWA*) operator in [48] and the simplified neutrosophic hybrid ordered weighted averaging (*SNNHOWA*) operator in [56].

*Example 2 [44].* Suppose a computer center in a university wants to select a new information system from the following four possible alternatives:  $X_1$ ,  $X_2$ ,  $X_3$ , and  $X_4$ . Three decision makers are asked to make a decision according to the following four criteria: (1)  $C_1$  is the costs of the hardware and software investment; (2)  $C_2$  is the contribution to organization performance; (3)  $C_3$  is the effort to transition from the current systems; and (4)  $C_4$  is the reliability of outsourcing software development; these are all benefit type criteria. Suppose the weights vector of decision makers  $d_1$ ,  $d_2$ , and  $d_3$  is  $\lambda = (\lambda^1, \lambda^2, \lambda^3)^T = (0.2, 0.5, 0.3)^T$  and the associated-weighting vector is  $\omega = (\omega^1, \omega^2, \omega^3)^T = (1/3, 1/3, 1/3)^T$ . Then, the decision maker  $d_k$  determines the weight vector of four criteria, which are  $\eta_j^{(1)} = (0.4, 0.3, 0.1, 0.2)^T$ ,  $\eta_j^{(2)} = (0.1, 0.3, 0.5, 0.1)^T$ , and  $\eta_j^{(3)} = (0.1, 0.2, 0.3, 0.4)^T$ , where  $j = 1, 2, 3, 4$ . According to their preferences, the decision makers also give the associated-weighting vectors of the four criteria:  $\xi_j^{(1)} = (0.4, 0.3, 0.2, 0.1)^T$ ,  $\xi_j^{(2)} = (0.3, 0.3, 0.2, 0.2)^T$ , and

TABLE 5: Ranking results for example 2.

Methods	Ranking values	Ranking results
Zhang method [44] (QIFEHWA and IFEWA operator)	$S(r_1) = 0.0913$ ; $S(r_2) = 0.3768$ ; $S(r_3) = 0.0736$ ; $S(r_4) = 0.1769$ .	$X_2 \succ X_4 \succ X_1 \succ X_3$
Peng method [58] (SNNHOWA operator)	$S(r_1) = 0.7609$ ; $S(r_2) = 0.8456$ ; $S(r_3) = 0.7281$ ; $S(r_4) = 0.7577$ .	$X_2 \succ X_1 \succ X_4 \succ X_3$
Liu method [48] (ESVNNWA operator)	$S(r_1) = 0.6486$ ; $S(r_2) = 0.7550$ ; $S(r_3) = 0.6519$ ; $S(r_4) = 0.6912$ .	$X_2 \succ X_4 \succ X_3 \succ X_1$
Our method (PFEHWA operator)	$S(r_1) = 0.4655$ ; $S(r_2) = 0.6142$ ; $S(r_3) = 0.5080$ ; $S(r_4) = 0.5543$ .	$X_2 \succ X_4 \succ X_3 \succ X_1$

$\xi_j^{(3)} = (0.5, 0.3, 0.1, 0.1)^T$ , where  $j = 1, 2, 3, 4$ . Considering that the value of each criterion is evaluated using the intuitionistic fuzzy information by the decision makers, we first transform IFVs into PFVs, as shown in Tables 2-4.

A comparison of the ranking results using different methods is shown in Table 5. We can see from Table 5 that different methods lead to different rankings. However,  $X_2$  is always the best alternative. We can also see that the method of Liu and our method generate the same ranking for four alternatives. The reason can be explained as follows. First, the shortcomings of IFSs and NSs that were discussed earlier can account for the differences in the final rankings. Second, these methods apply different types of ranking measures to rank IFSs or NSs, such as the score function or accuracy function. In the proposed method, a novel ranking function based on the parametric distance measure can distinguish two different PFVs while other ranking measures could not.

## 6. Conclusion

In this study, we have proposed a hybrid Einstein aggregation operator on the basis of the proposed picture Einstein operations for aggregating picture fuzzy information and

investigated their application in multicriteria group decision making. First, based on the picture Einstein operation laws, we have developed a new operator for aggregating PFVs. Then, we have utilized the proposed operator to develop a method for MCGDM problems in which the evaluation values are represented by PFVs. Finally, an example is conducted to illustrate the practicality and effectiveness of the proposed MCGDM approach. In future research, the proposed method could be extended to interval-valued picture fuzzy sets and trapezoidal picture fuzzy sets. Another interesting direction could be to develop other types of picture fuzzy aggregation operators.

## Appendix

### A. Proof of Theorem 2

*Proof:* We first prove that  $\alpha_1 \oplus_\epsilon \alpha_2$  is a PFV. Since  $0 \leq \mu_1, \mu_2, \nu_1, \nu_2, \gamma_1, \gamma_2 \leq 1$ ,  $0 \leq \mu_1 + \nu_1 + \gamma_1 \leq 1$  and  $0 \leq \mu_2 + \nu_2 + \gamma_2 \leq 1$ , we obtain  $1 - \nu_1 \geq \mu_1$ ,  $1 - \nu_2 \geq \mu_2$ ,  $1 - \gamma_1 \geq \mu_1$ , and  $1 - \gamma_2 \geq \mu_2$ . Thus, we have as follows:

$$\begin{aligned}
& \frac{\mu_1 + \mu_2}{1 + \mu_1\mu_2} + \frac{\nu_1\nu_2}{1 + (1 - \nu_1)(1 - \nu_2)} + \frac{\gamma_1\gamma_2}{1 + (1 - \gamma_1)(1 - \gamma_2)} \leq \frac{\mu_1 + \mu_2}{1 + \mu_1\mu_2} + \frac{\nu_1\nu_2}{1 + \mu_1\mu_2} + \frac{\gamma_1\gamma_2}{1 + \mu_1\mu_2} \\
& = \frac{\mu_1 + \mu_2 + \nu_1\nu_2 + \gamma_1\gamma_2}{1 + \mu_1\mu_2} \\
& \leq \frac{\mu_1 + \mu_2 + (1 - (\mu_1 + \gamma_1))(1 - (\mu_2 + \gamma_2)) + \gamma_1\gamma_2}{1 + \mu_1\mu_2} \\
& \leq \frac{1 - (\mu_1 + \mu_2 + \mu_1\mu_2 + \mu_1\gamma_2 + \mu_2\gamma_1)}{1 + \mu_1\mu_2} \leq 1,
\end{aligned} \tag{A.1}$$

that is, to say,  $\alpha_1 \oplus_\varepsilon \alpha_2$  is a PFV. Similarly, we can prove that  $\alpha_1 \otimes_\varepsilon \alpha_2$  is also a PFV.

We now prove that  $\lambda_\cdot \alpha$  is a PFV. To achieve this purpose, we first prove that  $m_\cdot \alpha$  is a PFV for any arbitrary positive integer. Let  $m$  be any positive integer and  $\alpha$  is a PFV, then

$$m_\cdot \alpha = \overbrace{\alpha \oplus_\varepsilon \alpha \oplus_\varepsilon \dots \oplus_\varepsilon \alpha}^m. \tag{A.2}$$

Now, we prove that equation (7) holds for all positive integers with induction method.

First of all, we prove that equation (7) holds for  $m = 1$ . Since

$$\begin{aligned}
1_\cdot \alpha &= \left( \frac{(1 + \mu)^1 - (1 - \mu)^1}{(1 + \mu)^1 + (1 - \mu)^1}, \frac{2\nu^1}{(2 - \nu)^1 + \nu^1}, \frac{2\gamma^1}{(2 - \gamma)^1 + \gamma^1} \right) \\
&= (\mu, \nu, \gamma) = \alpha.
\end{aligned} \tag{A.3}$$

Therefore, equation (7) holds for  $m = 1$ .

Second, if equation (7) holds for  $m = k$ , that is to say

$$k_\cdot \alpha = \overbrace{\alpha \oplus_\varepsilon \alpha \oplus_\varepsilon \dots \oplus_\varepsilon \alpha}^k. \tag{A.4}$$

When  $m = k + 1$ , we have the following:

$$\begin{aligned}
& \overbrace{\alpha \oplus_\varepsilon \alpha \oplus_\varepsilon \dots \oplus_\varepsilon \alpha}^{k+1} = \overbrace{\alpha \oplus_\varepsilon \alpha \oplus_\varepsilon \dots \oplus_\varepsilon \alpha \oplus_\varepsilon \alpha}^{k+1}, \\
& = \left( \frac{(1 + \mu)^k - (1 - \mu)^k}{(1 + \mu)^k + (1 - \mu)^k}, \frac{2\nu^k}{(2 - \nu)^k + \nu^k}, \frac{2\gamma^k}{(2 - \gamma)^k + \gamma^k} \right) \oplus_\varepsilon (\mu, \nu, \gamma), \\
& = \left( \frac{(1 + \mu)^k - (1 - \mu)^k}{(1 + \mu)^k + (1 - \mu)^k}, \frac{2\nu^k}{(2 - \nu)^k + \nu^k}, \frac{2\gamma^k}{(2 - \gamma)^k + \gamma^k} \right) \oplus_\varepsilon \left( \frac{(1 + \mu) - (1 - \mu)}{(1 + \mu) + (1 - \mu)}, \frac{2\nu}{(2 - \nu) + \nu}, \frac{2\gamma}{(2 - \gamma) + \gamma} \right), \\
& \quad \left( \frac{2\gamma^k / (2 - \gamma)^k + \gamma^k \times 2\gamma / (2 - \gamma) + \gamma}{1 + (1 - 2\gamma^k / (2 - \gamma)^k + \gamma^k)(1 - 2\gamma / (2 - \gamma) + \gamma)} \right), \\
& \quad \left( \frac{2\nu^k / (2 - \nu)^k + \nu^k \times 2\nu / (2 - \nu) + \nu}{1 + (1 - 2\nu^k / (2 - \nu)^k + \nu^k)(1 - 2\nu / (2 - \nu) + \nu)} \right), \\
& \quad \left( \frac{2\gamma^k / (2 - \gamma)^k + \gamma^k \times 2\gamma / (2 - \gamma) + \gamma}{1 + (1 - 2\gamma^k / (2 - \gamma)^k + \gamma^k)(1 - 2\gamma / (2 - \gamma) + \gamma)} \right) \\
& = \left( \frac{(1 + \mu)^{k+1} - (1 - \mu)^{k+1}}{(1 + \mu)^{k+1} + (1 - \mu)^{k+1}}, \frac{2\nu^{k+1}}{(2 - \nu)^{k+1} + \nu^{k+1}}, \frac{2\gamma^{k+1}}{(2 - \gamma)^{k+1} + \gamma^{k+1}} \right) \\
& = (k + 1)_\cdot \alpha
\end{aligned} \tag{A.5}$$

That is, to say that equation (7) holds for  $m = k + 1$ . Therefore, equation (7) holds for all positive integers.

Now, we prove equation (7) holds for all positive real numbers. Let  $\lambda$  be any positive real number. Since

$0 \leq \mu, \nu, \gamma \leq 1$  and  $0 \leq \mu + \nu + \gamma \leq 1$ , we obtain  $1 - \mu \geq \nu$ ,  $1 - \mu \geq \gamma$ . Thus, we have  $1 - \mu \geq \min(\nu, \gamma)$ . We also have  $\nu \geq \min(\nu, \gamma)$  and  $\gamma \geq \min(\nu, \gamma)$ . Knowing that

$$\begin{aligned} \frac{(1 + \mu)^\lambda - (1 - \mu)^\lambda}{(1 + \mu)^\lambda + (1 - \mu)^\lambda} &\leq 1 - \frac{2(1 - \mu)^\lambda}{(1 + \mu)^\lambda + (1 - \mu)^\lambda} \leq 1 - \frac{2(1 - \mu)^\lambda}{(1 + \mu)^\lambda + [\min(\nu, \gamma)]^\lambda} \\ \frac{2\nu^\lambda}{(2 - \nu)^\lambda + \nu^\lambda} &\leq \frac{2\nu^\lambda}{(1 + \mu)^\lambda + [\min(\nu, \gamma)]^\lambda}, \end{aligned} \quad (\text{A.6})$$

and

$$\frac{2\gamma^\lambda}{(2 - \gamma)^\lambda + \gamma^\lambda} \leq \frac{2\gamma^\lambda}{(1 + \mu)^\lambda + [\min(\nu, \gamma)]^\lambda}, \quad (\text{A.7})$$

we have

$$\begin{aligned} &\frac{(1 + \mu)^\lambda - (1 - \mu)^\lambda}{(1 + \mu)^\lambda + (1 - \mu)^\lambda} + \frac{2\nu^\lambda}{(2 - \nu)^\lambda + \nu^\lambda} + \frac{2\gamma^\lambda}{(2 - \gamma)^\lambda + \gamma^\lambda} \\ &= \frac{(1 + \mu)^\lambda + (1 - \mu)^\lambda - 2(1 - \mu)^\lambda}{(1 + \mu)^\lambda + (1 - \mu)^\lambda} + \frac{2\nu^\lambda}{(2 - \nu)^\lambda + \nu^\lambda} + \frac{2\gamma^\lambda}{(2 - \gamma)^\lambda + \gamma^\lambda} \\ &= 1 - \frac{2(1 - \mu)^\lambda}{(1 + \mu)^\lambda + (1 - \mu)^\lambda} + \frac{2\nu^\lambda}{(2 - \nu)^\lambda + \nu^\lambda} + \frac{2\gamma^\lambda}{(2 - \gamma)^\lambda + \gamma^\lambda} \\ &\leq 1 - \frac{2(1 - \mu)^\lambda}{(1 + \mu)^\lambda + [\min(\nu, \gamma)]^\lambda} + \frac{2\nu^\lambda}{(1 + \mu)^\lambda + [\min(\nu, \gamma)]^\lambda} + \frac{2\gamma^\lambda}{(1 + \mu)^\lambda + [\min(\nu, \gamma)]^\lambda} \\ &\leq 1 - \frac{2(\nu + \gamma)^\lambda - 2\nu^\lambda - 2\gamma^\lambda}{(1 + \mu)^\lambda + [\min(\nu, \gamma)]^\lambda}. \end{aligned} \quad (\text{A.8})$$

Since

$$\begin{aligned} &2(\nu + \gamma)^\lambda - 2\nu^\lambda - 2\gamma^\lambda \\ &= 2[(\nu^\lambda + \nu^{\lambda-1}\gamma + \nu^{\lambda-2}\gamma^2 + \dots + \nu\gamma^{\lambda-1} + \gamma^\lambda) - \nu^\lambda - \gamma^\lambda] \\ &= 2(\nu^{\lambda-1}\gamma + \nu^{\lambda-2}\gamma^2 + \dots + \nu\gamma^{\lambda-1}) \geq 0, \end{aligned} \quad (\text{A.9})$$

we have

$$\begin{aligned} &1 - \frac{2(\nu + \gamma)^\lambda - 2\nu^\lambda - 2\gamma^\lambda}{(1 + \mu)^\lambda + [\min(\nu, \gamma)]^\lambda} \\ &\leq 1 - \frac{2(\nu^{\lambda-1}\gamma + \nu^{\lambda-2}\gamma^2 + \dots + \nu\gamma^{\lambda-1})}{(1 + \mu)^\lambda + [\min(\nu, \gamma)]^\lambda} \leq 1. \end{aligned} \quad (\text{A.10})$$

Furthermore,

$$\begin{aligned} \frac{(1+\mu)^\lambda - (1-\mu)^\lambda}{(1+\mu)^\lambda + (1-\mu)^\lambda} &\geq 0, \\ \frac{2\nu^\lambda}{(2-\nu)^\lambda + \nu^\lambda} &\geq 0, \\ \frac{2\gamma^\lambda}{(2-\gamma)^\lambda + \gamma^\lambda} &\geq 0. \end{aligned} \quad (\text{A.11})$$

With the above analysis, we have

$$0 \leq \frac{(1+\mu)^\lambda - (1-\mu)^\lambda}{(1+\mu)^\lambda + (1-\mu)^\lambda} + \frac{2\nu^\lambda}{(2-\nu)^\lambda + \nu^\lambda} + \frac{2\gamma^\lambda}{(2-\gamma)^\lambda + \gamma^\lambda} \leq 1. \quad (\text{A.12})$$

That is, to say,  $\alpha_1 \otimes_\varepsilon \alpha_2$  is also a PFV for any positive real number.

Similar to  $\lambda_\varepsilon \alpha$ , we can prove that  $\alpha^\lambda$  is a PFV.  $\square$

## B. Proof of Theorem 4

*Proof:* First, according to Theorem 3, it is clear that the aggregated value with picture fuzzy Einstein hybrid-weighted average (PFEHWA) operator is also a PFV.

We now prove that equation (17) holds. According to the operations of PFVs defined in Definition 8, we have

$$\begin{aligned} \frac{\omega_{\varepsilon(j)}\lambda_j}{\sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j} \alpha_j &= \left( \frac{\left( (1+\mu_{\alpha_j})^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j} - (1-\mu_{\alpha_j})^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j} \right)}{\left( (1+\mu_{\alpha_j})^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j} + (1-\mu_{\alpha_j})^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j} \right)} \right. \\ &\quad \left. \frac{2\nu_{\alpha_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}}{\left( 2-\nu_{\alpha_j} \right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j} + \nu_{\alpha_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}}, \frac{2\gamma_{\alpha_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}}{\left( 2-\gamma_{\alpha_j} \right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j} + \gamma_{\alpha_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}} \right), \end{aligned} \quad (\text{B.1})$$

where  $j = 1, 2, \dots, n$ . We prove the correctness of equation (17) with inductive method.

(1) for  $n = 1$ , it is trivial.

(2) Suppose equation (17) holds for  $n = k$ , that is:

$$\begin{aligned} \text{PFEHWA}_{\omega, \lambda}(\alpha_1, \alpha_2, \dots, \alpha_k) &= \left( \frac{\prod_{j=1}^k (1+\mu_{\alpha_j})^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^k \omega_{\varepsilon(j)}\lambda_j} - \prod_{j=1}^k (1-\mu_{\alpha_j})^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^k \omega_{\varepsilon(j)}\lambda_j}}{\prod_{j=1}^k (1+\mu_{\alpha_j})^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^k \omega_{\varepsilon(j)}\lambda_j} + \prod_{j=1}^k (1-\mu_{\alpha_j})^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^k \omega_{\varepsilon(j)}\lambda_j}} \right. \\ &\quad \frac{2 \prod_{j=1}^k \nu_{\alpha_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^k \omega_{\varepsilon(j)}\lambda_j}}{\prod_{j=1}^k \left( 2-\nu_{\alpha_j} \right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^k \omega_{\varepsilon(j)}\lambda_j} + \prod_{j=1}^k \nu_{\alpha_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^k \omega_{\varepsilon(j)}\lambda_j}} \\ &\quad \left. \frac{2 \prod_{j=1}^k \gamma_{\alpha_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^k \omega_{\varepsilon(j)}\lambda_j}}{\prod_{j=1}^k \left( 2-\gamma_{\alpha_j} \right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^k \omega_{\varepsilon(j)}\lambda_j} + \prod_{j=1}^k \gamma_{\alpha_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^k \omega_{\varepsilon(j)}\lambda_j}} \right). \end{aligned} \quad (\text{B.2})$$

(3) When  $n = k + 1$ , according to Definition 9 and Theorem 3, we have as follows:

$$= \left( \frac{(1 + \mu_A) \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^n \omega_{\varepsilon(j)\lambda_j} - (1 - \mu_A) \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^n \omega_{\varepsilon(j)\lambda_j}}{(1 + \mu_{A_j}) \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^n \omega_{\varepsilon(j)\lambda_j} + (1 - \mu_{A_j}) \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^n \omega_{\varepsilon(j)\lambda_j}}, \frac{2\gamma_A \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^n \omega_{\varepsilon(j)\lambda_j}}{(2 - \gamma_A) \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^n \omega_{\varepsilon(j)\lambda_j} + \gamma_A \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^n \omega_{\varepsilon(j)\lambda_j}} \right) \quad (C.1)$$

## (2) Boundedness

Let  $f(x) = (1-x)/(1+x)$ ,  $x \in [0, 1]$ . Then,  $f'(x) = -2/(1+x)^2 > 0$  and thus,  $f(x)$  is a decreasing function. Since  $\min \mu_{A_j} \leq \mu_{A_j} \leq \max \mu_{A_j}$ , for all  $j$ , then  $f(\max \mu_{A_j}) \leq f(\mu_{A_j}) \leq f(\min \mu_{A_j})$ . Let  $\alpha = \dot{\omega}_{\varepsilon(j)\lambda_j} / \sum_{j=1}^n \omega_{\varepsilon(j)\lambda_j}$ . Therefore, we have as follows:

$$\frac{(1 - \max \mu_{A_j})}{(1 + \max \mu_{A_j})} \leq \frac{(1 - \mu_{A_j})}{(1 + \mu_{A_j})} \leq \frac{(1 - \min \mu_{A_j})}{(1 + \min \mu_{A_j})} \quad (C.2)$$

So, we can derive the following:

$$\frac{(1 - \max \mu_{A_j})^{\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^n \omega_{\varepsilon(j)\lambda_j}}}{(1 + \max \mu_{A_j})^{\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^n \omega_{\varepsilon(j)\lambda_j}}} \leq \frac{(1 - \mu_{A_j})^{\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^n \omega_{\varepsilon(j)\lambda_j}}}{(1 + \mu_{A_j})^{\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^n \omega_{\varepsilon(j)\lambda_j}}} \leq \frac{(1 - \min \mu_{A_j})^{\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^n \omega_{\varepsilon(j)\lambda_j}}}{(1 + \min \mu_{A_j})^{\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^n \omega_{\varepsilon(j)\lambda_j}}} \quad (C.3)$$

Thus,

$$\begin{aligned} \prod_{j=1}^m \frac{(1 - \max \mu_{A_j})^{\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^n \omega_{\varepsilon(j)\lambda_j}}}{(1 + \max \mu_{A_j})^{\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^n \omega_{\varepsilon(j)\lambda_j}}} &\leq \prod_{j=1}^m \frac{(1 - \mu_{A_j})^{\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j}}}{(1 + \mu_{A_j})^{\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j}}} \\ &\leq \prod_{j=1}^m \frac{(1 - \min \mu_{A_j})^{\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j}}}{(1 + \min \mu_{A_j})^{\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j}}} \\ &\Leftrightarrow \frac{(1 - \max \mu_{A_j})^{\sum_{j=1}^m (\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j})}}{(1 + \max \mu_{A_j})^{\sum_{j=1}^m (\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j})}} \leq \prod_{j=1}^m \frac{(1 - \mu_{A_j})^{\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j}}}{(1 + \mu_{A_j})^{\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j}}} \\ &\leq \frac{(1 - \min \mu_{A_j})^{\sum_{j=1}^m (\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j})}}{(1 + \min \mu_{A_j})^{\sum_{j=1}^m (\omega_{\varepsilon(j)\lambda_j} / \sum_{j=1}^m \omega_{\varepsilon(j)\lambda_j})}} \end{aligned}$$

$$\begin{aligned}
& \frac{1 - \max_j \mu_{A_j}}{1 + \max_j \mu_{A_j}} \leq \prod_{j=1}^m \frac{(1 - \mu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j}}{(1 + \mu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j}} \leq \frac{1 - \min_j \mu_{A_j}}{1 + \min_j \mu_{A_j}} \\
& \Leftrightarrow \frac{2}{1 + \max_j \mu_{A_j}} \leq 1 + \prod_{j=1}^m \frac{(1 - \mu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j}}{(1 + \mu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j}} \leq \frac{2}{1 + \min_j \mu_{A_j}} \\
& \Leftrightarrow \frac{1 + \min_j \mu_{A_j}}{2} \leq \frac{1}{1 + \prod_{j=1}^m (1 - \mu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j} / (1 + \mu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j}} \leq \frac{1 + \max_j \mu_{A_j}}{2} \tag{C.4} \\
& \Leftrightarrow \min_j \mu_{A_j} \leq \frac{2}{1 + \prod_{j=1}^m (1 - \mu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j} / (1 + \mu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j}} - 1 \leq \max_j \mu_{A_j} \\
& = \min_j \mu_{A_j} \leq \frac{2}{1 + \prod_{j=1}^m (1 - \mu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j} / (1 + \mu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j}} - 1 \leq \max_j \mu_{A_j} \\
& \Leftrightarrow \min_j \mu_{A_j} \leq \frac{(1 + \mu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j} - (1 - \mu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j}}{(1 + \mu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j} + (1 - \mu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j}} \leq \max_j \mu_{A_j}.
\end{aligned}$$

Let  $g(y) = (2 - y)/y$ ,  $y \in [0, 1]$ . Then,  $f'(y) = -2/y^2 < 0$ , and thus,  $g(y)$  is a decreasing function. Since  $\min_j \nu_{A_j} \leq \nu_{A_j} \leq \max_j \nu_{A_j}$  for all  $j$ , then  $g(\min_j \nu_{A_j}) \leq$

$g(\nu_{A_j}) \leq g(\max_j \nu_{A_j})$ . Let  $\alpha = \omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j$ . According to equation (19), we have as follows:

$$\frac{(2 - \max_j \nu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j}}{\max_j \nu_{A_j}^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j}} \leq \frac{(2 - \nu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j}}{\nu_{A_j}^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j}} \leq \frac{(2 - \min_j \nu_{A_j})^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j}}{\min_j \nu_{A_j}^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)} \lambda_j}} \tag{C.5}$$

So, we can derive the following:

$$\begin{aligned}
& \frac{\prod_{j=1}^m \left(2 - \max_j v_{A_j}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}}{\prod_{j=1}^m \max_j v_{A_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}} \leq \frac{\prod_{j=1}^m \left(2 - v_{A_j}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}}{\prod_{j=1}^m v_{A_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}} \leq \frac{\prod_{j=1}^m \left(2 - \min_j v_{A_j}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}}{\prod_{j=1}^m \min_j v_{A_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}} \\
& \Leftrightarrow \frac{2 - \max_j v_{A_j}}{\max_j v_{A_j}} \leq \frac{\prod_{j=1}^m \left(2 - v_{A_j}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}}{\prod_{j=1}^m v_{A_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}} \leq \frac{2 - \min_j v_{A_j}}{\min_j v_{A_j}} \tag{C.6} \\
& \Leftrightarrow \frac{2}{\max_j v_{A_j}} \leq \frac{\prod_{j=1}^m \left(2 - v_{A_j}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}}{\prod_{j=1}^m v_{A_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}} + 1 \leq \frac{2}{\min_j v_{A_j}} \\
& \Leftrightarrow \min_j v_{A_j} \leq \frac{2 \prod_{j=1}^m v_{A_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}}{\prod_{j=1}^m \left(2 - v_{A_j}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j} + \prod_{j=1}^m v_{A_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}} \leq \max_j v_{A_j}.
\end{aligned}$$

Similarly, we have as follows:

$$\min_j \gamma_{A_j} \leq \frac{2 \prod_{j=1}^m \gamma_{A_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}}{\prod_{j=1}^m \left(2 - \gamma_{A_j}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j} + \prod_{j=1}^m \gamma_{A_j}^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^n \omega_{\varepsilon(j)}\lambda_j}} \leq \max_j \gamma_{A_j}. \tag{C.7}$$

According to Definition 4, we can have  $A_{\min} \subseteq A \subseteq A_{\max}$ .

### (3) Monotonicity

Let  $A_j^1 = (\mu_{A_j}^1, \nu_{A_j}^1, \gamma_{A_j}^1)$  and  $A_j^2 = (\mu_{A_j}^2, \nu_{A_j}^2, \gamma_{A_j}^2)$  be two collections of PFVs, and  $\mu_{A_j}^1 \leq \mu_{A_j}^2$ ,  $\nu_{A_j}^1 \geq \nu_{A_j}^2$ , and  $\gamma_{A_j}^1 \geq \gamma_{A_j}^2$ . Let  $\text{PFEHWA}_{\omega, \lambda}(A_1^1, A_2^1, \dots, A_m^1) = A^1 = (\mu_{A^1}, \nu_{A^1}, \gamma_{A^1})$  and  $\text{PFEHWA}_{\omega, \lambda}(A_1^2, A_2^2, \dots, A_m^2) = A^2 = (\mu_{A^2}, \nu_{A^2}, \gamma_{A^2})$ . Let  $f(x) = (1+x)/(1-x)$ ,  $x \in [0, 1]$ ,  $\alpha \in [0, 1]$ . Thus,  $f(x)$  is an increasing function. If  $\mu_{A_j}^1 \leq \mu_{A_j}^2$  for all  $j$ , then  $f(\mu_{A_j}^1) \leq f(\mu_{A_j}^2)$ , i.e.,  $(1 + \mu_{A_j}^1)/(1 - \mu_{A_j}^1) \leq (1 + \mu_{A_j}^2)/(1 - \mu_{A_j}^2)$ . Let  $\alpha = \omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j$ . Therefore, we have as follows:

$$\begin{aligned}
& \frac{\prod_{i=1}^m \left(1 + \mu_{A_j}^1\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}}{\prod_{i=1}^m \left(1 - \mu_{A_j}^1\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}} \leq \frac{\prod_{i=1}^m \left(1 + \mu_{A_j}^2\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}}{\prod_{i=1}^m \left(1 - \mu_{A_j}^2\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}} \\
& \Leftrightarrow 1 + \frac{\prod_{i=1}^m \left(1 + \mu_{A_j}^1\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}}{\prod_{i=1}^m \left(1 - \mu_{A_j}^1\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}} \leq 1 + \frac{\prod_{i=1}^m \left(1 + \mu_{A_j}^2\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}}{\prod_{i=1}^m \left(1 - \mu_{A_j}^2\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}} \tag{C.8}
\end{aligned}$$

So, we can derive the following:

$$\begin{aligned}
& \Leftrightarrow \frac{2}{1 + \prod_{i=1}^m \left(1 + \mu_{A_j}^2\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j} / \prod_{i=1}^m \left(1 - \mu_{A_j}^2\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}} \\
& \leq \frac{2}{1 + \prod_{i=1}^m \left(1 + \mu_{A_j}^1\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j} / \prod_{i=1}^m \left(1 - \mu_{A_j}^1\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}} \\
& \Leftrightarrow 1 - \frac{2}{1 + \prod_{i=1}^m \left(1 + \mu_{A_j}^1\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j} / \prod_{i=1}^m \left(1 - \mu_{A_j}^1\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}} \\
& \leq 1 - \frac{2}{1 + \prod_{i=1}^m \left(1 + \mu_{A_j}^2\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j} / \prod_{i=1}^m \left(1 - \mu_{A_j}^2\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}} \tag{C.9} \\
& \Leftrightarrow \frac{\prod_{i=1}^m \left(1 + \mu_{A_j}^1\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j} - \prod_{i=1}^m \left(1 - \mu_{A_j}^1\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}}{\prod_{i=1}^m \left(1 + \mu_{A_j}^1\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j} + \prod_{i=1}^m \left(1 - \mu_{A_j}^1\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}} \\
& \leq \frac{\prod_{i=1}^m \left(1 + \mu_{A_j}^2\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j} - \prod_{i=1}^m \left(1 - \mu_{A_j}^2\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}}{\prod_{i=1}^m \left(1 + \mu_{A_j}^2\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j} + \prod_{i=1}^m \left(1 - \mu_{A_j}^2\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}} \\
& \Leftrightarrow \mu_{A^1} \leq \mu_{A^2}.
\end{aligned}$$

Let  $g(y) = (2 - y)/y$ ,  $y \in [0, 1]$ ,  $\alpha \in [0, 1]$ . Moreover, thus  $g(y)$  is an increasing function. Since  $\nu_{A_j^1} \geq \nu_{A_j^2}$  for all  $j$ , then  $g(\nu_{A_j^1}) \leq g(\nu_{A_j^2})$ , i.e.,  $(2 - \nu_{A_j^1})/\nu_{A_j^1} \leq (2 - \nu_{A_j^2})/\nu_{A_j^2}$ . Let

$\alpha = \omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j$ . According to equation (20), we have as follows:

$$\begin{aligned}
& \left(2 - \nu_{A_j^1}/\nu_{A_j^1}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j} \leq \left(2 - \nu_{A_j^2}/\nu_{A_j^2}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j} \\
& \Leftrightarrow \prod_{j=1}^m \left(2 - \nu_{A_j^1}/\nu_{A_j^1}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j} \leq \prod_{j=1}^m \left(2 - \nu_{A_j^2}/\nu_{A_j^2}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j} \\
& \Leftrightarrow 1 + \prod_{j=1}^m \left(2 - \nu_{A_j^1}/\nu_{A_j^1}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j} \leq 1 + \prod_{j=1}^m \left(2 - \nu_{A_j^2}/\nu_{A_j^2}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j} \\
& \Leftrightarrow \frac{2}{1 + \prod_{j=1}^m \left(2 - \nu_{A_j^2}/\nu_{A_j^2}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}} \leq \frac{2}{1 + \prod_{j=1}^m \left(2 - \nu_{A_j^1}/\nu_{A_j^1}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}} \\
& \Leftrightarrow \frac{\prod_{j=1}^m \left(\nu_{A_j^2}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}}{\prod_{j=1}^m \left(2 - \nu_{A_j^2}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j} + \prod_{j=1}^m \left(\nu_{A_j^2}\right)^{\omega_{\varepsilon(j)}\lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)}\lambda_j}}
\end{aligned}$$

$$\begin{aligned} & \frac{\prod_{j=1}^m \left( \nu_{A_j^1} \right)^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j}}{\prod_{j=1}^m \left( 2 - \nu_{A_j^1} \right)^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j} + \prod_{j=1}^m \left( \nu_{A_j^1} \right)^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j}} \\ & \Leftrightarrow \nu_{A_j^2} \leq \nu_{A_j^1}. \end{aligned} \quad (\text{C.10})$$

Similarly, we have the following:

$$\begin{aligned} & \frac{\prod_{j=1}^m \left( \gamma_{A_j^2} \right)^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j}}{\prod_{j=1}^m \left( 2 - \gamma_{A_j^2} \right)^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j} + \prod_{j=1}^m \left( \gamma_{A_j^2} \right)^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j}} \\ & \leq \frac{\prod_{j=1}^m \left( \gamma_{A_j^1} \right)^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j}}{\prod_{j=1}^m \left( 2 - \gamma_{A_j^1} \right)^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j} + \prod_{j=1}^m \left( \gamma_{A_j^1} \right)^{\omega_{\varepsilon(j)} \lambda_j / \sum_{j=1}^m \omega_{\varepsilon(j)} \lambda_j}} \\ & \Leftrightarrow \gamma_{A_j^2} \leq \gamma_{A_j^1}. \end{aligned} \quad (\text{C.11})$$

According to Definition 4, we have  $A^1 \subseteq A^2$ , which completes the proof of Theorem 5.  $\square$

## Data Availability

The data used to support the findings of this study are included within the article.

## Conflicts of Interest

The author declares that there are no conflicts of interest regarding the publication of this paper.

To investigate the effectiveness of identifying patients with Parkinson's disease (PD) from speech signals, various acoustic parameters including prosodic and segmental features are extracted from speech and then the random forest classification (RF) algorithm based on these acoustic parameters is applied to diagnose early-stage PD patients. To validate the proposed method of RF algorithm in early-stage PD identification, this study compares the accuracy rate of RF with that of neurologists' judgments based on auditory test outcomes, and the results clearly show the superiority of the proposed method over its rival. Random forest algorithm based on speech can improve the accuracy of patients' identification, which provides an efficient auxiliary method in the early diagnosis of PD patients.

## 1. Introduction

Parkinson's disease (PD) is a progressive neurodegenerative disease with ambiguous etiology. Although the exact reason is still unknown, the riskiest factor of PD is age, which causes the prevalence rate of PD to increase with the increase of age. The main pathological changes in patients with PD are the death and loss of dopaminergic neurons in the substantia nigra pars compacta which is irreversible. It means that patients with PD will never be cured, but anti-Parkinson's medication or deep brain stimulation surgery can slow down the progression of the disease [1]. So, early detection, early intervention, and early treatment of PD patients are essential to alleviate their pain and the burden of their families.

Patients with PD are usually diagnosed based on clinical symptoms (e.g., rest tremor, rigidity, and bradykinesia). In addition to traditional clinical symptoms, neuroimaging, genetic, and biochemical studies are applied for early detection of PD, whereas no reliable biomarkers can be used as the only valid criterion. Consequently, patients that are underdiagnosed and misdiagnosed are common [2]. A single biomarker is insufficient for the PD diagnosis, and a variety of methods need to be combined.

Speech characteristics that can serve as a novel clinical biomarker for PD diagnosis have been noticed by researchers. A longitudinal study has shown that the disturbance of speech acoustic parameters in Parkinson's disease (atypical range and variance of the fundamental frequency) occurs approximately 5 years before the onset of clinical symptoms [3]. Other related studies mainly focus on the speech differences between PD and healthy speakers which manifest in multiple speech subsystems, including phonation, articulation, and prosody, which can be used to distinguish PD patients from healthy adults [4].

Although speech disorder may be an early sign of PD, it is usually ignored by patients themselves and their caregivers [5, 6]. So, investigating the speech characteristics in PD patients, especially for patients in their early stages, is vital to early diagnosis of PD patients. Nevertheless, few studies have reported the contributions of speech features in the identification of PD patients.

## 2. Literature Review

As stated by previous studies, changes in prosodic and segmental speech features of speech (e.g., speech rate and articulatory deficits) are among the early symptoms in PD

patients, whereas the difference in phonation features of Parkinsonian and healthy speech is not significant [5,7]. So, prosodic and segmental features of PD speech are reviewed in the current study.

Less variability of fundamental frequency (F0) and narrower F0 range which are in close relation with monopitch or monotone is the most prominent feature of PD speech [8]. Previous studies have confirmed that F0 disorders in PD speakers exist not only in the prodromal stage but also in the later stage of the disease [7]. Ruzs et al. [9] reported that F0 variability is one of the most reliable acoustic indicators of Parkinson's disease. Studies targeting the relationship between acoustic features of PD speech and their motor symptoms show a significant negative correlation between F0 variability of parkinsonian speech and disease progression, with an explanation that the movement of vocal folds in PD patients is sensitive to reflect disease progression [10].

Deficits in speech timing are also observed in early PD speakers [11, 12]. Speech rate is affected by Parkinson's disease [13]. Compared to healthy speakers, PD patients speak at a faster or slower rate, showing a great individual variability [14]. Although speech rate has been used to study the pathological change in PD speech, its reliability to differentiate speakers with PD from healthy speakers remains uncertain. Rhythmic metrics play an important role in distinguishing pathological speech from normal speech. Liss et al. [15] stated for the first time that a set of rhythmic metrics (e.g., standard deviation of consonantal durations and proportion of vocalic durations) can be used to distinguish speakers with dysarthria from healthy individuals. In particular, Lowit et al. [12] found the proportion of vocalic durations in speech is a robust indicator of PD.

Studies of motor speech disorders have been focused on vowel production to investigate articulation impairments, and thus articulation deficits have been extensively studied in PD speakers. Vowel articulation impairment is considered an important marker for early-stage PD speakers [16, 17]. Various indices such as the ratio between the second formant of the vowels /i/ and /u/ ( $F2_i/F2_u$ ), vowel space area (VSA), and vowel articulation index (VAI) are used to characterize vowel articulation in previous studies; however, these studies show inconsistent results. Several studies show that VSA is less reliable than VAI in identifying PD speakers suffering from mild dysarthria [17–19], while other studies conclude that both VAI and VSA can identify articulation disorders of PD speakers [16].

Inconsistent results are also observed for stops in the PD speech. Longer voice onset times (VOTs) of consonants have been observed in PD speech [20, 21]. On the other hand, Ackermann and Ziegler [22] and Kim [23] found that stops have shorter VOTs in PD speech. Moreover, a recent study has found that there is no significant difference in VOT between speakers with PD and healthy individuals [24].

Although acoustic differences in speech between individuals with PD and healthy speakers are well documented, little is known about which acoustic features are the most important in distinguishing PD patients, in particular early-stage ones, from healthy adults. In contrast, neurologists

usually use clinical scales such as the United Parkinson's Disease Rating Scale [25], which however is subjective and may mislead their judgments of PD patients.

Therefore, this study focuses on two questions. First, which metrics are the most important in differentiating PD from healthy speakers? Second, is automatic classification more advantageous in identifying PD patients than auditory perception? To investigate these two questions, the machine learning algorithm based on both prosodic and segmental features of speech is used to explore the relative contributions of acoustic features and the accuracy rate of early-stage PD identification. Then, neurologists are recruited to judge whether the speaker is a PD patient or not after they hear the reading speech. The accuracy rate is compared with that of automatic classification.

### 3. Methods

To solve the two problems raised above, this study recruited PD patients in early stages and recorded their reading speech in quiet rooms (noise < 50 dB). Based on the reading speech, several acoustic metrics of speech are extracted. All speech data are divided into two sets, i.e., training set and testing set. Using random forest classification, we explored the accuracy rate of classification of early-stage PD patients and the relative contributions of these acoustic metrics to the classification. The framework of this study is shown in Figure 1.

**3.1. Participants and Materials.** To minimize the effects of dialects and special speaking styles on acoustic results, speakers who spoke with an accent or spoke in an unusual way were screened out [26]. So, thirty-six individuals with idiopathic PD (19 men and 17 women) aged 52 to 78 years (mean = 63.55, SD = 9.46) were recruited as the PD group. The Hoehn and Yahr score of PD was between 1 and 2.5, and the disease duration was less than 5 years, which meant that all patients were in the early stage of PD [27]. None of the patients had suffered from other diseases or had undergone deep brain stimulation surgery. All participants were native Mandarin speakers and scored at least 24 on the Mini-Mental State Exam.

Speech task is an important factor in voice disorder investigation [11, 28]. According to previous studies, passage reading is the optimum task to explore PD speech compared with sustained vowels and fast syllable repetition [21, 29], so passage reading is used in the current study. Before speech recording, the participants were instructed to read silently the passage *The North Wind and the Sun*, which consisted of 169 syllables in Mandarin. Then, all participants read the passage in a quiet room and speech was recorded using a Zoom H4n portable recorder at a sampling rate of 44100 Hz. The English translation of this passage is shown below.

The North Wind and the Sun were disputing which was the strongest, when a traveller came along wrapped in a warm cloak. They agreed that the one who first succeeded in making the traveller take his cloak off should be considered stronger than the other. Then, the North Wind blew as hard as he could, but the more he blew, the more closely did the

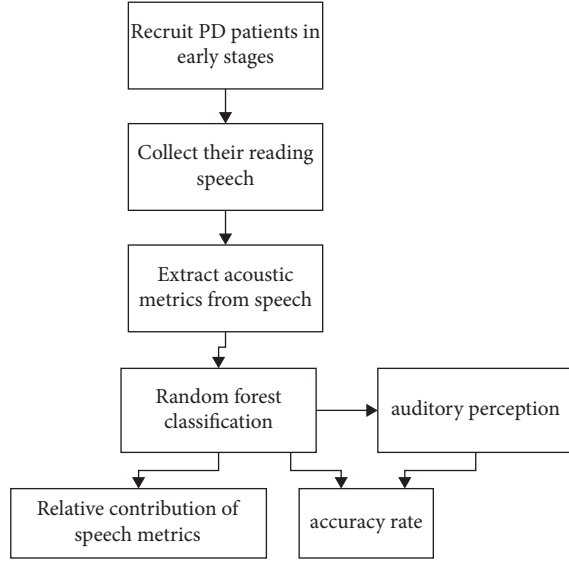

FIGURE 1: Framework of this study.

traveller fold his cloak around him, and at last the North Wind gave up the attempt. Then, the Sun shined out warmly, and immediately the traveller took off his cloak, and so the North Wind was obliged to confess that the Sun was the strongest of the two.

To avoid the influence of anti-Parkinson medication on speech production, speakers of PD stopped taking medication and were in a fasting state for at least 12 hours before the speech recording.

**3.2. Acoustic Measures.** Acoustic analysis was conducted on two aspects of acoustic measures. One aspect was the prosodic feature (fundamental frequency parameters, speech rate, and rhythm), and the other was the segmental feature (formants of vowels and voice onset time of stops). Details of the 13 acoustic measures are described below.

The measures of the fundamental frequency ( $F0$ ) were extracted from the Praat software. The autocorrelation algorithm in Praat generated  $F0$  tracks for every speech sample, and then gross  $F0$  errors were manually corrected according to the waveform and spectrogram. Five  $F0$  parameters were calculated from the  $F0$  tracks, namely, the minimum ( $F0_{\min}$ ), maximum ( $F0_{\max}$ ), mean ( $F0_{\text{mean}}$ ),

range (difference between  $F0_{\min}$  and  $F0_{\max}$ ,  $F0_{\text{range}}$ ), and standard deviation of  $F0$  ( $F0_{\text{std}}$ ). All  $F0$  values were converted from Hz to semitones (St) with 50 Hz as the reference frequency. The formula is as follows (fr is the  $F0$  value in Hz).

$$\text{St} = 12 \times \log_2\left(\frac{\text{fr}}{50}\right). \quad (1)$$

Both speech rate and articulation rate were calculated. Speech rate was defined as the total number of syllables divided by the total speech duration, and articulation rate was defined as the total syllables divided by the articulation duration. Pauses longer than 200 ms were marked and excluded from the measurement of articulation rate [30].

$$\text{Speech rate} = \frac{\text{the numbers of syllables}}{\text{total speech duration}},$$

$$\text{articulation rate} = \frac{\text{the number of syllables}}{\text{total speech duration} - \text{pause duration}}. \quad (2)$$

Among the rhythmic parameters commonly used to distinguish different types of language [31], proportion of vowel vocalic durations in speech (%V) was reported to be effective in identifying speakers with brain injury and Parkinson's disease as reported [12, 32], so %V was investigated as a rhythmic measure in this research.

$$\%V = \frac{\text{vocalic duration}}{\text{total speech duration}} \times 100\%. \quad (3)$$

Vowel articulation was measured by the ratio of the second formants of the vowels /i/ and /u/ ( $F2i/F2u$ ), and the triangular vowel space area (tVSA) and the vowel articulation index (VAI) were based on the corner vowels /a, i, u/ in the speech sample. The middle 60% interval of the whole vowel was extracted from the monosyllables containing these three vowels to obtain the stable values of the first and second formants ( $F1$  and  $F2$ ) of these three vowels. tVSA with unit  $\text{Hz}^2$  has been widely used to measure the distribution of vowels, and VAI has been associated with the concentration or dispersion of vowels. The more concentrated the vowels, the smaller the VAI (the minimum of VAI is 0.5). The formulas for tVSA and VAI are as follows [17]:

$$\text{tVSA} = \text{ABS} \left\{ \frac{[F1[i] \times (F2[a] - F2[u]) + F1[a] \times (F2[u] - F2[i]) + F1[u] \times (F2[i] - F2[a])]}{2} \right\}, \quad (4)$$

$$\text{VAI} = \frac{F2[i] + F1[a]}{F1[i] + F1[u] + F2[u] + F2[a]}.$$

Voice onset time (VOT) of stops reflects the precise time coordination between the movements of the supra laryngeal articulators (such as lips and tongue) and the vocal folds. In this study, the VOTs of the post-pausal stops

/p, p<sup>h</sup>, t, t<sup>h</sup>, k/ were compared between the two groups. Considering that speech rate has a direct impact on VOT, a normalized parameter, VOT ratio, was used in this study [24].

$$\text{VOT ratio} = \frac{\text{VOT}}{\text{syllable duration}} \times 100\%. \quad (5)$$

Because VOT is longer for aspirated stops than for unaspirated stops in Mandarin, the VOT ratios of post-pausal stops were calculated for aspirated  $/p^h, t^h/$  and unaspirated  $/p, t, k/$  (hence VOT ratio\_un and VOT ratio\_as), respectively. All the 13 acoustic measures are summarized in Table 1.

**3.3. Random Forest Classification.** Based on all these acoustic parameters, a random forest classification in R [33] was used to investigate the contribution of these acoustic parameters to the classification of PD individuals and healthy controls.

First, the minimum value of the mean error rate of the model was calculated based on out-of-bag (OOB) data, and the optimal number of variables of the binary tree in the node “mtry” was set to 3 in the package randomForest. Since the model error tends to converge when the number of decision trees approaches 500, the optimal number of decision trees nTree was set to 500. Among the experimental data, 70% were randomly selected as the training set and the remaining 30% were selected as the test set. Finally, the accuracy, sensitivity, and specificity were calculated.

**3.4. Auditory Perception Test.** To compare the effectiveness of acoustic classification and the auditory judgment by neurologists, an auditory perception test was performed.

An utterance of the following sentence for about 10 seconds: “They agreed that the one who first succeeded in making the traveller take his cloak off should be considered stronger than the other,” was selected from speech recording from each participant, so that 36 stimuli were collected as auditory stimuli. Five neurologists who had been working in the department of neurology for at least 2 years were recruited in the auditory perception test. All five listeners had rich clinical experience in the assessment of patients with PD, but they were unaware of the purpose of the study.

After the intensity was normalized to 70 dB using the Praat software, all 36 speech stimuli were played back in a random order to the listeners through earphones in a quiet room. The following prompt was displayed on the computer screen: “Please judge from the speech you heard whether the speaker is a patient with PD.” Then, after each speech stimulus was played back, two options appeared on the computer screen: “PD patients” and “healthy persons.” Listeners clicked the mouse to complete the forced choice.

## 4. Results

**4.1. Results of Random Forest Classification.** The results based on 13 acoustic measures showed that the classification accuracy of the random forest algorithm was 75.6%, and the sensitivity and specificity were 66.7% and 84.6%, respectively.

Figure 2 shows the importance of all 13 acoustic measures in distinguishing PD patients from healthy controls.

TABLE 1: Acoustic measures extracted from speech.

Acoustic measure	Type of feature
F0min (St)	Prosody
F0max (St)	
F0mean (St)	
F0range (St)	
F0std (St)	
Articulation rate (syl/s)	
Speech rate (syl/s)	
%V	Segments
F2i/F2u	
tVSA (kHz <sup>2</sup> )	
VAI	
VOT ratio_un	
VOT ratio_as	

The most important measures in identifying speakers with early PD were F0std, F2i/F2u, F0 range, and VAI.

**4.2. Results of Auditory Perception Test.** The perceptual accuracy of five neurologists ranged from 61.1% to 68.1%, with a mean accuracy of 64.2%, which was lower than the accuracy of random forest classification (75.6%).

## 5. Discussion

Speech disorders have been well documented in previous studies, whereas the current study focuses on the contributions of prosodic and segmental features of early PD speakers and the superiority of acoustic classification using the random forest algorithm to clinical auditory judgments.

The random forest classification based on 13 acoustic measures including both prosodic and segmental features showed that the most important measures in identifying early PD speakers were F0std, F2i/F2u, F0 range, and VAI. Among these 4 acoustic measures, F0std and F0 range were prosodic features while F2i/F2u and VAI were segmental features. The smaller F0 range and F0 variability (F0std) in the early-stage PD speakers suggested their less expressive pitch variation, consequently resulting in monotone as previous studies reported [3, 9]. Although previous studies reported that either F0 parameters or vowel articulation played roles in distinguishing PD from healthy speakers [9, 17], the current study further showed that both F0 and vowel articulation were important in identifying individuals with early PD.

The identification accuracy of speakers with early-stage PD was 75.6%, which was higher than that of auditory assessment by neurologists. Therefore, this objective algorithm could be an effective auxiliary method for neurologists to identify speech disorders in early-stage patients with PD that were not easily perceptible.

It should be noted that the accuracy of identifying speakers with early PD based only on acoustic measures was 75.6%, still far away from being perfect. There were two possible reasons. First, not all speakers with early PD had speech disorders. Second, in addition to these acoustic measures we investigated here, some other parameters may

FIGURE 2: Importance of acoustic measures.

also play roles in distinguishing early PD patients from healthy individuals. Therefore, our future study will explore more acoustic metrics and conduct multiple tasks, e.g., monologue and dialogue, to make a better identification of early-stage PD.

## 6. Conclusion

Random forest classification algorithm based on acoustic measures, especially fundamental frequency and vowel articulation, can be an auxiliary method to identify early-stage PD. There are diverse early biomarkers of PD such as clinical symptoms and neuroimages. However, the value of a single biomarker for early diagnosis is limited, and a variety of methods can be combined to improve the accuracy of diagnosis. The result of our research shows that a classification model based on speech acoustic parameters can provide a more economical, convenient, and effective way for early diagnosis, accurate assessment, and remote monitoring of PD patients. Nevertheless, acoustic parameters extracted from reading speech in this study are not yet comprehensive, and more acoustic features and multiple speech tasks should be considered in future studies.

With the increasing interest devoted to dynamic environments, a crucial aspect is revealed in context-aware systems to deal with the rapid changes occurring in users' surrounding environments at runtime. However, most context-aware systems with predefined context-aware rules may not support effective decision-making in dynamic environments. These context-aware rules, which take into account different context information to reach an appropriate decision, could lose their efficiency at runtime. Therefore, a growing need is emerging to address the decision-making issue leveraged by dynamic environments. To tackle this issue, we present an approach that relies on improving decision-making in the wake of dynamic environments through automatically enriching a rule knowledge base with new context-aware rules discovered at runtime. The major features of the presented approach are as follows: (i) a hybridization of two machine learning algorithms for rule generation, (ii) an extended genetic algorithm (GA) for rule optimization, and (iii) a rule transformation for the knowledge base enrichment in an automated manner. Furthermore, extensive experiments on different datasets are performed to assess the effectiveness of the presented approach. The obtained experimental results depict that this approach exhibits better effectiveness compared to some algorithms and state-of-the-art works.

## 1. Introduction

In context-aware computing, there exists a shift from static environments to dynamic environments [1]. This shift reflects a growing interest devoted to dynamic environments. With the growing interest, a crucial need is revealed for context-aware systems to be aware of and to adapt to their changing contexts in highly dynamic environments at runtime [2]. To support this need, a grand challenge is that context-aware systems should adjust their behaviors to the dynamics entailed in their surrounding environments at runtime. In order to meet this challenge, a decision-making process improvement by providing appropriate services to users situated in highly changing environments has emerged to make context-aware systems more resilient to dynamic environments at runtime. Nevertheless, at present, most

context-aware systems usually work well in static environments with predefined context-aware rules that can only behave to changes in environment attributes and context information [3]. They can handle neither dynamic environments nor context changes at runtime since predefined rules might not be suitable for the dynamic nature of environments. On that account, rules need to be constantly evolved to remain relevant over time [4]. This raises more attention to be paid to how to enrich a rule knowledge base through the generation of efficient rules to timely react to arising environment changes at runtime. As data mining and specifically machine learning could be more accurate for profiting better rules [5], exploring recent advances in the application of machine learning might be beneficial in offering a way to learn and generate a set of nonredundant rules that are easily comprehensible and are capable of

representing contextual knowledge in a very clear and efficient way.

To achieve this sustained attention, we propose, in this work, an approach that aims to automatically improve the decision-making process to support dynamic environments at runtime. The main feature of the proposed approach is to offer a rule knowledge base, where context-aware rules are fluid and evolutive at runtime for alleviating the burden of manually creating rules to react toward users' environment changes. The novelty and contribution of this approach could be drawn from threefold: first, we present a novel hybrid learning approach toward effectively generating a concise set of nonredundant association rules in an automated fashion by applying two learning algorithms. We hybridize machine learning algorithms to generate a more accurate and complete set of rules, to avoid redundancy, and to build a strong rule knowledge base in a context-aware system, in which we are interested. Second, we extend a genetic algorithm (GA) [6] with a multianalysis technique in the direction of rule optimization. The rule optimization is applied to find the well-performed rules from the generated rules since machine learning algorithms are not much proficient at optimizing rules. Third, we introduce an automatic transformation of obtained association rules to rules expressed in Jena [7]. Rule transformation is performed to express the well-performed rules in such a way that they can run over an ontology-based context model and a context-aware system can reason. Moreover, we conduct a range of experiments to assess the effectiveness of the proposed approach on different datasets from the UCI Machine Learning Repository [8]. First, we compare the proposed approach with the traditional association rule mining algorithms to analyze the number of generated rules. Then, we evaluate the performance of the proposed approach with the most common machine learning algorithms and certain state-of-the-art works. Finally, we analyze the computational time of the proposed approach and the machine learning algorithms. The provided results prove the effectiveness of the proposed approach by achieving the best result in terms of the number of rules, precision, recall, and accuracy among certain state-of-the-art works and algorithms such as apriori, FP growth, K-nearest neighbor, Naïve Bayes, JRip, and decision table.

The rest of this study is arranged as follows. We review the related work in Section 2. In Section 3, we introduce the proposed approach and outline the overall architecture and modules in detail. We present the experimental setup and the results obtained with an example of generated context-aware rules in Section 4. In Section 5, we illustrate the discussion of the results. Finally, we draw conclusions and highlight the direction for future work in Section 6.

## 2. Related Work

Data mining, especially machine learning and association rule mining, algorithms play a vital role in rule discovery from data. By searching through the literature, there is an extensive research basis to support association rule discovery from data to tackle the challenge of the decision-making

improvement. In the following, we review first some works for discovering rules within the area of context awareness. Then, we provide a discussion to highlight the research gaps that motivate us to propose our approach.

A large number of works for association rule learning have been introduced using association rule mining algorithms. In this sense, Gabroveanu and Diaconescu [9] proposed a recommender system for students. They used data obtained from the learning database and apriori as an association rule mining algorithm in order to identify strong association rules for students. Then, these rules, obtained in an offline mining process, are translated into Jena rules to allow reasoning over RDF models. In addition, Kaliappan and Sai [10] presented a new modified apriori algorithm for finding the association rules among large datasets to promote sales and user interaction. They showed that the proposed algorithm improved the efficiency of generating association rules. Moreover, Davagdorj and Ryu [11] offered an association rule mining method to discover useful patterns, which include medical knowledge, from a medical dataset. They applied the FP growth algorithm to extract a set of association rules. Then, the obtained rules are used to support medical decision-making for interpreting diagnosing patient information. Furthermore, Asadianfam et al. [12] introduced a new approach to improve recommendations that can be used to predict the next navigable page of users. One of the objectives considered in their approach is to provide appropriate recommendations to users who have different profiles from the existing users' profiles. To deal with the objective, the authors used the apriori algorithm to generate association rules from users' behaviors and then made appropriate recommendations. They showed that the generated association rules could increase the overall efficiency of the recommender system. More recently, Miswan et al. [13] proposed a framework of association rule mining in readmission tasks. The proposed framework consisted of two processes, namely, data preprocessing and rule mining extraction. Apriori algorithm is used to extract the hidden input variable patterns and relationships among admitted patients by generating supervised learning rules. The mined rules are discussed and validated by the domain expert, which is a valuable guide in making decisions on targeted patients' clinical resources based on various readmission durations.

Apart from these works, there are also few works exploring the association rule learning using machine learning algorithms. In this context, Hong et al. [14] proposed an agent-based framework for offering personalized services utilizing the extracting users' preferences and association rules. The decision tree algorithm is considered to infer association rules for recommending personalized services for users. Similarly, Zulkernain et al. [15] introduced an intelligent mobile interruption management system. The main idea of their proposed system is to intelligently assist users in their daily activities. To this end, a decision tree algorithm is used to make intelligent decisions. Moreover, Sarker [16] presented an association rule learning approach that can be used to discover a set of nonredundant and useful rules. In their approach, they considered, first, the Naïve

Bayes (NB) algorithm to eliminate noise from data and, second, the decision tree algorithm to generate a set of association rules. These algorithms are used to build a robust prediction model that could improve the prediction accuracy. Finally, Basha [17] provided a cardiovascular prediction system that combines the traditional K-nearest neighbor (KNN) algorithm with a GA to extract strong association rules for facilitating the decision-making process. First, the proposed system extracts association rules using the KNN algorithm. Then, the output rules become the population of the GA to remove redundant and irrelevant rules.

Nevertheless, a common weakness that can be found in the majority of discussed works [9–13] mainly stands in the use of traditional association rule mining algorithms, such as FP growth and apriori. This weakness is caused by the narrow applicability of these algorithms due to the huge number of association rules generated [18]. However, these works generate numerous redundant association rules, which lead to generating a huge number of uninteresting rules that become useless in making decisions. This redundant generation makes not only the rule set unnecessarily large but also makes the decision-making process more complex and ineffective. Therefore, the traditional association rule mining algorithms are not able to efficiently extract interesting association rules. Instead, employing machine learning algorithms can overcome this weakness and avoid rule redundancy and conflicts in the mining process. Despite that, in many cases, works based on machine learning algorithms [14–17] could not ensure high accuracy in generating association rules [19]. Furthermore, a limitation in some of these works [9, 13] is that they are only suitable for offline mining and not suitable for dynamic environments where new incoming changes are continuously received at runtime and so decisions may be wrongly predicted based on rules defined a priori. A further important limitation is that certain works like the work of Miswan et al. [13] require domain expert intervention to validate generated association rules. Following the above discussion, we aim to close gaps within the discussed works by proposing an approach that relies on automatically enriching a rule knowledge base with new context-aware rules generated at runtime to perform an efficient decision-making for dynamic environments. The proposed approach focuses on discovering and generating nonredundant and well-performed association rules through the use of machine learning algorithms along with an extended GA to reduce rule redundancy. To address the decision-making accuracy question, the proposed approach represents a hybridization idea that combines the strengths of two supervised machine learning algorithms, the decision tree, and the random tree algorithms. Moreover, it proceeds for a rule transformation to support the automatic enrichment of rule knowledge bases at runtime.

### 3. Proposed Approach

In this work, we propose an approach that supports the improvement of decision-making in dynamic environments

at runtime by allowing an automatic enrichment of a rule knowledge base with new generated context-aware rules. The proposed approach first aims to generate a concise set of nonredundant association rules following the IF-THEN structure, then to optimize the generated rules, and finally to transform rules to Jena rules for enriching the rule knowledge base and providing appropriate services to users situated in dynamic environments at runtime. Figure 1 illustrates a schematic view of the proposed approach architecture.

As illustrated in Figure 1, the proposed approach typically consists of two main modules, namely, the rule generation module and the rule transformation module. In the following, we discuss these modules and their roles in generating association rules and transforming them into Jena rules.

*3.1. Rule Generation Module.* The rule generation module is designed to automatically derive association rules needed to meet the changes occurring in users' dynamic environments. That means, it aims to preprocess a candidate dataset, to generate decision trees, and to infer the well-performed association rules in order to further enrich a rule knowledge base and improve the decision-making process at runtime. The present module runs every time when new changes are arrived and a priori rules are deemed not relevant to these changes. This module is defined considering two main phases as shown in Figure 1.

*3.1.1. Association Rule Learning.* The association rule learning phase is in charge of learning and extracting association rules from a candidate dataset. This phase includes various steps starting from the preprocessing of the dataset to the validation of rules.

*(1) Dataset Preprocessing.* This represents the first step of the association rule learning phase, which is applied to improve the quality of the candidate dataset so as to ensure accurate, consistent, and complete generated decision trees and further association rules. This step is responsible for preparing data from the candidate dataset. Hence, two major stages during the data preprocessing step, namely, data cleaning and data reduction, are performed. The first stage comprises both operations like filling missing data and smoothing noisy data. It aims to replace missing data with the average of existing data, using different traditional imputation methods (i.e., mean and median). To smooth noisy data, we carry out techniques, such as clustering, regression, and binning, to eliminate the noise in the dataset as it rises due to random variation. The second stage is data reduction that is used to obtain a simplified representation of a dataset with relevant data. To do it in the simplest manner, we remove redundant and inconsistent data.

*(2) Learning-Based Rule Generation.* After the data preprocessing step is completed, the learning-based rule generation step takes place first to automatically learn training models for building decision trees, then to derive association

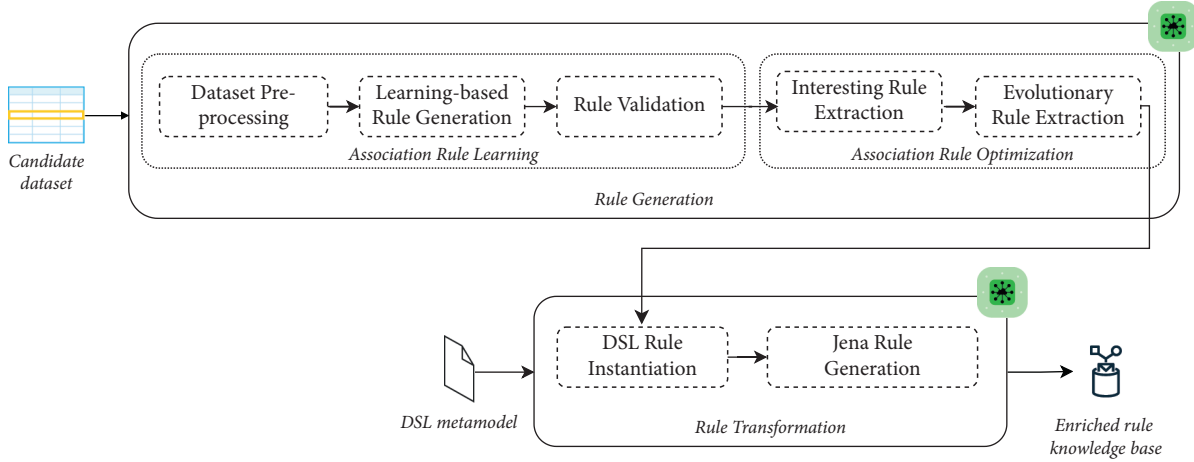

FIGURE 1: Proposed approach architecture.

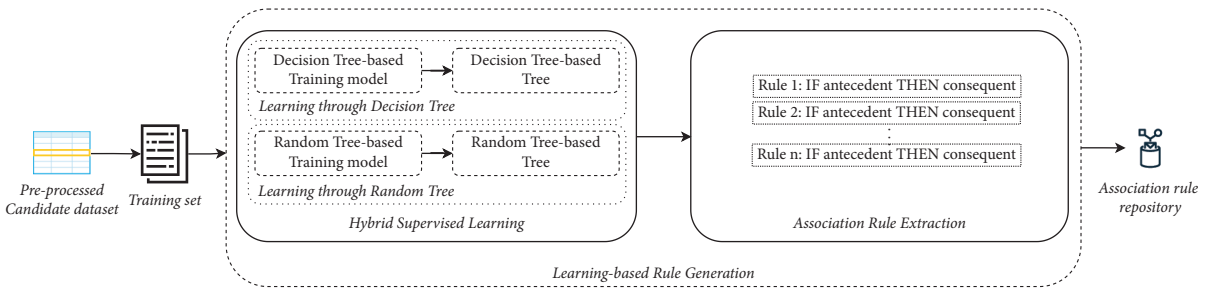

FIGURE 2: Learning-based rule generation step.

rules, and finally to integrate them into the association rule repository. To this end, the present step provides two elementary mechanisms. The main idea of these mechanisms can be simply described in Figure 2.

A first mechanism, called hybrid supervised learning, takes advantage of machine learning and pattern recognition in learning about data, extracting relevant relationships, and eliminating redundancy. Thus, it combines widely adopted supervised machine learning algorithms, namely, J48 decision tree [20] and random tree [21], to train the preprocessed dataset. As far as we know, this is the first time that J48 decision tree and random tree algorithms are combined to the association rule learning. To improve the accuracy of learning, we come up with the idea of hybridizing J48 decision tree and random tree algorithms as they are tree-based techniques that provide the highest accuracy diagram of a decision tree [22]. The resulting training models consist of a set of decisions in a tree structure, which could be utilized to generate rules from each leaf node [23]. As shown in Algorithm 1, this first mechanism trains the J48 decision tree to build the corresponding decision tree on the decision tree-based training model. Subsequently, it applies the random tree algorithm to get the second decision tree on the random tree-based training model.

The second mechanism, called association rule extraction, acquires association rules from previously trained decision trees. To do so, it tracks, in an automated fashion,

the path from the root node to each leaf node in both trees in order to detach the set of association rules.

The output of this mechanism is a set of association rules following IF-THEN statements: IF  $\langle A \rangle$  THEN  $\langle C \rangle$ , where the antecedent part  $\langle A \rangle$  represents user's surrounding contextual information such as temporal context, spatial context, social contexts, or others relevant contextual information, for example, "outlook = overcast," and the consequent part  $\langle C \rangle$  represents their corresponding behavioral activities for decision-making, for example, "play = yes."

(3) *Rule Validation*. After completing the generation step, the rule validation step is applied through the following methods:

- (i) Rule structure verification, which is responsible for checking whether extracted rules are preserving the inherent IF-THEN structure.
- (ii) Rule consistency verification, which is in charge of verifying the consistency of association rules. Given the fact that association rules are made up of antecedent constraints and a consequent constraint, the rule consistency is related to the satisfiability of constraints. To ensure a conflict-free association rule repository, a reasoner is used to enumerate all inconsistent rules, where the consequent constraint does not refer to the antecedent constraint.

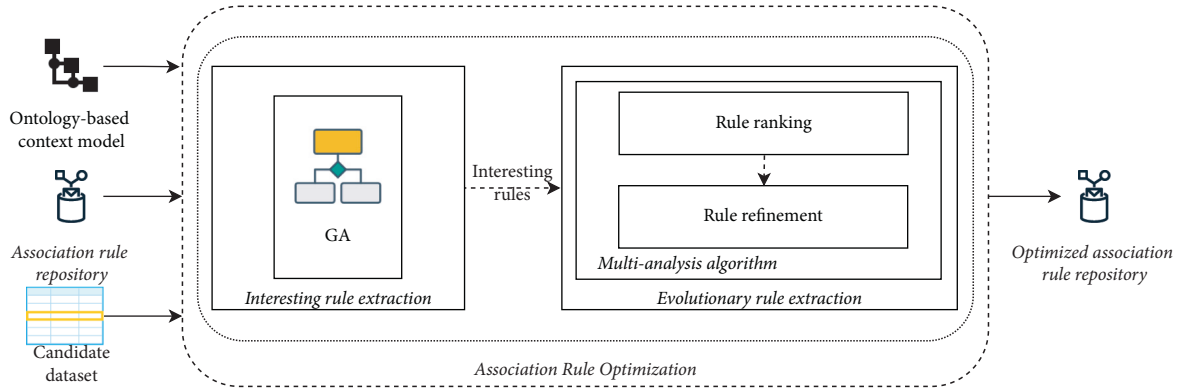

FIGURE 3: Rule optimization phase.

**3.1.2. Association Rule Optimization.** The association rule optimization is the second and last phase in the rule generation module. The present phase is in charge of identifying the well-performed rules from a set of earlier validated association rules. In this sense, a GA is extended to support a multianalysis technique. The main idea of extending a GA with a multianalysis technique is to optimize the set of association rules to find the well-performed rules by adopting the optimization strategies in GA. To be more precise, there are two main steps in this phase as depicted in Figure 3. First, the interesting rule extraction step is carried out using GA that is a kind of effective optimizing technique owing to the robust and global search ability [24]. Second, the evolutionary rule extraction step involves a multianalysis technique to extend the GA and extract the well-performed association rules.

*(1) Interesting Rule Extraction.* This step determines the interesting association rules by applying a GA to the candidate dataset. The GA is used to produce a strong level of association rules since supervised learning algorithms may generate irrelevant rules. The motivation behind this choice is twofold: first, the GA is one of the best methods for rule optimization [25], and second, it performs a global search technique to find out interesting rules with less complexity compared to other algorithms [26]. The GA creates an initial population as a collection of chromosomes, in which every chromosome represents an association rule. Then, it evolves the initial population over multiple generations through encoding, selection, crossover, and mutation operations to reach the optimal set of interesting association rules. In the end, it introduces a set of interesting association rules, which satisfies a fitness function. The flowchart of GA is shown in Figure 4.

The specific steps of the GA are as follows:

- (i) Step 1. Encoding step: The candidate dataset is encoded to initiate the experimentation of the GA. In our case, a binary encoding schema is used.
- (ii) Step 2. Initial population generation: An initial population of size  $K$  chromosomes is randomly generated as a set of solutions to be optimized. These chromosomes are a representation of the rules generated from the candidate dataset.

- (iii) Step 3. Calculating fitness: The fitness value of each chromosome in the population is calculated by a fitness function to find the association rules that their support and confidence are larger than other rules. To this end, a fitness function that has been described in the work of Qodmanan et al. [27] is considered as given in equation.

$$\text{fitness} = \frac{(1 + \text{supp}F(A \cup C))^2}{1 + \text{supp}(A)}. \quad (1)$$

In equation (1),  $\text{supp}(A \cup C)$  is the support of the  $A \rightarrow C$  and  $\text{supp}(A)$  is the support of the antecedent part of it.

- (iv) Step 4. Selection: A chromosome with a high fitness value is selected from the population on the basis of a fitness function.
- (v) Step 5. Crossover: The next generation of the population is generated based on the calculated fitness values. The idea behind crossover is to combine the two parent chromosomes to produce two new offspring. The result of crossover is the birth of two new chromosomes. Crossover is carried out according to a defined crossover probability.
- (vi) Step 6. Mutation: Mutation randomly changes chosen bits from 0 to 1 or from 1 to 0. It is applied to the new offspring with a certain mutation probability. The purpose is to maintain diversity among the different generations to increase the global optimization of the GA.
- (vii) Step 7: After a series of selection, crossover, and mutation, the GA is stopped when the generated chromosomes meet the optimality or the maximum number of generations. Otherwise, it turns back to step 3 to continue the rule optimization.

*(2) Evolutionary Rule Extraction.* In the previous step, the interesting association rules are selected. However, we cannot get the well-performed rules that could lead to achieve the appropriate decision-making performance due to the fact that the fitness function, defined in GA, might be

FIGURE 4: Flowchart of a GA.

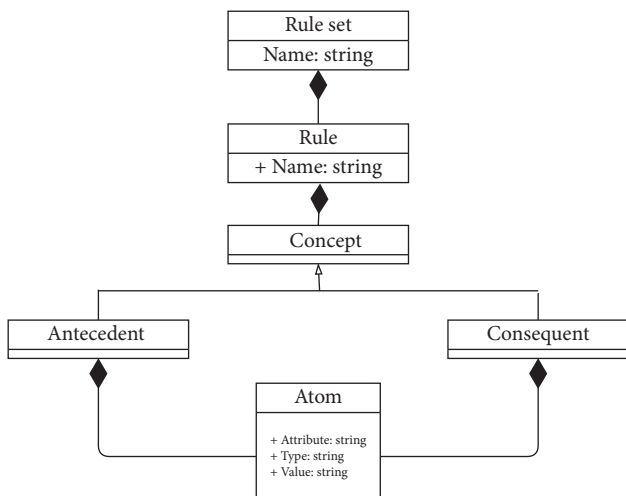

FIGURE 5: Jena rule definition metamodel.

in conflict. To deal with this issue, the evolutionary association rule step proposes a multianalysis technique for extending a GA in order to enhance the rule optimization

result. For that, rule ranking and refinement processes are applied as shown in Figure 3. The multianalysis technique starts with the rule-ranking process that is in charge of automatically analyzing and ranking the interesting association rules and the generated rules from supervised learning algorithms regarding their frequency of occurrence and their statistical information. In the proposed rule-ranking process, the rule occurrence frequency is considered as the highest priority to classify rules, followed by the statistical information, such as the fitness function weight. Then, the rule refinement process is performed to derive the set of well-performed rules. This process begins with finding a user who is related to generated rules, loading the user profile of the corresponding user from the ontology-based context model and inferring the well-performed rules that could significantly match with the profile.

**3.2. Rule Transformation Module.** The second module in the proposed approach is the rule transformation module since generating IF-THEN association rules is not enough. This module aims to obtain Jena rules from the well-performed

association rules in order to reason over an ontology-based context model and to infer high-level knowledge using the Jena inference engine. The motivation to opt for Jena is its built-in support for rule-based inference over RDF and OWL [28]. In this sense, the rule transformation keeps track of the well-performed association rule set, generated in the previous module, and transforms them into Jena rules according to the rule syntax of Jena. In the following, rules in Jena format induced from the well-performed association rules are loaded by the module into the rule knowledge base for an automatic enrichment purpose at runtime. The rule transformation module targets design time and runtime. At design time, a rule translation is ensured, where a metamodel for Jena rules is proposed to specify the abstract syntax of a Jena rule. Figure 5 shows the metamodel for Jena rules. A rule set consists of rules. A Jena rule has a name and is composed of concepts. A concept is interpreted as an antecedent and as consequent. Therefore, a Jena rule can contain one or more atoms in the antecedent part and only one atom in the consequent part. Each atom has an attribute, type, and value. Then, the proposed metamodel is translated into a domain-specific language (DSL) metamodel. The latter is defined as a textual structure using Xtext. A fragment of the DSL metamodel is depicted in Figure 6.

During runtime, the transformation module performs two paramount phases: (i) instantiation of the DSL metamodel and (ii) generation of the Jena rules on the basis of the DSL model as depicted in Figure 1.

**3.2.1. DSL Rule Instantiation.** The DSL rule instantiation phase is dedicated to introduce a DSL model, which is a formal rule specification of the defined DSL metamodel. The DSL model represents the well-performed obtained association rules. Here, the rule instantiation is automatically performed at runtime.

**3.2.2. Jena Rule Generation.** The Jena rule generation phase is considered for automatically generating the corresponding Jena rules based on the DSL model using Xtend as

a transformation language. Therefore, a set of Jena rules is generated from the DSL model while the semantic of the DSL metamodel is well-defined.

## 4. Experimental Results

In this experimental evaluation, we provide an example of generated rules by our proposed approach. In addition, we discuss the effectiveness of our proposed approach. For this, a range of experiments was carried out to investigate the effectiveness in terms of the number of rules, performance, and computational time.

**4.1. Experimental Setup.** All experiments were conducted on six benchmark datasets of varying complexity. The name, number of instances, number of attributes, and number of class labels in each dataset acquired from the UCI Machine Learning Repository are included in Table 1.

For evaluation purposes, we utilized standard open-source implementations of supervised learning algorithms and association rule mining algorithms provided by Weka [29] in a 10-fold cross-validation evaluation protocol in order to get accurate results for all datasets. In the 10-fold cross-validation protocol, the entire benchmark datasets are partitioned into ten parts of equal size, nine parts of them are used at a time for training, and the remaining one is used for testing. The process is repeated ten times, with different partitions used as training data and test data. In addition, we set the minimum expected weighted confidence threshold to 1 and support threshold to 0.5 in order to generate the results described in the next experiments. Furthermore, the various GA parameters were selected. Crossover and mutation probabilities were taken, respectively, as 0.5 and 0.01. The size of the initial population depends on the number of the generated rules from the benchmark datasets. Thus, the initial population size ranges from 14 to 439 and the maximum number of generations is set to 100.

**4.2. Experimental Metrics.** For analyzing the effectiveness of the proposed approach, some well-known metrics were used. Therefore, the following parameters were considered for these metrics:

- (i) True positive (TP) is the number of rules positively predicted that is actually positive.
- (ii) True negative (TN) is the number of rules negatively predicted that is actually negative.
- (iii) False positive (FP) is the number of rules positively predicted that is actually negative.
- (iv) False negative (FN) is the number of rules negatively predicted that is actually positive.

Based on the previous parameters, the following metrics were proposed for the evaluation:

- (i) Precision reflects the ability of an approach to return relevant rules among a set of irrelevant and relevant rules. The precision can be computed by equation.

- (1) *Input*: DS a preprocessed candidate dataset
- (2) *Output*: Decision trees
- (3) *Begin*
- (4) Apply J48 decision tree to learn on the DS and get the decision tree-based training model
- (5) Apply random tree to learn on the DS and get the random tree-based training model
- (6) Extract decision trees from both training models
- (7) *End*

ALGORITHM 1: Hybrid with decision tree and random tree.

TABLE 1: Characteristics of datasets used in experiments.

Dataset	Number of instances	Number of attributes	Number of classes
Breast	286	10	2
Heart	270	13	4
Hepatitis	155	19	2
Weather	14	5	3
Iris	150	4	3
Adult	48842	15	2

$$\text{Precision} = \frac{TP}{TP + FP} \quad (2)$$

- (ii) Recall reflects the ability of an approach to return relevant rules only. The recall is defined as given in equation.

$$\text{Recall} = \frac{TP}{TP + FN} \quad (3)$$

- (iii) Accuracy reflects the ability of an approach to return the accurate rules over the all rules made in the dataset as can be seen in equation.

$$\text{Accuracy} = \frac{TP + TN}{TP + FP + TN + FN} \quad (4)$$

Apart from these metrics, we considered the computational time that reflects the average time required for generating the set of IF-THEN association rules in terms of second.

**4.3. Rules for Knowledge Base Enrichment.** We present an example of context-aware rules generated from the weather dataset mentioned above using our approach. The candidate dataset contains four condition attributes, such as outlook, temperature, humidity, windy, and one decision attribute, that is, “play.” It is considered to generate rules that could help in making decisions regarding whether a user could go outside for playing or not. First, we show, in Table 2, a sample of generated IF-THEN rules obtained through training both decision tree and random tree algorithms. Looking more closely at Table 2, we can notice that the antecedent part of the rules reflects users’ contextual knowledge, and the consequent part represents their associated behavioral actions. Hence, real-time users’ environmental contexts such as outlook, wind, humidity, or temperature are used to make the play decision.

Then, we illustrate, in Tables 3 and 4, a sample of well-performed rules extracted from the generated rules through the optimization process considered in the proposed approach. As illustrated in Tables 3 and 4, the well-performed discovered association rules vary from one user to another according to their current profile. For example, a user with a pollen allergy, on a windy day, cannot go outside since the wind can trigger pollen allergy symptoms most. As a result, association rules, such as R9 and R10, which stated a day is windy (windy = true) and a user could have fun playing outside (play = yes), are overlooked for the user with a pollen allergy.

Finally, after the automatic DSL metamodel instantiation and transformation, we list, in Tables 5 and 6, a sample of the well-performed rules transformed to Jena rules to enrich the rule knowledge base and improve the decision-making process at runtime. Therefore, we can conclude that our proposed approach is capable of generating rules that could enrich a rule knowledge base.

#### 4.4. Effectiveness Analysis

**4.4.1. Rule Analysis.** In the first experiment, the number of association rules generated by the proposed approach and the traditional algorithms of association rule mining, such as apriori and FP growth, was evaluated. Figures 7–12 illustrate the number of generated rules for the different candidate datasets.

Observing Figures 7–12, we can see that the traditional algorithms generate the highest number of rules, while our approach generates the lowest number of rules on all candidate datasets. In particular, our approach generates 4,103 association rules on average against 6 datasets, whereas the apriori and FP growth algorithms derive 9,211 and 10,582 on average, respectively. Thus, the results show that the number of generated association rules using traditional algorithms is large and huge. The reason beyond these results is that traditional algorithms simply take into account all

FIGURE 7: Rule analysis for the breast dataset.

combinations of attributes while generating rules. In contrast, the results indicate that the number of generated rules by our approach is small. The downtrend reveals that our approach could generate the minimum number of association rules comparing the apriori and FP growth and could keep the number of discovered rules as small as possible. As a result, for a high confidence value, traditional algorithms satisfy significantly more associations than our proposed

approach. Therefore, our proposed approach could generate a reasonably smaller number of association rules compared with traditional association rule mining algorithms since it abandons the redundant rules and retains the nonredundant rules.

**4.4.2. Performance Analysis.** In the second experiment, we discussed the effectiveness of our approach in terms of performance measures such as precision, recall, and accuracy. For this purpose, we compare the performance of the proposed approach with well-known supervised learning algorithms, namely, NB, JRip, and decision table (DT). The reason for selecting these algorithms is that they generate rule-based classifiers and have high performance compared with other algorithms [30]. We also compare the performance of our approach with some similar state-of-the-art works, including Hong et al. [14], Sarker [16], and Basha

FIGURE 8: Rule analysis for the heart dataset.

FIGURE 9: Rule analysis for the hepatitis dataset.

[17]. Experimental results on performance measures are highlighted in Figures 13–18.

Our observations on candidate datasets show that our approach consistently outperforms the compared supervised learning algorithms for generating association rules by maximizing the precision and recall. In addition, our observations reveal that our proposed approach achieved better accuracy than NB, JRip, and DT on heart, hepatitis, weather, and iris datasets. For instance, the accuracies for NB, JRip, and DT on the iris dataset are 95.33%, 96%, 95.3%, and 92.66%, respectively, whereas for the proposed approach the accuracy is 98%. Moreover, the obtained results confirm that our approach has outstanding performance compared with state-of-the-art works. For instance, we achieve an approximately 2% and 3.2% accuracy gain compared with the works of Hong et al. [14], Sarker [16], and Basha [17] when dealing with breast and adult datasets, respectively. Thus, obtained results proved that our proposed approach tends to get reasonably high accuracy on all datasets. Therefore, we can conclude that our proposed approach is more effective relative to the compared supervised learning algorithms and state-of-the-art works while generating association rules since we capture association rules from both more performant supervised learning algorithms that lead to improve the performance results.

FIGURE 10: Rule analysis for the weather dataset.

FIGURE 11: Rule analysis for the iris dataset.

FIGURE 12: Rule analysis for the adult dataset.

4.4.3. *Computational Time Analysis.* In the third experiment, we compared and analyzed the computational time of the proposed approach, the supervised learning algorithms mentioned earlier, and the state-of-the-art works [14, 16]. In this experiment, we did not consider the work presented by Basha [17] since its GA is not publicly available. To this end, the sizes of the datasets were fixed since the computational time may vary based on the dataset size. Table 7 illustrates the time consumed by the proposed approach for generating association rules against the selected supervised learning algorithms and the state-of-the-art works in all datasets.

From the illustrated results, the average time spent on each dataset to generate a set of association rules is 0.38 seconds in the proposed approach. The experimental results

clearly show that the computational time of the proposed approach is slightly increased compared with the selected supervised learning algorithms and with the state-of-the-art works, but the computational time on the whole is not much different. The slight increase can be explained by the fact that we apply the GA for optimization on the basis of both

TABLE 7: Computational time analysis for our six datasets in seconds.

Dataset	NB	JRip	DT	Hong et al. [14]	Sarker [16]	Our approach

supervised learning algorithms, which could slightly increase the time complexity of the rule generation process compared with the selected supervised learning algorithms.

### 5. Discussion

We discuss the encouraging obtained results of the proposed approach. First, our approach outperformed compared to the well-known traditional association rule mining algorithms in terms of the number of rules by eliminating the redundant generation for each dataset. It generated, on average far, fewer association rules than those generated by the traditional algorithms included in the comparison. Thus, it provided a reasonably smaller number of rules on smaller and bigger datasets compared to the traditional algorithms. This is due to the fact that our approach is based on hybrid supervised learning that takes advantage of machine learning to extract the relevant relationships and to eliminate the redundancy while generating association rules. In brief, our approach significantly reduces the total number of generated rules and outputs a well-performed set of association rules using the GA. Such nonredundant and well-performed association rule generation makes our approach more effective and can be used to automatically improve a decision-making process regarding changes occurring in users' surrounding environments at runtime. Second, our approach exceeded the well-known selected supervised learning algorithms and certain state-of-the-art works in terms of precision, recall, and accuracy. In particular, our approach achieved the best accuracy on heart, hepatitis, weather, and iris datasets among all selected supervised learning algorithms. However, it got slightly worse results in terms of accuracy on breast and adult datasets since

imbalanced datasets may lead to slightly worse accuracy results. Even though not achieving the best accuracy results on these datasets, our approach achieves almost reasonably high accuracy in most datasets. Moreover, we must stress that the main advantage of our approach in contrast to the compared state-of-art works is its ability to achieve a good trade-off between precision, recall, and accuracy on multiple datasets. Third, our approach could be somewhat more time-consuming than the selected supervised learning algorithms and the compared state-of-the-art works. The slight increase in time is reasonable due to the hybridization and optimization. However, this loss of the little running efficiency will result in a significant improvement in the quality of the results in terms of the number of rules, precision, recall, and accuracy. Regarding the time-consuming results, it is noted that the effectiveness of the proposed approach does have room for improvement, which is also the need for further improvement in the future work.

Overall, the findings of the experimental study reveal that our approach can (i) effectively minimize the issues of redundant rule generation, (ii) provide a promising performance and a high accuracy to extract a concise set of association rules, and (iii) take slightly more time for generating a set of well-performed rules.

## 6. Conclusions

This work aimed to propose an approach for the decision-making improvement to face dynamic environments at runtime, where the enrichment of a rule knowledge base is performed through automatically generating and transforming context-aware rules. The proposed approach focused first on generating nonredundant association rules with a hybrid supervised learning mechanism, second on optimizing association rules using an extended GA, and finally on transforming association rules to context-aware rules in Jena syntax. As part of this work, we presented an experimental evaluation to assess the effectiveness of the proposed approach. The results showed that the proposed approach has the potential for achieving the best results in terms of the number of rules, precision, recall, and accuracy among all compared algorithms. Moreover, these results pinpointed the limitation of the proposed approach in terms of time-consuming that is mainly due to hybridization and optimization. Furthermore, in the near future, we intend to apply our approach to real scenarios for a context-aware system.

## Data Availability

The public datasets were collected from the UCI Machine Learning Repository. Requests for dataset access should be made to <https://archive.ics.uci.edu/ml/index.php/>.

## Conflicts of Interest

The authors declare that they have no conflicts of interest.

A single model is often used to classify text data, but the generalization effect of a single model on text data sets is poor. To improve the model classification accuracy, a method is proposed that is based on a deep neural network (DNN), recurrent neural network (RNN), and convolutional neural network (CNN) and integrates multiple models trained by a deep learning network architecture to obtain a strong text classifier. Additionally, to increase the flexibility and accuracy of the model, various optimizer algorithms are used to train data sets. Moreover, to reduce the interference in the classification results caused by stop words in the text data, data preprocessing and text feature vector representation are used before training the model to improve its classification accuracy. The final experimental results show that the proposed model fusion method can achieve not only improved classification accuracy but also good classification effects on a variety of data sets.

## 1. Introduction

Text classification originated in the 1950s. From the initial expert-based system to traditional machine learning approaches and now deep learning methods, text classification technology is gradually maturing [1]. In recent years, deep learning has been a hot topic in academic research. Great breakthroughs have been made in various fields by using deep learning technology, such as natural language processing, computer vision, and reinforcement learning. Text classification based on deep learning is both a trending subject and a long-term challenge for researchers.

In a study on text classification, Rocchio [2] first proposed the Rocchio text classification algorithm, which uses a training set to construct a prototype vector for each class and allocates an input document to a certain class by calculating the similarity between all documents in the training set and the prototype vector. This method is easy to implement and calculate. However, it does not perform well in tasks with multiple categories and is mostly suitable for document classification problems with fewer categories. Based on the Rocchio algorithm, Somya and Srinivasa [3] proposed a

Rocchio algorithm with a hierarchical structure. This algorithm adopts the term frequency-inverse document frequency (TF-IDF) feature extraction method to conduct large-scale multilabel text classification for hierarchical data sets and has a good classification effect on such data sets. However, it has poor performance on multitype data sets. Schapire [4] first proposed the boosting classification algorithm based on the idea of model fusion. This algorithm mainly fuses multiple weak learners into a strong learner, achieving an improved classification effect; then, he proposed the bagging algorithm [5]. Among these weak learners, random forests, boosting trees, and gradient boosting decision trees (GBDTs) [6] are the basic models used when combining decision trees with boosting and bagging algorithms; this approach provides a significantly improved classification effect. Based on the idea of boosting, Bloehdorn and Hotho [7] proposed an adaptive boosting algorithm with semantics. The model algorithm uses an integrated learning method to improve the stability and accuracy of text classification. However, the number of trained models is large; the calculations are very complicated; and the interpretability between models is reduced.

Kowsari [8] and others proposed a random multimodel classification method, which uses the network learning architectures of a deep neural network (DNN), recurrent neural network (RNN), and convolutional neural network (CNN) to randomly generate numbers of hidden layers and neurons for each model and obtain predictions through majority voting. As a result, this method has achieved improved text classification accuracy. However, since the numbers of hidden layers and neurons are randomly generated, the network structure generated each time is different, making the model training process difficult and the calculations very complicated. References [9–11] proposed a widely used Bayes classifier, which is a single classifier. It has a good classification effect on text data, and the calculations are fast and easy to implement. However, the Bayesian classifier performs poorly on text with sparse data. Therefore, Kim et al. [12] developed a method and a strong data distribution assumption to alleviate the problem regarding poor prediction for sparse data and solve the poor classification problem for sparse text data. Another powerful classifier is the support vector machine (SVM) [13], which uses a flexible and diverse kernel method to project data into a high-dimensional space, thereby using the hyperplane in the high-dimensional space to classify the data; the classification effect of this method is relatively good, but the effect of a single classifier is reduced when used on multiple data sets.

The traditional single classifier, which can be used to achieve good classification results, is used to train the network model for a specific data set. While the single classifier cannot handle various data sets, the integrated model can solve the problem of accuracy under various data sets, but the training of the integrated model is complex and time-consuming. The traditional single classification model and integrated model are improved in this paper, and the data sets are trained by combining multiple network models. First, a variety of optimizer algorithms are used to address text feature problems such as long texts and sparse texts. Second, the learning rate in the training process of the model is adjusted by the optimizer so that the trained model can handle data sets with different text characteristics and increase the flexibility of the model.

Improvements are made on the basis of three network architectures: DNN, RNN, and CNN. In the DNN network architecture, the BP algorithm and many optimizer algorithms are combined to train the model. In the RNN network architecture, the GRU [14] network with horizontal and vertical learning, multiple optimizer algorithms, and the ReLU [15] activation function training model are designed. In the CNN network architecture, multilayer convolution and pooling are used to extract text features and combined with a variety of optimizer algorithms [16] to train the model. Finally, the improved network architectures are used to obtain a powerful text classification model by using a fusion strategy and parallel training method.

## 2. Materials and Methods

The text classification process in this paper includes the following steps: text data preprocessing, text vector

representation, text feature extraction, optimizer selection, model design, model fusion, and model evaluation. Figure 1 shows the flowchart of the proposed method from preprocessing to model evaluation. The following describes the detailed process of the whole text classification in this article.

*2.1. Text Preprocessing.* The main purpose of text preprocessing is to clean the original text data. Most text and document data sets contain many unnecessary words, such as stop words, spelling errors, and slang. When determining word frequency statistics, these noisy data and unnecessary features adversely affect the performance of the models and the classification results. In this paper, the stop vocabulary list in the NLTK corpus is incorporated for word removal and processing. Additionally, regular expressions are used to remove spaces and some special characters to reduce the calculation cost and classification error of the model training.

*2.2. Word Representation.* Word representation converts a text string into a numerical vector that can be processed by a computer. The commonly used text vector representation methods are the bag-of-words [17] method, word2vec [18], and the GloVe [19] method. This paper uses the GloVe model for text vector representation. The basic idea is to construct a co-occurrence matrix through a corpus and then learn word vectors based on the co-occurrence matrix and the GloVe model. The model uses matrix decomposition with latent semantic analysis (LSA) derived global features and word2vec local context information to transform the matrix. Together, this approach not only realizes the global statistical features in the corpus but also uses local context features to represent vectors. When using the GloVe model for training, the word vector for the given text is calculated by introducing a loss function such as

$$\mathcal{J} = \sum_{i,j}^N f(X_{i,j}) (v_i^T v_j + b_i + b_j - \log(X_{i,j}))^2, \quad (1)$$

where  $v_i$  and  $v_j$  are the word vectors of word  $i$  and word  $j$ , respectively;  $b_i$  and  $b_j$  are bias terms;  $f$  is a weight function;  $\log(X_{i,j})$  represents the number of times word  $j$  appears in the context of word  $i$ ;  $N$  is the size of the vocabulary; and  $N * N$  is the dimensionality of the co-occurrence matrix. Additionally, the weight function of  $f$  is defined; this is done to prevent some weights from being too large. Additionally, some weights are too small, which affects the text classification accuracy, so function  $f(x)$  is defined as follows:

$$f(x) = \begin{cases} \left(\frac{x}{x_{\max}}\right)^\alpha, & x < x_{\max}, \\ 1, & \text{Other.} \end{cases} \quad (2)$$

*2.3. Feature Extraction.* The commonly used feature extraction methods are TF-IDF [20] and  $N$ -gram [21]. When

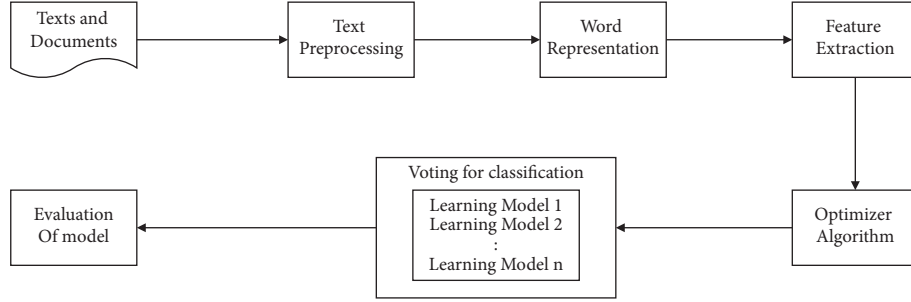

FIGURE 1: Overview of the text classification pipeline.

TF-IDF is used to extract text features, the sequence relationship between words cannot be captured, so the features of the text cannot be fully extracted. Therefore, this paper uses the  $N$ -gram method to extract text features. In text data, a sequence or a sentence is composed of  $m$  words. Then, the probability of the occurrence of the  $m$ -th word is related to the previous  $m-1$  words, and the probability value  $p(w_1, w_2, \dots, w_m)$  is calculated. According to the chain rule, the final calculation result is shown in the following equation:

$$p(w_1, w_2, \dots, w_m) = p(w_1) * p(w_2|w_1) * p(w_3|w_1, w_2) \dots p(w_m|w_1, \dots, w_{m-1}) \quad (3)$$

Compared with a 1-gram and a 2-gram, the  $N$ -gram method provides extracted text features that can detect more information.

#### 2.4. Optimizer Algorithm

**2.4.1. An Optimization Algorithm for Vibration Reduction Based on RMSProp.** When training the parameters of the model, the choice of the learning rate affects the efficiency and performance of the model. If the learning rate is too large, violent oscillations will occur when calculating the gradient, resulting in failure to converge to the global optimal solution, and if the learning rate is too small, the training speed will become very slow. The current method is the simulated annealing algorithm. When training model parameters, a threshold is defined for the learning rate change range, and the learning rate is adjusted. However, this approach requires a threshold to be defined in advance, and it cannot adapt to changing text data types. To solve the problem regarding learning rate threshold changes and oscillations, this paper uses the RMSProp algorithm based on Nesterov momentum. The algorithm first initializes the learning rate and continuously dynamically updates the learning rate during the training process to prevent this rate from being excessive or small during the training process, as this would affect the training results. The specific main steps are as follows. First, a minibatch containing  $m$  samples from the training set is formed, and the gradient sum and average of these small samples are calculated, as in equation (4). At the same time, an exponential decay coefficient such as equation (5) is used to control the amount of historical information, that is, the cumulative gradient, to dynamically

update the size of the learning rate (equation (6)) and the model parameters (equation (7)).

$$g = \frac{1}{m} \nabla_{\theta} \sum_i \mathcal{L}(f(x^{(i)}; \bar{\theta}), y^{(i)}), \quad (4)$$

$$r = \rho r + (1 - \rho) g * g, \quad (5)$$

$$v = \alpha v - \frac{\epsilon}{\sqrt{r}} * g, \quad (6)$$

$$\theta = \theta + v, \quad (7)$$

$$\bar{\theta} = \theta + \alpha v, \quad (8)$$

where  $r$  represents the exponential decay coefficient,  $v$  represents the update of the calculation decay,  $\theta$  represents the update of the parameters,  $g$  represents the gradient, and  $\alpha$  represents the momentum coefficient. At the same time, to reduce the violent oscillations observed when training the model parameters, an idea based on Nesterov momentum is adopted, and a momentum coefficient is added before calculating the gradient to slow the oscillations, as shown in equation (8). Therefore, the optimizer of the RMSProp algorithm combined with Nesterov momentum improves the training speed and accuracy of the model.

**2.4.2. An Optimal Deviation Correction Algorithm Based on Adam.** Adam is a simple and computationally efficient optimization algorithm that can overcome the problems encountered in large data sets and high-dimensional parameter spaces. Among traditional classification methods, such as naive Bayes classifiers and SVMs, for text data with large data sets, it is necessary to consider the memory consumption of the naive Bayes model training process and the model oscillation problem, while SVMs do not possess this problem. A kernel method puts text data into a high-dimensional space, and the resulting model has many parameters and is highly complicated to calculate. Therefore, the Adam algorithm with deviation correction is introduced to solve the shortcomings of traditional methods. The basic idea is that when Adam calculates the gradient, it introduces the first-order moment estimation (equation (9)) and the second-order moment estimation (equation (10)) and then corrects the deviation of the first-order moment (equation

(11) and that of the second-order moment (equation (12)) to address gradient sparseness and unevenness. Equation (9) updates the first-order moment by calculating the gradient  $g$  and the exponential decay rate  $\rho_1$  and simultaneously corrects the deviation through equation (11), speeding up the convergence of the model. Equation (10) introduces the second-order moment, and equation (12) corrects the deviation to improve the model's ability to deal with non-stationary targets. At the same time, the  $\Delta\theta$  parameter (equation (13)) is used to update the value of parameter  $\theta$  in equation (14). This paper uses the aforementioned algorithm in text classification to train the model parameters to reduce memory consumption and simultaneously solve the problem of convex model convergence.

$$s = \rho_1 s + (1 - \rho_1)g, \quad (9)$$

$$r = \rho_2 r + (1 - \rho_2)g * g, \quad (10)$$

$$\hat{s} = \frac{s}{1 - \rho_1^t}, \quad (11)$$

$$\hat{r} = \frac{r}{1 - \rho_2^t}, \quad (12)$$

$$\Delta\theta = -\varepsilon \frac{\hat{s}}{\delta + \sqrt{\hat{r}}}, \quad (13)$$

$$\theta = \theta + \Delta\theta, \quad (14)$$

where  $s$  represents the first-order moment,  $g$  represents the value of the sample gradient,  $\rho_1$  and  $\rho_2$  represent the estimated exponential decay rate,  $\theta$  represents the parameter calculated by the model,  $\delta$  represents a small constant used for numerical stability,  $\varepsilon$  represents the step size, and  $\Delta\theta$  is used to update the parameter  $\theta$ .

#### 2.4.3. An Improved Optimization Algorithm Based on SGD.

Before the introduction of the SGD algorithm, the most commonly used gradient algorithm was the batch gradient descent (BGD) algorithm, which is aimed at an entire data set and calculates the gradient direction for all samples. Although this method can obtain the global optimal solution, when the amount of data is large, the number of required calculations is large, and the calculation speed is slow. To overcome the shortcomings of the BGD method, this paper uses the SGD algorithm. SGD is a widely used optimization algorithm. It is an improvement over the classic gradient descent algorithm. The basic idea is that all training data can be obtained from the training data in each iteration. A random sample is taken to estimate the gradient of the objective function, so the time complexity of the algorithm is greatly reduced, and this approach is applied to large-scale text data sets. When using the SGD algorithm in this paper, a set of text training data is input into the model. The objective function is calculated as follows:

$$\min_{w \in \mathbb{R}^n} F(w) = \frac{1}{m} \sum_i \mathcal{L}(f(x^{(i)}; w), y^{(i)}), \quad (15)$$

where  $\mathcal{L}$  represents the experience loss of the model  $f(x^{(i)}; w)$ ; the model parameter values are calculated as follows:

$$w = \frac{1}{m} \sum_i w_i - \eta_i \nabla \mathcal{L}(f(x^{(i)}; w_i), y^{(i)}). \quad (16)$$

### 2.5. Model Structure and Fusion

**2.5.1. DNN Architecture.** The DNN structure in this paper is designed with an input layer, a hidden layer, and an output layer, as shown in Figure 2. The input layer is the processed text feature vector, and the ReLU activation function is used in the hidden layer (as in equation (17)) to reduce the required number of calculations when using the back-propagation algorithm to update the parameters. At the same time, the dropout algorithm is introduced to solve the problem of gradient disappearance in the training process, and finally, the softmax function, such as equation (18), is used to solve the multiclassification problem when outputting.

$$f(x) = \max(0, x), \quad (17)$$

$$\text{Softmax}(z_i) = \frac{e^{z_i}}{\sum_{c=1}^C e^{z_c}}, \quad (18)$$

where  $z_i$  represents the output value of the  $i$ -th node and  $c$  is the number of output nodes.

**2.5.2. RNN Architecture.** To solve the information loss problem in the traditional RNN network propagation process, the gate structures of LSTM [22] and GRU networks are generally used to retain important information. Because the network parameters of GRU are less than those of LSTM, the gradient disappearance problem can be prevented and reduce the computational complexity and the overfitting of the training data. The GRU network design unit is shown in Figure 3. This method uses a gating mechanism, which contains an update gate and a reset gate. The calculations are shown in equations (19) and (20), and the output vector is calculated via equations (21) and (22). The final RNN architecture is shown in Figure 4. Each GRU unit in the network can learn not only horizontally but also longitudinally to reduce the information loss problem in the communication process.

$$z_t = \sigma(\mathcal{W}_z * [h_{t-1}, x_t]), \quad (19)$$

$$r_t = \sigma(\mathcal{W}_r * [h_{t-1}, x_t]), \quad (20)$$

$$\tilde{h}_t = \tanh(\mathcal{W}_h * [h_{t-1} * r_t, x_t]), \quad (21)$$

$$h_t = (1 - z_t) * h_{t-1} + z_t * \tilde{h}_t, \quad (22)$$

where  $z_t$  represents the update gate vector at time  $t$ ,  $x_t$  represents the input text feature vector,  $\mathcal{W}$  represents the parameter matrix,  $\sigma$  represents the ReLU activation

FIGURE 2: DNN architecture.

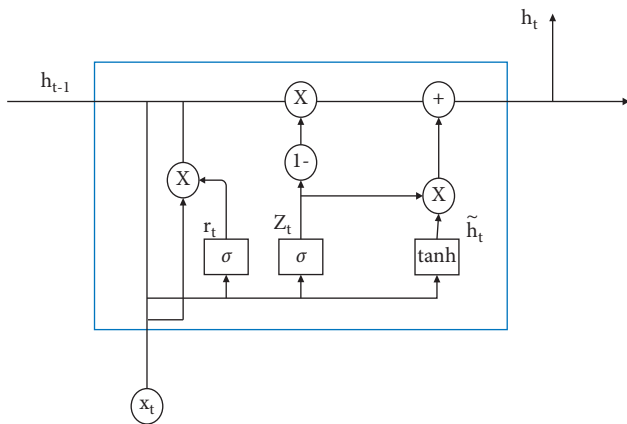

FIGURE 3: GRU network.

function,  $r_t$  represents the reset gate vector, and  $h_t$  represents the output vector.

**2.5.3. CNN Architecture.** CNNs were originally used to address image problems, but in natural language processing, the use of CNNs for text classification has achieved better results. In this paper, when the CNN is used for text classification, a six-layer convolution layer and a maximum pooling layer are used, as shown in Figure 5. The model adopts one-dimensional convolution. Without changing the width of the text sequence, the pooling layer uses the maximum pooling strategy to continuously extract important features from the text data through one-dimensional convolution and maximum pooling and then uses a pooling layer to combine the gathered text feature information and

input it into the fully connected layer. Finally, the category information of the classified text is output.

**2.5.4. Model Fusion.** Commonly used model fusion strategies include the averaging method, stacking method, and majority voting method. The main idea of the averaging method is to average the prediction results of each model and use the average value as the final prediction result. The stacking method uses model cross-validation, combining the features between models and training the newly combined features into a new model. Through this repeated feature stacking method, a strong classifier is finally obtained. The method of majority voting involves calculating the statistics of the classification results of each classifier. Among them, the classifier with the most votes divides the final data points in the corresponding category. This method is simple to calculate and easy to implement, and the classification effect is better than that of a single classification approach. The whole model fusion process is shown in Figure 6. The fusion steps of the entire model can be seen in Figure 6; first, the text data set is preprocessed, and the features are extracted and converted into a matrix  $(x_1, x_2, x_{m-1}, \text{ and } x_m)$ . Then, the text feature vector is input into the designed network architecture for parallel training, and each network architecture uses different optimization algorithms. A total of  $n$  models are calculated; then these  $n$  models are tested in parallel on the test sets to obtain the prediction results of each model; and finally, these  $k$  results are selected through the fusion strategy to select the final prediction result as the classification result of this mode.

Based on the above fusion strategy, the main idea is as follows: the total number of models trained in parallel is  $k$ ,

FIGURE 4: RNN architecture.

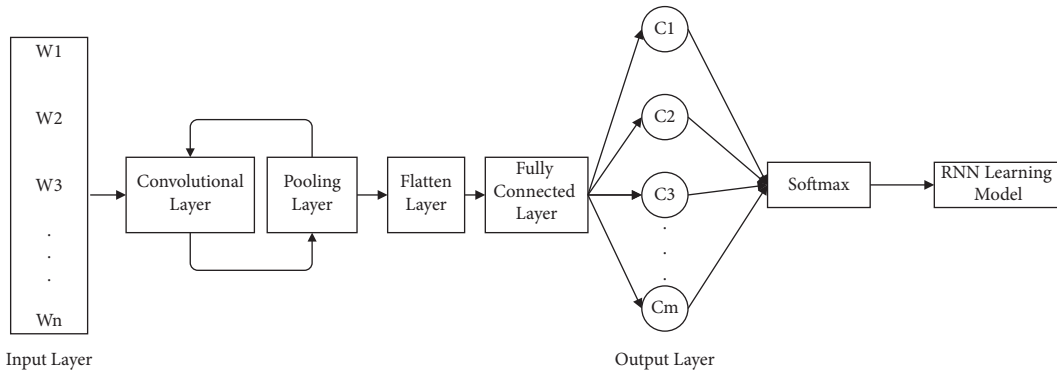

FIGURE 5: CNN architecture.

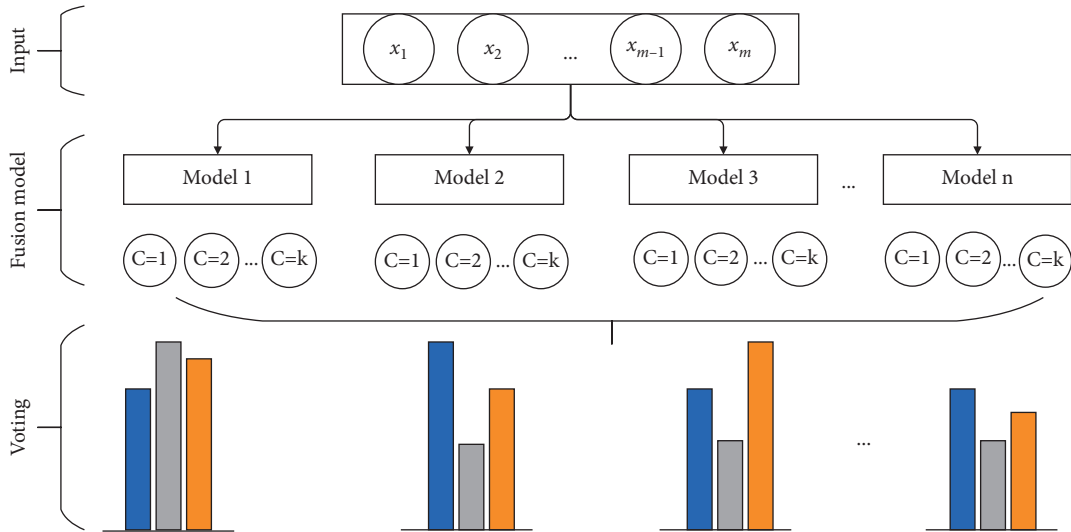

FIGURE 6: Model fusion structure.

the number of document categories is  $m$ , and the classification results of each model for text data  $i$  are counted. Among them, the text data  $i$  with the most votes is considered to belong to category  $c_{ij}$ . Finally, the accuracy rates belonging to category  $c_{ij}$  are summed and averaged as the final prediction result, and the calculations are shown in the following equations:

$$y_{ij} = [y_{i1}, y_{i2}, \dots, y_{ik}], \quad (23)$$

$$c_{ij} = \max[c_{i1}, c_{i2}, c_{i3}, \dots, c_{im}], \quad (24)$$

$$\hat{P}_{ij} = \frac{\sum_{n=1}^N \text{softmax}(y_{in})}{N}, \quad (25)$$

where  $y_{ij}$  represents the result of model  $j$  for the classification of text  $i$ ,  $k$  represents the number of training models,  $m$  represents the number of categories in the document,  $c_{im}$  represents the number of votes stating that text data  $i$  belongs to category  $m$ ,  $\hat{p}_{ij}$  represents the number of text data  $i$  belonging to the accuracy of category  $j$ , and  $N$  represents the number of votes.

### 3. Results and Discussion

**3.1. Datasets.** To verify that the fused model has generalizability, this paper uses three different data sets, as shown in Table 1: 20Newsgroups, Reuters, and Web of Science. The 20Newsgroups data set is mainly composed of 20 newsgroups for different topics. It contains 20,000 document data. The Reuters news data set contains 21,578 document data and a total of 90 categories. The Web of Science data set is a collection of academic article abstracts. The data sets include WOS5736 and WOS11967. This paper uses 80% of the documents as training data and 20% as test data. The relationships are shown in Table 1.

**3.2. Evaluation.** This paper uses accuracy, recall, and  $F_{1\text{-score}}$  to measure the classification performance of the model. The calculation equations are as follows:

$$\text{Accuracy} = \frac{(\text{TP} + \text{TN})}{(\text{TP} + \text{FP} + \text{FN} + \text{TN})}, \quad (26)$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}, \quad (27)$$

$$F_{1\text{score}} = \frac{2\text{TP}}{2\text{TP} + \text{FP} + \text{FN}}. \quad (28)$$

**3.3. Parameter Settings.** This paper uses the GloVe model to learn word vectors, as this model can realize global feature statistics in the corpus and local context feature vectors. At the same time, to prevent the overfitting of the training data, the dropout value is set to 0.5 in each network architecture. Each architecture model uses Adam, SGD, and RMSProp as three optimization algorithms and the ReLU activation function to improve the training speed of the model. The specific parameters are shown in Tables 2–4.

**3.4. Experimental Results.** To verify the classification performance of the proposed multimodal fusion approach and show that it is better than other single classification models, the experimental results obtained on three different public data sets are compared. The results are shown in Table 5.

Table 5 shows the classification results of the majority votes for nine models on the data sets. On the Reuters data set, the voting classification accuracy of the nine models reaches 89.23%, which is 0.66% higher than the model with the highest accuracy in the comparative experiments. The testing results of the fusion model are shown in Figure 7, and the comparative results of the four models are shown in

Figure 8. On the 20Newsgroups data set, when training the fusion model, 100 epochs are required for convergence, and the classification accuracy of the models reaches 88.87%, which is 5.13% higher than the model with the highest accuracy in the comparative experiments. The testing results of the fusion model and comparative models are shown in Figures 9 and 10, respectively. The classification accuracy rate that is achieved by the proposed models on the WOS5736 data set is 92.33%, which is 0.35% higher than the model with the highest accuracy in the comparative experiments. The testing results of the fusion model and comparative models are shown in Figures 11 and 12,

respectively. The classification accuracy rate of the proposed models on the WOS11967 data set is 85.08%, which is 1.11% higher than the model with the highest accuracy in the comparative experiments. The testing results of the fusion model and comparative models are shown in Figures 13 and 14, respectively. Additionally, on four data sets, the recall and  $F1_{score}$  of the fusion model are higher than DNN, RNN, and CNN models. In summary, the model fusion method used in this paper has a better classification effect than a single classifier, and the fusion model has a more generalizable effect, which is specifically manifested as not only a better classification effect on a data set but also a good classification effect on a variety of data sets.

#### 4. Conclusion

A new classification method is proposed in this paper to solve the problems of data sets and the accuracy of a single model. The combination of parallel training of multiple deep learning architectures and integrated strategies is used to obtain the model. To verify the efficiency of the fusion model, the experimental evaluation of the fusion model on the Reuters, 20Newsgroups, WOS5736, and WOS11967 data sets shows that the accuracy, recall, and  $F1_{score}$  are higher using the fusion model compared with the DNN, RNN, and CNN models. The results show that the fusion model can

also improve text classification and an integration strategy can be used to provide flexibility for classification. This model also provides a new text classification method, which can be applied to a wide range of data sets. In future research, we will further explore the network structure of the fusion model and the influence of each network parameter on the classification results and analyze whether a shallow model can be used to improve the accuracy of the ultimate model while increasing training speed.

## Data Availability

Three types of data sets from different pages include the following. 20Newsgroups data set contains 20,000 documents with 20 categories. Reuters data set contains 21,578 documents with 90 categories. The Web of Science data set contains WOS11967 and WOS5736. WOS11967 contains 11,967 documents with 35 categories, which include 7 parents categories. WOS5736 contains 5,736 documents with 11 categories, which include 3 parents categories. These links are provided in these statements. All links are given below: (1) <https://archive.ics.uci.edu/ml/machine-learning-databases/20newsgroups-mld/>, (2) <http://kdd.ics.uci.edu/databases/reuters21578/reuters21578.html>, and (3) <https://data.mendeley.com/datasets/9rw3vkcfy4/2>.

In this study, we use a tripartite evolutionary game model to analyze the financial support for science-tech enterprises' innovation with government participation. Based on the game model, the study uses replication dynamics to analyze the stability of evolutionary trajectory in the eight scenarios of enterprises, the government, and the financial institutes. Then, we discuss the effect of the reputation multiplier, the efficiency of firms' innovation output, and the positive socio-economic externalities multiplier by simulation as the important innovative points in this study. The study draws the following conclusions: (1) enterprises will choose high R&D intensity instead of low R&D intensity if the output of former exceeds that of the latter, (2) enterprises' R&D output is closely related to the strategy choices of the government and financial institutes, and (3) enterprises can attract government subsidy by boosting economic and social externalities. The government subsidies to enterprises with high R&D intensity will improve the innovation output by the innovation investment and reputation multiplier. So, the government can implement subsidy policy to boost high-intensive R&D activity. Financial institutes' strategy choice between equity investment and debt investment is influenced by investment yield difference and can influence enterprises' R&D intensity choices.

## 1. Introduction

Intensive innovation is an effective way for companies to improve their core competitiveness [1] (Frambach and Schillewaert) and is a core driver of high quality development. R&D intensity is the key to corporate innovation, and the strategic choice of R&D intensity by companies is mainly based on a cost-benefit analysis. The main source of funding for corporate innovation is internal and external financing, where external financing is constrained by the high risk of innovation projects, credit asymmetry, opportunism, and adverse selection [2, 3] (Brown et al.). Financial institutes disagree on firms' return on investment requirements [4] (Hall, 2002) and intensify financing constraints. Financial institutes' capital investment is considered beneficial to firms' R&D activities [5–7] (Fryges et al.), while higher financing costs arising from financing constraints reduce

firms' willingness to invest in R&D, thus reducing firms' willingness to innovate. Due to the positive externalities of technological innovation, governments are active promoters of firm innovation [8] (Yu et al.). A series of initiatives, including financial subsidies, can alleviate the financing constraints and stimulate firms to invest in innovation [9] (Zhou). On the one hand, government subsidies provide good investment signals for equity investment institutions [10–12] (Howell et al.), which is a disguised endorsement of firms' credit and R&D capabilities. On the contrary, government subsidies can reduce the cost of enterprise loan financing by the signal effect. Therefore, it is necessary for governments to understand how firms make choices about R&D intensity and how financial institutes make choices about loans or investment in R&D projects. Thus, government can influence the strategic choices of firms and financial institutes through subsidy policies.

Government subsidies provide the impetus for the development of enterprise innovation, enterprises are the subjects of innovation, and financial institutes provide financial services and financial support for enterprise innovation. Changes in the strategic choices of any of the participants in corporate innovation will lead to corresponding changes in stakeholder response strategies, both in terms of the continuous improvement of information structures and the adjustment of the rational level of multiple participants. There are a lot of research studies on enterprises' R&D strategy, financial institutes' investment strategy, and government subsidy policy. However, there is a lack of analysis that puts the three players in a comprehensive game framework. This study is based on this theoretical framework to introduce enterprises, financial institutes, and government into a comprehensive game in which enterprises choose high or low R&D intensity; financial institutes choose equity or debt investment, while the government chooses whether to provide subsidy. The government's subsidy policy, enterprises' R&D intensity choice, and financial institutions' investment structure influence each other. Therefore, the government can attract enterprises to choose high R&D intensity strategy and financial institutes to make equity investment by adjusting its subsidy policy.

The main innovations of this study are as follows:

- (1) Current research has focused on measuring risk-sharing ratios among financial institutes [13, 14] and lacks a holistic analysis of the behavior of governments, financial institutes and firms, and their interactions. However, examine the different strategic options and possible interactions between key players. Most previous research has only two players in the game framework without considering the function of government participating. The framework of this study is more complex with reality. The analysis focuses on the different strategic choices and possible interactions of firms, financial institutes, and governments in the process of obtaining external finance for firms with different R&D intensities. It draws some interesting conclusions.
- (2) Existing studies point out that government financial subsidies for business innovation vary across different types of enterprises [15]. The firms' R&D intensity has an impact on the effectiveness of government intervention. However, we find that the reputation multiplier of government subsidies also has the effect on firm innovation and the choice of investment approach by financial institutes. We also find that firms' innovation efficiency and strategy game affect the investment approach of financial institutes and the choice of government financial support, which in turn affects firms' financing costs.
- (3) Another possible contribution of this study is to explore how the efficiency of firms' innovation output and the positive socio-economic externalities generated by innovation impact on government and financial support decisions.

The remainder of this study is structured as follows. Section 2 briefly reviews the existing research on financial support for science-tech enterprises and evolutionary games and presents the literature gaps. Section 3 constructs a three-party evolutionary game model among SMEs, financial institutes, and government. Section 4 discusses the ESS of the tripartite game between the government, the financial institutes, and SMEs. Section 5 presents the numerical simulation result of the evolutionary game model, which discusses the effect of incentive-related parameters on the results. Section 6 provides discussion of evolutionary results and policy implications.

## 2. Literature Review

This study briefly reviews the literature on financial support for science-tech enterprises and evolutionary game models with the above objectives.

*2.1. Financial Support for Science-Tech Enterprises.* Through numerous studies, scholars have generally concluded that financing constraints have a negative impact on enterprises' R&D and innovation activities [16, 17] (Hottenrott et al.). Different scholars have conducted empirical studies using data from countries such as Germany, France, Spain, and Uruguay and have come to the consistent conclusion that financial support can be effective in stimulating enterprises' R&D investment [18–21] (Almus et al.). Some scholars studied the function of finance support to enterprise science-tech innovation through different channels. Abobal and Garda believed that technological innovation needs capital input such as bank loans [21]. Saint-Paul proposed financial development promotes technological progress by allowing economic entities to use technologies with greater risks but higher levels of productivity [22]. Luong et al. used firm-level data across 26 non-U.S. economies between 2000 and 2010 to show that foreign institutional ownership has a positive and causal effect on firm innovation [23]. Menezes and Pereira found financial product innovation speeds up technological innovation [15]. Kim et al. found that capital market financing could promote technological innovation of enterprises more than bank loans [24]. Research in China suggests that government and market forces need to work together to promote financial support for enterprises' innovation processes [25] (Gong et al.).

In the past few years, the effect of government subsidies on the external investors funding the enterprises' innovation has attracted significant scholarly attention. The government expects to stimulate R&D activities through direct subsidies. Sabrinaconduct that government subsidies have a positive effect on corporate patents [10]. Feldman & Kelley argue that companies that receive R&D subsidies are recognized by the government and send a signal that they are innovative and can attract more investment [26]. The idea is that companies that receive R&D grants are recognized by the government and send a signal that they are innovative, which can attract more investment [12, 27, 28] (Meuleman et al.). However,

the inevitable “rent-seeking behavior” can lead to resource misallocation due to government subsidies [29] (Lerner) and distortions in enterprises’ competitive behavior [30] (Guellec et al.) and distortions in the competitive behavior of enterprises. Chinese scholars have also demonstrated the positive effects of government subsidies on corporate R&D based on empirical evidence from China. For example, Liu et al. found that government subsidies stimulate enterprises’ R&D investment by using data on high-tech enterprises in Jiangsu [31].

**2.2. Evolutionary Game.** The central concepts of evolutionary game theory are evolutionary stable strategies and replicator dynamics, arguing that a group’s decisions can be achieved through dynamic behaviors such as imitation, communication, and learning between individuals, while having highly adaptive strategies. Strategies that are highly adaptive are more likely to be imitated by other participants; otherwise, these strategies are eliminated. The theory is an important mathematical tool because it is based on finite theory and finite information and is closer to reality.

In recent years, evolutionary games have rapidly developed into an active area of research in the socio-economic field and are an increasingly popular approach in the study of corporate innovation. Yang et al. developed an evolutionary game model between government, enterprises, universities, and research institutions to explore the mechanisms of intellectual property cooperation [32]. Han et al. used a game model to analyze the effect of cluster informal contracts on innovation cooperation among cluster enterprises and the impact of informal contracts on innovation cooperation among cluster enterprises [33]. Shen used evolutionary game theory to study firm decision-making behavior during open innovation [34]. The impact of heterogeneous structures on the evolution of innovation behavior has been discussed based on scale-free networks [35, 36] (Ma et al.; Su et al.). Some literature use the evolutionary game method to study the optimal government subsidy. For example, Meng and Zhao discussed the optimal subsidy that can promote the system to reach the ideal state by constructing the evolutionary game model between manufacturers and remanufacturers [37] (Meng and Zhao). Bi Peng and Chen used evolutionary game theory to study the cooperative innovation of key common technologies of the two equipment manufacturing enterprises, respectively, constructed an evolutionary game model with or without government macrocontrol, analyzed the key factors affecting the stability of system evolution, and pointed out the formulation of reasonable innovation income distribution scheme and effective regulation of enterprises by government departments [38]. Vaida believes that government policies and financial support are important factors affecting enterprise technological innovation [39]. Zhang constructs a tripartite evolutionary game model involving two manufacturing enterprises and the government in the monopolistic competitive market and analyzes the stability of each party’s strategy selection [40].

**2.3. Literature Gaps.** Most of the above studies have examined the impact of financing and government intervention on corporate technological innovation through an empirical approach, and these studies have clarified the impact of corporate financing on corporate technological innovation and the role of government in it. However, most of these studies have focused on the impact of government intervention or a single aspect of corporate financing constraints. The interaction between government, financial institutes, and enterprises is less often discussed. There is also little literature that explores in depth the different investment options of financial institutes. This study fills this gap by analyzing the interaction mechanism between government subsidies, financial institutes’ investment choices, and enterprises’ R&D investment intensity from a game perspective. Both equity financing and debt financing approaches are considered.

### 3. Research Methods

**3.1. Model Overview.** Science-tech enterprises, government, and financial institutes are very important stakeholders in innovation strategies. In this study, we will use the evolutionary game to study the influence of behavior interaction between the three game agents and analyze the evolutionary stability of the system under different circumstances and the important factors affecting its evolutionary stability.

The three-party game process is shown in Figure 1.

#### 3.2. Model Assumptions

**Assumption 1:** suppose the three game agents of science-tech enterprises, government, and financial institutes are limited rational agents with the goal of maximizing their own interests. They will constantly adjust and improve their strategic choices according to their own benefits in the game process.

**Assumption 2:** suppose the strategy of science-tech enterprises is “Innovation with High R&D Intensity” or “Innovation with Low R&D Intensity.” The government’s strategy is “Subsidy” or “no Subsidy,” and the strategy of financial institutes is “Equity investment” or “Debt investment.” The R&D expense of science-tech enterprises is all funding by the external financing from financial institutes and government.

**Assumption 3:** technological innovation can bring positive external economy and benefits to the government. The higher density of R & D investment in science-tech enterprises  $\alpha$ , the higher economic and social externality multiplier by innovation  $g$ , so we assume  $g_Q > g_L$ .

**Assumption 4:** reputation multiplier by government subsidies  $k(k > 1)$  enhance the output of enterprise innovation investment.

**Assumption 5:** government subsidies can share the risk of debt investment of financial institutes, so we assume  $r_S > r_N$ .

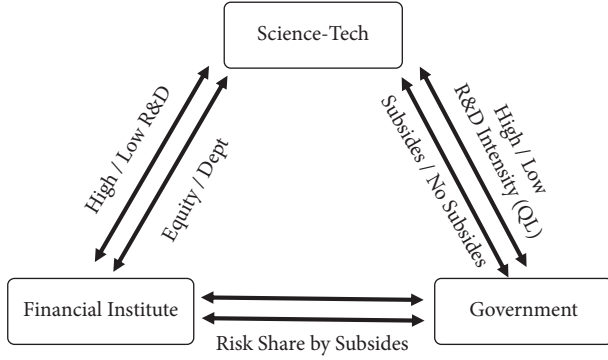

FIGURE 1: The three-party game process.

3.3. *Parameters' Setting.* The parameters' setting and explanations in the model are shown in Table 1.

3.4. *Model Construction.* Science-tech enterprise, government, and financial institute make strategic choices based on

$$\begin{aligned}
 E_Q &= yz(F_Q + S_Q)\alpha_Q\beta_Qk + (1-y)zF_Q\alpha_Q\beta_Q + y(1-z)[(F_Q + S_Q)\alpha_Q\beta_Qk - F_Q(r_S + 1)] \\
 &\quad + (1-y)(1-z)[F_Q\alpha_Q\beta_Q - F_Q(r_N + 1)], \\
 E_L &= yz(F_L + S_L)\alpha_L\beta_Lk + (1-y)zF_L\alpha_L\beta_L + y(1-z)[(F_L + S_L)\alpha_L\beta_Lk - F_L(r_S + 1)] \\
 &\quad + (1-y)(1-z)[F_L\alpha_L\beta_L - F_L(r_N + 1)], \\
 \bar{E}_I &= xE_Q + (1-x)E_L.
 \end{aligned} \tag{1}$$

4.1.2. *Government Expectation Function.* The expected return of government choosing "subsidy" is  $E_S$ , the expected

$$\begin{aligned}
 E_S &= x[(F_Q + S_Q)\alpha_Q\beta_Qkg_Q - S_Q - C_G] + (1-x)[(F_L + S_L)\alpha_L\beta_Lkg_L - S_L - C_G], \\
 E_N &= xF_Q\alpha_Q\beta_Qg_Q + (1-x)F_L\alpha_L\beta_Lg_L, \\
 \bar{E}_G &= yE_S + (1-y)E_N.
 \end{aligned} \tag{2}$$

4.1.3. *Financial Institute Expectation Function.* The expected return of financial institute choosing "equity investment" is

$$\begin{aligned}
 E_E &= xy(F_Q + S_Q)\alpha_Q\beta_Qk\delta + x(1-y)F_Q\alpha_Q\beta_Q\delta + (1-x)y(F_L + S_L)\alpha_L\beta_Lk\delta + (1-x)(1-y)F_L\alpha_L\beta_L\delta, \\
 E_D &= xyF_Qr_S + x(1-y)F_Qr_N + (1-x)yF_Lr_S + (1-x)(1-y)F_Lr_N, \\
 \bar{E}_F &= zE_E + (1-z)E_D.
 \end{aligned} \tag{3}$$

4.2. *Malthusian Replicated Dynamic Differential Equation Solution.* The replicated dynamic differential equation for the choice of an active strategy by science-tech enterprises,

self-willing. Assuming that the probability of science-tech enterprise choosing "innovation with high R & D intensity" strategy is  $x$ , the probability of choosing "innovation with low R & D intensity" strategy is  $1-x$ . The probability of the government choosing the "subsidy" strategy is  $y$ , and the probability of choosing the "no subsidy" strategy is  $1-y$ . If the probability of financial institutes choosing "equity investment" is  $z$ , the probability of choosing "debt investment" is  $1-z$ . Based on above, the income matrix of the three parties is shown in Table 2.

## 4. Results and Discussion

### 4.1. Construct Expectation Function

4.1.1. *Enterprise Expectation Function.* The expected return of enterprises' choosing strategy Q of "innovation with high R & D intensity" is  $E_Q$ , the expected return of enterprises choosing strategy L of "innovation with low R & D intensity" is  $E_L$ , and the average expected return  $\bar{E}_I$  will be

return of choosing "no subsidy" is  $E_N$ , and the average expected return  $\bar{E}_G$  will be

$E_E$ , the expected return of choosing "debt investment" is  $E_D$ , and the average expected return  $\bar{E}_F$  will be

government, and financial institutes can be expressed as follows:

TABLE 1: Parameter setting and explanations.

Parameters	Explanations
$F_Q$	Financial institutes' investments to enterprises with high R&D intensity
$F_L$	Financial institutes' investments to enterprises with low R&D intensity
$\alpha_Q$	R&D expense as % of financing for enterprises with high R&D intensity
$\alpha_L$	R&D expense as % of financing for enterprises with low R&D intensity
$\beta_Q$	Revenue per unit R&D expense for enterprises with high R&D intensity
$\beta_L$	Revenue per unit R&D expense for enterprises with low R&D intensity
$S_Q$	Government subsidies to enterprises with high R&D intensity
$S_L$	Government subsidies to enterprises with low R&D intensity
$k$	Reputation multiplier by government subsidies
$C_G$	Administrative costs of government subsidies
$g_Q$	Economic and social externality multiplier by innovation of enterprises with high R&D intensity
$g_L$	Economic and social externality multiplier by innovation of enterprises with low R&D intensity
$\delta$	Equity investment earnings as % of revenue
$r_S$	Debt investment yield with government subsidies
$r_N$	Debt investment yield without government subsidies
$x$	Probability of enterprises adopting high R&D intensity strategy
$y$	Probability of government adopting subsidy policy
$z$	Probability of equity investment from financial institutes

(1) Science-tech enterprises' replicated dynamic differential equation:

$$\begin{aligned}
F(x) &= \frac{dx}{dt} \\
&= x(E_Q - \bar{E}_I) \\
&= x(1-x)(E_Q - E_L) \\
&= x(1-x)[(1+yk-y)(\alpha_Q\beta_QF_Q - \alpha_L\beta_LF_L) + yk(\alpha_Q\beta_QS_Q - \alpha_L\beta_LS_L) - (1-z)(yr_S + r_N + 1 - yr_N)(F_Q - F_L)].
\end{aligned} \tag{4}$$

(2) Government's replicated dynamic differential equation:

$$\begin{aligned}
F(y) &= \frac{dy}{dt} \\
&= y(E_S - \bar{E}_G) \\
&= y(1-y)(E_S - E_N) \\
&= y(1-y)[x\alpha_Q\beta_Qg_Q(k-1)F_Q + x(\alpha_Q\beta_Qg_Qk-1)S_Q + (1-x)\alpha_L\beta_Lg_L(k-1)F_L + (1-z)(\alpha_L\beta_Lg_Lk-1)S_L - C_G].
\end{aligned} \tag{5}$$

(3) Financial institutes' replicated dynamic differential equation:

TABLE 2: Revenue matrix.

Strategy selection	Science-tech enterprises	Government	Equity investment ( $z$ )	Financial institute	Debt investment ( $1 - z$ )
Innovation with high/low R&D intensity	Q: high R&D intensity ( $x$ )	Subsidies ( $y$ )	$(F_Q + S_Q)\alpha_Q\beta_Q k(F_Q + S_Q)\alpha_Q\beta_Q k g_Q - S_Q - C_G(F_Q + S_Q)\alpha_Q\beta_Q k \delta$	$(F_Q + S_Q)\alpha_Q\beta_Q k - F_Q(\tau_s + 1)(F_Q + S_Q)\alpha_Q\beta_Q k g_Q - S_Q - C_G F_Q \tau_s$	
		No subsidies ( $1 - y$ )	$F_Q\alpha_Q\beta_Q F_Q\alpha_Q\beta_Q g_Q F_Q\alpha_Q\beta_Q \delta$	$F_Q\alpha_Q\beta_Q - F_Q(\tau_N + 1)F_Q\alpha_Q\beta_Q g_Q F_Q \tau_N$	
	L: low R&D intensity ( $1 - x$ )	Subsidies ( $y$ )	$(F_L + S_L)\alpha_L\beta_L k(F_L + S_L)\alpha_L\beta_L k g_L - S_L - C_G(F_L + S_L)\alpha_L\beta_L k \delta$	$(F_L + S_L)\alpha_L\beta_L k - F_L(\tau_s + 1)(F_L + S_L)\alpha_L\beta_L k g_L - S_L - C_G F_L \tau_s$	
		No subsidies ( $1 - y$ )	$F_L\alpha_L\beta_L F_L\alpha_L\beta_L g_L F_L\alpha_L\beta_L \delta$	$F_L\alpha_L\beta_L - F_L(\tau_N + 1)F_L\alpha_L\beta_L g_L F_L \tau_N$	

TABLE 3: Jacobian matrix eigenvalues.

Equalization points	Eigenvalues $\lambda_1$	Eigenvalues $\lambda_2$	Eigenvalues $\lambda_3$
$0(0, 0, 0)$	$\alpha_Q \beta_Q F_Q - \alpha_I \beta_I F_L - (r_N + 1)(F_Q - F_L)$	$\alpha_I \beta_I g_L (k - 1) F_L + (\alpha_I \beta_I g_I k - 1) S_L - C_G$	$(\alpha_I \beta_I \delta - r_N) F_L$

$B(0, 1, 0)$	$k \alpha_Q \beta_Q (F_Q + S_Q) - k \alpha_I \beta_I (F_L + S_L) - (r_S + 1)(F_Q - F_L)$	$-\alpha_I \beta_I g_L (k - 1) F_L - (\alpha_I \beta_I g_I k - 1) S_L + C_G$	$k \alpha_I \beta_I \delta (F_L + S_L) - r_S F_L$
$C(0, 1, 1)$	$k \alpha_Q \beta_Q (F_Q + S_Q) - k \alpha_I \beta_I (F_L + S_L)$	$-\alpha_I \beta_I g_L (k - 1) F_L - (\alpha_I \beta_I g_I k - 1) S_L + C_G$	$-k \alpha_I \beta_I \delta (F_L + S_L) + r_S F_L$
$D(1, 0, 0)$	$\alpha_I \beta_I F_L - \alpha_Q \beta_Q F_Q + (r_N + 1)(F_Q - F_L)$	$\alpha_Q \beta_Q g_Q (k - 1) F_Q + (\alpha_Q \beta_Q g_Q k - 1) S_Q - C_G$	$(\alpha_Q \beta_Q \delta - r_N) F_Q$
$E(1, 0, 1)$	$\alpha_I \beta_I F_L - \alpha_Q \beta_Q F_Q$	$\alpha_Q \beta_Q g_Q (k - 1) F_Q + (\alpha_Q \beta_Q g_Q k - 1) S_Q - C_G$	$-(\alpha_Q \beta_Q \delta - r_N) F_Q$
$F(1, 1, 0)$	$k \alpha_I \beta_I (F_L + S_L) + (r_S + 1)(F_Q - F_L) - k \alpha_Q \beta_Q (F_Q + S_Q)$	$-\alpha_Q \beta_Q g_Q (k - 1) F_Q + (\alpha_Q \beta_Q g_Q k - 1) S_Q - C_G$	$k \alpha_Q \beta_Q \delta (F_Q + S_Q) - r_S F_Q$
$G(1, 1, 1)$	$k \alpha_I \beta_I (F_L + S_L) - k \alpha_Q \beta_Q (F_Q + S_Q)$	$-\alpha_Q \beta_Q g_Q (k - 1) F_Q + (\alpha_Q \beta_Q g_Q k - 1) S_Q - C_G$	$r_S F_Q - k \alpha_Q \beta_Q \delta (F_Q + S_Q)$

$$\begin{aligned}
F(z) &= \frac{dz}{dt} \\
&= z(E_E - \overline{E_F}) \\
&= z(1-z)(E_E - E_D) \\
&= z(1-z)\{x[(yk+1-y)\alpha_Q\beta_Q\delta - yr_S - (1-y)r_N]F_Q + xyk\alpha_Q\beta_Q\delta S_Q + (1-x)[(yk+1-y)\alpha_L\beta_L\delta \\
&\quad - yr_S - (1-y)r_N]F_L + (1-x)yk\alpha_L\beta_L\delta S_L\}.
\end{aligned} \tag{6}$$

Combining three equations, we will get the replication power system of science-tech enterprise, government, and financial institutes as below:

$$\begin{cases}
F(x) = x(1-x)[(1+yk-y)(\alpha_Q\beta_Q F_Q - \alpha_L\beta_L S_L) - (1-z)(yr_S + r_N + 1 - yr_N)(F_Q - F_L)], \\
F(y) = y(1-y)[x\alpha_Q\beta_Q g_Q(k-1)F_Q + x(\alpha_Q\beta_Q g_Q k - 1)S_Q + (1-x)\alpha_L\beta_L g_L(k-1)F_L + (1-z)(\alpha_L\beta_L g_L k - 1)S_L - C_G], \\
F(z) = z(1-z)\{x[(yk+1-y)\alpha_Q\beta_Q\delta - yr_S - (1-y)r_N]F_Q + xyk\alpha_Q\beta_Q\delta S_Q + (1-x)[(yk+1-y)\alpha_L\beta_L\delta - yr_S - (1-y)r_N] \\
F_L + (1-x)yk\alpha_L\beta_L\delta S_L\}.
\end{cases} \tag{7}$$

### 4.3. Strategy Portfolio Stability Analysis

4.3.1. *Equilibrium of Dynamic System.* According to Takalo and Tanayama [11], we can judge the strategy portfolio stability by analyzing the Jacobian matrix; then, we conduct the replicated dynamic system Jacobian matrix:

$$J = \begin{pmatrix} P_{11} & P_{12} & P_{13} \\ P_{21} & P_{22} & P_{23} \\ P_{31} & P_{32} & P_{33} \end{pmatrix}. \tag{8}$$

Among them,

$$P_{11} = \frac{\partial F(x)}{\partial x}$$

$$= (1 - 2x)[(1 + yk - y)(\alpha_Q\beta_Q F_Q - \alpha_L\beta_L F_L) + yk(\alpha_Q\beta_Q S_Q - \alpha_L\beta_L S_L) - (1 - z)(yr_S + r_N + 1 - yr_N)(F_Q - F_L)],$$

$$P_{12} = \frac{\partial F(x)}{\partial y}$$

$$= x(1 - x)[(k - 1)(\alpha_Q\beta_Q F_Q - \alpha_L\beta_L F_L) + k(\alpha_Q\beta_Q S_Q - \alpha_L\beta_L S_L) - (1 - z)(r_S - r_N)(F_Q - F_L)],$$

$$P_{13} = \frac{\partial F(x)}{\partial z}$$

$$= x(1 - x)\left(yr_S + \text{tarts} - \text{with}(., 'hskip')\right)''hskip''\text{substring} - \text{after}(\text{preceding} - \text{sibling} :: \text{comment}()[\text{starts} - \text{with}(., 'hskip')], 'hskip')$$

(9)

In the dynamic system composed of three game agents, assuming  $F(x) = 0$ ,  $F(y) = 0$ , and  $F(z) = 0$ , we obtain eight Nash equilibrium points of the system: O(0, 0, 0), A(0, 0, 1), B(0, 1, 0), C(0, 1, 1), D(1, 0, 0), E(1, 0, 1), F(1, 1, 0), and G(1, 1, 1).

According to Lyapunov's first law, if the eigenvalues of the corresponding matrix are all negative, the equilibrium point is the system's ESS. The stability of each point is shown in Table 3.

**4.3.2. Equilibrium Stability Analysis.** The calculations reveal that this study should analyze the game's stabilization strategy in 8 scenarios.

Scenario 1: if the following conditions are satisfied, the equilibrium is G(1, 1, 1):

$$\begin{cases} \alpha_L\beta_L(F_L + S_L) < \alpha_Q\beta_Q(F_Q + S_Q), \\ C_G < \alpha_Q\beta_Q g_Q(k - 1)F_Q + (\alpha_Q\beta_Q g_Q k - 1)S_Q, \\ r_S F_Q < k\alpha_Q\beta_Q \delta(S_Q + F_Q). \end{cases} \quad (10)$$

When  $\alpha_L\beta_L(F_L + S_L) < \alpha_Q\beta_Q(F_Q + S_Q)$ ,  $C_G < \alpha_Q\beta_Q g_Q(k - 1)F_Q + (\alpha_Q\beta_Q g_Q k - 1)S_Q$ ,  $r_S F_Q < k\alpha_Q\beta_Q \delta(S_Q + F_Q)$ , the eigenvalues of the Jacobi matrix corresponding to the evolutionary stability point G(1, 1, 1) are negative, indicating that G(1, 1, 1) is ESS. This indicates that science-tech enterprises choose high R&D intensity when the benefits from innovation investment of high R&D intensity firms exceeds that of low R&D intensity firms. When the socio-economic benefits increased by government subsidies outweigh the administrative costs, the government chooses to implement subsidies for high R&D-intensive enterprises. Therefore, financial institutes choose to make equity investments when the return on equity investment in high R&D intensity enterprises that receive government subsidies is greater than the return on debt investment.

Scenario 2: if the following conditions are satisfied, the equilibrium is F(1, 1, 0):

$$\begin{cases} k\alpha_L\beta_L(F_L + S_L) + (r_S + 1)(F_Q - F_L) < k\alpha_Q\beta_Q(F_Q + S_Q), \\ C_G < \alpha_Q\beta_Q g_Q(k - 1)F_Q + (\alpha_Q\beta_Q g_Q k - 1)S_Q, \\ k\alpha_Q\beta_Q \delta(S_Q + F_Q) < r_S F_Q. \end{cases} \quad (11)$$

When  $k\alpha_L\beta_L(F_L + S_L) + (r_S + 1)(F_Q - F_L) < k\alpha_Q\beta_Q(F_Q + S_Q)$ ,  $C_G < \alpha_Q\beta_Q g_Q(k - 1)F_Q + (\alpha_Q\beta_Q g_Q k - 1)S_Q$ , and  $k\alpha_Q\beta_Q \delta(S_Q + F_Q) < r_S F_Q$ , the eigenvalues of the Jacobi matrix corresponding to the evolutionary stability point F(1, 1, 0) are negative, indicating that F(1, 1, 0) is ESS. This indicates that enterprises choose a high R&D intensity when the total benefits termed by the high R&D intensity technology are higher than those received by the low R&D intensity firm. The total benefits include the subsidies received from the government and the resulting reputational value added (this reputational value added mainly comes in the form of obtaining lower debt financing costs). The government will choose to subsidize high R&D intensity enterprises when the socio-economic benefits of government subsidies outweigh the administrative costs. Financial institutes, on the contrary, have a greater return on debt investment than on equity investment and therefore choose debt investment.

Scenario 3: if the following conditions are satisfied, the equilibrium is E(1, 0, 1):

$$\begin{cases} \alpha_L\beta_L F_L < \alpha_Q\beta_Q F_Q, \\ \alpha_Q\beta_Q g_Q(k - 1)F_Q + (\alpha_Q\beta_Q g_Q k - 1)S_Q < C_G, \\ r_N < \alpha_Q\beta_Q \delta. \end{cases} \quad (12)$$

When  $\alpha_L\beta_L F_L < \alpha_Q\beta_Q F_Q$ ,  $\alpha_Q\beta_Q g_Q(k - 1)F_Q + (\alpha_Q\beta_Q g_Q k - 1)S_Q < C_G$ , and  $r_N < \alpha_Q\beta_Q \delta$ , the eigenvalues of

the Jacobi matrix corresponding to the evolutionary stability point  $E(1, 0, 1)$  are negative, indicating that  $E(1, 0, 1)$  is ESS. This indicates that enterprises that receive equity investment from financial institutes for high R&D intensity will choose high R&D intensity when the return is greater than the return for low R&D intensity. The government will not subsidize when the economic and social benefits gained from government subsidies are not sufficient to offset the cost of administration. Financial institutes choose to make equity investments in high R&D intensity enterprises when the rate of return on equity investments in science-tech enterprises is greater than that of return on debt investments.

Scenario 4: if satisfy the following conditions, the equilibrium is D  $(1, 0, 0)$ :

$$\begin{cases} \alpha_L \beta_L F_L + (r_N + 1)(F_Q - F_L) < \alpha_Q \beta_Q F_Q, \\ \alpha_Q \beta_Q g_Q (k-1)F_Q + (\alpha_Q \beta_Q g_Q k - 1)S_Q < C_G, \\ \alpha_Q \beta_Q \delta < r_N. \end{cases} \quad (13)$$

When  $\alpha_L \beta_L F_L + (r_N + 1)(F_Q - F_L) < \alpha_Q \beta_Q F_Q$ ,  $\alpha_Q \beta_Q g_Q (k-1)F_Q + (\alpha_Q \beta_Q g_Q k - 1)S_Q < C_G$ , and  $\alpha_Q \beta_Q \delta < r_N$ , the eigenvalues of the Jacobi matrix corresponding to the evolutionary stability point D  $(1, 0, 0)$  are negative, indicating that D  $(1, 0, 0)$  is ESS. This indicates that enterprises that receive loans from financial institutes will choose high R&D intensity when the return of innovation investment for high R&D intensity is greater than the return for low R&D intensity. The government subsidizes when the economic and social benefits gained from government subsidies are not sufficient to offset the cost of administration. Financial institutes choose to make debt investments in high R&D intensity enterprises when the return on equity investment in science-tech enterprises is less than the return on debt investment.

Scenario 5: if the following conditions are satisfied, the equilibrium is C  $(0, 1, 1)$ :

$$\begin{cases} \alpha_Q \beta_Q (F_Q + S_Q) < \alpha_L \beta_L (F_L + S_L), \\ C_G < \alpha_L \beta_L g_L (k-1)F_L + (\alpha_L \beta_L g_L k - 1)S_L, \\ r_S F_L < k \alpha_L \beta_L \delta (S_L + F_L). \end{cases} \quad (14)$$

When  $\alpha_Q \beta_Q (F_Q + S_Q) < \alpha_L \beta_L (F_L + S_L)$ ,  $C_G < \alpha_L \beta_L g_L (k-1)F_L + (\alpha_L \beta_L g_L k - 1)S_L$ , and  $r_S F_L < k \alpha_L \beta_L \delta (S_L + F_L)$ , the eigenvalues of the Jacobi matrix corresponding to the evolutionary stability point C  $(0, 1, 1)$  are negative, indicating that C  $(0, 1, 1)$  is ESS. This indicates that the enterprises choose to make low R&D intensity, when the benefits of high R&D intensity are less than the benefits of low R&D intensity. The government chooses to subsidize when the economic and social benefits gained from government subsidies outweigh the administrative costs. Financial institutes choose to make equity investments in low R&D

intensity enterprises when the return on equity investment in low R&D intensity science-tech enterprises is greater than the return on debt investment. Science-tech enterprises receive government subsidies and equity financing to invest in R&D.

Scenario 6: if the following conditions are satisfied, the equilibrium is B  $(0, 1, 0)$ :

$$\begin{cases} k \alpha_Q \beta_Q (F_Q + S_Q) - (r_S + 1)(F_Q - F_L) < k \alpha_L \beta_L (F_L + S_L), \\ C_G < \alpha_L \beta_L g_L (k-1)F_L + (\alpha_L \beta_L g_L k - 1)S_L, \\ k \alpha_L \beta_L \delta (S_L + F_L) < r_S F_L. \end{cases} \quad (15)$$

When  $k \alpha_Q \beta_Q (F_Q + S_Q) - (r_S + 1)(F_Q - F_L) < k \alpha_L \beta_L (F_L + S_L)$ ,  $C_G < \alpha_L \beta_L g_L (k-1)F_L + (\alpha_L \beta_L g_L k - 1)S_L$ , and  $k \alpha_L \beta_L \delta (S_L + F_L) < r_S F_L$ , the eigenvalues of the Jacobi matrix corresponding to the evolutionary stability point B  $(0, 1, 0)$  are negative, indicating that B  $(0, 1, 0)$  is ESS. This indicates that the enterprises choose low R&D intensity, when the benefits of high R&D intensity are less than the benefits obtained from low R&D intensity. The government chooses to subsidize when the economic and social benefits gained from government subsidies outweigh the administrative costs. Financial institutes choose to make debt investments in low R&D intensity enterprises when the return on equity investment is less than the return on debt investment. Science-tech enterprises receive government subsidies and debt financing for R&D investment.

Scenario 7: if the following conditions are satisfied, the equilibrium is A  $(0, 0, 1)$ :

$$\begin{cases} \alpha_Q \beta_Q F_Q < \alpha_L \beta_L F_L, \\ \alpha_L \beta_L g_L (k-1)F_L + (\alpha_L \beta_L g_L k - 1)S_L < C_G, \\ r_N < \alpha_L \beta_L \delta. \end{cases} \quad (16)$$

When  $\alpha_Q \beta_Q F_Q < \alpha_L \beta_L F_L$ ,  $\alpha_L \beta_L g_L (k-1)F_L + (\alpha_L \beta_L g_L k - 1)S_L < C_G$ , and  $r_N < \alpha_L \beta_L \delta$ , the eigenvalues of the Jacobi matrix corresponding to the evolutionary stability point A  $(0, 0, 1)$  are negative, indicating that A  $(0, 0, 1)$  is ESS. This indicates that enterprises choose low R&D intensity when the return of innovation investment is less. The government will not subsidize when the economic and social benefits gained are not sufficient to offset the cost of administration. Financial institutes choose to make equity investments in low R&D intensity enterprises when the return is greater than that on debt investment.

Scenario 8: if the following conditions are satisfied, the equilibrium is O  $(0, 0, 0)$ :

$$\begin{cases} \alpha_Q \beta_Q F_Q - (r_N + 1)(F_Q - F_L) < \alpha_L \beta_L F_L, \\ \alpha_L \beta_L g_L (k-1)F_L + (\alpha_L \beta_L g_L k - 1)S_L < C_G, \\ \alpha_L \beta_L \delta < r_N. \end{cases} \quad (17)$$

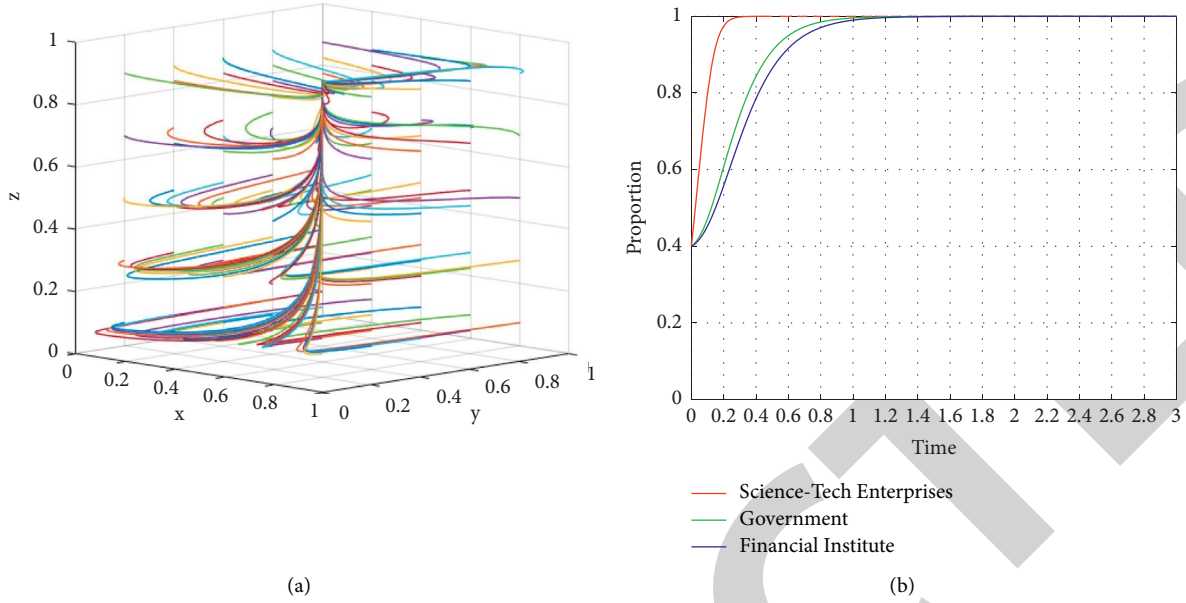

FIGURE 2: (a) Three-dimensional situation of evolutionary trajectory of  $G(1, 1, 1)$ . (b) Two-dimensional situation of evolutionary trajectory of  $G(1, 1, 1)$ .

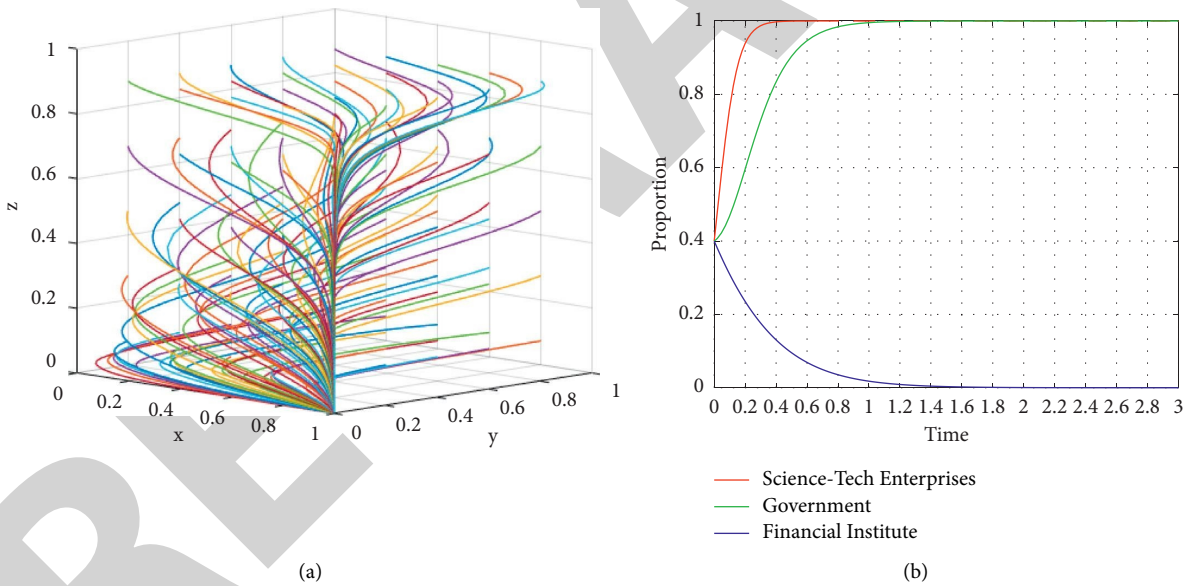

FIGURE 3: (a) Three-dimensional situation of evolutionary trajectory of  $F(1, 1, 0)$ . (b) Two-dimensional situation of evolutionary trajectory of  $F(1, 1, 0)$ .

When  $\alpha_Q \beta_Q F_Q - (r_N + 1)(F_Q - F_L) < \alpha_L \beta_L F_L$ ,  $\alpha_L \beta_L g_L (k - 1)F_L + (\alpha_L \beta_L g_L k - 1)S_L < C_G$ , and  $\alpha_L \beta_L \delta < r_N$ , the eigenvalues of the Jacobi matrix corresponding to the evolutionary stability point  $O(0, 0, 0)$  are negative, indicating that  $O(0, 0, 0)$  is ESS. This indicates that enterprises will choose low R&D intensity, when the profit of innovation investment is less. The government will not subsidize when the economic and social benefits gained from government subsidies are not sufficient to offset the cost of administration. Financial institutes choose debt investments in low

R&D intensity enterprises when the return on equity investments is less than the return on debt investments.

Based on the above evolutionary game model, we analyze the eight scenarios of different strategy portfolios chosen by enterprises, government, and financial institutes. For the three players, one's choice is the condition which can influence other two's choices. Enterprises choose high R&D intensity instead of low R&D intensity if the output of former exceeds that of the latter. Enterprises' R&D output is

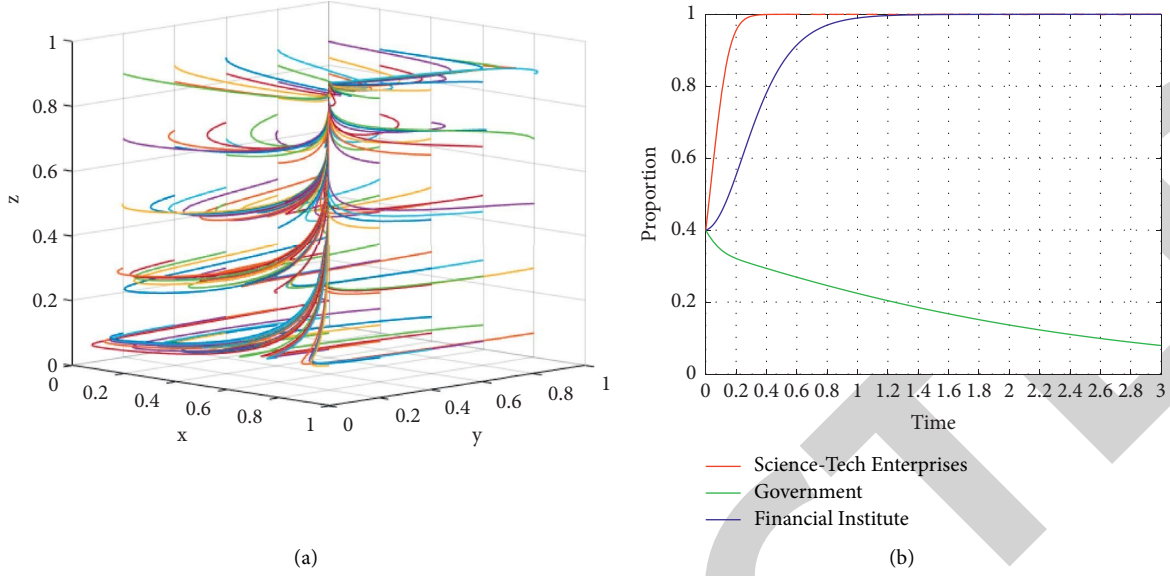

FIGURE 4: (a) Three-dimensional situation of evolutionary trajectory of E (1, 0, 1). (b) Two-dimensional situation of evolutionary trajectory of E (1, 0, 1).

FIGURE 5: (a) Three-dimensional situation of evolutionary trajectory of D (1, 0, 0). (b) Two-dimensional situation of evolutionary trajectory of D (1, 0, 0).

closely related to the strategy choices of the government and financial institutes. The government chooses provide subsidy if its benefits exceed its costs. As the government pays attention to broad economic and social targets, the benefits include not only the R&D output itself but also economic and social externalities and the regulation effect to enterprises. The cost includes subsidies as well as administrative costs. Financial institutes make strategy choices between equity investment and debt investment based on their investment yields. The debt investment yield is different with government subsidies from that without government subsidies.

## 5. Numerical Simulation

**5.1. The Evolutionary Trajectory of ESS.** For analyzing the dynamic evolution process, the strategy evolution process of the tripartite game in different scenarios can be simulated by changing the parameter settings. In this section, different stability conditions are brought into MATLAB R2022a to simulate the evolutionary trajectory.

- (1) Assume  $F_Q = 100$ ,  $F_L = 80$ ,  $\alpha_Q = 0.3$ ,  $\alpha_L = 0.2$ ,  $\beta_Q = 1.5$ ,  $\beta_L = 1.2$ ,  $S_Q = 10$ ,  $S_L = 8$ ,  $k = 1.2$ ,  $C_G = 1$ ,  $g_Q = 1.2$ ,  $g_L = 1.1$ ,  $\delta = 0.3$ ,  $r_S = 0.05$ , and  $r_N = 0.08$ . The evolutionary trajectory of G (1, 1, 1) is featured in

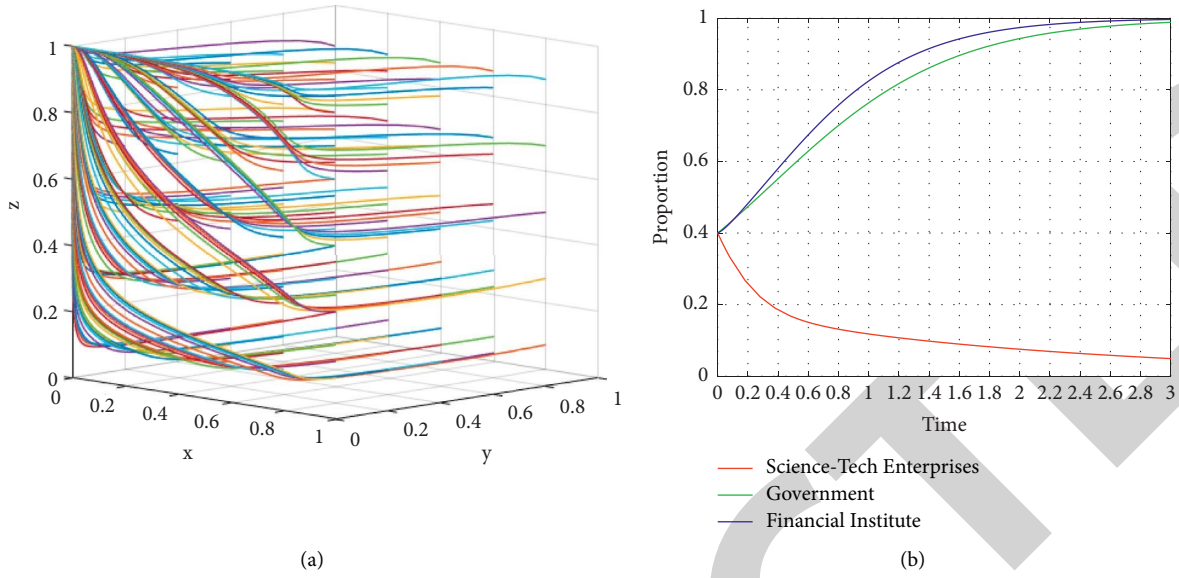

FIGURE 6: (a) Three-dimensional situation of evolutionary trajectory of  $C(0, 1, 1)$ . (b) Two-dimensional situation of evolutionary trajectory of  $C(0, 1, 1)$ .

