Inference 1: with the increase of the value of  $P_n$ ,  $M$ ,  $I_e$ ,  $F$ , and  $\alpha$ , the e-commerce company is more inclined to implement the nondifferential pricing strategy, when other parameters remain unchanged. Similarly, with the increase of the value of  $P_d$  and  $\Delta P$ , the e-commerce company is more inclined to implement the differential pricing strategy. It shows that the proportion of e-commerce company implementing nondifferential pricing strategy is directly proportional to the benefits of nondifferential pricing, the fines imposed by the government and platform on e-commerce company for differential pricing and the probability of consumers' discovery, and inversely proportional to the benefits of e-commerce company implementing differential pricing strategy.  $\square$

*Proof.* Since  $r_0 = (P_d + y\Delta P - P_n - \alpha y(M + I_e) - zF) / ((1 - \alpha)yM + (1 - \alpha y)I_e)$ , the volume of  $V_{x1}$  in Figure 2 represents the proportion of nondifferential pricing by the e-commerce company, and the corresponding volume of  $V_{x0}$  represents the proportion of differential pricing by the e-commerce company. When the value of  $P_n$ ,  $M$ ,  $I_e$ ,  $F$ , and  $\alpha$  gradually increases, the value of  $r_0$  will gradually decrease, and the volume of  $V_{x1}$  will increase at this time, indicating that the proportion of e-commerce company to implement nondifferential pricing increases; When the value of  $P_d$  and  $\Delta P$  gradually increases, the value of  $r_0$  will gradually increase, and the volume of  $V_{x1}$  will decrease at this time, indicating that the proportion of e-commerce company to implement nondifferential pricing decreases.  $\square$

**3.4.2. Strategy Stability Analysis of the Consumer.** Assuming that the expected benefit of the consumer when choosing loyalty strategy to e-commerce company is  $U_{21}$ , the expected benefit of the consumer when choosing disloyalty

FIGURE 2: Phase diagram of strategy evolution of e-commerce company.

strategy to e-commerce company is  $U_{22}$ , and the average expected benefit of the consumer is  $\overline{U}_2$ , which are defined as follows:

$$\begin{aligned}
 U_{21} &= xzrU_l + (1-x)zr[U_l - \Delta P + M + (1-\beta)F] \\
 &\quad + x(1-z)rU_l + (1-x)(1-z)r(U_l - \Delta P + M) \\
 &\quad + xz(1-r)U_l + (1-x)z(1-r) \\
 &\quad \cdot [U_l - \Delta P - C_c + \alpha M + (1-\beta)F] \\
 &\quad + x(1-z)(1-r)U_l + (1-x)(1-z) \\
 &\quad \cdot (1-r)(U_l - \Delta P - C_c + \alpha M) \\
 &= U_l - (1-x)\Delta P + (1-x)[M + (1-r)\alpha M] \\
 &\quad - (1-x)(1-r)C_c \\
 &\quad + (1-x)z(1-\beta)F, \\
 U_{22} &= xzrU_d + (1-x)zrU_d \\
 &\quad + x(1-z)rU_d \\
 &\quad + (1-x)(1-z)rU_d \\
 &\quad + xz(1-r)U_d \\
 &\quad + (1-x)z(1-r)U_d \\
 &\quad + x(1-z)(1-r)U_d \\
 &\quad + (1-x)(1-z)(1-r)U_d \\
 &= U_d, \\
 \overline{U}_2 &= yU_{21} + (1-y)U_{22}.
 \end{aligned} \tag{5}$$

According to the Malthusian dynamic equation, the replication dynamic equation of consumer is obtained as follows:

$$\begin{aligned}
 F(y) &= \frac{dy}{dt} \\
 &= y(U_{21} - \overline{U}_2) \\
 &= y(1-y) \left\{ \begin{array}{l} U_l - U_d - (1-x)\Delta P \\ + (1-x)[M + (1-r)\alpha M] \\ - (1-x)(1-r)C_c + (1-x)z(1-\beta)F \end{array} \right\}.
 \end{aligned} \tag{6}$$

The first partial derivative of  $F(y)$  for  $y$  is as follows:

$$\begin{aligned}
 F'_y(y) &= (1-2y)\{U_l - U_d - (1-x)\Delta P + (1-x)[M + (1-r)\alpha M] \\
 &\quad - (1-x)(1-r)C_c + (1-x)z(1-\beta)F\}.
 \end{aligned} \tag{7}$$

Based on the stability theorem of differential equations, consumer implements the strategy of loyalty in the stable state must meet the conditions:  $F(y) = 0$ , and  $F'_y(y) < 0$ .

**Proposition 2.** When  $x > x_0$ , the stable strategy of the consumer is loyalty; when  $x < x_0$ , the stable strategy of the consumer is disloyalty; when  $x = x_0$ , the consumer cannot determine the stable strategy. Where the threshold is as follows:

$$x_0 = \frac{U_l - U_d + M - \Delta P + (1-r)(\alpha M - C_c) + z(1-\beta)F}{M - \Delta P + (1-r)(\alpha M - C_c) + z(1-\beta)F}. \tag{8}$$

*Proof.* Assume  $H(x) = U_l - U_d - (1-x)\Delta P + (1-x)[M + (1-r)\alpha M] - (1-x)(1-r)C_c + (1-x)z(1-\beta)F$ , when  $M - \Delta P + (1-r)(\alpha M - C_c) + z(1-\beta)F > 0$ ,  $(\partial H/\partial x) > 0$ ,  $H(x)$  is considered to be an increasing function of  $x$ . When  $x > x_0$ ,  $H(x) > 0$ ,  $F(y)|_{y=1} = 0$ , and  $F'_y(y)|_{y=1} < 0$ , so  $y = 1$  has stability; When  $x < x_0$ ,  $H(x) < 0$ ,  $F(y)|_{y=0} = 0$ , and  $F'_y(y)|_{y=0} < 0$ , so  $y = 0$  has stability; When  $x = x_0$ ,  $H(x) = 0$ ,  $F(y) = 0$ , and  $F'_y(y) = 0$ , so  $y$  is stable at all levels in the range of 0 to 1, that is, the consumer's strategy does not change over time, regardless of the proportion of consumer choosing to be loyal.

Proposition 2 states that the increase of the proportion of nondifferential pricing of e-commerce company will change the stable strategy of consumer from disloyalty to loyalty; Similarly, the decline of the proportion of nondifferential pricing of e-commerce company will change the stable strategy of consumer from loyalty to disloyalty. Therefore, e-commerce company should reduce the degree of difference in pricing for consumers and try to retain consumers.

Based on Proposition 2, the phase diagram of the strategy evolution of consumer is shown in Figure 3.

Inference 2: with the increase of the value of  $U_l$ ,  $M$ ,  $F$ ,  $\alpha$ , and  $\beta$ , the consumer is more inclined to be loyalty strategy to

FIGURE 3: Phase diagram of strategy evolution of consumer.

the e-commerce company, when other parameters remain unchanged. Similarly, with the increase of the value of  $U_d$ ,  $\Delta P$ , and  $C_c$ , the consumer is more inclined to be disloyalty strategy to the e-commerce company. It shows that the proportion of consumer being loyalty strategy to e-commerce company is directly proportional to the utility obtained by the loyal consumer from purchasing goods, the fines imposed by the government and e-commerce platform for differential pricing of e-commerce company, and the probability of consumers' discovery, and inversely proportional to the utility obtained by the disloyal consumer in purchasing goods, the additional benefit obtained by the e-commerce company in implementing differential pricing, the proportion of fines imposed by the platform to the e-commerce company and the cost of consumer complaints.  $\square$

*Proof.* Since  $x_0 = 1 - (U_l - U_d / \Delta P + (1-r)C_c - [1 + (1-r)\alpha]M - z(1-\beta)F)$ , the volume of  $V_{y1}$  in Figure 3 represents the proportion of loyalty to e-commerce company by the consumer, and the corresponding volume of  $V_{y0}$  represents the proportion of disloyalty to e-commerce company by the consumer. When the value of  $U_b$ ,  $M$ ,  $I_e$ ,  $F$ , and  $\alpha$  gradually increases, the value of  $x_0$  will gradually decrease, and the volume of  $V_{y1}$  will increase at this time, indicating that the proportion of loyalty to e-commerce company by the consumer increases; When the value of  $U_d$ ,  $\Delta P$ ,  $\beta$  and  $C_c$  gradually increase, the value of  $x_0$  will gradually increase, and the volume of  $V_{y1}$  will decrease at this time, indicating that the proportion of loyalty to e-commerce company by consumer decreases.  $\square$

### 3.4.3. Strategy Stability Analysis of E-Commerce Platform.

Assuming that the expected benefit of the e-commerce platform when choosing the information supervision strategy is  $U_{31}$ , the expected benefit of the e-commerce platform when choosing the information nonsupervision strategy is  $U_{32}$ , and the average expected benefit of the e-commerce platform is  $\bar{U}_3$ , which are defined as follows:

$$\begin{aligned}
 U_{31} &= xy r(W - C_p + T_p) + x(1-y)r(W - C_p) \\
 &\quad + (1-x)(yrW - C_p + T_p + \beta F) \\
 &\quad + (1-x)(1-y)r(W - C_p + T_p) \\
 &\quad + xy(1-r)(W - C_p + \beta F) \\
 &\quad + x(1-y)(1-r)(W - C_p) \\
 &\quad + (1-x)y(1-r)(W - C_p + T_p + \beta F) \\
 &\quad + (1-x)(1-y)(1-r)(W - C_p + \beta F) \\
 &= W - C_p + F + yT_p - xF, \\
 U_{32} &= xy r(W + T_p) + x(1-y)rW \\
 &\quad + (1-x)yr(W - I_p + T_p) \\
 &\quad + (1-x)(1-y)r(W - I_p) \\
 &\quad + xy(1-r)(W + T_p) \\
 &\quad + x(1-y)(1-r)W \\
 &\quad + (1-x)y(1-r)(W - \alpha I_p + T_p) \\
 &\quad + (1-x)(1-y)(1-r)W \\
 &= W + yT_p - (1-x)rI_p - (1-x)y(1-r)I_p, \\
 \bar{U}_3 &= zU_{31} + (1-z)U_{32}.
 \end{aligned} \tag{9}$$

According to the Malthusian dynamic equation, the replication dynamic equation of e-commerce platform is obtained as follows:

$$\begin{aligned}
 F(z) &= \frac{dz}{dt} \\
 &= z(U_{31} - \bar{U}_3) \\
 &= z(1-z)\{\beta F - C_p + yT_p - x\beta F \\
 &\quad - (1-x)rI_p - (1-x)y(1-r)I_p\}.
 \end{aligned} \tag{10}$$

The first partial derivative of  $F(z)$  for  $z$  is as follows:

$$\begin{aligned}
 F'_z(z) &= (1-2z)\{\beta F - C_p + yT_p - x\beta F \\
 &\quad - (1-x)rI_p - (1-x)y(1-r)I_p\}.
 \end{aligned} \tag{11}$$

Based on the stability theorem of differential equations, e-commerce platform implements the strategy of information supervision in the stable state must meet the conditions:  $F(z) = 0$ , and  $F'_z(z) < 0$ .

**Proposition 3.** *When  $y > y_0$ , the e-commerce platform will choose information supervision as the stable strategy; when  $y < y_0$ , the e-commerce platform will choose information nonsupervision as the stable strategy; when  $y = y_0$ , the e-commerce platform cannot determine the stable strategy. Where the threshold is as follows:*

$$y_0 = \frac{C_p + x\beta F + (1-x)rI_p - \beta F}{T_p - (1-x)(1-r)I_p}. \quad (12)$$

*Proof.* Assume  $H(y) = F - C_p + yT_p - xF - (1-x)y(1-r)I_p$ , when  $T_p - (1-x)(1-r)I_p > 0$ ,  $(\partial H/\partial x) > 0$ ,  $H(y)$  is considered to be an increasing function of  $y$ . When  $y > y_0$ ,  $H(y) > 0$ ,  $F(z)|_{z=1} = 0$ , and  $F'_z(z)|_{z=1} < 0$ , so  $z = 1$  has stability; When  $y < y_0$ ,  $H(y) < 0$ ,  $F(z)|_{z=0} = 0$ , and  $F'_z(z)|_{z=0} < 0$ , so  $z = 0$  has stability; When  $z = z_0$ ,  $H(y) = 0$ ,  $F(z) = 0$ , and  $F'_z(z) = 0$ , so  $z$  is stable at all levels in the range of 0 to 1, that is, the e-commerce platform's strategy does not change over time, regardless of the proportion of e-commerce platform choosing information supervision.

Proposition 3 states that the increase of the proportion of consumer loyalty will change the stable strategy of e-commerce platform from information nonsupervision to information supervision. Similarly, the decline of the proportion of consumer loyalty will change the stable strategy of e-commerce platform from information supervision to information nonsupervision. Therefore, if the consumer can be loyal to the e-commerce company in the platform, the platform will also actively supervise its subordinate company.

Based on Proposition 3, the phase diagram of the strategy evolution of the e-commerce platform is shown in Figure 4.

*Inference 3:* with the increase of the value of  $F$ ,  $\beta$ , and  $T_p$ , the e-commerce platform is more inclined to implement the information supervision strategy, when other parameters remain unchanged. Similarly, with the increase of the value of  $C_p$  and  $I_p$ , the e-commerce platform is more inclined to implement the information nonsupervision strategy. It shows that the proportion of e-commerce platform implementing information supervision strategy is directly proportional to the fines imposed by the platform for differential pricing of e-commerce company, the proportion of fines imposed by the e-commerce platform for differential pricing of e-commerce company, and the reputation value brought by the loyal consumer to the platform, and inversely proportional to the cost of the platform's information supervision on e-commerce company and the fines by government imposed on the platform for nonsupervision of e-commerce company information resulting in differential pricing.  $\square$

*Proof.* Since  $y_0 = (C_p + (1-x)rI_p - (1-x)\beta F) / (T_p - (1-x)(1-r)I_p)$ , the volume of  $V_{z1}$  in Figure 4 represents the

proportion of information supervision of e-commerce company by the platform, and the corresponding volume of  $V_{z0}$  represents the proportion of information non-supervision by the platform. When the value of  $F$ ,  $\beta$ , and  $T_p$  gradually increase, the value of  $y_0$  will gradually decrease, and the volume of  $V_{z1}$  will increase at this time, indicating that the proportion of e-commerce platform to implement information supervision increases; When the value of  $C_p$  and  $I_p$  gradually increases, the value of  $y_0$  will gradually increase, and the volume of  $V_{z1}$  will decrease at this time, indicating that the proportion of e-commerce platform to implement information supervision decreases.  $\square$

**3.4.4. Strategy Stability Analysis of Government Regulatory Department.** Assuming that the expected benefit of government regulatory department when government implementing the strategy of strictly supervising is  $U_{41}$ , the expected benefit of government regulatory department when government implementing the strategy of loosely supervising is  $U_{42}$ , and the average expected benefit of the government regulatory department is  $\overline{U}_4$ , which are defined as follows:

$$\begin{aligned} U_{41} &= xyz(S - C_g + R) + x(1-y)z(S - C_g + R) \\ &\quad + (1-x)yz(S - C_g + I_e) + (1-x)(1-y)z(S - C_g + I_e) \\ &\quad + xy(1-z)(S - C_g + R) + x(1-y)(1-z)(S - C_g + R) \\ &\quad + (1-x)y(1-z)(S - C_g + I_e + I_p) \\ &\quad + (1-x)(1-y)(1-z)(S - C_g + I_e + I_p) \\ &= S - C_g + xR + (1-x)I_e + (1-x)(1-z)I_p. \\ U_{42} &= xyzS + x(1-y)zS + (1-x)yz(S - N + \alpha I_e) \\ &\quad + (1-x)(1-y)z(S - N) + xy(1-z)S \\ &\quad + x(1-y)(1-z)S + (1-x)y(1-z)(S - N + \alpha I_e + \alpha I_p) \\ &\quad + (1-x)(1-y)(1-z)(S - N) \\ &= S - (1-x)N + (1-x)y\alpha[I_e + (1-z)I_p], \\ \overline{U}_4 &= rU_{41} + (1-r)U_{42}. \end{aligned} \quad (13)$$

According to the Malthusian dynamic equation, the replication dynamic equation of the government regulatory department is obtained as follows:

$$\begin{aligned} F(r) &= \frac{dr}{dt} \\ &= r(U_{41} - \overline{U}_4) \\ &= r(1-r)\{-C_g + xR + (1-x)I_e + (1-x)(1-z)I_p \\ &\quad + (1-x)N - (1-x)y\alpha[I_e + (1-z)I_p]\}. \end{aligned} \quad (14)$$

The first partial derivative of  $F(r)$  for  $r$  is as follows:

FIGURE 4: Phase diagram of strategy evolution of e-commerce platform.

$$F'_r(r) = (1 - 2r) \left\{ -C_g + xR + (1 - x)I_e + (1 - x)(1 - z)I_p + (1 - x)N - (1 - x)y\alpha [I_e + (1 - z)I_p] \right\}. \quad (15)$$

Based on the stability theorem of differential equations, government regulatory department implements the strategy of strictly supervising in the stable state must meet the conditions:  $F(r) = 0$ , and  $F'_r(r) < 0$ .

**Proposition 4.** When  $z > z_0$ , the government regulatory department will choose strict supervision as the stable strategy; when  $z < z_0$ , the stable strategy of the government regulatory department will choose loose supervision as the stable strategy; when  $z = z_0$ , the government regulatory department cannot determine the stable strategy. Where the threshold is as follows:

$$z_0 = \frac{-C_g + xR + (1 - x)(1 - \alpha y)I_p + (1 - x)[(1 - \alpha y)I_e + N]}{(1 - x)(1 - \alpha y)I_p}. \quad (16)$$

*Proof.* Assume  $H(z) = -C_g + xR + (1 - x)I_e + (1 - x)(1 - z)I_p + (1 - x)N - (1 - x)y\alpha [I_e + (1 - z)I_p]$ , when  $(\partial H/\partial x) < 0$ ,  $H(z)$  is considered to be an increasing function of  $z$ . When  $z < z_0$ ,  $H(z) > 0$ ,  $F(r)|_{r=1} = 0$ , and  $F'_r(r)|_{r=1} < 0$ , so  $r = 1$  has stability; When  $z > z_0$ ,  $H(z) < 0$ ,  $F(r)|_{r=0} = 0$ , and  $F'_r(r)|_{r=0} < 0$ , so  $r = 0$  has stability; When  $z = z_0$ ,  $H(z) = 0$ ,  $F(r) = 0$ , and  $F'_r(r) = 0$ , so  $z$  is stable at all levels in the range of 0 to 1, that is, the government regulatory department's strategy does not change over time, regardless of the proportion of government regulatory department choosing to strict supervision.

Proposition 4 states that the decline of the proportion of information supervision of e-commerce company by e-commerce platform will change the stable strategy of government regulatory department from loose supervision to strict supervision; Similarly, the increase of the proportion of information supervision of e-commerce company by e-commerce platform will change the stable strategy of government regulatory department from strictly supervising to loosely supervising. Therefore, the government's strict

supervision on e-commerce company is the necessary measure under the unfavorable conditions of the e-commerce platform's information supervision on e-commerce company.

Based on Proposition 4, the phase diagram of strategy evolution of the government regulatory department is shown in Figure 5.

*Inference 4:* With the increase of the value of  $R$ ,  $I_e$ ,  $I_p$ , and  $N$ , the government regulatory department is more inclined to implement the strict supervision strategy, when other parameters remain unchanged. Similarly, with the increase of the value of  $C_g$  and  $\alpha$ , the government is more inclined to implement the loose supervision strategy. It shows that the proportion of government regulatory department implementing strict supervision strategy is directly proportional to the social benefits obtained, the fines punished by the government on e-commerce company and platform, and the social reputation loss caused by differential pricing under the government's loose supervision, and inversely proportional to the cost for the government to strictly supervise and the proportion of consumer discovering differential pricing.  $\square$

*Proof.* Since  $z_0 = 1 - (C_g - xR - (1 - x)[(1 - \alpha y)I_e + N]) / ((1 - x)(1 - \alpha y)I_p)$ , the volume of  $V_{r1}$  in Figure 5 represents the proportion of strictly supervised by the government, and the corresponding volume of  $V_{r0}$  represents the proportion of loosely supervised by government. When the value of  $R$ ,  $I_e$ ,  $I_p$ , and  $N$  gradually increases, the value of  $z_0$  will gradually increase, and the volume of  $V_{r1}$  will increase at this time, indicating that the proportion of strict supervision by government regulatory department increases; When the value of  $C_g$  and  $\alpha$  gradually increase, the value of  $z_0$  will gradually decrease, and the volume of  $V_{r1}$  will decrease at this time, indicating that the proportion of strict supervision by government regulatory department increases decreases.  $\square$

## 4. Results and Discussion

*4.1. ESS Analysis among Four-Party Game Players.* In the dynamic system of government regulatory department,

FIGURE 5: Phase diagram of strategy evolution of government regulatory department.

e-commerce platform, e-commerce company and consumer, the stability of the strategic combination of the four-party game subjects can be referred to as the nonlinear function stability discriminant method of First Law of Lyapunov. Ritzberger and Weibull [38] and Selten [39] pointed out that the stable solutions in the multi-group evolutionary game are strict Nash equilibrium, which must be the pure strategy. Therefore, this study analyzes 16 pure strategies in four-party evolutionary game learning from the research method of Sun and Su [40].

Due to the replication dynamic equation of each game subject, the Jacobian matrix is obtained as follows:

$$J = \begin{bmatrix} F'_x(x) & F'_y(x) & F'_z(x) & F'_r(x) \\ F'_x(y) & F'_y(y) & F'_z(y) & F'_r(y) \\ F'_x(z) & F'_y(z) & F'_z(z) & F'_r(z) \\ F'_x(r) & F'_y(r) & F'_z(r) & F'_r(r) \end{bmatrix}, \quad (17)$$

where the elements in the matrix are shown in Appendix A.

#### 4.1.1. ESS Analysis among Four-Party Game Players under the Strict Supervision of Government Regulatory Department.

When  $C_g - xR - (1-x)I_e - (1-x)(1-z)I_p - (1-x)N + (1-x)\gamma\alpha[I_e + (1-z)I_p] < 0$ , government regulatory department implements strict supervision. According to the Jacobian matrix shown in Appendix B, the equilibrium solution of the four-party evolutionary game can be obtained, and the stability analysis is shown in Table 3.

Condition (a):  $-P_n + P_d + \Delta P - M - I_e < 0$ ,  $C_g - R < 0$ , and  $-C_p + T_p < 0$

Condition (b):  $-P_n + P_d + \Delta P - M - I_e - F < 0$ ,  $C_g - R < 0$ , and  $C_p - T_p < 0$

It can be seen from Table 3 that there are two possible stable strategies under strict supervision by the government regulatory department, i.e. E5 (1, 1, 0, 1) and E8 (1, 1, 1, 1).

When the condition (a) is met, that is,  $-P_n + P_d + \Delta P - M - I_e < 0$ ,  $C_g - R < 0$ , and  $-C_p + T_p < 0$ . The sum of the benefits of differential pricing to loyal consumers by

TABLE 3: Asymptotic stability analysis of equilibrium point of replication dynamic system under the strict supervision of government regulatory department.

Equilibrium point	Eigenvalue symbol	Stability of equilibrium point
E1 (0, 0, 0, 1)	(+, X, X, X)	Instability point
E2 (1, 0, 0, 1)	(-, +, -, -)	Instability point
E3 (0, 1, 0, 1)	(+, X, X, -)	Instability point
E4 (0, 0, 1, 1)	(+, X, X, -)	Instability point
E5 (1, 1, 0, 1)	(-, -, -, -)	ESS in condition (a)
E6 (1, 0, 1, 1)	(-, +, +, -)	Instability point
E7 (0, 1, 1, 1)	(+, X, X, -)	Instability point
E8 (1, 1, 1, 1)	(-, -, -, -)	ESS in condition (b)

Note: X means uncertain of symbol, and ESS means the evolutionarily stable strategy.

e-commerce company is less than the sum of the benefits of nondifferential pricing by e-commerce company to the consumer and the fines to the e-commerce company for differential pricing and compensation of e-commerce company to consumer by the government. The strict supervision cost is less than the social benefits when controlling differential pricing for the government. And the reputation value produced by the loyal consumer to the platform is less than the cost of the platform information supervision. Then the strategy of each subject is stable at equilibrium point E5 (1, 1, 0, 1). E-commerce company implements nondifferential pricing, the consumer is loyal to the e-commerce company, e-commerce platform implements information nonsupervision, and the government strictly supervises e-commerce platform and e-commerce company. This situation may exist in the period of chaotic pricing for the e-commerce company. Since the e-commerce platform benefits less from the information supervision of e-commerce company, it has no motivation to supervise e-commerce company. Therefore, the government must come forward to supervise differential pricing, safeguard consumer rights and interests, and help e-commerce company gain consumer loyalty.

When the condition (b) is met, that is  $-P_n + P_d + \Delta P - M - I_e - F < 0$ ,  $C_g - R < 0$ , and  $C_p - T_p < 0$ . With the

improvement of consumers' awareness of differential pricing and the reduction of the cost of platform supervising information, the information supervision cost of the platform is less than the reputation value brought by the loyal consumer to the platform, and the e-commerce platform can also join into the supervision of e-commerce company. When the other conditions remain unchanged, the strategy of each subject is stable at equilibrium point E8 (1, 1, 1). The government and e-commerce platform jointly strengthen the supervision of differential pricing of e-commerce company, so that e-commerce company inclined to to be nondifferential pricing, and consumer is loyal to the e-commerce company.

#### 4.1.2. ESS Analysis among Four-Party Game Players under the Loose Supervision of Government Regulatory Department.

When  $C_g - xR - (1-x)I_e - (1-x)(1-z)I_p - (1-x)N + (1-x)y\alpha[I_e + (1-z)I_p] > 0$ , government regulatory department implements loosely supervision. According to the Jacobian matrix shown in Appendix C, the equilibrium solution of the four-party evolutionary game can be obtained, and the stability analysis is shown in Table 4.

Condition (c):  $-P_n + P_d + \Delta P - \alpha(M + I_e) - F < 0$ ,  $C_p - T_p < 0$ , and  $-C_g + R < 0$ .

As shown in Table 4 that there is a possible stabilization strategy under loose supervision by government regulatory authorities, i.e. E16 (1, 1, 1, 0).

When the condition (c) is met, that is,  $-P_n + P_d + \Delta P - \alpha(M + I_e) - F < 0$ ,  $C_p - T_p < 0$ , and  $-C_g + R < 0$ . The sum of the benefits of e-commerce company's differential pricing for the loyal consumer is less than the sum of the benefits of e-commerce company's nondifferential pricing for consumer, the fines punished by government regulatory department under loosely supervising and the compensation for the consumer for differential pricing of e-commerce company, and the fines imposed by e-commerce platform on the e-commerce company. The reputation value brought by the loyal consumer to the platform is greater than the cost of the platform information supervision. And the strict supervision cost is greater than the social benefits when controlling differential pricing for the government. Then the strategy of each subject is stable at equilibrium point E16 (1, 1, 1, 0). This situation may exist in the normative period of discriminatory pricing by the e-commerce company. At this time, as the proportion of the differential pricing of e-commerce company gradually decreases, the social benefits of the government's strict supervision of differential pricing decrease. When the social benefit is less than the strictly supervising cost of the government regulatory department, the strategy of the government regulatory department will change from strictly supervising to loosely supervising. The main responsibility of supervision will be transferred from the government to the e-commerce platform and consumer. Supervision and fines by e-commerce platform and consumer enable e-commerce company to conduct nondifferential pricing and promote the virtuous circle of the e-commerce industry ecosystem.

TABLE 4: Asymptotic stability analysis of equilibrium point of replication dynamic system under the loose supervision of government regulatory department.

Equilibrium point	Eigenvalue symbol	Stability of equilibrium point
E9 (0, 0, 0, 0)	(+, X, X, X)	Instability point
E10 (1, 0, 0, 0)	(-, +, X, X)	Instability point
E11 (0, 1, 0, 0)	(+, X, X, X)	Instability point
E12 (0, 0, 1, 0)	(+, X, X, X)	Instability point
E13 (1, 1, 0, 0)	(X, -, X, +V)	Instability point
E14 (1, 0, 1, 0)	(X, +, +, +)	Instability point
E15 (0, 1, 1, 0)	(+, X, X, X)	Instability point
E16 (1, 1, 1, 0)	(-, -, -, -)	ESS in condition (c)

Note: X means uncertain of symbol, and ESS means the evolutionarily stable strategy.

4.2. Numerical Simulation Analysis. In order to test the reliability of the model and more intuitively demonstrate the influence of key factors in the replication dynamic system on the evolutionary trajectory of stakeholders of the multi-party game, the model is given numerical value combined with the actual situation, and the numerical simulation is carried out by MATLAB2021.

For the e-commerce company operating in the e-commerce platform, the benefit of nondifferential pricing to the consumer is set as  $P_n = 10$ , and the benefit of differential pricing to the consumer is set as  $P_d = 9$ , and the additional benefit of differential pricing to the loyal consumer is set as  $\Delta P = 5$ . If differential pricing is discovered by the government, the compensation of the e-commerce company to the consumer is set as  $M = 4$ . The reputation value brought by the loyal consumer to the e-commerce company is set as  $T_e = 5$ , and the reputation value brought by the loyal consumer to the e-commerce platform is set as  $T_p = 5$ . The utility obtained by the loyal consumer when purchasing goods from the e-commerce company is set as  $U_l = 12$ , and the utility obtained by the disloyal consumer when purchasing goods from the e-commerce company is set as  $U_d = 11$ . The probability of loyal consumer discovering differential pricing under government loose supervision is set as  $\alpha = 0.2$  and the complaint cost of the loyal consumer is set as  $C_c = 3$ . The social benefit of nondifferential pricing obtained by the government under strict supervision is set as  $R = 7$ , and the cost of strictly supervised by the government is set as  $C_g = 6$ . The fine by government regulatory department for differential pricing of e-commerce company  $I_e = 3$ . The social reputation loss of the government caused by differential pricing under loose supervision is set as  $N = 8$ . The normal benefit obtained by the government from the operation of the platform is set as  $S = 6$ . The benefit of the platform reasonably providing information to e-commerce company is set as  $W = 5$ , and the cost of the platform's information supervision on e-commerce company is set as  $C_p = 7$ . The fine imposed by the platform to e-commerce company for differential pricing during information supervision is set as  $F = 3$ , and the proportion of fine imposed by the e-commerce platform for differential pricing of the e-commerce company is set as  $\beta = 0.6$ .

FIGURE 6: Influence of the establishment of government supervision mechanism on strategy evolution of all parties.

**4.2.1. The Influence of Government Supervision Mechanism.** To test whether the government supervision mechanism is effective in the process of differential pricing of e-commerce company, the proportions of government strict supervision are set as  $r=0$  and  $r=1$  to represent the two states of loose supervision and strict supervision of government supervision department. The evolution process of different initial strategies of the e-commercial company, consumer, and e-commerce platform is simulated and analyzed in three-dimensional space, and the simulation results with time are shown in Figure 6.

As shown in Figure 6(a) that when government regulatory department adopts the strict supervision strategy on the differential pricing of e-commerce company, although the e-commerce platform does not take information supervision strategy on account of the high cost for information supervision, the strategies of the e-commerce company and consumer can still incline to be stable in nondifferential pricing and loyalty. This shows that it is very necessary and effective for the government to adopt the strict supervision strategy. With the reduction of  $C_p$ , that is, the information supervision cost reduced, the platform will be inclined to adopt the strategy of information supervision, to achieve coordinated supervision to e-commerce company by the government and platform, then the company adopts

nondifferential pricing, and consumer is loyal to the e-commerce company. And the stable strategy portfolio is demonstrated in Figure 6(b). As is exhibited in Figure 6(c) that when government regulatory department implements the loosely supervising to e-commerce company for the differential pricing due to the high cost of strict supervision, if  $C_p$  is small, that is, the cost of information supervision on the e-commerce platform is small, and  $\alpha$  is at a high level, the consumer can actively discover the differential pricing of the e-commerce company and report it, the e-commerce company will also incline to nondifferential pricing. Therefore, although the government selects the loose supervision strategy, the differential pricing behavior of e-commerce company is supervised collaboratively by the platform and consumer. The strategy equilibrium is consistent with the previous analysis of the stability under different government supervision strategies.

**4.2.2. The Influence of Information Supervision Cost of E-Commerce Platforms.** If  $C_p = \{7, 4, 1\}$ , the stability of the system evolution of the four-party game subjects and the simulation results are shown in Figure 7.

According to Figure 7, with the reduction of the information supervision cost of the e-commerce platform, the

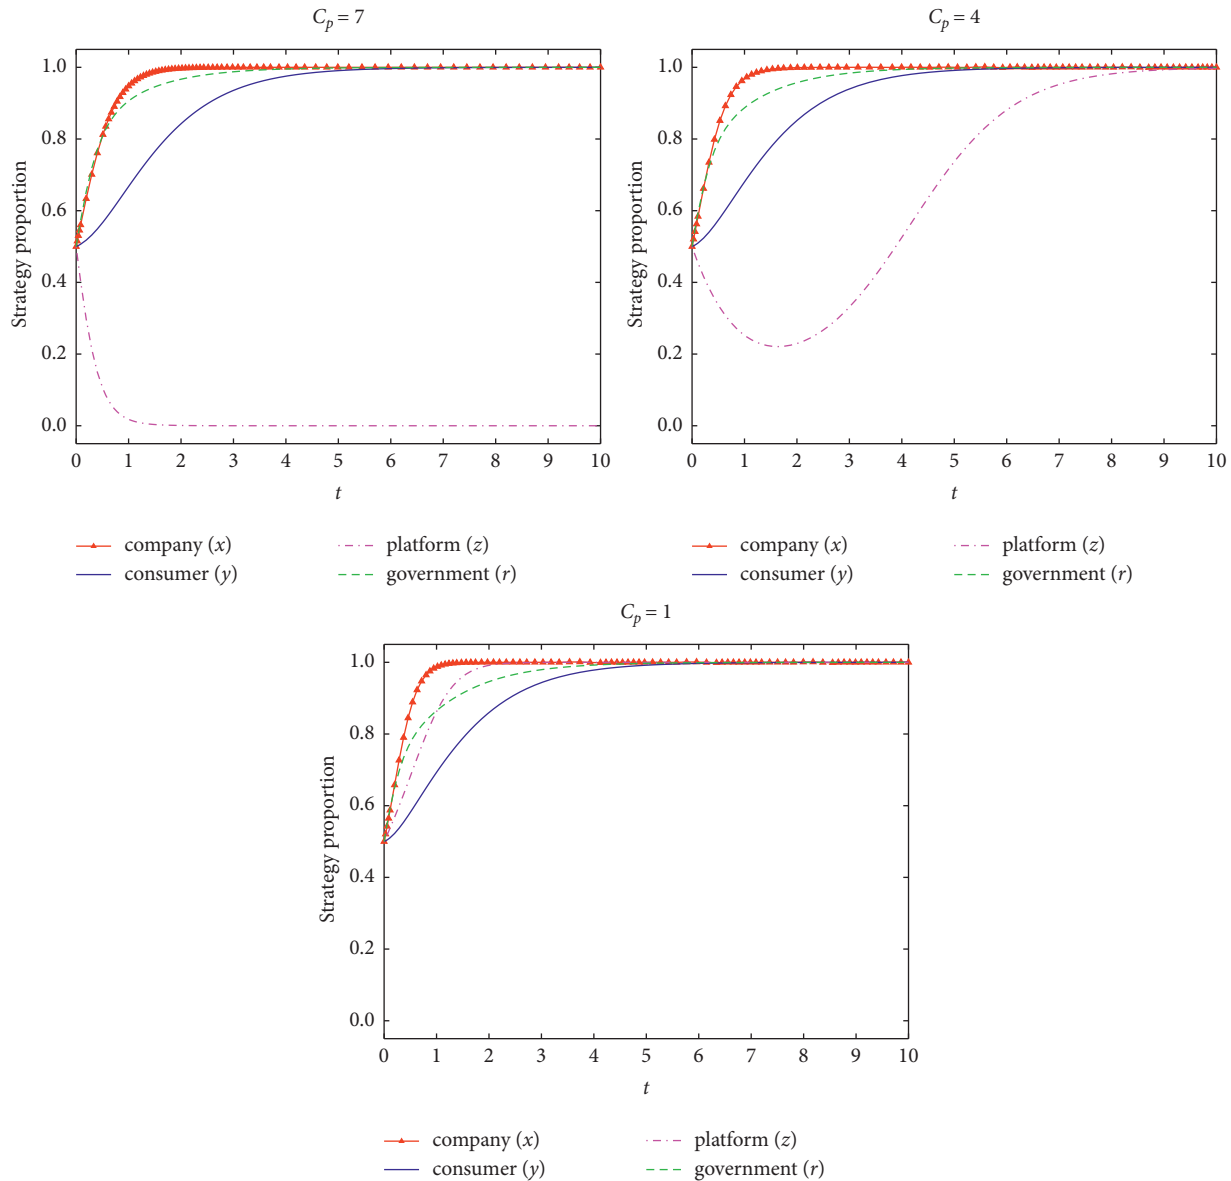

FIGURE 7: Influence of information supervision cost of e-commerce platform on strategy evolution of all parties.

supervision strategy of the platform will be transformed from information nonsupervision on e-commerce company to information supervision. Therefore, the platform can join the ranks of the government to regulate the company, and collaboratively supervise the differential pricing of the e-commerce company for loyal consumer. Moreover, the less the information supervision cost of the platform, the faster the stable strategy of information supervision. Therefore, active measures can be adopted to lower the cost for information supervising of e-commerce platform, to stimulate e-commerce platform to supervise the differential pricing behavior of e-commerce company on the platform.

4.2.3. *The Influence of the Strict Supervision Cost of Government Regulatory Department.* If  $C_g = \{6, 8, 10\}$ , the stability of the system evolution of the four-party

game subjects and the simulation results are shown in Figure 8.

According to Figure 8, the strict supervision cost of government affects the decision-making of government regulatory department, as well as affects the evolution of decision-making of the other subjects. With the increase of government supervision cost, the supervision strategy of the government regulatory department to the differential pricing of e-commerce company will be transformed from strict supervision to loose supervision, and gradually become the cyclical alternating strategy between strict supervision and loose supervision with medium proportion. The strategy of the e-commerce platform will be also transformed from information supervision to information nonsupervision of e-commerce company when strictly supervising cost of government Increasing. Free from the supervision of government regulatory department and platform, the pricing strategy of the company for the loyal

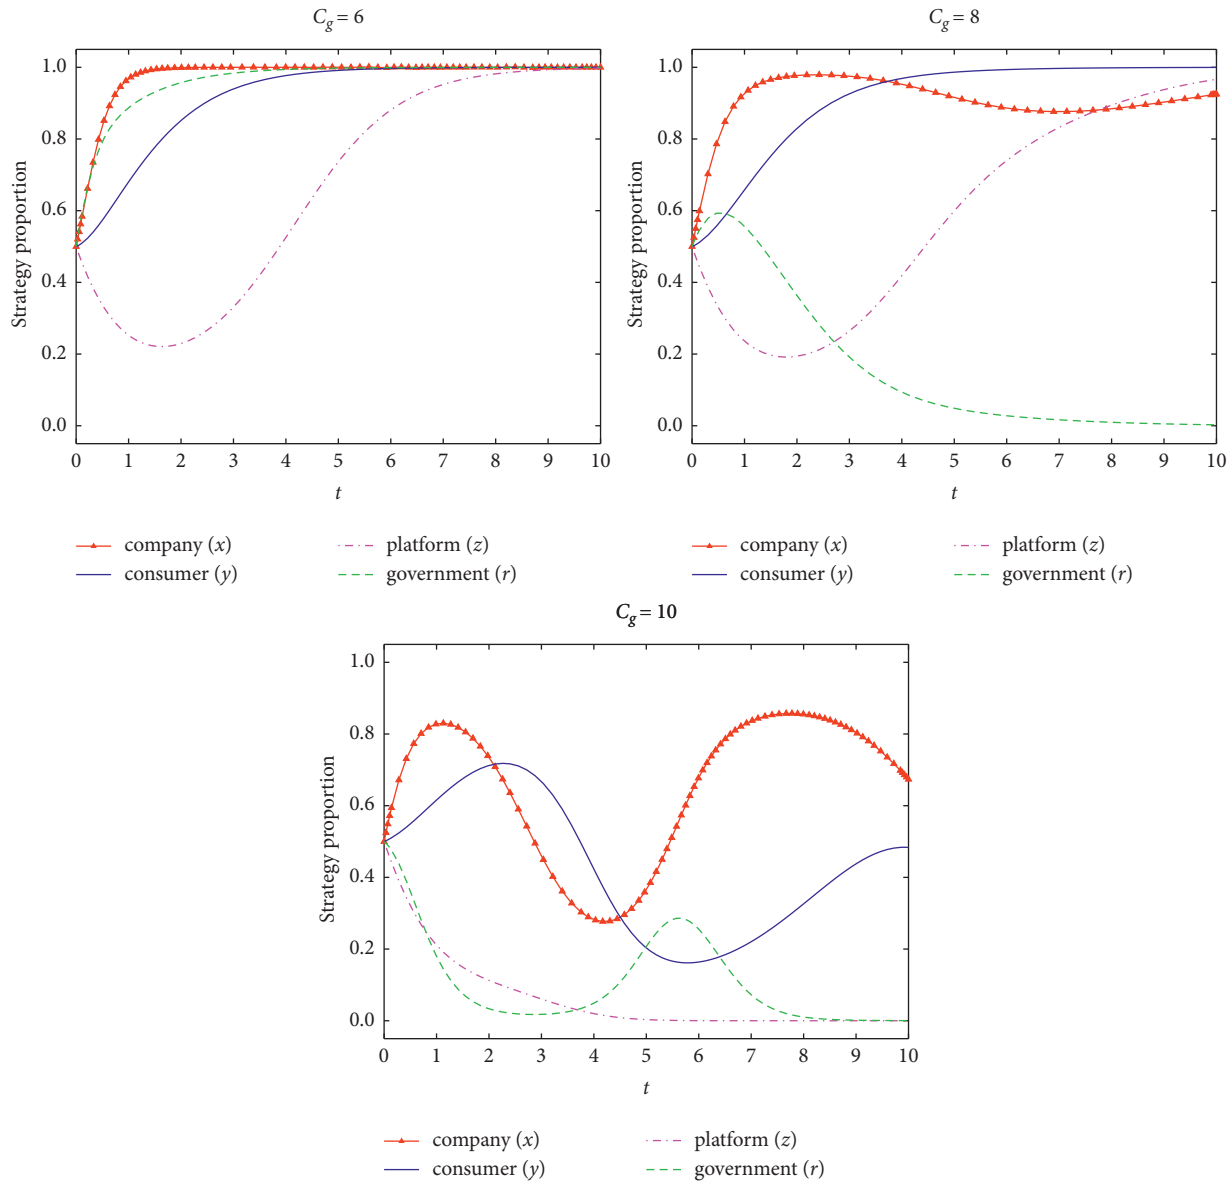

FIGURE 8: Influence of strict supervision cost of government regulatory department on strategy evolution of all parties.

consumer will be transformed from nondifferential pricing to moderate-proportion differential pricing, and the strategy change periodically. With the increase of the strictly supervising cost of government, the strategy of the consumer will be transformed from loyalty to e-commerce company to disloyalty. Therefore, the strict supervision cost of the government regulatory department is the key factor in restricting the differential pricing of the e-commerce company. Measures should be arranged to actively reduce the strictly supervising cost of the government regulatory department at a certain level, to stimulate platform and the consumer to regulate the behavior of e-commerce company in differential pricing.

4.2.4. The Influence of the Probability of Loyal Consumer Discovering Differential Pricing under Government’s Loose Supervision. If  $\alpha = \{0.1, 0.3, 0.5\}$ , the stability of the system

evolution of the four-party game subjects and the simulation results are shown in Figure 9.

According to Figure 9, with the increase of probability of loyal consumer discovering differential pricing under government loose supervision, the probability of exposure of differential pricing behavior of e-commerce company for loyal consumer increases, which will make e-commerce company gradually improve the proportion of nondifferential pricing and stabilize in the nondifferential pricing strategy. The e-commerce platform can also gradually improve the proportion of information supervision due to the increase of fines for nonsupervision of e-commerce company information resulting in differential pricing, and the behavior stabilizes in the information supervision strategy. The government regulatory department can gradually loose supervision and transfer the responsibility of supervision to e-commerce platform and

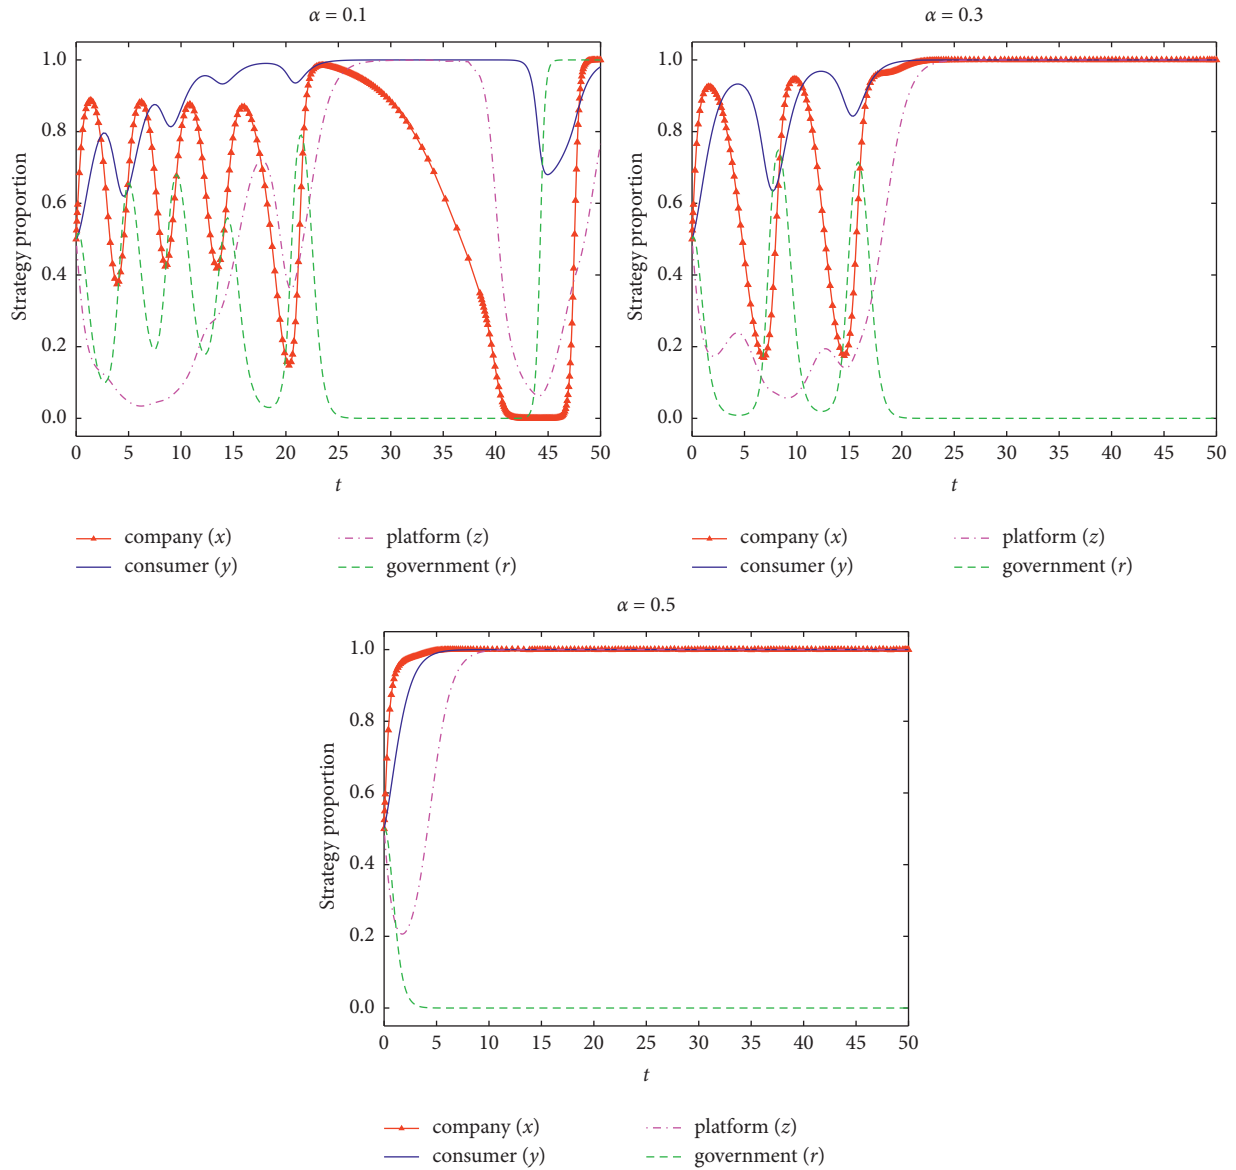

FIGURE 9: Influence of the probability of loyal consumer discovering differential pricing under government loose supervision on strategy evolution of all parties.

the consumer. Therefore, measures can be taken to encourage the consumer to report the differential pricing behavior of e-commerce company, to maintain the stable and sustainable progress of e-commerce platform and systems.

**4.2.5. The Influence of the Penalties for Differential Pricing of E-Commerce Company under Government's Loose Supervision.** If  $M = \{1, 2, 4\}$ ,  $I_e = \{1, 2, 4\}$ , and  $F = \{1, 2, 4\}$ , the evolution process and results of the strategy of the four-party game subjects are shown in Figure 10.

According to Figure 10, with the increase of the fines given by consumer, e-commerce platform, and government regulatory department for differential pricing of e-commerce company, the e-commerce company will gradually

increase the proportion of nondifferential pricing and stabilize in the nondifferential pricing strategy. The consumer will increase the proportion of loyalty to the e-commerce company and the behavior stabilize in the loyalty strategy when the compensation for differential pricing from e-commerce company increases to compensate for the loss of differential pricing. The e-commerce platform will also gradually improve the proportion of information supervision due to the increase of benefits from information supervision fines and the behavior stabilizes in the information supervision strategy. Therefore, the nondifferential pricing behavior of e-commerce company can be promoted by increasing the punishment for differential pricing, to realize the joint dynamic supervision of the e-commerce platform, the consumer, and the government on the pricing of the e-commerce company.

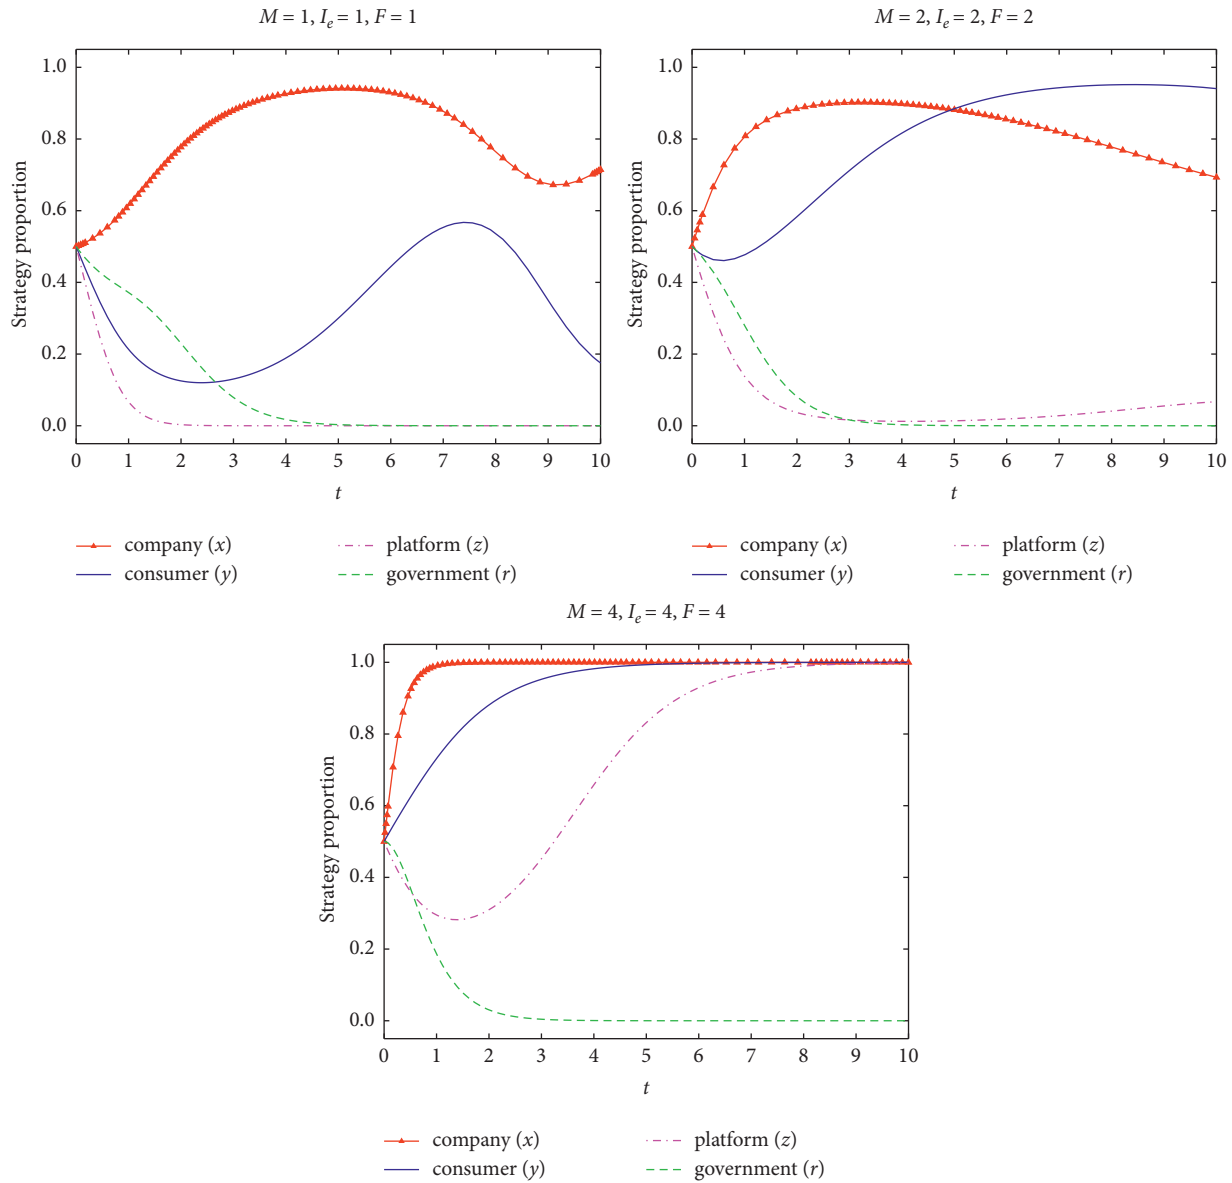

FIGURE 10: Influence of the penalties for differential pricing of e-commerce company under government loose supervision on strategy evolution of all parties.

### 5. Conclusions

Given the phenomenon of “big data killing” that e-commerce companies use customer information in the pricing process, this paper studies how to safeguard consumers’ pricing fairness in the context of the Internet, and builds the four-party evolutionary game model for the supervision on differential pricing of e-commerce company, analyzes the stability of the strategy selection of each subject in the model, and the stability of equilibrium point of the strategic combination in the replication dynamic system, and simulates and analyzes the influence of key elements on the strategy evolution. The main conclusions are as follows:

- (1) The government supervision mechanism can play an effective role to limit differential pricing of the e-commerce company. When the proportion of

strict government supervision adds, the sum of the benefits of differential pricing for loyal consumers by e-commerce company is less than the penalty cost of e-commerce company, and strict supervision cost of government is less than its social benefits, then e-commerce company inclines more to choose the strategy of nondifferential pricing. Since the reputation value of the e-commerce platform is less than the information supervision cost of platform, the platform inclines more to conduct information nonsupervision. Therefore, the equilibrium strategy of each subject is stable at point E5 (1, 1, 0, 1), which occurs in the early stage of the government’s strict supervision on the e-commerce company. With the reduction of the supervision cost of the platform, it is also willing to join the supervision on differential

pricing of e-commerce company for the platform and inclines more to choose information supervision strategy. Therefore, the equilibrium strategy of each subject is stable at point E8 (1, 1, 1, 1), which occurs in the stable stage of the government's strict supervision of e-commerce company, and the participation of the e-commerce platform relieved the pressure on government supervising on the company. When the strictly supervising cost of government increases, the reputation value of the platform is greater than the supervision cost of the platform, then the government regulatory department inclines more to loose supervision strategy. Therefore, the equilibrium strategy of each subject is stable at point E16 (1, 1, 1, 0), which occurs in the later stage of the government's strict supervision of e-commerce company. When both e-commerce platform and consumer realize the important role of supervision and conduct strong collaborative supervision, the government can take the way of auxiliary supervision to control the differential pricing of the e-commerce company.

- (2) The information supervision cost of the e-commerce platform is the main factor affecting the supervision strategy of the platform. When the supervision cost of the platform is greater than the reputation value of the platform, the platform inclines more to conduct information nonsupervision. However, as the information supervision cost of the platform decreases and is less than the reputation value of the platform, the stable strategy of the e-commerce platform will transform into information supervision and then promote nondifferential pricing for the e-commerce company. Moreover, the less the information supervision cost of the e-commerce platform, the faster the stable strategy of the e-commerce platform can transform into the information supervision strategy.
- (3) The strict supervision cost of government is the main factor affecting the strategies of all parties. When the strict supervision cost of government is so small as to be less than the social benefits of government strict supervision on differential pricing of e-commerce company, the equilibrium strategy of all parties is that both government regulatory department and e-commerce platform implement supervision, e-commerce company conduct nondifferential pricing, and consumer is loyal to the e-commerce company. However, when the strict supervision cost of government increases and exceeds the social benefits of government strict supervision on differential pricing of e-commerce company, the government gradually inclines to loose supervision strategy. At this moment, if platform and consumer can supervise the pricing of the e-commerce company to a certain extent, e-commerce company still incline to nondifferential pricing strategy. When the strict supervision cost of government increases to a very high level, not only the government cannot

strictly supervise, but also e-commerce platform will not supervise the information used by the e-commerce company. Then e-commerce company will incline to differentiate pricing, and the consumer will be disloyal.

- (4) The probability of the consumer discovering differential pricing under the government's loose supervision policy is an important factor affecting the strategies of all parties. As strict supervision cost of government is at a higher level, and the probability of consumer discovering differential pricing of the e-commerce company is small, neither the government nor the e-commerce platform can incline to the more stable behavioral strategy. Although customer inclines to be loyal to the e-commerce company, the strategies of four subjects cannot maintain the stable equilibrium, and the strategy of e-commerce company become cyclical alternating between differential pricing and nondifferential pricing. When the probability of consumer discovering differential pricing of e-commerce company increases, e-commerce company gradually inclines to nondifferential pricing strategy, e-commerce platform gradually inclines to information supervision strategy, and the government gradually inclines to loose supervision strategy. The equilibrium strategy of four-party behavior achieves. The higher the probability level of consumer discovering differential pricing, the faster the equilibrium strategy of four-party behavior achieves. This conclusion also confirms the conclusion in the research of Yu and Li [9] and Wu et al. [30] that the probability of consumer finding himself killed in price is the important factor affecting the strategy choice of consumer and company.
- (5) The penalties for differential pricing of e-commerce company under the government's loose regulatory are the important factors affecting the strategies of all parties. When consumers, e-commerce platform and government regulatory department impose the fines and compensation on differential pricing of e-commerce companies at a low level, the government and e-commerce platform incline to not supervise, and e-commerce company and consumer cannot maintain a stable equilibrium. When the penalties for differential pricing of e-commerce company is high, e-commerce platform inclines to supervise the information, consumer inclines to be loyal, while e-commerce company inclines to price nondifferentially, the government inclines to loose supervise, and the strategies remains stable. The higher the penalties for differential pricing of e-commerce company, the faster the equilibrium strategy of four-party behavior achieves.

In this study, the modeling analysis and simulation of the supervision of "big data killing" of e-commerce company are carried out, which breaks through the limitation of analyzing only two or three parties in the existing "big data killing"

problem. It is a beneficial supplement to systematic research on this issue that more participants consider their action strategies under the same system. The four-party evolutionary game model constructed also expands the application scope of the evolutionary game method in the study of pricing supervision of e-commerce company. The research conclusions can provide favorable theoretical support for the “big data killing” problem in practice.

Therefore, to better restrain the pricing behavior of e-commerce company, regulate differential pricing, and build a good e-commerce shopping environment, the following measures should be taken by the government regulatory department, e-commerce platform, e-commerce company, and consumer.

- (1) From the perspective of the government, the government regulatory department must supervise e-commerce company, especially in the early stage of price discrimination by using customer information. Therefore, the government needs to use economic and policy means to effectively manage the operation of e-commerce platform and company and promote the enthusiasm of e-commerce company to conduct nondifferential pricing. For example, adopting more advanced big data analysis technology to supervise price changes of e-commerce company; establishing more extensive and efficient reporting channels so that consumers can timely price complaints; improving corresponding legal measures to increase the violation cost of the e-commerce company and punishing “big data killing” from the aspects of economy and reputation. While supervising, it is also necessary to pay attention to reducing the strict supervision cost of the government regulatory department.
- (2) From the perspective of the e-commerce platform, as the important carrier of e-commerce operation, the e-commerce platform should strengthen information supervising of the e-commerce company. The e-commerce platform is the main body that controls customer information. E-commerce company conducts “big data killing” differential pricing based on the mastery of customer information. Therefore, the e-commerce platform needs to carry out information supervision when providing information for the e-commerce company and formulates policies to punish e-commerce company with differential pricing. It is also necessary to improve the technical management level of the e-commerce platform, and use innovative technology based on big data to monitor e-commerce company and reduce the supervision cost of the e-commerce platform.
- (3) From the perspective of consumers, they should actively protect their rights and interests. While online shopping brings convenience to consumers, it may also lead to the possibility of price discrimination with consumer information. In the process of e-commerce shopping, consumers will prefer some

e-commerce companies due to path dependence, and then form customer loyalty, but this path dependence should not be the reason for the differential pricing of e-commerce companies. Therefore, consumers should enhance price sensitivity and verify the displayed price of e-commerce companies through various channels, to reduce the infringement of consumer rights and interests by e-commerce companies.

- (4) From the perspective of the e-commerce company, although maximizing profits is the important motive of business behavior, the reputation and service in e-commerce shopping are the foundation for the long-term development of the e-commerce company. Under the market conditions where consumers’ transfer costs are getting lower and lower, the e-commerce company can grow gradually mainly based on gaining the loyal customer. Therefore, e-commerce company should not adopt the differential pricing strategy in pursuit of temporary benefits. Although the economic benefits brought by nondifferential pricing of e-commerce company are less in the short term, the reputation benefits and social benefits can create greater economic benefits for the development of the company in the long term, which are the wealth of e-commerce company. The reputation benefits and social benefits brought by nondifferential pricing can be benefit for the more fair and equitable overall development environment for e-commerce.

This study systematically analyzes the model on the supervision of “big data killing” in the e-commerce company. However, the mechanism setting of the four-party game in the study has been simplified to a certain extent, and the strategy space needs to be more detailed and in-depth, which should be improved in the future. Moreover, because the simulation data were conducted under simulated conditions according to actual conditions, there may be some deviations in the effectiveness of players’ behavior analysis in the “big data killing” game. In the future, methods such as data mining will be used to collect big data, and empirical analysis of evolutionary game will be carried out, to improve the research on the participants behavior of “big data killing” in e-commerce transactions.

## Appendix

### A. Jacobian Matrix of Replicated Dynamical Systems

$$J = \begin{bmatrix} F'_x(x) & F'_y(x) & F'_z(x) & F'_r(x) \\ F'_x(y) & F'_y(y) & F'_z(y) & F'_r(y) \\ F'_x(z) & F'_y(z) & F'_z(z) & F'_r(z) \\ F'_x(r) & F'_y(r) & F'_z(r) & F'_r(r) \end{bmatrix}. \quad (\text{A.1})$$

Among them,

$$\begin{aligned}
F'_x(x) &= (1-2x)\{P_n - P_d - y\Delta P + y(M + I_e)[r + (1-r)\alpha] + (1-y)rI_e + zF\}, \\
F'_y(x) &= x(1-x)\{-\Delta P + (M + I_e)[r + (1-r)\alpha] - rI_e\}, \\
F'_z(x) &= x(1-x)F, \\
F'_r(x) &= x(1-x)[y(M + I_e)(1-\alpha) - yI_e], \\
F'_x(y) &= y(1-y)\{\Delta P - [M + (1-r)\alpha M] + (1-r)C_c - z(1-\beta)F\}, \\
F'_y(y) &= (1-2y)\{U_l - U_d - (1-x)\Delta P + (1-x)[M + (1-r)\alpha M] - (1-x)(1-r)C_c + (1-x)z(1-\beta)F\}, \\
F'_z(y) &= y(1-y)\{(1-x)(1-\beta)F\}, \\
F'_r(y) &= y(1-y)\{(1-x)(-\alpha)M\} + (1-x)C_c\}, \\
F'_x(z) &= z(1-z)\{-\beta F + rI_p + y(1-r)I_p\}, \\
F'_y(z) &= z(1-z)\{T_p - (1-x)(1-r)I_p\}, \\
F'_z(z) &= (1-2z)\{\beta F - C_p + yT_p - x\beta F - (1-x)rI_p - (1-x)y(1-r)I_p\}, \\
F'_r(z) &= z(1-z)\{-(1-x)I_p + (1-x)yI_p\}, \\
F'_x(r) &= r(1-r)\{R - I_e - N - (1-z)I_p + y\alpha[I_e + (1-z)I_p]\}, \\
F'_y(r) &= r(1-r)\{-(1-x)\alpha[I_e + (1-z)I_p]\}, \\
F'_z(r) &= r(1-r)\{-(1-x)I_p + (1-x)y\alpha I_p\}, \\
F'_r(r) &= (1-2r)\{-C_g + xR + (1-x)I_e + (1-x)(1-z)I_p + (1-x)N - (1-x)y\alpha[I_e + (1-z)I_p]\}.
\end{aligned} \tag{A.2}$$

## B. Jacobian Matrix of Equilibrium Points of Reproduced Dynamic Systems under Government Strict Supervision

The Jacobian matrix of the equilibrium point E1 (0, 0, 0, 1) is as follows:

$$J_1 = \begin{bmatrix} P_n - P_d + I_e & 0 & 0 & 0 \\ 0 & U_l - U_d - \Delta P + M & 0 & 0 \\ 0 & 0 & \beta F - C_p - I_p & 0 \\ 0 & 0 & 0 & -I_e + C_g - N - I_p \end{bmatrix}. \tag{B.1}$$

The Jacobian matrix of the equilibrium point E2 (1, 0, 0, 1) is as follows:

$$J_2 = \begin{bmatrix} -P_n + P_d - I_e & 0 & 0 & 0 \\ 0 & U_l - U_d & 0 & 0 \\ 0 & 0 & -C_p & 0 \\ 0 & 0 & 0 & C_g - R \end{bmatrix}. \tag{B.2}$$

The Jacobian matrix of the equilibrium point E3 (0, 1, 0, 1) is as follows:

$$J_3 = \begin{bmatrix} P_n - P_d + \Delta P + M + I_e & 0 & 0 & 0 \\ 0 & -U_l + U_d + \Delta P - M & 0 & 0 \\ 0 & 0 & \beta F - C_p + T_p - I_p & 0 \\ 0 & 0 & 0 & C_g - (1 - \alpha)(I_e + I_p) - N \end{bmatrix}. \quad (\text{B.3})$$

The Jacobian matrix of the equilibrium point E4 (0, 0, 1, 1) is as follows:

$$J_4 = \begin{bmatrix} P_n - P_d + I_e + F & 0 & 0 & 0 \\ 0 & U_l - U_d - \Delta P + M + (1 - \beta)F & 0 & 0 \\ 0 & 0 & -\beta F + C_p + I_p & 0 \\ 0 & 0 & 0 & C_g - I_e - N \end{bmatrix}. \quad (\text{B.4})$$

The Jacobian matrix of the equilibrium point E5 (1, 1, 0, 1) is as follows:

$$J_5 = \begin{bmatrix} -P_n + P_d + \Delta P - M - I_e & 0 & 0 & 0 \\ 0 & -U_l + U_d & 0 & 0 \\ 0 & 0 & -C_p + T_p & 0 \\ 0 & 0 & 0 & C_g - R \end{bmatrix}. \quad (\text{B.5})$$

The Jacobian matrix of the equilibrium point E6 (1, 0, 1, 1) is as follows:

$$J_6 = \begin{bmatrix} -P_n + P_d - I_e - F & 0 & 0 & 0 \\ 0 & U_l - U_d & 0 & 0 \\ 0 & 0 & C_p & 0 \\ 0 & 0 & 0 & C_g - R \end{bmatrix}. \quad (\text{B.6})$$

The Jacobian matrix of the equilibrium point E7 (0, 1, 1, 1) is as follows:

$$J_7 = \begin{bmatrix} P_n - P_d - \Delta P + M + I_e + F & 0 & 0 & 0 \\ 0 & -U_l + U_d + \Delta P - M - (1 - \beta)F & 0 & 0 \\ 0 & 0 & -\beta F + C_p - T_p + I_p & 0 \\ 0 & 0 & 0 & C_g - (1 - \alpha)I_e - N \end{bmatrix}. \quad (\text{B.7})$$

The Jacobian matrix of the equilibrium point E8 (1, 1, 1, 1) is as follows:

$$J_8 = \begin{bmatrix} -P_n + P_d + \Delta P - M - I_e - F & 0 & 0 & 0 \\ 0 & -U_l + U_d & 0 & 0 \\ 0 & 0 & C_p - T_p & 0 \\ 0 & 0 & 0 & C_g - R \end{bmatrix}. \quad (\text{B.8})$$

### C. Jacobian Matrix of Equilibrium Points of Reproduced Dynamic Systems under Government Loose Supervision

The Jacobian matrix of the equilibrium point E9 (0, 0, 0, 0) is as follows:

$$J_9 = \begin{bmatrix} P_n - P_d & 0 & 0 & 0 \\ 0 & U_l - U_d - \Delta P + (1 + \alpha)M - C_c & 0 & 0 \\ 0 & 0 & \beta F - C_p & 0 \\ 0 & 0 & 0 & C_g - I_e - I_p - N \end{bmatrix}. \quad (\text{C.1})$$

The Jacobian matrix of the equilibrium point E10 (1, 0, 0, 0) is as follows:

$$J_{10} = \begin{bmatrix} -P_n + P_d & 0 & 0 & 0 \\ 0 & U_l - U_d & 0 & 0 \\ 0 & 0 & \beta F - C_p & 0 \\ 0 & 0 & 0 & -C_g + I_e + I_p + N \end{bmatrix}. \quad (\text{C.2})$$

The Jacobian matrix of the equilibrium point E11 (0, 1, 0, 0) is as follows:

$$J_{11} = \begin{bmatrix} P_n - P_d - \Delta P + \alpha(M + I_e) & 0 & 0 & 0 \\ 0 & -U_l + U_d + \Delta P - (1 + \alpha)M + C_c & 0 & 0 \\ 0 & 0 & \beta F - C_p + T_p - I_p & 0 \\ 0 & 0 & 0 & -C_g + (1 - \alpha)(I_e + I_p) + N \end{bmatrix}. \quad (\text{C.3})$$

The Jacobian matrix of the equilibrium point E12 (0, 0, 1, 0) is as follows:

$$J_{12} = \begin{bmatrix} P_n - P_d + F & 0 & 0 & 0 \\ 0 & U_l - U_d - \Delta P + (1 + \alpha)M - C_c + (1 - \beta)F & 0 & 0 \\ 0 & 0 & -\beta F + C_p & 0 \\ 0 & 0 & 0 & -C_g + I_e + N \end{bmatrix}. \quad (C.4)$$

The Jacobian matrix of the equilibrium point E13 (1, 1, 0, 0) is as follows:

$$J_{13} = \begin{bmatrix} -P_n + P_d + \Delta P - \alpha(M + I_e) & 0 & 0 & 0 \\ 0 & -U_l + U_d & 0 & 0 \\ 0 & 0 & -C_p + T_p & 0 \\ 0 & 0 & 0 & -C_g + R \end{bmatrix}. \quad (C.5)$$

The Jacobian matrix of the equilibrium point E14 (1, 0, 1, 0) is as follows:

$$J_{14} = \begin{bmatrix} -P_n + P_d - F & 0 & 0 & 0 \\ 0 & U_l - U_d & 0 & 0 \\ 0 & 0 & C_p & 0 \\ 0 & 0 & 0 & -C_g + R \end{bmatrix}. \quad (C.6)$$

The Jacobian matrix of the equilibrium point E15 (0, 1, 1, 0) is as follows:

$$J_{15} = \begin{bmatrix} P_n - P_d + \Delta P + \alpha(M + I_e) + F & 0 & 0 & 0 \\ 0 & -U_l + U_d + \Delta P - (1 + \alpha)M + C_c - (1 - \beta)F & 0 & 0 \\ 0 & 0 & -\beta F + C_p - T_p + I_p & 0 \\ 0 & 0 & 0 & -C_g + (1 - \alpha)I_e + N \end{bmatrix}. \quad (C.7)$$

The Jacobian matrix of the equilibrium point E16 (1, 1, 1, 0) is as follows:

$$J_{16} = \begin{bmatrix} -P_n + P_d + \Delta P - \alpha(M + I_e) - F & 0 & 0 & 0 \\ 0 & -U_l + U_d & 0 & 0 \\ 0 & 0 & C_p - T_p & 0 \\ 0 & 0 & 0 & -C_g + R \end{bmatrix}. \quad (C.8)$$

With the continuous development of the national economy and scientific productivity, urban construction and people's living standards are also getting higher and higher. Although people enjoy increasingly convenient life, the demand for intelligence is getting higher and higher. Digital intelligent equipment has the functions of data collection, calculation and analysis, diagnostic and early warning, and communication functions. Analyze the status quo and existing problems of the development of intelligent equipment, as well as analyze and research key monitoring technologies in the use and development of digital intelligent equipment and provide optimal solutions for intelligent equipment hardware development requirements, software development, and model algorithms. Intelligent equipment monitoring is related to all aspects of people's livelihood, and its intelligent development is related to the public role in this field in the future. Accurate results of monitoring can provide data support for schools, research institutions, the public, and the government. At the same time, it is also an important basis for formulating social policies. At present, the commonly used monitoring method usually adopts time series algorithm. Through literature review, it is found that the algorithm has the problem of distortion of correct data, which affects the accuracy of monitoring results. Based on the above reasons, this article combines the wavelet function with the planning algorithm and proposes a dynamic programming algorithm, which removes the redundant monitoring data in turn and clusters the distortion monitoring data with the wavelet function, which improves the accuracy and computational efficiency of the algorithm and gives full play to the monitoring of intelligence. The simulation results using MATLAB show that the planning algorithm can eliminate 90% of redundant monitoring data and improve the extraction rate of characteristic monitoring data. At the same time, the accuracy of the planning algorithm reaches 95%, and the calculation time is less than 25 s, which is better than the static planning algorithm. Therefore, the dynamic programming algorithm can better utilize the intelligence, convenience, and efficiency of the equipment to optimize the monitoring model.

## 1. Introduction

Intelligent devices have been widely used in engineering technology, industrial production, social services, medicine, and human health, and they have had an important impact. Intelligent equipment monitoring is an important part of social public health. It is not only the guarantee of Chinese public health but also the basis for the improvement of national quality [1]. The integration of intelligent equipment and modern technology not only enhances the intelligence of monitoring but also realizes its own function optimization. Continuous and dynamic intelligent equipment

monitoring and analysis of the public can help the government make health decisions and improve the disease resistance and physical quality of the public Beuchat et al. [2]. In the past, the public monitoring method was mainly planning algorithm. Although this algorithm can monitor the general health, it cannot carry out dynamic analysis, and the analysis results have some limitations. In addition, there are a lot of redundant data in intelligent equipment monitoring, which affects the monitoring results of college students [3]. At present, there are many researches on intelligent equipment device monitoring of college students, but the redundancy of monitoring data is also high, as shown

in Figure 1. Therefore, the application of dynamic programming method in the optimal control of intelligent equipment has very important theoretical significance. At the same time, the large-scale application of intelligent devices needs more effective algorithms as support, so this study can provide more practical cases, which has very important practical significance.

Some scholars such as Fortune et al. [4] also believe that the increasing intelligent characteristic data in the static programming algorithm will improve the intelligence of monitoring but reduce the accuracy of monitoring. Therefore, a dynamic programming algorithm is constructed and revised to improve the accuracy of the results [5]. As a processing method of comprehensive function, wavelet function can subcontract the content data into fragmented data groups, improve the processing capacity of initial data, and is widely used in the optimization of a large number of intelligent devices. However, it is not used in dynamic programming algorithm at present. Therefore, this article attempts to apply it to the dynamic programming algorithm and construct a new intelligent device optimization model, which aims to improve the data processing efficiency of intelligent devices and promote the development of intelligent devices. Dynamic programming algorithm is developed on the basis of static programming algorithm. It is to add time variables to the original algorithm and continuously combine the static programming algorithm. However, the fundamental difference between dynamic algorithm and static algorithm is to increase the coupling between different indexes and make the calculation results more continuous. At the same time, the improvement of coupling also increases the complexity of calculation and the incidence of redundant data. Based on the research of scholars at home and abroad, the integration of wavelet function and dynamic programming algorithm can use the subcontracting method of wavelet function to increase the data processing capacity of dynamic programming algorithm, reduce the occurrence rate of local extremum, and improve the accuracy of calculation results. Dynamic programming algorithm can continuously track intelligent devices without being affected by the increase of data volume. Therefore, the integration of wavelet function and dynamic programming algorithm has the advantage of comprehensive analysis and improves the processing capacity of calculation data. Based on the above reasons, this article combines the discrete wavelet function with the planning algorithm to construct a dynamic planning algorithm to optimize the health monitoring results of College Students' wearing devices [6]. Taking college students' physical health monitoring as an analysis case, this article improves the accuracy of the results, so as to better carry out intelligent health monitoring.

## 2. Algorithm Description of Intelligent Health Monitoring Devices

The key of intelligent equipment monitoring is to quantify the relevant indicators in intelligent equipment devices, so as to lay a mathematical foundation for dynamic monitoring. Among them, height, weight, 50-meter run, 800-meter run

(girls), and 1000-meter run (boys) have more wearing equipment [7], whereas there are relatively few data on vital capacity, standing long jump, sitting body flexion, sit ups, step test and pull-up, but the algorithm description of health monitoring data are required.

### 2.1. Intelligent Health Monitoring Process of College Students.

Intelligent health monitoring of intelligent equipment devices includes three aspects: the data structure  $x_i$  in sports intelligent equipment devices, the impact of intelligence on health monitoring  $x_j$ , and the dynamics  $x_k$  of health monitoring [8]. The data structure in the intelligent equipment device also includes the intelligent equipment device  $x_{i1}$ , the proportion of different sports  $x_{i2}$ , and the degree of cooperation between different sports  $x_{i3}$ ; similarly, the impact of intelligence on health monitoring include the promotion degree of intelligent technology to health monitoring  $x_{j1}$ , the integration degree of intelligent technology and health monitoring  $x_{j2}$ , and the promotion level of intelligent technology to health monitoring  $x_{j3}$ ; The dynamics of health monitoring include cooperation degree between cardio-pulmonary monitoring, blood oxygen monitoring, blood pressure monitoring, and exercise monitoring  $x_{k1}$ , cooperation between devices in different forms of intelligent technology  $x_{k2}$ , and communication cooperation between different intelligent technologies  $x_{k3}$ . According to the above analysis, college students' intelligent equipment monitoring involves many aspects, mainly including: height, weight, vital capacity, standing long jump, sitting forward flexion, 50 m running, sit ups, step test, pull up, 800 m running (girls), and 1000 m running (boys). At the same time, the collected monitoring data are massive (cloud monitoring data, a large number of applications of intelligent devices) and complex (there are a large number of unstructured monitoring data), which greatly reduces the accuracy of intelligent equipment monitoring in sports and cannot accurately reflect the intelligence of intelligent equipment devices. Because the mass and complexity are the inevitable trend of the development of intelligent equipment monitoring, a large amount of sports data of college students should be collected [9].

### 2.2. Data Flow Description of College Students' Intelligent Equipment Monitoring.

The stable wavelet function extracts the redundant data in college students' sports, makes discrete analysis on the intelligent equipment devices, and obtains the comprehensive monitoring data, so as to arrange the data in order to improve the accuracy of monitoring [10].

At the same time, the stable wavelet function uses discrete extraction to ensure the integrity of monitoring data in college students' sports and complete the single-phase characteristics of monitoring data in order. The specific monitoring data flow is described in Figure 2:

- (1) Assuming that the intelligent equipment monitoring result is  $A$  and any intelligent equipment device  $A_i = \{a_1, a_2, \dots, a_n\}$ , the relationship between  $A$  and each input monitoring data as follows:

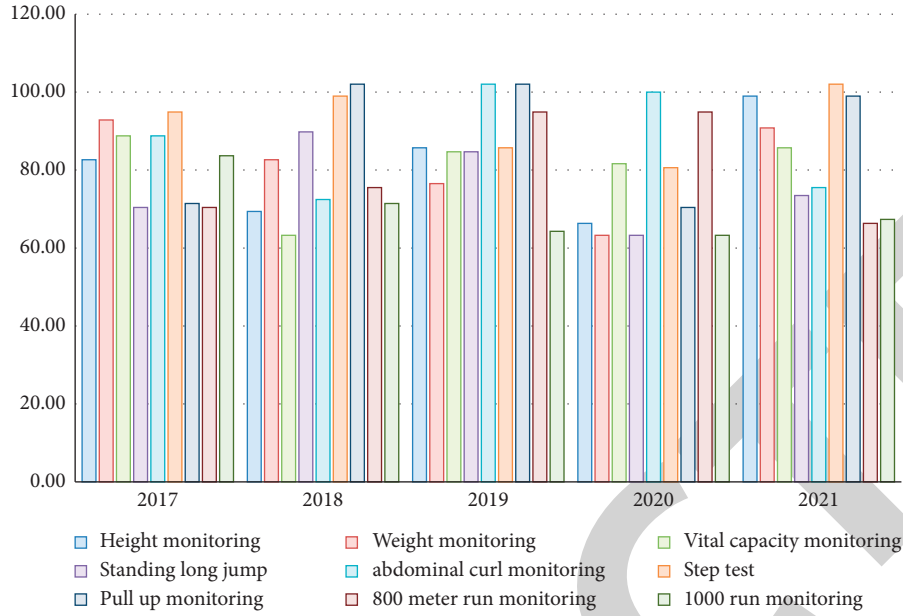

FIGURE 1: The monitoring proportion of intelligent equipment devices in different sports events from 2017 to 2021.

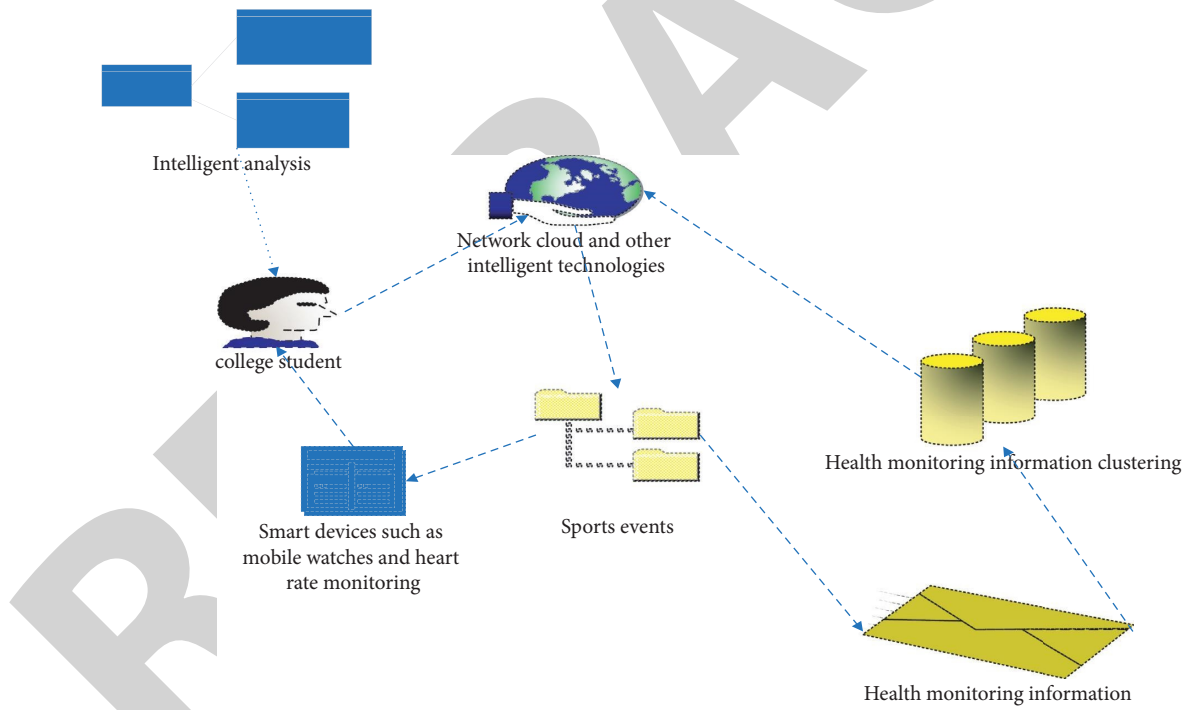

FIGURE 2: The intelligent equipment monitoring of intelligent equipment devices on College Students' sports events.

$$\sum_l^n A_l \overset{TS(\cdot)}{\underset{f(\cdot)}{\leftarrow}} \oint_n \overset{k\text{-means}}{\prod_{\text{indevie } i} \sum_i^n x_i \overset{g(\bullet)}{\rightleftharpoons} \sum_j^n x_j \overset{g(\bullet)}{\rightleftharpoons} \sum_k^n x_k}, \quad (1)$$

where  $i, j, k$  are natural numbers,  $TS(\cdot)$  is the dynamic programming function,  $f(\cdot)$  is the stable wavelet function,  $G(\cdot)$  is the forward function between different input indexes, and  $-G(\cdot)$  is the reverse function to complete the dynamic monitoring.

(2) Suppose that the monitoring result  $a_l$  of any sports event in intelligent health monitoring and the input  $z$  in the planning algorithm (data structure  $x_i$  in intelligent equipment devices [11], impact of intelligent technology on health monitoring  $x_j$ , and dynamic  $x_k$  of health monitoring),  $p$  is the proportion of monitoring data (structured monitoring data  $>70\%$ , semistructured monitoring data  $>70\%$ , unstructured monitoring data  $>70\%$ ),  $q$  is the processing method of monitoring data distortion

(reconstruction = 1, coefficient order = 2, quantification = 3, eigenvalue = 4, clustering = 4), then  $c_l$  is described as  $\text{Inc}_l^{o,p,q}$ ,  $o \in (1, 2, \dots, n)$ ,  $p \in (1, 2, 3, 4)$ ,  $q \in (1, 2, 3, 4)$ .

Among them, the logarithm in  $\ln(\cdot)$  of  $c_l$  is used to avoid  $|\infty|$  or extreme value 0, so as to ensure the effectiveness of the calculation results. The monitoring results of any sports are shown in Figure 2.

- (3) The data structure  $x_i$  in devices, the impact of intelligence on health monitoring  $x_j$ , and the dynamic  $x_k$  of health monitoring adopt the fusion function  $f(x)$  and propose the redundant monitoring data in college students' sports. The calculation formula of the function is as follows:

$$\varphi(x) = \frac{\left[ \left( \sum_{i=1}^n \alpha_1 x_i + \sum_{j=1}^n \alpha_2 x_j + \sum_{k=1}^n \alpha_3 x_k \right) + \xi \right]}{\sum_{i,j,k=1}^n (x_i + x_j + x_k)}, \quad (2)$$

where,  $\alpha_1$ ,  $\alpha_2$ , and  $\alpha_3$  are the weight coefficients of intelligent health monitoring equipment, college students, and sports, respectively, and  $\xi$  is the adjustment error. The weight coefficient  $\xi$  is calculated from the data published by the National College Students' intelligent health monitoring organization [12].

- (4) The health monitoring data of dynamic planning is mainly based on the statistical data of the National Center for Disease Control and Prevention. The intelligent health monitoring time is calculated as  $T$ , the evaluation results  $\theta$ , and the simplification rate of health monitoring data = (monitoring data before processing - monitoring data after processing) / (the total number of monitoring data obtained (100 m running, standing long jump, etc.) \* 100%). The specific formula is as follows:

$$\iota = \frac{\|H(\cdot) - G_{i,j,k}\|}{\|G_i + G_j + G_k\|} \cdot \begin{pmatrix} \alpha_i & 0 & 0 \\ 0 & \alpha_j & 0 \\ 0 & 0 & \alpha_k \end{pmatrix} \cdot 100\%, \quad (3)$$

where  $G_{i,j,k}$  is the intelligent monitoring data of  $x_i$ ,  $x_j$ , and  $x_k$ ,  $G_i$ ,  $G_j$ , and  $G_k$  is the total amount of  $x_i$ ,  $x_j$ , and  $x_k$ ,  $H(\cdot)$  is the processed intelligent monitoring data,

and  $\begin{pmatrix} \alpha_i & 0 & 0 \\ 0 & \alpha_j & 0 \\ 0 & 0 & \alpha_k \end{pmatrix}$  is the weight of the intelligent monitoring data in  $x_i$ ,  $x_j$ , and  $x_k$ .

- (5) In order to improve the complex data (structured, semi-structured and unstructured) in college students' sports, realize the "intelligence" of the transformation between health monitoring data and reduce the error of initial monitoring data, subcontracting can be used for processing. Because the attribute of intelligent monitoring data is relatively simple, the Euclidean distance can be used for

wavelet packet. First set the range of structured, unstructured, and semistructured monitoring data, and the formula is as follows:

$$|S| = \frac{c_l}{\left( \sum_{l=0}^n c_l + \mu^2 \right)}, \quad (4)$$

where  $|S|$  is the Euclidean distance of each monitoring data;  $c_l$  is the intelligent;  $c_0$  is the initial cluster value;  $\mu$  is the allowable error of clustering and is set by the power industry in the early stage of calculation,  $\sum_{l=0}^n c_l$  is the set of  $c_l$ . According to formula (1) to formula (4) steps to calculate the conclusion, the dynamic programming algorithm uses the judgment matrix of wavelet function to subcontract the overall data. At the same time, sort the subcontracted data to form an orderly data flow. On this basis, the data processing capacity of dynamic programming method decreases exponentially. At the same time, the continuous tracking of dynamic programming algorithm increases the total amount of data, but the amount of data processing can be further improved by setting the subcontracting value. Therefore, the advantages of wavelet function and dynamic programming algorithm in data processing are very obvious.

### 3. Build an Intelligent Health Monitoring Model Based on Dynamic Programming Algorithm

3.1. Construct the Relationship among College Students' Data Structure, Health Monitoring Impact, and Health Monitoring Dynamics. Intelligent health monitoring not only considers the monitoring accuracy of  $x_i$ ,  $x_j$ , and  $x_k$  but also considers the synergy among them. Therefore, the relationship operator between  $x_i$ ,  $x_j$ , and  $x_k$  should be constructed. It is assumed that the relationship between the three is divided into local fusion relationship ( $x_i$  and  $x_j$ ,  $x_i$  and  $x_k$ , and  $x_j$  and  $x_k$ ) and overall fusion relationship ( $x_i, x_j, x_k$ ), which are expressed by  $P_c$  and  $P_m$ , respectively. Then, the calculation formula is as follows:

$$P_c = P_m \begin{cases} P_{c_0} \\ \varphi(x) \left[ \frac{(P_{c_{x_i,j,k}} - P_{\min})}{\sum P_{c_{x_i,j,k}} - P_{\max}} \right], \\ P_m \approx 0 \text{ or } 1 \\ P_{\max} \langle 1, P_m \rangle 1 \end{cases} \quad (5)$$

where,  $P_{c_0}$  is local fusion, all fusion,  $P_{\min}$  and  $P_{\max}$  are the minimum  $P_c$  and  $P_m$  maximum values, which are set by local universities, and  $\varphi(x)$  is the fusion degree function of the above analysis, the value is between 0 and 1.

3.2. *Construct the Accuracy Model of College Students' Intelligent Health Monitoring.* Accuracy is the key index of intelligent health monitoring [13], and it is also the main

$$Inc_l^{o,p,q} = \begin{cases} 0 < Inc_l^{o,p,q} < 1 \\ Inc_l^{o,p,q} < \left\| \max [Inc_l^{n,n,n}] \right\| \\ \int_{I,j}^n \left( \sum_{I=1}^n \max (Inc_l^{o,p,q}) \right) \begin{matrix} \gg \\ \ll \end{matrix} \min (Inc_l^{o,p,q}) \end{cases} |tP_c \neq P_m, P_{\max} < 1, \text{ and } P_m > 1 \rangle \quad (6)$$

Since the accuracy of  $x_i, x_j$  and  $x_k$  is  $0 < Inc_l^{o,p,q} < 1$ ,  $0 < Inc_l^{o,p,q} < 1$  are required to shorten the range of  $\max (Inc_l^{o,p,q}) \gg \min (Inc_l^{o,p,q})$  calculation accuracy. At the same time, the fusion error of the calculation results should be reduced, so  $\prod \varphi(x) \lim_{l \rightarrow \infty} \oint_l \sin(\alpha_{1,2,3}) 0 \sim 0.1$  should be between 0 and 0.1.

3.3. *Calculation Steps of Operators in Intelligent Health Monitoring of College Students' Intelligent Equipment Devices*

- (1) Build an intelligent health monitoring data set,  $C_l = \{c_1, c_2, \dots, c_i\}$  and eliminate the intelligent monitoring data with digitization degree of  $< 60\%$ . Determine the weight coefficient and adjustment error according to the digital Economic Yearbook of power industry from 2015 to 2020;
- (2) The monitoring data  $c_l$  processed by wavelet function are processed structurally [14], semistructurally and unstructured to realize the "cleaning" of intelligent monitoring data.
- (3) Judge the fusion relationship of the monitoring data after "cleaning" and obtain the values of  $P_c$  and  $P_m$  of local and overall fusion relationships.
- (4) The iterative analysis of steps 1~4 is carried out using MATLAB software, and the accuracy, calculation time, and effectiveness of the calculation results are output. The result are shown in Figure 3.

## 4. The the Case Analysis of Intelligent Health Monitoring Based on Dynamic Programming Algorithm

4.1. *The Actual Case Analysis.* Taking college students in various regions as the research object, analyze the data structure  $x_i$  in intelligent equipment devices, the impact of intelligence on health monitoring  $x_j$ , and the dynamics of health monitoring  $x_k$  as the input indicators. Local universities and national CDC provide  $c_0 = 22.3$ ,  $\mu = 0.02$ ,  $\alpha_0 = 0.41$ , 100 iterations, and  $P_{\min} = 0.23$ ,  $P_{\max} = 0.99$ . The specific monitoring data are shown in Table 1.

purpose of dynamic programming algorithm optimization. Therefore, the accuracy operator should be constructed. The specific formula is as follows:

4.2. *The Comparison of Data Processing Capacity of College Students' Intelligent Health Monitoring.* The dynamic programming algorithm uses wavelet packet to preprocess the intelligent monitoring data [15], eliminate redundant monitoring data, and extract eigenvalues. The processing result is better than the static programming algorithm. The results are shown in Table 2.

It can be seen from Table 2 that the dynamic programming algorithm is consistent with the actual demand, while the monitoring data processing capacity of the static programming algorithm is quite different from the actual demand and does not change along the change of the actual demand curve. In the range of 0~25 iterations, there is no significant difference in the processing capacity of monitoring data between the two algorithms, but there are significant differences in the range of 25~50, 50~75 and 75~100 iterations, and the dynamic programming algorithm is better than the static programming algorithm, which is consistent with the results of relevant studies Wang [16]. With the increase of the number of iterations, the amount of monitoring data processing increases. The specific results are shown in Figure 4.

It can be seen from Figure 4 that in the monitoring stage of 0.6 years, the change range of dynamic programming algorithm is significantly less than that of static detection algorithm. Moreover, the processing capacity of dynamic programming algorithm is higher than the total data processing capacity. Therefore, the amount of data processing in dynamic programming algorithm is more reasonable. At same time, it can be seen from Figure 4 that the data processing capacity of dynamic programming is relatively stable without significant fluctuation, while the fluctuation of static programming algorithm is relatively large in the early stage and tends to be flat in the later stage, so the processing effect of dynamic programming is better, which is consistent with the results of relevant studies [17]. The comparison of the actual data processing capacity of the two methods is shown in Figure 5.

As can be seen from Figure 5, the area of dynamic programming algorithm is significantly larger than that of static programming algorithm. Although the height of static programming algorithm is higher than that of dynamic algorithm, the overall area of dynamic programming algorithm is larger.

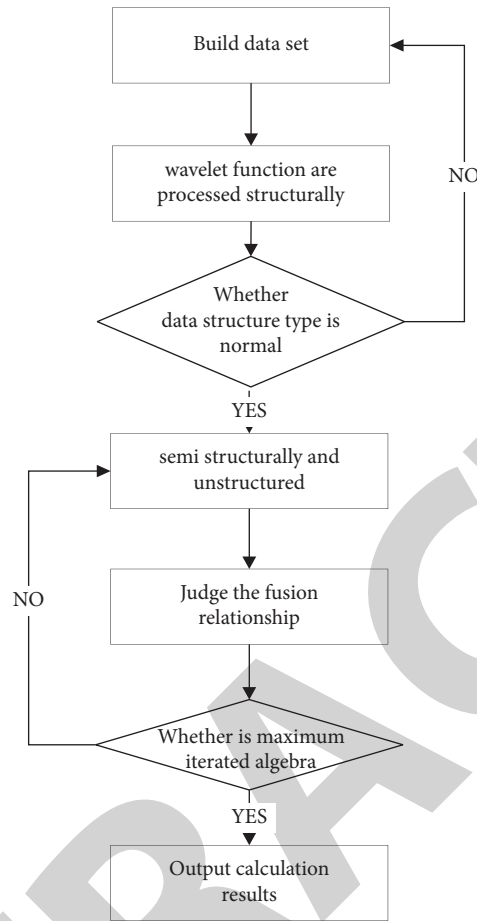

FIGURE 3: The Calculation flow of dynamic programming algorithm.

TABLE 1: The data sources of intelligent health monitoring of college students in actual cases.

Attribution area	Collection type	Collect content
Sports colleges and universities in Northeast China	ECG function monitoring, sleep quality, circulatory system	Big data, intelligent devices, cloud computing
Sports colleges and universities in North China	Subhealth, family history	Virtual simulation, smart client data collection
Physical education colleges and universities in Northwest China	Reproductive health, adolescent psychology, and blood health of female students	Intelligent device, mobile watch
Sports colleges and universities in Southeast China	Major genetic diseases and epidemic surveillance	Mobile hub, network platform
National Center for disease control and prevention	Prevention of sudden and serious diseases	Mobile phone, Big data
Private health monitoring organization	Sub ealth, blood pressure, blood lipid	University network platform
World health organization	Epidemic diseases, major diseases, and sudden diseases	QQ chatting software, VR game, Bluetooth headset big data,

Note: the monitoring data comes from the data of the National Center for Disease Control and prevention from 2015 to 2020. The choice of collection type and attribution area is based on the relevant literature at home and abroad and the actual survey results.

It can be seen from Figure 5 that the unit processing data of dynamic programming algorithm is significantly higher than that of static programming algorithm, which also fully explains the phenomenon that the processing process of dynamic programming algorithm is relatively stable. The main reason for the above problems is that the dynamic programming algorithm uses wavelet function for data subcontracting to reduce the complexity of data structure.

**4.3. The Calculation Accuracy.** The dynamic programming algorithm is used to analyze the data structure  $x_i$  in intelligent equipment devices, the impact of intelligence on health monitoring  $x_j$ , and the results of the dynamic  $x_k$  of health monitoring. The results are shown in Table 3.

It can be seen from Table 3 that the data structure  $x_i$  in intelligent equipment devices of dynamic programming algorithm, the impact of intelligence on health monitoring

The different methods	The calculation time (seconds)
The dynamic programming algorithm	82.32
The static programming algorithm	81.22

Note: the value range is 0~100.

$x_j$ , and the dynamic  $x_k$  accuracy and overall accuracy of health monitoring are better than those of static programming algorithm. It mainly understands that the planning algorithm integrates the weight coefficient and adjustment error, which is consistent with the results of relevant studies [18]. The above three indicators show small error changes in the dynamic planning algorithm, so as to avoid the interference of redundant monitoring data in the calculation and improve the accuracy of calculation. The results are shown in Figure 6.

As can be seen from Figure 6, the accuracy of dynamic programming algorithm is always higher than that of static algorithm, and the overall fluctuation range is small. The accuracy of dynamic programming algorithm is between 98% and 99%, whereas that of static

programming algorithm is between 90% and 95%. Moreover, the stability of dynamic programming algorithm is better, which is significantly higher than that of static programming algorithm. The results are consistent with relevant domestic studies. The results are shown in Table 4.

**4.4. The Time of Intelligent Health Monitoring.** It can be seen from Table 4 that the health monitoring processing time of dynamic planning algorithm is significantly less than that of static planning algorithm, and the whole health monitoring processing time is less than 25 s. According to the line segment slopes of the two algorithms, the health monitoring data of static planning show ups and downs, whereas the

FIGURE 7: The calculation time of different algorithms.

FIGURE 8: The change range of dynamic programming algorithm calculates time.

health monitoring data of dynamic planning change smoothly and the slope change range is small. This shows that the dynamic programming algorithm is better than the static programming algorithm, which can meet the requirements of intelligent health monitoring and also meet the standards of intelligent health monitoring by the ministry of health and local universities in 2021. The results are shown in Table 4.

As can be seen from Figure 7, the calculation time of dynamic programming method is always lower than that of static programming method, and the overall calculation time is almost the same. Therefore, the calculation time of dynamic programming is better. The variation range of

calculation time of different algorithms is shown in Figures 8 and 9.

As can be seen from Figures 7 and 8, the variation range of calculation time of dynamic programming algorithm is significantly lower than that of static programming algorithm. This fully explains the problem of stable calculation time of dynamic programming algorithm and also shows that the data processing effect of dynamic programming algorithm is better. The variation range of dynamic programming algorithm is 0.9%, while that of static programming algorithm is 100%. Therefore, the result of dynamic programming algorithm is more stable and can be used in data processing of high-end intelligent devices.

FIGURE 9: The change range of static programming algorithm calculates time.

## 5. Conclusion

By measuring the physical fitness of college students, evaluating the physical status and the effect of physical exercise, improving and urging the effective mechanism of college students to participate in physical activities, scientifically guiding college students to carry out physical activities, so as to continuously enhance the physical fitness of college students, thus also providing effective national physical fitness monitoring data can be done. Intellectualization is the requirement of the ministry of health and local colleges and universities for college students in 2020, and it is also the direction of future development and reform of colleges and universities [19]. Since 2010, the intelligent development of College Students' monitoring has gradually increased. However, due to the large amount of monitoring data involved in equipment public, relevant specifications, and other links, the previous static planning Bayesian and genetic algorithms have achieved accurate evaluation, which affects the implementation of later improvement measures [20]. In this article, wavelet function and static programming method are combined to build a dynamic programming algorithm model to evaluate the intelligent health monitoring. The results show that the following: (1) intelligent wearable devices are popular among contemporary college students and play an important supporting role in college students' intelligent health monitoring. At the same time, due to the great pressure of study and work, college students are not only the main subhealth population in society but also the key health monitoring object. The dynamic programming algorithm constructed in this article can continuously monitor the health of college students and has the advantages of continuous and complete monitoring data. Dynamic programming monitoring can provide redundant data and solve the problem of data distortion in static programming. (2) The constructed model can effectively eliminate redundant monitoring data and

accurately extract eigenvalues, which is consistent with the actual intelligent health monitoring requirements, and the calculation time is less than 25 s, and the evaluation process is stable. (3) Compared with static planning, the model is superior to static planning in terms of calculation accuracy. The accuracy of dynamic programming algorithm is between 98% and 99%, while that of static programming algorithm is between 90% and 95%. Moreover, the stability of dynamic programming algorithm is better, which is significantly higher than that of static programming algorithm. The results are consistent with relevant domestic studies. The monitoring data processing capacity and calculation time meets the standards of intelligent health monitoring by the ministry of health and local universities in 2021. The variation range of dynamic programming algorithm is 0.9%, while that of static programming algorithm is 100%. Therefore, the result of dynamic programming algorithm is more stable and can be used in data processing of high-end intelligent devices. Of course, this article has less research on the transmission technology and security technology of intelligent devices, and these contents are the guarantee of intelligence, so we will focus on the above two aspects in the future.

This paper makes a new attempt to identify the effectiveness of innovation factor allocation with a random forest method. This method avoids the evaluation bias of the relative effectiveness caused by the noneffective selection of production frontier in the nonparametric DEA method. It does not refer to other optimal subjects but shifts the focus to the judgment of its own effectiveness. In addition, it also gets rid of the constraints of the model and variables in the parameter SFA method, ensuring the reliability of the measurement results by resampling thousands of times. The data is collected from 30 provinces in China from 2009 to 2018. The findings show the innovation factor allocation in more than half of the provinces is not fully effective. It indicates that how to make use of innovation factor inputs to achieve the actual innovation output higher than own optimal levels is currently still in a period of exploration in China. To further improve innovation factor allocation efficiency, it deeply analyzes the impacts of innovation factor inputs and finds out the important innovation factor inputs. Furthermore, this study presents the nonlinear characteristics and optimal combination of important innovation factor inputs. According to this, it offers the detailed suggestions about how to adjust current important innovation factor inputs for each province in order to greatly enhance the effectiveness of innovation factor allocation in the future.

## 1. Introduction

After the outbreak of the new crown pneumonia epidemic, the global supply chain is forced to terminate, international and domestic demand are blocked, the barriers to the flow of factors are strengthened, and the phenomenon of factor misplacement aggravates. And the five major technologies of big data, cloud computing, Internet of Things, blockchain, and artificial intelligence emerge contribute to the vigorous development of the real economy and bring the great value of the digital economy. As a basic resource in the digital economy, data factors promote the transformation and upgrading of other production factors. The optimization of the spatial layout of regional innovation factors is inseparable from the support and guidance of government policies. This not only reflects that new innovation factors such as

data and institution have significantly affected the transformation of productivity and production relations, but also broadens the connotation scope of the original traditional innovation factors. In addition, the distribution of innovation factor inputs is uneven and innovation capability is generally low among provinces in China, while the calculation results of innovation efficiency are controversy. It is of great practical significance to identify the effectiveness of innovation factor allocation in each province under the new connotation of innovation factors. To this end, clarifying the multidimensional characteristics of innovation factors, selecting reliable measurement methods, and analyzing the current situation of innovation factor allocation in each province play a powerful role in stimulating the innovation factors potential and driving economic growth.

The existing literature measures the allocation efficiency of innovation factors roughly from the following three levels: First, different innovation inputs and innovation outputs. Duan et al. [1] construct a comprehensive index of innovation development from the three dimensions of innovation inputs, innovation organization, and innovation outputs. Dai et al. [2] use financial resources as scientific and technological financial inputs, and scientific and technological achievements as scientific and technological financial outputs. Tao and Peng [3] regard internal R&D expenditures and full-time equivalent of R&D personnel as technological innovation inputs, and the number of patent applications received, revenue from new product sales, and revenue from main operations as technological innovation outputs. Second, different innovation efficiency evaluation objects and various innovation efficiency measurement ways. Li et al. [4] decompose the innovation process into innovation development process and innovation transformation process and then calculate the innovation efficiency of 37 subsectors in China from 2004 to 2011. Wang and Lan [5] use the SFA model to estimate the innovation efficiency of China's A-share listed state-owned enterprises. Chen and Li [6] adopt a two-stage network DEA method to obtain the green innovation efficiency, green technology research and development efficiency, and green technology achievement conversion efficiency in China from 2003 to 2017. Third, measure the allocation efficiency by the factor allocation distortion. Dollar and Wei [7] find that the systematic distortion of capital allocation in China leads to uneven marginal returns across companies, regions, and departments. They point out that if capital can be allocated more effectively, it can lower capital intensity by 5% without sacrificing economic growth. Hsieh and Klenow [8] find that if capital and labor are redistributed so that the marginal output of China and India is equal to that of the United States, this will increase the total factor productivity of the manufacturing industries of the two countries, respectively, by 30%–50% and 40%–60%. Chen and Hu [9] show that resource misallocation leads to a gap of about 15% between actual output and optimal output in various subsectors of China's manufacturing industry.

Existing researches which discuss the allocation modes of innovative factors mainly can be divided into internal, external, and open innovation. Internal innovation means that the innovation subject relies on its own innovation factors to achieve innovative production. External innovation means that the innovation subject completes innovation activities with the help of external innovation factors. Open innovation means that the innovation subject breaks through its own innovation boundaries and coordinates internal and external innovation factors in the innovation process [10]. However, different ways of allocating innovation factors have different impacts on innovation performance. Hong and Shi [11] believe that independent R&D is significantly positively correlated with enterprise innovation performance. Chen and Hou [12] find that the influence of independent innovation on scientific and technological performance manifests a nonlinear threshold effect. Kafourous et al. [13] conclude that the impact of

academic cooperation on the innovation performance in Chinese emerging market companies is significantly positive. Asimakopoulou et al. [14] point out that there is an inverted U-shaped relationship between external knowledge and enterprise innovation efficiency. Berchicci (2013) [10] believes that the inverted U-shaped relationship between external R&D activities and enterprise innovation performance is the function of the substitution effect of its own R&D capabilities. Nieves and Petra [15] find that internal and external knowledge have substitution effects within a certain threshold and have a negative impact on enterprise innovation performance. When the threshold is exceeded, it will turn into a complementary effect and has a positive impact on the enterprise innovation performance.

In summary, the definition of the connotation of innovation factors in the existing literature is mostly based on the traditional innovation factors such as labor, capital, and technology. But it lacks the content of new innovation factors such as data and institution. The existing literature ignores the theoretical basis and operation process behind the innovation factor allocation. The efficiency measurement of the innovation factor allocation in the existing literature is mostly by means of the parametric SFA and the nonparametric DEA. In addition, there are few studies on the evaluation of innovation factor allocation effectiveness. Adopting a more reliable method to identify the effectiveness of innovation factor allocation is helpful to evaluate the situation of innovation factor allocation more accurately. In view of this, the main contributions of this article are as follows: On the one hand, with the introduction of the data and institution innovation factors, we build the index of multidimensional innovation factor, which not only weighs the internal and external coordination of traditional innovation factor from the cost theory, but also considers the moderating effect of new innovation factor from the coupling theory. Based on this, a four-dimensional integrated indicator is formed including internal innovation factors, external innovation factors, institutional innovation factors, and data innovation factors and the allocation of innovation factor is evaluated on the input-output process of innovation factor. On the other hand, we make a new attempt to identify the effectiveness of innovation factor allocation by a random forest method that is different from the previously used. This method can not only get rid of constraints including the model setting form, the number of variables, and the correlation between variables in the parameter SFA method, but also avoid the evaluation bias of the relative effectiveness caused by the noneffective selection of production frontier in the nonparametric DEA method. It shifts the focus on its own efficiency, ensuring the reliability of the measurement by resampling thousands of times. The above aspects are the contribution of the theoretical level. Furthermore, in the aspect of practical level, we draw many different conclusions from existing studies, which find that the innovation factor allocation in more than half of the provinces is not fully effective, data innovation factor inputs especially data integration and data applications have the significant contribution to innovation output, the marginal impact characteristics of important innovation factor inputs are all

nonlinear, and the gap between the current situation and the optimal combination of important innovation factor inputs in each province in China is obvious, etc.

The remaining structure of this paper is as follows: In Section 2, we present the definition and measurement method of innovation factor allocation. In Section 3, we identify the effectiveness of innovation factor allocation in each province in China and discuss the importance of innovation factor inputs. In Section 4, we determine the important innovation factor inputs, describe their nonlinear characteristics and optimal combination, and then point out the future adjustment direction of innovation factor inputs in each province in China. In Section 5, we offer the main conclusions and future research.

## 2. Innovative Factors: Definition, Indicator, and Measurement Method

### 2.1. Definition

*2.1.1. The Definition of Innovation Factors.* Production factors are the objective basis of production activities, and factors affecting production activities all belong to the category of factors [16]. The narrow defining of production factors can be understood as the factors joining in the production process, while the broad defining of production factors should also include factors that reflect the output benefits of the production process. Schumpeter [17] defines innovation as introducing a new combination of production factors and production conditions into the production system that has never been before. Combining modern production conditions with organizational models, innovation can be understood as not only the realization of new products (services) or procedures, the improvement of original products (services) or procedures, but also the process of new products (services) or procedures that are about to or have been commercialized [18–20].

To sum up, this article defines innovation factors as production factors that participate in the innovation process, influence innovation performance, and reflect innovation achievements. They have the characteristics of increasing marginal returns, which include not only traditional innovation factors such as labor, capital, and technology, but also new innovation factors such as data and institution.

*2.1.2. The Definition of the Multidimensional Innovation Factor Allocation.* The cost theory holds that the criterion for organizing economic activities is the minimization of internal production costs and external transaction costs. Drawing on Nieves and Petra (2014) [15], the innovation factors are divided into internal innovation factors and external innovation factors, the internal innovation factors are derived from the innovation subject itself, the external innovation factors are derived outside the innovation subject, and the internal and external innovation factors are mainly based on traditional innovation factors. On the one hand, the innovation subject relies on internal innovation human, material and financial resources, regards innovation

as an internal control process, completes all innovation links and leaves innovation output within the subject. On the other hand, the innovation subject combines their own existing innovation foundations and regards innovation as a R&D outsourcing process. By contacting external innovation partners, they achieve technology cooperation, absorption, and acquisition of external innovation and enlarge enterprise innovation outputs. If the innovation subject is overconcentrated on internal innovation, it will cause problems such as excessive risk and knowledge spillover, while overreliance on external source innovation will bring about problems such as rising negotiation costs and loss of initiative. Therefore, the innovation subject needs to effectively coordinate internal and external innovation factors to minimize the total cost of innovation activities.

The coupling theory states integrating the coordination channels of internal and external traditional innovation factors, enhancing the coupling viscosity of internal and external traditional innovation factors, and reducing the misallocation of internal and external traditional innovation factors, which require both the participation of innovation subjects themselves and innovation assistance from forces other than the subjects. We refer to analysis of Berchicci [10]. On the one hand, the government-led institutional innovation factors regulate the depth of internal and external innovation factors coordination, integration, and fit by intellectual property protection, financial education support, free trade in goods, market transaction quotas, financial development scale, and industrial pollution control. On the other hand, data innovation factors led by intermediaries regulate the breadth of internal and external innovation factors synergy, integration and adaptation by data production level, data transmission speed, data user groups, data application scope, data sharing degree, and data integration capabilities. Institution and data innovation factors play the regulatory role of institutions and information (intrinsic nature of data) on internal and external innovation factors, thereby forming a multidimensional integrated indicator of internal innovation factors, external innovation factors, institutional innovation factors, and data innovation factors.

Based on the above analysis, this article draws the definition of the multidimensional innovation factor allocation. The cost theory synergizes internal and external innovation factors. The measurement indicator of internal innovation factors can be from the three aspects of internal innovation human resources, material resources, and financial resources. The measurement indicator of external innovation factors can be from three aspects such as external innovation technologies cooperation, absorption, and acquisition. The regulation role of institution and data innovation factors depends on coupling theory. Institution innovation factor measurement indicator can be from six aspects including property rights protection, education support, trade freedom, trading markets, financial development, and pollution control. Data innovation factor measurement indicator can be from six aspects including data generation, transmission, use, application, sharing, and integration.

## 2.2. Indicator

**2.2.1. Indicator Composition.** This paper is based on the definition of innovation factors allocation, the operability of indicators, and the availability of data. Combining with the research of Tao and Xu [21], we select the specific quantitative indicator. The internal innovation human resources, financial resources, and material resources in the internal innovation factors are, respectively, measured from the full-time equivalent of R&D personnel, internal R&D expenditures, and the number of R&D organizations. The external innovation technology cooperation, absorption, and acquisition in external innovation factors are, respectively, measured from external R&D expenditures, foreign direct investment, and high-tech product imports. Property rights protection, education support, trade freedom, trading market, financial development, and pollution control in the institution innovation factors are, respectively, measured from the total number of patent enforcement cases, financial education subsidies, total regional goods exports, technology market turnover, deposits and loans of financial institutions, and industrial pollution control investment. The data generation, transmission, use, application, sharing, and integration in the data innovation factors are, respectively, measured from the number of Internet pages, Internet broadband access ports, Internet users, total software services, total post and telecommunications services, and the number of robots owned. Taking the above four dimensions of internal, external, institution, and data innovation factors as innovation inputs, and taking per capita sales income of new products as innovation output, we evaluate China's innovation factors allocation efficiency.

**2.2.2. Variables and Data.** This paper is based on the panel data of 30 provinces in China from 2009 to 2018 (except Tibet). The data are extracted from China Statistical Yearbook on Science and Technology, China Statistical Yearbook, China Internet Development Report, China Information Yearbook, and International Federation of Robotics. The acquisition of the variables and the processing of the data are performed as follows: Regarding the matches and fillings of the data, the first is the number of robots owned in China based on the industrial output value of the main applications of industrial robots in each province. The second is filling the missing data of provinces according to the difference between the national total and existing provinces total. In addition, with regard to the methods of the processing of the data, firstly, exchange rate adjustments are converted by the ratio of RMB to USD. Secondly, the price adjustment refers to the price index formula of Zhu and Xu [22]. The fixed asset investment index and the consumer price index are, respectively, assigned weights of 0.45 and 0.55. Regarding the year 2009 as the price base period, convert the nominal values into actual values. Thirdly, using the method of BEA for stock adjustment, based on the annual investment flow after price adjustments  $E_t$ , we calculate the average annual growth rate  $g_k$ . Then, considering amortization of intangible assets for at least 10 years, and referring to Wang and Gao [23], set the

residual value rate  $d_T$  to 10% and get the depreciation rate  $\delta = 1 - (d_T)^{1/T} = 0.2057$ . Lastly, the annual capital stock is based on  $K_0 = [E_1(1 - \delta/2)]/[g_k + \delta]$  and  $K_t = (1 - \delta)K_{t-1} + (1 - \delta/2)E_t$ . The above contents are detailed in Table 1.

**2.3. A Random Forest Method.** The existing researches of measuring efficiency mainly use nonparameter DEA method and parameter SFA method. The DEA method is used to evaluate relative efficiency by constructing the optimal production frontier. On the one hand, it refers to other effective subjects instead of its own optimum, which is difficult to purposely offer the adjustment direction according to itself current inputs. On the other hand, it may occur efficiency measurement bias if the optimal production frontier is selected mistakenly. In addition, the SFA method measures efficiency by determining the form of model and the number of variables in advance. It means the differences of the form of model and the number of variables lead to the different measurement results. Meanwhile, the collinearity between variables in the model also causes biased efficiency measurement. Compared with DEA and SFA, the random forest method not only gets rid of constraints including the form of model, the number of variables, and the correlation between variables, but also ensures the reliability of measurement by resampling thousands of times. With reference to Ouyang and Chen [24], the prediction of output can be regarded as the maximum output achieved under the full utilization of inputs by the random forest method. According to this, we can calculate own optimal output in terms of current inputs and then identify effectiveness by the ration of actual output to optimal output. It does not refer to other optimal subjects but shifts the focus to the judgment of its own effectiveness. Moreover, it gets the contribution rankings of various inputs to outputs from large to small based on the principle of minimum sum of squares of residuals. We further get the marginal impact characteristics of inputs and find out the optimal combination of inputs and thus put forward the further adjustment direction depending on own current situation of inputs. The introduction of random forest method is below in detail.

A random forest method is an ensemble learning method. This method uses resampling to randomly select sample data and sample characteristics to establish multiple regression numbers, and the mean value of the output results of multiple regression trees is used as the final prediction result. Based on the data of each input, this paper predicts the results of each output according to the random forest method. The detailed steps are as follows:

- (i) Suppose there are samples  $\{y_i, c_{i1}, \dots, c_{iK}\}_{i=1}^N$ ,  $N$  and  $K$ , respectively, represent total number of samples and features,  $y_i$  is the individual  $i$  output, and  $c_{i1}, \dots, c_{iK}$  is the individual  $i$  input. Based on this, samples are drawn randomly with replacement.
- (ii) Construct a regression tree with features  $m$  selected from the sample, and perform feature splitting according to the principle of the minimum sum of

TABLE 1: Multidimensional innovation factor allocation indicator.

Note: all the data are processed logarithmically to eliminate the influence of differences in indicator units.

squared residuals. Specifically for the input indicator  $c_k$ , the critical point at which the optimal threshold is known is  $d$  (the determination of  $d$  also adopts the principle of minimum sum of squares of residuals). Then according to the sample size of the left and right sides of the critical points  $T_{U1}$  and  $T_{U2}$ , we, respectively, get the sample of  $U1$  and  $U2$ :

$$\begin{aligned} U1(k, d) &= \{y_i, c_{i1}, \dots, c_{iK}/c_k \leq d\}_{i=1}^{T_{U1}}, \\ U2(k, d) &= \{y_i, c_{i1}, \dots, c_{iK}/c_k > d\}_{i=1}^{T_{U2}}. \end{aligned} \quad (1)$$

From this, the average value of the output results of each sample can be obtained:

$$\bar{y}_{U1} = \text{mean}(y_i/y_i \in U1), \quad \bar{y}_{U2} = \text{mean}(y_i/y_i \in U2). \quad (2)$$

The selection of the initial split node  $c_k$  of the regression tree is based on the following formula:

$$\min_{C_k} \left[ \min \sum_{i=1}^{T_{U1}} (y_i - \bar{y}_{U1})^2 + \min \sum_{i=1}^{T_{U2}} (y_i - \bar{y}_{U2})^2 \right]. \quad (3)$$

- (i) The selection of the remaining nodes of the regression tree is repeated based on step (ii). The prepruning rule is set to include at least 5 sample points for each node. When the rules are met, the regression tree immediately stops splitting.

- (ii) The loop steps (i)-(iii) form a large number of regression trees, and the average value of the above regression tree results is used as the final prediction of the output results.

In addition to regression analysis, the random forest method can also evaluate the importance of each input and its marginal influence on the output. The nodes of the regression tree are arranged from top to bottom according to the contribution of each input to the reduction of the residual sum of squares of the output. The top is the input with the largest contribution, and the bottom is the input with the least contribution. According to this, the importance of each input can be obtained. By sorting the importance of input, we can get the important order of input. The marginal effect is mainly used to measure the impact of a single input change on the output, which can be defined as

$$\bar{f}(c_k) = \frac{1}{N} \sum_{i=1}^N f(c_{i1}, \dots, c_k, \dots, c_{iK}). \quad (4)$$

In equation (4),  $f(c_{i1}, \dots, c_k, \dots, c_{iK})$  is the prediction result of the random forest model  $f(\cdot)$  when  $\{c_{i1}, \dots, c_k, \dots, c_{iK}\}_{i=1}^N$  is known.  $\bar{f}(c_k)$  is the mean of the predicted results for all samples. Traverse all possible values  $c_k$  to get the corresponding result  $\bar{f}(c_k)$ . This draws a trend graph  $\bar{f}(c_k)$  about  $c_k$  and visualizes the influence path of the input  $c_k$  on the mean value of output  $\bar{f}(c_k)$ .

### 3. Innovation Factors: Allocation Effectiveness and Importance Degree

*3.1. Effectiveness Identification.* We use random forest method, the algorithm is run 1000 times, and the average value of 1000 times is regarded as the final prediction of innovation output. Based on the above analysis, it is also the optimal innovation output achieved by innovation factor inputs. Then we get the ration of actual output to optimal output, which is the allocation efficiency of innovation factors from 30 provinces in China from 2009 to 2018. Based on this, we identify the effectiveness of innovation factor allocation for each province in China and offer the corresponding schematic graph shown in Figure 1.

In Figure 1, the black solid dots indicate that the province's actual innovation output exceeds its own optimal output, realizing the effective allocation of innovation factors, while the gray solid dots indicate that the province's actual innovation output is lower than its own optimal output. The effective allocation of innovation factors has not been completed. According to the allocation of innovation factors in each province from 2009 to 2018, each province is divided into the following three types: one is fully effective, and the province achieves an effective allocation of innovation factors during the entire sample period; the second is not fully effective, and the province only achieves the effective allocation of innovation factors in a part of the sample period; the third is totally ineffective, and the province does not meet the requirements of the effective allocation of innovation factors during the full sample period.

As can be seen from Figure 1, the provinces with innovation factor allocation fully effective are Tianjin, Shanxi, Shanghai, Zhejiang, Hubei, Hunan, Chongqing, and Ningxia. The above provinces can not only effectively coordinate internal and external innovation factors during the entire sample period, but also give full play to the coupling role of institution and data innovation factors, organically integrate the four-dimensional innovation factors into one, and obtain innovation output that exceeds its own best state. Although Chongqing and Ningxia are located in the relatively backward western regions, there is a certain gap in the innovation factor inputs compared with the developed regions, and the optimal output that can be achieved by the current innovation factor inputs is relatively low, so the actual output of the two provinces reaching the optimal level is also relatively easy. The provinces where the allocation of innovation factors is not fully effective are Beijing, Inner Mongolia, Liaoning, Jilin, Jiangsu, Anhui, Fujian, Jiangxi, Shandong, Guangdong, Guangxi, Gansu, Qinghai, and Xinjiang. In the abovementioned provinces, the innovation output obtained by the innovation factor inputs in only some years is higher than its own optimal level. Although Beijing, Jiangsu, Fujian, Shandong, and Guangdong are located in eastern regions with superior innovation conditions and abundant innovation resources, their innovation factor inputs are relatively more, and the optimal output that can be achieved by relying on their existing innovation factor inputs is also relatively high. The actual output beyond its own optimal level is also relatively difficult. The provinces where the allocation of innovation factors is totally ineffective are Hebei, Heilongjiang, Henan, Hainan, Sichuan, Guizhou, Yunnan, and Shaanxi. The actual output of the above eight provinces during the entire sample period was lower than their optimal level. Although Hebei is located in the economically developed eastern region, the relatively high innovation factor inputs have caused structural imbalance, and it is difficult to fully release the efficacy of innovation factor inputs.

*3.2. Importance Judgment.* From the foregoing, the random forest method can get the importance of the innovation factor inputs according to the contribution to the reduction of the square of the residual of the innovation output. It puts the most important innovation factor input at the top of the tree and the least important innovation factor input at the bottom of the tree. Therefore, the higher the innovation factor input located at the level of the tree, the greater the contribution to the innovation output. According to the importance of the innovation factor inputs from 2009 to 2018 (see Table 2), this paper draws a grid graph and a boxplot graph (see Figures 2 and 3). The grid graph reflects the contribution degree, the changing trend, and the abnormal time point. The larger the grid area, the greater the importance. The boxplot presents the average contribution and scatter degree. Based on the above analysis, it provides clear direction for improving the effectiveness of innovation factor allocation.

In Table 2 and Figure 2, it can be seen that the contribution of data application is the most prominent in 2009

FIGURE 1: Effectiveness of innovation factor allocation.

Note: the ranking results are based on the annual average value.

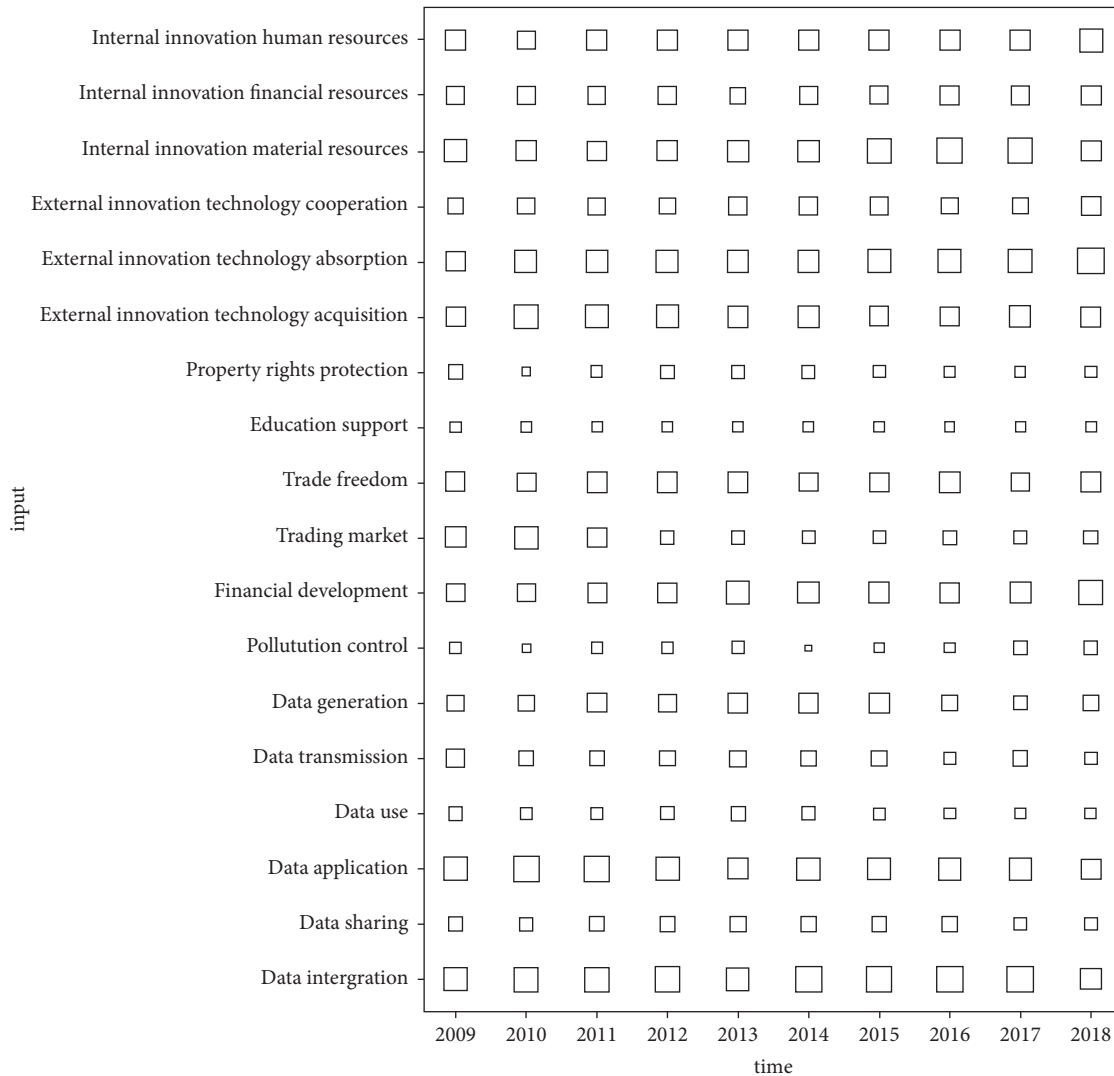

FIGURE 2: Grid graph of innovation factor inputs importance.

and 2010, the contribution of external innovation technology absorption is the most significant in 2013 and 2018, and the performance of data integration is the most eye-catching in the remaining years, which show that the data application, external innovation technologies absorption, and data integration have significant impacts on the innovation output during the entire sample period. In addition, the number

when the input of innovation factors contributes the most value itself is as follows. First, the number topping the list in 2018 is five, respectively, including internal innovation human resources, external innovation technology cooperation, external innovation technology absorption, financial development, and pollution control. Second, the number in 2010 is four, respectively, including external innovation

FIGURE 3: Boxplot of innovation factor inputs importance.

technology acquisition, education support, trading market, and data application. Third, the number in 2009 and 2016 is three, which, respectively, include property rights protection, data transmission and data use in 2009, and internal innovation financial resources, internal innovation material resources, and data integration in 2016. Forth, the number in 2013 is two, respectively, including trade freedom and data sharing, the input in 2015 is data generation, and there is none in 2011, 2012, 2014, and 2017. This shows that the input structure of innovation factors in 2018 is more reasonable than other years, it gives full play to the advantages of innovation factor inputs, and there is the most innovation factor input contributing its greatest impact.

In Table 2 and Figure 3, the average contribution of innovation factor inputs during the entire sample period is ranked from large to small, followed by data integration, data application, external innovation technology absorption, internal innovation material resources, external innovation technology acquisition, financial development, internal innovation human resources, trade freedom, internal innovation financial resources, data generation, external innovation technology cooperation, trading market, data transmission,

data sharing, data use, property rights protection, pollution control, and education support. The ranking top two belong to data innovation factors. It confirms not only the importance of the data innovation factor inputs, but also the data integration measured by the number of robots owned and the data application measured by the total amount of software business, which implies artificial intelligence and advanced manufacturing playing the important role within reforming the synergy of internal and external innovation factors and promoting the acceleration of innovation output. Data innovation factors have the characteristic of strong integration. They can overcome the limitations of time and space, which is conducive to the optimization and upgrading of internal and external innovation factors and the complementary advantages between internal and external innovation factors, which greatly promotes the improvement of innovation output. Internal innovation human resources, internal innovation financial resources, external innovation technology absorption, education support, pollution control, and data transmission all have outliers. Five have large outliers which all appear at the largest time point of its own contribution, and three appeared in 2018. It not only illustrates the relatively

reasonable input structure of innovation factors in 2018, but also implies that the overall input structure of innovation factors in China is undergoing continuous adjustment and improvement.

#### 4. Innovation Factors: Marginal Effects and Input Choices

*4.1. Marginal Effect Trend.* The above discusses the importance of each innovation factor input to the innovation output under the existing innovation factor inputs combination, which is the static analysis of the impact on the innovation output. If the innovation factor input has a significant impact on innovation output, will it continue to increase inputs or be subject to threshold constraints? The answer to this question requires us to give the dynamic changes in the marginal effect trend of innovation factor input.

Based on the importance ranking of innovation factor inputs, the top eight cumulative impacts exceeding 60% of the total impact are regarded as important innovation factor inputs, followed by data integration, data application, external innovation technology absorption, internal innovation material resources, external innovation technology acquisition, financial development, internal innovation human resources, and trade freedom. At the same time, it is found that the above inputs are evenly distributed in the internal, external, institution, and data innovation factors. In order to obtain the time changing trend of the marginal effects of each important innovation factor, the marginal effect graph of each important innovation factor input is given in the order of the abovementioned four-dimensional innovation factors (see Figure 4). We select 2009 (dotted line type), 2012 (lower solid line), 2015 (dashed line), and 2018 (higher solid line) for describing in detail.

There are three key boundary points in the marginal effect trend graph in Figure 4, which are two turning points (indicated by  $\times$ ) and the maximum slope point (indicated by  $*$ ). Before the first turning point is the initial stage of innovation factor input impact, and the marginal impact on innovation output is relatively flat. The first turning point to the maximum slope point is the marginal impact on innovation output from the increasing to the maximum. The stage between the maximum slope point and the second turning point is the marginal incremental impact of the innovation factor input fallen to the suspended. The second turning point is the innovation factor input required for maximum innovation output. The marginal impact of increasing the innovation factor input on innovation output is almost zero after the second turning point. It can be concluded that the optimal innovation factor is the amount of innovation factor input required when the innovation output reaches its maximum output. If all the important innovation factor inputs in a province have exceeded the second turning point, then the province's important innovation factor investment portfolio is the best. Based on this, we give the key boundary points of the marginal effect of

important innovation factor inputs in 2009, 2012, 2015, and 2018 (see Table 3).

Combining the time trend of the marginal effects of important innovation factors, we find that the impact on innovation output is nonlinear in whole process. In addition, the positions of the first turning point, the maximum slope point, and the second turning point are not exactly the same in 2009, 2012, 2015, and 2018. It can be seen that the demand for important innovation factor inputs in different periods is somewhat different. Details are as follows: Firstly, the first turning point of internal innovation human resources, financial development, and data integration between 2009 and 2015 is relatively closer. The distance of the first turning point in internal innovation material resources, external innovation technology acquisition, and data application between 2012 and 2015 is the shortest. At the same time, except for trade freedom, the first turning point of the other important innovation factor inputs in 2018 appears later than the other years. It shows that the amount of the important innovation factor inputs required at the starting point of increasing marginal effects in 2009, 2012, and 2015 is relatively stable, while the amount of the important innovation factor inputs required in 2018 is higher than that in 2009, 2012, and 2015. Secondly, the distance of all important factor inputs between the first turning point and the maximum slope point in 2018 is smaller than in 2009, 2012, and 2015. It indicates that, compared with other years, the important innovation factor inputs have the certain foundation and do not have a relatively long period of marginal effect growth in turn in 2018. Thirdly, the second turning point of internal innovation human resources in 2018 appears earlier than in 2009, 2012, and 2015, while the second turning point of the other important innovation factors in 2018 appears later than in 2009, 2012, and 2015. It indicates that, comparing 2018 with the other years, the demand for internal innovation human resources is relatively small, and the demand for other important innovation factors is greater in the optimal innovation factor inputs required to achieve the maximum innovation output.

*4.2. Inputs Selection Analysis.* The ranking top eight of the innovation factor inputs' importance in 2012 and 2018 are consistent with the result of the average contribution ranking in Table 2. Therefore, the input of important innovation factors in each province in 2012 and 2018 is carried out by grouping accordingly. It can not only analyze the time changes of important innovation factor inputs, but also propose future adjustment direction based on the current innovation factor inputs in each province.

According to the grouping of important innovation factor inputs in each province in 2012 and 2018 (see Table 4), combined with the marginal effect graph of important innovation factor inputs in 2012 and 2018 (see Figures 4(a)–4(h), respectively, corresponding to the lower and the higher solid line), the following important features are found: Firstly, part of important innovation factor inputs in some provinces have not exceeded the critical value of the first turning point. That means these important innovation factor

(h)	13.99	15.61	16.96	13.20	16.56	17.95	14.42	17.59	19.48	15.50	18.44	20.26

Note:  $\alpha$ ,  $\beta$ ,  $\gamma$ , respectively, represent the first turning point, the maximum slope point, and the second turning point boundary value.

inputs have not yet reached the starting point of increasing marginal effects. Secondly, all important innovation factor inputs in some provinces are between the first turning point and the second turning point. That indicates all important innovation factor inputs are in the stage where their marginal effect increases to the maximum and then to the gradual decline. Thirdly, part of important innovation factor inputs in some provinces have reached the second turning point threshold value, which means that these important innovation factors have completed the optimal inputs. Fourthly, all important innovation factor inputs in some provinces exceed the second turning point threshold value, which indicates that all important innovation factor inputs meet the optimal portfolio requirements. Based on the above four important characteristics, we classify the input of important innovation factors in each province in 2012 and 2018, analyze the characteristics of changes in the important innovation factor inputs, and propose future innovation development policies.

Based on the summary of important innovation factor inputs grouping characteristics in each province in 2012 and 2018 (see Table 5), the changes in the following grouping characteristics of each province are obtained: Firstly, the important innovation factor inputs in some provinces in

2012 and 2018 have always maintained the characteristics (a), such as Qinghai and Ningxia. Although Ningxia shows the innovation factor allocation is effective in 2012 and 2018, the optimal innovation output achieved is low due to its existing innovation factor inputs. It implies that the above provinces need to significantly increase the important innovation factor inputs, which can not only increase the actual innovation output, but also raise the optimal output threshold standard. Secondly, the important innovation factor inputs in some provinces in 2012 and 2018 remain at the characteristic (b), such as Tianjin, Hebei, Liaoning, Jilin, Anhui, Henan, Hunan, and Chongqing. The above provinces may refer to the contribution ranking of important innovation factor inputs and determine the appropriate direction for the increase in the important innovation factor inputs. There are also some provinces where the important innovation factor inputs have dropped from the characteristics (b) in 2012 to the characteristics (a) in 2018, such as Shanxi, Inner Mongolia, Heilongjiang, Jiangxi, Guangxi, Hainan, Guizhou, Yunnan, Gansu, and Xinjiang. The above provinces input less in data applications. The contribution of data application input is among the best. Increasing the inputs of data application can not only make the provinces get rid of the characteristics (a), but also promote the improvement of

Note: the input of important innovation factors is divided into group 1 before the first turning point, into group 2 between the first turning point and the maximum slope point, into group 3 between the maximum slope point and the second turning point, and into group 4 after the second turning point.

TABLE 5: Grouping characteristics of important innovation factor inputs.

Grouping characteristics	2012	2018
(a) Part of important innovation factor inputs has not yet reached the starting point of increasing marginal effect	Qinghai, Ningxia	Shanxi, Inner Mongolia, Heilongjiang, Jiangxi, Guangxi, Hainan, Guizhou, Yunnan, Gansu, Qinghai, Ningxia, Xinjiang
(b) All the important innovation factor inputs are in the marginal effects from increasing to maximum and then to falling flat stage	Tianjin, Hebei, Shanxi, Inner Mongolia, Liaoning, Jilin, Heilongjiang, Anhui, Fujian, Jiangxi, Henan, Hubei, Hunan, Guangxi, Hainan, Chongqing, Sichuan, Guizhou, Yunnan, Shaanxi, Gansu, Xinjiang	Tianjin, Hebei, Liaoning, Jilin, Anhui, Henan, Hunan, Chongqing
(c) Part of important innovation factors has completed the input required for the optimal combination of innovation factors	Beijing, Shanghai, Zhejiang, Shandong	Beijing, Shanghai, Jiangsu, Zhejiang, Fujian, Shandong, Hubei, Sichuan, Shaanxi
(d) All the important innovation factor inputs meet the requirements of optimal combination	Jiangsu, Guangdong	Guangdong

innovation output. There are also some provinces where the investment in important innovation factors has risen from the characteristic (b) in 2012 to the characteristic (c) in 2018, such as Fujian, Hubei, Sichuan, and Shaanxi. The grouping characteristics have been upgraded, and the above provinces need to continue to maintain this situation, or they can increase investment in innovation factors which have a large gap such as trade freedom and other factors. Thirdly, the input of important innovation factors in some provinces in 2012 and 2018 has always remained at the characteristic (c), such as Beijing, Shanghai, Zhejiang, and Shandong. The above provinces may be based on the gap of some important innovation factors between current and optimal inputs, combined with the contribution of important innovation factor inputs, giving priority to the important innovation factors with small gaps and large contributions. Fourthly, the inputs of important innovation factors in Guangdong in 2012 and 2018 have met the requirements of characteristics (d). It means that Guangdong has realized the effective allocation of innovation factors in 2018. If they want to improve the optimal innovation output standard, it is more difficult to start from the input end of innovation factors. It may be achieved by changing the existing innovation development patterns. The important innovation factor inputs in Jiangsu Province have declined from the characteristics (d) in 2012 to the characteristics (c) in 2018. Jiangsu Province may continue to increase inputs in financial development and data applications in the future.

### 5. Conclusions and Future Research

Innovation is the driving force of economic development, and effectively measuring the allocation of innovation factors is conducive to better playing the role of innovation. We use the random forest method to identify the effectiveness of innovation factor allocation in 30 provinces in China from 2009 to 2018 and explore the importance of the innovation factor inputs' contribution in the entire sample period and its own maximum contribution timing. Then we further grasp the marginal effect characteristics of important innovation factor inputs, catch the time changes of its key boundary points, analyze the actual inputs of each province based on the optimal combination of important innovation factor inputs, and finally propose future adjustment directions. The specific conclusions reached are as follows.

First, more than half of the provinces is not fully effective in the innovation factor allocation. How to rely on internal and external innovation factors and make use of institution and data innovation factors to achieve the actual innovation output higher than their own optimal levels is still in a period of exploration and adjustment. Second, from the perspective of the importance of innovation factor inputs, data innovation factors especially data integration and data applications have contributed significantly, which reflects the important impact of data innovation factors on innovation output. From the view of the maximum contribution time of innovation factor input, the most innovation factor inputs

contribute its own maximum value in 2018, suggesting that the structure of China's innovation factor input has an overall upward development trend. Third, the marginal effects of important innovation factor inputs are nonlinear, and the positions of the first turning point, the maximum slope point, and the second turning point of the marginal effect of important innovation factor inputs in different periods are different, indicating that the marginal effect of important innovation factor inputs on innovation output is not always the same. Based on this, we find out the optimal combination of important innovation factor inputs. Fourth, Guangdong Province has achieved the optimal combination of important innovation factor inputs or can change the existing innovation development pattern, while the remaining provinces have not yet reached the optimal factor input requirements and need to adjust the inputs to improve the current innovation choice.

Based on the above conclusions, the following policy implications can be obtained. Firstly is improving the effectiveness of the innovation factor allocation further. We not only need to pay attention to the coordination of internal and external innovation factors, but also focus on the coupling of institution and data innovation factors. Secondly is giving full play to the potential of data innovation factors, especially data application and data integration: Developed provinces may be able to make further development, while backward provinces may be able to achieve curve overtaking. Thirdly is grasping the marginal effects of important innovation factor inputs, and making good use of the impact trend of the important innovation factor inputs. Fourth, each province makes appropriate innovation development policies based on local conditions and rationally adjusts the current innovation factor inputs selection according to the optimal combination.

Needless to say, this paper has some limitations, which are also the basis of future research in this paper. Firstly, when evaluating the effectiveness of innovation factors allocation, this paper takes internal innovation factors, external innovation factors, institutional innovation factors, and data innovation factors as innovation factor inputs, and per capita new product sales revenue as innovation output. Except for per capita new product sales revenue, it can also be measured by indicators such as per capita gross national product in the evaluation of innovation output. Therefore, it is necessary to add other variables that can measure innovation output to identify the effectiveness of innovation factor allocation in further research, so as to more comprehensively show the allocation situation of innovation factors in various provinces in China.

Secondly, this paper takes China's provinces as the research object and evaluates the innovation factor allocation from the macrolevel. In addition, it also has practical significance of evaluating the innovation factor allocation from the meso- and microlevels. Therefore, it is necessary to analyze the innovation factor allocation from the industry level and the enterprise level and further explore the future adjustment direction of the innovation factor allocation at the meso- and microlevels.

Finally, when analyzing the impact of innovation factor input, this paper focuses on the marginal effect trend and key boundary points of important innovation factor input but does not show the impact of remaining innovation factor input on innovation output. Although the impact of this part of innovation factor inputs is not significant, they also make the marginal contributions to innovation output. In the future, we may further explore the marginal effect characteristics and key boundary points of such innovation factor inputs. It may draw other important conclusions.

## Data Availability

This paper is based on the panel data of 30 provinces in China from 2009 to 2018 (except Tibet). The data sources and processing methods are shown in Table 1.

## Conflicts of Interest

The authors declare no conflicts of interest.

## Authors' Contributions

Mo designed the computational frame work and wrote the manuscript. Y. W. designed the model and analyzed the data. C. Q. conducted empirical research. S. F. collected the relevant literature and determined the indicator. All authors discussed the results and contributed to the final manuscript. All authors have read and agreed to the published version of the manuscript.

## Acknowledgments

This research was supported by the characteristic and preponderant discipline of Key Construction Universities in Zhejiang Province (Zhejiang Gongshang University, Statistics), the National Natural Science Foundation of China (71763010 and 71803038), and Jiangxi Provincial Social Science "14th Five-Year" Plan Project (21YJ05).

To cope with the volatility of customer order demand, enterprises need to formulate a reasonable production plan based on customer demand for the completion period and their current manufacturing capacity. The existing studies have not fully considered the complex processing procedures, the features of manufacturing attributes, and the repetitive orders of stable consumers. To solve these problems, this paper explores the order management and completion date prediction of manufacturing job-shop based on deep learning. Specifically, the features of manufacturing attributes were extracted and used to predict the activities and completion time of different manufacturing tasks in order management. In addition, a deep learning prediction model was constructed based on a bidirectional long short-term memory network (BiLSTM) and self-attention mechanism, which completes the order management and completion date prediction.

## 1. Introduction

With the continuous development of the market economy and the advancement of science and technology, consumers expect ordered products to be delivered within a shorter cycle [1–7]. The increasingly market-centric order production method puts forward extremely strict requirements on the corporate capacity of production and timely completion [8–10]. To cope with the volatility of customer order demand, i.e., meet consumer requirements on the quality and completion date of ordered products, enterprises need to effectively control the ordered tasks in the manufacturing job-shop and to formulate a reasonable production plan based on customer demand for the completion period and their current manufacturing capacity [11–18]. In the manufacturing industry, order management runs through the entire production cycle. The accurate prediction of the product completion period is the main factor affecting the decision of order management and control [19–22].

Chen [23] constructed a system based on the knowledge of fuzzy neural networks, aiming to improve the performance of manufacturing job-shop in predicting completion

time and allocating internal delivery time. In the system, multiple experts construct their own fuzzy multiple linear regression (MLR) models and predict the job completion time/cycle. Drawing on concepts like machine learning, evolution, and metaheuristic learning, Patil [24] developed an enhanced differentiable dynamic quantization (DDQ) model based on an artificial neural network (ANN). Computational experiments show that the model outshines traditional ANN-based DDQ in the prediction of the completion date, in different job-shop environments and on different volumes of training data. To prevent overfitting from weakening the generalization ability of a single neural network, Zhu et al. [25] introduced a neural network ensemble to propose a Bagging approach based on the cluster analysis of the 0.632 prediction error and conducted a case study to illustrate the whole steps to predict the product due date by using neural network ensemble. The operation of manufacturing job-shop is difficult to manage, owing to the heterogeneity of raw materials, complex transformation process, and varied production flows. Dumetz et al. [26] provided a simulation framework enabling the comparison and evaluation of different production planning strategies and order management strategies. The framework integrates

a basic enterprise resource planning (ERP) system. The user can configure the production plan and order management process and evaluate the model performance in various market environments using the discrete event simulation model. After setting up a set of candidate features, Liu et al. [27] presented a feature selection algorithm based on the self-organizing map-feature-weighted fuzzy c-means (SOM-FWFCM) algorithm. Taking the production data of a job-shop as an example, the proposed algorithm was compared with four feature selection algorithms. The comparison demonstrates the effectiveness of that algorithm.

The completion time of ordered products can be predicted well by combining data mining with the analysis of the discrete data in the manufacturing industry, which are featured by scattered distribution, large volume, and poor authenticity. However, the existing studies have not fully considered the complex processing procedures, the features of manufacturing attributes, and the repetitive orders of stable consumers. To solve these problems, this paper explores the order management and completion date prediction of manufacturing job-shop based on deep learning. Section 2 extracts the features of manufacturing attributes, using the recursive feature elimination approach of random forest (RF), principal component analysis (PCA), and k-means clustering (KMC). Based on the extracted features, Section 3 predicts the activities and completion time of different manufacturing tasks in order management and constructs a deep learning prediction model based on bidirectional long short-term memory network (BiLSTM) and self-attention mechanism. The proposed model was proved effective through experiments.

## 2. Feature Extraction

In complex orders, the diverse products are manufactured in small batches through complicated and variable operations. As a result, it is not very desirable to predict the completion period of the products in complex orders by optimizing the processing operations of these products using heuristic algorithms. In the manufacturing job-shop, the order completion time is affected by complex, stochastic, and correlated factors. During real-world job-shop production, there is no ability to collect all the valuable and real information from the manufacturing process of ordered products. Therefore, it is particularly important to clarify the association between the information containing lots of abnormal data and the completion period of ordered products.

The completion date of ordered products is affected by the following factors: requirement on order quality, urgency of delivery, importance of consumers, profit margin of order, task volume of order, and complexity of operations. This paper proposes a hybrid algorithm for mining the factors affecting the completion period of ordered products. Firstly, the important features of manufacturing attributes were extracted by the recursive feature elimination approach of RF. Then, the linear features of manufacturing attributes were extracted through the PCA. After that, the KMC was applied to extract the nonlinear features of manufacturing

attributes. Finally, the extracted important features, linear features, and nonlinear features are fully fused.

**2.1. Extraction of Important Features.** The recursive feature elimination approach of RF is detailed as follows:

*Step 1.* Perform random sampling with the replacement on the manufacturing attribute samples in the original training set  $C$ . Suppose there are  $M$  original samples, and  $N$  samples are selected in each sampling. Denote the  $i$ -th bootstrap sample set generated through multiple random repetitive sampling as  $\delta_i$ .

*Step 2.* Select the splitting feature and the splitting point with the smallest Gini index to split the decision tree (DT), and build the  $i$ -th nonpruned and fully grown classification and regression tree (CART)  $\psi_i$  based on the bootstrap sample set  $\delta_i$ . Repeat this step until all DTs are constructed.

*Step 3.* Calculate the mean square error (MSE) of the RF model. For the  $i$ -th DT  $\psi_i$ , define the  $M-N$  samples not collected in the  $i$ -th random sampling as a set  $NDS_i$ . Let  $E_i^{\text{MSE}}$  be the MSE of DT  $\psi_i$ ,  $w_c$  be the true value of the test data, and  $w_{ic}^*$  be the predicted value of DT  $\psi_i$ . Then, the MSE can be calculated by the following:

$$E_i^{\text{MSE}} = \frac{\sum_{c=1}^{M-N} (w_c - w_{ic}^*)^2}{M - N}. \quad (1)$$

*Step 4.* Calculate the importance score of each feature of manufacturing attributes. The importance score  $\text{FR}_c$  of feature  $\text{FE}_c$  can be calculated by the following:

$$\text{FR}_c = \frac{1}{l} \sum_{i=1}^l (S_i^{\text{MSE}} - S_i^{\text{MSE}}). \quad (2)$$

*Step 5.* Output the feature set of manufacturing attributes corresponding to the minimum  $E_i^{\text{MSE}}$ , during the elimination of the feature with the smallest  $\text{FR}_c$ .

**2.2. Extraction of Linear Features.** Let  $C = \{c_1, c_2, \dots, c_t\}$  be the original training set composed of the column vectors of manufacturing attribute samples. In this paper, the PCA is adopted to extract the linear features from manufacturing attributes. In essence, the extraction searches for a unit projection vector  $\varphi$  that maximizes the projected variance of  $c_i$  on  $\varphi$ .

To eliminate the influence of the varied dimensionality between the column vectors of manufacturing attribute samples,  $C$  can be normalized by the following:

$$Q = \{q_1, q_2, \dots, q_t\} = \{c_1 - e, c_2 - e, \dots, c_t - e\}, \quad (3)$$

where

$$e = \frac{1}{t} \sum_{i=1}^t c_i. \quad (4)$$

Let  $\Lambda$  be the covariance matrix of sample set  $Q$ . The projection variance  $PV(q)$  of dataset  $Q = \{q_1, q_2, \dots, q_t\}$  on unit vector  $\varphi$  can be calculated by the following:

$$\begin{aligned}
FR(q) &= \frac{1}{t} \sum_{i=1}^t (q_i^\psi \phi)^2 = \frac{1}{t} \sum_{i=1}^t (q_i^\psi \phi)^\psi (q_i^\psi \phi) \\
&= \frac{1}{t} \sum_{i=1}^t \phi^\psi q_i q_i^\psi \phi = \phi^\psi \left( \frac{1}{t} \sum_{i=1}^t q_i q_i^\psi \right) \phi.
\end{aligned} \tag{5}$$

Thus, the PCA can be converted into the following mathematical problem:

$$\begin{cases} \max_{\phi} \phi^\psi \sum \phi \\ \text{s.t. } \phi^\psi \phi = 1 \end{cases}. \tag{6}$$

Let  $\mu$  be the Lagrangian multiplier. Formula (6) can be solved by the Lagrangian function  $U(\phi, \mu)$ :

$$U(\phi, \mu) = \phi^\psi \sum \phi - \mu \phi^\psi \phi. \tag{7}$$

Solving the partial derivative of  $U(\phi, \mu)$  for  $\phi$ :

$$\frac{\partial U(\phi, \mu)}{\partial \phi} = 2 \sum \phi - 2\mu \phi = 0 \Rightarrow \sum \phi = \mu \phi. \tag{8}$$

Combining  $\Lambda \phi = \mu \phi$  with formula (8):

$$FR(q) = \phi^\psi \left( \frac{1}{t} \sum_{i=1}^t q_i q_i^\psi \right) \phi = \phi^\psi \sum \phi = \mu \phi^\psi \phi = \mu. \tag{9}$$

Formula (9) shows that the eigenvalue of the covariance matrix  $\Lambda$  of manufacturing attribute sample  $q$  is its projection variance on unit vector  $\phi$ . The largest eigenvalue of  $\Lambda$  is the maximum projection variance, and the second largest eigenvalue of  $\Lambda$  is the next best projection variance. The rest can be obtained by analogy. The flow of the PCA is detailed as follows:

*Step 1.* Normalize the original training set  $C = \{c_1, c_2, \dots, c_t\}$  to eliminate the influence of the varied dimensionality between the column vectors of manufacturing attribute samples. That is, ensure that the mean projection  $e'$  of normalized dataset  $Q = \{q_1, q_2, \dots, q_t\}$  on projection vector  $\phi$  equals zero:

$$e' = \frac{1}{t} \sum_{i=1}^t q_i^\psi \phi = \left( \frac{1}{t} \sum_{i=1}^t q_i^\psi \right) \phi = 0. \tag{10}$$

*Step 2.* Compute the covariance matrix  $\Lambda$  of sample set  $Q$ :

$$\Lambda = \frac{1}{t} \sum_{i=1}^t q_i q_i^\psi. \tag{11}$$

*Step 3.* Decompose the eigenvalues of covariance matrix  $\Lambda$ , and sort them in descending order. Denote the ranked eigenvalues and the corresponding eigenvectors as  $\{\xi_1, \xi_2, \dots, \xi_t\}$  and  $\{\varphi_1, \varphi_2, \dots, \varphi_t\}$ , respectively.

*Step 4.* Map the eigenvectors  $\{\varphi_1, \varphi_2, \dots, \varphi_\nu\}$  corresponding to the top  $\nu$  eigenvalues. Let  $q_i^N$  be the mapped sample data. Then, the  $t$ -dimensional data can be mapped into  $\nu$ -dimensional data by the following:

$$q_i^{\text{new}} = \begin{bmatrix} \phi_1^\psi q_i \\ \phi_2^\psi q_i \\ \vdots \\ \phi_\nu^\psi q_i \end{bmatrix}. \tag{12}$$

The cumulative contribution rate  $\gamma$  can be determined by the following:

$$\gamma = \sqrt{\frac{\sum_{i=1}^{\nu} \xi_i^2}{\sum_{i=1}^t \xi_i^2}}. \tag{13}$$

*2.3. Extraction of Nonlinear Features.* The KMC was adopted to extract the nonlinear features of manufacturing attributes. Before feature extraction, the low-dimensional data on ordered products should be mapped into high-dimensional data through the following steps:

*Step 1.* Perform feature interaction on the original training set  $C = \{c_1, c_2, \dots, c_t\}$  and denote the resulting interactive feature set as  $C' = \{c_{0,1}, c_{1,2}, \dots, c_{t-1,t}\}$ . Let  $q_{ij}$  be the area feature interaction result between features  $q_i$  and  $q_j$ . The feature product interaction can be calculated by the following:

$$q_{i,j} = q_i \times q_j. \tag{14}$$

*Step 2.* Set the number of clusters for nonlinear manufacturing features and select an initial center randomly for each class. Find the optimal number of classes by the inflection point method for the within-cluster sum of squares, i.e., compute the within-cluster sum of squares at different  $k$  values. Let  $SU(f_1, f_2, \dots, f_K)$  be the within-cluster sum-of-squares;  $f_j$  be the center of the  $j$ -th cluster;  $q_i$  be the  $i$ -th sample in the  $j$ -th cluster;  $r_j$  be the total number of samples in the  $j$ -th cluster. Then, the optimal number of clusters can be calculated by the following:

$$SU(f_1, f_2, \dots, f_K) = \sum_{j=1}^K \sum_i^{r_j} (q_i - f_j)^2. \tag{15}$$

*Step 3.* Compute the distance between each cluster center and each interactive feature in the dataset. Based on the computed results, assign the interactive feature to the right cluster. Measure that distance with cosine similarity. The cosine similarity between samples  $q_1$  and  $q_2$  can be calculated by the following:

$$v = \frac{\sum_{i=1}^r q_{1i} q_{2i}}{\sqrt{\sum_{i=1}^r q_{1i}^2} \sqrt{\sum_{i=1}^r q_{2i}^2}} \tag{16}$$

*Step 4.* Update the center of each cluster based on the mean of the samples in that cluster. The partial derivative of the loss function can be calculated by the following:

$$\begin{aligned} \frac{\partial S U(f_1, f_2, \dots, f_h)}{\partial f_j} &= \sum_{j=1}^h \sum_i^{r_j} \frac{\partial (q_i - f_j)^2}{\partial f_j} \\ &= \sum_i^{r_j} \frac{\partial (q_i - f_j)^2}{\partial f_j} = \sum_i^{r_j} -2(q_i - f_j). \end{aligned} \quad (17)$$

Making formula (17) equal to zero:

$$\begin{aligned} \sum_i^{r_j} -2(q_i - f_j) &= 0, \\ r_j f_j - \sum_i^{r_j} q_i &= 0 \Rightarrow f_j = \frac{\sum_{i=1}^{r_j} q_i}{r_j}. \end{aligned} \quad (18)$$

Formula (18) shows that the loss is minimized, when the cluster center equals the mean of all samples in that cluster.

*Step 5.* Repeat Steps 3-4 until the termination condition is satisfied.

*Step 6.* Output the  $K$  cluster centers as the nonlinear features extracted from manufacturing attribute samples.

Figure 1 explains the flow of linear and nonlinear feature extractions. All completion date prediction models are verified on the test data. The above algorithm is adopted to extract the features of the factors affecting the completion date, according to the test error of each model. Then, the mean test error is computed, and the prediction model with the smallest test error is selected.

### 3. Prediction of Activities and Completion Time

Process mining of predictive order management helps job-shop managers identify abnormal, incompliant order management activities so that they could take emergency measures and crisis response measures. In the context of order management, the prediction of activities and completion time of each manufacturing task brings several advantages: effectively increasing job-shop production efficiency, significantly lowering operating costs, and accurately recognizing illegal activities.

Figure 2 presents the framework of the prediction model for order management activities and completion time. There are five layers in the framework: an input layer, an embedding layer, a BiLSTM layer, a self-attention layer, and an output layer.

The attributes in job-shop manufacturing logs should be extracted and converted into eigenvectors before being imported to the prediction model. Let  $K = \{\varepsilon_1, \varepsilon_2, \varepsilon_3, \dots, \varepsilon_m\}$  be the set of job-shop manufacturing logs, where  $\varepsilon_i = \langle o_{\tau 1}, o_{\tau 2}, o_{\tau 3}, \dots, o_{\tau m} \rangle$  represents the evolutionary trajectory of the  $i$ -th event, with  $m = |\varepsilon_i|$ . Each evolution trajectory needs to be converted into an eigenvector  $a = [a_1, a_2, a_3, \dots, a_{GR}]$ , with  $GR$  being the number of samples. In the eigenvector  $a =$

$[a_1, a_2, a_3, \dots, a_{GR}]$ , element  $a_i$  is a two-dimensional eigenvector, including both the event trajectory related to completion time and the number of event-related attributes. The latter covers numerical and non-numerical attributes.

Before an eigenvector is inputted to the neural network via the embedding layer, it is necessary to linearly map the high-dimensional sparse eigenvector  $a = [a_1, a_2, a_3, \dots, a_{GR}]$ . Let  $WS$  be the dimensionality of the code for the mapped eigenvector. Then, the mapped low-dimensional dense eigenvector can be expressed as  $o = [o_1, o_2, o_3, \dots, o_\tau]$ , with  $o_\tau \in R^{WS}$ . Then, we have the following:

$$\begin{aligned} GR(a_1, a_2, a_3, \dots, a_{GR}|a_i) &= \sum_{d=1}^{GR} GR(a_d|a_i), \\ o(a) &= - \sum_{i=1}^k \sum_{i=1}^k \log GR(a_{GR}|a_i). \end{aligned} \quad (19)$$

In our embedding layer, nonnumerical attributes are encrypted by one-hot encoding. This is because one-hot encoding features high-dimensional sparsity and involves no internal association through nonlinear mapping. Every embedding vector can be updated through the network training based on the embedding layer, completing the search for similarity between different vectors in a multi-dimensional space [28].

The BiLSTM consists of two LSTMs with the opposite propagation directions. Figure 3 explains the internal structure of an LSTM. As a modification of recurrent neural network (RNN), the LSTM has a strong ability of modeling time series and overcomes the memory problem and vanishing gradients of traditional RNN. The LSTM can update the hidden state  $YC_\tau$ , based on the input  $o_\tau$  of the previous layer and the previous hidden state  $YC_{\tau-1}$ . Let  $SR_\tau$ ,  $YW_\tau$ , and  $SC_\tau$  be the input gate, forget gate, and output gate, respectively. The input gate selectively preserves the input information and updates the cell state, the forget gate selectively forgets the redundant information, and the output gate determines which cell state should be outputted. Let  $\omega$  be the output weight;  $PO$  be the bias;  $JH_1$  and  $JH_2$  be the activation function sigmoid and the activation function tanh, respectively. Then, we have the following:

$$\begin{aligned} SR_\tau &= JH_1(\omega_{SR} * [YC_{\tau-1}, o_\tau] + PO_{SR}), \\ YW_\tau &= JH_1(\omega_g * [YC_{\tau-1}, o_\tau] + PO_{YW}), \\ GS'_\tau &= JH_2(\omega_{GS} * [YC_{\tau-1}, o_\tau] + PO_{GS}), \\ GS_\tau &= YW_\tau * GS_{\tau-1} + SR_\tau * GS'_\tau, \\ SC_\tau &= JH_1(\omega_{SC} * [YC_{\tau-1}, o_\tau] + PO_{SC}), \\ YC_\tau &= SC_\tau * JH_2(GS_\tau). \end{aligned} \quad (20)$$

The BiLSTM is an extension of unidirectional LSTM based on reverse time flow. Let  $YC'_\tau$  and  $YC''_\tau$  be the forward and backward order management states, respectively. Then, the current output state  $YC_\tau$  can be updated based on  $YC'_\tau$  and  $YC''_\tau$ . In addition, the one-way operation flow of the LSTM is denoted as  $K_{OW}$ . Compared with traditional one-way LSTM, the BiLSTM learns historical and

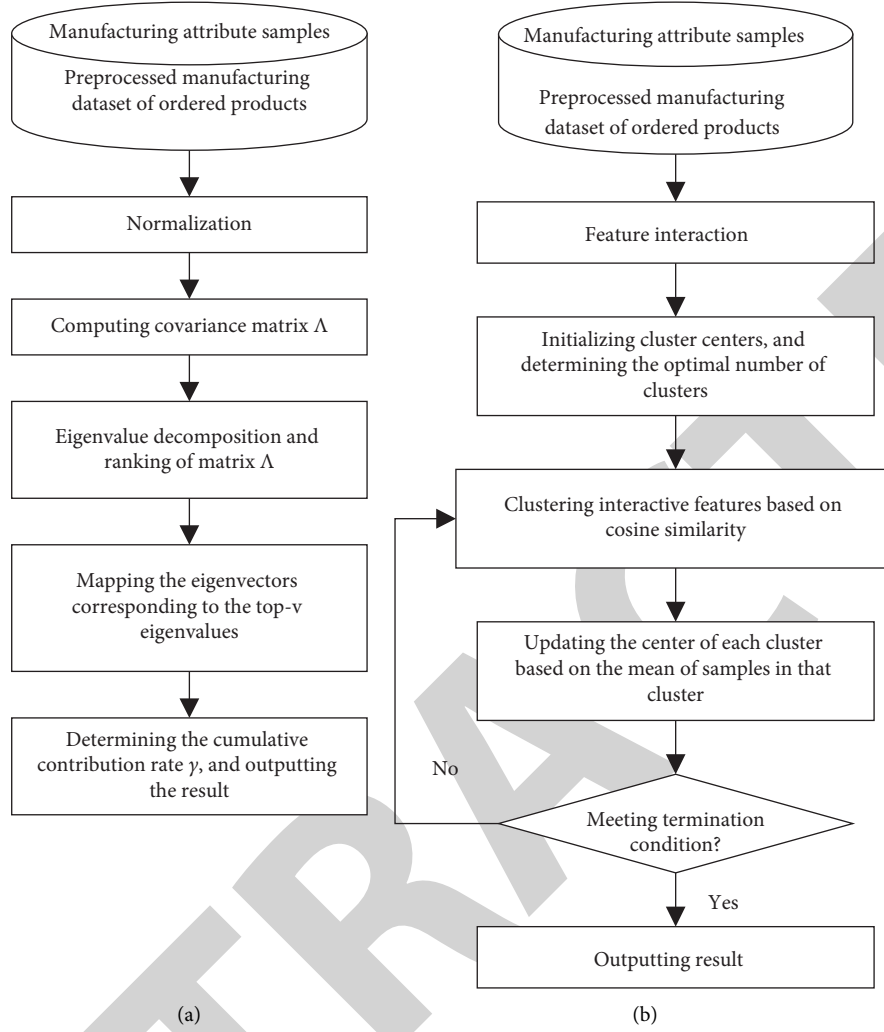

FIGURE 1: Flow of linear and nonlinear feature extractions. (a) Linear feature extraction; (b) nonlinear feature extraction.

future states of order management simultaneously, and acquires highly stable and reliable feature information. Then, we have the following:

$$\begin{aligned}
 YC'_{\tau} &= K_{OW}'(YC_{\tau-1}, o_{\tau}), \\
 YC''_{\tau} &= K_{OW}''(YC_{\tau+1}, o_{\tau}), \\
 YC_{\tau} &= [YC'_{\tau}, YC''_{\tau}].
 \end{aligned} \tag{21}$$

The job-shop orders placed by a stable consumer group tend to be repetitive. In fact, repetition is an obvious feature of predicting the activities and completion time of every manufacturing task during order management. This paper adds a self-attention mechanism to the network to forecast repetitive activities. Figure 4 explains the internal structure of the attention mechanism. The attention-based prediction model considers the weight coefficient between input eigenvectors, and the manufacturing tasks related to the current input eigenvector, without being distracted by the information weakly correlated with the current input eigenvector.

Let  $x_{\tau, \tau'}$  be the similarity matrix between hidden states  $YC_{\tau}$  and  $YC'_{\tau'}$  at moments  $\tau$  and  $\tau'$ , respectively;  $\omega_{YW}$  and

$\omega_{YW}'$  be the weight matrices of hidden states  $YC_{\tau}$  and  $YC'_{\tau'}$ , respectively;  $\omega_x$  be the weight matrix for nonlinear combination;  $PO_x$  and  $PO_{YW}$  be bias vectors. The vector matrix  $[YC_1, YC_2, YC_3, \dots, YC_{\tau}]$  of the previous BiLSTM is imported to the attention layer. Then, the similarity of any feature to every neighbor can be characterized by a self-attention matrix  $X$ :

$$\begin{aligned}
 YW_{\tau, \tau'} &= JH_2(\omega_{YW} YC_{\tau} + \omega_{YW}' YC'_{\tau'} + PO_{YW}), \\
 x_{\tau, \tau'} &= JH(\omega_x YW_{\tau, \tau'} + PO_x).
 \end{aligned} \tag{22}$$

The hidden state  $\tau'$  of the attention at moment  $\tau$  is the weighted sum of all hidden states  $YC'_{\tau'}$  and similarity matrix  $x_{\tau, \tau'}$  at moment  $\tau'$ :

$$k_{\tau} = \sum_{\tau'=1}^m x_{\tau, \tau'} \times YC'_{\tau'}. \tag{23}$$

For each manufacturing task in order management, the output layer should predict both activities and completion time. The activity prediction mainly transforms order management into multiple classes of manufacturing tasks.

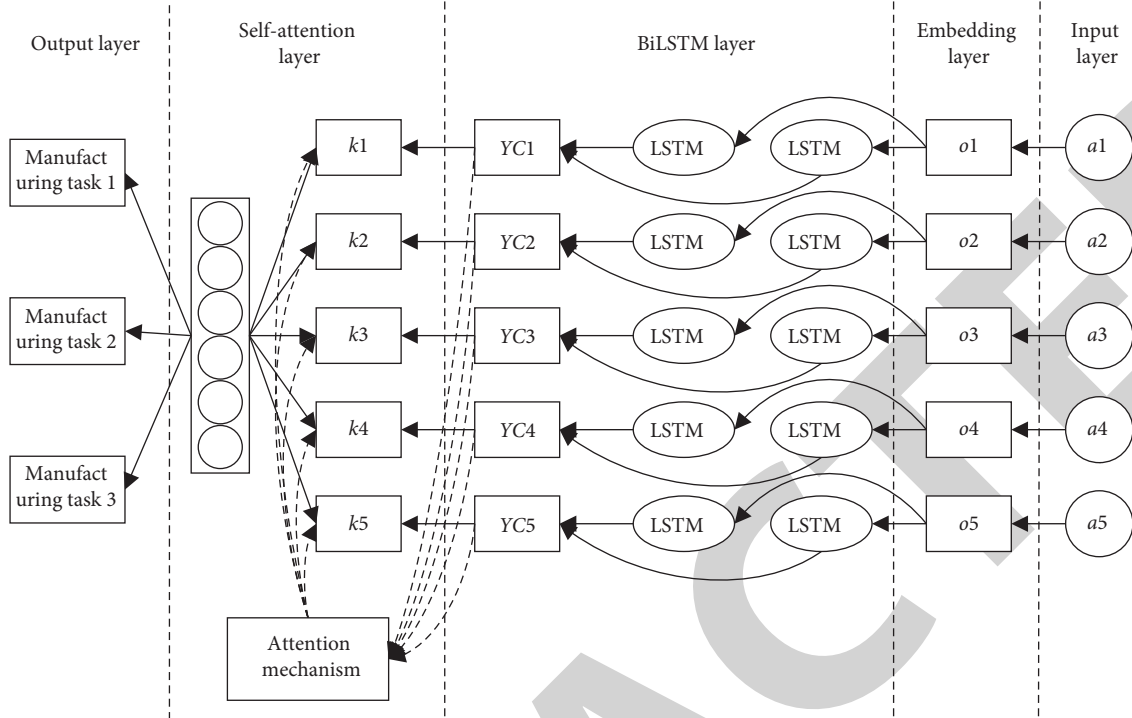

FIGURE 2: Prediction model for order management activities and completion time.

The softmax classifier is adapted to output the predicted activities of order management and the cross-entropy loss. Let  $a$  be the evolution trajectory of the input manufacturing event; FS be the total classes of manufacturing tasks;  $b_i$  be the true label class of the  $i$ -th class;  $g_i(a)$  be the predicted output of the model. Then, the cross-entropy loss can be calculated by the following:

$$\text{LOSS}(a) = - \sum_{i=k}^{FS} b_i \log g_i(a). \quad (24)$$

#### 4. Experiments and Results Analysis

Taking a furniture enterprise in Foshan, southern China's Guangdong Province as an example, this paper adopts the recursive feature elimination approach of RF to extract the important features from manufacturing attributes. The lowest-ranking feature was removed, and the feature extraction error was computed. These steps were repeated until all unimportant features were eliminated. Figure 5 reports the feature extraction errors at different numbers of residual features. It can be learned that the model was highly accurate at 5–7 residual features and relatively inaccurate at fewer than 4 residual features.

In this paper, the PCA is performed to extract the linear features of manufacturing attributes. The cumulative contribution rate was calculated under a different number of principal components (as shown in Figure 6). Referring to the cumulative contribution rates of all components, the minimum threshold was defined for the cumulative contribution rate (0.8). Hence, the top six principal components

were extracted. Table 1 shows the linear features extracted from the manufacturing attributes in view of the factors affecting the order completion period.

Next, the KMC was called to extract the nonlinear features of manufacturing attributes. The optimal number of clusters was determined as 15 by the inflection point and the within-cluster sum-of-square. After that, a cluster analysis was carried out on interactive features. Table 2 shows the nonlinear features extracted by KMC from manufacturing attributes.

The prediction performance of our model on manufacturing activities and completion time for ordered products was evaluated through experiments on a self-designed manufacturing attribute sample set. The sample set was divided into a training set and a test set by the ratio of 3 : 1. One-eighth of the training set was organized as a verification set. Figure 7 shows the training loss curve of our prediction model for the completion period. The curve demonstrates the convergence ability of our model.

Our prediction model was applied to predict the manufacturing activities and completion time on samples from different sources (as shown in Table 3). The prediction accuracy and error of our model were compared with those of stacked autoencoder and 1DCNN. From the manufacturing sample sets from different job-shops, the trajectories of manufacturing events with repeatable features involving orders from stable consumers were screened. In addition, our model was compared separately with the stacked autoencoder. Figure 8 compares their prediction accuracies of repetitive activities on samples from different sources. Facing samples from different sources, our model was far more accurate in predicting repetitive activities than

FIGURE 9: Predicted value vs. true value.

the stacked autoencoder. Of course, our model performance is slightly insufficient on the self-designed dataset: the learning ability was not fully exerted, and the obvious features of manufacturing attributes were not ideally extracted. The reason is that the manufacturing events in the job-shops are executed manually, which brings certain stochastic and changeable factors. In spite of that, the experimental results demonstrate that our model is feasible to predict the completion period of orders with repeatable features laid by stable consumers.

Next, our prediction model for the completion period of ordered products, which was constructed based on the features extracted from manufacturing attributes, was compared with machine learning through experiments. Table 4 shows the experimental results of the two prediction models on the test data. The results fully demonstrate the effectiveness of our model. Figure 9 compares the predicted value of our model with the true value. The small error between the two values visually demonstrates the superiority of our model in prediction.

## 5. Conclusions

Based on deep learning, this paper explores the order management and completion date prediction of manufacturing job-shop. Firstly, the important features, linear features, and nonlinear features were extracted from manufacturing attributes. Next, a deep learning prediction model was constructed based on BiLSTM and the self-attention mechanism. Based on the extracted features, the manufacturing task activities and their completion time were forecasted by the proposed model. Through experiments, the relevant features were extracted from manufacturing attributes by the recursive feature elimination approach of RF, PCA, and KMC. The training loss curve of the completion period prediction model was plotted, revealing the convergence ability of the model. In addition, our prediction model was applied to predict manufacturing activities and completion time on samples from different sources. The prediction error and accuracy were summarized. Furthermore, the experimental results of our model were compared with those of stacked autoencoder and 1DCNN. The comparison visually demonstrates the superior prediction effect of our model.

With the gradual expansion of the book logistics market and the year-on-year increase in book publications, the incidence of book reverse logistics continues to increase, and the problem of book companies' inventory backlog has become increasingly prominent. To effectively alleviate the current backlog of book returns and exchanges, this paper constructs a two-party game model of "book publisher-book retailer," analyzes the evolution process of book publishers and book retailers' participation strategies and the influence of parameter changes on stable strategies through theoretical analysis and numerical simulation, and draws the following conclusions. (1) Whether book publishers and book retailers choose to participate in the reverse logistics optimization of book returns and exchanges is closely related to their benefits and costs, and it also depends on whether the other party participates in the reverse logistics optimization of books. (2) When the cost of participating in book reverse logistics reaches a certain condition, the probability of both parties participating in the optimization is the greatest.

## 1. Introduction

With the rapid development of our country's society and economy, people's demand for spiritual culture is increasing day by day. The national inventory of books has increased substantially, reaching 6.64 billion books in 2014 [1]. At the same time, the incidence of reverse logistics in the book industry is the highest, generally around 30% [2]. In a certain period of time, the return rate of best-selling books will exceed 50% or even 60% [2]. Therefore, the problem of book backlog returns is no longer a disturbing factor affecting the economic development of the book industry but has become one of the leading factors that determine the economic development of the book industry. How to establish a good book reverse logistics between book publishers and book retailers to ensure the healthy and orderly development of the book logistics market is one of the key issues faced by managers and scholars in the industry.

To effectively alleviate the reverse logistics problem of book backlog inventory, Ma [3] established a book centralized inventory optimization model on the basis of analyzing the

problems of book reverse logistics. Ning [4] built a collaboration mechanism with the focus on the green supply chain. Morgan [5] linked the sustainable supply chain management, resource input, and operational performance of reverse logistics and analyzed the sustainability of reverse logistics. Faustino et al. [6] introduced the concept of sustainability into reverse logistics and established an applicable reverse logistics process reference model. To accurately analyze the relationship of interest groups when book publishers and book retailers participate or not participate in the optimization of book reverse logistics, this paper consults relevant documents and sorts them out. Yi [7] and Xia [8] established a Stackelberg game model to analyze the group interest behavior of manufacturers and recyclers in reverse logistics. Ye [9] used evolutionary game theory to analyze the relationship between residents, government, and residents in the reverse logistics of waste sorting and recycling. Chen [10] established a game model to analyze the impact of recyclers on the supply chain under different parameter settings of the recycling mode. Wang [11] used game theory to establish a recycling decision model and analyzed product recycling strategies between

manufacturers and retailers. Chen et al. [12], Shi et al. [13], and Ding et al. [14] used game theory to analyze the reverse logistics pricing of goods between manufacturers and recyclers.

Throughout the existing results, scholars at home and abroad have conducted little research on the evolution process and evolution law of the behavior of book reverse logistics interest groups, and they have rarely studied from the perspective of adaptation and evolution in reverse logistics scenarios to study the gradual change and evolution process of the book interest groups' participation strategies and behaviors by factors such as costs and benefits of reverse logistics. This paper takes book publishers and book retailers as research objects, explores the synergy between the two in the book reverse logistics optimization (hereinafter referred to as optimization), analyzes the behavioral evolutionary game of book publishers and book retailers participating in optimization decision making, and conducts numerical simulations to explore ways to effectively improve the active participation of both companies in book reverse logistics optimization, thereby reducing the inventory space occupied by the accumulation of books, reducing the resource waste of books, and making up for part of the vacancy in the study of the behavior evolution of the book reverse logistics interest groups.

## 2. Group Behavior Evolution Model of Book Publishers and Book Retailers

*2.1. Scene Reappearance and Model Assumptions.* In the book reverse logistics, because book publishers and book retailers consider complex and diverse factors when deciding whether to participate in the optimization of book reverse logistics, this paper makes the following assumptions without changing the nature of the problem:

- (1) Participants in the game: book publishers and book retailers are bounded rational subjects, and they will continue to learn and imitate the strategy choices of other individuals and improve their own revenue decisions, so strategies with higher returns will replace strategies with lower returns [15].
- (2) The strategic behavior of the game subject: both book publishers and book retailers can choose a positive strategy or negative strategy. The book publishers' strategy collection is (participation, non-participation), and the book retailers' strategy collection is (participation, non-participation).
- (3) The proportion of behavior strategy: assuming that in the initial stage of the evolutionary game, the proportion of book publishers participating in the optimization is  $X$ , then the proportion of not participating in the optimization is  $1 - X$ ,  $0 \leq X \leq 1$ ; the proportion of book retailers participating in the optimization is  $Y$ ; then, the proportion of not participating in the optimization is  $1 - Y$ ,  $0 \leq Y \leq 1$ .
- (4) Assume that the cost of book publishers choosing to participate in book reverse logistics optimization is

greater than the cost of not participating in book reverse logistics optimization, that is,  $C_1 > S_1$ .

- (5) Assume that the cost of book retailers choosing to participate in book reverse logistics optimization is greater than the cost of not participating in book reverse logistics optimization, that is,  $C_2 > F_2$ .

Based on the above assumptions, this paper constructs a mixed strategy payment matrix between book publishers and book retailers, as shown in Table 1.

The parameters and explanations involved in the hybrid strategy payout matrix are as follows.

- (1)  $\alpha_1$  and  $\alpha_2$ , respectively, represent the production and sales risk ratio of book publishers and book retailers. Production and sales risk refers to all the costs that book publishers and book retailers need to bear due to risks in the process of book reverse logistics, and  $\alpha_1 + \alpha_2 = 1$ .
- (2)  $N$  is all loss costs incurred in the process of book reverse logistics, including invisible losses such as negative impacts on the enterprise. Visible loss costs such as the backlog of unsalable books and excess shipping costs caused by reverse logistics and so on.
- (3)  $C_1$  and  $C_2$ , respectively, represent the cost of book publishers and book retailers choosing to participate in book reverse logistics optimization, including the cost of purchasing new equipment and new technology, and so on.
- (4)  $S_1$  and  $F_2$ , respectively, represent the cost of book publishers and book retailers choosing not to participate in book reverse logistics optimization, including the loading, unloading, handling, sorting, and other costs incurred in the process of book recycling.
- (5)  $B_1$  and  $L_2$ , respectively, represent the revenue of book publishers and book retailers choosing to participate in book reverse logistics optimization.
- (6)  $D_1$  and  $D_2$ , respectively, represent the revenue of book publishers and book retailers choosing not to participate in book reverse logistics optimization.

*2.2. Establishment of Replication Dynamic Equation.* According to the assumptions and the game payment matrix, this paper can get the expected returns  $E_{A1}$  and  $E_{A2}$  of book publishers choosing to participate in the strategy, non-participation strategy, and the average expected return  $E_A$  of book publishers.

$$\begin{aligned}
 E_{A1} &= Y(B_1 - C_1 - \alpha_1 N) + (1 - Y)(D_1 - C_1 - N) \\
 &= Y(B_1 - D_1 + N - \alpha_1 N) + D_1 - C_1 - N, \\
 E_{A2} &= Y(D_1 - S_1 - N) + (1 - Y)(D_1 - S_1 - N) \\
 &= D_1 - S_1 - N, \\
 \bar{E}_A &= XE_{A1} + (1 - X)E_{A2}.
 \end{aligned} \tag{1}$$

Then, we can get its dynamic replication equation  $F(X)$ .

TABLE 1: Matrix of payment.

Game subject		Book retailers	
		Participation (Y)	Non-participation (1 - Y)
Book publishers	Participation (X)	$B_1 - C_1 - \alpha_1 N,$ $L_2 - C_2 - \alpha_2 N$	$D_1 - C_1 - N,$ $D_2 - F_2$
	Non-participation (1 - X)	$D_1 - S_1 - N,$ $D_2 - C_2$	$D_1 - S_1 - N,$ $D_2 - F_2$

$$\begin{aligned}
F(X) &= \frac{dX}{dt} \\
&= X(E_{A1} - \bar{E}_A) \\
&= X(1 - X)(E_{A1} - E_{A2}) \\
&= X(1 - X)[Y(B_1 - D_1 + N - \alpha_1 N) + S_1 - C_1].
\end{aligned} \tag{2}$$

In the same way, this paper can get the expected returns  $E_{B1}$  and  $E_{B2}$  of bookretailers choosing to participate in the strategy, non-participation strategy. The average expected

return  $\bar{E}_B$  of bookretailers, and the replication dynamic equation  $F(Y)$ .

$$E_{B1} = X(L_2 - C_2 - \alpha_2 N) + (1 - X)(D_2 - C_2)$$

$$= X(L_2 - D_2 - \alpha_2 N) + D_2 - C_2,$$

$$E_{B2} = X(D_2 - F_2) + (1 - X)(D_2 - F_2)$$

$$= D_2 - F_2,$$

$$\bar{E}_B = YE_{B1} + (1 - Y)E_{B2}, \tag{3}$$

$$F(Y) = \frac{dY}{dt}$$

$$= Y(E_{B1} - \bar{E}_B)$$

$$= Y(1 - Y)(E_{B1} - E_{B2}),$$

$$= Y(1 - Y)[X(L_2 - D_2 - \alpha_2 N) + F_2 - C_2].$$

Thus, the replication dynamic equation, Jacobian matrix  $J$ , and the corresponding determinants and traces of the game system are obtained. For the sake of discussion below,

let  $\beta_1 = B_1 - D_1 + N - \alpha_1 N + S_1 - C_1$  and  $\beta_2 = L_2 - D_2 - \alpha_2 N + F_2 - C_2$ .

$$\begin{cases} F(X) = \frac{dX}{dt} = X(1-X)[Y(B_1 - D_1 + N - \alpha_1 N) + S_1 - C_1], \\ F(Y) = \frac{dY}{dt} = Y(1-Y)[X(L_2 - D_2 - \alpha_2 N) + F_2 - C_2], \end{cases} \quad (4)$$

$$J = \begin{bmatrix} \frac{\partial F(X)}{\partial X} & \frac{\partial F(X)}{\partial Y} \\ \frac{\partial F(Y)}{\partial X} & \frac{\partial F(Y)}{\partial Y} \end{bmatrix} \quad (5)$$

$$= \begin{bmatrix} (1-2X)[Y(B_1 - D_1 + N - \alpha_1 N) + S_1 - C_1] & X(1-X)(B_1 - D_1 + N - \alpha_1 N) \\ Y(1-Y)(L_2 - D_2 - \alpha_2 N) & (1-2Y)[X(L_2 - D_2 - \alpha_2 N) + F_2 - C_2] \end{bmatrix},$$

$$\det(J) = \begin{vmatrix} \frac{\partial F(x)}{\partial x} & \frac{\partial F(x)}{\partial y} \\ \frac{\partial F(y)}{\partial x} & \frac{\partial F(y)}{\partial y} \end{vmatrix} = \frac{\partial F(x)}{\partial x} \cdot \frac{\partial F(y)}{\partial y} - \frac{\partial F(y)}{\partial x} \cdot \frac{\partial F(x)}{\partial y}, \quad (6)$$

$$= (1-2X)[Y(B_1 - D_1 + N - \alpha_1 N) + S_1 - C_1] \cdot (1-2Y)[X(L_2 - D_2 - \alpha_2 N) + F_2 - C_2] - Y(1-Y)(L_2 - D_2 - \alpha_2 N) \cdot X(1-X)(B_1 - D_1 + N - \alpha_1 N),$$

$$\text{Tr}(J) = \frac{\partial F(x)}{\partial x} + \frac{\partial F(y)}{\partial y} \quad (7)$$

$$= (1-2X)[Y(B_1 - D_1 + N - \alpha_1 N) + S_1 - C_1] + (1-2Y)[X(L_2 - D_2 - \alpha_2 N) + F_2 - C_2].$$

### 3. Analysis on the Stability of Interest Groups Based on Evolutionary Game

This paper analyzes the evolution process of the strategic system of book publishers and book retailers and combines the replication dynamic equation (4) to obtain five evolutionary equilibrium points of system evolution  $(0, 0)$ ,  $(1, 0)$ ,  $(0, 1)$ ,  $(1, 1)$ ,  $(X_0, Y_0)$ , where  $X_0 = (C_2 - F_2)/(L_2 - D_2 - \alpha_2 N)$ ,  $Y_0 = (C_1 - S_1)/(B_1 - D_1 + N - \alpha_1 N)$ . If and only if  $0 < (C_2 - F_2)/(L_2 - D_2 - \alpha_2 N) < 1$ ,  $0 < (C_1 - S_1)/(B_1 - D_1 + N - \alpha_1 N) < 1$ ,  $(X_0, Y_0)$  may be the stable equilibrium point of the system. Since the parameter value range will affect the evolutionary stability strategy of the system, this paper will discuss the stability strategy of the evolutionary system in four cases.

- (1) Case 1:  $\beta_1 > 0, \beta_2 > 0$ . Substitute  $\beta_1 > 0$  and  $\beta_2 > 0$  into formulas (6) and (7) to obtain the expression of the determinant and trace of the system equilibrium point, as shown in Table 2.

To accurately analyze the relationship between book publishers and book retailers participating in the optimization, the parameters are assigned, as shown in Table 3. This paper can get the dynamic evolution path and trend of replication of book

publishers and book retailers in Case 1, as shown in Figure 1.

It can be seen from Case 1 that when  $\beta_1 > 0, \beta_2 > 0$ , that is,  $B_1 - C_1 + N - \alpha_1 N > D_1 - S_1$ ,  $L_2 - C_2 - \alpha_2 N > D_2 - F_2$ , the net revenue of book publishers and book retailers participating in the optimization is greater than the net revenue of not participating in optimization. The two stability policies that exist in the system are related to the initial states of  $X$  and  $Y$ . When both parties participate in a low proportion, the system tends to approach the  $(0, 0)$  strategy, that is, both parties choose not to participate in optimization. When both parties participate in a high proportion of optimization, the system tends to approach the strategy  $(1, 1)$ , that is, both parties choose to participate in optimization.

- (2) Case 2:  $\beta_1 < 0, \beta_2 > 0$ . In the same way, this paper obtains the expression of the determinant and trace of the equilibrium point of the system, as shown in Table 4.

Similarly, the parameters are assigned, as shown in Table 5. This paper can get the dynamic evolution path and trend of replication of book publishers and book retailers in Case 2, as shown in Figure 2.

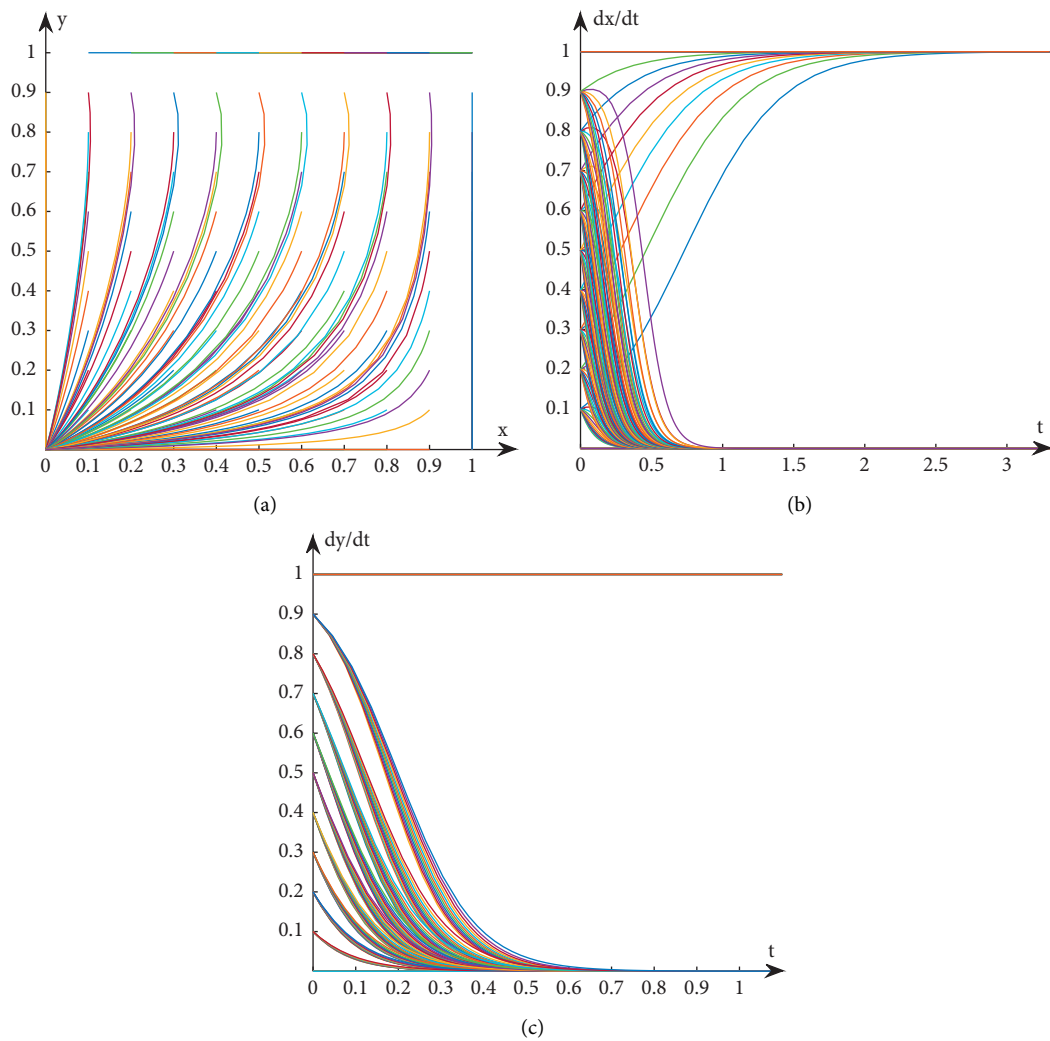

FIGURE 3: Evolution path diagram in Case 3. (a) Evolution path of system. (b) Evolution path of book publishers. (c) Evolution path of book retailers.

participate in the optimization, so (0,0) is an evolutionary stability strategy.

- (4) Case 4:  $\beta_1 < 0, \beta_2 < 0$ . In the same way, this paper obtains the expression of the determinant and trace of the equilibrium point of the system, as shown in Table 8.

Similarly, the parameters are assigned, as shown in Table 9. This paper can get the dynamic evolution path and trend of replication of book publishers and book retailers in Case 4, as shown in Figure 4.

It can be seen from Case 4 that when  $\beta_1 < 0, \beta_2 < 0$ , that is,  $B_1 - C_1 + N - \alpha_1 N < D_1 - S_1, L_2 - C_2 - \alpha_2 N < D_2 - F_2$ , the net revenue of book publishers and book retailers participating in the optimization is less than the net revenue of not participating in optimization. Thus, both parties chose not to participate in the optimization strategy.

## 4. Sensitivity Analysis of Group Behavior Evolution System

*4.1. The Influence of the Initial State on the Evolution Path of the System.* By changing the initial state of the proportion of book publishers participating in optimization  $X$  and the proportion of book retailers participating in optimization  $Y$ , this paper further analyzed the influence of different proportions of initial states on the evolution path and stability strategy of the system under the condition of Case 1 and obtained the simulation results by using MATLAB software.

### 4.1.1. The Evolution Path of Book Publishers

- (1) Discuss the evolution path of book publishers under different proportions of book retailers' selection strategies. It is assumed that when the proportion of book retailers participating in the optimization is selected with a probability of 0.5, the book publishers participate with the probability of 0.1, 0.3, 0.5, 0.7, and 0.9, respectively. The simulation results are shown in Figure 5.
- (2) Discuss the evolution path of book publishers under different proportions of book publishers' selection strategies. It is assumed that when the proportion of book retailers participating in the optimization is selected with a probability of 0.5, the book publishers participate with the probability of 0.1, 0.3, 0.5, 0.7, and 0.9, respectively. The simulation results are shown in Figure 6.

### 4.1.2. The Evolutionary Path of Book Retailers

- (1) Discuss the evolution path of book retailers under different proportions of book publishers' selection strategies. It is assumed that when the proportion of book retailers participating in the optimization is selected with a probability of 0.5, the book publishers participate with the probability of 0.1, 0.3, 0.5, 0.7,

and 0.9, respectively. The simulation results are shown in Figure 7.

- (2) Discuss the evolution path of book retailers under different proportions of book retailers' selection strategies. It is assumed that when the proportion of book publishers participating in the optimization is selected with a probability of 0.5, the book retailers participate with the probability of 0.1, 0.3, 0.5, 0.7, and 0.9, respectively. The simulation results are shown in Figure 8.

As can be seen from Figures 5–8, when the initial proportion of book publishers or book retailers choosing to participate in the optimization is relatively low, for example, when the value is 0.1, 0.3, or 0.5, its evolutionary path tends to the unsatisfactory state of not participating in the optimization. When the initial proportion of book publishers or book retailers choosing to participate in the optimization is relatively high, such as 0.7 or 0.9, its evolutionary path tends to the ideal state of participating in the optimization.

### 4.2. The Influence of Parameter Value Changes on the Evolutionary Game System

*4.2.1. Theoretical Analysis.* When the net revenue of book publishers and book retailers participating in the optimization is greater than the net revenue of not participating in the optimization, that is,  $\beta_1 > 0, \beta_2 > 0$ , the evolutionary system will eventually tend to the (0, 0) strategy that neither side will choose to participate in the optimization or both sides tend to choose (1, 1) strategy that participates in the optimization. Therefore, (0, 0) and (1, 1) are evolutionary stable strategies of the system, and the point  $D(X_0, Y_0)$  is the saddle point. The specific evolution process is shown in Figure 9.

The regional area of quadrilateral AOCD represents the probability that neither book publishers nor book retailers will participate in the optimization, while the regional area of quadrilateral ABCD represents the probability that both book publishers and book retailers will participate in the optimization. Therefore, the area size of the quadrilateral can represent the possibility that the two sides of the game choose different corresponding strategies, and its size is related to the position of the saddle point  $(X_0, Y_0)$ . The probability of system stability strategy can be changed by changing the numerical size of the saddle point parameter to guide the evolutionary game system to evolve towards the ideal state, where  $X_0 = (C_2 - F_2)/(L_2 - D_2 - \alpha_2 N)$ ,  $Y_0 = (C_1 - S_1)/(B_1 - D_1 + N - \alpha_1 N)$ .

Let  $S_{ABCD}$  represent the area of quadrilateral ABCD and  $S_{AOCD}$  represent the area of quadrilateral AOCD.

$$S_{ABCD} = 1 - \frac{1}{2} \left( \frac{C_2 - F_2}{L_2 - D_2 - \alpha_2 N} + \frac{C_1 - S_1}{B_1 - D_1 + N - \alpha_1 N} \right), \quad (8)$$

$$S_{AOCD} = \frac{1}{2} \left( \frac{C_2 - F_2}{L_2 - D_2 - \alpha_2 N} + \frac{C_1 - S_1}{B_1 - D_1 + N - \alpha_1 N} \right). \quad (9)$$

TABLE 8: The local stability of the equilibrium point in Case 4.

Equilibrium point	det ( $J$ )	tr ( $J$ )	Local stability	Strategy profile
(0, 0)	+	-	ESS	(Non-participation, non-participation)
(0, 1)	-	Uncertain	Saddle point	(Participation, non-participation)
(1, 0)	-	Uncertain	Saddle point	(Non-participation, participation)

$(X_0, Y_0)$	-	0	Saddle point	

TABLE 9: Assignment of each parameter in Case 4.

Parameter	$\alpha_1$	$\alpha_2$	$N$	$C_1$	$C_2$	$S_1$	$F_2$	$B_1$	$L_2$	$D_1$	$D_2$
Assignment	0.5	0.5	20	22	24	4	11	15	32	10	20

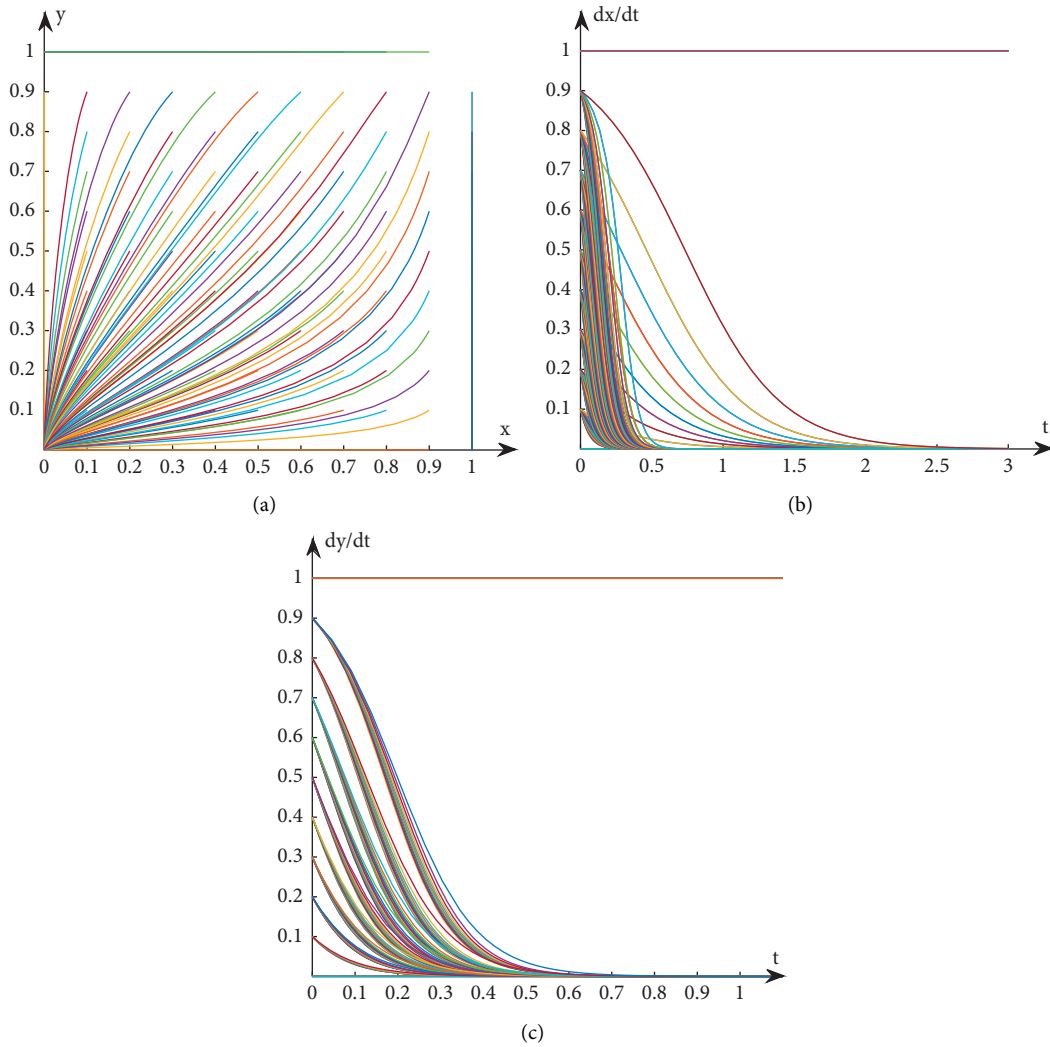

FIGURE 4: Evolution path diagram in Case 4. (a) Evolution path of system. (b) Evolution path of book publishers. (c) Evolution path of book retailers.

According to formulas (8) and (9), the parameters in the game model of book publishers-book retailers are analyzed, and Table 10 is obtained.

From Table 10, it can be seen that when the production and sales risk ratio of book publishers decreases and the cost

of reverse logistics decreases, the cost of book publishers and book retailers participating in optimization reduces and the revenue increases, and the cost of not participating in optimization reduces and the revenue decreases, and the system will reach the (1, 1) state more quickly. When  $N$

FIGURE 5: Evolution path when the initial state of  $X$  is the same.

FIGURE 7: Evolution path when the initial state of  $X$  is the same.

FIGURE 6: Evolution path when the initial state of  $Y$  is the same.

FIGURE 8: Evolution path when the initial state of  $Y$  is the same.

reaches condition  $X=1$ , the probability of both companies participating in the optimization of book reverse logistics is the greatest.

**4.2.2. Numerical Simulation.** To study the influence of parameter values on the evolution path and trend of the system, this paper selects an appropriate initial state,  $X=0.8, Y=0.8$ , and changes the values of  $\alpha_1, \alpha_2, N, B_1, L_2, C_1, C_2, S_1, F_2, D_1$ , and  $D_2$  at the same time. The specific

values are shown in Table 11. Group A is the control group, and the other groups are the experimental groups.

- (1) The influence of  $N$  changes on the evolution path. Keep other parameters unchanged and change the value of  $N$  (as shown in  $E$  in Table 11) to obtain a simulation diagram of the evolution trend of book publishers and book retailers, as shown in Figure 10.

FIGURE 9: Phase diagram of system evolution in Case 1.

TABLE 10: Influence of parameter changes on evolution stability results.

Variation of parameters	Basis of judgment	Result
$\alpha_1 \uparrow$	$\partial S_{ABCD}/\partial \alpha_1 = -(N(C_1 - S_1))/(2(B_1 - D_1 + N - \alpha_1 N)^2) < 0,$ $\partial S_{A OCD}/\partial \alpha_1 = (N(C_1 - S_1))/(2(B_1 - D_1 + N - \alpha_1 N)^2) > 0$	Both parties prefer not to participate in the optimization, and the evolutionary game system converges to the point (0, 0).
$\alpha_2 \uparrow$	$\partial S_{ABCD}/\partial \alpha_2 = -(N(C_2 - F_2))/(2(L_2 - D_2 - \alpha_2 N)^2) < 0,$ $\partial S_{A OCD}/\partial \alpha_2 = (N(C_2 - F_2))/(2(L_2 - D_2 - \alpha_2 N)^2) > 0$	
$D_1 \uparrow$	$\partial S_{ABCD}/\partial D_1 = -(C_1 - S_1)/(2(B_1 - D_1 + N - \alpha_1 N)^2) < 0,$ $\partial S_{A OCD}/\partial D_1 = (C_1 - S_1)/(2(B_1 - D_1 + N - \alpha_1 N)^2) > 0$	
$D_2 \uparrow$	$\partial S_{ABCD}/\partial D_2 = -(C_2 - F_2)/(2(L_2 - D_2 - \alpha_2 N)^2) < 0,$ $\partial S_{A OCD}/\partial D_2 = (C_2 - F_2)/(2(L_2 - D_2 - \alpha_2 N)^2) > 0$	
$C_1 \uparrow$	$\partial S_{ABCD}/\partial C_1 = -C_1/(2(B_1 - D_1 + N - \alpha_1 N)) < 0,$ $\partial S_{A OCD}/\partial C_1 = C_1/(2(B_1 - D_1 + N - \alpha_1 N)) > 0$	Both parties are more inclined to participate in the optimization, and the evolutionary game system converges to the point (1, 1).
$C_2 \uparrow$	$\partial S_{ABCD}/\partial C_2 = -C_2/(2(L_2 - D_2 - \alpha_2 N)) < 0,$ $\partial S_{A OCD}/\partial C_2 = C_2/(2(L_2 - D_2 - \alpha_2 N)) > 0$	
$S_1 \uparrow$	$\partial S_{ABCD}/\partial S_1 = S_1/2(B_1 - D_1 + N - \alpha_1 N) > 0,$ $\partial S_{A OCD}/\partial S_1 = -S_1/(2(B_1 - D_1 + N - \alpha_1 N)) < 0$	
$F_2 \uparrow$	$\partial S_{ABCD}/\partial F_2 = F_2/(2(L_2 - D_2 - \alpha_2 N)) > 0,$ $\partial S_{A OCD}/\partial F_2 = -F_2/(2(L_2 - D_2 - \alpha_2 N)) < 0$	
$B_1 \uparrow$	$\partial S_{ABCD}/\partial B_1 = C_1 - S_1/(2(B_1 - D_1 + N - \alpha_1 N)^2) > 0,$ $\partial S_{A OCD}/\partial B_1 = -C_1 - S_1/(2(B_1 - D_1 + N - \alpha_1 N)^2) < 0$	Both book publishers and book retailers have the greatest probability of participating in the optimization.
$L_2 \uparrow$	$\partial S_{ABCD}/\partial L_2 = (C_2 - F_2)/(2(L_2 - D_2 - \alpha_2 N)^2) > 0,$ $\partial S_{A OCD}/\partial L_2 = -(C_2 - F_2)/(2(L_2 - D_2 - \alpha_2 N)^2) < 0$	
$N$	$\text{当 } C_2 - F_2/(L_2 - D_2 - \alpha_2 N)^2 = C_2 - F_2/(B_1 - D_1 + N - \alpha_1 N)^2 \text{ 时}$	

It can be seen from Figure 10 that when  $N$  increases, the proportion of book retailers participating in the optimization greatly decreases, which means that the willingness of book retailers to participate in the optimization decreases, and the convergence speed of the system slows down; the proportion of book publishers participating in the optimization has a small increase, but its impact on the evolution path is too small, so the system will more slowly reach the

ideal state where both parties participate in the optimization.

- (2) The influence of  $\alpha_1$  and  $\alpha_2$  changes on the evolution path. Change the size of  $\alpha_1$  and  $\alpha_2$ , keep  $\alpha_1 + \alpha_2 = 1$  and other parameters unchanged, study their influence on the evolutionary system (as shown in  $G_1$  and  $G_2$  in Table 11), and obtain the evolutionary trend simulation diagram of book publishers and book retailers, as shown in Figure 11.

TABLE 11: Parameter values.

Parameter	$\alpha_1$	$\alpha_2$	$N$	$C_1$	$C_2$	$S_1$	$F_2$	$B_1$	$L_2$	$D_1$	$D_2$
$A$	0.5	0.5	20	17	24	10	11	15	50	10	20
$E$	0.5	0.5	30	17	24	10	11	15	50	10	20
$G_1$	0.8	0.2	20	17	24	10	11	15	50	10	20
$G_2$	0.3	0.7	20	17	24	10	11	15	50	10	20
$H_1$	0.5	0.5	20	22	24	10	11	15	50	10	20
$H_2$	0.5	0.5	20	17	19	10	11	15	50	10	20
$J_1$	0.5	0.5	20	17	24	5	11	15	50	10	20
$J_2$	0.5	0.5	20	17	24	10	16	15	50	10	20
$K_1$	0.5	0.5	20	17	24	10	11	25	50	10	20
$K_2$	0.5	0.5	20	17	24	10	11	15	60	10	20
$P_1$	0.5	0.5	20	17	24	10	11	15	50	5	20
$P_2$	0.5	0.5	20	17	24	10	11	15	50	10	15

FIGURE 10: The simulation diagram of the influence of  $N$  on the evolution path.FIGURE 11: The simulation diagram of the influence of  $\alpha_1$  and  $\alpha_2$  on the evolution path.

It can be seen from Figure 11 that when the production and sales risk ratio of book publishers decreases and the production and sales risk ratio of book retailers increases, it will speed up book publishers to reach the ideal state of participating in the optimization and slow down book retailers that have reached the ideal state of participating in the optimization. Under the condition of the same production and sales risk ratio, the proportion of book publishers participating in the optimization is greater than that of book retailers, indicating that the possibility of book publishers participating in the optimization is greater than the possibility of book retailers participating in the optimization when the production and sales risks are relatively high.

- (3) The influence of  $C_1$  and  $C_2$  changes on the evolution path. Keep other parameters unchanged and change the values of  $C_1$  and  $C_2$ , respectively (as shown in  $H_1$  and  $H_2$  in Table 11), to obtain a simulation diagram

of the evolution trend of book publishers and book retailers, as shown in Figure 12.

It can be seen from Figure 12 that when the cost of book publishers and book retailers participating in the optimization increases, the revenue of participating in the optimization will decrease, and the willingness to participate in the optimization will decrease, slowing down the speed at which the system converges to the ideal state participating in the optimization. On the contrary, it will increase the revenue of book publishers and book retailers participating in the optimization, increase the willingness to participate in the optimization, and accelerate the speed of convergence.

- (4) The influence of  $S_1$  and  $F_2$  changes on the evolution path. Keep other parameters unchanged and change the values of  $S_1$  and  $F_2$ , respectively (as shown in  $J_1$  and  $J_2$  in Table 11), to obtain a simulation diagram of

FIGURE 12: The simulation diagram of the influence of  $C_1$  and  $C_2$  on the evolution path.

FIGURE 13: The simulation diagram of the influence of  $S_1$  and  $F_2$  on the evolution path.

the evolution trend of book publishers and book retailers, as shown in Figure 13.

As can be seen from Figure 13, when  $S_1$  and  $F_2$  increase, the revenue of book publishers and book retailers not participating in the optimization will decrease, and both sides' willingness to participate in the optimization will be stronger, accelerating the convergence speed of the system and reaching the ideal state of participating in optimization more quickly. On the contrary, the result is the opposite.

- (5) The influence of  $B_1$  and  $L_2$  changes on the evolutionary path. Keep other parameters unchanged and change the values of  $B_1$  and  $L_2$  respectively (as shown in  $K_1$  and  $K_2$  in Table 11), to obtain a simulation diagram of the evolution trend of book publishers and book retailers, as shown in Figure 14.

It can be seen from Figure 14 that when the revenue of book publishers and book retailers participating in the optimization increases, the willingness to participate in the optimization will increase, speeding up the convergence of the system. Conversely, the willingness of book publishers and book retailers to participate in the optimization will decrease, which will slow down the system's convergence speed.

- (6) The influence of  $D_1$  and  $D_2$  changes on the evolutionary path. Keep other parameters unchanged and change the values of  $D_1$  and  $D_2$ , respectively (as shown in  $P_1$  and  $P_2$  in Table 11), to obtain a simulation diagram of the evolution trend of book publishers and book retailers, as shown in Figure 15.

FIGURE 14: The simulation diagram of the influence of  $B_1$  and  $L_2$  on the evolution path.

It can be seen from Figure 15 that when book publishers and book retailers do not participate in the optimization, revenue increases, and book publishers and book retailers will reduce their willingness to participate in the optimization, slowing down system convergence speed. Conversely, the willingness of book publishers and book retailers

FIGURE 15: The simulation diagram of the influence of  $D_1$  and  $D_2$  on the evolution path.

to participate in the optimization will increase, speeding up system convergence.

## 5. Conclusion

Based on the research of reverse logistics and evolutionary game theory by domestic and foreign scholars, this paper constructs an evolutionary game model between book publishers and book retailers, obtains two evolutionary stable strategies (participation, participation) and (non-participation, non-participation), and uses MATLAB to carry out numerical simulation to analyze the evolution path of the two companies under different evolutionary and stable strategies. The main conclusions are as follows. (1) Through exploring the stability of the interest groups of the evolutionary game in different situations and the influence of the initial state on the evolution path of the system, this paper finds that only when the net revenue of both parties participating in optimization is greater than the net revenue of not participating in optimization, the evolution game system can reach the ideal state where both parties participate in the optimization. When the initial ratio of book publishers and book retailers participating in the optimization is greater than or equal to 0.7, the system will eventually evolve into the ideal state of participating in optimization. (2) Through analyzing the influence of parameter value changes on the evolutionary game system, this paper found that when the cost of participating in the book reverse logistics reaches the condition of  $(C_2 - F_2)/(L_2 - D_2 - \alpha_2 N)^2 = (C_1 - S_1)/(B_1 - D_1 + N - \alpha_1 N)^2$ , the probability of both parties participating in the optimization is the greatest. Under the condition of the same production and sales risk ratio, the proportion of book publishers participating in the optimization is greater than the proportion of book retailers

participating in the optimization, indicating that when the production and sales risk ratio is relatively high, the possibility of book publishers participating in the optimization is greater than the possibility of book retailers participating in optimization. When the production and sales risk ratio of book publishers decreases and the cost of reverse logistics decreases, the cost of book publishers and book retailers participating in optimization reduces and the revenue increases, and the cost of not participating in optimization reduces and the revenue decreases, and the system will more quickly reach the ideal state where both parties participate in the optimization.

Since the country began to go global, the country's economy has developed rapidly, cultural exchanges between countries have become more and more frequent, and foreign cultures have begun to gradually spread to the country. At the same time, through the absorption of foreign community governance experience, domestic research on community governance has also begun to be put on the agenda. This paper aims to study the innovative exploration of urban community governance mechanisms through key high-performance computing algorithms. To this end, this paper proposes a combination of the Bayesian algorithm and distributed high-performance computing to analyze and explore the governance and management methods of the community through its efficient and stable computing power, and derive the most suitable community governance mechanism. An experiment was also set up for comparative analysis. The experimental results show that the community governance mechanism derived from the key distributed high-performance computing algorithm improves the community governance capability by 19.4%, effectively improving the community governance and management issues.

## 1. Introduction

In recent years, with the rapid development of Chinese politics, economy, and society, the process of urbanization has accelerated, and residential privatization has continued to advance. In a sense, Chinese cities are divided into multiple functional communities. Community is the basic unit of social management and bears the responsibility of building a harmonious society. At the beginning of 2010, the outline of China's national economic and social development's 12-year plan proposed to fully implement the construction of urban communities, improve the new type of community management and service system, and build communities. It promotes the urbanization process of community construction, expands the management model, improves the service management system, accelerates the pace of marketization and modernization, and builds a harmonious socialist society.

The themes of construction, development, and governance of urban communities have received more and more praise from political parties, experts at all levels, scholars, and urban residents. Moreover, with the further development of urban community construction, the diversity governance of urban communities has also produced huge social benefits. Urban community governance is an important foundation of urban governance in the new era, the basic work of modern city construction, and an important part of the reform of modern city management systems. According to specific conventions, it is recommended to build an urban community governance mechanism. By strengthening the construction of adjusted governance mechanisms such as participation in decision-making, response governance, and public consultation, the opposition in urban community governance in the policy system will be fundamentally resolved and alleviated. In order to

comprehensively improve the efficiency of urban community governance, it is necessary to promote the improvement of Chinese urban governance system and the modernization of governance capabilities. Through the use of distributed computing and key blockchain algorithms, it is very necessary to govern urban communities.

The research on the construction of foreign cities is relatively mature compared with China. Research uses the path from practice to theory, and then applies theory to practice. The research results mainly focus on the impact of social changes in urban communities, the research on the operating mechanism and process of urban communities, and the types of urban communities. A new parallel approximate Bayesian computational sequential Monte Carlo (pABC SMC) algorithm proposed by Jagiella et al. allows robust data-driven modeling of multi-scale biological systems, and proves the feasibility of multi-scale model parameterization through statistical inference [1]. However, the algorithm is mainly based on the parameters obtained by inference on the theoretical basis, and has not been verified by the experimental area. The interactive high-performance computing proposed by Mundani et al. is undoubtedly beneficial to many computing science and engineering applications, as long as the simulation results be visualized in real time during the calculation process. Because a few gigabytes of data per second is not uncommon for running simulations, a new method based on the sliding window technology is introduced and allows users to interactively study the large-scale and small-scale effects of the simulation results [2]. The problem of real-time visualization processing in the calculation process has not been solved well. JUDEHOWELL has studied the process of adaptive governance and authoritarian resilience from the perspective of community governance, bringing together unrelated research fields so far. He believes that adaptation will have unintended consequences and may threaten stability, but it will not necessarily lead to a political crisis [3]. Mullen has spent decades developing tools for the High-Performance Computing (HPC) community, teaching practitioners to use the power of parallel and distributed computing to familiarize student users with their target systems. The course materials are presented through the lens of common HPC use cases and parallelization strategies so that students are able to achieve performance improvements on their HPC systems [4]. However, the learning path of the students is still not clear enough, and the relevant display is not enough. Palmer B introduced the GridPACK™ framework, which is designed to help grid engineers develop modeling software that can run on high-performance computers. GridPACK™ contains modules for setting up a distributed grid network, assigning buses and branches with arbitrary behavior to the network, creating distributed matrices and vectors, and using parallel linear and nonlinear solvers to solve algebraic equations [5]. But there is no clear introduction to how the framework works on related modeling software. The problem of Turek simulating micro-scale urban traffic in a large environment provides a huge opportunity for the use of HPC systems. The parallel implementation of this

calculation is not simple. The simulation proposed in his article is based on the concept of controlled desynchronization of computation, which does not violate the model. The implementation of the Erlang language uses the Erlang distribution mechanism to build and manage computing clusters [6]. The difficulty in the parallel realization of the calculation process is still lack of explanation, which leads to the lack of clear understanding of the HPC system. Alawneh L believes that if you use trace analysis, you can more easily understand the interaction between the processes of the high-performance computing (HPC) system. So, he proposed a novel tracking abstraction method designed to facilitate the analysis of large-scale execution tracking generated by HPC applications. Their method allows the automatic segmentation of large traces into smaller and meaningful clusters, which reflect the various execution stages of the trace scenario [7, 8]. But there is no good elaboration on the principle of this novel tracking abstract method. The purpose of Arya and Wijaya's research is to let people know more about the role of women on the coast of Surabaya. The role of coastal women is not limited to their family role, and through social capital management, coastal women can also contribute to local governance. Research has found that coastal women groups can achieve success in social bonds, bridges, and connections. Under the leadership of a sufficiently effective women's group to manage the organization, people realized the need for a savings movement and had a process of sharing information and knowledge. The social bridge capital shown for establishing connections with other groups also provides a foundation for the construction of an urban society from another angle, which is convenient for later development [9]. The above documents are still very detailed for their main technologies, and the research on some technologies is also very in-depth. However, the above-mentioned literature mainly studies the related application fields of high-performance computing, and the research on its actual operability is not enough, and it is easy to have problems in the actual use process.