The evolutionary trajectory of A (0, 0, 1) is featured in Figure 8(a). When the initial probabilities of all three parties are 0.4, the evolutionary trajectory is displayed in Figure 8(b).

- (8) Assume  $F_Q = 100$ ,  $F_L = 95$ ,  $\alpha_Q = 0.3$ ,  $\alpha_L = 0.2$ ,  $\beta_Q = 1.05$ ,  $\beta_L = 1.7$ ,  $S_Q = 10$ ,  $S_L = 8$ ,  $k = 1.1$ ,  $C_G = 1$ ,  $g_Q = 1.1$ ,  $g_L = 1.05$ ,  $\delta = 0.1$ ,  $r_S = 0.06$ , and  $r_N = 0.08$ . The evolutionary trajectory of O (0, 0, 0) is featured in Figure 9(a). When the initial probabilities of all three parties are 0.4, the evolutionary trajectory is displayed in Figure 9(b).

## 5.2. Single-Factor Sensitivity Analysis

### 5.2.1. Impact of Reputation Multiplier by Government Subsidies.

To evaluate the impact of reputation multiplier “ $k$ ” by government subsidies on the evolutionary outcomes and trajectories of the innovation tripartite ESS, numerical simulations were conducted in this study. Set the initial parameters as follows. F (1, 1, 0):  $F_Q = 100$ ,  $F_L = 80$ ,  $\alpha_Q = 0.3$ ,  $\alpha_L = 0.2$ ,  $\beta_Q = 1.5$ ,  $\beta_L = 1.2$ ,  $S_Q = 10$ ,  $S_L = 8$ ,  $k = 1.2$ ,  $C_G = 1$ ,  $g_Q = 1.2$ ,  $g_L = 1.1$ ,  $\delta = 0.1$ ,  $r_S = 0.06$ , and  $r_N = 0.08$ .

Let  $k = 1.6, 1.4, 1.2, 1.1, 1$  and keep other parameters constant; the evolutionary outcomes and trajectories of tripartite ESS are as shown in Figures 10(a)–10(c). This indicates that the size of the reputation multiplier from government subsidies does not affect the R&D intensity of

FIGURE 11: Impact of economic and social externality multiplier by innovation of enterprises with high R&D intensity “ $g_Q$ ” (a)  $g_Q$  for science-tech enterprises; (b) for government; (c) for financial institutes.

science-tech enterprises. This means that enterprises will choose to invest in high R&D regardless of whether government subsidies send a positive signal to the market. As the reputation multiplier from government financial subsidies increases for enterprises, the government is more willing to provide subsidies to enterprises. However, for financial institutes, the reputation multiplier from government subsidies affects the investment decisions of financial institutes. As the reputation multiplier decreases, financial institutes will be more inclined to invest in debt and will accelerate the rate of evolution.

**5.2.2. Impact of Economic and Social Externality Multiplier by Innovation.** To evaluate the impact of economic and

social externality multiplier “ $g_Q$ ” by innovation of enterprises with high R&D intensity on the evolutionary outcomes and trajectories of the innovation tripartite ESS, numerical simulations were conducted in this study. Set the initial parameters as follows.  $F(1, 1, 0)$ :  $F_Q = 100$ ,  $F_L = 80$ ,  $\alpha_Q = 0.3$ ,  $\alpha_L = 0.2$ ,  $\beta_Q = 1.5$ ,  $\beta_L = 1.2$ ,  $S_Q = 10$ ,  $S_L = 8$ ,  $k = 1.2$ ,  $C_G = 1$ ,  $g_Q = 1.2$ ,  $g_L = 1.1$ ,  $\delta = 0.1$ ,  $r_S = 0.06$ , and  $r_N = 0.08$ .

Let  $g_Q = 1.4, 1.2, 1.1, 1, 0.9$  and keep other parameters constant; the evolutionary outcomes and trajectories of tripartite ESS are as shown in Figures 11(a)–11(c). This indicates that, as the economic and social externalities from innovation by high R&D intensity enterprises increase, the government is more willing to subsidize enterprises, and enterprises are more willing to choose high R&D intensity. In contrast, a negative economic and social externality from

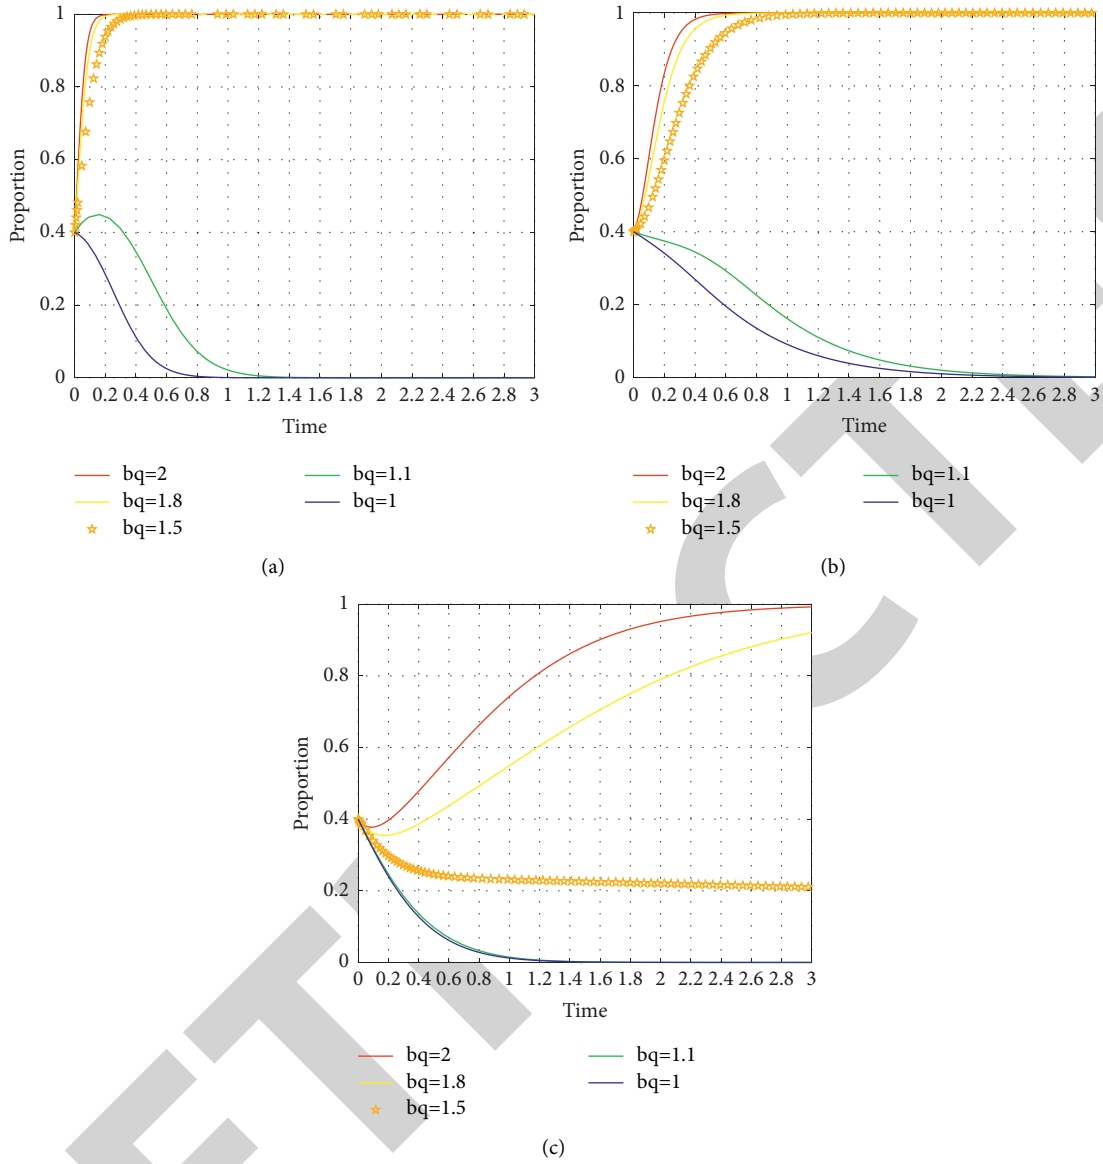

FIGURE 12: Impact of revenue per unit R&D expense for enterprises with high R&D intensity “ $\beta_Q$ ” (a)  $\beta_Q$  for Science-Tech Enterprises; (b) for government; (c) for financial institutes.

a firm’s innovation, i.e., a multiplier less than 1, increases the probability that the government will choose not to subsidize and that it will accelerate the rate of evolution. However, regardless of whether the socio-economic externality is positive or negative, financial institutes tend to choose debt investment to protect against risk.

**5.2.3. Impact of Revenue per Unit R&D Expense for Enterprises with High R&D Intensity.** To evaluate the impact of revenue per unit R&D expense for enterprises with high R&D intensity “ $\beta_Q$ ” on the evolutionary outcomes and trajectories of the innovation tripartite ESS, numerical simulations were conducted in this study. Set the initial parameters as follows.  $F(1, 1, 0)$ :  $F_Q = 100$ ,  $F_L = 80$ ,  $\alpha_Q = 0.3$ ,

$\alpha_L = 0.2$ ,  $\beta_Q = 1.5$ ,  $\beta_L = 1.2$ ,  $S_Q = 10$ ,  $S_L = 8$ ,  $k = 1.2$ ,  $C_G = 1$ ,  $g_Q = 1.2$ ,  $g_L = 1.1$ ,  $\delta = 0.1$ ,  $r_S = 0.06$ , and  $r_N = 0.08$ .

Let  $\beta_Q = 2, 1.8, 1.5, 1.1, 1$  and keep other parameters constant; the evolutionary outcomes and trajectories of tripartite ESS are as shown in Figures 12(a)–12(c). This indicates that science-tech enterprises are more inclined to high R&D intensity as the revenue per unit of R&D expense for enterprises with high R&D intensity, and vice versa. The probability of government subsidies also increases with the revenue per unit of R&D expense for enterprises with high R&D intensity increases. Financial institutes increase the probability of debt investment as the revenue per unit of R&D expense for enterprises with high R&D intensity decreases.

**5.2.4. Impact of Equity Investment Earnings as % of Revenue.**

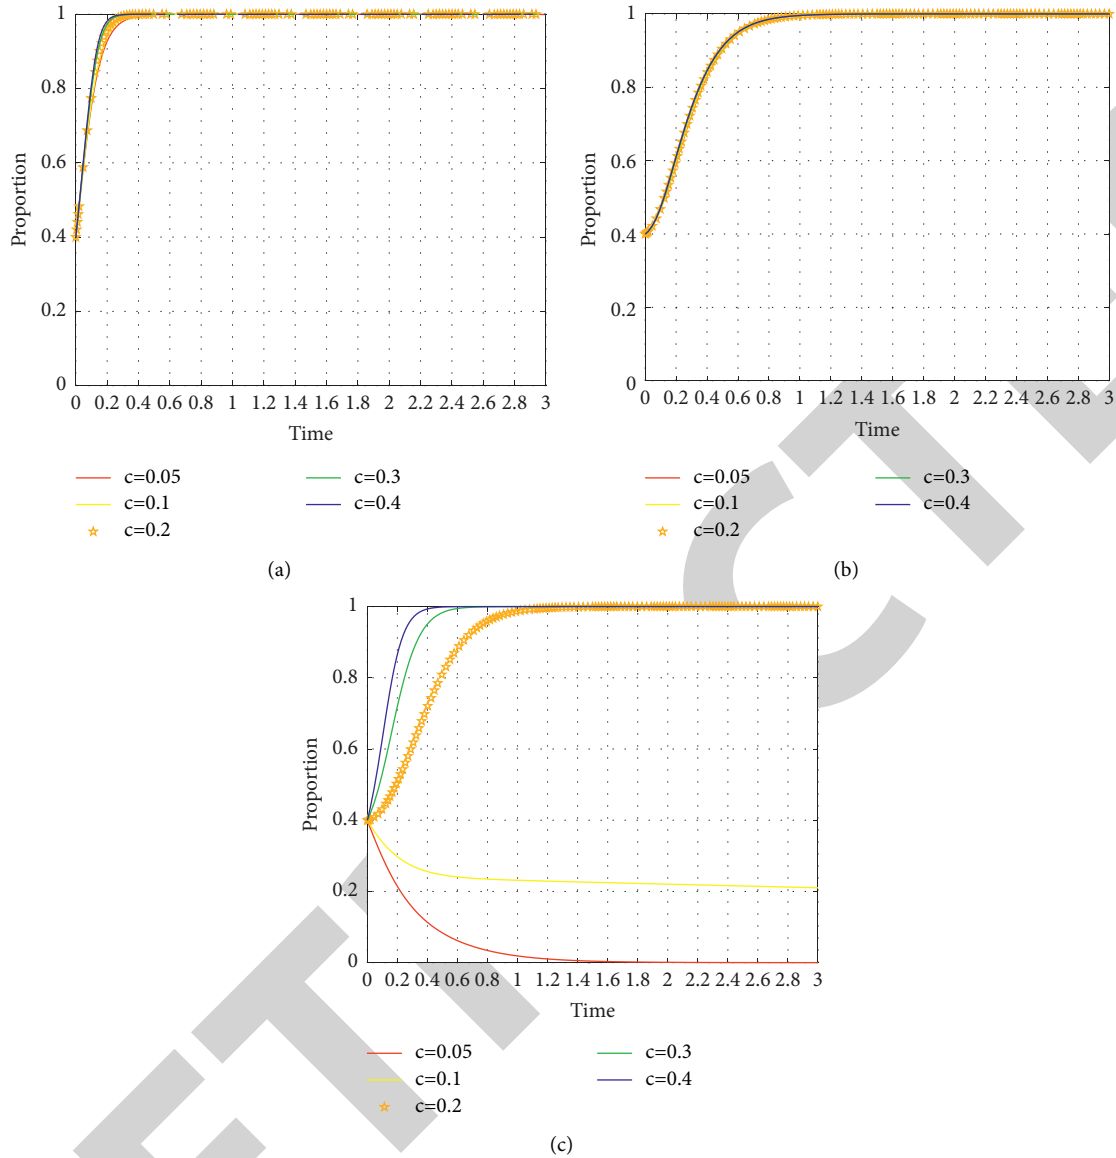

FIGURE 13: Impact of equity investment earnings as % of revenue “ $\delta$ ” (a)  $\delta$  for science-tech enterprises; (b) for government; (c) for financial institutes.

To evaluate the impact of equity investment earnings as % of revenue “ $\delta$ ” for science-tech enterprises “ $\delta$ ” on the evolutionary outcomes and trajectories of the innovation tripartite ESS, numerical simulations were conducted in this study. Set the initial parameters as follows.  $F(1, 1, 0)$ :  $F_Q = 100$ ,  $F_L = 80$ ,  $\alpha_Q = 0.3$ ,  $\alpha_L = 0.2$ ,  $\beta_Q = 1.5$ ,  $\beta_L = 1.2$ ,  $S_Q = 10$ ,  $S_L = 8$ ,  $k = 1.2$ ,  $C_G = 1$ ,  $g_Q = 1.2$ ,  $g_L = 1.1$ ,  $\delta = 0.1$ ,  $r_S = 0.06$ , and  $r_N = 0.08$ .

Let  $\delta = 0.05, 0.1, 0.2, 0.3, 0.4$  and keep other parameters constant; the evolutionary outcomes and trajectories of tripartite ESS are as shown in Figures 13(a)–13(c). This indicates that the probability of choice by firms and government is not affected by equity investment earnings as % of revenue. Regardless of the return on equity investment,

science-tech enterprises will tend to choose high R&D intensity, while the government will tend to choose subsidies. However, as the rate of return on equity investment increases, financial institutes will increase the probability of making equity investments in science-tech enterprises.

## 6. Conclusion

This study focuses on the tripartite decision-making mechanism between government, financial institutes, and technology companies on subsidies, investment patterns, and R&D intensity. The following conclusions are drawn from the study in this paper.

First, enterprises can attract government subsidy by boosting economic and social externalities. The higher density of R & D investment in the science-tech enterprises is, the higher positive external economy and benefits to the government is. As the government pays attention to broad economic and social targets, enterprises can choose the R&D projects with high positive economic and social externalities to provide incentive to the government to provide subsidy.

Second, government subsidy policy can influence the choices of enterprises and financial institutes. The government subsidies to enterprises with high R&D intensity will improve the innovation output by the innovation investment and reputation multiplier. So, the government can implement subsidy policy to attract enterprises to make high-intensive R&D activity and financial institutes to make equity investment. For small high-tech startups, government subsidy can improve their reputation in the market, which can help them to raise fund in the market and find good partners and increase the R&D output efficiency. It would be a better approach for the government to improve the market credible evaluation and subsidy recognition system for high-tech companies as a way to increase their reputation multiplier. In reality, government subsidies can take many forms and tax credit, for R&D expense is a popular policy.

Third, financial institutes' strategy choice is influenced by investment yield difference and can influence enterprises' R&D intensity choices. The policymakers can boost equity investment and R&D activity by developing capital market and optimizing subsidy policy. Supporting enterprises with high R&D intensity to go listing can attract financial institutes to make equity investment and enterprises to choose high R&D intensity strategy.

The above research results provide a good reference for policymakers to develop strategies for innovation. However, some limitations of this study still exist: this study only considers the effect of government subsidy behavior on the choice of investment patterns of financial institutions and the R&D intensity of firms, without further examining the effect of other incentive approaches. At the same time, research institutes (including universities and other institutes) need to be included in the analytical framework for exploration. Thus, multiparty decisions under multiple government incentive discretionary decisions will be the next step of research.

The industrial control data set has many features and large redundancy, which has a certain impact on the training speed and classification results of the neural network anomaly detection algorithm. However, features are independent of each other, and dimension reduction often increases the false positive rate and false negative rate. The feature sequencing algorithm can reduce this effect. In order to select the appropriate feature sequencing algorithm for different data sets, this paper proposes an adaptive feature sequencing method based on data set evaluation index parameters. Firstly, the evaluation index system is constructed by the basic information of the data set, the mathematical characteristics of the data set, and the association degree of the data set. Then, the selection model is obtained by the decision tree training with the data label and the evaluation index, and the suitable feature sequencing algorithm is selected. Experiments were conducted on 11 data sets, including Batadal data set, CICIDS 2017, and Mississippi data set. The sequenced data sets are classified by ResNet. The accuracy of the sequenced data sets increases by 2.568% on average in 30 generations, and the average time reduction per epoch is 24.143%. Experiments show that this method can effectively select the feature sequencing algorithm with the best comprehensive performance.

## 1. Introduction

With the development of industrial control systems [1] and digital communication technology, the industrial control network needs to face more and more external network access attacks [2–3]. Therefore, more research has been carried out on anomaly detection algorithm [4–8]. However, in the process of digitization, the feature dimensions in industrial control data increase, which increases the complexity of data processing tasks. This leads to the increase in learning cost and memory cost in anomaly detection, which limits the establishment of the learning model [9]. How to reduce the complexity between features and speed up the establishment of the model has become an urgent problem to be solved.

Methods in feature engineering are often used to reduce the complexity of features. Porizka et al. [10] applied the

principal component analysis algorithm to the Laser-Induced Breakdown Spectroscopy to process the detected multivariate signals (characteristic spectrum), but the principal component analysis algorithm will map the characteristic data, and the results are different from the original features. Chen et al. [11] used the ant colony algorithm to select features, eliminate redundant features, and improve the speed of deep reinforcement learning training, but the generalization ability of the model decreases after reducing features.

Feature sequencing methods have been widely used in various engineering projects, such as filtering method [12], Pearson correlation coefficient, Spearman correlation coefficient [13], information entropy [14], Lasso [15], elastic network [16], recursive feature elimination based on SVM [17], Bayesian kernel model [18], and gradient learning [19]. In addition, there are many studies on the application

in specific scenes. Pandeya et al. [20] applied the REF algorithm to the risk feature identification in the banking industry, designated the features of the data according to the value of credit risk classification, evaluated its value through repeated sampling, and gave weight. Then, these weights are used to separate the adjacent data of the same and different credit risks to complete the risk feature sequencing. In the structural damage detection of civil housing, Zhou et al. [21] processed the collected vibration acceleration signal through wavelet packet decomposition and converted it into the initial energy feature set, then eliminated the least important features through the RF-REF algorithm, evaluated the importance of the important sequence of features, and completed the reordering of features. Matej et al. [22] studied the problem of finding biomarkers, used random forest and RReliefF algorithms for feature sequencing, and compared the forward feature addition curve and reverse feature addition curve of the two algorithms in two different data sets, as well as the sequencing stability.

The above references all introduce feature sequencing algorithms, but the effect of the feature sequencing method on different data sets is obviously different. When the consistency between the method and the application scene features is low, there will be problems such as selection redundancy, unable to detect the relationship between all features, and high computational complexity [23, 24]. This paper presents a method to quickly find an appropriate feature reordering algorithm for data sets.

In view of the above problems, the main objectives of this paper could be summarized as follows: (1) Establish the evaluation index system of basic information of the data set. (2) Complete the adaptive feature sequencing method.

The current work can be divided into five sections. Section 1 introduces the necessity of improving the feature sequencing algorithm in an industrial control system. Section 2 describes the methods used in the current work. Then, Section 3 describes the experimental design. Section 4 describes the results, and the discussion and conclusion are described in detail in Section 5.

## 2. Method

In the field of industrial control anomaly detection, the feature sequencing algorithm is a preprocessing algorithm used in neural networks to detect system parameter information, mainly to solve the impact of the correlation uncertainty between dimensions on the neural network algorithm. The algorithm in this paper is mainly divided into an evaluation index system and decision tree model construction, as shown in Figure 1.

In this paper, the experimental data set is input, and the sequenced data set after sequencing is obtained by different feature sequencing algorithms. Then, the parameters of the sequenced data set in the evaluation index system are calculated. Finally, the Gini coefficient is used to construct the decision tree model to complete the selection method and realize the program function. The specific steps are shown in Figure 2.

*2.1. Evaluation Index System.* After investigation, a set of evaluation index systems was established to analyze the characteristics of different data sets from multiple perspectives [25, 26]. In this paper, the evaluation index system is constructed from the basic information of the data set, the mathematical characteristics of the data set, and the degree of association of the data set. The mathematical characteristics include data distribution, data association, and data collinearity. Finally, the evaluation indexes include 8 indexes in 3 categories and 5 subcategories. For different data sets and different feature sequencing algorithms, the evaluation indexes are used to evaluate the data sets. The indicators are shown in Table 1.

### 2.1.1. Evaluation Indexes

(1) *The Number of Dimensions.* The number of dimensions can reflect the complexity of the data set. Generally speaking, the more dimensions of the data set, the more information the data set contains.

(2) *The Number of Categories.* The number of categories is different in data sets. In the case of similar data collective quantity, the more categories the numbers represent, the more the data types contained and the higher the complexity of the data set. The number of classifications will directly affect the algorithm's detection effect of the data set. Therefore, the number of classifications is also used as the evaluation index parameter of the data set.

(3) *Variance.* Variance is a disperse measurement of a random variable or set of data in probability theory and statistics. Large variance indicates high degree of data dispersion, and small variance indicates strong degree of data aggregation.

(4) *The Imbalance Ratio between Categories.* In multi-classification data sets, each category contains different sample sizes. This situation leads to unbalanced distribution among data categories, which can be measured by the imbalance ratio (IR) between categories. The larger the value of IR is, the more unbalanced the category distribution of sample data is, which will easily affect the classification accuracy.

(5) *KL Divergence.* KL divergence is used to calculate the cumulative difference between the information entropy of real events and the information entropy of theoretical fitting. It can be used to measure the distance between two dimensional distributions. When the distribution in two dimensions is the same, KL divergence is zero. When the difference of the two dimensional distributions increases, KL divergence also increases.

(6) *Curve Fitting Degree.* Curve fitting degree (CFD) is also an embodiment of data repetition. The degree of data trend repetition can be measured by CFD. The degree of data redundancy in industrial control system can be calculated by CFD.

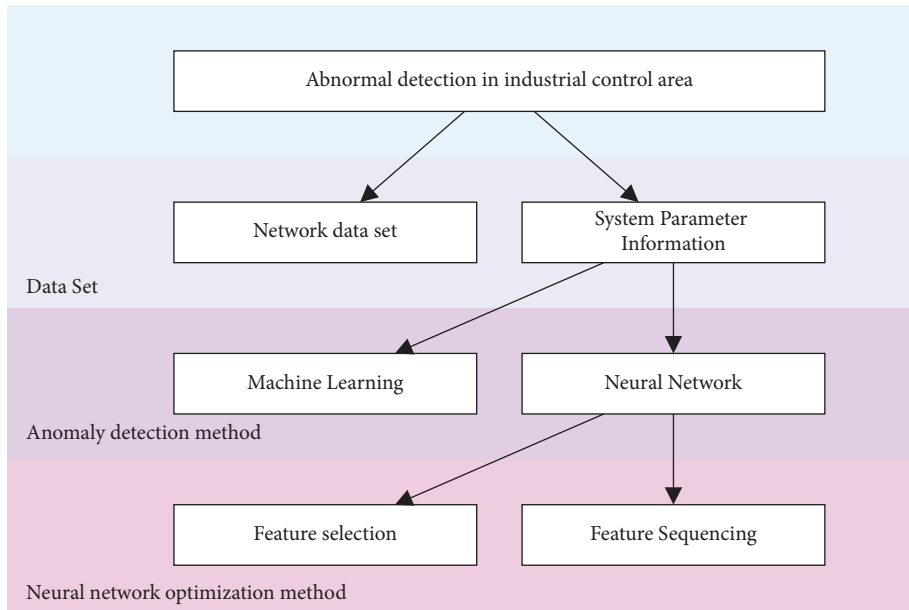

FIGURE 1: Technical subdivision of the industrial control field.

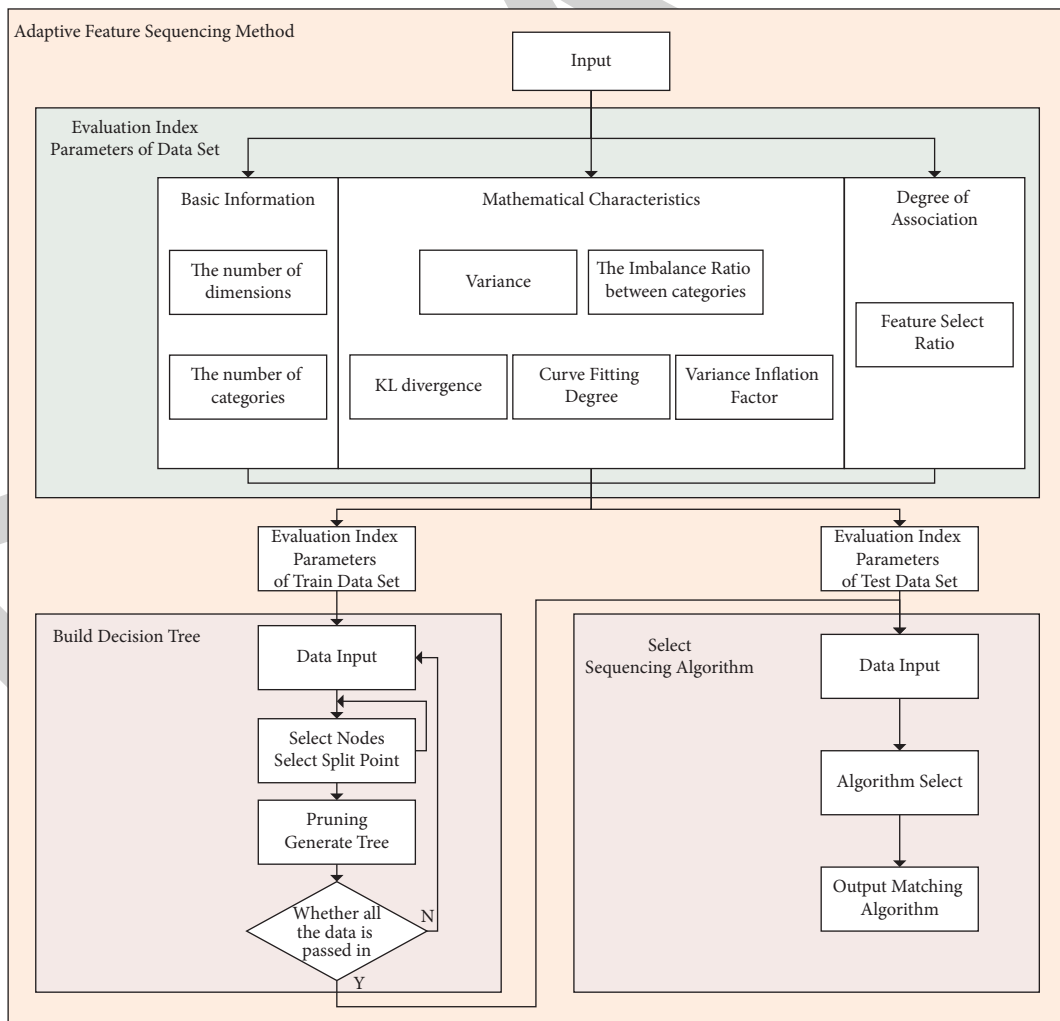

FIGURE 2: Diagram of the main program.

TABLE 1: Evaluation indexes.

Classification	Evaluation index	Abbreviation
Basic information	The number of dimensions	Dimension
	The number of categories	Category
Mathematical characteristics, data distribution	Variance	\
	The imbalance ratio between categories	IR
Mathematical characteristics, data association	KL divergence	KL
	Curve fitting degree	CFD
Mathematical characteristics, data collinearity	Variance inflation factor	VIF
	Degree of association	FS-R

(7) *Variance Inflation Coefficient*. Variance inflation coefficient (VIF) tests the linear correlation between features of the data set. This index parameter can select features with strong independence and increase the interpretability of the model.

(8) *Feature Select Ratio*. Feature selection can calculate the degree of association between dimensions, so the proportion of feature selection is taken as the evaluation index. When the feature selection method is used for feature screening of data sets, the number of retained features of different data sets is different. For example, the Lasso algorithm was used to select features from the Mississippi data set [27] and only 4 features were retained and 22 features were deleted. The same feature selection method was used for feature selection of the CICIDOS 2019 data set, and 34 features were retained and 4 features were deleted. The same feature selection method has a significant difference in the proportion of deleted features in the data set. Therefore, the proportion of retained features by feature selection is directly related to the characteristics of the data set, which can be used to measure the gap between data sets. The calculation formula of feature selection ratio is as follows:

$$R_{FS} = \frac{N_{FS}}{N}, \quad (1)$$

where  $N$  is the number of dimensions of the data set,  $N_{FS}$  is the number of features obtained by feature selection of the data set through Lasso algorithm, and  $R_{FS}$  is the proportion of features selected by feature selection algorithm in all dimensions.

2.1.2. *Calculation of the Evaluation Index System*. According to the feature sequencing method mentioned above, different methods were used to conduct feature sequencing for each data set and then the above-mentioned

evaluation indexes were calculated. The evaluation index parameter result of each data set was calculated as the parameters of this data set. After all data sets were calculated, the evaluation index parameter set was obtained.

In order to verify the above-mentioned evaluation index, five different data sets were selected to calculate the above-mentioned indicators, respectively. Data sets include the Mississippi data set [27], Oil Depot data set, the CICIDOS 2017 [28], the Wine data set [29], and the Csgo data set [30]. The results are shown in Figure 3.

As shown in Figure 3, the above-mentioned evaluation indexes have great differences in different data sets. And, indexes are highly independent of each other in distribution, which can distinguish different data sets. When using decision tree algorithm for classification, each index parameter can be used as a feature to construct nodes and then the parent-child relationship between nodes can be constructed according to the calculation results of evaluation indexes. The selected index parameter can reflect the situation of data sets from different angles and is suitable for decision tree algorithm.

2.1.3. *Label*. The data sets are labeled according to the sequencing algorithm of different features. According to the accuracy and time of the classification algorithm in the sequencing data set, the calculation formula of identification principle is as follows:

$$Acc_{ix} = \text{MAX}(Acc_{i1}, Acc_{i2}, \dots, Acc_{ij}). \quad (2)$$

$Acc_{ij}$  is the accuracy of abnormal detection neural network after the JTH feature sequencing algorithm is adopted for the Ith data set, and  $x$  is the selection method to select the  $x$  method for feature sequencing. When the same data set has more than one of the same highest accuracy (usually 100% accuracy at the same time), we use time to identify. The calculation formula is as follows:

$$\begin{cases} Acc_{ix1} = Acc_{ix2} = \dots = Acc_{ixk} = \text{MAX}(Acc_{i1}, Acc_{i2}, \dots, Acc_{ij}), \\ Time_{ix} = \text{MAX}(Time_{ix1}, Time_{ix2}, \dots, Time_{ixk}). \end{cases} \quad (3)$$

FIGURE 3: Effect pictures of evaluation indexes in different data sets.

$Time_{ixk}$  is the  $K$  TH of the sequencing algorithm with the highest accuracy among the remaining feature sequencing algorithms for the  $I$ th data set and the time of each substitution of neural network anomaly detection. After the selection result is method  $X$ , the data set is labeled as  $X$ .

**2.2. Feature Sequencing Algorithm.** Feature sequencing algorithm can find the dimension with high importance, and it can sequence features according to the importance score to change the distance between features. By this method, we can solve the problem of uncertain correlation between adjacent dimensions of industrial control system data and achieve convergence acceleration effect of anomaly detection algorithm through feature sequencing algorithm. In the previous experiment, Lasso regularization feature selection algorithm was used for feature sequencing, but the algorithm has different effects on different data sets. Therefore, this paper selects several common feature processing methods as feature sequencing algorithm for experiment.

Common sequencing methods include feature selection method, regularization method, random forest method, and top-level selection method. After the investigation, this paper selected a total of 4 categories and 7 algorithms, including Pearson correlation coefficient [13], linear regression, L1 regularization [31], L2 regularization [32], random forest [33], stability selection top-level selection algorithm [34], and recursive feature elimination top-level selection algorithm [35]. The experiment of selecting suitable feature sequence algorithm is carried out. The selection algorithm is shown in Table 2.

TABLE 2: List of feature sequencing algorithms.

Category	Algorithm	Abbreviation
Feature selection method	Pearson correlation coefficient	Pearson
	Linear regression	Linear
Regularization method	Lasso regularization	Lasso
	Ridge regularization	Ridge
Random forest method	Random forest	RF
Top-level selection method	Stability selection	SS
	Recursive feature elimination	RFE

**2.3. Decision Tree Model Construction.** Decision trees [36–38] can use complex nonlinear models to fit the data and change the measurement of impurity for regression analysis. Similar to the linear regression model, corresponding loss function is used and decision tree is used for regression to measure impurity [39]. The decision tree is constructed by taking evaluation indexes of each data set as nodes, and the most suitable feature selection algorithm is selected for different data sets after the evaluation index parameter sets and labels are passed in. The specific steps are as follows.

(1) *Feature Splitting Node.* All features are traversed, and the change value of information entropy before and after dividing the data set is calculated by  $H(X)$ . Then, the feature with the largest change of information entropy is selected as the basis for dividing the data set, that is, the feature with the largest information gain is selected as the split node.

$$H(X) = - \sum_{x \in X} p(x) \log p(x). \quad (4)$$

Here,  $p(x)$  represents the probability of the occurrence of element  $x$  in the dimension. When the probability  $p(x)$  is closer to 0 or 1, the value of information entropy is smaller. When the probability value is 1, the information entropy is 0 and the data category is single. In feature selection, the feature with the maximum information gain is selected, which physically makes the data transform in a single direction as far as possible. Information gain is a measure of the degree to which data become more sequenced.

(2) *Decision Tree Construction.* Firstly, the information entropy before data set partition is calculated. Secondly, the information entropy after dividing the data set according to each feature is calculated, and the feature with the largest information gain is selected as the data partition node to divide the data. Finally, all sub-data sets after partition are recursively processed, and the above steps are repeated from the features that have not been selected to select the optimal data partition feature to partition the molecular data set.

Recursion generally ends under two conditions: all features have been used or the information entropy gain after partition is small enough, that is, as many divided numbers as possible belong to the same category.

(3) *Decision Tree Pruning*. Due to the influence of noise and other factors, the values of some features of the sample do not match the categories of the sample itself and some branches and leaves of the decision tree generated based on these data will produce some errors. Especially in the decision tree near the end of the branches and leaves, due to fewer samples, the interference of irrelevant factors becomes more prominent. The resulting decision tree may be over-fitting, so the classification speed and accuracy of the whole decision tree can be improved by deleting unreliable branches by pruning.

After the establishment of the decision tree, it only needs to input the result data of the evaluation index parameter to select a matching feature sequencing algorithm, thus completing the design of the adaptive algorithm.

### 3. Experiment Details

The experiment environment is as follows:

Operating System Windows Server 2016 Datacenter  
 CPU Intel(R) Xeon(R) CPU E5-2650 v4 @ 2.20 GHz  
 GPU NVIDIA GeForce GTX 1080 Ti  
 Runtime Environment Python 3.8  
 Pytorch 1.7.0

*3.1. Data Set*. There were 11 data sets used in experiment, including Batadal data set [40], CICIDS 2017 [28], Mississippi data set [27], Oil Depot data set (self-build data set), Csgo data set [30], Mail data set [41], Water Quality data set [42], Wine data set [29], Mobile Phone Price data set [43], Mnist in Csv data set [44], and Music Genre data set [45].

Batadal data set is part of the Singapore water plant data set, which is established by Itrust, the network security research center of the university of science and technology design of Singapore. The data set is a full physical medium-sized water supply network, c-town water system. The system includes 1 independent reservoir, 5 valves, 5 pump stations, 11 pumps, 7 storage tanks, 388 interfaces, and 423 pipelines. From the aspects of safe water treatment and water supply system, the actual operation state of the system and the real data after the attack are sorted and recorded to form multiple public data sets for competition.

CICIDS 2017, published by the Canadian Institute for Cybersecurity (CIC) at the University of New Brunswick in Fredericton, is one of the several research public data sets for cybersecurity science research. It is an intrusion detection evaluation data set with positive and negative samples.

The Mississippi data set was published by Mississippi State University. In order to study the network traffic of the SCADA system under normal and attacked conditions, Mississippi State University constructed a set of SCADA systems based on all physical objects in 2014 and build a set of standardized data set. The data set includes network flow, process control, and process measurement characteristics of 28 attacks against two laboratory industrial control systems using the MODBUS application layer protocol. The natural gas tank data set is the underlying

business data set containing the attack. The attack types include reconnaissance attacks, response injection attacks, command injection attacks, and Denial-of-Service (DoS) attacks.

In addition, the Oil Depot data set is a data set provided by the cooperative unit, including 132,000 pieces of data and 126 feature dimensions. The positive and negative samples are divided into 11 classes. The other 7 data sets are public data sets released by the KAGGLE platform, and all data sets are in CSV format.

Some basic information of the data set is shown in Table 3.

*3.2. Experimental Procedure*. The experimental steps are as follows:

- (1) 11 data sets were divided into training sets and testing sets, among which 8 training data sets were used for model training and 3 test data sets were used for model testing
- (2) All data set evaluation indexes were calculated, and the specific indicators are shown in Section 2.1.1
- (3) Feature sequencing algorithm is used to preprocess 8 training data sets, and each feature sequencing algorithm generates a sequenced data set according to the original data set
- (4) Sequenced data sets are classified using anomaly detection algorithm to obtain accuracy and running time
- (5) The indicators of the training data set in Step 2 are taken as features, each data set is labeled according to the results of Step 4 as reference, they are input into the decision tree for training, and the selection model is obtained
- (6) The test data and indicators in Step 2 are input as features into the decision tree selection model to obtain the selection results

### 4. Result Analysis

The experimental data sets were divided into training set and testing set. The training set include Batadal data set, Oil Depot data set, Csgo data set, Mail data set, Water Quality data set, Mobile Phone Price data set, Mnist in Csv data set, and Music Genre data set. The testing set includes CICIDS 2017, Mississippi data set, and Wine data set. According to the calculation results of evaluation indexes, the training set is selected for decision tree generation and the feature sequencing algorithm is selected by the generation model.

ResNet anomaly detection algorithm was adopted in the experiment, and most of the final accuracy reached 100% in the processing of the above-mentioned data sets. In order to facilitate comparison, the stable results of iteration 30 generations were used in the experiment and the calculation accuracy and iteration speed were adopted. The results are shown in Table 4.

Table 4 shows the classification results of data sets in the training set by the ResNet algorithm. Accuracy refers to the accuracy of the result, and time refers to the classification

time. The bold part is the optimal item label determined according to the identification principle. After confirming the evaluation index parameters and labeling of the training set, the training set was input into the decision tree to complete the construction of the decision tree. Then, the testing set evaluation index parameter data were input to obtain the decision tree selection result of the testing set.

Table 5 shows the classification results of data sets in the testing set by the ResNet algorithm. The bold part is the decision result of the decision tree model. The comparison between the selected result and the results of other methods shows that the feature sequencing algorithm selected by the model on the three testing sets is optimal or better.

After the adaptive algorithm selects the optimal feature sequencing algorithm for sequencing, the results of the anomaly detection algorithm are compared with those before sequencing, as shown in Table 6.

From the bold part in Table 6, it can be seen that the results of 11 data sets after sequencing are generally better than those before and after sequencing except Csgo data set. The comparison of the two indicators is shown in Figure 4.

Figure 4 shows the comparison of accuracy and time before and after the sequencing algorithm for each data set. On the left is the accuracy comparison chart. It can be seen that the accuracy of Csgo data sets after sequencing is slightly lower than before, and the accuracy of other data sets is

higher than before or 100%. On the right is the comparison diagram of the average time of each generation. The sequencing algorithm of all data sets can reduce the calculation time.

## 5. Conclusion

This paper aims to design an adaptive algorithm to find the optimal feature sequencing algorithm for different data sets. Through a variety of evaluation indexes of the data set and decision tree algorithm, the appropriate feature sequencing algorithm is selected. The selected algorithm is used to sequence the features of the data set. Then, the sequenced data set is classified by neural network anomaly detection algorithm. This paper compares the effects of various feature sequencing algorithms on anomaly detection accuracy and training speed and verifies the effect of the algorithm selected by the adaptive method in this paper.

In this paper, 7 common feature sequencing algorithms are used and 11 public data sets in industrial control field and other fields are used for experiments. In the experimental results, the feature sequencing algorithms selected by this algorithm for all data sets are the algorithms with the highest accuracy and higher training speed than the average speed.

By comparing the original data set not processed by this algorithm with the processed 11 data sets in the anomaly detection algorithm, the results show that the accuracy of 30 generations of all data sets is improved by 2.568% on average and the average time of each generation of all data sets is shortened by 24.143%. This algorithm can effectively select the feature sequencing algorithm suitable for different data sets, improve the accuracy of anomaly detection, reduce the training time, and reduce the influence of feature distribution on the anomaly detection algorithm.

This paper mainly studies the adaptive algorithm applied to the data of industrial control systems. The selected experimental algorithm and index are highly targeted, so the algorithm has some limitations. The experimental results show that the accuracy of this algorithm is lower than that before processing in the experiment using Csgo data set. The next step is to improve the evaluation index system and increase the experimental data set to enhance the universality of the selection method.

In response to the problems in the signal identification of radiation sources during the communication process, the bispectral quadratic feature model is applied to the identification algorithm for communication signals. According to the signal eigenvalues obtained from the bispectrum of the diagonal slices in the radiation source signals, the eigenvalues of the bispectrum diagonal slices can be extended from the frequency domain to the complex plane through the chirp-z operation in this paper, and the relevant data are obtained based on the bispectrum quadratic feature model of the signals by using the separation rules corresponding to the extended Babbitt distance. The bispectral quadratic feature model method is used to establish a sparse observation model, and the communication signal processing problem can be transformed into an estimation problem of signal motion parameters through the construction of a parametric database. At the same time, the high-resolution distance of communication signals is tested, and the communication signals are estimated by using the variational inference method. Finally, practical cases are analyzed, and the results indicate that the algorithm proposed in this paper can be used to identify different types of communication signals in accordance with simulated and measured data in the processing of communication signals in various environments, which has the certain anti-interference capacity to noise, can improve the identification rate of communication signals, and has verified the effectiveness and practicality of the algorithm proposed in this paper.

## 1. Introduction

The identification of communication signals is one of the key means of the communication industry at present, and it has been widely used in all walks of life and in the military field. As carriers of information data transmission, signals contain the features of the radiation source, which can be used to achieve accurate identification and detailed analysis of the communication signal, obtain the communication radiation source bispectrum features, and provide a basis for the subsequent communication signal radiation source effective identification [1, 2]. At present, for the purpose of implementing accurate identification of communication radiation source signals, generally selected communication signal bispectral features should comply with the features of the time shift without changes, the size without changes, and the

phase without changes. In the signal bispectrum analysis, based on compliance with the aforesaid conditions while also needing to maintain high noise immunity, it is widely applied in different industrial fields [3, 4]. As the bispectrum analysis process is relatively simple and the workload of operations is relatively small, it can maintain a high level of higher-order spectral analysis features. Hence, it is more extensively used in the field of communication signal processing to acquire the bispectral quadratic features of the signal complex diagonal tangent on the basis of in-depth rooted communication signal bispectral quadratic features. Due to the existence of different identification accuracy of different high-performance computing subpaths, the use of the bispectral quadratic feature model can be obtained in accordance with the feature vector of the communication signal in the results of high-performance computing. Finally,

the results of the experiment indicate that the proposed method is practical for the secondary identification algorithm of the communication signal features using the baroclinic distance criterion [5, 6]. As the communication signal has the innate advantages of all-day real-time, long-range role, high resolution, and so on, it can be used on a large scale in many fields such as high-resolution processing, feature extraction, signal classification, and so on, and the use of transmitting bispectral quadratic feature model can increase the acquired high-distance resolution. At the same time, it can also shorten the features of the receiver transient bandwidth, complete hardware reduction, and according to the subpulse carrier, frequency sequence can effectively reduce the observation time while effectively improving the anti-interference performance of the communication signals. Communication signals mainly indicate the signals of different factors (noise, no role of the signal) fused together, and the transmission path is more complex [7–9]. Even if a higher function of the communication signal is used, the signal results that can be obtained are not ideal. Hence, it is not easy to obtain a physical feature of the initial signal. However, deconvolution is a method to obtain the original signal in accordance with the feedback from the fused signal. This method is extensively used in different fields such as communication, communication signals, speech, and medicine. One of the more technologically advanced methods at present is the variational difference recovery method proposed by Chan et al. This calculation uses a partial differential gradient projection method for the Lagrange multiplier term to minimize the difference [10–12]. Its advantages are fast convergence, stability, and so on, especially for signals with steep edges. With regard to the regular dynamic adaptive calculation method, the numerical value of the difference is compared accordingly.

The bispectral quadratic feature model algorithm is applied to the issue of high-performance computing identification and analysis of communication signals in this paper by converting the estimation of motion parameters of communication signal identification into the evaluation problem of identification and analysis of reconstruction. This method focuses on the effective synthesis of low signal-to-noise ratio HR-RP based on the parameters of the communication signal identification motion signal in the search interval. In this way, it can quickly implement the estimation of the motion parameter impact under the premise of solving the HRRP reconstruction error under a low signal-to-noise ratio to identify the local optimal value according to the population update speed and finally accomplish the accurate processing of the communication signal motion parameters.

## 2. Models and Algorithm

**2.1. Bispectral Quadratic Feature Model.** In accordance with the setting of the carrier frequency sequence of the communication signal, it is possible to obtain the results of the bispectral quadratic feature model in accordance with the complete step FM signal within [13, 14]. In this way, the

whole stepper FM signal contains  $N$  pulses, while  $M$  pulses ( $M < N$ ) are extracted according to the sequence.

As the signal carrier frequency sequence of the bispectral quadratic feature model is set to  $f_{sm} = f_c + g(m)\Delta f$ , in which  $\Delta f$  stands for the pulse bandwidth of the signal and  $g$  stands for a subset in the interval  $[0:N-1]$ , then the bandwidth of the bispectral quadratic feature model can be expressed as  $B = N\Delta f$ . Through the detailed analysis, it can be known that the corresponding correlation accumulation time is no greater than the whole communication signal step FM signal. Then the carrier frequency sequence of the communication signal can be set in accordance with the environmental information so that it possesses the enhanced anti-interference capability of itself.

It is assumed that the communication signal transmits a total of  $k$ -th groups of sparse step frequency modulation (FM) signals, then the sparse step FM high-performance operation of the first group can be expressed as follows:

$$s_1(t) = \sum_{m=0}^{M-1} \text{rect}\left(\frac{t - mT_R - kMT_R}{T_p}\right) \cdot \exp(j\pi\gamma(t - mT_R - kMT_R)^2) \cdot \exp(j2\pi f_{sm}(t - mT_R - kMT_R)), \quad (1)$$

where  $t = \hat{t} + mT_R + kMT_R$  ( $m = 1, 2, \dots, M$ ) stands for the whole calculation time,  $\hat{t}$  stands for the fast time, and  $\text{tect}(u)$  stands for the corresponding rectangular window. If the value of  $\text{tect}(u)$  is 1 when  $|u| \leq 1/2$ , then the value of  $\text{tect}(u)$  will become 0, in which  $\gamma$  indicates the modulation frequency of the communication signal and  $T_p$  and  $T_R$  stand for the pulse width of the communication signal and the number of pulse repetition periods in turn, respectively.

If the communication signal contains multiple scattering points, then the coefficient of the backward scattering of the  $p$  ( $p = 1, 2, \dots, P$ ) scattering point can be expressed as  $\sigma_p$ , which constitutes the ‘‘Stop-Go’’ model. The corresponding time delay value  $\tau_p(t)$  of the scattering point  $p$  within the pulse of the communication signal can be left unchanged, and then there will be  $\tau_p(t) \approx \tau_p(t_{m,k})$ ,  $t_{m,k} = mT_R + kNT_R$ . At the same time, with regard to the scattering point of the communication signal, the  $m$ -th subpulse echo under the  $k$ -th group of sparse step FM high-performance operation can be expressed as follows:

$$s_2(\hat{t}, m, k) = \sigma_p \text{rect}\left(\frac{\hat{t} - \tau_p(t_{m,k})}{T_p}\right) \cdot \exp(j\pi\gamma(\hat{t} - \tau_p(t_{m,k}))^2) \cdot \exp(j2\pi f_{sm}(\hat{t} - \tau_p(t_{m,k}))) + \varepsilon(\hat{t}), \quad (2)$$

where  $\tau_p(t_{m,k}) = 2R_p(t_{m,k})/c$ ,  $R_p(t_{m,k})$  stands for the instantaneous slope distance between the  $p$ -th scattering point and the communication signal emission signal, in which  $c$  is the speed of light and  $\varepsilon(\hat{t})$  indicates the additive noise. If the accumulation angle  $\theta_{m,k}$  of the signal to be processed is

reduced,  $R_p(t_{m,k}) = R(t_{m,k}) + x_p \sin \theta_{m,k} + y_p$ , in which  $R(t_{m,k})$  stands for the instantaneous slope distance between the communication signal,  $(x_p, y_p)$  stands for the reference point by the instantaneous slope distance, and the scattering point  $p$  of the communication signal is denoted by the coordinate value in its plane. Thus, for a high-speed communication signal, the distance between the signal reference point and the communication signal at the time point  $t_{m,k}$  can be obtained as  $R(t_{m,k}) = \tau_R + v_R t_{m,k} + 1/2 a_R t_{m,k}^2$ , where  $r_R$  stands for the distance between the communication signal and the communication signal at the initial time,  $v_R$  stands for the radial velocity of the signal, and  $a_R$  stands for the radial acceleration of the communication signal. The time delay of the communication signal can be expressed as  $\tau_{ref}(t_{m,k}) = 2R_{ref}(t_{m,k})/c$ , where  $R_{ref}(t_{m,k}) = r_R + \hat{v}_R t_{m,k} + 1/2 \hat{a}_R t_{m,k}^2$ . In general, the estimation of  $v_R$  and  $a_R$  can be obtained in the tracking phase of the communication

signal. Then, for the echoes to be solved by line frequency modulation, it can be assumed that  $\hat{f} = \gamma(\hat{t} - 2R(t_{m,k})/c)$ ; thus, the communication signalization is converted to the following equation:

$$s_3(\hat{f}, m, k) = \sigma_p \text{rect}\left(\frac{\hat{f}}{\Delta f}\right) \exp\left(j \frac{4\pi}{c} (f_{sm} + \hat{f}) \Delta R\right) \cdot \exp\left(j \frac{4\pi}{c} (\Phi_P + \Phi_B)\right) + \varepsilon(\hat{f}), \quad (3)$$

where  $\Delta R = x_p \sin \theta_{m,k} + y_p$  and  $\Phi_P$  and  $\Phi_B$  stand for the phase error due to interpulse translation of the communication signal and the phase error due to interpulse translation of the pulse string, respectively. Thus,  $\Phi_P$  and  $\Phi_B$  can be expressed as follows:

$$\left. \begin{aligned} \Phi_P &= \Phi_1 + \Phi_2, \Phi_B = \Phi_3 + \Phi_4 + \Phi_5 \\ \Phi_1 &= m^2 \left( \frac{1}{2} \Delta a_R f_0 T_R^2 + \Delta f \Delta v_R T_R + k \Delta f \Delta a_R M T_R^2 + \frac{1}{2} \hat{f} \Delta a_R T_R^2 \right), \Phi_2 = m^3 \left( \frac{1}{2} \Delta a_R \Delta f T_R^2 \right) \\ \Phi_3 &= m \left( \begin{array}{c} f_0 \Delta v_R T_R + k \Delta f \Delta v_R M T_R + k \Delta a_R f_0 M T_R^2 + \hat{f} \Delta v_R T_R + \\ \frac{1}{2} \Delta a_R \Delta f (k M T_R)^2 + k \Delta a_R \hat{f} M T_R^2 \end{array} \right) \\ \Phi_4 &= k (f_0 \Delta v_R M T_R + \hat{f} \Delta v_R M T_R), \Phi_5 = k^2 \left( \frac{1}{2} \Delta a_R f_0 (M T_R)^2 + \frac{1}{2} \hat{f} \Delta a_R (M T_R)^2 \right) \end{aligned} \right\}, \quad (4)$$

where  $\Delta v_R$  stands for the residual velocity;  $\Delta v_R = v_R - \hat{v}_R$ , in which  $\Delta a_R$  stands for the residual acceleration; and  $\Delta a_R = a_R - \hat{a}_R$ .  $\Phi_1$  stands for the  $m$  quadratic phase term, which will generate the primary flap spreading in the phase of distance synthesis of the communication signal.  $\Phi_2$  stands for the tertiary phase term of  $m$ ; the communication signal distance image is synthesized as an asymmetric paraflap; and then this term can usually be expressed in the order of  $10^{-4}$ . Hence, it can be neglected.  $\Phi_3$  contains the coupling terms of both  $m$  and  $k$ , which will lead to a distance image shift and cause the bending of the envelope.  $\Phi_4$  stands for the primary phase term of  $k$ , which causes an azimuthal shift in the image of the communication signal and can also be neglected.  $\Phi_5$  stands for the quadratic phase term of  $k$ . The azimuthal pulse pressure will cause the main flap spreading of the communication signal. For the purpose of constructing the reconstruction algorithm with sparse HRRP efficiently, the echoes can be converted into discrete form. If the number of pulse sampling points of each communication signal is set to  $N_r$ , which complies with  $\bar{L} = M \cdot N_r$  at the same time, then the  $k$ -th group of echoes can be expressed as  $s_k = [s_{0,k}, \dots, s_{m,k}, \dots, s_{M-1,k}]_{1 \times \bar{L}}^T$ , in which  $s_{m,k} = [s_{0,m,k}, \dots,$

$s_{N_r-1,m,k}]_{1 \times N_r}$ ,  $s_{n,m,k} = \exp(j4\pi/c(f_{sm} + n_r/N_r \Delta f)(\Delta R + \Delta v_R t_{m,k} + 1/2 \Delta a_R t_{m,k}^2)) + \varepsilon(n_r)$ .

The remaining transmission process parameters of the communication signal are introduced into the database, and then the sparse observation model of the communication signal can be expressed as follows:

$$s_k = D_k(\Delta v_R, \Delta a_R) \theta_k + n, \quad (5)$$

where  $D_k(\Delta v_R, \Delta a_R) \in \mathbb{C}^{\bar{L} \times \bar{L}}$  stands for the database matrix corresponding to the  $n$ -th echo,  $L = N \cdot N_r$ ,  $\theta_k \in \mathbb{C}^{L \times 1}$  stands for the HRRP corresponding to the  $k$ -th echo, and  $n$  stands for the noise vector. Thus,  $d_l^k$  can be obtained as follows:

$$d_l^k(\Delta \hat{v}, \Delta \hat{a}) = f_l \odot g_k \odot h_k, \quad (6)$$

where  $\odot$  stands for the inner product,  $f_l$  stands for the  $l$ -th column of the database  $F$ ,  $F = [F_0, \dots, F_{M-1}]_{L \times \bar{L}}^T$ ,  $g_k = [g_{0,k}, \dots, g_{M-1,k}]_{\bar{L} \times 1}^T$ , and  $h_k = [h_{0,k}, \dots, h_{M-1,k}]_{L \times 1}^T$ . In accordance with the  $m$ -th subpulse of the signal, it can be known that

$$F_m = \begin{bmatrix} W_m(0, 1) & \cdots & W_m(0, L-1) \\ \vdots & \vdots & \vdots \\ W_m(N_r-1, 0) & \cdots & W_m(N_r-1, L-1) \end{bmatrix}_{N_r \times L}, \quad (7)$$

$$g_{m,k} = [g_{m,k}(0) \cdots g_{m,k}(N_r-1)]^T, g_{m,k}(n_r) = \exp\left(j \frac{4\pi}{c} \left(f_{sm} + \frac{n_r}{N_r} \Delta f\right) \Delta v_R t_{m,k}\right),$$

$$h_{m,k} = [h_{m,k}(0) \cdots h_{m,k}(N_r-1)]^T,$$

$$h_{m,k}(n_r) = \exp\left(j \frac{2\pi}{c} \left(f_{sm} + \frac{n_r}{N_r} \Delta f\right) \Delta a_R t_{m,k}^2\right). \quad (8)$$

As the signal reconstruction method based on the bispectral quadratic feature model can operate on the real matrix, it can be expressed as follows according to equation (8):

$$y = \Phi\theta + \varepsilon. \quad (9)$$

In accordance with expression (9), the probability map model is established by using the Gamma-Gaussian algorithm [15, 16]. If the acquired noise  $\varepsilon$  is Gaussian white noise with 0 mean, then the probability of the signal echo  $y$  thus obtained is also Gaussian distributed, and the probability of  $\varepsilon$  distributed with  $y$  can be obtained as follows:

$$p(\varepsilon) = N(\varepsilon|0, \alpha^{-1}I), \quad (10)$$

$$p(y|\theta, \alpha) = N(y|\Phi\theta, \alpha^{-1}I),$$

where  $\alpha$  stands for the noise accuracy. The Gamma-Gaussian prior is introduced to the sparse vector  $\theta$ , and the following can be obtained:

$$p(\theta|\Lambda) = N(\theta|0, \Lambda^{-1}), \quad (11)$$

where the accuracy matrix  $\Lambda = \text{diag}(\lambda_1, \dots, \lambda_d)$  stands for the dimensional diagonal array, in which  $D = 2L$ . The accuracy parameters  $\lambda_d$  ( $d = 1, \dots, D$ ) and  $\alpha$  comply with the Gamma distribution, and the following can be obtained:

$$p(\lambda_d) = \text{Gamma}(\lambda|v_1, v_2), \quad (12)$$

$$p(\alpha) = \text{Gamma}(\alpha|v_3, v_4).$$

The product of the distributions according to the probability model can be obtained as follows:

$$p(y, \theta, \Lambda, \alpha) = p(y|\theta, \alpha)p(\theta|\Lambda)p(\alpha) \prod_d p(\lambda_d). \quad (13)$$

On the other hand, the posterior distribution of the random variables can be expressed as the joint distribution of the variables divided by the marginal distribution  $p(y)$ , and thus, the following can be obtained:

$$p(\theta, \Lambda, \alpha|y) = \frac{p(y, \theta, \Lambda, \alpha)}{p(y)}. \quad (14)$$

It is highly difficult to calculate the posterior distribution based on the model directly. Thus, high-performance

computing is carried out to resolve the approximate posterior distribution so as to enable the HRRP synthesis under the low signal-to-noise ratio (SNR) conditions.

## 2.2. Identification of High-Performance Computing of Communication Signals

### 2.2.1. Processing of Signals with Large Angle and Low Signal-to-Noise Ratio.

In the research on the performance of communication signals, the parameters related to the communication signals are analyzed, with the main parameters as follows:

- (1) Insertion loss (IL): The loss of signal power due to the addition of a device in a transmission line or fiber is denoted by decibels (dB). When the power transmitted to the load before insertion is  $P_{in}$  and at the same time the power received by the load after insertion is  $P_{\mathcal{L}}$ , then the equation for insertion loss in dB can be obtained as follows:

$$IL = 10 \log \frac{P_{in}}{P_{\mathcal{L}}} = -10 \log (1 - |\Gamma_{in}|), \quad (15)$$

where  $|\Gamma_{in}|$  stands for the reflection coefficient, which can be expressed as follows in accordance with the connection between IL and  $\mathcal{S}_{21}$ :

$$IL = 10 \log \frac{1}{|\mathcal{S}_{21}|^2} = -10 \log |\mathcal{S}_{21}|^2. \quad (16)$$

The relationship between  $P_{\mathcal{L}}$ ,  $P_{in}$ , and  $\mathcal{S}_{21}$  in equation (16) is as follows:

$$\frac{P_{in}}{P_{\mathcal{L}}} = \frac{1}{|\mathcal{S}_{21}|^2}. \quad (17)$$

- (2) Bandwidth represents the selected range of the signal, that is, the width of the spectrum to be passed, the unit of the frequency range width, which is expressed in Hz, with the following equation:

$$BW^{X\text{dB}} = f_H^{X\text{dB}} - f_L^{X\text{dB}}. \quad (18)$$

When the value of  $X$  is 3, 1, or 0.5,  $f_H$  and  $f_L$  stand for the frequencies on both sides of the passband

when the reduction in the values of insertion loss on the left and right sides of the center frequency is  $X$  (dB).

- (3) In-band fluctuation refers to the size of the fluctuation in the response amplitude of the passband, that is, the difference between the maximum and minimum values of the response amplitude. In the design process of communication signals, the smaller the in-band fluctuation, the better the performance of the communication signals.
- (4) Return loss (RL) refers to the functional loss in the signal returned or reflected by the discontinuity in the transmission line. Discontinuity may not comply with the terminating load or the equipment inserted into the line, which is expressed in decibels (dB). The reflection system of the communication signal is also referred to as the reflection loss. The equation for return loss is as follows:

$$RL = -10 \log \left[ \frac{VSWR - 1}{VSWR + 1} \right]^2. \quad (19)$$

When VSWR represents the voltage standing wave ratio, the magnitude of the return loss is related to the standing wave ratio (VSWR) and the reflection coefficient ( $\Gamma$ ). The increased return loss corresponds to a lower VSWR. Return loss is an index that measures how well the equipment matches the line. If the return loss is high, it means that the match is good. Generally, in the design of a communication signal, a high return loss and a low insertion loss mean that the performance of the communication signal is relatively good.

- (5) VSWR refers to the value of the impedance matching between the load and the transmission line or waveguide. A larger value of the VSWR indicates a higher degree of matching. The VSWR stands for the ratio of the amplitude of the partial standing wave at the wave web (maximum value) to the amplitude of the node along the line (minimum value).
- (6) The quality factor  $Q$  stands for the ability of the communication signal to allow separation of the neighboring frequencies in the signal, and its equation is as follows:

$$Q = \frac{f_o}{BW}. \quad (20)$$

When  $f_o$  represents the center frequency of the communication signal, BW stands for the 3 dB bandwidth. A larger value of  $Q$  indicates that the device has higher working stability, stronger frequency selectivity, lower loss, but narrower band; on the contrary, a smaller value of  $Q$  value indicates that the device's operating stability is lower, the frequency selectivity is weaker, the loss is relatively large, but the frequency band is wider. When the value of  $Q$  is increased in the design, the higher the  $Q$  value is, the stronger the performance of the device is.

- (7) Resonant frequency: With regard to the communication signals, there are multiple ways to resolve the resonant frequency. Thus, there are also various factors affecting the resonant frequency. Common factors affecting the resonant frequency include the structure of the communication signals, the shape and the resonant mode, and so on. In practice, four methods are often used to resolve the resonant frequency: the electro-nano method, the total set parameter method, the field solution method, and the phase method.

The indicators mentioned above are used to measure the performance of a communication signal. In practice, it is not required to set the limit for all indicators, and some of the indicators can be optimized according to the actual demand.

*2.2.2. Processing Result of Measured Signals.* The transfer function of a communication signal is a mathematical formula that expresses the frequency response features of the communication signal. With regard to the classical two-port communication signal, the transmission function equation is as follows:

$$|S_{21}(j\omega)^2| = \frac{1}{1 + \varepsilon^2 \mathcal{F}_n^2(\Omega)}, \quad (21)$$

where  $\varepsilon$  stands for the ripple coefficient,  $\mathcal{F}_n(\Omega)$  stands for the functional characteristic of the low-pass prototype, and  $\Omega$  stands for the frequency variable.

The features of communication signals are represented through the frequency response characteristics. With regard to the classification of communication signals as mentioned at the beginning of this paper, they can be divided into four types (i.e., low pass, high pass, band pass, and band resistance) according to the frequency response characteristics. The high pass, band pass, and band resistance can be obtained through the low-pass prototype of the frequency and components.

In the communication process, radiation source noise is mainly generated by the transmitter noise. In general, it refers to the amplitude of the communication signal, frequency, and pulse width and repetition frequency together causing abnormal changes, that is, the stability of the communication process signal resulting in radiation source noise. Signal instability can be roughly divided into two categories: regular instability and random instability. Regular instability is mainly due to inadequate power filtering, mechanical jitter, and so on; random instability is the noise generated by the transmitter tube and modulation pulse random jitter generated.

At present, the gradual improvement of communication signal protocol will help to improve the stability of transmitter. Thus, with the large-scale use of the main vibration amplification type of transmitter, the noise generated can mainly be divided into the following three aspects:

- (1) According to the amplitude frequency characteristics and phase frequency characteristics of the system, the cause of frequency-domain distortion can be analyzed.

- (2) The top of the modulated pulse generates vibration; the top begins to fall with the power supply fluctuations of the transmitter due to the signal corresponding to the parasitic phase or the amplitude caused by the time-domain distortion phenomenon.
- (3) The main control oscillator has insufficient frequency stability and phase stability. The different circuits or devices used for different communication transmitters result in different transmitter noises for various communications.

Hence, the uncoordinated modulation within the communication signal pulse is due to the transmitter noise. As the noise is generated due to various kinds of parasitic modulation. The communication signals present differences in signal features.

The noise output from the communication transmitter indicates more non-Gaussian and non-linear features, and in the bispectral analysis, the signal amplitude and phase information are maintained. At the same time, the effect of Gaussian non-color noise on non-Gaussian signals bispectrum is completely suppressed, which can be used for the extraction of unconscious modulation features. Thus, the following concept of bispectrum is obtained accordingly.

It is assumed that the high order cumulant  $c_{kx}(\tau_1, \tau_2, \dots, \tau_{k-1})$  is absolutely summable, that is, the following can be obtained:

$$\sum_{\tau_1=-\infty}^{\infty} \cdots \sum_{\tau_{k-1}=-\infty}^{\infty} |c_{kx}(\tau_1, \dots, \tau_{k-1})| < \infty. \quad (22)$$

The  $k$ -th-order spectrum is defined as the  $(k-1)$ -order discrete Fourier transform of the  $k$ -th-order cumulants, that is, the following can be obtained:

$$S_{kx}(\omega_1, \omega_2, \dots, \omega_{k-1}) = \sum_{\tau_1=-\infty}^{\infty} \cdots \sum_{\tau_{k-1}=-\infty}^{\infty} c_{kx}(\tau_1, \dots, \tau_{k-1}) \times \exp[-j(\omega_1 \tau_1 + \cdots + \omega_{k-1} \tau_{k-1})]. \quad (23)$$

Thus, the bispectrum, that is, the third-order spectrum, can be defined as follows:

$$B_x(\omega_1, \omega_2) = \sum_{\tau_1=-\infty}^{\infty} \sum_{\tau_2=-\infty}^{\infty} c_{3x}(\tau_1, \tau_2) \exp[-j(\omega_1 \tau_1 + \omega_2 \tau_2)]. \quad (24)$$

The bispectrum of the signal including phase noise can be obtained from the bispectrum estimation. The discrete noise signal obtained by Scout is represented by  $X(n) = s(n) + W(n)$ , where  $w(n)$  represents the Gaussian white noise signal,  $s(n)$  includes the signal of non-Gaussian noise output from the transmitter, and  $w(n)$  and  $s(n)$  are independent of each other. If the cumulative quantity is solved three times for  $x(n)$ , the following can be obtained:

$$c_{3x}(\tau_1, \tau_2) = E\{[s(n) + w(n)][s(n + \tau_1) + w(n + \tau_1)] \cdot [s(n + \tau_2) + w(n + \tau_2)]\}. \quad (25)$$

Equation (4) is expanded and combined to obtain the following:

$$c_{3x}(\tau_1, \tau_2) = c_{3s}(\tau_1, \tau_2) + c_{3w}(\tau_1, \tau_2) + E[w(n)][c_{2x}(\tau_1) + c_{2x}(\tau_2) + c_{2s}(\tau_2 - \tau_1)] + E[s(n)][c_{2w}(\tau_1) + c_{2w}(\tau_2) + c_{2w}(\tau_2 - \tau_1)]. \quad (26)$$

As long as the mean value of the signal and noise is zero, the following can be obtained:

$$c_{3x}(\tau_1, \tau_2) = c_{3s}(\tau_1, \tau_2) + c_{3w}(\tau_1, \tau_2). \quad (27)$$

As  $w(n)$  is a Gaussian noise signal,  $c_{3w}(\tau_1, \tau_2)$  can be excluded from the calculation. Thus, it can be known that the communication letter can be used to eliminate the white noise after the third-order accumulation, then the bispectrum can be determined by  $c_{3s}(\tau_1, \tau_2)$ , that is, the following can be obtained:

$$c_{3x}(\tau_1, \tau_2) = c_{3s}(\tau_1, \tau_2) = E\{s(n)s(n + \tau_1)s(n + \tau_2)\}. \quad (28)$$

In accordance with the above analysis, it can be observed that the evaluated bispectral features are mainly composed of the features of the signal itself and non-Gaussian noise. Hence, the bispectrum in the communication signal is assessed mainly based on the features specific to the signal itself, and it is also possible to obtain the features specific to various communications.

However, if the two-dimensional function can adopt the full-duplex spectrum as the signal feature to produce a two-dimensional template for matching, the number of operations can be excessively high, which will not comply with the high standard requirements for signal radiation source identification. The key to solving this issue lies in the introduction of high-performance computing bispectrum; in equation (28), the two-dimensional bispectrum is converted into a one-dimensional function. However, the high-performance computing bispectrum has the following defects:

- (1) The implementation of high-performance computing bispectrum is often a high-performance computation along each path. However, the secondary features obtained by this mode of computation are not consistent for the results to be recognized, and some of the bispectral points have relatively less effect on the results of the recognized targets and are subordinate to the ordinary bispectrum.
- (2) If there is a cross-term in the initial observed signal, the high-order accumulation calculated by using the multi-correlation function will lead to the result that the cross-term becomes more complicated. As the cross-term is generated by a random distribution, it is impossible to eliminate the cross-term based on the determined calculation method.

For the purpose of extracting the secondary features of the bispectrum as the features of the bispectrum and eliminating or decreasing the defects that occur in the process of high-performance computation of the

bispectrum, the characteristic parameters that are available for communication signals can be obtained with optimal separability in the secondary features of the bispectrum. As a result, it can effectively solve many problems such as cross-terms caused by ordinary bispectral points and high-performance computing.

In order to make the communication signal meet the actual performance characteristics, it is necessary to design an appropriate chamfer size in the design process. When the ring size becomes larger, the upper and lower passband edges move along the transmission zero point, and the attenuation pole becomes smaller. The intermediate frequency of the communication signal tends to be a higher frequency, which changes the frequency characteristics of the communication signal. With the shortening of the distance between patch resonances and the smaller the passband bandwidth, the attenuation point will first become smaller and then become larger. Therefore, HFSS software is used to optimize the structural parameters of the communication signal, and finally, the structural dimensions of the communication signal are obtained, as shown in Table 1.

By selecting a vector analysis instrument to test the communication signal, Figure 1 is the simulation test diagram corresponding to the communication signal. From Figure 1, it can be seen that the intermediate frequency of double passband communication signal is 3.8 GHz and 5.9 GHz, and the bandwidth corresponding to 3 dB is 13.5% and 6.2%, respectively. The minimum insertion loss in broadband is 0.7 dB and 1.3 dB in turn, and the return loss in the passband is not higher than 60 dB. In addition, there are zero points at the edges of the upper and lower passbands, which greatly improves the suppression characteristics of the stopband. The experimental data are in good agreement with the simulation data.

Since the conjugate prior is adopted in this paper for probabilistic modeling, the closed-form solution of the posterior distribution can be obtained directly by carrying out high-performance computing [17]. It is assumed that  $X$  stands for the observed data and  $w$  stands for the set of random variables; then the expression of the approximate posterior distribution can be obtained as follows:

$$\ln q(w_j) = E_{q_i \neq j} [\ln q(X, w)] + \text{const}, \quad (29)$$

where const. stands for a constant that guarantees the normalization of the posterior distribution. In the subsequent section, in accordance with the equation (18) and the probability model established, the approximate posterior distributions of the variables  $\theta$ ,  $\alpha$ , and  $\Lambda$  are solved for the sparse reconstruction by using the high-performance computing. In accordance with the mean field assumption, equation (14) is given in the form of the posterior multiplication of  $\theta$ ,  $\alpha$ , and  $\Lambda$ .

$$p(\theta, \Lambda, \alpha | y) \approx q(\theta)q(\Lambda)q(\alpha) = q(\theta) \prod_d q(\lambda_d)q(\alpha). \quad (30)$$

The steps for the  $\theta$  solution are described as follows:

TABLE 1: Structural parameters of level 1 UNICOM signal.

Structural parameters	Size (mm)
$a$	24
$b$	3
$c$	9
$d$	5
$e$	3
$f$	1.77
$g$	1.5
$L$	2

FIGURE 1: Simulation change diagram of communication signal.

*Step 1.* Initialization. Given  $\Phi$ ,  $v_1$ ,  $v_2$ ,  $v_3$ ,  $v_4$ ,  $\Lambda$ , and  $\alpha$  are initialized, the termination threshold is  $\eta_1$ , and the number of terminations is  $G_2$ .

*Step 2.* Update the variable  $\alpha$ , and its approximate posterior distribution is the Gamma distribution according to equation (14), as shown in the following equation:

$$q(\alpha) = \text{Gamma}(\alpha | a', b'), \quad (31)$$

where  $a' = v_3 + \bar{L}/2$  and  $b' = v_4 + 1/2 E_{q(\theta)} [(y - \Phi\theta)^T (y - \Phi\theta)]$ , in which  $\bar{L}$  stands for the length of  $y$ . At this point, the expectation of  $\alpha$  can be obtained as follows:

$$E_{q(\alpha)} [\alpha] = \frac{a'}{b'}. \quad (32)$$

*Step 3.* Update the variable  $\Lambda$ , and the approximate posterior distribution of the  $d$ -th element  $\lambda_d$  is the Gamma distribution, as shown in the following equation:

$$q(\lambda_d) = \text{Gamma}(\lambda_d | e'_d, f'_d), \quad (33)$$

where  $e'_d = v_1 + 1/2$  and  $f'_d = v_2 + 1/2 E_{q(\theta)} [\theta_d^2]$ . Thus, the expectation of  $\lambda_d$  can be obtained as follows:

$$E_{q(\lambda_d)} [\lambda_d] = \frac{e'_d}{f'_d}. \quad (34)$$

*Step 4.* Update the variable  $\theta$ , and its approximate posterior distribution is the Gaussian distribution, as shown in the following equation:

$$q(\theta) = N(\theta|\mu', \Sigma'), \quad (35)$$

where  $\Sigma' = (E_{q(\Lambda)}[\Lambda] + E_{q(\alpha)}[\alpha]\Phi^T\Phi)^{-1}$  and  $\mu' = E_{q(\alpha)}[\alpha]\Sigma'\Phi^T y$ . At this time, the following can be obtained:

$$E_{q(\theta)}[(y - \Phi\theta)^T(y - \Phi\theta)] = (y - \Phi\mu')^T(y - \Phi\mu') + \text{trace}(\Phi^T\Phi\Sigma'). \quad (36)$$

*Step 5.* Repeat Steps 2 to 4, and the iteration is suspended when the relative change of  $\hat{\theta}$  from the previous estimate does not exceed the threshold value  $\eta_1$ .

In the following section, the accuracy requirement for  $(\Delta\hat{v}_R, \Delta\hat{a}_R)$  is analyzed according to equation (4). With regard to the HRRP synthesis, the quadratic phase term  $\Phi_1$  can lead to distance image spreading. Hence, it is required that the change in the coherent accumulation time  $\Phi_1$  of the burst should be less than  $\pi/2$ . Thus, the following can be obtained:

$$\begin{aligned} |\Delta\hat{v}| &\leq \frac{c}{8M^2\Delta f T_R}, \\ |\Delta\hat{a}| &\leq \frac{c}{4f_0M^2T_R^2}. \end{aligned} \quad (37)$$

In practice, equation (26) can usually be met. Hence, the effect of  $\Delta\hat{a}$  on HRRP synthesis is neglected. For the purpose of eliminating the envelope bending caused by the first-order phase term field of  $\Phi_3$ , it is required that the envelope shift induced by the residual velocity and the residual acceleration during the processing observation time should not exceed the specified range. Thus, the following can be obtained:

$$\begin{aligned} |\Delta\hat{v}| &\leq \frac{c}{4M\Delta f (KMT_R)}, \\ |\Delta\hat{a}| &\leq \frac{c}{2M\Delta f (KMT_R)^2}. \end{aligned} \quad (38)$$

It should be noted that the linear phase of  $\Delta\hat{v}$  generated between the bursts leads to the shift and bending of the distance image and  $\Delta\hat{a}$  results in the widening and scattering of the azimuthal main flap.

For the purpose of obtaining excellent azimuthal focus, it is required that the peak reduction of the azimuthal image caused by the residual acceleration during the processing observation time should be no more than 3 dB; then the following can be obtained:

$$|\Delta\hat{a}| \leq \frac{7c}{4f_0(KMT_R)^2}. \quad (39)$$

Hence, azimuthal focusing requires higher accuracy of the acceleration estimation. Finally, for the purpose of obtaining a well-focused image, the signal residual velocity

and the residual acceleration should comply with equations (36) and (37). The subsequent experiments indicate that the algorithm proposed in this paper can comply with the requirement for estimation accuracy.

### 3. Simulation Experiment and Analysis

In this paper, the effectiveness of the proposed parameter estimation algorithm in the transmission process and the high resolution processing algorithm is verified based on the simulation data. The echoes of the satellite scattering point model (as shown in Figure 2 below) are generated in accordance with the parameters set out in Tables 2 and 3. It is assumed that the residual velocity and residual acceleration of the signals are 9 m/s and 1 m/s<sup>2</sup>, respectively. The bispectral quadratic feature model contains a total of 128 bursts, and each burst contains 64 randomly selected pulses from 80 consecutive full-band pulses (waveform 1). Through the addition of the complex Gaussian white noise to the echo, the echo signal-to-noise ratio can be increased from 0 dB to 15 dB in 5 dB steps. For each signal-to-noise ratio, 25 independent trials with different noise states are carried out with the number of genetic algorithm populations set to 40 and the number of genetic terminations set to 20. The algorithm proposed in this paper is compared with the PSO algorithm based on the parametric database (algorithm 1). In the comparison, the distance image entropy is weighted with the average distance image entropy as a signal function in accordance with algorithm 1.

The variation of the signal residual velocity and the acceleration estimation errors with the change in the SNR are shown in Figure 3. It can be observed that the estimation error of algorithm 1 at a low SNR is relatively large and fails to comply with equations (26) and (27). This is caused by the relatively large reconstruction error based on the OMP algorithm at the low SNR conditions. With the increase in the signal-to-noise ratio, the estimation error of algorithm 1 is decreased. However, the estimation results still fail to comply with the accuracy requirements and can result in image scattering. Compared with algorithm 1, the algorithm proposed in this paper is robust at any signal-to-noise ratio conditions. In addition, the errors of the residual velocity and residual acceleration estimation are  $1 \times 10^{-2}$  m/s and  $5 \times 10^{-3}$  m/s<sup>2</sup>, respectively, which can meet the estimation accuracy requirements of equations (26) and (27). The superior performance of the proposed algorithm in the motion parameter estimation under the low signal-to-noise ratio conditions is attributed to the following aspect: (1) the Gamma-Gaussian prior-based reconstruction algorithm that can implement the reconstruction of HRRP with high accuracy and (2) the excellent global optimization capability of the genetic algorithm.

As the estimation error of algorithm 1 at the signal-to-noise ratio of 0 dB is excessively large that the focusing processing cannot be implemented, for the purpose of a fair comparison, the database is established here in accordance with the motion parameter estimates obtained based on the proposed algorithm; then the OMP, GD, and high-performance calculations are carried out to resolve equation

FIGURE 3: Variation curve of the velocity acceleration estimation error with the change of SNR: (a) velocity estimation error and (b) acceleration estimation error.

(9); and the images thus obtained are shown in Figure 4. From Figure 4, it can be observed that the algorithm proposed in this paper corresponds to the processing results with clear contours, fewer false points, and a better focusing effect than the other methods. In particular, the proposed algorithm can be used to describe the details of the solar sail panel more properly. In addition, the image entropy corresponding to the three methods can be obtained as 0.3310, 0.2935, and 0.2915.

For the purpose of fully verifying the proposed algorithm put forward in this paper, the stability of the three algorithms is further compared. The signal identification effect in the presence of external interference is analyzed accordingly. Figure 5 below shows the corresponding time-domain waveforms of the signals.

In the process of high-performance computing identification of communication signals, it is impossible to ensure that the reception length and quality of the target signals and

FIGURE 4: Processing results of the simulation data waveform 1: (a) OMP, (b) GD, and (c) VBI.

FIGURE 5: Time-domain waveform of the actual measured signal.

the computing under a certain number of conditions can present the stability of features, which is taken as an essential evaluation criterion for the practicality of the algorithm. Excellent methods for feature value extraction should not be constrained by the number of training, and such methods should have good robust performance when they are applied. After taking this point into full consideration, the identification accuracy of the training samples by using the target experimental signals is studied accordingly. The number of signal samples in each segment contains 500 points. For each class, the number of signal test samples is set

to 100, and the number of training samples is adjusted to 50, 100, 150, and 200, respectively. The experiment is carried out 30 times. The mean value and variance of the identification rates obtained based on the three methods are recorded in turn, which are shown in Table 4.

In the empirical testing, different modulation methods are used to increase the number of training samples as shown in Table 1, which has effectively improved the identification rate of the proposed algorithm. As a result, the identification performance starts to be stabilized. When the real number identification is compared by using the three

TABLE 4: Effect of different sample sizes on the identification results based on the three methods.

Experimental signal	$N_r$ number	BSB		ISIB		Method put forward in this paper	
		Mean value (%)	Variance ( $10^{-4}$ )	Mean value (%)	Variance ( $10^{-4}$ )	Mean value (%)	Variance ( $10^{-4}$ )
1, 2, 3, 4, 5	50	73.05	14.41	81.04	4.48	85.02	3.62
	100	74.65	8.36	81.21	3.98	86.06	2.38
	150	76.68	4.21	83.75	2.62	86.75	1.32
	200	77.15	6.53	84.27	3.14	87.21	1.54

methods, the method proposed in this paper has the highest identification rate for the real signals measured, followed by the ISIB method, and the BSB method is the least effective. When  $N_r$  is increased from 50 to 200, the identification rate of the distance selected bispectrum of the BAS is improved by about 4%, while the ISIB and the method proposed in this paper show the improvement of about 3% and 2%, respectively. The results of the experiment indicate that the algorithm put forward in this paper has excellent stability, the identification results are less affected by the number of training samples, and the model thus established has good robustness, which suggests that the proposed algorithm has relatively strong practicality.

#### 4. Conclusion

On the basis of the research on the fine features in the bispectral analysis of individual identification of radiation sources, the bispectral secondary features extracted are optimized by using the extended Babbitt distance criterion in accordance with the in-depth analysis of the bispectral features of communication signals diagonally sliced. This method can be used to implement the bounded deviation and identify the observation error values quickly and perform the complexity calculation of variational parameters effectively. The experiments indicate that the method is effective. The information on the original signals can also be recovered in a low signal noise background. The statistical features of communication scattering points and noise are used. Through practical analysis, the experimental results indicate that the method proposed in this paper has reduced the usage time. In addition, it can be applied to multiple types of communication signals. The bispectral features thus obtained always have excellent robustness at a low signal-to-noise ratio (SNR). When the signal-to-noise ratio is 0, the identification rate of high-performance computing of communication signals can achieve more than 90%. However, in general, a series of individual identification methods based on bispectral analysis have the common issue of a relatively low identification rate. Taking into account the subtle features in the other aspects of the signals, a feature vector is formed, which can further improve the practical effectiveness of the algorithm proposed in this paper.

This study focuses on managing the gate assignment in the hub airport with both main terminal and satellite halls. We first formulate the gate assignment problem (GAP) as a binary linear programming model with multi-objective functions, where the practical constraints, e.g., gate time conflict and gate compatibility, are considered. Then, we incorporate the impact of gate assignment on transfer passengers and formulate the transfer demand-oriented gate assignment problem (TGAP) as a nonlinear model. A linearization approach and a heuristic approach are designed to solve the TGAP model. A case study is conducted based on the practical data of the Shanghai Pudong International Airport, where a comparison between the results of GAP and TGAP by the two proposed approaches is demonstrated. It shows that the proposed TGAP model and solution approaches can not only enhance the service for transfer passengers but also improve the gate utilization efficiency in the hub airport.

## 1. Introduction

Global air passenger demand and airport construction have experienced rapid growth over the past few decades, and passenger demand still grew steady in 2019 before the COVID-19 pandemic [1]. Driven by the recovery in domestic markets in China, many hub airports have returned to pre-pandemic levels in passenger demand and flight numbers; e.g., Shanghai Pudong International Airport was handling 110,000 domestic travelers and 900 domestic flights every day in March 2021, which are both more than that of 2019 [2]. As the import part of the hub-and-spoke system in air transportation, hub airports are experiencing rapid growth in passenger demand and flight numbers. To release operating pressure and provide better airplane/flight service and passenger service, many hub airports have built satellite halls connected with terminals by underground walkways or mass rapid transit (MRT) systems. This raises new challenges for efficient operations and passenger services in the hub airport.

Gates are a scarce resource at hub airports, facing intense air traffic and passenger demand pressure [3]. The gate operation connects air traffic (timetable and airplane

service), passenger service, and ground operations (including crew assignment), which makes it critical for efficient airport operations. The gate assignment problem (GAP) is to assign airplanes/flights to suitable boarding gates or the apron at the airport on an operating period (usually one day), according to the given flight timetable and airplane fleet assignment, also taking into account the airport layout, gate compatibility, airplane types, and so on. The typical objectives of GAP usually include two aspects, minimizing the operating costs and maximizing the efficiency of gate resources for airport operators; and maximizing satisfaction for passengers. The GAP has been extensively studied as one of the most important problems in the daily operations of the airport, and see [4, 5] for a detailed literature review, and we give an overview from airport and passenger perspectives.

From the airport operator perspective, the main objectives for GAP are efficient utilization of gate resources and reducing operating costs. Since the parking positions in the apron are usually far from the terminals and passengers need to take the shuttle bus. If airplanes are assigned to the apron, it will increase the waiting time of passengers and operation costs due to potential effects on ground operations and crew

assignment. The most common objective in GAP literature is to minimize the airplanes/flights assigned to the apron (Ding et al. [6], Dorndorf et al. [7, 8], Drexel and Nikulin [9], Deng et al. [10]). Some studies aim to minimize the total delay of airplanes when the airport is busy (Lim et al. [11], Kaliszewski et al. [12]). Moreover, as Karsu et al. [13] point out, hub airports may need to handle different types of flights (domestic/international) and airplanes, so minimizing the moves/costs of towing when airplanes need to move from a gate to another is also considered in the literature (Benlic et al. [14], Kumar and Bierlaire [15], Yu et al. [16]). We consider the gate compatibility instead of the towing operation in this study to capture the matching between airplane/flight types and gate facilities. It was also modeled in the objective function of Benlic et al. [14] and Neuman and Atkin [17]. Following the conclusion that the airport controls gate use will ensure they are used most efficiently in the survey of Gillen and Lall [18], we also consider the integrated operating of gates in terminal and satellite halls in the hub airport and include minimizing the number of used gates in the objective function.

Gate assignment also affects the passenger service quality in the airport [11], and it may influence the walking distance, waiting time, and transfer service of passengers. The consideration of passengers in the literature is mainly reflected in the objective function. Hub airports in metropolitan usually have multiterminals, and it may take a lot of time/distance to get the specific gate or transfer between gates, and many studies contribute to GAP to minimize walking time/distance of passengers. Bohr [19] proposed binary linear programming to minimize the passenger walking distance and solved it by the primal-dual simplex algorithm. Karsu et al. [13] formulated a mixed-integer nonlinear programming model for GAP to minimize the total walking distance of all passengers and the number of airplanes assigned to the apron and then proposed exact and heuristic approaches to solve it. Interested readers can also refer to Drexel and Nikulin [9], Haghani and Chen [20], Dell'Orco et al. [21], and Mokhtarimousavi et al. [22]. Besides, Yan and Huo [23] and Yan and Tang [24] are focused on minimizing the total passenger waiting time in GAP. However, from the survey of Entwistle [25], over 60% of passengers plan to shop in the airport, which means minimizing the waiting time is not always the objective of passengers, at least for some of them. Daş [26] proposed a multi-objective model to increase the shopping revenues in the airport through gate assignment, by minimizing the total passenger walking distance and assigning passengers to gates near the shop. We consider the transfer time budget of passengers in this study and propose a more comprehensive way to measure service for transfer passengers. A comparison with some abovementioned major-related studies is shown in Table 1.

In this study, we focus on the impacts of gate assignment on the service of transfer passengers in the hub airport with satellite halls. We proposed a novel transfer demand-oriented objective function considering the transfer time budget, together with objective functions of the airport operator, to explore the trade-off between airport operations and passenger service. Besides, we propose two optimization

models, namely a binary linear programming model for gate assignment problem (GAP) and a nonlinear model for transfer demand-oriented gate assignment problem (TGAP). A linearization approach and a heuristic approach are designed to solve the TGAP model, and then, case studies are performed using the data of Shanghai Pudong International Airport.

The remainder of this study is organized as follows. In Section 2, we give a detailed description of GAP and TGAP. The corresponding mathematic models are formulated in Section 3. Then, Section 4 develops the linearization approach and heuristic approach to solve the model. Case studies are illustrated in Section 5, and Section 6 concludes the study.

## 2. Problem Statement and Assumptions

**2.1. Problem Statement.** We consider a hub airport with the main terminal and several satellite halls, illustrated in Figure 1. Gates are available in both the terminal and satellite halls and integrated assigned by the airport operator, denoted by  $g \in G$ . Passengers can travel between the terminal and satellite halls via the MRT system. As shown in Figure 1, the airport also has parking positions for airplanes at the apron, denoted by  $G'$ , in case an airplane could not be assigned to a gate in the terminal or satellite halls.

The research period in this study is denoted by  $[T_1, T_2]$  (i.e., one day or one week) and discretized into equal-length time intervals  $t$ , and let  $t \in T$ . Some airplanes land and take off at the airport in this period, they occupy the gates for passenger arrivals and departures, and the set of airplanes is denoted by  $I$ . The services that provided by airplanes to transport passengers between airports are called a *flight*. For a specific airport, one airplane serves two flights, and we assume that the related flights of each airplane and the timetable are given. In Figure 2, we show the relationship between airplanes and related flights it serves. An airplane  $i \in I$  is considered, and it serves two flights: one arriving flight with arrival time  $a_i$  and one departing flight with departure time  $d_i$ , and it needs to occupy a gate  $g \in G$  or a parking position  $g \in G'$  during the time period  $[a_i, d_i]$ . Besides, the type of airplanes (wide/narrow-body) and related flights (domestic/international) are also given. Since the correspondence between aircrafts and flights is given, it is possible to model by either airplane or flight, and we use the airplane for modeling in this study.

As for the utilization of gates, the first thing to consider is time conflicts. As shown in Figure 3, airplanes  $i \in I$  and  $i' \in I$  use the same gate consecutively, and the usage time periods of the two airplanes  $[a_i, d_i]$  and  $[a_{i'}, d_{i'}]$  should not overlap. Besides, buffer time  $\tau_b$  should also be satisfied between serving two airplanes for ground operations. Secondly, because gates in terminal and satellite halls may have different functions (such as check-in facilities and passport control), we consider the gate compatibility in this study. In particular, for airplanes, we consider gate compatibility for wide/narrow-body types; for related flights, the gate compatibility is associated with serving domestic/international flights.

TABLE 1: Comparisons of major-related studies.

Paper	Airport-oriented objective	Passenger-oriented objective	Transfer passenger	Gate compatibility	Solution method
Bihr [19]	—	Walking distance	No	—	Simplex algorithm

FIGURE 1: Example layout of the hub airport with satellite halls.

FIGURE 2: Airplane and served flights.

FIGURE 3: Gate utilization and buffer time.

The gate assignment problem (GAP) is to assign airplanes  $i \in I$  to gates or apron  $g \in G \cup G'$  with considering constraints such as gate time conflict constraints and gate

compatibility, and the objective function mainly concerns making efficient use of gates or reducing the number of occupied gates. The decision variables are binary gate assignment variables  $x_{ig}$ ,  $i \in I, g \in G$ , and binary gate utilization variables  $x_g$ ,  $g \in G$ . In particular,  $x_{ig}$  equals 1 if airplane  $i$  is assigned to gate  $g$  and otherwise equals 0;  $x_g$  equals 1 if gate  $g$  is used by any airplane and otherwise equals 0.

We also attempt to consider the impact of gate assignment on passengers in this study. The set of passenger groups is denoted by  $P$ . As shown in Figure 4, each group of passengers  $p \in P$  transfers from the same arrival flight served by airplane  $i_p^1 \in I$  to the same departure flight served by airplane  $i_p^2 \in I$  (which can be abbreviated as  $i_1$  and  $i_2$ ). The transfer time budget for passenger group  $p$  is defined as  $B_p = d_{i_2} - a_{i_1}$ . The number of passengers in group  $p$  is given and denoted by  $n_p$ .

Gate assignment determines passengers' shortest transfer time, including processing time, walking time, and MRT time. It will affect passengers' transfer in the airport, especially hub airports with satellite halls. The layout in

FIGURE 4: Illustration for transfer time budget of passengers.

Figure 1 is taken as an example, and a passenger whose transfer time budget is 60 min is considered. Different transfer scenarios are illustrated in Table 2 when arriving and departing airplanes are assigned to different gates. In Scenario 1, both gates of arriving and departing airplanes are assigned in terminal  $T$ , and the shortest transfer time is much less than the transfer time budget  $B_p$  and transfer success. Passenger transfer is more stressful in Scenario 2 because the assigned gates of two airplanes are located at  $T$  and  $S1$ , respectively. Passengers in Scenario 3 and Scenario 4 fail to transfer due to the gate assignment.

Thus, passengers  $p$  may fail to transfer if the shortest transfer time is too long between two gates assigned to airplanes  $i_1$  and  $i_2$ , i.e., exceeding the transfer time budget  $B_p$ . The demand-oriented gate assignment problem (TGAP) in this study focuses on the trade-off between transfer passenger service and gate utilization efficiency in GAP when satellite halls are constructed in the hub airport.

**2.2. Assumptions.** To facilitate the presentation of our studied problem in this study, the following assumptions are made:

**A1:** (airport layout). Considering a hub airport with one terminal, several satellite halls, and an apron, the shortest transfer time between any two gates is given. There is no limit on the number and type of airplanes that use the apron simultaneously.

**A2:** (flight and airplane). Given the flight timetable in the research period, including arrival/departure time, flight types (domestic/international), and airplane types (wide/narrow-body).

**A3:** (gate service). Only one airplane can use a gate at a time. All of the gates have the same buffer time  $\tau_b$  between serving two airplanes. The gate compatibility for flights and airplanes is considered.

**A4:** (passenger demand). Since the satellite halls mainly affect transfer passengers, it is assumed that we only consider the transfer passenger demand. The quantity, associated flights, and transfer time budget of passengers are given.

### 3. Mathematical Formulation

In this section, we first formulate the model for GAP to clarify the resource utilization and constraints in the hub airport, and then, we propose the model for TGAP considering the service of transfer passengers in Section 3.2.

**3.1. Notations and Decision Variables.** Table 3 lists general indices, sets, parameters, and variables in optimization models that appeared in this study.

**3.2. Model for GAP.** In this subsection, the mathematic model of GAP is formulated to integrate using the gates in terminal and satellite halls, including constraints and multi-objective functions.

**3.2.1. Constraints.** The constraints of GAP usually include gate utilization and airplane service, which are next described in detail.

(1) *Gate Time Conflict Constraint.* A feasible gate assignment scheme should guarantee that airplanes assigned to the same gate do not overlap in time and observe the buffer time. The airplane time incidence parameter  $\delta_{it}$  is introduced, which equals 1 when  $a_i \leq t \leq d_i + \tau_b$  and otherwise 0. So, we have the following:

$$\sum_{i \in I} \delta_{it} \cdot x_{ig} \leq 1, \quad \forall t \in T, \forall g \in G. \quad (1)$$

The incidence parameter  $\delta_{it}$  and assignment variable  $x_{ig}$  associate airplanes, gates, and time.

(2) *Gate Utilization Constraints.* For gate  $g \in G$ , if it is used by any airplane, the variable  $x_g$  equals 1, otherwise 0. So, we have gate utilization constraints that indicate the relationship between  $x_{ig}$  and  $x_g$  as follows:

$$\sum_{i \in I} x_{ig} \leq M \cdot x_g, \quad \forall g \in G, \quad (2)$$

where  $M$  is a sufficiently large positive constant.

(3) *Airplane Service Constraints.* Each airplane must and can only be assigned to one gate or the apron, and then:

$$\sum_{g \in G \cup G'} x_{ig} = 1, \quad \forall i \in I. \quad (3)$$

(4) *Gate Compatibility Constraints.* We consider the gate compatibility in this model, because gates in the different areas of terminal and satellite halls may have different functions, which are mainly influenced by facilities and equipment. The airplane gate compatibility incidence parameter  $\sigma_{ig}$  is introduced, which equals 1 if airplane  $i \in I$  can be served by gate  $g \in G$  and otherwise 0. We can derive the values of  $\sigma_{ig}$  based on the given airplane and gate types.

$$x_{ig} \leq \sigma_{ig}, \quad \forall i \in I, \forall g \in G \cup G'. \quad (4)$$

TABLE 2: Transfer scenarios for passenger group  $p$  under different gate assignment schemes.

Scenarios	Gate of arriving airplane	Gate of departing airplane	Shortest transfer time	Transfer time budget $B_p$	Result
1	Gate 1 (T)	Gate 2 (T)	30 min	60 min	Success
2	Gate 1 (T)	Gate 3 (S1)	55 min		Success
3	Gate 1 (T)	Gate 5 (S2)	70 min		Fail
4	Gate 1 (T)	Gate 7 (apron)	> 70 min		Fail

TABLE 3: Main sets, indices, parameters, and variables.

Symbol	Definition
<i>Sets and indices</i>	
$G$	Set of gates in the terminal and satellite halls
$G'$	Set of parking positions in the apron
$I$	Set of airplanes
$P$	Set of passenger groups
$T$	Set of discretized time intervals
$g$	Index of all gates and parking positions, $g \in G \cup G'$
$i$	Index of airplanes, $i \in I$
$p$	Index of passenger groups, $p \in P$
$t$	Index of discretized time intervals, $t \in T$
<i>Parameters</i>	
$[T_1, T_2]$	Daily operation period
$\tau_b$	Buffer time of gates
$a_i$	Arrival time of airplane $i$
$d_i$	Departure time of airplane $i$
$\delta_{it}$	Airplane time incidence parameter
$\sigma_{ig}$	Airplane gate compatibility incidence parameter
$i_p^1$	Arriving airplane of passenger group $p$ , abbreviated as $i_1$
$i_p^2$	Departing airplane of passenger group $p$ , abbreviated as $i_2$
$B_p$	Transfer time budget of passenger group $p$
$n_p$	Number of passengers in group $p$
$\tau(g_1, g_2)$	Shortest transfer time between gate $g_1 \in G \cup G'$ and $g_2 \in G \cup G'$
$\tau_c$	Waiting time for passengers when fail to transfer
$M$	A sufficiently large constant
$\varepsilon$	A sufficiently small positive constant
$c$	Weights in the objective function
<i>Variables</i>	
$x_{ig}$	Binary assignment variable: $x_{ig} = 1$ if airplane $i \in I$ is assigned to gate $g \in G \cup G'$ , and $x_{ig} = 0$ , otherwise
$x_g$	Binary utilization variable: $x_g = 1$ if gate $g \in G$ is used, and $x_g = 0$ , otherwise
$\varphi_p$	Transfer pressure of passenger group $p$
$y_{i_1, i_2, g_1, g_2}$	Binary variable: $y_{i_1, i_2, g_1, g_2} = 1$ for passenger $p$ , if arriving airplane $i_1$ is assigned to $g_1$ and departing airplane $i_2$ is assigned to $g_2$ , and $y_{i_1, i_2, g_1, g_2} = 0$ , otherwise

In particular, the apron can serve all types of airplanes and  $\sigma_{ig} = 1$ ,  $g \in G'$ .

##### (5) Constraints for Decision Variables

$$x_{ig} = \begin{cases} 1 & \text{if airplane } i \text{ is assigned to gate } g, \\ 0 & \text{otherwise,} \end{cases} \quad \forall i \in I, \forall g \in G \cup G',$$

$$x_g = \begin{cases} 1 & \text{if gate } g \text{ is used,} \\ 0 & \text{otherwise,} \end{cases} \quad \forall g \in G.$$
(5)

Constraints (5) and (6) are binary requirements on the decision variables.

**3.2.2. Objective Function.** Gates are the scarce resource in an airport, and operational efficiency depends on the utilization of this bottleneck resource. Since the hub airport

has terminal and satellite halls simultaneously, the GAP aims to make efficient use of the gates in the terminal and satellite halls and minimizes the operating costs.

An airplane can use parking positions in the apron if it cannot be assigned to a gate, but the apron is usually far away from the terminal and satellite halls, and passengers need to take a shuttle bus between the terminal and the apron. This will increase the transfer time of passengers on the one hand and increase the operating costs of the airport on the other hand. To make efficient use of the gates and avoid assigning airplanes to the apron, the first objective is to minimize the number of airplanes assigned to the apron:

$$\min Z_1 = \sum_{i \in I} \sum_{g \in G'} x_{ig}. \quad (6)$$

This is a common objective in the literature of GAP (Ding et al. [6], Dorndorf et al. [7, 8], Drexler and Nikulin [9], Deng et al. [10]). It is equivalent to maximizing the number of airplanes assigned to gates. Furthermore, this objective can be easily extended to maximize the total usage time of gates since the dwell time of each airplane is given, but it has no significant impact on passenger service so we use the objective (6) in this study.

Besides, the GAP is multi-objective in nature and operation costs for gates are expensive (including ground operation costs), which motivates us to consider objectives more comprehensively. Apart from minimizing the apron operation, the GAP also needs to consider the objective that minimizes the number of used gates, i.e.,

$$\min Z_2 = \sum_{g \in G} x_g. \quad (7)$$

In this study, we consider the objective function that consists of the number of airplanes assigned to the apron and the number of used gates and then formulate the GAP as a multi-objective optimization problem. For GAP in a hub airport with the apron, if we only consider the objective (6), gate operating hours may not be fully utilized in some situations; only consider the objective (7) is obviously not feasible either, which would assign all of the airplanes to the apron. Thus, the combination and trade-off between objectives (6) and (7) is comprehensive for GAP. We use linear weight to handle these two objectives and formulate the objective function as follows:

$$\min Z_{\text{GAP}} = \alpha_1 \cdot Z_1 + \alpha_2 \cdot Z_2, \quad (8)$$

where  $\alpha_1$  and  $\alpha_2$  are positive weights to denote the trade-off between objectives. In particular, we can obtain a Pareto-optimal solution if  $\alpha_1$  and  $\alpha_2$  are set 1, or their values are set according to the preference of airport operators.

**3.2.3. Mathematical Model for GAP.** The GAP can be formulated as follows:

$$\begin{cases} \min Z_{\text{GAP}} = \alpha_1 \cdot \sum_{i \in I} \sum_{g \in G'} x_{ig} + \alpha_2 \cdot \sum_{g \in G} x_g, \\ \text{s.t. constraints (1) - (6).} \end{cases} \quad (9)$$

The mathematical model for GAP given in (9) is binary integer linear programming. The model for GAP focuses on the gate resource optimization when a hub airport has both main terminal and satellite halls, and next, we will consider the impact of GAP on passengers and further improve the model involving different stakeholders.

**3.3. Model for TGAP.** Gate assignment affects the service quality of passengers, especially the transfer passengers in the hub airport where both main terminal and satellite halls are providing passenger service. Passengers may take a longer time to get from the arriving flight to the departing flight gate due to the gate assignment and may even exceed the transfer time budget resulting in a failed transfer. Thus, we will incorporate the service of transfer passengers in the GAP in this section.

With the given flight timetable and transfer scheme (arriving airplane  $i_1$  and departing airplane  $i_2$ ) of passenger group  $p \in P$ , we can get the transfer time budget  $B_p = d_{i_2} - a_{i_1}$ . The gates serving airplanes  $i_1$  and  $i_2$  are denoted as  $g_1$  and  $g_2$ , respectively. Given the layout of terminal and satellite halls in the airport, the shortest transfer time  $\tau(g_1, g_2)$  (including processing time, walking time, and MRT time) between any two gates is also fixed.

The gate assignment will influence the shortest transfer time of passenger group  $p$ . Here, we introduce the transfer pressure to describe the airport's service level for transfer passengers. The transfer pressure is the ratio of shortest transfer time to transfer time budget, and the transfer pressure for passenger  $p$  is denoted by  $\varphi_p$  and defined as follows:

$$\varphi_p = \begin{cases} \frac{\tau(g_1, g_2)}{B_p}, & \text{if } i_1, i_2 \text{ are both assigned to gates,} \\ \frac{\tau_c}{B_p}, & \text{otherwise,} \end{cases} \quad (10)$$

where  $\tau_c$  is the total transfer time (including process time and shuttle bus time) for passengers associated with the apron. If both associate airplanes of a passenger group are assigned to gates in the terminal and satellite halls, passengers need to do a gate-gate transfer with transfer time  $\tau(g_1, g_2)$ ; otherwise, passengers need to do a gate-apron, apron-gate, or even apron-apron transfer with transfer time  $\tau_c$ . Note that  $\tau_c$  is longer than the shortest transfer time between any two gates because the parking positions in the apron are usually far away from the terminal and satellite halls.

Then, we introduce the objective that minimizes the transfer pressure for passengers to capture the passenger service in the GAP of the hub airport; i.e.,

$$\min Z_3 = \sum_{p \in P} \sum_{g_1 \in G \cup G'} \sum_{g_2 \in G \cup G'} x_{i_1 g_1} x_{i_2 g_2} \varphi_p n_p. \quad (11)$$

The GAP considering passenger transfer time budget can be formulated as follows:

$$\begin{cases} \min Z_{\text{TGAP}} = \alpha_1 \cdot \sum_{i \in I} \sum_{g \in G'} x_{ig} + \alpha_2 \cdot \sum_{g \in G} x_g + \alpha_3 \cdot \sum_{p \in P} \sum_{g_1 \in G \cup G'} \sum_{g_2 \in G \cup G'} x_{i_1 g_1} x_{i_2 g_2} \varphi_p n_p, \\ \text{s.t. constraints (1) - (6).} \end{cases} \quad (12)$$

The mathematical model given in (12) explicitly considers the transfer passenger service and shows the trade-off between passenger service and operating costs of GAP in the hub airport. The mathematical model (12) is nonlinear programming, and the nonlinearities come from the objective function associated with passenger, where the calculation of transfer pressure  $\varphi_p$  is a segmentation function.

Table 4 presents the complexity of the model for GAP and TGAP. It can be seen that the model size depends on the number of gates, airplanes, passenger groups, and demand discretization (number of discretized time intervals). Suppose that there is a hub airport with 10 gates and 100 airplanes with 100 transfer passenger groups, the research period is [0: 00 – 24: 00]. If the discretization time interval is 5 min, there will be 120 variables and 2500 constraints in the GAP model (9). The number of variables in the TGAP model (11) is 1120, with the addition of variables related to transfer passengers.

#### 4. Solution Approach

The mathematic model (9) for GAP is a binary integer linear programming and can be solved by several existing commercial solvers, such as CPLEX and Gurobi (see, e.g., Linderoth and Ralphs [27]; Atamturk and Savelsbergh [28]).

As for the mathematic model (12) for TGAP, it is nonlinear programming with linear constraints, and we next propose two approaches to solve it.

**4.1. Linearization Approach.** In this section, the origin nonlinear programming model (12) will be transformed into binary integer linear programming by introducing new binary variables and linear constraints.

Focusing on the nonlinear objective function of the model (12), the calculation of transfer pressure  $\varphi_p$  is a segmentation function as shown in Eq. (11). According to the analysis of transfer time under different scenarios in Section 3.3, only need to set the shortest transfer time associated with  $g \in G'$  as  $\tau_c$ , i.e.,  $\tau(g_1, g_2) = \tau_c, g_1 \in G'$  or  $g_2 \in G'$  the objective that minimizes the transfer pressure in (12) could be updated as follows:

$$\min Z_3 = \sum_{p \in P} \sum_{g_1 \in G \cup G'} \sum_{g_2 \in G \cup G'} \frac{x_{i_1 g_1} x_{i_2 g_2} \tau(g_1, g_2) n_p}{B_p}. \quad (13)$$

It can be observed that (13) is nonlinear because of productions of binary variables  $x_{i_1 g_1}$  and  $x_{i_2 g_2}$ , and they can be replaced by auxiliary binary variables  $y_{i_1, 2, g_1, 2}$ . Following Williams [29], the productions can be replaced by adding linear constraints:

$$\begin{cases} -x_{i_1 g_1} + y_{i_1, 2, g_1, 2} \leq 0 \\ -x_{i_2 g_2} + y_{i_1, 2, g_1, 2} \leq 0 \\ x_{i_1 g_1} + x_{i_2 g_2} - y_{i_1, 2, g_1, 2} \leq 1 \\ y_{i_1, 2, g_1, 2} \in \{0, 1\} \end{cases}, \quad \forall p \in P, \forall g_1, g_2 \in G. \quad (14)$$

Thus, the linearized model for TGAP considering the transfer passenger service can be formulated as follows:

$$\begin{cases} \min Z_{\text{TGAP}} = \alpha_1 \cdot \sum_{i \in I} \sum_{g \in G'} x_{ig} + \alpha_2 \cdot \sum_{g \in G} x_g + \alpha_3 \cdot \sum_{p \in P} \sum_{g_1 \in G \cup G'} \sum_{g_2 \in G \cup G'} \frac{y_{i_1, 2, g_1, 2} \tau(g_1, g_2) n_p}{B_p}, \\ \text{s.t. constraints (1) – (6), (14)}. \end{cases} \quad (15)$$

Note that model (15) is linear programming and can easily be solved by commercial solvers such as CPLEX and Gurobi to find a globally optimal solution.

As shown in Table 4, the number of auxiliary binary variables  $y_{i_1, 2, g_1, 2}$  is  $|P| \times (|G| + 1)^2$ . Based on the example in Section 3, there will be 121120 variables and 489000 constraints in the linearized model (15) for TGAP. Besides, when the number of passenger groups and airport gates increases, the number of variables and constraints increases rapidly, which takes a long computation time to solve the TGAP with commercial solvers. To address this issue, we further design a heuristic approach to solve the TGAP.

**4.2. Heuristic Approach.** The gate assignment problem is a complex nondeterministic polynomial hard (NP-hard) problem due to the complex layout of airports, multi-flights, passenger trips, and gate compatibility [30, 31], and many studies adopted heuristic approaches to solve it [16, 21, 24]. To solve TGAP in large hub airports requires an efficient

algorithm to obtain a satisfactory solution and solve the problem in reasonable CPU time. The simulated annealing (SA) algorithm is a metaheuristic to approximate the global optimization and has good robustness. Thus, we propose an approach for TGAP at large hub airports based on the framework of the SA algorithm.

In Algorithm 1, we adopt the following strategies to adjust the assignment scheme and get neighborhood solutions.

**4.2.1. Initial Solution.** The model (11) for TGAP has the same constraints as the model (9) for GAP, and we can use the optimal solution of model (9) as the initial solution. It is already efficient in terms of gate resource utilization. As for the model scales, note that the model (9) can be decomposed into two subproblems by gate compatibility on airplane types: one assignment for wide-body airplanes and associate gates and another for narrow-body airplanes and associate gates. In this way, the initial solution of TGAP is designed.

TABLE 4: Numbers of variables and constraints in the models.

Variables and constraints	Quantity
<i>Variables</i>	
$x_{ig}$	$ I  \times  G  +  I $
$x_g$	$ G $
$\varphi_p$	$ P $
$y_{i_1,2} \theta_{i_2}$	$ P  \times ( G  + 1)^2$
<i>Constraints</i>	
Gate time conflict constraint (1)	$ T  \times  G $
Gate utilization constraints (2)	$ G $
Airplane service constraints (3)	$ I $
Gate compatibility constraints (4)	$ I  \times  G  +  I $
Binary constraints (5)	$ I  \times  G  +  I $
Binary constraints (6)	$ G $

Note:  $|\cdot|$  represents the cardinality of a set.

**4.2.2. Passenger Service Adjustment Strategy.** The passenger service adjustment strategy aims to reduce the transfer pressure of passengers, which includes three options: insert option, swap operation, and remove operation. These operations are performed sequentially, with only one of them executed in each loop, and detailed options are shown as follows.

In the current solution, we already know the gate assignment scheme, i.e., the specific gate of each airplane. As we know the transfer information of passenger group  $p \in P$ ,  $P_i^1$  and  $P_i^2$  are denoted as the subset of passenger groups whose arriving and departing airplane is  $i \in I$ , respectively. Then, we denote  $\varphi_i$  as the total transfer pressure of passengers associated with airplane  $i$ , which is given as follows:

$$\varphi_i = \sum_{p \in P_i^1} \varphi_p n_p + \sum_{p \in P_i^2} \varphi_p n_p. \quad (16)$$

The total transfer pressure of each airplane is calculated by equation (16) and does the following operations: ① the airplane that has the maximum transfer pressure and is already assigned to a gate is selected. ② Insert operation: the subset of gates that has available time and already been used is found, the selected airplane is inserted into one of them randomly. If the subset is empty, the next operation is proceeded. ③ Swap operation: the subset of airplanes that has the same time interval and type (no violation of constraints (1) and (4)) is found, the selected airplane and one of them are randomly swapped. If the subset is empty, the next operation is proceeded. ④ Remove operation: if the above two operations are not executed, the subset of gates suitable for the selected airplane is found, one of them is chosen at random, and the selected airplane is assigned to this gate, and then, the airplanes with conflicts are assigned to the apron.

**4.2.3. Gate Utilization Strategy.** The gate utilization strategy concentrates on reducing the number of used gates, which includes two options: insert option and remove operation. Based on the current solution, we could know the set of airplanes assigned to gate  $g \in G$  and denoted by  $I_g$ .  $u_g$  is denoted as the time utilization ratio of gate  $g$ , which equals the ratio of occupied time to research period:

$$u_g = \sum_{i \in I_g} \frac{(\tau_b + d_i - a_i)}{(T_2 - T_1)}. \quad (17)$$

To reduce the number of used gates, the following operations are executed: ① the gate with the lowest time utilization ratio using (17) is found, and if the ratio is lower than a threshold value (such as 40%), then next options are done. ② insert operation: for airplanes assigned to the selected gate, the subset of gates that has available time and already used is found, and these airplanes are inserted in one of them randomly. ③ Remove operation: the rest of the airplanes are assigned to the apron after the previous option.

**4.2.4. Apron Airplane Adjustment Strategy.** The apron airplane adjustment strategy is designed to reduce the number of airplanes assigned to the apron and transfer pressure of passengers. Thus, included operations in this part of the strategy consider both of the two objectives. ① The total transfer pressure of each airplane in the apron by (16) is calculated and the maximum one of them is found. ② The insert and swap operations are executed. This airplane is randomly inserted into a gate that has available time periods; otherwise, it is swapped with another airplane assigned to a gate without violation of constraints (1) and (4). ③ If the above two operations are not satisfied, one of the airplanes in the apron is attempted insert into an available gate. ④ If there is any available empty gate, the airplane with the shortest overlap time period with other airplanes in the apron is found and assigned to the new gate.

The proposed heuristic approach shown in Algorithm 1 is based on the framework of the SA algorithm, together with three strategies for improving different parts of objective functions, and it would find a satisfactory solution of TGAP in the model (13).

## 5. Case Studies

To demonstrate the performance of the proposed models and solve approaches, we use the data of the Shanghai Pudong International Airport in China as a case study. We will describe the experiment data in Section 5.1. The numerical results are presented in Section 5.2.

All numerical tests are conducted on a personal computer with Intel® Core (™) 3.00 GHz processor and 16.00 GB RAM and Windows 10 Home Edition Operating System (64 bit). The YALMIP-R20190425 together with MATLAB R2019b is used to conduct the numerical tests. The commercial solver Gurobi optimization studio 8.1.1 (with academic license) is adopted to solve GAP and linearized TGAP models, and the solver used the branch-and-cut algorithm to find optimal solutions for the above two mixed-integer programming models.

**5.1. Data and Parameter Setting.** We consider a real-world case study on the Shanghai Pudong International Airport, which is an important hub airport in eastern China. The gates are integrated used in a terminal  $T$  and connected

ALGORITHM 1: Solving framework based on SA algorithm for TGAP.

satellite hall S, and both terminal T and satellite hall S could handle transfer processes for passengers. There is an MRT line that connects T and S to quickly transport passengers, assuming that passengers' MRT time for a one-way trip is 5 minutes (for layout, see Figure 5). We consider the GAP and TGAP for 28 gates in terminal T and 41 gates in satellite hall S and an apron, and the detailed information of gates can be found in Table 5. The compatibility of gates such as service for domestic/international flights and wide/narrow-body airplanes is also given.  $\tau_c$  is set as 180 minutes.

In this case study, the considered research period is set as [0: 00 – 24: 00], which covers a full day of operations. We select 296 airplanes related to the above gates of China Eastern Airlines and Xiamen Airlines on January 20, 2018. Table 6 shows several records as an example, and every record corresponds to one airplane, which services two flights. The information of airplanes includes the arrival and departure date, arrival and departure time, arrival and departure flights, airplane types (wide/narrow-body), and flight types (domestic/international).

Meanwhile, transfer information of more than 3000 passengers is selected and divided into groups based on arrival and departure flights. The example of information is shown in Table 7, which includes arrival and departure flight, arrival and departure date, and passenger number in groups. Combining with the information of airplanes and flights in Table 6, we can easily get the transfer time budget of each passenger group. Since the layout of the airport is set, the shortest transfer time  $\tau(g_1, g_2)$  between any two gates is also determined, including processing time, walking time, and MRT time. The buffer time of gates  $\tau_b$  is set to 45 minutes.

The linear weights in the model (10), (13), and (16) are, respectively,  $\alpha_1 = 296$ ,  $\alpha_2 = 1$ ,  $\alpha_3 = 10$ ; the algorithm parameters are set as follows:  $T_0 = 10^6$ ,  $T_f = 5$ ,  $m_{\max} = 50$ ,  $\theta = 0.5$ .

**5.2. Computational Results.** Given the above data and settings, the proposed solution approaches will be implemented for GAP and TGAP. The results of GAP, TGAP with linearization approach, and performance comparison are shown in Subsection 5.2.1; Subsection 5.2.2 shows the result of TGAP solved by the heuristic approach.

**5.2.1. Solutions of GAP and Linearized TGAP.** In this subsection, we solve the GAP and linearized TGAP by commercial solver Gurobi optimization, and the CPU time to solve GAP is 5.75s. The result of GAP is shown in Figure 6, and the horizontal axis represents the research period ([0: 00 – 24: 00] on January 20, 2018), and the vertical axis represents the total of 69 gates in terminal T and satellite hall S. The colored bars in Figure 6 represent the time period when the airplanes occupy the corresponding gates, and the buff time is not included. It can be clearly seen that airplanes satisfy the time conflict constraints of gates and buffer time is also held between two adjacent airplanes. One can find that airplanes arriving and departing during [0: 00 – 6: 00] usually occupy the gates for a long time as passengers tend not to travel at this period. The result of TGAP is shown in Figure 7, which also satisfies all of the constraints.

From Figure 6, we can find that several gates (S29, S30, S39, and S41) are not occupied by any airplane, and they are all serving wide-body airplanes. Meanwhile, Figure 8

shows that all wide-body airplanes are already assigned to gates in GAP and that ratio for narrow-body airplanes is 81%, and the total number of airplanes successfully assigned to the gates is 249. Here is why we consider the objective that minimizes the number of used gates in (7), which can improve the efficiency of gate utilization when one kind of resource is sufficient, i.e., gates for wide-body

airplanes. Thus, the combination of objectives (6) and (7) is more comprehensive for gate utilization in both GAP and TGAP.

Next, we compare the solution of GAP and TGAP, and values of different parts in objective functions are shown in Table 8, of which the value of  $Z_3$  (transfer pressure) in GAP is calculated based on the optimal solution of the model (10)

FIGURE 7: Optimal gate assignment scheme of linearized TGAP.

and services for passengers are not taken into account. It is obvious from Table 8 that when the first and second objectives (minimizing the number of apron airplanes  $Z_1$  and used gates  $Z_2$ ) are close in the GAP and TGAP, considering the objective  $Z_3$  can significantly reduce the transfer pressure of passengers (23.64% reduction). That is, model (12) of the TGAP can improve the service level of transfer passengers without increasing the resource requirement in the hub airport. Moreover, although the number of assigned airplanes has decreased in the TGAP solution, the time utilization rate of gates in terminal  $T$  and satellite hall  $S$  has increased, and the scheme in TGAP assigns airplanes serving more transfer passengers and with less occupation time to

the gates. This also demonstrates that considering the gate resource utilization and passenger service simultaneously is a more comprehensive way to address gate assignment in the hub airport.

5.2.2. *Solution of TGAP Adopting Heuristic Approach.* Although the proposed linearization approach in Section 4.1 can obtain the global optimal solution for TGAP, it takes a long time to converge. We adopted the commercial solver Gurobi optimization studio 8.1.1 to solve the linearized TGAP, and the CPU time to get the optimal solution is 6.09 h. The proposed heuristic approach takes

FIGURE 8: Assigned numbers and rates for different types of airplanes in GAP.

FIGURE 9: Gate assignment scheme of TGAP solved by the heuristic approach.

726s to solve the TGAP with the same input and parameters and only has a 2.59% solution GAP with linearization approach, and the gate assignment scheme is shown in Figure 9 as follows.

Passenger group no. 3 in Table 7 is taken as an example, passenger transfers from flight MU5698 arriving on January 20, 14:30, to flight MU545 departing at January 20, 16:10, and the transfer time budget is 100 min. In the GAP solution, airplanes separately serving the arrival and departure flight are assigned to gates S5 and T3. As the two gates are not in the same terminal, the shortest transfer time for passengers is 60 min. When we take the transfer pressure into account in TGAP, the above two airplanes are assigned to gates T18 and T5, which are both in the terminal *T*, passengers' shortest transfer time reduced to 35 min, and transfer pressure decreased from 0.60 to 0.35. Furthermore, the total transfer pressure of passengers in the solution of TGAP by the heuristic approach is still lower than that in the solution of GAP. This indicates that the TGAP well considered the service for passengers and realized the integrated assignment of gates in terminal and satellite halls.

As shown in Figure 10, gates in the terminal *T* are all used due to the shorter transfer time related to the gates in *T* than that in *S*, and there are 3 gates in the satellite hall *S* serving wide-body airplanes that are not used. The total utilization rate of gates is 96%, and the time utilization rate is 69.98%. For TGAP, although the gate time utilization rate in the solution of the linearized approach (70.21%) is higher than that of the heuristic approach, the difference is not significant.

Next, we compare the passenger transfer pressure in three cases: the GAP solution, linearized approach of TGAP solution, and heuristic approach of TGAP solution. The proportion of passengers within different transfer pressure intervals of the above three solutions are reported in Figure 11, where we observe that most of the passengers' transfer pressure remains at a relatively low level and lies in the range of [0.1, 0.5] in all three cases. Two solutions of TGAP are compared with the GAP solution, and we can see that the quantity of passengers who experience low transfer pressure ([0.1, 0.3]) in TGAP solutions is significantly more than that in the GAP solution, while in the high transfer

FIGURE 10: Gate utilization in terminal T and satellite hall S in TGAP.

FIGURE 11: Comparison of passenger transfer pressure.

pressure range  $([0.5, 1.0])$ , the proportion of passengers in TGAP solutions is less than that in the GAP solution. This result indicates that proposed TGAP models could improve the service for transfer passengers.

Turning now to solutions of TGAP by linearization approach and heuristic approach, the distributions of passenger transfer pressure in these two solutions are comparable, which means the proposed heuristic approach could obtain a satisfactory solution in a reasonable time. What is striking in Figure 11 is that some passengers in all three solutions have transfer pressure greater than 1 because related airplanes are assigned to the apron, and this situation is enhanced in TGAP solutions.

## 6. Conclusions and Future Research

In this study, we focus on the impacts of gate assignment on the service of transfer passengers in the hub airport with satellite halls. First, a binary linear programming model for GAP is proposed that considers the gate time conflict, gate compatibility constraints, and the airport operator-oriented objective functions. Then, we introduce the transfer time budget and transfer pressure to measure the passenger service and formulate the TGAP as a nonlinear programming with linear constraints. In particular, multi-objective functions were considered in the TGAP model, including transfer demand-oriented and operator-oriented objectives.

We proposed a linearization approach and a SA algorithm-based heuristic approach to solve the nonlinear model of TGAP. Finally, the case study based on practical data demonstrated the benefits of the proposed models and solution approaches. In the experimental results, it was verified that the proposed TGAP model and solution approaches can improve the service for transfer passengers and lead to more efficient utilization of gate resources in the hub airport.

Further research could consider the randomness of transfer passenger demand and the effects of random flight delay on gate assignment and transfer passenger service. We can also manage the fairness of passengers through transfer pressure in the gate assignment problem.

With the rapid development of science and technology, testing equipment and testing methods are constantly updated. Radar detectors have the advantages of losslessness, high efficiency, high resolution, and high-speed radar image capture. They can accurately locate defects in railway tunnels, respond to hidden dangers in time, and provide strong technical support for transportation. This paper proposes to optimize the defect detection of railway tunnel radar through the combination of multisensor technology and active interference suppression algorithm and designs the corresponding sensor system according to the content. This article analyzes several factors that affect the radar detection effect and makes a detailed summary from the detection environment and other aspects. At the same time, it uses the multisensor system combined with active interference suppression algorithm to design a railway tunnel detection simulation experiment. Experimental results show that the use of multisensors combined with active interference suppression algorithm to optimize radar detection can effectively improve the accuracy of railway tunnel defect detection. Through the analysis of the results of tunnel defect detection, the detection accuracy of this paper has reached 98.8%, which can provide an effective reference for the detection of railway tunnels.

## 1. Introduction

The current railway tunnel construction is a leapfrog development. There are many railway projects in the country under construction. These railways will be the most efficient bridge connecting the country in the future, and the economy will grow rapidly. Therefore, if the construction period is long, on-site construction will often ignore the physical quality of the project. Examples of problems in the operation of railway tunnels are not uncommon in news reports. The lessons are profound, and the results are tragic. Of course, there are many reasons for this tragedy. Everyone involved in the construction is responsible, but in the end, it is due to quality problems. Most of the accidents are caused by the phenomenon of cutting corners and reducing construction procedures during the construction process by the specific construction team at the construction site. At the

same time, the competent authority does not supervise such issues nor do a good job of source management that directly affects the quality of the project. It is precisely because many lessons have been learned that the government attaches great importance to the safe operation of railways. This of course puts forward higher requirements for construction quality. The ground penetrating radar method can effectively solve these problems and can guarantee the safety of the railway in operation for future operations.

There are many methods for tunnel quality inspection. The traditional method is to obtain target information by sampling through boreholes. The detection results obtained by the excavation sampling method are accurate and direct, but only partial information represented by the tunnel lining excavation site can be obtained, and the structure itself has been damaged. Therefore, the quality control of tunnel construction requires an efficient and economical method. It

provides continuous detection information without damaging the tunnel lining itself. Since the 1980s, ground penetrating radar detection technology has been expanding its application range due to its fast, nondestructive, and continuous characteristics. However, the complex environmental conditions of the tunnel under construction and many interference sources will affect the effectiveness of radar wave detection at the detection point. Some electromagnetic interference waves generated by these sources directly affect the reflected signal and the waveform of the target body, and it is difficult to remove them in the post-processing process. In the field test, it should try to avoid these interference sources. Or, it should choose appropriate equipment parameters according to the electromagnetic environment of the construction site to minimize the impact. At the same time, there are other interference factors that affect the accuracy of the detection results, such as environmental humidity, antenna speed, and coupling conditions. The use of ground penetrating radar to comprehensively inspect the tunnel lining structure, finding quality defects and hidden safety hazards and dealing with them in a scientific and timely manner, can avoid serious problems that may even affect the overall safety of the tunnel. It lays a solid foundation for the later completion acceptance and safe operation. It can provide good inspection results and reliable baseline data for project quality evaluation and processing.

In order to overcome active interference, Zhang and Pan proposed an adaptive polarization cancellation method based on dual-polarization radar. They obtain the components and characteristics of the actual target and active interference analysis signal through the vertical and horizontal polarization channels of the dual-polarization radar. Then, in an actual scenario, the weighting factor is subtracted in time to adjust the amplitude and phase difference of the active interference signals received from the two orthogonally polarized channels. This can completely eliminate active interference, but the actual target power will change. In addition, a target signal correction method has been developed to improve the accuracy of monopulse radar angle measurement. Then, through simulation, the factors affecting adaptive polarization cancellation are analyzed in detail. Finally, the experimental results show that it is very effective for the intervention of active blocking and active deception. However, the adaptive method they designed is not flexible enough to meet the actual detection requirements [1]. Zhao et al. researched electronic countermeasures (ECMs) systems to combat misleading electronic countermeasures (ECMs) technology. An adaptive detector uses the generalized probability ratio test (GRLT) standard to detect whether there is any misleading interference in the Fourier transform (FT) field. The proposed detector can analyze initial and auxiliary data through adaptive area echo and misleading interference. Finally, the extended radar network is analyzed as a special case, and the result proves the validity of the digital simulation in the proposed method. However, the scheme they studied is only for special interference [2]. Liu et al. studied the influence of DRFM active jamming technology on coherent pulse compression radar. By

introducing the radar signal detection model and radar equation, the influence of the signal generated by DRFM on the detection performance of the radar receiver is analyzed and the relationship between the radar detection probability and the interference power is obtained. Finally, the effective indicators for judging the interference phenomenon are summarized, and the amplitude of the active interference signal is determined. However, their research on the accuracy of radar detection is not deep enough [3]. Yang et al. proposed an error control method based on an active interference suppression control algorithm. It is used to check the parameter uncertainty and noise measurement of the ultrasonic flutter suppression model. The control method can be used to estimate the observed output signal and its time derivative, as well as to model dynamics and measurement noise. Numerical results show that the control method they invented can effectively suppress ultrasonic vibration in the range of large Mach numbers and has obvious adaptability to changes in stiffness parameters. However, the actual suppression effect of the interference suppression algorithm they studied cannot satisfy the research on geology [4]. Chen et al. proposed a new anti-jamming algorithm based on the minimum mean square error criterion to protect the acquisition stage. The basic idea of the proposed method is the grid search process of sharing synchronization parameters by suppressing interference and receiving signals. The simulation results show that the proposed method can keep the GNSS receiver running during the cold start period with interference signals. In addition, its performance is significantly better than the power reversal method. However, this research method has little meaning for radar detection effect [5]. Yang and Huang studied the interference suppression phenomenon of the integrated coil inductor topology. In the proposed topology, a traditional single-turn spiral inductor is integrated with a built-in tightly coupled LC resonator on the printed circuit board. Interference suppression is achieved by guiding the magnetic flux emitted by the spiral inductor to the tuner instead of other spiral inductors around it. From the experimental results of the comparative case, by changing the value of the coordinator capacitor, the proposed topology can provide design freedom in any frequency band of interest. However, the interference suppression method they proposed is very difficult in practical applications and needs to be simplified [6].

The innovation of this paper is the use of multiple sensors combined with active interference suppression algorithms to optimize the design of a sensor system for radar defect detection in railway tunnels. It uses a multisensor combination scheme to obtain information such as the angular velocity, acceleration, and magnetic field strength of the carrier. A specific calibration compensation method is selected to calibrate their output values, respectively, which realizes the real-time display of system output data. In this article, an interference suppression algorithm based on Fourier transform is introduced to optimize the interference elements encountered by the radar in the detection of radar. The algorithm first transforms the received data in the Fourier transform fractional domain and then separates the

interferometer in the transform domain. By optimizing the design of the gain coefficient, the retention of interference limits is suppressed while signaling time and the frequency response is maximized. Finally, the useful signal after interference suppression is obtained through a short-time inverse Fourier fractional transform. It effectively verifies the effectiveness and simplicity of this method.

## 2. Multisensor System Combined with Active Interference Suppression Algorithm

*2.1. The Working Principle of Radar.* The essence of radar is an electromagnetic sensor. The basic principle is to send an electromagnetic signal to the area of interest through an antenna [7–9] and judge whether there is a target at the end. At the same time, it receives interesting information such as the distance, radial velocity, angular direction, shape, and bandwidth of the target [10, 11]. The radar system can use this information to perform target detection, ranging, tracking, and imaging functions, as well as the process of determining whether the target exists, that is, radar target detection [12, 13].

Ground penetrating radar (GPR) is generally a method of electromagnetic technology [14, 15]. Compared with other detection methods, the geological radar method can directly see the reflected wave recorded by the radar and can directly analyze the distribution and shape of the structure and target in the tunnel [16, 17]. Combining with the preliminary judgment of the target nature and the detection requirements such as detection depth and minimum resolution, it selects antenna types with different frequencies for the highly selective antenna [18, 19]. The ground penetrating radar will not perform destructive testing on the lining surface, so the same section can be tested repeatedly without damaging the tunnel lining structure. The flexible ground penetrating radar has simple operation, high sampling rate, and fast detection speed. Once the speed and analysis ability reach the centimeter level, it can meet most of the requirements of tunnel structure and target detection, with excellent accuracy [20–22]. Its working principle is shown in Figure 1.

*2.2. Active Interference Suppression.* Active interference suppression generates realistic false signals in the radar's time domain, frequency domain, or image field by emitting interference signals that are very close to the echo signal, which affects the radar's detection of actual targets [23]. For active interference suppression, there are countermeasures from the radar system level and signal processing level [24]. However, most of these methods have active suppression. In order to effectively subdue the active suppression of the radar, it is necessary to study how to detect the active radar to suppress the interference [25].

The biggest difference between suppressive interference and deceptive interference is the degree of interference. It is difficult for the radar to obtain effective echo information because it can fully capture the true time and frequency and convert the echo. If the interceptor is powerful enough, it can completely paralyze the radar, making it impossible to fight against [26]. Active interference suppression mechanisms can

be divided into noise amplitude interference, radio frequency noise interference, noise frequency interference, and smart noise interference. According to the implementation strategy of actively suppressing interference, it can be divided into remote support intervention and self-defense intervention [27]. Figure 2 shows the classification of radar interference.

In the case of passive interference, the radar cannot work normally, mainly because the electromagnetic waves emitted by the radar are reflected or changed through the smoke screen. This kind of interference has a good interference effect, a wide range of influence, low cost, and a wide range of application scenarios. Compared with other types of suppressive interference, the interference effect of noise amplitude interference is smaller and its countermeasures are relatively complete [28]. Noise frequency interference is a new type of interference that mainly affects the chip signal. It can automatically target the center frequency of the radar and has a certain pulse compression gain advantage. In recent years, it has become the focus of interferometer technology research. This study mainly analyzes the differences between different types of interference through the modeling and extraction of feature suppression interference and lays the foundation for subsequent suppression of interference detection and identification. Figure 3 shows the process of obtaining target information from the radar.

*2.2.1. Active Interference Suppression Characteristics.* Among the interference factors that affect the radar detection effect, the interference wave generated by the electromagnetic interference object under the action of the electromagnetic field will have a corresponding impact on the radar imaging map. It will cause the imaging spectrum to have no fixed law and range of action. For active interference suppression, extracting its interference characteristics can lay the foundation for radar active interference suppression identification. The following analyzes the six interference patterns to understand their characteristics in the time domain and frequency domain. They extract several characteristic parameters of interference.

(1) *Aiming Frequency Interference.* The time domain expression of noise FM interference is

$$R(a) = Q_i \exp \left[ i \left( 2\phi f_i a + 2\phi H_{f_a} \int a(\varepsilon) b\varepsilon + \kappa_0 \right) \right]. \quad (1)$$

Here,  $Q_i$  indicates that the magnitude of the interference is a constant,  $f_i$  is the carrier frequency that suppresses the interference, and  $H_{f_a}$  is the frequency modulation slope of the FM noise.

The power spectral density of the frequency modulation function  $a(\varepsilon)$  can be expressed as follows:

$$H(\kappa) = \begin{cases} \frac{\phi_n^2}{\Delta\kappa}, & 0 < \kappa < \Delta\kappa, \\ 0, & \text{other,} \end{cases} \quad (2)$$

where  $\Delta\kappa$  is the modulation bandwidth of the modulation noise  $a(\varepsilon)$ .

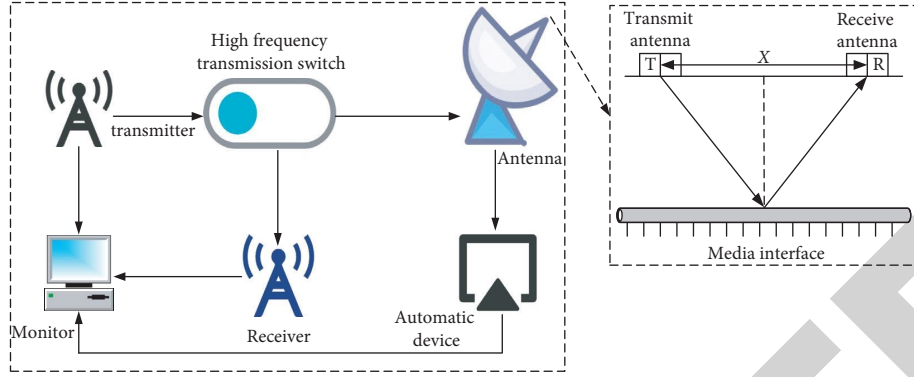

FIGURE 1: Radar working principle diagram.

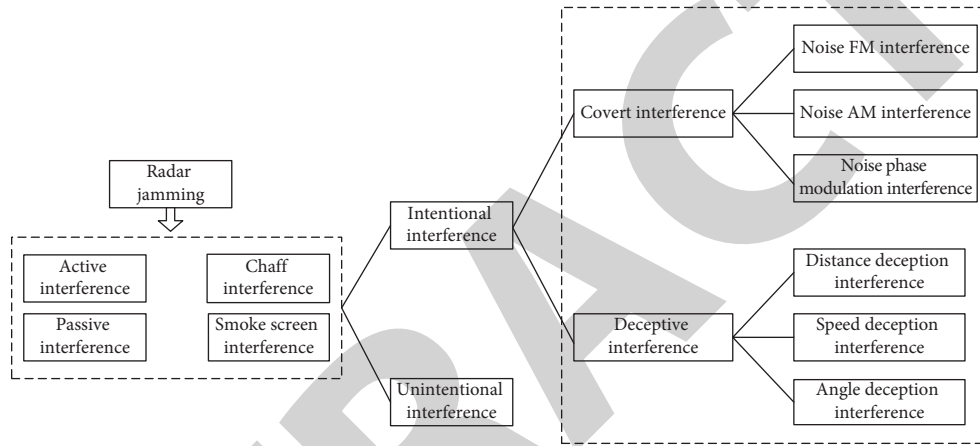

FIGURE 2: Radar jamming classification.

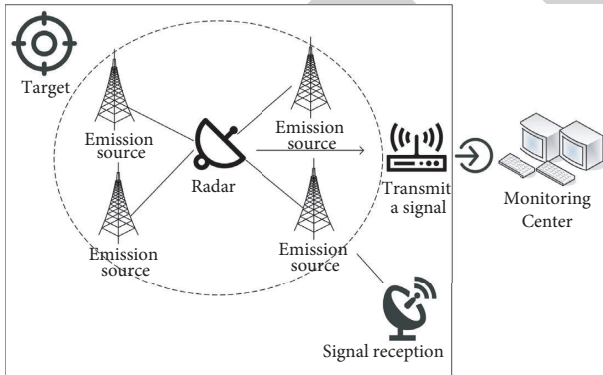

FIGURE 3: The process of radar acquiring target information.

The effective modulation index of the noise FM signal is defined as follows:

$$n_{ke} = \frac{H_{fa}\phi_n}{\Delta\kappa}. \quad (3)$$

Aiming frequency interference is a kind of noise frequency modulation interference, and its center frequency, interference bandwidth, and effective modulation index generally meet the following conditions:

$$\begin{aligned} f_i &= (\phi f + f_0), \\ \Delta\kappa_i &= (2 \sim 5)\kappa_r, \\ n_{fa} &< 0. \end{aligned} \quad (4)$$

Here,  $f_0$  represents the center frequency of the radar signal,  $\phi f$  represents the aiming frequency error,  $\Delta\kappa_i$  represents the bandwidth of the aiming interference signal, and  $\kappa_r$  represents the bandwidth of the radar signal. Target frequency interference usually requires that the frequency of the interferometer matches the center frequency of the radar. At the same time, it transmits interference signals with a narrow interference bandwidth, which covers the receiving bandwidth of the radar and requires a high-precision frequency detector to support interference. However, in recent years, with the development of radar frequency flexibility technology, it has become difficult to identify the center frequency of the radar from the interference part and it may be difficult to intercept the target frequency interference on the radar by using frequency interference.

(2) *Blocking Interference*. Blocking interference is a type of FM noise interference. The interference bandwidth and effective configuration index must usually meet the following conditions:

$$\begin{aligned} f_i &= (\phi f + f_0), \\ \Delta\kappa_i &= 5\kappa_r, \\ n_{fa} &> 0. \end{aligned} \quad (5)$$

(3) *Sweep Frequency Interference*. Sweep frequency interference can be regarded as a kind of aiming frequency interference whose center frequency is constantly changing. Under normal circumstances, this kind of interference needs to meet the following conditions:

$$\kappa_i = \phi f + f_0 + \frac{\Delta\kappa_b}{a} \times A - \frac{\Delta\kappa_b}{2} a \in [0, a_b]. \quad (6)$$

Here,  $\Delta\kappa_b$  is the bandwidth of the frequency sweep interference and  $a_b$  is the frequency sweep period of the frequency sweep interference.

The bandwidth of frequency sweep interference is very large, and it can compete well with flexible-frequency radars and multiple radars of different frequencies. If the given frequency bands are the same, the aggressive interference power will be higher than the cancellation interference power. However, this interference becomes discontinuous in the tie domain after passing through the receiver. The interference scanning frequency represents the number of times a scanning interference scans the entire interference bandwidth per unit time, expressed as follows:

$$\Delta\kappa_i = JSF = \frac{1}{A_b}. \quad (7)$$

Sweep frequency interference will form intermittent pulse interference after passing through the receiver, and the larger the pulse, the denser the pulse.

(4) *Comb Spectrum Interference*. Comb spectrum interference is an interference pattern composed of multiple narrowband interferences, and its expression can be summarized as follows:

$$R(a) = \sum_{i=1}^m R_i(a) + \frac{\Delta\kappa_a}{A} \quad i = 1, 2, \dots, m, \quad (8)$$

where  $m$  represents the number of narrowband interferences included in the spectrum interference. Each narrowband interference is independent of each other. There are different frequency points in the interference center, and spectrum interference can produce narrowband interference at multiple different frequency points. It can successfully deal with variable frequency radar systems such as flexible-frequency radars and frequency-fluctuation radars.

(5) *Noise Product Interference*. Noise product interference is a new type of interference directed at chirp signals. Its mechanism is to multiply the noise through the filter and the radar pulse signal intercepted by the jammer. This interference can be expressed as follows:

$$R(a) = m(a) \times b(a) \quad i = 1, 2, \dots, m, \quad (9)$$

where  $m(a)$  is the noise passing through the filter and  $b(a)$  is the chirp signal intercepted by the jammer, and its expression is

$$R(a) = \text{rect}\left(\frac{1}{A}\right) \exp\left(i2\phi\left(f_0 + \frac{1}{2} \times \frac{G}{A} a^2\right)\right). \quad (10)$$

The variable  $f_0$  represents the center frequency of the chirp signal,  $G$  represents the bandwidth of the FM signal, and  $A$  represents the time width of the FM signal. The spectrum of noise product interference can be expressed as follows:

$$I(f) = M(f) \otimes B(f). \quad (11)$$

(6) *Noise Convolution Interference*. Noise convolution interference is also a new type of interference for chirp signals. Its mechanism is to convolve the noise through the filter with the radar pulse signal intercepted by the jammer. This interference can be expressed as follows:

$$R(a) = m(a) \otimes B(f) a > 0. \quad (12)$$

It can be seen from the representation of the convergence noise interference frequency domain that the convergence noise interference coincides with the center frequency of the transmitting radar signal and the bandwidth is close; that is, the convergence noise interference can be aimed at the center frequency radar. Without precise frequency measurement, it can effectively affect flexible-frequency radars, frequency-differential radars, and other radar systems that allow flexible radar signal ranges. The essence of convergent noise interference can be thought of as amplifying the received chirp signal at different rates and then delaying the addition. Therefore, convergence noise interference can achieve a specific radar pulse compression gain, that is, after the interference is processed by the noise convolutional radar system, it can achieve the same interference effect as other low-power interference suppression.

**2.3. Interference Suppression Algorithm.** The analysis of active radar interference suppression mainly starts from the feature derivation. Various functional parameters are derived and analyzed from the time domain, frequency domain, and transform domain to lay the foundation for subsequent active radar interference detection. The interference characteristic parameters are as follows.

**2.3.1. Frequency-Domain Peak-to-Average Power Ratio after the Receiver.** Assuming that the radar echo signal is  $v(a)$ , the receiver noise is  $d(a)$  and the received interference is  $i(a)$ , then the radar received signal  $w(a)$  can be expressed as follows:

$$w(a) = v(a) + d(a) + i(a). \quad (13)$$

After sampling  $w(a)$ , perform the fast Fourier transform to obtain the following:

$$w_i(n) = \frac{w(n)}{\max(w(n))_{n=1}^n} \quad n = 1, 2, \dots, N. \quad (14)$$

The frequency-domain peak-to-average power ratio after the receiver is defined as follows:

$$P_i(a) = 10 \log_{10} \frac{\max_{n=1}^N w_i^2(n)}{1/N w_i^2(n)}. \quad (15)$$

The peak-to-average power ratio parameter in the frequency domain mainly reflects the signal variation range in the frequency domain. Its value is relatively high, and the range of comb spectrum interference can be identified by this feature. The flow of the interference suppression algorithm is shown in Figure 4.

The echo signal is divided into several time periods at equal intervals in the time domain. First, FT is applied to the first time period data, and the optimal order is obtained by searching. By analogy, the optimal order of each time window is obtained. After Fourier transform, the time-frequency aggregation of narrowband and broadband interference is obtained. Then, this is used to detect each time slice. If there is an interference signal, an adaptive gain control method is used to suppress the interference signal to complete the interference suppression.

We calculate the initial value of the argument of  $w(n)$ , adopt the principle of the main value interval, and use the optional interval  $(-\sigma \sigma)$  as the main value interval to ensure the odd symmetry of the argument with respect to  $n=0$ . To eliminate the phase ambiguity of logarithmic changes, there are

$$\ln(w(a)) = \ln(I(a)) + \ln(1 + d'(a)). \quad (16)$$

It can be seen from the formula that the real part and the imaginary part are, respectively,

$$\begin{aligned} R_w(a) &= ie[(w(a))] = \ln W_i + ie[d'(a)], \\ I_w(a) &= \ln[\ln w(a)] = \sigma_i + \ln[d'(a)]. \end{aligned} \quad (17)$$

Since both the deception interference and the echo signal are zero-average signals, the amplitude of the noise FM interference signal can be estimated as follows:

$$\widehat{W}_i = \exp\{\text{mean}[R_w(a)]\}. \quad (18)$$

We calculate the interference signal  $i(a)$  from the radar received signal  $w(a)$ ; then,

$$\begin{aligned} \widehat{d}(a) &= w(a) - \widehat{I}(a) \\ &= d'(a) + I(a) \left[ 1 - \frac{\widehat{W}_i}{W_i} \exp(i \ln(d'(a))) \right]. \end{aligned} \quad (19)$$

### 3. Experiment of Railway Tunnel Radar with the Multisensor System Combined with Active Interference Suppression Algorithm

As a kind of concealed project, tunnel construction will inevitably have defects in the construction process. Due to its concealment, defect detection has become a concern of tunnel workers. Geological radar detection is a fast and efficient detection method. Its principle is the same as that of the tunnel lining structure. The tunnel lining structure is combined with radar detection for tracking tunnel defects.

The ground penetrating radar is used for nondestructive testing of tunnel lining, and its main purpose is to ensure that the construction quality of tunnel lining meets the requirements of design specifications. The tested elements are the initial support, secondary lining and inverted arch, concrete thickness detector, double-layer secondary lining thickness, gaps and nonsolid areas, and concrete compression of the backfill layer.

Due to the unevenness of the coated concrete, when the electromagnetic wave propagates to the initial support and the secondary coating, the speed of the electromagnetic wave will change within a certain range. We need to adjust the parameters of the medium to be measured on the concrete. If we want to calibrate the relative permeability or electromagnetic velocity of shotcrete before the first support material inspection, we can use the core perforation sampling method to calibrate three or more positions and take the average value. In this paper, the tunnel is inspected in the part where the concrete thickness is known, because the core drilling sampling method will damage the back wall to calibrate the parameters of the secondary cladding concrete. The parameters of the radar include the number of sampling points, sampling rate, and band-pass filtering. The number of sampling points represents the number of sampling points in each acquisition dataset. This article sets the number of sampling points to 400. In order to make the recorded waveform more complete and controllable, the sampling rate is selected to be 6 times the antenna center frequency. In the processing of data and interference waves, band-pass filtering is used.

Due to the requirement of a safe step between the surface and cladding of the tunnel under construction, the construction of the tunnel cladding should be monitored quickly. Therefore, the initial support inspection should monitor the construction progress. It should take into account the inspection progress, that is, whether the age of the concrete can meet the inspection requirements. Before the inspection, the side walls of the cladding should be clearly marked with red paint every 5 meters, indicating the number of kilometers and the number of piles. If necessary, the detection location should be clearly marked to ensure the accuracy of the detection data.

The main control measures for the secondary cladding inspection of the tunnel are used for cavities, defects, cladding thickness, inverted thickness, filler layer and other cladding, the distribution of steel bars in the cladding, and the solid lining of the initial support. The main detection method is the geological radar method. The tunnel wall inspection is to place inspection lines on the tunnel warehouse, the center arch on both sides, the side walls, and the inverted arch on both sides. Or, it provides a basic overview of the cross section of the intersection. And, it focuses on the encrypted overview of specific tunnel sections or irregularly covered structural sections, as well as gives the basic knowledge of paving leaks, horizon cracks, and crevices. Figure 5 is a schematic diagram of radar defect detection in railway tunnels.

The tunnel defect detection system requires methane sensors, temperature and humidity sensors, wind speed and

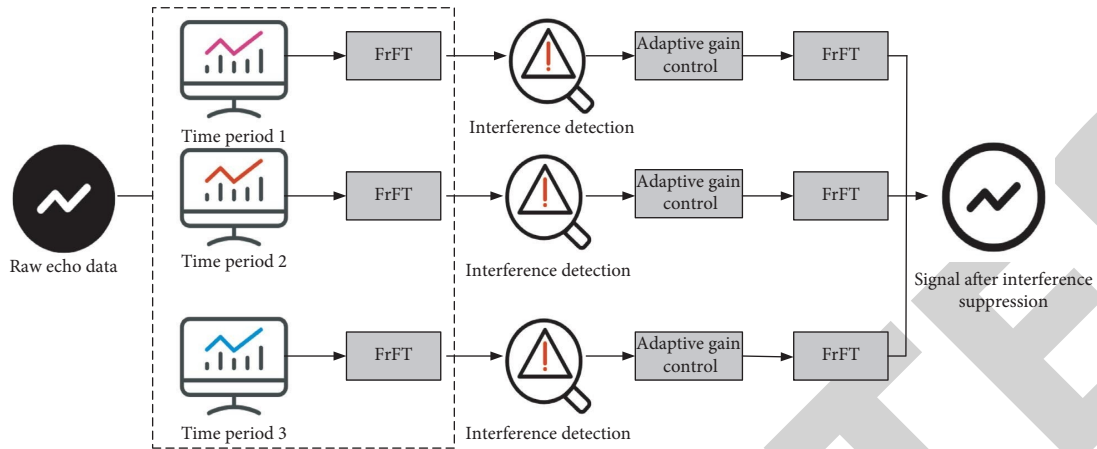

FIGURE 4: Flow chart of interference suppression algorithm.

FIGURE 5: Schematic diagram of railway tunnel radar defect detection.

direction sensors, noise sensors, brightness detectors, and air pressure detectors. At the same time, it cooperates with radar to detect railway tunnels. And, it provides statistics on the size and location of defects behind the tunnel lining and summarizes the distribution of specific types of defects. The defect classification table is now introduced. Table 1 is the tunnel defect classification table.

In the detection of railway tunnel defects, firstly, the relevant sensors in the defect detection system are used to obtain the data related to the tunnel defects at the moment and then the output data of the sensors are processed

accordingly. In this process, any calculation processing is based on sensor data. Therefore, the sensor plays a vital role in the tunnel defect detection system. Different sensors have different test principles and applicable conditions. These will affect the results of tunnel defect detection and the application environment of the system. Figure 6 is the design of a multisensor system for railway tunnel defect detection.

The noise sensor, temperature and humidity sensor, wind speed and direction sensor, and methane sensor are combined with a high-precision microprocessor as the control and calculation unit to obtain the relevant

information of the railway tunnel and obtain the environmental factors of the tunnel. Then, it cooperates with the air pressure detector, light brightness detector, and magnetic field detector to obtain the air pressure, light brightness, and magnetic field strength in the tunnel.

#### 4. Experimental Results and Analysis

**4.1. Simulation Analysis of the Multisensor System Combined with Active Interference Suppression Algorithm.** In order to analyze the algorithm more deeply, simulation experiments are carried out using the algorithm. Figure 7 is a histogram of phase statistics. It can be seen from the figure that the echo is widely distributed in the entire phase interval, and the echo and interference have obvious different phase distribution characteristics. In contrast, the interference is only concentrated on a limited phase. Therefore, the interference and echo can be identified through the conventional discrimination model of the tree.

Figure 8 shows the output waveforms of the radar-matched filter before and after interference suppression. It can be seen from Figure 8(a) that before the interference suppression of the matched filter, both the target and the interference spike exist in its output. Therefore, the radar cannot achieve the purpose of extracting real target information by selecting target spikes from multiple spikes. In contrast, the matched filter output in Figure 8(b) has only a target spike after interference suppression, and the radar can extract the distance information of the real target through this spike.

Figure 9 is a performance graph of the radar suppression algorithm. Under various conditions, the target echo similarity curve is consistent with the probability curve of correct target recognition after radar interference. It can be seen from this figure that as the signal-to-noise ratio

increases, the interference and echo similarity coefficient increases. And, the phase is sensitive to the influence of noise under low signal-to-noise ratio, and it is not easy to be distinguished.

Figure 10 is the comparison result of several methods under different frequency deviations. It can be seen from the figure that when the frequency estimation performance of the improved method reaches the optimum, the frequency deviation in the constraint condition can be satisfied. At this time, the frequency estimation accuracy of the improved method is significantly higher than that of the other three methods.

**4.2. Defect Detection Problems in Railway Tunnels.** As an important nondestructive testing method, radar has been accepted by engineers. At present, it is widely used in the inspection of heavy and large projects at home and abroad, and it controls the quality of the project very well. However, due to various factors, there are more or less problems in the application of geological radar. In response to these problems, the application scholars of the ground penetrating radar have done a lot of research in order to reduce the detection error of the ground penetrating radar. This article specifically studies and analyzes tunnel lining inspection and lists the factors that affect tunnel inspection, so as to improve the accuracy of domestic tunnel lining inspection. It provides safety guarantee for tunnel engineering.

Concrete is a relatively stable synthetic material. It is a nonelectric good conductor, that is, a nonconductive substance. From Table 2, we can see that the dielectric properties of concrete will also have an impact due to the difference in water content.

As shown in Figure 11, according to the dielectric constant results of concrete at different ages, the dielectric

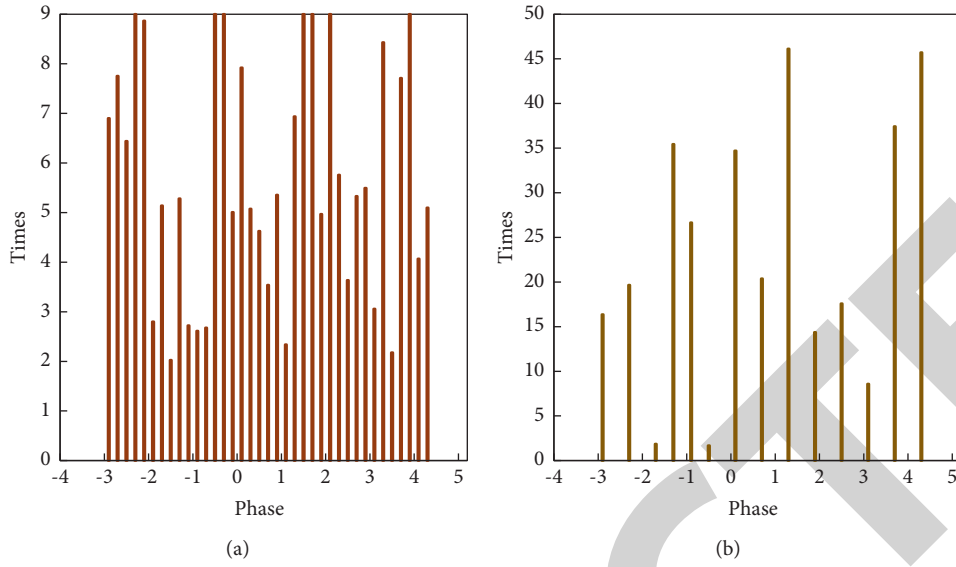

FIGURE 7: Source signal phase statistics histogram.

FIGURE 8: Radar-matched filter output waveform (a) before and (b) after interference suppression.

constant of concrete at 3d, 7d, 14d, and 28d age was analyzed.

In addition to the relative permittivity and permeability of the medium, the vertical resolution of the ground penetrating radar is also related to the center frequency of the antenna. When the medium is constant, the vertical resolution of the ground penetrating radar is inversely proportional to the center frequency of the radar antenna. Regarding the influencing factors, radar should pay attention to the selection of detection timing when detecting defects. At the same time, when facing electromagnetic interference, it should be far away from these interference sources or appropriate shielding measures should be selected to minimize the impact.

**4.3. The Detection Results of Railway Tunnel Radar Optimization.** In the process of detecting defects in railway tunnels, electromagnetic waves first pass through the air medium and enter the concrete medium. For air and concrete media, the reflection coefficient is negative. In other words, electromagnetic waves are negative. Therefore, the first wave of the measurement results is inconsistent and the difference is large. Table 3 shows the measurement location information of the first wave.

Figure 12 is the detection accuracy and error analysis results of the railway tunnel radar defect detection of the multisensor system combined with active jamming algorithm.

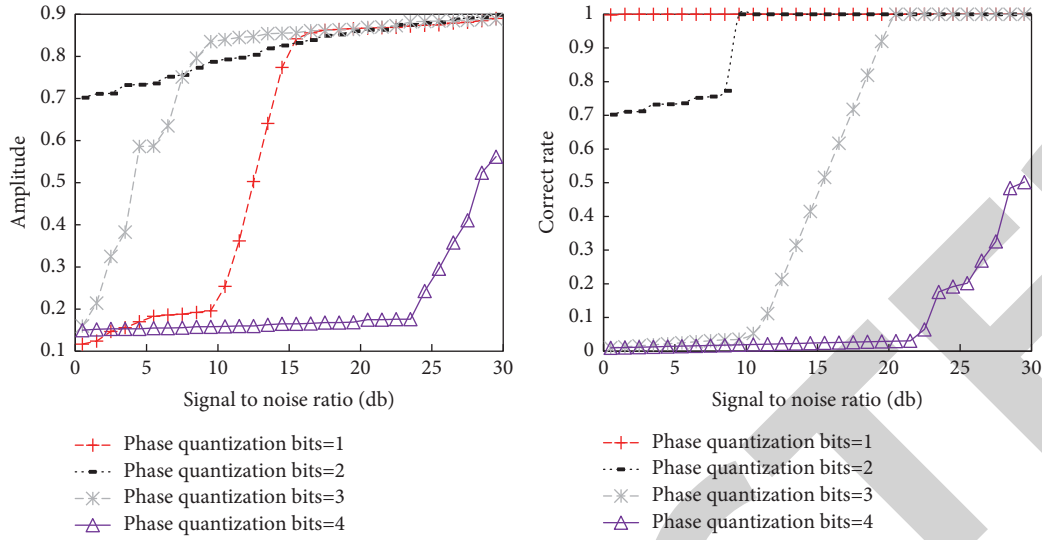

FIGURE 9: Radar suppression algorithm performance graph.

FIGURE 10: Comparison results of several methods under different frequency deviations.

TABLE 2: The difference between the dielectric constant of each parameter and the thickness of the test.

Dielectric constant		Volume ratio%		Concrete dielectric constant	Calculated lining thickness
Air	Water	Air	Water		
1	81	5	1	6.25	0.38
1	81	4	2	6.74	0.37
1	81	3	3	7.32	0.36
1	81	2	4	7.68	0.35
1	81	1	5	8.31	0.34

It can be seen from the figure that the traditional detection method can easily make the cladding thickness too large or too small, resulting in a large error of up to 0.042 m in the identification and evaluation of railway tunnel defects. It greatly reduces the reliability and is easy to make wrong estimates or cause unnecessary losses. The detection method

optimized by combining multiple sensors and active interference suppression algorithm can confirm that the error is within 0.02 m. The multisensor defect detection rate combined with the active interference suppression algorithm is 98.8%, which can effectively improve the detection accuracy.

FIGURE 11: The lining thickness of concrete of different ages.

## 5. Conclusion

In this paper, the defect detection of railway tunnels is optimized with the multisensor system combined with active interference suppression algorithm and a related sensor detection system is designed. The multisensor detection system includes temperature and humidity sensors, wind speed and direction sensors, methane sensors, and noise sensors. It can meet the needs of tunnel curve detection, and the multisensor detection system has higher stability and accuracy. It starts from the basic principles of ground penetrating radar and electromagnetic field theory, according to the propagation characteristics and laws of electromagnetic waves and various tunnel radar detection parameters and indicators, to study data acquisition, processing, and transmission methods. The results of radar detection factors of railway tunnels include the influence of equipment parameters and the influence of the external detection environment. In this paper, combined with relevant examples of mechanical substance detection, the specific application of ground penetrating radar in various factors that affect the quality of tunnel detection, matters needing attention, railway tunnel radar detection, etc., is analyzed. It focuses on analyzing the amplitude and polarity of the reflected wave, the spectral characteristics of the reflected wave, the morphological characteristics of the internal axis of the reflected wave, and the influence of interference waves. At the same time, this paper studies the influence of water and air on the dielectric constant of concrete and the influence of various factors on the radar detection, such as the choice of detection timing when detecting the thickness of concrete. Finally, it is hoped that the content studied in this article can provide useful information and reference value for radar operators.