The innovation of this paper is to use the key algorithm extraction of the blockchain combined with distributed high-performance computing as the technical support, the urban community governance theory as the theoretical support, and the research and analysis of the urban community governance as the research object. And in the experiment and analysis part, related experiments are designed to explore the effect of its governance, to ensure that the improved governance mechanism can be effectively implemented in practice. In addition, two key algorithms were selected for comparative analysis. On this basis, some more mature urban community governance theories in foreign countries were used to construct a governance path, learn from its experience, select the essence, and remove the dross, which combines the governance methods of China's socialist society to deduct the governance of urban communities, and with the support of high-performance computing capabilities, it deduces a governance method that is more suitable for most communities and improves the governance mechanism of the community.

## 2. High-Performance Computing Methods

*2.1. Blockchain Cloud Computing Method.* Cloud computing is a paid service, and users need to purchase corresponding cloud computing services on demand under the premise of fully evaluating their own situation. Cloud computing implements the abstraction of resources such as data computing, data storage, network transmission, and hardware equipment through key technologies such as virtualization, distributed parallel processing, and the Internet, and then provides these resources to users dynamically on demand. This provides users with a more flexible, convenient, and economical way to dynamically obtain computing resources and storage resources according to their needs [10]. For users, instead of purchasing and maintaining huge and expensive infrastructure and incurring huge costs, it is obviously better to dynamically and expandably rent the necessary cloud computing resources and storage resources according to their needs. In this way, users can not only avoid early-stage investment risks, but also avoid the inability of resources to meet demand due to the increase in the company's scale, which is very attractive to small- and medium-sized enterprises, especially start-ups. Although cloud computing is considered to be the service model of the next generation Internet and cloud computing services have become more and more perfect after this year's rapid development and research, data security and privacy protection are still the main challenges that currently restrict the further development of the cloud computing field (location information protection, mobile phone data protection, authority protection, etc.). Unlike the traditional computing model where users fully control data calculation and storage locally, cloud computing requires the user's data and physical servers to be centrally managed by the cloud service provider, and the user only retains some control rights over the leased virtual machine [11]. The advantages of traditional computing models compared with cloud computing models are mainly focused on the security protection of data because they completely control local data and storage, thus having higher security. The cloud computing method application service of blockchain is shown in Figure 1:

There are three common deployment models for cloud computing: public cloud, private cloud, and hybrid cloud. Users can choose to use different deployment models according to the type of data to be processed and the requirements for security and data management [12].

**Public Cloud:** In the public cloud, service providers use the Internet to provide users with computing resources including applications and storage. Public clouds are operated by third-party providers, and applications and service requests from different users are collectively run and processed on cloud servers, storage systems, and networks. Public cloud has the advantages of low cost, no maintenance, high scalability, and high reliability [13].

**Private Cloud:** A private cloud is a cloud computing service dedicated to a single user, which can be regarded as a user's private data service center. In a private cloud, infrastructure and services are managed and maintained on a dedicated network, and software and hardware services only

serve a single user. Private clouds can also be operated and maintained by third-party service providers. Private clouds are often favored by users who are sensitive to data security, such as government agencies and financial institutions. Private cloud services have the advantages of more flexibility, higher security and reliability, and high open scalability.

**Hybrid Cloud:** Hybrid cloud combines the user's infrastructure or private cloud and public cloud to obtain the advantages of both at the same time. In a hybrid cloud, data and applications can be securely transferred between private and public clouds for greater flexibility and more deployment options. Users can use the public cloud to perform operations with high storage capacity and low security while using the private cloud to perform secure operations on sensitive businesses. Hybrid cloud combines the advantages of the previous two, with advantages such as controllability and flexibility.

Cloud computing implements the abstraction of data computing, data storage, network transmission, and hardware equipment through key technologies such as resource management, distributed parallel processing, and the Internet, and then provides these resources to users dynamically on demand. Taking into account the above characteristics, this article adopts the hybrid cloud deployment model for related deployment. This service process mainly involves three aspects of technology, including resource management, Internet technology, and distributed computing. The research on distributed computing is the focus of this article. As shown in Figure 2, it is the key technology involved in the cloud computing process [14].

Resource management technology mainly includes virtualization technology and data center management technology. Virtualization technology is one of the core key technologies of cloud computing, which can abstract the details of physical hardware and provide virtualized resources for advanced applications. Virtual machine services with scalable performance can be provided to users through virtualization technology, which further improves the utilization efficiency and high scalability of physical servers in the case of multiple users. Data center is the core of the cloud computing architecture. Data center management technology is one of the most basic core technologies of cloud computing, which directly affects the performance of upper cloud data storage and computing services. Cloud computing data centers include technologies such as network topology, large-scale data storage, resource management and scheduling, and they need to have features such as autonomy, economies of scale, and scalability. In cloud computing, Internet technology is used to complete the interaction between the users and cloud resources. Cloud computing only requires the user's data and physical servers to be centrally managed by the cloud service provider, and the user only retains some control over the leased virtual machine. At present, most cloud computing service providers provide users with web-based cloud interactive interfaces. The B/S architecture-based approach not only reduces the development cycle, but also further reduces the resource occupation of the client [15].

FIGURE 1: Application services of blockchain cloud computing.

## 2.2. SVM Algorithm Optimization for Distributed Computing

### 2.2.1. Classification of Classification Algorithms

(1) *Decision Tree Algorithm.* The decision tree method is to first find the most informative attributes in the sample database as the nodes of the decision tree, and then construct various branches of the nodes according to the attribute values. Then, repeat this process for each one. It is used to establish the branch of the next node and its branches [16].

(2) *Bayesian Classification.* Bayesian classification is a statistical classification method. The classification principle is to use the pre-probability of the object and use the Bayesian equation to calculate the post-probability. In other words, the object has the probability of belonging to a specific category, and the category with the largest posterior probability is selected as the class the object belongs to [17].

For a training sample, suppose its prior probability is  $P$ ; according to Bayesian classification, the probability obtained is

$$p(z) = p(z/si) \cdot p(si)/p(x). \quad (1)$$

If

$$p(si/z) = \text{Max}_j p(sj/Z), i = 1, 2, 3 \dots, N, \quad (2)$$

then there is  $x \in si$ ; substituting formula (1) into formula (2),

$$p(z/si)p(si) = \text{Max}_j [p(z/sj)p(sj)], i = 1, 2, 3, \dots, N, j = 1, 2, \dots, N. \quad (3)$$

This is the most commonly used Bayes classification decision benchmark. As a result of years of research, the Bayesian classification is widely used. However, because the Bayesian sample size is large enough, the sample properties must be independent of each other; it is difficult to achieve this in practical applications, and hence it is difficult to achieve theoretical results with this method [18].

(3) *Neural Network Classification.* As shown in Figure 3, the neural network classification is mainly composed of three layers to form a multilayer feedforward neural network (Input layer, hidden layer, output layer) [19]. The multilayer feedforward neural network consists of an input layer, one or more hidden layers, and an output layer. The Back Propagation [BP] algorithm learns on the multilayer feedforward neural network, and the [multilayer] feedforward neural network using the BP algorithm is called the BP neural network.

The most commonly used multilayer feedforward neural network lies in classification. By setting the number of sample attribute values and controlling the sample type of the output layer, various classifications can be performed. But the problem that it is easier to fall into the minimum is one of its inherent shortcomings.

FIGURE 2: Key technologies involved in cloud computing.

(4) *Linear Classification.* The learning goal of a linear classifier is to find a classification hyperplane in the  $n$ -dimensional data space, and its equation can be expressed as

$$\omega^T z + b = 0. \quad (4)$$

As shown in Figure 4, in the two-dimensional plane, the solid line is the classification plane. We can make the classification function as

$$f(Z) = \omega^T z + b. \quad (5)$$

At the same time, use  $z$  to represent the “geometric distance” of the classification hyperplane;

$$\gamma = y \frac{\omega^T z + b}{\|\omega\|} = y \frac{f(z)}{\|\omega\|}. \quad (6)$$

Its mathematical expression is as follows:

$$\min_{\omega, b} \frac{1}{\|\omega\|}, s, t, y_i (\omega^T z_i + b) \geq 1, i = 1, 2, \dots, n. \quad (7)$$

The above problems can be equivalently transformed into the following problems:

$$\min_{\omega, b} \frac{1}{2} \|\omega\|^2, s, t, y_i (\omega^T z_i + b) \geq 1, i = 1, 2, \dots, n. \quad (8)$$

The constraints are integrated into the objective function through the Lagrangian function, as follows:

$$L(\omega, b, a) = \frac{1}{2} \|\omega\|^2 - \sum_{i=1}^n \alpha_i (y_i (\omega^T x_i + b) - 1). \quad (9)$$

Then make

$$\beta(\omega) = \max_{a_i \geq 0} L(\omega, b, a). \quad (10)$$

Our question is transformed into a request:

$$\min_{\omega, b} \beta(\omega) = \min_{\omega, b} \max_{a_i \geq 0} L(\omega, b, a). \quad (11)$$

Further transformed into

$$\max_{a_i \geq 0} \min_{\omega, b} L(\omega, b, a). \quad (12)$$

In order to solve equation (12), we first find the minimum values of  $\omega$  and  $b$  in equation (9), and calculate the extreme values of  $\omega$  and  $b$ , respectively, according to the extreme value conditions, namely:

$$\begin{aligned} \nabla_{\omega} L(\omega, b, a) &= 0 \\ \nabla_b L(\omega, b, a) &= 0. \end{aligned} \quad (13)$$

Solve to get

$$\omega = \sum_{i=1}^x \beta_i \alpha_i y_i. \quad (14)$$

$$\sum_{i=1}^n \alpha_i y_i = 0. \quad (15)$$

Substituting (14) and (15) into (12), the dual form of the original problem is obtained as follows:

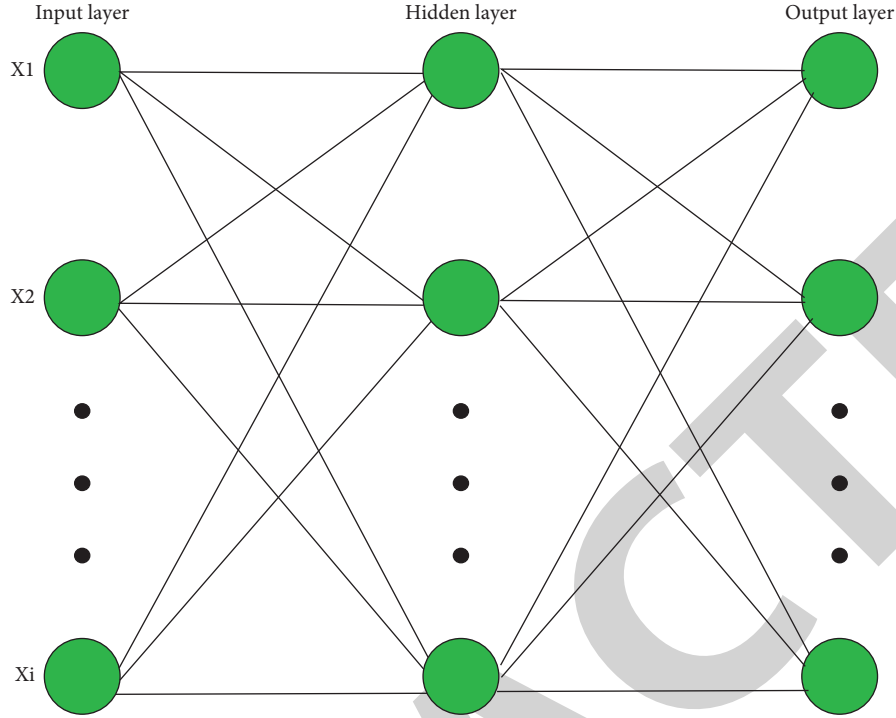

FIGURE 3: Multilayer feedforward neural network.

$$\max \sum_{i=1}^n \alpha_i - \frac{1}{2} \sum_{i,j=1}^n \alpha_i \alpha_j y_i y_j \quad f\Phi^2(X)dx < \infty. \quad (16)$$

Then, there are

$$t, s, \alpha_i \geq 0, i = 1, 2, \dots, n, \sum_{i=1}^n \alpha_i y_i = 0. \quad \iint K(z, z')\Phi(z')dzdz' > 0. \quad (22)$$

That is, the original nonlinear data are mapped to a new feature space through a nonlinearity, and the following function is obtained:

$$f(Z) = \sum_{i=1}^n \omega_i \varphi_i(Z) + b. \quad (17)$$

Assuming that the data can be obtained by the linear combination of training points, it can be expressed as the following formula:

$$f(Z) = \sum_{i=1}^n \alpha_i y_i \langle \varphi(Z_i) \cdot \varphi(Z) \rangle + b. \quad (18)$$

Assuming that the kernel is a function  $K$ , for all  $x, z \in x$ , satisfy

$$K(X, Z) = \langle \varphi(x) \cdot \varphi(z) \rangle. \quad (19)$$

Then,  $\Phi$  is the mapping from  $X$  to the inner product feature space  $F$ . The Gaussian kernel  $K$  is

$$K(z_i, z_j) = \exp\left(-\frac{\|z_i - z_j\|^2}{2\sigma^2}\right). \quad (20)$$

That is, for any  $\Phi(x) \neq 0$ , there is

We turn the linear inseparable problem into

$$\max_a \sum_{i=1}^n \alpha_i - \frac{1}{2} \sum_{i,j=1}^n \alpha_i \alpha_j y_i y_j K(x_i, x_j) \quad (23)$$

$$t, s, \alpha_i \geq 0, i = 1, 2, \dots, n, \sum_{i=1}^n \alpha_i y_i = 0.$$

By solving it, we can get an optimal SVM algorithm optimization method so as to improve it.

### 2.3. Distributed Collaborative High-Performance Computing.

The collaborative computing of the distributed model refers to the realization of simulation applications by coordinating and collaborating in a distributed environment with the help of computer, network technology, and model resources. This service sharing-based model not only enables the model to run in the best operating environment and ensures the safety of the model code, but also uses more computing resources and storage space to complete various complex application simulations. Using more computing resources and storage space to complete various complex application simulations can better protect the simulated data. Therefore, DCHF-SI needs to provide a collaborative environment for remote coupling and interaction of physical models located in different locations. The interaction process of the model is

FIGURE 4: An example graph of 2-dimensional separability.

transparent to the user and needs to meet the particularity of different spatial physical applications and general commercial applications; the structure of DCHF-SI is shown in Figure 5.

**2.3.1. Coupling Interaction Basic Framework Layer.** The coupling interaction mechanism is responsible for the interaction coupling and communication of remote model components. The coupled interaction basic framework is the core supporting platform of the entire framework operation [20].

**2.3.2. Framework Service Component Layer.** Fault-tolerant service components provide checkpoints for setting up network or grid resources and rollback recovery and other fault tolerance strategies and log strategies [21].

**2.3.3. Physical Model Component Layer.** The physical model components are mainly obtained by encapsulating the physical model.

**2.3.4. Graphical User Interface (GUI) Layer.** Model sharing provides researchers with a large amount of model resources. However, it is very difficult for researchers to select the model they need from the massive model resources, and it is impossible to study and analyze all the available models. In order to solve this problem, the screening of related resource models is essential. As shown in Figure 6, when the model component is coupled with the internal model, there are  $M * N$  assembly methods, which makes the application assembly more complicated [22].

Therefore, this paper proposes a new type of component-abstract domain component. Models in the same domain share an abstract domain component. It also has a unified

standard port for this type of model, but it is not responsible for its implementation; instead, the best model components are selected through the QOS service to participate in the calculation, thereby achieving transparent and intelligent assembly of applications and reducing the burden on developers. The following interfaces need to be added to realize the generation and connection of abstract components [23]. The design scheme of the QOS service customizable northbound interface describes the external form and the internal function model of the interface, and based on this scheme, a northbound interface that provides bandwidth and priority customizable services is implemented. The interface is tested in the SDN experimental network, and the test results show that the scheme can achieve the expected goal.

### 3. Investigation and Experiment on the Status Quo of Urban Communities

A city is a product formed to adapt to the times, a manifestation of mature economic development, and a settlement formed by a multifaceted population. As the center of trade, it continues to attract foreigners, the number of permanent residents also increases, and coupled with resource constraints and unreasonable urban layout, it has been greatly affected. In order to improve this situation, government departments have established urban communities. The specific implementation steps are: first, delineate a range, and then build concentration camps in this area, such as commercial housing communities, office communities, etc., to guide relevant people to reside in them, to save resources as much as possible, use limited space to house more people, and let them form a society with a large number of people and a high concentration of people. Housing in the city community is mostly engaged with nonagricultural work, which can accommodate people from various places and

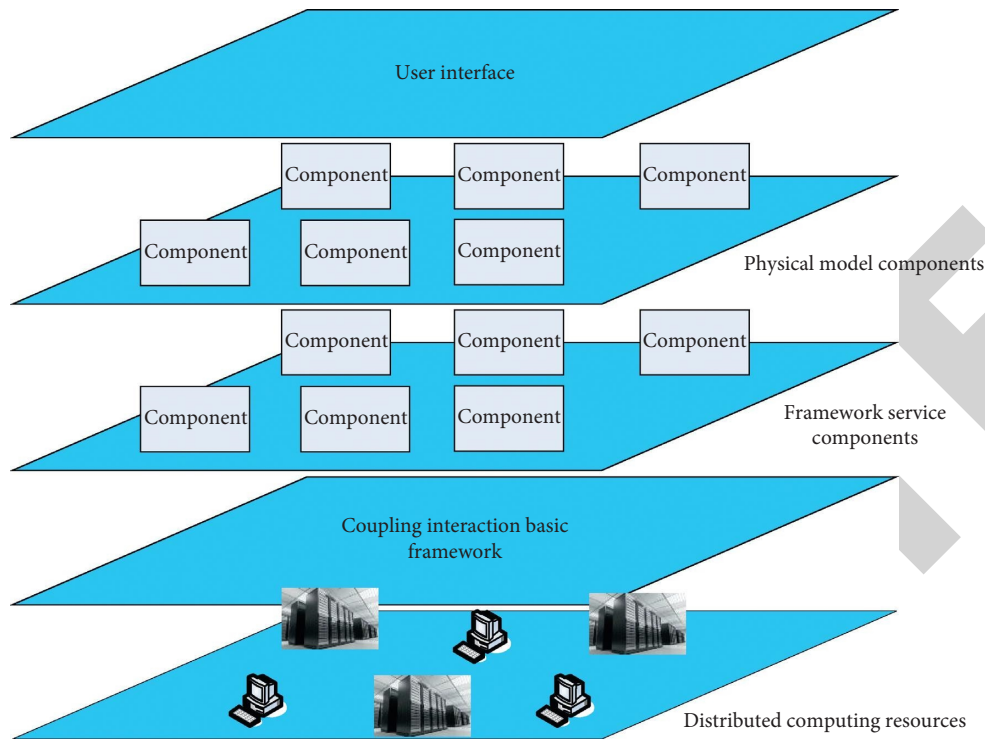

FIGURE 5: DCHF-SI structure diagram.

various types of work, and the rational use of space to create a small, densely populated social group. However, compared with rural areas, there is a lack of interpersonal communication [24].

At present, China's urban community governance has made great progress in terms of systems and mechanisms, but there are still many problems. There are many reasons for these problems, including the inertial effect of the original system, the influence of cultural traditions, and the lag in social development. For these issues cannot be ignored, it is necessary to explore the outstanding performance in different practices. This chapter is based on the status quo of community governance in urban communities, through combing the status of community governance practices, and discovering some potential problems in urban community governance so as to obtain beneficial enlightenment and help improve urban community governance. Here, we make a rough statistics of the number of communities within the scope of the survey statistics, as shown in Table 1:

It can be seen from the statistical data in the above table that social organizations have grown rapidly in the past two years, and the number of private units has grown relatively slowly; while foundations have no growth opportunities, the rapid growth of social organizations will lead to a management problem. If there is no good management and governance method, it is easy to cause problems. Therefore, a survey of satisfaction with the governance methods of urban community groups is added, as shown in Table 2:

Obviously, it can be seen that the problem caused by the excessively rapid growth of social organizations is that there are many governance problems, governance chaos, and the

satisfaction of group members is low, while private units basically grow slowly, showing satisfaction and dissatisfaction, and the satisfactory conditions are basically the same. The foundation has grown by one in three years, and this has resulted in them having enough time to administer the foundation, so that the vast majority of people can be satisfied, and the satisfaction will naturally increase [25].

**3.1. Weak Community Social Organizations.** In the context of modern development, urban community governance, such as the introduction of the participation of social forces, can add new vitality to community services. Social organizations participating in community governance can give full play to their role as a link, integrate their own resource advantages, broaden funding sources for community governance, assume part of the governance capacity, and use their professional capabilities to provide residents with market-oriented services.

A social survey experiment on the degree of understanding of community social organizations was organized here, and the experimental data obtained are shown in Table 3:

From the above table, we can see that in urban communities, children's understanding of community social organizations accounted for 2%, adults accounted for 8%, and the elderly 2%. It only accounts for 12% of the total, and the number of people who understand it is really too small. Children and the elderly have less knowledge of community social organizations, and it is mainly concentrated that adults have more knowledge of urban community organizations. As a result, most people have problems with the

FIGURE 6: Model component and internal model component coupling description.

TABLE 1: Statistics on the number of urban community groups.

Group	Social groups	Private unit	Foundation
2016	75	32	9

Satisfy	56	221	389
Dissatisfied	489	243	31

governance of the community. This also reflects the problems of small-scale social organizations, insufficient development, and insufficient influence in Chinese cities. Community funding is not guaranteed, and it is easy to be administrated. The inability to independently assume the responsibility of community management has led to inadequate governance in the community [26].

**3.2. Residents Lack Awareness of Active Participation.** Serving community residents is the purpose and goal of community governance, and all governance actions are based on safeguarding the interests of the residents. The extent of residents' participation in community autonomy to a large extent reflects the true level of community autonomy. From the survey of urban community residents participating in community activities in Table 4, it can be seen that the basis for the formation of this sense of identity and belonging is gradually disintegrating [27].

Analyzing the data in Table 4, we can see that the proportion of children who often participate is 4%, adults 6%, and the elderly 2%. These values are far lower than those of a healthy and qualified urban community. The proportion of participants is only 12%, the proportion of those who have participated in some is 30%, the proportion of those who have participated occasionally is 33%, and the proportion of those who have never participated is 25%. Similarly, some seldom participate in community activities, indicating that

there are fewer feedbacks on problems in this community, and people cannot conduct a good and effective management of the urban community. For this reason, we have also made a detailed survey on the reasons why people of different ages do not participate in community activities. The survey data are shown in Table 5:

From Table 5, we can still see that adults still pay attention to the interests of the majority, and this is one of the reasons why most people do not participate in community activities. The reason for this phenomenon is that the community's publicity is still insufficient, thus failing to make people develop the concept that community governance is related to everyone. This has also caused more and more people to lose confidence in community management.

Another questionnaire is designed here to investigate and reform the community governance system. There are 21 questions in the questionnaire, which consist of two parts: the first part is the basic information of the interviewee, covering nine aspects including gender, age, marital status, location of household registration, education level, residence time, identity, political outlook, and average monthly income. It forms a characterization description of the interviewee; the second part is a survey of the current community governance system. Questions include community party organizations, community neighborhood committees, community service stations, community intermediary organizations, residents' participation, community-related policies, and other elements of the community governance system.

## 4. Status Quo and Improvement of the Community

**4.1. Relevant Situation of the Community Governance System.** From the selection of residents, it can be found that almost ordinary people regard the community committee as the first choice to help them solve the difficulties in daily life, which shows that the community committee has a relatively high sense of identity in the hearts of residents, followed by government departments and community service stations. Compared with the other three governance bodies, the owners' committee and the property company do not seem to be "rooted" (the other three governance entities mainly include: private units, foundations, and social groups), which also reflects the absence of the two in community governance, which is not conducive to building a "social coordination" community governance system in the long run. The relevant situation investigation is shown in Figure 7:

From the table above, we can see that in urban communities, the number of residents who often live with neighborhood committees accounts for about 15%. Among them, children and the elderly account for more, while adults still account for a minority. About 40% of the people who don't care about the governance and management of the community and occasionally contact the neighborhood committee account for about 40%. Among them, children and adults account for a relatively large number, while the elderly are relatively small. Among those who almost never

contact the neighborhood committee, adults account for the overwhelming majority, while children and the elderly account for only a small proportion. In the statistics of familiarity, the proportion of people who know the neighborhood committee is about 25%. On the contrary, the proportion of children is the largest, while the proportion of adults and the elderly is relatively small. Among those who do not know the director of the neighborhood committee at all, children and adults account for a larger proportion, while the elderly are fewer. Among those who have heard of it but are not clear, there are more adults and fewer elderly and children. The statistics on the familiarity of community party organizations and the degree of recognition of their related governance methods are shown in Figure 8:

From the survey statistics in Figure 9 on the familiarity of community party organizations and the recognition of related governance methods, we can see that the managerial personnel in the community neighborhood committees still have a relatively high percentage of recognition of the governance methods of urban communities, reaching 15.9%; in addition, the managers of all organizations have a high degree of recognition of the governance methods, and the members of them generally do not agree with the governance methods, and they are maintained at a low level. The senior citizens who agree with party secretaries are the elderly, and most adults don't know the secretaries of the community's party organizations. When the main personnel in an urban community do not know the secretaries of the community's party organization, it can only indicate the urban community. The publicity of the community is still not in place, resulting in an insufficient sense of participation of community members and the inability to actively participate in the comprehensive governance and control of the community.

In summary, the "two committees" of the community are not closely connected to the residents, and the community party organizations and community neighborhood committees are precisely the "top people" who drive residents to actively participate in community governance. Therefore, the construction of the "two committees" in the community governance system needs to be further improved and strengthened. At the same time, the problem activities organized by the community are counted, as shown in Figure 9:

From the urban community's participation in community activities organized by the community, we can see that most of the adults in cultural and sports activities have not participated in any of the activities. The main reason is to let their children participate in some activities organized by the community, but if it's just like this, it means that they have not participated in community team activities at all. Children's participation in community activities does not have much effect on the progress of the community. Similarly, in terms of public welfare activities, the majority of children participate in activities, followed by the elderly who stay at home, and most adults do not participate in the governance of the community, which reflects the fact that the activities of the community mainly remain at the level of formality, and there is no in-depth understanding of the meaning of community activities.

From the above data results, we can find that most residents are not very active in participating in community activities, and community activities are one of the effective ways to increase the sense of belonging and identity of community residents to the community. Therefore, how to improve the community governance system and eliminate the gap in public participation is worthy of our deep consideration.

#### 4.2. Distributed High-Performance Computing Capability.

Analyze the phenomenon in the process of urban governance through the calculation and analysis of the surveyed data, and analyze the problems of urban community governance. Therefore, it is possible to deduce a most suitable governance method, cooperate with community managers to better manage the community, and creatively explore the most suitable governance methods for each urban community.

Here, we combine the experimental data investigated by the above analysis and analyze the community governance issues through distributed high-performance computing, coordinate the role of various organizations in urban communities, and actively guide community members to participate in the governance of the community. The analysis data are shown in Figure 10:

FIGURE 7: Statistics on the frequency and familiarity of residents' contact with neighborhood committees.

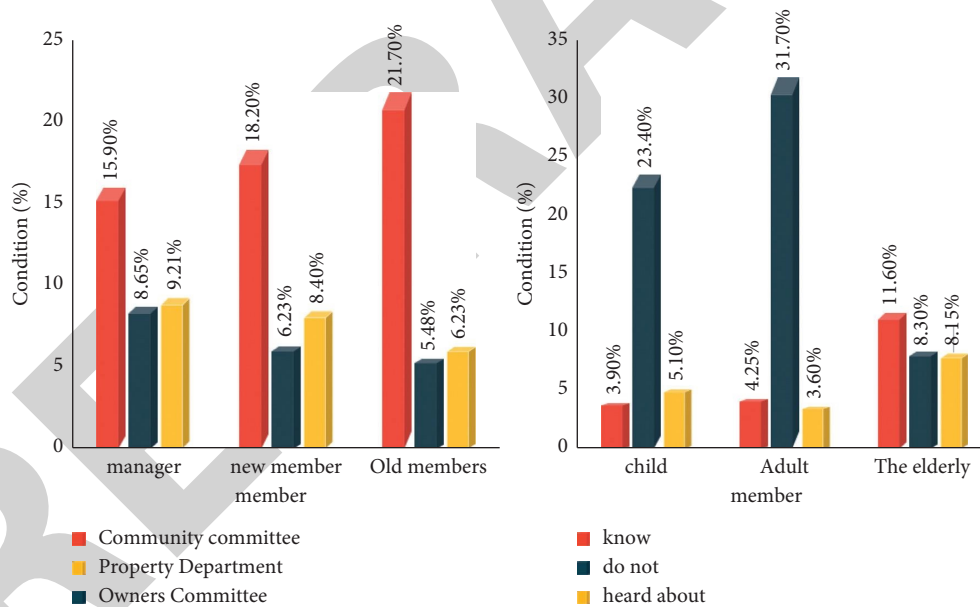

FIGURE 8: Statistics on the familiarity of community party organizations and the degree of recognition of their related governance methods.

From the above Figure 10, we can see that the development distribution curve of the community is more concentrated, which is more conducive to the stable construction of the urban community. Regarding the exponential growth of the community, the environment of the urban community has increased by 21.1% compared with previous years, and the community is safer than in previous years. With an increase of 11.1%, the development of urban communities has increased by 26% compared to previous years. The overall situation shows growth; it can be seen that using distributed high-performance computing to calculate

the various factors of the community, the most suitable community development plan can be deduced, which is more conducive to the development of the community. After implementation, the overall urban community governance has increased by 19.4%.

The data obtained through calculation and analysis is more conducive to our assumption of a sound and harmonious urban community and the establishment of a democratic rule of law, fairness and justice, honesty and friendship, full of activities, stability and order, and harmonious coexistence between people's living environments.

FIGURE 9: Residents' participation in cultural and sports activities and public welfare activities organized by the community.

FIGURE 10: The distribution curve of urban community development and the exponential growth of all aspects of the community.

### 5. Conclusions

This paper mainly conducts innovative research on the current domestic urban community governance methods, mainly using the computing power of distributed algorithms and the use of key algorithms of blockchain technology, and comprehensively analyzes and understands the current community through the combined use of the two. The goal of improving the current domestic community management

dilemma has been achieved by exploring the management methods and improving the management methods. At the same time, the analysis and comparison of the urban community governance mechanism after the analysis of distributed high-performance computing is carried out, and it is found that through the calculation derivation the proposed governance method can improve the overall governance effect of the community by 19.4%. It can be seen that the use of related distributed algorithms in this paper is

By leveraging neural networks, deep distance metric learning has yielded impressive results in computer vision applications. However, the existing approaches mostly focus a single deep distance metric based on pairs or triplets of samples. It is difficult for them to handle heterogeneous data and avoid overfitting. This study proposes a boosting-based learning method of multiple deep distance metrics, which generates the final distance metric through iterative training of multiple weak distance metrics. Firstly, the distance of sample pairs was mapped by a convolution neural network (CNN) and evaluated by a piecewise linear function. Secondly, the evaluation function was added as a weak learner to the boosting algorithm to generate a strong learner. Each weak learner targets the difficult samples different from the samples of previous learners. Next, an alternating optimization method was employed to train the network and loss function. Finally, the effectiveness of our method was demonstrated in contrast to state of the arts on retrieving the images from the CUB-200-2011, Cars-196, and Stanford Online Products (SOP) datasets.

## 1. Introduction

In the past decades, distance metric learning has been applied effectively in image retrieval, face recognition, person re-identification, clustering, etc. It is now a hot topic in the field of computer vision. Thanks to the recent success of convolutional neural networks (CNNs), deep distance metric learning methods have attracted lots of attention [1].

Each deep distance metric aims to map training samples to features via CNNs. The mapping should narrow the distance between similar sample pairs and increase that between dissimilar sample pairs. To learn deep distance metrics, many approaches have been developed based on sample pairs [2, 3], triplets [2, 4], or quadruplets [5]. This study attempts to learn the simple similarity functions of sample pairs. The distance metric was defined as the Euclidean distance between sample pairs, which can be computed rapidly compared with other metrics.

Most of the existing methods of deep distance metric learning try to improve the single loss function based on a single distance metric. However, a single distance metric is insufficient to handle all the samples from the given data

distribution. In fact, feature data are generally not distributed uniformly: the density varies from region to region in the data distribution [6, 7]. To solve the problem, some scholars resorted to ensemble technique and employed several learners to map each sample to multiple subspaces [8–10]. Nevertheless, these strategies do not support end-to-end training of the network and loss function of each weak learner. The lack of this training model suppresses the discrimination ability and increases the susceptibility of the metric to noise. The accuracy of deep distance metric learning could be further improved through joint training of the network and loss function.

This study aims to improve the adaptability of conventional deep distance metric between pairs of samples. The main idea is to divide the last fully connected layer of the CNN into multiple nonoverlapping groups (Figure 1), each of which is a separate feature mapping of the network. The distance metric of sample pairs mapped by one of the groups was evaluated by a piecewise linear function. Each group has a corresponding evaluation function, which is added as a weak learner to the boosting algorithm to generate a strong learner. This finally forms a multidistance metric ensemble.

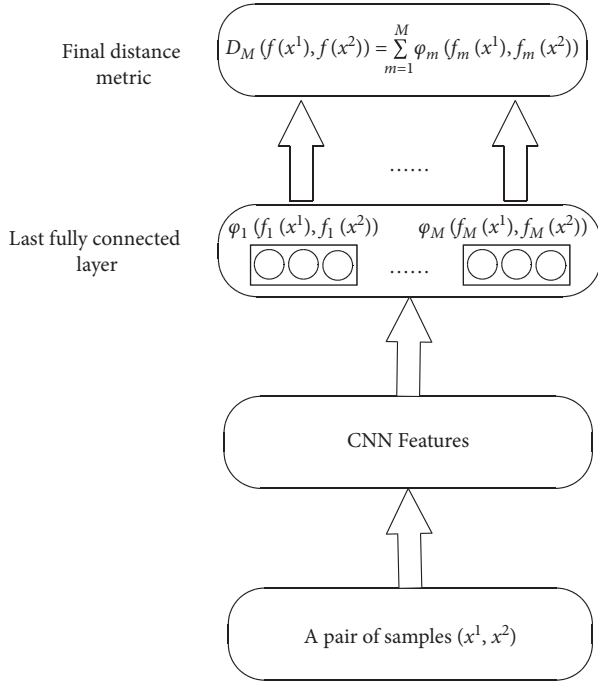

FIGURE 1: Structure of boosting-based deep distance metric.

In addition, the same underlying feature representation, which was pretrained through experiments, was applied to the fully connected layers of all groups. In this way, the high computing cost of CNN training in the boosting framework was significantly reduced. In that framework, each learner reweights the training samples for successive learners, according to the gradient of the loss function. As a result, the successive learners would focus on difficult sample features, producing more suitable feature representations. The final ensemble output is a linear composition of multiple weak learners. Furthermore, the performance of the conventional distance metric was improved by introducing a piecewise linear function, which evaluates the similarity of sample pairs in distance metric learning. This facilitates the joint training of the network and loss function. Through the evaluation of various deep distance metric learning methods in the image retrieval task, it can be seen that Recall@1 of the proposed method is 4.2, 2.8, and 0.4 higher than that of the previous best score on CUB-200-2011, Cars-196, and SOP datasets, respectively. Experimental results show that the proposed method outperforms the comparison methods, while avoiding overfitting to a certain extent.

The contributions of our work are as follows:

- (1) The last fully connected layer of the CNN was used to form multiple groups of features, which was designed to form a distance metrics ensemble and formulated as a boosting problem. Then, an alternating optimization method was adopted to jointly train the network and loss function.
- (2) A piecewise linear function was employed as the evaluation function of the distance metric of sample pairs mapped by CNN and added as a weak

learner to the boosting algorithm to generate a strong learner.

## 2. Literature Review

This section reviews the most closely related works out of the numerous publications on the hot topic of distance metric learning.

**2.1. Deep Distance Metric Learning.** Many methods employ a discriminative distance metric loss function to increase interclass distance and reduce intraclass distance [2, 4, 11–14]. For instance, contrastive loss is a popular tool of deep distance metric learning that minimizes the distance between the eigenvectors of positive sample pairs and widens the distance between the negative sample pairs [2, 3]. Based on contrastive loss, triplet loss creates a 3-tuple with a positive sample pair and a negative sample pair, in the light of the relative relationship between intraclass distance and interclass distance [2, 4], and ensures that the positive sample pairs are closer in the mapped feature space than the negative sample pairs. Many other loss functions have been extended from the above two losses, namely, histogram loss [15], quadruplet loss [5], N-pair loss [11], angular loss [12], and hierarchical triplet loss [16].

Taking a tuple of samples as training samples yields a huge amount of training data. Deep distance metric learning would be greatly enhanced by acquiring more effective samples. Recently, several scholars have designed sampling strategies to tackle hard and semihard negative mining [16–18]. For example, Xuan et al. [7] observed that easy positive samples help to preserve the intraclass difference and thus improve the generalization ability of triplet loss. However, the use of easy positive samples constantly underchallenges the metric, making the embedding space less discriminative.

**2.2. Ensemble Learning.** The methods above all strive to improve the loss function based on a single distance metric. However, it is difficult for them to adapt to all available data. Recently, ensemble learning, which iteratively trains an ensemble from several weak learners for the final prediction, has been incorporated to boost the generalization performance of deep metric learning.

Negrel et al. [8] explained how to use their boosting-based metric learning algorithm to compute hierarchical organizations of face databases. Kim et al. [9] introduced multiple attention-based learners for ensemble. Xuan et al. [10] grouped labels randomly to create a large family of related embedding models, which can serve as an ensemble. Sanakoyeu et al. [6] employed a divide-and-conquer strategy to divide the embedding space to several clusters and used each cluster to train a single learner.

**2.3. Other Related Metric Learning.** In addition, there are other types of distance metric approaches recently, such as sample selection, local metric, and hierarchical metric. Wu

et al. [19] proposed a distance-weighted sampling procedure, which selects more informative and stable examples than traditional approaches, achieving excellent results in the process. Wang et al. [13] generalized tuple-based losses and reformulated them as different weighting strategies of positive and negative pairs within a minibatch. Roth et al. [20] proposed to learn the distribution for sampling negative examples instead of using a predefined one. Local metric learning methods [21, 22] learn a collection of Mahalanobis distance metrics, each operating on a different subset of the data obtained by K-means or Gaussian mixture clustering. From [23, 24], we learn a two-level category hierarchy by using coarse and fine classifiers. Ge et al. [16] proposed a hierarchical version of triplet loss that learns the sampling all together with the feature embedding.

Different from the above approaches, our approach realizes the end-to-end training of the network and loss function of each weak learner, thereby enhancing the accuracy of deep distance metric and reducing the probability of overfitting.

### 3. Methodology

**3.1. Boosting-Based Deep Distance Metric Model.** Let  $X = [x_1, x_2, \dots, x_N]$  be  $N$  training sample pairs, each of which belongs to one of the two class labels  $y_n \in \{-1, +1\}$ . If the two samples belong to the same class, the pair is labeled  $y_n = +1$  and called a positive sample pair; if the two samples belong to different classes, the pair is labeled  $y_n = -1$  and called a negative sample pair.

We divide the last fully connected layer of the CNN into multiple nonoverlapping groups. The training sample pair  $x_n = (x_n^1, x_n^2)$  is fed into the CNN to generate an eigenvector pair  $f_m(x_n) = (f_m(x_n^1), f_m(x_n^2))$ , which is extracted from the  $m$ th group of the last fully connected layer. So, the training sample pair  $x_n$  can be mapped to generate multiple groups of features, which was designed to form a distance metrics ensemble and formulated as a boosting problem.

Drawing on the idea of the boosting algorithm, multiple weak learners are adopted to produce a strong learner of distance metrics between the mapping values of training sample pairs. The weak learners are trained on reweighted samples, according to the gradient of the loss function. In general, we want to a set of weak learners and their corresponding boosting model:

$$D_M(f(x_n^1), f(x_n^2)) = \sum_{m=1}^M \varphi_m(f_m(x_n^1), f_m(x_n^2)), \quad (1)$$

where  $M$  is the number of weak learners and  $\varphi_m$  is the distance metric evaluation function between the eigenvectors of the training sample pair mapped by the  $m$ th group of the fully connected layer.

In the above formula,  $\varphi_m$  was used to quantify the similarity between two training samples, and it responds to this similarity based on whether the two samples should be considered to represent the same class. Therefore, a

threshold was defined to deal with the distance metric between two training samples, and a piecewise linear function was adopted as the evaluation function. This function reduces the distance between similar training samples and increases that between dissimilar ones in the mapped space. The evaluation function can be defined as

$$\varphi_m(f_m(x_n^1), f_m(x_n^2)) = \begin{cases} \alpha_m, & \text{if } d(f_m(x_n^1), f_m(x_n^2)) < t_m, \\ \beta_m, & \text{else,} \end{cases} \quad (2)$$

where  $d(f_m(x_n^1), f_m(x_n^2))$  is a generic distance metric (the simple Euclidean distance),  $\alpha_m$  and  $\beta_m$  are the evaluated similarity and dissimilarity between the two samples, respectively, and  $t_m$  is a distance metric threshold. If the Euclidean distance between two mapped training samples is smaller than the threshold  $t_m$ , then the evaluation value is  $\alpha_m$ ; otherwise, it is  $\beta_m$  (Figure 2).

In each round of boosting, a new weak learner is trained on the reweighted training set in the minibatch, according to the gradient of the loss function, and then added to form a strong learner. As demonstrated by Friedman [25], the training of a single learner can be written as a loss function minimization problem:

$$\arg \min \sum_{i=1}^N \ell(y_i; D_{M-1}(x_i) + \varphi_m(x_i)), \quad (3)$$

where  $\ell$  is a loss function. Here, the exponential loss function  $\ell(y_i; D_M(x_i)) = e^{-y_i D_M(x_i)}$  is utilized. Inspired by Schapire and Singer [26], formula (3) can be rewritten as

$$\arg \min \sum_{i=1}^N w_i^m e^{-y_i \varphi_m(x_i)}, \quad (4)$$

where  $w_i^m$  is the weight of training sample  $x_i$  in iteration  $m$ . The weak learner is selected to minimize the loss function in each iteration to update the strong learner. Both  $\alpha_m$ ,  $\beta_m$ , and  $t_m$  of the distance evaluation function and  $w_m^{\text{net}}$  of the  $m$ th group of the fully connected layer need to be optimized.

The proposed approach is easily integrated into some deep metric learning approaches, such as triplet loss, N-pair loss, and hierarchical triplet loss. However, for some loss functions, such as histogram loss and angular loss, it is not applicable and needs to be improved.

**3.2. Joint Training.** As to formula (3), we need attempt to jointly learn both the network and loss function. We note that its function was nonconvex, which was difficult to solve in general. Referring to Zhang et al. [27], this study applies an alternating optimization method to jointly train the network and loss function.

Since a learner needs to be optimized in each round of boosting, the optimization problem (4) was investigated, while fixing parameters  $w_m^{\text{net}}$  of the  $m$ th group of the fully connected layer. Formula (4) can be decomposed into

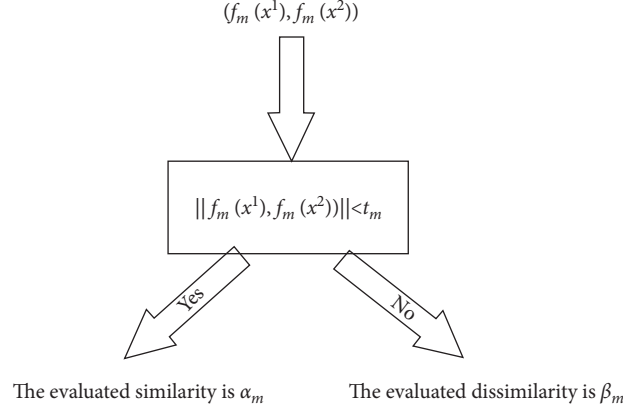

FIGURE 2: Operation of the evaluation function.

$$\sum_{i=1}^N w_i^m e^{-y_i \varphi_m(x_i)} = \sum_{y_i=1 \wedge d(x_i) < t_m} w_i^m e^{-\alpha_m} + \sum_{y_i=1 \wedge d(x_i) \geq t_m} w_i^m e^{-\beta_m} + \sum_{y_i=-1 \wedge d(x_i) < t_m} w_i^m e^{\alpha_m} + \sum_{y_i=-1 \wedge d(x_i) \geq t_m} w_i^m e^{\beta_m}. \quad (5)$$

Taking partial derivatives of formula (5) with respect to  $\alpha_m$  and  $\beta_m$  and setting both to zero to optimize each parameter,

$$\alpha_m = \frac{1}{2} \log \left( \frac{\sum_{y_i=1 \wedge d(x_i) < t_m} w_i^m}{\sum_{y_i=-1 \wedge d(x_i) < t_m} w_i^m} \right), \quad (6)$$

$$\beta_m = \frac{1}{2} \log \left( \frac{\sum_{y_i=1 \wedge d(x_i) \geq t_m} w_i^m}{\sum_{y_i=-1 \wedge d(x_i) \geq t_m} w_i^m} \right). \quad (7)$$

After each iteration, the weights of the training sample pairs are updated using the exponential loss function:

$$w_i^{m+1} = w_i^m e^{-y_i \varphi_m(x_i)}. \quad (8)$$

Then, the weights of all training sample pairs are normalized. As shown in formulas (6) and (7), the parameters that affect the evaluation function are only related to  $t_m$ , i.e., the optimal value obtained by the traversal method. If the training sample pairs are classified correctly, the weight of successive learners tends to be small; otherwise, the weight tends to be large. Hence, successive learners focus on different training sample pairs than previous learners, increasing the diversity among learners (Figure 3).

The next step is to update parameters  $w_m^{net}$  of the  $m$ th group of the fully connected layer, while fixing  $\alpha_m$ ,  $\beta_m$ , and  $t_m$  of the evaluation function. These parameters were trained with the contrastive loss function, using the standard backpropagation algorithm. In the forward process, the similarity distance metric is computed for each input training sample pair. In the backward process, the gradient of the loss function is iteratively propagated for each group (Figure 4).

For the contrastive loss function, the distance metric threshold  $t_m$  obtained through weak learning training serves as the distance margin of a negative training sample pair. Then, the contrastive loss function can be established as

$$\begin{aligned} \ell'(x_n^1, x_n^2) &= \frac{1}{2} (y_n + 1) d(f_m(x_n^1), f_m(x_n^2)) \\ &+ \frac{1}{2} (1 - y_n) [t_m - d(f_m(x_n^1), f_m(x_n^2))]_+. \end{aligned} \quad (9)$$

The training procedure is illustrated as Algorithm 1.

#### 4. Experiments and Results' Analysis

To verify its effectiveness, our method for deep distance metric learning was tested on three standard datasets: CUB-200-2011, Cars-196, and Stanford online products (SOP). Following the standard protocol proposed by Oh Song et al. [2], each dataset was broken down into a training set and a test set. For the CUB-200-2011 dataset, 5,864 images in the first 100 classes were allocated to the training set and 5,924 images in the last 100 classes were allocated to the test set. For the Cars-196 dataset, 8,054 images in the first 98 classes were allocated to the training set and 8,131 images in the remaining 98 classes were allocated to the test set. For the SOP dataset, 59,551 images of 11,318 classes were allocated to the training set and 60,502 images in 11,316 classes were allocated to the test set.

The performance of our method in retrieving images from the above datasets was evaluated by Recall@K. For each retrieval task, the authors computed the percentage of the testing images whose top-K retrieved images contain at least one image with the same class label. The K value was set to  $K \in \{1, 2, 4, 8, 16, 32\}$  for CUB-200-2011 and Cars-196, and  $K \in \{1, 10, 100, 1000\}$  for SOP. Our method was implemented under the framework of TensorFlow. Following Oh Song's approach [2], GoogLeNet was adopted as the feature extractor. The batch size was fixed at 128 in all experiments.

Since the deep distance metric could be affected by the number of weak learners, the influence of that number on our method was observed through experiments on each of the three datasets. As shown in Figure 5, with the growing number of weak learners, the Recall@1 score first increased

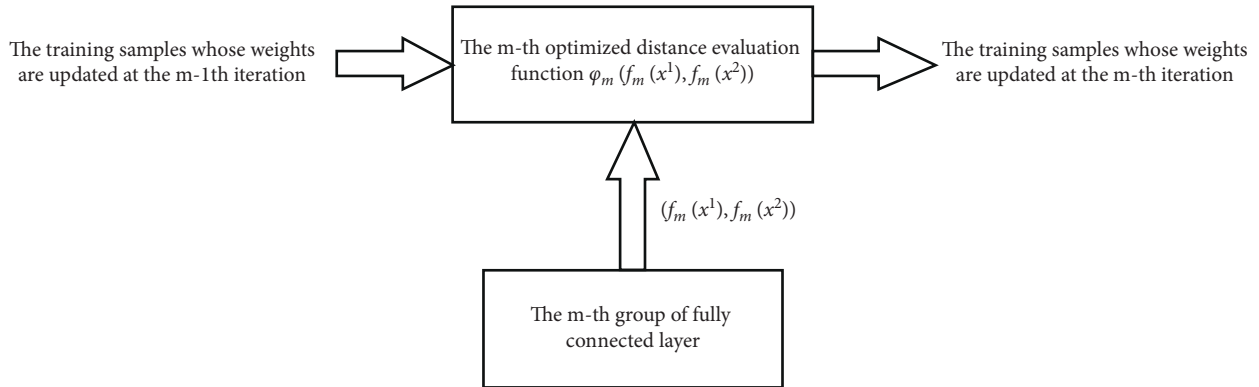

FIGURE 3: Optimization of the distance evaluation function with fixed parameters of the  $m$ th group of the fully connected layer.

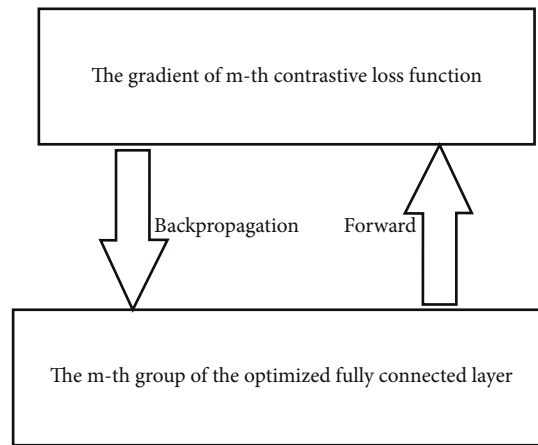

FIGURE 4: Optimization of the  $m$ th group of the fully connected layer with fixed parameters of the evaluation function.

```

Initialization: initialize distance metric threshold  $t_m$ ,  $m = 1, \dots, M$ , the weights of the training sample pairs  $w_n^m$ ,  $m = 1, \dots, M$  and  $n = 1, \dots, N$ ,
and parameters of the  $m$ th group of the fully connected layer  $w_m^{\text{net}}$ ,  $m = 1, \dots, M$ , randomly;
for  $m = 1$  to  $M$ 
  repeat
  for  $n = 1$  to  $N$ 
  Select the optimal value  $t_m$ , which minimizes formula (4), and update the weights  $w_n^m$  of the  $n$ th training sample pairs;
  Compute the derivatives of formula (9), and update the parameters  $w_m^{\text{net}}$  of the  $m$ th group of the fully connected layer via
  backpropagation;
  end
  until terminal condition.
 $D_m = D_{m-1} + \varphi_m$ 
end
Output  $D_M$ 

```

ALGORITHM 1: Training procedure of our method.

and then declined. The highest Recall@1 score was achieved at 8, 6, and 7 weak learners, for CUB-200-2011, Cars-196, and SOP, respectively. A possible reason is that the images in Cars-196 have relatively small variations, those in SOP face large view-point changes, and those in CUB-200-2011 feature a large pose variation and a strong background clutter. In the following experiments, the number of weak learners

was set to 8, 6, and 7, for CUB-200-2011, Cars-196 and SOP, respectively.

The eigenvector size also exerts a major effect on the deep distance metric. Hence, experiments were carried out on Cars-196 with 6 weak learners and different eigenvector sizes. Drawing on the work of Wang et al. [13], the eigenvector size was increased from 64 to 1,024. Figure 6

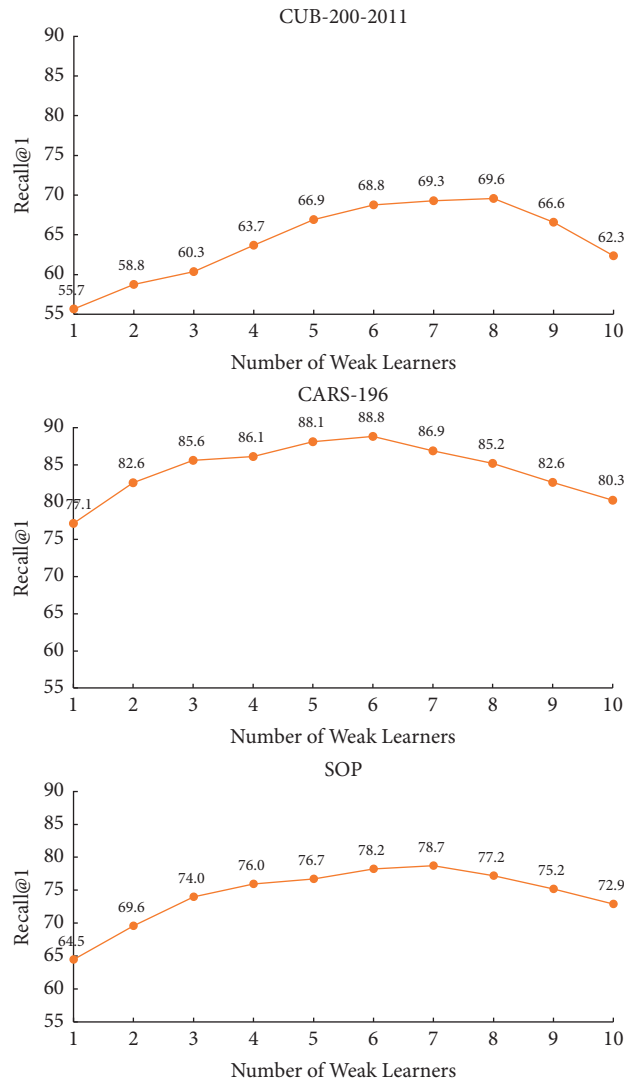

FIGURE 5: Influence of the number of weak learners over the performance of our method on different datasets.

FIGURE 6: Retrieval performance (R@1) at different eigenvector sizes on Cars-196.

compares the retrieval performance of our method with that of the multiscale (MS) method [13]. As shown in Figure 6, the retrieval performance of both methods gradually increased with the eigenvector size. Our

method performed stably, when the size was equal to or greater than 256, and always outshined the MS. Hence, the eigenvector size was fixed at 256 in subsequent experiments.

FIGURE 7: Training and testing results (R@1) on Cars-196.

FIGURE 8: Convergence curves of different methods on Cars-196.

Next, the training results and testing results were contrasted on Cars-196. As shown in Figure 7, the training R@1 only had a small gap from the testing R@1. On Cars-196, the R@1 score of the training set was around 93%, only 7% than that on the test set. This clearly shows that our method avoids overfitting.

Figure 8 shows the convergence curves of our method and several state-of-the-art methods on Cars-196. In the first 40 epochs, our method reached the performance of the state of the arts and converged faster than the other methods. However, according to the trend of the curve in Figure 8, that is, number of epochs from 0 to 50, the convergence rate of ours model was not the maximum. However, on the whole, the convergence rate of our method was satisfactory. Except for the MS, the contrastive methods took hundreds of epochs to converge. Thus, the training time of our method was compared with that of the MS. On a single NVIDIA Tesla V100 GPU, the mean running time of our method was 24.36s per epoch on CUB-200-2011 and 40.29s per epoch on Cars-196, while that of the MS was 28.45s and 43.58, respectively.

Finally, the image retrieval efficiency of our method was compared with that of the state-of-the-art methods on CUB-200-2011 and Cars-196, respectively. The comparison results (Tables 1 and 2) show that our method outperformed these methods, including higher-order tuples such as LiftedStruct and N-Pairs, as well as angular loss and ensemble methods such as annotation-based expansion (ABE) and deep randomized ensembles for metric learning (DREML). In particular, on the challenging CUB-200-2011 dataset, our

method led the best-performing state-of-the-art method by a large margin: 4.2% in R@1. On SOP, our method also attained the best performance (Table 3). On all the datasets, our method, with a low feature dimension, performed better than the existing methods, with high feature dimensions.

## 5. Conclusions

This study presents a deep distance metrics ensemble method based on boosting, which generates the final distance metric through iterative training of multiple weak distance metrics. Specifically, the last fully connected layer of the CNN was used to form multiple groups of features. The sample pairs were mapped by the CNN, and the distance between the mapped sample pairs was evaluated by a piecewise linear function. The function was added as a weak learner to the boosting algorithm to generate a strong learner. Then, an alternating optimization method was utilized to optimize the parameters of network and loss function. The effectiveness of our method was demonstrated on three datasets widely used in image retrieval tasks. The future research will further improve our method by cascading more models and combine our method with other loss functions.

The privacy protection for face images aims to prevent attackers from accurately identifying target persons through face recognition. Inspired by goal-driven reasoning (reverse reasoning), this paper designs a goal-driven algorithm of local privacy protection for sensitive areas in multiface images (face areas) under the interactive framework of face recognition algorithm, regional growth, and differential privacy. The designed algorithm, named privacy protection for sensitive areas (PPSA), is realized in the following manner: Firstly, the multitask cascaded convolutional network (MTCNN) was adopted to recognize the region and landmark of each face. If the landmark overlaps a subgraph divided from the original image, the subgraph will be taken as the seed for regional growth in the face area, following the growth criterion of the fusion similarity measurement mechanism (FSMM). Different from single-face privacy protection, multiface privacy protection needs to deal with an unknown number of faces. Thus, the allocation of the privacy budget  $\epsilon$  directly affects the operation effect of the PPSA algorithm. In our scheme, the total privacy budget  $\epsilon$  is divided into two parts:  $\epsilon_1$  and  $\epsilon_2$ . The former is evenly allocated to each seed, according to the estimated number of faces  $\rho$  contained in the image, while the latter is allocated to the other areas that may consume the privacy budget through dichotomization. Unlike the Laplacian (LAP) algorithm, the noise error of the PPSA algorithm will not change with the image size, for the privacy protection is limited to the face area. The results show that the PPSA algorithm meets the requirements  $\epsilon$ -Differential privacy, and image classification is realized by using different image privacy protection algorithms in different human face databases. The verification results show that the accuracy of the PPSA algorithm is improved by at least 16.1%, the recall rate is improved by at least 2.3%, and  $F1$ -score is improved by at least 15.2%.

## 1. Introduction

In the information age, the importance of data becomes more and more prominent. The value of data is highlighted in various fields in our society. Data-based services are widely applied in different industries. In particular, the application of image data has been developing rapidly. Thanks to the fast development of information technology and multimedia technology, it is now easier to acquire and share digital face images. The users can publish their own photos on social network platforms and other channels. Statistics show that more than 3.2 billion face images are shared by users of major social network platforms around

the world. These digital images usually contain a wealth of personally sensitive information. If the information is collected and analyzed by attackers, unmeasurable losses will occur, in addition to the leak of personal privacy.

The privacy protection of image data often relies on techniques like  $k$ -anonymity, access control, and privacy encryption. Fung et al. [1] and Xiao and Tao [2] proposed the  $k$ -same method based on the anonymization mechanism. The method anonymizes each published gray image, reducing the probability of attackers deriving user identity from the published image to less than  $1/k$ . Li et al. [3] applied access control to restrict user access to social network images. The transfer and visitor volumes of these images are

reduced to protect privacy. This approach, which protects images via access settings, is not a fundamental privacy protection method for images. If an attacker has a certain background knowledge, he/she may bypass the access control and acquire the user images and privacy information. To prevent the communication process from being eavesdropped, Terrovitis et al. [4] implemented homomorphic encryption on gray images. However, every data encryption technique makes some assumptions and designs the corresponding encryption algorithm based on these assumptions. However new it is, the encryption algorithm will soon be breached by attackers. Focusing on anonymized images on Facebook, Sweeney, and Anonymity [5] revealed that attackers can deduce the social security number (SSN) of the person in each anonymized image, based on the unique Friendster feature of Facebook, and identify the sensitive information (e.g., disease and address) from the SSN.

In 2006, Dwork [6] proposed differential probability, which disturbs sensitive data by adding noise to the output. Differential privacy can hide the impact of a single record: whether a record is in the dataset or not, the output probability of the same result will not change significantly. In this way, attackers are hampered from further reasoning. Compared with other privacy protection techniques, the differential probability is superior in that it makes no assumption about the background knowledge of attackers. Dwork further investigated differential privacy in a series of theses [7–11] and proposed its implementation mechanism [12, 13]. McSherry [14] pointed out that the differential privacy algorithm for complex privacy problems needs to satisfy two composition properties: sequence combination and parallel combination. In recent years, differential privacy has been mainly applied to the field of data publication. The differential privacy protection for data publication mainly attempts to ensure the accuracy of published data or query results while satisfying differential privacy. The relevant research focuses on adjusting the publication mechanism and algorithm complexity. The primary research method is a quantitative analysis based on calculation and learning theories.

By the realization environment, the differential privacy protection for data publication can be divided into interactive data publication and noninteractive data publication [12]. On interactive data publication, Roth and Roughgarden [15] presented a median algorithm that can respond to more queries. Hardt and Rothblum [16] developed a pulse wave modulation (PMW) mechanism capable of increasing the number of queries. Gupta et al. [17] proposed a universal iterative dataset generation mechanism. Fan and Xiong [18] designed a novel approach with filtering and adaptive sampling for releasing time series under differential privacy (FAST). Kellaris et al. [19] put forward a flow data publication algorithm with no limit on the number of publications. On noninteractive data publication, Xiao et al. [20] came up with the Privelet algorithm. Xu et al. [21] created the noise first and structure first algorithms. Li et al. [22] proposed the matrix mechanism. Li et al. [23] put forward a data- and workload-aware algorithm (DAWA) algorithm.

Owing to the complexity of image data, the current research is still in the exploratory stage concerning the differential privacy protection for sensitive information in images.

Images are often represented as matrices in the real number field. Any pixel in an image can be mapped to a value at the corresponding location in a two-dimensional (2D) matrix. To satisfy  $\epsilon$ -differential privacy, the most direct approach is to add a Laplace noise to all the values in the matrix. However, the disturbed image may be over distorted and become useless. Fourier transform and wavelet transform are common ways to compress images. Zhang et al. [24] proposed an image compression method based on discrete Fourier transform (DFT), which adds a unique Laplace noise to each target image. Despite suppressing the noise error, their approach introduces the reconstruction error to image compression. Considering the uncorrelation between the values in the image matrix, Liu et al. [25] converted the image gray matrix into a one-dimensional (1D) ordered data flow and modeled the data flow with the sliding window model. To protect the privacy of images, the privacy budget was allocated dynamically based on the similarity between the data of adjacent sliding windows. This highly available strategy is restricted to the 1D space. Liu et al. [26] utilized regional growth to expand the comparison between adjacent subgraphs to the 2D space and further optimized the privacy protection for face images.

The noises of the above methods cover the entire image. For face images, the sensitive information of the face only concentrates in the face area and even in some specific areas. The exposure of other nonsensitive areas will not lead to the leak of privacy. Therefore, this paper proposes a local privacy protection method for the sensitive areas in multiface images.

## 2. Background

### 2.1. Differential Privacy

*Definition 1.* Adjacent datasets of the face image

For a given image  $X$ , the gray matrix  $X_{mn}$  can be obtained by normalizing the image. Then, there exists

$$X|X_{mn} = \begin{bmatrix} x_{11}, x_{12}, & \cdots & x_{1n} \\ \vdots & \ddots & \vdots \\ x_{m1}, x_{m1}, & \cdots & x_{mn} \end{bmatrix}, \text{ where } x_{ij} \text{ in matrix } X_{mn}$$

represents the gray of the corresponding element. If there exists an  $X'$  with only one element difference from  $X$ ,  $|X - X'| = x_{ij}$  ( $1 \leq i \leq m, 1 \leq j \leq n$ ), then  $X$  and  $X'$  are adjacent datasets.

*Definition 2.* Differential privacy

For a given random algorithm  $M$  of image data publication, with the output range of  $\text{Range}(M)$ , the algorithm can provide  $\epsilon$ -differential privacy, if its arbitrary outputs on two adjacent gray images  $X$  and  $X'$  satisfy the following:

$$\Pr[M(X) \in S] \leq \exp(\epsilon) \times \Pr[M(X') \in S], \quad (1)$$

where  $\epsilon$  is typically a small positive number that balances privacy with accuracy. If  $\epsilon$  is small, the privacy is high and

accuracy is low. The inverse is also true. Normally,  $\epsilon$  is selected by the user by executing a privacy policy. When the adjacent datasets vary by only one record, the algorithm satisfies  $\epsilon$ -differential privacy. When the adjacent datasets vary by  $k$  records, the algorithm satisfies  $k\epsilon$ -differential privacy.

*Definition 3.* Global sensitivity

Let  $Q$  be a random query function meeting  $Q: D \rightarrow R^n$ . Then, the global sensitivity of  $Q$  can be expressed as follows:

$$\Delta Q_{GS} = \max_{X, X'} \|Q(D) - Q(D')\|_p. \quad (2)$$

**Theorem 1.** Laplace mechanism

Let  $Q$  be a query series of the length  $d$ . The random algorithm  $M$  receives database  $D$  and outputs the following vector that satisfies  $\epsilon$ -differential privacy:

$$M(D) = Q(D) + \langle \text{Lap}_1\left(\frac{\Delta Q_{LS}}{\epsilon}, \dots, \text{Lap}_d\left(\frac{\Delta Q_{LS}}{\epsilon}\right) \right). \quad (3)$$

As the most common noise addition mechanism, the Laplace mechanism disturbs the real output by adding the noise generated by Laplace distribution, thereby achieving differential privacy. The probability density function (PDF) of its noise distribution satisfies  $f(x|\mu, b) = 1/2be^{|x-\mu|/b}$ .

*Property 1.* Differential privacy-serial combination property

For a given dataset  $X$  and a set of differential privacy algorithms  $M_1(X), M_2(X), \dots, M_m(X)$  related to  $X$ , if the algorithm  $M_i(D)$  satisfies  $\epsilon_i$ -differential privacy, and the random processes of any two algorithms are independent of each other, then the algorithm combined from these algorithms satisfies  $\sum_{i=1}^m \epsilon_i$ -differential privacy.

## 2.2. Multitask Cascaded Convolutional Network (MTCNN).

With the development of CNN [27], Sun et al. [28] suggested that the CNN can be applied to localization face landmarks by virtue of its strong feature extraction ability. A three-layer deep CNN (DCNN) was designed to solve a thorny problem in landmark extraction: the inability to obtain the global optimal solution, due to the improper setting of initial values. Zhang et al. introduced multitask learning to face landmark localization and proposed a task-driven DCNN for face landmark localization (TCDCN). The TCDCN, a multitask learning model of four subtasks, has a smaller time complexity than traditional CNN [29]. Two years later, Zhang et al. developed the MTCNN, which effectively integrates face area detection with face landmark localization. The three cascading neural networks in MTCNN are responsible for face classification, bounding box regression, and key point localization, respectively [30]. Wu et al. [31] presented a tweaked CNN (TCNN), which relies on a mixed Gaussian model to cluster the features on different layers, and concluded that a deeper network layer can more accurately mirror face landmarks. In addition, many other methods have been adopted to locate face landmarks,

namely, principal component analysis (PCA) [32], support vector machine [33], Bayesian probabilistic network (BPN) [34], dynamic link architecture (DLA) [35], and Gabor wavelet network (GWN) [36].

The MTCNN is a multitask parallel face recognition method based on deep learning. This method has been widely recognized in the industry because it operates rapidly, and its accuracy meets the general requirements of face detection. The multitask parallel capacity of the MTCNN algorithm manifests as the simultaneous detection of multiple faces (detecting whether an image contains faces and finding the face locations in the image, as shown in Figure 1) and the localization of face landmarks (locating the five landmarks, namely, two eyes, nose tip, and mouth corners, as shown in Figure 2).

The MTCNN algorithm can be realized as a three-stage cascaded CNN. The first stage is called a proposal network (P-Net), which mainly obtains the candidate windows for the face area and the regression vector of the bounding box, carries out regression with the bounding box, calibrates the candidate windows, and merges highly overlapped candidate boxes through nonmaximum suppression (NMS). The structure of the P-Net is shown in Figure 3.

The second stage is called a refine network (R-Net), which eliminates the false positive areas through bounding box regression and NMS. That is, lots of nonface windows are denied by a more complex CNN in order to refine the face window. The structure of the R-Net is shown in Figure 4.

The third stage is called an output network (O-Net). With one more convolutional layer than the R-Net, the O-Net outputs more refined results. The functions of the O-Net are the same as those of the R-Net. But the O-Net carries out more supervision of the face area and output five landmarks. The structure of the O-Net is shown in Figure 5.

Each stage of the MTCNN is a multitask network, responsible for handling tasks like face/nonface judgement, face box regression, and landmark localization. The face/nonface judgement adopts the cross-entropy loss function:

$$L_i^{\text{det}} = -\left(y_i^{\text{det}} \log(p_i) + (1 - y_i^{\text{det}})(1 - \log(p_i))\right), \quad (4)$$

where  $p_i$  is the probability for the image to contain faces;  $y_i^{\text{det}} \in \{0, 1\}$  is the true background label.

The regression loss of face box can be calculated by Euclidean distance:

$$L_i^{\text{box}} = \|\hat{y}_i^{\text{box}} - y_i^{\text{box}}\|_2^2, \quad (5)$$

where  $\hat{y}$  is the background coordinates predicted by the network;  $y$  is the true background coordinates;  $y_i^{\text{box}} \in \mathbb{R}^4$  ( $\mathbb{R}^4$  is a 4-tuple composed of  $x$  of the upper left corner,  $y$  of the upper left corner, length, and width).

Landmark localization is calculated similarly as face box regression. The Euclidean distance between the predicted landmark location and the true landmark location is calculated and minimized:

$$L_i^{\text{landmark}} = \|\hat{y}_i^{\text{landmark}} - y_i^{\text{landmark}}\|_2^2, \quad (6)$$

where  $y_i^{\text{landmark}} \in \mathbb{R}^{10}$  is a 10-tuple, for five landmarks are being localized.

FIGURE 1: Face detection.

FIGURE 2: Landmark localization.

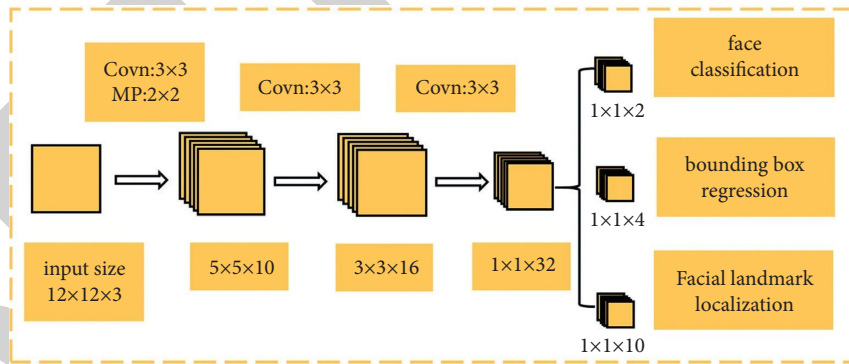

FIGURE 3: Structure of P-net.

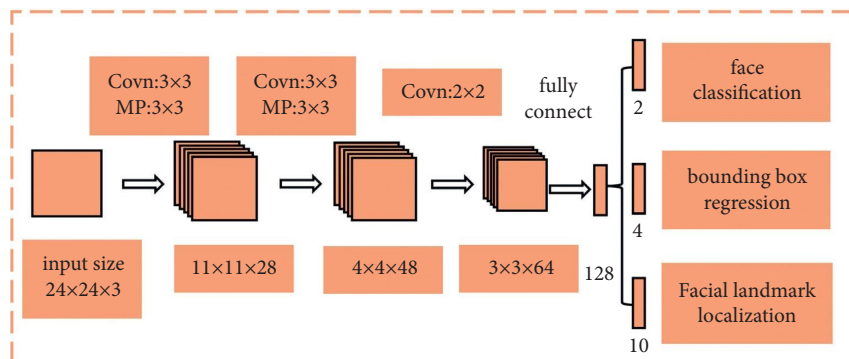

FIGURE 4: Structure of R-net.

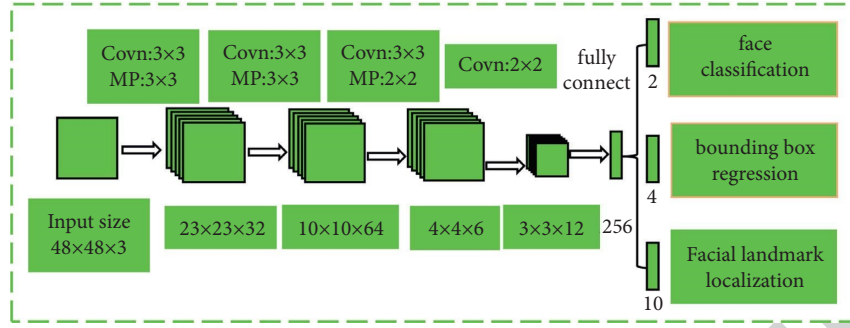

FIGURE 5: Structure of O-net.

The simplest function of the training process can be expressed as follows:

$$\min \sum_{i=1}^N \sum_{j \in \{\text{det}, \text{box}, \text{landmark}\}} \alpha_j \beta_i^j L_i^j, \quad (7)$$

where  $N$  is the number of training samples;  $\alpha_j$  is the importance of a task;  $\beta_i^j \in \{0, 1\}$  is a sample label. In the P-Net and R-Net,  $\alpha_{\text{det}} = 1$ ,  $\alpha_{\text{box}} = 0.5$ , and  $\alpha_{\text{landmark}} = 0.5$ . In the O-Net,  $\alpha_{\text{det}} = 1$ ,  $\alpha_{\text{box}} = 0.5$ , and  $\alpha_{\text{landmark}} = 1$ .

### 3. Methodology

**3.1. Laplacian (LAP) Algorithm.** This paper proposes the LAP algorithm based on the Laplace mechanism. In the LAP algorithm, every element  $x_{ij}$  in the gray matrix  $X_{m \times n}$  is regarded as an independent individual. This division method is the basis for applying the interactive mechanism to privacy protection. Each  $x_{ij}$  ( $1 \leq i \leq m$ ,  $1 \leq j \leq n$ ) consumes a privacy budget of  $\epsilon / (m \times n)$ . The LAP algorithm can be realized in the steps in Algorithm 1.

Compared with the original image  $X$ , the privacy protected image  $X'$  contains an additive noise of  $2m \times n \times (\Delta Q \times m \times n / \epsilon)^2$ . Admittedly, the LAP algorithm satisfies  $\epsilon$ -differential privacy. However, the noise results show that the LAP algorithm will have a huge error if it is applied to protect the privacy of an excessively large image. If so, the noisy image will be of low availability.

**3.2. Fusion Similarity Measurement Mechanism (FSMM).** This paper divides a face image  $X_{m \times n}$  into multiple non-intersecting subgraphs  $T_{ij}$  ( $1 \leq i \leq I$ ,  $1 \leq j \leq J$ ), each of which contains multiple pixels:

$$X_{m \times n} = \begin{bmatrix} x_{11}, x_{12}, & \cdots & x_{1n} \\ \vdots & \ddots & \vdots \\ x_{m1}, x_{m1}, & \cdots & x_{mn} \end{bmatrix} = \begin{bmatrix} T_{11}, T_{12}, & \cdots & T_{1J} \\ \vdots & \ddots & \vdots \\ T_{I1}, T_{I1}, & \cdots & T_{IJ} \end{bmatrix}. \quad (8)$$

Through the division, the nonintersecting subgraphs  $T_{ij}$  carry as much information of the original image as possible.

The key to regional growth is to determine the criterion. Due to the natural complexity of face images, the criterion should be designed by judging the various features of the original image. The traditional criterion for regional growth only focuses on the difference between gray values. The gray value of a single pixel cannot provide rich information about the image. By contrast, subgraphs as the basic units of regional growth can retain the luminance, contrast, structure, color, texture, and spatial distribution features of the image. This paper presents a new regional growth criterion called FSMM, which further improves the accuracy of area merging with subgraphs as the basic units. The FSMM can be realized in the steps in Algorithm 2.

As its name suggests, the new regional growth criterion relies on the FSMM, a brand-new similarity measure between images. In rows 3-4 of the algorithm, parameter  $\sigma$ , a very small positive number, appears to ensure the denominator is nonzero. In rows 7-9,  $u_X$  and  $u_Y$  are, respectively, the mean values of images  $X$  and  $Y$ , reflecting the luminance features of the images;  $\sigma_X$  and  $\sigma_Y$  are, respectively, the variances of images  $X$  and  $Y$ , reflecting the contrast features;  $C_1, C_2$  and  $C_3$  are very small positive numbers that ensure the denominator is nonzero. In Column 10,  $\alpha, \beta$ , and  $\gamma$  are parameters adjusting the proportion of different eigenvalues: if

$\alpha = \beta = \gamma = 1$ , then  $C_1 = (K_1 L)^2$ ,  $C_2 = (K_2 L)^2$ , and  $C_3 = C_2/2$ , with  $K_1 \ll 1$ ,  $K_2 \ll 1$ , and  $L$  being the dynamic range of the image. The final calculation method for FSMM( $X, Y$ ) can be expressed as follows:

$$\text{FSMM}(X, Y) = \frac{\phi \times (d(X, Y) / \rho(X, Y) + \sigma) \times (2u_X u_Y + C_1) \times (2\sigma_X \sigma_Y + C_2)}{(u_X^2 + u_Y^2 + C_1) \times (\sigma_X^2 + \sigma_Y^2 + C_2)}. \quad (9)$$

Input: original image  $X$ , privacy budget  $\varepsilon$ , parameters  $m$  and  $n$ , subgraph similarity expectation  $Th$   
 Output: Image  $X'$  satisfying differential privacy

- (1) Read the original image  $X$ , convert the image into gray matrix and store it in matrix  $X_{m \times n}$
- (2) for  $i = 1$  to  $m$
- (3)   for  $i = 1$  to  $n$
- (4)     $X'_{(i,j)} = X_{(i,j)} + \text{lap}(\Delta Q \times m \times n/\varepsilon)$
- (5)   end for
- (6)   end for
- (7) Output privacy protected picture  $X'$

ALGORITHM 1: LAP.

Input: image  $X$ , image  $Y$   
 Output: graph similarity  $\theta$

- (1) Convert the image to a grayscale image,  $X' = \begin{bmatrix} X_1 & \dots & \dots \\ \dots & \ddots & \dots \\ \dots & \dots & X_c \end{bmatrix}, Y' = \begin{bmatrix} Y_1 & \dots & \dots \\ \dots & \ddots & \dots \\ \dots & \dots & Y_c \end{bmatrix}$
- (2) Calculate the Euclidean distance between  $X'$  and  $Y'$ ,  $\theta = \sqrt{\sum_{i=1}^n (X_i - Y_i)^2}$
- (3) Calculate the Jaccard similarity index between  $X'$  and  $Y'$ ,  $\rho(X', Y') = |X' \cap Y'| / |X' \cup Y'|$
- (4)  $\theta = \theta / \rho(X', Y') + \sigma$
- (5) Combined with Hamming distance and perceptual hash algorithm  $\phi$ ,  $\phi = \begin{cases} \theta \times (\rho(X', Y') + \sigma) / d(X', Y') \mu(X', Y') < 0.078 \times c \\ 1, 0.078 \times c \leq \mu(X', Y') \leq 0.156 \times c \\ (1/\lg) \times (m \times n - \mu(X', Y')), \mu(X', Y') > 0.156 \times c \end{cases}$
- (6)  $\theta = \phi \times \theta$
- (7) Calculate the luminance relationship between  $X'$  and  $Y'$ ,  $l(X', Y') = (2u_{X'}u_{Y'} + C_1) / (u_{X'}^2 + u_{Y'}^2 + C_1)$
- (8) Calculate the contrast ratio relationship between  $X'$  and  $Y'$ ,  $c(X', Y') = (2\sigma_{X'}\sigma_{Y'} + C_2) / (\sigma_{X'}^2 + \sigma_{Y'}^2 + C_2)$
- (9) Calculate the structural relationship between  $X'$  and  $Y'$ ,  $s(X', Y') = (\sigma_{X'Y'} + C_3) / (\sigma_{X'}\sigma_{Y'} + C_3)$
- (10)  $\text{SSIM}(X', Y') = [l(X', Y')]^a \cdot [c(X', Y')]^b \cdot [s(X', Y')]^y$
- (11)  $\theta = \text{SSIM}(X', Y') \times \theta$
- (12) Output  $\theta$

ALGORITHM 2: FSMM.

### 3.3. Privacy Protection for Sensitive Areas (PPSA) Algorithm.

To achieve privacy protection of sensitive information (face area) in multiface images and reduce noise impact on the privacy protected images, this paper proposes a local privacy protection method for face images, which combines face recognition, regional growth, and differential privacy. The proposed algorithm is called the PPSA.

Inspired by goal-driven reasoning (reverse reasoning), the PPSA was designed with goal as the starting point. The privacy protection for face images aims to prevent attackers from recognizing the target persons through face detection. Therefore, the first step of PPSA design is to understand how attackers identify faces. Next, a privacy protection method should be provided for face images, targeting the face identification technique of attackers. In this way, the designed privacy protection algorithm can effectively curb privacy leak and mitigate the effects of noise on the availability of the privacy protected image.

The design of the PPSA needs to solve three key problems: (1) locate the sensitive area in the multiface image and recognize the landmarks in the area; (2) formulate the criterion for regional growth; (3) allocate the privacy budget reasonably to areas requiring different levels of protection.

The PPSA algorithm is designed to protect the sensitive information (face information) in multiface images in batches. Different from single-face privacy protection,

multiface privacy protection needs to deal with an unknown number of faces. Thus, the allocation of the privacy budget is crucial to PPSA design. The privacy protection should be tailored to areas with different protection requirements. In our scheme, the total privacy budget  $\varepsilon$  is divided into two parts:  $\varepsilon_1$  and  $\varepsilon_2$ . The  $\varepsilon_1$  is evenly allocated to each seed  $\text{Seed}_n$  (any subgraph containing a landmark is a seed), according to the estimated number of faces  $\rho$  contained in the image. During regional growth,  $\text{Seed}'_n$  (noisy seed) replaces the  $T_{(i,j)}$  (adjacent subgraph) meeting the growth criterion, thereby protecting the privacy of  $T_{(i,j)}$ . Note that the privacy protection of  $T_{(i,j)}$  does not consume any privacy budget. Meanwhile, the  $\varepsilon_2$  is allocated through dichotomization. This part of the privacy budget is consumed by the  $\text{Seed}_n$  outside the estimated number of faces  $\rho$ , the  $T_{(i,j)}$  failing to meet the growth criterion, and the  $\tilde{T}_{(i,j)}$  belonging to the sensitive area but not involved in regional growth. The PPSA algorithm can be realized in the steps in Algorithm 3.

The image preprocessing, privacy budget allocation, and regional growth are described in rows 1–6, rows 7–9, and rows 10–29, respectively. In row 30,  $\tilde{T}_{(i,j)}$  is the addition of Laplace noise to an unprotected subgraph in  $S'$ . In row 18, the PPSA limits the range of regional growth: if a  $T_{(i,j)}$  meeting the growth criterion but lying beyond the coverage of the current  $S'_i$  or the growth range of the current  $\text{Seed}_n$ , it will not be able to complete this area merging; the growth

Input: Original image  $X$ , privacy budget  $\varepsilon$ , estimated number of faces  $\rho$ , preset parameters  $\beta$ , estimate the number of faces in the image  $\omega$ , subgraph similarity expectation  $Th$

Output: Image  $X'$  satisfying differential privacy.

- (1) Read the original image  $X$ , convert the image into gray matrix and store it in matrix  $X_{m \times n}$
- (2) MTCNN is used to extract the face region  $S = (S_1, S_2, \dots, S_\omega)$  and face feature point  $K_S = (K_1, K_2, \dots, K_{5 \times \omega})$  in face image  $X$
- (3) Set the gray matrix  $X$  according to the preset parameters  $\beta$  It is divided into subgraph sets  $T_{(I,J)}$  with the same structure
- (4) If  $K_S$  belongs to a subgraph  $T_{(i,j)}$ , set  $T_{(i,j)}$  as  $\text{Seed}_n$
- (5) Find all backup  $\text{Seed}_N = (\text{Seed}_1, \text{Seed}_2, \dots, \text{Seed}_{5 \times \omega})$
- (6) Adjust the face image area  $S$  as  $S'$  according to the sub image size
- (7)  $\varepsilon = \varepsilon_1 + \varepsilon_2$
- (8)  $\varepsilon_1^{\text{left}} = \varepsilon_1$
- (9)  $\varepsilon_2^{\text{left}} = \varepsilon_2/2$
- (10) Set  $\text{Seed} = 0$ ,  $\widetilde{\text{Seed}}$  used to record whether this seed has been used during regional growth
- (11) Create a linked **list** to record the status of the current seed region merging process
- (12) while ( $\text{Seed} \leq 5 \times \omega$ )
- (13) if ( $\varepsilon_1^{\text{left}} > 0$ )
- (14) if ( $\text{list\_head} == \text{NULL}$ )
- (15) Pick unmarked  $\text{Seed}_n$  adds noise to it as  $\text{Seed}'_n$ ,  $\text{Seed}'_n = \text{Seed}_n + \text{lap}(\Delta Q \times 5 \times \rho / \varepsilon_1)$
- (16)  $\varepsilon_1^{\text{left}} = \varepsilon_1^{\text{left}} - \varepsilon_1 / 5\rho$
- (17) Attempt to merge adjacent  $T_{(i,j)}$  start regional growth
- (18) if ( $T_{(i,j)} \notin S' \parallel \text{Euclidean\_Distance}(T_{(i,j)}, \text{Seed}_n) \geq \text{Min}(\text{Euclidean\_Distance}(\text{Seed}_n, \text{Seed}_m) / 2)$ )
- (19) brake
- (20) else
- (21) if ( $\text{FSMM}(\text{Seed}'_n, T_{(i,j)}) \leq Th$ )
- (22)  $T_{(i,j)} = \text{Seed}'_n$
- (23) else
- (24)  $T'_{(i,j)} = T_{(i,j)} + \text{lap}(\Delta Q / \varepsilon_2^{\text{left}})$
- (25)  $\varepsilon_2^{\text{left}} = \varepsilon_2^{\text{left}} / 2$
- (26)  $\text{Seed}_n$  is set to marked,  $\widetilde{\text{Seed}} = \widetilde{\text{Seed}} + 1$
- (27) Release all data in the list, and the consolidation of this subregion is completed
- (28) else if ( $\varepsilon_1^{\text{left}} = 0$ )
- (29) Execute line 15–line 28, line 16  $\Delta Q \times 5 \times \rho / \varepsilon_1$  adjusted to  $\Delta Q / \varepsilon_2^{\text{left}}$ , line 17 is adjusted to  $\varepsilon_2^{\text{left}} = \varepsilon_2^{\text{left}} / 2$
- (30)  $\widehat{T}_{(i,j)} = \widehat{T}_{(i,j)} + \text{lap}(\Delta Q / \varepsilon_2^{\text{left}})$

ALGORITHM 3: PPSA.

range of  $\text{Seed}_n$  will be limited to half of the Euclidean distance to the nearest adjacent  $\text{Seed}_m$ . If  $\omega \leq \rho$ , only rows 10–27 will be executed for regional growth. If  $\omega > \rho$ , all the rows from 10–29 will be executed for regional growth.

**Theorem 2.** *The PPSA consumes a privacy budget smaller than  $\varepsilon$  and satisfies  $\varepsilon$ -differential privacy.*

*Proof.* In the PPSA, the total privacy budget  $\varepsilon$  is divided into two parts. Among them,  $\varepsilon_1$  is used to add noise to seeds. If  $\omega < \rho$ , there exists  $\varepsilon_1^{\text{left}} > 0$  after the end of the algorithm; if  $\omega \geq \rho$ , there exists  $\varepsilon_1^{\text{left}} = 0$  after the end of the algorithm. Meanwhile,  $\varepsilon_2$  is allocated by dichotomy:

$$\varepsilon_2 \times \left( \frac{1}{2^1} + \frac{1}{2^2} + \frac{1}{2^3} + \dots + \frac{1}{2^N} \right) < \varepsilon_2 \quad (N \rightarrow +\infty). \quad (10)$$

Thus, there exists the following:

$$\varepsilon - (\varepsilon_1^{\text{left}} + \varepsilon_2^{\text{left}}) > 0. \quad (11)$$

Therefore, the PPSA consumes a privacy budget smaller than  $\varepsilon$ . According to Property 1, the PPSA satisfies  $\varepsilon$ -differential privacy.

Q.E.D.

**Theorem 3.** *The error of the PPSA is no greater than that of the LAP, i.e.,*

$$\text{Error (DPLP)} < \text{Error (LAP)}. \quad (12)$$

*Proof.* In the PPSA, the privacy protected image contains four kinds of subgraphs, namely, noise-free subgraph  $P_{(i,j)}$ , seed  $\text{Seed}_n$ , subgraph merged in regional growth  $T_{(i,j)}$ , and subgraph belonging to a sensitive area but not involved in regional growth  $\widehat{T}_{(i,j)}$ .

(1) For  $P_{(i,j)}$ :

$$P'_{(i,j)\text{-PPSA}} = 0$$

$$P'_{(i,j)\text{-LAP}} = P_{(i,j)} + \text{lap}\left(\frac{\Delta Q \times I \times J}{\varepsilon}\right). \quad (13)$$

Subtracting the two formulas above, we have the following:  $\text{Error (PPSA}(P_{(i,j)})) < \text{Error (LAP}(P_{(i,j)}))$ .

(2) For  $\widehat{T}_{(i,j)}$ :

$$\begin{aligned}\hat{T}'_{(i,j)\text{-LAP}} &= \hat{T}_{(i,j)} + \text{lap}\left(\frac{\Delta Q \times I \times J}{\varepsilon}\right) \\ \hat{T}'_{(i,j)\text{-PPSA}} &= \hat{T}_{(i,j)} + \text{lap}\left(\frac{\Delta Q \times 2^M}{\varepsilon_2}\right).\end{aligned}\quad (14)$$

If  $2^M \leq I \times J$ , there exists  $\text{Error}(\text{PPSA}(P_{(i,j)})) < \text{Error}(\text{LAP}(P_{(i,j)}))$ .

If  $2^M > I \times J$ , there exists  $\text{Error}(\text{PPSA}(P_{(i,j)})) \approx \text{Error}(\text{LAP}(P_{(i,j)}))$ .

The validity of  $\text{Error}(\text{PPSA}(P_{(i,j)})) \approx \text{Error}(\text{LAP}(P_{(i,j)}))$  depends on the uniqueness of the gray image. In the gray image matrix, the gray value falls between 0 and 255. Under the Laplace mechanism, the smaller the  $\varepsilon$ , the greater the noise. For any other type of data, the noise effect will be huge, if  $\varepsilon$  is sufficiently small. For gray value, however, the fluctuation induced by noise is limited. Take  $\hat{T}'_{(i,j)\text{-PPSA}} = \hat{T}_{(i,j)} + \text{lap}(\Delta Q \times 2^M / \varepsilon_2)$  for example. When  $\text{lap}(\Delta Q \times 2^M / \varepsilon_2) \rightarrow +\infty$  时,  $\hat{T}'_{(i,j)\text{-PPSA}}$  value in the gray matrix will become 255. When  $\text{lap}(\Delta Q \times 2^M / \varepsilon_2) \rightarrow -\infty$ , that value will change to 0. Thus,  $\text{Error}(\text{PPSA}(P_{(i,j)})) \approx \text{Error}(\text{LAP}(P_{(i,j)}))$  holds, as long as  $I \times J$  is sufficiently great.

(3) For  $\text{Seed}_n$ :

There are two possible scenarios:  $\omega \leq \rho$  and  $\omega > \rho$ .

When  $\omega \leq \rho$ ,  $\text{Seed}'_{n\text{-DPLP}}$  only consumes  $\varepsilon_1$ . Then, there exists the following:

$$\begin{aligned}\text{Seed}'_{n\text{-PPSA}} &= \text{Seed}_n + \text{lap}\left(\frac{\Delta Q \times 5 \times \rho}{\varepsilon_1}\right) \\ \text{Seed}'_{n\text{-LAP}} &= \text{Seed}_n + \text{lap}\left(\frac{\Delta Q \times I \times J}{\varepsilon}\right).\end{aligned}\quad (15)$$

If  $5 \times \rho \ll I \times J$ , the numerical gap between  $\varepsilon_1$  and  $\varepsilon$  is so small as to be negligible. Subtracting the above two formulas, we have the following:  $\text{Error}(\text{PPSA}(\text{Seed}_n)) < \text{Error}(\text{LAP}(\text{Seed}_n))$ .

When  $\omega > \rho$ , the first  $\rho$  face areas consume  $\varepsilon_1$  until no budget in this part is left. In this case, there exists  $\text{Error}(\text{PPSA}(\text{Seed}_n)) < \text{Error}(\text{LAP}(\text{Seed}_n))$ . For the lack of space, the proof is omitted.

In the following  $\omega - \rho$  face images,  $\text{Seed}'_{n\text{-DPLP}}$  needs to consume  $\varepsilon_2$ . According to the proof of  $\hat{T}'_{(i,j)}$ , there exists  $\text{Error}(\text{PPSA}(\text{Seed}_n)) \approx \text{Error}(\text{LAP}(\text{Seed}_n))$  during the consumption of  $\varepsilon_2$ . Thus, it can be deduced that, in any scenario, there exists the following:

$$\begin{aligned}\text{Error}(\text{PPSA}(\text{Seed}_n))_{\varepsilon_1} + \text{Error}(\text{PPSA}(\text{Seed}_n))_{\varepsilon_2} \\ < \text{Error}(\text{LAP}(\text{Seed}_n))_{\varepsilon}.\end{aligned}\quad (16)$$

(4) For  $T_{(i,j)}$ :

There are also two possible scenarios:  $\omega \leq \rho$  and  $\omega > \rho$ . When  $\omega \leq \rho$ , the proof is as follows:

$$\begin{aligned}\text{Error}(\text{PPSA}(T_{(i,j)})) &= T'_{(i,j)\text{-PPSA}} = \text{Seed}_n + \text{lap}\left(\frac{\Delta Q \times 5 \times \rho}{\varepsilon_1}\right) - T_{(i,j)} \\ \text{Error}(\text{LAP}(T_{(i,j)})) &= T'_{(i,j)\text{-LAP}} = \text{lap}\left(\frac{\Delta Q \times I \times J}{\varepsilon}\right).\end{aligned}\quad (17)$$

Subtracting the above two formulas, we have the following:

$$\begin{aligned}\text{Error}(\text{PPSA}(T_{(i,j)})) - \text{Error}(\text{LAP}(T_{(i,j)})) \\ &= \text{Seed}_n + \text{lap}\left(\frac{\Delta Q \times 5 \times \rho}{\varepsilon_1}\right) - T_{(i,j)} - \text{lap}\left(\frac{\Delta Q \times I \times J}{\varepsilon}\right) \\ &= \left(\text{Seed}_n + \text{lap}\left(\frac{\Delta Q \times 5 \times \rho}{\varepsilon_1}\right)\right) - \left(T_{(i,j)} + \text{lap}\left(\frac{\Delta Q \times I \times J}{\varepsilon}\right)\right) \\ &= \text{Seed}'_{n\text{-PPSA}} - T'_{(i,j)\text{-LAP}}.\end{aligned}\quad (18)$$

For a gray image, when the privacy budget is sufficiently small under the Laplace mechanism,  $\text{Error}(T'_{(i,j)\text{-LAP}})$  is equivalent to  $\text{Error}(\text{Seed}'_{n\text{-LAP}})$ . Thus, we have the following:

$$\begin{aligned}\text{Seed}'_{n\text{-PPSA}} - T'_{(i,j)\text{-LAP}} \\ &= \text{Seed}'_{n\text{-PPSA}} - \text{Seed}'_{n\text{-LAP}} \\ &= \text{Seed}_n + \text{lap}\left(\frac{\Delta Q \times 5 \times \rho}{\varepsilon_1}\right) - \text{Seed}_n - \text{lap}\left(\frac{\Delta Q \times I \times J}{\varepsilon}\right) \\ &= \text{lap}\left(\frac{\Delta Q \times 5 \times \rho}{\varepsilon_1}\right) - \text{lap}\left(\frac{\Delta Q \times I \times J}{\varepsilon}\right) < 0.\end{aligned}\quad (19)$$

Thus,  $\text{Error}(\text{PPSA}(T_{(i,j)})) < \text{Error}(\text{LAP}(T_{(i,j)}))$ .

Similarly, when  $\omega > \rho$ , there exists  $\text{Error}(\text{PPSA}(T_{(i,j)})) \approx \text{Error}(\text{LAP}(T_{(i,j)}))$ . For the lack of space, the proof is omitted.

## 4. Experiments and Results Analysis

**4.1. Experiments.** To demonstrate its feasibility, the PPSA was tested on a  $750 * 1020$  image containing 8 faces from the WIDER FACE dataset. The original image was divided into 7,650 subgraphs of the size  $10 * 10$ . During the implementation of the PPSA, the original image (Figure 6) was first transformed into a gray image (Figure 7). Then, the MTCNN algorithm was called to recognize the face area  $S$  and landmark  $K_S$  (Figure 8). To meet the requirements of the

PPSA on regional growth, the face image was divided into multiple equal size  $T_{(I,J)}$  (Figure 9), using the preset parameters. The subgraph area (Figure 10) overlapping the landmark location was taken as the  $Seed_N$  (Figure 11) of regional growth. However, the  $S$  detected by the MTCNN is not compatible with the size  $fT_{(I,J)}$  (Figure 12). To solve the problem,  $S$  was resized to  $S'$  (Figure 13), according to the size of  $T_{(I,J)}$ .

Figure 14 provides the results of the LPA. Figure 15 presents the PPSA results under the same privacy budget.

FIGURE 9: Rendering of  $T(i, j)$ .FIGURE 10: Rendering of  $K_S$  and  $T(i, j)$ .FIGURE 11: Rendering of  $Seed_N$ .

Observations show that the PPSA operates within the face area while the LAP acts across the image. Besides, within the scope of the regional growth algorithm, the PPSA retained the recognizability of landmarks. Although not excluding the possibility of privacy leaks, this strikes a balance between the privacy and availability of the privacy protected multiface image. In addition, the relationship between the number of faces  $\rho$  estimated by the PPSA and the true number of faces  $\omega$  determines how much privacy budget can be obtained by a seed. The allocation of the privacy budget

will directly affect the error of the protected image. Figures 16 and 17 present the local results at different relationships between  $\rho$  and  $\omega$ .

**4.2. Results Analysis.** To verify the feasibility of our algorithm, multiple face images were collected from WIDER FACE dataset, i-bug face dataset, and AFW dataset and subjected to experiments using TensorFlow + AlexNet CNN. The experiments were carried out in

FIGURE 12: Rendering of  $Seed_N$ .

FIGURE 15: PPSA results.

FIGURE 13: Rendering of  $Seed_N$  and  $S'$ .

FIGURE 16: Local results at  $\omega \leq \rho$ .

FIGURE 14: LAP results.

FIGURE 17: Local results at  $\omega > \rho$ .

the environment of Intel® Core i9-9900K CPU @ 3.60 GHz, 32G memory, GTX 21080TI GPU, and Windows 10. The privacy budget was set to 1, 2, 3, 4, and 5, in turn. The face recognition performance was measured by precision, recall, and  $F1$ -score. The experimental results are displayed in Figures 18–26.

The experimental results show that the PPSA achieved different results on images from different datasets. The

difference arises from the varied image sizes of different datasets:  $760 * 1000$  in WIDER,  $500 * 800$  in i-bug, and  $1000 * 1500$  in AFW. In addition, the different background complexities between the face datasets also influence the operation effects of LAP, sliding window publication (SWP) algorithm, and region growing publication (RGP). By contrast, the operation of the PPSA is not affected by image size and background complexity.

FIGURE 18: WIDER and precision.

FIGURE 21: I-bug and precision.

FIGURE 19: WIDER and recall.

FIGURE 22: I-bug and recall.

FIGURE 20: IDER and F1-score.

FIGURE 23: I-bug and F1-score.

FIGURE 24: AFW and precision.

FIGURE 26: AFW and F1-score.

FIGURE 25: AFW and recall.

From the experimental results, it can be learned that the operation results of the PPSA mainly depend on the number of estimated faces  $\rho$  and  $S'$ . In the images from i-bug, there are relatively few faces in each image, but the face area takes up a large portion of the entire image. In the images from WIDER, there are many faces in each image, and the face area takes up a large portion of the entire image. In the images from the AFW, there are relatively few faces in each image, but the face area takes up a small portion of the entire image, for the images tend to be large. Therefore, it is expected that the PPSA's privacy protection effect is positively correlated with  $\omega$ , and negatively with  $S'$ . The prediction is consistent with the experimental results.

## 5. Conclusions

To protect the privacy of multiface images, this paper combines face detection, regional growth, with the Laplace mechanism of differential privacy to add noises to local sensitive areas in face images and realizes the privacy protection for the local sensitive areas in multiface images under an interactive framework. Compared with the LAP, SWP, and RGP, the proposed PPSA can effectively suppress the noise impact on the protected image and improve the availability of the privacy protected image. Moreover, the PPSA applies to images of various sizes, and its error does not increase with the image size.

Although the PPSA can effectively protect the face information in multiface images, the attackers may choose to attack the hair, clothes, and body of persons in the images. Besides, privacy leak may arise from the relationship between persons, and the correlation between each person and the background. The future work will further improve image privacy protection, trying to solve these potential risks.

This article focuses on the analysis of large-scale distribution network reconstruction fused with graph theory and graph partitioning algorithms. Graph theory and graph segmentation algorithms have been rushed by many researchers in the fields of medicine, drone, and neural network. It is a newcomer in the field of computer vision, which can not only realize the division in color but also divide it by image data. The distribution network is also indispensable for new energy, electric machines, but the traditional distribution network has many problems, such as not suitable for distributed power access and excessive network loss. To improve the performance of distribution networks and reduce network losses, this paper A multi-division model for distribution network construction and reconstruction is established, and a graph theory-based division algorithm method is proposed to effectively solve the problem of feeder-to-feeder reconstruction during large-scale distribution in distribution networks. Through its superconductivity phenomenon and the characteristics of clustering algorithm division, this paper uses formulas to show its division principle and gives examples of various distribution network reconstruction algorithms to explore which method of improvement can improve the performance of the distribution network and reduce network losses. The number of iterations is also strictly considered, and the value is taken after multiple iterations to reduce the error. Through the distribution network calculation example, the network loss reduction value is obtained, and the distribution network fault repair model is exemplified. The picture is used to briefly describe the process of distribution network reconstruction and find that the faults of the distribution network can be quickly located and isolated through the FTU, and quickly repaired. Finally, in order to reduce the network loss, reduce the load of power flow calculation, and solve the problem of local optimization, a JA-BE-JA optimization algorithm based on large-scale distribution network reconfiguration is proposed. The mixed sampling method is preferred to test the number of divisions in the four states, and the parameters are selected to test the performance of the improved annealing simulation algorithm, and the conclusion is drawn as follows: the improved graph segmentation algorithm has strong robustness, can avoid local optimization of graph data, and can reduce network loss. Compared with traditional distribution network reconstruction methods, the network loss can be reduced to 454.3 KW, which can be optimized by 10.68% compared with the initial network loss.

## 1. Introduction

As a rigorous and scientific theory, graph theory has now been widely used in various fields. The first successful application of graph theory occurred in the 1990s. Some scholars successfully applied it in the research of image segmentation, which attracted the attention and discussion of many scholars at that time. In the development of modern society, the theory of graph theory has also been applied more effectively and broadly, such as texture synthesis, image restoration, and the complicated construction and

reconstruction of power distribution networks in modern society. The emergence of graph theory has become extremely significant, which effectively helps in large-scale problems such as distribution networks. Therefore, by establishing a multipartition model for the construction and reconstruction of the distribution network, this paper proposes a partition algorithm based on graph theory to effectively solve the problem of reconfiguration between feeders during large-scale distribution in the distribution network. The proposal of this algorithm greatly reduces the computational pressure in network reconstruction and can

effectively arrive at the most reasonable solution based on the global distribution network. Since graph theory itself is a branch subject based on mathematics, the algorithm proposed in the article is a new and effective graph theory algorithm based on rigorous mathematical proofs. In the reconstruction of the distribution network, the image segmentation technology plays an extremely important role. The topology of the network is changed by constantly switching the switch states of the tie switch and the section switch, so as to regulate the flow of power in the entire distribution network. The branch exchange method, optimal flow mode method, genetic algorithm, etc., are all effectively applied in the construction of the distribution network. The improved graph segmentation algorithm can effectively reduce the network loss caused by the operation of the distribution network. In the subsequent reconstruction of the distribution network, graph segmentation algorithms have great research significance.

The purpose of this article is to study the analysis of large-scale distribution network reconstruction fused with graph theory and graph partitioning algorithms and to propose optimization algorithms to reconstruct the distribution network. The algorithms are tested before and after optimization through experiments and applied in the environment of distribution network reconfiguration, collecting the number of edge cuts in the distributed segmentation of 4 image datasets with data sizes ranging from small to large by the JA-BE-JA algorithm based on the BSP-Spark platform. Then, the edge cut numbers of the JA-BE-JA algorithm are collected based on the BSP-PeerSim platform in the same dataset, and they are all collected after 1200 supersteps to ensure the accuracy of the experiment, and the strong robustness of this algorithm and the characteristics of avoiding local optimization are obtained. A 16-bus distribution network is selected for testing, which contains 3 feeder parts, indicating that this algorithm can be applied to large-scale distribution networks and can reduce network losses. At the same time, it also shows that, in dealing with the problem of large-scale distribution network reconfiguration, the optimization algorithm proposed in this paper has a better effect, has a certain guiding significance, and has both theoretical and practical significance.

The improved algorithm designed in this article has a good application prospect in large-scale distribution network reconstruction. Based on the image segmentation method of graph theory-full variational approximation of the Ginzburg-Landau functional of graph clustering, the power flow algorithm of the distribution network reconstruction and the distribution network fault recovery model to perform certain segmentation of the distribution network and the graph theory explanation, the two do have certain commonalities. Then through experiments, the improved algorithm of graph theory and graph segmentation is integrated into the distribution network reconstruction. In order to avoid errors, there are some details in the experiment, such as the choice of encoder and the choice of iteration times. Finally, it is concluded that this graph partitioning improved algorithm can be better applied to a large-scale distribution network environment, and the

network loss and robustness are all optimized, which can play a certain guiding role in future development, and it can also be used for reference in other fields.

## 2. Related Work

The application of graph theory and graph segmentation algorithms in various fields has extremely optimistic development prospects, and all fields have never stopped the research and exploration of graph theory and graph segmentation algorithms in order to have a brighter development prospect. Li and Yang paid attention to the adaptive pinning synchronization problem of random complex dynamic network (CDN); based on the algebraic graph theory and Lyapunov theory, they deduced the design conditions of the pinning controller and performed a strict convergence analysis on the synchronization error of probabilistic meaning. Compared with the existing results, due to the use of graph theory, the topology of the random CDN remains unknown [1]. Keown et al. used a selective high-quality data subset from autism brain imaging data exchange (including 111 ASD and 174 typical developmental participants) and several graph theory indicators. They preprocessed and analyzed resting state functional magnetic resonance imaging data to detect low-frequency inherent signal correlation and concluded that compared with typical development participants, the Rand index (reflecting the similarity between the network organization and the normative network set) of ASD participants was significantly lower [2]. Glaria et al. stated that there are many benefits of compressing real-world graphs, such as improving or enabling visualization in small memory devices, graph query processing, community search, and mining algorithms. This work proposes a novel compact representation for real sparse and clustered undirected graphs. This method uses a fast algorithm to list all the largest cliques and defines a clique graph according to its largest clique [3]. Li et al. showed that the existing vector-based methods of machine learning usually use vector-based features to represent the program, but it is easy to ignore the control information between the basic block and the partition on the path other than the critical path. And they proposed a novel graph-based thread partitioning method to overcome these two bottlenecks. They used graphs to characterize the program, integrated features and control information, and successfully extracted a good partition scheme [4]. Ghasemi said that the problem of power distribution system reconfiguration is a complex optimization process to find a structure with the least loss, which needs to meet the satisfaction of both consumers and the power distribution system company. One of the most important parameters in this regard is to improve the reliability of the system. On the one hand, this parameter improves the satisfaction of electricity consumption, and on the other hand, it improves the economic benefits of power distribution enterprises [5]. Hong H et al. proposed a distribution network reconfiguration method based on a directed graph considering distributed generation. Two reconfiguration scenarios are considered: operating mode adjustment with the goal of minimizing active

power loss (case I) and service restoration with the goal of restoring the load to the greatest extent (case II). These two situations are modeled as a mixed integer quadratic programming problem and a mixed integer linear programming problem [6]. Although these studies have reached certain guiding conclusions, there are unavoidable errors, or insufficient optimization effects, insufficient demonstrations, etc., which need to be further improved.

### 3. Distribution Network Reconstruction Model and Graph Theory-Graph Segmentation Method

*3.1. Image Segmentation Algorithm Based on Graph Theory-Full Variational Approximation of the Ginzburg-Landau Functional of Graph Clustering.* The Ginzburg-Landau function is based on the phase transition theory, which combines superconducting phenomena such as quantum mechanics, electrodynamics, and quantum mechanics of superconductors to obtain related nonlinear partial differential equations [7]. Formula (1) expresses the relationship between phase change and phase separation. Letting  $S$  represent the open subset of  $R^t$ , the parameter  $u > 0$  is the spatial scale:

$$GL(v) := \frac{u}{2} \int_S |\nabla v(a)|^2 dx + \frac{1}{u} \int_S W(v(a)) dx. \quad (1)$$

The form of the Ginzburg-Landau function is a state transition equation, is closely related to the state transition equations such as Allen-Cahn and Chafee-Infante, usually because of the connection between the Ginzburg-Landau function and the total variational seminorm, and is regarded as the second approximation of the total variation, so it can solve the nonsmooth total variation minimization question [8]. The formula used when processing the image is

$$B(v) = GL(v) + \lambda f(v, v_0), \quad (2)$$

where  $f(v, v_0)$  is the distance function of the reconstructed image  $v$  and the given image  $v_0$ . The statistics of the model are closely related to the physical assumptions. Among them, the parameter  $\lambda > 0$  can control the influence of data fitting on regularization. Applying the  $L^2$  gradient descent method, the partial differential equation at this time can be known:

$$f(v, v_0) = \|v - v_0\|_{L^d(S)}^d, \quad d = 1, 2, \quad (3)$$

$$vt = -\frac{\beta GL}{\beta v} = u\Delta v - \frac{1}{u}W'(v) - \lambda \frac{\beta f}{\beta v}.$$

Because of the existence of the distance function  $f(v, v_0)$ , here we add a forced term  $\lambda\beta f/\beta v$ . Since  $B(v)$  is a nonconvex function, there cannot be a unique solution at this time, and the result depends on the initial conditions. The prior information of the image can be used as the initial input of the segmentation algorithm to achieve the goal of more accurate image segmentation in graph theory. Then, the segmented image can be classified with high-dimensional data, and then  $I := \{a = (a_1, a_2) \in C^2: 0 \leq a_1 \leq N-1; 0 \leq a_2 \leq M-1\}$  is set

to represent a rectangular image with  $K = N \times M$  pixels. The image neighborhood of  $a$  can be represented as set  $M(a), a \in I$ :

$$M(a) := \{b \in I: |a_1 - b_1| \leq \varepsilon \text{ and } |a_2 - b_2| \leq \varepsilon\}. \quad (4)$$

When  $\varepsilon \in M$ , there are  $(2\varepsilon + 1) \times (2\varepsilon + 1)$  size pixels centered on  $a$  in  $M(a)$ ; for  $K \in M$ , we can associate the feature vector  $c \in R^K$  selected by the  $a$  and  $M(a)$  neighborhoods. Let  $X$  be the pixel node,  $B$  the relationship between the vertices mapped to the edge of the graph,  $\omega$  the weight, and  $W$  the similarity matrix, then

$$\begin{aligned} \omega(a_z, a_i) &= \omega(a_i, a_z), \omega(a_z, a_i) > 0, \\ \omega(a_z, a_i) &= \hat{\omega}(\gamma(a_z), \gamma(a_i)) = \hat{\omega}(c_z, c_i), \end{aligned} \quad (5)$$

where  $\gamma$  is the characteristic function. At this time, in order to make the symbols consistent, let  $\omega(a_z, a_i) = \hat{\omega}(a_z, a_i)$ , facing the segmentation problem, take the weight of the edge connected to node  $x_z$  and the degree  $d_z$  of the vertex to obtain a diagonal matrix  $D$  of  $m \times m$ :

$$d_z = \sum_{i=1}^m \omega_{zi},$$

$$D = \begin{bmatrix} d_1 & \cdots & \cdots & \cdots \\ \cdots & d_2 & \cdots & \cdots \\ \vdots & \vdots & \ddots & \vdots \\ \cdots & \cdots & \cdots & d_m \end{bmatrix}. \quad (6)$$

When  $X$  is used to represent the space of  $X \rightarrow R$  of all functions,  $X \rightarrow X$  is its Laplacian  $L$ :

$$Lv(a) = \sum_{b \in X} \omega(a, b)(v(a) - v(b)), \quad a \in X,$$

$$L(a, b) := \begin{cases} d(a), & \text{if } (a = b) \\ 0 - \omega(a, b), & \text{otherwise} \end{cases}. \quad (7)$$

The related quadratic form  $H$  of  $L$  can be expressed as

$$H(v, Lv): \frac{1}{2} \sum_{a, b \in X} \omega(a, b)(v(a) - v(b))^2. \quad (8)$$

The non-negative real eigenvalue of  $L$  is  $\{\lambda_z\}_{z=1}^a$ , of which  $0 = \lambda_1 \leq \lambda_2 \leq \dots \leq \lambda_p$ , and under the large-scale limit,  $L$  can be appropriately scaled to achieve high stability of convergence. At this time, Tulaplas can be normalized:

$$L_p := D^{-1/2} L D^{-1/2} = I - D^{-1/2} W D^{-1/2}. \quad (9)$$

At this time, the matrix  $L_p$  presents a symmetric state, redefining the discrete Ginzburg-Landau function:

$$GL_d(v) := \frac{u}{2} H(v, L_p v) + \frac{1}{u} \sum_{a \in X} W(v(a)) + \sum_{a \in X} \frac{\chi(a)}{2} (v(a) - v_0(a))^2, \quad (10)$$

$$\omega(a, b) = \exp(-\|\gamma(a) - \gamma(b)\|^2 / \sigma^2), \quad \sigma > 0.$$

Because this image is an undirected graph,  $\omega(a, b)$  will be in a symmetrical state, that is,  $\omega(a, b) = \omega(b, a)$ . Here, in order to reduce the computational complexity, some feature vectors will be used to construct vectors for graph clustering, and then clustering algorithms will be used to divide their feature vectors to segment the image [9]. The feature vector value is related to the gray or RGB (red, green, blue) intensity value and the texture feature of the neighborhood.

**3.2. Power Flow Algorithm for Distribution Network Reconstruction.** When the distribution network is being reconfigured, when its topological structure is radial, the power flow algorithm can be used to calculate the operation of the distribution network, network losses, and voltage offsets [10]. At present, the power flow algorithms suitable for distribution networks are mainly divided into the Newton method, branch method, and bus method. However, there are certain limitations, and the power flow algorithm is not applicable to the distribution network in some cases. For example, the distribution network and the transmission network have different line parameters, different resistance and reactance ratios, or different numbers of OV nodes. The distribution network will have problems such as frequent line changes and complex structure.

Therefore, there will be more power flow algorithms used in the transmission grid than in the distribution network. Based on the increasing attention of the distribution network, improving the convergence, timeliness, and simplicity of the power flow algorithm has become a major goal of the research [11]. Figure 1 is a simple radial distribution network circuit diagram, and its parameters are explained as follows.

The radial distribution network mainly relies on the current quick-break protection at the line outlet, circuit breaker, load switch, and recloser to protect the circuit.

**3.2.1. Improving the Basic Principle of the Cow Pull Method.** Because it has a better solution effect for nonlinear equations, it is often used in power flow calculations of distribution networks. The Newton-Raphson method voltage polar coordinate formula is

$$\dot{U}_k = U_k < \beta_k = U_k (\cos \beta_k + i \sin \beta_k). \quad (11)$$

Let the distribution network have  $x$  OL nodes, denoted by  $1, 2, 3, \dots, x$ , respectively, and  $y - x - 1$  PV nodes, denoted by  $x + 1, x + 2, \dots, y - 1$ , plus a balance node, then all nodes satisfy

$$\begin{cases} \Delta O_k = O_{kr} - O_k = O_{kr} - V_k \sum_{i=1}^y V_i (W_{ki} \cos \beta_{ki} + M_{ki} \sin \beta_{ki}) = 0; k = 1, 2, \dots, y - 1, \\ \Delta L_k = L_{kr} - L_k = L_{kr} - V_k \sum_{i=1}^y V_i (W_{ki} \sin \beta_{ki} - M_{ki} \cos \beta_{ki}) = 0; k = 1, 2, \dots, x. \end{cases} \quad (12)$$

According to Taylor's expansion, the modified formula of Newton-Raphson's method can be obtained as

$$\begin{bmatrix} \Delta O \\ \Delta L \end{bmatrix} = - \begin{bmatrix} S & D \\ F & G \end{bmatrix} \begin{bmatrix} \Delta \beta \\ U_{H_2}^{-1} \Delta U \end{bmatrix}. \quad (13)$$

The small distance between the actual nodes will only form a small voltage difference between adjacent nodes, so in the calculation, the ground admittance parameter can be ignored. At this time, if  $k \neq i$ , then

$$\begin{aligned} S_{ki} &\approx \frac{\beta O_k}{\beta \theta_i} = U_k U_i M_{ki} \cos \theta_{ki}, \\ D_{ki} &\approx U_i \frac{\beta O_k}{\beta U_i} = -U_k U_i W_{ki} \cos \theta_{ki}, \\ F_{ki} &\approx U_i \frac{\beta L_k}{\beta \theta_i} = U_k U_i W_{ki} \cos \theta_{ki}, \\ G_{ki} &\approx U_i \frac{\beta L_k}{\beta \theta_i} = U_k U_i M_{ki} \cos \theta_{ki}. \end{aligned} \quad (14)$$

If  $k = i$ , then

$$\begin{aligned} S_{ki} &\approx \frac{\beta O_k}{\beta \theta_i} = -U_k \sum_{\substack{i=1 \\ i \neq k}}^y U_i M_{ki} \cos \theta_{ki}, \\ D_{ki} &\approx U_k \frac{\beta O_k}{\beta U_k} = U_k \sum_{\substack{i=1 \\ i \neq k}}^y U_i W_{ki} \cos \theta_{ki}, \\ F_{ki} &\approx U_k \frac{\beta L_k}{\beta \theta_k} = U_k \sum_{\substack{i=1 \\ i \neq k}}^y U_i W_{ki} \cos \theta_{ki}, \\ G_{ki} &\approx U_k \frac{\beta L_k}{\beta \theta_k} = U_k \sum_{\substack{i=1 \\ i \neq k}}^y U_i W_{ki} \cos \theta_{ki}. \end{aligned} \quad (15)$$

The iterative steps of improving the Niu La method are as follows: First, the voltage of the balance node and its phase angle are set, and the parameters of the other node lines are initialized. Then, the calculated parameter values are

FIGURE 1: Circuit diagram of a typical radial distribution network.

calculated for active and reactive power corrections, and the accuracy of the power flow calculation is judged until it meets the calculation requirements. Then, the above parameters are substituted into the Jacobian matrix to calculate the voltage amplitude correction amount and phase angle correction amount [12]. Let the number of iterations at this time be  $h$ , then

$$U_k^{(h+1)} = U_k^{(h)} + \Delta U_k^{(h)}; \theta_k^{(h+1)} = \theta_k^{(h)} + \Delta \theta_k^{(h)}. \quad (16)$$

Then, the above work is gradually repeated, and the iteration continues.

**3.2.2. Distribution Network Reconstruction with DG.** The reconstruction step is to initialize various parameters first and number the goals of the distribution network reconstruction and the simplified branches, reinitialize part of the variable value and judge the shape, determine whether it is radial and decide whether to reapply the value, then find the variable of another part of the branch of the distribution network that has been disconnected, and iterate the speed and position. After that, the hierarchical matrix is constructed and combined with the distributed power processing process, and it is pushed back to the power flow calculation before it is completed. Then, the next step is to compare the objective function values to determine the optimal population particle value, continue to iterate and judge the distribution network structure until it is radial and reaches the number of iterations, and finally output the optimal population particle value [13]. The steps are shown in Figure 2.

Here, we will take the IEEE69-node system as an example of distribution network reconstruction. At this time, there are 69 nodes, numbered from 1 to 69. The solid line is the segment switch, and the dashed line is the tie switch. The total system load in this distribution network topology is  $3814.6 + j2702.2$  kVA, and there are 98 iterations of the algorithm. The forward and backward power flow calculations are used to iteratively converge to achieve the minimum network loss. The topology of the distribution network is shown in Figure 3.

In the case of the reconfiguration of the distribution network without distributed power, the initial topology of

IEEE69 is that the dashed part denotes the contact switch is off and the solid line denotes the section switch is closed [14]. The reconstruction of the IEEE69-node system without DG is shown in Table 1.

At this time, the network loss of the common algorithm is reduced by 52.98% compared with that before reconstruction, while the algorithm in this paper is reduced by 57.08% compared with that before reconstruction, and the performance is increased by 4.1%, and the effect is better. The network loss of the reconfiguration of the distribution network with distributed power sources is shown in Table 2.

It can be seen that reasonable arrangement of grid-connected locations can reduce network loss. At this time, it has been reduced by 17.27% before reconstruction. After reconstruction, it is reduced by 69.74%. It can be seen that, with the DG power grid, the advantage of its topology is obviously higher than that of power grid without DG. That is, DG reconstruction can improve the voltage quality of the system nodes and improve the operation stability of the distribution network [15].

**3.3. Distribution Network Fault Recovery Reconstruction Model.** Normally, the realization principle of the distribution network fault recovery reconstruction is to use the application layer and the decision-making layer of the distribution network. The control system writes the reconstruction algorithm into the distribution network dispatching system, and the relevant FTU in the distribution network transmits real-time information at the section switch and contact switch. Incorporating data into the SCADA system, the faulty area is located, and here the SCADA system is the control center of the distribution network. Commands are sent to the FTU to isolate the faulty area by operating the switch, the self-healing system is used to generate the structure, optimize algorithm calculations, and control the data, and then the fault area recovery process is performed [16]. In this process, the optimization algorithm is the core part of the distribution network reconstruction, and the voltage, current, power, resistance, frequency, and other states of the distribution network need to be set, and give the range of functions in different states to explore the operation state of the distribution network at this

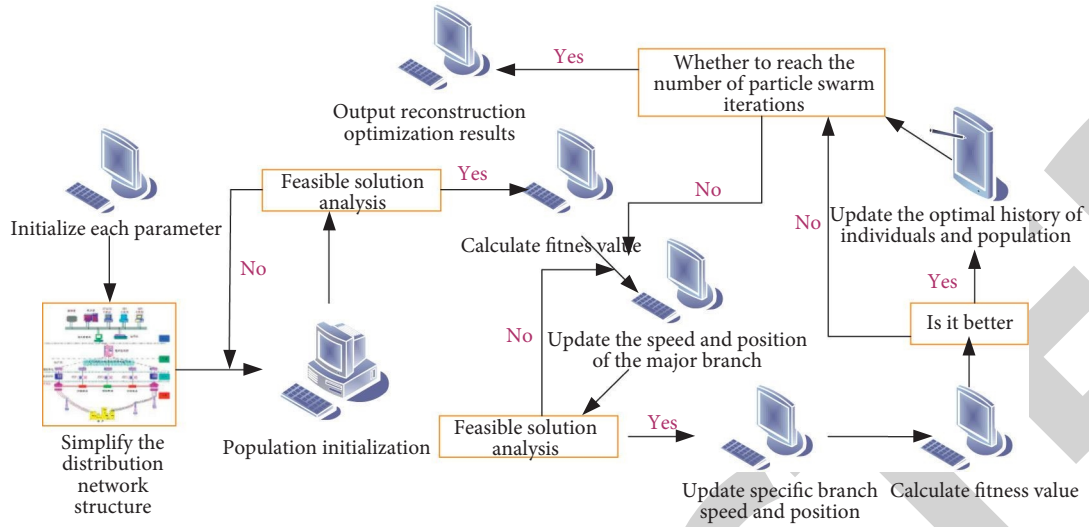

FIGURE 2: Distribution network reconstruction algorithm flow.

time, and then carry out the optimization search operation [17]. These states include the power grid emergency state, abnormal state, and realm state. The control process of the distribution network is shown in Figure 4.

In the restoration and reconstruction of the distribution network failure, the FTU can quickly locate and isolate the distribution network failure and quickly repair it.

*3.4. Improved Graph Segmentation Based on Graph Theory BSP-Spark System and Improved JA-BE-JA Algorithm Based on BSP-Spark Cluster.* This experiment will be carried out in the environment of a BSP-Spark distributed cluster composed of 4 PCs. Among the PCs, one is used for the main control system with 8 GB of memory, and three are used as slave computing nodes with 4 GB of memory. The software used for compilation is IntelliJ IDEA, and the program used for language writing is Scala. In order to minimize the experimental errors caused by various factors, the machines here will perform tasks one-to-one, and Spark on Yarn will complete resource management and scheduling in the experiment. The storage system is a distributed file system HDFS [18]. It is known that the BSP-Spark system architecture is an M/S architecture, with a complete master-slave relationship, implemented by 1 master node and 3 child nodes. The node deployment diagram is shown in Figure 5.

If it wants to achieve high-performance distributed partitioning, it must optimize the parameters of the BSP-Spark system, such as memory, parallelism, and data skew. Although Spark's calculation is based on memory, there are also algorithms that do not rely on memory. At this time, a caching mechanism needs to be added. In general, the caching method used is `spark.executor.memory`, and large-scale iterative algorithms need to use a storage mechanism to control the consumption of data access. This article will reduce the set cache to reduce memory consumption, and `System.setProperty` can just solve this problem [19]. Execution efficiency is closely related to Spark parallelism. Too low parallelism will lead to waste of resources, while too high will reduce efficiency. At this time, `spark.default.parallelism` is used to optimize the parallelism to ensure the number of tasks. One of the major problems of distributed systems is data skew. During Spark application development, memory overflow exceptions are usually caused. A relatively large amount of graph data corresponds to a relatively small number of node calculations, which will also cause its execution speed to tilt. At this time, shuffle is used to reduce the number of partitions. When small-scale data appear, broadcast variables can be used, and the time interval can be set by `spark.speculation.interval` [20].

The JA-BE-JA algorithm is a graph partitioning algorithm that combines point partitioning and edge partitioning for load balancing. It comes from the PeerSim environment. Based on the JA-BE-JA algorithm of the BSP-Spark platform, image nodes can be processed asynchronously on a regular basis, and a node only interacts with a small random range of adjacent nodes. The information dissemination between nodes is only through the edges of the image and is based on memory sharing. Its vertices

correspond to a single node host and process threads independently. The image dataset input by the improved JA-BE-JA algorithm is only in  $G(V,E)$  format, and the image data need to be preprocessed before dividing. Preprocessing includes split-transform-storage, and graph data cleaning uses transformation and action operators to generate new edge RDDs and vertex RDDs from the data source. The algorithm flow is shown in Figure 6.

The edge segmentation and point segmentation of the JA-BE-JA algorithm are realized by the `Graph.partitionBY` operator, and the mixed sampling method is preferred for the sampling strategy.

## 4. Results and Analysis

*4.1. Experimental Results and Analysis.* Here, we will collect the edge cuts of the JA-BE-JA algorithm based on the BSP-Spark platform in the distributed segmentation of 4 image datasets with data sizes ranging from small to large, then collect the edge cuts of the JA-BE-JA algorithm based on the BSP-PeerSim platform in the same dataset, and collect them after 1200 supersteps to ensure the accuracy of the experiment [21–23]. The experimental results are shown in Figures 7 and 8.

It can be seen that the size of the vertices and edges of the 4elt graph is small, and the difference in the number of edge cuts is small, while the size of the vibrobox graph is larger, and the trend of the number of edge cuts gradually tends to be flat.

Next, the improved annealing simulation algorithm is analyzed. It is known that the improved BSP-Spark algorithm has better load in large-scale graph segmentation, but it is easy to form a local optimal state. Therefore, this article will propose an improved annealing algorithm based on BSP-Spark and perform performance testing, taking two parameters  $u$  and  $v$  for performance measurement; let  $u$  be the parameter of the edge cut problem of the improved JA-BE-JA algorithm and be the system energy function value. The relationship between  $u$  and JA-BE-JA algorithm in the original BSP-PeerSim and BSP-Spark environments is shown in Figure 9.

It can be seen that the improved annealing simulation algorithm has a smaller edge cut when  $u = 2$ . This is because when this parameter is greater than 1, graph partitioning can reduce the number of communication edges without damaging the original topological structure of the graph and reduce information propagation and iteration time. When the parameter  $u = 3$ , the consumption of information dissemination will increase due to the reduction of the total effect value of the graph. This situation will become more serious as the parameter  $u$  increases. The improved annealing model algorithm can reduce the consumption when  $u = 2$  and reduce the probability of the local optimal problem of the JA-BE-JA algorithm. Let  $v$  be the cooling coefficient, which can represent the cooling rate, and the relationship between it and the edge cut number of the JA-BE-JA algorithm is shown in Figure 10.

It can be seen from the Figure 10 that based on the original BSP-PeerSim environment, the number of edge cuts increases with the increase of the parameter  $v$ , and  $v$  can

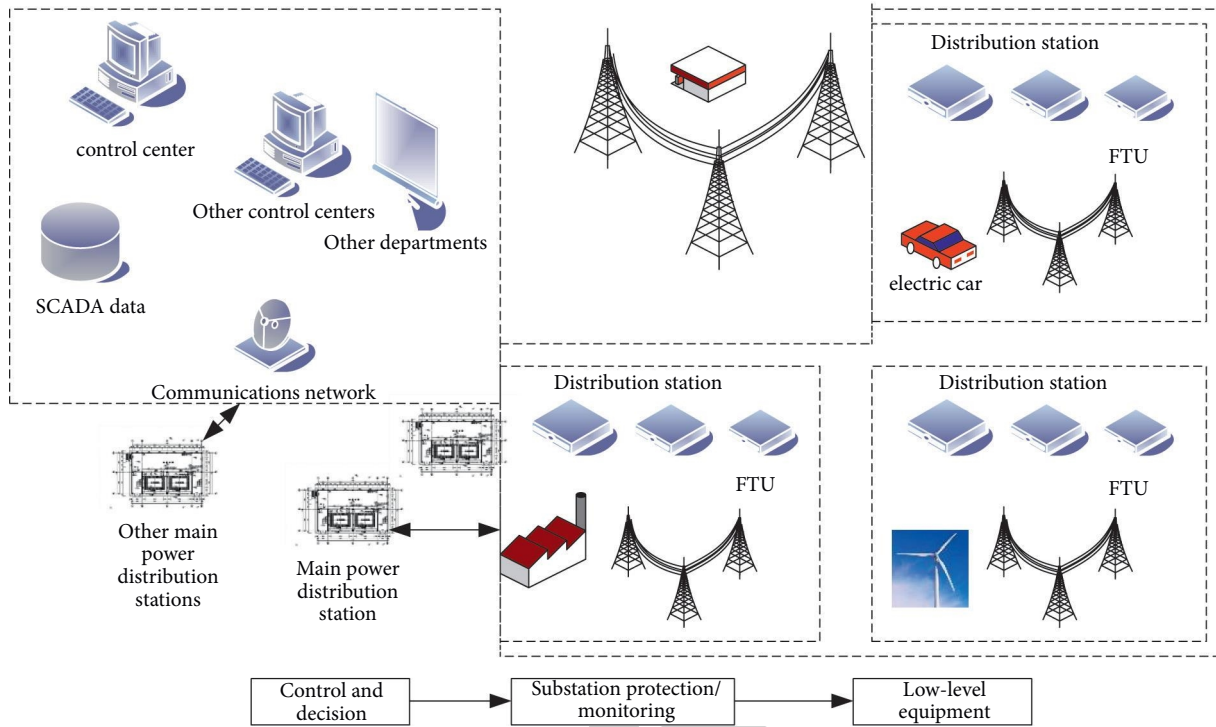

FIGURE 4: Distribution network control process.

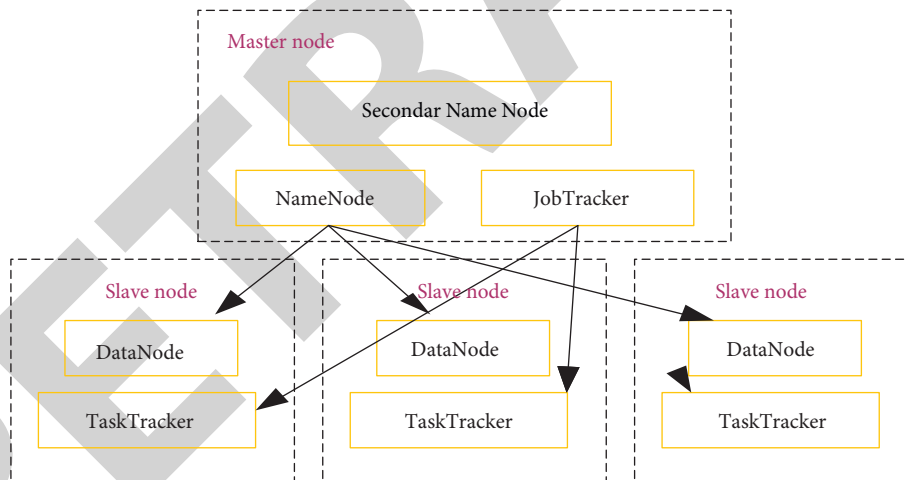

FIGURE 5: Node deployment.

represent the equalization effect of the number of exchanges and the quality of graph division. That is to say, the greater the number of exchanges, the longer the convergence time, and the information dissemination consumption will increase. Based on the BSP-Spark environment, the edge cut value of the obvious graph has robust stability for the parameter  $\nu$ .

In the improved data migration algorithm, local optimization problems can be avoided, and random functions can be used to reduce the number of communication edges. At this time, using different datasets for testing, it can be seen that a 4-way partition will cause 76.3% of the vertex data to migrate, and only 23.7% of the data moved to different partitions.

4.2. Improved Graph Theory and Graph Segmentation Method Cited into the Distribution Network Calculation Examples and Result Analysis. Here, we will use the improved JA-BE-JA algorithm to calculate the distribution network example. The 16-busbar system of the distribution network has 3 tie switches and 3 feeders, as shown in Figure 11.

The tie switch is closed, the weighting operation is performed on the 16-bus distribution system, the eigenvector is solved by the spectral division algorithm, and the critical edge of the above-mentioned distribution system and the node of division 1 are removed [24]. Figure 12 is available.

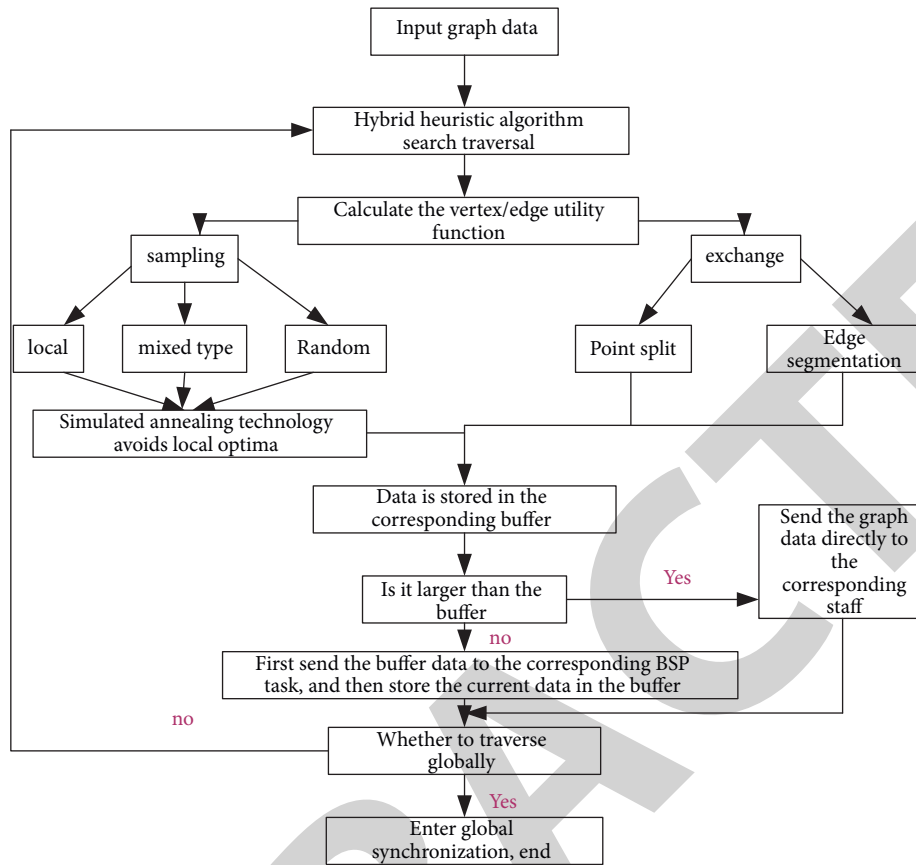

FIGURE 6: Improved JA-BE-JA algorithm flow.

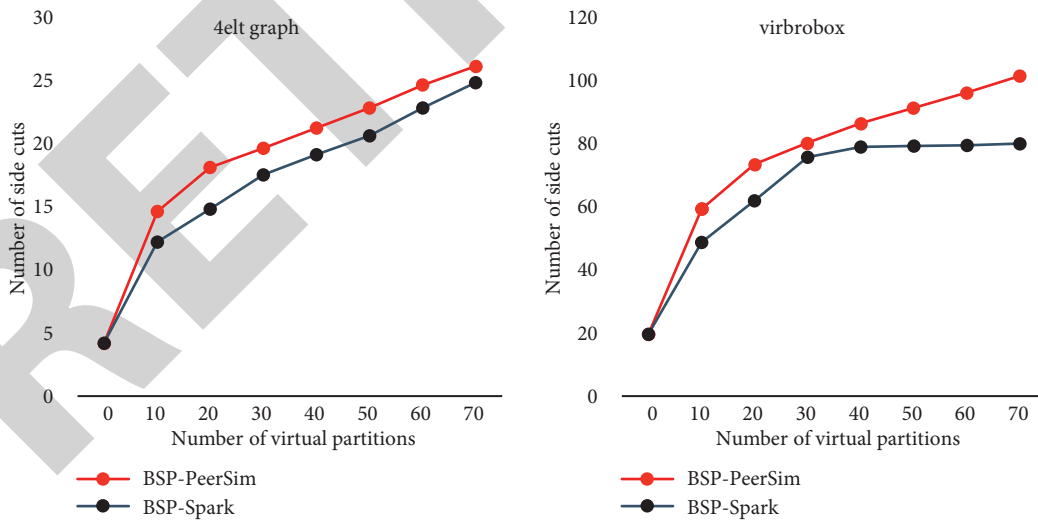

FIGURE 7: Relationship between the two partitions of 4elt graph and vibrobox and the edge cut number of the JA-BE-JA algorithm.

The above figure is a subgraph based on the feature evaluation value after the first scoring and sorting, and its feature evaluation value is shown in Figure 13 at the same time as the feature evaluation value after the second scoring and ranking. The distribution network nodes are divided into groups: group 1

is {1, 2, 4, 5, 6, 7, 8, 9, 11, 12}, group 2 is {3, 10, 13, 14, 15, 16}, which is recorded as division 1, and the rest of the system needs to be divided into two using the improved JA-BE-JA algorithm, that is, division 2: {1, 4, 5, 6, 7, 11} and division 3: {2, 8, 9, 12}, and Figure 13 can be obtained.

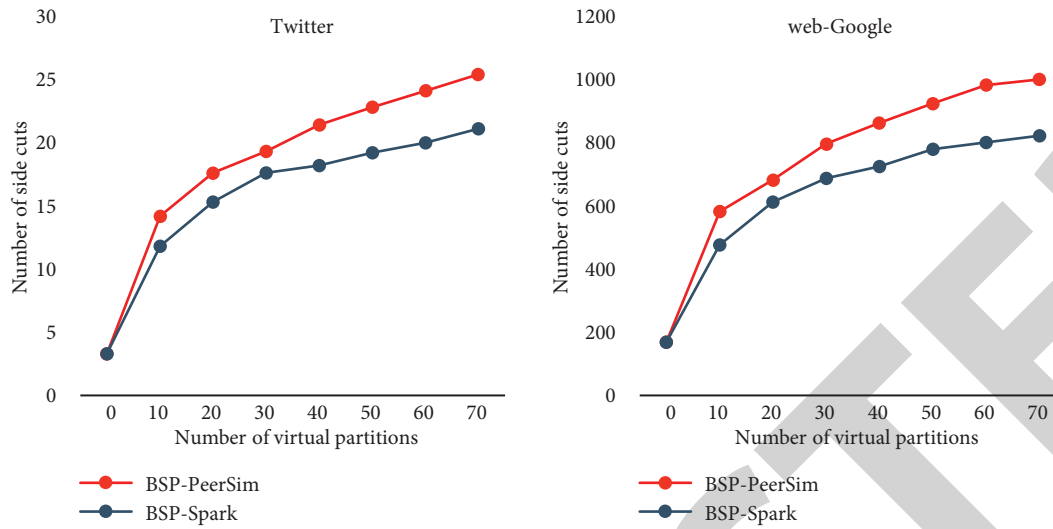

FIGURE 8: Relationship between the two partitions of Twitter and web-Google and the edge cut number of the JA-BE-JA algorithm.

FIGURE 9: Relationship between  $u$  and JA-BE-JA algorithm in the original BSP-PeerSim and BSP-Spark environments.

It can be seen that the final reconstruction result of the distribution network is to close the tie switch between nodes 10 and 14, close the tie switch between 5 and 11, open the section switch between 8 and 10, turn on the segment switch between 9 and 11, and use the improved JA-BE-JA algorithm graph theory to divide the network loss to 454.3 KW. The initial network loss is 508.6 KW, and the network loss is reduced by 10.68%. The power distribution system is often of large-scale and widely distributed, and there are multiple feeders. It can be seen that this algorithm is still applicable in large-scale distribution networks, reducing the burden of power flow calculation, reducing the network loss, and also solving the problem of local optimization.

## 5. Discussion

This article focuses on the analysis of large-scale distribution network reconstruction with graph theory and graph partitioning algorithms. Image segmentation based on graph theory has been developed in many fields and has made indelible contributions in medicine and neurology [25]. This article first describes many advantages of graph theory and graph segmentation technology in the application of distribution networks and then describes the research methods of graph theory and graph segmentation and distribution networks. For example, the image segmentation method based on graph theory-full variational approximation of the Ginzburg-Landau functional of graph clustering uses

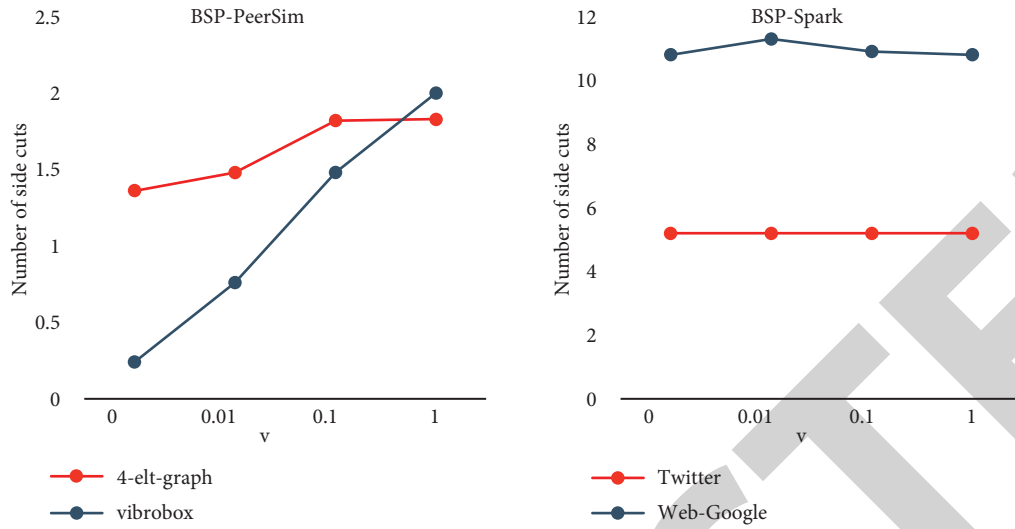

FIGURE 10: Relationship between  $v$  and the JA-BE-JA algorithm edge cut number.

FIGURE 11: Bus distribution system.

FIGURE 12: Subgraph after halving processing.

quantum mechanics, superconductor, electrodynamics, and other phenomena to derive relevant formulas, divides the feature vector through the clustering algorithm, and performs

image segmentation. For example, for the power flow algorithm of distribution network reconstruction, the radial circuit diagram is given in this article, and the power flow algorithm is used for calculation according to the topology of the distribution network. In this paper, the improved Niu pull method is used to improve convergence, timeliness, etc., phase angle correction and voltage correction are carried out, the distribution network reconstruction with DG is proposed, and the optimal value of the population particles is repeatedly iterated. The IEEE69 example is used to show the situation, and the forward and backward power flow calculations are used to iteratively converge to achieve the minimum network loss. It also describes the fault recovery model of the distribution network, using the application layer, decision-making layer, and control system of the distribution network to write the reconstruction algorithm into the distribution network dispatching system. The faults of the distribution network are quickly located and isolated through the FTU, and quickly

FIGURE 13: Comparison of feature evaluation values after the first and second sorting.

repaired. Finally, the graph theory algorithm and the performance of the improved JA-BE-JA algorithm are tested through experiments, and they are applied to the distribution network, and the relationship between each partition and the JA-BE-JA algorithm is compared. Substituting the parameters into the test, it can be seen that a 4-way partition will cause migration of a large number of vertex data, and migration of only a small part of the data to different partitions. Finally, a 16-bus distribution system example is used for testing, and the improved JA-BE-JA algorithm can reduce the loss by 10.68% compared with the previous one, and it can be applied to a multifeeder system, that is, the large-scale distribution network, which reduces the power flow calculation. It can also reduce network loss and prevent local optimization. It can be obtained that this improved algorithm can be better applied in large-scale distribution networks.

## 6. Conclusions

In the analysis of large-scale distribution network reconstruction with graph theory and graph partitioning algorithms, it is known that based on the BSP-Spark environment, the improved algorithm has robust stability and can avoid the problem of local optimization. A 4-way partition caused 76.3% of the vertex data migration, and only 23.7% moved to a different partition. The improved JA-BE-JA algorithm is also more obvious for the optimization of the distribution network. Using the improved JA-BE-JA algorithm with graph theory and graph division, the network loss is 454.3 KW, the initial network loss is 508.6 KW, and the network loss is reduced by 10.68%. In addition, the improved algorithm can effectively increase the number of edge cuts and the number of vertices exchanged on the distributed clusters. It is much more effective than the traditional graph segmentation algorithm in the processing of large-scale distribution networks.

Interference detection is an important part of the electronic defense system. It is difficult to detect interference with the traditional method of extracting characteristic parameters for interference generated at the same frequency as the original signal. Aiming at this special time-frequency overlapping interference signal, this paper proposes an interference detection algorithm based on the long short-term memory-support vector machines (LSTM-SVM) model. LSTM is used for the time series prediction of the received signal. The difference between the predicted signal and the received signal is used as the feature sample, and the SVM algorithm is used to classify the feature samples to obtain the recognition rate of whether the sample has interference. The LSTM-SVM model is compared with the gate recurrent unit-support vector machines (GRU-SVM) model, and the comparison results are visualized using a confusion matrix. The simulation results show that this LSTM-SVM model algorithm cannot only detect the existence of the interference signal but also can determine the specific position of the interference signal in the received waveform, and the detection performance is better than the GRU-SVM model.

## 1. Introduction

In the present study, algorithms based on deep learning are booming, and research on algorithms based on deep learning has been proposed in many fields. LSTM neural networks can better predict time series data, and various algorithms based on LSTM to predict future development are also being widely used. Natural disaster prediction is a very important application. LSTM is used to learn the spatiotemporal relationship between disasters in different locations, and this relationship is used to make predictions. Through the training of historical trajectory data, the trajectory prediction model is obtained, so that early warning can be achieved [1, 2]. In terms of health care, the use of an LSTM network to independently detect the contraction curve of an ECG or EMG signal, based on the predicted signal, provides a powerful assistant for medical staff to quickly diagnose and help patients recover [3–5]. Adopting LSTM can achieve higher accuracy than traditional mathematical models in predicting future disease trends [6]. In

terms of traffic prediction, new methods for urban traffic prediction combining spectrogram analysis and LSTM have been proposed [7, 8]. Using an LSTM network, electric cars can estimate future speed in real-time to estimate the precise value of brake pressure [9]. In addition, subway passenger flow prediction using LSTM can guide passengers to effectively select departure times and transfer from station to station [10]. It is widely used in fault detection, such as image forgery detection, analyzing discriminative features between different regions by combining encoder and LSTM networks, to predict whether the image has been tampered with [11]. LSTM can provide inpainting for video frames, using convolutional LSTM-based encoders and decoders to predict missing frames [12]. LSTM can achieve a predicted quantified output of the remaining mechanical life [13].

At present, the related research involving interference detection in wireless communication is increasing day by day, and some effective algorithms have been proposed. Some of these algorithms are based on computer network protocols and detect the presence of interference signals by

detecting the listening time of the carrier signal; Some algorithms analyze the signal according to the frequency domain transformation, and perform the frequency domain transformation on the signal to extract features, then analyze whether there is interference in the signal; some algorithms achieve the purpose of signal analysis by counting the mathematical characteristics of the signal and calculating the high-order statistics of the signal so as to extract the signal characteristics. Obviously, the above method belongs to the traditional interference detection method, which mainly analyzes the parameter characteristics such as the spectrum and power of the received signal, and then confirms whether there is interference. Secondly, when the signal overlaps with the interfering frequency, the eigenvalues of the interfering signal are difficult to detect [14].

Since communication signals belong to time series data, the time series prediction algorithm based on deep learning provides an idea for signal interference detection. Among them, the recurrent neural network has the characteristics of short-term memory. If the time series signal is long, it will affect the transmission of information. LSTM and gate recurrent unit (GRU) can solve short-term memory problems. Based on the existing research field, we combine LSTM and GRU with the SVM model and propose the LSTM-SVM and GRU-SVM models for signal interference detection [15].

## 2. Materials and Methods

A signal is a periodic time series data, and unknown sampling points can be predicted through the correlation between sampling points [16]. According to this feature, assuming that the training signals are all normal signals, the predicted future signals should also be normal signals. In this case, calculating the difference between the real signal and the predicted signal as the detection feature can get a good detection effect. The signal prediction problem can be solved by the LSTM network. In essence, signal prediction is a time series prediction problem with periodic characteristics. The previously received signal is used as the input, and the output is the signal at the moment you want to predict.

**2.1. Structure of LSTM.** The LSTM unit structure is shown in Figure 1. Compared with the RNN cell structure, LSTM adds a cell state to the structure. LSTM neurons consist of a forget gate, an input gate, and an output gate. The forget gate is used to determine the importance of information, the input gate is used to update the cell state, and the output gate is used to calculate the value of the hidden state.

**2.2. Structure of GRU.** The GRU unit structure is shown in Figure 2. Compared with the LSTM cell structure, the GRU reduces the cell state. The neurons of the GRU include an update gate and a reset gate [17]. The update gate is used to determine the importance of the information, while the reset gate is used to determine the proportion of retained information. Compared to LSTM, GRU has simpler neurons and therefore faster training.

**2.3. Activation Function: Tanh, Sigmoid.** The Tanh function is used to adjust the threshold of the function output. The value range is  $[-1, 1]$ , as shown in Figure 3.

$$f(x) = \frac{\sinh(x)}{\cosh(x)} = \frac{1 - e^{-2x}}{1 + e^{-2x}} \quad (1)$$

The activation function Sigmoid is similar to the tanh function, with a value range of  $(0, 1)$ , as shown in Figure 4.

$$\sigma = \frac{1}{1 + e^{-x}} \quad (2)$$

**2.4. Time Series Signal Forecasting.** 60% of the received signal is used for training datasets of LSTM and GRU. The remaining 40% of the signals, as the test dataset, are used for prediction. The eigenvalues are obtained by subtracting the test data from the predicted data. The process is shown in Figure 5 [18].

When the normal communication signal in the received signal adopts the cosine signal and the interference signal adopts the narrow-band Gaussian noise [19], the LSTM time series signal prediction is shown in Figure 6, the obtained eigenvalues are shown in Figure 7.

The first picture of Figure 6 is the original received signal. You can see that there are interference signals between 2500–3000. The second picture is the training and prediction time series of LSTM, where the first 60% is the training set, and the last 40% is the prediction value. The first picture in Figure 7 is the 40% of the received signal that needs to be predicted. The second picture is the comparison of the predicted value with the original received signal, and the third simulation plot is the eigenvalues [20].

**2.5. Windowing of Signal Sample Values.** In the detection process, when the deviation of each sampling point is used as a feature to train the SVM classifier, the difference calculated for the test dataset, especially the part containing the interference signal, contains many differences similar to the difference calculated from the normal signal points, and these points are difficult to detect. So, we add windows to the features based on the time step and detect them based on the waveforms and correlations of multiple feature points to overcome contingency. The windowing process is shown in Figure 8.

If only each sampling point were used as a feature of interference detection, the detection effect would be very poor due to the accidental error of calculating the difference. Therefore, here we select the mean value of the sampling points of each  $n$  continuous signal as a feature, and the method of constant translation is used to construct a complete feature of interference detection. As shown in Figure 8, the signal is windowed, the window length is “ $N$ ,” the step length is “ $S$ ,” and the input data is formed in time series. The value of  $S$  is 1, when  $N$  is an odd number, the  $i$ th eigenvalue is calculated according to formula (3), and when  $N$  is an even number, the  $i$ th eigenvalue is calculated according to formula (4).

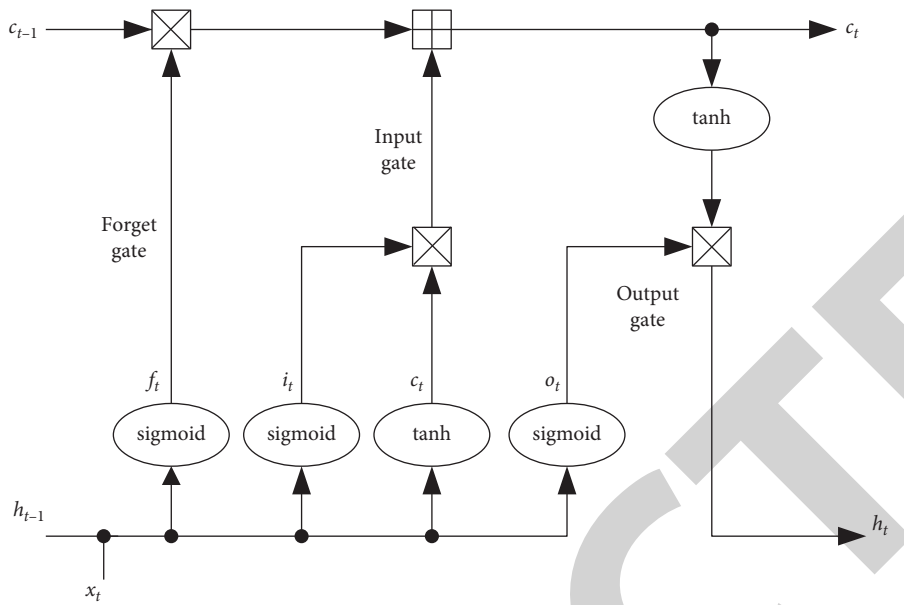

FIGURE 1: Structure of LSTM.

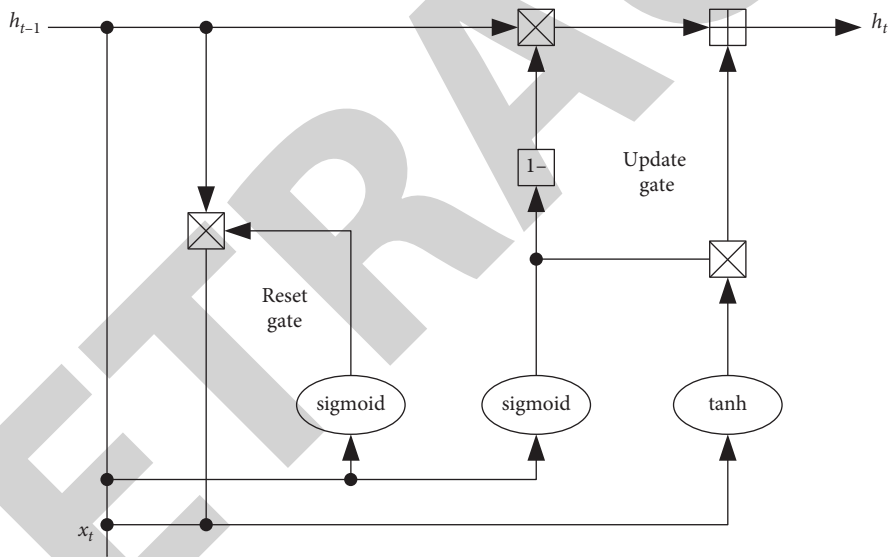

FIGURE 2: Structure of GRU.

FIGURE 3: Activation function tanh.

FIGURE 4: Activation function sigmoid.

FIGURE 5: Block diagram of the signal prediction process.

$$V_{i-e} = \frac{V_{i-(N-1)/2} + \dots + V_{i-1} + V_i + V_{i+1} + \dots + V_{i+(N-1)/2}}{N} \quad (3)$$

$$V_{i-e} = \frac{V_{i-N/2+1} + \dots + V_i + V_{i+1} + \dots + V_{i+N/2}}{N} \quad (4)$$

**2.6. Data Normalization Processing.** The eigenvalues are normalized and preprocessed, the normalization method adopted is according to the following formula:

$$f: x \longrightarrow y = \frac{x - x_{\min}}{x_{\max} - x_{\min}} \quad (5)$$

### 3. Results

In the AWGN channel environment, the sampling frequency of the received signal is 3 KHz, the center frequency of the communication signal and the interference signal is 1 KHz, and the signal power is 10 dB. The sampled signal of the received signal  $r(t)$  is  $r(n)$ , as shown in formula (6).

$$r(n) = s(n) + j(n) + w(n), n = 1, 2, \dots, N \quad (6)$$

In the above equation  $N$  is the sampling length,  $s(n)$  is the communication signal,  $j(n)$  is the interference signal, and  $w(n)$  is the Gaussian white noise.

**3.1. Comparison of the Influence of SNR on Interference Detection.** Both LSTM and GUR are set to train the first 0.6 parts of the time series of the data and test the remaining 0.4

parts at 100 training iterations. After obtaining the eigenvalues, the eigenvalues are not subjected to windowing processing, and the eigenvalues are classified in the SVM to obtain the interference detection rate. When the signal power is 10 dB, the SNR value range is 0dB–20 dB, and the step size is 2 dB, the interference detection accuracy is shown in Figure 9.

It can be seen from Figure 9 that, the difference data obtained by the LSTM and GUR time prediction models are not windowed. As the SNR increases, the detection rate of the difference signal by SVM also gradually increases.

**3.2. Comparison of Windowing Experiments.** Due to the continuity characteristics of the interference signal, taking into account the correlation between the sampling points, window processing is performed on the sampling points, which can overcome the influence of accidental errors. When the power of the signal is 10 dB and the SNR is 20 dB, the eigenvalues are processed by windowing. The window length is 1–10, the step size is 1, and the interference detection accuracy is obtained as shown in Figure 10.

It can be seen from Figure 10 that LSTM has the highest detection rate when the window length is 6, but the GRU windowing effect is not good. The detection rate is the highest when no window is added, so the window value is selected as 1.

**3.3. Interference Detection Accuracy under the Optimal Window.** The difference signal generated by the LSTM is

FIGURE 6: LSTM timing signal prediction.

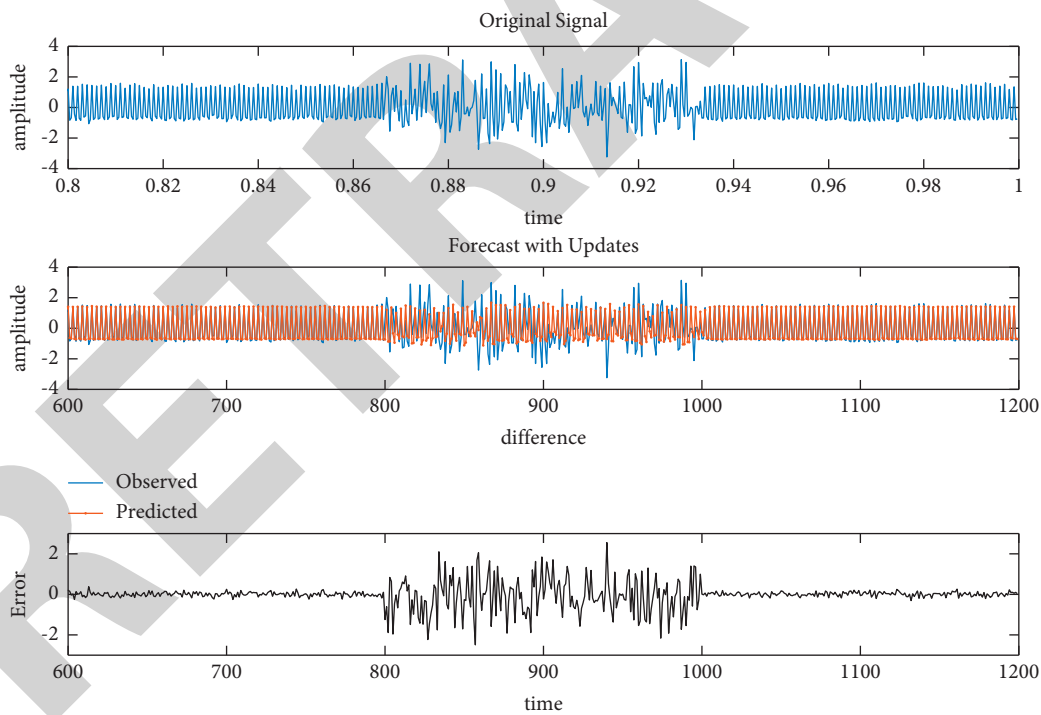

FIGURE 7: Eigenvalues.

windowed with a length of 6 and the difference signal generated by the GRU is not windowed. After normalization, it is sent to the SVM for classification. The classification result diagram is shown in Figure 11 [21].

It can be seen from Figure 11 that, when there is an interference signal, the interference detection accuracy of LSTM-SVM is 93.6%, and the interference detection accuracy of GRU-SVM is 89.6%.

**3.4. Confusion Matrix.** Since the SVM classification results cannot see the detection accuracy of each type, we use a confusion matrix to further refine the detection results. The confusion matrices for LSTM-SVM and GRU-SVM interference detection classification are shown in Figure 12 [22].

From Figure 12, it can be seen that, when there is no interference, the detection accuracy of the GRU-SVM is 100%, and that the detection accuracy of the LSTM-SVM

FIGURE 8: Signal data windowing process.

FIGURE 9: Influence of SNR on detection accuracy.

FIGURE 10: Effect of signal windowing on detection rate.

model is 99.5%. When there is interference, the detection accuracy of GRU-SVM is 68.7%, and the detection accuracy of LSTM-SVM is 81.8%. Overall, the false detection rate of GRU-SVM is 10.4%, and the false detection rate of LSTM-SVM is 6.4%. Therefore, the eigenvalues obtained by LSTM-SVM are more conducive to detecting the presence of interference signals.

#### 4. Discussion

The traditional interference detection starts from the received signal, analyzes the frequency domain characteristics of the received signal, extracts the characteristic value, and

then determines whether there is an interference signal. However, when the interference signal and the communication signal have the same frequency, it is difficult to extract the eigenvalues by using the traditional method. From the perspective of the time domain, this paper adopts the LSTM model, which has good prediction ability for time series signals. The eigenvalues are obtained from the difference between the predicted signal and the received signal, which solves the problem of signal interference detection in the case of interference.

The setting of the interference signal in the experiment described in this paper is relatively ideal. The interference signal used in this paper is a partial frequency band

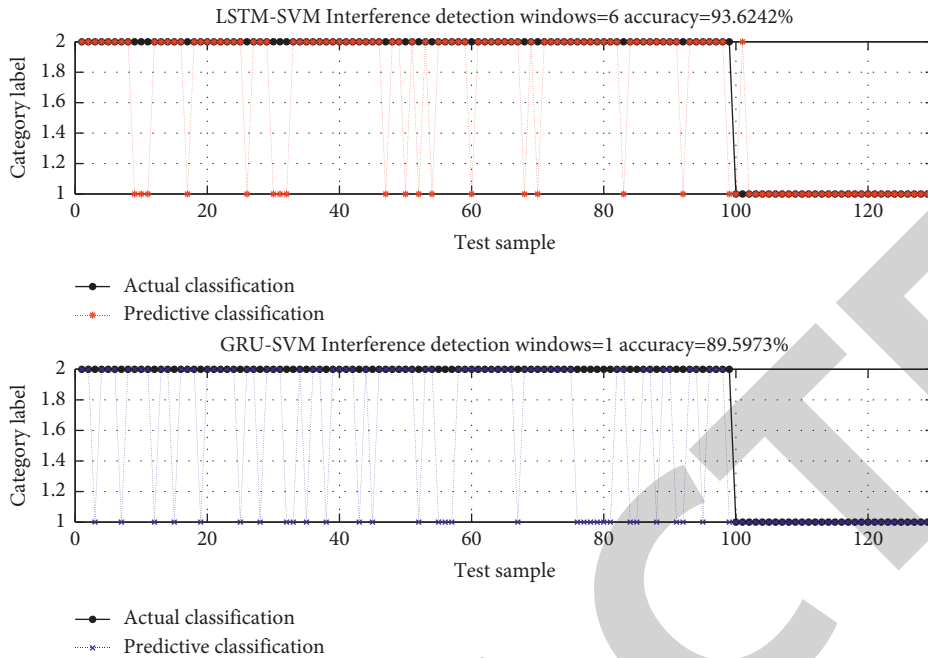

FIGURE 11: Simulation of interference detection accuracy.

FIGURE 12: Confusion matrix of LSVM-SVM and GRU-SVM classification.

interference signal, that is, the interference signal is generated by Gaussian noise through a narrow-band filter. You can try to use other interference signals to verify whether the experimental results in this paper are applicable.

### 5. Conclusion

Aiming at the detection of special time-frequency overlapping interference signals, an interference detection algorithm based on the LSTM-SVM model is proposed in this paper. LSTM is used for the time series prediction of received signals, and the difference between the predicted

signal and the received signal is used as a feature sample. This method can still be trained using a small amount of data and can obtain better prediction performance. The eigenvalue samples are windowed, and the SVM algorithm is used to classify and detect the eigenvalue samples. The LSTM-SVM model is compared with the GRU-SVM model. The comparison results show that the interference detection accuracy of the two models increases with the improvement of the SNR. Windowing the eigenvalues can significantly improve the interference detection performance of the LSTM-SVM model, but windowing the GRU-SVM model will reduce the accuracy. Under the optimal window, the detection

Establishing a coordinated governance mechanism for regional carbon emissions is an essential way to achieve carbon peak and carbon neutrality, while the study of interprovincial carbon emissions transfer is one of the important foundations of regional carbon emissions coordinated governance research. Based on the multiregional input-output (MRIO) model, this study calculated the carbon emissions from both the producers' perspective and the consumers' perspective and analyzed the interprovincial net carbon emissions transfer decision. Furthermore, the logarithmic mean Divisia index (LMDI) method was adopted to decompose the factors that affect the province's net carbon emissions into technological effect, structural effect, input-output effect, and scale effect. It was revealed that the input-output effect was the primary influencing factor of the net carbon transfer at the provincial level.

## 1. Introduction

China's economy has grown massively since the 21st century. As of 2020, China has achieved its first centenary goal—building a moderately prosperous society in all respects and is striding forward to its second centenary goal. However, the emission of carbon dioxide (CO<sub>2</sub>) is also rising along with the total economic volume, and China has become the world's largest carbon emitter. The issue of greenhouse gas emissions is getting more and more attention. On March 15, 2021, the Chinese government stated to have carbon emissions peak before 2030 and achieve carbon neutrality by 2060. This is a major decision under the goal of building a community of shared future for all humankind.

China has a vast territory. The differences in resource endowments and climate environment in different regions have not only brought differences in industrial structure between regions but also differences in CO<sub>2</sub> emissions of regional production activities. During regional trading, the production of goods and the provision of services lead to carbon emissions in production areas, but goods and services are actually consumed by consumption areas; therefore, CO<sub>2</sub> emissions are transferred along with the flow of goods and services. If the inter-regional transfer of carbon emissions is ignored during

the promotion of carbon emissions reduction, on the one hand, it may cause some regions to import high-carbon products from other regions for carbon emissions reduction. It will impair the effectiveness of emissions reduction policy, and even cause partial decrease with overall increase [1, 2]. On the other hand, it may cause high-polluting and high-energy-consuming industries to migrate from high-carbon emissions areas to low-carbon emissions areas. It is not conducive to take advantage of resource endowments in various regions, and neither conducive to promoting the development and utilization of clean energy and encouraging low-carbon consumption and low-carbon lifestyle. Therefore, to advance carbon emissions reduction, we need to think from the perspective of regional synergy. However, before planning how to scientifically promote the fair distribution of CO<sub>2</sub> reduction between regions, we need to pay attention to the following two issues. First, how is the regional distribution of carbon emissions transfer in China? Second, what are the main factors affecting the transfer of carbon emissions between regions in China? Therefore, this study is committed to carrying out the analysis of interprovincial carbon emission transfer, characterizing the relationship of carbon emission transfer, discussing its influencing factors, and consolidating the foundation for the research on carbon emission collaborative governance.

## 2. Literature Review

With respect to the calculation of carbon emissions transfer, more and more scholars adopted the multiregional input-output (MRIO) model in recent years. The single-region input-output (SRIO) model was first constructed by Leontief [3] and then expanded to multiple regions and widely applied in environmental impact assessment (EIA) [1, 2, 4].

Various scholars have integrated the MRIO model with the actual situation in China. Guo et al. [5], Yao et al. [6], and Zhang et al. [7] used the MRIO model to calculate and analyze China's interprovincial carbon emissions input-output, the carbon footprint of residents' consumption in China's eight major regions, and the carbon emissions input-output from various sectors in the eight major regions, respectively, revealing significant regional differences [5–7]. In addition, Liu et al. [8] used the 1997 inter-regional input-output table to analyze the transfer of carbon emissions from the perspective of industry and proposed a CO<sub>2</sub> emissions reduction model for industrial structure adjustment. The calculation demonstrated that structural adjustment of energy consumption of electric power industry and improving the efficiency of energy utilization in heavy industry were effective means to reduce carbon emissions [8]. Su and Ang [9, 10] explored the spatial agglomeration of carbon emissions transfer by calculating the carbon emissions transfer between major regions in China in 2002 and proposed to optimize interregional carbon emissions transfer from the mechanism level [9, 10]. Sun et al. [11] calculated carbon transfers between Indian economic sectors from 1995 to 2009 based on the SRIO model. The study found that CON (construction) transfers the largest amount, and EGW (electricity, gas, water supply) emissions account for 60% of CO<sub>2</sub> in the secondary industry [11]. Based on the MRIO model, Chen et al. [12] independently compiled China's inter-regional input-output table for 2012, calculated the amount of inter-provincial carbon emissions transfer, and analyzed the inter-provincial carbon equity from the perspective of carbon Gini coefficient [12]. Wang and Hu [13] used an inter-regional bilateral trade carbon transfer measurement model to measure the carbon emissions caused by interprovincial demand and interprovincial exports in China in 2007, 2010, and 2012. The study shows that cooperation and diffusion of emission reduction technologies can be effective suppress interprovincial carbon emissions transfer [13]. Han et al. [14] explored the flow of carbon emissions in China's provinces and other economies from a multi-regional perspective based on Nested IOA [14]. Based on the MRIO model, Wang et al. [15] analyzed the carbon-neutrality-oriented carbon emissions reduction model by studying the consumption-based carbon emissions and carbon transfer at the provincial and industry levels in China [15]. Liu et al. [16] deduced the calculation method of the value chain embodied carbon transfer based on the input-output table balance formula, and found that China's inter-regional value chain embodied carbon transfer and its net value both showed an increasing trend [16].

Regarding the decomposition of the influencing factors of carbon emissions transfer, the popular academic methods include the structural decomposition and the logarithmic

mean Divisia index (LMDI) decomposition, both of which have been widely used in various research scenarios. Based on the input-output model, Qian and Yang [17], as well as Jiang [18], employed the structural decomposition method to decompose carbon emissions embodied in international trade between East Asia and the BRICS, respectively [17, 18]. Guo [19], Du and Sun [20] and Huang et al. [21] applied the LMDI method to decompose the total carbon emissions, export embodied carbon emissions, and carbon emissions embodied in inter-provincial trade [19–21].

Existing studies have adequately applied the MRIO model to calculate the international and domestic carbon emissions transfer, used different methods to decompose the influencing factors, and analyzed interprovincial carbon equity from various perspectives and put forward corresponding proposals of carbon emissions reduction. On these bases, this study used a MRIO model to calculate the carbon emissions transfer between provinces based on the three-year data of 2012, 2015, and 2017, analyzed the transfer paths of inter-regional carbon emissions through social network, and then decomposed the factors affecting the net carbon emissions transfer at the provincial level using the LMDI method. We aimed to provide a basis for the construction of a coordinated governance mechanism for regional carbon emissions and emissions reduction plans to promote the achievement of carbon peak and carbon neutrality.

## 3. Interprovincial Carbon Emissions Transfer

Different provinces and cities in China have different resource endowments and natural environments. When designing emissions reduction plans, it will be not all-inclusive to consider only the differences in industrial structure between provinces and cities caused by different resource endowments. During the implementation of the emission reduction plans, because interprovincial trade will drive the transfer of interprovincial carbon emissions, with no restriction, some regions will purchase high-carbon emission products from other regions to replace local production for the purpose of carbon reduction, sabotaging overall emissions reduction. Due to differences in technological levels between regions, there may even be reduced partial emissions with increased overall emissions, the so called inter-regional carbon leakage. For that reason, we attempted to provide a basis for the coordinated governance mechanism of regional carbon emissions by calculating and analyzing the current interprovincial carbon emissions transfer, carbon transfer network, and carbon transfer path.

*3.1. Interprovincial Carbon Emissions Transfer Calculation Model.* In the present study, a MRIO model was adopted to calculate the carbon emissions from both the consumers' perspective and the producers' perspective and the inter-region carbon emissions transfers between 31 provinces and cities across China.

Assuming that in the MRIO model there are totally  $n$  provinces and cities and  $m$  industries in each province/city, the MRIO model has the following equation:

$$\begin{bmatrix} X_1^1 \\ X_2^1 \\ \vdots \\ X_m^n \end{bmatrix} = \begin{bmatrix} X_{1,1}^{1,1} + X_{1,2}^{1,1} + \cdots + X_{1,m}^{1,n} \\ X_{2,1}^{1,1} + X_{2,2}^{1,1} \cdots + X_{2,m}^{1,n} \\ \vdots \\ X_{m,1}^{n,1} + X_{m,2}^{n,1} + \cdots + X_{m,m}^{n,n} \end{bmatrix} + \begin{bmatrix} Y_1^{1,1} + Y_1^{1,2} + \cdots + Y_1^{1,n} \\ Y_2^{1,1} + Y_2^{1,2} + \cdots + Y_2^{1,n} \\ \vdots \\ Y_m^{n,1} + Y_m^{n,2} + \cdots + Y_m^{n,n} \end{bmatrix} + \begin{bmatrix} EX_1^1 \\ EX_2^1 \\ \vdots \\ EX_m^n \end{bmatrix}, \quad (1)$$

where  $X_i^I$  represents the total output of the industry  $i$  of province  $I$ ,  $X_{i,j}^{I,J}$  represents the intermediate input of the industry  $i$  of province  $I$  to the industry  $j$  of province  $J$ ,  $Y_i^{I,J}$

represents the final use of the industry  $i$  of province  $I$  by province  $J$ , and  $EX_i^I$  represents the output of the industry  $i$  of province  $I$ . Transform the intermediate input to get:

$$\begin{bmatrix} X_1^1 \\ X_2^1 \\ \vdots \\ X_m^n \end{bmatrix} = \begin{bmatrix} A_{1,1}^{1,1} & A_{1,2}^{1,1} & \cdots & A_{1,m}^{1,n} \\ A_{2,1}^{1,1} & A_{2,2}^{1,1} & \cdots & A_{2,m}^{1,n} \\ \vdots & \vdots & \ddots & \vdots \\ A_{m,1}^{n,1} & A_{m,2}^{n,1} & \cdots & A_{m,m}^{n,n} \end{bmatrix} \begin{bmatrix} X_1^1 \\ X_2^1 \\ \vdots \\ X_m^n \end{bmatrix} + \begin{bmatrix} Y_1^{1,1} + Y_1^{1,2} \cdots + Y_1^{1,n} \\ Y_2^{1,1} + Y_2^{1,2} \cdots + Y_2^{1,n} \\ \vdots \\ Y_m^{n,1} + Y_m^{n,2} \cdots + Y_m^{n,n} \end{bmatrix} + \begin{bmatrix} EX_1^1 \\ EX_2^1 \\ \vdots \\ EX_m^n \end{bmatrix}, \quad (2)$$

where  $A_{i,j}^{I,J} = X_{i,j}^{I,J} / \sum_{k=1}^n \sum_{l=1}^m X_{l,j}^{k,J}$  represents the products and services of the industry  $i$  of province  $I$  directly consumed by per unit of output of the industry  $j$  of province  $J$ .

The matrix form of equation (2) is

$$X = AX + Y + EX, \quad (3)$$

where  $X$  is the total output vector ( $mn \times 1$ ),  $A$  is the direct consumption coefficient matrix ( $mn \times mn$ ),  $Y$  is the final use vector ( $mn \times 1$ ), and  $EX$  is the export vector ( $mn \times 1$ ).

Transform equation (3) to get

$$X = (I - A)^{-1} (Y + EX). \quad (4)$$

Let  $B = (I - A)^{-1}$ , where  $B$  is the total input consumption coefficient matrix and the element  $B_{i,j}^{I,J}$  represents the intermediate products and final products provided by the industry  $i$  of province  $I$  to meet the per unit of final use in the industry  $j$  of province  $J$ .

Following the Intergovernmental Panel on Climate Change (IPCC) guidelines, this study calculates the carbon emissions of each industry in each province/city using the following equation:

$$\begin{aligned} C_i^I &= \sum_k CE_{ik}^I \\ &= \sum_k AD_{ik}^I \times NCV_k^I \times CC_i^I \times O_{ik}^I, \end{aligned} \quad (5)$$

where  $C_i^I$  is the total carbon emissions of the industry  $i$  of province  $I$ ,  $CE_{ik}^I$  is the carbon emitted by industry  $i$  of province  $I$  consuming energy  $k$ ,  $AD_{ik}^I$  represents the total amount of energy  $k$  consumed by the industry  $i$  of province  $I$ ,  $NCV_k^I$  represents the average low calorific value of energy  $k$ ,  $CC_k^I$  is the carbon emissions per unit of heat, and  $O_{ik}^I$  is the oxidation rate.

Then the total carbon emissions caused by final consumption is

$$CE = \hat{E} (I - A)^{-1} Y, \quad (6)$$

where  $\hat{E}$  is the carbon emissions intensity coefficient matrix ( $E_i^I = C_i^I / X_i^I$ ):

$$\hat{E} = \begin{pmatrix} E_1^1 & 0 & \cdots & \cdots & 0 \\ 0 & \ddots & \vdots & \vdots & 0 \\ \vdots & \cdots & E_i^I & \vdots & \vdots \\ \vdots & \cdots & \cdots & \ddots & 0 \\ 0 & 0 & \cdots & 0 & E_m^n \end{pmatrix}. \quad (7)$$

From the producers' perspective, the carbon emissions  $CE_p^I$  represent the CO<sub>2</sub> emissions produced by the production activity in province  $I$ :

$$CE_p^I = \sum_{K=1}^m \hat{E}^I (I - A)^{-1} Y^K. \quad (8)$$

From the consumers' perspective, the carbon emissions  $CE_c^I$  represents the CO<sub>2</sub> emissions from production activities in all provinces caused by province  $I$ 's demand for products and services:

$$CE_c^I = \sum_{K=1}^m \hat{E}^K (I - A)^{-1} Y^I. \quad (9)$$

Interprovincial carbon emissions transfer originates from interprovincial trade. That is, in order to meet the needs of other provinces and cities for products and services, one province or city needs to conduct a production activity. Then the amount of carbon emissions transfer  $CT^{I,J}$  is represented by the carbon emissions generated during the production process. It means that the carbon emissions of various industries in province  $I$  caused by the final use by province  $J$  is the carbon emissions transfer from province  $J$  to province  $I$ :

$$CT^{I,J} = \hat{E}^I (I - A)^{-1} Y^J. \quad (10)$$

*3.2. Carbon Emissions Results from Different Perspectives.* This study adopted the interregional input-output tables of 42 sectors in 31 provinces, municipalities, and autonomous regions in China in 2012, 2015, and 2017. According to the method of Chen et al. [12], the 42 sectors in the input-output tables were merged into 16 sectors. The energy consumption by each sector, each region in each year was from the official data released by CEADs (<https://www.ceads.net>). The results are shown in Table 1.

In 2012, 2015, and 2017, the highest total carbon emissions from the consumers' perspective were coastal provinces with large populations and high consumption levels, such as Shandong (566 million tons per year) and Guangdong (528 million tons per year). The lower ones were in regions with relatively small populations and low consumption levels including Tibet (15 million tons per year) and Qinghai (41 million tons per year). The primary reason is the large differences in the total population and consumption levels between regions. A large population and a high consumption level make the total final use large in that region, leading to high-carbon emissions from the consumers' perspective. It is the opposite way in sparsely populated areas with low consumption levels.

With respect to the time trend, benefit from the increase in consumption levels by economic development during the period, the total carbon emissions from the consumers' perspective in populous regions such as Guangdong, Jiangsu, and Henan were all rising. While regions such as Beijing, Shanghai, and Tianjin which already have high consumption levels demonstrated an overall decreasing pattern from the perspective of consumers. It indicated that economic development in areas with high consumption levels has brought about a low-carbon consumption structure.

From the perspective of the producers, the high total carbon emissions were in regions like Shandong (645 million tons per year), Hebei (556 million tons per year), and Shanxi (379 million tons per year). The industrial structure in these regions preferred high polluting industries such as steel and energy. The advantageous industries in Shandong include three high-polluting and high-energy-consuming industries, energy processing (petroleum and coal), nonferrous extractive metallurgy, and chemical raw material production, which resulted in much higher carbon emissions than other regions. The lower total carbon emissions from the perspective of producers were regions with advantages in the tertiary industry, such as Beijing (58 million tons per year), Hainan (35 million tons per year), and Tibet (0.05 million tons per year).

Regarding the time trend, the total carbon emissions were relatively stable from the perspective of producers, different from those of the perspective of consumers. Except for Inner Mongolia and Xinjiang whose changes were relatively big, the changes in total carbon emissions were small in other provinces/cities. The primary reason is that their

industrial structure is stable compared to the consumption level; therefore, the changes in total carbon emissions caused by industrial structure were small.

*3.3. Total Net Carbon Emissions Transfer.* According to the principle of "the consumers assume responsibility," the net carbon emissions transfer was calculated by subtracting the producers' total carbon emissions from the consumers' total carbon emissions, that is, equation (9) minus equation (8).

The regions with high annual net carbon emissions transfer-out in 2012, 2015 and 2017 were provinces/cities with large populations and high consumption levels such as Guangdong, Zhejiang, and Beijing. Their industrial structure could not support their own demand, so they purchased products from other provinces/cities and transferred the CO<sub>2</sub> that should be emitted in region for producing these products to other regions. The regions with high annual net carbon emissions transfer-in were regions with an industry structure preferring energy and heavy-industry, such as Inner Mongolia, Hebei, and Shanxi. On the one hand, the energy industry, as an important part of production and life, participates in the production process of other industries in the region. On the other hand, the region's own demand is far from releasing its production capacity. While a large number of products were sold by these regions, the CO<sub>2</sub> that should be emitted by other provinces/cities for producing these products was transferred in. With respect to the time trend, provinces/cities with negative annual net carbon emissions transfer have greater fluctuations compared to those with positive annual net carbon transfer. Especially the fluctuations in Chongqing, Yunnan, Shanghai, and Henan were big. While Shanghai and Henan even changed the direction of net carbon transfer.

By equation (10), we can get the interprovincial carbon emission transfer matrix, but it is difficult to display due to the large amount of data. To visualize the carbon emissions transfer relationship clearly between provinces/cities, the amount of carbon transfer from one province/city to the other provinces/cities was sorted by the proportion of the total transfer amount, and the top 60% was taken to generate the interprovincial carbon emissions transfer relationship matrix. Then the social network was drawn with arrows pointed the direction of CO<sub>2</sub> transfer (see Figure 1).

In general, the interprovincial carbon emissions transfer social network exhibited a star-like shape. The five provinces of Inner Mongolia (IM), Hebei (HB), Shanxi (SX), Liaoning (LN), and Shandong (SD) with high net carbon transfer-in not only received most transfer-out from Guangdong (GD), Zhejiang (ZJ), Beijing (BJ), Chongqing (CQ), Shanghai (SH), and Tianjin (TJ), the regions with high net carbon transfer-out but also served as the main transfer-out places of carbon emissions from other provinces/cities. They worked as the center of the interprovincial carbon emissions transfer network and were also the dominant regions from the perspective of producers. From the perspective of coordinated governance of regional carbon emissions, the impact of the emissions reduction policy on the central provinces could quickly spread through the transfer network, conducive to timely adjustment of policy based on actual effects.

TABLE 1: Carbon emissions results from different perspectives.

Year	Consumers' perspective			Producers' perspective

FIGURE 1: Interprovincial carbon emissions transfer social network (2017).

Although the net carbon transfer-in Henan was not high in 2015, and the net carbon emissions were transferred-out in 2017, it is still close to the center of the carbon emissions transfer network. It is because that the carbon emissions transferred to the “sub-center” Henan were far less than the amount transferred to the “central” provinces, and the carbon emissions transferred from Henan to other provinces were high too. Similarly, Jiangsu had a net carbon transfer-out of only 0.02 million tons in 2017, whereas it was still close to the center of the network. The main reason is also that provinces such as Inner Mongolia, Shanxi, and Liaoning

received most of the carbon emissions transfer, while carbon emissions transferred from Jiangsu’s to other provinces was high too.

#### 4. Decomposition of Factors Affecting Net Carbon Emissions Transfer

To support the construction of a coordinated governance mechanism for regional carbon emissions, it is not only necessary to grasp the current interprovincial carbon emissions transfer and carbon transfer network but also

need to fully understand the continuous and systemic influencing factors of net carbon emissions transfer. Thus, this article adopted the LMDI method to decompose the influencing factors of the net carbon emissions transfer at the provincial level.

**4.1. Establishment of the LMDI Model.** In order to explore the key factors affecting the net carbon emission transfer in each province, the contribution of various factors to the carbon emission transfer was evaluated. Since this study focused on the impact of carbon emissions intensity, output structure, demand-output ratio, and total demand on carbon emissions, the following equation is used for analysis:

$$C_{ex}^I = \sum_{j=1}^m \sum_{j=1}^n \left( \frac{C_j^{(I,J)}}{X_j^{(I,J)}} \right) \left( \frac{X_j^{(I,J)}}{X^{(I,I)}} \right) \left( \frac{X^{(I,I)}}{Y_T^I} \right) Y_T^I, \quad (11)$$

where  $E_{ex}^{(I,J)j} = C_j^{(I,J)}/X_j^{(I,J)}$ , representing the carbon emissions transferred per unit of output from province  $I$  to industry  $j$  of province  $J$ ;  $ST_{ex}^{(I,J)j} = X_j^{(I,J)}/X^{(I,I)}$ , representing the industry structure of production activities of province  $J$

to meet the needs of province  $I$ ;  $F_{ex}^{(I,J)j} = X^{(I,I)}/Y_T^I$ , representing the output of province  $J$  caused by per unit of final demand of province  $I$ ; and  $Y_{ex}^{(I,J)} = Y_T^I$ , representing the final demand scale of province  $I$ .

$$C_{im}^I = \sum_{j=1}^m \sum_{j=1}^n \frac{C_j^{(I,I)}}{X_j^{(I,I)}} \frac{X_j^{(I,I)}}{X^{(I,I)}} \frac{X^{(I,I)}}{Y_T^I} Y_T^I, \quad (12)$$

where  $E_{im}^{(I,I)j} = C_j^{(I,I)}/X_j^{(I,I)}$ , representing the carbon emissions transferred per unit of output from industry  $j$  of province  $J$  to province  $I$ ;  $ST_{im}^{(I,I)j} = X_j^{(I,I)}/X^{(I,I)}$ , representing the industry structure of production activities of province  $I$  to meet the needs of province  $J$ ;  $F_{im}^{(I,I)j} = X^{(I,I)}/Y_T^I$ , representing the output of province  $I$  caused by per unit of final demand of province  $J$ ; and  $Y_{im}^{(I,I)} = Y_T^I$ , representing the final demand scale of province  $J$ .

This article employed the LMDI method to decompose the factors that affect the provincial net carbon emissions into technical effect, structural effect, input-output effect, and scale effect:

$$\begin{aligned} \Delta C^I &= C_{ex}^I - C_{im}^I \\ &= \Delta C_E^I + \Delta C_{ST}^I + \Delta C_F^I + \Delta C_Y^I, \\ \Delta C_E^I &= \sum_{j=1}^m \sum_{j=1}^n W^{(I,J)j} \ln \frac{E_{ex}^{(I,J)j}}{E_{im}^{(I,I)j}} \dots \dots \text{technical effect}, \\ \Delta C_{ST}^I &= \sum_{j=1}^m \sum_{j=1}^n W^{(I,J)j} \ln \frac{ST_{ex}^{(I,J)j}}{ST_{im}^{(I,I)j}} \dots \dots \text{structural effect}, \\ \Delta C_F^I &= \sum_{j=1}^m \sum_{j=1}^n W^{(I,J)j} \ln \frac{F_{ex}^{(I,J)j}}{F_{im}^{(I,I)j}} \dots \dots \text{input - output effect}, \\ \Delta C_Y^I &= \sum_{j=1}^m \sum_{j=1}^n W^{(I,J)j} \ln \frac{Y_{ex}^{(I,J)}}{Y_{im}^{(I,I)}} \dots \dots \text{scale effect}, \end{aligned} \quad (13)$$

where  $W^{(I,J)j} = \begin{cases} (C_j^{(I,J)} - C_j^{(J,I)}) / \ln(C_j^{(I,J)} - C_j^{(J,I)}), & C_j^{(I,J)} \neq C_j^{(J,I)} \\ C_j^{(I,J)}, & C_j^{(I,J)} = C_j^{(J,I)} \end{cases}$ .

The technology effect reflects the differences in production technology between provinces in interprovincial trade. The structural effect reflects the contribution of the difference in the final demand structure of each province to the transfer of net carbon emissions. The input-output effect reflects the degree of correlation between the various industries in each province in the production process. The scale effect reflects the contribution of differences in the scale of final demand across provinces to the transfer of net carbon emissions implied by trade.

**4.2. Analysis of LMDI Decomposition Results.** This paper decomposed the annual net carbon transfer into technical effect, structural effect, input-output effect, and scale effect

via LMDI method. A positive contribution of an effect indicated that this effect made the regional carbon transfer-out greater than carbon transfer-in, and a negative contribution value indicated a larger carbon transfer-in than carbon transfer-out. The decomposition results are shown in Table 2. Due to the large amount of data, only data of 2017 are displayed.

The provinces/cities with a positive technical effect were concentrated in the economy developed regions such as Beijing, Guangdong, and Zhejiang, as well as the regions whose economic development did not rely on high-polluting and high-emission industries, such as Jiangxi and Yunnan. The main reasons might be that, the regions such as Beijing and Guangdong, have advanced carbon emission technology with developed economy compared to their trading regions, resulting smaller amount of carbon emissions of the

TABLE 2: LMDI decomposition results in 2017.

Xinjiang	-0.14	-0.86	-0.66	-1.05	-0.93	1.89	-0.57

corresponding equivalent commodities. Therefore, the carbon transfer-in caused by production was less than the carbon transfer-out caused by consumption. Provinces and cities that do not rely on high-polluting and high-emission industry for economic development such as Jiangxi and Yunnan had advantages in carbon emissions intensity when trading with regions with a large proportion of heavy industry, leading to net carbon emissions transfer-out. On this basis, during the coordinated governance of regional carbon emissions, we could encourage technology exchanges between regions with positive technical effects and regions with negative technical effect to speed up the spread of current low-carbon production technologies. In addition, we could strengthen support for technological innovation in regional with negative technical effect to guide the production technology toward low-carbon style.

The regions with positive structural effect included 16 provinces and cities, such as Jiangsu, Chongqing, Shanghai, and Tianjin. The main reason is that the provinces and cities, such as Jiangsu, Chongqing, and Shanghai, when trading with other regions, gained output in industries with low-carbon emissions such as transportation and storage and construction in their own regions. While the provinces such as Inner Mongolia, Shanxi, and Ningxia, gained output in industries with high-carbon emissions such as coal mining

and dressing, metal smelting and pressing, and power and heat supply. Therefore, the regions with positive structural effect would have a smaller carbon emissions transfer-in from production than the carbon emissions transfer-out from consumption, thus a net carbon transfer-out. Whereas the regions with negative structural effect would have a larger carbon transfer-in than transfer-out, thus a new carbon transfer-in. From the perspective of collaborative governance, it is necessary to fully consider the differences in resource endowments between provinces and cities, to guide the industrial structure of each region to give full play to its own advantages, and to rationally lead the transfer of high-polluting and high-emission industries between regions.

The regions with positive input-output effect were mainly distributed in areas with relatively immature industrial chains and weak economies such as the northwest and southwest. While regions with negative input-output effect were mainly distributed in the eastern and northern coastal areas, where the industrial chains were more mature and the input-output relationship between industries was more complex. When meeting the needs of other provinces, the total output increase of all industries brought by the equivalent demand from other provinces will be higher than that of regions with weaker inter-industry linkages. It is likely to cause larger carbon transfer-in from production

than carbon transfer-out from consumption, thus the net carbon transfer-in. The input-output effect was the dominant factor of net carbon transfer. Therefore, in the overall governance process, it is necessary to rationally consider the economic benefits of the increased production of various industries brought about by the interprovincial trade demand and the carbon emissions transfer that comes along, so as to improve the interprovincial industrial chain. Optimizing the industrial structure and leading the input-output relationship between industries toward low-carbon can be an effective practical direction to promote the coordinated governance of regional carbon emissions.

The regions with positive scale effect were mainly distributed in developed coastal provinces. They have large populations and high consumption levels, and the corresponding final consumption scales were larger than other provinces. Therefore, the scale of consumption would be greater than the scale of production in interprovincial trade, and the carbon emissions transfer-out from consumption would be larger than transfer-in from production, resulting in a net carbon transfer-out. From the perspective of coordinated governance of regional carbon emissions, it is necessary to build a reasonable horizontal inter-provincial carbon compensation mechanism, so that high-consumption regions could assume the carbon emission responsibility of consumed goods, and build a bridge of coordinated carbon governance between carbon transfer-out and transfer-in provinces and cities.

In terms of time trend, among the provinces with large changes in carbon emissions transfers in 2012, 2015, and 2017, the changes in total effect in Inner Mongolia, Liaoning, Jilin, Heilongjiang, Hunan, and Zhejiang were mainly due to the same direction changes of scale effect. The decline in total effect in Fujian was primarily due to the reduction in input-output effect. While for provinces and cities with drastic changes in the amount of carbon emissions transfer, the changes in total effect in Shanghai, Jiangsu, and Henan were mainly caused by the same direction changes of scale effect. It can be seen that the scale effect was the dominant factor causing changes in carbon emissions transfer. Presumably, it is because that the final consumption scale responded more quickly to changes in environmental factors such as consumers' preferences and industry policies than the industrial structure, technological level, and industry input-output relationships.

## 5. Conclusion and Suggestion

This study constructed an interregional input-output model for 31 provinces and cities in China to calculate and analyze the carbon emissions transfer between provinces and cities, carbon emissions from the perspective of producers and from the perspective of consumers. Furthermore, this study conducted influencing factor decomposition for net carbon emissions transfer using the LMDI method. The following conclusions are drawn:

- (1) High-carbon emission areas from the consumers' perspective are mainly distributed in populous provinces and cities such as Shandong, Guangdong, Jiangsu, and Henan, and the emissions are rising. While in regions with high consumption levels such as Beijing, Shanghai, and Tianjin, the carbon emissions are declining from the consumers' perspective. High-carbon emission areas from the producers' perspective are mainly distributed in regions with industrial structure preference toward high-polluting industries like steel and energy, including Shandong, Hebei, and Shanxi. And the carbon emissions the producers' perspective fluctuated little over time and are relatively stable.
- (2) The interprovincial carbon emissions transfer network is star-like. The five provinces, Inner Mongolia, Hebei, Shanxi, Liaoning, and Shandong, with high net carbon transfer-in are the primary transfer-out places of carbon emissions from other provinces, and they are located in the center of the carbon emissions transfer network.
- (3) The input-output effect is the dominant one that affects the net carbon transfer, indicating that the net carbon transfer is primarily affected by the completeness degree of the industrial chain. In the eastern and northern coastal areas, the industrial chain is relatively complete, and the input-output relationship between industries is more complicated. Their increases in total industrial output caused by the same demand are higher than that of other regions. Therefore, the carbon transfer-in from production is greater than the carbon transfer-out from consumption, resulting a net carbon transfer-in. The scale effect is the primary factor determining the carbon emissions transfer from 2012 to 2017. The reason for that is that compared with the industrial structure, technological level, and industry input-output relationships, the final consumption scale responds more quickly to changes in environmental factors including consumers' preferences and industry policies.

Based on the above-mentioned empirical results and research conclusions, the following suggestions are made. First, we should strengthen support for low-carbon industries and low-carbon technologies. On the one hand, to provide more support for low-carbon industries such as clean energy to improve energy efficiency and expedite the low-carbon shift in industrial structure. On the other hand, to encourage low-carbon technological innovation and lead high-polluting and high-emission industries to reduce pollution and emissions. At the same time, to promote low-carbon consumption and low-carbon lifestyle and guide the low-carbon shift in consumption concept. We should take full advantage of the relationship between the center regions with other regions in the interprovincial carbon emissions

transfer network, prioritize the industrial upgrading and transformation of the metal and nonmetal processing and manufacturing industry in center regions, and eliminate outdated production capacity with high pollution and high emissions. Then, we should improve the responsibility mechanism for interprovincial carbon transfer. We should fully review the differences in economic development between provinces, comprehensively consider the producers' principle and consumers' principle, and rationally allocate carbon reduction responsibility in major high-carbon production regions and major high-carbon consumption regions. Last but not least, we should think about the differences in resource endowments of various provinces and cities, improve the industrial chain, and promote the low-carbon shift of input-output structure of inter-provincial industries.

### Data Availability

Energy consumption by each sector and each region in each year was taken from the official data released by CEADs (<https://www.ceads.net>).

### Conflicts of Interest

The authors declare no conflicts of interest.

### Authors' Contributions

Y.Q. designed the model and the computational frame work and analyzed the data. G.P. wrote the manuscript. Lei conducted empirical research. Lu collected the relevant literates. Y.P. collected the data. All authors discussed the results and contributed to the final manuscript. All authors have read and agreed to the published version of the manuscript.

For the repair level and spare parts stocking decision problems, generally METRIC type methods and level of repair analysis (LORA) are used separately. In practical engineering, the repair level of large-scale systems is usually judged according to the failure modes. The method of judging the repair level by the maintenance success rate is no longer applicable. In the case of multiple failure modes of a large-scale system, considering the requirements of system availability, we build a spare parts stocking decision and service logistics cost optimization model of a two-echelon service logistics system. Aiming at the spare parts stocking allocation problem caused by multiple failure modes, we improve the iterative greedy heuristic algorithm to find the global optimal stocking allocation strategies. Finally, through the analysis of typical examples, the correctness and effectiveness of the model and algorithm are verified. The impact of multifailure mode spare parts stocking allocation strategies on availability and service logistics cost is analyzed. The research results are helpful to simplify the support engineering design process of system engineers and have certain theoretical and application value.

## 1. Introduction

Large-scale system can be decoupled or decomposed into multiple interrelated subsystems or modules. Each subsystem contains a variety of components, which are controlled by the same constraints or objectives to complete specific tasks. Therefore, any component's failure will cause system failure [1, 2]. The large number of components means that a reasonable service logistics strategy should be developed to meet the availability of spare parts and the economy of the service logistics system [3].

In terms of economy, due to the complex operational environment of large-scale system, the establishment of maintenance center for unified resource allocation and repair failure units could save a lot of costs compared to on-site maintenance [4]. In terms of availability, on-site maintenance would save the transportation waiting time of failed units and improve system availability [5]. Therefore, the aim

of service logistics strategy is to balance the relationship between maintenance level, spare parts stocking allocation, and service logistics cost under the constraint of system availability.

The METRIC model is the most commonly used in service logistics strategy. The original METRIC model used "echelon" to represent the levels of different types of warehouses [6]. Slay [7] developed the VAR-METRIC model, which assumes that the average number of components in repair is equal to the variance of the negative binomial distribution. Graves [8] explored the same distribution, elaborating both an approximate and an exact method for the multiechelon single-indenture case. On this basis, literature [9] provides an accurate method to evaluate multiechelon service logistics systems. Therefore, the VAR-METRIC model is the most common method used by scholars to solve spare parts stocking allocation problems.

The level of repair analysis (LORA) is an input decision parameter of the VAR-METRIC model to solve the spare parts stocking allocation, and it is used to determine the location of spare parts for repair [10]. Falkner [11] was the first scholar to mention joint optimization of spare parts stocking decision and repair in his paper. Performing the LORA first and then the spare parts stocking decision analysis, the sequential approach, may lead to a solution that is not optimal. Basten [12] proposed an integrated algorithm to find optimal solutions for two-echelon problems. He uses efficient points on the curve of costs versus expected number of backorders to represent the optimal solution. On this basis, he proposed an iterative algorithm to solve the joint problem of LORA and spare parts stocking decision in 2015. The basic idea is to solve the LORA decision first, then use the VARI-METRIC model to solve the spare parts stocking decision problem, and last use the results of VARI-METRIC to add an estimate of the holding costs to the LORA inputs and start a second iteration [10]. However, all the above studies assume that component failure is a single failure mode.

Large-scale systems have a large number of components, leading to a large number of complex failure mechanisms. That is, different failure modes have different degrees of influence on the system [13]. To define or distinguish these failure modes, many scholars will choose failure mode analysis according to failure mechanism, failure impact, failure rate, or other parameters [14]. Failure mode analysis is an important work item of system availability analysis, and it is the basis for maintainability analysis, safety analysis, testability analysis, and supportability analysis [15]. Therefore, before formulating LRU maintenance level and spare parts stocking decision strategies, failure modes analysis of key component should be done first.

The introduction of multiple failure modes would change the joint optimization model of METRIC and LORA. Different echelon warehouses need different types of spare parts. Therefore, a new two-echelon service logistics cost optimization model for large-scale system is built in this paper. We improve an iterative greedy heuristic algorithm based on literature [10]. Finally, the correctness and effectiveness of the model and algorithm are verified by a practical engineering case. The key influencing factors of spare parts stocking allocation decisions and system availability are revealed. This research has certain theoretical and application value in the optimization of service logistics strategy.

## 2. Model Description

This section describes the characteristics of two-level support system for a large-scale operation system. According to the current research, we consider the influence of multiple failure modes on system operation results and the impact on maintenance strategy of support system. It provides a theoretical basis for the construction of the spare parts stocking decisions optimization model.

*2.1. System Description.* According to the hierarchical structure of Figure 1, this paper proposes a large-scale operation system with multiple failure modes. The system contains  $k$  identical individual subsystems, and each subsystem consists of  $i$  ( $i = 1, 2, 3, \dots$ ) series components.  $LRU_i$  is the key component of the subsystem. In case of failure, it can be repaired at the maintenance site of the support system.

The structure of large-scale system is complex, and LRU often has a variety of failure modes  $FM_i$ ,  $n$  ( $n = 1, 2, 3, \dots$ ) [16–18].

The key components of subsystems are various, including electronic, mechanical, and optical components. A single failure mode cannot meet the requirements of system availability analysis. At present, scholars generally use three classification methods: the impact of failure on components, the impact of failure on maintenance strategies, and the impact of failure on operating system. The first type divides the failure into degraded function failure, nonfunction failure, partial function failure, intermittent function failure, and unexpected function failure [19, 20]. The second type divides the failure into maintainable failure and non-maintainable failure [21]. The third type divides failures into hard failure and soft failure [22–24].

Considering that our optimization model is a service logistics model, we pay more attention to the impact of spare parts stocking decision strategies on system operation results. Therefore, the third type is selected as the classification method in this paper. Soft failure usually causes system production reduction or inferior performance, while the system keeps functioning; hard failure can cause system failure, for example, the service logistics model of an offshore wind farm in literature [5]. According to the difficulty of maintenance caused by the marine environment and the impact of turbine failure on the system, hard failure and soft failure classification methods are used to formulate maintenance strategies for different failure modes.

Specifically, we ascribe the sudden failure modes such as circuit break, short circuit, and impact to hard failure, which will lead to the instantaneous loss of system function. We ascribe wear, aging, fatigue, and other degradation failure modes to soft failure, which reduces the key performance of the system. According to the above analysis, the basic assumptions of large-scale operation system in this study are as follows:

- (1)  $LRU_i$  ( $i = 1, 2, 3, \dots$ ) are independent of each other, and the demand for spare parts follows the Poisson distribution.
- (2) System failure would be caused by one LRU at most. Multiple failures that occur at the same time are not considered.
- (3) When there is a shortage of spare parts in a failure maintenance site, the system stops, and the system availability decreases.
- (4) The importance of all LRUs is the same, and the priority is not considered for maintenance.

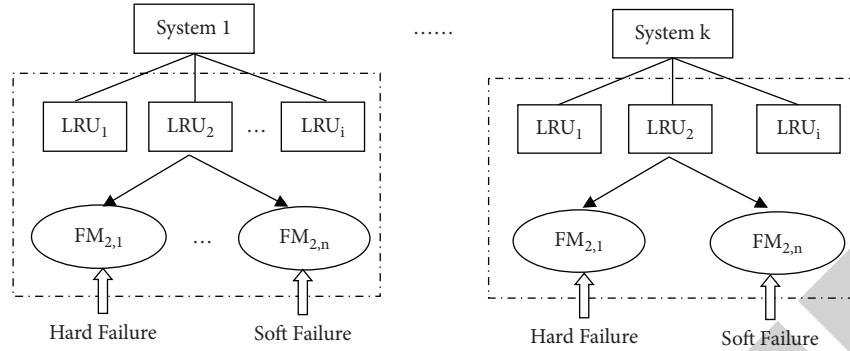

FIGURE 1: The large-scale operation system with multiple failure modes.

- (5) Failure diagnosis time and spare parts replacement time are ignored.
- (6) Each LRU has multiple failure modes  $FM_i$ ,  $n$  ( $n = 1, 2, 3, \dots$ ). The failure modes are mutually exclusive; that is, the simultaneous occurrence of multiple failure modes is not considered.
- (7) Failure modes are divided into hard failure and soft failure.

2.2. Two-Echelon Service Logistics System Description. When the operating system fails, the corresponding failed spare parts shall be replaced immediately, and the removed failed spare parts shall be sent to the maintenance site for repair [17]. In the level of repair analysis (LORA), the expensive resource cost usually leads to the repair work upstream of the maintenance network, while the expensive transportation cost leads to the downstream repair work close to the installation Base. Therefore, spare parts with cheap resources should generally be repaired locally, while spare parts requiring expensive resources should be repaired intensively [16].

Considering that the hard failure is mainly caused by overload, instantaneous impact, and electronic failure, it is assumed that the “Base” site of the service logistics system can completely repair this failure mode. However, the soft failure needs to be reprocessed and assembled. In such cases, maintenance activities are expensive to deploy to the complex operating environment on the Base site. Therefore, we assume that the soft failed spare parts are sent to a higher-grade maintenance site “Depot.” In this study, the purpose of considering multiple failure modes is to solve the problem of choosing the maintenance position of multiple spare parts types, which can make up for the spare parts allocation problem that LORA can only solve a single failure mode. Using failure mode characteristics to determine the maintenance level is more suitable for practical engineering.

The maintenance activities at different maintenance sites are different. We consider a two-echelon service logistics system. This system’s availability depends on the availability provided by any single maintenance site [17], and its structure is shown in Figure 2.

At each maintenance site of the service logistics system, maintenance resources such as maintenance tools,

FIGURE 2: The structure of two-echelon service logistics system.

maintenance personnel, and support equipment are configured to enable it to deal with different failure modes. The Base is usually set at the site of the operating system. In case of failure, if the spare part is in stocking in the Base, the spare part shall be extracted and replaced immediately to restore system availability. If the spare parts are out of stocking, an order will be issued to the Depot, and an  $(s - 1, s)$  replenishment strategy will be formulated [12, 17].

The maintenance of failed spare parts requires inspection to determine the failure mode and relevant maintenance activities: LRU with hard failure is repaired in Base, and LRU with soft failure is repaired in Depot. The Depot can be regarded as a warehouse with unlimited capacity. However, due to cost control, we still need to optimize the amount of LRUs stored in maintenance sites. When the failed spare part is repaired in the Depot, it will be sent to the source Base again [16].

According to the above analysis, the basic assumptions of the two-echelon service logistics system are as follows:

- (1) The maintenance site has the maintenance ability to deal with the corresponding failure mode; that is, discard decision is not considered
- (2) The hard failure shall be repaired in Base, and the soft failure can only be repaired in Depot
- (3) Base and Depot deal with different failures, their resource allocation and maintenance difficulties are different, and the repair time of failures is independent
- (4) The maintenance strategy selects perfect maintenance; that is, LRU is repaired as good as new
- (5) There are no lateral transshipments between locations at the same echelon level or emergency shipments from locations at a higher echelon level
- (6) Maintenance resources are nonconsumables and can be reused

The purpose of failure mode classification is to distinguish the types of spare parts. Under different failure modes, LRU needs different types of spare parts, different maintenance difficulties, and different maintenance positions. The optimization model in this study is also applicable to other failure mode classification methods. As long as the failure mode characteristics can be determined, the maintenance level problem can be solved according to the maintenance requirements of spare parts.

### 3. Two-Echelon Service Logistics Cost Optimal Modelling

The purpose of constructing this optimization model is to find the spare parts stocking allocation strategy that makes the service logistics cost optimal under the condition of meeting the requirements of system availability. We improve the LORA and METRIC joint model and design a new iterative algorithm. The model variables are shown in Table 1.

*3.1. Mathematical Model of Spare Parts Stocking Decision.* Generally, a variable is defined in the METRIC model to represent the maintenance capability of the maintenance site, representing the probability of successful repair by LRU<sub>*i*</sub> at *j*. This method is applicable to the case of single failure mode. In the case of multiple failure modes, the maintenance level should be determined in advance so that each maintenance point has sufficient capacity to deal with the current failure. This idea can not only clarify the resource allocation of different maintenance sites but also improve the efficiency of system availability management.

In this paper, the availability of the service logistics system is selected as the index to measure the effectiveness of the spare parts stocking decision [25]. The spare parts stocking holding cost optimization model of the two-echelon service logistics system is as follows:

$$\begin{cases} \min, & \sum \sum f c_{i,j} \cdot s_{i,j}, \\ s.t., & A(s_{i,j}) \geq A_{\min}. \end{cases} \quad (1)$$

Equation (1) indicates that the optimal spare parts stocking holding cost should meet the availability requirements  $A_{\min}$ .

When there are no LRU spare parts to be replaced in the warehouse of the maintenance site, the LRU will enter the shortage state, which will lead to the shutdown of the operating system and the decline of system availability. The relationship between availability and shortage of maintenance sites is as follows [26]:

$$A(s_{i,j}) = \left( 1 - \frac{\text{EBO}(s_{i,j})}{M_{i,j}} \right)^{M_{i,j}}, \quad (2)$$

where  $M_{i,j}$  is the assembly quantity of LRU<sub>*i*</sub> at *j*.

Since the failure of any LRU will cause system shutdown, it can be considered that the LRUs are in a series structure. The availability of the service logistics system  $A_{\text{sys}}$  is the product of the availability of all maintenance sites:

TABLE 1: Model variables.

$i$	Item number, LRU <sub><i>i</i></sub> , $i = 1, 2, 3, \dots, n$
$j$	Site number, Depot: $j = 0$ , Base: $j = 1, 2, 3, \dots, n$
$\lambda_{i,j}$	Single cycle demand mean value of item <i>i</i> at site <i>j</i>
$\lambda_{ih}$	Single cycle demand mean value of item <i>i</i> 's hard failure mode
$\lambda_{is}$	Single cycle demand mean value of item <i>i</i> 's soft failure mode
$T_{i,j}$	Repairing time of item <i>i</i> at site <i>j</i>
$O_{i,j}$	Order and ship time of item <i>i</i> from the Depot to the site <i>j</i>
$f c_i$	Price of item <i>i</i>
$s_{i,j}$	Level of stocking of item <i>i</i> at site <i>j</i>

$$A_{\text{sys}} = \prod_{j=1}^J \prod_{i=1}^I A(s_{i,j}) = \prod_{j=1}^J \prod_{i=1}^I \left( 1 - \frac{\text{EBO}(s_{i,j})}{M_{i,j}} \right)^{M_{i,j}}. \quad (3)$$

Take logarithms on the left and right sides of (3) to obtain

$$\begin{aligned} \ln A_{\text{sys}} &= M_{i,j} \cdot \ln \left( 1 - \frac{\text{EBO}(s_{i,j})}{M_{i,j}} \right) \approx M_{i,j} \cdot \left( -\frac{\text{EBO}(s_{i,j})}{M_{i,j}} \right) \\ &= -\text{EBO}(s_{i,j}). \end{aligned} \quad (4)$$

Equation (4) can be simplified by using the equivalent infinitesimal principle. Because of  $A_{\text{sys}} \in [0, 1]$  and  $\text{EBO}(s_{i,j}) \geq 0$ , finding the maximum value of system availability is equivalent to finding the minimum value of stocking shortage. Therefore, the solution of availability is transformed into the solution of stocking shortage and finally into the solution of the spare parts stocking decision of the service system [27].

EBO represents the LRUs' expected shortage when the service system stocking level is  $s_{i,j}$ . EBO can be expressed as

$$\text{EBO}(s_{i,j}) = \sum_{x=s_{i,j}+1}^{\infty} (x - s_{i,j}) p(x|N_{i,j}), \quad (5)$$

where  $N_{i,j}$  is the intermediate variable of the optimization model. It represents the average number of LRUs in maintenance status. After maintenance activities, it can be provided to the system again as new spare parts for storage. According to the Palm theorem, when the LRU demand obeys the Poisson process with mean value  $\lambda$  and the mean repair time is  $T$ , the steady-state probability distribution of  $N$  obeys the Poisson distribution with the mean value  $\lambda T$  [26]. That means

$$N = \lambda \cdot T. \quad (6)$$

Set the number of LRU<sub>*i*</sub> failures in a single cycle to  $\lambda_i$ . After inspection, the number of hard failures is set to  $\lambda_{ih}$ , and the number of soft failures is set to  $\lambda_{is}$ . Their relationship can be expressed as follows:

$$\lambda_i = \lambda_{ih} + \lambda_{is}. \quad (7)$$

In the case of multiple failure modes, the expected shortage of LRU<sub>*i*</sub> should also be divided into Depot expected shortage  $\text{EBO}(s_{i,0})$  and Base expected shortage  $\text{EBO}(s_{i,j})$ .

Since the failed spare parts in soft failure mode are repaired in Depot, the number of parts under repair in Depot is

$$N_{i,0} = \lambda_{is} \cdot T_{i,0}. \quad (8)$$

Bring (8) into (5), and LRU<sub>i</sub> expected shortage at the Depot is

$$EBO(s_{i,0}) = \sum_{x=s_{i,0}+1}^{\infty} (x - s_{i,0})P(x|\lambda_{is} \times T_{i,0}), \quad (9)$$

where  $EBO(s_{i,0})$  is a stocking-related variable. When the operating system fails, a replenishment request is sent to the Base for the first time. If the Base is short of spare parts, a request would be sent to the Depot. Due to the ordering and transportation time  $O_{i,j}$ , the number of spare parts under repair of Base  $j$  should consider transportation spare parts:

$$N_{i,j} = N_{i,j}^1 + N_{i,j}^2. \quad (10)$$

The number of parts under repair  $N_{i,j}^1$  in Base is

$$N_{i,j}^1 = \lambda_{ih,j} \cdot T_{i,j}. \quad (11)$$

The number of parts under transportation  $N_{i,j}^2$  should consider two situations:

- (1) When Depot has spare parts stocking, the number of spare parts under repair is the number sent to Depot:

$$N_{i,j}^{2'} = \lambda_{is,j} \cdot O_{i,j}. \quad (12)$$

- (2) When the Depot is short of spare parts, the spare parts should be sent back to Base after being repaired at Depot. The average number of spare parts waiting for maintenance is equal to the expected shortage:

$$N_{i,j}^{2''} = \lambda_{is,j} \cdot f_{i,j} \cdot \frac{EBO(s_{i,0}|\lambda_{is}T_{i,0})}{\lambda_{is}}, \quad (13)$$

where  $f_{i,j} = \lambda_{is,j}/\lambda_{is}$ , which indicates the proportion of LRU<sub>i</sub> sent by Base  $j$ . Based on the above analysis, the number of spare parts under repair in a single cycle can be expressed as

$$\begin{aligned} N_{i,j} &= N_{i,j}^1 + N_{i,j}^{2'} + N_{i,j}^{2''} \\ &= \lambda_{ih,j} \cdot T_{i,j} + \lambda_{is,j} \left[ O_{i,j} + f_{i,j} \cdot \frac{EBO(s_{i,0}|\lambda_{is}T_{i,0})}{\lambda_{is}} \right]. \end{aligned} \quad (14)$$

Therefore, the expected shortage of Base is a variable related to stocking level and expected shortage of Depot:

$$EBO(s_{i,j}) = \sum_{x=s_{i,j}+1}^{\infty} (x - s_{i,j})P(x|N_{i,j}). \quad (15)$$

**3.2. Mathematical Model of Service Logistics Cost.** The service logistics cost includes the spare parts stocking holding cost as well as maintenance cost and resource allocation cost. In general, maintenance cost and resource allocation cost are often defined in the LORA decision optimization model. If multiple failure modes are considered in service decisions, we find that the steps of iterating LORA model input variables can be simplified.

Maintenance service decisions usually include two kinds of decisions: on-site repair or move to repair. The decision cost can be expressed as  $vc_{i,j,d}$ ,  $d \in \{\text{repair}, \text{move}\}$ . The resource allocation cost can be expressed as  $rc_{r,j}$  ( $j = 1, 2, 3, \dots$ ).

In the case of the single failure model, maintenance service decisions and resource allocation decisions are selected by the method of repeatedly iterating the possibility of all maintenance sites. In the case of multiple failure modes, we believe that different levels of maintenance site service different failure modes and configure different resources. Therefore, the LORA decision model can be simplified as

$$\min \left[ \sum \sum \lambda_{ih,j} \cdot vc_{i,j,\text{repair}} + \sum \sum \lambda_{is,j} \cdot (vc_{i,j,\text{move}} + vc_{i,0,\text{repair}}) + \sum \sum rc_{r,j} \right]. \quad (16)$$

**3.3. Mathematical Model of Spare Parts Stocking Decision Strategy and Service Logistics Cost.** Combining (1) and (16),

we can obtain the spare parts stocking decision strategy and service logistics cost optimization model:

$$\text{s.t.} \begin{cases} \min & \left[ \sum \sum fc_{i,j} \cdot s_{i,j} + \sum \sum \lambda_{ih,j} * vc_{i,j,\text{repair}} + \sum \sum \lambda_{is,j} * (vc_{i,j,\text{move}} + vc_{i,0,\text{repair}}) + \sum \sum rc_{r,j} \right], \\ \text{s.t.} & A(s_{i,j}) \geq A_{\min} \quad (i = 1, 2, 3, \dots; j = 0, 1, 2, 3, \dots), \\ & \lambda_{ih} + \lambda_{is} = \lambda_i \quad (i = 1, 2, 3, \dots). \end{cases} \quad (17)$$

Literature [12] designed an algorithm of splitting and enumerating one by one when solving the two-echelon spare parts stocking decision model. The authors represent the

relationship between components and repair resources with a special graph, in which the vertex represents a resource and the edge represents components. The depth first search

algorithm is used to find the optimal solution. The advantage of this algorithm is intuitive and easy to understand, but the disadvantage is that it needs to be enumerated one by one, and the amount of calculation is huge. Therefore, it is necessary to find a new algorithm to solve the model in this paper.