Regenerative braking is one of the most promising and ecologically friendly solutions for improving energy efficiency and vehicle stability in electric and hybrid electric cars. This research describes a data-driven method for detecting and diagnosing issues in hybrid electric vehicle regenerative braking systems. Early fault identification can help enhance system performance and health. This study is centered on the construction of an inference system for fault diagnosis in a generalized fuzzy environment. For such an inference system, finite-state deterministic fully intuitionistic fuzzy automata (FDFIFA) are established. Semigroup of FDFIFA and its algebraic properties including substructures and structure-preserving maps are investigated. The inference system uses FDFIFA semigroups as variables, and FDFIFA semigroup homomorphisms are employed to illustrate the relationship between variables. The newly established model is then applied to diagnose the possible fault and their nature in the regenerative braking systems of hybrid electric vehicles by modeling the performance of superchargers and air coolers. The method may be used to evaluate faults in a wide range of systems, including autos and aerospace systems.

## 1. Introduction

Complex processes and phenomena are prevalent in modern science and technology, about which comprehensive knowledge is not always accessible. Mathematical models are created to address many types of systems having aspects of uncertainty in such instances. A substantial portion of these approaches is built on the so-called fuzzy sets, which are a new extension of conventional set theory. The fuzzy set proposed by Zadeh [1] is based on the formulation of membership function from  $X$  to  $[0, 1]$ , where the images are termed as membership grades or degrees of membership of elements of  $X$ . Atanassov [2] proposed the notion of an intuitionistic fuzzy set (IFS), which is an extension of the perception of the fuzzy set where the degree of

nonmembership is also considered along with the degree of membership. A finite-state machine (FSM) or finite-state automata (FSA) are a mathematical model of computation that can be changed from one state to another state in connection to suitable inputs. There are two types of FSMs, deterministic FSM (DFSM), the one who accepts or rejects a given string of inputs, following a state sequence uniquely obtained from the string, and nondeterministic FSM (NDFSM), which does not obey these restrictions. Moreover, for each NDFSM an equivalent DFSM can be constructed. Fuzzy automata are used to handle system uncertainties more accurately, whereas classical automata fail to cater to the circumstances. Fuzzy automata have been frequently employed since the introduction of fuzzy technology and neural networks [3–13]. Furthermore, there were

a variety of problems to be resolved, for example, medical diagnosis, car anti-crash radar, freeway management, urban road traffic control, and obstacle recognition in front of a vehicle, which required flexible, quick, and accurate decisions, and then, fuzzy neural network automata (FNNA) [14–17] are an excellent choice. FNNA had an increasingly prominent role, particularly in data communications. In FNNA, fuzzy technology is used to compare ordinary identification and control devices using several features and techniques of the neural network including fast and accurate numerical calculation of large numbers and self-organization learning ability. As a result, FNNA was able to solve a variety of problems in a flexible, quick, and precise manner and it had several advantages such as compact size, lightweight, and stability. The research findings also revealed that it has a significant ability for self-organization learning and the experimental results demonstrated fuzzy automata's superiority. Li and Qiu [18] introduced the technique of minimizing fuzzy automata and constructed a new automaton system that dealt accurately with many states at a time. They used an ordered lattice to reduce a fuzzy automaton of  $n$  states to another fuzzy automaton with  $m$  states ( $m < n$ ) that were functionally correspondent to the original fuzzy automata. Several language-preserving methods for minimizing deterministic fuzzy automata were established. Moghari and Zahedi's [19] method preserves both language and structure in minimization process. De Mendivil and Garitagoitia [20] described the factorization of fuzzy states that are used in the determination of fuzzy automata. Stamenkovic et al. [21] studied fuzzy automata and reduction in fuzzy automaton states and relational equations of the fuzzy system by considering the solution of the fuzzy equivalent equation. These solutions are then used to reduce the number of acceptable states. The solution of the fuzzy system of quasi-order number was also used to reduce the states of the fuzzy automaton.

The relationship between semigroup and FSA was established by Krohn and Rhodes' [22] discussed semigroup decomposition employing decomposing of FSA. A semigroup is an important algebraic structure, which serves as the theoretical foundation for a variety of scientific fields with several applications [23]. Semigroup's role in theoretical computer science is inevitable; in particular, semigroup and automata are widely studied and applied in artificial intelligence, game theory, dynamical system, system biology, and fault diagnosis. During the investigation, it was discovered that to diagnose a machine's problem situation, it is necessary to look at its operating state, fault degree, accuracy degree, and expected changes between states at different stages, which can be done by establishing an appropriate FSA. The uncertainty and ambiguity in the diagnostic process enforce to carry out the mathematical computation in a fuzzy environment. A semigroup of finite deterministic intuitionistic fuzzy automata (FDIFA) is used to detect default in any machine [24] by identifying its crucial components, and it can perform characteristic processing using its state transition mapping. Furthermore, because it accurately and efficiently detects the fault, the maximum value of the membership and nonmembership

grades can be used to diagnose the maximum default and current running state of any machine. Membership and nonmembership grades can be assigned based on the nature and seriousness of the fault. The algebraic properties of FDIFA semigroup are employed in the formulation of inference systems over FDIFA semigroup. Fuzzy inference is a method of formulating a rule or a mapping from a given set of inputs to a given set of outputs utilizing fuzzy logic. The fuzzy inference system is widely used in control systems [25], artificial intelligence [26, 27], decision-making [28], forecasting [29], and game theory [30]. Fuzzy set over a non-empty set  $X$  as defined by Zadeh is a function (membership function) from  $X$  to the closed interval  $[0, 1]$  so the representation of uncertain data using closed interval is equivalent to representation using fuzzy sets [31, 32]. The fuzzy inference of fuzzy automata is introduced and utilized in machine defect diagnosis as the impact of combination of fuzzy automaton rules and method of fuzzy set is greater than the classical automata. For the derivation of automata, some researchers used neural networks [33, 34]. Although neural networks and fuzzy systems are not the same, fuzzy inference has been widely applied in the disciplines of control and intelligence [35]. The fuzzy inference system and fuzzy automata and algebraic structures on fuzzy automata are investigated and successfully applied in computer science and engineering [36]. A intuitionistic fuzzy set is a very useful generalization of fuzzy set, which provides an effective framework to handle imprecision and uncertainties more accurately than the fuzzy set and logic. This motivates us to incorporate the concept of nonmembership grades in fuzzy automata. The work is based on the development of inference systems and automata in an intuitionistic fuzzy environment. Intuitionistic fuzzy automata have several states at a certain time or stage, each equipped with a certain grade of reliability and non-reliability. Thus, the intuitionistic fuzzy automata are more realistic and close to the objective. To achieve the goal, finite-state deterministic fully intuitionistic fuzzy automata (FDFIFA) are defined in Section 2. In Section 3, monoid on fully intuitionistic fuzzy automata is designed and its algebraic properties are investigated, and intuitionistic fuzzy inference rules on FDFIFA monoids are established in Section 4. In Section 5, the mathematical computations are supported and justified by conduction fault diagnosis in hybrid vehicle regenerative braking system in application (see Figure 1).

## 2. Fully Deterministic Finite-State Intuitionistic Fuzzy Automata

The sixfold  $AT = (T, I(T), \vartheta, s_i, E, G)$  is referred to as a fully deterministic finite-state intuitionistic fuzzy automata (FDFIFA) in which  $s_i \in I(T)$  is the initial state;  $T$  is a finite family of states;  $I(T)$  is an intuitionistic fuzzy subset of states with grade of membership  $\mu: T \rightarrow (0, 1]$  and grade of nonmembership  $\nu: T \rightarrow [0, 1)$ ;  $E$  is a finite family of input letters/symbols;  $G$  is an intuitionistic fuzzy set of terminal/accepting states with  $G \subseteq I(T)$ ; and  $\vartheta: I(T) \times E \rightarrow I(T)$  is the transitional mapping with  $\vartheta((t_i, \mu^{t_i}, \nu^{t_i}), e) = (t_j, \mu^{t_j}, \nu^{t_j})$ , where  $(t_i, \mu^{t_i}, \nu^{t_i}), (t_j, \mu^{t_j}, \nu^{t_j}) \in I(T), e \in E$ . These states

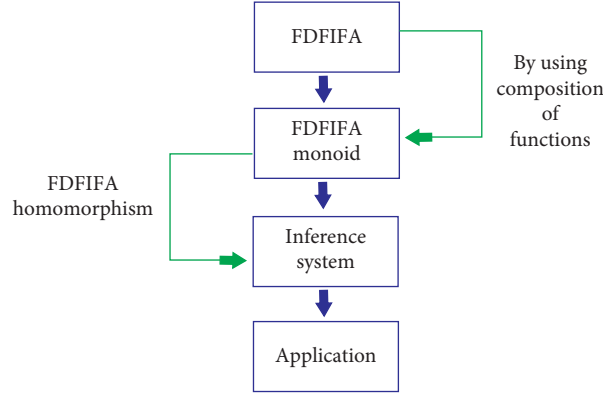

FIGURE 1: Fully intuitionistic fuzzy state transition.

$(t_j, \mu^{t_j}, \nu^{t_j}) \in I(T)$  exist in some accepted states. The extended transitional function  $\vartheta^*$  is defined as follows:

$$\vartheta^*((t_i, \mu^{t_i}, \nu^{t_i}), e_1 e_2 \dots e_n) = \begin{cases} (t_i, \mu^{t_i}, \nu^{t_i}), & \text{if } n = 0; \\ (\vartheta(\vartheta^*(t_i, \mu^{t_i}, \nu^{t_i}), e_1 e_2 \dots e_{n-1}), e_n), & \text{if } n \neq 0, \end{cases} \quad (1)$$

where  $e_1 e_2 \dots e_n \in E^*$  is the finite set of finite strings (words/sequences of input letters (symbols)) accepted by the automata.

*Example 1.* The following is considered:

- (1)  $T = \{t_1, t_2, t_3\}$ , the finite family of states.
- (2)  $I(T) = \{(t_i, \mu^{t_i}, \nu^{t_i}) : t_i \in T, \mu : T \rightarrow (0, 1], \nu : T \rightarrow (0, 1] \text{ and } 0 \leq \mu(t) + \nu(t) \leq 1\} = \{(t_1, 1, 0), (t_2, 0.4, 0.5), (t_3, 0.3, 0.7)\}$ , the finite family of states with  $s_i = (t_1, 1, 0)$  as initial state.
- (3)  $E = \{e_1, e_2\}$ , the collection of input letters/symbols.

The transitional mapping  $\vartheta : I(T) \times E \rightarrow I(T)$  for the accepting states  $t_3, t_2$  is defined as follows:

$$\begin{aligned} \vartheta((t_1, 1, 0), e_1) &= (t_1, 1, 0); \\ \vartheta((t_2, 0.4, 0.5), e_1) &= (t_1, 1, 0); \\ \vartheta((t_3, 0.3, 0.7), e_1) &= (t_2, 0.4, 0.5); \\ \vartheta((t_1, 1, 0), e_2) &= (t_3, 0.3, 0.7); \\ \vartheta((t_2, 0.4, 0.5), e_2) &= (t_3, 0.3, 0.7); \\ \vartheta((t_3, 0.3, 0.7), e_2) &= (t_3, 0.3, 0.7), \end{aligned} \quad (2)$$

with the transition diagram in Figure 2.

Then,  $G = \{(t_2, 0.4, 0.5), (t_3, 0.3, 0.7)\}$  is an intuitionistic fuzzy set of accepting states. Thus,  $AT = (T, I(T), \vartheta, s_i, E, G)$ . If we define mappings as follows:

$$\begin{aligned} f_{e_1}(t_1, 1, 0) &= \vartheta^*((t_1, 1, 0), e_1), \\ f_{e_1}(t_2, 0.4, 0.5) &= \vartheta^*((t_2, 0.4, 0.5), e_1), \\ f_{e_1}(t_3, 0.3, 0.7) &= \vartheta^*((t_3, 0.3, 0.7), e_1), \\ f_{e_2}(t_1, 1, 0) &= \vartheta^*((t_1, 1, 0), e_2), \\ f_{e_2}(t_2, 0.4, 0.5) &= \vartheta^*((t_2, 0.4, 0.5), e_2), \\ f_{e_2}(t_3, 0.3, 0.7) &= \vartheta^*((t_3, 0.3, 0.7), e_2), \\ f_{\wedge}(t_i, \mu^{t_i}, \nu^{t_i}) &= \vartheta^*((t_i, \mu^{t_i}, \nu^{t_i}), \wedge), \end{aligned} \quad (3)$$

where  $(t_i, \mu^{t_i}, \nu^{t_i}) \in I(T)$  and  $\wedge \in E^*$  (an empty sequence) make a table (see Table 1) for  $f_{\wedge}, f_{e_1}$  and  $f_{e_2}$  that shows their effects on the states  $t_1, t_2$  and  $t_3$ .

We are now interested to determine whether  $f_{\wedge}, f_{e_1}$  and  $f_{e_2}$  form a monoid under the composition of functions.

Elements  $f_{e_1 e_1}, f_{e_2 e_1}$  of Table 2 do not exist in the set. Therefore,  $\{f_{\wedge}, f_{e_1}, f_{e_2}\}$  is not a monoid. Now, it is expanded to  $\{f_{\wedge}, f_{e_1}, f_{e_2}, f_{e_1 e_1}, f_{e_2 e_1}\}$  and this is established as monoid  $M_{AT}$ , which corresponds to FDFIFA  $AT = (T, I(T), \vartheta, s_i, E, G)$ .

### 3. Monoid of Fully Deterministic Finite-State Intuitionistic Fuzzy Automata

Let  $AT = (T, I(T), \vartheta, s_i, E, G)$  be an FDFIFA. For any input string or sequence  $e_1 e_2 \dots e_n \in E^*$ , each state  $t_i \in T$  with

FIGURE 2: Fully intuitionistic fuzzy state transition.

TABLE 1: Mapping effects on states.

*	$f_{\wedge}$	$f_{e_1}$	$f_{e_2}$
$t_1$	$t_1$	$t_1$	$t_3$
$t_2$	$t_2$	$t_1$	$t_3$
$t_3$	$t_3$	$t_2$	$t_3$

TABLE 2: Composition of mappings.

$\circ$	$f_{\wedge}$	$f_{e_1}$	$f_{e_2}$
$f_{\wedge}$	$f_{\wedge}$	$f_{e_1}$	$f_{e_2}$
$f_{e_1}$	$f_{e_1}$	$f_{e_1 e_1}$	$f_{e_2 e_1}$
$f_{e_2}$	$f_{e_2}$	$f_{e_2}$	$f_{e_2}$

membership  $\mu^{t_i}$  and nonmembership  $\nu^{t_i}$  is transited to another state  $(t_j, \mu^{t_j}, \nu^{t_j}) \in G$ . If  $f_{e_1 e_2 \dots e_n}: I(T) \rightarrow I(T)$  is defined as  $f_{e_1 e_2 \dots e_n}(t_i, \mu^{t_i}, \nu^{t_i}) = \vartheta^*((t_i, \mu^{t_i}, \nu^{t_i}), e_1 e_2 \dots e_n)$  for each  $e_1 e_2 \dots e_n \in E^*$  and  $(t_i, \mu^{t_i}, \nu^{t_i}) \in I(T)$ , then  $M_{AT} = \{f_{e_1 e_2 \dots e_n}: e_1 e_2 \dots e_n \in E^*\}$  is a collection, which corresponds to FDFIFA AT. Clearly,  $\circ$  is a binary operation on  $M_{AT}$  such that for any  $f_{e_1 e_2 \dots e_k}, f_{e_1 e_2 \dots e_l}$  and  $f_{e_1 e_2 \dots e_m} \in M_{AT}$  with:

$$\begin{aligned}
 f_{e_1 e_2 \dots e_k}(t_i, \mu^{t_i}, \nu^{t_i}) &= \vartheta^*((t_i, \mu^{t_i}, \nu^{t_i}), e_1 e_2 \dots e_k), \\
 f_{e_1 e_2 \dots e_l}(t_i, \mu^{t_i}, \nu^{t_i}) &= \vartheta^*((t_i, \mu^{t_i}, \nu^{t_i}), e_1 e_2 \dots e_l), \\
 f_{e_1 e_2 \dots e_m}(t_i, \mu^{t_i}, \nu^{t_i}) &= \vartheta^*((t_i, \mu^{t_i}, \nu^{t_i}), e_1 e_2 \dots e_m),
 \end{aligned} \tag{4}$$

where  $(t_i, \mu^{t_i}, \nu^{t_i}) \in I(T)$  and  $k, l, m = 1, 2, \dots, n$  determine the length of string,  $I(T)$  is an intuitionistic fuzzy subset of states with grade of membership (HTML translation failed)

and grade of nonmembership  $\nu: T \rightarrow [0, 1]$ ,  $E^*$  is the finite set of finite strings (words/sequences of input letters/symbols) accepted by the automata, and  $\vartheta^*$  is the extended transitional function. We have the following:

$$f_{e_1 e_2 \dots e_k} \circ (f_{e_1 e_2 \dots e_1} \circ f_{e_1 e_2 \dots e_m}) = (f_{e_1 e_2 \dots e_k} \circ f_{e_1 e_2 \dots e_1}) \circ f_{e_1 e_2 \dots e_m}, \quad (5)$$

which turns FDFIFA  $M_{AT}$  into monoid, called an FDFIFA monoid (under the composition of mappings). The expression  $f_{e_1 e_2 \dots e_k} \circ f_{e_1 e_2 \dots e_1} = f_{e_1 e_2 \dots e_k e_1 e_2 \dots e_1}$  represents the overall state transition through  $\vartheta^*$  in the FDFIFA. FDFIFA contain a finite collection of states; thus, if the order of the collection

of  $I(T)$  is  $n$ , that is,  $|I(T)| = n$ , then the monoid order is  $|M_{AT}| \leq n^n$ .

*Definition 1.* Let  $(M_{AT}, \circ)$  be an FDFIFA monoid corresponding to the automata AT, where:

$$AT = (T, I(T), \vartheta, s_i, E, G), \vartheta((t_i, \mu^{t_i}, \nu^{t_i}), e) = (t_j, \mu^{t_j}, \nu^{t_j}). \quad (6)$$

The extended transitional function  $\vartheta^*$  is defined as follows:

$$\vartheta^*((t_i, \mu^{t_i}, \nu^{t_i}), e_1 e_2 \dots e_n) = \begin{cases} (t_i, \mu^{t_i}, \nu^{t_i}), & \text{if } n = 0; \\ (\vartheta(\vartheta^*(t_i, \mu^{t_i}, \nu^{t_i}), e_1 e_2 \dots e_{n-1}), e_n), & \text{if } n \neq 0. \end{cases} \quad (7)$$

$M_{AT1}$  is considered corresponding to the automata:

$$AT_1 = (T_1, I(T)_1, \vartheta_1, s_{i1}, E_1, G_1), \vartheta_1((t_{i1}, \mu^{t_{i1}}, \nu^{t_{i1}}), e) = (t_{j1}, \mu^{t_{j1}}, \nu^{t_{j1}}). \quad (8)$$

Then,  $\vartheta_1 = \vartheta/I(P)_1 \times E_1$ , and

$$\vartheta_1^* = \frac{\vartheta^*}{I(T)_1} \times E_1^*, \quad (9)$$

where  $(t_i, \mu^{t_i}, \nu^{t_i}), (t_j, \mu^{t_j}, \nu^{t_j}) \in I(T), e \in E, e_1 e_2 \dots e_n \in E^*, (t_{i1}, \mu^{t_{i1}}, \nu^{t_{i1}}), (t_{j1}, \mu^{t_{j1}}, \nu^{t_{j1}}) \in I(T)_1, e \in E_1 \subseteq E, T_1 \subseteq T, I(T)_1 \subseteq I(T), E_1^* \subseteq E^*, s_i = s_{i1}$  and  $G_1 \subseteq G$ . If  $M_{AT1}$  is closed under the binary operation  $\circ$ , symbolically,  $f_{e_1 e_2 \dots e_k} \circ f_{e_1 e_2 \dots e_1} \in M_{AT1} \forall f_{e_1 e_2 \dots e_k}, f_{e_1 e_2 \dots e_1} \in M_{AT1}$ , then  $(M_{AT1}, \circ)$  is known as a submonoid automaton of  $(M_{AT}, \circ)$ .

*Definition 2.* Any two FDFIFA monoids can be related to each other employing structure-preserving maps, commonly known as homomorphisms. Such maps not only preserve the binary operations used to design semigroups on FDFIFA but also the components involved in the formulation of FDFIFAs. Formally, if  $(M_{AT}, \circ)$  and  $(M_{AT1}, \circ_1)$  are any two FDFIFA monoids, then a map  $\theta: M_{AT} \rightarrow M_{AT1}$  defined as  $\theta(f_{e_1 e_2 \dots e_n}) = f_{\psi(e_1 e_2 \dots e_n)}$  is called an FDFIFA monoid homomorphism, and if  $\theta(f_{\wedge}) = f_{\psi(\wedge)} = f_{\wedge}$  and  $\forall f_{e_1 e_2 \dots e_k}, f_{e_1 e_2 \dots e_1} \in M_{AT}$ ,

$$\begin{aligned} \theta(f_{e_1 e_2 \dots e_k} \circ f_{e_1 e_2 \dots e_1}) &= \theta(f_{e_1 e_2 \dots e_k e_1 e_2 \dots e_1}) \\ &= f_{\psi(e_1 e_2 \dots e_k e_1 e_2 \dots e_1)} \\ &= f_{\psi(e_1 e_2 \dots e_k) \psi(e_1 e_2 \dots e_1)} \\ &= f_{\psi(e_1 e_2 \dots e_k)} \circ_1 f_{\psi(e_1 e_2 \dots e_1)} \\ &= \theta(f_{e_1 e_2 \dots e_k}) \circ_1 \theta(f_{e_1 e_2 \dots e_1}), \end{aligned} \quad (10)$$

where  $''\wedge''$  (an empty sequence)  $\in E^*$ ,  $''\wedge'''$  (an empty sequence)  $\in E_1^*$ , and  $\psi: E^* \rightarrow E_1^*$  is a mapping, defined as  $\forall e_1 e_2 \dots e_k, e_1 e_2 \dots e_l \in E^*, \psi(e_1 e_2 \dots e_k e_1 e_2 \dots e_l) = \psi(e_1 e_2 \dots e_k) \psi(e_1 e_2 \dots e_l)$ . If  $\theta$  is a homomorphism that also establishes a one-to-one correspondence between  $M_{AT}$  and  $M_{AT1}$ , then it is termed to be an isomorphism and the FDFIFA monoids are denoted by  $M_{AT} \cong M_{AT1}$ .

#### 4. Intuitionistic Fuzzy Inference Rule on FDFIFA Monoid

On the semigroup of FDFIFA, intuitionistic fuzzy inference is a cognitive procedure that proceeds to a new decision or statement based on one or more previous decisions or propositions. In general, FDFIFA inference is divided into two components. The premise is a well-known decision used as a starting point for inference. The second is the conclusion, which is a fresh decision generated by the proposition. The following inference rules are offered based on the characteristics of homomorphic mapping:

Premise 1: if  $a \in X$  semigroup, then  $b \in Y$  must be a semigroup.

Premise 2: if  $a \in X$  is a semigroup, then

Conclusion:  $b \in Y = X \circ (X \rightarrow Y)$ , where  $\circ$  is a binary operation and  $X \rightarrow Y$  is a homomorphism.

The intuitionistic fuzzy inference system is made up of certain inference rules that must obey certain arithmetic requirements. The relationship between  $X$  and  $Y$  for Premise 1 is  $X \rightarrow Y$ , which is a homomorphism, grades of membership and nonmembership corresponding to an intuitionistic fuzzy relation matrix  $F$ , which is defined as follows:

$$\begin{aligned}
F(p, q) &= (\mu_{X \rightarrow Y}(p, q), \nu_{X \rightarrow Y}(p, q)) \\
&= [(\mu_X(p) \wedge \mu_Y(q)) \vee (1 - \mu_X(p)), (\nu_X(p) \vee \nu_Y(q)) \wedge (1 - \nu_X(p) - \epsilon)],
\end{aligned} \tag{11}$$

where  $\mu_{X \rightarrow Y}(p, q), \nu_{X \rightarrow Y}(p, q)$  are the grades of membership and nonmembership for intuitionistic inference rule,  $\epsilon$  is an error of hesitancy,  $\mu_Y(q), \nu_Y(q)$  are the grades of membership and nonmembership for the assumption that  $q \in Y$  is a semigroup, and  $\mu_X(p), \nu_X(p)$  are the grades of membership and nonmembership for the assumption that  $p \in X$  is a semigroup, and  $\vee$  is an “or” operation and  $\wedge$  is an “and” operation:

$$Y = X \circ (X \rightarrow Y). \tag{12}$$

The inference relationship between  $X$  and  $X$  to  $Y$  can be used to synthesize the conclusion  $Y$ .  $F$  can be used to obtain the conclusion’s membership and nonmembership functions:

$$(\mu_Y(q), \nu_Y(q)) = (\mu_X(p), \nu_X(p)) \circ F(p, q). \tag{13}$$

The following is a description of  $\circ$ , the synthetic binary operator:

$$\begin{aligned}
(\mu_Y(q), \nu_Y(q)) &= (\mu_X(p), \nu_X(p)) \circ F(p, q) \\
&= \left[ \bigvee_{p \in X} \left\{ \mu_X(p) \wedge \mu_F(p, q) \right\}, \bigwedge_{p \in X} \left\{ \nu_X(p) \vee \nu_F(p, q) \right\} \right],
\end{aligned} \tag{14}$$

such that  $0 \leq \mu_Y(q) + \nu_Y(q) \leq 1$ . In the classical fuzzy inference system, grade on membership of the fuzzy subset is a variable and variables are related through the operations defined on membership grades. However, in the inference system of FDFIFA semigroup, the FDFIFA semigroup serves as a variable and relationship between variables is exhibited using FDFIFA semigroup homomorphism.

## 5. Application

Automobiles provide millions around the world with a sense of freedom. People may now live, work, and engage in ways that were previously impossible a century ago. The automobile industry is the world’s largest single most powerful economic driver. The earliest steam-powered vehicle was invented in 1672, and Nicolas-Joseph Cugnot created the first steam-powered automotive capable of human movement in 1770 [37], since then several automotive models are introduced with numerous modifications [38, 39]. The consumption of nonrenewable fuels, a major increase in the likelihood of unintentional fatality, the emission of noise and air pollution, and the production of greenhouse gases are only a few of the present negative repercussions of widespread automobile use. The key benefit of a hybrid automobile is that it uses less gasoline and emits less CO<sub>2</sub> [40] than a typical petrol or diesel-powered vehicle.

A hybrid vehicle is one that has multiple modes of propulsion, such as a gasoline or diesel engine and an electric motor. There are several kinds of hybrids, each of which functions differently [41]. Range extender hybrid automobiles (series hybrids) rely on their conventional engine to generate electricity to power a generator that recharges the batteries. Instead of propelling the car, the engine provides energy to the electric motor [42]. The well-known model is BMW i3 [43]. Plug-in hybrids are a kind of hybrid that

can be recharged both at home and on the go, as the title indicates [44]. The BMW 330e, Mitsubishi Outlander, and Volvo V60 are just a few of the plug-in hybrids on the market. The hybrid car moves by combining at least one electrical motor with a gasoline engine, while the mechanism recovers energy through regenerative braking [45]. As result, lesser gasoline is burnt, resulting in higher fuel economy. Most of them use a high-voltage battery pack (different from the car’s standard 12-volt battery) that is recharged by absorbing energy from deceleration that would otherwise be wasted to heat created by the brakes in traditional cars. (This is accomplished through the use of regenerative braking.)

The basic purpose of such regenerative braking is to transform kinetic energy (from the wheels) towards electrical energy and save it in batteries for future use in vehicle propulsion [46]. For reliable vehicle operation and control, these systems often use electric motors for both traction and regenerative braking. They also entail constant interactions between mechanical/electrical components and their controllers (electronic control units, ECUs). Faults in these technologies can have a substantial impact on the reliability and efficiency of automobile control and operation. According to the available literature, the focus of hybrid electric vehicle (HEV) studies has been on design and control methods for enhanced energy regeneration [47], best possible braking strategies [48], and mechanism level control to improve energy/fuel efficiency [49–51], with fault analysis receiving far less attention. A fault-tolerant power train topology for series hybrid electric vehicles was discussed by Song and Wang [52]. They looked at short-switch and open-switch failures that threaten motor drive unit reliability. Parsa and Toliyat [53] suggested a fault-tolerant control approach for five-phase permanent magnet motors. It was determined that the system could function securely with up to two phases lost without the need of any extra

equipment. A basic on-board fault detection technique built on reference frame theory for detecting electric motor defects in HEVs at start-up and idle circumstances is described in [54]. Rothenhagen and Fuchs [55] present a spectator residual generation technique to identify current sensor problems.

In cascaded multiple converter devices, Jayabalan and Fahimi [56] proposed using statistical moments of higher powers to identify open-circuit and short-circuit failures. Merzouki et al. [57] discussed a parity relation-based residual generation technique for detecting and isolating actuator faults in electric vehicles. Existing HEV failure diagnostic methods are component-centric and may not explicitly incorporate communication or scheme interactions. This research looks at hardware, programming, and communication defects in HEV's regenerative braking (RBS) and proposes a data-driven technique for detecting and identifying them. Parametric and sensor-related problems (underlying physical faults), software logic faults, and interprocess communication defects (missed messages, several messages, and obsolete message faults) are among the defects investigated. The use of a series-parallel power train with regenerative braking is contemplated. The automobile is normally propelled by two power sources: (i) an internal combustion engine (ICE) and an electric generator; and (ii) an electric motor having a battery as the power storage system [58]. The various constituent components of the drive train design (with a series-parallel power train

configuration) are shown in Figure 3. The car operates in an electricity-only mode when the speed or power demand is minimal (series mode). When the car's power requirement at the wheels is larger, the engine and the motor work together to push the vehicle forward (parallel mode). Ehsani et al. [59] provided further information about different drive train layouts. As a result, defining nominal and problematic behaviour, as well as developing detection and inference algorithms for rapid fault diagnosis, is crucial.

**5.1. FDFIFA Monoid.** Now, we construct an FDFIFA semigroup  $(M_{AT}, \circ)$  fault diagnosis model for the hybrid electric vehicle regenerative braking system. Let  $(M_{AT}, \circ)$  be an FDFIFA semigroup corresponding to the automata  $AT = (T, I(T), \vartheta, s_i, E, G)$ , where  $T$  is a collection of states that the hybrid electric vehicle regenerative braking system can be in, such as normal, medium, or serious faults;  $I(T)$  is an intuitionistic fuzzy subset of states  $T$  with grade of membership  $\mu: T \rightarrow (0, 1]$  and grade of nonmembership  $\nu: T \rightarrow [0, 1)$ ;  $E$  is an input character signal set;  $s_i \in I(T)$  is the initial state of the processing signal;  $G$  is a fault state set and a subset of  $I(T)$ ; and  $\vartheta: I(T) \times E \rightarrow I(T)$  is the transitional mapping with  $\vartheta((t_i, \mu^{t_i}, \nu^{t_i}), e) = (t_j, \mu^{t_j}, \nu^{t_j})$ , where  $(t_i, \mu^{t_i}, \nu^{t_i}), (t_j, \mu^{t_j}, \nu^{t_j}) \in I(T), e \in E$ . These states  $(t_j, \mu^{t_j}, \nu^{t_j}) \in I(T)$  exist in some accepted states. The extended transitional function  $\vartheta^*$  is defined as follows:

$$\vartheta^*((t_i, \mu^{t_i}, \nu^{t_i}), e_1 e_2 \dots e_n) = \begin{cases} (t_i, \mu^{t_i}, \nu^{t_i}), & \text{if } n = 0; \\ (\vartheta(\vartheta^*(t_i, \mu^{t_i}, \nu^{t_i}), e_1 e_2 \dots e_{n-1}), e_n), & \text{if } n \neq 0, \end{cases} \quad (15)$$

where  $e_1 e_2 \dots e_n \in E^*$  is the finite set of finite strings (words/sequences of input letters (symbols)) accepted by the automata. Because  $s_i \in I(T)$ ,  $I(T)$  denotes the entire states,  $G \subseteq I(T)$ , and  $\vartheta$  is a transition procedure from one state to another. The degree of FDFIFA semigroup membership and nonmembership can show the regenerative braking's degree of fault and accuracy. As a result, the degree of membership is utilized to indicate the severity of the defect.  $G$  and  $E$  are mostly treated in the following order:

- (i) Fault state or output variable set **G**: the normal working condition represented by  $W_1$ , battery current sensor fault represented by  $W_2$ , battery temperature sensor fault denoted by  $W_3$ , engine speed sensor fault denoted by  $W_4$ , motor 1 current sensor fault denoted by  $W_5$ , motor 1 speed sensor fault denoted by  $W_6$ , vehicle speed sensor fault denoted by  $W_7$ , wheel inertia fault denoted by  $W_8$ , engine message loss fault denoted by  $W_9$ , burst loss of engine message denoted by  $W_{10}$ , burst loss of message from PTC denoted by  $W_{11}$ , too many messages from battery denoted by  $W_{12}$ , battery initial SOC fault denoted by  $W_{13}$ , wheel radius fault denoted by  $W_{14}$ , engine message faulty data denoted

by  $W_{15}$ , motor 1 message faulty data denoted by  $W_{16}$ , and wheel message faulty data denoted by  $W_{17}$ . The range of values from  $W_1$  to  $W_{17}$  is included inside the  $[0, 1]$  interval. 0 in the interval denotes the absence of such a flaw. 1 denotes a major flaw [60].

- (ii) Processing signal or input variable set **E**: the following 25 felt parameters are chosen as input variables:  $e_1$ : battery SOC,  $e_2$ : motor 2 torque demand,  $e_3$ : wheel torque demand,  $e_4$ : motor 1 torque demand,  $e_5$ : engine torque demand,  $e_6$ : battery temperature,  $e_7$ : battery current,  $e_8$ : driver torque demand,  $e_9$ : motor 1 command,  $e_{10}$ : gearbox speed,  $e_{11}$ : wheel input speed,  $e_{12}$ : wheel output speed,  $e_{13}$ : wheel torque,  $e_{14}$ : vehicle linear speed,  $e_{15}$ : motor 1 speed,  $e_{16}$ : motor 1 current,  $e_{17}$ : clutch input speed,  $e_{18}$ : engine command,  $e_{19}$ : motor 2 command,  $e_{20}$ : motor 2 speed,  $e_{21}$ : motor 2 current,  $e_{22}$ : engine speed,  $e_{23}$ : clutch output speed,  $e_{24}$ : mechanical accessory torque, and  $e_{25}$ : wheel command [60].
- (iii) The degrees to which each fault and accuracy parameter corresponds to the categories of "normal," "serious," and "medium" are presented in terms of

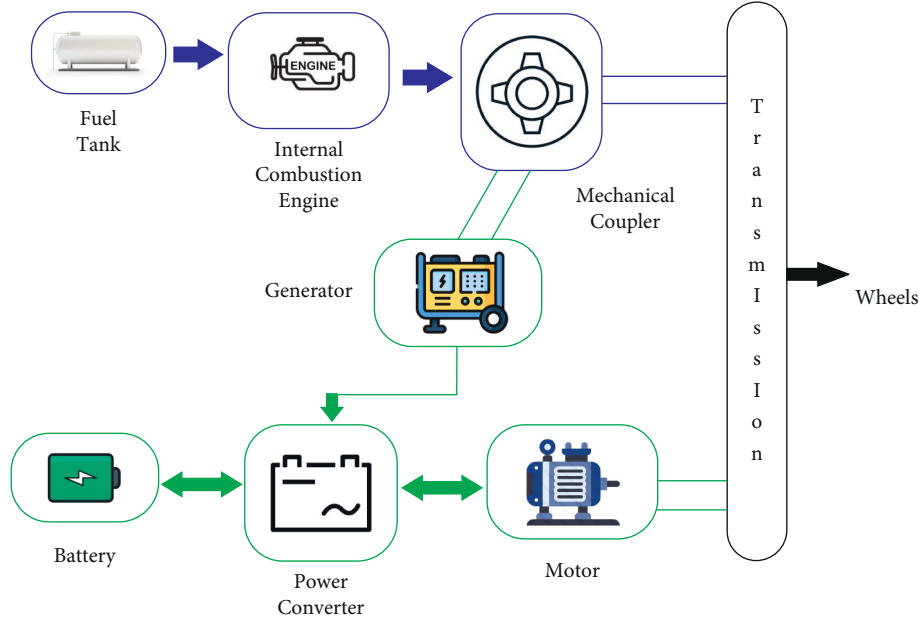

FIGURE 3: Series-parallel power train.

membership and the intuitionistic degree of non-membership grades as follows:

$$(\mu_{\text{normal}}, \nu_{\text{normal}}) = \begin{pmatrix} (1, 0) (0.2, 0.6) (0.1, 0.8) (0.2, 0.5) (0.1, 0.8) \\ (0, 0.9) (0, 0.8) (0.1, 0.6) (0.1, 0.7) \\ (0, 0.4) (0.2, 0.6) (0.1, 0.8) (0, 0.9) (0.2, 0.6) (0.2, 0.7) (0, 0.9) (0.1, 0.8) \end{pmatrix}, \quad (16)$$

$$(\mu_{\text{serious}}, \nu_{\text{serious}}) = \begin{pmatrix} (0, 0.6) (0.2, 0.7) (0.3, 0.7) (0.4, 0.5) (0.6, 0.2) (0.8, 0.1) (0.6, 0.3) \\ (0.7, 0.2) (0.1, 0.7) (0.3, 0.6) \\ (0.6, 0.4) (0.2, 0.8) (0.1, 0.9) (0.7, 0.2) (0.3, 0.7) (0.1, 0.9) (0.2, 0.8) \end{pmatrix}, \quad (17)$$

$$(\mu_{\text{medium}}, \nu_{\text{medium}}) = \begin{pmatrix} (1, 0) (0.3, 0.4) (0.2, 0.8) (0.1, 0.9) (0.4, 0.3) (0.3, 0.4) (0.3, 0.7) \\ (0.2, 0.7) (0.1, 0.8) (0, 0.6) (0, 0.9) (0.5, 0.4) \\ (0.2, 0.7) (0.3, 0.2) (0.4, 0.6) (0.2, 0.5) (0.4, 0.5) \end{pmatrix}. \quad (18)$$

**5.2. Intuitionistic Fuzzy Inference Model.** Faults are divided into three categories to make diagnosis easier: serious fault, medium fault, and no fault. The result is processed as follows, based on the output state of the intuitionistic fuzzy inference model of FDFIFA semigroup:

If  $0.60 \leq \mu(W_i) \leq 1$  and  $0 \leq \nu(W_i) \leq 0.40$ ,  $W_i$  is level 1, recognized as the serious fault.

When  $0.25 < \mu(W_i) < 0.60$  and  $0.40 < \nu(W_i) < 0.75$ ,  $W_i$  is level 2, recognized as the medium defect.

If  $\mu(W_i) \leq 0.25$  and  $\nu(W_i) \leq 0.75$ ,  $W_i$  is normal, recognized as no fault.

The seriousness of the defect can be obtained by utilizing this information. The FDFIFA semigroup's inference system has now been completely specified, comprising variables, membership functions, nonmembership functions, and the essential rules for diagnosing faults. The FDFIFA semigroup

rule viewer permits us to totally comprehend the entire intuitionistic fuzzy inference process at once. It also demonstrates the influences of the membership and non-membership functions on the overall outcomes of the intuitionistic fuzzy inference. Our prior work has a full description of how to design an intuitionist fuzzy inference system for fault detection [24]. If the problem being examined is complex in nature subject to several conflicting factors, then FDFIFA semigroup inference is an appropriate tool for its solution. Semigroup's intuitionistic fuzzy inference model is put to the test with a collection of real data to see whether it can correctly identify a hybrid electric vehicle regenerative braking system issue. The intuitionistic fuzzy inference model can be employed if the fault can be appropriately diagnosed. The corresponding parameters are monitored and their values are acquired when  $W_5, W_6, W_7,$

and  $W_8$  are defective. The data are utilized as input vectors in simulation functions to compute the output of an intuitionistic fuzzy inference model. The fault criterion is used to

determine whether or not a flaw exists. The test result shows that 5, 6, and 12 in  $W_i - out$  signify distinct types of faults illustrated as follows:

---

$$\begin{aligned} \text{Input vector} &= \begin{pmatrix} (0.2, 0.7) (0.1, 0.7) (0.2, 0.7) (0.6, 0.3) (0, 0.8) \\ (0, 0.9) (0.1, 0.7) (0.1, 0.8) (0, 0.9) (0.1, 0.7) (0.2, 0.7) \\ (0, 0.8) (0, 0.9) (0.1, 0.7) (0.1, 0.8) (0, 0.9) \end{pmatrix}, \\ \text{Cause of fault} &= W_5 \text{ serious fault,} \\ \text{Input vector} &= \begin{pmatrix} (0.2, 0.6) (0.1, 0.7) (0.2, 0.6) (0.1, 0.8) (0.4, 0.5) \\ (0, 0.8) (0.1, 0.7) (0.1, 0.8) (0, 0.9) (0.2, 0.6) (0.1, 0.7) \\ (0.2, 0.6) (0.1, 0.7) (0.2, 0.6) (0.1, 0.7) (0.2, 0.6) \end{pmatrix}, \\ \text{Cause of fault} &= W_6 \text{ medium fault,} \\ \text{Input vector} &= \begin{pmatrix} (0.2, 0.6) (0.1, 0.8) (0.2, 0.6) (0.1, 0.7) (0.2, 0.6) \\ (0.1, 0.7) (0.2, 0.6) (0.2, 0.7) (0.1, 0.8) (0, 0.8) (0.6, 0.3) \\ (0.1, 0.8) (0.1, 0.7) (0, 0.8) (0.1, 0.8) (0.1, 0.7) \end{pmatrix}, \\ \text{Cause of fault} &= W_{12} \text{ serious fault.} \end{aligned} \tag{19}$$

Suppose  $(M_{AT1}, \circ_1)$  be an FDFIFA semigroup corresponding to the automata  $AT1$ ,  $(M_{AT2}, \circ_2)$  be an FDFIFA semigroup corresponding to the automata  $AT2$  as constructed above, and  $\theta: M_{AT1} \rightarrow M_{AT2}$  is an inference rule in terms of FDFIFA homomorphism. In the aforesaid application, the inference model for fault diagnostics can be built as follows:

Premise 1: if  $M_{AT1}$  parameter  $a$  is normal,  $M_{AT2}$  output  $b$  is serious.

Premise 2: if  $M_{AT1}$  parameter  $a$  is medium, then

---

Conclusion: try to figure out what the fault level of the output  $b$  in  $M_{AT2}$ .

The degree of membership and nonmembership that corresponds to each inference step of the model can be determined using the intuitionistic fuzzy inference system, starting with the known condition.

Step 1: the intuitionistic fuzzy relation matrix  $F$  can be calculated using Premise 1 and the formula (11), as well as the intuitionistic fuzzy degree of membership and nonmembership given by the aforementioned expressions (16) and (17).

$$\begin{aligned}
\left( \mu_{M_{AT2}}(\hat{b}), \nu_{M_{AT2}}(\hat{b}) \right) &= \left( \mu_{M_{AT1}}(\hat{a}), \nu_{M_{AT1}}(\hat{a}) \right) \circ F(a, b) \\
&= \begin{pmatrix} (1, 0) (0.3, 0.4) (0.2, 0.8) (0.1, 0.9) (0.4, 0.3) (0.3, 0.4) \\ (0.3, 0.7) (0.2, 0.7) (0.1, 0.8) (0, 0.6) (0, 0.9) (0.5, 0.4) \\ (0.2, 0.7) (0.3, 0.2) (0.4, 0.6) (0.2, 0.5) (0.4, 0.5) \circ F(a, b) \\ (0.5, 0.3) (0.5, 0.3) (0.5, 0.3) (0.5, 0.3) (0.6, 0.2) (0.8, 0.1) \\ (0.6, 0.3) (0.7, 0.2) (0.5, 0.3) (0.5, 0.3) (0.6, 0.3) (0.5, 0.3) \\ (0.5, 0.3) (0.7, 0.2) (0.5, 0.3) (0.5, 0.3) (0.5, 0.3) \end{pmatrix}. \tag{21}
\end{aligned}$$

When compared to the degree  $(\mu_{\text{serious}}, \nu_{\text{serious}})$

$$\begin{pmatrix} (0, 0.6) (0.2, 0.7) (0.3, 0.7) (0.4, 0.5) (0.6, 0.2) (0.8, 0.1) (0.6, 0.3) (0.7, 0.2) \\ (0.1, 0.7) (0.3, 0.6) (0.6, 0.4) (0.2, 0.8) (0.1, 0.9) (0.7, 0.2) (0.3, 0.7) (0.1, 0.9) (0.2, 0.8) \end{pmatrix}. \tag{22}$$

of “serious” in  $M_{AT2}$ , which corresponds to the fault parameters  $W_1, W_2, \dots, W_{17}$ , the degree of  $b$  in  $M_{AT2}$  is as follows:

$$\begin{pmatrix} (0.5, 0.3) (0.5, 0.3) (0.5, 0.3) (0.5, 0.3) (0.6, 0.2) (0.8, 0.1) (0.6, 0.3) (0.7, 0.2) \\ (0.5, 0.3) (0.5, 0.3) (0.6, 0.3) (0.5, 0.3) (0.5, 0.3) (0.7, 0.2) (0.5, 0.3) (0.5, 0.3) (0.5, 0.3) \end{pmatrix}, \tag{23}$$

which signifies “more serious.” If  $\hat{a}$  is a medium fault, the inference result for the output  $b \in M_{AT2}$  is a more serious fault, which corresponds to objective reality.

## 6. Conclusion

Traditional HEV failure diagnostic methods are component-centric and may not explicitly incorporate communication or scheme interactions. This research assessed hardware, programming, and communication flaws in a hybrid electric vehicle’s regenerative braking system (RBS) and suggested a data-driven method for discovering and identifying them. The defects investigated include parametric and sensor-related issues (underlying physical faults), software logic flaws, and interprocess communication flaws (missed messages, multiple messages, and obsolete message faults).

The intuitionistic fuzzy set (IFS) is a well-known generalization of fuzzy sets that have been thoroughly studied, with significant research into its theocratic properties and applications in various disciplines. Because nonmembership grades are involved, IFS can handle uncertainties better than fuzzy sets. In this research, the effectiveness of IFS is used to detect flaws in a regenerative braking system. First, the finite deterministic fully intuitionistic fuzzy automata (FDFIFA) are defined, and then, a semigroup over FDFIFA is designed.

The algebraic properties of the FDFIFA semigroup are investigated and used to construct inference systems over it. The proposed method outperforms the previously published fuzzy inference method. Fuzzy inference can be obtained from intuitionistic fuzzy inference by considering only the membership values.

Furthermore, any machine’s maximum default and present running states can be diagnosed using the maximum value of the membership and nonmembership grades. Based on the given target qualities, the current techniques must create equations or expressions to deal with the target. The described approach, on the other hand, uses its state transition mapping to execute characteristic processing and just requires the selection of system parameters. There are a number of practical generalizations of fuzzy sets [9, 61–68], and inference rules for these generalizations can be developed using the same techniques. The proposed methodology’s superiority is demonstrated by the real-life example, which accurately and efficiently discovers the defect. The proposed methodology can be used to detect a failure in any machine by identifying its critical components, the factors that can cause any fault in those components, and the fault caused by these parameters. The nature and severity of the defect can be used to award membership and nonmembership grades.

## Data Availability

Data are collected from relevant stakeholders through questionnaire.

## Conflicts of Interest

The authors declare that there were no conflicts of interest regarding the publication of this article.

## Authors' Contributions

All authors contributed equally to the preparation of this manuscript.

As the typical application of computational intelligence in software engineering, cross-project defect prediction (CPDP) uses labeled data from other projects (source projects) for building models to predict the defects in the current projects (target projects), helping testers quickly locate the defective modules. But class imbalance and different data distribution among projects make CPDP a challenging topic. To address the above two problems, we propose a two-phase feature importance amplification (TFIA) CPDP model in this paper which can solve these two problems from domain adaptation phase and classification phase. In the domain adaptation phase, the differences in data distribution among projects are reduced by filtering both source and target projects, and the correlation-based feature selection with greedy best-first search amplifies the importance of features with strong feature-class correlation. In the classification phase, Random Forest works as the classifier to further amplify the importance of highly correlated features and establish a model which is sensitive to highly correlated features. We conducted both ablation experiments and comparison experiments on the widely used AEEEM database. Experimental results show that TFIA can yield significant improvement on CPDP. And the performance of TFIA CPDP model in all experiments is stable and efficient, which lays a solid foundation for its further application in practical engineering.

## 1. Introduction

Software defects may cause unexpected disasters in the application scenarios, threatening the security of software and even people's lives [1]. During the whole life cycle of software, defects that are found in the later period will cost more than those found in the earlier period to be repaired. Testers should find out the defects in time, helping developers fix them as soon as possible [2]. But focusing on all modules of the software will cost a large amount of time and manpower, which goes against our original intention and makes preidentification of potentially defective modules an urgent issue [3, 4].

Software defect prediction (SDP) is a method that can assist testers in quickly identifying potentially defective modules [5] so as to reduce the time spent by testers on troubleshooting and save testing costs as well [4]. The typical SDP usually uses historical data of software to build

prediction models for defect pattern recognition in new releases of the modules from the projects [3, 6, 7]. As the brand-new projects lack historical data, especially the historical data with defective or clean labels, SDP is unable to work well on them. To solve this problem, researchers propose a method called cross-project software defect prediction (CPDP). CPDP builds prediction models with historical data from other projects (source projects) and predicts the current projects (target projects) [8, 9].

Although CPDP focuses on the problem of lack of historical data, there are still two major problems to be solved. Due to a variety of factors such as project functionality and developers' habits, data distribution varies greatly from project to project. Differences in data distribution between projects are evident even when the same metrics are used to evaluate projects [10], which makes CPDP models built on source projects ineffective on the target project [11]. Therefore, how to reduce the differences

in data distribution between source and target projects is important to the performance of CPDP models [12, 13]. On the other hand, the number of the modules with defects is often much smaller than that of the modules without defects, which is called class imbalance problem [14]. The class imbalance problem can also affect the performance of CPDP models, because they may have a preference for the majority when classifying [15, 16].

To address the above problems, in this paper we propose a two-phase feature importance amplification (TFIA) CPDP model. Specifically, TFIA divides CPDP into two phases. In the domain adaptation phase, TFIA reduces differences in data distribution among source and target projects. After adding a certain proportion of samples from target projects to the source projects, the correlation-based feature selection method with a greedy best-first search strategy is proposed to amplify the importance of features with high feature-class correlation. The subset made up of the final selected items is used to filter the source and target projects for the purpose of removing redundant features as well as interfering items and reducing the dimensionality of the data. In the classification phase, resampling is conducted on the source project's data to make the numbers of clean and defective samples balanced. And an integrated learning method, Random Forest, is adopted to build the prediction model. The reason for adopting Random Forest is that integrated learning methods have shown their advantages in solving the class imbalanced problem [17]. In our case, the selected Random Forest uses a random sampling method; thus the trained model has small variance and high generalization ability, which can improve and effectively solve the class imbalance problem. Random Forest evaluates the relationship between features and classes during the training process [18], resulting in a ranking of feature-class correlation [19], further amplifying the importance of features with strong feature-class correlation for defect recognition.

In summary, our contributions lie in twofold.

- (1) We propose a two-phase feature importance amplification CPDP model (TFIA). TFIA reduces the effect of data distribution and class imbalance problems in domain adaptation phase and classification phase.
- (2) We conducted experiments on the AEEEM database to verify the validity of the method. In addition, we performed a number of ablation experiments to carefully analyse and dissect the detailed components of our method. And we also conducted comparison experiments to compare TFIA with other methods.

## 2. Related Work

CPDP usually includes two phases, called domain adaptation and classification. Domain adaptation is mainly addressed by data processing methods, such as data migration and feature selection. Classification is mainly handled by machine learning classifiers [20]. The researches on domain adaptation address the difference in data

distribution between the source and target projects, while the researches on classification methods improve the prediction performance from the perspective of algorithms. And also some researchers consider hybrid methods.

*2.1. Domain Adaptation Phase.* Turhan et al. [21] proposed Burak filter based on k-means clustering method. Burak filter calculated the Euclidean distance between all samples in the source project datasets. And for each sample in the target project datasets, they selected the  $k$  samples with the smallest Euclidean distance as training samples. Finally, the Naive Bayes method was used to predict the processed dataset. Burak filter improves the performance of CPDP model by filtering the samples of the source project datasets based on the target project datasets. Peters et al. [22] proposed Peters filter based on the source project datasets. For the samples in the source project datasets, the sample which was the closest to it in the target project datasets was selected by comparing the Euclidean distance. Then they labeled that sample. The sample of source project datasets with the closest distance to the labeled sample was selected as the training data in the prediction process. Pan et al. [23] proposed the TCA, which mapped the features of the source and target project to the latent space that makes them most similar, reducing the effect of differences in data distribution. Finally, Logistic Regression was used for prediction. He et al. [24] simplified the training set by TDSelector method and then classified it by Logistic Regression. Sun et al. [25] proposed a near-some source project selection by collaborative filtering (CFPS) method to filter source items, which has good results using SMO and Random Forest as classifiers. Alsawalqah et al. [26] proposed a SMOTE-ensemble method to optimize for class imbalance problems at the data level and algorithm level.

*2.2. Hybrid Method.* Yuan et al. [27] used TrAdaBoost to determine weights for samples based on Burak filter and used weighted support vector machines to build the model to improve the CPDP model. Chao et al. [28] proposed a two-phase CPDP method called TPTL, using a source project estimator to select source projects with similar data distribution as the target project and using two improved TCA + to construct models for prediction. Cong [29] proposed a DA-KTSVMO method using kernel twin support vector machines to improve the data distribution and using a quantum particle swarm optimization algorithm to optimize the method for prediction. Zhang et al. investigated seven composite algorithms; they believed that composite algorithms can improve the performance of CPDP models [30]. The method proposed by Chen et al. combines the data gravitation method and TrAdaBoost to reduce the effects of class imbalance in the source project [31]. Xu et al. proposed a multisource TrAdaBoost Algorithm. The proposed method uses semisupervised high-density-based clustering and a small amount of labeled target item data to obtain a large amount of labeled source item data. When using TrAdaBoost for integration, only the base classifier trained from the source item data most relevant to the target item is

selected. In the process of training, this method can ensure that the knowledge transferred is most relevant to the target project but ignores the influence of other source project data on the target project defect prediction model [32].

### 3. Methodology

In this section, we first introduce the framework of our proposed method TFIA. Then we show the details of important steps in our proposed method.

**3.1. Framework of TFIA.** Figure 1 is the flowchart of TFIA. TFIA adds a certain proportion of labeled samples from the target project datasets to the source project datasets, uses a correlation-based feature selection method, and searches for a subset of features using a heuristic greedy best-first search strategy. Then TFIA filters the feature of source and target projects, samples the source projects datasets with resampling, uses Random Forest on the source project datasets for training, and finally predicts the target project datasets.

TFIA reduces the difference in data distribution between source and target projects from the feature perspective and sample perspective, respectively. TFIA enhances the importance of features with strong class-feature correlation in model training. A resample approach is used to deal with class imbalance problems and reduce the impact generated by class imbalance problem. TFIA uses Random Forest as a classifier to train models with small variance and strong generalization ability to improve the accuracy of CPDP model for identifying defective modules.

In TFIA, we use Relief to evaluate the correlation of feature-feature and feature-class in TFIA. Relief[33] is a feature weighting algorithm that is sensitive to feature interactions. Relief of feature  $f$  can be formulated as

$$\text{Relief}_f = \frac{\text{Gini}' \times \sum_{f_v \in f} p(f_v)^2}{\left(1 - \sum_{c \in C} p(c)^2\right) \sum_{c \in C} p(c)^2}. \quad (1)$$

$p$  is the probability,  $C$  is the class variable,  $C = \{\text{defective}, \text{clean}\}$ ,  $f_v$  is the certain value of the sample's feature  $f$ , and  $\text{Gini}'$  is another attribute quality measure that can be calculated by

$$\begin{aligned} \text{Gini}' = & \left[ \sum_{c \in C} p(c)(1 - p(c)) \right] \\ & - \sum_{f_v \in f} \left( \frac{p(f_v)^2}{\sum_{f_v \in f} p(f_v)^2} p(f_v)^2 \sum_{c \in C} p(c f_v)(1 - p(c f_v)) \right). \end{aligned} \quad (2)$$

We use Relief to calculate correlation of feature-feature and feature-class in Section 3.2 and Section 3.3.

**3.2. Domain Adaptation Phase.** In order to amplify the role of features with strong feature-class correlation in the classifier and to deemphasize features with strong feature-feature correlation, we decide to select the features. In the feature selection phase, we use the filtering method called correlation-based feature selection (CFS) [34]. In this paper,

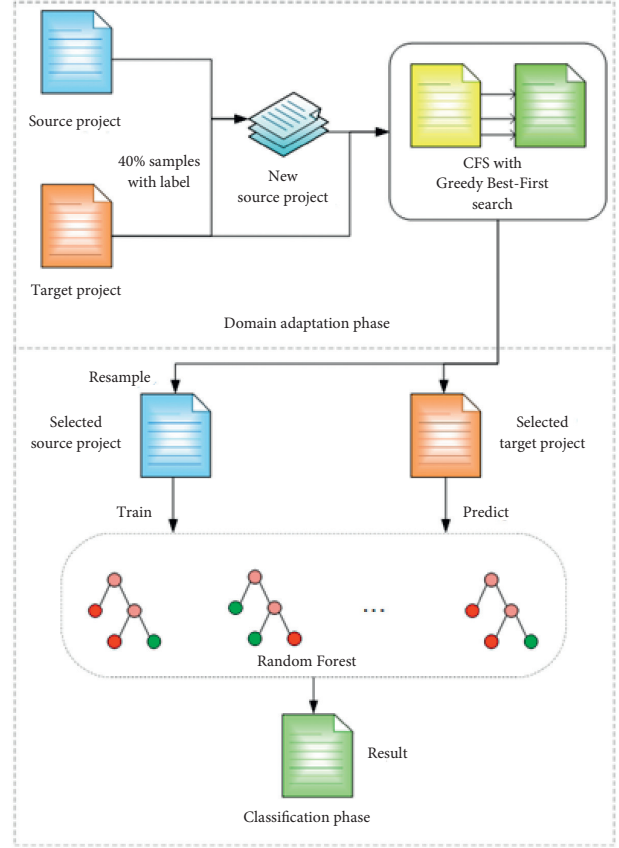

FIGURE 1: Flowchart of TFIA.

the heuristic search strategy used by CFS is greedy best-first search [35]. CFS evaluates the value of a subset of features by considering the individual predictive ability of each feature and the degree of redundancy between them [36].

As shown in Figure 2, CFS first computes the feature-class and feature-feature correlation matrices from the source project dataset and then searches the feature subset space using greedy best-first search.

To prevent the best-first search from exploring the entire feature subset search space, we follow the setting of [34] to impose a termination criterion. The search will terminate if five consecutive fully expanded subsets show no improvement over the current best subset. CFS filters features by a feature subset evaluation function, intending to find a subset of features that meet the conditions of low feature-feature correlation and strong feature-class correlation, thus sifting out redundant features [37]. The feature subset evaluation function is valued as the merit which can be calculated by

$$M_S = \frac{k \overline{r_{fc}}}{\sqrt{k + k(k-1) \overline{r_{ff}}}}, \quad (3)$$

$M_S$  is the value of the merit of feature subset with  $k$  selected features.  $\overline{r_{fc}}$  is the average feature-class correlation and  $\overline{r_{ff}}$  is the average feature-feature correlation.  $r$  is Relief in Section 3.1.

The algorithm is described as follows.

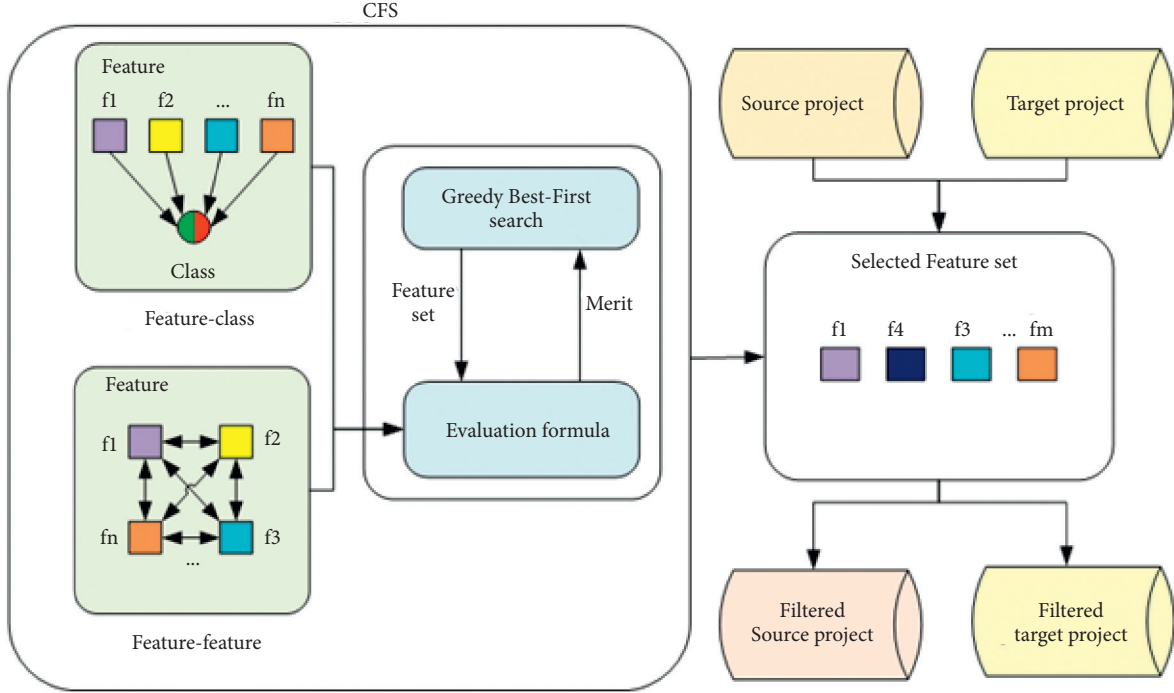

FIGURE 2: Flowchart of CFS.

3.3. *Classification Phase.* Random Forest is an integrated learning pattern recognition method [19, 38]. It has been demonstrated that Random Forest has good performance in CPDP [27, 39, 40] due to its high tolerance to outliers and noise. Random Forest is also less prone to fitting characteristics [18].

Figure 3 shows the process of Random Forest in this paper. Random Forest uses a bootstrap method to randomly scrape multiple samples from the original samples, modeling a Decision Tree for each sample set. Then we give a comprehensive conclusion from the results of all decision trees. The voting decision process of Random Forest is shown by

$$H(x) = \text{majority vote} \left\{ \max_C \sum_{i=1}^k I(h_i(x) = C) \right\}, \quad (4)$$

$H(x)$  denotes the combined classification model,  $h_i$  denotes the single subject Decision Tree,  $C$  is the set of class labels, and  $I(\cdot)$  is the indicative function.

There is a put-back from the source project dataset  $D$  processed in the domain adaptation phase to obtain a randomly selected subset  $D_{T_i}$  as the training set. And the sample size of the training dataset is the same as the original data.

This sampling method of Random Forest ensures the variability of the training set. For the sake of easy explanation, we assume that there are  $n$  samples in dataset  $D$ . The probability of each sample being picked is  $1/n$ . Repeat it for  $n$  times, so the probability of each sample in  $D$  not being picked is  $(1 - 1/n)^n$ . As  $n$  tends to infinity,  $\lim_{n \rightarrow \infty} (1 - 1/n)^n = 0.368$ . We can assume that 37% of the samples in  $D$  will not appear, which guarantees the variability of the training set.  $\lambda$  features are randomly selected

from the source project dataset to construct a Decision Tree, and each node is based on (2).

In a single Decision Tree, the *Gini'* metric is calculated for each attribute and a variable with the minimum *Gini'* metric is selected to split the current node. The Decision Tree is constructed by recursion until the stop criterion is reached.

The algorithm is described as follows.

## 4. Experimental Design

For our method TFIA, in this section, we raise four research questions and set up experiments to discuss and analyse each question.

4.1. *Research Question.* RQ1: Does the feature-level filtering approach proposed in this paper have any impact on the performance of the model?

In TFIA, we use filtering to reduce the data distribution difference in source and target projects datasets by CFS. Therefore we intend to analyse the role of filtering methods in the whole CPDP model.

RQ2: In the classification phase, does the choice of classifier affect the overall performance?

In TFIA, feature-class correlation is also amplified in the classification phase as we use Random Forest as the classifier. Classifiers behave diversely on different types of data, so we want to investigate how other classifiers would perform on our model, such as the linear classifiers Logistic Regression and Support Vector Classification, the Bayesian formula-based classifier Naive Bayes, and the tree-based classifier Decision Tree.

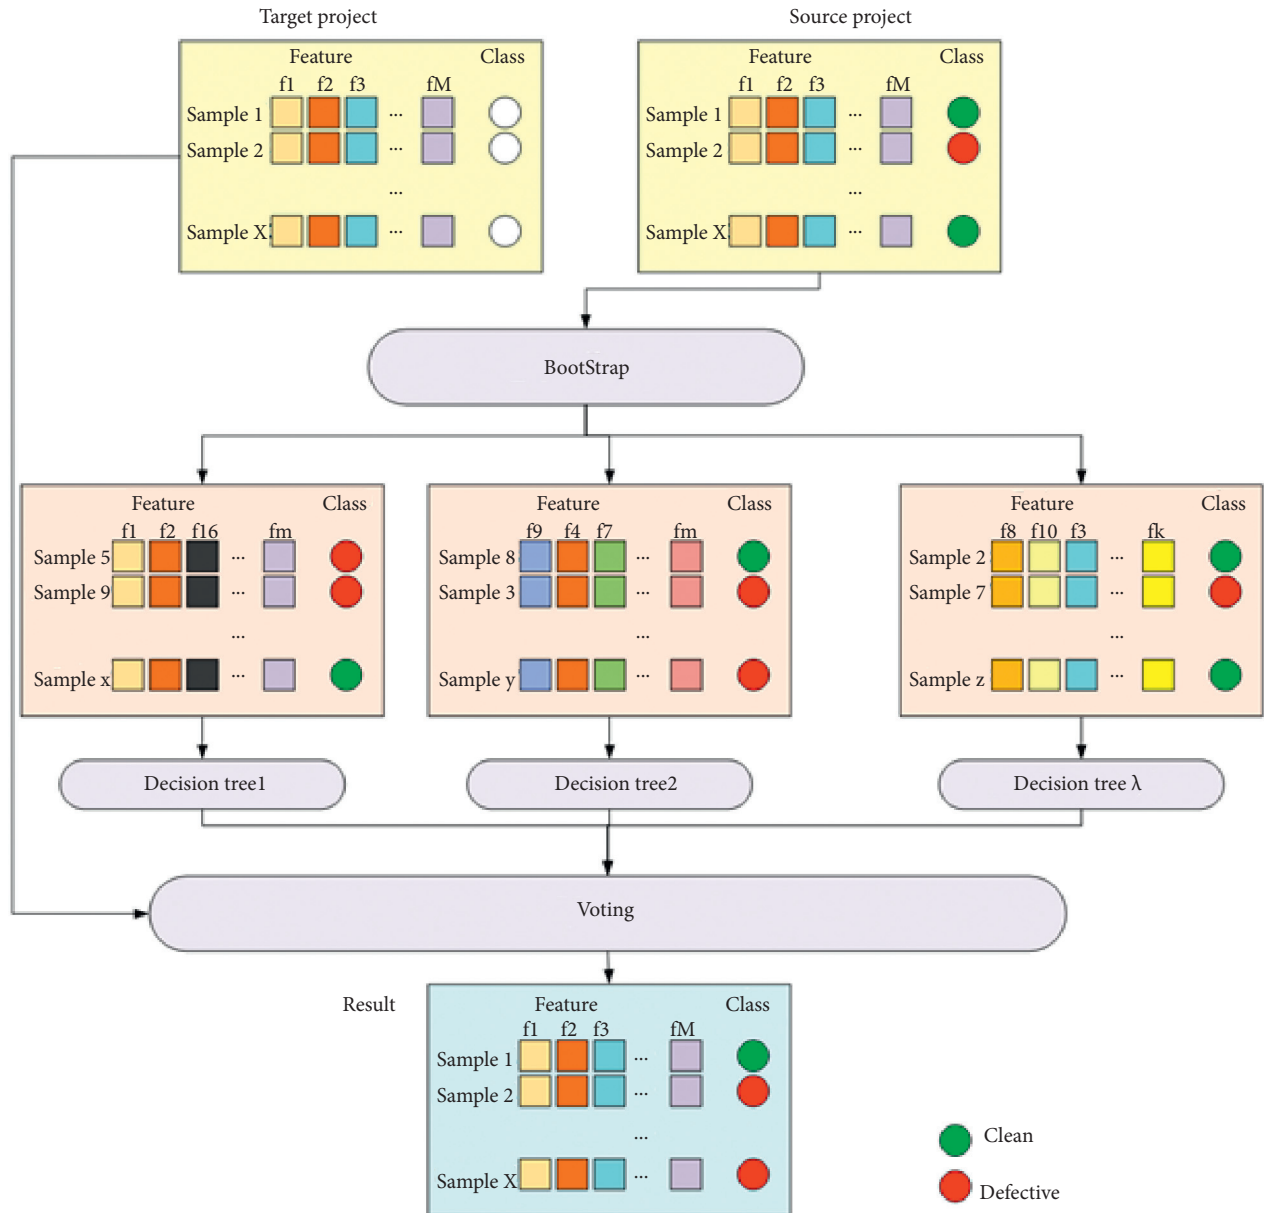

FIGURE 3: Flowchart of Random Forest.

RQ3: When features are transferred at the sample level, does the proportion of transfer affect the results?

In the domain adaptation phase of TFIA, a certain percentage of samples of the labeled target items are required. We want to analyse how different proportions of samples of labeled target items in the project affect the overall prediction performance.

RQ4: Compared with the classical method and the latest research, does the method proposed in this paper improve CPDP model's performance?

Various methods have been proposed by researchers for the CPDP problem, such as the classical methods TCA [23], Peters filtering method [22], Burak filtering method [21], and the newer method ALTRA [27]. We seek to analyse how the performance obtained by TFIA differs from these methods.

4.2. *Dataset.* In this paper, we use the AEEEM database, a widely used dataset in the field of software defect prediction research. The AEEEM database was collected and compiled by D'Ambrosio et al. [41]. Table 1 shows the details of the AEEEM database, including the projects names, the projects types, numbers of modules, numbers of defective modules, and the ratio of defective modules.

4.3. *Experimental Environment.* All of our codes are written in *Python 3.7*. The GPU used for the experiments is NVIDIA TITAN V and the CPU is Intel I9-9920X. Classifications are realized by WEKA [42] with default parameters.

4.4. *Performance Measure.* The confusion matrix is used to store the correct and incorrect decisions made by the

(i) Input:  $F$ , Feature set with  $n$  features and a class;  $F = \{f_1, f_2, \dots, f_n, C\}$   
(ii) Output:  $S$ , Subset of selected features,  $S \in F$   
1  $S = \{\emptyset\}$ ,  $F_1 = \{f_1\}$ ,  $F_2 = \{f_2\}$ , ...,  $F_n = \{f_n\}$   
2 compute the merit of  $F_1 = \{f_1\}$ ,  $F_2 = \{f_2\}$ , ...,  $F_n = \{f_n\}$  by (3)  
3 put the feature with the biggest merit of  $F$  into  $S$ , and remove it from  $F$   
4 compute merit of  $S$  ( $M_S$ )  
5 put the new feature with the biggest merit of  $F$  into  $S$ , compute  $M_S$ ,  $\text{merit}_{\text{new}} = M_S$   
6 if  $\text{merit}_{\text{old}} \geq \text{merit}_{\text{new}}$  then  
7 remove the new feature from  $S$   
8 else  
9 Update  $S$ , remove the new feature from  $F$ ,  $\text{merit}_{\text{old}} = \text{merit}_{\text{new}}$   
10 end if  
11 repeat step 5 to step 7 until  $F = \{\emptyset\}$  or  $\text{merit}_{\text{old}}$  has no change by a certain number of times  
12 return  $S$

ALGORITHM 1: CFS.

prediction model. The purpose of our defect prediction is to test out defective data. In this paper, we believe that a sample itself is defective, and the classifier also considers it defective, called True Positive (TP). The classification is False Negative (FN) if the classifier thinks it is clean. Similarly, if a sample does not have defects, the classifier classifies it as defective, called False Positive (FP); the classifier classifies it as free of defects, called True Negative (TN).

**4.5. F1-Measure.** F1-measure, also known as F-score, is a weighted summed average of Precision and Recall. Precision is the ratio of correctly predicted defective modules to all modules predicted to be defective, calculated as shown by

$$\text{Precision} = \frac{TP}{TP + FP}. \quad (5)$$

Recall is the ratio of correctly predicted defective modules to all truly defective modules, calculated as shown in

$$\text{Recall} = \frac{TP}{TP + FN}. \quad (6)$$

F1-measure is often used to evaluate the performance of a classification model. F1-measure can be calculated by

$$F1 - \text{measure} = \frac{2 * \text{Precision} * \text{Recall}}{\text{Precision} + \text{Recall}} = \frac{2TP}{2TP + FP + FN}. \quad (7)$$

**4.6. Area under the ROC Curve.** Area under the ROC curve (AUC) is used to evaluate the degree of discrimination obtained by the model. The value of AUC ranges in  $[0, 1]$ . AUC for random prediction is 0.5. The advantage of AUC is that AUC is insensitive to decision thresholds such as precision and recall. The higher the AUC, the better the prediction.

**4.7. Matthews Correlation Coefficient.** Matthews correlation coefficient (MCC) is used in machine learning as a measure

of binary (2-category) quality of classification, which is introduced from biochemistry by Brian W. Matthews in 1975 [43].

MCC takes into account true and false, positives and negatives, and is generally regarded as a balanced measure that can be used even if the classes are of very different sizes [44]. MCC is essentially a correlation coefficient between the observed and predicted binary classification. It returns a value between -1 and +1.  $MCC = +1$  indicates a perfect prediction,  $MCC = 0$  indicates that the model is not better than a random prediction, and  $MCC = -1$  indicates a complete inconsistency between prediction and observation.

The formula for the MCC is shown by

$$MCC = \frac{TP \times TN - FP \times FN}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}}. \quad (8)$$

## 5. Results and Discussion

In this section, we present the experimental results and give the answers to questions from Section 3.

**5.1. Answer for RQ1.** To answer RQ1, we designed two groups of experiments on the AEEEM database, where we formed a total of 20 source-target project pairs from the five projects, including EQ, JDT, ML, LC, and PDE. The first group of experiments performed no filtering on these 20 source-target project pairs. And the second group of experiments were filtered by CFS based on greedy best-first search strategy proposed in this paper. Both sets of experiments used Random Forest as the classifier. Both groups of experiments randomly added 40% of the target project data to the source project dataset and source project datasets were dealt with through resample.

Table 2 shows the results of the evaluation metrics obtained on 20 source-target project pairs without (Model 1) and with (Model 2) the filtering method proposed in this paper.

(i) Input:  $D_S$ , source project dataset;  $\text{sample}_T$ , sample from source project dataset  
 Output:  $C(\text{sample}_T)$  = classification of  $\text{sample}_T$

- (1) for  $\{i = 1, 2, \dots, \lambda\}$  do
- (2) use Bootstrap on  $D_S$  to get the training dataset  $D_{T_i}$
- (3) use  $D_{T_i}$  to generate a tree  $h_i$  without pruning
- (4) randomly select  $d$  features from  $D_S$ 's features
- (5) calculate the  $Gini'$  metric based on (2) at each node to select the optimal features based on the selected  $d$  features
- (6) Splitting until the tree grows to its maximum
- (7) end for
- (8) return  $C(\text{sample}_T) = \text{majority vote}\{h_i(\text{sample}_T)\}_{i=1}^{\lambda_{\text{tree}}}$

ALGORITHM 2: Random Forest.

The values in bold are results with the best performance of each instance.

From Table 2, it can be observed that the overall effect of the prediction models trained from the data processed by the filtering method is significantly improved (the data in bold), with an average F1-measure improvement of about 156.54%, AUC improvement of about 45.74%, and MCC improvement of about 173.46%. Numerically, in these 20 source-target project pairs, the models with filtering all work better than those without filtering.

Figure 4 is the boxplot of F1-measure, AUC, and MCC of model with filtering (Model 1) and model without filtering

(Model 2) based on data from Table 2. As can be seen from Figure 4, the prediction models trained from the data processed by the filtering have higher numerical intervals in the overall distribution compared to the data without filtering. In terms of box size and endline length, the overall performance of the model after processing with the filtering also becomes less volatile and the performance is more stable. Therefore, we can conclude that the filtering method proposed in this paper is effective in improving the performance of the CPDP model on these datasets.

FIGURE 4: Boxplot of F1-measure, AUC, and MCC of model with filtering (Model 1) and model without filtering (Model 2).

5.2. *Answer for RQ2.* To answer RQ2, 20 source-target projects from the AEEEM database were trained and validated using Naive Bayes (NB), Logistic Regression (LR), Decision Tree (DT), Support Vector Classification (SVC), and Random Forest (RF) as classifiers. Respectively, all the datasets were processed by the filtering method proposed in this paper. Every set of experiments randomly added 40% sample from the target project datasets to the source project datasets and the source project datasets were dealt with through resample.

Table 3 shows the F1-measure, AUC, and MCC of models with different classifications, including Naive Bayes (NB), Logistic Regression (LR), Decision Tree (DT), Support Vector Classification (SVC), and Random Forest (RF). The data in bold show the classification with the best performance in each set of experiments. The value of F1-measure shows that, on the data processed by our filtering method in this paper, RF has the best results, Decision Tree is the second best, and LR, NB, and SVC are more similar and differ from RF and DT. The situation is the same in AUC and MCC. This phenomenon could be caused by the idea that, in the first phase, our filtering method amplifies the proportion of features that have a strong correlation with the class. So it has better performance on DT and Decision Tree-based integrated method RF. The other three classifiers are relatively insensitive to the dataset of amplified features, so the results are worse than DT and RF.

Figure 5 is the boxplots of F1-measure, AUC, and MCC of models with different classifications, including Naive Bayes (NB), Logistic Regression (LR), Decision Tree (DT), Support Vector Classification (SVC), and Random Forest (RF). From Figure 5, it can be seen that the prediction models constructed with Random Forest

and Decision Tree as classifiers achieve higher performance metrics and less overall volatility. This indicates that the choice of classifier has an impact on the performance of the prediction model. On the dataset processed by the filtering method in this paper, classifiers that are more sensitive to feature importance will have better results.

5.3. *Answer for RQ3.* To analyse the effect of the proportion of samples from target projects datasets added to the source projects datasets on the prediction results, we added different proportions of labeled target item samples to the source projects datasets in steps of 10% from 0% and trained with TFIA. Every source project dataset had been dealt with through resample.

Table 4 shows the average F1-measure, AUC, and MCC values of models added samples from target projects to the source projects at different proportions on 20 source-target project pairs.

Then we smoothed the values to plot the graphs as Figure 6, from which we can see that the transformation of the three measures starts to become very small at around 70%, indicating that the model performance reaches its best at around 70%. But for the consideration of the actual prediction environment, it is not feasible to manually label the target projects samples at 70%, so we only consider the growth rate of indicators in this paper. It can be seen that the AUC starts to level off around 40%, and the improvement rates of F1-measure and MCC start to become smaller, so we believe that adding 40% of the labeled samples of the target projects to the source projects will have better results in these 20 source-target projects pairs.

TABLE 3: F1-measure, AUC, and MCC of models with different classifications, including Naive Bayes (NB), Logistic Regression (LR), Decision Tree (DT), Support Vector Classification (SVC), and Random Forest (RF).

5.4. *Answer for RQ4.* To answer RQ4, we used TCA, Burak filter, Peters filter, and ALTRA on 20 source-target project pairs in the AEEEM database for prediction and compared with our proposed method, respectively. To ensure the consistency of the experimental conditions, the source items in the dataset were randomly added to 40% samples of the target project datasets, and the source project datasets were dealt with through resample.

Table 5 shows the F1-measure, AUC, and MCC of ALTRA (Model 1), TCA (Model 2), Peters filter (Model 3), Burak filter (Model 4), and TFIA (Model 5).

As can be seen from the data in Table 5, compared with other methods, the proposed method in this paper shows significant improvements in F1-measure, AUC, and MCC. Taken as an example, the value of F1-measure is improved by about 126.62% over TCA, 98.64% over Burak filter, 86.46% over Peters filter, and by 31.12% over ALTRA.

Figure 7 is the boxplot of F1-measure, AUC, MCC of ALTRA (Model 1), TCA (Model 2), Peters filter (Model 3), Burak filter (Model 4), and TFIA (Model 5). From Figure 7, we can see that the method in this paper has smaller boxes and shorter endline lengths relative to the other methods, indicating that TFIA performs more consistently on the

datasets. Although ALTRA performs better than TCA, Burak filter, and Peters filter on the average F1-measure, the fluctuation of ALTRA is larger. Therefore, we can conclude that the method proposed in this paper possesses good stability and prediction effect on the AEEEM database compared to these methods.

5.5. *Threats to Validity.* In this paper, the threats to validity are mainly divided into internal and external validity.

The internal validity comes from the setting of classifier parameters. In this paper, we set the parameters defaulted by the references as well as the tool of WEKA, which may lead to some differences in the classification results. To mitigate this difference, we use the same default parameters provided by WEKA for the classification phase of our proposed method.

The external validity mainly comes from the dataset used. We use five project datasets from the publicly available AEEEM database and combine 20 source-target project pairs for our experiments. If other data sources are selected, especially those from real-world engineering datasets, different experimental results may be obtained.

TABLE 5: FI-measure, AUC, and MCC of ALTRA (Model 1), TCA (Model 2), Peters filter (Model 3), Burak filter (Model 4), and TFIA (Model 5).

## 6. Conclusion and Future Work

To tackle the problems of class imbalance and different data distribution among projects in cross-project defect prediction (CcrossPDP) which is the typical application of pattern recognition, we propose a model based on two-phase feature importance amplification (TFIA) in this paper. In the domain adaptation phase, TFIA reduces the differences in data distribution between the source and target projects by adding a certain percentage of samples from the target project to the source project. Meanwhile, correlation-based feature selection (CFS) with a greedy best-first search strategy for feature selection is utilized to obtain a feature subset with a weak feature-feature correlation and a strong feature-class correlation. The source and target project datasets filtered by this feature subset are input to the following classification phase. As the tree-based classifiers are sensitive to features with high feature-class correlation, Random Forest, the integrated method based on Decision Tree for pattern recognition, functions in the classification phase. Multiple decision trees can amplify the importance of features and help each other to improve the performance of the whole prediction model.

We conducted four experiments to validate TFIA on 20 project pairs from the widely adopted AEEEM dataset. The first experiment demonstrates that the domain adaptation approach we designed is effective and has a significant improvement on the overall model performance. The second experiment demonstrates that Random Forest outperforms other classifiers on the dataset processed by our domain adaptation approach. The third experiment analyses the

influence of the proportion of samples added from the target projects on the model. The experiment proves that adding 40% of the target item data makes great improvement on the model performance considering the practical application scenarios. In the fourth experiment, we compare TFIA with four other classical research methods, and the experimental result proves that TFIA provides better and more stable performance.

In this paper, our method has been proved to have an improvement effect on CPDP, but there are still some parts that need to be further studied. We will follow two aspects in our future research. The first is to validate the effectiveness of TFIA on other datasets and make it more scalable and robust since our experiments use the subprojects from the same root project. Secondly, since the parameters used in this paper are defaulted, which have a large impact on the prediction model, we will seek to find the effect of adjusting parameters on the model performance. We will also look for the most suitable parameters and the methods that can automatically adjust the parameters according to the real application scenarios.

## Data Availability

A publicly available dataset is used for this study (AEEEM).

## Conflicts of Interest

The authors declare no conflicts of interest.

Electricity can be provided to small-scale communities like commercial areas and villages through microgrid, one of the small-scale, advanced, and independent electricity systems out of the grid. Microgrid is an appropriate choice for specific purposes reducing emission and generation cost and increasing efficiency, reliability, and the utilization of renewable energy sources. The main objective of this paper is to elucidate the combined economic emission dispatch CEED problem in the microgrid to attain optimal generation cost. A combined cost optimization approach is examined to minimize operational cost and emission levels while satisfying the load demand of the microgrid. With this background, the authors proposed a novel improved mayfly algorithm incorporating Levy flight to resolve the combined economic emission dispatch problem encountered in microgrids. The islanded mode microgrid test system considered in this study comprises thermal power, solar-powered, and wind power generating units. The simulation results were considered for 24 hours with varying power demands. The minimization of total cost and emission is attained for four different scenarios. Optimization results obtained for all scenarios using IMA give a comparatively better reduction in system cost than MA and other optimization algorithms considered revealing the efficacy of IMA taken for comparison with the same data. The proposed IMA algorithm can solve the CEED problem in a grid-connected microgrid.

## 1. Introduction

Microgrid is one of the advanced small-scale centralized electricity systems and it usually contains energy storage resources, Distributed Generation (DG) units, and loads. Microgrids are generally designed and installed nearby energy consumers in a confined community [1]. But there has been a drastic increase in recent years regarding installing renewable energy sources in microgrids, owing to environmental advantages and low cost compared to its counterparts [2]. Microgrid meets different load

requirements in residential, commercial, agriculture, and industrial sectors [3]. Microgrids can function under two different modes: grid-connected and islanded modes. In the former mode, the microgrid and main grid are connected, while in the latter the microgrid is isolated from the main grid during an emergency outbreak. It continues its power delivery functions to local loads as usual [4]. There are loads of advantages present in using microgrid reduction of carbon emission and generation cost, thanks to renewable energy sources, and increased reliability and power quality, etc. [5].

Optimal operations and effective planning of electric power generation systems are the two most crucial elements in electric industries. Controlling and operating power systems, cost-efficient load dispatch (Economic Load Dispatch, i.e., ELD) related problems are too much concerning to address [6]. Power system optimization problems that employ ELD are useful in identifying the most suitable, cheap, and seamless operations with the regulation of outputs produced by different power generation units that meet the load demands. ELD has a primary aim to mitigate the overall cost incurred upon power generation without compromising or producing any constraints [7]. ELD determines active power output generated by different power generation systems to attain the objective functions and simultaneously overcome many problems [8]. It is important to develop novel power management algorithms to translate the microgrid as a viable and happening choice compared to traditional power systems [9]. The mitigation of both power generation costs and the emission of environmental pollutants is the sole aim of utility operators. For these goals, two contradictory objectives must be considered. Combined economic emission dispatch (CEED) is utilized to mitigate emission levels from all generating units and costs incurred by the operating units [9].

CEED problem has been discussed earlier by different authors who proposed several optimization techniques to overcome the issue [10]. In [10], the researchers proposed a balanced trade-off method to resolve the ECED (Environment Constrained Economic Dispatch) problem. The study conducted a first-of-its-kind comparative analysis of three methods: Fractional Programming (FP), ECED, and price penalty factor (PPF) to overcome the CEED problem. Chimp Optimization Algorithm (ChOA) was proposed to address the optimal design of microgrid which comprises PV panels, wind turbines, and battery storage systems [11]. Optimization results had been compared with Improved Grey Wolf Optimizer (IGWO) and Grey Wolf Optimizer (GWO). Optimal sizing of photovoltaic cell and solar water heater by considering environmental parameters and fuel-saving was carried out in [12]. Energy and economic analysis of solar energy-based cogeneration system for a building in Saveh City were studied. The researchers simulated the model in a 3-Unit dynamic test system incorporating renewable energy sources. In the study conducted by Alammoush [13], Bernstein-search differential evolution (BSDE) algorithm was proposed to resolve the Dynamic Combined Heat and Power Economic emission Dispatch (DCHPED) generation problem in microgrid comprised of renewable energy sources, fixed nondeferrable and deferrable loads, fossil-fuel combined heat and power units, and thermal energy storage devices. In [14], whale optimization algorithm (WOA) has been applied to carry out the combined economic emission dispatch problem. The simulation was performed by considering four different load sharing scenarios among the distributed energy resources. The researchers also conducted ANOVA and Wilcoxon signed-rank tests to validate the supreme characteristic of WOA. In [15], Stochastic Fractal Search (SFS) algorithm was applied to resolve multiobjective economic emission dispatch

problems that arise in combined heat and power (CHP) generation. This study was conducted in large microgrids in which solar-powered generating units, wind power units, and fossil-fuel-powered generating units were installed.

Collective Neuro Dynamic Optimization (CNO) method was proposed in the earlier study. In this study, the authors combined a heuristic approach and projection neural network (PNN) to optimize the scheduling of an electrical microgrid containing ten thermal generators and mitigate the costs incurred upon emission and generation [16]. A mixed-integer nonlinear programming formulation was proposed in [17] to dispatch the distributed generators cohesively. Further, the model was also aimed at fulfilling the water demands and the building's thermal energy requirements in a standalone water energy microgrid.

In [18], Giza Pyramids Construction (GPC) was proposed to implement the optimal design of an isolated microgrid. Net present cost (NPC), Levelized Cost of Energy (LCOE), loss of power supply probability, and availability index were considered objective functions. Modified adaptive accelerated particle swarm optimization (MAACPSO) algorithm was proposed to investigate the grid-tied PV systems reliability [19]. This study focused on the probability analysis and reliability assessment of the components of grid-tied PV systems through IEEE 24 bus integrated with PV system with four different case studies. A first-of-its-kind Sequential Optimization Strategy (SOS) was formulated in the study conducted earlier to allocate active and reactive power to Dispatchable Distributed Generator (DDG) units in an optimal manner. These DDG units are installed in a droop-controlled islanded AC microgrid [20]. The research proposed improved Quantum Particle Swarm Optimization (QPSO) earlier [21] to address the Short-Term Economic Environmental Dispatch (EED) problem in a microgrid. Recently, a multiobjective seeker optimization algorithm has been proposed to analyze the influence of charging and discharging behaviour of electric vehicles and demand side response resources on the economic functioning of PV-connected microgrid systems. The model considered three objectives: power fluctuation between microgrid and main grid, comprehensive operating cost of the microgrid, and utilization rate of photovoltaic energy [22].

In [23], the researchers proposed a mathematical optimization approach to achieve an optimal operation upon economic dispatch in DC microgrid. To allot the schedules for unit commitment and achieve economic dispatch in microgrid, the study conducted earlier [24] proposed an enhanced real-coded genetic algorithm in the enhanced mixed-integer linear programming (MILP) based method. The authors proposed a stochastic model in [25] to manage CHP-based microgrids optimally. The study took economic, reliability, and environmental aspects into consideration. Nonconvex and nonlinear stochastic problems are used to resolve complexity. The Exchange Market Algorithm (EMA) was proposed in a study. This study considered three contradictory objectives through a weighted sum approach to resolving the multiobjective problem as a single-objective problem.

A multiobjective optimal dispatch model was proposed in [26] for a grid-connected microgrid. In this study, the authors considered reducing environmental protection costs and the generation cost of the microgrid with the incorporation of an enhanced PSO algorithm. In [27], a genetic algorithm is applied to optimize the focal area of the parabolic trough concentration photovoltaic/thermal system. The objective function was considered a combination of electrical efficiency and thermal efficiency. A parabolic trough concentrating photovoltaic thermal (CPVT) was utilized to afford the energy required for a residential building [28]. CPVT was used as a source of heat and cooling and electrical energy for the building and simulation was carried out using TRNSYS software. Samy et al. addressed the problem of power outages in distant districts by taking advantage of the available renewable energy resources in the contiguous environment [29]. Hybrid Firefly and Harmony Search optimization technique (HFA/HS) was implemented to improve the net present cost of the proposed hybrid system which comprises photovoltaic (PV), wind turbine (WT), and fuel cell (FC). MINLP, a novel optimization model, was proposed in [30] to resolve the economic dispatch problem of a microgrid which contains numerous units of wind turbines (WTs), heat-only units, traditional power generators, photovoltaic (PV) systems, CHP units, and battery storage systems under certain uncertainties. In the study conducted earlier [31], MBGSA (Memory-Based Gravitational Search Algorithm) was proposed to overcome the ELD problem. In one of the research investigations [32], a novel Multiobjective Virus Colony Search (MOVCS) was proposed to elucidate the multiobjective dynamic economic emission dispatch (DEED) problem. This model aims to mitigate the emissions produced by fossil-fuel power generators and simultaneously reduce the cost incurred upon wind-thermal electrical energy costs. In [33], HOMER software is used to model and simulate a wind-solar hybrid system independent of the national grid in the northwest of Iran. A multiobjective particle swarm optimization technique is proposed to optimize the sizing of a green energy system connected to a randomly disrupted grid [34]. The energy cost for evaluating hybrid system economies, the loss of probability of power supply (LPSP) for reliability assessments, and the System Surplus Energy Rates (SSER) were considered objective functions for evaluating hybrid system compatibility and efficiency. A sustainable energy distribution configuration for microgrids integrated into the national grid using back-to-back converters in a renewable power system was examined in [35]. Different scenarios of several sustainability schemes of power management in microgrids were analyzed.

SGEO (Social Group Entropy Optimization) technique was proposed in [36] to resolve Fuel Constrained Dynamic Economic Dispatch (FCDED) with Demand Side Management (DSM). The technique combined the pumped hydrostorage plant with renewable energy sources. This research used a stochastic fractal search algorithm to overcome the biobjective combined heat and power economic dispatch (CHPED) problem [37].

In [38], mayfly algorithm (MA) was proposed by Dr. Konstantinos Zervoudakis in 2021. In this paper, an improved mayfly optimization algorithm was investigated with the help of a microgrid model under varying scenarios. The results were contrasted against recent state-of-the-art algorithms that also employed the same microgrid model.

The contributions of the current research paper are summarized herewith.

- (i) An improved version of the mayfly optimization algorithm incorporating Levy flight is proposed to elucidate the microgrid test system's CEED problem.
- (ii) An improved mayfly optimization algorithm is proposed in addition to Levy flight to overcome the CEED problem encountered in microgrid test system.
- (iii) Levy flight has been leveraged in this study since it possesses huge advantages in not engaging local optimal. An optimal trade-off is provided by the proposed algorithm between exploration and exploitation phases.
- (iv) The authors validated the supremacy of the proposed algorithm in terms of resolving the CEED problem under two different objective functions that involve advanced energy sources.
- (v) Compared with existing population-based optimization tools such as PSO and GA, only a few control parameters exist in IMA. This feature helps in making it the best optimization procedure. IMA-based CEED was authenticated as a unique and robust technique since it incurred less total generation cost than the solution even after conducting multiple random trials.

## 2. Mathematical Formulation of CEED for Microgrid

*2.1. Combined Economic Emission Dispatch (CEED).* The simultaneous mitigation of economic and environmental dispatch objective functions remains the primary objective for the CEED problem in the microgrid. In other terms, the total fuel cost must be reduced, while at the same time the emission levels should also be mitigated without compromising the constraints. So, it is suggested to formulate CEED as a single optimization problem as given herewith [9].

$$\min \text{TC} = \sum_{i=1}^{\text{NG}} \{F_i(P_{Gi}), E_i(P_{Gi})\}. \quad (1)$$

Here, TC denotes the total operating cost that should be minimized. The fuel cost of the  $i^{\text{th}}$  generator is represented as  $F_i(P_{Gi})$ , the emission level of the  $i^{\text{th}}$  generator is represented as  $E_i(P_{Gi})$ ,  $P_{Gi}$  denotes the  $i^{\text{th}}$  generating unit's output power, and finally, NG corresponds to the whole generating unit count.

**2.1.1. Minimization of Fuel Cost.** In general, the fuel cost function is denoted through the quadratic equation given below [9]:

$$F_t = \sum_{i=1}^{NG} F_i(P_{Gi}) = \sum_{i=1}^{NG} (x_i + y_i P_{Gi} + z_i P_{Gi}^2). \quad (2)$$

Here,  $F_t$  corresponds to overall fuel cost incurred in terms of \$ and  $x_i$  (\$/h),  $y_i$  (\$/MWh), and  $z_i$  (\$/MW<sup>2</sup>h) correspond to the cost coefficients of  $i^{\text{th}}$  generating unit.

**2.1.2. Minimization of Emission.** When fossil fuels are used, the generators emit different sorts of pollutants. So, pollution mitigation forms the primary goal of most power system operations. Equation (3) denotes the expression for total emission from [5, 9]:

$$E_t = \sum_{i=1}^{NG} E_i(P_{Gi}) = \sum_{i=1}^{NG} (\alpha_i + \beta_i P_{Gi} + \gamma_i P_{Gi}^2). \quad (3)$$

Here,  $E_t$  denotes the overall emission and  $\alpha_i$  (kg/h),  $\beta_i$  (kg/(MWh)),  $\gamma_i$  (kg/(MW<sup>2</sup>h)) correspond to the  $i^{\text{th}}$  generating unit's emission coefficients.

**2.1.3. Total Generation Cost of CEED Problem.** It is possible to convert the dual-objective optimization problem, focusing emission, and fuel cost, into a single-objective optimization problem with the induction of PPF (price penalty factor) as given earlier [9]:

$$\text{minTC} = F_t + \Lambda \times E_t. \quad (4)$$

Here,  $\Lambda$  denotes the price penalty factor (PPF), which is calculated as a ratio between fuel cost and the emission of the corresponding generating unit (\$/kg). PPFs are of different types, while in the current study, the authors use min-max types sourced from [5, 9] for comparison. Following is the equation for min-max type [9]:

$$\Lambda_i = \frac{F_t(P_{Gi}^{\min})}{E_t(P_{Gi}^{\max})}, \quad i = 1, 2, \dots, NG, \quad (5)$$

where  $P_{Gi}^{\max}$  and  $P_{Gi}^{\min}$  Here,  $\Lambda$  denotes the ratio between maximum fuel cost and maximum emission of the corresponding generator in \$/kg [9]. The maximum and minimum output power of the generator combines emission with fuel cost. Afterwards, TC corresponds to the total operating cost of \$.

The following is the list of steps to be followed to determine the price penalty factor for a specific load demand [39].

- (i) The ratio between minimum fuel cost and the maximum emission of every generating unit should be determined.
- (ii) Price Penalty Factor values are sorted out in ascending order.

(iii) The maximum capacity of every unit ( $P_{Gi}^{\max}$ ) one is added at a time that starts from the lowest  $\Lambda_i$ , until  $\sum P_{Gi}^{\max} \geq P_D$ .

(iv) Then,  $\Lambda_i$ , which has an association with the lowest unit in this process, remains the tentative PPF value ( $\Lambda$ ) for the load under consideration.

So, a modified PPF ( $\Lambda$ ) is utilized to arrive at the exact value for specific load demand based on the interpolation of  $\Lambda$  values corresponding to their load demand values.

**2.2. Cost Functions of Renewable Energy Sources.** Across the globe, renewable energy sources are the foremost choice of transmission when energy is produced, compared to traditional generators. In such a scenario, solar and wind power can be denoted as negative loads and can be used to mitigate the total load demand in the system [9]. However, the economic dispatch solution is considered a base to distribute the rest of the load demands on traditional generators. In the current study, the CEED solution for the microgrid takes cost functions of wind and solar-powered generating units into account. From [9], the input data for cost and emission coefficients are considered.

**2.2.1. Cost Function of Wind Power Generating Unit.** Current economic analysis is conducted for wind-based power generation and the specific cost can be determined with inputs, operation, maintenance, and equipment costs. This cost function is expressed as per [5, 9]:

$$C_w(P_w) = \left( \frac{r}{[1 - (1 + r)^{-N}]^P} + O^E \right) P_w. \quad (6)$$

Here,  $P_w$  denotes the wind power produced in terms of kW,  $r$  corresponds to the interest rate,  $a$  denotes the Annuitization coefficient,  $N$  corresponds to lifetime investment in terms of years, and  $l^P$  and  $O^E$  correspond to the costs incurred upon investment per unit installed power (\$/kW) and operating and maintenance costs per unit installed power (\$/kW), respectively.

The 24-hour data for the wind power generating unit is considered from [5]. The parameters required for wind power cost function are chosen from [5, 9].

**2.2.2. Cost Function of Solar Power Generating Unit.** Similar to wind power, solar-powered generating unit's cost function is expressed as in [5, 9]:

$$C_s(P_s) = \left( \frac{r}{[1 - (1 + r)^{-N}]^P} + O^E \right) P_s, \quad (7)$$

where  $P_s$  is the output power from the solar-powered generating unit,  $r$  corresponds to interest rate,  $N$  denotes lifetime investment in terms of years, and  $l^P$  and  $O^E$  correspond to investment costs made upon per unit installed power (\$/kW) and operating and maintenance costs per unit installed power (\$/kW), respectively.

The 24-hour data of the solar power generating unit is considered [5]. The parameters required for solar power cost function are chosen from [5, 9].

$$C_T = F_t + \Lambda \times E_t + \left( \frac{r}{[1 - (1 + r)^{-N}]^P} + O^E \right) P_w + \left( \frac{r}{[1 - (1 + r)^{-N}]^P} + O^E \right) P_s. \quad (8)$$

**2.4. Constraints.** The researcher considered both generator capacity and power balance constraints to contrast with existing optimization algorithms.

**2.4.1. Islanded Mode of Microgrid.** The current study considered islanded mode microgrid to compare with the optimization results achieved in [5, 9]. There is no trade-off for the power between the main grid and the microgrid in this mode. So, the microgrid needs to fulfil the local or confined community load demands.

**2.4.2. Power Balance Constraint.** The load demand must be equal to that of the total power generation [9].

$$\sum_{i=1}^{NG} P_{Gi} + P_w + P_s = P_D. \quad (9)$$

Here,  $P_D$  corresponds to the total load demand.

**2.4.3. Generation Capacity Constraints.** Every generating unit's output power gets flanked by both lower and upper bounds [9].

$$P_{Gi}^{\min} \leq P_{Gi} \leq P_{Gi}^{\max}. \quad (10)$$

Here,  $P_{Gi}^{\min}$  and  $P_{Gi}^{\max}$  correspond to the minimum and maximum output powers of the  $i^{\text{th}}$  generating unit correspondingly.

### 3. Improved Mayfly Algorithm

Mayfly algorithm takes its inspiration from the social behaviour of mayflies, especially how they mate with each other [38]. It is assumed that mayflies are instantly considered adults as soon as the eggs are hatched. Leaving beside the period of their life, only the fittest mayflies tend to survive. Each mayfly has a position in search space that corresponds to a solution that overcomes the problem. RAND functions are utilized in conventional mayfly algorithm to produce novel variables that lead to local optimal. To increase MA's searching ability and create an optimal solution, the researchers integrated MA with Levy flight. If a Levy flight-based approach is utilized for system identification, it achieves rapid convergence and does not entail derivative information [40], attributed to stochastic random search, in line with the Levy flight concept [41]. Levy flight contributes heavily to increasing the optimal solution's local

**2.3. Total Cost of CEED for Microgrid.** The equation for the total CEED cost for the microgrid is shown below. This value gets minimized based on the cost functions regarding wind and solar power [9].

search avoidance and local trapping [42]. The flowchart of the proposed IMA algorithm is shown in Figure 1.

The steps required for the proposed mayfly optimization algorithm works are described as follows:

**Step 1.** Two mayfly sets, each representing a male and a female population, should be generated randomly. Then, every mayfly is arbitrarily placed in problem space as a candidate solution which is denoted by a  $d$ -dimensional vector  $P_{Gi} = (P_{G1}, \dots, P_{Gd})$ . Then the performance is assessed based on the predefined objective function  $f(C_T(P_{Gi}))$ .

**Step 2.** A mayfly's velocity  $\mathbf{v} = (v_1, \dots, v_d)$  is initialized through its positional change. Its direction is decided as a hybrid interaction between individuals and the social flying experiences. To be specific, every mayfly tends to alter its trajectory in alignment with its personal best position (pbest) so far. It also alters based on the best position achieved by any other mayfly present in the swarm so far (gbest).

**Step 3.** The population of the male mayflies is initialized as  $P_{Gmi}$  ( $i = 1, 2, \dots, NG$ ) with velocities  $v_{mi}$ . The male mayflies, gathered in swarms, denote that the position of every mayfly gets altered in alignment with its individual's experience and that of the neighbor's.  $P_{Gi}^t$  is assumed to be the current position of mayfly  $i$  in search space at time step  $t$  and the position gets altered with the addition of velocity  $v_i^{t+1}$ , to the current position. This notation is formulated as given herewith.

$$P_{Gmi}^{t+1} = P_{Gmi}^t + v_i^{t+1}. \quad (11)$$

Male mayflies are considered as present a few meters above the water, with  $P_{Gim}^0 U(P_{Gmmin}, P_{Gmmax})$ , performing nuptial dance. It can be assumed that these mayflies lack great speeds due to constant movements. This results in the calculation of a male mayfly's velocity  $i$  as follows [38]:

$$v_{ij}^{t+1} = g * v_{ij}^t + a_1 e^{-\beta r_p^2} (pbest_{ij} - P_{Gmij}^t) + a_2 e^{-\beta r_g^2} (gbest_j - P_{Gmij}^t). \quad (12)$$

Here,  $v_{ij}^t$  corresponds to mayfly  $i$ 's velocity in dimension  $j = 1, \dots, n$  at time step  $t$ ,  $P_{Gmij}^t$  denotes the mayfly's  $i^{\text{th}}$  position in dimension  $j$  at time step  $t$ ,  $a_1$  and  $a_1$  correspond to positive attraction constants utilized in scaling up the contribution of cognitive and social components,

FIGURE 1: Flowchart of the proposed improved mayfly optimization algorithm.

respectively. Furthermore,  $\text{pbest}_i$  denotes the mayfly  $i^{\text{th}}$  best position which it had ever visited. Based on the minimization problems under consideration, the personal best position  $\text{pbest}_{ij}$  at the next time step  $t + 1$  is determined as given herewith.

$$\text{pbest}_i = \begin{cases} P_{\text{Gmi}}^{t+1}, & \text{iff } (P_{\text{Gmi}}^{t+1}) < f(\text{pbest}_i) \\ \text{is kept the same,} & \text{otherwise} \end{cases} \quad (13)$$

Following is the equation for the global best position  $\text{gbest}$  at time step  $t$ .

$$\begin{aligned} \text{gbest} &= \{ \text{pbest}_1, \text{pbest}_2, \dots, \text{pbest}_N, |f(\text{cbest}) \}, \\ &= \min \{ f(\text{pbest}_1), f(\text{pbest}_2), \dots, f(\text{pbest}_{\text{NG}}) \}. \end{aligned} \quad (14)$$

Here  $\beta$  represents the fixed visibility coefficient used in (7). It is utilized to confine the visibility of the mayfly to others. Further,  $r_p$  denotes the Cartesian distance between  $P_{\text{Gi}}$  and  $\text{pbest}_i$  and  $r_g$  corresponds to the Cartesian distance between  $P_{\text{Gi}}$  and  $\text{gbest}$ . Following is the equation used to determine these distances.

$$\|P_{\text{Gmi}} - X_i\| = \sqrt{\sum_{j=1}^n (P_{\text{Gmij}} - X_{ij})^2}, \quad (15)$$

where  $P_{\text{Gmij}}$  corresponds to the  $j^{\text{th}}$  element of mayfly  $i$  and  $X_i$  denotes the  $\text{pbest}_i$  or  $\text{gbest}$ . If the algorithm needs to function appropriately, then the best mayflies present in the swarm must continuously perform the up-and-down nuptial dance. So, the velocity of these best mayflies must be kept on changing which is calculated as follows [38]:

$$v_{ij}^{t+1} = v_{ij}^t + d \times r. \quad (16)$$

Here,  $d$  denotes the coefficient of nuptial dance whereas the random value in the range of  $[-1, 1]$  is denoted by  $r$ .

*Step 4.* In this step, the female mayfly population is initialized  $P_{\text{Gfi}} (i = 1, 2, \dots, \text{NG})$  with velocities  $v_{fi}$ . Female mayflies tend not to gather as a swarm alike males. Instead, it tends to fly towards its male counterparts for mating.  $P_{\text{Gfi}}^t$  is assumed as the current position of female mayfly  $i$  in search space at time step  $t$ , while its position gets altered with the addition of velocity  $v_i^{t+1}$  to the current position, i.e.,

$$P_{\text{Gfi}}^{t+1} = P_{\text{Gfi}}^t + v_i^{t+1}. \quad (17)$$

Here, due to  $P_{\text{Gfi}}^0 U(P_{\text{Gfmin}}, P_{\text{Gfmax}})$  one cannot randomize the attraction process. So, the model is decided to be a deterministic process. As a result, their velocities are determined as given herewith in the presence of minimization problems [38].

$$v_{ij}^{t+1} = \begin{cases} g * v_{ij}^t + a_2 e^{-\beta r_{\text{mf}}} (P_{\text{Gmij}}^t - P_{\text{Gfi}}^t), & \text{if } f(P_{\text{Gfi}}) > f(P_{\text{Gmi}}), \\ g * v_{ij}^t + fl \times r, & \text{if } f(P_{\text{Gfi}}) \leq f(P_{\text{Gmi}}). \end{cases} \quad (18)$$

Here,  $v_{ij}^t$  corresponds to the female mayfly's velocity  $i$  in dimension  $j = 1, \dots, n$  at time step  $t$ ,  $P_{\text{Gfij}}^t$  denotes the female mayfly  $i$ 's position in dimension  $j$  at time step  $t$ , and  $a_2$  denotes the positive attraction constant whereas it remains a fixed visibility coefficient. Further, the gravity coefficient is denoted by  $g$ , and  $r_{\text{mf}}$  corresponds to the Cartesian distance between male and female mayflies. Here  $fl$  corresponds to a random walk coefficient and  $r$  denotes the random value in the range of  $[-1, 1]$ . This value is determined based on (15).

*Step 5.* In this step, the Levy flight approach is involved in calculating the velocity of a mayfly candidate solution. Equation (19) is used to determine the velocity of the mayfly candidate solution [38].

$$v_{ij}^{t+1} = \begin{cases} V_{\max}, & \text{if } v_{ij}^{t+1} > V_{\max}, \\ -V_{\max}, & \text{if } v_{ij}^{t+1} < -V_{\max}. \end{cases} \quad (19)$$

This stage uses the Levy flight approach to alter the position of the global finest component. Though the Levy flight method has been used for exploration purposes so far, it is associated with a specific search.

Here,  $V_{\max}$  is calculated as follows:

$$V_{\max} = \text{Levy}(\lambda) * (P_{G\max} - P_{G\min}). \quad (20)$$

Here,  $\delta$  corresponds to a scale factor designed in alignment with the search space element. The author fixed  $\delta$  as 1.

$$\text{Levy}(\lambda) = 0.01 \frac{r_5 \sigma}{|r_6|^{1/\beta}} \quad (21)$$

Further,  $\sigma$  is calculated as follows [42]:

$$\sigma = \left[ \frac{\Gamma(1 + \lambda) \sin(\pi(\lambda/2))}{\Gamma((1 + \lambda)/2) \lambda [2^{(\lambda-1)/2}]} \right]^{1/\lambda}. \quad (22)$$

Here,  $\Gamma(x) = (x-1)!$ ,  $r_5$  corresponds to  $r_6$  indiscriminate numbers that lie in the range of [0, 1], and  $1 < \beta \leq 2$ , where there is a constant value, i.e., 1.5 incorporated for  $\beta$  in the current study [40–42].

$\text{Levy}(\lambda)$  denotes the step length, incorporated by Levy distribution with infinite variance and mean values with  $1 < \lambda < 3$ .  $\lambda$  corresponds to the distribution factor, whereas the gamma distribution function is denoted by  $\Gamma(\cdot)$ .

*Step 6.* Gravity coefficient value calculation [38]:

Gravity coefficient  $g$  value can be considered a fixed number that lies in (0, 1].

$$g = g_{\max} - \frac{g_{\max} - g_{\min}}{\text{iter}_{\max}} \times \text{iter}, \quad (23)$$

where  $g_{\max}$ ,  $g_{\min}$  correspond to maximum and minimum values which can be taken for the gravity coefficient, and  $\text{iter}$  denotes the algorithm's current iteration, whereas the maximum count of iterations is denoted by  $\text{iter}_{\max}$ .

*Step 7.* Mayflies are mated and the offspring are evaluated.

The mating process between the mayflies is discussed by the crossover operator as given herewith. From the male and female population, each one parent is selected through the same selection process, i.e., the attraction of females towards the males. Specifically, fitness function-based or random selection of the parents can be made. In terms of the fitness function, the best female mates with the best male, the second-best female with the second-best male, etc. This crossover results in two offsprings for which the formulation is given herewith [38]:

$$\begin{aligned} \text{offspring1} &= L \times \text{male} + (1 - L) \times \text{female}, \\ \text{offspring2} &= L \times \text{female} + (1 - L) \times \text{male}. \end{aligned} \quad (24)$$

Here, *male* denotes the male parent, and female corresponds to the female parent, while  $L$  is a random value within a specific range. The initial velocity of the offspring is fixed as zero.

*3.1. The Pseudocode of the Improved Mayfly Algorithm.* The pseudocode of the improved mayfly algorithm is devised as follows:

- (1) Formulate the objective function  $f(C_T(P_{Gi}))$ ,  $P_{Gi} = (P_{Gi1}, \dots, P_{Gid})^T$
- (2) Set the male mayfly population  $P_{Gmi}$  ( $i = 1, 2, \dots, NG$ ) and velocities  $v_{mi}$
- (3) Set the female mayfly population  $P_{Gfi}$  ( $i = 1, 2, \dots, NG$ ) and velocities  $v_{fi}$
- (4) Evaluate solutions
- (5) Determine global best gbest
- (6) Do While stopping criteria are not meet
- (7) Update velocities and solutions of males and females
- (8) Evaluate solutions
- (9) Rank the mayflies
- (10) Apply Levy flight approach to evaluate the velocity of a mayfly candidate solution
- (11) Determine the value of the gravity coefficient
- (12) Mate the mayflies
- (13) Evaluate offspring
- (14) Separate offspring to male and female randomly
- (15) Reinststate worst solutions with the best new ones
- (16) Update pbest and gbest
- (17) End While
- (18) Post-process results and visualization

## 4. Results and Discussion

The current study used a microgrid model with three conventional generators, solar, and wind units. One of the generators is a combined heat and power generator, whereas the other two conventional generators are synchronous. As per [9], three conventional generators and their daily load profile details were used in the current study. During the improved mayfly optimization algorithm implementation, various parameters were chosen for the optimal search process.

In order to assess the proposed IMA, various scenarios were considered as given herewith.

- (i) All sources included
- (ii) Thermal power generating units without renewable sources
- (iii) Thermal power generating units with wind source only
- (iv) Thermal power generating units with solar source only

*4.1. Case 1: All Sources Included.* In the first case, the proposed IMO was utilized in the elucidation of the CEED problem in the microgrid and the case considered both wind and solar energy-powered generators. The optimization results were obtained using the proposed IMA and contrasted with the results obtained from other optimization algorithms. The generation cost calculated by the proposed IMA and other published methods is shown in Table 1 for comparative purposes. Figure 2 shows the convergence characteristics required to mitigate the total generation cost incurred from MA and IMA algorithms. As shown in Figure 2, when cross-verifying the proposed algorithm's cost convergence characteristic, a quicker and more smooth transition was obtained than other optimization techniques considered. Further, Figure 3 shows the comparison results of total generation cost saving from CEED problem when using the mayfly algorithm and other such optimization algorithms. The results achieved from the simulation reveal that the proposed IMA is superior to MA and other optimization algorithms. Moreover, the total generation cost obtained using the proposed IMA algorithm was less than other optimization algorithms. In Figure 4, the total generation cost was obtained using IMA with MA and other published algorithms. It is observed from Figure 4 that improved mayfly optimization algorithm enhanced the total generation cost by 19.68%, 14.37%, 3.08%, 3.05%, 2.17%,

1.88%, 0.94%, and 0.23% over RGM, ACO, CSA, ISA, HIS, IAHS, MHS, and MA, respectively.

*4.2. Case 2: Thermal Power Generating Units without Renewable Sources.* In this case, the mayfly optimization algorithm was utilized to resolve the CEED problem in the microgrid. The case took a total of 3 fossil-fuel-powered thermal generation units under consideration. The optimization results achieved by IMA were contrasted with other such algorithm results. Table 2 shows the total generation cost achieved by the proposed IMA and other such optimization algorithms. The cost convergence profile results are shown in Figure 5 for the proposed IMA and other optimization algorithms. From the results, it can be understood that IMA has promptly converged to the optimal outcome. The comparison results of total generation cost savings are shown in Figure 6 for the CEED problem when using IMA. It shows that IMA achieved better results than MA and other optimization algorithms. The comparison of total generation cost savings obtained using MA and other published algorithms is presented in Figure 7. Figure 7 infers that the total generation cost improved when using the IMA algorithm by 18.52%, 14.67%, 2.93%, 3.3%, 3.27%, 1.32%, and 0.94% over RGM ACO, CSA, ISA, MHS, and MA, respectively. Furthermore, the total generation cost obtained

FIGURE 2: Convergence characteristics for total generation cost (case I).

FIGURE 3: Comparison of total generation cost for case 1.

in case 1 can be less than in case 2 due to incorporating renewable energy sources in a microgrid.

4.3. Case 3: Thermal Power Generating Units with Wind Sources Only. Improved mayfly optimization algorithm was deployed in this case to resolve the CEED problem found in microgrids. This case considered fossil-fuel-powered thermal generators in addition to wind sources. IMA and other models (MA, IHS, CSA, and ISA algorithms) were simulated, and the results were compared. Table 3 shows the generation cost calculated for IMA and other such

optimization algorithms. In Figure 8, the author shows the cost convergence characteristic for the optimization algorithms under comparison and the proposed IMA.

Further, Figure 8 also provides an inference; i.e., the convergence characteristic of the proposed LISA strategy II was smooth and quick compared to other strategies. In Figure 9, the researcher compared the total cost saving of IMA and other optimization algorithms from the CEED problem. It is observed from the application results that IMA yielded less total generation cost compared to MA, IHS, CSA, and ISA algorithms. Figure 10 shows the comparison results of operation cost savings obtained using IMA and

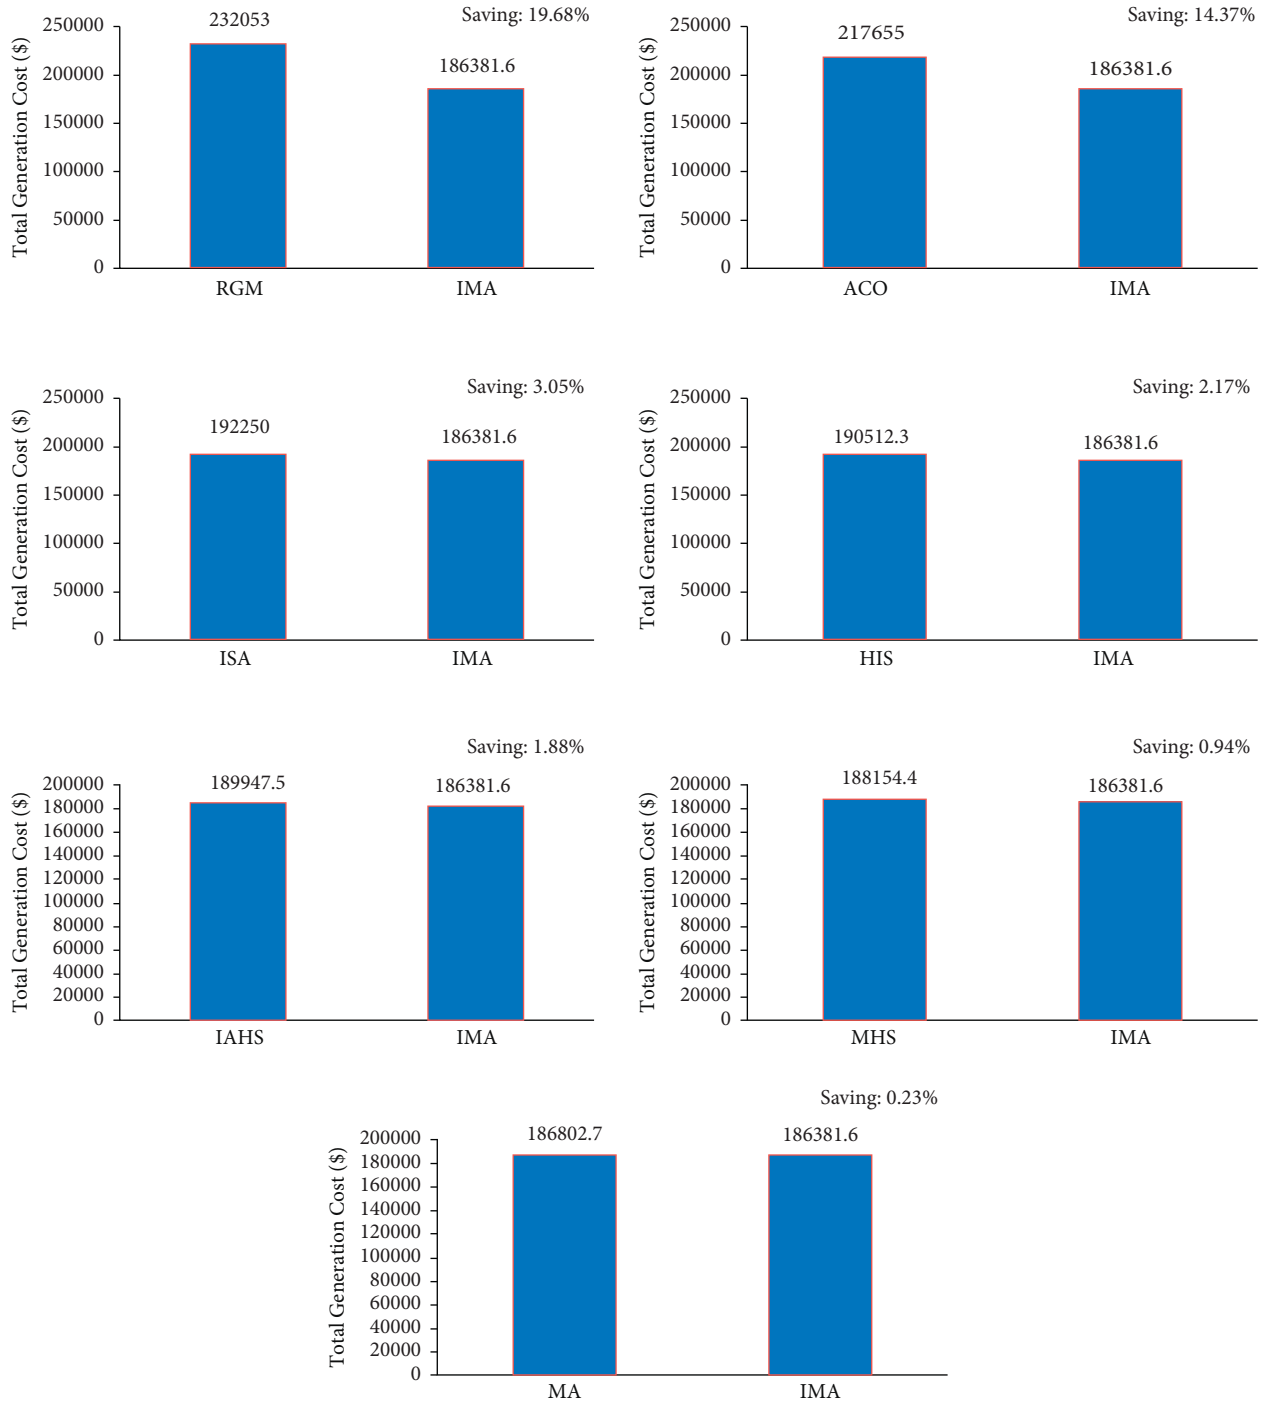

FIGURE 4: Total generation cost saving of CEED problem for case 1.

other published algorithms. It is observed from Figure 10 that IMA improved the operation cost by 3.66%, 3.64%, 1.6%, and 0.55% over CSA, ISA, MHS, and MA, respectively. Further, the total generation cost obtained in this case remains lower than in case 2 because of integrating a wind-powered energy source with the microgrid.

4.4. Case 4: Thermal Power Generating Units with Solar Source Only. The case scenario considered fossil-fuel-powered thermal generating units with solar sources. In this scenario, improved mayfly optimization algorithm was selected to resolve the CEED problem found in microgrids. Simulation results obtained using an improved mayfly optimization

algorithm are compared with the outcomes attained by MA and other such algorithms. The total generation cost of the improved mayfly optimization algorithm and other optimization algorithms is presented in Table 4. Figure 11 represents the convergence characteristics obtained to minimize total generation cost using MA and IMA. From Figure 11, it is concluded that the proposed IMA provides steady and quick convergence characteristics. Figure 12 show the comparison results of total generation cost saving achieved by IMA and other optimization algorithms for CEED problem found in microgrids. It is observed from the optimization results that an improved mayfly algorithm provides less total generation cost than other optimization techniques. Figure 13 shows the optimization results of total generation cost saving obtained using IMA and other published metaheuristic optimization algorithms. Figure 13 infers that the proposed IMA algorithm enhanced the total generation cost by 18.5%, 14.7%, 3.44%, 3.41%, 1.43%, and 0.41% over RGM, ACO, CSA, ISA, MHS, and MA, respectively. The authors also conclude that the total generation cost is less in this scenario than in case 2 because of the

incorporation of solar-powered energy sources with the microgrid.

*4.5. Comparison between the Cost Curves of All Scenarios.* Figures 14 and 15 show the comparison results of total generation cost curves under all the scenarios compared to IMA and MA algorithms 24 hours a day. Furthermore, Figure 16 shows the quantitative comparative results of total cost under all the scenarios using IMA. One can notice from Figures 14–16 that case 1 provides a minimum generation cost compared to other scenarios. Also, it can be observed from case 2 that the highest generation cost is obtained in this case. This might be attributed to the reason that renewable energy sources function as negative loads, while the rest are provided by the fossil-fuel-powered thermal generating units only. It reduces the total generation cost. Furthermore, the total generation cost obtained was less in case 3 than in case 4. It could have occurred due to heavy investment costs incurred upon solar power compared to wind power.

## 5. Conclusion

In the current study, the improved mayfly optimization algorithm (IMA) has been implemented to resolve the combined economic emission dispatch (CEED) with renewable energy sources. The study incorporated the proposed IMA as a solution for the CEED problem encountered in the microgrid. Solar and wind power are considered as the cost functions in this study. The proposed IMA algorithm was validated for its supremacy and efficiency in a microgrid model under varying scenarios. The outcomes of IMA and other algorithms were compared and contrasted. The comparison results show that the proposed IMA algorithm is better in cost reduction under all the scenarios. This infers that the proposed IMA is superior, robust, and efficient over other metaheuristic optimization algorithms published earlier. In future, the improved mayfly optimization algorithm can be applied to tackle the CEED problem in grid-connected microgrids comprising battery storage and electric vehicles to accomplish single and multiobjective optimization.

## Nomenclature

### List of Symbols

$a$ :	Annuity coefficient
$C_w$ :	Cost of wind power generating unit
$C_s$ :	Cost of solar-powered generating unit
$d$ :	Coefficient of nuptial dance
$E_i(P_{Gi})$ :	Emission level of the $i^{\text{th}}$ generator
$E_t$ :	Overall emission
$fl$ :	Random walk coefficient
$F_i(P_{Gi})$ :	Fuel cost of the $i^{\text{th}}$ generator

$F_t$ :	Overall fuel cost incurred
$g$ :	Gravity coefficient
gbest:	Global best
iter:	Current iteration
iter <sub>max</sub> :	Maximum no. of iterations
$L$ :	Random number
$l^p$ :	Costs incurred upon investment per unit installed power
$N$ :	Lifetime investment
NG:	No. of generating units
$O^E$ :	Operating and maintenance costs per unit installed power
pbest:	Personal best
$P_{Gi}^{\text{max}}$ :	Maximum output power of generator $i$
$P_{Gi}^{\text{min}}$ :	Minimum output power of generator $i$
$P_D$ :	Total load demand
$P_{Gi}$ , $P_{Gmi}$ , $P_{Gfi}$ :	Power output of $i^{\text{th}}$ generating unit
$P_s$ :	Output power from solar-powered generating unit
$P_w$ :	Output power from wind power generating unit
$r$ :	Interest rate
$r_p$ :	Cartesian distance between $x_i$ and pbest,
$r_g$ :	Cartesian distance between $x_i$ and gbest
$r_{mf}$ :	Cartesian distance between male and female mayflies
TC:	Total operating cost
$\beta$ :	Fixed visibility coefficient
$\Lambda$ :	Price penalty factor
$\Lambda_i$ :	Price penalty factor of $i^{\text{th}}$ generator
$\Delta$ :	Distribution factor
$\delta$ :	Scaling factor
$\Gamma(\cdot)$ :	Gamma distribution function
$\sigma$ :	Standard deviation.

## Abbreviations

BSDE:	Bernstein-search differential evolution
CEED:	Combined economic emission dispatch
ChOA:	Chimp optimization algorithm
CHP:	Combined heat and power
CHPED:	Combined heat and power economic dispatch
CNO:	Collective neurodynamic optimization
DCHPED:	Dynamic combined heat and power economic emission dispatch
DDG:	Dispatchable distributed generator
DE:	Differential evolution
DEED:	Dynamic economic emission dispatch
DSM:	Demand side management
ECED:	Environment constrained economic dispatch
EED:	Economic environmental dispatch
ELD:	Economic load dispatch
EMA:	Exchange market algorithm
FC:	Fuel cell
FCDED:	Fuel constrained dynamic economic dispatch
FP:	Fractional programming
GA:	Genetic algorithm
GWO:	Grey wolf optimizer
HFA/HS:	Hybrid Firefly and Harmony Search
IGWO:	Improved grey wolf optimizer
IMA:	Improved mayfly algorithm
ISA:	Interior search algorithm
LPSP:	Loss of probability of power supply
MA:	Mayfly algorithm
MAACPSO:	Modified adaptive accelerated particle swarm optimization
MBGSA:	Memory-based gravitational search algorithm
MG:	Microgrid
MILP:	Mixed-integer linear programming
MOVCS:	Multiobjective virus colony search
MT:	Microturbine
PPF:	Price penalty factor
PSO:	Particle swarm optimization
PV:	Photovoltaic

The evaluation of take-over performance and take-over safety performance is critical to improving the take-over performance of conditionally automated driving, and few studies have attempted to evaluate take-over safety performance. This study applied a binary logistic model to construct a take-over safety performance evaluation model. A take-over driving simulator was established, and a take-over simulation experiment was carried out. In the experiment, data were collected from 15 participants who took over the vehicle and performed emergency evasive maneuvers while performing non-driving-related task (NDRT). Then, to calibrate the abnormal trajectory, the Kalman filter is adopted to filter the disturbed vehicle positioning data and the belief rule-based (BRB) method is proposed to warn irregular driving behavior. The results revealed that the accident rate of male participants is higher than that of female participants in the three frequency take-over experiment, and the overall driving performance of female participants is higher than that of male participants. Meanwhile, medium and high take-over frequencies have a significant effect on the prevention of vehicle collisions. In the take-over safety performance evaluation model, the minimum time to collision (TTC) of 2.3 s is taken as the boundary between the dangerous group and the safety group, and the model prediction accuracy rate is 87.7%. In sum, this study enriches existing research on the safety performance evaluation of conditionally automated driving take-over and provides important implications for the design of driving simulators and the performance and safety evaluation of human-machine take-over.

## 1. Introduction

In recent years, with the strong promotion of communication technology, computer technology, vehicle sensor development, and vehicle positioning system, the research and development of automated driving technology have been continuously promoted. There has been an all-around development whether it is the research on perception, decision-making, control of automated driving vehicles, or the real vehicle test carried out with enterprises as the core. In February 2020, the “Smart Car Innovation Development Strategy” issued by the National Development and Reform Commission in conjunction with 11 departments [1] pointed out that by 2025, the technological innovation, infrastructure, regulations and standards, product

supervision, and network security system of China’s standard smart cars should be formed, and mass production of conditionally automated vehicles is carried out to realize the application of highly automated vehicles in related scenarios. However, at the current stage, there are still many problems to be solved in automated driving technology in terms of driver acceptance and driving safety.

A study on the acceptance of automated vehicles in Australia showed that although most respondents agree with the potential benefits of automated vehicles, they still have considerable concerns about automated vehicles [2]. Yuen et al. [3] used the innovation diffusion theory of perceived value and trust to establish a theoretical model, which identifies potential factors and tests their interrelationships, using a structural equation model to analyze the data obtained from the

questionnaire. The research results point out that the impact of innovation diffusion attributes on public acceptance is completely mediated by the public's perceived value of automated vehicles, and the impact of perceived value on public acceptance is regulated to a certain extent by the public's trust in automated vehicles. By extending the technology acceptance model (TAM) with social and personal factors, Zhang et al. [4] proposed the automated driving acceptance model, which aims to investigate the role of social and personal factors in the acceptance of automated vehicles. The results show that perception factors have a significant impact on user intentions in the initial stage of autonomous driving commercialization, and social influence and initial trust have the greatest impact on user acceptance. Haghzare et al. [5] showed that the older the elderly, the lower the acceptance, but the overall acceptance of automated driving for the elderly is very high.

Regarding the driving safety of automated vehicles, a research report issued by the Insurance Institute for Highway Safety (IIHS) in 2020 pointed out that in the analysis of the causes of the 5,000 major car accidents that occur in the United States each year, the automated vehicles can only reduce the accidents by 1/3. However, according to Tesla's safety report for the first quarter of 2021, Autopilot makes the car nearly nine times safer. After Autopilot turns on, an accident occurs every 6.74 million kilometers, which is 8.66 times lower than the national vehicle statistics. Wang et al. [6] evaluated the safety and effectiveness of 9 common and important automated driving technologies through meta-analysis and tested these technologies in 6 countries to conduct a comprehensive and quantitative assessment of the safety and effectiveness of automated driving technologies. The results show that if all the technologies were implemented in these six countries, an average of 3.4 million accidents can be reduced, of which India has the largest reduction (54.24%). Xiao et al. [7] studied the US cases based on meta-analysis, and it is estimated that intelligent and connected vehicles will reduce the number of fatal accidents by 5% and 13% in 2025 and 2035, respectively.

Currently, automated vehicles are in the transitional stage from L2 to L3. The main factors affecting the take-over performance of L3 automated vehicles are take-over requests (TOR), driver age, and NDRT. Yoon et al. [8] designed 7 types of automated vehicle take-over prompts with visual, auditory, tactile, and mixed sensations. The experimental results show that the take-over effect of driver is poor when there are only visual prompts, and the mixed auditory prompting method allows the driver to take over better. Chu et al. [9] pointed out that among the various possible ways to alert the driver about a TOR, vibrotactile alert provides a significant advantage.

In terms of studying the influence of driver age on take-over performance, the findings of Li et al. [10] show that compared with younger people, older people take over vehicles more slowly and unstable. Wu et al. [11] divided the experimenters into three groups according to their ages and performed non-driving task take-over experiments, and the take-over performance of older drivers was lower than that of younger drivers. However, both the elderly and the young have shown positive views on L3 automation, and the elderly are significantly more active than the young.

In terms of studying the impact of NDRT on take-over performance, Klingegrud et al. [12] designed a human-computer interaction platform to study the ability of drivers to perform NDRT in L4 driving automated vehicles in real traffic environments. NDRT is designed to have visual and cognitive requirements, and manual interaction is required. The results show that drivers can participate in NDRT to a large extent. Rauffet et al. [13] carried out a take-over experiment in a driving simulator where the non-driving task was playing video games. The ratio of browsing time in the game and the time between game sessions were used as indicators of game participation. The survey results showed that the participants were highly involved in NDRT, and the average take-over time was longer than if they were not engaged in NDRT. Ou et al. [14] designed experiments to allow drivers who are immersed in NDRT to detect TOR and quickly brake. The research results show that advanced predictive interfaces that provide directional information can significantly improve take-over performance.

When studying the take-over test of human-machine codriving, it is necessary to use a simulation platform to build relevant driving scenarios. Zhang and Zhu [15] used a longitudinal research design on a driving simulator based on Unity's complete cab to study the changes in driver state and behavior during multiple sessions of automated vehicle operation. Calvi et al. [16] use STISIM for driving scene simulation, plus a driving controller (wheels, pedals, and gears) connected to the workstation of the control system to convert it into a driving simulator. Experiments are conducted to study the behavior of the driver after the driver is inattentive and participating in secondary tasks during highly automated driving. Yoon and Ji's [17] driving simulator is based on the City Car software simulation scene, equipped with a real car seat, a Logitech racing force feedback wheel and pedal, and a 55-inch Samsung smart TV. In addition, an SMI eye tracker was used to collect the eye movement data of the participants.

In the research on the take-over performance of automated driving, Zhou et al. [18] proposed using eye tracking and self-report data to predict the situation perception during the transition of conditionally automated driving. The tree-integrated machine learning model light gradient boosting machine (LightGBM) is used to predict the situation perception. Then, the Shapley additive explanation (SHAP) value of the individual predictor variables in the model is calculated. The research on automated driving take-over performance is mainly based on objective data and selected relevant indicators for evaluation. In the study of Wiedemann et al. [19], the performance evaluation of the driver is divided into two parts: horizontal control and vertical control. The horizontal control index selects the vehicle lateral displacement and steering wheel angle, and the longitudinal control index selects the vehicle velocity. Du et al. [20] predicted the take-over performance of drivers before the TOR by analyzing physiological data such as driver's heart rate index, skin electrical response index, and eye-tracking index, and external environmental data such as scenario type, traffic density, and lead time of TOR. The study found that the random forest classifier can better

predict the driver's take-over behavior, using 3 s as the optimal time window for predicting take-over performance, with an accuracy rate of 84.3%.

In the human-machine codriving take-over experiment, the importance of take-over safety evaluation analysis cannot be ignored. Lin et al. [21] used binary logistic regression to establish a take-over safety evaluation model to evaluate the safety of L3 automated vehicles. The research results show that under the condition that the TOR time is 7 s, the main factors affecting the safety of take-over are the take-over response time and second tasks. The established take-over safety evaluation model has a prediction accuracy of 85.5%. As domestic automated driving is at an immature stage, there are relatively few studies on the safety evaluation of take-over.

Through the above research, it is found that the selection of driver behavior indicators in human-machine codriving is mainly the driver's visual characteristics and behavior characteristics. At the same time, the driving simulation platform can effectively reduce the cost of the experiment and ensure the safety of the experiment. Therefore, this article uses a driving simulator designed based on the CARLA driving simulation platform and Logitech G29 force feedback steering wheel pedal set to study the driver's take-over performance and its influencing factors when the driver performs the take-over operation under the L3 of automated driving (conditionally automated driving). Comparing the conditions of the same non-driving-related tasks and different take-over frequencies, the evaluation of the driver's take-over performance is completed by analyzing factors such as the average time to complete the tasks, the minimum TTC, the distance to obstacle, and the maximum braking acceleration. Combining the gender, age, temperament type, driving style, and other conditions of driver, this study studies the commonality and characteristics of automated driving take-over performance of different groups of people. Finally, the binary logistic model is applied to evaluate the safety of the test and find out the factors that affect the safety of the take-over.

## 2. Methodologies

### 2.1. Data Preprocessing Method

**2.1.1. Kalman Filter Method.** The Kalman filter is an efficient autoregressive filter, which can predict the dynamic state of the system in a series of incomplete and noisy measurement values. The Kalman filter can estimate the unknowns from the measured values at different times regarding their joint distribution, so the result obtained is more accurate than the prediction method based on only a single measured value. The Kalman filter is based on the state matrix, the localization data are the input of the filter, the system state prediction data are the output, and the prediction equation and the measurement equation are used to establish the relationship between input and output, which is a method of calculating the value of the system state with input and

output. The Kalman filter is composed of three parts: state prediction equation, state observation equation, and recursive equation. From  $k - 1$  to  $k$  moments, the calculation process is as follows.

The state prediction equation is as follows:

$$X_k = AX_{k-1} + B\mu_k + w_k, \quad (1)$$

where  $X_k$  represents the state vector of the system at time  $k$ ,  $A$  is the state transition matrix,  $B$  is the input gain matrix,  $w_k$  is the mean value of 0, and  $Q$  is the covariance matrix, and equation obeys the process noise of normal distribution.

The state observation equation is as follows:

$$Z_k = HX_k + v_k, \quad (2)$$

where  $Z_k$  represents the observation vector of the system at time  $k$ ,  $H$  is the measurement matrix,  $v_k$  is the mean value of 0, and  $R$  is the covariance matrix, and equation obeys the measurement noise of normal distribution.

The Kalman filter has three common kinematic models: constant velocity (CV) model, constant turn rate and acceleration model (CTRA), and constant acceleration (CA) model. Compared with the CA model, the calculation accuracy of CTRA model is improved slightly, but the calculation amount is increased significantly. Considering the calculation efficiency and accuracy comprehensively, the CA model is selected as the kinematic model of the Kalman filter in this study. Combined with the state prediction equation,  $X_k$  can be expressed as follows:

$$X_k = AX_{k-1} + w_k, \quad (3)$$

$X_k = [x_t, x'_t, x''_t, y_t, y'_t, y''_t]^T$ , where  $x_t, x'_t, x''_t$  represents the position, velocity, and acceleration of the system in the  $x$ -direction at time  $t$ , and  $y_t, y'_t, y''_t$  represents the position, velocity, and acceleration in the  $y$ -direction.

The recursive equation is as follows:

The linear estimate of the system at time  $k$  is predicted using the state value at time  $k - 1$ :

$$\hat{x}' = A\hat{x}_{k-1} + B\mu_k. \quad (4)$$

The new variance predicted by the error covariance and system noise  $Q$  at the last moment is as follows:

$$P'_k = AP_{k-1}A^T + Q. \quad (5)$$

The state correction process is as follows:

$$K_k = P'_k H^T (HP'_k H^T + R)^{-1}, \quad (6)$$

$$\hat{x}_k = \hat{x}'_k + K_k (Z_k - H\hat{x}'_k).$$

The state covariance estimates are updated:

$$P_k = (1 - K_k H)P'_k, \quad (7)$$

where  $\hat{x}_k$  is the Kalman estimation value,  $\hat{x}'$  is the prediction value,  $P_k$  is the Kalman estimation error covariance matrix,  $P'_k$  is the prediction error covariance matrix, and  $K_k$  is the Kalman gain.

**2.1.2. The Belief Rule-Based (BRB) Method.** The general expression form of the BRB method is as follows: if  $A_1^k \wedge A_2^k \wedge \dots \wedge A_T^k$ , then  $(C_1, \beta_{k1}), (C_2, \beta_{k2}), \dots, (C_N, \beta_{kN})$  with a rule weight  $\theta_k$  and attribute weights  $\delta_1, \dots, \delta_T$ ,  $\sum_{l=1}^N \beta_{kl} \leq 1$ , where  $A_1, \dots, A_T$  represents the premise attribute of the BRB,  $C_1, \dots, C_N$  represents the evaluation level of the evaluation result, and  $A_j^k \in \{C_{j1}, \dots, C_{jN}\}$  is an evaluation grade relative to the premise attribute  $A_j$ ,  $j \in \{1, \dots, N\}$ .  $\beta_{kl}$  is the confidence level of the result under the  $k$ th rule in the evaluation level  $C_l$ ,  $l \in \{1, \dots, N\}$ , and  $T_l$  is the total number of premise attributes under the  $k$ th rule. If  $\sum_{l=1}^N \beta_{kl} = 1$ , then the BRB is considered complete, otherwise it is incomplete. In this case, to establish a BRB, discrete evaluation levels such as high, medium, and low need to be defined for each premise attribute and result. Several types of parameters in the BRB system structures such as confidence, rule weights, and attribute weights can be obtained by training the collected sample data (velocity and acceleration). The sample data are shown in Table 1. The trained BRB system can now be used to predict the authenticity of the target.

**(1) BRB Input Conversion.** The input conversion of a premise attribute value refers to converting this value into different confidence levels and assigning these confidence levels to different reference values of the premise attribute. This is equivalent to converting an input value into a confidence distribution corresponding to the reference value of the premise attribute. In particular, the input value of a premise attribute  $P_i$  (its confidence level is set to  $x_i$ ) can be transformed by the following confidence distribution:

$$S(P_i, x_i) = \{(h_{in}, \alpha_{in}), n = 1, \dots, n_i\}, \quad i = 1, \dots, T_i, \quad (8)$$

where  $S$  represents the distribution of the estimated confidence level assigned to the input value of the premise attribute,  $h_{in}$  (the  $i$ th value) is the  $n$ -th reference value of the input premise attribute  $P_i$ , and  $\alpha_{in}$  ( $\alpha_{in} \geq 0$ ) is the confidence level corresponding to the reference value  $h_{in}$ . Among them,  $\sum_{n=1}^{n_i} \alpha_{in} \leq 1$  ( $i = 1, \dots, T_i$ ), where  $n_i$  is the quantity of the reference value.

In this study, the velocity and acceleration of the target point are selected as the premise attributes in the BRB framework. Their input values can be obtained from the radar data of the simulator, and the input values are converted into the membership degree of the corresponding premise attribute reference value. The reference values corresponding to velocity and acceleration are velocity (fast, normal, and low) and acceleration (high, medium, and low). At this point, these linguistic values (evaluation levels) can be assigned to the confidence level  $\alpha_{in}$  through expert evaluation, which is then distributed over the different reference values of the premise attributes  $h_{in}$  (high (H), medium (M), and low (L)) in terms of confidence level  $\alpha_{in}$ . The input conversion process of the above can be explained by formula.

High  $\geq x_i \geq$  Medium,

$$\begin{aligned} \text{Medium} &= \frac{\text{High} - x_i}{\text{High} - \text{Medium}}, \text{High} \\ &= (1 - \text{Medium}), \text{Low} = 0, \end{aligned} \quad (9)$$

$$\text{Medium} > x_i \geq \text{Low}, \text{Low} = \frac{\text{Medium} - x_i}{\text{Medium} - \text{Low}},$$

$$\text{Medium} = (1 - \text{Low}), \text{High} = 0.$$

Before the input conversion, the reference point value of the premise attribute needs to be set. Assume that the reference value distribution of the two premise attributes is as follows: velocity = {(fast, 41.7), (normal, 27.8), (low, 16.7)}; acceleration = {(high, 8), (medium, 5), (low, 3)}. Then, formula (9) is combined to complete the calculation of the confidence level  $\alpha_{in}$ . For example, a sample with velocity = 36.34 m/s and acceleration = 4.73 m/s<sup>2</sup> is selected, and then, the degree of velocity belonging to (fast, 41.7), (normal, 27.8), (low, 16.7) is (0.614, 0.386, 0). That is, medium = (41.7 - 36.34)/(41.7 - 27.8) = 0.386, high = 1 - 0.386 = 0.614, and low = 0. In the same way, the degree of acceleration belonging to (high, 8), (medium, 5), (low, 3) is (0, 0.865, 0.135).

**(2) Calculation of Activation Weight.** Generally, in the BRB, the connecting symbol “ $\wedge$ ” is usually applied to represent the logical relationship of the premise attribute. It means that only when all the premises in the rule are activated the results obtained at this time can be credible. According to the calculation of the above confidence distribution, the activation weight  $\omega_k$  under the  $k$ th rule can be calculated by the formula:

$$\begin{aligned} \omega_k &= \frac{\theta_k \prod_{i=1}^{T_k} (\alpha_{ik})^{\bar{\delta}_i}}{\sum_{l=1}^L \left[ \theta_l \prod_{i=1}^{T_l} (\alpha_{il})^{\bar{\delta}_i} \right]} \\ \bar{\delta}_i &= \frac{\delta_i}{\max_{i=1, \dots, T_k} \{\delta_i\}}. \end{aligned} \quad (10)$$

Among them,  $\alpha_{ik}$  ( $i = 1, \dots, T_k$ ) is the input confidence level of the  $i$ th premise attribute, representing the individual matching degree and evaluating the reference value  $A_i^k$  under the  $k$ th rule.  $\theta_k \prod_{i=1}^{T_k} (\alpha_{ik})^{\bar{\delta}_i}$  is the joint matching degree, which reflects the matching degree between the input value of the entire premise attribute and the reference value under the  $k$ th rule.  $\bar{\delta}_i$  (or  $\delta_i$ ) represents the attribute weight. It is worth noting that if  $\bar{\delta}_i = 0$ , then  $(\alpha_{ik})^{\bar{\delta}_i} = 1$ , which means that a premise attribute of zero importance will not have any effect on the activation weight; if  $\bar{\delta}_i = 1$ , then  $(\alpha_{ik})^{\bar{\delta}_i} = \alpha_{ik}^k$ , which means most of the premise attributes have a significant impact on the activation weight. With the calculation of the activation weights completed, the estimated output for a specific input vector can be inferred using ER theory.

TABLE 1: Experimental data sample.

Sample	1	2	3	4	5	6	7	8	9	10
Velocity (m/s)	36.21	36.34	36.63	37.04	37.59	38.48	39.44	40.66	41.88	43.13
Acceleration (m/s <sup>2</sup> )	4.86	4.73	4.88	4.61	4.69	4.77	4.94	4.83	4.66	4.72

(3) *ER Inference Output*. The ER theory is applied to collect all the premise attribute data groups under the  $L$  rule, to obtain the confidence level of each reference value in the result attribute through the given premise attribute  $P_i$  input value. This study adopts the analytical ER algorithm, and its output result is composed of the reference value of the result attribute, as shown in the following formula:

$$\beta_j = \frac{\prod_{k=1}^L (\omega_k \beta_{jk} + 1 - \omega_k \sum_{j=1}^N \beta_{jk}) - \prod_{k=1}^L (1 - \omega_k \sum_{j=1}^N \beta_{jk})}{\sum_{j=1}^N \prod_{k=1}^L (\omega_k \beta_{jk} + 1 - \omega_k \sum_{j=1}^N \beta_{jk}) - (N-1) \prod_{k=1}^L (1 - \omega_k \sum_{j=1}^N \beta_{jk}) - \prod_{k=1}^L (1 - \omega_k)} \quad (12)$$

The final merged result or the output expression obtained by ER inference is  $\{(C_1, \beta_1), \dots, (C_N, \beta_N)\}$ , where  $\beta_j$  is the final confidence level that belongs to the  $j$ th reference value  $C_j$  in the result attribute. The output distributions selected in this study are the real target and the false target, respectively. According to the sample data in Table 1, combined with formula (12), the final BRB after training is shown in Table 2.

The BRB in Table 2 describes the causal relationship between velocity and acceleration and the true target position. For example, rule 3 represents that the value of velocity is in the fast range and the value of acceleration is in the medium range at the current moment. The confidence level of the real target position and the false target position is 93.65% and 6.35%, and the confidence of this rule is 1. Therefore, the results obtained under this rule can be fully believed. The rest of the rules can be explained in the same way. Consequently, it has a certain degree of reliability to combine velocity and acceleration to test the trajectory of the target vehicle.

**2.2. Binary Logistic Regression Model.** In Natural Inheritance published in 1889, Francis Galton, a famous British biologist and statistician, first proposed that “The logistic regression model derived from the logistic curve are probabilistic regression, belonging to generalized linear regression.” The curve of the logistic function is a monotonously increasing function with no breakpoints but good continuity. The horizontal coordinate range (sample input range) of the curve is  $(-\infty, +\infty)$ , and the vertical coordinate ranges  $(0, 1)$ . The function distribution trend is exactly what many probability problems need to be or not. The derived logistic regression function, also known as the growth function, more often uses a binary dependent variable. The relationship between variables is used to make classification judgments on the prediction results.

The maximum-likelihood method is usually adopted for the estimation of logistic regression parameters. The basic

$$O(Y) = S(P_i) = \{(C_j, \beta_j), \quad j = 1, \dots, N\}, \quad (11)$$

where  $\beta_j$  represents the confidence level corresponding to a result reference value  $C_j$ . The calculation of  $\beta_j$  is obtained by the analysis formula (12) of the ER algorithm.

idea of the method is to establish the likelihood function and the logarithmic likelihood function first and then solve the parameter value corresponding to the maximum logarithmic likelihood function. The estimated value obtained is the called maximum-likelihood estimation of the parameter. It can be seen from formula (13) that the logistic model establishes the relationship between the probability of event occurrence and explanatory variables.

$$\ln \frac{p}{1-p} = \alpha + X\beta + \varepsilon, \quad (13)$$

where  $p$  is the probability of the event,  $\alpha = \begin{pmatrix} \alpha_1 \\ \alpha_2 \\ \vdots \\ \alpha_n \end{pmatrix}$  is the

intercept term of the model,  $\beta = \begin{pmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_n \end{pmatrix}$  is the parameter to

be estimated,  $X = \begin{pmatrix} x_{11} & x_{12} & \cdots & x_{1n} \\ x_{21} & x_{22} & \cdots & x_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ x_{n1} & x_{n2} & \cdots & x_{nk} \end{pmatrix}$  is the explana-

tory variable, and  $\varepsilon = \begin{pmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \vdots \\ \varepsilon_n \end{pmatrix}$  is the error term.

### 3. Data Collection and Analysis

#### 3.1. Experiment Design and Procedure

**3.1.1. Apparatus.** The driving simulator uses the CARLA driving simulation platform, 3ds Max, and Unreal 4 modeling software to construct virtual driving scenes, external Logitech G29 force feedback steering wheel pedal package, DXRacer car seat, two 40-inch screen 2K monitors, and one set of stereo, as shown in Figure 1. The Logitech G29 force feedback steering wheel pedal package includes a steering wheel, a manual gear, and a racing pedal with a clutch. The

FIGURE 1: Driving simulator.

steering wheel has a 900-degree steering range, which can simulate real driving behavior to the greatest extent. It also provides programmable keys and direction control keys. Two large-screen high-definition monitors serve as visual feedback devices to display virtual driving scenes. The stereos act as auditory feedback devices and take into account the Doppler effect to simulate real driving and environmental sound.

**3.1.2. Participants.** A total of fifteen participants with a valid driver's license were recruited for the driving simulator experiment. Nine participants were males, and six participants were females. The average age of the participants was 22.07 years (SD = 1.69 years). They had on average 2.27 years of driving experience (SD = 1.34 years). Before the experiment, the participants were required to tell their health conditions such as illness, fatigue, and drug misuse. After the experiment, monetary compensation (100 RMB) was offered for their participation.

The participants were required to take over for 1 time, 5 times, and 9 times, and the interval of each experiment was 3 minutes. The NDRT of the experiment was set to watch a video, which was playing on the tablet computer on the side of the control platform in the vehicle. The TOR time refers to the TTC between the self-vehicle and the vehicle or obstacle on the road ahead, which represents the urgency of the taking over. In this experiment, the TTC is 5 s, leaving enough time for the participants to react.

**3.1.3. Scenario Design.** The test road is the same two-way four-lane urban simulation road with a total length of about 5 km. The limitation of road velocity is 30 km/h, and the automated driving velocity is about 20–24 km/h. The test includes three different take-over frequencies (low take-over

frequency, medium take-over frequency, and high take-over frequency). The duration is 13 minutes, 16 minutes, and 18 minutes, respectively. This article mainly studies dangerous situations, the participant switches the automated driving mode to manual driving mode, takes over the vehicle, and bypasses obstacles or brakes. In this study, a simplified “ghost probe” driving scene was designed in the simulator. When the vehicle is driving to a certain position in the automated driving mode, a pedestrian crossing the road suddenly appears on the roadside ahead of the road. At this time, the vehicle take-over system will issue a TOR. The participant needs to take over and break the vehicle; otherwise, the vehicle will collide with a pedestrian in front of the vehicle and cause a traffic accident as shown in Figure 2.

$x_1$  is the lateral position where pedestrian appear,  $x_2$  is the lateral position of the vehicle head, and the vehicle is moving at a constant velocity. The upper and lower limits of the vehicle velocity  $v_{\diamond}$  are set as  $v_1$  and  $v_2$ , respectively,  $y$  is the longitudinal distance between the pedestrian and the vehicle, and  $l$  is the width of the vehicle. Pedestrians cross the road vertically at velocity  $v$ , and the vehicle collides with pedestrian without braking, and the parameters should meet:

$$\frac{x_1 - x_2}{v_2} > \frac{y + l}{v} > \frac{x_1 - x_2}{v_1}. \quad (14)$$

The pedestrian velocity ( $v$ ) in this study is set 2 m/s, the upper ( $v_1$ ) and lower ( $v_2$ ) limits of the velocity are 60 km/h and 20 km/h, the vehicle width ( $l$ ) is 2 m, and the longitudinal distance between the pedestrian and the vehicle ( $y$ ) is 1 m. Combining formula (14), comprehensively considering the time required for the participant to take over and operate, it is finally determined that the lateral distance between the vehicle and the pedestrian ( $x_1 - x_2$ ) is 16 m.

This study also assists the construction of dynamic and complex traffic scenes through logical reasoning and the use of vehicle kinematic models. For example, when a vehicle stops in front of a zebra crossing, blocking the sight of the following vehicle, the following vehicle changes lanes and overtakes the preceding vehicle and collides with the pedestrian walking on the zebra crossing, as shown in Figure 3.

**3.1.4. Procedure.** Before the experiment, participants were asked to sign an informed consent form and fill out a questionnaire. Then, the test personnel needed to introduce

FIGURE 2: Dangerous traffic scene.

FIGURE 3: Complex dangerous scene.

the test content such as the switching operation of the automated driving system, the scenes of emergency take-over, and non-driving-related tasks to the participants. In addition, about 10 minutes of practice time should be left for the participants. The practice content includes being familiar with the sensitivity of the steering wheel, accelerator, and brake pedal, being acquainted with the experimental road environment, and practicing switching of automated driving modes.

During the experiment, the vehicle was driving along the calibrated line in automated driving status. The participants always performed NDRT, looking at the tablet computer, with both hands relaxed on both sides of the body, and their right foot relaxed and not placed on the brake or accelerator pedal. When encountering an emergency take-over situation, the automated driving system issued the take-over prompt sound of “please take over” mixed with buzzer and human voice according to the set TOR time. At this time, the participant pressed the switch button on the steering wheel to switch to manual driving mode and bypassed the broken down vehicle or obstacle in front. After that, the participants drove the vehicle back to the middle lane as soon as possible and switched to the automated driving mode.

**3.1.5. Data Collection.** The data used in this article are collected by the warning assistance system supporting the CARLA driving simulation platform. The collected parameters include the lane departure, vehicle velocity, acceleration, heading angle, pitch angle, and tilt angle. The left and right data of the steering wheel, brake data, front-wheel angle data, throttle depth, handbrake status, and gear status of the driving simulator are shown in Table 3.

The throttle depth and brake depth are both represented by 0 or 1. The various statuses of gears are 1, 2, 3, and reverse (R). The handbrake status has two states: “Yes (Y)” and “No (N).”

**3.2. Data Preprocessing.** In Figure 4(a), the black line represents the actual displacement trajectory drawn according to the vehicle position information and the blue line represents the target trajectory drawn by the position information obtained by the GPS sensor. The red line indicates the GPS target trajectory filtered by the Kalman filter. X-direction position refers to the distance that the vehicle swings laterally, and y-direction position means the vertical swing distance of the vehicle during automated driving. It can be seen from the figure that due to the interference of noise, some position measurement values obtained by GPS have a comparatively larger slice offset than the actual value, but the Kalman filter effectively filters the interference of noise, making the filtered target trajectory becomes smoother and more closely to fit the actual displacement trajectory. The position deviation of each measurement point and the actual point filtered by the Kalman filter is shown in Figure 4(b), and the deviations fluctuate within 0–10 meters.

The result of using the BRB method to verify the velocity and acceleration of the vehicle is shown in Figure 5. It can be seen that the overall confidence level is maintained at a relatively high level before the 11th second but showed a significant downward trend after the 11th second. This is because the motion model of the vehicle in the simulation adopts the constant acceleration model. At the beginning of the simulation, the vehicle speed gradually exceeds the set

FIGURE 5: BRB verification confidence distribution.

range after driving for a short period of time. The BRB method judges that the simulated vehicle behavior is inconsistent with the conventional vehicle behavior and prompts that the vehicle is behaving abnormally at the 12th

second, so the confidence level continued to decrease. Overall, it is satisfactory that the target trajectory is effectively achieved by the verification of the simple kinematic model combined with the Kalman filter and the BRB method based on vehicle velocity and acceleration.

**3.3. Performance Evaluation.** In the low take-over frequency experiment, the vehicles driven by participants No.1, No.2, No.7, No.8, No.9, No.11, and No.14 on the driving simulator collided with obstacles, resulting the corresponding take-over failures. Therefore, in the descriptive statistics in Figures 6–9, the low-frequency take-over items do not have the data numbered above.

**3.3.1. Performance Evaluation Based on Experimental Parameters.** Figure 6 is a statistical histogram of the average time to complete take-over tasks of participants in the three experiments. It can be seen that as the frequency of take-overs increases, the average time for most participants to

FIGURE 6: Average time to complete take-over tasks in each experiment of all participants.

FIGURE 7: Average minimum TTC and change range in each experiment of all participants.

FIGURE 8: Average distance to obstacle in each experiment of all participants.

complete the tasks decreases. In the high-frequency take-over task, the participants performing the subtasks are more focused on completing the driving tasks, which are more efficient than the low-frequency and medium-frequency take-overs. However, there are a small number of participants who become cautious as the frequency of take-overs increases, resulting in a decrease in the efficiency of

completing tasks. For example, No. 3 and No. 5 participants are more relaxed under the low- and medium-frequency take-over intensity, and the complete efficiency of task is higher.

The minimum TTC reflects the risk acceptance level of participants during deceleration. The participants who crashed in the low-frequency experiments compare the

FIGURE 9: Average maximum braking acceleration in each experiment of all participants.

high-frequency data with the medium-frequency data, and other participants compare the high-frequency data with the low-frequency data. It can be seen from Figure 7 that the minimum TTC average value of all participants increases to varying degrees as the frequency of take-overs increases, which means that the risk awareness of participants has increased under the condition of increasing take-over frequency.

Due to the experiments excluding the minimum TTC data of the participants who collided in the low take-over frequency test, the variation range of some participants from low to medium take-over frequency is 0. It is not difficult to see that except for the participants who collided in the low take-over frequency, the minimum TTC change range of most participants from low to medium take-over frequency is significantly higher than the change range from medium to high take-over frequency. This shows that moderately increasing the take-over frequency can significantly improve the take-over effect of the participant, which is conducive to the concentration of participants. At the same time, the high take-over frequency does not significantly improve the participant's take-over performance compared with the medium take-over frequency.

The statistical results of the average distance to obstacle in the three experiments of all participants are shown in Figure 8. The driving style of each participant is different and there are differences between individuals, but with the increase in the take-over frequency, the average distance to obstacle of all participants increases to varying degrees. Among them, No. 8 and No. 14 increased significantly, which may be that the collision with obstacles in the low-frequency experiment makes them more focused on the take-over task in the high-frequency experiment. It shows that the increase in high frequency is more significant than that of low frequency. Therefore, it can be concluded that after the take-over frequency is increased from low to medium, the minimum TTC of the participant increases significantly, but if the take-over frequency continues to increase, the range of change is not obvious. In addition, there are high-frequency data of Nos. 2, 9, and 15 that have the same performance. Therefore, collisions cannot be used

as all the explanatory factors for the higher data in the participant's high-frequency experiment.

It can be seen from Figure 9 that the average maximum braking acceleration during the take-over process does not change regularly, which shows that the increase in the take-over frequency has little effect on the participant's braking behavior during the take-over process.

*3.3.2. Differentiated Performance Evaluation Based on Experimental Parameters.* Under the task of watching the video, the 5 s take-over request time can ensure the safety of take-over, but under the condition of low take-over frequency, 7 of 15 participants had a collision event, where 6 are males and 1 is female. The proportion of collision events among 9 males is 66.67%, while the proportion of 6 females is only 16.67%, and the total collision event rate is 46.67%. This shows that under the condition of low take-over frequency, even if the secondary tasks being performed by the participants and the take-over request time can ensure the safety of take-over, the probability of a collision event is still very high, and the participant is in a dangerous driving state. The collision probability of male participants is significantly higher than that of female participants under low take-over frequency, indicating that females have better risk awareness than males when performing take-over tasks. It can ensure the safety of the participant's take-over under the conditions of medium and high take-over frequency.

The average minimum TTC and the average distance to obstacles for male and female participants at three different frequencies (excluding collision data) are shown in Figure 10. It can be seen that the changing trends of the two parameters are very similar. In the low-frequency take-over experiment, the two parameter values of female participants are lower than the overall average level, but the males are higher than the average level. This indicates that the performance of males at low take-over frequency is severely polarized, and the take-over performance that can complete the take-over task is better, while the rest of the male participants have a collision. With the increase in take-over frequency, the two parameters of male and female have increased. Among them, the change in males is relatively gentle, which is approximately a low-slope linear shape. When the frequency of female take-over increases from low to medium, the increase in the parameters is larger and exceeds the average level. When the frequency of female take-over increases from medium to high, the increase is small, and the average level is slightly higher than that of males. Considering that there are more collisions among males at low frequency, females outperform males on average speed in the overall task.

The average speed of the male and female tasks is shown in Figure 11. The average speed in the task is the average speed of the participant during the period from taking over to the end of switching to automated driving again. It can be seen that under the conditions of low and medium frequency, the average driving speed of females is higher than that of males, and the average speed of both is significantly improved when the frequency changes from low to medium.

FIGURE 10: Average minimum TTC (a) and distance to obstacle (b) in each experiment (excluding collision data) of male and female participants.

When the frequency changes from medium to high, the average speed of males still increases significantly, while that for females decreases slightly. This means that when the take-over frequency increases within a certain range, the average speed of both males and females increases to a certain extent. When this range is exceeded, females generally become very cautious and lead to decrease in the average speed of the task, but males continue to increase, as does the overall trend.

The time to complete task and maximum braking acceleration of the participant at three different frequencies are shown in Figure 12. It can be seen from (a) that with the increasing frequency of take-over, the time for both males and females to complete the take-over task has been decreasing, and the change in frequency of take-overs from low to medium is more significant, but the time for females to complete take-over tasks is generally higher than that of males, indicating that females are very cautious when performing take-over tasks. In terms of maximum braking acceleration (b), males have the highest value at medium take-over frequency while females have the highest value at low frequency. The value of both males and females is the same at medium frequency. It can be seen that the take-over performance of females is inferior to that of males at low take-over frequency, and the other two take-over frequencies are similar between males and females.

### 3.4. Binary Logistic Take-Over Safety Evaluation Model.

The binary logistic regression method is used to construct a take-over safety evaluation model. The study in [22] pointed out that the minimum TTC lower than 1s can be used as an effective way to evaluate collisions. The minimum TTC is selected as the dependent variable, and the minimum TTC of 1s should be used as the boundary between the dangerous group and the safety group. However, the test driving scenes concluded in the references are mostly urban road scenes, and the vehicle speed is 50 km/h. Due to the limitation of the simulated

map, the vehicle velocity is 20–24 km/h, and the average value is 22 km/h. Under the same safety distance, the minimum TTC division limit should be taken as  $50 \times 1/22 \approx 2.3$  s. Therefore, this study chooses the minimum TTC less than or equal to 2.3 s as the dangerous group and more than 2.3 s as the normal group. Input variables select the time from the alarm to the braking reaction time, the maximum braking acceleration to take over, the gender of the participant, the distance to obstacle, and the duration of a single take-over. The method of selecting variables is “Backward Stepwise Regression: Maximum Partial Likelihood Estimate Likelihood Ratio Test (LR),” which means that all independent variables are first entered into the equation and then removed by the LR test. The probability cutoff value is set to 0.5. When the predicted probability value is greater than 0.5, the classification prediction value of the explained variable is considered to be 1 (dangerous group), and when it is less than 0.5, the classification prediction value is considered to be 0 (safe group).

The inspection results of model fitting are shown in Tables 4 and 5. Table 4 shows the Omnibus test of model coefficients, in which the “model” line outputs the likelihood ratio inspection results of whether all parameters in the logistic regression model are 0. A significant  $P < 0.05$  indicates the variables included in the fitted model. Among them, the OR value of at least one variable is statistically significant, and the overall model is meaningful.

Table 5 shows the test results of Hosmer and Lemeshow, indicating the goodness-of-fit results of the test model. When the  $P$  value is not less than the inspection level (i.e.,  $P > 0.05$ ), it is considered that the information in the current data has been fully extracted, and the model has a high degree of goodness of fit.

The likelihood values and significance changes when the model removes variables are shown in Table 6. If the significant change when removing a variable is less than 0.05, it

	Take-over time	0.154	0.088	3.090	0.079	1.166
	Constant	-2.243	1.925	1.357	0.244	0.106

The variable coefficients in the model regression process and their influence on the model are shown in Table 7. It can be seen that in the final model, gender and the distance to obstacle have a greater impact on the model.  $P(\text{gender}) = P(\text{distance to obstacle})$ , but  $\text{Wals}(\text{gender}) > \text{Wals}(\text{distance to obstacle})$ , and  $\text{Exp}(B)(\text{gender}) > \text{Exp}(B)(\text{distance to obstacle})$ , so the distance to obstacle is the variable that has the greatest impact on the model. After the simulation of the binary logistic model, it is concluded that the distance to obstacle is the variable that has the greatest impact on the participant's take-over performance. Among all the selected variables, the distance to obstacle is the variable that can most directly reflect the participant's take-over effect, which is consistent with the facts, and indicates that the results of model fitting are consistent with normal logical judgments.

In this model, females are set to 0, males are set to 1, and gender is the second most influential independent variable. Its regression coefficient B is negative, indicating that the female's take-over performance is poor. This is because the collision data are used in the model data. Excluding, in 3.3.2, the statistical results show that the number of female collisions is significantly less than that of males. However, in this model, taking the minimum TTC as the criterion for

take-over performance, it can only be concluded that the reaction time and operating time required by female participants are higher than those of male participants without a collision, which does not mean that male participants have significantly better take-over performance than female participants.

The final logistic regression equation is shown in equation (15), the model prediction accuracy rate is 87.7%, and the logistic classification table is shown in Table 8.

$$\text{Logit}(p) = -2.243 - 1.663x_1 + 0.282x_2 + 0.154x_3, \quad (15)$$

where  $x_1$  is the gender,  $x_2$  is the distance to obstacle, and  $x_3$  is the time taken for a single take-over.

Considering the effects of gender, reaction time, braking acceleration, distance to obstacle, and take-over time, the binary logistic model is applied to evaluate the take-over safety of L3 automated vehicles. The model is established with the minimum TTC as the dependent variable, and the Omnibus test and Hosmer and Lemeshow test are performed on the model coefficients to verify the validity and high fit of the model. The fitting results of the model are consistent with normal logic, and the prediction accuracy

TABLE 8: Logistic classification table.

	Minimum TTC $\leq 2.3$ s	Minimum TTC $> 2.3$ s	Percentage correction (%)
Minimum TTC $\leq 2.3$ s	5	14	26.3
Minimum TTC $> 2.3$ s	1	102	99
Total percentage (%)		87.7	

rate of the model is 87.7%, which is highly reliable. According to the analysis of the model, the variable that has the greatest influence on the participant's take-over performance is the distance to obstacle, which is also the variable that most directly reflects the participant's take-over effect among all the variables selected. In addition, gender, as the second most influential variable predicted by the model, also occupies a large proportion in performance analysis and safety evaluation. The reaction time, braking acceleration, and take-over time are also significantly related to take-over performance through model verification. Therefore, these factors are also indispensable when evaluating take-over performance and reflect the take-over effect to a certain extent. The influence mechanism of the above factors is complex and multidimensional.

According to the results obtained by the model, looking at the distance data of the participant to the obstacle in Figure 10(b), the take-over effect of males at low take-over frequency is significantly better than that of females, but the take-over frequency at medium and high take-over frequencies is roughly the same. Based on the evaluation of take-over performance in 3.3, both males and females perform better in the frequency of take-overs, which provides a reference for the study of the safety of conditionally automated driving.

#### 4. Discussion

This study studies the impact of take-over operations on take-over performance when the participant performs NDRT under L3 automated driving and evaluates the take-over safety of the experiment. To this end, by carrying out a simulation experiment on a driving simulator, collecting relevant driving data, and using the processed data to evaluate the take-over effect of the participant. Finally, the safety of take-over is evaluated based on the binary logistic model. With the deepening of the research, the results show that various factors affect the performance of the take-over, and the reasonable mode of control switching between the automated driving system and the driver needs to be further explored. This research promotes the research of data preprocessing methods, explores the research on take-over performance in L3 automated driving, and enriches the research on take-over safety.

A data preprocessing method based on the Kalman filter and BRB method is proposed. The target trajectory filtered by the Kalman filter is smoother and more suitable for the actual displacement trajectory. The BRB method associated with vehicle velocity and acceleration data is used as a trajectory tracking method to check the target position with high reliability and can effectively calibrate the abnormal behavior of the vehicle. The use of the Kalman filter is consistent with the current method of eliminating

interference in the literature [23], but more and more literature [24] combines the Kalman filter and other methods to track the trajectory or use other methods to achieve target tracking [25].

Descriptive and differential analysis of data such as the average time to complete the task, the minimum TTC, the distance to obstacle, and the maximum average braking acceleration shows that the take-over effect of females at low take-over frequency is weaker than that of males. However, the take-over performance of the medium and high frequencies is roughly equivalent. Due to males having too many collisions at low take-over frequency, the overall take-over performance of females is better than that of males. At present, most documents [26] are statistical analysis based on data, but there are also documents [27] that evaluate the take-over performance by constructing a structural equation model to provide new ideas for performance evaluation.

When evaluating the safety of take-over, a binary logistic model is applied to find out the variables that have a greater impact on the participant's take-over performance and further evaluate the safety of take-over based on these variables. Most of the take-over studies of L3 automated vehicles are based on test data for descriptive and differential analysis to evaluate take-over performance. In take-over-related research, take-over performance evaluation is mainly based on data [28]. At present, there are relatively few documents that determine the more significant variables through prediction.

#### 5. Conclusion

This study designs an urban road take-over scenario in a dangerous scenario based on a driving simulator, uses the data preprocessing method of the Kalman filter and BRB method, analyzes the impact of NDRT on take-over performance in L3 automated driving, and establishes a take-over safety evaluation model, and the specific conclusions are as follows.

The data preprocessing methods of the Kalman filter and BRB method have smaller deviations, are closer to the real trajectory, have certain reliability, and can effectively calibrate the abnormal behavior of the vehicle.

The overall driving performance of the participant improves as the frequency of take-overs increases. Under low take-over frequency conditions, it may be necessary to take appropriate measures to prevent the participant from focusing on the secondary task for a long time, such as intermittently reminding the participant to pay attention to the road conditions ahead, limiting the time for the participant to perform secondary tasks, etc. The overall driving performance of females is higher than that of males.

The binary logistic model uses the minimum TTC as the dependent variable to analyze that the variable that has the greatest impact on the take-over performance of participants is the distance to the obstacle, and gender is the second most influential variable. The prediction accuracy of the model is 87.7%, which has a high degree of credibility and validity.

The state vigorously develops the application of community sports and takes it as an important unit of social and economic development. With the development of the economy, residents' living standards are getting better, which also greatly promotes the development of community public sports. Community public sports have made great progress in terms of scale, hardware, and services, and their impact on society is getting worse. Come bigger. However, there are still some deficiencies in the development of community sports. How to accurately evaluate and predict its facilities, construction, and service levels and put forward corresponding development strategies is an urgent problem to be solved in the field of community public sports. In this paper, an iterative simulated annealing algorithm is proposed to evaluate the level of public sports services and help community public sports institutions identify their own development deficiencies. Through the simulation analysis of the community sports organizations, community members, venue facilities and funds, venue facilities and funds, administrators, and the community sports activities, it is found that the identification accuracy of the evaluation results of the five indicators is above 95%, while the initial threshold of community public sports and social and economic development and the prediction accuracy required by the standard of development status are both 10%. At the same time, the recognition time of the evaluation results in the five indicators is less than 7 seconds. In community public sports development trend prediction and service level judgment, the identification time of the evaluation result is less than 4 seconds, and the overall judgment result is better.

## 1. Introduction

With the development of digitization and computers, public sports and other related industries have developed rapidly, showing the characteristics of rapidity, diversity, and intelligence shown by Sadegh Barkhordari and Tehranizadeh [1]. Community sports mainly refer to the regional mass sports carried out nearby in a certain area where people live together, taking the natural environment and sports facilities of the jurisdiction as the material basis, taking all community members as the main body, and taking meeting the sports needs of community members, increasing the physical and mental health of community members, and consolidating and developing community feelings as the main purpose. Community sports have six elements: community sports organizations, community members, venues, facilities and funds, administrators, instructors, and community sports

activities. Public sports are affected by external and internal factors and cannot be accurately evaluated and analyzed by traditional data analysis methods, which affects the evaluation effect of service level (Bourliva et al. [2]) and limits the development of intelligent public sports. Some scholars believe that the purpose of the intelligent development of community public sports is to meet the development needs of the industry. Therefore, starting from the prediction of development trend, operation status, and the development of community public sports (Donoso [3]), a comprehensive evaluation of the public sports service level can provide a reference for the formulation of a service strategy. Some scholars also believe that the accuracy of intelligent evaluation in community public sports is low, and the proportion of unstructured data is high (Durmus [4]).

We can improve the accuracy of intelligent evaluation of public sports and reduce the interference of unstructured

data by extracting eigenvalues. Based on the above background, this paper uses metropolis acceptance criteria and a simulated annealing algorithm to analyze the eigenvalues and analyzes the service level of community public sports from the perspective of intelligence so as to improve the evaluation accuracy of public sports services. Based on the above reasons, this paper mainly introduces it from three aspects. Firstly, it describes the service level in the community of public sports mathematically, and introduces the intelligence of service level, the parameters of service level, and the processing of service level-related data. Secondly, a prediction model of public sports service level based on a simulated annealing algorithm is constructed. The constraints of the simulated annealing algorithm, the accuracy of public sports service level, and the prediction steps of public sports service level are analyzed. Thirdly, the simulation of public sports service level prediction model is based on a simulated annealing algorithm. We describe the cases of public sports services and analyze the accuracy and calculation time of prediction results.

From the above analysis, it can be seen that the rapid development of community public sports can promote the development of the social economy and make its decision-making develop in a positive direction. In order to better carry out the research of community public sports and make them play a role in economic promotion, it is necessary to introduce comprehensive judgment methods to improve the accuracy of calculation, which is of great practical significance. In addition, the comprehensive analysis of community public sports can also enhance the coupling between community public sports and economic development and provide support for development decision-making.

## 2. The Mathematical Description of Service Level Prediction in Community, Public Sports, and Social Economy under Simulated Annealing Algorithm

The iterative simulated annealing algorithm is a comprehensive calculation method, which can carry out iterative analysis on community public sports. This algorithm has the advantages of a simple calculation process and fast analysis speed. Compared with the classical simulated annealing algorithm, the iterative simulated annealing algorithm can carry out progressive calculation, eliminate redundant data, make the calculation result more accurate, and avoid local extremum.

*2.1. The Intelligent Description of Service Level.* Intelligent service level has two characteristics: on the one hand, it processes massive information, uncertain data, and diverse data, and the proportion of controllable data is >50%; on the other hand, multisource data are analyzed and dynamic information is obtained. The public sports data structure is as follows: the diversity of data sources, the comprehensiveness of public sports, and the diversity of calculation, observation, and measurement (Fitriingsih [5]), as shown in Figure 1.

The structure of public sports data is mainly in the form of controllable and uncontrollable factors and is combined with the economic data sources of public sports-related industries to form a large amount of public sports data. Public sports should start from the industry, conduct intelligent analysis in combination with industry development capacity, industry service status and trend, and improve the accuracy of public sports assessment.

It can be seen from Figure 2 that although the demand for sports for community public sports fluctuates, it is increasing on the whole. Therefore, community public sports play a vital role in the development of sports. Some scholars also believe that community public sports can also promote the development of a social economy. The specific contents are shown in Figure 3.

It can be seen from Figure 3 that there is a certain correlation between social public sports and the social economy, and the correlation is increasing year by year. In summary, community-based public sports play a supportive role in sport development and are somewhat correlated with social and economic development. In order to better carry out the development of community public sports and give play to their social promoting role, it is necessary to conduct in-depth research on community public sports. At the same time, depending on the current situation of public community sport, foresee its future development, in order to improve the development of sport and the social economy. As a result, a thorough analysis of community public sports is of great practical and theoretical importance.

*2.2. Description of Service Level Metrics.* The digitization of the level of public sports services and the diversification of the factors influencing demand increasingly highlight the characteristics of public sports data. The traditional level of service method cannot fully address the intelligent development needs of community-based public sports. Under the background of intelligent development, public sports prediction algorithms such as particle swarm optimization and support vector can meet the needs of large volume and multiple types and realize the prediction and analysis of public sports service level, community public sports service status, and public sports development trend. The parameters of the community public sports are set as follows (Haghverdi [6]): community sports organizations, community members, venue facilities and funds, administrators, directors, and coordinators of community sports activities.

- (1) Assume the community sports organizations are  $x_o$ , the community members are  $x_j$ , community outdoor fitness venues and funding are  $x_k$ , venue facilities and funds are  $x_b$ , administrators are  $x_m$ , the community sports activities is  $x_n$ , and the intelligent dataset of the community public sports service level is  $C$ . The result of the calculation shall be drawn up in accordance with the following formula:

$$C = \{c_1, c_2, \dots, c_i\}, \quad (1)$$

where  $c_i$  is shown in the following formula:

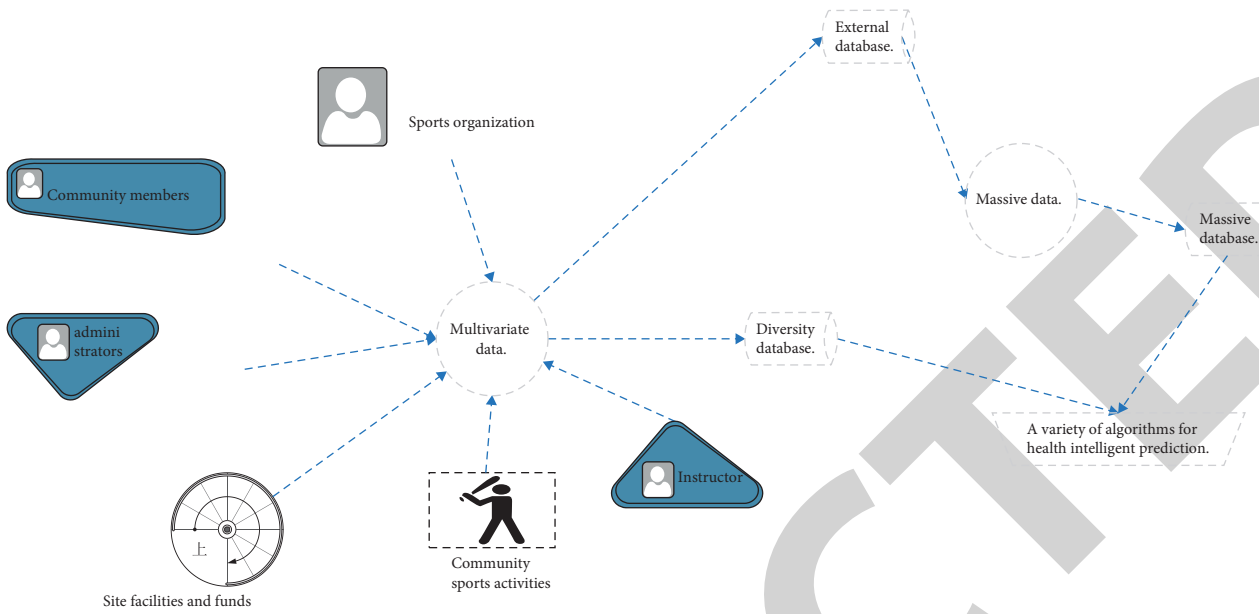

FIGURE 1: The data source of intelligent prediction of public sports in sports.

FIGURE 2: The demand for different sports for social public sports.

FIGURE 3: The correlation between community public sports and socioeconomic development.

$$c_i = \sum_{i,j,k}^n x_i + x_j + x_k + x_l + x_m + x_n, \quad (2)$$

where  $I, j, k, l, m, n$  belongs to natural numbers. The different data for the public service of sport come from different sectors.

- (2) Suppose  $n$  is an intelligent collection,  $i$  is the industry of data source,  $j$  is the structure type of data (uncontrollable factor data = 1, otherwise = 0),  $k$  is the data acquisition method (qualitative method acquisition = 1, quantitative method acquisition = 2, comprehensive acquisition method = 0),  $l$  is the intelligent development level (Note: 1~5 levels, the higher the value, the higher the level), and  $M$  is each data collection organization, then the data acquisition item can be described as  $N_{i,j,k,l,M,i,j,k,l,M} = (1, 2, \dots, n)$ , and  $n$  is a natural number.
- (3) Different public sports institutions divide similar industry sources, structure types, acquisition methods, and economic development level data into community public sports data sets.
- (4) Data from all data institutions are analyzed centrally by the Centre for Economic Analysis of Community Public Sport. Under the constraints of forecast accuracy, prediction time, and safety, the data obtained are classified according to the relevant weights and thresholds.
- (5) The collection time of health data and the intelligence level of health data in any given data organization are the same or similar (Han [7]).

- (6) For the stability of the data organization and analysis, the Fourier series method shall be adopted to reduce the interference of data organization, personnel, and

other nonresistance factors as shown in the following formula:

$$P(t) = a_0 + \sum_{i=1}^n \frac{[(y_i z_i u_i - y_{i-1} z_{i-1} u_{i-1})]}{2} + \frac{(y_i z_i u_i + y_{i-1} z_{i-1} u_{i-1})}{2} + \xi, \quad (3)$$

where  $P$  is the antiinterference ability described by the intelligent analysis of health data,  $t$  is the measured time of health data,  $y$  is the degree of intelligence,  $z$  is the interval of health data collection,  $u$  are the sports health standard, and  $\xi$  interference coefficient.

**2.3. Simplified Processing of Health Information Data.** The data gathered by the various public sports institutions must first be processed by K-means. The result is indicated in the form equation as follows:

$$\sum_{i=0}^n I_i = |S|. \quad (4)$$

Among them,  $S$  is the clustering range, the lower the value, the better the clustering effect.  $I$  is the data collected by the data organization, and  $I$  is the number of the data. In addition,  $S$  can be replaced by similarity  $J$  so as to improve the efficiency of the calculation. In order to simplify the process, the weight can be judged by using the frequency of a certain date, the data threshold collected by the data institution can be judged according to the previous historical data or the data frequency in the community public sports database, that is shown in the following formula:

$$w_i = \frac{H \cdot G_{ij}}{G_i + G_j}, \quad (5)$$

where  $G_{ij}$  is the number of times  $J$  data organization collects  $I$  data,  $G_i$  is the number of times  $I$  data appears in the community public sports database,  $G_j$  is the frequency  $j$  data organization sends data, and  $WI_i$  is the threshold of  $my$  data.

### 3. Construct a Public Sport Intelligence Prediction Model Based on a Simulated Annealing Algorithm

**3.1. The Limitations of the Simulated Annealing Algorithm.** Prior to the analysis of intersectoral data institutions in the community, public sports, all data institutions should be classified and judged according to applicable standards. In this paper, the metropolis acceptance criteria (Harkut et al. [8]) are adopted. If community-based public sports meet real needs, relevant data will be collected, otherwise, data organizing data will not be accepted. Metropolis accepts the judgment of the criteria and can save the resources of the community public sports, reduce the amount of data

processing, and improve the speed of intelligent development (Luo et al. [9]). Assuming that the state of the community public sports is  $the$ , we conduct metropolis acceptance criteria analysis to determine whether the state needs to be changed, that is, from  $my$  state to  $i+1$  intelligence. The calculation formula shall be

$$R(T) \begin{cases} R(T) = 0 \sim 0.5, \\ R(T) = 0.5 \sim 1. \end{cases} \quad (6)$$

The limitations of formula (2) appear in formula (7) as follows:

$$\begin{cases} f(i) \longrightarrow f(i), \\ f(i+1) \longrightarrow f(i+1), \\ \exp\left[\frac{f(i) - f(i+1)}{T_i}\right], \end{cases} \quad (7)$$

where  $\exp()$  is the expected function of service intelligence, which is to judge whether to be smart;  $R(T)$  is the result function of intelligence in community public sports. If the result of  $R(T)$  is  $0 \sim 0.5$ , it indicates that the degree of intelligence is low and the original state can be maintained. If the result ranges from  $0.5$  to  $1$ .

**3.2. The Appropriateness between Collective Sports and the Recut Algorithm.** The adjustment of communal public sports and the annealing algorithm is divided into (Luo [10]) local adjustment CP and global adjustment MP, which reflect the adjustment of the two under different aspects, which is also the premise of the calculation of the evaluation results. The larger the values of  $PC$  and  $Pm$ , the better the data fit. Since metropolis in 2.1 accepts the limitation of the criterion and requires both data to be optimized in order to become the calculation data, the calculation formula is as follows:

$$P_c \begin{cases} N_{1,1,0,1}, & R_c = R_{mg}, \\ \frac{\varphi_c(R_c - R_{\min})}{(R_{mg} - R_{\min})}, & R_c < R_{mg}, \end{cases} \quad (8)$$

$$P_m \begin{cases} N_{1,1,1,0}, & R_m = R_{mg}, \\ \frac{\varphi_m(R_m - R_{\min})}{(R_m - R_{\min})}, & R_m < R_{mg}, \end{cases} \quad (9)$$

where  $N_{1,1,0,1}$  is the initial value of  $P_c$ ,  $N_{1,1,1,0}$  is the initial value of  $P_m$ ,  $R_{\min}$  is the minimum value of the whole data,  $R_c$  is the local minimum value, and  $R_m$  is the overall minimum value.  $\varphi_c$  is the local fitting coefficient and  $\varphi_m$  is the overall fitting coefficient.

3.3. *The Accuracy of the Results for Predicting the Level of Public Sport Intelligence.* The corresponding datasets should be constructed before the prediction results are calculated. In

$$f(x \rightarrow y) = \min \left[ \int_{i,j}^n \sum_{i=1}^n \max(F(x_i), F(x_{i+1})), \sum_{j=1}^n \max(y_j), (y_{j+1}) \right] + \phi_i \sin(\xi_i), \quad (10)$$

where  $f(x \rightarrow y)$  is the relationship function between simulated annealing algorithm and community public sports, that is, the appropriate function, which reflects the matching degree between them. The maximum value of any two service data is as follows:

$$\sum_{i=1}^n \max(F(x_i), F(x_{i+1})). \quad (11)$$

The maximum value expected from any level of intelligence is as follows:

$$\sum_{j=1}^n \max(y_j), (y_{j+1}). \quad (12)$$

The level of information provided by public sports institutions to obtain the maximum or minimum of two points is as follows:

$$\int_{i,j}^n \left( \sum_{i=1}^n \max \left( F(x_i), F(x_{i+1}), \sum_{j=1}^n \max(y_j), (y_{j+1}) \right) \right). \quad (13)$$

The minimum of all extreme values is set out as follows:

$$\min \left[ \int_{i,j}^n \sum_{i=1}^n \max(F(x_i), F(x_{i+1})), \sum_{j=1}^n \max(y_j), (y_{j+1}) \right]. \quad (14)$$

3.4. *Steps in Predicting Community Public Sports Based on a Simulated Annealing Algorithm.* Using the above mathematical description, the following calculations are needed:

- (1) We set initial  $C = \{c_1, c_2, \dots, c_i\}$  values of community public sports, thresholds of data fitting (local fitting  $P_c$ , overall fitting  $P_m$ ) and calculation accuracy, intelligent prediction results  $N_i, j, k, l, m$  values, and initial metropolis acceptance criteria;
- (2) Gradient 200 iterative tests were performed on the fitted data (Reinaldi [13]);

this paper, the appropriate function is used to clarify the relationship between the simulated annealing algorithm and community public sports (Martin-Fernandez [11]). Under the conditions of preset accuracy and threshold constraints, the moderate function performs multiple iterative analyses, guides the operator to calculate in the positive direction, reduces the occurrence rate of local extreme values and "false eigenvalues" (Petroff [12]), and improves the accuracy of predictive results, as shown by the following formula:

- (3) We verify the calculation results according to metropolis acceptance criteria and constraints, incorporate the qualified results into the total scheme, and calculate the recognition accuracy and calculation time of the prediction results of the overall scheme (Ren e al. [14]);
- (4) We determine whether all the data we are going through will stop the calculation, otherwise proceed to step 3;
- (5) Finally, the minimum value should be taken out. The overall diagram and output of the computation process are shown. The specific process is presented in Figure 4.

## 4. Case Analysis of the Public Sports Information Prediction Model Based on a Simulated Annealing Algorithm

4.1. *The Case Introduction.* We take 4 provincial public sports establishments, 5 municipal public sports establishments, and 6 county public sports establishments from January 1, 2020, to December 2021 as examples. Song et al. [15] analyze the impact of the simulated annealing algorithm on the current state and trend of development of public sports services and determine the accuracy of the discrimination and time of the prediction results. The accuracy and calculation accuracy of data fitting (partial fitting PC and overall fitting PM) are set to 0.1 and the number of iterations is 200. Among them, the data collection is the statistical yearbook of public sports institutions, the website of public sports institutions, and a questionnaire survey (reliability and validity >0.7). The intelligence level is level 3 and follows the guidelines for the development status of community public sports (GB/T 31464) in 2015, The IP addresses of public sports institutions are 192.168.1.102~192.168.1.202.

4.2. *The Fit between Community Public Sports and Simulated Annealing Algorithm.* Through K-mean clustering and metropolis acceptance criteria, the data of intelligent and public sports industries are standardized, and 20 iterative

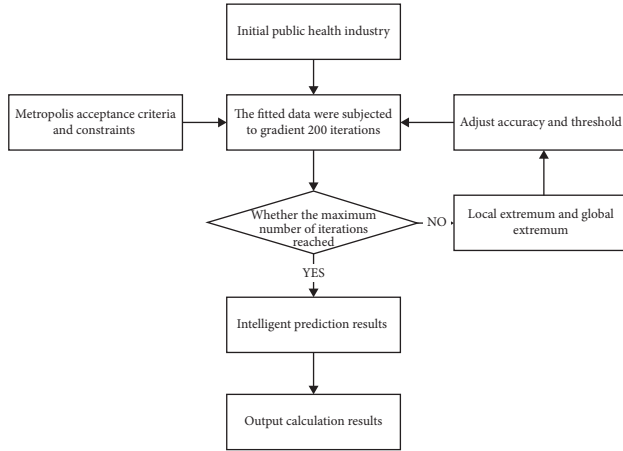

FIGURE 4: Community public sports analysis steps.

analyses are carried out to obtain the data fitting results, as shown in Table 1.

It can be seen from Table 1 that both local fitting and overall fitting are >95%, while the overall fitting is high and meets the threshold of 10% set by K-mean clustering and metropolis acceptance criteria. The results of the specific couplings are presented in Figure 5.

It can be seen from Figure 6 that there is a strong correlation between community public sports and social economy, which shows that community public sports present a large-scale and high-level development trend and can promote economic development and make it develop in a positive direction. At the same time, the rapid development of the economy also promotes the upgrading and development of community sports. For the classical simulated annealing algorithm, the iterative simulated annealing algorithm has a higher correlation, indicating that the correlation between social public sports and economic development is stronger, which lays the foundation for accurate calculation in the later stages.

#### 4.3. Community Public Sports and the Social Economy.

The results show that although the correlation between social public sport and social economy fluctuates in a small range, the overall correlation is high, between -20% and 180%. As a result, there is a strong relationship between community public sports and the social economy. The small fluctuation between community public sports and social economy is mainly determined by the whole society's sports policy and social-economic policy, and has nothing to do with the simulation results of the annealing algorithm in this paper. The specific outcomes are presented in Figure 6.

**4.4. The Accuracy of Prediction Results.** The community sports organizations are  $x_b$ , the community members are  $x_j$ , the venue facilities and funds are  $x_k$ , the venue facilities and funds are  $x_l$ , the administrators are  $x_m$ , and the community sports activities are  $x_n$ . The accuracy of the identification of predictive results in the five indicators directly determines the effectiveness of the entire model.

TABLE 1: Degree of adjustment of the various figures.

The adequacy of predictive data on the level of public athletic information	Iteration (times)	Fitting degree (%)
Local fitting	0~50	97.3
	50~100	98.7
Global fitting	0~50	97.2
	50~100	99.6
Total fitting degree	0~100	98.3

FIGURE 5: Results of local and global adjustment.

FIGURE 6: The correlation between community public sport and social economy.

Through MATLAB simulation analysis, it can be seen that the recognition accuracy of the prediction results in the abovementioned five indicators is >95%, while the initial threshold and the requirements in the criteria for the current service situation of community public sports are 0.1. At the same time, in the process of 40~50 iterations, the calculation accuracy changes greatly, which is mainly caused by the jumping change in social and economic development and does not affect the final calculation accuracy. So, the simulation results are better, and the results are shown in Table 2.

TABLE 2: Accuracy of forecast outcomes.

Judgment index	Iteration (times)	Fitting degree (%)
The community sports organizations	0~50	98.23
	50~100	97.23
The community members	0~50	96.62
	50~100	98.82
Venue facilities and funds	0~50	97.02
	50~100	98.32
Administrators	0~50	97.12
	50~100	98.24
The community sports activities	0~50	97.22
	50~100	97.12
Total fitting degree	0~100	98.62

FIGURE 7: Accuracy of predictive results for each index.

The precision of the specific calculation can be derived from the data in Table 2, and the results are illustrated in Figures 7–9.

It can be seen from Figure 8 that the service judgment result of social public sports is better, which is between 75 and 99% as a whole, better than 82~89% of the classical simulated annealing algorithm. We can see that the computation result of the iterative simulation annealing algorithm is better.

It can be seen from Figure 9 that the economic development trend is relatively stable, but there are significant changes in 10~20 iterations and 50~60 iterations, mainly due to the changes in economic policies at that time. However, the accuracy of the overall evolution meets the demands.

FIGURE 8: Judgment on the service status of communal public sports.

**4.5. Judgment Time of Prediction Results.** The characteristic of intelligence is that the data has a large amount of data processing and high processing complexity, so the identification time of prediction results is another verification index. The results show that the identification time of prediction results in community public sports service capability  $x_i$ , community public sports service status judgment  $x_j$ , and public sports service trend judgment  $x_k$  is less than 40 seconds. Compared with 0~10 iterations, the calculation time of 10~20 iterations is longer, mainly due to the large

amount of postprocessing data and the relatively complex calculation process. However, the identification time of the overall prediction results meets the requirements of the guidelines for the status of services in community public sports, and the results are shown in Table 3.

The overall calculation time of the level of public sports information can be derived from Table 3, as shown in Figure 10.

We can see in Figure 10 that the overall mounting time of the calculation result is better, between 0 and 1 s. That is, the

FIGURE 9: Outcome of the judgment trend in public sports services.

TABLE 3: Judgment time of forecast results.

Judgment index	Iteration (times)	Fitting degree (%)
The community sports organizations	0~10	$0.61 \pm 1.23$
	10~20	$0.53 \pm 0.92$
The community members	0~10	$0.32 \pm 2.01$
	10~20	$0.72 \pm 2.32$
Venue facilities and funds	0~10	$0.62 \pm 1.72$
	10~20	$0.72 \pm 0.93$
Administrators	0~10	$0.61 \pm 1.91$
	10~20	$0.73 \pm 0.12$
The community sports activities	0~10	$0.64 \pm 1.84$
	10~20	$0.71 \pm 0.82$
Total fitting time	0~20	$0.72 \pm 2.01$

FIGURE 10: The total fitting time.

overall mounting time is short. At the same time, under different iteration and accuracy requirements, the fitting time has not changed, indicating that the overall calculation time is relatively stable, which further proves the effectiveness of this method. Compared to the traditional simulated annealing algorithm, the computational time of the iterative simulated annealing algorithm is shorter.

## 5. Conclusion

The social economy is the basis for the development of community public sports. With the improvement of the economic level, the development of community public sports is getting better and better. The development and improvement of community public sports promotes the development of the social economy to a large extent and have an inseparable relationship. The rapid development of the intelligence level of the community public sports makes the intelligence level higher and higher (Tubishat [16]), and the data volume and complexity show characteristics (Twahirwa and Wang [17, 18]), which makes traditional analytical methods unable to meet the analytical requirements of relevant data institutions. The studies of Yagmur and Kesen [19] have resulted in a significant decline in the accuracy of forecast results. A method of analysis based on a simulation annealing algorithm is proposed in this document [20]. Through the standardized processing of public sports service data, fitting data with an accuracy of 0.1 is obtained (Svalina et al. [20]). Then, using iterative calculation, the prediction results and identification rates of public sports service capability judgment  $x_i$ , public sports service status judgment  $x_j$ , public sports service trend judgment  $x_k$ , and other indicators are obtained by Zolfi and Jouzdani [21, 22]. The MATLAB simulation results show that the recognition accuracy of the prediction results in the five indicators is  $>95\%$  (Ilin [23]), while the initial threshold and the requirements in the guidelines for the development status of community public sports are 0.1. At the same time, the identification time of the prediction results in the five indicators is less than 7 seconds, and the identification time of the prediction results in the judgment of public sports service trend and intelligence level is less than 4 seconds (He and Ye [24]). So, the overall judgment result is better (Chen et al. [25]). The global adjustment time of the calculation result is better, between 0 and 1 s, i.e., the global adjustment time is short. At the same time, under different iteration and accuracy requirements, the fitting time has not changed, indicating that the overall calculation time is relatively stable, which further proves the effectiveness of this method. Compared with the classical simulated annealing algorithm, the calculation time of the iterative simulated annealing algorithm is shorter. However, there is still insufficient research on the coupling between public sports intelligence level indicators and intelligent judgment in this paper. In future research, we will focus on the analysis of the above contents.

With the development of mobile Internet technology and the continuous popularization of the network, various kinds of network software come out constantly and people are becoming more and more dependent on them, while role authority management is of great importance for the security of software, the control of management process, and the usability of users. In terms of system implementation, virtual machine technology is often faced with problems such as high virtualization overhead, poor scalability, and long deployment time in spite of its good isolation effect. Container technology represented by Docker can well solve these problems and make it possible to quickly build, deploy, operate, and maintain as well as expand services. Based on Docker technology, this research compares and chooses from various authority control models and finally decides to take the role authority management model as the infrastructure. It designs the role authority control model based on cloud computing and Docker technology in combination with the Task Controller Function, the Project Controller Function, and the User Controller Function and realizes this model by adopting the MongoDB database combined with HTML/CSS/Javascript syntax and the Boor Strap framework. After the test, it is found that the Docker technology based role authority management system has satisfactory test performance consistent with expected outputs as well as strong robustness, which can meet the requirements of different objects and subjects.

In the era of data nowadays, role authority management is no longer limited by region or system but is gradually applied to all kinds of systems and has become one of their important components. Role authority management is applied in various systems with the purpose that the module can control and manage the system authorities [1–5]. System management authorities, if not rationally and effectively controlled and managed, will bring about system bugs, information leakages, and other problems that cause serious loss of users [6–10]. Therefore, in order to avoid such problems, it is of great necessity to strengthen the control and management of system authorities. This paper studies the design and realization of the role authority management system based on the cloud computing platform and obtains the implementation interface of the role authority management system based on the cloud computing platform, which enhance the robustness of role authority management system design and development and lower risks.

## 1. Research Status

With the development of mobile Internet technology and the continuous popularization of the network, various kinds of Web software come out in the sight of the public one after another. As the most commonly used function in Web systems, user role authority management is constantly studied.

Research on user role authority in software systems began in 1996 when Professor Ravi Sandhu et al. proposed the RBAC (Role-Based Access Control) model [11], where the concept of user role is introduced for the first time. At present, there are discretionary access control models, mandatory access control models, and role-based access control models. As cloud computing technology and distributed storage technology develop rapidly with the advent of the big data era, data security has become the focus of people's attention, and the access control of cloud systems

has become an urgent problem to be solved. In order to improve the security of traditional access control technology, constraint research based on role access control has become a research hotspot nowadays.

In 1997, Professor Ravi Sandhu proposed the ARBAC97 model (distributed RBAC management model) [12]. On the basis of these two models, the ARBAC99 model and the ARBAC02 model [13] improved the management function of RBAC. After the RBAC96 model, another famous RBAC model is the RBAC2001 model [14] proposed by the American National Institute of Standards and Technology. Up to now, RBAC is still a topic concerned and studied by relevant scholars. According to the relevant research of Mohsen Saffarian et al., they organically integrated DAC and RBAC model to construct the OB-RBAC model. This model can be more applicable to the settings of organizations with higher flexibility or those with lack of standardization. However, when authorities and users increase gradually, this authorization management method will become highly complicated [15, 16].

In China, researchers mainly put forward improvements to the RBAC model in specific practical studies. In order to strengthen the further management of user roles in the system, Fan et al. proposed a role management method based on the RBAC model in 2012 [17]. Zhang et al. proposed a dynamic role access control model based on attribute value variation in 2016 by setting attributes for roles [18], thus realizing the conversion between dynamic roles and static roles. On the basis of retaining the easy authorization and hierarchical management of roles of the RBAC model and in view of the SaaS (Software-as-a-Service) [19] multitenant mode, Xiong et al. proposed a multitenant, multidomain, and secure interoperation access control method based on the role-level tree [20]. In view of the limitations and complementarity of RBAC and ABAC (Attribute-Based Access Control) in large-scale environments, Zhou and Ren proposed an access control model combining attributes and roles in 2018. On this basis, the existing models are divided into three types: dynamic role models, attribute-centered models, and role-centered models [21].

Through the analysis of research status, problems such as low execution efficiency, unbalanced distribution of resources, and complex deployment process are found in the studies abovementioned. Docker provides great convenience to developers with not only standard container specification technology and image specification but also a series of user-friendly container management platforms. It quickly takes up a large market share and many systems have been deployed on Docker. Therefore, this paper employs the operation layer to realize the interaction of front page data, makes advantage of the related methods in the Dao layer to process background data, takes Docker technology as the basis for designing the technical framework, and combines the Task Controller Function, the Project Controller Function, and the User Controller Function to meet the requirements of different objects and subjects. The research idea and the model and framework designed also become the innovation point of this paper.

## 2. Overview of Docker Technology

In cloud computing, PaaS (Platform as a Service) is a service mode that can provide users with software platforms and development environments [22–25]. Docker is an open-source project realized on the basis of Golang and the application of Docker can accelerate the realization of PaaS mode [26]. In software development, we usually encounter software reuse failures caused by development environment difference, while Docker can effectively solve such problems. Whether during the development stage or test stage of software, Docker can create the same environment. In other words, it intervenes in the container configuration to guarantee the consistency of the dependence of all configurations within the container and to enable that the development, test, and release of software all occur in the same environment. Docker has three advantages. First, it can use the image repository. Second, it can conduct continuous deployment test. Third, it possesses high level of resource utilization. In this paper, the role-based authority management system is deployed on the Docker platform. After the server is started and the images are obtained, the installation of operating systems, repositories, and application services will be completed, which greatly shortens the system development process. Just because Docker does not need to start the slave operating system, enough disk space is spared, abundant system resources are saved, and the utilization rate of system resources is improved. It can also be considered that the virtualization of virtual machines is manifested in hardware level and the virtualization of Docker is manifested in operating system level. The architecture of Docker is as shown in Figure 1.

It can be seen in Figure 1 that the Server Docker is the kernel daemon which can be deployed not only locally but also in remote servers. The communication bridge between Server and Client is Rest APL. As the Client, Client Docker CLI can, besides providing corresponding interfaces for users, manage containers and images. After images are packaged, users can create containers by virtue of images and then operate them, during which Server can be invoked to control disk resources. Compose in Docker is employed to conduct rapid arrangement of container clusters before the operation of multiple containers. Practically, it is hard to provide sound operating conditions for the system by relying on only one single container, and the database and server need to be started simultaneously to guarantee the sound system operation. Besides, service and project are two important concepts in Compose. The first means that it can define the services required by the application in terms of the name, network, configuration environment, dependence condition, etc. Service is conducted in the granularity of container and each container carries one service. The second refers to the whole project that needs to be implemented by users. The content (container deployment, container management, etc.) disclosed in YMAL file can be deemed as a project and Compose will usually manage the project without extra interference.

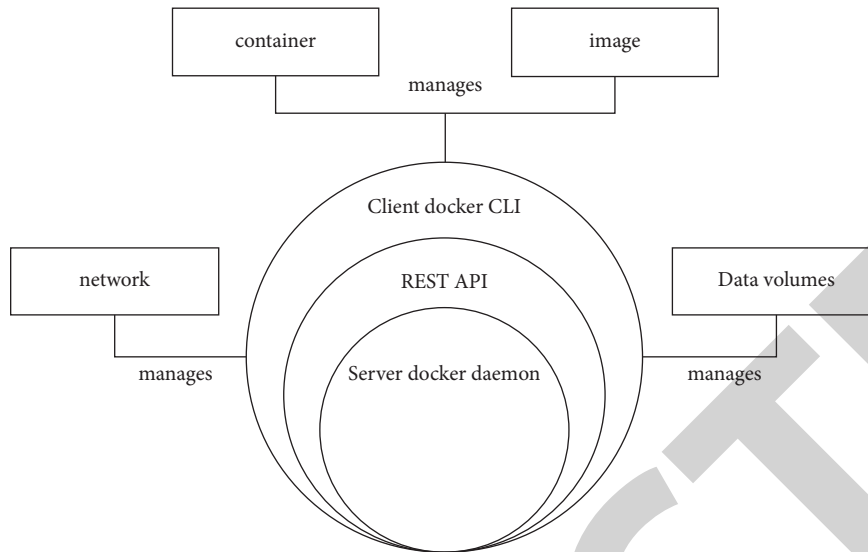

FIGURE 1: Architecture of Docker.

### 3. Model Building and Design of Background Authority Functions

**3.1. Basic Model Building.** Build the authority management system model on the basis of the role-based access control technology. Due to the large scale of the system, we can not conduct authority setting and role division for every user in traditional ways. The concept of user group should be introduced and users with the same authorities and characteristics should be divided into the same user group without changing the many-to-many relationship in role-based access control. One user can be divided into multiple user groups and one user group relates to multiple users. This can not only reduce the heavy and complicated workload but also facilitate subsequent management. Take the task management system as an example. Users can be divided into two user groups: first, the project participant user group, and second, the project administrator user group. Different user groups have different authorities. For example, roles in the administrator user group have authorities to modify and delete the project while roles in the participant user group only have authorities to preview and edit the tasks but cannot modify or delete the project. See Figure 2.

**3.2. Comparison and Option of Authority Control Models.** In user information management systems, authority control is one necessary link. The so-called authority means that users need to access authorized content in accordance with the security rules set by the system. Authority control can effectively identify user identity and avoid illegal invasion; therefore, authority control has been widely promoted in numerous user login systems. Current authority control technologies can fall into two categories: the system level security management, such as operating system level security management and database level authority management, etc., and the application-level security management which generally is closely related to specific system

requirements. From the perspective of implementation, authority control mainly employs three types of models: (1) the discretionary access control model; (2) the mandatory access control model; and (3) the role-based access control model.

**3.2.1. Discretionary Access Control.** It means that the subject with control power can authorize the access right of the object to other subjects [27]. In such access management model, one user can have different authorities to different resource objects while different users can have different authorities to one same resource object; one user can authorize his authority to other users without any limitation. In the discretionary access control model, users can formulate corresponding protection strategies for the resource object to be protected according to system requirements. Discretionary access control has advantages such as flexible authority distribution, simple and easy-to-use models, and strong expansibility; however, the discretionary pattern of authorization leads to low security level of the whole system while the high complexity of discretionary authorization is also a hard nut to crack.

**3.2.2. Mandatory Access Control.** Its main function is to prevent virus attacks and ensure the confidentiality and security of information [28]. The access control method is to mark the security of the elements in the system, that is, to give each subject (user, process) and object (file, data) a security level and restrict the access behavior of the subject to the object by comparing their different security levels. In the mandatory access control model, access control is executed mandatorily by the system and users do not have authority to change their security level. The most typical mandatory access control model is the Bell-LaPadula model, the relevant access control rules of which are as shown in Table 1.

It can be seen in Table 1 that there are four security levels for objects and subjects which are A (top-secret), B (secret),

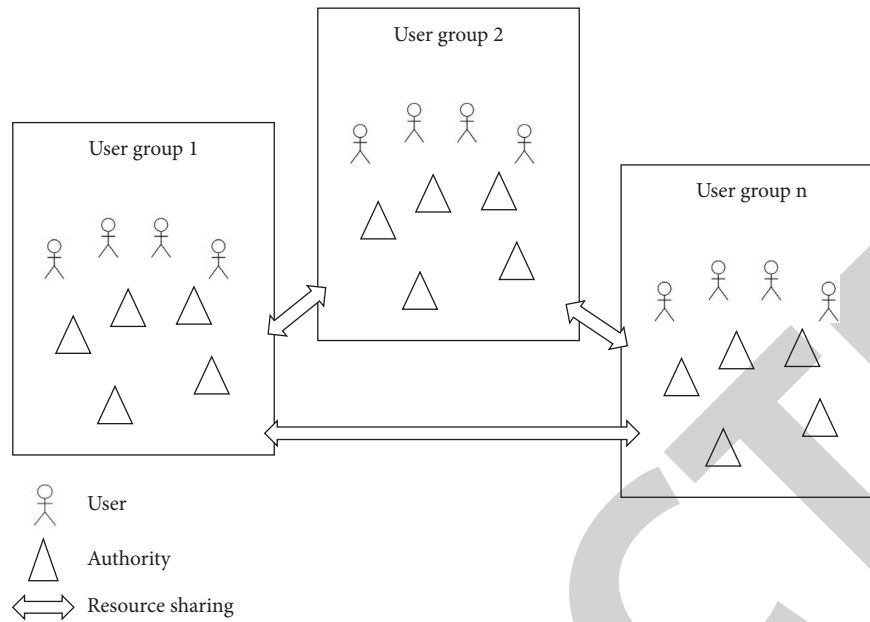

FIGURE 2: Basic model architecture of the authority management system.

TABLE 1: Decision rules.

		Object security level			
		A	B	C	D
Subject security level	A	I/Q	I	I	I
	B	Q	I/Q	I	I
	C	Q	Q	I/Q	I
	D	Q	Q	Q	I/Q

C (confidential), and D (unclassified) successively from top to bottom. Read and write operations are represented by I and Q in Table 1, respectively. The access control rules are as follows: (1) when the security level of the subject is higher than that of the object, the subject can execute the read operation to the object; (2) when the security level of the subject is lower than that of the object, the subject can execute the write operation to the object. Such feature is usually called “Read Down, Write Up.” Such access rules can effectively prevent subjects of lower security level from accessing resources of higher security level, which guarantees information confidentiality.

**3.2.3. Role-Based Access Control.** Such model successfully integrates the concept of role into users and authorities [29–31]. Users can play their required part of roles in a reasonable scope and all roles have their authorities and then work accordingly. The core structure of this model is as shown in Figure 3.

In this model, users and authorities are not completely corresponding for one user can play the part of multiple roles and one role can have multiple users on the contrary. As well, the relation between roles and authorities is not single but has many-to-many characteristics. The relation of the three is as shown in Figure 4.

Role-based access control has advantages such as increasing the flexibility of the system and facilitating the distributed management of the administrator. Such model can effectively solve the problems of system management complexity and security defects in access control and meanwhile design authority schemes that satisfy the requirements of roles by virtue of database interfaces. From this, such model can be regarded as a user + role + authority model.

In summary, comparing with the discretionary access control model and the mandatory access control model, the robe-based authority management model has remarkable advantages in terms of flexibility, security, and management modes; therefore, the role authority management model is selected as the system authority control model in this paper.

**3.3. Design of Background Authority Functions.** In the background architecture, the operation layer can facilitate the interaction of front page data and the related methods in the Dao layer can help with the processing of background data. Therefore, three types of background authority control functions are set here, namely, the Task Controller Function, the Project Controller Function, and the User Controller Function, so as to meet the requirements of different objects and subjects.

## 4. Design and Realization of Cloud Computing Based Role Authority Management Systems

### 4.1. Design of Cloud Computing Based Role Authority Management Systems

**4.1.1. Design of Database.** After the authority control scheme is implemented, the background database side is needed to conduct tests. For MongoDB database belongs to

FIGURE 3: Model core structure.

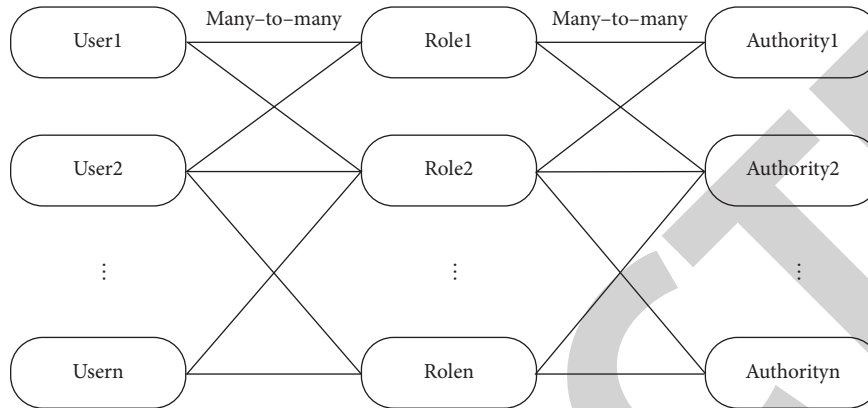

FIGURE 4: Relation diagram of users, roles, and authorities.

distributed file storage NoSQL database, interactive orders can be employed for the goal of operating and accessing the database; meanwhile the storage structure is flexible and changeable, and therefore Spring Boot is utilized to facilitate the design and realization of MongoDB database. Besides, to guarantee the effectiveness of authority control, the view mode is utilized to measure the authority of user groups. Specifically speaking, directly see the authorities possessed by roles in every user group in the form of views and then operate in the page accordingly.

**4.1.2. Design of Database Background Architecture.** The database background architecture is mainly composed of the Dao layer, the entity layer, and the operation layer. The entity layer here includes three entity classes, namely, the project, task, and user. The Dao layer enables operations such as deleting, adding, modifying, and querying of the database. The operation layer contains three related files, namely, the project, task, and user files. This layer can realize the front page data interaction; besides, it can also reasonably invoke the background data. And corresponding methods can be quickly found in the project class.

**4.1.3. Front Page Design and Parameter Passing.** HTML/CSS/Javascript grammars are utilized to realize the development of front pages and the Boor Strap framework is introduced to obtain better front pages. To guarantee the effective interaction between the front-end and rear-end pages, Spring Boot is also utilized here. Besides, in returning JSON objects to the front end, the parameter passing employs the value of Ajax function in JQuery.

**4.2. Realization of Cloud Computing Based Role Authority Management Systems.** For the test system utilizes Docker

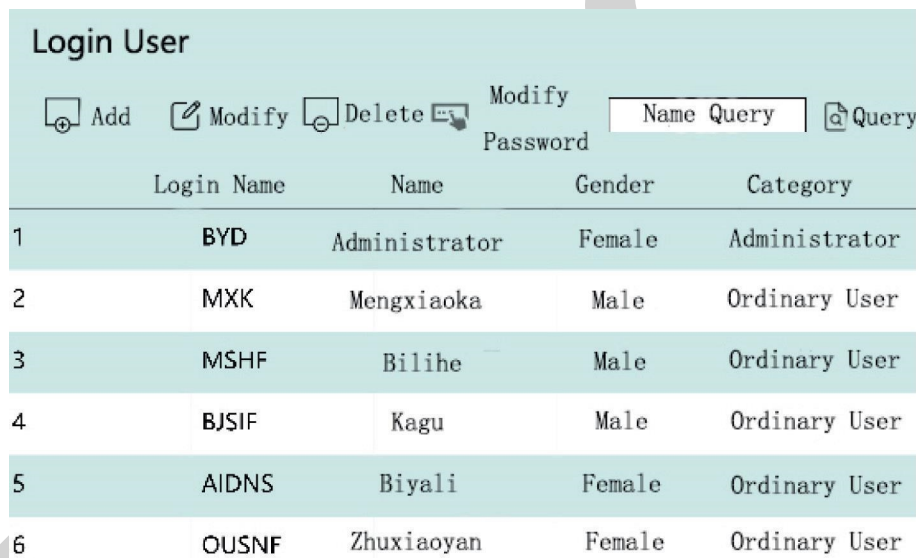

during the deployment, the environment and dependence required by the project should be stored. After the image construction is completed, the whole set of service can be obtained by directly operating images. Everyone who wants to test the project effect can test on his own simply by laying Docker environment in his host to build images and thus to reduce the tedious test process for the test personnel.

**4.2.1. Configuration Environment.** The hardware environment package of the cloud computing platform has multiple physical hosts matched with X86-64 chips. All the physical hosts carry Docker environments, chose Linux as the bottom layer operating system, and support 64-bit environment. Under the Ubuntu system, there are three steps in the configuration environment flow. First, examine the preparatory condition “uname-a” of the machine, upgrade the system kernel when it is found that the system kernel cannot meet the requirements of the design, and execute relevant installation operations only after the upgrading is completed. Meanwhile, to guarantee the normal installation of Curl order, add APT repository for assistance. Second, add GPG keys, renew the APT source, and then complete the installation of Docker software packages. Third, test the installation effect of Docker and execute “sudo docker info” order if the installation is determined to be normal. When no container or image is found in the order, the Docker environment is not completely installed, and we need to wait or reinstall it; otherwise, the installation of Docker environment is completed.

**4.2.2. Deployment File Writing.** Docker-compose.yml and Dockerfile are the two core files necessary for the system deployment. In docker-compose.yml file, two types of images need to be written-in. The first is the images of the

TABLE 2: System test results.

Item	Input/action	Expected output	Actual test result
Authority management	Users clicking the “Authority Management” button	Entering the role authority management interface	Test result consistent with the expected output
	Finding relevant content in the Find bar as needed	Displaying information found	Test result consistent with the expected output
	Clicking the “Modify” button	Displaying “Modify Authority”	Test result consistent with the expected output
Role management	Users clicking the “Role Management” button	Entering the role management interface	Test result consistent with the expected output
	Clicking the “Add” button	Displaying the user addition interface	Test result consistent with the expected output
	Clicking the “Modify” button	Displaying the user role modification interface	Test result consistent with the expected output
Node management	Clicking the “Query” button	Displaying all node definition information	Test result consistent with the expected output
	Clicking the “Delete” button	Displaying corresponding node to delete interface	Test result consistent with the expected output

The screenshot shows a web interface titled "Login User". At the top, there are several action buttons: "Add", "Modify", "Delete", "Modify", "Name Query", and "Query". Below these buttons is a table with the following columns: "Login Name", "Name", "Gender", and "Category". The table contains six rows of user data:

	Login Name	Name	Gender	Category
1	BYD	Administrator	Female	Administrator
2	MXK	Mengxiaoka	Male	Ordinary User
3	MSHF	Bilihe	Male	Ordinary User
4	BJSIF	Kagu	Male	Ordinary User
5	AIDNS	Biyali	Female	Ordinary User
6	OUSNF	Zhuxiaoyan	Female	Ordinary User

FIGURE 5: A part of the implementation interface of the cloud computing platform based role authority management system.

Spring Boot project. Spring Boot is a new framework developed by the Pivotal team to ease the difficulty of developing and building new Spring. Spring Boot is configured in a specific way rather than in traditional ways, avoiding manual configuration by developers. With this advantage, Spring Boot has been greatly promoted in the field of application development and has become the first choice of developers for system development. Spring Boot not only inherits the advantages of the Spring framework, but also optimizes the configuration, which further eases the difficulty of developing and building Spring applications. In addition, after the integration of a large number of frameworks, the problems of dependent package version conflict and application uncertainty are solved. The second is the images of MongoDB, the customization process of which is as follows: first, customize an nginx image and store the image in /usr/share/nginx/html/index.html file; second, input the From order and the RUN order; and third, execute

the building action under the storage directory of Dockerfile. After the images are successfully built, it is necessary to set the context path and construct the image instructions, such as constructing the parameter instructions, defining the anonymous data volume instructions, constructing the port declaration instructions, and establishing the working directory instructions. The system can only operate normally after the two types of images are written-in, while in Dockerfile, the environment and dependence required by the project should be defined to realize the independent compilation of Docker.

**4.2.3. Project Deployment.** Invoke and execute the “docker-compose up-d” order in the project, and then relevant images are obtained and the system is operated. The operation state of the containers can be directly checked through the “docker logs” order other than conducting

secondary examination of the MongoDB containers because the information of MongoDB is integrated into the images of the Spring Boot project. When MongoDB fails to start, the start of the project will terminate. The specific working process of the project is as follows: first, monitor the user's URL request; second, analyze the user request and filter the URL content; third, complete the selection of back-end processing functions according to different parameters and request contents; fourth, call the back-end processing function and get response; and fifth, transfer the content that needs to be returned to the user and present it on the front page.

## 5. System Test

After the deployment is completed, the system is tested to verify the sound interaction between the cloud computing platform and the role authority management system. The interaction service is carried out at the entrance of the user access system, which enables users to visually learn about the real-time status of the project and the requests of users can be processed accordingly. Details are as shown in Table 2.

It can be seen that the cloud computing platform based role authority management system has satisfactory test results consistent with expected outputs as well as strong robustness. A part of the implementation interface of the cloud platform based role authority management system test is presented as shown in Figure 5.

It can be seen that the cloud computing platform based role authority management system has complete functions and can effectively disclose member information. The cloud computing platform and role authority management system have good interaction, which confirms the feasibility of the design of this paper.

## 6. Conclusion

This paper first gives an overview of the research in this field, analyzes authority control models, Docker, and other related technologies, determines the role authority control model based on the basic framework of Docker, and designs the role authority management system on this basis. Finally, the cloud computing platform is deployed, its interaction with the role authority management system is completed, and the core authority function is realized. Through the test, the function of the cloud computing platform based role authority management system is fully verified, and the feasibility of the model design is confirmed. With the continuous research and development as well as optimization of the model, the basic framework can completely replace traditional role authority management modes and then promote the development of role authority management.

Docker is a lightweight virtual technology with advantages of shorter deployment time and higher resource utilization rate than virtual machines. The deployment of the project on Docker enables the system to realize the purpose of multiple operations at one time, which greatly shortens development and testing time, improves work efficiency, and is highly practical. However, this technology also has some

problems such as poor isolation performance and serious waste of storage resources, which affects the performance of the design architecture in this paper and indicates the direction for future research.

The protection of intangible cultural heritage has gradually attracted people's attention. In today's digital information age, the use of digital technology in the protection of intangible cultural heritage has become the focus of research in the field of intangible cultural heritage protection. For the protection of intangible cultural heritage to become the key goal of the continuous inheritance of China's traditional culture, this paper fully analyzes the problems existing in the inheritance and protection of intangible cultural heritage, and applies the high-performance computing method to the digital protection and development of intangible cultural heritage, which provides a strong basis for the protection of intangible cultural heritage. The accurate identification and protection of intangible cultural heritage can be achieved by using high-performance computing methods. In addition, the digital protection and development system of intangible cultural heritage is also designed. Finally, the example results show that the digital protection and development system of intangible cultural heritage proposed in this paper can effectively protect intangible cultural heritage and promote the continuous development of domestic local economy. At the same time, it can also strengthen the public awareness of the protection of intangible cultural heritage and effectively promote the inheritance and development of the protection of intangible cultural heritage.

## 1. Introduction

China's intangible cultural heritage has rich cultural connotation and cultural heritage value. In the process of continuous excavation, it can reproduce historical events and development tracks. Meanwhile, intangible cultural heritage also carries Chinese traditional cultural beliefs and inherits historical culture in a variety of ways, carries the historical culture with diversity and flexible development as a long-term development system of Chinese civilization. It can reflect the value of national tradition, cultural value and aesthetic value. The protection and inheritance of intangible cultural heritage are inherent spiritual needs of human beings [1–3]. However, the aesthetic status of intangible cultural heritage deserves further consideration, which is confirmed in the In terms of the continuous development of society, the continuous economic growth, the inheritance of traditional culture and the awareness of cultural values, and can be carried out in the protection and development of traditional intangible cultural relics, and the electronic

archives of intangible cultural heritage is established and other multi-channel protection methods are utilized to protect and develop the traditional intangible cultural heritage [4–6]. With the continuous progress of society, in the process of development and protection of intangible cultural heritage, digital protection will become the goal of in-depth research and exploration by Chinese and foreign scholars. The digital technology is used to electronically archive intangible cultural heritage, not only effectively processing massive data, be conducive to data storage and query, but also effectively avoid the loss and damage of data and information caused by natural and man-made disasters [7, 8]. The data mining technology can be used to deeply analyse the stored intangible cultural heritage data, provide valuable information data for visitors or users, and then complete the exchange and application of culture around the world. the high-performance computing and identification can be performed for the intangible cultural heritage as one of the most popular types of visual aggregation, which has become the focus of Chinese scholars' research [9–11].

However, how to obtain specific content sources from the initial intangible cultural heritage data that lacks the definition of intangible cultural heritage content has become a huge challenge for current high-performance computing of intangible cultural heritage, because intangible cultural heritage signals follows the way of time -sorting, which can use the high-performance computing in accordance with its stealth. At present, other classification methods are relatively simple, and the characteristics of intangible cultural heritage obtained are not accurate.

This paper proposes the digital protection and development of intangible cultural heritage. This method uses high-performance computing methods to extract the characteristics of intangible cultural heritage, calculate the weight of its protection space, integrate the space with high similarity in meaning, and build an intangible cultural heritage protection and development model. Intangible cultural heritage preserves cultural integrity through digitization, which is different from traditional cultural expressions and forms, because it is not a physical existence, but an information exchange across regions and countries. It covers scientific culture, social environment, civilized science and other cultures.

## 2. Technologies and Methods

**2.1. High-Performance Computing Methods.** The high-performance computing system can realize the I/O operation of the hard disk as little as possible based on the memory computing technology, and can also perform operation data analysis in the memory. Hadoop's MapReduce calculation engine saves the calculated intermediate value in the memory. In the next calculation, the original I/O request must be stored externally. Since high-performance computing directly stores intermediate values in memory and repeats them, high-performance computing reduces the time of data transmission as a whole compared with previous MapReduce, thereby ensuring the work efficiency of tasks [12, 13].

In view of the accuracy and diversity characteristics of intangible cultural heritage based on high-performance computing algorithms, the comprehensive analysis standard representation of data based on high-performance computing algorithms is defined, including

$$Eval(\pi_p) = \lambda Acu(\pi_p) + (1 - \lambda) Di v(\pi_p). \quad (1)$$

In the formula  $\lambda \in [0, 1]$ , the correctness and diversity of data processing are important degrees in the comprehensive analysis standard.

Formula (1) calculates the probability  $pro(\pi_p)$  that each data basic processing algorithm is selected as the analysis basic processing based on the diversity  $Div(\pi_p)$  of the basic processing of the high-performance computing algorithm. The calculation formula is as follows.

$$pro(\pi_p) = \frac{Div(\pi_p)}{\sum_{p=1}^B Div(\pi_p)}. \quad (2)$$

The purpose of the data processing network module is to make the color and spatial position of each reconstructed data to restore the inherent color and texture of the data. The loss function  $Lip$  of the data processing network module is defined by the formula. The above shown are processing loss for unmasked regions, processing loss for masked regions, perceptual loss, style loss, antiloss, and total difference loss.

$$L_{total}^{inp} = 2L_{valid} + 12L_{hole} + 0.04L_{per} + 100(L_{style}^1 + L_{style}^2) + 100L_{a_{dv}} + 0.3L_{var}. \quad (3)$$

The weight of each loss item is determined by analyzing the results of 50 independent experiments.

Manhattan distance uses the unmasked region of both the processed mode and the real mode to process the loss. In the equation,  $I_{dam}$  is the damage mode,  $M$  is an irregular binary mask (the corresponding processing area in the mask is 0, the others are 1), and  $I_{inp}$  is the processing result mode.  $I_{real}$  actually indicates there is no damage mode. The processing loss function for masked regions is similar to the expression:

$$L_{valid} = \|M \times (I_{inp} - I_{dam})\|_1, \quad (4)$$

$$L_{hole} = \|(1 - M) \times (I_{inp} - I_{dam})\|_1,$$

High-performance computing algorithms dynamically adjust appropriate parameter values based on the identification complexity of different regions of the data, so that the high-performance computing algorithm maintains a constant speed, and the generated metadata is more neatly unified in subsequent processing. In order to reduce the impact of the difference in the shape of the super data on the algorithm, this parameter does not need to be specified. Compare the  $I_{real}$  reduction identification points of intangible cultural heritage.  $h$  is the junction point of the first data, which is located in the data corresponding to the intangible cultural heritage database.  $0 \leq k \leq h(vx'_{2k+1,i}, vy'_{2k+1,i})$ , the following mining operations are performed on all identification points:

$$\begin{cases} dx'_k = vx'_{2k+1,i} - vx_{k,i} \\ dy'_k = vy'_{2k+1,i} - vy_{k,i} \end{cases},$$

$$\begin{bmatrix} vx'_{2k+1,i} \\ vy'_{2k+1,i} \end{bmatrix} = \begin{bmatrix} vx_{k,i} \\ vy_{k,i} \end{bmatrix} + \begin{bmatrix} \cos(-\theta) & -\sin(-\theta) \\ \sin(-\theta) & \cos(-\theta) \end{bmatrix} \times \begin{bmatrix} dx'_k \\ dy'_k \end{bmatrix}. \quad (5)$$

For each piece of data  $P_i$  and  $\tilde{P}_i$ , calculate the barycentric coordinates after removing the last point:

$$\begin{cases} \overline{vx}'_i = \frac{1}{h'_i - 1} \sum_{k=1}^{h'_i - 1} vx'_k \\ \overline{vy}'_i = \frac{1}{h'_i - 1} \sum_{k=1}^{h'_i - 1} vy'_k \end{cases} \begin{cases} \overline{vx}_i = \frac{1}{h_i - 1} \sum_{k=1}^{h_i - 1} vx_k \\ \overline{vy}_i = \frac{1}{h_i - 1} \sum_{k=1}^{h_i - 1} vy_k \end{cases} \quad (6)$$

In the formula,  $h$  is the length (number of nodes) of the  $i$ -th piece of data after the intangible cultural heritage database is divided; the  $h'_i$  data is embedded in the identified length, and the following two offset values are calculated:

$$\begin{cases} \Delta x_i = \frac{1}{2h_i - 2} \sum_{k=1}^{h_i-1} (vx_{k+1} - vx_k) P_k, \\ \Delta y_i = \frac{1}{2h_i - 2} \sum_{k=1}^{h_i-1} (vy_{k+1} - vy_k) P_k, \end{cases} \quad (7)$$

According to formula (12)~formula (15), calculate the identification point of the vertical and horizontal coordinates of each piece of data respectively.

①  $\Delta x_i \neq 0, \Delta y_i \neq 0$

$$\begin{cases} qx_j = \sum_{\{i|i/c=j\}} \frac{\overline{vx'_i} - \overline{vx_i}}{\Delta x_i} = \sum_{\{i|i/c=j\}} \tilde{b}_i \alpha = \tilde{c} \tilde{b}_j \alpha, \\ qy_j = \sum_{\{i|i/c=j\}} \frac{\overline{vy'_i} - \overline{vy_i}}{\Delta y_i} = \sum_{\{i|i/c=j\}} \tilde{b}_i \alpha = \tilde{c} \tilde{b}_j \alpha. \end{cases} \quad (8)$$

②  $\Delta x_i = 0, \Delta y_i \neq 0$

$$\begin{cases} qx_j = \sum_{\{i|i/c=j\}} \sum_{k=1}^{h_i-2} \frac{\overline{vx_{k,i}} - vx_{k,i}}{(vx_{k+1,i} - vx_{k,i}) P_k} = \sum_{\{i|i/c=j\}} \tilde{b}_i \alpha = \tilde{c} \tilde{b}_j \alpha, \\ qy_j = \sum_{\{i|i/c=j\}} \frac{\overline{vy'_i} - \overline{vy_i}}{\Delta y_i} = \sum_{\{i|i/c=j\}} \tilde{b}_i \alpha = \tilde{c} \tilde{b}_j \alpha. \end{cases} \quad (9)$$

③  $\Delta x_i \neq 0, \Delta y_i = 0$

$$\begin{cases} qx_j = \sum_{\{i|i/c=j\}} \frac{\overline{vx'_i} - \overline{vx_i}}{\Delta x_i} = \sum_{\{i|i/c=j\}} \tilde{b}_i \alpha = \tilde{c} \tilde{b}_j \alpha, \\ qy_j = \sum_{\{i|i/c=j\}} \sum_{k=1}^{h_i-2} \frac{\overline{vy_{k,i}} - vy_{k,i}}{(vy_{k+1,i} - vy_{k,i}) \circ P_k} = \sum_{\{i|i/c=j\}} \tilde{b}_i \alpha = \tilde{c} \tilde{b}_j \alpha. \end{cases} \quad (10)$$

④  $\Delta x_i = 0, \Delta y_i = 0$

$$\begin{cases} qx_j = \sum_{\{i|i/c=j\}} \sum_{k=1}^{h_i-2} \frac{\overline{vx_{k,i}} - vx_{k,i}}{(vx_{k+1,i} - vx_{k,i}) P_k} = \sum_{\{i|i/c=j\}} \tilde{b}_i \alpha = \tilde{c} \tilde{b}_j \alpha, \\ qy_j = \sum_{\{i|i/c=j\}} \sum_{k=1}^{h_i-2} \frac{\overline{vy_{k,i}} - vy_{k,i}}{(vy_{k+1,i} - vy_{k,i}) \circ P_k} = \sum_{\{i|i/c=j\}} \tilde{b}_i \alpha = \tilde{c} \tilde{b}_j \alpha. \end{cases} \quad (11)$$

Calculate the cultural information value for each piece of data:

$$\tilde{m}_j = \begin{cases} 1, \frac{qx_j + qy_j}{2} > 1, \\ 0, \frac{qx_j + qy_j}{2} < 1. \end{cases} \quad (12)$$

After extracting the cultural information, check the authenticity of the identification. This process uses the correlation coefficient  $cor(m, \tilde{m})$  to detect the similarity between the original recognition and the extraction recognition:

$$cor(m, \tilde{m}) = \frac{\sum_{i=0}^{n-1} (m_i \tilde{m}_i)}{\sqrt{\sum_{i=0}^{n-1} m_i^2} \sqrt{\sum_{i=0}^{n-1} \tilde{m}_i^2}} \quad (13)$$

In the formula,  $\tilde{m}$  is the cultural information extracted from the identified graphics;  $cor(m, \tilde{m})$  is the correlation coefficient of the cultural information  $m$  and  $\tilde{m}$ . When high-performance computing optimizes the BP algorithm, the roulette method is usually chosen. If the fitness of the  $i$ -th individual is  $f_i$ , the probability  $P_{si}$  of the  $i$ -th individual being left behind is

$$P_{si} = \frac{f_i}{\sum_{j=1}^n f_j}. \quad (14)$$

In this paper, as shown in (9), an overall crossover scheme is chosen.

$$\alpha = \begin{cases} \frac{f_{\max} - f_i}{f_{\max} - f_{avg}}, f_i \geq f_{avg}, \\ 0.35, f_i < f_{avg}. \end{cases} \quad (15)$$

In the formula,  $\alpha$  represents the gene-encoded combination coefficient,  $f_i$  represents the fitness value of the  $i$ -th individual in the parent population,  $f_{\max}$  and  $f_{avg}$  represent the maximum and average fitness values of the individuals in the parent population, respectively.

The final high-performance computing process is shown in Figure 1.

Effectively combining the compatibility of high-performance computing with more distributed systems, the main operating modes of the system can be divided into single-point mode and dispersion mode. This mode mainly uses YARN, Mesos or EC2 for resource allocation and scheduling. RDD is computed by using high-performance computing, and the memory with prominent operation characteristics can effectively improve the calculation efficiency of the model. RDD has the data characteristics of compatibility and parallelism, and can interact with the memory and external memory. If the storage cannot meet the requirements of a single RDD, the RDD will be transferred to the external memory. The digital protection and development algorithm can obtain better performance in the process of data mining. This algorithm can be used for training data to reduce the accuracy and performance. In order to solve this problem, the data mining method is used to directly determine the

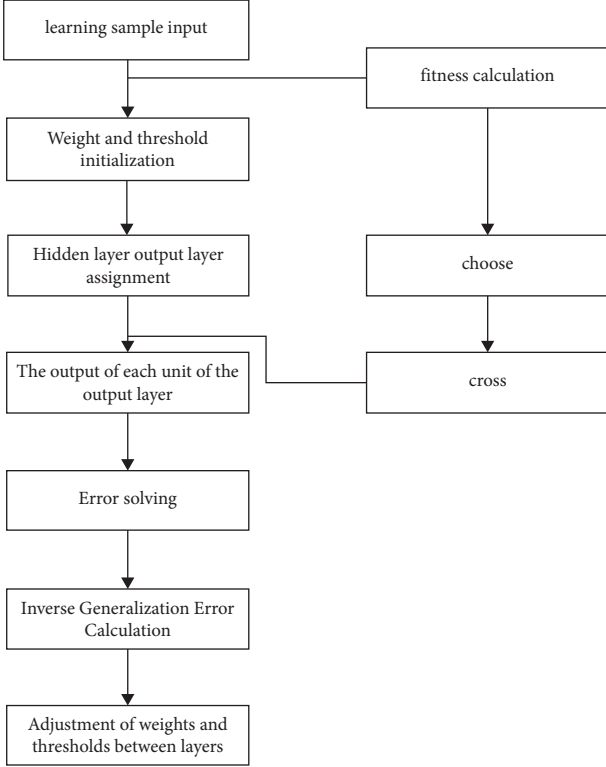

FIGURE 1: High-performance computing flow chart.

first category as the final data. As a result, the tie situation that cannot be solved by the average value cannot be fundamentally solved, so the drawbacks of the model can be effectively avoided. The classification performance of each classifier is protected using the Berius equation. The formulas that can be used are:

$$\text{weight}(i) = 1 - \frac{1/\text{con}(i)}{\sum_{j=1}^T 1/\text{con}(j)} - \frac{N-2}{N}. \quad (16)$$

In formula (1),  $N$  represents the total number of classifiers,  $\text{con}(k)$  represents the posterior probability of the classification result of the  $k$ th classifier in the Bagging algorithm, and  $\text{weight}(i)$  represents the weight of the  $i$ -th classifier.

Two properties of the formula:

- (1) The higher the classification accuracy rate, the higher the weight of the high-performance computing
- (2) Conform to the formula  $\sum_{j=1}^T \text{weight}(i) = 1$ , that is, all high-performance computing can meet the normalization conditions

The Bagging algorithm can be analyzed through out-off-bag data. The F1 value of out-off-bag is smaller than the Bayes formula according to the calculated verification probability. Therefore, in order to reduce the amount of calculation and give up the post-probability of the classification result, the F1 of Out-of-bag is used to judge the correctness of the classification. You can obtain formula (12) by modifying formula (11):

$$\text{weight}(i) = \frac{2}{N} - \frac{1/\text{oob}F_1}{\sum_{j=1}^T 1/\text{oob}F_1(j)}. \quad (17)$$

In formula (2),  $N$  represents the total number of classifiers,  $\text{oob}F_1(k)$  represents the F1 value of the out-of-bag of the  $k$ th classifier, and  $\text{weight}(i)$  represents the weight of the  $i$ -th classifier.

From the perspective of industrial connections, the collection of enterprises generally appears as a vertical chain connection, upstream and downstream enterprises are effectively linked through production links, and the cooperation and competition relationship is the center between enterprises. The SDA method assumes that  $n$  sample sets  $X$  are processed.

$$X = \{x_1, x_2, \dots, x_n\}. \quad (18)$$

The index used is  $p$ , and fuzzy clustering is performed according to the classification:

$$x_k = \{x_{k1}, x_{k2}, \dots, x_{kp}\}, x_{kj} = [a_{kj}, b_{kj}], 1 \leq k \leq n, 1 \leq j \leq p. \quad (19)$$

The relative membership degree of the matrix of the model is represented by  $U$ :

$$U = \{u_{ik}\}, (i = 1, 2, \dots, c; k = 1, 2, \dots, n). \quad (20)$$

$u_{ik}$  indicates the membership degree of sample point  $k$  to category  $i$ , and satisfies the following conditions.

$$\begin{cases} \sum_{i=1}^c u_{ik} = 1, \forall k, \\ 0 \leq u_{ik} \leq 1, \forall k, i. \end{cases} \quad (21)$$

The cluster center of the  $i$ -th category can be represented by  $g_i$ :

$$g_i = (g_{i1}, g_{i2}, \dots, g_{ip}), g_{ij} = [\alpha_{ij}, \beta_{ij}], 1 \leq i \leq c, 1 \leq j \leq p. \quad (22)$$

Here, the weight of the cluster is expressed by importing the adaptive parameter  $\lambda$ :

$$\lambda_k^m = (\lambda_{k1}^m, \lambda_{k2}^m, \dots, \lambda_{kp}^m). \quad (23)$$

The expression of comprehensive weight is

$$W = \sum_{i=1}^c \sum_{j=1}^n (u_{ik})^2 \Phi(x_k, g_i) = \sum_{i=1}^c \sum_{j=1}^n (u_{ik})^2 \cdot \sum_{j=1}^p \left[ \lambda_k^m \left( \frac{a_{kj} + b_{kj}}{2} - \frac{\alpha_{kj} + \beta_{kj}}{2} \right)^2 \right], \quad (24)$$

which satisfies

$$\begin{cases} \lambda_{ij}^m \geq 0, \\ \prod_{j=1}^p \lambda_{ij}^m = 1. \end{cases} \quad (25)$$

The Lagrangian method is used to derive the aggregation function to obtain

$$\begin{aligned}
\alpha_{ij} &= \frac{\sum_{i=1}^n (u_{ik})^2 a_{kj}}{\sum_{i=1}^n (u_{ik})^2}, \beta_{ij} = \frac{\sum_{i=1}^n (u_{ik})^2 b_{kj}}{\sum_{i=1}^n (u_{ik})^2}, \\
\lambda_{ij}^m &= \frac{\prod_{h=1}^p \left[ \sum_{k=1}^p (u_{ik})^2 (a_{kh} + b_{kh}/2 - \alpha_{ih} + \beta_{ih}/2)^2 \right]^{1/p}}{\sum_{k=1}^p (u_{ik})^2 (a_{kj} + b_{kj}/2 - \alpha_{ij} + \beta_{ij}/2)^2}, \\
u_{ik} &= \left[ \frac{\sum_{h=1}^c \sum_{j=1}^p \left[ \lambda_{ij}^m (a_{kh} + b_{kh}/2 - \alpha_{ih} + \beta_{ih}/2)^2 \right]}{\sum_{h=1}^c \sum_{j=1}^p \left[ \lambda_{hj}^m (a_{kh} + b_{kh}/2 + \alpha_{ih} + \beta_{ih}/2)^2 \right]} \right].
\end{aligned} \tag{26}$$

Generally speaking, the effect of enterprise concentration mainly comes from various factors such as natural resources, geographical environment and process technology. The initial integration mainly reflects the production and operation cooperation between different enterprises. Geographical location integration among enterprises is essentially based on competitive and cooperative relations, and the clustered enterprise matching degree is used for integrating internal resources of the enterprise, reducing trade costs as much as possible, and maximizing profits at the same time.

High-performance computing can build the most serialized time series models and use them on a large scale in the process of digital protection and development of intangible cultural heritage. The N states existing in the model can be set to  $S = \{S_1, S_2, \dots, S_n\}$ , then the state at time  $t$  is represented by  $q_t$ . Using  $A = \{a_{ij}\}$  in the transition matrix between different states, the following expression can be obtained:

$$\alpha_{ij}(k) = P[q_{t+1} = S_j | q_t = S_i], 1 \leq i, j \leq N. \tag{27}$$

For some samples, any state can reach other states in one transition; other samples, In other samples, only transitions between certain states can occur, that is,  $a_{ij} > 0$  occurs only for some  $i, j$ .

The difference between the sample and the random forest graph chain is that for each state, only one external value can be used for the observation, and the obtained observation vector is related to the state of the system, and this relationship can be discrete or continuous.

But for continuous distribution observation, the probability distribution of the observation vector corresponding to its state  $j$ :

$$b_j(v_t) = P[v_t | q_t = S_j], 1 \leq j \leq N. \tag{28}$$

Generally, the probability distribution is taken as the mixed Gaussian distribution, namely

$$b_j(v_t) = \sum_{m=1}^M \omega_{j,m} N(o_t, \mu_{j,m}, \Sigma_{j,m}). \tag{29}$$

M represents the number of mixed Gaussian distributions, and  $\bar{w}$  represents the positive mixture weight, but use  $N(o_t, \mu_{j,m}, \Sigma_{j,m})$  to represent the n-dimensional Gaussian distribution.

$$\pi_i = P[q_1 = S_i], 1 \leq i \leq N. \tag{30}$$

Therefore, the samples can be summarized into three groups  $\lambda=(A, B, \pi)$ . Then the observation sequence generated by this model can be expressed as  $O = o_1 o_2 \dots o_T$ ,  $o_t$  represents the vector that can be observed at time  $t$ , and  $T$  represents the total observation length.

*2.1.1. Digital Protection and Exploitation.* The time complexity and space complexity of high-performance computing of intangible cultural heritage are mainly affected by the dimension of the feature vector of intangible cultural heritage. In order to effectively improve the protection accuracy of the constructed model, the extraction of the model space can be determined by reducing the dimension of the intangible cultural heritage. In this paper, the information gain algorithm is used to calculate the average amount of information of the constructed model:

$$\begin{aligned}
G(w) &= - \sum_{k=1}^N P(c^k) \log_2 P(c^k) \\
&+ P(w) \sum_{k=1}^N P(c^k | w) \log_2 (P(c^k | w)) \\
&+ p(\bar{w}) \sum_{k=1}^N p(c^k | \bar{w}) \log_2 p(c^k | \bar{w}).
\end{aligned} \tag{31}$$

In the formula, represents the complementary set of  $w$ .  $\bar{w}$  corresponds to the number of spaces T: the average number of heritages in the intangible cultural heritage is trained. In the preprocessing stage, the preprocessed intangible cultural heritage is represented by word2 vec as a vector, and the intangible cultural heritage vectors with high similarity are combined to record the number of heritages. During the process of space selection in this paper, the meaning information of spatial agglomeration vectors is considered.

For built HPC, the space is traversed during state transitions. The sequence of the spatial output is expressed as using  $k$ , and  $k$  is expressed as the spatial sum that meets the similarity threshold. Therefore, in obtaining the intermediate state  $s_i$  of this model, the corresponding observation value distribution in the class  $c^k$  can be expressed as

$$b_{c_k}^i(w_{c_i}) = p\{k | s_i = w_{c_i}\}. \tag{32}$$

Taking into account that the distribution of  $b_{c_k}^i$  and spatial frequency is constrained, with the increase of spatial

distance in the whole processing process, the aggregation of different intangible cultural heritage will also be lower.

$$b_{c_k}^i(w_{c_i}) = IFI DF(i) = \frac{D_c^k(i) + 1}{\sum_c k D_c^k(i) + |C|} \times \frac{N_c^k(i) + 1}{\sum_c k N_c^k(i) + |C|}. \quad (33)$$

In the formula,  $D_c^k(i)$  represents the intangible cultural heritage business items containing  $w_{c_i}$  in  $c_k$ ;  $N_c^k(i)$  represents the number of occurrences of space  $w_{c_i}$  in the  $c_k$  category, then the number of occurrences in the same category will have The role of regularization.

For the state transition matrix, due to the high-performance computing of  $c_k$ , it can be summarized as the intangible cultural heritage in this category, then it will be transferred from the first state to the second stage state until the end of the state. The matrix of state transition  $A_c^k$  can be expressed as

$$a_{ij} = \begin{cases} 1, & j = i + 1, \\ 0, & j \neq i + 1. \end{cases} \quad (34)$$

Specify the probability  $\pi = \{1, 0, \dots\}$  of the initial state  $s_0$ . High performance computing for the category  $c_k$  can be expressed as

$$\lambda_k = \{\Pi, A_{c_k}, B_{c_k}\}. \quad (35)$$

**2.1.2. Digital Protection and Development of Intangible Cultural Heritage.** Because of the randomness of the collected data and the splitting of the node characteristics, it can ensure that there is no connection between the obtained deterministic numbers, and meanwhile, it can be used for the visual aggregation method of scientific computing, so that it has the characteristics of initial parallelism. Digital protection and development algorithms can effectively provide feedback on decision parallelization, node parallelization and feature selection.

The scientific computing visualization aggregation method is used to parallelize the collected data, which can realize the method of dispersing multiple computer nodes for the sample data during the operation. Compared with the traditional single machine identification method, it can effectively save I/O operations, and can reduce the use of more network bandwidth. According to the data obtained by parallel computing, the idea of parallelization of scientific computing visualization aggregation method is used in this paper, and combining the framework characteristics of high-performance computing, a parallel implementation strategy for scientific computing visualization aggregation is designed.

**(1) Sample Sampling Statistics of Feature Cut Points.** According to the optimal feature of the decision tree that needs to be determined, the cut point is selected for the selected feature, and the distribution feature of the data is used to sample and analyse different data features, and finally summarize to the master node of the data. This operation is mainly to perform the whole process of

computation based on different node pairs, but only a smaller bandwidth is used in the final stage of integration. Therefore, for the value of the entire eigenvalue of the data, during the process of sorting the data, the use of larger bandwidth and I/O operations should be avoided as much as possible.. The method of data collection will have a direct impact on the accuracy of the data.

**(2) Layer-By-Layer Training of Data Samples.** The deep optimization of high-performance computing in a single-sample mode is transformed into a priority strategy as the essence of each layer of training. In a distributed environment, in order to realize the training of each layer, the number of different loops that need to be constructed is the same as the maximum layer of the tree. In addition, during the loop stage, it is necessary to perform parameter statistics and judge on the split points of nonleaf nodes, according to the characteristics.

It is necessary to initialize the RFM parameters, and then use the Baum-Welch algorithm to perform operations. According to the use of the scientific computing visualization aggregation algorithm, the results obtained have a great relationship with the initial parameters. The transformation matrix needs to be initialized to determine whether the transition matrix is 0 or that after the iterative operation is 0. Define the observation sequence as

$$P(O|\lambda) \geq P(O|\lambda). \quad (36)$$

The way to compute  $P(O|\lambda)$  is a forward-backward algorithm. For the sample parameter  $\lambda$  and state  $i$ , define the forward probability  $\alpha_t(i)$ :

$$\alpha_t(i) = P(o_1 o_2 \dots o_T, q_t = i | \lambda). \quad (37)$$

That is,  $\alpha_t(i)$  is the probability that the parameter  $\lambda$  produces the sequence  $(o_1 o_2 \dots o_t)$  and the state at time  $t$  is  $o_t$ .

$P(O|\lambda)$  can be calculated by the following forward algorithm.

(1) Initialization

$$\alpha_1(j) = b_j(o_1), 1 \leq j \leq N. \quad (38)$$

(2) Recursion

$$\alpha_t(i) = b_i(o_t) \left[ \sum_{j=1}^N \alpha_{t-1}(j) \alpha_{ji} \right], 2 \leq t \leq T, 1 \leq i \leq N. \quad (39)$$

(3) Termination

$$P(O|\lambda) = \sum_{j=1}^N \alpha_T(j). \quad (40)$$

Define both  $\beta_t(i)$  and  $\xi_t(i, j)$

$$\begin{aligned} \beta_t(i) &= P(o_{t+1} o_{t+2} \dots o_T | q_t = i, \lambda), \\ \xi_t(i, j) &= P(q_t = i, q_{t+1} = j | O, \lambda). \end{aligned} \quad (41)$$

From the forward-backward calculation method,  $\xi_t(i, j)$  can also be expressed as [11, 12]:

TABLE 1: Experimental environment parameters.

Development program	Version
Operating system	Centos7.3
JDK	1.8.0-144
Internet	2 GB
Hadoop	2.7.0
High-performance computing	2.12.4
Master node	4 cores, hard disk 256G, 8G memory, one node
Worker node	1 core, 250G hard disk, 2G memory, five nodes

$$\begin{aligned} \xi_t(i, j) &= \frac{P(q_t = i, q_{t+1} = j | O, \lambda)}{P(O | \lambda)} = \frac{\alpha_t(i) \alpha_{ij} b_j(o_{t+1}) \beta_{t+1}(j)}{P(O | \lambda)} \\ &= \frac{\alpha_t(i) \alpha_{ij} b_j(o_{t+1}) \beta_{t+1}(j)}{\sum_{i=1}^N \sum_{j=1}^N \alpha_t(i) \alpha_{ij} b_j(o_{t+1}) \beta_{t+1}(j)} \end{aligned} \quad (42)$$

The probability  $\gamma_t(i, m)$  that the system is in the  $m$ -th mixed component of state  $i$  at time  $t$  is:

$$\gamma_t(i, m) = \left[ \frac{\alpha_t(i) \beta_t(i)}{\sum_{i=1}^N \alpha_t(i) \beta_t(i)} \right] \left[ \frac{\mu_{j,m} N(o_t, \mu_{j,m}, \Sigma_j, m)}{\sum_{m=1}^M \omega_{j,m} N(o_t, \mu_{j,m}, \Sigma_j, m)} \right]. \quad (43)$$

First, the labeled training set is used to train samples of various classes, respectively. Let the class that requires high-performance computing be  $k = \{1, 2, \dots, K\}$ , and each class corresponds to the model parameters  $\lambda_k$ . The maximum likelihood criterion is used to maximize the posterior probability, while considering the Bayes formula, then

$$\bar{k} = \arg \max_{1 \leq k \leq K} P(\lambda_k | O) = \arg \max_{1 \leq k \leq K} \frac{P(O | \lambda_k) P(\lambda_k)}{P(O)}. \quad (44)$$

Assuming that the prior probability  $P(\lambda_k)$  of each type is the same, because  $P(O)$  and  $k$  are not related, the decision is omitted as follows.

$$\bar{k} = \arg \max_{1 \leq k \leq K} P(O | \lambda_k). \quad (45)$$

Because  $P(O | \lambda_k)$  is very small, floating-point underflow will occur during computer operations, so logarithmic values are usually taken from it. For multiple observation sequences, only each formula needs to be weighted [14].

In the current intangible cultural heritage space identification industry, in order to meet the different needs of enterprises,  $i$  the individual needs of enterprises need to be responded to in a timely manner, and the intangible cultural heritage is mainly divided into two parts: development and design. On the basis of fully analyzing the changes in market demand, personalized services can be provided to enterprises in terms of the development process and design cycle of emerging intangible cultural heritage; meanwhile, personalized design of intangible cultural heritage can be carried out according to the actual needs of enterprises. The goals of these two links are not the same as the main tasks, but there is an internal connection. In the process of intangible cultural heritage space identification, modular and standardized design is carried out as the basis for the

intangible cultural heritage space identification process. Regarding the nonsegmented pieces of clothing in the process of intangible cultural heritage space identification, it should be transformed into a provincial virtual reality model, and it should include knowledge to support the development of new intangible cultural heritage and knowledge of corporate design according to corporate needs.

High-performance computing, which is based on virtual reality, "enhances" the real world by superimposing computer-generated virtual objects, scenes or system cues on the actual scene. High-performance computing can not only introduce virtual objects into the actual environment, but also dynamically show the position and posture of virtual objects to maintain the consistency of virtual objects and actual scenes, therefore the habit of observing high-performance computing environments with more personal eyes can be cultivated. This way of interaction looks more natural. On the other hand, since HPC keeps the actual scene, the output is more realistic [15–17].

If the high-performance computing is used, the cameras can be used to capture real-world situations to obtain video streams. The tracking method is used to process each frame in the video stream, the actual coordinates and state of the camera are calculated using geometric calculation methods, and the coordinates and states of the virtual objects registered in the actual background are used to form a virtual scene. The technology of video combination is used, to combine the virtual scene and the real background video stream are combined, and the combined result is transmitted to the display in time.

### 3. Experimental Results and Analysis

Each parallel frame in this experiment is constructed in the environment of high-performance computing cluster, the storage in the experiment is carried out by Hadoop, and the calculation of the data in the experiment is presided over by the high-performance computing program. The various development programs and their version numbers used in this experiment are shown in Table 1.

In order to verify the institutional hypothesis in the previous sentence, the verification model is set as follows.

$$ITU_{s_{ijkt}} = \alpha + \beta_1 f_{incol_{ijkt}} + \beta_2 X_{ijkt} + \vartheta_i + \tau_j + \varphi_t + \varepsilon_{ijkt}. \quad (46)$$

In the formula,  $k$ ,  $i$ ,  $j$ , and  $t$ , respectively represent the enterprise, industry, region and year;  $ITU_{s_{ijkt}}$  represents the transformation result of manufacturing enterprises;

$fincol_{ijkt}$  represents the spatial synergistic distribution between intangible cultural heritage and manufacturing;  $X_{ijkt}$  represents the control variable;  $\alpha$  represents the constant term;  $\varepsilon_{ijkt}$  is the random disturbance term. In addition,

industry fixed effects  $\vartheta_i$ , region fixed effects  $\tau_j$  and time fixed effects  $\varphi_t$  are added to the model.

The above combines the mathematical relationships between all attributes to validate the resulting attributes

FIGURE 4: Augmented reality renderings of cards before and after coloring.

obtained from the results of the classification model and evaluate the model performance against the metrics of the confusion matrix. Table 2 is the confusion matrix.

The experimental results are shown in Table 3. The experimental results show that the comparison of the accuracy of the protection of intangible cultural heritage is achieved by using the two algorithms to compare the experiments. Experiments also fully demonstrate the reliability of this method.

Figure 2 is an interface diagram of the AR module and the VR module. The module is introduced, and the interactive functions of video, voice, and intangible cultural heritage introduction are added. The origin of traditional cultural works, the production technology and development are described. Figure 3 is the effect of voice and text explanation. The VR module provides a detailed display function of VR 3D models. Users can enter the display page of VR 3D models of traditional cultural works by clicking the photos of traditional cultural works Save the model screen of interest. The AR module strengthens the relevant information of traditional cultural works through user scanning, and meanwhile paints for design on the traditional cultural works card, which enhances the interest and interaction of AR experience. This is to strengthen the display effect of the mobile terminal before and after the card is painted. In the feedback module, users can give feedback on the usage of the APP. Further enrich the functions of the APP to meet the needs of users.

In addition, the postcard design method using AR still contains traditional culture. In order to further protect the inheritance of intangible culture, the AR Postcard designed with traditional design methods according to Figure 4 can understand the traditional culture from the designed postcard. As an effective carrier of culture, the postcard can further improve the inheritance of intangible cultural inheritance, Users can use the mobile terminal to query and design ar postcards containing traditional cultural works. Ar postcards enhance the display of reality. Traditional handicrafts combine modern digital and interactive media technology to attract the younger generation to understand the production process and aesthetic characteristics of traditional handicrafts.

It is held to further publicize and popularize the protection of intangible cultural heritage. Traditional cultural works enter campus activities. Through activities in kindergartens, primary schools and other places around the city, the origin and manufacturing technology of traditional

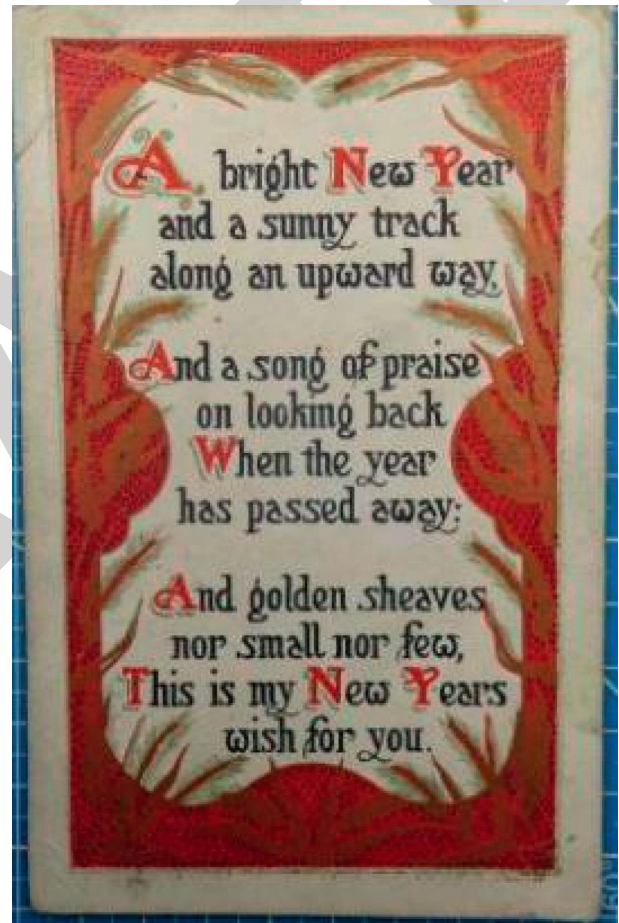

FIGURE 5: AR postcard display of traditional cultural works.

cultural works are displayed in 3D models of traditional cultural works. The mobile augmented reality APP test designed in this paper stimulates enthusiasm for learning from students and teachers to understand the intangible cultural heritage. Compared with the traditional intangible cultural protection method, this system improves the user's sense of experience and mutuality (Figure 5).

#### 4. Conclusion

In the process of the development of modern society, human's sense of inferiority towards traditional culture is not only the preservation, recording and display of cultural

The networking scale and traffic have exploded. At the same time, the rapid development of virtualization and cloud computing technologies not only poses a considerable challenge to the endurance of the network, but also causes more and more problems to the traditional network architecture with IP as the core. Cloud computing is a supercomputing model based on the Internet. With the rapid growth of network access and data traffic, the processing power and computing intensity will also increase, and a single server cannot afford the increase in business. In order to reduce network pressure and improve computing efficiency, load balancing for network computing is particularly important. This paper uses ant colony algorithm to design cloud computing load balance. The ant colony algorithm runs in the controller. According to the real-time network load situation provided by the controller, it calculates the link with the smallest load and provides a dynamic data stream forwarding strategy. The result of the experiments shows that the load-balanced ACO optimized technique can significantly provide an improved computational response. In the ACO algorithm, the average response time is about 30% lower than that in other algorithms. This shows that the use of the ant colony algorithm achieves a good optimization effect.

## 1. Introduction

Cloud computing is a relatively new technology based on software services such as electricity and computing. It does its job by providing service and feedback. Service provision and use conditions are important features that distinguish it from the previous complex. Low database efficiency will affect system performance, reduce system response time, and even more seriously cause node downtime. For the scheduling of cloud resources, the diversity of cloud components and the diversity of user needs make some nodes overloaded, affecting the use of the entire system and resources. Cloud computing can realize the sharing of resources, can process massive amounts of data, and can provide an unlimited amount of storage space. Therefore, cloud computing is applied to military, school, medicine, scientific research, and other fields. However, when cloud computing faces such a large number of users, it has to deal with a lot of data and tasks. When a large number of requests are processed at the same time, this will affect the

performance of the entire system. Therefore, how to achieve source access load balancing has become one of the most important issues in the implementation of cloud computing.

Cloud computing is already a significant area of research as a computer scientist. Load balancing technology is considered to be one of the most vital research directions in cloud computing and is a popular research direction that is constantly evolving. In cloud computing, the evolution must rely on the development of load balancing technology. So far, there is no ideal research result for downloading load balancing technology used in cloud environment, so it can be studied from different aspects. Due to its positive feedback mechanism and robustness, ant colony algorithm has been extensively studied and improved since it was proposed, especially for combinatorial optimization problems in application. Ant colony algorithm shows great advantages, so this article will use ant colony algorithm as the basis to apply it to the resource allocation problem in cloud computing.

A large amount of research has been done by domestic and international experts on the application of ant colony algorithms. Zhao et al. proposed a fault classification technique for neutral and invalid grounding systems based on binary ant colony algorithm (BACA) with fuzzy neural network (FNN). Test samples and field experimental findings indicate the high accuracy and good adaptability of the proposed fault classification method [1]. Vu et al. proposed the development of a quantum ant colony algorithm (QACA) to improve silent human transmission from dangerous areas to safe areas. Compared to the ACO (ant colony optimization) method, QACA has the ability to find better solutions faster using fewer individuals due to quantum representation and pheromone information and has a stronger potential. Experimental results show that the proposed method has more effective performance [2]. Pham et al. proposed a new algorithm that combines scene filtering procedures, precise algorithms, and parallel ant colony algorithms. Experiments show that building multiple initial solutions with reduced scene sets for the ant colony algorithm can significantly reduce the total time required to find the best solution. The proposed algorithm can be used for the automated construction of reliable control systems [3]. Jiang et al. used the ACO algorithm, which uses anaerobic digestion (AnD) for combination to increase biogas production to increase the release of organic waste from various waste sources in real time. An enrichment plant has been developed based on a virtual case study of organic waste affecting urban wastewater treatment plants and agri-food operations. Studies have shown the importance of the ACO method in supporting decision-making processes that help improve organic waste management and SWS control [4]. As for load balancing methods, there are fewer related studies. Hajiesmaili et al. proposed a traffic load balancing framework that seeks to strike a balance between network applications (such as total delivery delays) and green energy consumption. The statistical results show that the proposed traffic load balancing process can achieve adjustable compensations between the use of grid power and the total traffic delivery delay and saves a lot of network-connected energy at a certain cost [5]. Sarma et al. reviewed the program documentation proposed by current load balancing technologies. In addition, the advantages and disadvantages associated with many load balancing algorithms are also discussed, and the main challenges of these algorithms are identified, so that more efficient load balancing systems can be developed over time [6]. Akbari et al. proposed another algorithm with less complexity for the load balancing problem. The algorithm provides worst-case performance guarantees and describes a simple way to approximate user associations for a given input by a bias factor. Next, there is a small-scale algorithm for the overall optimization problem, with an algorithm based on the following approximate method, which has been used for nonextension optimization problems [7]. Zhao J proposed a new heuristic method for the physical host selection problem of the deployment request task, which is called Bayesian and clustering-based load balancing. As demonstrated by the results of the simulation, the proposed approach significantly reduces the

failures of the mission deployment incidents, improves the amount of throughput, and optimizes the outside-in service performance of the hybrid service in the cloud data center compared to existing work [8]. These studies provide a great reference for this article, but there are few studies on the application of ant colony optimization algorithms to cloud computing loads.

The article introduces the basic knowledge of cloud computing and the problem of resource allocation in the cloud computing environment. The objective function is proposed, and the improved genetic ant colony algorithm proposed is applied to the resource allocation problem. The operation steps and process of the algorithm are listed in detail. We integrate file size, file access speed, CPU performance, memory size, bandwidth, and other factors and perform data migration based on comprehensive load. The article takes the functional characteristics of the cloud computing platform as the background and, on the basis of the preliminary development of the current cloud computing platform resource management technology, further researches the elastic load balancing technology under the cloud computing platform.

## 2. Cloud Computing Load Balancing Method

*2.1. Cloud Computing.* Cloud computing is a super-computing model based on the Internet. It realizes the sharing of resources, and the resources and software in the cluster are allocated to users on demand. The goal of cloud computing is based on network technology to bring together traditional scattered computers to form a cluster. This combined cluster strengthens the processing capacity of the entire system.

The basic idea of cloud computing is that, in a distributed computing environment, each user can freely find the services he/she needs in this system quickly [9]. How to improve the average service response rate of the system has become a crucial issue in cloud computing [10]. The results of the cloud computing system are shown in Figure 1.

Cloud computing can be roughly divided into three categories, called the SPI model: software as a function, platform as a function, and infrastructure as a function. The infrastructure as a service provides the basis for platform services [11]. The platform as a service uses the infrastructure as a service to provide software as a service [12]. The platform as a service is similar to the web hosting service in the web hosting market. The corresponding relationship is shown in Figure 2.

Cloud computing has the following three characteristics:

- (1) Cloud computing is based on virtualization technology to realize rapid deployment of resources and access to services.
- (2) Cloud computing is provided to users in the form of services that are oriented to massive amounts of information and provided through the Internet.
- (3) The resources of cloud computing can be dynamically expanded and configured according to the needs of users and paid according to the actual use of

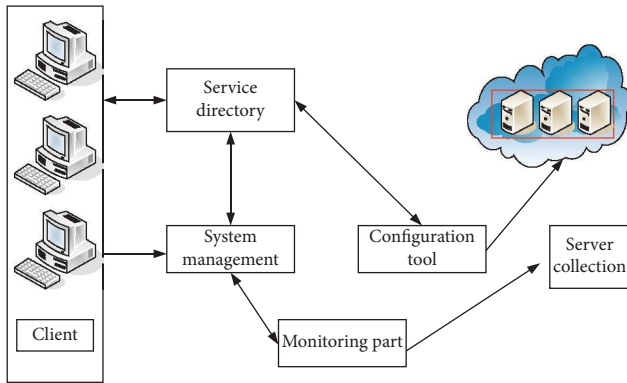

FIGURE 1: Cloud computing system.

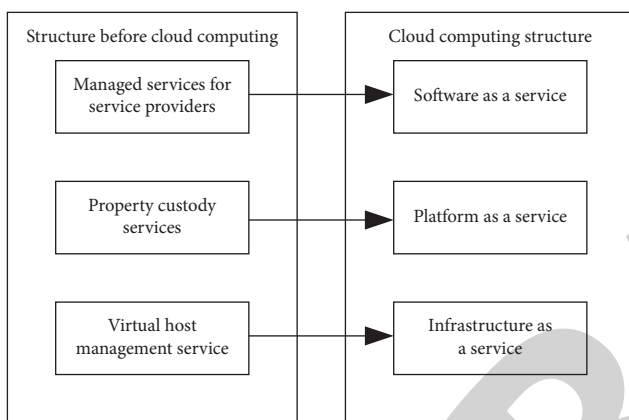

FIGURE 2: Cloud computing hierarchy.

users. Users do not need to manage them themselves, which can reduce the burden of users' processing and dependence on IT expertise.

Cloud storage uses grid technology, aggregation technology, or file sharing technology to fully organize and coordinate multiple clouds of different storage devices on each device in the cloud-covered data center [13]. Cloud storage is a cloud computing storage system. User data is stored in the cloud. For users, local storage systems and storage devices are not required [14]. More specifically, cloud storage is a service in which data is provided by a collection of multiple storage devices and servers, and users purchase services on demand.

Cloud storage deals with massive amounts of data, and it is necessary to complete the storage and management of massive amounts of data. The storage layer is composed of storage devices and storage device management systems. The storage application management system mainly completes the maintenance and upgrading of storage facilities and the monitoring of storage equipment. The structure of the cloud storage system is shown in Figure 3.

Cloud data centers usually include thousands of servers; these server nodes are heterogeneous and unevenly distributed. The storage and scheduling of resources are coordinated by many servers, and the user's access to the server is random, diversified, and complicated. The existence of

these factors can easily cause some server nodes to be idle. While other server nodes are in a state of overload saturation; that is, the load of server nodes is not balanced. The load of server nodes includes not only the load of data storage, but also the load of resource scheduling. Obviously, the existence of this imbalance will cause a waste of cloud resources, increase the burden on the network, and affect the use of users. Therefore, it is essential that the issue of load balance in relation to cloud computing is addressed. A suitable load balancing strategy allows for optimal configuration of services and increased working power.

**2.2. Load Balancing Algorithm.** Load balancing is realized by monitoring the usage of resources on each physical node and then analyzing the collected resources; by analyzing the algorithm of load balancing, the load on the node is dynamically migrated to the node with a small load; and finally the purpose of load balancing is achieved. Any computer or server source can be optimized, the response time can be as short as possible, and the processor performance can be as high as possible. Under normal circumstances, the user partition is finally obtained by analyzing the source of each controller (such as CPU usage, memory space, and bandwidth). Normally, the architecture of load balancing is shown in Figure 4.

A load balancing system is mainly composed of three parts: the cloud platform of the IaaS layer realizes the collection of resources, the realization of the load balancing strategy in the PaaS layer, and the web customer service terminal of the SaaS layer makes requests. At the IaaS layer, the underlying virtualization is mainly realized through the OpenStack cloud platform, and the monitoring function is mainly used to monitor and collect the resources of each node through Ganglia.

The PaaS layer is the core module to achieve load balancing, which is achieved through load balancing based on the dynamic load balancing algorithm mentioned in Section 3. In this layer, the dynamic scheduling of virtual machines on the nodes is realized through WSO2 software. The PaaS layer is mainly used to implement load balancing strategies and scheduling. The core processing module is the strategy controller and the queue manager. The strategy selection is mainly to analyze the load data collected by the server. By analyzing which physical machines and virtual machine resources are overloaded, underloaded, etc. and saving the data in the database, the corresponding data needs to be fetched from this database during scheduling. However, the queue manager mainly queues data.

Common load balancing algorithms include round-robin balancing algorithms, weighted round-robin symmetry, temporary balancing algorithms, and mechanical balancing algorithms.

The rotation balance algorithm used is to determine the rotation frequency before sending the request and then divide the request, rotation, etc. on the respective servers according to this process.

At the weighted round-robin balancing algorithm, the performance of each server is not considered in the round-

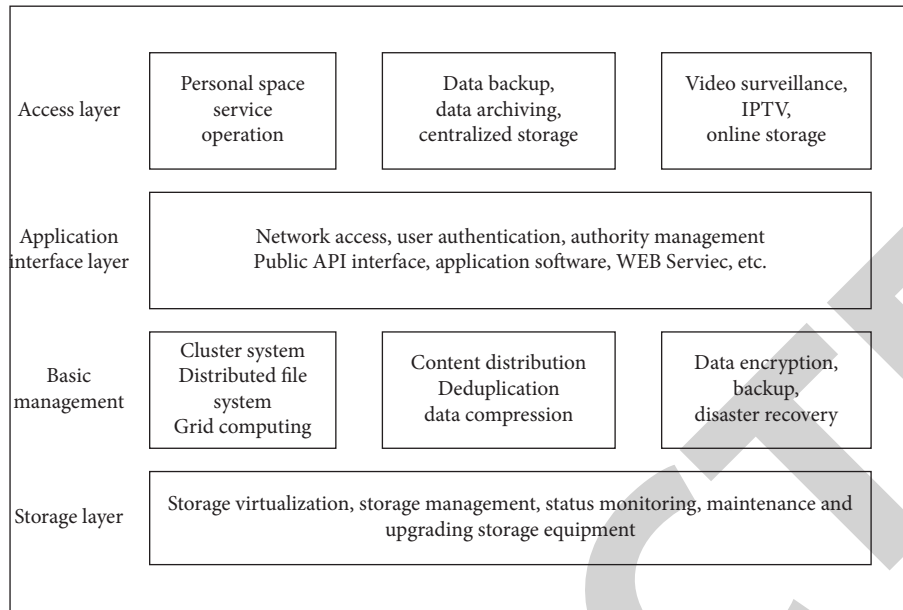

FIGURE 3: Cloud storage system structure.

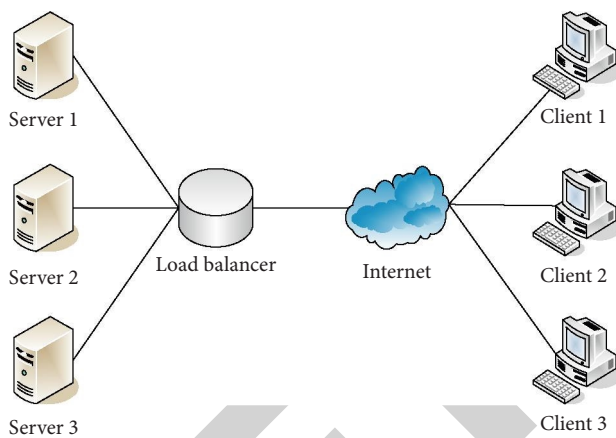

FIGURE 4: Load balancing architecture.

robin balancing algorithm. The performance of each server is inconsistent, and greater configuration and processing capacity mean greater weight; then, the load allocated to the server will be more, and the higher the load, the more efficient the operation.

The concept of load balancing is first introduced at each server node in the static payload trading algorithm, and then the corresponding function is allocated to each server, rather than the estimated resource power allocation. In the process of adjusting the concept and load balancing, the load status of each server is taken, but a value is assigned to the load, and this value will not change with the change of the load.

Consequently, the dynamic burden balancing method is a very good solution. The animated workload trading algorithm overcomes the weaknesses of static payload trading. The algorithm balances by monitoring the source status of each server and analyzing the load capacity adjustment of each node.

Through the above analysis and comparison of several load balancing algorithms, this article chooses a dynamic load balancing algorithm to achieve resource load balancing. The collection of PM (physical machine) and VM (virtual machine) data of each node in the cluster is the basis of load balancing, because algorithm balancing can be completed through the loading function of each node, and finally load balancing is determined. Because load balancing is implemented dynamically, real-time collection is required when collecting node resource information. Through analysis of the collected data, the causes of uneven load of virtual machine resources can be efficiently analyzed and processed. While collecting nodes, it is necessary to monitor the resource status of each node in real time, and the related scheduling work can be realized at the end through monitoring.

### 3. Ant Colony Algorithm

For the network, load balancing technology is the basis for the stable operation of the network and the saving of operating resources. The article will use ant colony algorithm to achieve load balancing of network links. At the same time, through the experimental analysis and selection of some parameters in the ant colony algorithm, we finally obtain a better load balancing effect.

The principle of the ant colony algorithm is that when insects carry food, they will leave a recognizable pheromone on the street, and other ant colonies can recognize this pheromone and know the concentration of the pheromone. Then, a pathway with a high pheromone concentration will be more likely to be selected, other ant colonies will pay attention to this pathway accordingly, and the pheromone concentration will increase accordingly, thus forming a positive feedback system. Therefore, the pheromone on the street will also change over time, and the pheromone concentration will decrease

accordingly, which will affect the choices of other insects. Then, in the area where the insects search for food and bring the food back to the nest, because a large number of ants continue to carry the food, it is likely that the shortest route from the nest to the foraging location will appear, and the food will eventually be collected successfully [15].

The specific expression of the ACO algorithm is shown in the following equation:

$$P_{ij}^K(t) = \begin{cases} \tau_{ij}^\alpha(t) * \kappa_{ij}^\beta(t) \\ s \in \text{allowedk} \tau_{is}^\alpha(t) * \kappa_{is}^\beta(t), s \in \text{allowedk} \\ 0, s \in \text{allowedk} \end{cases} \quad (1)$$

Among them,  $\kappa_{ij}^\beta$  is the heuristic factor of the distance perceived by the ants between  $i$  and  $j$ , and the size is related to the distance between the two cities.

$$\kappa_{ij}(t) = \frac{1}{d_{ij}}. \quad (2)$$

It can be seen from this formula that if the distance between  $(i, j)$  is smaller and the heuristic factor is greater, then the transition probability is greater. The calculation formula of  $d_{ij}$  is as follows:

$$d_{ij} = (x_i - x_j)^2 + (y_i - y_j)^2. \quad (3)$$

At all  $\tau_{ij}$  in the ACO algorithm, there are pheromone updates on the path. With the following equation, the pheromones are updated:

$$\tau_{ij}(t+1) = (1 - \gamma) * \tau_{ij}(t) + \gamma * \Delta\tau_{ij}(t, t+1). \quad (4)$$

$\gamma$  represents the pheromone volatilization coefficient between  $(0-1)$ . The specific formula of is as follows:

$$\Delta\tau_{ij}(t, t+1) = \sum_{k=1}^m \Delta\tau_{ij}(t, t+1). \quad (5)$$

Accordingly, in order to prevent the ants from traversing town  $i$  again after traversing town  $i$ , a contraposition table would be added to the ant colony algorithm to record the towns that have been traversed by the ant in a time period. After the round of traversal is complete, it will be cleared and a new round of traversal will be performed. The calculation model formula is as follows:

$$\Delta\tau_{ij}(t, t+T) = \begin{cases} K, & k \in (i, j), \\ Ln, & \text{other.} \\ 0, & \end{cases} \quad (6)$$

In the initial stage of path search, ants can choose more paths to ensure the diversity of solutions and expand the search space of solutions. Here, the  $k$ -th ant can transition from state  $i$  to state  $j$  with the following probability:

$$j = \begin{cases} \arg \max\{\tau(\gamma)^\rho\}, \\ J. \end{cases} \quad (7)$$

The article studies the mathematical principles, theories, and related applications of the ant colony algorithm. In particular, it proposes an improved ant colony algorithm for the shortcomings of the algorithm that is prone to stagnation, and finally verifies its effectiveness with specific TSPs.

Through simulation experiments, the influence of parameter range on the optimal solution is studied. The main parameters are as follows:  $\alpha$  is the relative importance of pheromone (pheromone heuristic factor);  $\beta$  is the relative importance of heuristic factor (expected heuristic factor);  $\rho$  is the pheromone volatilization coefficient ( $(1 - \rho)$  represents the persistence coefficient of pheromone);  $m$  is the number of ant colonies.

In the cloud computing environment, the problem of resource allocation is still a combination optimization problem. In the cloud computing environment, there are many factors affecting resource allocation, which correspond to the length of the intercity path in the traveling salesman problem. From the above application experiment of genetic ant colony algorithm (GACA) which improves ant colony algorithm through genetic algorithm, it is known that the fusion of intelligent algorithms is a more efficient and correct way to solve the problem. However, the merged algorithm can still have premature convergence in the later stage. Therefore, we need to maintain the diversity of the population in the iterative process and expand the search solution space to a certain extent, so as to prevent the occurrence of premature convergence to a certain extent. The definition of matching factor is introduced to express the matching degree of each task and each resource node.

$$\text{Match}_{ij} = \frac{1}{\sqrt{\sum_{n=1}^4 (T_{xi} - V_{yj})^2}}. \quad (8)$$

Supposing  $X$  is a mapping sequence of tasks and resources, the degree of load balance is defined as follows:

$$\text{Load}(X) = \sqrt{\sum_{i=1}^n \left(1 - C_1 \frac{Y_i}{Lv_i}\right)^2}. \quad (9)$$

Among them,  $Y_i$  indicates how many tasks are allocated to resource node  $i$ .

Approximate nondeterministic tree search (ANTS) is an ACO algorithm that uses mathematical programming ideas. The ANTS algorithm uses a new action selection rule and pheromone update rule, as shown in the following formula:

$$P_{ij}^k = \frac{\gamma\tau_{ij} + (1 - \gamma)\eta_{ij}}{\sum_{i \in N_i^k} \gamma\tau_{ij} + (1 + \gamma)\eta_{ij}},$$

$$\tau_{ij} \leftarrow \tau_{ij} + \sum_{k=1}^m \Delta\tau_{ij}^k, \quad (10)$$

$$\Delta\tau_{ij}^k = \begin{cases} \theta \left(1 - \frac{C^k - LB}{L_{\text{avg}} - LB}\right) \\ 0 \end{cases}$$

Among them,  $\theta$  is a parameter, and LB is an optimal solution calculated at the beginning of the algorithm.

For any given data, there is a uniquely determined membership function value  $\mu_A(x) \in [0, 1]$  corresponding to it, which can be expressed as follows:

$$\mu_{\tilde{A}}(x): X \longrightarrow [0, 1]. \quad (11)$$

Usually, the expression is as follows:

$$\tilde{A} = \frac{\mu_A^-(x_1)}{x_1} + \frac{\mu_A^-(x_2)}{x_2} + \dots + \frac{\mu_A^-(x_n)}{x_n}. \quad (12)$$

This kind of representation can be represented by sequential even representation:

$$\tilde{A} = \{(x_1, \mu_A^-(x_1)), (x_2, \mu_A^-(x_2)), \dots, (x_n, \mu_A^-(x_n))\}, \quad (13)$$

or using vector notation:

$$\tilde{A} = \{\mu_A^-(x_1), \mu_A^-, \dots, \mu_A^-(x_n)\}. \quad (14)$$

In the cloud computing system  $t$ , there are  $N$  tasks that need to be allocated to  $M$  nodes for processing, and the current load status of each server is different. The load balancing strategy is to find the most reasonable task allocation plan, so that the average processing time of tasks is the shortest, and the service quality of the cloud computing system is improved. The load deviation rate is used to measure the system load distribution after assigning tasks, and the load deviation rate is calculated as follows:

$$E(x_1, x_2, \dots, x_n) = \frac{1}{n} \sqrt{\sum_{i=1}^M e_i^2}. \quad (15)$$

Among them,  $M$  represents the predicted value of the resource load required on the  $i$ -th server under this task allocation plan, and the calculation formula is as follows:

$$e_i = f_i(x_i, L_i) - F(x_1, x_2, \dots, x_n). \quad (16)$$

Among them,  $f_i(x_i, L_i)$  represents the predicted value of resource load required on the  $i$ -th server under this task allocation plan, and the calculation formula is as follows:

$$f_i(x_i, L_i) = (x_i + 1) * L_i. \quad (17)$$

In the current server running state, the calculation formula for the impact of allocating a unit of computing resource on the load is as follows:

$$F(x_1, x_2, \dots, x_n) = \frac{1}{M} \sum_{i=1}^M f_i(x_i, L_i). \quad (18)$$

According to the above calculation formula, the load deviation rate takes a value in the range of 0 to 1. The smaller the value, the more balanced the load distribution of the

cloud computing system, and the better the performance of the current system [16].

## 4. Experiments and Results of Cloud Computing Load Balancing

**4.1. Experiment Preparation.** The cloud computing simulation platform is selected to conduct experimental analysis and evaluation of the cloud computing load balancing process based on virtual machine relocation. The main performance indicators are the load balance of CPU, memory, and other sources and the average operating time. By monitoring the load situation in the network in real time, the ant colony algorithm can give the forwarding link with the smallest load, so as to realize the relative balance of dynamic link load. This can optimize the configuration of limited network resources and effectively solve the problems of low network bandwidth utilization and low throughput. In order to simplify the processing and reflect the reliability of the experimental results of different strategies, in this simulation experiment, the cloud computing data center is configured with the same type of servers, virtual machines with the same parameters, and the same network environment and performs a set of the same tasks. The specific conditions are shown in Table 1.

It is measured by the load standard deviation for the CPU and memory of the system. Their corresponding utilization standard difference will be calculated by detecting the CPU or memory utilization at a given time for each host.

The level of memory load balancing is compared between layered management-based virtual machine migration strategy (MLVM) and agent-based virtual machine migration strategy (PAVM). After that, the entire CPU utilization of the system is read at different time points, and the standard deviation of the system CPU load balance is calculated. The experimental results are shown in Table 2.

Through experiments, the task response time for different task requests is counted, and the average task response time is calculated. The average task response time of the two strategies is shown in Table 3.

**4.2. Algorithm Optimal Solution.** We perform statistics on the optimal solutions for different  $\alpha$  values in the ant colony algorithm, and the results are shown in Figure 5.

The heuristic factor  $\alpha$  characterizes the relative importance of the pheromone accumulated by the ants in the process of constructing the solution for the path selection in the ant search. The larger the value of  $\alpha$ , the more likely the ants will pick the previous paths they traveled and the searching paths will be less stochastic. When  $\alpha$  takes different values, the corresponding optimal iterative optimal solution and number of iterations are shown in Figure 6. When  $\alpha = 1$ , the iterative optimal solution gets the minimum value, and then as  $\alpha$  increases, the iterative optimal solution value also increases; the number of

TABLE 1: Comparative experimental parameters.

20	5.97	5.99
50	6.01	6.02
100	6.23	6.21
150	6.51	6.65
200	7.34	7.82
250	7.64	7.92
300	8.01	9.25
400	8.54	9.73

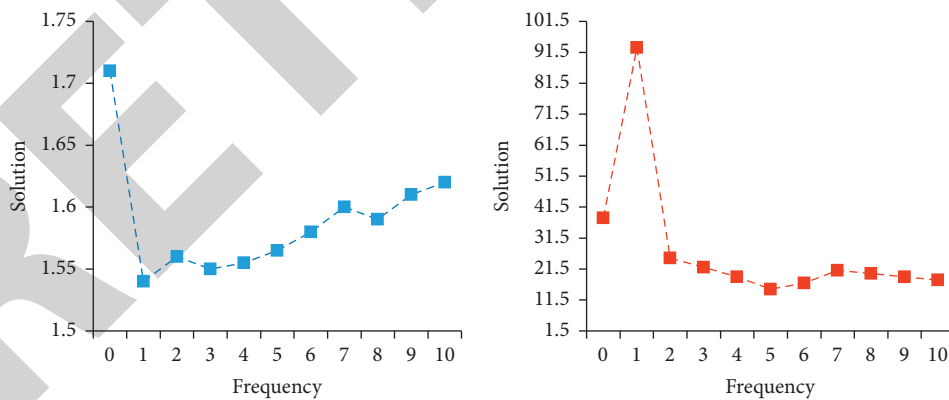

FIGURE 5: The value of the heuristic factor solution.

iterations also decreases as  $\alpha$  increases. This reflects the overall impact of  $\alpha$  on the algorithm, that is to say, the larger the value of  $\alpha$ , With the greater likelihood of selecting previously traveled paths, the more likely the ants are to choose previously walked paths; there will be less randomness in the search paths, they will converge faster, and they will be easily restricted to limiting themselves to locally optimal solutions.

We carry out statistical analysis on the load quantity of each resource of MLVM and PAVM, and the results are shown in Figure 7.

It can be seen that PAVM accepts the criteria to increase the possibility of finding a better allocation method, which is subject to certain restrictions on the execution time of the algorithm, but there is a certain improvement in the scheduling time. We compare the task time spans of several

FIGURE 6: The relationship between the optimal solution and the number of iterations.

FIGURE 7: The amount of load for each resource.

FIGURE 8: Task time span.

most commonly used algorithms, such as ant colony algorithm, genetic ant colony algorithm, and improved algorithm, and the results are shown in Figure 8.

In a load balancing system, validity is an important criterion for judging the quality of its algorithm, so it is

particularly important to verify this criterion. Due to the instability of the experimental results, the method of seeking a tie for each set of experiments is used to obtain the final result. We judged the effectiveness of different methods by the response time when reading files of different sizes. The experimental results are shown in Figure 9.

It can be seen that the response time for reading each file varies, and this time is not completely related to the file size, which means that not all large files have a long response time, and not all small files have a short response time. However, in the ACO algorithm, the average response time is about 30% lower than that in other algorithms. This shows that the ACO algorithm can play a role.

## 5. Discussion

In order to avoid data loss and improve system reliability, copy technology is usually used in cloud storage systems. The copy technology is to make multiple copies of a data block, store them on multiple nodes, and use data redundancy to ensure data reliability. The use of copy technology can well solve the load balancing problem of the system. Multiple copies are distributed on different server nodes. By accessing the copy, the load of a single server node is distributed to multiple nodes, thereby reducing the load of the nodes and achieving load balancing.

The ant colony optimization algorithm has undergone more than ten years of development since it was proposed and has achieved remarkable results in algorithm theory research and application. Its application scope involves various optimization fields such as routing problems, allocation problems, scheduling problems, subset problems, machine learning problems, and emergence of ant colony algorithm bionic hardware, showing the strong vitality and broad development of ant colony optimization algorithm prospect.

With the continuous update and development of computer technology, the number of users has doubled, the architecture of traditional IP networks has become more and more complex, and the development of the network structure is relatively lagging. In this paper, the load balance is realized by using the ant colony algorithm, which is implanted in the controller, and the network load is

FIGURE 9: Response time for different file sizes.

monitored in real time through the traffic monitoring software. Through the execution of the ant colony algorithm in the controller, the data stream will be transmitted along the link with the least load at a certain moment, which can effectively use network resources, reduce network congestion, increase network throughput, and realize network dynamic load balancing of each link in the network. We also carried out theoretical experimental research and analysis on the heuristic factor, the pheromone volatilization coefficient, and the number of ants in the ant colony algorithm. Through the selection of parameters, the performance of the ant colony algorithm was improved, and the load balancing was also able to obtain better results. We conduct load balancing experiments on the self-defined network topology. Through the analysis of experimental data, the introduction of ant colony algorithm can achieve dynamic load balancing of each link.

## 6. Conclusion

For the purpose of this paper, we will be looking at the allocation of resources for cloud computing. According to the existing algorithm, the intelligent algorithm is fused, and the pheromone initial allocation of the ant colony algorithm is introduced to solve the blind search problem and avoid the later local optimal solution problem. The improved algorithm was applied to the specific problem of cloud computing resource allocation, and experimental calculation and analysis were performed. It was found that the time span performance and resource load degree had relatively good results, which proved the applicability of the algorithm. The improved algorithm proposed in this paper has certain performance optimization but also has certain disadvantages. The algorithm becomes slightly more complicated and has a great test on the execution speed. Moreover, the actual situation should be fully considered in the actual application process; for example, issues such as more diverse and dynamic user needs and complexity of resources require comprehensive consideration of the needs and interests of users and providers. In addition, the ant colony algorithm is often aimed at a certain type of special problem, and its versatility is poor. In future research, if we want to use the

ant colony algorithm in other fields, we need to improve its universality. In addition, the research in this paper only considers the small network with few hosts and single controller and does not consider the load balancing of the large network with multiple hosts and multiple controllers, and the researcher hopes that this part of the research can be completed through corresponding experiments in the future.

In recent years, with the rapid development of the Internet, online social networks have been continuously integrated with traditional interpersonal networks and research on information dissemination in social networks has gradually increased. This article studies and analyzes the multidimensional information network big data mining algorithm based on the finite element analysis method. This paper firstly introduces the finite element analysis and calculation process, a finite element data mining simulation application software management system will integrate current data, calculation, and background data into one, then analyzes the data mining clustering algorithm, and conducts an experimental exploration of the influential node mining algorithm in complex networks. The experimental results show that the LIC algorithm is better than the CC algorithm, the DC algorithm, and the BC algorithm; its overall performance is improved by 30%, and the effect is better. The LIC algorithm can effectively and quickly determine the influential nodes, which is helpful for social network analysis.

## 1. Introduction

The important purpose of the research on the mining algorithm for the number of nodes with far-reaching influence in the social Internet is to excavate the number of  $k$  important nodes with far-reaching influence in the number of nodes in the entire social Internet and finally make these  $k$  nodes in an important position. Under this transfer mechanism, as many network nodes as possible are affected. In a word, the problem of important network nodes that are discovered from social networks and have a huge social influence also constitutes a problem of maximizing social influence to some extent. Among them, mining influential nodes in the network can inhibit or accelerate the dissemination and diffusion of information in the network. It takes the mined top- $k$  nodes as a set of known seed nodes and finally maximizes the influence through a certain propagation strategy.

Due to the development of social Internet technology, the Internet has completely changed the way people communicate. Social networking on the Internet is recognized by more and more people, especially by young people, which

directly results in the rapid expansion of the social Internet. The corresponding results are roughly as follows: First, the number of user groups in the social Internet is huge, and the interpersonal network established between user groups and user groups is becoming more and more complex; the update and change speed of community Internet information content is increasing, and the relationship between users and applications is also dynamic, which makes it more difficult to predict information content. Therefore, the research and development of social Internet-oriented data mining algorithms with the characteristics of efficiency and practical value has practicality and great scientific significance for solving real problems in the community. At the same time, the research on the mining algorithm and information dissemination model of influential nodes in social network has certain scientific research value and significance for real life.

According to the research progress at home and abroad, different scholars have also carried out certain cooperative researches in finite element analysis, multidimensional information network and big data mining inside the dormitory. Elliott and Thomas defined a new finite element method for

numerical approximation of the solution of partial differential equations in the volume domain and surface partial differential equations lying on the boundary of the volume domain. The key idea is to perform a polyhedral approximation to the whole region containing the union of simplexes and to use piecewise polynomial boundary surfaces as the approximation of the surface [1]. Salonitis et al. proposes a new user-friendly optimization method for lattice component design for weight minimization, which combines finite element analysis and evolutionary calculations [2]. Li et al. analyzes the higher-order, central, finite-difference scheme of the diffusion equation in a finite interval. They analyzed stability through Gustafsson, Kreiss, and Sundström theories and eigenvalue visualization methods for semidiscrete and fully discrete schemes, followed by numerical tests to prove and validate the analytical results [3]. In order to retain important information related to mining of large data sets in multidimensional information networks, Xu presented an algorithm for constructing association rule mappings. On this basis, he proposed a multidimensional information network big data mining subalgorithm and an association rule generation algorithm, which were used for multidimensional information network big data mining and association rule generation, respectively. Finally, he demonstrated the feasibility and effectiveness of the algorithm through theoretical analysis and experimental comparison [4]. Wang proposed an indoor localization algorithm combining RSSI and nonmetric multidimensional scaling (NMDS) (RSSI-NMDS) to solve the problem that the indoor target localization algorithm based on received signal strength (RSSI) is susceptible to interference and large fluctuations in the Internet of Things environment [5]. Xu et al. takes a broader perspective on privacy issues related to data mining and studies various methods that help protect sensitive information. He identified four different types of users involved in data mining applications: data providers, data collectors, data miners, and decision makers [6]. However, these scholars did not rely on the finite element analysis method to study and analyze the multidimensional information network big data mining algorithm but only discussed its significance unilaterally.

The innovation of this article is as follows: (1) First, the finite element analysis calculation process is introduced. (2) The data mining clustering algorithm is analyzed, and the clustering analysis method refers to the analysis method of studying and processing the given object by means of computational mathematics. (3) Experimental analysis of the mining algorithm of influential nodes in complex networks is carried out.

## 2. Materials and Methods

A finite element data mining simulation uses a software management system that integrates current data, computing and background data. In the actual work of the finite element simulation analysis system, it first allows the user to use the software system to perform the preliminary data processing work of the finite element calculation with the help of the finite element data mining front-end. During this period, the

structural model must be added first, and then the automatic mesh generation program is called directly to complete the setting of the finite element mesh pattern, and finally sets important technical parameters such as material properties through communication with users [7]. Finally, a scripted document of the initial data model can be obtained as input to the finite element calculation program. In the finite element calculation process, due to the deformation caused by the finite element meshing, after the finite element data mining is completed, the meshing program must be called to obtain the calculation data. Finally, after using the program, the user can perform an in-depth study and statistical analysis of the results of the finite element calculation process. In the entire finite element calculation process, the most important is the finite element solver. Other functional modules are used for the calculation of finite element solutions, but they are also an integral part of the system. Without any module, the system cannot work properly. Figure 1 shows the service mode diagram of the finite element analysis and simulation system.

Although the finite element operation processing program is the most important part of the whole set of finite element analysis methods, the finite element operation processing program alone cannot provide an effective explanation for the actual project engineering. Therefore, on the one hand, the finite element calculation method involves many types of practical problems and a large amount of data and information. In the manual method to complete the data processing, the workload is large, the work efficiency is reduced, and errors are prone to occur; on the other hand, because the amount of information generated by the finite element operation is large and complicated, it is quite troublesome to analyze and use [8]. The finite element pre- and postprocessing software is a software technology that has flourished under this historical background.

Behavior is a series of purposeful, organized activities. There are usually two types: extrinsic behavior and intrinsic behavior. Learning behavior refers to the sum of activities that students undertake to achieve a certain learning effect under the guidance of a certain motivation. It is usually a series of activities in which students interact with their surroundings. Online learning behavior refers to the online learning that students conduct around certain learning goals, which can be set by themselves or designated by teachers. It is a collection of various explicit or implicit behaviors in learning activities. For example, uploading and downloading learning resources, learning courses on demand, publishing learning and troubleshooting, and communicating with other students [9, 10].

A large number of research results and applications in the field of data analysis and mining can be regarded as an important result of the natural evolution of technology. Strictly speaking, "data mining" usually refers to a broad concept in the industry, which should be more accurately called "mining knowledge from data" or "discovering knowledge from data"; the "data mining" in the strict sense is only a basic work stage in the entire scientific research workflow [11]. The general process of mining knowledge from data is shown in Figure 2.

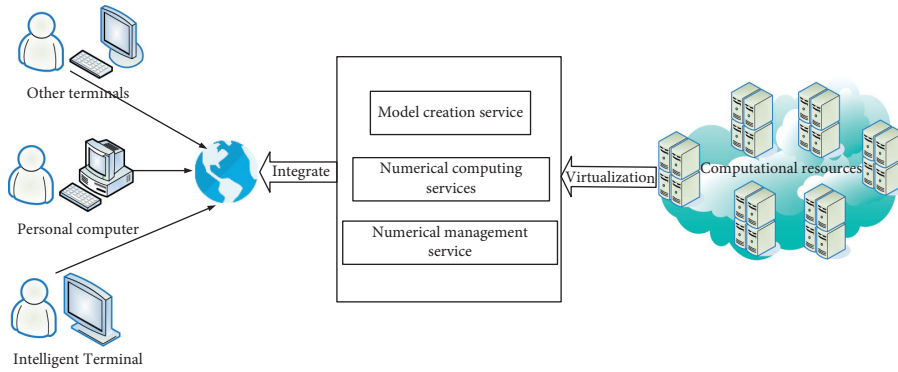

FIGURE 1: Service mode diagram of the finite element analysis simulation system.

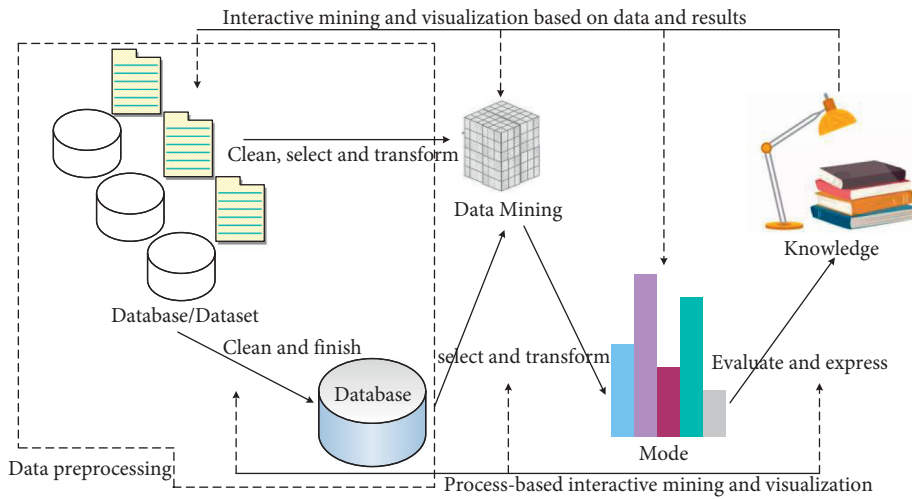

FIGURE 2: The whole process of knowledge discovery in data.

The goal of data analysis and mining is to find meaningful or potential content from the information database. The main service functions are as follows:

- (1) Concept description: concept description can also be called data synthesis. Its main purpose is to extract and compress data, and then describe the complete information, or compare it with other objects. Summary Statistics gives a general overview of the statistics.
- (2) Analysis methods and predictions: classification methods and predictions are two completely different forms of statistical analysis data, which can be used to establish models to describe important statistical categories and to predict the future development of analysis methods [12]. In practical applications, classification prediction is widely used. For example, a classification model can be established to classify mobile users and return visits to high-frequency attrition groups as soon as possible to reduce user attrition; it is also possible to classify traffic flow information by establishing a classification model to predict future traffic congestion. Cluster analysis: The basic principle of cluster

analysis is high cohesion and low mutual coupling. The final conclusion is that it has a high similarity to the same class of objects and a low similarity to other class objects [13].

- (3) Lonely point analysis: some objects in the database system may be different from the general behavior and model of data analysis, for this kind of object, we call it a lonely point. When people design data mining algorithms, they usually try to minimize the harm of lonely points, but in some special applications, the lonely point itself can also be an important judgment information. For example, in telecommunication spoofing checks, lonely spots can indicate spoofing activity [14].
- (4) Time series analysis: in time series analysis, the attribute values of data are constantly changing with time. These data are generally obtained at the same time interval but may be obtained at different time intervals. Data can be more visualized with time series plots.

Clustering refers to the process of distinguishing data signals according to specific conditions and rules. In this step, there is no prior knowledge of the relevant type, and

there is no teacher's guidance, so it is in the scope of unsupervised classification.

Cluster analysis method refers to an analysis method that uses computational mathematics to study and process a given object. Clustering is an important and human act because a person's developmental process learns to recognize things by constantly reshaping subconscious aggregation patterns. The traditional cluster analysis method strictly defines various statistical objects to be aggregated, and the boundaries between classifications are very clear, so we can call it hard classification [15]. However, in general practical use, because most objects lack strict characteristic attribute definitions, and there is an unclear intermediary between the form and the class characteristic attributes, they have the characteristics of one and the other, so they are suitable for implementing soft classification.

**2.1. Mathematical Model of Cluster Analysis.** Supposing  $A = \{a_1, a_2, \dots, a_m\}$  is the whole object to be clustered (i.e. domain of discourse), among them, each object  $a_i$  ( $1 \leq i \leq m$ ) is called a sample, and the object is described by a plurality of parameter values, which represent a feature of the object. So each object  $a_i$  corresponds to a vector  $V(a_i) = (a_{i1}, a_{i2}, \dots, a_{in})$ , where  $a_{ij}$  ( $1 \leq j \leq n$ ) is the assignment of  $a_i$  on the  $j$ th feature and  $V(a_i)$  is called the feature vector of  $a_i$  [16]. Cluster analysis is to analyze the spatial distance between the feature vectors corresponding to the samples in the universe  $A$  and their distribution and divide them into  $l$  disjoint pattern subsets according to the distance relationship between each sample and satisfy the following formula conditions:

$$\begin{aligned} A_1 \cup A_2 \cup \dots \cup A_l &= A, \\ A_i \cap A_j &= \emptyset \quad (1 \leq i, j \leq l, i \neq j). \end{aligned} \quad (1)$$

Membership function  $u_{ij}$  represents the membership of sample  $a_j$  ( $1 \leq j \leq m$ ) with respect to subset (class)  $A_i$  ( $1 \leq i \leq l$ ), as follows:

$$u_{a_i}(a_j) = u_{ij} = \begin{cases} 1 & (a_j \in A_i), \\ 0 & (a_i \in A_j). \end{cases} \quad (2)$$

As shown in the previous formula, the membership function must satisfy  $u_{ij} \in N_{sl}$ , that is, each sample can only belong to one of the classes, and each subclass is required to be a nonempty set.

$$N_{sl} = \left\{ u_{il} | u_{ij} \in \{0, 1\}, \sum_{j=1}^m u_{ij} = 1, \forall j; 0 < \sum_{i=1}^l u_{ij} < m, \forall i \right\}. \quad (3)$$

In the real world, the membership degree of a sample may not be either one or the other. From this, fuzzy theory is introduced, which becomes a fuzzy set class, and the sample set  $A$  is divided into multiple fuzzy subsets  $\tilde{A}_1, \tilde{A}_2, \dots, \tilde{A}_l$ , and the membership function  $u_{ij}$  of the sample is extended from the binary case of  $\{0, 1\}$  to the  $[0, 1]$  interval, satisfying the conditions:

$$\begin{aligned} \sup v(\tilde{A}_i) &= A, u_{ij} \in [0, 1], \\ \sum_{i=1}^l u_{ij} &= 1 (\forall j), 0 < \sum_{j=1}^m u_{ij} < n, \end{aligned} \quad (4)$$

where  $\sup$  represents the support set of the fuzzy set.

**2.2. Fuzzy Clustering Objective Function.** Mathematical model based on cluster analysis, if fuzzy concept is introduced. It uses the membership degree  $o_{il}$  of the sample point  $a_i$  and the sample prototype of the  $i$ -th class as the weight to weight the distance. At this time, the objective function of the cluster analysis is given as follows:

$$J_1(O, V) = \sum_{i=1}^b \sum_{l=1}^m o_{il} (h_{il})^2, \quad O \in R_s. \quad (5)$$

After fuzzy clustering the objective function of the hard clustering analysis method, it uses the sum of squares of membership to transform the objective function of the sum of squares of errors into the objective function of all weighted sums of squares of errors, namely,

$$J_2(O, V) = \sum_{i=1}^b \sum_{l=1}^m o_{il}^2 (h_{il})^2, \quad O \in R_s. \quad (6)$$

**2.3. Objective Function of General Fuzzy Cluster Analysis.** Among the more general expressions are

$$J_n(O, V) = \sum_{i=1}^b \sum_{l=1}^m o_{il}^n (h_{il})^2, \quad O \in R_s, \quad (7)$$

where  $h_{il}$  is a distance norm, and the distance  $h_{il}$  between the sample point  $a_i$  and the cluster center  $v_i$  of the  $i$ -th class represents the similarity between the sample point and the cluster center, which can generally be expressed as follows:

$$\begin{aligned} h_{il}^2 &= a_i - v_{iX} \\ &= (a_i - v_i)^Q X(a_i - v_i), \end{aligned} \quad (8)$$

where  $n \in [1, \infty)$  is the weighting index, also known as the smoothing parameter, which controls the fuzzy degree of fuzzy clustering. The larger the  $n$  is, the larger the blurring degree is; the smaller the  $n$  is, the smaller the blurring degree is [17]. Because  $n$  controls the degree to which membership is shared among classes, the larger  $n$ , the greater the ambiguity. After research, it is found that for different application scenarios, the optimal  $n$  can be in the range of 1 to 5, and  $n = 2$  is usually selected.

**2.4. Analysis and Solution Process Based on Objective Function Clustering Algorithm.** In order to obtain the optimal solution of the objective function of fuzzy clustering, the criterion of clustering can be taken, that is,  $\sum_{i=1}^b o_{il} = 1$  and  $\min\{J_n(O, V)\}$  are obtained under the constraints of the mechanism, namely,

$$\begin{aligned} \min\{J_n(O, V)\} &= \min\left\{\sum_{l=1}^m \sum_{i=1}^l (o_{il})^n (h_{il})^2\right\} \\ &= \sum_{l=1}^m \min\left\{\sum_{i=1}^b (o_{il})^n (h_{il})^2\right\}. \end{aligned} \quad (9)$$

Therefore, this problem can be understood as follows: under the condition of membership degree,  $\sum_{i=1}^b o_{il} = 1$ , obtain

$$\min\left\{\sum_{i=1}^b (o_{il})^n (h_{il})^2\right\}. \quad (10)$$

Using Lagrange's theorem to solve, we can get the expression of the membership degree corresponding to the  $j$ th object:

$$o_{il} = \frac{1}{\sum_{i=1}^b [h_{jl}/h_{il}]^{2/n-1}}. \quad (11)$$

The fuzzy classification matrix usually satisfies the following conditions:

- (1)  $o_{il} \in [0, 1]$ , that is, each element in the matrix is between 0 and 1 closed interval
- (2)  $\sum_{i=1}^b o_{il} = 1$ , the sum of the elements of each column is 1, that is, the sum of the membership degrees of each element to all classes is 1
- (3)  $\sum_{i=1}^b o_{il} > 0$ , this condition ensures that each class is not empty

Similarly, the cluster center of fuzzy clustering can be obtained as follows:

$$V_i = \frac{\sum_{l=1}^m (o_{il})^n a_l}{\sum_{l=1}^m (o_{il})^n}. \quad (12)$$

It can be seen that the cluster center can be obtained from the membership degree. The purpose of cluster analysis is to discover the implicit grouping information in the data. In order to represent this accuracy well, the effectiveness of clustering needs to be analyzed. When evaluating clustering results, the optimal number of clusters is usually an important indicator of effectiveness [18, 19].

In the process of optimizing the objective function, people have tried many methods such as dynamic programming, but the large storage space and long running time limit its popularization and application. The most widely used in practice is the iterative optimization algorithm, which is easy to enter the extreme point of the local area, so it is more sensitive to initialization, and one of the important input parameters is the number of clusters  $k$ . Although the exact value of  $k$  may not be known, it is usually possible to approximate the value of  $k$  by evaluating the quality of the clustering results at different  $k$ . Given an ideal cluster index, such as average radius or diameter, as long as the number of an imaginary cluster is less than or greater than the actual number of clusters, the index will tend to rise very slowly [20]. However, when trying to acquire far fewer clusters than

the true number, the index increases rapidly. A schematic diagram of the above idea is shown in Figure 3.

Among them, for the evaluation of fuzzy clustering, the separation coefficient is expressed as follows:

$$G(O, h) = \frac{1}{m} \sum_{i=1}^m \sum_{j=1}^h (o_{ij})^2, \quad (13)$$

where  $o_{ij}$  is the fuzzy membership degree of data object  $i$  belonging to cluster  $j$ , assuming all clustering results here, then the number of clusters  $k$  is given by the following formula:

$$\max\{\max G(O; h)\}, h = 2, 3, \dots, m-1. \quad (14)$$

Similarly, a variant of the separation coefficient can be obtained, the separation entropy index:

$$L(O, h) = -\frac{1}{m} \sum_{i=1}^m \sum_{j=1}^h o_{ij} \log(o_{ij}). \quad (15)$$

The corresponding number of clusters is given as follows.

If  $o_{ij}$  is close to 0 or 1, the smaller the entropy value and the better the clustering result. If  $o_{ij}$  is close to 0.5, the clustering ambiguity is high, the entropy value is large, and the corresponding clustering result is not good. These two indicators are proposed for partition-based fuzzy clustering, which is sensitive to fuzzy factors [21].

In the fuzzy k-means algorithm, due to the introduction of  $\sum_{i=1}^b o_{ih} = 1$ , in the case that the sample set is not ideal, it can be assumed that there are several isolated points far away from the clustering center of each class. Because the isolated point itself actually belongs to a certain class, under the original constraints, it will have a large degree of membership to various types or be approximately equal to each type of membership degree. This situation will affect the correctness of the final clustering results [22]. To overcome this shortcoming, we can relax the constraint and change it to

$$\sum_{i=1}^b \sum_{h=1}^m o_{ih} = \beta, \beta \in [1, m]. \quad (16)$$

That is, the sum of the membership degrees of all samples to each category is  $\beta$ , a positive integer value. At this time, on the premise of Formula (16), obtain  $\min\{J_n(O, V)\}$ , and the solution method is the same as above. At this point, the membership degree should be

$$o_{ih} = \beta \frac{1}{\sum_{i=1}^b \sum_{i=1}^m [s_{jh}/s_{ih}]^{2/n-1}}. \quad (17)$$

Obviously, this condition is completely different from the membership function in the traditional sense, and the membership degree estimated by the improved fuzzy k-means algorithm may exceed 1. If necessary, the obtained membership value can be normalized, which will not affect the final clustering result under normal circumstances.

FIGURE 3: Trend diagram of the number of  $k$  versus the average diameter of clusters.

The improved method has better adaptability than the original algorithm. It can not only obtain better processing results for clustering in the case of special isolated points but also relax the constraints of membership degree. As a result, the original result is less sensitive to the predetermined number of clusters than the clustering result. When the number in the cluster analysis method determined in advance is much lower than the value of the theoretical number of clusters, the fuzzy k-means calculation using this method can obtain a more accurate cluster analysis method center result.

However, if a certain cluster center is very close to a certain sample in the iterative process, then a cluster containing only one sample may be obtained in the end. To prevent this from happening, a nonlinear process can be added to the distance operation in  $o_{ih}$ , so that the minimum calculated distance is not less than a certain threshold.

The usual distance measure in classical k-means clustering algorithm and fuzzy k-means clustering algorithm adopts Euclidean distance or Manhattan distance. The Kowski distance is a generalization of these two distances, and it is defined as follows:

$$s(i, j) = \left( |a_{i1} - a_{j1}|^t + |a_{i2} - a_{j2}|^t + \dots + |a_{iv} - a_{jv}|^t \right)^{1/t}. \quad (18)$$

When  $t = 1$ , it is the Manhattan distance, and when  $t = 2$ , it means the Euclidean distance.

In cluster analysis, often fields in a data set may maintain an established or obvious weighting relationship. For example, in the cluster analysis of mobile customers, the age, income, and other classification weights of customers are significantly larger, while the weight of noise points is significantly smaller. So, we get the weighted Euclidean distance:

$$s(i, j) = \left( u_1 |a_{i1} - a_{j1}|^2 + u_2 |a_{i2} - a_{j2}|^2 + \dots + u_v |a_{iv} - a_{jv}|^2 \right)^{1/2}. \quad (19)$$

The advantage of this method is that it can find more accurate cluster centers than the original algorithm, the disadvantage is that it is difficult to determine the size of the

weights. In order to realize the automation and intelligence of weight judgment, it can consider weighting each sample through the improved membership function. The weights of noise samples after relaxing the membership constraints are usually small, so the expected purpose is achieved. Then, the minimum value of the objective function is obtained to realize cluster analysis. Figure 4 shows the cluster analysis process.

### 3. Results and Analysis

**3.1. Influential Node Mining Algorithm for Complex Networks.** The evaluation of the influence of nodes in complex networks can make information spread faster and more widely, which is of great significance in practical applications. According to the characteristics of complex networks, this article proposes a Local Importance Centrality Algorithm (LIC), which is a new method for evaluating the influence of nodes in complex networks based on network local characteristics, such as degree and clustering coefficient. The local importance centrality algorithm can more effectively identify influential nodes.

**3.2. Experimental Data Set.** The data sets used in this experiment are collected from real networks: Netscience, E-mail, and Power.

Netscience data set publishes a topological graph of collaborations between authors of articles on topic networks, in which scientists represent nodes and collaborations represent edges. The data set contains a total of 1589 scientists, using the largest subgraph with 379 nodes in it. The basic data parameters of the data set are shown in Table 1.

E-mail data set represents the topology of e-mail forwarding relationships among Rovira University members, where Rovira University members represent nodes and forwarding relationships between members represent edges. The data parameters are shown in Table 2.

Power data set contains an undirected and unweighted topology map of the National Grid in the western United States. Nodes represent transformers, substations, and generators, and the relationship is a high-voltage transmission line. The basic data parameters of the network are shown in Table 3.

#### 3.3. Experimental Results and Analysis

**3.3.1. Relationship between the Rank Evaluated by Various Centrality Algorithms and the Average Influence Value  $\langle F(t) \rangle$ .** In this article, the SIR infectious disease model is used to simulate the propagation on three real network data sets, and the top-rank of the influence ranking obtained by the DC algorithm, the BC algorithm, the CC algorithm, and the LIC algorithm is compared experimentally.

Only one node is selected as the initial infection node for each execution of influence propagation, and other nodes are susceptible nodes. Then, the information or virus spreads according to the mechanism of the SIR infectious disease model. After  $n$  executions (each node has one and only one

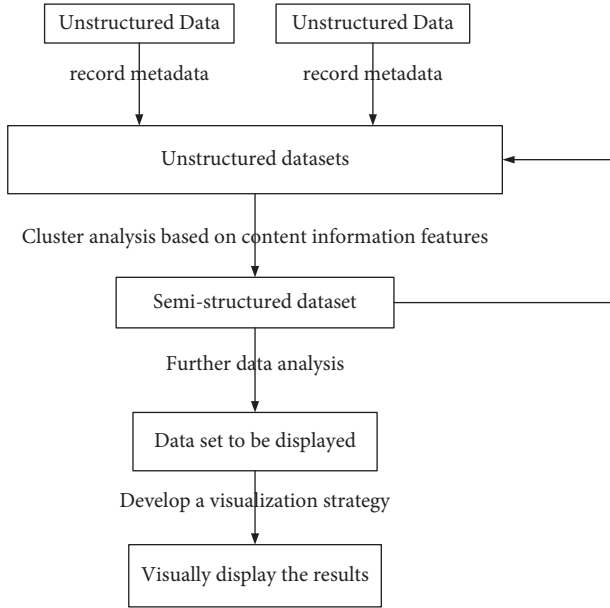

FIGURE 4: Cluster analysis.

TABLE 1: Basic network parameters of the Netscience data set.

Statistical item	Statistics	Statistical item	Statistics
Number of nodes ( $n$ )	381	Maximum degrees	36
Number of sides ( $m$ )	916	Clustering coefficient	0.39
Average degrees	4.79	Average shortest distance	5.98

TABLE 2: Basic network parameters of E-mail data set.

Statistical item	Statistics	Statistical item	Statistics
Number of nodes ( $n$ )	1098	Maximum degrees	69
Number of sides ( $m$ )	5469	Clustering coefficient	0.13
Average degrees	9.57	Average shortest distance	3.697

TABLE 3: Basic network parameters of the Power data set.

Statistical item	Statistics	Statistical item	Statistics
Number of nodes ( $n$ )	5021	Maximum degrees	20
Number of sides ( $m$ )	6603	Clustering coefficient	0.13
Average degrees	2.58	Average shortest distance	19.02

initial infection node), the correlation between the node influence value  $F(t)$  and the four centrality algorithms can be examined. In order to further clarify the performance of several centrality algorithms, calculate the average influence value  $\langle F(t) \rangle$  of the top- $k$  nodes of each algorithm, where  $\langle F(t) \rangle$  is the average of all  $F(t)$ s after  $n$  executions.

Comparisons are made on the Netscience data set. As shown in Figure 5, if the propagation performance of the centrality algorithm is good, then the top- $k$  ranking Rank and  $\langle F(t) \rangle$  should be negatively correlated, and the curve is downward sloping. That is, as the Rank increases, the nodes can influence (infect) fewer nodes.

Figure 6 shows the curves of the four algorithms are all downward sloping, and the curve of the degree centrality algorithm (DC) fluctuates greatly, which shows that the Rank calculated by the DC algorithm is quite different from the actual influence value. The curve of the DC algorithm is at the bottom of the four curves, which further shows that the top- $k$  nodes discharged by the DC algorithm have a relatively low influence. The betweenness centrality algorithm (BC) also has a large curve and performs worse than the closeness centrality algorithm (CC) and the locally important centrality algorithm (LIC). The performance of the LIC algorithm is slightly better than that of the CC algorithm, and the two curves are relatively close.

On the E-mail data set, Figure 6 shows that the experimental results of the four centrality algorithms in this data set are all good. The top- $k$  nodes sorted by the four algorithms can affect many nodes. It can be seen that the effect of the LIC algorithm is the best among the four centrality algorithms, and its curve fluctuation is relatively smooth. The effect of the CC algorithm in the figure is also very good. The  $\langle F(t) \rangle$  of the BC algorithm and the DC algorithm are very high, but the curve fluctuations of the two are relatively large and the correlation is poor.

**3.3.2. Comparison of the Influence of Top 10 Nodes Based on the Sorting of Several Centrality Algorithms.** In this round of experiments, the random sorting algorithm was added for comparison. This article compress the influence  $F(t)$  of different nodes in the top-10 node list evaluated by these five algorithms. Because the same nodes in the top-10 list are excluded, the performance of each algorithm can be compared better. Figures 7 and 8 show that on the Netscience data set, the LIC algorithm is compared with the BC algorithm, the CC algorithm, the DC algorithm, and the random algorithm. The total number of infected and immune nodes increases with time  $t$  and eventually reaches a stable value. It can be seen that although the convergence speed of the LIC algorithm is slightly lower than that of the CC algorithm and the DC algorithm, it can infect more nodes than the two algorithms. The LIC algorithm can obviously infect more nodes than the Random algorithm.

Figure 9 shows the comparison of the influence  $F(t)$  of the LIC algorithm and the DC algorithm at time  $t$  on the E-mail data set and the Power data set, respectively. The convergence speed of the LIC algorithm is significantly higher than that of the DC algorithm.

In Table 4, the average  $F(t)$  value of the top-10 nodes of the four algorithms is calculated. It can be seen that the average value of  $F(t)$  of the LIC algorithm is slightly better than that of the CC algorithm, its performance is improved by 30%, and the effect is better, and both are better than the DC algorithm and the BC algorithm.

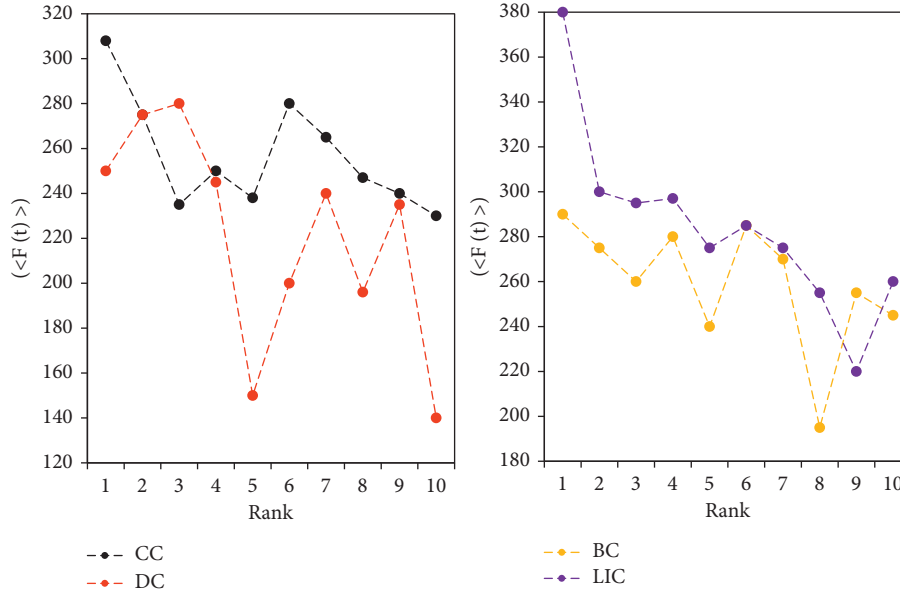

FIGURE 5: Comparison of the correlation between Rank and  $\langle F(t) \rangle$  on the Netscience data set.