When solving the lowest spare parts stocking holding cost, a greedy heuristic algorithm is often used [28]. The authors of [10] proposed an approximate method for solving joint optimization, iterative algorithm, but they did not mention spare parts stocking decision optimization, which makes iterative algorithm difficult to solve the model in this paper. Therefore, we improve an iterative greedy heuristic algorithm [23] to solve the optimization model, as shown in Figure 3.

Greedy heuristic algorithm is often used in the decision-making of repairable system spare parts stocking. This algorithm can realize a fast search but can only find a local optimal solution. Iterative method is often used in joint optimization of maintenance level and spare parts allocation strategy. This algorithm traverses the whole world by iterating one by one, but it takes a long time. Combining the advantages of the above two methods, an iterative greedy heuristic algorithm is developed in this study. By iterating spare parts stocking, the local optimal solution of all spare parts allocation strategies is calculated to find the global optimal solution.

The algorithm focuses on balancing spare parts allocation and cost. According to the VAR-METRIC theory [26], we use the marginal analysis method to set the initial stocking of spare parts as 1, increase one stocking step by step until the target availability is met, and then end the algorithm. When the algorithm obtains several groups of Base and Depot stocking combinations, we select the optimal combination to guarantee the system cost.

Step 1: set  $s_{i,j} = 1 + k$ ;  $s_{i,0} = 1 + k$ .

$k$  indicates the number of iterations.  $k = 0$  indicates that the initial stocking level of Base and Depot is 1.

Step 2: set  $\delta_{i,j} = \text{EBO}(s_{i,j}) - \text{EBO}(s_{i,j} + 1)/fc_{i,j}$ ;  $\delta_{i,0} = \text{EBO}(s_{i,0}) - \text{EBO}(s_{i,0} + 1)/fc_{i,j}$ .

$\delta$  is the marginal ability gene. It considers the marginal benefit of adding one item to the stocking [15].

Step 3: select the best value for  $\delta$ . Increase one unit in the stocking of item  $i$  at site  $j$ .

Step 4: calculate the actual availability  $A$ :

if  $A < A_{\min}$ ,  $k = k + 1$ , go to step 2;

if  $A \geq A_{\min}$ , stop the calculation.

Step 5: adjust the stocking parameter and input it into the service logistics cost optimal model.

The iterative process will produce multiple sets of spare parts stocking allocation strategy combinations, and the calculation will stop when the calculated availability is greater than the target availability, which is the local optimal solution of a combination. In this study, the local optimal solutions of all combinations are extracted, and the cost is

calculated. The global optimal solution can be found from the local optimal solution.

Generally speaking, the iterative algorithm can be stopped when the availability satisfies the target availability for the first time. At this moment, the service logistics cost is the optimal cost. In order to be able to traverse the global optimal solution, iteration stops when stocking increases to the number of LRU assemblies ( $M_{i,j}$ ).

## 4. Numerical Experiment

*4.1. Optimization Calculation.* In this section, the energy system of a large-scale laser device is taken as an example to verify the validity of the model and algorithm. The energy system includes 96 homogeneous energy modules. Each module includes three key LRUs: Control Communication module ( $\text{LRU}_1$ ), Gas Switch module ( $\text{LRU}_2$ ), and Trigger module ( $\text{LRU}_3$ ). Due to the different tasks completed by these three LRUs, they were assigned to three different Base sites and managed by the same Depot site, as shown in Figure 4.

These three LRUs will fail randomly. In the study of large-scale system maintenance strategy, literature [29] considered the impact of failure on the delay time of system tasks when distinguishing failure mode. In this example, when distinguishing between hard failure and soft failure, we also consider the impact of failure on system task effect. We attribute the failure that leads to system task cancel to soft failure and the failure that continues to perform tasks through repair at the Base site to hard failure. The specific failure data are shown in Table 2.

Compared with soft failure, hard failure has less impact on system task results and maintenance difficulty. Therefore, the maintenance resource cost of hard failure is lower than that of soft failure. The advantage of soft failure centralized maintenance is to reduce the difficulty and cost of operating environment configuration. To ensure the execution of tasks, large-scale systems have high requirements on the availability of spare parts. We set the minimum availability requirement at 0.98. The specific parameters and cost settings of the optimization model are shown in Table 3.

Spare parts stocking decision cost, maintenance cost, and resource allocation cost of Depot are not comparable with Base. We assume that the transportation costs between the two echelons are the same, and the maintenance resources and components have a one-to-one maintenance relationship. The specific maintenance parameters are shown in Table 4.

According to the iterative greedy heuristic algorithm, we set the initial stocking allocation decision: Base (1, 1, 1) Depot (1, 1, 1). The calculated availability does not meet the requirements obviously. In the iterative process, we can get multiple sets of spare parts stocking allocation combinations. Under the constraints of limited resources, the guaranteed availability calculation results of each combination are shown in Table 5.

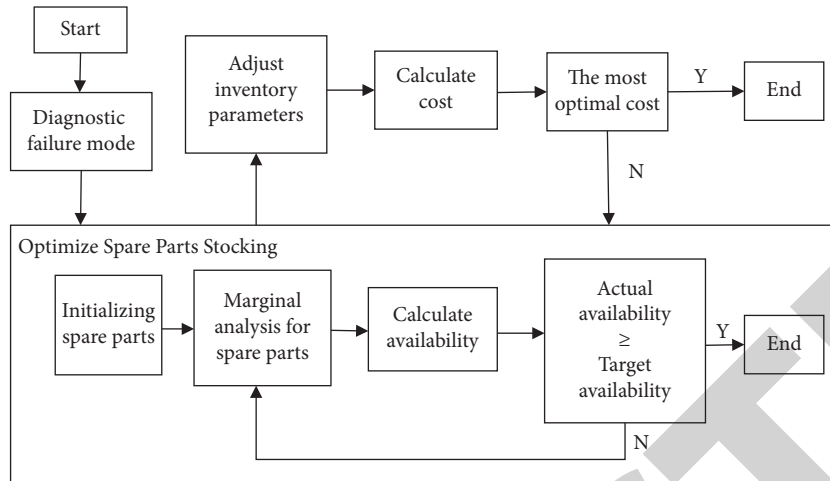

FIGURE 3: The improved iterative greedy heuristic algorithm.

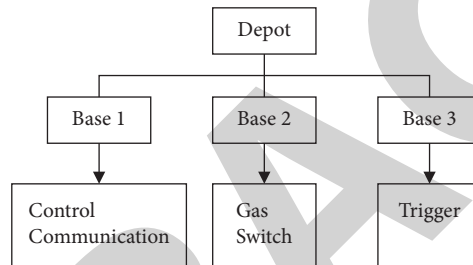

FIGURE 4: Two-echelon service logistics structure of three LRUs.

TABLE 2: LRUs' failure data.

Failure mode	Control communication (LRU <sub>1</sub> )			Gas switch (LRU <sub>2</sub> )			Trigger (LRU <sub>3</sub> )		
	Failure cause	Quantity	Influence	Failure cause	Quantity	Influence	Failure cause	Quantity	Influence
Hard failure	Communication blocking	3	Restart	Communication blocking	3	Restart	Communication blocking	1	Restart
	Software failure	3	Restart	Electromagnetic interference	3	Restart	Electromagnetic interference	1	Restart
	Electromagnetic interference	6	Restart	Barometric instability	2	Delay time	Unstable pilot tube pressure	1	Delay time
Soft failure	PLC controller damaged	3	Cancel	Insulation performance degradation	8	Cancel	Pilot tube performance degradation	10	Cancel
Total		17			16			13	

Extract the three groups of stocking decisions in Table 5 and calculate the service system cost by using formula (17), respectively. The results are shown in Table 6.

We get that the optimal cost is  $214.7 * 10^6$  yuan, and the optimal stocking allocation decision is Base (3, 4, 4) Depot (1, 1, 2). The optimization result conforms to the idea of an iterative greedy heuristic algorithm. That is, when the actual availability meets the minimum requirement, the stocking allocation decision is the optimal decision. Due to the simplified optimization model, the spare parts stocking is the only variable parameter, and the optimal stocking allocation decision guarantees the optimal service logistics cost.

Introducing multiple failure modes into the joint spare parts stocking decision and repair level optimization model can simplify the optimization process and make the optimization results more intuitive and easier to understand.

Combining the results in Tables 4 and 5, it can be found that when the Depot stocking level is (1, 1, 1), no matter how many times the Base stocking iterations are, it cannot satisfy the system availability requirement. This is because the stocking level of Depot plays a decisive role in the system availability. We analyze the relationship between Depot stocking level and system availability in the next section.

TABLE 3: LRUs' parameters.

Parameter cycle: 100 days	Depot

$rc_{r,j}$ * 10 <sup>6</sup> yuan	3	4	5	4	6	8

4.2. *The Relationship between Depot Stocking Level between System Availability.* We select the data in Table 4 and set the horizontal axis as the total stocking level  $S$  of Depot and Base. The vertical axis indicates the system availability, as shown in Figure 5.

Obviously, the improvement of stocking level is very important to improve system availability. In particular, increasing the stocking level of LRU<sub>3</sub> improves the availability significantly.

Because LRU<sub>3</sub> has the largest number of soft failures, it is the most difficult to repair. The optimization model will consider LRU<sub>3</sub> as a key factor affecting decision-making. We can also analyze the importance of the three LRUs under different availability requirements.

4.3. *Importance Analysis of LRUs.* Under different availability requirements, the optimal stocking allocation decisions are shown in Figure 6.

It can be seen that, in the process of improving availability requirements, the ratio of LRU<sub>3</sub> is always the highest. And the ratio of LRU<sub>1</sub> is always the lowest. Compared with LRU<sub>3</sub>, LRU<sub>1</sub> is the factor with the lowest EBO in Depot. Therefore, LRU<sub>1</sub> has the lowest ratio in stocking allocation.

In the lower availability requirement stage (0.80~0.93), the stocking ratio of LRU<sub>2</sub> is the same as LRU<sub>3</sub>. In the higher availability requirement stage (0.93~0.99), the impact of LRU<sub>2</sub> on optimization decision is reduced. This means that as the difficulty of improving availability increases, the allocation of resources concentrates on the most difficult parts to repair.

From the above analysis, it can be seen that (1) the stocking level of the Depot plays a decisive role in ensuring the availability of the system; (2) the LRU with the highest failure rate has the highest influence on the stocking

allocation decisions. In order to improve system availability, repairing time  $T_{i,j}$  is also a key factor that cannot be ignored.

4.4. *Repairing Time Impact Analysis.* We reduce Depot repairing time and Base repairing time, respectively. The above optimization results are reversely iterated. The changes in the availability of stocking allocation decisions are shown in Table 7.

It is obvious that reducing Depot repairing time can improve the availability of service logistics system significantly. At this point, the stocking allocation decision is Base (3, 4, 4) Depot (1, 1, 1). According to the calculation, the service logistics cost of this decision is 206.7 \* 106 yuan, saving 8 \* 106 yuan. However, the reduction of Base repairing time has little effect on the optimization results, which only shows that the availability is improved slightly. From this point of view, Depot repairing time is a key factor that could affect both system availability and service logistics cost.

Reducing Depot repairing time can save a lot of service logistics costs. However, if the Depot's maintenance capacity and stocking resources are limited, the improvement of system availability needs to consider the fronting failure mode. That is, soft failure spare parts are allocated at base site.

4.5. *Fronting Failure Mode.* Combined with Table 4 and Figure 5, we find that when the stocking level of the Depot is (1, 1, 1), no matter how to increase the stocking level of Base, the availability of the service logistics system would never meet the minimum availability requirement.

Fronting failure mode is required.

We consider the front "insulation performance degradation" of LRU<sub>2</sub> and the "pilot tube performance degradation" of LRU<sub>3</sub> into Base site. Their impact on the task of the operating system changes from "cancel" to

TABLE 5: The system availability of different stocking allocation decisions.

3	4	4	1	1	2	214.7
3	3	3	1	2	2	217.9
3	3	3	1	2	3	225.9

FIGURE 5: Relationship between stocking level and system availability.

“delay time.” The repairing time, spare parts stocking decision cost, and other parameters should be changed accordingly. Fronting failure mode will increase the cost of resource configuration, increase the category of spare parts at the Base maintenance point, and reassign parameters in the optimization model. The specific data are shown in Table 8.

After optimization, the stocking allocation strategy is Base (3, 3, 4) Depot (1, 1, 1), the availability is 0.9803, and the service

logistics cost is 230.9 \* 106 yuan. Thus, if the maintenance capability of the Base could cope with soft failure mode, then the availability of the service logistics system would be improved greatly.

In conclusion, Depot repairing time and Base maintenance capacity are key factors affecting the service logistics system. Reducing Depot repairing time could save service logistics costs; improving Base maintenance capability could improve system availability.

## 5. Conclusion

In this paper, we construct a two-echelon service logistics cost optimization model for large-scale systems. Considering the influence of multiple failure modes on spare parts stocking decisions, the joint optimization model of spare parts stocking decision and repair level was simplified. The iterative greedy heuristic algorithm is improved to find the global optimal solution of stocking allocation strategies. Finally, the validity of the model and algorithm is verified by a practical engineering case.

The contributions and innovations of this paper are as follows: (1) Multiple failure modes are introduced into the joint optimization model to fundamentally simplify the

LORA decisions and reduce the calculation process of the service logistics cost optimization. (2) The improved iterative greedy heuristic algorithm can effectively traverse the global optimal solution. (3) Depot stocking level plays a decisive role in ensuring system availability, and LRU with the highest failure rate has the highest influence on stocking allocation decisions. (4) Depot repairing time and Base maintenance capability are key factors affecting the service logistics system. Reducing Depot repairing time could save costs; improving Base maintenance capability could improve system availability.

As a further improvement, multiple failure modes would lead to discard risk. The maintenance strategy of soft failure could choose imperfect repair. A multiechelon service

logistics system has a potential stocking. The increase of echelons will lead to the increase of stocking iterative combination and the complexity of the algorithm. It can be solved by an improved genetic algorithm [30, 31] and ant colony algorithm [32]. Asset management related to life cycle cost should be considered in maintenance decision-making and spare parts stocking decision management.

## Data Availability

The rapid development of social economy not only increases people's living pressure but also reduces people's health. Looking for a healthy development prediction model has become a domestic concern. Based on the analysis of the influencing factors of health development, this paper looks for a model to predict the development of public health, so as to improve the accuracy of health development prediction. In this paper, the linear sequential extreme learning machine algorithm can be used to evaluate the health status of a large number of data, analyze the differences of each evaluation index, and construct the analysis model of health status. Therefore, this paper introduces rough set theory into linear sequential extreme learning machine algorithm. Rough set can analyze the double analysis of evaluation scheme, predict the health development of different individuals, and improve the evaluation accuracy of mass health evaluation. The simulation results show that the improved line sequential extreme learning machine algorithm can accurately analyze the mass health and meet the needs of different individuals' health evaluation.

## 1. Introduction

With the acceleration of the pace of life and the increase of people's work pressure, people pay more and more attention to their health. People pay attention to their own health. Health is divided into subhealth, health, and various diseases. However, due to the individual differences, basic diseases, and their own health quality, the health judgment scheme cannot effectively meet the needs of the public [1]. The survey results show that by 2020, the number of patients with health abnormalities in China will reach 2232/100000, and by 2030, this data will increase by 30%. Among them, 20% of the underground people are unable to take corresponding measures in time due to unreasonable prediction. Therefore, it is an urgent problem to formulate an effective judgment scheme according to personal constitution. Local governments, society, and nongovernmental organizations regularly monitor their health to let the public know their health [2]. At the same time, local governments should also elaborate on the methods of health prediction and publicize

them through television, Internet, and other channels. At present, the key of health prediction is how to evaluate relevant indicators and guide different individuals to carry out health test [3]. Some scholars believe that the formulation of health prediction scheme should be combined with personal situation, carry out multiangle regression analysis, and determine the impact of different factors on the test results. Some scholars also believe that the reasonable formulation of health prediction scheme and test plan will enable the public to more accurately understand their health condition; otherwise, it will affect the public's health. At present, there are many methods to analyze mass health, mainly including Bayesian method, genetic algorithm, time series algorithm, and differential evolution algorithm based on vague local search strategy [4]. However, the above algorithm only makes a unified analysis of mass health and cannot realize the differential analysis of different bodies. In order to solve this problem, some scholars put forward the health prediction model based on the combination of rough analysis method and linear sequential extreme learning

machine and analyzed the mass health index by using rough set. Rough set method is used to couple the eigenvalues of the data in the health index, and the eigenvalues are extracted by threshold [5], penalty coefficient, weight coefficient, and mean value to obtain more accurate pre-processed data. It can be seen that the linear sequential extreme learning machine algorithm has been applied in the healthy development, but there are few application cases, which need to be further analyzed. Linear sequential extreme learning machine method has the advantage of continuous prediction of healthy development, and rough set has the advantage of massive data processing. The combination of the two can carry out continuous analysis of healthy development prediction. The difference analysis of linear sequential extreme learning machine and its own iterative operation can obtain the optimal set of health data. Among them, the constraint conditions and constraint coefficients can avoid the local extremum problem and improve the efficiency of the calculation results [6]. To sum up, domestic scholars' research on health prediction and analysis mainly focuses on the improvement of indicators, ignoring the coupling between indicators and the rationality of prediction scheme. Therefore, the prediction of healthy development urgently needs a model that can always carry out coupling analysis of various indicators. However, there is less research on continuous prediction of healthy development in China, and there is less research on the application of rough set and linear sequential extreme learning machine. Compared with China, there are many researches on online sequential extreme learning machine abroad, and it is combined with k-clustering and rough set to evaluate the healthy development and achieved good results. So, it is urgent to improve the linear sequential extreme learning machine and apply it to the prediction of healthy development. On this basis, in order to find a more effective model, the improvement of line sequence extreme learning machine and its application to healthy development prediction have become the key to solve the above problems. In addition [7], a single analysis of mass health will not only reduce the accuracy of evaluation results but also affect the future prediction of health. In addition, although the linear sequential extreme learning machine can carry out iterative analysis and predict the mass health, it cannot analyze the individual health. Some scholars believe that the combined analysis of personality and unity can promote the development of health prediction and play a positive role in the improvement of health [8]. Therefore, by optimizing the line sequential extreme learning machine algorithm and combining the rough set processing method, we can accurately evaluate the mass health and obtain the Pareto optimal set. Based on the above theoretical analysis, this paper proposes an improved line sequential extreme learning machine to study mass health [9]. The specific content includes three aspects: the first part introduces the research status of rough set line sequential extreme learning machine and mass health. In the second part, an improved line sequential extreme learning machine algorithm is constructed, and the numerical judgment and constraints of rough set are explained. The third part verifies and analyzes

the improved line sequential extreme learning machine algorithm to judge the accuracy and time of mass health calculation [10]. Compared with other studies at home and abroad, this paper optimizes the line sequential extreme learning machine algorithm and combines this method with rough set to obtain the Pareto optimal set under the constraint coefficient [11]. Through the joint analysis of unified health judgment and individual health, we can realize the dual verification of the above two aspects, improve the accuracy of the analysis results, promote the reasonable construction of health evaluation scheme, and finally achieve the purpose of improving mass health.

## 2. The Algorithm Description Based Online Sequential Extreme Learning Machine

The linear sequential extreme learning machine algorithm was first applied to the diagnosis of space engine. It can predict the abnormal situation of aircraft through equal weight processing of data. However, the algorithm cannot realize the analysis of massive data, and the speed of processing massive data is slow. Rough set is a set proposed by Pawlak Z. It can comprehensively process incomplete data through induction, learning, and mining to build a relatively clear and concise data system to support subsequent composition analysis. Based on the above analysis, this paper uses rough set theory to collect mass physical health data [12], supplement incomplete data and indicators, and finally get a clearer data system. The specific data processing flow is shown in Figure 1.

As can be seen from Figure 1, the first step is to obtain physical health data, analyze the data types, and classify them according to the types. The second step is to formulate physical health plan or adjust the plan according to the analysis results of physical health data. The third step is to test the physical health of the masses, compare the effects of different exercise methods, and record the matching results between the exercise scheme and the masses. The fourth step is to record the optimal matching scheme into the database and eliminate the mismatched evaluation scheme. Medical institutions, rehabilitation centers, elderly care centers, sports centers, and fitness centers in four provinces were observed, and preliminary unified data were obtained by means of video recording, heartbeat detection, and vital capacity test. Combined with relevant domestic literature [13], 23 physical health indexes and 12 physical health evaluation indexes are obtained. After experts' determination and 120 sampling questionnaires, there is no significant correlation between the above indexes, which can be used as evaluation indexes and samples. The visit sites are located in the northeast, northwest, southeast, and southwest [14], as well as north and central China. The access data come from online questionnaires, actual data collection, official published materials, and other internal materials. The time span of accessing data is 2–3 years, and the personnel span is more than 4. The validity and reliability of the survey results were >0.7. Finally, specific evaluation indicators are obtained, as shown in Table 1.

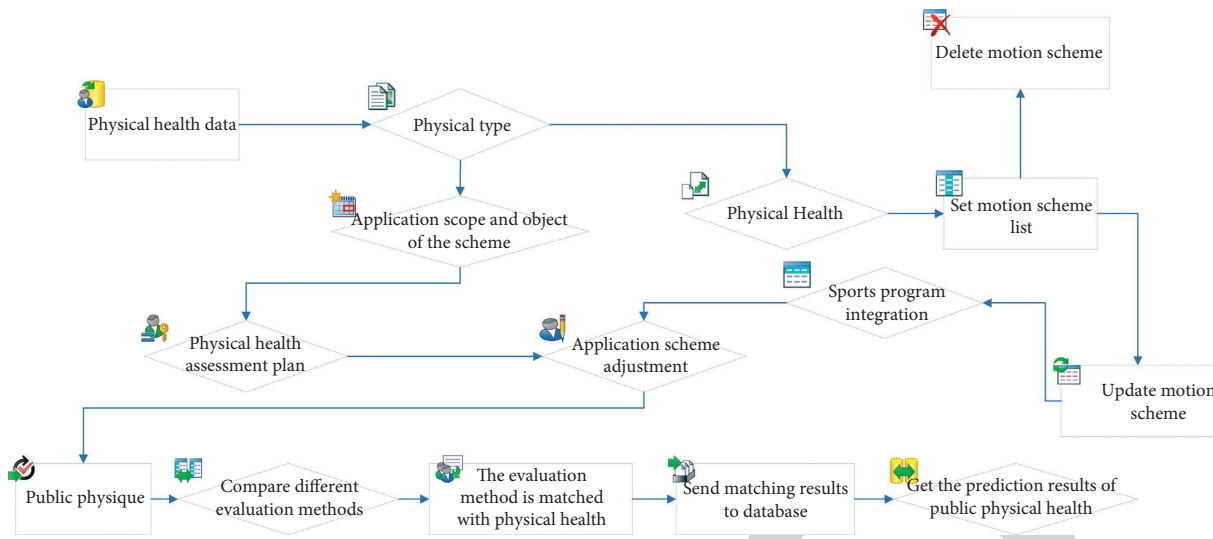

FIGURE 1: The data processing process of physical health development prediction.

TABLE 1: The mass physique and health evaluation index.

The index category		The quantity	The correlation with other indicators
Amount of exercise	Type of motion	4	0.232
	Exercise time	3	0.767
	Exercise intensity	2	0.562
Body function	Blood oxygen content	9	0.222
	Respiratory rate	4	0.721
	Cardiac blood supply	6	0.492
	Lung volume	3	0.662
	Inflammatory factor index	2	0.892

Note. There is no significant correlation between the indicators, and the reliability and validity are >0.7. The data come from online literature and actual survey.

### 3. The Prediction Model of Physical Health Development Based on Linear Sequential Extreme Learning Machine Algorithm Matrix Is Established

3.1. Improved Line Sequence Extreme Learning Machine Algorithm Matrix. First, add rough sets. In the physical health analysis, the physical health database, physical prediction database, and their correlation database are established by rough set method. Then, rough set uses the above database to analyze the algorithm matrix of linear sequential extreme learning machine and determine the mass constitution. In the process of analysis [15], the weight of different physical health prediction schemes is determined through the correlation, dependence, and correlation between physical health prediction schemes and mass physique. Due to individual differences, basic diseases, knowledge level, and other factors, there are deviations in the impact of the prediction scheme on the prediction results of physical health. Rough set regulates the calculation direction of feature data by setting penalty value, avoids the local extremum problem of line sequential extreme learning machine algorithm matrix, and improves the accuracy of calculation results.

Second, add discrete clustering. The data in rough set present discrete state. Although the weight coefficient is set, it is still unable to realize the continuous analysis of data. How to use finite eigenvalues and feature points to construct continuous rough set sequences is the key of this paper [16]. In this paper, rough set is introduced to classify eigenvalues, and discrete data sequences are constructed by using the correlation and complementarity between adjacent features. At the same time, rough set uses the concept of fuzzy mathematics to eliminate the eigenvalues with high dispersion, calculate the membership relationship between eigenvalues more accurately, and realize the data optimization of linear sequential extreme learning machine algorithm matrix. The improvement process of linear sequential extreme learning machine algorithm matrix is shown in Figure 2.

According to the analysis in Figure 2, rough set analysis is carried out on structured and semistructured data to realize data coupling, fusion, and eigenvalue extraction. Rough set realizes the preprocessing of mass health data. Rough set realizes the orderly arrangement of characteristic data, improves the accuracy of data processing, reduces the data processing time, and increases the amount of pre-processed data.

FIGURE 2: The physical health assessment scheme and prediction.

**3.2. Analysis of Mass Physical Health Evaluation Scheme Based on Linear Sequential Extreme Learning Machine Algorithm Matrix.** In the case of individual differences, the physical health evaluation scheme has a significant impact on the evaluation results, and there are significant differences in the effects of blood oxygen index, blood pressure, and heart rate [17]. Although the linear sequential extreme learning machine algorithm matrix can carry out progressive analysis on mass physical health data, the analysis results are discrete. Rough set can cluster the discrete results, submit the accuracy of the results, and arrange the eigenvalues of the results in order. Rough set can double analyze the physical health scheme and physical data, so as to further improve the accuracy of the results. Therefore, the combination of linear sequential extreme learning machine algorithm matrix and rough set can orderly arrange the characteristic data, improve the accuracy of data analysis results, and realize the double evaluation of mass physical health. The specific evaluation scheme is shown in Figure 3.

It can be seen from Figure 3 that different masses adopt different physical fitness assessment scheme, and different schemes will also have different effects on physical health. Therefore, we should adjust the physical fitness assessment

scheme according to the individual differences of masses, so as to achieve the best regulation of physical health.

### 3.3. The Algorithm Construction

**3.3.1. Objective Function Construction of Physical Health Evaluation.** Assuming that the evaluation objective of physical health is  $X$ ,  $y_i$  is the physical fitness assessment scheme,  $i$  is the exercise program number, and  $j$  is the correlation between the physical fitness assessment scheme and physical health,  $X_{ij}$  is the evaluation objective of any physical health; the calculation results are shown in

$$\min X = \sum_{i,j}^T f[x_{ij}(1 - x_{ij-1})]S_{ij} + \zeta(y_{ij}), \quad (1)$$

where  $S_{ij}$  is the implementation effect of  $j$  exercise program,  $\zeta(y_{ij})$  is the impact rate of  $j$  exercise program on physical health, and  $T$  is the implementation process of physical fitness assessment scheme.  $\zeta(y_{ij})$  is the influence rate of the evaluation scheme; the calculation results are shown in

$$\zeta(y_{ij}) = \alpha_i + \beta_i y_{ij-1} + \chi_i y_{j-1}^2, \quad (2)$$

FIGURE 3: The implementation process of linear sequential extreme learning machine algorithm matrix.

where  $\alpha_i$ ,  $\beta_i$ , and  $\chi_i$  are the influence coefficients of the evaluation scheme.

### 3.3.2. Evaluation Function Construction of Aerobic Regimen.

It is assumed that the evaluation  $H$  of aerobic scheme is in three states: scientific and reasonable state  $a_i$ , vague state  $b_i$ , and negative influence state  $d_i$ ; the calculation results are shown in

$$H(y_{ij}) = \prod_{i=1}^T \sum_{i=1}^T A_{ai} + B_{bi} + Cc_i. \quad (3)$$

Among them,  $A$ ,  $B$ , and  $C$  are the evaluation coefficients, and  $T$  is the time node of different evaluation schemes. The evaluation coefficient is mainly determined by the mass health association, aerobic fitness association, and Chinese Medical Association. At the same time, the evaluation coefficient of each region can be adjusted according to the statistical data of 10 years, and the adjustment proportion is less than 0.3.

3.3.3. Construction of Constraint Function. It is assumed that the upper limit of the evaluation result of physical fitness assessment scheme is  $L_{max}$  and the lower limit is  $L_{min}$ . The upper limit of physical health evaluation was  $l_{max}$ , and the lower limit was  $l_{min}$ . The calculation results are shown in

$$Z(X, H) = \sum_{\min=0}^{\infty} \frac{\max(X, H) - (A_{ai} + B_{bi} + Cc_i)'}{(A_{ai} + B_{bi} + Cc_i)' - \min(X, H)} \cdot \prod_{\min} f[x_{ij}(1 - x_{ij-1})]S_{ij}', \quad (4)$$

where  $\max(X, H)$  is the maximum value set of evaluation results,  $\min(X, H)$  is the minimum value set of evaluation

results, and  $(A_{ai} + B_{bi} + Cc_i)'$  is any maximum value.  $S_{ij}'$  is optimal physical fitness assessment scheme. The specific construction process is shown in Figure 4.

It can be seen from Figure 4 that the calculation process of physical fitness assessment scheme and physical health prediction exceeds the expected maximum and minimum values, indicating that the setting of constraints can limit the differential evolution process of vague local search strategy. At the same time, the physical fitness assessment scheme and the improvement of physical health did not change significantly, showing regular ups and downs. At the same time, the following picture in Figure 4 shows a large depression, indicating that the data here are an inflection point. However, the data in the depression still changes smoothly, which further shows that the data processing effect is better.

3.4. The Construction of Linear Sequential Extreme Learning Machine Algorithm Matrix. The linear sequential extreme learning machine algorithm matrix based on vague local search strategy is mainly in three aspects. The calculation results are shown in

$$|E| = Z(\cdot) \times \begin{cases} \sum_{i,j=0}^n \frac{x_{ij}, y_{ij}}{\dots} \\ \sum_{i=0}^n S_j^{H((2\pi/2)(x_{ij}, y_{ij}))} \end{cases}, \quad (5)$$

where  $x_{ij}$  and  $y_{ij}$  are the approximate set of  $x_{ij}$  and  $y_{ij}$ , and  $|E|$  is the coupling set.  $i \neq j$ ,  $i, j \in \{1, \dots, n\}$ ,  $\cup_{i,j=1}^n X_{ij}, H_{ij} = U$ .  $U$  is the correlation between  $X_{ij}$  and  $H_{ij}$ . The second aspect is to cluster discrete eigenvalues by using rough set method to reduce the discreteness of eigenvalues. The specific formula is as follows.

FIGURE 4: The constraint analysis of physical fitness assessment scheme and physical health prediction.

Assuming the sample set  $X = \{x_{11}, x_{12} \cdots x_{ij}\}$ ,  $H = \{h_{11}, h_{12} \cdots h_{ij}\}$ , the clustering center  $V$  of each dimension is shown in

$$V = \{v_{11}, v_{12} \cdots v_{ij}\}. \quad (6)$$

The membership matrix  $u$  of each cluster center  $V$  is shown in the formula. The calculation results are shown in

$$u = \begin{bmatrix} u_{11} & \cdots & \cdots & u_{1j} \\ \vdots & \ddots & & \vdots \\ u_{i1} & & & u_{ij} \end{bmatrix}, \quad (7)$$

where  $u_{ij}$  is the subordinate relationship between the sample  $u_i$  and  $u_j$ . The formula of rough set function is shown in

$$\min F(u_{ij}, v_i) = \sum_{i=1}^{\tau} \sum_{j=1}^{\tau} u_{ij}^{\tau} (x_{ij} - v_i), \quad (8)$$

where  $\tau$  is the clustering index between  $X_{ij}$  and  $H_{ij}$ . The calculation of  $v_i$  cluster center is shown in

$$v_i = \frac{x_{ij}}{\sum_{i=1}^{\tau} u_{ij}^{\tau} (x_{ij} - v_i)} \sum u_{ij}^{\tau} (x_{ij} - v_i). \quad (9)$$

The calculation of membership relationship is shown in

$$u_{ij} = \frac{(1/\Delta x_{ij})^{1/(\tau-1)}}{\sum_{i=1}^{\tau} [1/(\Delta x_{ij} - v_i)]^{1/(\tau-1)}}. \quad (10)$$

The third aspect is to determine the weight coefficient. In order to more accurately analyze the physical fitness assessment scheme and realize the comprehensive evaluation of the impact of physical health [18], the weight of each index should be assigned. At the same time, the weight assignment

can avoid the local extreme value problem and improve the accuracy of the evaluation results. Firstly, each objective function is regarded as a conditional attribute [19], its weight is obtained, and the optimal template function  $X$  value is calculated. Secondly, the evaluation template attribute set is obtained [20]. The optimal scheme obtained under different physical fitness assessment scheme is  $h$ ; then, any physical fitness assessment scheme in  $X$  is  $u_{ij}$ .

Therefore, the dependence between physical fitness assessment scheme and physical health evaluation is shown in the formula. Firstly, each objective function is regarded as a conditional attribute,  $w_i = 1/n_i$  weight is obtained, and the optimal template function  $X$  value is calculated. Secondly, the evaluation template attribute set  $D = \{X\}$  is obtained. The optimal scheme obtained under different physical fitness assessment scheme is  $H$ ; then, any physical fitness assessment scheme in  $X$  is  $u_i$ .

Therefore, the dependence between physical fitness assessment scheme and physical health evaluation is shown in

$$r_i(H) = \frac{\sum \rho[r_i[F]_D]}{\rho(u_i)}. \quad (11)$$

The degree of dependence between evaluation objectives is shown in

$$\Delta r_i(H) = \frac{\sum \rho[\Delta r_i[F]_D]}{\rho(\Delta u_i)}. \quad (12)$$

The importance of the  $i$ th physical health assessment is shown in

$$\sigma(X, H) = r_i(H) - \Delta r_i(H). \quad (13)$$

The weight between the  $i$ th physical health assessment and physical health is shown in

$$w_i = \sigma(X_i, H_i) / \sum \sigma(X, H). \quad (14)$$

In order to give weight more accurately, increase the residual value of weight change. The calculation results are shown in

$$w_i = \sigma(X_i, H_i) / \sum \sigma(X, H) + \xi, \quad (15)$$

where  $\xi$  is the residual value of weight, which is mainly determined by the development of physical health in different regions.

**3.5. The Output of Physical Health Evaluation Results under Linear Sequential Extreme Learning Machine Algorithm Matrix.** Firstly, the physical fitness assessment scheme output of different individuals: physical health is multidimensional, complex, and irregular, so it is affected by individual physical quality, basic diseases, training methods, training time, and other factors.

Assuming that different influence factors are  $k_i$ , the output of physical fitness assessment scheme under different factors is shown in

$$H(y_{ij})_k = v_i \cdot \prod_k \lambda \cdot \sum_{i=1}^T A_{ai} + B_{bi} + Cc_i, \quad (16)$$

$v_i$  is the data after rough set,  $k$  is the influencing factor,  $H(y_{ij})_k$  is the output optimal physical fitness assessment scheme, and  $\lambda$  is the differential evolution coefficient. Therefore, the application of rough set method improves the adaptability of physical fitness assessment scheme, meets the exercise needs of different individuals, and realizes the effective aggregation of discrete eigenvalues.

**3.6. Physical Health Evaluation Output of Different Physical Fitness Assessment Schemes.** Different physical fitness assessment schemes have different effects on physical health, so it is necessary to accurately evaluate physical health. Generally speaking, the improvement of physical health is judged in the form of ten-point system. Under the action of rough set, the output results of physical health evaluation are calculated. The calculation results are shown in

$$X_{H_i} = \frac{w_i \cdot \varsigma(y_{ij}) \sum_{i,j}^T f[x_{ij}(1 - x_{ij-1})] S_{ij} + \varsigma(y_{ij})}{v_i \cdot \prod_k \lambda \cdot \sum_{i=1}^T A_{ai} + B_{bi} + Cc_i}, \quad (17)$$

where  $H_i$  is different physical fitness assessment scheme and  $\lambda$  is the coefficient of differential evolution.

Secondly, the calculation steps of physical health evaluation results. Through the above analysis, the overall overview of physical health analysis can be obtained. The specific steps are as follows.

First, construct a rough set of the impact of such exercise on physical health, and form  $X = \{x_{11}, x_{12} \cdots x_{ij}\}$  and  $H = \{h_{11}, h_{12} \cdots h_{ij}\}$  sets.

Secondly, the data set is constrained, the clustering center  $V$  of the data is calculated, the weights of physical fitness assessment scheme and physical health are obtained,

and the corresponding iterative operation is carried out. If the calculation results  $X$  and  $H$  are greater than  $\max\{X, H\}$ , the results shall be included in the calculation results; otherwise, they shall be eliminated. If the calculation result is less than  $\min\{X, H\}$ , the result shall be included in the calculation result; otherwise, it shall be eliminated.

Third, when all 35 indicators are traversed, output  $H(y_{ij})_k$ ,  $X_{H_i}$ ; otherwise, repeat Step 2.

## 4. The Cases of Physical Health Assessment and Prediction

**4.1. The Research Data through the 35 Indicators Obtained from the Survey: A Case Study Is Carried Out.** The data in the case mainly comes from 6 randomly selected cities, and the verification method is mainly to compare before and after (note: the validity and reliability of the data are  $>0.7$ ) [21]. At the same time, the linear sequential extreme learning machine algorithm matrix is compared with the original algorithm (note: linear sequential extreme learning machine algorithm is not combined with rough set). The verification period is January, March, June, and December, and the exercise intensity is 60 H/week. The subjects were 25–65 years old, with an average age of  $32.2 \pm 2.32$  years [22]; BMI 23–40, average BMI  $28.2 \pm 1.12$ . Inclusion criteria: (1) Meet the 1994 edition of American diagnostic criteria for physical health. (2) The subjects had no previous physical health and circulatory diseases. (3) Get the consent of the ethics committee of the hospital and sign the informed consent form. (4) The tester can express himself. (5) The tester has some fitness experience. The results are shown in Table 2.

The data in Table 2 are the evaluation contents in different test time periods, mainly including training intensity and training score, and the data are from the experimental results and network literature. In order to ensure the accuracy of the test, the tester should be analyzed before the test. According to different methods, they were divided into improvement group and original group. The improved group adopts the differential evolution algorithm of improved vague local search strategy, and the original group adopts the differential evolution algorithm of vague local search strategy. The results are shown in Table 3.

It can be seen from Table 3 that there is no significant difference between the two groups in physical health, pulmonary respiratory capacity, blood pressure, quality of life, blood oxygen content, and pulse, so it can be compared and analyzed.

**4.2. Evaluation of Physical Fitness Assessment Scheme by Linear Sequential Extreme Learning Machine Algorithm Matrix.** The accuracy of physical fitness evaluation scheme evaluation is the key of evaluation. The linear sequential extreme learning machine algorithm improves the fuzzy local search strategy. The specific evaluation results are shown in Figure 5.

It can be seen from Figure 5 that the average accuracy of physical fitness assessment scheme is more than 90%, and the effective scheme is more than 60%. At the same time, the

FIGURE 5: The evaluation results of physical health.

effective program of physical health was the highest at 96% and then decreased. The results of this study are consistent with relevant domestic studies. The reason is that after the human physical health reaches the maximum limit, the body's self-protection mechanism starts, resulting in a decline in the improvement of physical health. The linear sequential extreme learning machine algorithm matrix is compared with the original algorithm, and the results are shown in Figure 6.

It can be seen from Figure 6 that the linear sequential extreme learning machine algorithm matrix has high evaluation accuracy of physical health, greater than 99%, while the accuracy of the original algorithm is greater than 90%; the results of this study are consistent with relevant domestic studies. This shows that the linear sequential extreme learning machine algorithm matrix is better in physical fitness assessment scheme. It can be seen from the figure that

the evaluation results of the two methods change smoothly. However, the model proposed in this paper changes straightly, while the original line sequence extreme learning machine algorithm changes at the positions of the 4th, 6th, 11th, 13th, 16th, 22nd, 24th, 26th, 28th, 32<sup>nd</sup>, and 33rd times. Therefore, the model proposed in this paper is better.

4.3. *The Evaluation of Physical Health by Linear Sequential Extreme Learning Machine Algorithm Matrix.* Physical health evaluation is the computational goal of differential evolution algorithm to improve vague local search strategy, and it is also an effective embodiment of physical health calculation. The evaluation results of physical health are shown in Figure 7.

It can be seen from Figure 7 that the changes of 35 physical health evaluation indexes are relatively stable,

FIGURE 6: The evaluation results of physical health under different algorithms.

FIGURE 7: The physical health evaluation results.

indicating that the contribution rate of physical health indexes under different algorithms is relatively stable, which verifies the effectiveness of physical health indexes; the results of this study are consistent with relevant domestic studies [23]. At the same time, the evaluation result

of physical health under the linear sequential extreme learning machine algorithm matrix is better, and its change range gradually reduces to 100%. In contrast, the differential evolution algorithm based on vague local search strategy has not changed, and the result is about

FIGURE 8: The coupling of physical health regimen and physical health.

FIGURE 9: The coupling of physical health regimen and different indexes of physical health.

7%. The reason is that the rough set method improves the index aggregation of physical health, provides effective physical fitness assessment schemes for different individuals, and realizes the significant improvement of physical health. Although the differential evolution

algorithm of vague local search strategy also provides effective evaluation scheme for physical health, in the case of randomness, physical fitness assessment scheme presents beneficial and unhelpful changes, resulting in the final improvement of 7%.

**4.4. The Coupling between Physical Fitness Assessment Scheme and Physical Health.** The coupling between physical fitness assessment scheme and physical health is not only the advantage of differential evolution algorithm to improve vague local search strategy, but also the result of two-way evaluation. For better analysis, linker analysis method is selected (uncoupled, general coupling, general, coupling, and comparative coupling, with values of 1–7 respectively). The calculation results are shown in Figure 8.

As can be seen from Figure 8, the coupling between physical fitness assessment scheme and physical health shows an upward trend and approaches the value of 5, indicating that the coupling between the two is better. The results of this study are consistent with relevant domestic studies [24]. Relatively speaking, the linear sequential extreme learning machine algorithm matrix has better coupling, which is significantly better than the differential evolution algorithm with vague local search strategy. The above results also show that rough set can greatly improve the coupling of linear sequential extreme learning machine algorithm matrix and realize the two-way evaluation of physical fitness assessment scheme and physical health. In order to further verify the coupling results, 35 specific indicators are analyzed, and the results are shown in Figure 9.

It can be seen from Figure 9 that the coupling of 35 indicators is better. The results of this study are consistent with relevant domestic studies. Among them, the linear sequential extreme learning machine algorithm matrix has better coupling [Note: 24 red indicators], and the coupling under the two algorithms meets the maximum and minimum constraints of penalty value.

## 5. Conclusion

At present, the research on the impact of physical health on subdivision function has the problem of single evaluation [25], which cannot realize the dual evaluation of physical fitness assessment scheme and the improvement of physical health, so that physical fitness assessment scheme cannot effectively improve physical health. Therefore, how to effectively use physical fitness assessment scheme to improve people's physical health and realize national fitness is an urgent problem to be solved. Based on this background, this paper improves the differential evolution algorithm of vague local search strategy and integrates the rough method set to realize the dual evaluation of physical fitness assessment scheme and physical health. In this paper, firstly, rough set is used to calculate the eigenvalues of physical fitness assessment scheme and physical health evaluation, then rough set is used to eliminate redundant data, and finally the dual evaluation of physical fitness assessment scheme is done. In order to submit the accuracy of evaluation, the constraint conditions and penalty values of rough set are set. MATLAB simulation results show that the linear sequential extreme value learning machine algorithm matrix combined with rough set has a good effect on physical health evaluation and prediction. The result accuracy is greater than 95% and the fitting degree is 98%, which is better than the result of linear sequential extreme value learning machine algorithm

matrix. Therefore, using linear sequential extreme value learning machine algorithm matrix combined with rough set can realize physical health evaluation and prediction, improving the accuracy of the results. However, the interaction between physical health assessment and prediction is not analyzed in the process of rough set analysis in this paper. This aspect will be emphatically analyzed in future research.

The arrival of the “double carbon” era indicates that industrial carbon reduction with high energy consumption and high carbon emission is imperative. From the perspective of carbon emission driving factors, industrial carbon emission is decomposed into five influencing factors: energy intensity, energy structure, industrial structure, economic efficiency, and employee scale. Taking the data of 41 subindustries of industrial industry in Liaoning Province from 2010 to 2019 as the research sample, the carbon emission is calculated. The LMDI model is used to analyze and point out the difference in the driving contribution of carbon emissions of each subindustry. The results show that the total carbon emission of Liaoning province gradually decreases, decreases for the first time in 2014, and gradually turns from flat to upward. Economic efficiency is the only and most important reason to drive the increase of industrial carbon emissions in Liaoning Province, and energy efficiency is the primary factor to curb carbon emissions. High carbon industries play a significant role in promoting the increase of carbon emissions, while the medium and low carbon industries have a better effect on restraining carbon emissions. It provides reference and theoretical basis for the government to adjust the industrial structure, control industrial overcapacity, and realize the “double carbon” goal as soon as possible. It is of great significance for the country to optimize energy layout, ensure energy security, and implement the new energy strategy.

## 1. Introduction

As one of the most important material production departments in the national economy, industry is responsible for processing and assembling natural resources and raw materials, providing raw materials, fuel, and driving force for the industry itself and other sectors of the national economy, as well as providing industrial and industrial consumer goods for the people’s material and cultural life. After the industrial revolution, with the large-scale development and use of fossil fuels such as coal, oil, and natural gas, the concentration of carbon dioxide in the Earth’s atmosphere increased significantly, and the global carbon emission reached more than 34 billion tons in 2019. NASA observation data show that compared with the end of the 19th

century, with the increase of global carbon emissions, the current global average temperature has also increased by more than 1.2°C, causing a series of extreme climate problems. More scientists predict that if this trend cannot be curbed, the glaciers in Antarctica will melt at the rate of 250–300 billion tons a year until they disappear completely, which will lead to a rise of at least 56 meters in the global sea level, which is a disaster for mankind. \* \* \* Countries must take decisive steps. China will increase its national independent contribution, adopt more effective policies and measures, strive to reach the peak of carbon dioxide emissions by 2030, and strive to achieve carbon neutrality by 2060. So far, the “double carbon” era has officially arrived, and carbon neutralization and carbon peak have also become the consensus of global green and sustainable

development, marking the largest new industrial revolution since human society entered the industrial revolution. In the “double carbon” era, it is of great significance for the country to further adapt to the global trend and tide by measuring and decoupling the carbon intensity of various industries in order to better achieve the double carbon goal and point out the direction for the industry as the fundamental guarantee of national economic independence, political independence, and national defense modernization. According to statistics, the carbon emissions of the world’s major carbon-emitting countries will reach 34.17 billion tons in 2019; among them, China’s carbon emissions accounted for 28.76, the United States accounted for 14.53, and India accounted for 7.26, ranking among the top three; Russia, Japan, and Germany rank 4th, 5th, and 6th, respectively, with carbon emissions of 1.533 billion tons, 1.123 billion tons, and 684 million tons, respectively [1]. Among China’s domestic provincial carbon emission intensity in 2019, Xinjiang, Shanxi, Inner Mongolia, and Ningxia have higher carbon emission intensity [2].

## 2. Literature Review

From the global perspective: Based on the data of 25 upper-middle-income countries from 1985 to 2014, Mujtaba et al. study the growth, correlation, and causality of kinked index among economic growth, energy consumption, population, trade openness, and carbon dioxide emissions. The results show that economic growth is negatively correlated with CO<sub>2</sub> emissions and trade openness, respectively, while energy consumption is positively correlated with CO<sub>2</sub> emissions and population. The determinants of carbon dioxide emissions are directly proportional to the country’s CO<sub>2</sub> emissions. There is a two-way causal relationship between population and economic growth, and trade openness and economic growth [3]. Georgia proposed that the Royal Court had revealed that in order to achieve net-zero carbon emissions, a series of measures would be taken, including banning some production materials and making 75% of food menus free of meat [4]. André and Valenciano-Salazar considered the environmental management system standards, the AHP method was used to analyze 24 companies and institutions in Costa Rica, and the results showed that the score of carbon neutrality (CN) is higher than the environmental management system standards. Therefore, they suggested that the adoption of environmental certification by organizations should be treated as a multistandard problem considering environmental sustainability, economy, and strategy [5].

From the industries perspective: Demetriou et al. considered that energy advantages and short driving distance make Cyprus a test field for an all-electric vehicle fleet, and they gave four different scenarios of minimum cost (LCSc), business as usual (BAU), carbon capture and storage (CCSc), and renewable energy (RESc) in parallel, deduced the hourly profile of weekly power production and consumption in winter and summer, and predicted that in 2050, RESc will have the highest power generation cost (0.115 euro/kWh) and the highest power loss rate (40%) and need 5600 mwh of domestic battery energy storage, and the current battery capacity in Europe is 3400 mwh [6]. Anonymous pointed out

that the road map of the California Nevada Cement Association (CNCA) showed that by 2045, the three ways for the cement industry to realize net-zero carbon operation were to reduce production process emissions, reduce combustion emissions through fuel switching, and increase distributed power generation [7]. Srivastava et al. discussed the properties of available wastes and different strategies for decomposition or hydrolysis, and efficient microbial systems are emphasized. Some representative examples of biomass sources are used for biomass energy production by providing key information, as well as bioenergy production and environmental problems of plant organics. They also conducted efficient microbial and chemical process research on advanced biofuels extracted from organic matter, so as to promote the use of plant biomass to produce biofuels [8].

Comparing the literature above, the highlight of this paper is that we measure the carbon dioxide emissions of Liaoning industrial segments in different years and analyze the reasons for this phenomenon. At the same time, based on the LMDI decomposition method, we find out the real driving factors behind the growth of carbon dioxide emissions from industrial industries in Liaoning Province and give targeted suggestions from the macro and micro levels, so as to provide a method for the country to conduct horizontal comparison among provinces and vertical comparison among subdivided industries, which is of certain significance to achieve the goal of “double carbon” with high quality.

## 3. Research Method

*3.1. Calculation Example of Carbon Strength.* Carbon dioxide emissions can be divided into natural emissions and artificial emissions. Natural emission refers to the emission of carbon dioxide into the atmosphere from soil, ocean, forest, and other ecosystems; artificial emissions refer to carbon dioxide emissions caused by human activities, mainly from fossil energy consumption and biomass fuel combustion. There are three main research methods on carbon dioxide emissions by scholars at home and abroad, namely, emission coefficient method, material balance algorithm, and measurement method. Because the research object of this paper is industrial carbon emissions, it is mainly aimed at fossil energy, and the emission coefficient method is used to calculate. The calculation coefficients of various energy sources are shown in Table 1. The calculation formula is based on the reference formula proposed by the United Nations Intergovernmental Panel on climate change (IPCC) in 2006 (this part of the 2019 inventory guide has not changed) [10], combined with the availability and acceptability of variable data and the specific characteristics of national industries, and the calculation way is as follows:

$$\begin{aligned} \text{CO}_2 &= \sum_{i=1}^N (\text{CO}_2)_i \\ &= \sum_{i=1}^N E_i \times \text{NCV}_i \times \text{CC}_i \times \text{COF}_i \times \frac{44}{12} \end{aligned} \quad (1)$$

TABLE 1: Calculation correlation coefficient of various energy sources [9].

Energy name	Conversion coefficient of standard coal	Average low calorific value	Carbon content per unit calorific value (ton carbon/TJ)	Carbon oxidation rate	Carbon dioxide emission coefficient
Raw coal	0.7143 kgce/kg	20908 kJ/kg	26.37	0.94	1.9003 kg-CO <sub>2</sub> /kg
Gasoline	1.4714 kgce/kg	43070 kJ/kg	18.9	0.98	2.9251 kg-CO <sub>2</sub> /kg
Diesel oil	1.4571 kgce/kg	42652 kJ/kg	20.2	0.98	3.0959 kg-CO <sub>2</sub> /kg
Fuel oil	1.4286 kgce/kg	41816 kJ/kg	21.1	0.98	3.1705 kg-CO <sub>2</sub> /kg
Natural gas	1.3300 kgce/m <sup>3</sup>	38931 kJ/m <sup>3</sup>	15.3	0.99	2.1622 kg-CO <sub>2</sub> /m <sup>3</sup>

where  $I$  represents the type of energy;  $E$  is energy consumption; NCV is the average low calorific value; CC is carbon content; COF is carbon oxidation factor, expressed as a percentage of IPCC default value; 44 and 12 are the molecular weights of CO<sub>2</sub> and C, respectively.

According to China's national standards, the division of industrial industries and the classification of main energy consumption are shown in Figure 1.

Since *China's industrial Statistical Yearbook* will no longer publish a separate total industrial output value of subdivided industries after 2009, *Liaoning Provincial Statistical Yearbook* has an accurate calculation of the data. Considering the availability and accuracy of the data, 41 subindustries of the Liaoning industry from 2010 to 2019 are selected as the research object. The data on the energy consumption of kerosene and coke are short. In order to ensure the accuracy of the calculation, these two data are excluded, so five raw materials of fossil energy raw coal, gasoline, fuel oil, diesel, and natural gas are selected for calculation, and a few missing data are estimated and completed by linear interpolation method. Relevant data are from the 2006 IPCC guidelines for national greenhouse gas inventories, *Liaoning Statistical Yearbook* and *China Energy Statistical Yearbook*. After calculation and sorting, the change trend of total carbon emission and total industrial output value of each subindustry of Liaoning industry from 2010 to 2019 is shown in Figure 2, and the carbon emission is shown in Table 2 (considering comprehensive application, international practice is adopted).

**3.2. Results' Analysis.** In 2019, the industrial economy of Liaoning Province continued to optimize and upgrade the industrial structure along with the government's cultivation and growth of new industries and upgrading of traditional industries. However, affected by the escalation of Sino-US trade friction, the larger decline in the price of industrial products, the lack of domestic demand, and other factors, the industrial economy of Liaoning Province as a whole presents a situation of great difficulty in production and operation, slow pace, and falling profits. According to the calculation of carbon emissions of 41 industrial subindustries in Liaoning Province in recent ten years, the total carbon emissions of electric power, thermal power production, and supply industry and ferrous metal smelting and rolling processing industry are large, which are 162.0196 million T and 75.6808 million T, respectively,

ranking first and second in 41 subindustries, accounting for 68.7% of the total carbon emissions of the whole industrial industry.

Compared with 2010, with the continuous progress of industrial production means, the downward trend of carbon emissions of most industries is more obvious. However, some industries still have the phenomenon of increasing carbon emissions instead of reducing carbon emissions. The largest increase is in the oil, coal, and other fuel processing industry, reaching 218.9%. The comprehensive utilization of waste resources followed, with an increase of 199.57%, and the carbon emission increased from 46700 t in 2010 to 139900 t in 2019. On the contrary, most equipment manufacturing industries have performed well, and the goal of energy conservation and emission reduction has been basically achieved through the joint action of various factors such as industrial upgrading, technological progress, and talent drive.

In 2019, the added value of industries above the designated size increased by 6.7% over 2018. Among them, the added value of the mining industry increased by 2.0% over the previous year, the added value of the manufacturing industry increased by 7.6%, and the added value of the high-tech manufacturing industry increased by 18.7%. The added value of power, heat, gas, and water production and supply also increased by 5.1% over last year.

In terms of specific industries, the added value of 25 of the 41 major industries maintained year-on-year growth, with a growth rate of 61.0%, and one industry was flat. Agricultural and sideline food processing industry increased by 7.1%, food manufacturing industry and textile industry decreased by 9.3% and 14.0%, respectively, the added value of petroleum, coal, and other fuel processing industry increased by 14.9%, the added value of chemical raw materials and chemical products manufacturing industry increased by 11.1%, pharmaceutical manufacturing industry increased by 9.1%, ferrous metal smelting and rolling processing industry, and nonferrous metal smelting and rolling processing industry increased by 5.0% and 3.3%, respectively, the nonmetallic mineral products industry increased by 2.7%, the general equipment manufacturing industry increased by 5.0%, and the special equipment manufacturing industry decreased by 2.1%; in terms of transportation, the automobile manufacturing industry increased by 2.5%, and the railway, ship, aerospace, and other transportation equipment manufacturing industry increased by 4.5%.

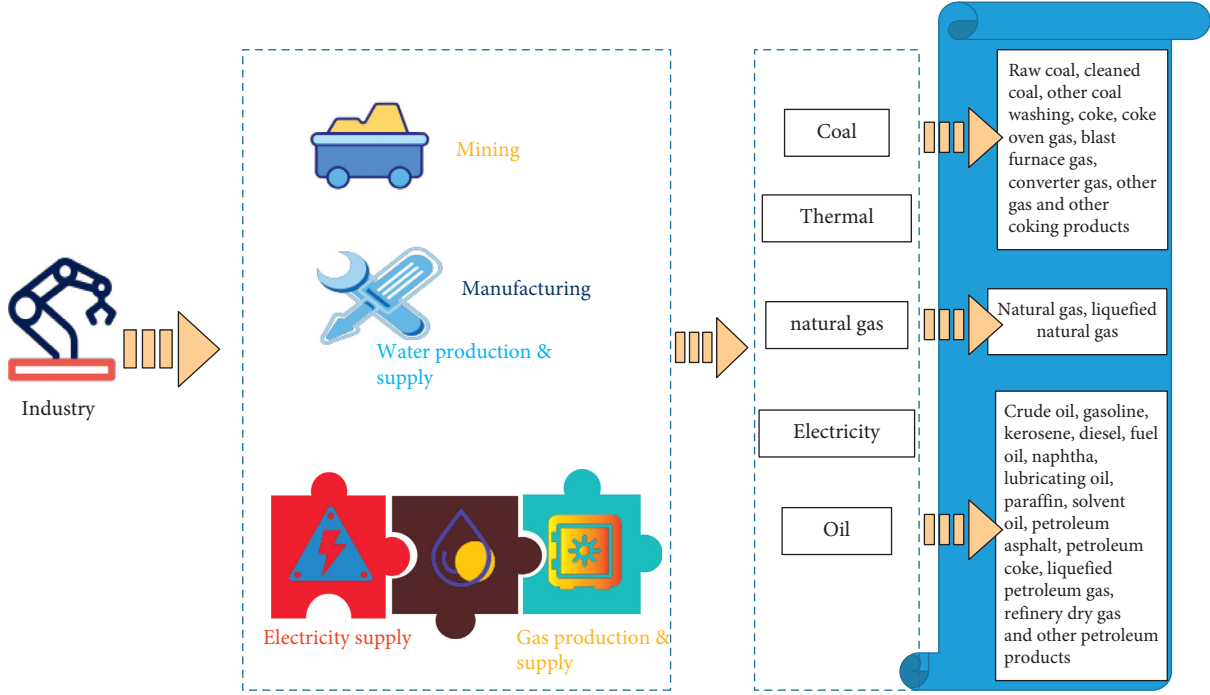

FIGURE 1: Industrial industry division and main energy consumption classification under national standards.

3.3. *Analysis of Influencing Factors.* Decomposing the core influencing factors of carbon emissions and studying the contribution of various factors to carbon emissions can not only provide theoretical reference for the government to formulate policies for phased economic and social green development but also provide a solid foundation for the country to achieve double carbon goals, maintain the bottom line of energy security, and lead high-quality development of the country. At present, the most commonly used methods for calculating carbon emissions are the following:

- (1) IPAT model: a quantitative model used to analyze the relationship between human activities and the environment. With the rapid growth of population and the progress of science and technology, people's pursuit of material life and the exploitation and utilization of resources have brought great pressure to the Earth's resources and environment. In other words, resources and environment are limited, but the human desire for material pursuit is unlimited. The model represents the pressure of human beings on the environment as the product of three factors, namely, the number of people, the degree of abundance, and the progress of science and technology, that is,  $I = P (\text{Pop}) \times A (\text{Aff}) \times T (\text{Tech})$ . Although the method is clear and simple in the calculation, it is not considered that environmental, resource, and social development are not linear in practice.
- (2) EKC: the environmental Kuznets curve, which was put forward by American economist Simon Smith Kuznets in 1955, mainly outlines the changes in the distribution of income along with the economic development process, also known as the inverted U

curve. The formula is expressed as  $E = \beta_0 + \beta_1 Y + \beta_2 Y^2 + \mu$ . Among them,  $E$  is the environmental pressure of the country or region, and  $Y$  is the economic output of the country or region. This method holds that when the economic development reaches a critical point, environmental pollution will tend to be stable no matter how the per capita income increases.

- (3) STIRPAT model: this method extends the IPAT model, adds randomness, and breaks through the limitation of unit single line assumption, and the calculation formula is expressed as  $I_i = \delta_0 P_i^{\delta_1} A_i^{\delta_2} T_i^{\delta_3} e_i$ .
- (4) LMDI model: compared with the first three methods, this method does not need to calculate with the help of an input-output table [11]. It is relatively simple to use, involves the nature of time series, and has more consistent aggregation, zero residual, and independent path [12]. Since the LMDI decomposition method has the advantages of complete decomposition, aggregation consistency, and path independence, this method is adopted in this paper.

The carbon emissions are decomposed in (1), as shown in the following:

$$\begin{aligned}
 C &= \sum_{i=1}^I \sum_{j=1}^J C_{ij} \\
 &= \sum_{i=1}^I \sum_{j=1}^J \frac{C_{ij}}{E_{ij}} \times \frac{E_{ij}}{Y_j} \times \frac{Y_j}{Y} \times \frac{Y}{P} \times P,
 \end{aligned} \tag{2}$$

FIGURE 2: Change trend of total carbon emission and output value of various subindustries of Liaoning industry from 2010 to 2019.

where  $C_{ij}$  represents the carbon emission of energy type  $i$  in  $j$  industry;  $E_{ij}$  represents the energy  $i$  consumption of  $j$  industry;  $E_j$  represents the total energy consumption of  $j$  industry;  $Y_j$  represents the total output value of the industrial  $j$  industry;  $Y$  represents the total industrial output value.  $ED_{ij} = C_{ij}/E_{ij}$  represents the carbon emission intensity of

energy  $i$  in industrial  $j$  industry;  $EM_{ij} = E_{ij}/E_j$  represents the energy structure of energy  $i$  in industrial  $j$  industry;  $ET_j = E_j/Y_j$  represents the energy efficiency of energy  $i$  in industrial  $j$  industry;  $ES_j = Y_j/Y$  represents the industrial structure of the industrial  $j$  industry;  $EE = Y/P$  represents the economic efficiency of energy  $i$  in industrial  $j$  industry;  $P$  represents the

number of employees. The decomposition formula of each carbon emission factor is calculated as shown in (3)–(8).

$$D_{ED} = \sum_{i=1}^I \sum_{j=1}^J \omega_{ij} \ln \frac{ED_{ij}^{t+1}}{ED_{ij}^t}, \quad (3)$$

$$D_{EM} = \sum_{i=1}^I \sum_{j=1}^J \omega_{ij} \ln \frac{EM_{ij}^{t+1}}{EM_{ij}^t}, \quad (4)$$

$$D_{ET} = \sum_{i=1}^I \sum_{j=1}^J \omega_{ij} \ln \frac{ET_j^{t+1}}{ET_j^t}, \quad (5)$$

$$D_{ES} = \sum_{i=1}^I \sum_{j=1}^J \omega_{ij} \ln \frac{ES_j^{t+1}}{ES_j^t}, \quad (6)$$

$$D_{EE} = \sum_{i=1}^I \sum_{j=1}^J \omega_{ij} \ln \frac{EE_i^{t+1}}{EE_i^t}, \quad (7)$$

$$D_{EP} = \sum_{i=1}^I \sum_{j=1}^J \omega_{ij} \ln \frac{P_j^{t+1}}{P_j^t}. \quad (8)$$

Among them,  $\omega_{ij}$  is the weight of energy type  $I$  in  $J$  industry, and the calculation formula is shown in the following:

$$\begin{aligned} \omega_{ij} &= L(C_{ij}^{t+1}, C_{ij}^t) \\ &= \frac{C_{ij}^{t+1} - C_{ij}^t}{\ln C_{ij}^{t+1} - \ln C_{ij}^t}. \end{aligned} \quad (9)$$

In view of using the two forms of “addition” and “multiplication” in the LMDI decomposition model, the final results are the same, and the addition is more intuitive

and clear than “multiplication”, so “addition” is selected for factor decomposition in this paper, and the calculation formula is shown in the following:

$$IC^{t+1} - CI^t = D_{ED} + D_{EM} + D_{ET} + D_{ES} + D_{EE} + D_{EP}. \quad (10)$$

**3.4. Case Analysis.** As a major industrial province, Liaoning has always undertaken the important task of providing technical equipment for various industries of China’s national economy and national defense construction and has played an indispensable role in the whole process of industrialization. In 2020, faced with the impact of COVID-19 and the severe external environment of the world, Liaoning always adhered to the working keynote of steady progress. The industrial added value of above scale industries increased by 1.8% compared with that in 2019, of which the mining industry decreased by 0.6% compared with the same period last year, and the manufacturing industry grew by 1.8% over the same period last year. The electricity, water, gas, and aquatic industries and supply also increased by 3.6% over the same period last year.

Considering the national development of the green economy and the realization of the “double carbon” goal, Liaoning needs to balance economic growth and carbon emission, so take Liaoning as an example for LMDI decomposition analysis. In view of space, 41 industrial industries in Liaoning Province are numbered, as shown in Table 3. According to the carbon emissions of each sub-industry, it is divided into high, medium, and low carbon industries, as shown in Table 4.

According to the LMDI model, 2010–2019 is selected as the research period to decompose the total industrial carbon emission in Liaoning Province and calculate the contribution degree and direction of five influencing factors such as energy intensity, energy structure, industrial structure,

TABLE 3: Industrial code of Liaoning Province.

Number	Industry name
1	Average coal mining and washing industry
2	Oil and gas extraction industry
3	Ferrous metal mining and dressing industry
4	Nonferrous metal mining and dressing industry
5	Nonmetallic ore mining and dressing industry
6	Mining professional and auxiliary activities
7	Other mining
8	Agricultural and sideline food processing industry
9	Food manufacturing
10	Wine, beverage, and refined tea manufacturing
11	Tobacco products industry
12	Textile industry
13	Textile and garment industry
14	Leather, fur, feather, and their products and shoe-making industry
15	Wood processing and wood, bamboo, rattan, palm, and grass products
16	Furniture manufacturing
17	Paper and paper products industry
18	Printing and recording media reproduction industry
19	Culture and education, industrial beauty, sports, and entertainment products manufacturing
20	Petroleum, coal, and other fuel processing industries
21	Chemical raw materials and chemical products manufacturing
22	Pharmaceutical manufacturing
23	Chemical fiber manufacturing
24	Rubber and plastic products industry
25	Nonmetallic mineral products industry
26	Ferrous metal smelting and rolling processing industry
27	Nonferrous metal smelting and calendering industry
28	Metal products industry
29	General equipment manufacturing
30	Special equipment manufacturing
31	Automobile manufacturing
32	Manufacturing of railway, ship, aerospace, and other transportation equipment
33	Electrical machinery and equipment manufacturing
34	Computer, communication, and other electronic equipment manufacturing
35	Instrument manufacturing
36	Other manufacturing

38	Metal products, machinery, and equipment repair industry
39	Electricity and thermal production and supply industry
40	Gas production and supply industry
41	Water production and supply

TABLE 4: Carbon emission classification of industrial subindustries in Liaoning.

Carbon emission classification	Subindustry name and number
High carbon	1, 4, 6, 7, 20, 37, 39
Medium carbon	2, 3, 5, 8, 9, 10, 11, 12, 17, 21, 22, 23, 24, 25, 26, 27, 28, 31, 32, 34
Low carbon	13, 14, 15, 16, 18, 19, 29, 30, 33, 35, 36, 38, 40, 41

economic efficiency, and population effect to industrial carbon emission. The results are shown in Table 5.

In terms of energy intensity, from 2010 to 2019, the industrial energy intensity of Liaoning Province generally showed a downward trend, indicating that the industrial production technology of Liaoning Province has been improved to a certain extent. In terms of energy structure, from 2010 to 2019, the change of energy structure leads to the phenomenon of positive and negative alternation of

industrial carbon emission year by year, with large fluctuation. The final cumulative carbon emission is  $-65.5186$  million T, and compared with the other four influencing factors, the impact effect is the weakest, and the contribution rate is only 0.75%. In terms of industrial structure, most of the carbon emissions during the study period were negative, the cumulative carbon emissions decreased by 781259.98 million T, and the contribution rate to carbon emissions was 89.35%, indicating that it is the most important inhibitory

TABLE 5: Effect decomposition results of influencing factors of industrial carbon emission in Liaoning Province from 2010 to 2019.

2017-2018	-3149.61	-3009.94	-425147.36	5739.87	-1425.34
2018-2019	-2753.30	-275.44	-50361.95	3531.02	-737.02
Cumulative value	-6551.86	-78475.97	-781259.98	1473.86	-9553.82

factor of carbon emissions and plays a vital role in reducing carbon emissions in Liaoning Province. Economic efficiency is closely related to the total industrial output value, reflecting the progress of the economic level and technical means of the whole industry. As can be seen from Table 5, the cumulative increase of carbon emissions caused by economic efficiency has reached 1473.86 million T, which is the only driving factor leading to the increase of carbon emissions. The population effect reflects the attribute of social evaluation. During 2010–2019, the contribution rate to carbon emission reached 1.09%, second only to economic efficiency.

From 2010 to 2019, the cumulative carbon emission of industrial high carbon industries in Liaoning Province reached 39.15194 million T. The industry of comprehensive utilization of waste resources has the highest growth rate, accounting for 30.67% of the cumulative carbon emissions. The industry of oil, coal, and other fuel processing ranked second, with cumulative carbon emissions accounting for 29.65%. Among the influencing factors, most of the energy structure has a positive role in promoting, and only has a certain inhibitory effect on mining professionals and auxiliary activities; energy efficiency has the most obvious inhibitory effect on electricity, thermal production, and supply industry. The driving force of industrial structure on mining professional and auxiliary activities is relatively strong; economic efficiency and the size of employees have contributed a certain inhibitory force to the increase of carbon emissions in industrial high-carbon industries, but the emission reduction effect is also very weak in some industries, as shown in Table 6.

In the ten years from 2010 to 2019, the carbon emission of Liaoning's industrial carbon industry reached -1640377600 t. Carbon emissions from all industrial sectors have played a negative inhibitory role. From the perspective of influencing factors, the inhibition of energy structure is most significant, followed by energy efficiency indicators. The index of industrial structure has played a certain role in promoting the increment of industrial carbon emissions, as shown in Table 7.

During the study period, the cumulative carbon emissions of Liaoning's industrial low carbon industry reached -413557.2 million T. The driving force of promoting carbon emissions is strong in instrumentation manufacturing, gas production and supply, textile and clothing, and apparel industries. From the point of view of influencing factors,

energy structure only has positive effects on gas production and supply industry and has played an inhibitory role in other low carbon industries. Energy efficiency has only played a catalytic role in the manufacturing of culture, education, industry, sports, and entertainment products, and the emission reduction effect of the remaining low carbon industries is outstanding. The three factors, including industrial structure, economic sub-Olympic Green, and the scale of employees, played a positive role in promoting the increase of carbon emissions in some low-carbon industries, but the impact was weak, as shown in Table 8.

#### 4. Results and Discussion

From the perspective of the whole industrial sector, the total carbon emission of 41 industrial subindustries in Liaoning Province increased from 327372400 t to 360141300 t from 2010 to 2019, with an absolute increase of 1.1 times. From the perspective of evolution trend, the growth rate of total industrial carbon emission in Liaoning province gradually decreased from 2010 to 2013, and the carbon emission decreased for the first time after 2014. The decline rate of total carbon emission in Liaoning province gradually leveled off from 2014 to 2016, and there was an upward trend from 2016 to 2019.

From the analysis results of influencing factors and indicators, economic efficiency is the main and only reason driving the increase of carbon emissions from industrial industries in Liaoning Province; energy efficiency is the primary factor to restrain the carbon emission of industrial industry in Liaoning Province, followed by the industrial structure, while the impact of employee size and energy structure on the carbon emission of the whole industry is relatively weak.

From the perspective of the fine molecule industry, the high carbon industry plays an extremely significant role in promoting the increase of industrial carbon emissions, among which the driving role of comprehensive utilization of waste resources is the most prominent; medium and low carbon industries have good effects on restraining industrial carbon emissions in Liaoning Province. Therefore, the carbon emissions of the industrial sector mainly come from high carbon emission industries, so it is necessary to carry out energy conservation, emission reduction, upgrading, and transformation for subindustries.

TABLE 6: Decomposition of influencing factors of high-carbon industry emission.

Industry number	$D_{EM}$	$D_{ET}$	$D_{ES}$	$D_{EE}$	$D_{EP}$	Cumulative value

To sum up, now that China has made clear the goal of “double carbon”, how to quickly unlock the carbon bondage has become the key to the next step. Future scholars can apply this method to the analysis of other regions or other industries to accurately eliminate the high dependence on fossil energy. Based on this, the government should refine

the specific targets of carbon emissions by industry segments and build a green energy economic system, so as to reduce the consumption of fossil fuels. All industries should take the initiative to implement energy conservation and emission reduction and technological upgradings, such as carbon capture, storage, or negative emission technologies, so as to

prevent carbon emissions from rising again and realize the two parallel rounds of optimizing the industrial structure and realizing the goal of “double carbon”.

Risk dynamic early warning is of great importance for financing risk decision-making. Intellectual property (IP) pledge financing is an effective way to alleviate the financial difficulties for technologically small- and medium-sized enterprises (SMEs). It is very important to study the financing risk decision-making because of its higher risk compared with other mortgage loans. Based on Kalman filter, we establish the pledge financing risk decision-making model and extract the key variables affecting financing risk by principal component analysis. We test the model with 88 listed SMEs. The results show that the average error between the predicted and the real values is 8.5% and the overall recognition accuracy of the model is 89.1%. The risk decision-making model has high discriminant accuracy and can provide evidence to risk decision-making.

## 1. Introduction

Technology SMEs are counted as one of the most technologically advanced enterprises that assign great large amount of money to their development [1, 2]. Furthermore, intellectual property pledge financing is an effective way to alleviate the financing difficulties of technology SMEs. As the significant differences between IP pledges and traditional physical pledges lead to specificity in both asset valuation risk and disposal risk, risk is a primary consideration when stakeholders make financing decisions. However, the risk is an uncertain event or condition that, if it occurs, has a negative effect, and it could happen at any stage without warning [3]. Therefore, many scholars have studied the IP pledge financing risks in different aspects. Pennington & Sanchez (2007) and Crawford & Strasser (2008) studied the IP pledge financing risks in different stages from three dimensions: credit risk, infringement risk, and compensation risk [4, 5]. Moreover, from the essence of IP pledge financing risk, in addition to the quality of the pledged goods, the stakeholders of pledge financing pay more attention to the financial and operational conditions of the financing enterprises. Liu Peipei (2011) believes that the risk of IP pledge financing depends on the value of the pledged goods

formally, but on the overall business capacity of enterprises essentially [6], which has also been shared by most scholars. While the financial status and operating conditions of an enterprise are a dynamic process that develops and changes in real time, a dynamic risk decision model could better characterize the risk of IP pledge financing.

The current research on the risk of IP pledge financing mainly focuses on the construction of a financing risk index system [7–9], while the research on financing risk decisions is limited to static evaluation and analysis. In addition, an advanced tool for validating decisions is necessary to ensure the smooth operation of corporate activities [10]. Although common methods can be used to evaluate financing risks, including factor analysis method [11], VIKOR method [12], interval number TOPSIS [13], hierarchical analysis method, and fuzzy comprehensive evaluation method [14], they mainly use the cross-sectional data, which cannot reflect the cumulative formation process of risks, so the models of traditional methods are not stable enough, which reduces the accuracy of risk decision-making. Besides, decision-making action that effectively extracts and utilizes enough data about decision based on big data is a trend [15].

In order to improve the effectiveness of risk decision-making, scholars have tried to introduce a dynamic risk

decision model called BP neural network that calculates the error between the calculated output value and the true value, and continuously adjust it until the acceptable error level [16, 17]. Zeng and Ming evaluate the risk of IP pledged financing for technology-based SMEs empirically [18]. BP neural network achieves early warning of dynamic risk with the deep learning algorithms, but it is essentially an approximation algorithm for linear weight functions, which is more effective if there is no correlation among processing data. As for the strong correlation of time series data of business operations, it would reduce the effectiveness of early warning of dynamic risk. Therefore, IP pledge financing risk requires methods that can analyze data with correlated time series and reflect the risk formation process, and Kalman filtering meets these needs well. Compared with other methods, the Kalman filter has two advantages. First, the correlation among processing data will not affect the results. Second, the filtering process is an acyclic recursive process of automatically updating “prediction-correction” with the latest data, and it does not need to save the historical measurement data. The enterprise’s IP pledge financing risk is a dynamic state with enterprise operation, and the previous risk will affect the status of the next period state. Therefore, the Kalman filtering method can predict the dynamic financing risk and determine the level of financing risk.

Kalman filtering has been widely used in the field of management for monitoring risk [19], especially for dynamic risk. Sun et al. established a Kalman filter dynamic early-warning model for financial crises, and the results showed that Kalman filter-based dynamic model is more accurate than other prediction models [20]. Zhu studied the financial crises in different life cycle stages of enterprises based on the dynamic model of Kalman filter combined with the logistic regression method [21]. Fu et al. constructed an early-warning model of financial risk with the fusion of neural network and Kalman filter and verified that enterprise financial index data has a good predictive effect on the enterprise financial risk [22].

In summary, the Kalman filter theory is more applied to the dynamic early warning of enterprise financial risk, not to the financing risk decision-making. Since the Kalman filter can describe the cumulative process of risk change and provide risk early warning by the time series data, we will try to establish a financing risk decision-making model based on Kalman filter and test the accuracy and effectiveness of the model.

The possible contributions of this paper are mainly reflected in two aspects: (1) We construct a dynamic decision-making model instead of the previous static model, which improves the accuracy of risk decision. (2) We introduce a risk decision-making method which is not affected by time series correlation data. The Kalman filtering method could eliminate the adverse effects of the correlation data. According to the dynamics and accumulation of financing risk, we use the self-cyclic recursive characteristics of Kalman filter to identify the parameters of the model and estimate the risk status with the time series financial data, and visualize the financing risk level.

## 2. A Risk Dynamic Decision-Making Model

*2.1. Kalman Filtering.* Kalman filter is a method based on state-space model, which can estimate the hidden state of the system in real time through the observation with noise, so as to solve the problem of state-space estimation. The method can also include any number of unknowns; it treats the signal process as the output of a linear system under the action of white noise and uses the state equation to describe this input-output relationship, using the statistical properties of the system state equation, the observation equation, and the white noise excitation (system noise and observation noise) to form a filter with recursive characteristics algorithm. The core consists of the following five equations:

State updating equation: the state estimation of the current time point from the previous state is as follows:

$$\hat{x}_t = A_t \hat{x}_{t-1} + u_t. \quad (1)$$

The calculation of the estimated covariance of the current time point state is as follows:

$$P_t^- = A_t P_{t-1} A_t^T + Q_t. \quad (2)$$

Measuring updating equation: the calculation of Kalman gain is as follows:

$$K_t = \frac{P_t^- H_t^T}{H_t P_t^- H_t^T + R_t}. \quad (3)$$

$y_t$  is measured to update the state estimation.

$$\hat{x}_t = \hat{x}_t^- + K(y_t - H_t \hat{x}_t^-). \quad (4)$$

Updating error covariance is as follows:

$$P_t = (I - K_t H_t) P_t^-. \quad (5)$$

The state update equation estimates the state of the current time point using the estimated value obtained from the previous time point and the covariance of the error to obtain a priori estimate. On the other hand, the measurement update equation combines the obtained a priori estimate with the measured value to obtain an improved a posteriori estimate, which serves as feedback to the state update equation and continues to estimate the next time point. Thus, a recursive process of “prediction-correction” is formed. Among them, Kalman gain plays a role in adjusting the weight between the observed value and the predicted value, so as to make the posterior estimate closer to the real value.

*2.2. Establishing State-Space Model for Risk Decision-Making.*

In this equation,  $X_t$  is composed of random variables  $x_t$ , representing the financing risk status of financing enterprises in the period, and  $Y_t$  is composed of observation values of various specific indicators  $y_t$ , representing the principal component data after indicator-specific data processing. Assuming that the operating conditions of financing enterprises in each year are regarded as a discrete

control process system and their real operating conditions cannot be observed, but can be predicted by the relationship between the observed values and white noise incentives, the state-space model of dynamic early warning of financing risks can be expressed by the following state equation and observation equation, respectively:

$$x_t = A_t x_{t-1} + B_t u, \quad (6)$$

$$y_t = H_t x_t + v. \quad (7)$$

The parameter vector  $A_t$  is estimated according to the historical data of the operation status of the financing enterprises. The parameter  $H$  used to measure the system is the value of the measurement index of the financing risk of the enterprises and corresponds directly to the output results.  $u_t$  and  $v_t$  represent the process noise and the measurement noise of the system, respectively, being a white noise sequence:

$$u_t \sim N(0, Q_t), \quad (8)$$

$$v_t \sim N(0, R_t). \quad (9)$$

The spatial state model of pledge financing risk is a single model and single measurement, and with the advance of filtering, it has convergence, so the initial value is set to 0. This dynamic early-warning model of IP pledge financing risk based on Kalman filter is constructed by time series data as the following equations.

$$Y_t = (11)X_t, \quad (10)$$

$$X_t = \begin{pmatrix} 1 & 0 \\ 0 & A \end{pmatrix} X_{t-1} + \begin{pmatrix} u_t \\ v_t \end{pmatrix}, \begin{pmatrix} u_t \\ v_t \end{pmatrix} \sim N(0, H). \quad (11)$$

$A$  and  $H$  will be updated continuously with the promotion of the financial data filtering of the test samples in the equations.

### 3. Methodology

**3.1. Data.** According to the characteristics of the IP pledge financing enterprises that have been obtained from the official website of the State Intellectual Property Office in China, it can be seen that most of the IP pledge financing enterprises are small- and medium-sized technological enterprises. Accordingly, we choose the listed companies of technological SMEs as samples and exclude the following: (1) ST and \*ST enterprises, which have unrepresentative debt repayment ability and abnormal financial data; (2) financial insurance enterprises; (3) enterprises with incomplete data disclosure. Combining the requirements of Kalman filtering and the characteristics of loan repayment risk, this paper uses net profit and net operating cash flow as two indicators to measure the degree of financing risk of enterprises, and 88 sample enterprises are selected. The less the interval data of Kalman filtering model, the better the filtering effect, so quarterly and semiannual reports should be the appropriate data for empirical analysis. However,

because of the lack of quarterly data, we use the financial data of semiannual reports from 2013 to 2016. Data mainly comes from the WIND database, and individual index data is obtained by searching the financial reports of listed companies.

**3.2. Constructing Early-Warning Index System of Dynamic Risk.** The IP pledge financing risk is mainly reflected in the financial risk and operational risk of enterprises. The influence of nonfinancial information in the operation status of enterprises will be concentrated on the financial indicators of enterprises which contain a lot of information and can be used to predict the operation status of enterprises [23]. There are obvious differences in the financial indicators between the enterprises with financial crisis and enterprises with health financial position [24]. Before the company's financial crisis begins to worsen, the relevant characteristics will be reflected in financial indicators in advance [25]. Whether the financial indicators are calculated directly or indirectly through financial reports, they can be used effectively to study the financial risk [26]. Therefore, following the principles of scientificity, comparability, and data availability, we added the indicators of cash flow and innovation ability on the basis of traditional financial risk measurement dimensions of solvency, profitability, operation ability, and growth ability to test the risk of IP pledge financing. As shown in Table 1, a risk early-warning evaluation index system of pledge financing with 21 indicators in 6 dimensions is constructed.

**3.3. Global Principal Component Analysis of Dynamic Data.** We obtained 616 sets of multidimensional time series stereo data from 88 families in 7 periods. In order to quickly extract important information from the stereo data table and analyze the dynamic law of the system, the global principal component analysis method was used to reduce the dimension of indicators, and several interrelated numerical indicators were transformed into a few independent comprehensive indicators; that is, fewer indicators are used instead of multiple indicators to combine most of the original information. We used the global principal component method to analyze the three-dimensional data table by SPSS 20.0. The total variance and coefficient matrix are shown in Tables 2 and 3.

In order to obtain the most orthogonal principal component factors while retaining most of the information and to get the optimal input database, the first 15 global principal component factors were extracted. The cumulative contribution rate reached more than 94%, which means the effect was good. These global principal component factors are all represented by a linear combination of 21 financial indicators. According to the coefficient matrix, the formula of each principal component is shown as

$$F_n = \alpha_1 x_1 + \alpha_2 x_2 + \alpha_3 x_3 + \dots + \alpha_{20} x_{20} + \alpha_{21} x_{21}. \quad (12)$$

Among them,  $n$  is the number of extracted principal components ( $n = 1, 2, 3 \dots 15$ ),  $\alpha$  is the coefficients of each

The value of  $F$  means that the financing risk was represented by 15 principal components instead of 21 original evaluation indicators, and the interpretation rate can reach 94%. Due to the space constraints, we only listed the formula of  $F_1$  as sample. The result data will be used for the next filtering calculation.

## 4. Results

**4.1. Dividing Risk Level.** Although the risk of IP pledge financing is an asymptotic dynamic process of the enterprise's financial situation from good to bad, the degree of risk of IP pledge financing is different at the early-warning level. Generally speaking, the most serious degree of financial risk is bankruptcy due to insolvency, while the most serious degree of IP pledge financing risk is the lack of enough cash to repay the financing money due, but far from liquidation bankruptcy. Therefore, besides the net profit, the most important factor in measuring the risk of pledge financing is adequacy of cash flow. Consequently, in this paper, we defined the degree of risk of IP pledge financing from two indicators: net profit and net operating cash flow. The specific level of risk is divided according to the following standards:

**Healthy enterprises:** If the net profit and net operating cash flow of enterprises are both positive during the investigation period and show an increasing trend, the enterprises are identified as healthy ones. There are 44 healthy enterprises in the 88 samples, of which 28 are forecast samples and 16 are test samples.

**Mild-risk enterprises:** If the net cash flow of enterprises is negative at the end of the inspection period, the net cash flow is positive at T-1 and T-2 periods, and the net profit of any period is negative during the inspection period, the enterprises are identified as mild-risk ones. There are 24 mild-risk

enterprises in the 88 samples, of which 16 are forecast samples and 8 are test samples.

**High-risk enterprises:** According to the data of listed companies on SME technology boards, only 11 of the 75 samples with negative net operating cash flow in three consecutive periods have positive net operating cash flow in 2015. That is, if an enterprise has negative net cash flows in periods T and T-1, it has an 85% probability of negative net cash flows in period T-2, which shows that the net operating cash flow has certain sustainability. Therefore, we identified the degree of high risk which is the negative value of net operating cash flow and twice the negative value of net profit in three consecutive periods. There are high-risk 20 enterprises among the 88 samples, of which 12 are forecast samples and 8 are test samples.

In summary, the 88 sample companies are divided into two groups: the first group is the forecast sample group, which consists of 56 companies, including 28 healthy companies and 28 risky companies, and the second group is the test sample group, which consists of 32 companies, including 16 healthy companies and 16 risky companies. Predictive samples are used as training sets to optimize the model, and test samples as detection sets to verify the effectiveness of risk decision-making model.

**4.2. Defining Risk-Level Threshold.** In this study, statistical analysis was used to extract judgment thresholds for the risky companies based on the data from the forecast sample. With a 95% confidence probability and a confidence coefficient of 1.6449, a mean value of 0.056 and a standard deviation of 0.016 were calculated for the risky sample. The lower confidence limit for a crisis in the risky sample of companies is as follows:

$$\text{down} = \text{mean} - \alpha \times \text{Standard Deviation} = 0.056 - 1.6449 \times 0.016 = 0.030. \quad (14)$$

Similarly, under the precondition of 95% confidence probability, the confidence coefficient is 1.6449, the mean value of the calculated state for healthy samples is 0.063, and

$$\text{up} = \text{mean} + \alpha \times \text{Standard Deviation} = 0.063 + 1.6449 \times 0.007 = 0.075 \quad (15)$$

According to the above results, the lower confidence limit is 0.030, and the upper confidence limit is 0.075. That is, when the predicted value of financing risk is less than 0.030, the high financing risk probably happens; when the predicted value of financing risk is greater than 0.075, the financing enterprises are in a healthy state; and when the predicted value of financing risk is between 0.030 and 0.075, the financing enterprises are likely to be in a state of mild financing risk.

**4.3. Testing the Dynamic Risk Decision-Making Result.** According to the global principal component analysis, we have obtained 15 principal components' factor loads and constructed a comprehensive index of the company's financial situation in each period from the characteristic value  $F$  and contribution rate  $\beta$  (Table 2), which is the linear combination of each principal component. We have obtained a general index  $X_t$  reflecting the financing risk status of each half year of the test sample, and the results are shown in Table 4.

$$Z = \beta_1 F_1 + \beta_2 F_2 + \beta_3 F_3 + \cdots + \beta_{14} F_{14} + \beta_{15} F_{15}. \quad (16)$$

Inputting the data of 32 test samples from 7 periods into the Kalman filtering model, we obtained the predicted values of each year. The results of some samples are shown in Table 4.

Due to the space constraints, we choose four enterprises' dynamic forecasting charts of financing risk, including two healthy enterprises and two risky enterprises, in Figure 1.

**4.4. Result Analysis.** The results of Table 4 and Figure 1 show that the dynamic pledge financing risk decision-making model based on Kalman filter is a recursive updating process. After the initial estimation of the formation state, the initial estimation is modified by inputting the updated data information every year, and the stable state of the predicted value and the real value is gradually achieved. The model is based on the cumulative deviation of the financial situation of an enterprise over time to represent the evolution process of the financing risk of an enterprise. In a certain period of time, the financial situation of a healthy enterprise is basically in a good category, and the trend of change is gradually better, but it does not exclude a temporary weakening state. The financing risk of a risky company is gradually getting worse from mild crisis to severe crisis. There are

the standard deviation is 0.007. The upper confidence limit for healthy sample companies in crisis is as follows:

significant dynamic early-warning characteristics to predict the financing risk by cumulative variation rather than a cross-sectional state. In addition, we can determine whether the financing risk is temporary crisis or continuous deterioration in the shape of the forecast chart and observe the change point of the financing risk state, so as to realize the visual effect of financing risk decision-making. Next, we choose one of the healthy samples and risky samples to illustrate the forecast chart.

We take Yunnan Luoping Zinc & Electricity Co., Ltd. (stock code: 002114) as an example of a healthy enterprise. The enterprise was founded in 2000 and is a high-tech enterprise. Its main business is lead-zinc ore mining, zinc smelting, hydroelectric power generation, and comprehensive utilization of resources. It also has an integrated industrial chain of "mine-electricity-smelting." At present, it has successfully developed a number of advanced production technologies for comprehensive utilization of resources, such as germanium-indium extraction, purification of workshop slag treatment, leaching slag flotation of silver, and zinc powder mill pulverizing process transformation. From the forecast chart, only the sixth observation period is slightly lower than the healthy threshold, while other observation periods are above the healthy threshold, indicating that the company's overall solvency is strong. The annual value in 2015 is much lower than that in 2014 for the reason that in the second half of 2015, due to the steady recovery of the US economy and the expected increase in interest rates, the high domestic zinc price has fallen back and continued to fall. Although it adapted to the rapid adjustment of its business ideas in the market, it is still affected by the overall business risk and financial risk. In 2016, due to the influence of such favorable factors as "capacity removal, inventory removal, deleveraging, cost reduction, and shortage compensation board," the decline of zinc price eased and slowly rebounded. It can be seen from the forecast chart that although the actual value is low, the forecast value is above the healthy threshold line, and the actual value at the end of 2016 is much higher than the healthy threshold line, which shows the accuracy of the model. The actual value and forecast value of other prediction points are in the same healthy area, and the change direction of forecast value is consistent with the change direction of actual value in the next period, which further proves that Kalman filter model has good tracking and early warning of the risk of pledge financing.

We take Carrier Holdings Co., Ltd. (stock code: 002072) as an example of risk-based enterprises. The enterprise is a cotton

TABLE 4: The real values and the predictive values of sample companies.

textile enterprise listed in 2006. Its main products are extra wide decorative fabric series, large and small jacquard fabric series, and so on. It is at high risk according to the risk classification criteria for pledge financing of the original samples. From the results of the forecast chart of the observation period, the enterprise is in the area of lower risk threshold for most of the time, and the overall situation is a high risk.

In 2014, affected by many factors, such as the downturn of domestic real economy and the rising price of factors of production, cotton textile enterprises had increased operating pressure causing domestic demand to slump continuously and its international market competitiveness to be declined significantly; in addition, the development of the textile industry has become more difficult. From individual observation points, the true values of the third and sixth phases are above the lower limit of the risk threshold, but the predicted values are in the severe risk area, and the subsequent fourth and fifth phases return to the severe risk area, thus confirming the accuracy of the decision-making results.

*4.5. Total Discrimination Accuracy Analysis.* The overall discriminatory accuracy analysis is shown in the following three areas:

- (1) Overall prediction accuracy analysis. Any risk decision-making model has its limitations or neglected influencing factors. Therefore, there is no perfect model which achieves 100% prediction accuracy. Prediction accuracy refers to the goodness or disadvantage of the fitting degree between the predicted value and the actual value produced by the prediction model, which reflects the fitting degree of the prediction model, and is also an important index to judge whether the prediction method has applicability. According to the test results, the average error between the predicted value and the real value of the seven-period semiannual reports is 8.5%, and the average error of the model in the last period is only 5.1%. Accordingly, the prediction accuracy of the model is high and the prediction effect is good.
- (2) Analysis of the results of risk-based test samples. From the predicted value calculated by the dynamic model of Kalman filter, if the last stage of the whole sample is risk-based, and 93% of the test samples in the sixth period are correctly predicted before the crisis occurs, that is, before the risk situation appears at the end of 2016, they have already fallen below the threshold of mild crisis or entered the area of high risk, and 93% of

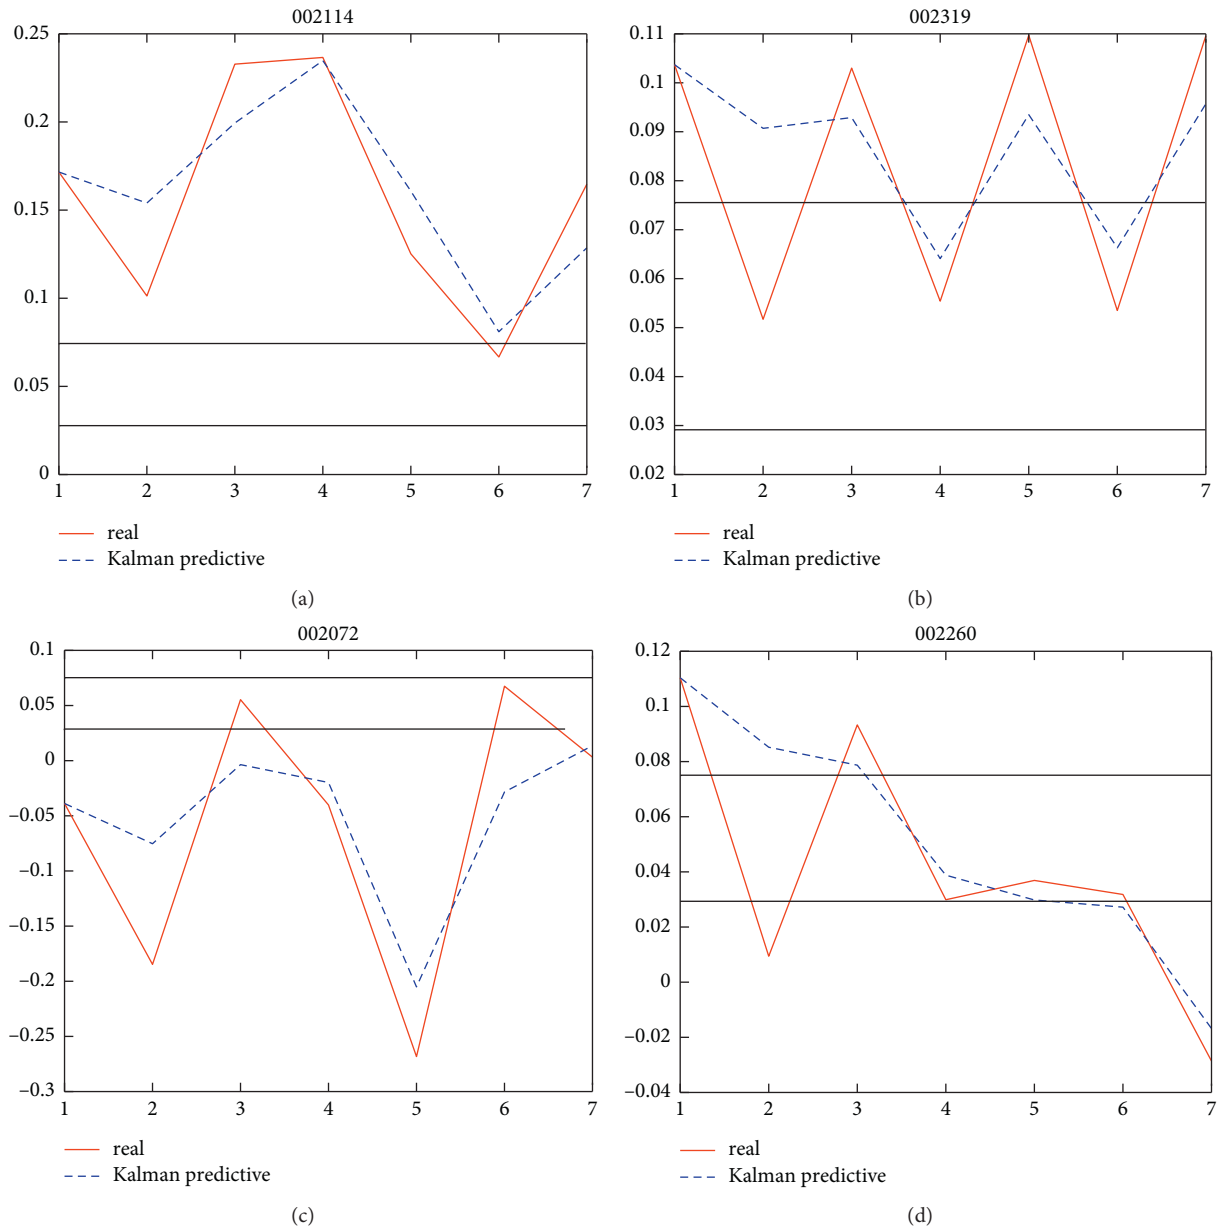

FIGURE 1: Some of the predictive value curves of testing the financing risk.

the samples have the mild financing risk two times in advance.

- (3) Analysis of the results of healthy-type test samples. From the predicted results of healthy samples, the predicted values of most healthy enterprises are above the warning line of mild-risk threshold. The predicted values of individual samples have temporarily deviated from the normal values at a certain point, but the dynamic model then corrects the situation in time. Even if they belong to mild-risk area, the predicted values of some healthy enterprises also deviate from the normal values, which means they are slightly below the warning line and are at a temporary mild risk. The results of 112 groups of dynamic

data from 16 healthy enterprises showed that the recognition accuracy of healthy samples in the sixth period was 93.75% and the overall recognition accuracy was 87.5%.

This paper further classifies the errors in classification recognition: class A and class B errors. When a risky financing enterprise is misjudged as a healthy enterprise, this is called class A error. If it is correctly identified, it is considered to be sensitive. Conversely, when a healthy enterprise is misjudged as a risky enterprise, this is called class B error. If it is correctly identified, it is considered to be specific. No matter what kind of mistake occurs, it may lead to wrong decision-making and cause serious losses. The accuracy of decision-making model in identifying risk categories is shown in Table 5.

TABLE 5: Recognition accuracy of Kalman filter model.

Date	Class A error ratio (%)	Sensitivity (%)	Class B error ratio (%)	Specificity (%)	Recognition accuracy (%)
2016.12	6.25	93.75	6.25	93.75	93.75
2016.06	12.5	87.5	6.25	93.75	90.6
2015.12	6.25	93.75	12.5	87.5	90.6
2015.06	6.25	93.75	18.75	81.25	87.5
2014.12	12.5	87.5	12.5	87.5	87.5
2014-06	12.5	87.5	18.75	81.25	84.3

According to the results in Table 5, the Kalman filter model has a high comprehensive judgment rate, which shows that the Kalman filter model has good robustness and prediction ability. The rate of misjudging a risky company as a healthy enterprise is 9.4%, the rate of misjudging a healthy company as a risky company is 12.5%, and the overall accuracy of the model is 89.1%. Among them, the rate of risky enterprises misjudged as healthy ones is lower than that of healthy enterprises misjudged as risky ones, which can further reduce the risk of pledge financing.

In addition, the results also illustrate that the risk criteria for IP pledge financing are likely to be more stringent than those of other financing ways. For banks and other lending institutions, it is necessary to change the previous cautious attitude towards IP pledge financing business.

## 5. Conclusion

Dynamic prediction can provide sufficient evidence for financing risk decision-making and reduce financing decision risk. In this paper, we established the pledge financing risk decision-making model based on Kalman filter, because of cumulative and time-varying characteristics of financing risks, and extracted the key variables affecting financing risk by principal component analysis method. Listed SMEs are tested and analyzed, and we found the following: (1) The average error between the predicted and the real values is 8.5%, so the model has higher fitting precision. (2) The rate of a risky company wrongly judged to be a healthy company is 9.4%. Conversely, the rate is 12.5% for a healthy company wrongly judged to be a risky company. The overall recognition accuracy of the model is 89.1%. (3) The risk decision-making model has high discriminant accuracy and can provide evidence to risk decision-making.

In this paper, we only established the pledge risk decision-making model based on Kalman filter. As we all know, the risk of IP pledge is a very complex problem. In future research, we will explore the establishment of a risk decision-making model based on combination of Kalman filter and neural network, so as to further improve the accuracy and effectiveness of the risk decision-making model.

The classification inaccuracy occurs to the evaluation calculation of the total factor production impact in the traditional digital economy development area. This paper applies the fuzzy hierarchical (Visualization in Scientific Computing, VISC) algorithm to the calculation method of the total factor production impact evaluation in the digital economy development area. The quantitative recursive method is used to evaluate the ability of the data information model, to achieve the ability of controlling the acquisition of characteristic resources, and complete the classification and summary of the index parameters of the total factor production impact of the digital economy development area. Finally, the experiment proves that this calculation method is used to develop the evaluation of the impact of total factor production digital economy development area and improve the information integration and analysis capabilities, the accuracy of the evaluation of the impact of total factor production, and the efficiency of the use of digital economy development resources.

## 1. Introduction

As an important transportation infrastructure, several regions are also windows for foreign economic development, providing a guarantee for regional economic development and trade. Since the new century, due to the expansion of city scale and the continuous improvement of regional functions, the digital economy development area is not only the main link of economic development, but also a key link in the economic structure. The transformation of the business structure of the digital economy development area has also become an important research topic [1, 2]. Compared with the traditional regional business development model, the all-factor production structure can effectively utilize the resource advantages of the digital economy development area, reduce the risk of operation, and improve the regional profitability. Therefore, it has been widely used in many digital economy development areas. Digital economy development areas are difficult to get rid of traditional thinking patterns when determining all-factor production strategies.

In many cases, companies do not fully consider the total factor production strategy, and the effect is usually not significant. For example, the management system is not sound or the industry to be expanded is inappropriate, which may cause the failure of the regional total factor production strategy and will eventually drag down the main production industries in the region. How to choose an appropriate business strategy for a digital economy development area will be a serious test for regional business managers [3].

After the 1990s, digital economy promoted a large number of new industries, new formats, and new models, and the research of digital economy began to sprout. So far, the research on digital economy mainly focuses on the following aspects: first come the definition and evolution characteristics of digital economy [4]. The essence of digital economy is a special economic form of trading goods and services in a virtual way. Its development is closely related to the information and communication technology industry and accelerates the penetration and

change of the operation mode of relevant industries. Chinese scholars have been studying and deepening the connotation and characteristics of digital economy since 2008. He Xiaoyin believes that digital economy is not only a trade behavior dominated by e-commerce, but also an economic process of manufacturing and providing digital products and services; Kang Tiexiang uses a nondefinition method to describe in detail the remarkable characteristics of digital economy, such as virtuality, high permeability, and values added; Yang Xinming expounds the digital economy by analyzing the economic logic of digital economy to the transformation of traditional economy. Second, it introduces the development strategy of digital economy at home and abroad [5]. In order to protect the digital content industry, the British government promulgated the digital economy 2010 law in 2010; in order to achieve the objectives of broadband construction, government development, and Internet education, the Australian government launched the national digital economy strategy in 2011. Third, there is the calculation method of digital economy. Kang Tiexiang uses the sum of the total added value of the digital industry sector and the added value created by digital auxiliary activities to calculate the scale of the digital economy.

Some scholars have found that digital economy can promote economic growth, but few explain its correlation with technological innovation. According to the new economic growth theory, innovation is the driving force of technological progress and the source of economic growth. As an important index to measure technological innovation, total factor productivity analyzes the impact of digital economy on total factor productivity, which is of great significance to speed up the development of economy. Quality development has certain reference value [6].

This article carries an in-depth analysis of the advantages and disadvantages of the selection of total factor production strategies in the digital economy development area and at the same time comprehensively considers domestic and foreign policies, industrial structure, finance, ownership of resources, and corporate managers, etc. The effective implementation of the strategy provides theoretical support and practical testing [7].

## 2. Methodology and Algorithm

To correctly evaluate the impact of total factor production in a digital economy development area, first of all, an information sample model that restricts the impact of total factor production needs a digital economy development area to be built. Combined with the fuzzy hierarchical VISC algorithm, statistical analysis of the factor production impact is carried out. The total factor production impact constraint index parameter of the digital economy development area is a set of nonlinear time series. Construct the total factor production impact analysis and evaluation parameter of the digital economy development area [8].

$$x_n = x(t_0 + n\Delta t) = h[z(t_0 + n\Delta t)] + \omega_n. \quad (1)$$

In the formula,  $\omega_n$  is the error measuring function of evaluation. The solution vector of the analysis and evaluation in the total factor production impact of the digital economy development is calculated by the correlation fusion method, and the digital economy development analysis and evaluation is obtained, and the following conditions are met.

$$\begin{aligned} \Sigma &= \text{diag}(\delta_1, \delta_2, \dots, \delta_r), \quad \delta_i = \sqrt{\lambda_i}, \quad \forall i \neq j, \\ \bigcup_{i=1}^L S_i &= V - v_s. \end{aligned} \quad (2)$$

Let  $x_{n+1} = \mu x_n (1 - x_n)$  be the influence of total factor production in a digital economy development area, where  $(I_i)_{i \in N} = \{x_1, x_2, \dots, x_m\}$ . For the multivariate group, the analysis and evaluation statistical characteristic distribution sequence  $x(n)$  of digital economy development category, the data information flow model of the total factor production impact of the digital economy development area is built based on the previous statistical measurement values:

$$\begin{aligned} c_{1x}(\tau) &= E[x(n)] = 0, \\ c_{2x}(\tau) &= E\{x(n)x(n+\tau)\} = r(\tau) \\ c_{kx}(\tau_1, \tau_2, \dots, \tau_{k-1}) &\equiv 0, k \leq 3. \end{aligned} \quad (3)$$

When  $q=2$ , the total factor production in the digital economy development area affects the classroom assessment teacher's strength level and the digital economy development resource distribution level, to meet the  $(2+1)$  dimensional continuous functional condition. In other words, the course of the development of the digital economy needs to be analyzed and evaluated.

$$\psi_x(\omega) = \ln \Phi_x(\omega) = -\frac{1}{2}\omega^2 \sigma^2. \quad (4)$$

Exclusive analysis appraisal data information flow model of digital economic development built provides an accurate data input basis for the analysis and evaluation of the total factor production and constructs a set of scalar sampling sequence components.

The control objective function for constructing the total factor production impact forecast estimation of the digital economy development area is

$$\begin{aligned} \max_{x_{a,b,d,p}} & \sum_{a \in A} \sum_{b \in B} \sum_{d \in D} \sum_{p \in P} x_{a,b,d,p} V_p, \\ \text{s.t.} & \sum_{a \in A} \sum_{d \in D} \sum_{p \in P} x_{a,b,d,p} R_p^{bw} \leq K_b^{bw}(S), \quad b \in B. \end{aligned} \quad (5)$$

The gray model is used to quantitatively and recursively evaluate the level of total factor production impact capacity of digital economy development. Assuming the historical data  $\{x_i\}_{i=1}^N$  of the distribution of the total factor production impact capacity of the digital economy development, the initial value of the feature is fixed and the budgetary estimate density functional is estimated from the factor production impact prediction of the digital economy development [9].

$$u_c(t) = Kx_c(t). \quad (6)$$

The total factor production impact continuous function of the calculation model of forecast estimation system of the digital economy development area is  $u: I \times IR^d \rightarrow IR$ ; after  $k-1$  iterations,  $k \geq 1$ , the gray-scale sequence of the total factor production impact of the digital economy development area satisfies  $N(k) < L$ , and the fuzzy hierarchical VISC algorithm is adopted, to obtain the output indicator of analysis evaluation of the impact of the economic production of all factors, which is the  $K$  adjacent sample values of the distributed big data information flow:

$$P_{1j} = \sum_{d_i=KNN} \text{Sim}(x, d_i) y(d_i, C_j). \quad (7)$$

The method of fusion of big data information is used to construct the total factor production impact and construct the objective function of analyzing and evaluating the interdomain classification of the distributed data information flow. That is, the objective function of a big data cluster is

$$J_m(U, V) = \sum_{k=1}^n \sum_{i=1}^c \mu_{ik}^m (d_{ik})^2. \quad (8)$$

The researched digital economy development curriculum is analyzed, to quantitatively analyze and evaluate the exponential correlation distribution sequence  $\{x_n\}_{n=1}^N$ , find an excellent method of  $K$  value, and obtain the quantitative recursive feature extraction result of the digital economy development analysis and evaluation:

$$x_n = a_0 + \sum_{i=1}^{M_{AR}} a_i x_{n-i} + \sum_{j=0}^{M_{MA}} b_j \eta_{n-j}. \quad (9)$$

In the formula,  $a_0$  is the sampling range of the evaluation of the impact of total factor production in the initial stage of digital economy development;  $x_{n-i}$  is scalar time series;  $b_j$  is the vibration attenuation value of the digital economy development arrangement and analysis evaluation.

Relevant data about the development of the digital economy is listed gradually in the classroom. Mainly, time, class, curriculum, classroom, teacher, and other related factors belong to the optimization decision problem of multiple factors. The fuzzy hierarchical VISC algorithm is a constant weighted evaluation, and the constant easily leads to the unfairness of the evaluation. In the course importance assessment, a part of the component must be activated, and that weight increases with the increase of the factor scores. The method of optimizing the weight vector with the state vector of each indicator  $(x_1, x_2, \dots, x_m)W = (\omega_1, \omega_2, \dots, \omega_m)$  forms the concept of incentive variable weight. The equilibrium function is integrated into variable weights, and the new variable weight formula is obtained:

$$\omega_i(x_1, x_1, \dots, x_m) = \frac{\omega_1 x_1^{a-1}}{\sum_{i=1}^m \omega_i x_i^{a-1}}. \quad (10)$$

When  $a > 1$ ,  $\omega_i(x_1, x_2, \dots, x_m)$  is the incentive variable weight. During the process of comprehensive evaluation, if an index value is very large, its comprehensive evaluation value will increase rapidly; that is,  $x_i$  will increase, and  $\omega_i$  will become larger [10].

Construct a constraint of the influence of total factor production in the digital economy development area and use the fuzzy hierarchical VISC algorithm to analyze of the influence of the total factor production in the digital economy development area. The least squares problem is to find the consistent estimate of the resource constraint vector  $\beta$  of the total factor production in the digital economy development area, so that  $\|Y - X\beta\|$  reaches the minimum, where  $\|\cdot\|$  is the F-norm in the European norm, and the entropy feature extraction value of the total factor production impact constraint feature information in the digital economy development area obtained is

$$P_{\text{loss}} = 1 - \frac{1 - p_0}{\rho} = \frac{p_0 + \rho - 1}{\rho} = \sum_{n=1}^N p_{K,n}. \quad (11)$$

Given that  $d_i$  is the disturbance feature vector for the analysis and evaluation of the total factor production impact, the estimation formula of the total factor production impact of the digital economy development area is transformed into the least square solution:

$$\begin{aligned} z(t) &= x(t) + iy(t) \\ &= a(t)e^{i\theta(t)} + n(t), \end{aligned} \quad (12)$$

where  $x(t)$  is the real part of the time series for evaluating the distribution of big data;  $y(t)$  is the imaginary part of the total factor production impact constraint index sequence for the digital economy development area.

The surrogate data method is used to randomize the amplitude of the impact of factor production in the development of the digital economy. It is also possible to perturb the empirical distribution data of the functional analysis evaluation of the  $k$ -th digital economy development and obtain the  $k$ -th subgroup, which represents the utilization rate of the resource distribution of the digital economy.

$$U_{\text{util}} = \gamma \bar{X}. \quad (13)$$

Constructing a hierarchical tree, big data analysis methods are used to establish the main component characteristics of the out-of-time analysis evaluation of the total factor production of the digital economy development, and the ambiguous close filling method is used to solve the similarity of the resource distribution of the digital economy.

$$\text{Sim}_1(d_i, d_{1j}) = \frac{\sum_{k=1}^M W_{ik} \times W_{1jk}}{\sqrt{\sum_{k=1}^M W_{ik}^2} \cdot \sqrt{\sum_{k=1}^M W_{1jk}^2}}, \quad (14)$$

where  $d_i$  is the prior distribution feature vector of the total factor production impact of the digital economy development area;  $d_{1j}$  is the  $K$ -means clustering center vector of the first-level big data.

Combining the fusion method of linear correlation characteristics, the clustering and integration of the index parameters of the total factor production impact assessment of the digital economy development is realized, and the fusion formula of the output digital economy development resource information is as follows.

$$P(w|x) = P(x|w)/P(x). \quad (15)$$

If the quantitative recursive feature is  $(N(i) \bmod L) < m$ , the probability density feature of total factor production affecting resource distribution is  $p(i) = \lfloor N(i)/L \rfloor$ , the big data stream of the digital economy development area total factor production influence  $X(i)$  is divided into  $p(i)$  sub-matrices  $X_{ij}$  whose size is  $N_{ij} \times m$ , and, through index parameter clustering and integration, the corresponding total factor production impact resource allocation plan is compiled. As a result, the optimization of the influence of all-factor production in the digital economy development area has been realized.

### 3. Analysis and Result

**3.1. Data Sampling Method.** As the most important feature of the digital economy, innovation has created a subversive business model on the “cloud network end” platform of the new generation infrastructure. Driven by Internet enterprises, the construction of a large-scale information platform has accelerated the digitization process of other industries and greatly improved the operation efficiency and business coverage radius of enterprises. The new generation infrastructure maximizes the innovation capacity and innovation potential of individual and small enterprises and reduces the information cost paid by the whole country to the greatest extent. The connection of the Internet promotes the vitality of the industry and endows the industrial innovation value. The digital economy presents connection benefits and output, driving economic growth and prosperity. At the same time, the development level of digital technology affects the digital literacy of the whole people. The digital literacy level of individuals and enterprises reflects their adaptability in the digital age. Whether massive digital information can be effectively obtained, transmitted, and utilized is a necessary condition for enterprises and individuals to improve the level of productivity. For a country, the digital literacy of the whole people determines the comprehensive quality of the country, and it is also an important factor for the country to improve innovation and development in the digital age. The drive of digital economy to regional economic growth is based on the following three aspects: first, drive the demand for innovation. Consumers in the Internet era are also data producers. Big data records commodity purchase behavior, choices, and attitudes, explores consumers’ hidden needs, and opens up a huge new consumer market by using electronic online retail. Second, drive innovation supply. As emerging production factors, cloud computing and the Internet have reshaped the market production relations, solved the current problems faced by small- and medium-sized enterprises, such as shortage of

funds and insufficient supply of labor and talents, and created emerging business systems and business supply models. Third, improve the “global village market.” Digital economy not only upgrades and transforms traditional industries such as manufacturing, agriculture, construction, and industry, but also improves and transforms service industries such as education and medical treatment with high barriers. Digital economy breaks the industrial boundary and forms a new business ecological model of cross-border industrial chain.

**3.2. Construction of Digital Economy Index of System.** Regarding the selection of digital economy indicators, refer to the indicators and measurement methods issued by the State Statistical Bureau, China Academy of Telecommunication Research of MIIT (CAICT), Tencent Research Institute, etc., and follow the high principle of digital economy development, reliability, and accuracy of indicator sources, to determine the following indicators and weights: first, there is digital infrastructure. Digital facilities are the foundation and the technical support for the development of the digital industry. Five data including Internet penetration rate, mobile phone penetration rate, Internet port access, IPv4 number, and the proportion of CN domain names to the total number of domain names are selected to measure this indicator, and the weight of each indicator is set to 20%. Secondly, there is digital ecologicalization [6, 7]. The ability of technological innovation determines the development realm of an enterprise. The high-frequency iterative technological innovation of the digital economy and the cruelly competitive business ecological model are important characteristics of the digital industry ecology. The ICT industry’s fixed investment in the total investment ratio of the whole society, the number of unicorn companies, software business revenue, software product revenue, and software integration revenue indicators are selected to measure the degree of digital ecologicalization, and the weight of each indicator is set to 20%. Thirdly, there are digital talents. The digital economy is a knowledge-based and innovative economy. High-quality talents and high-level scientific research capabilities are the infinite driving force for the sustainable development of the digital economy. In this thesis, the number of degrees awarded by the major in ordinary high schools and high schools is used as the basic data for measuring digital talents, and the weight of each index is set to 50%. Fourthly come the industry value lags behind digit. The added value of industry, the added value of the primary industry, and the added value of the tertiary industry are highly integrated with the digital industry in various fields. However, due to the lagging development of the digital economy in this period, these three indicators are selected to reflect the preliminary industrial development data of the digital economy decolonization and expropriation as a factor of the next development period. The weight of each index is equal to the weight of each level index. The weight of each index is set to 33.3%.

**3.3. Data Sources and Calculation Results.** The above indicator data comes from the State Statistical Bureau and the “Statistical Report on China’s Internet Development,” etc. The starting year of the software industry statistics is 2011, so the starting year of the data selected here is 2011. According to the data from 2011 to 2020, the software business revenue, software product revenue, system integration revenue, tertiary industry increase, and industrial value-added index are first standardized. All indicators are weighted, and the results of the digital economy index are shown in Table 1.

Measured from the digital economy index of China’s 30 provinces from 2011 to 2020, the leading regions of China’s digital economy development are mainly located in the Circum-Bohai-Sea, the Yangtze River Delta, and the Pearl River Delta. Judging from the results at the level, Guangdong Province has always occupied the top position. Based on the guidance of excellent digital infrastructure, industrial development, and policy guidance, Guangdong has become a leader. In 2020, Guangdong committed to building and improving big data foundation and social big data public service platform, etc. Beijing, Shanghai, Tianjin, and Zhejiang continue to develop digitally. These provinces are the areas with a high penetration rate of digital life (such as online car reservation, third-party online settlement, bicycle sharing, and making). The hot spots centered on Sichuan, Hubei, Fujian, Shaanxi, and Shandong have huge potential for economic development. With the provincial capital as the center, we will cooperate with neighboring cities to complement each other and form a digital ecological dialogue. In March 2020, China’s first national-level big data comprehensive pilot zone was established in Guizhou Province. In October 2020, the Inner Mongolia Autonomous Region approved China’s only national big data comprehensive test zone for infrastructure construction plans and development and also approved two span type comprehensive test zones and four regional demonstration comprehensive test zones for the Beijing-Tianjin-Hebei and Pearl River Delta. They are generally “from observation to exploration, from preliminary construction and development, partial integration, key breakthroughs to balanced development, and this road will move forward.” Large and fast-growing provinces will become a new driving force for China’s digital economy development from 2020 to 2030.

**3.4. Empirical Test.** The original data of each variable comes from the “China Science and Technology Statistical Yearbook” (2011–2020) and State Statistical Bureau. The very few missing data are supplemented by the average method. RD (registered trademark) and PG (registered trademark) are flattened according to the index based on 2011. For descriptive statistics of variables, please refer to Table 2.

The descriptive statistical results of the main indicators are shown in Table 3 and Figure 1.

**3.5. Analysis of Basic Estimation Results.** First of all, to determine whether the mixed regression model or the fixed model is to exclude the mixed regression model through F check. Second, through Hausman’s inspection, the model is

determined, and finally it is shown that the choice of fixed-effect model is scientific [11]. Here, the specific estimation results of the fixed-effect model are shown in Table 4. And the coefficients are all significant at the 1% level, which also verifies the assertion that the digital economy proposed in hypothesis 1 directly promotes regional total factor production. From the point of view of the control variables, the government intervention (gov) and the coefficient of openness to the outside world are obviously negative in the impact on the advancement of the industrial structure. This is basically consistent in the existing research, which shows that when the degree of government intervention is high, it will affect the advanced development of the industrial structure. The degree of opening to the outside world restricts the advancement of the industrial structure. This may be related to China’s long-term position at the low end of the international division of labor value chain, and most of its exports are labor-intensive products. The coefficient of marketization level (market) is significantly correct showing that the higher the degree of marketization, the more conducive it is to the realization of advanced industrial structure. Among the influencing factors of industrial structure rationalization, the coefficients of government intervention (gov), marketization level (market), and fixed asset investment level (invest) have dropped significantly, which has a significant role in promoting the rationalization of industrial structure.

In order to verify the mechanism of the digital economy on regional total factor production, this paper uses the intermediary effect model, taking human capital and scientific and technological innovation as intermediate variables, respectively, to analyze the influence mechanism of the digital economy on the advancement of the industrial structure and the rationalization of the industrial structure. The specific analysis results are shown in Table 5. Consistently with hypothesis 2, it indicates that the digital economy has an indirect impact on regional total factor production.

It can be seen from Table 5 that taking human capital as a mesomeric variable, the influence coefficient of the digital economy on human capital is positive, with a significant level of 1%, and the development of the digital economy has a positive impact on the improvement of human capital. The regression coefficients of human capital and digital economy for the advancement of the industrial structure are also significantly positive, and the RI regression coefficients for the rationalization of the industrial structure are all significantly negative; the digital economy shows that, by positively affecting human capital, it can indirectly promote the advancement of the industrial structure and the rationalization of the industrial structure. Other factors remain unchanged. Each additional unit of the comprehensive development of the digital economy will directly increase the level of industrial structure by 0.799 units. Meanwhile, the level of human capital will be increased to 2.797 units, which indirectly rises to 0.080 units. The indirect effect accounts for 9.10% of the total effect. In addition, the comprehensive development level of the digital economy is that, for every additional unit, the rationalization of the industrial structure will directly increase to 0.804 units.

F value	18.59	58.26	9.02	23.46	56.9	8.70

While increasing the level of human capital, it will promote the rationalization of the industrial structure, indirectly increasing by 0.233 units, with a total effect of 1.027 units. Indirect effects account for 21.71% of all effects.

When considering technological innovation as a mesomeric variable, it can be seen from Table 4 on technological innovation that the regression coefficient is significant at the 1% significance level. The regression

coefficients of technological innovation and digital economy to the advancement of the industrial structure are significantly positive. The digital economy shows that, by improving the level of technological innovation, it can indirectly promote the advancement and the rationalization of the industrial structure. Other factors remain unchanged. For each additional unit of the comprehensive development of the digital economy, the advanced industrial structure will directly increase to 0.776 units, and the level of technological innovation will be increased to 0.038 units, resulting in an indirect increase of 0.103 units in the advanced industrial structure. The effect is 0.879 units, and the indirect effect accounts for 11.72% of the total effect. In addition, for every additional unit of the comprehensive, the rationalization of the industrial structure will directly increase to 0.736 units. While the digital economy promotes the improvement of the level of technological innovation, it indirectly promotes the rationalization of the industrial structure by 0.289 units, with a total effect of 1.025 units. The indirect effect accounts for 28.20% of the total effect.

On the whole, when human capital is a mesomeric variable, the ratios of the digital economy on the advancement and rationalization of industrial structure are 1 and 4:1; when technological innovation is the intermediary variable, the ratio of the direct effect and the indirect effect of the digital economy on the advancement of the industrial structure and the rationalization of the industrial structure is 8:1 and 3:1, respectively. Whether it is based on the advancement of the industrial structure or the rationalization of the industrial structure, the direct effect of the digital economy on regional total factor production exceeds that of the digital economy, improving the indirect effect of human capital accumulation and increasing the level of technological innovation on regional total factor production [12, 13]. Therefore, from the analysis of this paper, the influence of digital economy on regional total factor production is mainly direct promotion, supplemented by indirect promotion.

**3.6. Nonlinear Analysis.** In order to investigate the nonlinear relationship between the digital economy and regional total factor production, the panel threshold model is used to test, and the level of numerical economic development is selected as the threshold variable in this paper. First, confirm the existence of the threshold variable. Empirical results are available on request (due to space limitations, no specific results are listed). There are double thresholds for the impact on the rationalization of the industrial structure of the digital economy, and each threshold is significant at a significant level of 1%, which verifies the hypothesis 3 proposed above. Based on this, the model that sets the specific threshold number is regressed, and the specific nonlinear regression results are shown in Table 6.

The reason for this phenomenon may be that if the development level of the digital economy is low, the digital economy will have a greater role in promoting labor productivity and the optimization of the proportion of the three industries to a certain extent. As the development

level of the digital economy increases, the industrial proportional relationship is relatively complete, and the increase in labor productivity is slow. The two will not change as much as when the development level of the digital economy is low. Therefore, the role of the digital economy in promoting the advancement of the industrial structure is weakening.

When it is in the range of [0.550, 0.563], the digital economy significantly promotes the rationalization of the industrial structure. When it is greater than 0.563, the digital economy significantly affects the rationalization of the industrial structure. The promotion effect increases from 0.531 to 0.526, showing the increasing tendency of the boundary effect. As a general-purpose technology, digital technology is applied to various subindustries. The nonlinear impact of the digital economy on the rationalization of the industrial structure is due to the above characteristics. In the early stage of the development of the digital economy, the level of development of digital technology is not high, and it is mainly used in life service fields, such as medical care, education, and shopping, and there may be an insignificant phenomenon. With the rapid development of digital technology, the digital economy has gradually been applied to the field of manufacturing, which has a significant positive impact on optimizing the three industrial structures and promoting the rationalization of the industrial structure.

**3.7. Analysis of Heterogeneity.** In order to test whether on regional total factor production, this paper divides 30 provinces into three regions: east, middle, and west according to the traditional division method that is, three subsamples. Analyze the heterogeneous impact of digital economy on regional total factor production, and the regression results are shown in Table 7.

It can be seen from Table 7 that, from the perspective of the three major regions of the east, middle, and west, the digital economy has a significant role in promoting the advancement of the industrial structure and the regression coefficients are all significant at a significant level of 1%.

From the perspective of the degree of digital economy's promotion of advanced industrial structure, the impact of the digital economy has regional differences. Specifically, "the central region < western region < eastern region;" in other words, compared with the eastern region, the central and western regions can obtain more dividends. The digital economy and nonlinearity analyzed above are related to the impact of the advancement of the industrial structure. It not only promotes the advancement of the industrial structure, but also effectively narrows the gap between backward and developed regions. The impact of the digital economy on the rationalization of the industrial structure is different from the impact on the advancement of the industrial structure. The impact of the digital economy on the rationalization of the industrial structure in the eastern region is not significant. From the perspective of the central and western regions, the development of the digital economy has a significant role in promoting the rationalization of the industrial structure, and the regression coefficients are all significant at a significant level of 1%. However, the western region can get more dividends from the development of the digital economy. This proves once again that the development of the digital economy can further reduce the differences in the industrial structure between regions and promote the rationalization and development of the regional industrial structure. In view of the existence of the above economic phenomena, this paper believes that the main reasons are as follows: (1) the digital economy in the eastern region has developed rapidly and the level of development is relatively high. The industry tends to be "service-oriented," and the dividends of the digital economy that affect the production of the entire region may have been released in advance. (2) The internal gap in the development level of the digital economy in the eastern region is significantly larger than that in other regions. The comprehensive development level index at the beginning of the survey was [0.559, 0.710]. Before the final exam, this level index was in the range of [0.582, 0.939]. The development level of the digital economy with too large gap will produce the phenomenon of "overly sparse" and "overdense" elements. Moreover, because it is

not conducive to the coordinated development of the industry, the digital economy in the eastern region has an insignificant impact on the rationalization of the industrial structure.

#### 4. Discussion

Research on the impact of digital economy on economic growth and the development trend of digital economy will be done in the future. Liu Chunmei et al. studied the development process and economic characteristics of information economy (digital economy) and made an empirical regression on the quality of economic growth. The results show that information economy affects long-term economic growth by affecting the quality of economic growth. It establishes a vector autoregressive model to regress TFP and finds that information factors have a positive role in promoting TFP. The contribution of digital economy to GDP has gradually increased, bringing millions of new jobs. It is the most active field of economic development in recent years. Digital economy uses science and technology to change the current social lifestyle and industrial model and reshape the core competitiveness of the industry. Based on the above literature analysis, the following is found: firstly, scholars have enriched the meaning and characteristics of digital economy from different angles, dimensions, and directions, but it also makes it difficult to construct indicators to measure digital economy. Secondly, most scholars pay attention to the development trend and development strategy of digital economy, but the research on the impact of all-factor production of digital economy is insufficient.

In this paper, the digital economy index has a significant role in promoting technological innovation. The variable coefficients of each digital economy index are positive, indicating that the development of digital economy brings economic progress. From the perspective of interaction term coefficients, some coefficients are significantly nonzero. Therefore, when there are nonlinear interaction terms, the model can more accurately describe the current phenomenon. The negative coefficient

indicates that the smaller the number of effective invention patents of Industrial Enterprises above Designated Size, the greater the marginal effect of digital economy on total factor productivity. This shows that the degree of digital technology innovation in China is still at a low level and the current innovative industries prefer nondigital technology, resulting in the phenomenon that the marginal effect of digital technology is negative. In addition, when digital technology is integrated with real industries, there is an uneven penetration of the three industries, resulting in an unbalanced development of technology driven industries. Secondly, the impact of digital economy index on innovation in different regions is different. From the above regression results, the digital economy in the eastern coastal area plays the greatest role in promoting total factor productivity. At present, digital technology is in the early stage of integration with industry, which is manifested in the overheated development of low-end industries and the overvaluation of domestic economics, meal delivery, and other industries in the capital market. In big cities and mega cities, enterprises are facing more complex competitive markets and more serious information asymmetry, which has greatly changed the survival of the fittest mechanism. We need to pay attention not only to quality and price fluctuation, but also to marketing means and methods. The new innovation model makes the current real economy face great pressure, so the government's ability of governing the market needs to be improved.

## 5. Conclusions

In view of the research on the optimization of the total factor production impact assessment model of the digital economy development area, the digital economy development area total factor production impact method is proposed on the fuzzy hierarchical VISC algorithm proposed in this paper. The fuzzy hierarchical VISC algorithm is used to carry out an analysis of the relevant information of the total factor production impact assessment. Experiments have proved that, by using this calculation method to carry out the evaluation of the total factor production impact of the digital economy development area, the information combination analysis ability is high, the accuracy of the total factor production impact capacity evaluation is greatly improved, and the utilization efficiency of the digital economy development resources is improved.

Based on the above analysis, this paper focuses on the development of digital economy and industrial integration. There is an obvious positive correlation between the development of digital economy and regional distribution, and it has brought great demonstration effect and amplification to urban economic development. Therefore, to promote the innovation and Entrepreneurship of regional digital economy, we need not only large enterprises with leading role, but also small enterprises with strong momentum, also in addition to enterprises that dare to reform and innovate to

jointly drive the high-quality development of regional economy.

Seismic noise attenuation plays an important role in seismic interpretation. The empirical mode decomposition, synchrosqueezing wavelet transform, variational mode decomposition, etc., are often applied trace by trace. Multivariate empirical mode decomposition, multivariate synchrosqueezing wavelet transform, and multivariate variational mode decomposition were proposed for lateral continuity consideration. Due to large input data, mini-batch multivariate variational mode decomposition is proposed in this paper. The proposed method takes advantages both of variational mode decomposition and multivariate variational mode decomposition. This proposed method firstly segments the input data into a series of smaller ones with no overlapping and then applies multivariate variational mode decomposition to these smaller ones. High frequency-domain noise is filtered through sifting. Finally, the denoised smaller ones are concatenated to form components (or intrinsic mode functions) of the input signal. Synthetic and field data experiments validate the proposed method with different batch sizes and achieve higher signal-to-noise ratio than the variational mode decomposition method.

## 1. Introduction

Seismic noise attenuation plays an important role in seismic interpretation [1–3]. A variety of methods have been proposed for attenuating or removing random noise in order to enhance the signal-to-noise ratio (SNR) [4–8]. The transform-based methods, such as Fourier transform [9], wavelet transform [10], curvelet transform [11], and seislet transform [12], assume that the input signal has sparse representation with predetermined base, and under the predetermined base, noise and clean signal can be separated in the transform domain [7, 13–15].

Apart from these fixed basis methods mentioned above, there are also some data-driven methods [16]. Empirical mode decomposition (EMD) [17–19] recursively decomposes an input signal into so-called intrinsic mode functions (IMF); these IMFs are amplitude and frequency modulated subsignals with slow variations. EMD is widely used for trend detection and spectrum analysis in conjunction with Hilbert transform. Lack of a rigorous theory background for

the EMD method leaves room for other decomposition methods to come. Synchrosqueezing wavelet transform (SWT) [20], a hybrid of wavelet transform and reassignment method, squeezes values of wavelet transform to its ridges in order to sharpen the time-frequency distribution. Another data-driven method is a nonparametric one called singular spectrum analysis (SSA) [21], which firstly computes the singular value decomposition of a covariance matrix derived from the input signal. After that, SSA decomposes the input signal into a sum of components with meaningful interpretations. SSA captures the basic periodicity of an input signal and is widely used in different areas [22]. Variational mode decomposition (VMD) [23] utilizes the alternative direction method of multipliers (ADMM) and non-recursively decomposes an input signal into some principal modes. Like EMD and SSA methods, the decomposed modes of the VMD method are narrow banded and compact around some center frequencies.

Denoising methods based on EMD, VMD, and SSA, except in *f-x* fashion, are often applied trace by trace; lateral

continuity is not considered [24–26]. In order to improve SNR, the multichannel spatial coherence needs to be considered. Multivariate empirical mode decomposition (MEMD) [27] and multivariate synchrosqueezing wavelet transform (MSWT) [28], as extensions of EMD and SWT, have been proposed to try to separate multivariate modes of faster oscillations from slower ones as a whole. Recently, multivariate variational mode decomposition (MVMD) [29], an extension of VMD, has emerged to seek a collection of multivariate modulated components with minimum collective bandwidth and full signal reconstruction property. These extended methods have been used in wide areas with multivariate data analysis, such as EEG and ECG applications [30–32]. With their effectiveness of these multivariate methods, they usually accompanied with high computational complexity due to large input data. Furthermore, it is a tricky problem for the parameters' setting. In view of these situations above, mini-batch multivariate variational mode decomposition (MB-MVMD) is proposed in this paper. The proposed method firstly segments the input data into a number of batches of fixed size with no overlapping. After that, it applies VMD or MVMD for the segmented data, depending on the input data which are segmented trace by trace or not. Noise on high-frequency domain is filtered through the sifting process. Finally, the decomposed data are concatenated to form components (or IMFs) of the input signal. The proposed method has the following advantages:

- (i) VMD and MVMD are two special cases of the proposed method.
- (ii) Initial parameters can be set differently depending on different batch sizes.
- (iii) Lateral continuity is considered if the data are not segmented trace by trace.
- (iv) Instead of directly decomposing the input data as a whole, the MB-MVMD method segments the input signal into a series of smaller ones. Solutions to the smaller ones are then combined to give a solution to the original problem. This divide-and-conquer technique, therefore, promotes the computing efficiency.

## 2. From Univariate to Mini-Batch Multivariate Variational Mode Decomposition

*2.1. Univariate Variational Mode Decomposition.* The univariate variational mode decomposition seeks  $K$  number of intrinsic mode functions  $u_k(t)$  such that

$$x(t) = \sum_{k=1}^K u_k(t), \quad (1)$$

where  $u_k(t) = a_k(t)\cos\phi_k(t)$ . These modes  $u_k$  are chosen to minimize the bandwidths sum and fully reconstruct the input signal  $x(t)$ ; these can be mathematically written as [23]

$$\begin{aligned} \min_{\{u_k\}, \{\omega_k\}} & \sum_{k=1}^K \left\| \partial_t [u_k^+(t)e^{-j\omega_k t}] \right\|_2^2, \\ \text{s.t.} & \sum_{k=1}^K u_k(t) = x(t), \end{aligned} \quad (2)$$

where  $\{\omega_k\}$  denotes the center frequency and  $u_k^+(t)$  denotes the analytic signal corresponding to  $u_k(t)$ :

$$u_k^+(t) = u_k(t) + j\mathcal{H}u_k(t), \quad (3)$$

where  $\mathcal{H}$  denotes the Hilbert transform:

$$\mathcal{H}u(t) = \frac{1}{\pi} \int_{-\infty}^{+\infty} \frac{u(x)}{t-x} dx. \quad (4)$$

Equation (2) uses frequency modulation and Wiener filtering techniques.

For gratified solutions, two constraints are added to optimization (2) to form a Lagrangian problem:

$$\begin{aligned} \mathcal{L}(\{u_k\}, \{\omega_k\}, \lambda) &= \frac{\alpha}{2} \sum_{k=1}^K \left\| \partial_t [u_k^+(t)e^{-j\omega_k t}] \right\|_2^2 \\ &+ \left\| x(t) - \sum_{k=1}^K u_k(t) \right\|_2^2 + \left\langle \lambda(t), x(t) - \sum_{k=1}^K u_k(t) \right\rangle. \end{aligned} \quad (5)$$

Alternative direction method of multipliers (ADMM) [23], summarized in algorithm (1), is used for the solution of optimization (5) in time domain.

For computational simplicity, the ADMM algorithm for VMD in time domain is transformed to frequency domain and is summarized in algorithm (2).

VMD nonrecursively decomposes input signal into modes with compacted bandwidths and limited amplitudes' variations. Since VMD decomposes input signal trace by trace, lateral continuity is not considered.

*2.2. Multivariate Variational Mode Decomposition.* Suppose the input signal consists of  $M$  channels, that is,  $\mathbf{x}(t) = [x_1(t), x_2(t), \dots, x_M(t)]$ . As an extension of the VMD method, we try to find  $K$  multivariate modulated components  $\{\mathbf{u}_k(t)\}_{k=1}^K$  that will fully construct the input signal  $\mathbf{x}(t)$ :

$$\mathbf{x}(t) = \sum_{k=1}^K \mathbf{u}_k(t), \quad (6)$$

where the  $k$ th multivariate component  $\mathbf{u}_k(t)$  is a vector with  $M$  components:

$$\mathbf{u}_k(t) = \begin{bmatrix} u_{k,1}(t) \\ u_{k,2}(t) \\ \vdots \\ u_{k,M}(t) \end{bmatrix} = \begin{bmatrix} a_{k,1}(t)\cos(\phi_{k,1}(t)) \\ a_{k,2}(t)\cos(\phi_{k,2}(t)) \\ \vdots \\ a_{k,M}(t)\cos(\phi_{k,M}(t)) \end{bmatrix}. \quad (7)$$

Let  $\mathbf{u}_k^+(t)$  denote the Hilbert transform of  $\mathbf{u}_k(t)$ :

```

Initialization:  $u_k^0, \omega_k^0, \lambda^0$ , maxiter, eps,  $n = 0$ 
while  $n < \text{maxiter}$  and  $\text{tol} < \text{eps}$  do
  for  $k = 1: K$  do
     $u_k^{n+1} := \arg \min_{u_k} \mathcal{L}(\{u_{i < k}^{n+1}\}, u_k, \{u_{i > k}^n\}, \{\omega_i^n\}, \lambda^n)$ 
  end
  for  $k = 1: K$  do
     $\omega_k^{n+1} := \arg \min_{\omega_k} \mathcal{L}(\{u_i^{n+1}\}, \{\omega_{i < k}^{n+1}\}, \omega_k, \{\omega_{i > k}^n\}, \lambda^n)$ 
  end
   $\lambda^{n+1} := \lambda^n + \tau(x - \sum_k u_k^{n+1})$ 
   $n := n + 1$ 
end

```

ALGORITHM 1: ADMM for VMD in time domain.

```

Initialization:  $\hat{u}_k^0, \omega_k^0, \hat{\lambda}^0$ , maxiter, eps,  $n = 0$ 
while  $n < \text{maxiter}$  and  $\text{tol} < \text{eps}$  do
  for  $k = 1: K$  do
     $\hat{x}(\omega) - \sum \hat{u}_i^{n+1}(\omega)$ 
     $\hat{u}_k^{n+1}(\omega) := -\sum_{i < k} \hat{u}_i^n(\omega) + (\hat{\lambda}^n(\omega)/2)^{1/2} + 2\alpha(\omega - \omega_k^n)^2$ 
  end
  for  $k = 1: K$  do
     $\omega_k^{n+1} := \int_0^\infty \omega |\hat{u}_k^{n+1}(\omega)|^2 d\omega / \int_0^\infty |\hat{u}_k^{n+1}(\omega)|^2 d\omega$ 
  end
   $\hat{\lambda}^{n+1} := \hat{\lambda}^n + \tau(\hat{x} - \sum_k \hat{u}_k^{n+1}(\omega))$ 
   $n := n + 1$ 
end

```

ALGORITHM 2: ADMM for VMD in frequency domain.

$$\mathbf{u}_k^+(t) = \begin{bmatrix} u_{k,1}^+(t) \\ u_{k,2}^+(t) \\ \vdots \\ u_{k,M}^+(t) \end{bmatrix} = \begin{bmatrix} u_{k,1}(t) + j\mathcal{H}u_{k,1}(t) \\ u_{k,2}(t) + j\mathcal{H}u_{k,2}(t) \\ \vdots \\ u_{k,M}(t) + j\mathcal{H}u_{k,M}(t) \end{bmatrix} = \begin{bmatrix} a_{k,1}(t)\exp(j\phi_{k,1}(t)) \\ a_{k,2}(t)\exp(j\phi_{k,2}(t)) \\ \vdots \\ a_{k,M}(t)\exp(j\phi_{k,M}(t)) \end{bmatrix}. \quad (8)$$

We modulate the  $k$ th multivariate component  $\mathbf{u}_k(t)$  by  $\omega_k$ ; corresponding to equation (2), the constrained optimization problem for MVMD is

$$\begin{aligned} & \arg \min_{\{u_{k,i}\}, \{\omega_k\}} \sum_{k=1}^K \sum_{i=1}^M \left\| \partial_t [u_{k,i}^+(t) e^{-j\omega_k t}] \right\|_2^2, \\ & \text{s.t.} \quad \sum_{k=1}^K u_{k,i}(t) = x_i(t), \quad i = 1, 2, \dots, M. \end{aligned} \quad (9)$$

The Lagrangian function with added two constraints is

$$\begin{aligned} \mathcal{L}(\{u_{k,i}\}, \{\omega_k\}, \lambda_i) &= \frac{\alpha}{2} \sum_{k=1}^K \sum_{i=1}^M \left\| \partial_t [u_{k,i}^+(t) e^{-j\omega_k t}] \right\|_2^2 \\ &+ \sum_{i=1}^M \left\| x_i(t) - \sum_{k=1}^K u_{k,i}(t) \right\|_2^2 + \sum_{i=1}^M \left\langle \lambda_i(t), x_i(t) \right. \\ &\left. - \sum_{k=1}^K u_{k,i}(t) \right\rangle. \end{aligned} \quad (10)$$

Just like algorithm (1), ADMM algorithm [29] is used for the solution of equation (10) in time domain and is summarized in algorithm (3).

ADMM algorithm [29] for MVMD in frequency domain is summarized in algorithm (4); it is simpler than MVMD in time domain.

MVMD takes multivariate input signal as a whole and tries to seek  $K$  number of multivariate components from the input signal with minimum sum of bandwidths. With big data input, ADMM for MVMD in frequency domain may have high computation complexity.

**2.3. Mini-Batch Multivariate Variational Mode Decomposition.** Mini-batch multivariate variational mode decomposition (MB-MVMD) takes the advantages of both VMD and MVMD methods. MB-MVMD segments the input data into a series of smaller ones with no overlapping; after the segmentation, these smaller ones are decomposed using ADMM method just as the MVMD or VMD. This

```

Initialization:  $\{u_{k,i}^0\}, \{\omega_k^0\}, \lambda_i^0$ , maxiter, eps,  $n=0$

         $\hat{x}_i(\omega) = \sum_{j,i} \hat{u}_{j,i}^{n+1}(\omega)$ 
         $\hat{u}_{k,i}^{n+1} := -\sum_{j>k} \hat{u}_{j,i}^n(\omega) + (\hat{\lambda}_i^n(\omega)/2) / 1 + 2\alpha(\omega - \omega_k^n)^2$ 
      end
    end
    for  $k=1: K$  do
       $\omega_k^{n+1} := \sum_{i=1}^M \int_0^\infty \omega |\hat{u}_{k,i}^{n+1}(\omega)|^2 d\omega / \sum_{i=1}^M \int_0^\infty |\hat{u}_{k,i}^{n+1}(\omega)|^2 d\omega$ 
    end
    for  $i=1: M$  do
       $\hat{\lambda}_i^{n+1} := \hat{\lambda}_i^n + \tau(\hat{x}_i(\omega) - \sum_k \hat{u}_{k,i}^{n+1}(\omega))$ 
    end
     $n = n + 1$ 
  end
end

```

ALGORITHM 5: ADMM for MB-MVMD in frequency domain.

FIGURE 1: VMD decomposition. From the top to bottom are the input signal and its VMD decomposition components.

mini-batch technique not only considers lateral continuity of the input data but also promotes the computational efficiency using divided-and-conquer technique.

Suppose the input data are  $\mathbf{X}$  with  $N$  traces (or columns). We firstly set the batch size and then compute the number of batches using floor function “ $\lfloor \cdot \rfloor$ ”:

$$\text{Number of batches} = \left\lfloor \frac{N}{\text{Batch size}} \right\rfloor. \quad (11)$$

After that, we extract the  $l$ th mini-batch data from the input data  $\mathbf{X}$ :

$$\mathbf{x}_l = \mathbf{X}[(l-1) * (\text{bs}) : l * (\text{bs})], \quad (12)$$

where “bs” denotes the batch size previously determined. Following the segmentation above, we use ADMM algorithm in frequency domain to decompose the  $l$ th mini-batch data and lastly concatenate the decomposed data to form components.

The computation processes of MB-MVMD in frequency domain are summarized in algorithm (5).

### 3. Experimental Results

Figure 1 shows a single seismic trace and its four extracted components using the VMD method. These four components are narrow banded. Figure 2 shows the sum of the four

FIGURE 2: Seismic trace and its sum of VMD components: “Original” is the input seismic signal, “Fit” is the sum of VMD components in Figure 1, and “Difference” is the difference between the input signal and its VMD approximation.

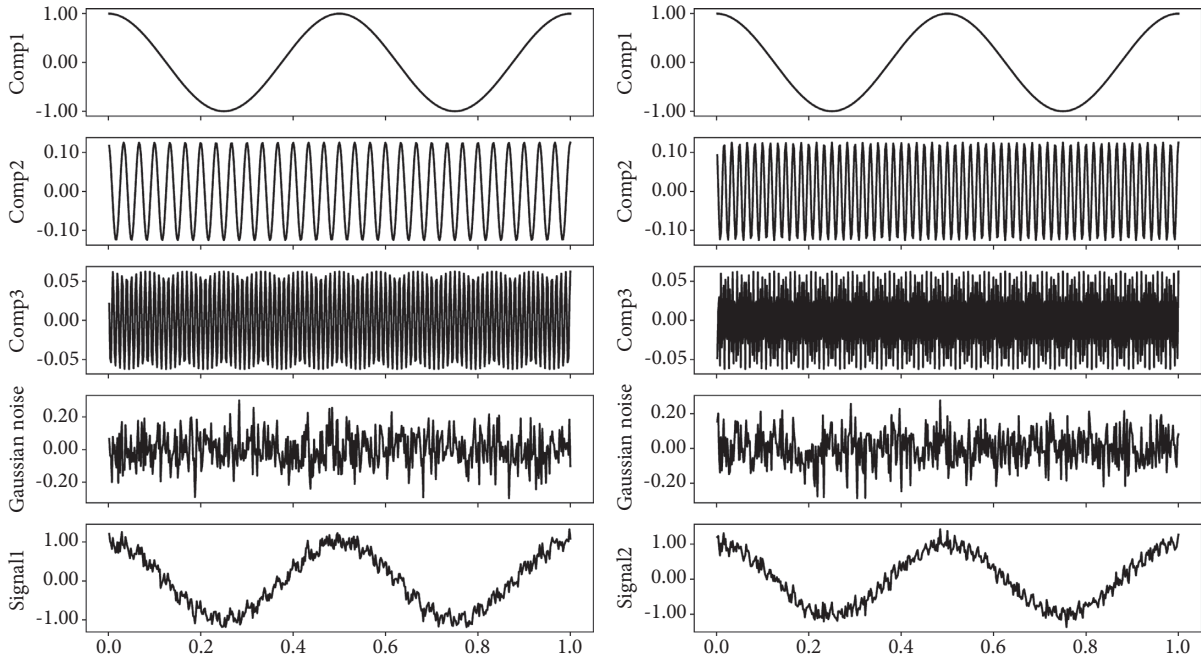

FIGURE 3: Bivariate signal: each has three components and a certain percentage of Gaussian noise. (a) The bottom of left column consists of three different tones (the top three signals in left column) and a certain percentage of Gaussian noise (the fourth signal in left column). (b) The bottom of right column also consists of three different tones and a certain percentage of Gaussian noise.

extracted components in Figure 1 and the difference between the sum and the original input single seismic trace. From these figures, we see that VMD extracts sub signals with compacted bandwidth subject to full signal reconstruction. The parameters for VMD decomposition are number of components  $K=4$  and bandwidth constraint  $\alpha = 500$ .

A bivariate signal with three different tones and a certain percentage of Gaussian noise is shown in Figure 3. We apply MVMD to this signal; the extracted components are shown in Figure 4(a). The parameters for the MVMD method are number of components  $K=4$  and bandwidth constraint  $\alpha = 500$ . For comparison, the MEMD method is also used to

decompose this bivariate signal; results are shown in Figure 4(b). From these figures, we see that MVMD uses fewer components than the MEMD method to represent the input signal.

SNR is often used as a qualitative indicator to show the effectiveness of a denoising method; it is defined as the ratio of signal power to the noise power and is often expressed in decibels:

$$\text{SNR} = 20\log_{10} \left[ \frac{A_s}{A_n} \right], \quad (13)$$

where  $A_s$  and  $A_n$  represent signal and noise powers.

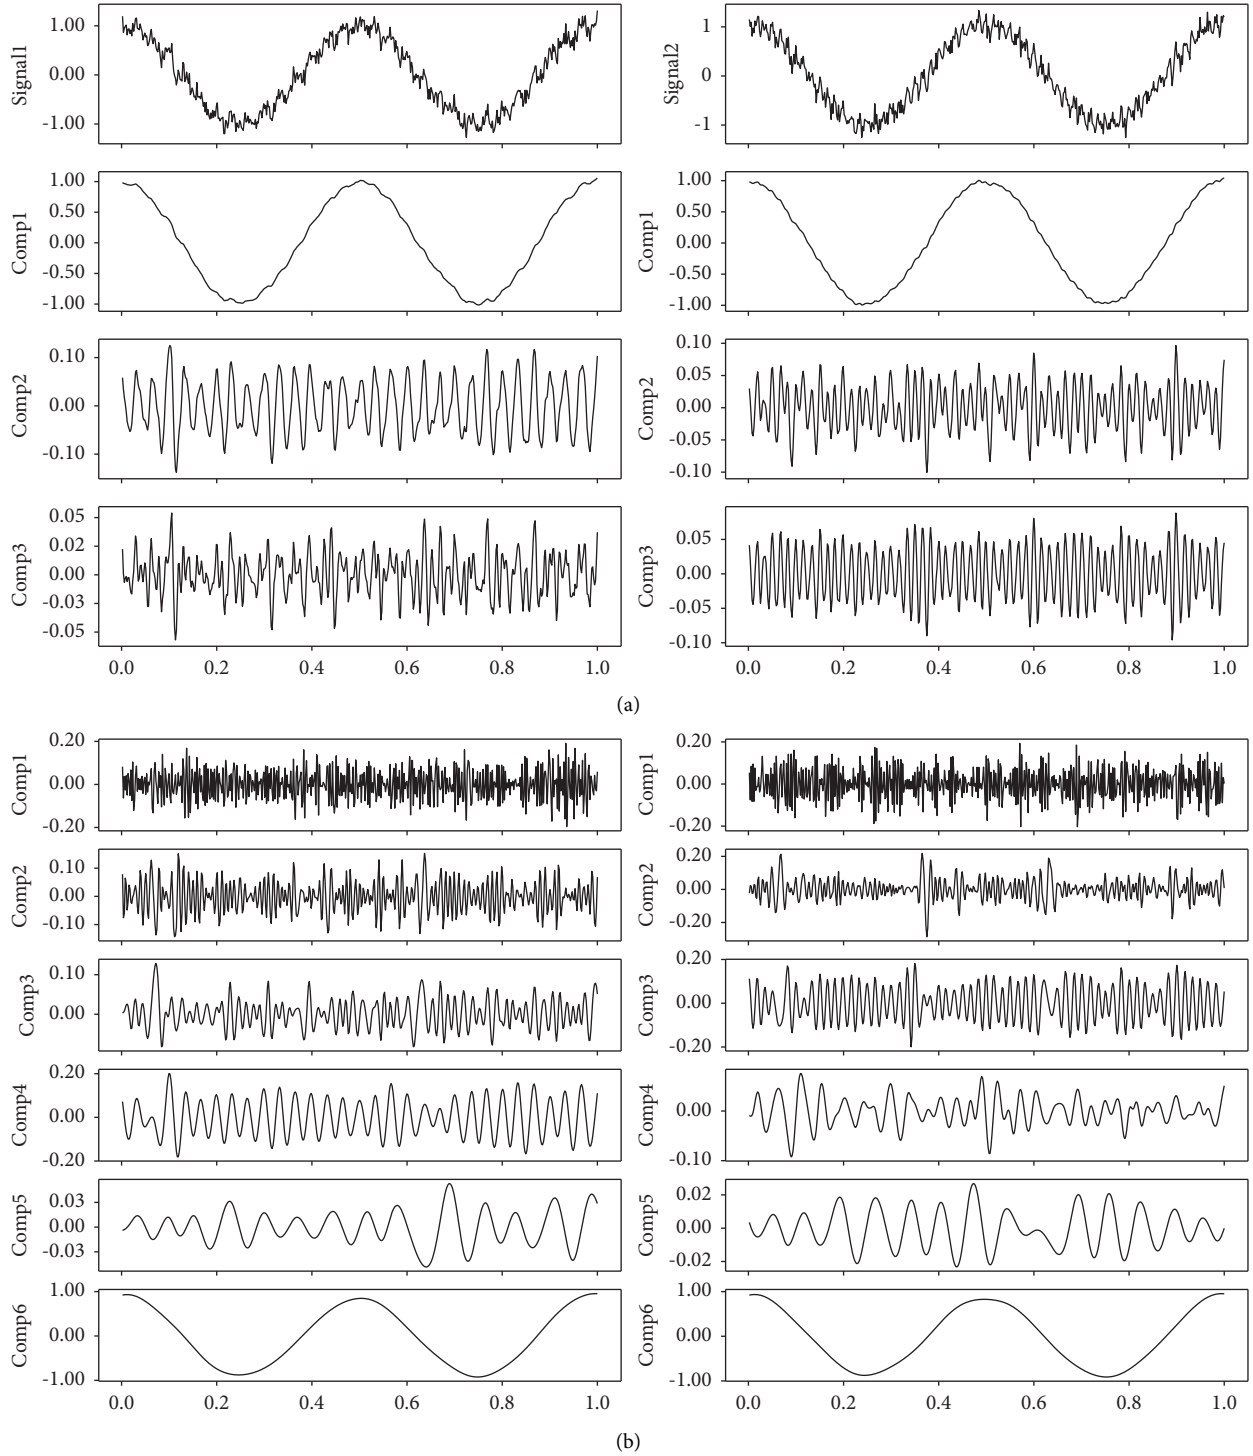

FIGURE 4: Decomposition of the bivariate signal in Figure 3. (a) MVMD: three components. (b) EMD: six components.

**3.1. Synthetic Data.** A synthetic seismic data with four linear events are used for test. The synthetic data have 256 traces, with time step  $\Delta t = 0.004$  and 512 samples. Figures 5(a), 5(b), and 5(c) are the synthetic signal, the random Gaussian noise, and the noisy data, respectively. Figure 6 shows denoised results using three different methods: FX-DECON, VMD, and MB-MVMD. Figures 6(a), 6(b), and 6(c) show the denoised result, removed noise using FX-DECON, and

the similarity between them. Figures 6(d), 6(e), and 6(f) show the denoised result, removed noise using VMD, and the similarity between them. The parameters of the VMD method are bandwidth constraint  $\alpha = 2000$  and  $\tau = 0.0$  and number of components  $K=4$ . Figures 6(g), 6(h), and 6(i) show the denoised result, removed noise using MB-MVMD of batch size eight, and the similarity between them. The parameters of the MB-MVMD method are

FIGURE 5: Synthetic seismic data with four linear events. (a) Clean data. (b) Gaussian random noise. (c) Data with noise added.

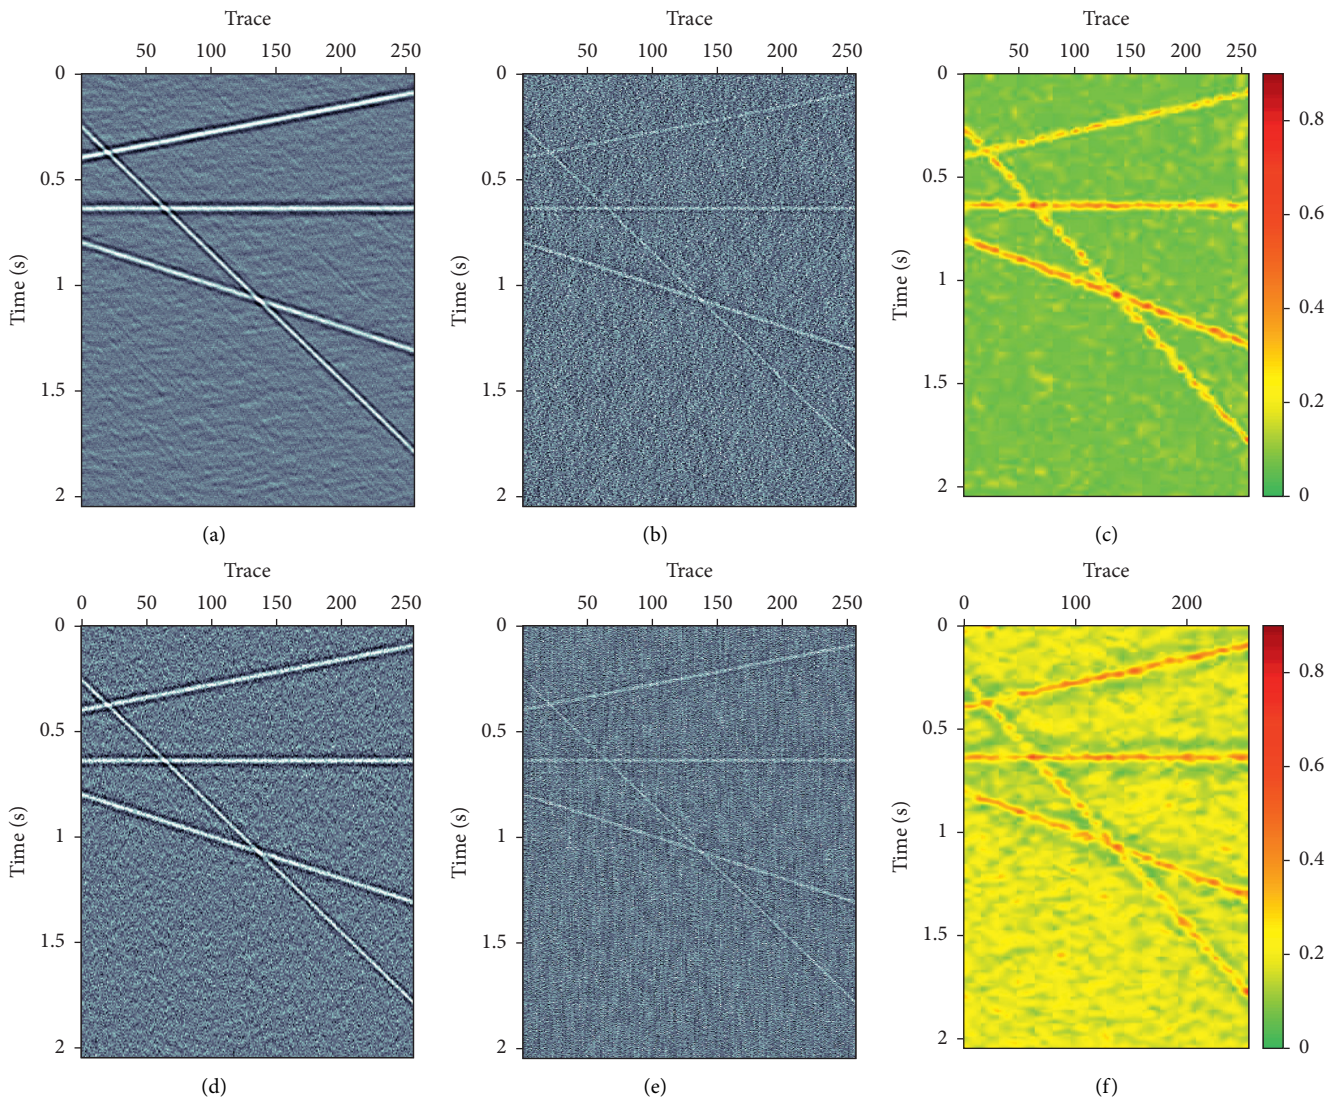

FIGURE 6: Continued.

FIGURE 6: Denoise comparisons. (a) Denoised data using FX-DECON. (b) Removed noise using FX-DECON. (c) Similarity between denoised data and its removed noise using FX-DECON. (h) Removed noise using MB-MVMD of batch size eight. (i) Similarity between denoised data and its removed noise using MB-MVMD of batch size eight.

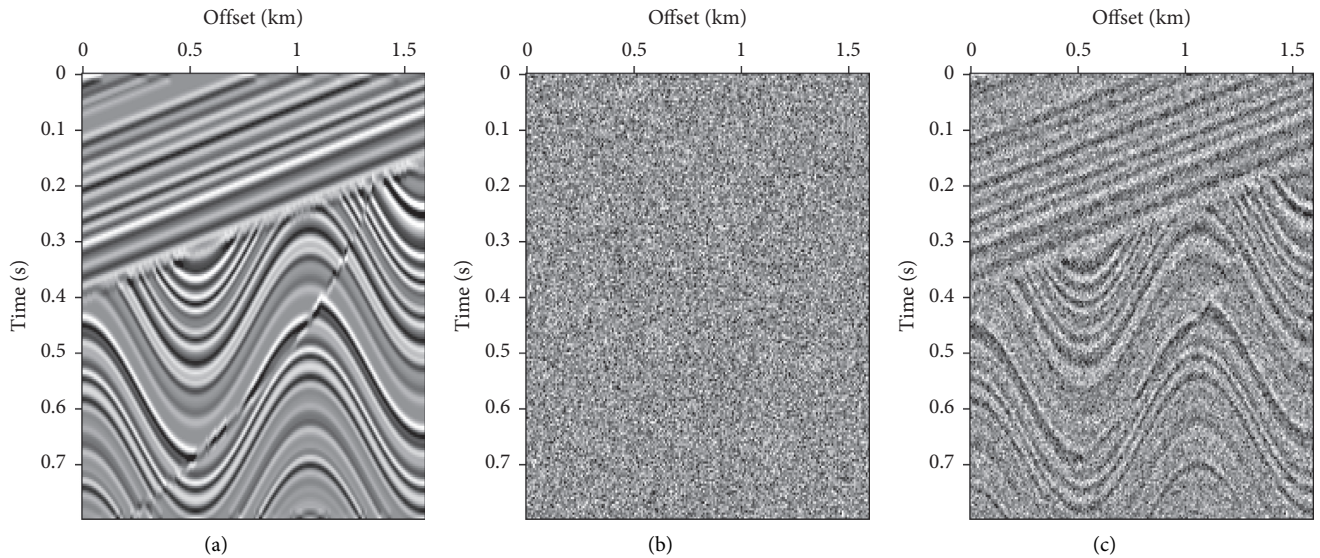

FIGURE 7: Synthetic seismic data with Gaussian noise. (a) Clean data. (b) Gaussian random noise. (c) Data with noise added.

$\alpha = 1000$ ,  $\tau = 0.5$ , and  $K = 4$ . From these figures, we can see that the denoised data of FX-DECON is better than the denoised one of VMD. The denoised data of MB-MVMD of batch size eight are the best, which can be seen from the denoised results, the removed noises, and the similarities of these three methods.

Another synthetic mode (shown in Figure 7) is used to test the proposed method. Figures 8(a), 8(b), and 8(c) are the denoised data, removed noise using FX-DECON, and similarity between them. Figures 8(d), 8(e), and 8(f) are the denoised data, removed noise using VMD, and similarity

between them. Figures 8(g), 8(h), and 8(i) are the denoised data, removed noise using MB-MVMD of batch size four, and similarity between them. The parameters of the VMD method are bandwidth constraint  $\alpha = 2000$  and  $\tau = 0.0$  and number of components  $K = 4$ . Parameters for MB-MVMD of batch size four are  $\alpha = 1000$ ,  $\tau = 0.5$ , and  $K = 4$ . The denoised result of FX-DECON is better than the denoised result of VMD; the denoised data of MB-MVMD are the best among these three denoising methods. The MB-MVMD method considers the lateral continuity of the input data; some degree of signal is removed as noise, which can be

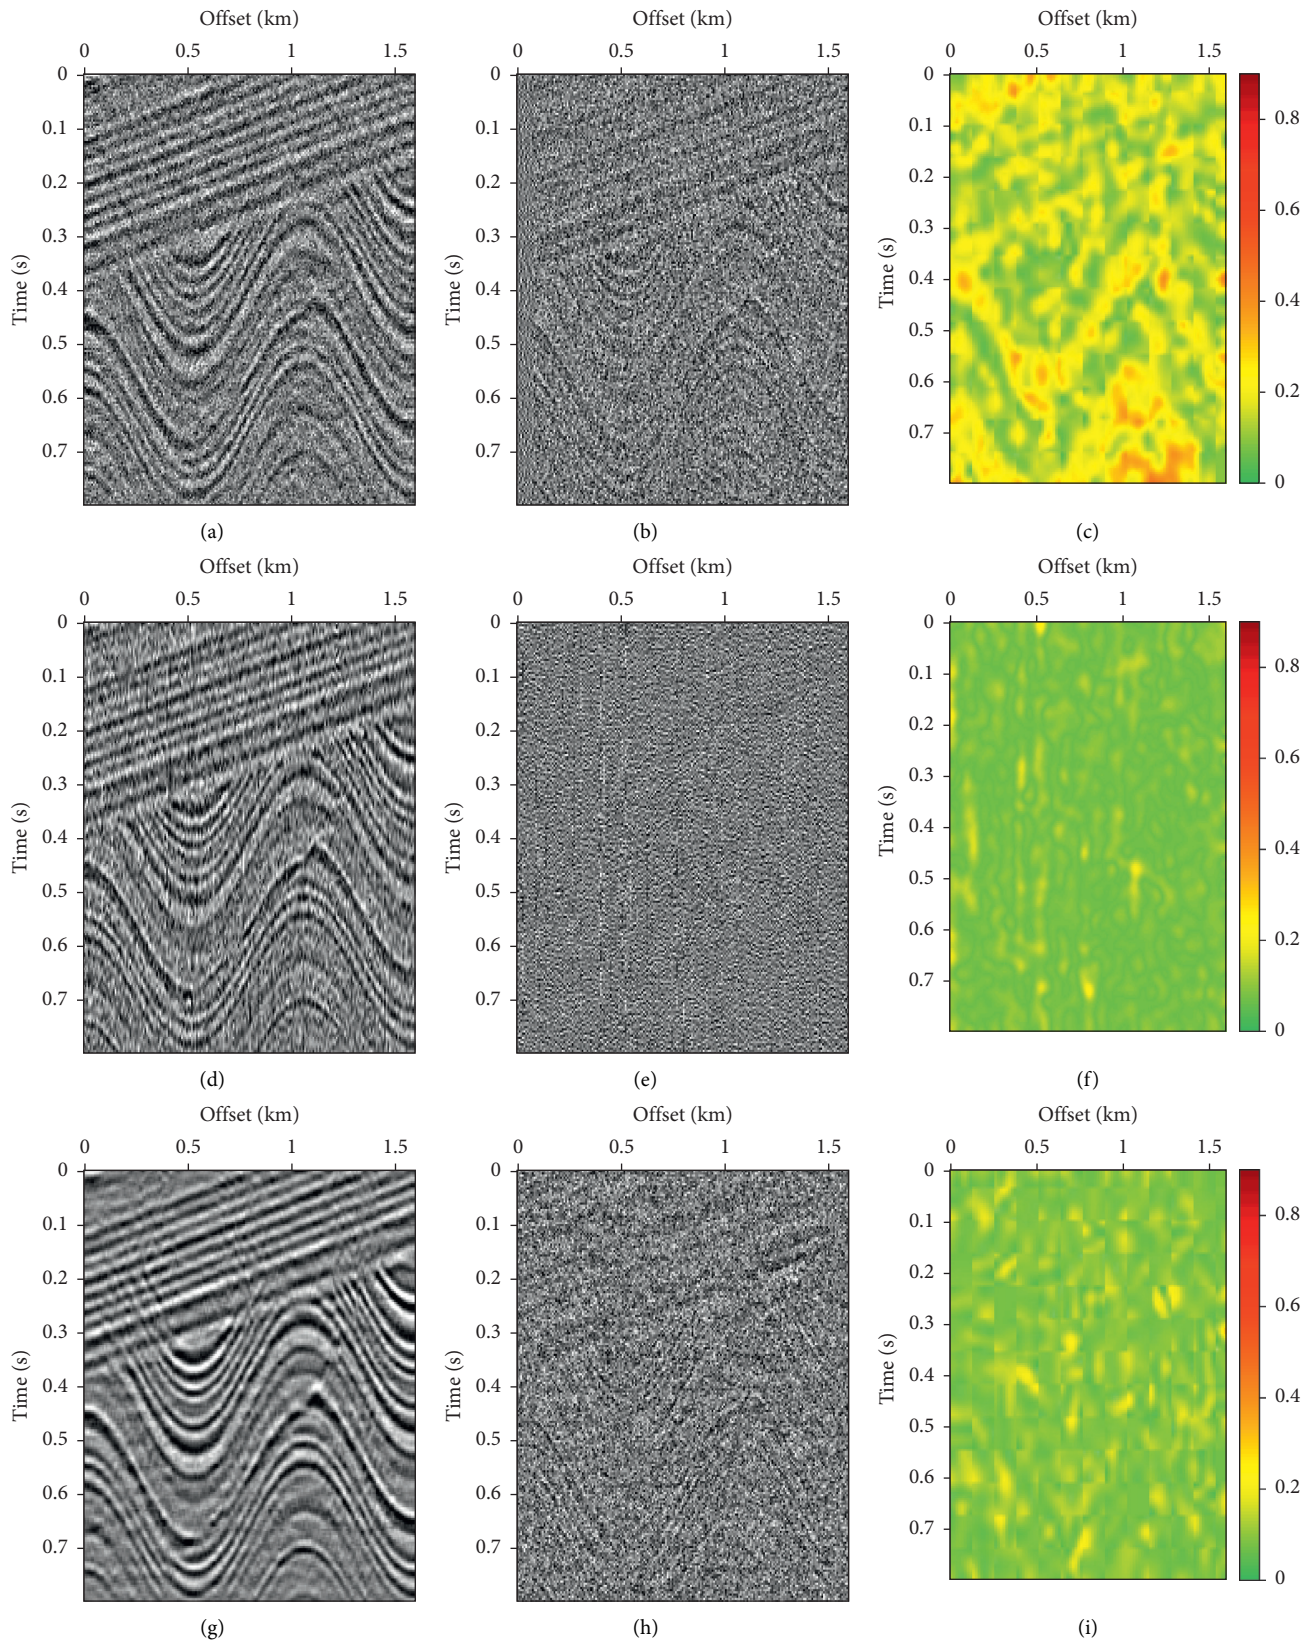

FIGURE 8: Denoise comparisons. (a) Denoised data using FX-DECON. (b) Removed noise using FX-DECON. (c) Similarity between denoised data and its removed noise using FX-DECON. (d) Denoised data using VMD. (e) Removed noise using VMD. (f) Similarity between denoised data and its removed noise using VMD. (g) Denoised data using MB-MVMD of batch size four. (h) Removed noise using MB-MVMD of batch size four. (i) Similarity between denoised data and its removed noise using MB-MVMD of batch size four.

TABLE 1: SNRs (in decibels) comparison using different batch sizes.

Batch size	2	4	8	16	32	64	128	256
Model 1	4.78	4.81	<b>6.89</b>	6.55	6.43	6.10	5.97	5.43
Model 2	5.89	<b>6.27</b>	6.12	5.83	5.74	5.61	5.57	4.98

FIGURE 9: Field data with Gaussian noise. (a) Field data. (b) Gaussian random noise. (c) Field data with noise added.

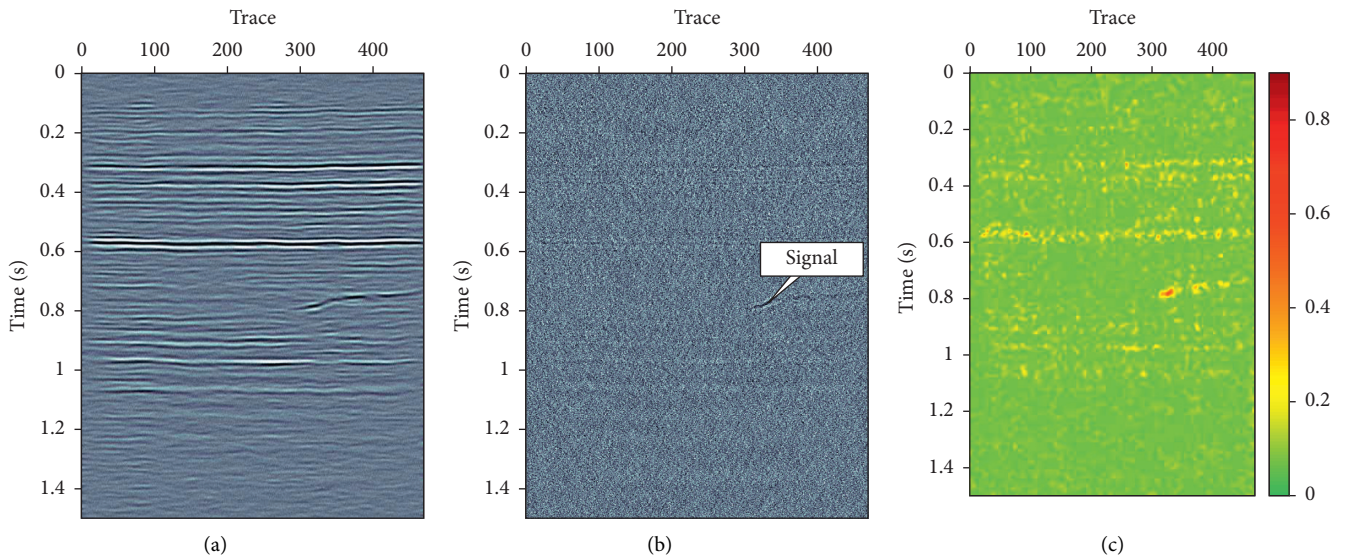

FIGURE 10: Continued.

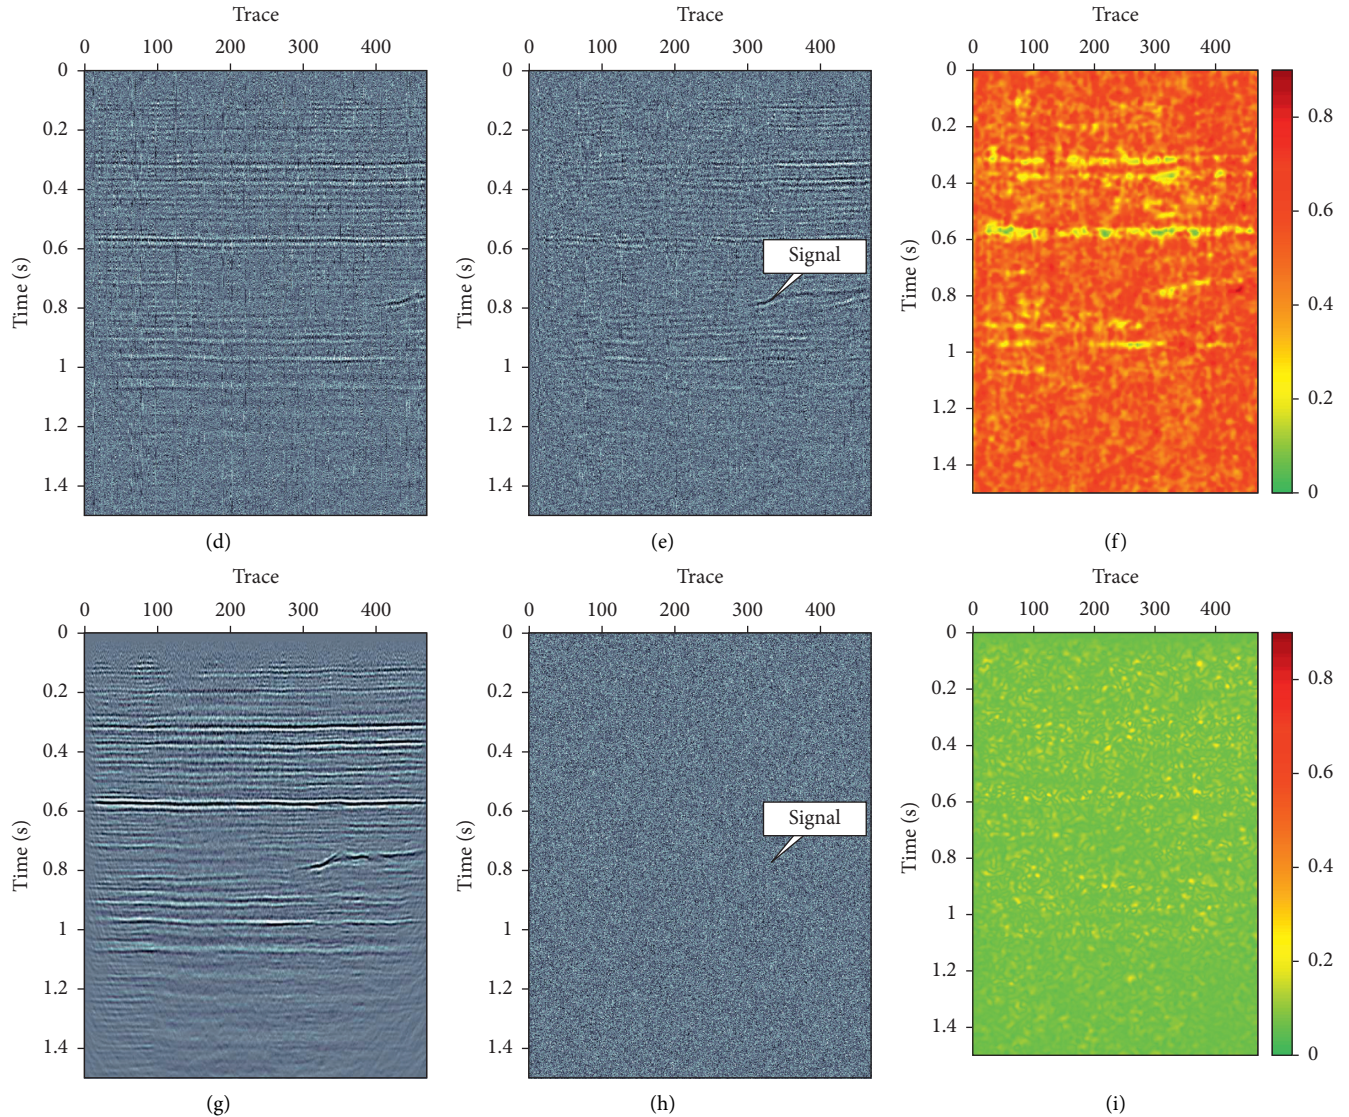

FIGURE 10: Denoise comparisons. (a) Denoised data using FX-DECON. (b) Removed noise using FX-DECON. (c) Similarity between denoised data and its removed noise using FX-DECON. (d) Denoised data using VMD. (e) Removed noise using VMD. (f) Similarity between denoised data and its removed noise using VMD. (g) Denoised data using MB-MVMD of batch size four. (h) Removed noise using MB-MVMD of batch size four. (i) Similarity between denoised data and its removed noise using MB-MVMD of batch size four.

seen from the removed noise data. Similarity of MB-MVMD of batch size four also reveals the effectiveness of the proposed method in random noise attenuation.

Table 1 shows the SNRs of the above two models using different batch sizes (Model 1 is the linear synthetic model and Model 2 is the synthetic model of Figure 7). The results show that the SNR of batch size eight is best for model 1, and the SNR of batch size four is best for model 2.

**3.2. Field Data.** Figure 9 shows a marine data; the data have 470 traces. Figures 9(a), 9(b), and 9(c) are the clean field data, Gaussian random noise, and the noisy data, respectively.

FX-DECON, VMD, and MB-MVMD of batch size five are used to denoise the noisy data. Figures 10(a), 10(b), and

10(c) are the denoised data, the removed noise using FX-DECON, and the similarity between them. Figures 10(d), 10(e), and 10(f) are the denoised data, the removed noise using VMD, and the similarity between them. Figures 10(g), 10(h), and 10(i) are the denoised data, the removed noise using MB-MVMD of batch size five, and the similarity between them. The removed noises show that a lot of signals are removed from the data for the VMD method, which is confirmed by the similarity of the VMD method (the “Signal” boxes indicate signal is removed as noise.). The removed signal as noise is least for the MV-MVMD method, which is also confirmed by the similarity of the MV-MVMD method.

Table 2 shows the SNRs of the three models using different denoising methods. “Model 1” is the synthetic model with linear events, “Model 2” is the second model, and “Field

TABLE 2: SNRs' (in decibels) comparison using FX-DECON, VMD, and MB-MVMD.

	FX-DECON	VMD	MB-MVMD
Model 1 (linear events)	4.78	-0.94	6.89
Model 2 (synthetic data)	1.81	1.25	6.27
Field data	5.90	-1.87	7.35

Data" is the field data model. The SNRs reveal that the MV-MVMD method is the best with respect to denoising results.

#### 4. Conclusion

MB-MVMD considers the lateral continuity of the input data; it seeks a sparse representation of the input signal. This divide-and-conquer method bridges VMD and MMVD methods. The proposed method achieves better denoising results compared with the VMD method in seismic random noise denoising.

Although the proposed method has many advantages, there is still room for improvement. For example, the decomposition parameters are set manually; is there a way to automatically select the best parameters for the decomposition?

Policy formulation is one of the main problems in multirobot systems, especially in multirobot pursuit-evasion scenarios, where both sparse rewards and random environment changes bring great difficulties to find better strategy. Existing multirobot decision-making methods mostly use environmental rewards to promote robots to complete the target task that cannot achieve good results. This paper proposes a multirobot pursuit method based on improved multiagent deep deterministic policy gradient (MADDPG), which solves the problem of sparse rewards in multirobot pursuit-evasion scenarios by combining the intrinsic reward and the external environment. The state similarity module based on the threshold constraint is as a part of the intrinsic reward signal output by the intrinsic curiosity module, which is used to balance overexploration and insufficient exploration, so that the agent can use the intrinsic reward more effectively to learn better strategies. The simulation experiment results show that the proposed method can improve the reward value of robots and the success rate of the pursuit task significantly. The intuitive change is obviously reflected in the real-time distance between the pursuer and the escapee, the pursuer using the improved algorithm for training can get closer to the escapee more quickly, and the average following distance also decreases.

## 1. Introduction

The research of multirobot system has been widely applied in industrial manufacturing, medical health, military operations, and other fields. The multirobot system [1] first appeared in the 1970s, due to the demand of practical application is increasing, it is difficult for a single robot to handle a lot of complex tasks, researchers have gradually turned their attention to multirobot systems. Unlike single robot system, multiple robots can share information to learn better strategy to accomplish cooperative tasks. The learning mechanism in the multirobot system enables robots to acquire environmental perception, information memory, and behavioral decision-making abilities in the process of interacting with the environment.

The multirobot systems application is pursuit-evasion problem that is a typical problem in the study of multiagent cooperation and coordination strategies [2]. In essence, the pursuit-evasion problem is a multiagent cooperative

decision problem. Robots study the optimal decision algorithm in multirobot system through the cooperative competition between the pursuers and the evaders. The methods to solve the problem of multirobot pursuit-evasion are mainly divided into the difference method and the combination method. The former converts the physical constraints of the robot into differential constraints and models and can only obtain local optimal solutions, but this method is widely used in solving the “simultaneous arrival” problem. [3]. The idea of latter method is to convert the pursuit problem into graph theory or dynamic programming problem and use greedy optimal return [4, 5], model predictive control [6], and other methods to learn the optimal strategy of the robot. Greedy algorithm [7, 8] is a typical combination method to fulfil the distance assignment task. This algorithm mainly realizes the allocation by minimizing the distance between the robot and the target. The application of this method is simple and extensive, but there will be a situation of allocation “deadlock.” Reference [9] uses the

negotiation method [10] to redistribute the coincidentally assigned round-up points that effectively settle the problem of deadlock. Traditional methods usually require complex mathematical calculation process to solve the multirobot pursuit-evasion problem. With the development of artificial intelligence, more researchers adopt machine learning methods to seek optimal chasing strategies.

Deep reinforcement learning (DRL) is a new machine learning method combining deep learning (DL) and reinforcement learning (RL). Compared with supervised and unsupervised learning, deep reinforcement learning combines the perceptual ability of deep learning with the decision-making ability of reinforcement learning [11] providing a solution to the complex and uncertain environment problems in multirobot systems [12, 13]. Volodymyr et al. first proposed deep Q-learning network (DQN) and obtained superhuman performance on Atari video games [14]. DQN is only applicable to discrete action space, and deep deterministic policy gradient (DDPG) is proposed to settle continuous action space issues [15]. Multiagent DDPG (MADDPG) is a multiagent policy gradient algorithm where agents learn a centralized critic based on the observation and actions of all agents [16, 17]. This method has already applied in the field of multirobot system. Kwak et al. [18] used reinforcement learning to train multirobot systems to obtain the optimal pursuit time. Li et al. [19] combined the data mining method of association rules with reinforcement learning and proposed a segmented reinforcement learning method, which solved the chase problem in the known environment. Liu et al. [20] used layered reinforcement learning to train the pursuit robot and designed an independent learning mechanism for the upper and lower stages [20] to balance the value function of different stages. The deep reinforcement learning method formulates an end-to-end strategy and is more targeted than traditional methods. However, the problem of inconsistent pursuit strategies in the phased training still exist. Additionally, the rewards of multirobot hunting scenes are sparse, and the algorithm stability performance is not satisfactory.

This paper considers the pursuit-evasion problem and uses a deep reinforcement learning technique to solve this problem. The sparse rewards and excessive exploration affect the training process of the robot, resulting in the failure to complete the pursuit mission. This paper proposes an improved MADDPG multiagent decision-making algorithm via combining environmental rewards and intrinsic rewards. The purpose of this paper is to solve the problem of excessive exploration after adding intrinsic rewards and sparse environmental rewards in multirobot pursuit-evasion. This method adds a curiosity module based on state similarity to the robot's reward function, under the premise of ensuring that the pursuit task is completed, a greater cumulative return is obtained. In addition, a threshold for similarity constrains the amount of intrinsic reward to overcome the problem of overexploration. The idea of this method is to combine environmental rewards and intrinsic rewards to facilitate the robot to learn better policies. This idea is maybe a general idea for improving multiagent decision-making algorithms.

FIGURE 1: Robot motion model.

## 2. Multirobot Chase Model

**2.1. Robot Motion Model.** In the multirobot pursuit-evasion problem, this paper treats the individual robot as a particle, and the motion model of the robot is established in a two-dimensional plane. Both pursuers and evaders are randomly distributed in a 2D plane, and the dynamics model is the same for each robot. The information for each robot includes coordinate, velocity, direction, and detection radius, as shown in Figure 1. The kinematics model of the  $i$ th robot is expressed by where  $(x_i, y_i)$  represents the coordinate position of the  $i$ th robot,  $r_i$  is the radius of the sensing field of the  $i$ th robot,  $\theta_i$  is the included angle between the heading and the horizontal direction of the robot,  $v_i$  represents the robot speed along the heading,  $u_i$  is the change rate of the heading angle of the  $i$ th robot, and  $f_0$  is the damping coefficient.

$$\begin{cases} x = x_i, \\ y = y_i, \\ r = r_i, \\ v_{x_i} = v_i \cos \theta_i, \\ v_{y_i} = v_i \sin \theta_i, \\ \dot{\theta} = u_i, \\ f = f_0. \end{cases} \quad (1)$$

**2.2. Multirobot Cooperative Pursuit Problem.** Multirobot cooperative pursuit is to study how to instruct a group of autonomous mobile robots (pursuers) to cooperate with each other to chase another group of mobile robots (evaders), which involves cooperation between pursers and confrontation between pursers and evaders [21]. Compared with single robot pursuit, the uncertainty of multirobot system environment and the diversity of information bring great difficulties to the pursuit task. The multirobot pursuit scenario is shown in Figure 2. The red circle represents the pursuer, the blue circle represents the evaders, and the gray area represents the obstacle. A collision occurs when the distance between the center of mass of the two objects is less than the sum of the radii of the two objects. The red robot

FIGURE 2: Schematic diagram of multirobot chase and escape scene.

needs to get as close as possible to the blue robot without collision between red robots to accomplish the pursuit task. The distance between red robot and blue robot is an indicator to measure the quality of the strategy. Red robot collides with blue robot is the best case but most case is that red robot follows blue robot keeping a certain distance.

There are some constraints in the multirobot pursuit-evasion scene. According to the robot motion model and multirobot pursuit process, the constraints are divided into control quantity constraint, initial state constraint, and distance constraint. Among them, the distance constraint including the obstacle constraint in the pursuit process of the robot and the safety distance constraint between the robots. The obstacle constraint requires no collision between robot and obstacle. Likewise, the safety distance constraint requires no collision between robots.

The control quantity constraint is reflected in the constraint on the change rate of the heading of each robot  $u_i$ .  $u_{i,\max}$  is the change rate of the maximum heading angle allowed by each robot, and the control quantity constraint of the  $i$ th robot is described as

$$|u_i| \leq u_{i,\max}. \quad (2)$$

The initial state includes the initial position and the initial heading angle, which are  $(x_0, y_0)$  and  $\theta_0$ , respectively. The initial constraint state corresponding to the  $i$ th robot is shown as

$$\begin{aligned} x_i(t_1) &= x_0, \\ y_i(t_1) &= y_0, \\ \theta_i(t_1) &= \theta_0, \end{aligned} \quad (3)$$

where  $x_i(t_1)$ ,  $y_i(t_1)$ , and  $\theta_i(t_1)$  represent the coordinates and heading angle of the  $i$ th robot at the starting time  $t_1$ .

The distance constraint is embodied in the distance between robots and the distance between robots and obstacles. There are  $N$  obstacles as shown in the gray shadow part in Figure 2. In the process of cooperative pursuit, any pursuer must not collide with obstacles at any time and maintain a certain safe distance. Assuming that

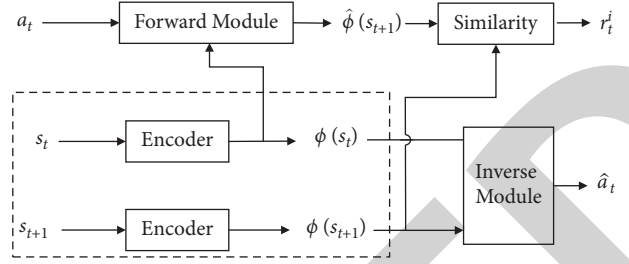

FIGURE 3: Curiosity module based on state similarity.

$D_i = [x_i, y_i]^T$ , the obstacle constraint of the  $i$ th robot is expressed as

$$\begin{aligned} \|D_i - D_n\|_2 &\geq r_n, \\ \forall i \in \{1, 2, \dots, S\}, \forall n \in \{1, 2, \dots, N\}, \end{aligned} \quad (4)$$

where  $n$  is the number of the obstacle;  $S$  is the total number of pursuers;  $N$  is the total number of obstacles;  $D_n$  is the center coordinate of the  $n$ -th obstacle; and  $r_n$  is the maximum radius of the  $n$ th obstacle.

The safe distance of each pursuer is considered to avoid collision occurs. Pursuers need to meet the following constraints between each other described as

$$\begin{aligned} \|D_i(t) - D_j(t)\|_2 &\geq R_s, \\ \forall t \in [t_1, t_f], \forall i, j \in \{1, 2, \dots, S\}, i < j, \end{aligned} \quad (5)$$

where  $R_s$  is the safe distance between pursuers and  $D_i(t)$  and  $D_j(t)$  are the coordinates of  $i$ th and  $j$ th robot at time  $t$ .

### 3. Methods

**3.1. Curiosity Module Based on State Similarity.** Intrinsic curiosity module (ICM) [22] is a solution to the sparse reward and insufficient exploration motivation in multi-agent environment. The error between the real state and the predicted state at the next moment is regarded as the intrinsic reward of agents in ICM to encourage agents to explore. According to the principle of intrinsic rewards, the larger the error between predicted state and real state, the more rewards agents obtain. Obeying this rule, supposing that the agent is exploring against real state direction at some point, it will always in wrong direction driven by abundant intrinsic reward that leads failure of pursuit task. Moreover, insufficient or excessive curiosity reward leads to unsatisfactory results [23]. Therefore, this paper adds a curiosity reward mechanism based on state similarity with threshold constraint on the basis of curiosity module. The degree of similarity between the predicted state and the real state represents the size of the prediction error, and the amount of intrinsic rewards to agents is effectively controlled by the constraint interval of similarity. When the similarity between the predicted state and the real state is below the lower threshold, agents cannot get internal excitation in order to prevent overexploration. In analogous cases, similarity exceeding higher threshold results in ignorance of intrinsic reward.

The intrinsic curiosity module is composed of three parts of neural network, encoder module, forward state prediction network, and reverse action prediction network, as shown in Figure 3. The encoder is used for agent state feature extraction, and the forward module makes use of the current state  $\mathcal{O}(s_t)$  and the current action  $a_t$  to estimate the state of the next generation  $\widehat{\mathcal{O}}(s_{t+1})$ . The inverse module employs a self-supervised style of predicting the current action by projecting forward the two  $\mathcal{O}(s_t)$  and  $\mathcal{O}(s_{t+1})$  outputs of the network to predict action  $\widehat{a}_t$ . The output of ICM is the two norm of  $\widehat{\mathcal{O}}(s_{t+1})$  and  $\mathcal{O}(s_{t+1})$ . Intrinsic rewards in this way do not take into account the problem of overexploration. Therefore, this method adds a similarity module to overcome this issue, as shown as Figure 3.

The state similarity module measures the degree of similarity between  $\widehat{\mathcal{O}}(s_{t+1})$  and  $\mathcal{O}(s_{t+1})$  by the Pearson coefficient (as shown in equation (6)). At the same time, this method overcomes the under-reward and over-reward by the threshold constraint of similarity. The intrinsic rewards produced by state similarity module is described as equation (7), where  $P$  is the Pearson correlation coefficient between  $\widehat{\mathcal{O}}(s_{t+1})$  and  $\mathcal{O}(s_{t+1})$  and  $\mu$  is the reward coefficient. Agents only gain intrinsic reward when Pearson coefficient is between *low* and *high*, *low* is the lower boundary of  $P$ , while *high* is the upper boundary of  $P$ .

$$P(x, y) = \frac{E[(x_i - \bar{x})(y_i - \bar{y})]}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2} \sqrt{\sum_{i=1}^n (y_i - \bar{y})^2}}, \quad (6)$$

$$r_t^i = P * \mu \quad (\text{low} < P < \text{high}). \quad (7)$$

**3.2. Improved MADDPG.** Multiagent reinforcement learning algorithm is an effective method to settle the problem of multirobot pursuit-evasion. Each robot's decision is controlled by its own neural network, and the pursuers can complete the task of chasing fugitives through communication interaction and cooperative decision. MADDPG algorithm is improved on the basis of DDPG algorithm by Lowe ([16]) and applied to multiagent decision-making scenarios. Its core idea is to find the optimal global strategy by means of centralized training and distributed execution, which solves the problems of nonstationarity and the failure of experience replay method in multiagent environment. However, robots lack exploring motivation due to sparse rewards, which causes low rewards and model difficult to converge.

This paper combines intrinsic reward and external environment reward as the agents' overall rewards via introducing the curiosity module based on state similarity into MADDPG. In this way, this method not only simulates the enthusiasm of the robot to study strategy but also prevents the excessive behavior. The model convergence speed and cumulative return value of the model are significantly improved using this method. Multiagent training is a process of searching for strategies that generate maximum total reward expectation and is described as shown in equation (8).

$$\max_{\theta_p} E_{\pi(s_t; \theta_p)} \left[ \sum_t r_t \right], \quad (8)$$

where  $\theta_p$  is the neural network parameter and  $r_t$  is the total reward value of the agent at time  $T$ . The total reward value consists of two parts, namely, the internal motivation is  $r_t^i$  and the external environment motivation is  $r_t^e$ , as shown in equation (9). In general, the intrinsic motivation is 0. When the intrinsic curiosity module is added, the intelligence will take the similarity error between the predicted value and the actual value of the next state  $s_{t+1}$  as the intrinsic reward according to the current state  $s_t$  and the given action  $a_t$ , as shown in

$$r_t = r_t^i + r_t^e. \quad (9)$$

Improved MADDPG algorithm training framework adds an internal curiosity module on the basis of MADDPG, and its overall architecture is shown in Figure 4. As a whole, the actor-critic framework is still adopted [24, 25] Each agent is training by Actor network, Critic network, Target Actor network, and Target Critic network. The parameters of actor network and critic network are updated via gradient descent computing the overall loss. The parameters of the target network update via copying the parameters of the local network through soft update within a certain period of time.

This method adds a module named ICM, as shown in Figure 4. The inputs to this module are current real state  $S_t$ , next real state  $S_{t+1}$ , and current action  $a_t$  of each robot. The output is the intrinsic reward generating by state similarity module. The sum of intrinsic reward  $r_t^i$  and external reward  $r_t^e$  is put into replay buffer to update network. Through the optimized reward calculation method, the improved algorithm gives appropriate rewards to the robot resulting in better strategy that guides robots to catch up on the target robot faster and more accurately.

**3.3. Algorithm Process.** The improved algorithm flow is shown in Table 1. Before training of agents, the replay buffer and exploration noise have been initialized, the network parameters of actor, critic, and the additional curiosity module also have been initialized. Every robot's state is reset at the begin of each episode, a quadruple  $s_t, a_t, r_t, s'_t$  will update after each robot chooses an action and then is put into replay buffer,  $s_t$  and  $s'_t$  are robot's current state and next state,  $a_t$  is current action of robot, and  $r_t$  is the whole reward of robot. The value network and target network parameters will be updated by sampling in the replay buffer.

## 4. Design of the Multirobot Pursuit Strategy

**4.1. State Space.** For the multirobot pursuit-evasion scene, both the pursuer and the evaders are treated as particles, and the state space of the pursuit scene is divided into the pursuer and the evader.

The pursuer's state space includes the pursuer's centroid position  $c(t)$ , the distance  $d(t)$  from other pursuer, the distance  $l(t)$  from the obstacle's centroid, the distance  $w(t)$

from the evader, the heading angle  $\varphi(t)$ , and the heading speed  $v(t)$ . The pursuer's state space at time  $t$  is defined as follows:

$$s_p(t) = [c(t), d(t), l(t), w(t), \varphi(t), v(t)] = \begin{bmatrix} (x, y), (d_1, d_2, \dots, d_N), (l_1, l_2, \dots, l_M), (w_1, \dots, w_K), \\ \varphi, (v_x, v_y) \end{bmatrix}, \quad (10)$$

where  $(x, y)$  is the pursuer's coordinate,  $(d_1, d_2, \dots, d_N)$  is the distance between the current pursuer and peer pursuers,  $N$  is the number of peer pursuers,  $(l_1, l_2, \dots, l_M)$  is the

distance between the pursuer and the center of mass of the obstacle,  $M$  is the number of obstacles,  $(w_1, \dots, w_K)$  is the distance between the pursuer and the evader,  $K$  is the

number of evaders,  $\varphi$  is the heading angle, and  $v_x, v_y$  are the velocities along the  $x$  and  $y$  directions, respectively.

The state space of the evader includes the position  $c(t)$  of the center of mass of the evader, the distance  $d(t)$  between

$$s_b(t) = [c(t), d(t), l(t), w(t), \varphi(t), v(t)] = \left[ \begin{array}{c} (x, y), (d_1, d_2, \dots, d_{K-1}), (l_1, l_2, \dots, l_M), (w_1, \dots, w_{N+1}), \\ \varphi, (v_x, v_y) \end{array} \right]. \quad (11)$$

**4.2. Action Space.** This paper regards multirobot pursuit-evasion as a continuous process. Therefore, the action space is complex and continuous rather than simple and discrete. In accordance with the movement characteristics of the robot, the action space at time  $t$  is designed, as shown in

$$\begin{aligned} A(t) &= \{\Delta\varphi, \Delta v\} \\ &= \{\varphi(t) + \mu t, v(t) + at\}, \end{aligned} \quad (12)$$

where  $\Delta\varphi$  is the heading angle change value,  $\mu$  is the angle change rate,  $\Delta v$  is the heading velocity change value, and  $a$  is the acceleration. The movement process of the robot is mainly related to the speed and direction, angle change rate controls direction, and acceleration controls velocity.

**4.3. Reward Function.** With the design idea of improved MADDPG algorithm, the reward function is divided into two parts, including external environment reward and internal incentive reward.

In the multirobot pursuit-evasion scenario, pursuer is rewarded for catching up evaders. On the contrary, evaders who are caught are punished. However, sparse reward is not conducive to improving the comprehensive performance of the pursuer. Therefore, distance reward is also taken as an external reward in the design of reward function in this paper.

The relative position reward of the pursuer and the evader can be described, as shown in equation (13),  $\omega$  is the relative distance reward coefficient,  $M$  is the number of pursuers,  $N$  is the number of evaders,  $x_{\text{predator}}, y_{\text{predator}}, x_{\text{prey}}, y_{\text{prey}}$  are the  $x$  and  $y$  coordinates of the pursuer and the evader, respectively.

$$r_t^e = \omega * \sum_{i=1}^M \sum_{j=1}^N \left\| (x_{\text{predator}}^i, y_{\text{prey}}^j) - (x_{\text{predator}}^j, y_{\text{prey}}^i) \right\|. \quad (13)$$

The reward of the pursuer for completing the pursuit task is described, as shown in equation (13).  $\delta$  is the reward base value and the pursuer and the evader get negative reward.

$$r_t^e = \begin{cases} +\delta, & \text{if agent is predator,} \\ -\delta, & \text{if agent is prey.} \end{cases} \quad (14)$$

As for intrinsic reward, it is designed to encourage robots to learn optimal strategy. This paper describes intrinsic reward as equation (15),  $\mu$  is the reward coefficient and the

the evader and fellow evaders, the distance  $l(t)$  between the center of mass of the obstacle, the distance  $w(t)$  between the pursuer, the heading angle  $\varphi(t)$ , and the heading speed  $v(t)$ . The state space of the evader at time  $t$  is defined as follows:

intrinsic reward is generated by similarity error between the predicted state  $\hat{s}_{t+1}$ , and current state  $s_{t+1}$  at time  $t + 1$ .

$$r_t^i = \mu * P(\hat{s}_{t+1}, s_{t+1}). \quad (15)$$

The total reward  $r_t$  is the sum of external environment reward and internal incentive reward described as

$$r_t = r_t^e + r_t^i. \quad (16)$$

## 5. Simulation Experiment

**5.1. Experimental Configuration.** This paper adopts the hypothetical scenario in Figure 2 to complete a series of experiments, in which the pursuers cooperate to chase the evaders. The starting point of the task is when the pursuers start to move, and the end point is when they catch up with all the evaders. The simulation environment was redesigned on the basis of MPE environment and Python. OpenAI Gym reinforcement learning platform was adopted, and Pytorch deep learning framework was used to complete the simulation experiment of multirobot cooperative pursuit task.

The training of robots is a close-loop process, robots obtain environmental information by taking actions through strategy they have learned to update their own status information, then optimize pursuit-evasion strategy by means of the feedback information. The hyperparameters in the experiment are shown in Table 2. The whole training process iterates  $2 * 10^5$  times, each episode includes 100 steps. The critic network learning rate is slightly higher than actor network learning rate so that critic correctly guides actor. Discount factor represents the degree to which each training session is learned from the previous experience. The size of replay buffer and batch size depend speed of experience feedback.  $\Delta T$  is the time interval for each simulation playback.

Different from deep learning, deep reinforcement learning has no data set. The agent obtains data from the simulation environment and uses the deep neural network for strategy optimization to train the model. Combined with the characteristics of deep reinforcement learning and the actual multirobot pursuit-evasion scenario, the following assumptions are made for the simulation environment:

- (1) To prevent the motivation generated by the internal curiosity module from keeping the robot exploring without stopping, this method limits environment boundaries and maximum stride length per turn.

TABLE 2: The training hyperparameters.

Training parameter	Values
Max_steps	$2 * 10^5$
Maximum episode length step_len	100
Discount factor $\gamma$	0.96
Actor network learning rate $\alpha_a$	$10^{-4}$
Critic network learning rate $\alpha_c$	$10^{-3}$
Size of replay buffer $M$	$10^6$
Batch size	256
Simulation time step $\Delta T$	0.1 s

- (2) All pursuers have exactly the same parameters, and they communicate with each other by share status information.
- (3) Considering the characteristics of deep reinforcement learning, the robot's range of activity is a two-dimensional infinite space. But the robot only moves within a certain range in practice, thereby this paper limits the multirobot pursuit scene to a two-dimensional finite space in that the robot is randomly initialized with coordinates between  $-1$  and  $1$ . Robots who are beyond the limited range are given certain punishment, and the environment is composed of  $N$  pursuers,  $K$  evaders, and  $M$  obstacles.

**5.2. Experimental Analysis.** Deep reinforcement learning models usually judge algorithm performance from two aspects: convergence speed on the one hand and reward value after convergence on the other hand. In the experiment, the algorithm performance of MADDPG and the improved MADDPG algorithm in the multirobot pursuit-evasion problem are compared. Those methods including MADDPG, MADDPG with ICM, and improved MADDPG are tested in the 3VS1 scenario. The curve between the robot's average reward value and the number of iterations is drawn to evaluate the performance of algorithms, as shown in Figure 5. The reward value of the robot is the most intuitive manifestation of the performance of the algorithm. In the multirobot reinforcement learning training process, the average return value of the robot is calculated after each training episode to measure the quality of strategy and whether the algorithm has converged is judged by observing the training curve.

Figure 5 indicates that the overall average reward of the improved algorithm is significantly improved, and the method of adding state predicts error into intrinsic curiosity module accelerates the model convergence speed and has better convergence stability.

From the trend of the curves in Figure 5, the convergence value of the black curve (i.e., the MADDPG algorithm) is significantly lower than that of the other two curves. The red curve shows the trend of the reward value after adding the original curiosity module. The reward is increasing compared with MADDPG under the influence of increasing explore motivation via intrinsic reward generation by ICM. However, in the convergence stage, the curve oscillates greatly caused by excessive exploration. When the rules of

FIGURE 5: Average reward value of simulation scenarios.

giving intrinsic rewards are changed, the threshold of state similarity module limits intrinsic reward produced by ICM and guides the robot to explore rationally. Although the overall reward value is not greatly improved, the stability in the convergence stage is improved as shown by the blue curve.

In addition, in order to test the stability of the algorithm model, the trained model was tested in the 3VS1 scenario, and the average reward and task completion rate under 1000 tasks were counted. The results are shown in Figure 6 and Table 3.

The test results shown in Figure 6 show that the improved MADDPG algorithm has significantly improved in both average reward value and task success rate. Taking task completion rate as a performance indicator, the improved algorithm has improved the success rate by 2–4 percentage points compared with the original algorithm.

Figure 6 shows the specific experimental data of the three algorithms in the form of a bar chart. Figure 6(a) shows the average reward of the robot, and Figure 6(b) shows the success rate of the multirobot system under the three algorithms. Table 3 indicates that both reward and success rate are increasing and proves the effectiveness of the improved algorithm.

In the pursuit-evasion scenario of 3VS1, the distance between the pursuer and the evader is also an important indicator to measure the performance of the algorithm. Figure 7 shows the track graph of a pursuit-evasion process and the real-time distance trend graph of the pursuer and the evader. The improved MADDPG algorithm enables the robot to follow the target more quickly and get closer to the target on average within the specified time. The statistical results are shown in Table 4.

The four pictures in Figure 7 intuitively show the robot's pursuit-evasion process, where Figures 7(a) and 7(c) are the trajectories of the robot tested using MADDPG and the

FIGURE 6: 1000-times test results. (a) Average reward. (b) Success rate.

TABLE 3: Average reward value and success rate.

Algorithm	Average	Success rate (%)	Improvement (%)

(a) Trajectory of the robot using MADDPG; (b) real-time distance between the pursuer and escaper using MADDPG; (c) trajectory of the robot using improved MA-DDPG; (d) real-time distance between the pursuer and esca-per using improved MADDPG.

TABLE 4: Average distance between the pursuer and evader in the 3VS1 scenario.

Algorithm	Average distance		
	robot_0	robot_1	robot_2
MADDPG	0.56	0.30	0.15
Ours	0.73	0.21	0.14

improved algorithm. It is obvious that the improved algorithm drives more robots to approach the target robot, and their ability to follow the target is significantly improved. Figures 7(b) and 7(d) describe the real-time distance between the pursuer and the evader during the entire pursuit-evasion process. The average distance between the pursuer and the evader in a test is shown in Table 4. The improved algorithm can reduce the average distance between robot\_1 and robot\_2 and the target robot, which represents an improvement in the performance of robot hunting. Although robot\_0 performs poorly, it does not affect the success of this pursuit task. One possible reason is that the robot sacrifices itself to provide other partners with richer information, thereby making other robots faster approach target.

## 6. Conclusion

To address the problem of changeable environment and sparse rewards in the process of multirobot pursuit-evasion, this paper proposes an intelligent multirobot pursuit-evasion method based on deep reinforcement learning. A multirobot pursuit-evasion model was built to describe motion model of robot and some constraints in the multirobot pursuit-evasion scene. The improved

curiosity module with state similarity based on threshold constrain is introduced into the MADDPG algorithm to resolve sparse reward and unstable model caused by excessive exploration. The improved MADDPG algorithm is better applied to the multirobot pursuit-evasion scene by designing the state space, action space, and reward function of the agent. Comparing the improved MADDPG algorithm with the MADDPG algorithm, the results show that the improved algorithm can not only solve the problem of multirobot pursuit-evasion but also the average reward of the agent is obviously higher than the original algorithm.

At present, the improved algorithm has better results for specific scenarios, the next step is to further optimize the algorithm so that it can play a better role in different scenarios.

## Data Availability

No data set was used in this paper, and the data used in reinforcement learning were obtained by the agent from the simulation environment.

## Conflicts of Interest

The authors declare that there are no conflicts of interest.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

At present, with the development of society and economy, some new problems have emerged continuously. Among them, the more serious problem is that enterprises pay too much attention to economic benefits, which leads to problems in the development of many enterprises. Therefore, the problem caused by too much emphasis on economic benefits is one of the major economic problems. After this problem, our country's economy began to focus on economic input and output in the subsequent development process. And, related personnel have also studied the economic input-output technology and model, which is an economic quantitative analysis method that has been widely used in various aspects of the economic field since its emergence. This paper firstly elaborates the theoretical knowledge involved, such as economic data, economic variables, and visualization techniques. Secondly it analyzes the application of scientific visualization techniques in the processing of economic variable data, which includes the techniques of preprocessing, mapping, drawing, and displaying the data. Finally, this paper investigates the application of mathematical models in economic variables input and output and the application of mathematical models in economic research, which can help us to better understand and use the knowledge of economics, thus providing strong support for solving practical problems. Also, this helps people to understand and grasp more about the macroarea, microaspect, and even the country as a whole.

## 1. Introduction

Beginning in the late 1970s, some foreign researchers have made in-depth discussions on visualization-related issues, such as measurement, mathematical models, and so on. Since 1980, our country began to pay attention to the fields of scientific visualization theories and methods. In addition, many countries have done a lot of research on the economic input-output model, which makes the economic input-output model more widely used in the economic development of enterprises [1]. The input-output model is mainly used for the analysis of the chain impact of product price changes, the analysis of investment-induced effects, and the analysis of industrial structure adjustment. At present,

domestic scholars have not formed a systematic and effective framework to serve quantitative analysis. It is also an important problem to be solved at present to conduct a deeper research on how to establish the relationship between the input and output of a set of economic variables [2].

In summary, this paper mainly studies the following contents:

Mathematics is a highly abstract discipline that covers many fields and has a wide range of applications in economics, sociology, and psychology, among others. We can see that classifying variables from different perspectives often requires the consideration of several factors at the same time. For example, when people are faced with a problem in their lives, they choose to think about all the possible

solutions to the problem before making a decision [3]. Mathematical visualization is the use of computer technology to visualize areas that do not require precise data, such as functions and probabilities. It allows us to use existing knowledge to solve practical problems more easily, quickly, and effectively. The variables involved in this process can also produce a certain degree of “backward” effect or partially offsetting effect (which is unpredictability and nonordered error) with time change, thus affecting the effect of mathematical modeling, which makes the visualization theory more comprehensive and accurate to play its proper value [4, 5]. In this paper, we introduce some visualization variables based on previous research and then build a mathematical model and dig deeper into it.

Economic variables are important factors in explaining the production function and can generally be reflected by the ratio of a given output to income. In real life, there are usually one or more economic variables that are related to output, have some correlation, and can be expressed in different quantities. For example: when unit output value =  $GDP * (X1 + Y0)/y$ , the sales price of its product is zero; for the same linear equation, it is output per unit  $\times x$  value. That is, each production function has more than two given quantities and another known variable, and each output value has more than two known quantities and another unknown variable [6].

Mathematical models can concretize abstract, non-quantitative problems, and in practical applications it has a profound impact on people's lives. In the traditional method, some situations are unpredictable or difficult to explain by decision makers, and this method can be used to solve them. The word “precision” first appeared in the mid-19th century. With the progress of the times and the technological revolution, the word “precision” was introduced. A mathematical model is a tool for describing, reasoning, and calculating the relationships between things and the laws arising from changes in their nature by using certain quantitative and quantifiable objects. Precise mathematical models play an important role in economic research, which can help people to simplify complex problems and solve practical problems, so it is getting more and more attention and application [7, 8].

The application of mathematical models is mainly to solve the visualization of economic variables, and in reality, some data cannot be directly obtained, so it needs to be transformed into something that can visually reflect the essential characteristics and inner laws of things, reflect the nature of the problem, or describe things, and other functions are clearer and easier to understand and grasp the interconnection and influence relationship between the phenomena under study. This requires us to pay attention to the actual situation as well as to grasp the development trend of scientific knowledge itself. Mathematical models as an effective method can be used to solve some difficult problems in the visualization of economic variables, which are widely used in many fields [9].

Scientific visualization refers to the realization of human-computer interaction with the knowledge and information involved in the process of data acquisition,

processing, and analysis through computer technology, so that people can understand and use it. Essentially, it is a way of thinking. In traditional mathematical models, only the relationship between variables and the internal structure characteristics of variables are usually studied to describe the degree of influence of random events, which ignores its internal laws and state change trends. However, modern visualization can help researchers to understand and analyze the problems, causes, and development prospects in complex systems more deeply, so visualization technology is more and more widely used in mathematical research [10, 11].

The economic data is the basis for the construction of the visualization model. In the process of building it, it is necessary to classify the variables under study and then analyze the interrelationships and internal logical relations between these indicators. For example, for the attribute of production (output), cost of production, etc., it is a function, while for the attribute of consumer demand it is utility. These two sets of regression coefficients and test results are used to determine the level of economic development, how it determines the amount of input, and whether it grows and thus affects the rationality of the visualization modeling, which provide valid support for policy makers.

For mathematical visualization, scholars at home and abroad have carried out research from different angles and achieved some good results. These theories can be used to solve practical problems. There are many related discussions on science abroad. For example, two of the famous foreign economists Kahneman and Delphi put forward the “strategic” concept (Non-Levin); Professor James Gist of Harvard University in the United States believes that visualization is not only an information processing technology or tool, but also a source of human wisdom. The research on mathematical visualization in our country started late, and the research on visualization mainly focuses on economic variables, explanatory variables, and application fields. There is no complete system about how to apply the mathematical model to practice.

Scientific visualization refers to people's intuitive, concrete, and vivid definition of complex problems or phenomena and makes them a clear and easy-to-understand expression through visual and auditory methods. It mainly includes three aspects: the first is to make an accurate judgment on the existence of a large number of uncertain factors in the objective world; the second is to make an abstract generalization of the natural system in essence; the third is to describe the nature and various phenomena involved in the process of social development and their interrelations and interactions. The research model based on visual analysis is shown in Figure 1.

Based on the economic study of scientific visualization, we analyze the following aspects. Firstly, mathematical modeling: In the traditional field of economics, it is usually assumed that a variable can be expressed by a simple formula; secondly, the mathematical methods are improved and refined and applied to real life, converting the data that were impossible or partially unavailable to the results that can be obtained by simply calculating a functional

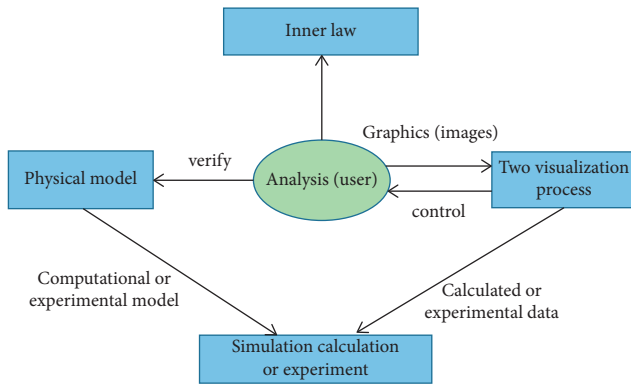

FIGURE 1: Research model based on visual analysis.

expression, which is called a visualization algorithm. Finally, computer-aided technology is used to combine economic indicators with other nonquantitative factors to obtain quantitative indicators [12].

## 2. Materials and Methods

**2.1. Data Preprocessing.** For data processing we usually use some mathematical methods, such as statistical models, image models, and so on. However, these common econometric research tools often require a large number of complex and detailed models of the sample in practice. Therefore, in this paper, we will select appropriate and reasonable information that can reflect the real situation and representative information as the essence, so as to better provide more useful information for decision makers to make accurate choices and reference data for decision making; at the same time, it can also provide more useful information for specific decision makers, so that they can make more accurate and rational choices. The block diagram of data preprocessing is shown in Figure 2.

In this paper, mathematical tools based on the “least squares” algorithm (SURF) and the LM heuristic algorithm are used to complete the data preprocessing process. Among them, the “least squares” algorithm (SURF) is mainly used for data correction; i.e., when there is only random error in the variables, as described in formula (1), and when there is significant error in the variables, the algorithm is described in formula (2).

$$x^m = x + \varepsilon. \quad (1)$$

$$x^m = x + \varepsilon + b. \quad (2)$$

One of the characteristics of display technology is the display of the amount of data that needs to be processed, especially image data. As the resolution of image capture tools increases, the amount of image data per frame increases exponentially. Therefore, the storage and transmission of data have a negative impact, which means that the capacity of internal/external memory must be expanded to increase the speed of data communication. One of the technical methods to overcome this difficulty is to

use data compression technology. Traditionally, data compression technology has always been one of the main research materials in digital image processing. Data compression technology can be divided into lossless compression and lossy compression according to the degree of distortion of information after compression. And its compression time is relatively long, but when the data block is processed and compressed, it is prone to overflow. The development of scientific computing screen technology and the development of multimedia computing technology have promoted the development of data compression technology. The current data compression technology can reduce the data storage capacity, but its computational complexity is high, and it needs continuous improvement. In recent years, data compression algorithms and standardization have developed rapidly, and integrated circuits and dedicated hardware used for compression applications have become the main topics of current research. The data compression technology flowchart is shown in Figure 3. The implementation of the data algorithm is in Algorithm 1.