FIGURE 6: Correlation comparison between Rank and  $\langle F(t) \rangle$  on the E-mail data set.

This article proposes a new centrality algorithm based on network local importance for mining the influence of nodes in social networks. To verify the effectiveness and superiority of the algorithm, it uses the SIR infectious disease model to simulate the actual spreading influence of sorted list nodes evaluated by different centrality algorithms. The experimental results on three real social network data sets show that the influence nodes mined by the local importance centrality algorithm (LIC) are significantly better than the betweenness centrality algorithm (BC) and the degree centrality algorithm (DC). The influence effect is close to the closeness centrality algorithm (CC) and is much lower than

the closeness centrality algorithm (CC) in computational time complexity. This shows that the LIC algorithm can solve the shortcomings and deficiencies of the existing centrality algorithms and can effectively and quickly determine the influential nodes, which is helpful for social network analysis and has important practical significance.

#### 4. Discussion

The current research results show that some network nodes in social portals have great social influence, which can promote or limit the dissemination of information to

FIGURE 7: Comparison of the number of infected nodes between the LIC algorithm and other algorithms in time  $t$  (1).

FIGURE 8: Comparison of the number of infected nodes between the LIC algorithm and other algorithms in time  $t$  (2).

a certain extent. These network nodes reduce the energy consumption of traditional Internet computing resources to a certain extent and give full play to the function of effectively optimizing traditional Internet information resources. Therefore, finding and classifying influential network nodes has become an urgent problem for many experts and scholars. The characteristic of the social network analysis method compared with the other

two methods is to analyze the network characteristics without destroying the network structure. This method is universal and suitable for most social networks. The social network analysis method mainly relies on analyzing the basic topological characteristics of the network, such as the degree of the node, the shortest path, the eigenvector, and other indicators to evaluate the influence of the node.

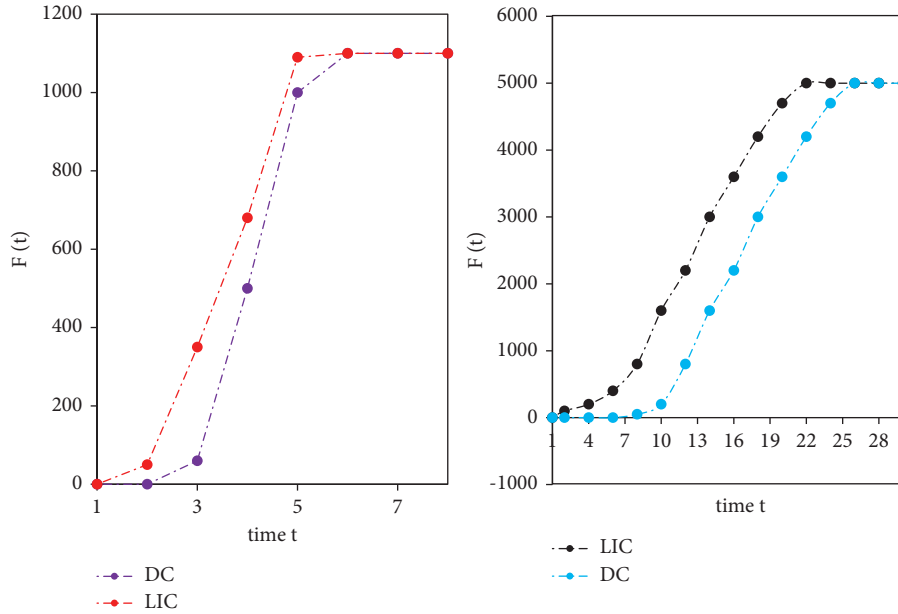

FIGURE 9: Comparison of the influence  $F(t)$  between the LIC algorithm and the DC algorithm at time  $t$ .

TABLE 4: Average  $\langle F(t) \rangle$  values of top 10 nodes for each centrality algorithm.

Data set	LIC	DC	BC	CC
Netscience	359.8	358.7	357.3	358.3
E-mail	1009.8	996.2	1005.5	1010
Power	1399.6	589.1	1389.7	1393.2

## 5. Conclusion

In this article, the influence of nodes is approximated by the local importance of nodes in the network, and a new algorithm based on the local importance centrality of the network (LIC algorithm) is proposed. The local importance of nodes is calculated and evaluated according to local information such as network moderateness and aggregation coefficient, so the computational time complexity is relatively low. By comparing it with the degree centrality algorithm (DC), the betweenness centrality algorithm (BC) and the closeness centrality algorithm (CC), it proves that it has a high influence correlation with the local important centrality algorithm, so that important influential nodes can be well mined. In this article, the research on mining key nodes in the social Internet is mainly based on the current more common way to evaluate the influence of nodes through node centrality. But in real, online, social networking sites, users' influence is not only evaluated by topological characteristics among users, but some more personalized characteristics, such as user attributes, preferences, and the like. Therefore, the next research work is to add attributes such as user personalization characteristics on the basis of complex network topology characteristics to evaluate user influence.

Most of the existing region-matching algorithms need to match all regions, resulting in a waste of computing resources, increasing the cost of simulation technology and data redundancy, and resulting in the reduction of network data stream transmission efficiency. This paper presents a parallel region-matching knowledge recognition algorithm. Combined with the shortcomings of existing matching algorithms, a simulation technology is constructed to realize the parallel matching of multiple regions in HLA distributed simulation. The algorithm can realize the parallel matching calculation of multiple changed regions in one simulation. At the same time, the basic idea based on mobile intersection is adopted in the matching calculation, and the historical information before and after the region range is moved is used. The matching is limited to the moving interval, and the moving crossover theory is applied to the matching calculation to realize the relevant historical information before and after the region. Simulation results show that the parallel region-matching knowledge recognition algorithm can support HLA distributed simulation evaluation. In the matching calculation, the basic idea based on moving intersection is adopted, and the matching is limited to the moving interval by using the historical information before and after the region is moved, which reduces a large number of irrelevant calculations. Theoretical analysis and experimental results show that the algorithm is particularly suitable for the application needs of building large-scale distributed simulation based on multi-core computing platform.

## 1. Introduction

With the continuous development of social economy, engineering construction projects have started to be implemented one after another [1, 2]. For large-scale construction, relying only on traditional design drawings may not fully meet the needs [3–5]. Therefore, experts within the industry have introduced computer simulation technology to further shorten the corresponding period, improve the corresponding training quality, and save the corresponding expenditure. It has been widely applied in many fields [6–8]. There are also many in-depth explorations in China and other countries, such as proposing corresponding high-level architecture (HLA), creating corresponding distributed simulation based on a flexible and customized architecture, and realizing the interoperability and reusability of various

modules and simulation bodies. For HLA, it mainly includes rules, interface specifications, and object templates. In the specific simulation process, distributed simulation can be regarded as a complete dataset, and each simulation component can be called a member [9, 10]. In the existing HLA simulation process, if the relationship between the simulation models is coupled, it will cause the corresponding system to lack a certain degree of flexibility and cause the overall simulation efficiency to decrease [11, 12]. Therefore, if the dynamic and orderly allocation of resources is to be achieved, the simulated client terminal and the server need to be effectively separated. Some scholars integrate grid technology and simulation technology to improve the above shortcomings and use the separation of the simulated client terminal and the server to achieve dynamic adjustment [12, 13]. Such a fusion method has certain advantages, such

as dynamic adjustment and automatic allocation of data resources, full-process support for the entire life cycle of simulation, strong support for security performance, adaptability to dynamic changes of the grid, automation of resource selection, performability of operating data, automatic collection of simulation results, enhancement of fault tolerance performance, and so on [14, 15].

As the scale of simulation continues to increase, the efficiency of simulation calculation has declined. For simulation entities with a huge amount of data, they all have considerable communication or connection with each other, and these data volumes often show exponential changes or growth. Especially in a specific practical application environment, how to achieve effective data distribution and data simulation in such a situation is a problem worthy of in-depth study [16, 17]. The first is to filter a large amount of data based on related data filtering methods, aiming to reduce the transmission and reception of redundant data during the data simulation operation, thereby reducing the feasibility and data flow of the unit to receive the corresponding redundant data [18–20]. Secondly, as the number of simulation entities increases, HLA distributed simulation experiments will have a large amount of data movement during each simulation experiment [21, 22]. In order to ensure the effectiveness and rationality of data distribution, it is necessary to perform reasonable overlap matching on the overlapping relational areas. Meanwhile, the more the number of entities in the simulation entity, the greater the difficulty of matching. Therefore, the matching algorithm directly determines the efficiency of the simulation and also affects the scalability of corresponding simulation. In view of these needs and deficiencies, based on the parallel region-matching knowledge recognition algorithm, the corresponding simulations are used to achieve parallel matching of multiple regions through combining the business logics of HLA distributed simulation, and the theory of mobile intersection is used in matching calculations to achieve the historical information related to forward or backtracking region, which is limited to a fixed threshold, reducing invalid operations and aiming to improve the effectiveness of HLA distributed simulation.

### 1.1. HLA Distributed Evaluation Method

*1.1.1. Concepts Related to Regional Matching.* In view of area matching, in the specific simulation specification, the management of data distribution is based on the corresponding area. The data collector or producer uses the effective designation of the fixed area to achieve data production, and the data user uses search for a specific area to achieve reception of the data. Take a specific area overlap as an example, as shown in Figure 1.

*Definition 1.* Dimension: the so-called dimension is based on a specific named interval, which is essentially a non-negative interval. The downward limit is 0, and the upward limit varies according to the specific dimensions. Its value needs to be defined in the corresponding dimension table.

FIGURE 1: Description of overlapping regions in a two-dimensional interest space.

*Definition 2.* Range: it is different from dimension. It is a continuous integer half-open interval and is a sub-dataset of related dimensions. It is specifically defined by an ordered integer. The specific first number can be considered as the downward limit of the range, and the second integer is the upward limit.

*Definition 3.* Region description: it is a specific range dataset, that is, the corresponding dimension described by the range contained in the area is used. For each dimension described in a specific area, it can only have one range.

*Definition 4.* Region realization: the so-called region realization is to realize attribute update, interactivity, data query, etc. through specific associations.

*Definition 5.* Region: it is the general term for the description and realization of the region.

*Definition 6.* Update region (publish region): The parallel area mainly realizes the real-time update of data to meet the conditions of data query.

*1.1.2. Parallel Region-Matching Knowledge Recognition Algorithm.* The essence of the so-called region-matching algorithm is to determine whether there is a corresponding overlap in the individual interest units of the region, and the specific matching efficiency and accuracy determine the relevant efficiency of specific interest matching [23, 24]. The specific typical matching algorithm can be divided into direct matching, grid matching, mixed matching, classification matching, mobile intersection matching, etc. according to the matching principle or method [25, 26].

For direct matching, its essence is to use a separate data structure to update the range of data and the specific range of query subscriptions. When users query specific data, the algorithm in this paper will identify the corresponding data information according to specific conditions and then calculate the overlapping area with the identification. This method is relatively simple, not requiring additional information, and can ensure accurate matching. However, this algorithm has a relatively large computational complexity. For a large number of areas of large-scale simulation, this

algorithm is difficult to adapt to this simulation calculation [27, 28].

For grid matching, the essence is to use the simulation system to divide the full-dimensional regular grid in advance and set the corresponding data-related channel for each network logic, especially for the specific calculation of the regional boundary to determine the correlated network covered by the region, so as to clarify the relevant channels of data transmission. If the data update area and the query data area have the same unit, then grid matching can be performed. The complexity of the network matching algorithm is relatively simple compared with direct matching, but network matching often generates redundant links and requires manual data filtering. From the overall effect, the specific network matching algorithm is difficult to reconcile in the specific matching speed and accuracy to a certain extent, and the size of the grid affects the efficiency of the overall algorithm.

In regard to the limitations of the direct matching and network matching algorithms, some scholars have proposed a related algorithm of hybrid matching, which uses specific network matching to achieve one-to-one mapping of all regions to a specific network and realizes the exact matching simple compared with specific network. On the one hand, this hybrid algorithm can ensure the accuracy of matching but also reduce the complexity of the entire direct matching algorithm. However, consistent with the network algorithm, the integrity of the hybrid matching algorithm still needs to be restricted by the size of the network.

For the classification matching algorithm, its essence is to use all areas of the system to perform multi-dimensional projection sorting, realize the overlap analysis of two or more dimensions on the projection, and indicate that these ranges have a certain intersection and overlap. The complexity of the classification matching algorithm is relatively moderate, that is, the classification matching algorithm can be used to complete the overlap judgment of the corresponding area at one time. This judgment can realize the misalignment of the operation and the improvement of the matching efficiency. However, because parallel matching recognition is to effectively detect the corresponding region, in the actual simulation process, if some recognition regions change, the system will be recalculated, resulting in the decline of recognition rate.

The specific mobile matching is used to achieve dynamic matching, the essence of which is that only part of the region of the large-scale simulation system changes, so it only needs to change according to the information before and after the area change to realize the information movement of the matching calculation and the effective change of matching range, while effectively reducing the amount of specific matching calculations. During the process of mobile matching, the specific algorithm matching degree only needs to be related to the number of change regions and has nothing to do with the total number of regions of the entire system. Therefore, it can be seen that mobile matching is not only dynamic but also accurate and efficient.

Therefore, it is necessary to use multi-core CPUs for actual processing. When the computing platform becomes multi-core and uses distributed interactive simulation on a larger scale, specific high-performance parallel computing can be used to improve specific simulation performance and achieve support for complex systems. Although the above matching algorithm causes certain restrictions and limitations to large-scale simulation calculations, there are also certain limitations, which are restricted by the bottleneck of computational complexity. Therefore, it is worthy of in-depth exploration and research to realize efficient parallel computing on a multi-core, distributed computing platform.

First, a specific domain scanning method is used to collect data, and the specific sequence is shown in Figure 2. When there is overlap between  $p$  and the surrounding area pixels, it is necessary to fully consider the scanning speed to avoid repetitive scanning. Figure 2(b) shows a specific scanning scheme, in which the shaded parts of the diagonal lines are overlapping areas. During scanning, these parts do not need to be scanned repeatedly, and only important grid parts are scanned for specific pixel point judgment. [1, 8] is used to determine the scan template.

A specific two-dimensional array is used as a scanning template, each specific row is used as a scanning template, each column of data is used as the number of scanning points included, and the rest are filled with 0. When a specific pixel point is scanned, the adjacent points need to be assigned to the specific periphery, and the circular labeling is realized according to the specific point.

The breadth-first method is used to search the parallel region-matching knowledge recognition algorithm. Assuming that the image is a two-dimensional image with  $M$  rows and  $N$  columns, the valueless represents black pixels, and value 1 represents white pixels. The specific steps are shown below.

- (1) First, create a specific tag array to indicate whether the pixels of the image have been processed. When the image is scanned, the array with tag attributes gives different tag values for each specific area.
- (2) The principle of left-to-right and top-to-bottom is used to effectively scan the image. When realizing a specific marked pixel scan, if the pixel is marked, it needs to be recorded for subsequent mark analysis.
- (3) When searching for the area at the starting point of the area, a fixed algorithm needs to be specifically called, and the label value of the area is set to a fixed value; when the function completes the specific call, the coordinates of all pixels in the area can be obtained.
- (4) Scan the image through  $p$ , repeat steps 2 and 3 iteratively, until the specific image is scanned, and the algorithm process ends.

On the basis of the above steps, the specific number of regions can be obtained, and the corresponding parameters can be used to mark each part of the region to achieve the specific mark value to obtain the corresponding region containing points. In the specific steps, it is necessary to

FIGURE 2: Pixel 8 neighborhood priority order, scan template, and two-dimensional array. (a) Scan-line order. (b) Scanning templates for *p*'s different neighborhoods. (c) Array of the scanning templates.

implement the algorithm call of the connected region through the algorithm, and the single-region binary graph is shown in Figure 3.

In order to realize the flow of the algorithm, the serial number is marked according to the specific search order. As shown in Figure 4, when the image is scanned to a specific value (1), the value of the corresponding array is recorded as 0, and it is taken as the starting point and ending point of the new region, the total number of corresponding regions is increased accordingly, and in the meantime, the value of the array is recorded as the corresponding array. On the one hand, it can indicate that this point has been scanned accordingly; on the other hand, it also belongs to certain region.

FIGURE 3: Binary graph of a single region.

- (1) Use the corresponding queue to record the coordinates of the corresponding recording point and the scan mark.
- (2) The circular identification is performed for the corresponding queue; it is necessary to ensure that the queue is not null. When reading the point value at the head of the queue, it needs to be identified according to the specific scan template, and the inspection and marking are given in the corresponding order. Meanwhile, the marked points that are not scanned are appended to the queue through the corresponding array value, and then the scanned point is removed.

FIGURE 4: Pixel numbers given from top left to bottom right.

The specific calling process is shown in Figure 5, the number in the circle represents the specific label of the scan template at a certain point, and the specific underlined point can be identified as the critical point of the same point. It can be seen from the running results of Figure 5 that if a different scanning sequence is used to scan the region of pixels, it is often unnecessary to traverse the surrounding points, and only 5 points need to be traversed at most. This scanning method effectively improves the operating efficiency. There is no specific mark conflict in the whole scanning process, and the final region will be scanned in the corresponding order from top left to bottom right.

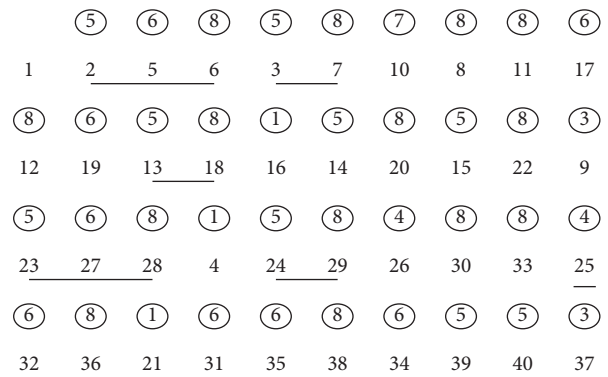

FIGURE 5: Points of the regional operation process.

As the computing performance of the computer has been significantly improved, in order to facilitate the use of the computer, make maximum use of computing power, use

connectivity detection to analyze the effectiveness of each pixel, and analyze the specific connection relation between the pixels before and after. The specific region merging is

realized through related parallel algorithms, and different algorithms are used to realize the different complexity of parallel algorithms in dealing with specific region overlaps. If a specific function is called directly, you can directly obtain the relevant computing performance of the computer and divide the image according to the computing power. If it is a two-core computing power, it is divided into two parts, and the region detection of the two parts is performed according to the above method. When the calculation is completed, the overlapping region is effectively scanned, and then the relevant regions are merged.

By setting the corresponding image size, using multiple computers for calculation, and using specific parameters to

represent specific threads, formulas (1) and (2) are used to calculate the start lines and end lines of the thread.

$$starline = (threadNum - 1) \times H/N, \quad (1)$$

$$endline = threadNum \times H/N - 1. \quad (2)$$

HLA-distributed simulation data are collected by sensor equipment and stored in large capacity data storage equipment. After data processing, it is sent to the corresponding program for operation.

$$T(a, a_1) = \frac{\sum_{i=1}^n ((q_i - s)^2 (q_i - s - l))(q_i - s^2 (q_i - s - l))}{\sqrt{\sum_{i=1}^n (q_i - s^2 (q_i - s - l))^2 + (q_i - s^2 (q_i - s - l))^2}}, \quad (3)$$

where  $T(a, a_1)$  is the set of characteristic attributes of HLA distributed data and HLA distributed characteristic expression;  $q_i$  is the number of data features after classification for HLA distributed data; and  $s$  is the feature content of the HLA distribution. It is a numeric argument, a property specific to HLA distributed data. After identifying the characteristics of HLA distributed data, non-characteristic attributes must be removed. It can reduce the error and improve the speed when collecting. The redundant data removal formula is as follows:

$$L = \vec{q} + \frac{\sum_{i=1}^n (T(a, a_1))_i (q - e)}{\sum_{i=1}^n [T(a, a_1)]_i^2}, \quad (4)$$

where  $L$  defines the removal benchmark and removes those that meet the benchmark;  $\vec{q}$  indicates the filter request to be used when removing;  $e$  represents an existing redundant data removal request. The features of the data can be obtained by filtering.

$$C = \beta \left( \prod_{i=1}^n e_i + \frac{\sum_{i=1}^n T(a, a_1) \cdot (a, a_1)_i d^{i\theta}}{\sum_{i=1}^n T(a, a_1)_i^2} \right) + (1 - \beta) \left( q_i + \frac{\sum_{i=1}^n (T(a, a_1)_i - \bar{X}) \cdot T(a, a_1)_i^2}{\sum_{i=1}^n (T(a, a_1) - \bar{X})^2} \right), \quad (5)$$

where  $\alpha$  represents the ownership value of the data feature and  $\beta$  represents the correlation coefficient of the balance factor. Assume input vectors  $x_i$  and label values  $y_i$ . The softmax loss function expression used in this paper is

$$L = -\frac{1}{m} \sum_{i=1}^m \log \frac{e^{f_{y_i}}}{\sum_{j=1}^n e^{f_j}} = -\frac{1}{m} \sum_{i=1}^m \log \frac{e^{W_{y_i}^T x_i + b_{y_i}}}{\sum_{j=1}^n e^{W_j^T x_i + b_j}}, \quad (6)$$

where  $x_i$  represents the  $i^{th}$  HLA distributed simulation evaluation efficacy image feature;  $y_i$  represents the real category label corresponding to  $i^{th}$  HLA distributed simulation evaluation efficacy image;  $W_j$  represents the category

weight;  $b_j$  represents the error value of the category;  $m$  and  $n$  represent the number of training samples and the number of categories in turn; and  $f_j$  represents the inner product relationship  $f_j = W_j^T x_i + b_j$  between the category weight  $W_j$  and the bias value  $b_j$  when the fully connected layer is activated. The HLA distributed simulation evaluation efficacy identification technology should satisfy the following conditions in the HLA distributed simulation evaluation efficacy feature value: the distance between the same HLA distributed simulation evaluation efficacy features needs to be minimized, and the distance between different HLA distributed simulation evaluation efficacy features needs to be maximized.

The corresponding sequential marking algorithm is used to mark the overlapping regions, which cannot ensure the sequential arrangement, so the process of merging the regions will be more complicated. Therefore, this paper proposes a reverse merging algorithm for this limitation. That is, in the process of reverse merging, the processing is performed from the second-to-last overlapping row, and each time a row is processed; the corresponding thread will analyze and correspond to determine whether the merging process is required.

In view of the limitations of existing region-matching algorithms, this paper constructs a parallel region-matching algorithm for HLA distributed simulation, which integrates mobile matching and parallel computing methods and divides the tasks of multiple mobile matching in the simulation into different cores, and the multi-threading methods are used to achieve specific parallelized calculation of region matching, so as to improve the calculation of region-matching ability. Similarly, in each specific thread calculation, the method of using a mobile region to match the region is realized, to reduce the number of redundant calculations and improve the actual efficiency of matching.

For the parallel region-matching knowledge recognition algorithm, its specific principles are as follows. First, when a specific single region is effectively moved, the overlap change between other regions and the part of the region is actually

related to the movement of the single region. Therefore, when updating a specific region, there is no need to consider the range outside the actual region movement region. The overlap of these regions cannot be directly changed; in the specific simulation process, there is certain irrelevance in regions of the same type. The changes in multiple regions of the same type are overlapped by multiple calculations, as shown in Figure 6.

Figure 6 shows the changes in the overlap of the two-dimensional region during the specific simulation advancement process. When a specific change occurs in the corresponding region, a specific update region can be realized through the boundary of the region, and specific overlapping parallel calculations can be realized from the specific region, and the parallel computing performance can be effectively realized.

When a specific region changes to a certain extent, the relevant core of the matching calculation is caused according to the region, and the position query before and after the movement is realized to ensure the region where the region moves. Here, the dimensional data stored in the region are realized in an orderly manner through a specific index, that is, the data of each dimension in a specific multi-dimensional space are used along with the index for storage. On the one hand, it uses the indexed ordered table to store the specific update region data. On the other hand, it is used to store the range boundary value of various region projections in specific dimensions. Each group is combined through two specific ordered tables, one index table stores the closed point of lower boundary of the range, and the other index table is used to store the opening point of the upper boundary. The definition of the specific data structure of the node is as follows:

```

struct Node {
    int id; //range id
    Struct Node * Next; //Node pointer
}

```

The ordered list of each index implements a specific pointer array index, uses the size of the array to set the dimension, and compares the boundary value with the corresponding index value of the array element, as shown in Figure 7.

It can be seen from Figure 7 that for fixed nodes with no moving range, redundant operation analysis that is not within the operating range can be achieved without effective matching, which effectively saves related computing resources and can achieve accurate analysis and matching in specific ranges, and there is no specific false connection problem.

From the framework of Figure 8, in view of multi-threading, the calculation of overlapping regions is realized, including control threads and multiple computing threads, to complete the calculation task through the task queue. After a specific movement range occurs in the control thread region, it is responsible for the specific task generation node, and it is listed in the specific task queue, and the calculation of the result is completed by the calculation

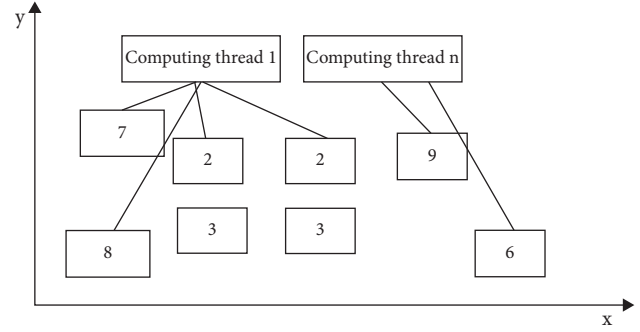

FIGURE 6: Schematic diagram of the intersecting changes of regional movement.

FIGURE 7: Range representation based on indexed ordered list.

of the control thread. In each simulation advancement process, the first thing that each computing thread needs to process is the update region, until all tasks are processed. The semaphore mechanism is used to synchronize between the threads.

The specific steps of the so-called control thread algorithm are as follows.

For (every simulation advancement process)

- (1) For each announcement range  $a_m$ , if  $a_m$  moves, insert  $a_m$  into the announcement task queue pq.
  - (2) For each order range  $b_n$ , if  $b_n$  moves, insert  $b_n$  into the order task queue sq.
  - (3) If pq is not null, for each computing thread 1, release the semaphore  $m\_publish\_i$ , which is used to notify the computing thread to start processing and update the task queue.
  - (4) Wait for the completion semaphore  $m\_publish\_finish\_i$  of each computing thread  $i$  until all update tasks are processed.
  - (5) If sq is not null, for each calculation line  $i$ , release the semaphore  $m\_subscribe\_i$ , which is used to notify the calculation thread to start processing the order task queue.
  - (6) Wait for the completion semaphore  $m\_subscribe\_finish\_i$  of each calculation thread  $i$  until all the subscription overlap calculations are completed.
- end for

**1.1.3. Simulation Experiment.** In order to verify the effectiveness of the parallel region-matching knowledge

FIGURE 8: Parallel region-matching method framework.

FIGURE 9: Algorithm performance test results for different numbers of regions (2000, 4000, 8000).

FIGURE 10: Algorithm performance test results at different dimensional upper limits.

recognition algorithm, the following simulation experiments are set up in this paper. First, a specific two-dimensional space is generated according to specific user input, and a specific publishing region and ordering region are generated

in the two-dimensional space, and corresponding algorithm comparison experiments are designed.

Corresponding tests are carried out for the algorithm performance in different numbers of regions, and the HLA

distributed simulation evaluation changes of the matching algorithm in the corresponding cases of 2000, 4000, and 8000 are calculated, respectively, as shown in Figure 9. It can be seen from the results that the parallel region-matching knowledge recognition algorithm is relatively appropriate in terms of time consumption.

For different upper dimensional limits, as shown in Figure 10, the performance of parallel region-matching knowledge recognition algorithm is obviously better than other algorithms. When the upper limit of dimensionality is greater than 5000, the algorithm performance is the same as the grid matching performance with a grid number of 100, and there is no false connection phenomenon in grid matching.

The parallel region-matching knowledge recognition algorithm is closely related to the number of threads of calculation. From the corresponding simulation experiment results, compared with the traditional method, the parallel region-matching knowledge recognition algorithm does not change the performance with the increase of the specific number of regions, but in terms of specific dimensions, it has a change relationship with the specific upper limit of the dimension. Through multi-core computing power, better acceleration ratio is realized, especially for large-scale regional changes. Therefore, the parallel region-matching knowledge recognition algorithm is more suitable for HLA distributed simulation evaluation.

## 2. Conclusion

The development of industry requires HLA distributed simulation to provide specific support for the long-term, stable, and healthy development of industrial economy. Most of the existing region-matching algorithms need to match all regions, resulting in a waste of computing resources. At the same time, it is difficult to give full play to the parallel computing advantages of multi-core platform mainly based on the idea of serial matching. In view of these needs and shortcomings, based on the parallel region-matching knowledge recognition algorithm, this paper realizes the parallelism of region-matching calculation through multi-core platform. At the same time, for HLA distributed simulation, this paper constructs a simulation system to realize multi-region parallel matching. In the matching calculation, the mobile crossover theory is used to realize the relevant historical information of regional prepositions or backtracking, and it is limited to a fixed threshold range to reduce invalid operations. It has efficient matching and good acceleration performance and can support HLA distributed simulation evaluation. The experimental results show that the algorithm has high matching efficiency, does not cause false connections, and has good acceleration performance. It can give full play to the computing performance of multi-core computing platform and meet the needs of large-scale distributed simulation data distribution and management.

The Internet of vehicles (IoV) is an important research area of the intelligent transportation systems using Internet of things theory. The complex event processing technology is a basic issue for processing the data stream in IoV. In recent years, many researchers process the temporal and spatial data flow by complex event processing technology. Spatial Temporal Event Processing (STEP) is a complex event query language focusing on the temporal and spatial data flow in Internet of vehicles. There are four processing models of the event stream processing system based on the complex event query language: finite automata model, matching tree model, directed acyclic graph model, and Petri net model. In addition, the worst-case response time of the event stream processing system is an important indicator of evaluating the performance of the system. Firstly, this paper proposed a core algorithm of the temporal and spatial event stream processing program based on STEP by Petri net model. Secondly, we proposed a novel method to estimate the worst-case response time of the event stream processing system, which is based on stochastic Petri net and queuing theory. Finally, through the simulation experiment based on queuing theory, this paper proves that the data stream processing system based on STEP has good dynamic performance in processing the spatiotemporal data stream in Internet of vehicles.

## 1. Introduction

Internet of vehicles is an important application of intelligent transportation with Internet of things, and it is also an important part of smart city [1–6]. In Internet of vehicles system, there are various types of data sources that produce large amounts of temporal and spatial uninterrupted data flow. Processing these data stream is an important research direction of big data [7]. Now, there are some products of processing the data flow of Internet: Twitter's Storm system [8], Yahoo's simple scalable streaming system (S4) [9], Facebook's Data Freeway and Puma system [10], LinkedIn's Kafka system [11], and an interactive real-time computing systems Berkeley's Spark [12].

Because the data stream of Internet of vehicles is different from the Internet, therefore, we cannot directly use the Internet data stream processing method to process the temporal and spatial data stream of Internet of vehicles. In recent years, there is some progress in processing the

temporal and spatial data streams of Internet of vehicles using the complex event processing technology. In the event driven architecture Internet of vehicles, all kinds of temporal and spatial data stream generated by the sensing devices were abstracted into basic temporal and spatial events. Through a complex event query language, the system will get the meaningful complex event from the basic temporal and spatial event by certain pattern matching filter. Moody proposed a complex event query language SpaTec, and it will be applied to London's bus monitoring system [13, 14]. Jin et al. have proposed a complex event query language CPSL, and it can describe a variety of spatial and temporal properties of the event [15]. Li and Chen have proposed a temporal and spatial constraints event query language STEP, which can effectively describe the Temporal and Spatial constraint information of Internet of vehicles [16]. Xu et al. have proposed a spatiotemporal event interaction model STEIM to express the spatiotemporal information of the spatiotemporal event flow in the V2X [17].

There are four types processing model of the event stream processing system based on complex event query language: finite automata model, matching tree model, a directed acyclic graph model, and Petri net model. The worst response time of the event stream processing system is an important indicator of the performance evaluation of the system. Akili and Weidlich began to focus on the worst response time of the event stream processing system [18]. Um et al. have proposed an associated constraint labelling method to estimate the worst response time of the event stream processing system [19]. Jiang et al. present a model of the outward transmission of vehicle blockchain data and then give detailed theoretical analysis and numerical results [20]. Hu et al. present a novel double-layered federation model to analyze the performance of the data processing system of Internet of vehicles [21].

The current work has not analyzed the dynamic performance of the stream processing algorithm. In this paper, the dynamic performance of the algorithm is analyzed through the queuing theory model, thereby verifying the feasibility of the algorithm theoretically. In this paper, we proposed a method to estimate the worst case response time

of the STEP event stream processing system, which is based on stochastic Petri net and queuing theory. The simulation results demonstrate the effectiveness of the method. The remainder of this paper is structured as follows: Section 2 introduces the complex event query language STEP. Section 3 introduces the stochastic Petri net theory and queuing theory. Section 4 gives the architecture of the STEP event stream processing system and the core algorithms. Section 5 analyzes four types structured event stream processing program instances by queuing theory. Section 6 verifies the relevant conclusion is correct through the simulation. Finally, the last section concludes this paper.

## 2. Event Query Language: STEP

STEP is a Spatial-Temporal Constraint Event Query Language, which focuses on processing the spatial and temporal constraint data of the Internet of vehicles. The syntax of STEP contains five types of Boolean expressions, and the event instances of Boolean expression EBEXP were composed by the others. Syntax rules of STEP are as follows:

The object identifier Boolean expression OBEXP:

$$obexp ::= \text{TRUE} | \text{FALSE} | x_{id} = ID | x_{id} \neq ID | obexp_1 \wedge obexp_2 | obexp_1 \vee obexp_2. \quad (1)$$

The general numerical attributes Boolean expression ABEXP:

$$abexp ::= \text{TRUE} | \text{FALSE} | x_a = A | x_a \neq A | |x_a > A | x_a < A, \\ | abexp_1 \wedge abexp_2 | abexp_1 \vee abexp_2. \quad (2)$$

The temporal properties Boolean expression TBEXP:

$$tbexp ::= \text{TRUE} | \text{FALSE} | x_t \text{ BEFORE } T | x_t \text{ EQUAL } T | |x_t \\ \text{ OVERLAP } T | x_t \text{ DURING } T, \\ | tbexp_1 \wedge tbexp_2 | tbexp_1 \vee tbexp_2. \quad (3)$$

The spatial properties Boolean expression LBEXP:

$$lbexp ::= \text{TRUE} | \text{FALSE} | x_t \text{ EQ } LOC | x_t \text{ OPLOC} | x_t \text{ IN } LOC | x_t \text{ NORTH } LOC, \\ | lbexp_1 \wedge lbexp_2 | lbexp_1 \vee lbexp_2. \quad (4)$$

The event instances Boolean expression EBEXP:

$$ebexp ::= \text{TRUE} | \text{FALSE} | obexp | tbexp | |lbexp | abexp | ebexp_1 \wedge ebexp_2 | ebexp_1 \vee ebexp_2. \quad (5)$$

## 3. Stochastic Petri Net and Queuing Theory

**3.1. Stochastic Petri Net.** Stochastic Petri net model linked a random delay time with each transition between the case where it can be implemented and its implementation. The performance analysis of stochastic Petri net is built on the foundation that its state space is isomorphism as the Markov chain. Stochastic Petri net provides a good description means of the

performance model of the system, and Markov random process provides a solid mathematical foundation of its evaluation.

*Definition 1.* In continuous time stochastic Petri net, a transition requires a delay time from the case where it can be implemented to the case where it has implemented. It is seen as a continuous random variable  $x_i$  (take a positive real number). Because of the speed of the data flow in the

queuing system subjecting to the Poisson distribution, therefore, the delay time subject to an exponential distribution function is as follows:

$$\forall t \in T: F_t = 1 - e^{-\lambda_t x}. \quad (6)$$

Stochastic Petri net is denoted as  $SPN = (S, T; F, M_0, \lambda)$ , where  $((S, T; F, M_0))$  is a Petri net system, and  $\lambda = \{\lambda_1, \lambda_2, \dots, \lambda_m\}$  is the average implementation rate collection of the transition. Among them, the real parameter  $\lambda t > 0$  is the average implementation rate of the transition  $t$ , and it indicates the average implementation times per unit time. The inverse of the average implementation rate of the transition  $t_i$  is called average implementation delay or average service time.

There are three performance equivalence formulas of the series, parallel, and selection structured stochastic Petri net model, and the relevant conclusions are as follows:

**Theorem 1.** *The system B consists of n series transitions. Assume that the delay times of the n series transitions are the independent random variables, and they were subject to exponential distribution function with parameters  $\lambda_1, \lambda_2 \dots \lambda_n$ . So, the total equivalent delay time is as follows:*

$$\frac{1}{\lambda} = \sum_{i=1}^n \frac{1}{\lambda_i}. \quad (7)$$

**Theorem 2.** *The system B consists of n parallel transitions. Assume that the delay times of the n parallel transitions are the independent random variables, and they were subject to exponential distribution function with parameters  $\lambda_1, \lambda_2 \dots \lambda_n$ . So, the total equivalent delay time is as follows:*

$$\frac{1}{\lambda} = \sum_{i=1}^n \frac{1}{\lambda_i} - \sum_{i=1}^{n-1} \sum_{j=i+1}^{n-1} \sum_{k=j+1}^n \frac{1}{\lambda_i + \lambda_j + \lambda_k} + \dots \quad (8)$$

**Theorem 3.** *The system B consists of n selection transitions. Assume that the delay times of the n selection transitions are the independent random variables, and they were subject to exponential distribution function with parameters  $\lambda_1, \lambda_2 \dots \lambda_n$ . Assume that the implementation probability of the transition  $t_i$  is  $\alpha_i$ . So, the average delay time of the n selection transitions and the total equivalent delay time are as follows:*

$$\frac{1}{\lambda} = \sum_{i=1}^n \frac{\alpha_i}{\lambda_i}. \quad (9)$$

**3.2. Queuing Theory.** Queuing theory, also known as stochastic service system theory, is a mathematical discipline that studies crowding phenomenon. It solves the optimal system design and optimal control through the probabilistic characteristics of a variety of services in queuing system. Queuing theory is an important branch of operational research and an important branch of applied probability. The research has a strong practical background, which originated

by the Danish telecommunication engineer A. K. Erlang's research in the 20th century. Now, it is a mature theory.

Queueing phenomenon consists of two aspects: one obtains services, and the other tries to give services. The first one is called customer, which requires services. The servers give others services. The customers and servers constitute a queuing system.

**Definition 2.** The queuing system consists of three parts: the input process, queuing rules, and servers. These three parts of the queuing system are an organic whole, which describes the queuing system from different aspects.

- (1) The input process describes how the customer arrives at the queuing system. It is usually described by the probability distribution of the customer arrival time. The common distribution is as follows: fixed-length input, negative exponential input (Poisson stream), geometric input, Erlang input, and so on.
- (2) The queuing rules of the queuing system are the order of the customers accepting services. And it can be divided into first come first serve (FCFS), last come first serve (LCFS), and so on.
- (3) The structure of the server means the number of the servers and the service time of a customer. The common customer service time distributions are as follows: fixed-length distribution, the negative exponential distribution, and geometric distribution.

The queuing system model is as follows (see Figure 1). The mathematical representation of the queuing system is given in Theorem 4.

**Theorem 4.** *A queuing system can be expressed with a three-letter symbol A/B/C. A represents the customer arrival time distribution, B shows the distribution of the service time, and C represents the number of the servers. A and B will be M, D, and G. M represents a negative exponential distribution, D represents the distribution of fixed length, and G represents the general distribution.*

The key performance indicators of a queuing system are as follows:

- (1) The average queue length  $L$ , that is, the number of customers of the queuing system and its mathematical expectation formula, is as follows:

$$E[L] = \frac{\rho}{1 - \rho} = \frac{s}{\mu - s}. \quad (10)$$

- (2) The average staying time of the customer  $W$ , that is, the processing time of each customer in the system and its mathematical expectation formula, is as follows:

$$E[W] = \frac{1}{\mu - s}. \quad (11)$$

FIGURE 1: Queuing system model.

- (3) The average waiting time of the customer  $W_q$ , that is, the waiting time of each customer of the system and its mathematical expectation formula, is as follows:

$$E[W_q] = \frac{\rho}{\mu(1-\rho)}. \quad (12)$$

## 4. The STEP Event Stream Processing System

### 4.1. The Architecture of STEP Event Stream Processing System.

The architecture of spatial and temporal event stream processing system based on STEP in Internet of vehicles is shown in Figure 2. Firstly, the user writes the event query expressions by STEP and sends these expressions to the event stream processing system. Secondly, the event stream processing system receives the event query expressions and converts the expressions into event stream processing model. Then, the event stream processing system generates the corresponding event stream processing program according to the event stream processing model. The event stream processing program will begin processing the received event stream and producing the query results. Event stream processing program begins processing the received event stream and producing query results. Finally, the query results will be sent to the user.

To complete the event stream query, we need to convert the event query expression into the event stream processing model. There are four types of event stream processing models: tree model, directed acyclic graph model, automata model, and Petri net model. The Petri net model can be used to simulate the concurrency, asynchronous, distributed, nondeterministic, and parallelism systems. Therefore, we used Petri net to model the event processing system.

**4.2. The Core Algorithm of STEP Event Stream Processing System.** The main function of the STEP event stream processing system is to receive the event stream processing Petri net model and return the processing results. The core algorithm of the system is shown in Table 1.

In the algorithm, all input transitions of the Petri net model are divided into three categories: the beginning transition (TransitionStart), the middle transition (TransitionMid), and the end transition (TransitionEnd). The function of the TransitionStart is to detect the attribute values of the received event instance. The TransitionStart transmits the information through sharing the Place with the connected TransitionMid: the output Place of the TransitionStart shares the same variable with the input Place of the TransitionMid. The TransitionEnd is a special kind of transition: it has no successor.

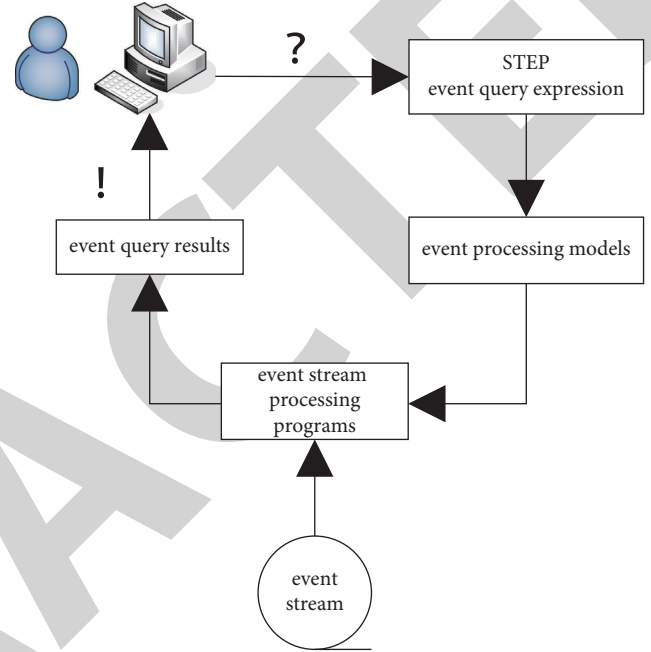

FIGURE 2: Architecture of the event stream processing system.

In the algorithm, the TransitionStart will be implemented firstly, and the other transitions will be implemented step by step until the TransitionEnd along the Petri net structure. Because the number of the transitions is limited from the TransitionStart to the TransitionMid, therefore, the algorithm is terminated for an event instance. Assume that there are  $n$  transitions in the Petri net model, and then the complexity of the algorithm is  $O(\log n)$ .

**4.3. The Queuing Theory Model of the STEP Event Stream Processing System.** The queuing theory model of the STEP event stream processing program based on Algorithm 1 is shown in Figure 3. It can clearly express the overall framework and processing process of Algorithm 1 in the queuing theory model.

We analyze the dynamic performance of the system by queuing theory. The dynamic performance of the queuing system mainly refers to the degree of change in the processing time of the service system when the speed of input data changes. Firstly, the event stream is transferred into the system memory, and these event instances will queue in there. Then, they will be processed by the event stream processing program one by one. The event stream in Internet of vehicles can be seen as Poisson stream. The service rule is first come first serve (FCFS), and the queuing system model of event stream processing system is an  $M/M/1$  queuing system.

TABLE 1: The core algorithm of the STEP event stream processing system.

Algorithm event stream processing algorithm based on Petri net model	
<b>Input:</b>	event stream, petri net model of the query expressions

(26)	<b>end</b>
(27)	<b>end</b>
(28)	Delete the current event, the pointer point the next event;
(29)	<b>end</b>

There are two important parameters to analyze the dynamic performance of the queuing system: the parameter  $s$  of the Poisson event stream and the parameter  $\mu$  of the service time distribution of the event stream processing system.

Because the physical meaning of the parameter  $s$  of the Poisson event stream is the data transfer rate of networks, the parameter can be determined according to the network transmission environment. Next, we focus on the parameter  $\mu$  of the service time distribution.

The stochastic Petri net is a powerful tool to analyze the dynamic performance of the system. According to Definition 1, we can build the stochastic Petri net model of the event stream processing system. And we can analyze the dynamic performance of the event stream processing system by Theorem 4.

The example is shown as follows:

As shown in Figure 4, there are three independent random variables of the transition's delay time, and they were subject to parameters  $\lambda_1$ ,  $\lambda_2$ ,  $\lambda_3$  exponential distribution functions. The three random variables represent the processing time in each step of the computation in the data stream processing system.

Assume that the overall delay time of the stochastic Petri net obeys the exponential distribution function with parameter  $\lambda$ . According to the Theorem 4, we get

$$\frac{1}{\lambda} = \left( \frac{1}{\lambda_1} + \frac{1}{\lambda_2} - \frac{1}{\lambda_1 + \lambda_2} \right) + \frac{1}{\lambda_3}. \quad (13)$$

So, we can get the value of parameter  $\lambda$  in the end.

Assume that the processing rate  $\mu$  of event stream processing program is proportional to the speed  $\lambda$  of the stochastic Petri net model:  $\mu = k\lambda$  (where  $k > 0$  and the value of  $k$  is related to the processor speed of the operating environment). So, we can analyze the dynamic performance of an event stream processing program according to the speed parameter  $\mu$  of the event stream processing program and the transmission rate parameter  $s$  of the event stream.

## 5. Case Study

There are four different structured event stream processing program models, shown in Figure 5. And we analyze these examples by stochastic Petri net model and the queuing theory.

As shown in Figures 5(a)–5(d), there are four event stream processing programs: Example 1, Example 2, Example 3, and Example 4. In the examples, structure  $a$  represents a mixed calculation process of two AND operations. Structure  $b$  represents a mixed calculation process in which an OR operation is performed first, and then an AND operation is performed. Structure  $c$  represents a mixed calculation process in which an AND operation is performed first, and then an OR operation is performed. Structure  $d$  represents a mixed calculation process in which an OR operation is performed first, and then an AND operation is performed. In these examples, the transmission rate of the event stream is  $s_1$ ,  $s_2$ ,  $s_3$ , and  $s_4$ . Their event stream processing rate is  $\mu_1$ ,  $\mu_2$ ,  $\mu_3$ , and  $\mu_4$ . Because the service intensity of the queuing system  $\rho = s/\mu$ , and the necessary and sufficient conditions of the queuing system have the steady state distribution as  $\rho < 1$ , so assume that  $\rho_1 = s_1/\mu_1 < 1$ ,  $\rho_2 = s_2/\mu_2 < 1$ ,  $\rho_3 = s_3/\mu_3 < 1$ , and  $\rho_4 = s_4/\mu_4 < 1$ .

In order to compare these four structural examples' performance, we set the parameters as in Table 2. In the stream data processing structure of this paper, the former data processing generally takes less time, while the latter data processing takes more time. Therefore, according to this situation, we assume the parameter settings as shown in Table 2. According to Theorem 4, we can get the overall rate of these examples shown as the  $\lambda$  column of the table. Assume that the transition probability of each branch is equal in the selection structure.

According to the Theorem 4, the dynamic performance of the example 1 can be calculated as follows:

Assume that the event stream transmission rate is  $s_1$ , and the processing rate of the event processing program is  $\mu_1 = 33/23 k$ .

The queuing system's service intensity  $\rho_1 = s_1/\mu_1 = 23s_1/33k$ ;

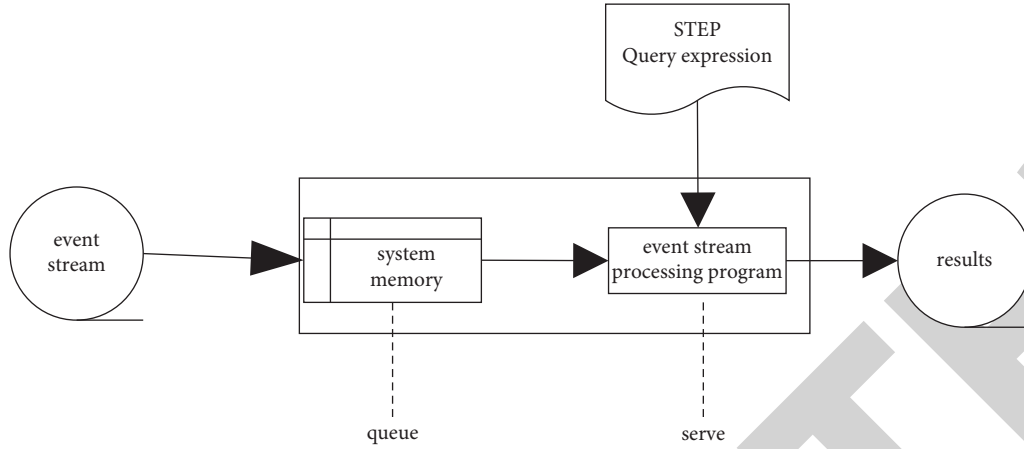

FIGURE 3: The queuing theory model of STEP event stream processing program.

FIGURE 4: An example of event stream processing program's stochastic Petri net model.

The amount of the waiting events of the queuing system

$$E[L_1] = \rho_1/1 - \rho_1 = s_1/\mu_1 - s_1 = 23s_1/33k - 23s_1;$$

The residence time of each event of the queuing system

$$E[W_1] = 1/\mu_1 - s_1 = 23/33k - 23s_1;$$

The waiting time of each event of the queuing system

$$E[W_{q1}] = \rho_1/\mu_1(1 - \rho_1) = 529s_1/(33k - 23s_1)33k;$$

The proportion of waiting time of the queuing system

$$E[W_{q1}]/E[W_1] = 23s_1/33k;$$

Similarly, according to the Theorem 4, the dynamic performance of example 2 can be calculated as follows:

Assume that the event stream transmission rate is  $s_2$ , and the processing rate of the event processing program is  $\mu_2 = 16/5k$ ,

The queuing system's service intensity  $\rho_2 = s_2/\mu_2 = 5s_2/16k$ ;

The amount of the waiting events of the queuing system  $E[L_2] = \rho_2/1 - \rho_2 = s_2/\mu_2 - s_2 = 5s_2/16k - 5s_2$ ;

The residence time of each event of the queuing system  $E[W_2] = 1/\mu_2 - s_2 = 5/16k - 5s_2$ ;

The waiting time of each event of the queuing system  $E[W_{q2}] = \rho_2/\mu_2(1 - \rho_2) = 25s_2/(16k - 5s_2)16k$ ;

The proportion of waiting time of the queuing system  $E[W_{q2}]/E[W_2] = 5s_2/16k$ ;

Similarly, according to Theorem 4, the dynamic performance of example 3 can be calculated as follows:

Assume that the event stream transmission rate is  $s_3$ , and the processing rate of the event processing program is  $\mu_3 = 12/5k$ ,

The queuing system's service intensity  $\rho_3 = s_3/\mu_3 = 5s_3/12k$ ;

The amount of the waiting events of the queuing system  $E[L_3] = \rho_3/1 - \rho_3 = s_3/\mu_3 - s_3 = 5s_3/12k - 5s_3$ ;

The residence time of each event of the queuing system  $E[W_3] = 1/\mu_3 - s_3 = 5/12k - 5s_3$ ;

The waiting time of each event of the queuing system  $E[W_{q3}] = \rho_3/\mu_3(1 - \rho_3) = 25s_3/(12k - 5s_3)12k$ ;

The proportion of waiting time of the queuing system  $E[W_{q3}]/E[W_3] = 5s_3/12k$ ;

Similarly, according to the Theorem 4, the dynamic performance of example 4 can be calculated as follows:

Assume that the event stream transmission rate is  $s_4$ , and the processing rate of the event processing program is  $\mu_4 = 168/83k$ ,

The queuing system's service intensity  $\rho_4 = s_4/\mu_4 = 23s_4/33k$ ;

The amount of the waiting events of the queuing system  $E[L_4] = \rho_4/1 - \rho_4 = s_4/\mu_4 - s_4 = 83s_4/168k - 83s_4$ ;

The residence time of each event of the queuing system  $E[W_4] = 1/\mu_4 - s_4 = 83/168k - 83s_4$ ;

The waiting time of each event of the queuing system  $E[W_{q4}] = \rho_4/\mu_4(1 - \rho_4) = 6889s_4/(168k - 83s_4)168k$ ;

The proportion of waiting time of the queuing system  $E[W_{q4}]/E[W_4] = 83s_4/168k$ ;

In order to more clearly analyze the dynamic performance of the above examples, the discussion is now divided into two scenarios:

**5.1. Application Scene One.** The event stream's arrival rate  $s$  is changing, and the processing speed of the computer  $k$  is not changing. Assume that the constant  $k = 100$  and the dynamic performance of the system are as shown in Table 3.

The diagrams of the data in the Table 3 are shown in Figure 6. There are four subgraphs in the Figure 6. The diagram of the average amount of the waiting events in the queuing system of the four examples is Figure 6(a). The

FIGURE 5: Four examples of event stream processing program's stochastic Petri net model.

TABLE 2: The parameters of four examples.

No.	$\lambda_1$	$\lambda_2$	$\lambda_3$	$\lambda_4$	$\lambda_5$	$\lambda_6$	$\lambda_7$	$\lambda$
Example 1	2	4	10	20	20	None	None	33/23
Example 2	2	4	10	20	20	20	20	16/5
Example 3	2	4	10	20	20	20	None	12/5
Example 4	2	4	10	20	20	20	None	168/83

diagram of the average residence time of the events in the queuing system of the four examples is Figure 6(b). The diagram of the average waiting time of the events in the queuing system of the four examples is Figure 6(c). And the diagram of the proportion of the waiting time of events in the queuing system of the four examples is Figure 6(d).

As can be seen in Figure 6 when the computer processing rate is not changing, so there is an increase in the event stream transmission rate, the average amount of the waiting events, the average residence time of the events, the average waiting time of the events, and the proportion of the waiting time of events, which is in the queuing system of the four examples. In addition, it can be seen from the figure that it takes the maximum processing event time in example 1 and the minimal processing event time in example 2.

5.2. *Application Scene Two.* The event stream's arrival rate  $s$  is not changing, and the processing speed of the computer  $k$  is changing. Assume that the constant  $s = 200$  and the dynamic performance of the system are as shown in Table 4.

The diagrams of the data in the Table 4 are shown in Figure 7. There are four subgraphs in Figure 7. The diagram of the average amount of the waiting events in the queuing system of the four examples is Figure 7(a). The diagram of the average residence time of the events in the queuing system of the four examples is Figure 7(b). The diagram of the average waiting time of the events in the queuing system

of the four examples is Figure 7(c). And the diagram of the proportion of the waiting time of events in the queuing system of the four examples is Figure 7(d).

As can be seen in Figure 7, when the event stream transmission rate is not changing, there is an increase in the computer processing rate, the average amount of the waiting events, the average residence time of the events, and the average waiting time of the events, and the proportion of the waiting time of events is reducing, which is in the queuing system of the four examples. In addition, it can be seen from the figure that it takes the maximum processing event time in example 1 and the minimal processing event time in example 2.

## 6. The Simulation and Results

In order to verify the derivation results of the dynamic performance of the previous section about the four examples, we build the four simulations of the examples by the queuing theory simulation tools Java Modelling Tools v0.9.1. For each example, the simulation program will run 100,000 times, and we get the average value of the results. In the simulation experiments, the boundary conditions are  $k = 100$  and  $s > 0$ .

6.1. *Simulation Experiment One.* The experiment corresponds to the application scenario one. When the event stream arrival rate is changing, and the computer processing

speed is not changing (here set  $k=100$ ), the simulation results are shown in Tables 5–8.

We plotted the simulation results in scatterplot and compared them with the diagram of theoretical reasoning results in Figure 8.

As can be seen from the above figure, the simulation results have agreed well with the previous theoretical results. In addition, as can be seen from the scatterplot of the experimental results, along with the event stream's arrival rate getting closed to the threshold, the event processing time has

FIGURE 9: Continued.

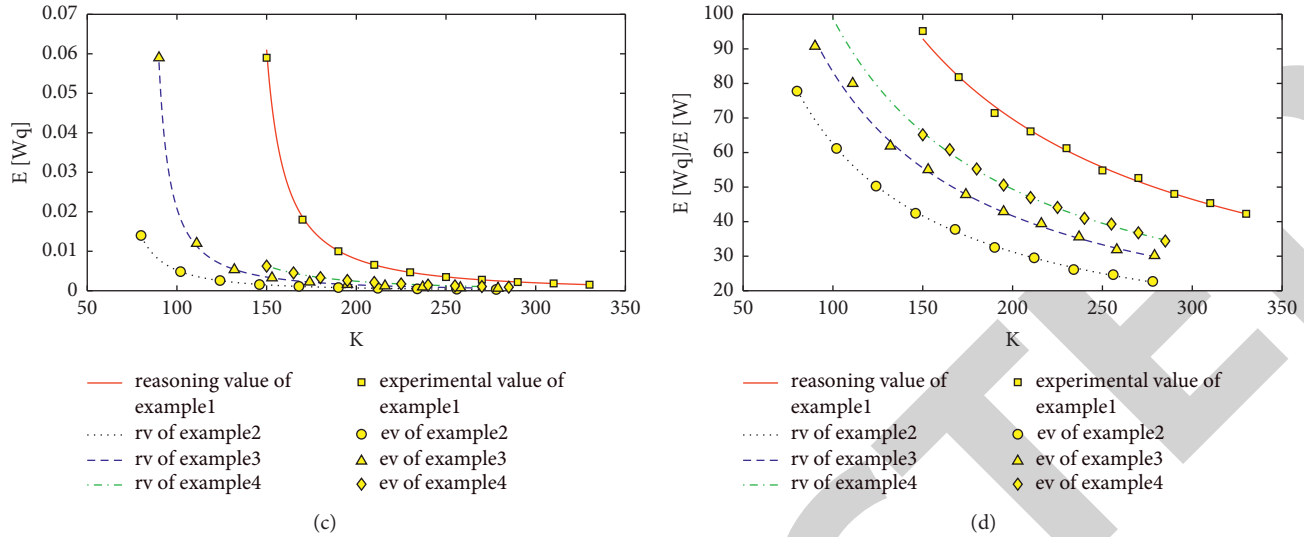

FIGURE 9: The comparison chart of dynamic performance of the examples in application scene two.

In addition, as can be seen from the scatterplot of the experimental results, along with the computing speed increasing, the event processing time has quickly reduced. But the ratio of the waiting time and the processing time has uniformly changed.

## 7. Conclusions

In this paper, we proposed the architecture and the core algorithm of STEP event stream processing system at first. Secondly, we analyzed the dynamic performance of the event stream processing system with stochastic Petri net and queuing theory. These dynamic performances include the queue length of the event stream, the processing time of each event instance, the waiting time of each event instance, and the proportion of the event waiting time. Finally, we gave four structured examples and gave their theoretical dynamic performance. We also built their simulation program to verify the correctness of the reasoning results, which shows the effectiveness of the relevant methods.

Federated learning has demonstrated strong capabilities in terms of addressing concerns related to data islands and privacy protection. However, in real application scenarios, participants in federated learning have difficulty matching. For example, two companies distributed in different regions do not know that the other party also needs federated learning in the case of information asymmetry. Therefore, it is difficult to build alliances. To enable suppliers and consumers to find one or more federated learning objects that are relatively satisfactory in a short time, this paper considers the idea of establishing a federated learning advertising platform, where data transactions need to consider privacy protection. A sponsored search auction mechanism design method is introduced to solve the problem of ranking the presentation order of participant advertisements. Due to the potential malicious bidding problem, which occurs when using the classic sponsored search auction mechanism under the federated learning scenario, this paper proposes a novel federated sponsored search auction mechanism based on the Myerson theorem, improving upon the ranking index used in the classic sponsored search auction mechanism. A large number of experimental results on a simulation data set show that our proposed method can fairly select and rank the data providers participating in the bidding. Compared with other benchmark mechanisms, the malicious bidding rate is significantly decreased. In the long run, the proposed mechanism can encourage more data providers to participate in the federated learning platform, thus continuously promoting the establishment of a federated learning ecosystem.

## 1. Introduction

In recent years, with the application of artificial intelligence in all walks of life [1], data privacy protection has become increasingly valued by individuals and organizations. On the one hand, people are unwilling to share data that contain personal information any more, due to the potential risk of privacy leakage. On the other hand, regulatory agencies in various regions and countries have also issued a series of policies and regulations to protect the security of private data. For example, the General Data Protection Regulation (GDPR) [2], officially implemented by the European Union in May 2018, puts forward the most stringent requirements for data privacy and security. This is currently the most comprehensive and widely used privacy protection law in the world. In China, the

“Implementation Regulations of the Consumer Protection Law of the People’s Republic of China”, promulgated in August 2016, applies to most companies that deal with consumer data, forcing companies to take responsibility for their obligations to protect consumer personal information.

Federated Learning (FL) has demonstrated strong capabilities in addressing data islands and privacy protection. Within the past few years, federated learning has developed rapidly, in terms of algorithms, frameworks, platforms, and applications, since Google first proposed the concept in 2016. To incentivize high-quality data providers to contribute their data to the federation, researchers have designed different incentive mechanisms. However, in the real environment, data are stored at the edge nodes of various institutions.

For a certain federated learning task, some uncertain information exists in the following aspects:

- (1) Which data providers have the willingness to contribute data? What is the sample size that they can provide? What are the features? How much will it cost?
- (2) Which data users have a demand for data? What types of data do the data users need? What is the quantity demand? How much will they pay for it?

To enable suppliers and consumers to find one or more FL objects that are relatively satisfactory in the shortest time, it is necessary to provide a Federated Learning advertising platform. The data provider, on the supply side, can publish a brief introduction about their data on the advertising platform. Data users, on the demand side, can also find their intended customers on the platform. After matching, the data provider and the data user will train a machine learning model together using federated learning. As shown in Figure 1, the federated learning advertising platform provides advertising slots and charges advertising fees. Data providers post advertisements on the platform and pay the fees. Data users then browse the advertisements, and send out invitations to intended customers for federated learning.

Generally speaking, some data providers want their ads to appear in the most attractive slot: the first place in the result page. However, the slots for displaying advertisements are limited. Therefore, for each search, the FL advertising platform faces the problem of matching advertisements with slots. In addition, the FL advertising platform also needs to determine the price that each data provider needs to pay. Data providers naturally prefer eye-catching slots. Therefore, to allocate a slot and determine the corresponding bid, the FL advertising platform needs a ranking system. There are an increasing number of data providers who want to post ads on the platform, but the number of available ad slots remains the same. To solve this problem, we can use an auction mechanism. These auctions are called Sponsored Search Auctions [3]. In a typical sponsored search auction, the data provider is invited to bid on the keywords, that is, for each click on the advertisement, the advertiser expresses the maximum amount they are willing to pay. This is usually referred to as cost-per-click (CPC). According to the bid submitted by the advertisers for a specific keyword, the search engine selects a set of advertisements and determines their presentation order. The actual price of the search engine also depends on the bid submitted by the customers. However, the sponsored search auction mechanism (GFP, GSP, VCG) mentioned above is not directly applicable to the scenario of federated learning as, if the bid is the only factor considered in the allocations of data providers, it may lead to malicious bidding and the emergence of monopoly issues. Many data providers which have noisy data in their data set will make higher bids to occupy the top slots on the advertising platform. Obviously, this is irresponsible to both the suppliers and consumers. In the long run, the advertising platform will suffer serious losses.

To resolve the above problems, we propose a new mechanism, called Federated Sponsored Search Auction Mechanism (FSSA), which is specific to the scenario of federated learning. Based on the bids, this paper also adds an

index to reflect the average contribution of data providers in their previous federated learning scenarios, and assign certain weights to these two indices. Thus, a new ranking index is formally defined, ranking scores, which is more in line with the scenario of federated learning. The core idea is to consider both the bid and contribution to rank the data providers, such that some data providers whose data quality is poor but have strong economic strength can gain higher ad slots in the advertising platform; in the same way, some participants who lack money but who have better data quality can also rank highly on the advertising platform. Most importantly, this mechanism curbs the monopoly problem, to a certain extent, and secures the platform's long-term prosperity. Extensive experimental results on a simulation data set show that the FSSA can filter and rank the data providers participating in the bidding. Compared with the classic sponsored search auction mechanism, the malicious bidding rate can be significantly decreased, effectively avoiding the problem of inconsistency between the bid and the actual contribution ability.

Our contributions can be summarized as follows:

- (i) In response to the difficulty of matching data providers and data users in federated learning, we first propose the idea of establishing an FL advertising platform. This platform can help both the suppliers and consumers to find a relatively satisfactory federated learning object in the shortest time. Furthermore, a new ranking mechanism is proposed to solve the problem of ranking advertisement slots.
- (ii) For the classic sponsored search auction mechanism, only bids are considered for the ranking, thus leading to malicious bids. We propose a new ranking index—ranking scores—which considers both the bids and historical average contributions of federated learning participants. To a certain extent, the problem of malicious bids can be avoided.
- (iii) We conduct extensive experiments on different simulation data sets to verify the effectiveness of our proposed method. The experimental results show that our method can effectively rank data providers. Compared with the classic sponsored search auction mechanism, the rate of malicious bidding is significantly decreased.

The remainder of this paper is arranged as follows: We summarize the related literature in Section 2. The method and results are detailed in Section 3. In Section 4, we conclude the paper and discuss some prospects for future work. To the best of our knowledge, this is the first time that the theory of sponsored search auctions has been applied to a federated learning scenario. The factors which we consider are not only the bids of data providers but also a comprehensive survey of their contributions. A novel mechanism is proposed to ensure that the data providers of the FL advertising platform are treated fairly, as well as to encourage more data providers to participate in the federated learning

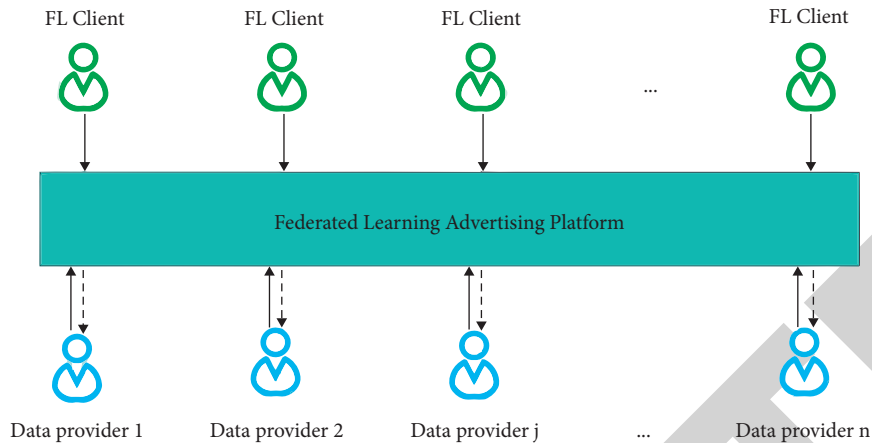

FIGURE 1: Schematic diagram of the Federated Learning Advertising Platform.

platform, in order to promote the establishment of the federated learning ecology.

## 2. Literature Review

We review the related literature from the following three aspects: Federated learning, mechanism design, and sponsored search auctions.

**2.1. Federated Learning.** Federated learning is a distributed machine learning framework [4, 5], which aims to solve the problems of user privacy and data islands which occur in the process of machine learning. Without data transmission, this method can train a machine learning model through using data from various devices. Since Google first proposed federated learning in 2016 [6], it has been favored by many technology companies, and many specialized research teams have been established. Not only have they achieved a lot of research results in frameworks and algorithms but also have actively explored and advanced the business landing applications of federated learning. Yang et al. [7] have expanded the concept and application of federated learning. According to the distribution features of data islands, federated learning can be divided into three types: horizontal federated learning, vertical federated learning, and federated transfer learning.

Recent research into federated learning has mainly focused on privacy protection and incentive mechanisms. To prevent the leakage of private data during gradient and parameter sharing in federated learning, researchers have applied traditional privacy protection techniques to federated learning, mainly divided into the following aspects: Secure multi-party computing [8–10], homomorphic encryption [11, 12], and differential privacy [13–15]. Some studies have begun to use the immutability of blockchain technology [16, 17] for privacy protection in federated learning. In terms of incentive mechanism design, Cong et al. [18] have established a research framework for the design and reasoning of federated learning incentive mechanisms, and proposed a precise definition of the FML incentive mechanism design problem. They divided this big problem into demand and supply-side problems for research and design. Zeng et al. [19] conducted a comprehensive research review on the design of

federated learning incentive mechanisms. They showed that the Federated Shapley value retains the desirable properties of the canonical Shapley value; it can be calculated without incurring additional communication costs, and it can also capture the influence of the participation order on data value. Different from the above works, Wei et al. [20] have proposed the concept of contribution index—a new metric based on Shapley value—which is suitable for evaluating the contribution of each data provider in the joint model of joint learning training. To solve the problem related to the large amount of calculations needed for the contribution index, they proposed two gradient-based methods. In addition, many scholars have introduced auction theory into the design process of the reward mechanism of federated learning. Kim et al. [21] have studied the incentive mechanism and privacy protection of federated learning from the perspective of mechanism design. Jiao et al. [22] have proposed an auction-based market model to encourage data owners to participate in joint learning, and designed two auction mechanisms for the federated learning platform to maximize the social welfare of the federated learning service market. In this paper, when defining the ranking scores of the FL advertising platform, we use a federated learning participant contribution index, which was defined and used by Wei et al. [20]. The contribution of each participant in federated learning can be measured fairly, to a certain extent, which, to some degree, represents the quality of the data held by the participant.

**2.2. Mechanism Design.** Hurwicz [23] first proposed the concept of mechanism design in the 1960s. He defined mechanism design as systems that can communicate with each other. It is the process of assigning results to participants, based on pre-made rules and information received in each round. In 1961, Vickrey published a paper on the second-price sealed-bid auction (i.e., a Vickrey Auction) [24], which was a milestone in the field of mechanism design. Three papers on incomplete information game theory, published by Harsanyi in the 1960s [25, 27], laid a solid foundation for mechanism design. Hurwicz introduced the concept of incentive compatibility into the field of mechanism design in 1972, thus opening up a period of rapid development in mechanism design [28]. Soon after, Clarke

[29] and Groves [30] extended the Vickrey mechanism to a more general quasilinear environment, and developed a more general incentive compatibility. In the 1970s, thanks to the joint efforts of a group of outstanding scholars, such as Gibbard [31] and Maskin [32], mechanism design made great progress in the revelation principle and implementation theory. As time progressed, mechanism design has been applied to many different disciplines, such as auctions, design of markets and trading institutions [33, 34], social choice theory [35], computer science [3], and so on.

**2.3. Sponsored Search Auctions.** The auction is the core content of mechanism design research, and sponsored search auctions have been a hotspot in the field of computer science over the past decade [36]. For traditional revenue optimization, Myerson [37] solved the single-term problem in the Bayesian–Nash equilibrium environment. Krysta et al. [38] have studied the multi-unit optimal auction. Since the first sponsored search auction was initiated in 1997, a series of auction mechanisms have been proposed, such as Overture’s Generalized First Price (GFP) auction [39] and Google’s Generalized Second Price (GSP), which has caused sponsored search auctions to become an important source of income for online platforms. Due to the inauthenticity of GSP, Garg et al. [40], based on the previous work, modeled the sponsored search auction on the Internet as a mechanism design problem, and designed a novel optimal auction mechanism (OPT), which can maximize the expected benefits of search engines while achieving Bayesian incentive compatibility and individual rationality. Lahaie et al. [41] have proposed another idea of compressing GSP parameters to increase income. Ostrovsky et al. [42] applied these works and studied the impact on Yahoo using auctions with the best reserve price. Zhang et al. [43] proposed an online reverse auction scheme for cloud computing service allocation based on Vickrey–Clarke–Groves (VCG) mechanism and online algorithm (OA), which can help cloud users and providers to build workflow applications in the cloud computing environment. This analytical approach has important implications for measuring the performance of the proposed algorithm without assuming the distribution of cloud provider bids.

As for the trade-off between different goals, some related studies can be found in the literature. Sundararajan et al. [44] have considered a convex combination of income and welfare to improve the forecast. Li et al. [45] constructed an integrated system with a mixed arrangement of advertising and organic items, and determined the best trade-off between instant income and user experience. In addition, for different settings and actual requirements, they extended the proposed optimal truthful allocation mechanism to meet these realistic conditions. With the help of real data, they verified the advantages of the proposed mechanism over the classic Myerson optimal advertising mechanism. Lian et al. [46] have optimized the advertising pruning of sponsored search based on reinforcement learning. This is the first time that reinforcement learning technology has been used to address this problem. More importantly, it has been

successfully implemented in Baidu’s sponsored search system, and online long-term A/B tests have shown a significant increment in revenue.

### 3. Method and Results

#### 3.1. Preliminary Knowledge and definition

##### 3.1.1. Typical Service Process of FL Advertising Platform

*Step 1.* As shown in Figure 2, the federated learning client enters keywords to search for a certain learning task on the advertising platform.

*Step 2.* After receiving the keywords, the federated learning advertising platform ranks the  $n$  bids  $b^{(j)}$  associated with the keywords of data providers using the ranking allocation rules, which are set in advance. After ranking,  $m$  data providers are selected, who are then ranked according to their ranking scores  $r^{(j)}$ .

*Step 3.* The customer browses the data set information provided by data providers on the advertising platform, selecting one or more data providers that they are satisfied with. Then, the client sends them an invitation for federated learning, and matches them according to their intentions to form a federated learning alliance.

*Step 4.* The paired data providers and customers conduct federated learning as an alliance, and the benefits are allocated according to the profit allocation rules set in advance (not the focus of this paper, and will not be repeated). After completing federated learning, the final contribution index  $c^{(j)}$  of each participant is the output.

*Step 5.* The FL advertising platform charges the data providers for advertising fees  $p_j$ , in accordance with the payment rules.

**3.1.2. Mechanism Design Environment Setting.** In this paper, we propose an ad-sponsored search platform for federated learning. Aiming to solve the matching problem of participants in the federated learning scenario, our goal is to find a set of optimal allocation rules and payment rules to maximize the benefits of the FL advertising platform and meet certain constraints on the design of sponsored search auction mechanisms. Our assumptions were as follows:

- (1) There are  $n$  data owners  $j$  who are interested in a certain federated learning task, where  $J = \{1, 2, \dots, n\}$  represents a set of data providers. In addition, the alliance has  $m$  advertising slots  $k$ , where data providers can place their own basic data information (e.g., sample size, characteristics, data quality, and data cost), where  $K = \{1, 2, \dots, m\}$  denotes the set of these advertising slots.
- (2)  $\alpha_{jk}$  is the probability that a data user clicks when the data provider  $j$  is in the  $k^{\text{th}}$  advertisement slot, where

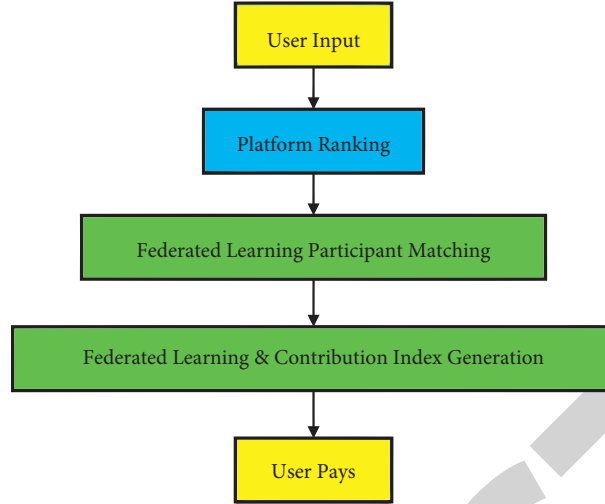

FIGURE 2: Schematic diagram of the advertising space of the FL advertising platform.

slot 1 represents the highest slot (the most prominent slot). We assume that  $\alpha_{jk}$  satisfies the following conditions:

$$1 \geq \alpha_{j1} \geq \alpha_{j2} \geq \dots \geq \alpha_{jm} \geq 0 \forall j \in J \forall k \in K. \quad (1)$$

- (3) For any federated learning task, each data provider  $j$  who is interested in this task makes a bid  $b^{(j)} \geq 0$ , where  $b^{(j)}$  depends on their economic behavior in the real market environment, with a certain degree of randomness.
- (4) Each data provider knows exactly how much value they can get when any data user clicks on their advertisement once. We assume that this value has nothing to do with the ad position, and this value only depends on whether the data user clicks on its ad. The data provider  $j$  does not know the value that other data providers get from one click of the data user. Formally, we assume that the value that data provider  $j$  gets from each click of a data user is  $v^{(j)}$ . The parameter  $v^{(j)}$  is called the valuation of data provider  $j$ , and the set of possible valuations of this provider is denoted as  $V^{(j)}$ .
- (5) Each data provider  $j$  has a federated learning contribution index  $c^{(j)}$ , which measures the quality of their own data. It is worth noting that the contribution degree represents the true contribution ability of the data provider; it has nothing to do with the bid and can truly reflect the value of the data owned by the data provider. This contribution can be calculated through a variety of mechanisms. In this paper,

we use the method proposed by Wei et al. [20] to calculate the contribution index based on the Shapley value.

- (6) Each data provider  $j$  is rational and intelligent, which means they pursue the maximum expected value of the utility function  $u^{(j)}$ , which we define later.

According to the above model assumptions, the sponsored search auction problem of the FL advertising platform can be accurately described as follows. Whenever the FL advertising platform receives the keywords of this federated learning task, it uses the bid profile  $b = (b^{(1)}, b^{(2)}, \dots, b^{(j)}, \dots, b^{(n)})$  and contribution index profile  $c = (c^{(1)}, c^{(2)}, \dots, c^{(j)}, \dots, c^{(n)})$  to determine: (1) Which data providers can win the slots to present their advertisements, as well as the order in which their advertisements are presented and (2) when data users click on their advertisements, the amount of money each data provider should pay to the platform. The former is the allocation rule, and the latter is the payment rule.

We define the problem environment of the sponsored search mechanism design in a typical FL advertising platform as follows:

- (i) Result set  $X$ : A result of the federated advertising sponsored search auction is a vector  $x = (y_{jk}, p_j)$ ,  $\forall j \in J; \forall k \in K$ , where  $y_{jk}$  is the probability that data provider  $j$  is assigned to slot  $k$ , and  $p_j$  is the cost-per-click paid by the data provider to the FL advertising platform. Therefore, the feasible result set can be expressed as:

$$X = \left\{ (y_{jk}, p_j) \mid y_{jk} \in \{0, 1\}; \sum_{j=1}^n y_{jk} \leq 1; \sum_{k=1}^m y_{jk} \leq 1; p_j \geq 0, \forall j \in J; \forall k \in K \right\}. \quad (2)$$

- (ii) Utility function  $u^{(j)}(\bullet)$ : Given a result  $x$ , the utility function of data provider  $j$  can be expressed as:

$$u^{(j)}(x(r), b^{(j)}) = \left( \sum_{k=1}^m y_{jk} \alpha_{jk} \right) (b^{(j)} - p_j). \quad (3)$$

- (iii) Social surplus function  $W$ : In this case, the utility of all data providers constitutes the social surplus function of the entire alliance. This is expressed as:

$$W = \sum_{j=1}^n u^{(j)}(x(r), b^{(j)}), \quad \forall j \in J. \quad (4)$$

For convenience, we summarize the defined symbols and their meanings in Table 1.

**3.2. Federated Learning Advertising Platform Sponsored Search Auction Mechanism Design.** We define the sponsored search mechanism design problem of a typical federated learning advertising platform as follows:

Let  $b = (b^{(1)}, b^{(2)}, \dots, b^{(j)}, \dots, b^{(n)})$  and  $c = (c^{(1)}, c^{(2)}, \dots, c^{(j)}, \dots, c^{(n)})$  be the bid profile and contribution index profile of data provider  $j$ , respectively. Let  $b^{(-j)}$  and  $c^{(-j)}$  denote the bid and contribution index profile of all other participants except for data provider  $j$ , respectively. As the bid profile is affected by multiple factors in actual production and the real world, it has a certain degree of randomness, which may lead to the problem of malicious bidding. For this reason, we propose a new ranking index,  $r = (r^{(1)}, r^{(2)}, \dots, r^{(n)})$ , which

TABLE 1: List of mathematical symbols and their definitions.

Symbol	Meaning
$j$	Index of the data provider
$k$	Index of the advertising slot
$\alpha_{jk}$	Probability that the data user clicks the $k^{\text{th}}$ ad slot
$b^{(j)}$	Bid from data provider $j$
$v^{(j)}$	Valuation from data provider $j$
$c^{(j)}$	FL contribution index of data provider $j$
$r^{(j)}$	Ranking score of data provider $j$
$x = (y_{jk}, p_j)$	Result set
$u^{(j)}(\bullet)$	Utility function of data provider $j$
$W$	Social surplus function

is composed of the bid profile  $b^{(j)}$  and the contribution index profile  $c^{(j)}$ , that is,

$$r^{(j)}(b^{(j)}) \stackrel{\text{def}}{=} (\beta \varphi^{(j)}(b^{(j)}) + (1 - \beta) c^{(j)}(\varphi^{(j)}(b^{(j)}))), \quad (5)$$

where  $c^{(j)}(\bullet)$  is contribution index function. In Ref. [20], Wei et al. proposed an effective federated learning contribution index calculation method based on the Shapley value. We also use a similar method to calculate the contribution index:

$$\begin{aligned} c^{(j)}(\varphi^{(j)}(b^{(j)})) \\ = \sum_{S \subseteq J \setminus \{j\}} \frac{|S|! (|J| - |S| - 1)!}{|J|!} \{v'(S \cup \{j\}) - v'(S)\}, \end{aligned} \quad (6)$$

where  $S$  is a subset of  $J$ ,

$$\begin{aligned} v'(S \cup \{j\}) &= \sum_{j' \in (S \cup \{j\})} \varphi^{(j')}(b^{(j')}) = \sum_{j' \in (S \cup \{j\})} \left( b^{(j')} - \frac{1 - F^{(j')}(b^{(j')})}{f^{(j')}(b^{(j')})} \right), \\ v'(S) &= \sum_{j' \in S} \varphi^{(j')}(b^{(j')}) = \sum_{j' \in S} \left( b^{(j')} - \frac{1 - F^{(j')}(b^{(j')})}{f^{(j')}(b^{(j')})} \right), \end{aligned} \quad (7)$$

where  $\varphi^{(j')}$  represents the virtual value of data provider  $j'$ ,

$$\varphi^{(j')}(b^{(j')}) = b^{(j')} - \frac{1 - F^{(j')}(b^{(j')})}{f^{(j')}(b^{(j')})}, \quad (8)$$

where  $F^{(j')}(b^{(j')})$  is the cumulative distribution of its bid, and the corresponding probability density function is  $f^{(j')}(b^{(j')})$ . These need to satisfy the following assumptions:

**Assumption 1** (Distribution of bid). For each data provider  $j$ , we assume that their bid  $b^{(j)}$  is independently—but not necessarily identically—drawn from a known cumulative distribution  $F^{(j)}(b^{(j)})$ , where the corresponding probability density function is  $f^{(j)}(b^{(j)})$ .

**Assumption 2** (Monotonicity of virtual value). For each data provider  $j$ , we assume that the cumulative distribution of its bid  $F^{(j)}(b^{(j)})$  satisfies the regular condition; thus, the virtual value  $\varphi^{(j)}(b^{(j)})$  is monotone nondecreasing.

Note that  $\beta \in [0, 1]$  is a variable parameter indicating the proportion of virtual value  $\varphi^{(j)}(\bullet)$  to the contribution index  $c^{(j)}(\bullet)$ . We provide its calculation method later.

After the FL advertising platform receives the participant's bids, the platform calculates the ranking score  $r$ , and then ranks the participants according to their ranking score. Therefore, a mechanism  $X = (x(r), p(r))$  consists of two rules, the allocation rule  $x(r)$  and the payment rule  $p(r)$ ; more specifically,  $x(r) = (x_1(r), x_2(r), \dots, x_n(r))$  and  $p(r) = (p_1(r), p_2(r), \dots, p_n(r))$ , where  $x_j(r) = \sum_{k=1}^m y_{jk} \alpha_{jk}$ ,  $\forall j \in J$ ;  $\forall k \in K$ ,  $y_{jk}$  is the probability that the data provider  $j$  is assigned to the  $k^{\text{th}}$  slot, and  $p_j$  is the cost-per-

click that the data provider pays to the FL advertising platform. Therefore, the feasible result set,  $X$ , can be expressed as:

$$X = \left\{ (y_{jk}, p_j) \mid \forall y_{jk} \in \{0, 1\}; \sum_{j=1}^n y_{jk} \leq 1; \sum_{k=1}^m y_{jk} \leq 1; p_j \geq 0, \forall j \in J; \forall k \in K \right\}. \quad (9)$$

It is worth noting that random results are also included in the above result set, which means that random mechanisms are also part of the mechanism space.

Given the result  $x$ , the utility function  $u^{(j)}(\bullet)$  of the data provider  $j$  can be expressed as:

$$u^{(j)}(x(r), b^{(j)}) = \left( \sum_{k=1}^m y_{jk} \alpha_{jk} \right) (b^{(j)} - p_j). \quad (10)$$

In the FL advertising platform system, to ensure that data providers always have the willingness to auction, we require that the utility of data provider  $j$  should not be less than zero, that is, we demand that each data provider satisfies individual rationality. We define this as follows:

*Definition 1* (Individual Rationality).

$$u^{(j)}(x(r), b^{(j)}) \geq 0, \quad \forall j \in J; \forall k \in K. \quad (11)$$

In addition, to avoid malicious bidding by data providers, we impose Bayesian Incentive Compatibility (BIC) constraints on the designed mechanism:

*Definition 2* (Bayesian Incentive Compatibility).

$$u^{(j)}(x(r), v^{(j)}) \geq u^{(j)}(x(r), b^{(j)}), \quad \forall j \in J. \quad (12)$$

If and only if a mechanism meets the conditions of IR and BIC, we call it a feasible mechanism. Myerson's theorem gives equivalent expressions for IR and BIC. Similarly, we can also design a mechanism with IR and BIC on the FL advertising platform, as shown below:

**Lemma 1** (Myerson theorem) [37]. *If and only if a mechanism satisfies IR and BIC, for any advertisement item from*

*data provider  $j$  and bids of other items  $b^{(-j)}$ , the allocation rule  $y_j(b^{(j)}, b^{(-j)})$ , is monotone nondecreasing on  $b^{(j)}$ , and the payment rule is as follows:*

$$p_j(b) = \begin{cases} b^{(j)} - \frac{\int_0^{b^{(j)}} y_j(x^{(j)}, b^{(-j)}) dx^{(j)}}{y_j(b)}, & y_j(b) \neq 0. \\ 0, & \text{else.} \end{cases} \quad (13)$$

In summary, we have the following mechanisms.

(1) Allocation rules

$$y_{jk}(b) = \begin{cases} 1, & \text{if } r^{(j)}(b^{(j)}) \text{ is } k^{\text{th}} \text{ highest ranking score, } k \in K, \\ 0, & \text{else.} \end{cases} \quad (14)$$

(2) Payment rules

$$p_j(b) = \begin{cases} b^{(j)} - \frac{\int_0^{b^{(j)}} y_j(x^{(j)}, b^{(-j)}) dx^{(j)}}{y_j(b)}, & y_j(b) \neq 0. \\ 0, & \text{else.} \end{cases} \quad (15)$$

Now, we give the calculation method for the coefficient  $\beta$ . Specifically, in such a mechanism, we require that the total social utility should be maximized, that is, the total social surplus  $W$  is maximized under certain constraints, making the malicious bidding rate  $\mu$  (defined later) lower than that in classic sponsored search auction mechanisms.

$$\max W. \quad (16)$$

$$\text{s.t.} \begin{cases} u^{(j)}(x(r), b^{(j)}) \geq 0; \\ u^{(j)}(x(r), v^{(j)}) \geq u^{(j)}(x(r), b^{(j)}); \\ \sum_{k=1}^m y_{jk} \leq 1; \\ \sum_{j=1}^n y_{jk} \leq 1; \\ 0 \leq y_{jk} \leq 1; \\ p_j \geq 0; \\ \forall j \in J; \\ \forall k \in K. \end{cases} \quad (17)$$

For the above constrained programming, we use the Lagrange multiplier method to solve the equation. The Lagrange function can be expressed as follows:

$$L = W + \left( \lambda \sum_{j=1}^n u^{(j)}(x(r), b^{(j)}) + \sum_{j=1}^n (u^{(j)}(x(r), v^{(j)}) - u^{(j)}(x(r), b^{(j)})) \right. \\ \left. + \sum_{j=1}^n \left( 1 - \sum_{k=1}^m y_{jk} \right) + \sum_{k=1}^m \left( 1 - \sum_{j=1}^n y_{jk} \right) + \sum_{j=1}^n \sum_{k=1}^m (1 - y_{jk}) + \sum_{j=1}^n \sum_{k=1}^m y_{jk} + \sum_{j=1}^n p_j \right), \quad (18)$$

where  $\lambda$  is the Lagrange multiplier,  $\lambda = (\lambda_1, \lambda_2, \dots, \lambda_{4n+m+2mn})$ .

For ease of the descriptions, we use  $\Omega$  to represent all the constraints. Thus, the Lagrange function can be expressed as follows:

$$L = W + \lambda \cdot \Omega, \quad (19)$$

where  $\Omega \geq 0$ .

As  $W$  is a linear function of  $y$ , the constraints are also linear in  $y$ , and the result set is a convex set, and the constrained program in (16) and (17) consists of convex optimization. We can obtain the optimal value of the coefficient  $\beta$  in the equation of ranking score by Lemma 2.

**Lemma 2** (Optimal estimation of coefficient) [45]. *ie constrained program with constraints given in (17) is equivalent to the unconstrained programming with coefficient  $\beta^*$  and, when the optimal Lagrange multiplier is  $\lambda^*$ , the coefficient can be expressed as  $\beta^* = 1/(\|\lambda^*\| + 1)$ . We obtain  $\|\lambda^*\|$  by Algorithm 1. Then, we can obtain  $\beta^*$ .*

Algorithm 1 shows the detailed process for calculating the ranking score  $r^{(j)}$  of each data provider  $j$ . Specifically, lines 1–12 are the calculation of coefficient  $\beta$ , while lines 13 and 14 are the calculation of the ranking score  $r^{(j)}$ .

**Theorem 1** (FSSA). *When a federated learning advertising platform satisfies Assumptions 1 and 2 under the conditions of Definitions 1 and 2, and takes Equation (5) as the ranking score, an optimal mechanism can be obtained.*

*Proof.* When Assumptions 1 and 2 are satisfied, we can construct a ranking score based on contribution index and virtual value with the help of Equations (6) and equation (8), that is, Equation (5). As it is under the conditions of Definitions 1 and 2, Lemma 1 holds, and the calculation expressions of allocation rules and payment rules can be obtained. As the linear program constructed under the above conditions satisfies convexity, Lemma 2 holds, and the optimal estimate of the coefficients in the ranking score can be obtained. Q.E.D.

**3.3. Simulation Experiment Design.** To evaluate the performance of our proposed federated learning advertising platform sponsored search auction mechanism (FSSA)

algorithm, we carried out many simulation experiments using *Python*. To verify whether the malicious bidding rate of FSSA had changed, we compared it with four classic mechanisms based on bid  $b_i$  ranking, under the same simulation data set and experimental environment settings. The experiment was run on a Windows 10 desktop with 32 GB main memory, an Intel Xeon E5-2690 v3 @2.60 GHz(X2) CPU with 12 cores and 24 threads, and an NVIDIA GeForce GTX1060 6 GB graphics card.

**3.3.1. Data Set.** In a real market environment, a data provider's bid is related to many factors, and the data provider may not report its bid  $b^{(j)}$  in a truthful way. Therefore, in this experiment, we assumed that each bid  $b^{(j)}$  obeys a uniform distribution, that is,  $b^{(j)} \sim U(0, 1)$ . Moreover, as the number of data providers and the number of advertising slots cannot be determined, we divided it into two situations to conduct separate experiments: (1) When  $n > m$ , assume that the number of data providers  $n$  is 8, and the number of ad slots  $m$  is 5, 6, or 7. The method of setting the click-through rate obeys the following principle: the click-through rate increases at equal intervals from 0.1 to 0.9, according to the number of ad slots (e.g., when  $m = 5$ , the click probability  $\alpha_{jk}$  of each advertising spot, from bottom to top, is from 0.1 to 0.9, having the same interval of 0.2 increases successively) and (2) when  $n \leq m$ , assume that the number of data providers  $n$  is 5, and the number of ad slots is  $m$  and the click probability  $\alpha_{jk}$  are the same as when  $n > m$ .

Algorithm 2 shows the detailed process for generating the training data set. Specifically, line 1 is the process of generating all possible ranking results set. As for each sample in the training data set, lines 3–17 show its generation process. Lines 18–20 show the process of generating a label for each training data sample, initializing the set  $\{r^{(j)}\}$  to set  $\{r_{\text{order}}^{(j)}\}$  first, then ranking the elements in it in the descending order, using  $r_{\text{order}} = (r_{\text{order}}^{(1)}, r_{\text{order}}^{(2)}, \dots, r_{\text{order}}^{(j)}, \dots, r_{\text{order}}^{(n)}) \in \{\text{list}_l | l = 1, 2, \dots, (\min(m, n))!\}$  to represent the ranking result. Finally,  $r_{\text{order}}$  is matched in the set  $\{\text{list}_l\}$ , and the index of the matched  $\text{list}_l$  is taken as the label of the training data sample.

**3.3.2. Comparison Algorithm.** We compared the malicious bidding rate of the proposed method with those of three classic sponsored search auction algorithms, which have been summarized by Narahari et al. in Ref. [3]. Due to space

Input : bid  $b^{(j)}$  of each data provider  $j$ ; cumulative distribution  $F^{(j)}(b^{(j)})$ ; probability density function  $f^{(j)}(b^{(j)})$ ; any positive number  $\delta$ ; initial upper bound  $\|\lambda\|_{up}$  which makes  $\Omega \geq 0$ ; lower bound  $\|\lambda\|_{low}$ .

Output :  $b^{(j)}$ .

- (1) Initialize  $\|\lambda\|$  to 0 and  $\beta$  to 1 respectively.
- (2) if  $\Omega \geq 0$  then
- (3)  $\|\lambda^*\| \leftarrow 0$ .
- (4) else
- (5)  $\|\lambda\|_{low} \leftarrow 0$ .
- (6) while  $\|\lambda\|_{up} - \|\lambda\|_{low} > \delta$  do:
- (7)  $\|\lambda\|_{temp} \leftarrow \text{mean}(\|\lambda\|_{up}, \|\lambda\|_{low})$ .
- (8) Assign  $\|\lambda\|_{temp}$  to  $\|\lambda\|_{up}$  when it makes  $\Omega \geq 0$ , otherwise assign it to  $\|\lambda\|_{low}$ .
- (9) end while:
- (10)  $\|\lambda^*\| \leftarrow \|\lambda\|_{temp}$ .
- (11) end if
- (12)  $\beta^* \leftarrow 1/(\|\lambda^*\| + 1)$ .
- (13) Use Equations (1 – 3) to obtain  $r^{(j)}$ .
- (14) return  $r^{(j)}$

ALGORITHM 1: Calculation of the ranking score  $r^{(j)}$ .

Input : ranking score  $r^{(j)}$  of each data provider  $j$ , bid  $b^{(j)}$  of each data provider  $j$ ,  $\forall j \in J$ , training data set size  $N$ .

Output : training data set  $\{x_i\}$  where  $x_i = (y_{jk}, p_j)$ ,  $\forall j \in J, \forall k \in K$ ; label label <sub>$i$</sub>  of each training data sample,  $i = 1, 2, \dots, N$ .

- (1) Generate all possible ranking results set  $\{\text{list}_l | l = 1, 2, \dots, (\min(m, n)!) \}$  of set  $\{r^{(j)} | \forall j \in J\}$  by full permutation operation.
- (2) for each  $i \in \text{range}(N)$  do
- (3) for each  $j \in \text{range}(n)$  do
- (4) for each  $k \in \text{range}(m)$  do
- (5) if  $r^{(j)}(b^{(j)})$  is the  $k^{\text{th}}$  highest ranking score then
- (6)  $y_{jk} \leftarrow 1$ .
- (7) else
- (8)  $y_{jk} \leftarrow 0$ .
- (9) end if
- (10) end for
- (11) if  $y_j = 1$  then
- (12)  $p_j \leftarrow b^{(j)} - \int_0^{b^{(j)}} y_j(x^{(j)}, b^{(-j)}) dx^{(j)} / y_j(b)$ .
- (13) else
- (14)  $p_j \leftarrow 0$ .
- (15) endif
- (16) end for
- (17)  $x_i \leftarrow (y_{jk}, p_j)_i$ .
- (18) Initialize  $\{r^{(j)}\}$  to  $\{r_{\text{order}}^{(j)}\}$ .
- (19) Rank the elements in  $\{r_{\text{order}}^{(j)}\}$  in descending order.
- (20) Match  $\{r_{\text{order}}^{(j)}\}$  with each element in set  $\{\text{list}_l\}$  to obtain label <sub>$i$</sub> .
- (21) return  $x_i, \text{label}_i$ .
- (22) end for

ALGORITHM 2: Training data set generation.

limitations, we do not review these algorithms in detail; instead, brief summaries are provided in the following.

**GFP.** This algorithm is the generalized first price auction mechanism. Under this mechanism, the  $m$  advertising positions are allocated to advertisers in the descending order, according to their bids.

**GSP.** This algorithm is the generalized second-price auction mechanism, which is adapted from the generalized first price auction mechanism. Due to the instability of the generalized first price, the entire system has low

allocation efficiency; thus, GSP was proposed. This mechanism is completely consistent with the GFP allocation rules, but changes its payment rules. The participant who gets slot 1 pays the bid of the participant who wins slot 2, and so on.

**VCG.** This algorithm is the abbreviation of the Vickery–Clark–Groves mechanism, which is the most widely used mechanism in the field of mechanism design. In a quasilinear environment, the VCG mechanism not only has allocation efficiency but also incentive compatibility.

**3.3.3. Evaluation Metrics.** To evaluate whether our proposed algorithm can effectively reduce the probability of malicious bidding problems or not, we defined a new evaluation index, the malicious bidding rate  $\mu$ , which represents the cumulative number of malicious bidding events happening in  $N$  bidding scenarios.

$$\mu \stackrel{\text{def}}{=} \frac{1}{N} \sum_{i=1}^N M, \quad (20)$$

where  $M$  represents a malicious bidding event. We define the distance between the result of the bid  $b$  or the ranking score  $r$  and the benchmark ranking  $c$  as the similarity  $d$ . If the similarity  $d$  is not 0, it indicates that a malicious bidding event  $M$  has happened, that is,

$$d(r_{(.)}, r_{(c)}) \stackrel{\text{def}}{=} \begin{cases} \frac{1}{\text{score}(r_{(.)}, r_{(c)})}, & \text{if } \text{score}(r_{(.)}, r_{(c)}) \neq 0, \\ +\infty, & \text{else,} \end{cases} \quad (21)$$

where  $r_{(.)}$  represents the result of ranking by bid  $b$  or ranking score  $r$ ;  $r_{(c)}$  represents the result of ranking by the contribution index  $c$ , which we call benchmark ranking; and  $\text{score}(r_{(.)}, r_{(c)})$  represents the matching score between the ranking results. That is, for two sequences with the same length of  $m$ , starting from the first slot, if the  $k^{\text{th}}$  slot of  $r_{(.)}$  and  $r_{(c)}$  is the same, then the match of this slot is successful, and 1 point is counted; otherwise, 0 points are counted. Formally, we define the rank score as  $\text{score}(r_{(.)}, r_{(c)}) \stackrel{\text{def}}{=} \sum_{k=1}^m \text{Match}(r_{(.)}, r_{(c)})$ , where  $\text{Match}(r_{(.)}, r_{(c)})$  represents the matching situation, which is:

$$\text{Match}(r_{(.)}, r_{(c)}) \stackrel{\text{def}}{=} \begin{cases} 1, & \text{if } r_{(.)}^{(k)} = r_{(c)}^{(k)}, \quad \forall k \in K. \\ 0, & \text{else,} \end{cases} \quad (22)$$

Algorithm 3 shows the calculation process for the malicious bidding rate. In lines 1–7, we use Equation (22) to calculate the matching score and, in line 8, we use Equation (21) to calculate the similarity. Finally, we use Equation (20) to calculate the evaluation index malicious bidding rate  $\mu$  in lines 9 and 10.

**3.3.4. Experimental Setup.** In this paper, a convolutional neural network (CNN) model was used for training. Algorithm 4 shows the training process of the convolutional neural network (CNN) model, using the training data set and label set generated in Algorithm 2. Lines 1–3 show the initialization of the model parameters and the setting of the learning rate, while Lines 4–10 show the process of obtaining the optimal parameters of the neural network model through the backward propagation algorithm. Specifically, the model consists of two convolution layers and three fully connected

layers. The output of each hidden layer is activated by the ReLU activation function, the dropout is set to 0.5. The backward propagation algorithm is used to solve the parameters, the optimizer is set to Adam, the loss function is set to sparse categorical crossentropy, and the learning rate is set to 0.001. The training batch size is set to 124, and the number of iterations is 200 rounds.

**3.3.5. Analysis of Results.** As shown in Figure 3, the experimental results under different simulation experimental data sets confirmed that the performance of the FSSA mechanism proposed in this paper was better than that of the other benchmark mechanisms. This further proves the effectiveness and robustness of the FSSA mechanism for the ranking of the advertising slots in federated learning advertising platforms.

Specifically, when  $n \leq m$  (i.e.,  $n = 5$ ), from the horizontal perspective,  $m$  continues to increase. The accuracy of the four mechanisms showed little change. In this case, the number of participants was always less than the number of advertisements, so the participants were always fully allocated, and the complexity of the model changes mainly depend on  $\min(n, m)$ . Therefore, even if the number of advertising slots continues to increase, the accuracy of the model does not change much, and the model is relatively stable.

When  $n > m$  (i.e.,  $n = 8$ ), from a horizontal perspective, with the continuous increase of  $m$ , the accuracy of the four mechanisms gradually decreased, and the speed of convergence also decreased. In this case, the number of participants was always greater than the number of advertisements, so there was the situation where there were remaining participants. The complexity of the model mainly depends on  $\min(n, m)$ . Therefore, with the continuous increase of  $m$ , the allocation rules that need to be considered are more complicated and the model complexity is high. In the end, the model converges slowly and the accuracy of the convergence is also reduced, in accordance with the actual situation.

For each case of  $m$ , with  $m$  is fixed, vertical comparison between  $n = 5$  and  $n = 8$  indicated that, when  $n = 5$ , the number of participants is less than the number of advertising slots, and the advertising slots cannot be fully allocated. Compared with  $n = 8$ , the latter had a richer allocation and a higher allocation efficiency, thus facilitating model convergence.

In Table 2, our testing accuracy of the model in different situations is shown. It can be seen that, no matter the situation, the testing accuracy of our proposed FSSA mechanism was higher than that of the benchmark.

As can be seen from Figure 4, when  $n = 5$ , that is, participants were always less than the number of advertisements. With the increase of  $m$ , the accuracy of the four mechanisms showed little change, and this is because the remaining advertising space is always sufficient. For each participant, they are not sensitive to the dynamic changes of

```

Input : label set  $\{\text{label}_{r_i}\}$  based on  $r$ ; label set  $\{\text{label}_{c_i}\}$  based on  $c$ ,  $i = 1, 2, \dots, N$ ; label set  $\text{label}_i$ ,  $i = 1, 2, \dots, N$ ; all possible ranking results set  $\text{label}_i$ ,  $i = 1, 2, \dots, (\min(m, n))!$ 
Output : malicious bidding rate  $\mu$ .
(1) for each  $i \in \text{range}(N)$  do
(2)   for each  $j \in \text{range}(n)$  do
(3)     if  $\text{list}_{\text{label}_{r_i}}^{(j)} = \text{list}_{\text{label}_{c_i}}^{(j)}$  then

(7)   Backward Propagation (Loss).
(8)    $\delta = d\text{Loss}/dPAR$ 
(9)    $PAR \leftarrow PAR - \eta * \delta$ .
(10) end for
(11) return  $\omega, \tau$ .

```

ALGORITHM 4: CNN Training.

allocation rules or payment rules in the process of competition. Therefore, the learning degree of the model to the data features contained in the sample data tensor tends to be saturated. And, in this scenario, the testing accuracy of our proposed FSSA mechanism was higher than others. This means that FSSA can still learn the data distribution law relatively deeply when the data features are not obvious, so as to estimate the model parameters more accurately.

As can be seen from Figure 5, when  $n = 8$ , that is, participants were always more than the number of advertisements. With the continuous increase of  $m$ , the testing accuracy of various mechanisms varies. And, in this scenario, there were remaining participants, and the complexity of the model mainly depends on  $\min(n, m)$ . Due to the fierce competition, the data tensor contains rich features, but it is also easy to cause the phenomenon of over fitting of model parameters, which makes the generalization ability of the model insufficient. In this case, GFP mechanism and GSP mechanism are difficult to deal with such problems, while VCG mechanism and FSSA mechanism alleviate the over fitting phenomenon on the premise of ensuring relatively high accuracy, and FSSA mechanism can still maintain relatively high testing accuracy. Thus, the feasibility and stability of the model are trustworthy.

We summarize the malicious bidding rates in different situations in Table 3. It can be seen, from the table, that the malicious bidding rate under our proposed FSSA mechanism was as low as 0.01016. Compared with the classic sponsored search auction mechanisms, the malicious bidding rate was greatly decreased under the same conditions, effectively reducing the probability of malicious bidding in the auction process for advertising slots on the Federated Learning advertising platform.

In addition, it can be seen, from Figure 6, that when  $n = 5$ ,  $m$  increased, as all participants were allocated, and they had no motivation to lie. Therefore, the trend of the malicious bidding rate for the four mechanisms was not obvious. Within the same group of  $m$  and  $n$ , the malicious bidding rate under the conditions of GFP mechanism and GSP mechanism is relatively high. Therefore, it can be seen that the response ability of these two mechanisms to the phenomenon of malicious bidding is insufficient. In contrast, VCG mechanism reduces the malicious bidding rate to about 0.077, which is relatively obvious. Even so, the malicious bidding rate of our proposed FSSA mechanism was still far lower than other benchmark mechanisms, and it is always lower than 0.04. As shown in the figure, this mechanism has a significant effect on reducing the malicious bidding rate.

(8,7)	0.22284	0.21506	0.16589	0.01857

FIGURE 6: Malicious bidding rate under different mechanisms at  $n = 5$ .

However, Figure 7 shows that, at  $n = 8$ , due to the surplus of participants, participants had greater motivation to lie. Therefore, when  $m$  increase linearly, the rate of malicious bidding also gradually increased; however, that of the proposed mechanism was still lower than those of the other benchmark mechanisms, in line with our expectations. Moreover, when we compare the experimental results shown in Figure 7 with those shown in Figure 6, we find that when  $m$  takes the same value, that is, when the same number of

advertisements are supplied, the competition among participants is fierce, that is, as shown in Figure 7, the response ability of GFP, GSP, and VCG to malicious bidding is weakened, and only FSSA has not received any negative impact. Compared with the experimental results shown in Figure 6, its response ability to malicious bidding rate is more significant, and the malicious bidding rate is further reduced.

In summary, compared with other benchmark sponsored search auction mechanisms, our proposed FSSA

FIGURE 7: Malicious bidding rate under different mechanisms at  $n = 8$ .

mechanism can effectively curb the generation of malicious bidding in the process of sponsored search auctions for federated learning advertising slots without imposing incentive-compatible constraints, which still allows for the social resources to be fully allocated.

#### 4. Conclusions

In this paper, we proposed a novel Federated Sponsored Search Auction Mechanism (FSSA) for the scenario of federated learning. Based on the original bidding, the average contribution index of the data providers in their previous federated learning scenarios is considered, and a certain weight is assigned to them. A new ranking index is formally defined, that we call ranking scores, which make the proposed mechanism more in line with the scenario of federated learning. We conducted a large number of experiments on different simulation data sets to verify the effectiveness of our proposed method. The experimental results demonstrated that our method can rank data providers fairly. Compared with classic sponsored search auction mechanisms, the malicious bidding rate was reduced significantly through the use of the proposed mechanism. The social resources were effectively allocated, and the establishment of the federated learning ecology was promoted.

However, when studying slot allocation in an FL advertising platform, we only considered the situation where there are a small amount of data providers and advertising slots. When the number of participants continues to increase, the stability of the model will decrease and the generalization ability of the model needs to be improved. In addition, due to the experimental cost and the requirements of data privacy protection regulations, we did not obtain a real experimental data set and only conducted our experiments on a simulated experimental data set. Our future work will focus on optimizing the parameters in order to improve the generalization ability of the used neural network models as well as to obtain real experimental data.

#### Data Availability

The data used to support the results of this study are currently in the privacy protection stage and can be obtained from the corresponding author upon request 6 months after the article is published.

MICE tourism has received the attention and support from relevant departments and tourism industry with the growth rate of recent years. In this paper, the dynamics mechanism of urban exhibition tourism development is studied by using high-performance computing, and the dynamics mechanism model of exhibition tourism is constructed. To improve the performance, the solution constructed in the adaptive joint algorithm is used as the initial solution, and then the initial solution is improved using the method proposed by the new neighborhood strategy. It promotes the development of MICE tourism and urban MICE tourism by combining research on theoretical aspects related to tourism development, such as the relationship between tourism development and exhibition, and the development dynamics and stages of MICE tourism. The research results show that, in the assessment of the development mechanism of urban MICE tourism, tourism resources, economic, and policy factors have a relatively large weight, among which the weight coefficient of tourism resources factor is 0.2411. It can be seen that the development power of MICE tourism should start from tourism resources, so that the development power mechanism of urban MICE tourism can be optimized and improved, which not only provides new methods and new ideas for the transformation and upgrading of tourism industry but also promotes tourism enterprises and related departments to creatively develop tourism resources and design competitive tourism products, so as to improve the supply quality of MICE tourism, and then continuously promote the process of supply-side reform of MICE tourism.

## 1. Introduction

Scheduling and scheduling tools for high-performance computing (HPC) machines have a key role in mapping jobs to available resources, trying to maximize performance and quality of service (QoS). Bridi et al. demonstrated the first search-based HPC machine job allocation and scheduling method, working in a production environment. The scheduler is based on constraint programming, which is an effective programming technique for optimization problems. Tests on various operating conditions show that, in midlevel HPC machines equipped with the most advanced business rules-based scheduler, waiting and QoS have been significantly improved. In addition, Bridi et al. analyzed the conditions under which their method was superior to commercial methods to create a combination of scheduling algorithms that ensure robustness, flexibility, and scalability. Although their method has certain reference value for the

study of this article, it is of little value [1]. Computational models can easily promote the mechanical understanding of multiscale biological processes, such as cell proliferation in constantly changing biological tissues. Although there are tools for constructing and simulating multiscale models, the statistical inference of unknown model parameters is still an open question. Jagiella et al. demonstrated and benchmarked the Parallel Approximate Bayesian Computing Sequential Monte Carlo (pABC SMC) algorithm, which is tailored for high-performance computing clusters. Their research proved the principle of robust data-driven modeling of multiscale biological systems, and the feasibility of multiscale model parameterization through statistical inference. The algorithm is too complicated, and errors may occur in the calculation [2]. Wang et al. discussed the design trade-offs of extremely scalable system software. They proposed a general system software classification method by deconstructing general HPC system software into its basic

components. They provided a system method for building scalable system software by decomposing it into basic components, allowing system software to be classified according to the characteristics of these components for design evaluation through simulation or actual implementation. The results show that it helps to lay the foundation for the development of next-generation HPC system software for extreme scale. But this research is still in its infancy, and it is too basic [3]. The high-performance computing (HPC) community has spent decades developing tools and teaching practitioners to use the power of parallel and distributed computing. In order to create a scalable and flexible educational experience for practitioners at all stages of their careers, Mullen turned to Massive Open Online Courses (MOOC). He introduced in detail the design of a unique self-paced online course, and the course materials are presented through the lens of common HPC use cases and parallelization strategies. Using a personalized path, he teaches researchers how to identify the consistency between scientific applications and traditional HPC use cases so that they can focus on learning parallelization strategies that are critical to their workplace success. However, the high-performance computing method he proposed is not specific enough to be discussed in depth [4]. Fu's et al. research examines the potential dimensions of place attachment in the exhibition environment and its impact on participant satisfaction. The study took the China (Shenzhen) International Cultural Industry Expo as a case and proposed and tested a series of multiple intermediary models, divided into two groups: first-time participants and repeat participants. The exhibition attachment determines a function-emotion-identity sequence, examining direct and mediating effects and multiple group comparisons. Although most hypotheses have been confirmed, emotional attachment plays a negative role in predicting exhibition satisfaction, and visit frequency shows significant differences in the impact of exhibition dependence on satisfaction. The research provides specific theoretical and management enlightenment for the exhibition attachment and exhibition satisfaction of the participants. However, the model they put forward is too dependent on the subjective opinions of users and cannot objectively obtain the satisfaction of participants [5]. Lai and Wong developed a ternary reciprocal causality model to study how the knowledge created by customers affects the quality of the relationship and guarantees the perceptual performance of the report. Partial least squares analysis was performed on the data collected by 395 exhibitors in Macau. The results show that the participation of exhibitors in the preparation work has a positive impact on the three factors of relationship quality (satisfaction, trust, and commitment), and these three factors have a positive impact on the perceived performance of the report. Compared with exhibitors at public exhibitions, trust has a greater impact on exhibitors' commitments at trade shows. Research shows the integration of relationship quality theory, customer engagement theory, and social knowledge theory. Only for the three factors of the quality of exhibition participation relations, further research can be done. Yi's research draws on the theory of place attachment and puts forward an

innovative concept of exhibition attachment. Based on an in-depth literature review, a conceptual model of exhibition attachment was constructed, including push/pull motivation, attachment, and loyalty. To test the model, empirical data was collected from the participants of the trade show. The results show that there is a certain degree of correlation between the participants' push motivation and pulling motivation. Pulling motivation has a significant impact on exhibition dependence, which in turn has a positive and strong impact on the identity of the exhibition. The push-pull motives he studied have little correlation [6]. Harris and Dieringer conducted an economic analysis of a proposed zoning change that would allow the City of Treasure Island, Florida, to attract more visitors. The proposed zoning change will result in hotel renovations and new hotel construction in Treasure Island, Florida. Harris uses tax analysis to understand how this change will increase taxable property values as well as increase tourism development tax revenues [7]. Giampiccoli et al. explored the intersection between sustainable tourism and community-based tourism (CBT) and revealed a serious mismatch in the concept of sustainability and that addressing its negative environmental impacts is a fundamental requirement for tourism. A. Giampiccoli argues that sustainability in tourism should be an intrinsic and universal principle that governments should implement for all forms of tourism. In fact, traditional tourism causes most of the environmental damage and because of this, it should upgrade its role to become a solid promoter of sustainable measures that promote environmentally friendly and sustainability-friendly practices [8]. Wang et al. proposed a method to supplement fixed lockers with mobile parcel lockers to meet last-mile delivery needs. With the objective of minimizing operational costs, the location and route optimization problems of mobile delivery lockers are integrated into a nonlinear integer programming model. Embedded GA has been developed to simultaneously and optimally determine the location of delivery points, the number of mobile parcel lockers required at each delivery point, and the schedule and route of mobile parcel lockers [9]. Li et al. proposed a novel combined parametric modeling and design optimization technique for microwave components using neural networks. The proposed technique provides an iterative mechanism between artificial neural network model training and design optimization updates. This iterative mechanism is fully automated and does not require human intervention. In addition, the proposed technique overcomes the limitation of common artificial neural network optimization strategies, where the fixed training area of the artificial neural network model limits the degrees of freedom for design optimization. The proposed technique automatically expands the ANN training region until an optimized solution satisfies the user design specification [10]. In order to improve the thermal efficiency of blast furnace to achieve the goal of energy saving and consumption reduction, Zha Ng and Li optimized the blast furnace combustion control process by collecting a large amount of field data and introducing isolated point removal strategy for preprocessing with semisupervised clustering algorithm. The method has been experimentally

validated and shows significant energy savings compared with the traditional data preprocessing strategy [11]. Wang et al. proposed a multiobjective evolutionary algorithm based on a decomposition-based differential evolutionary strategy to solve the multiobjective model. A series of nondominated solutions are obtained, which represent the optimal spare parts supply solutions. In order to measure the performance of these solutions comprehensively, suitable quantitative metrics are selected and the efficiency of the obtained optimal solutions is evaluated using a cross-efficiency data envelopment analysis (DEA) model based on secondary objectives [12]. Ramazan proposed an adaptive particle filter (APF). In the APF, the adaptive fuzzy square root untraced Kalman filter (AFSRUKF) is used to generate the proposed distribution. In APF, the resampling process is done based on particle swarm optimization (PSO) in order to increase the diversity of particles. With this resampling strategy, particles with small weights are modified to particles with large weights without duplicating and eliminating particles [13].

The innovation of this paper is to use high-performance computing technology to study the dynamic mechanism of urban exhibition tourism development and establish the dynamic mechanism model of urban exhibition tourism based on the theory of tourism dynamic mechanism and tourism stakeholder theory. At the same time, it combines theoretical research and actual cases of city exhibition tourism to analyze and propose implementation plans. According to the evaluation system and the dynamic mechanism of exhibition tourism development, the dynamic characteristics of various types of power are sorted out, the development path is planned, and development suggestions are put forward. According to the weight difference of each factor of the index, the corresponding countermeasures are proposed to provide preliminary theoretical reference for tourism development researchers. From the load balancing scheduling mechanism, the overall load balancing algorithm can be divided into three categories: static load balancing algorithm, dynamic load balancing algorithm, and adaptive load balancing algorithm.

Convention and exhibition tourism is an important direction of world tourism development, an important part of urban tourism, and a model for the development of urban related industries. Convention and exhibition tourism has now become an important channel for economic and trade exchanges between countries. The convention and exhibition industry, including convention and exhibition industry, exhibition industry, and incentive tourism industry, is a huge industry in the world. Related industries with about 1% of the world's total GDP benefit from the report, and the exhibition industry contributes 8% to the global economy. Therefore, the tourism departments of various countries attach great importance to the development of exhibition tourism.

## 2. Optimization of Urban Exhibition Tourism Development

The characteristics of exhibition tourism are that exhibitors have strong spending power, the tourism industry benefits

more, tourists stay for a long time, there are more travel opportunities, and there are more potential participants, which can provide a broad platform for the development of the tourism industry.

The developmental dynamic mechanism refers to the organic collection with specific functions formed by the interaction of elements. The internal mode of interaction between elements is the structure of the system, in which each element is organized into a process for a specific purpose. The current research on the dynamic system of tourism development mainly involves the research on the dynamic mechanism of urban tourism development. These studies determine the supply of urban tourism products and the core competitiveness of urban tourism. We will jointly guide the emergence and development of urban exhibition tourism under the interaction of various dynamics such as stimulating the demand for exhibition tourism, protecting the urban environment, and supporting the country. Figure 1 is a model of the dynamic mechanism of urban exhibition tourism development.

The development of urban convention and exhibition tourism is driven by different forces, so as to realize the rapid development of convention and exhibition tourism. The factors that affect the development of urban exhibition tourism are divided into two types: driving factors (resources, economy, location, services, etc.) and supporting elements (policy, technology, culture, etc.), and their effects on urban exhibition tourism are presented as driving forces and guiding force. The figure shows the law of behavior among various factors affecting the development of exhibition tourism from the analysis of the entire city system. Among them, policy, technology, culture, economy, resources, location, and service are regarded as development driving factors.

The shift-share analysis method usually takes the economic development status of the region where the city is located as a reference, uses the gross national product as an index to evaluate the economic aggregate, and studies the change process of the regional economic industrial structure through the dynamic development process [14, 15]. When constructing the shift-share model, three indicators of the total economic volume of the case are generally selected: the first is the amount of change in the standardization industry department of the case study area based on the average growth rate of the region, that is, the deviation share  $W$ ; the second is the impact of the structural difference between the case area and the regional economy, that is, the deviation of the industrial structure from the share  $R$ ; the third is the difference in the level of economic activity caused by the difference in economic growth between the various industrial sectors within the region and the corresponding industrial sector in the case, that is, the deviation of competitiveness from the share  $L$ . Suppose that, in time  $s$ , in region  $A$ , the overall economic aggregate and industrial structure of the region have undergone some changes, and suppose that the overall economic aggregate and industrial structure of the region have undergone some changes. Assuming that the economic aggregate of this time period is  $T_{all}$  and the economic aggregate of the last year is  $F_{all}$ , then

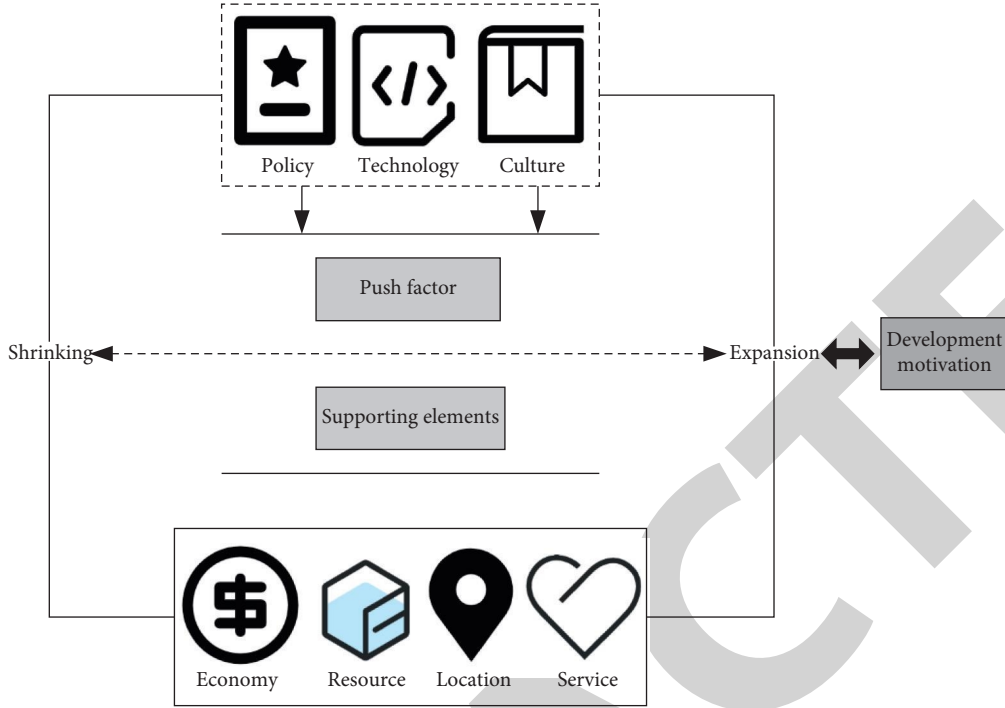

FIGURE 1: The dynamic mechanism model of city convention and exhibition tourism development.

the relevant mathematical model of the deviation-share analysis method of area  $A$  can be expressed as

$$\begin{aligned}
 H_a &= W_a + R_a + L_a = T_{all} + F_{all}, \\
 W_a &= \frac{T_a}{F_a} * T_{all} - F_{all}, \\
 R_a &= \sum_{a=1}^N \frac{T_a}{F_a} \times T_{all}, \\
 L_a &= T_{j,a} - \sum_{a=1}^n \frac{T_a}{F_a} \times (T_{all} + F_{all}).
 \end{aligned} \tag{1}$$

Among them,  $W_a$  is the deviation share of region  $a$ ,  $R_a$  is the deviation share of the industrial structure of region  $a$ , and  $L_a$  is the competitiveness share of region  $a$ .

$$\begin{aligned}
 (R + L)_a &= R_a + L_a = T_{all} - \frac{T_a}{F_a}, \\
 \eta &= \frac{T_{i,a}}{\sum_{a=1}^n (T_a/F_a) \times F_{j,a}}.
 \end{aligned} \tag{2}$$

$\eta$  is the regional competition effect index, which can more accurately analyze the status quo of the industrial structure of the economic development of region  $a$ .

High-performance computing refers to a device with a very powerful computing capability to complete a specified amount of computing work in a short period of time, mainly used to deal with complex calculation problems, and the development dynamic mechanism of exhibition tourism in this paper needs to calculate various dynamic factors in

exhibition tourism. At present, high-performance computing is widely used in scientific research fields, such as national defense and military industry, molecular chemistry, computer engineering assistance, global long-term meteorology, weather and disaster forecasting, process improvement and environmental protection, biological information technology, and medical and new drug research. Currently, the data is growing massively, from the Internet of Things to cloud computing, from big data to artificial intelligence, from Bitcoin to blockchain [16, 17], and the information revolution is rapidly promoting the development of the industry, subverting traditional concepts, and affecting around the world. Often companies need to make faster development and greater innovation in their business, accompanied by fast, stable, strong, and more demand for new computing capabilities. In the field of artificial intelligence, the rapid development of deep learning technology represented by graphics, images, audio, and video requires high-performance computing power to provide support [18, 19].

Figure 2 is the general architecture of the high-performance computing hardware platform.

With the deepening of scientific research, fierce competition, and rapid growth of data volume, digital and analog calculations are becoming more and more accurate, and the demand for computer resources is also increasing. Higher and more comprehensive requirements are put forward for data storage, computing speed, response time, and network bandwidth. Simulation has become an indispensable tool for researchers to explore the system without resorting to actual experiments. In any case, increasing the size and accuracy of the model will increase the amount of calculation [20, 21]. Consider computing, storage, and networking from three

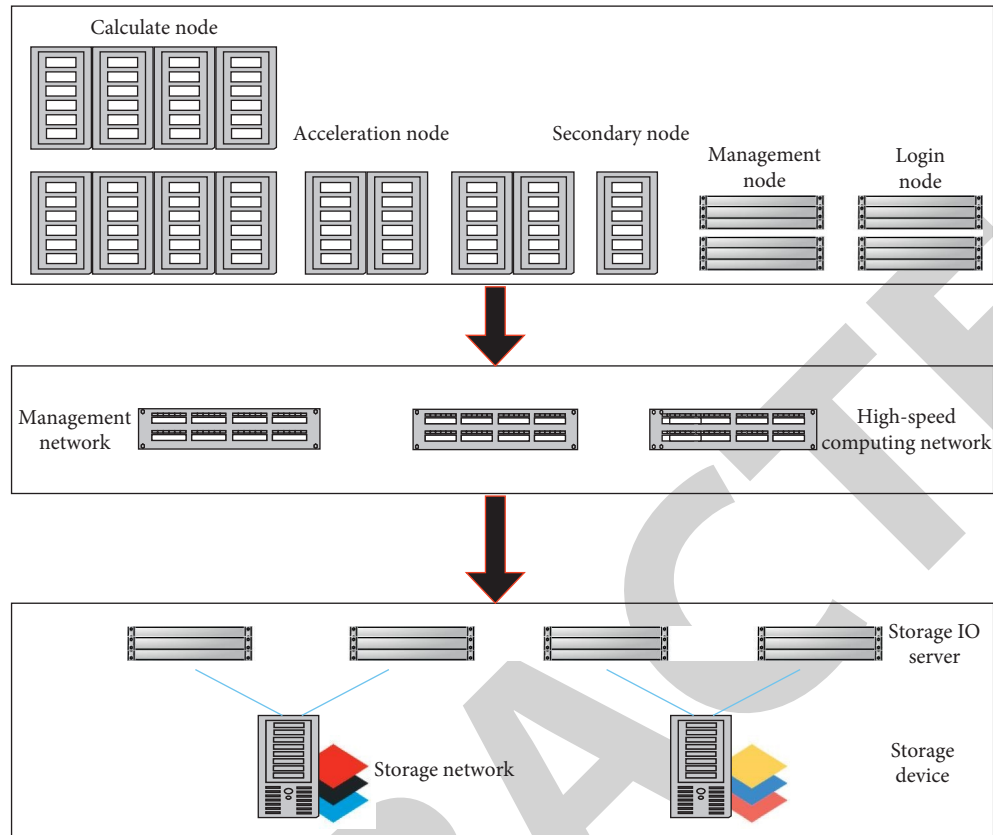

FIGURE 2: General architecture of high-performance computing hardware platform.

perspectives. IT mainly includes computer nodes, acceleration nodes, auxiliary nodes, connection nodes, and management nodes. There are three network levels in the network: high-speed computer network, storage network, and management network; separate the management levels inside and outside the area, and the management network system and business system do not share the same level [22, 23]. When the business system fails, the administrator can also manage the server through the offline management network console [24].

From computers, minicomputers, to mainframes, the rapid development of computers is still unable to meet the needs of computing. Scientific computing, network computing, terminal computing, cloud computing, supercomputing, intelligent computing, GPU (Graphics Processing Unit) computing, and other computing modes, concepts, technologies, and applications dominate the progress and development of science and technology. Quantum computing, brain-like computing, borderless computing, human-machine-object ternary fusion computing, data-intensive computing, etc. have brought computing into the multielement era [25, 26]. Calculations allow humans to explore the unknown. The future development is no longer simply a certain technology or a certain type of calculation; it must be a combination of multiple calculations, and multiple theories cooperate with each other to develop together [27]. Figure 3 shows the workflow of high-performance computing.

The terminal allocates the work and sends a message to each node to let them perform their own part of the work. The work is put into the high-performance computing unit and sent to each node at the same time, and each node is usually expected to give a result at the same time as a response. The results from each node are returned to the host application through another message provided by MPI, and then all messages are received by the application.

**2.1. Balanced Load.** Load balancing refers to the processing of a large amount of data requests or a large amount of data requests in a short period of time through resource scheduling and task allocation. It balances the distribution of load and avoids overload, so as to maximize the use of system resources, maximize system throughput, and minimize task idle time. Generally speaking, load balancing is a global optimization scheduling problem. Load balancing scheduling is classified according to types and can be divided into local and global scheduling strategies. Global scheduling strategy is divided into dynamic load balancing and static load balancing; dynamic load balancing is divided into centralized and distributed scheduling strategies, etc. Here from the load balancing scheduling mechanism, the overall load balancing algorithm can be divided into three categories: static load balancing algorithm, dynamic load balancing algorithm, and adaptive load balancing algorithm. The balanced load model is shown in Figure 4.

FIGURE 3: High-performance computing job workflow.

FIGURE 4: Balanced load model.

Supposing  $a$  represents an effective task scheduling strategy, then  $K(a)$  represents all the time the task set  $K$  is executed on the server node  $R$ , and the goal that the task scheduling needs to meet is to require the optimal span. Here, make  $K(a)$  as small as possible.

Let  $H$  denote the set of load balancing indicators, and set  $H = \{H_1, H_2, \dots, H_n\}$ ; then,

$$H_i(a) = \frac{1}{K(a)} \sum_{i=1}^s S_{ij} \times T_{ij}, \quad (3)$$

where  $i \in \{1, 2, \dots, n\}$ , and you can get  $0 < H_i(a) \leq 1$ , and suppose that the standard deviation  $\phi(a)$  of the load index is defined as  $\phi(a)$ ,

$$\varphi(a) = \sqrt{\frac{1}{m} \left( H_i(a) - \frac{1}{m} \sum_{i=1}^m H_i(a) \right)^2}. \quad (4)$$

According to  $0 < H_i(a) \leq 1$ ,  $0 \leq \phi(a) < 0.5$  and  $\gamma(a)$  is the standard deviation of the load index; then  $\gamma(a)$  is defined as

$$\gamma(a) = 1 - (2 \times \phi(a)). \quad (5)$$

According to  $0 \leq \phi(a) < 0.5$ ,  $0 < \lambda(a) \leq 1$  can be obtained.

According to the mathematical model, the task scheduling algorithm can be described as looking for a task scheduling strategy that makes  $K(a)$  as small as possible and  $\gamma(a)$  as large as possible, which is the optimal solution.

In order to improve performance, the solution constructed in the adaptive joint algorithm is used as the initial solution  $x$ , and then the method proposed by the new neighborhood strategy is used to improve  $x$ . First, determine and select the last scheduled task on all nodes, and the first improvement has been made. This method involves finding all the inactive time intervals of the node and trying to insert the operation of the selected task while respecting the constraints. The optimal time selection parameter represents the processing time of tasks on all nodes. The processing time from the first to the last vertex of the path is expressed as

$$WL(a, b) = \left( \sum_{i \in e_{ab}} W_{a,b} \right) + W_i. \quad (6)$$

Among them,  $W_{a,b}$  is the collection of all the data before the job; calculate the workload of each operation, and according to the total workload, sort the jobs in the order of the highest workload to the lowest workload.

$$WL(a) \begin{cases} \arg \left\{ \max_{a \in E(a)} [\delta_i^k]^j \right\}, \\ s > s_0. \end{cases} \quad (7)$$

Among them,  $s$  represents the information between paths,  $\delta_i^k$  represents the heuristic distance between them, and  $E(a)$  represents a random number uniformly distributed in  $[0, 1]$ .

$$\begin{aligned} \delta_{ij}(a+1) &= (1-g)\delta_{ij}(a) + \nabla\delta_{ij}, \quad 0 < g < 1, \\ \Delta\delta_{ij}(a) &= \sum_{k=1}^{ij} \delta_{ij}^k(a). \end{aligned} \quad (8)$$

When all the data in the job distribution process constructs a complete path from the beginning to the last vertex, each data will be marked to provide pheromone for each directional arc.

$$\nabla\delta_{ij}^k(a) = \begin{cases} WL(a), & (ij, ea) \in v^k(a), \\ 0, & \text{others.} \end{cases} \quad (9)$$

**2.2. Task Division.** Task division has a significant effect on data-intensive applications, but its ability to execute complex

data structures and control flow instructions is not good. When the problem scale is small or the frequency of use is low, different task division methods are used.

Consider the program running time; suppose  $s$  is the program running time,  $s_{\text{cpu}}$  is the CPU preprocessing time,  $s_{\text{copy}}$  is the data copy time,  $s_{\text{gpu}}$  is the kernel execution time, and  $s_{\text{ret}}$  is the return time of the abnormal data copy function. Then when the exception copy is not used, there are

$$S = S_{\text{cpu}} + S_{\text{copy}} + S_{\text{gpu}}. \quad (10)$$

When using asynchronous data copy, there are

$$s = \max \left\{ (s_{\text{cpu}} + s_{\text{ret}}), (s_{\text{copy}} + s_{\text{gpu}}) \right\}. \quad (11)$$

Neglecting the execution time of kernel and the return time of the asynchronous data copy function, it can be expressed as

$$s = \begin{cases} s_{\text{cpu}} + s_{\text{copy}}, \\ \max \{ s_{\text{cpu}}, s_{\text{copy}} \}. \end{cases} \quad (12)$$

It is not difficult to see from the formula that when the preprocessing time is close to the data copy time, the use of asynchronous data copy can shorten the program running time by half. The concurrent operation of data copy and execution has the effect of the pipeline, which can effectively hide the delay and improve the report and document classification program performance.

For a single job in the system, without considering the impact of other jobs, there may be a time interval between the occurrence of communication events during its execution. The analysis of communication characteristics in the time dimension of parallel applications mainly focuses on the interval distribution of the communication interval, and the interval is

$$\begin{aligned} g\{f(p, w+1)\} - f(p, w) &= P(a), \\ W(a) &= \{(w-1)f(w-1, a) - wf(w, a)\}, \end{aligned} \quad (13)$$

where  $g$  represents the mathematical expectation and  $P(a)$  is the proportional coefficient. If the  $a+1$  interval appears in the middle of the previous  $a$  interval, it will increase on the basis; then,

$$g\{f(1, a+1)\} - f(1, a) = \varepsilon - P(a)f(1, a) \quad (0 < \varepsilon(a+1) < 1). \quad (14)$$

It can be seen that there is an intersection of the communication intervals of multiple communication events. When there is no noncommunication interval among them, no communication event occurs.

Using the principles and steps of analytic hierarchy process, construct the quantitative evaluation index system of the urban exhibition tourism development dynamic mechanism to determine the weight of its evaluation factors. The development motivation factor is used as the first-level evaluation index, including policy, technology, culture, economy, resources, location, and service, expressed in  $T_1-T_7$ . Then the factors under the first-level indicators are

used as the second-level indicators, and the detailed evaluation indicators are shown in Tables 1 and 2.

The secondary indicators of the development momentum of exhibition tourism include economics, policies, resources, services, location, technology, culture, and other content. The level of economic and industrial development reflects the inherent support for the development of urban exhibition tourism. The urban economy has the early advantages of urban construction. Convention and exhibition tourism uses typical industries as growth engines. It is understandable that typical industrial development drives urban development. Especially as a tourist city, the development of tourism affects all aspects of urban construction. Therefore, the level of economic development and the development of typical industries directly affect the development of tourist cities. Among them, the stable and healthy development of the exhibition tourism industry requires a good market order, which requires the government to formulate relevant laws and regulations to regulate various commercial behaviors in the industry. On the basis of improving the current industry standards and regulations, the government has formulated more comprehensive qualification assessment standards, evaluation mechanisms, market competition, market supervision, and related laws, regulations, and preferential policies in the exhibition and tourism industry. It is used to coordinate the interest relationship between all parties and prevent the vicious competition in the market caused by the interests of all parties, so as to create a good market order and realize the healthy and stable development of Guilin convention and exhibition tourism.

According to the quantitative nature of the indicators, construct indicators for the dynamic development mechanism of urban exhibition tourism. The first-level indicators are elements of support and promotion, and the second-level indicators are improvements to the first-level indicators, which can more fully reflect the reporting situation of the city, judging the relative importance of each element at each level, and expressing the judgment in the form of a digital table to create a judgment matrix. The structure of the judgment matrix is shown in Figure 5.

By constructing a judgment matrix, calculating the factor weights layer by layer, and then obtaining the ranking of the importance of the factors that affect the complex problem, the evaluation of the development momentum of urban conventions and exhibitions is mainly based on the weight difference of various factors, and the corresponding development path of the convention and exhibition tourism planning will not have a major impact on development trends and changes due to factors such as time.

From the perspective of tourists' recognition, this study established a city exhibition tourism satisfaction evaluation system through questionnaire surveys and expert interviews. Through the analysis of the development factors of exhibition tourism, the development process of urban exhibition tourism is analyzed. The problems and effective ways to improve the competitiveness of city exhibition tourism are put forward. In this task, we distributed 150 questionnaires to different target groups and collected first-hand raw data

through the questionnaires. We selected evaluation indicators through on-site visits and inspections, participation in relevant exhibitions, study and research of relevant departments, and the perceived satisfaction of exhibition exhibitors, tourists, and local residents. We used the data collected from the survey to directly collect the original data. Figure 6 shows a framework for analyzing and investigating MICE tourism satisfaction.

### 3. Optimization Results of Urban Exhibition Tourism Development

The exhibition tourism industry is a huge driving force for urban development and product brand building. With the increasing frequency of economic and trade cooperation and exchanges in various regions, large-scale exhibitions in various cities have become important promoters of economic and trade cooperation, economic introduction, and products going abroad. Convention and exhibition tourism has gradually developed into an important industry in the economic development of each city. At the same time, according to the increasingly fierce competition in urban development location and the continuous segmentation of products and markets, it has a clear position in the development of exhibition tourism. The positioning of these cities for the development of exhibition tourism undoubtedly determines the trend and positioning of the city in the future development. It also determines the trend pattern of future exhibition tourism development and the overall strength of the city's development. The tourism development of city A in recent years is shown in Figure 7.

Figure 7 shows the tourist arrivals and growth rate of city A in recent years. It can be seen that, from 2015 to 2019, the annual tourist arrivals and tourism growth rate of city A have increased significantly. According to statistics, the annual profit of exhibition tourism in the tourism market of city A is more than 20%–25%, and there are more than 400 large-scale exhibitions each year, which is in the upper reaches of the country.

From Figure 8, combined with the number of tourists in Figure 7, it can be seen that the exhibition tourism market in city A has shown great development potential. Among tourists, conference tourists account for 10.3% of the total tourists, second only to vacation and sightseeing tours. Its unique tourism resources, rich leisure, and entertainment activities and perfect service system have exerted a strong pull on the development of exhibition tourism in city A.

According to the first- and second-level evaluation indicators of the development momentum of exhibition tourism constructed in the previous article, the weight coefficients contained in each indicator are calculated. Table 3 is the judgment matrix of the first-level index weight coefficient, which determines the weight of each evaluation factor and then improves and optimizes its development motivation mechanism, so that the exhibition tourism can develop in a healthy and orderly manner.

Analyzing the weights of the first-level evaluation indicators, it can be seen that tourism resources and economic factors and policy factors have a relatively high weight.

TABLE 1: Evaluation indexes for the development motivation mechanism of convention and exhibition tourism.

Factor	First-level evaluation index	Factor	Secondary evaluation index	Sort
$T_1$	Economy	$S_1$	Capital investment	3
		$S_2$	Featured industry cluster	
		$S_3$	International level	
$T_2$	Resource	$S_4$	Travel resources	1
		$S_5$	Exhibition facilities	
		$S_6$	Infrastructure	
		$S_7$	Human resources	
$T_3$	Location	$S_8$	Political culture	2
		$S_9$	Natural economy	
		$S_{10}$	Regional market	
$T_4$	Service	$S_{11}$	Travel services	6
		$S_{12}$	Expo services	

TABLE 2: Construction of evaluation indexes for motive mechanism of exhibition tourism development.

Factor	First-level evaluation index	Factor	Secondary evaluation index	Sort
$T_5$	Policy	$S_{13}$	Industrial policy	4
		$S_{14}$	Exhibition system	
		$S_{15}$	Government resources	
$T_6$	Culture	$S_{16}$	Citizen quality	7
		$S_{17}$	The image of a city	
		$S_{18}$	City safety	
$T_7$	Technology	$S_{19}$	Exhibition technology	5
		$S_{20}$	Management technology	
		$S_{21}$	Information technology	

( $T$ )	$S_1$	$S_2$	$S_3$	...	$S_n$
$S_1$	$S_{11}$	$S_{12}$	$S_{13}$	...	$S_{1n}$
$S_2$	$S_{21}$	$S_{22}$	$S_{23}$	...	$S_{2n}$
...	...	...	...	...	...
$S_n$	$S_{n1}$	$S_{n2}$	$S_{n3}$	...	$S_{nn}$

FIGURE 5: Evaluation index judgment matrix.

Among them, the weight coefficient of tourism resources is 0.2411, which has the highest weight. After the judgment and analysis of the index matrix, and the consistency test of the single-level and total rankings, the weight coefficients of the secondary indicators are analyzed. Figure 9 shows the weights of the secondary evaluation indicators of the exhibition tourism development dynamic mechanism.

From the perspective of system science, the analysis of tourism power mainly includes the attraction system based on tourism demand, the attraction system based on tourism

supply power, the tourism promotion power system, and the supporting power formed by its development. Therefore, the development of exhibition tourism has common characteristics. Secondly, from the internal analysis of the dynamic system, these factors are not independent, nor are they purely linear. There is a certain causal effect and feedback influence between them. Refer to the previous evaluation index composition, combined with the relevant data of the current situation, to obtain the power index of the power factor index of the exhibition tourism development.

FIGURE 8: x city's tourist purpose in recent years.

TABLE 3: Judgment matrix of first-level index weight coefficient.

Power	$T_1$	$T_2$	$T_3$	$T_4$	$T_5$	$T_6$	$T_7$	$W$
$T_1$	1.97	1.85	2.68	2.12	1.11	2.08	2.86	0.1523
$T_2$	1.55	2.85	1.98	1.82	2.96	2.98	1	0.2411
$T_3$	1.66	1.33	2.2	1.11	2.1	2.05	1.36	0.1804
$T_4$	2.79	2.39	2.58	2	1.42	1.33	2.59	0.0993
$T_5$	2.89	1.76	2.5	1.17	2.33	1.8	1.73	0.1458
$T_6$	2.6	1.66	2.02	1.01	1.53	1.6	2.05	0.0769
$T_7$	1.32	2.75	1.71	1.54	1.23	2.97	2.82	0.1042

FIGURE 9: The weight of the secondary evaluation index of the development dynamic mechanism of exhibition tourism.

FIGURE 10: Motivation factors and index assignments for the development of exhibition tourism.

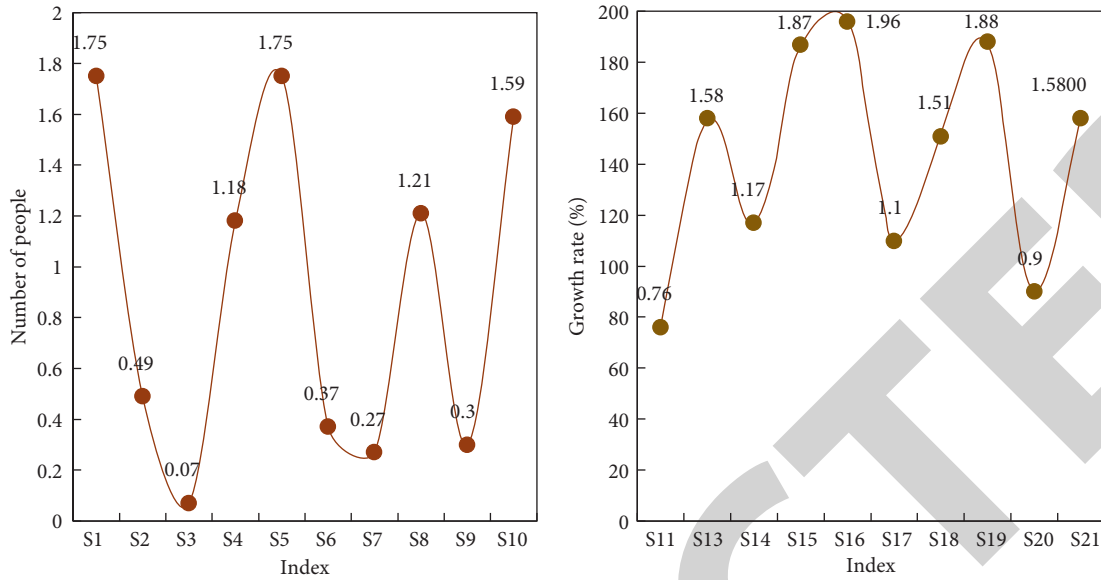

FIGURE 11: Development momentum index.

FIGURE 12: Satisfaction statistics of MICE tourism.

The power index and the index assignment are shown in Figures 10 and 11.

Use index assignment to determine the weight of dynamic factors and determine the degree of influence of different dynamic factors on the development of exhibition tourism. That is, the evaluation of the dynamic factor and the index assignment mainly adopt the analytic hierarchy process.

After calculating the weights of the indicators, the indexes of the dynamic factors at various levels are obtained. It can be seen that although the tourism resources of city A are relatively rich, the actual power is more, and the location and environmental factors are relatively strong. However, in

view of the current driving force of the development of exhibition tourism in which resources play a major role, the driving force of resource factors on the development of exhibition tourism is still relatively strong.

The most important thing in MICE tourism is the degree of satisfaction of tourists during their travel. Only when the tourists are satisfied can they attract more tourists to travel. Through the survey of tourist satisfaction in exhibition tourism, we can analyze and study the development direction of Hu Zhan tourism and the improvement of exhibition tourism service quality. Figure 12 is the questionnaire analysis on the satisfaction of exhibition tourism.

In the questionnaire for residents' satisfaction, urban factors, exhibition facilities, exhibition environment, tourism resources, tourism costs, and other indicators are set to analyze the satisfaction of exhibition tourism. Through the analysis of survey statistics, we can use evaluation indicators to make it clearer that customers attach great importance to those issues in the development of exhibition tourism, but the customer perception evaluation is very low. These need to be strengthened and improved by the exhibition management department and related organizers.

#### 4. Conclusions

This paper analyzes the dynamic mechanism of urban exhibition tourism development through high-performance computing and conducts research on the optimization countermeasures of exhibition tourism. Under the premise of clarifying the differences in the development of city convention and exhibition tourism, the dynamic factors of the development of convention and exhibition tourism industry are analyzed. Regarding the main characteristics and content of the seven main driving factors of exhibition tourism development, refer to the relevant evaluation index system to subdivide the driving factors of exhibition tourism development, economic factors, selection policy factors and resource factors, and other location factors. Taking into account the factors of the investigation, the concept and composition of each element are refined layer by layer, and finally a multifactor evaluation system for the development of exhibition tourism is formed. We used surveys and detailed layering procedures to determine the weights of all levels of measurement. From the weighted results, we can see the characteristics of the power structure of the city's exhibition tourism in the emergence stage. The load balancing algorithm is mentioned in the article, and load balancing is a global optimization scheduling problem. Combined with the principle of dynamic factors, it analyzes and summarizes the characteristics and main development paths of exhibition tourism under the combined effect of various factors. However, there are still some shortcomings in the article research, such as the lack of depth in the current research on the dynamic mechanism of the development of exhibition tourism in the city, and the selection of evaluation factors and mechanism research on the dynamic mechanism of exhibition tourism are not perfect. We hope it can be improved in the future work.

To attract customers and landlords to join the platform is an important problem to be solved when expanding the size of the shared accommodation platform, and subsidy policies have been proven to be an effective approach in many areas of sharing. In order to analyze the strategies of all parties in the subsidy policy of the shared accommodation platform, a three-party evolutionary game model of shared accommodation platform, consumers, and landlords was built. The strategy stability of each game subject was analyzed, and the equilibrium point stability was explored based on Lyapunov's method. The game model and influencing factors were simulated and analyzed by MATLAB 2016. Results demonstrated that the consumers and landlords were promoted to join the shared accommodation platform by increasing subsidies to consumers and landlords and reducing consumers' time costs and landlords' service fees from the early stage to the rapid development stage of the shared accommodation platform; with the increase of the proportion of landlord's share in expenses and the decrease of the opportunity loss of platform nonsubsidizing, the strategy of the platform gradually evolves from subsidy to nonsubsidy. The conclusions of this study provide guidance for the mature path of the shared accommodation platform and also give suggestions for the development of the sharing economy.

## 1. Introduction

The comprehensive application of emerging technologies such as the Internet and big data in the market brings special operation mode, effective realization tools, and high-quality value creation, which have opened up a new road for the development of market industries and accelerated the evolution of the global economic format. In recent years, benefiting from technological advances and the increasing awareness of people's awareness towards sustainability, the ranges of shared products have increased dramatically [1]. Sharing has turned from a "nonreciprocal prosocial behavior" [2] to a unique economic model [3], which brings innovation and efficiency to local development [4]. According to Juniper Research, the global market for the sharing economy is expected to reach \$40.2 billion in 2022 [5]. Sharing platforms are springing up all over the world, and the emerging business model of "Internet Plus" is

gradually becoming the important engine for global economic upgrading and transformation. The sharing economy has started to develop in many industries around the world, such as Airbnb, an online travel and housing rental company established in 2008, and Uber, an online car service established in 2009. As an important trend for future development [6], the sharing economy has had a profound impact on the social economy to change people's consumption behavior and consumption patterns [7] and develop many new models by integrating with various industries [8]. Among the industries, the development of the shared accommodation industry has been remarkable [9].

The traditional accommodation industry is an important sector of the service industry, providing entertainment and dining services to travelers. However, with rapidly changing market conditions and competition, shared accommodation is a new way for the industry to develop as a result of the deep integration of the accommodation industry with

information technology. According to the “China Sharing Economy Development Report 2020,” the market size of shared accommodation in China was about 22.5 billion yuan, increasing of 36.4% over the previous year, and the revenue of the shared accommodation industry accounted for 7.3% of the total revenue of the accommodation industry in 2019. The growing shared accommodation industry is bound to have a profound impact on the development of the industry. Therefore, it is important to analyze the development law of shared accommodation and understand the model in the development stage, which will be guiding significance for promoting the shared accommodation industry and socioeconomic development.

As a disruptive innovation, shared accommodation has become an important model to allocate urban accommodation resources, revitalize the rural tourism industry, and activate the development potential of the service industry [10–12]. Some companies have already achieved success in shared accommodation, represented by HomeAway and Airbnb Inc. [13]. The research on shared accommodation has gradually increased since 2013, with the market size of shared accommodation expanding [14]. The development of the shared accommodation industry in many areas imitated Airbnb, but the process is difficult for the trust barriers and legal regulation problems among various stakeholders [15]. Some scholars have proposed that the development of shared accommodation in China draws on the successful experience of Airbnb [16, 17], but it also faces the dilemma of “acclimatization” [18]. Therefore, how to keep the market alive of shared accommodation has become a problem that needs to be solved by shared accommodation companies in the global.

Shared accommodation is a type of nonstandard accommodation in which homeowners rent out their idle rooms to travelers for a short period through an online network platform [19]. Compared to traditional accommodation, shared accommodation has a wider variety of room types and caters to travelers’ desire to “live like a local” with an authentic destination experience [20], which makes it popular among customers [21]. There are three parties involved in shared accommodation: the landlord (the operator providing the room for rent), the shared accommodation platform, and the consumer (the renter) [22]. The shared accommodation platform is the intermediary connecting landlords and consumers, increasing the efficiency for matching and reducing the search costs. As the intermediary organization, the platform charges the service fee for both landlords and consumers. Due to the characteristics of nonneutral, cross-network externalities in bilateral market pricing, shared accommodation platform usually charges the service fee on one side and no fees on the other [23]. However, compared with hotel staff, most of the landlords attracted by shared accommodation platforms are untrained, nonprofessional training staff [24], and they also face ordinary consumers. There are many problems such as short development time, weak foundation, small development size, low participation enthusiasm in the development of the shared accommodation platform. Some scholars’ studies have found that the profit has a greater influence on

professional landlords in the operation process and the price level of their rooms is higher by comparing the operating conditions of the sellers operating a single room with those operating multiple rooms at the same time [25, 26]. There is a lack of research on how to change landlords’ pricing strategies and develop reasonable pricing strategies.

As a successful sharing economy model, the shared accommodation platform is widely recognized in the world, and the reasonable operation strategy is the key to the development of the platform. Given the characteristics of sharing platforms, the products served by the sharing economy are different from traditional bilateral markets. In order to expand the size of the platform, many platforms consider using subsidies to regulate the balance between the supply and demand of bilateral users during their development phase, which has laid a good foundation for the successful operation of platforms, for example, Uber subsidized drivers and DiDi subsidized passengers. Subsidies can also be used as an incentive method to promote the increase of the number of participants in the development of shared accommodation platforms. It has been studied in the field of sharing economy platforms that the equilibrium market size obtained by subsidizing suppliers is larger than that obtained by subsidized customers [27]. As shared accommodation platforms adopt subsidies to expand the market size, subsidy policies need to be updated accordingly. Therefore, it is relevant and urgent to research the subsidy policies of shared accommodation platforms.

In order to promote the development of the accommodation industry in the context of big data and build a bilateral accommodation platform based on information technology, to make up for the insufficiency of previous research with two parties as game subjects, the behavioral strategies of all parties in the operation of the shared accommodation platform should be more comprehensive and systematic considered. This paper adopts evolutionary game theory to analyze the evolutionary mechanism and process among platform, landlord, and consumer under subsidy policy of the platform from a dynamic perspective and explores the influences of subsidy amounts, landlord service fee, consumer time cost, and the proportion of landlord’s share in expenses on system stability. Finally, corresponding countermeasures are suggested for the subsidy mechanism of the platform. This paper answers the following three key questions: (1) How to determine the strategic conditions for shared accommodation platforms to conduct subsidies and the utilities obtained by consumers and landlords participating in shared accommodation. (2) How to achieve the equilibrium strategies of shared accommodation platforms, landlords, and consumers under platform subsidy mechanism. (3) To explore the factors affecting the equilibrium strategies.

## 2. Related Literature

Most of the research on shared accommodation focuses on the factors of willingness to participate of consumers and landlords and the factors influencing the price of shared accommodation.

Many scholars have explored consumers' willingness to participate based on different perspectives, and the studies have found that the material, energy-saving, psychological, and social interaction willingness promote consumers to participate in shared accommodation [28]. Extrinsic material benefits positively attract consumers to participate in shared accommodation platforms [29], and low-priced housing is the choice of most frugal consumers, which explains the attitude of consumers to use Airbnb [30]. Consumers tend to use rather than own products, which avoids the waste of social resources, and such behavior is expected to alleviate social problems such as excessive consumption and environmental pollution by reducing the cost of economic coordination [31]. Trust, familiarity, loyalty, authenticity, and hedonistic can also influence consumer participation in shared accommodation [32–34]. Social interactivity attracts consumers to share and helps to develop new social relationships during consumption [29, 35], enhancing social interaction stickiness [36]. Although the consumers' willingness to participate is affected by many factors, few studies consider the cross-network externalities between consumers and landlords.

Existing studies on landlords' willingness to participate are mostly centered on the economic value, functional value, security value, and trust value dimensions. The prerequisite for landlords to join the platform is the platform's sustainable development prospects, functional values of operational compatibility, and ability to respond to crises and solve problems [37]. By registering room resources online, the rental of idle rooms can be realized, and the participation enthusiasm of landlords can be stimulated by monetary value so that the landlords can directly obtain economic benefits [38, 39]. But landlords still have doubts about the safety and security of personal property in the platform [40]. Trust is the key factor to overcome uncertainty and reduce [41], so the importance of information security governance is particularly prominent [42]. It is necessary to clarify the influencing factors of landlords' participation in home-sharing so that the platform can formulate corresponding strategies to attract landlords to join.

The factors influencing the pricing of shared accommodation platforms are mainly the structure characteristics and accommodation facility features of the room, location characteristics, trust, and sociality [43–45]. The rental price is mainly determined by the landlord [43]. At the same time, the rental price is affected by the comment score and room quality, with higher pricing for high star rating listings [46]. The improvement in one room quality has the spillover effect on the prices of the other room [47]. There is a correlation between external factors and room rental prices. The internal facilities of the room and the supply of parking spaces have a positive impact on the room rental price, while instant booking has a negative effect on room rental prices [43, 48]. The authenticity of the photo has a significant impact on the rental price of the shared room; the more authentic the photo, the more purchase opportunities and economic benefits it brings [49]. However, few studies have discussed how to formulate reasonable strategies for sharing accommodation platforms to take into account the interests of all

parties in sharing accommodation and achieve the optimal system utility.

The existing research methods on shared accommodation platforms are mainly to analyze the dynamic optimal allocation of idle rooms in the platform [50] and the game research between the participants of shared accommodation. However, most of the game models are studied from the perspective of two subjects, and there are few comprehensive studies on shared accommodation platforms, consumers, and landlords. The dynamic evolution law of the three stakeholders in the development process of the shared accommodation platform has not been deeply discussed; especially, the subsidy strategy of shared accommodation platforms has not been well explained. This study attempts to fill the gap by analyzing the impact of subsidy policies of shared accommodation platforms on the dynamic evolution of strategies among platform, consumer, and landlord, explores the evolution stage and influencing factors of platform subsidy implementation, and puts forward corresponding suggestions for platform development.

### 3. Materials and Methods

*3.1. Problem Description.* The shared accommodation platform can realize the sharing of information and resources and promote the rapid development of the shared accommodation industry. Currently, the shared accommodation industry is in the development stage, the platform's capacity is insufficient, the landlords are not dependent on the platform, and the consumers have limited access to information about room resources. Therefore, shared accommodation platform companies can give some subsidies for landlords and consumers to promote them to join the platform. The landlords share their idle rooms through the platform and obtain certain utilities, and consumers find satisfactory rooms through the shared accommodation platform. In this study, "platform" refers to the shared accommodation platform, "consumer" refers to the demander of the rental idle room, and "landlord" refers to the supplier of the rental idle room. The landlord ( $L$ ) posts his or her idle room on the shared accommodation platform ( $P$ ), and the consumer ( $B$ ) rents it through the platform. The platform charges fees to the landlord and the consumer.

The shared accommodation platform, landlords, and consumers are very important stakeholders in the development of the shared accommodation industry, and the three parties are connected through the rooms for rent, as shown in Figure 1.

*3.2. Model Assumptions.* In order to build the subsidy strategy model of a shared accommodation platform based on the evolutionary game in the context of big data, each party's strategy and the equilibrium point of the evolutionary game system are analyzed, and the following assumptions are made.

*Assumption 1.* In the network transaction system consisting of "shared accommodation platform-consumer-landlord," each game participant is finite rational, and their

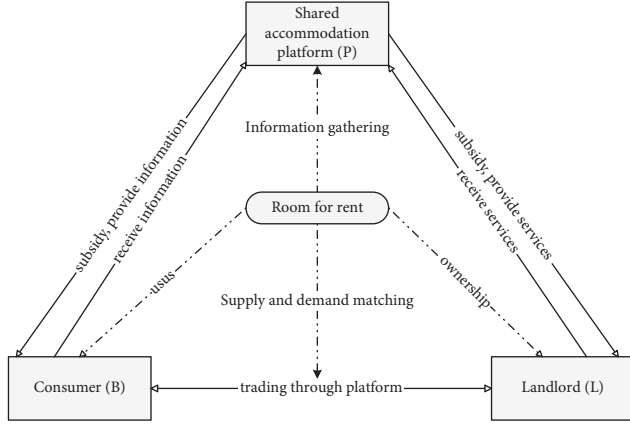

FIGURE 1: Relationship among shared accommodation platform, landlord, consumer, and room for rent.

information is asymmetric. In the game, the behaviors of the participants are random and interactional, which means that the participants cannot obtain the optimal strategies through one game but needs to go through trial and error and learn and improve their past strategies in the multiple rounds game. This means that each participant cannot obtain the optimal strategy through one game and needs to improve their strategies through continuous trial and error and learning in multiple rounds of games so as to make behavioral decisions that best match the current situation.

*Assumption 2.* In this paper, the goal of all parties is to maximize benefits under the subsidy policy of the platform. The platform determines whether to provide subsidies to consumers and landlords based on profit maximization; consumers decide whether to participate in sharing platform transactions based on their own needs to obtain the maximum utility of participating in sharing accommodation; landlords choose whether to join the platform based on the maximum net income of participating in the sharing platform. The maximum amounts of subsidy provided by the platform to landlords and consumers are, respectively,  $S_L$  and  $S_B$ . The platform determines the intensity of subsidies according to the participation of landlords and consumers, and the proportion of subsidies provided by the platform to consumers and landlords is, respectively,  $\alpha$  and  $\beta$ . Subsidies are given to landlords and consumers in the form of coupons or cash.

*Assumption 3.* In the process of operation, the sharing platform will charge corresponding fees to the landlords and consumers.  $P_B$  is the total cost paid by consumers to participate in shared accommodation, including the service fee charged by the platform and the fee charged by the landlord.

The proportion of landlord's share in expenses paid by consumers is  $\phi$ . The fee charged by the landlord is  $\phi P_B$ , and the service fee charged by the platform is  $P_B(1 - \phi)$ .  $P_L$  is the service fee charged by the platform to the landlord, and the service includes priority recommendation of room information, taking photos of the room, and providing smart locks.

*Assumption 4.* The strategy choice of shared accommodation platform is subsidy and nonsubsidy, the proportion of platform implementing subsidy is represented as  $x(0 \leq x \leq 1)$ , and the proportion of implementing nonsubsidy is denoted as  $(1 - x)$ ; the strategy choices of consumer are participation and nonparticipation, the proportion of consumer implementing participation is represented as  $y(0 \leq y \leq 1)$ , and the proportion of implementing nonparticipation is denoted as  $(1 - y)$ ; the strategy choices of the landlord are sharing and unsharing, the proportion of landlord implementing sharing is represented as  $z(0 \leq z \leq 1)$ , and the proportion of implementing unsharing is denoted as  $(1 - z)$ , where  $x, y, z \in [0, 1]$ .

*Assumption 5.* The purpose of adopting the subsidy is to enable consumers and landlords to participate in the shared accommodation platform, and the platform mainly obtains benefits by charging landlord service fees and the proportion of consumers paying room fees. Therefore, the initial subsidy of the platform needs to be more than the reputation benefit in order to better attract consumers and landlords to join the shared accommodation, that is,  $\alpha S_B > R_B$  and  $\beta S_L > R_L$ . Due to more contact with landlords on the sharing platform, the cross-network externalities utility of consumers received from participating in shared accommodation is more than the price paid by consumers, that is,  $N_B > P_B$ .