Through this article, we can understand that data compression technology can effectively expand storage capacity and accelerate the speed of data communication; now there are various data compression systems on the market. The performance metrics should include (1) minimum error density; (2) maximum variance rate as well as minimum entropy value; (3) minimum generative model; 4–6 are the missing values of metrics; i.e., the weights and maximum entropy values are selected as the measurement factors without considering the nonordered visualization.

Data compression techniques can be divided into lossless compression and lossy compression according to the degree of distortion to the information after compression. Lossless compression technique is to segment data points with certain characteristics, which is characterized by reducing the amount of information required in random measurements; it is a probability density estimation technique; this can simplify the calculation of statistics. Lossy compression is characterized by a higher compression ratio than lossless compression, but it usually causes distortion after decompression. Also, the number of variables is uncertain and the variables are closely related to each other.

According to the output distribution characteristics of the compressed information source, data compression can be divided into statistical coding and dictionary coding. Statistical compression is one of the earliest compression techniques used and it is associated with classical data compression. Vocabulary encoding is also called LZ encoding. The basic principle is to select a character string from the source output data, save each character string code as an identifier, and use the dictionary search principle to encode the compressed character string and perform character string encoding.

Data compression technology can reduce data storage capacity. The principle of data compression technology is as follows: due to some redundancy between image data, this makes data compression possible. Shannon, the founder of information theory, proposed to treat data as a combination

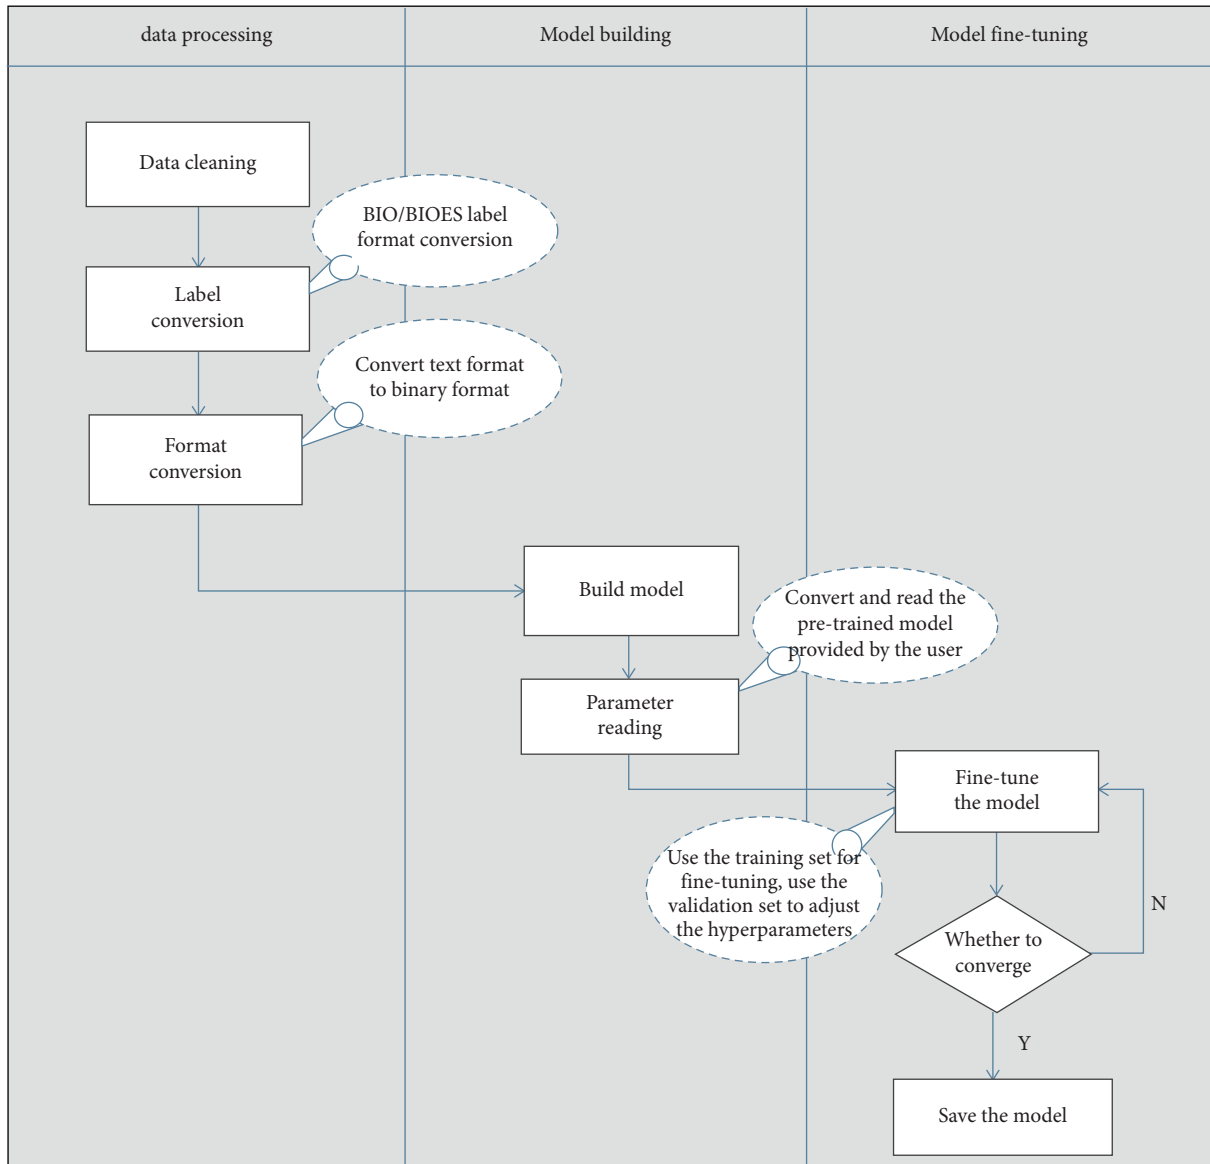

FIGURE 2: Data preprocessing flowchart.

of information and redundancy. The so-called redundancy is due to the high correlation between the pixels of the image, so many coding methods can be used to remove them, so there is no need to reduce the compressed data.

One of the characteristics of visualization technology is the display of the amount of data that needs to be processed. The application of visualization technology in mathematics is mainly reflected in, first, the integration of data and information, through the transformation of complex abstract problems into simple and clear, easy-to-understand-and-grasp features; second: the simplification of the model can be easily applied to many fields, for example, the relationship between variables in the function model and the correlation matrix representation between parameters. Third, by constructing

mathematical models, data information can be combined with the actual situation, thus realizing the characteristics of high accuracy of visualization.

**2.2. Mapping (Modeling).** The concept of mapping (PERT): it has the properties of fixed state, regular change, and uncertainty and satisfies the measurable characteristics; i.e., there is a certain number or correspondence between variables. When analyzing a mathematical model, it is important to understand the domain of definition and its properties [13]. For the problem we are studying, it can usually be seen as a constraint or a function to describe the existence of some connection between the state quantities; and when it comes to the actual situation that

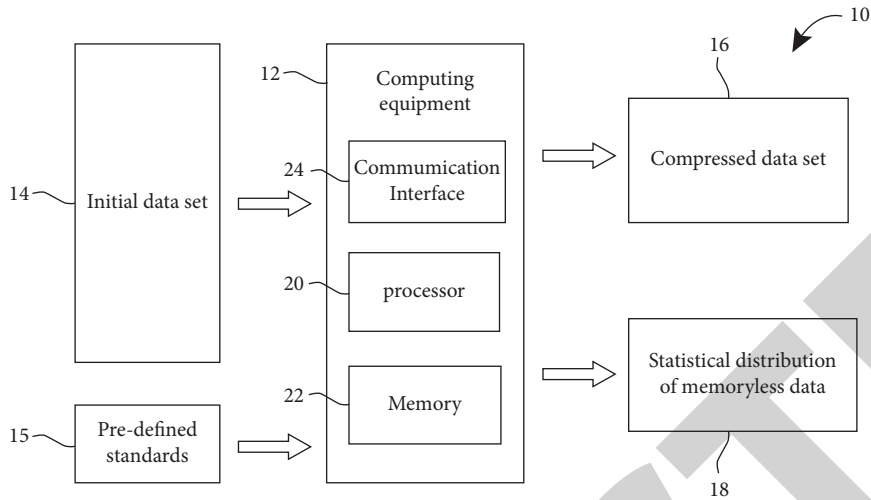

FIGURE 3: Flowchart of data compression technology.

```

int Rle_Encode_N (unsigned char * inbuf, int inSize, unsigned char * outbuf, int onuBufSize)
{
    unsigned char * src = inbuf;
    int i;
    int encSize = 0;
    while (src < (inbuf + inSize)){
        if((encSize+2) > onuBufSize)/*Not enough space in the output buffer*/
        {return -1;}
        unsigned char value = * src++; i = 1; while(src == value) && (i < 255)){
            src++;
            i++;
        }
        outbuf[encSize++] = i;
        outbuf[encSize++] = value;
    }
    return encSize;
}
    
```

ALGORITHM 1: Processing of economic variable data.

needs to calculate some specific values with definite integrals, the mapping (PERT) is used as one of the solutions, which is also an important prerequisite for the study of variables. For example, according to the mathematical function (3), the corresponding map can be drawn as shown in Figure 4.

$$y = \begin{cases} x^2 - 4x + 4, & (x \geq 2) \\ \frac{x}{2} - 1, & (x < 2) \end{cases} \quad (3)$$

FIGURE 4: Function map.

2.3. *Drawing.* The drawing function can complete the process of converting any data into drawing data. As we all know, the principles and methods of adult computer graphics provide many rendering algorithms for display technology. Scan conversion includes hidden surface removal, light mode, shadow, transparency and shadow, texture mapping, and antialiasing technology. In general, the rendering method provided by the graphics computer can meet the needs of the rendering module in the display

technology, so the research on the rendering function is not the main issue of the display technology. However, as mentioned earlier, in some new fields of display research, rendering technology can also become an important research technology, such as volume rendering technology.

Volume rendering technology is a relatively important research technology, and volume rendering technology is based on the image lighting model. The basic

principle is a method based on optical diagrams. This method maps the three-dimensional data field into the basic modeling unit of the system with transparency and voxel characteristics. The system describes various light spots, colors, and other light characteristics passing through the volume data field under certain lighting conditions and uses this to represent the internal information of the data field.

In traditional visualization models, we simply describe the data, but it is not possible to visualize the problem itself. Therefore, in order to better represent the mathematical ideas and methods applied to real-life problem solving, firstly, a solid diagram can be drawn to realize the function of software technology analysis; secondly, it can be converted into images, text, and other forms in computer language and expressed to the user through the combination of graphics and text; finally, the model can be processed on the computer using visualization tools to get the final result.

According to the different rendering order, the volume rendering algorithm can be divided into the volume rendering algorithm in the order of the image space and the volume rendering algorithm in the order of the object space. There are also certain differences between the two. The volume rendering algorithm occupies the image space from each pixel on the screen and emits light according to the direction of the view. These rays pass through a three-dimensional data field, and the same sampling is performed on the rays to find the sampling point. These rays pass through a three-dimensional data field, and the same sampling is performed on the rays to find the sampling point. The volume rendering algorithm occupies the object space according to a specific projection area and projection direction. Starting from a three-dimensional data field, project all the frames onto an image plane in a certain order, calculate the contribution of each data point, and obtain the final image on the screen. The typical representative of this type of algorithm is the method of throwing snowballs.

The commonly used method in the volume rendering algorithm described in this article is the ray casting algorithm. The principle of the algorithm is to decompose complex nonsimple objects into several small units; these units are called "blocks," that is, a basic unit. In the actual calculation, there are often some seemingly contradictory but interconnected units, and the relationship between these units is often very complex, so how to simplify the processing of these units has become one of the key issues in the visualization algorithm; the most common processing method is the local optimal solution method.

The main advantage of the ray casting method is that the use of gradients to change the boundary of the material can better reflect the normal direction of the surface of the object; using the phone model, specular reflection,

diffuse reflection, and environment reflection can achieve better lighting effects, and the sampling step can be adjusted to reflect local details.

*2.4. Showing.* The visualization display module is a function in the visualization-based student domain statistics software to provide data processing and graphical presentation. The system consists of three main parts: (1) raw data acquisition; (2) calculation and analysis of results output; (3) attribute assignment and weighting coefficients for input variables and other operations [14].

First, all information available within the scope of the defined original element is extracted, and then this information is converted into subblocks that represent the name, nature, and type of the data object in the visual display module, as needed. The subblocks representing the names of the data objects can be converted directly into the information contained in the visual display module, or the information can be encoded and then represented in numerical or pictorial form by a computer or software for the original elements' characteristic property variables and other related relationships.

*2.5. Application of Mathematical Models to Inputs and Outputs of Economic Variables.* The application of mathematical models in economic modeling is very broad and complex, and it is mainly used in the calculation and analysis of macroeconomics between factors of production, between capital and labor, and in the field of microeconomics. It is particularly important to use mathematical modeling to solve practical problems in some special cases.

*2.6. Mathematical Production Function Model.* A production function is a mathematical description of the quantitative relationship between factor inputs, product output, and technological progress in a production process. The production function can be used to describe a company or industrial production process. When studying macroeconomic problems, the production process can also be described by considering the whole economic system as a whole enterprise. It is widely used in economic theory research, production modeling, technical progress measurement, production capacity analysis, and economic forecasting. Since 1928, when the production function was proposed by researchers, economists have paid great attention to the production function. Production function models include Cobb-Douglas production function, constant elasticity of substitution production function, variable elasticity of substitution production function, and transcendental logarithmic production function [15].

The most widely used production function is the Cobb-Douglas production function whose general form is shown in the following formula:

$$Y = AK^\alpha L^\beta. \quad (4)$$

In the formula,  $Y$  represents output,  $K$  and  $L$  represent the input of capital and labor,  $A$ ,  $\alpha$ , and  $\beta$  are parameters and  $A > 0$ ,  $0 < \alpha < 1$ ,  $0 < \beta < 1$ . The Cobb-Douglas production function is generally called the C-D production function.

There are some improved forms of the Cobb-Douglas production function. One of them is the transcendental production function, whose form is shown in the following formula:

$$Y = AK^\alpha L^\beta e^{\alpha' L + \beta' L}, A > 0, \alpha', \beta' \leq 0. \quad (5)$$

If  $\alpha'$  and  $\beta'$  are equal to zero, the formula is simplified to the Cobb-Douglas production function form. Take the logarithm as shown in the following formula:

$$\ln Y = \ln A + \alpha \ln L + \beta \ln K + \alpha' L + \beta' K. \quad (6)$$

For this function, the marginal product may rise before it eventually falls. This function also allows output elasticity and substitution elasticity to vary with input changes.

The second improved form of the Cobb-Douglas production function is the Zellner-Revankar production function, whose form is shown in

$$Ye^{cY} = AL^\alpha K^\beta, c \geq 0. \quad (7)$$

Here, if  $c = 0$ , it is simplified to the form of Cobb-Douglas production function. Take the logarithm as shown in

$$\ln Y + cY = \ln A + \alpha \ln L + \beta \ln K. \quad (8)$$

The third improved form of the Cobb-Douglas production function is the Nerlove-Linstad production function, whose form is shown in

$$Y^{1+c \ln Y} = AL^\alpha K^\beta, c \geq 0. \quad (9)$$

Here, if  $c = 0$ , it is simplified to the form of Cobb-Douglas production function.

The fourth improved form of the Cobb-Douglas production function is the transcendental logarithmic production function, and its form is shown in

$$\ln Y = \ln A + \alpha \ln L + \beta \ln K + \gamma \ln L \ln K + \delta (\ln L)^2 + \varepsilon (\ln K)^2. \quad (10)$$

**2.7. MCD Mathematical Production Function Model for Analysis of Economic Production Function.** The production function is a mathematical description of the quantitative relationship between the input of production factors, product output, and technological progress in the production process. Production functions can be used to describe company or industrial production processes. When studying macroeconomic issues, the entire economic system can also be regarded as a whole enterprise to describe

the production process. It is widely used in the fields of economic theory research, production model establishment, technological progress measurement, production capacity analysis, and economic forecasting. Since the production function was proposed by researchers in 1928, economists have paid great attention to the production function. Production function models include Cobb-Douglas production function, fixed substitution elastic production function, variable substitution elastic production function, and transcendental logarithmic production function.

Since its inception, the Cobb-Douglas production function has been widely studied and applied by many economists due to its excellent economic properties and easy solution. The quantitative economic model derived from the Cobb-Douglas production function has been widely used in economic theory and production practice research. With the deepening of production and technology research and development, one-sided shortcomings have gradually appeared. The academic circles have never stopped arguing about this, and research on improvements and revisions will continue [16].

First of all, some basic properties of the Cobb-Douglas production function are very related to the actual production process. If the output elasticity does not change, the factor substitution elasticity is 1. For the same research object, if the sampling interval is different, the output elasticity and factor substitution elasticity should be different. Although the research objects are the same and the sampling interval is the same, for different sample data points, because the ratio of input factors to production factors is different, the elasticity of output and the elasticity of substitution must be different.

Second, this model is limited in structure. The relationship and structure of variables in the economic system are very complex, which leads to the fact that the Cobb-Douglas production function often cannot match historical data with satisfactory accuracy in practical applications. Reason analysis shows that, with the advancement of science and technology, the innovation of production equipment, the improvement of production department functions, the improvement of production efficiency, and the diversification of products, the production process of most enterprises or industries shows the characteristics of multiple input elements and diversified structures. The entire production process of most enterprises or industries may have subproduction processes, and these subproduction processes are mutually influencing and interrelated. When scholars need to use the production function to describe the total production output of a specific company or industry and the functional relationship between capital and labor input, they often use indicators such as average production elasticity and average technological progress. It is not difficult to see from the form of the Cobb-Douglas production function that it is suitable for describing the input-output relationship that represents a single production process. It is difficult to describe the complex production structure using Cobb-Douglas production function. This requires people to develop new production functions.

In actual economic production activities, the entire production process of a company or industry with a

diversified production structure consists of several sub-production units. Based on the previous discussion, coupled with the idea of additive nonparametric regression model, it is reasonable to assume that a production function showing this input-output relationship must be a combination of several basic production functions. That is, a model is a group of production subunits used to express each other's effects. Because the Cobb-Douglas production function has good economic properties, it is widely used by economists. This article assumes that a reasonable production function model should be a composite of several Cobb-Douglas production functions, expressed as

$$Y = F(K, L) = F(K^{\alpha_1} L^{\beta_1}, K^{\alpha_2} L^{\beta_2}, \dots, K^{\alpha_m} L^{\beta_m}). \quad (11)$$

Therefore, this paper constructs a production function with the characteristics of multiple production structure, which is used to describe the input-output function relationship of a certain industry and enterprise. The specific form is shown in

$$Y = \sum_{i=1}^m A_i K^{\alpha_i} L^{\beta_i}. \quad (12)$$

It is reversed from the digital form. This article calls this type of power exponential summation production function called MCD production function (Modified Cobb-Douglas Production Function). It can not only maintain some good properties of the Cobb-Douglas production function, but also improve the fitting accuracy of the production function to historical data. At the same time, it can also reflect the diversified structural characteristics of production to a certain extent [17].

The econometric form of the MCD production function is shown in

$$Y = \sum_{i=1}^m A_i K^{\alpha_i} L^{\beta_i} + \mu. \quad (13)$$

In order to make the expression concise, suppose the  $A_i$  in the MCD production function is expressed as

$$A = \sum_{i=1}^m A_i, \lambda_i = \frac{A_i}{A}. \quad (14)$$

The above hypothetical model (11) can be expressed as shown in the following formula:

$$Y = A \sum_{i=1}^m \lambda_i K^{\alpha_i} L^{\beta_i} + \mu. \quad (15)$$

### 3. Experimental Analysis and Results

**3.1. Input-Output Line Model.** Suppose that the economy of a country (or region) is divided into  $n$  sectors, and each sector produces one (or one type of) product, the total of intermediate use and final use in each department, minus transfers and imports. This result is equal to the total output of the department, as shown in

$$\sum_{j=1}^n x_{ij} + (r_i + p_i + q_i + c_i + s_i + d_i + e_i) - o_i - i_i = y_i, i = 1, 2, \dots, n. \quad (16)$$

Let  $z_i = r_i + p_i + q_i + c_i + s_i + d_i + e_i - o_i - i_i$ ; get the following formula:

$$\sum_{j=1}^n x_{ij} + z_i = y_i, \quad i = 1, 2, \dots, n. \quad (17)$$

The direct consumption coefficient is the core of the static input-output model. It can organically combine economic factors with technical factors, and it can combine technical factors for economic analysis. In a certain period of time, if the role of production technology and intermediate products does not change, it can be considered that  $a_{ij}$  is relatively stable. Substitute  $x_{ij} = a_{ij}x_j$  into formula (17) to obtain

$$\sum_{j=1}^n a_{ij}x_j + z_i = y_i, \quad i = 1, 2, \dots, n. \quad (18)$$

**3.2. Input-Output Column Model.** The production input of each department is composed of three parts, namely, intermediate input, fixed asset depreciation, and initial input. From this, a balance equation can be obtained as shown in

$$\sum_{i=1}^n x_{ij} + E_j + w_j + b_j + t_j + m_j = x_j, \quad j = 1, 2, \dots, n. \quad (19)$$

Marked as  $h_j = E_j + w_j + b_j + t_j + m_j$ , then formula (19) can be changed to

$$\sum_{i=1}^n x_{ij} + h_j = x_j, \quad j = 1, 2, \dots, n. \quad (20)$$

Write the above formula in matrix form; get the following formula:

$$A_c X + H = X, \quad (21)$$

where  $H = (h_1, h_2, \dots, h_m)^T$  is the value-added column vector, as shown in

$$A_c = \begin{pmatrix} \sum_{i=1}^n a_{i1} & & \\ & \ddots & \\ & & \sum_{i=1}^n a_{in} \end{pmatrix}. \quad (22)$$

**3.3. Revision Method of the Input-Output Direct Consumption Coefficient.** The direct consumption coefficient is the basis for calculating the absolute consumption coefficient and establishing the mathematical model. The accuracy of the consumption coefficient directly affects the overall balance and quality of the plan. In order to ensure the accuracy of the direct consumption coefficient, it is important to master the quality of basic statistical data. At the same time, it is necessary

to understand some factors that directly affect consumption changes before the coefficient can be corrected.

In the revision of the visual model, the variables defined in the input-output model can be directly referenced, or they can be transformed into a correction independent of the established functions and not dependent on other known information. However, this approach is flawed in practical applications. If the previous year's data is used as the reference object, the estimation results will be biased from the real situation; if the time series factors are taken into account in the next year and the next months' statistics, we get a constant that was not included in the previous calculation of the variables defined in the visualization model and therefore cannot be revised directly, but only as a variable [18].

The establishment of the input-output model should follow the following principles:

- (1) The economic variables and GDP per capita are linearly related over a certain period of time, and their trends are basically consistent
- (2) There is interdependence between economic phenomena and other factors for a specific unit in the field under study

The following issues should be noted when constructing a mathematical visualization and quantitative analysis framework. Firstly, the relationship between quantitative and qualitative analysis should be paid attention to when constructing the mathematical visualization model. Secondly, the mathematical model should reflect the scientific and artistic aspects as much as possible. Finally, the indicators should be selected, adjusted, and applied according to the actual situation to meet the requirements of the prudence principle.

Today the direct consumption factor method has undergone many changes and it is mainly divided into non-mathematical methods and mathematical methods. Nonmathematical methods are such as the actual survey method and the expert assessment method. There is a mathematical method: the most basic one is the RAS method.

The RAS correction method is a direct consumption coefficient correction method, which is essentially an iterative correction method. The basic assumption of the RAS correction method is that the direct consumption coefficient changes come from two aspects.

The RAS method was proposed by the researcher Richard Stone in the 1960s. This method is also known as the bilateral proportional method. The idea of this method is to use the total average annual usage as the control amount for rows, and the average total input in the target year as the control amount for columns. The intermediate input matrix lists the conditions for double reduction, full utilization of the target year, and full input in the target year. Estimates are made using conventional statistical data, which greatly reduces the cost of the input-output table.

The most basic mathematical method in the direct consumption factor method is the RAS method, which has many advantages. (1) Using RAS directly as the basic idea of the correction model can make the calculation results more intuitive and clear, and it does not require any complicated and tedious mathematical steps in practical operation. (2) The visualization method enables us to observe, analyze, and understand the data from more perspectives.

#### 4. Results

- (1) The input-output model can be used to study many important proportional relationships in the national economy, which can be used to measure issues such as production or technological progress. For example, it can study the rate of intermediate products and the rate of final products, the value composition of products in a certain department, and so on.
- (2) Study the impact of changes in each final demand on the output value of each department, labor remuneration, and social net income, for example, the increase and decrease of the military budget, the expansion and compression of the scale of infrastructure construction, and the impact of the increase and decrease of imports and exports on the national economy.
- (3) Analyze the impact of changes in wages and taxes on the prices of products in each department.  $\Delta P$ ,  $\Delta V$ , and  $\Delta M$  are used to represent the column vectors composed of changes in prices, wages, and profits and taxes, respectively, as shown in

$$\Delta P = (I - A^T)^{-1} \Delta V, \Delta P = (I - A^T)^{-1} \Delta M. \quad (23)$$

- (4) Analyze the impact of changes in the price of a product on the prices of other products.
- (5) Conduct energy consumption analysis. Use the input-output table to calculate A and B, and further calculate the energy consumption indicators of the unit output value of the main sectors of the national economy. This is an important technical indicator, from which we can see the technical content and energy waste of products in the leading sectors of our national economy. It is helpful to find the gap and reduce the comprehensive energy consumption per unit of product.

#### 5. Conclusions

In short, the application of scientific computing visualization technology can greatly accelerate data processing, and it can realize image communication between people and computers. It also enables scientists to guide and control the calculation process and consciously control scientific calculations so that they can run. The development of scientific

As a tool for aviation exploration, aircraft plays a pivotal role in the aerospace field. The aircraft's lightweight can ensure that the aircraft can carry more loads, so it is of great significance to the research on the key technologies of aircraft lightweight. This paper organizes the intelligent technology system from the multiobjective fusion technology relationships and considers the complex changes between technology units. A technology group model for the intelligent technology system of spacecraft welding is formed to provide a decision-making basis for the realization of batch, stable, and efficient intelligent and lightweight manufacturing of spacecraft. We expand the technology development research from single technology research to technology system research. We research and build a three-dimensional perspective intelligent technology system based on technology unit, technology system, and technology group. It reveals the internal relationship description of technological development and expands and perfects the current research theory of technological development.

## 1. Introduction

Aircraft has been widely used and plays a pivotal role in the aerospace field [1–3]. As one of the key technologies in aircraft research and development, lightweight design has received extensive attention [4, 5]. Currently, intelligent technologies related to lightweight are being deeply integrated with traditional manufacturing processes and accelerate the conventional manufacturing process and development mode [6, 7]. It is triggering a new round in lightweight technology and industrial development models [8]. This change is reflected in increasingly lightweight designs that entirely apply intelligent technology to achieve an all-round digital and intelligent transformation of the manufacturing process, research and development, production, management, and service [9]. The quality of aircraft products and the production efficiency have been

continuously improved. It has driven the rapid development of many related intelligent technologies, intelligent equipment, and intelligent products, providing necessary manufacturing process support for the manufacturing industry [10, 11]. Therefore, the integration of lightweight and intelligent technology is of great significance for the development of aircraft intelligent manufacturing.

In recent years, many scholars have done a lot of research on lightweight technology. To sum up, it mainly includes the following three aspects: lightweight design technology, lightweight material technology, and lightweight manufacturing technology. Wu et al. [12] and Fiedler et al. [6] achieved the effect of lightweight design through topology optimization design under the premise of satisfying safety. Zuo [7] carried out structural optimization under the constraints of static stiffness and dynamic frequency stiffness and achieved good lightweight effect. Cho et al. [13] used the size optimization method to

optimize the design of the rail transit car body and achieved a lightweight effect by reducing the body weight by 29%. Hou et al. [14] optimized the multiobjective design of structural performance, cost, and mass and reduced the mass of the components while increasing the structural stiffness. Emirci and Yildiz [15] compared and analyzed the anticollision and energy-absorbing characteristics of the body energy-absorbing box using aluminium alloy and high-strength steel. Through lightweight material technology, the aluminium-made energy-absorbing box is better than the energy-absorbing effect per unit mass and the target of the steel energy-absorbing pack. Parsa and Darbandi [16] analyzed the application of hydroforming in car body forming and achieved lightening from the manufacturing technology.

Although the above lightweight methods have achieved good results, the applied methods are relatively single, and the influence of the mutual coupling of multiple factors has not been considered. For aircraft, various factors such as product quality, performance, and manufacturing cycle require higher lightweight technology [17]. Especially in the welding process of lightweight materials, it is urgent to change the current situation of unstable quality of welding products and dependence on operator skills [18–20]. The application of intelligent digital technology and lightweight knowledge base can realize the optimization of welding process parameters and the identification of welding defects [21, 22]. At the same time, uncontrollable factors such as welding cracks and deformation are eliminated, welding accuracy is improved, the welding production mode is changed, and high-quality and high-efficiency manufacturing of lightweight material welded products is supported [23]. To better combine intelligent technology with lightweight goal, it is necessary to clarify the correlation factors between lightweight technology and system analysis method. At the same time, a set of technical systems is formed according to its technical units, and a multiobjective fusion decision-making model is established. It will be of great significance to describe the development of technology units in the way of technology group [24–26].

This paper presents a multiobjective fusion decision model applied to the key technology of spacecraft. The model fully considers the complex changes between technical units, organizes the intelligent technology system, and forms a technology group for spacecraft intelligent lightweight technology system. The research on the development of lightweight technology is expanded from single technology research to the technical system of the connection between technical units. The three-dimensional perspective intelligent technology system of technology unit, technology system, and technology group is constructed. It provides a decision-making basis for spacecraft batch, stable, efficient, and lightweight manufacturing.

## 2. Concept and Method

*2.1. Mathematical Representation of the Technical System.* The technology system construction method aims to reveal the specific relationship research object of the intelligent technology unit set to the technology system with specific

relationships (defined as). The technology group (defined as) can be described as a set of specific relationships. The corresponding representations of the three are as follows:

Technical unit set:  $Y = \{1, 2, 3, \dots, y\}$

Technical system set:  $P = \{Y_1, Y_m, Y_n, \dots\}$

Technology cluster:  $T = \{T_1, T_m, T_n, \dots\}$ ,  $T$  for a specific connection

The system construction of technology development can be described as defining a specific relationship  $T$  on the set  $Y$ , which describes the specific relationship from the technology unit set  $Y$  to the case set  $S$ , which is described as  $T \subseteq Y \times S$ . That is, the relationship  $T = \{Y, T_C\}$  is defined on the technical unit set and the relationship  $T = \{S, T_Q\}$  is defined on the case set, so  $T$  describes  $T$ , respectively,  $T_C$  and  $T_Q$  define two specific relation operations on sets  $Y$  and  $S$ , so that a group of things with regular interaction or interdependence form a whole, that is, the technical system  $P$ ,  $P$  is described as the abstract system subset  $P: T \subseteq Y \times S \rightarrow Y$  formed by the relation operation from the technical unit set  $Y$  to the specific relation  $t$  of the case set  $S \times S \rightarrow Y$ . The specific relationship of  $S$  is the mapping from  $T$  to  $Y$ . Furthermore, the technical system  $P$  is described as  $Y, \times, S$ . That is, the technical system  $P$  is a subset of the specific relationship  $T$  from the technical unit set  $Y$  to the case set  $S$ .

*2.2. Unit Analysis of the Technical System.* Make a good selection of technical units with specific internal relations to form a technical system around internal ties. Several technical systems form a technical group with specific internal ties. This method includes a dynamically related technical unit technical system-technical group to describe the relationship between the development of intelligent technology. Based on technical units, the technology group and technology system for decision-makers can be optimized, and the technology system can be adjusted and optimized through the technology group, or the new technical units can be expanded and supplemented to form a set of dynamic evolution correspondence. The technical system composes technical units, and the technical units are continuously developed and evolved. For a specific technical unit of a system, it will not only be affected by other technical units in the system but also by changes in the external environment and be reorganized with changes in the objectives of the technical system, as shown in Figure 1.

Y1 The technical complexity of Y2 and Y3 is different. For example, the technical system composed of special alloy precision casting technology, comprehensive design optimization technology, and virtual manufacturing technology based on product life cycle management describes the technical system of special alloy precision casting facing the full life cycle of products with different dimensions of process, process design and process production management, and the comprehensive design optimization technology refers to special alloy. In the design stage of gold casting products, the technology or technical complexity required is different from the whole life cycle management of precision casting equipment

FIGURE 1: Evolution of technology unit relationship.

and the manufacturing process. Similarly, the coverage and complexity of special alloy precision manufacturing equipment technology, comprehensive design optimization technology, and life cycle management technology of manufacturing process are also different. At the same time, the comprehensive design optimization technology has many common applications, which can be used in other technical systems outside the technical system and can also improve its design optimization ability and methods due to the changes of the external development environment, the comprehensive optimization design technology itself also needs to consider the ability of special alloy precision casting technology. The comprehensive optimization design beyond the capability is not supported by special process equipment for equal material manufacturing. The two are combined, as shown in Figure units Y3 and Y7. Product life cycle management technology can be used both inside and outside the technical system. As shown in Figure 1, Y2 technical units will also be greatly affected by changes in technical means or environment outside the technical system.

The specific relationship between Y1 and Y6 and Y3 and Y7 described in the technical unit also has the difference of sequential relationship and cross-relationship. For example, the technical system is composed of welding process real-time monitoring and detection technology, welding defect automatic identification technology, high-precision welding robot, and welding power supply. The welding process real-time monitoring and detection technology are the premise of welding defect automatic identification technology. With the welding process real-time monitoring and detection technology, the welding defect automatic identification technology can be carried out. The two restrict each other, appear in a sequence, and work together, as shown in Y1 and Y6 in Figure 2. The high-precision welding robot and welding power supply are closely connected, overlapped, and crossed to form an association relationship between connecting electric energy and forming a stable execution action, as shown in Y3 and Y7 in Figure 1. The diagram only shows the order and cross between technical units, and there may be more connections.

Y2 described in the technical unit interacts with the outside of the technical system, which may be affected by the external technical system or environment or may affect the external technical system or environment. For example, the welding expert system Y2 will not only affect the welding production system but also affect the welding production process layout. In addition, the technical system is also affected by process objectives or value objectives, and even the changes of objectives and systems caused by changes in the external environment should be considered. For example, there are differences in the correlation model of technical units of a welding system aiming at high precision or high efficiency; for another example, for a certain product, whether the market is easy to accept personalized customization or more inclined to mass manufacturing also has a great impact on the technical system.

**2.3. Correlation Analysis of the Technical System.** The technology system is composed of technology units with specific association relations. Different association relations have a great impact on the technology system. There are many kinds of association relationships. For example, there is a relationship between process and function between product process and intelligent function. There is a relationship between product quality improvement and production line production efficiency, stability, and consistency, as well as process optimization and automation improvement. As shown in Table 1, List T1 (production line production efficiency), T2 (intelligent smelting system), and T3 related to its technical unit (equipment fault prediction and diagnosis) is a specific correlation. Based on the listed correlations, the technical unit forms a specific target-oriented technical system or technology group. It describes the technical systems of the four types of correlation on the right side of the table. Due to the correlation, the orderly combination of multiple technical units is realized to form the technical system described in the table. The correlation of the technical system is the decisive factor of organizing the technology units and is also the goal of the formation of the technology system.

**2.4. Technical System Construction of Multiobjective Fusion.** In the construction of the technical systems, we often consider the fusion scheme aiming at a variety of correlation relations and comprehensively consider the complex changes between technical units to form a multiobjective fusion technical system [27–29]. It is precise because of the complexity of the integration of multiple relationships and the complexity of the relationship between technical units that constitute the complexity and uncertainty of the technical system. The technical systems constructed are different due to different technical associations T1 and T2; due to other fusion targets TM and TN, other technical systems are built, as shown in Figure 2.

Figure 2 reveals the complexity and diversity of intelligent technology systems. It can be seen from the diagram that the cluster  $T = \{T_1, T_m, T_n, \dots\}$ . The research of technology connection based on the technology unit library has

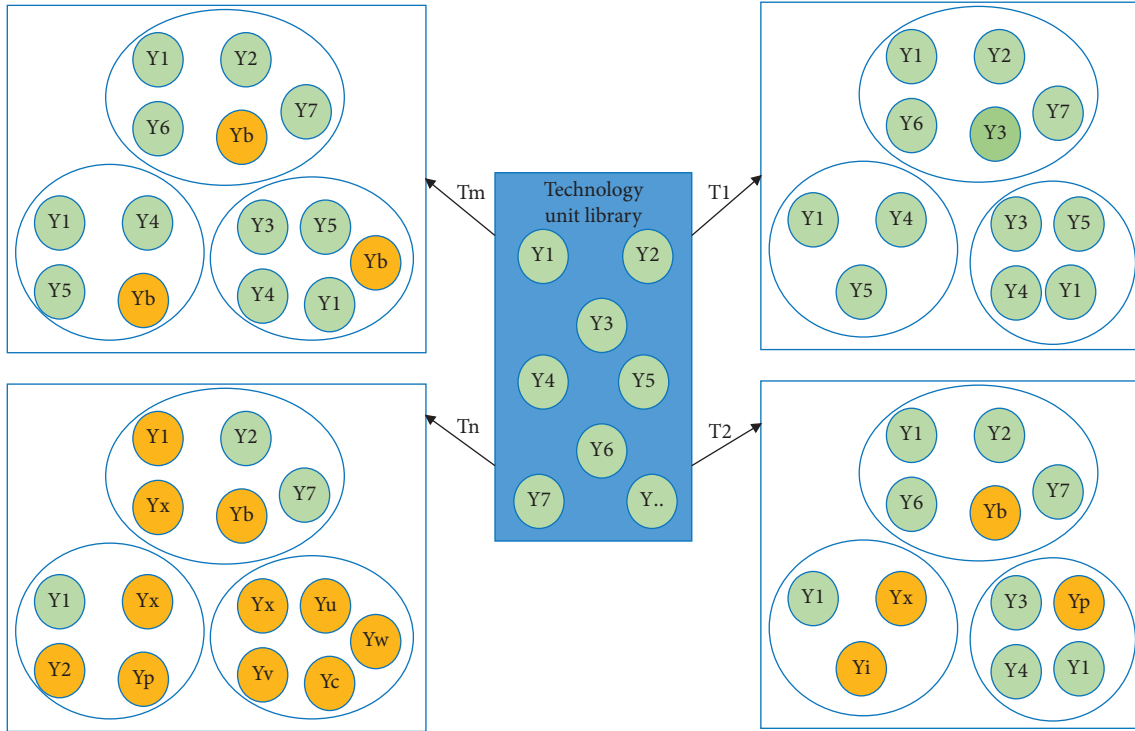

FIGURE 2: Technical system construction diagram of multitarget fusion.

TABLE 1: Example of system association relationship construction.

Number	Association relationship	Technical system example
T1	Production efficiency of the welding production line	Intelligent welding process control: welding seam forming control technology based on visual sensing, constant pressure adaptive control technology, welding path adaptive control technology, and arc length adaptive control technology based on laser sensor tracking. These four central technical units constitute a technical system for realizing the automatic control of welding path and welding process parameters and improving the automatic control level of the welding process.
T2	Casting melting intelligent system	Casting intelligent melting system: it is composed of intelligent feeding and unloading technology, online detection technology of molten iron parameters, LIMS (Laboratory) information management technology, and intelligent 3D printing technology of casting mould. These four main technical units constitute the technical system to cast the intelligent melting.
T3	Fault prediction and diagnosis of forging equipment	Equipment fault prediction and diagnosis: it comprises equipment fault diagnosis system technology, product data acquisition technology using RFID, QR code/bar code, intelligent control, intelligent decision support, and visualization tool technology. These three main technical units aim at equipment fault prediction and diagnosis.

become an eternal theme. It can also be considered that the research on the development of intelligent technology focuses on the change of technology units and technology connections. The change of technology units, technology connection, and the evolution of external environment of technology system constitute a complete system of technology development.

### 3. Multiobjective Fusion Decision-Making Model

Because of the above specific problems of the aircraft welding process, the key to the development of intelligent

technology lies in the intelligent improvement of the quality, performance, and manufacturing cycle of relevant products, that is, the target relationship of aircraft lightweight material welding technology system. The traditional lightweight material welding workshop has some prominent problems. Product quality control does not form a closed loop, process design depends on human experience, low degree of equipment automation, backward detection means, and so on. There is an urgent need to transform and upgrade to the intelligent direction to achieve the synchronous improvement of product consistency, manufacturing flexibility, and efficiency. A multiobjective fusion relationship has been formed for such problems, then selecting relevant

technology units from the Technology Library and external technology environment, as shown in Figure 3.

Based on the final goal and demand of lightweight material welding, combined with the technical unit library, seven intelligent technology systems  $P = \{Y_1, Y_2, \dots, Y_7\}$  for the intelligentization of lightweight material welding workshops are analyzed and the following seven major process problems are solved, respectively:

$P = \{$

Question 1: describe the welding method, process parameters, and scope of the configuration of the welding equipment, drive, and control system.

Question 2: establish a database to store and compile the data of various existing welding production processes for sharing by all welding workstations.

Question 3: according to the welding method, welding material types, and specifications and other data, formulate a program for optimizing welding process parameters.

Question 4: according to the workpiece shape, size, and the preset deviation limit of the seam, the automatic correction and compensation program are compiled.

Question 5: according to the image of the welding area, according to the shape of the welding arc and the welding bead, the image recognition, and remote monitoring program are compiled.

Question 6: prepare the automatic fault diagnosis, alarm, and repair program for the drive system and control system of welding equipment, wire feeder, and welding power source.

Question 7: manage, distribute, and collect the data between the welding equipment control system and the DCS control system operating station and realize the monitoring and remote diagnosis functions of the processing process.

$\}$

The corresponding eight technical systems are as follows:

Y1 refers to rapid interchange clamping (flexibility). Y2 refers to the instrumentalization of weld quality inspection. Y3 refers to the digitization of welding production management. Y4 refers to the real-time management of welding control. Y5 refers to the paperless basic welding database. Y6 refers to the computerization of weldability analysis. Y7 refers to the intellectualization of welding process analysis.

From the dimensions of different fusion associations, the decision model for the association between technical units-technical systems-technical groups is described as follows.

From the shop floor construction and target demand dimension. DCS unified the control and deployment of the intelligent welding workshop, the production tasks issued by the management, the manufacturing unit prefabricated action program, and test data according to the instructions to determine the entire manufacturing process. Everything is ready, the work program starts the welding command, and the main control unit collects the processing parameters in

real time. At the same time, online inspection, quality control, welding process monitoring, analysis, and process optimization and adjustment are carried out from the dimension of welding technology development. Intelligent welding technology effectively improves the accuracy and reliability of product quality. Focusing on the continuous improvement of welding control technology such as welding quality, welding efficiency, and welding spatter, foreign manufacturers have taken the lead in realizing the application of full digitalization in welding equipment, including the precise operation control and working process control of the microprocessor to achieve various welding performances. These digital and intelligent applications make welding integrated and simplified, no more reliance on welders and traditional welding processes. At the same time, in a concise time, the change of arc length can be controlled accurately and reliably. The software upgrade of the welding equipment can also be applied to the needs of different occasions to ensure the beauty of the welding seam. Due to the precise computing capability of the microprocessor, various welding specifications and precise arc starting and ending can be achieved.

Therefore, the aircraft welding workshop is applied to seven technical systems through the decision model with the dimensions of different correlation and technology development, integration, quick interchange clamping (flexibility), totalization of weld quality inspection, vitalization of welding production management, real-time welding control management, closed-loop welding process quality control, paperless welding basic database, datalization of weldability analysis, and intellectualization of welding process analysis. It is precisely because of the application of the technology group formed by the construction of these eight technical systems that the batch, stable, and efficient manufacturing of aircraft is realized manufacturing capacity.

#### 4. Results and Discussion

To further improve the production capacity and technical level of the welding process of aircraft lightweight materials, China has carried out a series of intelligent technology innovations for domestic aircraft manufacturing enterprises with the support of 04 unique project. The technical means adopted for the welding process of lightweight aircraft materials are shown in Figure 4.

The main problems existing in the welding of lightweight aircraft materials can be summarized into the trial set to be solved by the technology group, that is, the correlation set:

$T = \{$

T1: traditional methods based on manual and experience are primarily used in auxiliary links such as clamping and measurement, automatic welding, parameter selection, and process control. There are still difficulties of insufficient product quality stability and low efficiency.

T2: product quality depends on the skills of skilled workers, and there is no closed loop of product quality

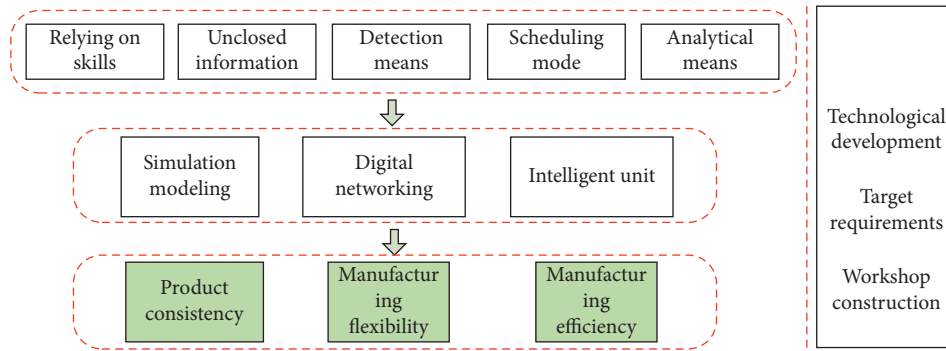

FIGURE 3: Element Atlas of lightweight material welding workshop.

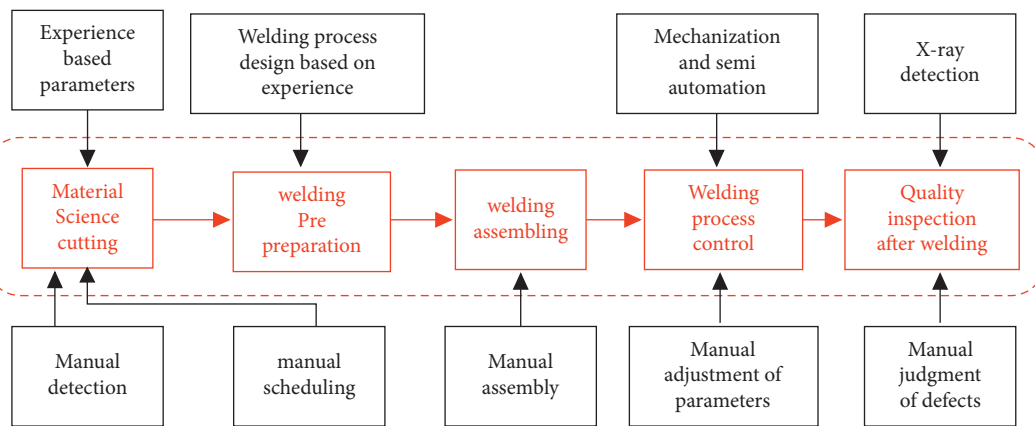

FIGURE 4: Manufacturing technology means of the current welding workshop.

control, and the stability of product quality is difficult to control.

T3: restricted by the relatively backward parameter, optimization level and detection methods, defect determination, scheduling method, clamping methods, and other factors, the demand for fast and efficient manufacturing is difficult to achieve.

T4: product manufacturability analysis still relies on personal knowledge and experience. The flexibility of product welding and manufacturing and the ability to quickly replicate the production line cannot meet the actual needs.

}

First, the leading technical units in lightweight material welding are analyzed. Manufacturing enterprises in automobiles and airplanes in industrialized countries have widely applied automation technology, sensor technology, intelligent technology, information technology, robot technology, etc., and gradually realized the digitization and intelligence of manufacturing workshops, representing a higher level of development of manufacturing workshops. Among them, the more typical technical groups influencing factors for the development of technical units are the following: (1) The rapid development of products or equipment is realized by digital modelling and simulation of products

and workshops, and some products or components have been successfully developed, shortening the product development cycle to achieve rapid response manufacturing. (2) Through the upgrade of the digital network of the manufacturing site, to realize the monitoring of equipment operating parameters in the production process of the enterprise and the process monitoring of production system failures. (3) Realize workshop intelligence with the precision and intelligence of manufacturing equipment units.

Second, combined with the relationship of multi-objective fusion of aircraft, the improvement of welding manufacturing efficiency, manufacturing flexibility, and product consistency of lightweight materials can be achieved. The intelligent welding workshop adopts advanced technical means such as intelligent manufacturing unit, simulation modelling, and digital networking. To solve various existing problems. Through the intelligent upgrade, the elements of technology development dimension, target demand dimension, and workshop construction dimension are satisfied. It is also the influencing factor of the technology group in the development of the technology unit.

Finally, the influence of technology group development is analyzed from the perspective of welding technology and process function. The technical units of the unit library of multiple welding workshops are selected for analysis. Taking a typical welding workshop as an example, its process and

corresponding technical units are described as follows: (1) Define the welding method, process parameters, and scope. (2) A database is established to store the data of various welding production processes and shared by all welding workstations. (3) According to the data of welding method, welding material type and specifications, etc., formulate a program for optimizing welding process parameters. (4) According to the workpiece shape, size, and the preset deviation limit of the seam, the automatic correction and compensation program are compiled. (5) According to the real-time recording of the welding area image during the welding process, the remote monitoring program is compiled according to the welding arc and welding beam shape parameters. (6) Set up automatic fault diagnosis alarm and repair procedures, which are applied to the driving system and control system of welding equipment, as well as wire feeder and welding power supply. (7) Manage, distribute, and collect the data between the welding equipment control system and the DCS control system operating station and realize the monitoring and remote diagnosis functions of the processing process.

## 5. Conclusions

This article proposes a multiobjective fusion decision-making model for aircraft intelligent lightweight key technologies. The model fully considers the complex changes between technical units and describes the development of technical units in a technical system in the form of technical groups. Extend the lightweight technology from single technology research to a technology system that studies the connection between technology units. In this paper, a technical unit technical system-technical group three-dimensional perspective intelligent technology system is constructed. It reveals the description of the internal connection of technology development and expands and perfects the current research theory of technology development. And it provides a decision-making basis for the batch, stable, efficient, and lightweight manufacturing of spacecraft. At the same time, the model can further expand the scope of industrial applications, which is very beneficial for improving the decision-making method of various equipment and systems' lightweight and provides a powerful tool for the lightweight design of various equipment.

To sum up, this paper studied the multiobjective of the key technology of aircraft intelligent lightweight and proposed a multiobjective fusion decision-making model. Due to the limitations of experimental conditions, time, and energy, the model needs to be further improved: first, the key technologies of intelligent lightweight cover a wide range, and the factors are influenced and coupled with each other, and it is difficult to cover the expert knowledge fully. The selected experimental cases and technical analysis are inevitably one-sided and limited, so it is necessary to improve the model further. Second, due to the small number of aircraft samples, the selected technical units, technical systems, and technical groups have limitations in the stereoscopic perspective. Further analysis, mining, and improvement are needed to increase the scope of application.

## Data Availability

The data used to support the findings of this study are included within the article.

## Conflicts of Interest

The authors declare that they have no conflicts of interest.

Online shopping has led to the rapid development of e-commerce, and at the same time, the pressure of offline distribution has increased abruptly. Therefore, a current development trend is to share end-to-end distribution against the background of the Internet. The main research content of this paper is the benefit distribution mechanism of shared end distribution. Based on an analysis of the current situation of interest distribution, this paper proposes factors that affect interest distribution from the perspectives of individuals and groups. The suitable income distribution mode of enterprise alliances is chosen from two dimensions—cooperation mode and coordination mechanism. Based on extant theory, this paper proposes a benefit distribution scheme-selection mechanism based on the modified Shapley value method and takes the terminal distribution in the Haidian District of Beijing as an example. The revised income distribution results better reflect the income-generating abilities of different enterprises within a cooperative organization and assign different benefit proportions to this cooperative organization based on different income-generating capacities to provide development incentives and, at the same time, better achieve income distribution.

## 1. Introduction

The terminal distribution cost of logistics enterprises remains constantly high; the key problem is that the dependence on human resources limits the ability of these enterprises to reduce human costs, and the allocation of logistics facilities resources is unreasonable [1–3]. The logic behind “Internet+logistics” is not applied to solve the problem of low-efficiency logistics operations. For example, cost waste is caused by an invalid operation caused by circuitous transportation, no-load transportation, and secondary distribution. To eliminate the dependence on human resources, improve the allocation efficiency of logistics facilities resources, and reduce the chances of invalid operations, it is necessary to make the end distribution operations automated, large-scale, systematic, and intelligent. Shared end distribution means that a number of logistics enterprises participate in the end distribution, that is, through

connecting transfer points, order consolidation, and other ways to integrate end distribution infrastructure resources to provide low-cost and efficient end distribution services [4, 5]. Shared end distribution through horizontal logistics integration, that is, the unified scheduling of the resources of many logistics enterprises, is carried out to realize the scale and intensification of regional end distribution operations and to better adapt to the current economic development situation from the two aspects of efficiency and effectiveness so as to achieve low-cost and high-efficiency end distribution services. The joint distribution mode, which takes the logistics enterprise as the hub and connects the e-commerce platform with the logistics terminal distribution service, is the solution to the bottleneck problem encountered by the current e-commerce platform in the terminal distribution link. As the sharing mode of the third-party collection platform expands in the form of joining, it is difficult to standardize and standardize the work in this process. The

joint distribution model participates in a variety of enterprise levels, which is not conducive to the coordination between enterprises and the integration of resources. The intelligent express cabinet sharing mode takes the intelligent express cabinet as the carrier to connect the terminal logistics service and users; on the one hand, it saves the increase in operating costs caused by decentralized business outlets, and on the other hand, it uses mobile Internet technology to integrate offline physical resources and collect online service data, which not only reduces costs and increases efficiency but also simplifies the traditional terminal distribution service process and improves the quality of terminal distribution service. Let the terminal distribution service realize digitalization, informationization, and intellectualization.

When constructing the alliance of shared end distribution logistics enterprises, we have to consider the size of each enterprise, the core competitiveness, and the logistics demand of each region. Is it possible to build alliances among enterprises of different sizes? If so, what principles do you need to follow to build an alliance? In the formation of the enterprise alliance, how to protect the core competitiveness of the enterprise itself without affecting the interests of the whole enterprise alliance? In addition, what factors will hinder or promote the establishment and stability of logistics enterprise alliance? Answering the above questions is of great significance for building a shared terminal distribution platform for logistics enterprises. The main research of this paper is aimed at studying the cost-sharing ratio of each enterprise from the perspective of resource utilization efficiency, and most of the literature focuses on improving this ratio by increasing the risk factor or effort level on the basis of the Shapley value method. From the perspective of the sharing economy, this paper studies the impact of enterprises on cost allocation due to resource utilization efficiency from the point of view of the better promotion of resource integration.

## 2. Literature Review

*2.1. Research Status of Shared End Distribution.* Against the background of "Internet+logistics," sharing economy thinking is applied to the logistics industry, which continuously releases the resource dividend of integrated logistics. For the "theme of shared terminal distribution," scholars have mainly focused on the following three aspects: site selection for terminal distribution outlets, the optimization of terminal distribution path, and research on sharing terminal distribution mode. Perez-Mesa et al. [6] established a location selection model for FMCG's agricultural product distribution center with the lowest total cost. Zhang and Liu [7] proposed the method of a gray demand logistics distribution center location and model of a gray sales demand logistics distribution center location planning, which can solve the problem of gray sales demand in logistics distribution center location. Kexin et al. [8] adopted the node centrality index of complex network theory to evaluate the importance of existing terminal distribution outlets. Evari et al. [9] found that using friends in a social network to assist

in last-mile delivery greatly reduces delivery costs and total emissions while ensuring speedy and reliable delivery. In addition, Li et al. [10] analyzed the ability of logistics enterprises to meet the diversified needs of service objects through the differentiation of asset allocation. Moreover, Yu et al. [11] believed that the application of the ant colony algorithm has good feasibility for the distribution path optimization of logistics terminals. Tang et al. [12] solved the model based on multiphase particle swarm optimization algorithm (MPPSO) and Matlab. Masoud et al. [13] applied a genetic algorithm and hybrid genetic algorithm to calculate path optimization schemes and compared the results. At present, genetic algorithms are more commonly used to solve this type of problem [14–17].

Studies on the theme of the shared terminal distribution mode mainly include the following. Patterson et al. [18] established a carrier selection model, the results of which show that third-party logistics are more dependent on multimodal transport than are other terminal carriers. Lu et al. [19] applied the routing optimization algorithm to establish a multiagent simulation model to solve the routing optimization problem for electric vehicles. In the context of "Internet plus Internet of Things," Ryu et al. [20] proposed an integrated semantic service platform to support ontological models in various IoT-based service domains of a smart city. The driving factors for the formation of end-to-end joint distribution alliance are as follows. First, to meet the needs of e-commerce economic development, with the increasing maturity of e-commerce, with the upgrading of consumption, the end distribution business shows a substantial growth, and the traditional end distribution model can no longer adapt to large-scale offline distribution business [21]. The second is the need to reduce the cost structure. On the one hand, because of the high intensity of work and low wages, the mobility of end distribution employees is extremely high, and the human cost of end distribution remains high. On the other hand, the scale of operation and market limits the ability of a single enterprise to integrate resources. Third, the need to improve the efficiency of distribution. Due to the large number of service objects and the scattered geographical location, express delivery enterprises usually increase the distribution cost because of unreasonable distribution routes, high load rate, secondary distribution, and other problems [22]. Fourth, the needs of high-quality end distribution services; end distribution services gradually show a face trend, that is, with user experience as the core, personalized end distribution services are provided based on user portraits through big data, artificial intelligence, and other technologies. Fifth, to advocate the need of green logistics, the establishment of end-to-end joint distribution alliance is conducive for the integration of logistics infrastructure and other resources, and for reasonable planning of vehicle transport routes, so as to reduce traffic pollution and achieve energy saving and emission reduction.

*2.2. Research Status of the Benefit Distribution of Logistics Alliances.* Releasing the dividend of logistics integration enables end distribution enterprises to reduce costs and

increase efficiency. The design and operation of logistics alliances are critical, especially the distribution of benefits. The current research in this field is mainly classified as below.

Based on the Shapley value method and modified to put forward a benefit distribution strategy, an increasing number of scholars have used the Shapley value method to conduct benefit distribution research [23, 24]. Gong et al. [25] examine the production coordination problem from the perspective of asymmetric information. Wei [26] constructed a Shapley value model of income distribution in the information flow of a construction supply chain under asymmetric information to ensure the security of the synchronous control of information flow and a more balanced benefit distribution. Pan and Fang [27] established an integrated energy service benefit distribution model based on the improved Shapley value method to break the imbalance between the environment and economy of integrated energy services to realize overall sustainable development. Improving the Shapley value method can reduce the economic loss caused by downtime and promote multi-factory cooperation [28]. In addition, through the application of the improved Shapley value method, the production and delivery time cycle will be shortened and found that it can be applied to any industry of concern to improve operations [29].

There are many studies on the distribution of multi-agent interests, and the methods used are very diverse. Lian [30] through constructing a fuzzy time window-based scheduling optimization model for the cross-docking of cold chain logistics found that the distribution time of cold chain logistics can be significantly shortened and the distribution cost, damage cost, and economic benefits can be significantly reduced. Ma et al. [31] established a cold chain dynamic game model involving a milk manufacturer and two downstream oligopoly supermarkets under a wholesale price contract. Sun et al. [32] proposed a two-layer programming model to find the optimal location of a logistics distribution center by considering the advantages of customers and logistics planning departments. Some scholars have used the benefit distribution model of coastal port intelligent logistics supply chains based on intelligent bionic swarm evolution optimization control [33–35] or the profit distribution model based on agents [36–38] to realize the benefit distribution among multiple agents. Nadia et al. [39] through investigation and analysis proposed the necessity and importance of establishing alliances for enterprises and analyzed the interests of an alliance as a whole by using the Shapley value method. Meng et al. [40] studied multiorganization cooperation under the sharing economy model, which provided a theoretical basis for core enterprises to formulate reasonable income distribution strategies and promote the sustainable development of the sharing economy. Shang et al. [41] adopted cooperative game theory and the Shapley value method to solve the benefit distribution scheme, which improved overall risk management ability and business stability and stimulated the development potential of the enterprise.

On the whole, scholars focus on the macro research and analysis of the mode construction of shared end distribution, and pay more attention to the path optimization and site selection in shared end distribution on the micro level, but rarely analyze and study the problems in the practice of shared end distribution from the perspective of enterprise cooperation. How to complete the terminal distribution operation with the lowest cost, the least manpower, and the highest efficiency is the main problem that express delivery enterprises are facing. At present, the repeated construction of business outlets leads to the waste of social resources, the recruitment difficulties of grass-roots express salesmen, and the secondary distribution caused by the timeliness of information, making the “lone Wolf” tactic easy to suffer losses in the terminal distribution service, so it is imperative to jointly build and share logistics. It is very important to design a fair and reasonable benefit distribution mechanism to realize the sustainable development of sharing terminal distribution alliance.

### 3. Research on the Benefit Distribution Mechanism of Shared End Distribution

This paper investigates the factors that affect the benefit distribution of enterprises from the perspective of groups and individuals, as shown in Table 1, and gives the income distribution model of shared end distribution, as shown in Table 2, as follows:

When rational people participate in games involving economic activities, the two problems that need to be solved are that related to cooperation and that related to coordination. The cooperation mode is defined as the negotiating and signing of agreements to define the responsibilities and obligations of participants, and the coordination mechanism to achieve stable income expectations through good institutional design provides incentives and signals for all parties to maintain cooperation loyalty. Different cooperation modes mean that cooperative organizations have different degrees of alliance cohesion, and coordination mechanisms with different stable income expectations have different incentives and signals for members to provide cooperation. In addition, because the problems of cooperation and coordination are the two sides of game behavior, respectively, a certain cooperation model is bound to correspond to a coordination mechanism. As shown in Figure 1, the cooperation type of outsourcing business in the form of a market contract corresponds to the fixed wage model that allows for payment for a certain volume of business according to the settlement scheme; the strategic alliance model that aims to dilute the enterprise boundary to realize the sharing of management rights corresponds to the payment mode of land rent based on the distribution of alliance income on the basis of fixed payment. The ecological competition type with Internet technology as the background corresponds to the shared profit model, which is based on the coconstruction and sharing of logistics infrastructure and information resources as well as the benefits of the alliance.

TABLE 1: Influencing factors of enterprise benefit distribution in end-to-end distribution.

	Influencing factors	Meaning
Group.Visual angle	Strength and status	It determines the size of the bargaining chips of the members in the distribution of interests
	Service unit price and demand	It determines the bottom line in terms of cost that the enterprise alliance can bear and the ceiling of profit expectation
	Alliance stability	It determines whether the alliance cooperation relationship is long term or short term
Individual.Visual angle	Cost input	It determines the proportion of benefit distribution among participants
	Risk bearing	It can be divided into external and internal risk
	Service level	It determines user satisfaction
	Marginal contribution	The higher the marginal contribution rate is, the higher the sovereign status in the distribution of interests

TABLE 2: Income distribution model of shared end distribution.

	Income distribution model	Concrete
Cooperation mode of sharing resources	Outsourcing collaboration	Outsourcing of noncore logistics business
	Strategic alliance type	Dilution of enterprise boundaries through organizational cooperation agreements
	Ecological competition and cooperation	Drawing of lessons from the social organization of human beings and the operating mechanism of natural ecosystem
Coordination mechanism of income distribution	Fixed wage model	Expected coordination mechanism in the environment of outsourcing collaboration
	Mode of paying land rent	Specific monetary quantification of the benefits from resource acquisition
	Shared profit model	Emphasize that all parties should participate in the construction of logistics infrastructure and share the benefits of such cooperation

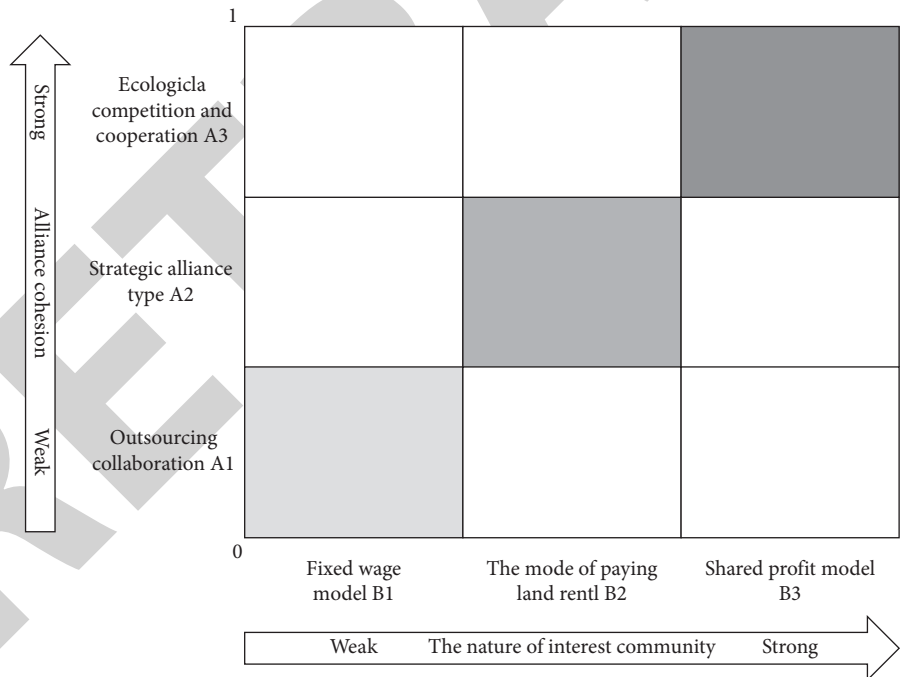

FIGURE 1: Income distribution mode selection matrix.

#### 4. The Benefit Distribution Scheme of the Modified Shapley Value Method

The Shapley value method is proposed by L. S. Shapley to solve the n-person cooperative game problem. The application of this mathematical algorithm to the benefit distribution of alliance members can effectively avoid

egalitarianism in distribution. The contribution ability of the members of the cooperative organization is included in the income distribution, which effectively arouses the production enthusiasm of the members. If  $n$  individuals participate in a social and economic activity, when the cooperative nature of the parties is greater than the competitive nature, the parties can obtain higher benefits by forming a

cooperative relationship than under the conditions of individual operation, and with the increase of the scale of the cooperative organization, the industrial synergy effect based on resource sharing and information exchange will become more prominent, and the income of the cooperative organization will gradually increase. A reasonable distribution scheme will provide corresponding organizational incentives to the members of the cooperative organization, and then ultimately ensure that the interests of all n-person cooperation can be maximized.

**4.1. Shapley Value Method Based on Contribution Degree Distribution.** For  $f$  a weighted voting scheme used by  $n$  voters to choose between two candidates, the  $n$  Shapley-Shubik Indices (or Shapley values) of  $f$  measure how much control each voter can exert over the overall outcome [42]. Suppose that there are  $n$  individuals participating in cooperation, and all participating members are denoted by  $N = \{1, 2, \dots, n\}$ ; any subset  $S$  of  $N$  (any cooperative combination in n-person cooperation) has a corresponding real-value function  $V(S)$ , that is, the benefits that can be obtained by any cooperative combination  $S$ .  $V(\emptyset) = 0$ , which means that if there are no participants in the cooperative organization, then the total income of the alliance is 0. Suppose that  $S_1$  and  $S_2$  are any two kinds of cooperative combinations in  $N$  and satisfy  $S_1 \cap S_2 = \emptyset$ . The profit created by an alliance formed by these two combinations is greater than the sum of the profits generated by these two combinations; that is,  $V(S_1 \cup S_2) > V(S_1) + V(S_2)$ . Thus,  $[N, V]$  is called the n-person cooperation strategy set. In a set of allocation strategies, it is assumed that  $X_i$  indicates that the maximum income  $V(N)$  obtained by member  $N_i$  in the alliance is a share of income, that is, the Shapley value, and the distribution strategy set of the alliance in the cooperative game is represented by  $X = \{X_1, X_2, \dots, X_n\}$ . The distribution set should meet two basic constraints—overall and individual rationality. That is, the sum of the benefits of the alliance as a whole is equal to the sum of the benefits of each member, and the income of individual members in the alliance is greater than that of individual members who complete the task alone, which is expressed by the following mathematical formula:

$$\begin{aligned} \text{overall rationality: } \sum_{i=1}^n x_i &= V(N), \\ \text{Integrated rationality: } X(i) &> V(i). \end{aligned} \quad (1)$$

According to the basic theorem of the Shapley value method, in the cooperative organization of  $n$  people, under characteristic function  $V$ , the income of each member is expressed by  $X = \{X_1, X_2, \dots, X_n\}$ . According to the Shapley value method, the income of each member can be obtained as follows:

$$X_i = \sum_{s \in S_i} W|S| [V(S) - V(S - i)]. \quad (2)$$

The formula explains the following:

- (1)  $|S|$  represents the size of the organization
- (2)  $W(|S|)$  is a weighting factor,  $W(|S|) = ((s) - 1!(n - |S|)!/n!)$ .
- (3)  $V(S - i)$  represents the benefits of the organization when member  $i$  is removed from organizational alliance  $S$
- (4)  $V(S) - V(S - i)$  represents the contribution made by member  $i$  in the organizational alliance.

According to the above introduction to the Shapley value method, we know that this method takes the contribution of each member as the distribution standard in the benefit distribution, and the premise behind this distribution method being considered reasonable and fair is that the members of the organizational alliance conform to the rational person hypothesis, and the costs and risks borne within the organizational alliance are consistent. However, compared with the specific practice, due to the differences between enterprise qualification and the competitive environment, there is a gap between the cost and risk shared by enterprises with different strengths in the organizational alliance because of the differences in their competitiveness. This kind of risk and cost gap can be shown through the cooperation mode and income distribution mechanism in the organizational alliance. When calculating members' income by the Shapley value method, it is assumed that members' ability to share the cost is consistent with the risk, which leads to the final calculation result of the Shapley value method deviating from the facts and being unable to provide the corresponding compensation mechanism for those enterprises that bear high costs and risks. Therefore, this paper hopes to modify the results calculated by the Shapley value method by measuring the evaluation indicators of different cooperation modes and income distribution mechanisms and forming weighted factors to obtain a more reasonable benefit distribution scheme that takes into account the costs and risks borne by enterprises in the cooperative organization.

**4.2. Revision of the Shapley Value Method and Establishment of the Model.** In this paper, the evaluation standard of enterprises under an established cooperation mode is based on the influencing factors of benefit distribution from the perspective of groups and evaluates the influencing factor  $A_i$  of an enterprise on organizational income output under this cooperation system from three aspects: the strength and status of alliance members, the unit price and market demand of services, and the stability of the logistics alliance relationship. The cooperation mode of sharing resources explores the influencing factors of interest distribution at the macro level of cooperative organizations, while the coordination mechanism of income distribution explores those at the micro level of alliance members. From the perspective of individual enterprises, the influencing factors of benefit distribution mainly have the following four levels: cost input, risk taking, service level, and marginal contribution. The correction results for the two angles are shown in Tables 3 and 4.

TABLE 3: Enterprise evaluation system from a group perspective.

Influencing factors of benefit distribution from a group perspective	Weight	Enterprise 1	Enterprise 2	Enterprise 3
Strength and status of the members of the alliance	0.5	$a_{11}$	$a_{21}$	$a_{31}$
Service unit price and market demand	0.3	$a_{12}$	$a_{22}$	$a_{32}$
Stability of the logistics alliance	0.2	$a_{13}$	$a_{23}$	$a_{33}$
Correction factor of enterprise i	—	$A_1$	$A_2$	$A_3$

TABLE 4: Enterprise evaluation system from an individual perspective.

Influencing factors of benefit distribution from an individual perspective	Weight	Enterprise 1	Enterprise 2	Enterprise 3
Cost input	0.3	$b_{11}$	$b_{21}$	$b_{31}$
Risk bearing	0.3	$b_{12}$	$b_{22}$	$b_{32}$
Service level	0.3	$b_{13}$	$b_{23}$	$b_{33}$
Marginal contribution	0.1	$b_{14}$	$b_{24}$	$b_{34}$
Correction factor of enterprise i	—	$B_1$	$B_2$	$B_3$

The influencing factors of the three cooperation modes on the income distribution strategy are expressed by  $A_i = \{A_1, A_2, A_3\}$ , and the following conditions are met:

- (1)  $-1 < A_i < 1; -1 < a_{ij} < 1$
- (2)  $\sum_{j=1}^3 a_{ij} = 1$
- (3)  $\sum_{j=1}^3 A_j = 0$

The influencing factors of the three income distribution coordination mechanisms on the income distribution strategy are expressed by  $B_i = \{B_1, B_2, B_3\}$ , and the following conditions are met:

- (1)  $-1 < B_i < 1; -1 < b_{ij} < 1$
- (2)  $\sum_{j=1}^3 b_{ij} = 1$
- (3)  $\sum_{j=1}^3 B_j = 0$

#### 4.3. Establishment of the Modified Shapley Value Model.

The Shapley value has become popular in the Explainable AI (XAI) literature, thanks, to a large extent, to a solid theoretical foundation, including four ‘‘favourable and fair’’ axioms for attribution in transferable utility games. The Shapley value is probably the only solution concept satisfying these axioms [43]. From the overall rational point of view, this paper probes into correction factor  $A_i$  of each enterprise in three aspects: the strength and status of alliance members, the unit price of service and market demand, and the stability of logistics alliance relationships from a group perspective. Yokote [44] introduced a new axiom, called equilibrium contribution property of equal contributors, and proved that this axiom characterizes a new class of solutions together with validity and weak covariance, providing a new axiom basis for analyzing variations of Shapley values in a uniform way. Brin [45] proved that the Shapley value is characterized by this fairness, efficiency, and the nature of the person in the empty game, and these three axioms also characterize the Shapley value of a simple game class. From the perspective of individual rationality, this paper studies the correction factor  $B_i$  of enterprises under the four dimensions of cost input, risk taking, service level, and marginal sharing. To make the final quantitative results more in line with the specific situation in practice, the

evaluation indicators of all levels and dimensions are divided into different weights, thus reflecting the unequal impact of various factors on the final benefit distribution scheme [46, 47]. After quantification, we obtain correction factor  $A_i$  of each enterprise under overall rationality and the correction factor of individual rationality  $B_i$ . By taking the average of both, we finally obtain the comprehensive correction factor of each enterprise, that is,  $1/2 * (A_i + B_i)$ . Through the comprehensive correction factor calculation, we can obtain the correction value that should be obtained by each enterprise and finally obtain the benefit distribution scheme.

In a cooperative organization of  $n$  people, under characteristic function  $V$ , the benefit of each member is expressed by  $X = \{X_1, X_2, \dots, X_n\}$ . Taking the Shapley value as the basic original value  $X_i$ , the cooperative income distribution strategy is modified from the two aspects of the cooperation mode of shared resources and the coordination mechanism of income distribution; correction factor  $1/2 * (A_i + B_i)$  is obtained; and correction value  $\Delta X_i$ ,  $\Delta X_i = (1/2) * X_i * (A_i + B_i)$  is obtained. The income of each member after the amendment is expressed by  $X' = \{X'_1, X'_2, \dots, X'_n\}$ ,  $X'_i(V) = X_i(V) + \Delta X_i(V)$ . The specific correction process is shown in Figure 2.

## 5. Example Analysis

5.1. Enterprise End-to-End Distribution Costs. Bi et al. [48] conducted an empirical study on five express delivery enterprises in China and made a comparative analysis of the results. Li [49] analyzed the problems existing in logistics distribution of express delivery enterprises, discussed various factors affecting customer satisfaction, and put forward empirical analysis assumptions. So the example analysis of this paper selects express delivery enterprises under joint distribution as the research objects and applies the correction method to modify the initial Shapley value based on the Shapley value method to obtain a more realistic distribution scheme. This paper takes 10 distribution outlets of Yuantong, Zhongtong, and Best Express enterprises in Haidian District as the research objects and studies the distribution costs borne by each enterprise under three

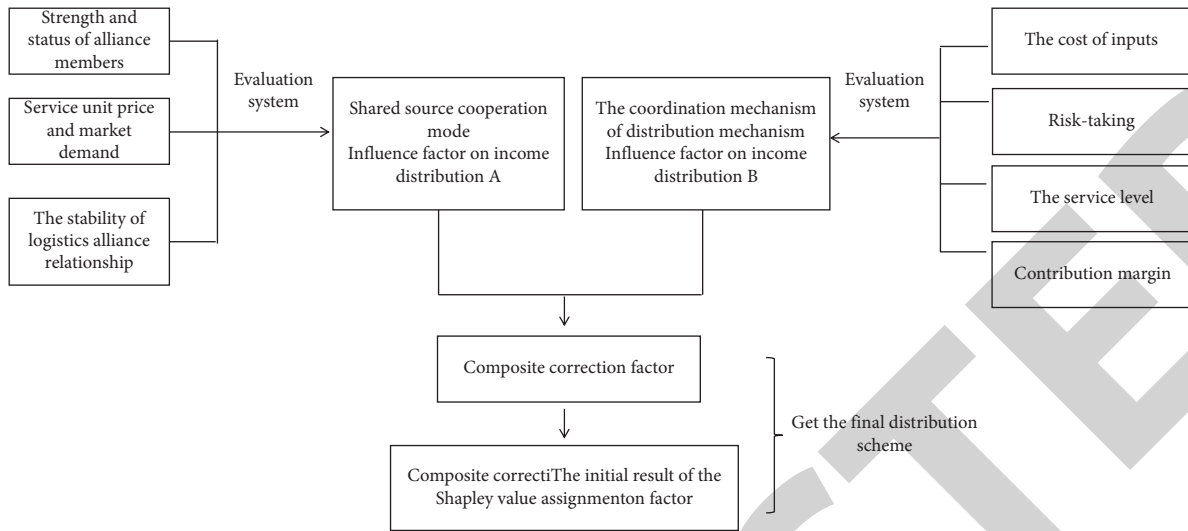

FIGURE 2: Modification process of the Shapley value method.

forms of distribution: three enterprises participate in the distribution task alone; two enterprises cooperate to participate in the joint distribution, and another enterprise participates in the distribution alone; and three enterprises cooperate to participate in the joint distribution. The corresponding distribution outlets and their numbers are shown in Table 5.

5.1.1. *Three Enterprises Participate in Distribution Separately.* The scheme and cost for the three enterprises to participate in distribution separately is shown in Table 6:

5.1.2. *Two Enterprises Cooperate to Participate in Distribution.* A. Yuantong cooperates with Zhongtong to participate in distribution, and Yunda distributes separately, the distribution path and cost are shown in Table 7:

B. Yuantong and Yunda cooperate to participate in distribution, and Zhongtong distributes separately, the distribution path and cost are shown in Table 8:

C. Yunda cooperates with Zhongtong to participate in distribution, and Yunda distributes separately, the distribution path and cost are shown in Table 9:

5.1.3. *Three Enterprises Participate in Joint Distribution.* The distribution cost under the cooperation of the three enterprises is shown in Table 10:

5.2. *Distribution of Alliance Income by the Shapley Value Method.* By calculating the costs of distribution schemes under the above cooperation modes, we can obtain the costs shared by enterprises in different distribution schemes and the benefits generated by joint distribution. On this basis, the initial Shapley values of the three enterprises after forming a cooperative organization can be calculated. To facilitate the latter description, Yuantong, Zhongtong, and Yunda enterprises are replaced by enterprises 1, 2, and 3, respectively.

As can be seen from Table 11, the participation of enterprises in joint distribution can effectively help them generate organizational cooperation income, with all three companies undertaking distribution tasks alone as the lowest threshold. When the number of enterprises participating in joint distribution continues to increase, the overall cooperation income increases significantly. In the example analysis of this paper, the total cost of the three enterprises participating in the distribution alone is 285.95. However, when the two enterprises cooperate, they obtain the benefits of the cooperative organization relative to the other enterprise that does not participate in the cooperation. Cooperation between Yuantong and Zhongtong can generate 91.1 units of income, and that between Yuantong and Yunda enterprises can generate 106.15 units of income. Moreover, cooperation between Zhongtong and Yunda enterprises can produce 89.2 units of benefits. From the perspective of bilateral cooperation, the profits of enterprises are better when they cooperate with stronger enterprises. The income from cooperation among Yuantong, Zhongtong, and Yunda is higher than that between Zhongtong and Yunda. From the perspective of multilateral cooperation, with the increase in the number of cooperative enterprises, the income of cooperative organizations also significantly increases. When the three enterprises work together to participate in a joint distribution, the terminal distribution cost can be significantly reduced by 60.6%. As a result, the profit ceiling of each enterprise at the end of distribution is raised. As large logistics enterprises gradually complete the primitive accumulation of enterprise development, gradually move toward the intelligent logistics mode in the unmanned era, and eliminate the dependence on human resources, small and medium-sized logistics enterprises, due to limited funds and a lack of technology, on the one hand, cannot realize the reform of operation mode in a short period of time. On the other hand, if enterprises continue to follow the traditional logistics management model, then they still face the constraints of human costs, so the living space of

small and medium-sized logistics enterprises is gradually narrowed. In this paper, through an analysis of examples, we know that when small and medium-sized enterprises are facing strong competitors such as large logistics enterprises, if they want to overtake them, then the establishment of a cooperative cooperation model and benefit distribution coordination mechanism suitable for the development of enterprises is necessary for their long-term development.

According to the above model of the Shapley value method and combined with the research object in the example analysis, we know that our research objects are three express delivery enterprises, namely, enterprises 1, 2, and 3, represented by the set  $N = \{1, 2, 3\}$ . The income earned by each enterprise in the cooperative organization is expressed by  $X = \{X_1, X_2, X_3\}$ . The calculation process and results are shown in Tables 12–14.

According to the above calculations, under the Shapley value model, the income of each enterprise participating in the joint distribution is as follows:

$$\begin{aligned}
 X_1 &= 15.19 + 17.7 + 28.98 = 61.86, \\
 X_2 &= 15.19 + 14.87 + 23.33 = 53.39, \\
 X_3 &= 17.7 + 14.87 + 28.35 = 60.91.
 \end{aligned}
 \tag{3}$$

In the distribution scheme of the Shapley value model, there is little difference in the organizational income of the enterprises participating in the joint distribution, which stems from the assumption at the beginning of the establishment of the model: the differences among participants should be ignored. However, due to the different qualifications of each enterprise, the contribution ability of the heterogeneous enterprise resources to the cooperative organization is different. When the heterogeneous enterprise resources help the cooperative organization achieve high returns, this part of the income should be compensated to the enterprise in terms of contribution ability to provide the cooperative organization with the development incentive of “contributing enterprise resources.” Only in this way can the sustainable and coordinated development of the cooperative organization be realized.

5.3. *Modification of the Initial Shapley Value.* The following is the correction of the initial Shapley value of each enterprise obtained through the example analysis. The source of the correction factor is based on the evaluation indicators of each enterprise in three aspects: the strength and status of alliance members, service unit price and market demand, and the stability of the logistics alliance relationship. The feedback source of the evaluation index of the enterprise is mainly obtained by network enterprise data and offline interviews and quantifies the evaluation index of each enterprise according to first-hand data.

The initial Shapley value of the enterprise is modified from the point of view of the cooperation mode of sharing resources, and the details of the correction factors of each enterprise are shown in Table 15.

The initial Shapley value of the enterprise is modified from the point of view of the coordination mechanism of income distribution, and the correction factors of each enterprise are shown in Table 16.

Through the above calculations, the final benefit distribution correction factors of the three enterprises participating in joint distribution can be obtained. To make the correction results more reasonable by averaging the

correction factors from two perspectives, by calculating the final correction factors of each enterprise, correction value  $\Delta Xi, \Delta Xi = Xi * 1/2 (Aj + Bj)$  is finally obtained. The specific results are shown in Table 17.

Yuantong Express is ahead of the other two enterprises in terms of overall market share and service quality, and its business orders are also greater in amount and number than are those of the other two enterprises, which will make an important contribution to the income of the whole cooperative organization in the process of building the alliance. Yunda Express has weak market share and resource scheduling ability compared with Yuantong and Zhongtong enterprises, showing positive externalities to organizational income. With the help of cooperative organizations, the Yunda enterprise reduces the cost of terminal distribution and obtains the opportunity to share the benefits from cooperation, but to compensate for the contribution of Yuantong and Zhongtong, part of its income needs to be allocated to them to send a positive incentive signal to them in terms of contribution. Therefore, by observing the correction factors of various enterprises, we can see that those of the Yuantong and Zhongtong enterprises are positive, while the correction factor of the Yunda enterprise is negative.

	Yuantong	Zhongtong	Yunda
Shapley value method	61.86	53.39	60.91
After correction	18.90	12.95	-33.38

Since the main purpose of this step is to calculate the correction value of each enterprise, the correction value further modifies the distribution scheme on the basis of that obtained by the Shapley value method, so the sum of the correction value of each enterprise should be equal to 0; that is, the correction scheme of the paper does not change the income of the cooperative organization in the whole correction process. On the basis of this modified value, we can obtain the final distribution scheme by adding the initial Shapley value calculated by the Shapley value method, and the final distribution scheme is compared with that obtained by the Shapley method, as shown in Table 18:

Through the above comparison, we can see that the distribution scheme of the Shapley value method pays more attention to the distribution of cooperative income from the perspective of average distribution, and there is little difference in the respective income of the three enterprises. This "average" distribution method does not give

compensation and incentives to the contribution ability of enterprises with different qualifications, which is not conducive for the sustainable development of cooperative organizations. In the example analysis of this paper, we can see that based on the distribution scheme according to the Shapley value method, the cooperative benefits shared by the three enterprises are not very different, and the difference is controlled within 9 units. The distribution scheme under the average principle cannot reflect the utility of each individual in the cooperative organization, quantify this utility, and reward this utility through reasonable benefit compensation. In the example analysis of this paper, the Yuantong enterprise can bring higher business order and resource scheduling ability to the cooperative organization and can share its offline logistics resources with other enterprises; after revision, the income of the Yuantong enterprise is obviously higher than that of the Zhongtong and Yunda enterprises.

The case study of this paper takes joint distribution as the research background, so in general enterprise practice, we usually choose the cooperation mode of diluting enterprise boundary, which is higher than outsourcing cooperation. The core of collaborative joint distribution is sharing orders. When strong enterprises share internal low-profit orders with members of cooperative organizations, while other members complete these orders to harvest enterprise profits, it is necessary to pay a corresponding proportion of “rent” to stronger enterprises, which is also the basic idea of the mode of paying land rent in the coordination mechanism of income distribution. This kind of “rent” incentive is to make stronger enterprises more willing to participate in the construction of cooperative organizations, so as to maintain the sustainable development of cooperative organizations. In this case, because of its limited market share and service level, Yunda enterprise undertakes the terminal distribution business of high cost and low volume when it operates alone. However, when the distribution business is optimized through joint distribution, from its own vertical comparison, Yunda enterprise not only completes the corresponding distribution tasks but also obtains the benefits of cooperation. However, the stability of this form of cooperation depends on the comparison of the strength of their respective enterprises, which is mainly reflected in the market share; comprehensive service capacity; and complete infrastructure. In terms of logistics resource scheduling ability, when the strength of enterprises is very different and the balance of cooperation is broken, enterprises with greater discourse power will force weaker enterprises to accept organizational agreements that are not conducive for the development of enterprises, which is likely to break the calm mode of cooperation.

## 6. Conclusions

This paper focuses on the difficult problem of enterprise cooperative benefit distribution in end distribution, takes the benefit distribution principle as the basic constraint, and constructs a two-dimensional enterprise evaluation system from the group and individual perspectives. The income distribution mode selection matrix is constructed from the two dimensions of the cooperation mode and coordination mechanism. Under these different practical backgrounds, all enterprise parties choose the appropriate cooperation mode and income distribution mode in the income distribution mode selection matrix and obtain the income distribution correction factor from the evaluation system within the selected range, which is modified on the basis of the initial Shapley value. Compared with the initial Shapley value method, which pursues income equalization, the revised income distribution results more so reflect the income-generating ability of different enterprises in the cooperative organization and give different proportions of benefits to the cooperative organization based on different income-generating capacities to provide incentives for the development of the cooperative organization. This paper holds that the influence of the income distribution scheme of cooperative organizations depends on the close relationship between the

cooperation mode of shared resources and the coordination mechanism of income distribution. Under this two-dimensional mechanism, the final benefit distribution should be determined based on the evaluation of the enterprise and not on only the Shapley value mathematical model. The two-dimensional selection mechanism based on income distribution can better reflect the income-generating ability that enterprises can exert in the specific cooperation practice. From a rational point of view, this paper proposes what kind of cooperation mode and coordination mechanism enterprises should be established to realize the sustainable development of cooperative organizations. However, in practice, it is still necessary to make prudent cooperation decisions based on an enterprise’s internal resources, enterprise strategy, enterprise organizational structure, and the external environment.

This paper focuses on studying and solving the problem of the benefit distribution of various enterprises, puts forward a framework solution from the perspective of static research, and presents a two-dimensional selection matrix of income distribution based on overall and individual rationality. The Shapley value algorithm is modified from the point of view of the cooperation mode and income distribution coordination mechanism. Although this paper takes into account the influencing factors of overall rationality on income distribution and individual rationality on income distribution, it does not specifically analyze the influence of the negotiation premium power between different enterprises on the whole income distribution, that is, taking into account the rationality of the establishment of cooperative organizations and the rationality of individual participation in cooperative organizations, but there is no dynamic research perspective for analyzing the continuous growth of enterprises in cooperative organizations. Whether the old cooperation model and distribution mechanism can still be established needs to be further studied. Therefore, this paper does not consider the dynamic cooperative development of enterprises, and the static research perspective on the distribution of interests of enterprises inevitably makes the final research results deviate from the practices of specific enterprises.

Many encryption systems face two problems: the key has nothing to do with the plaintext; only a single chaotic sequence is adopted during the encryption. To solve the problems, this paper proposes an image encryption method based on Hopfield neural network and bidirectional flipping. Firstly, the plaintext image was segmented into blocks, the resulting image matrix was block scrambled, and each block was bidirectionally flipped to complete the scrambling process. After that, the plaintext image was processed by the hash algorithm to obtain the initial values and control parameters of the chaotic system, producing a pseudo-random sequence. Then, a diffusion matrix was generated through the optimization by Hopfield neural network and used to derive a ciphertext image through diffusion transformation. Experimental results show that our algorithm is highly sensitive to plaintext, strongly resistant to common attacks, and very efficient in encryption.

## 1. Introduction

The safety of digital images, an important carrier of information, has attracted much interest and concern [1]. To ensure the safety of image information, it is highly necessary to develop a good encryption algorithm [2]. The chaotic system lays a good foundation for encryption systems, due to its excellent sensitivity to initial values. Due to the sensitivity of the initial value, small changes can get completely different results, so each small change can achieve completely different encryption results during encryption, which can provide good security. As a result, the chaotic system is being integrated to more and more encryption algorithms. In the past two decades, researchers have proposed various encryption methods and applied them to image encryption, drawing on the unique properties of the chaotic system (e.g., sensitivity to initial values, unpredictability, and pseudo-randomness) and the natural bound between the system and cryptology [3–10]. Some scholars put forward several new chaotic systems and designed the corresponding encryption strategies [4–8]. Some scholars presented encryption algorithms based on existing chaotic systems, focusing on the

design of encryption strategies [9–16]. Some scholars combined spatiotemporal chaos with DNA sequencing [6] and proposed image encryption algorithms based on the cryptological features of spatiotemporal nonadjacent coupled map lattices [17] and mixed linear-nonlinear coupled map lattices [18], respectively. The safety performance of an encryption algorithm can be measured by an important criterion: the ability to resist various attacks, namely, violent attack, statistical attack, and differential attack. Some algorithms are unable to withstand chosen-plaintext attack [19–24]. Besides, many algorithms are inefficient in encryption and need multiple encryptions to achieve a good effect. To solve the above defects, this paper explores key generation and image encryption strategy and proposes a chaotic image encryption algorithm based on Hopfield neural network and the image scrambling approach of bidirectional flipping. Firstly, the plaintext image was segmented into multiple  $N \times N$  blocks, and the resulting image matrix was block scrambled. Each block was bidirectionally flipped and merged into a scrambled image. Next, the plaintext image was processed by the hash function, producing a hash array. On this basis, the control parameters

and initial values of the chaotic system were determined to generate a random pseudo-matrix. Multiple sequences were taken as the initial conditions of Hopfield chaotic neural network, which creates the key flow of the diffusion matrix. Then, the scrambled image was segmented along the diagonal, and the key flow was converted into a key matrix. Afterwards, symmetric diffusion was performed on the key matrix and the scrambled image to obtain the encrypted image. Finally, the safety and reliability of our algorithm were demonstrated by comparing it with similar algorithms developed since 2017.

## 2. Image Encryption Strategy

*2.1. Hopfield Neural Network.* Proposed by American physicist Hopfield in 1982, the Hopfield neural network mimics the memory mechanism of biological neural networks. In this fully connected neural network, every node transmits a signal to other nodes, which eventually return the signal to the transmitter. Therefore, the Hopfield neural network has a feedback mechanism. A typical Hopfield neural network can be expressed as

$$x = -x_i + \sum_{i=1}^3 w_{ij}v_i, \quad (1)$$

where  $v$  is the hyperbolic tangent function:

$$v_i = \tanh(x_i) = \frac{e^{x_i} - e^{-x_i}}{e^{x_i} + e^{-x_i}}, \quad (2)$$

and  $w$  is the weight function:

$$w = \begin{bmatrix} 2 & -1 & 0 \\ 1.7 & 1.71 & 1.1 \\ -2.5 & -2.9 & 0.56 \end{bmatrix}. \quad (3)$$

*2.2. Encryption Flow.* Our algorithm calls logistic mapping repeatedly:

$$x_{n+1} = rx_n(1 - x_n), \quad (4)$$

where  $r \in (0, 4]$  is a control parameter. If  $3.5699456 \leq r \leq 4$ , the logistic mapping will be chaotic; as  $r$  gradually approaches 4, the mapping becomes more and more chaotic and generates a chaotic sequence  $x_n$  of a better quality.

Taking an  $M \times M$  plaintext image  $P$  for example, this paper designs a novel image encryption algorithm. There are three steps of the algorithm: image segmentation, block scrambling, and symmetric diffusion. After scrambling and diffusion, the plaintext image  $P$  is improved into a highly secure encrypted image.

## 3. Encryption Algorithm

Like most encryption strategies, our encryption strategy consists of two steps: scrambling and diffusion.

*3.1. Bidirectional Flipping.* Image scrambling aims to change the position of image pixels. The specific process of scrambling through block-based triangular transform is as follows.

Firstly, the original image is segmented into  $N \times N$  blocks, each of which is subjected to triangular transform. The segmented image matrix consumes less resources in the process of computing encryption and can be further scrambled. Suppose the original image is of the size  $256 \times 256$  and is broken down into  $8 \times 8$  blocks. Then, the scrambling can be realized in the following steps:

*Step 1.* The hash function is applied on the plaintext image to generate a hash array. The relevant values are extracted from the array for initialization, producing the initial values and control parameters of the chaotic system. Then, a pseudo-random sequence is generated through the logistic chaotic system and is taken as the initial values of the Hopfield chaotic neural network. The optimal random sequence is thereby obtained.

*Step 2.* After segmentation, the image matrix is scrambled with the random sequence obtained by Hopfield chaotic neural network.

*Step 3.* The random sequence is numerically calculated. The rotation direction and angle of the blocks on the first layer of the image matrix are solved through remainder operation, with  $90^\circ$  as a unit. On this basis, the scrambling model is determined for the entire matrix. The calculation formulas are as follows:

$$\begin{aligned} Z(i) &= \text{floor}[(z(i) \times 10^n) \bmod 256], \\ H(i) &= Z(i) \bmod M. \end{aligned} \quad (5)$$

*Step 4.* Each image block is transformed into a matrix. The matrix of each block is rotated clockwise or counter-clockwise. As required by the algorithm, the adjacent layers are rotated in opposite directions.

*Step 5.* The scrambled block matrices are merged to a matrix as large as the original image matrix. This is the final result of image scrambling.

*3.2. Image Diffusion.* Image diffusion mainly segments the original image matrix along the diagonal. The specific diffusion process is as follows:

*Step 1.* The initial state  $x_2$  and control parameter  $r_2$  of the logistic mapping are calculated as described in Section 2.1.

*Step 2.* Logistic mapping is implemented iteratively 200 times, producing chaotic sequences A1–A3. These sequences are imported to Hopfield chaotic neural network as initial parameters and converted into a diffusion key flow, forming a key matrix.

*Step 3.* The key matrix and scrambled image CC1 are segmented along the same direction. Suppose the matrix is of the size  $8 \times 8$ . The diagonal segmentation model is illustrated in Figure 1.

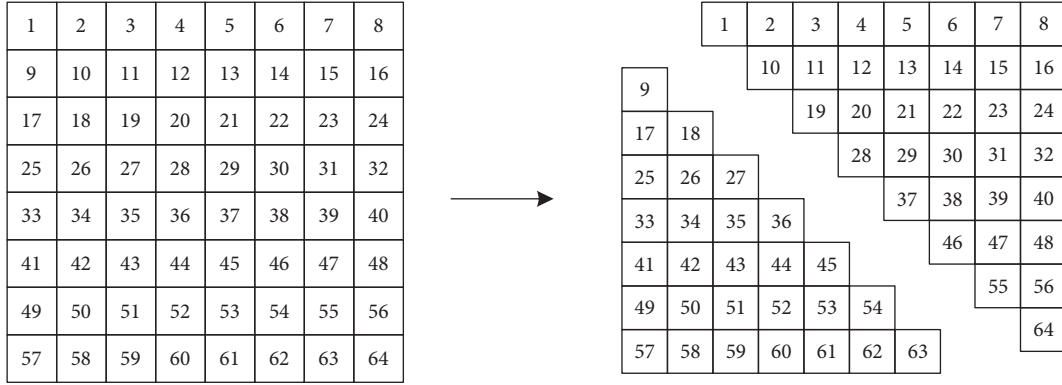

FIGURE 1: Diagonal segmentation model.

*Step 4.* After the diagonal segmentation model is determined, the diffusion is performed by (see Figure 2)

$$\begin{cases} W_T'(i, j) = W_T(i, j) \oplus Q_K(i, j) \\ B_T'(i, j) = B_T(i, j) \oplus W_T'(i, j) \end{cases} \quad (6)$$

*Step 5.* The diffusion image is obtained through the diffusion operation, and the final encrypted image  $C$  is outputted.

The decryption is the inverse process of encryption.

#### 4. Simulation Results

To verify its effectiveness, our encryption algorithm was simulated on multiple images, using the simulation software GNU Octave. Through an experiment, the initial values of logistic mapping were determined as  $x_1(0) = 0.8761$  and  $x_2(0) = 0.7323$ ; the control parameters of logistic mapping were finalized as  $r_1 = 3.9695$  and  $r_2 = 3.8925$ ; the total number of iterations (TNI) was set to 200; different hash arrays  $H$  were generated from different plaintext images.

Our simulation uses the gray image of Lena ( $256 \times 256$ ) and the color image of peppers. For the color image, firstly, the gray level of the color image is transformed, and the layer is divided into three different gray levels: R, G, and B, which are encrypted in the corresponding encryption process. Figure 3 shows the generated encrypted images and decrypted images.

#### 5. Safety Analysis

An ideal encryption algorithm should be able to resist various attacks, such as violent attack, statistical attack, and

differential attack, and chosen-plaintext attack. To verify the safety of our algorithm, this paper theoretically analyzes and numerically simulates the algorithm in five aspects and compares it with the state-of-the-art chaotic theory-based algorithms [25–30].

**5.1. Histogram Analysis.** The ability of an encryption algorithm to resist statistical attack can be directly measured by the histogram of the ciphertext image, which describes the pixel distribution of the image. The statistical attack can easily steal some information from an image with uneven pixel distribution. Image itself is a form of data information, and image itself can be used as a carrier or directly as a kind of information transmission. The pixel distribution of the original image is distributed according to the content level of the image, so important content can be stolen and obstructed through statistical analysis attacks.

It can be known that the pixels were not evenly distributed on the plaintext histograms but evenly distributed on the ciphertext histograms. Therefore, the ciphertext images obtained by our encryption algorithm can resist the statistical attack.

**5.2. Correlation Analysis.** A high correlation between adjacent pixels indicates that the plaintext image is prone to the statistical attack. Thus, it is necessary for the encryption algorithm to reduce the correlation between adjacent pixels. 10,000 pixels were randomly selected from the plaintext and ciphertext images of the gray image of Lena, respectively. Then, the correlations between adjacent pixels in the horizontal, vertical, and diagonal directions were calculated by

$$\begin{aligned} r_{xy} &= \frac{\text{cov}(x, y)}{\sqrt{D(x)}\sqrt{D(y)}}, \quad \text{cov}(x, y) = \frac{1}{N} \sum_{i=1}^N (x_i - E(x))(y_i - E(y)), \\ D(x) &= \frac{1}{N} \sum_{i=1}^N (x_i - E(x))^2, \quad E(x) = \frac{1}{N} \sum_{i=1}^N x_i. \end{aligned} \quad (7)$$

FIGURE 2: Schematic diagram of symmetrical segmentation.

FIGURE 3: Simulation results. (a) Original image of Lena. (b) Encrypted image of Lena. (c) Decrypted image of Lena. (d) Original image of peppers. (e) Encrypted image of peppers. (f) Decrypted image of peppers.

In addition, the correlations between adjacent pixels in the ciphertext image of Lena obtained by our algorithm were compared with those in the ciphertext image of Lena obtained by other algorithms (Table 1).

**5.3. Information Entropy Analysis.** Information entropy is an important indicator of the randomness of information:

$$H(s) = \sum_{i=0}^{2^n-1} p(m_i) \log_2 \frac{1}{p(m_i)}, \quad (8)$$

where  $p(s_i)$  is the probability of  $s_i$ .

In theory, the probability of information leak decreases as the information entropy approaches 8. Table 2 compares the information entropy of the cyphertexts of two test images obtained by our algorithm with that obtained by three other algorithms [25–27]. On both test images, the information entropy was approximately 8 in the ciphertexts obtained by our algorithm. The information entropy obtained by our algorithm was closer to 8 than that of any other algorithm. Therefore, the ciphertext images obtained by our algorithm are unlikely to suffer from information leak and are robust against the statistical attack.

**5.4. Differential Attack.** Differential attack is a kind of chosen-plaintext attack. During the attack, the attacker makes minor modifications to the plaintext image, encrypts the modified image and the original image separately, and compares the two encrypted images to find the correlations between plaintext and ciphertext images. The differential attack is commonly evaluated by the number of pixel change rate (NPCR) and the unified average changing intensity (UACI):

$$\text{NPCR} = \frac{1}{W \times H} \sum_{i=1}^W \sum_{j=1}^H D(i, j) \times 100\%, \quad (9)$$

$$\text{UACI} = \frac{1}{W \times H} \left( \sum_{i=1}^W \sum_{j=1}^H \frac{|c_1(i, j) - c_2(i, j)|}{255} \right) \times 100\%,$$

where  $W$  and  $H$  are image width and height, respectively;  $c_1$  is the original plaintext image; and  $c_2$  is the plaintext image derived from  $c_1$  by changing 1 bit of pixel value. If  $c_1(i, j) \neq c_2(i, j)$ , then  $D(i, j) = 1$ ; otherwise,  $D(i, j) = 0$ .

Theoretically, the result is good if NPCR and UACI approach 99.6093% and 33.4635%, respectively. Without changing the keys, our encryption algorithm was adopted to encrypt  $c_1$  and  $c_2$ , respectively. Next, the NPCR and UACI were calculated for the two resulting ciphertext images.

(c) Encrypted image of Lena with noise on the level of 0.1. (d) Decrypted image of Lena with noise on the level of 0.01. (e) Decrypted image of Lena with noise on the level of 0.05. (f) Decrypted image of Lena with noise on the level of 0.1.

Tables 3 and 4 compare the NPCR and UACI of the ciphertexts obtained by our algorithm with those of the ciphertexts obtained by three other algorithms. Compared with those of other algorithms, the NPCR and UACI of our algorithm were mostly approximately 99.6093% and 33.4635%, respectively.

**5.5. Robustness Analysis.** Robustness is an important indicator of the anti-disturbance ability of a cryptosystem. Robustness analysis means that the decryption algorithm can still decrypt the content of the image even when the image is disturbed by other information and means, and the corresponding information can be obtained through the decrypted image, so as to prove the robustness of the algorithm. The robustness of our algorithm was tested by noise attack and denial-of-service (DoS) attack. Noise interference is an important issue in actual communication. Common noises include Gaussian noise, salt-and-pepper

noise, etc. The salt-and-pepper noise stands out for its significant impact on ciphertext images. Therefore, this paper mainly tests the influence of the addition of salt-and-pepper noise to the plaintext image over our algorithm performance. Without changing the keys, different levels of salt-and-pepper noises were added to the plaintext image of Lena, and the noisy image was encrypted and decrypted by our algorithm. Figure 4 shows the encrypted and decrypted images of the plaintext image of Lena with salt-and-pepper noise on the level of 0.01, 0.05, and 0.1, respectively. Even when the noise level was 0.1, the plaintext image could be distinguished in the image decrypted by our algorithm, evidencing the strong resistance of our algorithm to noise attack.

The robustness of our algorithm was also tested against the DoS attack. Firstly, different portions of the information on the ciphertext image of Lena were blocked and then decrypted by our algorithm. Obviously, the quality of the decrypted image is negatively correlated with the amount of

FIGURE 5: DoS attack test results. (a) Plaintext image of Lena with 6.25% of information being blocked. (b) Plaintext image of Lena with 25.44% of information being blocked. (c) Plaintext image of Lena with 40.20% of information being blocked. (d) Plaintext image of Lena with 87.89% of information being blocked. (e) Decrypted image of Lena with 6.25% of information being blocked. (f) Decrypted image of Lena with 25.44% of information being blocked. (g) Decrypted image of Lena with 40.20% of information being blocked. (h) Decrypted image of Lena with 87.89% of information being blocked.

information being blocked. Figure 5 presents the decrypted images of the ciphertext image of Lena with 6.25%, 25.44%, 40.20%, and 87.89% of information being blocked. It can be inferred that the main information of the plaintext image of Lena could still be recognized from the decrypted images. Therefore, our algorithm can effectively withstand the DoS attack and boasts strong robustness.

## 6. Conclusions

This paper mainly designs a chaotic image encryption algorithm based on Hopfield neural network and bidirectional flipping, a scrambling strategy. Firstly, the plaintext image was segmented into multiple blocks, and each block was scrambled. Then, SHA-512 hash algorithm was combined with the plaintext image to generate a hash array. On this basis, the initial values and control parameters were determined for the initialization of the chaotic mapping, and the control parameters were configured for scrambling and diffusion. Compared with other image encryption algorithms, our algorithm innovatively applies Hopfield neural network to encrypt images and adopts brand-new scrambling and diffusion models. Through simulation and theoretical analysis, it was confirmed that our algorithm is robust and effective in resisting statistical attack, differential attack, noise attack, and DoS attack.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Mapping knowledge domain (MKD) is an important application in bibliometrics, which is a method of visually presenting and explaining newly developed interdisciplinary scientific fields using data mining, information analysis, scientific measurement, and graphic rendering. This study combines applied mathematics, visual analysis technology, information science, and scientometrics to systematically analyze the development status, research distribution, and future trend of the heterogeneous traffic flow by using the MKD software tools VOSviewer and CiteSpace. Based on the MKD and Bibliometrics approaches, 4709 articles have been studied, which were published by Science Citation Index Expanded (SCIE) and Social Sciences Citation Index (SSCI) from 2004 to 2021 in the field of heterogeneous traffic flows. Firstly, this paper presents the annual numbers of articles, origin countries, main research organizations, and groups as well as the source journals on heterogeneous traffic flow studies. Then, cocitation analysis is used to divide heterogeneous traffic flow into three main research directions, which include “heterogeneous traffic flow model,” “traffic flow capacity analysis,” and “traffic flow stability analysis.” The keyword cooccurrence analysis is applied to identify five dominant clusters: “modeling and optimization methods,” “traffic flow characteristics analysis,” “driving behavior analysis,” “simulation experiment,” and “policies and barriers.” Finally, burst keywords were studied according to the publication date to present more clearly the change of research focus and direction over time.

## 1. Introduce

As the production and ownership of automobiles increase year by year, vehicles not only provide convenience and comfort to people but also bring many negative impacts, such as traffic safety, congestion, and air pollution [1, 2]. Vehicle crashes result in about 63,194 fatalities in China, and direct property losses reached 11.18672 million yuan in 2018 [3]. In terms of energy consumption, China’s road transportation industry consumes 60.1% of the nation’s oil and produces 14% of greenhouse gases [4], while America’s transportation industry consumes 70% of oil and 33.6% of greenhouse gases [5]. In the face of increasingly severe security, energy, and environmental problems, autonomous driving technology, as an important component of the intelligent transportation system, has incomparable

advantages in improving travel efficiency, alleviating traffic congestion, and reducing gasoline consumption and other aspects and is an important way to achieve green and efficient development of the automobile industry.

Like many new technologies, although some autonomous driving technologies have been implemented, most of them are still in the experimental and conceptual stage, and the industrialization of autonomous driving vehicles still needs a long process. Boston Consulting Group predicts that “it will take 15–20 years for the global market share of autonomous vehicles to reach 25%,” and as autonomous vehicles are expected to hit the market in 2021, this means that autonomous vehicles will account for 25% of the global market in 2035–2040 [6]. Therefore, in the process of the rapid development of the autonomous vehicle industry, there will be a transitional stage of the heterogeneous

transportation system composed of artificial and autonomous vehicles [7].

Heterogeneous traffic flow is an extremely complex problem in the field of traffic flow, which involves the combination of traditional traffic flow research and autonomous driving technology. Although some article reviews have studied the related content of heterogeneous traffic flow, previous article reviews have adopted qualitative rather than quantitative methods to conduct research, which largely relies on the author's experience and subjective judgment in this field, requiring the author to accumulate, summarize, and refine in this field for a long time. In addition, the previous review article lacks visual analysis of all heterogeneous traffic flow studies, so it is difficult to reveal the panorama of heterogeneous traffic flow research, and it is difficult to describe the cocitation relationship and keyword evolution law between articles [8].

In this paper, the bibliometrics method was used to review the article. The WOS platform was used to search 4709 related articles published in the field of heterogeneous traffic flow in the recent 17 years (2004–2021). The following tasks were completed: which countries/regions are the most important research results; what is the collaboration between the main authors in the research area; what are the core publications in the research area; what are the most influential research results in the field of heterogeneous traffic flow research; which are the most active research field of heterogeneous traffic flow and its present situation and deficiency? Research and review related aspects from a new perspective clarify the development context of the heterogeneous traffic flow field, identify key topics and research progress in domestic and foreign research, find the shortcomings of current research, and provide reference and comparison for researchers.

The rest of the paper is organized as follows: Section 2 introduces the data sources of the sample literature as well as the analytical tools and methods; Section 3 carries out quantitative statistical analysis from aspects of publication year, country, institution, journal, and keywords through sorting out 4709 high-level sample literature related to heterogeneous traffic flow; Section 4 draws conclusions and provides a brief discussion of the future research plan.

## 2. Data Sources and Analysis Methods

**2.1. Data Source.** This article aims to conduct a quantitative and visualized analysis of the representative works related to heterogeneous traffic flow through MKD methods. Web of Science (WOS) is an online subscription-based science citation index service that provides access to multiple databases containing more than 148 million records (journals, books, and conference proceedings) dating back to the beginning of the 20th century [9]. Therefore, the SCIE and SSCI citation index database in the WOS Core Collection were retrieved as the source in this study. To obtain the maximum number of relevant documents related to simulated driving, we collected and stored data for the defined search terms using the “Topic” search in Web of Science Core Collection. The keywords used for the initial data

collection included “heterogeneous traffic flow\*” OR “Mixed traffic flow\*” OR (“Penetration rate\*”) AND (“connected and autonomous vehicle\*” OR “intelligent connected vehicle\*” OR “connected vehicle\*” OR “autonomous vehicle\*” OR “adaptive cruise control” OR “cooperative adaptive cruise control”), where “\*” represents fuzzy search.

The excluded categories were veterinary medicine, clinical medicine, food science, engineering, etc., with a time span of 1985 to 2021 and retrieval date of January 2, 2021, 754 English journal articles, conference papers, research reviews, and conference abstractions were obtained. To ensure the completeness and accuracy of the article collection, this paper added the cited articles of 754 articles obtained from article retrieval and removed the remaining 3955 articles after self-cited articles. Finally, a total of 4709 articles were obtained for article analysis, involving 7046 authors and 13,224 keywords. To cover as much additional information as possible, the “full records and references” of all articles are exported in “TXT” format for bibliometrics analysis.

**2.2. Analysis Method.** Bibliometrics is an interdisciplinary science that uses mathematical and statistical methods to quantitatively analyze relevant articles, mainly studying the quantitative relationship of the article (various publications, in particular, journal papers and citations are in the majority) [10], journal information sources (the situation of journals in which article is published) [11], author relationship (the cooperative relationship between the author, the organization, or the group) [12], and keywords (the core words that repeatedly appear in the article) [13].

In bibliometrics analysis, the mapping knowledge domain (MKD) is a method to visually present and explain the newly developed interdisciplinary scientific field using data mining, information analysis, scientific measurement, and graph rendering, aiming at simplifying the information acquisition process in the research field and clarifying the knowledge structure [14]. The MKD has dual properties and characteristics of “graph” and “spectrum,” which means that it is not only a visual knowledge map but also a serialized knowledge map. The MKD can show the development process and structural relations of scientific knowledge as well as the implied complex relations, including network, structure, interaction, intersection, evolution, or derivation between knowledge units or knowledge clusters [15]; understanding these complex knowledge relationships can produce new knowledge.

The mapping (or creation) of MKD includes article cocitation analysis, keyword cooccurrence analysis, and burst detection analysis, as described as follows:

- (a) Document cocitation analysis: a document cocitation is a new form of article coupling, which refers to the frequency of two articles being cited simultaneously [16]. Document cocitation analysis refers to the statistics of the number of two documents simultaneously cited by one or more documents, to conduct network analysis and cluster analysis on the

cited documents, to analyze the knowledge base of the specific subject represented by these documents [17]. The knowledge base of this field is constructed by quoting articles, and the research frontier of a certain field is formed by analyzing the knowledge base.

- (b) Keywords cooccurrence analysis: official academic publications are generally accompanied by keywords, which not only reflect the core content of the research results and condense the author's academic views but also provide an important way of retrieval. Keywords cooccurrence analysis is to count the number of occurrences of a group of keywords in the same article in pairs [17]. Based on this, network analysis and cluster analysis are conducted for these words, to reflect the affinity relationship between these words and the structural changes of the subject they represent [18]. Therefore, the more frequently a keyword appears, the more relevant research results, and the stronger the concentration of research content [19].
- (c) Burst detection analysis: the burst detection analysis considers the change of keyword frequency and determines the keywords with the characteristics of burst growth in a certain period in a certain research field, which can be used to study the development trend of a certain topic. It is different from the burst detection analysis based on a threshold value. Although the frequency of each keyword may be relatively low, the burst keyword can be found according to the change of keyword frequency, so the latest research trends can be predicted by such keywords.

**2.3. Analysis Tools.** In this study, the method of MKD in bibliometrics was selected to analyze the article according to its attributes and characteristics, and the knowledge was visualized. CiteSpace and VOSviewer were used in the study. CiteSpace was developed by Professor Chen Chaomei, chair professor of Changjiang Scholars in Dalian University of Technology [20]. The software focuses on the potential knowledge contained in scientific analysis. At first, it specifically analyzes the cocitation of articles and excavates the knowledge clustering and distribution in citation space. In subsequent updates, cooccurrence analysis between other knowledge units will also be provided, such as author, institution, and country or region collaboration. VOSviewer software was developed by Van Eck and Waltman of Leiden University in the Netherlands. Visualization of Similarities (VOS) technology is used to perform a visualization analysis of article knowledge units. Cooccurrence matrix is used to generate a knowledge map. Its core principles include the construction of similarity matrix and the VOS layout method [21].

**2.4. Construction of MKD.** By normalizing the cooccurrence matrix, the similarity matrix was obtained by correcting the differences in the total occurrence times or common

frequency of elements in the cooccurrence matrix (i.e., author, institution, country/region, keywords, etc.). VOSviewer uses association strength, also known as proximity index, to measure the similarity between pairs of elements in the cooccurrence matrix. The similarity  $S_{ij}$  between two items  $i$  and  $j$  is calculated as

$$S_{ij} = \frac{c_{ij}}{w_i w_j}, \quad (1)$$

where  $S_{ij}$  denotes the similarity between the elements  $i$  and  $j$ ,  $c_{ij}$  denotes the number of times the element  $i$  and the element  $j$  cooccur, and  $w_i$  and  $w_j$  denote the total number of occurrences of the element  $i$  and the element  $j$ , respectively. It can be seen that the normalized value is between 0 and 1, where the larger the value, the higher the similarity between elements, and the smaller the value, the smaller the similarity between elements.

**2.5. Layout Method.** The layout method adopted in this paper is to reflect the similarity between any pair of elements  $i$  and  $j$  by the spatial distance  $s_{ij}$  to determine the position of elements in two-dimensional space. The closer the distance between elements, the higher the similarity [22]. To make the clustering effect more obvious, the main idea of VOS is to minimize the sum of the weighted Euclidean distances of all objects in each cluster; the formula is as follows [21]:

$$D(x_1, \dots, x_n) = \sum_{i < j} s_{ij} x_i - x_j^2, \quad (2)$$

where  $n$  is the number of elements to be laid out,  $\|\bullet\|$  denotes the Euclidean norm, and vector  $x_i = (x_{i1}, x_{i2})$  denotes the location of item  $i$  in a two-dimensional map. To avoid all elements being in the same position, the objective function is minimized under the following constraints:

$$\frac{2}{n(n-1)} \sum_{i < j} x_i - x_j = 1. \quad (3)$$

### 3. Article Statistical Analysis

**3.1. Annual Distribution Statistics of the Article.** The annual distribution of articles refers to the difference in the distribution of the number of articles in the same time zone, which can reflect the development process of people, institutions, or subject research and divide the active trend of subject research. The change in the number of academic papers on a subject is an important indicator of the development trend of the research field, and it is also a reflection of the change in the scope of subject knowledge. By drawing a graph of the number of documents and conducting multivariate statistical analysis, one can understand the research level and future development trend of a certain field.

To better explore the relevant characteristics and conditions in the field of heterogeneous traffic flow in a period, this paper considers the number of documents in the field of heterogeneous traffic flow, which are divided into three

stages based on the growth of the article during the period, namely, “initial stage (2004–2009),” “preliminary development stage (2010–2015),” and “rapid development stage (2016–2020).” On the one hand, segmenting the field according to the same time can better compare and analyze the growth of articles and the characteristics of research trends in each period. On the other hand, because the research on heterogeneous traffic flow started late and the period is not long, it is relatively reasonable to set 5 years as an academic research cycle.

According to the search results, the earliest research article on heterogeneous traffic flow was published in 2004 and lasted until 2021. It already contains 4703 related documents. The annual distribution statistics are shown in Figure 1. It is worth noting that due to 2020 the data is still being updated, so the data in the statistics is small.

**Initial stage (2004–2009):** from the first article published in 2004 to 2008, there were few related research results in this field, and only 73 papers (2009) were published each year, which means that there is research on qualitative traffic flow has just started, and a complete document system has not yet been formed.

**Primary development stage (2010–2015):** as countries pay more and more attention to road safety, autonomous driving has set off a research boom and has begun to enter the primary development stage. The number of relevant documents at this stage has increased significantly, with an average increase of 33 documents per year. It can be considered that the field of heterogeneous traffic flow research was initially formed during this period.

**Rapid development stage (2016–2020):** after the accumulation of knowledge in the initial stage and the primary development stage, the number of relevant documents in this stage has grown rapidly. This shows that the research enthusiasm in the field of heterogeneous traffic flow is continuously increasing and has entered a stage of rapid development.

**3.2. Country and Regional Statistics.** For national and regional factors, this article presents four indicators to analyze the distribution area and situation of the documents, namely, the number of documents (articles), the percentage of documents in the total number of documents, the total number of citations of documents (times), and the average single document. The number of citations is shown in Table 1. The use of these indicators mainly considers two aspects: on the one hand, the number of documents in a country can reflect the research enthusiasm of researchers in each country in the field; on the other hand, the total number of citations and the average number of citations per article can be to a certain extent. This indicates the quality of the article of national researchers, reflecting the depth of research in this field by researchers from various countries.

According to the retrieved results, the article on heterogeneous traffic flow mainly comes from 88 countries (or regions). Table 1 lists the top 10 countries in the field of heterogeneous traffic flow research from 2004 to the present. Japanese science historian Yuasa (1962) defined a country

with more than 25% of the world’s major scientific achievements as the center of scientific activity. According to the data in Table 1, China ranks first with 2087 articles, accounting for 44.28% of the total number of articles. The average number of citations per article is 8.27, followed by the United States (1139) and India (342). The center of scientific activity in the field of heterogeneous traffic flow research is as follows. Four Asian countries (China, India, Japan, and South Korea) among the top ten countries in the number of articles indicate that Asian countries have performed well in research on heterogeneous traffic flow. European countries have excellent performance in the average number of citations per article, such as Germany (average number of citations per article 15.49), the United Kingdom (average number of citations per article 14.61), and the Netherlands (average number of citations per article 13.57), which shows that the article published in these countries has been highly recognized by researchers.

In VOSviewer, citation analysis is used to generate a scientific knowledge map of the country in the field of heterogeneous traffic flow. This article uses VOSviewer software to analyze the collected data and make a density view based on the distribution of national documents. The density view can visually display the situation of the country/region in the density dimension. Each label in the figure represents a country, and the label is the center point to form a region. The size and color of the region depend on the country/region represented by the label the number of published documents, the larger the number, the brighter the color, and the smaller the number, the darker the color. The location of the tag depends on the number of items near the tag and their importance. The density view can help understand the overall structure of the map and draw attention to the most important areas of the map.

This article sets the display conditions for countries/regions with five or more related article achievements, a total of 60 countries/regions, as shown in Figure 2. The density view can see the overall structure of the distribution of national or regional documents. In the figure, China and the United States are in the center of the figure, indicating that China and the United States play an important role in the field of heterogeneous traffic flow.

**3.3. Analysis of Main Research Institutions.** By analyzing the cooperation relationship between research institutions, information about the most outstanding organizations and groups in a certain field in the discipline can be determined. To analyze the cooperative relationship between the research institutions related to the article, this paper uses VOSviewer to construct a cooperation network between major research institutions to analyze the participating institutions of heterogeneous traffic flow research, as shown in Figure 3.

In the interinstitutional cooperation network diagram, the label is the name of the research institution, the size of the node indicates the number of standardized documents, and the connection indicates the cooperative relationship between the two connected research institutions. The closer the cooperation, the closer the node distance, the wider the

FIGURE 1: Quantitative distribution of published articles in heterogeneous traffic flow studies, 2004–2020.

TABLE 1: The top ten countries in the number of articles in the heterogeneous traffic flow research field.

Rank	Country/territories	Quantity	Percentage	Total cited times	The average number of citations per article
1	China	2087	44.28	17251	8.27
2	USA	1139	24.17	11518	10.11
3	India	342	7.26	2894	8.46
4	Germany	206	4.37	3190	15.49
5	England	187	3.97	2732	14.61
6	Australia	167	3.54	1906	11.41
7	Netherlands	152	3.23	2063	13.57
8	Canada	139	2.95	1283	9.23
9	Japan	131	2.78	1122	8.56
10	South Korea	121	2.57	720	5.95

FIGURE 2: Density distribution of heterogeneous traffic flow in major countries.

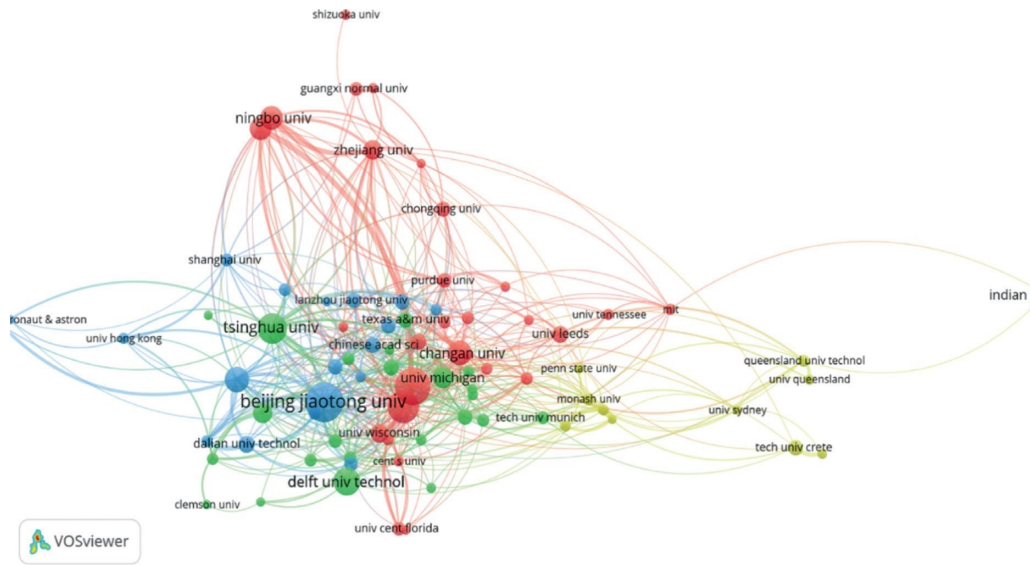

FIGURE 3: Collaborative networks among major research institutions.

scope of cooperation, the more connections. Figure 3 shows that Beijing Jiao tong University is at the center of the gathering point, indicating that Beijing Jiao tong University and other research institutions have established close cooperation in the field of heterogeneous traffic flow.

The number of published documents of research institutions is also one of the important indicators to measure the contributions made by research institutions in the field. The article in this field comes from a total of 2512 organizations. Table 2 lists the top 10 organizations with the largest number of published articles. The research strength of a university is often an indicator of the national scientific research and innovation ability. Table 2 shows that a total of 9 universities contributed 1173 papers, accounting for 24.89% of the total number of heterogeneous traffic flow publications. Among them, Chinese universities and research institutes are heterogeneous traffic. The main contributors to stream research are as follows: these organizations have published 1059 papers, accounting for 22.47% of the total number of papers. Among Chinese universities, Beijing Jiaotong University ranked first in the number of publications of 213 articles, with an average of 161.85 citations per article, indicating that Beijing Jiaotong University is in a leading position in the field of heterogeneous traffic flow research. Southeast University (187 articles) and Tongji University (154 articles) followed closely. Among the 2512 organizations, only 87 organizations published 20 papers or more, accounting for 3.46% of the total. This result shows that the published documents are concentrated in a few organizations.

**3.4. Coauthor Analysis of the Main Research Group.** Counting the number of articles published by authors on the topic and comparing and analyzing them can understand the main authors and core author groups in the field and can further establish their important role and influence in related

fields by understanding the author's research progress and by paying attention to them. The research direction and focus, to understand its leading and leading role in the development of the whole discipline, is of great significance for further understanding the current situation and future development of special research. Because the research in the field of heterogeneous traffic flow is highly interdisciplinary, researchers come from different fields such as traffic engineering, traffic planning, mathematics, psychology, computer science, medicine, and statistics, and cooperation can achieve complementary advantages. The creation and analysis of the knowledge graph of the coauthor network of the article can provide valuable information for research institutions to develop cooperation groups and seek cooperation opportunities for individual researchers and for publishers to form editorial teams (publishing books or special issues in journals). In VOSviewer, use coauthor analysis to generate a knowledge domain map of the coauthors of the main research group.

In the coauthor relationship diagram of major research groups, the label is the abbreviation of the author's name, the node size represents the number of articles published by the author after standardization, and the line represents the cooperative relationship between the two authors connected. The closer the cooperation, the closer the node distance, the wider the scope of cooperation, and the more links. According to VOSviewer's calculations, there are 7046 authors involved in the heterogeneous traffic flow field. To clearly show the cooperative relationship between authors, the minimum number of published papers of authors is set as 5, the minimum number of citations is set as 100, and a total of 224 authors are displayed at last. Figure 4 reflects the visualization of authors' cooperative relationship network in the heterogeneous traffic flow field, which shows a relatively large number of authors' achievements with the close cooperative relationships. The results show that the

TABLE 2: Organization of the top 10 research achievements in heterogeneous traffic flow from 2004 to 2021.

Rank	Organization	Link strength	Quantity	Percentage	Cited times	The average number of citations per article
1	Beijing Jiaotong University	125	213	4.52	2276	161.85
2	Southeast University	129	187	3.97	1116	143.58
3	Tongji University	106	154	3.27	852	142.86
4	Tsinghua University	86	133	2.82	1200	147.99
5	Delft University technology	24	120	2.55	1874	192.28
6	Beihang University	80	100	2.12	1803	169.31
7	Changan University	52	93	1.97	456	86.69
8	Ningbo University	103	92	1.95	1013	128.08
9	Jiangsu Provincial Collaborative Innovation Center modern urban	109	87	1.85	892	110.16
10	Indian Institute of Technology	4	81	1.72	1106	66.43

strengthening of cooperative relationships between authors can improve research efficiency and promote the development of heterogeneous traffic flow fields.

**3.5. Source Journal Analysis.** The source journal is an important information carrier for the dissemination and inheritance of scientific achievements. The analysis of journals in the academic field will determine the distribution of core journals in the field. According to the retrieved results, 4709 articles were published in 1095 journals, covering engineering, psychology, transportation, computer science, and other research fields.

Table 3 lists the top ten journals with the number of publications of heterogeneous traffic flow. "Transportation research part c-emerging technologies" publishes the largest number of documents in the field of heterogeneous traffic flow, up to 283 articles, with a total of 6129 citations. The article has been cited 21.66 times, with an impact factor of 6.077. The journal mainly deals with the development, application, and impact of transportation systems and emerging technologies, especially the impact of emerging technologies on the performance of transportation systems in terms of monitoring, efficiency, safety, and reliability. "Physical a-statistical mechanics and its applications" has the second largest number of publications, with a total of 265 articles and a total of 4485 citations, with an average of 16.92 citations per article. The journal's impact factor is 2.924. "Transportation Research Record" ranked third in the number of articles published, with a total of 235 articles, with a total of 1754 citations, with an average of 7.46 citations per article.

**3.6. Cocitation Analysis of Documents.** The document cocitation analysis was proposed by Henry Small in 1973. Its main principle is to measure the similarity between the documents by the number of times two documents are cited together; that is, if two documents are cited by the third document at the same time, the first two documents constitute a "cocitation" relationship, and their cocitation relationship increases with the increase in the number of citations. Document cocitation analysis is often used to explore the internal connections of scientific documents and

describe the dynamic structure of scientific development. Document cocitation network shows the spatial location of the most cited results in the research field in the form of graphs.

This section screens all the documents with the minimum number of citations of 40. A total of 149 documents meeting the threshold condition are extracted from 4709 documents. The visualization results of the document cocitation view are shown in Figure 5. The document cocited knowledge graph shows the scientific knowledge base and research frontiers. The size of the node in the graph indicates the total frequency of a document being cited. The larger the node, the higher the cited frequency and the greater the influence of the document; the color of the node indicates the document. Belonging to the cluster, the documents of the same cluster have greater similarity in the research topic. As shown in Figure 5, the entire knowledge network map is divided into three color-coded clusters using the default clustering approach:

- (1) Cluster 1 (Red): traffic capacity: in this cluster, the classic article with the largest density is "Enhanced Intelligent Driver Model to Access the Impact of Driving Strategies on Traffic Capacity" by Kesting et al. published in philosophical transactions of the royal society A. The number of cocitations is 283 and the total link strength is 24, indicating that this paper plays an important role in the structure of the cocitations network. In this article, Kesting investigates the influence of variable percentages of ACC vehicles on traffic flow characteristics through simulation and proposes a new car-following model that is based on the intelligent driver model (IDM) and inherits its intuitive behavioral parameters: desired velocity, acceleration, comfortable deceleration, and desired minimum time headway. At the same time, he eliminates some unrealistic behavior of the IDM. Simulation results show that sensitivities of the order of 0.3, i.e., 1 percent more ACC vehicles will lead to an increase in the capacities by about 0.3 percent with a suitable strategy. This sensitivity multiplies when considering travel times at actual breakdowns [23].

Another important article is “Impacts of Cooperative Adaptive Cruise Control on Freeway Traffic Flow” by Shladover et al. published in *Transportation Research Record: Journal of the Transportation Research Board*. The number of cocitations is 247 and the total link strength is 11. This study estimates the effect on highway capacity of varying market penetrations of vehicles with adaptive cruise control (ACC) and cooperative adaptive cruise control (CACC). The results showed that the use of ACC was unlikely to change lane capacity significantly [24].

- (2) Cluster 2 (Blue): traffic flow model: in this cluster, the classic article with the largest density is “Short-Term Traffic Forecasting: Where We Are and Where We’re Going” by Vlahogianni et al. published in the *Transportation Research Part C: Emerging Technologies*. The number of cocitations is 418 and the total link strength is 4. In this article, ten challenging but relatively under-studied directions of short-term traffic forecasting models are presented, and the existing challenges are summarized to make recommendations for future work [25].

In this field, we also recommend “A Markov Model for Headway/Spacing Distribution of Road Traffic” and “Three-Phase Traffic Theory and Two-Phase Models with a Fundamental Diagram in the Light of Empirical Stylized Facts” as two important articles according to the ranking.

“A Markov Model for Headway/Spacing Distribution of Road Traffic” by Chen and Li is published in *IEEE Transactions on Intelligent Transportation Systems*. The authors link two research directions of road traffic—the mesoscopic headway distribution model and the microscopic vehicle interaction model—together to account for the empirical headway/spacing distributions. In this model, empirical headway/spacing distributions are viewed as the outcomes of stochastic car-following behaviors and the reflections of the unconscious and inaccurate perceptions of space and/or time intervals that people may have [26].

“Three-Phase Traffic Theory and Two-Phase Models with a Fundamental Diagram in the Light of Empirical Stylized Facts” by Treiber et al. is published in *Transportation Research Part B*. This article compares Kerner’s three-phase traffic theory with the phase diagram approach for traffic models with a fundamental diagram and demonstrates that models created to reproduce three-phase traffic theory create similar spatiotemporal traffic states and associated phase diagrams, no matter whether the parameters imply a fundamental diagram in equilibrium or nonunique flow-density relationships [27].

- (3) Cluster 3 (Green): traffic flow stability analysis: traffic jams are usually related to the instability of traffic flow. Two kinds of traffic flow models can be used for stability analysis: the micro model and the macro

model. In this cluster, “Analytical Studies on the Instabilities of Heterogeneous Intelligent Traffic Flow” by Ngoduy uses microscopic models, particularly the effect of intelligent vehicles on heterogeneous (or multiclass) traffic flow instabilities. The analytical results show that time delay destabilizes traffic flow as found in the article and that the higher intelligent vehicle percentages, the more stable traffic flow with respect to a small perturbation for a given model parameter set [28].

In this field, we also recommend “Analysis on Traffic Stability and Capacity for Mixed Traffic Flow with Platoons of Intelligent Connected Vehicles” and “Longitudinal Emissions Evaluation of Mixed (Cooperative) Adaptive Cruise Control Traffic Flow and Its Relationship with Stability” as two important articles.

“Analysis on Traffic Stability and Capacity for Mixed Traffic Flow with Platoons of Intelligent Connected Vehicles” by Xin Chang and Haijian Li (2020) is published in *Physica A*. In this paper, analytical methods for the stability and the fundamental diagram models of mixed traffic flow are developed, and the results of the sensitivity analysis demonstrated that ICVs can improve the stability of the mixed traffic flow at a critical speed. However, if this critical speed is exceeded, an increase in the number of ICVs may degrade the stability of the mixed traffic flow [29].

“Longitudinal Emissions Evaluation of Mixed (Cooperative) Adaptive Cruise Control Traffic Flow and Its Relationship with Stability” by Yanyan Qin (2020) shows the impacts of the mixed CACC-MDV traffic on fuel consumption and emissions, by taking into consideration partial degenerations from stable CACC vehicles to unstable ACC vehicles. The results show that stability situations of the mixed traffic qualitatively influence the impact trend of CACC MPRs on fuel consumption and emissions [30].

**3.7. Keyword Cooccurrence Analysis.** Keyword cooccurrence analysis is a common research method in bibliometrics. By studying the cooccurrence relationship of cooccurring keywords in a large number of documents, it is used to analyze the link strength between cooccurring keywords. Its usage is to describe the internal relationship and structure of a certain academic field and to reveal the research front of the subject. The research front refers to the conceptual combination of temporary research topics and basic research issues, as well as theoretical trends and new topics that arise or emerge unexpectedly. In VOSviewer, cooccurrence analysis is used to generate a heterogeneous traffic flow research cooccurring keyword network, as shown in Figure 6.

In Figure 6, it can be seen that the frontier topics of heterogeneous traffic flow research form five groups, and the keywords in the same group show greater similarity in the research topics. According to the characteristics and current situation of heterogeneous traffic flow research, the following five categories are analyzed:

TABLE 3: The top ten journals of heterogeneous traffic flow publications.

Rank	Journal	Impact factor	Quantity	Cited times	The average number of citations per article
1	Transportation Research Part C: Emerging Technologies	6.077	283	6129	21.66

FIGURE 4: Coauthor relationships among major research groups.

3.7.1. *Group 1 (Red): Analysis of Modeling and Optimization Methods for Heterogeneous Traffic Flow.* This cluster contains a total of 55 keywords, mainly including model, systems, algorithm, optimization, and framework. The visualization results of the cluster show that keywords such as model, algorithm, and optimization are cooccurring high-frequency words.

From the perspective of research, the traffic flow model can be divided into a macro traffic flow model and a micro traffic flow model [31]. The microscopic traffic flow model processes traffic flow into dispersed particles to reflect the characteristics of traffic flow [32–35]. The macroscopic traffic flow model regards all vehicles on the whole road as a compressible continuous fluid, deduces the relationship among vehicle density  $\rho$ , the average velocity  $V$ , and flow  $Q$ , and thus describes the mathematical model of traffic flow operation law [36–39]. So far, the researchers have developed a variety of traffic models used to study the complex

phenomenon and obtained many important results [40, 41]; however, these traditional traffic flow models did not consider the information interaction between the vehicle and synergy, also lack the research of vehicle heterogeneous factors, and therefore, cannot be directly used to study the heterogeneous traffic flow.

To study the heterogeneity of traffic flow, Tang et al. [42] proposed a new vehicle following model based on the properties of heterogeneous traffic flow and the relationship between micro and macro variables, establishing a new dynamic model for heterogeneous traffic flow. Ngoduy et al. [43] established a new macro traffic flow model based on the aerodynamic method to describe the driving behavior of vehicle queues and analyze the influence of intelligent vehicle permeability. Levin M W et al. [44] developed a vehicle following model for predicting scene capacity and wave speed in combination with driver response time. The research results show that travel time has a linear relationship

FIGURE 5: Cluster density view of document cocitation network.

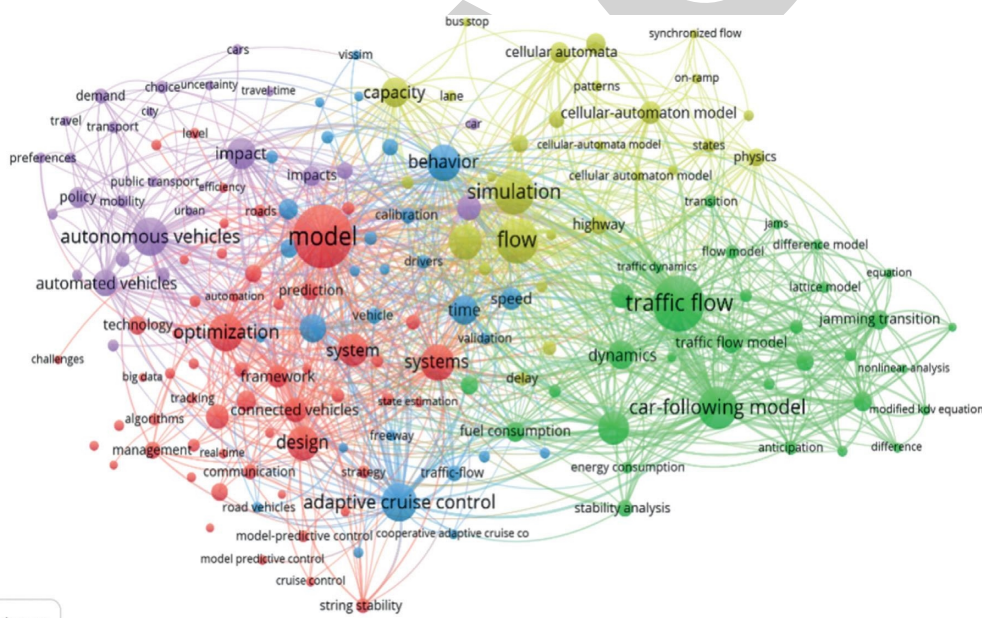

FIGURE 6: Keywords cooccurrence network of intelligent vehicles studies.

with the proportion of autonomous vehicles, and the travel time will be significantly reduced when the penetration rate of autonomous vehicles reaches over 80%.

**3.7.2. Group 2 (Green): Analysis of Macroscopic Traffic Flow Characteristics of Heterogeneous Traffic Flow.** This cluster contains a total of 32 keywords, mainly including traffic flow, stability, waves, fuel consumption, and jamming transition.

In traffic flow research, the impact of autonomous vehicles on traffic flow stability and traffic flow capacity is an important research topic. Many current works have explored the traffic capacity and stability of heterogeneous traffic flow

and intelligent traffic. Kesting et al. [44] proposed an intelligent driver model, that is, automatic real-time detection of traffic conditions based on local information, to adapt to the driving characteristics of ACC.

The results of the test show that at a 25% penetration rate, ACC vehicles can eliminate congestion during specific peak periods of the simulation. Shladover et al. [24] conducted a simulation study on the traffic capacity of single-lane expressways with CACC vehicles mixed with different permeability, and the results showed that the ACC model could not significantly improve the traffic capacity, while the CACC model with medium and high permeability could greatly improve the traffic capacity. Arnaout et al. [45]

studied the influence of permeability on traffic capacity under different traffic demand conditions and found that CACC permeability had a significant impact on traffic capacity when traffic demand was high. At the same time, Arnaout et al. [46] studied the impact of different CACC permeability on traffic efficiency under different traffic demands, and the results showed that CACC permeability had no impact on traffic capacity when traffic demand was low. However, when the traffic demand is high and the permeability exceeds 40%, the permeability has a substantial impact on the increase of traffic capacity.

*3.7.3. Group 3 (Blue): Analysis of Driving Behavior in Heterogeneous Traffic Flow.* There are 29 keywords in this cluster, mainly including behavior, time, adaptive cruise control, safety, risk, and accidents.

When a car is running, the driver needs to control the car based on information provided by the environment, road signs, signals, and instrumentation in the car. Information can be obtained through visual, tactile, and auditory means. Among them, more than 80% of the driver's information is obtained through visual channels, followed by hearing. Driving behavior can be seen as a repetitive message processing model composed of information perception, judgment, and decision-making and actions; that is, judgment and decision-making are the execution of manipulation actions after receiving the perception signal [47]. In the traditional traffic flow field, the analysis of driving behavior generally adopts subjective questionnaire data and objective driving data. Through a reasonable questionnaire, drivers can be divided into various types (such as aggressive, cautious, slow). However, drivers tend to hide their usual aggressive driving behaviors when conducting self-evaluation through the questionnaire, so the collected questionnaire cannot truly describe drivers' driving behaviors. The collected objective driving data of drivers can be used to classify drivers according to clustering analysis or principal component analysis, but during data collection, drivers will feel that they are in a monitoring environment and change their real driving behavior.

In the field of heterogeneous traffic flow, researchers have built different driver models mainly to stimulate and recognize the behavior of human-driven vehicles in heterogeneous traffic flow. These researches are mainly divided into driver behavior models based on control theory and driver behavior models based on machine learning theory. The driver behavior model based on control theory mainly assumes that the driving trajectory is known, studies the driver and the vehicle as a whole, and predicts the vehicle trajectory in the future in real-time according to the historical running state of the vehicle. For example, Song et al. [48] established a "single-lane auto-manual driving mixed traffic flow model considering driving behavior" and a "three-lane auto-manual driving mixed traffic flow model considering driving behavior" based on cellular automata and conducted simulation tests. Zhu et al. [49] used Bando's model and a modified Bando's model to describe human driver behavior and autonomous vehicle, respectively, and

conducted stability analysis on heterogeneous traffic flow. Zheng et al. [50] established a "random model of auto-manual driving mixed traffic flow" based on fully considering the uncertainty of human driving behavior and the interaction between automatic driving and manual driving vehicles. The driver behavior model based on machine learning theory uses the big data of vehicle operation to obtain the characteristic information of the driver and then describes the decision-making process of the driver, to establish the driver behavior model. Wang et al. [51] organized drivers to carry out the following test, analyzed the difference of speed difference cycle in the following process, divided driver types according to driving parameters through cluster analysis, and established an improved IDM model. Michael et al. [44] developed the following model including driver reaction time to study the traffic capacity and backward wave speed of autonomous vehicles under different permeability. Chen et al. [52] used the driver's driving behavior data obtained by the simulation platform to classify the characteristics of the following behavior obtained and solved the problem of operation difference caused by sequence transformation of vehicles in the fleet.

*3.7.4. Group 4 (Yellow): Simulation Experiment Analysis of Heterogeneous Traffic Flow.* There are 28 keywords in this cluster, mainly including simulation, cellular-automaton model, delay, and states.

With the gradual maturity of autonomous driving technology, the heterogeneous traffic flow phenomenon formed by autonomous driving vehicles and manual driving vehicles must exist for a long time. Due to the uncertainty of heterogeneous traffic flow, such as safety, coordination ability, and efficiency, people have raised doubts about the safety of autonomous vehicles. Although the above problems can be verified by establishing a real road test field for real vehicle test, the cost of real vehicle test is too high, there are too few test bases with test qualification, and the test results are susceptible to the influence of the environment and test conditions. The traffic flow simulation test has the characteristics of repeatability, safety, economy, and effectiveness, which can facilitate researchers to carry out tests at lower costs under the same initial conditions.

A simulation model is a mathematical/logical representation of a real-world system, which takes the form of software that is executed experimentally on a digital computer. Common simulation models used in traffic flow include CORSIM, MITSIM, and VISSIM, but most of these models are based on homogeneous traffic conditions and are not suitable for studying the characteristics of heterogeneous traffic flow. Therefore, Vander Werf et al. [53] used Monte Carlo simulation to estimate the impact of vehicle types on lane capacity based on models in the literature and conducted a sensitivity analysis of ACC and CACC vehicle time-interval parameters in simulation tests. Van Arem et al. [54] applied the intelligent vehicle test simulation platform to simulate and analyze the influence of different CACC vehicle ratios on traffic capacity because of the bottleneck section of the expressway with fewer lanes. Talebpour and Mahmassani

[55] applied the ACC vehicle and CACC vehicle following model and conducted numerical simulation experiments to present scatter diagrams of mixed traffic flow concerning density under different traffic demands and different CACC/ACC vehicle ratios. The influence of CACC vehicles and ACC vehicles on-ramp capacity is analyzed. Based on simulation experiments, Lioris [56] studied the impact of the Internet of vehicles' fleet on the capacity of urban road system intersections. Hartmann et al. [57]. studied the influence of CAV on the capacity of the German expressway network through a micro traffic flow simulation experiment. Bujanovic and Lochrane [58] quantitatively analyzed the influence of CAV on the capacity of basic sections of expressways and applied VISSIM simulation software to verify and analyze the proposed model.

*3.7.5. Group 5 (Purple): Policies and Barriers in Heterogeneous Traffic Flow.* There are 26 keywords in this cluster, mainly including policy, impacts, delay, and emissions.

It is widely believed that autonomous driving can provide safer and more comfortable driving and is an important part of urban intelligent transportation systems. In this regard, the United States, Japan, Europe, and other developed countries and regions have increased their research and development and investment in autonomous driving in terms of policies. In particular, the United States has already carried out strategic planning and technical testing of autonomous driving technology as an important part of intelligent transportation systems at the national level.

However, on the other hand, the application of autonomous vehicles may also have adverse effects on the existing traffic system, such as interfering with road traffic, affecting the safety of other vehicles, and other potential threats. Due to the high initial cost of autonomous vehicles, unclear accident liability details, and uncertain privacy issues, the acceptance of autonomous vehicles is not high among the general public. Therefore, many domestic and foreign scholars have a strong interest in the policies and obstacles of autonomous driving vehicles.

Daniel [59] explores the feasible aspects of AVs and discusses their potential impacts on the transportation system. And this paper explores the feasible aspects of AVs and discusses their potential impacts on the transportation system. Another paper "Policy and Society Related Implications of Automated Driving: A Review of Article and Directions for Future Research" by Milonakis is published in the *Journal of Intelligent Transportation Systems*. In this paper, the potential effects of automated driving that are relevant to policy and society are explored, findings discussed in the article about those effects are reviewed, and areas for future research are identified [60].

*3.8. Analysis of Burst Detection: Research Trends of Heterogeneous Traffic Flow.* The burst detection algorithm was first proposed by Kleinberg in 2003. It identifies keywords with high-frequency density characteristics in the article by detecting the density of keyword frequency changes. Burst detection analysis can be used to detect the

frequency of sudden increase of words in topics and keywords and to obtain the start time, end time, and weight of sudden keywords. Through this information, the emergent hot spots and research trends in the field of heterogeneous traffic flow research can be analyzed. CiteSpace regards this kind of mutation information as a way to measure deeper changes. Burst detection in CiteSpace can be used for two types of variables: one is the frequency of words or phrases used in the cited documents, and the other is the frequency of citations obtained from the cited documents. Import the data into the CiteSpace tool and run it for burst detection. The parameters are set as follows:  $\gamma=1.0$ , the number of states = 2.0, and minimum duration = 2. Select the top 20 meaningful keywords with the largest burst weight for visual analysis, as shown in Figure 7.

As shown in Figure 7, "Start year" and "end year" represent the year of burst keyword duration from start to end. Intensity represents the frequency of keyword occurrences. From the point of view of burst intensity, cellular automata, traffic flow, numerical simulation, and other links have high intensity. It can be seen that traditional traffic flow studies focus on using the cellular automata model for modeling and carry out numerical simulation calculation; related articles include spatial-temporal patterns in heterogeneous traffic flow with a variety of driver behavioral characteristics and vehicle parameters. Different from the traditional heterogeneous traffic flow research, heterogeneous traffic flow research in the new period is mostly dependent on artificial intelligence, cloud computing, big data, and other new-generation network technologies represented by the Internet of vehicles. Related articles include Linear Stability Analysis of Heterogeneous Traffic Flow considering Degradations of Connected Automated Vehicles and Reaction Time. Capacity and stability are macro characteristics of heterogeneous traffic flow, which have a great impact on the safety and efficiency of heterogeneous traffic flow. Related articles include Controllability Analysis and Optimal Control of Mixed Traffic Flow with Human-Driven and Autonomous "Vehicles," Stability Analysis, and the Fundamental Diagram for Mixed Connected Automated and Human-driven Vehicles and Analysis on Traffic Stability and Capacity for Mixed Traffic Flow with Platoons of Intelligent Connected Vehicles.

The burst intensity of the dynamic model, car-following model, and adaptive cruise control was 29,108, 55,438, and 3085, respectively. Adaptive cruise control not only has the function of cruise control but also adaptively adjusts the motion state of the vehicle in front according to the motion state of the vehicle, which has a certain influence on the traffic flow research: "Cooperative Adaptive Cruise Control and Exhaust Emission Evaluation Under Heterogeneous Connected Vehicle Network Environment in Urban City," "Cooperative Adaptive Cruise Control and Intelligent Traffic Signal Interaction: A Field Operational Test with Platooning on a Suburban Arterial in Real Traffic," and "Longitudinal Emissions Evaluation of Mixed (Cooperative) Adaptive Cruise Control Traffic Flow and Its Relationship with Stability."

FIGURE 7: Keywords of the top 20 burst weights from 2004 to 2021.

#### 4. Conclusion

This paper uses VOSviewer software to conduct a bibliometric analysis of 4709 documents related to heterogeneous traffic flow, from the annual distribution statistics of the article, national and regional statistics, analysis of major research institutions, analysis of coauthors of major research groups, analysis of source journals, and key. In terms of word and burst detection analysis, the research results in the field of heterogeneous traffic flow in recent years (2004–2021) are analyzed from multiple angles, and the existing article review in this field is supplemented to consolidate the research results in the field of heterogeneous traffic flow. The analysis results show that cocitation analysis divides heterogeneous traffic flow into three main research directions, which include “heterogeneous traffic flow model,” “traffic flow capacity analysis,” and “traffic flow stability analysis.” The keyword cooccurrence analysis is applied to identify five dominant clusters: “modeling and optimization methods,” “traffic flow characteristics analysis,” “driving behavior analysis,” “simulation experiment,” and “policies and barriers.” The main research conclusions are as follows:

- (1) The number of documents in the field of heterogeneous traffic flow research continues to grow, indicating that the international academic community pays more attention to the field of heterogeneous traffic flow, and related research is also in progress. According to the distribution of the article in various countries, China, the United States, and India rank high, indicating that these countries are active areas for heterogeneous traffic flow research. In terms of research institutions, Beijing Jiaotong

University, Southeast University, and Tongji University have the highest research output, and the cooperation between major research institutions has been further strengthened. Judging from the analysis results of the main author groups, the international exchanges and cooperation among highly productive authors are quite active. In terms of source journals, “transportation research part c-emerging technologies,” “physical a-statistical mechanics and its applications,” and “transportation research record” are authoritative journals in the field of heterogeneous traffic flow research and are also important platforms for publishing research results.

- (2) Through the analysis of the cooccurrence network diagram of heterogeneous traffic flow keywords, the research directions represented by these keywords can be divided into four categories: “modeling and optimization methods,” “macroscopic traffic flow characteristics analysis,” “driving behavior analysis,” “simulation experiment analysis,” and “policies and barriers.” These five representative keywords also reflect the research trends in this field in recent years. The establishment of a safe and reliable model is of great significance to the development of autonomous driving and has received more and more attention in recent years. Related researches on the macroscopic traffic flow characteristics of heterogeneous traffic flow are also emerging. In addition, with the continuous development of information technology, sensor technology, computer technology, and other technologies, there are also many studies exploring the improvement of people’s living standards and traffic environment from the perspective of

simulation from the perspective of heterogeneous traffic flow.

- (3) This study also has some shortcomings. The search keywords used in this research are representative of the research in this field and cannot completely contain all the keywords in this research field. In addition, the search scope of this study is only for the SCIE and SSCI citation index databases in the core collections of the Web of Science (WOS). This study does not discuss the proportions and partnerships of each topic. At the same time, this research aims to provide a visual analysis method using the MKD method, which is also applicable to other keywords and databases. In terms of visualization methods, different goals based on analysis of different visualization methods can be further considered in future work.

Aviation ordnance handling is critical to the firepower projection of the time-critical cyclic flight operation on aircraft carriers. The complexity of the problem depends on the supply and demand features of ordnance. This paper examines the scheduling of aviation ordnance handling of an operational aircraft carrier under the framework of hybrid flow shop scheduling (HFS) and derives a method based on the simulated annealing (SA) algorithm to get the HFS problem's solution. The proposed method achieves the minimum possible flow time by optimizing the ordnance assignment through different stages. The traditional SA algorithm depends heavily on the heuristic scheme and consumes too much time to compute the optimal solution. To solve the problem, this paper improves the SA by embedding a task-based encoding method and a matrix perturbation method. The improved SA remains independent of the heuristic scheme and effectively propagates the local search process. Since the performance of SA is also influenced by its embedded parameters, orthogonal tests were carried out to carefully compare and select these parameters. Finally, different ordnance loading plans were simulated to reveal the advantage of the improved SA. The simulation results show that the improved SA (ISA) can generate better and faster solution than the traditional SA. This research provides a practical solution to stochastic HFS problems.

## 1. Introduction

This study focuses on the ordnance dispatching scheduling problem observed onboard the aircraft carrier flight operation, which plays an important role in the air wing firepower projection in its sortie generation [1]. The ordnance handling process involves many stages, equipment, and hundreds of personnel operating in a limited work space [2]; finding an optimal dispatch scheduling for a given ordnance load plan, plus the time critical nature of cyclic flight window requires, is a challenging problem. Traditionally, ordnance dispatching scheduling is made by a human operator's hand in a spreadsheet with experience, which is always nonoptimal, or even leading to delays that left aircraft launching without firepower. Thus, robust optimal scheduling is essential to conduct the ordnance handling procedure. However, such problem has seldomly been studied, which can be casted in the hybrid flow shop (HFS) scheduling framework.

The HFS scheduling problem [3] can be regarded as the combination of the flow shop scheduling (FSS) [4] problem

and parallel machine scheduling (PMS) problem, where the former is to decide the job sequences through the shop and the latter is to allocate jobs to machines, given the processing times of each job on each machine according to one or several given criteria, aiming to minimize the makespan [5–7]. For an  $n$  jobs  $m$  stages problem, there are a total of  $(n!)^m$  possible schedules, which proves to be NP-hard [8]. If the numbers  $n$  of jobs and  $m$  of stages are very small, the optimal schedule may be determined by exhaustion, such as branch and bound (B&B) [9] or integer programming techniques [10]. However, these approaches are not applicable to HFS problems with numerous jobs and stages, due to their enormous computing time and memory occupation.

Thus, for scheduling different HFS configurations, a large number of approximation and heuristics algorithms have been proposed [11, 12]. The computational complexity of HFS propelled scholars to develop many heuristics algorithms to obtain good enough solutions in a short time for medium-to-large problems, such as different scheduling rules [13], but the heuristic methods are too problem-

specific, it often cannot be applied to generalized problem. For the past decades, many general schemes on improving the performance of simple heuristics have been successfully developed, most of which are named as metaheuristics, such as genetic algorithm (GA) [14], ant colony optimization (ACO) [15], tabu search (TS) [16], neural networks (NN) [17], artificial immune systems (AIS) [18], and simulated annealing (SA) [19]. They inhere with higher level of abilities in searching the vast solution space, which have better performance than the simple heuristic methods.

Since different heuristics work effectively for different problems, when it encounters the flow shop scheduling problem, Maaroju [20] tested all the metaheuristic methods and found that the genetic algorithm and simulated annealing outperformed others, for hill climbing, swarm intelligence, and neural networks yielded only marginal improvements. However, the computation time for the GA is larger than that for SA. Thus, the SA-based algorithm is chosen in dealing with the ordnance handling problem under the HFS framework. Simulated annealing origins from the metallurgy technology, where a material cools down from high temperature to get minimum energy state. In the algorithm, the current state  $s$  and neighbor states  $s'$  are considered, and the algorithm decides the state transition probability from  $s$  to  $s'$  based on current system energy (known as temperature). This process continues until a good enough state has been found or the computation threshold has been reached. Such mechanism guarantees approximating to global optimum without getting stuck in local minimum for solving large complex optimization problems. However, the traditional SA algorithm has several defects [21], which include heuristic-dependent, parameter-specific, and long computation time; thus, the performance of the algorithm is yet to be improved. To overcome the above defects, this paper presents a Monte Carlo [22] perturbation method, which directly perturbs the solution matrix in each iteration of SA cooling, eliminating the dependence on any heuristic method, whereas SA performance also depends on cooling parameters; this paper carefully plans the calibration of these parameters to accelerate the computation process by adding double thresholds and setting the memory method of the SA.

The organizations of this paper are as follows: Section 2 introduces the ordnance handling process in detail; Section 3 discusses the methodology of the SA and improves the SA by embedding a new decoding method and matrix perturbation method; Section 4 evaluates the improved SA algorithm through computational experiments; Section 5 summarizes the research findings and gives the directions of future research.

## 2. Ordnance Handling Procedure

The ordnance handling procedure is specified in a daily loading plan, which lists the amount and types of weapons (throughout this paper, ordnance and weapon are used interchangeably) to be loaded onto the corresponding aircraft. Figure 1 shows the layout of aircraft carrier decks, where the construction and transfer of ordnance origin from the magazines located in lower decks to the awaiting aircraft

FIGURE 1: The layout of the ordnance handling routes aboard an aircraft carrier.

on flight deck following a series of stages. In stage I, the ordnances are retrieved from magazines by bomb skids and delivered to lower-stage elevators. In stage II, the ordnances are lifted to the hangar deck by lower-stage elevators. In stage III, the ordnances are transferred to the staging area of the hangar deck, assembled in that area, and moved to upper-stage elevators. In stage IV, the ordnances are transferred to the flight deck by upper-stage elevators. In stage V, the ordnances are moved directly to and loaded on the aircraft waiting on the flight deck. The flowchart of this procedure is shown in Figure 2. For a common aircraft carrier layout (Figure 1), there are at least 4 magazines in the delivering stage, 8 elevators in the lower-lifting stage, 2 assemble centers in the assembling stage, 4 elevators in the upper-lifting stage, and around 10 aircraft spots in the loading stage. According to Gupta [8], the two-stage flow shop problem with one stage containing a single machine can be NP-hard. Thus, the ordnance handling problem is far from trivial, especially for ordnance officers in making timely decisions of the flight operations.

This paper examines the ordnance handling problem in the HFS framework. The definition of hybrid flow shop system is as follows: in a factory, the set of  $n$  jobs  $J = \{1, 2, \dots, j, \dots, n\}$  is going to be processed through  $m$  stages  $M = \{1, 2, \dots, i, \dots, m\}$  in sequence, while each stage  $i$  contains  $M_i = \{1, 2, \dots, k, \dots, m_i\}$  identical machines, and the processing time of job  $j$  on machine  $k$  is  $p_{jk} \geq 0$ . The objective is always to minimize makespan. Similarly, in the ordnance handling problem,  $n$  batches of weapons are

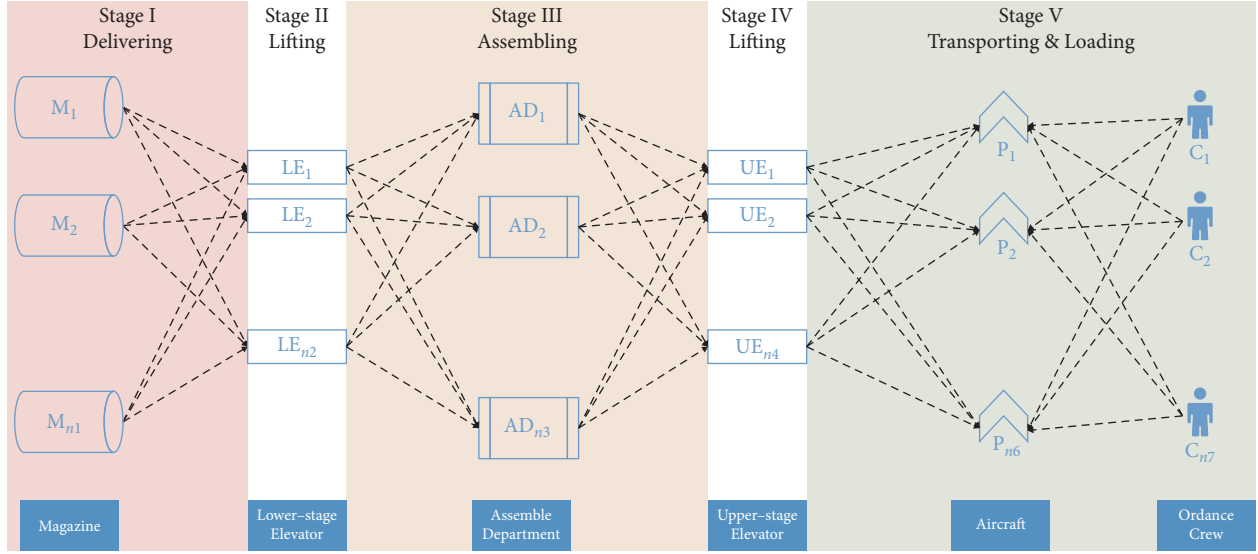

FIGURE 2: Flowchart of ordnance handling process. Note:  $M$  = magazine;  $LE$  = lower-stage elevator;  $AD$  = assembly department;  $UE$  = upper-stage elevator;  $P$  = aircraft parking spot.

considered as jobs; they also shall be processed in the same order through  $m$  stages by facility  $k$  (as shown in Figure 2) with processing time  $p_{jk}$ , and the objective is to decide the weapons' sequences and the allocations of weapons to facilities to get the minimum flow time. This is a combinatorial optimization problem with  $(n!)^m$  possible schedules, which is considered as NP-hard so that it is difficult to find the optimal solution in polynomial time. For a simple case of 10 batches of weapons in our problem, there can be  $(10!)^5 = 6.3 \times 10^{32}$  different schedules for

the ordnance officer to choose, which is beyond human mind's reach in conducting the time-critical flight operations.

The ordnance configuration of aircraft on the carrier depends on the specific mission [23]. It is assumed that each transfer equipment or personnel only transfers one type of ordnance at a time [24]. For each type of ordnance, the number loaded in one skid is denoted as  $r_w$ . Thus, the batches of ordnances needed to complete the task of all aircraft can be determined by

$$\text{task} = \left\{ \begin{array}{l} 1 \ (1, \text{num}_1) \ (2, \text{num}_2) \ \dots \ (w, \text{num}_w) \\ 2 \ (1, \text{num}_1) \ (2, \text{num}_2) \ \dots \ (w, \text{num}_w) \ \dots \ (W, \text{num}_W) \\ \dots \\ a \ (1, \text{num}_1) \ (2, \text{num}_2) \ \dots \ (w, \text{num}_w) \ \dots \ (W, \text{num}_W) \end{array} \right\}, \quad w = 1, 2, \dots, W, \quad (1)$$

where  $a$  is the number of aircraft to be loaded,  $w$  is the type of ordnance, and  $\text{num}_w$  is the actual number of ordnance types  $w$ .

$$\xi = \sum_{i=1}^a \sum_{j=1}^w \frac{\text{num}_w}{r_w}, \quad i = 1, 2, \dots, a, \quad j = 1, 2, \dots, w, \quad (2)$$

where  $r_w$  is the number of type  $w$  ordnances in one skid,  $a$  is the number of aircraft, and  $w$  is the number of ordnance types to be loaded on the aircraft. That is, an ordnance should be transferred to the required aircraft, once being retrieved from the magazine.

**2.1. Stage I: Weapons Retrieving.** Multiple magazines are located in the bow and aft of the carrier, and the ordnances can be transferred by multiple elevators. The ordnances are firstly retrieved from magazines by skids with the setup time

$T_0$ . From the same magazine, the ordnances should be retrieved with an interval no shorter than  $t_{\text{int}}$ . Then, the skids deliver the ordnances to lower-stage elevators. The time consumed to transfer ordnances from magazines to lower-stage elevators can be expressed as

$$T_M^L = \begin{bmatrix} t_1^1 & t_1^2 & \dots & t_1^L \\ t_2^1 & t_2^2 & \dots & t_2^L \\ \vdots & \vdots & \ddots & \vdots \\ t_M^1 & t_M^2 & \dots & t_M^L \end{bmatrix}, \quad (3)$$

where  $M$  is a magazine and  $L$  is a lower-stage elevator.

**2.2. Stage II: Weapons Buildup.** The ordnances are loaded onto lower-stage elevators and lifted vertically with constant speed to the hangar deck. The time consumed in this stage (lifting time) is denoted as  $T_L$ .

2.3. *Stage III: Weapons Assembling.* The ordnances are preassembled in the staging area of the hangar deck, with a sufficient lead time to meet the short turnaround time of the flight schedule. The assembling time  $T_K^{ass}$  varies with the types of ordnances. Note that the assembling time of the staff fluctuates in the real world. Therefore, the interval of assembling time was set to  $[-T_{f1}, T_{f1}]$ . The real assembling time is denoted as  $T_K^{ass} + t_1$ , where  $t_1$  is a random number within  $[-T_{f1}, T_{f1}]$ .

2.4. *Stage IV: Weapons Striking Up.* The ordnances are transferred to the flight deck by upper-stage elevators. The time consumed in this stage (transport time) is denoted as  $T_U$ .

2.5. *Stage V: Weapons Loading.* Some ordnance crew members on the flight deck transport the ordnances from the upper-stage elevators to the aircraft. The time consumed in this stage can be expressed as

$$T_U^A = \begin{bmatrix} t_1^1 & t_1^2 & \cdots & t_1^A \\ t_2^1 & t_2^2 & \cdots & t_2^A \\ \vdots & \vdots & \vdots & \vdots \\ t_U^1 & t_U^2 & \cdots & t_U^A \end{bmatrix}, \quad (4)$$

where  $U$  is an upper-stage elevator and  $A$  is an aircraft.

The other ordnance crew members load the ordnances onto the aircraft. It is assumed that the different groups consume the same time to load the same ordnance and different types of ordnances need different time to be loaded. The time needed to load each type of ordnance is denoted as  $T_K^{load}$ . The interval of the loading time was set as  $[-T_{f2}, T_{f2}]$ . The real loading time is denoted as  $T_K^{load} + t_2$ , where  $t_2$  is a random number within  $[-T_{f2}, T_{f2}]$ .

The ordnance crew members can be shared across groups. The loading cannot proceed unless ordnance crew members are available. The walking time for interstation transfer between different aircraft can be expressed as

$$T_A^A = \begin{bmatrix} t_1^1 & t_1^2 & \cdots & t_1^A \\ t_2^1 & t_2^2 & \cdots & t_2^A \\ \vdots & \vdots & \vdots & \vdots \\ t_A^1 & t_A^2 & \cdots & t_A^A \end{bmatrix}. \quad (5)$$

Referring to the standard three-field notation for scheduling problems, our problem can be described as follows:  $FH5, (PM^{(k)})_k^2 = 1, (RM^{(k)})_{k=3}^4 | prmu, M_j^{(5)}, block | C_{max}$ . Specifically,  $FH5$  is a five-stage HFS problem: stage I involves  $M^{(1)}$  identical magazines that store ordnances; stage II involves  $M^{(2)}$  lower-stage elevators to transport the ordnances; stage III has  $M^{(3)}$  identical assembling personnel to assemble the ordnances; stage IV has  $RM^{(4)}$  independent upper-stage elevators to transport the ordnances; and stage V has  $RM^{(5)}$  independent aircraft to be loaded. Note that  $prmu$  indicates that the ordnances are handled in the same

order in every stage;  $M_j^{(5)}$  (eligibility constraint) means that the handling of ordnance  $j$  is limited to the aircraft set  $M$  in stage V;  $block$  indicates that the capacity of buffer between stages is constrained, for instance, the weapons have to wait in the current stage till enough room is released for the next stage of handling.

In total, the completion time for batch  $i$  of ordnances can be calculated by

$$C_i = T_M^L + T_L + T_K^{ass} + t_1 + T_U + T_U^A + T_A^A + T_K^{load} + t_2 + T_{wating}, \quad i = 1, 2, \dots, \xi, \quad (6)$$

where  $T_{wating}$  is the whole waiting time in the transporting process, for an ordnance cannot be handled unless machines or ordnance crew members are available.

The general objective of ordnance handling is to complete all transporting operations as efficiently as possible within the specified time and to generate a reasonable schedule for ordnance handling. Therefore, for our ordnance handling problem, the minimization of makespan is set as goal, so that sufficient ordnances can be loaded to the awaiting aircraft to fly in the next flying window.

$$\text{Object} = \min(C_{max}). \quad (7)$$

### 3. Improved Simulated Annealing Algorithm

The SA is a technique capable of searching for good solutions to various combinatorial problems in material science and physics. The pseudocode of the algorithm is as follows.

The SA includes three major functions: state generation, state acceptance, and temperature update. The first is to make perturbations of the given initial solution, in order to search for the optimal solution effectively in the vast solution space. The second decides whether to accept a newly generated solution with a certain probability in case of trapping in the local minimum. The third offers a cooling scheme that mimics the physical annealing process to get a stable state for the problem. The SA performance can be augmented by adjusting various parameters and operators [25], such as initial temperature, descent gradient of temperature, and termination rule, which have to be adjusted manually. This paper mainly improves the search efficiency (timeliness) of the SA, without sacrificing the optimization quality. Thus, encoding scheme, initial solution, neighborhood search structure (NSS), type of cooling schedule, and two criteria (internal cycle termination and external cycle termination) are modified as described in the following subsections.

3.1. *Task Encoding.* This paper presents a task-based encoding method for the ordnance handling problem, where ordnances are coupled with aircraft. Each job of the HFS is defined as an operation  $o^{xy}$ , where  $x$  is the type of ordnance and  $y$  is the aircraft to be loaded. Then, a solution can be expressed as

Input: A initial  $S$  solution and a cost value function  $F(x)$ .  
Output: A  $S'$  solution that minimizes the cost value function  $F(x)$ .  
 $T \leftarrow$  initializing Temperature//a method for assigning an initial temperature  
**while**  $T > B$  not freezing **do**//a definition of "frozen,"  
    **for**  $i = 1$  to  $C$  **do** while not at equilibrium **do**//a definition of "equilibrium,"  
         $S' \leftarrow$  new permutation of  $S$ .  
        If  $F(S') < F(S)$  or Random value  $< e^{(F(S') - F(S))/DT}$  then  $S \leftarrow S'$ //a selection criterion  
    **end**  
     $T \leftarrow$  reduced temperature//a way of calculating the next temperature  
**end**

ALGORITHM 1: Standard simulated annealing.

$$S = \begin{pmatrix} o_1^{xy} & m_{11} \cdots & m_{n1} \\ o_2^{xy} & m_{21} \cdots & m_{n1} \\ \vdots & \vdots & \vdots \\ o_i^{xy} & m_{n1} \cdots & m_{nn} \end{pmatrix}, \quad (8)$$

where the first column is a permutation of the task sequence, the following columns are the corresponding stages, and  $m_1$  to  $m_n$  are machines assigned randomly to execute the tasks.

**3.2. Initial Solution.** As mentioned above, the initial solution has a great impact on the final solution of the SA. According to the heuristic methods mentioned in [26], we generate the initial solution by the following rule: first, the permutation of tasks is determined by assigning each type of weapon  $x$  to its corresponding aircraft  $y$ , defined as operation  $o_i^{xy}$ , according to the ordnance loading plan  $P$ . Then, the tasks are assigned to the earliest available machine. If there are more than one earliest available machines, one of them will be chosen randomly. The initial solution will be generated as  $S_{i \times m}$  with  $i$  tasks through  $m$  stages.

For example, Table 1 shows the ordnance loading plan of the aircraft waiting to operate in the next fly window. There are three aircraft and four types of ordnances. Aircraft 1 requires 2 skids of type 1 ordnances and 1 skid of type 2 ordnances.

Here, the operations are permuted by aircraft number (equal priority) in ascending order:  $o_i^{xy} = \{o_1^{11}, o_2^{11}, o_3^{21}, o_4^{12}, o_5^{32}, o_6^{43}\}$ . First, a random permutation of jobs (tasks) is generated. Then, the optimal available elevator is assigned to each operation. The final plan can be written as

$$\begin{pmatrix} 3 & 1 & 1 & 1 & 1 & 1 \\ 5 & 2 & 2 & 2 & 2 & 2 \\ 1 & 3 & 3 & 1 & 3 & 3 \\ 4 & 4 & 4 & 2 & 4 & 1 \\ 2 & 1 & 1 & 1 & 1 & 2 \\ 6 & 2 & 2 & 2 & 2 & 3 \end{pmatrix}. \quad (9)$$

The meaning of such matrix can be explained as follows: taken the third row for illustration, operation  $o_1^{11}$  is extracted out of the third magazine, transferred by the third lower-stage elevator to the first staging area, moved by the third

upper-stage elevator to the flight deck, and loaded to the corresponding aircraft by the No. 3 ordnance crew.

**3.3. Neighborhood Perturbation.** The NSS can generate a new solution by slightly modifying the current candidate solution. Traditionally, many different NSSs are adopted in each iteration of SA computation, such as swap, shift, and reversion [27], to realize the task permutation in the first stage. Then, the same heuristic rules are applied in the following stages to generate a new solution  $S'$ . The quality of the solution depends on the selected heuristic rules. If the rules are too greedy, the algorithm may fall into the local optimum, being unable to get convergence to the final optimal result.

The quality of the SA solution is highly sensitive to the selection of candidate solutions. Therefore, the perturbation scheme is crucial to the good performance of the SA algorithm. To ease the dependence of neighborhood search on heuristics, this paper proposes a Monte Carlo perturbation technique, which directly perturbs the initial solution matrix. The initial solution is changed significantly in one step, eliminating the effect by heuristic methods. The matrix perturbation is described as follows.

The following is an example of the matrix perturbation process: for instance, a  $6 \times 3$  matrix, a rectangle  $R_{a \times b}$  randomly generated a size of  $4 \times 3$  matrix.

$$\begin{pmatrix} 3 & 1 & 2 \\ 4 & 2 & 1 \\ 6 & 3 & 2 \\ 2 & 1 & 3 \\ 1 & 2 & 1 \\ 5 & 3 & 3 \end{pmatrix} \text{ which covers the matrix of } \begin{pmatrix} 4 & 2 & 1 \\ 6 & 3 & 2 \\ 2 & 1 & 3 \\ 1 & 2 & 1 \end{pmatrix}.$$

$$\text{Then, matrix } R \text{ is reversed as } R' = \begin{pmatrix} 1 & 2 & 1 \\ 2 & 1 & 3 \\ 6 & 3 & 2 \\ 4 & 2 & 1 \end{pmatrix}.$$

$$\text{Then, the new solution can be obtained as } S' = \begin{pmatrix} 3 & 1 & 2 \\ 1 & 2 & 1 \\ 2 & 1 & 3 \\ 6 & 3 & 2 \\ 4 & 2 & 1 \\ 5 & 3 & 3 \end{pmatrix}.$$

TABLE 1: Ordnance loading plan.

Aircraft type of ordnance	1	2	3
1	2	1	—
2	1	—	—
3	—	1	—
4	—	—	1

- (1) Randomly generate a rectangle  $R_{a \times b}$ , with width  $a \in (0, i]$  and length  $b \in (0, m]$ ;
- (2) Put  $R$  in the solution matrix  $S$  and mark the four vertices  $(o_i^{xy}, o_{i+a}^{xy}, o_{i+a}^{x+b, y+b}, o_i^{x+b, y+b})$ ;
- (3) The subsequence of the  $R$  area is reversed,  $o_i^{xy} \rightarrow o_{i+a}^{x, y}$  and  $o_i^{x+b, y+b} \rightarrow o_{i+a}^{x+b, y+b}$ ;
- (4) Get the new solution  $S' = \begin{pmatrix} o_{i+a}^{xy} & \dots & o_{i+a}^{x+b, y+b} \\ \vdots & \ddots & \vdots \\ o_i^{xy} & \dots & o_i^{x+b, y+b} \end{pmatrix}$ .

ALGORITHM 2: Matrix perturbation.

Hence, the matrix perturbation process is completed:

$$\begin{pmatrix} 3 & 1 & 2 \\ 4 & 2 & 1 \\ 6 & 3 & 2 \\ 2 & 1 & 3 \\ 1 & 2 & 1 \\ 5 & 3 & 3 \end{pmatrix} \rightarrow \begin{pmatrix} 3 & 1 & 2 \\ 1 & 2 & 1 \\ 2 & 1 & 3 \\ 6 & 3 & 2 \\ 4 & 2 & 1 \\ 5 & 3 & 3 \end{pmatrix}.$$

**3.4. Cooling Schedule.** The SA behavior can be regulated by the temperature and its descent gradient. To avoid the local optimum trap, inferior solutions may be accepted depending on the falling temperature, under the mechanism of cooling schedule. Here, the exponential cooling rate is adopted:

$$T_l = \frac{(T_0 - T_f)(N + 1)}{N(l + 1)} + T_0 - \frac{(T_0 - T_f)(N + 1)}{N}; \quad l = 1, 2, \dots, N, \quad (10)$$

where  $T_0$  and  $T_f$  are initial temperature and final temperature, respectively, and  $N$  is the number of temperatures between  $T_0$  and  $T_f$ .

The SA needs to accept the new state through probability judgment, in order to avoid the local minimum. When the initial temperature is sufficiently high, the cooling is slow enough (i.e., each temperature is held for a sufficiently long time), and the final temperature approaches zero; the SA will converge to the global optimal solution with the probability of 1. However, it is very difficult to fulfil the global convergence condition. Besides, the current state may be worse than some intermediate states in the search trajectory, owing to the probability acceptance mechanism. Thus, the SA algorithm often converges to an approximate optimal solution, or a solution poorer than the best intermediate solution. The search efficiency is inevitably affected. To preserve the best-known state and improve search efficiency, this section makes the following improvements to the SA:

- (1) Memorize the best intermediate solution in the search process and update it immediately. The

improvement of memory turns the SA into an intelligent algorithm.

- (2) Set up two thresholds, internal cycle threshold and external cycle threshold, to reduce the computing load while maintaining optimality. The internal cycle threshold refers to the number of cycles that the new solution of continuous disturbance does not generate a better solution at a certain temperature, while the external cycle threshold refers to the number of cycles that the new solution generated by continuous cooling does not generate a better solution. The two thresholds are determined as follows.

First, determine whether the number of internal cycles reaches the threshold; if yes, lower the temperature by one step; otherwise, judge if it conforms to Markov chain. If not, reconduct the process of state generation, state acceptance, and algorithm termination; otherwise, lower the temperature by one step. Second, determine whether the number of external cycles reaches the threshold; if yes, terminate the algorithm and obtain the final solution; otherwise, judge whether the algorithm meets the termination conditions. If yes, terminate the algorithm and obtain the final solution; otherwise, reconduct the process of state generation, state acceptance, and algorithm termination. Terminate the algorithm once the number of iterations  $i$  surpasses the prior fixed constant  $MaxIter$ . In our experiments,  $MaxIter$  was set to  $10^4$ .

The flow of the improved SA is shown in Figure 3.

## 4. Experiments

To test the effectiveness of SA-based algorithm, we first evaluate the control factors of the SA and suggest a good parameter setting. Then, the solution quality and efficiency of the ISA were verified through several experiments. The algorithms are implemented in our previously published carrier-based flight operations simulation [28], which is written by C++ and ran on Microsoft Windows operating system with 4 GB RAM and dual core CPU.

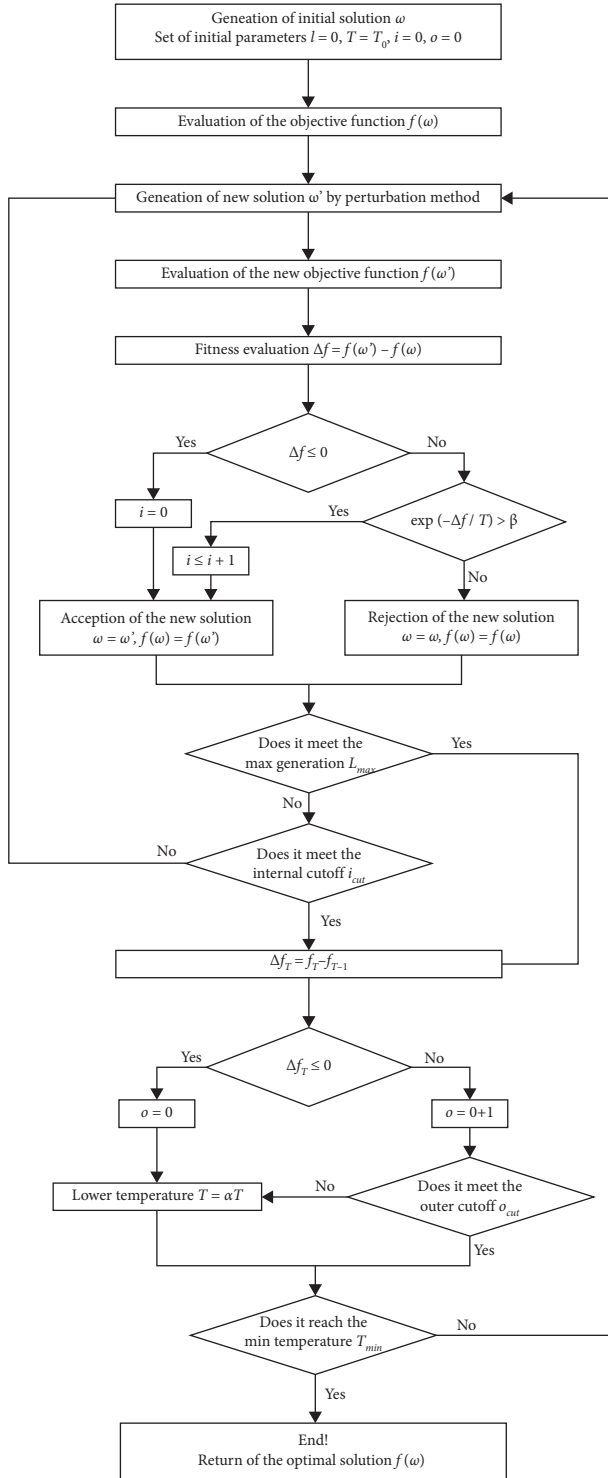

FIGURE 3: Flow of the improved SA.

**4.1. Parameter Tuning.** The efficiency of the SA algorithm is greatly affected by the design of parameters and operators. The full factorial design tests all possible combinations. Such an approach becomes too laborious in the face of numerous factors. Taguchi utilized orthogonal arrays to examine lots of decision variables in a few tests [29] and measured the importance of each factor by its influence on algorithm

performance, using the signal-to-noise ratio:  $10 \log_{10} (\text{objective})^2$ . Following Taguchi's method, the SA control factors were configured as follows: initial solution, initial temperature, cooling rate, and number of neighborhood searches in every temperature. Table 2 shows the different levels of these factors.

Hence, the SA has one 3-level factor and three 4-level factors. The best design among the orthogonal arrays is L16. Thus, additional transform was performed to fit L16 (Table 3).

The relative percentage deviation (RPD) was also adopted to measure the performances:

$$\text{RPD} = \frac{\text{Alg}_{\text{sol}} - \text{Min}_{\text{sol}}}{\text{Min}_{\text{sol}}} \cdot 100\%, \quad (11)$$

where the best solution obtained for one instance is denoted as  $\text{Min}_{\text{sol}}$ , while the objective value is marked as  $\text{Alg}_{\text{sol}}$ . Table 4 lists the S/N ratios and RPD values of each level of the factor value. The results show that A(3), B(4), C(4), and D(4) are the best levels of the factors.

**4.2. Experimental Settings.** The size of the test instances was set to  $n = \{15, 30, 45, 60\}$  tasks, which corresponds to a common mission of strike sorties of 5, 10, 15, and 20 aircraft, respectively. The processing time for jobs on each machine was generated by triangle distribution with mean time according to [30]. There are resource constraints of five types of weapons, four lower-stage elevators, 10 assembling crews, four upper-stage elevators, and six loading crew members, see Tables 5–9 for comprehensive data.

**4.3. Makespan Analysis.** The test of problem uses an ordinance loading plan, ranging from 5 to 20 aircraft. At first, the experiment tries to solve a standard small size problem with optimal solution and preliminarily demonstrates the adaptability and feasibility of the ISA. Then, the proposed ISA was adopted to solve larger size problems and compared with the other methods to reveal its superiority.

To compare the ISA with the SA, control factors were configured as those in the preceding section. The permutation of machines was arranged in ascending order. The initial temperature  $T_0 = 10^3$ , final temperature  $\varepsilon = 0.5$ , cooling rate  $\alpha = 0.99$ , and length of Markov chain  $L = 2000$ .

The base case includes 15 tasks. As the temperature declined (Figure 4(a)), the ISA converged to the optimal solution in 2.705 s, faster than the SA, which converged to the optimal solution in 2.965 s (Figure 5(a)). Although the initial scheduling time of the ISA was higher than that of SA, its faster convergence procedure suggests the good performance of the ISA. Note that the computing time of the ISA was 85.3637 s, much shorter than that (143.7861 s) of the SA.

Next, the ISA performance on larger problems was tested, whereas more tasks bring a greater computing effort for the heuristic. Table 10 lists the average scheduling time and computing time of different tasks, with each task running for 30 times. Figure 6 shows the corresponding plot. The results showed that the ISA achieved a shorter

60	8000	8600	260	450

FIGURE 6: Performance of the ISA and the SA on medium and large problems. (a) Scheduling time. (b) Computing time.

scheduling time and a faster computing speed than the SA. Comparing with the SA, the average scheduling time of the ISA reduces from 300 to 600 seconds in each ordnance turnaround cycle for 30 to 60 tasks and the average computing time saves from 110 to 190 seconds. Note that there are usually ten or more cycles in a general flight day; the scheduling time saved by implementing ISA equals one more group sortie generation, which in turn enhanced the firepower capacity of carrier air wing.

The results also show that the bottleneck of ordnance handling is the loading process, where the number of loading crews heavily influences the aircraft turnaround time. When there is high intensity of surge operations, more loading crews should be arranged to handle ordnances.

## 5. Conclusions

This paper treats the aviation ordnance scheduling problem under the HFS framework with multistages, independent parallel machines, and several processing constraints. The simulated annealing algorithm was modified with dual threshold selection to generate faster and better schedules using the proposed matrix perturbation method that keeps the SA independent of the heuristic schemes. The influencing parameters of the improved algorithm are carefully tuned by Taguchi's method. The experimental results demonstrate the effectiveness of ISA, which provides a practical solution to a broad application in dealing with stochastic hybrid flow shop scheduling problems.

The forecast error characteristic analysis of short-term photovoltaic power generation can provide a reliable reference for power system optimal dispatching. In this paper, the total in-day error level was stratified by fuzzy C-means algorithm. Then the historical PV output data based on the numerical characteristics of point prediction output were classified. A General Gauss Mixed Model was proposed to fit the forecast error distribution of various photovoltaic output forecast error distribution. The impact of meteorological factors together with numerical characteristics on the forecast error was taken into full consideration in this analysis method. The predicted point output with high volatility can be accurately captured, and the reliable confidence interval is given. The proposed method is independent of the point prediction algorithm and has strong applicability. The General Gauss Mixed Model can meet the peak diversity, bias, and multimodal properties of the error distribution, and the fitting effect is superior to the normal distribution, the Laplace distribution, and the  $t$  Location-Scale distribution model. The error model has a flexible shape, a concise expression, and high practical value for engineering.

## 1. Introduction

Facing the double pressure of energy crisis and environmental pollution, people pay more and more attention to the new energy generation technology with clean and environmental protection characteristics. Compared with wind power, photovoltaic power generation requires less geographical environment and is more suitable for multiregional promotion and application. However, PV power generation is highly random and intermittent, and large-scale grid connection affects the stability and economy of the system [1]. The accuracy of photovoltaic power prediction has a direct impact on its consumption. Domestic and foreign scholars have conducted relevant studies, and the existing prediction models are divided into two categories: first, direct prediction algorithms such as regression models [2–4], gray prediction models [5–7], neural network models [8–11], and probabilistic models [12] are used; second,

indirect prediction algorithms such as electronic component models [13], simple physical models [14, 15], and complex physical methods [16, 17] are used. The use of different prediction algorithms can have different degrees of prediction errors.

There are only a few literatures on the forecast error of PV power generation at home and abroad, and the description of the prediction error of PV output in some literature is based on the assumption that it obeys normal distribution. The PV output uncertainty needs to be considered when studying the optimal scheduling of power systems, and most of the literature uses the actual output value in the form of the sum of the predicted output and the forecast error. Literature [18] shows that a 10% forecast error produces deviated power exceeding 15% of the rated power value, while a 15% forecast error produces deviated power exceeding 25% of the rated power value, and the forecast error directly affects the safe and stable operation of the

system. Based on the assumption that the forecast error obeys normal distribution, the results obtained in [19–21] are different from the actual statistical results. The research in [22] shows that weather factors have great influence on the forecast error, and the forecast error of solar volts in sunny days is close to normal distribution. The feasibility of using  $t$  Location-Scale model to describe the forecast error of PV output is proposed and verified in [23]. The statistical results show that the PV output forecast error distribution has multiple peaks, while the existing research using single distribution model is weak in describing the multi-peaks. Therefore, [24–26] propose to model the forecast error by Gaussian mixture model (GMM), but the value range of GMM is from negative infinity to positive infinity, which is obviously not applicable for the description of the actual PV output forecast error directly. Literature [27] trains artificial neural networks with a large number of samples to build a forecast error model for photovoltaic power generation, which can avoid the deviation of prediction accuracy caused by model setting and parameter estimation. Literature [28] introduces regularized penalty function and error function to construct the objective function of PV prediction model; the Pearson correlation coefficient between PV power generation and each feature is analyzed, and the abnormal data of the features are also preprocessed. The above studies all focus on the optimization of the model. Because of the random characteristics of meteorological factors such as solar irradiation, temperature, and wind speed, the forecast error of photovoltaic output does not have a certain distribution characteristic, and it is difficult for the established forecast error model to achieve ideal accuracy. The distribution characteristics of PV output forecast error under different meteorological conditions and numerical characteristics cannot be ignored, so it is necessary to cluster the forecast error according to the conditions. At present, there are few researches in this field, so a flexible distribution model is needed, which can meet the requirements of skewness and peak diversity of PV output forecast error.

In this paper, the effects of meteorological and numerical characteristics on the real-time power forecast error of photovoltaic power generation are studied. Based on the corresponding meteorological data, the historical error samples are clustered into three categories by fuzzy C-means clustering, and the error areas are divided into two categories according to the error size. In order to describe the forecast error distribution more accurately, a general Gaussian mixture model based on the traditional Gaussian distribution is proposed. Compared with the traditional Gaussian model, this model can describe the error distribution of different kurtosis and shape more accurately.

In addition, this method is universal and is not affected by photovoltaic power prediction algorithm and the geographical location of photovoltaic power stations.

## 2. Cluster Analysis of Photovoltaic Output Forecast Error

Short-term forecast error of photovoltaic output is mainly affected by weather and numerical characteristics of

prediction points. Among the factors representing weather, weather type, temperature, temperature difference, and wind speed are selected as indicators to analyze the correlation with photovoltaic forecast error. Therefore, firstly, the PV intraday forecast error samples are clustered into three categories according to the weather characteristics, and then the error samples obtained by classification are used as training samples to discriminate the subsequent errors. After determining the classification, the forecast error is divided into large error and small error according to its numerical characteristics. Finally, Gaussian mixture distribution is used for statistical fitting within the class, and a reliable confidence interval is provided for predicting the PV error distribution according to the fitting information.

To determine the confidence interval of photovoltaic error distribution, the steps are shown in Figure 1:

- (1) According to meteorological factors, the historical data of photovoltaic power generation forecast error are clustered into three categories
- (2) Taking amplitude and step size as indexes, the error data in cluster are divided into large error and small error
- (3) The error database will be established according to the error samples clustered by meteorological factors, which is convenient to provide the error interval meeting the error requirements

## 3. Influencing Factors of Photovoltaic Power Forecast Error

Photovoltaic panels absorb solar energy and generate electricity based on Volta effect. Its power generation is affected by meteorological factors, especially illumination and temperature [29]. Literature [30] proposes a photovoltaic power prediction method based on clear coefficient and multilevel similarity matching. In addition, the statistical results show that the forecast error of photovoltaic power generation is directly related to the amplitude and climbing of predicted output. Therefore, this paper studies the factors that affect the error distribution of PV power prediction from two angles of meteorological and numerical factors, which provides important reference information for error discrimination clustering and obtaining reliable confidence intervals.

*3.1. Analysis of the Influence of Meteorological Factors on Forecast Error.* To study the influence of meteorology on forecast error, we should first index meteorological factors concretely. In order to accurately scale meteorological factors, four factors are selected to express: weather type, intraday difference between maximum and minimum temperature, maximum temperature, and wind speed. After that, the influence of these four factors on forecast error is studied, which also provides variables for later error discriminant analysis.

The British statistician R. A. Fisher put forward the variance analysis method in the 1920s. [31]. The variance analysis method can determine the factors that have the

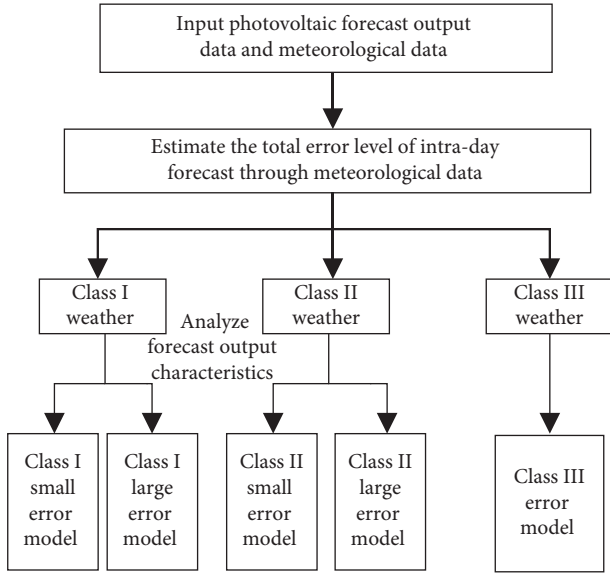

FIGURE 1: Schematic diagram of the research method of photovoltaic output forecast error distribution.

main effect on the target object from many factors. It determines the influence of research elements on the target object by analyzing the contribution of different elements to the overall target. The specific operation process is to analyze the differences between different groups and within groups. The specific discrimination process is as follows:

$$\begin{cases} MSb = \frac{SSb}{dfb}, \\ MSw = \frac{dfb}{dfw}, \end{cases} \quad (1)$$

where  $SSb$  represents the intergroup differences;  $SSw$  represents intragroup differences;  $dfb$  and  $dfw$  are the degrees of freedom between groups and within groups, respectively. Whether the experimental factors have obvious influence on the research object is judged by the ratio of  $MSb/MSw$  and the  $F$  distribution composed of  $MSb/MSw$ . The probability  $P$  value of  $F$  value greater than a specific value under the test hypothesis can be obtained by consulting the  $F$  boundary value table. Select 0.05 as the test critical value. When  $P < 0.05$ , it is considered that the test factors have significant differences on the research objects; otherwise, it is considered that there is no obvious influence. When studying the influence of weather factors on the forecast error of photovoltaic power generation, the selected test factors and levels are shown in Table 1.

The influence of meteorological factors on PV forecast error is analyzed. Firstly, the meteorological factors are indexed as weather type  $A$ , intraday temperature difference  $B$ , intraday maximum temperature  $C$ , and wind speed grade  $D$ . Photovoltaic forecast error is quantified by sum of squares of errors (DSSE), and weather types are quantified by sunny degree assignment [1–3]. Taking PV in Brussels area in 2016 as an example, the results of the analysis of variance are shown in Table 2.

In Table 2, the main effect of four variables and the interaction effect between two variables are selected as factors, and the sum of squares of variance, degree of freedom, mean square, observed value of  $F$  distribution, and test  $P$  value are used as indexes for analysis. As can be seen from Table 2, the  $P$  values of principal factor  $B$ , principal factor  $C$ , and interactive factor  $B^*C$  are less than 0.05. That is to say, at the significant level of 0.05, the effects of principal factor  $B$ , principal factor  $C$ , and interactive factor  $B^*C$  are significant. At the significant level of 0.05, other factors are not significant. From the results, we can see that, among the single factors selected in the early stage, factor  $D$  has the least significant influence on the error. In order to remove its influence on other factors and extract the components more accurately, factor  $D$  is removed and then does variance analysis again. The results are shown in Table 3.

As can be seen from Table 3, after removing the influence of factor  $D$ , the influence of factors  $A$ ,  $B$ , and  $C$  is more significant. At a significant level of 0.05, weather type, intraday temperature difference, maximum temperature, and the interaction between intraday temperature difference and maximum temperature have the most significant influence on the total forecast error level.

**3.2. Analysis of the Influence of Numerical Characteristics of Photovoltaic Output on Forecast Error.** Photovoltaic panels usually run in the maximum power tracking state. When external factors such as illumination and temperature change, the controller controls the operating point of PV array to change, so the forecast error of photovoltaic output is related to the performance of the controller. The prediction power amplitude is selected as factor  $E$ , and the adjacent prediction output difference is factor  $G$ , and the influence of the two factors on the short-term photovoltaic output forecast error is analyzed. The rated capacity of two factors is taken as the reference value to make the standard output, and the specific level values are shown in Table 4.

Based on the photovoltaic power generation data of Brussels region in Belgium in 2016, the output amplitude and climbing power are used as indexes for principal component analysis. The results are shown in Table 5.

At a significant level of 0.05, all factors in Table 5 passed the test. Therefore, it can be seen that both the amplitude of photovoltaic output and climbing power have a significant impact on the forecast error.

**3.3. Cluster Analysis of Influencing Factors of Photovoltaic Forecast Error.** From the above analysis, it can be seen that there are many factors affecting photovoltaic forecast error. In order to facilitate the subsequent study of forecast error, it is necessary to reduce the variable dimension. In this paper, the fuzzy C-means clustering method is used to cluster the historical data DSSE, and the meteorological data are classified according to the clustering results, which can be used to discriminate and analyze the meteorological types of the forecast days and estimate the total forecast error level of the day.

Fuzzy C-mean clustering method is used in cases where there are no clear boundaries between the classified objects. Therefore, fuzzy C-means clustering method is used to combine the meteorological factors obtained above into three categories, namely, Class I, Class II, and Class III. Taking the total error level of photovoltaic prediction DSSE as the error index, the observation matrix is listed in days:

$$X = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} = \begin{pmatrix} x_{11} & \cdots & x_{1p} \\ \vdots & \ddots & \vdots \\ x_{n1} & \cdots & x_{np} \end{pmatrix}, \quad (2)$$

where each row of  $X$  is a sample of one day and each column has  $p$  observations within one day; i.e.,  $X$  is a matrix consisting of observations of  $p$  variables over  $n$  days;  $X_{np}$  represents the observed value of the  $p$ -th variable on the  $n$ -th day;  $n$  samples are divided into  $c$  classes ( $2 \leq c \leq n$ ) and  $V = \{v_1, v_2, \dots, v_c\}$  is recorded as  $c$  cluster centers. Samples  $x_k$  are not strictly divided into a certain class but belong to a certain class by membership degree  $u_{ik}$ , and  $0 \leq u_k \leq 1, \sum_{i=1}^c u_{ik} = 1$ . Define the target function:

$$J(U, V) = \sum_{k=1}^n \sum_{i=1}^c u_{ik}^m d_{ik}^2, \quad (3)$$

where  $U = (u_{ik})_{c \times n}$  is the membership matrix;  $d_{ik} = \|x_k - v_i\|$ .  $J(U, V)$  represents the sum of weighted

square distances from samples to cluster centers in each class. Based on fuzzy C-means clustering method, Lagrange multiplier method [32] and iterative method [31] are often used to solve the objective function to obtain the minimum values of  $U$  and  $V$ .

Fuzzy C-means clustering method is used to cluster photovoltaic short-term forecast errors. The results are shown in Figure 2, where dots represent error samples. It can be seen from the figure that all error samples are clustered into three classes, and Class I error is the smallest, Class III error is the largest, and Class II error is moderate. After getting the error clustering results, the corresponding meteorological data are also classified and archived and used as their own training samples to discriminate and analyze the weather on the forecast day.

Figure 3 shows the percentage of sunny, rainy, and snowy weather on the left side and the sample mean values of intraday temperature difference, maximum temperature, and minimum temperature on the right side, which shows the clustering of meteorological data according to DSSE value clustering date. As can be seen from the above figure, the proportion of various weather types of Class I weather and Class II weather is similar, but the temperature of Class I weather is low and the temperature difference is small. The intraday temperature and temperature difference of Class II weather and Class III weather are similar, but cloudy days account for a high proportion and sunny and rainy days account for a small proportion in Class III weather.

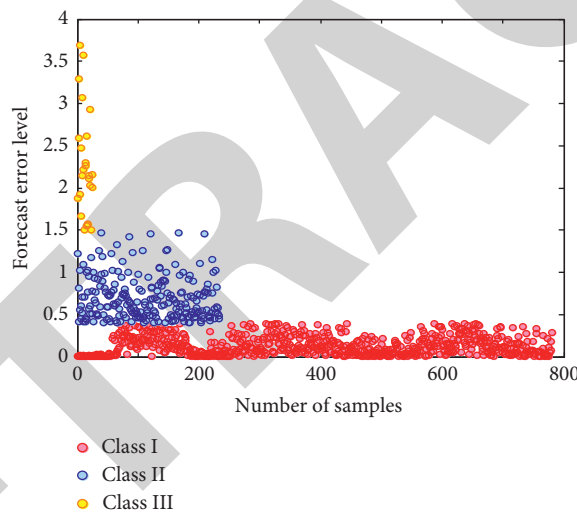

FIGURE 2: Fuzzy C-means clustering results.

FIGURE 3: Clustering results of meteorological data.

In order to get the weather category of the forecast day, it is necessary to train each group of meteorological data as samples. In the training process, the intraday temperature difference range is [0°C, 18°C], and the intraday maximum

temperature range is [-3°C, 34°C]. Mahalanobis distance, proposed by Indian statistician P.C. Mahalanobis, is a measure of similarity between two points in multidimensional space, which can effectively calculate the similarity

between two unknown sample sets. Different from Euclidean distance, Mahalanobis distance between two points is independent of the measurement unit of the original data and is not affected by dimension. It can be seen from formula (4) that Mahalanobis distance is the product of Euclidean distance and spatial covariance inverse matrix. When the covariance matrix is unit matrix, Mahalanobis distance degenerates to Euclidean distance. For the factors with obvious differences, Mahalanobis distance is used to calculate the similarity, as shown in the following formula:

$$d^2(x, y) = (x - y)^T \Sigma^{-1} (x - y). \quad (4)$$

**3.4. Classification Processing of Forecast Error.** The research results in Section 3.2 of this paper show that the amplitude and step size of the predicted output have a significant interaction. In Section 3.2, the mean absolute error (MAE) of the samples combined by two factors at different levels is counted. The results are shown in Figure 4, and the data values are detailed in Table 6.

The statistical situation in Figure 4 is classified and described as three cases: in case 1, the combination of  $E$  and  $G$  values is missing in the lower left corner and the lower right corner of the figure, that is,  $\{7, 1\}$ ,  $\{8, 1\}$ ,  $\{8, 2\}$ ,  $\{8, 7\}$ ,  $\{7, 8\}$ ,  $\{8, 8\}$  combined samples; in case 2, the dotted box area with the highest heat in the middle of Figure 2 is a large error area  $E \in [3, 6]$  and  $G \in [3, 6]$ ; in case 3, the area that belongs neither to the large error area nor to the missing area is annularly distributed around the large error area, which is defined as the small error area.

Based on the clustering results of meteorological data, according to the characteristics of prediction output amplitude and step size, the historical data of Class I and Class II forecast errors are further divided into small error area and large error area; Class III error itself has high uncertainty and less samples, so it is no longer classified.

## 4. Forecast Error Model of Short-Term Photovoltaic Power Generation Output

**4.1. General Gaussian Mixture Model.** The statistical distribution of PV short-term output forecast error has the characteristics of asymmetry, diverse kurtosis, and multiple peaks. The traditional probability density function of Gaussian mixture distribution is defined as formula (5), where the sum of coefficients of each Gaussian term is 1.

$$f(x|\theta) = \sum_{k=1}^n a_k \phi(x|\theta_k), \quad (5)$$

where  $a_k$  is the weighting factor,  $a_k \geq 0$ ,  $\sum_{k=1}^n a_k = 1$ ;  $\theta_k = (\mu_k, \sigma_k^2)$ ;  $\phi(x|\theta_k)$  is Gaussian distribution function as shown in the following formula:

$$\phi(x|\theta_k) = \frac{1}{\sqrt{2\pi}\sigma_k} \exp\left(-\frac{(x - \mu_k)^2}{2\sigma_k^2}\right), \quad (6)$$

and its cumulative distribution function is

$$F(x|\theta) = \sum_{k=1}^n a_k \int_{-\infty}^x \phi(x|\theta_k) dt. \quad (7)$$

The random variable range of Gaussian mixture distribution is  $(-\infty, +\infty)$ , but the short-term forecast error of photovoltaic is not the same in practice. To solve this problem, a general Gaussian mixture model (GGMM) is proposed based on the traditional Gaussian mixture distribution. The definition formula of GGMM is basically the same as the traditional Gaussian mixture distribution, except that there is no strict and unique restriction on the sum of the weight coefficients of each Gaussian term. Theoretically, the proposed general Gaussian mixture model is more flexible than the traditional Gaussian mixture model, and it is more applicable to describe the short-term photovoltaic output with asymmetric and multiplex characteristics.

**4.2. Model Parameter Estimation and Accuracy Evaluation.** In this paper, the least square method is used as the main method to estimate the model parameters, and the estimated parameters are obtained by the nonlinear curve fitting function `lsqcurvefit` in MATLAB. Multivariate determination coefficient ( $R^2$ ) is also called goodness of fit, and its value determines the close degree of correlation. When  $R^2$  is closer to 1, the reference value of related equations is higher. On the contrary, the closer it is to 0, the lower the reference value. Root mean square error (RMSE), also called standard error, is very sensitive to a set of extra-large or extra-small errors in fitting, so it can well reflect the precision of fitting. The closer RMSE is to 0, the higher the fitting precision is. The calculation formula is as follows:

$$\begin{cases} R^2 = 1 - \frac{\sum (y_i - \hat{y}_i)^2}{\sum (y_i - \bar{y})^2}, \\ RMSE = \sqrt{\frac{\sum (y_i - \hat{y}_i)^2}{i}} \end{cases} \quad (8)$$

where  $y_i$  is the actual statistical probability density,  $\hat{y}_i$  is the curve fitting value,  $\bar{y}$  is the average value, and subscript  $i$  represents the  $i$ - the error interval.

## 5. Example Analysis

In order to verify the effectiveness and applicability of the proposed method, the historical data of PV short-term prediction in Brussels, Belgium, is used as an example to simulate in MATLAB software. Among them, the historical data from 2014 to 2016 are used as training samples to establish the forecast error model, and some data from 2017 are selected as test data to test the accuracy of the model. The data in this article comes from the official website of Elia, Belgium.

Elia official website makes the next day's output forecast at 11:00 a.m. every day and updates the next day's 24-hour (96 o'clock) output at 11:45 a.m., with a time resolution of point/15 min. The collected photovoltaic output data and

meteorological data have the problems of missing data and abnormal data. For the lack of intraday meteorological data, the output data of the solar photovoltaic system will not be

used. And when either the predicted data or the measured data is missing and cannot be repaired, the data will not be used.

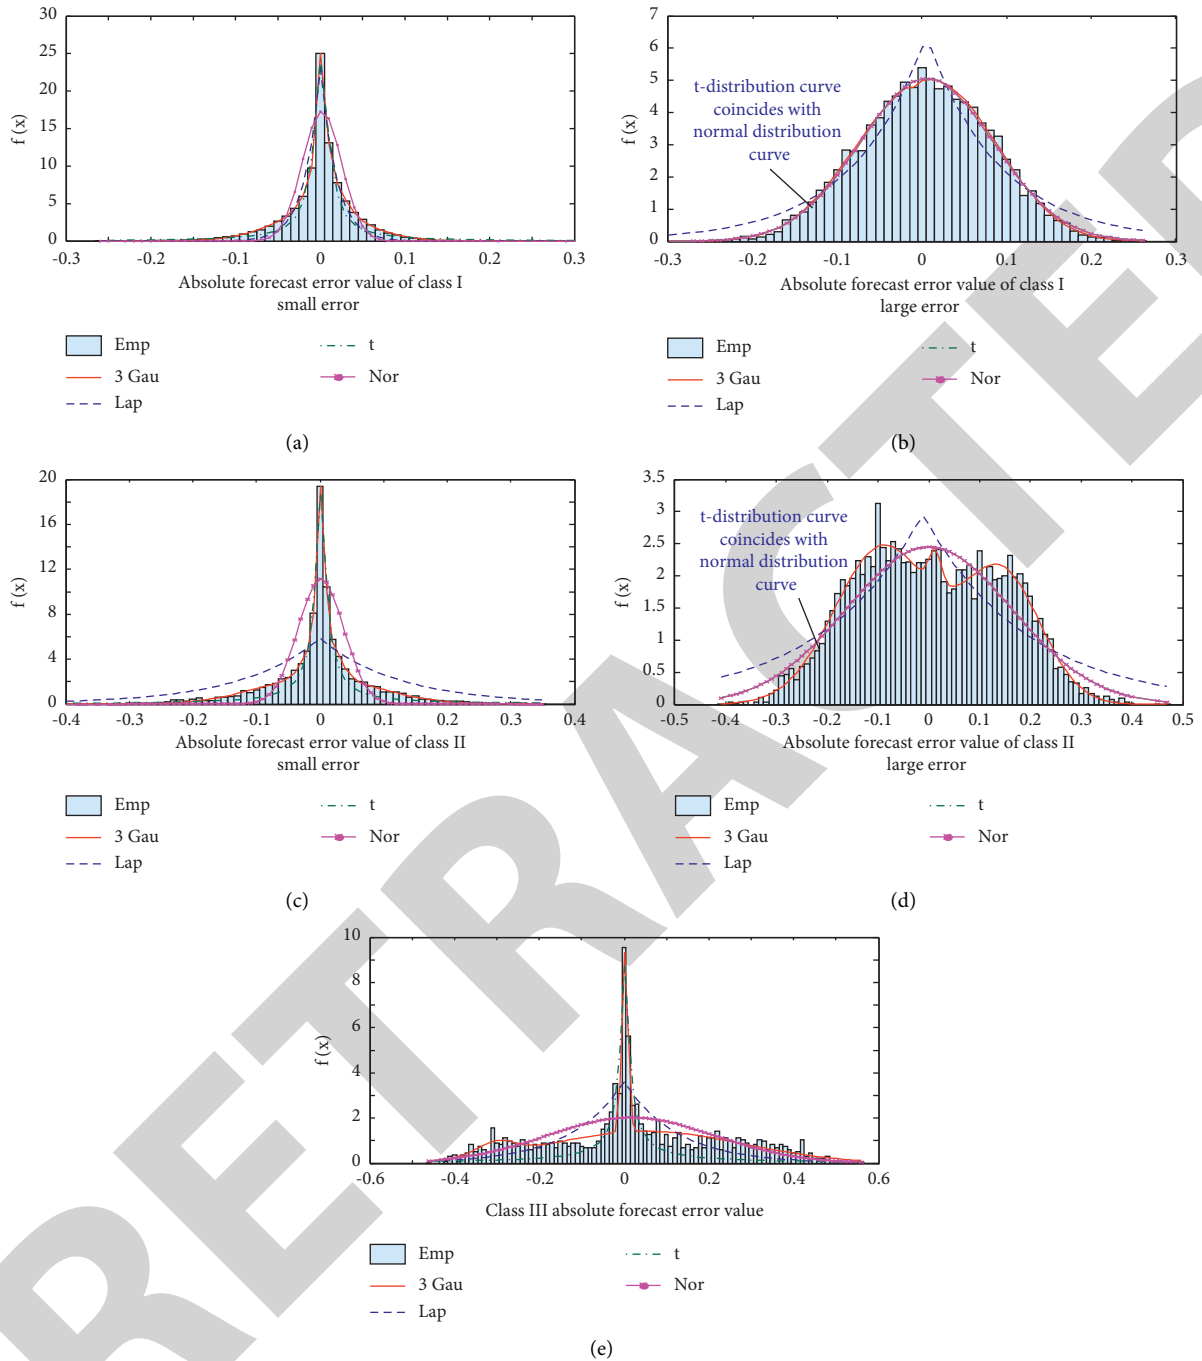

FIGURE 5: Comparison chart of distribution fitting of five groups of errors.

**5.1. Comparison of Model Accuracy.** In order to verify the accuracy and superiority of the model, the PV forecast error distribution model commonly used in the existing literature is used for comparison. The detailed fitting results of each model are shown in Table 7, and the fitting results are shown in Figure 5. In the figure, Emp represents the original error statistical results, 3Gau represents the proposed third-order general Gaussian mixture distribution, Lap represents Laplace distribution,  $t$  represents  $t$  Location-Scale distribution, and Nor represents normal distribution.

It can be seen from the results in Figure 5 that when the fitting distribution presents Class I and Class II small errors with higher peak degree, the accuracy of normal distribution is the lowest, followed by Laplace and Location-Scale distribution, and the proposed general Gaussian mixture distribution has the best effect. Normal distribution is obviously not enough to track spikes. When the fitting distribution shows large errors of Class I and Class II with gentle kurtosis, the effects of the three distributions mentioned above are not comparable to those of the general Gaussian mixture

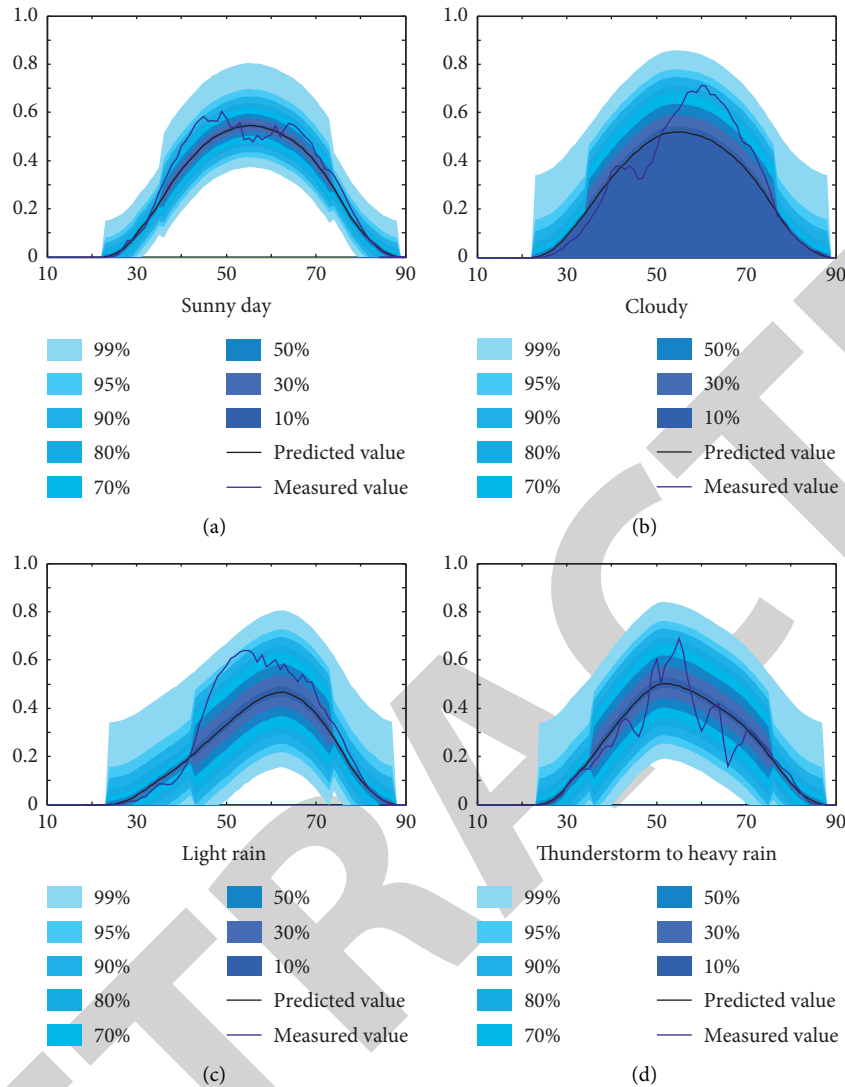

FIGURE 6: The predicted value, measured value, and GGMM confidence interval under different weather in July.

distribution. The fitting effect of normal distribution is better outside the peak value, but it is lower than the empirical value at the peak value. Class III error distributes gently outside the peak value but has prominent peak value. Therefore, when fitting Class III errors, the normal distribution and Laplace distribution are obviously deficient, and  $t$  Location-Scale is more accurate in describing the peak but obviously distorted in the nonpeak areas. The proposed general Gaussian mixture distribution has obvious advantages in describing the whole distribution. The proposed general Gaussian mixture distribution model can flexibly change the weight coefficient of each Gaussian term, so it can take into account the requirements of waist flexibility and peak value of the distribution curve and has obvious advantages in describing the short-term photovoltaic power generation output forecast error distribution.

**5.2. Applicability Analysis of Model.** In order to see whether the generalized Gaussian mixture distribution model can

perform well in different meteorological environments, the historical data of different weather type days in high temperature season: July 4th (sunny day), July 8th (cloudy day), July 17th (light rain), and July 20th (thunderstorm to heavy rain) in 2017, are selected to test the applicability of the model. Using the cluster analysis method in Section 3.3, sunny days are classified as Class I generalized weather, and cloudy, light rain and thunderstorm to heavy rain are classified as Class II generalized weather. The data are counted once every 15 minutes, and the time series points with intervals of (10, 90) are selected for analysis. The model test results are shown in Figure 6.

Figure 6 shows the predicted values, measured values, and confidence interval bands of errors of photovoltaic power generation in four different weather conditions. It can be seen from the figure that the error band width of the same confidence level is different in different weather, and the error band is the narrowest in sunny days, and the worse the weather, the wider the error band. This shows that the forecast error of photovoltaic power generation is small in

FIGURE 7: The predicted value, measured value, and GGMM confidence interval under different weather in November.

sunny days, and the probability of increasing the forecast error of photovoltaic power generation is greater with the deterioration of weather, which is consistent with the actual situation. In Class II and Class I weather, the difference between measured and predicted values is mainly concentrated at the peak value, while the measured curve at the waist is in good agreement with the predicted curve. This is because the peak belongs to the large error area, and the waist and bottom output belong to the small error area. Even so, the measured output at the peak is within the confidence interval of 95% of the predicted power.

In order to test the applicability of the model in low temperature season, the predicted, measured, and meteorological data of November 13, 14, 15, 16, 18, and 19, 2017 are selected in Figure 7 to test the applicability of the model to ambient temperature.