*3.3. Model Building.* The parameters of this paper are described in Table 1.

According to the above assumptions, the shared accommodation platform, consumer, and landlord are the three main players in the game, and the game model benefit matrix is shown in Table 2.

### 3.4. Model Analysis

*3.4.1. Stability Analysis of Shared Accommodation Platform Strategies.* The expected utility of shared platform selecting subsidy is  $\pi_x$ , the expected utility of shared platform selecting nonsubsidy is  $\pi_{1-x}$ , then the average expected utility of the shared platform is  $\bar{\pi}_x$ , and  $\bar{\pi}_x = x\pi_x + (1 - x)\pi_{1-x}$ , which are defined as follows:

$$\begin{aligned} \pi_x &= yz * [-C_p + P_B(1 - \phi) + P_L + R_B + R_L - (\alpha S_B + \beta S_L)] + (1 - y)(1 - z) * (-C_p) + (1 - y)z \\ &\quad * (-C_p + R_L + P_L - \beta S_L) + y(1 - z) * (-C_p + R_B - \alpha S_B). \\ \pi_{1-x} &= yz * [-C_p + P_B(1 - \phi) + P_L - H] + (1 - y)(1 - z) * (-C_p - H) + (1 - y)z * (-C_p + P_L - H) + y(1 - z) * (-C_p - H). \end{aligned} \quad (1)$$

TABLE 1: Parameter description.

Parameter	Description
$C_P$	Platform operating costs
$R_B$	Reputational benefits of platform subsidizing to consumers
$R_L$	Reputational benefits of platform subsidizing to landlords
$S_B$	Maximum subsidy amount of the platform to consumers
$A$	The proportion of subsidies provided by the platform to consumers, $\alpha \in [0, 1]$
$S_L$	Maximum subsidy amount of the platform to landlords
$B$	The proportion of subsidies provided by the platform to landlords, $\beta \in [0, 1]$
$H$	Opportunity loss of platform nonsubsidizing
$P_L$	Fees charged to landlords for the platform services
$P_B$	Fees paid by consumers participating in shared accommodation platforms
$\Phi$	The proportion of landlord's share in expenses paid by consumers, $\emptyset \in [0, 1]$
$N_B$	Cross-network externalization utility gained by consumers with landlords on the shared platform
$C_B$	Time cost of consumers
$B$	Fees paid by consumers for renting room through offline channels
$U_B$	The utility of platform service for the consumer
$N_L$	Cross-network externalities utility gained by landlords with consumers on shared platform
$U_L$	The utility of platform service for the landlord
$C_L$	The cost of room and service provided by the landlord
$A$	Income by the landlord with unsharing room in the platform

According to the Malthusian dynamic equation, the replication dynamic equation of shared accommodation platform is obtained:

$$F(x) = \frac{dx}{dt} = x(1-x) * [y * (R_B - \alpha S_B) + z * (R_L - \beta S_L) + H],$$

$$F'_x(x) = \frac{\partial F(x)}{\partial x} = (1-2x) * [y * (R_B - \alpha S_B) + z * (R_L - \beta S_L) + H].$$

According to the stability theorem of the replication dynamic equation, the evolutionary stability strategy of the shared platform must be satisfied with the conditions that  $F(x) = 0$  and  $F'_x(x) < 0$ . And the threshold of shared platform strategy transformation is  $y^* = -((z * (R_L - \beta S_L) + H) / (R_B - \alpha S_B))$ .

**Proposition 1.** *In the evolution process, when  $0 < y < y^* < 1$ , the stabilization strategy of shared accommodation platform is subsidy. When  $0 < y < y^* < 1$ , the stabilization strategy of shared accommodation platform is nonsubsidy.*

*Proof:* Assume  $G(y) = y * (R_B - \alpha S_B) + z * (R_L - \beta S_L) + H$ ; when  $R_B - \alpha S_B < 0$ ,  $G(y)$  is considered to be a decreasing function of  $y$ . When  $y > y^*$ ,  $G(y) < 0$ ,  $F(x)|_{x=0} = 0$ , and  $F'_x(x)|_{x=0} < 0$ ,  $x=0$  is the stabilization point; that is, the nonsubsidy of the shared accommodation platform is the stabilization strategy; when  $y < y^*$ ,  $G(y) > 0$ ,  $F(x)|_{x=1} = 0$ , and  $F'_x(x)|_{x=1} < 0$ ,  $x=1$  is the stabilization point; that is, the subsidy of the shared accommodation platform is a stabilization strategy; when  $y = y^*$ ,  $x$  is stable in the interval from 0 to 1; that is, regardless of the initial proportion of the strategy selected by the shared accommodation platform, the platform will not change the strategy.

Proposition 1 shows that when the reputational benefits of platform subsidy to consumers are less than the subsidy amount of the platform to consumers, the reduction of consumer participation will change the stability strategy of the shared accommodation platform from nonsubsidy to subsidy. Similarly, the increase of consumer participation will change the stability strategy of the shared accommodation platform from subsidy to nonsubsidy. Therefore, the participation strategy of consumers is crucial to the implementation of platform subsidy, and it is also the basis of platform subsidy strategy.

The phase diagram of the strategic evolution of the shared accommodation platform is shown in Figure 2.

Figure 2 shows that the volume of  $V_1$  represents the proportion of subsidy of the shared accommodation platform, and the volume of  $V_2$  represents the proportion of nonsubsidy of the shared accommodation platform, which is calculated as follows:

$$V_1 = \int_0^1 \int_{-H/(R_L - \beta S_L)}^1 \frac{z * (R_L - \beta S_L) + H}{R_B - \alpha S_B} dz dx = \frac{(H + a_1)^2}{2a_1 * b_1},$$

$$V_2 = 1 - V_1,$$

TABLE 2: Game model benefit matrix of shared accommodation platform, consumer, and landlord.

Landlord	Strategy choice		Shared accommodation platform		
	Consumer	Subsidy ( $x$ )	Subsidy ( $x$ )	Nonsubsidy ( $1-x$ )	
Share ( $z$ )	Participation ( $y$ )	$U_B - C_P + P_B(1-\phi) + P_L + R_B + R_L - \alpha\delta_B - \beta S_L - P_B - C_B + U_B + \alpha\delta_B + N_B\phi P_B - C_P + P_B(1-\phi) + P_L - H - P_B - C_B + U_B + N_B\phi P_B + N_L + U_L - C_L - P_L$ $+ \beta S_L + N_L + U_L - C_L - P_L$	$U_B - C_P + P_B(1-\phi) + P_L + R_B + R_L - \alpha\delta_B - \beta S_L - P_B - C_B + U_B + \alpha\delta_B + N_B\phi P_B - C_P + P_B(1-\phi) + P_L - H - P_B - C_B + U_B + N_B\phi P_B + N_L + U_L - C_L - P_L$ $+ \beta S_L + N_L + U_L - C_L - P_L$	$U_B - C_P + P_B(1-\phi) + P_L + R_B + R_L - \alpha\delta_B - \beta S_L - P_B - C_B + U_B + \alpha\delta_B + N_B\phi P_B - C_P + P_B(1-\phi) + P_L - H - P_B - C_B + U_B + N_B\phi P_B + N_L + U_L - C_L - P_L$ $+ \beta S_L + N_L + U_L - C_L - P_L$	$U_B - C_P + P_B(1-\phi) + P_L + R_B + R_L - \alpha\delta_B - \beta S_L - P_B - C_B + U_B + \alpha\delta_B + N_B\phi P_B - C_P + P_B(1-\phi) + P_L - H - P_B - C_B + U_B + N_B\phi P_B + N_L + U_L - C_L - P_L$ $+ \beta S_L + N_L + U_L - C_L - P_L$
	Nonparticipation ( $1-y$ )	$-C_P + P_L + R_L - \beta S_L - \beta S_L + U_L - C_L - P_L$	$-C_P + P_L + R_L - \beta S_L - \beta S_L + U_L - C_L - P_L$	$-C_P + P_L + R_L - \beta S_L - \beta S_L + U_L - C_L - P_L$	$-C_P + P_L + R_L - \beta S_L - \beta S_L + U_L - C_L - P_L$
Unshare ( $1-z$ )	Participation ( $y$ )	$-C_P + R_B - \alpha\delta_B\alpha\delta_B - C_B A$	$-C_P + R_B - \alpha\delta_B\alpha\delta_B - C_B A$	$-C_P - H - C_B A$	
	Nonparticipation ( $1-y$ )	$-C_P - B A$	$-C_P - B A$	$-C_P - H - B A$	

FIGURE 2: Phase diagram of strategy evolution of shared accommodation platforms. (a)  $y = -((z * (R_L - \beta S_L) + H)/(R_B - \alpha S_B))$ , (b)  $y > -((z * (R_L - \beta S_L) + H)/(R_B - \alpha S_B))$ , and (c)  $y < -((z * (R_L - \beta S_L) + H)/(R_B - \alpha S_B))$ .

where  $a_1 = R_L - \beta S_L$  and  $b_1 = R_B - \alpha_1 S_B$ .  $\square$

**Corollary 1.** *The proportion of shared accommodation platform subsidy is positively correlated with the reputation benefits of the platform subsidizing and the opportunity loss of the platform nonsubsidizing and negatively correlated with the subsidy amount of the platform subsidizing to consumers and landlords.*

*Proof:* According to the formula (4), when  $H > \beta S_L - R_L$ ;  $H > \alpha S_B - R_B$ , the first-order partial derivative of each element is obtained as follows:  $(\partial V_1 / \partial R_L) > 0$ ,  $(\partial V_1 / \partial R_B) > 0$ ,  $(\partial V_1 / \partial H) > 0$ ,  $(\partial V_1 / \partial \beta S_L) < 0$ , and  $(\partial V_1 / \partial \alpha S_B) < 0$  (see Appendix A). Therefore, the increase of  $R_L$ ,  $R_B$ , and  $H$  and the decrease of  $\beta S_L$  and  $\alpha S_B$  can increase the proportion of subsidizing for shared accommodation platforms.

Corollary 1 shows that, with the increase in the reputation benefits of the platform due to subsidies to consumers and landlords and the opportunity cost of the platform nonsubsidy, the sharing accommodation platform is more inclined to adopt the subsidy strategy. As the amount of subsidies provided by the platform to landlords and consumers increases, the shared accommodation platform is more inclined to adopt a nonsubsidy strategy.  $\square$

**3.4.2. Stability Analysis of Consumer Strategies.** The expected utility of the consumer choosing to participate is  $\pi_y$ , the expected utility of the consumer choosing nonparticipating is  $\pi_{1-y}$ , then the average expected utility of the consumer is  $\bar{\pi}_y$ , and  $\bar{\pi}_y = y\pi_y + (1-y)\pi_{1-y}$ , which are defined as follows:

$$\begin{aligned} \pi_y &= xz * (-P_B - C_B + U_B + \alpha S_B + N_B) + (1-x)(1-z) * (-C_B) + x(1-z) \\ &\quad * (\alpha S_B - C_B) + (1-x)z * (-P_B - C_B + U_B + N_B), \\ \pi_{1-y} &= xz * (-B) + (1-x)(1-z) * (-B) + x(1-z) * (-B) + (1-x)z * (-B). \end{aligned} \quad (5)$$

According to the Malthusian dynamic equation, the replication dynamic equation of consumer is obtained:

$$\begin{aligned} F(y) &= \frac{dy}{dt} = y(1-y) * [z * (-P_B + N_B) + x * \alpha S_B + U_B - C_B + B], \\ F'_y(y) &= \frac{\partial F(y)}{\partial y} = (1-2y) * [z * (-P_B + N_B) + x * \alpha S_B + U_B - C_B + B]. \end{aligned} \quad (6)$$

According to the stability theorem of the replication dynamic equation, the evolutionary stability strategy of the consumer must be satisfied with the conditions that  $F(y) = 0$  and  $F'_y(y) < 0$ . And the threshold of the consumer strategy transformation is  $z^* = (-x * \alpha S_B + C_B - U_B - B) / (N_B - P_B)$ .

**Proposition 2.** *In the evolution process, when  $0 < z^* < z < 1$ , the stabilization strategy of consumer is participation. When*

$0 < z^* < z < 1$ , the stabilization strategy of consumer is nonparticipation.

*Proof:* Assume  $G(z) = z * (-P_B + N_B) + x * \alpha S_B + U_B - C_B + B$ ; when  $N_B > P_B$ ,  $C_B - U_B - B > \alpha S_B$ ,  $G(z)$  is considered to be an increasing function of  $z$ . When  $z > z^*$ ,  $G(z) > 0$ ,  $F(y)|_{y=1} = 0$ , and  $F'_y(y)|_{y=1} < 0$ , then  $y = 1$  is the stabilization point; that is, consumer participation is the

stabilization strategy; when  $z < z^*$ ,  $G(z) < 0$ ,  $F(y)|_{y=0} = 0$ , and  $F'_y(y)|_{y=0} < 0$ ,  $y = 0$  is the stabilization point; that is, the nonparticipation of the consumer is the stabilization strategy; when  $z = z^*$ ,  $y$  is stable in the interval from 0 to 1; that is, regardless of the initial proportion of the strategy selected by the consumer, the consumer will not change the strategy.

Proposition 2 shows that the strategic choice of the landlord will affect the consumer's choice. When the cross-network externalization utility gained by the consumer with the landlord on the shared platform is more than the fees paid by the consumer participating in the shared accommodation platform, with the increase of the landlord's share, the consumer's stabilization strategy will be changed from nonparticipation to participation. Similarly, the decrease in landlord's share will change the consumer's stabilization strategy from participation to nonparticipation. Therefore, to promote consumer participation in shared accommodation, the platform should take proactive measures to allow more landlords to share their rooms and improve the network cross-externalities utility between consumers and landlords to make it habitual for consumers to participate in shared accommodation.

The phase diagram of the strategic evolution of the consumer is shown in Figure 3.

Figure 3 shows that the volume of  $V_3$  represents the proportion of consumers participating in shared accommodation, and the volume of  $V_4$  represents the proportion of consumers nonparticipation in shared accommodation, which is calculated as follows:

$$V_3 = \int_0^1 \int_{-C_B+U_B+B/\alpha S_B}^1 \frac{-x * \alpha S_B + C_B - U_B - B}{N_B - P_B} dx dy \quad (7)$$

$$= \frac{2a_2 * b_2 - a_2^2 - b_2^2}{2a_2 * c_2},$$

$$V_4 = 1 - V_3, \quad (8)$$

where  $a_2 = \alpha S_B$ ,  $b_2 = C_B - U_B - B$ , and  $c_2 = N_B - P_B$ .

**Corollary 2.** *The proportion of consumer participation in shared accommodation is positively correlated with the subsidy amount given to consumers by the platform, the utility of platform service for the consumer, the fees paid by consumers for renting rooms through offline channels, and the cross-network externalization utility gained by consumers with landlords on the shared platform. The proportion of consumer participation in shared accommodation is negatively correlated with the consumers' time cost and the fees paid by consumers participating in shared accommodation platforms.*

*Proof:* According to the formula (8), when  $C_B > U_B + B$ ;  $C_B - U_B - B > N_B - P_B$ , the first-order partial derivative of each element is obtained as follows:  $(\partial V_3 / \partial \alpha S_B) > 0$ ,  $(\partial V_3 / \partial C_B) < 0$ ,  $(\partial V_3 / \partial U_B) > 0$ ,  $(\partial V_3 / \partial B) > 0$ ,  $(\partial V_3 / \partial N_B) > 0$ , and  $(\partial V_3 / \partial P_B) < 0$  (see Appendix B). Therefore, the increase of  $\alpha S_B$ ,  $U_B$ ,  $B$ , and  $N_B$  and the decrease of  $C_B$  and  $P_B$  can increase the proportion of consumer participation in shared accommodation.

Corollary 2 shows that, with the increase of the subsidies amount for consumers gained from the platform, the utility of platform services for the consumer, the fees paid for obtaining rooms through offline channels, and the utility of cross-network externalities of landlords to consumers, the consumer is more inclined to adopt the participation strategy. As the time cost of consumers and the payment price of consumers' participation in shared accommodation increase, the consumer is more inclined to adopt the nonparticipation strategy.  $\square$

**3.4.3. Stability Analysis of Landlord Strategies.** The expected utility of the landlord choosing to share the rooms is  $\pi_z$ , the expected utility of the landlord choosing to unshare the rooms is  $\pi_{1-z}$ , then the average expected utility of landlord is  $\bar{\pi}_z$ , and  $\bar{\pi}_z = z\pi_z + (1-z)\pi_{1-z}$ , which are defined as follows:

$$\begin{aligned} \pi_z &= xy * (\phi P_B + \beta S_L + N_L + U_L - C_L - P_L) + (1-x)(1-y) * (U_L - C_L - P_L) \\ &\quad + x(1-y) * (\beta S_L + U_L - C_L - P_L) + (1-x)y * [\phi P_B + N_L + U_L - C_L - P_L], \quad (9) \\ \pi_{1-z} &= xy * A + (1-x)y * A + x(1-y) * A + (1-x)(1-y) * A. \end{aligned}$$

According to the Malthusian dynamic equation, the replication dynamic equation of landlord is obtained:

$$F(z) = \frac{dz}{dt} = z(1-z) * [y * (\phi P_B + N_L) + x * \beta S_L + U_L - C_L - P_L - A], \quad (10)$$

$$F'_z(z) = \frac{\partial F(z)}{\partial z} = (1-2z) * [y * (\phi P_B + N_L) + x * \beta S_L + U_L - C_L - P_L - A].$$

FIGURE 3: Phase diagram of the evolution of the consumer's strategy. (a)  $z = ((-x * \alpha S_B + C_B - U_B - B)/(N_B - P_B))$ , (b)  $z > ((-x * \alpha S_B + C_B - U_B - B)/(N_B - P_B))$ , and (c)  $z < ((-x * \alpha S_B + C_B - U_B - B)/(N_B - P_B))$ .

According to the stability theorem of the replication dynamic equation, the evolutionary stability strategy of the landlord must be satisfied with the conditions that  $F(z) = 0$  and  $F'_z(z) < 0$ . And the threshold of the consumer strategy transformation is  $x^* = (-y * (\phi P_B + N_L) - U_L + C_L + P_L + A)/\beta S_L$ .

**Proposition 3.** *In the evolution process, when  $0 < x^* < x < 1$ , the stabilization strategy of landlord is sharing. When  $0 < x < x^* < 1$ , the stabilization strategy of landlord is unsharing.*

*Proof:* Assume  $G(x) = y * (\phi P_B + N_L) + x * \beta S_L + U_L - C_L - P_L - A$ ; when  $C_L + P_L + A - U_L > \phi P_B + N_L$ ,  $G(x)$  is considered to be an increasing function of  $x$ . When  $x > x^*$ ,  $G(x) > 0$ ,  $F(z)|_{z=1} = 0$ , and  $F'_z(z)|_{z=1} < 0$ ,  $z = 1$  is the stabilization point; that is, the share of the landlord is the stabilization strategy; when  $x < x^*$ ,  $G(x) < 0$ ,  $F(z)|_{z=0} = 0$ , and  $F'_z(z)|_{z=0} < 0$ ,  $z = 0$  is the stabilization point; that is, the

unshare of the landlord is the stabilization strategy; when  $x = x^*$ ,  $z$  is in an evolutionary stabilization state; that is, regardless of the initial proportion of the strategy selected by the landlord, the landlord will not change the strategy.

Proposition 3 shows that the strategy choice of shared accommodation platforms will affect the choice of the landlord. The increase in the proportion of the platform subsidy will change the landlord's stabilization strategy from nonsharing to sharing. Similarly, the reduction of the platform subsidy proportion will change the landlord's stabilization strategy from sharing to nonsharing. Therefore, platform subsidy is a powerful means to promote landlords to share.

The phase diagram of the strategic evolution of the landlord is shown in Figure 4.

Figure 4 shows that the volume of  $V_5$  represents the proportion of the landlord sharing the rooms, and the volume of  $V_6$  represents the proportion of the landlord unsharing the rooms, which is calculated as follows:

$$V_5 = \int_0^1 \int_{-U_L+C_L+P_L+A/\phi P_B+N_L}^1 \frac{-y * (\phi P_B + N_L) - U_L + C_L + P_L + A}{\beta S_L} dy dz = \frac{2a_3 * b_3 - a_3^2 - b_3^2}{2a_3 * c_3}, \quad (11)$$

$$V_6 = 1 - V_5, \quad (12)$$

where  $a_3 = \beta S_L$ ,  $b_3 = -U_L + C_L + P_L + A$ , and  $c_3 = \phi P_B + N_L$ .

**Corollary 3.** *The proportion of the landlord sharing rooms in the shared accommodation platform is positively correlated with the subsidy amount of the platform to landlords, the utility of platform service for the landlord, the fees paid by consumers participating in shared accommodation platforms, and the cross-network externalities utility gained by landlords with consumers on the shared platform. The proportion of the landlord sharing rooms is negatively correlated with the income by the landlord with unsharing room in the platform, the cost of room and service provided by the landlord, and the fees charged to landlords for the platform services.*

*Proof:* According to the formula (11), when  $C_L + P_L + A > U_L$  and  $C_L + P_L + A - U_L > \beta S_L$ , the first-order partial

derivative of each element is obtained:  $(\partial V_5 / \partial \beta S_L) > 0$ ,  $(\partial V_5 / \partial C_L) < 0$ ,  $(\partial V_5 / \partial P_L) < 0$ ,  $(\partial V_5 / \partial A) < 0$ ,  $(\partial V_5 / \partial U_L) > 0$ ,  $(\partial V_5 / \partial \phi P_B) > 0$ , and  $(\partial V_5 / \partial N_L) > 0$  (see Appendix C). Therefore, the increase of  $\beta S_L$ ,  $U_L$ ,  $\phi P_B$ , and  $N_L$  and the decrease of  $A$ ,  $C_L$ , and  $P_L$  can increase the proportion of the landlord participating in the shared rooms.

Corollary 3 shows that, with the increase of subsidy amount of the platform to landlords, the utility of platform service for the landlord, the fees paid by consumers participating in shared accommodation platform, and the utility of cross-network externalities of consumers to landlords, the landlord is more inclined to adopt the share strategy. As the increase of the income by the landlord with unsharing room, the cost of room and service provided by the landlord, and the fees charged to landlords for the platform services, the landlord is more inclined to adopt the nonshare strategy.  $\square$

FIGURE 4: Phase diagram of evolution strategy of the landlord. (a)  $x = ((C_L + P_L + A - y * (\phi P_B + N_L) - U_L) / \beta S_L)$ , (b)  $x > ((C_L + P_L + A - y * (\phi P_B + N_L) - U_L) / \beta S_L)$ , and (c)  $x < ((C_L + P_L + A - y * (\phi P_B + N_L) - U_L) / \beta S_L)$ .

## 4. Results and Discussion

**4.1. Strategy Portfolio Stability Analysis.** In the dynamic system of the shared accommodation platform, consumers, and landlords, the stability of the strategic combination of the three-party evolutionary game can be referred to Liapunov's nonlinear function stability discriminant method. When all eigenvalues of the Jacobi matrix are less than zero, the equilibrium point must be asymptotically stabilization; when the first-order bias of the matrix is positive or semipositive and one or two of the eigenvalues of the Jacobi matrix are greater than zero, the equilibrium point is the unstable point or the saddle point. Therefore, in the three-party evolutionary game, the stability of the eight pure strategy equilibrium will be analyzed in this paper. That is,  $E1(0, 0, 0)$ ,  $E2(1, 0, 0)$ ,  $E3(0, 1, 0)$ ,  $E4(0, 0, 1)$ ,  $E5(1, 1, 0)$ ,  $E6(1, 0, 1)$ ,  $E7(0, 1, 1)$ , and  $E8(1, 1, 1)$ .

According to the dynamic equations of each game subject, the Jacobian matrix is obtained as follows:

$$J = \begin{bmatrix} F'_x(x) & F'_y(x) & F'_z(x) \\ F'_x(y) & F'_y(y) & F'_z(y) \\ F'_x(z) & F'_y(z) & F'_z(z) \end{bmatrix}, \quad (13)$$

where the values of the Jacobi matrix are shown in Appendix D and the Jacobian matrix of the equilibrium point is shown in Appendix E.

According to the Jacobian matrix, the stability analysis of the equilibrium point of the three-party evolutionary game can be obtained, and it is shown in Table 3.

When condition I is satisfied, that is  $\alpha S_B + U_B - C_B < B$ ;  $\beta S_L + U_L - C_L - P_L < A$ , the dynamic system has a stable point, that is,  $E2(1, 0, 0)$ . The consumer chooses not to participate in shared accommodation when the sum of the subsidy amount and the net utility gained by consumers from the platform is less than the fees paid by consumers for renting rooms through offline channels. The landlord chooses to unshare the rooms when the sum of the subsidy amount and the net utility gained by the landlord from the platform is less than the income by the landlord with unsharing room in the platform. The stable strategy of sharing accommodation platforms is the subsidy. This may happen in the early stage of the development of shared accommodation. When shared accommodation platform is just getting started, landlords and consumers do not know

enough about shared accommodation. The platform adopts a subsidy strategy to attract landlords and consumers. When the shared accommodation platform has just started, the platform adopts the subsidy strategy to attract landlords and consumers to join in because of their insufficient awareness of shared accommodation.

When condition II is satisfied, that is  $\alpha S_B + \beta S_L - R_B - R_L < H$ ;  $P_B + C_B - B < N_B + \alpha S_B + U_B$ ;  $C_L + P_L + A < \phi P_B + \beta S_L + N_L + U_L$ , the dynamic system has a stable point, that is,  $E8(1, 1, 1)$ . The shared accommodation platform chooses the subsidy strategy when the difference between the total subsidy amount and the reputational benefits of the platform is less than the opportunity loss of platform nonsubsidizing. The consumer chooses to participate in shared accommodation when the difference between the time cost and the fees of consumers in the shared accommodation platform and the fees paid by the consumer for renting rooms through offline channels is less than the utility and benefit that the consumer obtains on the sharing platform. The landlord chooses to share the rooms when the utility and benefit that the landlord obtains on the sharing platform are more than the sum of the cost paid by the landlord on the sharing platform and the income by the landlord with unsharing room in the platform. This may happen during the rapid development of shared accommodation platform. The platform develops appropriate subsidy strategies, such as issuing coupons and cash rewards, to promote more consumers to participate in shared accommodation and landlords to share the rooms, which make landlords and consumers form the habits of participating in sharing accommodation.

When condition III is satisfied, that is  $\alpha S_B + \beta S_L - R_B - R_L > H$ ;  $P_B + C_B - B < N_B + U_B$ ;  $C_L + P_L + A < \phi P_B + N_L + U_L$ , the replicated dynamic system has a stable point, that is,  $E7(0, 1, 1)$ . The shared accommodation platform chooses the subsidy strategy when the difference between the total subsidy amount and the reputational benefits of the platform is more than the opportunity loss of platform nonsubsidizing. The consumer chooses to participate in shared accommodation when the difference between the time cost and the fees of consumers in the shared accommodation platform and the fees paid by the consumer for renting rooms through offline channels is less the utility gained by consumers on the shared platform. The landlord chooses to share the rooms when the utility and benefit that

TABLE 3: Stability analysis of equilibrium point of evolutionary game.

Equilibrium point	Eigenvalue symbol	Stability of the equilibrium point	Condition
$E1(0, 0, 0)$	$(+, +, -)$	Saddle point	\
$E2(1, 0, 0)$	$(-, X, X)$	ESS	I
$E3(0, 1, 0)$	$(+, +, -)$	Saddle point	\
$E4(0, 0, 1)$	$(+, -, +)$	Saddle point	\
$E5(1, 1, 0)$	$(+, +, -)$	Unstable point	\
$E6(1, 0, 1)$	$(-, X, +)$	Unstable point	\
$E7(0, 1, 1)$	$(X, X, X)$	ESS	III
$E8(1, 1, 1)$	$(X, X, X)$	ESS	II

Note.  $X$  means uncertainty of symbol, and ESS means the evolutionarily stable strategy. Condition I:  $\alpha S_B + U_B - C_B < B$ ;  $\beta S_L + U_L - C_L - P_L < A$ . Condition II:  $\alpha S_B + \beta S_L - R_B - R_L < H$ ;  $P_B + C_B - B < N_B + \alpha S_B + U_B$ ;  $C_L + P_L + A < \phi P_B + \beta S_L + N_L + U_L$ . Condition III:  $\alpha S_B + \beta S_L - R_B - R_L > H$ ;  $P_B + C_B - B < N_B + U_B$ ;  $C_L + P_L + A < \phi P_B + N_L + U_L$ .

the landlord obtains on the sharing platform are more than the sum of the cost paid by the landlord on the sharing platform and the income by the landlord with unsharing room in the platform. This may happen in the mature stage of shared accommodation platform development. The landlords and the consumers have already understood shared accommodation, and the platform has developed a series of sound policies to push the information and serve the landlords and consumers. The platforms can make considerable gains by choosing nonsubsidizing.

**4.2. Simulation Analysis.** In order to test the reliability of the model and to more intuitively observe the evolution trajectory of stakeholders and their sensitivity to parameters, this paper uses MATLAB2016 to simulate the evolution stability strategy and related parameters.

**4.2.1. Model Testing.** When condition I is satisfied, the simulation parameters are set as follows:  $C_P = 5$ ,  $C_B = 11$ ,  $C_L = 3$ ,  $R_B = R_L = 2$ ,  $S_B = S_L = 5$ ,  $P_L = P_B = 5$ ,  $\alpha = 0.1$ ,  $\beta = 0.3$ ,  $\phi = 0.7$ ,  $A = H = 3$ ,  $B = 6$ ,  $N_B = 6$ ,  $N_L = 2$ ,  $U_B = 1$ , and  $U_L = 3$ . Selecting four different initial strategies, all four groups of initial strategies all evolve towards  $E2(1, 0, 0)$ , and the results of simulation and evolution with time are shown in Figure 5.

It can be seen from Figure 5 that when shared accommodation platform is in the early stage of development, the consumer and landlord do not have a certain understanding of the sharing accommodation platform. For the needs of market expansion, shared accommodation platform subsidizes consumers and landlords to promote them to join the shared accommodation platform.

When condition II is satisfied, the simulation parameters are set as follows:  $C_B = 8$ ,  $P_L = 3$ ,  $\alpha = 0.6$ , and  $\beta = 0.5$ , and other parameters are the same with the equilibrium point  $E2(1, 0, 0)$ . Selecting four different initial strategies, all four groups of initial strategies all evolve towards  $E8(1, 1, 1)$ , and the results of simulation and evolution with time are shown in Figure 6.

It can be seen from Figure 6 that, with the reduction of the time cost of the consumer participating in shared accommodation and the increase of the service utility and the subsidies to consumers by the platform, the actual cost of consumer participating in shared accommodation is less

than the cost through offline channels. Therefore, the consumer will choose to participate in shared accommodation platform. With the increase of the subsidy to the landlord and reduction of the service fee for the landlord to participate in the shared accommodation platform, the landlord's revenue from shared rooms is more than the loss of the landlord's inventory for nonparticipating in sharing rooms. The landlord will adopt the strategy to actively join the shared accommodation platform to share rooms. In the end, the platform, consumers, and landlords will tend to adopt the positive strategies.

When condition III is satisfied, the simulation parameters are set as follows:  $C_L = 1$ ,  $P_B = 3$ ,  $\phi = 0.9$ , and  $H = 1$ , and other parameters are the same with the equilibrium point  $E8(1, 1, 1)$ . Selecting four different initial strategies, all four groups of initial strategies all evolve towards  $E7(0, 1, 1)$ , and the results of simulation and evolution with time are shown in Figure 7.

It can be seen from Figure 7 that, with the reduction of the time cost for consumers and the fees of the landlords to participate in shared accommodation, the consumer and landlord are promoted to participate in the shared accommodation platform. When the consumers and landlords become accustomed to participating in the shared accommodation platform to reduce the opportunity loss of platform nonsubsidizing, the platform can appropriately reduce the subsidies and the cost paid by consumers to participate in shared accommodation and increase the share of the revenue for landlords. Consumers and landlords will still choose to participate in shared accommodation. In the mature stage of the development of the shared accommodation platform, the platform can set the reasonable price for consumers and the preferential proportion of the landlord's share in expenses under the nonsubsidy policy, the landlords, and consumers can continue to participate in the shared accommodation to maximize the interests of all three parties.

**4.2.2. The Influence of Different Subjects' Initial Willingness to Participate.** The initial proportions of the strategies of the shared accommodation platform, the consumer, and the landlord are set as follows:  $(0.2, 0.2, 0.2)$ ,  $(0.5, 0.5, 0.5)$ , and  $(0.9, 0.9, 0.9)$ . The stability of the system evolution is shown in Figure 8.

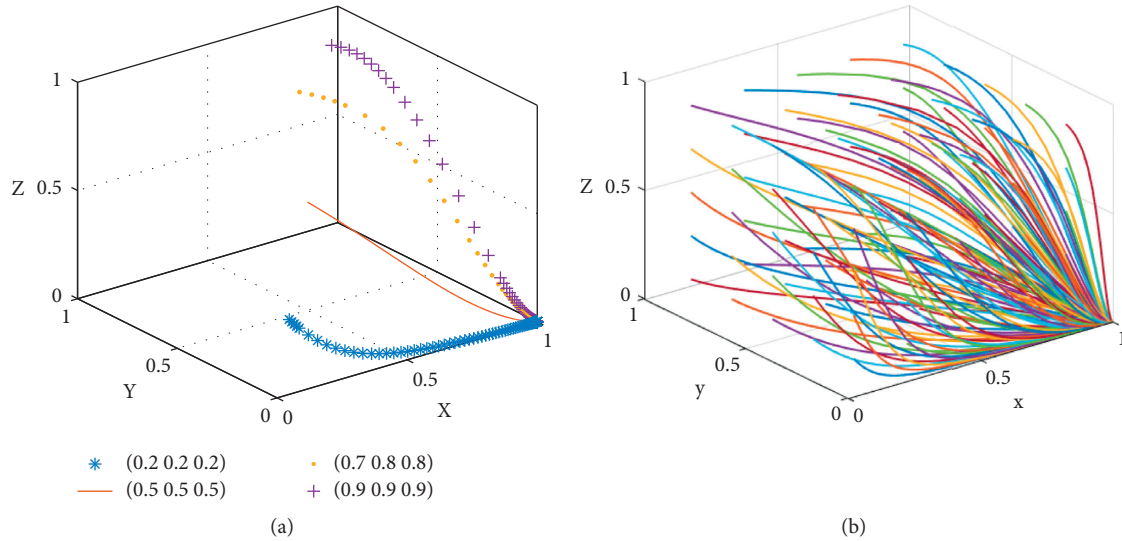

FIGURE 5: Evolutionary equilibrium diagram at the point  $E2(1, 0, 0)$ .

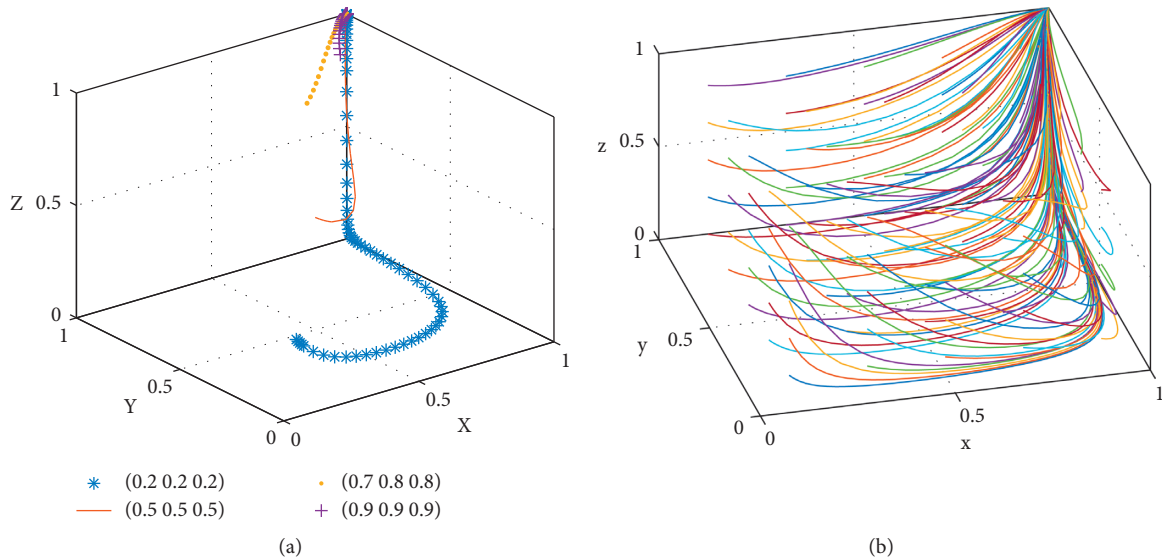

FIGURE 6: Evolutionary equilibrium diagram at the point  $E8(1, 1, 1)$ .

It can be seen from Figure 8 that, under the parameter conditions of the evolutionary stability strategy  $E8(1, 1, 1)$ , the behavioral strategies of the shared accommodation platform, consumers, and landlords finally evolve into the strategies of “subsidy,” “participation,” and “share” with the initial proportions of the strategies of  $(0.2, 0.2, 0.2)$ ,  $(0.5, 0.5, 0.5)$ , and  $(0.9, 0.9, 0.9)$ . This indicates that the stable state of the system is independent of the initial proportions of the strategies. Further analysis reveals that, in the case of low initial willingness to participate, landlords choose the unsharing strategy because they can obtain the rental income of the rooms in other ways. When the platform’s subsidy for consumers and landlords increases and the time cost of consumers and landlords’ service fees to participate in shared accommodation platform decreases, the consumer chooses to participate, and landlord will choose to share. When the initial willingness of the platform, consumer,

and landlord is high, all three participants will continue to evolve steadily to the strategies of “subsidy,” “participation,” and “share.” The closer the initial proportion is to the proportion of an evolutionary stable state, the shorter the time for evolution to reach the stable state is.

*4.2.3. The Influence of the Proportion of Subsidies Provided by the Platform to Consumers.* If  $\alpha = \{0.1, 0.4, 0.6\}$ , the stabilization strategy of each participant is obtained as shown in Figure 9.

From Figure 9, it can be seen that, with the increase of the proportion of subsidy to the consumer, the evolutionary stability strategy transitions from  $E2(1, 0, 0)$  to  $E8(1, 1, 1)$ . The critical value of the proportion of subsidy to consumers is between 0.4 and 0.6. When the proportion of subsidies to the

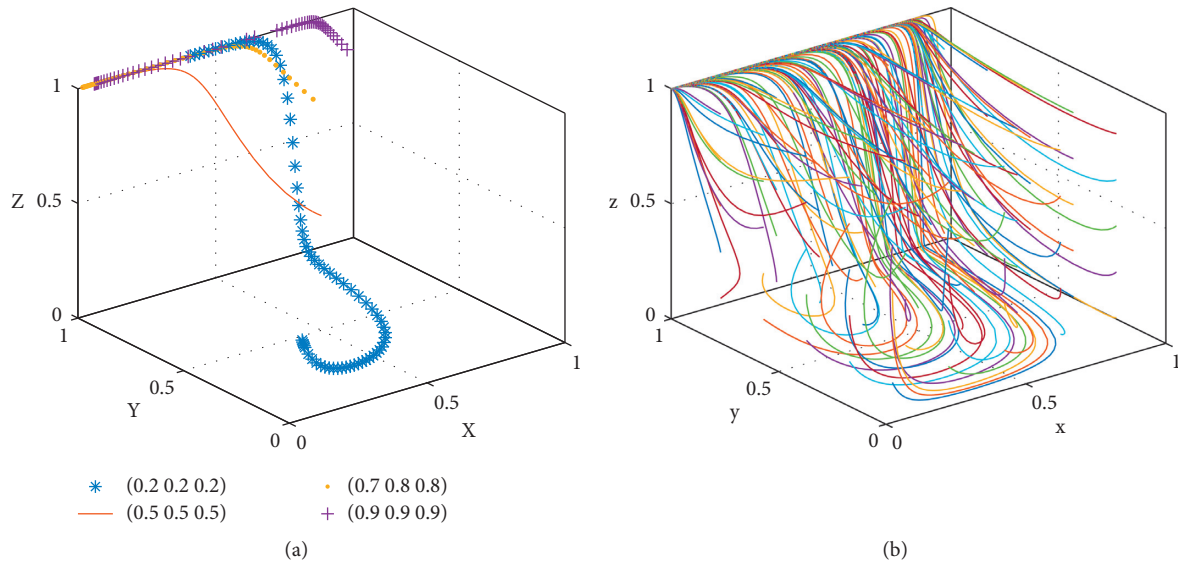

FIGURE 7: Evolutionary equilibrium diagram at the point  $E7(0, 1, 1)$ .

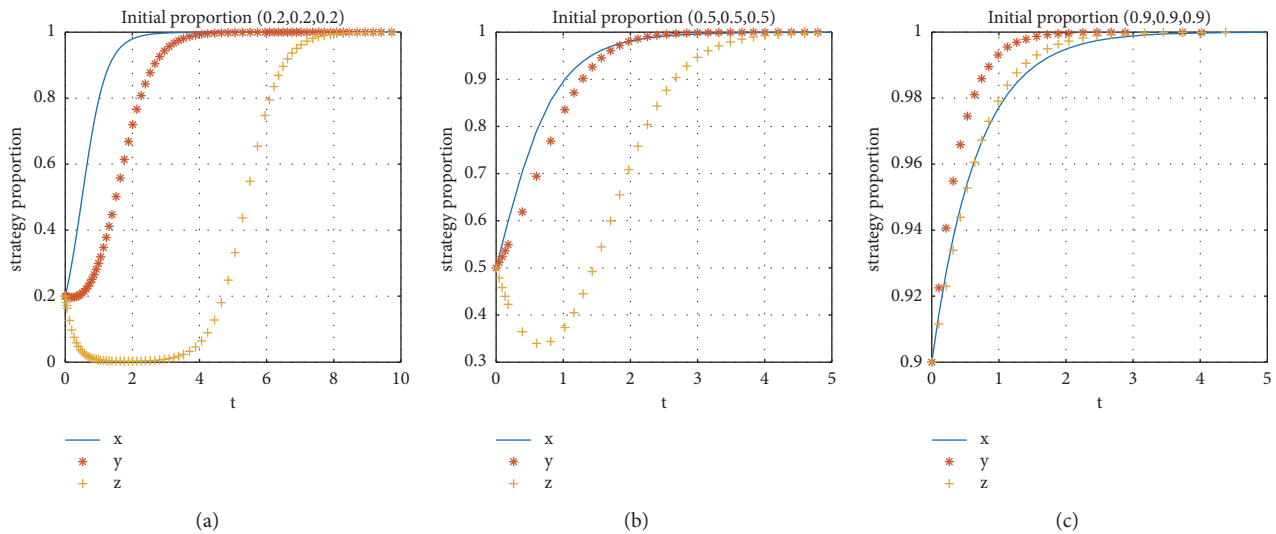

FIGURE 8: Influence of different subjects' initial willingness to participate on the evolutionary.

consumer is larger than the critical value, the evolutionary stability strategy of the three-party game converges to  $E8(1, 1, 1)$ , and the larger the proportion of consumer subsidies is, the faster the evolutionary stability strategy converges. When the proportion of consumer subsidies is less than the critical value, consumer chooses not to participate in the shared accommodation platform, the landlords choose to unshare the rooms, and the time for the landlord to reach stability is faster than that for consumers. Therefore, the platform can increase the proportion of subsidy for consumers to promote the participation of the consumer and the landlord.

**4.2.4. The Influence of the Proportion of Subsidies Provided by the Platform to Landlords.** If  $\beta = \{0.3, 0.5, 0.6\}$ , the stabilization strategy of each participant is obtained as shown in Figure 10.

From Figure 10, it can be seen that, with the increase of the proportion of the subsidy to the landlord, the evolutionary stability strategy transitions from  $E2(1, 0, 0)$  to  $E8(1, 1, 1)$ . The critical value of the proportion of the subsidy to the landlord is between 0.5 and 0.6. When the proportion of subsidies to the landlord is larger than the critical value, the evolutionary stability strategy of the three-party game converges to  $E8(1, 1, 1)$ , and the larger the proportion of landlord subsidies is, the faster the evolutionary stability strategy converges. When the proportion of subsidies to the landlord is less than the critical value, the consumer chooses not to participate in the shared accommodation, the landlord chooses to unshare the rooms, and the time for the landlord to reach stability is slower than that for the consumer to reach stability. It is a benefit for landlords to participate in the shared accommodation platform to increase the subsidies to landlords. Therefore, in the early stage of the platform's development, choosing the more

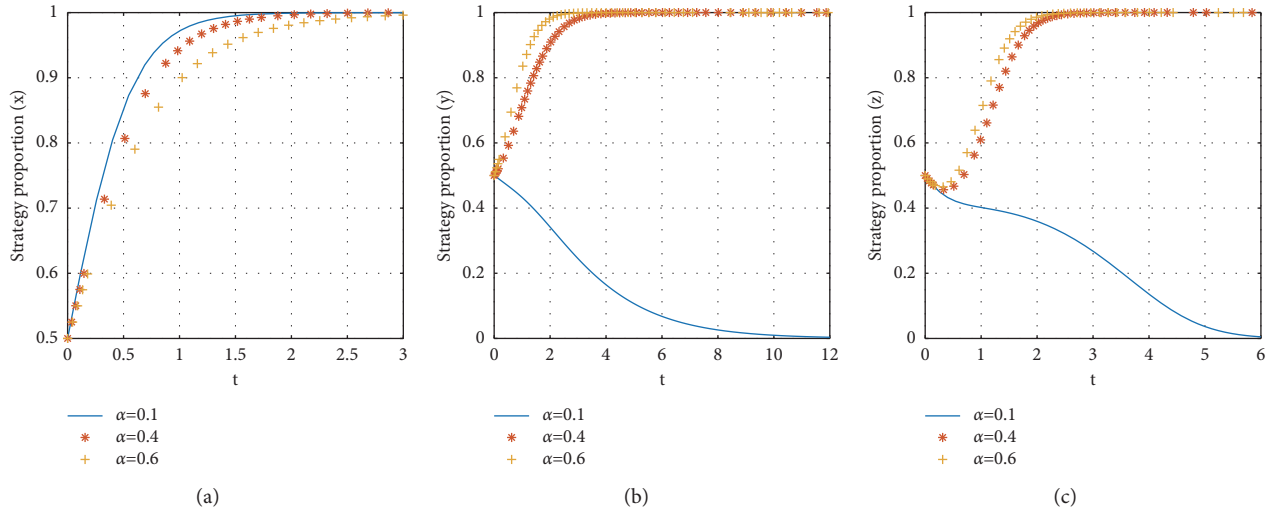

FIGURE 9: The influence of the proportion of subsidies to the consumer on evolutionary stabilization strategies of subject behaviors.

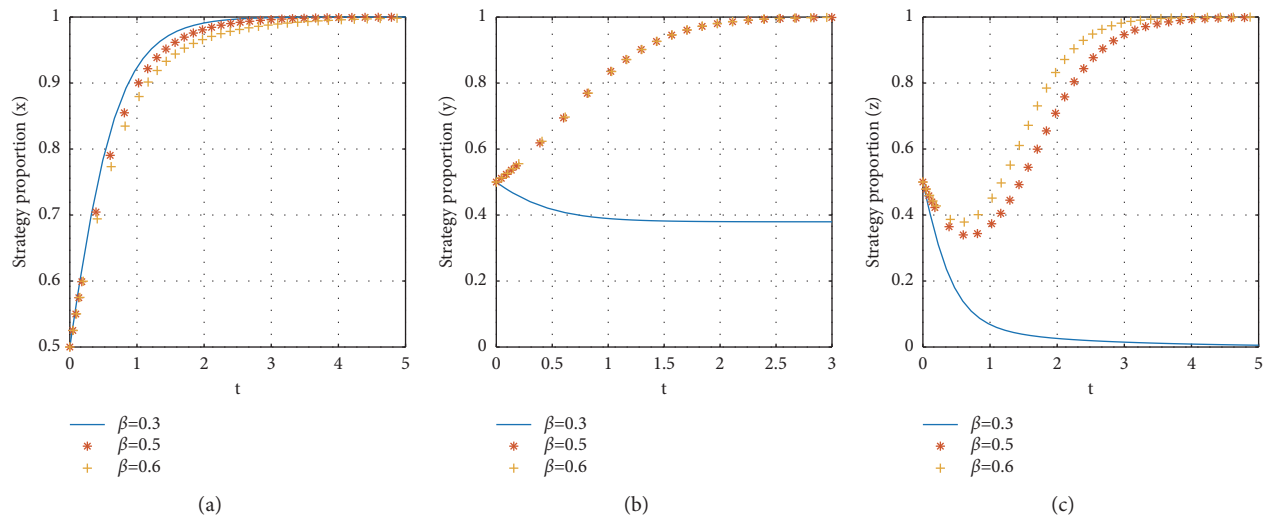

FIGURE 10: The influence of the proportion of subsidies to the landlord on evolutionary stabilization strategies of subject behaviors.

share of subsidy to the landlord can promote consumers and landlords to join the shared accommodation platform more quickly.

4.2.5. *The Influence of the Fees Charged to Landlords for the Platform Services.* If  $P_L = \{3, 4, 5\}$ , the stabilization strategy of each participant is obtained as shown in Figure 11.

From Figure 11, it can be seen that, with the decrease of the fees charged to landlords for the platform services, the evolutionary stability strategy transitions from  $E2(1, 0, 0)$  to  $E8(1, 1, 1)$ . The critical value of the fees charged to landlords for the platform services is between 4 and 5. When the fees to the landlord for the platform services are less than the critical value, the evolutionary stability strategy of the three-party game converges to  $E8(1, 1, 1)$ , and the less the fees to the

landlord for the platform services are, the faster the evolutionary stability strategy converges. When the fees to the landlord for the platform services are more than the critical value, the consumer chooses not to participate in shared accommodation, the landlord chooses to unshare the rooms, and the time for the landlord to reach stability is slower than that for the consumer to reach stability. Therefore, in the early stage of the platform’s development, charging fewer fees to landlords for the platform services can promote consumers and landlords to join the shared accommodation platform more quickly.

4.2.6. *The Influence of the Time Costs of the Consumer.* If  $C_B = \{8, 9, 10\}$ , the stabilization strategy of each participant is obtained as shown in Figure 12.

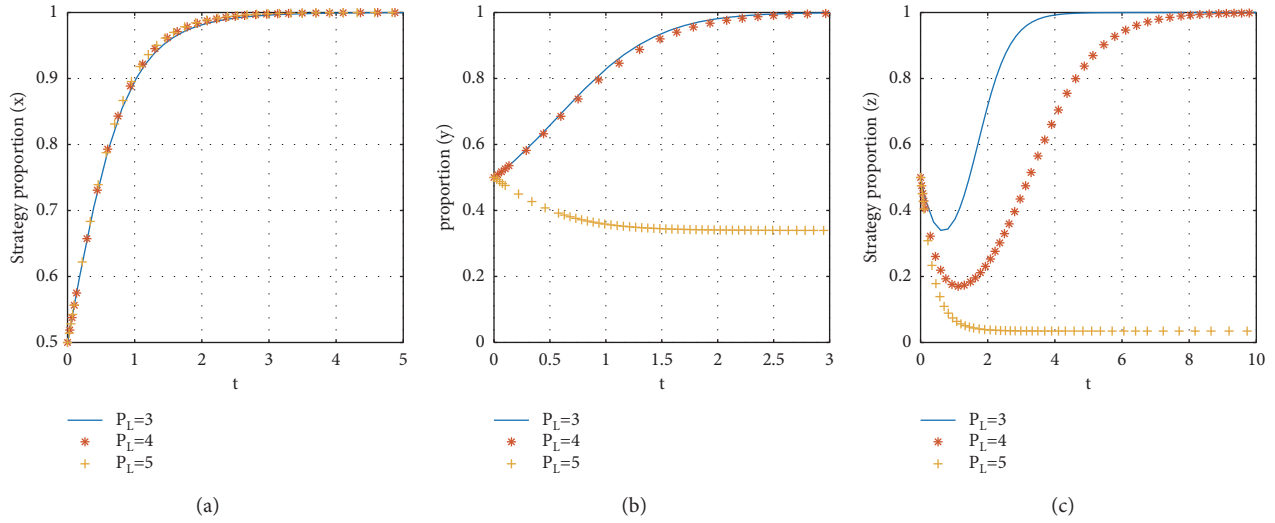

FIGURE 11: The influence of the fees to the landlord for the platform services on evolutionary stabilization strategies of subject behaviors.

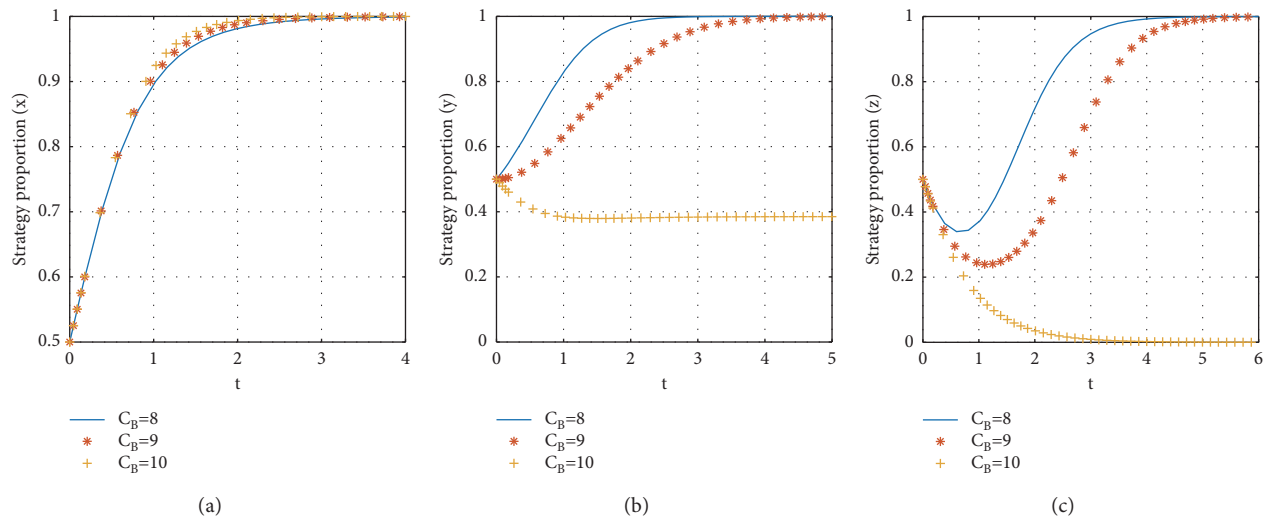

FIGURE 12: The influence of the consumer's time costs on evolutionary stabilization strategies of subject behaviors.

From Figure 12, it can be seen that, with the decrease of the consumer's time costs, the evolutionary stability strategy transitions from  $E2(1, 0, 0)$  to  $E8(1, 1, 1)$ . The critical value of the time cost of the consumer to participate in the shared accommodation platform is between 9 and 10. When the time costs of the consumer are less than the critical value, the evolutionary stability strategy of the three-party game converges to  $E8(1, 1, 1)$ , and the less the consumer's time costs are, the faster the evolutionary stability strategy converges. When the consumer's time costs are more than the critical value, the consumer chooses not to participate in the shared accommodation, the landlord chooses to unshare the rooms, and the time for the landlord to reach stability is slower than the time for the consumer to reach stability. Therefore, in the early stage of the platform's development, decreasing the time costs of the consumer can promote

consumers and landlords to join the shared accommodation platform more quickly.

4.2.7. *The Influence of the Proportion of Landlord's Share in Expenses Paid by Consumers.* If  $\phi = \{0.7, 0.8, 0.9\}$ , the stabilization strategy of each participant is obtained as shown in Figure 13.

From Figure 13, it can be seen that, with the increase of the proportion of landlords' share in expenses, the evolutionary stability strategy transitions from  $E8(1, 1, 1)$  to  $E7(0, 1, 1)$ . The critical value of the proportion of the landlord's share in expenses paid by consumers is between 0.7 and 0.8. When the proportion of the landlord's share in expenses is less than the critical value, the evolutionary stability strategy of the three-party game converges to  $E8(1, 1, 1)$ . When the value of the proportion

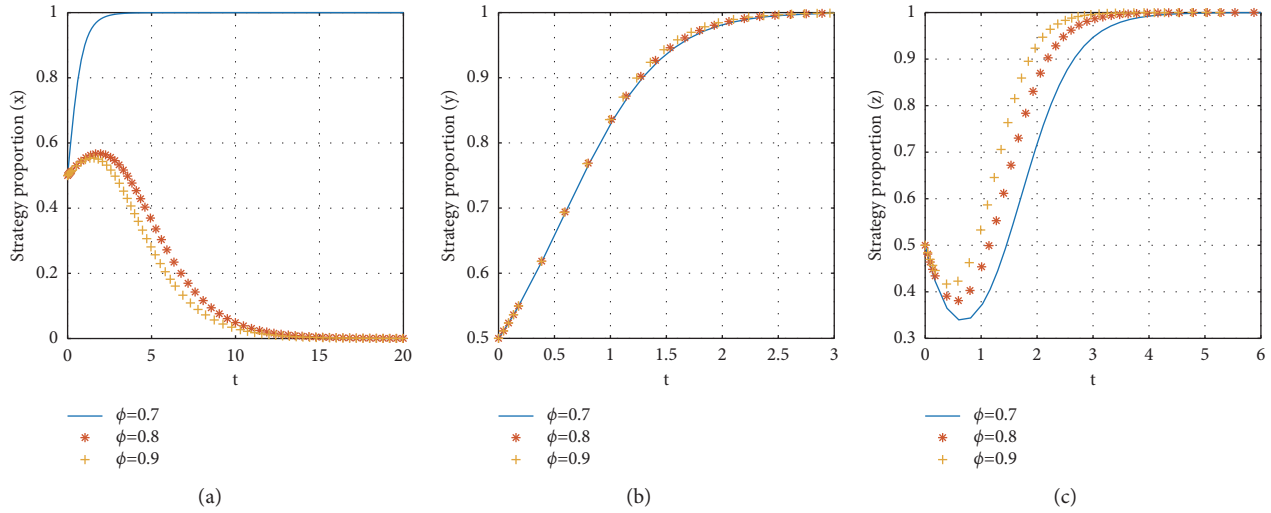

FIGURE 13: The influence of the proportion of landlord’s share in expenses on evolutionary stabilization strategies of subject behaviors.

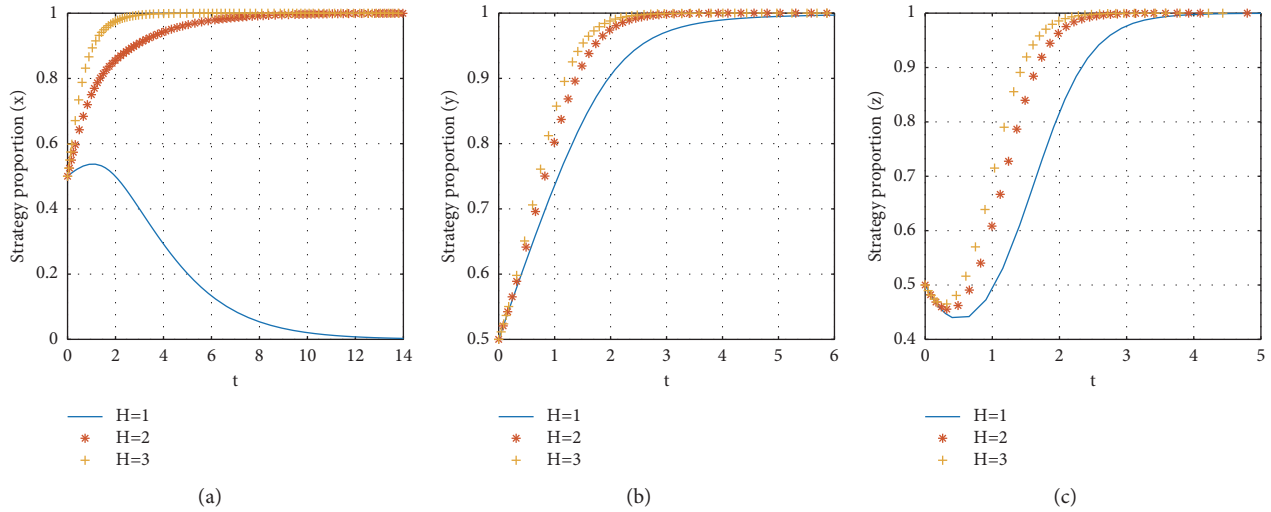

FIGURE 14: The influence of the platform’s opportunity loss on evolutionary stabilization strategies of subject behaviors.

of the landlord’s share in expenses is larger than the critical value, the shared accommodation platform chooses the non-subsidy strategy. And the larger the proportion of the landlord’s share in expenses is, the faster the evolutionary stability strategy of the shared accommodation platform converges. Therefore, in the rapid development of shared accommodation platforms, increasing the proportion of landlords’ share in expenses to meet the interests of landlords can stabilize the choice of the landlord participating in the shared accommodation platform. When the net income of landlords and consumers reaches a certain level with the increase of the scale, the shared accommodation platform can achieve the optimization of system benefits with nonsubsidizing.

4.2.8. *The Influence of the Opportunity Loss of Platform Nonsubsidizing.* If  $H = \{1, 2, 3\}$ , the stabilization strategy of each participant is obtained as shown in Figure 14.

From Figure 14, it can be seen that, with the decrease of the opportunity loss of platform nonsubsidizing, the evolutionary stability strategy transitions from  $E8(1, 1, 1)$  to  $E7(0, 1, 1)$ . The critical value of the opportunity loss of platform nonsubsidizing is between 1 and 2. When the opportunity loss of platform nonsubsidizing is more than the critical value, the evolutionary stability strategy of the three-party game converges to  $E8(1, 1, 1)$ . And when the opportunity loss of platform nonsubsidizing is less than the critical value, the shared accommodation platform chooses the nonsubsidy strategy. The less the opportunity loss of platform nonsubsidizing is, the faster the evolutionary stability strategy of the shared accommodation platform converges. Therefore, in the rapid development of shared accommodation platforms, the decrease of the opportunity loss of platform nonsubsidizing indicates that the consumer and landlord have formed the habit of participating in shared accommodation platform, and the

strategy of the platform gradually evolved to the nonsubsidy.

## 5. Conclusions

Internet and big data technologies provide the technological impetus for the development of new economic formats, and effective governance has become the key to the success of platforms [51, 52]. Platform-based companies aim to maximize the revenue of the platform, and gaining economic benefits is also the important intention of each subject to participate in collaborative consumption [53]. Aiming at the subsidy strategy of shared accommodation platform, an evolutionary game model was established, the system stability was analyzed and simulated, and the main conclusions of this paper are as follows:

- (1) The evolutionary stability strategy of the shared accommodation platform based on subsidizing can go through three stages. At the early stage of platform establishment, the shared accommodation platform attracts consumers and landlords to join through subsidizing due to the need for market expansion. At this time, consumers refuse to join the shared accommodation platform for the high time cost, landlords refuse to join for the high service fee paid, and the system will stabilize on the strategic combination of  $E2$ (subsidy, nonparticipation, unsharing). In this state, consumers and landlords have a preliminary understanding and experience of the sharing accommodation platform. When the difference between the time cost and the fees of consumers in the shared accommodation platform and the fees paid by the consumer for renting rooms through offline channels is less than the utility and benefit that the consumer obtains on the sharing platform, the consumer chooses to join the shared accommodation platform. When the utility and benefit that the landlord obtains on the sharing platform are more than the sum of the cost paid by the landlord on the sharing platform and the income by the landlord with unsharing room in the platform, the landlord chooses to join in the shared accommodation platform. At this time, the system stabilizes on the strategic combination of  $E8$ (subsidy, participation, sharing). Due to the influx of landlords and consumers, the shared accommodation platform is expanding rapidly. When the difference between the total subsidy amount and the reputational benefits of the platform is more than the opportunity loss of platform nonsubsidizing, the platform chooses the nonsubsidy strategy. At this time, it is necessary to meet that the utility of consumers and landlords is more than their costs, and the system will stabilize on the strategic combination of  $E7$ (nonsubsidy, participation, sharing). The shared

accommodation platform no longer needs subsidy to attract landlords and consumers and relies on quality services to achieve good operation of the platform, and the shared accommodation platform reaches the mature stage of development. The dynamic change analysis of the strategies in these three stages makes up for the deficiency of the subsidy strategy of the accommodation platform in the existing research.

- (2) When the strategy combination of the three parties transitions from  $E2$ (subsidy, nonparticipation, unshare) to  $E8$ (subsidy, participation, share), it can be achieved by increasing the subsidies to consumers and landlords and reducing consumers' time costs and service fees charged to the landlord. These measures to increase the profits of consumers and landlords and to reduce their losses are all aimed at attracting consumers and landlords to join the shared accommodation platform. This is consistent with the conclusion proposed by Guo et al. [27] that the bilateral platform of the sharing economy can adopt the subsidy strategy.
- (3) When the strategy combination of the three parties transitions from  $E8$ (subsidize, participate, share) to  $E7$ (nonsubsidy, participation, share), it can be achieved by reducing the opportunity loss of platform nonsubsidy and increasing the proportion of the landlord's share in expenses paid by consumers. Therefore, as consumers and landlords form the habit of participating in shared accommodation platform, landlords and consumers can maintain good profits for the three parties through normal transactions so that the loss of the platform nonsubsidy is reduced, and the strategy of the platform is gradually changed from subsidy to nonsubsidy.

In this paper, the evolutionary game model of three parties in the shared accommodation platform is established, and it is found that the subsidy strategy of the shared accommodation platform can encourage consumers and landlords to participate in shared accommodation. By adjusting the subsidies to customers and landlords, the time cost of consumers, the service fees of landlords, the proportion of landlord's share of consumers' fees, and the loss of the platform's nonsubsidy, the evolutionary equilibrium of the game strategy can be changed. This study makes up for the deficiency of three-party game analysis in the existing literature and does in-depth research on sharing economy by using the game theory.

In order to activate the sharing market and further develop the sharing economy platform, the following suggestions are put forward:

- (1) The subsidies can be used by the platform to attract landlords and consumers. When the platform is in the initial development stage, the subsidies are an effective way to expand the number of platform users. However, the specific subsidy amount must be

considered in combination with the use costs of consumers and landlords, and the platform will try to give an attractive subsidy amount. If the construction of the platform goes smoothly, the subsidy policy can also be adjusted to realize the normal operation of the shared accommodation platform.

- (2) In the development process of the platform, by fully excavating the massive and scattered rooms, the diversity of shared accommodation products is ensured to provide consumers with diverse accommodation options. The platform can use information integration to optimize the platform interface for reducing the time for consumers to choose room information. On this basis, the standardization of shared accommodation services is promoted to further improve the quality of products and services.
- (3) The service utility of the platform to the landlords can be increased to maintain the stability of the landlord's rooms in order to ensure the supply for customers. The platform can reduce the service fee charged to the landlord and increase services quality for landlords. For example, Airbnb provides photo services to landlords, smart door locks, face-brushing check-in, and so on. The platform can also establish a quick communication channel between landlords and customers to help landlords reduce communication costs.

This study establishes a three-party game evolution model based on subsidy policies. Due to the limitations of model assumptions, under the condition of asymmetric information and bounded rationality, the benefits of shared accommodation platforms, consumers, and landlords are maximized in subsidy policies, and the possibility of unsuccessful matching between consumers and landlords in the shared accommodation platform is not considered. Therefore, in order to improve the operating mechanism of the shared accommodation platform, it will be the further research direction to consider the role of factors affecting participants' participation in the strategic evolution, such as the possibility of matching between consumers and landlords, as well as the location and facility differences of rooms.

## Appendix

### A. Supplementary Proof of Corollary 1

The proportion of subsidy strategy of shared accommodation platform is  $V_1$ , and the first-order partial derivative of each element is proved as follows:

$$V_1 = \frac{(H + a_1)^2}{2a_1 * b_1}, \quad (\text{A.1})$$

where  $a_1 = R_L - \beta S_L$  and  $b_1 = R_B - \alpha_1 S_B$ .

When  $b_1 < 0$  and  $H + a_1 > 0$ ,

$$\begin{aligned} \frac{\partial V_1}{\partial R_L} &= \left( \frac{(H + a_1)^2}{2a_1 * b_1} \right)' = -\frac{H(H + a_1)}{a_1^2 * b_1} > 0, \\ \frac{\partial V_1}{\partial R_B} &= \left( \frac{(H + a_1)^2}{2a_1 * b_1} \right)' = -\frac{(H + a_1)^2}{2a_1 * b_1^2} > 0, \\ \frac{\partial V_1}{\partial H} &= \left( \frac{(H + a_1)^2}{2a_1 * b_1} \right)' = \frac{H + a_1}{a_1 * b_1} > 0, \\ \frac{\partial V_1}{\partial \beta S_L} &= \left( \frac{(H + a_1)^2}{2a_1 * b_1} \right)' = -\frac{\partial V_1}{\partial R_L} < 0, \\ \frac{\partial V_1}{\partial \alpha S_B} &= \left( \frac{(H + a_1)^2}{2a_1 * b_1} \right)' = -\frac{\partial V_1}{\partial R_B} < 0. \end{aligned} \quad (\text{A.2})$$

### B. Supplementary Proof of Corollary 2

The proportion of participating strategy of the consumer is  $V_3$ , and the first-order partial derivative of each element is proved as follows:

$$V_3 = \frac{2a_2 * b_2 - a_2^2 - b_2^2}{2a_2 * c_2}, \quad (\text{B.1})$$

where  $a_2 = \alpha S_B$ ,  $b_2 = C_B - U_B - B$ , and  $c_2 = N_B - P_B$ .

$$\begin{aligned} \frac{\partial V_3}{\partial \alpha S_B} &= \left( \frac{2a_2 * b_2 - a_2^2 - b_2^2}{2a_2 * c_2} \right)' = \frac{b_2^2 - 2b_2 * c_2 - a_2^2}{2a_2^2 * c_2} > 0, \\ \frac{\partial V_3}{\partial C_B} &= \left( \frac{2a_2 * b_2 - a_2^2 - b_2^2}{2a_2 * c_2} \right)' = \frac{c_2 - b_2}{a_2 * c_2} < 0, \\ \frac{\partial V_3}{\partial U_B} &= \frac{\partial V_3}{\partial B} = \left( \frac{2a_2 * b_2 - a_2^2 - b_2^2}{2a_2 * c_2} \right)' = -\frac{\partial V_3}{\partial C_B} > 0, \\ \frac{\partial V_3}{\partial N_B} &= \left( \frac{2a_2 * b_2 - a_2^2 - b_2^2}{2a_2 * c_2} \right)' = \frac{a_2^2 + b_2^2}{2a_2 * c_2^2} > 0, \\ \frac{\partial V_3}{\partial P_B} &= \left( \frac{2a_2 * b_2 - a_2^2 - b_2^2}{2a_2 * c_2} \right)' = -\frac{\partial V_3}{\partial N_B} < 0. \end{aligned} \quad (\text{B.2})$$

### C. Supplementary Proof of Corollary 3

The proportion of share strategy of the landlord is  $V_5$ , and the first-order partial derivative of each element is proved as follows:

$$V_5 = \frac{2a_3 * b_3 - a_3^2 - b_3^2}{2a_3 * c_3}, \quad (\text{C.1})$$

where  $a_3 = \beta S_L$ ,  $b_3 = -U_L + C_L + P_L + A$ , and  $c_3 = \phi P_B + N_L$ .

$$\frac{\partial V_5}{\partial \beta S_L} = \left[ \frac{2a_3 * b_3 - a_3^2 - b_3^2}{2a_3 * c_3} \right]' = \frac{b_3^2 - 2b_3 * c_3 - a_3^2}{2a_3^2 * c_3} > 0,$$

$$\frac{\partial V_5}{\partial C_L} = \left[ \frac{2a_3 * b_3 - a_3^2 - b_3^2}{2a_3 * c_3} \right]' = \frac{c_3 - b_3}{a_3 * c_3} < 0,$$

$$\frac{\partial V_5}{\partial P_L} = \frac{\partial V_5}{\partial A} = \left[ \frac{2a_3 * b_3 - a_3^2 - b_3^2}{2a_3 * c_3} \right]' = \frac{\partial V_5}{\partial C_L} < 0,$$

$$\frac{\partial V_5}{\partial U_L} = \left[ \frac{2a_3 * b_3 - a_3^2 - b_3^2}{2a_3 * c_3} \right]' = -\frac{\partial V_5}{\partial C_L} > 0,$$

$$\frac{\partial V_5}{\partial \phi P_B} = \left[ \frac{2a_3 * b_3 - a_3^2 - b_3^2}{2a_3 * c_3} \right]' = \frac{a_3^2 + b_3^2}{2a_3 * c_3} > 0,$$

$$\frac{\partial V_5}{\partial N_L} = \frac{2a_3 * b_3 - a_3^2 - b_3^2}{2a_3 * c_3} = \frac{\partial V_5}{\partial \phi P_B} > 0.$$

(C.2)

## D. Jacobian Matrix of Replicator Dynamic System

The elements of the Jacobian matrix is as follows:

$$F(x) = \frac{dx}{dt} = x(1-x) * [y * (R_B - \alpha S_B) + z * (R_L - \beta S_L) + H],$$

$$F'_x(x) = \frac{\partial F(x)}{\partial x} = (1-2x) * [y * (R_B - \alpha S_B) + z * (R_L - \beta S_L) + H],$$

$$F'_y(x) = \frac{\partial F(x)}{\partial y} = x(1-x) * (R_B - \alpha S_B),$$

$$F'_z(x) = \frac{\partial F(x)}{\partial z} = x(1-x) * (R_L - \beta S_L),$$

$$F(y) = \frac{dy}{dt} = y(1-y) * [z * (-P_B + N_B) + x * \alpha S_B + U_B - C_B + B],$$

$$F'_x(y) = \frac{\partial F(y)}{\partial x} = y(1-y) * \alpha S_B,$$

$$F'_y(y) = \frac{\partial F(y)}{\partial y} = (1-2y) * [z * (-P_B + N_B) + x * \alpha S_B + U_B - C_B + B],$$

$$F'_z(y) = \frac{\partial F(y)}{\partial z} = y(1-y) * (-P_B + N_B),$$

$$F(z) = \frac{dz}{dt} = z(1-z) * [y * (\phi P_B + N_L) + x * \beta S_L + U_L - C_L - P_L - A],$$

$$F'_x(z) = \frac{\partial F(z)}{\partial x} = z(1-z) * \beta S_L,$$

$$F'_y(z) = \frac{\partial F(z)}{\partial y} = z(1-z) * (\phi P_B + N_L),$$

$$F'_z(z) = \frac{\partial F(z)}{\partial z} = (1-2z) * [y * (\phi P_B + N_L) + x * \beta S_L + U_L - C_L - P_L - A].$$

(D.1)

### E. Jacobian Matrix of Equilibrium Points of Replicator Dynamic System

The Jacobian matrix of the equilibrium point  $E1(0, 0, 0)$  is as follows:

$$J_1 = \begin{bmatrix} H & 0 & 0 \\ 0 & U_B - C_B + B & 0 \\ 0 & 0 & U_L - C_L - P_L - A \end{bmatrix}. \quad (E.1)$$

The Jacobian matrix of the equilibrium point  $E2(1, 0, 0)$  is as follows:

$$J_2 = \begin{bmatrix} -H & 0 & 0 \\ 0 & \alpha S_B + U_B - C_B + B & 0 \\ 0 & 0 & \beta S_L + U_L - C_L - P_L - A \end{bmatrix}. \quad (E.2)$$

The Jacobian matrix of the equilibrium point  $E3(0, 1, 0)$  is as follows:

$$J_3 = \begin{bmatrix} R_B - \alpha S_B + H & 0 & 0 \\ 0 & -U_B + C_B - B & 0 \\ 0 & 0 & \phi P_B + N_L + U_L - C_L - P_L - A \end{bmatrix}. \quad (E.3)$$

The Jacobian matrix of the equilibrium point  $E4(0, 0, 1)$  is as follows:

$$J_4 = \begin{bmatrix} R_L - \beta S_L + H & 0 & 0 \\ 0 & U_B - C_B + B - P_B + N_B & 0 \\ 0 & 0 & -U_L + C_L + P_L + A \end{bmatrix}. \quad (E.4)$$

The Jacobian matrix of the equilibrium point  $E5(1, 1, 0)$  is as follows:

$$J_5 = \begin{bmatrix} -R_B + \alpha S_B - H & 0 & 0 \\ 0 & -\alpha S_B - U_B + C_B - B & 0 \\ 0 & 0 & \phi P_B + N_L + \beta S_L + U_L - C_L - P_L - A \end{bmatrix}. \quad (E.5)$$

The Jacobian matrix of the equilibrium point  $E6(1, 0, 1)$  is as follows:

$$J_6 = \begin{bmatrix} -R_L + \beta S_L - H & 0 & 0 \\ 0 & -P_B + N_B + \alpha S_B + U_B - C_B + B & 0 \\ 0 & 0 & -\beta S_L - U_L + C_L + P_L + A \end{bmatrix}. \quad (E.6)$$

The Jacobian matrix of the equilibrium point  $E7(0, 1, 1)$  is as follows:

$$J_7 = \begin{bmatrix} R_B - \alpha S_B + R_L - \beta S_L + H & 0 & 0 \\ 0 & P_B - N_B - U_B + C_B - B & 0 \\ 0 & 0 & -\phi P_B - N_L - U_L + C_L + P_L + A \end{bmatrix}. \quad (E.7)$$

The Jacobian matrix of the equilibrium point  $E8(1, 1, 1)$  is as follows:

$$J_8 = \begin{bmatrix} -R_B + \alpha S_B - R_L + \beta S_L - H & 0 & 0 \\ 0 & P_B - N_B - \alpha S_B - U_B + C_B - B & 0 \\ 0 & 0 & -\phi P_B - N_L - \beta S_L - U_L + C_L + P_L + A \end{bmatrix}. \quad (E.8)$$

The characteristics of pulmonary *tuberculosis* are complex, and the cost of manual screening is high. The detection model based on convolutional neural network is an essential method for assisted diagnosis with artificial intelligence. However, it also has the disadvantages of complex structure and a large number of parameters, and the detection accuracy needs to be further improved. Therefore, an improved lightweight YOLOv4 pulmonary *tuberculosis* detection model named MIP-MY is proposed. Firstly, over 300 actual cases are selected to make a common dataset by professional physicians, which is used to evaluate the performance of the model. Subsequently, by introducing the inverted residual channel attention and the pyramid pooling module, a new structure of MIP is created and used as the backbone extractor of MIP-MY, which could further decrease the number of parameters and fuse context information. Then the multiple receptive field module is added after the three effective feature layers of the backbone extractor, which effectively enhances the information extraction ability of the deep feature layer and reduces the miss detection rate of small pulmonary *tuberculosis* lesions. Finally, the pulmonary *tuberculosis* detection model MIP-MY with lightweight and multiple receptive field characteristics is constructed by combining each improved modules with multiscale structure. Compared to the original YOLOv4, the model parameters of MIP-MY is reduced by 47%, while the mAP value is raised to 95.32% and the miss detection rate is decreased to 6%. It is verified that the model can effectively assist radiologists in the diagnosis of pulmonary *tuberculosis*.

## 1. Introduction

Pulmonary *tuberculosis* has become a global public health emergency, in which people are infected with a chronic infectious disease caused by *Mycobacterium tuberculosis* [1]. According to the World Health Organization (WHO) survey, pulmonary *tuberculosis* is one of the leading causes of death from infectious diseases around the world. It is estimated that about 64% of 10 million pulmonary *tuberculosis* cases are detected and treated each year [2]. Improving the awareness rate and early detection rate of pulmonary *tuberculosis* plays a vital role in the treatment of the disease, as well as the prevention of the spread of the disease [3]. Computed tomography (CT) is one of the auxiliary imaging diagnostic methods for *tuberculosis* screening, having a lower missed detection and false detection rate than chest radiographs. It is a more efficient choice to adopt CT

technology to identify substantial chest lesions and detect the severity of lung diseases in patients with *tuberculosis* [4].

With the development of artificial intelligence, some scholars have gradually begin to integrate the deep learning image processing algorithm of deep learning with CT technology to achieve a more accurate diagnosis and detection of lung diseases. Many deep learning models of computer-aided diagnosis have been built based on the deep convolution neural network (DCNN). Gao et al. [5] combined with CT technology proposed a high-precision classification model of five types of pulmonary *tuberculosis* based on CNN and support vector machine. Ma et al. [6] proposed an automatic detection model of active pulmonary *tuberculosis* based on U-Net [7], which can detect the location of lesions more accurately. Liu et al. [8] built simulated and real data sets based on CT images of lung cancer lung nodules and realized automatic detection of lesions

through an improved single-stage target detection network YOLOv3 [9]. Yang et al. [10] took the two-stage target detection network Faster-RCNN as the main body, which improved the detection accuracy of pulmonary *tuberculosis*. However, its parameter scale was large and was not conducive to generalization.

Considering that the current detection model for pulmonary CT disease has the problem of excessive parameters and does not use effective lightweight methods, it may be a feasible strategy to learn from the lightweight methods in other detection fields. In reference [11], Ye et al. [11] replaced the backbone network of YOLOv4 [12] through MobileNetv3 [13] and realized the lightweight of the model. Although Mobilenetv3 reduces the amount of parameters, if it is directly used in the detection of pulmonary *tuberculosis* CT, it may lack the mining of deep feature information of the image, which is not enough to solve the problem of missed detection rate of small targets by YOLOv4, and the detection accuracy needs to be further improved. Reference [14] achieves lightweight by reducing the number of convolution layers in YOLOv5 [15], which obviously improves the detection speed. However, because the lightweight YOLOv5 focuses on the detection of large targets, the detection performance of small targets is still slightly insufficient. Small lesions on pulmonary *tuberculosis* CT cannot be ignored. The structure and performance of YOLOv5 are less different from those of YOLOv4. Therefore, improving on YOLOv4 is an effective strategy. CT images of pulmonary *tuberculosis* have mainly have typical features such as cavity [16] and tree-in-bud pattern [17]. However, open data sets are uneven and there is no uniform format, so it is essential to design a set of standard datasets. Additionally, the existing *tuberculosis* detection model has a large number of parameters and consumes a lot of computing resources, which makes it difficult to be applied to medical institutions with a large number of high-performance equipment. Therefore, it is an important goal to realize the lightweight of the model. At the same time, an ordinary lightweight detection model cannot obtain the deeper semantic information of CT images, resulting in a high rate of missed detection. Therefore, ensuring high detection accuracy and efficiency of *tuberculosis* simultaneously is one of the main objectives of this study, which is of great significance for *tuberculosis* screening and diagnosis.

The major contributions in our study can be summarized as follows.

- (1) At present, some existing models lack the ability to distinguish small objects, so that the miss detection rate stays in a high position without going down. For this reason, a new module of the multiple receptive field block (MRFB) with dilated convolution is designed in this paper. This module expands the acceptance range of the pulmonary *tuberculosis* detection model. It enhances the ability of feature extraction for various sizes of lesions to prevent some small size lesions that are detrimental to identify from being omitted.

- (2) Location, classification, and the confidence score of pulmonary *tuberculosis* lesions are equally important factors affecting the detection capability of the model. Taking these three factors as optimization objects can further improve the detection accuracy of the model. Consequently, an integrated loss function is designed which can train these three factors simultaneously. In the iterative training process of the model, the actual location of the lesions will be continuously updated continuously by the integrating loss function, the classification of the lesions will be determined, and the reliability of all lesions will be optimized simultaneously.
- (3) Lightweight convolution layers are constructed to reduce the number of model parameters, and a new backbone extractor MIP is designed. Its internal inverted residual channel attention module and pyramidal pooling layer can assist the model in extracting the deeper semantic information of pulmonary *tuberculosis* lesions. It realizes lightweight in structure and avoids overfitting to a certain extent, enhances the relationship between the different sizes of regions on feature maps, and completes the fusion of multiscale feature information.

The remainder of this paper is organized as follows. In Section 1, a standard data set of pulmonary *tuberculosis* is built, which contains CT slices of 300 patients with pulmonary *tuberculosis*. And a lightweight method is also introduced that is used in the pulmonary *tuberculosis* detection model. In Section 2, a pulmonary *tuberculosis* detection model MIP-MY is designed based on an improved YOLOv4 algorithm. In section 3, we carry out a quantitative analysis and score comparison on the results of networks. Finally, we discuss some related issues and make conclusions in Section 4.

## 2. Dataset and Lightweight Method

Currently, the public data set on CT of pulmonary *tuberculosis* CT is scarce, with incomplete image data, and the format is not unified. Therefore, it is imperative to design a standard data set for the research of this study. The lightweight detection model is one of the targets to be achieved in this paper. While completing the lightweight, we must ensure a higher accuracy, which is also the difficulty in designing the pulmonary *tuberculosis* detection model.

**2.1. Creation of Dataset.** The experimental data for this study is the actual data set provided by the Imaging Department of Beijing Chest Hospital, China. A total of 300 CT cases of pulmonary *tuberculosis* are collected to form the experimental data set. Each CT slice is segmented according to the thickness standard of 1.25 mm, of the which the CT sections of pulmonary *tuberculosis* cavity and the tree-in-bud pattern accounted for 50%, respectively. The cavity diameter in the data set ranges from 10 mm to 126.4 mm, and the tree-in-bud pattern with uniform density is selected as the sample. The areas from  $16 \times 16$  to  $128 \times 128$  on the CT slices are

defined as a cluster of tree-in-bud pattern lesions, respectively. The distribution maps of the size of the lesions size in the dataset are shown in Figure 1. As shown from Figures 1(a) and 1(b), there are more small cavities with a diameter less than or equal to 30 mm, accounting for about 33% of the total. And more samples of tree-in-bud patterns in clusters with the size from  $32 \times 32$  to  $64 \times 64$  account for about 40% of the total. The standard for the above data set was established by three clinical doctors with more than five years of experience at Beijing Chest Hospital after discussion at the meeting, and the Labellmg tool [18] tool was used to outline and calibrate the lesion of pulmonary *tuberculosis*, providing a guarantee of the consistency and validity of the dataset.

The unified preprocessing of each CT image is carried out, and its format is converted from DICOM to PNG, which is more convenient for processing. The resolution is adjusted to  $512 \times 512$ , and the number of coding bits is 24. Additionally, to reduce interference to the detection model, background information is filtered, including bed board and clothing outside the outline of the lung.

The data set contains a total of 3764 CT slices of cavity and tree-in-bud pattern, from which 70% are randomly selected as the train set, the remaining 10% as test set 1, and the last 20% as test set 2. Test Set 1 is responsible for subsequent ablation experiments, while test set 2 is responsible for evaluating the diagnostic level of the pulmonary *tuberculosis* detection model.

Data enhancement enriches the diversity of the data set. Specifically, each CT image of the train set has a 40% chance of scaling and flipping horizontally and randomly distorting the input image with an aspect ratio of 0.8 to 2.0. These measures double the number of samples in the train set. This study has signed a patient information confidentiality agreement with the Imaging Department of Beijing Chest Hospital to filter out patients' sensitive information by technical means, and the right to use the dataset is merely effective in this study.

**2.2. Lightweight Method.** At present, the detection model based on the convolutional neural network has some problems such as a large number of parameters and long training time, which requires high hardware computing capacity. Therefore, this paper will adopt a lightweight method to modify the model to make it suitable for general hardware devices.

MobileNetv3 is a lightweight neural network commonly used in image processing. It is based mainly on the principle of separable depthwise convolution [19] to achieve the lightweight target.

Compared with traditional convolution, depthwise separable convolution has fewer parameters. The Depthwise Separable Convolution traverses only one by one corresponding to the input channel and then expands the number of output channels by  $1 \times 1$  Pointwise Convolution. The principle of Depthwise Separable Convolution is shown in Figure 2.

The number of parameters required for traditional convolution and Depthwise Separable Convolution is set to

$N_1$  and  $N_2$  respectively, and their calculation formulas are shown in formulas (1) and (2).

$$N_1 = i_h \cdot i_w \cdot c_{in} \cdot c_{out} \cdot k^2, \quad (1)$$

$$N_2 = i_h \cdot i_w \cdot c_{in} \cdot (k^2 + c_{out}), \quad (2)$$

where  $i_h$  and  $i_w$  are the height and width of the input tensor,  $k$  is the size of the selected convolution kernel, and  $c_{in}$  and  $c_{out}$  respectively represent the number of input and output channels. Furthermore, as shown in formula (3)

$$\frac{N_1}{N_2} = \frac{k^2 \cdot c_{out}}{k^2 + c_{out}}. \quad (3)$$

In practical application,  $N_2$  is much less than  $N_1$ , which means Depthwise Separable Convolution can reduce computational overhead to a greater extent.

The model in reference [11] replaced YOLOv4's backbone extractor CSPDarkNet53 [20] by MobileNetv3, which reduces the number of parameters to a great extent. However, it is difficult to achieve high accuracy if this model is directly used to detect pulmonary *tuberculosis*. If the lightweight of the model is improved at the expense of detection accuracy, that will be contrary to the main target of our study. Therefore, this article will ameliorate the MobileNetv3 and YOLOv4 to reduce the parameters of the pulmonary *tuberculosis* detection model, improve detection efficiency as well as the accuracy.

### 3. Design of Pulmonary Tuberculosis Detection Model

The structure of the pulmonary *tuberculosis* detection model refers to the YOLOv4 method, and the structure of YOLOv4 is shown in Figure 3. As can be seen from Figure 3, the original YOLOv4 enhances the learning feature information ability by virtue of the CSPDarkNet53 as the backbone part, which reduces model overfitting through the combination of traditional convolution and residuals. The neck part is spliced with SPP module (spatial pyramid pooling) [21] and PAN module (path aggregation network) [22] to complete the multiscale feature information fusion of different regions. Finally, the multiscale feature information is collected by using the three Heads in the prediction part to generate the final prediction bounding box. The original YOLOv4 focuses on efficiency and accuracy, but has not yet achieved satisfactory results in the field of pulmonary *tuberculosis* detection.

Different from the original YOLOv4, the developed pulmonary *tuberculosis* detection model named MIP-MY comprises three parts: a backbone extractor, enhanced feature extractor, and a bounding box generator. A new backbone extractor MIP is designed for MIP-MY, which is the lightweight module of the detection model. MIP uses the newly designed IRCA (Inverted Residual Channel Attention) module and pyramid pooling module to achieve lightweight. MIP can extract abundant contextual information and make preliminary sampling for pulmonary

FIGURE 1: Distribution maps of the size of the lesions size. (a) Distribution maps of the cavity. (b) Distribution maps of the tree-in-bud pattern.

FIGURE 2: Principle of depthwise separable convolution.

*tuberculosis*. Then, in order to capture lesions of different sizes, we designed MRFB (multiple accept field block) module to construct the enhanced feature extractor, which can have a wider acceptance field to reduce the missed detection of small lesions. According to the momentous information (lesion location, classification, and confidence score) output by the bounding box generator, a comprehensive loss function is designed to regression the lesion location and optimize the confidence score.

**3.1. Backbone Extractor MIP.** The function of the backbone feature extractor MIP is to analyze the CT images of pulmonary *tuberculosis* and extract the image features of pulmonary *tuberculosis* lesions. In this paper, according to the inverted residuals structure of MobileNetv3, a new IRCA (Inverted Residuals Channel Attention) module is constructed using channel attention mechanism. By virtue of the inverted residuals structure, this module can build a deeper network without a gradient explosion. An introduced channel attention mechanism can capture the corresponding context information on each IRCA module and improve the feature extraction ability of the network. The structure of IRCA is shown in Figure 4. As a significant part of MIP, IRCA module constructs seven effective feature layers for MIP to extract the lesions information of pulmonary *tuberculosis*. The MIP connects a pyramid pool module in the last effective feature

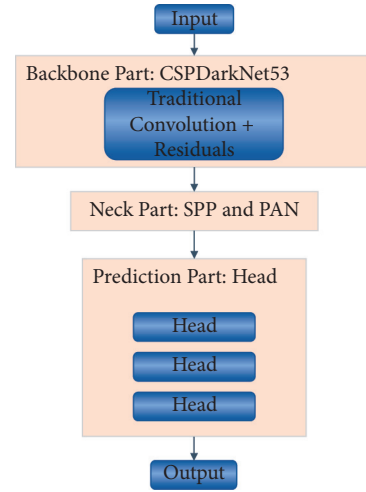

FIGURE 3: The structure of YOLOv4.

layer to obtain multiple scale feature information. The structure of MIP and pyramid pooling module is shown in Figure 5.

Before completing the  $1 \times 1$  Pointwise Convolution operation, the IRCA module carries out Global-Average pooling to obtain the feature graph with a smaller size, and calculate the weight of the feature map through Relu6 and Hard-Swish activation function. Finally, the weighted multiplication is performed through channel attention. The calculation formula of Global-Average pooling is shown in formula (4).

$$y_{\text{avg}} = \frac{\sum_{i=0}^n \sum_{j=0}^n x_{i,j}}{n^2}, \quad (4)$$

where  $x_{i,j}$  is the pixel on the 2D slices of feature maps and  $y_{\text{avg}}$  is the pixel mean of the Global-Average pooling. The calculation formula of Relu6 and Hard-Swish activation function is shown in formulas (5) and (6).

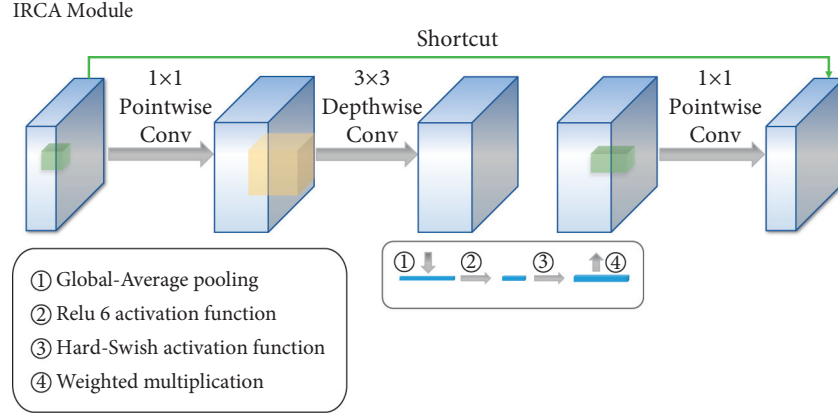

FIGURE 4: The structure of the IRCA module.

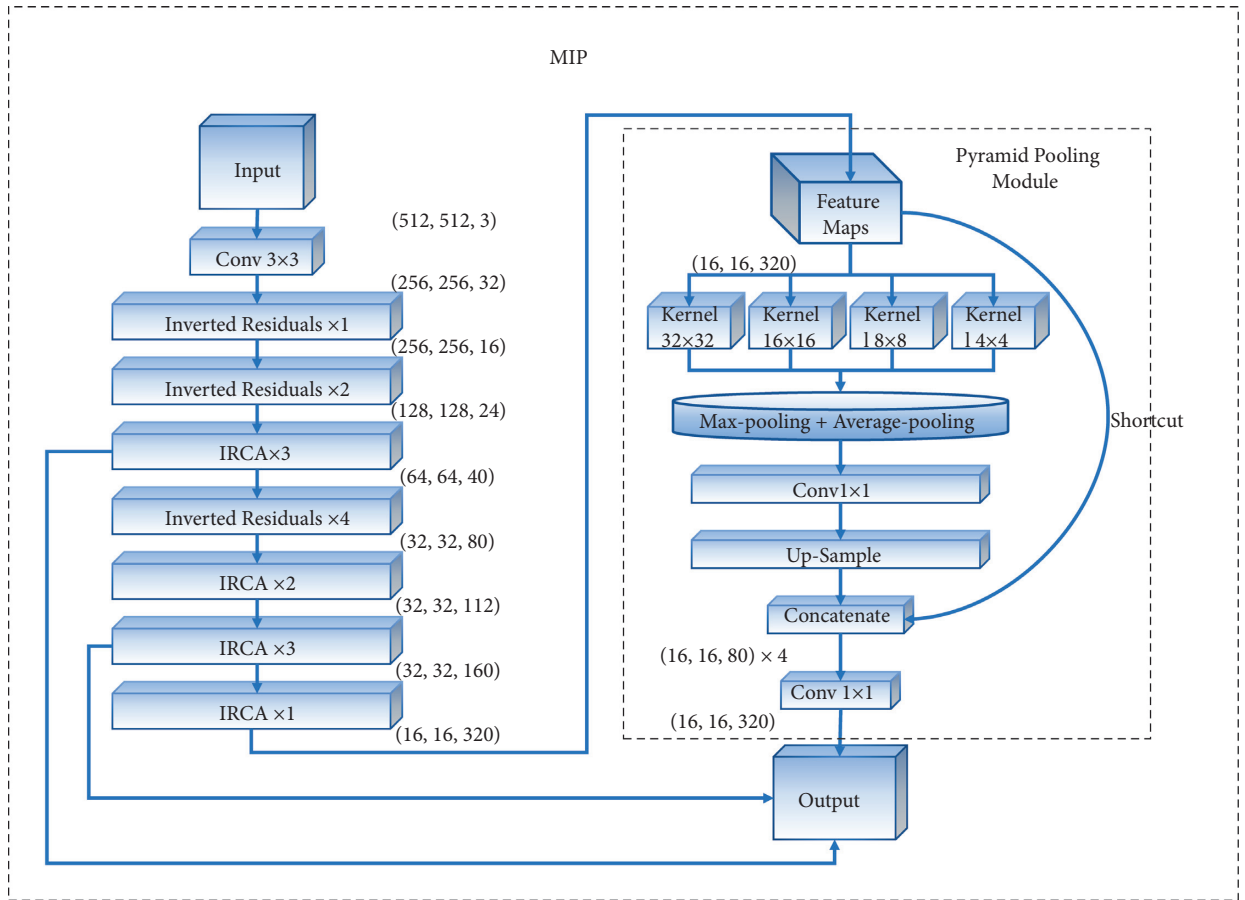

FIGURE 5: The structure of MIP and pyramid pooling module.

$$f_1(y_{\text{avg}}) = \min(\max(0, y_{\text{avg}}), 6), \quad (5)$$

$$f_2(y_{\text{avg}}) = y_{\text{avg}} \cdot \frac{f_1(y_{\text{avg}} + 3)}{6}, \quad (6)$$

where  $f_1(y_{\text{avg}})$  is the activation result of ReLU6, and the upper limit of this value is 6.  $f_2(y_{\text{avg}})$  is the activation result of Hard-Swish. It is found that the accuracy of a neural network can be enhanced by using the hard-swish activation function in deeper convolution layers.

$$f_3 = X \cdot f_2(f_1(y_{\text{avg}})), \quad (7)$$

where the output  $X$  of the ‘‘Depthwise Separable Convolution’’ in formula (7) is a characteristic graph composed of  $n^2$  pixels, and  $f_3$  is the weighted calculation result of the whole channel attention.

In order to enable the backbone extractor to acquire information about the lesions information of different scales, this design draws lessons from the structure of PSPNet (Pyramid Scene Parsing Network) [23] and designs a

pyramid pooling module as the integrated pooling layer of the backbone extractor (max pooling + average pooling), which combines four pooled kernels of various scales ( $32 \times 32$ ,  $16 \times 16$ ,  $8 \times 8$  and  $4 \times 4$ ) to further analyze the location, size and other information about the lesions.

In summary, this design is improved by using the IRCA module and pyramid pooling module to compose the structure of a new backbone extractor MIP.

**3.2. Enhanced Feature Extractor Dominated by MRFB.** The last three effective feature layers of the MIP backbone extractor MIP will export feature maps with the resolution of the original image of 1 to 8, 1 to 16, and 1 to 32, respectively, providing pixel information of different sizes of lesions in pulmonary *tuberculosis* for subsequently enhanced feature extractor.

The initially enhanced feature extractor of YOLOv4 is mainly composed of SPP module and PAN module. SPP will take the result of the last feature layer of the backbone extractor as input and divide the feature map into three subregions of different sizes ( $8 \times 8$ ,  $4 \times 4$ , and  $2 \times 2$ ) for maximum pooling, collecting multiscale eigenvalues. The PAN is a reciprocating structure responsible for collecting the output of three effective feature layers of the backbone extractor to build a feature pyramid. Each effective feature layer integrates the sampling information of the other two layers to complete multiscale feature lesions.

Although the initially enhanced feature extractor uses a multiscale feature fusion method to collect image information, the utilization of multireceptive field information is far from enough, and it is easy to ignore the feature expression of small targets. Therefore, in this section, combining the ideas of expansion convolution and receptive field amplification [24], the MRFB module is designed to optimize the enhanced feature extractor of YOLOv4. The structure of MRFB is shown in Figure 6.

Combined with the structure of the MRFB module, it can see that the MRFB module adopts parallel expansion convolution, and expands and samples the receptive field of the feature map through the collocation of three expansion rates (dilated rate takes 1, 3 and 5) and three convolution kernels (size takes  $1 \times 1$ ,  $3 \times 3$ , and  $5 \times 5$ ), and adds residual shortcut to prevent the loss of feature information, and finally splices the sampling results of each convolution to fuse the information of multiple receptive fields. As shown in Figure 6, the MRFB module, as the probe of PAN, is connected with the backbone feature extractor MIP, which makes up for the deficiency of PAN feature map information collection.

**3.3. Bounding Box Generator and Decoder.** The function of the bounding box generator is to achieve regression of the information from the pulmonary *tuberculosis* lesion (lesion size, class, and location), which is composed of three decoupling heads and a decoder. Each head generates three bounding boxes of different sizes on the multiscale feature map sampled by PAN to surround the pulmonary *tuberculosis* lesion. The parameters of the bounding box include the coordinates of the center point coordinates, size, class of lesion, and confidence

score. However, this parameter information cannot directly reflect the position of the final bounding box in the picture. The information of the bounding box needs to be further decoded by the decoder.

**3.3.1. Decoding of Bounding Box.** The bounding box is decoded with Anchor. Anchor is a predefined bounding box on each feature point of the input image. The activation function for its decoding is shown in formula (8).

$$\sigma(t) = \frac{1}{1 + e^{-t}}, \quad (8)$$

where  $t$  represents the confidence score and category probability of the bounding box, and these two kinds of parameters are mapped to the range of  $[0,1]$  by function  $\sigma(t)$ . The decoding definition of the center point coordinates  $(C_x, C_y)$  of the bounding box is shown in formulas (9) and (10).

$$C_x = \sigma(x_{\text{offset}}) + A_x, \quad (9)$$

$$C_y = \sigma(y_{\text{offset}}) + A_y, \quad (10)$$

where the coordinate offset ( $x_{\text{offset}}$  and  $y_{\text{offset}}$ ) from the center point of the prediction box is the coordinate offset and the coordinate offset is relative to the center point of the prediction box.  $(A_x, A_y)$  is the center point coordinate of the Anchor, and the center point coordinates  $(C_x, C_y)$  of the bounding box is obtained after decoding.

The decoding formulas for the height and width of the bounding box are shown in formulas (11) and (12).

$$H = e^h \cdot A_H, \quad (11)$$

$$W = e^w \cdot A_W, \quad (12)$$

where the  $h$  and  $w$  are the height and width of the bounding box before decoding,  $A_H$  and  $A_W$  are the height and width of Anchor, and the height  $H$  and width  $W$  of the decoded bounding box is calculated, respectively.

After decoding, the pulmonary *tuberculosis* lesions at the same position in the image will be surrounded by a large number of bounding boxes, so it is necessary to filter the redundant bounding boxes according to the Intersection of Union threshold (IOU) (usually set to 0.5), and then filter out these bounding boxes with the highest confidence score through the nonmaximum suppression algorithm [25]. The mathematical definition of the IOU is shown in formula (13).

$$\text{IOU} = \frac{|b \cap b^{gt}|}{|b \cup b^{gt}|}, \quad (13)$$

where the denominator represents the intersection of the area of the bounding box  $b$  and the real box  $b^{gt}$ , and the numerator represents the union. IOU reflects the similarity between the predicted results of the detection model and the ground truth.

**3.3.2. Integrated Loss Function.** The integrated loss function of the pulmonary *tuberculosis* detection network is mainly composed of regression loss  $L_{\text{CIou}}$ , class loss  $L_{\text{Class}}$  and confidence loss  $L_{\text{Conf}}$ .

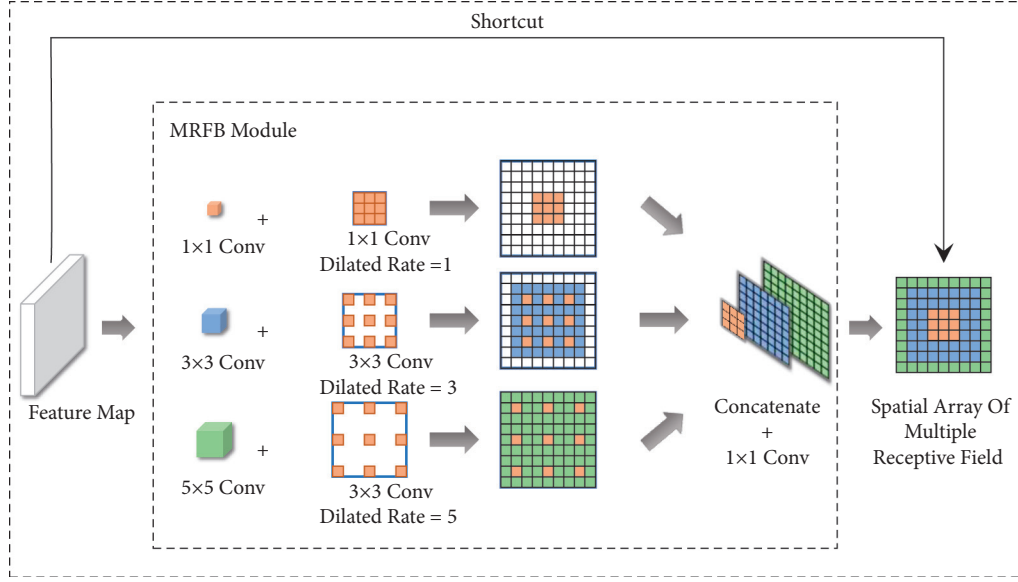

FIGURE 6: The structure of MRFB module.

The general loss function of the detection model is shown in formula (14).

$$L = L_{\text{CIou}} + L_{\text{Confidence}} + L_{\text{Class}} \quad (14)$$

The mathematical expression of regression loss  $L_{\text{CIou}}$  is shown in formula (15).

$$\begin{cases} v_{i,j} = \frac{4}{\pi^2} \left( \tan^{-1} \frac{W_{i,j}^{gt}}{H_{i,j}^{gt}} - \tan^{-1} \frac{W_{i,j}}{H_{i,j}} \right)^2, \\ \alpha_{i,j} = \frac{v_{i,j}}{1 - \text{IOU}_{i,j} + v_{i,j}}, \\ L_{\text{CIou}} = \sum_i^{S^2} \sum_j^N \left[ 1 - \text{IOU}_{i,j} + \frac{\rho(b_{i,j}, b_{i,j}^{gt})}{d_{i,j}^2} + \alpha_{i,j} v_{i,j} \right], \end{cases} \quad (15)$$

where the subscript  $(i, j)$  shows the serial number of the  $j$  bounding box on the pixel point in the feature map,  $S$  is the resolution size of the feature maps and  $i$  is the number of predicted bounding boxes on every feature map.  $W_{i,j}^{gt}$  and  $H_{i,j}^{gt}$  are the width and height of the corresponding ground truth,  $\alpha_{i,j} v_{i,j}$  is the penalty factor of  $L_{\text{CIou}}$ , and  $\rho(b_{i,j}, b_{i,j}^{gt})$  is the Euclidean distance between the center point of the predicted bounding box and the ground truth, and  $d_{i,j}$  represents the diagonal distance of the smallest enclosed area that can contain both the predicted bounding box and the ground truth. The definition of class loss is shown in formula (16).

$$L_{\text{Confidence}} = \sum_i^{S^2} \sum_j^N O_{i,j} [-\log(E_{i,j})] + \lambda \sum_i^{S^2} \sum_j^N (1 - O_{i,j}) [-\log(1 - E_{i,j})], \quad (16)$$

where the  $O_{i,j}$  is a binary number to judge whether the pulmonary *tuberculosis* focus is in the predicted bounding box, and  $E_{i,j}$  represents the confidence of every pulmonary

*tuberculosis* focus.  $\lambda$  sets as 1 when the IOU is greater than the threshold, otherwise takes 0. The class loss  $L_{\text{Class}}$  is defined in formula (17).

$$L_{\text{Class}} = \sum_i^{S^2} \sum_j^N O_{i,j} \sum_{c \in \text{Classes}}^M [P_i(c) \log(P_i^{gt}(c)) + (1 - P_i(c)) \log(1 - P_i^{gt}(c))], \quad (17)$$

where  $M$  is the number of classes,  $P_i(c)$  is the class score of the detection network decision, and  $P_i^{gt}(c)$  represents class score of the ground truth.

By improving the structure of the pulmonary *tuberculosis* detection model and the selection of the loss function, the *tuberculosis* detection model developed in this paper is named MIP-MY (MobileNet with Inverted residuals and Pyramid pooling - Multiple receptive fields of YOLO). The model creates a lightweight trunk extractor MIP based on the basis of YOLOv4 and uses the MRFB module to replace the ordinary convolution layer that enhances the partial redundancy of the feature extractor, which only takes up less memory to enhance the ability to obtain multiple receptive field features. Finally, the integrated loss function is aimed at completing the regression and classification of pulmonary *tuberculosis* lesion information at the model training.

The overall structure of the improved pulmonary *tuberculosis* detection model MIP-MY is shown in Figure 7.

**3.4. Evaluation Method.** The evaluation of the pulmonary *tuberculosis* detection model is mainly determined by the number of parameters, detection time of per CT, Precision, Recall, miss detection rate, and mean Average Precision (mAP) [26]. The Precision  $F_{Pr}$  is as shown in formula (18).

$$F_{Pr} = \frac{TP}{TP + FP}, \quad (18)$$

where TP is the true positive of the sample, FP is the false positive, and the sum of them is the prediction result of the model. The recall rate  $F_{Re}$  is shown in formula (19).

$$F_{Re} = \frac{TP}{TP + FN}, \quad (19)$$

where the FN is false negative, and the sum of FP and FN is the total amount of the real box. In this study, the miss detection rate is mapped from the average miss detection rate of pulmonary *tuberculosis* CT in the test set 2 to the logarithmic space, and its mathematical definition is as shown in formula (20).

$$\left\{ \begin{array}{l} mr_i = 1 - \frac{TP_i}{TP_i + FP_i}, \\ F_{Lamr} = e^{-\frac{1}{Q} \sum_{i=1}^Q \log(\max(mr_i, \varepsilon))}, \end{array} \right. \quad (20)$$

where  $mr_i$  represents the miss rate of a single CT slice and  $Q$  represents the total number of CT slices. Besides,  $\log(0)$  has no mathematical meaning, a smaller value  $\varepsilon$  is set to prevent the independent variable of the logarithmic function from being zero.

The IOU by a threshold of 0.5 is set to determine the TP and FP of the sample, and the P-R curve of the detection model is constructed with Precision and Recall as horizontal and vertical coordinates, respectively. The mAP is equal to

the mean area under the P-R curve of all categories. The mathematical definition of the mAP is shown in formula (21), where  $n$  is the total number of categories.

$$mAP = \frac{\sum_0^n \int E_{pr} \cdot E_{red}(E_{re})}{n}. \quad (21)$$

## 4. Experimental Setting and Analysis

The operating system for this experiment is Windows 10, and the processors are Intel Core i7 and RTX 2060. Take PyCharm as the integrated development environment and utilize the deep learning framework of Keras based on Python3.8. To adapt to model training, the initial learning rate is set at  $1.0 \times 10^{-4}$ . Adam optimizer and 1000 iterative training are also selected. Finally, the cosine annealing algorithm is used so that the pulmonary *tuberculosis* detection model can adaptively adjust the learning rate according to the number of iterations.

**4.1. Ablation Experiment.** For the sake of investigating the contribution of the integrated loss function and different components (MIP and MRFB) to improve the accuracy of detection model MIP-MY, we selected test set 1 to carry out two groups of ablation experiments.

The first group verifies the influence of different sub-losses (regression loss  $L_{CIou}$ , class loss  $L_{Class}$  and confidence loss  $L_{Conf}$ ) in the integrated loss function on the detection performance of the model, and then compares them with the traditional cross-entropy loss.

The quantitative comparison of performance on each loss function is shown in Table 1. Any single sub-loss can not optimize the detection accuracy of the model, and it is accompanied by a huge miss detection rate. Similarly, the combination of any two sub-losses has no obvious improvement on the detection accuracy and miss detection rate. The experimental results show that the coordinate location, class, and confidence score of pulmonary *tuberculosis* lesions are indispensable factors and only by combining these three seed losses can we effectively improve the overall performance of MIP-MY. Compared with traditional loss of the cross-entropy loss function, integrated loss can obtain better training results.

The second group verifies the effectiveness of the improved components in this paper, that is, we observe the effects of the addition and deletion of MIP module and MRFB module on the mAP, the number of parameters, miss detection rate and detection time. And compared with the lightweight model in reference [11]. To facilitate differentiation, we named the lightweight model introduced by Model 1 in reference [11] as MobileNetv3-YOLOv4, the model that uses only MIP is called Model 2 and the model that uses only MRFB is called Model 3. MIP-MY integrates all the improved modules.

The results of the ablation experiment are shown in Table 2. From these data, it can be inferred that, compared with Model 1, the number of parameters of Model 2 is only increased by 0.93 M, but the mAP is increased by 2.64%, and

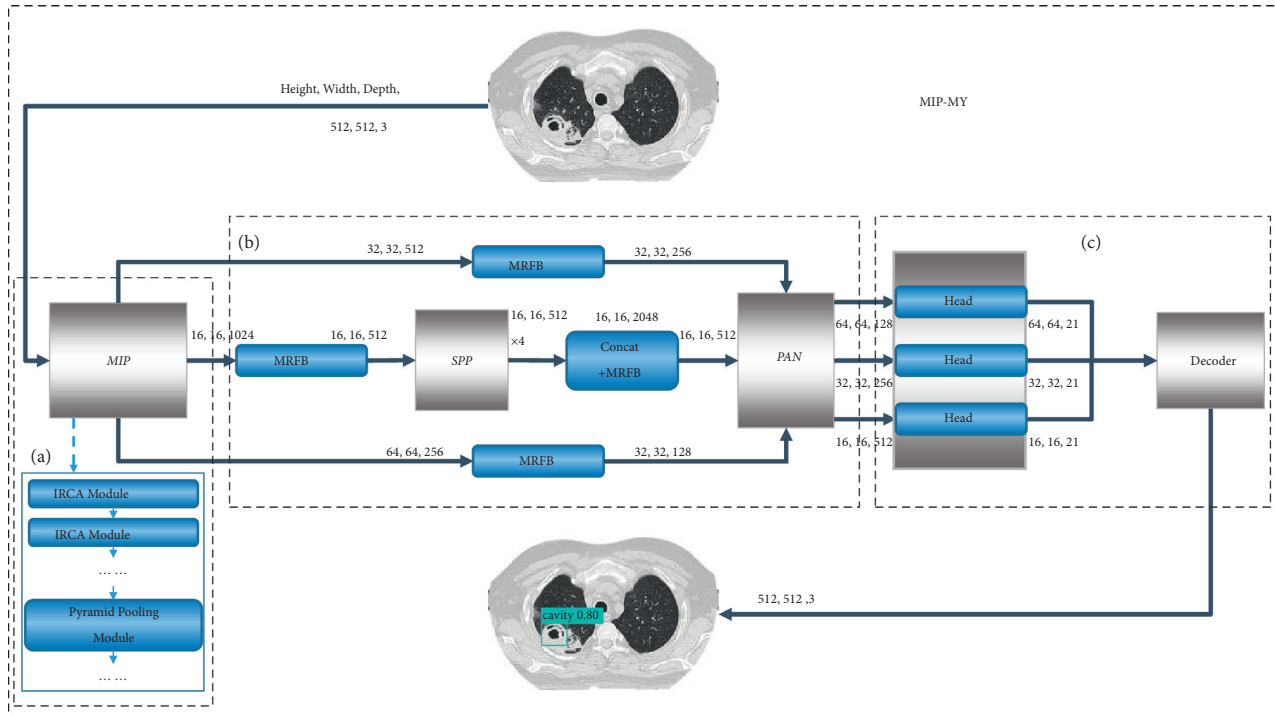

FIGURE 7: The overall structure of MIP-MY (a) Backbone extractor MIP; (b) MRFB enhanced feature extractor with MRFB; (c) boundary box generator and decoder.

TABLE 1: The quantitative comparison of performance on each loss function.

Method	mAP (%)	Miss detection rate (%)
$L_{CIUO}$	79.47	20
$L_{Class}$	78.81	20
$L_{Conf}$	76.15	21
$L_{CIUO} + L_{Class}$	87.41	14
$L_{CIUO} + L_{Conf}$	85.06	17
$L_{Class} + L_{Conf}$	84.29	18
Cross-entropy loss	90.36	11
Integrated loss	95.59	6

TABLE 2: The influence of each improved module on the pulmonary *tuberculosis* detection model.

Model	mAP (%)	Parameters (M)	Miss detection rate (%)	Detection time (s)
Model 1	85.86	38.64	16	6.95
Model 2	88.50	39.57	13	7.87
Model 3	91.92	58.29	10	8.86
MIP-MY	95.59	33.91	6	5.88

the miss detection rate is reduced by 3%. Model 3 only uses MRFB to improve its mAP to 91.92%, but because it does not adopt the lightweight module MIP, the number of parameters is still high and with lower detection efficiency. MIP-MY combines the advantages of two improved modules to make the structure lightweight with the expansion of the receptive field feature mapping. Its mAP jumps to 95.59%, 9.73% higher than model 1, and the miss detection rate decreases by 10%. Meanwhile, the number of parameters decreases by 4.73 M, and the detection time of 1.07 s is shortened.

**4.2. Comparative Experiment of Mainstream Models.** Generally, the *tuberculosis* detection model is highly efficient, highly precise and low memory consumption and easy to apply to clinical diagnosis. To further verify the reliability of the MIP-MY model, we use the test set 2 to compare with several mainstream target detection models. The test set 2 contains 347 cavity samples and 539 tree-in-bud pattern samples. These CT samples are used to evaluate the performance of different detection models.

The P-R curve of the cavity of pulmonary *tuberculosis* cavity and the tree-in-bud pattern detected by different

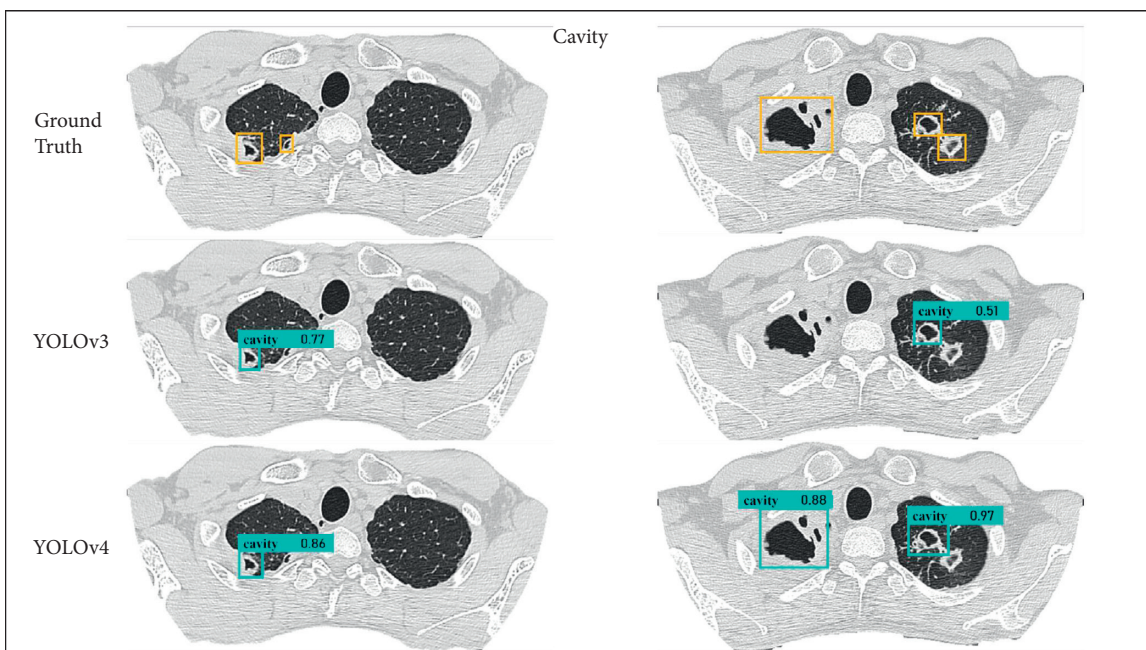

FIGURE 9: Detection of cavity detection results by YOLOv3 and YOLOv4.

FIGURE 10: Detection of cavity by U-Net, Faster-RCNN and MIP-MY.

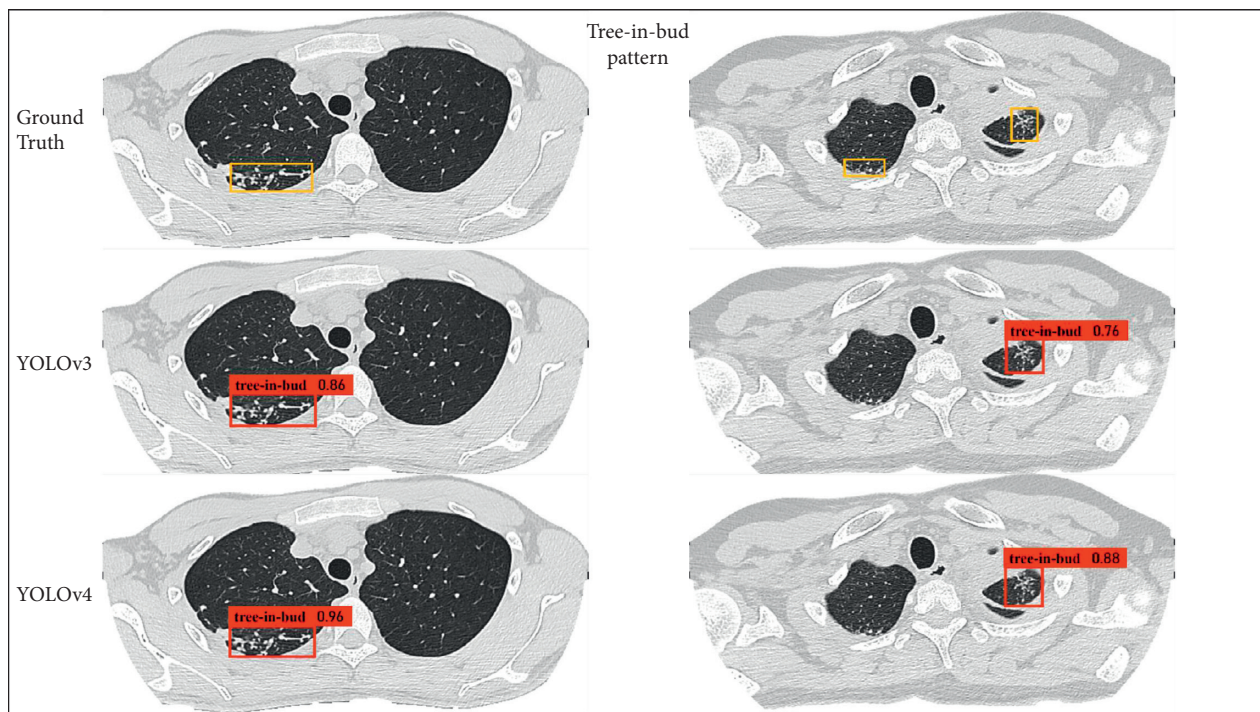

FIGURE 11: Detection of the tree-in-bud pattern by YOLOv3 and YOLOv4.

models is shown in Figure 8. As can be seen from the graph, compared to other mainstream detection models, the scope surrounded by the P-R curve of MIP-MY is the largest. Especially in Figure 8(b), the optimization effect of MIP-MY on the P-R curve for detecting the tree-in-bud pattern is the most obvious, indicating that this model is easier to capture the clustered tree-in-bud pattern.

Table 3 shows the evaluation results of different pulmonary tuberculosis detection models on test set 2. Through quantitative analysis, the performance of the single-stage detection model of YOLOv3 in reference [8]

and YOLOv4 in reference [12] is not up to the mark. The reason is that there are many small cavities and clusters of tree-in-bud pattern in test set 2, which can easily be confused with normal bronchi in the lung region, resulting in a high rate of missed detection in both models. In contrast, the U-Net in reference [6] and the two-stage detection model Faster-RCNN in reference [10] have adequate mAP and low miss detection rate, but these two models have a large number of parameters, so they may not be suitable for equipment with general computing power, and the detection time is slightly

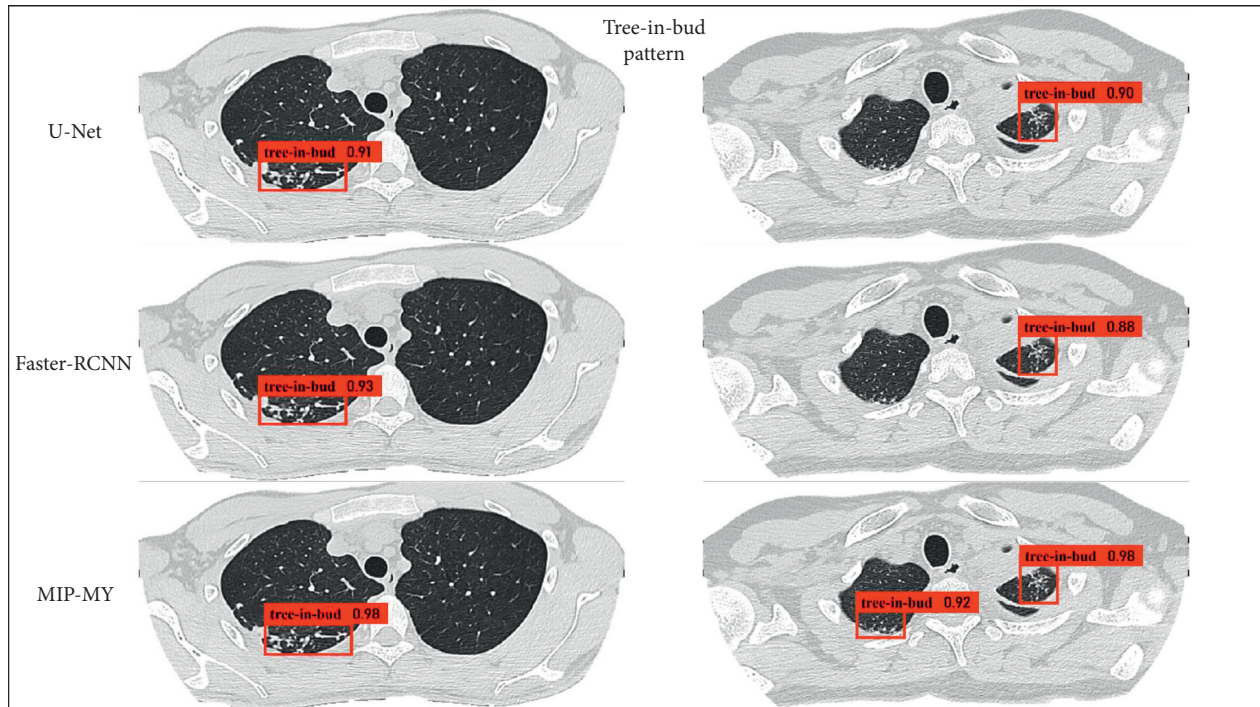

FIGURE 12: Detection of tree-in-bud pattern by U-Net, Faster-RCNN, and MIP-MY.

longer, so it is difficult to achieve the requirements of high efficiency.

The MIP-MY model proposed in this paper has a remarkable performance in test set 2. Compared with the YOLOv4 model, the precision is increased by 5.22%, recall is increased by 4.47%, mAP is increased by 8.11%, the number of parameters is reduced by about 47%, and the error detection rate is reduced by 8%. Furthermore, MIP-MY also has a higher detection efficiency, the detection time of a single pulmonary *tuberculosis* image is shortened by 5.9 s compared to the Faster-RCNN.

From the numerical analysis of the evaluation results, MIP-MY can meet the target of high detection accuracy, and its model parameters take up less space, further reinforces the degree of lightweight.

In this paper, the pulmonary *tuberculosis* detection effect of the proposed MIP-MY model MIP-MY proposed needs to be shown more intuitively. The detection results of cavity in each model are shown in Figures 9 and 10, and the detection results of tree-in-bud pattern are shown in Figures 11 and 12. Ground Truth is the real label prescribed by the imaging doctors, the pulmonary *tuberculosis* cavity is marked as “cavity” in the bounding box, the tree-in-bud pattern is marked as “tree-in-bud” in the bounding box, and the corresponding confidence score is attached to the bounding boxes, which reflects the credibility of these lesions identity.

Through the analysis of the detection results of YOLOv3 and YOLOv4, it is found that the confidence score of YOLOv3 detection cavity and tree-in-bud pattern is low, which may be due to the underutilization of multiscale feature information by YOLOv3. Although YOLOv4 has a high confidence score, it fails to detect small lesions because the down sampling scale of the backbone extractor is too

large and the spatial and pixel information of some small lesions is ignored in the layer-by-layer feature extraction. However, if the down sampling scale is reduced, the detection accuracy of other targets cannot be guaranteed. In Figure 10, it shows that U-Net makes miss detection in a tiny cavity, compared with the ability of Faster-RCNN to accurately capture cavities of various sizes. But in the example in Figure 12, U-Net and Faster-RCNN also omitted the detection in some inconspicuous tree-in-bud pattern.

MRFB module can effectively solve these problems of missed detection about lesions. MIP-MY was observed to capture small cavities and clusters of tree-in-bud patterns that are difficult to identify, indicating that the multiple-receptive field information collection ability of the MRFB module produces a marked effect and avoids the risk of small targets being missed. At the same time, the pulmonary *tuberculosis* lesion detected by MIP-MY has a high-level confidence score, which provides a reliable digital explanation for the automatic diagnosis ability of the detection model.

## 5. Conclusions

In this paper, a lightweight detection model MIP-MY with multiple receptive fields is developed for the automatic detection of pulmonary *tuberculosis*. Through ablation experiments, the contribution of MIP module in model lightweight is verified, and the superior performance of MRFB module and integrated loss function in improving model detection accuracy is also verified. Comparative experiments with other references show that MIP-MY has a lower number of parameters, better detection efficiency and accuracy, and its multiple receptive field characteristics

strengthen the attention to small lesions and greatly reduce the possibility of misdetection. To sum up, the improved model MIP-MY achieves higher detection accuracy, realizes the automatic detection of pulmonary tuberculosis cavity and tree-in-bud pattern with lower calculation cost, and has excellent imaging diagnostic potential of pulmonary tuberculosis. In subsequent studies, more effective data enhancement techniques can be used to enrich the diversity of pulmonary tuberculosis CT data, such as generating game networks (GAN) to generate more samples. In addition, the generality of the model will be studied to make MIP-MY model suitable for the detection of common lung diseases, including lung cancer and pneumonia.

## Data Availability

The dataset used to support the findings of this study has not been made available because the dataset is provided by the partner hospital and includes patient information.

## Conflicts of Interest

The authors declare that they have no conflicts of interest.

Based on the perspective of complex system management of forest biomass power generation (FBPG) supply chain, this paper explores a new way to reduce the operation cost of forest biomass raw materials supply chain and improve the operation efficiency of forest biomass supply chain in China. Firstly, the supply chain model of FBPG is summarized through the survey data, and the existing problems are found. Then, the behavior strategies among farmers, middlemen, and enterprises are analyzed, and the data that cannot be obtained in the model are estimated by using statistical methods. Finally, the complex supply chain system is simulated by computer. Through setting different forestry policies, this paper compares and analyzes the profit of the supply chain and puts forward policy suggestions to promote the development of the FBPG industry in China. In this paper, the actual situation, principles of statistics, and system simulation are effectively combined to make the behavior rules of various stakeholders fit the reality, and the research conclusions are more practical.

## 1. Introduction

With the development of society, the importance of the ecological environment has become increasingly prominent. As a renewable and clean energy industry, biomass energy industry is of great significance to improve environmental quality and develop circular economy. Forest biomass power generation (FBPG) industry is an important part of biomass energy industry. It can generate economic benefits by making rational use of forestry resources and bring substantial ecological benefits by reducing pollutant emissions to protect the natural environment. Especially for the northwest area with poor natural conditions in China, the energy development of tending residues such as pruning shrubs can improve the income level of local farmers and the local natural environment.

Although the utilization of forest biomass energy is essential, China's FBPG industry is still in the initial stage of development, and there are many problems in actual development. For example, farmers lack the will to collect,

so it is difficult to collect forest biomass raw materials on a large scale. In addition, the cost of raw materials remains high, and the degree of marketization is low. Therefore, from the perspective of the complex system of forest biomass raw materials supply chain, it is of great significance to mobilize the enthusiasm of farmers to collect and reduce the cost of raw materials by optimizing the policy combination so as to maximize the overall profit of the supply chain and ensure the sustainable and stable operation of biomass power generation enterprises.

This paper combines the supply chain of FBPG with computer simulation technology. Firstly, the paper models the complex supply chain system composed of farmers, middlemen, and biomass power generation enterprises and constructs a multiagent raw materials supply chain simulation model. Then, the paper puts forward the optimal combination scheme and policy suggestions for the development of the FBPG industry through simulating the simulation results under different parameters, which has important practical significance for expanding the scale of the FBPG industry in China.

## 2. Literature Review

Forest biomass refers to the organic matter formed by photosynthesis of woody plants such as forest trees. Forest biomass energy is the energy stored in forest biomass after conversion; that is, the energy can be used for power generation or heating through direct combustion or modern conversion technologies [1, 2]. Forest biomass resources can be divided into three categories: forest tending and pruning residues, “three forestry residues” (cutting residues, material residues, and processing residues), and energy forest mining residues. The overall availability of forest biomass energy resources in China is increasing year by year, and the supply capacity is significant. In particular, Inner Mongolia has the most extensive available forest biomass energy resources, accounting for 9% of China [3]. The forest biomass energy industry in the western region has great development potential.

The development of the biomass energy industry still faces problems such as difficult raw materials collection, low equipment utilization, and high operation and maintenance costs [4, 5]. By 2016, the global consumption of biomass power generation accounted for about 40% of the total consumption of biomass energy [6]. Energy has not been fully utilized, which restricts the sustainable development of biomass energy industry to a great extent. Insufficient purchase of raw materials is one of the important factors limiting the development of forest biomass energy industry [7]. At present, China’s forest biomass energy mainly depends on government policy support [8]. It is urgent to explore the enthusiasm of various agents from the internal system and put forward corresponding incentive measures.

The simulation modeling method based on multiagent started in the late 1990s. This method adopts bottom-up modeling thought and emphasizes the authenticity of microindividuals during modeling. The model establishes the relationship between agents through the message mechanism and then forms the macroframework of the simulation system. Many scholars have applied multiagent simulation technology to the supply chain of forestry, agricultural products, and other fields. For example, Hanafizadeh and Sherkat [9] built a supply chain distribution model based on multiagent system, improved the convergence of agent adaptability by introducing a genetic algorithm, and then studied the related problems of distribution in supply chain management. Wang et al. [10] used NetLogo software to build a simulation model of agricultural product supply chain and explored the relationship between supervision, farmers’ cooperation, and agricultural product quality. Zhang and Lin [11] established a simulation model based on multiagent to study the impact of the subsidy policy issued by the Chinese government on the profit distribution of supply chain members and carried out experiments under different subsidy levels. Terrada and Ouajji [12] applied multiagent simulation technology to the complex system of supply chain management to provide solutions to the decision-making problems among supply chain members. Awaga et al. [13] built a simulation analysis model of enterprise green product production behavior with multiagent

participation and simulated the impact of different government guidance and supervision strategies on the strategic choices of two parties (enterprises and government). In addition, few scholars have studied biomass power generation industry. Shastri et al. [14] simulated biomass supply system in Illinois based on multiagent simulation technology, and the simulation revealed the impact of miscanthus energy crop on raw materials supply contract. Li [15] established an industrial system model including farmer, enterprise, market, and government and put forward suggestions on the construction scale of China’s straw power generation and the centralized utilization of straw. Luo [16] constructed four biomass raw materials supply game models based on game theory and multiagent simulation technology. Then he analyzed the effect, applicability, and corresponding implementation strategies of biomass power generation raw materials supply mode.

Because of the different characteristics of supply chains, there are also differences in agent behavior rules. The multiagent modeling of the FBPG supply chain is more considered from the perspective of raw materials supply. According to the research results, farmers, middlemen, and enterprises can be abstracted as agents with independent decision-making, learning, and memory ability. There are obvious differences in the decision-making rules of agents, the interaction rules between agents and between agents, and the external environment. The use of multiagent simulation technology shows obvious advantages. The behavior rules of simulation agents are designed according to the actual behavior of individuals. Through the interaction of microagents, various emergent behaviors and self-organization phenomena in the system can be effectively explored [17].

In conclusion, the forest biomass energy industry has extensive development space. The existing problems are mainly backward technology, lagging policy, insufficient supply of raw materials, and high production cost. Therefore, it is necessary to study the supply chain of forest biomass energy raw materials from the perspective of microagents. Policy factor greatly impacts biomass power generation industry, which can promote industrial development through economic policy adjustment. In addition, although the multiagent simulation method is not widely used in the forest biomass energy supply chain, there have been many studies in the field of forestry and agriculture. Therefore, it is reasonable to summarize the industrial policy suggestions through a series of simulation experiments.

## 3. Forest Biomass Power Generation Supply Chain

*3.1. Characteristics of Supply Chain.* The characteristics of FBPG supply chain are as follows:

- (1) As a biomass enterprise, the power generation product cannot be saved.
- (2) Raw materials have a wide production area and large output, but the collection has periodicity and is greatly affected by factors such as environment and season.

- (3) There are many alternative uses of raw materials, resulting in large supply fluctuation.
- (4) Raw materials are susceptible to moisture and decay, with low weight and value density. The cost of transportation and storage is high.
- (5) The raw materials supply of enterprise is generally subject to many farmers and middlemen. The enterprise does not occupy a dominant position.

It can be seen that FBPG supply chain is essentially different from the conventional production supply chain. The latter usually only focuses on the uncertainty of the consumption market, while the former pays more attention to the uncertainty of upstream raw materials supply.

In addition, compared with biomass raw materials such as straw, the geographical distribution of forest biomass raw materials is more special, the collection quantity is more uncertain, and the transportation cost is more expensive. Therefore, the upstream of FBPG supply chain is relatively complex, and the supply is unstable. By signing contracts and expanding the scope of purchase, the cooperative relationship between various agents can be stabilized. When establishing the simulation model, seasonal and other random factors will be set to reflect supply uncertainty.

**3.2. Composition of Supply Chain.** The first-hand data used in this paper was obtained by issuing questionnaires in Wushen Banner and Hangjin Banner of Inner Mongolia Autonomous Region, and Zhongwei City of Ningxia Hui Autonomous Region, as well as in-depth interviews with enterprises' leaders. The survey covers the basic information and raw materials purchase information of enterprises. In this survey, 5 enterprises were visited, and 127 questionnaires of farmers related to biomass energy were completed. Fifty-four farmers have sold raw materials in two ways (Table 1).

In the upstream supply chain of FBPG, there are mainly two kinds of raw materials transportation modes. One is that forest farmers directly sell to FBPG enterprises; the other is that forest farmers sell to middlemen and then sell to enterprises by middlemen. The downstream supply chain is relatively simple. The only customer is the State Grid Corporation of China (SGCC). The whole FBPG supply chain system can be shown in Figure 1. Next, the supply chain is divided into cost supply chain and sale supply chain to analyze the upstream and downstream customers outside the enterprise.

**3.2.1. The Upstream Supply Chain.** The upstream supply chain of FBPG enterprises in China is mainly two-level or three-level supply chain: (1) two-level supply chain: farmers/upstream companies/enterprises (independently cultivated raw materials)-power generation enterprises; (2) three-level supply chain: farmers-middlemen-power generation enterprises. Specifically, power generation enterprises mainly obtain raw materials through four modes: first, power generation enterprises independently cultivate economic forests as raw materials for power generation; second,

enterprises cooperate with upstream companies to obtain raw materials, which are generally molding fuel enterprises; third, enterprises purchase crops or forest residues from farmers; fourth, enterprises purchase raw materials from middlemen. These middlemen are mainly individual farmers. Due to the market economy, they have spontaneously become a hub connecting upstream and downstream raw materials.

The choice of raw materials supply mode depends on many factors such as business plan, capital status, geographical location, and other factors. Enterprises often choose mixed modes. Mode 1 belongs to internal production of enterprises and has a low degree of application. Mode 2 is interest cooperation among enterprises. Mode 3 and mode 4 are transactions between individual farmers and enterprises. Therefore, this paper mainly studies mode 3 and mode 4.

**3.2.2. The Downstream Supply Chain.** The downstream supply chain of FBPG is a two-level supply chain: power generation enterprises-SGCC. In addition to a few enterprises using the advantage of biomass power generation to increase sideline income, SGCC is the only downstream customer in the sale chain of the whole industry. Therefore, the formulation of policies on FBPG largely determines the survival and development of power generation enterprises.

At present, the feed-in tariff standard of biomass energy in China is 0.75 yuan/kWh. The feed-in tariff is the price of power commodity delivered to SGCC by power production enterprises. As China has formulated the priority scheduling policy, the sale of biomass power generation will be guaranteed. Moreover, according to the Renewable Energy Law, biomass power is preferentially connected to the grid and does not participate in peak regulation. Therefore, these policies reduce the impact of changes in electricity consumption of end customers on biomass power generation industry and ensure the stability of sale of biomass power generation enterprises.

## 4. Construction of the Simulation Model

This part establishes the three-level supply chain simulation model consisting of farmers, middlemen, and biomass power generation enterprises and uses NetLogo software for simulation. The role of the government appears in the form of subsidy parameters in the simulation system. The behaviors of farmers and middlemen adopt the "economic man" hypothesis. Middlemen will adjust their purchase scope according to the price of enterprise to maximize their profit. The simulation system takes enterprise as the core node of the whole supply chain to simulate the optimal purchase price and government subsidy when the enterprise reaches production capacity. The parameters and some processes of the model are mainly based on the relevant data of the Maowusu biomass thermal power plant in Erdos, Inner Mongolia. The enterprise takes the branches of sandy shrubs (mainly *Salix psammophila*) pruned from the roots as raw materials.

TABLE 1: Ways for farmers to sell raw materials.

Selling mode of farmers	Farmers sell to enterprises	Farmers sell to middlemen
Farmers take the initiative to transport	19	24
Farmers waiting to be acquired	4	7
Total	23	31

FIGURE 1: The supply chain system of FBPG.

*4.1. Simulation Assumptions and Process.* Under the premise of ensuring the authenticity of the system as much as possible, the simulation model is simplified, and the following assumptions are made according to the actual situation:

- (1) There is only one biomass power generation enterprise in a particular region, and there is no competition for raw materials among multiple biomass power generation enterprises.
- (2) During the simulation period, the area of woodland and the number of labor forces in the region do not change, and the positions of biomass power generation enterprise, middlemen, and farmers do not change.
- (3) The enterprise has no difficulty in selling products; that is, all electricity can be sold, and the enterprise is only responsible for purchase, not transportation.
- (4) According to the current policy, the government implements the tax policy of “immediate levying and refunding,” so the impact of bank tax is not considered in the model.
- (5) Farmers know the purchase price of middlemen and enterprise last time before pruning. The behaviors of farmers adopt the “economic man” hypothesis.
- (6) The distribution of forest biomass resources is extensive, uniform, and unitary. The woodland area is infinite. The species are single, and all of them are *Salix psammophila*. They are evenly distributed in the region.
- (7) Middlemen take the initiative to purchase raw materials from farmers’ homes.

In the simulation processes of FBPG supply chain, firstly, initialize the system state to generate the farmer agent, the

middleman agent, and the biomass power generation enterprise agent. Secondly, the enterprise sets the price for purchasing raw materials, and middlemen set a reasonable purchase range according to the current price. Thirdly, farmers decide whether to collect and sell forest biomass raw materials according to the purchase price of enterprise and middlemen. If the farmers sell to middlemen, the middlemen are responsible for transportation and primary processing and then sell to the enterprise; if farmers sell directly to the enterprise, farmers need to pay the cost of transportation. After purchasing raw materials, the enterprise processes and generates electricity and then sells electricity to SGCC to obtain government subsidy. Finally, calculate the profit of the biomass power generation enterprise. Judge whether the quantity of purchase can meet the demand of enterprise. If the enterprise reaches the production capacity, the program will stop; if the production capacity is not reached, the enterprise will increase the purchase price until the program stops when the production capacity is reached. At the same time, calculate the profit of farmers and middlemen in each cycle.

The simulation system finally solves the following three problems: (1) How much purchase price can make the biomass power generation enterprise reach production capacity and obtain the maximum ecological benefits. (2) How much government subsidy can ensure that the enterprise does not lose money at the purchase price of reaching production capacity. (3) What policy can be implemented to improve the overall efficiency of the supply chain.

#### 4.2. Construction of the Simulation Model

*4.2.1. Property and Parameter Setting of the Farmer Agent.* According to the survey data of Inner Mongolia, about 140 farmers directly transport raw materials to the enterprise

every year, involving 100–300 kilometers. About 20 middlemen transport raw materials to the enterprise every year, also involving 100–300 kilometers. Each middleman purchases raw materials from about 20 farmers. Therefore, there are about 540 farmers involved in selling raw materials. At the same time, in the farmers' questionnaires, the number of farmers who have sold raw materials in recent three years accounts for 48.1% of the respondents. It is roughly estimated that the number of forest farmers within 300 kilometers of the enterprise is about 1123. Moreover, because farmers prune every three years, it is estimated that the number of farmers is about 3369. Each  $1/15 \text{ hm}^2$  *Salix psammophila* can produce about 1t branches [18]. However, pruning *Salix psammophila* is greatly affected by external factors such as season and family labor force. The actual unit collection is often less than 1t. Therefore, a random variable  $\alpha$  (value between 0.5~1) is designed to more truly reflect the pruning situation of farmers. The pruning cost is mainly labor cost, and the pruning cost per ton of raw materials is about 70~200 yuan.

According to the survey, the woodland area of farmers ranges from 5 to 5400 mu. Through the K-S test, the woodland area data is not a normal distribution, and there are obvious abnormal values. Clean the woodland area data, sort the data from small to big, and take 25% as the upper quartile FL and 75% as the lower quartile Fu. The quartile distance IQR is Fu-FL. Then the upper bound of the data is  $Fu + 1.5 \times \text{IQR}$ , the lower bound is  $FL - 1.5 \times \text{IQR}$ , and the data ranges from 5 to 1585 mu after cleaning.

Grouping the data with 200 as group interval, it can be found that the data distribution is close to the exponential distribution. After fitting the exponential distribution, the fitting function and goodness of fit are obtained, and the fitting effect is good, as shown in Figure 2.

Based on the previous analysis and survey data, the main parameters of the farmer are sorted into Table 2.

**4.2.2. Property and Parameter Setting of the Middleman Agent.** Middlemen purchase branches from farmers but are not responsible for the harvesting and collecting branches. The purchase price is 180 yuan/ton. The cost of raw materials primary processing (including chipping and bundling) ranges from 20 yuan/ton to 35 yuan/ton. The main parameters of the middleman are sorted into Table 3.

#### 4.2.3. Property and Parameter Setting of the Enterprise Agent

- (1) Calculation of raw materials demand of the enterprise: taking Maowusu power plant as an example, the unit installed capacity is  $2 \times 12 \text{ MW}$ , and the power generation per hour is  $2 \times 1.2 \text{ kW}$ . As pruning and collecting of *Salix psammophila* occur on the sand, the raw materials after chipping contain a large amount of sand. It is necessary to shut down for 20–25 days every year to clean the tube wall; otherwise, the pipeline will be blocked and the service life of the unit will be reduced. Therefore, if the generator unit reaches production capacity,

assuming that it needs to be shut down for 25 days, the annual power generation is 195.84 million ( $2 \times 1.2 \times 24 \times 340$ ) kWh. According to the survey data, 1.25 Kg *Salix psammophila* can be converted into 1 kWh, so at least 156672 tons ( $19584 \times 10^4 / 1.25 / 10^3$ ) *Salix psammophila* can meet the needs of the enterprise. In fact, considering that the enterprise has other raw materials besides *Salix psammophila*, the demand is about 100000 tons. (2) Cost and profit: at present, the feed-in tariff of SGCC is 0.75 yuan/kWh, of which 0.277 is the benchmark price. Without considering the bank cost, the power generation cost per kWh is 0.292 yuan. The main parameters of the enterprise are sorted into Table 4.

**4.2.4. Behavior Rules of the Farmer Agent.** Farmers aim to maximize their profit and choose a reasonable sale object. Farmers' profit is sale income plus government subsidy and minus all costs. Farmers need to pay the collection cost of collecting biomass raw materials; the income of farmers mainly comes from biomass raw materials in their woodland. If it is sold directly to the enterprise, it also needs to pay the transportation cost. The main influencing factors of biomass raw materials transportation cost include vehicle technical performance, vehicle operating cost, characteristics of crops, collection mode, and radius [19]. Because the actual route is generally curved, the road tortuosity factor  $\lambda$  ( $\lambda = \sqrt{2}$ ) is introduced for correction. At the same time, the round-trip transportation is considered, so the distance should be twice the actual distance. Therefore, some formulas of farmers' behaviors are as follows:

- (1) Quantity of raw materials collected ( $Q$ ) =  $FS \times UAmo \times \alpha$ .
- (2) Pruning cost ( $FC_1$ ) =  $FCost \times Q$ .
- (3) Transportation cost of the farmer  $FC_2 = 2\sqrt{2} \times FE_d \times$  transportation cost per unit distance.
- (4) The transportation cost per unit distance varies with the collection quantity. According to the questionnaires, the type and performance of vehicles mainly used by farmers are shown in Table 5.

It is known that the average oil price in Inner Mongolia is 5 yuan/L. The transportation cost per unit distance of farmer with different collection quantity can be expressed as follows:

When  $0 < Q \leq 0.5$ , the tricycle is used for transportation, and the transportation cost per kilometer is 0.5 yuan.

When  $0.5 < Q \leq 1.5$ , the tractor is used for transportation, and the transportation cost per kilometer is 0.75 yuan.

When  $Q \geq 1.5$ , the four-wheel vehicle is used for transportation, and the transportation cost per kilometer is  $[Q/2.5]$  yuan.

$[Q/2.5]$  means to take the smallest integer larger than itself.

FIGURE 2: Distribution of the woodland area.

TABLE 2: Property and parameter setting of farmers.

Property	Letter representation	Meaning	Assigned value
Woodland area	FS	Woodland area owned by each farmer	$141.06e^{-0.523x}$ mu
Farmer-enterprise distance	FEd	Distance from farmer to biomass enterprise	0~300 km uniform distribution
Interval time of pruning	t	Time since last pruning	0~5 years random distribution
Number of farmers	FNum	Number of farmers in the region	1000~4000 (sliding strip)
Unit amount collected	UAmo	Quantity of raw materials collected per unit woodland	1 t/mu
Actual collection rate	$\alpha$	Random factors such as season	0.5~1 random distribution
Unit pruning cost	FCost	Cost of raw materials collected per unit woodland	70~200 yuan/t (sliding strip)
Unit pruning subsidy	CSub	Government subsidy for unit woodland pruning	Input box input (yuan)

TABLE 3: Property and parameter setting of the middleman.

Property	Letter representation	Meaning	Assigned value
Middleman-enterprise distance	MEd	Distance from middleman to enterprise	100~300 km uniform distribution
Number of middlemen	MNum	Number of middlemen in the region	10~50 (sliding strip)
Middlemen purchase price	MPri	Price of raw materials purchased from farmer by middleman	150~200 yuan (sliding strip)
Unit processing cost	MCost	Raw materials primary processing cost	20~35 yuan/t (sliding strip)

TABLE 4: Property and parameter setting of the enterprise.

Property	Letter representation	Meaning	Assigned value
Enterprise purchase price	EPri	Purchase price of raw materials for enterprise	350 yuan/t (initial value)
Production capacity of the enterprise	EQua	Raw materials required for power generation when reaching production capacity	100000t
Unit power generation cost	ECost	Power generation cost of enterprise	0.292 yuan/kWh
Feed-in tariff	Price	Sale price per kWh	0.55~1.55 yuan/kWh (sliding strip)
Purchase subsidy	GSub	Subsidy price of raw materials per cycle when production capacity is not reached	10 yuan/t
Raw materials conversion rate	$\mu$	How much power is generated per ton of raw materials	800 kWh/t

TABLE 5: Type and performance of farmers' vehicles.

Vehicle type	Tricycle	Tractor	Four-wheel vehicle
Fuel consumption per 100 km (L)	10	15	20
Unit quantity of transportation (t/vehicle)	0.5	1.5	2.5

Therefore, the transportation cost of the farmer ( $FC_2$ ) can be calculated.

- (5) The profit of farmer from selling raw materials to the enterprise is

$$W_1 = EPri \times Q + FS \times CSub - FC_1 - FC_2. \quad (1)$$

- (6) The profit of farmer from selling raw materials to the middleman is

$$W_2 = MPri \times Q + FS \times CSub - FC_1. \quad (2)$$

- (7) The farmer compares  $W_1$  and  $W_2$  to choose to prune or not, and whether to sell to the middleman or sell to enterprise. Calculate the quantity of raw materials actually transported to the enterprise ( $Q_{fe}$ ) and the quantity of raw materials actually transported to the middleman ( $Q_{fm}$ ) in each cycle.

The specific behavior rules of farmer are shown in Figure 3.

It should be noticed that *Salix psammophila* matures in about three years, and the more it is cut, the more lush it is. If the grown branches are not cut off, it will become dead branches in less than seven years. Because the government has public welfare forest subsidy for energy forest, once *Salix psammophila* dies, farmers will not be able to obtain public welfare forest subsidy, which will cause great losses to farmers. Therefore, the system assumes that farmers must choose to prune in the cycle, and the frequency of pruning is set to one time every three years. Moreover, the purchase scope of the middleman may not cover all farmers, so the farmer needs to judge whether he/she is within the purchase scope of the nearest middleman in advance so as to make the next decision of choosing to prune or not and selecting sale object.

**4.2.5. Behavior Rules of Middleman Agent.** Middlemen also aim to maximize their profit and hope to acquire and sell as many raw materials as possible. Middlemen are responsible for the initial processing and transportation of raw materials in the supply chain. The transportation route consists of two parts: one is that the middleman purchases from the farmer and then transports raw materials to the processing point (the location of the middleman), and the other is that the middleman transports raw materials from the processing point to the biomass power generation enterprise. Middleman decides the current purchase scope based on the current purchase price of the enterprise.

According to the questionnaires, there are two main types of vehicles used by middlemen, as shown in Table 6. It is assumed that a large four-wheel vehicle is mainly used when

middleman purchases raw materials from retail farmers, and a truck is mainly used to transport the biomass raw materials after chipping to the enterprise. Because the middleman can purchase from multiple households at the same time, it can be seen that the vehicle is always fully loaded during the purchase of raw materials from retail farmers:

- (1) When middleman purchases raw materials from retail farmers, the unit transportation cost is 0.25 yuan/ton-km (the calculation formula is  $25 \times 5/100/5$ ).

Because the middleman cannot accurately estimate the purchase quantity before determining the purchase scope, the unit transportation cost transported to the enterprise is temporarily calculated as full load so as to calculate the purchase radius  $R$  of the middleman.

- (2) The estimated unit transportation cost of transporting raw materials to the enterprise is 0.067 yuan/ton-km (the calculation formula is  $40 \times 5/100/30$ ).
- (3) The purchase radius  $R$  of the middleman should base on the economy of cost. According to the calculation method of purchase radius in reference [20], the unit cost of the middleman should be less than the purchase price of the enterprise ( $EPri$ ). The road tortuosity factor and round-trip transportation which are the same as farmers are considered. The formula is expressed:  $MPri + MCost + 2\sqrt{2} \times 0.25 \times R + 2\sqrt{2} \times 0.067 \times MEd \leq EPri$

The maximum purchase radius of the middleman is

$$R = \frac{EPri - MPri - Mcost - \sqrt{2} \times 0.133 \times MEd}{\sqrt{2} \times 0.5}. \quad (3)$$

- (1) The purchase quantity of the middleman is the sum of the quantity of raw materials within the purchase scope:

$$Q_m = \sum Q_{fm}. \quad (4)$$

- (2) The primary processing cost of the middleman is  $MC_1 = MCost \times Q_m$ .
- (3) The actual transportation cost of the middleman is

$$MC_2 = 2\sqrt{2} \times \left( 0.25 \times R + \left[ \frac{Q_m}{30} \right] \times 2 \times MEd \right). \quad (5)$$

- (4) The profit of middleman is

$$W_3 = (EPri - MPri) \times Q_m - MC_1 - MC_2. \quad (6)$$

The specific behavior rules of middleman are shown in Figure 4.

FIGURE 3: Flowchart of farmer's behavior.

TABLE 6: Vehicle type and performance for middlemen.

Vehicle type	Large four-wheel vehicle	Truck
Fuel consumption per 100 km (L)	25	40
Unit quantity of transportation (t/vehicle)	5	30

FIGURE 4: Flowchart of middleman's behavior.

**4.2.6. Behavior Rules of the Enterprise Agent.** The enterprise plays a leading role in the whole supply chain. The change of enterprise's purchase price will have an impact on the purchase scope of middlemen and farmers' willingness to sell. The initial price of the enterprise is set according to the current market price. If the production capacity is not reached, the purchase price of the enterprise in the next cycle will increase by 5 yuan/ton. If output exceeds demand, the price in the next cycle will be reduced by 5 yuan/ton to reach an equilibrium state.

Some formulas are calculated as follows:

- (1) Price change function:  $EPri = EPri + 5$
- (2) Total quantity of raw materials purchased by the enterprise:  $Q_e = Q_m + Q_{fe}$

- (3) Power generation of the enterprise:  $q = 800 \times Q_e$
- (4) Power generation cost:  $EC_1 = 0.292 \times q$
- (5) Purchase cost of the enterprise:  $EC_2 = EPri \times Q_e$
- (6) The profit of the enterprise:  $W_4 = 0.9 \times \text{Price} \times q - EC_1 - EC_2$

In (6), 0.9 means that 90% of the electricity of the enterprise is for sale and 10% for self-use.

## 5. Analysis of Simulation Results

**5.1. Simulation Interface and Model Verification.** The initial parameters used in the simulation system come from the survey data of farmers in many towns in Inner Mongolia and

Ningxia. Except for unit pruning subsidy, other parameters are assigned in the form of sliding strip. The initial values of number of farmers, number of middlemen, middlemen purchase price, and feed-in tariff are all taken from the survey data as described in Section 4.2.1. The unit pruning cost of farmers usually ranges from 70 to 200 yuan/ton, and the unit processing cost of middlemen ranges from 20 to 35 yuan/ton. The values with high frequency in the survey data are taken as the initial parameter values, which are 100 yuan/ton and 25 yuan/ton, respectively. According to the actual situation of the survey, the initial value of unit pruning subsidy is set to 10.

First, input the initial parameters into the system, as shown in Figure 5.

After inputting the initial parameters, design the view interface of the FBPG raw materials supply chain network, as shown in Figure 6 (the figure shows the transportation of raw materials in a cycle). The gray area is the woodland after pruning ( $n=0$ ), the light green area is the woodland within three years after pruning ( $n<3$ ), and the dark green area represents the woodland that can be used for pruning ( $3\leq n\leq 5$ ). Farmers are represented by small triangles, middlemen are represented by white squares, and the enterprise is represented by a red dot in the center. With the dynamic change of cycle, the interface can visually show the change of pruning and the transportation of raw materials.

Under the setting conditions in Figure 5, export the data obtained from the system to EXCEL and draw the relationship between purchase price and purchase quantity, as shown in Figure 7. According to the above analysis, the amount of raw materials required by the enterprise for power generation is about 100000 tons. If the raw materials purchased by the enterprise can meet the demand when reaching production capacity, the purchase price needs to be between 425 and 435 yuan. At this time, the purchase quantity and purchase price of the enterprise tend to be stable.

Under the setting conditions, the profit of enterprise is negative. Similarly, export the relevant data of enterprise's profit, as shown in Figure 8. After the purchase quantity and purchase price of the enterprise tend to be stable, the loss is about 1.16~1.3 million yuan. In order to make the enterprise more profitable, government subsidy should be gradually increased; that is, the feed-in tariff should be increased.

Therefore, continue to adjust the feed-in tariff to study when enterprise generates profit. When the feed-in tariff reaches 0.85 yuan/kWh, the power generation profit of the enterprise is still negative, with a loss of about 3 million yuan. Continue to gradually increase the feed-in tariff by 0.01 yuan until 0.95 yuan/kWh, and the enterprise can achieve profitability under the condition of meeting the raw materials demand, as shown in Figure 9.

It is not difficult to find that the simulation result is basically consistent with the survey data of existing policy. At present, the purchase price of forest biomass raw materials is 400 yuan per ton, and the enterprise can only purchase 80000~90000 tons of raw materials. In the survey, it is found that most biomass power generation enterprises are in a state of loss at the price of 0.75 yuan/kWh. Therefore, it can

be verified that the model construction is basically reasonable.

*5.2. Simulation Experiments.* The previous section has verified the rationality of the model. Therefore, adjust the parameters from the perspective of supply chain, internal agent, and external environment, and further discuss the influence of parameter change on supply chain. Several comparative experiments are carried out based on the initial parameters.

*5.2.1. From the Perspective of Supply Chain.* The policy subsidy sharing contract can help the whole supply chain achieve coordination [21]. The supply of middlemen is affected by the raw materials market. When the market supply is less than demand, middlemen need to spend a higher price to buy raw materials from other regions. It is difficult for the whole supply chain to achieve coordination in this condition. Middlemen are more inclined to seek a smaller order quantity to ensure that their profit is as large as possible. Therefore, based on the subsidy sharing contract, middlemen are willing to sign a higher order quantity with the enterprise, which improves the enthusiasm for purchase. Similarly, this kind of contract coordination is applicable to farmers and enterprises. Therefore, the enterprise can increase the overall profit of the supply chain by increasing the purchase price. How to determine the optimal subsidy proportion of the enterprise ( $\beta$ ) is very important. In the above initial environment, compare the profit of middleman, enterprise, and farmer, as shown in Figure 10.

When the feed-in tariff remains unchanged (price = 0.95), two periodic nodes are selected, which are the node that does not reach equilibrium and the node that reaches equilibrium. For example, at the two nodes of  $t=7$  (not reaching equilibrium) and  $t=17$  (reaching equilibrium), the two nodes' raw materials purchase price of the enterprise is different, which are 380 yuan per ton and 420 yuan per ton, respectively. Compare the profit of each agent and the whole of the supply chain under the two nodes, and sort out the relevant data of the nodes in Table 7.

When the purchase price of the enterprise increases, the overall profit of the supply chain increases significantly, which verifies the rationality of the experiment. In this experiment, the government subsidy ( $t$ ) is 0.673 yuan/kWh (0.95~0.277), which is equivalent to 538.5 yuan/ton of forest biomass raw materials. At this time, the purchase price is 420 yuan/ton, and the subsidy coefficient ( $\beta$ ) can be calculated as 0.074.

*5.2.2. From the Perspective of the Internal Agent.* The purchase price of enterprise plays a leading role in the whole supply chain. In addition, other parameters also have an impact on the supply of forest biomass raw materials. Such as the unit operating cost of power generation, the unit pruning cost of farmers, and the initial processing cost of middlemen. Reducing these costs can effectively improve the operation efficiency of the supply chain. Next, the paper will

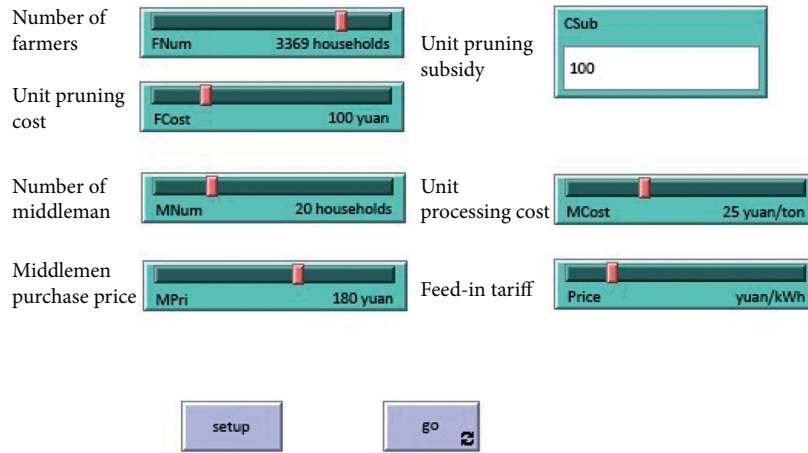

FIGURE 5: Input parameters interface.

FIGURE 6: Main view interface.

FIGURE 7: Relationship between purchase price and purchase quantity.

study which cost reduction is the most effective in improving the efficiency of forest biomass supply chain. Under the condition that the external environment parameters remain unchanged, several experiments are

carried out, and the results are shown in Table 8. Because the experiments have certain randomness, the results are given according to the average level of many simulation experiments.

FIGURE 8: Profit of the enterprise (price = 0.75).

FIGURE 9: Profit of the enterprise (price = 0.95).

FIGURE 10: The average profit of the agents of supply chain.

The unit pruning cost can continue to be reduced, and the supply chain is more sensitive to the unit pruning cost. Reducing the pruning cost by 30 yuan per mu can greatly reduce the purchase price of the enterprise. Therefore, for the western region in China, improving the mechanization level of raw materials collection and reducing labor cost will be an effective way to improve the efficiency of biomass supply chain. In addition, the reduction of the initial processing cost of middlemen did not cause great changes

in the purchase price of enterprise. Because middlemen have original capital and initial investment, there is little space for the decline of unit initial processing cost. Finally, for enterprises, reducing the operation cost of power generation can effectively avoid the loss. Through technical improvement, strengthening the construction of the management team, and reducing management cost, enterprises can seek survival space under the existing feed-in tariff level.

TABLE 7: Profit index of agents under different purchase prices.

Profit index of agents	Epri = 380	Epri = 420

Unit pruning cost (farmers)	The initial processing cost (middlemen)	Unit operating cost of power generation (enterprise)	Purchase price of enterprise when reaching production capacity	The feed-in tariff*
100	25	0.292	420–430	0.95
70	25	0.292	285–295	0.65
100	20	0.292	420–430	0.95
100	25	0.25	420–430	0.70

\*The feed-in tariff here refers to the minimum price that can ensure that power generation enterprise does not suffer losses.

### 5.2.3. From the Perspective of the External Environment.

Although the government is not a main agent in the forest biomass supply chain, as an important force to promote the development of the FBPG industry, policy subsidy is an important way to improve the supply of forest biomass raw materials. In addition to the feed-in tariff subsidy mentioned above, the existing subsidies include “immediate levying and refunding” for enterprise tax and pruning subsidy for farmers. In particular, the pruning subsidy of farmers is still in the exploratory stage and has important research value. In addition, it is found in the simulation that the number of farmers and middlemen in the region has a great impact on the whole supply chain. Under the condition that the internal main parameters remain unchanged, several experiments are carried out, and the results are shown in Table 9.

Pruning subsidy can effectively help reduce the purchase price of enterprise and alleviate the pressure on enterprise to purchase raw materials. The number of farmers (or woodland area) in the region has a great impact on the whole supply chain. Therefore, when selecting the site, it is necessary for enterprises to investigate the local forest biomass energy potential and choose the area with rich resources as the power generation address. The number of middlemen will also have a certain impact on the raw materials purchase of enterprises. If the number of middlemen in the region is too small, it will also increase the difficulty for enterprises to acquire raw materials. In particular, it is difficult to acquire raw materials from farmers in remote areas and small areas.

5.3. *Result Analysis.* The simulation experiment is carried out by adjusting the parameter value, and the results are summarized as follows:

- (1) Combined with the actual operation of the current enterprises in China, the current feed-in tariff of 0.75

yuan per kWh (including subsidy) is low for biomass power generation enterprises, and most enterprises are facing the crisis of bankruptcy. The survey also found that 69 farmers believe that the current purchase price of raw materials is unreasonable. The simulation results show that when the feed-in tariff is increased to about 0.95~1.0 yuan per kWh, the biomass power generation enterprises will not suffer losses when reaching the production capacity. At the same time, the purchase price of the enterprises needs to be improved. Under the current purchase price, the supply of raw materials is insufficient. It is more appropriate that the purchase price of raw materials should increase about 25 yuan at the current level of 400 yuan per ton.

- (2) Unit pruning cost has a great impact on the whole supply chain. The increase of pruning cost will lead enterprises to reach the production capacity at a higher purchase price. At the same time, the feed-in tariff that meets the profitable conditions of enterprises will also increase. Therefore, combined with the relevant policies of energy subsidy in the western region of China, the government can adopt appropriate subsidy for purchasing agricultural machinery to realize large-scale mechanized collection and greatly reduce the cost of artificial pruning. The government gives farmers a pruning subsidy, which can also promote some farmers to participate in pruning and increase the supply of raw materials.
- (3) When selecting the site, biomass power generation enterprises need to take the external environment factors into account to ensure that the number of local farmers can provide enough forest biomass raw materials. In addition, the enterprises should establish a long-term and stable partnership with

TABLE 9: Simulation experiment results of changing external parameters.

Number of farmers	Number of middlemen	Pruning subsidy	Purchase price of enterprise when reaching production capacity	The feed-in tariff*
3369	20	0	420–430	0.95
3369	20	100	270–280	0.72
3000	20	0	515–520	1.05
3369	10	0	490–500	1.02

\*The feed-in tariff here refers to the minimum price that can ensure that power generation enterprise does not suffer losses.

middlemen, reasonably plan the number of middlemen, and ensure a stable supply of raw materials.

## 6. Conclusions

FBPG industry is of great significance to protect the ecological environment and promote the increase of farmers' income in the western region of China. Research and survey found that the current bottleneck of industrial development in China is mainly due to the insufficient supply of raw materials and serious losses of enterprises. In order to solve this problem, this paper discusses the coordination of the FBPG supply chain on the premise of uncertain supply. This is a supplement to a subdivided field of straw biomass power generation supply chain research. At the same time, the combination of empirical research and case analysis makes up for the defect of excessive parameter value deviation in the simulation processes and enriches the research content of multiagent simulation of the supply chain. The conclusions of this paper are as follows.

Firstly, it is relatively difficult to collect forest biomass raw materials in China, which has a great relationship with the terrain. Farmers' collection cost is high, and they generally believe that the purchase price of enterprises is low. Because the labor income level has been increasing in recent years, this leads to the low willingness of farmers to collect and sell raw materials. In addition, forest biomass raw materials also have many other values besides being sold to enterprises, such as covering sand layer (sand-prevention) and self-use as an alternative fuel. There are many methods to sell biomass raw materials collected by farmers. The choice of farmers depends on which method can obtain the greatest profit. Therefore, through reasonably increasing the purchase price and giving subsidy for purchasing agricultural machinery, the participation of forest farmers can be improved. It is conducive to the stable supply of raw materials and helps the sustainable and stable development of enterprises.

Secondly, middlemen are an important and stable source for FBPG enterprises to purchase raw materials. At present, the government only provides a feed-in tariff subsidy for biomass power generation enterprises. If the enterprise transfers part of the subsidy to middlemen, the purchase quantity of middlemen will increase, and the profit of the enterprise will also increase. Therefore, enterprises can improve the supply enthusiasm of middlemen by means of increasing purchase price and ensure that the raw materials of FBPG enterprises meet the production capacity demand as much as possible. It also avoids the loss of stock shortage.

Finally, at the current stage, if the enterprise is expected to meet the production capacity demand, the purchase price of 425 yuan per ton is reasonable. In this case, the feed-in tariff can be increased to about 0.95 yuan per kWh to ensure the sustainable operation of biomass power generation enterprises. In addition, reducing the power generation operation cost of enterprises, promoting the use of brush cutters, reducing labor cost, and providing pruning subsidy can also promote the overall efficiency of the supply chain.

Although this paper simulates the reality of the FBPG supply chain in China as much as possible, there are still some details to be further considered due to the complexity of reality. For example, there is a time gap (usually one year) in the issuance of policy subsidy, which may lead to insufficient funds for enterprises to purchase biomass raw materials in that year, and many farmers think that it is difficult to prune, which may lead to a lack of labor. So middlemen need to hire labor from other provinces in China, increasing the cost of pruning.

These complex situations may become important factors hindering the development of biomass enterprises in China. Therefore, the prospects are put forward in the follow-up research:

- (1) The simulation model is only applicable to the forest biomass raw materials supply chain in the western region of China, which can be improved and optimized to make it applicable to other regions.
- (2) Continue to enrich the behavior rules of agents, such as the behavior rules of enterprises. The current setting of enterprise is that price is set on a uniform basis. As a result, farmers close to the enterprise can get rich income, while farmers far away can get less income. So the hierarchical pricing strategy can be further considered. There are different purchase prices for farmers at different distances, which can reduce the cost of enterprises.
- (3) The distribution of farmers, middlemen, and enterprise in the model is different from reality, so a regional map can be introduced to optimize the simulation effect.
- (4) Further discuss the problem of labor shortage in the western region of China.

**Objective.** As the preclinical stage of Alzheimer's disease (AD), Mild Cognitive Impairment (MCI) is characterized by hidden onset, which is difficult to detect early. Traditional neuropsychological scales are main tools used for assessing MCI. However, due to its strong subjectivity and the influence of many factors such as subjects' educational background, language and hearing ability, and time cost, its accuracy as the standard of early screening is low. Therefore, the purpose of this paper is to propose a new key technology of fast digital early warning for MCI based on eye movement objective data analysis. **Methodology.** Firstly, four exploratory indexes (test durations, correlation degree, lengths of gaze trajectory, and drift rate) of MCI early warning are determined based on the relevant literature research and semistructured expert interview; secondly, the eye movement state is captured based on the eye tracker to realize the data extraction of four exploratory indexes. On this basis, the human-computer interactive 2.5-minute fast digital early warning paradigm for MCI is designed; thirdly, the rationality of the four early warning indexes proposed in this paper and their early warning effectiveness on MCI are verified. **Results.** Through the small sample test of human-computer interactive 2.5 fast digital early warning paradigm for MCI conducted by 32 elderly people aged 70–90 in a medical institution in Hangzhou, the two indexes of “correlation degree” and “drift rate” with statistical differences are selected. The experiment results show that AUC of this MCI early warning paradigm is 0.824. **Conclusion.** The key technology of human-computer interactive 2.5 fast digital early warning for MCI proposed in this paper overcomes the limitations of the existing MCI early warning tools, such as low objectification level, high dependence on professional doctors, long test time, requiring high educational level, and so on. The experiment results show that the early warning technology, as a new generation of objective and effective digital early warning tool, can realize 2.5-minute fast and high-precision preliminary screening and early warning for MCI in the elderly.

## 1. Introduction

Mild cognitive impairment (MCI) is an unstable clinical transition state between normal age and dementia. The study

found that people with MCI above 70 have a high prevalence rate, and 21.8% of them progress to dementia 3~5 years after the onset of MCI. The possibility of transferring to Alzheimer's disease (AD) in patients with MCI is 2.8 times

higher than that in healthy aging [1, 2]. As we all know, Alzheimer's disease is still incurable, whose pathological changes are difficult to reverse and the curative effect is poor in the middle and late stage, bringing psychological, physiological, and economic pressure to the patients and their families [3]. However, studies have found that if patients are identified early and reasonably intervened in MCI stage, the reversal rate of mild cognitive impairment to normal cognitive function is more than 30% [4]. Therefore, moving the MCI early warning window forward at the daily home level based on the key technology of human-computer interactive 2.5-minute fast digital early warning is of great significance to improve the life quality of patients and reduce the social burden.

According to the diagnostic guidelines of MCI, its clinical diagnosis is mainly based on medical history collection and neuropsychological scale assessment [5]. Although the neuropsychological scales commonly used in clinic have good reliability and wide application in screening cognitive impairment, some defects are still widespread, such as strong subjectivity, long time consumption, insufficient sensitivity for MCI early warning, and so on [6]. Thus, in order to make up for the deficiencies of cognitive screening scales, more and more computerized cognitive assessment tools [7, 8] appear, but most of them need professionals to carry out the standardized operation, and the subjects need to go to the clinic or examination centers, which immensely limit the universality of detection.

Moreover, the latest research found that, compared with other cognitive fields, the earliest occurrence of cognitive impairment in MCI patients is the decline of visuospatial function, and at present, many studies have used eye movement related examinations to assess early cognitive impairment [6, 9, 10]. At the same time, the powerful computing and data processing ability of intelligent algorithm has its unique advantages in the analysis of eye movement examination results and eye movement trajectory. Many studies have shown that task assessment saccade mode based on eye tracking can be used to detect MCI and early signs of cognitive decline. Detection indexes and forms vary from research to research [11, 12], but all show that task paradigm can be designed to check various visual features of saccade or eyes under relevant stimuli, and eye tracker can be used for activity monitoring to realize extensive and convenient cognitive function examinations.

Based on the summary of previous studies, it can be found that the current tools for MCI early warning and screening have various shortcomings at different levels. Most of scales and questionnaires which are the most commonly used have deficiencies such as long time-consuming and lack of objective assessment data, while the computerized cognitive assessment tools developed in the early stage also have the characteristics such as various inspection types and parameters and complex calculation process and large population variability.

Thus, taking advantage of noninvasive, short time consumption, low cost, and high feasibility of eye movement tracking data acquisition, this paper puts forward four exploratory MCI early warning indexes including "test

duration," "lengths of gaze trajectory," "correlation degree," and "drift rate" based on the review and summary of relevant research literature and semistructured expert interviews, in visuospatial function and dynamic eye movement monitoring perspectives.

At the same time, based on the key technology of digital early warning, a human-computer interactive 2.5-minute fast digital early warning paradigm for MCI is designed. Finally, the elderly aged 70–90 with clinical diagnosis conclusion of MCI are included in the subjects, and the human-computer interactive 2.5-minute fast digital early warning paradigm designed in this paper is benchmarked with the clinical diagnosis conclusion, so as to verify the effectiveness of the new digital early warning paradigm in this study.

The new early warning key technology studied in this paper has the advantages of short time consumption and simple operation together with objective and accurate assessment, which can realize the real-time feedback of eye movement trajectory and the accurate preliminary early warning for MCI in the elderly population in 2.5 minutes.

The rest of the paper is organized as follows. In Section 2, this paper introduces the related work on MCI early warning in the literature. In Section 3, this paper explains the research methods of this paper. And this paper introduces the relevant work of the experiment, including the paradigm and principle of experiment, the key technologies of digital early warning, and basic information of experiment in Section 4. In Section 5, this paper analyzes the data processing results. A short discussion of the proposed scheme is presented in Section 6.

## 2. Related Work

By reviewing the literature on MCI early warning methods in Pubmed, Web of Science, and other literature libraries in recent 10 years, we find that, compared with other cognitive fields, visuospatial dysfunction may be the earliest cognitive impairment field in MCI patients [13, 14]. A research [15] showed that there is no significant difference between AD mice and normal control mice when performing olfactory tasks, but on the contrary, the visuospatial function including percentage of visuospatial correct decisions and speed of visuospatial relearning of AD mice was significantly worse than that of control mice, which also confirmed that the decline of visuospatial function may be used as an early sensitive index for MCI screening. A study [16] shows that the scores of spatial structure and connection test of MCI patients are low, speculating that visual reasoning, connection, and spatial structure test may be sensitive to the early diagnosis of MCI patients, or the cognitive function reflected by such test, that is, visuospatial and executive function, has diagnostic effect for MCI early diagnosis. In addition, some pathologists [17] found that the initial lesion location of numerous patients with MCI is not the well-known hippocampal region, but the visual contact cortex, which also shows that the loss of visuospatial function may occur before the symptoms of hippocampal involvement (such as memory decline).

At present, many studies have used examinations related to eye movement to assess early cognitive impairment. Study of Bylsma has found that frequency of saccadic intrusion of patients with cognitive impairment may increase due to the decline of attention and working memory function, which is negatively correlated with MMSE scores [18]. VisMET, designed and developed by Haque et al. [19], can assess the visuospatial memory of healthy aging and mild cognitive impairment by analyzing the subjects' gaze points and gaze duration, so as to realize assessment for MCI.

With the continuous development of modern medicine, there are more and more types of computerized cognitive screening systems. Bartoli et al. [20] used Omni robot to control and move the patient's arm to complete a test and analyzed the visuospatial ability of MCI patients through the recorded trajectory and eye movement data. Nevertheless, this study analyzed many variables and needs long time to complete, so it is difficult for the elderly. A computerized cognitive screening test developed by Canadian researchers can screen cognitive impairment through three cognitive domains: information processing speed, working memory, and executive function [21], but it takes 10 minutes and lacks scalability for rapid screening of large-scale populations. Besides, Papp et al. team [22] developed a long-term episodic memory management and measurement method suitable for those at risk of AD by using image stimulation from the perspective of episodic memory. Subjects can detect episodic memory ability through a mobile application, but it mainly assesses cognitive ability from the memory dimension, with low efficiency of MCI early screening and warning.

Consequently, although the existing cognitive screening information system has many advantages, the screening for MCI patients still has the following deficiencies:

- (1) Systematic screening needs professional doctors. At present, it is difficult to carry out large-scale community screening under the current situation of lacking doctor resources.
- (2) The system test is highly difficult and time is too long, so it is not suitable for fast primary screening in large-area home crowd.
- (3) The design of test paradigm is not objective enough, the degree of standardization is low, and there is a lack of objective and quantitative assessment indexes. The early warning effectiveness is not enough, and it is difficult to meet the needs of screening.
- (4) There are still few studies on digital early warning screening for detecting MCI from the perspective of visuospatial dysfunction.

See Table 1 for more detailed analysis of deficiencies, which also shows the research gaps found in previous studies in the field of MCI early warning.

At the same time, we found that numerous studies assess early cognitive impairment through eye movement data, indicating that eye movement test is a relatively simple and objective assessment and screening tool for MCI at present.

Although detection indexes and forms vary from research to research, the assessment of eye movement test in these studies often focuses on test durations, eye drift, and so on. Based on this, aiming at the shortcomings of MCI early warning at present, a human-computer interactive digital early warning paradigm for MCI is designed based on visuospatial function assessment and dynamic eye movement monitoring. It realizes eye movement dynamic follow-up and real-time feedback under time sequence and outputs visual dynamic analysis results in time on the basis of the concept of scene activation. Concurrently, the fast, accurate, and digital early warning and screening for MCI high-risk population based on eye movement objective data analysis is realized.

### 3. Methodology

*3.1. Semistructured Interview.* In order to get more reliable information, we use semistructured interview to determine the effective early warning indexes for MCI. The 20 experts participating in the interview are composed of neurologists, interdisciplinary scholars of neurocomputing, and elderly health management experts, who all have rich experience in the assessment and diagnosis of MCI in large general hospitals.

Based on previous literature review [25–28], this paper formulates an interview outline. By designing the outline of behavioural event interview, the interviewees are reviewed in an open-ended manner so as to dig out the indexes related to MCI early warning. Three days before the formal interview, the interview outline was provided for the interviewees for preparation, so as to improve the effect and quality of the interview. In addition, before the formal implementation of the interview, this paper clearly informed the interview process and the purpose of the obtained data, so as to avoid the interviewees' worries. The outline of the interview is shown in Table 2.

*3.2. Key Technology of Eye Movement Objective Data Acquisition.* The objective data acquisition of eye movement is realized by Tobii eye tracker, composed of two eye movement sensors, dark pupil illumination light sources, bright pupil illumination light source, and multiple signal processing chips, whose internal structure is shown in Figure 1.

Tobii eye tracker uses multiple near-infrared light sources as reference points for auxiliary analysis. By collecting the reflected light from the pupil and cornea, the eye tracker analyzes the relative position of eyes and then obtains the focus of the user's line of sight. On the basis of multi-reference point complementary technology, the user's head trajectory compensation is realized to ensure the accuracy of the collected data. Figure 2 shows light source reflection diagram. The technology adopted by Tobii eye tracker is an improved version of the traditional pupil center cornea reflection (PCCR) eye tracking technology (US patent us7572008) [29], and the principle is as follows:

TABLE 1: Previous studies and research gap.

\end{aligned} \tag{1}$$

Based on the principle shown in Figure 3, the human-computer interactive 2.5-minute fast digital early warning paradigm for MCI studied in this paper is completed on a computer equipped with eye tracker. Below the computer display is the eye tracker used in this study. In order to explain the calculation method more clearly, we define the position information of the subject's line of sight on the display collected by the eye tracker as "gaze sample," whose sampling rate studied in this paper is 60 Hz, which is about to collect the subject's "gaze sample" every 0.0167 seconds. The principle of human-computer interactive eye tracking is shown in Figure 3.

## 4. Experimental Design

*4.1. Experimental Design of Human-Computer Interactive Fast Digital Early Warning Paradigm for MCI.* The key technology of early warning proposed in this paper serves the elderly high-risk groups with cognitive impairment and is committed to the early warning and screening of MCI in the home or community scene, which should meet the use needs of high-risk groups with cognitive impairment. First of all, designing digital games for elderly users need to be user-centered, which should be suitable for the knowledge and understanding of elderly players [30]. Therefore, this

study is based on the principle of human factors engineering, follows the user-centered design principle, and finally completes the game design based on the preexperiment of multiple schemes in the early stage.

Through the preliminary preexperiment, we found that most of the elderly in the community have varying degrees of vision problems, and most of them are right-handed. Hence, considering the actual situation of users and the reasonable distance of data measurement, this study uses a 32-inch 4K ultraclear display screen, equipped with high-performance miniaturized eye tracker (Tobii eye tracker 5) and Xbox handle as operating device. The eye tracker can be installed under the computer display for eye movement perception and acquisition. During the experiment, each subject needs to sit 55 cm away from the device to meet the requirements of vision and data acquisition.

The subjects complete the test through operating handle, which is easy to move and has a round touch. Besides, the rocker is mainly used in the operation, which is an easier operation method to master, compared with the keyboard and mouse. It is simple to use and can enhance the sense of main control and have a high degree of adaptability to the aging.

In terms of paradigm design, the interface designed in this study is mainly black and white, and the object controlled by the subjects is a red ball. The color contrast between red ball and the interface is strong, making the target prominent. As for designing obstacles and eliminating targets, the subjects are mostly right-handed operation, so the main obstacles are set on the left side of the interface to facilitate the subjects to operate in a relatively fixed posture. Meanwhile, considering that the elderly have obstacles in understanding that the targets need to be removed from the paradigm, the four targets in the interface are set to dynamic 3D rotation. See Figure 4 for overall presentation.

Through the preexperiment of 80 samples in the early stage, it is found that the total time for most people with normal cognition to complete the paradigm will not exceed

1. What do you think is the goal of MCI early warning?
2. What do you think is the most effective way to assess MCI?
3. Which objective early warning indexes do you think can realize MCI early warning?
4. What do you think are the shortcomings of the current MCI early warning methods?
5. What are your expectations and suggestions for MCI early warning mode in the future?

FIGURE 1: Internal structure of eye tracker.

FIGURE 2: Light source reflection diagram.

2.5 minutes (150 seconds). Thus, when designing the paradigm, 2.5 minutes will be taken as cut-off point of the reference paradigm time. Subjects who still fail to complete the paradigm after 2.5 minutes are considered to have a high risk of MCI. Figure 5 shows a case of experiment.

The paradigm we designed consists of three modules: information entry, white cube elimination, and data feedback. In order to ensure that the equipment can accurately detect the subject's eyes, the equipment needs to be calibrated before the test. The test rules and the method of operating the equipment will be orally informed to the subjects by professionals. In the module of information entry, the staff can click the start button to conduct the formal test after entering the subject's name. In the module of white cube elimination, subjects need to use the rocker of the Xbox handle to control the movement of the red ball to collide and eliminate four white cubes. The test paradigm is shown in Figure 6.

After the four white cubes are all eliminated, the subjects can receive their test durations in the module of data feedback on the screen. What is more, the eye movement trajectory will be displayed also. Both the test data are fed back to the user as soon as the test ends, as shown in Figure 7.

#### 4.2. Experiment Implementation

**4.2.1. Data Acquisition and Principle in Test Paradigm.** Based on the summary of relevant literature and semi-structured expert interviews, we dug out four exploratory MCI early warning indexes including test durations, lengths of gaze trajectory, correlation degree, and drift rate. The digital paradigm and mathematical analysis technology are applied to assess the visuospatial function and dynamically monitor the eye movement, so as to realize the preliminary screening and early warning for MCI. This technology is mainly realized by designing the paradigm scene in which the subjects control the red ball to eliminate the four white cubes in the virtual environment through collision. Finally, the test durations and the dual trajectories graph of gaze and read ball will be fed back to users. The framework of key technology of human-computer interactive fast digital early warning for MCI is shown in Figure 8.

Moreover, in order to observe and analyze data more accurately and intuitively, Ecarts is used to visualize the data in this study. As shown in Figure 9, in the 3D coordinate diagram, the  $X$  axis represents the abscissa of the red ball movement trajectory and gaze trajectory, the  $Y$  axis represents the ordinate of the red ball movement trajectory and

FIGURE 3: The principle of human-computer interactive eye tracking.

gaze trajectory, and the  $Z$  axis represents the time of the paradigm. Then, the gaze sample position, red ball position, and four white cube positions in the paradigm are represented in the figure with different color labels, respectively. In the graph, dark red curve represents the red ball movement trajectory and navy-blue curve represents the gaze sample trajectory. Purple, yellow, green, and red lines, respectively, to represent the positions of four white cubes.

Subjects can obtain the visualization results of paradigm data after the paradigm ends and retain the corresponding trajectory by checking different labels. 3D dual trajectories graph from different angles is shown in Figure 10. Non-technical personnel can make an intuitive comparison by observing the similarity between the gaze trajectory and the red ball trajectory and then get a general judgment, while professional data analysis needs further calculation.

**4.2.2. Definition and Quantitative Analysis of Key Indexes in Test Paradigm.** Based on the previous literature review and semistructured interviews, this study identified four key indexes including test durations, lengths of gaze trajectory, correlation degree, and drift rate. In this paradigm, the total time is  $T(s)$ , the sampling time of the gaze samples and the position of the red ball in  $T$  is  $I$ , the time point of single sampling is  $t_i$ , the single gaze sample position is  $Gaze_i$ , and the single position of red ball is  $Ball_i$  ( $0 < i \leq I, i \in N^*$ ).

$L_{Gaze}$  means length of gaze trajectory in this paradigm, which is the total length of the gaze sample trajectory. The calculation method is as follows:

Make  $d_i$  the distance between two adjacent gaze samples:

$$d_i = \sqrt{(X_{Gaze_{i+1}} - X_{Gaze_i})^2 + (Y_{Gaze_{i+1}} - Y_{Gaze_i})^2} \quad (1 \leq i \leq I - 1, i \in N^*) \quad (2)$$

where  $X_{Gaze_{i+1}}$  refers to the abscissa of the gaze point at the  $i + 1$ th sampling, and  $X_{Gaze_i}$  refers to the abscissa of the gaze sample at the  $i$ th sampling;  $Y_{Gaze_{i+1}}$  refers to the ordinate of the gaze sample at the  $i + 1$ th sampling, and  $Y_{Gaze_i}$  refers to the ordinate of the gaze sample at the  $i$ th sampling.

Lengths of gaze trajectory  $L_{Gaze}$  can be obtained:

$$L_{Gaze} = \sum_{i=1}^{i=I-1} d_i. \quad (3)$$

In this paradigm, the correlation degree is used to describe the similarity between the red ball trajectory and the gaze trajectory. The algorithm of the correlation degree is based on the correlation coefficient, which is the quantity of the linear correlation degree between the research variables. The formula is as follows:

$$\text{corr}(a, b) = \frac{\text{cov}(a, b)}{\sqrt{\text{var}[a] \times \text{var}[b]}} \quad (4)$$

$\text{cov}(a, b)$  is the covariance between  $a$  and  $b$ ,  $\text{var}[a]$  is the variance of  $a$ , and  $\text{var}[b]$  is the variance of  $b$ .

Because the red ball trajectory (the red ball coordinate position sequence,  $Ball$ ) and the gaze trajectory (the gaze coordinate position sequence,  $Gaze$ ) are not simple one-dimensional random variable data, the abscissa and ordinate of the two sequences are separated to form the corresponding sequence separately.  $X_{Ball}$  is the red ball abscissa sequence,  $Y_{Ball}$  is the red ball ordinate sequence,  $X_{Gaze}$  is the abscissa sequence of gaze samples, and  $Y_{Gaze}$  is the ordinate sequence of gaze samples. At this time, correlation degree of  $X_{Ball}$  and  $X_{Gaze}$ , that is,  $X_{corr}$ , and correlation degree of  $Y_{Ball}$  and  $Y_{Gaze}$ , that is,  $Y_{corr}$ , can be calculated, respectively.

Finally, the correlation degree is obtained:

FIGURE 4: Overall presentation. (a) Paradigm interface of red ball. (b) Eye tracker. (c) Handle.

FIGURE 5: A case of experiment. (a) The scene of the test starting. (b) The scene of the test going to end.

$$corr = \frac{X_{corr} + Y_{corr}}{2}. \quad (5)$$

In this study, Ecarts is used to visualize the test results of MCI early warning paradigm, and the 3D dual trajectories graph of the gaze trajectory and red ball trajectory of the subjects is formed. The experimental legend shows that the trajectory of some subjects shows the sharp angle of gaze trajectory and is far away from the red ball trajectory, which is unreasonable, because the goal of the paradigm designed in this paper is to let the subjects control the red ball to eliminate the white cubes. At the same time, when setting the numerical range, this test allows a certain limit of line-of-sight offset caused by vision, sitting position, and instrument

error. Therefore, if the distance between the subject's gaze sample and the red ball position exceeds a certain range at the same time, it is regarded as eye drift.

In this study, the project team explored the value of eye drift threshold between 100 px and 1000 px and took every 50 px as the standard interval, with a total of 21 methods. The Apriori algorithm is used to analyze the correlation between the subjects' gaze sample data under different values and the subjects' final judgment results. The results show that the confidence is the highest at the thresholds of 400 px, 450 px, and 500 px, all reaching 0.89. Furthermore, the project team conducted logistic regression analysis on the three groups of data with the highest confidence. It was found that the prediction effect was the best at the threshold of 450 px.

FIGURE 6: Test paradigm for the purpose of eliminating cubes.

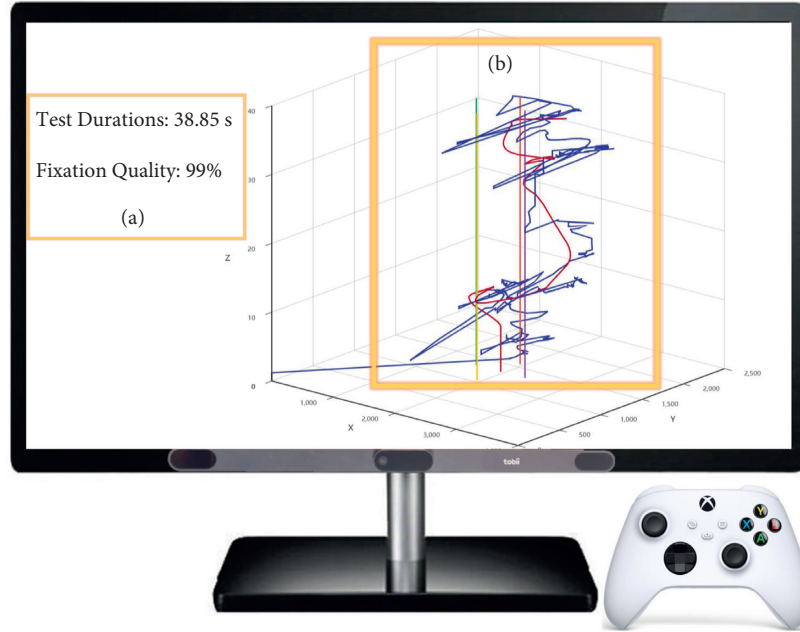

FIGURE 7: Data feedback. (a) Test durations. (b) Gaze trajectory and ball trajectory.

Drift rate is calculated as follows:

In formula (6),  $L_{Gaze-Ball_i}$  is the length between the gaze sample and the position of the red ball at the  $i$ th sampling.

$$L_{Gaze-Ball_i} = \sqrt{(X_{Gaze_i} - X_{Ball_i})^2 + (Y_{Gaze_i} - Y_{Ball_i})^2} \quad (6)$$

Formula (6) is a function to judge whether the gaze drifts away. In formula (7),  $D$  is the number of distances beyond 450 (px) between the red ball and the gaze sample in all samples. That is,  $L_{Gaze-Ball} \geq 450$  (px).

$$f(L_{Gaze-Ball_i}) = \begin{cases} 1 & L_{Gaze-Ball_i} \geq 450 \text{ (px)} \\ 0 & L_{Gaze-Ball_i} < 450 \text{ (px)} \end{cases} \quad (i \leq I, i \in N^*), \quad (7)$$

$$D = \sum_{i=1}^{i=I} f(L_{Gaze-Ball_i}) \quad (0 < i \leq I, i \in N^*) \quad (8)$$

Finally, drift rate is obtained:

$$\text{Drift Rate} = \frac{D}{I} \times 100\% \quad (9)$$

**4.2.3. Participants.** MCI patients and the normal cognitive aged in a medical institution in Hangzhou were taken as the research objects; the human-computer interactive 2.5-minute fast digital early warning paradigm test for MCI was carried out. As four early warning indexes of MCI fast digital early warning, test durations, lengths of gaze trajectory, correlation degree, and drift rate were recorded.

Inclusion criteria of MCI group are as follows: (1) at the age of 70–90 years; (2) with a clear clinical MCI diagnosis; (3) able to complete the test independently. Inclusion criteria of normal cognitive group are as follows: (1)

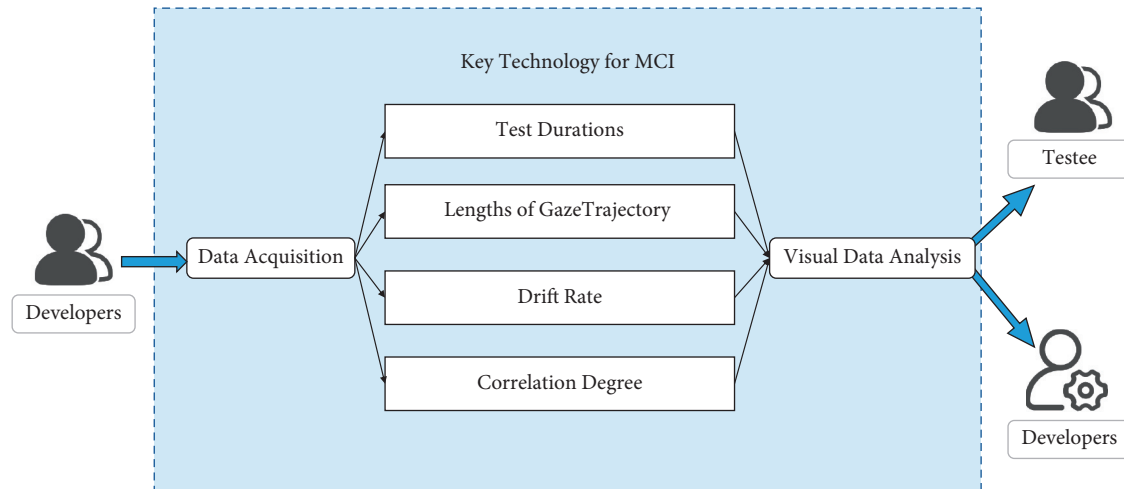

FIGURE 8: Key technology of human-computer interactive fast digital early warning for MCI.

cognitive impairment being excluded clinically; (2) with a clear clinical MCI diagnosis; (3) able to complete the test independently;

See Table 3 for exclusion criteria.

**4.2.4. Rationality Test of Key Indexes for MCI Early Warning.** SPSS 26.0 statistical software is used for data processing. The measurement data conforming to the normal distribution is represented by  $\bar{x} \pm s$  and data between two groups are analyzed by independent sample  $t$ -test. The measurement data not conforming to the normal distribution are represented by the  $M$  (quartile) and data between two groups are analyzed by nonparametric test. Compare the characteristics of test durations, lengths of gaze trajectory, correlation degree, and drift between MCI group and normal cognitive group ( $p < 0.05$ ). The prediction performance for MCI of each index is analyzed by ROC curve and AUC.

## 5. Results

**5.1. Results of Semistructured Interview.** This study summarizes the interview results, as the following shows.

- (1) The important goal of constructing MCI early warning paradigm is to detect and screen MCI quickly and effectively, so as to reduce the conversion rate of MCI to AD and reduce the burden on families and society.
- (2) Eye movement examination is an effective way to detect and assess MCI.
- (3) The objective early warning indexes for MCI mainly include test duration, lengths of gaze trajectory, correlation degree, and drift rate.
- (4) The deficiency of current MCI early warning technology is the lack of objective dynamic assessment index and fast assessment mode.
- (5) It is expected to build a new fast digital early warning model for MCI in the future.

Figure 11 shows indexes and coefficient with high frequency based on semistructured interview.

### 5.2. Results of the Experiment

**5.2.1. Participants Characteristics.** A total of 36 subjects were collected in this experiment, and 4 cases were excluded due to cataract, stroke, and depression. A total of 32 subjects meeting the above criteria were included, including 16 patients with MCI and 16 normal cognitive aged. There was no significant difference in sex ratio ( $p = 0.373$ ), age ( $p = 0.064$ ), and education level ( $p = 0.175$ ) between the two groups, which eliminated the effect of age, gender, and education level on the follow-up test results. See Table 4 for statistical analysis results.

**5.2.2. Comparison of Three Indexes between MCI Group and NC Group.** In order to further determine whether the indexes of key technology of human-computer interactive fast digital early warning between MCI group and NC group is discriminative, this paper statistically analyzed the test durations, lengths of gaze trajectory, correlation degree, and drift rate between two groups. The results are shown in Table 5.

Test durations (s) of MCI group are 50.44 (85.89) and those of NC group are 43.39 (42.22). There is no significant difference in test durations between the two groups ( $p = 0.407$ ). Lengths of gaze trajectory (pixels) in MCI group are 11562.63 (9539.73), and those in NC group are 10474.51 (6638.62). There is no significant difference in the distribution of lengths of gaze trajectory between the two groups ( $p = 0.274$ ). Correlation degrees of MCI group are  $0.74 \pm 0.19$ , and those of NC group are  $0.87 \pm 0.08$ . There is significant difference in correlation degrees between the two groups ( $p = 0.001$ ). Drift rate of MCI group is 0.28 (0.27), and that of NC group is 0.16 (0.18). There is significant difference in drift rate between the two groups ( $p = 0.019$ ). The measured values of correlation degree in MCI group are slightly lower than that of NC group and drift rate of MCI group is greater than that of

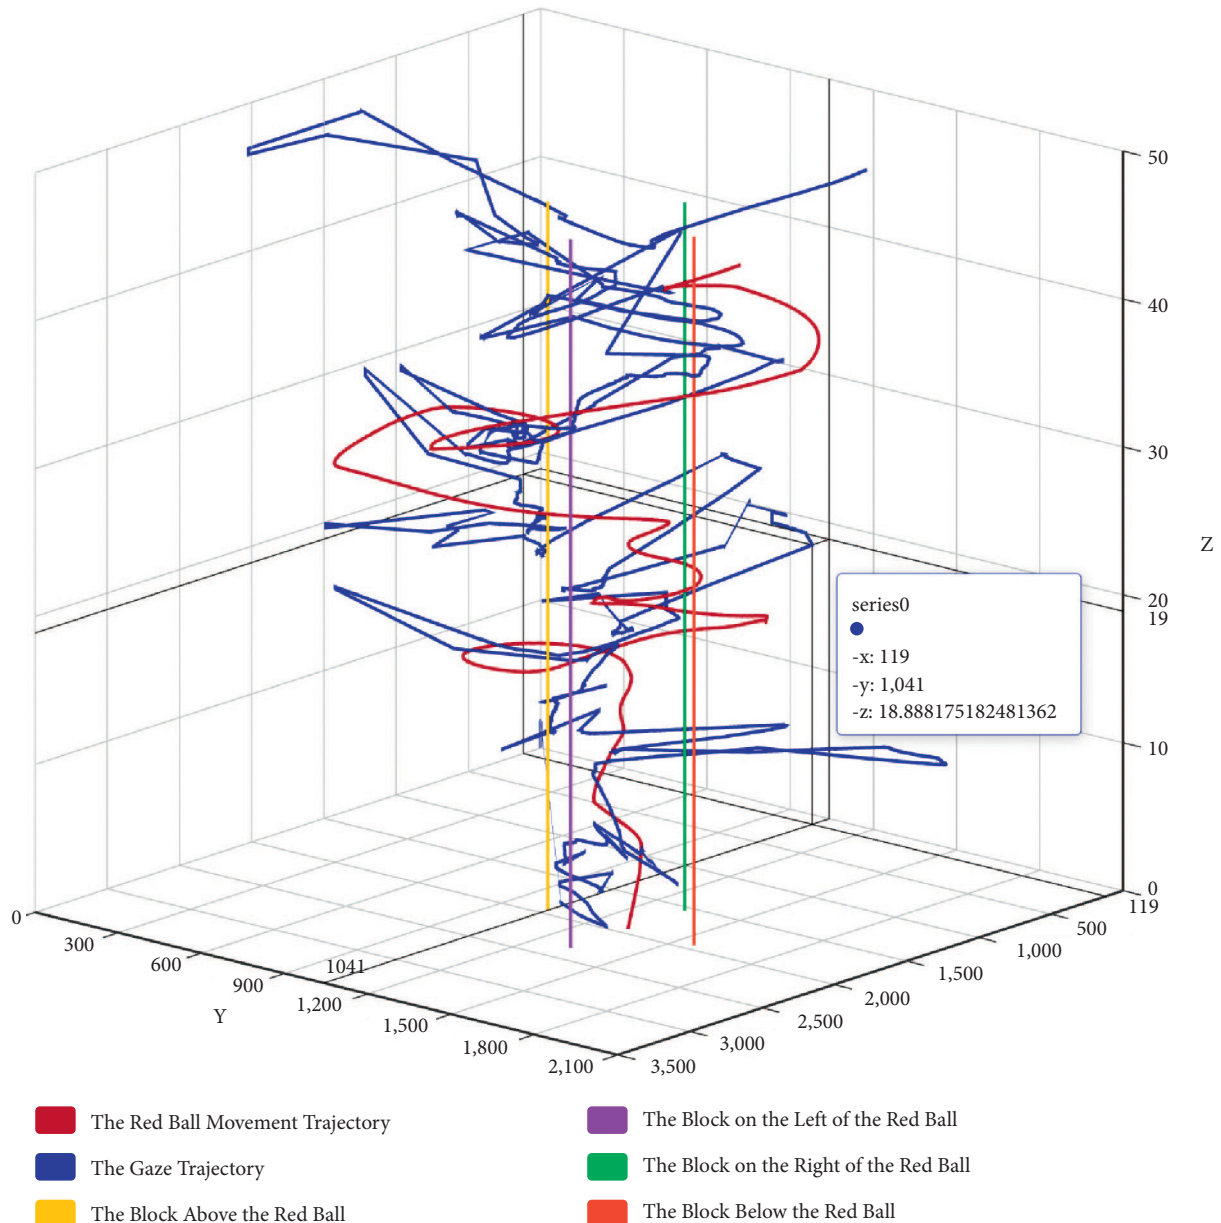

FIGURE 9: A case of 3D dual trajectories graph.

NC group, and the data between the two groups are statistically significant.

Figure 12 is drawn by Graphpad Prism 9.0, showing the general distribution of data between the two groups.

**5.2.3. Assessment Results of Key Indexes Screening Rate Based on ROC Curve.** The prediction performances for MCI early warning of the two indexes (correlation degree and drift rate) in human-computer interactive 2.5-minute fast digital early warning test for MCI are determined using a ROC analysis. An area under the ROC curve (AUC) is used as an index of prediction performance for discriminating MCI from normal cognitive aged.

Firstly, we explored the ROC curve and the area under the ROC curve (AUC) for MCI early warning of correlation

degree and drift rate, respectively. As shown in Figure 13, AUC of correlation degree is 0.809, and AUC of drift rate is 0.742.

In order to further improve the prediction performance for MCI early warning, we paired the two indexes with discriminative significance (correlation degree and drift rate) and operated the ROC curve analysis. As shown in Figure 14, AUC of combining correlation degree and drift rate is 0.824.

## 6. Discussion

Firstly, based on the key technology of human-computer interactive 2.5-minute fast digital early warning, this paper explores the early warning performance of the four indexes of test durations, lengths of gaze trajectory, correlation

degree, and drift rate for MCI through the small sample test of 32 subjects aged 70–90. In the preexperiment, we found that the maximum test durations of the normal cognitive population (including the elderly with unskilled operation) in the human-computer interactive early warning paradigm in this paper are 1 minute and 50 seconds. In order to prevent special situations, we have extended it by 40 seconds (for avoiding some special minor situations during the test, so the elderly with the test durations more than 2.5 minutes can end the test and directly determine being at the risk of MCI. After the experiment, it is found that there is no significant difference in test durations and lengths of gaze trajectory between MCI and NC ( $p > 0.05$ ), and there are significant differences in correlation degree and drift rate between the two groups ( $p < 0.05$ ). The results confirm that the human-computer interactive 2.5-minute fast digital early warning paradigm for MCI designed in this paper is not related to test durations in people with normal cognition and early MCI, if test durations are less than 2.5 minutes, which breaks our view that the longer the test durations are, the more serious the MCI condition is (even when the test duration of MCI patients is less than that of people with normal cognition). Nevertheless, the two MCI early warning indexes, correlation degree and drift rate, still show good early warning effectiveness. Hence, within 2.5 minutes of the early warning prediction paradigm, some normal cognitive aged will increase the test durations due to their unskilled

operation of electronic devices, but the increase will not affect the two key MCI early warning indexes: correlation degree and drift rate.

Secondly, we analyze the early warning performance of correlation degree and drift rate for MCI, respectively. In the analysis of early warning performance of the single index for MCI, the AUC of correlation degree is 0.809; the AUC of drift rate is 0.742, which is consistent with the research conclusion [31] that saccadic intrusions greatly increase in eye movement dynamic examination in patients with impaired cognition. Based on the above results, we can conclude that, under the mode of early warning performance of the single index, the prediction effectiveness of correlation degree is slightly higher than that of drift rate. Thus, the early warning effectiveness of correlation degree is better.

Subsequently, we further explored the ROC curve of MCI early warning after the combination of correlation degree and drift rate. AUC of combining correlation degree and drift rate is 0.824, which is higher than AUC of correlation degree (0.809) and AUC of drift rate (0.742), indicating the MCI prediction performance of combining correlation degree and drift rate is higher than that of single index in the experiment.

Next, in order to further explore the prediction performance of MCI early warning indexes, two indexes (correlation degree and drift rate) with discriminative significance and two key indexes (test durations and lengths of gaze trajectory) are combined for joint early warning analysis. Although there is no significant difference in the distribution of test durations and lengths of gaze trajectory between the two groups in part 5.2.2, the experiment results show that the area under the ROC curve (AUC) is improved when the two key indexes are combined with two indexes with discriminative significance as shown in Figure 15. The area under the ROC curve of combining test durations, lengths of gaze trajectory, correlation degree, and drift rate for MCI early warning and prediction is up to 0.895, which is higher than the early warning effect of the combined use of the two digital biomarkers. The occurrence of these situations may be related to the small sample size of this paper.

Group	Test durations		Lengths of gaze trajectory		Correlation degree		Drift rate	
	<i>M</i> (quartile)	<i>p</i> value	<i>M</i> (quartile)	<i>p</i> value	Mean $\pm$ SD	<i>p</i> value	<i>M</i> (quartile)	<i>p</i> value
MCI group	50.44 (85.89)	0.407	11562.63 (9539.73)	0.274	0.74 $\pm$ 0.19	0.01	0.28 (0.27)	0.019
NC group	43.39 (42.22)		10474.51 (6638.62)		0.87 $\pm$ 0.08		0.16 (0.18)	

FIGURE 12: Comparison of indexes between MCI and NC. (a) Distribution of test durations. (b) Distribution of lengths of gaze trajectory. (c) Distribution of drift rate. (d) Distribution of correlation degree.

In conclusion, the key technology of human-computer interactive 2.5-minute fast digital early warning for MCI proposed in this paper (1) realizes the collection of eye movement objective data through eye tracker and achieves the extraction and analysis of eye movement data by using the objective assessment key technology, which overcomes the lack of objective assessment data of screening scales in

common use. (2) And by assessing visuospatial function which is an early sensitivity assessment dimension for MCI, it makes up for the defects of low sensitivity and screening rate of screening scales for MCI. Besides, (3) based on the dynamic automatic paradigm scene combined with human-computer interaction, it overcomes the shortcomings of long time consumption and requiring professionals to assess

FIGURE 13: ROC curve of single index for MCI early warning. (a) ROC of correlation degree. (b) ROC of drift rate.

FIGURE 14: ROC curve of joint indexes for MCI early warning.

FIGURE 15: ROC curve of combing two indexes with discriminative significance and two key indexes for MCI early warning.

screening scales and previously developed computer systems, which makes it easier for subjects to obtain an activated test experience in the test. Early warning in the elderly population through experimental verification realizes the fast and high-precise MCI screening and early warning in 2.5 minutes among the elderly population and constructs a new model for MCI early warning based on “correlation degree” and “drift rate.”

There are three shortcomings of this paper. (1) The subjects of this study are in the age range of 70–90 years, who are generally older. It is found that the sensitivity is low when carrying out the human-computer interaction paradigm for some people under the age of 60. Therefore, in the later stage, we will develop grouping devices of different ages to automatically adjust the early warning sensitivity according to different ages. (2) In this paper, the subjects only cover MCI and normal cognitive aged, not including AD population. (3) The total sample size of this experiment is limited, and further experiments need to be carried out to expand the

universality of the research results. Future research will explore the utility of this technology in the mild cognitive impairment, and AD population of different ages and establish free MCI human-computer interactive early warning program and public case database for all researchers in <https://brainhealth.zcmu.edu.cn/en/mciw>.

### Data Availability

The datasets used in the experiments and discussed in the paper are available from the corresponding author on reasonable request.

### Ethical Approval

The present study was approved by Medical Ethics Committee of Zhejiang Chinese Medical University (Approval no. 20210806-1).

## Consent

All participants gave written informed consent, and identifiable participants gave written consent to publish their images.

## Conflicts of Interest

None of the authors have conflicts of interest related to the research and results presented in this paper.

## Authors' Contributions

Nan Li and Xiaotong Yang These authors contributed equally to this work and should be considered co-first authors

The era people live in is the era of big data, and massive data carry a large amount of information. This study aims to analyze RFID data based on big data and clustering algorithms. In this study, a RFID data extraction technology based on joint Kalman filter fusion is proposed. In the system, the proposed data extraction technology can effectively read RFID tags. The data are recorded, and the KM-KL clustering algorithm is proposed for RFID data, which combines the advantages of the K-means algorithm. The improved KM-KL clustering algorithm can effectively analyze and evaluate RFID data. The experimental results of this study prove that the recognition error rate of the RFID data extraction technology based on the joint Kalman filter fusion is only 2.7%. The improved KM-KL clustering algorithm also has better performance than the traditional algorithm.

## 1. Introduction

Since human society entered the information age, information technology-related industries have rapidly developed, driving changes in many fields such as computers, communications, and data storage. With the advent of this change, the main content of people's daily work has gradually changed to the processing of various data information. With the support of software and hardware technology, a huge amount of data in various forms has become an important part of people's lives. However, these massive data information often have no obvious structural characteristics at first glance, and traditional methods and ideas are difficult to achieve the purpose of fully understanding and understanding them. Coupled with the huge amount of data and rich types of data, traditional statistical methods cannot fully extract effective information, and it becomes more difficult to obtain valuable information in the data. On top of this predicament, data mining technology has received extensive attention. With the help of data mining technology, people can extract originally hidden, unknown, and valuable information from a large amount of disorganized data. By using it in other fields, the value of information has been fully reflected. Data mining technology is a multidisciplinary field technology, which has rapidly

developed under the huge demand for information data processing technology in the past ten years.

This study mainly analyzes the reasonable solution to the problem of time and space requirements and tries to propose an effective clustering scheme for RFID data. Compared with previous studies, this study mainly has the following two innovations: (1) based on big data technology, the RFID data extraction technology has been improved, and the RFID data extraction technology based on joint Kalman filter fusion is proposed. (2) An improved KM-KL clustering algorithm is proposed.

*1.1. Related Work.* RFID technology is one of the important technologies of the internet of things and big data. It realizes the transmission between things, and a large amount of data is generated during the transmission process. There are many research studies at home and abroad. Wang and Jiang proposed an OCT prediction method utilizing a combination of order and real-time shop floor RFID data. It uses accurate RFID data to describe the real-time load situation of the job shop and tries to mine the mapping relationship between RFID data and OCT from historical data [1]. Fazzinga et al. investigated a method for interpreting RFID

data in the context of object tracking. It consists of converting readings generated by RFID-tracked moving objects into semantic locations on a map by exploiting some integrity constraints [2]. Martinus et al. created a system for supermarket shopping research that enables people to scan items themselves and quickly pay. They focus on using RFID technology in the system [3]. Microcontrolled devices were studied by Novikov et al., and their aim was to develop a personal portable effective dose dosimeter with an RFID data channel without built-in power supply [4]. In the process of analysis, cluster analysis is often used for massive RFID data. Yunoh et al. focused on the analysis of fatigue strain signals based on clustering and classification methods. They grouped the feature extraction using the K-means clustering method to obtain the appropriate number of datasets. The classification process is performed by using an artificial neural network (ANN) for optimal pattern recognition. Experiments show that their algorithm is about 92% accurate [5]. Wang et al. predict natural disasters by modeling meteorological disasters. They clustered natural disasters through the detention analysis method, summarized the characteristics of each weather system, and designed disaster control projects based on this. Their experiments show that control engineering has a high centrality with the occurrence of disasters, and engineering implementation can reduce disasters [6]. Chen used MATLAB software to perform statistical analysis and cluster analysis on the daily PM<sub>(2.5)</sub> concentrations observed in Shanghai in 2014. The results show that the PM<sub>(2.5)</sub> concentration in spring and winter is higher than that in summer and autumn, and the annual distribution of PM<sub>(2.5)</sub> concentration is U-shaped [7]. Balik et al. compared health indicators and health expenditures in 28 European Union (EU) countries, 6 EU candidate countries, and 3 European Free Trade Association (EFTA) countries using a cluster analysis method. As a result of the cluster analysis, the countries were divided into 3 clusters, the first cluster including Turkey had the lowest average per capita public, private, and out-of-pocket health expenditure of the three clusters [8]. It can be easily seen from the related research that the research on RFID technology is more on its application level than on data analysis, so the cluster analysis for RFID data is rarely studied.

## 2. RFID Technology

Wireless identification technology, also known as radio-frequency identification technology, is often referred to as RFID (radio-frequency identification) technology. This communication technology originated from the identification application of British fighter jets during World War II and has been commercialized since the 1960s. In particular, the promotion and application of the US Food and Drug Administration (FDA) and Walmart supermarkets, such as real-time detection of fresh commodities in supermarkets, intelligent price tag system, inventory control system, and intelligent shopping cart, have greatly expanded the application market of RFID technology in the world [9, 10].

The RFID system is generally composed of three parts: reader (Reader), electronic label (Tag), and application software. The tag can be divided into two parts: an antenna and a special chip, and the chip is attached with a unique identification code, indicating the basic information attached to the object. The principle is that the reader transmits the emitted radio-frequency signal to the electronic tag by means of electromagnetic or inductive coupling, so as to drive the electronic tag circuit to transmit its internal data to the reader. The reader accepts and interprets the relevant data in sequence and uses the software system for relevant processing [11]. Radio-frequency identification has the characteristics of noncontact, not affected by environmental factors, a large amount of stored information, readable and writable, fast recognition speed, long recognition distance, and anticollision function. It can process multiple radio-frequency cards at the same time, and the two identification methods of RFID are shown in Figure 1:

The peculiar way in which RFID devices acquire data leads to serious uncertainty in their data [12, 13]. There are three main reasons for the uncertainty of RFID data, namely, missing reading, overreading, and dirty data. Compared with the three, multireading and dirty data phenomena are more contingent and less likely to occur. The phenomenon of missing reading is relatively common, which is the main factor leading to the uncertainty of RFID data.

*2.1. The Principle of Antong Data Collection.* Because RFID technology has the advantages of fast and real time, it also has extensive analysis in the field of its data collection. The RFID data acquisition system generally includes three parts: the target with the electrical label, the RFID base station, and the information center. The system composition is shown in Figure 2:

Based on the working principle of RFID technology, the RFID data acquisition system performs radio-frequency identification on the target equipped with electronic tags and transmits the identification data to the traffic information center. Its working principle is as follows: (1) the system enters the acquisition state from the dormant state and (2) determines whether to stop the acquisition by judging the stop flag bit of reading the radio-frequency tag. If there is no stop command, the system starts to read the target information. (3) The RFID base station judges whether a tag enters the radio-frequency field through radio-frequency technology. (4) After sending the request, the mark is selected to confirm whether to detect the specific target. (5) After the verification is passed, the resident writer starts to read the tag carried by the target and returns and transmits the read response data to the information center after the operation is successful. The workflow of the RFID data acquisition system is shown in Figure 3:

*2.2. Joint Kalman Filter Fusion of RFID Technology and Coil Technology.* For the fusion methods of multisensor information of the same detection section, the fusion methods suitable for dynamic traffic parameters mainly include joint

FIGURE 1: RFID (radio-frequency identification) technology.

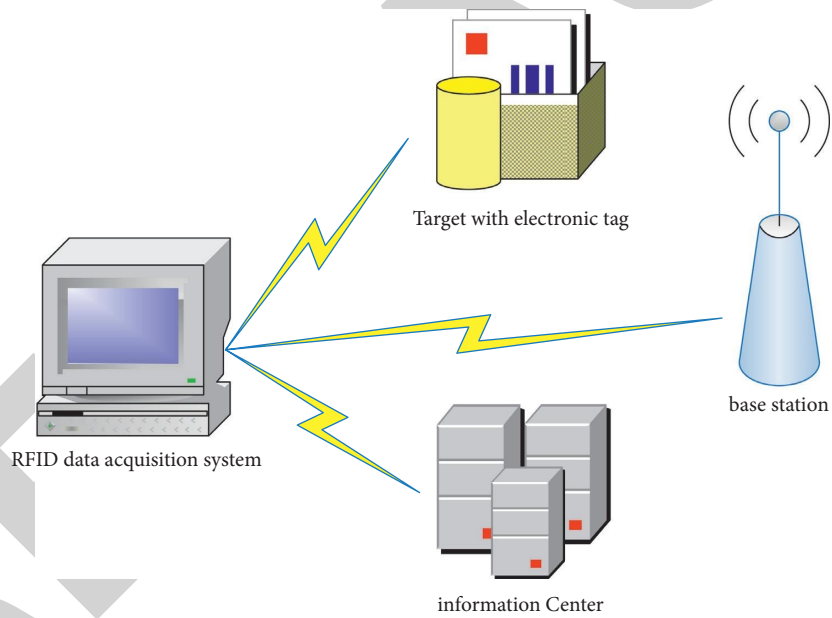

FIGURE 2: Composition of RFID traffic data collection system.

filter fusion, centralized filter fusion, and neural network-based fusion methods.

The basic structure of the joint Kalman filter adopts the method of two-stage processing of data and scattered filtering. The combined filter consists of the main filter and several subfilters.

The structure diagram of the joint Kalman filtering algorithm used in this study is shown in Figure 4:

In the structure of the joint Kalman filter in Figure 4, the subfilter first performs independent filtering, transmits the filtering result to the main filter, and at the same time completes the optimal fusion of the collected information.

Among them, the state formula and measurement formula of the filter are equations (1) and (2), respectively:

$$X_i(k) = \Phi(k, k-1) \cdot X_i(k-1) + W_i(k-1), \quad (1)$$

$$Y_i(k) = H_i(k) \cdot X_i(k) + V_i(k). \quad (2)$$

where  $W_i(k-1)$  is the noise of the dynamic model, and its covariance is  $Q_i(k-1)$ .  $V_i(k)$  is the observation noise, and its covariance is  $R_i(k)$ . Since the traffic volume collected by the coil sensor is slightly smaller than the actual value, this study improves the joint Kalman filter. In this study, a sensor with a known acquisition error is selected as the reference

FIGURE 3: RFID traffic data collection system operation process.

sensor, and the method of the first comparison and then fusion is adopted. Its filtering formula is shown in equations (3) and (4):

$$X_i(k+1) = \Phi(k+1, k) \cdot X_i(k), \quad (3)$$

$$P_i(k+1, k) = \Phi(k+1, k)P_i(k)\Phi^T(k+1, k) + Q_i(k). \quad (4)$$

The main filter does not perform filtering but directly performs data fusion. The fusion method is shown in equations (5) and (6):

$$X_g = P_g \left( \sum_{i=1}^{n,m} P_i^{-1} X_i \right), \quad (5)$$

$$P_g = \left( \sum_{i=1}^{n,m} P_i^{-1} \right)^{-1}; \quad i = 1, 2. \quad (6)$$

When the main filter is fused, it feeds back information to the subfilters according to the fusion result, where the feedback factors are shown in equations (7) and (8):

$$\beta_i = (p_1^{-1} + p_2^{-1})^{-1} \cdot p_i^{-1}, \quad (7)$$

$$p_i^{-1}(k) = \beta_i \cdot p_g^{-1}(k). \quad (8)$$

When the condition of  $Q1 < Q2$  is not satisfied, it can be seen from equations (5) to (7) that  $\beta_1 + \beta_2 = 1$ .  $X_g = \beta_1 X_1 + \beta_2 X_2$ , that is, the fusion result  $X_g$  will take a value between  $X_1$  and  $X_2$ , and change between the two values as the feedback factor changes. At the same time, the subfilters are fed back according to the fusion result, and the information is redistributed to improve the fusion accuracy.

Compared with the centralized Kalman filter and artificial neural network, the joint Kalman filter has the advantages of flexible design, a simple algorithm, better fault tolerance, and more suitable for real-time systems.

In this study, the data  $Q1$  collected by RFID technology and the data  $Q2$  collected by the coil sensor are directly combined with Kalman filtering (hereinafter referred to as general fusion). At the same time, it compares the size of  $Q1$  and  $Q2$  and then fuses them according to the fusion method (hereinafter referred to as improved fusion), as shown in Figure 5.

As can be seen from Figure 5, when the traffic volume collected by the RFID technology and the coil sensor is smaller than the actual value, the fusion effect is poor. When the traffic volume collected by RFID technology is smaller than that of the coil sensor, the traffic volume collected by the coil sensor is directly taken as the fusion value. The fusion curve coincides with the traffic volume change curve collected by the coil sensor, which significantly improves the accuracy of the fusion result.

It can be seen from Table 1 that in dataset 1, the error of the improved fusion is the same as that of the general fusion, so the improved fusion method in this study has certain applicable conditions. That is, when the traffic volume collected by RFID technology is smaller than the traffic volume collected by the known small sensor or larger than the traffic volume collected by the known large sensor, the improved fusion proposed in this study produces better results. From dataset 2 and dataset 3, it can be seen that the relative error is significantly reduced by using the improved method in this study for fusion.

Average	9.37	5.66	4.64	2.77

### 3. Analysis and Result

3.1. Cluster Analysis. Pattern recognition is to study the automatic processing and interpretation of patterns through the use of mathematical techniques by computers, and the environment and objects are collectively referred to as “patterns.” With the development of computer technology, it is possible for human beings to study the complex information processing process. An important form of the process is the recognition of the environment and objects by the living body. In the field of pattern recognition and statistical analysis, cluster analysis has always been the focus and research direction of the academic community. So far, a large number of theories and methods have been proposed, and remarkable

research results have been achieved. After a long period of research and development, clustering analysis can be divided as follows [14, 15]:

3.1.1. Partition-Based Approach. The typical algorithm is the K-means algorithm and its characteristics are summarized in Table 1, so it will not be repeated here.

3.1.2. Hierarchical Approach. Hierarchical clustering methods use top-down splitting or bottom-up agglomeration to represent datasets in a hierarchical tree structure. Each object is first treated as a separate cluster, and these clusters are merged into larger and larger clusters until a

given end condition is met. This clustering method is a bottom-up agglomerative clustering method. Divisive hierarchical clustering is just the opposite, where all objects are first grouped into one large cluster. Then, it is gradually divided into smaller and smaller clusters according to the similarity, until the end condition is satisfied.

**3.1.3. Density-Based Methods.** Density-based methods are divided into different clusters according to different aggregation densities in data object sets, and clusters with similar densities are divided into one cluster. However, its calculation is large, usually is  $O(n^2)$ . In addition, based on the density, the setting of parameters has a great influence on the performance of the algorithm, and there is no good solution at present, which mainly depends on the user's experience to select parameters.

**3.1.4. Grid-Based Approach.** Grid-based clustering method divides the data space into a certain number of ultra-rectangular grid cells according to the partition parameters, maps the data objects to the corresponding grid cells, and then merges the adjacent grid cells into a connected region, that is, a cluster. Grid-based clustering method has good scalability for the size of datasets, can handle large-scale datasets, and can find clusters with arbitrary shapes. Grid-based clustering method is usually combined with the density-based clustering method [16].

**3.1.5. Model-Based Approach.** The model-based clustering method is to use a specific model for cluster analysis and try to optimize the fit between the actual data and the model. Neural network-based clustering methods and statistical learning-based clustering methods are two types of model-based clustering methods. Among the neural network models commonly used in cluster analysis are the self-organizing map (SOM) model [17], the adaptive resonance theory model [18], and the learning vector quantization (LVQ) model. The EM clustering algorithm based on the Gaussian mixture model is a typical clustering method based on statistical learning [19].

**3.1.6. Fuzzy Clustering Method.** The clustering method described above can be regarded as hard clustering. Different from hard clustering, fuzzy clustering is a soft clustering method. Fuzzy C-means clustering algorithm [20] is a popular fuzzy clustering algorithm at present, which transforms the clustering problem into an optimization problem and uses an iterative method to solve it. It has a simple design, good clustering performance, and wide application. However, the algorithm is sensitive to the initial conditions, easily falls into local optimum, requires a large amount of computation, and has a low resolution for objects in the overlapping area of class boundaries.

Table 2 summarizes the clustering methods commonly used at present, and the advantages and disadvantages of each method, in which NCA means to determine the number of classes sensitive to initial values and outliers in advance.

### 3.2. Partition-Based Clustering Algorithm—KM-KL Algorithm

**3.2.1. The Basic Concept of KM-KL Algorithm.** In the traditional partition-based clustering algorithm, the set of uncertain objects is divided into given  $K$  clusters according to their mutual distances. The KM-KL algorithm in this study follows the idea of the traditional partition-based clustering algorithm and divides the uncertain dataset  $O$  containing  $n$  uncertain objects into  $k$  clusters. They are denoted as  $C_{1,L}, C_k$ , respectively, use the symbol  $C_i$  as the center point of each cluster, and use the center point to represent the cluster  $C_i$ . In the partition-based clustering algorithm, the following properties are included as follows:

- (1) All clusters belong to the uncertain dataset, that is  $C_i \subseteq O (1 \leq i \leq k)$ .
- (2) Each cluster contains at least one data record, that is  $C_i \neq \varphi$ .
- (3) Each data record belongs to one cluster and belongs to only one cluster, that is, when equation (9) is satisfied, equation (10) can be satisfied:

$$U_{i=1}^k C_i = O, \quad i \neq j, \quad (9)$$

$$C_i \cap C_j = \varphi. \quad (10)$$

On the basis of traditional partition-based clustering, the KM-KL algorithm in this study uses KL divergence as a similarity measure.

The algorithm divides uncertain objects into  $k$  clusters and selects an optimal cluster center point for each cluster to minimize the sum of the overall KL divergence. In the clustering algorithm, in the division formed by a clustering process, the sum of the KL divergence among all objects is shown in the following:

$$\text{TKL} = \sum_{i=1}^k \sum_{P \in C_i} D(PC_i). \quad (11)$$

This formula is used to measure the quality of the clustering. The larger the TKL value, the worse the quality of this clustering is, and the smaller the TKL value is, the better the quality of this clustering is. In equation (11),  $D(PC_i)$  represents the KL distance from the object  $P$  to the cluster center point  $C_i$ , which is used to assign the object to each cluster.

$$\sum_{P \in C_i} D(PC_i). \quad (12)$$

Formula (12) represents the sum of the KL distances from each object  $P$  in the cluster  $C_i$  to the cluster center point  $C_i$ , according to which the structure of the cluster  $C_i$  can be adjusted.

**3.2.2. KM-KL Algorithm Description.** The KM-KL algorithm in this study is an extension of the K-medoids algorithm using KL divergence as a similarity measure. This algorithm

TABLE 2: Types of clustering methods.

Type	Advantage	Insufficient
Based on partition method	Wide application, fast convergence, incremental clustering, and suitability for large-scale data	It is necessary to determine the NCA, which is sensitive to initial values and outliers, so as to find circular clusters
Hierarchy-based method	It does not need to determine the NCA and can find clusters of any shape, which is suitable for data of any attribute and has strong clustering ability	No backtracking, no exchange of data objects between classes, no full processing of large-scale data, and no incremental clustering
Density-based method	It does not need to determine the NCA, can find clusters of different shapes, can detect outliers, and has good adaptability to large datasets	It is very sensitive to parameters. For datasets with uneven density distribution, the quality of clustering results is not high

clusters uncertain data on probabilistic similarity [11–22]. The algorithm is divided into two parts, the initial clustering division stage and the center replacement stage.

(1) *Initializing the clustering stage.* In the initial clustering and division stage, the algorithm selects  $k$  cluster center points one by one to initialize the clustering and division of other objects. The first center point  $C_1$  selects the object with the smallest sum of KL divergence of other objects in the uncertain object set  $O$ , that is, formula:

$$C_1 = \arg \min \left( \sum_{P' \in O} D(P'P) \right), \quad (13)$$

The remaining  $k - 1$  center points are iteratively selected. At the  $i$ -th iteration, the algorithm selects the object  $C_i$  that minimizes TKL. When it is calculated that  $P'$  will be allocated to the cluster with  $P$  as the new cluster center point, the contribution of this allocation to reducing TKL is shown in the following:

$$\max(0, \min_{j=1}^{i-1} (D(P'C_j) - D(P'C_i))) \quad (14)$$

From formula (14), it can be calculated the sum of the reduction in TKL by the division of all unselected objects in this round, which is expressed as  $\text{DEC}(P)$ . In the KM-KL algorithm, the center point selected by the  $i$ -th iteration is the object with the largest  $\text{DEC}(P)$ , that is, formula:

$$C_i = \arg \max_{P \in O \{C_1, \dots, C_{i-1}\}} (\text{DEC}(P)). \quad (15)$$

This ensures that the initial cluster center point selected at each time is optimal, because this selection can minimize the dissimilarity between clusters. The initial clustering division phase ends when all  $k$  cluster center points are selected and then enters the second phase of the algorithm, the center replacement phase.

(2) *Center replacement stage.* In the center replacement stage, the algorithm iteratively replaces the cluster center points with all noncenter points in the cluster and selects the optimal cluster center point to improve the clustering quality. Every time redistribution occurs, it records the TKL reduction value after redistribution and selects the object with the largest value as the new cluster center, as shown in the following:

$$P_{\max} = \arg \max_{P \in O \{C_1, \dots, C_{i-1}\}} (\text{DEC}(P)). \quad (16)$$

At this time, if it is  $\text{DEC}(P_{\max})$ , it means that this round of exchange improves the clustering effect. Otherwise, the algorithm ends and the final clustering is generated. The example shown in Figure 6 is used to illustrate the KM-KL algorithm flow.

As shown in Figure 6, Figure 6(a) shows the distribution of the uncertain object set. Supposing that the uncertain objects  $a_1$ ,  $a_2$ , and  $a_3$  satisfy the same distribution, it forms a cluster. The uncertain objects  $b_1$ ,  $b_2$ , and  $b_3$  satisfy another distribution and it forms another cluster, which is the clustering result of the benchmark. Figure 6(b) shows the KL divergence between uncertain objects and the initialized TKL value. Due to the asymmetry of KL divergence, in Figure 6(a), for example, the divergence from  $a_1$  to  $a_2$  is not equal to the divergence from  $a_2$  to  $a_1$ . At this time, the KM-KL algorithm is used to cluster the uncertain objects in Figure 6(a), and the input parameter  $k$  is equal to 2.

Finally, the KM-KL algorithm forms two clusters  $\{a_1, a_2, a_3\}$  and  $\{b_2, b_1, b_3\}$  with  $a_1$  and  $b_2$  as the center points, respectively, and the division is the optimal division.

*3.3. Algorithm Performance Test and Effectiveness Analysis.* The experimental platform is configured as follows: Intel(R) processor, 2.94 GHz main frequency, 2G memory, using Windows7 operating system. The experimental program is written in C++ language, compiled and run on VS2010, and simulated by MATLAB.

This study generates datasets on discrete and continuous domains, respectively. In the continuous domain, an uncertain object is a sample taken from a continuous distribution, and in the discrete domain, the dataset is transformed from a continuous model. The continuous domain is discretized using a meshing method, dividing each dimension into two equal parts, thus dividing the  $d$ -dimensional data space into the same 2D cells. The probability of an object in a certain unit is the sum of the probabilities of all sample points of the object in this unit. The value range of the data is  $[0, 1]^d$ . Three different probability distributions will be used in this study, namely, uniform distribution, Gaussian distribution, and inverse Gaussian distribution, which is generated by Gaussian distribution, as shown in Figure 7.

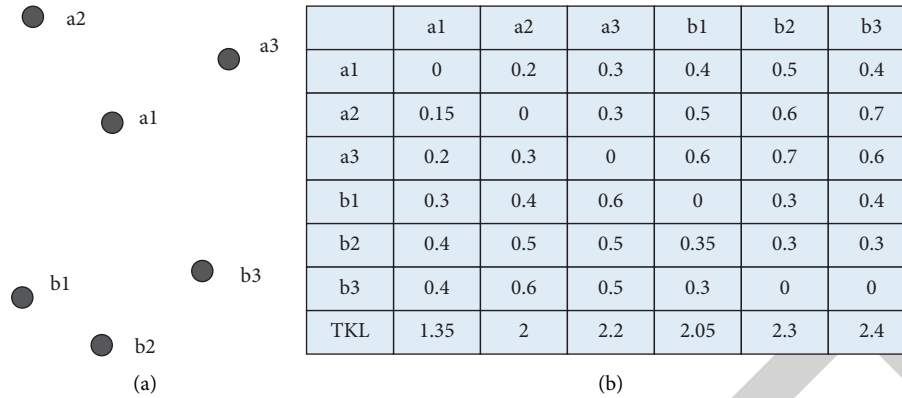

FIGURE 6: Data objects and their KL divergence.

FIGURE 7: Three different distributions. (a) Evenly distribution. (b) Normal distribution. (c) Inverse Gaussian distribution.

The experiments in this study are mainly divided into three parts: first, the effect of the clustering algorithm using KL divergence is analyzed. Second, it shows the improvement of the computational efficiency of the clustering algorithm in this study after using an efficient implementation method and an improved fast Gaussian transform. Finally, experiments show the scalability of the algorithm on large datasets.

In classical partition-based and density-based clustering algorithms, KL divergence and geometric distance are used as similarity measures, respectively, to compare clustering quality. Among the partition-based clustering algorithms, the UK-means algorithm using geometric distance (denoted as UK) and the KM-KL and RKM-KL algorithms proposed in this study are compared. Among the density-based clustering algorithms, the FDBSCAN algorithm using geometric distance (denoted as FD) and the DB-KL algorithm in this study are compared.

In the experiment, the base number of objects is set to  $n = 100$  by default, each object contains  $s = 100$  sample points, the data dimension  $d = 4$ , and the default setting of clustering produces  $k = 6$  clusters. For the density-based algorithm,  $k$  is not used as a parameter, and the parameters' density threshold  $\mu$  and distance radius  $\varepsilon$  need to be set here. Among them, the density threshold is  $\mu = 5$  according to the recommendation, and the distance radius  $\varepsilon$  is continuously adjusted in the experiment so that the z FD and DB-KL can produce clustering results' approximate to  $k$  clusters.

Since the complexity of the density-based algorithm DB-KL exponentially increases with respect to the number of

data objects, the algorithm is not suitable for a large number of data objects. The scalability of the RKM-KL algorithm is mainly tested here. The dataset defaults to 4 dimensions and contains 10 clusters.

Figures 8 and 9 show the effect of the RKM-KL algorithm and the RKM-KL-FGT algorithm on the clustering quality of the algorithm when the data object cardinality is large and the number of object samples is large. It can be seen that when the object cardinality is large or the number of samples is large, the algorithm has a similar quality trend as when the amount of data is small. Moreover, as in the previous experimental analysis, the clustering quality of the RKM-KL-FGT algorithm will be reduced to a certain extent compared to the RKM-KL algorithm.

Figure 10 shows the running time of the RKM-KL algorithm and the RKM-KL-FGT algorithm when the dataset is large. It can be seen that the running time of the RKM-KL algorithm linearly increases as the cardinality of the data objects increases. The RKM-KL-FGT algorithm uses an improved fast Gaussian transform to obtain approximations, so the running time of the algorithm is shorter, and the running time smoothly increases with the increase in cardinality. However, since the calculation of the sum of KL-divergence squarely increases with respect to the number of samples of the object, the calculation time of the algorithm RKM-KL rapidly increases with the increase in the sample data volume. While the computation time of the RKM-KL-FGT algorithm is almost unaffected (it grows linearly), obviously, RKM-KL-FGT is more effective when the amount of data is large.

In order to improve the effect of intelligent teaching and give full play to the role of intelligent technology in modern physical education, in this paper, cloud computing and deep learning methods are used to comprehensively evaluate the teaching effect of colleges and universities, and calculate the evaluation effect and accuracy. Cloud computing and deep learning algorithm combine the teaching evaluation scale, teaching content, and characteristics to formulate teaching plans for different students and realize targeted teaching evaluation. The results show that the teaching evaluation method proposed in this paper can improve students' learning interest by about 30%, enhance learning initiative by about 20%, and the matching rate between the actual teaching effect and the expected requirements is 98%. Therefore, cloud computing and deep learning model can improve the accuracy of teaching effect evaluation in colleges and universities, provide support for the formulation of teaching evaluation schemes, and promote the development of intelligent teaching in colleges and universities.

## 1. Introduction

Cloud computing and deep learning was first applied in the field of power and gradually developed to the field of teaching in the later stage. Cloud computing and deep learning can have a key impact on the improvement of students' learning status and teaching content, and improve the overall teaching effect. In 2017, China Education Commission put forward the strategy of "comprehensive quality education" and the concept of "double reduction," which reduced the college tennis teaching time from 48 hours in 2012 to 32 hours in 2020, with a decrease of 30% [1]. The results are shown in Figure 1. In this paper, tennis intelligent teaching is taken as an example to analyze the advanced nature and intelligent advantages of intelligent teaching. At the same time, the increase of multimedia, online teaching, and practical courses also greatly reduces the teaching hours of college tennis physical education. With the continuous reduction of teaching hours, the teaching pressure of tennis teachers is increasing and even affects the effect of classroom teaching. Therefore, "teaching optimization of cloud computing and deep learning" has been

put on the agenda [2] and has become the research focus of tennis teaching in major universities. Cloud computing is the mainstream algorithm at present. Through the intelligent search of the data in the network, the horizontal teaching effect evaluation can be realized. Deep learning is the in-depth study of teaching contents and methods to realize the vertical analysis of teaching effect. The integration of cloud computing and deep learning can realize the comprehensive analysis of intelligent teaching and improve the accuracy of effect evaluation. Although cloud computing and deep learning methods are traditional teaching evaluation methods, this paper integrates the two and constructs a new theoretical model, which belongs to a new model attempt. The advantage of the first mock exam is very obvious. It can not only expand the scope of the evaluation of the intelligent teaching effect but also increase the depth of assessment and effectively remedy the deficiency of the single model. Foreign scholars began to study cloud computing and deep learning in 2010, and gradually introduced it into the evaluation of intelligent teaching effect. At the same time, foreign countries have achieved good research results in data preprocessing in cloud

FIGURE 1: Changes in tennis teaching hours.

computing and data mining in deep learning. However, there is a gap between China and foreign countries in terms of intelligent devices and development procedures. Moreover, the national conditions and policies of foreign countries are different from those at home, so it is impossible to copy them. Therefore, domestic scholars should strengthen the research of cloud computing and deep learning, and integrate it with intelligent teaching.

At present, tennis teaching mainly adopts the form of “unified” teaching, which has the advantages of unified teaching content and simple teaching methods, but it cannot meet the “personalized” requirements of students [3]. Under the background of reducing teaching time, increasing teaching pressure, and improving the requirements of quality education, there will be problems of reduced interest in learning and lack of learning law. On this basis, this paper proposes a cloud computing and deep learning model to integrate students’ learning data, classify students’ interests, and analyze the learning results, in order to improve the effect of tennis teaching.

As can be seen from Figures 1 and 2, in college physical education, the demand for tennis courses increases year by year, while the actual course supply decreases year by year. There is a balance between demand and supply in 2015, and the gap will increase from 2015 to 2020. Therefore, tennis teaching has great potential and needs to be solved more accurately.

## 2. Literature Review

There are many research studies on the cloud computing and deep learning model in tennis teaching, but it mainly stays at the theoretical level and lacks practical case studies [4]. Some scholars believed that the increase of tennis content, the application of information technology, and the reduction of teaching time affected the effect of tennis teaching. Some scholars also believed that the intelligent storage student management scale can realize the management of tennis teaching content and can improve the teaching effect of tennis [5]. Some scholars believed that students’ classification and

FIGURE 2: The supply and demand of tennis courses.

achievement integration can improve students’ potential and realize personalized teaching [6]. Some scholars believed that the integration of teaching theory and practice and the division of grades can improve the effect of classroom teaching [7]. Some scholars also believed that the intelligent score management scale, score grade, and potential development were the indicators for the evaluation of tennis teaching effect [8], which can realize the comprehensive analysis of students and tennis teaching. In conclusion, scholars at home and abroad believed that the student intelligent score management scale and cloud computing and deep learning method can improve the teaching effect, realize the integration of students’ potential and teaching requirements, and meet the requirements of quality education [9]. However, there was a lack of practical case analysis at home and abroad. On this basis, this paper integrates theory and practice to analyze the effect of cloud computing and deep learning [10].

## 3. Research Model

**3.1. Cloud Computing and Deep Learning Theory.** Cloud computing and deep learning can meet the complex needs of students’ learning and is composed of multiple management units. Cloud computing and deep learning can realize the “personalized service” of students and the resource sharing of tennis teaching [11]. First, the tennis teaching scheme is used to divide the “virtual file” for students in the tennis course management center. Then, a management table is built and stored in each student’s client node  $l$  to form a small-scale data search [12]. Finally, any client node  $l$  calculates the management table of adjacent clients (node  $l+1$ , node  $l-1$ ) to find the required teaching effect data and return the key value of the corresponding client, node  $i$ ,  $\xrightarrow{\text{keyvalue}} \text{DiskTracker}_i(\text{ID}_i)IP_k$  datacenter.

**3.2. Basic Theory of Cloud Computing and Deep Learning.** It is based on the multivariate difference equation, and its mathematical expression is as follows:

$$\begin{cases} \text{node}_i = A \cdot \text{DiskTracker}_i + B \cdot \text{ID}_j + C \cdot \text{IP}_k, \\ \text{keyvalue}_j = D \cdot \text{DiskTracker}_i + E \cdot \text{ID}_j + F \cdot \text{IP}_k + P \sin\left(2k\pi\left(f_e + \frac{f_D}{f_s}\right)\right) \times T(k). \end{cases} \quad (1)$$

Among them, A, B, C, and D are the coefficient values of corresponding parameters in tennis teaching;  $f_e$ ,  $f_s$ , and  $f_D$  are the collected data, sent data, and feedback data;  $P$  is the data amplification factor, which aims to improve the data recognition rate of “abnormal students,” and  $T(k)$  is the data actually received by the center. According to the results of  $f_e$ ,  $f_s$ , and  $f_D$ , the level of students’ tennis teaching is judged. If  $f_e = f_s = f_D \neq 0$  students’ tennis teaching is normal, and if  $f_s \neq f_D = 0$  is near the extreme value, it indicates that students’ tennis teaching is abnormal [13].

### 3.3. Cloud Computing and Deep Learning Process in Tennis Teaching.

- (1) Data access to students’ teaching archives. The access process to students’ teaching archive data can be described by a nonlinear Lagrange equation [14], and the mathematical formula is as follows:

$$g = \frac{d\text{DiskTracker}_i}{d\text{node}_i} \quad (2)$$

$$= -v'(\text{DiskTracker}_i) + F_0 + g(\text{node}_i).$$

Among them,  $g(\text{node}_i)$  is the gap between students’ academic achievements;  $F_0$  represents the collection amount of student effect data;  $F_0$  is a nonlinear discrete function, which  $v'(\text{DiskTracker}_i)$  is the sharing of teaching resources and the satisfaction of individual needs.

- (2) Adjustment of the number of student files. The adjustment of the number of student files is a key factor in the cloud computing and deep learning level, which determines the degree of tennis teaching pressure, and its mathematical calculation formula is as follows:

$$E[g(\text{node}_i)g(\text{node}_i + \alpha)] = 6Kg(\text{node}_i - \alpha) + \xi, \quad (3)$$

where  $K$  is the frequency of tennis resource acquisition;  $\xi$  is the error value of tennis learning achievement change;  $E$  is the adjustment coefficient of the total number of students [15].

- (3) Effective data transmission. The effective data transmission  $F_0$  determines the level of tennis teaching, and its mathematical calculation formula is as follows:

$$F_0 = A_0 \cos(2\pi f_0 \text{node}_i). \quad (4)$$

Among them,  $A_0$  is the function amplitude of students’ achievement change, and  $f_0$  is the frequency of teaching, which together determine the amount of

tennis teaching; teaching effect grade = actual assessment result/expected teaching result \* 100%.

- (4) Shared and personalized service satisfaction. Cloud computing and deep learning requires to evaluate students’ tennis learning effect and meet the sharing of public resources and the satisfaction of individual resources [16], which  $v'(\text{DiskTracker}_i)$  is expressed by a function, and its mathematical calculation formula is as follows:

$$v'(\text{DiskTracker}_i) = \frac{m}{m+n} f_g(\text{DiskTracker}_i)^2 + \frac{n}{m+n} f_h(\text{DiskTracker}_i)^4, \quad (5)$$

where  $m$  and  $n$  are the proportion of shared resources and individual needs in the virtual file, respectively;  $f_g$  and  $f_h$  are a resource sharing function and personality satisfaction function, both of which are internal algorithms in the tennis teaching scheme [17].

- (5) Judgment of critical value. By deriving formula (5), its inflection point can be obtained, that is

$$v''(\text{DiskTracker}_i) = 2 \frac{m}{m+n} f'_g(\text{DiskTracker}_i) + 4 \frac{n}{m+n} f'_h(\text{DiskTracker}_i). \quad (6)$$

After substituting formula (4), it shows that the proportion of shared resources and personalized service resources is in a two-way balance, that is  $A_0 < \sqrt{4m^2 + mn/27n(m+n)}$ , and the proportion between tennis teaching requirements and actual tennis teaching is the best. In order to better analyze the effect of students’ tennis teaching, it will be limited to  $[-\sqrt{4m^2 + mn/27n(m+n)}]$ .

- (6) Identification of abnormal students. The amplification factor is  $\lambda$ , which is added in tennis teaching to identify the abnormal changes of academic performance. If there is a significant change in the scores of any students in the process of tennis teaching, it indicates that the relationship between tennis teaching and students’ learning is normal teaching, otherwise, it is students’ abnormal learning, and the corresponding data are amplified to identify abnormal students.

*3.4. Constraints of Cloud Computing and Deep Learning Model.* In the cloud computing and deep learning of tennis teaching, the original tennis teaching management method is too simple, leaving the analysis of shared resources and

personalized service resources to teachers, increasing the work pressure of teachers, and reducing the management level of students Martins et al. [18]. In view of the above problems, this paper introduces to jointly optimize tennis teaching management and transfer the analysis of some students' teaching to students.

Firstly, metropolis constraint, this paper uses metropolis constraints to judge the effectiveness of student information, so as to reduce the impact of invalid information on the results. If the result is "0," it indicates that the data is invalid, eliminated, or the value is enlarged, otherwise, the corresponding calculation is conducted. After the data is constrained by metropolis, a value is assigned to it to make the constraint result "0" or "1," and the standardization process is completed. According to the above analysis, the mathematical conditions are as follows:

$$\begin{cases} \text{keyvalue}_j \neq \text{keyvalue}_{j+1} \neq 0, \\ \text{keyvalue}_j = \text{keyvalue}_{j+1}, \text{keyvalue}_j \neq 0, \end{cases} \quad (7)$$

where  $M(\cdot)$  is the judgment function of metropolis constraint.

Secondly, the matching between actual teaching and expected teaching effect. The matching between the actual teaching and the expected teaching effect is complex and multidimensional. The actual teaching effect of tennis is not only affected by the number of students but also by the requirements of "sharing degree" and "personality degree." Assuming that the matching of "sharing degree" is  $P_u$  and the matching of "personality degree" is  $P_v$ , formula (5) can be optimized as follows:

$$P = \left\{ \prod \left[ \sum_i^{\infty} v'(\text{DiskTracker}_i) + \varsigma \right], \frac{\kappa(P_u - P_{\min})}{P_{\max} - P_{\min}, P_u < P_v}, \frac{\lambda(P_v - P_{\min})}{P_{\max} - P_{\min}, P_v < P_u} \right\}, \quad (8)$$

where  $P_{\max}$  and  $P_{\min}$  are the maximum and minimum bearing matching values of tennis teaching, the adjustment coefficient of personalized matching, and the matching coefficient of sharing degree.

Thirdly, the effective evaluation and student volume of cloud computing and deep learning. In order to reduce the

overload impact of teaching time on tennis teaching, a part of the analysis of teaching effect is analyzed by students, and the management table is introduced to judge the degree of teaching sharing. The original formulas (2) and (3) are optimized into the following formulas:

$$\begin{cases} R = \int_{i,j}^n \sum_l^{\infty} \lim g(\text{node}_l) [-v'(\text{DiskTracker}_i)] + H_i \cdot f(\widehat{\text{DiskTracker}}_i, \widehat{\text{node}}_l), & R = 1, \\ U = \int_{i,j}^n \sum_l^{\infty} \lim g(\text{node}_l) \left\{ E[g(\text{node}_l)] + H_i \cdot f(\widehat{\text{node}}_l, g(\widehat{\text{node}}_l)) \right\}, \end{cases} \quad (9)$$

where  $R$  is the number of visits to teaching resources, and its value is 0, indicating that teaching resources are not accessed, and students can use the management list to search resources among students;  $U$  is the number of user visits. The number of students in the preset time is compared with the maximum standard required by tennis teaching. If the ratio is  $> 9/10$ , it indicates that the effect of network teaching is good, and the research is strengthened on corresponding teaching contents;  $f(\text{node}_l, g(\text{node}_l))$  is the calculation function of students' misunderstanding rate in tennis delivery;  $H_i$  is the adjustment coefficient of misunderstanding. The judgment process is shown in Figure 3.

Fourthly, the construction steps of cloud computing and deep learning optimization model. According to the student learning scale and the data description formula of tennis

teaching, the simulation model is built. The specific steps are as follows:

- (1) In the cloud computing and deep learning scale, the more frequent the intragroup teaching visits between students through the management scale, the less the pressure of actual tennis teaching and the higher the tennis teaching effect. Therefore,  $\text{node}_i \xleftrightarrow{\text{keyvalue}}_{\text{DiskTracker}_i(ID_j)IP_k}$  datacenter is the best critical value required first, and this value is taken as the stable threshold of the whole tennis teaching. The result of the threshold must be in  $[-\sqrt{m^2 + mn/n(m+n)}, \sqrt{4m^2 + mn/27n(m+n)}]$ .
- (2) Identifying abnormal students in tennis teaching. The abnormality of data transmission in cloud

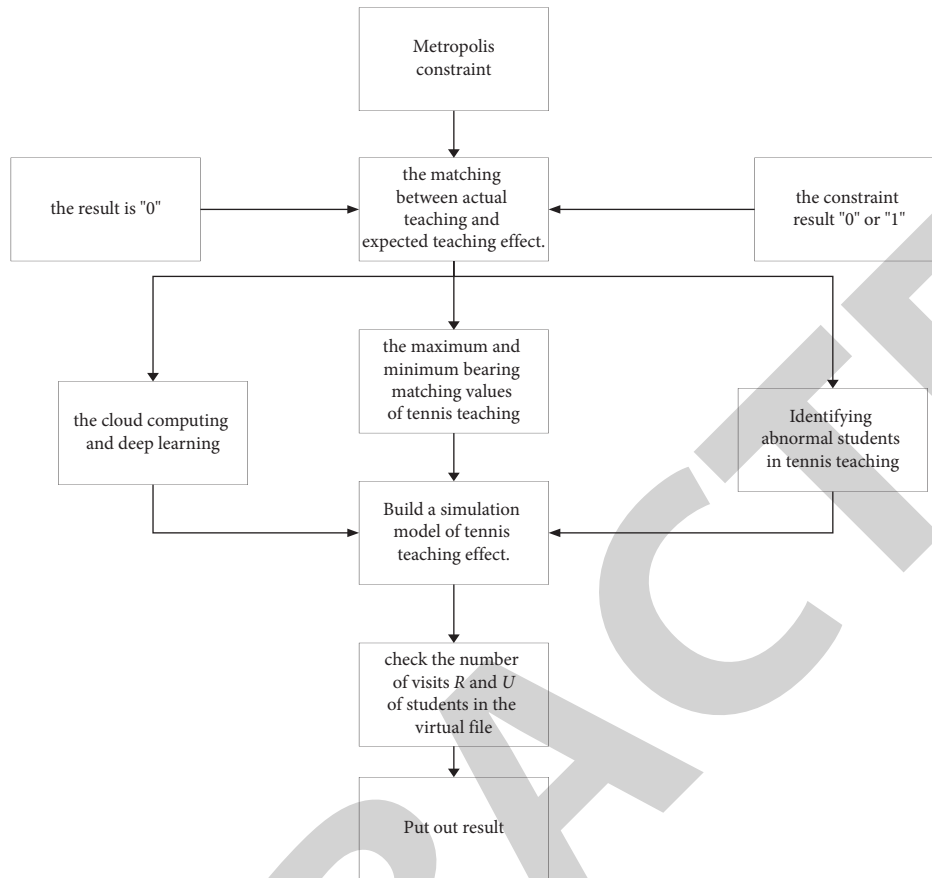

FIGURE 3: The judgment process of tennis courses.

computing and deep learning is an important optimization index. The occurrence of abnormal data is determined by many factors, such as the management table, the integration of DHT and tennis teaching scheme, the division of virtual space in tennis teaching, field type, byte size, access time, and system load. Under the constraint of  $\text{keyvalue}_j \neq \text{keyvalue}_{j+1} \neq 0$ ,  $A_0 < \sqrt{4m^2 + mn/27n(m+n)}$  is the data transmission relatively stable, and the data transmission between tennis teaching and cloud computing and deep learning is normal.

- (3) Building a simulation model of tennis teaching effect. The teaching effect is the final result of tennis teaching and students' understanding, and is affected by the requirements of quality education, teaching time, teaching methods (multimedia, online, and offline), as well as students' own interests. The actual effect of tennis teaching is consistent with the expected requirements, indicating that the effect of tennis teaching meets the requirements. Among them, the calculation of teaching effect is divided into shared resource teaching  $P_u$  and personalized service teaching  $P_v$ . In the calculation process, the number of visits  $R$  and  $U$  of students is checked in the virtual file, and the consistency between the teaching level and the teaching requirements is judged.

#### 4. Case Analysis of Cloud Computing and Deep Learning Model on Tennis Teaching Effect Evaluation

**4.1. Case Introduction.** Taking the 48 h tennis teaching course of a university as an example, 32 classes of offline students are managed. Tennis teaching evaluation needs 1 server, 4 PCs, and 12 mobile phones. The storage mode of students' virtual archives is the combination of disk and solid state, and the storage space is 723 t. The specific circuit diagram is shown in Figure 3. Each student carries out wireless communication through the terminal and sets up their own LAN. Teachers accept students' real-time data and historical data. The data interfaces are filtered signal interface, setting out signal interface, AD conversion interface, and data metering port.

**4.2. Judgment and Comparison of Tennis Teaching Results by Cloud Computing and Deep Learning.** The model built by Simulink in MATLAB software is used for analysis, and the results are shown in Figure 4. Firstly, the data fit. In the cloud computing and deep learning of tennis teaching, the fitting degree between actual teaching and expected teaching is an important management evaluation index. The results are shown in Figure 4.

It can be seen from Figure 4 that the simulation of intelligent teaching is carried out by using a time timer and

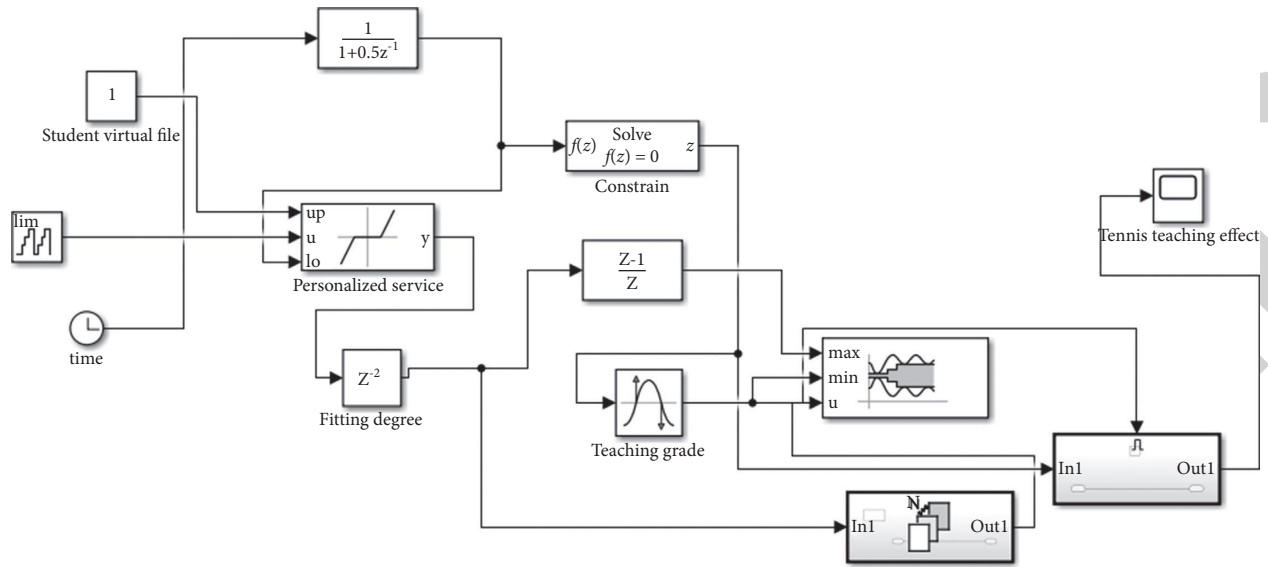

FIGURE 4: The cloud computing and deep learning simulation of college tennis teaching.

FIGURE 5: The fit ratio of data transmission between actual teaching and expected teaching requirements.

input waveform device; the maximum value, intermediate value, and minimum value are analyzed. Among them, the matching rate between the actual teaching data and the expectation is shown in Figure 5.

It can be seen from Figure 5 that the expected evaluation requirements of intelligent teaching are basically consistent with the actual requirements, indicating that the constructed simulation model can analyze cloud computing and deep learning. In short, the simulation model constructed in this paper is effective and can be used for practical case analysis.

It can be seen from Figures 4 and 5 that the fitting degree  $p$  between the actual teaching and the expected teaching requirements is good. The reason is that before judging, the tennis teaching effects are carried out, and the amplification effects are analyzed. In addition, the teaching data in Figure 6 is relatively stable and the slope changes less. At the same time, the change range of the actual teaching data is relatively stable, which shows that the data processing of the actual teaching is relatively stable,

FIGURE 6: The changes in actual teaching data.

FIGURE 7: The comparison between cloud computing and deep learning and the original management method.

FIGURE 8: The comparison of teaching effect levels of different methods.

FIGURE 9: The personalized service/resource sharing ratio of the two algorithms.

FIGURE 10: The improvement degree of teaching effect of the two algorithms.

which further shows the effectiveness of the algorithm. The reason is that the “group” built by students themselves and the sharing of tennis teaching resources can realize students’ autonomous learning and more efficient understanding of tennis content, and continuously improve their own knowledge combined with offline teaching content.

Secondly, the level of tennis teaching effect. Tennis teaching level is the focus of cloud computing and deep learning, which involves the content of practical operation and theoretical students. Compared with the traditional centralized mode, cloud computing and deep learning mode

has a higher level of teaching effect. On the whole, the evaluation data of actual teaching effect changes little, and the overall comparison process meets the evaluation requirements of learning effect. The reason is due to the self-help learning among students and the effective utilization of teaching resources. The results are shown in Figure 7.

As can be seen from Figure 7, the teaching level under the cloud computing and deep learning method is higher, and the teaching level is also higher than the original evaluation method. At the same time, the fluctuation range of the two algorithms is different. The fluctuation range of

the algorithm proposed in this paper is small and meets the requirements of teaching effect evaluation. The comparison of teaching levels of different methods is shown in Figure 8.

As can be seen from Figure 8, the cloud computing and deep learning method is higher than the original management method in terms of personalized service/resource. Compared with the original method, the algorithm proposed in this paper can evaluate the teaching effect more effectively. The main reason is the horizontal analysis of cloud computing and the vertical analysis of deep learning so as to realize the comprehensive judgment of the effect of intelligent teaching. The comparison of the personalized service/resource sharing ratio of different methods is shown in Figure 9.

As can be seen from Figures 9 and 10 that the calculation results of the two algorithms are higher in terms of service and resource sharing. Compared with the original method, the algorithm proposed in this paper mainly focuses on the core area of the radiograph. Therefore, the personalized strategy and resource sharing of the algorithm proposed in this paper are better than the original algorithm sharing ratio. This shows that under the same teaching time, the cloud computing and deep learning method can provide a higher proportion of personalized services. As we all know, personalized service is one of the important contents of quality education. The cloud computing and deep learning method improves the processing efficiency of tennis teaching on relevant teaching contents and reduces tennis teaching time according to the optimization methods such as the management table so as to better provide personalized management services to students.

## 5. Conclusion

Cloud computing and deep learning can evaluate the effect of tennis teaching in colleges and universities [19]. Cloud computing and deep learning can make up for the deficiency of single teaching and improve the accuracy of tennis teaching effect evaluation. At the same time, cloud computing and deep learning can shorten the evaluation time of teaching effect and make tennis teaching better meet the intelligent requirements. Cloud computing and deep learning is a management method based on middle school teaching. This method comprehensively evaluates the tennis teaching effect by preprocessing the tennis teaching evaluation data so that the evaluation results are more in line with the actual requirements. Cloud computing and deep learning methods reduce the amount of preprocessed data and evaluate the effect faster by identifying "abnormal data." MATLAB simulation results show that under cloud computing and deep learning, the fitting degree  $p$  between the actual tennis teaching effect and the expected teaching effect is better, and the tennis teaching effect level and the ratio of personalized service/resource sharing are higher than the original teaching method. Therefore, in the case of limited teaching time and complex teaching content, the cloud computing and deep learning method can effectively improve the tennis teaching effect and realize the personalized training of students.

With the extensive application of virtual technology and simulation algorithm, motion behavior recognition is widely used in various fields. The original neural network algorithm cannot solve the problem of data redundancy in behavior recognition, and the global search ability is weak. Based on the above reasons, this paper proposes an algorithm based on genetic algorithm and neural network to build a prediction model of behavior recognition. Firstly, genetic algorithm is used to cluster the redundant data, so that the data are in fragment order, and then it is used to reduce the data redundancy of different behaviors and weaken the influence of dimension on behavior recognition. Then, the genetic algorithm clusters the data to form subgenetic particles with different dimensions and carries out coevolution and optimal location sharing for subgenetic particles with different dimensions. Through simulation test, the algorithm constructed in this paper is better than genetic algorithm and neural network algorithm in terms of calculation accuracy and convergence speed. Finally, the prediction model is constructed by setting the initial value and threshold to predict the behavior recognition, and the results show that the accuracy of the model constructed in this paper is improved in the analysis of behavior recognition.

## 1. Introduction

In recent years, the state has put forward the development model of behavior intelligence, and major scientific research institutions attach great importance to behavior analysis. According to the survey data of behavior intelligence in 2020 [1], behavior recognition and behavior prediction account for 45.6% of the development of intelligent technology, resulting in the increasing demand for behavior intelligence development analysis and penetration into society. China has established research institutions of artificial intelligence, artificial voice, and artificial portrait and applied behavior recognition to video monitoring to provide data for artificial intelligence analysis [2]. Some scholars believe that behavior recognition is the judgment of different behavior points. The advantage of genetic algorithm is to analyze the gradual process of behavior and judge the final result of behavior. However, genetic algorithm also has its own shortcomings, which cannot adjust the analysis depth according to the

behavior results. Neural network makes up for the deficiency of genetic algorithm. Its advantage is to carry out self-learning, analyze the relationship between different behaviors, and make the theoretical behavior consistent with the actual behavior. Compared with the general algorithm, the combination of genetic algorithm and neural network increases the coupling between different behavior nodes and makes the behavior analysis more dynamic. At the same time, the increase of coupling can reduce the computational complexity and obtain the calculation results more accurately. The combination point of genetic algorithm and neural network is the judgment of behavior nodes and coupling between nodes. Genetic algorithm gives play to its advantage of progressive analysis of behavior nodes, and neural network analyzes the coupling between nodes, so as to improve the accuracy of analysis results. Behavior recognition is a dynamic process, which involves many factors. It is generally calculated by genetic algorithm. Although the node analysis of genetic algorithm can judge different

behaviors, it lacks threshold adjustment and cannot realize the dynamic analysis of behaviors. The combination of genetic algorithm and neural network can not only judge the behavior points but also judge the relationship between different behaviors. Therefore, the research advantage of this paper is to realize the comprehensive judgment of behavior and improve the accuracy of behavior recognition. On the basis of previous studies, this paper establishes a behavior recognition prediction model to provide accurate information and technology for behavior recognition prediction in sports and enrich relevant theories.

As can be seen from Figure 1, the application of behavior recognition in the field of sports is deepening and increasing and has become the focus of the development of intelligent sports. Among them, shooting, track and field, ball games, and other fields have been improved from 2015 to 2019, but the proportion of various sports has not changed. It can be seen that the social research degree of sports behavior recognition is increasing, which indicates the importance of verification of sports behavior recognition. The influencing factors of sports behavior recognition have the characteristics of semi-structured and nonlinear relationship, and the genetic algorithm has better semi-structured data analysis ability and can analyze it well. The neural network assigns value to each influencing factor and calculates it. If the output does not meet the requirements, adjust the assignment and propose the factor with assignment  $<0.3$ . Through continuous proposal, the purpose of simplifying factors is achieved. Finally, the factor with a value  $>0.6$  is the key factor, and subsequent calculation is carried out. It uses the mapping characteristics between various factors to carry out repeated iteration and self-learning [3], better process behavior recognition data, and meet the requirements of nonlinear analysis. Some scholars have established a behavior recognition development prediction model combining Apriori algorithm and genetic algorithm [4] to analyze domestic behavior recognition. The results show that the joint analysis results of genetic algorithm and Apriori algorithm are better, and each index is significantly better than Apriori algorithm[5]. Genetic algorithm belongs to a comprehensive analysis method, which integrates the learning mechanism of neural network to cluster a series of problems to achieve the purpose of fuzzy analysis. Therefore, based on genetic algorithm, this paper predicts behavior recognition [6]. In previous studies, the neural network is improved mainly from the following aspects. (1) Parameter adjustment and learning strategy change: the development trend of behavior recognition is studied and three behavior recognition prediction methods are compared. The results show that selecting appropriate methods can solve the eigenvalues of single index and multi-index in a certain period of time [7]. (2) A collection of analysis methods with other behavior recognition: some scholars have proposed a hybrid adaptive neural network algorithm, which integrates K-means clustering into the neural network. The algorithm can classify the behavior recognition data [8], divide the neural network according to different clustering weights, and improve the search speed of the optimal value. However, this method is greatly affected by the Euclidean distance,

FIGURE 1: The application of behavior recognition in sports.

which is not conducive to the calculation of the global optimal value [9]. From the perspective of communication delay, the neural network algorithm is used for large-scale scheduling calculation of distributed behavior recognition, and the dynamic and random cluster analysis [10] is used to prove that the algorithm has high accuracy. (3) Compared with classical theories, such as Bayesian theory, grey theory, chaos theory, and rough set, the improved neural network method has strong time-series sensitivity to data [11]. The above research is based on this, but neural network algorithm's calculation accuracy, search time, and overall convergence are still not ideal. In this paper, K-means clustering is used to improve the neural network algorithm and then combined with genetic algorithm to build a behavior recognition prediction model and verify it.

## 2. The Description of Behavior Recognition Algorithm Based on Genetic Algorithm and Neural Network

**2.1. Behavior Identification.** Behavior recognition is to judge the behavior of natural organisms. Behavior recognition is divided into two parts. One part is behavior recognition, that is, the movement of limb behavior. The other part is psychological behavior, which is the psychology that dominates the behavior of natural organisms. Generally speaking, behavior recognition refers to limb behavior, that is, the behavior and movement of natural organisms. Behavior recognition is related to the surrounding environment, movement trend, and movement purpose. Behavior recognition is not only a combination of individual behaviors but also a judgment of future behaviors.

**2.2. The Neural Network Theory.** Neural network was first proposed by Box and Jenkins in 1927 [12]. It belongs to a statistical analysis method, which mainly solves the problems of behavior description, behavior analysis, and future prediction, and is widely used in various fields. The algorithm is superior in nature, which is reflected in the description of data persistence. The neural network randomly selects irregular points for cyclic analysis. Neural network algorithm principle and structure are as follows: let  $G_{it}$  be the

dataset of  $t$  time in  $i$  multi-dimensional space and  $x$  belong to  $G_{it}$ . Hypothesis 1:  $P_j(x) = \sum_{i,t=1}^n \{x_{it}^j \cdot k + \varphi(k)\}$ ,  $k \in (1, \dots, n)$ ; if the deviation  $\varphi(k) = C(x, \varepsilon)$  is satisfied, then  $P_j(x)$  is the best genetic set where  $C(x, \varepsilon)$  is the adjustment coefficient of  $x$  and  $\varepsilon$ , and  $\varepsilon$  is the “core point” on the right side of the neural network. When,  $x_{it} = 2 \sin(\tan \pi t/\rho)$  and  $\rho$  is the minimum prime set  $2 \sin(\tan \pi t/\rho)^j \cdot k < \sum_{i,j,t=1}^n \{x_{it}^j \cdot k$ , the data link of the neural network list is shorter.

The relevant theories of neural network are as follows.

**Theorem 1.** *If the local deviation of  $P_n(x)$  is  $\varphi(x \cdot k)$  and  $f(\cdot) \in B_t$  ( $B_t$  is the redundancy function class of  $t$  time), the calculation formula of the redundancy function is*

$$\int_{x \in G_{ij}} f(x) dx - \sum_{j=1}^n f(P_j(x)) < Q(f(x)) \cdot \varphi(k), \quad (1)$$

where  $Q(f(x))$  is the global redundancy of  $f(\cdot)$ .

**Theorem 2.** *If the following conditions are satisfied  $f(x)$ , then any function value of  $f(x) < \varepsilon$ ,  $f(x)^i < \varepsilon, \dots, f(x)^j < \varepsilon$ , on the right side of the neural network is within the integral of  $f(x)$ , and the error of the redundant data on the right side is less than  $\ln(1/x)$ .*

**Theorem 3.** *If any data point  $x_{it}$  is normally distributed on the behavior recognition axis, the calculation formula of uniform deviation of  $D(x)$  any point is as follows.*

$$D(x, f(x)) = \ln\left(\frac{1}{\sqrt{x}} \cdot \sqrt[{}^t]{\log(P_j(x))}\right), \quad (2)$$

where  $D(x, f(x))$  is between sets  $[0, 1]$ .

It can be seen from Theorems 1 and 2 that the relationship between the right redundancy amplitude and the amount of data  $x$  can be obtained by using the approximate integration of neural network, which is independent of spatial dimension  $i$  and time  $t$ . Therefore, neural network function provides a good theoretical basis for multi-dimensional number calculation and time-dependent calculation and reduces the impact of unstructured data form on the calculation results. According to Theorem 3, the local deviation of the data in the neural network is  $\ln(1/x)$  and the uniform deviation is  $\ln(1/\sqrt{x} \cdot \sqrt[{}^t]{\log(P_j(x))})$ , indicating that the local deviation can control the redundancy amplitude on the right side due to the uniformly distributed deviation. Combining neural network with rough set algorithm, an improved algorithm of right redundant amplitude control is proposed, which proves the ability of neural network to control redundant data and verifies the superiority of this method. This paper uses this method for reference to transform the composition of behavior recognition data and takes it as the initial data group for continuous analysis.

**2.3. Genetic Algorithm.** In this paper, genetic algorithm is selected for model optimization. This method belongs to a clustering method with fuzziness and adaptability. It can

realize self-learning [13] and constantly revise the membership function of cluster set and complete set. Genetic algorithm can be defined by “IF” judgment mode. Under constraint rule  $Z$ , neural network algorithm clustering process is as follows:

$$\begin{aligned} \text{IF: } x_i \in g_{ij} \text{ and } Z(x) = C(x_i, x_{i-1}), \\ \text{then } y = \sum_{i=1}^n y_i = \sum_{i=1}^n \frac{Z(x_i) \cdot \lambda(x_i)}{\lambda(x_i)}, \end{aligned} \quad (3)$$

where  $\lambda(x_i)$  is the clustering function,  $g_{ij}$  is the clustering set,  $M(x)$  is the constraint function,  $C(x_i, x_{i-1})$  is the relationship between any adjacent data  $x$ , and  $y$  is the clustering result. The input part of genetic algorithm is clear, the processing part is fuzzy, and the output part is clear, so the output result can be inferred by fuzzy method to obtain the output combination.

Assuming that any input variable is  $x_i$ , the membership relationship between each input variable  $x_i$  and output variable  $y_i$  can be obtained by constraint rule  $Z$ , as shown in the following formula:

$$C \cdot g_{ij} = \sum_{i,j=1}^n \exp\left\{\frac{(x_i - c_{ij})}{b_{ij}}\right\}. \quad (4)$$

where  $c_{ij}$  and  $b_{ij}$  are, respectively, the center and degree of membership of the membership function;  $C$  is a relational function; and  $g_{ij}$  is a fuzzy set.

By clustering the above membership relations, the continuous operator of clustering can be obtained, as shown in the following formula:

$$C \cdot g_{ij} = \delta \cdot \sum_{i,j,k=1}^n g_{ij}^k(x), \quad (5)$$

where  $\delta$  is the cluster adjustment coefficient and  $k$  is the derivation coefficient. According to the cluster calculation, the output value of the cluster can be obtained, as shown in the following formula:

$$y = \frac{[\delta \cdot \sum_{i,j,k=1}^n g_{ij}^k(x) \cdot f(P_j(x))]}{\max \sum_{i,j=1}^n g_{ij}^k(x)}. \quad (6)$$

Genetic algorithm not only shortens the processing time of behavior recognition data but also increases the amount of initial data processing. Genetic algorithm performs multi-dimensional clustering according to the initial data volume [14] and labels it with time to form a continuous data chain. Adjust the relationship function  $C$  and clustering coefficient of  $\delta$  the data according to the output result  $y$ .

### 3. The Construction of Behavior Recognition Model Based on Genetic Algorithm and Neural Network Algorithm

**3.1. Coevolution of Initial Behavior Identification Data.** In this paper, the model takes into account the multi-dimensional and global nature of the data, reduces the local convergence, improves the search ability of the characteristic

data, and shortens neural network algorithm's own learning time. Reflected in the evolution strategy of initial sequence and multi-dimensional sequence, the convergence threshold and weighting factor are used to promote the coevolution of distributed population, and the optimal value of right redundancy amplitude is obtained.

**3.1.1. Initialization of Genetic Algorithm.** The neural network algorithm considers that the initial sequence is in random distribution. If the sequence uncertainty is very strong, that is, nonnormal distribution, it will make the sequence calculation fall into local optimization, reduce the calculation time of global optimization solution, and increase the error rate of calculation results. In order to enhance the normality of the sequence, we should expand the scale of the sequence and increase the types of data. Based on the principle of classical neural network, this paper expands the number of sequences of initial data and improves the diversity of sequences.

Figures 2 and 3 show multi-dimensional initial neural networks processed by a random method and the genetic algorithm method, respectively. The number of segments of the neural network is 100. Through comparison, it is found that the initial sequence generated by random method is more chaotic and nondirectional. Through the comparison of Figures 2 and 3, it can be seen that the behavior recognition particles in random mode are more chaotic and concentrated, which increases the complexity of calculation. However, the behavior recognition particles processed by genetic algorithm are more uniform, which reduces the computational complexity and lays the foundation for later calculation. The sequences processed by genetic algorithm are more concentrated and directional. According to Theorems 1 and 2 of neural network algorithm, the dataset constructed by this algorithm is independent of spatial dimension and is suitable for multi-dimensional data processing. Moreover, each time the point is taken, the distribution effect of the initial sequence is the same, and the stability of the dataset is high. To sum up, genetic algorithm is selected to process the initial sequence.

FIGURE 2: Initial neural network constructed by random method.

FIGURE 3: Initial neural network constructed by genetic algorithm.

**3.1.2. Multi-Strategy Collaboration.** Global search ability is an important measure of the algorithm. In the initial stage of calculation, the algorithm focuses on global search and then advances to local search [15]. In order to improve the computational efficiency of the algorithm, this paper introduces a multi-strategy cooperation method, which allows particles to search according to different behavior sequences (saving repeated calculation time), and realizes global search and local search at the same time. At present, there are standard neural network algorithms and other improved algorithms.

(1) Classical behavior recognition model:

$$y_{ij}(t+1) = \square \bar{w} \cdot y_{ij}(t) + c_1 \cdot r_1 \cdot \frac{[\delta \cdot \sum_{i,j,k=1}^n g_{ij}^k \{x(t) \cdot f(P_j[x(t)])\}]}{\max \sum_{i,j=1}^n g_{ij}^k [x(t)]} \quad (7)$$

(2) Group behavior recognition model:

$$y_{ij}(t+1) = \omega \cdot y_{ij}(t) + c_2 \cdot r_2 \cdot \frac{[\delta \cdot \sum_{i,j,k=1}^n g_{ij}^k \{x(t) \cdot f(P_j[x(t)])\}]}{\max \sum_{i,j=1}^n g_{ij}^k [x(t)]} \quad (8)$$

(3) Behavior recognition judgment model:

$$y_{ij}(t+1) = n \cdot \left| \frac{\left[ \delta \cdot \sum_{i,j,k=1}^n g_{ij}^k \{x(t) \cdot f(P_j[x(t)])\} \right]}{\max \sum_{i,j=1}^n g_{ij}^k [x(t)]} - \frac{\left[ \vec{\delta} \cdot \sum_{i,j,k=1}^n g_{ij}^k \{x(t) \cdot f(P_j[x(t)])\} \right]}{\max \sum_{i,j=1}^n g_{ij}^k [x(t)]} \right| \quad (9)$$

(4) General behavior recognition model:

$$y_{ij}(t+1) = \omega \cdot y_{ij}(t) + \sum_{i=1}^2 c_i \cdot r_i \cdot \frac{\left[ \delta \cdot \sum_{i,j,k=1}^n g_{ij}^k \{x(t) \cdot f(P_j[x(t)])\} \right]}{\text{avg} \sum_{i,j=1}^n g_{ij}^k [x(t)]}, \quad (10)$$

where  $c_1$  and  $c_2$  are the synergy coefficients of different strategies,  $r_1$  and  $r_2$  are the correlation coefficients of different strategies,  $\omega$  is the average weight of different strategies ( the values are from relevant literature at home and abroad ), and  $n$  is the number of different strategies.

This paper improves the standard neural network function in two aspects. On the one hand, it expands the search range. For each iterative calculation, a neural network form will be randomly selected from the above 5 forms for genetic algorithm calculation. Genetic algorithm can avoid local optimal results and expand the search range. The random selection calculation form can maintain the population diversity and increase the possibility of obtaining the local optimal value. On the other hand, it can improve the convergence. In order to balance the ability of global search and local search of neural network,  $\alpha$  (nonlinear adjustment coefficient) and  $\omega$  (linear weight) are added to improve the calculation speed. The formula is as follows:

$$\alpha = \frac{\text{Line}_t^d - 1}{\text{Line}_T^D}, \quad (11)$$

where  $e$  is the logarithmic base,  $t$  is the time,  $T$  is the maximum time,  $d$  is the number of iterations, and  $D$  is the maximum number of iterations. In the initial stage, the attenuation degree of  $\alpha$  is low, and the global optimal value can be calculated. In the middle and later stages of  $\alpha$  calculation, the attenuation degree increases gradually, and the local optimal value can be calculated. The linear weight is calculated as follows:

$$w = \sum_{d=1}^D \left[ \frac{(\widetilde{w_{\max}} - \sum_{t=1}^T \Delta w_i)}{(\sum_{t=1}^T \Delta w_i - w_{\min})} \right]^d, \quad (12)$$

where  $w_{\max}$  and  $w_{\min}$  are the maximum and minimum weights, respectively, and the values of  $d$ ,  $t$ ,  $D$ , and  $T$  are the same as above.

**3.1.3. The Behavior Recognition and Collaboration Strategies among Different Dimensions.** The algorithm adopts differentiated operations and strategies for data of different dimensions and adjusts corresponding parameters to realize multi-dimensional distributed collaboration, so as to

complete the process of collaborative evolution. In the model, the neural network data are divided into five dimensions, and each dimension represents the subspace of the solution space [16]. In each iteration, the five dimensions evolve simultaneously. After an iterative calculation, compare the fitness values of different dimensions and record the location of the global optimal value of each dimension. Then, each subdimension learns gradually to the global optimal value and obtains the optimal position of the subdimension in the most concise way, so as to improve the speed and efficiency of search and calculation.

**3.2. The Behavior Recognition and Judgment Method Based on Genetic Algorithm and Neural Network.** The basic idea of genetic algorithm is multi-dimensional coevolution. The initial value and threshold of neural network (the values are from relevant literature at home and abroad) are adjusted and optimized [17] to obtain the optimal solution and reduce the redundancy rate in behavior recognition.

The judgment process is shown in Figure 4.

**Step 1.** Determine the dimension and sequence structure of the neural network and determine the data structure of the neural network according to the data characteristics and problem-solving needs. The initial weight and threshold of the whole data are mapped to the neural network as a whole. The dimension of each neural network is the opportunity of weight and threshold. According to the actual application, the dimension of neural network in this paper is  $g = 433$ .

**Step 2.** Data initialization: the relevant parameters of the neural network are initialized randomly. Let the number of neural networks be  $n = 100$ , the maximum weight be  $w_{\max} = 0.7$ , the minimum weight be  $w_{\min} = 0.3$ , the synergy constant between different dimensions be  $c_1, c_2 = 3.22$ , and the maximum number of iterations be  $D = 10$ .

**Step 3.** Generate the appropriate function. The genetic algorithm theory is used to generate the initial sequence of neural network, which is mapped to the neural network as the initial weight and threshold. Through the self-learning and training of formulas (1)–(8), the synergy coefficient of the neural network algorithm will continue to increase and adapt. The accuracy of each neural network is calculated, and

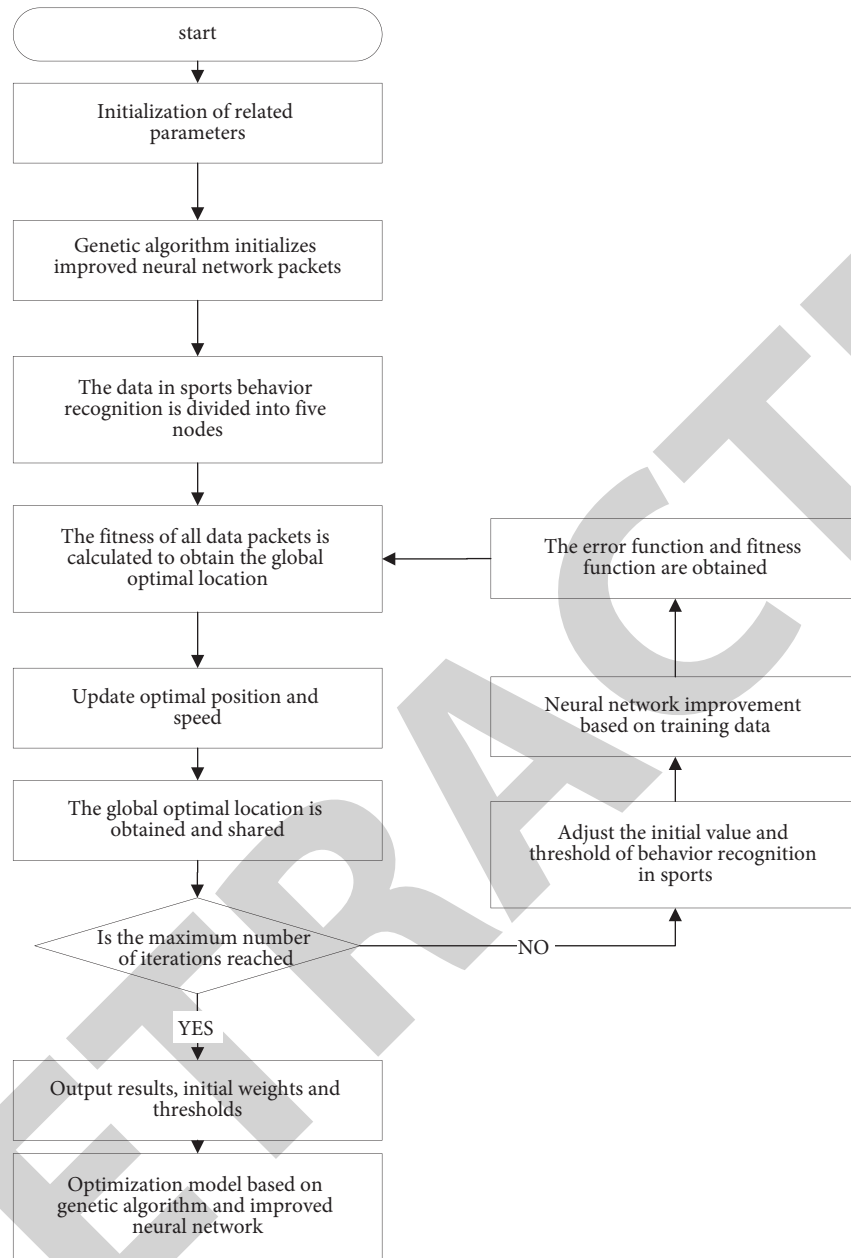

FIGURE 4: Calculation flowchart based on genetic algorithm and neural network.

the absolute value of the sum of squares is taken as an appropriate function.

*Step 4.* Globally search the optimal position of the neural network and the optimal position of each subgenetic particle. The initial neural network is randomly divided into five subsequences, the fitness ratio is obtained, and the optimal global position and the optimal position of each subsequence are recorded.

*Step 5.* Iteration of optimal position and speed: in the evolution of 5 seed sequences, one is randomly selected for evolution, such as formulas (8)–(11), and  $\alpha$  is nonlinear

adjustment coefficient and  $\omega$  is linear weight, such as formulas (12) and (13).

*Step 6.* All subsequences coevolute at the same time. After one iteration, the optimal global computing location is selected and shared with other subsequences. Other subsequences gradually iterate to this position to obtain the best position result.

*Step 7.* Determine whether to stop the iteration. If the number of iterations  $D$  is less than the maximum number of iterations  $D$ , repeat Steps 2–6; otherwise, stop the iteration and return the results such as threshold, weight, and optimal position.

#### 4. Case Analysis of Sports Behavior Identification

*4.1. Model Performance Judgment.* The classical neural network algorithm, neural network algorithm, and neural network algorithm based on genetic algorithm which are tested with Filer, Rastring, Ackley, and other functions to verify the performance of the model proposed in this paper.

Filer function is the globally unique minimum value function of the test model [18], and the formula is as follows:

$$F_1(x) = \sum_{i=1}^n [x_i^2]. \quad (13)$$

Rastring function generates local minimum frequently through cosine modulation transfer function to verify the practicability of model solution [19]. The formula is as follows:

$$F_2(x) = \sum_{i=1}^n [x_i^2 - 10 \cos(2\pi x_i) + 10]. \quad (14)$$

Ackley function is a gradient optimization function of multi-dimensional points to test the calculation speed of multi-dimensional data to detect the global convergence speed. The formula is as follows:

$$F_3(x) = -20 \exp \left\{ -0.2 \sum_{i=1}^n \sqrt{\frac{1}{n} \sum_{i=1}^n x_i^2} \right\} - \exp \left\{ \frac{1}{n} \sum_{i=1}^n \cos(2\pi x_i) \right\} + 20 + e, \quad (15)$$

where  $n$  is the total number of indicators for calculating data and  $x_i$  is any number of indicators. The value range of  $x_i$  in filer function is  $\{-100100\}$ , that in rastring function is  $\{-5.12, 5.12\}$ , and that in Ackley function is  $\{-32, 32\}$ .

In order to facilitate calculation, the number of neural networks in this paper is  $n = 100$ , the maximum number of iterations is  $D = 30$ , and the maximum time is  $T = 16$  months. The above three functions are tested, respectively. In order to reduce the impact of randomness on the results, take the average of 7 times the results. The specific calculation results are shown in Table 1.

The convergence diagram of each data in Table 1 is shown in Figures 5-7.

It can be seen from Table 1 that compared with neural network and genetic algorithm, the genetic algorithm and neural network algorithm proposed in this paper is closer to the global optimal value. In terms of standard deviation, average value, and value range, genetic algorithm and neural network algorithm are better than the other two algorithms. According to the curve changes in Figures 5-7, the genetic and neural network algorithms have better stability and faster convergence speed. Therefore, the convergence speed, calculation accuracy, and summation stability of genetic and neural network algorithms are better.

*4.2. Case Data and Preprocessing.* There are some missing data in the sample data in this paper, which is compensated by default value in the later stage. The prediction dataset of behavior recognition includes digital behavior, bionic behavior, natural behavior, psychological behavior, and expected behavior. After preliminary data preprocessing, 1982 lines of structured data and 38 lines of semistructured data are obtained. In order to facilitate data analysis, behavior recognition is divided into five levels: relatively intelligent, intelligent, general, not intelligent, and relatively not intelligent. The processing results of data volume are shown in Table 2.

Due to lack of some data in this paper, the data from January 1, 2019, to July 22, 2020, are taken as the training set, with a total of 1345 pieces; the data from July 22, 2020, to December 1, 2021, are taken as the test set, with a total of 676 pieces.

*4.3. Test Results.* In order to verify the genetic and neural network algorithms proposed in this paper, the results are compared with those of genetic algorithm and neural network algorithm. The results are shown in Figure 8.

As can be seen from Figure 8, in terms of calculation accuracy, The accuracy of the algorithm proposed in this

FIGURE 5: The optimization convergence result of filer function.

FIGURE 6: The convergence results of rastring function optimization.

paper is higher than the single genetic algorithm and neural network algorithm, respectively, after analysis the error rate is also lower than that of the single genetic algorithm and neural network algorithm. In addition, the algorithm proposed in this paper has better computational stability, which is better than the single genetic algorithm and neural network algorithm. The calculation results of different algorithms are shown in Table 3.

It can be seen from Table 3 that the single neural network algorithm and genetic algorithm have the problems of insufficient accuracy and large variation of calculation results in different levels of behavior recognition and prediction. Compared with the neural network algorithm, the accuracy

of the algorithm constructed in this paper is significantly improved. At the same time, the accuracy is close to that of neural network algorithm, which is more than 80%, which is better than genetic algorithm. In order to further verify the advantages of genetic and neural network algorithms, the optimal fitness values of different algorithms are compared, and the results are shown in Figure 9.

It can be seen from Figure 9 that the optimization of fitness function results of genetic and neural network algorithms is more significant. The reason is that genetic algorithm and neural network add synergy coefficients, improvement weights, and convergence factors in different dimensions.

## 5. Conclusion

To sum up, the model of genetic algorithm combined with neural network constructed in this paper can identify and predict behavior more accurately and quickly, and its calculation results are basically consistent with the actual requirements. This paper puts forward the theory of genetic algorithm and improves the neural network algorithm combined with multi-dimensional coevolution method. At the same time, the threshold and weight of the neural network algorithm are set, and the behavior recognition analysis model is constructed. The results show that compared with the classical neural network algorithm and genetic algorithm, the prediction accuracy and convergence of behavior recognition based on genetic algorithm combined with neural network algorithm are better, and the behavior recognition can be judged. However, in this model, the multi-dimensional cooperation strategy pays too much attention to the global search ability, resulting in the relative decline of the local search ability and the reduction of the calculation speed of the optimal solution. Therefore, in the future research, the equilibrium coefficient and filter function will be added to improve the solving ability of the model.

Support vector machine (SVM) is an efficient classification method in machine learning. The traditional classification model of SVMs may pose a great threat to personal privacy, when sensitive information is included in the training datasets. Principal component analysis (PCA) can project instances into a low-dimensional subspace while capturing the variance of the matrix  $A$  as much as possible. There are two common algorithms that PCA uses to perform the principal component analysis, eigenvalue decomposition (EVD) and singular value decomposition (SVD). The main advantage of SVD compared with EVD is that it does not need to compute the matrix of covariance. This study presents a new differentially private SVD algorithm (DPSVD) to prevent the privacy leak of SVM classifiers. The DPSVD generates a set of private singular vectors that the projected instances in the singular subspace can be directly used to train SVM while not disclosing privacy of the original instances. After proving that the DPSVD satisfies differential privacy in theory, several experiments were carried out. The experimental results confirm that our method achieved higher accuracy and better stability on different real datasets, compared with other existing private PCA algorithms used to train SVM.

## 1. Introduction

In the past decade, more and more personal information has been stored in electronic databases for machine learning and personalized recommendation. The data sharing and analysis bring lots of convenience to people's lives, but pose a great threat to personal privacy. Support vector machine (SVM) [1] is a popular classification method that searches for the best hyperplane that separates two class instances by solving a quadratic optimization problem. It has been applied in pattern recognition such as image recognition and text classification. In the classification model of SVM, the most serious privacy issue is that the support vectors (SVs) are directly obtained from the training datasets [2]. Therefore, the classification model should be privately published to avoid disclosing personal sensitive information.

Differential privacy (DP) [3–6] has a strict mathematical definition and the level of privacy protection can be quantified by a small parameter  $\epsilon$  named privacy budget. DP

has been becoming an accept standard. It guarantees that the result of an analysis is virtually independent of the addition or removal of one record. DP has attracted a growing research attention [7]. The common mechanisms for implementing DP include Laplace mechanism [8], Gaussian mechanism [9], and exponential mechanism [10].

Principal component analysis (PCA) [9] solves a low-rank subspace, which completely captures the variance of matrix  $A$ . The main advantages of working with the low-rank approximation of  $A$  include higher time and space efficiency, less noise, and removal of correlation between features. Through PCA, the original instances are projected into a low-dimensional subspace and the features become linearly independent. Eigenvalue decomposition (EVD) and singular value decomposition (SVD) are two common algorithms to perform PCA. They are related to the familiar theory of matrix diagonalization. The EVD is used for a symmetric matrix and SVD for an arbitrary matrix. Furthermore, SVD does not need to compute the matrix of covariance compared with EVD [11].

This study researches the privacy leakage problem of SVM classifier. To overcome some shortcomings in the existing private SVMs, a differentially private singular value decomposition (DPSVD) algorithm is proposed to keep SVs private in the classification model of SVM. This study makes the following innovations:

- (i) The authors proposed an idea that projecting the training instances into the low-dimensional singular subspace and the SVM can train the classification model on it while not violating the privacy requirements for the training data.
- (ii) The projection process of the DPSVD satisfies DP, and the generated singular vectors are also private which can be provided directly to users for classification testing.
- (iii) In the DPSVD, the projection process is implemented by SVD. The main advantage is that SVD does not need to calculate the matrix of covariance compared with EVD. It takes up a lot of memory space for high-dimensional data.
- (iv) Our method protects privacy of the training instances before training the classification model; many optimization methods of SVMs can be applied directly to the training progress.
- (v) After proving that the DPSVD satisfies differential privacy in theory, several experiments were carried out. The experimental results confirm that our method achieved higher accuracy and better stability on different real datasets, compared with other existing private PCA algorithms used to train SVM.

## 2. Related Work

From a privacy perspective, SVMs have serious privacy issues, because SVs tend to be directly obtained from the training datasets. There is a lot of work to solve this privacy problem based on DP. Chaudhuri et al. [12, 13] proposed two perturbation-based methods for problems like linear SVM classification. For nonlinear kernel SVM, they derived the kernel function through random projection and linearized the function. However, it is hard to analyze the sensitivity of the output perturbation, and the differentiability criteria are required in the loss function of objective perturbation. To learn SVM privately, Rubinstein et al. [14] developed two feature mapping methods by adding noise to the output classifier. But their methods only apply to the kernels that do not change with translation. Li et al. [15] designed a mixed SVM, which alleviate much of the noise through Fourier transform based on a few open-consented information. Zhang et al. [16] proposed DPSVMDVP by adding Laplace noise to the dual variables based on the error rate. Liu et al. [17] presented an innovative private classifier called LabSam by random sampling under the exponential mechanism. Sun et al. [18] proposed the DPWSS, which introduces randomness into SVM training; they also proposed another private SVM algorithm DPKSVMEL based on

exponential and Laplace hybrid mechanism [19] for the kernel SVM to prevent privacy leakage of the SVs.

PCA constructs a set of new features to describe the instances in a low-dimensional subspace. When the generated projection vectors are private, the new instances in the low-dimensional subspace are private as well, and they can be used directly to train SVMs without compromising the privacy of the instances. There are several researches on private PCA. Blum et al. [20] developed SuLQ by disturbing the matrix of covariance with Gaussian noise. However, the greatest eigenvalue might be not real, due to the asymmetry of the noise matrix. Chaudhuri et al. [21] modified SuLQ framework with a symmetric noise matrix and used it for data publishing. Dwork et al. [9] disturbed the matrix of covariance with Gaussian noise. Imtiaz and Sarwate [22, 23] and Jiang et al. [24] disturbed the matrix of covariance with Wishart noise and it guarantees that the perturbed matrix of covariance is positive semidefinite. Xu et al. [25] and Huang et al. [26] added symmetric Laplace noise to the matrix of covariance. Those methods above all generate the perturbed matrix of covariance by adding a noise matrix and then perform EVD to implement PCA. And only [26] measured the availability of the private PCA by SVM, but not to research private PCA from the privacy perspective of SVM. Recently, SVD has been widely used in collaborative filtering [27], deep learning [28], data compression [29, 30], and images watermarking [31]. There are few researches on privacy-preserving data mining based on SVD. Keyvanpour et al. [32] defined a method that combined SVD and feature selection to benefit from the advantages of both domains. Li et al. [33] gave a new algorithm for protecting privacy based on nonnegative matrix factorization and SVD. Kousika et al. [34] proposed a methodology based on SVD and 3D rotation data perturbation for preserving privacy of data.

## 3. Background

Table 1 summarizes the symbols used in this study.

*3.1. Support Vector Machines.* Given training instances  $x_i \in R^d$  and labels  $y_i \in \{1, -1\}$  the classification model of SVM can be obtained by solving the following optimization problem [35]:

$$\min_{\alpha} f(\alpha) = \frac{1}{2} \alpha^T Q \alpha - e^T \alpha. \quad (1)$$

$$\text{Subject to } \begin{aligned} 0 \leq \alpha_i \leq C, i = 1, \dots, l \\ y^T \alpha = 0, \end{aligned} \quad (2)$$

where  $\alpha$  is a dual vector;  $Q$  is a symmetric matrix,  $Q_{ij} = y_i y_j K(x_i, x_j)$ , and  $K$  is the kernel function.

Let  $x$  be a new instance. The label of  $x$  can be predicted by the decision function as follows:

$$f(x) = \sum_{i=1}^n \alpha_i y_i K(x_i, x) + b. \quad (3)$$

TABLE 1: Symbols.

Symbol	Description
$D, D'$	The adjacent matrix of datasets
$A, \bar{A}$	Matrix of covariance
$x_i \in \mathbb{R}^d$ .	Train instance
$y_i \in \{1, -1\}$ .	Label
$A$	Dual vector
$Q$	Symmetric matrix for kernel function
$K$	Kernel function
$E$	Vector composed entirely of ones
$C$	Upper limit of $\alpha$
$\lambda_i$	Eigenvalue
$v_i$ .	Eigenvector
$\Gamma$	The accumulative contribution rate of principal components
$U, V$	The singular vectors or eigenvectors matrix
$\Sigma, S$	The singular values or eigenvalues diagonal matrix
$\sigma_i$	Singular value
$I$	Unit diagonal matrix
$M$	A randomized mechanism
$O$	All subsets of possible outcomes of mechanism $M$
$\epsilon$	Privacy budget
$\beta, \delta$	Privacy parameter
$S_1, S_2$	The $\ell_1$ and $\ell_2$ sensitivity of function
$Laplace(b)$	Laplace noise (mean: 0; scale: $b$ )
$N(0, \tau^2)$	Gaussian noise with (mean: 0; deviation: $\tau$ )

In the classification model, only the SVs determine the maximal margin and correspond to the nonzero  $\alpha_i$ s, and others equal zero. From a privacy perspective, the classification model has serious privacy issues as the SVs are intact instances.

**3.2. Principal Component Analysis.** PCA computes a low-rank subspace and achieves the dimensionality reduction for high-dimensional data, shedding light on the use of private SVM in high-dimensional data classification. For a given data matrix  $D \in \mathbb{R}^{n \times d}$  with  $d$  features of  $n$  instances, the  $i$ -th row of  $D$  is denoted by  $x_i$ , and assumes that its  $\ell_2$  norm satisfies  $\|x_i\|_2 \leq 1$ . After the matrix is centralized by column, the matrix of covariance can be obtained as

$$A = \frac{1}{n} D^T D = \frac{1}{n} \sum_{i=1}^n x_i^T x_i. \quad (4)$$

The matrix of covariance is a real symmetric matrix; therefore its eigenvalues and corresponding eigenvectors can be obtained by EVD:

$$A v_i = \lambda_i v_i, \quad (5)$$

where  $\lambda_i$  is one of the eigenvalues and  $v_i$  is its corresponding eigenvector. The  $\lambda_i$  could be treated as variance of the  $i$ -th

principal component to denote its importance and is sorted in descending order. Generally, the threshold of the accumulative contribution rate of principal components  $\gamma$  ( $0 \leq \gamma \leq 1$ ) is set to decide the target dimension  $k$  by

$$\frac{\sum_{i=1}^k \lambda_i}{\sum_{i=1}^d \lambda_i} \geq \gamma. \quad (6)$$

According to the diagonalization theory of matrix and (5), it obtains another representation of EVD as follows:

$$A = V \Sigma V^T, \quad (7)$$

where  $V$  is an orthogonal matrix consisting of eigenvectors in columns and  $\Sigma$  is a diagonal matrix taking eigenvalues as diagonal entries. Compared with EVD, SVD can be applied to an arbitrary real matrix and it does not need to calculate matrix of covariance. The representation of SVD is shown as follows:

$$D = U S V^T, \quad (8)$$

where  $U$  and  $V$  are the left and right singular matrices, which consist of left and right singular vectors, respectively;  $S$  is a diagonal matrix taking singular values as diagonal entries. The singular value  $\sigma_i$  is also sorted in descending order. The relationship between EVD and SVD is as follows:

$$A = \frac{1}{n}D^T D = \frac{1}{n}(USV^T)^T(USV^T) = \frac{1}{n}VSU^T USV^T = \frac{1}{n}VSSV^T = \frac{1}{n}VS^2V^T, \quad (9)$$

$$\tilde{A} = \frac{1}{n}DD^T = \frac{1}{n}(USV^T)(USV^T)^T = \frac{1}{n}USV^T VSU^T = \frac{1}{n}USSU^T = \frac{1}{n}US^2U^T, \quad (10)$$

where  $U^T U = I$  and  $V^T V = I$ , because  $U$  and  $V$  are both made up of unit orthogonal vectors; they also are called orthonormal basis matrices. The coefficient  $1/n$  has nothing to do with the eigenvectors and the proportionality of eigenvalues. We generally use  $D^T D$  to approximate the matrix of covariance. From (9) and (10), we can conclude that the SVD of an arbitrary real matrix yields a similar result to the EVD of its matrix of covariance. In the SVD of  $D$ , the right singular vectors serve as the eigenvectors of  $D^T D$ , and the left ones serve as those of  $DD^T$ . The singular values equal the square roots of the nonzero eigenvalues of  $D^T D$  and  $DD^T$ .

### 3.3. Differential Privacy

*Definition 1* (differential privacy (see [3])). A stochastic mechanism  $M$  satisfies  $(\epsilon, \delta)$ -differential privacy, provided that, for every two adjacent matrices  $D$  and  $D'$  differing in exactly one row, and for all subsets of probable outcomes  $O \subseteq \text{Range}(M)$ ,

$$\Pr[M(D) \in O] \leq \exp(\epsilon) \times \Pr[M(D') \in O] + \delta. \quad (11)$$

When  $\delta$  equals zero,  $M$  satisfies  $\epsilon$ -differential privacy.

*Definition 2* (sensitivity (see [3])). For a given function  $q: D \rightarrow R^d$ , and adjacent matrices  $D$  and  $D'$ , the sensitivities  $S_1$  and  $S_2$  of function  $q$  can be, respectively, expressed as

$$S_1 = \max_{D, D'} \|q(D) - q(D')\|_1 \text{ and } S_2 = \max_{D, D'} \|q(D) - q(D')\|_2. \quad (12)$$

$S_1$  corresponding to  $\ell_1$  norm is usually used in Laplace mechanism, while  $S_2$  corresponding to  $\ell_2$  norm is used in Gaussian mechanism.

*Definition 3* (Laplace mechanism (see [8])). For a numeric function  $q: D \rightarrow R^d$ , with scale factor  $b = S_1/\epsilon$ . The Laplace mechanism, which adds independent random noise distributed as  $\text{Laplace}(b)$  to each output of  $q(D)$ , ensures  $\epsilon$ -differential privacy.

*Definition 4* (Gaussian mechanism (see [9])). For a numeric function  $q: D \rightarrow R^d$ , let  $\beta = S_2 \sqrt{2 \ln(1.25/\delta)}/\epsilon$ . The Gaussian mechanism, which adds independent random noise distributed as  $N(0, \beta^2)$  to each output of  $q(D)$ , ensures  $(\epsilon, \delta)$ -differential privacy.

## 4. Materials and Methods

To overcome the shortcomings in the existing private SVMs, we proposed the DPSVD. The DPSVD privately projects the

original instances to a low-dimension singular subspace and trains a SVM classification model in it to protect the privacy of training instances.

*4.1. Algorithm Description: Algorithm 1 Is the Pseudocode of the DPSVD.* The algorithm 1 describes the implementation process of the DPSVD for training a private classification model of SVM. Firstly, it generates a noise matrix sampled from Gaussian distribution, and this step does not need to symmetrize the noise matrix as the existing private PCA algorithms. Secondly, it adds the noise matrix to the raw data matrix rather than the matrix of covariance of the raw data. When features far outnumber instances, the matrix of covariance will take up a lot of memory space, especially for high-dimensional data. Meanwhile, the matrix of covariance will magnify errors in the raw data to some extent. Thirdly, the DPVSD algorithm computes the singular values and singular matrices by SVD, while the existing private PCA algorithms use EVD. Generally, SVD can be considered a black box and has higher execution efficiency compared with EVD, although the two decomposition methods generate the same projection subspace by singular vectors or eigenvectors under the nonprivate situation. There are similar computing processes with the EVD in the next three steps. Lastly, the DPSVD distributes the private classification model to predict the new instances, prior to idea that it projects them to the same singular subspace by the private singular vectors. In brief, the DPSVD trains a private SVM classifier for predicting the new instances in future.

*4.2. Privacy Analysis.* Firstly, the sensitivity of the function  $q(D)$  is analyzed, and then the DPSVD is demonstrated to satisfy  $(\epsilon, \delta)$ -differential privacy. In the DPSVD algorithm, the noise matrix is added to the data matrix  $D$ ; therefore  $q(D) = D$ . Given that two adjacent data matrices  $D$  and  $D'$  differ by exactly one row corresponding to an instance, we set  $D'$  obtained from  $D$  by deleting the last row,  $D = [x_1, \dots, x_n]^T \in R^{n \times d}$  and  $D' = [x_1, \dots, x_{n-1}]^T \in R^{(n-1) \times d}$ , and assume each row has unit  $\ell_2$  norm  $\|x_i\|_2 \leq 1$  at the most.

**Lemma 1.** *The sensitivity of the function  $q(D)$   $S_2$  equals one.*

*Proof.* According to Definition 2, it obtains  $S_2$  by the following inequation:

$$S_2 = \max_{D, D'} \|q(D) - q(D')\|_2 = \max_{D, D'} \|D - D'\|_2 = \max_{D, D'} \|x_n\|_2 \leq 1 \quad (13)$$

Therefore, the sensitivity of the function  $q(D)$  equals one.

4	Splice	1000	60	[-1, 1]

**Theorem 1.** *The DPSVD satisfies  $(\epsilon, \delta)$ -differential privacy.*

*Proof.* To demonstrate that the DPSVD satisfies  $(\epsilon, \delta)$ -differential privacy, it is necessary to demonstrate every step in the algorithm satisfies it. According to Lemma 1, it obtains that  $S_2$  equals one. Let  $\beta = S_2 \sqrt{2 \ln(1.25/\delta)}/\epsilon = \sqrt{2 \ln(1.25/\delta)}/\epsilon$ ; then Step (1) and Step (2) satisfy DP according to Definition 4. Step (3) and Step (4) postprocess the private data matrix  $D'$ ; they also satisfy DP. Step (5) generates the private singular vectors  $V_k$ ; the projected instances  $Y$  in the low-dimensional singular subspace are private as well. Meanwhile,  $Y$  does not need to be distributed to users. Step (6) and Step (7) compute the classification model based on private projection instances and distribute it together with private singular vector to predict the new instances. The last three steps do not violate the privacy requirement of DP. Therefore, the DPSVD satisfies  $(\epsilon, \delta)$ -differential privacy.

**4.3. Algorithm Comparison.** The three algorithms were compared theoretically between DPSVD, AG [9], and DPPCA-SVM [26] summarized in Table 2. Other ones have been compared by the DPPCA-SVM algorithm. Our algorithm uses SVD to perform PCA; it does not need to

compute matrix of covariance and symmetrize the noise matrix as the description above. It obtains the same noise scale as AG algorithm, because they use identical mechanism of DP to generate the noise matrix.

Therefore, the classification model and the singular vectors for projection are both private; they can be used to predict the new instances in the same singular subspace. The main advantage of the DPSVD compared with other private SVMs is that our algorithm trains the classification model in the private low-dimensional singular subspace generated by SVD. In this way, the features of the instances in the singular subspace become linearly independent and low-dimensional and therefore have higher time and space efficiency for training the classification model. The difference between our algorithm with other private PCA algorithms is that it does not need to calculate the matrix of covariance or symmetrize the noise matrix. Meanwhile, the DPSVD protects privacy of the training instances before training the classification model; many optimization methods of SVMs can be applied directly to the training progress.

## 5. Results

describes their basic information, including the number of the instances, the number of the features, and the ranges of values in the data. They are accessible at <https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/> and <http://archive.ics.uci.edu/ml/datasets.php>. It trains the SVM to compare the performance of algorithms based on LIBSVM (version

3.25) [36] with the radial basis function as the kernel function and default parameters.

5.2. Algorithm Performance Experiments. The performance of the DPSVD was compared with AG, DPPCA-SVM, and the nonprivate SVM on the four real datasets. In the

FIGURE 4: Accuracy at various  $\epsilon$  on dataset Splice.

FIGURE 5: SV at various  $\epsilon$  on dataset A1a.

experiments, it designed two metrics of algorithm performance *Accuracy* and *SV*. *Accuracy* denotes how accurate the classification is, and *SV* denotes how many SVs are contained in the classifier. The higher the *Accuracy*, the greater the usability of the classifier. The closer *SV* to that of nonprivate SVM, the better the stability of the algorithm. The privacy budget  $\epsilon$  was set at 0.1, 0.5, and 1,  $\delta$  at  $1/n^2$ , and the accumulative contribution rate of principal components

$\gamma$  at 90%. Three private algorithms were implemented five times under every privacy budget parameter. The mean values, standard deviation, and maximum and minimum values of the two metrics are given in Table 4.

From the experiments results in Table 4, the DPSVD was the most accurate in classification than the other two private classifiers under different privacy budget for most of the datasets. Sometimes, our algorithm even outperformed the

FIGURE 6: SV at various  $\epsilon$  on dataset Mushrooms.

FIGURE 8: SV at various  $\epsilon$  on dataset Splice.

FIGURE 7: SV at various  $\epsilon$  on dataset Musk.

nonprivate SVM. This is mainly because our algorithm removes the linear dependence between features and unimportant features by SVD. Meanwhile, our algorithm has the better stability of the algorithm as its SV is much closer to the nonprivate SVM. To compare algorithm performance more intuitively, the mean values of the two metrics for the four algorithms are shown in Figures 1–8.

In Figure 1 to Figure 3, the DPSVD achieved the highest classification accuracy in the three private algorithms and closer to the nonprivate SVM than the other two algorithms. In Figure 4, the AG achieved the higher classification accuracy than the DPSVD as the privacy budget increases. In Figure 5 to Figure 8, the DPSVD contained the closer

number of SVs in the classifier to the nonprivate SVM than the other two algorithms. Therefore, the PDSVD achieved higher classification accuracy and better algorithm stability on most of the datasets and approximated the performance of the nonprivate SVM. The AG algorithm on dataset Musk in Figure 3 and the DPPCA-SVM algorithm on dataset Splice in Figure 4 have relatively lower classification accuracy. It also shows that the DPSVD has better algorithm stability.

## 6. Conclusions

To solve the privacy leak of SVM classifiers, especially on high-dimensional data, the DPSVD algorithm was proposed to project the training instances into the low-dimensional singular subspace and train a private SVM classifier on it while not violating the privacy requirements for the training data. The DPSVD is proved to satisfy DP. The main advantages of the DPSVD include three aspects. Firstly, it trains the classification model in the private low-dimensional singular subspace; therefore it has higher time and space efficiency compared with other private SVMs. Secondly, it does not need to calculate the matrix of covariance or symmetrize the noise matrix and has higher classification accuracy and better stability of the algorithm than other existing private PCA algorithms through the comparison experiments. Thirdly, it protects privacy of the training instances before training the classification model, and many optimization methods of SVMs can be applied directly to the training progress. Meanwhile, its algorithmic ideas can be applied to other machine learning areas to solve data privacy problems. However, the DPSVD can only solve the linear dependence between the data features. In future work, we will consider the nonlinear dependence to train a private classification model. In addition, the problem of data instances compression through SVD is another research direction.

## Data Availability

The raw data of the four datasets are available at <https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/> and <http://archive.ics.uci.edu/ml/datasets.php>.

## Conflicts of Interest

The authors declare that they have no conflicts of interest.

Aiming at the characteristics of timely transmission, rapid update, and large magnitude of microgrid data, based on the large data samples generated by microgrid operation, a fault diagnosis and analysis method of microgrid systems supported by big data is proposed in this paper. The multisource joint feature vectors of microgrid are extracted using Wavelet transform, Rayleigh entropy, and big data technology, which combine short-circuit current and voltage. The extracted feature dataset is clustered and segmented to realize deep data mining. Combining BP neural network and big data, the fault diagnosis of microgrid is realized. The simulation results show that the BP neural network algorithm based on big data support can accurately identify the type and phase of internal faults in microgrid, which is more suitable for extracting the temporal characteristics of information and spatiotemporal correlation of data to realize the prediction of big data and solve the core problems in the analysis of big data of microgrid faults, and the accuracy is as high as 96.8%.

## 1. Introduction

Big data refers to the dataset that cannot be captured, managed, and processed by conventional software tools within a certain period of time. It is a massive and diversified information asset of high growth rate that needs a new processing mode to have stronger decision-making power, insight, and process optimization ability. “Volume, Variety, Value, Velocity, and Veracity” are the “5V” characteristics of big data. Relevant research and surveys have pointed out that the global annual data growth rate is basically twice or even higher than that of the previous year. In the next 10 years, nonstructural data will account for about 90% and the data patterns will be different. It will become impossible to analyze based on previous experience. Therefore, it is necessary to study relevant data mining technologies and understand and master the basic “5V” characteristics of big data, which is particularly important for data analysis based on big data. BP neural

network can be applied to the prediction of models and the study of the relationship between different models. Therefore, the combination of big data technology and BP neural network can deal with large and complex nonlinear structural problems from a statistical point of view, with high stability and accuracy. Big data fault analysis refers to collecting a large amount of data through real-time analysis and mining of microgrid fault information to master the microgrid operation characteristics, accurately predict the microgrid topology behavior, and improve the capabilities of service and risk control. The key to big data is to be able to quickly obtain useful information from a large amount of data or quickly realize big data assets. Therefore, the information processing of big data is often based on cloud computing. Cloud computing is the product of a new era. Taking cloud computing as the development strategy, big data is applied to cloud computing to obtain a series of data that can be used for fault analysis, so as to form a big data fault diagnosis model.

The reasonable development and utilization of green and clean energy have become an important topic with increasingly prominent energy crisis, environmental pollution, and slow recovery caused by large power grids. Microgrid has been widely used because of its flexible installation locations, less pollution, and high energy efficiency. Its technical problems have also attracted the extensive attention of researchers at home and abroad. One of the important research fields is fault diagnosis technology, which guarantees safe and reliable operation. The common fault types of internal lines in the microgrid are single-phase grounding short circuit, two-phase short circuit, three-phase short circuit, etc. Conventional fault diagnosis methods cannot be directly applied to microgrid and work well due to the difference between current and voltage and bidirectional power flow. It is an urgent problem to find new fault diagnosis and identification methods for microgrid because of the changing characteristics of fault voltage and current.

A lot of research has been carried out and been applied in practice to the fault diagnosis technology of microgrid. The research mainly focuses on the following two aspects: Firstly, fault diagnosis is carried out according to the changes of circuit breakers, the flexible topology, protection elements, and other equipment status in the microgrid. For example, the voltage and bus current signals of the low-voltage circuit breaker are used for fault diagnosis. Using SOM neural network and multiagent systems, the simulation results show that good diagnosis results can be achieved for a single fault, but the situation of multiple faults in the same period needs further study [1, 2]. In [3], a Petri net analysis model using line fault protection information is established. The corresponding protection set information needs to be updated while the topology changes without remodeling, which can adapt to the variability of the microgrid topology structure. However, the identification accuracy of fault diagnosis will be affected when the protection device and circuit breaker have such factors as refusing to operate or misoperation.

Secondly, the abnormal change of voltage or current is used to diagnose the fault in the microgrid. The transient recovery performances of microgrid under different control modes are compared and analyzed by studying the change of current amplitude and the transient duration of overvoltage when a short-circuit fault occurs in the microgrid [4, 5]. According to the impedance and impedance angle, the symmetrical component method was used to analyze the voltage and current in the microgrid during a fault. However, it is difficult to accurately extract the fault component when the system is unstable, is oscillating, has interference, or has continuous fault. At the same time, its effect is a lack of experimental verification while only theoretical and methodological research is carried out.

The fault voltage and current signal are used to realize fault diagnosis and identification in a combined wavelet packet with a neural network, but the fault phase cannot be accurate to the line [6, 7]. The voltage signal of the optical storage microgrid line is analyzed to realize the safe and reliable operation of the optical storage microgrid based on genetic algorithm [8]. Another fault

detection scheme based on deep neural networks and wavelet transform for microgrid was proposed in [9]. The authors in [10] employed an approach focusing on identifying and evaluating the faulted line section by implementing data mining and wavelet packet transform. At present, the scale of microgrid data has increased exponentially, and the traditional data processing methods cannot afford to process large-scale data. At the same time, the big data of the microgrid system runs through all nodes of smart grid, which is far beyond the scope of traditional power system monitoring. The current data processing platform is difficult to meet the requirements of smart grid for the processing of power system data. In particular, it is difficult to achieve real-time data, which results in the loss and repetition of power grid data. In the era of big data, how to process microgrid data to analyze and diagnose the working conditions of power equipment is an urgent task for the development of intelligent microgrids. In order to solve the problems of incomplete fault information, single information structure, and imperfect diagnosis results in the existing microgrid fault diagnosis methods, this paper extracts and reconstructs the features of multisource data using BP neural network based on big data technology, obtains the spatiotemporal correlation characteristics between different data, and then realizes fault prediction and diagnosis better.

The main contributions of this paper are as follows: First, most of the existing research literature is about the relationship between the amplitude of voltage, current, and fault, but less about the relationship between the time-frequency characteristics of voltage and current and the impact of time-frequency characteristics on fault. In fact, the time-frequency characteristics of voltage and current on the fault will have a greater impact. Secondly, this paper not only analyzes the relationship between voltage and current but also studies the regulatory role of voltage, current, and fault. Third, this paper combines BP neural network and big data to predict the spatiotemporal correlation of data in order to realize fault diagnosis using big data analysis. Considering that the voltage and current of three-phase lines contain rich transient sudden change signals when the internal lines of the microgrid fail, which can effectively reflect the fault characteristics, this paper obtained the high-frequency and low-frequency details of the signal using wavelet analysis, Rayleigh entropy, and other theoretical methods to extract the characteristic vectors of three-phase line fault voltage and current from massive microgrid data. Based on the analysis of fault information, the BP neural network is applied to fault diagnosis and identification. Trained with historical data as samples, the BP neural network model supported by big data is constructed to realize the accurate diagnosis of fault type and phase.

The rest of this paper is arranged as follows: Section 2 describes fault characteristics; Section 3 gives wavelet packet decomposition and energy entropy; Section 4 provides construction of the BP neural network fault diagnosis model; Section 5 describes fault diagnosis algorithm and process;

Section 6 gives simulation analysis and experimental verification; Section 7 concludes the study.

## 2. Fault Characteristics Analysis

**2.1. Microgrid Prototype.** A microgrid prototype is shown in Figure 1. The bus voltage is 220 V and connected to the distribution network through the PCC of the common connection point. DG1 is a photovoltaic power generation unit with a capacity of 60 kVA. DG2 is a wind power source with a capacity of 20 kVA. There are three power transmission lines in the microgrid: WL1 is 1 km long with 8 kW load; WL2 is 5 km with 50 kW load; and WL3 is 2 km long with 15 kW load. The fault resistance and grounding resistance are both set as 0.001  $\Omega$  when single-phase faults happen, while the grounding resistance is set as 10 m $\Omega$  when two-phase or three-phase short circuits occur.

The three-phase output voltage and current are symmetrical when the microgrid operates normally. The current waveform is shown in Figure 2. The three-phase output current is equal, and the phase difference is 120°.

**2.2. Fault Analysis.** The Matlab simulation platform is used to analyze the variation of line voltage and current under different fault types and fault positions. In this paper, Matlab/Simulink 2018b software is mainly used in the process of modeling and simulation. Simulink is mainly responsible for the construction of the whole system and offline simulation verification. At the same time, it can be combined with StarSim HIL and StarSim RCP software of Yuankuan; then, the hardware in the loop test is realized. The simulation analysis is carried out at 10%, 50%, 70%, and 85% of the microgrid side, respectively, while single-phase ground fault, phase-to-phase short circuit, two-phase ground fault, or three-phase short-circuit fault happens. The simulation time is set as 0.5 s, and the fault will be removed in 0.4 s after the fault occurs in 0.1 s. When the fault occurs, the voltage and current at the fault point are shown in Figure 3.

Figure 3 shows that the voltage at the fault point decreases significantly after the short circuit, the amplitude of fault current increases, and there are certain components of harmonic and aperiodic components. It is very likely to cause microgrid instability and protection misoperation even after the fault is removed. The fault diagnosis method based on the single signal has certain limitations, so it is necessary to consider the voltage and current signals to build a new feature vector for fault diagnosis.

The fault data information during microgrid operation includes steady-state data, parameter data, alarm events, etc. The circuit information includes frequency, voltage, current, harmonic voltage, harmonic current, voltage imbalance, current imbalance, flicker, power and power factor in the circuit, power grid clutter interference, vibration, temperature and humidity, harmonic interference, abnormal events, and other indicators. Through the analysis and

processing of these data, accurate fault characteristics can be extracted to realize fault identification and diagnosis.

## 3. Wavelet Packet Decomposition and Energy Entropy

**3.1. Wavelet Packet Decomposition.** The wavelet packet selects the optimal basis to decompose the original signal in the frequency domain, which improves the ability of signal analysis, avoids the defect of fixed time frequency of wavelet decomposition, and accurately reflects the nature and characteristics of the signal. It has good time-domain and frequency-domain positioning characteristics and excellent signal adaptability.