The forecast days selected in Figure 7 belong to Class I generalized weather. Similar to the test results in Figure 6, the measured values at the peak value deviate from the predicted values to a higher degree than those at the waist and bottom, but the measured values are all within the confidence interval of 95%, which shows that the model is very sensitive to the output value with large fluctuation.

To sum up, under different weather types, ambient temperatures, predicted output amplitude, and step size, the proposed general Gaussian mixture model can accurately describe the distribution of short-term PV power output forecast error, and the model has strong applicability. In addition, according to the weather conditions on the forecast day, the model can give the error bands under different confidence levels of PV short-term forecast power in advance.

## 6. Conclusion

Accurate description of wind and solar output uncertainty is the basis of establishing stochastic optimal dispatching model of power system with wind and solar power sources. In order to describe the short-term forecast error of photovoltaic power generation relatively accurately, a short-

term forecast error model of photovoltaic power generation output considering meteorological factors and numerical characteristics is established in this paper, and a general Gaussian mixture model is proposed to describe the short-term forecast error of photovoltaic power generation. The model considers the influence of different meteorological conditions on the forecast error and combines numerical characteristics for analysis. Finally, taking the photovoltaic power generation system in Brussels area as an example, the effectiveness of this method is verified, and the main conclusions are as follows:

- (1) The short-term PV power forecast error is affected by three weather factors: weather type, temperature difference, and maximum temperature, and is also related to the output amplitude and climbing power at the predicted time
- (2) The general Gaussian mixture model proposed in this paper can flexibly change the weight coefficient of each Gaussian probability density, so that it can take into account the requirements of waist flexibility and peak value of distribution curve at the same time, and has obvious advantages in describing the forecast error distribution of short-term photovoltaic power generation output

In this paper, the analysis of the problem is limited by the acquisition of meteorological data. If more detailed and accurate meteorological data are obtained in the future, we can further analyze the influence of meteorological factors on the forecast error at every moment in the day and establish a more comprehensive error model in order to narrow the confidence interval and obtain more accurate results.

## Data Availability

The data used to support the findings of this study are included within the article.

## Conflicts of Interest

The authors declare that they have no conflicts of interest.

This paper proposes and demonstrates a single-line discontinuous track recognition system by associating the track recognition problem of a humanoid robot with the lane detection problem. The proposal enables the robot to achieve stable running on the single-line discontinuous track. The system consists of two parts: the robot end and the graphics computing end. The robot end is responsible for collecting track information and the graphics computing end is responsible for high-performance computing. These two parts use the TCP for communication. The graphics computing side uses PolyLaneNet lane detection algorithm to train the track image captured from the first perspective of the darwin-op2 robot as the data set. In the inference, the robot end sends the collected tracking images to the graphics calculation end and uses the graphics processor to accelerate the calculation. After obtaining the motion vector, it is transmitted back to the robot end. The robot end parses the motion vector to obtain the motion information of the robot so that the robot can achieve stable running on the single-line discontinuous track. The proposed system realizes the direct recognition of the first perspective image of the robot and avoids the problems of poor stability, inability of identifying curves and discontinuous lines, and other problems in the traditional line detection method. At the same time, this system adopts the method of cooperative work between the PC side and the robot by deploying the algorithm with high computational requirements on the PC side. The data transmission is carried out by stable TCP communication, which makes it possible for the robot equipped with weak computational controllers to use deep-learning-related algorithms. It also provides ideas and solutions for deploying deep-learning-related algorithms on similar low computational robots.

## 1. Introduction

The humanoid robot track and field project mainly requires the robot to reach the end point in the shortest time through various trajectories without human control. The evaluation criteria mainly include the passing time of the robot, the correct movement along the trajectory direction, and the recognition effect of obstacles on the trajectory. Common track and field runways are single continuous line and curve, double continuous line and curve, single discontinuous line and curve, double discontinuous line and curve, etc. Some tracks also include up and down slopes, up and down stairs, obstacles, crossroads, and other elements, which greatly tests the comprehensive technical level of robots and their teams. Our design focuses on identifying

single continuous and discontinuous trajectories captured by first-person robots. In essence, the track recognition of humanoid robot in track and field competition is mainly to identify one or several lines in the picture captured by the first person of the robot. These lines have different colours, continuous state, intersection, and other characteristics, which play a guiding role in the movement of robots, similar to the track line of human track and field competition and the lane line of vehicles driving on the road. The robot uses various algorithms to identify the track and obtains the offset position and guiding direction of different forms of track. Then, the postprocessing analysis is carried out on the offset position and orientation direction of the trajectory to determine the motion direction of the robot at the next moment, using a fixed step to modify the

lateral offset of the movement or directly providing a direction vector.

There are many kinds of track recognition algorithms for humanoid robot track and field competitions. The simplest algorithm is the recognition method based on photoelectric sensor, which uses the colour difference between the track line colour and the track bottom colour to identify. Some of the complex algorithms are various visual algorithms based on cameras. The camera deployed on the robot captures the first person or non-first-person real-time images of the robot for recognition, including traditional recognition algorithms such as pixel-by-pixel comparison method, Hough [1] transform method, connected domain recognition method, line segments angles computation [2], and deep learning recognition algorithms [3–14] such as deep convolutional neural network recognition algorithm. In the track and field competition of humanoid robot, single-line or double-line noncontinuous track is often more difficult to identify than continuous track. In order to solve the problem of rapid and accurate recognition of single-line noncontinuous track by robots, this paper comprehensively examines various visual recognition algorithms and nonvisual recognition algorithms, combined with the lane line detection algorithm PolyLaneNet [15]; a deep learning algorithm is deployed on the humanoid robot with low computing power, so that it can accurately identify the track line in the track and field competition of humanoid robot, so as to achieve the effect of high-level competition.

PolyLaneNet algorithm constructs the recognition problem of lines into the task of polynomial formula analysis of lines. Common lanes or racetracks can be resolved as an  $N$ -order polynomial ( $N$  is the natural number). PolyLaneNet first puts the image into the deep convolutional neural network (one of EfficientNet [16, 17], ResNet34 [18], ResNet50, and ResNet101) for feature extraction and then the extracted features are postprocessed to obtain the polynomial formula that can accurately describe the line. It ensures high recognition accuracy and has high computing speed. The PolyLaneNet algorithm was originally used to solve the lane line detection problem. Because the lane line recognition problem in humanoid robot track and field competition is similar to the lane line detection problem and even in most cases it is simpler than the lane line problem (reducing the occlusion of the lane line by the side car, there are many lanes, there are many types of lane lines, and the lane line is thicker and more obvious than the lane line and it is easier to identify), this paper will transplant the PolyLaneNet algorithm with excellent performance in the lane line detection problem to the track recognition problem of humanoid robot track and field competition.

The single-line noncontinuous track recognition system designed in this paper consists of two parts: the robot end and the graphics computing end. The graphics computing end is composed of a computer or GPU (graphics processing unit) server containing an independent graphics computing card. After the robot camera captures the real-time picture, the picture is transmitted to the graphics computing end through TCP (Transmission Control Protocol) communication. The graphics computing end performs

PolyLaneNet algorithm reasoning on the real-time picture received by TCP communication and processes the reasoning results to obtain the direction vector that the robot should move next. The direction vector is transmitted back to the robot through TCP communication. The robot receives the direction vector and controls the steering gear to move. The average speed and recognition stability of darwin-op2 robot in this scene have been significantly improved. Specifically, the darwin-op2 robot runs stably on the track and field track at its own 0.5 times speed (actual 0.12 m/s) and 0.7 times speed (actual 0.15 m/s), which meets the running requirements of the robot on the track and field track. And the robot performed well even at full speed, only occasionally running out of the field. Good performance has been achieved in many experiments and controls.

## 2. Relevant Algorithms

*2.1. Track Line Recognition Algorithms.* In the humanoid robot track and field race, the teams used various methods to identify the track line. The following will introduce several common recognition methods in humanoid robot track and field competition.

To begin with, the first recognition method is based on a photoelectric sensor. The photoelectric sensor has a light intensity receiving terminal, which can convert the received light intensity into an electrical signal with analog value. Due to the difference between the colour of the track line and the background colour of the track in the race, the reflected light intensity is different and the analog value converted into electrical signal is also different. The recognition algorithm based on photoelectric sensor uses the above principle to recognize the track line and distinguishes the track line from the track background by distinguishing different simulation value intervals. The disadvantage of this recognition method is that it is easily affected by the external light intensity environment, the threshold changes greatly, and the generalization ability of different light conditions is weak. It needs to adjust the sensor threshold before each race. And because of the characteristics of the sensor itself, it cannot support the rapid movement of the robot and cannot recognize the discontinuous track.

The second pixel-by-pixel comparison method is based on camera. Firstly, the image captured by the camera is preprocessed by Gaussian filtering, binarization, expansion, and corrosion to get a binarization image, where the track line is white and the background is black or the track line is black and the background is white. Then, the pixels of the binary image are traversed according to a certain rule and the pixel position of the track line in the picture is obtained. The disadvantage of this algorithm is that it is easy to form false recognition to the noise or large area colour block after image preprocessing; also, the recognition effect of discontinuous track is poor.

Furthermore, the connected domain recognition algorithm based on camera is used frequently. Firstly, the image captured by the camera is preprocessed by Gaussian filtering, binarization, expansion, and corrosion to get a binary image. Then, the connected domain of the binary image is identified

and the largest connected domain is the track line. The lateral offset, inclination angle, and other information of the track line can be obtained by calculating the connected domain. The algorithm still cannot eliminate the interference of large area colour block and the recognition effect of discontinuous track is also poor.

The Hough transform algorithm based on camera is also one of recognition methods. The image is preprocessed by Gaussian filtering, edge detection, and binarization. Then, the image is mapped from the Cartesian coordinate system to the polar coordinate system. The algorithm takes the local maximum value, sets the threshold, and filters the noise for each point in the polar coordinate system. Finally, the points in polar coordinate system are transformed back to Cartesian coordinate system, which is the straight line in the original image recognized by the algorithm. This algorithm can identify the interference of discontinuous track, immune noise, and large-area colour blocks and has strong recognition ability for straight lines. However, it is easy to form false detection for long strip interference and has weak recognition ability for curves.

**2.2. Lane Detection Algorithms.** The common methods of track line identification described above all have defects in different aspects. In this paper, we notice that the recognition of track lines in humanoid robot track and field events is essentially to find or fit one or more long lines in an ROI (region of interest) region of the image, which is used to guide the robot to a certain direction. The problem of lane detection in the field of automatic driving is essentially to find or fit the lane in an ROI region of the image, which is used to guide the car to a certain direction. At the same time, the lane detection is similar to the track recognition; there are continuous line and discontinuous line, different degrees of noise interference and occlusion, and real-time problems. Therefore, this paper considers that the problem of track line recognition in humanoid robot track and field events and the problem of lane line detection in automatic driving are essentially the same kind of problems. They are all used to identify one or more lines in the ROI region to guide the direction of movement, which can be solved by the same or similar methods. The problem of lane detection takes the colour picture as the input and the image segmentation examples, some points, or parameters as the output. This paper summarizes some common lane detection methods as follows.

The traditional lane detection algorithm is mainly based on Hough transform and the detection method is the same as the Hough transform detection method mentioned above. In recent years, with the rapid development of deep learning and the continuous success of convolutional neural network in many computers vision tasks, various research teams gradually move the solution of lane detection problem closer to the deep learning method. At present, several commonly used lane detection methods based on deep learning mainly include detection method, grid method, polynomial regression method, and anchor-based detection method.

Detection methods mainly include Lanenet [19], Scnn [20], Sad, and so on. Lanenet algorithm is a classic algorithm and it is widely used in industry. It belongs to instance segmentation algorithm, but its disadvantage is that it relies on clustering and the detection result is unstable. Scnn algorithm is a semantic segmentation algorithm, which uses the method similar to RNN to learn the spatiotemporal information. It defines K lines in advance, makes K classification prediction for each pixel, and finally combines the points with the same results to get the lane lines to be detected, but the disadvantage is that the recognition speed is slow. Sad algorithm is also a segmentation algorithm; its structure is lighter than Scnn algorithm, so the recognition speed is faster than the Scnn algorithm, but the recognition accuracy is relatively low.

The main idea of the gridding method is to turn the pixel problem of the image into a cell problem, which is similar to the idea of downsampling. The recognition speed is faster, but because it is equivalent to reducing the resolution of the image, the recognition accuracy of the algorithm is low.

Polynomial regression method is to fit the lane line into an n-order polynomial (n is a natural number). The speed of recognition is faster, but the disadvantage of the polynomial regression method is that it relies on a priori and has low flexibility in complex scenes

The detection method based on anchor point is similar to the target detection method. Some lines with various angles are defined in advance and their offsets are learned. This detection method also depends on a priori and has low flexibility in complex scenes.

### 3. Algorithm Selection

**3.1. The Original Algorithm.** Before carrying the track line recognition algorithm used in this design, the track line recognition algorithm used by our team is the pixel-by-pixel comparison method based on the camera mentioned above.

First, a camera is used to capture an image of the robot from the first view. Then, the image is transformed from a three-channel colour image to a single-channel grey image and the grey image is binarized according to a certain threshold (the threshold needs to be adjusted manually according to the colour and illumination of the competition venue), so as to change the colour of the track into black and the colour of the track line into white. The transformation process is shown in Figure 1.

Then, the binary image is divided into two regions (the height range of the region is adjustable) and the two regions are compared pixel by pixel to find the track line. After the lateral offsets of the track lines in the upper and lower regions are obtained, the weighted sum of the two lateral offsets and the offset are added based on some decision-making methods. The final offset is the lateral offset that the robot needs to move forward at the next moment.

The specific process of pixel-by-pixel comparison is to traverse the pixels of each region from top to bottom. For each row of pixels, traverse from the middle to both sides. When three consecutive white pixels are encountered, it is the track line that meets white (after binarization). The

FIGURE 1: Image processing by pixel comparison method: original image (a), grey image (b), and binary image (c).

abscissa position of the pixel is recorded and stored in the array. After the end of line-by-line traversal, the abscissa of the white track line found in each line and stored in the array is averaged and then the abscissa of the middle point in the image is subtracted to get the average lateral offset of the current area track. If there is no track in the current area, the lateral offset is 0. The time complexity of this method is  $O(n^2)$ .

The pixel-by-pixel comparison method based on camera has simple logic and short time consumption, but it compares the pixels, only identifies the local, and then combines the results of local recognition to form a global decision. The disadvantage of local recognition is that it is easy to be interfered by noise and large area colour block (as shown in Figure 2). Once there is interference in the picture which is far away from the real track line, the final global decision will be inaccurate. Because of its line-by-line recognition of pixels and small track area (generally speaking, the camera only captures a small part of the track in front of the robot), once it encounters a discontinuous track line, it will not find the track line.

**3.2. The PolyLaneNet Algorithm.** In order to reduce or eliminate the noise and large area colour block interference and realize the recognition of discontinuous track, we need an algorithm to recognize the global information and increase the area of the track captured by the robot first person picture. Common algorithms such as Hoff transform map Cartesian coordinate system to polar coordinate system, reorganize all local information, then carry out local recognition in polar coordinate system and use global information in disguised way, eliminate noise and nonlong bar colour block interference, and realize recognition of discontinuous linear track, but they cannot recognize curve track better. Convolution neural network can recognize local information and global information by using many convolutions check images for several times and extract higher dimension features, which can fully satisfy the interference of noise and large area colour block and can recognize not only discontinuous linear track, but also discontinuous curve track, The ability of anti-jamming is enhanced and the ability of track line recognition is improved. The disadvantage is that the calculation is large and a large amount of data is needed to train the model. After considering several methods mentioned above, this paper finally decides to use the method of deep learning (deep convolution neural network) to identify the track line. The method of deploying the model on PC (personal computer)

and communicating with robot through wireless LAN (local area network) solves the problem that the computer human controller cannot bear the convolution neural network calculation.

The previous paper lists several different principles and effects of lane detection methods based on deep learning. Compared with lane detection in automatic driving, the scene of track line recognition in humanoid robot track and field race is simpler (as shown in Figure 3), but it requires higher real-time performance. Therefore, this paper selects polynomial regression method, which has faster recognition speed and higher recognition accuracy, but higher requirements for scene environment. The PolyLaneNet (lane estimation via deep polynomial regression) algorithm proposed in 2020 is an excellent polynomial regression algorithm in lane detection. The theoretical FPS (frames per second) of the algorithm is up to 115 and the accuracy of the algorithm is up to 93% in TuSimple data set. If it is transplanted to the track line recognition of humanoid robot track and field race, its high FPS can reduce the time cost and improve the real-time performance as much as possible and the simpler scene in the track line recognition also reduces the false detection and missing detection rate of the algorithm and ensures the accuracy of the recognition. Therefore, this paper uses PolyLaneNet algorithm to identify the track line.

## 4. Algorithm Design Based on PolyLaneNet

**4.1. Principle Overview.** In practical application, there are many problems in the recognition of lane line or track line in track and field competition, such as occlusion, wear, discontinuous line, and so on. The shape of the line is thin and long, which leads to sparse supervision signal, which is difficult to detect. At the same time, the task requires high real-time. Based on convolutional neural network, the PolyLaneNet algorithm used in this paper uses ResNet series network or EfficientNet network as backbones to extract features from images. The extracted features pass through a layer of full connection layer to get several one-dimensional vectors; each vector contains the information of the highest point, the lowest point of a line in the graph confidence information and polynomial coefficient information. The algorithm structure is shown in Figure 4.

PolyLaneNet expects as input images taken from a forward-looking vertical camera, and outputs, for each image,  $M_{\max}$  lane marking candidates (represented as polynomials), as well as the vertical position  $h$  of the horizon line, which helps to define the upper limit of the lane

FIGURE 2: Image processing with noise and colour block: original image (a), grey image (b), and binary image (c).

FIGURE 3: Lane detection pending image (a) and track detection pending image (b).

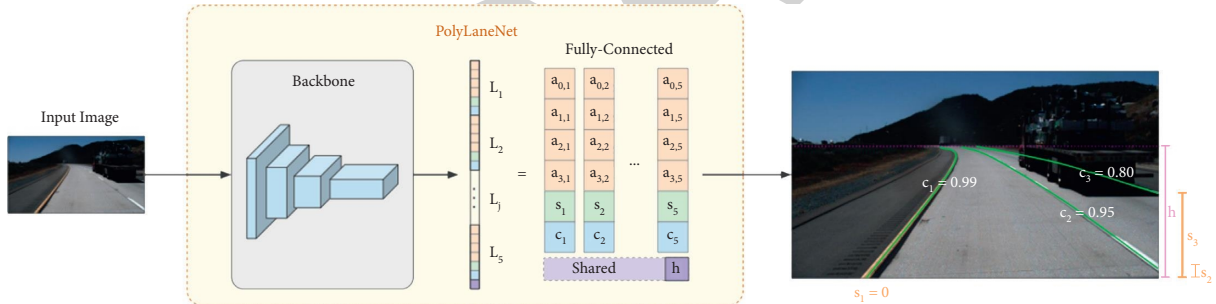

FIGURE 4: PolyLaneNet structure diagram.

markings. The architecture of PolyLaneNet consists of a backbone network (for feature extraction) appended with a fully connected layer with  $M_{\max} + 1$  outputs, being the output  $1, \dots, M_{\max}$  for lane marking prediction and the output  $M_{\max} + 1$  for  $h$ . PolyLaneNet adopts a polynomial representation for the lane markings instead of a set of points. Therefore, for each output  $j, j = 1, \dots, M_{\max}$ , the model estimates the coefficients  $p_j = \{a_{k,j}\}_{k=0}^K = 0$  representing the polynomial, shown as follows:

$$p_j(y) = \sum_{k=0}^K a_{k,j} y^k, \quad (1)$$

where  $K$  is a parameter that defines the order of the polynomial. As illustrated in Figure 4, the polynomials have restricted domain: the height of the image. Besides the coefficients, the PolyLaneNet estimates, for each lane marking  $j$ , the vertical offset  $s_j$ , and the prediction confidence score  $c_j \in [0, 1]$ . In summary, the PolyLaneNet model can be expressed as follows:

$$f(I; \theta) = \left( \{p_j, s_j, c_j\}_{j=1}^{M_{\max}}, h \right), \quad (2)$$

where  $I$  is the input image and  $\theta$  is the model parameters. At inference time, as illustrated in Figure 4, only the lane marking candidates whose confidence score is greater than or equal TO a threshold are considered as detected.

**4.2. Backbone Process.** The original meaning of backbone is human backbone and then extended to the meaning of pillar, core, and so on. Backbone represents the foundation of the whole model in deep learning, because the subsequent tasks such as classification, detection, and generation are based on the extracted features, so in the visual field, backbone is the process of image feature extraction. In the field of machine vision, depth convolution neural network is mainly used to extract image features. Convolution neural network uses convolution check image of specified size to convolute and obtains image texture and other features and then uses these features for various postprocessing. Convolution neural

network uses back propagation, gradient descent, and other methods to learn and update the parameters of convolution kernel and the weight parameters of convolution kernel do not need to be adjusted manually. Due to the strong non-linear modelling ability of neural network, convolutional neural network can solve most problems in many application scenarios. The basic structure of convolutional neural network is shown in Figure 5.

PolyLaneNet algorithm takes ResNet series network or EfficientNet series network as the backbone of the model for feature extraction. ResNet network and EfficientNet network belong to deep convolution neural network. The ResNet series network realizes the deeper development of the network through the “residual unit,” which enables the network to recognize more advanced features. The EfficientNet series network comprehensively improves the depth, width, and resolution of the input image of the network and uses the network structure search method to search the network structure, so as to obtain the results of low resource consumption, high efficiency, and low-cost network with high recognition accuracy.

**4.3. Posttreatment Process.** The input image is transformed into a one-dimensional vector with the length of  $(6 * n + 1)$  after feature extraction by the depth convolution neural network in the backbone. We transform it into a two-dimensional feature of  $7 * n$  (7 one-dimensional vectors) for output, which contains the information of  $N$  lines. The information of each line includes four polynomial coefficients, one ordinate of the lowest point, one ordinate of the highest point, and one confidence level. After several steps of postprocessing, we need to use an array of points to represent the recognized line.

First of all, we filter out the vector that does not recognize the line (the vector with the confidence of 0) and leave the vector that recognizes the line (because this system does single track identification, only the vector with the highest reliability is retained). Then, we traverse these vectors, extract the vertical axis coordinates of the highest point and the lowest point of each line, construct an array of 100 based on the two vertical coordinates, and divide its height into 100 equal parts. Then, we fit the line according to the four polynomial coefficients and the array with a length of 100 and combine the abscissa calculated with the ordinate divided into 100 parts to form 100 coordinates, which represent the specific shape of the line we fit.

Finally, the decision-making process of the fitted line is carried out. We take the highest point, the middle point, and the lowest point to calculate the weighted difference and get the direction vector which needs to control the robot at the next moment and send it to the robot through TCP communication.

The whole postprocessing flow chart is shown in Figure 6.

## 5. Realization of the Discontinuous Track System

**5.1. System Flow.** Because the computing power of cm740, the core control board of darwin-op2 robot, is not enough to

support PolyLaneNet algorithm for reasoning, the gtx1650 super graphics card on PC is used for model reasoning. The information transmission between robot and PC is supported by wireless LAN.

The single-line discontinuous track recognition system of the whole robot consists of discontinuous track, robot, PC terminal, and a local area network, as shown in Figure 7.

Because the communication between robot and PC requires high stability and UDP (User Datagram Protocol) communication has the problem of packet loss, we choose more stable TCP communication instead of UDP communication.

The whole operation process of the system is as follows:

- (i) The robot and PC handshake in LAN to establish TCP communication.
- (ii) The robot camera captures the single track picture from the first perspective, packages the picture into a socket package, and transmits it to the PC through TCP communication.
- (iii) After receiving the socket packet, the PC transcodes the data into pictures.
- (iv) On the PC side, the transcoded image is put into the PolyLaneNet algorithm for forward reasoning and  $N$  one-dimensional vectors are obtained after feature extraction by backbone.
- (v) The PC end carries on the postprocessing to the  $N$  one-dimensional vectors obtained from the forward reasoning, fits the array which can represent the track line, and extracts the coordinates of the highest point, the middle point, and the lowest point of the track line.
- (vi) The PC end calculates the coordinates of the highest point, middle point, and lowest point of the extracted track line, obtains the direction vector of the track line (that is, the direction vector that the robot needs to move at the next moment), and packages it into a socket package, which is sent to the robot through TCP communication.
- (vii) After receiving the socket packet, the robot transcodes the data into an array vector and transmits the value of the vector to the API that controls the robot to run in the specified direction.
- (viii) At the next moment, the robot camera will continue to capture the single track picture from the first perspective and repeat steps 2–7.

The operation flow chart of the system is shown in Figure 8.

**5.2. Data Set.** In this paper, 3141 images with common floor as the track and 5 cm purple line as the track line are collected and the RGB three channels are rearranged and combined and a data set of 18846 images is obtained. The data set is shown in Figure 9.

On the PC side, the image is first scaled to  $640 * 360$  for saving and the data set is shown in Figure 9. Then, the image is annotated with “Label Me” annotation software. Each

FIGURE 5: Basic structure of convolutional neural network.

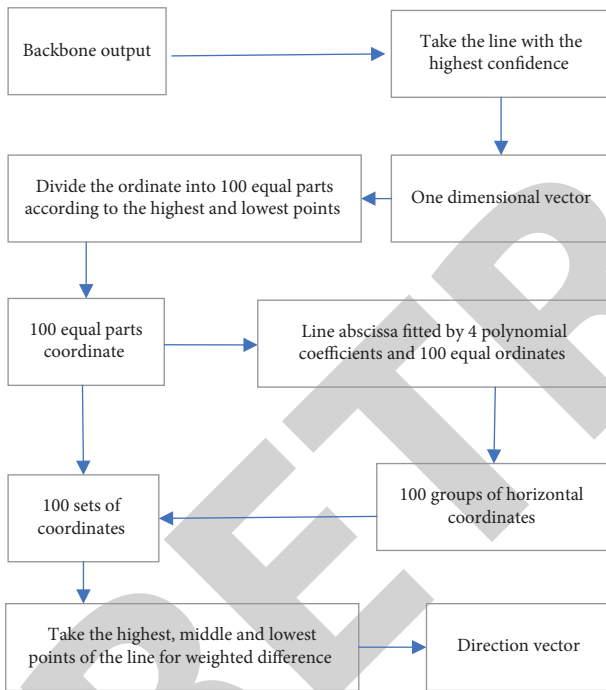

FIGURE 6: Postprocessing flow.

picture is marked with 7 points to represent the track line, as shown in Figure 10.

## 6. Results and Optimization

**6.1. Preliminary Results.** The system is tested on a green track and 5 cm wide white track. In order to ensure the stability of recognition, the half speed of the normal speed (0.24 m/s) of the robot is used to test and the average speed is about 0.11 m/s. The average speed is about 0.14 m/s and the recognition stability is poor. Finally, the normal speed is used to test, the average speed is about 0.15 m/s, and the

recognition stability is very poor. The FPS of the system in three cases is always 6–9. The experimental results are summarized in Table 1.

**6.2. Increasing the FPS of the System.** According to the preliminary results, it can be seen that the FPS of the system is very low, which leads to the slow reaction speed of the robot, resulting in its frequent off track. This problem can be alleviated and solved by reducing the movement speed of the robot and the time consumption in the system program. The generalization ability of the system is poor and the robot can only recognize the green track and white track line. If the colour of the track or track line is changed, the robot cannot recognize it. This problem can be solved by using more data sets for training and normalizing the colour of the screen.

Because the ultimate goal of humanoid robot track and field competition is to reach the destination with the fastest speed and reducing the robot’s movement speed can enhance the stability, but it is contrary to the ultimate goal, this method can cure the symptoms but not the root cause. Therefore, it is necessary to improve the system FPS by reducing the time consumption of the system program. Through the separate detection of the time consumption of each process of the system, it is found that the most time-consuming process is the TCP communication transmission picture part, the postprocessing part of the PC algorithm, and the control part of the robot movement. Because the part that controls the robot’s movement calls the underlying API directly, it cannot be optimized, so this paper attempts to optimize the TCP communication part and the algorithm postprocessing part.

In this paper, the main details of the screen are not lost and the recognition accuracy rate is not affected. Firstly, the image is reduced from 320 \* 240 to 40 \* 22 resolution and then packaged into socket packet for

FIGURE 7: Schematic diagram of track and field competition between the robot and PC.

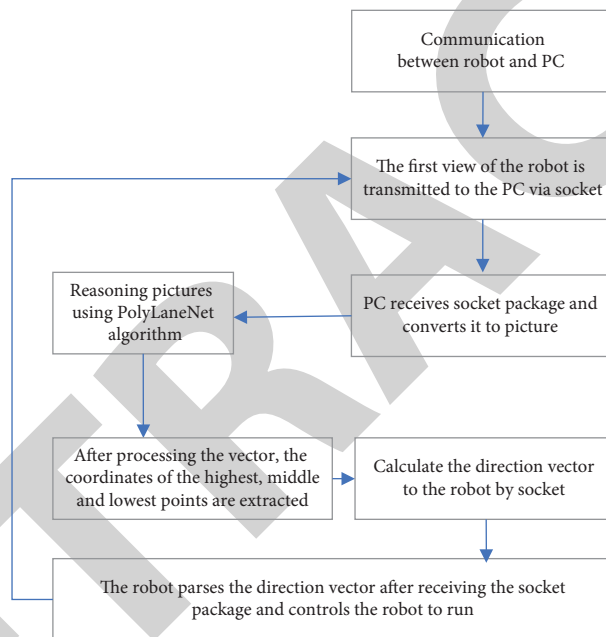

FIGURE 8: System flow chart.

FIGURE 9: Filtered and scaled data set.

transmission. This greatly reduces the amount of data when TCP communication transmits the picture, thus greatly shortening the transmission time. After the image is compressed, the proportion can be reduced by half.

While the main information of the image is retained, the data quantity changes to 0.01146 times of the original, which makes the time consuming of transmission picture greatly reduced.

FIGURE 10: Labeling data sets.

TABLE 1: Summary of experimental results.

Theoretical velocity	Actual average speed	Off track times	FPS
0.5 times speed	0.11 m/s	1	6–9
0.7 times speed	0.14 m/s	3	6–9
1 time speed	0.15 m/s	6	6–9

TABLE 2: Summary of experimental results after system improvement.

Theoretical velocity	Actual average speed	Off-track times	FPS
0.5 times speed	0.11 m/s	0	12–15
0.7 times speed	0.14 m/s	0	12–15
1 time speed	0.15 m/s	1	12–15

The results after system optimization are shown in Table 2.

It can be seen that the average speed, recognition stability, and system FPS of the robot in this scene have been significantly improved, which meets the requirements of the robot running on the track and field track.

## 7. Conclusions

This design uses the method based on deep learning (deep convolution neural network) to detect the single line, curve, continuous, and discontinuous track line in humanoid robot track and field race. It is found that the essence of the track line detection problem in humanoid robot track and field race is the same as that in automatic driving. Therefore, the solution of lane detection in automatic driving is applied to the problem of track detection in humanoid robot track and field events. The high-FPS and high-precision PolyLaneNet model is selected to detect the single track continuous and

discontinuous track lines in track and field events. Thanks to the strong nonlinear modelling ability of deep neural network, the system can recognize the first-person image of robot directly and avoid all kinds of problems in traditional line detection methods (poor stability, unable to recognize curves, discontinuous lines, etc.). However, due to the limited computing power of the cm740 controller of darwin-op2 robot, it is unable to directly carry the deep neural network. Therefore, this system uses the method of working with the robot on the PC side, deploys the PolyLaneNet algorithm with high computing power demand on the PC side, uses the LAN to connect the PC side and the robot, and transmits data through stable TCP communication. It makes it possible for darwin-op2 robot equipped with weak computing power controller to use deep learning correlation algorithm and also provides ideas and solutions for deploying deep learning correlation algorithm on similar low computing power robots.

Subsequently, we will solve the problem of noise in the result vector obtained by the PolyLaneNet algorithm of the picture captured by the camera due to strong jitter during robot running and we can alleviate and solve the problem by using Kalman filter and other methods for the result vector obtained by the PolyLaneNet algorithm. Using dynamic information, Kalman filter can not only filter out the noise caused by picture jitter, but also predict the guidance direction of the track line at the next moment. Theoretically, it can alleviate the noise problem caused by strong picture jitter to a certain extent.

Reducing mineral processing water costs and freshwater consumption is a challenging task in the mineral processing water distribution (MPWD). The work presented in this paper focuses on two aspects of the MPWD optimization model and the MPWD optimization method. To achieve MPWD optimization effectively, a nonlinear constrained multiobjective model is built. The problem is formulated with two objectives of minimizing the mineral processing water costs and maximizing the amount of recycled water. In this paper, an optimization method named enhancing the multiobjective artificial bee colony (EMOABC) algorithm is proposed to solve this model. The EMOABC algorithm uses four strategies to obtain the Pareto-optimal solutions and to achieve the MPWD optimal solutions. With the three benchmark functions, the EMOABC algorithm outperforms the other two widely used algorithms in solving complex multiobjective optimization problems. The EMOABC algorithm is then applied to two cases. Results have shown that the proposed algorithm has the ability to solve the MPWD optimization model. The developed model and the proposed algorithm provide decision support for the actual MPWD problem.

## 1. Introduction

Mineral processing is the process of obtaining the raw materials for smelting and consumes large amounts of water. For water distribution, the decision-makers in mineral processing plants need to make decisions concerning different objectives, such as water costs and freshwater minimization, to maximize the comprehensive benefits of mineral processing plants. The solution to the multiobjective optimization problem often results from both an optimization model and an optimization algorithm. Thus, this paper focuses on solving mineral processing water distribution (MPWD) optimization problems from these two perspectives.

Over the years, many works have examined the water distribution optimization problem and presented many mathematical models and conventional methods such as linear programming [1, 2], nonlinear programming [3], and integer linear programming [4], which have been applied to solve the problem. However, these methods suffer from severe limitations in handling discreteness, nonlinearity,

complex constraints, and local convergence [5]. To overcome the limitations of classical optimization methods, the heuristic methods have been proposed to solve water distribution optimization, such as simulated annealing (SA) algorithms [6, 7], genetic algorithms (GA) [5, 8, 9], differential evolution (DE) algorithms [10–12], particle swarm optimization (PSO) [13–15], ant colony optimization (ACO) [16–18], strength Pareto evolutionary algorithm (SPEA) [19], and shuffled frog leaping algorithm (SFLA) [20, 21]. Despite the success of these heuristic methods in certain aspects, they have not been applied to solve MPWD problems. Currently, MPWD problems are mainly based on manual scheduling. Therefore, building MPWD model and applying heuristic methods to solve the model represent an important issue of our current concern.

Heuristic methods have been widely used in various fields [22–25]. The artificial bee colony (ABC) algorithm is a relatively new heuristic method that has been proven to be an excellent competitor in multiobjective problems [26]. Several multiobjective ABC algorithms (MOABCs) have been proposed for multiobjective problems [27–29].

However, compared to the huge in-depth studies of other heuristic methods, such as nondominated sorting genetic algorithm II (NSGA-II) [30] and multiobjective particle swarm optimization (MOPSO) [31], on multiobjective problems, improving the performance of MOABCs is still a challenge.

MPWD is a complex process in which interrelated factors are multiple. In addition to meeting the total amount of mineral processing water, many factors, such as the flow of the water source, the pressure of the water source, and maximizing the use of recycled water, need to be considered. The traditional linear model is difficult to describe the relationship between these complex factors for MPWD with the above characteristics and cannot treat multiple constraints appropriately.

The purpose of this paper is to build a nonlinear and multiobjective model for MPWD and to develop an MOABC algorithm for solving the MPWD optimization problem. The MPWD optimization model has two objectives: one objective is to minimize mineral processing water costs, and the other objective is to maximize the amount of recycled water. The proposed MOABC algorithm called enhancing multiobjective artificial bee colony (EMOABC) algorithm integrated multiple strategies to improve its performance. Therefore, some of the contributions of this paper are as follows:

- (1) The developed model for MPWD is the nonlinear model that has two objective functions
- (2) The proposed EMOABC algorithm can improve the population diversity and obtain better global convergence

The rest of the paper is organized as follows: In Section 2, the MPWD optimization model is built. Section 3 first gives a review of the basic ABC algorithm and then proposes the EMOABC and presents the results of the EMOABC algorithm compared with other algorithms on three widely used benchmark functions. In Section 4, the implementation of the EMOABC on the MPWD optimization problem is presented. Section 5 outlines the conclusions.

## 2. MPWD Model

According to categories of water source, the mineral processing water can be divided into fresh water, tailings water, clean water, and in-plant water, and they are from rivers and lakes, tailings reservoirs, wastewater treatment plants, and in-plant recycled systems, respectively (Figure 1). The cost of using the tailings water, the clean water, and in-plant water is relatively high for proper treatment and long-distance transmission before entering into the mineral processing plant. Although the cost of using fresh water is very low due to no treatment required, it is important to minimize the use of fresh water for environmental reasons. Mineral processing water becomes wastewater after mineral processing. The MPWD problem in this paper is to optimize two competing objective functions simultaneously, minimizing the mineral processing costs and maximizing the amount of recycled water including tailings water, clean

water, and in-plant water, while satisfying several equality and inequality constraints. Generally, the problem is formulated as follows.

**2.1. Decision Variable.** The vector of the mineral processing water is expressed as  $\mathbf{Q}$ , including the freshwater as  $\mathbf{Q}_1$ , tailings water as  $\mathbf{Q}_2$ , clean water as  $\mathbf{Q}_3$ , and in-plant water as  $\mathbf{Q}_4$ . The mineral processing water except freshwater is called the recycled water. The vector of the recycled water is expressed as  $\mathbf{Q}' = \{\mathbf{Q}'_1 | \mathbf{Q}_2 \cup \mathbf{Q}_3 \cup \mathbf{Q}_4\}$ .  $q_i$  is a flow of the  $i$ th water source;  $a$ ,  $b$ ,  $c$ , and  $n$  are positive integers, and  $n$  is the number of water sources. Decision variables are defined as follows:

$$\begin{aligned} \mathbf{Q} &= (q_1, q_2, \dots, q_n), \\ \mathbf{Q}_1 &= (q_1, q_2, \dots, q_a), \\ \mathbf{Q}_2 &= (q_{a+1}, q_{a+2}, \dots, q_b), \\ \mathbf{Q}_3 &= (q_{b+1}, q_{b+2}, \dots, q_c), \\ \mathbf{Q}_4 &= (q_{c+1}, q_{c+2}, \dots, q_n). \end{aligned} \quad (1)$$

**2.2. Objective Function.** Let  $c_i$  be the cost coefficient of the  $i$ th water source; its meaning is the total power consumption required to lift one meter per unit volume of water. Then the mineral processing water costs in a certain hour are expressed as

$$C(\mathbf{Q}) = \sum_{i=1}^n c_i q_i (100 p_i + h_i), \quad (2)$$

where  $h_i$  is the elevation difference of the  $i$ th water source; the integer 100 is used for unit conversion.  $p_i$  is the pressure of the  $i$ th water source. Equation (2) also can be transformed into

$$C(\mathbf{Q}) = \sum_{i=1}^n c_i q_i [100 f(q_{\text{sum}}, q_i, q_i q_j) + h_i], \quad (3)$$

where  $f(q_{\text{sum}}, q_i, q_i q_j)$  is the macro model of the water supply network. This  $q_{\text{sum}}$  is the total flow of mineral processing water required in the mineral processing plant.

The yields of freshwater are low, but its prices are high. So it is important for cost reduction that the recycled water is used in mineral processing. While the total water consumption of mineral processing is met, the recycled water should be used in mineral processing as much as possible. The amount of the recycled water used in mineral processing can be expressed as

$$M(\mathbf{Q}') = M(q_{a+1}, q_{a+2}, \dots, q_n) = \sum_{i=a+1}^b \alpha_i q_i + \sum_{i=b+1}^c \beta_i q_i + \sum_{i=c+1}^n \chi_i q_i, \quad (4)$$

where  $\alpha$  is the penalty factor of tailings water;  $\beta$  is the penalty factor of clean water; and  $\chi$  is the penalty factor of in-plant water.

2.3. *Constraint Condition.* The sum of the flow from the water source should be equal to the total flow of mineral processing water required in mineral processing:

$$\sum_{i=1}^n q_i = q_{\text{sum}}. \quad (5)$$

Each water source should be between the maximum and minimum water supply capacity:

$$q_i^{\min} \leq q_i \leq q_i^{\max} \quad i = 1, 2, \dots, n, \quad (6)$$

where  $q_i^{\max}$  and  $q_i^{\min}$  are upper and lower limits for the flow of the  $i$ th water source.

To ensure efficient transmission, the output pressure of each water source should be restricted as follows:

$$p_i^{\min} \leq p_i \leq p_i^{\max} \quad i = 1, 2, \dots, n, \quad (7)$$

where  $p_i^{\max}$  and  $p_i^{\min}$  are upper and lower limits for the pressure of the  $i$ th water source. Equation (7) also can be transformed into

$$p_i^{\min} \leq f(q_{\text{sum}}, q_i, q_i q_j) \leq p_i^{\max} \quad i = 1, 2, \dots, n. \quad (8)$$

To ensure the pressure requirements of the mineral processing plant, there should be a lower limit for the pressure at the control point.

$$cp_i \geq cp_i^{\min} \quad i = 1, 2, \dots, n, \quad (9)$$

where  $cp_i$  is the pressure at the control point of the  $i$ th water source;  $cp_i^{\min}$  is lower limit for the pressure at the control point of the  $i$ th water source. Equation (9) also can be transformed into

$$f'(q_{\text{sum}}, q_i) \geq cp_i^{\min}, \quad i = 1, 2, \dots, n, \quad (10)$$

where  $f'(q_{\text{sum}}, q_i)$  is the macro model of the pressure control point.

2.4. *Final Model.* In summary, the water optimization model for the mineral processing plant is a two-objective optimization model and its final model is expressed as follows:

$$\begin{aligned} & \min\{C(Q)\}, \max\{M(Q')\}, \\ & \text{s.t.} \begin{cases} \sum_{i=1}^n q_i = q_{\text{sum}}, \\ q_i^{\min} \leq q_i \leq q_i^{\max}, \quad i = 1, 2, \dots, n, \\ p_i^{\min} \leq f(q_{\text{sum}}, q_i, q_i q_j) \leq p_i^{\max}, \quad i = 1, 2, \dots, n, \\ f'(q_{\text{sum}}, q_i) \leq cp_i^{\min}, \quad i = 1, 2, \dots, n. \end{cases} \end{aligned} \quad (11)$$

### 3. Enhancing Multiobjective Artificial Bee Colony Algorithm

With the above model and constraints, the appropriate optimization algorithm is applied to optimize the MPWD problem. In this study, an EMOABC algorithm was proposed to solve the developed MPWD model.

3.1. *Basic ABC Algorithm.* ABC algorithm is a swarm intelligence optimization method proposed by Karaboga to simulate the process of bees searching for nectar [32]. In the framework of the artificial bee colony algorithm, the location of the food source represents the possible candidate solutions of the problem to be optimized, the number of nectars in the food source represents the fitness (objective function value) corresponding to the candidate solutions, and the size of the bee colony is equal to the number of solutions. The basic structure of the ABC algorithm can be divided into the four following stages.

The first is initial stage, where ABC algorithm randomly generates a matrix  $\mathbf{X} = [x_{ij}]_{N \times D}$ ,  $N$  is the population size and represents the number of candidate solutions, and  $D$  is the number of solution parameters,  $i \in (1, 2, \dots, N)$ ,  $j \in (1, 2, \dots, D)$ .  $D$ -dimensional vector  $\mathbf{X}_i = [x_{i1}, x_{i2}, \dots, x_{iD}]$  is one of the candidate solutions.  $x_{ij}$  are randomly generated by

$$x_{ij} = x_j^{\min} + \text{rand}_j(x_j^{\max} - x_j^{\min}), \quad (12)$$

where  $x_j^{\max}$  and  $x_j^{\min}$  are the upper and lower bound constraints of the  $j$ th variable of  $\mathbf{X}_i$ , respectively, and  $\text{rand}_j$  is a uniformly distributed random number within the range [0, 1].

The second is employed bee stage, where an employed bee is to modify and generate a new candidate solution based on the currently collected information, as well as to calculate its fitness. If the fitness of the new candidate solution is higher than the fitness of the original candidate solution, the new candidate solution replaces the original candidate solution; otherwise, the original candidate solution is retained. After all employed bees complete the search task, they share the information on the location of the food source (candidate solution) and the amount of nectar (fitness) they found with onlooker bees. The new candidate solution is generated by

$$v_{ij} = x_{ij} + \varphi_{ij}(x_{ij} - x_{kj}), \quad (13)$$

where  $k$  and  $j$  are randomly chosen indexes,  $k \neq i$ .  $\varphi_{ij}$  is a random number in the range [-1, 1]. The fitness of a solution can be defined as

$$\text{fit}(X_i) = \begin{cases} \frac{1}{1 + f(X_i)}, & \text{if } f(X_i) > 0, \\ 1 + |f(X_i)|, & \text{if } f(X_i) \leq 0. \end{cases} \quad (14)$$

The third is onlooker bee stage, where onlooker bees assess the fitness of candidate solutions passed from the employed bee and then select food sources based on the probability corresponding to the amount of nectar. In this case, the onlooker bee updates the candidate solution based on the original candidate solution and calculates its fitness; if the fitness of the new candidate solution is higher than the original candidate solution, the new candidate solution replaces the original candidate solution; otherwise, the original candidate solution is retained. The probability of a food source chosen by an onlooker bee can be calculated by

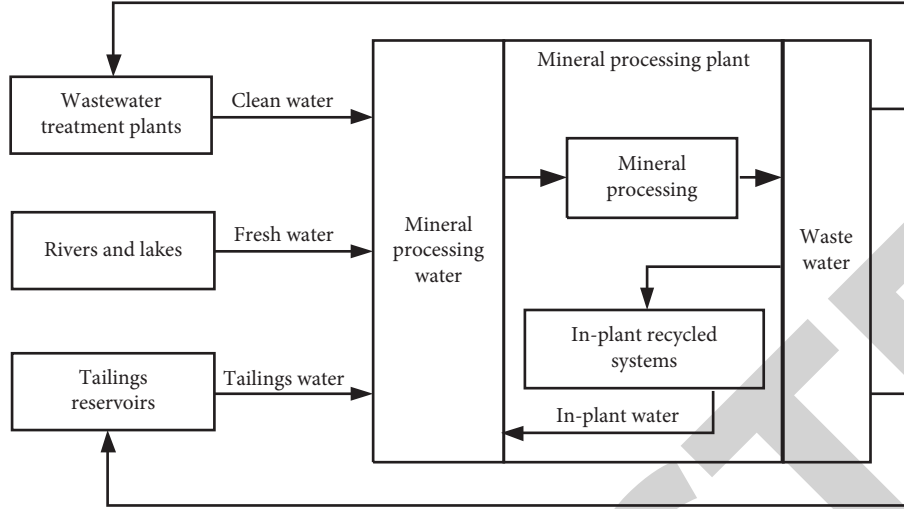

FIGURE 1: The composition of water source in the mineral processing plant.

$$P_i = \frac{\text{fit}(X_i)}{\sum_{i=1}^N \text{fit}(X_i)}. \quad (15)$$

The fourth is scout bee stage; if the nectar of the discovered food source is too inferior to find better solutions several times in a row (“*limit*” is denoted as the maximum number of times), it will be replaced by a new food source that a scout bee randomly found, and then the new food source is generated by (12).

**3.2. Proposed Method.** This section presents a detailed description of the proposed EMOABC algorithm. It can be observed from the literature that this approach to mineral processing water has not yet been extensively explored.

Inspired by the idea of NSGA-II algorithm [30] and DNSPSO algorithm [33], in this paper, the EMOABC is integrated with a series of multiobjective optimization strategies. It includes four important multiobjective strategies: noninferior ranking strategy, Pareto-optimal strategy, crowding distance strategy, and search strategy to evaluate the food source location multiobjectively and select the nondominated solution, so they are presented as follows:

- (1) Noninferior ranking strategy: all individuals in the population that are not dominated by other solutions (noninferior solutions) are defined as rank 1; that is, the virtual fitness of the individual is 1; then these individuals are removed from the population, and new noninferior solutions are identified from the remaining individuals, which are defined as rank 2; that is, the virtual fitness of the individual is 2; the above process is repeated until all individuals in the population have been assigned the corresponding rank. By storing the current solution and all the individuals in the population in a hierarchical manner, the high-performance individuals can have a higher probability of survival and the population rank can be improved rapidly.

- (2) Pareto-optimal strategy: the Pareto set is multiple viable solutions, which can provide multiple viable solutions in the supply of water to the mineral processing plant and can also reduce supply efficiency. Manual Pareto selection suffers from a variety of subjective uncertainties, which can make the selected solution less than optimal.

Define a function  $\eta_i$ , representing the proportion of the  $i$ th objective function value of a solution in the Pareto set that is located along the direction of that objective function in front of the Pareto. The function  $\eta_i$  is expressed as

$$\eta_i = \begin{cases} 1, & V_i \leq V_i^{\min} \\ \frac{V_i^{\max} - V_i}{V_i^{\max} - V_i^{\min}}, & V_i^{\min} \leq V_i \leq V_i^{\max} \\ 0, & V_i \geq V_i^{\max} \end{cases}, \quad (16)$$

where  $V_i^{\max}$  and  $V_i^{\min}$  are the maximum and minimum values of the  $i$ th objective function in the Pareto set, respectively;  $V_i$  is the function value of the  $i$ th objective function. For each noninferior solution  $k$ , the normalized membership function  $\eta^k$  is calculated by the following equation:

$$\eta^k = \frac{\sum_{i=1}^{N_{ob}} \eta_i^k}{\sum_{j=1}^M \sum_{i=1}^{N_{ob}} \eta_i^j}, \quad (17)$$

where  $M$  is the number of noninferior solutions in the Pareto set, and  $N_{ob}$  is the number of objective functions. The larger the value of  $\eta^k$ , the better the performance of  $k$  in coordinating multiple objective functions. Sorting the Pareto set by the  $\eta^k$  value gives a priority sequence of noninferior solutions.

- (3) Crowding distance strategy: the crowding distance is used to estimate how dense a solution is with other solutions around it. For each objective function, the set of noninferior solutions is sorted by the objective function value; then, for each solution  $x$ , the sum of the two sides of the rectangle formed by the solutions  $x+1$  and  $x-1$  is calculated; the final result is the crowding distance  $x_{\text{dist}}$  of the solution  $x$ . The crowding distance of the boundary solution is infinite. When two solutions have the same rank (i.e., the same virtual fitness), the superiority of the two solutions can be compared by the crowding distance. It can be seen that  $x$  individual is superior to  $y$  individual when and only when  $x_{\text{rank}} < y_{\text{rank}}$  or  $x_{\text{rank}} = y_{\text{rank}}$  and  $x_{\text{dist}} > y_{\text{dist}}$ .

- (4) Search strategy: as one of the most representative variants, DNSPSO algorithm is characterized by introducing a global NS operator [33]. Therefore, the search strategy in this paper also adds that operator, and it can be expressed as follows:

$$v_{ij} = r_1 x_{ij} + r_2 x_{\text{best}} + r_3 (x_{aj} - x_{bj}), \quad (18)$$

where  $r_1$ ,  $r_2$ , and  $r_3$  are three mutually exclusive numbers which are randomly chosen from (0, 1), and they have to meet another condition:  $r_1 + r_2 + r_3 = 1$ ;  $x_{\text{best}}$  is the global best solution of the entire population; the indices  $a$  and  $b$  are mutually exclusive integers randomly chosen from (1, 2, ...,  $N$ ), and they are different from the base index  $i$ . It is necessary to point out that  $r_1$ ,  $r_2$ , and  $r_3$  are generated anew in each generation, but they are kept the same for all dimensions in each generation. Once the trial solution is generated, its associated food source has to compete with it for entering the next generation. It implies that the one with a better fitness value has the chance to survive.

Combining the above multiobjective strategies and the ABC algorithm, the basic flow of the EMOABC algorithm is shown in the following:

Step 1: set the number of solution parameters ( $D$ ), the number of populations ( $N$ ), the maximum number of cycles (MNC), and “*limit*” value; randomly generate candidate solutions ( $\mathbf{X} = [x_{ij}]_{N \times D}$ ).

Step 2: calculate the fitness of each objective function, noninferior rank, and the crowding distance.

Step 3: randomly select two solutions and choose the better storage solution. In this way,  $N/2$  better solutions are selected.

Step 4: search in the manner of equation (10) to produce  $N/2$  solution, and if there is a solution beyond the boundary, it is placed on the boundary.

Step 5: identify the better  $N$  solutions from the population of steps 3 and 4 according to noninferior rank and the crowding distance.

Step 6: generate  $N$  new solutions by equation (15), and if there are any solutions beyond the boundary, they are placed on the tenth boundary.

Step 7: select the better  $N$  solutions to form a new population according to noninferior rank and the crowding distance from the solutions in steps 1, 3, and 6.

Step 8: determine if the termination condition is met; if so, output the Pareto front; otherwise, go to step 2.

Step 9: arrange all solutions in the Pareto-optimal set, using equations (13) and (14), and then export a priority list of solutions.

**3.3. Performance of the Proposed Algorithm.** To verify the effectiveness of the EMOABC proposed in this paper, its performance is compared with those of NSGA-II and MOPSO. Convergence and diversity are usually chosen as evaluation criteria, and their specific mathematical expressions can be found in the literature [30, 31]. To ensure the fairness of algorithm testing, the size of the initial population  $N$  is set to 60 and the maximum number of cycles is 1000 for all algorithms on each test function. To achieve the best performance of the other two algorithms, their control parameters were set using the recommended values from the corresponding original literature. For EMOABC, the *limit* was set to  $0.6 \times D \times N$ . To avoid the adverse effect of randomness on algorithm evaluation, each algorithm was run 30 times independently, and the mean value and the standard deviation of convergence and diversity were calculated, and the results of each algorithm for three benchmark functions ZDT1, ZDT2, and ZDT3 are shown in Table 1. Detailed expressions of ZDT1, ZDT2, and ZDT3 can be found in the literature [30]. Three algorithms have been run in MATLAB R2020a on a personal computer with Core 2 Duo 2.13 GHz processor and 4 GB memory.

From Table 1, the best values have been marked in bold. In terms of diversity, compared to other algorithms, the EMOABC algorithm obtained the most uniform Pareto front for each test problem with good distribution characteristics, indicating that the EMOABC algorithm has obvious advantages in distribution characteristics; in terms of convergence, for the ZDT3 problem, the EMOABC algorithm performs slightly worse than the NSGA-II algorithm but better than the MOPSO algorithm. Besides, the standard deviations of convergence and diversity obtained by the EMOABC algorithm are small, indicating that this algorithm is more stable and can almost always converge to the optimal nondominated frontier within the maximum number of cycles, which proves the effectiveness of the EMOABC algorithm to obtain a wider, uniform, and realistic Pareto solution set frontier.

Table 1 cannot completely reflect the results obtained by three algorithms; for this reason, and Figure 2 shows the noninferior optimal solution sets of three benchmark functions obtained by three algorithms.

TABLE 1: The comparable results between EMOABC, NSGA-II, and MOPSO.

Criteria	Algorithm		ZDT1	ZDT2	ZDT3
Convergence	EMOABC	Mean	$3.6239e-3$	$2.2485e-2$	$6.3256e-2$
		Std	$2.3514e-2$	$2.6594e-1$	$2.6585e-3$
	NSGA-II	Mean	$3.9635e-3$	$2.9651e-2$	$5.5883e-2$
		Std	$2.6985e-2$	$2.9985e-1$	$1.4154e-3$
	MOPSO	Mean	$4.1265e-3$	$2.8654e-2$	$7.9562e-2$
		Std	$3.6517e-2$	$3.9914e-1$	$3.1953e-3$
Diversity	EMOABC	Mean	$6.6263e-3$	$5.6156e-2$	$3.6989e-2$
		Std	$4.5696e-4$	$4.2654e-3$	$2.5359e-3$
	NSGA-II	Mean	$3.3659e-2$	$3.4889e-1$	$3.7569e-1$
		Std	$5.6387e-2$	$3.1245e-1$	$3.1245e-2$
	MOPSO	Mean	$6.9159e-2$	$7.6385e-2$	$4.7646e-1$
		Std	$5.4512e-2$	$6.2589e-3$	$3.6632e-2$

As can be seen in Figure 2, the Pareto-optimal solutions of the EMOABC algorithm on ZDT1–3 can approximate the theoretical Pareto-optimal solution of each function very well, which has especially a good distribution. This experimental result once again verifies the effectiveness and advancement of the EMOABC algorithm for the multiobjective optimization problem.

#### 4. Simulation and Discussion

The proposed method has been applied to two cases of mineral processing plants with different water sources and it is compared with MOPSO and NSGA-II to solve this problem. Parameters settings for three algorithms applied to two cases are the same as those set in Section 3.3.

**4.1. Case 1.** Case 1 is that the proposed algorithm is applied to the MPWD model based on mineral processing supplied by four water sources. The parameters about upper and lower limits for Case 1 are shown in Table 2, where 1 represents freshwater, 2 represents tailings water, 3 represents clean water, and 4 represents in-plant water. For recycled water, the lower cost with water source should be used first. In Case 1, since  $c_2 < c_4 < c_3$ , set the penalty factor  $\alpha = 3$ ,  $\beta = 14$ , and  $\chi = 8$ . The macro model, which uses historical data as a sample, is built by a stepwise regression approach [34]. The macro model of the water supply network and the macro model of the pressure control point in Case 1 are given in Tables 3 and 4, respectively. The following macro models (in Tables 3–6) are all simulation models.

To optimize both mineral processing water costs and the amount of recycled water simultaneously, the proposed EMOABC algorithm has been applied in the MPWD model with  $q_{\text{sum}} = 3000$  and  $4000$ . The five best solutions and best  $\eta k$  are summarized in Tables 7 and 8. The higher the value of  $\eta k$  for a solution, the higher the priority of the solution. From Table 7, we can see that  $C(Q)$  in  $S_2$  and  $S_3$  is slightly different, but  $q_1$ – $q_4$  in  $S_2$  and  $S_3$  are completely different. Also, the difference between  $q_1$ – $q_4$  in  $S_2$  and  $S_5$  is not significant, but the difference of  $C(Q)$  in  $S_2$  and  $S_5$  is obvious. The above denotes that a set of optimal solutions are obtained by the proposed EMOABC algorithm. The comparison between Tables 7 and 8 shows that when  $q_{\text{sum}}$  rises

from 3000 to 4000,  $q_1$ ,  $q_2$ ,  $q_3$ , and  $q_4$  increase accordingly, while  $q_3$  generally declines.  $q_2$  increases the most due to its low cost, and the decline in  $q_3$  is due to its high cost. The results of using EMOABC algorithm to schedule the flow of different water sources are consistent with those of manual regulation.

The MPWD model is solved using EMOABC, NSGA-II, and MOPSO. A comparison of the results obtained by three algorithms is shown in Table 9. It is seen that the EMOABC algorithm yields a lower cost of mineral processing water and a higher amount of recycled water (in bold) than the other two algorithms.

From Figure 3, it can be observed that EMOABC can discover a well-distributed and diverse solution set for this problem, while the other two algorithms only find some sparse distributions.

**4.2. Case 2.** Case 2 is that the proposed algorithm is applied to the MPWD model based on mineral processing supplied by six water sources. The parameters about upper and lower limits for Case 2 are shown in Table 10, where 1 represents freshwater no. 1, 2 represents freshwater no. 2, 3 represents tailings water no. 1, 4 represents tailings water no. 2, 5 represents clean water, and 6 represents in-plant water. For recycled water, the water source with a lower cost should be used first. In Case 2, since  $c_3 < c_4 < c_6 < c_5$ , set the penalty factor  $\alpha_1 = 3$ ,  $\alpha_2 = 4$ ,  $\beta = 14$ , and  $\chi = 8$ . The macro model of the water supply network and the macro model of the pressure control point in Case 2 are given in Tables 5 and 6.

In this case,  $C(Q)$  and  $M(Q')$ , two competing objectives, are optimized simultaneously by the EMOABC algorithm, and the five best solutions are shown in Tables 11 and 12. From Tables 11 and 12, the convergence of the solutions in Case 2 is as good as that in Case 1. It is worth noting that as the number of water sources increases, the water selection options are diverse. A comparison of the results obtained by MOPSO, NSGA-II, and EMOABC in Case 2 is shown in Table 13. From Table 13, we can observe that the EMOABC algorithm obtains the optimal solution (in bold) in Case 2 similar to Case 1.

Figure 4 shows the distribution of nondominated solutions obtained by NSGA-II, MOPSO, and EMOABC in Case 2. It is seen from them that EMOABC spreads well

on the optimization problem, the function value obtained by EMOABC is significantly better than that obtained by NSGA-II, and MOPSO and EMOABC can find a better spread and more solutions in the entire Pareto-optimal region than the other two algorithms. It is indicated that the proposed algorithm is more effective than the other

algorithms for solving the MPWD problem. Figures 3 and 4 also show that the two objectives of maximizing the amount of recycled water and minimizing mineral processing water costs conflict. As mineral processing water costs increase, the recycled water consumption decreases, and vice versa.

TABLE 14: Computing time of all algorithms for both cases.

	Computing time (s)		
	EMOABC	NSGA-II	MOPSO
Case 1	58.6	40.2	47.8
Case 2	74.4	59.5	64.7

**4.3. Algorithm Complexity Analysis.** Complexity analysis of the above algorithms was performed using the time response for both cases. The average computation time for all algorithms over 30 runs is given in Table 14. From Table 14, it can be seen that EMOABC takes the most computation time. This can be explained by the fact that the multiple strategies integrated in EMOABC enhance the search capability at the cost of increased computation. In conclusion, EMOABC requires more computation time to achieve better results compared to other algorithms.

## 5. Conclusions

The main goal of this study was to solve the MPWD problem effectively. In this study, an MPWD optimization model was developed to maximize the amount of recycled water and minimize mineral processing water costs, with consideration of various constraints. To solve this multiobjective model, the EMOABC algorithm was proposed as an optimizer derived from the ABC algorithm. This study has shown that the developed model was theoretically valid and reasonable

and could be utilized to provide decision support for actual MPWD. The study has also shown that the proposed algorithm is competent to solve the MPWD problem and is better than NSGA-II and MOPSO in both benchmark functions and cases.

A limitation of this study is that the developed model only has two objectives. The MPWD problem described as a three-objective or even four-objective model may be more realistic. Therefore, building a three-objective or even four-objective model for this MPWD problem is a matter of future work. Meanwhile, continued research of the multiobjective artificial bee colony (MOABC) algorithm is also a focus. In particular, aiming at a three-objective or even four-objective model for this MPWD problem, the concept of multihives bee will be introduced into the ABC algorithm to further improve the performance of the MOABC algorithm.

The intuitionistic fuzzy set (IFS) and bipolar fuzzy set (BFS) are all effective models to describe ambiguous and incomplete cognitive knowledge with membership, non-membership, negative membership, and hesitancy sections. But in daily life problems, there are some situations where we cannot apply the ordinary models of IFS and BFS, separately. Hence, there is a need to combine both the models of IFS and BFS into a single one. A tripolar fuzzy set (TFS) is a generalization of IFS and BFS. In circumstances where BFS and IFS models cannot be used individually, a tripolar fuzzy model is more dependable and efficient. Further, the IFS and BFS models are reduced to corollaries due to the proposed model of TFS. For this purpose in this article, we first consider some novel operations on tripolar fuzzy information. These operations are formulated on the basis of well-known Dombi T-norm and T-conorm, and the desirable properties are discussed. By applying the Dombi operations, arithmetic and geometric aggregation operators of TFS are proposed, and we introduce the concepts of a TF-Dombi weighted average (TFDWA) operator, a TF-Dombi ordered weighted average (TFDOWA) operator, and a TF-Dombi hybrid weighted (TFDHW) operator and explore their fundamental features including idempotency, boundedness, monotonicity, and others. In the second part, we propose TF-Dombi weighted geometric (TFDWG) operator, TF-Dombi ordered weighted geometric (TFDOWG) operator, and TF-Dombi hybrid geometric (TFDHG) operator. The features and specific cases of the mentioned operators are examined. Enterprise resource planning (ERP) is a management and integration approach that organizations employ to manage and develop many aspects of their operations. The study's primary contribution is to employ TFS to create certain decision-making strategies for the selection of optimal ERP systems. The proposed operators are then used to build several techniques for solving multiattribute decision-making (MADM) issues with TF information. Finally, an example of ERP system selection is investigated to demonstrate that the techniques suggested are trustworthy and realistic.

## 1. Introduction

Decision making (DM) is a method of resolving real-world problems by selecting the ideal choice from a range of viable options. MADM is an area of operations research in which the best answer is found after weighing all of the options against a set of criteria. In real life, there are numerous

challenges that are ambiguous and uncertain. To deal with uncertain and ambiguous information, Zadeh developed fuzzy set (FS) theory [1]. The idea of intuitionistic fuzzy set (IFS) developed by Atanassov [2, 3] comprised two degree membership functions, namely, accepting and denying. IFS is a potential generalization of the notion of a FS [1], whose degree component contained only accepting degree.

Decision science is a continuously growing ground in the modern technological era. In the decision process, experts select an optimal alternative under some preference values imposed by the experts in a given finite set of alternatives. Decision-making methods have been used in several areas of modern science, for example, Xu [4] developed the use of IFS in arithmetic aggregation operators (AOPs) and initiated many valuable operators. Afterwards, Xu and Yager [5] developed some geometric AOPs and demonstrated the use of these operators in MADM. Since its inception, the IFS has attracted a lot of interest, including dynamic MADM in the IF setting [6, 7], IF aggregation operators [8–13], IF entropy [14–16], IF generalized Dice similarity measures [16], IF TOPSIS [14–16], and IF gray relational analysis [17–19]. Many generalizations of IFS were developed in the literature after the successful stages of IFS. The bipolar fuzzy set (BFS) [20, 21] was developed to measure the uncertain and cognitive information presented in the form of positive polarity and negative polarity in real-world scenarios. The objects in a universe in BFS are characterized by positive polarity and negative polarity, and the BFS has range of membership in  $[-1, 1]$ . Chen et al. [22] studied an empirical examination of attribute interrelationships that are heterogeneous in a MADM. For MADM, a unique consensus model based on multigranular HFLTSs was established in [23]. In [24], a method was developed and implemented in MADM issues to present a linguistic distribution assessment (LDA) using a hesitant linguistic distribution (HLD). A new strategy for dealing with MCGDM problems with unbalanced HFLTSs was established in [25] taking psychological behaviour of DMs. The notion of a BFS has been employed in many potential areas including bipolar logical reasoning and other set theoretical abstract structures [20], theoretical approach to traditional medicine of China [26], computational psychiatry [27], decision analysis and organizational modeling [28], and quantum computing [29]. Recently, Dombi [30] studied decision methods by developing some arithmetic and geometric AOPs with the help of Dombi operations and BFSs. The topics in fuzzy information aggregation operators are developing rapidly, and many researchers are involved to construct feasible and advanced models to deal with decision processes. In [31], Liu applied Hamacher AOPs in interval-valued IF numbers (IVIFNs) and constructed MAGDM methods. Wang and Garg [32] defined some Pythagorean fuzzy interaction aggregation operators with the aid of Archimedean t-conorm and t-norm (ATT) to aggregate the numbers. Zhang [33] proposed IVIFNs in Frank AOPs and considered the applications in MAGDM. Zhang and Zhang [34] defined Einstein hybrid AOPs for IFNs and applied it to the MADM method.

A new fuzzy extension has just been developed, dubbed tripolar FS (TFS), which is a generalization of IFS and BFS [35]. In instances where IFS and BFS models are difficult to apply, a TF model can be used. In TFS, we consider a triplet of real numbers, namely, the membership, non-membership, and negative membership degrees, which is used to define an object in a TFS. Similar to BFS, the range of membership of the TFS is also  $[-1, 1]$ . A TFS model can easily be applied in situations where IFS and BFS models fail.

Wei [8] developed several novel operations known as Dombi T-norm (DTN) and Dombi T-conorm (DTCN), which have a high potential for parameter variation. Han et al. [26] took advantage by performing Dombi operations on IFSs and developing MAGDM problems utilizing the Dombi Bonferroni mean operator and IF information. Wei et al. [21, 36], in a single-valued neutrosophic environment, constructed a MADM problem utilizing Dombi operations. Lu and Busemeyer [27] defined typhoon disaster assessment using Dombi operations in a HF context. In this paper, we presented various AOPs in a TF environment by using an expanded idea of IFS and BFS. The following points describe the novelty of proposed operators:

- (i) The ability of a TFS is to express IFS and BFS information at once in a single notion called tripolar fuzzy environment which makes it exceptional in literature. The qualitative characteristics of IFS and BFS are combined in a single TFS. As a result, the work is presented in a TFS context to deal with tripolarity type of fuzzy information.
- (ii) The flexibility parameter involved in Dombi operations has the ability to produce more accurate results in a decision process.
- (iii) The proposed model can be applied in situations where the traditional models of IFS and BFS fail.
- (iv) Dombi operations' flexible parameter make it simple to investigate the stability of ranking order of alternatives.
- (v) The score function was crucial in creating a ranking order among the choices in DM situations. By integrating the concepts of IFS and BFS score functions, a new concept of score function is constructed in the proposed study.

The rest of the paper is structured as follows.

The essential ideas of the IFS, BFSs, and TFSs, as well as the operational regulations of TFNs, will be addressed in the next section. In Section 3, we established the TF-Dombi weighted average (TFDWA), TF-Dombi ordered weighted average (TFDOWA), TF-Dombi hybrid average (TFDHA), TF-Dombi weighted geometric (TFDWG), TF-Dombi ordered weighted geometric (TFDOWG), and TF-Dombi hybrid geometric (TFDHG) operators. The peculiarities and specific cases of these operators are also explored. In Section 4, we used these operators to come up with some solutions to the TF MADM challenges. Section 5 examines an illustrated example of ERP system selection. Some remarks are made in Section 6, where we conclude the article.

## 2. Preliminaries

In this section, we review the definitions of IFS, BFS, and TFS extracted from [1–3, 37], and then we construct a novel notion of score and accuracy functions and introduce a new comparison technique for TFS.

*Definition 1* (see [2, 3]). An IFS  $f$  of a non-empty set  $\tilde{X}$  is an object of the form

$$\tilde{f} = \langle \mu_{\tilde{f}}^-, \lambda_{\tilde{f}}^- \rangle = \left\{ \langle x, \mu_{\tilde{f}}^-(x), \lambda_{\tilde{f}}^-(x) \rangle \mid x \in \tilde{X} \right\}, \quad (1)$$

where  $\mu_{\tilde{f}}^-: \tilde{X} \rightarrow [0, 1]$  and  $\lambda_{\tilde{f}}^-: \tilde{X} \rightarrow [0, 1]$  represent the degree of membership and non-membership of an element  $x$  in FS  $\tilde{f}$ , respectively, and  $0 \leq \mu_{\tilde{f}}^-(x) + \lambda_{\tilde{f}}^-(x) \leq 1$  for all  $x \in \tilde{X}$ .

**Definition 2** (see [37]). A BFS  $A$  of a non-empty set  $\tilde{X}$  is an object with a shape

$$\tilde{A} = \langle \mu_{\tilde{A}}^-, \delta_{\tilde{A}}^- \rangle = \left\{ \langle x, \mu_{\tilde{A}}^-(x), \delta_{\tilde{A}}^-(x) \rangle \mid x \in \tilde{X} \right\}, \quad (2)$$

where  $\mu_{\tilde{A}}^-: \tilde{X} \rightarrow [0, 1]$  and  $\delta_{\tilde{A}}^-: \tilde{X} \rightarrow [-1, 0]$  indicate the degree to which an element  $x$  satisfies the associated property to BFS  $\tilde{A}$ , as well as the implicit counter property to BFS  $\tilde{A}$  and

$$-1 \leq \mu_{\tilde{A}}^-(x) + \delta_{\tilde{A}}^-(x) \leq 1, \quad (3)$$

for all  $x \in \tilde{X}$ .

**Definition 3** (see [35]). A TFS  $\tilde{A}$  of a non-empty set  $\tilde{X}$  is an object

$$\tilde{A} = \langle \mu_{\tilde{A}}^-, \lambda_{\tilde{A}}^-, \delta_{\tilde{A}}^- \rangle = \left\{ \langle x, \mu_{\tilde{A}}^-(x), \lambda_{\tilde{A}}^-(x), \delta_{\tilde{A}}^-(x) \rangle \mid x \in \tilde{X} \right\}, \quad (4)$$

where  $\mu_{\tilde{A}}^-: \tilde{X} \rightarrow [0, 1]$ ,  $\lambda_{\tilde{A}}^-: \tilde{X} \rightarrow [0, 1]$  and  $\delta_{\tilde{A}}^-: \tilde{X} \rightarrow [-1, 0]$  such that  $0 \leq \mu_{\tilde{A}}^-(x) + \lambda_{\tilde{A}}^-(x) \leq 1$ . The membership degree  $\mu_{\tilde{A}}^-(x)$  is the amount to which the element  $x$  satisfies the condition to the TFS  $\tilde{A}$ ,  $\lambda_{\tilde{A}}^-(x)$  characterizes the extent that the element  $x$  satisfies to the irrelevant property corresponding to tripolar FS  $\tilde{A}$ , and  $\delta_{\tilde{A}}^-(x)$  characterizes the extent that  $x$  satisfies to the implicit counter property of TF set  $\tilde{A}$ . For simplicity, we denote by  $-t = \langle \mu, \lambda, \delta \rangle$  a TFS and call it a TFN.

**Remark 1.** In Definition 3, for a TFS  $-t = \langle \mu, \lambda, \delta \rangle$ , if  $\delta = 0$ , then, it reduces to an IFS  $-t = \langle \mu, \lambda \rangle$ , and if  $\lambda = 0$ , it reduces to a BFS,  $-t = \langle \mu, \delta \rangle$ .

In order to rank TFNs, we need to define the score and accuracy functions.

**Definition 4.** The score function  $\odot(-t)$  of a TFN,  $-t = \langle \mu, \lambda, \delta \rangle$ , is defined as follows:

$$\odot(-t) = \frac{1 + \mu + \lambda + \delta}{3}, \odot(-t) \in [0, 1]. \quad (5)$$

**Definition 5.** The accuracy function  $ac(-t)$  of a TFN  $-t = \langle \mu, \lambda, \delta \rangle$  is evaluated as follows:

$$ac(-t) = \frac{\mu - \delta}{2}, \quad ac(-t) \in [0, 1]. \quad (6)$$

Note that  $ac(-t)$  measures the degree of accuracy of  $-t = \langle \mu, \lambda, \delta \rangle$ . Largest value of  $ac(-t)$  shows that the TFN,  $-t = \langle \mu, \lambda, \delta \rangle$ , is more accurate. In the following, we create an

ordered relationship between two TFNs,  $-t_1 = (\mu_1, \lambda_1, \delta_1)$  and  $-t_2 = (\mu_2, \lambda_2, \delta_2)$ , using  $sc(-t)$  and  $ac(-t)$ .

**Definition 6.** If  $\odot(-t_1) < \odot(-t_2)$  or  $\odot(-t_1) = \odot(-t_2)$  but  $ac(-t_1) < ac(-t_2)$ , then  $-t_1$  is less than  $-t_2$  referred to as  $-t_1 < -t_2$ ; if  $\odot(-t_1) = \odot(-t_2)$  and  $ac(-t_1) < ac(-t_2)$ , then  $-t_1 = -t_2$ .

The following are some basic TFN operations.

**Definition 7.** Let  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, 2$ ), and  $-t = (\mu, \lambda, \delta)$  be any three TFNs and  $\kappa > 0$ ; then, we have

- (i)  $-t_1 \oplus -t_2 = (\mu_1 + \mu_2 - \mu_1 \mu_2, \lambda_1 \lambda_2, -|\delta_1| |\delta_2|)$ .
- (ii)  $-t_1 \otimes -t_2 = (\mu_1 \mu_2, \lambda_1 + \lambda_2 - \lambda_1 \lambda_2, \delta_1 + \delta_2 - \delta_1 \delta_2)$ .
- (iii)  $\kappa(-t) = (1 - (1 - \mu)^\kappa, \lambda^\kappa, -|\delta|^\kappa)$ .
- (iv)  $(-t)^\kappa = (\mu^\kappa, 1 - (1 - \lambda)^\kappa, -1 + |1 + \delta|^\kappa)$ .
- (v)  $(-t)^c = (\lambda, \mu, |\delta| - 1)$ .
- (vi)  $-t_1 \subseteq -t_2$  if and only if  $\mu_1 \leq \mu_2$ ,  $\lambda_1 \leq \lambda_2$  and  $\delta_1 \geq \delta_2$ .
- (vii)  $-t_1 \cup -t_2 = (\max\{\mu_1, \mu_2\}, \min\{\lambda_1, \lambda_2\}, \min\{\delta_1, \delta_2\})$ .
- (viii)  $-t_1 \cap -t_2 = (\min\{\mu_1, \mu_2\}, \max\{\lambda_1, \lambda_2\}, \max\{\delta_1, \delta_2\})$ .

We may simply obtain the following operations from Definition 7.

**Theorem 1.** Let  $-t_j = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, 2$ ), and  $-t = (\mu, \lambda, \delta)$  be any three TFNs and  $\kappa, \kappa_1, \kappa_2 > 0$ ; then,

- (1)  $-t_1 \oplus -t_2 = -t_2 \oplus -t_1$ .
- (2)  $-t_1 \otimes -t_2 = -t_2 \otimes -t_1$ .
- (3)  $\kappa(-t_1 \oplus -t_2) = \kappa(-t_1) \oplus \kappa(-t_2)$ .
- (4)  $(-t_1 \otimes -t_2)^\kappa = (-t_1)^\kappa \otimes (-t_2)^\kappa$ .
- (5)  $\kappa_1 - t \oplus \kappa_2 - t = (\kappa_1 + \kappa_2) - t$ .
- (6)  $(-t)^{\kappa_1} \otimes (-t)^{\kappa_2} = (-t)^{\kappa_1 + \kappa_2}$ .
- (7)  $((-t)^{\kappa_1})^{\kappa_2} = (-t)^{\kappa_1 \kappa_2}$ .

*Dombi product and Dombi sum are special cases of triangle norms and conorms, which are defined further below.*

**Definition 8** (Dombi [38]). Assume that  $\alpha$  and  $\beta$  can be any two real numbers. The following formulas define Dombi T-norms and T-conorms.

$$\text{Dombi}(\alpha, \beta) = \frac{1}{1 + \left\{ (1 - \alpha/\alpha)^\Re + (1 - \beta/\beta)^\Re \right\}^{(1/\Re)}}, \quad (7)$$

$$\text{Dombi}^c(\alpha, \beta) = 1 - \frac{1}{1 + \left\{ (\alpha/1 - \alpha)^\Re + (\beta/1 - \beta)^\Re \right\}^{(1/\Re)}}, \quad (8)$$

where  $\Re \geq 1$  and  $(\alpha, \beta) \in [0, 1] \times [0, 1]$ .

**2.1. TF-Dombi Operations.** In light of DTN and DTCN, we use TFNs to clarify Dombi operations in this section. On the basis of Dombi operations, we will suggest some TFN operating laws.

**Definition 9.** Let  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, 2$ ), be TFNs and  $\mathfrak{R} \geq 1$  and  $\kappa > 0$ ; then, the D T-norm and T-conorm operations of TFNs are introduced as follows:

- (i)  $-t_1 \oplus -t_2 = (1 - \frac{(\mu_1/1 - \mu_1)^{\mathfrak{R}} + (\mu_2/1 - \mu_2)^{\mathfrak{R}}}{(1/1 + \{(\mu_1/1 - \mu_1)^{\mathfrak{R}} + (\mu_2/1 - \mu_2)^{\mathfrak{R}}\}^{(1/\mathfrak{R})})}, \frac{(1/1 + \{(1 - \lambda_1/\lambda_1)^{\mathfrak{R}} + (1 - \lambda_2/\lambda_2)^{\mathfrak{R}}\}^{(1/\mathfrak{R})})}{(-1/1 + \{(\delta_1 + 1/|\delta_1|)^{\mathfrak{R}} + (\delta_2 + 1/|\delta_2|)^{\mathfrak{R}}\}^{(1/\mathfrak{R})})})$ .
- (ii)  $-t_1 \otimes -t_2 = (\frac{(1/1 + \{(1 - \mu_1/\mu_1)^{\mathfrak{R}} + (1 - \mu_2/\mu_2)^{\mathfrak{R}}\}^{(1/\mathfrak{R})})}{\mathfrak{R}\}^{(1/\mathfrak{R})}), 1 - \frac{(1/1 + \{(\lambda_1/1 - \lambda_1)^{\mathfrak{R}} + (\lambda_2/1 - \lambda_2)^{\mathfrak{R}}\}^{(1/\mathfrak{R})})}{-1 + (1/1 + \{(|\delta_1|/\delta_1 + 1)^{\mathfrak{R}} + (|\delta_2|/\delta_2 + 1)^{\mathfrak{R}}\}^{(1/\mathfrak{R})})})$ .
- (iii)  $\kappa(-t_1) = (1 - \frac{(1/1 + \{\kappa(\mu_1/1 - \mu_1)^{\mathfrak{R}}\}^{(1/\mathfrak{R})})}{+ \{\kappa(1 - \lambda_1/\lambda_1)^{\mathfrak{R}}\}^{(1/\mathfrak{R})}}, (-1/1 + \frac{\kappa(\delta_1 + 1/|\delta_1|)^{\mathfrak{R}}}{\mathfrak{R}\}^{(1/\mathfrak{R})})$ .
- (iv)  $(-t_1)^\kappa = (\frac{(1/1 + \{\kappa(1 - \mu_1/\mu_1)^{\mathfrak{R}}\}^{(1/\mathfrak{R})})}{\mathfrak{R}\}^{(1/\mathfrak{R})}), 1 - \frac{(1/1 + \{\kappa(\lambda_1/1 - \lambda_1)^{\mathfrak{R}}\}^{(1/\mathfrak{R})})}{-1 + (1/1 + \{\kappa(|\delta_1|/\delta_1 + 1)^{\mathfrak{R}}\}^{(1/\mathfrak{R})})})$ .

**2.2. TF Dombi Averaging AOs.** In this section, we create and examine the basic features of the TF-Dombi weighted averaging (TFDWA) operator, TF-Dombi ordered weighted averaging (TFDOWA) operator, and TF-Dombi hybrid weight averaging (TFDHWa) operator, which are all arithmetic aggregation operators using TFNs.

**Definition 10.** Let  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, \dots, p$ ), be a collection of TFNs. Then, the TF-Dombi TFDWA operator is a mapping TFDWA:  $-t^n \rightarrow -t$  such that

$$\text{TFDWA}_\Phi(-t_1, -t_2, \dots, -t_p) = \bigoplus_{r=1}^p (\Phi_r - t_r), \quad (9)$$

where  $\Phi = (\Phi_1, \Phi_2, \dots, \Phi_p)^T$  is the weight vector of  $-t_r$ , ( $r = 1, \dots, p$ ) with the conditions  $\Phi_r > 0$  and  $\bigoplus_{r=1}^p \Phi_r = 1$ .

**Remark 2.** In Definition 10, the collection of TFNs  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, \dots, p$ ), we have

- (i) If  $\delta_r = 0$ , for all  $r$ ,  $1 \leq r \leq p$ , then the family of TFNs,  $-t_r$ , ( $r = 1, \dots, p$ ), reduces to a family of IFNs,  $-t_r = (\mu_r, \lambda_r)$ , ( $r = 1, \dots, p$ ).
- (ii) If  $\lambda_r = 0$ , for all  $r$ ,  $1 \leq r \leq p$ , then the family of TFNs,  $-t_r$ , ( $r = 1, \dots, p$ ), reduces to a family of BFNs,  $-t_r = (\mu_r, \delta_r)$ , ( $r = 1, \dots, p$ ).

In the theorem mentioned below, we use the Dombi operation on TFNs and develop TFDWA operator for the aggregation of TFNs.

**Theorem 2.** Let  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, \dots, p$ ), be a family of TFNs; then, the aggregated value of this family by using the TFDWA operator is also a TFN, and

$$\begin{aligned} & \text{TFDWA}_\Phi(-t_1, -t_2, \dots, -t_p) \\ &= \bigoplus_{r=1}^p (\Phi_r - t_r) = \left( \frac{1 - \frac{1}{1 + \{\bigoplus_{r=1}^p \Phi_r (\mu_r/1 - \mu_r)^{\mathfrak{R}}\}^{(1/\mathfrak{R})}}, \frac{1}{1 + \{\bigoplus_{r=1}^p \Phi_r (1 - \lambda_r/\lambda_r)^{\mathfrak{R}}\}^{(1/\mathfrak{R})}}}{-1} \right. \\ & \left. \frac{-1}{1 + \{\bigoplus_{r=1}^p \Phi_r (1 + \delta_r/|\delta_r|)^{\mathfrak{R}}\}^{(1/\mathfrak{R})}} \right), \end{aligned} \quad (10)$$

where  $\Phi = (\Phi_1, \Phi_2, \dots, \Phi_p)^T$  is the weight vector of  $-t_r$ , ( $r = 1, \dots, p$ ) with  $\Phi_r > 0$  and  $\bigoplus_{r=1}^p \Phi_r = 1$ .

*Proof.* The mathematical induction approach can be used to prove this theorem. Thus,

- (i) When  $p = 2$ , based on TFNs' Dombi operation, as defined in Definition 9, we obtain

$$\text{TFDWA}_\Phi(-t_1, -t_2) = \Phi_1 - t_1 \oplus \Phi_2 - t_2 = \Phi_1 (\mu_1, \lambda_1, \delta_1) \oplus \Phi_2 (\mu_2, \lambda_2, \delta_2). \quad (11)$$

For the RHS of equation (10), we have

$$\begin{aligned}
 & \left( \frac{1 - \frac{1}{1 + \{\Phi_1(\mu_1/1 - \mu_1)^{\Re} + \Phi_2(\mu_2/1 - \mu_2)^{\Re}\}^{(1/\Re)}}}}{1 + \{\Phi_1(1 - \lambda_1/\lambda_1)^{\Re} + \Phi_2(1 - \lambda_2/\lambda_2)^{\Re}\}^{(1/\Re)}}}, \frac{1}{1 + \{\Phi_1(1 - \lambda_1/\lambda_1)^{\Re} + \Phi_2(1 - \lambda_2/\lambda_2)^{\Re}\}^{(1/\Re)}}} \right) \\
 & \left( \frac{-1}{1 + \{\Phi_1(1 + \delta_1/|\delta_1|)^{\Re} + \Phi_2(1 + \delta_2/|\delta_2|)^{\Re}\}^{(1/\Re)}}} \right) \\
 & = \left( \frac{1 - \frac{1}{1 + \{\sum_{r=1}^2 \Phi_r(\mu_r/1 - \mu_r)^{\Re}\}^{(1/\Re)}}}}{1 + \{\sum_{r=1}^2 \Phi_r(1 - \lambda_r/\lambda_r)^{\Re}\}^{(1/\Re)}}}, \frac{1}{1 + \{\sum_{r=1}^2 \Phi_r(1 - \lambda_r/\lambda_r)^{\Re}\}^{(1/\Re)}}} \right) \\
 & \left( \frac{-1}{1 + \{\sum_{r=1}^2 \Phi_r(1 + \delta_r/|\delta_r|)^{\Re}\}^{(1/\Re)}}} \right).
 \end{aligned} \tag{12}$$

Thus, equation (9) holds for  $p = 2$ .

(ii) Assume that equation (9) holds for  $p = k$ , where  $k \in \mathbb{N}$  (set of natural numbers); then, equation (9) becomes

$$\begin{aligned}
 & \text{TFDWA}_{\Phi}(\xi_1, \xi_2, \dots, \xi_k) \\
 & = \bigoplus_{r=1}^k (\Phi_r - t_r) = \left( \frac{1 - \frac{1}{1 + \{\sum_{r=1}^k \Phi_r(\mu_r/1 - \mu_r)^{\Re}\}^{(1/\Re)}}}}{1 + \{\sum_{r=1}^k \Phi_r(1 - \lambda_r/\lambda_r)^{\Re}\}^{(1/\Re)}}}, \frac{1}{1 + \{\sum_{r=1}^k \Phi_r(1 - \lambda_r/\lambda_r)^{\Re}\}^{(1/\Re)}}} \right) \\
 & \left( \frac{-1}{1 + \{\sum_{r=1}^k \Phi_r(1 + \delta_r/|\delta_r|)^{\Re}\}^{(1/\Re)}}} \right).
 \end{aligned} \tag{13}$$

Now for  $p = k + 1$ , we have the following equation.

$$\begin{aligned}
 & \text{TFDWA}_{\Phi}(-t_1, -t_2, \dots, -t_k, -t_{k+1}) \\
 & = \bigoplus_{r=1}^k (\Phi_r - t_r) \oplus (\Phi_{k+1} - t_{k+1}) \\
 & = \left( \frac{1 - \frac{1}{1 + \{\sum_{r=1}^k \Phi_r(\mu_r/1 - \mu_r)^{\Re}\}^{(1/\Re)}}}}{1 + \{\sum_{r=1}^k \Phi_r(1 - \lambda_r/\lambda_r)^{\Re}\}^{(1/\Re)}}}, \frac{1}{1 + \{\sum_{r=1}^k \Phi_r(1 - \lambda_r/\lambda_r)^{\Re}\}^{(1/\Re)}}} \right) \\
 & \left( \frac{-1}{1 + \{\sum_{r=1}^k \Phi_r(1 + \delta_r/|\delta_r|)^{\Re}\}^{(1/\Re)}}} \right) \\
 & \oplus \left( \frac{1 - \frac{1}{1 + \{\Phi_{k+1}(\mu_{k+1}/1 - \mu_{k+1})^{\Re}\}^{(1/\Re)}}}}{1 + \{\Phi_{k+1}(1 - \lambda_{k+1}/\lambda_{k+1})^{\Re}\}^{(1/\Re)}}}, \frac{1}{1 + \{\Phi_{k+1}(1 - \lambda_{k+1}/\lambda_{k+1})^{\Re}\}^{(1/\Re)}}} \right) \\
 & \left( \frac{-1}{1 + \{\Phi_{k+1}(1 + \delta_{k+1}/|\delta_{k+1}|)^{\Re}\}^{(1/\Re)}}} \right) \\
 & = \left( \frac{1 - \frac{1}{1 + \{\sum_{r=1}^{k+1} \Phi_r(\mu_r/1 - \mu_r)^{\Re}\}^{(1/\Re)}}}}{1 + \{\sum_{r=1}^{k+1} \Phi_r(1 - \lambda_r/\lambda_r)^{\Re}\}^{(1/\Re)}}}, \frac{1}{1 + \{\sum_{r=1}^{k+1} \Phi_r(1 - \lambda_r/\lambda_r)^{\Re}\}^{(1/\Re)}}} \right) \\
 & \left( \frac{-1}{1 + \{\sum_{r=1}^{k+1} \Phi_r(1 + \delta_r/|\delta_r|)^{\Re}\}^{(1/\Re)}}} \right).
 \end{aligned} \tag{14}$$

Thus, equation (9) is true for  $p = k + 1$ . Therefore, equation (9) is true for any  $p \in \mathbb{N}$ .  $\square$

*Remark 3.* In Theorem 2, as part of a collection of TFNs,  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, \dots, p$ ), if

$$\begin{aligned} & \text{IFDWA}_\Phi(-t_1, -t_2, \dots, -t_p) \\ &= \bigoplus_{r=1}^p (\Phi_r - t_r) = \left( 1 - \frac{1}{1 + \{\bigoplus_{r=1}^p \Phi_r (\mu_r/1 - \mu_r)\}^{\mathfrak{R}} (1/\mathfrak{R})}, \frac{1}{1 + \{\bigoplus_{r=1}^p \Phi_r (1 - \lambda_r/\lambda_r)\}^{\mathfrak{R}} (1/\mathfrak{R})} \right). \end{aligned} \quad (15)$$

(ii) If  $\lambda_r = 0$ , for all  $r$ , then the collection of TFNs,  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , becomes a collection of BFNs,  $-t_r = (\mu_r, \delta_r)$ , ( $r = 1, \dots, p$ ), and the TFDWA

(i)  $\delta_r = 0$ , for all  $r$ , then the collection of TFNs,  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , becomes a collection of IFNs,  $-t_r = (\mu_r, \lambda_r)$ , ( $r = 1, \dots, p$ ), and the TFDWA operator reduces to the IFDWA operator, as shown below.

operator reduces to the BFDWA operator, as given below.

$$\begin{aligned} & \text{BFDWA}_\Phi(-t_1, -t_2, \dots, -t_p) \\ &= \bigoplus_{r=1}^p (\Phi_r - t_r) = \left( 1 - \frac{1}{1 + \{\bigoplus_{r=1}^p \Phi_r (\mu_r/1 - \mu_r)\}^{\mathfrak{R}} (1/\mathfrak{R})}, \frac{-1}{1 + \{\bigoplus_{r=1}^p \Phi_r (1 + \delta_r/|\delta_r|)\}^{\mathfrak{R}} (1/\mathfrak{R})} \right). \end{aligned} \quad (16)$$

The TFDWA operator has a number of essential qualities, which are given below.

**Theorem 3 (idempotency property).** If  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, \dots, p$ ), is a set of TFNs that all have the same value, i.e., if  $-t_r = (\mu_r, \lambda_r, \delta_r) = -t = (\mu, \lambda, \delta)$  for all  $r$ , then

$$\text{TFDWA}_\Phi(-t_1, -t_2, \dots, -t_r) = -t. \quad (17)$$

*Proof.* Since  $-t_r = (\mu_r, \lambda_r, \delta_r) = -t$  ( $r = 1, \dots, p$ ), then by using equation (9), we have

$$\begin{aligned} & \text{TFDWA}_\Phi(-t_1, -t_2, \dots, -t_r) \\ &= \bigoplus_{r=1}^p (\Phi_r - t_r) = \left( \frac{1 - \frac{1}{1 + \{\bigoplus_{r=1}^p \Phi_r (\mu_r/1 - \mu_r)\}^{\mathfrak{R}} (1/\mathfrak{R})}}{1 + \{\bigoplus_{r=1}^p \Phi_r (1 - \lambda_r/\lambda_r)\}^{\mathfrak{R}} (1/\mathfrak{R})}, \frac{-1}{1 + \{\bigoplus_{r=1}^p \Phi_r (1 + \delta_r/|\delta_r|)\}^{\mathfrak{R}} (1/\mathfrak{R})} \right) \\ &= \left( 1 - \frac{1}{1 + \{(\mu/1 - \mu)\}^{\mathfrak{R}} (1/\mathfrak{R})}, \frac{1}{1 + \{(1 - \lambda/\lambda)\}^{\mathfrak{R}} (1/\mathfrak{R})}, \frac{-1}{1 + \{(1 + \delta/|\delta|)\}^{\mathfrak{R}} (1/\mathfrak{R})} \right) \\ &= \left( 1 - \frac{1}{1 + (\mu/1 - \mu)}, \frac{1}{1 + (1 - \lambda/\lambda)}, \frac{-1}{1 + (1 + \delta/|\delta|)} \right) = (\mu, \lambda, \delta). \end{aligned} \quad (18)$$

Thus,  $\text{TFDWA}_\Phi(-t_1, -t_2, \dots, -t_r) = t$ .

In a similar manner, we can verify the following properties of the TFDWA operator.  $\square$

**Theorem 4 (boundedness property).** Let  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, 2, \dots, p$ ), be a family of TFNs, and  $-t^- = \min\{-t_r\}$  and  $-t^+ = \max\{-t_r\}$ . Then,

$$-t^- \leq \text{TFDWA}_\Phi(-t_1, -t_2, \dots, -t_p) \leq -t^+. \quad (19)$$

**Theorem 5 (monotonicity property).** If  $-t_r = (\mu_r, \lambda_r, \delta_r)$ ,  $(r = 1, \dots, p)$ , and  $-t'_r = (\mu'_r, \lambda'_r, \delta'_r)$ ,  $(r = 1, 2, \dots, p)$ , are the families of TFNs, such that  $-t_r \leq -t'_r$  for all  $r$ , then

$$\text{TFDWA}_\Phi(-t_1, -t_2, \dots, -t_p) \leq \text{TFDWA}_\Phi(-t'_1, -t'_2, \dots, -t'_p). \quad (20)$$

Now we will go through the fundamental features of the TFDWA operator.

**Definition 11.** Let  $-t_r = (\mu_r, \lambda_r, \delta_r)$ ,  $(r = 1, \dots, p)$ , be a collection of TFNs. A TFDWA operator of dimension  $p$  is a mapping  $\text{TFDWA}_\omega: -t^p \rightarrow t$  with an associated weight

vector  $\omega = (\omega_1, \omega_2, \dots, \omega_p)^T$  such that  $\omega_r > 0$ , and  $\oplus_{r=1}^p \omega_r = 1$ . Therefore,

$$\text{TFDWA}_\Phi(-t_1, -t_2, \dots, -t_p) = \oplus_{r=1}^p (\Phi_r - t_{r(\sigma)}), \quad (21)$$

where  $(\sigma(1), \sigma(2), \dots, \sigma(p))$  are the permutations of  $\sigma(r)$   $(r = 1, 2, \dots, p)$  for which  $-t_{\sigma(r-1)} \geq -t_{\sigma(r)}$  for all  $r = 1, 2, \dots, p$ .

The following theorem is a consequence of Definition 10 and Theorem 2.

**Theorem 6.** Let  $-t_r = (\mu_r, \lambda_r, \delta_r)$ ,  $(r = 1, \dots, p)$ , be a family of TFNs. A TFDWA operator of dimension  $p$  is a mapping from  $-t^p$  to  $t$  with the associated weight vector  $\omega = (\omega_1, \omega_2, \dots, \omega_p)^T$  such that  $\omega_r > 0$  and  $\oplus_{r=1}^p \omega_r = 1$ . Then,

$$\begin{aligned} & \text{TFDWA}_\omega(-t_1, -t_2, \dots, -t_p) \\ &= \oplus_{r=1}^p (\Phi_r - t_{r(\sigma)}) = \left( \frac{1 - \frac{1}{1 + \left\{ \oplus_{r=1}^p \omega_r (\mu_{\sigma(r)} / 1 - \mu_{\sigma(r)})^{\Re} \right\}^{(1/\Re)}}}}{1 + \left\{ \oplus_{r=1}^p \omega_r (1 - \lambda_{\sigma(r)} / \lambda_{\sigma(r)})^{\Re} \right\}^{(1/\Re)}}, \frac{1}{1 + \left\{ \oplus_{r=1}^p \omega_r (1 + \delta_{\sigma(r)} / |\delta_{\sigma(r)}|)^{\Re} \right\}^{(1/\Re)}}} \right), \end{aligned} \quad (22)$$

where  $(\sigma(1), \sigma(2), \dots, \sigma(p))$  are the permutations of  $\sigma(r)$   $(r = 1, 2, \dots, p)$  for which  $-t_{\sigma(r-1)} \geq -t_{\sigma(r)}$  for all  $r = 1, 2, \dots, p$ .

**Remark 4.** In Definition 10, the collection of TFNs  $-t_r = (\mu_r, \lambda_r, \delta_r)$ ,  $(r = 1, \dots, p)$ , we have

- (i) If  $\delta_r = 0$ , for all  $r$ , then the TFDWA operator decreases to IFDWA operator and

$$\begin{aligned} & \text{IFDWA}_\omega(-t_1, -t_2, \dots, -t_p) \\ &= \oplus_{r=1}^p (\Phi_r - t_{r(\sigma)}) = \left( 1 - \frac{1}{1 + \left\{ \oplus_{r=1}^p \omega_r (\mu_{\sigma(r)} / 1 - \mu_{\sigma(r)})^{\Re} \right\}^{(1/\Re)}}, \frac{1}{1 + \left\{ \oplus_{r=1}^p \omega_r (1 - \lambda_{\sigma(r)} / \lambda_{\sigma(r)})^{\Re} \right\}^{(1/\Re)}}} \right). \end{aligned} \quad (23)$$

- (ii) If  $\lambda_r = 0$ , for all  $r$ , then the TFDWA operator decreases to BFDWA operator and

$$\begin{aligned} & \text{BFDWA}_\omega(-t_1, -t_2, \dots, -t_p) \\ &= \oplus_{r=1}^p (\Phi_r - t_{r(\sigma)}) = \left( 1 - \frac{1}{1 + \left\{ \oplus_{r=1}^p \omega_r (\mu_{\sigma(r)} / 1 - \mu_{\sigma(r)})^{\Re} \right\}^{(1/\Re)}}, \frac{1}{1 + \left\{ \oplus_{r=1}^p \omega_r (1 + \delta_{\sigma(r)} / |\delta_{\sigma(r)}|)^{\Re} \right\}^{(1/\Re)}}} \right). \end{aligned} \quad (24)$$

The following properties of a TFDOWA operator can easily be proved.

(P1) (idempotency property). If  $-t_r = (\mu_r, \lambda_r, \delta_r)$  ( $r = 1, 2, \dots, p$ ) are all equal, i.e.,  $-t_r = -t$  for all  $r$ , then  $\text{TFDOWA}_\omega(-t_1, -t_2, \dots, -t_p) = t$ .

(P2) (boundedness property). Let  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, 2, \dots, p$ ), be a family of TFNs and  $-t^- = \min -t_r$  and  $-t^+ = \max -t_r$ . Then,

$$-t^- \leq \text{TFDOWA}_\omega(-t_1, -t_2, \dots, -t_p) \leq -t^+. \quad (25)$$

(P3) (monotonicity property). If  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, 2, \dots, p$ ), and  $-t'_r = (\mu'_r, \lambda'_r, \delta'_r)$ , ( $r = 1, 2, \dots, p$ ), are two TFNs such that  $-t_r \leq -t'_r$  for all  $r$ , then

$$\text{TFDOWA}_\omega(-t_1, -t_2, \dots, -t_p) \leq \text{TFDOWA}_\omega(-t'_1, -t'_2, \dots, -t'_p). \quad (26)$$

*Definition 12.* A TFDHWA operator of dimension  $p$  is a mapping  $\text{TFDHA}: -t^p \rightarrow t$  with the associated weight vector  $w = (w_1, w_2, \dots, w_p)$  such that  $w_r > 0$  and  $\oplus_{r=1}^p w_r = 1$

and the TFDHWA operator is provided by the following equation:

$$\begin{aligned} & \text{TFDHWA}_{(w, \Phi)}(-t_1, -t_2, \dots, -t_p) \\ &= ((w_1 - t_{\sigma(1)}), (w_2 - t_{\sigma(2)}), \dots, (w_p - t_{\sigma(p)})) \\ &= \left( \frac{1 - \frac{1}{1 + \left\{ \oplus_{r=1}^p w_r (\mu_{\sigma(r)} / 1 - \mu_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}}}}{1 + \left\{ \oplus_{r=1}^p w_r (1 - \lambda_{\sigma(r)} / \lambda_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}}, \frac{1}{1 + \left\{ \oplus_{r=1}^p w_r (1 + \delta_{\sigma(r)} / |\delta_{\sigma(r)}|)^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}} \right), \end{aligned} \quad (27)$$

where  $-t_{\sigma(r)}$  is the  $r^{\text{th}}$  largest WTF number  $-t_r$ , ( $-t_r = p\Phi_r - t_r$ ,  $r = 1, 2, \dots, p$ ) and  $\Phi = (\Phi_1, \Phi_2, \dots, \Phi_p)^T$  is the weight vector of  $-t_r$  with the condition  $\Phi_r > 0$  and  $\oplus_{r=1}^p \Phi_r = 1$ , where  $p$  is the balancing coefficient. Some important properties of (TFDHWA) operator are given below:

(i) When  $w = ((1/p), (1/p), \dots, (1/p))$ , then TFDWA operator is a special case of TFDHA operator.

(ii) When,  $\Phi = ((1/p), (1/p), \dots, (1/p))$ , then TFDOWA operator is a special case of the TFDHWA operator. As a result, we conclude that the TFDHWA operator is a generalization of both the TFDWA and TFDOWA operators.

*Remark 5.* In Definition 12, the collection of TFNs  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, \dots, p$ ), we have

- (i) If  $\delta_r = 0$ , for all  $r$ , then the TFDHWA operator reduces to IFDHWA operator and

$$\begin{aligned}
 & \text{IFDHWA}_{(w,\Phi)}(-t_1, -t_2, \dots, -t_p) \\
 &= ((w_1 - t_{\sigma(1)}), (w_2 - t_{\sigma(2)}), \dots, (w_p - t_{\sigma(p)})) \\
 &= \left( 1 - \frac{1}{1 + \left\{ \oplus_{r=1}^p w_r (\mu_{\sigma(r)}/1 - \mu_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}}, \frac{1}{1 + \left\{ \oplus_{r=1}^p w_r (1 - \lambda_{\sigma(r)}/\lambda_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}} \right).
 \end{aligned} \tag{28}$$

- (ii) If  $\lambda_r = 0$ , for all  $r$ , then the TFDHWA operator reduces to BFDHWA operator and

$$\begin{aligned}
 & \text{BFDHWA}_{(w,\Phi)}(-t_1, -t_2, \dots, -t_p) \\
 &= ((w_1 - t_{\sigma(1)}), (w_2 - t_{\sigma(2)}), \dots, (w_p - t_{\sigma(p)})) \\
 &= \left( 1 - \frac{1}{1 + \left\{ \oplus_{r=1}^p w_r (\mu_{\sigma(r)}/1 - \mu_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}}, \frac{1}{1 + \left\{ \oplus_{r=1}^p w_r (1 + \delta_{\sigma(r)}/|\delta_{\sigma(r)}|)^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}} \right).
 \end{aligned} \tag{29}$$

We now, give an illustrative example for the verification of Definition 13.

*Example 1.* Consider four TFNs,  $-t_1 = (0.5, 0.4, -0.3)$ ,  $-t_2 = (0.6, 0.4, -0.3)$ ,  $-t_3 = (0.7, 0.2, -0.3)$ , and

$-t_4 = (0.2, 0.4, -0.4)$ , and let  $\Phi = (0.20, 0.30, 0.30, 0.20)^T$  be the associated weight vector. Then, by Definition 13, the aggregated value of TFNs for  $\mathfrak{R} = 3$ , and by using the TFDHWA operator, we get

$$\begin{aligned}
 -t_1 &= \left( \frac{1 - \frac{1}{1 + \left\{ 4 \times 0.20 (0.5/1 - 0.5)^3 \right\}^{(1/3)}}, \frac{1}{1 + \left\{ 4 \times 0.20 (1 - 0.4/0.4)^3 \right\}^{(1/3)}}}{\frac{-1}{1 + \left\{ 4 \times 0.20 (1 - 0.3/0.3)^3 \right\}^{(1/3)}}} \right) \\
 &= (0.4814, 0.4179, -0.3158) \\
 -t_2 &= \left( \frac{1 - \frac{1}{1 + \left\{ 4 \times 0.30 (0.6/1 - 0.6)^3 \right\}^{(1/3)}}, \frac{1}{1 + \left\{ 4 \times 0.30 (1 - 0.4/0.4)^3 \right\}^{(1/3)}}}{\frac{-1}{1 + \left\{ 4 \times 0.30 (1 - 0.3/0.3)^3 \right\}^{(1/3)}}} \right) \\
 &= (0.6144, 0.3855, -0.2873)
 \end{aligned}$$

$$\begin{aligned}
-t_3 &= \left( \begin{array}{c} 1 - \frac{1}{1 + \{4 \times 0.30 (0.7/1 - 0.7)^3\}^{(1/3)}} \frac{1}{1 + \{4 \times 0.30 (1 - 0.2/0.2)^3\}^{(1/3)}} \\ \frac{-1}{1 + \{4 \times 0.30 (1 - 0.3/0.3)^3\}^{(1/3)}} \end{array} \right) = (0.7126, 0.1904, -0.2874) - t_4 \\
&= \left( \begin{array}{c} 1 - \frac{1}{1 + \{4 \times 0.20 (0.2/1 - 0.2)^3\}^{(1/3)}} \frac{1}{1 + \{4 \times 0.20 (1 - 0.4/0.4)^3\}^{(1/3)}} \\ \frac{-1}{1 + \{4 \times 0.20 (1 - 0.4/0.4)^3\}^{(1/3)}} \end{array} \right) = (0.1883, 0.4179, -0.4179). \quad (30)
\end{aligned}$$

Scores of  $-t_r$ , ( $r = 1, 2, 3, 4$ ) are calculated as follows:

$$\begin{aligned}
\textcircled{\text{S}}(-t_1) &= (1 + 0.4814 + 0.4179 - 0.3158/3) = 0.5278, \\
\textcircled{\text{S}}(-t_2) &= (1 + 0.6144 + 0.3855 - 0.2873/3) = 0.5708, \\
\textcircled{\text{S}}(-t_3) &= (1 + 0.7126 + 0.1904 - 0.2874/3) = 0.5385, \\
\textcircled{\text{S}}(-t_4) &= (1 + 0.1883 + 0.3179 - 0.4179/3) = 0.3961.
\end{aligned}$$

Since  $\textcircled{\text{S}}(-t_2) > \textcircled{\text{S}}(-t_3) > \textcircled{\text{S}}(-t_1) > \textcircled{\text{S}}(-t_4)$ , then  $-t_{\sigma(1)} = -t_2 = (0.6145, 0.3855, -0.3158)$ ,  $-t_{\sigma(2)} = -t_3 = (0.7126, 0.1904, -0.2874)$ ,  $-t_{\sigma(3)} = -t_1 = (0.6145, 0.3179, -0.2874)$ , and  $-t_{\sigma(4)} = -t_4 = (0.1884, 0.3419, -0.4180)$ . Therefore, by using TFDHWA operator for  $\mathfrak{R} = 3$ , we get

$$\begin{aligned}
&\text{TFDHWA}(-t_{\sigma(1)}, -t_{\sigma(2)}, \dots, -t_{\sigma(4)}) \\
&= \textcircled{\text{S}}_{r=1}^4(\Phi_r - t_{\sigma(r)}) \\
&= \left( \begin{array}{c} 1 - \frac{1}{1 + \left\{ \sum_{r=1}^4 \Phi_r (\mu_{\sigma(r)}/1 - \mu_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}} \frac{1}{1 + \left\{ \sum_{r=1}^4 \Phi_r (1 - \lambda_{\sigma(r)}/\lambda_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}} \\ \frac{-1}{1 + \left\{ \sum_{r=1}^4 \Phi_r (1 + \delta_{\sigma(r)}/|\delta_{\sigma(r)}|)^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}} \end{array} \right) \quad (31) \\
&= \left( \begin{array}{c} 1 - \frac{1}{1 + \{0.2(0.6145/1 - 0.6145)^3 + 0.3(0.7126/1 - 0.7126)^3 + 0.3(0.6145/1 - 0.6145)^3 + 0.2(0.1884/1 - 0.1884)^3\}^{(1/3)}} \\ \frac{1}{1 + \{0.2(1 - 0.3855/0.3855)^3 + 0.3(1 - 0.1904/0.3179)^3 + 0.3(1 - 0.3179/0.3179)^3 + 0.2(1 - 0.3419/0.3419)^3\}^{(1/3)}} \\ \frac{-1}{1 + \{0.2(1 - 0.3158/0.3158)^3 + 0.3(1 - 0.2874/0.2874)^3 + 0.3(1 - 0.2874/0.2874)^3 + 0.2(1 - 0.4180/0.4180)^3\}^{(1/3)}} \end{array} \right) \\
&= (0.1831, 0.1890, -0.2602).
\end{aligned}$$

**2.3. TF Dombi Geometric Aggregation Operators.** In this section, we will propose and examine several Dombi geometric AOs, namely, the TFDWG operator and the TFDOWG operator, utilizing TFNs.

**Definition 13.** Let  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, \dots, p$ ), be a family of TFNs. The TFDWG operator is a representation  $-t^p \rightarrow -t$  such that

$$\text{TFDWG}_{\Phi}(-t_1, -t_2, \dots, -t_p) = \textcircled{\text{S}}_{r=1}^p(-t_r)^{\Phi_r}, \quad (32)$$

where  $\Phi = (\Phi_1, \Phi_2, \dots, \Phi_p)^T$  is the weight vector of  $-t_r$ , ( $r = 1, 2, \dots, p$ ) such that  $\Phi_r > 0$  and  $\sum_{r=1}^p \Phi_r = 1$ .

We can easily derive the following theorem from Definition 14.

**Theorem 7.** Let  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, 2, \dots, p$ ) be a collection of TFNs. Then, the aggregated value of TFNs is again a TFN, and by using TFDWG operator, we obtain

$$\begin{aligned} & \text{TFDWG}_\Phi(-t_1, -t_2, \dots, -t_p) \\ &= \otimes_{r=1}^p (-t_r)^{\Phi_r} = \left( \frac{1}{1 + \{\oplus_{r=1}^p \Phi_r (1 - \mu_r / \mu_r)\}^{\mathfrak{R}} (1/\mathfrak{R})}, 1 - \frac{1}{1 + \{\oplus_{r=1}^p \Phi_r (\lambda_r / 1 - \lambda_r)\}^{\mathfrak{R}} (1/\mathfrak{R})}, \right. \\ & \quad \left. -1 + \frac{1}{1 + \{\oplus_{r=1}^p \Phi_r (|\delta_r| / 1 + \delta_r)\}^{\mathfrak{R}} (1/\mathfrak{R})} \right), \end{aligned} \quad (33)$$

where  $\Phi = (\Phi_1, \Phi_2, \dots, \Phi_p)^T$  is the weight vector of  $-t_r$ , ( $r = 1, 2, \dots, p$ ) such that  $\Phi_r > 0$  and  $\oplus_{r=1}^p \Phi_r = 1$ .

*Proof.* By using mathematical induction, the proof is straightforward.  $\square$

*Remark 6.* In Theorem 7,

(i) If  $\delta_r = 0$ , for all  $r$ , then the (TFDWG) operator reduces to the IFDWG operator, as given below.

$$\begin{aligned} & \text{IFDWG}_\Phi(-t_1, -t_2, \dots, -t_p) \\ &= \otimes_{r=1}^p (-t_r)^{\Phi_r} = \left( \frac{1}{1 + \{\oplus_{r=1}^p \Phi_r (1 - \mu_r / \mu_r)\}^{\mathfrak{R}} (1/\mathfrak{R})}, 1 - \frac{1}{1 + \{\oplus_{r=1}^p \Phi_r (\lambda_r / 1 - \lambda_r)\}^{\mathfrak{R}} (1/\mathfrak{R})} \right). \end{aligned} \quad (34)$$

(ii) If  $\lambda_r = 0$ , for all  $r$ , then the TFDWG operator reduces to the BFDWG operator, as given below.

$$\begin{aligned} & \text{BFDWG}_\Phi(-t_1, -t_2, \dots, -t_p) \\ &= \otimes_{r=1}^p (-t_r)^{\Phi_r} = \left( \frac{1}{1 + \{\oplus_{r=1}^p \Phi_r (1 - \mu_r / \mu_r)\}^{\mathfrak{R}} (1/\mathfrak{R})}, -1 + \frac{1}{1 + \{\oplus_{r=1}^p \Phi_r (|\delta_r| / 1 + \delta_r)\}^{\mathfrak{R}} (1/\mathfrak{R})} \right). \end{aligned} \quad (35)$$

TFDWG operators have some properties which are listed below:

P1 (idempotency property). If  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, \dots, p$ ), is a family of TFNs so that they are all equal, i.e., if  $-t_r = (\mu_r, \lambda_r, \delta_r) = -t = (\mu, \lambda, \delta)$  for all  $r$ , then

$$\text{TFDWG}_\Phi(-t_1, -t_2, \dots, -t_r) = -t. \quad (36)$$

P2 (boundedness property). Let  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, 2, 3 \dots, p$ ) be a family of TFNs and  $-t^- = \min -t_r$  and  $-t^+ = \max -t_r$ . Then,

$$-t^- \leq \text{TFDWG}_\Phi(-t_1, -t_2, \dots, -t_p) \leq -t^+. \quad (37)$$

P3 (monotonicity property). If  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, 2, \dots, p$ ), and  $-t'_r = (\mu'_r, \lambda'_r, \delta'_r)$ , ( $r = 1, 2, \dots, p$ ), are two TFNs such that  $-t_r \leq -t'_r$  for all  $r$ , then

$$\text{TFDWG}_\Phi(-t_1, -t_2, \dots, -t_p) \leq \text{TFDWG}_\Phi(-t'_1, -t'_2, \dots, -t'_p). \quad (38)$$

The next section introduces the TFDOWG operator.

*Definition 14.* Let  $-t_r = (\mu_r, \lambda_r, \delta_r)$ , ( $r = 1, 2, 3 \dots, p$ ), be a family of TFNs. The TFDOWG operator is a mapping  $-t^p \rightarrow -t$  such that

$$\text{TFDOWG}_w(-t_1, -t_2, \dots, -t_p) = \otimes_{r=1}^p (-t_{\sigma(r)})^{w_r}, \quad (39)$$

where  $w = (w_1, w_2, \dots, w_p)^T$  is an associated weight vector of  $-t_r$ , ( $r = 1, 2, \dots, p$ ) such that  $w_r > 0$  and  $\oplus_{r=1}^p w_r = 1$  and  $(\sigma(1), \sigma(2), \dots, \sigma(p))$  are the permutations of  $-t_r$ , ( $r = 1, 2, \dots, p$ ) for which  $-t_{\sigma(r-1)} \geq -t_{\sigma(r)}$  for all  $r = 1, 2, \dots, p$ .

Using TFDOWG operator, we have the theorem mentioned below.

**Theorem 8.** Let  $-t_r = (\mu_r, \lambda_r, \delta_r)$ ,  $(r = 1, 2, \dots, p)$ , be a family of TFNs. The TFDOWG operator is a mapping  $-t^p \rightarrow -t$  such that

$$\begin{aligned} & \text{TFDOWG}_w(-t_1, -t_2, \dots, -t_p) \\ &= \otimes_{r=1}^p (-t_{\sigma(r)})^{w_r} = \left( \begin{array}{l} \frac{1}{1 + \left\{ \oplus_{r=1}^p \Phi_r(1 - \mu_{\sigma(r)}/\mu_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}}, 1 - \frac{1}{1 + \left\{ \oplus_{r=1}^p \Phi_r(\lambda_{\sigma(r)}/1 - \lambda_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}}, \\ -1 + \frac{1}{1 + \left\{ \oplus_{r=1}^p \Phi_r(|\delta_{\sigma(r)}|/1 + \delta_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}} \end{array} \right), \end{aligned} \quad (40)$$

where  $w = (w_1, w_2, \dots, w_p)^T$  is an associated weight vector of  $-t_r$ ,  $(r = 1, 2, \dots, p)$  such that  $w_r > 0$  and  $\oplus_{r=1}^p w_r = 1$  and  $(\sigma(1), \sigma(2), \dots, \sigma(p))$  are the permutations of  $-t_r$ ,  $(r = 1, 2, \dots, p)$  for which  $-t_{\sigma(r-1)} \geq -t_{\sigma(r)}$  for all  $r = 1, 2, \dots, p$ .

**Remark 7.** In Theorem 8,

- (i) If  $\delta_r = 0$ , for all  $r$ , then the (TFDOWG) operator reduces to the IFDOWG operator, and

$$\begin{aligned} & \text{IFDOWG}_w(-t_1, -t_2, \dots, -t_p) \\ &= \otimes_{r=1}^p (-t_{\sigma(r)})^{w_r} = \left( \begin{array}{l} \frac{1}{1 + \left\{ \oplus_{r=1}^p \Phi_r(1 - \mu_{\sigma(r)}/\mu_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}}, 1 - \frac{1}{1 + \left\{ \oplus_{r=1}^p \Phi_r(\lambda_{\sigma(r)}/1 - \lambda_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}} \end{array} \right). \end{aligned} \quad (41)$$

- (ii) If  $\lambda_r = 0$ , for all  $r$ , then the TFDOWG operator reduces to the BFDOWG operator, and

$$\begin{aligned} & \text{BFDOWG}_w(-t_1, -t_2, \dots, -t_p) \\ &= \otimes_{r=1}^p (-t_{\sigma(r)})^{w_r} = \left( \begin{array}{l} \frac{1}{1 + \left\{ \oplus_{r=1}^p \Phi_r(1 - \mu_{\sigma(r)}/\mu_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}}, -1 + \frac{1}{1 + \left\{ \oplus_{r=1}^p \Phi_r(|\delta_{\sigma(r)}|/1 + \delta_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}} \end{array} \right). \end{aligned} \quad (42)$$

The TFDOWG operators have the following properties.

(P1) (idempotency property). If  $-t_r = (\mu_r, \lambda_r, \delta_r)$ ,  $(r = 1, \dots, p)$ , is a family of TFNs such that they all equal, i.e., if  $-t_r = (\mu_r, \lambda_r, \delta_r) = -t = (\mu, \lambda, \delta)$  for all  $r$ , then

$$\text{TFDOWG}_\Phi(-t_1, -t_2, \dots, -t_r) = -t. \quad (43)$$

(P2) (boundedness property). Let  $-t_r = (\mu_r, \lambda_r, \delta_r)$ ,  $(r = 1, 2, \dots, p)$ , be a family of TFNs and  $-t^- = \min -t_r$  and  $-t^+ = \max -t_r$ . Then,

$$-t^- \leq \text{TFDOWG}_\Phi(-t_1, -t_2, \dots, -t_p) \leq -t^+. \quad (44)$$

(P3) (monotonicity property). If  $-t_r = (\mu_r, \lambda_r, \delta_r)$ ,  $(r = 1, 2, \dots, p)$ , and  $-t'_r = (\mu'_r, \lambda'_r, \delta'_r)$ ,

( $r = 1, 2, \dots, p$ ), are two TFNs such that  $-t_r \leq -t'_r$  for all  $r$ , then

$$\text{TFDOWG}_\Phi(-t_1, -t_2, \dots, -t_p) \leq \text{TFDOWG}_\Phi(-t'_1, -t'_2, \dots, -t'_p). \quad (45)$$

**Definition 15.** A TFDHWG operator of dimension  $p$  is a mapping  $\text{TFDHWG}: -t^p \rightarrow t$  with associated weight vector

$w = (w_1, w_2, \dots, w_p)$  such that  $w_r > 0$ ,  $\oplus_{r=1}^p w_r = 1$ , and TFDHWG operator can be evaluated as

$$\begin{aligned} & \text{TFDHWG}_{(w, \Phi)}(-t_1, -t_2, \dots, -t_p) \\ &= \otimes_{r=1}^p (-t_{\sigma(r)})^{w_r} = \left( \begin{array}{l} \frac{1}{1 + \left\{ \oplus_{r=1}^p w_r (1 - \mu_{\sigma(r)} / \mu_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}}, 1 - \frac{1}{1 + \left\{ \oplus_{r=1}^p w_r (\lambda_{\sigma(r)} / 1 - \lambda_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}}, \\ -1 + \frac{1}{1 + \left\{ \oplus_{r=1}^p w_r (|\delta_{\sigma(r)}| / 1 - \delta_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}} \end{array} \right), \end{aligned} \quad (46)$$

where  $-t_{\sigma(r)}$  is the  $r^{\text{th}}$  largest weighted tripolar fuzzy number, denoted by  $-t_r$ , and  $(-t_r = p\Phi - t_r, r = 1, 2, \dots, p)$  and  $\Phi = (\Phi_1, \Phi_2, \dots, \Phi_p)^T$  are the weight vectors of  $-t_r$  with  $\Phi_r > 0$ ,  $\oplus_{r=1}^p \Phi_r = 1$ , where  $p$  is the balancing coefficient. A TFDHWG operator has some special cases:

As a result, the TFDHG operator is a generalization of both the TFDWG and TFDOWG operators, reflecting the degrees of the provided arguments as well as their ordered locations.

**Remark 8.** In Definition 15,

- (i) When  $w = ((1/p), (1/p), \dots, (1/p))$ , then (TFDWG) operator is a special case of TFDHWG operator.
- (ii) When  $\Phi = ((1/p), (1/p), \dots, (1/p))$ , then (TFDOWG) operator becomes a special case of TFDHWG operator.

- (i) If  $\delta_r = 0$ , for all  $r = 1, 2, \dots, p$ , then TFDHWG operator reduces to IFDHWG operator and

$$\begin{aligned} & \text{IFDHWG}_{(w, \Phi)}(-t_1, -t_2, \dots, -t_p) \\ &= \otimes_{r=1}^p (-t_{\sigma(r)})^{w_r} = \left( \frac{1}{1 + \left\{ \oplus_{r=1}^p w_r (1 - \mu_{\sigma(r)} / \mu_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}}, 1 - \frac{1}{1 + \left\{ \oplus_{r=1}^p w_r (\lambda_{\sigma(r)} / 1 - \lambda_{\sigma(r)})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}} \right). \end{aligned} \quad (47)$$

- (ii) If  $\lambda_r = 0$ , for all  $r$ , then TFDHWG operator reduces to BFDHWG operator and

$$\begin{aligned} & \text{BFDHWG}_{(w,\Phi)}(-t_1, -t_2, \dots, -t_p) \\ &= \otimes_{r=1}^p (-t_{\sigma(r)})^{w_r} = \left( \frac{1}{1 + \left\{ \oplus_{r=1}^p w_r (1 - \mu_{\sigma(r)}^{\delta_{\sigma(r)}} / \mu_{\sigma(r)}^{\delta_{\sigma(r)}}) \right\}^{\mathfrak{R}}} \right)^{(1/\mathfrak{R})}, -1 + \frac{1}{1 + \left\{ \oplus_{r=1}^p w_r (|\delta_{\sigma(r)}| / 1 - \delta_{\sigma(r)}) \right\}^{\mathfrak{R}}} \right)^{(1/\mathfrak{R})}. \end{aligned} \quad (48)$$

For the validity of Definition 15, we consider the following example.

*Example 2.* Let  $-t_1 = (0.5, 0.4, -0.3)$ ,  $-t_2 = (0.6, 0.3, -0.3)$ ,  $-t_3 = (0.7, 0.2, -0.3)$ , and  $-t_4 = (0.2, 0.3, -0.4)$  be four

TFNs and  $\Phi = (0.20, 0.30, 0.30, 0.20)^T$  and  $w = (0.2, 0.1, 0.3, 0.4)^T$  be the weight vector of TFNs and associated weight vector, respectively. Then, by Definition 15, for aggregated value of TFNs for  $(\mathfrak{R} = 3)$  and by using TFDHG operator, we have

$$\begin{aligned} -t_1 &= \left( \frac{1}{1 + \{4 \times 0.2 (1 - 0.5/0.5)^3\}^{(1/3)}}, 1 - \frac{1}{1 + \{4 \times 0.2 (0.4/1 - 0.4)^3\}^{(1/3)}}, \right. \\ &\quad \left. -1 + \frac{1}{1 + \{4 \times 0.20 (0.3/1 - 0.3)^3\}^{(1/3)}} \right) \\ &= (0.4814, 0.4179, -0.3158), \\ -t_2 &= \left( \frac{1}{1 + \{4 \times 0.3 (1 - 0.6/0.6)^3\}^{(1/3)}}, 1 - \frac{1}{1 + \{4 \times 0.3 (0.3/1 - 0.3)^3\}^{(1/3)}}, \right. \\ &\quad \left. -1 + \frac{1}{1 + \{4 \times 0.30 (0.3/1 - 0.3)^3\}^{(1/3)}} \right) \\ &= (0.5820, 0.3158, -0.3158), \\ -t_3 &= \left( \frac{1}{1 + \{4 \times 0.3 (1 - 0.7/0.7)^3\}^{(1/3)}}, 1 - \frac{1}{1 + \{4 \times 0.3 (0.2/1 - 0.2)^3\}^{(1/3)}}, \right. \\ &\quad \left. -1 + \frac{1}{1 + \{4 \times 0.30 (0.3/1 - 0.3)^3\}^{(1/3)}} \right) \\ &= (0.6841, 0.2121, -0.3158), \\ -t_4 &= \left( \frac{1}{1 + \{4 \times 0.2 (1 - 0.2/0.2)^3\}^{(1/3)}}, 1 - \frac{1}{1 + \{4 \times 0.2 (0.3/1 - 0.3)^3\}^{(1/3)}}, \right. \\ &\quad \left. -1 + \frac{1}{1 + \{4 \times 0.20 (0.4/1 - 0.4)^3\}^{(1/3)}} \right) \\ &= (0.1883, 0.3158, -0.4179). \end{aligned} \quad (49)$$

Scores of  $-t_r$ , ( $r = 1, 2, 3, 4$ ) can be approximated:

$$\begin{aligned}
 \textcircled{S}(-t'_1) &= \frac{1 + 0.4814 + 0.4179 - 0.3158}{3} = 0.5278, \\
 \textcircled{S}(-t'_2) &= \frac{1 + 0.5820 + 0.3158 - 0.3158}{3} = 0.5273, \\
 \textcircled{S}(-t'_3) &= \frac{1 + 0.6841 + 0.2121 - 0.3158}{3} = 0.5268, \\
 \textcircled{S}(-t'_4) &= \frac{1 + 0.1883 + 0.3851 - 0.4179}{3} = 0.3620.
 \end{aligned} \tag{50}$$

Since  $\textcircled{S}(-t'_1) > \textcircled{S}(-t'_2) > \textcircled{S}(-t'_3) > \textcircled{S}(-t'_4)$ , then we have

$$\begin{aligned}
 -t'_{\sigma(1)} &= -t'_1 = (0.4814, 0.4179, -0.3158), & -t'_{\sigma(2)} &= -t'_2 = (0.5820, 0.3158, -0.3158), \\
 -t'_{\sigma(3)} &= -t'_3 = (0.6841, 0.2121, -0.3158), & -t'_{\sigma(4)} &= -t'_4 = (0.1883, 0.3158, -0.4179).
 \end{aligned} \tag{51}$$

According to Definition 15, the aggregated values under TFDHWG operators for  $(R = 3)$  are calculated as

$$\begin{aligned}
 &\text{TFDHWG}_{(w,\Phi)}(-t_1, -t_2, \dots, -t_4) \\
 &= \otimes_{r=1}^4 (-t'_{\sigma(r)})^{w_r} = \left( \begin{array}{c} \frac{1}{1 + \left\{ \sum_{r=1}^4 w_r (1 - \mu'_{\sigma(r)}/\mu'_{\sigma(r)})^3 \right\}^{(1/3)}}, 1 - \frac{1}{1 + \left\{ \sum_{r=1}^4 (\lambda'_{\sigma(r)}/1 - \lambda'_{\sigma(r)})^3 \right\}^{(1/3)}}, \\ -1 + \frac{1}{1 + \left\{ \sum_{r=1}^4 (|\delta'_{\sigma(r)}|/1 + \delta'_{\sigma(r)})^3 \right\}^{(1/3)}} \end{array} \right) \\
 &= \left( \begin{array}{c} \frac{1}{1 + \left\{ 0.2(1 - 0.4814/0.4814)^3 + 0.1(1 - 0.5820/0.5820)^3 + 0.3(1 - 0.6841/0.6841)^3 + 0.4(1 - 0.1883/0.1883)^3 \right\}^{(1/3)}}, \\ 1 - \frac{1}{1 + \left\{ 0.2(0.4179/1 - 0.4179)^3 + 0.1(0.3158/1 - 0.3158)^3 + 0.3(0.2121/1 - 0.2121)^3 + 0.4(0.3158/1 - 0.3158)^3 \right\}^{(1/3)}}, \\ -1 + \frac{1}{1 + \left\{ 0.2(0.3158/1 - 0.3158)^3 + 0.1(0.3158/1 - 0.3158)^3 + 0.3(0.3158/1 - 0.3158)^3 + 0.4(0.4179/1 - 0.4179)^3 \right\}^{(1/3)}} \end{array} \right) \\
 &= (0.0799, 0.2351, -0.3452).
 \end{aligned} \tag{52}$$

### 3. Models for MADM with TF Information

To solve a MADM problem using TF information, we will use the TFDA operators established in the preceding sections. The MADM problem is represented using the following technique or notations for prospective evaluation of developing technology commercialization using TF information. Let  $A = \{A_1, A_2, \dots, A_m\}$  present a discrete set of alternatives and  $G = \{G_1, G_2, \dots, G_n\}$ , the set of attributes. Let  $\Phi = (\Phi_1, \Phi_2, \dots, \Phi_n)$  be the weight of attributes in the form of real numbers with the conditions  $\Phi_j > 0$  and  $\sum_{j=1}^n \Phi_j = 1$ . Suppose that  $M = (\tilde{m}_{ij})_{m \times n} = (\mu_{ij}, \lambda_{ij}, \delta_{ij})_{m \times n}$  is the TF decision matrix, where  $\mu_{ij}$  represent the degree of

membership,  $\lambda_{ij}$  represent the degree of non-membership, and  $\delta_{ij}$  denote the degree of negative membership such that,  $\mu_{ij} + \lambda_{ij} \leq 1$  and  $\mu_{ij}, \lambda_{ij} \in [0, 1]$  and  $\delta_{ij} \in [-1, 0]$ , ( $i = 1, 2, \dots, n$ ) and ( $j = 1, 2, \dots, m$ ). The process of utilizing the TFDWA (or TFDWG) operator to solve an MADM problem is listed below (Algorithm 1).

### 4. Illustrative Example

To present the practical output of the constructed model, we consider the MADM problem (adapted from [27]) of the ERP systems. We suppose that an organization wants to employ the ERP systems. The first step for the ERP

*Step 1.* We apply the TFDWA operator to process the information in the decision matrix  $M$  and to compute the overall values of the alternatives  $A_i$  ( $i = 1, 2, \dots, m$ ), and we have

$$\begin{aligned} \tilde{m}_i = (\mu_i, \lambda_i, \delta_i) &= \text{TFDWA}_\Phi(\tilde{m}_{i1}, \tilde{m}_{i2}, \dots, \tilde{m}_{in}) = \Phi_{j=1}^n (\Phi_j \tilde{m}_{ij}) \\ &= \left( \begin{array}{l} 1 - (1/1 + \left\{ \sum_{j=1}^n \Phi_j (\mu_{ij}/1 - \mu_{ij})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}), (1/1 + \left\{ \sum_{j=1}^n \Phi_j (1 - \lambda_{ij}/\lambda_{ij})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}), \\ (-1/1 + \left\{ \sum_{j=1}^n \Phi_j (1 + \delta_{ij}/|\delta_{ij}|)^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}). \end{array} \right) \end{aligned}$$

Or if we select the TFDWG operator, instead of TFDWA operator, then we have

$$\begin{aligned} \tilde{m}_i = (\mu_i, \lambda_i, \delta_i) &= \text{TFDWG}_\Phi(\tilde{m}_{i1}, \tilde{m}_{i2}, \dots, \tilde{m}_{in}) = \otimes_{j=1}^n (\tilde{m}_{ij})^{\Phi_j} \\ &= \left( \begin{array}{l} (1/1 + \left\{ \sum_{j=1}^n \Phi_j (1 - \mu_{ij}/\mu_{ij})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}), 1 - (1/1 + \left\{ \sum_{j=1}^n \Phi_j (\lambda_{ij}/1 - \lambda_{ij})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}), \\ -1 + (1/1 + \left\{ \sum_{j=1}^n \Phi_j (|\delta_{ij}|/1 + \delta_{ij})^{\mathfrak{R}} \right\}^{(1/\mathfrak{R})}). \end{array} \right) \end{aligned}$$

*Step 2.* Find the score values  $\odot(\tilde{m}_i)$  ( $i = 1, 2, \dots, m$ ) of all the alternatives.

*Step 3.* Rank all  $A_i$  ( $i = 1, 2, \dots, m$ ) according to the score values  $\odot(\tilde{m}_i)$ , ( $i = 1, 2, \dots, m$ ). In case  $\odot(\tilde{m}_i)$  and  $\odot(\tilde{m}_j)$  values are equal, then calculate the accuracy values  $\text{acc}(\tilde{m}_i)$  and  $\text{acc}(\tilde{m}_j)$  to rank the alternatives  $A_i$  and  $A_j$ , respectively.

*Step 4.* Select the best alternative(s).

#### ALGORITHM 1: MADM steps.

system is to construct a team of experts which contained CIO and two other senior experts from the source institute. The expert's team collects all the data regarding ERP vendors and system, in the form of TFS. Secondly, the team selects five potential ERP systems, treated as  $A_i$ , ( $i = 1, 2, 3, 4, 5$ ), as candidates. The team also imposes four attributes for the evaluation of this MADM problem of  $A_i$  ( $i = 1, 2, 3, 4, 5$ ):

- $G_1$  = function and technology.
- $G_2$  = strategic fitness.
- $G_3$  = vendor's reputation.
- $G_4$  = vendor's ability.

The expert team gave some weighting for the selection of optimal candidate as  $\Phi = (0.2, 0.1, 0.3, 0.4)$ , and the information collected is in the form of TFSs, satisfying the above four attributes. The rating of the team is presented in the matrix given below.

To find the most favorable ERP systems, we employ the TFDWA operator (or TFDWG operator) in the following to construct a solution to MADM problems based on TF information, which may be summarized as follows.

*Step 1.* Let  $\mathfrak{R} = 1$ . By applying the TFDWA operator, we compute the overall preference values  $\tilde{m}_i$  of the ERP system  $A_i$  ( $i = 1, 2, 3, 4, 5$ ):

$$\begin{aligned} \tilde{m}_1 &= (0.0013, 0.9455, -0.9871), \\ \tilde{m}_2 &= (0.0010, 0.9800, -0.9964), \\ \tilde{m}_3 &= (0.0004, 0.9788, -0.8852), \\ \tilde{m}_4 &= (0.0001, 0.9976, -0.9936), \\ \tilde{m}_5 &= (0.0037, 0.9562, -0.9814). \end{aligned} \tag{53}$$

*Step 2.* Find the score values  $\odot(\tilde{m}_i)$ , ( $i = 1, 2, 3, 4, 5$ ), of the overall TF numbers, TFNs,  $\tilde{m}_i$ , ( $i = 1, 2, 3, 4, 5$ ):

$$\begin{aligned} \odot(\tilde{m}_1) &= 0.3199, \\ \odot(\tilde{m}_2) &= 0.3282, \\ \odot(\tilde{m}_3) &= 0.3646, \\ \odot(\tilde{m}_4) &= 0.3347, \\ \odot(\tilde{m}_5) &= 0.3261. \end{aligned} \tag{54}$$

*Step 3.* Rank all the ERP systems  $A_i$ , ( $i = 1, 2, 3, 4, 5$ ), according to the respective score values of the overall tripolar fuzzy numbers, and we get  $A_3 > A_4 > A_2 > A_5 > A_1$ .

*Step 4.* According to score values,  $A_3$  is the most considerable ERP system.

If we use the TFDWG operator instead of TFDWA operator, then we solve the problem similarly as above:

*Step 1.* For  $\mathfrak{R} = 1$ , aggregate all TFNs via the TFDWG operator to derive the overall TFNs  $\tilde{m}_i$  ( $i = 1, 2, 3, 4, 5$ ) of the ERP system:

$$\begin{aligned}\tilde{m}_1 &= (0.9959, 0.0000, -0.0004), \\ \tilde{m}_2 &= (0.9944, 0.0002, -0.0015), \\ \tilde{m}_3 &= (0.9875, 0.0002, -0.0000), \\ \tilde{m}_4 &= (0.9674, 0.0023, -0.0008), \\ \tilde{m}_5 &= (0.9984, 0.0001, -0.0003).\end{aligned}\quad (55)$$

*Step 2.* Calculate the score values  $\textcircled{\text{S}}(\tilde{m}_i)$ , ( $i = 1, 2, 3, 4, 5$ ), of the overall TF numbers, TFNs,  $\tilde{m}_i$ , ( $i = 1, 2, 3, 4, 5$ ):

$$\begin{aligned}\textcircled{\text{S}}(\tilde{m}_1) &= 0.6651, \\ \textcircled{\text{S}}(\tilde{m}_2) &= 0.6643, \\ \textcircled{\text{S}}(\tilde{m}_3) &= 0.6625, \\ \textcircled{\text{S}}(\tilde{m}_4) &= 0.6563, \\ \textcircled{\text{S}}(\tilde{m}_5) &= 0.6660.\end{aligned}\quad (56)$$

*Step 3.* Rank all the ERP systems  $A_i$ , ( $i = 1, 2, 3, 4, 5$ ), according to the respective score values of the overall TF numbers, and we get  $\textcircled{\text{S}}A_5 > \textcircled{\text{S}}A_1 > \textcircled{\text{S}}A_2 > \textcircled{\text{S}}A_3 > \textcircled{\text{S}}A_4$ .

*Step 4.* By the score values,  $A_5$  is the most ideal ERP system.

Based on the above discussion, it is determined that, while ranking values of the alternatives change when utilizing the TFDWA (TFDWG) operator, the ranking orders of the ERP system did not remain the same, i.e., the most ideal ERP system through using TFDWA operator is  $A_4$ , while using TFDWG operator, it is  $A_5$ . The reason for different optimal alternatives is the use of different methods in the decision process.

In Figure 1, the comparison of the ERP system is shown, where it is observed that the graph of TFDWA operator (green line) has some fluctuations in the middle values of ranking order of ERP system while the graph of TFDWG operator (brown line) is stable. This means that the ranking order of ERP systems is more stable in TFDWG operator as compared to the ranking order of ERP systems in TFDWA operator.

**4.1. Influence of Parameter.** To describe the impact of the operational parameters  $\mathfrak{R}$  on MADM outcomes, we will rank the alternatives using different values of  $\mathfrak{R}$ . The results of score function and ranking order of the ERP system  $A_i$  ( $i = 1, 2, 3, 4, 5$ ) in the range of  $\mathfrak{R} \in [1, 10]$  applying TFDWA and TFDWG operators are presented. The corresponding scores and ranking of the ERP system  $A_i$ , ( $i = 1, 2, 3, 4, 5$ ), are shown in Tables 1 and 2.

Table 3 shows that altering the value of  $\mathfrak{R}$  in the TFDWA operator changes the ranking orders, and the associated best alternatives are not similar. Several ranking orders of the

FIGURE 1: Graphs of TFDWA and TFDWG operators.

TF matrix values				
$M =$	$(0.7, 0.2, -0.3)$	$(0.2, 0.4, -0.8)$	$(0.2, 0.5, -0.3)$	$(0.8, 0.2, -0.2)$
	$(0.6, 0.3, -0.4)$	$(0.3, 0.6, -0.5)$	$(0.5, 0.3, -0.4)$	$(0.4, 0.3, -0.6)$
	$(0.4, 0.5, -0.2)$	$(0.4, 0.4, -0.1)$	$(0.3, 0.2, -0.5)$	$(0.5, 0.4, -0.4)$
	$(0.2, 0.6, -0.6)$	$(0.3, 0.4, -0.7)$	$(0.4, 0.6, -0.2)$	$(0.5, 0.4, -0.3)$
	$(0.7, 0.3, -0.3)$	$(0.5, 0.4, -0.4)$	$(0.5, 0.3, -0.4)$	$(0.4, 0.3, -0.4)$

alternatives for subintervals of  $[2, 30]$  by using TFDWA and TFDWG operators of the operational parameter  $\mathfrak{R}$  are shown in Tables 2 and 4.

Ranking orders of the alternatives for subintervals of  $[2, 30]$  by using TFDWG operators of the operational parameter  $\mathfrak{R}$  are shown in Table 5.

The corresponding graphs in Figures 2 and 3 are provided to diagnose the influence of parameter  $\mathfrak{R} \in [1, 10]$  on the ranking of alternatives in TFDWA and TFDWG operators.

From Figures 2 and 3, we observe that the ranking order of the ERP systems in TFDWA operator (Figure 2) has more fluctuations than the ranking order of alternatives in TFDWG operators (Figure 3). Therefore, the proposed method of TFDWG operator produced stable results of the ERP system.

**4.2. Comparative Analysis.** To compare the developed models with the existing literature to describe the advantages of the proposed models, we consider the following two special cases of the suggested models, given in Examples 1 and 2. In Example 1, we dropped the implicit counter property from the information given in Table 1 and the reduced matrix becomes the IF information which is given in Table 6.

*Example 3.* Recall the TF information decision matrix given in Table 1. The modified decision matrix contained IF information given in Table 6, and the normalized decision matrix is shown in Table 7, respectively.

By applying IFDWA and IFDWG operators on Table 7, the aggregated IFNs are summarized in Table 8.

By calculating the score values of the aggregated IFNs of Table 9, we get the following table.

In Table 10, a comparison of the ranking of alternatives by using IFDWA operator and TFDWA operator is shown, and the graphical view of these operators is highlighted in Figure 4.

From Figure 4, we can see that the ranking order of alternatives for the TFDWA operator (brown line) is stable from  $A_1$  to  $A_2$ , increasing from  $A_2$  to  $A_3$ , decreasing from  $A_3$  to  $A_4$ , and stable from  $A_4$  to  $A_5$ . From  $A_4$  it becomes stable. On the other hand, if we consider the IFDWA operator (green line), the ranking order of alternatives is decreasing continuously from  $A_1$  to  $A_4$  and increasing from  $A_4$  to  $A_5$ , and hence we observe no stability in ranking produced by IFDWA operator. Therefore, the proposed method of TFDWA operator gives more stable ranking than the existing methods in literature.

A comparison of the ranking of alternatives by using IFDWG operator and TFDWG operator is shown in

FIGURE 2: Graphs of alternatives in TFDWA operator ( $\alpha \in [2, 30]$ ).

FIGURE 6: Comparison of alternatives in TFDWA and BFDWA operators.

generalization of both the notions of IFNs and BFNs and can handle problems involving IFN and BFN in the single model.

Now, we discuss the case of proposed operators by dropping the degree of non-membership from the information given in the decision matrix of Table 1. The following example illustrate the case of dropping the degree of non-membership.

*Example 4.* Reconsider the decision matrix given in Table 1 and drop the non-membership degree from each triplet of this matrix. The modified matrix is reduced to a BF decision matrix given in Table 12.

For the comparison of the proposed models, we apply BFDWA and BFDWG operators on Table 12 and the aggregated BFNs are summarized in Table 13.

The score values of the aggregated BFNs are summarized in Table 14.

The ranking of alternatives by using BFDWA/BFDWG operator is shown in Table 15.

In Table 16, we compare the ranking order of alternatives obtained by the proposed method and BFDWA/BFDWG operators.

In Figures 6 and 7, we compared the proposed operators and existing operators of BFDWA/BFDWG operators.

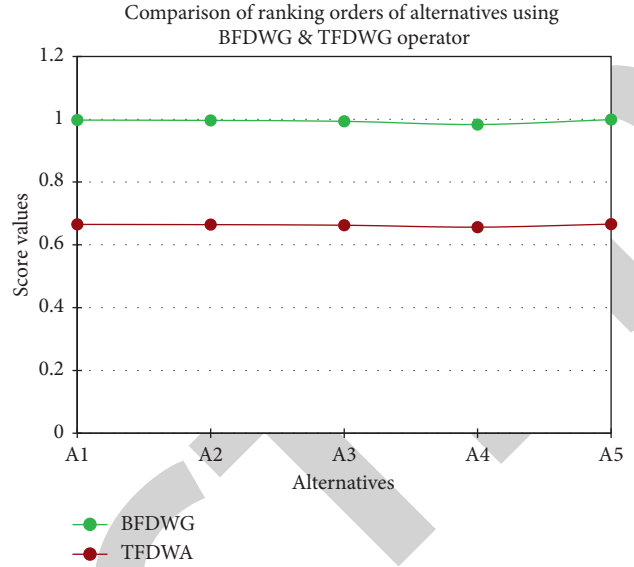

FIGURE 7: Comparison of alternatives in BFDWG and TFDWG operators.

From Figure 7, it is clearly seen that the ranking of alternatives using BFDWA operator (brown line) and TFDWA operator (green line) is not fully stable in between  $A_1$  to  $A_5$ .

From Figure 7, we observed that the ranking order of alternatives in BFDWG operator (green line) and TFDWG operator (brown line) is stable. This means that the proposed operators and existing operator behave similar. But the proposed operators are generalization of both the IFS and BFS, which combine both the notions into a single model.

### 5. Conclusion

In this article, we addressed MADM problems with TF information. From the inspiration of Dombi operations, we incorporated arithmetic and geometric operations to develop certain TF Dombi aggregation operators:

- (i) TFDWA operator.
- (ii) TFDOWA operator.
- (iii) TFDHWA operator.
- (iv) PFDWG operator.
- (v) TFDOWG operator.
- (vi) TFDHWG operator.

Different aspects of these suggested operators are highlighted. Then, we utilized these operators to broaden a few mechanisms to cope with MADM problems. Ultimately, a realistic example of an ERP system is provided to develop the strategy and show the effectiveness of the proposed method. In future research, we will investigate DM theory, risk theory, and other areas in an ambiguous environment for the suggested tripolarity models.

The method introduced in this paper is a generalization of IF and BF environments, and the present model deals with the tripolar fuzzy environment. The existing methods of IF

TABLE 17: Comparison of proposed and existing methods.

Methods	Describe fuzzy information easier	More flexible by a parameter
Dombi [30]	Yes	No
Xu and Yager [5]	Yes	No
Proposed operator	Yes	Yes

sets and BF sets [5, 30] for MADM problems have restrictions; in IFS, we cannot discuss the implicit counter property of objects while the BFS models failed to consider the non-membership property of objects in decision process, and definitely these deficiencies in IF models as well as in BF models will lose the information in the process. The present method combines the two concepts of IF and BF models together. In a nutshell, the suggested MADM technique for TFDWA and TFDWGA operators has improved DM reliability. Our suggested approaches are more comprehensive and adaptable than conventional methods for controlling IF and BF models. We compared our method with Dombi's method [30] and Xu and Yager's method [5]. The comparative results are shown in Table 17. As a conclusion, our suggested approaches are more flexible and adaptable than available methods for controlling IF and BF MADM challenges.

Air pollution control as the background of a cost allocation method is based on the Shapley value to determine the core stakeholder, so fair pollution control projects and the establishment of the atmospheric pollution of governance cost allocation model are put forward for the solution of air pollution coordinated by the government supervision and the atmospheric pollution control collaborative group. The results show that the cost allocation model of air pollution control based on Shapley value is more reasonable, and the cost of stakeholders is reduced to a certain extent, and the risk of the participants is reduced so that it maximizes social benefits.

## 1. Introduction

Over the past 30 years of the Reform and Opening-up policy, China has made some progress in air pollution prevention and control. A part of single atmospheric pollutants has reached the emission standard step by step. However, new pollution caused by the mixing of multiple pollution sources has attracted widespread attention with the complexity of production and living activities. PM<sub>2.5</sub> or haze is formed by a mixed reaction of various pollutants, such as gases and particulates, including volatile organic compounds (VOCs). Exposure to fine particulate matter (PM<sub>2.5</sub>) with a diameter of < 2.5 μm is a recognized cause of respiratory diseases in children [1]. At present, the generation of air pollutants is continuing to increase. Effective pollution prevention and control should decrease the increment and storage of pollutants. At present, the problem of air pollution control is still facing many difficulties and needs to be solved urgently.

In my country's urban development system, the urban development of the Beijing-Tianjin-Hebei region has driven the overall economic development of our country, but the environmental problems in these areas have gradually become the main concern of people. [2] The Beijing-Tianjin-Hebei

region, which is a key area of pollution prevention and control, suffers from grave ecological and environmental problems, especially serious air pollution and frequent haze. At the same time, the Beijing-Tianjin-Hebei region, which has a resource-dependent economy dominated by clusters of heavy industries, has long borne the highest PM<sub>2.5</sub> pollution levels in China, prompting serious concerns about the region's disease burden. [3] The overall air quality in the Beijing-Tianjin-Hebei region affects each other and cannot be prevented and controlled individually. It is urgent to strengthen regional ecological protection and construction. However, the integration of the Beijing-Tianjin-Hebei region is still at an early stage, and many systems need to be further established and refined. It is also difficult to significantly improve the quality of the atmospheric environment in the short term. Under this circumstance, coordinating the contradiction between the environmental demand and environmental capacity of the Beijing-Tianjin-Hebei region is prominent.

Noncooperative policies for transboundary pollution abatement are inefficient and ineffective, but cooperative policies for pollution abatement are seldom successful in regions that have different development goals and conflicting interests. [4] To reduce the harm of haze to the life and health of residents and accelerate the coordinated prevention and

control of air pollution in the Beijing-Tianjin-Hebei region require more resources and capital investment. However, the Beijing-Tianjin-Hebei cooperation has not clearly defined and divided rights, responsibilities, and benefits in air pollution prevention and control, especially the cost-sharing mechanism, so it is difficult to achieve effective integration.

In response to the above problems, this paper conducts a theoretical analysis on the cost allocation of the Beijing-Tianjin-Hebei cooperation in air pollution control. We propose to establish a cost-sharing model of atmospheric pollution in Beijing, Tianjin, and Hebei by using Shapley value. This model can better identify stakeholders in the cooperative governance, maximize the overall and individual interests, reduce the cost of air pollution prevention and control, and finally solve the coordination problem of air pollution control in Beijing, Tianjin, and Hebei.

## 2. Literature Review

Haze pollution not only negatively influences public health but also causes great economic losses [5, 6]. In the existing research on air pollution control, the main focus is on the causes of air pollution and the control measures of air pollution. Yang et al. quantitatively evaluated the vulnerability of the atmospheric environment in the Beijing-Tianjin-Hebei region through space-time comparison [7]. The relationship between atmospheric environmental vulnerability and exposure index, sensitivity index, and adaptability index is helpful to analyze atmospheric environmental vulnerability. The results show that the air environment vulnerability of 13 cities in the Beijing-Tianjin-Hebei region shows obvious spatial heterogeneity. Liang and Wang systematically summarized the Beijing-Tianjin-Hebei urban agglomeration implemented air pollution control mode, which is multilevel, cross regional, and multidirectional [8]. This includes a state-agglomeration-city linkage structure, multiprovincial, and cross-regional linkage governance, and multidirectional linkage mechanisms involving industrial access, energy structure, green transportation, cross-regional assistance, monitoring and early warning, consultation, and accountability to analyze the temporal and spatial characteristics by using the concentration data of six kinds of air pollutants. Sun et al. selected indicators from the three aspects of air pollution characteristics, natural condition characteristics, and trade characteristics, and used the entropy-top SIS method to determine the priority order of the JPCAP region [9]. By determining the key areas of four regions, key areas of air pollution control were identified, providing practical guidance and theoretical basis for regional joint control of air pollution. Piersanti et al. discussed the scenarios developed for 2030 in Italy's National Air Pollution Control Programme, using 2010 as the reference year, and also used these scenarios to provide a comprehensive approach to calculating the impact of the plan on health effects (mortality) and associated costs, providing an important framework and assessing measures to reduce air pollution with an integrated approach [10]. Ikeuchi et al. proposed that health risks caused by PM<sub>2.5</sub> would increase with the decrease of precipitation duration and incidence

[11]. Schwartz et al. believed that particulate air pollution at common concentrations is associated with daily death [12]. Gulia et al. highlighted the problem of high spatiotemporal variation of air pollution levels in urban areas and the methods that can be used to eliminate pollutants. The efficiency of the prototypes/devices developed using these processes has also been compared worldwide, and studies have shown that such controls would be very useful in reducing air pollution in hot spots with large spatiotemporal variability [13].

Given the formation reasons of haze and its harm to human health, Elzbieta believed that the biggest cause of smog and air pollution is the burning of garbage in the stoves; other causes include exhaust from large factories, burning coal in the stoves, and automobile exhaust [14]. Urbanization, industrialization, and increasing fossil fuel consumption are generally identified as the main contributors to poor air quality [15]. Zhao and Yuan innovatively used precipitation as an instrumental variable to alleviate the endogeneity of haze pollution variable and found that haze pollution seriously reduces the quality of China's economic development. The loss of labor supply, deurbanization, and interruption of human capital are the three transmission channels through which haze pollution affects the quality of China's economic development [16]. Wang et al. studied the changes in the physical and chemical properties of air particles collected in Beijing during the typical transition from haze to dust [17]. The study found that detailed information on the physical and chemical properties of atmospheric particles in the typical heavy pollution process could be provided in a short time, and such short-term changes should be taken into account to more accurately assess the environmental, climatic, and health impacts of airborne particulate matter. Intense economic and human activities in megacities lead to air pollution emissions, resulting in high concentrations of air pollutants in the atmosphere that harm human health, cause regional haze and acid deposition, damage crops, affect regional air quality, and contribute to climate change [18]. Zhang et al. studied the diurnal variation of atmospheric boundary layer height, analyzed temperature, wind direction and vertical structure of wind, and characteristics of velocity in the boundary layer; the weak vertical exchange between the boundary layer and the upper layer will promote the formation of fog and haze [19].

SO<sub>x</sub>, NO<sub>x</sub>, CO<sub>x</sub>, volatile organic compounds (VOCs), and Hg vapor directly and indirectly harm the atmospheric environment and human health by contributing to the formation of photochemical smog, acid rain, and haze and posing risks of potential toxicity (e.g., carcinogenicity) [20]. Wang and Yuan tested the impact of air pollution control on ecological total factor energy efficiency and the moderating effect of ownership structure by using panel data of 37 subindustries of China's industrial sectors from 2003 to 2014. They found that high-pollution industries had a significant short-term positive impact, while medium-pollution industries had a significant short-term negative impact. Low pollution industries have a significant long-term negative impact. Finally, some concrete policy

suggestions are put forward [21]. Kim et al. determined the causal relationship between the risk perception of particulate matter and satisfaction of outdoor activities in South Korea, conducted an online survey of 412 people, and conducted confirmatory factor analysis using the structural equation model. The results showed that the perceived risk of particulate matter was higher when people had no interest or trust in public opinion or policy, which increased people's perception of health risks and, in turn, reduced their satisfaction with outdoor activities [22]. Zhao et al. studied the Beijing-Tianjin-Hebei region as an example, used the Shapley value method to reasonably distribute the model benefits, construct the optimal emission reduction plan, and determine the optimal annual decision of each province. The results show that the model reduces the total cost of SO<sub>2</sub> pollution reduction [23]. Gao et al. evaluated the risk of particulate pollution to human health by comparing samples collected from seven different functional areas in Beijing [24].

At present, haze air pollution seriously harms global human health. Many scholars at home and abroad have made detailed explanations on the sources of air pollutants, mainly from organic compounds such as SO<sub>x</sub>, NO<sub>x</sub>, and CO<sub>x</sub>, open incineration of garbage, and automobile exhaust emissions. For the study of air pollution, many scholars focus on empirical research. However, the Shapley value method is a model of the income distribution of participants in dynamic cooperative alliances. At present, the Shapely value method is mainly used to solve the income distribution in cooperative projects at home and abroad. The Shapley value method is seldom used to study the cost of air pollution control.

In this paper, the cost of air pollution control is allocated according to the Shapley value method. Compared with the existing research work, this model avoids equal distribution and other relatively simple distribution to a certain extent, which is scientific, reasonable, and fair. This paper establishes an air pollution control cost-sharing model based on the Shapley value and determines the core stakeholders to make the cost allocation more reasonable, scientific, and fair. The Shapley model reduces the charges of each stakeholder, disperses the risks of participants to a certain extent, and effectively ensures the smooth progress of the project. We found that the cost distribution model based on Shapley value can optimize the cost and maximize the social benefit. Because air pollution control needs a long process, the reduction of cost and risk can effectively ensure the completion of air pollution control, which plays an important role in promoting air pollution control.

### 3. Basic Theory of Air Pollution Control Cost Allocation

**3.1. Shapley Value Method.** Let  $I = \{1, 2, \dots, n\}$  be the total number of project participants,  $S$  be any subset of  $I$ , and  $V$  be the characteristic function defined above  $I$ , that is, the benefit of a certain cooperation  $S$ .

$$\begin{aligned} V(\emptyset) &= 0(1), \\ V(S_1 \cup S_2) &\geq V(S_1) + V(S_2), S_1 \cap S_2 = \emptyset. \end{aligned} \quad (1)$$

With  $Y_i$  said  $I$  in the case of a project  $I$  partners from the alliance profit maximum  $V(I)$  in income, namely, the income gained by the each participant in the  $I$  uses letters to represent  $Y$ , this model is a cost allocation which should not only meet the rationality of overall but also at the same time to meet the individual rationality [25, 26], as shown below:

$$\begin{aligned} \text{the overall rational: } & \sum_{i=1}^n Y_i = V(I), i = 1, 2, \dots, n, \\ \text{individual rationality: } & Y_i \geq V(i), i = 1, 2, \dots, n, \end{aligned} \quad (2)$$

where  $V(I)$  represents the benefit that  $I$ , a participant, can obtain by completing the project alone, and  $V(I)$  represents the maximum benefit that can be obtained in many cooperative alliances [27, 28]. At this point, we get the Shapley value we want to find, which is called  $Y_i$  ( $v$ ):

$$\begin{aligned} Y_i(v) &= \sum_{S_{res}} W(|S|) [V(S) - V(S \setminus i)], i = 1, 2 \dots n, \\ W(|S|) &= \frac{(n - |S|)! (|S| - 1)!}{n!}, \end{aligned} \quad (3)$$

where  $S$  is a subset of all combinations of  $I$ , and  $|S|$  is the number of project-related stakeholders in a collaboration  $S$ , and  $W(|S|)$  is the weight.  $V(S)$  refers to the cooperation benefits obtained or costs borne by this subset  $S$ , and  $V(S \setminus i)$  refers to the benefits obtained or costs borne by other members of  $S$  after the elimination of participant  $I$  [29].

**3.2. Stakeholder Theory.** Rowley, a foreign scholar, was the first to establish the stakeholder theory. In a narrow sense, a stakeholder means that an individual and a group participate in the same project, provide human, financial, and other resources in the project, bear a part of the project risks, and finally share interests [30, 31]. In the late 1990s, there emerged a method represented by Mitchell and Wood, called the "Mitchell scoring method," which mainly divided legitimacy, power, and urgency into three attributes. According to these three attributes, stakeholders can be divided into three types: the first type is the defining stakeholder, which has three attributes at the same time and is the primary object to be paid attention to. The second type is the anticipatory stakeholder, with any combination of two attributes. The third type is the potential stakeholder, in which participants have only one of the three characteristics [32].

## 4. Air Pollution Control Cost Allocation Model

**4.1. Core Stakeholders of Air Pollution Control Cost Allocation Project.** According to the participation of each participant in the process of air pollution control project and the degree of influence of each participant on air pollution control, [33] stakeholders in the air pollution control model are divided into three categories through analysis, as shown in Table 1.

In atmospheric pollution control projects, as core stakeholders are the key members of air pollution control

and also the main body to share the cost of air pollution, they play a vital role in air pollution control, so it is particularly important to determine the cost allocation among core stakeholders [34].

**4.2. Cost Allocation Model of Air Pollution Control Based on Shapley Value.** Based on the above analysis of stakeholders, a model is established for the allocation process of air pollution treatment costs. Combined with the relevant knowledge of Shapley value, hypotheses are firstly proposed for the model. The main hypotheses are as follows:

Assume that participants  $I = \{1, 2, \dots, n\}$ , including government departments of two places and enterprises of two places, are represented by A, B, C, D, E, and F, respectively. A represents government departments of Beijing, B represents enterprises of Beijing, C represents the government of Hebei, D represents enterprises of Hebei, E represents the government of Tianjin, and F represents enterprises of Tianjin as shown in Table 2.

Based on the analysis of the above characteristic functions and the Shapley value method, the cost allocation model of regional cooperative air pollution control is established, which is mainly calculated according to the following two formulas.

$$W(|S|) = \frac{(n - |S|)(|S| - 1)!}{n!}, \quad (4)$$

$$Y_i(V) = \sum_{S_i \in S} W(|S|)[V(S) - V(S/i)], \quad i = 1, 2, \dots, n. \quad (5)$$

**4.3. Cost Allocation of Beijing Government Departments in the Air Pollution Control Project Alliance.** The values in the table are calculated according to formula (4) and formula (5). The constituent elements in the subset S represent the stakeholders involved in the project. They, respectively, say that the cooperative alliance  $V(S)$  participated by Beijing government departments represents the air pollution control costs borne by the cooperative alliance participated by the Beijing municipal government  $V(S/I)$  represents the removal of Beijing city. After the government, this cooperative alliance would have borne the cost and  $[V(S) - V(S/i)]$  refers to the cost borne by the project with the participation of Beijing municipal government minus the cost borne by the project without the participation of Beijing municipal government.  $W(|S|)$  refers to the proportion of this cooperation alliance in cooperation with the participation of Beijing municipal government. The sum of  $W(|S|)$  is 1.  $W(|S|)[V(S) - V(S/i)]$  represents the Shapley value of Beijing municipal Government in this cooperative alliance, from which we can get the best cost allocation of Beijing municipal government. According to the formula, the final cost that Beijing municipal government should bear is as shown in Table 3.

$$\begin{aligned} Y_i(V) = & \frac{1}{6} V(S1) + \frac{1}{30} [V(S5) - V(S2)] + \frac{1}{30} [V(S7) - V(S4)] + \frac{1}{30} [V(S9) - V(S3)] \\ & + \frac{1}{30} [V(S7) - V(S4)] + \frac{1}{30} [V(S9) - V(S3)] + \frac{1}{60} [V(S11) - V(S6)] + \frac{1}{60} [V(S13) - V(S8)] \\ & + \frac{1}{60} [V(S14) - V(S10)] + \frac{1}{60} [V(S15) - V(S12)] + \frac{1}{30} [V(S19) - V(S17)] + \frac{1}{30} [V(S23) - V(S16)] \\ & + \frac{1}{60} [V(S31) - V(S21)] + \frac{1}{60} [V(S32) - V(S20)] + \frac{1}{60} [V(S33) - V(S18)] + \frac{1}{60} [V(S35) - V(S24)] \\ & + \frac{1}{60} [V(S37) - V(S26)] + \frac{1}{60} [V(S38) - V(S22)] + \frac{1}{60} [V(S40) - V(S25)] + \frac{1}{60} [V(S43) - V(S34)] \\ & + \frac{1}{60} [V(S45) - V(S36)] + \frac{1}{60} [V(S49) - V(S39)] + \frac{1}{60} [V(S50) - V(S27)] + \frac{1}{60} [V(S51) - V(S29)] \\ & + \frac{1}{60} [V(S52) - V(S41)] + \frac{1}{60} [V(S53) - V(S28)] + \frac{1}{60} [V(S54) - V(S42)] + \frac{1}{60} [V(S55) - V(S30)] \\ & + \frac{1}{30} [V(S58) - V(S44)] + \frac{1}{30} [V(S59) - V(S48)] + \frac{1}{30} [V(S60) - V(S46)] + \frac{1}{30} [V(S61) - V(S47)] \\ & + \frac{1}{30} [V(S62) - V(S56)] + \frac{1}{6} [V(S63) - V(S57)]. \end{aligned} \quad (6)$$

TABLE 1: Classification of stakeholders of air pollution control projects.

Stakeholders	Institutions	Mechanism classification basis
Core stakeholders	Local governments and enterprises in Beijing, Tianjin and Hebei	The indispensable participants of the air pollution control project have an inseparable interest with the control and cost sharing of the project
General stakeholders	Beijing-Tianjin-Hebei and surrounding areas' air pollution prevention and control collaborative group	Participants who are closely connected with air pollution control projects have a certain degree of project participation and bear certain risks
Marginal stakeholders	The central government	It has a little influence on air pollution control projects and does not directly contact each participant

& + \frac{1}{30}[V(S62) - V(S60)] + \frac{1}{6}[V(S63) - V(S17)].
\end{aligned} \tag{11}$$

Therefore, through the above results, we can know that the total cost of governance is the cost borne by the three governments plus the cost borne by the enterprise is  $V(S15)$ . In the air pollution control project, it is necessary to determine the total cost  $V(S15)$ , the separate treatment cost  $V(S1)$  of the government in Beijing, and the cost  $V(S2)$  of the government alone to control air pollution. Therefore, through the above results, we can know that the total cost of governance is the cost borne by the three governments plus the cost borne by the enterprise is  $V(S15)$ . In the air pollution control project, it is necessary to determine the total cost  $V(S15)$ , the separate treatment cost  $V(S1)$  of the government in Beijing, and the cost  $V(S2)$  of the government alone to control air pollution. Hebei government alone treatment cost  $V(S3)$  and Hebei enterprise independent control cost  $V(S4)$ , Tianjin government independent treatment cost  $V(S16)$ , Tianjin enterprise independent treatment cost  $V(S17)$ , by knowing the cost of the combination of the two of them, the cost of the combination of any three, the cost of the combination of any four, the combination of any five, and the cost of their joint governance, we can determine the respective costs borne by the government and enterprises in the treatment of air pollution in Beijing, Tianjin, and Hebei.

## 5. Example Analysis and Correction Based on Shapley Value

**5.1. Numerical Calculation of Distribution Model.** After collecting relevant data and sorting out the costs of air pollution control, we get the relevant costs for the treatment of air pollution in Beijing and Hebei. Taking Beijing and Hebei as examples, simplify the cost allocation model. Use A for Beijing Municipal Government, B for Beijing enterprises, C for Hebei provincial government, and D for Hebei enterprises, specific data as shown in Table 4.

According to the model established in the above section, the costs that Beijing municipal government, Beijing municipal enterprises, and Hebei provincial government should bear when

establishing a cooperative alliance to control air pollution can be calculated. The specific results are shown in Table 5.

The sum of the data in the last row of the table can get the cost that Beijing government departments should bear in the joint governance of Beijing and Hebei. The final result is 229.167 billion Yuan, which is the optimal the cost. The specific results are shown in Table 6.

The sum of the data in the last row of the table can get the cost that Beijing enterprises should bear in the joint governance of Beijing and Hebei. The final result is 82.5 billion Yuan, which is the optimal cost. The specific results are shown in Table 7.

The sum of the data in the last row of the table can get the cost that the Hebei government should bear in the joint governance of Beijing and Hebei. The final result is 224.167 billion Yuan, which is the optimal cost. The specific results are shown in Table 8.

The sum of the data in the last row of the table can get the cost that enterprises in Hebei should bear in the joint governance of Beijing and Hebei region. The final result is 86.667 billion Yuan, which is the optimal cost.

**5.2. Result Analysis.** Based on the Shapley value method, when Beijing and Hebei implement joint governance, the total cost is 622.5 billion Yuan, which can effectively solve the cooperation needs of 620 billion Yuan. Meanwhile, Beijing municipal government departments bear 229.167 billion Yuan in the cooperative governance, Beijing enterprises bear 82.5 billion yuan of governance cost, the Hebei government bears 2,241 Yuan and 6.7 billion Yuan, and the cost borne by Hebei enterprises bear 86.667 billion yuan.

Because what is allocated as the cost, the Shapley value method is generally used for the distribution of income, so its assumption condition is generally positive; that is, the income obtained is positive; then on the contrary, the cost paid is negative; that is, A bears 229.167 billion yuan in cooperative governance, B bears 82.5 billion yuan, C bears 224.167 billion yuan, and D bears 86.667 billion yuan.

S15	6200	6700	-500	1/4	-125.00

According to the Shapley value allocation, the cooperation cost is shown in Table 9.

It can be seen from the above table that the cost borne by the cooperation is less than the cost generated by the

individual governance, which also satisfies the individual rationality. At the same time, compared with the individual governance in each region, the cost borne by each stakeholder in the joint governance is significantly less than that

TABLE 8: Expenses borne by Hebei Enterprises in air pollution control projects (unit: 100 million Yuan).

C, D	-7200	-3108.33
A, D	-7100	-3158.33
B, C	-7050	-3066.67
A, C	-7000	-4533.33
B, D	-7150	-1691.67
A, C, D	-6900	-5400.00
B, C, D	-6800	-3933.33
A, B, C	-6500	-5358.33
A, B, D	-6700	-5400.00

borne by the individual governance. In the absence of relevant stakeholders,  $V(\emptyset) = 0$  and  $V(S_1 \cup S_2) \geq V(S_1) + V(S_2)$  are satisfied.

To sum up, the cost obtained by using the Shapley value method is less than the cost of independent cooperation or independent governance, which can make the cost allocation more scientific, fair, and reasonable, reduce the risks borne by each stakeholder in participating in project governance, and promote the progress of the project governance. At the same time, in the actual situation, we must adjust the cost according to the actual situation and pay attention to risk control, to ensure the smooth completion of air pollution control.

5.3. *Modifying the Model.* Through the above analysis, the four benefit distribution factors, namely, cost bearing, risk bearing, contribution degree, and contract execution degree, should be considered. For convenience, the influential factors are set  $T = \{T\}$ ,  $T = 1, 2, 3,$  and  $4,$  respectively, representing these four factors. And in the cooperation mode set  $S$  of participants, the modification value of the influence factor on  $t$  cost allocation of the  $i^{\text{th}}$  participant is BIT. The specific results are shown in Table 10.

According to the above table, the following coefficient matrix  $B$  can be obtained:

$$\begin{aligned}
 B_1 &= \begin{bmatrix} b_{A1} \\ b_{A2} \\ b_{C1} \\ b_{D1} \\ b_{E1} \\ b_{F1} \end{bmatrix}, \\
 B_2 &= \begin{bmatrix} b_{A2} \\ b_{B2} \\ b_{C2} \\ b_{D2} \\ b_{E2} \\ b_{F2} \end{bmatrix}, \\
 B_3 &= \begin{bmatrix} b_{A3} \\ b_{B3} \\ b_{C3} \\ b_{D3} \\ b_{E3} \\ b_{F3} \end{bmatrix}, \\
 B_4 &= \begin{bmatrix} b_{A4} \\ b_{B4} \\ b_{C4} \\ b_{D4} \\ b_{E4} \\ b_{F4} \end{bmatrix}.
 \end{aligned} \tag{12}$$

If we arrange the matrix  $B$ , we get the matrix  $B' = \{b'_{it}\}_{6 \times 4}$

In the process of atmospheric governance, several experts are needed to score the influencing factors. At this time, there will be a fractional coefficient matrix  $A = [A1, A2, A3, A4]$ , and a new coefficient matrix  $D = B^* A = [D1, D2, D3, D4, D5, D6]$  can be obtained.

TABLE 10: Correction coefficient table.

	1. (the expenses)	2. (risk taking)	3. (contribution)	4. (Degree of contract execution)
A	bA1	bA2	bA3	bA4
B	bB1	bB2	bB3	bB4
C	bC1	bC2	bC3	bC4
D	bD1	bD2	bD3	bD4
E	bE1	bE2	bE3	bE4
F	bF1	bF2	bF3	bF4

Therefore, after adjustment, the cost to be borne by each region is

$$Y'_i(V) = \sum_{S_j \in S} W(|S|)[V(S) - V(S/i)] + D_j i \quad (13)$$

$$= 1, 2 \dots n.$$

The adjusted Shapley value is closer to the reality, and more influential factors are considered so that the cost sharing is not only more objective but also to ensure the smooth implementation of the project so that the goal of atmospheric governance can be realized faster, and the cost distribution scheme is more fair, reasonable, and scientific.

## 6. Conclusion

This paper focuses on the issue across regional pollution control cost allocation. We established an air pollution control cost-sharing model based on the Shapley value and determined the core stakeholders to make the cost allocation more reasonable, scientific, and fair. The Shapley model reduces the charges of each stakeholder, disperses the risks of participants to a certain extent, and effectively ensures the smooth progress of the project. We found that the cost distribution model based on Shapley value can optimize the cost and maximize the social benefit. Because air pollution control needs a long process, the reduction of cost and risk can effectively ensure the completion of air pollution control, which plays an important role in promoting air pollution control.

The subsequent studies could consider factors such as risk, contribution rate, and the bearing capacity of each stakeholder. Determining the influencing factors according to the different situations of stakeholders can make the cost more reasonable and realistic. Besides, the governance in different regions is not the same. The prevention and control method based on the local conditions could make the cost allocation model more widely used, better solve the air pollution problem, and maximize social benefits.

## Data Availability

The data of this project were obtained through the investigation of "National Joint Research Center for Air Pollution Prevention and Control Project Topic: Regional Dynamic and High Spatial-Temporal Resolution Air Pollution Source Emission Inventory."

## Conflicts of Interest

The authors declare that they have no conflicts of interest.

“Road rage,” namely, driving anger, has been becoming increasingly common in auto era. As “road rage” has serious negative impact on road safety, it has attracted great concern to relevant scholar, practitioner, and governor. This study aims to propose a model to effectively and efficiently detect driving anger states with different intensities for taking targeted intervening measures in intelligent connected vehicles. Forty-two private car drivers were enrolled to conduct naturalistic experiments on a predetermined and busy route in Wuhan, China, where drivers’ anger can be induced by various incentive events like weaving/cutting in line, jaywalking, and traffic congestion. Then, a data-driven model based on double-layered belief rule base is proposed according to the accumulation of the naturalistic experiments data. The proposed model can be used to effectively detect different driving anger states as a function of driver characteristics, vehicle motion, and driving environments. The study results indicate that average accuracy of the proposed model is 82.52% for all four-intensity driving anger states (none, low, medium, and high), which is 1.15%, 1.52%, 3.53%, 5.75%, and 7.42%, higher than C4.5, BPNN, NBC, SVM, and kNN, respectively. Moreover, the runtime ratio of the proposed model is superior to that of those models except for C4.5. Hence, the proposed model can be implemented in connected intelligent vehicle for detecting driving anger states in real time.

## 1. Introduction

“Road rage” is a particular driving emotion resulting from pressure or frustration from daily life or adverse traffic environments or discourteous behaviors from surrounding traffic participants [1]. The driving emotion has been becoming an increasingly common issue affecting road safety in auto era all over the world. A report from National Highway Safety Administration of US indicated that the ratio of traffic accidents because of emotional driving like road rage accounted for 9.2%~14.8% of the total [2]. In

China, another report showed that road rage brought about 17.33 million illegal acts, leading to 83,100 traffic accidents in 2015, 1.22% higher than that of 2014 [3]. As anger has a negative impact on a driver’s perception, identification, decision, and volition process, the driver will inevitably have a degraded driving performance finally [4]. Then, an angry driver is prone to make more mistakes or lapses or violations, leading to more traffic accident involvements [5]. Therefore, a driving anger detection/warning method should be designed for effective intervening to deal with road rage in connected intelligent vehicles nowadays.

*1.1. Literature Review.* To effectively and efficiently identify different emotional states based on multisource heterogeneous data, it is important to select a suitable classification method. Additionally, appropriate emotion elicitation method is also necessary as it is a precondition for emotion detection research. Hence, a brief review of related studies is shown as follows.

*1.2. Emotion Elicitation.* When a target emotion is evoked by a specific stimulating scenario, the evoking process is called emotion elicitation. At present, most of emotion elicitation has been executed in quiet laboratory. Kessous et al. [6] adopted a voice interaction with an agent through speaking a sentence in a special contextualization to elicit several common emotions like anger, fear, happiness, and sadness. Juslin and Sloboda [7] proposed a music-based anger elicitation approach by means of different combinations of valences (positive/negative) and arousals (high/low), showing that the greatest anger occurred under the context of negative music with high arousal. Besides those ordinary emotions in daily life, driving emotion elicitation has been becoming a hot research topic. Lei et al. [8] firstly selected video clips extracted from Chinese well-known films including “The Rape of Nanking” and “Fist of Fury” as the anger induction materials in driving simulator experiment to study vehicles’ velocity characteristics in anger state. Roidl et al. [9] also induced the subjects’ anger with short film clips from word-wide famous film “Schindler’s List” to study their driving performances including lateral and longitudinal velocity and acceleration in anger state. Abdu et al. [10] made the subjects recall incentive events encountered in their daily life in detail before conducting driving simulator experiment, to elicit their anger for studying their skilled driving behavior and risk taking behavior in anger state. Based on multiple networked driving simulators, Cai and Lin [11] elicited the subjects’ anger state according to mutual interactions like blocking or changing lane abruptly in front of the subject car in networked driving simulators. Danaf et al. [12] used a series of adverse events in controlled intersection to induce the subjects’ anger state in driving simulator experiments for modeling anger and aggressive driving behavior. Nevertheless, most of emotion elicitation methods in those studies are on the basis of video, music, verbal, or behavior interaction or incentive situations in virtual environment, which inevitably limit the universality of the elicitation approaches due to individual cultural background or personal preference. Moreover, the emotion elicited in inner lab is not valid as that elicited in real traffic environment, owing to some demand characteristics or social desirability [13].

*1.3. Emotion Recognition.* At present, most of emotion recognition is realized through machine learning algorithms, which can effectively deal with multisource data. Flidlund and Izard [14], at the earliest, identified several emotions including delightfulness, sadness, anger, and fear by linear discriminants based on the subjects’ facial electromyography characteristics. Wang and Gong [15] identified various driving emotions based on a factorization model using physiological features including blood volume pulse, skin conductance (SC), respiration rate

(RR), and skin temperature. Katsis et al. [16] effectively differentiated car-racing drivers’ several emotions such as high/low stress, dysphoria, and euphoria in a driving simulator environment based on decision tree and Naïve Bayesian classifier (NBC) with features of facial electromyography, electrocardiogram, respiration, and electrodermal activity (EDA). Wan et al. [17] implemented a linear discriminant model combined with receiver operating characteristic (ROC) curve analysis to identify driving anger based on five physiological features consisting of SC, RR, heart rate (HR), and relative power spectrum of beta wave ( $\beta\%$ ) and theta wave ( $\theta\%$ ) in electroencephalogram (EEG). Except for the physiological features, a driver’s operational behaviors and driving performances as well as vehicle motions have also been used for recognizing driving emotions. Malta et al. identified driver’s frustration state based on Bayesian network (BN) with EDA and brake/acceleration pedal actuation features [18]. Lanatà et al. recognized high and low driving stress through a nearest mean classifier (NMC) based on respiration activity, heart rate variability (HRV) and electrodermal response (EDR) together with steering wheel angle corrections, velocity variance [19]. Wan et al. [20] proposed a detection model of driving anger based on SVM and multivariate time series features of driving behaviors including steering wheel angle and vehicle lateral position. Danaf et al. [12] proposed a dynamic choice-latent variable model to predict driving anger level with the features of driver personality, incentive situations, and vehicle motion states acquired in driving simulator experiments. In addition, other machine learning algorithms like backpropagation neural networks (BPNN), decision tree (C4.5), and k-nearest neighbor (kNN) are often employed to recognize kinds of driving mental states [21].

So far, most of the aforementioned studies aim to recognize some usual emotions like delightfulness, sadness, stress, and frustration under lab conditions. Few studies have been conducted to recognize driving anger in real traffic environment, especially in metropolitan area of China, where road rage is a common and serious traffic psychology issue threatening road safety. Furthermore, too many physiological indicators collected by biosensors were utilized in the aforementioned studies. However, most of the current biosensors are intrusive for a driver to some extent due to various electrodes adhering to their skin surface, which may have a negative impact on their naturalistic driving performances. Additionally, most of the current studies only tackle binary discrimination of a certain mental state (e.g., fatigue or not), without more subdivision according to its intensity, which is not helpful to take target intervening measures for a specific mental state with a certain intensity. Moreover, the recognition of driving mental states in those studies is mostly based on neural network (NN), support vector machine (SVM), fuzzy logic, and Bayes network (BN), which lack effective weight allocation in input indexes and training rules, and its accuracy depends on the completeness of data samples, leading to inefficient data use. Further, those models are not suitable to be applied for recognition system requiring high instantaneity in practice when increasing input variables. For example, the conditional probability tables of BN will have exponential growth when adding a new input, which demands much more computational consumption. Last but not least, when constructing those recognition models, either

vehicle or driver data are utilized without considering the effect of driving environment on mental state whose induction is extremely dependent on a certain environment.

Aiming at that, a high-arousal driving anger elicitation approach is firstly proposed through stimulation of specific incentive situations according to naturalistic driving experiments conducted in real traffic environment, during which nonintrusive measurements like vehicle motions and driving environments, as well as driver personal attributes, will be collected. Secondly, in order to fully utilize the multisource heterogeneous data with uncertainties to effectively and efficiently recognize driving anger states, a double-layered belief rule base (BRB) approach is utilized to propose a recognition model of driving anger states with different intensity. Then, the influencing factors of driving anger could be divided into several groups according to the attribute or category of those factors. In each group, the inference process can be separately executed in an iterative way, which reduces dimensions of the BRB greatly, especially for only one layer, meaning less complicated computation and higher instantaneity. Finally, the effectiveness and efficiency of the proposed model are evaluated and compared with other widely used classification algorithms.

## 2. Experimental Designs

**2.1. Scene Design.** In order to make every subject generate anger as much as possible, a special test route containing many busy sections across Wuchang and Hankou District of Wuhan was designed for naturalistic driving experiments conducted in this study (see Figure 1(a)). The test route was almost 50.8 km, which included two tunnels, two expressways, three central business districts, 42 signalized intersections, and 59 zebra crossings. When conducting the experiment, every subject would often confront incentive environmental events or situations, such as weaving/cutting in line, jaywalking/motorcycle occupying road, traffic jams, or traffic light waiting, which randomly and frequently happened, especially during morning and evening rush hours (see Figures 1(b)–1(d)). Hence, each subject was required to begin the experiment at about 8:00 a.m. or 5:00 p.m. In order to induce more anger further, every subject was promised to get extra paid if they could complete the experiment ahead of reference time. Note that no speeding was permitted during the whole experiment. Simultaneously, to induce anger as real as possible, the driving experiments are designed to be single-blind, namely, naturalistic, which means that every subject would conduct the whole experiment alone without any interference, according to their own driving style in daily life.

**2.2. Participants.** Forty-two private car drivers with valid C1 license were enrolled from Wuhan, a fast-growing central metropolis in China, to conduct naturalistic experiments. In order to maximize the statistical power, much more male subjects were chosen in this study, as males are more prone to be involved in angry driving than females [22]. The average age of the subjects was 37.8 (SD = 5.4) years, while their

average driving age was 9.8 (SD = 4.6) years. The population distribution of the subjects with different demographic characteristics is shown in Table 1. It is noted that every subject should be checked to be in good mental condition through a profile of mood states (POMS) questionnaire, which is important to verify the effectiveness of the driving anger elicitation approach proposed in this study. Additionally, an observer (expert) with rich driving experience (>20 years) in driving behavior field was recruited to assess every subject's anger level according to the video replay of the whole experiment process.

**2.3. Apparatus.** Related research indicated that dangerous driving behaviors such as fatigue, anger, and distraction can be identified according to lateral and longitudinal vehicle motions including yaw rate, acceleration (longitudinal), and lane departure [23, 24]. Hence, a car (see Figure 2(a)) instrumented with Mobileye C2-270 system (see Figure 2(b)) and Inertial Navigation System RT2500 (see Figure 2(c)) was used as the experimental vehicle for conducting naturalistic driving experiments. It is noted that Mobileye C2-270 system is a collision warning system that can collect time headway and lane departure data, while Inertial Navigation System RT2500 is a precise vehicle motion acquisition system that can collect the heading, pitch, and roll motion characteristics of vehicle movements like yaw angular acceleration rate and longitudinal acceleration. Moreover, a clock was equipped on dash board of the test car to remind every subject of the remaining time of the experiment.

Additionally, three high-definition cameras with resolution ratio of 800 \* 640 and frame rate of 30 (see Figure 2(d)) were pasted on the front windshield of the test vehicle to record every subject's physical or behavior reaction and driving environments around. In more detail, the first camera was used to record driving environments around like unfavorable traffic environments (i.e., jam and congestion) and incentive events from surrounding traffic participants (i.e., jaywalk and cutting in line). The second one was implemented to record the subject's facial (i.e., frown and straight face) or verbal (i.e., curse and name-calling) expression and head movement. The third one was utilized to roughly record the subject's fiercely operational (high frequency or large amplitude) behaviors of steering wheel, gear lever, and other physical behaviors like slapping steering wheel or frequent honking. The video replay from the three cameras will be implemented as intuitive evidence to calibrate driving anger level for every subject and the expert.

### 2.4. Experiment Procedure

- (1) *Experimental Protocol Signing*. Each subject was demanded to sign an experimental protocol with us if they agreed on the requirements and payment stated in the protocol. ① Each subject had to begin the formal experiment from 8:00 a.m. or 5:00 p.m. ② Each subject was prohibited from violating any traffic regulation like running red lights and speeding

FIGURE 1: The test route and traffic environment of field experimental system. (a) The test route (shown as red line). (b) Jaywalking collectively. (c) Electrical motorbike occupying the road. (d) Cutting in line in traffic congestion.

TABLE 1: The population distribution of the subjects with different demographic characteristics.

Gender		Age				Temperament			
Male	Female	22–29	30–39	40–49	50–59	Melancholic	Phlegmatic	Sanguineous	Choleric
33	9	9	12	12	9	6	15	12	9

(speed limit is 70 km/h in the whole city). ③ Each subject could get the basic paid of 300RMB (Chinese currency) for accomplishing the whole experiment, and they could get extra paid with 15 RMB/min if they completed the whole experiment ahead of reference time, i.e., 120 minutes, within which it was proved to be a little pressure for the test according to the results of several pretests. Especially, all subjects can get the basic paid of 300RMB without any deduction if they could not accomplish the experiment within the reference time, based on the spirit of institutional review board (IRB) and Chinese law on scientific research. ④ They had to report their anger level objectively and truthfully without hiding their true feelings in the following step of self-report after finishing the experiment as they were informed that there was no right or wrong about their self-reports.

(2) *Personal Characteristics Collection*. Every subject's personal characteristics such as age, gender, and driving years were simultaneously collected when

signing the experimental protocol, and temperament, strongly related with driving style, was acquired by Chen Huichang Temperament Inventory [25].

(3) *Adaptive Driving Practice*. Every subject conducted 10-minute driving practice to accommodate to handling performance of the experimental vehicle, in order to eliminate discomfort or tension when firstly driving the experimental vehicle.

(4) *Formal Naturalistic Experiment*. Every subject had to accomplish the experiment alone without any interference. Note that they could finish the experiment in their habitual driving style. Meanwhile, all driving environments including the unfavorable traffic environments and incentive events (behaviors) from surrounding traffic participants, the subject's facial/verbal expression, and physical behaviors were automatically recorded by the three HD cameras during the whole experiment.

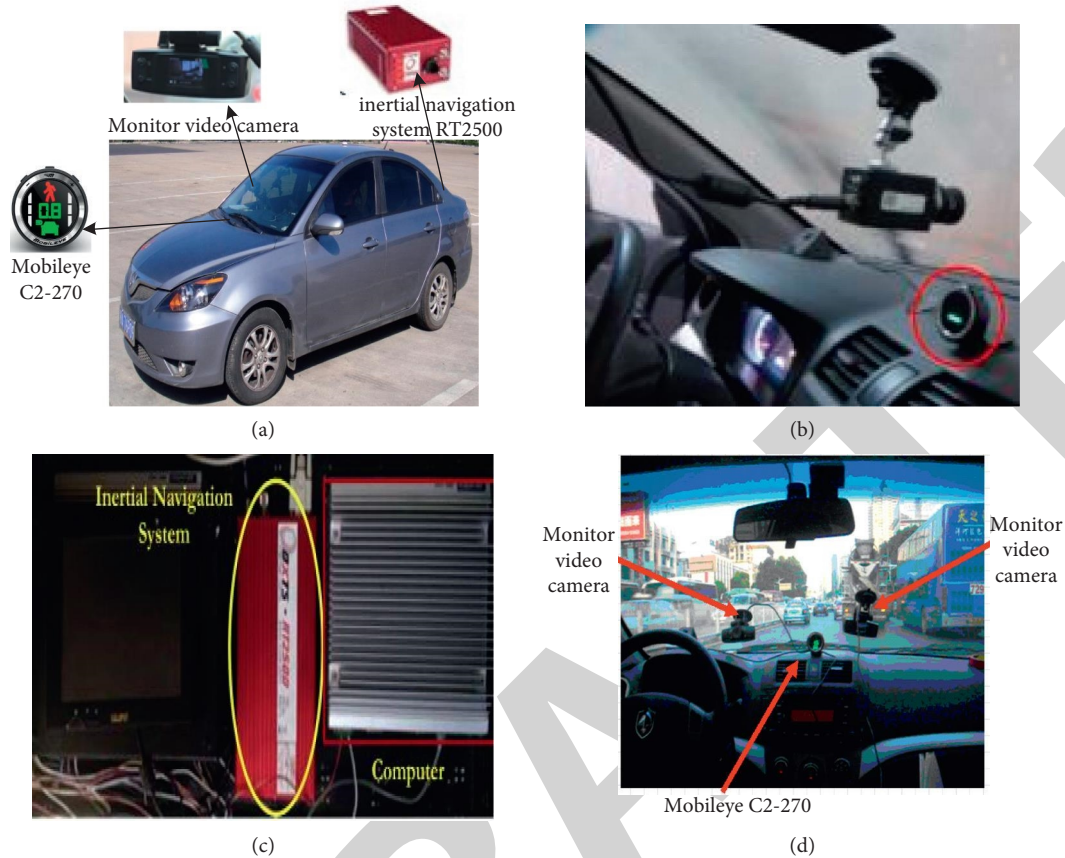

FIGURE 2: The apparatus of naturalistic experimental system. (a) Overall sketch of the apparatus system. (b) Mobileye C2-270 system. (c) Inertial Navigation RT 2500 System. (d) Monitoring video camera.

(5) *Self-Report after Experiment.* Once the experiment was completed, every subject was immediately required to recall and report their emotional type and level with a ten-point scale from 0 (not at all) to 9 (very much) every two minutes during the experimental process, or any occasion when an incentive event happened during the process, through the video replay from the three cameras in a quiet lab. Meanwhile, the observer also utilized the ten-point scale to evaluate the subject's emotional level, so as to correct some subjects' terribly subjective self-report, which had seriously deviated from the truth.

### 3. Data Reanalysis

*3.1. Driving Anger Inducing Effect.* According to the feedback from all subjects, every subject underwent several different emotions throughout the whole experimental process. Then, it is necessary to verify if the target emotion (i.e., anger) has been induced out during driving using the novel anger induction approach proposed in this study. Here, the hit rate was applied as an indicator to assess driving anger inducing effect. As each subject had to self-report their emotional type and level every two minutes and any instant an incentive driving environment (situations) occurred during driving, 2414 emotional cases in all were acquired from all subjects,

1194 of which are anger instances. As indicated in Table 2, the hit rate is 8.27% if no incentive situations occurred during driving, meaning that the extra paid for accomplishing experiment ahead of reference time did give the subjects a little time pressure. Note that the hit rate under stimulus of jaywalking/motorcycle occupying road is highest with 82.03%, while the lowest with 56.94% under the stimulus of traffic lights waiting. To sum up, the average hit rate of anger under the incentive situations reaches 74.25% (i.e.,  $(1194-75)/(2414-907)$ ), significantly higher than that under no incentive situations. Therefore, the novel anger induction approach proposed in this study is effective.

*3.2. Driving Anger Intensity Calibration.* In order to effectively and efficiently reduce the negative effect of road rage on traffic safety and efficiency, it is extremely critical to take the target warning or intervening for different driving anger states with different intensity. In this study, different anger states were calibrated based on the subjects' self-reported anger levels. It is noted that when calibrating driving anger states, any subject's self-report would be immediately adopted if the assessment discrepancy between the subject and the observer is smaller than 2, or else, three more independent experts (driving years  $\geq 25$ ) in the field of traffic psychology would be invited to reassess the subject's anger level based on the replayed video. Here, four kinds of anger

TABLE 2: Hit rate of five emotions from the scenarios with and without incentive situations.

Incentive situations	<i>Fear</i>	<i>Happy</i>	<i>Anger</i>	<i>Sad</i>	<i>Neutral</i>	<i>Total</i>	<i>Hit rate (%)</i>
No incentive situations	8	40	75	5	779	907	8.27
Jaywalking/motorcycle occupying road	44	4	388	10	27	473	82.03
Weaving/cutting in line	55	5	366	20	36	482	75.88
Traffic jam/congestion	17	8	242	27	42	336	72.02
Traffic lights waiting	12	7	123	23	51	216	56.94
Total	136	64	1194	85	935	2414	

intensity were defined in this research, namely, neutral or none anger (anger level = 0), low anger (anger level = 1, 2), mediate anger (anger level = 3, 4), and high anger (anger level  $\geq 5$ ). Consequently, 1194 anger-related samples including low anger, mediate anger, and high anger, as well as 935 neutral (none anger) samples, shown in Figure 3, were determined for the following study.

As aforementioned, some typical vehicle motions characteristics like yaw rate, acceleration, and lane departure can reflect dangerous or aggressive driving behavior. In addition, some personal characteristics including gender, age, and temperament, as well as environmental (situational) like traffic congestion and illegal traffic behaviors around, are decisive influencing factors of road rage [26]. Therefore, after calibrating the four kinds of driving anger states (modes) in terms of intensity, those corresponding vehicle characteristics, human characteristics, and environmental characteristics in line with a certain driving anger mode at that moment were all screened for constructing driving anger detection model. Then, 2129 driving samples including 1194 anger-related samples and 935 neutral (none anger) samples are partly listed in Table 3. According to the feedbacks from the participants, it is worth noting that any anger state with certain intensity would remain unchanged about 6~10 seconds until the new elicitation situation with different intensity occurs. Hence, vehicle motion signals lasting 8 (i.e., average) seconds from the moment the elicitation situation occurred were chosen for study driving anger characteristics.

## 4. Methodology

**4.1. Belief Rule Base (BRB) Inference Approach.** Yang et al. proposed an innovative inference approach, called belief rule base (BRB), to solve complicated decision-making problem [27]. The BRB approach can effectively deal with quantitative and qualitative information with uncertainty, incompleteness, subjectivity, and nonlinearity. The core of the approach is a hybrid rule base, which is established with a belief structure based on evidence theory of Dempster-Shafer, decision theory, and fuzzy inference [28]. In order to improve the approach's inference accuracy, the weights of rules and attributes as well as belief degree of output are introduced on the basis of traditional rule expression methods like fuzzy inference, during the BRB inference process using evidential reasoning (ER).

**4.1.1. Belief Rule Base Structure.** With regard to BRB inference methodology, the  $k$ th rule  $R_k$  of the rule base is expressed as follows:

FIGURE 3: Instances of different anger states.

$$R_k: \text{ If } x_1 \text{ is } A_1^k \wedge x_2 \text{ is } A_2^k \wedge \dots \wedge x_{T_k} \text{ is } A_{T_k}^k, \text{ then } \{(D_1, \beta_{1k}), (D_2, \beta_{2k}), \dots, (D_N, \beta_{Nk})\}, \quad (1)$$

with a rule weight  $\theta_k$  and attribute weight  $\delta_{ik}$ . If the  $k$ th ( $k = 1, 2, \dots, L$ ) rule is complete, then

$$\sum_{j=1}^N \beta_{jk} = 1. \quad (2)$$

If the  $k$ th rule is incomplete, then

$$\sum_{j=1}^N \beta_{jk} < 1, \quad (3)$$

where  $x_i$  ( $i = 1, 2, \dots, T_k$ ) denotes the  $i$ th antecedent attribute (input variable) in the  $k$ th rule ( $R_k$ );  $T_k$  is the number of antecedent attributes in  $R_k$ ;  $A_i^k$  is the referential value of the  $i$ th antecedent attribute in  $R_k$ ;  $D_j$  is the  $j$ th ( $j = 1, 2, \dots, N$ ) consequent (output variable) in  $R_k$ ;  $\beta_{jk}$  is the belief degree of  $D_j$ ;  $N$  is the number of all consequents;  $\theta_k$  is the weight of  $k$ th rule;  $L$  is the number of all rules in rule base.  $\delta_{ik}$  is the weight of  $i$ th antecedent attribute in  $R_k$ .

According to equation (1), we can see that the belief if-then rule structure proposed is superior to traditional if-then rule, where the consequent is either 100% true or 100% false, leading to a strictly limited ability when representing rule (knowledge) in a real and complex world. The proposed structure can provide better flexibility in representing rule with simple or complicated, quantitative or qualitative, continuous or discrete, certain or uncertain relationship between the input and output.

TABLE 3: Partial sample data of driving anger about human, vehicle, and environment characteristics.

ID	Human			Vehicle			Environment		Driving state
	Gender	Age	Temperament	Yaw angular acceleration (deg/s <sup>2</sup> )	Longitudinal acceleration (m/s <sup>2</sup> )	Lane departure (m)	Traffic flow	Traffic behavior around	
1	Male	42	Phlegmatic	1.7001	0.6703	0.2542	Smooth	Normal	Neutral
2	Male	37	Phlegmatic	1.7611	0.8764	0.3339	Less smooth	Less severe	Neutral
3	Female	51	Phlegmatic	1.7687	1.6145	0.5007	Smooth	Severe	Low anger
4	Male	22	Choleric	2.5362	2.3043	0.7866	Less smooth	Severe	High anger
5	Female	35	Sanguineous	1.7325	0.5587	0.3176	Less smooth	Normal	Neutral
...									
2125	Female	44	Melancholic	2.1348	1.8818	0.7031	Smooth	Severe	Moderate anger
2126	Male	46	Choleric	1.8842	1.1207	0.3777	Less smooth	Less severe	Low anger
2127	Male	32	Phlegmatic	2.5575	1.4677	0.6273	Smooth	Less severe	Moderate anger
2128	Male	38	Phlegmatic	1.9329	1.5429	0.6646	Obstructive	Less severe	Low anger
2129	Male	24	Choleric	2.4033	2.3567	0.6987	Obstructive	Less severe	Moderate anger

4.1.2. *BRB Inference Using ER.* In order to compute the activation weight of  $k$ th rule  $R_k$ , the matching degree (i.e., membership) of the input  $x_i$  to the referential values of this antecedent attribute of  $R_k$  needs to be calculated firstly. The membership can be calculated by using utility-based equivalence transformation techniques, shown as follows:

$$a_{i,q}^k = \frac{(A_{i,q+1}^k - x_i)}{(A_{i,q+1}^k - A_{i,q}^k)}, \quad A_{i,q}^k < x_i \leq A_{i,q+1}^k, \quad (4)$$

$$a_{i,q+1}^k = \frac{(x_i - A_{i,q}^k)}{(A_{i,q+1}^k - A_{i,q}^k)}, \quad A_{i,q}^k < x_i \leq A_{i,q+1}^k,$$

where  $x_i$  ( $i = 1, 2, \dots, T_k$ ) denotes the  $i$ th input variable in  $R_k$ ;  $A_{i,q}^k, A_{i,q+1}^k$  are the two adjacent referential values of  $x_i$ , respectively;  $a_{i,q}^k$  is the degree to which the input  $x_i$  belongs to the referential value  $A_{i,q}^k$ , while  $a_{i,q+1}^k$  is the degree to which the input  $x_i$  belongs to the referential value  $A_{i,q+1}^k$ .

After determining  $a_{i,q}^k$ , the activation weight of the  $k$ th rule  $w_k$  is calculated as follows:

$$\beta_n = \frac{\prod_{k=1}^L (w_k \beta_{n,k} + 1 - w_k \sum_{i=1}^N \beta_{i,k}) - \prod_{k=1}^L (1 - w_k \sum_{i=1}^N \beta_{i,k})}{\sum_{j=1}^N \prod_{k=1}^L (w_k \beta_{j,k} + 1 - w_k \sum_{i=1}^N \beta_{i,k}) - (N-1) \prod_{k=1}^L (1 - w_k \sum_{i=1}^N \beta_{i,k}) - \prod_{k=1}^L (1 - w_k)} \quad (7)$$

After  $\beta_n$  is determined, the driving anger states with different intensity can be calculated as follows:

$$\text{Anger}(Y) = D_1 \beta_1 + D_2 \beta_2 + \dots + D_N \beta_N. \quad (8)$$

As the driving anger states defined in this study are comprised of neutral, low anger, moderate anger, and high

$$w_k = \frac{\theta_k \prod_{i=1}^{T_k} (\alpha_{i,q}^k)^{\bar{\delta}_i}}{\sum_{l=1}^L \left[ \theta_l \prod_{i=1}^{T_l} (\alpha_{i,q}^l)^{\bar{\delta}_i} \right]}, \quad (5)$$

where  $\bar{\delta}_i = \delta_i / \max_{i=1, \dots, T_k} \{\delta_i\}$ . If  $\bar{\delta}_i = 0$ , then  $(\alpha_{i,q}^k)^{\bar{\delta}_i} = 1$ ; it indicates that the  $i$ th antecedent attribute does not have any impact on activation weight of  $R_k$ . If  $\bar{\delta}_i = 1$ , then  $(\alpha_{i,q}^k)^{\bar{\delta}_i} = \alpha_{i,q}^k$ ,

It indicates that the  $i$ th antecedent attribute has the biggest impact on activation weight of  $R_k$ .

Given that the input is denoted by  $X$ , the outcome of BRB inference is then denoted as follows:

$$Y(x) = \{(D_j, \beta_j), j = 1, 2, 3, \dots, N\}. \quad (6)$$

Equation (6) can be interpreted as the consequent is  $D_1$  with a belief degree of  $\beta_1$ ,  $D_2$  with a belief degree of  $\beta_2, \dots$ , and  $D_N$  with a belief degree of  $\beta_N$ . Based on the analytical format of ER approach, the combined belief degree  $\beta_j$  can be calculated as follows:

anger, in terms of intensity, Anger (Y) can also be expressed as follows:

$$\text{Anger}(Y) = D_1 \beta_1 + D_2 \beta_2 + D_3 \beta_3 + D_4 \beta_4. \quad (9)$$

Hence, Anger (Y) is a continuous value within the range of  $[0, 3]$ . In order to directly compare the estimated output of

the proposed model and the observed output from the subjects' self-reports, it is necessary to discretize Anger ( $Y$ ), shown as follows:

$$\text{Estimated\_Anger}(y) = \begin{cases} 0 & 0 \leq \text{Anger}(y) \leq 0.5, \\ 1 & 0.5 < \text{Anger}(y) \leq 1.5, \\ 2 & 1.5 < \text{Anger}(y) \leq 2.5, \\ 3 & 2.5 < \text{Anger}(y) \leq 3. \end{cases} \quad (10)$$

**4.1.3. Training of BRB Model.** The initial belief rule base including BRB model parameters comprised of  $\theta_k$ ,  $\beta_{jk}$  and  $\delta_{ik}$  for the  $k$ th rule ( $R_k$ ) can be generated randomly or specified by famous experts in the fields of driving behavior or traffic psychology. Correspondingly, the initial belief rule base is inaccurate to some extent because of the experts' subjectivity or arbitrariness. Therefore, the initial belief rule base needs to be trained for optimization. In this study, abundant historical samples data collected in the naturalistic experiments were utilized to train the initial belief rule base for better representing actual rules (knowledge). The training process is illustrated as shown in Figure 4.

As indicated in Figure 4,  $\widehat{x}_m$  ( $m = 1, 2, 3, \dots, M$ ) is the input of the real system and the BRB system proposed in this study,  $\widehat{y}_m$  is the observed output of the real system,  $y_m$  is the estimated output of the BRB system, and  $\xi(p)$  is the discrepancy between the observed output and the estimated output. The objective of the training process is to get the minimum of  $\xi(p)$ ; i.e., the objective function can be defined as follows:

$$\min \xi(p) = \frac{\sum_{m=1}^M (y_m - \widehat{y}_m)^2}{M}, \quad (11)$$

subject to

$$0 \leq \beta_{jk}, \theta_k, \delta_{ik} \leq 1. \quad (12)$$

where  $p = p(\beta_{jk}, \theta_k, \delta_{ik})$  is a parametric vector in the objective function;  $m$  ( $1, 2, 3, \dots, M$ ) is the number of input-output pairs. Essentially, the training process is to solve the multiobjective optimization problem with linear constraints, and the best parametric vector  $p(\beta_{jk}, \theta_k, \delta_{ik})$  can be obtained as a result of the training process, which is usually executed with certain optimization tool box of MATLAB software.

**4.2. Driving Anger Detection Model Based on BRB.** Considering different structures and sources of input data for driving anger detection model, a double-layered BRB (DL\_BRB) system is proposed in this study, as shown in Figure 5. The first layer consists of human (driver) status inference subsystem, vehicle status inference subsystem, and environment status inference subsystem. The second layer is to determine the driver's anger state based on the three subsystem's inference results, which are used as the inputs of the second layer. For the subsystem1, there are three human characteristics ( $x_1, x_2, x_3$ ) used as the inputs, while three vehicle characteristics ( $x_4, x_5, x_6$ ) and two environmental characteristics ( $x_7, x_8$ ) are used as the inputs for subsystem 2

FIGURE 4: The training process of BRB inference system.

and subsystem 3, respectively. Especially,  $u_1, u_2, u_3$  are intermediate variables to denote driver status, vehicle status, and environment status, respectively, which are used to inference the driver's anger states ( $y$ ). The definition of all input variables ( $x_1, x_2, \dots, x_8$ ) and output variable ( $y$ ) is listed in Table 4. For example,  $x_1, x_2, x_3$  represent the driver's gender, age, and temperament, respectively.

As indicated in Figure 5, the input variables of the proposed model were comprised of three types of characteristics including human, vehicle, and environments, while the output variable of the proposed model is driving anger state ( $y$ ). Moreover, the human characteristics consisted of gender ( $x_1$ ), age ( $x_2$ ), and temperament ( $x_3$ ), the vehicle characteristics consisted of yaw angular acceleration ( $x_4$ ), longitudinal acceleration ( $x_5$ ), and lane departure ( $x_6$ ), and the environment characteristics consisted of traffic flow state ( $x_7$ ) and surrounding traffic behaviors ( $x_8$ ), shown in Table 4.

According to the distribution trait of those human, vehicle, and environment characteristics data, the interpretation or the reference values for every input variable with different grades were determined, as shown in Table 5. For instance, temperament, denoted by  $x_3$ , can be classified in to 4 different grades including melancholic, phlegmatic, sanguineous, and choleric, while the longitudinal acceleration, denoted by  $x_5$ , can be graded into 3 levels with references of  $1 \text{ m/s}^2$ ,  $1.5 \text{ m/s}^2$ , and  $2 \text{ m/s}^2$ , respectively. It is noted that the reference value for the different grades of yaw angular acceleration ( $x_4$ ), longitudinal acceleration ( $x_5$ ), and lane departure ( $x_6$ ) were determined according to their statistical data for the four driving anger states including neutral, low anger, moderate anger, and high anger. The relevant statics were studied in several previous research conducted by the authors in this study [20, 24, 29]. Moreover, traffic behavior around, denoted by  $x_8$ , was graded in to 3 different types, namely, normal, less severe, and severe, respectively. It is noted that waiting traffic lights belongs to normal traffic behavior around, and weaving/cutting in line or traffic jam/congestion belongs to less severe traffic behavior around, while jaywalking/motorcycle occupying road belongs to severe traffic behaviors around.

In this study, the initial belief rules of the proposed model were constructed based on the relevant expert knowledge and historical driving anger data with certain subjectivity. It is worth noting that, in terms of the second layer of the proposed model, all intermediate variables ( $u_1, u_2, u_3$ ) were graded into three levels, and then there exists 27 rules (33), shown in Table 6. Moreover, the final consequents were expressed in four types of driving anger states, namely,

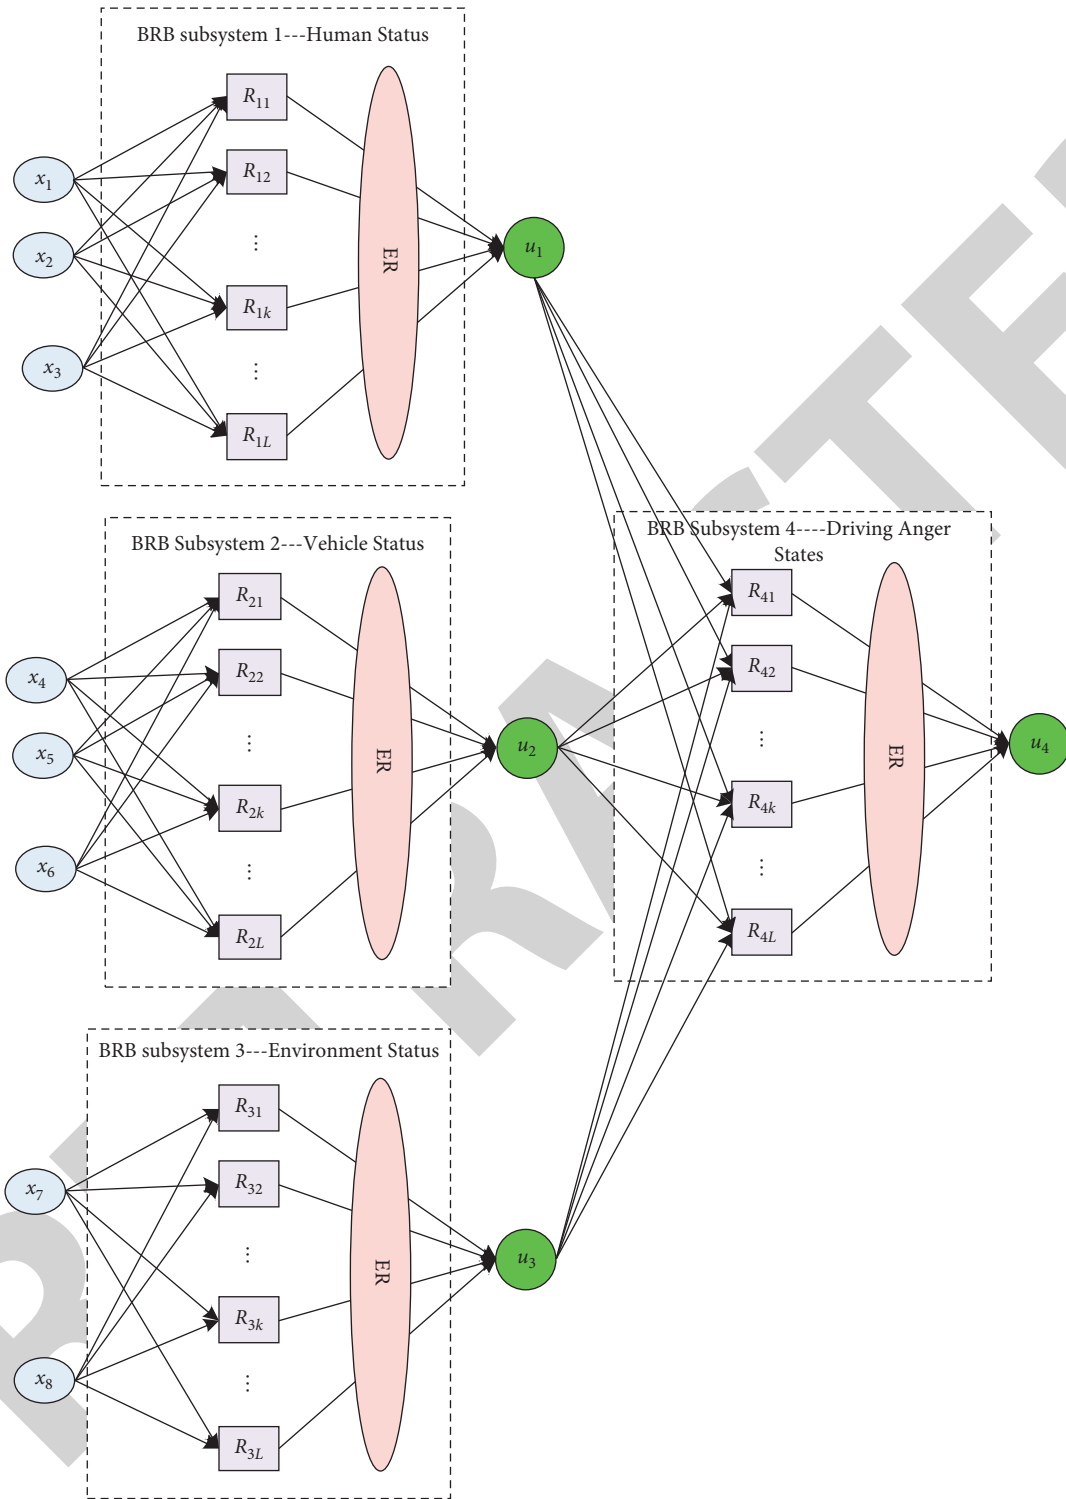

FIGURE 5: Schematic diagram of driving anger detection model based on DI\_BRB system.

neutral (none anger), low anger, moderate anger, and high anger, with a belief degree of  $\beta_{1k}, \beta_{2k}, \beta_{3k}$  and  $\beta_{4k}$  respectively.

As the initial belief rule base (BRB) is imprecise with certain subjectivity, the training of the initial BRB system was conducted according to equations (11) and (12). Then, 60% of samples were randomly selected from the original

2129 driving anger-related samples collected in the naturalistic experiments for training the initial BRB systems. The training processes were executed in optimization toolbox of Matlab, which mainly included computing the matching degree of the input ( $x_i$ ) to the reference value ( $A_i^k$ ), the activation weight of rule ( $R_k$ ), the belief degree of the  $j$ th consequent (output) in  $R_k$ , and minimizing the discrepancy

between the observed output and the estimated output calculated by the proposed model. After finishing the training process, the optimal rule base of BRB subsystem 4 was obtained, as shown in Table 7.

#### 4.3. Test Results

**4.3.1. Evaluation Criteria.** To verify the identification accuracy of the DI\_BRB model proposed in this study, an evaluation method of receiver operating characteristic (ROC) curve analysis was implemented. The ROC method was widely used to evaluate classification performance of a classifier in discrimination fields like medical diagnosis, military monitoring, and human decision-making [30]. For a specific discrimination threshold, namely, cut-off point, it can differentiate positive samples from negative ones with a certain true positive rate (TPR) and false positive rate (FPR). When depicting the cut-off point in a coordinate system with horizontal and vertical ordinate, represented by TPR and FPR, respectively, a complete ROC curve will be formed by connecting all the possible cut-off points with a broken line in the coordinate system. Moreover, the greater the area under the ROC curve (AUC) is, the higher the identification accuracy of the classifier is. Except for TPR, FPR, and AUC, other statistical indexes such as positive predictive accuracy (PPA), *F1* and *Acc* are also extensively applied when evaluating a classifier's classification performance. Those statistical indexes are calculated as follows:

$$\begin{aligned}
 TPR &= \frac{TP}{TP + FN}, \\
 FPR &= \frac{FP}{TN + FP}, \\
 PPA &= \frac{TP}{TP + FP}, \\
 F1 &= \frac{2 \times TPR \times PPA}{TPR + PPA}, \\
 Acc &= \frac{TP + TN}{TP + FN + TN + FP},
 \end{aligned} \tag{13}$$

where *TP* is the number of positive samples, which were correctly identified as positive ones; *FP* is the number of negative samples, which are falsely identified as positive ones; *TN* is the number of negative samples, which are correctly identified as negative ones; *FN* is the number of positive samples, which are falsely identified as negative ones. Here, driving anger samples with a specific intensity are assumed to be positive, while the other driving anger samples are assumed to be negative. Note that *PPA* demonstrates the correct identification probability of the samples, which are identified as positive ones.

**4.3.2. Identification Performance.** The identification performance of the proposed model (DI\_BRB) for four driving anger states with different intensity was evaluated using a test set accounting for 40% of the total samples, which was

comprised of 374 neutral (none anger) samples, 218 low anger samples, 172 moderate anger samples, and 88 high anger samples. Further, in order to verify the superiority of the proposed model, we compared it with other 5 widely used classifiers like C4.5, NBC, SVM, kNN, and BPNN in terms of AUC of the corresponding ROC curves for the four driving anger states, illustrated in Figure 6.

As indicated in Figure 6, the identification performance of DI\_BRB model proposed in this study outperforms C4.5, NBC, KNN, SVM, and BPNN, as the proposed model has an average AUC of 0.8632, which is the biggest among them, according to the ROC curves for all driving anger states. Specially, the performance of the proposed model is evidently higher than the other five models when identifying neutral (none anger) state ( $p = 0.074$ ) and high anger state ( $p = 0.069$ ) in terms of AUC, yet the superiority is small and not significant when the significance level is set to be 0.05. In addition, when identifying the low anger state, the differences of AUC between the proposed model and other five models are much smaller than those of the other three driving anger states. Moreover, the average of AUC of all six identification models is the smallest for low anger state. The possible reason is that the changes of human, vehicle, and environmental characteristics under low anger state are evidently smaller than those of other driving anger states.

Furthermore, in order to evaluate the effectiveness of the proposed model, the five-fold cross-validation method was used to test the six classification models, with the results being indicated in Figure 7. We can see that the proposed DI\_BRB model achieves better identification performances in terms of PPA, TPR, and *F1* when compared with C4.5, BPNN, NBC, SVM, and kNN. Especially, the identification performances of the proposed model are remarkably ( $p = 0.038 < 0.05$ ) better than those of the other five models in terms of the three criteria for high anger state. However, for FPR, another important evaluation criterion, the proposed model does not perform the best, as the model of C4.5 has the lowest value of FPR when identifying all driving anger states.

In summary, the average of the aforementioned criteria and the total accuracy for identifying all driving anger states using the proposed model (DI\_BRB) and the other five widely implemented models were statistically analyzed, with the results being shown in Table 8. Then, we can see that the proposed model outperforms the other five models in most aspects including *TPR* (0.8433), *PPA* (0.9187), *F1* (0.8793), and *Acc* (0.8367). Though the model of C4.5 is superior to the proposed model in terms of FPR, the mean value of FPR of the proposed model is only 0.0792, ranking the second among these models, which is acceptable for detecting driving anger states in practice. Additionally, in order to verify the efficiency of the proposed model, the run speed of these models was compared in MATLAB environment for the same test data. Here, we let the runtime of BPNN model as unit one, and the runtime ratio of the other five models was computed, with the results being shown in the last row of Table 8. It is shown that the runtime ratio of the proposed model ranks the second, just behind C4.5, among the six models, indicating that the computation ability of the

proposed model is enough for detecting driving anger in real time. In conclusion, the proposed DL\_BRB model is effective and efficient enough for detecting different driving anger states in practice.

## 5. Discussion and Conclusions

There are two contributions made in this study to the traffic psychology and driving behavior fields especially angry driving. The first one is that a novel driving anger elicitation approach was proposed to collect the relevant human (driver), vehicle, and environment characteristics in driving anger state. The second one is to propose an effective model based on those heterogeneous characteristics to identify different driving anger states with different intensity. Then, in practice, some soft interferences like releasing soft or relaxed music or comfortable human-machine interaction through conversation can be executed when low or moderate anger state is detected, while some hard interferences like controlling steering wheel or brake or acceleration pedal is taken over by human-machine codriving system when high anger state is detected in intelligent connected vehicle in the near future.