Let  $\phi(x)$  be an orthogonal scaling function and  $\psi(x)$  be a wavelet function; then, the two-scale function equation is as follows:

$$\begin{aligned}\phi(x) &= \sqrt{2} \sum_k h_k \phi(2x - k), \\ \psi(x) &= \sqrt{2} \sum_k g_k \phi(2x - k),\end{aligned}\quad (1)$$

where  $h_k$  is the scale coefficient and  $g_k$  is the wavelet coefficient.

Defining a basis function  $u_0(x) = \phi(x)$  and  $u_1(x) = \psi(x)$ , then the two-scale equation is generalized as follows:

$$\begin{cases} u_{2n}(t) = \sqrt{2} \sum_{k \in \mathbb{Z}} h_k u_n(2t - k), \\ u_{2n+1}(t) = \sqrt{2} \sum_{k \in \mathbb{Z}} g_k u_n(2t - k), \end{cases}\quad (2)$$

where the constructed sequence  $\{u_n(x)\}$  is the wavelet packet of basis function  $u_0(x) = \phi(x)$ .

The parameter  $j$  is the scale index,  $k$  is the position index, and  $n$  is the oscillation number; then,

$$\begin{cases} d_k^{j,2n} = \sum_{i \in \mathbb{Z}} h_{k-2i} d_i^{j+1,n}, \\ d_k^{j,2n+1} = \sum_{i \in \mathbb{Z}} g_{k-2i} d_i^{j+1,n}. \end{cases}\quad (3)$$

The wavelet packet reconstruction algorithm is as follows:

$$d_k^{j+1,n} = \sum_{i \in \mathbb{Z}} (h_{k-2i} d_i^{j,2n} + g_{k-2i} d_i^{j,2n+1}).\quad (4)$$

Taking 3-level wavelet packet decomposition as an example, the process of wavelet packet decomposition and reconstruction is shown in Figure 4. Node  $(i, j)$  represents the  $j$ th node in layer  $i$  ( $i = 0, 1, 2, 3; j = 0, 1, 2, \dots, 7$ ), and each node represents a signal with certain characteristics. For example, the node  $(0, 0)$  represents the original signal  $S$ , node  $(1, 0)$  represents the low-frequency coefficient of the first layer of wavelet packet decomposition, and node  $(1, 1)$  represents the high-frequency coefficient of the first layer.

The relationship between the original signal  $S$  and its decomposition coefficient is as follows:

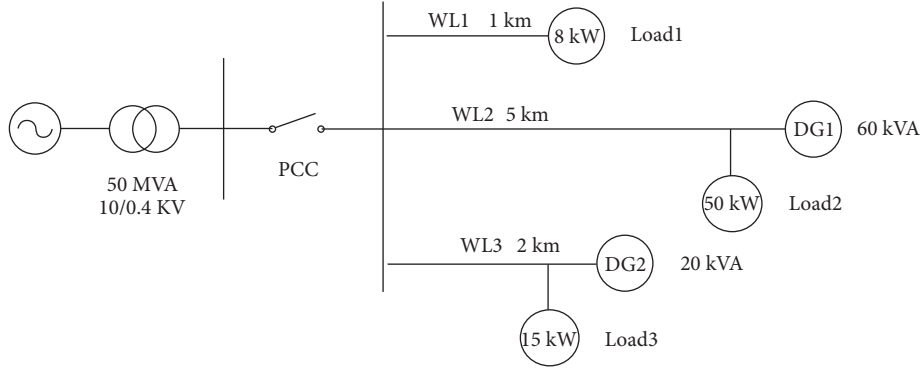

FIGURE 1: System structure.

$$S = S(3, 0) + S(3, 1) + \dots + S(3, 7). \quad (5)$$

**3.2. Feature Entropy Extraction and Multisource Joint Eigenvector Construction.** Entropy can measure the degree of information uncertainty in information theory, such as information entropy and relative entropy [11, 12]. The Shannon entropy extracted from the wavelet packet decomposition and reconstruction can reflect the high-frequency and low-frequency characteristics of the signal more accurately and has stronger anti-interference performance [6]. The time complexity of the frequency component of the signal transient can be accurately expressed by the singular entropy of the Rayleigh wavelet packet, which is more conducive to the identification and diagnosis of fault signals.

Let the random signal  $X = \{x_0, x_1, \dots, x_{N-1}, x_N\}$ ; the probability of occurrence of  $x_i$  is

$$p_i = p(x_i), \quad i = 0, 1, 2, \dots, n-1, \quad (6)$$

$$\sum_{i=0}^N p_i = 1.$$

Then, the Rayleigh entropy of  $X$  is

$$H_q(X) = \frac{1}{1-q} \ln \sum_{i=1}^N p_i^q. \quad (7)$$

The expression of energy entropy fused with wavelet packet decomposition is

$$E_{i,j} = \frac{1}{1-q} \ln \sum_j p_{i,j}^q. \quad (8)$$

The vector  $T$  is composed of the energy entropy of each frequency band:

$$T = [E_{i,0}, E_{i,1}, E_{i,2}, \dots, E_{i,2^n-1}]. \quad (9)$$

To facilitate signal analysis, the vector  $T$  can be normalized and represented by  $T'$  when the energy entropy of each frequency band is relatively large.

FIGURE 2: Three-phase output current waveform in normal operation.

$$E = \sum_{j=0}^{2^n-1} E_{i,j}, \quad (10)$$

$$T' = \frac{T}{E} = \left[ \frac{E_{i,0}}{E}, \frac{E_{i,1}}{E}, \frac{E_{i,2}}{E}, \dots, \frac{E_{i,2^n-1}}{E} \right].$$

After feature entropy extraction, the voltage and current signals are fused by the interval crossing method to form a new multisource fault feature vector for fault diagnosis. The final signal eigenvector is obtained.

#### 4. Construction of the BP Neural Network Fault Diagnosis Model

In 1986, the BP neural network was proposed by Rumelhart and McClelland, which has become one of the most popular neural network models because of its strong functions of self-learning and adaptability. The BP network can solve the fault diagnosis problem of some complex systems and provide theoretical research and technical implementation methods for more intelligent diagnosis methods.

With the support of big data technology, the development of the BP neural network gradually tends to mature.

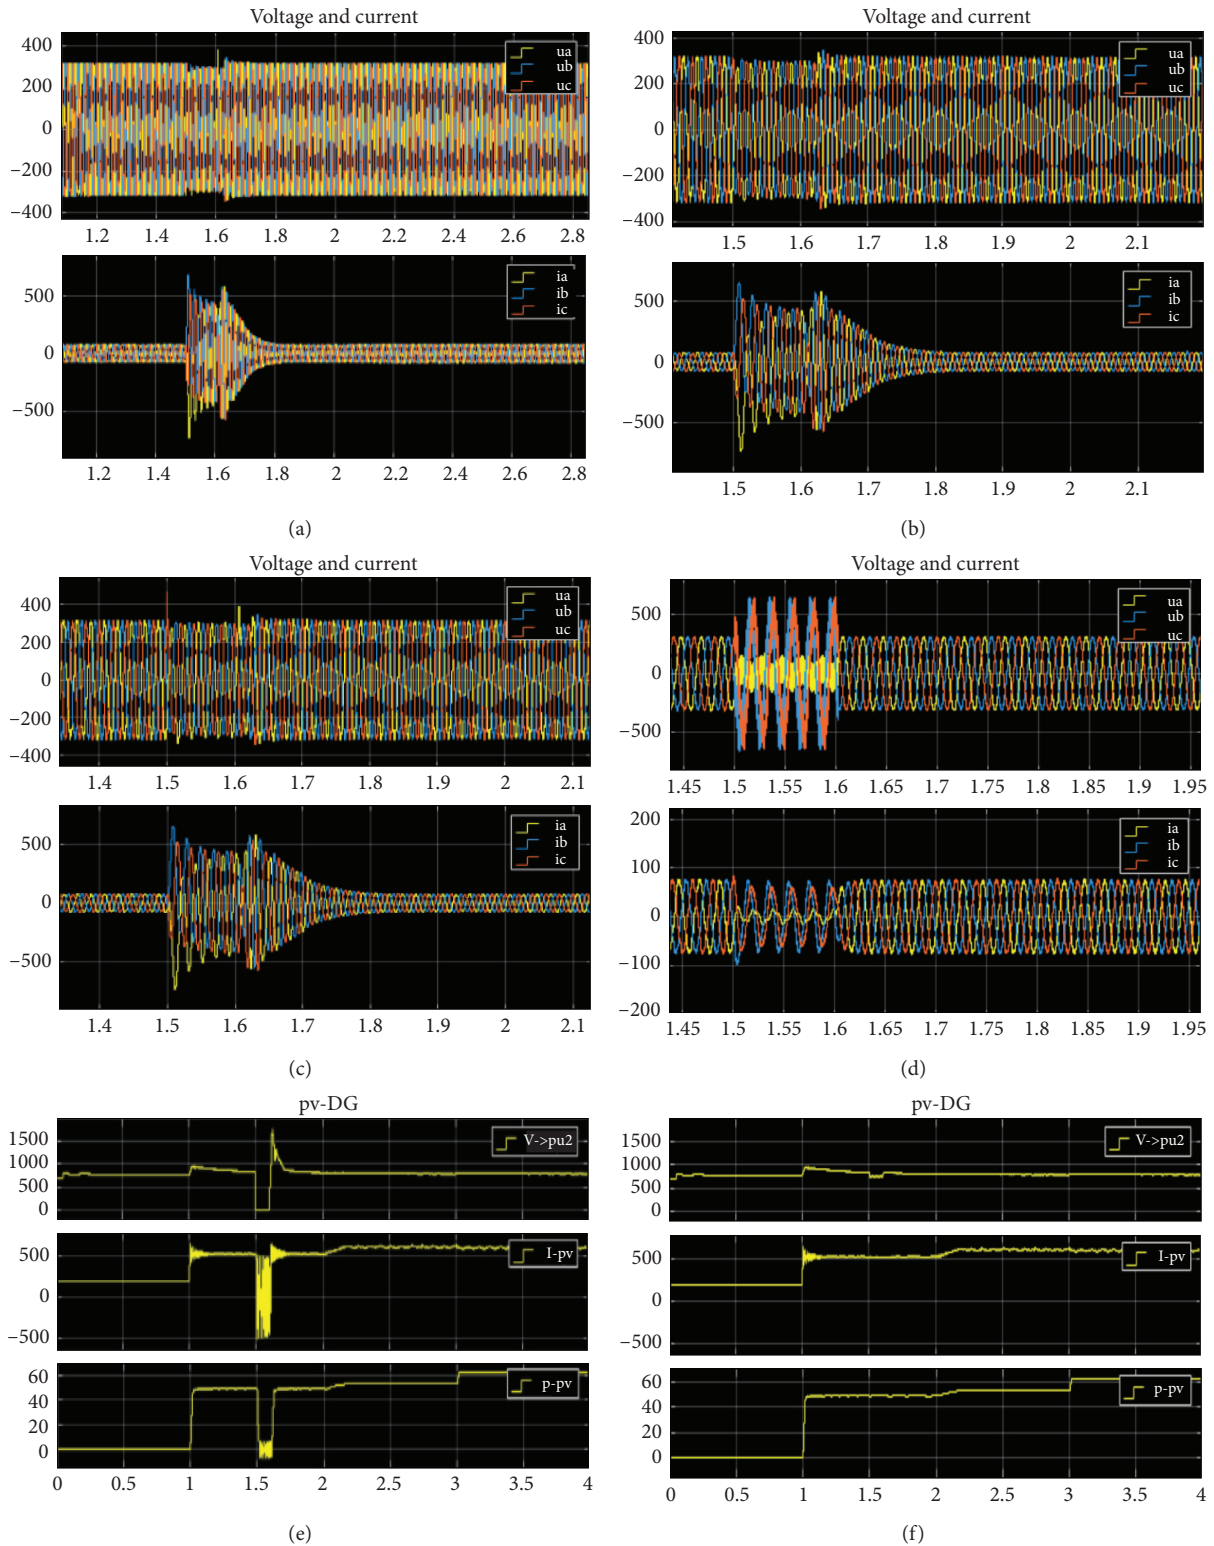

FIGURE 3: Partial fault voltage and current curves: (a) three-phase short circuit (1.5 s–1.6 s); (b) two-phase short circuit (1.5 s–1.6 s); (c) two-phase ground fault (1.5 s–1.6 s); (d) single-phase ground (1.5 s–1.6 s); (e) PV parameters of three-phase fault; (f) PV parameters of single-phase fault.

When analyzing and diagnosing power grid faults, it can convert relay protection information into model input and take the possible faults of microgrid as an output. On this

basis, it completes the selection of the sample set. Then, it cleans and segments the sample, compares the difference between the actual output and the expected output, realizes

FIGURE 4: 3-level wavelet packet decomposition structure.

the layer-by-layer adjustment of the weight and threshold, and stops after repeated times, and the difference is consistent with the standard. The BP neural network is mainly composed of an input layer, a hidden layer, and an output layer. The topological structure of a typical three-layer BP neural network is shown in Figure 5.

Regulation:  $J$  is the number of nodes in the input layer, the node serial number is  $j$ , input vector  $\dot{X} = [x_1, x_2 \dots x_j \dots x_J]$ ,  $j = 1, 2 \dots J$ ,  $K$  is the number of nodes in the output layer, node serial number is  $k$ ,  $\dot{O} = [o_1, o_2 \dots o_k \dots o_K]$  is the output vector,  $k = 1, 2 \dots K$ ,  $L$  is the number of nodes in the hidden layer, the node serial number is  $l$ ,  $W_{jl}$  represents the connection weight between the  $j$ th neuron in the input layer and the  $l$  neuron in the hidden layer,  $T_{lk}$  represents the connection weight between the  $l$ th neuron in the hidden layer and the  $k$ th output neuron in the output layer, and the input of the  $l$ th node in the hidden layer is  $I_l$ . The output is  $y_l$ . The activation function is  $f(\cdot)$ . Then, the input and output of the  $l$ th neuron are expressed as

$$I_l = \sum_{j=1}^J W_{jl} x_j, \quad (11)$$

$$y_l = f(I_l).$$

Given  $N$  samples  $(\dot{X}_n, \dot{d}_n)$  ( $n = 1, 2, \dots, N$ ), the expected output vector of the input vector  $\dot{X}_n$  is  $\dot{d}_n$ . The objective function is defined as the sum of error squares between the expected output and the actual output during backpropagation.

$$E_n = \frac{1}{2} \sum_{k=1}^K [d_n(k) - O_n(k)]^2. \quad (12)$$

The total error of  $N$  samples is defined as

$$E = \frac{1}{2N} \sum_{n=1}^N \sum_{k=1}^K [d_n(k) - O_n(k)]^2. \quad (13)$$

FIGURE 5: Topological structure of the BP neural network.

By adjusting the connection weight and threshold, the total error  $E$  is minimized and the weight changes along the negative gradient direction of the error function.

$$W_{jl}(t+1) = W_{jl}(t) - \eta \frac{\partial E}{\partial W_{jl}}, \quad (14)$$

where  $t$  is the number of iterations and  $\eta$  is the step size.

## 5. Fault Diagnosis Algorithm and Process

Based on the algorithm of the first two sections, a new method of short-circuit fault diagnosis for microgrid is proposed in this paper. The fault feature is extracted by wavelet packet decomposition, and the energy entropy is calculated. The multisource joint eigenvector is composed of voltage and current characteristic entropy, which is used as the BP network input and realizes fault diagnosis. Firstly, the time-frequency analysis of the three-phase current and voltage signals is carried out by wavelet packet decomposition. Then, the Shannon energy entropy is calculated as the signal feature vector, and the multisource joint eigenvector is composed of cross fusion and used as the input of the BP neural network for training and learning. The fault type and phase of microgrid can be accurately identified and diagnosed. The algorithm flow is shown in Figure 6.

500 groups of line fault sample data are randomly selected. Firstly, wavelet packet decomposition is used to analyze the signal time frequency, and then, Shannon energy entropy is used to extract the signal feature vector as the input signal of the BP neural network. The sample size for neural network training and learning is 80%. Another group of 10% data is used for verification, and the third group of 10% data is used for testing.

Using the BP neural network algorithm model, the multilayer feedforward network is trained according to the error backpropagation algorithm of microgrid fault output data, and then, through a large amount of sample learning, the input-output mode mapping relationship of the fault is stored, which can realize real-time and online mapping of fault information, making the complex nonlinear relationship in the output data samples become obvious. The accuracy of fault diagnosis is greatly improved, and the data error rate is reduced.

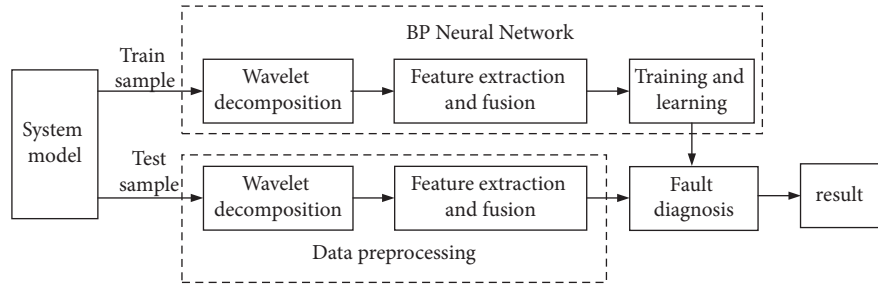

FIGURE 6: The flow chart of microgrid fault diagnosis.

## 6. Simulation Analysis and Experimental Verification

**6.1. Wavelet Packet Decomposition of Fault Current in Microgrid.** According to the experimental analysis and comparison, the frequency band distribution of 2-level wavelet packet decomposition is too wide and the resolution is low, while those of the 4-level wavelet packet decomposition and 3-level wavelet packet decomposition are the same, but the amount of calculation is significantly increased. Therefore, this paper chooses 3-level wavelet packet decomposition for the signal.

As an example, the step of extracting the wavelet packet energy entropy of the A-phase current signal is illustrated by the A-phase single-phase grounding short-circuit current of line WL3 away from the microgrid side. The waveform diagram of the single-phase grounding short-circuit current is shown in Figure 7.

Comparing Figures 7 and 5, it can be found that when the system is short-circuited, the current changes suddenly and has transient fault information. The db6 wavelet base is selected to further extract the effective fault information. The A-phase current signal is decomposed by 3-level wavelet multiresolution using formula (2), which can obtain the wavelet packet decomposition coefficient and wavelet reconstruction signal. The current decomposition signal is shown in Figure 8.

It can be seen from the detailed diagram that the first impulse current wave is received at 800 sampling points and the second impulse current wave is received at 3500 sampling points. Considering the period, it can be used as the basis for the fault location of microgrid.

The wavelet packet reconstruction of the short-circuit current and voltage wavelet signal shows that the fault signal contains rich nonstationary fault signal components, so the wavelet packet reconstruction signal will immediately have obvious fluctuations at the time of fault, which can be used as an important criterion to judge whether the fault occurs in the internal lines of the microgrid and to calculate the wavelet energy entropy value. The fault types and fault phases of the internal lines of the microgrid can be well prepared using the BP neural network.

**6.2. Extraction and Construction of Multisource Joint Eigenvector.** The energy entropy of 8 wavelet reconstruction signals of A-phase short-circuit current is calculated using

FIGURE 7: Short-circuit current of a single-phase earth fault.

Shannon entropy formula (8), and then, an eigenvector  $E$  is formed as follows:

$$E = [E_{30}, E_{31}, E_{32}, E_{33}, E_{34}, E_{35}, E_{36}, E_{37}]^T, \quad (15)$$

where  $E_{30}, E_{31}, E_{32}, E_{33}, E_{34}, E_{35}, E_{36}, E_{37}$  is the entropy of wavelet reconstruction signals. Because the wavelet packet Shannon entropy can detect small abnormal changes in the signal, when the signal-to-noise ratio is low, it can extract the effective weak signal and eliminate the noise very well. The smaller the entropy value is, the more orderly the signal is, and vice versa. It has little influence on the accuracy of judgment with the amount of calculation being multiplied in the process of fault diagnosis and recognition using BP neural network; at the same time, the high-frequency signal component is more than one order of magnitude smaller than the low-frequency signal component, so  $E_{30}, E_{31}, E_{32}, E_{33}$  can be taken as the input of BP neural network.

$$E = [E_{30}, E_{31}, E_{32}, E_{33}]^T. \quad (16)$$

In the same way, the other two-phase current and voltage signals are processed and 16-dimensional wavelet energy entropies are obtained. The multisource fault information is fused by the interval cross mode to form the feature vector for fault diagnosis. The fusion mode is shown in Figure 9.

Some multisource feature eigenvectors are shown in Table 1.

Compared with the normal state energy entropy, some results are shown in Figure 10.

The energy entropy  $E_{31}, E_{32}, E_{33}$  of phase A is surely increased when A phase shows ground fault but B and C phases almost remain unchanged; the energy entropy  $E_{31}, E_{32}, E_{33}$  of two phases A and B are significantly increased when two-phase short circuit or two-phase grounding short

circuit occurs; the energy entropy  $E_{31}$ ,  $E_{32}$ ,  $E_{33}$  of three phases are all improved when A, B, and C three-phase short-circuit occurs. This can be used as a basis for fault type identification and fault phase judgment in microgrid.

**6.3. Training Results of BP Neural Network.** Three-phase current and voltage eigenvalues constitute a multisource fault eigenvector which is taken as the input vector of the BP neural network. The fault signal of microgrid is decomposed and reconstructed with a wavelet, and the number of input neuron nodes is set as 16. The state of the three phases and the neutral line are taken as output vectors, so the number of output neuron nodes of the neural network is set as 4. The output value of 1 indicates that the corresponding line is at fault or the fault phase is grounded, and 0 indicates that the corresponding line has no fault. The number of hidden layer neurons affects the training results of the model. The training accuracy is poor if too few nodes are selected; the training time and step size are relatively large when there are too many nodes, and it is easy to fit. This is verified by experiments, and combined with the empirical formula  $L = \sqrt{J + K} + \alpha$ , this paper chooses 10 hidden layer nodes. The BP network stops the model training and learning when the training error meets the given requirements. The training curve is shown in Figure 11.

The fitting degree curve of neural network training is shown in Figure 12. Through observation, the fitting degree of neural network is high, the fitting degree of training and testing is more than 0.9, and the fitting degree of verification is also 0.88. Thus, BP neural network can accurately diagnose and identify faults.

**6.4. Hardware in the Loop Simulation Test.** Because the actual microgrid systems are built outdoors, where the natural conditions are bad and the system structure is complex,

FIGURE 11: Training curve.

including a large number of power electronic device load units, the voltage level is high and dangerous. However, the construction of a traditional electrical laboratory has high construction costs and site requirements. It is difficult to simulate and research some special conditions such as faults considering safety and equipment maintenance. Therefore, the hardware in the loop simulation technology is applied to the experimental environment based on the existing equipment and conditions of the laboratory. The hardware in the loop simulation platform is composed of PXI hardware and StarSim HIL and StarSim RCP software developed by Yuanquan energy to realize microgrid fault identification and diagnosis. The hardware in the loop platform is shown in Figure 13, the system framework is shown in Figure 14, and the microgrid interface is shown in Figure 15.

**6.5. Fault Diagnosis and Identification.** The multisource feature vectors of microgrid test samples are brought into the trained BP neural network to diagnose and identify the fault

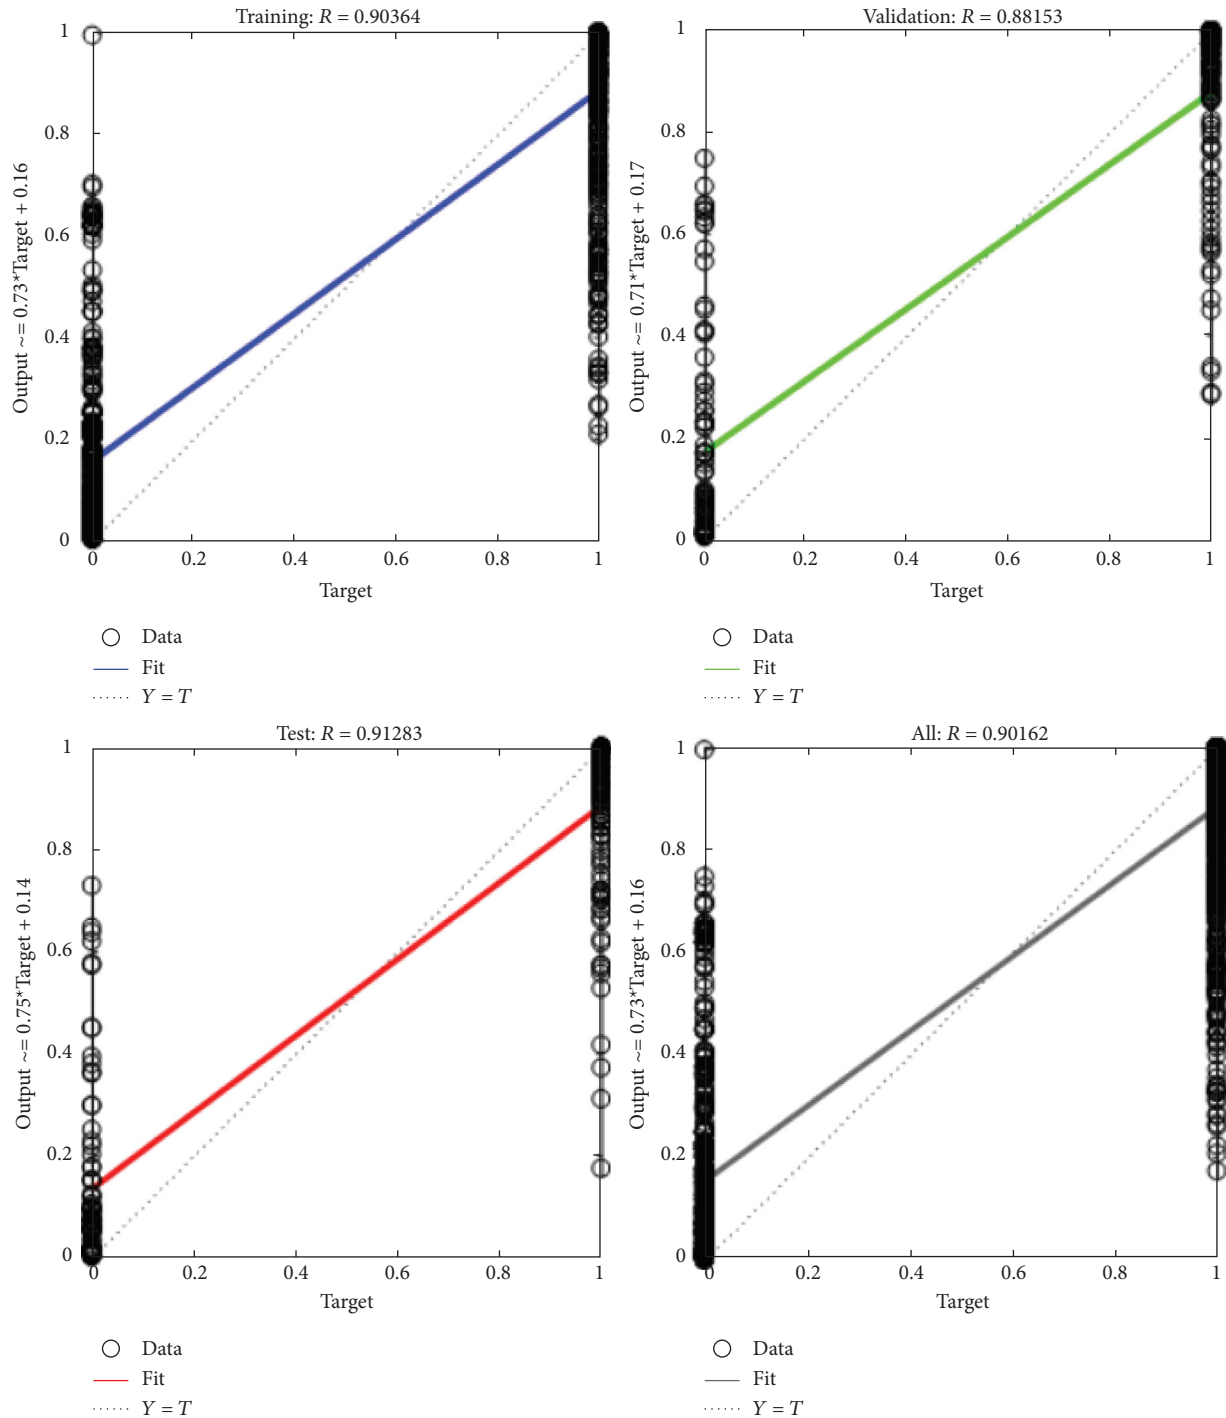

FIGURE 12: Fitting curve.

type and phase. The actual output signal of the test sample is compared with the expected output signal. Some test samples and their fault diagnosis results are shown in Table 2.

The BP neural network method based on big data analysis extracts and abstracts the features of fault data and strengthens the spatiotemporal correlation of heterogeneous data to realize the prediction of fault type and phase. At the same time, the BP neural network method based on big data obtains accurate data information by constructing many

invisible models and performing a large amount of data analysis and training. It can be seen from Table 2 that the trained BP neural network model can accurately and effectively identify the fault type and fault phase and the error between the actual output and the expected output value meets the requirements of fault diagnosis. The test results show that two samples have fault diagnosis among 50 samples; the accuracy rate reaches 96%, which meets the requirements for intelligent fault diagnosis of microgrid lines.

## 7. Conclusions

Aiming at the characteristics of real-time transmission, fast updating, and large-scale fault information data of microgrid, a microgrid fault diagnosis and analysis technology supported by big data is proposed in this paper. This technology combines Rayleigh entropy, wavelet packet decomposition method, and BP neural network to extract the fault feature vector of microgrid. The BP neural network method based on big data strengthens the spatiotemporal correlation of heterogeneous data to realize the prediction of fault type and phase. The BP neural network method based on big data obtains accurate results by constructing many invisible models and a large amount of data training. The experimental results show that the fault diagnosis and analysis technology based on big data support proposed in this paper has an accuracy of 96%, which fully meets the needs of engineering practical application. However, due to the complex topology and many fault types of microgrid, only five line fault types are considered in this paper. Therefore, in the next step, the technical method proposed in this paper needs to be applied to other fault diagnosis to verify the universality of the technical method proposed in this paper.

Cloud manufacturing is a new service-oriented efficient and low-consumption agile manufacturing mode integrating information, manufacturing, Internet of Things, and other technologies. One of the key decisions of production enterprises is production task allocation based on cloud robot cell-line, which determines the efficiency and flexibility of the production system and affects various production links, such as job-shop logistics, production planning, and production scheduling. This paper explores the production task allocation, from the angle of the optimal combination of cloud manufacturing resources. First, a mathematical model was established, based on the transport cost of different sub-tasks and the tardiness cost of product delivery, and solved by quantum firefly algorithm (QFA). Next, QFA was proved superior to traditional firefly algorithm (FA), improved FA, and the FA optimized by cat swarm optimization (CSO-FA), in terms of time complexity and spatial complexity. The research enriches the theory and methodology of allocating operation-level cloud manufacturing resources based on cloud robot cell-line and provides decision support to manufacturers, which want to implement operation-level allocation of cloud manufacturing resources based on cloud robot cell-line.

## 1. Introduction

Big manufacturers like China are improving the intelligence level of the manufacturing industry. Cloud intelligence can increase the utilization efficiency of production lines, lower the production cost, and avoid repeated investment and construction, contributing to the improvement of our living standards.

Unlike traditional flow lines, the cell-line combines a few similar stations into a novel type of production line. There are two advantages of the cell-line: First, it is of the same production efficiency as a conveyor belt flow line. Second, the flexible production of production units adapts well to the market needs of various small batches of products. Therefore, the cell-line is regarded as an ideal production mode to realize massive customization. Besides, the cell-line provides a green and economic production method.

Scholars at home and abroad have explored robotic automation production lines extensively. Focusing on the variable process pathway, Tian et al. [1] established a minimum delay time function and constructed a scheduling module, in the light of collaborative, differentiated agents. In addition, agents were adopted to realize global optimization, aiming to minimize the makespan. Zacharia and Nearchou [2] summarized the features of job-shop scheduling with multiple robotic manufacturing units, created a mathematical model for minimizing the makespan of the problem, and solved the model effectively with a hybrid genetic algorithm. Liu et al. [3] utilized the minimum completion time to solve the flexible job-shop scheduling with loading/unloading robots, established a mathematical model of the problem, and searched for the scheduling results with a tabu search and greedy algorithm. Miyake [4] used the minimum production cycle to solve the multi-process job-shop scheduling with transport time, constructed a nonlinear

mathematical model, and solved the model with improved genetic algorithm, realizing batch scheduling. Du et al. [5] explored the reconstruction and scheduling of multi-stage variable-batch production lines in labor-intensive enterprises, adopted different algorithms for production lines of different scales, and compared the applicable scopes of two joint optimization algorithms with examples. Wu et al. [6] studied the optimal control of event-driven conveyor belt feeding and processing system.

There are some limitations that present opportunities for future research. Our Stackelberg game modeled the operator as the leader and the suppliers as the followers. It might be beneficial for practical applications to explore other power structures. In future research, a supplier-led power structure (e.g., a large-scale enterprise building a platform) could be an important extension of this model. Moreover, we studied two types of substitutable cloud services that can satisfy client demands. In reality, there might be multiple types of cloud services that meet the same requirement. Future research should consider the case of multiple types of substitutable cloud services in the CMfg system.

Cao et al. [7] stated that there are some limitations that present opportunities for future research. Our Stackelberg game modeled the operator as the leader and the suppliers as the followers. It might be beneficial for practical applications to explore other power structures. In future research, a supplier-led power structure (e.g., a large-scale enterprise building a platform) could be an important extension of this model. Moreover, we studied two types of substitutable cloud services that can satisfy client demands. In reality, there might be multiple types of cloud services that meet the same requirement. Future research should consider the case of multiple types of substitutable cloud services in the CMfg system. Carlucci et al. [8] observed that a key limitation of the research is the use of homogeneous resources shared in the network. Future research could take into account different categories of resources that are characterized by different rules in order to determine the win or lose state. Another important research issue to further investigate is the dynamic composition of the network based on the obtained performance, i.e., how the participant in the network can decide to enter or leave the network.

To sum up, there are very few studies on cell-line cloud manufacturing resource scheduling based on cloud robots, which could avoid resource waste, repetitive building of production lines, and low utilization of units. This paper explores production task allocation from the angle of the optimal combination of cloud manufacturing resources. Specifically, a mathematical model was established based on the transport cost of different sub-tasks and the tardiness cost of product delivery, and solved by quantum firefly algorithm (QFA). The effectiveness of the model and algorithm was demonstrated through example analysis.

At present, there are many researches on the single technology of cloud manufacturing. With the in-depth research and application of cloud manufacturing, the cloud manufacturing service platform oriented to the whole life cycle of products will become the next research hotspot. New product development is an important life cycle stage of

complex electronic products. There are very few researches on cloud manufacturing resource scheduling of the Japanese unit production line based on cloud robot. However, the results of researches can avoid the waste of resources, repeated line construction, and low utilization rate of units.

The driving effect of electronic information industry to China's economic growth is showing a sustained and scale of growth. Moreover, the promotion and penetration effect to the upgrading of traditional industrial structure gradually increases. The high-tech industry represented by the electronic information industry has developed far faster than the traditional industry, and the export of high-tech products has shown a rapid growth trend. By observing the development of electronic information industry and the track of technological upgrading, it is concluded that China has a strong and obvious comparative advantage in processing and assembly, and the manufacturing of electronic information products in the world is forming a tendency to be concentrated in some areas of China. First, due to the epidemic, foreign orders have increased, and some manufacturers have blindly expanded production scale, resulting in serious excess production capacity. However, some manufacturers have insufficient orders and idle production resources. Second, the processing technology of small batch products is more and more complex and often the production resources of an enterprise cannot meet the requirements of product processing. The cloud platform can contact enterprises in multiple regions to complete manufacturing resource scheduling tasks together.

## 2. Problem Formulation

In 2010, James first put forward the definition of "cloud" robot; it points out that the cloud robotics is robot to store and retrieve information, such as a robot with a camera around the photo upload cloud server, a search on the server, find the similar photos, to plan the robot path tracing, and store the pictures, as search information for the back of the machine. All robots can share this library to reduce the developer effort and time.

Suppose there are requests for  $I$  types of products on the cloud platform. Each product request contains  $N$  sub-tasks  $F_i$ ,  $i = \{1, 2, \dots, N\}$  to be processed on  $k$  intelligent cloud scheduling production lines. Each sub-task contains  $P_i$  operations, and  $K_i$  optional production lines. The production task can be expressed as follows:

$$F = \min(f_1, f_2), \quad (1)$$

where  $f_1$  is the minimum processing time of the manufacturing resources of a task, which depends on the sub-task with the longest processing time:

$$f_1 = \min \left( \max_{t=1}^T \sum_{i=1}^I \sum_{k=1}^K (e_{tik} \varepsilon_{ti} L_{tik} + x_{k,k+i} q_{tik} h_{ti}) \right), \quad (2)$$

where  $e_{ikt}$  is a 0–1 variable (if  $e_{ikt} = 1$ , product  $i$  is processed through  $t$  stages on production line  $k$ ; if  $e_{ikt} = 0$ , product  $i$  is not processed through  $t$  stages on production line  $k$ );  $\varepsilon_{ti}$  is

the number of product  $i$  through  $t$  stages;  $l_{ikt}$  is the processing time of product  $i$  through  $t$  stages on production line  $k$ ;  $q_{tik}$  is the transport time of 1,000 products  $i$  from production line  $k$  to production line  $k+1$ ;  $x_{k,k+i}$  is a 0-1 variable (if  $x_{k,k+i} = 1$ , product  $i$  is transported from production line  $k$  to production line  $k+1$  through  $t$  stages; if  $x_{k,k+i} = 0$ , product  $i$  is not transported from production line  $k$  to production line  $k+1$  through  $t$  stages);  $h_{ti}$  is the multiple of 1,000 products  $i$  through  $t$  stages.

$f_2$  is the minimum cost of all sub-tasks of manufacturing resource processing:

$$f_2 = \min \left( \max_{t=1}^T \sum_{i=1}^I \sum_{k=1}^K (e_{tik} \varepsilon_{ti} C_{tik} + (f_{itk} - s_{itk}) * d_{it}) \right), \quad (3)$$

where  $C_{tik}$  is the manufacturing cost of product  $i$  through  $t$  stages on production line  $k$ ;  $f_{itk}$  is the processing time of product  $i$  through  $t$  stages on production line  $k$  (including transport time);  $s_{itk}$  is the delivery period of product  $i$  through  $t$  stages on production line  $k$ ; and  $d_{itk}$  is the tardiness cost constraint of product  $i$  through  $t$  stages.

The processing of the current operation of a sub-task should not begin before the completion of the previous operation:

$$\sum_{k=1}^{M_{ij}} e_{ijk} = 1, \quad (4)$$

where  $t_{\text{end},j}$  and  $t_{\text{start},i(i+1)}$  are the completion time of the previous operation and the start time of the current operation, respectively.

Operation is the minimum granularity of scheduling. Each operation can only occupy one logic manufacturing resource.

### 3. Algorithm Design

The QFA is designed in the following steps [9-14]. First, a swarm of  $h$  quantum fireflies is generated. Each quantum firefly has a quantum position and a position. The position of each quantum firefly is represented by a  $D$ -dimensional numerical string  $\{0, 1\}$ , with  $D$  being the dimensionality of the solution space. In the  $t$ -th iteration, the quantum position of the  $i$ -th quantum firefly can be expressed as follows:

$$v_i^t = \begin{bmatrix} \alpha_{i1}^t & \alpha_{i2}^t & \dots & \alpha_{iD}^t \\ \beta_{i1}^t & \beta_{i2}^t & \dots & \beta_{iD}^t \end{bmatrix}, \quad (5)$$

where  $(\alpha_{ij}^t)^2 + (\beta_{ij}^t)^2 = 1$  ( $i = 1, 2, \dots, D$ ). The quantum positions  $\alpha_{ij}^t$  and  $\beta_{ij}^t$  satisfy  $0 \leq \alpha_{ij}^t \leq 1$ , and  $0 \leq \beta_{ij}^t \leq 1$ . At the beginning, all the quantum positions of the quantum fireflies are initialized as 1. For simplicity, the quantum position of the  $i$ -th quantum firefly in the  $t$ -th iteration can be denoted as  $v_i^t = (v_{i1}^t, v_{i2}^t, \dots, v_{iD}^t)$  ( $i = 1, 2, \dots, h$ ). The position of a quantum firefly can be derived from the measured quantum position. The position of the  $i$ -th quantum firefly can be expressed as  $x_i^t = (x_{i1}^t, x_{i2}^t, \dots, x_{iD}^t)$  ( $i = 1, 2, \dots, h$ ). The global optimal position of the  $i$ -th

quantum firefly in the  $t$ -th iteration can be expressed as  $p_g^t = (p_{g1}^t, p_{g2}^t, \dots, p_{gD}^t)$ .

According to the fluorescein update rule, the fitness  $F$  ( $p_i^t$ ) of quantum firefly  $i$  ( $i = 1, 2, \dots, h$ ) at the local optimal position in the  $t$ -th iteration can be converted into fluorescein  $L_i(t)$ :

$$L_i(t) = (1 - \gamma)L_i(t-1) + \varepsilon F(p_i^t), \quad (6)$$

where  $\gamma \in [0, 1]$  is the disappearance rate of fluorescein, which gradually weakens with the growing distance and media absorption;  $\varepsilon$  is the update rate of fluorescein. The  $i$ -th quantum firefly obtains the learning neighborhood by certain rules. The quantum fireflies are selected from the neighborhood based on the fluorescein value and position similarity. In the  $t$ -th iteration, the  $i$ -th quantum firefly obtains the learning neighborhood by the following equation:

$$N_i(t) = \{q | D - d_{iq}(t) \leq r_i(t) \text{ and } L_i(t) \leq L_q(t)\}, \quad (7)$$

where  $N_i(t)$  is the set of labels of the learning neighborhood of the  $i$ -th quantum firefly;  $d_{iq}(t)$  is the distance between the local optimal positions of the  $i$ -th and  $q$ -th quantum fireflies;  $r_i(t)$  is the radius of the dynamic decision domain of the  $i$ -th quantum firefly; and  $L_q(t)$  is the fluorescein value of the  $q$ -th quantum firefly in the  $t$ -th iteration. The number of quantum fireflies in the learning neighborhood equals the number of labels in the label set of that neighborhood in the current iteration.

In each iteration, each quantum firefly selects its moving direction according to the quantum fireflies in the neighborhood. In the  $t$ -th iteration, the probability for the  $i$ -th quantum firefly to move to the  $q$ -th quantum firefly in its neighborhood can be expressed as

$$P_{iq}' = \frac{L_q(t) - L_i(t)}{\sum_{j=N_i(t)} [L_j(t) - L_i(t)]}. \quad (8)$$

In each iteration, if the learning neighborhood of the  $i$ -th quantum firefly is empty, then the evolution of the 1-th dimensional quantum position of that quantum firefly can be expressed as follows:

$$v_{il}^{t+1} = \begin{cases} N v_{il}^t \theta_{il}^{t+1} = 0 \text{ and } \mu_{il}^{t+1} < c_1, \\ \text{abs}[U(\theta_{il}^{t+1}) v_{il}^t] \end{cases}, \quad (9)$$

where quantum rotation angle  $\theta_{il}^{t+1} = e_1 (p_{il}^t - x_{il}^t) + e_2 (p_{gl}^t - x_{il}^t)$  ( $i = 1, 2, \dots, h; l = 1, 2, \dots, D$ ;  $e_1$  and  $e_2$  are the degree of influence of local optimal position and global optimal position on quantum rotation angle, respectively;  $\mu_{il}^{t+1}$  is a random number uniformly distributed in  $[0, 1]$ ;  $c_1$ , a constant in  $[0, 1/D]$ , is the mutation probability of the quantum position at the quantum rotation angle of 0;  $\text{abs}(\cdot)$  is the absolute value that limits each dimension of the quantum position in  $[0, 1]$ ;  $U(\theta_{il}^{t+1}) = \begin{bmatrix} \cos \theta_{il}^{t+1} & -\sin \theta_{il}^{t+1} \\ \sin \theta_{il}^{t+1} & \cos \theta_{il}^{t+1} \end{bmatrix}$  is the quantum rotation gate; and  $\bar{N} = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$  is the quantum NOT gate.

If the learning neighborhood of the  $i$ -th quantum firefly is not empty, each quantum firefly labeled  $z$  in the neighborhood satisfies  $z = \arg \max_{q \in N_{il}} \{ \overline{P}_{iq}(t) \}$ . In the  $t$ -th iteration, then the evolution of the  $l$ -th dimensional quantum position of the  $i$ -th quantum firefly can be expressed as follows:

$$v_{il}^{t+1} = \begin{cases} \overline{N}v_{il}^t & \theta_{il}^{t+1} = 0 \text{ and } d\mu_{il}^{t+1} < c_2 \\ \text{abs}[U(\theta_{il}^{t+1})v_{il}^t] & \end{cases}, \quad (10)$$

where quantum rotation angle  $\theta_{il}^{t+1} = e_3(p_{il}^t - x_{il}^t) + e_4(p_{zl}^t - x_{il}^t) + e_5(p_{gl}^t - x_{il}^t)$ ;  $i = 1, 2, \dots, h$ ;  $l = 1, 2, \dots, D$ ;  $p_{zl}^t$  is the  $l$ -th dimension of the local optimal position, i.e., the position with the highest fluorescein, in the learning neighborhood of the  $i$ -th quantum firefly;  $e_3, e_4$ , and  $e_5$  are the degree of influence of the local optimal position of the  $i$ -th quantum firefly, the local optimal position, i.e., the position with the highest fluorescein, in the learning neighborhood of the  $i$ -th quantum firefly, and the global optimal position of the  $i$ -th quantum firefly on quantum rotation angle, respectively;  $c_2$ , a constant in  $[0, 1/D]$ , is the mutation probability of the quantum position at the quantum rotation angle of 0. The position of the  $i$ -th quantum firefly can be derived from the measured quantum position:

$$x_{il}^{t+1} = \begin{cases} 1, \eta_{il}^{t+1} > (\alpha_{il}^{t+1})^2 \\ 0, \eta_{il}^{t+1} \leq (\alpha_{il}^{t+1})^2 \end{cases}, \quad (11)$$

where  $l = 1, 2, \dots, D$ ;  $\eta_{il}^{t+1} \in [0, 1]$  is a random number obeying uniform distribution;  $(\alpha_{il}^{t+1})^2$  is the probability of zero appearing at quantum position  $v_{il}^{t+1}$ .

The radius of the dynamic decision domain of the  $i$ -th quantum firefly can be updated by the following expression:

$$r_i(t+1) = \min\{R_s, \max[0, r_i(t) + \zeta\{n_t - \text{size}[N_i(t)]\}]\}, \quad (12)$$

where  $\zeta$  is a constant update rate of the dynamic decision domain;  $R_s \geq r_i(t)$  is a constant perception domain;  $\min$  and  $\max$  are the minimum and maximum functions, respectively;  $n_t$  is the parameter controlling the number of quantum fireflies in the learning neighborhood; and  $\text{size}[N_i(t)]$  is the number of quantum fireflies in the learning neighborhood of the  $i$ -th quantum firefly.

For the cloud scheduling of production line, the fitness function of the QFA should minimize the production time of the production line. After computing the maximum production time and cost of cloud scheduling, the minimization of the two values is adopted as the optimization goal. Then, the fitness function of the current position  $x_i^t = (x_{i1}^t, x_{i2}^t, \dots, x_{iD}^t)$  ( $i = 1, 2, \dots, h$ ) of the  $i$ -th firefly can be expressed as follows:

$$F(x_i^t) = \begin{cases} -MSLL(x_i^t), & \text{If } crat \leq erat \\ -\rho \cdot MSLL(x_i^t) & \end{cases}, \quad (13)$$

where  $MSLL(x_i^t)$  is the maximum production time and cost of cloud scheduling constructed by  $x_i^t$ ;  $\rho \leq 1$ ;  $crat$  and  $erat$

are the calculated and expected coverage rates, respectively [15–19].

Based on the QFA, the production time and cost of the cloud manufacturing production line can be minimized through the following steps:

*Step 1.* Establish the mathematical model of the production time and cost of cloud computing production line, determine the key parameters of the QFA corresponding to the production time and cost, initialize the quantum positions of quantum fireflies, and measure their positions.

*Step 2.* Map the position of each quantum firefly to the corresponding parameters of the established model, import these parameters to the fitness function, compute the fitness at the position of the quantum firefly, and determine the local and global optimal positions according to the fitness.

*Step 3.* Update the fluorescein value and learning neighborhood of each quantum firefly, according to the fitness at the local optimal position of that quantum firefly.

*Step 4.* Change the quantum position of each quantum firefly with new data.

*Step 5.* Change the radius of the dynamic decision domain of each quantum firefly with new data.

*Step 6.* Compute the fitness of each firefly at the new position by the fitness function and determine the local and global optimal positions according to the fitness again.

*Step 7.* If the maximum number of iterations is reached, execute Step 8; otherwise, return to Step 3.

*Step 8.* Output the global optimal position [20–25]. (Flow chart as Figure 1)

The test example and calculation results are shown in Tables 1 and 2, respectively.

## 4. Example Analysis

Two swarms were initialized in our example. For convenience, each type of the product can be used after completion one production cycle. The initial swarms 1 and 2 were combinations of ones in each row of Table 1. Our algorithm IFA was compared with traditional firefly algorithm (FA), improved FA, and the FA optimized by cat swarm optimization (CSO-FA). The swarm size for all these intelligent optimization algorithms was fixed at 50 (Set in the program). The maximum number of iterations was set to 350 (Set in the program), the expected coverage rate to 0.7 (In (13),  $erat$  is the expected filling rate),  $\rho = 0.001$  (In Formula (13)  $\rho \leq 1$ ), the update rate of dynamic decision domain to 0.8 (Formula (12)  $\zeta$  is the update rate of the dynamic decision domain), the initial fluorescein value to 5,  $e_1 = 0.06$ ,  $e_2 = 0.03$ ,  $e_3 = 0.06$ ,  $e_4 = 0.03$ ,  $e_5 = 0.01$ ,  $\theta_{il}^{t+1} = e_3(p_{il}^t - x_{il}^t) + e_4(p_{zl}^t - x_{il}^t) + e_5(p_{gl}^t - x_{il}^t)$ ;  $i = 1, 2, \dots, h$ ;  $l = 1, 2, \dots, D$ ;  $p_{zl}^t$  and  $e_2$  are the degree of influence of local optimal position

and global optimal position on quantum rotation angle,  $\theta_{il}^{t+1} = e_3(p_{il}^t - x_{il}^t) + e_4(p_{zl}^t - x_{il}^t) + e_5(p_{gl}^t - x_{il}^t)$ ;  $i = 1, 2, \dots, h$ ;  $l = 1, 2, \dots, D$ ;  $p_{zl}^t$  is the  $l$ -th dimension of the local optimal position, i.e., the position with the highest fluorescein, in the learning neighborhood of the  $i$ -th quantum firefly;  $e_3$ ,  $e_4$ , and  $e_5$  are the degree of influence of the local optimal position of the  $i$ -th quantum firefly) and  $c_1 = c_2 = 0.1/D$ .

## 5. Conclusions

This paper mainly solves the cloud robot scheduling of a cell-line involving various small batches of products, which are produced in multiple cycles, in the light of transport cost. The QFA was adopted to reasonably allocate the resources in the cloud environment. Besides, the ideas of quantum computing were added to the FA to speed up the search, while maintaining the swarm search ability. Compared with the traditional FA, improved FA, and CSO-FA, the proposed QFA (as Figures 2 and 3) achieves excellent optimization ability and a fast search speed. Finally, our algorithm was demonstrated through an example analysis on the production order scheduling of an electronic product manufacturer. The results show that the QFA is capable of effectively solving the multiobjective scheduling of cloud manufacturing resources [26, 27].

Rough set theory, presented by Pawlak in 1981, is one of the most well-known methods for communicating ambiguity by estimating an item based on some knowledge rather than membership. The concept of a rough function and its convexity and differentiability in regard to its boundary region are discussed in this work. The boundary notion is also used to present a new form of rough programming issue and its solutions. Finally, numerical examples are provided to demonstrate the proposed method and emphasize its advantages over other approaches.

## 1. Introduction

Rough set theory has been used to a wide range of problems. In rough set theory, knowledge is said to be dependent on the ability to classify objects, and the indiscernibility relation, which is an equivalence relation, is used to represent it formally [1]. The indiscernibility relation generates an approximation space made up of indiscernible item equivalence classes that spans the entire universe. Pawlak et al. [2] established the concept of a rough set, and one of the most prominent theories to explain ambiguity using the boundary area of a set rather than membership is Pawlak's theory [3]. A rough set, on the one hand, is distinct from ordinary and fuzzy sets in terms of concept. A characteristic function identifies an object in an ordinary set; however, in a fuzzy set, the data's uncertainty is reflected by a partial degree of membership between 0 and 1 [4]. A rough set, on the other

hand, approximates an object based on some prior knowledge. The following are some examples of rough mathematical programming problems:

- (i) *1st class*: using a rough feasible set and a crisp objective function and solving mathematical programming problems
- (ii) *2nd class*: problems in mathematical programming with a crisp feasible set and a rough target function
- (iii) *3rd class*: problems requiring a rough feasible set and a rough objective function in mathematical programming

In rough mathematical programming problems, the ideal solution set is characterized in a rough sense by four optimal sets, each spanning a distinct level of feasibility and optimality [5] (Table 1).

TABLE 1: Optimal solution set covering the different possible degree of feasibility and optimality.

	Optimality		
		Possibly	Surely
Feasibility	Possibly Surely	FOpp FOsp	FOPs FOss

- (1) FOss is the set of solutions that are certain to be feasible and certain to be optimal
- (2) FOsp signifies the set of all possible optimal solutions that are certain to be practicable
- (3) FOPs is a term that refers to a collection of all potentially viable and unquestionably optimal alternatives
- (4) FOpp signifies the collection of all possible and optimal solutions

The viable region in the second class is a crisp set; therefore, FOPs = FOss and FOpp = FOsp.

It is clear that FOss  $\subseteq$  FOsp  $\subset$  FOpp, FOss  $\subset$  FOPs  $\subset$  FOpp, and FOss = FOsp  $\cap$  FOPs.

Pawlak et al. [2] and Pawlak [3] were the first to propose the concept of a rough set [3]. Only in these instances, rough set theory is used to represent unclear data, and we just contribute to the “postprocessing step” of the data mining process. Rough multiple objective programming (RMOP) problems are the name for these innovative tasks, and they are grouped into three groups based on where the problem’s roughness appears. There are many applications for the rough set theory such as artificial intelligence, expert systems, civil engineering [6–10], medical data analysis [11], data mining (Munakata; [12, 13], Pattern recognition [14]; and [15], and decision theory [16] and [15,17–20], and [21–23]. After turning the random rough variables in the constraint set into crisp ones, Xu and Yao [24] suggested an interactive technique to solve a class of multiobjective programming problems with random rough coefficients. Osman et al. [25] investigated a method for solving a multiobjective transportation issue with rough parameters using a solution approach. Attaya [26] described and solved various objective programming problems with a degree of vagueness in their formulation. Brikaa et al. [27] solved constrained matrix games with fuzzy rough payoff matrices using an effective fuzzy multiobjective programming method. In their proposed model, Ghosh and Roy [28] built a multiobjective product mixing fixed-charge transportation problem with truckload constraints, and an extra cost that was considered as a type-I fixed charge was explored, as well as truck load limits. In a neutrosophic context, Ahmad et al. [29] proposed a new approach for addressing multilevel linear fractional programming problems, with the objective function coefficients represented by rough intervals.

The concept of a rough function, and its convexity and differentiability depending on its boundary region, which are all important concepts to understand, is introduced in this study. In addition, using the concept of a border

region, a novel sort of rough programming challenge is investigated, as well as its answers. Many authors studied the roughness in the optimization problems [30–34].

In terms of its boundary region, this research explores the concept of a rough function, as well as its convexity and differentiability, using inspiration from the above literature. Moreover, the boundary notion is also used to present a new form of rough programming issue and its solutions. It has the distinction due to the inclusion of the following feature time in literature:

- (1) Rough multiobjective programming problem
- (2) Kuhn–Tucker. Saddle point of rough programming (RP) problem
- (3) Optimal solution-based scenario

The following are the study’s key goals:

- (i) To distinguish between many forms of optimal solutions for a rough multiobjective programming issue.
- (ii) To use a numerical example to validate the suggested study

The rest of the paper can be summarized as shown in Figure 1.

## 2. Preliminaries

Some rough function definitions and convexity based on its boundary region are recalled in this part.

*Definition 1* (see [5]). In the rough mathematical programming problem, the optimum value of the objective function is a rough number  $f^*$  specified by lower and upper approximation bounds, denoted by  $f^{*(UAI)}$  and  $f^{*(LAI)}$ ; respectively.

If  $f^{*(UAI)} = f^{*(LAI)}$ , then the optimal value  $f^*$  is exact, otherwise,  $f^*$  is rough.

Roughness can be found everywhere in the rough mathematical programming problem. Rough feasibility and rough optimality are two novel concepts that have piqued our interest. Only in the first and third classes, where the feasible set is a rough set, rough feasibility does arise. The following solutions have varying degrees of feasibility:

- (i) If a solution  $x \in X$  belongs to the lower approximation of the feasible set, it is certain to be feasible
- (ii) If a solution  $x \in X$  belongs to the upper approximation of the feasible set, it is possibly feasible
- (iii) If a solution  $x \in X$  does not belong to the upper approximation of the feasible set, it is most likely not feasible
- (iv) Rough optimality can be found in a variety of rough mathematical programming problems, with variable degrees of optimality, as demonstrated below:
- (v) if  $f(x) = f^{*(UAI)}$ , the solution  $x \in X$  is unquestionably optimal
- (vi) if  $f(x) \geq f^{*(UAI)}$ , a solution is possibly optimal

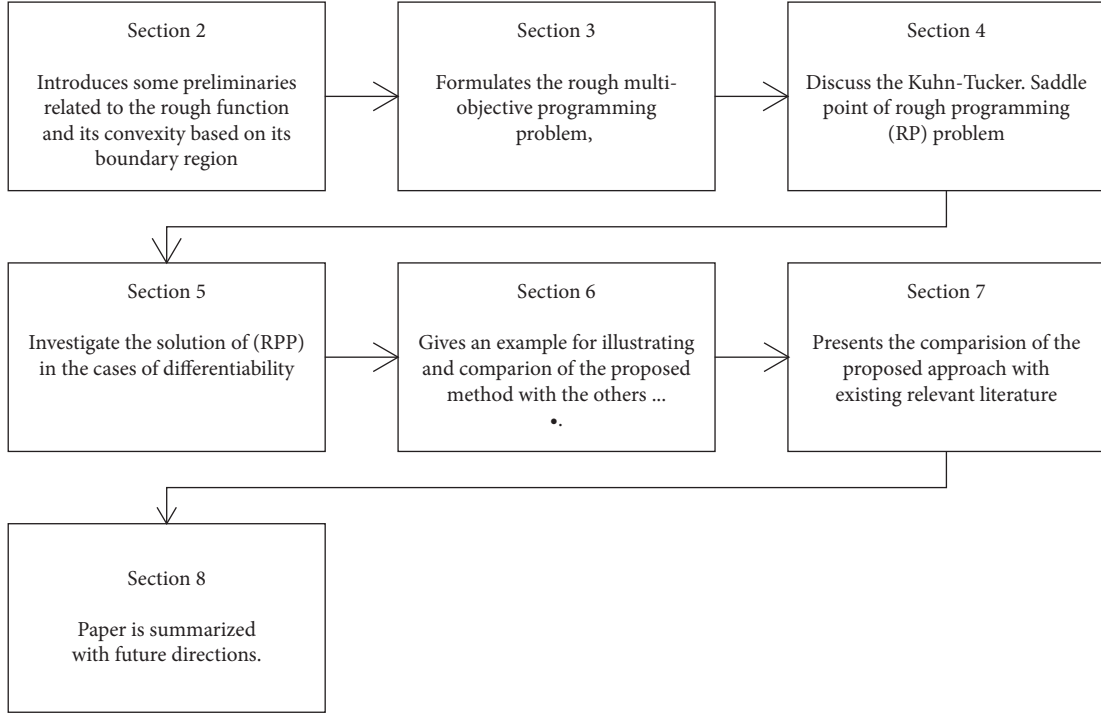

FIGURE 1: Layout of the remaining paper.

(vii) if  $(x) < f^{*(\text{UAI})}$ , a solution  $x \in X$  is unquestionably not optimal

In rough mathematical programming problems, the optimal solution sets are defined in a rough sense by four optimal sets covering the different possible degree of feasibility and optimality.

*Definition 2.* Let  $\tilde{f}^R: \mathbb{R}^n \rightarrow \mathbb{R}$  and  $r, \check{r}, r < \check{r}$ ; we suppose that a set of functions  $U (U = \{f(x), f(x): \mathbb{R}^n \rightarrow \mathbb{R}\})$  is called the universe set. The set of functions  $\{f_j\} \subset U$  is a lower approximation  $L(\tilde{f}^R(x))$  of  $\tilde{f}^R(x)$  which is denoted by  $f^{LAI}(x)$  and is defined by  $f^{LAI}(x) = \{f_j(x) \in U: |f_j - \tilde{f}^R| < r\}$ , and the set of functions  $\{f_k\} \subset U$  is an upper approximation  $U(\tilde{f}^R(x))$  of  $\tilde{f}^R(x)$  which is symbolized by  $f^{UAI}(x)$  and is characterized with  $f^{UAI}(x) = \{f_k(x) \in U: |f_k - \tilde{f}^R| < \bar{r}\}$ , where  $\{f^{LAI}(x)\} \subset \{f^{UAI}(x)\}$ . The function  $\tilde{f}^R(x)$  is called rough function if  $f^{LAI}(x) \neq f^{UAI}(x)$ .

*Definition 3.* The boundary of the rough function  $\tilde{f}^R(x)$  is  $F(x) = f^{UAI}(x) - f^{LAI}(x)$ , where  $f^{LAI}(x)$  and  $f^{UAI}(x)$  are the lower and upper approximation of  $\tilde{f}^R(x)$ .

*Definition 4.* Let  $\tilde{f}^R: \mathbb{R}^n \rightarrow \mathbb{R}$  and  $u, \hat{u} \in \mathbb{R}, u < \hat{u}$ . We suppose that the universal set  $V (V = \{f(x): tfn: q\mathbb{R}^n h \rightarrow \mathbb{R}\})$ . The set of functions  $\{f_j\} \subset V$  is the lower and upper approximation of  $\tilde{f}^R$  which is denoted by  $f^{LAI}(x)$  and  $f^{UAI}(x)$ , respectively, and they are defined as

$$f^{LAI}(x) = \left\{ f \in V: |f_j - \tilde{f}^R| < u \right\}, \quad (1)$$

$$f^{UAI}(x) = \left\{ f \in V: |f_j - \tilde{f}^R| < \hat{u} \right\}. \quad (2)$$

The function  $\tilde{f}^R$  is called rough function if

$$f^{LAI}(x) \neq f^{UAI}(x). \quad (3)$$

*Definition 5.* The boundary function of the rough function  $\tilde{f}^R$  is  $F(x) = f^{UAI}(x) - f^{LAI}(x)$ , where  $f^{LAI}$  and  $f^{UAI}$  are defined in (1) and (2), respectively.

*Definition 6.* A rough function  $\tilde{f}^R$  is said to be convex if the boundary function  $F(x)$  is convex.

*Definition 7.* Let  $X$  be an open set on  $X$ . An interval-valued function  $f: X \rightarrow \mathbb{R}$  with  $f(x) = [f^{LAI}(x), f^{UAI}(x)]$  is called weakly differentiable at  $x_0 \in X$  if the real-valued functions  $f^{LAI}$  and  $f^{UAI}$  are differentiable at  $x_0$ .

### 3. Problem Statement and Solution Concepts

A rough programming (RP) problem can be stated as

$$(RP) \min \tilde{f}^R(x). \quad (4)$$

Subject to

$$X = \{x \in \mathbb{R}^n: h_r(x) \leq 0, r = \overline{1, m}\}, \quad (5)$$

where  $f_k^{LAI}(x)$  and  $f_k^{UAI}(x)$  are the lower and upper approximations of  $\tilde{f}^R(x)$ , respectively, and  $f_k^{LAI}(x) \leq$

$\tilde{f}_k^R(x) \leq f_k^{\text{UAI}}(x)$ ,  $k = \overline{1, \overline{K}}$ , and  $X$  represents the convex crisp feasible region, and  $h_r(x)$ ,  $r = 1, 2, \dots, m$  are the convex and continuous functions.

In order to solve the (RP) problem, let us solve the following boundary problem (BP):

$$(BP) \min F(x) = f^{\text{UAI}}(x) - f^{\text{LAI}}(x). \quad (6)$$

Subject to

$$X = \{x \in \mathbb{R}^n : h_r(x) \leq 0, r = 1, 2, \dots, m\}, \quad (7)$$

where  $X$  is the convex set and  $h_r(x)$ ,  $r = 1, 2, \dots, m$  are the convex and continuous functions.

The BP can be separated into the following two sub-problems as

$$(LAP) \max f^{\text{LAI}}(x). \quad (8)$$

Subject to

$$X = \{x \in \mathbb{R}^n : h_r(x) \leq 0, r = \overline{1, m}\}, \quad (9)$$

$$(UAP) \min f^{\text{UAI}}(x).$$

Subject to

$$X = \{x \in \mathbb{R}^n : h_r(x) \leq 0, r = 1, 2, \dots, m\}, \quad (10)$$

where  $f^{\text{LAI}}(x)$  and  $f^{\text{UAI}}(x)$  are the concave and convex functions, respectively.

Let the optimal solutions of (LAP) and (UAP) be denoted by  $f^{\text{LAI}}(x^*) = \max_{x \in X} f^{\text{LAI}}(x)$ , and

$$f^{\text{UAI}}(x^*) = \min_{x \in X} f^{\text{UAI}}(x), \quad (11)$$

respectively.

**Definition 8.**  $x^*$  is said to be the optimal solution of the RP problem if  $f^{\text{LAI}}(x^*) \leq \tilde{f}^R(x^*) \leq f^{\text{UAI}}(x^*)$  where  $S^L$  and  $S^U$  are the sets of the solutions of problems (LAP) and (UAP), respectively.

**Definition 9**

- (1) A solution  $x^* \in S^L \cap S^U$ ,  $F(x^*) = 0$  is called a surely optimal solution of the RP
- (2)  $x^* \in S^L \cap S^U$ ,  $F(x^*) \neq 0$  is called a possibly optimal solution of the RP
- (3)  $x^* \in S^L \cap S^U$  is called a nearly possibly optimal solution of the RP

**Lemma 1.** If  $x^*$  is the solution of (BP), then  $x^*$  is the solution for (LAP) and (UAP).

*Proof.* Let  $x^*$  be a solution of BP; then,

$$f^{\text{UAI}}(x^*) - f^{\text{LAI}}(x^*) \leq f^{\text{UAI}}(x) - f^{\text{LAI}}(x); \forall x. \quad (12)$$

We suppose that  $x^*$  is not a solution for (LAP) and (UAP), then there exists an  $\bar{x} \in X$  such that  $f^{\text{UAI}}(\bar{x}) \leq f^{\text{UAI}}(x^*)$  implies that

$$f^{\text{UAI}}(\bar{x}) - f^{\text{LAI}}(\bar{x}) < f^{\text{UAI}}(x^*) - f^{\text{LAI}}(\bar{x}), f^{\text{LAI}}(x^*) < f^{\text{LAI}}(\bar{x}) \text{ which leads to}$$

$$f^{\text{UAI}}(x^*) - f^{\text{LAI}}(x^*) > f^{\text{UAI}}(x^*) - f^{\text{LAI}}(\bar{x}). \quad (13)$$

Thus,  $f^{\text{UAI}}(\bar{x}) - f^{\text{LAI}}(\bar{x}) < f^{\text{UAI}}(x^*) - f^{\text{LAI}}(x^*)$  contradicts that  $x^*$  is a solution of BP. Therefore,  $x^*$  is a solution of the two problems (LAP) and (UAP).  $\square$

#### 4. Rough Kuhn–Tucker Saddle Point

We consider the rough problem

$$\min \tilde{f}^R(x). \quad (14)$$

Subject to

$$X = \{x \in \mathbb{R}^n : h_r(x) \leq 0, r = \overline{1, m}\}, \quad (15)$$

$$f^{\text{LAI}}(x) \leq \tilde{f}^R(x) \leq f^{\text{UAI}}(x).$$

The rough Kuhn–Tucker saddle point for problem (15) takes the form

$$\begin{aligned} & \tilde{f}^R(x^*) + \sum_{r=1}^m \gamma_r h_r(x^*) + \gamma_{m+1} (f^{\text{LAI}}(x^*) - \tilde{f}^R(x^*)) + \gamma_{m+2} (\tilde{f}^R(x^*) - f^{\text{UAI}}(x^*)), \\ & \leq \tilde{f}^R(x^*) + \sum_{r=1}^m \gamma_r^* h_r(x^*) + \gamma_{m+1}^* (f^{\text{LAI}}(x^*) - \tilde{f}^R(x^*)) + \gamma_{m+2}^* (\tilde{f}^R(x^*) - f^{\text{UAI}}(x^*)), \\ & \leq \tilde{f}^R(x) + \sum_{r=1}^m \gamma_r^* h_r(x) + \gamma_{m+1}^* (f^{\text{LAI}}(x) - \tilde{f}^R(x)) + \gamma_{m+2}^* (\tilde{f}^R(x) - f^{\text{UAI}}(x)), \end{aligned} \quad (16)$$

or

$$\begin{aligned}
& (1 - \gamma_{m+1} + \gamma_{m+2})\tilde{f}^R(x^*) + \sum_{r=1}^m \gamma_r h_r(x^*) + \gamma_{m+1} f^{\text{LAI}}(x^*) - \gamma_{m+2} f^{\text{UAI}}(x^*), \\
& \leq (1 - \gamma_{m+1}^* + \gamma_{m+2}^*)\tilde{f}^R(x^*) + \sum_{r=1}^m \gamma_r^* h_r(x^*) + \gamma_{m+1}^* f^{\text{LAI}}(x^*) - \gamma_{m+2}^* f^{\text{UAI}}(x^*), \\
& \leq (1 - \gamma_{m+1}^* + \gamma_{m+2}^*)\tilde{f}^R(x) + \sum_{r=1}^m \gamma_r^* h_r(x) + \gamma_{m+1}^* f^{\text{LAI}}(x) - \gamma_{m+2}^* f^{\text{UAI}}(x).
\end{aligned} \tag{17}$$

**Theorem 1.** If  $(x^*, \gamma_r^*)$ , where  $\gamma_r^* \geq 0, r = \overline{1, m+2}$ , and  $\sum_{r=1}^{m+1} \gamma_r^*$  is a rough Kuhn-Tucker saddle point (KTSP), then  $x^*$  is a solution of RP.

*Proof.* We assume that  $(x^*, \gamma_r^*), r = \overline{1, m+2}$  is a rough KTSP; then, for  $\gamma_r \geq 0, \gamma_r \in \mathbb{R}^{m+2}$ , we get

$$\begin{aligned}
& (1 - \gamma_{m+1} + \gamma_{m+2})\tilde{f}^R(x^*) + \sum_{r=1}^m \gamma_r h_r(x^*) + \gamma_{m+1} f^{\text{LAI}}(x^*) - \gamma_{m+2} f^{\text{UAI}}(x^*), \\
& \leq (1 - \gamma_{m+1}^* + \gamma_{m+2}^*)\tilde{f}^R(x^*) + \sum_{r=1}^m \gamma_r^* h_r(x^*) + \gamma_{m+1}^* f^{\text{LAI}}(x^*) - \gamma_{m+2}^* f^{\text{UAI}}(x^*), \\
& \leq (1 - \gamma_{m+1}^* + \gamma_{m+2}^*)\tilde{f}^R(x) + \sum_{r=1}^m \gamma_r^* h_r(x) + \gamma_{m+1}^* f^{\text{LAI}}(x) - \gamma_{m+2}^* f^{\text{UAI}}(x).
\end{aligned} \tag{18}$$

From the first inequality, we have

$$\begin{aligned}
& (1 - \gamma_{m+1} + \gamma_{m+2})\tilde{f}^R(x^*) + \sum_{r=1}^m \gamma_r h_r(x^*) + \gamma_{m+1} f^{\text{LAI}}(x^*) - \gamma_{m+2} f^{\text{UAI}}(x^*), \\
& \leq (1 - \gamma_{m+1}^* + \gamma_{m+2}^*)\tilde{f}^R(x) + \sum_{r=1}^m \gamma_r^* h_r(x) + \gamma_{m+1}^* f^{\text{LAI}}(x) - \gamma_{m+2}^* f^{\text{UAI}}(x),
\end{aligned} \tag{19}$$

or

$$\begin{aligned}
& (1 - \gamma_{m+1} + \gamma_{m+2} + 1 - \gamma_{m+1}^* + \gamma_{m+2}^*)\tilde{f}^R(x^*) + \sum_{r=1}^m (\gamma_r - \gamma_r^*) h_r(x^*) \\
& + (\gamma_{m+1} - \gamma_{m+1}^*) f^{\text{LAI}}(x^*) - (\gamma_{m+2} - \gamma_{m+2}^*) f^{\text{UAI}}(x^*) \leq 0,
\end{aligned} \tag{20}$$

which implies to

$$\left( \gamma_{m+1} - \gamma_{m+1}^* \right) \left( f^{\text{LAI}}(x^*) - \tilde{f}^R(x^*) \right) + \left( \gamma_{m+2} - \gamma_{m+2}^* \right) \left( \tilde{f}^R(x^*) - f^{\text{UAI}}(x^*) \right) + \sum_{r=1}^m (\gamma_r - \gamma_r^*) h_r(x^*) \leq 0. \tag{21}$$

This inequality is true for all  $\gamma_r, \gamma_r^*, \gamma_{m+1}, \gamma_{m+1}^*, \gamma_{m+2}, \gamma_{m+2}^*$ . In the case  $\gamma_{m+1} = \gamma_{m+1}^*$  and  $\gamma_{m+2} = \gamma_{m+2}^*$ , we have  $\sum_{r=1}^m (\gamma_r - \gamma_r^*) h_r(x^*) \leq 0$ . We assume that  $\gamma_r = \gamma_r^*, r = 1, 2, \dots, i-1, i+1, \dots, m$  and  $\gamma_i^* = \gamma_i - 1$ . Then,  $h_r(x^*) \leq 0$ . By repeating this for all  $i$ , we have

$h_r(x^*) \leq 0$ , and hence,  $x^*$  is the feasible point. Since  $\gamma_r^* \geq 0$  and  $h_r(x^*) \leq 0$ , we get  $\sum_{r=1}^m \gamma_r^* h_r(x^*) \leq 0$ . Again from the first inequality, where  $\gamma_{m+1} = \gamma_{m+1}^*$  and  $\gamma_{m+2} = \gamma_{m+2}^*$ , and by setting  $\gamma_r$ , we obtain  $\sum_{r=1}^m \gamma_r^* h_r(x^*) \geq 0$ . Hence,  $\sum_{r=1}^m \gamma_r^* h_r(x^*) = 0$ . Thus,

$$(\gamma_{m+1} - \gamma_{m+1}^*)(f^{\text{LAI}}(x^*) - \tilde{f}^R(x^*)) + (\gamma_{m+2} - \gamma_{m+2}^*)(\tilde{f}^R(x^*) - f^{\text{UAI}}(x^*)) + \sum_{r=1}^m (\gamma_r - \gamma_r^*)h_r(x^*) \leq 0. \quad (22)$$

By taking  $\gamma_{m+1} = \gamma_{m+1}^* - 1$  and  $\gamma_{m+2} = \gamma_{m+2}^* - 1$ , we have  $(\gamma_{m+1} - 1 - \gamma_{m+1}^*)(f^{\text{LAI}}(x^*) - \tilde{f}^R(x^*)) + (\gamma_{m+2} - 1 - \gamma_{m+2}^*)(\tilde{f}^R(x^*) - f^{\text{UAI}}(x^*)) + \sum_{r=1}^m \gamma_r h_r(x^*) \leq 0$ . This leads to

$$\begin{aligned} & (f^{\text{LAI}}(x^*) - \tilde{f}^R(x^*)) + (\tilde{f}^R(x^*) - f^{\text{UAI}}(x^*)) \\ & + \sum_{r=1}^m \gamma_r h_r(x^*) \leq 0. \end{aligned} \quad (23)$$

Since the inequality is valid for each  $\gamma_r \geq 0$ , then for  $\gamma_r = 0$ , we get

$$\begin{aligned} & (f^{\text{LAI}}(x^*) - \tilde{f}^R(x^*)) + (\tilde{f}^R(x^*) - f^{\text{UAI}}(x^*)) \leq 0, \\ & f^{\text{UAI}}(x^*) - f^{\text{LAI}}(x^*) \leq 0. \end{aligned} \quad (24)$$

Taking  $\gamma_{m+1} = \gamma_{m+1}^* + 1$  and  $\gamma_{m+2} = \gamma_{m+2}^* + 1$ , we have

$$(\gamma_{m+1} + 1 - \gamma_{m+1}^*)(f^{\text{LAI}}(x^*) - \tilde{f}^R(x^*)) + (\gamma_{m+2} + 1 - \gamma_{m+2}^*)(\tilde{f}^R(x^*) - f^{\text{UAI}}(x^*)) + \sum_{r=1}^m \gamma_r h_r(x^*) \leq 0. \quad (25)$$

Thus,

$$\begin{aligned} & (f^{\text{LAI}}(x^*) - \tilde{f}^R(x^*)) + (\tilde{f}^R(x^*) - f^{\text{UAI}}(x^*)) \\ & + \sum_{r=1}^m \gamma_r h_r(x^*) \leq 0. \end{aligned} \quad (26)$$

Since the inequality is valid for each  $\gamma_r \geq 0$ , then for  $\gamma_r = 0$ , we have

$$\begin{aligned} & (f^{\text{LAI}}(x^*) - \tilde{f}^R(x^*)) + (\tilde{f}^R(x^*) - f^{\text{UAI}}(x^*)) \leq 0, \\ & f^{\text{UAI}}(x^*) - f^{\text{LAI}}(x^*) \geq 0. \end{aligned} \quad (27)$$

Hence from (24) and (27), we conclude  $f^{\text{LAI}}(x^*) = \tilde{f}^R(x^*) = f^{\text{UAI}}(x^*)$  (i.e.,  $x^*$  is a surely optimal solution for the RP)

From the second inequality, we have

$$\begin{aligned} & (1 - \gamma_{m+1}^* + \gamma_{m+2}^*)\tilde{f}^R(x^*) + \sum_{r=1}^m \gamma_r^* h_r(x^*) + \gamma_{m+1}^* f^{\text{LAI}}(x^*) - \gamma_{m+2}^* f^{\text{UAI}}(x^*), \\ & \leq (1 - \gamma_{m+1}^* + \gamma_{m+2}^*)\tilde{f}^R(x) + \sum_{r=1}^m \gamma_r^* h_r(x) + \gamma_{m+1}^* f^{\text{LAI}}(x) - \gamma_{m+2}^* f^{\text{UAI}}(x). \end{aligned} \quad (28)$$

Since  $\sum_{r=1}^m \gamma_r^* h_r(x^*) = 0$ , then

$$\begin{aligned} & (1 - \gamma_{m+1}^* + \gamma_{m+2}^*)(\tilde{f}^R(x^*) - \tilde{f}^R(x)) \leq \sum_{r=1}^m \gamma_r^* h_r(x) + \gamma_{m+1}^* (f^{\text{LAI}}(x) - f^{\text{LAI}}(x^*)) \\ & + \gamma_{m+2}^* (f^{\text{UAI}}(x) - f^{\text{UAI}}(x^*)) \tilde{f}^R(x^*) - \tilde{f}^R(x) \leq \frac{\sum_{r=1}^m \gamma_r^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} h_r(x) \\ & + \frac{\gamma_{m+1}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} (f^{\text{LAI}}(x) - f^{\text{LAI}}(x^*)) + \frac{\gamma_{m+2}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} (f^{\text{UAI}}(x) - f^{\text{UAI}}(x^*)). \end{aligned} \quad (29)$$

For  $x^* \in S^L \cap S^U$ , we have  $f^{\text{LAI}}(x) \leq f^{\text{LAI}}(x^*)$  and  $f^{\text{UAI}}(x) \geq f^{\text{UAI}}(x^*)$ . Since  $\sum_{r=1}^{m+1} \gamma_r = 1$  and  $\gamma_{m+1}^* = \gamma_1^* +$

$\gamma_1^* + \dots + \gamma_m^*$ , then  $1 - \gamma_{m+1}^* + \gamma_{m+2}^* \leq 0$  which implies to  $\tilde{f}^R(x^*) \leq \tilde{f}^R(x)$ ,  $x \in X$ . Hence,  $x^*$  is a possible

optimalsolution of the rough problem. For  $x^* \in S^L, x^* \notin S^U$ , we obtain  $f^{LAI}(x^*) \geq f^{LAI}(x)$  and

$$\tilde{f}^R(x^*) - \tilde{f}^R(x) \leq \frac{\gamma_{m+2}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} (f^{UAI}(x) - f^{UAI}(x^*)). \quad (30)$$

Now, there are two cases:  $\square$

*Case 1.*  $f^{UAI}(x^*) - f^{UAI}(x) \leq 0; \forall x \in X$  implies that  $x^*$  is a nearly possibly optimal solution.

*Case 2.*  $f^{UAI}(x^*) - f^{UAI}(x) > 0$ .

Let  $x^*$  be not a nearly possible optimal solution of rough problem; then, there is  $\bar{x} \in X: \tilde{f}^R(\bar{x}) < \tilde{f}^R(x^*)$ . Since  $x^* \in S^L, x^* \notin S^U$ , so  $x^*$  is not a solution for the boundary problem BP, i.e., there is  $\bar{x}$ :

$$\begin{aligned} f^{UAI}(\bar{x}) - f^{LAI}(\bar{x}) &< f^{UAI}(x^*) - f^{LAI}(x^*), f^{LAI}(x^*) \\ &- f^{LAI}(\bar{x}) < f^{UAI}(x^*) - f^{UAI}(\bar{x}). \end{aligned} \quad (31)$$

(i) If  $f^{UAI}(x^*) < f^{UAI}(\bar{x})$ , then  $f^{LAI}(x^*) < f^{LAI}(\bar{x})$ . This contradicts that  $x^* \in S^L$ , and hence,  $x^*$  must be a nearly possible optimal solution for the RP problem.

(ii) If  $f^{UAI}(x^*) > f^{UAI}(\bar{x})$ , then we may write  $f^{UAI}(x^*) = f^{UAI}(\bar{x}) + \theta, \theta > 0$ , which implies to  $f^{LAI}(x^*) - f^{LAI}(\bar{x}) < \theta, \theta > 0$ . Then, we have two cases:

- (a)  $f^{LAI}(x^*) > f^{LAI}(\bar{x})$ , which is not considered, where  $x^* \in S^L$
- (b)  $f^{LAI}(x^*) < f^{LAI}(\bar{x})$ , which contradicts that  $x^* \in S^L$ , and hence,  $x^*$  must be a nearly possible optimal solution for the RP problem

For  $x^* \in S^U, x^* \notin S^L$ , we obtain  $f^{UAI}(x^*) \leq f^{UAI}(x)$  and

$$\tilde{f}^R(x^*) - \tilde{f}^R(x) \leq \frac{\gamma_{m+1}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} (f^{LAI}(x) - f^{LAI}(x^*)). \quad (32)$$

So, there are two cases:

*Case 3.*  $f^{LAI}(x^*) - f^{LAI}(x) \leq 0; \forall x \in X$ ; this implies that  $x^*$  is a nearly possibly optimal solution.

*Case 4.*  $f^{LAI}(x^*) - f^{LAI}(x) > 0$ .

Let  $x^*$  be not a nearly possible optimal solution of the rough problem; then, there is  $\bar{x} \in X: \tilde{f}^R(\bar{x}) < \tilde{f}^R(x^*)$ . Since  $x^* \in S^U, x^* \notin S^L$ , so  $x^*$  is not a solution for the boundary problem (BP), i.e., there is  $\bar{x} \in X$ :

$$\begin{aligned} f^{UAI}(\bar{x}) - f^{LAI}(\bar{x}) &< f^{UAI}(x^*) - f^{LAI}(x^*), f^{UAI}(\bar{x}) \\ &- f^{UAI}(x^*) < f^{LAI}(\bar{x}) - f^{LAI}(x^*). \end{aligned} \quad (33)$$

(i) If  $f^{LAI}(\bar{x}) < f^{UAI}(x^*)$ , then  $f^{UAI}(\bar{x}) < f^{LAI}(x^*)$ . This contradicts that  $x^* \in S^U$ , and hence,  $x^*$  must be a nearly possible optimal solution for the (R – MOP) problem.

(ii) If  $f^{LAI}(\bar{x}) > f^{UAI}(x^*)$ , then we may write  $f^{LAI}(x^*) = f^{LAI}(\bar{x}) + \theta, \theta > 0$ , which implies to  $f^{UAI}(\bar{x}) - f^{UAI}(x^*) < \theta, \theta > 0$ . Then, we have two cases:

- (a)  $f^{LAI}(x^*) > f^{LAI}(\bar{x})$ , which is not considered, where  $x^* \in S^U$
- (b)  $f^{UAI}(x^*) < f^{UAI}(\bar{x})$ , which contradicts that  $x^* \in S^U$ , and hence,  $x^*$  must be a nearly possible optimal solution for the RP problem

## 5. Rough Function Differentiability

A rough function  $\tilde{f}^R(x)$  is said to be differentiable if its boundary.

$F(x) = f^{UAI} - f^{LAI}$  is differentiable. Then,  
 $F - F(x^*) = (\delta/\delta x)F(x^*)(x - x^*) + \vartheta(x^*, \gamma(x - x^*))$   
 $\|x - x^*\|$ , or equivalently  
 $\tilde{f}^R - \tilde{f}^R(x^*) = (\delta/\delta x)\tilde{f}^R(x^*)(x - x^*) + \vartheta(x^*, \gamma(x - x^*))$   
 $\|x - x^*\|$ , where

$$\lim_{\vartheta \rightarrow 0} \vartheta(x^*, \delta(x - x^*)) = 0. \quad (34)$$

*5.1. Kuhn–Tucker's Conditions under Roughness.* The rough Kuhn–Tucker (KT) conditions for the RP problem takes the form

$$\begin{aligned} \frac{\delta}{\delta x} \tilde{f}^R(x^*) + \sum_{r=1}^m \gamma_r^* h_r(x^*) + \gamma_{m+1}^* \frac{\delta}{\delta x} (f^{LAI}(x^*) - \tilde{f}^R(x^*)) + \gamma_{m+2}^* \frac{\delta}{\delta x} (\tilde{f}^R(x^*) - f^{UAI}(x^*)) &= 0, \\ \gamma_r^* h_r(x^*) = 0, r = \overline{1, m}; \gamma_{m+2}^* (\tilde{f}^R(x^*) - f^{UAI}(x^*)) &= 0; \gamma_r^* \geq 0, r = \overline{1, m+2}. \end{aligned} \quad (35)$$

Let  $\sum_{r=1}^{m+1} \gamma_r^* = 1$ . Then,

$$(1 - \gamma_{m+1}^* + \gamma_{m+2}^*) \frac{\delta}{\delta x} \tilde{f}^R(x^*) + \gamma_{m+1}^* \frac{\delta}{\delta x} f^{\text{LAI}}(x^*) - \gamma_{m+2}^* \frac{\delta}{\delta x} f^{\text{UAI}}(x^*) + \sum_{r=1}^m \gamma_r^* \frac{\delta}{\delta x} h_r(x^*) = 0, \quad (36)$$

or, in other words

$$\begin{aligned} & \frac{\delta}{\delta x} \tilde{f}^R(x^*) + \frac{\gamma_{m+1}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} \frac{\delta}{\delta x} f^{\text{LAI}}(x^*) - \frac{\gamma_{m+2}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} \frac{\delta}{\delta x} f^{\text{UAI}}(x^*) \\ & + \frac{\sum_{r=1}^m \gamma_r^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} \frac{\delta}{\delta x} h_r(x^*) = 0 \\ & \frac{\sum_{r=1}^m \gamma_r^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} \frac{\delta}{\delta x} h_r(x^*) = 0, \\ & r = \overline{1, m}, \end{aligned} \quad (37)$$

$$\frac{\gamma_{m+1}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} f^{\text{LAI}}(x^*) = 0$$

$$\frac{\gamma_{m+2}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} f^{\text{UAI}}(x^*)$$

$$\gamma_r^* \geq 0,$$

$$r = \overline{1, m+2}.$$

**Theorem 2.** Let  $\tilde{f}^R$ ,  $f^{\text{UAI}}$ , and  $h$  be the convex and differentiable functions at  $x^*$ , and let  $f^{\text{LAI}}$  be a concave and differentiable at  $x^* \in X$ . We suppose that  $f^{\text{UAI}}(x^*) > 0$  and  $f^{\text{LAI}}(x^*) > 0$ . If  $(x^*, \gamma_r^*)$ , where  $\gamma_r^* \geq 0, r = \overline{1, m+2}$  is a solution of the KT conditions, then  $x^*$  is a solution for RP

*Proof.* Let  $(x^*, \gamma_r^*)$  be a solution of the rough KT conditions. Since  $\tilde{f}^R$  is a convex and differentiable at  $x^*$ , we get  $\tilde{f}^R - \tilde{f}^R(x^*) \geq \delta x / \delta \tilde{f}^R(x^*)(x - x^*)$ . Since  $\delta / \delta x \tilde{f}^R(x^*) = \gamma_{m+2}^* / (1 - \gamma_{m+1}^* + \gamma_{m+2}^*) \delta / \delta x f^{\text{UAI}}(x^*) - \gamma_{m+1}^* / (1 - \gamma_{m+1}^* + \gamma_{m+2}^*) \delta / \delta x f^{\text{LAI}}(x^*) - \sum_{r=1}^m \gamma_r^* / (1 - \gamma_{m+1}^* + \gamma_{m+2}^*) h_r(x^*)$ , and  $f^{\text{UAI}}$ ,  $f^{\text{LAI}}$ , and  $h_r$  are differentiable, then

$$f^{\text{UAI}} - f^{\text{UAI}}(x^*) = \frac{\delta}{\delta x} f^{\text{UAI}}(x^*)(x - x^*) + \vartheta(x^*, \gamma(x - x^*))x - x^*,$$

$$f^{\text{LAI}} - f^{\text{LAI}}(x^*) = \frac{\delta}{\delta x} f^{\text{LAI}}(x^*)(x - x^*) + \vartheta(x^*, \gamma(x - x^*))x - x^*, \quad (38)$$

$$h_r - h_r(x^*) = \frac{\delta}{\delta x} h_r(x^*)(x - x^*) + \vartheta(x^*, \gamma(x - x^*))x - x^*.$$

Then,

$$\begin{aligned}
\tilde{f}^R - \tilde{f}^R(x^*) &\geq \frac{\gamma_{m+2}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} (f^{UA} - f^{UA}(x^*) - \vartheta(x^*, \gamma(x - x^*))x - x^*) \\
&\quad - \frac{\gamma_{m+1}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} (f^{LAI} - f^{LAI}(x^*) - \vartheta(x^*, \gamma(x - x^*))x - x^*) \\
&\quad - \frac{\sum_{r=1}^m \gamma_r^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} (h_r - h_r(x^*) - \vartheta(x^*, \gamma(x - x^*))x - x^*).
\end{aligned} \tag{39}$$

Since  $\lim_{\vartheta \rightarrow 0} \vartheta(x^*, \delta(x - x^*)) = 0$ , then

$$\begin{aligned}
\tilde{f}^R - \tilde{f}^R(x^*) &\geq \frac{\gamma_{m+2}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} (f^{UAI} - f^{UAI}(x^*)) - \frac{\gamma_{m+1}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} (f^{LAI} - f^{LAI}(x^*)) \\
&\quad - \frac{\sum_{r=1}^m \gamma_r^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} (h_r - h_r(x^*)).
\end{aligned} \tag{40}$$

From the Kuhn–Tucker conditions,

$$\begin{aligned}
\frac{\sum_{r=1}^m \gamma_r^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} h_r(x^*) &= 0, \\
r &= \overline{1, m}, \\
\frac{\gamma_{m+1}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} f^{LAI}(x^*) &= 0, \\
\frac{\gamma_{m+2}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} f^{UAI}(x^*) &= 0.
\end{aligned} \tag{41}$$

Then, the following inequality  $\tilde{f}^R(x) - \tilde{f}^R(x^*) \geq \frac{\gamma_{m+2}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} f^{UAI} - \frac{\gamma_{m+1}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} f^{LAI} - \frac{\sum_{r=1}^m \gamma_r^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} h_r$  is valid for each  $\gamma_r^* \geq 0, r = \overline{1, m+2}$ , and for  $\gamma_r^* = 0$ , we have

$$\tilde{f}^R - \tilde{f}^R(x^*) \geq \frac{\gamma_{m+2}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} f^{UAI} - \frac{\gamma_{m+1}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} f^{LAI}. \tag{42}$$

If  $\gamma_{m+1}^*; \gamma_{m+2}^* > 0$ , then from the Kuhn–Tucker conditions, we obtain  $\tilde{f}^R(x^*) = f^{LAI}(x^*)$  and  $\tilde{f}^R(x^*) = f^{UAI}(x^*)$ . Then,  $x^*$  is a surely optimal solution of the RP problem.

If  $x^* \in S^L \cap S^U$ , then  $f^{UAI}(x^*) \leq f^{UAI}(x); \forall x \in X$  and  $f^{LAI}(x^*) \geq f^{LAI}(x); \forall x \in X$ , and then we grt

$$\begin{aligned}
\tilde{f}^R - \tilde{f}^R(x^*) &\geq \frac{\gamma_{m+2}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} f^{UAI}(x^*) \\
&\quad - \frac{\gamma_{m+1}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} f^{LAI}(x^*).
\end{aligned} \tag{43}$$

In addition, from the Kuhn–Tucker conditions  $\tilde{f}^R - \tilde{f}^R(x^*) \geq 0$ , this leads to  $\tilde{f}^R(x^*) \leq \tilde{f}^R(x)$ , i.e.,  $x^*$  is a possibly optimal solution.

If  $x^* \in S^L, x^* \notin S^U$ , then  $f^{LAI}(x^*) \geq f^{LAI}(x); \forall x \in X$ , and we have

$$\begin{aligned}
\tilde{f}^R - \tilde{f}^R(x^*) &\geq \frac{\gamma_{m+2}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} f^{UAI}(x^*) - \frac{\gamma_{m+1}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} f^{LAI}(x^*), \\
\tilde{f}^R - \tilde{f}^R(x^*) &\geq \frac{\gamma_{m+2}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} f^{UAI}.
\end{aligned} \tag{44}$$

From the assumption that  $f^{UAI}(x^*) > 0$ , and  $x^*$  is not solution for BP,  $\gamma_{m+2}^*/(1 - \gamma_{m+1}^* + \gamma_{m+2}^*) = 0$ .

Hence,  $\tilde{f}^R - \tilde{f}^R(x^*) \geq 0$  leads to  $\tilde{f}^R(x^*) \leq \tilde{f}^R; \forall x$ . Then,  $x^*$  is a nearly possibly optimal solution for RP.

TABLE 2: Comparisons of different researchers' contributions.

Author's name	Weighting method	$\varepsilon$ - constraint method	KKT optimality	Efficient solution	Parametric study	Environment
Khalifa [30]	√	×	×	√	×	Rough set
Osman et al. [25]	×	×	×	√	×	Fuzzy set
Ammar and Emsimir [31]	√	×	√	√	×	Fuzzy set
Ahmed [35]	×	×	√	√	×	Fuzzy set
Ammar and Al- Al- Asfar [32]	√	×	√	√	×	Fuzzy set
Our investigation	√	√	√	√	√	Rough set

If  $x^* \in S^U, x^* \notin S^L$ ; then,  $f^{UAI}(x^*) \leq f^{UAI}(x); \forall x$ , and we have

$$\begin{aligned} \tilde{f}^R(x) - \tilde{f}^R(x^*) &\geq \frac{\gamma_{m+2}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} f^{UAI}(x^*) \\ &\quad - \frac{\gamma_{m+1}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} f^{LAI}(x^*). \end{aligned} \quad (45)$$

From KT conditions, we have

$$\tilde{f}^R - \tilde{f}^R(x^*) \geq \frac{\gamma_{m+1}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} f^{LAI}. \quad (46)$$

From the assumption that  $f^{LAI}(x^*) > 0$ , and  $x^*$  is not solution for BP,

$$\frac{\gamma_{m+1}^*}{(1 - \gamma_{m+1}^* + \gamma_{m+2}^*)} = 0. \quad (47)$$

Thus,  $\tilde{f}^R(x) - \tilde{f}^R(x^*) \geq 0$ , which implies to  $\tilde{f}^R(x^*) \leq \tilde{f}^R(x); \forall x$ . Then,  $x^*$  is a nearly possibly optimal solution for RP.  $\square$

## 6. Numerical Example

We consider the following problem  $\tilde{f}^R(x): X \rightarrow \mathbb{R}$  with  $f^{LAI}(x) = x_1 + x_2$ ,  $f^{UAI}(x) = 1/3x_1^3 - 2x_1^2 - 10x_2 + 100$  and consider the following RP problem as

$$(RP) \min \tilde{f}^R(x). \quad (48)$$

Subject to

$$X = \{(x_1, x_2) \in \mathbb{R}^2: x_1 + x_2 \leq 10, 3.5 \leq x_1 \leq 6, x_2 \leq 6, x_1 + x_2 \geq 1\}. \quad (49)$$

Then,

$$(LAP) \min f^{LAI}(x) = x_1 + x_2. \quad (50)$$

Subject to

$$x \in X, \quad (51)$$

$$(UAP) \min f^{UAI}(x) = \frac{1}{3}x_1^3 - 2x_1^2 - 10x_2 + 100.$$

Subject to

$$x \in X. \quad (52)$$

Hence, the BP is

$$(BP) \min F(x) = f^{UAI}(x) - f^{LAI}(x). \quad (53)$$

Subject to

$$x \in X. \quad (54)$$

The solution of the LAP is  $S^L = \{(5, 5)\}$ , and the solution of the UAP is  $S^U = \{(1 - \lambda)(6, 4) + \lambda(4, 6), 0 \leq \lambda \leq 1\}$ . Then,

- (1) There is no one-size-fits-all answer (Definition 9.1)
- (2) The best conceivable solution is (5,5), where  $(5, 5) \in S^L \cap S^U$  and  $F(5, 5) \neq 0$  (Definition 9.2)
- (3) The nearly possibly solution is  $\{(1 - \lambda)(6, 4) + \lambda(4, 6), 0 \leq \lambda \leq 1\} \cup \{(5, 5)\}$  (Definition 9.3)

## 7. Discussion

The proposed approach is compared to some existing literature in this section to show the benefits of the proposed approach. Table 2 investigates this comparison in the case of some parameters

## 8. Concluding Remarks and Future Works

This paper introduces the concept of a rough function, as well as its convexity and differentiability based on its boundary region. The boundary area notion has also been used to investigate a new sort of rough programming challenge and its answers. This research could be expanded to include more fuzzy-like structures in the future (such as interval-valued fuzzy sets, neutrosophic sets, pythagorean fuzzy sets, and spherical fuzzy sets), and more discussion and suggestions could also be included in the future studies. The key features of this study can be summarized as follows:

The proposed study can be extended by developing

- (i) Intuitionistic fuzzy set with a possibility interval value
- (ii) Intuitionistic fuzzy set with a probability interval
- (iii) Fuzzy hypersoft expert set is a possibility
- (iv) Possibility fuzzy pythagorean set
- (v) Possibility picture fuzzy set
- (vi) For example, a spherical fuzzy set

The following are some ideas for further research:

- (1) For rough multiobjective programming, determine the link between rough weights and rough parameters
- (2) An investigation of duality in the context of a rudimentary multiobjective programming problem
- (3) A parametric study of a rough programming issue in which the objective function has roughness
- (4) A parametric investigation of a rough programming problem with rough constraints
- (5) Determine the link between the rough weights and the rough parameter in rough multiobjective programming
- (6) A duality investigation on the problem of rough multiobjective programming
- (7) A parametric analysis of a rough programming problem in which the goal function and restrictions are both rough [36–38]

## Data Availability

No data were used in this manuscript.

## Conflicts of Interest

The authors declare that there are no conflicts of interest.

## Acknowledgments

The researchers would like to express their gratitude to Qassim University's Deanship of Scientific Research for supporting the publishing of this study.

With the continuous reform and innovation of Internet technology and the continuous development and progress of social economy, Big Data cloud computing technology is more and more widely used in people's work and life. Many parallel algorithms play a very important role in solving large linear equations in various applications. To this end, this article aims to propose and summarize a cloud computing task scheduling model that relies on the solution of large linear equations. The method of this paper is to study the technology of solving large-scale linear equations and propose an M-QoS-OCCSM scheduling model. The function of the experimental method is to solve the problem of efficiently executing  $N$  mutually dependent parallel tasks within limited resources, while fully satisfying users' expectations of task completion time, bandwidth rate, reliability, and cost. In this paper, the application experiment of large-scale linear equations in task scheduling is used to study task scheduling algorithms. The results show that when the task load is 10 and 20, the convergence speed of the MPQGA algorithm is 32 seconds and 95 seconds faster than that of the BGA algorithm, respectively.

## 1. Introduction

The rapid development of the Internet has also promoted the development of cloud computing, and people's research on cloud computing has become more and more in-depth and extensive. Large-scale data mining and distributed processing technology on the Internet have also been paid more and more attention. This paper combines the characteristics of the two and proposes a model combining text mining and task scheduling under cloud computing. Cloud computing is a new business computing model that uses network connections to obtain various applications, data, and IT services. The core of cloud computing is the integrated scheduling and management of cloud environment and task resources submitted by users according to user needs, and users only need to pay on demand. Therefore, for cloud services, how to meet the different needs of different users for quality of service (QoS) is an important issue that needs to be considered when scheduling cloud computing.

The study of resource deployment and task scheduling problems and their solutions in the cloud computing

environment is of great significance and value for the theoretical research and application practice of cloud computing. As a business service, cloud computing must not only consider optimizing task scheduling strategies to improve the service capabilities of the system but also consider the service revenue of cloud service providers. There are some controversies in this area, but there is no efficient solution yet. Therefore, studying cloud computing task scheduling strategies has important theoretical value and practical significance for improving the service capabilities of cloud computing systems.

This paper proposes a balanced clone scheduling algorithm that can effectively improve resource utilization and task scheduling efficiency. This paper proposes a model that combines data mining and task scheduling in a cloud environment. Combining the advantages of data mining and distributed computing, this model can calmly deal with data processing of massive amounts of information and provide efficient services for users. This paper comprehensively considers the transmission cost, processing time, processing cost, and transmission time of data in the cloud computing

environment, and proposes a mathematical model for task scheduling optimization. And this paper proposes a mathematical model and particle swarm optimization algorithm design based on the increase of the variable neighborhood. The simulation results show that the proposed optimization model and optimization algorithm can not only optimize the time, but also optimize the cost.

## 2. Related Work

The road to solving large-scale linear equations has never stopped. In recent years, people have gradually combined it with task scheduling in order to achieve unexpected results. Wang et al. propose an SSLE method for general constrained optimization based on the mixed exact penalty function. He added automatic adjustment rules to the algorithm for the selection of penalty parameters to ensure that the number of updates of penalty parameters is limited. He also extended the Facchinei activity set recognition technology to general constrained optimization and gave the corresponding recognition function. In each iteration, the algorithm only solves two or three simplified linear equations with the same coefficients to obtain the search direction. Without assuming strict complementarity and weaker than strong second-order sufficient conditions, the convergence rate of the algorithm is proved to be super linear [1]. Phuc and Verbitsky obtained the global solution of quasi-linear equations with metric coefficients and solved a large number of model problems [2]. Lv and Wang studied the existence, uniqueness, and asymptotic stability of traveling wave fronts for discrete quasilinear equations with time delays. He first established the existence of traveling wave fronts using hyperon solutions and monotonic iteration techniques. Then he proved that the traveling wave front is unique before the translation. Finally, he used the comparison principle and compression technique to prove that the traveling wave front has a phase shift and is globally asymptotically stable [3]. Mingtong introduced the basic process of automatic modeling of large buildings. By extending the L-system theory, using elevation maps and automatic river recognition, he researched and proposed an automatic road generation method for complex terrain. Experiments show that the results given by his method are consistent with the surrounding terrain environment. It can automatically generate modifiable roads in complex terrain constrained by altitude and rivers. The road generation algorithm, based on the Voronoi diagram he proposed, can effectively make up for the lack of road changes generated by the system [4]. Samriya et al. proposed a multiobjective penguin optimization algorithm. The proposed method is analyzed through binary gravity search algorithm, ant colony optimization, and particle swarm optimization, which makes it suitable for virtual machines in data centers. Compared with other strategies, the algorithm he proposed is energy-efficient and has significant differences [5]. Jabir et al. proposed an enhanced antlion optimization algorithm mixed with the popular particle swarm optimization algorithm to optimize workflow scheduling specifically for the cloud. The research aims to provide enhanced workflow scheduling that is safer

than the existing framework. It enhances the program's ability to evaluate according to cost, load, and completion time [6]. Tang et al. proposed an energy-saving workflow task-scheduling algorithm based on DVFS, whose purpose is to obtain more energy savings and maintain service quality on the premise of meeting deadlines. This algorithm can recycle useful idle time after the server is merged and obtain the entire makespan and deadline based on the heterogeneous-earliest-finish-time algorithm [7]. Gruzlikov et al. proposed a pipeline workshop scheduling method for the calculation process in a distributed real-time system. This method is based on a solvable system with a simple optimization scheduling algorithm. This method opens up ideas for improving the efficiency of the assembly line workshop [8, 9].

## 3. Linear Equations Solution Method and Task Scheduling Method

*3.1. Common Large-Scale Linear Equation Solving Technology.* There are two methods for solving linear equations in direct method and iterative method [10]. Small and medium-sized equations ( $n < 10000$ ) are often solved by the direct method, and the direct method needs to decompose the coefficient matrix  $A$ . Under normal circumstances, matrix sparsity cannot be guaranteed. As the degree  $n$  increases, the amount of memory required becomes  $O(n^2)$ , and the amount of floating-point operations required becomes  $O(n^3)$ . The sparse direct method based on sorting has some control over memory requirements and time consumption, allowing modern single-CPU personal computers to solve 100,000-order matrices. However, the success of the sparse direct method is related to the nature of the matrix itself, and higher-order linear systems are powerless [11]. Therefore, iterative methods are often used for large or very-large equations. In simple terms, the iterative method is to create a modified  $S_k$  for the initial approximate solution vector  $X_0$  of each step. This makes the next approximate solution vector  $X_{k+1}$  equal to the current approximate solution plus the correction vector  $S_k$ .

$$X_{k+1} = S_k + X_k. \quad (1)$$

This produces an iterative vector sequence  $\{X_k\}$ . It can be seen that the ideal correction vector should be

$$S_k = X^* - X_k = Q(b - Q \cdot r_k), \quad (2)$$

where  $X^*$  is the solution of the simultaneous equations, and  $r_k$  represents the  $k$ th residual vector. However, in order to obtain this ideal correction vector, this article needs to solve equation  $Q \cdot r_k = X_k$ , which is actually the same problem as solving the original equation. Different iterative methods represent different methods of calculating the correction vector  $S_k$  [12]. The classic iterative method is based on matrix division, assuming that the coefficient matrix  $A$  has the following divisions.

$$A = P - Q, \quad (3)$$

where  $P$  is the invertible matrix and the original system of equations is  $(P - Q)x = b$ . Therefore, the following iteration sequence is constructed.

$$X = P^{-1}Q_{xk} + P^{-1}b. \quad (4)$$

In order to avoid calculating  $P^{-1}Q_{xk}$  and  $P^{-1}b$ , it can turn to solving the equations in the following way:

$$P_{xk} = Q_{xk} + b. \quad (5)$$

Different  $P$  choices have different segmentation methods and different iterative methods [13]. Assumptions:

$$A = D - C_L - C_K. \quad (6)$$

Among them,  $D$  is the diagonal part of  $A$ ,  $C_L$  is the lower triangular part of  $A$ , and  $C_K$  is the upper triangular part of  $A$ .

In order to achieve better results, people constructed a symmetric over-relaxation method (SSOR method), splitting  $A$  into  $A = P_{ssos} - Q_{ssor}$ , where

$$P_{SSOR} = \frac{w}{2-w} \left( \frac{1}{w} D - C_L \right) D^{-1} \left( \frac{1}{w} D - C_K \right). \quad (7)$$

In addition, there are methods such as alternating direction iteration, Hermitian and anti-Hermitian splitting, and multiple splitting, all of which are based on practical problems and are all numerically algebraic [14]. The coefficient matrix of the linear equation system obtained by the finite-element method or the method of moments is generally a complex symmetric matrix, which can be described in the following format.

$$(A + iB)(z + iy) = b + ic. \quad (8)$$

Among them,  $A, B \in R$  is a real symmetric matrix. The Krylov subspace method of common asymmetric matrices (such as GMRES, BICGSTAB, and QMR) can be used to solve complex symmetric linear equations. However, using these methods to solve the problem does not take advantage of the symmetry of the matrix. Some solutions transform the symmetric system into an equivalent real symmetric system and then use the Krylov method to solve the real symmetric matrix [15]. The following are some iterative methods for directly solving (8). Using the concept of quasi inner product  $(x, y) = x^T y$ , where the  $x, y \in C$  superscript letter  $T$  represents transpose instead of conjugate transpose, the QMR method can recursively reach the minimum in a short time. This type of quantity and special matrix are often encountered in actual engineering [16]. The key to the success of the Krylov subspace method is the choice of prerequisites. The preprocessing is to transform a linear equation system into another linear equation system with the same solution, but the transformed equation system has the characteristic of facilitating iterative solution. The prerequisite is to generate a matrix for this transformation. If  $P$  is an invertible matrix somewhat similar to  $A$ , then the preprocessed system looks like the following equation:

$$P^{-1}A_x = P^{-1}b. \quad (9)$$

If there is the same solution as equation (1), and there is an equation that is easy to solve, then  $P$  is called a prerequisite. Equation (9) is preprocessed from the left side and can also be preprocessed from the right side.

$$AP^{-1}y = b, \quad x = P^{-1}y. \quad (10)$$

Or, preprocess both sides at the same time:

$$P_1^{-1}AP_2^{-1}y = P_1^{-1}b, \quad x = P_2^{-1}y. \quad (11)$$

Then, the precondition in formula (11) is  $M = M_1M_2$ . A good precondition should have the following two properties: the system after the precondition should be easy to solve, the precondition should be easier to construct and the cost of applying the precondition should not be too high [17].

In modern computer architecture systems, the biggest problem with incomplete decomposition of prerequisites is that it is not easy to parallelize the process of construction and use. Approximate prerequisites for adapting to modern computer structure systems have appeared, and their implementation has natural parallelism [18]. In recent years, the algebraic multigrid (AMG) method that combines the area division (DD) method, multigrid (MG), and physical background to solve partial differential equations (PDEs) has become a hot spot in numerical computing [19].

**3.2. M-QoS-OCCSM Scheduling Model Based on Cloud Computing.** The architecture of the M-QoS-OCCSM collaborative scheduling model proposed in this chapter is shown in Figure 1.

As shown in Figure 1, the execution process of the entire M-QoS-OCCSM scheduling model is as follows. First, the user submits the application task with the deadline of the bottom line and the scheduling budget target constraint to the task scheduler. Then the task scheduler sends the QoS target constraint conditions and other related parameter information of the application task to the extension module of the M-QoS-OCCSM model [20]. Next, the extension module of the M-QoS-OCCSM model first applies the method described in the previous section to model the application task with multiobjective constraints. Then comprehensively consider the application task's QoS target constraints and user expectations and based on a membership function, apply the method described to convert the application task's multiple QoS target constraints into a single-objective constraint optimization problem. Finally, the reconstructed genetic algorithm is applied to approximate the optimal solution of the mentioned single-objective optimization problem [21]. The calculated result is the final scheduling decision plan, which is returned to the scheduler. The scheduler selects appropriate computing resources for the application tasks for scheduling according to the optimization results, thereby completing the scheduling decision.

The extension module serves as an integrated unit in the entire M-QoS-OCCSM scheduling model architecture. For some applications, it can be designed as a separate middleware module for real task-scheduling scenarios [22].

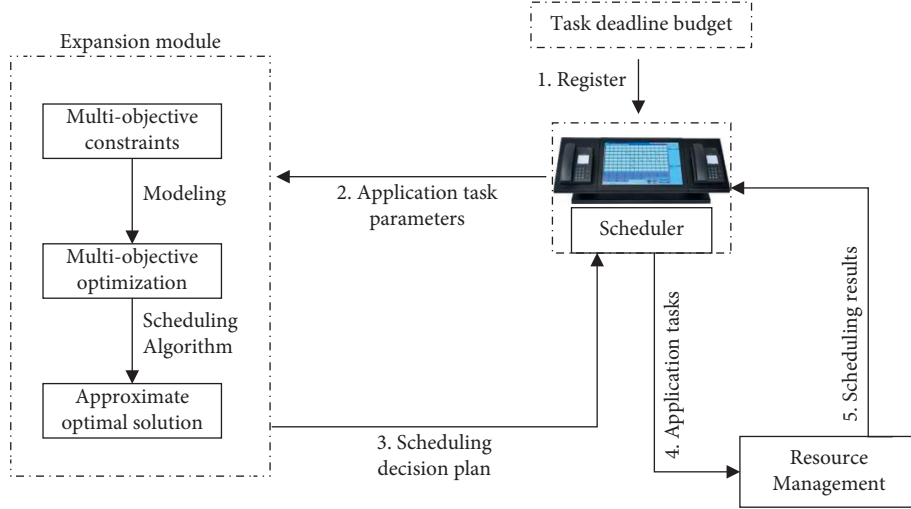

FIGURE 1: M-QoS-OCCSM system architecture.

From the user's point of view, the user always hopes to complete all application task scheduling requests within a desired time interval. This means that the actual execution of application tasks should be reduced as much as possible on the assigned computing nodes. At the same time, for a specific resource  $R$  available on a computing node, the total computing power consumed by all application tasks on the resource  $R$  cannot exceed the computing power that the resource can provide [23].

It can be seen from the analysis that the QoS target constraint of the aforementioned time limit bottom line can be expressed as follows:

$$\begin{aligned} \min(O_{\text{deadline}}) &= \sum_{t=1}^T \sum_{n=1}^N M_{tn} V_{tn}, \\ \text{s.t. } \sum_{t=1}^T \sum_{n=1}^N \sum_{k=1}^K M_{tn} R &\leq \sum_{n=1}^N \sum_{k=1}^K S(CN_{tn}). \end{aligned} \quad (12)$$

On the contrary, users always want to save scheduling costs as much as possible while obtaining satisfactory services. Therefore, the cloud system should complete the scheduling and execution of all tasks as much as possible under the constraints of the established scheduling budget [24]. In other words, in an established cloud computing environment, the system should reduce the total scheduling cost of all tasks as much as possible. In addition, for a specific application task  $t$ , the sum of the scheduling costs consumed by all available resources on the target computing node cannot exceed the task scheduling budget.

According to the analysis, the QoS target constraint of the application task scheduling budget can be expressed as follows:

$$\min(O_{\text{budget}}) = \sum_{t=1}^T \sum_{n=1}^N M_{tn} C_{tn}, \text{ s.t. } \sum_{n=1}^N M_{tn} C_{tn} \leq B_n, \forall n \in T. \quad (13)$$

This paper compares the algorithm based on QoS constraints with the basic genetic algorithm. The relationship between tasks with interdependence constraints is shown in Figure 2, and the specific parameters and weight vector settings are shown in Table 1.

The user wants to pay as little scheduling cost as possible for the scheduling request of the application task. In real-world cloud computing application scenarios, the cost of scheduling application tasks is often directly proportional to the user's satisfaction with completing the scheduling goals. Therefore, users want to spend less on their application task scheduling budget, assuming they have a satisfactory scheduling service [25]. As shown in formula (14), assuming that a satisfactory scheduling service is obtained, the membership function of the task scheduling expenditure can be used to express the membership of the task scheduling budget and the scheduling target.

$$Y_{nm}^{\text{budget}} = 1 - \frac{C_{\min}}{C_{nm}}. \quad (14)$$

In the formula,  $C_{\min}$  represents the minimum expected value of the scheduling overhead of the application task  $t_n$ , and  $C_{nm}$  represents the scheduling budget when the application task  $t_n$  is scheduled on the target computing node  $C_{nm}$ . It can be seen from equation (14) that as the scheduling budget expenditure  $C_{nm}$  of the application task  $t_n$  decreases, the membership function value  $Y_{nm}^{\text{budget}}$  of the scheduling budget decreases. Since users want to pay as little task scheduling budget as possible, the goal of the final task scheduling solution is to minimize the value of the mentioned membership function as much as possible [26].

Through the analysis of the two QoS target constraints, deadline and scheduling budget. This article finds that with less scheduling budget and the shortest possible deadline, everything needed to complete an application task scheduling request has increased. It tries to minimize the aforementioned period. The membership function value of time and the membership function value of scheduling budget expenditure. Based on this conclusion, two membership

TABLE 1: Task scheduling algorithm parameter setting table.

	Two task scheduling algorithms
Total resources	15
Total number of tasks	45
Unit price of virtual machine resources	7
Virtual machine computing performance (million instructions per second)	1500
Task length (one hundred instructions)	10,000
Virtual machine resource bandwidth (Mb)	1024
Expected time (seconds)	65
Expected bandwidth (Mb)	910
Expected cost	4500
Number of generations	125
Crossover probability parameter	$k1 = 0.6, k2 = 0.8$
Mutation probability parameter	$k3 = 0.2, k4 = 0.06$
Variation gene range parameter, $d$	5

functions can be used to transform the task scheduling multi-QoS objective constraint optimization problem into a single-objective constraint optimization problem. The transformed single-objective constrained optimization problem is shown as follows:

$$\min(O) = w_1 \min(O_{\text{deadline}}) + w_2 \min(O_{\text{budget}}). \quad (15)$$

In the formula, the deadline and scheduling budget weight parameters  $w_1$  and  $w_2$  satisfy  $\sum_{n=1}^2 w_n = 1, 0 \leq w_1 \leq 1$ . When scheduling tasks, pay attention to the deadlines and the scheduling budget constraints of each user. Therefore, when constructing the objectives of the mentioned task scheduling scheme, adjusting the two weight parameters for different users can meet the various QoS target constraints of users.

By default, Hadoop usually adopts a first-come first-serve strategy. The advantages of this strategy are simplicity and low overhead, while reducing the burden of the job tracker [27]. The basic idea of solving the problem is to queue up all tasks submitted by the end customer according to the time when the job was submitted. The execution order of the job queue is usually determined by priority and transmission order. That is, the job submitted first by the system has a higher priority by default and will be processed earlier. But the disadvantage of the FIFO strategy is that it is

unfair. According to the solution idea of this strategy, for those jobs with low priority, the chance of being processed will be greatly reduced, and the waiting time for idle machines will be particularly long. That is to say, it is difficult to guarantee the QoS for jobs with low priority. This strategy lacks consideration of differences in job requirements.

**3.3. Cloud Computing Task Scheduling Strategy.** Cloud computing resources include storage resources, computing resources, network resources, and so on. In fact, these resources are abstracted into services through virtualization technology and provided to the outside world. On the contrary, there is a correlation between service quality and resource occupancy rate, service quality, and energy consumption. Therefore, when optimizing resources, this article must consider comprehensively, rather than biasing one aspect. Therefore, when optimizing resource deployment and scheduling, all resources must be fully considered and jointly managed and optimized. It is necessary to optimize the QoS, while optimizing energy consumption and cost [28].

The state of task scheduling in the cloud computing environment can be explained as follows. The total number of resources is  $P$ , and the corresponding set is  $R = \{r1, r2 \dots rn\}$ . The total number of jobs submitted by

users is  $M$ , corresponding to set  $J = \{J1, J2 \dots JM\}$ . Assuming that the  $M$  jobs corresponding to the set  $T = \{T1, T2 \dots TN\}$  are divided into  $N$  tasks, the  $Jm$ th job is divided into  $T_{Num}(Jm)$  tasks, and then the total number of tasks corresponding to the total number of tasks is as follows:

$$N = T_{total}(M) = \sum_{m=1}^M T_{Num}(Jm). \quad (16)$$

Network bandwidth is an important indicator to measure network usage [29]. The size of the bandwidth determines the size of the network transmission capacity, which in turn affects the communication efficiency in the cloud environment. The more frequent the communication, the greater the amount of information, and the higher the bandwidth requirements. Let  $B_{wm}$  be the resource bandwidth of the cloud computing environment,  $B_{user}$  represents the expected bandwidth of the job  $Jm$  specified by the user, and  $B_i$  represents the expected bandwidth of the task  $T_i$  divided by the job  $Jm$ , then

$$B_{user} = \sum_{m=1}^{T_{Num}(Jm)} B_i. \quad (17)$$

The function of user satisfaction  $w$  obtained bandwidth is as follows:

$$W = \left[ \frac{\theta}{T_{Num}(Jm)} \right] \sum_{m=T_{total}(M-1)}^{T_{total}(M)} \ln \left( \frac{B_{wm}}{B_i} \right). \quad (18)$$

Assuming that the resource failure rate in the cloud computing environment is  $P$  (which can be obtained through the resource monitoring system) and the user's expected task completion rate is  $P_{succ}$ , the user satisfaction function of the job completion rate is as follows:

$$W_{succ}(Jm) = \theta \ln \left[ \frac{(1-p)}{P_{succ}} \right]. \quad (19)$$

Cost constraint is one of the most popular QoS constraints, and cost is one of the important components of user QoS. Assuming that resources are billed per unit,  $P_i$  is the number of resources, and  $C_{cpu}$ ,  $C_{men}$ ,  $C_{stor}$ , and  $C_{BW}$  represent the prices of CPU, memory, storage, and bandwidth resources. Then, the total cost of task  $T_i$  can be expressed as follows:

$$C_i = P_1 C_{cpu} + P_2 C_{men} + P_3 C_{stor} + P_4 C_{BW}. \quad (20)$$

Through the previous related research on the existing results of the equations solution, it can be found that each equation solution must have a suitable data center network structure, such as a centralized structure, a distributed structure, and a hierarchical structure [30]. In view of this, before introducing the DRMS equation solution introduced by the task scheduling system architecture in the cloud computing environment, first introduce the data center network structure that implements the equation solution.

As shown in Figure 3, the data center that implements the DRMS equations solution is a hierarchical structure. This

FIGURE 3: Cloud computing data center network structure diagram.

structure is mainly composed of three types of nodes: regional host node, regional head node, and ordinary host node (also called site, or Site) [31].

## 4. Task Scheduling Experiment and Analysis Based on Cloud Computing

**4.1. Application of Large-Scale Linear Equations in Task Scheduling.** In mathematics, the Gaussian elimination method is also known as the Gauss Jordan elimination method, which is an algorithm for solving linear algebra system problems using linear equations [32]. The algorithm first determines the rank of the matrix, and then calculates the inverse of the invertible square matrix. When designing the Gauss method that can cancel the inverse allocation process, the elimination method also reduces the unknown coefficients on the main diagonal to zero. The elimination method does not need to replace the diagonal coefficient matrix equation, this method is called Jordan elimination method. However, the number of multiplication and division operations in Jordan elimination is twice that of pure Gaussian elimination. This is not desirable when solving linear equations, but it is useful when solving inverse matrices.

The operating speeds of Gauss elimination method, and Jordan elimination method are shown in Tables 2 and 3, respectively.

The experimental results are shown in Table 4 by running the Gauss elimination method on a 4-core

FIGURE 4: Speedup analysis of two elimination methods (two nodes).

multiprocessor to process the Poisson equation. From the data in the table, the speedup for solving the Poisson equation under four cores can be calculated as shown in Figure 5.

The following conclusions can be drawn from analyzing the graphs in this article: ① When the scale of meshing reaches a certain level, compared with the serial solution of single-core, the parallel solution of four-core will highlight its advantage in solution time. Because, when the scale of grid division is small, the communication time between each process takes a larger proportion than the overall running time. Therefore, the parallelism of multiple cores does not show its advantages in the process of solving a smaller meshing scale. ② Analyzing the speedup ratio of various improved parallel algorithms in Figure 5, it can be seen that the nonblocking method can indeed improve the efficiency of parallel solving. And on this basis, overlapping a part of the calculation with nonblocking message passing can further improve the efficiency of parallel solving. ③ From the analysis of the speedup ratio of the parallel algorithm in Figure 5, it can be seen that if the number of processes is

fixed, the parallel efficiency will increase as the size of the subdomain problem increases. As the problem grows, the number of Gauss-Jordan iterations also increases. Moreover, the increase in the number of iterations of the Gauss elimination method has a linear trend with the increase of the grid division scale, which shows the rationality of solving large-scale sparse linear equations by the Gauss elimination method. This paper also proposes a task scheduling optimization strategy based on service quality optimization, taking into account system load conditions. This article also gives the approximate service cost of the system and its related proofs. Through experiments, this article analyzes the model and TSSQO strategy in detail and compares them with representative strategies. It verifies that the strategy in this article can more reasonably schedule tasks, so that the entire system can not only achieve high service quality, but also relatively low service costs.

**4.2. Multimode Automata Matching Experiment.** Most application services in cloud computing must be decomposed into several subtasks for scheduling, and the decomposed subtasks have different degrees of dependence. How to improve the parallelism, real-time and dynamics of coupling-dependent task scheduling, improve system utilization, and perform reasonable scheduling, and deployment of

dependent task requests has become a hot spot to be solved in current distributed computing and cloud computing.

This experiment tests the time performance of the multimode automata matching method. The tested hardware environment is 200G hard disk, 16G memory, and two 4-core CPUs. The computer operating system is Ubuntu Linux. This experiment tested the matching algorithm on a 1G data set file and compared the time consumption of the traditional algorithm and the multimode automata algorithm when the comparison rules are the same.

It compares the scheduling length and communication overhead performance of TDDPS with HEFT and Min\_Min algorithms in a distributed system composed of three heterogeneous processor nodes with different task sets. And its statistics use TDDPS algorithm to carry on the system load balance that depends on the task scheduling.

The task graph is randomly generated in the experiment. The number of nodes in each task graph [1~100], task dependencies, the amount of communication data between nodes [1~100], and the execution time of each task on different processors [1~100] are all randomly generated. The experiment compares the three scheduling ideas from the three aspects of scheduling length, communication energy consumption, and node resource utilization. Figure 6 shows the scheduling length and communication overhead of the three on different task sets.

According to the results of Figure 6, it can be seen that the TDDPS algorithm has good performance in terms of scheduling length and communication overhead. Owing to the distributed negotiation and scheduling mechanism, each execution node in the heterogeneous system first evaluates the load of the node, and it makes a negotiation response message to the task request according to the real-time load situation of the node. This ensures a certain degree of load balance and improves resource utilization.

In order to test the performance of the BCSOA algorithm, this paper uses the CloudSim simulation platform to simulate and build a data center. At the same time, the algorithm is compared and tested with the DFGA algorithm and the ASAP algorithm. At present, the ASAP algorithm and the DFGA algorithm are typical algorithms in the field of cloud computing task scheduling research. It has achieved relatively ideal experimental results in the specific application process.

The experimental test contains two aspects: the first type of experiment is mainly compared from the perspective of task completion time, and the second type of experiment is mainly compared from the perspective of the balance factor. Figure 7 shows the comparison of the task completion time

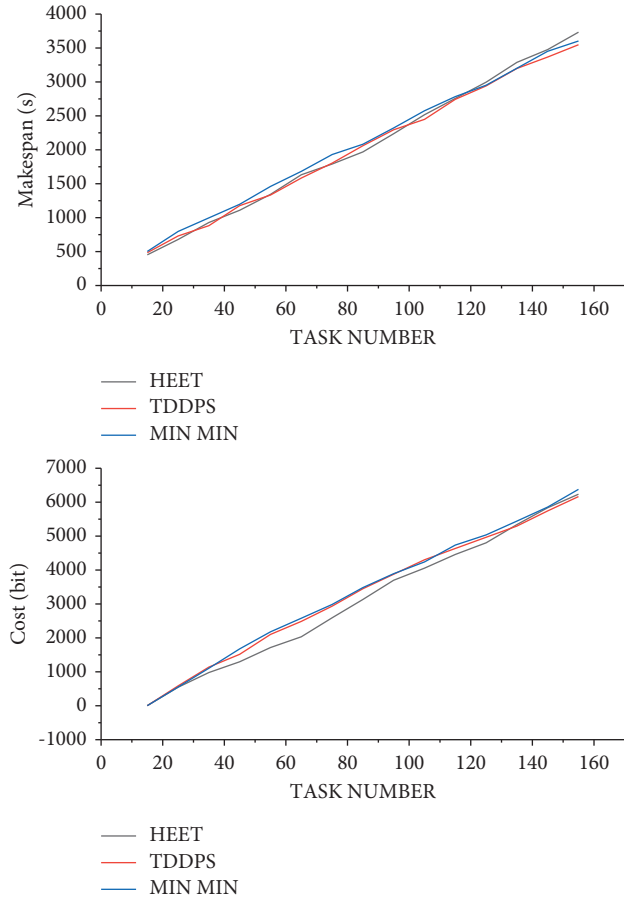

FIGURE 6: Comparison of scheduling length and communication energy consumption of different task sets on three nodes.

of the three task scheduling algorithms when the number of tasks in the system is  $n = 1000$ .

Experimental data show that the traditional matching algorithm has severe time performance degradation when the number of rules increases, and the matching mechanism using multimode automata can greatly improve the matching speed when the rule set is large. Through the comparison of the results of the four rule sets, the time performance of the matching based on the multimodal automata has been greatly improved compared with the traditional algorithm.

**4.3. Task-Scheduling Algorithm.** In order to verify the performance of the MPQGA task-scheduling algorithm, this paper compares the algorithm with the previously mentioned heuristic algorithms HEFT-T, HEFT-B, CPOP, and the basic random search algorithm BGA. This article carried out related tests on two test sets of actual application program graph and randomly generated DAG application table.

The MPQGA algorithm is implemented by C programming. The DAG task graph is represented by a class, and its members include a series of tasks. It uses a two-dimensional matrix to represent the computing speed of each task in a heterogeneous processor and uses another two-dimensional matrix to represent the amount of

FIGURE 7: Comparison of task completion time of three task scheduling algorithms ( $n = 1000$ ).

communication data between each pair of tasks. The task in the program is also a class, and its members include the predecessor and successor of the task, the input and output of the task, and the amount of data calculation of the task. To implement an FFT with an input vector of  $k$ , there are  $2k - 1$  recursive calls and  $k \log_2 k$  butterfly operations (this article assumes that  $k = 2^i$ ,  $i$  is an integer). In the FFT task graph, each path from the start of the task to the end of the task is a critical path. As the computational cost of tasks at any level is the same, the communication costs of all paths between the two levels are the same. Figure 8(a) shows the average SLR of the task scheduling algorithm for FFT task graphs of different sizes, in which the MPQGA algorithm is better than the average SLR of other algorithms. Figure 8(b) shows the efficiency of different algorithms with 64 data nodes, and the MPQGA algorithm is also better than other algorithms in efficiency.

In the experiment of this article, the value of CCR is set to 0.2, 0.4, 0.6, 1.0, 5.0, and 8.0. Figure 9 shows the average SLR and the efficiency value of the algorithm with different CCR values and different numbers of heterogeneous processors.

Figure 9(a) shows that when the CCR value increases, the average SLR of the algorithm also increases. Figure 9(b) shows the efficiency of the algorithm in the case of different numbers of processors.

In these experiments, this paper uses randomly generated task graphs to evaluate the performance of the algorithm. In order to generate random graphs, this article implements a random graph generator that allows users to generate random graphs with different characteristics. The input parameters of the generator: the number of tasks in the graph, the number of instructions for each task (calculation), the number of subsequent tasks (parallelism), and the CCR value. This article evaluates the performance of the algorithm

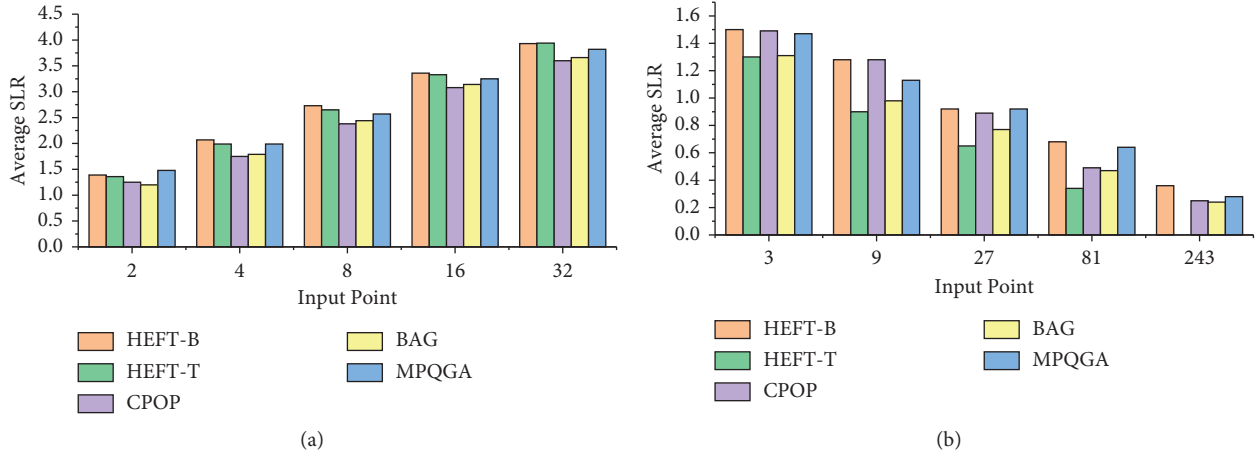

FIGURE 8: Algorithm average SLR and efficiency of fast Fourier transform: (a) algorithm average SLR vs. FFT graph size and (b) algorithm efficiency vs. number of processors.

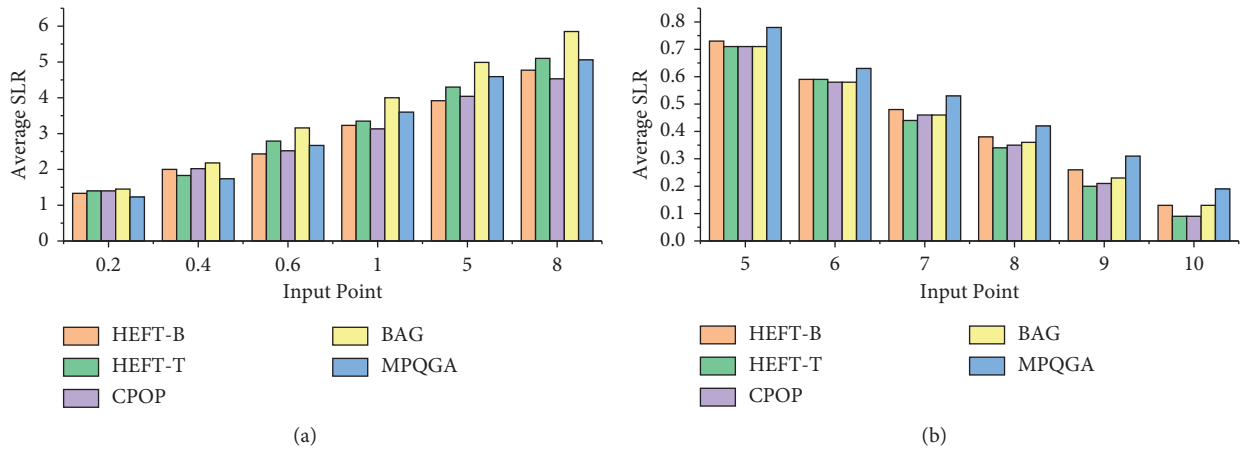

FIGURE 9: Algorithm average SLR and efficiency of molecular dynamics code: (a) algorithm average SLR vs. CCR and (b) algorithm efficiency vs. number of processors.

under different parameters, including different numbers of tasks, different numbers of heterogeneous processors, and different CCR values. The value in Figure 10 is the average maximum and minimum completion time of more than 100 different random DAG graphs.

Figure 10 shows the convergence process of the maximum completion time for a set of randomly generated DAG application graphs (size 10 and 20, respectively). This article can observe that when the DAG application graph is small, the convergence speed of the MPQGA algorithm and the BGA algorithm is very fast. When the DAG application becomes very large, the convergence speed of the algorithm becomes slow, but the convergence speed of the two algorithms is different. The MPQGA algorithm proposed in this paper converges faster than the BGA algorithm, and the final minimum and maximum completion time obtained is better than the BGA algorithm.

In general, with the development of network reliability, cheap computer hardware and software, virtualized hardware technology, and service-oriented architecture, more

and more companies have begun to invest in the development and application of cloud computing technology. More and more companies and individuals are beginning to use cloud computing technology. It continues to promote the progress and development of cloud computing technology. Today, cloud computing, as the core of the next generation of IT technology, has great advantages such as high flexibility, scalability, ease of use, economies of scale, green energy saving, and environmental protection. It is considered to be the next-generation network after the Internet.

## 5. Discussion

Cloud computing has become a trend in the field of IT technology. This article has conducted in-depth research on the task scheduling strategy of cloud computing and has achieved some results. Nevertheless, the work of this article is not yet full and mature enough. At the same time, due to the rapid development of cloud computing technology, there are still many problems in the field of cloud computing

FIGURE 10: The convergence speed of the algorithm under different number of tasks: (a) number of random tasks = 10 and (b) number of random tasks = 20.

technology that need to be further improved and resolved. These problems are mainly reflected in the following aspects: user privacy and data security. The development of cloud computing requires the participation of a large number of users. How to ensure that the user information stored in the cloud is sufficiently safe to ensure that user privacy and user data will not be collected or leaked by cloud service providers and will not be stolen or illegally used by third parties. This is not only a technical issue but also a legal issue. It needs the joint promotion of researchers and government departments. Scholars in the future should strengthen the study of compressed storage of sparse matrices. In this article, the matrix storage of the MPI experiment program is a file that stores all zero elements in the sparse matrix, which will greatly waste the system's memory resources and affect the performance of the parallel program.

## 6. Conclusion

This paper has conducted in-depth analysis and research on the task-dependent scheduling mechanism in cloud computing, including the characteristics and shortcomings of the existing scheduling model, and the problems to be solved by task-dependent scheduling. This paper proposes a new system model suitable for cloud computing environment and a dynamic parallel dependent task scheduling mechanism. In this paper, aiming at the resource-matching problem in the scheduling process, a parallel matching method based on multimode automata is proposed. When the task amount is 10, the calculation speeds of the BGA algorithm and the MPQGA algorithm are 43 and 11, respectively, and when the task amount is 20, the calculation speeds of the BGA algorithm and the MPQGA algorithm are 108 and 13, respectively. It can be seen that the MPQGA algorithm is more excellent, and the more tasks, the more obvious the advantage.

This paper focuses on the phenomenon of “big data killing” implied in e-commerce and discusses how to take the government as the lead to coordinately supervise the price discrimination behavior of e-commerce companies towards loyal customers. First, the four-party evolutionary game model of the government regulatory department, e-commerce platform, e-commerce company, and consumer is built. Second, the stability of the strategy choice of each game subject is analyzed. On this basis, the evolutionary stable strategy in the system based on First Law of Lyapunov is explored. Finally, the influences of key elements on system evolution are simulated and analyzed by MATLAB2021. Results demonstrate that (1) the government supervision mechanism can effectively supervise the price discrimination of e-commerce company based on big data to loyal customers; (2) when the government chooses the strict supervision strategy, reducing the information supervision cost of the e-commerce platform and the strict supervision cost of the government enable the government and the e-commerce platform to coordinate supervision and make the e-commerce company incline to choose the nondifferential pricing strategy; (3) when the government chooses the loose supervision strategy, reducing the information supervision cost of the e-commerce platform and increasing the probability of consumer discovering differential pricing and the penalties for differential pricing of e-commerce company enable the e-commerce platform and consumer to coordinate supervision, and make the e-commerce company incline to choose the nondifferential pricing strategy. The results of this study can provide theoretical guidance for the government and companies to make beneficial strategic decisions in the development of e-commerce.

## 1. Introduction

With the rise of big data, e-commerce is becoming more and more prosperous. E-commerce can bring convenience to consumers with a variety of options and also collect consumer consumption data and draw user portraits by using big data technology [1]. While the application of algorithms injects new growth drivers into social and economic development, problems caused by the unreasonable application of algorithms such as algorithm discrimination, “big data killing,” and inducing addiction also profoundly affect the normal communication in the market and destroy the market order. Online supply chain stores have different pricing based on user location. On some online booking

websites, the price of hotel rooms for Apple customer is higher than that for Windows customer. The well-known e-commerce company, Amazon, was found to use big data to “kill regular” [2]. It priced for different consumers according to their information and purchasing data on the platform. Loyal customers made purchase transactions based on their trust and path dependence on the Amazon platform, but due to the asymmetry of information in the transaction process, some regulars pay higher prices than strangers. This “big data killing” behavior has exposed the hidden dangers of moral hazard in the e-commerce market and makes the industry encounter an unprecedented crisis of trust. “Big data killing” has become an urgent problem to be solved in the fast development of online business [3].

The essence of big data killing is price discrimination. Price discrimination refers to formulating different price strategies for different customer groups. However, in traditional business, both “stranger” and “regular” may be discriminated against, while with the participation of algorithm technology, there are more “killing regular” in Internet business. Even in the process of “killing regular,” big data has become a necessary tool. Each platform will collect a lot of user information, and then the company uses technology to offer different prices and discounts for different customers based on the information. Traditionally, companies have not been able to predict the upper limit of the price that buyers want to pay, but based on the technology of big data, the companies can determine the maximum willing price with a high degree of accuracy with sophisticated algorithms [4]. As the collection of consumer data becomes more common, online companies are now more capable of price discrimination than ever [5]. As customer of the Internet commercial company, VIP customer with higher loyalty and stronger consumption power pay much more for the same service than new customers, but gain even lower service quality. Big data killing will cause a variety of harm. Moriarty [6] proposed that customer information is widely used in online retail pricing, and although the benefit of online retailers will increase, price discrimination can cause serious fairness concerns and even violation of regulations and laws. Antimonopoly issues in the digital economy, especially the antimonopoly issues of big data and discrimination algorithms, have been brought to the attention of experts and practitioners. “Killing regular” is algorithmic price discrimination, with which online platforms charge long-term customers higher prices. It is believed that this kind of price discrimination violates the law on antimonopoly and should be held accountable according to the relevant law. The Cyberspace Administration of China (CAC) issued the regulations on The Management of Algorithm Recommendation for Internet Information Services to regulate the “big data killing,” stepping into the era of strict supervision of the industry related to algorithm recommendation. The EU also prohibits discrimination on certain grounds and strictly regulates unfair business practices in B2C relationships [7].

Although some studies have carried out related discussion on the problem of big data killing [2, 8], some solutions are proposed [9, 10]. However, existing studies are mostly limited to the pricing between e-commerce companies and consumers [11, 12], the strategic choice between e-commerce platform and consumer, and the supervision strategy choice between e-commerce platform and government [9, 13]. There are few systematic studies on the four-party strategy composed of multiple subjects related to “big data killing.” Therefore, this study establishes an evolutionary game model dominated by government supervision that affects the decision-making of consumer, e-commerce company, and platform, analyzes and simulates that different supervision costs of government and e-commerce platform, consumer discovery levels, and the penalties for differential pricing of e-commerce company affect

system equilibrium, evolutionarily stable strategy, and the pricing strategy of e-commerce company, and also establishes the platform-consumer-government collaborative supervision mechanism for e-commerce company pricing behavior. This research contributes to curbing the “big data killing” behavior of e-commerce company, enhance consumers’ confidence in online shopping, and has a positive effect in promoting the development of e-commerce.

## 2. Related Literature

Existing research on price discrimination in e-commerce companies mainly focuses on three aspects: the prevalence of price discrimination by using customer information, the influence factors of price discrimination, and the supervision and management of price discrimination:

On the prevalence of price discrimination by e-commerce companies using customer information, although many media outlets provide various evidence of price discrimination, most of them are not based on scientific and systematic methods. Therefore, scholars have researched whether e-commerce companies use big data to discriminate against consumers in price. Botta and Klaus [14] qualitatively proposed that algorithmic price discrimination is different from offline differential pricing and is related to the collection of consumer information, which is a unique feature of the digital economy. With the wide application of big data and the gradual deepening of algorithm technology, the e-commerce company can price discriminate against consumers with great precision [4], and these were confirmed empirically [4, 15]. The pricing ecosystem of the online platform is a dynamic pricing system [15]. Algorithmic price discrimination [16], artificial intelligence techniques, and digital system fingerprints [15] enable the e-commerce company to have the ability of price discrimination. Price discrimination is not only widespread in the field of commodity sales, and there are also discrimination and price difference by using customer information in the field of online car-hailing [8] and the field of advertising recommendation [7, 17]. While consumers benefit from accurate recommendations, sellers may use this information to discriminate on price. Thus, price discrimination is not favored by people [18].

Scholars have done a lot of studies on the influence factors of price discrimination in e-commerce companies. Some scholars believe that the premise of “big data killing” is the information asymmetry between e-commerce company and customers [1]. Consumer information data is an influencing factor for the e-commerce company to be able to discriminate in price [19], such as consumer characteristics, location [14], etc., and these data also relate to consumers’ privacy [12]. Nuccio and Marco [20] studied how pricing technology and information transparency are changing merchants’ pricing behavior in online transactions. The price sensitivity and heterogeneity of consumers are factors that affect e-commerce company to set price differentials [11]. Some scholars have analyzed the effects of reference price and search cost on differential pricing and find that

consumers' search cost has become one of the obstacles affecting consumers' online shopping, which has formed an unequal situation for consumers [21] and has become a tool for e-commerce companies to formulate differential prices [22, 23]. The target of "big data killing" of e-commerce companies is focused on loyal consumers, which has been confirmed by many scholars. For example, Tang et al. [24] found in the research on the group-buying market that with the improvement of consumer retention rate, the best strategy of sellers is changed from quality difference to price discrimination. Chandra and Lederman [25] argued that if consumers have differences in potential willingness to pay and brand loyalty, e-commerce companies may increase price differences among some consumers while reducing price differences among the other consumers. Although differential pricing is an important way for e-commerce companies to obtain profits [26], its focus on loyal consumers is contrary to the principle of fair pricing [24], which will reduce consumer satisfaction and create distrust [27, 28].

After the problem of "big data killing" was exposed, it has been attracted widespread attention by scholars, and its supervision and governance have also become an important research topic. Bar-Gill [29] proposed that the normative evaluation of price discrimination depends on the object of discrimination, and the algorithmic price discrimination has the advantages to improve efficiency, but it will harm consumers, which should be governed by rules set by regulators to seriously exploit the potential of personalization. Yu and Li [9] also believed that consumers' discovery and reporting of being "killed" is the mean to monitor price discrimination of e-commerce company. Xing et al. [3] found that when regulars account for a high proportion of platform customer, giving consumers the right to data portability can curb the phenomenon of "big data killing" to a certain extent. In addition to consumers' self-discovery of price discrimination by the e-commerce company, many scholars believe that with the help of government supervision [13], increasing penalties and the commission coefficient of government departments [30] can effectively reduce the "killing regular" pricing tendency of e-commerce platforms. However, in the supervision process of existing research, there was little distinction between e-commerce platform and company, and the research is carried out in a mixed way. Most of the discussions focus on the pricing of e-commerce platforms known for its scale. Differential pricing of e-commerce company on the platform is rarely discussed separately, and there is still a lack of research considering multichannel collaborative supervision.

Existing studies have adopted a variety of methods for the problem of price discrimination in the e-commerce company. For example, the dynamic pricing method is used in specific pricing. Lindgren et al. [31] studied dynamic pricing by intertemporal price discrimination theory and proposed that retailers should change prices randomly over time. Chevalier and Kashyap [32] proposed the method for aggregating prices when retailers use periodic sales to discriminate price against heterogeneous customers. Tremblay

[5] designed more efficient Pareto price discrimination. Game methods are often used in the selection of pricing strategies. Choe et al. [33] analyzed pricing strategy with a two-stage dynamic game model. Zhou et al. [34] adopted two-stage game analysis on joint pricing and bandwidth demand optimization. On the game of price discrimination, the bounded rationality assumption in the evolutionary game makes the research more realistic [30], so many scholars use evolutionary game methods to study this problem [1, 13, 30, 35] and extended to multiple fields of online transactions, such as manufacturing business [36]. However, most studies are limited in the two-party game [22, 37], it is still unclear to analyze the relationship and role of e-commerce company, consumer, e-commerce platform, and the government in the "big data killing" problem system, and their decision-making mechanism needs further research.

Therefore, as the price discrimination of e-commerce companies is generated with new technologies, the existing research on this phenomenon is still in the exploratory stage. Most perspectives of the previous research are from both sides of the transaction in traditional business, and there are few differences in the analysis of the e-commerce platform and the companies in the platform. Moreover, the supervision on the differential pricing of the e-commerce company using big data technology to the loyal customers is not very perfect, and some policies and supervision methods are still under discussion. This study systematically analyzes the government, e-commerce platform, e-commerce company, and consumer involved in the supervision of "big data killing," which makes up for the insufficiency of the existing research and provides useful help for further regulating such behavior.

### 3. Materials and Methods

*3.1. Problem Description.* The e-commerce company will use the platform to collect consumer information during the operation in the network platform. Based on the information provided by the platform, e-commerce company analyzes consumers and raise prices by judging their consumption habits. The pricing strategy of "big data killing" is price discrimination caused by e-commerce company using the feature of opaque information in the online transaction process to different pricing of consumers through big data and complex algorithms. This kind of behavior will bring consumers' distrust of e-commerce companies and e-commerce platforms, which is not conducive to the development of e-commerce. Therefore, both the government regulatory department and e-commerce platforms should take necessary measures to supervise the price discrimination behavior of e-commerce companies. This study mainly discusses the following three questions: (1) in the context of big data development, how can the government regulatory department take supervision measures to reduce the proportion of price discrimination by e-commerce company? (2) How can e-commerce platform be motivated to supervise information on e-commerce companies? (3) How can

consumers be guided to actively safeguard their rights and interests and maintain consumption fairness.

This study builds a multi-agent game model for the supervision of price discrimination in e-commerce companies involving the e-commerce platform, the e-commerce company, the consumer, and the government regulatory department. The logical relationship among four-party game subjects is shown in Figure 1.

**3.2. Model Assumption.** To build the multisubject supervision model of the e-commerce company pricing in the background of big data, the behavioral strategies of government regulatory department, e-commerce platform, e-commerce company, and consumer are studied, and the following assumptions are made.

*Assumption 1.* Government regulatory department, e-commerce platform, the e-commerce company, and consumer are selected as the game subjects. Each game subject is bounded rationality and pursues the maximization of their interests in e-commerce transactions. Due to the information asymmetry between game subjects, random behavior strategies, and interactive effects, the optimal strategy cannot be obtained through one game. It is necessary to continuously try and learn in multiple rounds of games to improve the strategy, to formulate the best match of behavioral decision. Therefore, the evolutionary game should be used to analyze the four-party equilibrium strategy. The proportion of e-commerce company implementing nondifferential pricing is represented as  $x$  ( $0 \leq x \leq 1$ ), and the proportion of e-commerce company implementing differential pricing is denoted as  $(1-x)$ ; the proportion of consumer loyalty is represented as  $y$  ( $0 \leq y \leq 1$ ) and the proportion of consumer disloyalty is represented as  $(1-y)$ ; the proportion of e-commerce platform to supervise company information is represented as  $z$  ( $0 \leq z \leq 1$ ), and the proportion of e-commerce platform with information nonsupervision is denoted as  $(1-z)$ ; the proportion of the government regulatory department strictly supervising e-commerce platform and company is denoted as  $r$  ( $0 \leq r \leq 1$ ), and the proportion of loosely supervises e-commerce platform and the company is denoted as  $(1-r)$ .

*Assumption 2.* The benefit of nondifferential pricing of the e-commerce company is  $P_n$ , and the basic benefit of differential pricing is  $P_d$ . When the e-commerce company implements differential pricing for loyal consumer, additional benefit  $\Delta P$  can be obtained due to the increase in selling price, and  $P_d < P_n < P_d + \Delta P$ . The probability of loyal consumers discovering differential pricing of the e-commerce company is  $\alpha$ . When consumer purchases goods, the utility obtained by the loyal consumer is  $U_b$ , and the utility obtained by the disloyal consumer is  $U_d$ , and  $U_l > U_d$ . The reputation value of the loyal consumer to the e-commerce company is  $T_e$  and the reputation value of the loyal consumer to the e-commerce platform is  $T_p$ .

*Assumption 3.* When the government strictly supervises, if price discrimination of the e-commerce company is found, loyal consumers who are subject to differential pricing will be compensated with the compensation amount of  $M$ ; When the government loosely supervises, if the loyal consumer is the price-sensitive consumer, he may use Internet information for comparison and analysis, and then find that he has been "killed". If the cost of reporting is small and the procedure is simple, the consumer will carry out to inform the government regulatory department, and then the e-commerce company must be forced to compensate the consumer. The consumer's complaint cost is  $C_c$ .

*Assumption 4.* The normal benefit that the government obtains from the operation of the e-commerce platform is  $S$ . The cost of strict supervision by government departments is  $C_g$ . The social benefit obtained by the government is  $R$  if there is no price discrimination by the e-commerce company. If the government adopts the loose supervision policy, consumer complaints will bring social reputation loss as  $N$ . After receiving the information, the e-commerce company for price discrimination will be penalized by the government regulatory department, and the fine will be  $I_e$ .

*Assumption 5.* The price discrimination of e-commerce company depends on the information provided by the platform. The benefit of the platform reasonably providing information to the e-commerce company is  $W$ , and the cost of the platform information supervision on e-commerce company is  $C_p$ . When the e-commerce platform finds the price discrimination of e-commerce company on the consumer, the fine to e-commerce company is  $F$ . The e-commerce platform and consumers share this fine in the ratio of  $\beta$  and  $1-\beta$ . When the government finds price discrimination by the e-commerce company, it will impose the fine of  $I_p$  for the platform's unfavorable supervision to e-commerce company information.

The parameters are described in Table 1.

**3.3. Model Framework.** According to the above analysis, the mixed-strategy game matrix of the four-party game subjects of government regulatory department, e-commerce platform, e-commerce company, and consumer is shown in Table 2.

### 3.4. Model Analysis

**3.4.1. Strategy Stability Analysis of the E-Commerce Company.** Assuming that the expected benefit of the e-commerce company when choosing the nondifferential pricing strategy is  $U_{11}$ , the expected benefit of the e-commerce company when choosing the differential pricing strategy is  $U_{12}$ , and the average expected benefit of the e-commerce company is  $\bar{U}_1$ , which are defined as follows:

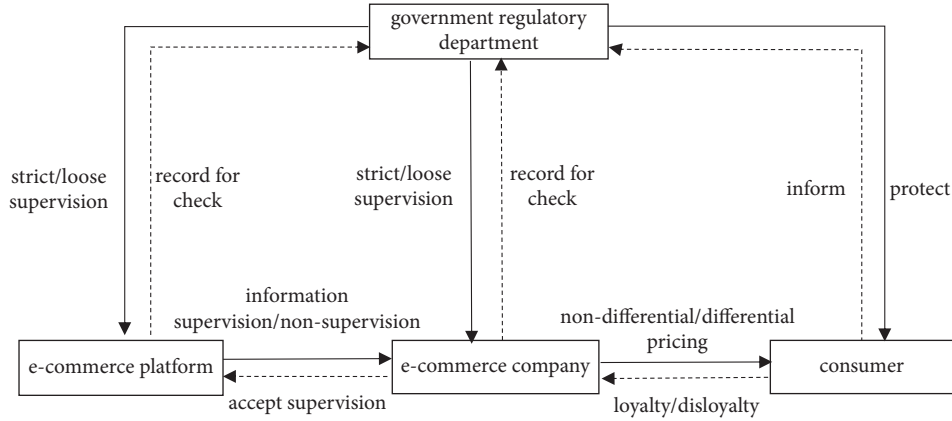

FIGURE 1: Game model logic relationship of multisubject supervision on e-commerce company pricing.

TABLE 1: Parameter description.

Parameter	Description
$P_n$	The benefit of nondifferential pricing by e-commerce company to consumer
$P_d$	The benefit of differential pricing by e-commerce company to consumer
$\Delta P$	The additional benefit of differential pricing by e-commerce company to the loyal consumer
$M$	Compensation of e-commerce company to the loyal consumer for differential pricing
$T_e$	The reputation value of the loyal consumer to e-commerce company
$U_l$	The utility obtained by the loyal consumer from purchasing goods
$U_d$	The utility obtained by the disloyal consumer from purchasing goods
$C_c$	The cost of consumer complaint
$\alpha$	Probability of loyal consumer discovering differential pricing under government loose supervision, and $\alpha \in [0, 1]$
$C_g$	The cost of strict supervision by the government regulatory department
$N$	Social reputation loss caused by differential pricing under government loose supervision
$R$	The social benefit of nondifferential pricing under the government strict supervision
$I_e$	Fine by government regulatory department for differential pricing to e-commerce company
$I_p$	Fine by government imposed on the platform for nonsupervision of e-commerce company information resulting in differential pricing
$S$	The normal benefit obtained by the government from the operation of the e-commerce platform
$W$	The benefit of the platform reasonably providing information to the e-commerce company
$C_p$	The cost of the platform's information supervision on the e-commerce company
$F$	Fines imposed by the platform to e-commerce company for differential pricing during information supervision
$\beta$	The proportion of the fine imposed by the e-commerce platform for differential pricing of e-commerce company, $\beta \in [0, 1]$
$T_p$	The reputation value of the loyal consumer to the e-commerce platform

TABLE 2: Game model benefit matrix of government regulatory department, e-commerce platform, e-commerce company, and consumer

Strategy choice		Government regulatory department				
		E-commerce company	Strict supervision, $r$		Loose supervision, $1 - r$	
			Loyalty $y$	Disloyalty $1 - y$	Loyalty $y$	Disloyalty $1 - y$
E-commerce platform	Information supervision $z$	Nondifferential pricing $x$	$P_n + T_e$	$P_n$	$P_n + T_e$	$P_n$
			$U_l$	$U_d$	$U_l$	$U_d$
	Information nonsupervision $1 - z$	Differential pricing $1 - x$	$W - C_p + T_p$	$W - C_p$	$W - C_p + T_p$	$W - C_p$
			$S - C_g + R$	$S - C_g + R$	$S$	$S$
E-commerce company	Information supervision $z$	Nondifferential pricing $x$	$P_d + \Delta P + T_e - M - I_e - F$	$P_d - I_e - F$	$P_d + \Delta P + T_e - \alpha M - \alpha I_e - F$	$P_d - F$
			$U_l - \Delta P + M + (1 - \beta)F$	$U_d$	$U_l - \Delta P - C_c + \alpha M + (1 - \beta)F$	$U_d$
	Information nonsupervision $1 - z$	Differential pricing $1 - x$	$W - C_p + \beta F + T_p$	$W - C_p + F$	$W - C_p + \beta F + T_p$	$W - C_p + F$
			$S - C_g + I_e$	$S - C_g + I_e$	$S + \alpha I_e - N$	$S - N$
Government regulatory department	Information supervision $z$	Nondifferential pricing $x$	$P_n + T_e$	$P_n$	$P_n + T_e$	$P_n$
			$U_l$	$U_d$	$U_l$	$U_d$
	Information nonsupervision $1 - z$	Differential pricing $1 - x$	$W + T_p$	$W$	$W + T_p$	$W$
			$S - C_g + R$	$S - C_g + R$	$S$	$S$
Consumer	Information supervision $z$	Nondifferential pricing $x$	$P_d + \Delta P + T_e - M - I_e$	$P_d - I_e$	$P_d + \Delta P + T_e - \alpha M - \alpha I_e$	$P_d$
			$U_l - \Delta P + M$	$U_d$	$U_l - \Delta P - C_c + \alpha M$	$U_d$
	Information nonsupervision $1 - z$	Differential pricing $1 - x$	$W - I_p + T_p$	$W - I_p$	$W - \alpha I_p + T_p$	$W$
			$S - C_g + I_e + I_p$	$S - C_g + I_e + I_p$	$S + \alpha I_e + \alpha I_p - N$	$S - N$

$$\begin{aligned}
U_{11} &= yzr(P_n + T_e) + (1 - y)zrP_n + y(1 - z)r(P_n + T_e) + (1 - y)(1 - z)rP_n \\
&\quad + yz(1 - r)(P_n + T_e) + (1 - y)z(1 - r)P_n + y(1 - z)(1 - r)(P_n + T_e) + (1 - y)(1 - z)(1 - r)P_n \\
&= P_n + yT_e, \\
U_{12} &= yzr(P_d + \Delta P + T_e - M - I_e - F) + (1 - y)zr(P_d - I_e - F) \\
&\quad + y(1 - z)r(P_d + \Delta P + T_e - M - I_e) + (1 - y)(1 - z)r(P_d - I_e) \\
&\quad + yz(1 - r)(P_d + \Delta P + T_e - \alpha M - \alpha I_e - F) + (1 - y)z(1 - r)(P_d - F) \\
&\quad + y(1 - z)(1 - r)(P_d + \Delta P + T_e - \alpha M - \alpha I_e) + (1 - y)(1 - z)(1 - r)P_d \\
&= P_d + y(\Delta P + T_e) - y(M + I_e)[r + (1 - r)\alpha] - (1 - y)rI_e - zF, \\
\bar{U}_1 &= xU_{11} + (1 - x)U_{12}.
\end{aligned} \tag{1}$$

According to the Malthusian dynamic equation, the replication dynamic equation of the e-commerce company is obtained as follows:

$$\begin{aligned}
F(x) &= \frac{dx}{dt} \\
&= x(U_{11} - \bar{U}_1) \\
&= x(1 - x)\{P_n - P_d - y\Delta P + y(M + I_e) \\
&\quad \cdot [r + (1 - r)\alpha] + (1 - y)rI_e + zF\}.
\end{aligned} \tag{2}$$

The first partial derivative of  $F(x)$  for  $x$  is as follows:

$$\begin{aligned}
F'_x(x) &= (1 - 2x)\{P_n - P_d - y\Delta P + y(M + I_e) \\
&\quad \cdot [r + (1 - r)\alpha] + (1 - y)rI_e + zF\}.
\end{aligned} \tag{3}$$

Based on the stability theorem of differential equations, the e-commerce company implements the strategy of nondifferential pricing in the stable state must meet the conditions:  $F(x) = 0$ , and  $F'_x(x) < 0$ .

**Proposition 1.** *When  $r > r_0$ , the stable strategy of the e-commerce company is nondifferential pricing; when  $r < r_0$ , the stable strategy of the e-commerce company is differential pricing; when  $r = r_0$ , the e-commerce company cannot determine the stable strategy. Where the threshold is as follows:*

$$r_0 = \frac{P_d + y\Delta P - P_n - \alpha y(M + I_e) - zF}{(1 - \alpha)yM + (1 - \alpha y)I_e}. \tag{4}$$

*Proof.* Assume  $H(r) = P_n - P_d - y\Delta P + y(M + I_e)[r + (1 - r)\alpha] + (1 - y)rI_e + zF$ , when  $y[M - \alpha(M + I_e)] > 0$ ,  $(\partial H/\partial r) > 0$ , then  $H(r)$  is considered to be an increasing function of  $r$ . When  $r > r_0$ ,  $H(r) > 0$ ,  $F(x)|_{x=1} = 0$ , and  $F'_x(x)|_{x=1} < 0$ , so  $x=1$  has stability; When  $r < r_0$ ,  $H(r) < 0$ ,  $F(x)|_{x=0} = 0$ , and  $F'_x(x)|_{x=0} < 0$ , so  $x=0$  has stability; when  $r = r_0$ ,  $H(r) = 0$ ,  $F(x) = 0$ , and  $F'_x(x) = 0$ , so  $x$  is stable at all levels in the range of 0 to 1, that is, the company's strategy does not change over time, regardless of the proportion of company choosing to price differentially.

Proposition 1 states that the increase of the proportion of the government strict supervision to e-commerce company will change the stable strategy of e-commerce company from

differential pricing to nondifferential pricing; Similarly, the decline of the proportion of the government strict supervision to e-commerce company will change the stable strategy of e-commerce company from nondifferential pricing to differential pricing. Therefore, the government's strict supervision for e-commerce company is essential, and the government should take measures to improve strict supervision for the e-commerce company.

Based on Proposition 1, the phase diagram of the strategy evolution of e-commerce company is shown in Figure 2.