First, in order to induce real anger emotion during driving, a particularly busy route was selected as the test

route for the naturalistic experiments. On the test route, every participant inevitably came across sorts of incentive situations like jaywalking, motorcycle occupying road, weaving or cutting in line, traffic jam or congestion, and traffic light waiting, especially in morning or evening rush hours. The study results indicate that the hit rate of anger under the incentive situations reaches 74.25%, significantly higher than that under no incentive situations, and the highest hit rate (82.03%) of anger happened under the stimulus of jaywalking/motorcycle occupying road. Hence, some targeted and detailed countermeasures can be taken in practice. For example, once those kinds of uncivil (illegal) traffic behaviors are captured by cameras of electrical police, the personal information of pedestrian or the motorcycle rider like their portrait or the ID card number will be exposed on the big screen located on the intersection or roadside based on image identification and big data technology. Moreover, they might be fined if there is a real traffic police on the scene, as well as an increased insurance next year if they have driving license. In addition, every traffic participant should be encouraged to report those uncivil (illegal) traffic behaviors through some official APPs designed by traffic management authorities. Therefore, the novel anger elicitation approach proposed in this study is effective based on the induction of those incentive situations

in real environments and the stimuli of extra paid for finishing the whole test ahead of the reference time. Interestingly, there was inconsistency with previous findings, in which the most driving anger provoking event was discourtesy behavior from surrounding traffic participants in western countries like USA [31] and France [32]. The possible reason for that might be Chinese drivers often travelled with strong mixed traffic modes including motor and nonmotor vehicles and pedestrians competing with each other on the limited road lanes in a rapid pace of life nowadays. Additionally, different traffic rules, life style, culture background, and safety awareness also exerted an effect on the differences of driving anger provoking situations. Moreover, in China, Feng et al. [33] found that the most driving anger provoking situation for professional drivers was traffic obstruction; especially the road works sign was not set when the road was under reconstruction, showing a little disagreement with this study, in which Jaywalking/motorbike occupying road was the most driving anger provoking for private car drivers. Therefore, more target countermeasures should be put forward on monitoring and regulation of uncivilized or illegal travelling behaviors for driving training or traffic management authorities in China.

Secondly, according to previous research conducted by the authors in this study, the human characteristics like gender, age, and temperament, the environmental characteristics like traffic behaviors around and traffic flow state, and the vehicular characteristics like yaw angular acceleration, longitudinal acceleration, and lane departure have close relationship with driving anger [26, 29]. Then, those human, vehicular, and environmental characteristics were selected as the inputs for the establishing driving anger detection model. In this study, a data-driven model based upon belief rule base (BRB), which can continually utilize the accumulated filed data collected during the naturalistic experiments, is proposed to detect driving anger states with different intensity. The BRB based model has much advantage in processing not only objective information like vehicular characteristics data but also subjective information such as human and environmental characteristics data [27]. Moreover, a double-layered BRB (DI\_BRB) system including four BRB subsystems for inferring human, vehicular, and environmental state was constructed to reduce the number of rules to be estimated at the same time for improving the timely response. The study results show that the average identification accuracy (*Acc*) of the proposed model for detecting all driving anger states including neutral, low anger, moderate anger, and high anger reaches 83.67%, which is 1.15%, 1.52%, 3.53%, 5.75%, and 7.42% higher than C4.5, BPNN, NBC, SVM, and kNN, respectively. Besides, the proposed model is superior to those models in terms of other evaluation criteria such as TPR, PPA, and F1, indicating that the proposed model is effective to detect driving anger states in practice. However, the evaluation criterion of false positive rate (FPR) of the proposed model does not have superiority when compared with C4.5, a widely used decision tree algorithm. The reason for this is that maybe the inputs of the proposed model do not include any physiological

characteristics, which can precisely reflect the driver's mental fluctuation [34, 35]. Correspondingly, more physiological characteristics should be taken into consideration when constructing a driving anger detection model. In addition, the run time of the proposed model does not perform best amongst these widely used classification models, which means that the input variables set needs more optimization by feature selection algorithms to reduce the proposed model's computation complexity.

Nevertheless, there still exist several obvious limitations in this study. Firstly, considering easy recruiting and significant anger induction effect, much more male drivers were recruited as the participants for the naturalistic experiments conducted in this study. Then, much more female drivers should be recruited to improve the universality of the proposed model afterwards. Additionally, female drivers frequently get angrier than males when confronting traffic block. Nonetheless, they are inclined to make more adaptive adjustments instead of aggression behaviors when they get angry [22]. Thus, more traffic situations like traffic congestion, red light waiting, and jaywalking can be used to trigger anger for female drivers. And the measurements including physiological or facial expression characteristics instead of physical behaviors and verbal aggressions can be utilized to demonstrate anger expression differences between female drivers and male drivers. Secondly, the naturalistic experiments for this study were conducted in Wuhan, a typical central metropolis in China. Nevertheless, there exist some geography variances of pace of life, traffic safety awareness, or quality between Wuhan and other typical western cities (e.g., Chengdu), northern cities (e.g., Beijing), eastern cities (e.g., Shanghai), and southern cities (e.g., Guangzhou). Therefore, the succeeding experiments should be added in those typical cities due to the geography differences, which can result in the differences of anger induction factors. Thirdly, with the rapid development of wearable devices and intelligent connected vehicles, some physiological indicators like heart rate and respiration rate can be collected to detect driving anger states more accurately.

### Data Availability

The data are generated from experiments and can be made available by the corresponding author upon request.

### Conflicts of Interest

The authors declare that they have no conflicts of interest.

To promote urbanization in the next stage, it is of great significance to explore the ecological efficiency of green ecological regions and advance the sustainable development of a social economic system. However, spatial heterogeneity has not been fully considered in the existing evaluation models or methods for regional ecological efficiency (REE), and the corresponding decisions on sustainable development are not the optimal solutions. To solve the problems, this paper explores the evaluation of REE and intelligent decision support for sustainable development by analyzing environmental big data. Firstly, the spatiotemporal evolution of REE was examined based on environmental big data to clarify the spatial layout of REE and the sources of the spatial differences. Next, a multiobjective optimal decision-making model was established for the sustainable development of a regional ecosystem, and the solving method was presented for the model. The proposed model was proved valid through experiments.

## 1. Introduction

Urban development faces several problems, namely, the development model is extensive, the newly developed areas are underpopulated, and the resources are in short supply. With the development of the industry, these problems have intensified the contradiction between population, environment, and resources [1–5]. Rather than pursuing the single goal of economic interest, the sustainable development of the urbanization system aims to organize production for the composite goal of resources/energy, environment, economy, and society.

China is vigorously implementing a strategy of regional ecosystem development and environmental protection, which will continuously enhance the coordination between the regional environment, regional economy, and regional society [6–12]. Against this backdrop, in order to promote urbanization in the next stage, it is of great significance to explore the ecological efficiency of green ecological regions and advance the sustainable development of the social economic system [13–21].

Environmental pollution is a potential bottleneck of stable economic growth. As an effective measure of sustainable development, ecological efficiency can fully reflect the actual level of coordinated development between economy and environment. Liu and Sun [22] constructed a data envelopment analysis (DEA) model with environmental pollution and resource consumption as inputs and total economy as the output. Ratner [23] described the monitoring of ecological and economic efficiencies of the activities in the regional economic system, compared the applicability of several methods to the dynamic DEA model, and attempted to generate time series based on environmental and economic efficiency points. To evaluate the performance of the urban system, Giordano et al. [24] divided the urban system into traffic subsystem, built environment subsystem, and social economy subsystem, evaluated the efficiency of each subsystem by Takagi–Sugeno model, and recursively derived the overall efficiency of the entire system. Hoang and Alauddin [25] designed an input-oriented DEA framework, which allows the measurement

and decomposition of economic, environmental, and ecological efficiencies in agricultural production of different countries.

On the sustainable development of the urban ecological system, Wang and Li [26] set up an overall framework for the sustainable urban spatial development model based on smart cities. The framework, involving such four dimensions as the monitoring, collection, interconnection, and sharing of urban data, provides an important guide for the spatial planning and construction of smart cities. Ma et al. [27] analyzed the evolution of an urban ecosystem and its dissipation structure and constructed an evaluation index system (EIS) for the sustainable development capability of the urban ecosystem.

The existing studies provide some useful references. However, the evaluation models and methods for regional ecological efficiency fail to fully consider spatial heterogeneity, take account of the dynamic evolution of ecological efficiency distribution, and thoroughly discuss the key factors affecting the ecological efficiency identification and animal habitat changes in different regions and at different levels. Concerning sustainable development, the available decision-making models overlook the balance of relative development for the regional ecosystem in spatiotemporal evolution and cannot converge to the optimal decisions. To solve the problems, this paper explores the evaluation of REE and intelligent decision support for sustainable development based on environmental big data. Section 2 analyzes the spatiotemporal evolution of REE based on environmental big data, identifies the spatial layout and spatial difference of REEs, and discusses the key environmental factors. Section 3 establishes a multiobjective optimal decision-making model for the sustainable development of the regional ecosystem and presents the solving method for the model. Experimental results demonstrate the effectiveness of our model.

This research discusses the inherent linking mechanism of system sustainable development with environmental, economic, and social impacts, and optimizes the absolute performance of sustainability and relative development simultaneously.

## 2. Spatiotemporal Evolution Analysis

This paper identifies the sources of environmental data for the spatiotemporal evolution of REE. Table 1 lists the REE evaluation items based on big data. Several environmental types are enumerated, namely, building area, traffic area, water area, and landscape area, and the corresponding factors that affect ecological efficiency are presented in detail.

As mentioned before, this paper aims to clarify the spatial layout of REE and the sources of the spatial differences and realize the REE evaluation and make intelligent decisions for sustainable development. For this purpose, the spatial distribution of ecological efficiency was described intuitively based on environmental big data. Then, the degree of spatial differences of REE was investigated, and the sources of these differences were revealed. Finally, the dynamic evolution law of REE was explored through kernel density estimation (KDE) and Markov chain.

*2.1. Spatial Difference Analysis.* Through Dagum's decomposition of the Gini coefficient, this paper analyzes the spatial differences of global and local ecological efficiencies of the ecosystem in the study area. Dagum's decomposition method was selected for its capability of considering the overlap between subsamples, solving heterogeneous sources of REE spatial differences, and measuring how much overall regional differences are affected by the intraregional difference, inter-regional difference, and transvariation intensity.

Let  $b_{uv}$  and  $b_{gs}$  be the urban ecological efficiencies of the  $u$ -th and  $g$ -th regions, respectively; let  $\lambda$  be the mean ecological efficiency of all cities in a region,  $m$  be the total number of samples (cities),  $l$  be the number of regions, and  $m_u$  and  $m_g$  be the number of cities in the  $u$ -th and  $g$ -th regions, respectively. Then, the relative difference between all cities in a region in ecological efficiency can be measured by the regional overall Gini coefficient:

$$GN = \frac{\sum_{u=1}^l \sum_{g=1}^l \sum_{v=1}^{m_u} \sum_{s=1}^{m_g} |b_{uv} - b_{gs}|}{2m^2\lambda}. \quad (1)$$

To decompose the Gini coefficient by a regional subsystem, the first step is to sort all cities in a region by mean ecological efficiency as follows:

$$\lambda_1 \leq \lambda_2 \leq \dots \leq \lambda_g \leq \dots \leq \lambda_u \leq \dots \leq \lambda_l. \quad (2)$$

Ecological efficiency is the ratio of ecological outputs to ecological inputs. The outputs refer to the value of products and services provided by enterprises or economies, while the inputs refer to the resources and energies consumed by enterprises or economies, as well as the environmental load caused by enterprises or economies. The Gini coefficient of the  $u$ -th region can be calculated by

$$GN_u = \frac{(1/2\lambda_u) \sum_{v=1}^{m_u} \sum_{s=1}^{m_u} |b_{uv} - b_{us}|}{m_u^2}. \quad (3)$$

The intraregional contribution difference  $H_q$  can be calculated by

$$H_q = \sum_{u=1}^l GN_u t_u. \quad (4)$$

The inter-regional Gini coefficient  $GN_{ug}$  between the  $u$ -th and  $g$ -th regions can be calculated by

$$GN_{ug} = \frac{\sum_{v=1}^{m_u} \sum_{s=1}^{m_g} |b_{uv} - b_{gs}|}{m_u m_g (\lambda_u + \lambda_g)}. \quad (5)$$

The inter-regional contribution difference  $H_{mr}$  can be calculated by

$$H_{mr} = \sum_{u=2}^l \sum_{h=2}^{u-1} GN_{ug} (t_u e_h + t_h e_u) C_{ug}. \quad (6)$$

The transvariation intensity contribution  $H_d$  can be calculated by

TABLE 1: REE evaluation based on environmental big data.

Environmental type	Parameters	Influencing factors of ecological efficiency
Building area	Newly built area, energy consumption per unit area, and energy consumption structure	Energy-efficient design, building energy conservation and emission reduction, and green building material utilization
Traffic area	Passenger capacity per unit time	Public transit travel rate and green travel rate
Water area	Water supply and sewage treatment capacity	Water-saving equipment usage, water-saving indices, and wastewater and sewage reuse rate
Landscape area	Green area and greening rate	Vegetation coverage and regional carbon sequestration capacity

$$H_d = \sum_{u=2}^l \sum_{g=2}^{u-1} \text{GN}_{ug}(t_u e_g + t_g e_u)(1 - C_{ug}), \quad (7)$$

where  $e_i = m_i \lambda_i / (m \lambda)$  and  $t_j = m_j / m$ . Let  $c_{ug}$  be the ecological efficiency difference between regions;  $t_{ug}$  be the first moment of transvariation. Then, the relative influence  $C_{ug}$  of the unit ecological efficiency of the  $u$ -th and  $g$ -th regions can be calculated by

$$C_{ug} = \frac{c_{ug} - t_{ug}}{c_{ug} + t_{ug}}. \quad (8)$$

Let  $O_u$  and  $O_g$  be the cumulative density distribution functions of the  $u$ -th and  $g$ -th regions, respectively. Then,  $c_{ug}$  can be characterized by the mathematical expectation of the sum of the positive sample values for the difference between the ecological efficiencies,  $b_{uv}$  and  $b_{gs}$ , of the cities in the  $u$ -th and  $g$ -th regions:

$$c_{ug} = \int_0^{\infty} dO_u(b) \int_0^y (b-a) dO_g(a). \quad (9)$$

In addition,  $t_{ug}$  can be calculated by

$$t_{ug} = \int_0^{\infty} dO_g(b) \int_0^y (b-a) dO_u(a). \quad (10)$$

**2.2. Dynamic Evolution of Distribution.** The traditional KDE, a popular tool in spatial nonequilibrium analysis, is a nonparametric estimation approach. It can describe the form of each random variable with a continuous curve. In this way, virtually no statistical error will be incurred by the improper setting of ecological efficiencies in the region. Let  $M$  be the total number of cities in the region,  $A_i$  be the independent identically distributed observations,  $a^*$  be the mean value,  $\tau$  be the bandwidth, and  $\Gamma(\cdot)$  be the kernel function. Then, the density function  $\mu(a)$  of the random variable  $A$  can be calculated by

$$\mu(a) = \frac{1}{M\tau} \sum_{i=1}^M \Gamma\left\{\frac{(A_i - a^*)}{\tau}\right\}. \quad (11)$$

The greater the  $\tau$  value, the larger the neighbourhood of  $a$ . If  $\tau$  is too large, the kernel density function  $\Gamma(\cdot)$  will be too smooth. Then, some important features of the function will be smoothed out, causing a large deviation. Hence, the  $\tau$  value should be minimized if possible. Thus,  $\Gamma(\cdot)$  needs to meet the following condition:

$$\begin{cases} \lim_{a \rightarrow \infty} \Gamma(a) \cdot a = 0, \\ \Gamma(a) \geq 0, \quad \int_{-\infty}^{+\infty} \Gamma(a) da = 1, \\ \sup \Gamma(x) < +\infty, \quad \int_{-\infty}^{+\infty} \Gamma(a) da < +\infty. \end{cases} \quad (12)$$

The dynamic evolution features of REE distribution can be estimated by the Gaussian kernel function:

$$\Gamma(a) = \frac{1}{\sqrt{2\pi}} e^{-a^2/2}. \quad (13)$$

**2.3. Long-Term Transition Trend.** This paper adopts the Markov chain to describe the ecological efficiency of each city in a region, that is, sets up the transition probability matrix of the Markov chain. Let  $\{A(p), p \in \psi\}$  be the stochastic process of the discrete events corresponding to the Markov chain,  $N$  be the finite set of the solutions, and  $\psi$  be the set of indices for different stages of the stochastic process. The Markov chain highlights that, historical dynamic actions share the same features as future dynamic actions. In our problem, the identicalness of the features manifests as follows: the state of urban ecological efficiency  $A$  in year  $p+1$  directly bears on the probability for  $A$  to belong to type  $j$  in year  $p$ . Let  $GR_{ij}$  be the probability for urban ecological efficiency belonging to type  $i$  in year  $p$  to transfer to type  $j$  in year  $p+1$ ; that is, the maximum likelihood estimation of the transition is  $GR_{ij} = m_{ij}/m_i$ ; let  $m_{ij}$  be the number of cities shifting from type  $k$  in year  $p$  to type  $j$  in year  $p+1$  and  $m_i$  be the total number of cities belonging to type  $i$  in the study period. Then, we have

$$\begin{aligned} GR\{A_p = j | A_{p-1} = i, A_{p-2} = i_{p-2}, A_0 = i_0\} \\ = GR\{A_m = j | A_{m-1} = i\} = GR_{ij}. \end{aligned} \quad (14)$$

By dividing urban ecological efficiencies in the region into  $x$  states, it is possible to obtain an  $x \times x$  state transition probability matrix of the Markov chain.

### 3. Multiobjective Optimal Decision-Making Model

**3.1. Preliminaries.** Figure 1 summarizes the evaluation attributes for the sustainable development of the regional ecosystem. The evaluation system for the sustainable development of the regional ecosystem involves multiple

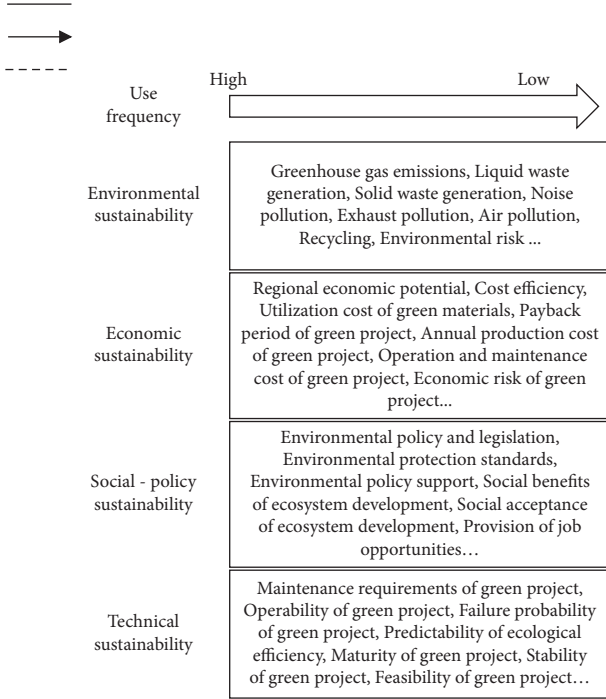

FIGURE 1: Evaluation attributes for the sustainable development of regional ecosystem.

dimensions, such as environmental sustainability, economic sustainability, social policy sustainability, and technical sustainability. The evaluation dimensions can all be quantified. For the sustainable development of the regional ecosystem, decision makers can also set up individualized evaluation systems based on objective needs and subjective judgement.

To clarify the incremental costs and benefits of regional ecosystem development, this paper focuses on the incremental costs incurred during the optimization of plan design and measures implementation for regional ecosystem development. The costs of these two stages are mainly invested continuously by green project investors, developers, and implementers. The incremental benefits will continue to appear after the optimization measures are implemented in the regional ecosystem. Figure 2 details the costs and benefits of the regional ecosystem in a development cycle.

Our problem is to sustainably improve the regional ecosystem, that is, combining and optimizing multiple optional measures for the ecosystem optimization to realize multiple goals under specific constraints, in reference to multiple sets of environmental big data in different periods, such that the optimized regional ecosystem is much more sustainable than the original system. This paper builds a weighted multiobjective optimization model to improve the sustainability of the regional ecosystem in multiple dimensions, relying on optimization measures. On this basis, the authors strived to make sustainable intelligent decisions.

**3.2. Model Construction and Solving.** Targeting the regional ecosystem, our model tries to improve the ecological efficiency of the ecosystem by adopting the improved

combination of optimization measures for sustainable development. Figure 3 provides the specific steps to improve sustainable development efficiency: characterization of the regional ecosystem, sustainable development evaluation of REE, sustainable development optimization of REE, and sustainable development improvement of REE.

The optimal decision making for the sustainable development of REE involves multiple steps and goals in four dimensions, including environmental sustainability, economic sustainability, social policy sustainability, and technical sustainability. The decision-making process is complicated by the diverse constraints on the different goals and the interference of uncertain decision-making factors. Hence, this paper presents a multiobjective optimal decision-making model (Figure 4) for the sustainable development of the regional ecosystem. The proposed model consists of two parts, namely, the characterization of the ecosystem, and construction and solving of sustainable development decision-making model and opens the path to improve the sustainable development of the regional ecosystem through spatiotemporal evolution.

The proposed multiobjective optimal decision-making model is targeted at regional ecosystems, whose ecological efficiencies obey different spatial distributions. The model was constructed through composite weighting of each subobjective, setting weighted objectives and sustainable objectives, and solving the model. Firstly, the interval analytic hierarchy process (IAHP) was adopted to assign composite weight to each objective, eliminating the need to consider the interaction between subobjectives. The composite weighting begins with the construction of an interval comparison matrix.

The subjective weight of each subobjective was quantified through expert judgement, which is uncertain to a certain extent. Therefore, the comparison matrix is composed of the following interval numbers:

$$F = \begin{bmatrix} [1, 1] & [f_{12}^K, f_{12}^V] & \cdots & [f_{1m}^K, f_{1m}^V] \\ [f_{21}^K, f_{21}^V] & [1, 1] & \cdots & [f_{2m}^K, f_{2m}^V] \\ \vdots & \vdots & \ddots & \vdots \\ [f_{m1}^K, f_{m1}^V] & [f_{m2}^K, f_{m2}^V] & \cdots & [1, 1] \end{bmatrix}, \quad (15)$$

where  $m$  is the number of optimization subobjectives;  $[f_{ij}^K, f_{ij}^V]$  is the relative importance of subobjective  $i$  to subobjective  $j$ , both of which are expressed as interval numbers. Next, the interval comparison matrix  $F$  was converted into the interval priority matrix  $S$ :

$$S = \begin{bmatrix} [0.5, 0.5] & [s_{12}^K, s_{12}^V] & \cdots & [s_{1m}^K, s_{1m}^V] \\ [s_{21}^K, s_{21}^V] & [0.5, 0.5] & \cdots & [s_{2m}^K, s_{2m}^V] \\ \vdots & \vdots & \ddots & \vdots \\ [s_{m1}^K, s_{m1}^V] & [s_{m2}^K, s_{m2}^V] & \cdots & [0.5, 0.5] \end{bmatrix}, \quad (16)$$

where

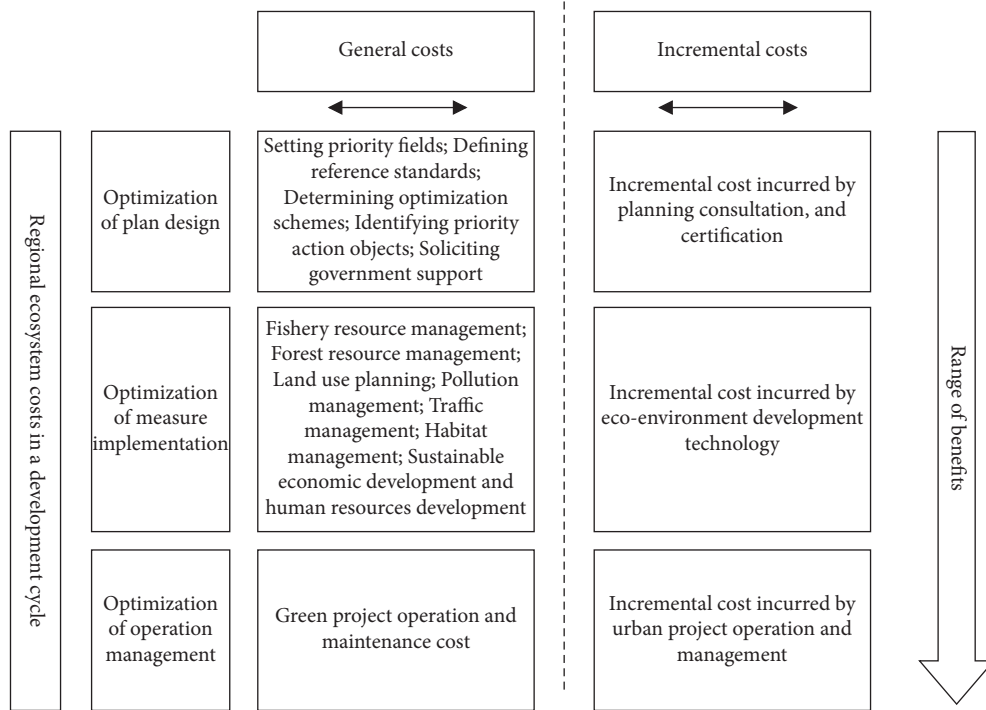

FIGURE 2: Costs and benefits of regional ecosystem in a development cycle.

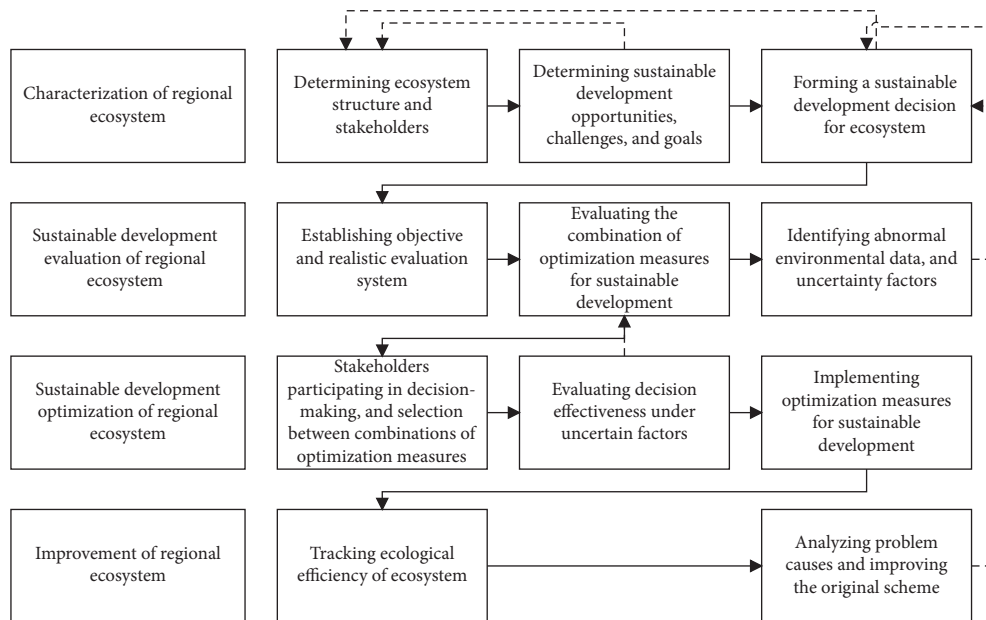

FIGURE 3: Improvement of sustainable development efficiency.

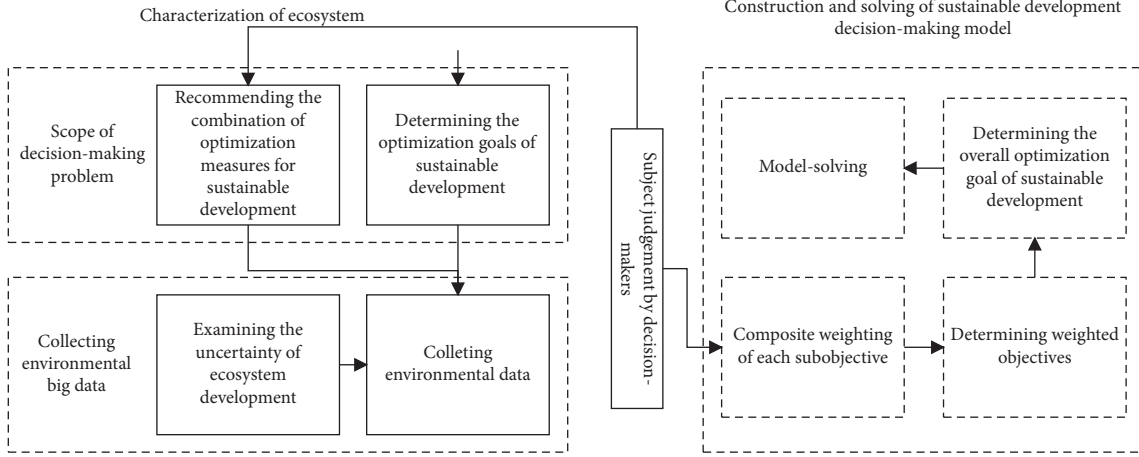

FIGURE 4: Multiobjective optimal decision-making model for the sustainable development of regional ecosystem.

$$\bar{s}_{ij} = \frac{f_{ij}^-}{f_{ij}^- + f_{ij}^+}, s_{ij}^+ = \frac{f_{ij}^+}{f_{ij}^- + f_{ij}^+}. \quad (17)$$

After that, the subjective weights were calculated. Let  $d_i^V$ ,  $d_i^K$ ,  $c_i^V$ , and  $c_i^K$  be the positive and negative biases in objective programming, respectively;  $[v_i^K, v_i^V]$  be the interval value range of the relative importance for each subobjective corresponding to the optimal solution. Then, the optimal solution of matrix  $S$  can be obtained by

$$\begin{aligned} \text{Min } \delta &= \sum_{i=1}^m (d_i^V + d_i^K + c_i^V + c_i^K), \\ \text{s.t. } v_i^K + \sum_{j=1, j \neq i}^m v_j^V &\geq 1, \\ v_i^U + \sum_{j=1, j \neq i}^m v_j^K &\leq 1, \\ 0 \leq v_i^K \leq v_i^V &\leq 1, \\ \left( \sum_{j=1}^m s_{ij}^K - m + 0.5 \right) v_i^K + \sum_{j=1, j \neq i}^m r_{ij}^K v_j^V - d_i^V + d_i^K &= 0, \\ \left( \sum_{j=1}^m s_{ij}^V - m + 0.5 \right) v_i^V + \sum_{j=1, j \neq i}^m s_{ij}^V v_j^K - c_i^V + c_i^K &= 0, \\ d_i^V, d_i^K, c_i^V, c_i^K &\geq 0. \end{aligned} \quad (18)$$

The subjective weight of each objective can be obtained by

$$q_i^e = \frac{(v_i^K + v_i^V)}{\sum_{i=1}^m (v_i^K + v_i^V)}. \quad (19)$$

The overall objective for the sustainable development of the regional ecosystem combines multiple subobjectives,

which are impossible to achieve all at once. To realize the overall objective, the traditional subobjective setting approach needs to adjust the subobjectives repeatedly. Based on multiple sets of environmental big data on the optimization system in different periods, this paper puts forward a novel weighted subobjective setting strategy.

According to the weights of subobjectives for the sustainable development of the regional ecosystem as well as the sustainable performance of each subobjective reflected by the multiple sets of environmental big data, the weighted subobjectives can be configured under a constraint as follows:

$$\begin{aligned} \max SG_i^* &= q_i \times \left[ \sum_{j \in T} (\psi_j \times \bar{\gamma}_{ij}^V) \right], \\ \text{s.t. } \psi_j(1 - \psi_j) &= 0, T \in D, \end{aligned} \quad (20)$$

where  $\bar{\gamma}_{ij}^V$  be the performance value of subobjective  $i$  reflected by the normalized environmental sample data  $j$  (If  $\psi_j = 1$  or 0 in  $\psi_j(1 - \psi_j) = 0$ , then the  $j$ -th set of environmental sample data can or cannot serve as a reference);  $D$  is the constraint;  $T \in D$  is the requirement that any combination of optimization measures must satisfy  $D$ .

Through the above steps, all weighted subobjectives can be obtained as  $SG^* = [SG_1^*, SG_2^*, \dots, SG_m^*]$ . Each weighted subobjective corresponds to a specific model. Each combination  $T_i^*$  of optimization measures leads to the optimal solution to each specific model.

This paper likens the set of optimal solutions on all weighted subobjectives as the ideal solution to the objective of sustainable development, which can be vectorized as

$$\vec{E}(JL) = [SG_1^*, SG_2^*, \dots, SG_m^*]. \quad (21)$$

The ideal solution above can be transformed to an actual solution under the condition  $T_1^* = T_2^* = \dots = T_m^*$ . For any

feasible solution, the corresponding combination of optimization measures  $T_b$  can be vectorized as

$$\begin{aligned}\vec{E}(T_b) &= [\vec{E}(T_b^K), \vec{E}(T_b^V)], \\ &= \{[SG_1(T_b^K), SG_1(T_b^V)], [SG_2(T_b^K), SG_2(T_b^V)], \dots, [SG_m(T_b^K), SG_m(T_b^V)]\}.\end{aligned}\quad (22)$$

Considering the length and direction of vector functions, the degree of absolute improvement of sustainable development in the ideal solution IS can be given by

$$N(\text{IS}) = \|\vec{E}(\text{IS})\| = \sqrt{\sum_{i=1}^m (SG_i^*)^2}. \quad (23)$$

The degree of absolute improvement of sustainable development in the feasible solution  $b$  can be given by

$$\begin{aligned}N(T_b) &= [N(T_b^K), N(T_b^V)] = [\|\vec{E}(T_b^K)\|, \|\vec{E}(T_b^V)\|], \\ &= \left[ \sqrt{\sum_{i=1}^m (SG_i(T_b^K))^2}, \sqrt{\sum_{i=1}^m (SG_i(T_b^V))^2} \right].\end{aligned}\quad (24)$$

The equilibrium of relative development of multiple weighted subobjectives in the ideal solution IS can be given by

$$\cos(F(\text{IS})) = \left( \frac{\vec{E}(\text{IS}) \cdot \vec{E}(\text{IS})}{\|\vec{E}(\text{IS})\| \cdot \|\vec{E}(\text{IS})\|} \right) = 1. \quad (25)$$

The equilibrium of relative development of multiple weighted subobjectives in the feasible solution  $b$  can be given by

$$\begin{aligned}\cos(F(T_b)) &= [\cos(F(T_b^K)), \cos(F(T_b^V))] = \left[ \min \left\{ \left( \frac{\vec{E}(\text{IS}) \cdot \vec{E}(T_b^K)}{\|\vec{E}(\text{IS})\| \cdot \|\vec{E}(T_b^K)\|} \right), \left( \frac{\vec{E}(\text{IS}) \cdot \vec{E}(T_b^V)}{\|\vec{E}(\text{IS})\| \cdot \|\vec{E}(T_b^V)\|} \right) \right\}, \right. \\ &\quad \left. \max \left\{ \left( \frac{\vec{E}(\text{IS}) \cdot \vec{E}(T_b^K)}{\|\vec{E}(\text{IS})\| \cdot \|\vec{E}(T_b^K)\|} \right), \left( \frac{\vec{E}(\text{IS}) \cdot \vec{E}(T_b^V)}{\|\vec{E}(\text{IS})\| \cdot \|\vec{E}(T_b^V)\|} \right) \right\} \right] \\ &= \left[ \min \left\{ \left( \frac{\sum_{i=1}^m [SG_i^* \times SG_i(T_b^K)]}{\sqrt{\sum_{i=1}^m (SG_i^*)^2} \times \sqrt{\sum_{i=1}^m [SG_i(T_b^K)]^2}} \right), \left( \frac{\sum_{i=1}^m [SG_i^* \times SG_i(T_b^V)]}{\sqrt{\sum_{i=1}^m (SG_i^*)^2} \times \sqrt{\sum_{i=1}^m [SG_i(T_b^V)]^2}} \right) \right\}, \right. \\ &\quad \left. \max \left\{ \left( \frac{\sum_{i=1}^m [SG_i^* \times SG_i(T_b^K)]}{\sqrt{\sum_{i=1}^m (SG_i^*)^2} \times \sqrt{\sum_{i=1}^m [SG_i(T_b^K)]^2}} \right), \left( \frac{\sum_{i=1}^m [SG_i^* \times SG_i(T_b^V)]}{\sqrt{\sum_{i=1}^m (SG_i^*)^2} \times \sqrt{\sum_{i=1}^m [SG_i(T_b^V)]^2}} \right) \right\} \right].\end{aligned}\quad (26)$$

By the principle of vector projection, the equilibrium of relative development of weighted subobjectives can be unified with the absolute improvement of sustainable development. In ideal conditions, the optimal degree of improvement of regional sustainable development can be given by

$$SP(\text{IS}) = [N(\text{IS}) \times \cos(F(\text{IS}))] = \sqrt{\sum_{i=1}^m (SG_i^*)^2}. \quad (27)$$

The improvement effect of the feasible solution  $T_b$  on sustainable development can be quantified by

$$SP(T_b) = [SP(T_b^K), SP(T_b^V)] = [N(T_b^K) \times \cos(F(T_b^K)), N(T_b^V) \times \cos(F(T_b^V))]. \quad (28)$$

The intelligent decision making of the objective of sustainable development can be derived from formulas (27) and (28). To display the decision-making process more intuitively, an objective achievement rate was introduced to transform the two formulas:

$$\text{OBJ}(T_l) = [\text{OBJ}(T_l^K), \text{OBJ}(T_l^V)] = \left[ \frac{SP(T_l^K)}{SP(\text{IS})}, \frac{SP(T_l^V)}{SP(\text{IS})} \right] \times 100\%. \quad (29)$$

The above formula shows that the objective achievement rate of IS is 1 and that of  $T_b$  falls in between (0, 1) (the closer the value is to 1, the better the optimization effect). Through the above analysis, the overall optimization objective of sustainable development for the regional ecosystem can be expressed as

$$\begin{aligned} & \text{Max OBJ}(T_l), \\ & \text{s.t. } T_l \in D. \end{aligned} \quad (30)$$

The above formula also outputs an interval number. Under uncertainty conditions, the model can be solved by probability comparison:

$$S_{(a>t)} = \mathbf{max} \left\{ 1 - \mathbf{max} \left( \frac{W_t^V - W_a^K}{W_t^V - W_a^K + W_t^V - W_a^K}, 0 \right), 0 \right\}. \quad (31)$$

Any interval numbers  $W_t = [W_t^K, W_t^V]$  and  $W_a = [W_a^K, W_a^V]$  can be compared in terms of probability. If  $W_a > W_b$ , i.e.,  $S_{(a>t)}, S_{(a>t)} > 0.5$  means  $W_a$  is probably better than  $W_b$ ; the inverse is also true. Similarly, if  $W_t^V < W_a^V$  and  $W_t^K < W_a^K$ ,  $W_a$  must be better than  $W_t$ .

#### 4. Experiments and Result Analysis

Figure 5 presents the evolution trends of the overall ecological efficiency of the study area in 2005–2020. The REEs exhibited obvious features of phased development, dropping from 0.6024 in 2006 to the lowest point of 0.5785 in 2013. From 2014 to 2020, the REEs rose significantly and peaked at 0.6549. The reasons for the phased development are as follows:

In the early phase of the sample period, the regional economy developed extensively in the traditional model, and the society had poor awareness of ecoenvironmental protection. That is why the REEs in the study area continued to decline. In 2013–2014, the cities in the study area quickly adjusted their development pattern and publicized ecological civilization, which contribute to the continuous growth of REEs.

There were some differences between regions in ecological efficiency. Region A, a transportation hub in a strategic location, remained the leader of ecological efficiency throughout the 15-year-long sample period. The ecological efficiencies of Regions A and B oscillated similarly as the overall ecological trend of the study area. After 2015, the ecological efficiency of Region B increased markedly each year, with increasingly strong momentum. Region C

FIGURE 5: REE trends in 2005–2020.

had the lowest ecological efficiency, which grew stably over the 15 years.

Figure 6 compares the REE evolution trends of each pair of the three regions. Through the sample period, the largest regional difference in ecological efficiency existed between Regions A and B, whose mean Gini coefficient was 0.274. The second-largest regional difference was observed between Regions A and C, whose mean Gini coefficient was 0.261. The smallest regional difference was observed between Regions B and C, whose mean Gini coefficient was 0.253.

In general, the ecological efficiency gap between Regions A and C continued to narrow at an annual change rate of  $-2.14\%$ . The gap between Regions B and C widened after 2010, despite some fluctuations, with an annual change rate of  $0.87\%$ . Specifically, the gap between Regions A and C declined with fluctuations from 0.347 in 2006 to 0.206 in 2020, reaching the valley of the sample period. The gaps between Regions A and B, and between Regions B and C both decreased first and then increased. The gap between Regions A and B minimized at 0.223 in 2016, while that between Regions B and C minimized at 0.204 in 2010.

To sum up, the relevant government departments should strengthen the coordination between Regions B and C in green development and reduce the spatial difference between regions in ecological efficiency without ignoring the regional difference between A and B.

Through Gini coefficient decomposition, this paper looks for the sources of REE spatial differences, that is, analyzes the contributions of intraregion difference, inter-regional difference, and transvariation intensity to overall regional spatial differences. Table 2 presents the calculated results on intra and inter-regional contributions.

Through the sample period, the inter-regional difference of A and B contributed the greatest to the spatial gap of REE, followed in turn by that of B and C, and that of A and C; the intraregional difference of C contributed the greatest to the spatial gap of REE, followed in turn by that of A and that of B. It can be observed that the spatial imbalance of REEs can be effectively solved by reducing inter-regional differences.

FIGURE 6: Trends of regional REE differences.

2019	11.76	11.53	1.26	6.58	22.72	27.36
2020	10.05	9.74	2.65	6.75	23.45	31.65
Mean	12.94	11.94	4.37	7.21	19.09	14.76

Regions A and B should be the focus of regulation because their inter-regional difference is the major contributor to the spatial gap of REE.

Tables 3–5 report the transition probability matrices of the Markov chain for Regions A–C, respectively. Note that period  $p_1$  has a one-year lag, and period  $p_2$  has a two-year lag. The long-term transition trend of REE can be derived from these matrices. In each matrix, the elements to the left of the diagonal were smaller than those to the right, indicating that the overall ecological efficiency of each region moves clearly from the low level to the high level. Meanwhile, the REE had a greater stable probability than transition probability. This means that the state transition of ecological efficiency is accompanied by apparent polarization. As period  $p_1$  changed to period  $p_2$ , i.e., the lag increased from 1 year to 2 years, the overall ecological efficiency of the study area

basically remained the same, with a very slight decline. In addition, there were many nonzero elements on both sides of the diagonal in each matrix, suggesting the difficulty for the study area to realize the leapfrog transition of ecological efficiency.

This paper employs the multistage method to measure the contributions of intraregion difference, inter-regional difference, and transvariation intensity in 2005–2020. The results are presented in Table 6 and Figure 7. The measured results of our method have a smaller variation than those of the traditional DEA. The following can be inferred from the data in Table 6. In 2005–2020, the mean contribution was 0.813, 0.990, and 0.821 for intraregional difference, inter-regional difference, and transvariation intensity, respectively. Overall, the study area had relatively high ecological efficiency since 2005. The regional economic development

achieves a high cost effectiveness in terms of energy-saving technology and green environmental investment. In 2010 and 2013, the contribution of inter-regional difference was merely 0.758 and 0.761, respectively. In 2009–2011 and 2013–2016, the inter-region contributions

were below the mean of the 15 years. Through the 15-year-long sample period, the transvariation intensity made relatively high contributions, reflecting the good effect of technical and management measures adopted by the regional ecosystem.

## 5. Conclusions

Based on the analysis of environmental big data, this paper investigates the evaluation of REE and intelligent decision support for sustainable development. Specifically, the spatiotemporal evolution of REE was analyzed based on environmental big data, and the spatial layout of REE and the sources of the spatial differences were both clarified. In addition, the authors constructed a multiobjective optimal decision-making model for the sustainable development of a regional ecosystem and presented the solving method for the model. After that, experiments were carried out to analyze the REE changes and inter-regional REE differences in 2005–2020. The experimental results demonstrated the feasibility of our analytical method. Furthermore, the authors discussed the contributions of intraregional difference, inter-regional difference, and transvariation intensity to the overall spatial difference of regional ecological efficiency, constructed the transition probability matrix of the Markov chain for the REE in each region, and provided the measured results on regional REEs.

The future research will try to develop a decision model capable of considering and solving different interest preferences and demands of different decision makers and realize multirole, multiattribute decision making as well as multirole, multiobjective decision making.

A data-driven intelligent analysis method is proposed in this paper to explore and identify the enterprise's technological innovation influencing factors. Questionnaire surveys or expert interviews are usually adopted by the traditional evaluation methods for indicators of technological innovation selection. However, it inevitably involves human factors and experts' subjective judgments, which may affect the result of enterprises evaluation. The research presents an improved text clustering method based on a semantic concept model to explore and analyze the key influencing factors of enterprise's technological innovation. The study collects textual data from 400 enterprises in Beijing and smart analyzes the critical influencing factors of enterprise's technological innovation by using the proposed method. The influencing factors can be divided into seven categories. In addition, compared with the traditional K-means clustering method, the proposed method has a good effect. We proposed a methodology to conduct an intelligent analysis for enterprise's technological innovation under the data-driven. It can provide more objective and auxiliary suggestions for the evaluation of the enterprise's technology innovation.

## 1. Introduction

Technological innovation is the foundation of the survival and development of enterprises and the driving force for the country's economic and social development. It is essential for an enterprise to gain a competitive advantage by correctly analyzing and evaluating the technological innovation capability. Since the middle of the 18th century, the world has experienced three industrial revolutions. Social development is entering the era of data revolution with the development and application of new-generation information technologies such as cloud computing, big data, mobile Internet, artificial intelligence, and the Internet of Things. The production and circulation of massive data gave birth to "big data" and set off the fourth industrial revolution.

The digital economy era has given birth to new production factors represented by big data. Data-driven continuous growth and innovative development are the main lines of enterprise digital transformation. Compared with the past process-driven, data-driven allows companies to use massive and multidimensional data to establish a more

comprehensive evaluation system, create direct business innovation growth, and continuously improve operational efficiency. It is an essential means to maintain sustainable development in market competition. With the continuous development of enterprises, various forms of technical documents and text information continue to spew. According to statistics, 80% of enterprise data exist in unstructured conditions, such as Web pages, technical papers, e-mails, etc. Especially in enterprise's technological innovation, related technological innovation activity reports, meeting minutes, annual corporate reports, patent technology files, project application reports, and textual information are increasing with each passing day. Most of the time, enterprises often need to deal with disordered unstructured textual data except structured data. Ignoring the text information generated by corporate technological innovation activities will inevitably affect the result of technical innovation management. Enterprises need to deal with these collected files and explore the value and knowledge behind these massive amounts of data. Therefore, the rise of big data and the development of intelligent text analysis technology

have used many unstructured and fragmented textual data that enterprises initially neglected. However, it is a significant challenge for the era of big data to mine knowledge from massive unstructured data and provide auxiliary decision-making for enterprise technological innovation.

Text mining generally refers to the process of extracting valuable, nontrivial patterns or knowledge from a large amount of unstructured or semi-structured text files. Therefore, text mining provides an effective measure for textual data collation, analysis and, mining. It meets the massive demand for processing and analyzing an enormous amount of unstructured and semi-structured textual data. To a certain extent, it solves the labour and material cost problems of manual text processing. Text mining, as a representative of the intelligent measure method, has been widely applied in various fields. For example, the evaluation of business intelligence and enterprise technology analysis [1–3], the enterprise technology opportunity identification [4, 5], correlation analysis of enterprise technology cooperation behavior [6–8], the analysis of enterprises technology maturity [9–11], and prediction of enterprise technology development trend, etc. [12–14].

The intelligent text mining algorithm can quickly and high-quality organize amounts of information into a few meaningful clusters and obtain the hidden potential knowledge or patterns. The rapid growth of textual data, especially in enterprise's technological innovation, has become diverse, high-dimensional, complex data loaded with semantic information. Therefore, it is feasible to explore the essential influencing factors of enterprise's technological innovation based on intelligent analysis algorithms and realize the semantic organization for technological innovation evaluation. This paper collects technical data from 400 enterprises in Beijing. It combines the proposed intelligent text clustering algorithm to realize knowledge mining and acquire enterprise's technological innovation at the semantic level.

The remainder of this paper is organized as follows. The second section presents the related works. The third section provides the implementation process of the proposed methodology and makes a performance comparison validation with the traditional K-means clustering method. While section four presents the result and the section five give a discussion of this research. In the final section, we conclude this paper's work.

## 2. Related Works

The previous studies of enterprise's technological innovation usually focus on theory research and evaluation methods. In the early stage, the evaluation system of enterprise's technological innovation was mostly constructed by questionnaire or expert interview. The influencing factors of an enterprise's technological innovation capability were obtained by the questionnaire design or expert experience. However, these methods are often affected by the limitation of the sample size and the subjective factors of expert opinions. It is difficult to objectively and comprehensively reflect the status of enterprise's technological innovation

capabilities. Many scholars make a comprehensive evaluation of enterprise technological innovation. They usually use various evaluation methods to express the overall characteristics of enterprise technological innovation. These evaluation methods are mainly divided into the following aspects.

Some scholars adopted the fuzzy evaluation method to evaluate the enterprise technological innovation ability. The main feature of this method is first to design a set of evaluation index systems, determine the weight of each index, establish a fuzzy comment set, and then use the fuzzy evaluation method to judge the innovation ability of the enterprise. For example, Du et al. [15] established a risk evaluation model for technological innovation based on fuzzy evaluation. Suder and Kahraman [16] proposed a Fuzzy TOPSIS method to evaluate technological innovation investments using eight different criteria. Feng and Ma [17] identified the influencing factors of service innovation in manufacturing enterprises by using the fuzzy DEMATEL method. The shortcomings of this type of method are that human factors play a prominent role, and the data collection and processing are human-oriented, which lack objectivity and needs a lot of labour.

Some scholars used the Analytic Hierarchy Process (AHP) and its variants to evaluate the enterprise technological innovation capability. Mu et al. [18] established an index system for the technological innovation capabilities of small and medium-sized enterprises through the AHP method. Pan et al. [19] combined the AHP and osculating value process (OVP) to evaluate the green innovation ability of manufacturing enterprises. In addition, some scholars have used the improved AHP and fuzzy evaluation method to establish a model for assessing the technological innovation capabilities of enterprises [20]. The weight of each indicator in the AHP method depends on the subjective judgment of experts, and it is inevitable to have a certain degree of subjectivity.

Some researchers evaluated the enterprise technological innovation capability with the Data Envelopment Analysis (DEA) method. Wang et al. [21] constructed a high-tech industrial evaluation framework of technical innovation efficiency based on two-stage network data envelopment analysis (DEA). Ma et al. [22] used the DEA method to evaluate and analyze the innovation capability of 233 listed companies in 5 major industrial sectors defined by the China Securities Regulatory Commission (CSRC). Li et al. [23] measured the technical efficiency, scale efficiency, and pure technical efficiency of innovation in China's semiconductor industry using a three-stage DEA model. Although the DEA method can realize the multiple inputs and output, it is only an efficiency evaluation method and cannot indicate the actual technical level of the research object.

Some scholars proposed to use intelligent decision-making methods to evaluate the technological innovation capabilities of enterprises. The intelligent decision-making method applied the artificial intelligence-related theoretical methods and fusing traditional decision-making mathematical models for intelligent reasoning and solving, such as genetic algorithm, ant colony algorithm, rough set, and so

on. At present, there is little literature on the application of intelligent decision-making methods to evaluate enterprise technological innovation capabilities. Shang [24] proposed the evaluation model of strategic management capability based on the Back-Propagation (BP) neural network algorithm. Zhen and Yao [25] analyzed the lean production and technological innovation in the manufacturing industry based on Support Vector Machine (SVM) algorithms and data mining technology.

Most of the related works about enterprise's technological innovation evaluation methods rely on the experts' subjective experience. Hence, the evaluation results are varied due to the different experts' opinions. Less-comprehensive impact indicators selected by experts may not reflect the actual status of the enterprise's technological innovation capability. The lack of objectivity in the evaluation method will not be conducive for identifying and cultivating enterprise's technological innovation capabilities. At present, it can objectively reflect the actual level of enterprise's technological innovation capabilities by applying big data-driven intelligent analysis methods. In addition, it can use massive and multidimensional data to establish a more comprehensive evaluation system.

### 3. Methodology

This paper proposed an improved semantic clustering algorithm combined with the concept of semantic similarity and relatedness based on domain ontology. After text preprocessing, a corpus containing the keywords was built and the keywords were mapped to the concepts in the domain ontology of the enterprise's technological innovation. The calculation of semantic similarity and relatedness between concepts was one of the critical steps. It needs to use the semantic similarity and relatedness method proposed in this paper to establish the compound similarity matrix. Finally, the keyword set in the corpus is clustered according to the improved semantic text clustering algorithm proposed in this paper. Figure 1 shows the framework of semantic-based text clustering in the field of enterprise technology innovation. According to the framework, there are mainly three steps in the improved methodology and the details are as follows, and the main parameters used in the following equations are shown in Table 1.

**3.1. Text Concept Mapping.** After collecting the data from the enterprise's technological innovation, preprocessing the data, including Chinese word segmentation, custom dictionary, POS selection, and stop words removing, etc., obtained the text keyword sets. The keyword set is mapped to the ontology of the enterprise technology innovation domain to obtain the concept set. Two situations need to be considered.

- (1) When the dataset's keywords can directly match with the concepts in the domain ontology, the keywords  $T = \{t_1, t_2, \dots, t_n\}$  are directly mapped with the concepts  $C = \{c_1, c_2, \dots, c_m\}$ .

- (2) When the keywords in the dataset cannot directly match the concepts in the domain ontology and appear frequently, the keywords should be reserved as unregistered words. Calculate the occurrence frequency TF of the keyword. If  $TF > \mu$ , keep the keyword in the unregistered word sets  $W = \{w_1, w_2, \dots, w_l\}$ , otherwise delete the keyword.

**3.2. Semantic Similarity and Relatedness Calculation.** Before text clustering, the semantic similarity and relatedness calculation method need to be used to construct the semantic matrix. We proposed a new semantic measurement method that combines the concepts of semantic similarity and relatedness. Firstly, calculate the semantic similarity of concepts based on the semantic distance in the established domain ontology of enterprise's technological innovation, as shown in Figure 2. Secondly, assign the weights to the path of two concepts connected in the domain ontology. The semantic distance between two concepts was obtained by traversing the sum of the weights of the connection paths instead of calculating the number of edges connecting the two concepts. The specific calculation is shown in equation (1). Then, calculate the semantic relatedness of concepts through the co-occurrence in the text. Finally, combine the semantic similarity and the relatedness to establish the compound similarity matrix  $M$ .

$$M = \begin{bmatrix} 1 & \dots & \text{sim\_rel}_{i1} & \dots & \text{sim\_rel}_{j1} & \dots & \text{sim\_rel}_{l1} \\ \vdots & \ddots & \dots & \vdots & \dots & \vdots & \vdots \\ \text{sim\_rel}_{i1} & \dots & 1 & \dots & \text{sim\_rel}_{ji} & \dots & \text{sim\_rel}_{li} \\ \vdots & \vdots & \dots & \ddots & \dots & \vdots & \vdots \\ \text{sim\_rel}_{j1} & \dots & \text{sim\_rel}_{ji} & \dots & 1 & \dots & \text{sim\_rel}_{lj} \\ \vdots & \vdots & \dots & \vdots & \dots & \ddots & \vdots \\ \text{sim\_rel}_{i1} & \dots & \text{sim\_rel}_{i1} & \dots & \text{sim\_rel}_{lj} & \dots & 1 \end{bmatrix}, \quad (1)$$

$$\begin{aligned} \text{Sim\_Rel}(c_i, c_j) &= \alpha \times \text{sim}(c_i, c_j) \\ &+ (1 - \alpha) \times \text{rel}(c_i, c_j) \\ &= \alpha \times \frac{1}{1 + \lambda \text{dist}(c_i, c_j)} + (1 - \alpha) \times \log 2 \frac{f^k(c_i, c_j)}{f^c(c_i) \times f^c(c_j)}, \end{aligned}$$

where  $\alpha$  denotes the adjusting parameter,  $\lambda$  denotes the factor of influence degree of semantic distance on semantic similarity,  $\text{dist}(c_i, c_j)$  denotes the semantic distance between  $c_i$  and  $c_j$  in the domain ontology,  $f^k$  denotes the co-occurrence frequency of concept  $c_i$  and concept  $c_j$  in the  $k$  words window of the entire corpus.  $f^c(c_i)$  and  $f^c(c_j)$  represent the frequency of concept  $c_i$  and concept  $c_j$  in the whole corpus.

**3.3. Improved K-Means Algorithm.** The traditional clustering algorithm based on vector space defines the text document set as  $D = \{d_1, d_2, d_3, \dots, d_m\}$  and each document can be

FIGURE 1: Implementation process of text clustering method based on semantic similarity and relatedness.

TABLE 1: The main parameters in equations' definitions.

Elements	Definition
$t_n$	Text keywords
$c_m$	Concepts in the domain ontology
$w_l$	Unregistered word
TF	The frequency of the keyword in dataset
$\mu$	The threshold value of keyword frequency
$M$	The semantic similarity and the relatedness matrix
$\text{dist}(c_i, c_j)$	The semantic distance between concepts $c_i$ and $c_j$ in ontology
$\lambda$	The influence factor of semantic distance on semantic similarity
$f^k(c_i, c_j)$	The number of times that concept $c_i$ and $c_j$ appear simultaneously in the $k$ words window at the entire corpus
$f^c(c_i)$	The frequency of the concept $c_i$ at the entire corpus
$\text{rel}(c_i, c_j)$	Relatedness between concept $c_i$ and $c_j$
$\text{Sim\_Rel}(c_i, c_j)$	Semantic similarity and relatedness between concept of $c_i$ and $c_j$
$\alpha$	The adjusting parameter
$d_i$	The text document
$w_{ij}$	The weight of the term $t_j$ in the document $d_i$
$t_j$	The feature vector of the document
$z_l$	The cluster centre
$\hat{t}_j$	The new document feature vector derived from $t_j$
$\bar{z}_l$	The cluster centre derived from $z_l$

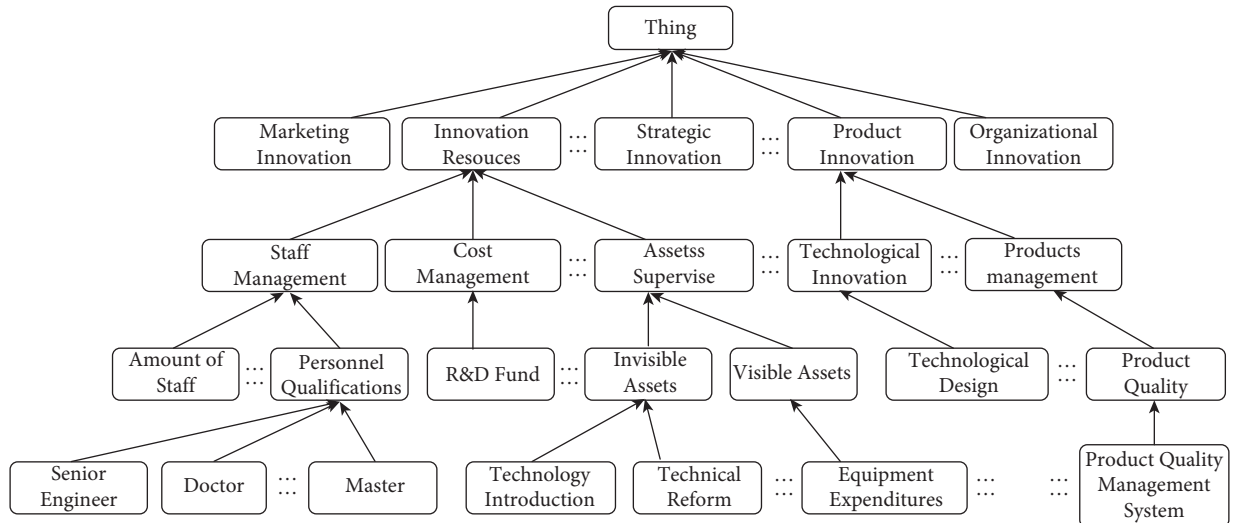

FIGURE 2: Structure of partial enterprise's technological innovation domain ontology.

represented as  $d_i = (w_{i1}, w_{i2}, w_{i3}, \dots, w_{in})$ . The term set extracted from the document set can be expressed as  $T = \{t_1, t_2, t_3, \dots, t_n\}$ .  $w_{ij}$  means the weight of the term  $t_j$  in the document  $d_i$ . The traditional clustering algorithms are usually determined by the number of occurrences of the term  $t_j$  appearing in the document  $d_i$ , that is, the term frequency, or the term frequency-inverse document frequency (TF-IDF), is used to assign weights. The traditional K-means algorithm selected  $K$  points randomly from the sample as the initial cluster centre candidate. Then, it usually calculated the distance from the sample points to the centre with the Euclidean distance formula (shown in equation (2)) and divided the points to the nearest centre. Finally, it iteratively calculated the centre of the cluster until the centre of each group does not change.

$$\begin{aligned} \text{dis}_{EU}(d_1, d_2) &= \sqrt{(d_1 - d_2)(d_1 - d_2)^T} \\ &= \sqrt{\sum_{j=1}^n (w_{1j} - w_{2j})^2}. \end{aligned} \quad (2)$$

This paper proposed an improved K-means algorithm, which improves the algorithm mainly by selecting initial cluster centres and semantic-based clustering. According to the semi-positive semantic similarity and relatedness of  $n \times n$  matrix  $M$  obtained by Step3,  $M = W^T W$  can be obtained by orthogonalization of the positive semi-positive matrix, where the column in  $W$  represents the document vector. According to the semantic similarity and relatedness matrix  $M$ , the Euclidean distance formula can be improved as the following equation.

$$\begin{aligned} \text{dis}_{EU \text{ improved}}(d_1, d_2) &= \sqrt{(d_1 - d_2)(M d_1 - d_2)^T} \\ &= \sqrt{(d_1 - d_2)W^T W (d_1 - d_2)^T} \\ &= \sqrt{((d_1 - d_2)W)((d_1 - d_2)W)^T} \\ &= \sqrt{(\hat{d}_1 - \hat{d}_2)(\hat{d}_1 - \hat{d}_2)^T}. \end{aligned} \quad (3)$$

where  $\hat{d}_1 = d_1 W$ ,  $\hat{d}_2 = d_2 W$ , the modified distance measurement considered the semantics between words based on the semantic similarity and relatedness matrix. Therefore, the distance between the document and the cluster can be measured by the definition of the following equation:

$$\begin{aligned} \text{dis}_{EU \text{ improved}}(t_j, z_l) &= \sqrt{(t_j W - z_l W)(t_j W - z_l W)^T} \\ &= \sqrt{(\hat{t}_j - \hat{z}_l)(\hat{t}_j - \hat{z}_l)^T}, \end{aligned} \quad (4)$$

where  $t_j$  represents the feature vector of the document,  $z_l$  defines the cluster centre,  $\hat{t}_j$  is the new document feature vector derived from  $t_j$ , and  $\hat{z}_l$  is the cluster centre derived from  $z_l$ .

Firstly, randomly select a data point  $z_l$  as the initial cluster centre from the input dataset. Secondly, for each point  $c_i$  in the dataset, the distance from  $c_i$  to  $z_l$  is calculated

by the Equation  $D(c_i) = \arg \min \|c_i - z_j\|_2^2, j = 1, 2, \dots, k$ . The point  $c_i$  with the maximum distance  $D(c_i)$  from  $z_l$  is selected as the new cluster centre  $z_2$ . Then, repeat the above steps until  $K$  initial cluster centres are found. Finally, the remaining data points in the sample set are allocated to the nearest or most similar clusters according to the principle of maximum similarity. The cluster centres in the  $K$  clusters are recalculated and iterated until the termination condition is met. The step of the improved K-means algorithm is described in Algorithm 1.

The improvement to the traditional K-means algorithm proposed in this paper based on semantic similarity and relevance mainly includes (1) using the improved method based on the maximum similarity to determine the initial cluster centre and reduce the random position of the cluster centre. (2) The improved Euclidean distance with semantic similarity and relatedness is used to measure the similarity between cluster centres and sample sets, instead of the traditional K-means algorithm, which ignores the semantic relationship between terms. (3) By adding convergence conditions, the original K-means algorithm solved the problem of unstable clustering results.

### 3.4. Validation

**3.4.1. Validation Methods.** The paper mainly used the SSE and SC methods to compare the clustering results of the traditional K-means method and the improved K-means method. The SSE method calculates the total error value between any data point and the cluster centroid, and the calculation method is shown in equation (5).  $\text{dis}$  represents the distance function,  $p$  is any data point in the cluster of  $c_i$ , and  $m_i$  is the cluster centroid. The lower value of SSE equates to better performance of clustering. Otherwise, a higher value represents a worse clustering effect. The Silhouette Coefficient method combines clustering cohesion and separation to evaluate the effect of clustering, and the value is between  $[-1, 1]$ . The higher value of the Silhouette Coefficient indicates the better clustering performance. The calculation method of Silhouette Coefficient was shown in equation (6).  $a(i)$  represents the average distance of the data point  $i$  to all other points in the cluster to which the data point  $i$  belongs.  $b(i)$  represents the minimum value of the average distance from the data point  $i$  to all points of each of the other groups.

$$\text{SSE} = \sum_{i=1}^k \sum_{p \in c_i} \text{dis}(p, m_i)^2, \quad (5)$$

$$S(i) = \frac{b(i) - a(i)}{\max\{a(i), b(i)\}}. \quad (6)$$

**3.4.2. Validity Comparison of the Proposed Method.** To compare the clustering performance between the traditional K-means algorithm based on Bag-of-words and the improved K-means algorithm based on semantic similarity and relatedness, the number of  $K$  is selected from 3 to 10. The

**Input:** preprocessed dataset  $D = \{d_j | j = 1, 2, \dots, m\}$ ; the dataset contains  $N$  terms  $C = \{c_i | i = 1, 2, \dots, n\}$ , semantic similarity, and relatedness matrix  $M$ ; the number of cluster  $K$ ; iteration termination condition  $\epsilon$ ; the maximum number of iterations  $\text{MaxStep}$ ;

**Output:**  $K$  cluster result;

**BEGIN**

- (1) start = 0  
 $k = 0$ ; //initialization  
load dataset  $D$  and select an initial cluster centre  $z_1$  randomly from  $D$  saving to the initial cluster centre  $Z_j = \{z_j, j = 1, 2, \dots, k\}$ ;
- (2) Calculate the distance between each sample and the initial point  $z_l$ , find the point  $c_i$  with the largest distance from  $z_l$  according to the equation (4), take the sample point  $c_i$  as the second initial cluster centre  $z_2$ , and save it to the initial point set  $Z_j = \{z_j, j = 1, 2, \dots, k\}$ ;
- (3) repeat step 2 until the  $k$ th initial cluster centre is found;
- (4) according to the  $D(c_i) = \arg \min \|c_i - z_j\|_2^2$ , assign each sample  $c_i$  to the class of the nearest  $k$  initial cluster centres;
- (5) update the centre of each cluster through the mean value  $Z_i(O) = \sum_{i=1}^{n_i} c_i/n_i$ ,  $n_i$  represents the number of sample points in the group;
- (6) the measure function  $E = \sum_{l=1}^k \sum_{j=1}^m \sum_{i=1}^{n_i} W_{lj} \text{dis}_{EU \text{ improved}}(\tilde{z}_{li}, \hat{c}_{ji})$ ,  $\tilde{z}_{li}$  represents the cluster centre,  $\text{dis}_{EU \text{ improved}}(\tilde{z}_{li}, \hat{c}_{ji})$  represents the distance between the  $j$ th data point and the  $l$ th cluster centre;  $w_{lj}$  represents the semantic matrix;
- (7) if the number of iterations reaches  $\text{MaxStep}$  or satisfies  $|E_1 - E_2| < \epsilon$ , the iteration is terminated;  
Otherwise,  $O = O + 1$ ,  
return to step 5 and step 6
- (8) end;

ALGORITHM 1: Improved semantic similarity and relatedness-based K-means clustering algorithm.

experimental results of the SSE and Silhouette Coefficient are shown as follows.

Table 2 shows that as the number of  $K$  clusters increases, the SSE value of the improved K-means algorithm is significantly smaller than that of the traditional K-means algorithm. It shows that the clustering performance of the improved K-means algorithm is better than the traditional K-means algorithm. As shown in Figure 3, when the number of clusters ( $K$ ) equals 8, the improved K-means algorithm and the traditional K-means algorithm have an elbow (inflection point) within the SSE value. It shows that when the number of clusters is 8, performance clustering might be the best. It provides a reference for the value of  $K$  in K-means clustering.

As shown in Table 2, with the increasing number of clusters  $K$ , the Silhouette Coefficient value of the improved K-means algorithm is significantly higher than the traditional K-means algorithm. The higher value of the Silhouette Coefficient in the dataset indicates the better the clustering performance. Hence, it shows that the performance of the improved K-means algorithm is better than the traditional K-means algorithm. As shown in Figure 4, when the number of clusters ( $K$ ) equals 8, the improved K-means algorithm and the traditional K-means algorithm have relatively higher values. Hence, comprehensive analysis shows that the optimum value of  $K$  is 8. The red dotted lines in Figure 5 represent the Silhouette Coefficient of the traditional K-means algorithm and improved semantic K-means algorithm. The bar chart is the category of clusters. Most of the samples in a group have a higher Silhouette Coefficient value and are distributed near the red dotted line, representing a better clustering effect. On the contrary, if the sample points have a lower Silhouette Coefficient value and the distribution is scattered, the clustering effect is worse. Figure 5 shows that the Silhouette Coefficient value of the improved K-means algorithm is higher, and the sample distributes near the red

dotted line. Hence, the result indicates the performance of an improved K-means algorithm based on semantic similarity, and relatedness is better than the traditional K-means algorithm based on the Bag-of-Words model.

## 4. Experiment Results

**4.1. Data Collection.** The experimental data in this paper mainly collect the technological innovation information of 400 enterprises in Beijing and uses the document information as a text collection. The collected textual data mainly consist of the enterprise's primary status, the development of enterprise technological innovation activities, enterprise innovation projects, enterprise organizational structure, enterprise main products and services, enterprise profitability, etc. Table 3 briefly shows the details of the data collection result.

After data cleaning and selection, there are 867 valid texts, and the overall data size is about 20 M. The experimental operating environment is the Windows 10 system, 2.70 GHz core processor, 8.0 GB memory, and Python 3.6.2. After the preprocessing, including the custom dictionary, part-of-speech filtering, and stop words removing, the keywords vocabulary was obtained and shown in Figure 6. Then, map the keywords to the concept in domain ontology and get the semantic similarity matrix  $P$  and relatedness matrix  $Q$  by calculating the semantic similarity and relatedness.

**4.2. Results Analysis.** Figure 7 shows the result obtained by text clustering based on semantic similarity and relatedness. The most important 15 feature words in each cluster are selected to represent the topic based on the feature weight, as shown in Table 4. According to the topic reflected by each group, there are eight types of main factors affecting

TABLE 2: The performance comparison between improved K-means algorithm based on semantic and traditional K-means algorithm.

K Value	SSE		Silhouette coefficient	
	Traditional K-means algorithm based on bag-of-word model	Improved K-means algorithm based on semantic similarity and relatedness	Traditional K-means algorithm based on bag-of-word model	Improved K-means algorithm based on semantic similarity and relatedness
3	683.2779	672.4002	0.075280	0.363640
4	671.9479	577.2000	0.081084	0.355436
5	667.6426	532.9228	0.028152	0.352955
6	668.5414	519.1228	0.072469	0.355115
7	660.5026	461.7781	0.064319	0.328729
8	<b>645.9339</b>	<b>385.5498</b>	<b>0.075842</b>	<b>0.352197</b>
9	654.0991	392.1088	0.071101	0.362227
10	632.2624	373.0217	0.018480	0.344523

When the value of  $K$  equals 8, the improved  $K$ -means algorithm and the traditional  $K$ -means algorithm have a relatively higher value.

FIGURE 3: Statistical comparison of SSE. (a) Traditional K-means algorithm. (b) Semantic K-means algorithm.

FIGURE 4: Statistical comparison of silhouette. (a) Traditional K-means algorithm. (b) Semantic K-means algorithm.

enterprise technological innovation. We combined the eighth cluster and the third cluster because they reflect the same theme. The analysis of the seven influencing factors about the technological innovation of enterprises is as follows.

Cluster 1: manufacturing capability. The main feature words of this cluster mainly focus on the new products, new processes, new materials, process technology, equipment level, etc. The content of these feature words is related to the manufacturing capabilities of products

FIGURE 5: The histogram of silhouette coefficient. (a) Traditional K-means algorithm. (b) Semantic K-means algorithm.

TABLE 4: The text clustering result of enterprise’s technological innovation when  $K=8$ .

Cluster	Proportion of included samples (%)	Top 15 topic feature words
Cluster 1	16.1	New product, Internet application, new technology, construction technique, information technology, new technique, advanced level, composite material, design and development, quality control, process technology, technical process, industrialization, high-tech, equipment level, individuation
Cluster 2	16	Engineer, senior engineer, senior expert, R&D expenditure, R&D, total assets, employees’ number, equipment original value, expenditure on science and technology activities, main business proportion, bachelor degree or above, enterprise scale, asset-liability ratio ownership structure, technology introduction
Cluster 3	19.2	Mechanism innovation, organization and implementation, operating mechanism, rewards system, organizational construction, management system, organizational structure, performance reviews, post doctor, rules and regulations, excellent talents, organization, incentive mechanism, communication channel, guarantee mechanism
Cluster 4	9.7	Patent, industry-standard, gross profit on sale, main business product sales revenue, science and technology progress award, method number, number of patent applications, industrial output, industrial added value, platform, number of technology development projects, number of new product development projects, software copyright, utility model, design patent
Cluster 5	7.3	Competitive advantage, social benefit, brand influence, market competitiveness, core competence, reputation, diversification, business area, marketing, market-driven, market demand, development trend, market occupancy, market share, products sale
Cluster 6	5.7	Intellectual property, intellectual property protection, intellectual property management, independent intellectual property, intellectual property application, property rights transformation, transfer of property rights, license, patent warning, confidential agreement, trade secrets, technology protection, protection method, promote application, intellectual property layout
Cluster 7	21.7	Industry-university-research cooperation, industry-university-research, internal and external resources, integration, resource integration, core competence, strategic planning, research institutes, colleges and universities, R&D team, technical cooperation, technology exchange, overall planning, leader, technology fusion
Cluster 8	4.3	Technical staff, innovation mechanism, management mechanism, director of technology centre, manager, scientists, technology leader, positivity, talent team, innovation team, outstanding contribution, postgraduate, technical experts, talent incentive mechanism, youth technology leader

and processes. The influence of manufacturing capability on technological innovation of enterprises is mainly reflected in the capability to transform the research and development results into manufacturing. The word “equipment level” reflects the advanced manufacturing equipment, the phrases “Construction technique, Process technology, Technical process, High-tech” reflect the topic of process design capability, and the term “quality control” reflects the content of

product quality management. “Internet application, Information technology, Industrialization” reflect the theme of product innovation activities. Therefore, the cluster’s words with high feature weights reflect that manufacturing capability is essential for an enterprise’s technological innovation.

Cluster 2: innovation resources. The words “engineer,” “senior engineer,” and “R&D expenditure” in this cluster have a high proportion of feature weight. The

words “Engineer, Senior engineer, Senior expert, Employees number, Bachelor degree or above” reflect the quantity and quality of the R&D staff. The words “R&D expenditure, R&D, Total assets, Expenditure on science and technology activities, Main business proportion” reflect the financial investment on R&D. The word “Equipment original value” reflects the equipment investment of R&D. The phrases “Enterprise scale, Asset-liability ratio ownership structure, Technology introduction” represent the investment of enterprises in non-R&D including of enterprises own capability. The investment of innovation resources mainly refer to the quantity and quality of enterprise’s investment in technological innovation resources. It is reflected in the investment of staff, funds, and equipment in R&D. The investment of innovation resources is one of the influencing factors of enterprise technological innovation.

Cluster 3: mechanism innovation. The top feature words of this cluster can reflect directly that the topic is mainly about the mechanism innovation, which is an essential factor that affects enterprises’ technological innovation. The feature words such as “Rewards system, Performance review, Post-doctor, Excellent talents, Incentive mechanism” indicate that enterprises attach importance to the incentive mechanism of personnel. The words “Organization and implementation, Operating mechanism, Organizational construction, Management system, Organizational structure” reflect the influence of the organizational management mechanism on the technological innovation of enterprises. An effective innovation mechanism can stimulate talents and cooperate effectively. The eighth group’s theme is the same as cluster 3, and the sample proportion is only 4.3%. Hence, we merge the contents of cluster 3 and cluster 8.

Cluster 4: innovation output. The feature words in this cluster, such as “Patent, Industry standard, Gross profit on sale, Main business product sales revenue,” have higher feature weight. It indicates that this cluster mainly reflects the topic of innovation output. The words “Patent, Industry standard, Science and technology progress award, Method number, Number of patent applications, Number of technology development projects, Number of new product development projects, Software copyright, Utility model, Design patent” reflect the technological output of enterprise’s innovation. The words “Gross profit on sale, Main business product sales revenue, Industrial output, Industrial added value” reflect the innovation benefits. Therefore, from the distribution of feature words, the innovation output is also an important performance that affects the technological innovation of an enterprise.

Cluster 5: market innovation. The words “Competitive advantage, Social benefit, Market competitiveness” have high feature value in this cluster. The keywords tend to reflect market innovation, which means

product sales and promotion innovations can meet market demands. With the continuous expansion of market scale and the increase of market demand, the market-oriented product sales innovation model has become one of the important factors affecting the development of enterprise technological innovation.

Cluster 6: protection measures. “Intellectual property, Intellectual property protection, Intellectual property management, Independent intellectual property” are high feature value words in this cluster, reflecting the content of intellectual property protection measures. Technical knowledge protection can promote technology diffusion and ensure attracting foreign capital and technology introduction. Therefore, the protection measures for intellectual property and technology are conducive to promoting the technological innovation of enterprises and are an important influencing factor.

Cluster 7: innovation strategy. This cluster contains the most significant proportion of samples. The keywords “Industry-University-Research Cooperation, Industry-University-Research, Internal and external resources, Integration, Resource Integration” reflect the topic of innovation strategy. It refers to the integration and arrangement of internal and external innovation resources and technologies based on the enterprise’s overall strategy with enterprise operation. The phrases “Industry-University-Research Cooperation, Industry-University-Research, Research institutes, Colleges and universities, R&D team” represent the content of the joint innovation strategy of enterprises and industry, university, and research. The phrases “Internal and external resources, Resource Integration” reflect the integration and allocation of internal and external resources. The terms “Technical cooperation, Technology Exchange, Technology fusion” reflect the strategic plan of enterprises for technology integration and innovation. The phrases “Core competence, Strategic planning, Overall planning, Leader” represent the innovation capability and strategy of the enterprise leader or decision-maker. Therefore, the topic of this cluster is innovation strategy, and the correctness of the innovation strategy also has an important impact on enterprise technological innovation.

Figure 8 shows the framework of the influencing factors for enterprises’ technological innovation. There are 7 types of impacts factors: manufacturing capability, innovation resource, mechanism innovation, innovation output, market innovation, protection measures, and innovation strategy. Through analysis of the linking feature words of each cluster, the meso-level concept can be concluded, as shown in Figure 8.

## 5. Discussion

*5.1. Policy Suggestions.* It can be seen from the framework of influencing factors of enterprise’s technological innovation, and the four clusters results that are particularly prominent include the “Protection measure,” “Innovation strategy,”

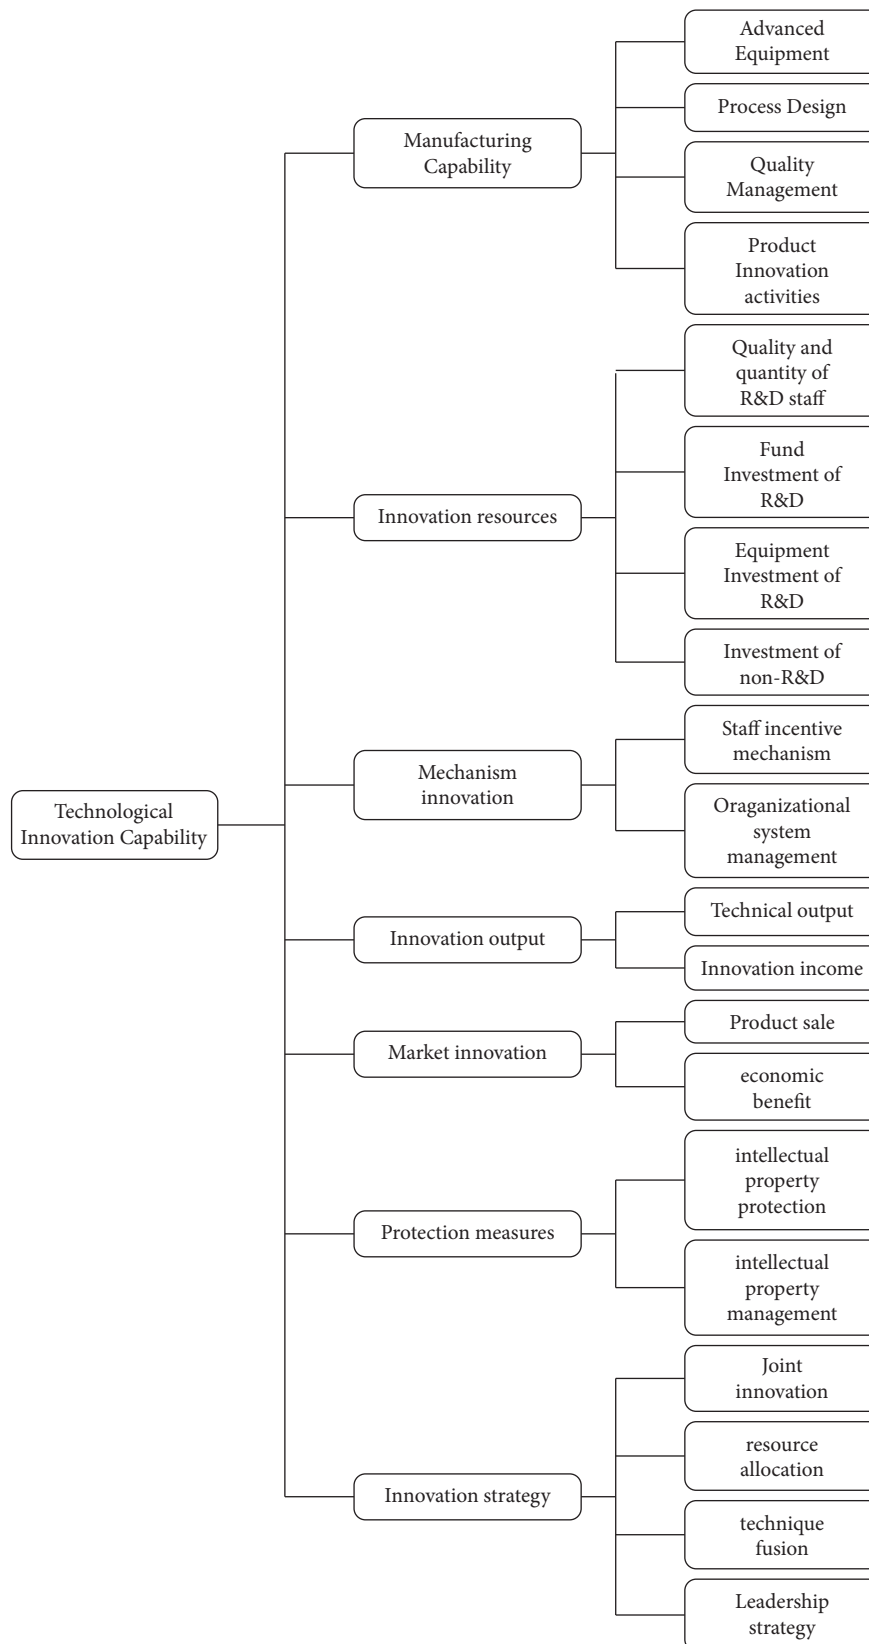

FIGURE 8: The framework of influencing factors of enterprise's technological innovation.

“Market innovation,” and “Mechanism innovation” except the “Manufacturing capability,” “Innovation resources,” and “Innovation output,” which are included in most of the researches. The four aspects are relatively new in the field of enterprise’s technological innovation. Thus, the paper provides policy suggestions from these four aspects for the enterprise’s technological innovation.

The innovation capability of intellectual property is an important aspect to measure the innovation output of enterprises. In the current fierce competition environment, enterprises are rushing to develop scientific and technological achievements through various channels for survival and development, and seek legal protection by applying for patents. However, it is not uncommon for enterprises to suffer heavy losses because their competitors registered the patents and trademarks in advance. Therefore, enterprises should strengthen their awareness of intellectual property protection, set up special intellectual property departments, and pay attention to cultivating professional intellectual property talents.

The innovation strategy is a plan and methodology for enterprises to develop new products and services in the future. It aligns the development of innovations with future corporate goals, which requires formulation based on the external environment and internal conditions. Thus, the innovation strategy directly reflects leadership decision-making. The weak sense of innovation or lack of innovative decision-making power for senior decision-makers will bring risks to the enterprise. The enterprises should plan and layout the innovative strategic cooperation in advance. In addition, it strengthens the collaboration between schools and industry and establishes strategic partners, which is helpful for the enterprise’s technological innovation.

Market innovation is mainly reflected in marketing and management capabilities. From the formation of initial products to the market introduction, the whole process is inseparable from professional marketers and marketing strategies. Therefore, to strengthen the market development, enterprises need to expand sales channels, explore new sales models, and improve the sales platforms. Moreover, enterprises should build their own sales team, introduce professional marketing personnel, and strengthen the training and management of marketing.

Introduce innovative management talents and improve the enterprise innovation mechanism. The enterprises need to construct a suitable organizational framework and formulate the innovation management system, including a talent introduction mechanism, talent training mechanism, innovation incentive system, reasonable innovation evaluation system, innovation achievements protection mechanism, etc. It can mobilize the enthusiasm of corporate managers and employees by improving the incentive mechanism, including interest incentives, competence incentives, power incentives, and responsibility incentives. The interest incentives include salary, welfare, bonus, etc. Competence incentives include training, competitive employment, etc. The power incentives mainly refer to promotion, and responsibility incentives mainly refer to a reasonable assessment system. Mobilizing the enthusiasm

and creativity of employees can effectively enhance the enterprise’s technological innovation capabilities.

*5.2. Implication for Theory and Practice.* This paper enriches and deepens the theoretical research on evaluating enterprise’s technological innovation capability from the theory aspect. The paper first extracts prominent factors that affect enterprise technological innovation based on the collected textual data. It provides a reference for the construction method of the enterprise’s technological innovation evaluation index system. Moreover, the process of enterprise’s technological innovation is dynamic and continuous. Traditional assessment methods for enterprise technology innovation lack automatic processing ability and cannot meet the needs of large-scale, high-quality, and in-depth knowledge acquisition. As a high-tech knowledge processing technology, the text mining method has significant advantages in the intelligent analysis of enterprise technological innovation capabilities. It can reflect the objective level of enterprise’s technological innovation under the data-driven. This paper proposes a method for discovering enterprise technological innovation knowledge based on semantic mining technology. It is helpful to explore the potential factors of influencing the enterprise technological innovation by revealing the inherent complex associations of enterprise’s textual data and extracting valuable patterns and knowledge. To our knowledge, this research is the first attempt to apply the semantic text clustering algorithm in enterprise’s technological innovation. In addition, this paper analyzed the development status and trends of the enterprise’s technological innovation capabilities based on the collected textual data from 400 enterprises in Beijing. It helps to promote technological innovation of the enterprises by smart analysis under the data-driven. Thus, the potential benefits of the proposed model can help drive and facilitate the enterprise’s technical innovation capability.

## 6. Conclusions

This paper utilizes a data-driven intelligent mining method based on a semantic conceptual model to analyze the influencing factors of enterprise technology innovation. Some scholars believe that technological innovation’s evaluation system construction method is a questionnaire design and survey analysis. However, it inevitably involves human factors and the subjective judgments of experts. This study proposed a systematic process for evaluating the enterprise’s technological innovation based on sizeable textual data. Computer information processing analyzes the evaluation factors and indicators that affect enterprise technology innovation from objective data. Furthermore, the traditional text clustering algorithm based on the Bag-of-words model ignores the semantic relationship between concepts, resulting in an unsatisfactory clustering effect. Therefore, this paper proposed an improved semantic concept-based clustering algorithm to analyze enterprise’s collected textual data. The performance of the improved K-means clustering method based on semantic similarity

and relatedness is superior to the traditional K-means clustering method. The proposed method realized the clustering of critical factors in the field of enterprises technological innovation, and the analysis of experimental results can obtain the seven key factors that affect the technological innovation of enterprises.

More than 50% major road accidents are caused by risk driving behaviors from professional drivers of Heavy Duty Vehicles (HDVs). The quantitative estimation of driving performance and driving behaviors portrait for professional drivers is helpful to measure the driver's driving risk and inherent driving style. Previous studies have attempted to evaluate risk driving behavior, but most of them rely on high-demand vehicle and driving data. However, few studies can dig into the causes and correlations behind individual driving behavior and quantify the driving behaviors portrait for professional driver based on long-term naturalistic driving. In this study, the data is from On-Board Unit (OBU) devices mounted in the HDVs in China. Based on the driving behavior pattern diagram and the frequency and ranking of drivers' typical driving patterns, a driving behavior portrait approach is proposed by comprehensively considering the vehicle safety, driving comfort, and fuel economy indicators. The similarities and differences of different drivers' driving behaviors are quantitatively analyzed. The high precision and sampling frequency data from vehicles are used to verify the proposed approach. The results demonstrated that the driving behavior portrait approach can digitally describe the individual driving behaviors styles and identify the potential driving behaviors with long-term naturalistic driving data. The development of this approach can help quantitatively evaluate the individual characteristic of risk driving behaviors to prevent road accidents.

## 1. Introduction

More than 50% major road accidents are caused by risk driving behaviors from professional drivers of HDVs [1]. Due to drivers' personal characteristic and driving style, most of the road accidents are caused by risk driving behaviors [2]. Quantifying analysis drivers' driving style and identifying driving behavior portrait is helpful to prevent road accidents.

In recent years, many studies have attempted to evaluate risk driving behavior, but most of them rely on high-demand vehicle and driving data, which is not conducive to large-scale application, and most of the previous studies focus on driving safety levels or identify the driving behaviors based on real time or offline with short-term data analysis ([3–12]; Yan et al., 2019). However, few studies can dig into the

causes and correlations behind individual driving behavior and quantify the driving behaviors portrait for professional driver based on long-term naturalistic driving.

Various driving behaviors can be seen as the responses to complex driving conditions. Due to the personal characteristics and driving skills of different drivers, their driving behaviors are also different. Some drivers have aggressive driving styles, fast acceleration, and braking with high risk driving, while others are more cautious with less risk. Therefore, the quantitative estimation of driving performance and driving behaviors portrait is helpful to measure the driver's driving risk and inherent driving style, so as to prevent traffic accidents.

With the development of autonomous and connected vehicle, various sensors can be installed on the vehicle to collect real time data with naturalistic driving. However, the

positioning data is the most widely used and has high precision with large-scale application in real traffic until now.

In this paper, the data is from OBD devices mounted in the HDVs in China, and high precision and sampling frequency data from vehicles are used to verify the proposed approach. Based on the driving behavior pattern diagram and the frequency and ranking of drivers' typical driving patterns, a driving behavior portrait approach is proposed by comprehensive considering the vehicle safety, driving comfort, and fuel economy indicators, to quantitatively evaluate the personalized driving behavior of different drivers and identify potential risk driving behaviors, so as to improve the assessment accuracy of the risk model and reduce the accident risk.

## 2. Literature Review

The majority of road accidents are caused by risk driving behaviors of professional drivers with HDVs. Therefore, scholars from all parties have carried out assessment studies on drivers' driving safety and driving risk, mainly from the following three aspects.

*2.1. Risk Driving Behavior Identification Based on Statistical Methods.* Some risk driving behavior studies are related by applying statistical method or machine learning algorithm to classify and identify risk driving. Constantinescu et al. modeled driving styles based on positioning data and divided drivers into different driving styles by cluster analysis and principal component analysis [8]. Suzdaleva et al. studied the stochastic modeling of driving style and its online estimation during driving based on Bayesian theory, and their research used recursive algorithm to estimate hybrid parameters and actual driving style [7]. Martinez et al. introduced a vehicle driving style feature and recognition correction algorithm based on current and future development trends with machine learning methods [9]. Qi et al. studied two thematic models: mLDA and mHLDA, which can discover the information of differentiated driving styles with hidden structures from the data of real driving behaviors and can identify the different driving styles [10]. Zhu et al. proposed an unsupervised clustering algorithm that can reflect different driving styles [13]. Han et al. proposed a method of driver behavior uncertainty identification based on statistics [11]. Wang et al. used semi-supervised support vector machines to classify driving styles. In order to solve the problem that supervised learning method requires a large amount of marked training data and it is time-consuming to manually label a large amount of driving data, a semisupervised support vector machine method is used in this paper to classify drivers into aggressive driving style and conventional driving style according to several marked data points [6]. Siordia et al. proposed an autonomous driving risk rating system. The system is based on a driving simulator that uses driver, road, and vehicle information to train five different data mining algorithms to predict the level of driving risk [14].

*2.2. Risk Driving Behavior Identification Based on Safety-Related Driving Events Detection.* Another commonly used method for classifying driving risks is to detect safety-related driving events, such as sharp acceleration, sharp deceleration, and sharp turns. In Johnson et al.'s study, a dynamic time structuring algorithm (DTW) was used to detect the driving styles with data from smartphone sensors [15]. In this case, they need some predefined templates for the detected driving events. Itkonen has made a trade-off between the compact but erratic behavior of driving and the loose and smooth following behavior of driving. They call it "tight" and "smooth" driving and suggest that this trade-off can be used as a potential factor to evaluate potential driving styles [16]. In these studies, the use of predefined driving events is essential, but the thresholds used to define these driving events are not consistent. For example, in Paefgen et al.'s study, the threshold value used for rapid acceleration and deceleration is  $\pm 0.1$  g [17]. Fazeen uses  $\pm 0.3$  g [3]. Wang et al. proposed a self-designed driving style scale, which is suitable for evaluating the driving style of drivers with Chinese national conditions [18]. Bagdadi proposed a method based on critical jerk, to identify safety critical braking events during car driving [19]. Chen et al. proposed a method to predict risk driving events and defined risk driving events by using the risk attribute diagram (ARM) [4].

*2.3. Risk Driving Behavior Identification Based on Risk Modeling.* Some scholars have also modeled the safety of drivers' driving behavior. Ellison et al. assessed the risk driving behavior by modeling driver behavior. The frequency and size of overspeed event, aggressive acceleration event, and aggressive braking event were used as the behavior measurement indexes, and their spatial and temporal characteristics were used as the influencing factors. Based on these parameters, the behavioral characteristics of drivers were established and the total score representing driving risk was given [5]. Bejani et al. developed the system to consider the impact of traffic levels and vehicle types on driving style assessments. The system consists of three subsystems, which use smart phones for calibration, driving action classification, and driving style evaluation [20]. Hong et al. used sensors such as Android smartphones, On-Board Diagnostics (OBD), and Inertial Measurement Units (IMU). By collecting driving behavior characteristics such as maximum speed and acceleration, average value, and standard difference, the relationship between driving characteristics and driving style was modeled by using naive Bayes classifier [21]. Jachimczyk et al. proposed a method to objectively evaluate driving style based on eight indexes related to speed, acceleration, engine speed, and driving time. This method is an embedded system based on the conceptual design of the Internet of things to evaluate three driving style standards: safety, economy, and comfort [22]. Meseguer et al. designed an Android application that can monitor physiological data from drivers and diagnostic data from vehicles in real time to study the correlation between heart rate and driving style [23]. Chu et al. proposed an improved curve speed model that takes into account driving style, vehicle, and road

factors. On the basis of vehicle-road interaction model, driver behavior factor is introduced to quantify the driving style selected for the speed of curve [12, 24]. Deng et al., in order to identify driving styles, reasonably modeled three driving styles (aggressive, moderate, and mild) by means of hidden Markov model according to the driver's braking characteristics and realized efficient analysis of driving styles [25]. An early warning system has been proposed for risk driving based on statistical modeling. They used a semi-supervised learning method to grade the driving risk and evaluate the safety of the driving time series data [26].

In summary, most of the risk driving behaviors studies focus on the classification of driving styles or the scoring of risk driving behaviors. The purpose of these previous studies is mostly to classify drivers into different driving safety levels, such as safe, normal, or dangerous, and rarely pay attention to individual driving behavior characteristics. In addition, the use of predefined risk driving behaviors models or events is essential, but the thresholds used to define these driving events are not consistent. However, a few studies focusing on the risk driving behavior model for professional driver of HDVs and a fixed risk driving threshold may not fit in all drivers due to various driving styles from individual drivers and understanding of the driving skills and experience.

In recent years, Internet portrait technology is widely used to quantify the characteristics of users. A driving habit graph (DHG) was proposed to model driving behaviors graphical model [4], which can quantify the behaviors parameters in naturalistic driving data and visual presentation of driving behaviors. Inspired by that study, this paper proposes an individual driving behavior portrait by comprehensively considering the vehicle safety, driving comfort, and fuel economy indicators to quantify the potential risk driving behaviors and driving styles.

### 3. Methodology

**3.1. Driving Behavior Pattern Diagram.** Driving behavior is the driver's response to different driving situations, and driving behavior patterns reflect these continuous driving behaviors over time; in this case, each driver has individual typical driving mode. We need to identify these driving behavior patterns and extract the representative ones to judge the driver's driving style based on the driving patterns of different drivers to evaluate the driver's driving safety level. In the process of method exploration, we use the Symbol Aggregation Approximation (SAX) method to convert the original driving data into the corresponding driving acceleration level code to reduce the complexity of original driving data [27]. SAX algorithm was proposed by Lin et al. in 2003 [28]. Based on the Piecewise Aggregation Approximation (PAA) method, this method retains its advantages of simplicity and low complexity and provides high sensitivity and selectivity in the process of range query. In addition, the symbolic feature representation provides a favorable condition for the existing rich data structures and string processing algorithms. The SAX process consists of two steps. First, convert the original data into a segmented

aggregation approximation (PAA) representation. Second, convert PAA data to the corresponding string according to the location of the breakpoint. In this study, the driving behavior data was ultimately converted into a numeric code rather than a string. This research includes four steps: data standardization, data grading and coding, typical driving behavior pattern extraction, and driving behavior pattern graph generation.

**3.1.1. Data Standardization.** In this study, the longitudinal acceleration change of the driver is used as the standard to reflect the driving behavior. Longitudinal acceleration is chosen as the standard because acceleration is a typical index closely related to driving safety, and the change of acceleration also represents the change of speed, which is another important index of driving safety.

The driving acceleration data of a certain driver is standardized by Z-standardization method, so that its mean value is 0 and the standard deviation is 1. The purpose of this is to make the offset and amplitude consistent so that it has the same dimension as other driver data.

**3.1.2. Data Grading and Coding.** The grading and encoding of data require the use of SAX method. The SAX method first converts the original data into PAA representation. The PAA data is then converted to the appropriate string based on the location of the breakpoint.

This study divided the data into 7 levels. Theoretically, the SAX method can divide the data into up to 20 levels and provide corresponding thresholds. Based on data analysis, after testing the classification of 3, 5, 7, 9, and 11 grades, we found that the classification of 7 grades had the best effect. Only the odd number level is tested because the median level always represents a neutral behavior. In this study, the median represents the driving behavior of the vehicle approaching uniform cruising speed. Since the mean of the normalized data is 0, level 3 represents neutral behavior. Taking the acceleration data as an example, level 3 represents the acceleration value close to  $0 \text{ m/s}^2$ , that is, uniform speed cruising. Levels 0, 1, and 2 represent negative acceleration, or deceleration. The amplitude range of data values for each level increases as the level decreases. As the number of levels decreases, the deceleration behavior becomes more obvious. Levels 4, 5, and 6 represent positive accelerations, or accelerations. The amplitude range of data values for each level increases with the level. As the rank value increases, the accelerating behavior becomes more obvious.

**3.1.3. Typical Driving Behavior Pattern Extraction.** After the data is graded and coded, the driving mode that exists in it needs to be detected. Driving is a continuous process in which the vehicle is controlled by the driver's constant adjustment to achieve the desired driving condition. Limited by people's physiological and psychological factors, the reaction speed of the driver to the stimulus is limited. Under general conditions, the reaction time for complex selective reactions is 1~3 s, and the reaction time for complex

judgment and recognition is 3~5 s on average. Studies have shown that three seconds is a window of time to measure driving behavior, during which the driver can adjust the vehicle to the desired state. Thus, the driving mode is defined as a change in driving behavior (speed, acceleration, steering, etc.) every three seconds. To make sure the timing is right, this article also tested using 4, 5, and 6 seconds. The results show that if these intervals are used as the detection time, a large number of driving mode types are generated, and the graph is not as clear as the result of 3 seconds. Starting from the starting point of the data, a moving window of window size 3 s is used to detect the existing driving mode. Due to the differences in driving skills and personal characteristics, each driver has his own unique driving habits. According to all the driving behavior patterns detected by different drivers, the driving behavior patterns with high frequency are used to represent the driving habits of drivers. For each driver, more frequent driving behavior patterns, that is, typical driving behavior patterns, were extracted. Driving patterns with the same sequence of combinations naturally converge into a group and count the number of patterns contained in each group. Then, the incidence of each driving behavior pattern was calculated. For example, if driving mode “123” occurs “ $m$ ” times in a continuous acceleration data set of length “ $n$ ,” the incidence of driving behavior mode “123” is “ $m/(n-2)$ ”. For each driver, the 30 most frequent driving behavior patterns were extracted and regarded as their typical driving behavior patterns. On the premise of collecting enough driving data to cover various external factors such as traffic conditions and road types, these typical driving behavior patterns can describe drivers’ internal driving habits. In addition, these typical driving behavior patterns are independent of external driving conditions and reflect drivers’ inherent driving preferences.

**3.1.4. Driving Behavior Pattern Graph Generation.** The typical driving patterns were plotted in descending order of frequency to obtain the driving behavior pattern of individual drivers. Driving behavior data can be transformed into a graph through the four steps described above. The typical driving behavior pattern reflects the driver’s personalized driving behavior, but also includes the driver’s driving styles and hidden driving risks. In this study, the driving behavior patterns of drivers were plotted based on the acceleration data. For all driving behaviors, the first 30 driving patterns are extracted as the typical driving patterns. These 30 patterns are enough to reflect the driver’s driving behavior characteristics. In addition, considering that acceleration and deceleration are two important and independent operations, the typical driving patterns of acceleration and deceleration are extracted, respectively, to illustrate the driving behavior characteristics of drivers and distinguish the differences between drivers’ driving styles.

The abscissa in Figure 1 represents the first 30 typical driving behavior patterns that appear from high to low frequency after the extraction of typical driving patterns. The ordinate represents the seven acceleration levels of 0–6 after data classification and coding. That is, the combination of

every three connected line points in the figure is a typical driving behavior pattern, and the corresponding abscissa is the occurrence frequency ranking of the behavior pattern, while the ordinate represents the corresponding acceleration level change of the driving behavior pattern within three seconds. Acceleration level 3 represents the neutral behavior, which is close to the acceleration value of 0 m/s<sup>2</sup>, that is, the average speed of travel. Acceleration levels 0, 1, and 2 represent the negative acceleration value, that is, the deceleration behavior. The amplitude range of data values for each level increases as the level decreases. As the number of levels decreases, the deceleration behavior becomes more obvious. The acceleration levels of 4, 5, and 6 represent the positive acceleration value, that is, the acceleration behavior. The amplitude range of data values for each level increases with the level. As the rank value increases, the accelerating behavior becomes more obvious. Taking the first typical driving behavior pattern “333” as an example, the frequency of this pattern is the highest. During the duration of this behavior pattern, the driver’s acceleration level changes to “3-3-3.” The second driving behavior pattern, “343,” was the second most frequent. During the 3 seconds of this behavior pattern, the driver’s acceleration level changed to “3-4-3.” The driver’s driving behavior pattern diagram can clearly present the composition and sequence of the driver’s typical driving behavior pattern.

**3.2. Modeling Driving Behavior Risk.** The driving behavior pattern graph is the visual representation and qualitative description of the driver’s driving pattern. However, the frequency and ranking of typical driving patterns and the gradation of the patterns themselves offer possibilities for quantitative analysis. Therefore, taking acceleration data and typical driving patterns as influencing factors, this paper proposes a personalized driving behavior evaluation model from three aspects of vehicle safety, driving comfort, and fuel economy to comprehensively evaluate vehicle driving safety.

$$\text{SCORE} = 0.7 * \text{score}_{\text{safe}} + 0.2 * \text{score}_{\text{comfort}} + 0.1 * \text{score}_{\text{economy}} \quad (1)$$

As shown in formula (1), SCORE is the comprehensive evaluation index of driving behavior, which consists of three parts. The first part is the safety evaluation index based on the driver’s typical driving behavior, which reflects the driver’s driving safety degree and the severity of acceleration and deceleration. The second part is the evaluation and analysis of vehicle comfort based on acceleration data, which reflects the degree of comfort in driving behavior to some extent. The third part is the evaluation index of fuel economy based on acceleration, which reflects the degree of fuel consumption. Combined with literature, considering the operation of the vehicle in the process of driving safety is most important, followed by the comfort in the process of transportation, and finally to fuel economy, giving three sections of the score to the corresponding proportion of weight (i.e., safety weight with 70%, comfort with 20%, and the economy with 10%), comprehensive comparing to the driver’s driving behavior evaluation.

FIGURE 1: Driving behavior pattern diagram.

$$\text{score}_{\text{safe}} = \sum_{i=1}^{30} \text{freq}_i * \{ \text{abs}[\text{mean}(\text{CODE}) - 3] + \text{std}(\text{CODE}) \} \quad (2)$$

As shown in formula (2), in the first part,  $i$  is the order of the typical driving mode, and  $\text{freq}_i$  is the proportion of the typical driving pattern in all driving patterns. CODE is the code for a typical driving pattern, such as "234." Mean and std were used to calculate the mean and standard deviation of driving patterns, respectively. For example, the mean of pattern "234" is  $(2 + 3 + 4)/3 = 3$ , and the standard deviation is 1. Abs stands for absolute value. This evaluation method can reflect the degree of safety of driving behavior, because it takes into account the amplitude and variation of acceleration value by using the mean value and standard deviation. The amplitude of driving acceleration and the change of acceleration are important indexes, so the mean value and standard deviation are added. In  $\text{abs}[\text{means}(\text{CODE}) - 3]$ ,  $-3$  is the acceleration amplitude used to evaluate acceleration and deceleration behavior, because CODE 3 represents uniform driving behavior. This quantitative analysis method can consider the amplitude and change of acceleration at the same time, which can reflect the change of vehicle state and the change of vehicle control stability. Clearly, lower scores mean safer driving behavior.

$$\text{score}_{\text{comfort}} = \left[ \frac{1}{T} \int_0^T a_w^2(t) dt \right]^{1/2} \quad (3)$$

In the second part,  $\text{score}_{\text{comfort}}$  represents the root mean square value of weighted acceleration.  $T$  is the period (s) of vibration analysis;  $a_w(t)$  is the axial acceleration ( $\text{m/s}^2$ ); time history  $a(t)$  is the time history of weighted acceleration obtained by the weighted function filter  $w(f)$  of the corresponding frequency. This method refers to the evaluation standard of vehicle comfort formulated by ISO and only considers the influence of longitudinal acceleration on vehicle comfort. Lower scores mean a more comfortable driving.

$$\text{score}_{\text{economy}} = \begin{cases} \text{MOE}_e = e^{\sum_{i=0}^3 \sum_{j=0}^3 (L_{i,j}^e * v^i * a^j)}, a \geq 0 \\ \text{MOE}_e = e^{\sum_{i=0}^3 \sum_{j=0}^3 (M_{i,j}^e * v^i * a^j)}, a < 0 \end{cases} \quad (4)$$

In the third part,  $\text{score}_{\text{economy}}$  represents the fuel consumption of the vehicle. Here, VT-Micro fuel consumption model proposed by Virginia Tech University is adopted. This method can be used to calculate instantaneous fuel consumption based on vehicle speed and acceleration, and it is proved that the model results have a high degree of fit with the actual fuel consumption, where  $\text{MOE}_e$  is the instantaneous fuel consumption ( $L/s$ ) of the vehicle;  $v$  is the instantaneous speed of the vehicle ( $\text{km/h}$ );  $A$  is the instantaneous acceleration of the vehicle ( $\text{km/h/s}$ );  $L_{i,j}^e$  is the fitting coefficient of the instantaneous fuel consumption model when the vehicle is accelerating; the power of velocity  $v$  is  $i$  and the power of acceleration is  $j$ .  $M_{i,j}^e$  is the fitting coefficient of the instantaneous fuel consumption model when the vehicle slows down and the power of velocity  $v$  is  $i$  and the power of acceleration is  $j$ . The fitting coefficient can be obtained by querying the coefficient value table of the model. Lower scores for this segment mean more economical fuel consumption for vehicles. It should be noted that the overall driving behavior evaluation score consists of three evaluation index scores, and these evaluation indexes have different orders of magnitude and dimensions. If the original index data value is directly used for summation analysis, the results are easy to be unreliable; that is, the index with higher value will be highlighted, while the index with lower value level will be weakened. Therefore, the scores of different indicators need to be standardized.

#### 4. Driving Behavior Characteristics and Risk Analysis

**4.1. Acquisition of Experimental Data.** The data used in this paper was collected by the information acquisition equipment installed on the HDVs. The collection device includes a GPS module for collecting location data, an OBU module for

collecting vehicle movement data, and a cellular network module for uploading the collected data to a server. The collected information is uploaded to the Internet of vehicles service platform in real time. The parameters collected include the vehicle's GPS time, speed, direction, mileage, position, longitude, latitude, ACC state, and positioning state, etc. The data sampling frequency is 1 Hz.

The natural driving data of 10 HDVs were collected, including driving behavior data. The driving environment of these experimental vehicles includes different grades of roads such as highway, national highway, provincial highway, county highway, and rural highway. The professional drivers are generally older and the average daily driving distance of vehicles is more than 100 kilometers. There is a one-to-one correspondence between the driver and the vehicle. Data collection period is from June 29, 2019, to July 29, 2019, a total of 30 days; more than 6 million pieces of driving data are collected. The drivers in the experiment did not have fixed working hours or rest days, and most of them drove during the day. The working period was from 7:00 AM to 17:00 PM. The data collection time was long enough and of high quality to reflect the driving behavior of individual drivers and meet the needs of the experiment.

For the practicality of the proposed approach in real life, meanwhile, considering the positioning data is the most widely used and has high precision with large-scale application in real traffic until now; in addition, the acceleration is a typical index closely related to driving safety; the change of acceleration also represents the change of speed, which is another important index of driving safety. Therefore, in the analysis of driving behavior, this study mainly uses the longitudinal acceleration data of drivers.

**4.2. Driving Safety Preassessment.** Before analyzing the driving behavior pattern, this study needs to make a prejudgment on the driving situation of individual drivers, that is, to preliminarily evaluate driving safety by identifying the frequency of risk driving events. In this paper, two risk driving behaviors of sharp acceleration and sharp deceleration are considered, and the acceleration threshold value of  $\pm 0.3g$  proposed by Fazeen in this paper is used to detect these two driving behaviors. Using these thresholds, a quantified scoring method was used to assign each driver a driving safety label. Firstly, the proportion (percentage) of individual drivers' accelerated driving behavior (acceleration greater than  $3\text{ m/s}^2$ ) and decelerated driving behavior (acceleration less than  $-3\text{ m/s}^2$ ) in the total driving behavior was calculated. The total proportion of drivers is high, indicating that the driver operates frequently with rapid acceleration and has relatively low safety in driving behavior. The evaluation results are shown in Figure 2.

As can be seen from Figure 2, the accelerated or decelerated behaviors of different drivers account for a low proportion of all driving behaviors. The proportion of rapid deceleration behavior of most drivers is higher than that of rapid acceleration behavior. The proportion of acceleration behavior and deceleration behavior of different drivers conforms to the same trend. The driver with a high proportion of risk driving behavior has a tendency of more risk

FIGURE 2: Overall proportion of drivers' risk driving behavior.

driving behavior. For example, the driver Q01868D has a higher proportion of accelerated behavior than other drivers. However, drivers with a low proportion of risk driving behaviors can temporarily consider their driving behaviors to be relatively safe, such as D41777 and D41981. In order to facilitate the subsequent comparative analysis, we divided the ten drivers into two groups. Assume that the top 5 with the highest proportion of total behaviors of rapid acceleration and deceleration include B32781, B32791, B66980, F63022, and Q01868D as drivers in the relatively dangerous group. The 5 drivers with a low proportion of rapid acceleration and deceleration behavior, including B67845, D41777, D41981, D46109, and F63030, were taken as the drivers in the relative safety group. The following will explore the personalized driving styles of different drivers more specifically by analyzing the driving behavior pattern.

**4.3. Integrated Driving Behaviors.** As can be seen from Figures 3 and 4, the most frequent driving behavior pattern of all drivers was cruising "333." The driving behavior pattern of individual drivers can clearly understand the driving styles of different drivers and their behavioral preferences in some driving situations. The shape and distribution of driving patterns can reflect the driving behavior characteristics of drivers, such as D41981 and Q01868D. The degree of dispersion and fluctuation of the driving behavior pattern of the two drivers can obviously reflect the degree of driving aggressiveness of the drivers. Some driving preferences of drivers can also be reflected in the figure. For example, compared with other drivers, driver Q01868D have high ranking of driving patterns "222" and "444." The ranking of risk driving behavior patterns such as rapid acceleration and deceleration and the amplitude of acceleration and deceleration fluctuation can reflect the driver's driving behavior and potential danger, but some drivers with a more stable overall style also have risk driving behavior patterns. That is, drivers in the relative safety group had more risk driving behavior patterns (e.g., "000") than those

FIGURE 3: Dangerous group driving behavior pattern diagram.

in the relative safety group. In addition, the low proportion of rapid acceleration and deceleration in the overall driving behavior does not mean that the driver’s driving style is stable. It is necessary to judge the driver’s driving style by combining the type and distribution of specific driving behavior patterns. It also illustrates the importance of judging individual drivers’ driving styles.

4.4. Accelerated Driving Behavior. As can be seen from Figures 5 and 6, each chart represents the ranking from high to low of the occurrence frequency of the

corresponding driver’s accelerated driving pattern. The acceleration pattern diagram represents the similarities and differences and preferences of each driver in the acceleration pattern he or she chooses when taking the accelerated driving behavior. As can be seen from the figures, the occurrence frequency and ranking of the fast accelerating driving patterns defined as dangerous drivers, such as “555,” “666,” are generally higher than those of safe drivers. However, some safe drivers ranked higher than dangerous drivers in the accelerated driving pattern (e.g., mode “666”). For another example, for driver F63030, his rapid

FIGURE 4: Safety group driving behavior pattern diagram.

acceleration and deceleration frequency is not high in the proportion of the overall driving behavior, but the driver's preference in acceleration is relatively aggressive. This shows that the overall proportion of risk driving behavior can only reflect the driver's driving risk on one hand. The reason is that the increase of the frequency of safe driving mode will reduce the overall frequency proportion of some risk driving modes, leading to the concealment of some risk driving behaviors. Some drivers generally have a smooth driving style but are prone to violent driving behavior at certain moments. Although the frequency of these risk driving behaviors is not high, the problem of increasing

accident probability caused by these behaviors cannot be ignored, which reflects the tendency of risk driving behaviors of drivers. Rankings and frequencies can complement each other to accurately differentiate the driving styles of different drivers.

It can be seen from the acceleration patterns of several drivers who are defined as safe drivers that with the increase of safety degree (the decrease of the overall proportion of drivers' acceleration and deceleration behaviors), such as "555," "666," the occurrence frequency and ranking of this dangerous pattern significantly decreased, and the acceleration behavior became more and

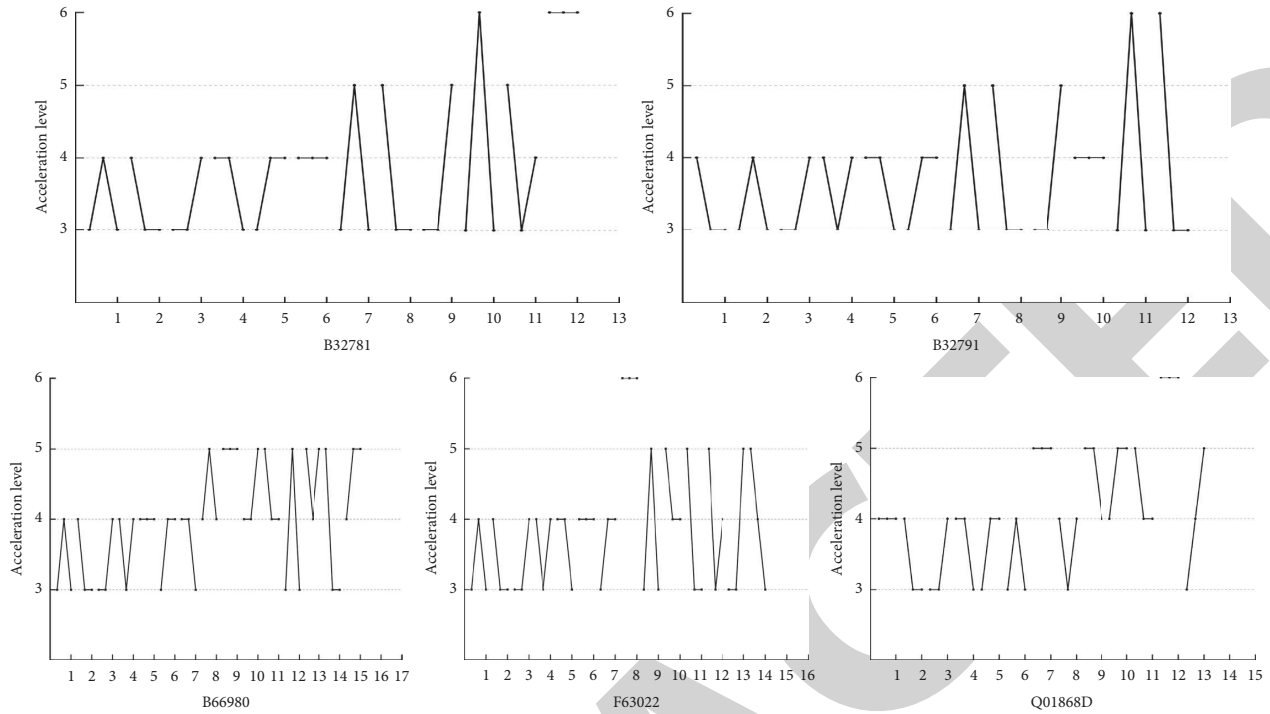

FIGURE 5: Dangerous group driving behavior pattern diagram.

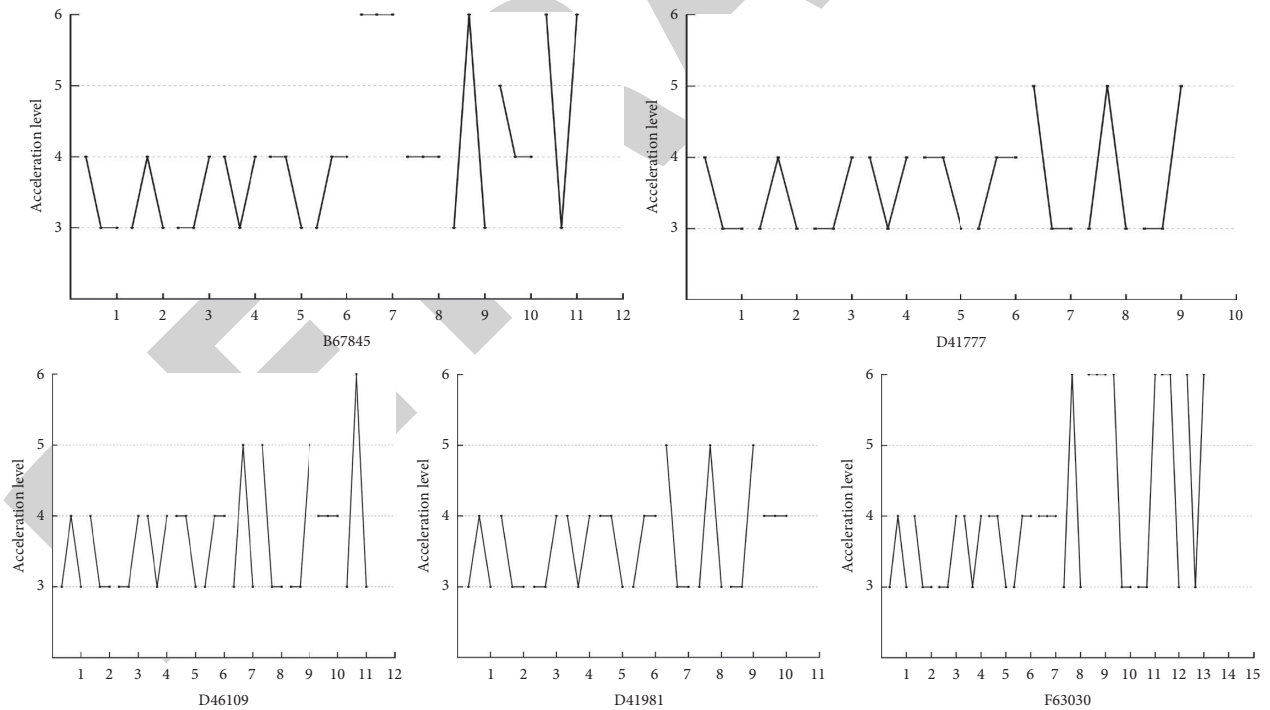

FIGURE 6: Safety group driving behavior pattern diagram.

more stable. In fact, in addition to the actual driving pattern occurrence frequency, the interaction between the “555” and “666” patterns and other patterns may also affect the driver’s driving safety level. In addition, the degree of driving safety is determined by acceleration and deceleration behavior, not just acceleration.

4.5. *Decelerated Driving Behavior.* As can be seen from Figures 7 and 8 for the occurrence frequency of the driver’s deceleration driving behavior pattern, the deceleration driving behavior pattern diagram represents the similarities and differences and preferences of each driver in the deceleration driving behavior. The pattern “000” and

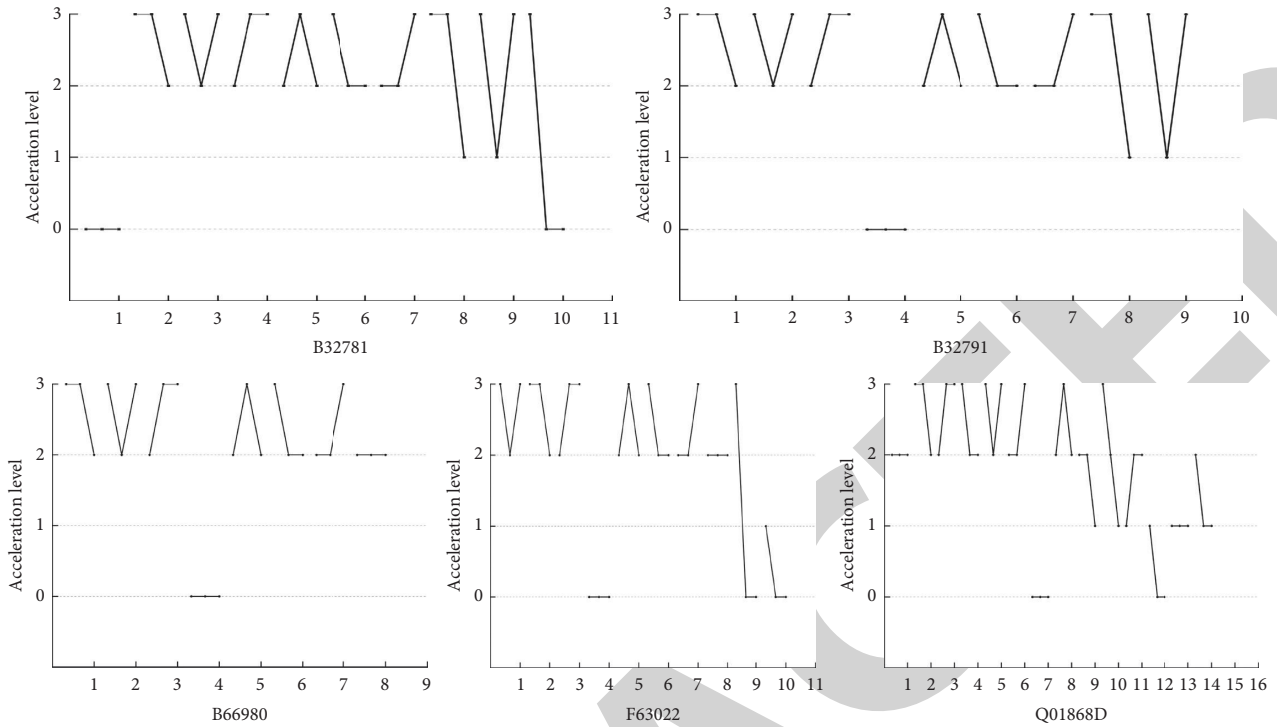

FIGURE 7: Dangerous group driving behavior pattern diagram.

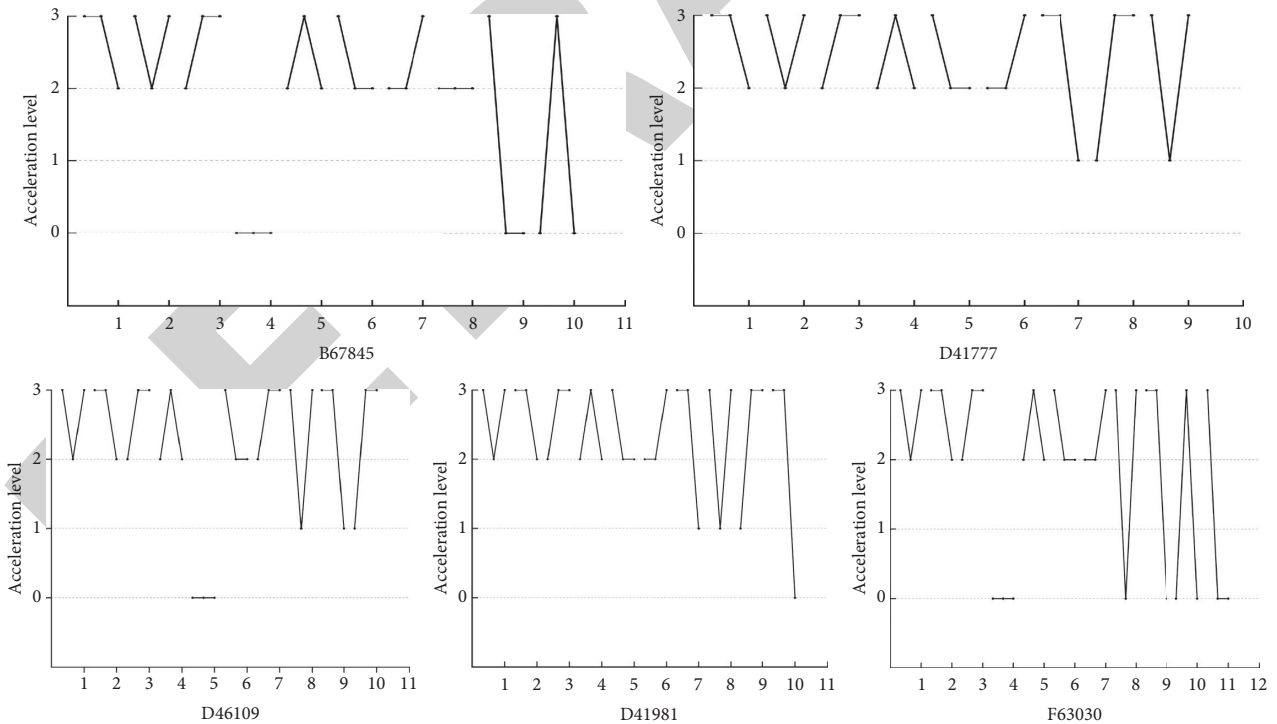

FIGURE 8: Safety group driving behavior pattern diagram.

deceleration patterns with large acceleration variations are good indicators of the driver’s style in deceleration driving behavior. The presumed danger group ranked higher in the “000” patterns, and some of their driving patterns reflected how hard they drove when slowing down. Drivers assumed

to be in the safety group also experienced sharp deceleration patterns, such as mode “000,” but were generally more stable. It should be noted that the deceleration driving behavior pattern of B67845 and F63030 in the safety group indicates that their deceleration driving behavior is risky.

The reason is that the driving pattern “000” ranks high, and there is a more aggressive driving pattern with large acceleration fluctuation. The F63030, in particular, was even more aggressive than some dangerous drivers in slowing down. In the previous two parts, it is also mentioned that the driver’s integrated acceleration and deceleration behavior is not much, but in the face of acceleration and deceleration driving behavior, the driver’s aggressive style, there is a potential accident risk. According to the deceleration pattern of different drivers, the driving preference and possible risk of each driver can be judged better.

**4.6. Driver Acceleration Level Distribution.** In order to further explore the acceleration preference adopted by drivers in acceleration and deceleration behavior, this section excludes drivers’ uniform driving behavior (acceleration level 3) and calculates the proportion of acceleration and deceleration behavior of each level in the integrated acceleration and deceleration behavior. Based on the radar chart, the behavior data of different drivers are visually evaluated, and the results are shown in Figures 9 and 10.

The hexagons of the radar map represent different levels of acceleration. Level 3 is removed here to exclude the influence of a large number of uniform driving behaviors on the acceleration and deceleration behavior proportion. The percentages of each driver’s different levels of acceleration are shown on the radar chart. The radar map clearly shows drivers’ preferences at various levels of acceleration. It can be found from the radar maps of the two groups that the occurrence ratio of dangerous group drivers is generally higher than that of safety group drivers for the more severe acceleration behavior (acceleration level 6) and the more severe deceleration behavior (acceleration level 0). For acceleration level 5 and acceleration level 1, the average proportion of drivers in the danger group was higher than 10% and close to 15%. The safety group averaged closer to 10 percent. The distribution in the figure shows that the acceleration and deceleration behaviors of drivers in the safety group are generally more gradual than those in the dangerous group. However, there are certain exceptions in each group. The acceleration and deceleration behaviors of drivers F63030 in the safety group were extreme, with more slight acceleration and deceleration behaviors (grade 4 and grade 2) and severe acceleration and deceleration behaviors (grade 6 and grade 0), which were reflected in the figure as hourglass. The acceleration and deceleration behaviors of drivers in the dangerous group Q01868D also tended to moderate, especially the slight deceleration.

**4.7. The Influence of Road Administrative Grade on Driving Behavior Pattern.** Road administrative grade has a certain influence on the driving speed and acceleration and deceleration behavior of drivers. In order to further explore the influence of road administrative grade on drivers’ driving behavior, this study selected a driver who had roughly the same driving time in the three road grades of national highway and above, provincial highway, prefectural highway, and below as a case to analyze. The driving behavior

FIGURE 9: Acceleration rating of dangerous group drivers.

FIGURE 10: Acceleration rating of safe group drivers.

patterns of the driver under three different road administrative levels were compared, as shown Figure 11.

With the improvement of road administrative grade, the driver’s driving behavior becomes more stable; that is, the relatively safe driving mode ranks higher and occurs more frequently. The driving behavior pattern with higher potential risk occurred more frequently and ranked lower. For example, in driving mode “000,” it can be clearly seen that as the administrative level of the road is lowered, the driving mode’s ranking keeps rising. Driving pattern “000” is a typical driving behavior pattern with certain characteristics, which reflects the

FIGURE 11: Patterns of driving behavior under three administrative levels of roads.

driver's driving preferences and habits. Under the conditions of three different administrative levels of roads, the driving patterns (e.g., driving pattern "000") with individual characteristics of drivers all appear, but the ranking of the modes in their respective road conditions is different. This also reflects that the driver's driving style is relatively fixed and he can maintain his own driving style in different road conditions. The driving behavior pattern diagram can not only show the distribution of driving behavior, but also clearly present the driving styles and driving risks of drivers under different road grades. Compared with the traditional method of fixed threshold, the driving behavior pattern diagram can avoid the problem that the fixed threshold is not suitable for drivers in different situations and can show the driver's unique driving habits without being influenced by the environment.

**4.8. Quantitative Assessment of Driving Risk.** The driving behavior of drivers was comprehensively evaluated by the comparative evaluation model of driving risk. This section divides the driver's driving behavior into three parts: overall driving behavior score, accelerated driving behavior score, and decelerated driving behavior score.

As can be seen from Figure 12, the scores of different behaviors of different drivers reflect the level of drivers. The higher the score, the higher the risk of driving behavior, and the lower the comfort and economy of driving. In general, the scoring trend of different drivers is roughly the same as the ranking trend of drivers' behavior scale graph based on fixed threshold. Drivers with a high proportion of risk driving behavior scored higher on acceleration, deceleration, and overall driving behavior. Those who drove more consistently, with less risky driving, tended to have lower scores. But there are some exceptions. The two drivers, B32781 and B32791, had a high proportion of overall risk driving behaviors, but their overall evaluation score was low. According to the data, this is because the driving behavior patterns of these two drivers are scattered, and the proportion of the first 30 typical driving patterns in the overall driving pattern is lower than that of other drivers, resulting in a lower score. The reason why the driving behavior evaluation score chart and the driving behavior ratio chart based on the threshold are not completely consistent is that there is still a lack of a clear definition of potential risks in the safety analysis of driving behavior. This method can describe the driver's personalized driving behavior characteristics,

FIGURE 12: Driving behavior evaluation score.

comprehensively consider three factors of vehicle safety, driving comfort, and fuel economy, and quantitatively evaluate and compare the driver's driving risk.

In addition, the overall driving behavior score was different from that of only acceleration or deceleration. This is due to the difference in the pattern structure and frequency, and some drivers have more acceleration behavior or deceleration behavior. This phenomenon is acceptable. As can be seen from the figure, there are similar trends in the scores of these three behaviors among different drivers.

## 5. Discussion and Conclusion

According to the positioning data in the Internet of HDVs platform environment, this paper proposes an approach to evaluate the driver's driving risk and driving style with undefined threshold. Based on the vehicle driving data and the time series change of driver's driving behavior, the driving behavior pattern diagram was established. Through the driving behavior pattern diagram and driving risk modeling evaluation, the personalized driving behavior risk of different drivers was quantitatively evaluated, and the driving styles of different drivers were qualitatively and quantitatively compared. The main work and conclusions of this paper are as follows:

- (1) A graphic qualitative and quantitative analysis of individual driving behavior is carried out based on the change of driving behavior time series. Based on the positioning data of the actual HDVs, the driving behavior pattern was established to evaluate the driving behavior style and safety degree. The method is to evaluate the undefined threshold of the driver's driving style. Based on the vehicle driving data, a driving behavior pattern was established by using the driver's driving behavior changing with time.
- (2) Based on the driving behavior pattern diagram, the driving style of drivers is analyzed and evaluated qualitatively and quantitatively. The evaluation results show that the driving behavior pattern can reflect the driver's driving habits and potential risks. The ranking of risk driving behavior patterns such as rapid

acceleration and deceleration and the amplitude of acceleration and deceleration fluctuation can reflect drivers' driving habits and risks. Drivers with a more stable overall style also have some risk driving patterns. It is necessary to judge the driver's driving style by combining the type and distribution of specific driving modes. Even less risk driving behaviors may lead to the occurrence of driving accidents, and these risk driving behaviors are easy to be hidden by the overall driving data. Drivers will have different preferences in the degree of acceleration and deceleration of their driving behavior when faced with acceleration or deceleration. The driver's acceleration grade distribution also further reflects the driver's driving habit and style. In general, drivers with a low proportion of rapid acceleration and deceleration will adopt more moderate driving behavior and lower acceleration level in the face of acceleration and deceleration. The driving behavior pattern diagram can reflect the distribution of driving behavior and clearly present the driving style, habits, and driving risks of drivers.

- (3) According to the frequency and ranking of typical driving modes of drivers, a risk assessment modeling method for driving behavior was proposed from three aspects of vehicle safety, driving comfort, and fuel economy, and the similarities and differences of driving behaviors of different drivers were quantitatively analyzed. The evaluation results show that drivers with a high proportion of risk driving behavior scored higher on acceleration, deceleration, and overall driving behavior. Those who drove more consistently, with less risky driving, tended to have lower scores. But there are some exceptions.

## Data Availability

The data used in this paper were collected by the information acquisition equipment installed on the HDVs. The collection device includes a GPS module for collecting location data, an OBU module for collecting vehicle movement data, and a cellular network.

In August 2019, People's Bank of China launched the reform of Loan Prime Rate (LPR) quotation formation mechanism and then made continuous progress in the order of “new loans first, followed by exiting loans,” dredging the interest rate transmission channel of “policy interest rate, LPR, loan interest rate.” In 2020, Chinese financial institutions have mainly referred to LPR pricing for loans, and the marketization level of loan pricing has significantly improved. This paper analyzed the policy effects transmitted by LPR through constructing a Dynamic Stochastic General Equilibrium (DSGE) decision model, and it was found that the financial market structure, pricing ability of commercial banks, and the degree of LPR application all affected the policy rate transmission effect and had an impulse impact on macroeconomic growth. Based on the above analysis, this paper proposed policy suggestions on the path of interest rate market-oriented reform and coping measures of commercial banks in China.

## 1. Introduction

In August 2019, the market-oriented reform of China's interest rate was further deepened. People's Bank of China launched the reform of the formation mechanism of LPR in the loan market and continued to promote it in the order of “new loans first, followed by exiting loans,” forming a rate transmission mechanism of “policy interest rate, LPR, loan interest rate.” By the end of 2020, Chinese financial institutions have mainly referred to LPR pricing for loans, and the marketization level of loan pricing has significantly improved. However, it is worth noting that China's financial system structure is dominated by indirect financing, and there are some problems such as information asymmetry, implicit high leverage, and inadequate expectation management in the financial market. It is difficult to give full play to the profit-seeking function of capital, and the actual impact of interest rate reform on economic output is worth discussing. From the perspective of international experience, through the reform of interest rate marketization, it is conducive to narrowing the interest rate corridor, reducing short-term interest rate fluctuations, enhancing the sensitivity of real economic deposits interest rate and loan interest

rate to policy interest rate, improving the transmission efficiency of monetary policy between different interest rates, and strengthening financial services in the real economy. Under the background of the imperfect system of China's financial market, after the reform of the LPR pricing mechanism, how efficient is the transmission efficiency of monetary policy? What is the actual impact on economic output? These are all issues that need to be studied. The study of the above problems will help us to further dredge the transmission path of monetary policy in a targeted manner, reduce the financing cost of the real economy, force the market-oriented development of the pricing method of funds of commercial banks, and further improve the efficiency of macroeconomic regulation and control.

Therefore, it is of great significance to study the transmission effect of LPR pricing mechanism and its impact on economic growth. At present, the research mainly focuses on the effect evaluation of quantitative control tools and price control tools of monetary policy and the effect evaluation of interest rate regulation and interest rate market-oriented reform, and some studies believe that too fast interest rate market-oriented reform will increase the risk of financial institutions. However, there is a lack of research on the

transmission effectiveness of LPR interest rate reform and the impulse impact on macroeconomic growth under different degrees of marketization. In order to further explore these questions, the paper constructs a DSGE model with financial market friction, studies the marketization degree in the process of LPR reform by difference scenarios, and analyzes the effectiveness of models such as calibration analysis, parameter estimation, and impulse response, so as to provide objective theoretical support for a comprehensive understanding of the policy effect of LPR.

## 2. Literature Review

The study on the transmission effect of monetary policy rate began as early as the late 19th century. Tobin [1] and Modigliani [2] pointed out that monetary policy transmission relied on not only interest rate transmission channels, but also nonmonetary assets price channels, such as enterprise Tobin's Q channel (assets price), the resident's wealth effect channel, and the exchange rate channel for transmission. Relying on the IS-LM model, Bernanke and Blinder [3] and Bernanke and Gertler [4] explained that not only the total money supply from the central bank, but also changes of bank credit supply quantity, both have a significant impact on monetary policy transmission. Due to incomplete information and agency costs in financial markets, expansion or shrinkage of bank credit quantity can cause economic agents to make different financing decisions and affect economic behaviors such as investment, consumption, etc. According to the above viewpoints, Mishkin [5] divide the monetary policy transmission channels into the interest channel, the credit channel, the assets price channel, and the exchange rate channel. Since then, a large number of empirical studies have begun to quantitatively measure the transmission efficiency of different channels. For example, Evans and Mashall [6] used Vector Autoregressive model (VAR) to study the role of monetary policy and inflation expectation on the term structure of interest rate and pointed out that tight monetary policy had a positive but temporary effect on short-term interest rate, while long-term interest rate was almost not affected. De Bondt [7] studied the European banking sector and found out through analysis that the market structure of the banking sector affected the transmission effect of monetary policy to some extent. The highly monopolistic banking would weaken the transmission effect of monetary policy, while market-oriented banking would make commercial banks more sensitive to interest rate changes and improve the transmission effect of the central bank monetary policy. Bolton and Freixas [8] further indicated that the capital adequacy ratio rules of commercial banks, while enhancing the risk prevention ability of commercial banks, reduced the ability of commercial banks to derivate money and weakened the transmission effect of the central bank's monetary policy in the commercial bank system. Milani and Treadwell [9] and Gomes et al. [10] show that the monetary policy with full expectation management has greater degree of macro-control on the economy and longer attenuation period of impact effect. Empirical studies on DSGE models based on

open economy done by Meinus and Tillmann [11] and Ge [12] manifest that the transmission efficiency of price monetary policy shows a significant improvement trend during the sample period, while the macrocontrol effect of quantitative monetary policy is gradually weakening.

At present, the domestic literature on interest rate transmission mainly focuses on the transmission effect study of traditional loan and deposit benchmark rates, while there are few studies on transmission effect of LPR reform. Yingkun Jiang et al. [13] argued that the bank credit transmission channel played an important role in China's monetary policy transmission channels. However, the constraints of China's traditional credit system, as well as the state-owned nature and limited competition of commercial banks, can slow down the central bank's interest rate policy transmission and cause efficiency losses. Dong He and Honglin Wang [14] pointed out that, different from developed countries, China gradually formed a monetary policy framework with the dual interest rate system as the main feature in the market-oriented reform. China transmitted the monetary policy to market interest rate through various policy instruments and realized the monetary policy regulation with the credit quantity. Li Ma et al. [15] showed that the deposit reserve ratios of commercial banks were important factors that restricted the interest rate policy transmission effect of commercial banks. Deposit reserve ratio adjustment could guide market changes and macro-economic development and promote the transmission effect of monetary policy by changing the adaptive expectations of market participants. Jun Ma et al. [16] constructed a DSGE decision model and pointed out that China's financial system, with indirect financing as the main body, faced many institutional constraints. The transmission of central bank's policy rate adjustment to each financial market rate would be influenced by China's financial market structure, loan scale restrictions, deposit reserve ratio, etc. Daoping Wang [17] used the panel data of 88 countries around the world to study the relationship between interest rate marketization and banking crisis which also shows that the improvement of marketization will significantly increase the probability of banking crisis. Ning Xu et al. [18] believed that China's LPR reform based on Medium-Term Lending Facility (MLF) tends to be more market-oriented and improves the transmission efficiency of monetary policy.

In summary, the existing research results showed that, due to China's monetary market structure with indirect financing as the main body, policy rate changes were mainly transmitted through bank credit. But the transmission mechanism was not smooth enough and the effectiveness of interest rate policy was low due to factors such as capital constraints of commercial banks, deposit reserve ratio constraints, and prudent management behaviors under imperfect competition. At present, the LPR interest rate has a typical market-oriented attribute, but its transmission efficiency and impact on economic growth are still lacking forward-looking empirical analysis. Based on the research methods of Zihan Huo et al. [19] and Long Zhang et al. [20] using DSGE model to analyze the impact effect of China's monetary policy on macroeconomy, this paper constructs a

DSGE model including five subjects: government, residents, enterprises, central bank, and commercial banks to perspective dynamic changes of the regulation effect of LPR channel, in order to provide reference for improving the regulation of monetary policy.

### 3. Research Mechanism

*3.1. Transmission Mechanism of Price-Based Regulatory Monetary Policy.* When a country's economy is in a rising phase, the actual GDP growth rate is often higher than the country's potential economic growth rate, which tends to cause a continuous rise in CPI and drives residents' inflation expectations, thus intensifying the inflationary trend. To prevent the overheated economic fluctuations, the country's government often adopts a tight monetary policy to hold down the inflationary trend. In the price-based monetary policy regulation, the monetary authority often stimulates the rise in the financial market interest rate through open market operations, which makes medium- and long-term funds flow into the capital market. The shortage of funds will prompt commercial banks to increase the loan rate and squeeze the momentum of enterprise investment, raising the enterprise investment cost and slowing down the trend of overheated economy.

When a country's economy is in a downward phase, the actual GDP growth rate is usually lower than the country's potential economic growth rate, resulting in a continuous downturn of the CPI and causing deflation. Therefore, it is required to implement an accommodative monetary policy to stimulate economic growth. In the price-based monetary policy regulation, the monetary authority often promotes the decline of financial market interest rate through open market operations to squeeze medium- and long-term capital outflows from the capital market. The sufficient funds will prompt commercial banks to reduce loan rate, which is conducive to enterprises to increase the investment scale, thus promoting economic recovery.

Since the mid-20th century, major developed countries have successively improved their monetary operation procedures by implementing a deposit and loan facility system, increasing the frequency of open market operations, narrowing the interest rate corridor range, as well as carrying out interest compensation on deposit reserves, adopting average reserve assessment, strengthening policy communication, and improving transparency, which can make money market interest rate deviate less from the central bank's target level and is more beneficial to the interest rate guidance of central bank. In October 2006, People's Bank of China introduced Shanghai overnight interbank offered rate (Shibor) by borrowing from London interbank offered rate (Libor), Euro interbank offered rate (Euribor), and other interest rates and made an active exploration in cultivating the market benchmark interest rate. However, due to the great fluctuation of Shibor in actual operation, combined with the single transaction structure of the money market, the borrowed funds basically showed a single flow direction (from large banks to small-sized and medium-sized banks), while large banks all belonged to the price quotation units of

Shibor interest rate, which was easy to form a monopolistic interest rate to some extent, and had low market recognition as a monetary policy benchmark interest rate. In this process, People's Bank of China continuously enriched the means of interest rate regulation, built long-term, medium-term, and short-term policy interest rate system including 3-month, 6-month, and 1-year MLF interest rate and improved the efficiency of monetary policy interest rate transmission.

*3.2. Four Stages of LPR Mechanism Transmission.* In October 2013, People's Bank of China launched the LPR, aiming to further stimulate market-oriented reform, improve the benchmark interest rate system, and guide the pricing of loan on credit market products. However, the LPR has been following the 1-year benchmark interest rate of loans announced by the central bank, and the interest rate level has been maintained at around 4.31%, which is much higher than the 1-year MLF interest rate of 3.30% and the 1-year Shibor interest rate of 3.52%. In August 2019, People's Bank of China further optimized the calculation method of LPR based on the mode of "new loans first, followed by exiting loans," adopted the way of 1-year LPR equal to 1-year MLF plus base point for loans, and expanded the range of quoting banks. From the current operation condition, the transmission can be divided into four stages: In the first stage, the central bank lowers the MLF quotation rate to influence the financial market interest rate. In the second stage, the quoting bank adopts the way of "MLF + base point" for the LPR quotation, which should be calculated and published by China Interbank Offer Center. In the third stage, commercial banks adjust the loan rate according to the LPR quotation. In the fourth stage, commercial bank lending rate affects the investment and financing decisions and costs of enterprises and residents, thus affecting macrotargets such as economic growth, inflation, and employment. The transmission path is MLF→LPR→commercial bank lending rate→real economy→economic target (Figure 1).

In 2019, only 20% of the loans of Chinese commercial banks were floating priced up and down according to the LPR quotation, and about 80% of the loans were still floating priced up and down according to the loan benchmark interest rate published by the central bank in the past. By the end of 2020, commercial bank loans had realized transformation from policy benchmark interest rate to market interest rate, so as to ensure that the policy operation intention of People's Bank of China can be effectively transmitted to other markets.

*3.3. Main Idea of DSGE Decision Model Construction.* The estimation of the DSGE decision model is generally divided into three steps: First, based on the economics theory and the economic operation characteristics in China, the optimal behavior characteristic of each economic agent when the economic system is in equilibrium is set. Second, the policy equation of the economic variables is solved, and the model parameters are estimated by running calibration and Bayesian estimation. Third, the impulse response is used to

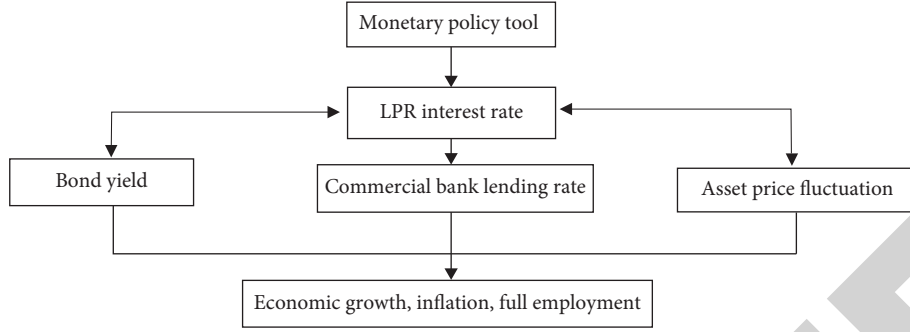

FIGURE 1: LPR mechanism transmission framework diagram.

carry out efficiency analysis of the model and test the explanatory ability of the model for the actual economic problems.

Foreign studies on the transmission mechanism of monetary policy mainly focus on how market rate changes affect economic operation through financial markets, while there are few studies on the impact of policy rate changes transmitted to the real economy. This is mainly because the financial systems of developed countries are often dominated by the direct financing market, where regulatory policies have fewer constraints on financial markets and benchmark market interest rate is mostly determined by transactions between financial markets. In contrast, China's financial system is dominated by the indirect financing market, where the policy rate changes have a significant impact on the real economy. Based on this, this paper constructs a DSGE model that includes five entities: government, residents, enterprises, central banks, and commercial banks, and defines the corporate loan interest rate as adjusting according to the LPR pricing level and according to the three scenarios of 50%, 80%, and 100% loans with reference to LPR pricing, to discuss the impact of the change of the unit policy interest rate on economic growth.

## 4. Research Method

### 4.1. DSGE Decision Model Frameworks of 5 Sectors

**4.1.1. Resident Sector.** The resident sector realizes the maximization of economic utility by supplying labor, earning income, and consumption. Its utility equation is as follows:

$$U\left(C_t, N_t, \frac{M_t}{P_t}\right) = Z_t^c \frac{C_t^{1-\sigma_c}}{1-\sigma_c} + Z_t^m \frac{(M_t/P_t)^{1-\sigma_m}}{1-\sigma_m} - Z_t^n \frac{N_t^{1+\sigma_n}}{1+\sigma_n}. \quad (1)$$

The expected utility is

$$\max: E_t \left[ \sum_{t=0}^{\infty} \beta^t U\left(C_t, N_t, \frac{M_t}{P_t}\right) \right]. \quad (2)$$

The constraint condition is

$$\text{s.t: } C_t + \frac{M_t}{P_t} = \alpha_t^s N_t^s + \frac{M_{t-1}}{P_t}, \quad (3)$$

where  $E_t$  is the mathematical expectation, and  $\beta^t$  is the discount factor ( $0 < \beta \leq 1$ ).  $C_t$  is the household consumption

level, and  $N_t$  is the labor supply of the household to society.  $M_t$  is the nominal assets balance held by the household, and  $P_t$  is the product price in the current period.  $M_{t-1}$  is the household's nominal assets balance held in period  $t-1$  and substituted into period  $t$ .  $(M_t/P_t)$  is the actual assets balance held by the household.  $Z_t^c$ ,  $Z_t^m$ , and  $Z_t^n$  are exogenous impact variables for consumption demand, labor supply, and holding assets, respectively.  $\sigma_c$ ,  $\sigma_n$ , and  $\sigma_m$  are the consumption demand elasticity, labor supply elasticity, and money demand elasticity, respectively.  $\alpha_t^s$  is the average wage level.

**4.1.2. Enterprise Sector.** The enterprise sector obtains the maximum enterprise welfare by investing capital and labor. The objective function is  $\max: E_t [\sum_{t=0}^{\infty} \beta_t^p \lg C_t^p]$ , where  $\beta_t^p$  is the discount rate of the manufacturer and  $C_t^p$  is the remuneration obtained by the business owner. Suppose the production equation of the manufacturer is

$$Y_t^p = A_t^p (K_t^p)^{\alpha_1} (N_t^p)^{1-\alpha_1}, \quad (4)$$

where  $Y_t^p$  is the output of the enterprise, and  $A_t^p$  is the production technology level of the enterprise.  $K_t^p$  is the capital invested by the enterprise, and  $N_t^p$  is the labor invested by the enterprise.  $\alpha_1$  is the output elasticity of capital input, and  $\alpha_1 \in (0, 1)$ .

Refer to the research of Xiangyang Li et al. [21]; this paper assumes that the resource constraint equations of the enterprise are as follows:

$$(1 - T_p)Y_t^p + L_t^p + (1 - \varepsilon)K_{t-1}^p - L_{t-1}^p \frac{1 + R_t^p}{\pi_t}, \quad (5)$$

$$C_r^p - K_t^p = 0,$$

$$L_t^p \frac{1 + R_t^p}{\pi_t} = m_p K_t^p,$$

where  $T_p$  is the tax rate to be paid by the enterprise, and  $\varepsilon$  is the depreciation rate.  $L_t^p$  is the loan balance obtained by the enterprise in period  $t$ , and  $R_t^p$  is the loan interest rate.  $m_p$  is the asset-liability ratio of the enterprise. Enterprise loans are generally restricted by the loan interest rate and the asset-liability ratio.

**4.1.3. Government Sector.** The basic behavior characteristics of the government are simply simulated in this model; that is, the government obtains funds through tax revenue and debts, and these funds are mainly used for government investment and government consumption, except for paying back debt and interest of the last period. The government budget constraint is

$$\frac{g_t}{p_t} + T_t + T_p Y^t = B_t + G_t, \quad (6)$$

where  $g_t$  is the funds received by the government from issuing treasury bonds, and  $P_t$  is the inflationary price of the current period.  $T_t$  is the tax revenue paid by the residents and  $T_p Y^t$  is the government tax revenue (where  $T_p$  is the tax rate and  $Y^t$  is the enterprise output).  $B_t$  is the government consumption expenditure, and  $G_t$  is the government investment expenditure.

**4.1.4. Central Bank.** People's Bank of China is now gradually abandoning the money supply as the intermediate target and more focusing on the adoption of policy rate. There are generally 4 ultimate objectives: price stability, promoting economic growth, maintaining employment, and balance of international payment. However, considering Mundell's Impossible Trinity, this paper mainly considered price stability, economic growth, and maintaining employment. Accordingly, the monetary policy constraint equation of People's Bank of China is as follows:

$$\frac{R_t}{R} = \left( \frac{R_t}{R_{t-1}} \right)^{\theta_R} \left[ \left( \frac{\pi_t}{\pi_{t-1}} \right)^{\varphi_\pi} \left( \frac{Y_t}{Y_{t-1}} \right)^{\varphi_y} \left( \frac{M_t}{M_{t-1}} \right)^{\varphi_m} \left( \frac{p_t}{p_{t-1}} \right)^{\varphi_p} \right]^{1-\theta_R} Z_t^r, \quad (7)$$

where  $(R_t/R_{t-1})$  is the changing value of policy rate (this paper adopted MLF interest rate).  $(M_t/M_{t-1})$  is the changing value of money supply and  $(\pi_t/\pi_{t-1})$  is the changing value of unemployment rate.  $(Y_t/Y_{t-1})$  is the changing value of total social output, and  $(p_t/p_{t-1})$  is the changing value of inflation rate. The parameters  $\theta_R$ ,  $\varphi_\pi$ ,  $\varphi_y$ ,  $\varphi_m$ , and  $\varphi_p$  are the elasticity of interest rate, unemployment rate, total output, money supply, and inflation from their steady-state deviation degree with respect to interest rate, respectively.  $Z_t^r$  is the exogenous impact variable of China's monetary policy.

**4.1.5. Commercial Bank.** Commercial banks mainly face Net Interest Margin (NIM) constraints in business operations. Commercial banks earn interest income from loans to cover the deposit interest cost and maintain interest spread income. Therefore, the budget constraint equation for commercial banks is as follows:

$$\begin{aligned} D_t r_t + F_t &= L_t^p R_t^p + B_t^G R_t^G, \\ R_t^p &= LPR_t + K_t, \end{aligned} \quad (8)$$

where  $r_t$  is the deposit interest rate, and  $D_t$  is the commercial bank deposit balance.  $F_t$  is the commercial bank profit, and  $R_t^p$  is the enterprise loan interest rate (LPR<sub>t</sub> plus floating

point  $K_t$ ).  $R_t^G$  is the government financing rate.  $L_t^p$  is the balance of enterprise loans and  $B_t^G$  is the balance of government financing.

**4.2. Data Selection, Parameter Calibration, and Economic Steady State.** We consider that  $Y = C_t + Y_t + F_t + G_t + R_t$ . Among them,  $Y$  represents the total output of the economy,  $C_t$  represents the resident sector,  $Y_t$  represents the corporate sector,  $B_t$  represents the commercial banking sector,  $G_t$  represents the government sector, and  $R_t$  represents the central bank sector. In order to further examine the effectiveness and efficiency of monetary policy transmission after the implementation of LPR reform, we will select the main observation data according to the DSGE model framework of the five departments and simulate the transmission of monetary policy by means of calibration analysis.

**4.2.1. Data Selection.** The sample interval for this section is from January 1980 to December 2021. The main observational variables include interest rate data (1-year MLF interest rate, 1-year LPR interest rate, 1-year bank deposit rate, 1-year bank loan interest rate, and 1-year treasury bond interest rate); bank data (bank deposit balance as a proportion of GDP, bank loan balance as a proportion of GDP, new loans to new social financing, new government bonds to new social financing, and bank net interest margin); economic data (GDP growth rate, inflation rate, unemployment rate, M2 growth rate, and corporate asset-liability ratio). The data are all from the WIND database. Here, considering the substitution of wealth management products for resident deposits, the deposit interest rate adopts the average expected yield of 1-year wealth management products of large commercial banks. This paper first deflates GDP, bank deposits, and bank loans, then uses the X12 method to seasonally adjust all data, and finally takes all the data logarithmic and first-order differences. The statistical description of the data is shown in Table 1.

**4.2.2. Parameter Calibration.** The steady-state value of the variable  $R_t$  is defined as  $R_t^*$ , and  $\widehat{R}_t$  is the steady-state deviation of the variable  $R_t$  with respect to  $R_t^*$ , that is,  $\widehat{R}_t = \log R_t - \log R_t^*$ . The linear policy equation of the DSGE decision model can be obtained by conducting first-order differential and first-order Taylor expansion. After that, the a priori calibration method and automatic model solution are required to obtain the estimated values of the parameters.

In this paper, Carlstrom et al. [22] study and calibrate some static parameters with relatively stable values and then focus on the Bayes method to estimate the dynamic structural parameters related to the degree of marketization and interest rate transmission. For example, this article uses  $\theta_R$  as an indicator of the degree of financialization; we estimated three marketization degree coefficients based on three samples of different periods, of which from January 1980 to December 2007, the marketization degree coefficient was 0.012, which was the interest rate control stage; from January 2008 to December 2018, the marketization degree

TABLE 1: Descriptive statistics of all variables.

Name	Obs	Mean	Std.	Min	Max
MLF interest rate	504	3.1341	0.5999	2.9500	3.3000
LPR interest rate	504	4.6842	1.7160	3.8000	5.7700
Deposit rate	504	4.9905	0.1464	3.000	30.0000
Loan interest rate	504	5.5948	0.8816	4.7500	7.5600

coefficient was 0.4523, and the market benchmark interest rate system represented by Shibor was constructed, which was the market cultivation stage; from January 2019 to December 2021, with the advancement of the reform of China's LPR interest rate pricing system, the degree of marketization coefficient was 0.6851, which was the stage of gradual market liberalization. Considering the above factors, the final calibration value of  $\theta_R$  is 0.4832. The estimation results are shown in Table 2.

**4.2.3. Steady-State Simulation.** This section uses the impulse response analysis of the DSGE model to explore the role of changes in the benchmark interest rate of monetary policy on economic output. When People's Bank of China lowers the MLF rate, the LPR goes down and affects the total output of the economy through the response of banks, businesses, and residents and then gradually returns to the vicinity of steady state. Taking into account the uncertainty of COVID-19 in 2020–2021, this is a comparative analysis of the 2019 national economic statistics before the epidemic: in the year LPR (1 year) dropped 3 times, with a year-end value of 4.15%, which was down by 26BP compared with the beginning of the year. The LPR (5-year period) was set up in August 2019, 1 time lower, and the value at the end of the year was 4.80%, which decreased by 5BP compared with the initial value. The annual price index is 102.90%, with an increase of 0.2 percentage point from the previous year. The proportion of RMB loans balance as a percentage of GDP is 154.52% and the proportion of RMB deposit balance as a percentage of GDP is 97.10%. The new RMB loans account for 66.0% of the new social financing scale in the same year. The year-on-year growth rate of the money supply M2 balance is 8.70%, with an increase of 0.1 percentage point from the previous year. The NIM of commercial banks is 2.19%, with an increase of 0.14 percentage point compared with the end of the previous year (Table 3).

This paper analyzes the matching degree between benchmark model simulation results and China's macro-economic data in 2019 in terms of interest rate level, bank scale, and the real economy.

TABLE 2: Calibration values of main parameters.

Interest rate level	Value	Parameter	Value	Parameter	Value
$\beta^t$	0.988	$T_p$	0.412	$\varphi_\pi$	0.023
$\sigma_c$	0.331	$\varepsilon$	0.201	$\varphi_y$	0.921
$\sigma_n$	0.355	$\beta_i^p$	0.122	$\varphi_m$	0.634
$\sigma_m$	0.423	$r_i$	0.311	$\varphi_p$	0.123
$\alpha_1$	0.562	$\theta_R$	0.483	$m_p$	0.913

In terms of policy rate level, the 1-year MLF interest rate (3.35%) and LPR interest rate (4.90%) simulated by the model are both higher than the corresponding actual interest rate levels. The simulated loan interest rate (5.25%), deposit interest rate (2.80%), and government bond interest rate (2.70%) are all lower than the corresponding actual interest rate levels. This indicates that the monetary policy transmission mechanism in China still has a serious obstacle in practice. The prudent risk behavior of the banking system in the credit process makes its loans with a relatively long period and large loan limit and concentration; i.e., the actual loan interest rate corresponding to the policy rate is higher than the equilibrium interest rate level simulated by the model. The actual deposit interest rate corresponding to the policy rate is also higher than the equilibrium interest rate simulated by the model due to the competition for residents' deposits and the substitution of fixed time and current deposits by certificate deposits and finance products.

In terms of bank scale, the proportions of deposit and loan balances as a percentage of GDP simulated by the model are highly consistent with the actual data. However, the proportion of new loans as a percentage of new social financing is lower than the actual value, and the proportion of new government bonds as a percentage of new social financing is higher than the actual value, which indicates that China's financial market structure is still unsatisfactory, with a high proportion of credit financing and a relatively low proportion of capital market financing. The net interest margin enjoyed by Chinese commercial banks is still higher than the equilibrium value due to the blockage of policy rate transmission, indicating that the policy dividends still exist.

TABLE 3: Comparison of model simulation results with actual data of China's economy (2019).

Interest rate level	$R_t$	LPR <sub>t</sub>	$R_t^P$	$r_t$	$R_t^G$
Model	3.35	4.90	5.25	2.80	2.70
Data	3.26	4.80	5.50	3.80	2.85
Bank scale	Deposit/GDP	Loans/GDP	New loans/new social financing	New government bonds/new social financing	Net interest margin
Model	96.7%	155.1%	60%	20%	2.05%
Data	97.1%	154.5%	66%	18.5%	2.19%
Real economy	GDP growth rate	Inflation rate	Unemployment rate	M2 growth rate	Enterprise asset-liability ratio
Model	6.3%	2.7%	4.3%	8.6%	62%
Data	6.1%	2.9%	4.5%	8.7%	64%

In terms of the development of the real economy, the GDP growth rate, inflation rate, unemployment rate, M2 growth rate, and enterprise asset-liability ratio simulated by the model are all superior to the actual data, which indicates that the blockage of policy rate transmission has aggravated the business difficulties of the real economy and reduced the operating efficiency of China's economy.

## 5. Results and Discussion

This paper used the Dynare tool to estimate the dynamic response of each variable in the economy to the temporary impact of the given policy rate with the advancement of the LPR interest rate reform. Specifically, it can be divided into the following scenarios: (i) LPR pricing mechanism loans account for 50% of the existing loans; (ii) LPR pricing mechanism loans account for 80% of the existing loans; (iii) LPR pricing mechanism loans account for 100% of the existing loans. This paper takes the weighted average interest rate of one-year loan, the interest rate of one-year time deposit, and the yield of one-year treasury bond as observation variables.

From August 2019 to the end of 2021, in order to hedge the impact of COVID-19, China's monetary policy was in an easing cycle. The 1-year LPR interest rate has been lowered by 6 times and the cumulative 35BP has been lowered.

*5.1. LPR Pricing Mechanism Loans Account for 50% of the Existing Loans.* In this scenario, we assume that there are no other changes in policy constraints. The model results showed that when the policy rate decreased by 35 BP, the loan interest rate, deposit interest rate, and government bond interest rate declined by 21 BP, 15 BP, and 26 BP. This indicates that when LPR pricing mechanism loans account for 50% of the existing loans, the transmission efficiencies of the policy rate to the loan interest rate, deposit interest rate, and government bond interest rate are 60%, 43%, and 74%, respectively (Figure 2).

Generally speaking, when the policy rate falls, the price of borrowing funds from the central bank by commercial banks decreases, and commercial banks will reduce their demand for deposits, thus resulting in a decline in deposit interest rate, which in turn leads to a diversion of residents' deposits to Internet finance as well

as the stock and bond markets. In practice, however, the falling range of deposit interest rate will be smaller because the deposit interest rate is relatively stable, while commercial banks, due to the price reduction of funding sources, will cut enterprise loan interest rate accordingly in order to gain more loan market shares, thus bringing down the enterprise financing cost. Accordingly, the price of bond financing in the financial market will also decline. Therefore, from the model, when the policy rate decreases, the loan scale of commercial banks will increase, while the deposit scale will decline.

*5.2. LPR Pricing Mechanism Loans Account for 80% of the Existing Loans.* Similarly, in this scenario, we assume that there are no other changes in policy constraints. The model results showed that when the policy rate decreased by 35 BP, the loan interest rate, deposit interest rate, and government bond interest rate declined by 24 BP, 18 BP, and 29 BP, respectively. Thus it is indicated that when LPR pricing mechanism loans account for 80% of the existing loans, the transmission efficiencies of the policy rate to the loan interest rate, deposit interest rate, and policy bond interest rate are 69%, 51%, and 83%, respectively.

*5.3. When LPR Pricing Mechanism Loans Account for 100% of the Existing Loans, The Benchmark Interest Rates of Deposits and Loans Are Removed.* Similarly, in this scenario, we assume that there are no other changes in policy constraints. The model results showed that when the policy rate decreased by 35 BP, the loan interest rate, deposit interest rate, and government bond interest rate declined by 28 BP, 25 BP, and 32 BP, respectively. Thus it is indicated that when LPR pricing mechanism loans account for 100% of the existing loans, the transmission efficiencies of the policy rate to the loan interest rate, deposit interest rate, and policy bond interest rate are 80%, 71%, and 91%, respectively.

*5.4. The Impact Effect of a Unit Interest Rate Change on Economic Output under Three Different Scenarios.* Under the above three different marketization degrees, the adjustment of LPR interest rate can have an impact on the actual output. Further observing the impulse intensity under different

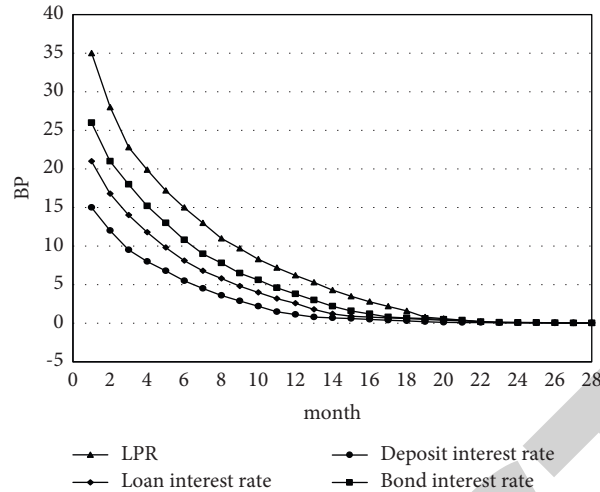

FIGURE 2: Effect of LPR interest rate on deposit, loan, and treasury bond interest rate.

marketization degrees, we can find that, with the continuous relaxation of interest rate control, output is becoming more sensitive to interest rate adjustments. From the perspective of transmission mechanism, the reduction of LPR interest rate means the decline of policy interest rate, which is a loose monetary policy and can effectively promote economic growth. This paper uses the year-on-year growth of real GDP as the measurement index of economic output and uses Dynare tool to estimate the impact of economic output on the temporary impact of reducing one unit of LPR interest rate. The following results can be obtained: during the period when the LPR pricing mechanism loans account for 50% of the loan stock, reducing the LPR interest rate by 1 BP will increase the year-on-year growth rate of real GDP by 0.005 percentage points; in the period when the LPR pricing mechanism loan accounts for 80% of the loan stock, reducing the LPR interest rate by 1 BP will increase the year-on-year growth rate of real GDP by 0.009 percentage points; in the period when the LPR pricing mechanism loan accounts for 100% of the loan stock, reducing the LPR interest rate by 1 BP will increase the year-on-year growth rate of real GDP by 0.012 percentage points, as shown in Figure 3.

The results show that the LPR pricing system reform implemented by People's Bank of China makes the interest rate marketization enter a new stage, can effectively improve the interest rate transmission efficiency of monetary policy, and plays a positive role in promoting economic growth. First, it really decouples the loan pricing of commercial banks from the policy benchmark interest rate and promotes the LPR interest rate to 100% existing loan pricing, indicating the substantive progress in the market-oriented reform of interest rate; second, it adopts the gradual principle to promote the application of LPR interest rate and takes MLF interest rate as the reference standard to prevent the excessive fluctuation of market interest rate to a certain extent; third, LPR interest rate has a certain impact on real GDP growth, and the impact effects are quite different under different marketization degrees, which means that financial market friction has a certain obstacle to the transmission

FIGURE 3: Impulse effect of LPR interest rate on economic growth under different degrees of marketization.

efficiency of monetary policy. Since LPR not only inherits the advantages of gradual reform, but also integrates market-oriented elements, the interest rate transmission mechanism after its emergence needs to be researched. In addition, it is worth noting that the monetary transmission efficiency in the DSGE theoretical model is generally better than the actual data. This means that the efficiency loss faced by monetary policy in the actual transmission process during the regulation period is much greater than the theoretical expectation. At the same time, it also shows that LPR, an important reform that takes into account both robustness and market attributes, will become a useful attempt in the process of interest rate marketization.

## 6. Research Conclusions

This paper constructs a DSGE model to compare and analyze the impact of LPR reform on monetary policy transmission mechanism and economic output under different

marketization degrees and mainly draws the following conclusions. First, interest rate regulation has a real loss on the transmission efficiency of monetary policy, which is far greater than the theoretical expectation; second, with the advance of LPR reform, the response of real GDP year-on-year growth to LPR interest rate has become more and more sensitive, indicating that LPR interest rate reform can effectively affect economic growth; third, the higher the degree of marketization of LPR interest rate is, the more significant the transmission effect on deposit interest rate, loan interest rate, and treasury bond interest rate will be, and the efficiency of interest rate transmission mechanism will be improved. Consider that LPR pricing mechanism is still in the process of improvement, and in the meantime, there is a negative impact of COVID-19 on China's economy. The empirical results of this paper need to be further improved and verified.

At the same time, we still need to deeply realize that there are still some differences between the theoretical expectation and practical effect of the reform. Especially in the stage of complete marketization, the actual efficiency loss of progressive reform is much higher than the theoretical expectation. For example, at the beginning of implementing the interest rate corridor model by the European Central Bank, the width of the interest rate corridor reached 250 BP. After 2003, in the face of the chain impact of the subprime mortgage crisis of the US, the European Central Bank continuously narrowed the interest rate corridor, of which the interest rate corridor was narrowed to 100 BP in December 2008 and 50 BP in June 2014 and is now maintained at 65 BP. This has led to a sharp narrowing of the interest spreads of deposit and loan of commercial banks, and some banks have thus got into trouble. This means that there are many hidden costs in the regulated interest rate transmission mechanism. At the same time, it also shows that only by fundamentally promoting the complete market-oriented reform will the interest rate transmission efficiency be fundamentally changed.

It is suggested that People's Bank of China continues to strengthen its research on improving the marketization of interest rates: First, a more complete interest rate corridor mechanism should be created, and the interest rate corridor range should be gradually narrowed, so as to ensure to give full play the role of the interest rate corridor mechanism. Second, the monetary policy transmission mechanism should be improved, and the function of the MLF as a medium-term policy rate should be exerted while strengthening the guidance of short-term policy rate. Third, the benchmark interest rates of loans and deposits determined by the central bank should be removed appropriately. Fourth, the direct financing channels should be vigorously developed and the monetary policy transmission mechanism should be improved. In this process, as the LPR reform is a gradual implementation process, the depth and breadth of its application have an important impact on the transmission of policy rate to market rate.

It is suggested that the commercial banks actively adapt to the process of interest rate marketization reform. First, it is necessary to establish a more scientific and reasonable

pricing mechanism and improve the depth of application of LPR. Second, it is necessary to enhance the foresight of interest rate risk management, establish a mechanism for hedging interest rate exposures, and reasonably use interest rate swaps and other derivative instruments to carry out hedging operations. Thirdly, the innovation of interest rate derivative products can ensure the effect of interest rate market reform and further unblock the efficiency of monetary policy transmission.

## Data Availability

The data were taken from the WIND database and relevant information from People's Bank of China. Due to confidentiality requirements, they cannot be provided to research institutions outside of mainland China.

## Conflicts of Interest

The author declares that there are no conflicts of interest.

Fog computing (FC) based sensor networks have emerged as a propitious archetype for next-generation wireless communication technology with caching, communication, and storage capacity services in the edge. Mobile edge computing (MEC) is a new era of digital communication and has a rising demand for intelligent devices and applications. It faces performance deterioration and quality of service (QoS) degradation problems, especially in the Internet of Things (IoT) based scenarios. Therefore, existing caching strategies need to be enhanced to augment the cache hit ratio and manage the limited storage to accelerate content deliveries. Alternatively, quantum computing (QC) appears to be a prospect of more or less every typical computing problem. The framework is basically a merger of a deep learning (DL) agent deployed at the network edge with a quantum memory module (QMM). Firstly, the DL agent prioritizes caching contents via self organizing maps (SOMs) algorithm, and secondly, the prioritized contents are stored in QMM using a Two-Level Spin Quantum Phenomenon (TLSQP). After selecting the most appropriate lattice map ( $32 \times 32$ ) in 750,000 iterations using SOMs, the data points below the dark blue region are mapped onto the data frame to get the videos. These videos are considered a high priority for trending according to the input parameters provided in the dataset. Similarly, the light-blue color region is also mapped to get medium-prioritized content. After the SOMs algorithm's training, the topographic error (TE) value together with quantization error (QE) value (i.e., 0.0000235) plotted the most appropriate map after 750,000 iterations. In addition, the power of QC is due to the inherent quantum parallelism (QP) associated with the superposition and entanglement principles. A quantum computer taking " $n$ " qubits that can be stored and execute  $2^n$  presumable combinations of qubits simultaneously reduces the utilization of resources compared to conventional computing. It can be analyzed that the cache hit ratio will be improved by ranking the content, removing redundant and least important content, storing the content having high and medium prioritization using QP efficiently, and delivering precise results. The experiments for content prioritization are conducted using Google Colab, and IBM's Quantum Experience is considered to simulate the quantum phenomena.

## 1. Introduction

Fog computing (FC), at the edge of a sensor network, as an extension to cloud computing, offers storage, processing, and communication control services [1, 2]. In the period of

next-generation telecommunication and through the massive development of the Internet of Things (IoT) based smart devices, applications required ultralow latency because IoT networks induce strain not only on the backhaul but the fronthaul causing adverse situations for interruption

sensitive applications [3, 4]. These problems can be resolved through FC, which provides distributed computing and communication facilities from centralized servers in the edge direction. A central base band unit (BBU) pool is not robust for every control, communication, or any other processing function; therefore, FC-based radio access networks (F-RANs) were introduced. In F-RANs, the local BBUs or even remote radio heads (RRHs) are dedicated to such tasks through edge caching (EC) [5–9]. Due to an intermediate fog layer between end-users and the cloud, mobile edge computing (MEC) is introduced.

Although the idea of F-RANs seems to be propitious to provide all the tasks confronted by the cloud radio access networks (CRANs) or heterogeneous cloud radio access networks (HCRANs). However, some setbacks might cause performance deterioration or the quality of service (QoS) degradation, bringing about fronthaul congestion. The main issue that requires to be solved is EC as well as restricted storing capability in RRHs [10]. Limited vital interests associated with the EC trending in F-RANs are reducing fronthaul burden, backhaul, or even backbone, optimizing endwise latency issues, and dynamic applications of content responsive approaches performance improvements. Fog access points (FAPs) usually have a relatively minimal caching capacity mostly because of the limited memory linked to the caching processes executed in centralized CRANs or HCRANs. Nevertheless, an increase in cache size in the base stations (BS) has a balance in the middle of improved throughput and network spectral efficiency [11]. Consequently, caching techniques in FAPs, together with caching strategies and allocation of cache resources policies, need to be managed logically and dynamically for augmented F-RAN performance.

The main contribution of this research is to predict the high priority content through the deep learning (DL) technique. It is the leading task that must be carried out when the contents are requested repeatedly and placed in the caches. The rest of the content should be discarded. When the high priority content is predicted through the DL agent, efficient content management and placement are achieved through the proposed framework and the quantum memory modules (QMM) to store the content. This paper describes an EC-based deep learning-associated quantum computing (DLAQC) framework. The framework is based on two parts: one for caching content prioritization and the other one for caching content stored within the edge. The DL-based quantum computing (QC) approach associated with quantum information processing is deployed to enhance the performance of F-RANs. The framework is basically a merger of a DL agent deployed at the network edge and a QMM. Firstly, the DL agent prioritizes caching contents via Self-Organizing Maps (SOMs) algorithm, and secondly, the prioritized contents are stored in QMM using a Two-Level Spin Quantum Phenomenon (TLSQP). SOMs algorithm is staunchly suitable to pick up contents in colored cluster form without reducing the dimensionality of the feature space.

The paper's organization is as follows. Section 2 describes the related work for edge caching, SOMs applications, and Stern–Gerlach experiment (SGE). In Section 3, the

framework and algorithm are described, followed by an overview of the model. The DL agent in edge and TLSQP is also discussed. The experiments and results are analyzed and discussed in Section 4. Finally, conclusion is presented in Section 5.

## 2. Literature Review

In this section, a literature study is carried out to throw light on attempts of different researchers to enhance EC to improve efficiency and quality of service (QoS) in F-RANs. Several pieces of research related to the DL-based algorithm and SGE highlight their applications in various fields, which has proved to be a great source of guidance for the proposed idea.

The authors in [12] described the key features of MEC, especially in the context of next-generation and IoT-based applications. The role of MEC and its challenges in the context of edge intelligence is also described. By keeping in view, the latency, context awareness, and energy-saving criteria, it is compared with the conventional MCC by considering the following key enabling features: virtual reality/augmented reality, software defined network, network function virtualization, smart devices, information-centric networking, network slicing, and computation off-loading. Additionally, a use case is also provided to help understand the edge intelligence in the IoT-based scenarios.

The critical challenges in the F-RANs are (i) the content placement in caches and (ii) the joint user associations. These challenges are tinted due to the complexity of different approaches used to find optimal solutions. In [13], authors considered optimization problems as mixed-integer non-linear programming (MINL). A hierarchical game theory approach is applied, and a series of deep reinforcement learning (DRL) based algorithms are designed for user association, content popularity prediction, and content placement to enhance the FAPs. In [14], a cooperative EC scheme using the DRL approach to place and deliver contents in vehicular edge computing networks is presented. The deep deterministic policy gradient algorithm provides a sensible solution for long-term MINL problems. A scheme for vehicle scheduling and bandwidth allocation is designed to make it less complex to manage adaptive resources and make decisions.

A user preference-based learning EC policy is described in [15] to predict the online content popularity and an offline learning algorithm. A sigmoid function is exploited to construct a logistic regression model to estimate user preferences regarding online content popularity prediction. It is considered complicated to make a preference model for each user due to the high-dimensional feature space. Therefore, a follow-the-regularized-leader proximal inspired algorithm is also proposed for offline user preference learning.

The federated learning (FL) framework and deep reinforcement learning (DRL) techniques were integrated into MEC in [16] to optimize EC, computing, and communication. The key challenge is primarily faced by authors to place the DRL agents due to (i) the massive and redundant

data transmissions in the cloud and (ii) the privacy risks as well as the lesser computing capabilities in UEs. The proposed technique has outperformed the conventional caching policies for EC like Least Recently Used, Least Frequently Used, and First In First Out. However, for computation offloading, the DRL technique by FL offered close results to the centralized DRL technique; on the other hand, again, it outperformed the following baseline policies: mobile execution, edge node execution, and greedy execution.

The authors in [17] have presented an on-demand and collaborative deep neural networks (DNN) coinference framework. The presented framework worked in two ways. Firstly, the DNN computation is partitioned between devices and the edge to make use of hybrid computation resources, and it can exit early in the DNN right-sizing at some suitable intermediate DNN layer. Therefore, it can avoid further computation latency and have implemented their prototype on Raspberry Pi. Secondly, the visualization of higher-dimensional data is taken into account to effectively analyze and conclude the data and results. The following two strategies have been used to visualize the multidimensional and minimal data by a scatter plot established on dimensionality reduction: (i) the direct visualization and (ii) the projection methods.

Failure modes and effects analysis (FMEA) is a methodology for risk analysis and problem prevention by identifying and defining failures of the system, process, or service. FMEA has some shortcomings related to the worksheet and usage complexity, which have been dealt with by the SOMs algorithm in [18]. SOMs algorithm is exploited to achieve perceptibility for corrective actions. A risk priority interval is used to evaluate these corrective actions in groups to make it easier for the users.

SOMs for multiple travelling salesman problem (MTSP) with minmax objective is exploited for the robotic multigoal path planning problem [19]. The main issue in deploying this framework was to detect the collision-free paths to evaluate the distances in the winner selection phase. The collision-free path was needed to adapt the neurons to the presented input signals. To address this issue, simple approximations of the shortest path are considered and verified through cooperative inspection. The presented SOMs approach is used to solve this inspection task by MTSP-minmax and compared with the MTSP-GENIUS algorithm.

In [20], the SOMs have been used to classify astronomical objects like stars' stellar spectra. The algorithm is used to make different spectral classes of the Jacoby, Hunter, and Christian library. The 158 spectra were chosen to classify by 2799 data points each. 7 clusters were formed from O to M, and 12 out of 158 spectra were misclassified, giving a 92.4% success rate. Otto Stern and Walther Gerlach, in 1922, performed an experiment that separated an electron beam while passing through a nonuniform magnetic field. When a beam passed through a magnetic field, two distinguished beams were observed on the screen. The experiments conducted by Otto Stern and Walther Gerlach gained popularity and were used in multidisciplinary studies by researchers.

In [21], the SGE is exploited in physical chemistry to investigate the magnetic response of the Fe@Sn12 cluster. A comparison is carried out between Mn@Sn12 and Fe@Sn12 clusters by passing their beams through magnetic fields separately. The molecular beam of Fe@Sn12 cluster exclusively deviates more towards increasing the magnetic field. The beam deviates even at the shallow temperature due to the distortions of tin-cage induced by Jahn-Teller. Hence, in the magnetic dipole moment, the role of electronic orbital angular momentum is significant. The magnitude of the magnetic dipole moment is calculated from the transfer of the beam.

In [22], the SGE is oppressed to explore the spin  $\frac{1}{2}$  neutral particles' motion and how their motion is dependent on the initial phase difference between two internal spin states. If the particles are moving horizontally, the initial phase difference between spin states results in particle splitting in the longitudinal direction and in the lateral direction due to the quantum interference. This interference provides an alternate way of measuring the initial phase difference between spin states and helps determine the amplitude and phase of atoms in the same SGE. To study this phenomenon, the ultracold temperature is maintained to make the ideal condition for the atom to behave like a quantum wave packet instead of a particle. In general, an atom is not in a pure state, rather a mixed state and cannot be characterized as a single wave function.

The content priority is deduced by the adaptive neurofuzzy inference system (ANFIS) in [23] in which the following five input variables were carefully selected: video\_elapsed\_time, video\_size, views, likes, and downloads. Each input variable has three membership functions having priorities high, medium, and low, and fifteen similar functions are made in the Sugeno inferencing mode. A rule base function was also created. After content prioritization through ANFIS, a theoretical explanation of the SGE is specified as a TLSQP for storing the prioritized content in quantum repositories.

Considering media requirements explicitly, EC seems to alleviate certain challenges. Occasionally, multimedia contents get heavier than even the encyclopedias, resulting in higher hardware and network capacities. EC can support such kinds of throughput requirements proportionally. Moreover, the scalability of streaming servers, which require special provisioning of these servers, can also be handled during live events. However, reducing the distance between end devices and BS will not be sufficient for increased network throughput; high-speed backhaul connectivity is also required between all the BS and the BBU Pool where centralized servers reside. The network traffic load can be reduced by minimizing redundant traffic. The traffic load mainly comprises content deliveries for the most requested/popular content at different times. If at all this redundant traffic is managed so that popular content is predicted and placed within the edge, the idea's effectiveness to increase network efficiency can be justified. Researchers and network specialists also have incorporated different AI techniques, including machine learning, to minimize the redundancy of network traffic and optimize the overall network efficiency,

from predicting popular content to optimizing specific parameters and much more [24–27]. In this digital era, IoT-based devices have generated an enormous amount of data daily, which is one reason for the possible growth of DL algorithms [28]. The DL algorithms require a massive amount of data to learn from.

### 3. Deep Learning-Associated Quantum Computing Framework

Edge computing acts as an intermediary between cloud and user equipment through the network edge. Researchers and engineers are continuously trying to accelerate content deliveries further and make mobile services better. The intelligence of edge systems is enhanced by introducing a DL agent in network edge. The DL agent is used to prioritize (i) the caching content according to its popularity determined by the considered parameters and (ii) the content to be managed logically within the planned framework. Prioritizing the content intelligently for caching only is not adequate to optimize the overall performance of the system. The prioritized contents need to be stored efficiently in caches and accessed multiple times with instantaneous delivery response. Within edge caches, the TLSQP will take over to avoid limited storage issues.

*3.1. Overview.* To understand the workflow, a model is presented wherein the fog environment is described together with the proposed DLAQC framework and shown in Figure 1.

A particular region is considered from where user requests are generated. The cloud servers initialize the fog environment’s monitoring cycle from the BBU pool. In the fog layer, at every moment, numerous user requests are generated and served through the F-APs. In order to accelerate content deliveries or response time, a DLAQC framework is presented, and a brief overview is as follows:

- (1) Synchronizer: cache synchronization and inter-F-APs information sharing is carried out every moment to update the regional user set for particular F-APs in the region
- (2) Regional user set: it refers to the group of users from a particular region allotted to a locally installed F-AP for a particular period.
- (3) Local and neighboring F-APs: the F-APs are capable of caching and computation and serve user requests by searching through the caches within the edge. A particular user request is immediately served if the content is available locally. The content must be looked up from the neighboring F-APs caches when a local cache is missed. In case if the contents are not available in the neighboring F-APs, the offered framework will update the respective contents in caches’ QMM.
- (4) DL agent for content prioritization: in case of a cache miss, the content is intelligently updated through the DL agent deployed at the edge. It comprises SOMs and helps to

predict the contents’ priorities. The contents having maximum demand are considered highly prioritized. However, this module is used to logically manage the contents (specifically that need to be updated).

- (5) Quantum memory module: it is one of the most critical modules in the given setup. Once the contents are prioritized intelligently through the DL agent, the contents need to be stored optimally in caches to enable caching content management. The synchronizer module is used to do so. The requested content may also be served through (i) F-APs located in the same region or (ii) user dynamics or load balancing. The QMM is incorporated especially to place contents physically in caches as quantum particles when it is prioritized. As a case, in this model, Repository 1 is assigned for storing highly prioritized contents, and Repository 2 is assigned for the medium prioritized contents, respectively. QMM is used to store and serve (the requested) contents separately. Due to the lower demand, every time, the low-priority contents are discarded from the caches.

The proposed framework comprises two modules: DL agent and QMM. The DL agent is used to prioritize and logically manage the caching contents by making use of SOMs. The QMM is used to store the contents in a quantum regime by exploiting a TLSQP. The proposed framework’s problem (working) and solution (implementation) domains are described as follows.

#### 3.2. Framework (Problem)

*3.2.1. Deep Learning Agent in Edge.* The DL agent is deployed at the network edge and prioritizes the caching contents through SOMs [29]. It gives results similar to the clustering approaches, and the prioritized contents can be visualized through light and dark color concentrations. The graphical output given by SOMs is a kind of feature map for input space. It makes SOM suitable for prioritizing the content using specific parameters. In this study, the media contents are explicitly targeted. Dataset for Trending YouTube Videos Statistics has been downloaded from Kaggle. The dataset includes the statistics for trending videos in the region of the United States. To achieve the requirements, four input variables for each video are carefully selected from the dataset and which are as follows: views, likes, dislikes, and comment\_count. The identified relationship between input parameters is helpful for visualizing the trending contents’ priorities using SOMs. The structure and function of SOMs are explained by the mathematical model as follows. SOMs work by fitting the map (grid of nodes) up to the given number of iterations of the simulated dataset. During diverse iterations, the adjustments are required while nodes’ weights are adjusted to bring the map nodes closer to the data points. It is called the convergence of SOMs, and the structure for SOMs is given in Figure 2.

The main package is included to construct, evaluate, and visualize the map is Minisom. An input layer (4-dimensional) and feature space  $\mathbf{M}$  of the map are defined by the

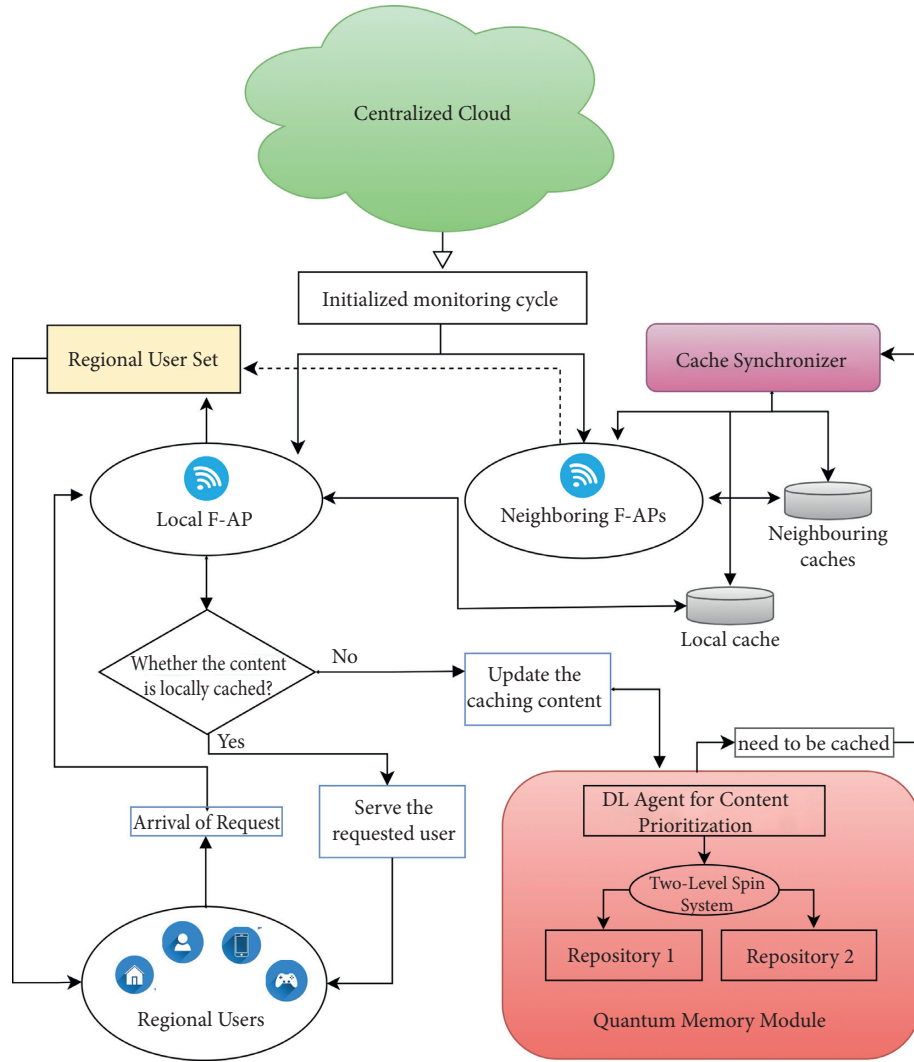

FIGURE 1: The proposed deep learning-associated quantum computing (DLAQC) framework.

FIGURE 2: Structure of Self-Organizing Maps.

rule of thumb. The rule of thumb states that there should be  $5 \cdot \sqrt{N}$  neurons in the lattice to get desired results, where  $N$  is the total number of samples in the dataset (the training dataset). The training dataset has 40960 samples; thus, the lattice should contain  $5(\sqrt{40949}) = 1011.8$  neurons.

Therefore, the dimensions of the lattice are selected as  $32 \times 32$ . Each node in the lattice has a weight vector  $W_{ij}$  and has the same dimensions as input vectors  $V$ . The preliminary step of training is to set weights of every node and is initialized as  $W_{ia} : W_{ib} : W_{ic} : W_{id}$  where  $i$  represents node

number and  $\mathbf{a}$ ,  $\mathbf{b}$ ,  $\mathbf{c}$ , and  $\mathbf{d}$  represent input vectors. When the weights are initialized, the best matching unit BMU is calculated by iterating through every node and by calculating the Euclidean distance between input vector  $\mathbf{V}$  and each node's weight  $\mathbf{W}$ . Finally, the smallest  $\mathbf{W}$  is selected. The process is given as follows:

$$\mathbf{D} = \sqrt{\sum_{i=0}^n (\mathbf{V}_i - \mathbf{W}_i)^2}. \quad (1)$$

When the BMU is finalized, the neighborhood nodes whose weights need to be updated are determined. To achieve this, the Gaussian neighborhood function is used. In this function, the "bell-shaped curve" like weighting is considered to update the nodes depending upon their relative distances from the BMU. Initially, the sigma  $\sigma_0$  is used to denote the spread of the neighborhood function, and all nodes (come in this spread) are updated. The respective spread shrinks iteratively by using the function (decay function) described as follows.

$$\sigma_t = \frac{\sigma_0}{(1 + t)/(T/2)}, \quad (2)$$

where  $\mathbf{T}$  is the iterations set having  $\{t_0, t_1, t_2, t_3, \dots, t_n\}$  and  $\sigma_t$  is the spread size at iteration  $t$ . Every node in the neighborhood of BMU is updated by

$$\mathbf{W}_{(t+1)} = \mathbf{W}_t + \Theta_t [\mathbf{L}_t (\mathbf{V}_t - \mathbf{W}_t)]. \quad (3)$$

A decaying function of learning is given as follows, where  $\mathbf{L}_t$  is the learning rate.

$$\mathbf{L}_t = \frac{\mathbf{L}_0}{(1 + t)/(T/2)}. \quad (4)$$

Moreover,  $\Theta_t$  is the distance effect from the BMU on the specific node and is given as follows:

$$\Theta_t = e^{-[D^2/2\sigma^2]}. \quad (5)$$

Hence, blocks with similar color zones are visualized. Any new input will stimulate nodes in the zone with similar weight vectors. The process described above results in projection of all the data points onto the map that allows topology of high-dimensional input data to be preserved into two-dimensional output space. However, the visual inspection is not enough to determine (i) how well the map converges to the given data points or (ii) how well the map represents the underlying data. Some quality measures are developed to oblige the purpose of evaluating when the map is trained. Therefore, the Quantized Error (QE) is used for vector quantization to evaluate the quality of the map. It is achieved by summing up the distances between the nodes and the data points as per the average distance given as follows.

$$\text{QE}(\mathbf{M}) = \frac{1}{\mathbf{N}} \sum_{i=n}^n \|\varphi(\mathbf{x}_i) - \mathbf{x}_i\|, \quad (6)$$

where the feature space of the map is denoted as  $\mathbf{M}$ .  $\mathbf{N}$  is used to represent the total number of data points and  $\varphi(\mathbf{x}_i)$  is used for mapping of data point  $\mathbf{x}_i$  from input space to the map.

Hence, it is considered as; the smaller the value of QE, the better it fits the data points. However, this quality measure can be used to compare maps by considering the same dataset and choosing the best one, not as the only quality assessment.

One of the primary aims of SOMs to determine quality is the topological preservation of high-dimensional input space in the two-dimensional output space. The topographic error (TE) is used to evaluate how well the individual data point is modeled to the map node by calculating the positions of 1<sup>st</sup> BMU and 2<sup>nd</sup> BMU. If these are located next to each other, the topology is preserved, and the TE is said to be zero for individual input. Similarly, summing up the errors for every input and calculating the data points as average are considered TE for the map as follows:

$$\text{TE}(\mathbf{M}) = \frac{1}{\mathbf{N}} \sum_{i=n}^n \mathbf{t}(\mathbf{x}_i), \quad (7)$$

where  $\mathbf{t}(\mathbf{x}_i)$  is a piecewise function; it is 0 if 1<sup>st</sup> BMU and 2<sup>nd</sup> BMU are neighbors or 1 otherwise. TE is evaluated to quantify the topology preservation by evaluating local discontinuities in the output map. Mostly, a tradeoff is realized between quality measures when increasing the projection quality and seems to decrease when some information is lost during this process.

### 3.2.2. Quantum Phenomenon

(1) *Quantum Computing-Overview.* The QC is based upon physics' natural laws and claims to solve many (sub) atomic level problems that are inflexible for old style computers. Quantum parallelism is a distinctive feature established on superposition and entanglement and offers exponential acceleration of computation over conventional computers, especially for cryptosystems, making them acutely fast [30]. A quantum computer taking " $n$ " qubits that can be stored and execute  $2^n$  imaginable combinations of qubits simultaneously by joining them in an uncommon fashion recognized as superposition and defined as follows:

$$|\Psi\rangle = \alpha_0|0 \dots 00\rangle + \alpha_1|0 \dots 01\rangle + \dots + \alpha_{2^n-1}|1 \dots 11\rangle, \quad (8)$$

where  $\alpha_i \in \mathbb{C}$  complex numbers known as probability amplitudes of qubits and  $\sum |\alpha_i|^2 = 1$ .

In quantum information processing, electrons or photons in a coherent state is encoded with some required information (known as qubits) and pass to another qubit via a quantum bus. The passed information is accessible to many qubits in a system, accelerating the speed of computation, unlike classical computation [31, 32]. Trapped ion architecture, QC using superconducting qubits, and QC with nitrogen-vacancy center in diamonds are few of the hardware architectures considered for thorough research in well-equipped labs [33].

Like classical computation, quantum computation is carried out with the help of quantum gates. The information that has been obtained from quantum gates can be reversed. The representation of a single qubit quantum system is in the

form of a Bloch (shown by Figure 3). Each quantum gate is represented by a matrix containing complex coefficients and can be applied on the qubit (state vector in Bloch sphere) to change state as a vector. A qubit is a state vector in two-dimensional Hilbert space. This vector can have any direction from the sphere's center to its periphery, i.e., it can connect to any point on the sphere's surface. The poles indicate the ground and excited states, and anywhere between these points is the superposed state of the qubit. Different qubit transitions indicate rotations about the axes changing the state of that qubit [34, 35]. Moreover, these rotations occur as a result of the quantum gate(s), which act on that qubit (see Figure 3).

(2) *Two-Level Spin System*. As described earlier, logical content prioritization is achieved through the DL agent to know about the requested content's priorities. Once the priority is known, the particle is encoded according to the relevant content priority. By taking into account the high and medium priorities, the contents can be stored physically in QMM by dividing it into two groups for which SGE is exploited. The information is encoded through the spin  $\pm 1/2$  particles;  $+1/2$  upward spin and  $-1/2$  downward spin. The highly prioritized data are coded by spin-up particles, whereas through the spin-down particles, the likewise and medium prioritized data are encoded.

Due to the spinning environment, the electron has a magnetic field. The magnetic field can be canceled by another electron having an opposite spin in an atom. In an atom, the electrons are either paired or unpaired. To decide the spinning effect, the unpaired electrons leave the orbitals. Electrons are accrued like a beam, divided into two illustrious beams of equivalent power even though passing through a nonuniform magnetic field. Therefore, a massive tendency is shown in Figure 4.

A quantum organization is indicated by its state vector. But at times, the system is said to be in mixed state having statistical ensemble of various state vectors. Such a system has equal probabilities or chances to designate in either pure state. The pure state is basically a quantum state useful in the quantum system and determines the statistical behavior of the measurement. At the beginning of the TLSQP, all electrons are located in a mixed state since the states are indefinite. Due to the half-half chances of existence in any of the pure states ( $|0\rangle$  and  $|1\rangle$ ), the particles have a mixed state. Density matrices are used to represent the statistical state of the quantum system or a particle. The chances for result can be calculated from the density matrix for the system. The density matrices for states (i.e., mixed and pure) represented that the particles are initially in the mixed state when accrued like a single beam.

$$\rho = \begin{bmatrix} \frac{1}{2} & 0 \\ 0 & \frac{1}{2} \end{bmatrix}. \quad (9)$$

A nonuniform magnetic ground is formed by employing two magnets in a perpendicular way along the  $z$ -axis. When

FIGURE 3: Representation of a qubit in a 2-dimensional Bloch sphere.

a beam passes through the magnetic field, electrons are bent alongside the axis comparative to the  $z$ -component. After passing through a magnetic field, some of the particles are in the Eigen state  $|Z+\rangle$  of the  $S_z$  operator. The matrix for this state vector is given as follows:

$$\rho_{Z+} = |Z+\rangle\langle Z+| = \begin{bmatrix} 1 \\ 0 \end{bmatrix} \begin{bmatrix} 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}. \quad (10)$$

The trace of this density matrix's square is 1, which clearly shows that it is a pure state. The state of the rest of the particles after passing through the magnetic field becomes 1 ( $|Z+\rangle$ ). The matrix for this state is given as follows.

$$\rho_{Z-} = |Z-\rangle\langle Z-| = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \begin{bmatrix} 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}. \quad (11)$$

Again, this density matrix's trace is 1 and shows that it is a pure state. In contrast, if considered these two separated beams together, we again get the mixed state consisting of an equal mixture of particles in Eigen states  $|Z+\rangle$  and  $|Z-\rangle$ , as follows:

$$\rho = \frac{1}{2}|Z+\rangle\langle Z+| + \frac{1}{2}|Z-\rangle\langle Z-| = \begin{bmatrix} \frac{1}{2} & 0 \\ 0 & \frac{1}{2} \end{bmatrix}. \quad (12)$$

The trace of the square of this density matrix is  $1/2$  which is less than 1, showing a mixed state. Before passing via a magnetic field, the electrons' spin can point in any direction of the space, being equally probable, so there is no state vector but for pure states.

The mixed beams can be stored in QMM distinctly. The  $|Z+\rangle$  state represents Repository 1 electrons devising pure state  $|0\rangle$  wherever (high) prioritized contents are stored. The  $|Z-\rangle$  state signifies Repository 2 electrons taking pure state  $|1\rangle$ , and the intermediate prioritized

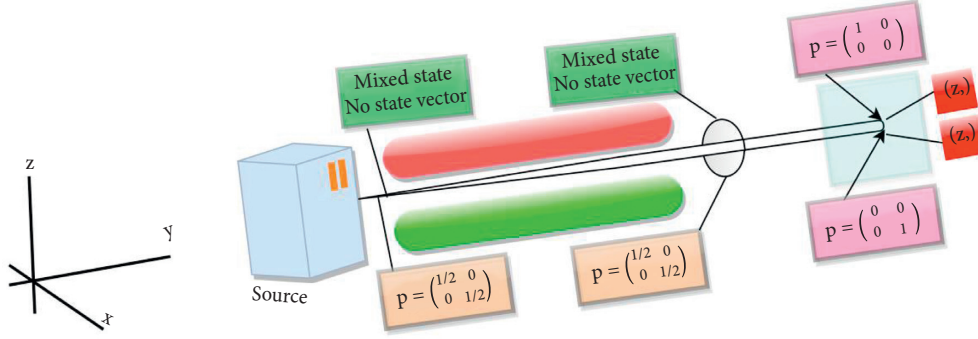

FIGURE 4: Electron beam splitting into two while passing through a magnetic field [23].

contents are stored. Therefore, electrons containing certain contents' information are categorized based on the established priorities by using TLSQP. The stated repositories help in storing the modified contents in every interval of time.

The ion-trap architecture of QMM is useful and effective for this specific scenario. The quantum data can be stored by qubits using atomic ions. The qubits (atomic ions) are trapped and designed by groupings of static and oscillating electric fields [33, 36, 37]. In what way, these quantum data are stored in these repositories which are beyond the scope of this research. The quantum information can be managed (processed or transferred) through the ions' cooperative quantized motion and is also recognized as quantum parallelism. The respective parallelism leads to an increase in the processing time as compared to the classical architectures. It has long been known that classical physics principles do not allow for causally efficacious understanding; yet, the intrinsic indeterminism and characteristic duality of quantum physics is that it contains give fertile ground for comprehension through physical modeling.

Measuring probability for spin-up and spin-down particles is an important aspect that will help determine the category of data encoded in a particular spin-type particle. So, to interpret the idea, IBM's QC simulator is exploited to yield some meaningful results. The resulting probability  $p$  for a particle to emerge as a spin-up particle can be found out by  $\cos^2(\theta/2)$ , and for a particle to emerge as spin-down can be found out by  $\sin^2(\theta/2)$ , where  $\theta$  is the angle of rotation along  $Z$ -axis. Different angles of rotation will yield different likelihoods for spin-up and spin-down elements. The formula to find the probabilities of spin-up and spin-down elements is explained as the trace of density matrix and projection operator on that pure state-directed to some angle  $\theta$  as follows:

$$\mathbf{p} = \text{Tr} [\rho \mathbf{P}_{\hat{n}}], \quad (13)$$

where  $\rho$  is the density matrix of pure states already described above and  $\mathbf{P}_{\hat{n}}$  is the projection operator on a pure state which is directed to some  $\hat{n}$  so that  $\hat{n}_\theta = (\cos\theta, 0, \sin\theta)$ . Hence,

$$\begin{aligned} \mathbf{P}_{\hat{n}} &= \frac{1}{2} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} + \frac{1}{2} \begin{bmatrix} 0 & \sin\theta \\ \sin\theta & 0 \end{bmatrix} + \frac{1}{2} \begin{bmatrix} \cos\theta & 0 \\ 0 & -\cos\theta \end{bmatrix} \\ &= \begin{bmatrix} \cos^2\frac{\theta}{2} & \frac{1}{2}\sin\theta \\ \frac{1}{2}\sin\theta & \sin^2\frac{\theta}{2} \end{bmatrix}. \end{aligned} \quad (14)$$

So, the trace of the product of  $\rho$  and  $\mathbf{P}_{\hat{n}}$  comes out to be  $\cos^2(\theta/2)$  for  $|Z+\rangle$  particles and  $\sin^2(\theta/2)$  for  $|Z-\rangle$  particles, respectively.

Quantum computers have stimulated the rotation produced by the magnetic field in the SGE by applying quantum gates. For instance, a **T** gate is used to produce rotation at  $\theta = \pi/4$ . This gate rotates the state of the qubit in the superposed form by angle  $\pi/4$  along the  $Z$ -axis. So, it is necessary to apply the Hadamard gate (**H**) before applying the **T** gate, as the **H** gate helps create superposition. Matrix representation of a Hadamard gate is shown as follows:

$$\frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}. \quad (15)$$

It converts the  $|0\rangle$  basis state of the qubit to  $((|0\rangle + |1\rangle)/\sqrt{2})$  form (also known as  $|+\rangle$ ), and  $|1\rangle$  basis state to  $((|0\rangle - |1\rangle)/\sqrt{2})$  form (also recognized as  $|-\rangle$ ). Therefore, a superposition is created as there is an equal probability to be either 0 or 1. It produces two rotations simultaneously:  $\pi$  at the  $z$ -axis and  $\pi/2$  at the  $y$ -axis and is shown by Figure 5(a).

After creating superposition, the **T** gate is applied to rotate the superposed qubit at  $\pi/4$  along the  $z$ -axis. This is a single qubit gate (from the family of phase shift gates), which does not change the probability of the  $|Z+\rangle$  and  $|Z-\rangle$  somewhat changing the phase of the qubit's state. This gate acts on the  $|1\rangle$  base state, whereas exiting the  $|0\rangle$  base state remains unaffected. So,  $|+\rangle$  will be converted to  $((|0\rangle + i\pi/4|1\rangle)/\sqrt{2})$  and  $|-\rangle$  will be converted to  $((|0\rangle - i\pi/4|1\rangle)/\sqrt{2})$  because these are mixed states. Matrix representation of **T** gate is described as follows:

FIGURE 5: The gates are represented through a Bloch sphere. (a) Hadamard (H) gate representation in a Bloch sphere, (b) The rotation is produced by T gate and shown in a Bloch sphere.

$$\begin{bmatrix} 1 & 0 \\ 0 & e^{i\pi/4} \end{bmatrix}. \quad (16)$$

The rotation produced through the T gate and is shown in Figure 5(b).

As soon as the T gate is applied, another H gate is again useful to maintain qubit's superposition. Alternatively, it would have lost its quantum state and collapsed into a classical one that is of course 0 or 1 depending upon the qubit chosen. The equation which satisfies this circuit is given as follows:

$$\frac{1}{2} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & e^{i\pi/4} \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} \frac{1}{2} + \frac{1}{2}e^{i\pi/4} \\ \frac{1}{2} - \frac{1}{2}e^{i\pi/4} \end{bmatrix}. \quad (17)$$

When more than one gate is applied on a qubit in a serially wired circuit, dot product (usual matrix multiplication) is carried out for all the gates, resulting in a combined gate acting on that qubit. As mentioned in equation (17), H, T, and H gates have been combined by dot product and applied on  $|0\rangle$ . The resultant matrix shows the probability amplitudes of spin-up and spin-down, as complex numbers, just before the measurement. It can also be written as follows:

$$\left(\frac{1}{2} + \frac{1}{2}e^{i\pi/4}\right)|0\rangle + \left(\frac{1}{2} - \frac{1}{2}e^{i\pi/4}\right)|1\rangle. \quad (18)$$

The probability amplitude  $\alpha^2$  of  $|0\rangle$  is  $|(1/2) + (1/2)e^{i\pi/4}|^2$ , equal to 0.853534, approximately 85%, and that of  $|1\rangle$  is the leftover probability which is of course 0.146466 (approximately 15%). Hence,  $|0\rangle$  basis state has a greater probability, so classically, a 0 is obtained by measuring the state if the T gate is applied. Similarly, some other appropriate sequence of H gates and phase shift gates can also be applied in order to produce a distinct rotation and obtain

different probabilities of spin-up and spin-down particles. It depends upon which type of particle is needed to encode the data to be stored in the relevant repository.

A quantum computer can help to determine these complex probability amplitudes in terms of real numbers. It can then be classically interpreted and ultimately helping in encoding data.

**3.3. Flowchart and Algorithm (Solution).** The flowchart of the proposed framework is represented in Figure 6. An algorithm is described (and also shown by Algorithm 1) as follows.

The algorithm comprises three functions: (1) cache\_synchronization [], (2) cache\_update [], and (3) Serve\_UE\_Phase []. The cache\_synchronization [] function is used for cache synchronization and cooperation. It has parameters  $t$ , and  $S$ :  $t$  is the time interval after which cache information is shared, while  $S$  is a set of regional users for a particular  $t$ . It returns the regional user set for a particular time interval by considering the time interval, set of user requests, the workload on the edge node, and distance  $d$  of UE from the edge node. The information of  $R$ ,  $d$ , and  $w_E$  at a specific time, quantum  $t$  is shared in Step 1.  $R$  is used for the set of user requests  $\{r_1, r_2, \dots, r_k, \dots, r_n\}$ ,  $d$  is the distance of UE from edge node receiving a request, and  $w_E$  is the workload on a particular edge node. Step 2 will return a list of  $S$  for the particular  $t$ . In Step 3, assigned edge node  $E_A$  to a particular user set,  $S$ . Step 4 is used as a counter for  $t$  and Step 5 will repeat Step 1.

The cache\_update [] function is used to update the caching contents. It consumes (as input) the list  $L$  of contents with extracted features and produces (as output) the prioritized caching content to be placed in F-AP. Step 1 selects the appropriate map size: horizontal  $x$  and vertical  $y$  dimensions of the map. Step 2 defines the color intensity of map nodes to depict classes for low, medium, and high priority contents. Step 3 is used to run the SOMs algorithm

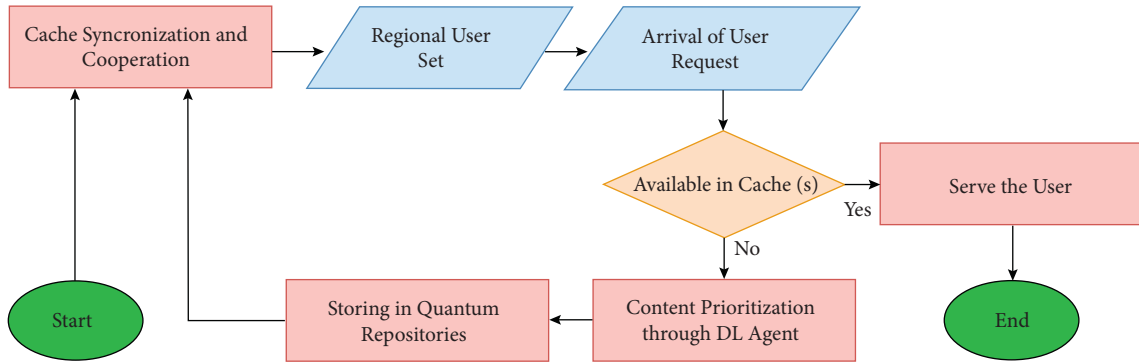

FIGURE 6: The flowchart of the proposed framework.

after initializing weights  $W_{ij}$ . The mapping of  $n_{DB}$  and  $n_{MB}$  on  $L$  to get  $C_p$  in the Step 4. The map nodes with dark blue  $n_{DB}$  and medium blue  $n_{MB}$  color showing high priority and medium priority content as  $L$ .  $C_p$  are the prioritized contents to be placed in cache.

Serve\_UE\_Phase [] function is used to serve a user request  $r_k$ . It takes regional user set and assigned edge node as input and activate to serve for an incoming request. If there is a cache hit in Step 1, it will serve  $r_k$ ; otherwise, it will first update the cache and then serve  $r_k$ .

#### 4. Content Prioritization Results through Deep Learning

**4.1. Self-Organizing Maps.** Multimedia content needs to be prioritized with considerable views, likes, dislikes, and comments. SOMs algorithm learns from the given dataset and displays on the map by the grid of nodes. The degree of the relationship between data points is shown through the color intensity. As a proof of concept, a tool is implemented using Python programming language and is exploited through a Jupyter notebook in Google Colab. As mentioned earlier, the four input vectors, i.e., views, likes, dislikes, and comment\_count, are selected utilizing the dataset to simulate. The feature scaling is achieved through the MinMax scaler. To train the SOMs algorithm, the tuning parameters with their values are simulated through the tool and shown in Table 1.

To select an appropriate lattice size, different lattice sizes are tested by the hit and trial method to validate the formula. The experiment shows that the batch training yields many exact results; however, it is a bit slower than the random training. The recorded data are shown in Table 2. A histogram also represents the recorded data in Figure 7. On  $x$ -axis, different lattice sizes (i.e.,  $10 \times 10$ ,  $15 \times 15$ ,  $20 \times 20$ , and  $32 \times 32$ ) with different number of iterations (i.e., 250,000, 500,000, 750,000, and 1,000,000) are shown by different colors. On the  $y$ -axis, the error values are displayed (given in Table 2). Evaluating the data carefully proves that the error values are recorded minimum on the lattice size  $32 \times 32$  with 750,000 iterations; therefore, this lattice size is considered appropriate.

The map's outputs of different iterations for lattice size  $32 \times 32$  are shown in Figure 8. The color scale for iterations 250,000, 500,000, 750,000, and 1,000,000 are shown in Figures 8(a)–8(d), respectively. Nodes with color (values)

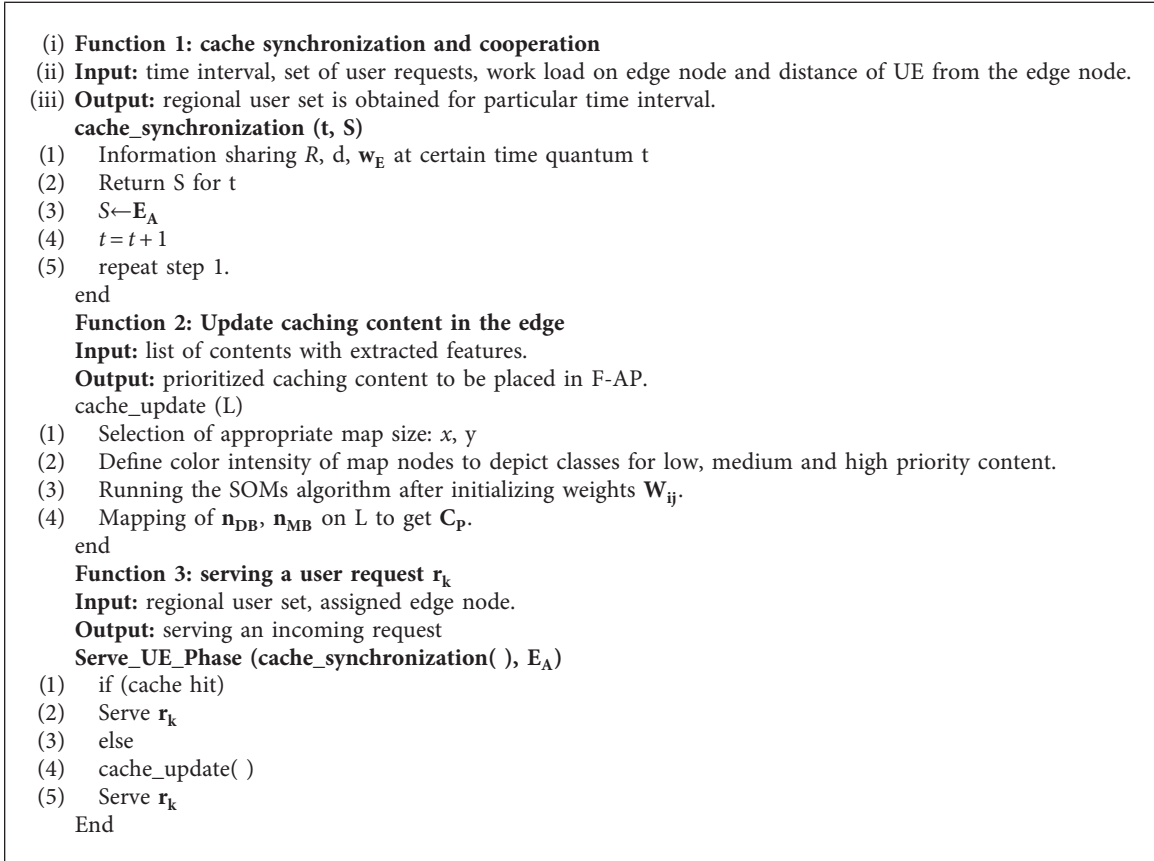

range from 0.8 to 1.0 (dark blue) which represent the group of data having high priority contents (maximum number of views, likes, dislikes, and comments). The medium priority contents are represented with light bluish color nodes ranging from 0.4 to 0.8. The medium priority contents follow the high priority contents. The remaining nodes with color values below 0.4 are considered the least priority contents and must not be deliberated in the caches.

After the SOMs algorithm's training through different lattice sizes, the QE needs to be extracted to check the validity of the data. According to the data described in Table 2, the best map among all is  $32 \times 32$  lattice-sized map with 750,000 iterations. The QE value is recorded even less than 0.000024 as shown by the graph in Figure 9(a). It is not reduced any further after 0.000024 QE value. The TE is plotted by Figure 9(b) to determine how well the topology of the map is preserved at 750,000 iterations. The TE value at this point is logged as 0.092. Although the TE is recorded a little bit higher but its value, together with QE value (i.e., 0.0000235) plotted the most appropriate map after 750,000 iterations. By taking into account the curves shown in Figures 9(a) and 9(b), it can be analyzed that the map is trained efficiently and delivers precise results.

After selecting the most appropriate lattice map ( $32 \times 32$ ) in 750,000 iterations, the data points located below the dark blue region are mapped onto the videos' data frame. Similarly, the light-blue color region is also mapped to get medium prioritized content. Table 3 is used to describe the mapping data of high priority contents from one of the nodes from the dark blue region (27, 2). Also, it shows twelve highly trending videos (in rows from 0 to 11) with respect to views, likes, dislikes, and comment\_count (in columns). These videos are considered as a high priority for trending according to the input parameters provided in the dataset.

The rest of the nodes from bluish-white to white are located in the lighter region and can be ignored because this region contains the least priority content.

**4.2. Quantum Self-Organizing Maps.** Quantum-SOM (QuSOM) has a different learning method than SOM. The number of presynaptic neurons corresponds to the number of neurons in both layers and interconnections between them when designing the QuSOM layout, which comprises

ALGORITHM 1: Cache content management.

TABLE 1: Tuning parameters and their values.

Tuning parameters with symbols	Values
$x$ -dimension of the lattice ( $x$ )	32
$y$ -dimension of the lattice ( $y$ )	32
Learning rate ( $L_t$ )	0.1
Initial spread value ( $\sigma_0$ )	1.0

TABLE 2: The errors' values with respect to different lattice sizes and the number of iterations.

Dimensions of lattice	No. of iterations			
	250,000	500,000	750,000	1,000,000
$10 \times 10$	0.0001555	0.0001563	0.0001584	0.0001643
$15 \times 15$	0.0001218	0.0001110	0.0000970	0.0000890
$20 \times 20$	0.0000847	0.0000727	0.0000594	0.0000460
$32 \times 32$	0.0000355	0.0000353	0.0000235	0.0000241

the number of all model parameters and the set of potential data classifications. There is only one connection between a neuron in the input layer and a neuron in the output layer. QuSOM attracts all vectors of  $v$ , ( $v(i) \in i, i = 1, 2, \dots, N$ ), just once. The competitive and weight update is accomplished through a series of procedures, which is a parallel processing capability. As a result, in QuSOM, the traditional repetitive learning procedure is modified to learn only once. Algorithm 2 of the QuSOM is as follows:

The QuSOM, in QC, may shift research directions in the artificial neural network (ANN) field depending on the computation environment and application property [38]. The parallelism aspect of the QuSOM is its most intriguing feature. A quantum mechanics computer can exist in a state of superposition and perform several operations simultaneously. A QuSOM gate array is depicted in Figure 10 as a schematic. The register's initial state is on the left, and time moves from left to right. The  $W^s$  gate is a weight operator at  $s$ ;  $D^s$  gate is a distance operator at  $s$ ;  $d^s(i, j_{\min})$  is a Grover searching oracle;  $W^{s+1}$  is a winner weight updating operator at  $t$ ;  $U$  is a weight transformation operator at  $s, u = QW^{t+1}$ ;  $\vartheta$  is an observable extracted information from register, according to the above summarized QuSOM algorithm. The operations of these transformation and operation matrices are used to create QuSOM. The vectors are only entered into the map once, and the output (weight) should converge if the sequence is repeated.

In the traditional meaning of computation, putting all parameters in inputs as neurons may be unfeasible, and QuSOM operation will be time consuming due to parallelism.  $N = 2$  input vectors with  $M = 4$  total input items and  $P = 2$  prototypes, for example, and the number of neurons in both input and output layers should be  $2 \times 4 \times 2 = 16$ . This figure is four times that of SOM. Fortunately, this is not an issue in quantum computing. Quantum theory's peculiar properties can be used to express information with a neuron

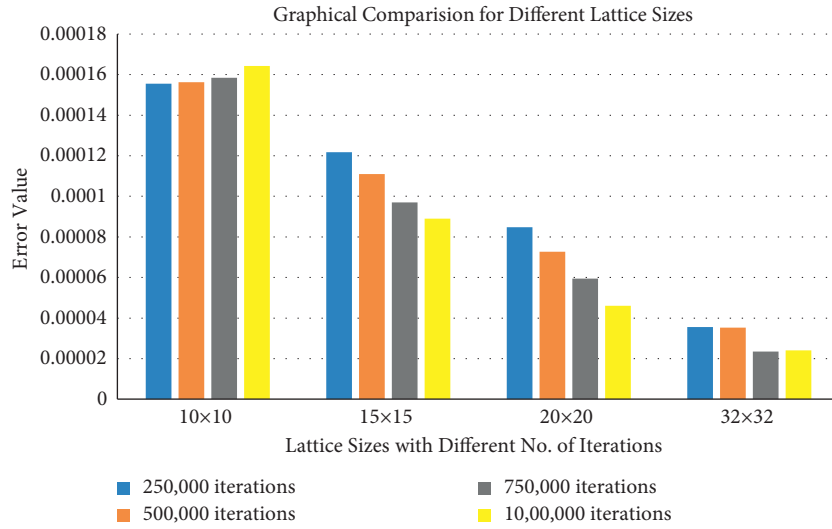

FIGURE 7: Comparison of different lattice sizes with the errors values by selecting different number of iterations.

FIGURE 8: The color scales for different iterations at lattice size  $32 \times 32$  are shown. (a) Output map at 250,000 iterations. (b) Output map at 500,000 iterations. (c) Output map at 750,000 iterations. (d) Output map at 1,000,000 iterations.

number of exponential capacity. The number of neurons is exponentially decreased to  $\log_2$  for the input signals,  $v(i, k)$ ,  $i = 1, \dots, Z$ ,  $k = 1, \dots, Y$ ,  $j = 1, \dots, P$ , by adopting quantum representation ( $M \times N \times P$ ). QuSOM requires only 4 qubits in the example above. The input data from YouTube streaming may be more than 4 vectors with 40960 elements in some edge caching systems. The SOM configuration was used with

4 neurons in the input layer and  $32 \times 32 = 1024$  neurons in the output layer. The network might be configured with 27 quantum input/output neurons, or qubits, representing roughly 41943040 SOM neurons using QuSOM. So, it can be determined that the gain difference in terms of computation and time consumption between the deep learning method based on quantum computing and conventional method as

the measures of conventional computing are almost four times the quantum computing that clearly shows extensive use of resources in conventional computing.

#### 4.3. Simulation Results for Quantum Phenomenon in Caching.

For the experiments, a cloud-based QC system (from IBM Quantum Experience) is used. The IBMQ\_QASM\_Simulator is basically a simulator backend, allows sampling circuits with a 32 qubits processor. The circuit to produce rotation of the particles is shown in Figure 11. It is a serially wired circuit comprising three gates (two

Hadamard and one  $T$  gate). The respective circuit is used to act on qubit  $|0\rangle$  and is known as a standardized measurement operator along the  $z$ -axis. The primary (first) wire, labeled as  $q[0]$ , is a quantum wire representing the passage of time. It is not considered a physical wire. The gates are applied in unit time. The second wire, labeled as  $c1$ , is a classical wire, and the output from the quantum computer is determined once the measurement is applied. The vertical arrow from the measurement operator shows that the information is now retrieved from the quantum regime to the classical regime.

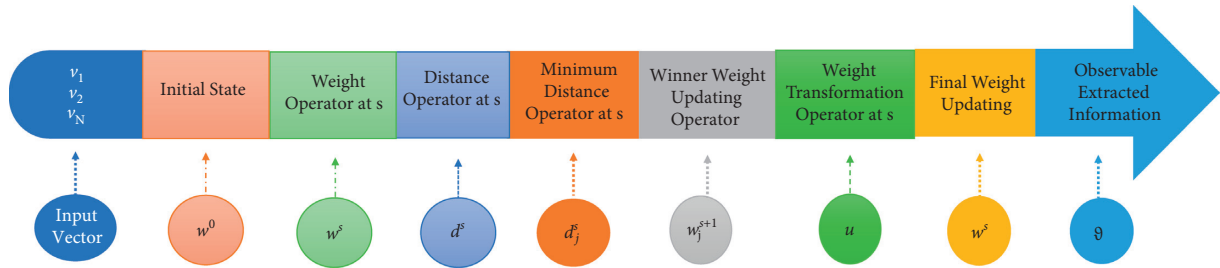

FIGURE 10: The general QuSOM structure contains gate array.

FIGURE 11: The circuit to produce rotation of the particles is shown from IBM QASM Simulator.

To evaluate circuit on the simulator, a parameter *number of shots* is needed to set before execution. The *number of shots* is simply a parameter having a value that determines the number of iterations, representing the number of times a quantum circuit executes. With the increase in the *number of shots*, the probability values of spin-up and spin-down are improved. The resultant probabilities are demonstrated by Figure 12 with different numbers of shots (i.e., 1024, 4096, and 8192 shots) and actual measurements. The horizontal axis of the histogram represents the computational basis states 0 and 1. The vertical axis represents the probability of observing that basis state. The histogram in Figure 12 also represents the exact probability measurement of the basis states.

As clearly depicted from Figure 12, there is a slight difference between the actual and simulated results. The first and last simulated results are realized by 1024 and 8192 shots, respectively. The probability measurement difference is reduced as compared with the actual result. The probability measurements are close to the actual result by 8192 shots. The results are concluded (by comparing actual and simulated) in Table 4.

All the prioritized contents are grouped in the form of color clusters. The color intensity of the nodes in the feature map makes it easier to prioritize the content. The nodes with less intense color illustrated the low prioritized content. The selection of highly prioritized and medium prioritized contents is achieved conveniently through the SOMs algorithm. The algorithm took less time and computational overhead than other DL algorithms. The use of TLSQP facilitates the overall management of most requested content within the edge for providing an instantaneous content delivery response. The concept of storing content in QMM by employing this quantum phenomenon is entirely unconventional and challenging at the same time. Nevertheless, its advantage overshadows other conventional approaches of the classical regime in terms of storage capacity and processing speed due to its unusual properties, i.e., quantum parallelism.

FIGURE 12: The simulated resultant probabilities with different number of shots, i.e., 1024 shots; 4096 shots; and 8192 shots; and the actual probability measurements are shown.

## 5. Discussion

The framework is basically a merger of a DL agent deployed at the network edge and a QMM. Firstly, the DL agent prioritizes caching contents via SOMs algorithm, and secondly, the prioritized contents are stored in QMM using TLSQP. The study of QuSOM follows the development tendency of ANN. The adaptation of ANN in the parallel computing environment will be interesting for both ANN and QC, especially for the simulation of human learning and memorizing features by using more powerful computing tools. In Kohonen's SOM, the learning and weight updating are organized in the same sequence. This sequence is like the human's repeated learning manner. In QuSOM, due to its once learning property, the weight updating is managed separately with learning and updating. This manner may appear more similar to human's once learning way. QuSOM has the same convergence property as Kohonen's SOM, but its time and space complexities are more simplified. To verify the valuation and efficiency of the algorithm, in this study, we have compared the gain difference in terms of

computation and time consumption between the deep learning method based on quantum computing and conventional method which can be summarized as the measures of conventional computing are almost four times the quantum computing.

To verify the algorithm, we conduct extensive experiments to demonstrate that the algorithm improves the generalizability of the conventional SOM through optimization and is robust to the choice of hyperparameters, as listed in Table 5.

A hybrid approach was used for this work: one (i.e., SOM) for classifying the videos dataset and a second (i.e., TLSQP) for the storage of prioritized content. It can be inferred that the proposed framework DL-QC is deployed for edge caching in sensor network traffic to improve the prioritization and storage processes by exploiting the capabilities of DL and QC. Dataset has been selected that incorporates multimedia content that has been infrequently used in the past for other studies. The dataset contains four features and 40960 samples. Google Colab and IBM's

Quantum Experience are utilized in this work with high certainty because of their capabilities of creating legitimate outcomes that mirror certain domains of intelligence and quantum. The gathered information has been recorded for prioritization levels and will notify the prioritized cases to the QMM storage through TLSQP, whereas the most minor prioritized cases will be removed with a higher accuracy rate. The DL algorithm SOM is precisely applied to the identified dataset for prioritization in a  $32 \times 32$  lattice size. The selected DL classifiers accomplished the particular task with accuracy and precision, as discussed above. It will help characterize the high priority and medium priority network traffic to ensure the optimized caching services in the edge computing environment, and TLSQP ensures maximum data storage in QMM. Due to the research scope, some common types of multimedia content parameters have been selected, but in the future, more categories of innovative content and features in the DL-QC environment can be incorporated to better understand and cope with the identified issues. Furthermore, innovative algorithms can also be designed, or existing ones can be modified to prioritize and storage than already discussed to improve efficiency and accuracy. Moreover, the QuSOM can be replicated on conventional computers as well as quantum computers provided that the availability of resources to understand the results better.

## 6. Conclusion

The caching content's storage is mainly the primary source of immediate delivery responses. This research work has presented an intelligent DLAQC framework for updating the EC content in F-RANs. The caching content is logically prioritized through an intelligent DL agent in the network edge using the SOMs algorithm. The caching content is physically stored in QMM, exploiting the TLSQP phenomenon to update the caches and provide ample content storage for immediate delivery response against the unpredicted amount of static and dynamic user requests. The framework is evaluated using multimedia content and provides effective outcomes, especially by reducing computation overhead and time. The purpose is to form clusters to separate high, medium, and low-prioritized contents in an unsupervised manner. SOMs algorithm is staunchly suitable to pick up contents in colored cluster form without reducing the dimensionality of the feature space.

While the experiments have been conducted for multimedia content only, other contents can be considered, especially in IoT-based scenarios where unpredictable amounts of static and dynamic requests are generated day by day. EC is capable of handling each request immediately; it is still challenging and can be considered to explore further. Besides, innovative algorithms can also be designed, or existing can be modified to prioritize and storage than already discussed to get better efficiency and accuracy. Moreover, the QuSOM can be replicated on conventional computers as well as quantum computers provided the availability of resources to better understand the results.

## Data Availability

A publicly available dataset is used for this study (Trending YouTube Video Statistics).

## Conflicts of Interest

The authors declare no conflicts of interest.

## Authors' Contributions

All authors have made a substantial, direct, and intellectual contribution to the work and approved it for publication.

## Supplementary Materials

The data used to support the findings of this study are provided in "Annexure." (*Supplementary Materials*)

In this paper, a robust observer-based sliding mode control algorithm is proposed to address the modelling and measurement inaccuracies, load variations, and external disturbances of flexible articulated manipulators. Firstly, a sliding mode observer was designed with exponential convergence to observe system state accurately and to overcome the measuring difficulty of the state variables, unmeasurable quantities, and external disturbances. Next, a robust sliding mode controller was developed based on the observer, such that the output error of the system converges to zero in finite time. In this way, the whole system achieves asymptotic stability. Finally, the convergence conditions of the observer were theoretically analyzed to verify the convergence of the proposed algorithm, and simulation was carried out to confirm the effectiveness of the proposed method.

## 1. Introduction

Flexible manipulators are increasingly applied in industrial and aerospace fields, such as welding robots, industrial production lines, mechanical arms of aircraft, and so on, owing to their energy efficiency, high speed, and low contact impact. More and more attention has been paid to the research of flexible manipulators, along with the development of aerospace technology, robotics, marine engineering, and industrial engineering. Flexible manipulators are now extensively used to comfort humans in different areas of work, which involves risky and tedious works such as painting, cutting, dispensing, material handling, machine tending, machining, and assembly. However, each flexible manipulator is an extremely complex, dynamic system with highly nonlinear, strongly coupled, and time-varying features. The system behaviors are complex and dynamic due to load variations, uncertain external perturbations, and inherent vibrations [1–3]. Hence, flexible manipulators can hardly be modelled or measured accurately, calling for a well-designed controller [4–8]. Against this backdrop, it is theoretically and practically significant to explore the response speed and control accuracy of trajectory tracking for the double-linked flexible-joint manipulator [9].

To address the above problems, Lee et al. [10] designed an adaptive proportional-derivative (PD) controller to improve the trajectory tracking accuracy of the flexible-joint manipulator but did not consider the stability of the manipulator system. Lee and Lee [11] proposed a hybrid control strategy to optimize the design of the controller and generate hybrid trajectories. The strategy enhances the robustness of the flexible-joint manipulator system, yet it failed to take into account the trajectory tracking accuracy of the manipulator. Dong et al. [12] presented a fuzzy optimal control method for the design of a robust adaptive controller and demonstrated that the method ensures accurate and robust trajectory tracking of the flexible-joint manipulator. However, the manipulator's response speed of trajectory tracking was not taken into consideration. Abd Latip et al. [13] automatically adjusted the control gain online with an adaptive proportional-integral-derivative (PID) controller, which supports the control of the single-link flexible manipulator even after the actuator failure.

Ahanda et al. [14] addressed the robust adaptive control of a robotic manipulator under uncertain dynamics and joint space constraints and adopted command filters to overcome the time derivatives of virtual control, eliminating

the need for differentiating the desired trajectory. In addition, a barrier Lyapunov function was introduced to handle joint space constraints, and a robust adaptive support vector regression architecture was employed to suppress filtering errors, approximation errors, and dynamic uncertainties. Based on unknown input observer (UIO), Wang et al. [15] put forward a novel funnel nonsingular terminal sliding mode control (FNTSMC) method for servomechanisms with unknown dynamics, e.g., nonlinear friction, uncertainties, and external disturbances. He et al. [16] created a full-state feedback neural network (NN) control to mitigate the uncertainties and enhance the robustness of the dynamic system of a flexible-joint manipulator. Through a Lyapunov stability analysis, it was demonstrated that the controller can ensure the stability of the flexible-joint manipulator system and guarantee the boundedness of system state variables, by choosing appropriate control gains. Rahmani and Belkheiri [17] came up with a novel approach for adaptive control of flexible multilink robots in the joint space, proved that the approach is valid for a class of highly uncertain systems with arbitrary but bounded dimensions, and realized trajectory tracking by developing a stable inversion for robot dynamics using only joint angle measurements. Guo et al. [18] investigated the repetitive motion planning (RMP) of robotic manipulators under the high precision of joint angle repeatability and end-effector motion and applied a special difference rule to discretize the existing RMP scheme with  $P$ -based formulation, yielding a novel pseudoinverse-based ( $P$ -based) RMP scheme for robotic manipulators.

Through the above analysis, this paper proposes a sliding mode control strategy based on the robust observer. Firstly, a sliding mode robust observer was designed in light of the unmeasurable state, the modelling uncertainty, and the external disturbance moment of the flexible-joint manipulator. Next, a sliding mode controller was designed to track the positions of the first and second joints of the manipulator, aiming to realize the finite-time control of the system. Meanwhile, the convergence of the observer and controller was analyzed to present the convergence conditions. Finally, the effectiveness of the proposed method was verified through simulation.

## 2. Problem Description

The dynamics of the flexible-joint manipulator can be expressed as

$$\begin{cases} I\ddot{\theta} + K(\theta - \theta_m) + Mgl \sin q = 0, \\ J\ddot{\theta}_m - K(\theta - \theta_m) = u, \end{cases} \quad (1)$$

where  $\theta$  and  $\theta_m$  are the angular positions of the link and rotor, respectively;  $I$  and  $J$  represent the rotational inertia of the link and rotor, respectively;  $K$  is the joint stiffness coefficient;  $M$ ,  $g$ , and  $l$  are the link mass, gravitational acceleration at the link's center of gravity, and joint length, respectively; and  $u$  is the motor torque input.

Let  $x_1 = \theta$ ,  $x_2 = \dot{\theta}$ ,  $x_3 = \theta_m$ , and  $x_4 = \dot{\theta}_m$  be state variables. Considering modelling uncertainty and external disturbance moments, the underdriven form of equation (1) can be obtained as

$$\begin{cases} \dot{x}_1 = x_2, \\ \dot{x}_2 = a_1 x_3 + f_1(x_1) + \Delta_1(t), \\ \dot{x}_3 = x_4, \\ \dot{x}_4 = a_2 u + f_2(x_1, x_3) + \Delta_2(t), \end{cases} \quad (2)$$

where  $a_1 = (K/I)$ ;  $f_1(x_1) = -(Mgl/I) \cdot \sin x_1 - (K/I) \cdot x_1$ ;  $a_2 = (1/J)$ ;  $f_2(x_1, x_3) = (K/J) \cdot (x_1 - x_3)$ ;  $\Delta_1(t)$  and  $\Delta_2(t)$  are the uncertainty part and the external disturbance moment, respectively; and  $|\Delta_1(t)| \leq \rho_1$ ,  $|\Delta_2(t)| \leq \rho_2$ .

The following lemma was introduced to facilitate the observer and controller stability analysis.

**Lemma 1** (see [1]). *For  $V: [0, \infty) \in R$ , the solution of  $\dot{V} \leq -\alpha V + f$  with  $\forall t \geq t_0 \geq 0$  can be expressed as an inequality:*

$$V(t) \leq e^{-\alpha(t-t_0)}V(t_0) + \int_{t_0}^t e^{-\alpha(t-\tau)}f(\tau)d\tau, \quad (3)$$

where  $\alpha$  is an arbitrary constant.

## 3. The Observer and Controller Design

**3.1. The Observer Design.** The observer of  $x_2$  and  $x_4$  was designed as follows.

To realize  $x_2$  and  $x_4$  observations, the following reconfiguration system was developed:

$$\begin{cases} \dot{\lambda}_1 = \lambda_2 + l_1(x_1 - \lambda_1) + D_1(x_1 - \lambda_1), \\ \dot{\lambda}_2 = a_1 x_3 + f_1(x_1) + \overline{D}_2(x_1 - \lambda_1), \\ \dot{\lambda}_3 = \lambda_1 + l_2(x_3 - \lambda_3) + D_3(x_3 - \lambda_3), \\ \dot{\lambda}_4 = a_2 u + f_2(x_1, x_3) + \overline{D}_4(x_3 - \lambda_3), \end{cases} \quad (4)$$

where  $l_1, l_2, D_1, \overline{D}_2, D_3$ , and  $\overline{D}_4$  are the positive real numbers to be designed and  $\lambda_1, \lambda_2, \lambda_3$ , and  $\lambda_4$  are meaningless intermediate state variables.

Then, the observer was designed as

$$\begin{cases} \hat{x}_1 = \lambda_1, \\ \hat{x}_2 = \lambda_2 + l_1(x_1 - \lambda_1), \\ \hat{x}_3 = \lambda_3, \\ \hat{x}_4 = \lambda_4 + l_2(x_3 - \lambda_3), \end{cases} \quad (5)$$

where  $\hat{x}_i$  is the state estimation. The estimation error can be defined as

$$\tilde{x}_i = x_i - \hat{x}_i. \quad (6)$$

From equations (4)–(6), we have

$$\begin{cases} \dot{\hat{x}}_1 = \lambda_2 + l_1(x_1 - \lambda_1) + D_1(x_1 - \lambda_1) = \hat{x}_2 + D_1\tilde{x}_1, \\ \dot{\hat{x}}_2 = a_1x_3 + f_1(x_1) + \bar{D}_2(x_1 - \lambda_1) + l_1(x_2 - \hat{x}_2 - D_1\tilde{x}_1) \\ = a_1x_3 + f_1(x_1) + l_1\tilde{x}_2 + (\bar{D}_2 - l_1D_1)\tilde{x}_1, \\ \dot{\hat{x}}_3 = \lambda_4 + l_2(x_3 - \lambda_3) + D_3(x_3 - \lambda_3) = \hat{x}_4 + D_3\tilde{x}_3, \\ \dot{\hat{x}}_4 = a_2u + f_2(x_1, x_3) + \bar{D}_4(x_3 - \lambda_3) + l_2(x_4 - \hat{x}_4 - D_3\tilde{x}_3) \\ = a_2u + f_2(x_1, x_3) + l_2\tilde{x}_4 + (\bar{D}_4 - l_2D_3)\tilde{x}_3. \end{cases} \quad (7)$$

Note that  $D_2 = \bar{D}_2 - l_1D_1$  and  $D_4 = \bar{D}_4 - l_2D_3$ . Then,

$$\begin{cases} \dot{\hat{x}}_1 = \hat{x}_2 + D_1\tilde{x}_1, \\ \dot{\hat{x}}_2 = a_1x_3 + f_1(x_1) + l_1\tilde{x}_2 + D_2\tilde{x}_1, \\ \dot{\hat{x}}_3 = \hat{x}_4 + D_3\tilde{x}_3, \\ \dot{\hat{x}}_4 = a_2u + f_2(x_1, x_3) + l_2\tilde{x}_4 + D_4\tilde{x}_3. \end{cases} \quad (8)$$

$$\begin{aligned} \dot{V} &= \tilde{x}_1(x_2 - \hat{x}_2 - D_1\tilde{x}_1) + \tilde{x}_2(\Delta_1 - l_1\tilde{x}_2 - D_2\tilde{x}_1) + \tilde{x}_3(x_4 - \hat{x}_4 - D_3\tilde{x}_3) + \tilde{x}_4(\Delta_2 - l_2\tilde{x}_4 - D_1\tilde{x}_3) \\ &= (1 - D_2)\tilde{x}_1\tilde{x}_2 + (1 - D_4)\tilde{x}_3\tilde{x}_4 - D_1\tilde{x}_1^2 - l_1\tilde{x}_2^2 - D_3\tilde{x}_3^2 - l_2\tilde{x}_4^2 + \Delta_1\tilde{x}_2 + \Delta_2\tilde{x}_4. \end{aligned} \quad (10)$$

Taking  $D_2 = D_1 = 1$  and the inequality  $\rho_i^2/2 + \tilde{x}_j^2/2 \geq \rho_i |\tilde{x}_j| \geq \Delta_i \tilde{x}_i$ , we have

$$\dot{V} \leq -D_1\tilde{x}_1^2 - l_1\tilde{x}_2^2 - D_3\tilde{x}_3^2 - l_2\tilde{x}_4^2 + \frac{\rho_1^2}{2} + \frac{\tilde{x}_2^2}{2} + \frac{\rho_2^2}{2} + \frac{\tilde{x}_4^2}{2}. \quad (11)$$

Inequality (11) can be rectified as

$$\dot{V} \leq -\left(D_1\tilde{x}_1^2 + D_3\tilde{x}_3^2 + \left(l_1 - \frac{1}{2}\right)\tilde{x}_2^2 + \left(l_2 - \frac{1}{2}\right)\tilde{x}_4^2\right) + \frac{\rho_1^2}{2} + \frac{\rho_2^2}{2}. \quad (12)$$

Taking  $l_1 \geq (1/2) + r$ ,  $l_2 \geq (1/2) + r$ ,  $D_1 \geq r$ , and  $D_3 \geq r$  with  $r$  being the positive real number to be designed,

$$V(t) \leq e^{-2r(t-t_0)}V(t_0) + Qe^{-2rt} \int_{t_0}^t e^{2r\tau} d\tau = e^{-2r(t-t_0)}V(t_0) + \frac{Qe^{-2rt}}{2r} (e^{2rt} - e^{2rt_0}) = e^{-2r(t-t_0)}V(t_0) + \frac{Q}{2r} (1 - e^{-2r(t-t_0)}). \quad (15)$$

That is,

$$V(t) \leq \frac{Q}{2r} + \left(V(t_0) - \frac{Q}{2r}\right)e^{-2r(t-t_0)}. \quad (16)$$

Then, all the signals of the system are semiglobally bounded and satisfy

$$\lim_{t \rightarrow \infty} V(t) \leq \frac{Q}{2r}. \quad (17) \quad \square$$

*Remark 1.* From equation (17), it can be inferred that the observation accuracy of the state depends on the upper bound  $\Delta_1(t)$  and the initial error  $\Delta_2(t)$  of the observer.

The following theorem was introduced to facilitate the proof of observer convergence.

**Theorem 1.** For system (2) and observer (5), if the initial conditions satisfy  $V(0) \leq p$ , where  $p$  is any positive real number, there exists a condition that all the signals  $l_1, l_2, D_i (i = 1, \dots, 4)$  of the system are semiglobally consistent and bounded, and the observation error converges to an arbitrarily small residual set.

*Proof.* According to equations (5) and (6), the Lyapunov function is taken as

$$V = \frac{1}{2} \sum_{i=1}^4 \tilde{x}_i^2. \quad (9)$$

The following can be derived from equation (9):

$$D_1\tilde{x}_1^2 + D_3\tilde{x}_3^2 + \left(l_1 - \frac{1}{2}\right)\tilde{x}_2^2 + \left(l_2 - \frac{1}{2}\right)\tilde{x}_4^2 \geq r(\tilde{x}_1^2 + \tilde{x}_3^2 + \tilde{x}_2^2 + \tilde{x}_4^2). \quad (13)$$

Thus,

$$\dot{V} \leq -r(\tilde{x}_1^2 + \tilde{x}_3^2 + \tilde{x}_2^2 + \tilde{x}_4^2) + \frac{\rho_1^2}{2} + \frac{\rho_2^2}{2} \leq -2rV + Q, \quad (14)$$

where  $Q = \rho_1^2/2 + \rho_2^2/2$ .

According to Lemma 1, the solution to inequality (14) is

When parameter  $r$  is infinitely large, the observation error will be arbitrarily small.

*Remark 2.* Without considering the modelling uncertainty  $\Delta_1(t) = 0$  and the external disturbance moment  $\Delta_2(t) = 0$ ,  $(\rho_1^2/2) + (\rho_2^2/2) = 0$ , that is, if  $\dot{V} \leq -2rV$ , then  $V(t) \leq e^{-2r(t-t_0)}V(t_0)$ . At this point, the observer converges exponentially.

**3.2. Design and Analysis of Observer-Based Sliding Mode Controller.** Observer-based sliding mode control is a new sliding mode control method in recent years. It solves the unknown disturbance problem directly from the sliding

mode design side by purposefully designing the switching function and realizes the global nonsingular control of the system. At the same time, it inherits the finite-time convergence characteristics of sliding mode. Compared with the traditional sliding mode control, it can make the control system converge to the desired trajectory in finite time and has high steady-state accuracy. It is especially suitable for high-speed and high-precision control.

Let  $x_1$  and  $x_2$  be the controlled targets of  $x_d$  and  $\dot{x}_d$ , respectively. The design error can be expressed as

$$\begin{cases} e_1 = x_1 - x_d, \\ e_2 = \dot{e}_1 = x_2 - \dot{x}_d, \\ e_3 = \ddot{e}_1 = \dot{x}_2 - \ddot{x}_d = a_1 x_3 + f_1(x_1) - \ddot{x}_d, \\ e_4 = \ddot{\ddot{e}}_1 = a_1 \dot{x}_3 + \dot{f}_1(x_1) - \dot{\ddot{x}}_d = a_1 x_4 + \dot{f}_1(x_1) - \dot{\ddot{x}}_d. \end{cases} \quad (18)$$

Then, the error of the observer can be expressed as

$$\hat{s} = c_1 \tilde{e}_1 + c_2 \tilde{e}_2 + c_3 \tilde{e}_3 + \tilde{e}_4 = c_1 \tilde{x}_1 + c_2 \tilde{x}_2 + c_3 (a_1 \tilde{x}_3 + f_1(x_1) - \hat{f}_1(x_1)) + a_1 \tilde{x}_4 + \dot{f}_1(x_1) - \hat{f}_1(x_1). \quad (22)$$

Then, the control law can be designed as

$$u = -\frac{1}{a_1 a_2} \left[ c_1 (\tilde{x}_2 - \dot{x}_d) + c_2 (a_1 \tilde{x}_3 + \hat{f}_1(x_1) - \ddot{x}_d) + c_3 (a_1 \tilde{x}_4 + \dot{f}_1(x_1) - \dot{\ddot{x}}_d) + a_1 \hat{f}_1(x_1, x_3) + \hat{f}_1(x_1) - \dot{\ddot{x}}_d + \eta \hat{s} \right], \quad (23)$$

where  $\eta > 0$ .

$$\begin{cases} \hat{e}_1 = \hat{x}_1 - x_d, \\ \hat{e}_2 = \hat{x}_2 - \dot{x}_d, \\ \hat{e}_3 = a_1 \hat{x}_3 + \hat{f}_1(x_1) - \ddot{x}_d, \\ \hat{e}_4 = a_1 \hat{x}_4 + \hat{f}_1(x_1) - \dot{\ddot{x}}_d. \end{cases} \quad (19)$$

From equations (18) and (19), we have

$$\begin{cases} \tilde{e}_1 = e_1 - \hat{e}_1 = \tilde{x}_1, \\ \tilde{e}_2 = e_2 - \hat{e}_2 = \tilde{x}_2, \\ \tilde{e}_3 = e_3 - \hat{e}_3 = a_1 \tilde{x}_3 + f_1(x_1) - \hat{f}_1(x_1), \\ \tilde{e}_4 = e_4 - \hat{e}_4 = a_1 \tilde{x}_4 + \dot{f}_1(x_1) - \hat{f}_1(x_1). \end{cases} \quad (20)$$

The design sliding mode function can be expressed as

$$s = c_1 e_1 + c_2 e_2 + c_3 e_3 + e_4, \quad (21)$$

where  $c_i > 0$  is designed by  $i = 1, 2, 3$ .

Then,

Then, we have

$$\begin{aligned} \dot{s} &= c_1 \dot{e}_1 + c_2 \dot{e}_2 + c_3 \dot{e}_3 + \dot{e}_4 \\ &= c_1 (x_2 - \dot{x}_d) + c_2 (a_1 x_3 + f_1(x_1) - \dot{x}_d) + c_3 (a_1 x_4 + \dot{f}_1(x_1) - \dot{\ddot{x}}_d) + a_1 (a_2 u + f_1(x_1, x_3)) + \ddot{f}_1(x_1) - \dot{\ddot{x}}_d \\ &= c_1 (x_2 - \dot{x}_d) + c_2 (a_1 x_3 + f_1(x_1) - \dot{x}_d) + c_3 (a_1 x_4 + \dot{f}_1(x_1) - \dot{\ddot{x}}_d) \\ &\quad - \left[ c_1 (\tilde{x}_2 - \dot{x}_d) + c_2 (a_1 \tilde{x}_3 + \hat{f}_1(x_1) - \dot{x}_d) + c_3 (a_1 \tilde{x}_4 + \hat{f}_1(x_1) - \dot{\ddot{x}}_d) + a_1 \hat{f}_1(x_1, x_3) + \hat{f}_1(x_1) - \dot{\ddot{x}}_d + \eta \hat{s} \right] \\ &\quad + a_1 f_1(x_1, x_3) + \ddot{f}_1(x_1) - \dot{\ddot{x}}_d \\ &= c_1 \tilde{x}_2 + c_2 a_1 \tilde{x}_3 + c_3 a_1 \tilde{x}_4 + c_2 (f_1(x_1) - \hat{f}_1(x_1)) \\ &\quad + c_3 (\dot{f}_1(x_1) - \hat{f}_1(x_1)) + a_1 (f_1(x_1, x_3) - \hat{f}_1(x_1, x_3)) + (\ddot{f}_1(x_1) - \hat{f}_1(x_1)) - \eta (s - \hat{s}). \end{aligned} \quad (24)$$

Take the Lyapunov function as

$$V_c = \frac{1}{2}s^2. \quad (25)$$

Then,

$$\begin{aligned} \dot{V}_c &= s\dot{s} = s \left[ c_1\tilde{x}_2 + c_2a_1\tilde{x}_3 + c_3a_1\tilde{x}_4 + c_2(f_1(x_1) - \hat{f}_1(x_1)) + c_3(\dot{f}_1(x_1) - \hat{\dot{f}}_1(x_1)) \right. \\ &\quad \left. + a_1(f_1(x_1, x_3) - \hat{f}_1(x_1, x_3)) + (\ddot{f}_1(x_1) - \hat{\ddot{f}}_1(x_1)) - \eta(s - \bar{s}) \right] \\ &= -\eta s^2 + \eta s \left( c_1\tilde{x}_1 + c_2\tilde{x}_2 + c_3(a_1\tilde{x}_3 + f_1(x_1) - \hat{f}_1(x_1)) + a_1\tilde{x}_4 + \dot{f}_1(x_1) - \hat{\dot{f}}_1(x_1) \right) \\ &\quad + s \left[ c_1\tilde{x}_2 + c_2a_1\tilde{x}_3 + c_3a_1\tilde{x}_4 + c_2(f_1(x_1) - \hat{f}_1(x_1)) + c_3(\dot{f}_1(x_1) - \hat{\dot{f}}_1(x_1)) \right. \\ &\quad \left. + a_1(f_1(x_1, x_3) - \hat{f}_1(x_1, x_3)) + (\ddot{f}_1(x_1) - \hat{\ddot{f}}_1(x_1)) \right] \\ &= -\eta s^2 + s \left[ \eta c_1\tilde{x}_1 + (\eta c_2 + c_1)\tilde{x}_2 + (\eta c_3a_1 + c_2a_1)\tilde{x}_3 + (\eta a_1 + c_3a_1)\tilde{x}_4 \right. \\ &\quad \left. + (\eta c_3 + c_2)(f_1(x_1) - \hat{f}_1(x_1)) + (\eta + c_3)(\dot{f}_1(x_1) - \hat{\dot{f}}_1(x_1)) \right. \\ &\quad \left. + a_1(f_1(x_1, x_3) - \hat{f}_1(x_1, x_3)) + (\ddot{f}_1(x_1) - \hat{\ddot{f}}_1(x_1)) \right] \\ &= -\eta s^2 + s\chi(\tilde{x}) \leq -\eta s^2 + \frac{1}{2}s^2 + \frac{1}{2}\chi^2(\tilde{x}) \\ &= \left(\frac{1}{2} - \eta\right)s^2 + \frac{1}{2}\chi^2(\tilde{x}) = (1 - 2\eta)V_c + \frac{1}{2}\chi^2(\tilde{x}), \end{aligned} \quad (26)$$

where

$$\begin{aligned} \chi(\tilde{x}) &= \left[ \eta c_1\tilde{x}_1 + (\eta c_2 + c_1)\tilde{x}_2 + (\eta c_3a_1 + c_2a_1)\tilde{x}_3 + (\eta a_1 + c_3a_1)\tilde{x}_4 \right. \\ &\quad \left. + (\eta c_3 + c_2)(f_1(x_1) - \hat{f}_1(x_1)) + (\eta + c_3)(\dot{f}_1(x_1) - \hat{\dot{f}}_1(x_1)) \right. \\ &\quad \left. + a_1(f_1(x_1, x_3) - \hat{f}_1(x_1, x_3)) + \ddot{f}_1(x_1) - \hat{\ddot{f}}_1(x_1) \right]. \end{aligned} \quad (27)$$

Since observer (5) converges exponentially, i.e., at time  $t \rightarrow \infty$ ,  $\tilde{x}_1$  converges exponentially to  $\tilde{x}_2$ , and  $\tilde{x}_3$  to  $\tilde{x}_4$ . According to the Taylor series expansion of  $f_1(x_1) = -Mg/I \cdot \sin x_1 - K/I \cdot x_1$  and  $f_2(x_1, x_3) = K/I \cdot (x_1 - x_3)$ ,  $f_1(x_4) \rightarrow \hat{f}_1(x_1)$  converges exponentially to  $\dot{f}_1(x_1) \rightarrow \hat{\dot{f}}_1(x_1)$ ,  $f_1(x_1, x_3) \rightarrow \hat{f}_1(x_1, x_3)$ . Thus,  $\ddot{f}_1(x_1) \rightarrow \hat{\ddot{f}}_1(x_1)$  also converges exponentially to 0.

Considering the observer and the controller, the Lyapunov function of the closed loop is taken as

$$V = V_c + V_o. \quad (28)$$

According to equation (28), we have

$$\begin{aligned} \dot{V} &= \dot{V}_o + \dot{V}_c \leq -2rV_o - (2\eta - 1)V_c \\ &\quad + \frac{1}{2}\chi^2(\tilde{x}) \leq -\eta_1V + \chi(\cdot)e^{-\sigma_0(t-t_0)}, \end{aligned} \quad (29)$$

where  $\eta_1 = \{2r, (2\eta - 1)\}_{\max}$ ;  $\chi(\cdot)$  is the class  $K$  function of  $\|\tilde{x}(t_0)\|$ ; and  $\sigma_0 > 0$ .

According to Lemma 1, the solution to  $\dot{V} \leq -\eta_1V + \chi(\cdot)e^{-\sigma_0(t-t_0)}$  can be expressed as an inequality:

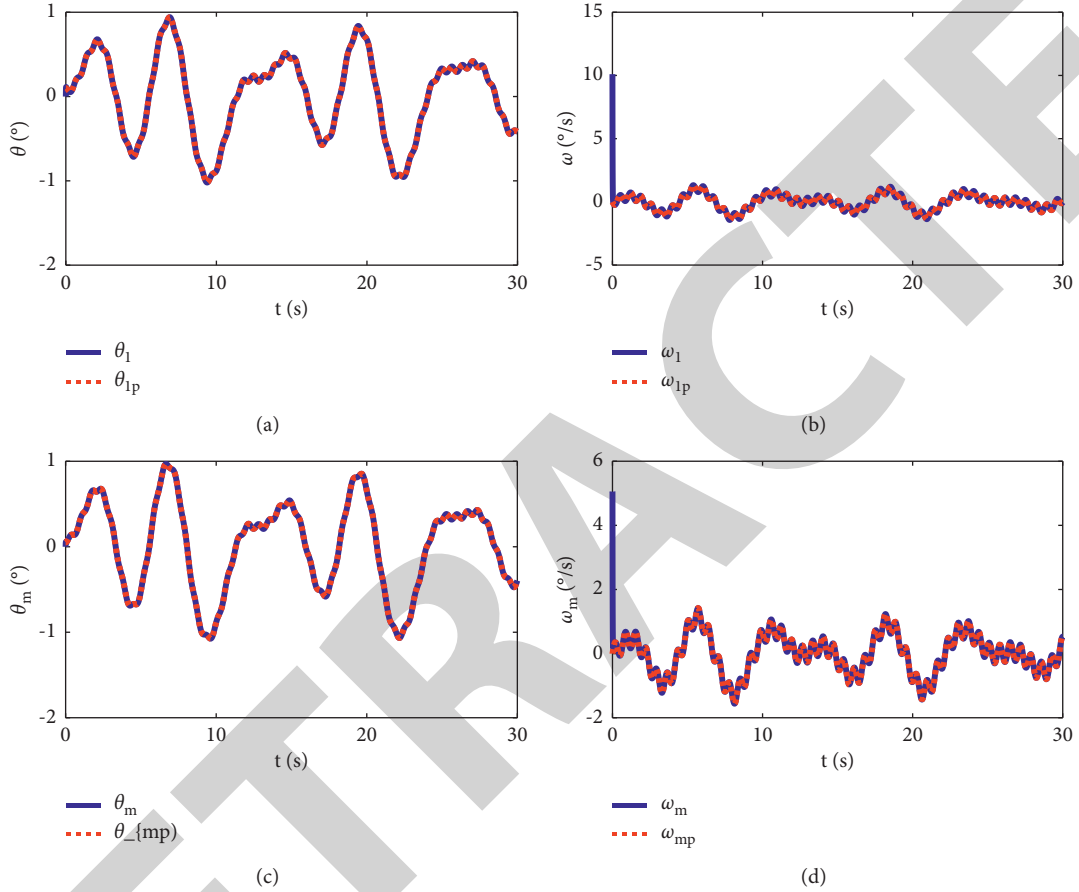

FIGURE 1: Simulation structure of the observer.

FIGURE 2: State estimations. (a)  $\theta$  state estimation. (b)  $\omega$  state estimation. (c)  $\theta_m$  state estimation. (d)  $\omega_m$  state estimation.

$$\begin{aligned}
 V(t) &\leq e^{-\eta_1(t-t_0)}V(t_0) + \chi(\Delta) \int_{t_0}^t e^{-\eta_1(t-\tau)} e^{-\sigma_0(\tau-t_0)} d\tau \\
 &= e^{-\eta_1(t-t_0)}V(t_0) + \chi(\cdot) e^{-\eta_1 t + \sigma_0 t_0} \int_{t_0}^t e^{\eta_1 \tau} e^{-\sigma_0 \tau} d\tau \\
 &= e^{-\eta_1(t-t_0)}V(t_0) + \frac{\chi(\Delta)}{\eta_1 - \sigma_0} e^{-\eta_1 t + \sigma_0 t_0} \left. e^{(\eta_1 - \sigma_0)\tau} \right|_{t_0}^t \\
 &= e^{-\eta_1(t-t_0)}V(t_0) + \frac{\chi(\Delta)}{\eta_1 - \sigma_0} e^{-\eta_1 t + \sigma_0 t_0} \left( e^{(\eta_1 - \sigma_0)t} - e^{(\eta_1 - \sigma_0)t_0} \right) \\
 &= e^{-\eta_1(t-t_0)}V(t_0) + \frac{\chi(\cdot)}{\eta_1 - \sigma_0} \left( e^{-\sigma_0(t-t_0)} - e^{-\eta_1(t-t_0)} \right).
 \end{aligned} \tag{30}$$

That is,  $\lim_{t \rightarrow \infty} V(t) \leq 0$ .

Since  $V(t) \geq 0$ , when  $t \rightarrow \infty$ ,  $V(t) = 0$ , and  $V(t)$  converges exponentially. The convergence accuracy depends on  $\eta_1$ , i.e.,  $r$  and  $\eta$ .

*Remark 3.* When the controller reaches the sliding mode surface, that is,  $s = 0$ , we have  $e_4 = -c_1 e_1 - c_2 e_2 - c_3 e_3$ . If

$$E_1 = [e_1 \ e_2 \ e_3]^T \quad \text{and} \quad A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -c_1 & -c_2 & -c_3 \end{bmatrix}, \quad \text{then}$$

$\dot{E}_1 = AE_1$ . Through the design of  $c_1$ ,  $c_2$ , and  $c_3$ ,  $A$  is Hurwitz zeta function. Thus, at time  $t \rightarrow \infty$ ,  $E_1 = [e_1 \ e_2 \ e_3]^T \rightarrow 0$ . To make  $A$  as a Hurwitz zeta function, the real root part of the following equation must be negative:

 FIGURE 3: State estimation errors. (a)  $\theta$  estimation error. (b)  $\omega$  estimation error. (c)  $\theta_m$  estimation error. (d)  $\omega_m$  estimation error.

FIGURE 4: Angle and angular velocity tracking with the proposed method. (a) Angle tracking. (b) Angular velocity tracking.

$$|A - \lambda I| = \begin{vmatrix} -\lambda & 1 & 0 \\ 0 & -\lambda & 1 \\ -c_1 - c_2 & -c_3 - \lambda & \end{vmatrix} = \lambda^2(-c_3 - \lambda) - c_1 - c_2\lambda. \quad (31)$$

That is,  $-\lambda^3 - c_3\lambda^2 - c_2\lambda - c_1 = 0$ . Taking the eigenvalue of  $-10$ ,  $(\lambda + 10)^3 = 0$ , from  $\lambda^3 + 9\lambda^2 + 27\lambda + 27 = 0$ , we can obtain that  $\lambda^3 + c_3\lambda^2 + c_2\lambda + c_1 = 0$ ,  $c_1 = 1000$ ,  $c_2 = 300$ , and  $c_3 = 30$ . Hence, the convergence condition can be satisfied.

## 4. Results and Discussion

**4.1. The Simulation of the Observer.** To verify the feasibility of the robust observer, a system was developed to run in an open loop and modelled considering the following external disturbance moments and modelling uncertainties:

$$\begin{cases} \dot{\theta}_1 = \omega_1, \\ \dot{\omega}_1 = a_1\theta_m + f_1(\theta_1) + \Delta_1(t), \\ \dot{\theta}_m = \omega_m, \\ \dot{\omega}_m = a_2u + f_2(\theta_1, \theta_m) + \Delta_2(t), \end{cases} \quad (32)$$

where  $\theta_1$ ,  $\omega_1$ ,  $\theta_m$ , and  $\omega_m$  are the position of rod 1, the angular velocity of rod 1, the position of rod  $m$ , and the angular velocity of rod  $m$ , respectively. The parameters were configured as follows:  $x = [\theta_1 \omega_1, \dots, \theta_m \omega_m]^T$ ,  $\Delta_1(t) = \sin t$ ,  $\Delta_2(t) = \cos t$ ,  $J = 1 \text{ kg} \cdot \text{m}^2$ ,  $Mgl = 5 \text{ Nm}$ , and  $K = 40 \text{ Nm/rad}$ . Before simulation, the system state was initialized as  $x(0) = [0.1 \ 0 \ 0.05 \ 0]^T$ , and the observer state is initialized as  $\lambda(0) = [0 \ 0 \ 0 \ 0]^T$ . The observer adopts the form of (4) and (5), with  $r = 100$ . Based on  $l_1 \geq 1/2 + r$  (5),  $l_2 \geq 1/2 + r$ ,  $D_1 \geq r$ , and  $D_2 \geq r$ , the following parameter values were selected:  $l_1 = l_2 = 101$ ,  $D_2 = D_4 = 1.0$ , and  $D_1 = D_3 = 101$ .

The simulation structure of the observer is given in Figure 1, and the simulation results are shown in Figures 2 and 3. Specifically, Figure 2 presents the flexible modes of the position states of the two joints and their derivatives (i.e., velocities), and Figure 3 displays the tracking errors of the states. It can be inferred that the proposed observer can completely observe each state of the system (as suggested by Figure 2) and fully track the states of the upper two joints after only 0.1 s (as indicated by the error curve in Figure 3, the errors are 0.001, 0.15, 0.0015, and 0.12 for Figures 3(a)–3(d)). Therefore, our method was proved to be fast and effective. Although there are disturbances in the system, i.e.,  $\Delta_1(t) = \sin t$  and  $\Delta_2(t) = \cos t$ , the observation results show the anti-interference ability and good robustness of the proposed observer.

**4.2. The Simulation of the Control Algorithm.** To verify the effectiveness of the proposed control algorithm, the system with  $\Delta_1(t) = 0.15 \sin t$  and  $\Delta_2(t) = 0.23 \cos t$  was taken as shown in equation (32), where  $x(0) = [0.2 \ 0 \ 0 \ 0]^T$  and disturbance torque is  $\lambda(0) = [0 \ 0 \ 0 \ 0]^T$ . The other parameters were kept the same as in simulation 1. The controller takes equation (23), with  $c_1 = 1000$ ,  $c_2 = 300$ ,  $c_3 = 30$ , and  $\eta = 1.5$ . The desired trajectory of joint 2 is  $\theta_{1d} = \sin$ . The simulation results are shown in Figures 4 and 5. The former presents the angle and angular velocity of the second joint of the manipulator, and the latter exhibits the observed values of each state of the manipulator.

As shown in Figure 4, the system state was stabilized in a limited time, despite the presence of external disturbances and fault signals, indicating that the system converges well under this controller. Because the initial state of the system is  $x(0) = [0.2 \ 0 \ 0 \ 0]^T$  and due to the existence of interference, there is a large error at the initial time. However, with the increase of control time, the system error decreases rapidly. Hence, our control method can effectively deal with the above problem. Figure 5 shows the results with PID controller; it can be seen that there is a large error in the position of PID control, and especially when the position reaches the maximum and minimum, the error is large.

As shown in Figure 6, our disturbance observer could observe the state information of the system with high accuracy and effectiveness. That is, the observed signals can be used in the controller design, which further illustrates the effectiveness of the method.

## 5. Conclusions

The improvement of a robust observer-based sliding mode is improved, and the efficiency of the model is improved in this paper. Aiming at the problems of high nonlinearity, strong coupling, and external interference in the system, we firstly designed a state observer for the system through the auxiliary reconstruction system, solved the state observation problem of the system, clarified the convergence condition of the observer through theoretical analysis, and verified it through simulation. Then, the position and velocity tracking problem was tackled. Considering the external disturbance, a sliding mode control of the flexible-joint manipulator was derived based on the robust observer. The control method ensures that the system state can converge exponentially to zero in finite time under different inputs and outputs. The simulation results show that the observer can quickly observe the state variables of the system. Also, combined with the sliding mode controller, the system error can quickly converge to zero. The proposed control strategy is simple and easy to implement.

Intrinsically disordered proteins (IDPs) possess at least one region that lacks a single stable structure in vivo, which makes them play an important role in a variety of biological functions. We propose a prediction method for IDPs based on convolutional neural networks (CNNs) and feature selection. The combination of sequence and evolutionary properties is used to describe the differences between disordered and ordered regions. Especially, to highlight the correlation between the target residue and adjacent residues, multiple windows are selected to preprocess the protein sequence through the selected properties. The shorter windows reflect the characteristics of the central residue, and the longer windows reflect the characteristics of the surroundings around the central residue. Moreover, to highlight the specificity of sequence and evolutionary properties, they are preprocessed, respectively. After that, the preprocessed properties are combined into feature matrices as the input of the constructed CNN. Our method is training as well as testing based on the DisProt database. The simulation results show that the proposed method can predict IDPs effectively, and the performance is competitive in comparison with IsUnstruct and ESpritz.

## 1. Introduction

Intrinsically disordered regions (IDRs) of proteins often play an important role in many biological functions while lacking a single stable structure in vivo [1]. Intrinsically disordered proteins (IDPs) can be fully or partially unstructured and generally include one or more IDRs [2]. IDPs are very common in eukaryotes. They carry out many important functions such as cell signaling and translation and can promote molecular recognition as well as protein-protein interactions [3]. Many functions of IDPs are directly associated with their structural attributes [4]. Moreover, previous studies have shown that IDPs are key players in human disease [5]. For example, 79% of cancer-related proteins are IDPs and 57% of cardiovascular disease-related proteins are IDPs [6, 7]. Besides, IDPs are also correlated with genetic diseases, neurodegenerative diseases, and Alzheimer's disease [8, 9]. Therefore, accurate prediction of IDPs is not only

important for protein description and functional annotations but also contributing to the drug design.

There are a lot of experimental techniques for identifying IDPs, such as X-ray crystallography, nuclear magnetic resonance (NMR), and circular dichroism (CD) spectroscopy. However, the experimental methods are expensive and time-consuming due to the difficulty of purification and crystallization [10]. Therefore, it is necessary to predict IDPs based on computational methods.

During the past decade, many computational methods are proposed for the prediction of IDPs. These methods can be roughly divided into three categories [11]. (1) Physicochemical-based methods: these methods are based on physicochemical properties and propensity scales of amino acids, such as FoldIndex [12], GlobPlot [13], and IsUnstruct [14]. FoldIndex predicts IDPs by calculating the ratio of average hydrophobicity to average net charge of protein sequences. GlobPlot establishes a mapping scale to reflect the relative tendency of each amino acid residue in the ordered

or disordered state based on the probability of each amino acid being in a regular secondary structure or random curl and predicts IDPs through a kernel function and filter. IsUnstruct uses the Ising model to describe the interaction between ordered and disordered states and achieves good performance. Thus, we select it as one of comparison methods. (2) Machine learning-based methods: these methods treat IDPs prediction as a binary classification problem that use positive and negative samples to distinguish ordered and disordered residues. Commonly used classification algorithms include neural network (NN), radial basis function network (RBFN), support vector machine (SVM), random forest, and so on. The representative methods in this category contain DisPSSMP [15], Dispredict [16], SPINE-D [17], ESpritz [18], RFPR-IDP [19], and so on. DisPSSMP combines RBFN and a matrix PSSMP to predict IDPs. The matrix PSSMP is a condensed position-specific scoring matrix (PSSM) according to different physico-chemical properties. Dispredict uses three kinds of features which include sequence information, evolutionary information, and structural information and predicts IDPs based on SVMs with Radial Basis Function kernel. SPINE-D is based on NN with two-hidden-layer neural network and an additional one-layer filter for smoothing prediction results. ESpritz is an ensemble of three NNs for predicting the N-terminal, internal, and C-terminal of proteins, respectively. Based on bidirectional recursive neural network, it achieves good prediction performance. Thus, it is also selected as a comparison method. (3) Meta methods: these methods combine various prediction methods into one model to further improve the prediction performance, such as MetaDisorder [20], DisCop [21], and MobiDB-lite [22]. MetaDisorder has 13 independent predictors. The final prediction result of MetaDisorder is obtained by the weighted value of the results of these 13 predictors. It possesses high prediction accuracy, but the operation is slow because it contains so many independent predictors. DisCop uses a rational design to construct a metapredictor, which selects the best performance set of 6 predictors from 20 basic predictors. The prediction results of these methods are then combined by using a regression model. MobiDB-lite is constructed based on 8 predictors, whose final consensus prediction is determined by voting.

In this paper, we propose a method to predict IDPs based on CNN and feature selection. Considering that CNN has achieved very good results in computer vision, natural language processing, and other fields, we expect to extract more hidden features by using CNN. Our previous work [23] confirms this expectation. In this paper, we improve the preprocessing process and reconstruct and train the CNN and further improve the prediction performance. The input features include sequence properties and evolutionary properties. Moreover, to highlight their specificity, sequence and evolutionary properties are preprocessed by multiple windows, respectively. Then, the preprocessed features are combined into a feature matrix as the input of the prediction model. Through preprocessing, the input information can reflect the relationships between each feature and its neighboring

features in the feature matrix and enrich the feature information extracted from protein sequences. Our prediction model contains two convolutional layers and one fully connection layer and is trained and tested on the DisProt database [24]. Finally, the proposed method is compared with two competitive prediction methods IsUnstruct and ESpritz based on the same test set.

## 2. Materials and Methods

We select 12 sequence properties and 20 pieces of evolutionary properties. The two kinds of properties are pre-processed, respectively, to highlight their specificity. Then, we train a CNN model which includes two convolutional layers and one fully connected layer to predict IDPs.

**2.1. Dataset.** The DisProt database is used to train and test the proposed methods. There are 803 protein sequences, which contain 1,254 disordered regions and 1,343 ordered regions, corresponding to 92,418 disordered residues and 315,856 ordered residues, respectively. The 803 protein sequences are randomly divided into two subsets according to the ratio of 9:1. The large dataset is the training set, containing 721 sequences with 85,184 disordered residues and 289,983 ordered residues. The small dataset is the test set, containing 82 sequences with 7,234 disordered residues and 25,873 ordered residues. Table 1 lists the specific information.

**2.2. Selected Properties.** Since the complexity of the protein sequence denotes how it can be rearranged in different ways, the low complexity regions are more likely to be disordered than ordered. We select five complexity features discussed in our previous work [25], which include topological entropy, Shannon entropy, and three amino acid propensities. Among these features, topological entropy may not be calculated directly from the protein sequence because the sequence contains 20 amino acids elements and the length of sequence does not satisfy the conditions for calculating topological entropy. Thus, before calculating the topological entropy, we map the protein sequence to 0-1 sequence. Considering the characteristics of disordered residues, large hydrophobic amino acid residues (I, L, and V) and aromatic amino acid residues (F, W, and Y) are mapped to 1, and other residues are mapped to 0. Given a protein region  $\{w(j), 1 \leq j \leq N\}$  of length  $N$ , its topological entropy  $H_T(w)$  can be calculated as follows:

$$H_T(w) = \frac{1}{N - (2^n + n - 1) + 1} \sum_{l=1}^{N-(2^n+n-1)+1} \frac{\log_2 p_{w_l^{2^n+n-1}}(n)}{n}, \quad (1)$$

where  $p_{w_l^{2^n+n-1}}(n)$  denotes the number of different subsequences with length of  $n$  in the region  $w(l) \dots w(2^n + n - 1)$ . The length of subsequences  $n$  satisfies the following:

$$2^n + n - 1 \leq |w| < 2^{n+1} + (n + 1) - 1. \quad (2)$$

TABLE 1: Datasets used in this paper.

Datasets	Disordered regions	Ordered regions	Disordered residues	Ordered residues
Training set	1,120	1,198	85,184	289,983
Test set	134	145	7,234	25,873
Total	1,254	1,343	92,418	315,856

For the same protein region  $w$ , the Shannon entropy  $H_S(w)$  can be described as follows:

$$H_S(w) = - \sum_{k=1}^{20} f_k \log_2 f_k, \quad (3)$$

where  $f_k$  ( $1 \leq k \leq 20$ ) is the probability of 20 amino acids appearing in the region  $w$ .

Three amino acid propensities are selected from GlobPlot [13], which contain Remark 465, Deleage/Roux, and Bfactor (2STD). For these three propensities, the protein region  $w$  is mapped to them, and then the average values of the mapped regions are calculated as follows:

$$\begin{aligned} m_p(w) &= [m_{p1}(w), m_{p2}(w), m_{p3}(w)] \\ &= \frac{1}{N} \sum_{l=1}^N w^{pi}(l), \quad i = 1, 2, 3. \end{aligned} \quad (4)$$

In (4), the parameter  $w^{pi}$  represents the mapped region of  $w$  with the  $i$ -th propensity, where  $i = 1, 2, 3$  correspond to Remark 465, Deleage/Roux, and Bfactor, respectively.

In addition, it has been demonstrated that disordered regions and ordered regions usually show different physicochemical properties, and thus physicochemical properties are very useful in IDPs prediction. We select seven commonly used physicochemical properties, which is collected by Jens et al [26]. They are steric parameter, polarizability, volume, hydrophobicity, isoelectric point, helix probability, and sheet probability. Following that, the average value of the mapped target region is calculated:

$$m_a(w) = [m_{a1}(w), \dots, m_{a6}(w), \dots, m_{a7}(w)] = \frac{1}{N} \sum_{l=1}^N w^{ai}(l). \quad (5)$$

Similar to (4), the parameter  $w^{ai}$  in (5) represents the mapped region of  $w$  with the  $i$ -th physicochemical properties and  $i = 1, 2, \dots, 7$ .

Finally, the PSSM is used to describe the evolutionary of each protein sequence as the evolutionary properties to enrich the information of protein sequences. They are obtained by performing three iterations of PSI-BLAST (Position-Specific Iterative Basic Local Alignment Search Tool) on NCBI (National Center for Biotechnology Information) nonredundant database with default parameters. For a protein sequence with length  $L$ , a  $L \times 20$  matrix  $M_{pssm-L}$  can be obtained. Then, the evolutionary properties of the region intercepted by the window of length  $N$  can be expressed by a  $N \times 20$  matrix  $M_{pssm-w}$ .

**2.3. Preprocessing.** In order to highlight their specificity, sequence and evolutionary properties are preprocessed, respectively. Given a protein sequence of length  $L$ , we select a window of length  $N$  and append  $N/2$  zeros to both ends of the protein sequence. For sequence properties, each region is intercepted by the window, and a 12 dimensional vector  $v_i$  ( $1 \leq i \leq L$ ) can be calculated by the following:

$$v_i = [H_T(w), H_S(w), m_p(w), m_a(w)]^T. \quad (6)$$

Assign  $v_i$  to each residue in the  $i$ -th window. Sliding the window, each residue is associated with multiple  $v_i$ . For each residue, the sequence feature vector  $x_j^{seq}$  ( $1 \leq j \leq L$ ) is the average of all  $v_i$  about it, which can be described as follows:

$$x_j^{seq} = \begin{cases} \frac{1}{j+N_0} \sum_{i=1}^{j+N_0} v_i, & 1 \leq j \leq N_0, \\ \frac{1}{N} \sum_{i=j+N_0-N+1}^{j+N_0} v_i, & N_0 < j \leq L - N_0, \\ \frac{1}{L_0 - j - N_0 + 1} \sum_{i=j+N_0-N+1}^{L_0-N+1} v_i, & L - N_0 < j \leq L. \end{cases} \quad (7)$$

In (7),  $X_j = [x_j^1 x_j^2 \dots x_j^{N_{win}} \dots x_j^{N_{win}}]$ , and  $X_j = [x_j^1 x_j^2 \dots x_j^{N_{win}} \dots x_j^{N_{win}}]$  denotes the sequence length after appending zeros.

For evolutionary properties, each region is intercepted by the window gets a  $N \times 20$  matrix  $M_{pssm-w}$ . We calculate the average value of the matrix of the intercepted region and obtain a 20 dimensional vector which is served as the evolutionary feature vector  $x_j^{evo}$  ( $1 \leq j \leq L$ ) for the central residue in the region:

$$x_j^{evo} = \left( \frac{1}{N} \sum_{l=1}^N M_{pssm-w}(l, 1:20) \right)^T. \quad (8)$$

Then, for each residue, a 32-dimensional feature vector  $x_j = [x_j^{seq}; x_j^{evo}]$  can be obtained.

In this paper, we select multiple windows to perform the preprocessing. According to the preprocessing, each residue can get a 32-dimensional feature vector  $X_j = [x_j^1 x_j^2 \dots x_j^{N_{win}} \dots x_j^{N_{win}}]$  for each window, where  $X_j = [x_j^1 x_j^2 \dots x_j^{N_{win}} \dots x_j^{N_{win}}]$  denotes the label of the window. Then, the feature vectors calculated by different windows are combined into a feature matrix. Assuming that the number

of selected windows is  $X_j = [x_j^1 x_j^2 \dots x_j^{n_{win}} \dots x_j^{N_{win}}]$ , the feature matrix of each residue  $X_j = [x_j^1 x_j^2 \dots x_j^{n_{win}} \dots x_j^{N_{win}}]$  can be expressed as follows:

$$X_j = [x_j^1 x_j^2 \dots x_j^{n_{win}} \dots x_j^{N_{win}}]. \quad (9)$$

So, each residue can obtain a feature matrix of  $32 \times N_{win}$ , where each row represents the preprocessing results of a certain feature at different windows and each column represents the preprocessing results of 32 features at a certain window. Thus, there are some correlations between the rows and columns of the feature matrix.

**2.4. Designing and Training the CNN.** We design a convolutional neural network (CNN) with two convolutional layers as well as one fully connected layer, and each convolutional layer is followed by a pooling layer, as shown in Figure 1. Since the scale of the feature matrix calculated is small, the convolution kernels are set to small scales when the CNN is designed. At the same time, because of the large number of learning samples, fewer convolution kernels and convolutional layers are selected to simplify the operation.

In the network, the activation functions of the convolutional layers are ReLu functions and the activation functions of the output layer are softmax functions. The parameters of the first convolutional layer (conv1) are set to  $3 \times 3 \times 1 \times 8$  preliminarily, where  $3 \times 3$  is the size of the convolution kernel, and 1 denotes the number of channels and 8 denotes the number of convolution kernels. Similarly, the parameter of the second convolutional layer (conv2) is  $2 \times 2 \times 8 \times 8$ . In each convolutional layer, the convolution step is 1 and performs same padding with zero. The two pooling layers use max pooling with  $2 \times 2$  filters.

In the designed CNN, the gradient descent algorithm is replaced by the Adam algorithm in the backward propagation to update parameters. In order to improve the operation speed, minibatch is used to update parameters. That is, the sample set is divided into multiple subsets of equal scale for each iteration, and each subset is used to calculate the gradient and update the parameters one by one. Finally, combined with the feature selection and extraction, Figure 2 shows the prediction procedure of the proposed method.

### 3. Results and Discussion

**3.1. Performance Evaluation.** Four metrics are used to evaluate the proposed method, which include sensitivity (Sens), specificity (Spec), weighted score (Sw), and Matthews correlation coefficient (MCC). The Sw and MCC can be computed as follows:

$$Sw = Sens + Spec,$$

$$MCC = \frac{(TP \times TN) - (FP \times FN)}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}} \quad (10)$$

where  $Sens = TP/(TP + FN)$ ,  $Spec = TN/(TN + FP)$ , and TP, TN, and FN as well as FP are corresponding to the

number of true positives, true negatives, false negatives, and false positives.

**3.2. Impacts of Different Number of Windows.** The lengths of windows are selected in the interval of [7, 55] firstly. The odd numbers in the interval are selected as the window lengths, which is [7, 9, . . . , 55]. Then, starting from the length of 7, we increase the step length from 1 to 4 to select windows, and thus the numbers of selected windows are 25, 13, 9, and 7, respectively. At this point, the parameters of conv1 and conv2 are set to  $3 \times 3 \times 1 \times 8$  and  $2 \times 2 \times 8 \times 8$ , respectively. The  $2 \times 2$  filters are used in the pooling layers to perform max pooling. The learning rate is 0.005. Table 1 and Figure 3 show the prediction results of 10-fold cross validation on the training set with different number of windows.

From Table 2, with the decrease in the number of windows, the value of Sens fluctuates and the value of Spec has an upward trend. And at the same time, the values of Sw and MCC increase with the decrease in the number of windows, as shown in Figure 3. Since the number of windows is inversely proportional to the distance between windows, when the window distance is small, that is, the number of windows is large, the redundancy of the calculated feature matrix is relatively high, and the prediction performance is damaged.

Considering that the prediction result of  $N_{win} = 7$  is similar to  $N_{win} = 9$ , we add some longer windows to them and make the length of the longest window around 90. In the case of  $N_{win} = 7$ , the set of window is [7, 15, . . . , 55]. We increase the number of windows by the distance between them which is equal to 8. Then, the window data set becomes [7, 15, . . . , 87] and  $N_{win} = 11$ . Similarly, in the case of  $N_{win} = 9$ , the set of window [7, 13, . . . , 55] is increased to [7, 13, . . . , 91], and the number of windows in the new set is  $N_{win} = 15$ . The prediction results of them are shown in Table 3.

From Table 3, adding some longer windows can improve the value of Sw. And the Sw of  $N_{win} = 11$  and  $N_{win} = 15$  is similar. However, the MCC of  $N_{win} = 11$  is much larger than that of  $N_{win} = 15$ , so we choose the windows in  $N_{win} = 11$ , that is, [7, 15, . . . , 87].

**3.3. Impacts of Different Number of Convolutional Layers.** Our CNN model is designed by several submodules which contain a convolutional layer and a pooling layer. Thus, when we add a convolutional layer, it is followed by a pooling layer. In this section, we add convolutional layers on the basis of the network structure in Figure 2, which includes 2 convolutional layers. For all the additional convolutional layers, the parameter is set to  $2 \times 2 \times 8 \times 8$ . Table 4 shows the prediction results of 10-fold cross validation on the training set with different convolutional layers.

In Table 4, with the increase in the number of layers, although the values of Spec fluctuated, the values of Sens show downward trend and the values of Sw and MCC also show downward trend. Therefore, we still use two convolutional layers in the prediction model.

FIGURE 1: The structure of the CNN.

FIGURE 2: The prediction procedure of the proposed method.

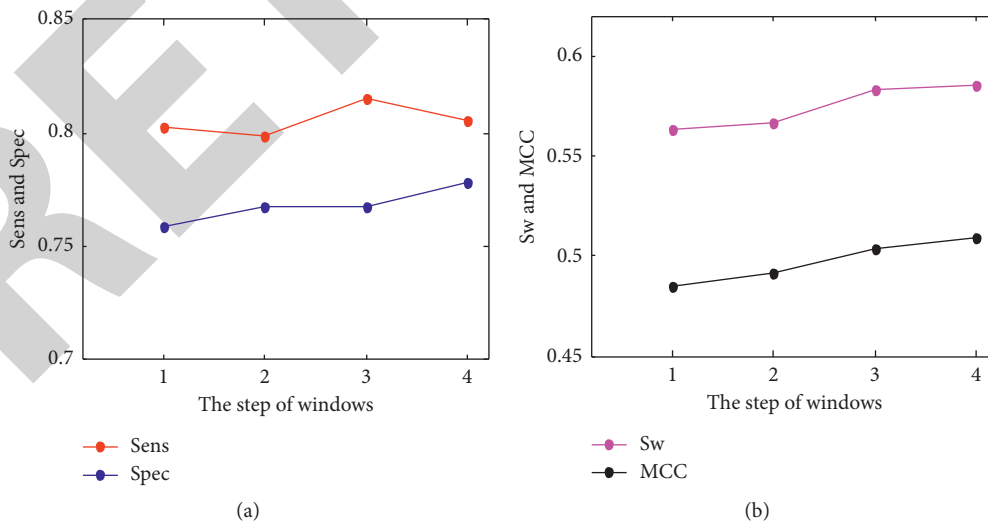

FIGURE 3: The trend of each evaluation parameter with different number of windows.

**3.4. Impacts of Different Scales of Convolution Kernels.** We change the scale of convolution kernels to analyze the influence on the prediction performance. Firstly, the number

of convolution kernel in conv1 is set to 8, and the parameter of the second convolution layer conv2 is  $2 \times 2 \times 8 \times 8$ . At the same time, the scale of the convolution kernel in conv1 is

TABLE 2: Prediction performance of different number of windows.

Step length	$N_{win}$	Sens	Spec	Sw	MCC
1	25	0.8032	0.7594	0.5626	0.4852
2	13	0.7991	0.7676	0.5667	0.4909
3	9	0.8153	0.7676	0.5829	0.5038
4	7	0.8061	0.7787	0.5848	0.5089

TABLE 3: Prediction performance of different number of windows.

Window distance	$N_{win}$	Sens	Spec	Sw	MCC
8	7	0.8061	0.7787	0.5848	0.5089
8	11	0.7833	0.8146	0.5979	0.5332
6	9	0.8153	0.7676	0.5829	0.5038
6	15	0.8914	0.7056	0.5970	0.5012

TABLE 4: Prediction performance of different convolutional layers.

Number of convolutional layers	The scale of convolutional parameter	Sens	Spec	Sw	MCC
2	$3 \times 3 \times 1 \times 8, 2 \times 2 \times 8 \times 8$	0.7833	0.8146	0.5979	0.5332
3	$3 \times 3 \times 1 \times 8, (2 \times 2 \times 8 \times 8) \times 2$	0.7813	0.7961	0.5774	0.5092
4	$3 \times 3 \times 1 \times 8, (2 \times 2 \times 8 \times 8) \times 3$	0.7654	0.7945	0.5599	0.4946
5	$3 \times 3 \times 1 \times 8, (2 \times 2 \times 8 \times 8) \times 4$	0.7513	0.8028	0.5541	0.4932

changed as shown in Table 5. Since the scale of feature matrix is only  $32 \times 11$ , the scale of convolution kernel should not be too large. We select four scales for comparison. Table 5 shows the prediction results of 10-fold cross validation on the training set with different convolution kernels in conv1. Although kernel of  $2 \times 2$  gets the highest Sens and kernel of  $4 \times 4$  gets the highest Spec, these four scales of convolution kernel obtain similar Sw and MCC. Considering that the Sw of kernel of  $2 \times 2$  is slightly higher than others, we finally set the convolution kernel of conv1 to  $2 \times 2$ .

After determining the scale of convolution kernel in conv1, we change the scale of convolution kernel in conv2. In this case, the parameter of conv1 is  $2 \times 2 \times 8 \times 8$ . Similar to the selection of conv1, we also compare the same four scales for conv2. The predicted results are shown in Table 6.

The convolution kernels of  $5 \times 5$  and  $3 \times 3$  obtain the highest Sens and Spec, respectively. However, the kernel of  $2 \times 2$  possesses much better Sw. Therefore, the scale of convolution kernel in conv2 is set to  $2 \times 2$ .

### 3.5. Impacts of Different Number of Convolution Kernels.

In this section, the number of convolution kernels is changed to analyze the influence on the prediction performance. In the design of CNN, the numbers of two convolution layers are set to be the same in analyzing the influence of the number of convolution kernels. Table 6 shows the prediction results of 10-fold cross validation on the training set when  $N_{c1} = N_{c2} = 4, 8, 16, 32$ .

From Table 7, with the increase in number of kernels, the values of Sw and MCC show downward trend, and  $N_{c1} = N_{c2} = 4$  gets better prediction performance.

TABLE 5: Prediction performance of different scales of convolution kernel in conv1.

The scale of conv1	Sens	Spec	Sw	MCC
$2 \times 2$	0.7972	0.8090	0.6062	0.5373
$3 \times 3$	0.7833	0.8146	0.5979	0.5332
$4 \times 4$	0.7553	0.8414	0.5967	0.5457
$5 \times 5$	0.7573	0.8377	0.5950	0.5423

TABLE 6: Prediction performance of different scales of convolution kernel in conv2.

The scale of conv2	Sens	Spec	Sw	MCC
$2 \times 2$	0.7972	0.8090	0.6062	0.5373
$3 \times 3$	0.7715	0.8291	0.6006	0.5422
$4 \times 4$	0.7832	0.8047	0.5879	0.5210
$5 \times 5$	0.8169	0.7734	0.5902	0.5114

TABLE 7: Prediction performance of different number of convolution kernel in conv1.

$N_{c1}, N_{c2}$	Sens	Spec	Sw	MCC
4	0.7960	0.8321	0.6281	0.5654
8	0.7972	0.8090	0.6062	0.5373
16	0.7442	0.8349	0.5791	0.5282
32	0.8226	0.7436	0.5660	0.4838

Thus, the number of convolution kernel in conv1 is fixed on 4.

Then, we only change the number of convolution kernel in conv2. Table 8 shows the prediction results when  $N_{c2} = 4, 8, 16, 32$ . From Table 8, it obtains better Sw and MCC when  $N_{c2} = 4$ . Therefore, the parameters of conv1 and conv2 are set to  $2 \times 2 \times 1 \times 4$  and  $2 \times 2 \times 4 \times 4$ , respectively.

TABLE 8: Prediction performance of different number of convolution kernel in conv1.

$N_{c1}, N_{c2}$	Sens	Spec	Sw	MCC
4	0.7960	0.8321	0.6281	0.5654
8	0.7972	0.8090	0.6062	0.5373
16	0.7442	0.8349	0.5791	0.5282
32	0.8226	0.7436	0.5660	0.4838

TABLE 9: Prediction performance of different number of convolution kernel in conv1.

Methods	Sens	Spec	Sw	MCC
Our method	0.7264	0.8301	0.5565	0.5060
IsUnstruct	0.7513	0.7855	0.5368	0.4711
ESpritz	0.7255	0.8135	0.5389	0.4840

3.6. *Comparison with Other Methods.* Our method is compared with other two state of the art methods IsUnstruct and ESpritz in this section. Table 9 shows the prediction performance of three methods based on the test set. The prediction results of IsUnstruct and ESpritz are obtained by their respective network predictors. As shown in Table 9, our method gets the best Spec and similar Sens as ESpritz and thus obtains higher Sw and MCC.

## 4. Conclusions

In this paper, we propose a method to predict IDPs based on CNN and feature selection. Sequence properties and evolutionary properties are used to describe the differences between disordered residues and ordered residues. To highlight their specificity, sequence and evolutionary properties are pre-processed by 11 windows from length 7 to length 87, respectively. Then, the preprocessed features are combined into a feature matrix as the input of the prediction model. CNN can reflect the relationship between each feature and its neighboring features in the protein feature matrix and find out more information from different features and thus enrich the information proposed by protein sequences. Thus, we construct a CNN prediction model with two convolution layers and one fully connected layer, and each convolution layer is followed by a pooling layer. The parameters of each convolution kernel are set to  $2 \times 2 \times 1 \times 4$  and  $2 \times 2 \times 4 \times 4$ , respectively. The simulation results show that the prediction performance of the proposed method gets better Sw and MCC than two competitive prediction methods IsUnstruct and ESpritz.

## Data Availability

The datasets supporting the conclusions of this article are available on the DisProt database [24] (<http://www.disprot.org/>).

## Additional Points

In this paper, the authors add the technical details and experiments, improve the preprocessing process, retrain the prediction network, and improve the prediction performance.

## Disclosure

The previous work “Prediction of Intrinsically Disordered Proteins with Convolutional Neural Networks Based on Feature Selection” [23] is published in 2021 International Conference on Computer Engineering and Artificial Intelligence. The funding bodies have no role in the design of the study and collection, analysis, and interpretation of data and in writing the manuscript.

## Conflicts of Interest

The authors declare that they have no conflicts of interest.

With the support of network information technology, the Online Knowledge Community (OKC) has emerged. Among different OKC applications, some entered into the new era of popular knowledge production, while others experienced the process to decline. In order to solve the dilemma faced by the OKC platforms, the needs-affordances-features (NAF) perspective on OKC is proposed by taking Zhihu, one of the most popular OKC applications in China as an example. According to NAF, the psychological needs of individuals motivate the use of Zhihu to the extent to which Zhihu offers affordances that satisfy the individuals' needs. By collecting data through questionnaires and using SPSS and AMOS for data analysis, the relationship between individuals' psychological needs and Zhihu affordances is identified. This paper generates two aspects of implications. In terms of theoretical implications, a more comprehensive framework is developed for the affordances of OKC as a whole, and the NAF model is leveraged to identify related psychological needs which motivate the use of a specific OKC application—Zhihu. Further research can leverage NAF to identify different OKC platform features which satisfy the psychological needs of their targeting users to optimize the system of OKC platforms. As for practical implications, by building the relationship between the affordances of OKC platforms and users' psychological needs, marketers have to realize that although the digital platform system has a certain degree of imitability, the value positioning, user community, and core capabilities behind those platforms are all different. Thus, the platform system must also be differentiated. In order to determine the appropriate business model, a clear understanding of these organizational features should be identified.

## 1. Introduction

Knowledge management has attracted the attention of many researchers due to its close relationship with organizational performance [1]. In the Internet age, the “Online Knowledge Community” (OKC) that integrates the functions of “knowledge sharing” and “online social networking” has emerged. With the opening of registration restrictions, a large number of ordinary users have poured in. Representative OKC platforms such as Douban and Zhihu have entered the second stage of development from the early stage of highly acclaimed and rapid development: the era of popular knowledge production [2]. The vast information capacity and random insertion and editing at any time have significantly increased the amount of information and the

level of confusion, which changed the traditional online communication methods [3]. At the same time, the operation of knowledge communities is facing a complex situation. For example, although Wukong Questions and Answers (Q&A) application persuaded over about 300 influencers of Zhihu to join with a high salary in 2017, the server of Wukong Q&A ceased operation in 2021 [4]. During the same period, Zhihu ushered in its tenth birthday celebration, and there were rumors of listing on the stock market. There is the success of Zhihu, while there is also the shutdown of Encarta, the failure of Google Answers, the decline of Wikipedia [5, 6], and the quit of Wukong Q&A, which operated less than four years independently.

Of these OKC platforms, why do high-quality creators prefer Zhihu? From a social-technical perspective, the OKC

platform is a collection of users' behavioral possibilities and needs in social media and organizational environments [7]. Its value is created by digital technology and is cocreated by the interaction between the user, the technology, and the purpose of use [8]. Ongus [9] also mentioned that the quality and relevance of technology resources and information content are closely related to users' needs. Therefore, the platform functions or resources enabled by platform features are essential for users' needs. However, the current literature has not yet studied this mechanism, resulting in a "black box" of the platform system. In the research of Facebook using motivations, the needs-affordances-features (NAF) model was first suggested by focusing on platform characteristics in the context of social media [10]. According to NAF, the psychological needs of individuals motivate the use of applications to the extent to which these applications offer affordances that satisfy individuals' needs (ibid). As OKC is similar to social media given the "online social networking" functions, the NAF model is proposed to address the following questions:

- (1) What innate psychological needs do people seek to satisfy through OKC?
- (2) What are the main affordances provided by OKC?
- (3) Which of these OKC affordances meet which psychological needs?

In this paper, according to the literature review, the needs-affordances-features (NAF) model is used to identify the relationship between psychological needs, affordances, and features. Based on the research of psychological needs, OKC affordances, and Zhihu features, hypotheses of this paper are suggested, and the conceptual framework is sorted out. In the final, from data collection and analysis, the relationship between individuals' psychological needs and Zhihu affordances is identified. The result shows that each of the Zhihu affordances is likely related to fulfilling some psychological needs. For example, the need for autonomy can motivate people to use Zhihu that has the affordance of browsing others' content, while the need for relatedness can motivate the use of Zhihu that has affordances of self-presentation, relationship formation, and meta-voicing.

In terms of the research gap, although current research has noticed that the platform's community ecology and value cocreation may play an essential role in optimizing the platform, the platform is mainly regarded as an intermediary connection point and ecological core node [11, 12]. That is to say, there is a lack of analysis of the internal micro-mechanism based on the platform's individualization and differentiation. Therefore, this paper will address the "black box" of the platform system. With the consideration of platform affordances, the interaction relationship between the platform and users will be studied from the dimensions of core functions and resources to enrich the theoretical system of the platform further and achieve theoretical innovation. In the view of practice, from the fact that Wukong Q&A has invested billions in the construction of the community, although it still fell to the ground, it can be seen that different platform affordances could create different

community ecology. The research of this topic can guide more platforms to design more effective OKC applications under the premise of unifying user needs and organizational characteristics, which could lead to avoiding waste of social resources and improving the success rate of Internet innovation.

## 2. Literature Review

*2.1. Online Knowledge Community (OKC).* Online Knowledge Community (OKC) refers to a virtual space where users scattered in different regions carry out knowledge exchange and interpersonal interaction with the support of network information technology [13], which is a typical social-technical system [14]. OKC has the collaborative ordering of the social and knowledge systems, and users are the driving force of ordering the two systems [3, 15].

Currently, OKC research focuses on three hot areas: user research, content research, and community research [2]. User research mainly explores OKC users' behavior characteristics and patterns and analyzes user motivation for participation and the interaction between users. Content research focuses on content quality measurement and evaluation, semantic analysis, and topic recognition, influencing factor analysis, relationship research, and so forth. Community research is about conducting research on community operation mechanisms, content generation models, and community comparisons. The representative viewpoints are as follows: the field of information management emphasizes the impact of IT technology on knowledge proliferation [16]; the field of sociology pays more attention to the impact of trust on online interaction [17]. Guan et al. [18] believed that knowledge inflow is the key and examine the antecedents of knowledge contribution behavior in multiple dimensions. In contrast, Lai et al. [19] and Zhao and Huang [20] believed that knowledge search is equally important. They examine the antecedents of knowledge search behavior from the perspectives of behavior attitude, subjective norms, and ability beliefs. In terms of user research, opinion leaders or leading users usually have more experience or mastered more professional knowledge, so their behaviors are more exploratory or creative, and they are easier to gain trust. In addition, knowledge contribution is their important active behavior [21].

*2.2. Affordance Theory.* Affordance originally refers to the support that objective things can provide for a certain behavior, that is, action possibilities permitted by properties of objects [22]. In recent years, it has become more popular in organizational research and can be used to better understand the impact of the combination of new technologies and organizational characteristics on organizational innovation and operations [23]. "Affordance" provides not only a strong theoretical perspective for studying the relationship between technology and personnel in an organization but also a better language for the structured and patterned description of specific practices [24].

As a commonly used communication method, social media affordances have an important influence on the organization's communication process, employee and user behavior, and psychology, so it is currently a hot topic of affordance research. Postigo [25] first analyzed, from the perspective of social-technical interaction, how YouTube guides users to conduct behaviors that are beneficial to the commercial interests of the platform through the design of platform architecture. Rice et al. [7] defined social media affordances as the relationship between the action possibility and the need (or purpose) perceived by users aggregated in social media and the organizational environment under the constraints of the potential features/functions of the social media platforms. Majchrzak and Faraj [23] studied the relationship between the different ways through which employees participate in publicly visible conversations on social media platforms and knowledge sharing. Sun et al. [26] divided the use of social media platforms into three categories: interactivity (conversations between users and comments on related information), accessibility (users can obtain relevant information), and sociality (users establish connections with other users).

There are many research results around the dimension of affordances. Treem and Leonardi [27] proposed four dimensions of social media affordances, visibility, associating, editability, and persistence, which have been commonly used [24, 26, 28]. Majchrzak and Faraj [23] proposed four dimensions of affordances for knowledge sharing (meta voicing, trigger attending, network-informed associating, generative role-taking). In addition, there are six dimensions of functional media affordances [7], ten dimensions of communication affordances [29], and six dimensions of social business technology affordances [30]. As for new media affordances, Pan and Liu [31] proposed production affordances (including editability, reviewability, replicability, scalability, and associability), social affordances (including greet-ability, emotion-ability, coordinate-ability, and connect-ability), and mobile affordances (including portability, availability, locatability, and multimodality), which reflect the initiative of the information prosumer.

The most integrated literature is proposed by Karahanna et al. [10], who divide social media affordances into ego-centric and allocentric affordances based on the theory of self-determination and psychological ownership. In addition, the research framework for social media adoption and use is proposed, which is the needs-affordances-features (NAF) model, and an empirical study of affordances is conducted with Facebook as an example. Zhang and Huang [32] discussed the realization of platform affordances from aspects of technology affordances and social affordances and emphasized that users' perceptions and actions must be considered when gaining insight into the complex relationship between technology and society.

Based on the above literature, OKC affordances could be divided into platform affordances and product affordances in this research. Platform affordances include technology affordances and social affordances. However, this paper focuses on the relationship between individuals' psychological motivations and OKC affordances. Compared to

technology affordances which provide technical support for platform affordances, social affordances can better reflect the relationship between platform affordances and people's psychological needs for using a certain OKC platform. As a result, social affordances will be used as platform affordances in this research, which is realized by platform functions, such as Zhihu platform features. Product affordances focus on the affordances of OKC knowledge resources, referred to as knowledge affordances (see Table 1).

*2.3. NAF Perspective for OKC.* The psychology literature shows that people are driven to engage in activities that fulfill their innate psychological needs. Therefore these psychological needs are stimulating states that act as motivations for action [33]. Based on this premise, a needs-affordances-features (NAF) perspective shows that innate psychological needs motivate people to use OKC apps, which have affordances to satisfy their psychological needs potentially. For example, OKC apps provide the affordance to connect with others, through features such as "Following" and "Chatting" on Zhihu. This affordance can be used to satisfy people's psychological needs for relatedness. Therefore, this psychological need drives them to participate in using Zhihu features that provide this affordance to meet this psychological need (see Figure 1).

*2.4. Relationship between Psychological Needs and OKC Affordances.* Although there is no research to categorize psychological needs in the OKC context, research on human motivations shows that "motivation can be conceived as a duality" [34]. On the one hand, people focus on the self. On the other hand, they strive for relationships between the self and others. Hermans [35] suggested the former motivation as the S-motive and the latter as the O-motive. Based on self-determination theory (SDT) [33, 36] and psychological ownership theory (POT) [37–39], seven psychological needs are listed, which span the two polarities and illustrate people's self-focused and other-focused motivations. Thus, these two theories are synthesized in this paper to show psychological needs in a more comprehensive way. According to the terminology of Hermans [35], these seven psychological needs are divided into the self-focused group, also called S-needs (need for autonomy, competence, having a place, coming to know the self, maintaining continuity of self-identity, and one aspect of expressing self-identity), and the other-focused group, also called O-needs (need for relatedness and one aspect of expressing self-identity).

According to Karahanna et al. [10], there are 12 social media affordances, which constitute egocentric affordances (self-presentation, content sharing, and interactivity) and allocentric affordances (presence signaling, relationship formation, group management, browsing other's content, meta-voicing, communication, collaboration, competition, and sourcing). As OKC is a typical social-technical system equipped with the function of "online social networking," these 12 social media affordances will be used to analyze the OKC social affordances. However, in addition to social

TABLE 1: OKC affordances concept system.

	Affordance concept system		Platform factors

	Product affordances	Knowledge affordances	Platform resources

FIGURE 1: Logic of the NAF perspective.

affordances, OKC has its specific product, which is knowledge. According to Shi et al. [40], knowledge affordances are defined as unique attributes of knowledge that meet the needs of consumers, which can be measured in 4 dimensions (reliability, economies, selectivity, and uniqueness). In order to map the OKC affordances to psychological needs, Table 2 is shown based on former research [10] and six OKC researchers (see Table 3 for details of term definitions).

**2.5. Literature Gaps.** First, there is a lack of platform features in the context of OKC research. At present, the OKC research has three hot areas: users, content, and communities/platforms, and OKC affordances have also attracted much attention. However, the OKC research focuses on the field of subrole characteristics and its socialization mechanism and lacks attention to platform differences. Second, people’s attention to the role of psychological needs in motivating the use of the OKC platforms is limited. In particular, there has not been a comprehensive theoretical-based attempt to determine a set of psychological needs that are salient in the OKC environment. In most studies, the focus is not on theorizing around psychological needs, but the needs variable is one of the many variables included in the research model. Third, current studies did not adopt a systematic method to identify the OKC affordances that meet these needs. On the contrary, most people measure need satisfaction to confirm whether affordances meet people’s psychological needs. The focus on the relationship between psychological needs and OKC affordances provides valuable operational design guidelines for information system researchers and practitioners. Our research aims to address these gaps.

### 3. Research Model and Hypotheses

There are three steps of developing the NAF model in the use of the Zhihu application. Firstly, to understand what psychological motivations of using this app, the affordances provided by the Zhihu platform should be identified. In 2011, the mission of Zhihu was officially launched, which is “allowing people to share knowledge, experience and insights better and find their own answers” [58]. After nearly ten years of development, Zhihu announced the brand

renewal and upgrade at the 2021 New Knowledge Youth Conference. The brand slogan has been upgraded from “If there is a question, go to Zhihu” to “If there is a question, there will be an answer” (ibid). These show that self-presentation, content sharing, browsing others’ content, and sourcing are salient affordances of Zhihu. Based on the functions of chatting and live Q&A, liking or collecting others’ content, and voting for what others posted, it is obvious that communication and meta-voicing are also affordances of Zhihu. In addition, there is a function of “Quanzi” in Zhihu, which offers a community for the group of people who have common interests, where they could share and communicate about their experience and opinions in their own circle. As a result, relationship formation is also one of the social affordances of Zhihu. After identifying salient affordances, the most popular features of Zhihu were selected from a synthesis of research on the condition that affordances are provided by specific features of an object [52, 57, 59, 60]. With the combination of its knowledge properties, six researchers with research expertise in OKC (three faculty and three doctoral students) are asked to map the features to the 13 OKC affordances listed in Table 2. Table 4 illustrates the result of the mapping of Zhihu features to Zhihu affordances. Therefore, Zhihu affordances are identified as self-presentation, content sharing, relationship formation, browsing others’ content, meta-voicing, communication, sourcing, and knowledge attributes.

In order to predict which Zhihu affordances meet which psychological needs, the hypotheses are suggested as follows.

According to Deci [61], autonomy is defined as people’s innate psychological needs to act authentically in their own life. Everyone is inherently eager for autonomy [62]. They participate in activities, not because of social norms or pressures but because they are free to choose [33, 63]. Therefore, we suggest that self-presentation, content sharing, relationship formation, browsing others’ content, and sourcing are affordances that motivate users to use Zhihu. For example, those affordances allow individuals of Zhihu to choose how to present themselves (through uploading video and photos, disclosing locations), what content to share, whom to follow, what kind of community to join, and what questions to suggest or answer, which leads to hypothesis 1.

TABLE 2: Mapping of the psychological needs to OKC affordances.

OKC Affordances		Needs						
		S-NEEDS			O-NEEDS			
		A	C	HP	CK	MC	ES	R
Social Affordances	Self-presentation	√		√		√	√	√
	Content Sharing	√		√		√	√	
	Interactivity	√		√				
	Presence Signaling							√
	Relationship Formation	√					√	√
	Group Management		√					√
	Browsing Others' Content	√			√			√
	Meta-voicing		√		√		√	√
	Communication						√	√
	Collaboration		√		√			√
	Competition		√		√			
	Sourcing	√	√					
Knowledge Affordances	Knowledge attributes		√					

Note: A = autonomy; C = competence; HP = having a place; CK = coming to know the self; MC = maintaining continuity of self-identity; ES = expressing self-identity; R = relatedness.

H1: The need for autonomy can motivate the use of Zhihu that has these affordances: self-presentation, content sharing, relationship formation, browsing others' content, and sourcing.

In 1991, Deci and Ryan illustrated that relatedness is individuals' innate psychological need to be connected to others. In 2000, Deci and Ryan extended the definition as the need "to love and care and to be loved and cared for." Thus, we posit that a set of Zhihu affordances—self-presentation, relationship formation, browsing others' content, meta-voicing, and communication—can help people satisfy the need for relatedness by creating social connections with others. This can be realized by reaching a lot of users, joining an online group, knowing what others are doing, reacting to others' posts, and so forth [64, 65]. For example, in the context of Zhihu, users can increase social interactions by posting personal information (self-presentation), following a user (relationship formation), browsing others' posts (browsing others' content), voting for a post (meta-voicing), sending an instant message to others (communication), and so forth. Therefore, the H2 is proposed as follows.

H2: The need for relatedness can motivate the use of Zhihu that has these affordances: self-presentation,

relationship formation, browsing others' content, meta-voicing, and communication.

Bauer and McAdams [66] analyzed that competence refers to people's innate psychological needs to deal with their environment effectively. It is the psychological needs that can be achieved by having an impact on individuals or the environment. White [67] showed that individuals need to feel competent in controlling or altering the environment and finding opportunities to increase their own knowledge or skills. Therefore, people who have a high demand for competence are more likely to seek affordances that provide them with opportunities to apply or expand their knowledge in the environment. Thus, we suggest that the affordances of meta-voicing, sourcing, and knowledge attributes can fulfill individuals' needs for competence by providing feedback to others' posts, responding to others' questions, searching answers, subscribing to valuable content, attending online courses, and so on. Thus, hypothesis 3 is suggested.

H3: The need for competence can motivate the use of Zhihu that has the following affordances: meta-voicing, sourcing, and knowledge attributes.

In terms of having a place, it refers to people's innate psychological needs to possess a place where they can create their own space [68, 69]. Pierce et al. [70] suggest

TABLE 3: OKC affordances.

Affordances	Definitions	Example features
	Social affordances	
Self-presentation	Users can display and present information related to themselves. This includes sharing information that somehow portrays users and shows who they are, their values and preferences, their expertise, etc. Updating descriptive information about themselves, such as gender, occupation, and location; and posting content involving pictures and videos related to themselves [41–44]	Posting my own content on Zhihu; sharing my own video on YouTube; updating my profile on Zhihu; writing personal opinions on Zhihu
Content sharing	Users can share and distribute content unrelated to them to others (e.g., sharing posts, video) [27, 45, 46]	Sharing links of other people’s articles on Zhihu; sharing others’ videos and photos on Instagram
Interactivity	Users can walk around in real time and change their virtual environment (e.g., to build in-world artifacts) [41]	Moving around in World of Warcraft
Presence signaling	Users can indicate their existence and know whether other users are accessible [43, 44, 47]	“Who is online” on Instagram
Relationship formation	Users can establish relationships with others, including joining groups or online communities [27, 45]	Following other users on Zhihu; joining an online community (e.g., “Quanzi” on Zhihu)
Group management	Users can form groups and online communities and manage them. The focus is on the management or administration of groups [45, 46]	Illegal content management on Zhihu, forming a “Quanzi” on Zhihu
Browsing Other’s content	Users can view others’ content and receive alerts to pay attention to others’ content [41, 42, 45]	Browsing others’ content on Zhihu, receiving notifications on LinkedIn
Meta-voicing	Users can participate in online conversations by responding to other people’s status, profile, content, and activities online and viewing other people’s responses to their status, profile, content, and activities. In meta-voice, the user “not only has to express his or her opinion, but also add meta-knowledge to content already online.” [23, 48]	Voting on a post on Zhihu, answering questions on Zhihu, liking what others post on Zhihu
Communication	Users can chat or send messages with others directly [41, 44, 47]	Chatting on Zhihu, communicating with others on Google+
Collaboration	Users can collaborate with others, such as collaborating with others to create content on Wikipedia [23, 43, 48]	Adding, deleting, and editing content on Zhihu
Competition	Users are able to compete with others, which includes competing in online games [10]	Completing tasks in World of Warcraft
Sourcing	Users are able to ask for resources or funds, including meeting others’ requests for funds or resources [10]	Asking or answering questions on Zhihu
	Knowledge affordances	
Knowledge attributes	Reliability: It refers to the extent to which the answers on social Q&A websites make users feel trustworthy and reliable [49]. Users think that the answer is of high quality only when they believe that the source and content of the answer are reliable [50]	The reliability of Zhihu content is reflected in its questions, answers, articles, videos, pictures, etc.
	Selectivity: Users can subscribe to specific content or sources of information [51]	Zhihu involves popular and unpopular content in multiple sections, and the content knowledge within each section is highly subdivided [52]
	Economies: It means that the subject obtains relatively maximum benefits with relatively minimum investment to obtain benefits most economically and meet the needs of survival and development [53]	Zhihu provides users with a free Q&A community [54]. Users can spend less money to ask questions to experts in related fields
	Uniqueness: It is defined as individuals pursuing unique characteristics different from others by acquiring, using, and disposing of consumer goods [55]. Novelty is a concept closely related to uniqueness. Novelty refers to the extent to which the answers on social Q&A websites make users feel innovative. Innovative answers will bring new ideas to users and will also be regarded as high-quality answers by users [49, 56]	In-depth content production is different from the knowledge provided by other Q&A platforms. Online and offline knowledge products are carried out at the same time [57]

1-7: self-presentation, content sharing, relationship formation, browsing others' content, meta-voicing, communication, sourcing, and knowledge attributes.

that a sense of having a place can be partly realized by the personalization of individuals' surroundings. Applying this definition to cyberspace, users can fulfill their needs for having a place by investing time, energy, or emotion in creating their own virtual world through self-presentation (such as posting personal photos or videos on Zhihu) and content sharing (such as sharing others' content on Zhihu). In this way, a sense of having a place can be created by engaging in personalizing the cyberspace. As a result, hypothesis 4 can be proposed.

H4: The need for having a place can motivate the use of Zhihu that has these affordances: self-presentation and content sharing.

As for coming to know the self, Pierce et al. [71] illustrated it as individuals' innate psychological needs to identify who they are and learn about themselves. Self-identity can be developed through self-awareness, such as comparing themselves with others when people interact with their surroundings [72]. In addition, the sense of coming to know the self can be achieved by receiving feedback from others and seeing how other people think of themselves [73]. Thus, people can reflect their feelings, thoughts, and behaviors, which enable them to discover what kind of people they are. Therefore, the psychological needs for coming to know the self can be fulfilled by these affordances: browsing others' content (which helps individuals compare themselves to others) and meta-voicing (which enables individuals to see reflected appraisal). Therefore, hypothesis 5 is suggested.

H5: The need for coming to know the self can motivate the use of Zhihu that has these affordances: browsing others' content and meta-voicing.

Expressing self-identity is defined as people's innate psychological needs to communicate their identities with others [71]. For example, Zhihu users can satisfy their needs for expressing self-identity by self-presentation (through disclosing their personal information such as profile photos and education), content sharing (through sharing articles), relationship formation (through following other Zhihu users or joining online communities), meta-voicing (through commenting on or voting for others' posts), and communication (through chatting directly with other Zhihu users). Therefore, hypothesis 6 can be proposed.

H6: The need for expressing self-identity can motivate the use of Zhihu that has these affordances: self-presentation, content sharing, relationship formation, meta-voicing, and communication.

The final psychological needs suggested in this paper are maintaining continuity of self-identity, which shows individuals' innate psychological needs to maintain emotional connections between past and present [71]. Taking Zhihu as an example, self-presenting and content sharing enable users to see who they were and who they are by the questions they asked or answered, articles they shared, photos and videos they posted, and so forth. All the content constitutes one's self-identity. Thus, we posit hypothesis 7.

H7: The need for maintaining continuity of self-identity can motivate the use of Zhihu that has these affordances: self-presentation and content sharing.

Based on the above hypotheses, the conceptual framework can be shown in Figure 2.

## 4. Research Methods

**4.1. Questionnaire Design.** Based on previous research of psychological needs and Zhihu features, questionnaire 1 and questionnaire 2 are designed to test the model of this paper. In order to measure seven variables of psychological needs, 20 question items are suggested. A adopts three-question items from Deci [61] and Deci and Ryan [33, 62, 63]. R is measured by the scale of the research from Deci and Ryan [63, 74], Jenkins-Guarnieri et al. [64], and Seder & Oishi [65]. C adopts the scale from Bauer and McAdams [66] and White [67]. HP adopts two-question items from Barki et al. [68], Harrison and Barthel [69], and Pierce et al. [70]. CK is measured by the scale of Pierce et al. [71], Festinger [72], and Mead [73] while ES and MC adopt the source from Pierce et al. [71] to be the measurement scale (see in questionnaire 1). In questionnaire 2, 17 question items are suggested to measure the extent to which the use of or feeling Zhihu features. In this study, every measurement item is measured using the five-point Likert scale. 1 for "strongly disagree," 2 for "disagree," 3 for "undecided," 4 for "agree," and 5 for "strongly agree."

TABLE 5: Scale items.

Construct	Abbr.	Questionnaire 1 Items	Sources
Autonomy	A	Psychological needs I need freely choose what I want. I need present myself in my own way	Deci [61]; Deci and Ryan [33, 62, 63]
Relatedness	R	I have the need to act freely I need participate in group activities I need connect with other people	Deci and Ryan [63, 74]; Jenkins-Jenkins-Guarnieri et al. [64]; Seder and Oishi [65]
Competence	C	I need be close to many people I need expand my knowledge I need show my capabilities I need feel competent	Bauer and McAdams [66]; White [67]
Having a place	HP	I need a place of my own I need create a place which makes me feel like home	Barki et al. [68]; Harrison and Barthel [69]; Pierce et al. [70]
Coming to know the self	CK	I need to know who I am. I need to know how other people think of me.	Pierce et al. [71]; Festinger [72]; Mead [73]
Expressing self-identity	ES	I need to develop a sense of self-identity. I need to show people who I am. I need to express my personality.	Pierce et al. [71]
Maintaining continuity of self-identity	MC	I need to show my self-identity. I need to compare my past and today. I need to show other people who I were and who I am. I need my past to be an important part of my self-identity.	Pierce et al. [71]

All items were measured on a 5-point scale: 1 = strongly disagree; 5 = strongly agree

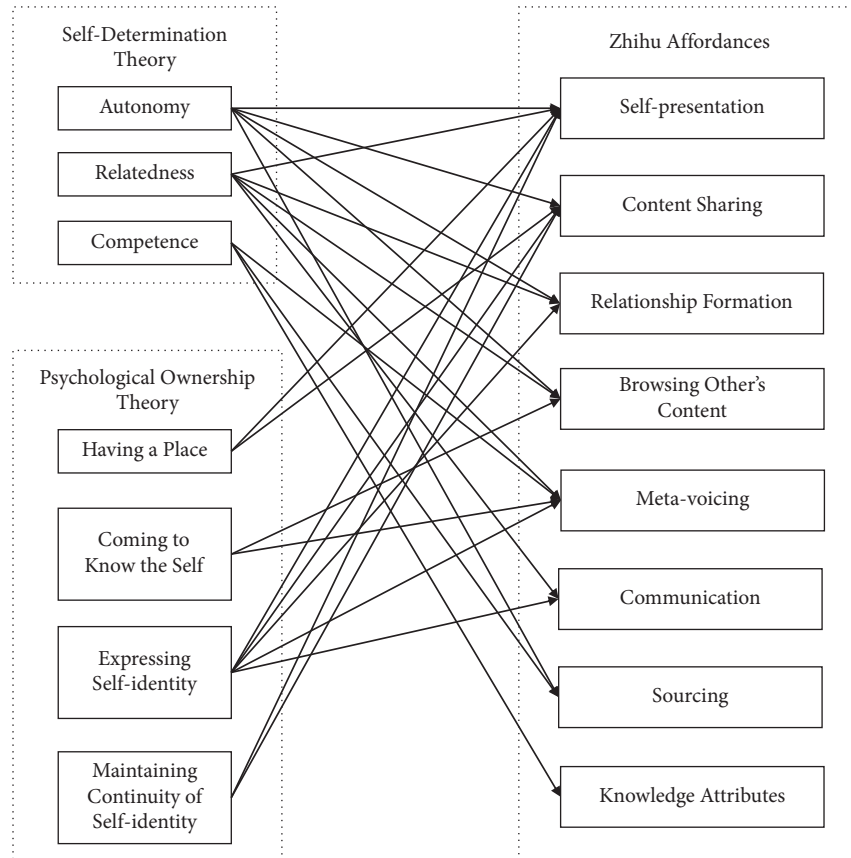

FIGURE 2: NAF model for Zhihu affordances use.

4.2. Data Collection. Taking into account the time constraints and sample size, the research scope is mainly selected in the first-tier cities in China that have a large number of people using Zhihu. First, the questionnaire was distributed and collected in a small range through the social network of teachers and classmates to conduct a preliminary

test of the questionnaire. After the questionnaire was revised, a professional survey company was commissioned to invite Zhihu users in China's first-tier cities to respond online. The survey period was from June 2021 to July 2021. A total of 300 questionnaires were returned. After excluding uncompleted and regular answers, 300 questionnaires were

finally returned, with 208 valid questionnaires, and the effective response rate was 69.3%. Based on the final sample, this paper mainly adopts SPSS26.0 and Amos24.0 software to analyze the sample data as shown in Table 5.

## 5. Results and Analysis

In this study, SPSS26.0 software and Amos24.0 software are used to analyze the research samples. Among them, the analysis methods involved in SPSS26.0 include reliability test and regression analysis, while Amos24.0 is used for confirmatory factor analysis.

*5.1. Reliability and Validity Test.* Reliability refers to the consistency or stability of the measurement results obtained by measurement tools [75]. In this paper, Cronbach's Alpha reliability test is used for testing variables. In terms of validity, it refers to the degree to which measurement tools can accurately measure the things that need to be measured [76]. This paper uses confirmatory factor analysis to test the validity of variables, which is mainly used to verify convergent validity and discriminant validity. According to Hair [76], the absolute value of factor loading should be at least 0.5 or more, and the best index value should be more than 0.7. In addition, the average variance extraction (AVE) index value should be more than 0.5. The value of the construct reliability should be higher than 0.7 to judge whether it has convergent validity. Fornell and Larcker [77] pointed out that the existence of discriminant validity should be judged based on whether the square root of AVE is higher than the correlation coefficient value between the two-factor constructs. This study uses the maximum likelihood method to estimate the model, and  $\chi^2/df$ , RMSEA, SRMR, NFI, CFI, TLI, IFI indicators are used to verify the model fitting degree in this paper.

It can be seen from Table 6 that the reliability of A, R, C, HP, CK, ES, and MC is 0.886, 0.748, 0.843, 0.767, 0.855, 0.801, and 0.832, respectively, indicating that the questionnaire has good reliability. In addition, as the result shows that  $\chi^2/df=1.330$ , RMSEA=0.040, SRMR=0.043, NFI=0.905, CFI=0.974, TLI=0.967, IFI=0.975, it indicates that the confirmatory factor analysis model fits well. The composite reliability values of A, R, C, HP, CK, ES, and MC are 0.887, 0.752, 0.843, 0.767, 0.857, 0.808, and 0.835, which are all above 0.7, and the AVE values are 0.723, 0.503, 0.644, 0.666, 0.584, and 0.629, respectively, which are above 0.5, so it shows that the questionnaire has good convergent validity.

Table 7 shows the mean and standard deviation of A, R, C, HP, CK, ES, and MC. The AVE values of A, R, C, HP, CK, ES, and MC are 0.850, 0.709, 0.802, 0.789, 0.816, 0.764, and 0.793, respectively, which are higher than their corresponding correlation coefficients, which shows that the questionnaire has good discriminant validity.

*5.2. Regression Analysis.* Regression analysis is a statistical analysis method to determine the interdependent

relationship between two variables or multiple variables. Therefore, this paper chooses regression analysis to test the hypothesis, in which gender, age, and Internet experience (in years) are used as control variables.

Table 8 shows the predictive effect of the predictor variables on the dependent variables and the magnitude of the explanation rate. Thus, the results are shown below.

Taking self-presentation as the dependent variable, it can be seen that relatedness, having a place, and expressing self-identity have a significant positive predictive effect on self-presentation ( $\beta=0.223$ ,  $p<0.01$ ;  $\beta=0.300$ ,  $p<0.001$ ;  $\beta=0.219$ ,  $p<0.01$ , respectively). In addition, the explanatory rate of the predictor variables to self-presentation is 29.4%.

Taking content sharing as the dependent variable, it is shown that having a place and expressing self-identity have a significant positive predictive effect on content sharing ( $\beta=0.260$ ,  $p<0.001$ ;  $\beta=0.179$ ,  $p<0.05$ , respectively). The explanatory rate of the predictor variables to content sharing is 15.1%.

Taking relationship formation as the dependent variable, it can be seen that relatedness and expressing self-identity have a significant positive predictive effect on relationship formation ( $\beta=0.245$ ,  $p<0.01$ ;  $\beta=0.340$ ,  $p<0.001$ , respectively). The explanatory rate of the predictor variable to relationship formation is 25.2%.

Taking browsing others' content as the dependent variable, it is shown that autonomy and coming to know the self have a significant positive predictive effect on browsing others' content ( $\beta=0.309$ ,  $p<0.001$ ;  $\beta=0.246$ ,  $p<0.01$ , respectively). The explanatory rate of the predictor variable to browsing others' content is 16.9%.

Taking meta-voicing as the dependent variable, it can be seen that relatedness, competence, coming to know the self, and expressing self-identity have a significant positive predictive effect on meta-voicing ( $\beta=0.227$ ,  $p<0.01$ ;  $\beta=0.270$ ,  $p<0.001$ ;  $\beta=0.189$ ,  $p<0.01$ ;  $\beta=0.167$ ,  $p<0.05$ , respectively). The explanatory rate of predictor variables for meta-voicing is 39.7%.

Taking communication as the dependent variable, it can be seen that the predictive effects of the various variables of psychological needs are not significant.

Taking sourcing as the dependent variable, it can be seen that competence has a significant positive predictive effect on sourcing ( $\beta=0.366$ ,  $p<0.001$ ), and the explanatory rate of the predictor variable to sourcing is 14.9%.

Taking knowledge attributes as the dependent variable, it can be shown that competence has a significant positive predictive effect on knowledge attributes ( $\beta=0.369$ ,  $p<0.001$ ), and the explanatory rate of the predictor variable to knowledge attributes is 14.4%.

## 6. Discussion

From the data results above, the following observations could be reached. One is that each of the Zhihu affordances is likely to be related to fulfilling some psychological needs. At the same time, the salient psychological needs that drive people to use Zhihu could be identified. The other is that links between individuals' psychological

needs and Zhihu affordances could be identified. Details are as follows.

The need for autonomy can motivate people to use Zhihu that has the affordance of browsing others' content. However, it has no relationship with self-presentation, content sharing, relationship formation, and sourcing. This means that although Zhihu users do have the freedom to determine what content to browse and when, there are some restrictions that limit users' freedom to show themselves, share content, and establish relationships. In the discussion area of the Zhihu platform, we can see many people complaining about the privacy problems of Zhihu. Some people think that it is strongly required that Zhihu set a function that can determine whether users are willing to disclose their dynamics, including the behavior of liking, collecting, and

following. Otherwise, when users' friends or other people who follow the users click into the accounts, they can easily know what the users are doing or thinking in recent time. Mainly when subscribing to sensitive and private topics, users feel that their privacy has been violated. In addition, although the Internet search index improves the accuracy of predicting users' preferences and behavior [78], the recommender system used in the application may also disclose users' privacy [79]. In this case, due to social norms and impression management concerns, users may feel that their behavior cannot be entirely determined by themselves and finally think that the platform cannot meet their needs for autonomy. This view is further confirmed by the comparative study between Facebook and Twitter. Facebook's real name policy makes many users feel limited in expressing

themselves, while Twitter's anonymity system reduces users' social pressure and enables people to express themselves more freely [10, 80, 81].

The need for relatedness can motivate the use of Zhihu that has affordances of self-presentation, relationship formation, and meta-voicing, but there is no significant link from relatedness to browsing others' content and communication. Although browsing others' content and communication are also likely to help users develop their relationships with others, our results show that these affordances are not able to meet the psychological needs of relatedness. This may be because when users are provided with various affordances that can meet the same psychological needs, they will choose the one that can directly meet their psychological needs. In addition, compared to social platforms such as Wechat, OKC platforms such as Zhihu have weaker functions in chatting, which may also be why people are less likely to use chatting on Zhihu to meet needs for relatedness. According to results, the features which enable affordances of self-presentation, relationship formation, and meta-voicing are used to meet needs for relatedness on Zhihu.

The need for competence is significantly related to affordances of meta-voicing, sourcing, and knowledge attributes. As a successful OKC platform, the functions provided by Zhihu, such as commenting on posts, collecting and liking, voting for posts, suggesting questions, and searching answers, as well as the high-quality content of Zhihu, meet people's demands for applying and expanding their knowledge. The emergence of OKC platforms has changed the way people obtain information. Every online interaction or behavior of searching is the process of

ingesting content through the Internet. This method has brought many positive effects, such as a variety of content and quick access to information, but there will also be some negative effects, for example, how to filter meaningful information which indeed enables users to acquire competence. In order to achieve substantial development, Zhihu should avoid information redundancy and maintain high-quality content to win everyone's favor in the era of information overload.

The result supports the link between the need for having a place and the use of self-presentation and content sharing affordances. This shows that people create their own space by posting self-related content, writing the column, or sharing others' posts. Zhihu heavy users may invest a lot of time or money in engaging in Zhihu activities. In this way, people are able to be immersed in the environment they personalize for their own. As a result, the need for having a place can motivate the use of Zhihu that has affordances of self-presentation and content sharing.

The need for coming to know the self can also drive people to use Zhihu that has affordances of browsing others' content and meta-voicing. People can establish self-identity by receiving feedback from others and comparing themselves with other people [72, 73]. On the one hand, Zhihu can establish an effective feedback mechanism through such functions as liking and commenting so that users can constantly improve their answers, obtain new ideas, and may find the direction they are interested in and explore their potential. On the other hand, users will compare with their own articles or ideas by browsing other people's articles or opinions. Thus, they can find their own shortcomings and enhance their self-awareness. For example, by communicating with other users in the

comment area, users may continue to be inspired and feel the differences between themselves and others to form a clearer understanding of themselves.

The result shows that individuals who have a great need to express self-identity may use Zhihu that provides affordances of self-presentation, content sharing, relationship formation, and meta-voicing. However, the affordance of communication could not fulfill people's psychological need for expressing self-identity. By joining an online community or following others (enable the affordance of relationship formation) on Zhihu, individuals are easy to express self-identity by establishing connections with other people. However, when users are high on the need for communicating their identities, the function of chatting may not be as rich as uploading their content, sharing others' content, commenting, or voting for others' posts (enable the self-presentation, content sharing, and meta-voicing affordances). In addition, as we mentioned before, compared to Wechat in China, the chatting function of Zhihu is not its superior function. Therefore, individuals are more likely to use self-presentation, content sharing, relationship formation, and meta-voicing to express self-identity.

Finally, the need for maintaining continuity of self-identity plays a nonsignificant role in driving Zhihu use.

We expect that the realization of this psychological need may only be a by-product of using Zhihu. Individuals could express their identity by posting their own content or sharing others' content. These constitute the user's previous and current experiences and records. Unless this material is specifically deleted, the information will be persistent, which provides continuity in time and a retrospective perspective for self-identity.

## 7. Implications and Future Research

*7.1. Theoretical Implications.* The characteristics of a particular OKC application provide insights into the affordances provided by that application. In addition, from the logic of NAF, this paper provides the mapping of the psychological needs that motivate using the application to its affordances. Therefore, people can predict their psychological needs based on the features provided by the OKC application. On the contrary, based on the people's level of psychological needs, it is possible to predict which affordances of the OKC application they may use.

Taking Zhihu as an example, this paper determines the psychological needs that drive the use of Zhihu from the perspective of the NAF model. Through the features of Zhihu, Zhihu affordances are identified, so the connection between affordances and psychological needs is established. Through the data collection and analysis, the results show that the salient psychological needs that motivate users to use Zhihu are autonomy, relatedness, competence, having a place, coming to know the self, and expressing self-identity, and these psychological needs are fulfilled by the affordances of browsing others' content (for autonomy), self-presentation, relationship formation and meta-voicing (for relatedness), meta-voicing, sourcing and knowledge attributes

(for competence), self-presentation and content sharing (for having a place), browsing others' content and meta-voicing (for coming to know the self), and self-presentation, content sharing, relationship formation, and meta-voicing (for expressing self-identity). These results demonstrate how to use the NAF model to determine the relationship between a specific OKC platform and psychological needs.

*7.2. Practical Implications.* From the fact that Wukong Q&A has invested billions in the construction of the community although it still fell to the ground, different platform affordances could create different community ecology. The research of this topic can guide more platforms to design more effective OKC applications under the premise of unifying user needs and organizational characteristics, which could lead to avoiding waste of social resources and improving the success rate of Internet innovation. Outwardly, the digital platform system has a certain degree of imitability and reproducibility. In fact, it contains differences in corporate value pursuit, user community, and core capabilities. The platform system is a collection of affordances generated during the interaction between the organizational characteristics of the platform enterprise and the needs of users. The platform must clearly understand the dominance and decisive role of these organizational characteristics in operations. Different organizational characteristics naturally require different digital technologies and combination options to achieve differentiated functions, interfaces, and processes and produce different user interaction effects. In addition to the social affordances provided by the platform, content platforms such as Zhihu should also focus on the affordances of knowledge content, that is, whether the content resources meet the platform positioning and user needs. Furthermore, platform strategies should be used to guide content production behavior and user consumption behavior to build a good user-content collaborative ecosystem.

*7.3. Future Research.* NAF model can be extended to design science research. For example, our results can be used to provide guidance on how to develop effective OKC application features. These features should be able to meet the natural psychological needs of users. In addition, although we have studied how each type of affordance meets specific psychological needs, it is also possible that affordances have joint complementary effects. Therefore, future research can explore whether a specific combination of affordances can provide better means to meet the psychological needs or whether a specific combination of characteristics can provide specific affordances in a better way. Third, it is unclear whether OKC applications should strive to provide multiple functions to meet a single demand or provide multiple functions to meet multiple needs in order to succeed. Our empirical research in the context of Zhihu shows that although Zhihu provides a variety of affordances to meet the needs for relatedness, only three of them may be significantly related to the need for relatedness. Although other affordances may also help individuals develop relationships with

others, our results seem to indicate that this is not why users use them. This may be because when individuals are provided with multiple affordances that can meet the same psychological needs, they will choose the affordance that most directly meets the psychological needs. This is worthy of further study. Finally, we mentioned earlier that compared to other Q&A platforms, Zhihu has carried out in-depth content production and provided online and offline knowledge products. Whether users meet their psychological needs online or offline may depend on whether OKC provides better functions to meet their needs than offline. These questions are interesting directions for future design scientific research and provide potential ways for future OKC research to reveal how to attract users effectively.

The rise of FinTech has been meteoric in China. Investing in mutual funds through robo-advisor has become a new innovation in the wealth management industry. In recent years, machine learning, especially deep learning, has been widely used in the financial industry to solve financial problems. This paper aims to improve the accuracy and timeliness of fund classification through the use of machine learning algorithms, that is, Gaussian hybrid clustering algorithm. At the same time, a deep learning-based prediction model is implemented to predict the price movement of fund classes based on the classification results. Fund classification carried out using 3,625 Chinese mutual funds shows both accurate and efficient results. The cluster-based spatiotemporal ensemble deep learning module shows better prediction accuracy than baseline models with only access to limited data samples. The main contribution of this paper is to provide a new approach to fund classification and price movement prediction to support the decision-making of the next generation robo-advisor assisted by artificial intelligence.

## 1. Introduction

In recent years, machine learning and deep learning have been widely used in finance to meet financial needs [1–5]. As an application of these novel techniques, robo-advisors are favored by a growing number of fund companies, and thus, the advisors have played an important role in global investments and asset allocations. Since the reform and opening up initiated 40 years ago, China has shown rapid economic growth and has become the second-largest wealth management market in the world. To satisfy residents' wealth management needs, public funds have gradually become one of the main tools for wealth management, because of their rich investment targets, professional operations, and open and transparent information environment. At the same time, with a timely supplement of technology to the financial market, the participating cost of residents to realize customized financial services has been gradually reduced. In addition, as robo-advisors are affordable to common investors, these advisors have become one of the main tools for financial institutions to carry out wealth management innovation for several advantages, e.g.,

they can manage long-term asset allocation, applying modern portfolio theory with technologies, such as big data, and implementing cloud computing. They can also automatically provide clients with fund investment suggestions through the Internet, with the consideration of investors' risk preferences, property status, and financial objectives. Therefore, the application of artificial intelligence technology outperforms traditional investment advisors by optimally dealing with several practical problems encountered by traditional advisors, e.g., cost cutting and customer reach.

There are two steps that the robo-advisors need to go through in the process of generating investment plans: fund selection and asset allocation. Fund selection can be further divided into two aspects: fund classification and fund return prediction. In China, current fund classification is generally based on the primary classification (Step 1) issued by the China Securities Regulatory Commission (CSRC). There are two main styles of funds categorized by CSRC: stock funds and bond funds. For Step 2 classification, stock funds can further be classified given their market capitalization and the style of their holdings, while bond funds can be classified based on the share of equities held in their position.

In terms of fund classification by machine learning, there are two common methods: partition clustering (represented by K-means clustering) and network clustering (represented by SOM). The partition clustering method has the merits of simpler principle, fewer parameters input, and faster convergence speed; however, the shape of circular clustering may be too simple, which would compromise the accuracy of classification results. The network clustering method can effectively deal with multidimensional clustering problems, but it is subject to dimensional disasters and the network model is relatively sensitive to the selection of parameters. In terms of fund movement prediction, ARIMA, artificial neural network (ANN), and backpropagation neural network (BP) are frequently used, while their weakness are that parameters are difficult to estimate and models are subject to overfitting.

In order to solve the above problems, we employ the Gaussian mixture clustering method (GMM) in this paper. GMM can effectively solve the problem that the cluster shape is too simple when using a simple parameter. For empirical analysis, we use data from the Chinese market. We continue our analysis using two-step classification to further distinguish the styles and characteristics of stock funds and bond funds of our collected data. Based on the GMM results, we use the spatiotemporal ensemble deep learning model to predict the short-term price movement of each category of funds. We then make full use of the idea of clustering and ensemble learning with the aim to effectively improve the implication and prediction ability of the model, especially when the access to big data is rather limited.

To compare the performance of predicting fund net asset values of our model, we compare it with several basic models, that is, residual network (ResNet, hereafter) model, long- and short-term memory network (LSTM, hereafter) model, and one-dimensional convolutional neural network (CNN, hereafter) model. We examine their performance in predicting the short-term returns of the four main classified categories in our results by employing the mean absolute error (MAE) and correlation coefficient  $R^2$  as evaluation indicators.

Our main findings are as follows. Our two-step GMM method can generate the probabilities that the funds belong to a certain category, according to their risks and returns, and thus outperform the traditional K-means model in classifying funds. Our model also improves the prediction ability, with a reduced prediction error, of fund price movements when compared with other models, i.e., ResNet, LSTM, and CNN models.

The main contributions of this paper are as follows: (1) we propose a new two-step GMM model to effectively distinguish the mutual funds in China using simple fund characteristics and (2) we construct an ensemble deep learning model to predict the short-term price movement of different categories of funds.

## 2. Literature Review

*2.1. Literature on Fund Classification.* Fund classification is the basis of fund evaluation. Different types of funds need

different analysis methods and evaluation dimensions due to their distinct characteristics such as risk and return. Thus, fund classification ensures the effectiveness and comparability of fund evaluation. There are two methods of fund classification: ex ante classification and ex post classification. The ex ante classification method determines the fund category according to its investment objectives and strategies, which are specified in the fund issuance announcement. However, in the actual operation, the specified information frequently deviates from the original agreements. Dibartolomeo et al. [6] find that after regressing the net value of the fund using the William Sharp's attribution method, more than 40% of the stock funds have misclassification, and they argue that the main reasons for the misclassification are the imprecision of the ex ante classification method and the ex post deviating manipulation by fund managers due to peer pressure. Luo et al. [7] classify 54 funds listed in China through factor and cluster analyses, and they find that nearly 40% of the funds are inconsistent with the investment style described in their prospectus. In contrast, ex post classification method specifies fund types according to their performance after fund operation and their characteristics specified in the issuance announcement. As an improvement to this classification method, Brown et al. [8] use a factor model to capture the nonlinear characteristics of fund returns and map them into the mainstream of investment managers' style to classify funds. Kim et al. [9] choose more market characteristics, through principal component analysis (PCA), and classify funds based on these newly identified variables. However, the ex post classification method also has limitations, for example, the collinearity of factors in multiple regressions.

Fortunately, the introduction of machine learning mitigates the limitations of the traditional fund classification methodology because of its ability to capture nonlinear features and its independence of data characteristics, for example, sample size, under unsupervised learning. Marathon et al. [10] classify funds by K-means clustering to find that 43% of the fund samples were inconsistent with the investment types the funds were originally described. They also find that many fund categories under traditional classification methods show very similar risk and return characteristics, thus suggesting that the introduction of classification analysis reduces the complexity of fund management. Lajbcygier et al. [11] maintain that the boundaries of funds with different styles should be continuous rather than strictly being divided. Thus, they use a flexible clustering method of fuzzy C-means and find that this method can obtain better classification results. Menardi et al. [12] employ a two-step clustering method, and the first step of which is to reduce the dimensionality of 24 fund characteristics using PCA, and the second step is to classify 1436 public funds into those 24 categories of characteristics using hierarchical clustering. For the extraction of nonlinear characteristics, Moreno et al. [13] classify 1,592 funds from the Spanish market by using self-organizing mapping neural network (SOM) and find that compared with K-means clustering, SOM can effectively reduce misclassification.

*2.2. Literature on Fund Return Prediction.* Yaser et al. (1996) argue that financial time series itself is noisy and is a nonstationary process, which means the historical information is not enough to explain the relationship between past and future returns. They also argue that the financial market is not completely unpredictable due to the existence of the price trend effect. Cao et al. (2001) maintain that financial time series can be predicted by both univariate and multivariate analyses. They argue that the input of the univariate analysis model is the time series itself, which is predicted by the autoregressive integral moving average (ARIMA) model. However, ARIMA's performance is not satisfactory, mainly because (1) it requires the parameters to be estimated *ex ante* and (2) it assumes that the time series is stable and linear, which violates reality. Concerning multivariate analysis, artificial neural network (ANN) is one of the main prediction methods due to its ability in accommodating more available information and its outstanding performance in handling nonstationary processes. Schneburg [14] uses several methods, such as MADALINE and BP models, to predict stock returns of three listed companies in the German market and reveals that the accuracy of prediction reaches 90%. Schneburg [14] also finds that the BP model performs better than other methods considered, which confirms the effectiveness of neural networks in predicting fund returns. Kimoto [15] uses a modular neural network to develop a trading strategy for Tokyo Stock Exchange and find that the modular neural network can connect more basic neural networks and help generate a more accurate prediction. For improvement, Vapnik et al. (1996) propose a new method based on the support vector machine (SVM) to improve the generalization of neural networks by solving nonlinear regression problems. In addition, Cao et al. (2001) argue that artificial neural network has overfitting problems, and extra care is needed for parameter estimations and training to get satisfactory results. Khashei et al. [16] maintain that to produce accurate results a large amount of historical data is needed, while the financial market is full of uncertainty and changes rapidly. Accordingly, a new hybrid method, which combines the advantages of artificial neural networks and fuzzy regression, is proposed to overcome the limitations of traditional artificial neural networks. Their empirical results then show that this hybrid model is an effective way to improve prediction accuracy. Liu et al. [17] and Li et al. [18] predict stock returns by employing a CNN-LSTM model and find that introducing an attention mechanism could help improve the accuracy of the CNN-LSTM model.

### 3. Data

The data used in this paper are mainly from the WIND database. The collected data are the full samples of stock funds, hybrid funds, and bond funds under the classification caliber of CSRC. QDII funds, closed-end funds, alternative funds, and monetary funds are not included in the analysis due to their peculiarity to our chosen funds. The date of April 30, 2021, is taken as the cut-off date. The funds that have been established more than two years before the cut-off

date, with a total asset value of above 50 million RMB, and have not undergone type conversion during their operation period are selected. This selection process leads to a total number of 3,625 funds.

The fund fee normally includes the daily subscription fee, daily redemption fee, management fee, and custody fee. The fund fee used in this paper is the sum of the management fee and custody fee. The value of the fee is adopted as of April 30, 2021. For fund returns, we focus on their rolling rate of return, which is defined as the ratio of the funds' compound net value on that day to the funds' compound net value  $N$  days ago, where  $N=1, 5, 20, 60, 120,$  and  $250$  days as rolling windows. The number of fundholders, shares per capita, shares that are held by institutions and individual holders, shares purchased and redeemed by the fund managers, and ratios of the market value of stocks and bonds to funds' total value are collected from their quarterly reports. Since the publication time of the quarterly reports varies across funds, we take the last trading day in January, April, July, and October of each year as the observation date to obtain the latest published data before that date. If no new data is published in the latest quarter, the value of the previous quarter will be used. Table 1 summarizes the data used in this paper.

## 4. The Model

In this section, we develop the model framework, including the clustering model and the prediction model, as shown in Figure 1. First, we cluster the fund via GMM using fund features described in the previous section, from which the dimension of the fund features is reduced using the PCA method. Then, we develop a deep learning-based prediction model to predict the fund trend based on the clustering results. Therefore, we will briefly introduce the PCA and GMM at first. The deep learning-based model is then presented in detail.

*4.1. Clustering Models.* This paper uses two models for analysis, that is, principal component analysis (PCA) and the Gaussian mixture model (GMM). In this paper, we employ PCA to reduce the dimension of the rolling yield data of funds with different maturities used in the first step of classification.

*4.1.1. PCA.* Principal components analysis (PCA) is a dimension reduction method, namely, transfers the original feature space into a brand-new feature space. It is generally used for data preprocessing. For example, assume that there are  $n$  fund samples, with each fund sample contains 2,000 features. Among these features, there exists the vast amount of noises or useless information. Therefore, PCA can be conducted to reduce noises and save computational resources. Table 2 shows the number of eigenvalues used and the reducibility using PCA. One can notice that the PCA method has a high degree of reducibility, and the higher the reducibility, the more rolling days are selected, keeping the

TABLE 1: Summary statistics.

Item	Observations	Frequency	Step of clustering
Rate of return in the past 1 day	$237 \times 3,604$	Daily	First
Rate of return in the past 5 days	$237 \times 3,604$	Daily	First
Rate of return in the past 20 days	$237 \times 3,604$	Daily	First
Rate of return in the past 60 days	$237 \times 3,604$	Daily	First
Rate of return in the past 120 days	$237 \times 3,604$	Daily	First
Rate of return in the past 250 days	$237 \times 3,604$	Daily	First
Rate of fund fee	$36 \times 4 \times 1$	As of April 30, 2021	Second
Number of fund holders	$10 \times 3,604$	Quarterly	Second
Shares per capita	$10 \times 3,604$	Quarterly	Second
Shares held by institutions (%)	$10 \times 3,604$	Quarterly	Second
Shares held by individuals (%)	$10 \times 3,604$	Quarterly	Second
Shares purchased by fund managers	$10 \times 3,604$	Quarterly	Second
Shares redeemed by fund managers	$10 \times 3,604$	Quarterly	Second
Ratios of stocks to total assets (%)	$10 \times 3,604$	Quarterly	Second
Ratios of bonds to total assets (%)	$10 \times 3,604$	Quarterly	Second

FIGURE 1: Model framework.

TABLE 2: PCA result for data used in classification.

Data	Number of eigenvalues	Reducibility (%)
Rate of return in the past 1 day	100	94.89
Rate of return in the past 5 days	100	99.19
Rate of return in the past 20 days	100	99.81
Rate of return in the past 60 days	100	99.94
Rate of return in the past 120 days	100	99.97
Rate of return in the past 250 days	100	99.98

number of eigenvalues constant. A detailed description of PCA is shown in Appendix A.

**4.1.2. GMM.** GMM clustering is the main classification model, which can give the probability that the sample belongs to a certain category. The so-called Gaussian mixture model is the combination of multiple Gaussian distributions, and it uses the likelihood function as the objective function for parameter estimation. Although a larger sample size could help improve the accuracy of the model, the increased sample size will add the complexity of the model and could thus cause overfitting problem. Therefore, we rely on Akaike information criterion (AIC) and Bayesian information

criterion (BIC) to assess the quality of classification. A detailed description of GMM is presented in Appendix B.

**4.2. Deep Learning Model.** Applying the idea of ensemble learning to the field of financial studies, we build a spatiotemporal ensemble deep learning model for fund price prediction. The rationale of this model is summarized in three steps. Given the layout and the article length, the descriptions of the components of this model are presented in Appendix C. First, encode the data that are used (i.e., historical value of the fund) to obtain the semantic information of the data. Second, insert the encoded data into three basic models, that is, residual network (ResNet), long-

and short-term memory network (LSTM), and one-dimensional convolutional neural network (CNN), to train the model and obtain the output from these three models. The detailed mechanism of ResNet, LSTM, and CNN is shown in Appendixes C.1, C.2, and C.3, respectively. Third, calculate final output; model weights are optimized by the attention mechanism, the rationale of which is shown in Appendix C.4. Those three models are employed to extract complex nonlinear correlations (ResNet), capture time correlations (LSTM), and calculate spatial correlations (CNN). In this paper, we compare the performance of our model with these three benchmark models, and the results are shown in Section 5. The detailed spatiotemporal ensemble deep learning model and the inner structure are shown in Figure 2.

## 5. Results

**5.1. Clustering Analysis.** The rolling returns of the fund in the past 1, 5, 20, 60, 120, and 250 days are used as the input of the first step GMM, in which we rely on AIC to determine the optimal number of categories. As shown in Figure 3, when the number of categories (clusters) is greater than 10, the AIC value begins to rise, which means the optimal number of classifications is 10.

We then measure our classification results of the first step GMM from multiple dimensions; the results are shown in Table 3. We start by examining the average ratio of the market value of funds' holdings of stocks and bonds to funds' total value (disclosed in their 2020 annual report) for each category. We define that for each fund when its market value of stocks accounts for less than 60% of its total value, this fund does not belong to stock funds. Thus, one can see that categories 1 and 10 are not classified as stock categories, while others are classified as stock categories. In addition, the average stock holding of category 10 is higher than that of category 1. Therefore, we define category 1 as pure bond funds while category 10 as bond-like funds. Notice that funds in category 1 have an average ratio of bonds to fund value that is greater than 100%; this is a special characteristic of bond funds that utilize leverage through repurchase agreement (repo); a similar phenomenon also occurs in Table 4. Due to a large number of funds within these two categories (more than 500 funds), we will conduct a secondary classification for these two categories, the results of which will be shown in Table 4.

Regarding the other eight categories classified as stock funds, we further define their styles according to the following criterion: a fund is defined as an industry-themed fund if more than 30% of its investments are in a certain industry or if above 50% of its holdings go to less than three specific industries. If a category of funds contains at least 50% of funds within the same industry or above 50% shares of this category is industry-themed funds, this category is defined as an industry category. Take category 4 as an example, the largest industry invested by this category is pharmaceuticals, and 91% of funds (96 out of 106) within this category invest more than 30% of their shares in the pharmaceuticals industry. Therefore, this category is defined

as the pharmaceuticals-themed (industry) category. The classification results of the categories are shown in Table 5.

For other categories, that is, categories 2, 6, 8, and 9, belonging to the category of stock but found not falling into the style of industry-themed ones, we conduct a separate classification. For category 2, its fund holdings are rather dispersed, that is, there is no representing industry. Therefore, this category is classified as a market category. Category 6 contains a large portion of funds investing in small and medium enterprises (SME), and their holdings are also relatively dispersed across industries. Therefore, category 6 is classified as an SME market category. Most funds within category 8 invest in large blue-chip industries such as banking, nonbanking finance, and food and beverage. Therefore, category 8 is classified as a large-cap style. Category 9 is found to have similar characteristics to those of category 6, while the top three industries invested by category 9's funds are pharmaceuticals, electronics, and science and technology, which are growing industries in the Chinese market. Therefore, category 9 is classified as SME growth style. The classification results of these categories are summarized in Table 6.

We continue our analysis by conducting the second step of classification for categories 1 and 10, the results of which are shown in Figure 4. According to AIC, the optimal number of clusters for each category exceeds 10, which is not practical in real-world scenarios. Bond funds are hard to be distinguished by pure quantitative measures due to their low volatility, and thus, we choose to make the minor adjustment by combining classification results with our practical experience. We can see that AIC decreases significantly when cluster number reaches 3, and bond funds are usually separated by the involvement of equity assets. As a result, we set the number of subcategories of these two categories as three to distinguish among pure bond funds, bond funded with equity, and special-purpose bond funds.

Subcategory 1 of category 1 has no excessive leverage ratio, and its share in stocks is less than 10%, which implies that subcategory 1 belongs to the primary bond category. Subcategory 2 has no positions in stocks, and its ratio of the market value of the bond to its total value is higher than that of subcategory 1. Thus, subcategory 2 can be classified as a pure bond. Subcategory 3 is classified as an institutional-customized bond category as its market value of term bonds accounts for a high proportion of its total value and its average number of holders is in single digit, implying that these funds are mainly held by several institutional investors.

Regarding category 10, the holdings of stocks of subcategory 1 accounts for more than 20%, and there is no excessive leverage. Accordingly, subcategory 1 is classified secondary bond. Subcategory 2 is classified as low dividend stock as most of its funds invest in low dividend stocks. Subcategory 3 has a very similar feature to subcategory 1 in terms of shares of stock and bond holdings. However, further investigation shows that the average market value of the funds within subcategory 3 is less than 1 billion RMB (while the figure for subcategory 1 is 1.9 billion RMB), and there is a relatively high proportion of hybrid funds within this subcategory. This indicates that subcategory 3 is mainly

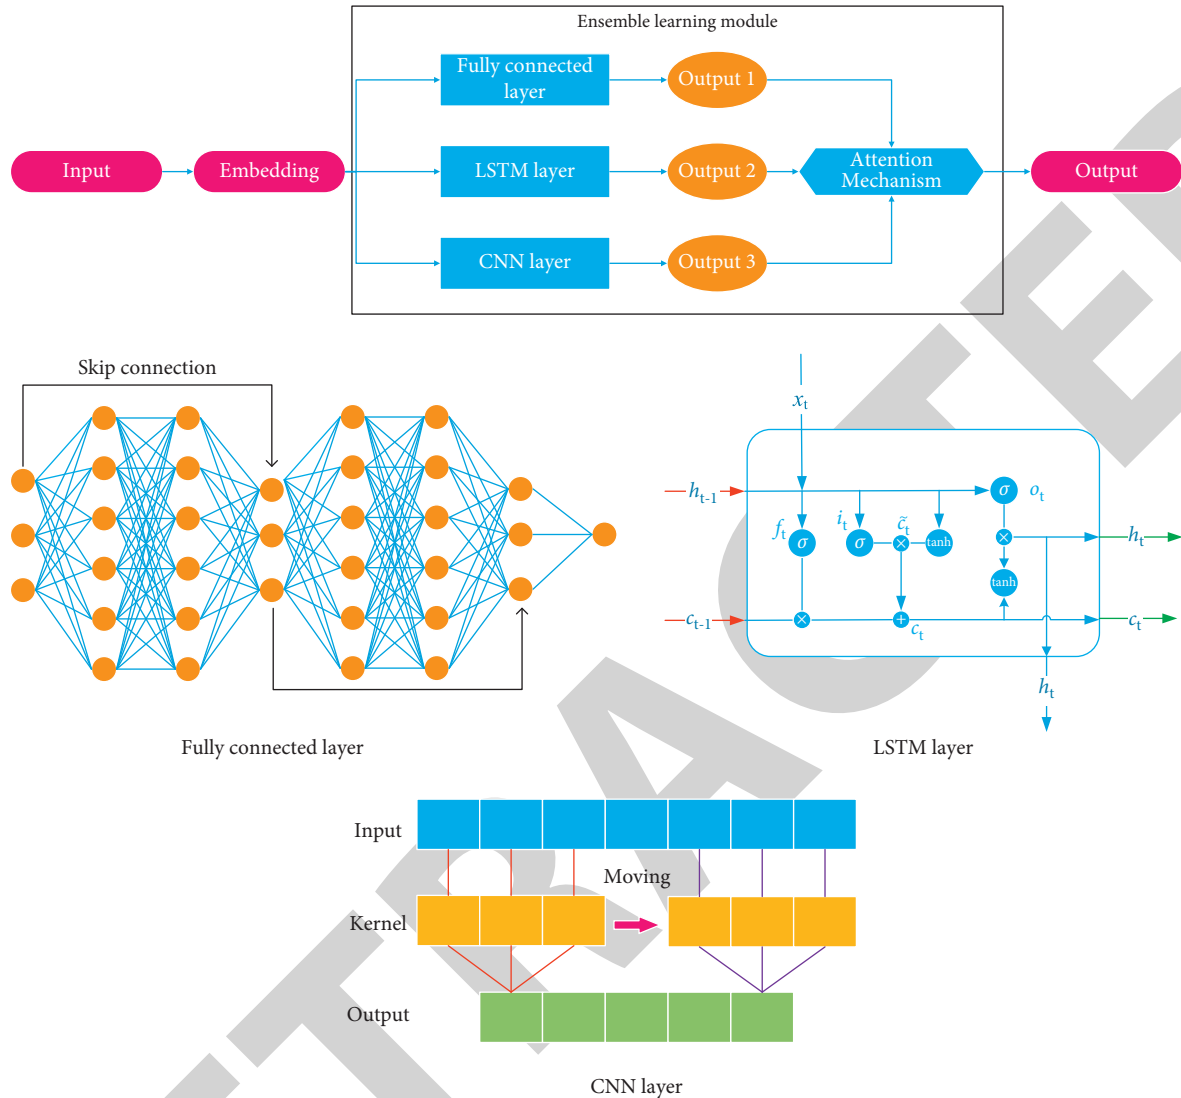

FIGURE 2: Diagram of spatial-temporal ensemble learning.

FIGURE 3: Number of main classes.

made up of fixed income and new funds established for the issuance of new stocks in the primary market. Thereby, subcategory 3 is classified as a new stock category. The secondary classification results for categories 1 and 10 are shown in Table 6.

To test the creditability of our classification results, we average the daily rate of return of the funds in each category and employ several industry style indexes (in which we select CITIC class I industry classification index as the industry index and we employ Juchao index as style index) as reference. We conduct our test by calculating the correlation coefficient between the calculated return in each category and the reference index. The results are shown in Table 7. One can see from Table 7 that category 3 has the highest correlation with CITIC food and beverage index, reaching 94%. The correlation between the return in category 4 and the CITIC pharmaceuticals index is high at 97%. The correlation between the rate of return of category 5 and the

9	482	23	49	Pharmaceuticals	26	SME-growth

CITIC power and new energy index is 94%. The rate of return of category 7 has a high correlation coefficient with CITIC power and new energy, computers, electronics, and military industry indexes.

Table 8 summarizes the correlation between fund returns and Juchao style index for categories 2, 6, 8, and 9, which are not classified as industry-themed categories, as in Table 6. (Thus, industry indexes, such as CITIC indexes, are inappropriate to evaluate its industry classification results, while

style index, for example, Juchao index, are more suitable for the evaluation of their style classifications.) From Table 8, we can see that our classification method has high accuracy in identifying the styles of these categories. To be specific, category 2 has a higher correlation with market style indexes defined by the Juchao style index; category 6 is closer to SME market; category 8 is similar to market value, and category 9 alike SME growth. (In recent years, fund managers pay more attention to funds that are growing while less attention is

**5.2. Return Prediction Analysis.** We use the four industry-themed categories (i.e., categories 3, 4, 5, and 7) for the fund price prediction analysis. The data used is the cumulative return of all funds in these four categories from February 2019 to July 2021, totaling 604 days. The PyTorch deep learning framework is used to build the model; 80% of the data sets are used to train the model, and 20% are used to test the model. The input data is divided into 10 dimensions through embedding. The ResNet model includes 7 layers of fully connected networks, containing 16, 16, 10, 16, 16, 10, and 1 neuron. The LSTM model is made up of 1 layer and 64 neurons. The CNN model consists of three layers, and the number of filters is 8, 8, and 1, with the size of convolution kernel of 3. The batch size of all basic models is 1. The final

FIGURE 6: Prediction results for different categories.

output is obtained using the weighted summation of outputs of these three benchmark models (i.e., ResNet, LSTM, and CNN). The loss function curve of the model is shown in

Figure 5, from which one can notice that the loss function training and verification set become stable after the 20<sup>th</sup> iteration, and the convergence is good.

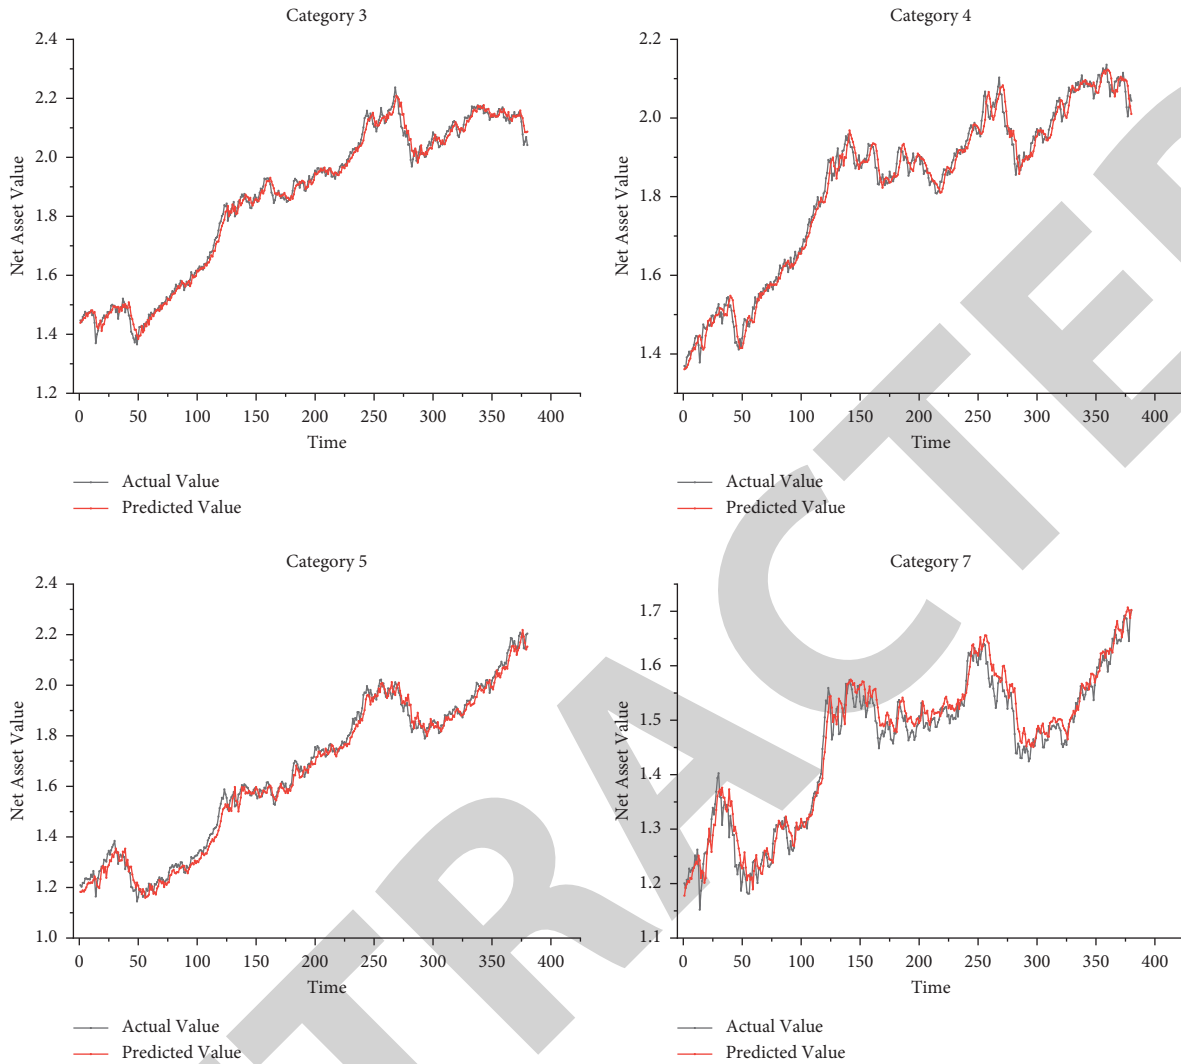

FIGURE 7: Comparison between the actual values and predicted values.

We then evaluate the performance of our model and three basic models using four indicators: RMSE, MAE,  $R^2$ , and WMAPE. The results are shown in Tables 9 and 10 and Figure 6. One can see the prediction ability of ResNet is relatively the best in all categories in question (compared with other benchmark models) based on these indicators. For example, the average value of RMSE is 0.034 for all categories, which is lowest when compared with other benchmark models, and  $R^2$  is 0.96, which is the highest among other benchmark models. Although LSTM is one of the most effective models dealing with time series problems, it does not perform well as expected, with the average value of RMSE around 0.040 and  $R^2$  around 0.95, owing to limited features available and an insufficient number of samples. The poor performance of CNN, with an average value of RMSE around 0.037 and  $R^2$  around 0.95, is due partially to its inability to record historical information. As expected, one can see that our spatiotemporal ensemble deep learning model has a better performance in predicting the fund price, which reduces the mean of RMSE to around 0.026 and improves  $R^2$  to nearly 0.98. We can thus conclude that our

model greatly improves the predictability, that is, the prediction accuracy, of fund price movement compared with these benchmark models as our model obtains the lowest (mean) values of RMSE, MAE, and WMAPE and the highest (mean) value of  $R^2$ . The improvements lie in the merits of ensemble learning, which complements the advantages of these three benchmark models.

Finally, we show the comparison between the actual values of those funds with our predicted values. The results are shown in Figure 7. We can see that the predicted values and actual values show a high degree of similarity. This means our spatiotemporal ensemble deep learning model generates a good prediction for fund price, which suggests our model can provide a proper application for robo-advisors in terms of predicting fund price movements.

## 6. Conclusion

This paper presents a novel fund price prediction tool, i.e., a spatiotemporal ensemble deep learning model, relying on fund classification, to predict the price of our selected funds,

in the Chinese market. In this paper, we propose a two-step GMM to classify the mutual funds into different categories to ensure the funds classified in the same category have similar risk and return characteristics. We then employ our proposed model to predict the short-term price movement of each fund category.

The main conclusions of this paper are summarized as follows. (1) Compared with the traditional K-means clustering method and network clustering method, our two-step GMM method can generate the probabilities that the funds belong to a certain category, (2) This paper adopts the idea of ensemble learning to improve the prediction ability of fund price movements of other models, i.e., ResNet, LSTM, and CNN models. (3) We classify funds based on their risk and return, which can effectively mitigate the problems of large fluctuations and disorders in the prediction process and thus improve the generality and application of our model.

## Appendix.

### A. PCA

Principal components analysis (PCA) is a kind of dimension reduction method and transfers the original feature space into a brand-new feature space. It is generally used for data pre-processing. For example, assume that there are  $n$  fund samples, with each fund sample with 2,000 features. Among these features, there exists the large amount of noises or useless information. Therefore, the PCA can be conducted for dimension reduction, thus reducing noises and computational resources.

Assume the feature matrix of fund samples as  $(n, m)$ , where  $n$  is the fund sample number and  $m$  is the fund feature number. The PCA can be conducted as follows.

*Step 1.* Compute the mean of each column and subtract the mean using each column to ensure the mean of each column is zero. The dimension of the feature matrix after processing is  $n \times m$ .

*Step 2.* Compute the covariance matrix of the feature matrix. The dimension of the covariance matrix is  $m \times m$ .

*Step 3.* Compute the eigenvalues and eigenvectors of the covariance matrix. The eigenvalues correspond to the eigenvectors one to one. Order the eigenvalues from largest to smallest and order the eigenvectors according to columns. Assume there are  $e$  eigenvalues, the dimension of the eigenvector matrix is  $m \times e$ .

*Step 4.* The final data can be obtained by the feature matrix after processing multiplying the eigenvector matrix. The dimension of the final data is  $n \times e$ .

*Step 5.* Choose an appropriate principal component from all principal components. Assume the  $e$  eigenvalues are  $\alpha_1, \alpha_2, \alpha_3 \dots \alpha_e$  from large to small. Then, after retaining the principal components corresponding to the first  $k$  eigenvalues, the retained variance percentage  $p$  can be obtained by the following equation:

$$p = \frac{\sum_{j=1}^k \alpha_j}{\sum_{j=1}^e \alpha_j}. \quad (\text{A.1})$$

### B. GMM

Gaussian mixture model (GMM) is a kind of probabilistic clustering model. Different from the k-means clustering model, GMM can give the probability that a sample belongs to a category. For example, the hybrid fund may belong to both the consumer category and the technology category. Therefore, this kind of clustering method is certainly practical and explanatory for fund clustering.

GMM is the combination of several Gaussian distributions. Assume there are  $k$  Gaussian distributions for the fund samples. Then the probability density function of the sample is shown as the following equation:

$$p(x) = \sum_{i=1}^k \alpha_i \cdot p\left(x|\mu_i, \sum_i\right), \quad (\text{B.1})$$

where  $x$  follows the mixed normal distribution  $N(\mu, \sum)$ ,  $\mu$  is the vector with means,  $\sum$  is the covariance matrix with a dimension of  $k \times k$ ,  $\mu_i$  and  $\sum_i$  are the mean and variance of the  $i^{\text{th}}$  Gaussian distribution,  $\alpha_i$  is the mixing coefficient of a single Gaussian distribution,  $\sum_{i=1}^k \alpha_i = 1$ , and  $\alpha_i \geq 0$ . The probability density function of a single Gaussian distribution is shown in the following equation:

$$p\left(x|\mu, \sum\right) = \frac{1}{(2\pi)^{n/2} |\sum|^{1/2}} e^{-((x-\mu)^T(x-\mu)/2\sum)}. \quad (\text{B.2})$$

As mentioned above, the parameters of the GMM are the mixing coefficient, the mean vector, and the covariance matrix  $\alpha, \mu, \sum$ . The maximum likelihood estimation method is adopted for parameter estimation. The maximum likelihood function is shown as equation (B.3). The analytical solution of the likelihood function cannot be obtained, so the idea of the maximum expectation (EM) algorithm is adopted to conduct parameter estimation.

$$L = \log \prod_{j=1}^n p(x) = \sum_{j=1}^n \log \left( \sum_{i=1}^k \alpha_i \cdot p\left(x|\mu_i, \sum_i\right) \right). \quad (\text{B.3})$$

Therefore, the probability that the JTH sample belongs to the ITH Gaussian distribution is shown in the following equation:

$$p(z_j = i|x_j) = \frac{\alpha_i \cdot p(x|\mu_i, \sum_i)}{\sum_{i=1}^k \alpha_i \cdot p(x|\mu_i, \sum_i)}. \quad (\text{B.4})$$

Based on the above analysis, assume the feature matrix of fund samples as  $(n$  and  $m)$ , where  $n$  is the fund sample number and  $m$  is the fund feature number. The GMM can be then carried out as follows:

*Step 6.* Initialize  $k$  Gaussian distributions with parameters  $\mu_i, \sum_i, \alpha_i$ .

*Step 7.* E step: calculate the probability that each sample belongs to each Gaussian distribution according to equation (B.4).

*Step 8.* M step: Update the mean vector  $\mu$  and the covariance matrix  $\Sigma$  of the Gaussian mixture distribution.

*Step 9.* Steps 2 and 3 are repeated until the increase in the loss function is less than a preset threshold or the maximum number of iterations is reached. The loss function is the likelihood function as shown in equation (B.3).

*Step 10.* Output the probability of each sample belonging to each Gaussian distribution and cluster the samples into the category with the largest probability.

We apply the Akaike information criterion (AIC) to evaluate the clustering results. AIC is a standard for evaluating the statistical model, which can be used to measure the model complexity and the goodness of fit. It can be obtained as shown in the following equation:

$$\text{AIC} = 2k - 2\ln(L), \quad (\text{B.5})$$

where  $k$  is a parameter, representing the model complexity, and  $L$  is the value of the likelihood function, representing the model goodness of fit. Generally speaking, the smaller the AIC value, the lower the model complexity, the higher the model goodness of fit, and the better the overall performance of the model.

## C. Deep Learning-Based Prediction Model

*C.1 Fully Connected Neural Network Layer.* The FCNN is generally the multilayer perceptron machine, including input layer, hidden layer, and output layer. In this study, we introduce the idea of the residual network (ResNet) into the FCNN, called residual FCNN (R-FCNN), namely adding a residual connection to the FCNN so as to alleviate the problem of gradient disappearance and gradient explosion in deep neural networks.

The ResNet is proposed in 2015 as shown in Figure 8 and equation (C.1). Assume the input is  $X$  and the output is  $F(X)$ . The  $F(X)$  usually includes operations such as convolution and activation. The idea of the ResNet is to add input  $X$  to the function of output  $F(X)$ , as shown in equation (C.1), which can be used to describe the nonlinear relationship between the input and output. Without using the new formula and theory, the residual connection just changes a new express so as to solve the problems of gradient disappearance and gradient explosion in deep network training.

$$x^{l+1} = F(x^l) + x^l. \quad (\text{C.1})$$

The architecture of the R-FCNN is shown in Figure 9. In this study, the R-FCNN is mainly used to extract the nonlinear correlation between input information and output information. The input is the semantic vector after embedding, and the output is the vector containing only one element, that is, the average fund value of a certain fund category in the next period.

FIGURE 8: Diagram of residual connection.

*C.2 Long Short-Term Memory Layer.* A recurrent neural network (RNN) as shown in Figure 10 is a kind of powerful neural network that can deal with not only time series but also images. The input of RNN includes not only the current information but also the previous information. The historical information can be remembered by neurons and then passed forward through a feedforward neural network. The data flow is shown in equation (C.2), where  $\varnothing(\cdot)$  is the activation function,  $x_t$  is the input of the current time step,  $h_{t-1}$  is the saved historical information of the last time step, and  $W$ ,  $U$ , and  $V$  are the weight matrix.

$$\begin{aligned} h_t &= \varnothing(Wx_t + Uh_{t-1}), \\ y_t &= Vh_t. \end{aligned} \quad (\text{C.2})$$

However, when processing long sequence data, the RNN is likely to encounter the problem of gradient disappearance or gradient explosion, which makes RNN have only short-term memory, that is, RNN can only obtain the information of the near sequence when dealing with long sequence data but has no memory function for the earlier sequence, thus losing information. To solve this kind of problem, the LSTM structure is proposed by Hochreiter et al. LSTM is also a kind of recurrent neural network, which is mainly used to solve the problem that common RNN cannot remember long historical information. The data flow is shown in equation (C.3), where  $c$  is the memory cell matrix;  $\odot$  indicates the Hadamard product; the initiation of  $c$  and  $h$  is zero;  $\sigma$ ,  $\tanh$ , and sigmoid are activation function;  $W$ ,  $U$ , and  $V$  are weight matrices; and  $b$  is the bias vector.

A single LSTM cell is shown in Figure 11, which contains three gates, input gate ( $i_t$ ), forgetting gate ( $f_t$ ), and output gate ( $o_t$ ). They determine which information can be input, which information can be forgotten, and which information can be output, respectively. There is also a memory cell ( $c_t$ )

FIGURE 9: Diagram of the residual fully connected neural network layer.

FIGURE 10: Diagram of recurrent neural network.

$$f_t = \sigma(W_f x_t + U_f h_{t-1} + V_f c_{t-1} + b_f),$$

$$i_t = \sigma(W_i x_t + U_i h_{t-1} + V_i c_{t-1} + b_i),$$

$$\tilde{c}_t = \tanh(W_c x_t + U_c h_{t-1} + b_c)$$

$$c_t = f_t \odot c_{t-1} + i_t \odot \tilde{c}_t,$$

$$o_t = \sigma(W_o x_t + U_o h_{t-1} + V_o c_t + b_o) \quad (C.3)$$

$$h_t = o_t \odot \tanh(c_t),$$

$$\sigma(x) = \frac{1}{1 + e^{-x}}$$

$$\tanh(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}}$$

FIGURE 11: Diagram of LSTM cell.

that records the current state of the system and is controlled by three gates.

In this study, the LSTM is mainly applied to extract the temporal information in the fund data sequence. The input and output are the same as that of the R-FCNN, with the semantic vector after embedding as the input and the average fund value of a certain fund category in the next period as the output.

**C.3 Convolutional Neural Network Layer.** CNNs consist of one-, two-, and three-dimensional convolutional neural networks. The input data of the three operations correspond to different dimensions. The input data of the one-dimensional convolutional nerve needs to be one-dimensional, which is equivalent to the fully connected layer in the convolutional operation, as shown in Figure 12. The kernel in the convolution operation moves from left to right to get the final output. One-dimensional CNN is mainly used to extract the spatial correlation between input information and output information. Through the convolution operation of the multilayer convolutional kernel, the correlation between a single element and all other elements in the input information are effectively extracted.

Because the fund data is one-dimensional, we apply the one-dimensional CNN to extract the spatial correlations in the fund data sequence. The input is the semantic vector after embedding. The output of the CNN is

In healthcare research, medical expenditure data for the elderly are typically semicontinuous and right-skewed, which involve a point mass at zero and may exhibit heteroscedasticity. The problem of a substantial proportion of zero values prevents traditional regression techniques based on the Gaussian, gamma, or inverse Gaussian distribution, which may lead to understanding the standard errors of the parameters and overestimating their significance. A common way to counter the problem is using zero-adjusted models. However, due to the right-skewness in the nonzeros' response, conventional zero-adjusted models such as zero-adjusted gamma, zero-adjusted Inverse Gaussian, and classic Tobit may not perform well. Here, we firstly generalize those three types of the conventional zero-adjusted model to solve the problem of right-skewness in health care. The generalized zero-adjusted models are very flexible and include the zero-adjusted Weibull, zero-adjusted gamma, zero-adjusted inverse Gaussian, and classic Tobit models as their special cases. Using the Chinese Longitudinal Healthy Longevity Survey, we find that, according to the AIC, SBC, and deviance criteria, the zero-adjusted generalized gamma model is the best one of these generalized models to predict the odds of zero cost accurately. In order to depict the predictors affecting the amount expenditure, we further discuss the situations where the mean, dispersion of a nonzero amount expenditure and model the probability of a zero amount of ZAGG in terms of predictor variables using suitable link functions, respectively. Our analysis shows that age, health, chronic diseases, household income, and residence are the main factors influencing the medical expenditure for the elderly, but the insurance is not significant. To the best of our knowledge, little study focused on these situations, and this is the first time.

## 1. Introduction

The ageing of the population is a universal law of the development of human society. According to the definition of the United Nations, if more than 10% of the total population of a country or region is seniors over 60 or over 7% are seniors over 65. The country or region has entered an ageing society. At present, most countries in the world, including the United States, the United Kingdom, and Japan, are about to experience the effects of population ageing. China has no exception and is also facing the complex ageing situation. The proportion of the population over 60 in China has increased from 10% in 1999 to 18% in 2019, nearly doubling in the next twenty years. The weakening of the physiological functions of the elderly will naturally increase their chances

of illness, leading to an increase in the demand for health services, which in turn brings about a large number of health and medical security problems for the elderly. Statistics from the China Health Commission showed that approximately 17% of the elderly consume nearly 70% of medical expenses. In addition, the ageing of the population will also inevitably bring about an increase in the life expectancy of the population. Experience has shown that chronic diseases are naturally associated with ageing. Therefore, the ageing population will result in a substantial increase in the prevalence of various chronic diseases. Ingmar et al. [1] discovered exceeding 60% of aged 65 and older had three or more coexisting chronic diseases in Germany. More than 180 million older adults in China suffer from chronic diseases, and the coexistence of multiple diseases is common.

According to the statistics of China's health and family planning, the medical expenditure of chronic diseases accounts for more than 70% of the health expenditure. However, due to the imperfections of China's existing medical security system, the out-of-pocket medical expense is relatively large, and medical security is insufficient [2, 3]. When the elderly's out-of-pocket medical expenditure reached or exceeded their ability to pay, some elderly people are not going to see the doctor after they become ill. Compared with other diseases, chronic diseases have the characteristics of insidious onset and long course, which will not only significantly increase the medical expenditure of the elderly [4, 5] but also cause some older adults to fail to receive medical treatment for minor illnesses. Therefore, accurate prediction of medical expenditure for the elderly will not only help the elderly arrange their consumption expenditure reasonably and improve their health status but also be advantageous to the country allocating medical resources more effectively.

Nevertheless, due to the different personal economic conditions of different elderly groups, they will have differences in medical expenditures after they fall ill. These phenomena will lead to a large number of zero consumption expenditures in the medical expenditure data of the elderly [6, 7], which also will result in right-skewed problems in the distribution of medical consumption data. Because of the point mass at zero and skewness, these problems can hardly be taken into account by traditional regression models such as Poisson, OLS, and gamma models. Ignoring these phenomena would lead to misspecified regression-based estimators and overestimated/underestimated effects. In order to predict more accurately, the medical expenses of the elderly new models need to be proposed. The aim of this paper is to propose a type of generalized zero-adjusted model to better fit the semicontinuous data, explore the influencing factors of elderly's medical expense, use this type of model to predict the amount of medical consumption of the elderly, and compare the results with conventional models.

The specific contributions of this paper include the following: (1) three types of generalized zero-adjusted models such as zero-adjusted generalized gamma model, zero-adjusted generalized inverse Gaussian model, and generalized zero-adjusted Tobit model for predicting the medical expenditure were proposed which included many traditional models and have not been used in health economic cost data modelling before. (2) Selected the best model zero-adjusted generalized gamma model according to different criteria and explored the marginal effects of predictors of medical expenditures. (3) Discovered the relationship between the dispersion of medical expenditure and explanatory variables due to the heterogeneity of variance.

The rest of this paper is organized as follows: detailed literature and related work are given in Section 2. Conventional zero-adjusted models and generalized zero-adjusted models are highlighted in Section 3. Numerous experimental results and comparisons of different models are suggested in Sections 4 and 5. Discussion is shown in Section 6. In the end, conclusions are summarized, and future research is presented in Section 7.

## 2. Related Works

There was much literature about modelling health care costs, although the health economist or health services researcher faced several difficulties. One type of published approaches for the medical expenditure involved modelling the cost using ordinary squares regression directly [8, 9]. Although the ordinary least squares model was used, this method was criticized because the distribution of strictly positive health expenditures was typically skewed, kurtotic (thick-tailed), and heteroskedastic, exhibiting a nonconstant variance that increased with expenditures [10]. These properties make the traditional approach, such as ordinary least squares (OLS) estimation biased and inefficient. Therefore, lots of work had been done on the problems of modelling medical expenditure. In order to solve the right-skewed of the medical expenditure data, Jones transformed the dependent variable using a log transformation to reduce the effect of extreme observations and right skewness and improved the goodness of fit [11]. Manning and Mullahy assumed the medical expenditures to be distributed to an exponential function of the explanatory variables and used log ordinary least squares and the gamma model with a log link to find a more robust alternative estimator than the OLS regression [12]. However, such transformations were likely to be problematic in heteroskedastic errors on the transformed scale [13, 14]. Alternately, there was a large and growing literature on using inherently nonlinear specifications to model medical expenditures, which benefited from estimating effects on the natural scale of costs. The generalized linear model (GLM) and exponential conditional mean models were considered. The generalized linear model was first proposed by Nelder and Wedderburn in the 70s last century and has been widely applied in many fields as once proposed [15]. The generalized linear model assumed that the dependent variable obeyed a type of exponential distribution family, which included many common distributions such as Poisson and normal and supposed the variance of the random error term was not required to be equal. Within the GLM family, it was usual to make assumptions about the functional form of the mean and variance of the distribution. Although the generalized linear model could effectively deal with the problem of heteroscedasticity, it perhaps failed to account explicitly for the issues of skewness and the fat tail, which had implications for the efficiency and robustness of estimators [16]. More flexible distributions for a greater range of estimated skewness and kurtosis coefficients were explored. Manning et al. proposed the generalized gamma models (GGM) to solve the problem of healthcare costs. The GGM model included important parametric distributions as nested and special cases, such as the gamma (GA) and log-normal (LN) distribution. Each model had been selected to model healthcare costs in lots of literature [14]. Because the GGMs was also a special limiting case of the generalized beta of the second kind (GB2), Jones investigated GB2 as part of a comparison of many different methods for modelling US healthcare costs. Mullahy [16] considered the use of the Singh–Maddala distribution (SM) in order to control the heavy right-hand tail of cost data, which was also nested within the GB2.

Where the censored approach to medical expenditure was concerned, the Tobit regression using a single distribution had been suggested as one of the methods to be used for modelling [17]. In Tobit regression, there was an assumption about the response variable based on a zero-truncated normal distribution. Obviously, the constant variance was assumed in this linear regression setting, and the response variable was right-skewed, which was inadequate for medical expenditure data. Therefore, the Gaussian assumption might not be suitable for fitting medical expenditure with the Tobit model. The censored Gamma regression was introduced to overcome the skewed nature of the response [18]. Unfortunately, the Tobit model could not also handle the excess zeros that was a phenomenon that there were more zeros than from the underlying distribution in the medical expenditure data. From the perspective of the data-generating process, semicontinuous medical expenditure data should be considered as arising from two different stochastic processes. Firstly, the patients might choose whether to see a doctor according to their health status, severity of illness, financial burden, and other reasons, which governed the occurrence of zeros. Secondly, the patients who enjoyed more medical services and higher income were likely to incur higher medical expenditures than those less inclined to use these services, which resulted in extremely asymmetry in the nonzero medical expenditures data. Therefore, a two-part mixture model was an ideal choice for dealing with such data, which separately model the probability of any medical services use and the level of expenditures conditional on use [19]. A large number of papers previously were explicitly devoted to changing the different distributions in the second process, and the binomial distribution or logistic regression model was used frequently in the first process. A log-normal distribution was often chosen to model the positive medical expenditure data [20]. However, many alternative distributions were used to relax the log-symmetry condition imposed by the log-normal distribution because the log-normal distribution was not enough to fit the right-skewed and heavy tail features in the data [21, 22]. To the best of our knowledge, there were many studies about the two-part mixture models used in medical healthcare, but the proposed approach had already been applied in many other fields. Heller et al. used the two-part model to predict the total claim count. The one part was the negative binomial distribution for modelling the claim counts, and the other was the inverse Gaussian for the claim amount that occurred. To estimate the total claim amount [23]. Chai et al. analyzed the semicontinuous arterial calcification scores by introducing a two-part skew log-normal [24, 25]. Liu et al. found that the generalized gamma model provided a superior fit in their analysis of daily alcohol consumption by comparing generalized gamma, log-skew-normal, and box-cox-transformed two-part models [26].

In recent years, there has been an increase in the use of Tweedie exponential family models to fit semicontinuous data [27]. The Tweedie family of distributions belongs to the exponential family with variance and has a compound Poisson-gamma interpretation with a probability mass at zero. The primary advantage of fitting such Tweedie models was to

avoid the two-part model of fitting the frequency and then the amount. It is a single distribution. Frees et al. predicted the insurance claim amount using Tweedie model [28]. Christoph F.K showed the better fit of the Tweedie model by comparing it with two-part models and Tobit model [29]. However, there was also another problem that the proposed Tweedie was not allowed to be fitted explicitly as a function of explanatory variables, according to Smyth and Jorgensen [27].

As an alternative, a recent study has perceived that a zero-adjusted regression model, which mixed discrete and continuous distribution. The discrete distribution of the zero adjusted regression model was represented by the Bernoulli distribution. In contrast, the continuous distribution can be represented by any continuous distribution with a positive range and right skewness. The zero-adjusted model could be regarded as a case of a two-part model. The zero-adjusted model focused more on the probability of zero value. When the probability of the observed zero value was much greater or less than the standard normal distribution, gamma, Weibull, and so on, the zero-adjusted model might be established. These could make the probability of zero occurrences predict more actually. Several applications of zero-adjusted gamma (ZAGA) and zero-adjusted inverse Gaussian (ZAIG) regression models could be found in insurance claims [30, 31]. Nevertheless, it appeared that there had been little work done in health economic cost data modelling before. This study attempted to use zero-adjusted models to predict medical expenditure. Throughout this paper, three types of generalized zero-adjusted models were presented, which comprised the classic Tobit model, ZAGA model and ZAIG model, and could improve the accuracy of the prediction. As far as we knew, there was almost little literature to study on those generalized zero-adjusted models, especially in the field of health care.

### 3. Methodology

**3.1. Spliced Distribution.** This study aims to use models to predict the medical expenditure for the elderly and discover the factors affecting the cost as accurately as possible. One way to dealing with excess zeros and positive skewness is to apply zero-adjusted models. The zero-adjusted model can be considered as a case of spliced distribution. Klugman et al. proposed a splicing method for creating new distributions [32], and it had been applied in modelling heavy tail for operational risk [33]. The density function of an  $n$ -component spliced distribution is defined as follows [32]:

$$f(x) = \begin{cases} a_1 f_1(x), & \text{if } x \in C_1, \\ a_2 f_2(x), & \text{if } x \in C_2, \\ \vdots & \\ a_n f_n(x), & \text{if } x \in C_n. \end{cases} \quad (1)$$

Here  $a_1, \dots, a_n$  are positive weights that add up to

$$a_1 + a_2 + \dots + a_n = 1. \quad (2)$$

The functions  $f_i(x) (i = 1, 2, \dots, n)$  are legitimate density functions with all probability on the interval  $C_i$ :

$\int_{C_i} f_i(x) dx = 1$ . The intervals  $C_i$  and  $C_j$  are mutually exclusive:  $C_i \cap C_j = \Phi, \forall i \neq j$ . The intervals of  $C_i$  are also sequentially ordered. That is to say,  $x < y$  if  $x \in C_i$  and  $y \in C_j$  for all  $i < j$ . There is an advantage of the spliced distribution allowing the inclusion of point mass distributions.

**3.2. Zero-Adjusted Model.** The zero-adjusted model can be regarded as a case of  $n$ -component spliced distributions when  $n$  equals 2. The first part has zero expenditure amounts, and the second part has nonzero expenditures, which are assumed to have a continuous distribution that accommodates heavy right-skewed. Let  $y_i$  be the expenditures of the  $i$ th older people,  $i = 1, \dots, n$ . The density function of zero-adjusted distribution may be written as follows:

$$f(y|x) = \begin{cases} \pi, & \text{if } y = 0, \\ (1 - \pi) \cdot g(y|x), & \text{if } y > 0. \end{cases} \quad (3)$$

where  $g(y)$  is the density of a continuous, right skewed distribution, and  $\pi$  is the probability of zero medical expenditure. The cumulative distribution of a zero-adjusted model (ZAM) can be expressed as

$$F(y|x) = \pi I_{\{y=0\}} + [\pi + (1 - \pi)G(y|x)] I_{\{y>0\}}, \quad (4)$$

where  $I(\cdot)$  is an indicator function.

**3.3. Discrete Part of ZAP.** Suppose the probability of an older person is distributed to the Bernoulli. Let  $\omega_i$  be a binary variable indicating the occurrence of the outcome for the older person with medical expenditure in one year and  $\pi_i$  be the probability of the positive medical expenditure, on person  $i$ .  $\pi_i$  may be a constant such as in equation (3) or be a random variable distributed as follows:

$$f(\pi_i|x) = \pi_i^{\omega_i} (1 - \pi_i)^{1 - \omega_i}, \quad \omega_i = 0, 1. \quad (5)$$

We consider the factors affecting the medical expenditure of the older person and incorporate covariates through the logit link function on  $\pi_i$ :

$$\log \frac{\pi_i}{1 - \pi_i} = \eta_i. \quad (6)$$

The predictor  $\eta_i$  is any form of a function related to factors, but generally is assumed to be a linear system  $\eta_i = \beta X_i$ ,  $\beta = (\beta_1, \dots, \beta_p)$ ,  $X_i$  is the vector of factors and  $\beta$  is the parameter. According to equation (6), we can predict the probability of medical expenditure for the elderly and determine the influencing factors of their medical decision-making.

**3.4. Continuous Part of the Zero-Adjusted Model.** Another advantage of spliced distributions is that they allow us to model different parts of a response variable with distributions. There are many candidate distributions for the nonzero heavy-tailed distribution modelling medical expenditures  $g(y|x)$ , such as the gamma, inverse Gaussian, log-normal (LN), Weibull (WEI), and log-skew-normal. In

this study, we considered two specifications of the spliced distributions. The first specification used the generalized gamma (GG) distribution, which includes the standard gamma, inverse gamma, Weibull, and log-normal distributions as special cases [21, 26]. Another was the generalized inverse Gaussian (GIG) distribution, which includes the inverse Gaussian as a special case and the gamma distribution and inverse gamma distributions as limiting cases [34, 35]. The Tobit distribution was also presented as a baseline comparison for the others, and we generalized the traditional Tobit model.

**3.4.1. Gamma Distribution (GA) and Inverse Gaussian Distribution (IG).** There was much work to deal with the problem of skewness and heteroscedasticity by transforming data. The data transformed seemed to be more homogeneous and symmetric. However, homoscedasticity was hardly achieved in fact, which resulted in biased estimation [36, 37]. Instead, we used gamma and inverse Gaussian distribution, which belonged to the generalized models taking into account heteroscedasticity and retaining the original dollar scale of the data. Furthermore, the gamma and inverse Gaussian models could accommodate skewness in the expenditures [38]. The GA model and IG model are included in the generalized linear model, which is mainly composed of three parts:

- (1) Systems part: the system part is a linear component which can be seemed like the traditional linear models similarly:

$$\eta_i = x_i' \beta, \quad (7)$$

where  $x_i$  is a column vector of covariates for observation  $i$ ,  $\beta$  is a column vector of the parameters, and  $\eta_i$  is a column vector of prediction  $i$ .

- (2) Link functions: the link functions  $g$  is often defined a monotonic and differential, which combines the prediction and the systems part and describes how the expected value of a response  $y_i$  is related to the linear predictors:

$$g(\mu_i|x) = x_i' \beta, \quad (8)$$

where  $g$  is often defined a log function.

- (3) Random parts: the response variables  $y_1, y_2, \dots, y_n$  are independent and distributed from an exponential family which implies there are a relationship between the variance and mean. The general form of exponential family is

$$f(y|\theta, \varphi) = \exp \left[ \frac{y\theta - b(\theta)}{a(\varphi)} + c(y, \varphi) \right], \quad (9)$$

where  $\theta$  is called the canonical parameter and represents the location, while  $\varphi$  is the dispersion parameter and represents the scale. Many distributions besides GA and IG models belong to the exponential distribution family, for example, normal, Weibull,

Poisson, negative binomial distributions, and so on. Because of skewness and heteroscedasticity of the outcome, the densities of the gamma distribution and inverse Gaussian distributions are

$$\text{gamma: } f(y|\mu, \sigma) = \frac{y^{1/\sigma^2-1} e^{-y/(\sigma^2\mu)}}{(\sigma^2\mu)^{1/\sigma^2} \Gamma(1/\sigma^2)}, \quad y > 0, \mu > 0, \sigma > 0. \quad (10)$$

Inverse Gaussian:

$$f(y|\mu, \sigma) = \frac{1}{\sqrt{2\pi\sigma^2 y^3}} \exp\left[-\frac{1}{2\mu^2\sigma^2 y}(y - \mu)^2\right], \quad y, \mu, \sigma > 0. \quad (11)$$

Suppose the mean of gamma and inverse Gaussian distribution is  $E(Y|x) = \mu$ . The variance of gamma distribution is  $\text{Var}(Y|x) = \mu^2\sigma^2 = (E(Y|x))^2\sigma^2$ , and  $E(Y^r|x) = \mu^r \sigma^{2r} \Gamma(1/\sigma^2 + r) / \Gamma(1/\sigma^2)$ , for  $r > -1/\sigma^2$ . The skewness of gamma distribution is  $2\sigma$ , and excess kurtosis is  $6\sigma^2$ . The gamma distribution is appropriate for positively skewed data. At the same time, the variance of inverse Gaussian distribution is  $\text{Var}(Y|x) = \sigma^2\mu^3$ , and the skewness of inverse Gaussian is  $3\mu^{1/2}\sigma$ , the excess kurtosis is  $15\mu\sigma^2$ . The inverse Gaussian distribution is also appropriate for highly positively skewed data. We can see that the variance of response is a function of its mean. Note that the variance function for the inverse Gaussian GLM increases more rapidly with the mean than the gamma GLM.

**3.4.2. Generalized Gamma Distribution (GG).** Although the standard gamma model was fairly robust when we analyzed the positive medical expenditures([39]), it was inefficient when the data were heteroskedastic and heavily right-skewed([14]). The generalized gamma was available among other continuous distributions handling values only on the positive values. The density of the generalized gamma probability distribution is parameterized as a function of  $\kappa, \mu, \sigma$  and is given by [14, 21]

$$f(y; k, \mu, \sigma) = \frac{\theta^\theta}{\sigma y \sqrt{\theta} \Gamma(\theta)} \exp[z\sqrt{\theta} - \mu], \quad y \geq 0, \quad (12)$$

where  $\theta = |\kappa|^{-2}$ ,  $z = \text{sign}(\kappa)\{\ln(y) - \mu\}/\sigma$  and  $\mu = \theta \exp(|\kappa|z)^5$ . Because  $dz = (1/\sigma y)dy$ , equation (12) could be interpreted as the standard normal distribution ( $z$ ) scale for log-transformed  $y$ . If  $Y$  is a random variable distributed to density (12), then its mean was given by

$$E(Y|x) = \exp\left\{\mu + \frac{\sigma \log(\kappa^2)}{\kappa} + \log\left[\Gamma\left(\frac{1}{\kappa^2} + \frac{\sigma}{\kappa}\right)\right] - \log\left[\Gamma\left(\frac{1}{\kappa^2}\right)\right]\right\}. \quad (13)$$

The other moments of the generalized gamma distribution were  $m$ -th moment  $= E(Y^m|x) = [\exp(\mu) \cdot \kappa^{2\sigma/\kappa}]^m \{\Gamma[(1/\kappa^2) + (m\sigma/\kappa)]/\Gamma(1/\kappa^2)\}$

And, the variance was

$$\begin{aligned} \text{variance} &= E(Y^2|x) - E^2(Y|x) \\ &= [\exp(\mu) \cdot \kappa^{2\sigma/\kappa}] \\ &\quad \left\{ \left[ \frac{\Gamma((1/\kappa^2) + (2\sigma/\kappa))}{\Gamma(1/\kappa^2)} \right] - \left[ \frac{\Gamma((1/\kappa^2) + (\sigma/\kappa))}{\Gamma(1/\kappa^2)} \right]^2 \right\}. \end{aligned} \quad (14)$$

The standard gamma, inverse gamma, Weibull, and log-normal distributions were special cases of the generalized gamma distribution. For example, the generalized gamma distribution density reduced to a standard gamma distribution when the shape parameter  $\theta = \kappa^{-2}$  and the scale parameter  $\nu = \kappa^2 \exp(\mu)$ , i.e., the density follows as  $f(y; \nu, \theta) = (1/\nu^\theta \Gamma(\theta)) y^{\theta-1} \exp(-y/\nu)$ , and the mean was  $\exp(\mu)$ , the variance was  $\kappa^2 \exp(2\mu)$ . Let  $\kappa = -\sigma$ ,  $\sigma > 0$ , and the inverse gamma distribution was also obtained. The generalized gamma distribution reduced to an inverse gamma distribution defined as Robert [40], as follows.

$f(y; \varepsilon, \theta) = \varepsilon^\theta / \Gamma(\theta) (1/y)^{\theta+1} \exp(-\varepsilon/y)$ , where  $\varepsilon = \theta \exp(\mu)$ . When the parameter  $\kappa$  in equation (12) was fixed at a special value, for example,  $\kappa = 1$ , density (12) reduces to the probability density function of a Weibull distribution. In addition, if the parameter  $\kappa \rightarrow 0$ , density (12) reduced to the lognormal distribution, i.e.,  $f(y; \mu, \sigma) = 1/\sigma y \sqrt{2\pi} \exp\{-(\log(y) - \mu)^2/2\sigma^2\}$ .

**3.4.3. Generalized Inverse Gaussian Distribution (GIG).** We introduced the GIG distribution because the GIG was right-skewed, single-peaked distribution, and had a broader range of shapes. The standard gamma was a case of the GIG. Thus, the GIG could be a more flexible alternative to the standard version of the gamma [39]. The probability density function of the model was parameterized in terms of its mean, dispersion, and shape parameters. The parameterization of the generalized Inverse Gaussian distribution, denoted by  $GIG(\mu, \sigma, \nu)$ , was given by

$$f(y; \mu, \sigma, \nu) = \left(\frac{b}{\mu}\right)^\nu \left[\frac{y^{\nu-1}}{2K_\nu(\sigma^{-2})}\right] \exp\left[-\frac{1}{2\sigma^2}\left(\frac{by}{\mu} + \frac{\mu}{by}\right)\right], \quad (15)$$

for  $y > 0$ , where  $\mu > 0$ ,  $\sigma > 0$ , and  $-\infty < \nu < \infty$ . In the above equation (15),  $b = [K_{\nu+1}(\sigma^{-2})][K_\nu(\sigma^{-2})]^{-1}$  and  $K_\lambda(t)$  was a modified Bessel function of the second kind [40]:  $K_\lambda(t) = 1/2 \int_0^\infty x^{\lambda-1} \exp\{-1/2t(x+x^{-1})\} dx$ . With this parameterization, the mean  $E[Y|x] = \mu$  and variance  $\text{Var}[Y|x] = \mu^2 [2\sigma^2/b(\nu+1) + 1/b^2 - 1]$ . The skewness of GIG is

$$\begin{aligned} \text{skewness} &= \mu^3 \frac{[2 - 6\sigma^2/b(\nu+1)(\nu+2)\sigma^4 - 2/b^2 + 2\sigma^2/b^3(\nu+2)]}{[\text{Var}(y)]^{1.5}}, \\ \text{excess kurtosis} &= \mu^4 \frac{\left\{ \begin{aligned} &-6 + 24\sigma^2/b(\nu+1) + 4/b^2 [2 - \sigma^4(\nu+1)(7\nu+11)] + 4\sigma^2/b^3 [2\sigma^4(\nu+1)(\nu+2)(\nu+3) - 4\nu - 5] + \\ &1/b^4 [4\sigma^4(\nu+2)(\nu+3) - 2] \end{aligned} \right\}}{[\text{Var}(y)]^2}. \end{aligned} \quad (16)$$

Unlike the majority of models for insurance losses, our general approach could determine the distribution of each risk class based not only on the mean parameter, which was traditionally modelled in terms of covariates but also by using regressors on the dispersion and shape parameters, which described the shape of the GIG distribution. This could be regarded as a very useful property. Additionally, the GIG was a very wide family which included many well-known distributions depending on the estimated values of the dispersion and shape parameters which were modelled as functions of risk factors as was well known. For example, as could be seen,  $\text{GIG}(\mu, \sigma, -0.5) = \text{IG}(\mu, \sigma\mu^{-1/2})$ . Therefore, the gamma was a special case of GIG when  $b = 1$  and  $\nu = -1/2$ . According to Jorgensen [35],  $K_\lambda(t) \sim \Gamma(\lambda)2^{\lambda-1}t^{-\lambda}$  as  $t \rightarrow 0$ , for all  $\lambda > 0$ . And, when  $\sigma \rightarrow \infty$ ,  $\text{GIG}(\mu, \sigma, \nu)$  had limiting distribution  $GA(\mu, \nu^{-1/2})$  for all  $\nu > 0$ .

**3.4.4. Tobit Distribution.** Tobit model was first introduced to model dependent variables with a large fraction of zeros by Tobin [17]. The classic Tobit model assumed that the response was continuous, censored, and normally distributed underlying latent dependent variable  $y^*$ . We were interested in designing the latent variable  $y^*$  as a linear regression model:

$$\begin{aligned} y^* &= x_i'\beta + \varepsilon_i, \quad i = 1, \dots, n \\ y_i &= \begin{cases} y^*, & \text{if } y^* \leq L, \\ L, & \text{if } y^* > L, \end{cases} \end{aligned} \quad (17)$$

where  $\varepsilon \sim N(0, \sigma^2)$ ,  $x_i$  is an exogenous and observable explanatory variable. Specifically, if the latent variable  $y^*$  values equal to zero are censored, such as the medical expenditure for the elderly,  $L$  became zero. Then, the probability of a censored observation sample was

$$\Pr(y^* \leq L) = \Pr(x_i'\beta + \varepsilon \leq L) = \Phi\left[\frac{(L - x_i'\beta)}{\sigma}\right], \quad (18)$$

where  $\Phi(\cdot)$  was the standard normal cumulative distribution. We could present the truncated expected value of the noncensored observation  $y_i$

$$E(y_i | x_i, y_i > L) = x_i'\beta + \sigma \frac{\phi[(x_i'\beta - L)/\sigma]}{\Phi[(L - x_i'\beta)/\sigma]}, \quad (19)$$

where  $\phi(\cdot)$  was the density function of standard normal distribution. The classic Tobit model was appropriate when the response had two properties: one was that the error  $\varepsilon$

was a normal distribution, and the other was that the negative values of response were censored at  $L$ .

**3.4.5. New Type of Generalized Tobit Distribution.** The classic Tobit model was extremely sensitive to its underlying assumptions of normality and homoscedasticity. Therefore, the classic Tobit model should never be fit unless the data were truly normal and censored distribution. However, these were hardly met in real data [41, 42]. Many researchers claimed that a large mass at zero was censored observations when they were not censored, especially for health expenditure data. We provided another generalized Tobit model which was different from the generalized Tobit selection model by Heckman [43]. The Heckman selection model was considered as a generalized Tobit model and mainly connected the two latent outcomes by inverse mills ratio. However, the response variable was assumed to be normally distributed yet. In this paper, we mainly generalized the part where the latent  $y^*$  greater than zero. We selected the *student t* family model in order to compare the classic Tobit model. The *Student t* family model was introduced by Lange et al. [43] and was defined by assuming that  $Y = \mu + \sigma T$ , where  $T \sim t_\nu$  had a standard *t* distribution with  $\nu$  degrees of freedom. In this study, the PDF of *Student t* family distribution was given by

$$f_Y(y; \mu, \sigma, \nu) = \frac{1}{\sigma B(1/2, \nu/2)\nu^{1/2}} \left[ 1 + \frac{(y - \mu)^2}{\sigma^2 \nu} \right]^{-(\nu+1)/2}, \quad (20)$$

for  $-\infty < y < +\infty$ , where  $-\infty < \mu < +\infty$ ,  $\sigma > 0$ ,  $\nu > 0$ , and  $B(a, b) = \Gamma(a)\Gamma(b)/\Gamma(a+b)$  is the beta function. Note that  $T = (Y - \mu)/\sigma$  had a standard *t* distribution with  $\nu$  degrees of freedom. It was obvious that the *t* distribution had higher kurtosis than the normal distribution and more suitable for modelling leptokurtic data [43]. The excess kurtosis of *t* distribution was  $6/\nu - 4$  (if  $\nu > 4$ ).

**3.4.6. Modelling the Probability of Zero Expenditures and Expected Nonzero Expenditures in Terms of Explanatory Variables.** We focused on the factors influencing the medical decision and the number of medical expenditures but paid attention to the accuracy of prediction. The mean  $\mu$  of regression model determined the number of medical expenditures and the dispersion  $\sigma$  could affect the accuracy

of prediction. Therefore, we would consider the zero-adjusted regression modes in different cases.

Case 1: when the probability of not seeing a doctor was constant, model (6) degenerated to

$$P(y = 0|x) = \pi, \quad (21)$$

$$\log(\mu) = \eta_1 = X_1^T \beta_1 + \varepsilon, \quad (22)$$

where the dispersion  $\sigma$  was considered as a constant and not affected by the predictor variables,  $X$  was the vector of predictors,  $\beta$  was the vector of parameters, and  $\varepsilon$  was the error. We used the log link function according to the exponential family [38].

Case 2: zero amount was not constant, which was affected by predictor variables, and the dispersion  $\sigma$  was still a constant. Then, the probability of a zero medical expenditure and mean is shown as

$$\logit(\pi) = \eta_2 = X_2^T \beta_2 + \varepsilon, \quad (23)$$

$$\log(\mu) = \eta_3 = X_3^T \beta_3 + \varepsilon, \quad (24)$$

where  $X$ ,  $\beta$ , and  $\varepsilon$  were the same as in equation (21) and (22). Theoretically, the factors that affected the decision-making equation (23) and the amount equation (24) were different. However, many studies assumed that they were the same, that was  $X_2 = X_3$ .

Case 3: the mean  $\mu$ , dispersion  $\sigma$ , and the probability of a zero amount  $\pi$  included in zero-adjusted model were all influenced by the predictors, which were modelled in terms of predictor variables using suitable link functions:

$$\logit(\pi) = \eta_4 = X_4^T \beta_4 + \varepsilon, \quad (25)$$

$$\log(\mu) = \eta_5 = X_5^T \beta_5 + \varepsilon, \quad (26)$$

$$\log(\sigma) = \eta_6 = X_6^T \beta_6 + \varepsilon, \quad (27)$$

where we could choose the same or different predictors  $X$  in equations (25)–(27). There had been much literature studying case 1 and case 2, and almost little to discuss case 3 to our best knowledge. In this study, we would analyze the three cases and compare their results.

**3.4.7. Maximum Likelihood Estimation.** According to the zero-adjusted model, given  $n$  independent observations  $y_i$  for  $i = 1, 2, \dots, n$ , the likelihood function was given by

$$L = L(\psi|y) = \prod_{i=1}^n f(y_i|x) = \prod_{i=1}^n \left[ \sum_{k=1}^2 \pi_k f_k(y_i|x) \right], \quad (28)$$

where  $\psi = (\theta, \pi)$ ,  $y = (y_1, y_2, \dots, y_n)^T$  and  $f_k(y_i) = f_k(y_i|\theta_k)$ . The log-likelihood function was given by

$$l = l(\psi|y) = \sum_{i=1}^n \log[\pi f_1(y_i|x) + (1 - \pi) f_2(y_i|x)]. \quad (29)$$

We wished to maximize the log-likelihood  $l$  concerning  $\theta$  and  $\pi$ . Nevertheless, the problem was that the logarithm of

the second summation in equation (29) made the solution difficult. In this paper, we used an algorithm provided by Rigby and Stasinopoulos [44] and was based on penalized likelihood estimation.

### 3.5. Model Validation and Verification

**3.5.1. Graphic Verification.** There were some approaches used for verification and selecting the best model among those models after fitting statistical probability models on the medical expenditures data, which mainly included two types of procedures: the graphical and the numerical approaches [45]. The graphical methods were used to verify whether the model described the systematic part and the independence of the normalized quantile residuals and their normality. In this study, we could obtain the mean, variance, skewness, and kurtosis to check the independence of the normalized quantile residuals and their normality by inspecting the residual versus fitted value plots, residual density plots, and Q-Q plots [44]. To assess the goodness-of-fit of the model, Akaike's information criterion (AIC) [46] and the Schwarz Bayesian criterion (SBC) [47] were considered as the numerical methods for validating and selecting the best model among the verified models. In addition, one goal of this study is to estimate the expected medical cost for individuals ( $\hat{y}_i = E[y_i|x_i]$ ). The mean prediction error can be thought as measuring the bias between the predicted outcome and the true response, which is often measured by the mean squared error (MSE).

**3.5.2. Information Criteria.** To compare the models and select the best one among the fitted models, we used the AIC, SBC, and the global deviance criteria. The AIC is computed based on the Kullback–Leibler distance in information theory, and the SBC is based on the integrated likelihood of Bayesian theory, which both impose the appropriate penalty on the average of the log-likelihood of models estimated given the number of coefficients estimated. A model with the lowest AIC and SBC values will be selected probably. The AIC is given as follows:

$$\text{AIC} = -2 \log(L) + 2p, \quad (30)$$

where  $L$  is the likelihood and  $p$  is the number of parameters in the model. The SBC is defined as:

$$\text{BIC} = -2 \log(L) + 2p \log(n), \quad (31)$$

where  $L$  and  $p$  are the same as in AIC and  $n$  is the sample size. As suggested by Rigby and Stasinopoulos [44] for parametric GAMLSS models, each model could be assessed by its fitted global deviance (GD) given by

$$\text{GD} = -2l(\hat{\theta}), \quad (32)$$

where  $l(\hat{\theta}) = \sum_{i=1}^n l(\theta_i)$ .

**3.5.3. Bias and Accuracy.** The bias measures the average deviation of the predicted value  $f(x)$  from the true value

$f(x)$  in a large number of the repeated sampling processes. The bias is often defined as followed given X:

$$\text{Bias}[\hat{f}(x)] = E[\hat{f}(x)] - f(x). \quad (33)$$

MSE can be thought of as measuring the bias of predictions and be defined as

$$\text{MSE}[\hat{f}(x)] = E[y - \hat{f}(x)]^2. \quad (34)$$

We can prove the MSE is minimized when  $\hat{f}(x) = E[y|x]$ . MSE is obtained through the sample value  $\text{MSE} = 1/N \sum_{i=1}^N (\hat{y}_i - y_i)^2$ , where  $\hat{y}$  denotes the estimated and  $y$  is the true value and  $N$  is the sample size. The MSE is an unbiased estimator of deviation.

**3.5.4. Out-of-Sample Analysis.** There is the last step to examine the appropriateness of the estimated models and the generalization ability of the model. We applied the bootstrap procedure to investigate how the results of our statistical analysis would be generalized to another data set. Given a data set  $D$  containing  $m$  samples, we could sample it and generate another data set  $D'$ . A sample was randomly selected from the data set  $D$  and put into the data set  $D'$ , and then the sample was put back into the initial data set  $D$ , so that the sample might be still drawn next time. After repeating this process  $m$  times, we were able to get a data set  $D'$  consisting of  $m$  samples. It was obvious that some samples in the data set  $D$  would appear multiple times in  $D'$ , while other samples maybe would not appear. The probability that a sample was never selected in  $m$  sampling was  $(1 - 1/m)^m$ , and its limit was  $\lim_{m \rightarrow \infty} (1 - (1/m))^m = 1/e \approx 0.368$ . About 36.8% of the samples in the data set  $D$  by the bootstrap sampling method did not appear in the sampling data set  $D'$ . In this way, we could use  $D'$  as the training set and  $(D - D')$  as the test set. In practical application, 1/3 of the sample size was generally selected as test set and 2/3 as the training set.

## 4. Empirical Analysis

**4.1. Data Description.** The aim of this paper was to discover the factors affecting the medical expenditures of the elderly in China and predict the amount using data from the Chinese Longitudinal Healthy Longevity Survey (CLHLS). This survey is a nationally representative panel study, containing observations on individuals aged 65 years or older covering more than half of the counties and cities from 23 provinces, cities, and autonomous regions in China. Since the start of the survey in 1998, it was repeated to follow the same group of the elderly every two or three years, which have been conducted eight waves until 2018. The survey includes questions about the health status, quality of life, medical care, and security needs of the elderly. We used data from the latest survey in 2018, which was a mixed cross-sectional data set collected from 1998 to 2018. In total, the sample consists of 15874 individuals. We finally selected 6832 samples after deleting the data with missing and no response. In what follows, we described variables retained for analysis. We began with the aimed response variable, the

medical expenditures, followed by other main independent variables such as income, health, and education.

**4.2. Description of Variables.** The distribution of medical expenditure for the elderly with the entire sample is shown in Figure 1. We could find that there were a large of zeros, and the histogram of the medical cost was right-skewed and heavily fat tail. From the empirical cumulative distribution plot (Figure 2), it could be seen that the medical expenditure data in the upper right part seriously deviates from the straight line. Therefore, the OLS regression model was not suitable for the data, and other transformed models must be considered. The histogram is shown in Figure 1 suggested a mixture of point distribution and a continuous distribution on the positive side. Consequently, a Tobit model may lead to biased inferences due to there being far more zero observations than expected under the Tobit formulation. The zero-adjusted models offer us a viable framework to deal adequately with the excess of zeros.

For this study, we were interested in revealing the factors affecting medical consumption behavior. In addition to the response variable, we included a set of explanatories in the regressions that turned out to affect the medical expenditure. Typical variables that emerged from the existing literature are age, sex, household income, marriage, and education [1–5]. We incorporated all these variables and added several other variables to the analysis that significantly improved the estimation of the zero-adjusted models. These variables describe the characteristics of the elderly, such as insurance, health status, action limited, individual education, residence, and heart disease or not.

The Andersen Behavioral Model of Health Service Use usually provided a framework for the study of hospitalization that outlined the three determinants: predisposing, enabling, and need factors [48]. In light of this, we evaluated the effects of health status and functional disabilities, as need factors and associated social-demographic factors, as predisposing and enabling factors, on hospitalization utilization. A complete list of the variables used and their descriptive statistics is presented in Table 1. We treated the variables medical expenditure, education, and household income as numerical. For the convenience of calculation, we divided the medical expenditure and the annual household income by 1000. All other variables were categorical and entered into the regressions as dummy variables.

The density distributions of  $f(y)$ , for nonzero medical expenditure are given in Figure 3. In this study, six right-skewed distributions were considered: the normal, student  $t$ , gamma, inverse Gaussian, generalized gamma and generalized inverse Gaussian distributions. The normal distribution was also presented as a benchmark comparison for the other, right-skewed distributions. All of the candidate distributions were subsequently fitted on a training set of a random 70% subsample. Figure 3 suggested that the normal distribution had the worst fit for the histogram of nonzero medical expenditure and other right-skewed distributions seemed to be fit better. The fitted values of the normal, inverse Gaussian, generalized gamma, and generalized

Note: medical expenses and annual household income are in thousands of yuan.

inverse Gaussian distributions underestimated the actual value at the lower points of medical expenditure. However, they showed better fit at other points. The fitted value of the gamma distribution overestimated the lower points.

Therefore, there seemed to be no obvious evidence to show which one was the best from the histogram. We must combine other statistical indicators to choose the best model, which was also done in the following section.

## 5. Results

According to the experience above, we chose 4872 samples as training data set. Table 2 listed the marginal effects estimation results obtained from the training for the models discussed above. We selected ten predictors according to the demand for health and health care of the Grossman model. The estimates of the Tobit model were quite different from others in the value range and sign, which had the largest values of AIC, SBC, and global deviance. This suggested that the Tobit model fitted the data very badly. The new generalized Tobit model and other zero-adjusted models were more similar. Many estimates shared the same sign and had comparable values, resulting in similar conclusions. In terms of the standard errors of the parameters, the errors of the Tobit model were

significantly higher than others. All zero-adjusted models had lower standard errors of the parameters. Furthermore, the AIC, SBC, and global deviance (GD) of the zero-adjusted generalized gamma model and zero-adjusted generalized inverse Gaussian model were obviously smaller than those of other models. However, the values of the zero-adjusted generalized gamma model were the smallest. The smaller these values are, the better the goodness-fit of the model is. Therefore, the ZAGG model was the best model we chose.

To assess model fit, we created the quantile residuals plots. If the models were adequate for the data, the residuals approximated a random sample from the standard normal distribution [38]. Figure 4 plots the normalized quantile residuals and shows much difference in the residuals among these models. The residuals of the new generalized Tobit

model showed bimodal kurtoses, ZAGA and classic Tobit models presented the aiguille characteristics, and the residuals of the ZAIG model appeared to right-skewed. The residuals of ZAGG and ZAGIG seemed to be similar, but the ZAGG model exhibited a better model fit from Figure 4.

We used worm plots to further study the residuals of these models. Worm plots of the residuals were introduced by van Buuren and Fredriks [49] to identify regions (intervals) of an explanatory variable within which the model does not adequately fit the data. These points in the worm plot, such as Figure 5, showed how far the ordered residuals were from their (approximate) expected values represented by the horizontal dotted line. The closer the points were to the horizontal line, the closer the

distribution of the residuals was to a standard normal distribution. Additionally, if the model was correct, we would expect approximately 95% of the points to lie between the two elliptic curves and 5% outside in Figure 5. A higher percentage of the points outside the two elliptic curves indicated that the fitted distribution of the model was inadequate to explain the response variable. The shape of the fitted curve to the points of the worm reflected different inadequacies in the model. A linear trend (positive or negative), quadratic shape (U or inverse U), or cubic shape (S shape) indicated a problem with the variance, skewness, or kurtosis of the residuals, respectively. This, in turn, highlighted a problem with the fitted distribution. Figure 5 shows that the fitted curves of the worm

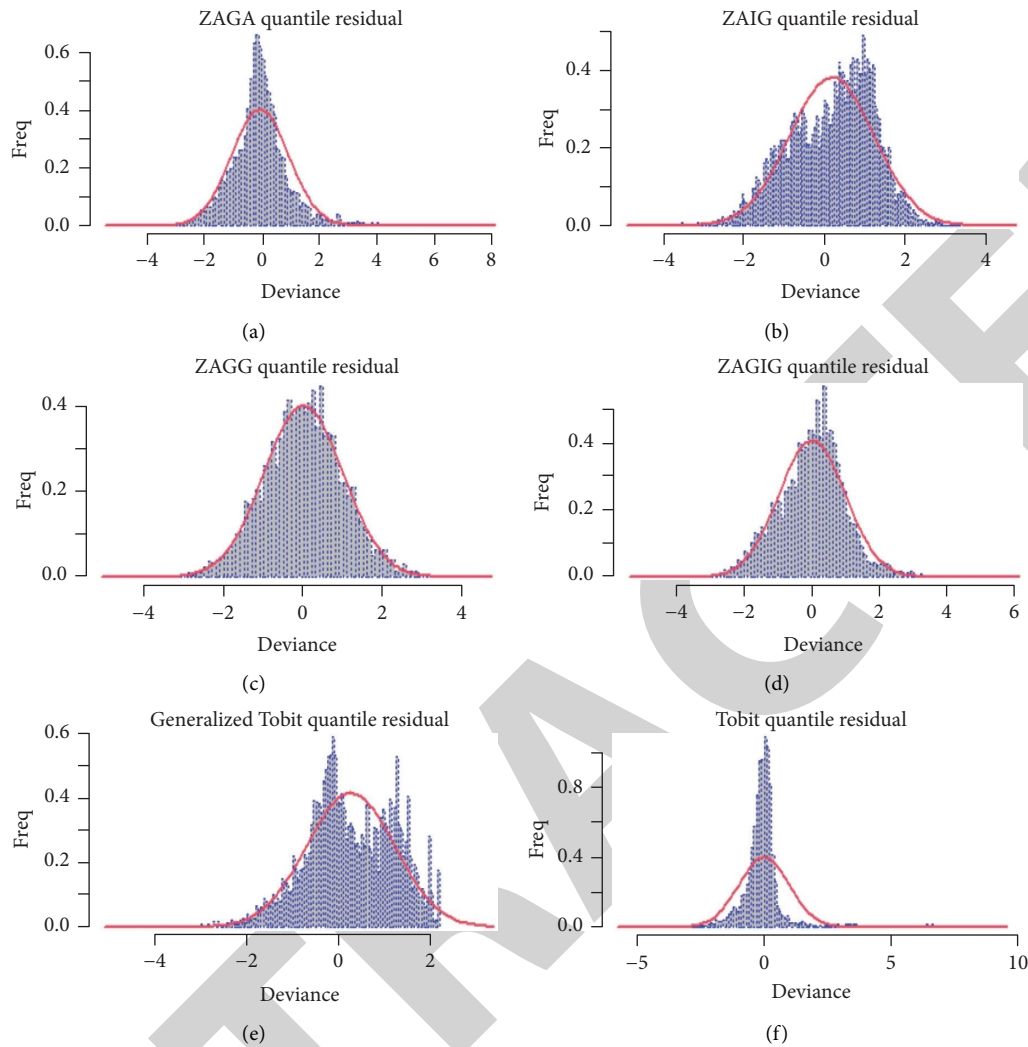

FIGURE 4: Quantile residual for regression models. (a) ZAGA quantile residual. (b) ZAIG quantile residual. (c) ZAGG quantile residual. (d) ZAGIG quantile residual. (e) Generalized Tobit quantile residual. (f) Tobit quantile residual.

for all models except the zero-adjusted generalized gamma model was S-shaped, which also suggested that the ZAGA model was generally a better fit again.

After the verification of 1960 samples in the test data set, two Tobit models and the ZAIG model had larger MSE values. ZAGG and ZAGIG models again produced very similar results. ZAGIG had the lowest MSE with a value of 671.3679. However, ZAGG was slightly higher with a value of 675.1498 than ZAGIG. Considering the goodness of fit, we chose the ZAGG model for further study.

We chose ZAGG models with different parameters  $\pi$ ,  $\sigma$ , and  $\nu$  and used the default log link function to discover which factors affecting the medical expenditure for the elderly. Table 3 shows the results of different parameters using 6832 data of the whole population. The predictors for the logarithm of average medical consumption shared almost the same sign and had similar values in the three models. Age, health, and chronic diseases were the main predictors influencing medical expenditure. With the increase of age, the medical expenditure of the elderly was decreasing. Part

of the reason might be that the elderly under 80 years old had a higher risk of serious diseases like cancer than the elderly over 80 years old. After experiencing this age stage, most of higher aged elderly were in good health. The elderly in good health had relatively less medical expenditure. As a chronic disease, heart disease significantly increased the medical expenses of the elderly. Compared with the elderly living in cities, the medical expenditure of the elderly living in urban and rural areas was relatively small, which might be related to the relative lack of medical resources in urban and rural areas of China. The higher the family income is, the more the medical expenditure of the elderly is. The predictor of medical insurance value was negative but not significant, which implied that medical insurance maybe reduced the medical expenditure of the elderly and released their financial burden. However, the effect was not obvious.

The scenario of the ZAGG(I) model: the proportion of  $p$  of zero medical expenditure and the scale parameter  $s$  relating to variance were both constant. Because the logit link function was used by default in the regression model, the

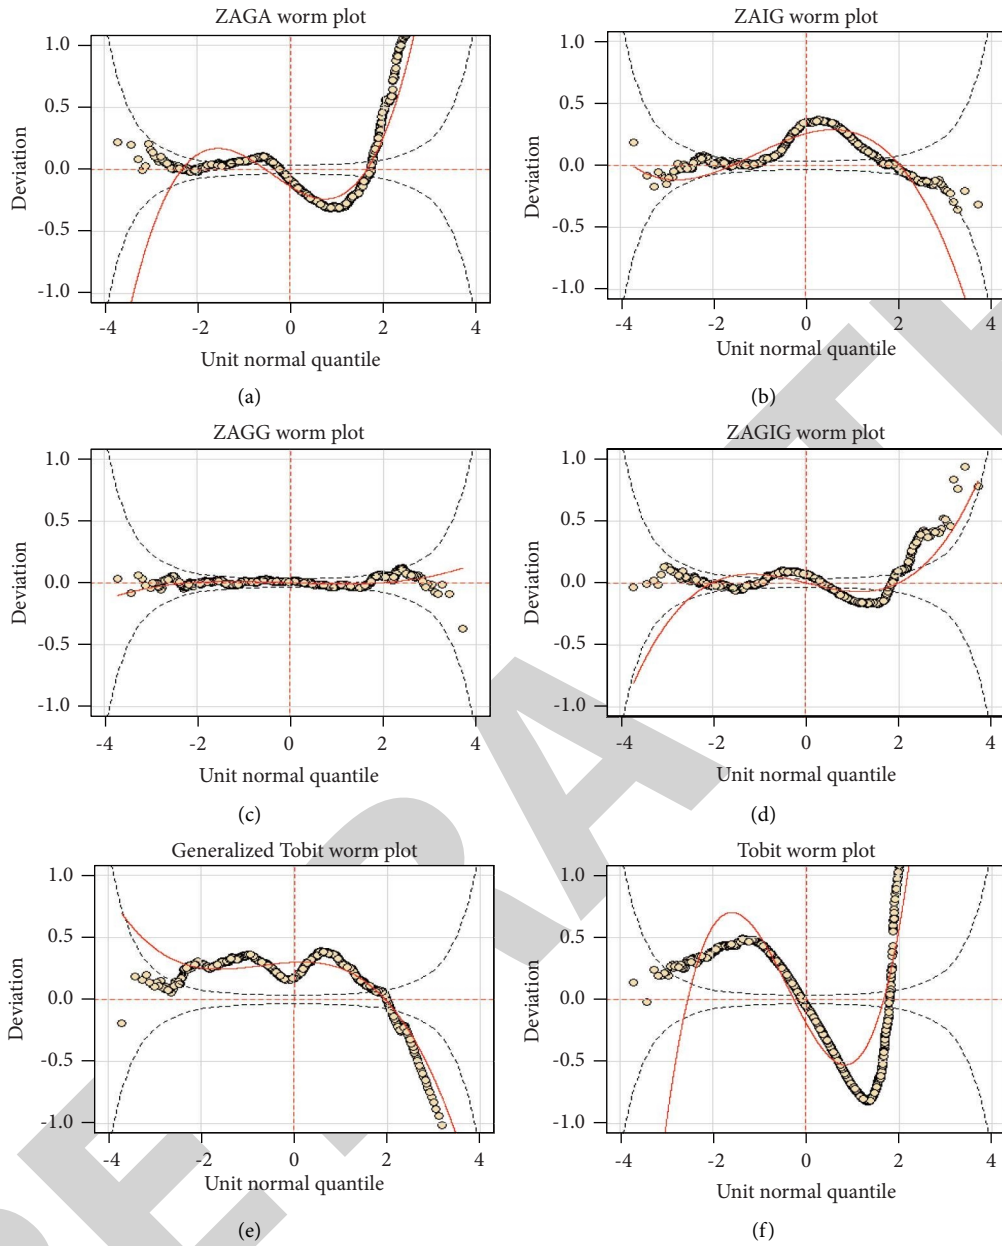

FIGURE 5: Worm plots for regression models. (a) ZAGA worm plot. (b) ZAIG worm plot. (c) ZAGG worm plot. (d) ZAGIG worm plot. (e) Generalized Tobit worm plot. (f) Tobit worm plot.

proportion of zero medical expenditure  $\pi$  was  $1/(1 + \exp(1.2984)) = 0.2144$ , which was very close to the proportion 0.2147 of zero cost in the population.

The scenario of the ZAGG (II) model: the occurrence of zero medical expenditure varied and was affected by the predictors. We found that some predictors for the medical decision shared different signs. For example, higher values of family income result in lower odds of zero medical expenditure. Perhaps, the elderly with high-income families are more likely to obtain medical resources, and the utilization of medical services was relatively high. The elderly with action limited were often in poor health, so their medical expenditures were more.

The scenario of the ZAGG (III) model: up to now, we had modelled the only  $\pi$  as a function of explanatory variables, but there were occasions in which the assumption of a constant scale parameter was not appropriate according to equation (14). On these occasions, modelling  $s$  as a function of explanatory variables could solve the problem. We could conclude from Figures 6–8 that almost all points of the worm plot failed inside the 95%-pointwise confidence intervals, indicating that the three models appeared to be adequate. Furthermore, the line shape with the negative slope in Figure 6 showed the variance was too low, and the fitted scale was too high. The s-shape with left bent down suggested the tails of fitted distribution was too light.

Kolmogorov-Smirnov test is a nonparametric test method that can be used to compare the cumulative empirical distributions of two samples. The  $D_n$  ( $D_n = \sup_x |F_n(x) - F(x)|$ ) statistics is used to compare the maximum value of the difference between the empirical distributions of two samples. If this value is too large, we believe that the two distributions are different. Therefore, we used the two tailed Kolmogorov-Smirnov test to verify the consistency between ZAGG model and empirical distribution. The results are shown in the last row of Table 3. From the results, the  $p$  values were all greater than 0.05, which meant we could not reject the null hypothesis that there was almost no difference between the ZAGG model and empirical distribution.

## 6. Discussion

This paper explored and empirically validated zero-adjusted models with semiparametric formulation for estimating medical expenditures using CLHLS survey data. In reaction

to the limitations of conventional Tobit, zero-adjusted gamma, and zero-adjusted inverse Gaussian models, we generalized the three models to improve the accuracy of prediction and discover the factors affecting the elderly medical decision. The zero-adjusted generalized gamma model outperformed the zero-adjusted generalized Tobit and zero-adjusted generalized Inverse Gaussian model. Thus, the ZAGG mode provided an interesting alternative for modelling health care utilization expenditure data as it included many conventional models such as the zero-adjusted Weibull model, the zero-adjusted lognormal model, and the zero-adjusted gamma model. The ZAGG model included log-additive components for the mean and dispersion of medical expenditure given that expenditure occurs, as well as a logistic additive component for the probability of a zero expenditure. The model components were estimated independently and could be fitted with the same set of covariates. In this paper, we firstly chose ZAGG models with different parameters  $\pi$ ,  $\sigma$ , and  $\nu$  and used the default log link function to discover which factors affecting the medical expenditure for the elderly. There was much literature on the influence of factors on the parameter  $\pi$ , but there was almost no work discussing the influence of factors on the parameter  $\sigma$  and  $\nu$ . We found that some factors might affect the distribution shape and scale change of ZAGG model and then affected the accuracy of the model. These were also contributions of this paper.

Our empirical application had focused on the assessment of the predictive accuracy and the predictors affecting medical expenditure. We found that ZAGG and ZAGIG gave similar results. Moreover, ZAGG was appreciated for the fact that the generalization errors of ZAGIG were 671.36, which was less than that of ZAGG from mean square errors. However, the ZAGG model seemed to perform better in the aspects of global deviance, AIC and SBC. Whether one of the two models is superior to the other remains an open question, which needs to be determined according to different problems and situations. ZAGG and ZAGIG models, respectively, extended the ZAGA and ZAIG models, and many conventional zero-adjusted models are special forms of these generalized models. Moreover, both of these generalized models increased the difficulty in parameter estimation. For example, the standard errors of parameters were not reliable when the QR decomposition method was used, which could not solve the Hessian matrix. In this paper, we reported the QR-based standard errors using a likelihood-based confidence interval method introduced by Rigby and Stasinopoulos [44, 50, 51].

Although the ZAGG model is complex in application and calculation, it still has some advantages. One benefit of the ZAGG model is that the three components of the mixture model provide the analyst with a three-way interpretation by estimating the factors affecting the medical decision, the factors predicting the amount of the medical expenses, and the factors influencing the dispersion of the expenditure amount. The scale dispersion estimates can be used to provide more conservative estimates when the parameters were less robust. Another advantage of the ZAGG

model is that the regression method does not imply a “black box” approach for interpreting the effects of individual covariates. The interpretation of the marginal effect for the model is relatively explicit.

We surprisingly discovered that basic medical insurance had no significant effect on the medical expenditure of the elderly. The main reason was that the basic medical insurance had covered nearly 95% of the population in China up to now, leading to no obvious difference in the impact of medical insurance [2, 52–54]. The elderly with high-income families spent more on health care, which indicated a relatively unfair phenomenon that the poor subsidized the rich in the utilization of medical services in China. At the same time, the medical expenditure in urban and rural areas was relatively low, which also showed that the distribution of medical resources was not balanced.

Finally, attention should be paid to the limitations of our study. One limitation of this study was that it did not consider the causal relationship between the predictors and response because we were interested in predicting the amount of medical expenditure and unraveled the significant predictors influencing the expenditure. Possible solutions for this causal relationship were either to study only the impact of truly exogenous independent or to apply instrumental variable techniques. Another limitation was that the zero-adjusted models were seemed to be two-stage models, and there existed a variety of models in the continuous part. In this paper, we compared only a few models. Instead, other types of skewed distributions could be considered for further research. Finally, our study has used the two-stage model to predict the amount of medical expenditure. We treated the two parts as independent. However, there perhaps existed a relationship. There were further opportunities to develop potentially superior models by considering the correlation, such as copula function. Moreover, it should be noted that if the relationship were considered, the difficulty of parameter estimation would increase, and the effects of individual explanatory variables could not be interpreted conveniently.

## 7. Conclusions

In this paper, we have predicted the amount of medical expenses for the elderly and explored the marginal effect of the predictors in China, using CLHLS survey data. In reaction to the limitations of conventional Tobit and zero-adjusted models, we generalized these models. This allowed us to estimate the medical expenditure using more flexible models. The zero-adjusted generalized gamma model was the best to fit this data. We focused on the zero-adjusted generalized gamma regression model to reveal the significant factors influencing the medical amount. Several conclusions could be drawn from this work. The health status, family income, residence, and chronic diseases of the elderly significantly affect their medical expenditure, while the influence of basic medical insurance is not significant. We used a logistic model to discover the factors that affected the medical decision of the elderly. We found that the elderly in

the higher age group had the lower occurrence of zero medical amount, which indicated they were better health. In addition, this paper accurately estimated the proportion of the elderly with zero medical expenditure using a logit model. In the ZAGG model, we found that the scale dispersion was also affected by the explanatory variables, which could improve the robustness of the standard errors of parameters.

To the best of our knowledge, this is the first time that using the zero-adjusted generalized gamma model predicts the medical expenditure. The current approach appeared to be effective. However, some limitations merit attention, such as the causal relationship between the predictors and response and the correlations of the two parts in the zero-adjusted models. These limitations required further investigation in the near future.

## Data Availability

The data in this paper are obtained from the Chinese Longitudinal Healthy Longevity Survey (CLHLS) in 2018.

## Conflicts of Interest

The authors declare that they have no conflicts of interest.

Risk management and stock investment decision-making is an essential topic for investors and fund managers, especially in the context of the COVID-19 pandemic. The problem becomes easier if the market is efficient, where stock prices fully reflect potential risk. Nevertheless, if the market is not efficient, investors may have an opportunity to find an effective investment method. Vietnam is one of the emerging markets; the efficiency is still weak. Thus, there will be an opportunity for astute investors. This study aims to test the weak-form efficient market and provide a modern approach to investors' decision-making. To achieve that aim, this study uses historical data of stocks in the VN-Index and VN30 portfolio to buy and sell within a one-day period under the rolling window approach to test the Ho Chi Minh City Stock Exchange (HoSE) through a runs test and to perform stock trading using the support vector machine (SVM) and logistic regression. The buying/selling of stocks is guided by the forecasted outcomes (increase/decrease) of logistic regression and SVM. This study adjusted the return rate in proportion to the risks and compared it with index investments of VN-Index and VN30 to evaluate investment efficiency. The test results dismissed the weak-form efficient-market hypothesis, which opens up many opportunities for short-term traders. This study's primary contribution is to provide a stock trading strategy for short-term investors to maximize trading profits. Because logistic regression and SVM have proven effective trading methods, investors can use them to achieve abnormal returns.

## 1. Introduction

Risk management and stock investing decision-making are critical topics for investors and fund managers, particularly regarding the COVID-19 pandemic. If the market is efficient, where stock prices adequately represent a possible risk, the issue becomes simpler to solve [1, 2]. Some investors often use technical analysis to select stocks as historical data (mainly price and trading volume) in the short term. Some technical analysis tools forecast price movement direction, deciding whether to buy or sell stocks [3]. Mizrach and Weerts [4] used technical indicators, price, and volume history to forecast future stock returns, sometimes called "chartists" because they use graphical trading representations. Azzopardi [5] applied principles to study how human emotions impact financial decision-making. SVM and

artificial neural networks (ANN) identify market abnormalities in many financial markets worldwide [6]. Nevertheless, Fama [7] proposed efficient-market hypothesis casts doubt on the reliability of the technical analysis. This theory will not help beat the market because it assumes that the price of a security fully reflects all available information [8–10]. That said, each market is efficient to a certain extent; specifically, there are three types of efficient markets in ascending order: weak, semistrong, and strong. Even in the weak form, the stock's price fully reflects its historical data.

For that reason, the security price cannot be predicted solely based on past prices [11]. Some empirical evidence suggests that markets are not truly efficient, which implies that investors may use templates or prediction models to achieve a higher rate of return [12, 13]. Hawaldar et al. [14] tested the weak-form efficient-market hypothesis of the

Bahrain Bourse stock market for the period 2011 to 2015 and concluded that the Kolmogorov–Smirnov goodness-of-fit test, run test, and autocorrelation test reject the weak-form efficient-market hypothesis. Kumar et al. [15] supported India’s weak-form efficient-market hypothesis for 2012–2017 but rejected the medium-form efficient-market hypothesis. Mensi et al. [16] studied the daily closing prices on the global and regional GIPSI stock markets in the USA and five GIPSI stock markets in Europe from January 1, 2009, to September 8, 2017. GIPSI, worldwide, and US markets are all inefficient, particularly in the short term. Whatever the time range, the Greek stock market is the most inefficient of all markets. In the short and long run, Portugal and Ireland have the least inefficient marketplaces. These findings also suggest that stock markets may not be suitable for risk diversification in asset allocation or risk hedging. The author also suggests that these findings have significant consequences for investors and policymakers. In reality, investors may utilize knowledge about long-term memory and the differential threshold for persistence across time horizons to outperform the market and generate abnormal returns.

A recent trend in behavioral finance theory is to explain that anomalies complement the shortcomings of the efficient-market hypothesis. Kahneman and Tversky, a pioneering researcher, point out that investors rely heavily on emotions and instincts rather than rationality to make decisions [17]. Emotional decision-making can lead to mistakes when making irrational investment choices. Some anomalies associated with behavioral finance theory include calendar, fundamental, and technical anomalies [18]. Some experiments show the weekend effect, holiday effect, turn-of-the-month effect, and January effect [19]. Rossi studied calendar anomalies in the Milan Stock Exchange from January 2005 to December 2015. They found that returns were negative on Monday and positive on Wednesday. Thus, investors should buy on Monday and sell on Wednesday. One limitation of these studies is that the effects may disappear or even reverse [20]. As a result, investors may be exposed to risks when using these investment trends.

This study aims to test the weak-form efficiency of the HoSE market and determine whether investors using logistic regression and the SVM model can outperform the market. The runs test approach rejects the weak form of an efficient market. These findings suggest that classic econometric and statistical models are likely to beat the market. However, the constantly evolving machine learning algorithms provide a viable alternative to traditional regression models. Some studies on the SVM application in finance have obtained many positive results, such as Cao and Tay [21], Huang et al. [22], Lu et al. [23], Mohamed [24], Azimi-Pour et al. [25], and Syriopoulos et al. [26]. The rolling window drives the buying and selling of securities by the logistic regression model’s output and the SVM algorithm. Input variables include close (closing price); HL (the highest minus lowest price); LO (lowest price minus opening price); variation (the difference in closing price between 2 consecutive trading sessions); ma7, ma14, and ma21 (average price of 7, 14, and 21 consecutive sessions, respectively); sd7 (standard

deviation of 7 consecutive sessions); vnc (the difference in closing prices of VN-Index for 2 consecutive sessions); vnipc (return rate of VN-Index portfolio); and insect (time trend). The data covers all stocks in the VN30 basket from January 28, 2000, to July 30, 2021. As a result, the SVM investment strategy beat the market with an extremely high average return rate.

Machine learning may discover weak-form efficient markets and develop trading methods for short-term investors, thereby maximizing earnings. Predicting the movement of stock prices using algorithms, such as the SVM model, has demonstrated a high accuracy. The parameters of the machine learning model were accurately predicted using the rolling window technique. Since a sample’s representativeness may be impaired by a period too short or too lengthy, 365 days is a good choice for a historical data set. Stock investing in a weak market is usually tricky for short-term investors. The SVM model, in particular, is a valuable tool for predicting the direction of price movement in the market. It is necessary to modify the investment returns to reflect the inherent risks to raise the degree of trust in the investment performance review. The Sharpe ratio is used to manage risk, while the *T*-test is used to evaluate trading methods. Due to the SVM model’s superb accuracy, the trading strategy employing it has produced a great return.

The following diagram depicts the flow of this study. Next, a brief review of relevant literature is provided: the efficient-market hypothesis (EMH), logistic regression, support vector machine (SVM). Section 3 of the study provides the conceptual foundation for the paper, including the theories of weak-form efficient-market hypothesis testing and price movement forecasting decision. Section 4 focuses on empirical data and outcomes. Section 5 provides further in-depth explanations of the study’s findings. In Section 6, the conclusions of this study and the limits and potential for further research are summarized and explained.

## 2. Literature Review

*2.1. Efficient-Market Hypothesis (EMH).* Fama [11] first proposed EMH in the 1970s. This article is significant because it paved the way for many other studies on the accuracy of the EMH theory. The concept of efficiency refers to the rapid absorption of information instead of the resources that produce maximum output as in other fields of economics. Information is defined as news that can affect prices and is unpredictable. In capital markets, efficient markets can be interpreted in various ways. The market in which prices always reflect available information is called an efficient market [11]. Meanwhile, Malkiel [27] argued that a capital market is efficient if it wholly and correctly reflects all relevant information in determining security prices. Generally, however, markets are considered efficient for certain types of information if disclosing that information to participants does not affect stock prices. EMH includes the following hypotheses:

Weak-form efficiency hypothesis: this degree of efficiency exists when a security’s price reflects historical data

about a security's price, including stock price and trading volume. In other words, one can forecast current stock prices on past stock prices. Testing the weak-form efficient-market hypothesis mainly concerns whether there is a statistical dependence between price changes. In other words, if the price changes are random, the market is a weak-form efficient market. Several frequently used testing techniques are autocorrelation and Ljung–Box's Q [28], variance ratio, LM-test [29], CD-test [30], Wright's test [31], runs test, January effect, and unit root test [32].

Semistrong-form efficiency hypothesis: this degree of efficiency exists when a security's price reflects publicly accessible market information, including historical data on security prices and publicly available information in the market, such as those in an issuer's prospectus. The semistrong-form efficient market encompasses the weak-form hypothesis because all market information, including stock prices, interest rates, and trading volume, must be publicly analyzed using the weak-form efficient-market hypothesis. Public information includes all nonmarket data, such as earnings and dividend announcements, P/E ratio, D/P ratio, P/B ratio, stock splits, and political economy information. Studies examining semistrong-form EMH can be classified into these two categories:

- (i) Studies that sought to forecast future rates of return using publicly accessible data, except for pure market data such as price levels and trading volumes, have been included in the weak-form test. These studies may include time series analysis of returns or cross-sectional distribution of returns of individual stocks. EMH proponents argue that it is impossible to use publicly available information to predict future returns using past returns or to forecast future cross-sectional distributions of returns (e.g., highest quartiles or deciles of returns) [33–36].
- (ii) Event studies investigate how quickly stock prices change in response to specific key economic events. One practical approach is to test whether it is feasible to invest in stocks and earn an extraordinarily high rate of return after a significant event (such as stock merges, stock splits, central economic data, and principal) is publicly announced or not. Again, EMH proponents expect stock prices to adjust rapidly so that investors cannot earn high returns by buying after public announcements and paying regular transaction costs [37–40].

Strong-form efficiency hypothesis: this degree of efficiency exists as all information is fully reflected in stock prices, including nonpublic information such as internal information. The strong-form efficient-market hypothesis combines both the weak-form and the semistrong-form efficient hypothesis. The strong-form efficient-market hypothesis extends the assumption of efficient markets, in which prices reflect publicly available information to a perfect market, and all information is free and available. It is necessary to know when internal or insider information arises to evaluate strong-form efficient markets. This timing

is hard to identify. Strong-form efficient markets are often researched in developed countries. For emerging markets, most studies focus on weak- and semistrong-form EMH. The exploration of strong form effectiveness is still a controversial matter among scholars [41–43].

**2.2. Logistic Regression.** Logistic regression is a statistical technique that describes the relationship between independent variables and binary dependent variables (which can also be applied to discrete dependent variables). Through this relationship, logistic regression allows the output prediction of a given set of input values. In predicting the output using logistic regression, this study calculates the probability that the output takes the value 1 with the given observation data to find  $P(Y = 1|X)$ . With the assumption of binomial distribution of the dependent variable, this study considers the odd ratio as follows:

$$G(X) = \frac{P(Y = 1 | X)}{P(Y = 0 | X)} = \frac{P(Y = 1 | X)}{1 - P(Y = 1 | X)}. \quad (1)$$

Taking the logarithm on both sides of (1), this study has

$$\ln G(X) = \ln \left( \frac{P(Y = 1 | X)}{1 - P(Y = 1 | X)} \right) = X\beta, \quad (2)$$

where  $\beta = (\beta_0, \beta_1, \dots, \beta_k)$  that are the parameters to be estimated.

From equation (2), this study makes the equivalent transformation as follows:

$$P(Y = 1 | X) = \frac{e^{X\beta}}{1 + e^{X\beta}}. \quad (3)$$

Usually, the maximum likelihood estimation (MLE) method is used to estimate the parameter  $\beta$ . The classification rule is determined by equation (3) as follows:

$$y_i = \begin{cases} 1, & P(y_i = 1 | X) \geq 0.5, \\ 0, & P(y_i = 1 | X) < 0.5. \end{cases}$$

Logistic regression is applied in many fields for the binary dependent variable. In finance, Han et al. [44] used a sample of 76 firms and 32 variables related to their financial ratios to predict precarious financial situations. The authors used the backward stepwise method in logistic regression and obtained results with high accuracy of 92.86%. Konglai and Jingjing [45] used logistic regression to analyze listed companies' credit risk in China. The data used included 130 companies with 6 dependent variables and was divided into 90 companies for the training set and 40 for the testing set. The training sample has an accuracy of 87.8%, while the testing set has a precision of 75%. Table 1 summarizes some publications that have used typical logistic regression.

**2.3. Support Vector Machine (SVM).** The SVM algorithm was proposed by Vapnik and Lerner [50] to solve the classification issue. SVM is a supervised mathematical algorithm used to classify data in different dimensions. Suppose that  $Y$

TABLE 1: Logistic regression in prior studies.

Authors	Research	Accuracy
Jabeur [46]	Bankruptcy prediction using partial least squares logistic regression	~70%
Rafatnia et al. [47]	Financial distress prediction across firms	83.3%
Jovanović et al. [48]	Financial indicators as predictors of illiquidity	95.5%
Strzelecka et al. [49]	Application of logistic regression models to assess household financial decisions regarding debt	70.5%

is a categorical variable with two possible values  $-1$  and  $1$  and  $X$  is an input variable. The classification hyperplane is defined by the equation:  $wx^T + b = 0$ , where  $w$  and  $b$  are the coefficients. The coefficients  $w$  and  $b$  should be chosen such that  $wx^T + b \geq 1$  if  $y_i = 1$  and  $wx^T + b \leq -1$  if  $y_i = -1$ . The training set is used to find  $w$  and  $b$  such that  $\|w\|$  is minimized, and the vectors  $x_i$  in which  $|y_i|(wx_i^T + b) = 1$  are called support vectors. To improve classifier efficiency, a kernel function is used to map the data to a high-dimensional space where the data will be more clearly segregated. The kernel function is defined by the dot product:  $K(x, y) = \langle f(x), f(y) \rangle$ . Some common kernel functions are linear, polynomial, and radial basic function. Nevertheless, for some complex data sets, it is impossible to find a perfect hyperplane. Hence, Cortes and Vapnik [51] propose to add soft margins, that is, accepting some misclassified observations. The SVM algorithm is now minimized:  $\min_{w,b,\xi} (1/2w^T w + C \sum_{i=1}^n \xi_i)$  given that  $y_i(w^T w\phi(x_i) + b) \geq 1 - \xi_i$ , where  $C$  is a hyperparameter and  $\phi$  is a conversion mapping from low- to high-dimensional space.

SVM is often used in financial research. For instance, Kim [52] has used SVM to predict hotels' bankruptcy in Korea. Between 1995 and 2002, a sample of 33 hotels was collected, and the forecast results achieved 95% accuracy. In the Japanese market, Huang et al. [22] used SVM to predict the direction of the NIKKEI 225 Index and showed that SVM outperformed other classification methods in their study, including random walk model, quadratic discriminant analysis (QDA), and ANN. Ren et al. [45] integrated SVM with investor behavior analysis in the Chinese market. This study forecasted the SSE 50 Index's movement from 2014 to 2016 in 485 trading days, used both fivefold and rolling window methods, and reached a maximum accuracy of 89.93%.

### 3. Research Data and Methods

**3.1. Research Data and Variable Description.** Research data includes 30 companies in the VN30 basket (unadjusted price), VN-Index, and VN30 index in a one-day period. Table 2 describes the tickers and their observations in the VN30 basket.

The data collection period was from July 28, 2000, to July 30, 2021, in which some companies were newly established, and there were some days off. Hence, the number of observations of these companies was varied. The data was collected from the website <https://www.hsx.vn> (Ho Chi Minh City Stock Exchange). Each observation included date, ticker, closing price, opening price, highest price, lowest price, and trading volume. The variables in the study are described in Table 3.

TABLE 2: Tickers and observations in the VN30 basket.

Ticker	Observations	Ticker	Observations	Ticker	Observations

### 3.2. Research Method

#### 3.2.1. Testing the Weak-Form Efficient-Market Hypothesis.

According to the weak-form efficient-market theory, a security's past prices cannot forecast current prices and generate abnormal returns. There are other testing techniques available, but these studies employ runs tests like some previous studies, including Fawson et al. [57], Moustafa [58], Ahmad et al. [59], Nisar and Hanif [60], Hamid et al. [61], and Wei [62]. The runs test, known as the Wald-Wolfowitz test, is a nonparametric statistical test that examines the randomness hypothesis on a two-state data series [63]. The runs test will assess whether the elements of the series appear independently. In other words, if assuming the price increases or stays the same as (+) and decrease as (-), then a weak-form efficient market implies that price changes are independent. When the sample size is large enough, the statistic  $Z = R - \bar{R}/s_R \sim N(0, 1)$ , where:

$R$ : number of runs in the sample (each run is a sequence of consecutive "+" or "-" signs)

$\bar{R}$ : expected value of  $R$ , calculated by the formula  $\bar{R} = 2n_1n_2/n_1 + n_2 + 1$

$s_R^2$ : the standard error of the runs,  $s_R^2 = 2n_1n_2(2n_1n_2 - n_1 - n_2)/(n_1 + n_2)^2(n_1 + n_2 - 1)$  ( $n_1, n_2$  are the number of "+" and "-" signs, respectively)

Mainly this method explores the randomness in the changes of the VN-Index and VN30 index. If this variation is random, it supports the weak-form efficient-market hypothesis, suggesting that traditional forecasting models using historical data are unlikely to produce an excess return.

Finally, to test the influence of factors affecting price movements, we performed logistic regression for all data in the research period. This result also implies that investors with little experience in academic knowledge can still base

TABLE 3: Variable description.

Variables	Formula	Description	Source
$close_t$		The closing price at date $t$	Schöneburg [53]
$fore\ dir_t$	$fore\ dir_t = \begin{cases} 1, & close_t \geq close_{t-1} \\ -1, & close_t < close_{t-1} \end{cases}$	The direction of price movement (foredir = 1 implies that the closing price increases from the previous day)	Ren et al. [54]
$HL_t$	$high_t - low_t$	The fluctuation of the price within a trading day	
$LO_t$	$low_{t-1} - open_t$	The difference between the lowest price and the opening price	
$variation_t$	$close_t - close_{t-1}$	The fluctuation of closing prices between 2 consecutive days	
$ma7_t$	$1/7 \sum_{i=0}^6 close_{t-i}$	The average closing price of 7 consecutive trading sessions	Vijh et al. [55]
$ma14_t$	$1/14 \sum_{i=0}^{13} close_{t-i}$	The average closing price of 14 consecutive trading sessions	
$ma21_t$	$1/21 \sum_{i=0}^{20} close_{t-i}$	The average closing price of 21 consecutive trading sessions	
$sd7_t$	$\sqrt{\text{var}(close_t, close_{t-1}, \dots, close_{t-6})}$	The standard deviation of the closing price of 7 consecutive trading sessions	
$vnic_t$	$vmin\ de\ x_t - vmin\ de\ x_{t-1}$	Fluctuation of VN-Index between 2 consecutive trading sessions	Qiu and song [56]
$vnipc_t$	$vmin\ de\ x_t - vmin\ de\ x_{t-1} / vmin\ de\ x_{t-1} \times 100$	The return rate of the VN-Index portfolio	
$insec_t$		Time trend variable (the default origin is January 1, 1970)	

the fluctuations of variables (variables with strong impact) to make investment decisions.

**3.2.2. Price Movement Forecasting and Investment Decision-Making.** This study focuses on two models, logistic regression and SVM, to forecast price movement direction. Assuming that the historical data has a maximum value of 1

year, the study will use fixed training data of 365 observations to make forecasts using the “rolling window” method. Algorithms are used to identify the optimal parameters for the first 365 observations, forecast the 366th observation, and continue until the last observation, as shown in Figure 1.

### 3.3. Forecasting Model

$$\widehat{foredir}_{t+1} = f(close_t, HL_t, LO_t, variation_t, ma7_t, ma14_t, ma21_t, sd7_t, vnic_t, vnipc_t, insec_t). \quad (4)$$

The sigmoid function is employed for the logistic regression model, and the MLE method is used to estimate the regression coefficients. For the SVM algorithm, the kernel function radial and  $\gamma = 0.1$  are used. Based on the logistic regression and SVM models, the investors will buy/sell stocks, respectively. To assess investment performance, this study adjusts risks using the Sharpe ratio [64, 65]:  $\text{SharpeRatio} = r_p - r_f / \sigma_p$ , where

$r_p$ : return rate of the portfolio (or security)  $p$

$r_f$ : risk-free rate (1-year treasury note)

$\sigma_p$ : standard deviation of the portfolio (or security)  $p$

Finally, this study compares the performances of investments made by the logistic regression model and SVM with investments made by the  $T$ -test according to VN30 and VN-Index. Furthermore, this study seeks to determine whether holding a single stock is more efficient than holding a market portfolio index. The novelty of this study is to provide a securities trading method using a logistic regression model and SVM.

## 4. Results

**4.1. Descriptive Statistics.** The descriptive statistics of the variables are described in Table 4 below. The table shows that the price fluctuates from 0.233 USD/share to 23.233 USD/share; the average price is 2.266 USD/share. The foredir ends up with 39,096 observations resulting in a decrease in closing price compared to the day before. The remaining 29,420 observations of closing price were not decreased; the specific amount is shown in Figure 2. The most muscular daily closing price movement-down 7.108 USD/share on a day, occurred to VNM ticker on July 5, 2007 (exchange rate USD/VND = 22,748).

The fluctuations of the variables close and variation are better shown in the boxplot on Figures 3 and 4. Some tickers such as FPT, REE, SSI, and STB tilted to the right and had unusually high closing prices in some trading sessions. Still, the tickers' variation is mostly stable. This study noticed an anomaly that FPT plummeted 7.429 USD/share on May 21, 2007, the most profound fall across all stocks in the VN30 portfolio in all trading sessions. The decline in share price is

FIGURE 4: Variation movement of the tickers.

due to FPT's dividend payment policy with a payout ratio of 2:1, which shows that one more FPT share will be awarded for every two FPT shares an investor holds.

For the market, this study has a summary table detailing the variables closevn (closing price of VN-Index), vnic, vnipc, closevn30 (closing price of VN30 index), rvn30 (return rate of VN30 index), and rf (the interest of 1-year government bonds). Table 5 and Figure 5 show that the closing prices of the VN-Index and VN30 index primarily fluctuate together, while bond interests are primarily stable and tend to decrease. From the beginning of 2020, this study noticed that both the VN-Index and VN30 dropped significantly and then rose again. This result was because of the COVID-19 pandemic, which obstructed the production and trading activities of businesses. When the businesses stabilized, the cash flow poured into the financial investments, leading to increased stock prices.

**4.2. Runs Test Results.** Runs test results showed that the weak-form efficient-market hypothesis is dismissed at 1%, implying that technical analysis can obtain an abnormal return.

**4.3. Accuracy of Price Movement Forecasting Models.** This study used the logistic regression model and SVM to forecast the increase and decrease of stocks based on the rolling window method. The accuracy value (the number of correct predictions out of the total predictions) is summarized in Table 6. The average accuracy in forecasting 30 stocks of the logistic regression model and SVM are 58.93% and 92.48%. The SVM model has proven to be more effective than the logistic regression model.

**4.4. Stock Trading Results.** Stocks were traded on the stock price increase and decrease forecasts made by the logistic regression and the SVM models. The results of average daily return before and after risk adjustment are in Table 7. As seen in Tables 5 and 7, the SVM model outperforms the logistic regression model and the portfolio index investment (including VN30 and VN-Index). To determine the efficacy of the trading strategies, this study conducted five one-sided

*T*-tests with the null hypothesis (investments are not more efficient than index portfolio investments) and the alternative hypothesis (investment methods are more efficient). Table 8 summarizes the results of the tests by *p*-value. The terminologies in Tables 7 and 8 are explained in Table 9.

**4.5. Factor Affecting the Stock Price Movement.** This study performed logistic regression for the entire data to determine the factors affecting the stock price movement. Logistic regression results are shown in Table 10. The regression result in Table 10 shows that the factors HL, LO, variation, vnic, vnipc, insec, and sd7 have a statistically significant impact, of which vnipc has the most substantial impact. This conclusion shows that market portfolio return is the strongest indicator of price change expectations; for every extra percentage rise in market portfolio return, investors anticipate the odds ratio increasing by 0.2. In addition, the model also shows that the moving average indicators (MA) are not statistically significant at 0.1, that is, the MA indicator does not affect stock trading. Volatility indicators HL and LO have regression coefficients of 0.055 and 0.061, respectively. Both are statistically significant, showing that these fluctuations increase the possibility of bullish forecasting for the next trading session. Nevertheless, the vnic indicator has a negative coefficient and is statistically significant, showing that the greater the market volatility, the more it predicts that the price will decrease.

## 5. Discussion

The nonparametric runs test examines the randomness of a sequence of rising/falling states of stock prices. The weak-form efficient market implies that prices rise/fall randomly [66]. This study performs a runs test on two rising/falling ranges of the VN30 and VN-Index portfolios with the null hypothesis that the direction of price movement is random. Runs test results in Table 11 have a *p*-value less than 0.01. This study rejects the null hypothesis for both tests [67]. This result implies that the weak-form efficient-market hypothesis is rejected. This result is also consistent with some previous research [61, 68–70]. Market weakness is not guaranteed to present an opportunity for short-term traders

looking for past patterns to rely on when buying/selling to maximize trading profits.

This study implements three trading strategies: the logistic regression model, the SVM model, and holding stocks for the long term. In the first two strategies, the models forecast the increase/decrease of the stock price, resulting in buying and selling correspondingly. Compared to the traditional logistic regression model, the SVM model better

predicts price movement direction. On all 30 tickers in Table 6, the SVM model defeated the logistic regression model. Additionally, its accuracy is exceptional, averaging 92.48% and 58.93%. This finding is much like prior studies, which show that SVM produces greater accuracy than the logistic regression model [71–74].

The accuracy of the SVM model in Table 6 is very high, with most of them correct over 90%, except for the two

tickers: the VJC ticker and VPB ticker. Moreover, its lowest accuracy is 86.66%, and the highest is 96.94% (for TPB ticker). This result is better than similar studies such as Kim [75], Kara et al. [76], Patel et al. [77], and Duong et al. [78]. One success in the SVM model comes from its model estimation method. Compared to other methods, the “rolling window” is more efficient because the continuous-time series ensures the input parameters’ accuracy. The 365-day period is a reasonable choice. If it is longer, the data will become too outdated. If it is shorter, the collected data may not be a good representation of the whole. Specifically, the training data is permanently fixed for the latest 365 observations. Because of the continual updating of the training data set, the initial parameters are adjusted accordingly, increasing the forecasts’ accuracy.

In contrast, the sample’s representativeness will be a problem if the data set is split into two independent sets. For example, Vijn et al. [55] divided the data set into two sets: the training data set (June 4, 2009–March 4, 2017) and the testing data set (April 4, 2017–May 4, 2019). The parameters calculated by the training data set are too outdated for forecasting; using data from 2017 to forecast for 2019 does not seem to be reasonable. Cao and Tay [21] and Ji et al. [79] divided the data set into three sets: training, validation, and testing data. While rationality is much better when applied

historical data, performance will be significantly less than the rolling window.

The superior predictive power of the SVM model has led to excellent trading performance. From Table 7, using the SVM model for trading has achieved an average rate of return of 1.426%/day with the corresponding Sharpe ratio of 0.781, which is much greater than using the logistic regression model. Although the logistic regression method is not as effective as the SVM model, it still produces a great result with an average return rate of 0.348%/day and a Sharpe ratio of 0.146. In contrast, the average rate of return of VN30 and VN-Index is only 0.06% per day and 0.04% per day, respectively. The efficiency test results of all three methods (trading under the SVM model, logistic regression, and long-term holding of individual stocks) in Table 8 suggest that the SVM method is more efficient than investment according to the VN30 and VN-Index with a significance level of 0.001 (the  $p$ -values are approximately 0). Trading using the logistic regression model is effective when 25 out of 30 stocks achieved statistical significance at 0.1. For long-term holding of individual stocks, the average return rate is 0.052%/day, higher than VN-Index (0.04%/day) but lower than the VN30 index (0.06%/day). Furthermore, the  $p$ -values are all greater than 0.1, implying that the investing strategy of long-term holding individual stocks cannot outperform the market.

TABLE 9: Glossary of variables.

Variable	Definition
SVM	The average rate of return using the SVM model
Logistic	The average rate of return using the logistic regression model
Return	The average rate of return on investment for holding securities
Adj SVM, adj logistic, and adj return	Risk-adjusted rate of return
p_LR_vn30, p_LR_vni, p_SVM_vn30, and p_SVM_vni	The $p$ -value for testing if LR and SVM methods are more effective than investing by VN30 index and VN-Index
p_return	The $p$ -value for testing the efficiency of holding a single stock compared to holding the VN-Index

TABLE 11: Runs tests results.

VN30 index	VN-Index
Approximate runs test data: VN30	Approximate runs test data: VN-Index
Runs = 1,482; $p$ -value = 0.006332; alternative hypothesis: two-sided	Runs = 1,466; $p$ -value = 0.001233; alternative hypothesis: two-sided

Logistic regression results reveal that indicators such as HL, LO, variation, vnnc, vnipc, and sd7 impact stock price movement. Specifically, the increase of HL, LO, vnipc, and sd7 predicts that the price will increase, and VNC ticker increase predicts that the price will decrease. Indicators related to MA and close are not statistically significant and therefore do not have a predictive function of stock price movement.

## 6. Conclusion

Financial markets are efficient when old and new information is quickly reflected in the current price of a security. Therefore, because the current price includes historical information, technical analysis will not guarantee an excess return. Unfortunately, the test results reveal that the HoSE market is inefficient, meaning that technical analysis might generate abnormal returns.

The study's main contributions are identifying weak-form efficient markets and providing trading strategies for short-term investors by applying the machine learning model to optimize profits. Stock price movement forecasting algorithms, particularly the SVM model, have shown the predicting effectiveness, with an average accuracy of up to 92.48% and the peak accuracy of 96.94% (for the ticker TPB). The rolling window approach performed well in predicting the parameters of the machine learning model. The duration of the historical data is critical because the sample's representativeness may be compromised by a period that is too short or too long; hence, 365 days is considered a suitable option. Stock trading in an underperforming market is always a challenge for short-term investors. One trading strategy investors should consider there is the logistic regression model (especially the SVM model) to forecast price movement direction. Because high investment returns often conceal underlying risks, investment results should be adjusted accordingly to increase the confidence level in the investment performance evaluation. This study chooses the Sharpe ratio for risk adjustment and uses the  $T$ -Test to determine the effectiveness of trading strategies. Due to the high accuracy of the SVM model, the trading strategy using it has earned an exceptional rate of return.

Moreover, as the HoSE stock market is inefficient, short-term investors can rely on past patterns to maximize returns in trading. Short-term investors should consider using the SVM model and logistic regression models when making buying/selling decisions. The decision to choose trading stocks should be based on several indicators such as intraday price movement, price movement between two consecutive trading sessions, moving average, the standard deviation of the stock, and market volatility. It is possible to synthesize the SVM model from those indicators into an indicator for the final forecast. For long-term investors, it is better to

invest in a diversified portfolio or a portfolio index rather than holding individual stocks. Medium- to long-term investors should invest in a diversified portfolio or use fundamental analysis to select good stocks for a longer-term plan. Investors with limited knowledge related to pattern analysis can rely on indicators such as intraday price movement, price movement between two straight days, market volatility, and the stock's overall risk in the short term to forecast an increase or decrease in a security's price. Moreover, the return on the market portfolio is the most potent indicator because it reflects an optimistic attitude towards the market. If returns are positive, investors are more optimistic about market growth and thus decide to buy more; as a result, the stock price will increase.

Although this trading method has obtained an unprecedented return rate on short-term trading, the study omitted several factors such as transaction costs, taxes, and liquidity risk. Superior returns also use historical information, which is only valuable for inefficient market conditions. Therefore, more experiments are needed on inefficient markets to increase the reliability of the model. Further research may expand in two directions. First, the model's effectiveness in different markets has to be tested, and other factors such as tax transaction costs has to be considered. Second, the other authors can apply machine learning algorithms such as tree decision, deep learning, and neural networks to increase the model's predictive ability.

This study aims to solve the credit problems in the supply chain commodity and currency circulation links from the perspective of the ledger, while the game model method has been adopted. The research firstly reviews the relationship between distributed ledger technology and the essential functions of currency. Then, by constructing two-agent single-period and multi-period game models in the entire supply chain, the researchers analysed the incentive mechanism and equilibrium solution of distributed nodes of Central Bank Digital Currency (CBDC). The results of this study include the incentive mechanism and optimization of distributed nodes based on licensed distributed ledger technology, which is an important issue that CBDC faces when performing currency functions. The implications of this study mainly cover the limitations of the underlying technology of the public chain and its reward mechanism in the supply chain management and provide support for the rationality of the CBDC issuance mechanism based on state-owned commercial banks, which provides a reference for the CBDC practice. The main value of the research not only serves the decision-making department of the CBDC issuance but also provides ideas on the operation mode of digital currency for the field of digital currency research.

## 1. Introduction

At present, the global macroenvironment is complex and severe, economic growth has fallen, commodity prices have risen, epidemic trends and economic trends have become complex, and risks and challenges continue. In this context, complying with the digital development trend and doing an excellent job in commodity quality management in a long-term and reliable way has become an essential topic in supply chain management.

Commodity quality management and credit issues have long been concerns in the research field of supply chain management. Although studies have shown that information sharing between supply chains can significantly improve product quality and business performance [1], and producers can contract design and revenue distribution mechanisms to avoid immoral behavior of suppliers [2]; there is still a gap in the research on the authenticity guarantee of credit and commodity quality at the technical

level. Some studies have pointed out that blockchain is a new and revolutionary technology that significantly affects the supply chain network and discussed the significance of blockchain technology in supply chain management [3, 4]. Therefore, nowadays, with the innovation and development of distributed ledger technology and its application in Central Bank Digital Currency (CBDC) research and development, using CBDC to support information sharing activity and solving credit and commodity quality management problems in the supply chain scenario has gradually become possible.

Distributed ledger technology can express rules through algorithm programs to enable participants to trust standard algorithm programs and establish mutual trust in the R & D and application of CBDC to solve the trust problem of commodity quality management in the supply chain scenario with higher efficiency and lower cost. This study intends to take this as the research goal, build a game model to simulate the incentive selection of distributed nodes in

distributed ledger technology, and obtain the optimal trusted manager of commodity quality by analyzing the equilibrium solution, to provide a reference for the application of distributed ledger technology in supply chain management and CBDC practice.

The follow-up structure of this paper is organized as follows. Section 1 discusses the theoretical basis for the possible realization of the function of digital currency by distributed ledger technology and briefly describes its optimization mechanism for the existing currency and how to use distributed ledger technology to realize the function of currency and what problems to be solved urgently. Section 2 analyses digital currency's incentive and restraint mechanism based on distributed ledger technology by constructing a game model. Section 3 attempts to solve the equilibrium conditions and puts forward the optimal digital currency distributed nodes selection. Section 4 is the conclusion of this paper.

## 2. Related Works

*2.1. Overview of Distributed Ledger Technology.* Distributed ledger technology is based on cryptography. Designing and implementing the "consensus" mechanism in multiple distributed nodes can completely and accurately record the complete historical process of transactions and payments. The ledger based on the distributed ledger technology is a publicly visible decentralized shared ledger. "Consensus" is a necessary condition for the distributed ledger to achieve the consistency of multinode records, the robustness of consensus protocols, the efficiency of reaching a steady state through high-speed convergence, and the security of the system [5]. From the technical perspective, the currently recognized consensus mechanisms include proof of work (POW), proof of stake (POS), PBFT, RSCoin, hybrid consensus, and consensus mechanism based on DAG technology.

*2.2. Currency Function under Licensed Distributed Ledger Technology.* Under the licensed distributed ledger technology, each transaction and payment is updated to the ledger by the licensed distributed node. A consensus is reached through confirmation if it is confirmed as a real transaction or payment by an absolute majority. Among them, how to design the absolute majority protocol to ensure that the distributed node data changing with the transaction and payment is confirmed by the absolute majority protocol and finally reach an agreement, that is, the "consensus" mechanism. At present, it has been used in security settlement systems, trade settlement systems, central bank digital currency design, and "stable currency."

In a single transaction and payment, the specific process is as follows: different licensed distributed nodes update the ledger according to their respective transactions and payments. Each update needs to be confirmed by an absolute majority of agreements. If it is confirmed as a real transaction and payment, it will be updated in the decentralized shared ledger (DSL). The working principle of the licensed distributed ledger technology is shown in Figure 1.

In society's transactions and payments, smart contracts will record the transactions of goods and services and the receipt and payment process of funds. The use of smart contracts facilitates the recording and verification of distributed ledgers. For manufacturers that generate inferior products and provide inferior services mixed in the transaction and payment process, most nodes of the licensed distributed ledger will verify and update the information and provide the information to the fund payer for decision-making. The working principle of licensed distributed ledger technology in social transactions and payments is shown in Figure 2.

The main role of distributed ledger technology in performing monetary functions is to prevent "double flowers." All transactions and payments, either using traditional online or offline modes or equipped with smart contracts, can be verified by licensed nodes using distributed ledger technology to avoid the "double flower" problem. The transactions and payments under the distributed ledger technology are recorded through cryptography technology. We can know whether the historical records have been tampered with by encryption and decryption. If the absolute majority is verified to be "true" by the licensed distributed nodes, it proves that the digital currency has not been a "double flower," and the transactions and payments are effective.

### 2.3. Problems Faced by Digital Currency Performing Monetary Function Based on Distributed Ledger Technology

*2.3.1. How to Select Distributed Nodes?* Under the unlicensed distributed ledger technology, any willing and capable economic individual can act as a distributed node to update and verify the ledger. The current public chain chooses to use the unlicensed distributed ledger technology. However, the demanders for digital currency involve almost all economic individuals, and the number of transactions and payments is vast. Each transaction and payment need to be confirmed based on the absolute majority of the consensus mechanism. It takes a lot of computing power under the distributed ledger technology without a license. At the same time, considering the rapid layout and development of quantum technology, the tamper-proof function based on a large amount of computing power investment is at risk of being cracked. Therefore, digital currencies with high-security requirements should adopt licensed distributed ledger technology.

However, even with licensed distributed ledger technology, digital currency still faces the problem of distributed node effectiveness in performing its currency function. Effective distributed nodes need incentives to provide real authentication information to achieve antitampering and avoid "double flowers." For licensed distributed nodes, it is difficult to technically ensure that they fully participate in the verification and signature of each transaction, and it is also difficult to technically prohibit them from verifying multiple account books with conflicting accounting items. Because of this, how to select the desired distributed nodes to correctly select and verify the "right" ledger and the "wrong" ledger?

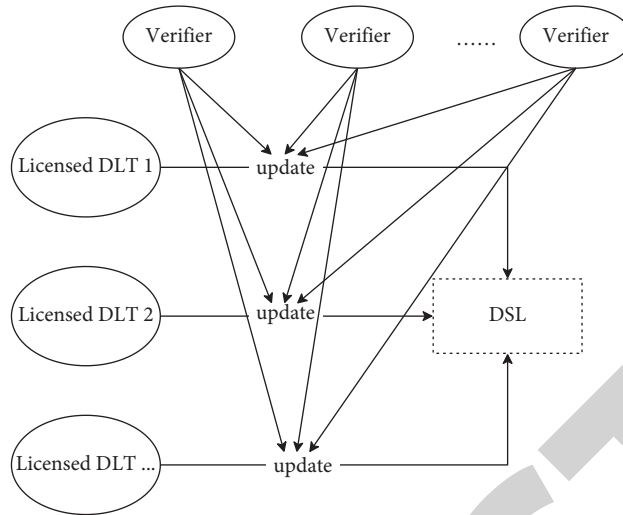

FIGURE 1: How the licensed distributed ledger technology works?

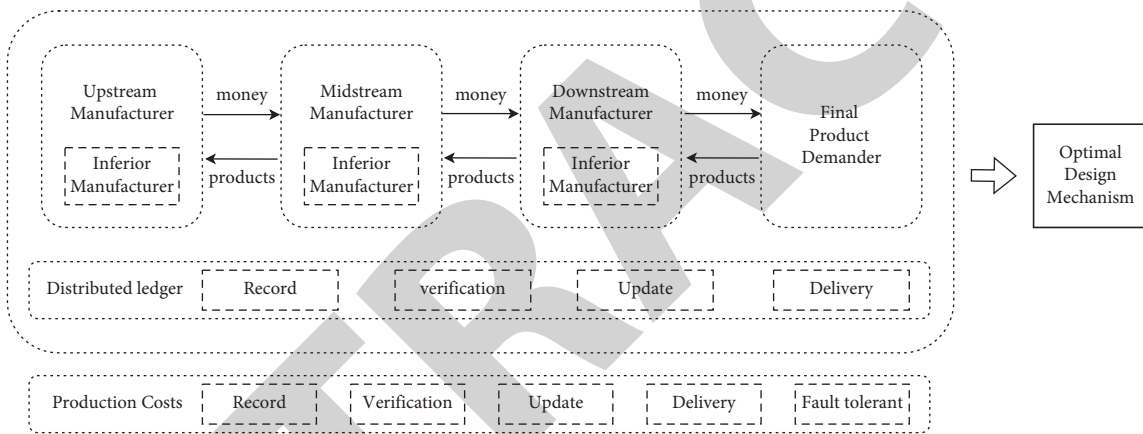

FIGURE 2: How the licensed distributed ledger technology works in social transactions and payments?

2.3.2. *How to Design Incentive Mechanism?* How to design an incentive mechanism to ensure the integrity and authenticity of verification for acceptable licensed distributed nodes? The selected distributed nodes can provide real authentication information and ensure that each transaction can be verified. In addition, how to design a better incentive mechanism so that the verification process of distributed nodes can promote the improvement of transaction scale and quality in the economy?

In this regard, Nosal and Rocheteau [6] proposed that if distributed nodes can publicly obtain historical transaction data, they will have less motivation to make false verification. At the same time, due to reducing the verification cost, it may improve the integrity of verification. Furthermore, the disclosure of historical transactions can help promote the completion of transactions to promote economic growth and high-quality development. However, historical transaction data cannot be obtained completely and in real time [7]. How to design an effective incentive mechanism under the condition of incomplete information so that the income obtained by the information verifier is greater than the cost so that the distributed nodes can provide “pair” verification

and verify each transaction and improve the transaction scale and quality at the same time? What is included in the incentive mechanism?

### 3. Methods

3.1. *Model Overview.* The unlicensed distributed ledger technology may be more vulnerable to historical tampering attacks based on the above analysis. Therefore, the model constructed in this paper should be based on licensed distributed ledger technology. At the same time, under the assumption of incomplete information, an incentive mechanism should be constructed to enable the desired distributed nodes to provide “right” verification as the verifier of transaction information to verify each transaction and improve the decision-making of transaction scale and quality. Therefore, the incentive mechanism should enable the verifier’s “verification of” to be partially observed and rewarded, and vice versa. In this regard, Carlsson and Damme [8] proposed the research methods of multiagent information incomplete multistage game and global game, which is the modelling method of this research. It is assumed

that decision makers can only observe the profit and loss with continuous noise in the game in the economy with incomplete information, and the equilibrium result is unique, which is a research method with high consistency with the research purpose of this paper.

Morris and Shin [9–11] have used this method to make a series of studies on the self-realization mechanism of the financial crisis and put forward policy suggestions according to the equilibrium results. Brown et al. [12], Hakenes and Schliephake [13], He and Manela [14], Schilling [15], and Yang et al. [4] all used game analysis methods to study the liquidity and system stability in the financial field. Some studies have also used game theory to study the interaction between suppliers and sellers in the supply chain [16, 17]. Therefore, this paper intends to build a game model on this basis and design the digital currency transaction verification incentive mechanism and consensus mechanism based on the licensed distributed ledger technology according to the equilibrium results of the model.

**3.2. Model Assumptions.** Based on the working principle of licensed distributed ledger technology in social transactions and payments shown in Figure 2, this study establishes a model to analyze the selection of producers and verifiers. The operation of the model follows the following assumptions.

**Assumptions 1.** The whole social production is divided into two stages, and consumers can only obtain utility from the final products or services provided by downstream manufacturers. The producers are divided into stage-I producers and stage-II producers. The former produces raw materials, including upstream and midstream manufacturers in Figure 2, and the stage-II producers produce final products, i.e., downstream manufacturers in Figure 2.

**Assumptions 2.** In the whole society, consumers are producers. Then, consumers include stage-I producers and stage-II producers, that is, the demander of the final product in Figure 2.

**Assumptions 3.** Inferior producers and inferior service providers only exist in stage-II producers. This is because the stage-II producers produce the final products, and the stage-II producers consume the final products. Therefore, for the stage-II producers, this group consumes the goods produced or services they provide. Therefore, it is assumed that there is no possibility of producing inferior products or providing inferior services.

**Assumptions 4.** Based on the licensed distributed ledger technology, since only stage-I producer may choose to produce inferior goods or provide inferior services, only stage-I producer may be involved in whether the confirmed transaction and payment information are “true.” Therefore, it is assumed that the confirmation of whether the transaction and payment information is “true” can only be completed by stage-II producers.

**Assumptions 5.** The transaction and payment system contain several cycles. In the first production cycle, if the stage-II producer provides false information as the information confirmer, it will be punished by being excluded from the transaction and payment system. Therefore, it is assumed that the stage-II producer will not provide false information in the first production cycle.

**Assumptions 6.** Each entity makes the current strategy choice according to the historical decisions of other entities.

### 3.3. Model Development

**3.3.1. Utility Analysis of Various Subjects.** If the proportion of manufacturers’ producing inferior products and providing inferior services in the stage I is  $f$  ( $f$  stands for fault), the total number of manufacturers in the stage II becomes  $1 - f$  (this is because the manufacturers producing inferior products and providing inferior services in the stage I are observed, so they are excluded from the stage-II trading system) of the total number in stage I.

**(1) Stage-I Qualified Producers.** The utility of a qualified producer in stage I comes from the difference between the goods or services enjoyed and the goods or services provided. Therefore, the utility function of a qualified producer in stage I is

$$U_1 = U_1[(1 - f)y_2] - P(1 - f)y_2 - y_1 + Py_1, \quad (1)$$

where  $U_1$  represents the utility function of qualified producers in stage I,  $y_1$  refers to the qualified goods or services produced and sold by producers in stage I, that is, the qualified goods or services consumed by producers in stage II,  $y_2$  means the qualified goods or services produced and sold by the stage-II producer, that is, the qualified goods or services consumed by the stage-I producer, then  $(1 - f)y_2$  refers to the qualified goods or services consumed by qualified producers in stage I,  $U_1[(1 - f)y_2]$  refers to the utility obtained by a qualified producer in stage I from the qualified goods or services consumed by him,  $P$  represents the general price level of goods or services,  $Py_1$  represents the production income of qualified producers in stage I, and  $P(1 - f)y_2$  represents the consumption expenditure of qualified producers in stage I.

**(2) Inferior Producers and Inferior Service Providers in Stage I.** The utility of inferior producers and service providers in stage I comes from the qualified goods or services in stage II. Therefore, the utility function of inferior producers and service providers in stage I is

$$U_{1f} = U_1(fy_2) - Pfy_2, \quad (2)$$

where  $fy_2$  refers to the qualified goods or services consumed by inferior producers in stage I,  $U_1(fy_2)$  refers to the utility obtained by inferior producers in stage I from the qualified goods or services consumed by them, and  $Pfy_2$  represents the consumption expenditure of inferior producers in stage I.

(3) *Stage-II Qualified Producers.* The utility of the stage-II producer comes from the difference between the utility enjoyed by the qualified goods or services purchased from stage I producer as raw materials and the goods or services provided. Therefore, the utility function of the stage-I producer is

$$U_2 = U_2(y_1) - Py_1 - y_2 + Py_2, \quad (3)$$

where  $U_2(y_1)$  refers to the utility enjoyed by the stage-II producer in purchasing qualified goods or services as raw materials from the stage-I producer and  $Py_2$  represents the production income of stage-II producers.

### 3.3.2. Game Strategy Selection of Various Subjects

(1) *Stage-I Producers.* At stage I, producers can choose two strategies: one is to produce qualified products or provide qualified services, and the other is to produce inferior products or provide inferior services.

(2) *Stage-II Producers.* According to the analysis of the hypothesis part of this paper, the stage-II producers can only produce qualified products or provide qualified services, so there is no strategy selection in production. As shown in Figure 2, the strategy selection of stage-II producers may occur in the information confirmation stage based on licensed distributed ledger technology. At the same time, according to the analysis of the hypothesis part of this paper, only stage-I producers may choose to produce inferior products or provide inferior services. Therefore, only stage-I producers may involve the confirmed information, which means the stage-II producers can choose two strategies: one is confirmed as “true,” and the other is not confirmed as “true.”

### 3.3.3. Game Profit and Loss Matrix of Various Subjects

(1) *Profit and Loss Matrix in the First Complete Production Cycle.* In the first production cycle, various entities do not master the historical strategy choices of other entities; especially, the stage-II producers, who undertake the task of information confirmation, are likely to make wrong decisions in the first production cycle. According to the utility analysis of various entities, the following four quadrant profit and loss matrix is obtained, as shown in Table 1.

**Profit and Loss Analysis of Each Entity in the First Quadrant.** If all stage-I producers choose to produce qualified products or provide qualified services, and stage-II producers, as information confirmers, make correct judgment and confirm it as “true,” the profit and loss obtained by stage-II producers is as follows.  $U_2(y_1) - Py_1 - y_2 + Py_2 + R$  refers to the utility enjoyed by qualified goods or services purchased as raw materials from stage-I producers, minus the consumption expenditure paid for this, then excluding the payment for stage-II production, plus the income obtained therefrom and finally plus the remuneration obtained

as an information confirmer. The profit and loss obtained by the producer in the corresponding stage I is  $U_1(y_2) - Py_2 - y_1 + Py_1$ , that is, the utility enjoyed by qualified goods or services purchased from stage-II producers, minus the consumer expenditure paid for this, and then excluding the payment for stage-I production, plus the income obtained therefrom.

**Profit and Loss Analysis of Each Entity in the Second Quadrant.** If stage-I producer chooses to produce inferior products or provide inferior services, and the stage-II producer, as the information confirmer, makes a wrong judgment and confirms it as “true,” the profit and loss obtained by the stage-II producer is  $U_2[(1-f)y_1] - Py_1 - y_2 + Py_2 + R$ , which refers to the utility enjoyed by qualified goods or services purchased as raw materials from stage-I producers minus the consumption expenditure paid for it. Since stage-II producers can only obtain utility from qualified products or services provided by stage-I producers, but do not confirm inferior products, they can only enjoy the utility of  $1-f$  ratio. However, it is necessary to pay for all products or services (including inferior products and services), exclude the payment for the stage-II production, add the income thus obtained, and finally add the remuneration obtained as the information confirmer. The profit and loss obtained by the producer in the corresponding stage I is  $U_1(fy_2) - Pfy_2 + Py_1$ , that is, the utility enjoyed by qualified goods or services purchased from stage-II producers, minus the consumer expenditure paid for this, plus the income from the provision of all products or services (including inferior goods and inferior services).

**Profit and Loss Analysis of Three Quadrant Entities.** If all stage-I producers choose to produce qualified products or provide qualified services, but stage-II producers, as information confirmers, identify the part with proportion  $F$  as inferior product producers or inferior service providers, and therefore do not confirm it as “true,” the profit and loss obtained by stage II producers is  $U_2[(1-f)y_1] - P(1-f)y_1 - y_2 + Py_2 + (1-f)R$ , which refers to the utility enjoyed by qualified goods or services purchased from stage-I producers as raw materials, minus the consumption expenditure paid for this, and then excluding the payment for stage-II production, plus the income obtained therefrom. It should be explained that based on the licensed distributed ledger technology if the information is determined not to be “true,” it does not need to be confirmed, so it is impossible to obtain the remuneration of the information confirmer. Therefore, in this case, the stage-II producer only obtains the corresponding confirmation remuneration for the part confirmed as “true.” The profit and loss obtained by the producer in the corresponding stage I is  $U_1(y_2) - Py_2 - y_1 + P(1-f)y_1$ , that is, the utility enjoyed by qualified goods or services purchased from stage-II producers, minus the consumer expenditure paid for this, excluding the payment for stage-I production, plus the income from products or services confirmed as “real.”

**Profit and Loss Analysis of Four Quadrant Entities.** If stage-I producer chooses to produce inferior products or

TABLE 1: Profit and loss matrix of each entity in the first complete production cycle.

		Stage-I producers	
		Produce qualified products	Produce inferior products
Stage-II producers	Confirm it as "true"	$U_2(y_1) - Py_1 - y_2 + Py_2 + R$ and $U_1(y_2) - Py_2 - y_1 + Py_1$	$U_2[(1-f)y_1] - Py_1 - y_2 + Py_2 + R$ and $U_1(fy_2) - Pfy_2 + Py_1$
	Not confirm it as "true"	$U_2[(1-f)y_1] - P(1-f)y_1 - y_2 + Py_2 + (1-f)R$ and $U_1(y_2) - Py_2 - y_1 + P(1-f)y_1$	$U_2[(1-f)y_1] - P(1-f)y_1 - y_2 + Py_2 + (1-f)R$ and $U_1(fy_2) - Pfy_2$

provide inferior services and the stage-II producer, as the information confirmer, makes a correct judgment and does not confirm it as "true," the profit and loss obtained by the stage II producer is  $U_2[(1-f)y_1] - P(1-f)y_1 - y_2 + Py_2 + (1-f)R$ , i.e., the utility enjoyed by the qualified goods or services purchased as raw materials from the producers in stage I, minus the consumption expenditure paid for this purpose and plus the recognition remuneration obtained for the part confirmed as "true." The profit and loss obtained by the producer in the corresponding stage I is  $U_1(fy_2) - Pfy_2$ , that is, the utility enjoyed by qualified goods or services purchased from stage-II producers minus the consumer expenditure paid for this.

(2) *Profit and Loss Matrix in Subsequent Production Cycles.* Under the assumption of adaptive expectation, the stage-II producer as the information confirmer can obtain feedback according to the consumption feeling after the first production cycle and identify and eliminate the inferior producers and inferior service providers from the trading and payment system, so as to adjust the information confirmation in the subsequent production cycle. Based on this, the stage-II producer as the information confirmer may make a wrong judgment because stage-I producer no longer provides qualified products or services and chooses to produce inferior products or provide inferior services. Based on this, the following four-image limit profit and loss matrix for the subsequent production cycle is obtained, as shown in Table 2.

**Profit and Loss Analysis of Each Entity in the First Quadrant.** If all the stage-I producers choose to produce qualified products or provide qualified services and the stage-II producers, as the information confirmer, make a correct judgment and confirm it as "true," the profits and losses obtained by the stage-II producers are the same as those in the first complete production cycle and will not change.

**Profit and Loss Analysis of Each Entity in the Second Quadrant.** In the first production cycle, the stage-II producers did not exclude the stage-I producers who chose to provide inferior products or services from the trading and payment system, but they were identified after consumption experience. The "missed fish" can only be lucky once. Therefore, in the subsequent production cycle, it is only possible for the stage-I producers to choose to provide inferior products or services, At the same time, the stage-II producer, as the information confirmer, makes a wrong judgment and confirms it as "true." Therefore, the profits and losses of producers in stage I and stage II of each production cycle remain unchanged, but the individual producers in stage I who choose to provide inferior products or services have changed.

**Profit and Loss Analysis of Three Quadrant Entities.** The profit and loss of the three quadrants in the subsequent production cycle are similar to that of the two quadrants. The misjudgment made by the stage-II producer in the first production cycle will be identified afterwards through the consumption experience, and the misjudgment will only occur once. Therefore, in the subsequent production cycle, it can only be a new misjudgment, and the stage-I producer providing qualified products or services is not confirmed as "true." Therefore, the profits and losses obtained by producers in stage I and stage II of each production cycle remain unchanged, but the misjudged individuals have changed.

**Profit and Loss Analysis of Four Quadrant Entities.** As the stage-II producers in each production cycle correctly identify the stage-I producers providing inferior products or services and remove them from the trading and payment system, there should be fewer and fewer stage-I producers actively choosing to provide inferior products or services; then, the profit and loss obtained by the stage-II producers is  $U_2[(1-f)^n y_1] - P(1-f)^n y_1 - y_2 + Py_2 + (1-f)R$ ; the profit and loss obtained by the producer in the corresponding stage I is  $U_1(f^n y_2) - P f^n y_2$ .

## 4. Results and Discussion

### 4.1. Equilibrium Solution in the First Complete Production Cycle

**4.1.1. When Stage-I Producer Provides Qualified Products or Services.** For the stage-II producer as the information confirmer, when the stage-I producer chooses to provide qualified products or services, the stage-II producer will choose to make a correct judgment and confirm the production, payment, and transaction information of the stage-I producer as "true." This is because, from the profit and loss matrix, when  $U_2(fy_1) - Pfy_1 + fR > 0$ , the benefit obtained by the stage-II producer when it is confirmed as "true" is greater, and the utility obtained by the stage-II producer from the stage-I producer must be greater than the expenditure, so  $U_2(fy_1) > Pfy_1$ . At the same time, the stage-II producer misjudgment rate  $f > 0$ , and the information confirmation reward  $R > 0$ .

Therefore, when the stage-I producer chooses to provide qualified products or services, the stage-II producer will choose to make a correct judgment and confirm the production, payment, and transaction information of the stage-I producer as "true."

TABLE 2: Profit and loss matrix of each entity in subsequent production cycles.

		Stage-I producers	
		Produce qualified products	Produce inferior products
Stage-II producers	Confirm it as "true"	$U_2(y_1) - Py_1 - y_2 + Py_2 + R$ and $U_1(y_2) - Py_2 - y_1 + Py_1$	$U_2[(1-f)y_1] - Py_1 - y_2 + Py_2 + R$ and $U_1(fy_2) - Pfy_2 + Py_1$
	Not confirm it as "true"	$U_2[(1-f)y_1] - P(1-f)y_1 - y_2 + Py_2 + (1-f)R$ and $U_1(y_2) - Py_2 - y_1 + P(1-f)y_1$	$U_2[(1-f)^n y_1] - P(1-f)^n y_1 - y_2 + Py_2 + (1-f)R$ and $U_1(f^n y_2) - Pf^n y_2$

*4.1.2. When Some Stage-I Producers Provide Inferior Products or Services.* When some stage-I producers provide inferior products or services, whether the stage-II producers can choose to make a correct judgment and not confirm the production, payment, and transaction information of the stage-I producers as "true" depends on the information available to confirm the reward  $R$ . This is because it can be obtained from the profit and loss matrix when  $Pfy_1 - fR > 0$ ; the income obtained by the stage-II producer when it is not confirmed as "true" is greater, that is, when  $R$  is smaller, the stage-II producer is more likely to make a correct judgment. However,  $R$  is the incentive means for stage-II producers as information confirmers. If  $R$  is too small, stage-II producers lack the incentive to confirm information.

Therefore, when some stage-I producers provide inferior products or services, stage-II producers may not be willing to become information confirmers, or it is difficult to make a correct judgment, and the production, payment, and transaction information of stage-I producers providing inferior products or services are not confirmed as "true."

*4.1.3. When the Stage-II Producer Confirms the Information as "True".* When the stage-II producer confirms the information as "true," the stage-I producer will choose to provide inferior products or services. This is because, from the profit and loss matrix, when  $U_1(y_2) - Py_2 - [U_1(fy_2) - Pfy_2] - y_1 < 0$ , the income of producers providing inferior products or services in stage I is greater. According to the principle of diminishing marginal utility, the difference between the utility and expenditure of producers in stage I decrease with the increase of consumption, and the above inequality is true.

*4.1.4. When the Stage-II Producer Does Not Confirm the Information as "True".* When the stage-II producer does not confirm the information as "true," whether the stage I producer chooses to provide inferior products or services depends on the rate  $f$  that the stage-II producer thinks it provides inferior products. This is because, from the profit and loss matrix, when  $U_1(y_2) - Py_2 - [U_1(fy_2) - Pfy_2] - y_1 + P(1-f)y_1 < 0$ , the income of producers providing inferior products or services in stage I is greater. According to the principle of diminishing marginal utility, the difference between the utility and expenditure of producers in stage I decreases with the increase of consumption. At the same time, the greater  $F$ , the greater the possibility of the above inequality.

That is, failure to confirm the information as "true" will bring incentives for producers in stage I to provide inferior products or services.

*4.1.5. Analysis of Equilibrium Solution in the First Complete Production Cycle.* According to the above analysis, based on Hypothesis 4, the stage-II producers should be given a certain information confirmation reward as an incentive. At this time, confirmed as "true," providing inferior products or services is the Nash equilibrium of the game matrix, and the profit and loss combination at this time is  $U_2[(1-f)y_1] - Py_1 - y_2 + Py_2 + R$  and  $U_1(fy_2) - Pfy_2 + Py_1$ .

Under the Nash equilibrium, the stage-II producers who only consider the current income have more incentive to confirm the information as "true" and obtain corresponding remuneration. The stage-I producers who only consider the current income will partially tend to provide inferior products or services, so as to enjoy the income from selling products or providing services, but pay less costs. It can be seen that the incentive mechanism should be optimized for the short-sighted behavior of various subjects, and the long-term equilibrium should be solved by constructing a multiproduction cycle game model.

## 4.2. Equilibrium Solution in Subsequent Production Cycles

*4.2.1. When Stage-I Producer Provides Qualified Products or Services.* When the producers in stage I choose to provide qualified products or services, the profit and loss matrix is in the same form as the first production cycle, so the equilibrium point is also the same. The producers in stage II will choose to make a correct judgment and confirm the production, payment, and transaction information of the producers in stage I as "true."

That is, when the stage-I producer chooses to provide qualified products or services, the stage-II producer will choose to make a correct judgment and confirm the production, payment, and transaction information of the stage-I producer as "true."

*4.2.2. When Some Stage-I Producers Provide Inferior Products or Services.* When some stage-I producers provide inferior products or services, whether the stage-II producers can choose to make a correct judgment and not confirm the production, payment, and transaction information of the stage-I producers as "true" depends on the ratio  $F$  of the stage-I producers providing inferior products or services and the

information confirmation reward  $r$  available. This is because, from the profit and loss matrix, when  $U_2[(1-f)^n y_1] - U_2[(1-f)y_1] - P(1-f)^n y_1 + P y_1 - fR > 0$ , the income obtained by the stage-II producer is greater when it is not confirmed as “true,” that is, when  $f$  and  $R$  are small, the stage-II producer is more likely to make a correct judgment. However, similarly, the size of  $f$  is difficult to control, and too small  $R$  will lead to the lack of incentive of confirmation information for stage-II producers.

Therefore, when some stage-I producers provide inferior products or services, stage-II producers may not be willing to become information confirmers, or it is difficult to make a correct judgment, and the production, payment, and transaction information of stage-I producers providing inferior products or services are not confirmed as “true.”

*4.2.3. When the Stage-II Producer Confirms the Information as “True”.* When the stage-II producer confirms the information as “true,” the profit and loss matrix is the same in form as the first production cycle, so the equilibrium point is also the same. The stage-I producer must choose to provide inferior products or services.

*4.2.4. When the Stage-II Producer Does Not Confirm the Information as “True”.* When the stage-II producer does not confirm the information as “true,” whether the stage-I producer chooses to provide inferior products or services depends on how many production cycles in the stage-II producer acts as the information confirmer and the ratio  $f$  that the stage-II producer believes it provides inferior products. This is because, as can be seen from the profit and loss matrix, if the stage-II producer acts as the information confirmer for a long time, there may be insufficient consumption in the economy due to the elimination of too many stage-I producers in the transaction and payment system;  $U_1(y_2) - P y_2 - [U_1(f^n y_2) - P f^n y_2]$  may be negative first and then positive, but with the increase of the rate  $f$  that stage-II producers think stage-I producers provide inferior products, the value of  $-y_1 + P(1-f)y_1$  will also decrease; then,  $U_1(y_2) - P y_2 - [U_1(f^n y_2) - P f^n y_2] - y_1 + P(1-f)y_1 < 0$  is more likely to be established.

That is, failure to confirm the information as “true” and acting as the information confirmer for a long time will bring incentives for producers in stage I to provide inferior products or services.

*4.2.5. Analysis of Equilibrium Solution in Subsequent Production Cycle.* According to the above analysis, confirmed as “true,” providing inferior products or services is the Nash equilibrium of the game matrix, and the profit and loss

combination at this time is  $U_2[(1-f)y_1] - P y_1 - y_2 + P y_2 + R$  and  $U_1(f y_2) - P f y_2 + P y_1$ .

Under the Nash equilibrium, the stage-II producers have more incentive to confirm the information as “true.” As they act as information confirmers in multiple production cycles, the stage-II producers have more incentive to confirm the transactions and payments of “right.” Of course, at the same time, the producers of false transactions and payments are excluded, and they will be rewarded if they are confirmed as “true.” In stage I, producers will partially tend to provide inferior products or services, so as to enjoy the income from selling products or providing services, but pay less costs.

*4.3. Better Selection of Distributed Nodes.* From the above multiperiod game analysis and equilibrium results of incomplete information, it can be seen that, from the perspective of individual participants, if the stage-II producer acts as the information confirmer, it will face the contradiction of whether it acts as the information confirmer for multiple consecutive periods: if it acts as the information confirmer only in a few production cycles, it is possible to confirm too much as “true” to obtain remuneration. If you act as an information confirmer in consecutive production cycles, there is a risk of insufficient consumption in the economy. At the same time, producers at stage I are also vulnerable to incentives to provide inferior products or services.

Therefore, a better choice is to try to use trusted financial intermediaries as licensed distributed nodes. Trusted financial institutions represented by systemically important banks have a clear motivation to identify producers who provide inferior products or services and can also avoid the problem of false confirmation as “true” in order to obtain information confirmation remuneration. Under this mechanism, the stage-II producer will no longer act as the information confirmer, but trusted financial institutions such as commercial banks that have more information about the manufacturer will assume the function of confirming the information. The transaction information can be confirmed in the form of associated smart contracts, and the transaction information can be confirmed as “true” if it is consistent with the bank account. The optimization scheme of digital currency distributed nodes based on permitted DLT is shown in Figure 3.

## 5. Conclusion

The relationship between currency and credit is inseparable. Currency must have a good credit foundation. At the same time, currency performs its essential functions relying on credit. With the innovative development of distributed ledger technology, the requirements of currency on credit

FIGURE 3: Digital currency distributed node optimization scheme based on permitted DLT.

may be further met. This paper explores the close relationship between currency, credit, and account book and provides a theoretical explanation for solving the credit problem in currency from the perspective of account book. Based on the highly consistent relationship between distributed ledger technology and the essential functions of currency, this paper analyses the incentive mechanism of distributed nodes of digital currency. It obtains the equilibrium solution by constructing two main body single-stage and multistage game models. This study found that if the producer of the final product or the provider of the final service is the most licensed distributed node, it may lead to the risk of over recognition and insufficient consumption in the economy. On this basis, aiming at the above possible problems and combined with the reality of China's digital currency issuance, this paper puts forward the optimal selection of digital currency distributed nodes. It uses trusted financial intermediaries as licensed distributed nodes, providing a reference basis for the research and development of China's digital currency and its practice in economy and finance.

Therefore, this paper has some contributions to the research in the field of CBDC. Bis [11] and Xiao (2020) have proposed that since CBDC involves huge transaction and payment data, the distributed ledger technology without a license is not applicable when selecting distributed nodes. For this, Nosal and Rocheteau [6] have demonstrated that licensed distributed ledger technology can improve verification integrity. However, for licensed distributed nodes, it is difficult to technically prohibit them from verifying multiple ledgers with conflicting accounting items. This paper agrees with this view and, on this basis, further discusses how to select the distributed node of CBDC to ensure that it can perform the monetary function well and take into account the cost problem, that is, how to select the desired distributed node so that it can correctly select the account book that verifies "right" and the account book that does not verify "wrong."

In addition, there are still some limitations of this study. This paper puts forward the viewpoint of taking the systemically important commercial bank as the optimally distributed node. This viewpoint is based on the conclusion that the final product producer or the final service provider cannot be the optimally distributed node. Therefore, it still lacks rigorous mathematical inference, which will also be the

research direction and focus in the next step. Moreover, because digital currency has not been widely used in any country or region, the conclusion of this paper also lacks the support of empirical data, which will be supplemented in the subsequent stage of research with the continuous application of digital currency.

### Data Availability

The data used to support the findings of the study are available from the corresponding author upon request.

### Conflicts of Interest

The authors declare that they have no conflicts of interest to declare and state that (i) no support, financial or otherwise, has been received from any organization that may have an interest in the submitted work and (ii) there are no other relationships or activities that could appear to have influenced the submitted work.

Nowadays, the health level of residents has become the focus of people's attention. Under the background of the development of health service from "disease-centered" to "health-centered," it is very important to improve the level of urban health and clarify the factors affecting urban health. Therefore, this paper quantifies the relationship between residents' health literacy level and environment, average life expectancy, infectious disease mortality, and other indicators by selecting appropriate indicators and establishing a mathematical model. Based on the reciprocal linear combination of the collected index data and the corresponding health level value, the prediction model of social health literacy level (SPM) was established, and the qualitative prediction and quantitative analysis of citizens' health literacy level were studied in depth. Based on the SPM model, we can roughly predict the level of health literacy in a region only based on the main variables identified in this paper. The consistency of the experiment shows that the model is effective and robust, and it reveals that environmental factors are the most important factors affecting residents' health literacy level. The actual data show that THE SPM model is a timely and reasonable framework to measure the health literacy level of residents.

## 1. Introduction

Health literacy refers to the ability of individuals to acquire and understand health information and to use it to maintain and promote their own health, including basic knowledge and ideas, healthy lifestyle and behavior, and basic skills. It is an evaluation index that comprehensively reflects the development of national health undertakings [1, 2].

Health literacy is not an isolated concept. Health literacy is related to education [3–7], age [8], race [9], air pollution [10], chronic diseases [11, 12], social medical system [13], etc. However, due to the lack of objective indicators to reflect the overall health literacy level of residents in a certain region or country, the relationship between these indicators and the health literacy level of residents has not been well understood, which is often controversial. Therefore, it is not only of great significance in scientific research, but also of great value in helping people live a healthy life to quantify various indicators and establish a quantitative model to evaluate the health literacy level of residents in a region or country.

With the development of society, people pay more and more attention to the level of residents' health literacy. For the tool to measure health literacy [14], some use experimental methods to evaluate health literacy level [15], some use Delphi survey technology [16], some use HLS-EU-Q questionnaire to measure health literacy level [17, 18], some use mixed multicriteria decision-making (MCDM) method to establish evaluation model [19], and some use dynamic factor model (DFM) [20].

Taking Shenzhen as an example, this paper discusses the relationship between indicators and residents' health literacy level from the perspective of data analysis. By visiting government websites such as Health and Family Planning Commission, Statistical Bureau, Baidu, Souhu, Xinlang, and other search engines and news websites, this paper explores the relationship between health literacy and its multiple variables and makes a quantitative study of their correlation.

In order to explore the influence of many variables on health literacy, we selected 12 factors related to the level of health literacy in combination with 66 articles of health

literacy of Chinese citizens. Then the main variables are obtained by fitting and screening. Using search engine results or data on social media as proxy shows that the main variables do greatly affect the real value of health literacy. The root of this phenomenon lies in three aspects: influencing citizens' basic knowledge and concept, healthy lifestyle and behavior, and basic skills.

Several factors were selected to study the time series of health literacy, and the relationship between the indicators and the level of health literacy was explored. The results showed that PM2.5 (microgram cubic meters), health expenditure accounted for local financial expenditure, infectious disease mortality, and average life expectancy had the highest goodness of fit.

The paper is divided into six parts: the first part is the introduction. The second part includes data source, determination of variables, main variables, and time interval. In the third part, we studied four main variables related to health literacy: PM2.5 (microgram cubic meters), health expenditure, infectious disease mortality, and life expectancy. Then, in the fourth part, we constructed a health literacy level prediction model based on fitting results. The fifth part examines the accuracy and stability of the prediction model. Finally, the conclusions and discussions are presented in Part VI.

## 2. Data

Thirteen sets of data collected from the National Health and Family Planning Commission and the Local Health and Family Planning Commission from 2000 to 2017 were used for research in Shenzhen and the whole country. We will analyze the indicators affecting residents' health prediction level through the trend and fitting of each variable in the past 18 years.

**2.1. Data Sources.** The National Health and Family Planning Commission (NHPC) includes the real values of national health level and the annual changes of various factors over the years. The real health level of local cities can be collected from the local health and family planning committee. Baidu, 360, and other large engines provide all kinds of news reports on health literacy level. At the same time, CCTV, Sohu, and Sina also broadcast in real time. In addition, local TV stations review the course of health literacy in the light of their own characteristics and development trends, in order to continuously improve and look forward to the future.

**2.2. Definition of Variables.** Through a thorough understanding of Article 66 of Chinese Citizens' Health Literacy, combining basic knowledge and concept, healthy lifestyle and behavior, and basic skills, we have established 13 research directions of residents' health literacy  $S(t)$ , maternal mortality  $P(t)$ , the ratio of household registration to non-household registration  $H(t)$ , the number of college graduates  $A(t)$ , the number of hospitals  $N(t)$ , the drinking water standard rate  $W(t)$ , the number of beds  $B(t)$  per 1,000 population, the number of people participating in fitness

activities  $E(t)$ , infant mortality  $I(t)$ , PM2.5  $M(t)$ , health expenditure  $F(t)$ , infectious disease mortality  $G(t)$ , and life expectancy  $L(t)$ . Twelve basic variables except  $S(t)$  were established.

By fitting the basic variables and comparing the trend charts of each factor and health literacy level from 2000 to 2017, four variables with higher fitting degree are obtained, including PM2.5  $M(t)$ , health expenditure accounting for local financial expenditure  $F(t)$ , infectious disease mortality  $G(t)$ , and life expectancy  $L(t)$ .

**2.3. Time Interval  $\Delta t$ .** The true value of health literacy has been calculated since 2000. Every year, the relevant departments will test the level of citizens health literacy nationwide and locally, with an interval of one year. Therefore, we choose one year as our time interval ( $\Delta t$ ), which is consistent with the frequency of the government updating the true value and ranking of health literacy.

## 3. Relevant Variables

**3.1. Variable Screening.** In order to find out the optimal model which can predict residents' health literacy level, we first considered the 12 factors of maternal mortality  $P(t)$ , percentage of household registration and nonhousehold registration  $H(t)$ , number of college graduates  $A(t)$ , number of hospitals  $N(t)$ , drinking water compliance rate  $W(t)$ , number of beds per 1,000 people  $B(t)$ , number of participants in fitness (more than 1000)  $E(t)$ , infant mortality rate  $I(t)$ , PM2.5 content  $M(t)$ , health expenditure accounts for local financial expenditure  $F(t)$ , infectious disease mortality rate  $G(t)$ , and average life span  $L(t)$ .

In this paper, 12 considered variables were fitted with the health literacy level of residents, and the results can be seen in Figure 1. We found that the optimal model was fitted by four variables: PM2.5 content  $M(t)$ , health expenditure accounts for local financial expenditure  $F(t)$ , infectious disease mortality rate  $G(t)$ , and average life span  $L(t)$ .

**3.2. The Health Literacy Level of Residents  $S(t)$ .** The level of residents' health literacy reflects the health literacy status of residents in a country or a region. This article uses the data published by the National Health and Wellness Committee and the Local Health and Wellness Committee as the standard. This paper collected the national residents' health literacy level  $C(t)$  and Shenzhen residents' health literacy level  $S(t)$  between 2000 and 2017, as shown in Figure 2.

Figure 2 shows the development trend of the national residents' health literacy level  $C(t)$  and Shenzhen residents' health literacy level  $S(t)$  from 2000 to 2017. We found that the health literacy level of residents in Shenzhen and the whole country is in a growth trend. In 2016, two solid lines intersect. Figure 2 shows that the national residents' health literacy level  $C(t)$  is higher than the Shenzhen residents' health literacy level  $S(t)$  from 2000 to 2015, and the Shenzhen residents' health literacy level  $S(t)$  is higher than the national residents' health literacy level  $C(t)$  from 2016 to 2017 (see the yellow line section). The intersection point corresponds to

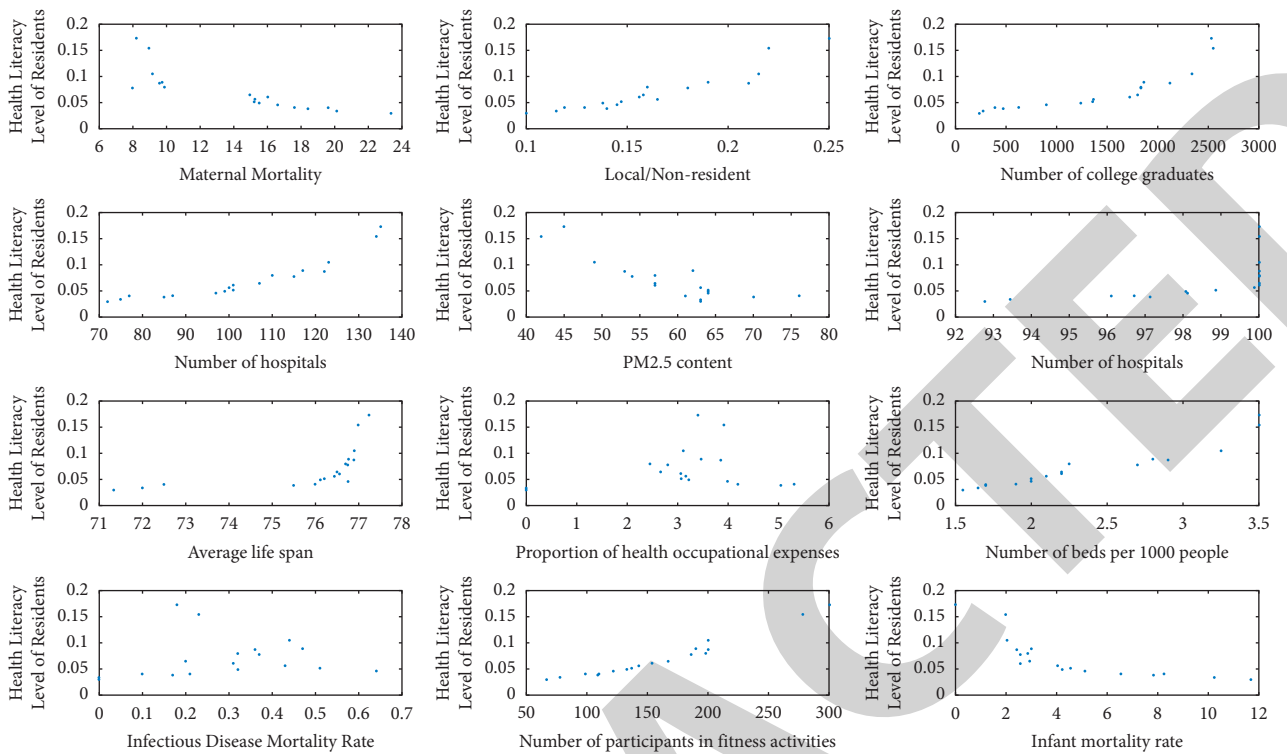

FIGURE 1: Scatter plot of 12 variables and residents' health literacy level.

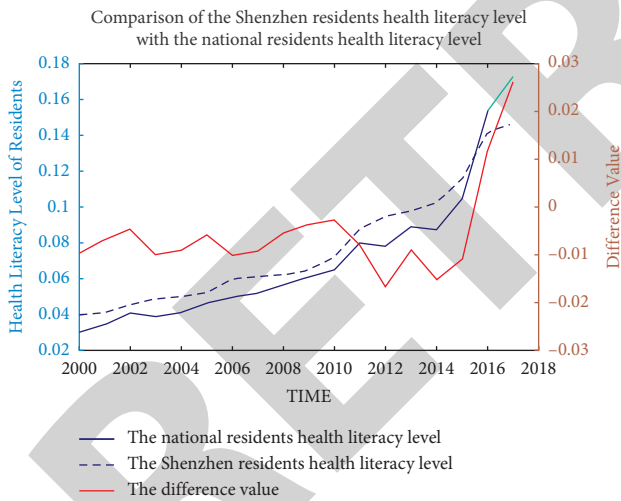

FIGURE 2: The illustration of Shenzhen residents' health literacy level and national residents' health literacy level, where the difference  $D(t)$  between Shenzhen residents' health literacy level and the national residents' health literacy level, national residents' health literacy level  $C(t)$ , and Shenzhen residents' health literacy level  $S(t)$  are shown in dotted red, blue, and red, respectively. The  $x$ -coordinate is time. The left  $y$ -coordinate is the national residents' health literacy level  $C(t)$  and Shenzhen's health literacy level  $S(t)$ . The right  $y$ -coordinate is the difference  $D(t)$  between Shenzhen residents' health literacy level and the national residents' health literacy level.

the Shenzhen Municipal Government's vigorous development of people's livelihood in 2016, which is "to improve the quality of people's livelihood and enhance the level of

people's livelihood security." The document "The implementation opinions of Shenzhen Municipal Government on deepening the reform of medical and health system and building a strong city of health" was issued, along with the reform of medicine and health to establish a higher quality medical and health service system. In 2016, the Shenzhen government also issued "The Shenzhen Solid Waste Pollution Prevention and Control Action Plan" to promote environmental protection and ecological civilization construction in Shenzhen. Therefore, the results show that the residents' health literacy level is closely related to healthcare and ecological environment.

3.3. *The Infectious Disease Mortality Rate  $G(t)$ .* The infectious disease mortality rate  $G(t)$  is an index reflecting the severity of life-threatening diseases, indicating the frequency of death due to a disease in a certain period of time. The incidence of infectious diseases is an indicator of the severity of life-threatening diseases. Influencing factors of reducing mortality rate of infectious diseases in a certain area include improvement of sanitary conditions, improvement of water sources, education (especially women's education), provision of medical services and infrastructure construction. These factors can also obviously affect people's physical and mental health. Therefore, it is reasonable to take the mortality rate of infectious diseases as one of the factors to measure the health literacy level of residents in a certain area. Figure 3 shows the trend of infectious disease mortality and residents' health literacy. As shown in the figure, the lower the mortality rate of infectious diseases, the higher the level of health literacy in the region. When  $G(t) > 0.4$ , the data

FIGURE 3: The scatter plot of the relationship between the mortality rate of infectious diseases  $G(t)$  and the health literacy level  $S(t)$  of residents from 2000 to 2017, and this graph fits a regression line.

points are more concentrated and fit well with the fitting line. When  $G(t) < 0.4$ , the distribution of data points is scattered and the fitting degree is not as good as before. This may be because with the improvement of medical and health conditions, the mortality rate of infectious diseases is decreasing dramatically and tends to be stable, so the influence of the mortality rate of infectious diseases on the health literacy level of residents is weakening.  $R^2 = 0.333$ . Therefore, we can choose the mortality rate of infectious diseases as an index to measure the health literacy level of residents.

**3.4. The Health Expenditure Accounts for Local Financial Expenditure  $F(t)$ .** Health expenditure refers to the financial allocation for health services by governments at all levels. Health expenditure includes public health service funds and public medical expenses. The proportion of health expenditure in local financial expenditure shows the relationship between public resources consumed by a country (or region) for medical services and those consumed by other public services in a certain period of time. The relationship between health expenditure and residents' health literacy is shown in Figure 4. Figure 4 shows that when  $F(t) > 4$ , health expenditure is closely related to residents' health literacy level, which may be due to the importance of government intervention when residents' health literacy level is relatively low. This also explains the negative correlation between health expenditure and residents' health literacy: when residents' health literacy level is low, people have weak self-awareness, and they need to rely on the government to increase health expenditure, and when residents' health literacy level is high, they can also reduce expenditure. The scatter plot fits the straight line, and its  $R^2$  is 0.202. We choose health expenditure as an indicator of residents' health literacy.

**3.5. The PM2.5 Content  $M(t)$ .** PM2.5 refers to particles smaller than or equal to 2.5 microns in ambient air. PM2.5 can carry a large number of harmful substances through the nasal cavity, directly into the lungs, or even into the blood, so

FIGURE 4: A scatter plot of the relationship between health expenditure in local financial expenditure  $F(t)$  and residents' health literacy  $S(t)$  from 2000 to 2017. The straight line in the graph is a fitting line fitted by the scatter plot.

PM2.5 is also known as particulate matter into the lungs, which is closely related to lung cancer, asthma, and other diseases. PM2.5 is the main killer of black lung and haze days and has great harm to human health. The relationship between PM2.5 content and residents' health literacy level is shown in Figure 5. Figure 5 shows that the higher the PM2.5 content, the lower the health literacy level of residents. Therefore, PM2.5 content is negatively correlated with residents' health literacy level. The scatter plot shows that, except for individual points, scatter points are mostly distributed around the fitting line, and  $R^2 = 0.399$ . We regard PM2.5 content as one of the indicators to measure residents' health literacy level.

**3.6. The Average Life  $L(t)$ .** Average life is the average number of years that a person can continue to live in the same period. The life expectancy index comprehensively reflects the level of disease prevention and health services in a country or region. Average life is generally regarded as an important index to measure the quality of life and medical and health level of residents in a country or region and also an important index to evaluate the quality of life and medical level of population in a country or region. The relationship between life expectancy and residents' health literacy is shown in Figure 6. Figure 6 shows that, with the rapid development of regional economy, the remarkable improvement of medical treatment level, and the improvement of people's material living standard, the average life expectancy of population has been growing steadily and rapidly in recent years. But there are several special points that influence this trend. The red dot in Figure 6 corresponds to the residents' health literacy level in 2016 and 2017. In the past two years, the government has fully implemented the project of benefiting the people and actively implemented the strategic plan of building a beautiful China; thus the residents' health literacy level has been significantly improved.

The fitting line  $R^2$  is 0.323 based on scatter plot. We choose life expectancy as one of the indicators to measure the health literacy level of residents in a certain area.

FIGURE 5: A scatter plot of the relationship between PM2.5 content and health literacy level from 2000 to 2017. The straight line in the graph is a fitting line which is fitted by scatter plot.

FIGURE 6: A scatter plot of the relationship between life expectancy and health literacy between 2000 and 2017. The straight line in the graph is a fitting line which is fitted by scatter plot.

#### 4. Health Literacy Level Model of Residents

The fourth part shows that the content of PM2.5  $M(t)$ , the proportion of health expenditure in local financial expenditure  $F(t)$ , the mortality rate of infectious diseases  $G(t)$ , and the average life span  $L(t)$  all affect the health literacy level of residents. However, a linear fit  $y(t) = Ax(t) + C$  of each individual indicator measure to the observed residents' health literacy level results in  $R^2 < 0.3$ , except for  $1/M(t)$ , where  $R^2 = 0.361$ . Therefore, there is no single indicator that can adequately measure the health literacy level of residents. This indicates that it is necessary to measure the health literacy level of residents through the combination of indicators (see Appendix for the correlation of variables).

We therefore explored the predictive power of the sum of these variables with multipliers obtained via an ordinary least squares (OLS) fitting process, resulting in  $R^2 = 0.78$ ; the  $p$  values of  $F$ -test for all variables are shown in Table 1. The  $p$  values of variables  $1/G(t)$  and  $1/F(t)$

TABLE 1:  $p$  values and  $\beta$ -coefficients.

	$1/M(t)$	$1/G(t)$	$1/F(t)$	$L(t)$
$p$ value	$\leq 0.001$	0.179	0.423	0.03
$\beta$ -coefficients	0.639	0.183	-0.13	0.621

were greater than 0.05, so the two variables did not pass the test.

We found that the four indexes multiplied and then fitted variables can pass the test and the prediction ability is not much different from the above model. Fitting formula

$$(SPM). S_M(t) = A \frac{F(t)}{M(t)} \frac{L(t)}{G(t)} + C. \quad (1)$$

$R$ -square is 0.640. The  $p$  value of variable  $F$ -test is less than 0.001, which passes the test, so the SPM model is accepted. That is to say, the SPM model is the best model in the models we tested.

According to model 1, we assessed that the impact of that indicator on the health literacy level of residents was greater. Standardized  $\beta$ -coefficient is the corresponding regression coefficient in the regression equation calculated after data standardization [21, 22]. The standardized  $\beta$ -coefficient eliminates the influence of the unit of dependent variable and independent variable [23, 24], and its absolute value can directly reflect the influence degree of independent variable on dependent variable. Table 1 show that the content of PM2.5 is the strongest factor affecting the health literacy level of residents.

#### 5. Experiments

Several experiments were designed to verify the predictive ability of the model SPM:

Firstly, we use the data of the first ten years as training data to get the model coefficients  $A = 0.329$  and  $C = -0.516$ . Then we use this model to predict the health literacy level of residents in the next seven years (Figure 7). We found that this model can accurately predict the health literacy level of residents. Figure 7(a) shows that we compare the predicted value with the real value and find that the scatter points are around the line  $y=x$ , which indicates that the predicted value  $S_M(t)$  is closely related to the real value  $S(t)$ . Figure 7(b) shows the difference between the observed and the real values.  $\Delta S_M(t) = S(t) - S_M(t)$ . The scatter points are distributed around the straight line on the day of  $X=0$  and the fluctuation is small, which indicates that the difference between the predicted value and the real value of the model is acceptable. Figure 7(c) is a comparison between the 95% prediction interval and the true value. We can see from the figure that most of the values are included in the prediction interval. There is a very low deviation in residents' health literacy level because in some years, the official website of the government did not publish its exact value, so there may be permissible error in the value

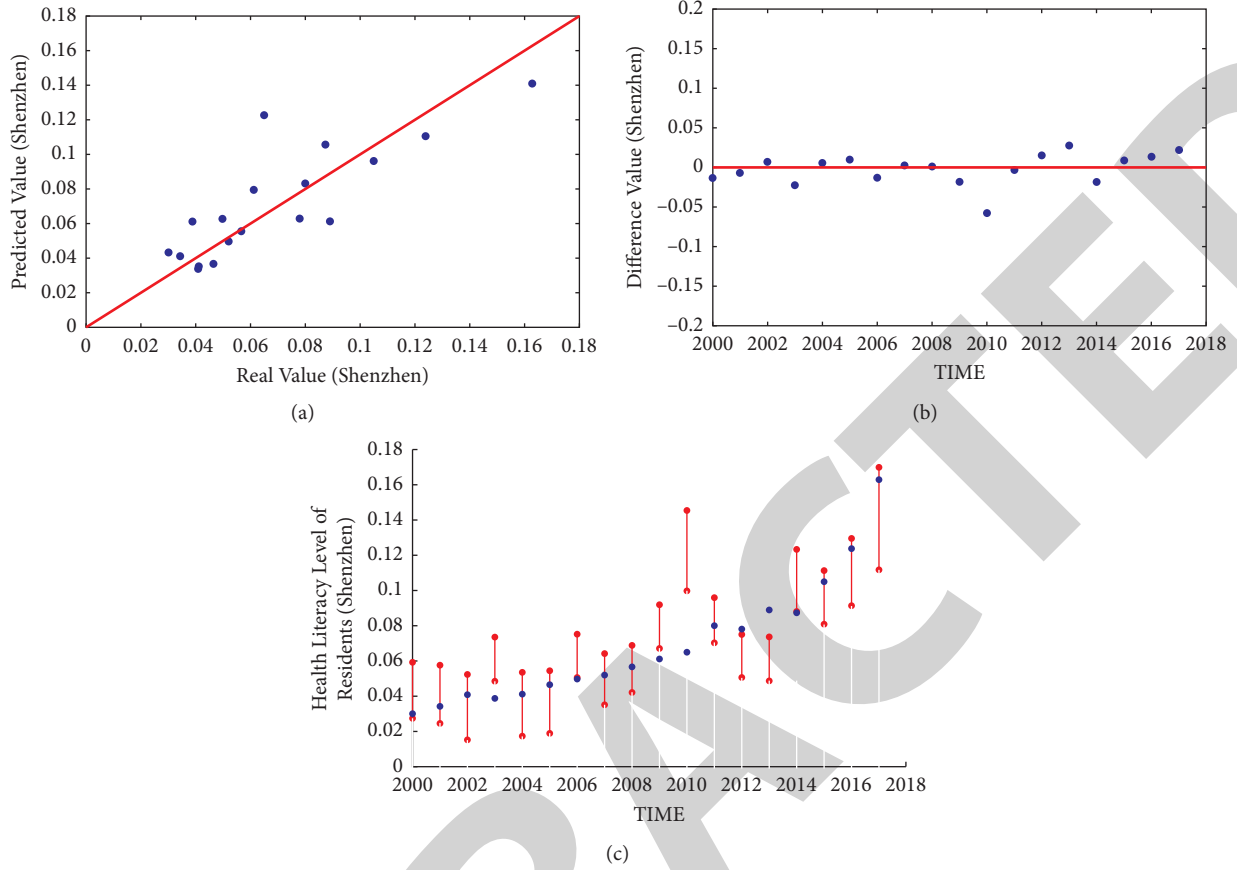

FIGURE 7: Predicting the health literacy level of residents. (a) Based on the data of the previous decade to determine the parameters  $A = 0.329$  and  $C = -0.516$  and to make a scatter plot comparison between the predicted value and the real value. The straight line in the figure is  $y = X$ . (b) is a scatter plot of difference: the difference between the real value and the predicted value is plotted as a scatter plot. Each warehouse (box) in (c) represents the predicted range within a 95% confidence interval.

	Significance (bilateral)	0.228	0.482		0.130
	$N$	18	18	18	18
$1/M(t)$	Pearson	-0.012	0.124	0.370	1
	Significance (bilateral)	0.961	0.623	0.130	
	$N$	18	18	18	18

\*\*Significant correlation was found at 0.01 level (bilateral).

of residents' health literacy level. Overall, Figure 7 shows that once the PM2.5 content  $M(t)$ , health expenditure accounts for local financial expenditure  $F(t)$ , infectious disease mortality rate  $G(t)$ , and average life span  $L(t)$  are obtained in a certain area, the health literacy level of residents in this area can be predicted. Next, we will carry out further experiments.

Next, we use the national data for further experimental proof. We use SPM model to predict the health literacy level of Chinese residents from 2000 to 2017. We can see from Figure 8(a) that the scatters of predicted and real values are distributed around the  $Y=X$  straight line, which shows that the two values are closely related. Figure 8(b) shows that the difference between the predicted value and the real value fluctuates at  $Y=0$ , and the floating range is small, which further shows that the predicted value of this model has strong predictive ability. Figure 8(c) shows that the model is capable of capturing real values. Therefore, we can say that SPM model has a

good predictive effect on residents' health literacy level.

## 6. Discussion and Conclusions

In recent years, the National Health and Family Planning Commission has incorporated the evaluation index of residents' health literacy into the national health development plan as an evaluation index to comprehensively reflect the development of national health. In this study, we try to quantify the relationship between residents' health literacy and indicators and predict residents' health literacy by indicators.

Because residents' health literacy covers a wide range of areas, it is difficult to obtain it directly. So we selected 12 variables, and after screening, we got four indexes with the highest fitting degree—PM2.5  $M(t)$ , health expenditure accounted for local financial expenditure  $F(t)$ , infectious disease mortality  $G(t)$ , and life expectancy  $L(t)$ . These four indicators can be measured separately. Therefore, this paper establishes a prediction model of residents' health literacy (SPM) based on four indicators. We find that when we input the index data, the

difference between the predicted value and the actual value produced by the model is very small, even neglected. For individual outlier data, we investigated the local information and found that the government website did not publish its exact value, so there may be permissible error in the value of their residents' health literacy level.

Of course, with the rapid development of society, various health problems are constantly emerging. We still have a long way to go in the future on how to predict and control the response and how to find new indicators to measure the level of health literacy in order to continuously improve the model in this paper. At the same time, we hope that the SPM model in this paper can be easily extended to other areas where indicators are easy to measure. For example, health monitoring, land planning, and decision-making [25], asset accumulation and portfolio decisions in the financial sector [26, 27], natural gas demand forecasting [28], food safety, and other indicators are similar to health literacy tests. At the same time, it is hoped that this study can help improve the residents' health literacy level, correctly grasp the basic knowledge and concepts, master healthy lifestyle and behavior, and learn the basic skills of health first aid.

## Appendix

### Variable correlation

Table 2 shows the correlation results of four variables: PM2.5 content  $M(t)$ , proportion of health expenditure in local financial expenditure  $F(t)$ , mortality rate of infectious diseases  $G(t)$ , and average life expectancy  $L(t)$ . The results show that no single index can fully measure the level of health literacy of residents; it is necessary to combine indicators to measure the level of health literacy of residents.

### Data Availability

Thirteen sets of data collected from the National Health and Family Planning Commission and the Local Health and Family Planning Commission from 2000 to 2017 were used for research in Shenzhen and the whole country.

### Conflicts of Interest

The authors declare that they have no conflicts of interest.

### Acknowledgments

This paper proposes a mixed decision strategy for freight and passenger transportation in metro systems during off-peak hours (MTS-OPH). The definition of the mixed decision strategy is proposed, and fixed and flexible loading modes are considered for different passenger flow volumes. A mathematical model of the MTS-OPH is proposed and solved using an improved variable neighborhood search algorithm. Case studies demonstrate the performance and applicability of the proposed model and algorithm, and the MTS-OPH is discussed for different delivery distances, passenger flows, and metro network types. The proposed strategy is suitable for long-distance delivery, and the proposed model framework can be applied to different types of metro networks with different levels of complexity. The mixed decision strategy provides a decision support tool for metro and freight companies and can propose corresponding solutions according to different passenger flows.

## 1. Introduction

With the continuous development of e-commerce and home deliveries, urban freight transport has emerged as a key link in urban economic and social development [1, 2]. Road transportation is the primary mode for urban freight transportation [3], and 85–90% of freight is transported by road in France [4]. However, the freight transportation by vehicles poses a series of problems pertaining to urban traffic congestion, greenhouse gas emissions, and noise. Urban freight accounts for 10% of total transportation, but it accounts for 40% of urban pollutant emissions [5]. Therefore, optimizing the transportation structure, strengthening the cooperation of different transportation modes, promoting the organic connection between intercity trunk transportation and city-end distribution [6], and encouraging the development of intensive distribution models are of great significance for creating a green and efficient logistics system.

As mentioned above, the freight transportation needs to change towards more efficient and sustainable transportation systems to cope with increasing demand for freight transportation in urban areas. The metro has the advantages of high efficiency, large capacity, and sustainability, but most

metro networks suffer from insufficient utilization of metro trains due to the low passenger flow during off-peak hours [7]. Therefore, introducing goods into the metro network during off-peak hours is a very potential way of freight [8]. The present mixed transport strategy for freight and passenger transportation in metro systems is usually by subjective experience [9], lacking reasonable theoretical framework and mathematical formulation. Furthermore, the entire metro network should be considered to deal with the freight, rather than a single metro line [10]. Therefore, a general theoretical framework and model for constructing the mixed passenger and freight transportation strategy on the metro network during off-peak hours are indispensable.

The purpose of this study is to combine the existing metro network with the first- and last-mile delivery services operated by logistics companies and propose a feasible passenger and freight flow mixed transport strategy for metros during off-peak hours (MTS-OPH). The paper considers fixed and flexible loading modes under different passenger flows and analyzes different cargo characteristics and delivery time requirements. A model for quantitatively evaluating the mixed transportation strategy is established, and an improved variable neighborhood search (VNS) algorithm is designed. They are then applied to the cargo

transportation of Ningbo and Beijing metro networks, respectively, and the mixed transportation strategy under different delivery distances, passenger flows, and metro network types is analyzed. The model and method can also be applied to the metro network of other rail transit cities.

The remainder of this paper is organized as follows: Section 2 reviews related research on metro mixed transportation. Section 3 formulates a nonlinear programming model of the MTS-OPH, and then, an improved VNS algorithm is designed to solve the proposed model in Section 4. Subsequently, two case studies are implemented to verify the proposed model in Section 5. In Section 6, the conclusions of the study and scope for future research are presented.

## 2. Literature Review

*2.1. Urban Freight and Passenger Transportation.* Nash [11] first proposed the use of urban public transportation for freight transportation. Later, based on the concept of sharing, Trentini et al. [12] proposed to introduce urban freight transportation into passenger transportation to achieve the purpose of sharing transportation resources and transportation infrastructure. On this basis, the flow of urban freight and passenger transport was quantified, and a new urban transport system for passenger and freight was constructed and implemented in La Rochelle, France [13]. Gonzalez-Feliu [14] used a socioeconomic cost-benefit analysis to assess the applicability of tram freight transport in the Paris region. The study showed the potential of the tram freight transport mode. Fatnassi et al. [15] integrated personal rapid transportation and freight rapid transportation modes and used electric vehicles to achieve mixed passenger and freight transportation on automatic rails. Masson et al. [16] proposed a hybrid freight method based on the integration of passenger and freight systems to solve mixed urban traffic problems. This method used buses to transport goods from the central distribution center to the transfer point and then used a tricycle to transport the goods from the transfer point to the destination.

There are some successful cases of urban passenger and freight transportation. In Dresden, the tram line from the Volkswagen warehouse to the city center can transport 300,000 tons of goods a year, 10 times a day, which significantly reduces carbon dioxide emissions [17]. In Paris, the commuter line D transports household goods, leisure products, and other goods from the MONOPRIX warehouse (Combs-la-Ville and Lieusaint) on the outskirts of Paris to the Bercy station [18]. These goods are then transported to stores through trucks that use natural gas vehicle fuel to satisfy the emission reduction principles along the logistics line. In New York, subway waste is collected through stations using modified metro trains [19]. However, most of the existing research on mixed transportation modes is based on road and railway transportation. These above studies can be applied into the mixed freight and passenger transportation in the metro system. Since the operation mode, transportation efficiency, and transportation timeliness of metro are different from railways, the mixed

transportation of freight and passenger transportation in the metro systems needs further research.

*2.2. Urban Freight and Passenger Transportation in Metro Systems.* The feasibility and application prospects of urban metro freight have been studied in a few research papers. Rijsenbrij and Pielage [20] discussed the feasibility of using the metro for mixed passenger and freight transportation, which gained the attention of national and international scholars on metro freight transportation. Kikuta et al. [9] conducted a test study on the combination of the public metro service and conventional truck operation to prove the feasibility of this mode of transportation. For the metro distribution service, Motraghi and Marinov [21] collaborated with the Newcastle metro network to theoretically analyze urban freight transportation. However, further research is required before actual implementation of their findings. The above research made some explorations on the mixed transportation of freight and passengers in metro systems but did not establish an implementation ability and systematization theory framework. Therefore, a general mixed transportation theoretical framework in the metro systems should be designed to realize the freight and passenger mixed transportation strategy.

In addition, a few studies focused on metro freight. Brice et al. [22] reported a baggage transfer system to facilitate passengers transporting luggage from Newcastle city center to Newcastle International Airport via the metro. They proved the feasibility of the new baggage transfer solution and reported that the corresponding cost is higher than that of the existing service. Ghilas et al. [23] found that integrated freight and scheduled line services can potentially reduce the operating costs of logistics service providers and the public transportation sector can obtain additional revenue. However, the existing mixed transportation models are established based on a single metro line. Considering the different directions of goods circulation, existing models cannot accurately describe the mixed transport strategy in metro systems. Therefore, a mixed transportation model on the metro network should be established to realize the circulation of goods.

*2.3. Optimization Method of Urban Freight and Passenger Transportation.* Location and route selection have long been the significant issues in the freight and passenger transportation domain. Fatnassi et al. [15] proposed two mathematical formulas to solve the vehicle route between stations and used dynamic optimization methods and developed algorithms to solve the shared transportation of goods and passengers. Zhao et al. [24] proposed a segmentation method of urban metro network, using complex network theory and the TOPSIS model to determine the candidate metro distribution hubs for the location model. Dong et al. [25] analyzed the characteristics of underground cargo capacity and established a mixed integer programming model to select the location of metro distribution hubs. However, the limitation of the frequency of goods transfer in the metro network is barely considered in these studies.

Likewise, time window constraint is a critical issue along with the rapid increase in freight demand during recent years. Behiri et al. [8] studied an environment-friendly urban freight transportation alternative using a passenger railway network and proposed a heuristic based on dispatching rules and a single-train-based decomposition heuristic to solve the Freight-Rail-Transport-Scheduling Problem. Yang et al. [26] studied the vehicle routing problem with mixed backhauls and time windows for city logistics, and the time-dependent pickups and deliveries can be depicted by extending the state dimensions. However, freight transportation in the passenger transportation system focuses on the study of the cargo time window, ignoring the impact on the normal operation time window of the passenger transportation system.

In addition, the development of solving algorithms has attracted the attention of researchers and practitioners. Bräysy [27] introduced the internal design of variable neighborhood descent and variable neighborhood search algorithms in detail, analyzed the vehicle routing problem with time windows problem, and pointed out that the variable neighborhood search algorithm is one of the most effective methods to solve the vehicle routing problem with time windows problem. de Armas and Melián-Batista [28] studied a dynamic rich vehicle routing problem with time windows and proposed a meta-heuristic algorithm based on variable neighborhood search to solve this problem. However, the stability and reliability of the calculation results need to be strengthened. Therefore, we design two types of neighborhood structures to obtain high-quality solutions.

**2.4. Contribution.** The main contributions of this study are summarized as follows:

- (i) We propose a general theoretical framework of MTS-OPH. This framework includes new concept and transportation standards of MTS-OPH. This definition clarifies the process and applicable time of mixed transportation. Relative to previous study on the types of mixed transportation goods [13, 29], MTS-OPH further explored the types of goods suitable for mixed transportation on the basis of transporting small goods. The mixed transportation standard of separate loading of passengers and cargo and priority transportation of passenger flow is established. Furthermore, fixed and flexible cargo loading modes are proposed according to different off-peak passenger flows.
- (ii) We formulate a nonlinear programming model for the MTS-OPH. Based on the research of Fatnassi et al. [15] and Zhao et al. [30], our model improves the mixed transportation strategy research to a mixed transportation strategy research under load rates of passenger flow during off-peak hours. To the best of our knowledge, this is the first time that the problem of mixed passenger and freight transportation under different passenger flows has been addressed in the context of metro transportation during off-peak

hours. Moreover, an improved VNS algorithm is designed to solve the model, which provides a decision support tool for logistics companies.

- (iii) We presented the real case study of the Ningbo and Beijing metro network to verify the practicality and efficiency of the proposed model. The applicability of the model is discussed from the distribution distance, off-peak passenger flow, and metro network type. Our results show that the proposed model can be applied to different metro networks. Furthermore, the mixed transportation mode in the metro systems has the advantages of high speed, high punctuality, low economic investment, low environmental impact, and low energy consumption [31–33].

### 3. Mathematical Formulation

This section provides a detailed description of the MTS-OPH, analyzes the types of goods suitable for mixed transportation, and provides different mixed transportation methods based on different load rates of passenger flow during off-peak hours. Finally, a nonlinear programming model of a mixed transportation strategy is constructed.

**3.1. Description of MTS-OPH.** MTS-OPH integrates the existing urban metro network with the first- and last-mile delivery services operated by logistics firms. The key aspect of this strategy is to transport goods and passengers together without affecting the metro passenger flow. Thus, the transportation standard of separate loading of passengers and cargo and priority transportation of passenger flow should be considered. First, metro train carriages are divided into passenger carriages and freight carriages, similar to the passenger carriages and freight carriages set in the Shenzhen metro trains in China [34]. Different types of carriages are set with boundary lines and dedicated passages to divide the passenger and freight flows, as shown in Figure 1. To minimize the impact of cargo flow on passengers, we introduce relevant constraints on the types of cargo used for mixed transportation. For ease of operation, all goods are placed in a same-size freight box as freight parcels. Concurrently, small cargo packages should be selected for metro mixed transportation. A similar conclusion has been reported in related studies on bus freight [13] and metro freight [9, 29]. Thus, goods in the freight parcel should be small goods, such as documents, books, clothing, and small mechanical parts, rather than fresh goods that need to be frozen and kept fresh, which are not affected by time and the environment, in order to maintain the metro carriage environment tidy.

Second, to satisfy the passenger flow priority transportation standard without changing the headway and stop time of metro trains during off-peak hours, this study proposes different mixed transportation methods based on different load rates of passenger flow during off-peak hours. When the number of passengers and freight demand is greater than the metro capacity, each train adopts a mixed passenger and cargo transportation mode during off-peak

FIGURE 1: Processing of the second stage.

hours, as shown in Method 1 (i.e., fixed loading mode) in Figure 2. When the number of passengers and freight demand is less than the metro capacity, one of every two trains is selected to employ the mixed transportation mode while the other train is used for passenger transportation, as shown in Method 2 (i.e., flexibility loading mode) in Figure 2. In Figure 2,  $t_{\text{interval}}$  represents the headway of metro trains during off-peak hours.

In summary, MTS-OPH is a transportation strategy based on the aforementioned mixed transportation standard, which satisfies the optimal distribution cost of the cargo flow under the condition of determining the origin and terminal stations of the goods. The transportation strategy is to use the metro passenger transportation network, which is composed of cargo distribution centers, metro stations, terminal cargo stations, metro trains, and freight vehicles, as shown in Figure 3.

In Figure 3, the operation process of MTS-OPH is divided into five stages. The first and fifth stages are vehicle delivery, second and fourth stages are manual transshipments, which transfer cargo from the vehicle to metro carriage, and third stage is metro delivery. The transfer of goods between each stage is completed by trolley.

In the first stage, the cargo is packed in freight parcels, placed in freight boxes, loaded onto transportation vehicles, and delivered to the departure metro station via freight vehicles. Then, the freight boxes are unloaded from the vehicle and loaded on the trolley. In the second stage, the freight boxes are transported to the metro platform via trolleys and transported to the metro freight carriage when the train enters the platform. In the third stage, freight boxes are transported on the metro network (transfers are performed via trolleys). Here, the train operation mode is from the first station to the last station regardless of the train service route. The freight boxes enter the fourth stage after being transported via the metro train. The freight boxes are unloaded from the metro freight carriage and transported via trolleys to the arrival metro station. In the last stage, the freight boxes are loaded onto the freight vehicle and transported to the corresponding terminal cargo station. All the aforementioned stages constitute the MTS-OPH operation process, while the third stage of the operation period in MTS-OPH is the off-peak hours of metro operation.

**3.2. Assumptions and Notations.** The MTS-OPH model can be described as the process of delivering multiple freight stations from a cargo distribution center with the optimal delivery cost

as the goal. The number of terminal cargo stations is determined, but the freight stations are located in different geographical locations. All transportation paths are based on the actual shortest distance of the road network or metro network. Thus, certain assumptions have been considered as follows:

- (i) The freight is placed in a standardized unit parcel to measure the arrival demand of the terminal cargo stations.
- (ii) There is no storage function at the metro exit station, and freight vehicles are arranged for delivery immediately after the cargo arrives at the metro exit station.
- (iii) The freight vehicles used for transportation are of the same model with the same fuel consumption and load capacity.
- (iv) The freight vehicles run at a uniform velocity without consideration of the road conditions. Furthermore, after the freight is transported, the vehicles are not required to return to the cargo distribution center or arrival metro stations.
- (v) Up to two freight transfers occur in the urban metro network.

Table 1 summarizes the notations used throughout the paper.

### 3.3. System Constraints

#### 3.3.1. Number of Freight Carriages Constraints

$$E = D - \left\lceil \frac{\max N}{\text{cap}_M} \right\rceil, m = 1, \dots, M. \quad (1)$$

Equation (1) determines the number of freight carriages ( $x$ ) represents the smallest integer greater than  $x$ ).

#### 3.3.2. Freight Loading Mode Constraints

$$r = \begin{cases} 1, & \frac{Q_{i'}}{E \times \text{cap}_M} > 1, \\ 2, & \frac{Q_{i'}}{E \times \text{cap}_M} \leq 1, \end{cases} \quad i' = 1, \dots, I'. \quad (2)$$

The freight loading mode is selected by Equation (2). Among them,  $r = 1$  is a fixed loading mode; that is, each train uses a mixed passenger and freight transportation

FIGURE 2: Two transportation methods of MTS-OPH.

TABLE 1: Notations.

Index sets	$J$	Set of departure metro stations, $j \in J$
	$J'$	Set of arrival metro stations, $j' \in J'$
	$I'$	Set of terminal cargo stations, $i' \in I'$
	$V$	Set of freight vehicles, $v \in V$
	$M$	Set of metro, $m \in M$
	$N$	Set of maximum cross-section passenger flow collection during off-peak hours, $N_m \in N$ , where $N_m$ is the maximum cross-section passenger flow of metro $m$ during off-peak hours

TABLE 1: Continued.

Parameters	$i$	Cargo distribution center ( $i = 1$ )
	$n$	Index of freight vehicles ( $n \in V$ )
	$Q_{i'}$	Number of cargos received at terminal cargo station $i'$
	$C_v$	Fixed operating cost for one vehicle
	$C_{ij}$	Cost of per unit cargo transportation by vehicles from $i$ to $j$
	$C_O$	Cost of per unit cargo transfer after one transfer
	$t_O$	Time taken to complete a transfer
	$D$	Number of train carriages
	$E$	Number of freight carriages
	$\text{cap}_V$	Capacity of transport vehicles
	$\text{cap}_M$	Freight capacity of one metro carriage
	$O_{jj'}$	Number of transfers on metro transport path ( $j, j'$ )
	$s_j^m$	On the metro line where station $j$ is located, the departure time of the first station of train $m$
	$t_j$	Cargo loading time at station $j$
	$t_{ij}$	Time taken to complete path ( $i, j$ )
	$[\text{ET}_{i'}, \text{LT}_{i'}]$	Receiving time window of the terminal cargo station $i'$
	$r$	1 represents Method 1 of MTS-OPH, 2 represents Method 2 of MTS-OPH
$\alpha$	Delay cost of unit cargo	
$\lambda$	0, if the delivery time is less than the latest delivery time, $\alpha$ , otherwise	
$Z$	A large positive number	
Decision variables	$x_{ij}^v$	1, if the transport path ( $i, j$ ) is served by the vehicle $v$ , 0, otherwise
	$y_{jj'}^{i'm}$	1, if the cargo from the terminal cargo station $i'$ is delivered by the metro train $m$ from the departure station $j$ to the arrival station $j'$ , 0, otherwise
	$\text{SET}_{i'}$	Time taken to start delivery to the terminal cargo station $i'$
	$\text{SLT}_{i'}$	Time taken to complete delivery to the terminal cargo station $i'$
	$K$	Quantity of transport vehicles ( $K \in Z$ )

mode during off-peak hours;  $r = 2$  is a flexible loading mode; that is, one of every two trains chooses to use a mixed transportation mode and the other for passenger transportation.

**3.3.3. Vehicle Line Capacity Constraints.** Vehicles in the “first mile and last-mile” distribution network should meet vehicle capacity constraints, vehicle number constraints, and line capacity constraints.

$$\sum_{v=1}^n x_{ij}^v = 1, \quad i = 1, j = 1, \dots, J, \quad (3)$$

$$\sum_{v=n+1}^V \sum_{j'=1}^{J'} x_{j'i'}^v = 1, \quad i' = 1, \dots, I', \quad (4)$$

$$Q_{i'} \leq \sum_{v=n+1}^V \sum_{j'=1}^{J'} x_{j'i'}^v \text{cap}_V, \quad i' = 1, \dots, I', \quad (5)$$

$$\sum_{j=1}^J \sum_{v=1}^n x_{ij}^v + \sum_{j'=1}^{J'} \sum_{i'=1}^{I'} \sum_{v=n+1}^V x_{j'i'}^v = K, \quad i = 1. \quad (6)$$

Equation (3) assigns a unique route for each vehicle from the cargo distribution center to the departure metro station. Equation (4) imposes the restriction that each vehicle can have one unique route from one arrival metro station to one terminal cargo station in the third stage. Equation (5) constrains the capacity on the route. The total number of

vehicles in the complete distribution process should be restrained, as shown in Equation (6).

**3.3.4. Metro Line Capacity Constraints.** The goods in the metro network by train should meet the train capacity constraint and the number of transfer constraints.

$$Q_{i'} \leq E \times \text{cap}_M \times \sum_{m=1}^M \sum_{j=1}^J \sum_{j'=1}^{J'} y_{jj'}^{i'm}, \quad i' = 1, \dots, I', \quad (7)$$

$$\sum_{j=1}^J O_{jj'} \leq 2, \quad j' = 1, \dots, J'. \quad (8)$$

Equation (7) expresses the capacity limit of the metro. Equation (8) stipulates the number of transfers in the metro network.

**3.3.5. Delivery Time Constraint.** The mixed transportation is based on the off-peak hours of urban rail transit, and the departure time of mixed transportation trains shall not be earlier than the start time of off-peak hours.

$$\sum_{s=1}^{j-1} t_s + s_j^m \leq t_j, \quad j = 1, \dots, J, m = 1, \dots, M, \quad (9)$$

$$t_j - t_{ij} - (1 - x_{ij}^v)Z \leq \text{SET}_{i'}, \quad i = 1, j = 1, \dots, J, v = 1, \dots, n, i' = 1, \dots, I', \quad (10)$$

$$ET_{i'} \leq SET_{i'} \leq LT_{i'}, \quad i' = 1, \dots, I'. \quad (11)$$

Equation (9) determines the earliest time when the freight to cargo station is loaded into the train at a station. In this equation,  $t_s$  represents the running time between  $S$  and  $S-1$  when the train is at station  $S$ , and when  $s=1$ ,  $t_s=0$ . Equation (10) ensures the time to start delivery for the terminal cargo station. Equation (11) is the time window constraint of the terminal cargo station.

The delivery time of the train in the whole mixed transportation process meets the sum of the delivery time of the ‘‘first mile and last-mile’’ and the metro delivery time.

$$\begin{aligned} SLT_{i'} &= SET_{i'} + t_{ij} + (t_{jj'} + r \times t_{\text{interval}}) y_{jj'}^{i'm} + O_{jj'} t_O \\ &\quad + t_{j'i'}, \quad j = 1, \dots, J, \\ j' &= 1, \dots, J', i' = 1, \dots, I', m = 1, \dots, M. \end{aligned} \quad (12)$$

Equation (12) addresses the relationship between the start time and end time of delivery from the cargo distribution center to the terminal cargo station.

The delay cost coefficient is affected by the delivery time window of the goods. Failure to complete the delivery within the time window needs to calculate the delay cost based on the delay cost coefficient.

$$\lambda_{i'} = \begin{cases} 0, & SLT_{i'} \leq LT_{i'}, \\ \alpha, & SLT_{i'} \geq LT_{i'}, \end{cases} \quad i' = 1, \dots, I'. \quad (13)$$

Equation (13) addresses the delay cost due to the failure to complete the delivery within the time window; the delay cost is related to the time of completion of the delivery.

**3.3.6. Decision Variable Constraints.** The relevant decision variables are constrained as follows. Equation (14) expresses the constraint on the initial number of vehicles.

$$K \geq 2, \quad (14)$$

$$SET_{i'}, SLT_{i'} \geq 0, \quad i' = 1, \dots, I', \quad (15)$$

$$x_{ij}^v \in \{0, 1\}, \quad i = 1, \dots, I, j = 1, \dots, J, v = 1, \dots, n, \quad (16)$$

$$\begin{aligned} x_{j'i'}^v \in \{0, 1\}, \quad j' = 1, \dots, J', i' = 1, \dots, J', \\ v = n+1, \dots, V, \end{aligned} \quad (17)$$

$$\begin{aligned} y_{jj'}^{i'm} \in \{0, 1\}, \quad j = 1, \dots, J, j' = 1, \dots, J', \\ i' = 1, \dots, I', m = 1, \dots, M. \end{aligned} \quad (18)$$

**3.4. Composition of the Objective Function.** The objective function of MTS-OPH is composed of vehicle transportation cost, transfer cost, and delay cost. Each cost parameter is described in the following.

**3.4.1. Vehicle Transportation Cost.** The transportation cost of vehicles is mainly composed of the transportation

distance, number of vehicles, number of freight parcels, and fixed operating cost of vehicles. Therefore, the transportation cost  $f_{vij}$  in route  $(i, j)$  is as shown in

$$f_{vij} = Q_{i'} y_{jj'}^{i'm} x_{ij}^v C_{ij}. \quad (19)$$

To express  $f_{vij}$  clearly, Equation (19) is simplified as

$$Q_{ij} = Q_{i'} y_{jj'}^{i'm} x_{ij}^v, \quad (20)$$

$$f_{vij} = C_{ij} Q_{ij}. \quad (21)$$

Therefore, the vehicle transportation cost  $f_{vj'i'}$  in the route  $(j', i')$  can be obtained similarly.

$$f_{vj'i'} = C_{j'i'} Q_{j'i'}. \quad (22)$$

In summary, Equation (23) represents the vehicle transportation cost.

$$f_v = \sum_{i=1}^J \sum_{j=1}^n \sum_{v=1}^V C_{ij} Q_{ij} x_{ij}^v + \sum_{j=1}^J \sum_{i'=1}^{I'} \sum_{v=n+1}^V C_{j'i'} Q_{j'i'} x_{j'i'}^v + KC_v. \quad (23)$$

**3.4.2. Transfer Cost.** The number of freight parcels and frequency of transfer constitute the transit cost. The number of transfers is mainly determined by the number of times the cargo is loaded and unloaded; the completion of one loading and unloading of cargo is regarded as one transfer. Equation (24) shows the calculation method for the node transfer cost  $f_n$ .

$$f_n = 2C_O \left( \sum_{i'=1}^{I'} Q_{i'} + \sum_{j=1}^J \sum_{j'=1}^{J'} \sum_{i'=1}^{I'} \sum_{m=1}^M O_{jj'} y_{jj'}^{i'm} Q_{i'} \right). \quad (24)$$

**3.4.3. Delay Cost.** The delay cost is caused by the freight arriving at the terminal cargo station in an unexpected time window. The delivery time window of MTS-OPH is based on the off-peak start time, so the delay cost will only be calculated if the delivery time window is exceeded. This is expressed with  $f_d$ , as in

$$f_d = \sum_{i'=1}^{I'} \lambda_{i'} Q_{i'}. \quad (25)$$

Because only part of the metro carriages is used for freight, the weight of the cargo is much smaller than that of the metro. Therefore, the delivery cost of MTS-OPH is not affected by metro fixed operating cost and metro transportation distance.

In summary, the delivery cost  $f_C$  is the sum of the vehicle transportation cost  $f_v$ , node transit cost  $f_n$ , and delay cost  $f_d$ , i.e.,  $f_C = f_v + f_n + f_d$ . Hence, the mathematical formulation of the MTS-OPH model is built as follows:

$$\min Z = f_C. \quad (26)$$

Equation (26) denotes the smallest delivery cost, and the calculation process is, respectively, performed using Equations (19)–(25).

In the MTS-OPH model, the pickup and delivery constraints of the time window and transshipment value are considered [8, 35, 36] and the mode selection constraints are added according to the two loading modes of the proposed mixed transport strategy. This model is developed based on the generalized assignment problem, which belongs to a NP-hard problem [37–39] and is usually solved by heuristic algorithms.

## 4. Solution Approaches

The heuristic algorithm for solving the MTS-OPH is based on the VNS [40, 41]. VNS provides a flexible framework for constructing heuristics for approximately solving combinatorial optimization problems and nonlinear optimization problems. The main idea is to dynamically change the neighborhood structure set during the search process to expand the search range and obtain local optimal solutions. Using such a variable neighborhood strategy, it is possible to move away from the optimum and finally reach convergence after multiple iterations. In the VNS algorithm used in this study, the objective function (indicated by  $Z_c$ ) in Equation (8) is used as an evaluation index for evaluating the quality of the generated solution, as shown in the following:

$$f(c) = Z_c. \quad (27)$$

In this study, the VNS algorithm includes the following three parts: initial solution, shaking process, and variable neighborhood descent (VND) process. We use  $c$ ,  $c'$ , and  $c''$  to denote the solutions generated in the algorithm.  $G$  represents the neighborhood structure set included in the shaking process, where  $G = \{1, 2, 3, \dots, p, \dots, |G|\}$ , and  $H$  represents the neighborhood structure set included in the VND process, where  $H = \{1, 2, 3, \dots, p, \dots, |H|\}$ . The detailed structure of the improved VNS algorithm is shown in Algorithm 1.

The shaking process is a perturbation operator in the VNS. The process is used to generate different neighborhood solutions. The remaining initial solution and VND process are described in detail in the next section.

**4.1. Initial Solution.** The initial delivery route  $R$  of the MTS-OPH is formed by constructing a line of length  $2I'$  according to the number  $i'$  of a terminal cargo station. The initial route  $R$  is mainly composed of  $i'$  departure metro stations and  $i'$  arrival metro stations shown in Figure 4. Herein, each  $j_{i'}$  in  $[j_1, j_2, \dots, j_{i'-1}, j_{i'}]$  corresponds to each  $j'_{i'}$  in  $[j'_1, j'_2, \dots, j'_{i'-1}, j'_{i'}]$  individually, and a group  $[j_{i'}, j'_{i'}]$  constitutes a metro distribution route. The following conditions should be met:  $j \in J$ ,  $j' \in J'$ , and  $J = J'$ .

**4.2. Neighborhood Structure.** Two types of neighborhood structures are applied. The first consists of neighbors which exchange strategies on existing delivery routes. The second consists of neighbors obtained by updating the distribution strategy on the existing route. The methods for generating neighbors for the first type of neighborhood structure are

Swap-2 and Inserting-t [42]. For the second type of neighborhood structure, Alter-t method of producing neighbors is designed in our study.

Swap-2 refers to the random exchange of two adjacent or nonadjacent rows in the initial solution, as shown in Figure 5(a). Insertion-t is formed by repeating  $t$  times on the basis of Insertion-1. As shown in Figure 5(b), Insertion-1 randomly deletes a row from the initial solution and randomly inserts it into other positions. In Figure 5(c), Alter-1 randomly selects a position  $j_{i'}$  in the initial solution and selects a new number from the set  $J$  to replace  $j_{i'}$ . Alter-t is to repeat the Alter-1 operation  $t$  times. In addition, to prevent the value of  $t$  from being too large and destroying the stability of the obtained solution structure, the value of  $t$  is controlled to be in the range of  $[0, 5]$  in the insertion operation and change operation of this study. The iterations of repeated deletions, changes, and insertions let the algorithm search in a larger solution space, thereby enhancing the ability of the neighborhood search algorithm to move away from the local optimal region.

**4.3. Shaking Procedure.** We use  $G = \{\text{Alter-3}, \text{Alter-4}\}$  as the set of neighborhood structures in the shaking procedure. For each structure  $G_v \in G$ , it maps a given solution  $r$  to a series of neighborhoods  $G_v(c)$ . When the shaking procedure is applied, a solution will be randomly chosen from the neighborhoods. Accordingly, the detailed procedure is given in Algorithm 2.

**4.4. Variable Neighborhood Descent.** During a local search in VND, when a better solution than the current solution cannot be found in this neighborhood, the search is continued by moving to the next neighborhood solution. Contrarily, if a better solution than the current solution is found in this neighborhood, the first neighborhood solution will be returned to restart the search. For a better solution, the first neighborhood solution should be returned and the search should be started again. The local optimal solution obtained through such a search process is likely to be the global optimal solution. A detailed operation of the VND process is provided in Algorithm 3.

## 5. Numerical Experiments

Case studies of the Ningbo metro network and Beijing metro network were conducted to evaluate the accuracy and efficiency of the proposed model and method. Examples of the application in different delivery distances, different passenger flows, and different types of metro networks were illustrated. The proposed algorithm framework was coded in MATLAB 10.0 on a Window 10 personal computer with 4.0 GB processor. The MTS-OPH problem is solved by IBM CPLEX 12.5 Academic Version on the same platform.

**5.1. Small-Scale Case Study.** In this section, based on the logistics information of a certain express company in Ningbo, we considered a distribution situation between the

**Step 1:** a solution  $c$  is randomly generated in a given range, and the initial solution is brought into the objective function calculation program to obtain the initial target value  $f(c)$ ; go to Step 2.

**Step 2:** let  $p = 1$  until  $p = |G|$ ; go to Step 3.

**Step 3:** substitute the initial solution  $c$  into Shaking, and perform the  $k$ -th neighborhood operation of Shaking to generate a new solution  $c'$ ; go to Step 4.

**Step 4:** substitute  $c'$  into the VND, generate multiple neighborhood solutions related to  $c'$ , and perform a local search among the generated multiple neighborhood solutions to obtain the local search optimal solution  $c''$ ; go to Step 5.

**Step 5:** if  $f(c'') < f(c)$ , it means that  $c''$  is better than the current optimal solution  $c$ ; then, let  $c = c''$  and continue to search within the current neighborhood structure ( $p = 1$ ); otherwise, let  $p = p + 1$ . Meanwhile, if  $p = |G|$ , go to Step 6. Otherwise, go to Step 3.

**Step 6:** until the termination criterion is met, the optimal solution  $c$  is returned.

ALGORITHM 1: Procedure of VNS algorithm.

FIGURE 4: Initial path diagram.

express delivery distribution center and six terminal express delivery stations. For convenience, the cargo distribution center is represented by  $I$  and the six cargo stations are named A, B, C, D, E, and F, respectively, i.e.,  $i' = \{1, 2, 3, 4, 5, 6\}$ ,  $i' \in I'$ . The geographical location of freight stations is evenly distributed, and the receipt volume of each cargo station obeys the uniform distribution of [40, 60]. The metro network of the Ningbo Urban Rapid Rail Transit Construction Plan (2013–2020) [43] was considered as an example, as shown in Figure 6.

The airport logistics park near the metro line was selected as the express delivery distribution center, which is represented by a red star in Figure 6. L1–L5 indicate each metro line. Considering the actual situation and model solution, each metro line station was uniformly numbered according to positive integers from left to right, with the letter “I” representing the departure metro station and “O” representing the arrival metro station.

The average speed of freight vehicles was 20 km/h [30], and the delivery cost of unit express delivery per unit distance of freight vehicles was assumed to be 2 yuan [44]. The values of the other parameters are listed in Table 2. In the experiment, the distribution data and time window are shown in Table 3.

In the algorithm parameter setting process, this study sets the number of neighborhood solutions in one iteration to 100 and the total number of iterations to 50 [27]. The neighborhood structures of VND and shaking are as follows: VND, {Alter\_3, Alter\_5, Insertion\_2, Insertion\_1, Opt\_2}; Shaking, {Alter\_3, Alter\_5}.

For related problems in route planning and distribution, the genetic algorithm (GA) is widely used [45–47]. Therefore, the GA and the improved VNS algorithm are used to solve the problem. The population size of the GA is 100, the number of iterations is 50, the crossover probability is 0.6, and the mutation probability is 0.1 [48]. The optimization results of the two algorithms were obtained by running 20 times, as shown in Table 4. Although GA has a shorter calculating time, VNS can obtain the best delivery cost of higher quality, and

after many repeated trials, the results show that the stability of the optimal solution obtained by VNS is better than that of GA, which verifies the effectiveness of the algorithm.

In order to further prove the effectiveness of the improved VNS algorithm, we first give the actual maximum cross-section passenger flow to Equation (12), making MTS-OPH an integer linear programming model. Secondly, the ILOG CPLEX solver is used to solve it. After implementations, we finally obtained the returned solution with a calculation time of 328 s, where the relative gap turns out to be 5.00%. The approximate optimal objective value is 5861.0 yuan, which is consistent with the solution result of the improved VNS algorithm. Therefore, the proposed algorithm is effective.

Finally, the optimal solution for the delivery of vehicles is calculated. Meanwhile, the optimal transportation strategy during off-peak hours for the individual distribution of freight vehicles is calculated; this transportation strategy is called VTS-OPH. Table 5 shows the comparison between the MTS-OPH and VTS-OPH. The delivery time of VTS is mainly composed of two parts: loading and unloading time and transportation time. Among them, the loading and unloading time is determined according to the quantity of goods and the transportation time is determined by the transportation distance and the transportation speed. If the delivery time is less than 1 min, it is approximated to 1 min.

As evident from Table 5, the MTS-OPH and VTS-OPH complete deliveries within the time window. The average time to complete a delivery in the VTS-OPH is 69 min, and in the MTS-OPH, the average time is 73 min. However, the MTS-OPH spends approximately one-third of the delivery cost of the VTS-OPH to complete a delivery. According to this small-scale case analysis results, the MTS-OPH has certain advantages when compared with the VTS-OPH.

The delivery route is shown in Table 6, and the result shows that for the express station “F” delivery, the MTS-OPH requires less time than the VTS-OPH, and for the delivery of the other express stations, the VTS-OPH requires less time than the MTS-OPH. Therefore, further investigation is required regarding the applicability of the MTS-OPH for different distances.

*5.2. Applicability of MTS-OPH considering Different Delivery Distances.* To study the applicability of the MTS-OPH for different delivery distances, we divide the actual express

FIGURE 5: Three methods of producing neighbors. (a) Swap-2. (b) Insertion-1. (c) Alter-1.

**Step 1:** enter the initial solution  $c$  and the index of neighborhood structure  $G$ ; go to Step 2.  
**Step 2:** select a solution from  $G_v(c)$  at random, and then go to Step 3.  
**Step 3:** a random chosen solution  $c'$  is returned.

ALGORITHM 2: Shaking procedure.

**Step 1:** enter the initial solution  $c'$  and neighborhood structure set  $H$  of the VND; go to Step 2.  
**Step 2:** let  $p = 1$  until  $p = |H|$ , and then go to Step 3.  
**Step 3:** use the neighborhood structure  $H$  to perform a local search to generate a new solution  $c''$ , and then go to Step 4.  
**Step 4:** if  $f(c'') < f(c')$ , it means that  $c''$  is better than the current optimal solution  $c'$ ; then, let  $c' = c''$  and continue to search within the current neighborhood structure ( $p = 1$ ); otherwise, let  $p = p + 1$ . Meanwhile, if  $p = |H|$ , go to Step 5; otherwise, go to Step 3.  
**Step 5:** until the termination criterion is met, the optimal solution  $c'$  is returned.

delivery information provided by the airport logistics park into three different distribution range data tables. The metro network of Ningbo is shown in Figure 7.

According to the metro network and express delivery information data, Ningbo is divided into three areas with different distribution scopes as S1, S2, and S3. Twenty delivery destinations (terminal express delivery stations) are selected with uniform locations in each area, as shown in Figure 8. Each delivery area is separated by a blue dotted line, where S1 is a short-distance delivery area, S2 is a medium-distance delivery area, and S3 is a long-distance delivery area. According to different distribution ranges, different time window requirements are allotted [44], as shown in Table 7.

In the experiment, the time horizon is considered to be 9:00–12:00, which is the off-peak period of metro operation. In addition, the metro model in Ningbo is type B composed of six carriages with a total capacity of 1,460 people. According to statistics from the Ningbo Rail Transit Group, the maximum load rate during off-peak hours in the Ningbo metro network is 90%. Hence, at least five metro carriages are required for passenger transportation during off-peak hours, and the remaining one carriage is used for goods transportation. The remaining parameter values and algorithm parameter settings are consistent with the small-scale case study presented in Section 5.1.

**5.2.1. Analysis of the Short-Distance Delivery Area.** The demand and time window of the terminal express station in S1 are listed in Table 8.

The data in Table 8 are used in the VNS algorithm for 20 calculations to obtain the optimal solution for the MTS-OPH and VTS-OPH, as shown in Table 9, and the optimal delivery routes of the two strategies are given in Table 10.

In Table 9, the delivery cost of the MTS-OPH is approximately 66.4% higher than that of the VTS-OPH. In addition, 12 of the 20 terminal express delivery stations in the MTS-OPH failed to deliver on time, while the VTS-OPH completed all deliveries with the set time window. In the short-distance distribution area, the success rate of the MTS-OPH to complete the delivery within the time window was 40%. However, the MTS-OPH reduces the vehicle delivery distance by 56.7% when compared with that of the VTS-OPH. Although the vehicle transportation distance is reduced, the delivery time is increased, as shown in Table 10. According to the above analysis, in the short-distance delivery area, the MTS-OPH is not suitable for multitarget delivery and the overall operation of express delivery companies, but the single-target delivery remains to be studied. This corresponds well with the study of high-speed railway freight distribution by Pazour et al. [49].

**5.2.2. Analysis of the Medium-Distance Delivery Area.** The demand and time window of the terminal express station in S2 are listed in Table 11.

Similarly, the data in Table 11 are used in the VNS algorithm for 20 calculations, and the optimal solution is listed in Table 12.

As shown in Table 12, the delivery cost of the VTS-OPH is 8.0% higher than that of the MTS-OPH, but the average delivery time of the VTS-OPH is 33.7% less than that of the

Transportation strategy	Delivery cost /(yuan)	Delivery distance by vehicles (km)	Average delivery time (min)	Number of express delivery stations that did not deliver on time
MTS-OPH (Method 1)	35582.5	94.1	86	2
VTS-OPH	38661.6	378.4	57	0

MTS-OPH. In addition, the specific delivery time, delivery route, transfer times, and train number of each express station under the two modes are shown in Table 13. Concurrently, VTS-OPH completed all deliveries within the time window. There were two express delivery stations in the MTS-OPH that failed to deliver on time. The vehicle delivery distance in MTS-OPH is 24.7% of that in VTS-OPH.

Combining the results listed in Tables 9 and 12, the number of express stations that did not deliver on time significantly improved when the MTS-OPH was selected in the medium-distance delivery area, when compared with the MTS-OPH in the short-distance delivery area. From the original 12 express stations that failed to deliver on time, two express delivery stations failed to deliver on time. Therefore, although the VTS-OPH requires less time to complete 100% on-time distribution, the MTS-OPH delivery cost is slightly lower and the MTS-OPH significantly reduces the vehicle transportation distance. This means that when choosing the MTS-OPH for delivery, the transportation distance of vehicles can be reduced and pressure on urban roads can be reduced. According to the above analysis, the MTS-OPH is more suitable for the medium-distance distribution area than for the short-distance distribution area. The MTS-OPH and VTS-OPH exhibit varied advantages in medium-distance delivery areas; however, considering the urban system, the MTS-OPH is better than the VTS-OPH.

*5.2.3. Analysis of the Long-Distance Delivery Area.* The demand and time window of the terminal express station in S3 are shown in Table 14.

According to the above experimental data, the VNS algorithm is used to solve the two transportation strategies of MTS-OPH and VTS-OPH 20 times and the optimal solution obtained is shown in Table 15. The delivery route information is shown in Table 16.

As shown in Tables 15 and 16, we obtained a different delivery result when compared with results of previous analyses. In the long-distance delivery area, all indicators of the MTS-OPH are better than those of the VTS-OPH, except for the average delivery time. The delivery cost of MTS-OPH is 52.2% of VTS-OPH, the vehicle delivery distance is 17.6% of VTS-OPH, and the average delivery time is slightly worse than that of VTS-OPH. A significant change is observed in the number of express delivery stations that failed to deliver on time. In the MTS-OPH, all express delivery stations completed the delivery within the time window, while in the VED mode, there were four express stations that failed to complete the delivery within the time window. Thus, the MTS-OPH is suitable for long-distance distribution areas. A similar result was reported in a high-speed rail express delivery study conducted in [50].

Concurrently, by comparing the calculation results in Tables 9, 12, and 15, it is further verified that the MTS-OPH is suitable for long-distance delivery. On the one hand, as the distribution distance increased, the distribution cost of the MTS-OPH changed slightly and the vehicle delivery distance increased at an average growth rate of 18%, which was much smaller than that of the VTS-OPH and increased with an

average growth rate of 86%. The above analysis proves the feasibility and stability of the MTS-OPH. On the other hand, from short-distance delivery to medium-distance delivery to long-distance delivery, the number of express stations that failed to complete the delivery within the time window under the MTS-OPH changed from twelve to zero and that of the VTS-OPH changed from zero to four.

*5.2.4. Relationship between MTS-OPH and VTS-OPH under Different Delivery Distances.* To further explore the relationship between the MTS-OPH and VTS-OPH under different delivery distances, we assumed that there was one terminal express station, did not consider the time window constraints, and quantitatively analyzed the delivery costs of the two transportation strategies.

$$f_c^m = Q * (2 * (L_{ij} + L_{j'i'}) + C_o * (O_{jj'} + 2)) + 2 * \frac{Q}{cap_v} * C_v, \quad (28)$$

$$f_c^v = 2Q * L_{ii'} + \frac{Q}{cap_v} * C_v, \quad (29)$$

where  $f_c^m$  represents the delivery cost of MTS-OPH,  $f_c^v$  represents the delivery cost of VTS-OPH,  $Q$  is the number of express parcels,  $C_v$  is the fixed operating cost of the vehicle,  $cap_v$  is the capacity of freight vehicles,  $L$  is the vehicle transportation distance between two points,  $C_o$  is per unit cargo transfer cost after one transfer, and  $O$  is the number of transfers between two stations.

The delivery costs of the two transportation strategies are shown in Equations (28) and (29). Assuming that the number of express deliveries for delivery is 60 parcels that reach the upper limit of vehicle loading and the number of transfers is 2, the relationship between the two transportation strategies is

$$L_{ii'} > 1.45 + (L_{ij} + L_{j'i'}). \quad (30)$$

Equation (30) shows that when the vehicle delivery distance of VTS-OPH is greater than the sum of 1.45 and the vehicle delivery distance of MTS-OPH, the MTS-OPH should be adopted; otherwise, the VTS-OPH should be selected. The above conclusions further prove that the MTS-OPH is more suitable for long-distance delivery.

*5.3. Impact on MTS-OPH under Different Load Rates of Passenger Flow during Off-Peak Hours.* In this section, we analyze the impact of different load rates of passenger flow on MTS-OPH. We selected case data in S3 for analysis, the total number of express deliveries is 975 packages, and three train carriages are required as freight carriages. This determines the 50% full-load rate during off-peak hours as the boundary. Concurrently, following the principle of passenger and cargo diversion, according to the statistics of Ningbo Rail Transit Group, the maximum passenger flow load rate of the Ningbo metro network during off-peak hours is 90% and 5 train carriages are required as passenger

FIGURE 9: Transportation methods under different load rates of passenger flow.

less than the capacity of the metro train, the flexibility loading mode should be selected, the full-load rate of passenger flow should be (50%, 90%], the total number of goods and passengers is greater than the capacity of the metro train, and the fixed loading mode should be selected. When the full-load rate of passenger flow is greater than 90%, the metro is used for transporting passengers.

To further compare the two transportation methods in the MTS-OPH, with the load rates of passenger flow of 50% and 90% as the boundary, the VNS algorithm was run 20 times to obtain the optimal results, as shown in Table 17.

In Table 17, the delivery cost and the vehicle delivery distance are equal in Methods 1 and 2, but considering the average delivery time, Method 2 is shorter than Method 1. When the load rate of passenger flow satisfies the boundary conditions, the delivery efficiency of Method 2 is better than that of Method 1 for the same delivery time. Considering long-term transportation, MTS-OPH has the potential and has huge positive effects; for example, it can alleviate traffic congestion, has huge economies of scale [51, 52], and has much lower fuel consumption than the VTS-OPH. The MTS-OPH is adopted during off-peak hours, which can

TABLE 17: Optimal solution for the two transportation methods of MTS-OPH.

FIGURE 10: Metro network of Beijing.

fulfill the use of the idle resources of the metro and does not require excessive initial investment.

**5.4. Applicability of MTS-OPH considering Different Metro Networks.** In order to further prove the applicability and feasibility of the model, we selected the Beijing metro network for numerical experiments. The Beijing metro network is one of the most complex metro networks in China, with 24 metro lines totaling 331 stations, including 62 transfer stations, as shown in Figure 10. In Figure 10, the green dots indicate the terminal express delivery stations, totaling 20. The red five-pointed star indicates the express delivery distribution center, which is the airport logistics park near

the capital airport. Different from Ningbo’s radial metro network, Beijing’s metro network is a ring-shaped radial network with more diversified route selections between lines. Therefore, we increased the maximum number of transfers in the model to 4 times.

In the experiment, the considered time horizon is set as 9:00–12:00, which is the off-peak period of metro operation. According to the data of Beijing Subway Operation Company, the maximum passenger load rates of passenger flow in the Beijing metro network during off-peak hours is 94.3%. The metro train is composed of 6 carriages, and it needs to occupy 5 carriages for passenger transportation. Thus, the loading mode of Method 1 for mixed transportation is selected. Some parameters in the experiments

20	I → L15I3 → L1O2 → 20 (2)	110/2	I → 20 (0)	102

are set as follows. That is, the delivery time window is set to 2 hours or 3 hours, and the demand and time windows of each terminal express station are shown in Table 18. The

remaining parameter values and algorithm parameter settings are consistent with the small-scale case study presented in Section 5.1.

The experimental data in Table 18 are used in the VNS algorithm for 20 calculations. The optimal solution and delivery route information are listed in Tables 19 and 20, respectively.

In Table 19, the delivery cost of MTS-OPH is 59.5% of VTS-OPH and the vehicle transportation distance is 34.1% of VTS-OPH. The average delivery time of MTS-OPH is slightly better than that of VTS-OPH, and the delivery tasks are all completed within the time window. However, under the VTS-OPH mode, there are 3 terminal express stations that failed to complete the delivery within the time window. In Table 20, terminal express stations closer to the express distribution center use VTS-OPH for shorter delivery time, while terminal express stations farther away from the express distribution center use MTS-OPH for shorter delivery time. In general, the MTS-OPH mode can complete the delivery within the time window, and the average delivery time is shorter, which is better than the VTS-OPH mode.

According to the case analysis results in Tables 19 and 20, MTS-OPH is more suitable for long-distance multitarget delivery. Compared with VTS-OPH, MTS-OPH has lower total delivery cost, shorter vehicle transportation distance, and higher service level. The above analysis results are consistent with the Ningbo metro case analysis results, which prove that our proposed model can be applied to different types of metro networks with different levels of complexity.

## 6. Conclusion

This paper proposes a new mixed transport strategy based on the metro network during off-peak hours to determine the freight mode and its distribution cost under off-peak metro passenger flow. The mixed transportation standard of passenger flow priority and separate transportation of passenger and cargo flows of the same train are proposed. According to the aforementioned criteria, a nonlinear programming model of the mixed transport strategy is constructed. In addition, an improved VNS algorithm is designed to solve the model. Finally, considering the Ningbo and Beijing metro network as an example, it is verified that the proposed model and mixed transport strategy can provide decision support for logistics companies. The main contributions of the study are as follows.

A theoretical framework of the mixed transport strategy for different metro passenger flows during off-peak hours was developed via comparisons with related studies [9, 20, 29]. Thus, a mixed transportation standard with passenger flow priority and separate transportation of the same train passenger and cargo flows was established, which expanded the integrated transportation of urban freight and metro passenger transportation.

In practice, the model of the mixed transportation strategy proposed in this study can provide decision support for logistics companies based on different delivery distances, different off-peak passenger flows, and different types of metro networks. First, when the vehicle transportation distance under separate VTS-OPH is greater than the sum of 1.45 and the vehicle transportation distance of MTS-OPH,

the MTS-OPH should be adopted; otherwise, the VTS-OPH should be selected. Second, when the number of passengers and freight transportation demand are greater than the metro capacity, the fixed loading mode of the MTS-OPH should be selected for transportation; otherwise, the flexibility loading mode of the MTS-OPH should be selected for transportation. Finally, the proposed model framework can be applied to different types of metro networks with different levels of complexity.

This study has some limitations to be further solved, such as freight vehicle scheduling and route planning and metro station and line performance evaluation [53, 54]. The study should mainly focus on the following aspects: (1) Freight vehicle routes should be planned to improve vehicle utilization, and train schedule issues should be analyzed from a data-driven perspective [55]. (2) Owing to the uneven distribution of passenger flow in the urban metro system during off-peak hours, the remaining loading capacity of other carriages can be considered in future studies. (3) To ensure the mixed strategy realizable, the metro turnover and rolling stock circulation and selecting the unloading stations should be considered.

## Data Availability

In order to explore the impact of different decision-making methods on the profits of various entities in the supply chain of the community e-commerce platform, this paper adopts the method of the Stackelberg game. For the community e-commerce platform supply chain composed of suppliers, community e-commerce platforms, and grid station service providers, considering the degree of supplier value cocreation efforts, this paper studies the optimal decisions under centralized decision-making, supplier-led decentralized decision-making, and community e-commerce platform-led decentralized decision-making, respectively. The results show that the supply chain obtains the highest profit in centralized decision-making; under decentralized decision-making, the dominant party will get higher profits; and the supplier value cocreation sensitivity coefficient is positively correlated with sales price, value cocreation effort level, and total supply chain value. The results are helpful to improve the competitiveness of the community e-commerce platform supply chain in the market and are of great significance to the long-term development of the community e-commerce industry.

## 1. Introduction

The community e-commerce platform is a shopping platform that has emerged in recent years, such as Jingxi Pinpin, Meituan Preferred, and Duoduomai, gradually participating in people's lives. Buying goods online and picking up offline, this combination of online and offline shopping provides consumers with many conveniences. Consumers can purchase products using mobile apps, reducing the inconvenience of traditional offline shopping, and meet the fast pace of modern life, which is widely accepted by people. At the same time, there are more and more community e-commerce platforms, and the competition between platforms has become increasingly fierce. Therefore, while providing convenience to consumers, community e-commerce platforms should also pay attention to their own profits. The competition between community e-commerce platforms has gradually escalated to between supply chains, considering value cocreation is an effective way for the supply chain to

gain a competitive advantage. By integrating resources between enterprises and the interaction between enterprises and consumers, corporate profits and supply chain profits can be improved. With the deepening of consumer theory, the value cocreation centered on consumers has become the source of obtaining new competitive advantages [1]. Through consumers' value cocreation, enterprises can obtain information about consumers' needs, increase customer loyalty and supply chain value by providing products or services that satisfy consumers. At the same time, the dominant position in the supply chain is very important, which directly affects its optimal decision and maximum profit.

## 2. Literature Review

Research on supply chain value cocreation is mostly based on case studies to analyze the specific content and impact of value cocreation in a certain field. Wan et al. connected the

open innovation subject with the value creation model of supply chain and conducted numerical analysis on supply chain value and consumer value [2]. Shen et al. found that a large part of the value creation of brand community e-commerce companies is through the positive contributions of consumers [3]. Hein et al. constructed a platform enterprise ecosystem model based on value creation, analyzed its value creation system, and studied the cooperative relationship between all parties, expounding the value relationship between all stakeholders [4].

Previous studies on supply chain decision focused on the impact of different power structures on decision-making. Luo et al. established a multistage game model to study the impact of different power structures on pricing decisions, retailer, and manufacturer profits [5]. Ma et al. believed that only the dominant manufacturer can benefit from the wholesale price strategy, while both manufacturers and retailers can benefit from the channel strategy [6]. Zhao and Li established a Nash game model and a Stackelberg game model for a low-carbon supply chain consisting of manufacturers and retailers [7]. Gao et al. considered sales effort and explored the impact of different rights structures on the optimal decision-making and performance of a closed-loop supply chain [8, 9].

At present, there are few studies on the community e-commerce platform, mainly focusing on its development and model. Liu analyzed the development status and mode of fresh community e-commerce and believed its market demand and potential are huge [10]. Some scholars have also studied consumers' purchasing intention. Li explored the differences in purchasing intention and influencing factors of different consumers in community e-commerce [11]. Jian and Yang constructed a consumer purchase decision model of community e-commerce and explored the mechanism of community e-commerce characteristics and trust on consumers' purchasing intention [12].

The current research on supply chain value cocreation is still in the aspect of the case and empirical research, and there is very little research on model analysis. Therefore, this paper takes the community e-commerce platform supply chain as the research object, and supplier value cocreation effort level is considered. It explores the impact of different power structures on sales prices, sales volume, and profit creation.

### 3. Research Method

**3.1. Stackelberg Game Method.** The Stackelberg game method is the main research method used in this article. It is a game model proposed by economist Stackelberg in the 1930s to reflect asymmetric competition between enterprises. Assuming that there are two participants in the game, enterprise 1 first decides its output, and enterprise 2 makes output decisions based on enterprise 1's decision. Therefore, enterprise 1 must consider how enterprise 2 will respond when making decisions.

Since the decision-making sequence is involved in the game, the position of each player should be judged first. The dominant position is the leader of the game, and the other is

the follower. The follower's reaction to the market is easily predicted by the leader, and the leader makes decisions that are beneficial to him based on the response of the followers. Most of the current research on supply chain decision-making regards the supplier as the leader of the supply chain. According to the retailer's sales forecast and market demand function, the supplier makes the optimal decision combining with the cost and other factors to determine the wholesale price. Then, retailers determine retail prices based on wholesale prices.

Nevertheless, in real life, with the development of online sales channels such as e-commerce and community e-commerce platforms, the position of each participant in the supply chain is changing gradually. Taking the community e-commerce platform supply chain as an example, some community e-commerce platforms may play a leading role in the supply chain. Therefore, the impact of the decision-making approach on the profitability of the supply chain and each participant has to be fully considered. Because community e-commerce platforms and suppliers occupy an important position in the supply chain, grid station service providers are in a noncore position, only responsible for the selection and distribution of goods, and do not involve operation decisions within the supply chain such as product pricing and order quantities. Therefore, the grid station service provider is no longer added to the decision-making of the supply chain. Based on this, there are three decision-making methods: centralized decision-making in the community e-commerce platform supply chain, decentralized decision-making led by the supplier, and decentralized decision-making led by the community e-commerce platform.

### 3.2. Related Theories

**3.2.1. Supply Chain Decision Theory.** According to the decision-making mode, it can be divided into centralized decision-making and decentralized decision-making.

Centralized decision-making refers to the collective decision-making of the main participants in the supply chain and takes the maximization of the overall benefit of the supply chain as the decision-making goal [13]. However, in fact, centralized decision-making is an ideal state, participants often pursue the maximization of their own profits, and it is difficult to achieve the maximization of overall profit.

Decentralized decision-making means that each participant in the supply chain makes decisions independently and pursues their own best profits rather than the maximization of overall profit.

Section 5 discusses the situation of the community e-commerce platform supply chain under centralized and decentralized decision-making. Among them, decentralized decision-making is divided into two situations. One is a supplier-led supply chain, where the community e-commerce platform acts as a follower and makes relevant decisions based on the supplier's strategy. The other is dominated by community e-commerce platforms, where suppliers act as platform followers and make strategies based on platform decisions.

**3.2.2. Market Demand Theory.** Market demand is the total amount of goods that a particular group of consumers may purchase in a given region, time, and circumstances [14]. Moreover, it is affected by total demand and price. Higher prices decrease the quantity demanded, and lower prices increase the quantity demanded, expressed by formula  $Q = a - bP$ , where  $a$  is the total market demand,  $b$  is the sensitivity coefficient of demand to price, and the main factors affecting demand include the product price, consumer preference, and other factors.

In this paper, the basic hypothesis of Section 4 uses the market demand theory to represent the relationship between market demand and cost faced by community e-commerce platforms.

**3.2.3. Diminishing Marginal Effect.** The diminishing marginal effect refers to the continuous input of a certain element under other conditions remaining unchanged [14]. When the input increases to a certain amount, the increment that can be achieved by the unit element becomes less. In other words, the cost per unit increment is going to be higher.

In this paper, the basic hypothesis in Section 4 uses the theory of diminishing marginal effect to represent the cost of suppliers participating in value cocreation.

## 4. Result

**4.1. Model Description.** The SCG supply chain studied in this paper is a three-level supply chain composed of suppliers (S), community e-commerce platform (C), and grid station service provider (G). The structure is shown in Figure 1. The supplier is responsible for the production and supply of goods. The community e-commerce platform provides a platform for consumers to browse and order goods. It sets up goods on the platform and publishes information on goods and activities. Consumers determine the purchase by browsing relevant information. In addition, the community e-commerce platform is also responsible for collecting consumer feedback on goods. Grid station service provider picks and distributes goods according to consumer order content.

This paper considers the value cocreation efforts of suppliers in the decision-making of this three-level supply chain. As the source of the supply chain, suppliers provide goods or services for the entire supply chain and sell them through the community e-commerce platform [15]. The quality of goods or services directly affects consumer experience and satisfaction. Only when consumers approve the goods or services will they repeat purchases of the goods or services in the future, thereby increasing the sales volume of the supply chain and occupying a unique competitive advantage in the fierce market competition. Suppliers' value cocreation behavior is reflected in all aspects of product production and design. In terms of product design, suppliers widely absorb consumer demand and opinions and design and improve goods according to demand to meet more consumers. In terms of production, select more appropriate

FIGURE 1: Supply chain structure of community e-commerce platform.

raw materials and processes to meet consumer demand for quality and so on.

### 4.2. Basic Assumptions

**Hypothesis 1:** Based on the hypothesis of economic man and rational man, all the research subjects in this paper are completely rational. They aim to maximize their own profits and assume information sharing among enterprises in the chain.

**Hypothesis 2:** Assume that the wholesale price of the supplier to the community e-commerce platform is  $W$  and production cost is  $C_1$ . The selling price of the community e-commerce platform is  $P$ , and the cost of the unit product is  $C_2$ . The income of the grid station service provider for product selection and distribution per unit is  $Z$ .

**Hypothesis 3:** Assume the value cocreation effort cost of the supplier is  $C(v) = (1/2)\alpha v^2$ . According to the diminishing marginal effect, the marginal utility of unit cost is diminishing when the level of effort becomes higher, and the cost of unit effort is increasing. Among them,  $\alpha$  is the supplier's value cocreation cost coefficient,  $v$  is the supplier's value cocreation effort level, and the value range is  $0 \leq v \leq 1$ .

**Hypothesis 4:** Assuming that the market demand is related to the price and the degree of cocreation of supplier value, the market demand function is  $Q = a - bP + sv$ . Among them,  $P$  and  $Q$  are the price and sales volume of the product, respectively,  $a$  represents the maximum capacity of the market,  $b$  represents the sensitivity coefficient of demand to price, and  $s$  is the sensitivity coefficient of supplier value cocreation, where  $a$ ,  $b$ , and  $s$  are constants greater than zero.

**4.3. Model Construction.** According to the above model description and basic assumptions of the SCG community e-commerce platform supply chain, the value function of each participant can be obtained.

The value of the supplier is

$$\pi_1 = (W - C_1)Q - \frac{1}{2}\alpha v^2. \quad (1)$$

The value of the community e-commerce platform is

$$\pi_2 = (P - W - C_2 - Z)Q. \quad (2)$$

The grid station service provider value is

$$\pi_3 = ZQ. \quad (3)$$

The supply chain value of the SCG community e-commerce platform is

$$\pi_{\text{SCG}} = \pi_1 + \pi_2 + \pi_3 = (P - C_1 - C_2)Q - \frac{1}{2}\alpha v^2. \quad (4)$$

## 5. Discussion

**5.1. Centralized Decision-Making.** Under centralized decision-making, all enterprises in the supply chain aim to achieve the maximum profit of the supply chain. Jointly decide the optimal price  $P_c^*$  and supplier value cocreation effort level  $v_c^*$  together. At this point, the profit function of supply chain decision is

$$\pi_{\text{SCG}} = (P - C_1 - C_2)(a - bP + sv) - \frac{1}{2}\alpha v^2. \quad (5)$$

First, calculate the second derivative of  $P$  and  $v$  separately from equation (5) to obtain the Hessian matrix:

$$H = \begin{bmatrix} \frac{\partial^2 \pi_{\text{SCG}}}{\partial P^2} & \frac{\partial^2 \pi_{\text{SCG}}}{\partial P \partial v} \\ \frac{\partial^2 \pi_{\text{SCG}}}{\partial v \partial P} & \frac{\partial^2 \pi_{\text{SCG}}}{\partial v^2} \end{bmatrix} = \begin{bmatrix} -2b & s \\ s & -\alpha \end{bmatrix}. \quad (6)$$

Since  $|H| \geq 0$ , the second-order Hessian matrix is a positive definite matrix, and  $\pi_{\text{SCG}}$  is a strictly concave function of  $P$  and  $v$ . At this time, there is a unique optimal solution.

Combine first-order conditions  $(\partial \pi_{\text{SCG}} / \partial P) = 0$  and  $(\partial \pi_{\text{SCG}} / \partial v) = 0$ , which can be solved as

$$P_c^* = \frac{\alpha a + (ab - s^2)c_1 + c_2}{2ab - s^2}, \quad (7)$$

$$v_c^* = \frac{sa - sb(c_1 + c_2)}{2ab - s^2}.$$

Substituting the result into the market demand function, we can obtain

$$Q_c^* = \frac{\alpha ab - \alpha b^2(c_1 + c_2)}{2ab - s^2}. \quad (8)$$

At this time, the overall maximum profit of the SCG supply chain is

$$\pi_{\text{SCG}} = \frac{\alpha[a - b(c_1 + c_2)]^2}{2(2ab - s^2)}. \quad (9)$$

In summary, we can get Conclusion 1.

**Conclusion 1.** In the case of centralized decision-making, the optimal decision of SCG community e-commerce platform supply chain is  $P_c^* = (\alpha a + (ab - s^2)c_1 + c_2) / (2ab - s^2)$ ,  $v_c^* = (sa - sb(c_1 + c_2)) / (2ab - s^2)$ ,  $Q_c^* = (\alpha ab -$

$\alpha b^2(c_1 + c_2)) / (2ab - s^2)$ , and the maximum profit of the supply chain is  $\pi_{\text{SCG}} = \alpha[a - b(c_1 + c_2)]^2 / 2(2ab - s^2)$ .

## 5.2. Decentralized Decision-Making

**5.2.1. Community E-Commerce Platform-Led Decentralized Decision-Making.** In decentralized decision-making, the members of the supply chain make decisions independently and take their own maximum profit as the decision-making goal. In the case of community e-commerce platform leading, the community e-commerce platform first considers its own maximum profit. The decision sequence is as follows: firstly, the community e-commerce platform decides the sales price  $P$  and the order quantity  $Q$ , then the supplier decides the wholesale price  $W$  and the supplier value cocreation effort level  $v$ , and uses the backward induction method of the Stackelberg game to solve the model [16].

By backward induction, first calculate the response function of the supplier, then substitute the profit function of the community e-commerce platform to obtain the optimal decision of the community e-commerce platform and, finally calculate the optimal value of each subject. Since directly substituting the wholesale price  $W$  into the supplier's profit function cannot calculate the optimal solution, assume that the supplier's profit per unit of a commodity is  $n$ , and the sales price  $P$  is expressed as  $P = W + n$ .

Therefore, the profit function of suppliers in the SCG supply chain is

$$\pi_1 = (W - C_1)Q - \frac{1}{2}\alpha v^2, \quad (10)$$

$$W - C_1[a - b(w + n) + sv] - \frac{1}{2}\alpha v^2.$$

Similar to the derivation process of centralized decision-making, the second derivative of  $W$  and  $v$  can be obtained by calculating the second derivative of  $W$  and  $v$ , respectively, to obtain the Hessian matrix:

$$H_2 = \begin{bmatrix} \frac{\partial^2 \pi_1}{\partial W^2} & \frac{\partial^2 \pi_1}{\partial W \partial v} \\ \frac{\partial^2 \pi_1}{\partial v \partial W} & \frac{\partial^2 \pi_1}{\partial v^2} \end{bmatrix} = \begin{bmatrix} -2b & s \\ s & -\alpha \end{bmatrix}. \quad (11)$$

Since  $|H_2| \geq 0$ , we can get that  $\pi_1$  is a strictly concave function about  $W$  and  $v$ , and  $\pi_1$  has the only optimal solution.

Combine first-order conditions  $(\partial \pi_1 / \partial W) = 0$  and  $(\partial \pi_1 / \partial v) = 0$ , which can be solved as

$$W_1^* = \frac{\alpha a + bc_1 - s^2 c_1 - \alpha bn}{2ab - s^2}, \quad (12)$$

$$v_1^* = \frac{s[a - bc_1 - bn]}{2ab - s^2}.$$

Next, find the optimal strategy of the community e-commerce platform. The profit function of the community e-commerce platform is

$$\pi_2 = (P - W - C_2 - Z)(a - bp + sv). \quad (13)$$

Substitute  $P = W + n$  into the profit function and simplify to obtain

$$\pi_2 = (n - C_2 - Z)(a - bw - bn + sv). \quad (14)$$

Find the second partial derivative of  $n$  with respect to  $\pi_2$ ,  $(\partial^2 \pi_2 / \partial n^2) = -2b < 0$ . Therefore,  $\pi_2$  is a concave function about  $n$ , and there is a unique optimal solution. Letting  $(\partial \pi_2 / \partial n) = 0$ , we can get

$$n_1^* = \frac{a - bc_1 + b(C_2 + Z)}{2b}. \quad (15)$$

Substituting  $n^*$  into  $W^*$  and  $v^*$ , we can get

$$W_1^* = \frac{\alpha[a + b(3c_1 - c_2 - Z)] - 2s^2 c_1}{2(2ab - s^2)}, \quad (16)$$

$$v_1^* = \frac{s[a - b(c_1 + c_2 + Z)]}{2(2ab - s^2)}.$$

Substituting  $n^*$  and  $W^*$  into the function  $P = W + n$ , the sales price  $P^*$  of the community e-commerce platform can be obtained:

$$P_1^* = \frac{ab^2((c_1 + c_2 + Z) + b[3\alpha a - s^2(c_1 + c_2 + Z)]) - as^2}{2b(2ab - s^2)}. \quad (17)$$

Substituting  $P^*$  into the market demand function  $Q = a - bp + sv$ ,  $Q^*$  can be obtained by calculation and simplification:

$$Q_1^* = \frac{ab[a - b(c_1 + c_2 + Z)]}{2(2ab - s^2)}. \quad (18)$$

**Conclusion 2.** Under the decentralized decision-making led by the community e-commerce platform, the optimal strategy of the SCG supply chain is the sales price

$$\begin{aligned} P_1^* &= \frac{ab(c_1 + c_2 + Z) + b[3\alpha a - s^2(c_1 + c_2 + Z)] - as^2}{2b(2ab - s^2)}, \\ Q_1^* &= \frac{ab[a - b(c_1 + c_2 + Z)]}{2(2ab - s^2)}, \\ v_1^* &= \frac{s[a - b(c_1 + c_2 + Z)]}{2(2ab - s^2)}. \end{aligned} \quad (19)$$

**5.2.2. Supplier-Led Decentralized Decision-Making.** In the case of supplier-led, the supplier first considers the maximization of its own interests. The decision sequence is as follows: the supplier decides the wholesale price  $W$  and the supplier value cocreation effort level  $v$ , and then the community e-commerce platform decides the sales price  $P$  and order quantity  $Q$  of the product.

First, calculate the optimal strategy of the community e-commerce platform. The profit function of the community e-commerce platform is

$$\pi_2 = (P - W - C_2 - Z)Q = (P - W - C_2 - Z)(a - bp + sv). \quad (20)$$

Find the second partial derivative of  $P$  with respect to  $\pi_2$ ,  $(\partial^2 \pi_2 / \partial P^2) = -2b$ . Therefore,  $\pi_2$  is a strictly concave function, and there is a unique optimal solution. So letting  $(\partial \pi_{SCG} / \partial P) = 0$ , we can get the optimal sales price of community e-commerce platform  $P_2^*$ :

$$P_2^* = \frac{a + sv + b(w + z + c_2)}{2b}. \quad (21)$$

Next, solve the supplier's optimal strategy, and the supplier's profit function is

$$\pi_1 = (W - C_1)Q = W - C_1 a - bp + sv - \frac{1}{2}\alpha v^2. \quad (22)$$

Substitute  $P_2^*$  into equation (22) and simplify

$$\begin{aligned} \pi_1 &= aw - w^2 b - bcw + svw - ac_1 + wbc_1 \\ &\quad + bc_1(c_2 + z) - svc_1 - \frac{1}{2}\alpha v^2. \end{aligned} \quad (23)$$

Calculating the second derivative of  $W$  and  $v$ , respectively, for equation (23), we can get the Hessian matrix:

$$H_3 = \begin{bmatrix} \frac{\partial^2 \pi_1}{\partial W^2} & \frac{\partial^2 \pi_1}{\partial W \partial v} \\ \frac{\partial^2 \pi_1}{\partial v \partial W} & \frac{\partial^2 \pi_1}{\partial v^2} \end{bmatrix} = \begin{bmatrix} -2b & s \\ s & -\alpha \end{bmatrix}. \quad (24)$$

Since  $|H_3| \geq 0$ , we can get that  $\pi_1$  is a strictly concave function about  $W$  and  $v$  and  $\pi_1$  has the only optimal solution.

Combining the first-order conditions  $(\partial \pi_1 / \partial W) = 0$  and  $(\partial \pi_1 / \partial v) = 0$ , we can solve it

$$W_2^* = \frac{a\alpha + ab(c_1 - Z - c_2) - s^2 c_1}{2ab - s^2}, \quad (25)$$

$$V_2^* = \frac{s[a - b(z + c_1 + c_2)]}{2ab - s^2}.$$

Substituting  $W^*$ ,  $v^*$  into  $P$ ,  $P^*$ ,  $Q^*$  can be calculated

$$\begin{aligned} P_2^* &= \frac{3a\alpha + [(b\alpha - 2s^2)(z + c_1 + c_2)]}{2(2ab - s^2)}, \\ Q_2^* &= \frac{ab[a - b(c_1 + c_2 + Z)]}{2(2ab - s^2)}. \end{aligned} \quad (26)$$

**Conclusion 3.** Under the supplier-led decentralized decision-making, the optimal price is  $P_2^* = (3a\alpha + [(b\alpha - 2s^2)(z + c_1 + c_2)])/2(2ab - s^2)$ , and  $Q_2^* = ab[a - b(c_1 + c_2 + Z)]/2(2ab - s^2)$ .

$$2(2\alpha b - s^2), W_2^* = (\alpha a + ab(c_1 - Z - c_2) - s^2 c_1)/(2\alpha b - s^2), \\ v_2^* = s[a - b(z + c_1 + c_2)]/(2\alpha b - s^2).$$

5.3. *Comparative Analysis of Models.* Through the above solution, the optimal strategy in these three cases can be obtained, as shown in Table 1.

By sorting out the results in Table 1, the optimal sales price, supplier value cocreation effort level, and supplier wholesale price under different decentralized decisions have the following relationship:  $P_1^* < P_2^*$ ,  $W_1^* < W_2^*$ ,  $V_1^* > V_2^*$ .

*Proof.*  $P_1^* - P_2^* = (s^2[b(c_{1+c_2+Z}) - a]/2b(2\alpha b - s^2)) < 0$ ,  $v_1^* - v_2^* = -(s[a - b(z + c_1 + c_2)]/(2\alpha b - s^2)) < 0$ ,  $W_1^* - W_2^* = (s[b(z + c_1 + c_2) - a]/2(2\alpha b - s^2)) < 0$ .

This shows that different dominant modes will bring different optimal strategies to the supply chain of the community e-commerce platform and have different effects on the supply chain. In the case of community e-commerce platform dominance, the optimal selling price, supplier value cocreation effort, and the optimal wholesale price are all smaller than the optimal selling price in the case of supplier dominance.  $\square$

5.4. *Numerical Analysis.* In the calculation above, we have obtained a series of results under different decision modes. In order to further analyze and verify the optimal decisions of community e-commerce platforms, suppliers, and grid service providers under different decision modes, we will conduct numerical analysis in this section.

By referring to previous literature, this paper assumes that the values of each parameter are as follows:  $a=100$ ,  $b=0.7$ ,  $c_1=7$ ,  $c_2=2$ ,  $Z=1$ ,  $\alpha=0.2$ ,  $s=0.15$ . The optimal decision and maximum profit under different decision modes are shown in Table 2.

Change the value of  $s$ , so  $a=100$ ,  $b=0.7$ ,  $c_1=7$ ,  $c_2=2$ ,  $Z=1$ ,  $\alpha=0.2$ ,  $s=0.2$ . The optimal decision and maximum profit under different decision modes are shown in Table 3.

It can be seen from Table 2 that the results calculated by the calculation example are consistent with the conclusions drawn from the above model analysis.

- (1) The first thing that can be obtained is that when the SCG supply chain makes decentralized decision-making, the optimal decision will be affected by the dominant power. Under the supply chain dominated by community e-commerce platforms, the wholesale price of suppliers is 43.12, the sales price is 112.54, and the supplier value cocreation effort level is 27.08. When the supplier leads, the wholesale price is 79.23, the sales price is 118.35,

and the supplier value cocreation effort level is 54.17. When the community e-commerce platform dominates the supply chain, to maximize its own profits, the community e-commerce platform uses the dominant advantage of the supply chain to lower the wholesale price of suppliers as much as possible, while suppliers keep their profits from falling sharply by lowering the level of value cocreation. When the supplier is the leader of the supply chain, it will keep the wholesale price at a high level as much as possible and increase the level of value cocreation to meet the needs of more consumers and increase sales. Through these two methods to obtain their own maximum profits.

- (2) When decentralized decision-making, different power structures will bring different effects to community e-commerce platforms, suppliers, grid station service providers, and even the entire supply chain. When the community e-commerce platform is the leader of the supply chain, the profit of the community e-commerce platform is 1679.1, the profit of the supplier is 839.78, the profit of the grid station service provider is 25.28, and the total profit of the supply chain is 2544.16. When the supplier occupies the leading position in the supply chain, the profit of the community e-commerce platform is 913.11, the profit of the supplier is 1532.53, the profit of the grid station service provider is 25.28, and the total profit of the SCG community e-commerce platform supply chain is 2470.93. It can be seen that the dominant power will have different effects on the profits of different entities in the supply chain. When the community e-commerce platform is the dominant player, the profit of the community e-commerce platform is greater than that of the supplier. When suppliers dominate, supplier profits are much higher than community e-commerce platform profits.
- (3) Under centralized decision-making, the maximum profit of the SCG supply chain is 3409.59. The overall profits of the supply chain under different decentralized decisions are 2544.16 and 2470.93, respectively, which are less than the profits obtained under the centralized decision-making model.
- (4) It can be seen from Tables 2 and 3 that whether it is in centralized decision-making or decentralized decision-making, when the supplier value cocreation sensitivity coefficient  $s$  increases, the sales price  $P$ , supplier value cocreation level  $v$ , and supply chain total value  $\pi$  all increase accordingly. Therefore, it

TABLE 1: Comparison of the supply chain of community e-commerce platforms under different decision-making modes.

Centralized decision	Decentralized decision-making	
	Community e-commerce platform dominates	Supplier-led
$P^*$	$(\alpha a + (\alpha b - s^2)c_1 + c_2)/(2\alpha b - s^2)$	$(3\alpha a + [(b\alpha - 2s^2)(z + c_1 + c_2)]/2(2\alpha b - s^2)) / (2\alpha b - s^2)$
$V^*$	$(sa - sb(c_1 + c_2))/(2\alpha b - s^2)$	$s[a - b(z + c_1 + c_2)] / (2\alpha b - s^2)$
$Q^*$	$(\alpha ab - \alpha b^2(c_1 + c_2))/(2\alpha b - s^2)$	$\alpha b[a - b(c_{1+c_2+z})] / 2(2\alpha b - s^2)$
$W^*$		$(\alpha a + \alpha b(c_1 - c_2 - Z) - s^2 c_1) / (2\alpha b - s^2)$

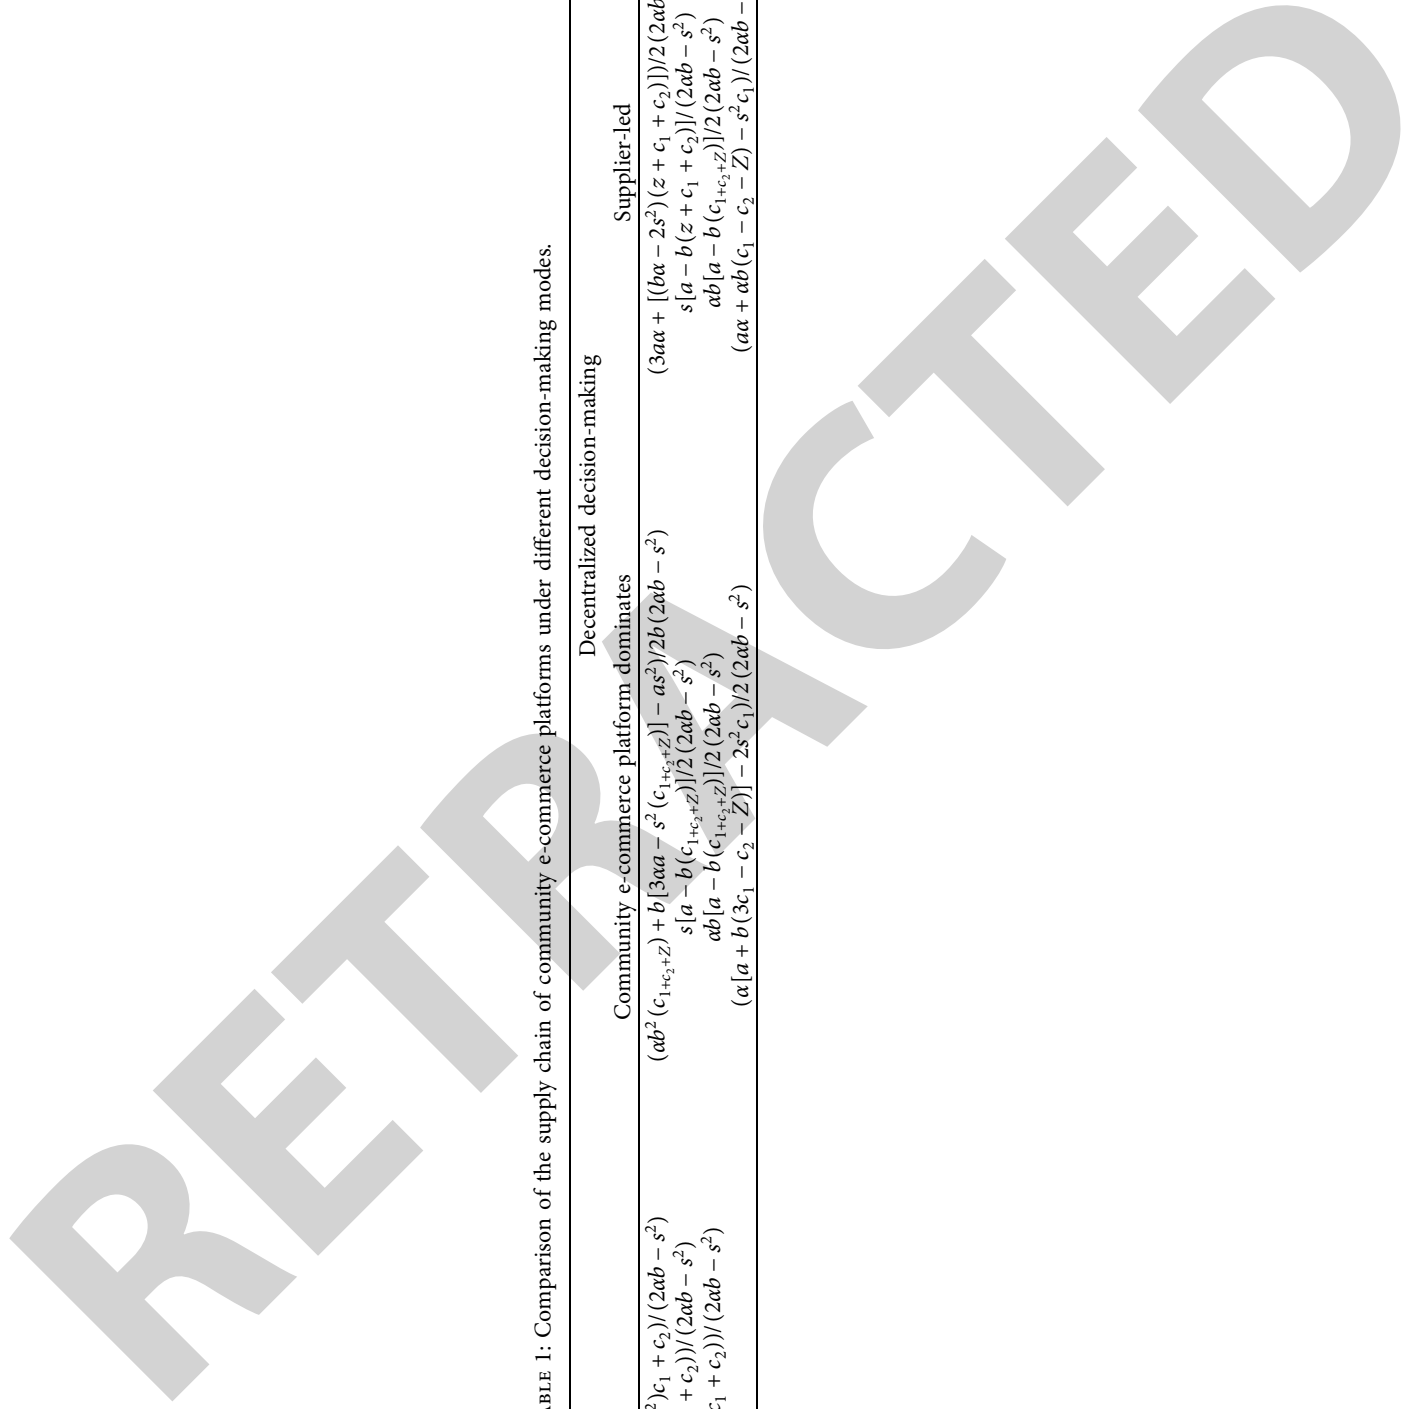

TABLE 2: Results analysis of different decision-making modes of SCG community e-commerce platform supply chain.

can be seen that  $s$  is positively correlated with sales price  $P$ , supplier value cocreation level  $\nu$ , and total supply chain value  $\pi$ .

## 6. Conclusion

This paper is aimed at a community e-commerce platform supply chain composed of suppliers, community e-commerce platforms, and grid station service providers and considers the value cocreation of suppliers. It analyzes the centralized decision-making and decentralized decision-making of the SCG model and gets the following conclusions.

- (1) Different decision-making modes will bring different optimal strategies to the supply chain. The profit generated by the supply chain in centralized decision-making is greater than that generated by decentralized decision-making, and different power structures will bring different revenue situations to enterprises in the supply chain. Therefore, to maintain a high degree of coordination, all companies in the supply chain need to focus on coordination and cooperation to provide a good foundation for centralized decision-making. In order to ensure that companies in the supply chain can obtain information from each other timely and accurately, some emerging information technologies such as blockchain, big data, and Internet of Things technologies can be introduced into the supply chain of community e-commerce platforms. In addition, some measures must be taken to guarantee

cooperation between supply chains. Enterprises in supply chains can find a reasonable profit distribution from the perspective of profit redistribution to benefit all enterprises in supply chains [17].

- (2) Under decentralized decision-making, when the supplier is the leader, the effort cost of the supplier participating in value cocreation is higher than that when the community e-commerce platform is the leader. In this case, the wholesale price of goods will be higher than the price of the community e-commerce platform to obtain higher income. The position of the enterprise in the supply chain affects the profit of the enterprise directly. When it is a leader, the profit reaches the maximum, and when it is a follower, the profit is the smallest. Therefore, companies can improve their competitive advantages, enhance their irreplaceability in the supply chain, and strive for supply chain leadership to obtain their maximum profits. The publicity and sales activities of the platform itself and the products sold on the platform are valued by the community e-commerce platform. Consumers' opinions and suggestions on the platform and products, paying attention to the emotional value of the consumers, are widely absorbed by it [18]. The platform has been satisfied and recognized by consumers by improving the service level from consumers' perspective, and the number of audiences has been increased [19]. In this way, the community e-commerce platform can increase its brand influence, thereby improving its position in the supply chain; they improve their income and contribute to the overall efficiency of the supply chain. Suppliers can consolidate their position in consumers and the supply chain by improving the quality of their products and producing unique products to gain leadership advantages [20].
- (3) Whether in centralized or decentralized decision-making, the sensitivity of supplier value cocreation is positively correlated with community e-commerce platform prices, supplier value cocreation efforts, and total supply chain profits. The greater the sensitivity, the higher the profitability of the supply chain. This shows that the increase in

the supplier value cocreation sensitivity coefficient can increase the profit of the community e-commerce platform, the profit of the supplier, and the overall profit of the supply chain. Therefore, suppliers are more willing to participate in value cocreation and take some measures to increase the sensitivity coefficient, such as cultivating consumers' consumption habits and adopting value cocreation methods that are more acceptable to consumers.

Through combing the literature, it is found that the existing literature mainly studies the model and development trend of the community e-commerce platform supply chain, and there are few studies on the supply chain decision-making. In addition, there are few studies on supply chain value cocreation from the perspective of model analysis. Therefore, the main contribution of this paper is to introduce the degree of supplier value cocreation effort to the decision-making model of community e-commerce platform supply chain and explore the influence of supplier value cocreation on sales price, retail price, and profit of each enterprise, which provides a theoretical basis for the development of community e-commerce platform supply chain. However, this research is not unlimited. Firstly, when establishing the decision-making model, it is assumed that the members of the community e-commerce platform supply chain have already realized information sharing, and the noninteroperability of information is not considered. Secondly, there are often multiple suppliers and multiple commodities. This paper only studies the situation of a single supplier and single commodity. Therefore, in future research, other factors and subjects will be further considered in the model to obtain a conclusion closer to the implementation situation.

Increased frequency of disasters keeps reminding us of the importance of effective resource distribution in postdisaster. To reduce the suffering of victims, this paper focuses on how to establish an effective emergency logistics system. We first propose a multiobjective optimization model in which the location and allocation decisions are made for a three-level logistics network. Three objectives, deprivation costs, unsatisfied demand costs, and logistics cost, are adopted in the proposed optimization model. Several cardinality and flow balance constraints are considered simultaneously. Then, we design a novel effective IFA-GA algorithm by combining the firefly algorithm and genetic algorithm to solve this complex model effectively. Furthermore, three schemes are proposed to improve the effectiveness of the IFA-GA algorithm. Finally, the numerical results provide several insights on the theory and practice of relief distribution, which also illustrate the validity of the proposed solution algorithm.

## 1. Introduction

Large-scale natural or man-made disasters, such as the 2010 Haitian Earthquake, the 2011 tsunami in Japan, the civil war in Syria, and the 2019 coronavirus disease, have occurred frequently throughout the world, resulting in tremendous consequences of enormous casualties and property losses. The world has witnessed a steadily increased number in both disasters and affected people since the 1900s. After large-scale disasters, a great need for medical and daily supplies will be invoked in the affected areas, which lack adequate relief resources. Thus, the rapid distribution of external commodities is critical to mitigating the losses caused by disasters. Therefore, emergency logistics has received wide attention from both practical managers and scholars [1]. However, how to design an efficient emergency logistics system is a big challenge [2]. Before the last decade, most research on emergency management focused on the responses of public servants, government agencies, and insurance firms in times of crisis [3]. Emergency logistics, also

commonly known as humanitarian logistics, is emerging and becoming a hot spot of operations management in the recent decade.

In most of the current related research, emergency logistics problems are studied based on the analytical formulations of the traditional commercial sector, unlike the commercial scenario, whose decision objective is to minimize the logistics cost. In emergency relief cases, the scientific community is encouraged to provide effective logistics systems to reduce human suffering. Therefore, the adapted objectives in commercial and emergency logistics are radically different. The modified analytical formulations of the traditional logistics are not very suitable for emergency logistics problems [4].

To derive an appropriate objective function for emergency logistics, Holguín-Veras et al. [5] incorporated welfare economic principles into emergency management and introduced the deprivation costs, which express the economic value of human suffering caused by a lack of access to resources or services. Since then, some studies using

deprivation costs have been conducted in the emergency logistics field [6]. For example, Pérez-Rodríguez and Holguín-Veras [7] developed an inventory-allocation-routing model for the optimal critical supplies by minimizing logistics and social costs. Ismail [3] studied a relief distribution problem by considering the logistics and deprivation costs. Some other papers also considered human suffering in the emergency logistics field. Chapman and Mitchell [8] studied the distribution centers selection problem by minimizing the suffering of the population. Cotes and Cantillo [9] developed a facility location model for repositioning supplies in preparation for disasters. Their formulation considers deprivation costs in the objective function. Rivera-Royero et al. [10] proposed a dynamic model to serve rescue demand. They considered the level of urgency of demand points. Moreno et al. [11] presented a novel model to optimize location, transportation, and fleet sizing for emergency logistics with considering deprivation costs. Cantillo et al. [12] assessed transportation network vulnerability from logistical costs and deprivation costs. Zhu et al. [13] studied the emergency relief routing optimization problem considering injured degree and deprivation cost.

Similar to the above literature, we adopt the deprivation costs to characterize human suffering in this paper. We study a location-allocation problem of emergency logistics. Three objectives, deprivation costs, unsatisfied demand losses, and logistics costs, are adopted in the proposed optimization model. The fairness objective of this paper equalizes the supplies between affected areas, which has the same purpose as unmet demand minimization in [14]. In addition, our literature also lies in the stream of multiobjective programming, which is widely used to solve emergency optimization problems. Sun et al. [15] proposed a robust optimization model to decide the facility location, resource allocation, and casualty transportation in a three-level rescue chain composed of casualty clusters, temporary facilities, and general hospitals. Their objectives are to minimize the total Injury Severity Score (ISS) and logistics cost. Zhou et al. [2] studied the multiperiod dynamic emergency resource scheduling problem by a proposed multiobjective optimization model. Cao et al. [16] proposed a multiobjective nonlinear programming model for resource distribution regarding the beneficiary perspective on sustainability. The model is solved by maximizing the lowest victims' perceived satisfaction and minimizing the largest deviation of victims' perceived satisfaction. Çelik et al. [17] studied the stochastic debris clearance problem among postdisaster operations. They determined a sequence of roads to clear with the goal of maximizing satisfied relief demand. Gralla et al. [18] developed a method to value the objective functions of emergency logistics based on expert preferences over five key attributes. They found that the amount of cargo delivered is the most valued objective and cost the least important. In a similar vein, we conduct the optimization problem based on a three-level emergency logistics network. Considering the complexity of reality, we formulate the problem by a multiobjective mixed-integer nonlinear programming with cardinality and flow balance constraints.

Most optimization problems of emergency logistics are hard to solve effectively by exact algorithms, especially in the limited available time. In such situations, adopting a metaheuristic algorithm is imperative [19]. The third related literature stream of this paper is algorithm design. Zhou et al. [2] designed an evolutionary algorithm based on decomposition (MOEA) to solve a multiobjective multiperiod dynamic emergency resource scheduling problem. Cao et al. [16] adopted genetic algorithm to solve a relief distribution model. Haghgi et al. [20] proposed a multiobjective location and transportation programming model, which is solved by a nondominant sorting genetic algorithm. Eisenhandler and Tzur [21] modeled a food rescue problem as a routing resource allocation problem with the equitable allocations objective. They presented a heuristic approach based on the large neighborhood search framework to solve the model. Zhang et al. [22] determined the truck and drone routes in a humanitarian relief network by combining column generation and tabu search algorithms. This paper designs a metaheuristic algorithm named IFA-GA by combining the firefly algorithm and genetic algorithm. Some improved schemes are embedded into IFA-GA to obtain better solutions.

The contributions of this paper can be summarized as follows: first, we propose a new multiobjective location-allocation optimization model for emergency logistics, in which deprivation costs, fairness, and operation costs are considered. The numerical results show that deprivation costs have a significant effect on location decisions. Second, we design a new IFA-GA algorithm based on the combination of the firefly algorithm and genetic algorithm. Three schemes, population initialization, search strategy, and update mechanism of population, are proposed to improve IFA-GA. The computational results illustrate that the proposed IFA-GA has better solving performance than the other algorithms.

The remainder of this paper is organized as follows: Section 2 presents some presumptions and notations. The detailed descriptions of the three objective functions and model formulation are also given in Section 2. Section 3 develops the hybrid IFA-GA algorithm for solving the proposed model and gives the improved schemes. Section 4 conducts numerical studies and analyses. Finally, Section 5 presents conclusions and future work.

## 2. Problem Description and Formulation

In this section, we first give some presumptions and notations. Then, three relief-related objective functions are proposed to represent human suffering, fairness, and logistics cost. Finally, we present a multiobjective location and resource allocation model for three-level emergency logistics.

*2.1. Presumptions and Notations.* Emergency supplies mainly come from two sources: local rescue warehouses or external dispatching. Local rescue warehouses can provide supplies immediately after disasters occur, but the amount is

limited. External dispatching mainly comes from the Strategic National Stockpile (SNS), which integrates different parties' resources and provides the primary resources to the affected areas by railway or airplane in the subsequent relief phase. In this paper, we consider an emergency logistics problem in the second case. Most emergency logistics systems have a three-tier structure, including SNS, regional transfer center (RTC), and local distribution point (LDP). In reality rescue practice, large amounts of emergency resources must be transported from SNS to affected points as soon as possible. To improve the efficiency of the rescue, RTCs are proposed as hubs to bridge SNS and LDP. This work proposes a joint facility location and resource allocation model for this three-level emergency logistics system. Some assumptions used in our model are as follows:

- (1) There are one SNS, some RTCs, and a fixed number of LDPs. The resources are first transported from SNS to RTCs and then transported from RTCs to LDPs. LDPs are equivalent to affected points that have resource demands. SNS, RTCs, and LDPs have enough capacity to store resources. The capacity constraints are ignored in our optimization model.
- (2) The demand quantity of resources in each affected point can be predicted, and the total available quantity of resources is also known.
- (3) The rescue resources are transported by trucks. Moreover, there are enough available trucks in each supply point.
- (4) The locations of RTCs are decided in the postdisaster phase. After establishing RTCs, all roads from RTCs to SNS and LDPs are fixed. This work does not consider the uncertainty of road networks. Therefore, the delivery time between two supply points is determined by the speed of the truck.
- (5) The rescue demand has an additional time-related attribute. If the actual delivery time exceeds the required threshold, the deprivation costs of victims will be invoked to represent the economic valuation of the human suffering associated with a lack of access to a good or service.

The RTCs are established in selected reasonable sites the first time after the disaster occurs. In commercial logistics, RTCs can quickly move goods from the central warehouse, manufacturers to retailers. In emergency logistics, large-scale disaster is characterized by a wide range of affected points, great demand, and long duration. Therefore, the appropriate location of RTCs has a more critical role in improving the transport efficiency of resources. With the above assumptions, the location decision of RTCs, the allocation decisions from SNS to RTCs and from RTCs to LDPs will be studied in our proposed multiobjective optimization model. The notations used in the following text are listed as follows:

- (i)  $O$ : the SNS point;
- (ii)  $I$ : the candidate location set of RTCs,  $i = 1, 2, \dots, I$ ;

- (iii)  $J$ : the location set of LDPs,  $j = 1, 2, \dots, J$ ;
- (iv)  $d_{Oi}$ : the distance from SNS  $O$  to RTC candidate  $i$ ;
- (v)  $d_{ij}$ : the distance from RTC candidate  $i$  to LDP  $j$ ;
- (vi)  $C_{OI}$ : the unit transport cost from SNS to RTC;
- (vii)  $C_{IJ}$ : the unit transport cost from RTC to LDP;
- (viii)  $C_i$ : the construction cost of RTC  $i$ ;
- (ix)  $CV_i$ : the unit operation cost of RTC  $i$ ,  $CV_i$  multiplied by inventory equal to the total operation cost of RTC  $i$ ;
- (x)  $D_j$ : the demand quantity of LDP  $j$ ;
- (xi)  $Q_o$ : the initially available quantity of the resource in SNS;
- (xii)  $Q_i$ : the initially available quantity of the resource in RTC  $i$ ;
- (xiii)  $\pi_{jt}$ : the unit deprivation cost of each victim in LDP  $j$  at time  $t$ ;
- (xiv)  $\delta_j$ : the deprivation costs of LDP  $j$  at time  $t$ ;
- (xv)  $l_{oj}$ : the loss function of unsatisfied demand of LDP  $j$ ;
- (xvi) OC: the total operation cost of emergency logistics;
- (xvii)  $t_{ij1}$ : the first delivery time of resources from RTC  $i$  to LDP  $j$ ;
- (xviii)  $t_{ij2}$ : the second delivery time of resources from RTC  $i$  to LDP  $j$ ;
- (xix)  $v$ : the speed of truck;
- (xx)  $z_i$ : 0–1 variables, if candidate  $i$  is selected as RTC,  $z_i = 1$ , else,  $z_i = 0$ ;
- (xxi)  $x_{oi}$ : the allocated quantity of emergency resources from SNS to RTC  $i$ ;
- (xxii)  $y_{ij1}$ : the first allocated quantity of emergency resources from RTC  $i$  to LDP  $j$ ;
- (xxiii)  $y_{ij2}$ : the second allocated quantity of emergency resources from RTC  $i$  to LDP  $j$ ;
- (xxiv)  $\varepsilon_{ij}$ : auxiliary variable,  $\varepsilon_{ij} = 1$  if RTC  $i$  provides resources to LDP  $j$ , else  $\varepsilon_{ij} = 0$ .

**2.2. Multiobjective Optimization Model.** There are three objectives in our model that reflect three service levels of emergency logistics: (1) minimizing the total deprivation costs of victims, (2) minimizing the loss of unsatisfied demand, and (3) minimizing the total cost of the emergency logistics system. The formulations consider a relief group that first delivers critical supplies from SNS to RTCs and then delivers goods from RTCs to demand nodes. Furthermore, RTCs also have a limited initial inventory of critical supplies. Therefore, there are twice transportations from RTC  $i$  to LDP  $j$  if RTC  $i$  is selected as a hub to supply LDP  $j$ . RTC  $i$  first provides resources by its own inventory. The first resources reach LDP  $j$  at time  $t_{ij1}$ . Then, RTC  $i$  transfers the second resources which come from SNS and arrive at LDP  $j$  at time  $t_{ij2}$ . During a planning horizon  $T$ , the relief group's decisions are which RTCs should be selected,

how much, and when to deliver to the demand nodes in need of supplies.

**2.2.1. The Deprivation Costs.** Human suffering is one of the critical factors in humanitarian logistics. The theory of deprivation costs [5] provides an excellent method to bring human suffering factors into the decision objective. Conceptually, deprivation cost is the economic value of human suffering caused by a lack of access to resources or services.

$$\delta_j = \pi(t_{ij1})\min(D_j, y_{ij1}) + \pi(t_{ij2})\min(\max(D_j - y_{ij1}, 0), y_{ij2}) + \pi(T)\max(D_j - y_{ij1} - y_{ij2}, 0), \quad (1)$$

where  $t_{ij1}$  is dependent on the distance between RTC  $i$  and LDP  $j$ .  $t_{ij2}$  is dependent on the distance from SNS to LDP  $j$  via RTC  $i$ . The first part of  $\delta_j$  is the deprivation costs of the satisfied demand in the first supply. The second part of  $\delta_j$  is the deprivation costs of the satisfied demand in the second supply. The third part of  $\delta_j$  is the deprivation costs of the remaining unsatisfied demand at the end.

It should be noted that the beneficiaries had already experienced a deprivation cost at time  $t < t_{ij1}$ . Therefore, the

$$\sum_{j \in J} \delta_j = \sum_{i \in I, j \in J} at_{ij1}^2 \min(D_j, y_{ij1}) + at_{ij2}^2 \min(\max(D_j - y_{ij1}, 0), y_{ij2}) + aT^2 \max(D_j - y_{ij1} - y_{ij2}, 0). \quad (2)$$

**2.2.2. The Loss of Unsatisfied Demand.** In the context of emergency rescue, decision-makers should try their best to meet the supplies needs in each affected point, but the goods are inadequate at the first time. Therefore, another important objective in emergency logistics is to keep fairness. In this work, we provide a loss function of unsatisfied demand to evaluate the fairness of rescue. The loss function  $l_{oj}$  is an S type curve of unsatisfied demand in LDP  $j$ . This reflects that the unsatisfied demand has a learning effect on the emergency service level. If the unsatisfied demand takes the maximum value, the loss function becomes constant, and no more losses will occur. In addition, developed regions tend to be densely populated, which have more severe consequences if emergency demands are not met. Thus, the demand quantity is considered in the loss function, which can be given by

$$l_{oj} = \max(D_j - y_{ij1} - y_{ij2}, 0)P(h_j), \quad (3)$$

where  $P(h_j) = be^{-h_j/(1-h_j)}$  and  $h_j = (\sum_{i \in I} y_{ij1} + y_{ij2}/D_j)$ .  $h_j$  is the proportion of satisfied demand in LDP  $j$ . Obviously,  $1 - h_j$  is the ratio of unsatisfied demand.  $P(h_j)$  is related to service level, which converges to loss upper bound  $b$  if  $h_j$  tends to 0, and 0 if  $h_j$  tends to 1. Thus, we use the above loss function to quantify the fairness in this paper. The total unsatisfied demand loss of emergency logistics is given as follows:

Suppose LDPs at which identical individuals experience the same unit deprivation cost  $\pi(t)$  at time  $t$ . According to the theory of deprivation costs, the deprivation costs function  $\delta_j$  is discontinuous, increases with deprivation time, and then drops to zero when a delivery large enough to fulfill the needs of all individuals is received. The total deprivation costs at node  $j$  are equal to the aggregation of individual costs:

classical deprivation costs theory evaluates the cumulative cost function up to time  $T$ . For simplification, this work only considers the deprivation costs at the arrival times of supplies and the end time of the period. The unite deprivation cost  $\pi(t)$  is increasing convex function with respect to  $t$ ,  $0 < t \leq T$ . In this paper, we use a quadratic function  $\pi(t) = at^2$  to specify deprivation cost and  $a$  is a cost coefficient. Thus, we can easily obtain the total deprivation costs at the end of period  $T$ , which can be expressed as

$$\sum_{j \in J} l_{oj} = \sum_{i \in I, j \in J} \max(D_j - y_{ij1} - y_{ij2}, 0)P(h_j). \quad (4)$$

**2.2.3. The Operation Cost.** The operation cost of emergency logistics includes three parts: the construction cost of RTCs, the transport cost, and the inventory holding cost in RTCs. In the setting of this paper, the SNS already exists before disasters occur. The LDPs will distribute the relief resources as soon as they are received. Thus, we only consider the holding cost of RTCs because they are newly built. Then, the operation cost objective can be given by

$$OC = \sum_{i \in I} [z_i C_i + C_{oi} d_{oi} x_{oi} + \sum_{j \in J} C_{ij} d_{ij} (y_{ij1} + y_{ij2}) + CV_i (x_{oi} + Q_i)]. \quad (5)$$

**2.3. Mathematical Formulation.** Based on the above analysis, we suppose that the emergency manager's goals are to minimize the deprivation costs, the loss of unsatisfied demand, and the operation cost. Without loss of generality, we adopt two weight parameters  $\alpha$  and  $\beta$  ( $0 < \alpha, \beta, 1 - \alpha - \beta < 1$ ) to simplify this multiobjective optimization to scalar objective optimization. Meanwhile, the manager also needs to consider some realistic constraints, such as path constraint and capacity constraints. Then, the logistics optimization model is formulated as follows:

$$\min \alpha \sum_{j \in J} \delta_j + \beta \sum_{j \in J} lo_j + (1 - \alpha - \beta)OC, \quad (6)$$

$$\text{s.t. } \delta_j = \sum_{i \in I} at_{ij1}^2 \min(D_j, y_{ij1}) + at_{ij2}^2 \min(\max(D_j - y_{ij1}, 0), y_{ij2}) + aT^2 \max(D_j - y_{ij1} - y_{ij2}, 0), \quad \forall j \in J, \quad (7)$$

$$lo_j = \max(D_j - y_{ij1} - y_{ij2}, 0)P(h_j), \quad \forall j \in J, \quad (8)$$

$$P(h_j) = be^{(-h_j/1-h_j)}, \quad \forall j \in J, \quad (9)$$

$$h_j = \frac{\sum_{i \in I} y_{ij1} + y_{ij2}}{D_j}, \quad \forall j \in J, \quad (10)$$

$$OC = \sum_{i \in I} \left[ z_i C_i + C_{oi} d_{oi} x_{oi} + \sum_{j \in J} C_{ij} d_{ij} (y_{ij1} + y_{ij2}) + CV_i (x_{oi} + Q_i) \right], \quad (11)$$

$$t_{ij1} = \frac{d_{ij}}{v}, \quad \forall i \in I, j \in J, \quad (12)$$

$$t_{ij2} = \frac{d_{ij} + d_{oi}}{v}, \quad \forall i \in I, j \in J, \quad (13)$$

$$\sum_{i \in I} \epsilon_{ij} = 1, \quad \forall j \in J, \quad (14)$$

$$\sum_{j \in J} \epsilon_{ij} y_{ij1} = Q_i, \quad \forall i \in I, \quad (15)$$

$$\sum_{j \in J} \epsilon_{ij} y_{ij2} = x_{oi}, \quad \forall i \in I, \quad (16)$$

$$y_{ij1} \leq M \epsilon_{ij} z_i, \quad \forall i \in I, j \in J, \quad (17)$$

$$y_{ij2} \leq M \epsilon_{ij} z_i, \quad \forall i \in I, j \in J, \quad (18)$$

$$\epsilon_{ij} \leq z_i, \quad \forall i \in I, j \in J, \quad (19)$$

$$\sum_{i \in I, j \in J} \epsilon_{ij} (y_{ij1} + y_{ij2}) = \min \left( Q_o + \sum_{i \in I} Q_i, \sum_{j \in J} D_j \right), \quad (20)$$

$$x_{oi} \leq M z_i, \quad \forall i \in I, \quad (21)$$

$$\sum_{i \in I} x_{oi} = Q_o, \quad (22)$$

$$z_i, \epsilon_{ij} \in \{0, 1\}, \quad \forall i \in I, j \in J, \quad (23)$$

$$x_{oi}, y_{ij1}, y_{ij2} \in R^+, \quad \forall i \in I, j \in J. \quad (24)$$

The objective function shown in equation (6) has been described detailedly in the above. Constraints (7), (8), and (11) show the computational formulas of the three objectives, respectively. Constraints (9) and (10) describe the loss

function and the satisfied demand rate used to calculate the second objective. Constraints (11) and (12) describe the relationship between transport distance and delivery time. Constraint (14) restricts that each LDP can only receive

goods from one RTC. Constraints (15) and (16) balance the flows of resources in each RTC for the first and second deliveries. Constraints (17) and (18) guarantee that RTC  $i$  can provide relief supplies to LDP  $j$  only if  $i$  has been selected and  $j$  is allocated to it. Here,  $M$  is a sufficiently large number. Constraint (19) ensures that only a selected RTC can provide emergency supplies to LDPs. Constraint (20) indicates that all goods need to be shipped if the supply is less than demand; else, the delivered quantity is equal to demand. Constraint (21) ensures that only the selected RTC can receive goods from SNS. Constraint (22) indicates the flow balance of resources in SNS. Finally, constraints (23) and (24) define the decision variables.

### 3. A Hybrid Heuristic Solution Approach

The proposed model is one of the location-allocation type problems, most of which is NP-hard. Therefore, the optimal solution of the proposed model is difficult to be obtained in a short time. However, the actual emergency decision-making often has higher requirements on timeliness, which inspires us to adopt metaheuristic algorithms. This section combines an improved firefly algorithm with a genetic algorithm to design a new hybrid algorithm called IFA-GA. Furthermore, some schemes are also proposed to increase the solution quality.

**3.1. The Firefly Algorithm (FA).** FA is a nature-inspired swarm-based optimization algorithm proposed by Yang [23], which is designed to imitate the natural phenomenon of fireflies. FA supposes that all fireflies are homogeneous. Each firefly will be attracted and move close to a brighter firefly. If there are no brighter fireflies nearby, the firefly will move randomly. For an optimization problem, fireflies represent feasible solutions. The brightness of the firefly has a positive relationship with its objective value.

Similar to some other metaheuristic algorithms, FA also successfully implements the exploration and exploitation steps to solve optimization problems. The exploration step is carried out by the movement of fireflies from the current position to a brighter position. The exploitation step is realized by the random movements of the rest fireflies. Suppose  $X_n$  is a solution (firefly) in the  $n$ -th iteration of FA, the update movement equation of this firefly is

$$X_{n+1} = X_n + \beta_0 e^{-\gamma r^2} (\bar{X}_n - X_n) + \alpha_n \varepsilon_n, \quad (25)$$

where  $\beta_0$  is the maximum attractiveness between fireflies.  $r$  is the Euclidean distance between two fireflies  $\bar{X}_n$  and  $X_n$ .  $\gamma$  is the light absorption coefficient that adjusts the change of attraction.  $\alpha_n$  is a weight coefficient between  $[0, 1]$ , and  $\varepsilon_n$  is a random vector in  $[0, 1]$ .

**3.2. The Genetic Algorithm (GA).** GA is initially motivated by the Darwinian principle of evolution through natural selection and genetic mechanisms, which has been successfully applied to a wide range of real-world problems of significant complexity. Unlike the iterative update mechanism in other

algorithms, GA derives a new solution by operating the existing solutions directly. There are two genetic operators in GA: crossover and mutation. A typical design for a classical GA can be given as follows:

- (1) Initialize a population in which chromosomes are generated randomly.
- (2) Calculate the fitness of each chromosome in the population.
- (3) Generate new chromosomes by the following steps: (a) select two chromosomes using the proportional fitness selection, and then cross the selected chromosomes to obtain a child chromosome; (b) select one chromosome using the proportional fitness selection, and apply uniform mutation to it with a mutation rate to produce another child chromosome.
- (4) Update the population. Add new chromosomes to the population and dispose of the worst chromosomes to maintain the size of the population.
- (5) If the stopping criteria have not been met, return to Step 2.

GA is first proposed by Holland [24] to solve computationally intractable problems. The development and success of GAs have greatly enriched the computational approaches for the optimization problem. Particularly, GA is very suitable for combinatorial optimization problems whose structure and character can avoid the tedious coding and decoding works of chromosomes.

**3.3. The IFA-GA Algorithm.** FA has a good convergence speed due to the attraction of fireflies. However, the solution of FA may fall into a local optimum because of its limited exploration capability, especially when the fireflies encounter extreme values. In contrast, GA can explore the solution space widely due to the crossover and mutation operators. However, the convergence rate of GA is relatively slow due to the lack of directionality. Fortunately, both FA and GA have specific and understandable procedures which are easy to implement. Furthermore, both of them are suitable to be hybridized with other optimizers due to their multimodalities. Inspired by these privileges, we introduce an IFA-GA algorithm by combining the desirable characteristics of FA and GA. The emergency logistics model of this paper includes location decisions and allocation decisions. Considering the characteristics of FA and GA algorithms, we plan to use FA to solve location decisions and use GA to solve allocation decisions. Before presenting the detailed implementation of the proposed hybrid algorithm, we give some schemes for improving the algorithm efficiency.

**3.4. Schemes for Improving the IFA-GA Algorithm.** Most of the metaheuristic algorithms would suffer from two problems: metaheuristic algorithms usually have an earlier convergence, and the initial solution and the diversity of the solution space often affect their search quality. To overcome

these two shortcomings, we enhance the proposed IF-GA algorithm through three schemes in this section.

**3.4.1. Scheme 1: Population Initialization.** The initial population has a significant effect on the convergence speed and the quality of the final solutions. In most metaheuristic algorithms, a population is generated by random initialization. In this paper, we initialize the population by a myopic strategy.

Suppose RTCs can be located at any point of two-dimensional space with the cardinality constraint that the total number of RTCs is no more than  $I$ . First, the LDPs are clustered into  $I$  groups by considering the weight of demand. The locations of RTCs are selected at the center of gravity in each group. Then, we get a solution  $\vec{z} = [z_1, z_2, \dots, z_I]$ . The population of location decisions is generated by random initialization around  $\vec{z}$ . Second, for each location decision, allocating the resources according to the proportion of demand, we can obtain an even solution  $\vec{x} = [x_{o1}, x_{o2}, \dots, x_{oI}]$ ,  $\vec{y}_1 = (y_{ij1})$ , and  $\vec{y}_2 = (y_{ij2})$ . Select two elements of  $\vec{x}$  randomly. The first element subtracts a random number which is added to the second element. The random number is not bigger than the first element. The corresponding rows of  $\vec{y}_2$  should be changed accordingly. For  $\vec{y}_1$ , we introduce a random matrix  $\vec{w} = (w_{ij})$ , each row of  $\vec{w}$  only has two nonzero elements in random columns with a random value  $\tilde{w}$  and  $-\tilde{w}$ . Adding  $\vec{y}_1$  to  $\vec{w}$ , we obtain a new  $\vec{y}_1$ . Finally, the initial population is obtained by repeating the above process.

**3.4.2. Scheme 2: The Improved Search Strategy of FA.** In this paper, FA is used to solve the facility location decision of RTCs. As is mentioned above, each decision variable  $z_i$  has a corresponding position. To be more realistic, we do not constrain the positions and only consider a cardinality constraint of RTCs. Therefore, we use coordinate variable  $X_i = (p_i^x, p_i^y)$  to replace  $z_i$  for simplification and define  $X = [X_1, X_2, \dots, X_I]$ . The objective function determines the fitness of firefly  $X$ . The direction and brightness of fireflies depend on the Euclidean distance between them and their fitness.

A dimmer firefly (worse solution) will be attracted by a brighter one (better solution) in FA. This mechanism is beneficial to the convergence of the algorithm. Thus, FA can find the optimal solution quickly. However, FA may fall into premature convergence if it encounters local extrema because the incomplete exploration of nondominated fireflies is one of the main reasons to cause the local convergence of FA. To overcome this weakness, we introduce a new update function for nondominated fireflies, described as follows:

$$X_{n+1} = X_n + \alpha_n(\varepsilon_n - 0.5)X_M, \quad (26)$$

where  $X_M = X_{\text{Max}} - X_n$  if  $\varepsilon_n > 0.5$  and  $X_M = X_n - X_{\text{Min}}$  if  $\varepsilon_n < 0.5$ .  $X_{\text{Max}}$  is the upper bound of search space, and  $X_{\text{Min}}$  is the lower bound. Furthermore, for dominated fireflies, we consider the attraction of the best solution, and the iterative equation is modified as follows:

$$X_{n+1} = X_n + \beta_0 e^{-\gamma r^2} (\tilde{X}_n - X_n) + \beta_0 e^{-\gamma r_{\text{opt}}^2} (\tilde{X}_{\text{opt}} - X_n) + \alpha_n \varepsilon_n, \quad (27)$$

where  $\tilde{X}_{\text{opt}}$  is the brightest firefly in population and  $r_{\text{opt}}$  is the distance between  $\tilde{X}_n$  and  $\tilde{X}_{\text{opt}}$ .

**3.4.3. Scheme 3: The Update Mechanism of Population.** A good algorithm should have an excellent performance in exploring the solution space and have a good ability in convergence. In this paper, the IFA is nested into GA for solving the location problem. GA already has an elimination mechanism that replaces poor solutions to maintain the size of the population. However, the number of eliminated solutions is usually fixed in the original GA. Reference [25] proposed an adaptive mechanism to replace poor solutions dynamically. The number of eliminated solutions decreases in the iterative process. Therefore, the algorithm first tends to explore the solution space better and then moves to the local search. With the same purpose, we introduce the mutated number of GA as follows:

$$q = \left\lceil \text{rand}(0, 1) * \text{PS} * \left(1 - \frac{t}{G_{\text{MAX}}}\right) \right\rceil, \quad (28)$$

where  $\lceil \cdot \rceil$  is the ceiling operator, PS is the population size,  $t$  is the current number of iterations, and  $G_{\text{MAX}}$  is the maximum number of iterations.

The procedure of IF-GA is described in Algorithm 1 in detail.

## 4. Numerical Studies

In order to illustrate the proposed model and validate the performance of IFA-GA, a small-scale instance with one SNS, 10 RTCs, and 40 LDPs is first used. Although the number of nodes in emergency logistics is not considerable, the proposed model has 820 ( $2 * 10 * 40 + 10 + 10$ ) decision variables. It is an extremely complex optimization problem. The results with different objective functions are presented to show the decision differences related to deprivation costs. Furthermore, a comparison is made between IFA-GA, FA, GA, and particle swarm optimization (PSO) based on the same population initialization. The adjustment method for the infeasible solutions in Algorithm 1 is also used in each algorithm to satisfy the constraints  $t$ . Finally, instances extracted from large-scale disasters are used to demonstrate the effectiveness of the designed IFA-GA algorithm furtherly. All experiments are implemented using MATLAB 2019 on a ThinkPad T460s laptop with Intel i5-6200u CPU, 2.3 GHz frequency, and 12 GB memory.

**4.1. Parameter Setting.** In this experiment, we initialize the affected areas in a  $100 * 100$  two-dimensional space randomly. The demand of each affected area is sampled uniformly in  $[50, 150]$ . We assume that the RTCs can be located at any point of the space; then, the distance between a selected RTC and the other node is easily calculated by the

**Input:**

The demands of affected areas. The location and inventory of SNS. The locations and inventories of candidate RTCs. The parameters of the deprivation cost, unsatisfied loss, and operation cost. The weight parameters in the objective function. The parameters of FA and GA algorithms.

**Output:**

The obtained optimal solution set.

**Initialization:**

Initialize the solution population as described in scheme 1. Calculate the distances between points. Calculate the delivery time of each LDP. Then, calculate the values of the fitness function associated with each solution by equation (6).

**Update:**

IFA: represent solutions by fireflies and fix the allocation variables of fireflies. Update the location variables as follows:

- (1) Fireflies are sorted to find the optimal individuals whose  $\text{rand} = 1$  are the nondominated fireflies, and the other individuals are the dominated fireflies.
- (2) For the nondominated fireflies, the update formulations are described as equation (26). For the dominated fireflies, the individuals move following the formulation equation (27). If there are multiple optimal solutions,  $\bar{X}_{\text{opt}}$  in equation (27) is chosen randomly.

GA: recalculating the value of the individual fitness function, the sum of them is denoted by  $\text{SUM}_F$ . Fix the location variables and update the allocation variables as follows:

- (1) Obtain the selection probability based on  $(\text{individual fitness}/\text{SUM}_F)$ , and select two individuals according to this probability. Get the crossover point by an integer at interval  $[1, I + 2J]$ . Do the crossover operation for selected individuals and get two new individuals. Correct the unfeasible individual by elimination and recrossover until all individuals are feasible. The number of newly generated individuals is determined by equation (28).
- (2) Calculate the number of mutated solutions by equation (28). For each mutated solution, select two adjacent variables  $y(i)$  and  $y(i + 1)$  randomly, and execute mutation by  $y(i) + (y_{\text{max}} - ((y(i) + y(i + 1))/2)) * \text{rand}$  and  $y(i + 1) - (y_{\text{max}} - ((y(i) + y(i + 1))/2)) * \text{rand}$ . Correct the unfeasible individual by elimination and remutation until all individuals are feasible.
- (3) An intermediate population is generated by merging the current population with the previous population. Then, the last  $q$  poor individuals in the previous population and the last  $q$  poor individuals in the newly generated population are eliminated from the next generation.

Repeat IFA and GA until the termination criterion is satisfied.

ALGORITHM 1: IFA-GA.

Euclidean distance equation. The cost parameters and other variables in the proposed model are shown in Table 1.

It is essential to select suitable parameters for meta-heuristic algorithms. Additionally, to evaluate the performance of the proposed IFA-GA, we compare it with the standard FA, GA, and PSO. The parameter settings of these algorithms are displayed in Table 2.

#### 4.2. Computational Results regarding Deprivation Costs.

As discussed above, the deprivation cost is an essential factor for the relief decision. To visually illustrate its impact on decision-making, we analyze the location results of RTCs which are shown in Figure 1. Because each RTC is linked to SNS, which is located at point  $(0, 0)$  in our setting, we ignore the paths between SNS and RTCs for simplification. Figure 1 has six pictures. The first three pictures (a), (b), and (c) present the RTCs' locations with a single objective. The subsequent pictures present the RTCs' locations with two and three objectives. Obj1 refers to the deprivation cost objective. Obj2 refers to the unsatisfied demand loss. Obj3 refers to the operation cost. By comparing Figures 1(a) and 1(c), we can find that the locations of RTCs are closer to the affected areas in (a) than in (b). It is realistic because closer to demand will shorten the delivery time. In Figure 1(b), the locations are strange at first glance. It should be noted that objective 2 does not have any path-related cost, so the locations move randomly in the algorithm and have no practical meaning.

TABLE 1: The values of parameters.

Notation	Value
$O$	1
$I$	10
$J$	40
$v$	20
$a$	2
$b$	100
$C_{OI}$	0.08
$C_{IJ}$	0.1
$C_i$	1000
$CV_i$	0.5
$Q_o$	2000
$Q_i$	100

Figures 1(d) and 1(e) confirm the random location results in (b), which have the same results as Figures 1(a) and 1(c), respectively. Figure 1(f) shows the tradeoff location results by objective 1 and objective 3. Figure 1 illustrates that the deprivation cost impacts RTCs' locations, which makes RTCs closer to LDPs.

4.3. Computational Results of Different Algorithms. In this section, we further present several cases to illustrate the effectiveness of the proposed algorithm. For the small-scale case, the iteration results of IFA-GA, FA, GA, and PSD are shown in

TABLE 2: The parameter settings of algorithms.

Algorithm	Parameter	Value
IFA-GA	Population size	200
	Number of iterations	300
	Maximum attractiveness $\beta_0$	0.1
	Absorption parameter $\gamma$	0.001
	Crossover probability	0.5
	Mutation probability	0.2
FA	Population size	200
	Number of iterations	300
	Maximum attractiveness $\beta_0$	0.1
	Absorption parameter $\gamma$	0.001
GA	Population size	200
	Number of iterations	300
	Crossover probability	0.5
	Mutation probability	0.2
PSO	Population size	200
	Number of iterations	300
	Social acceleration coefficient	2
	Personal acceleration coefficient	2

FIGURE 1: The comparison of location decision with the different objective function. (a) Obj1. (b) Obj2. (c) Obj3. (d) Obj1 + Obj2. (e) Obj2 + Obj3. (f) Obj1 + Obj2 + Obj3.

Figure 2. From Figure 2, we can see that the proposed IFA-GA has the best performance in both convergence and objective value. FA and PSD are almost unchanged because the flow balance constraints in the optimization model make the most newly generated solutions infeasible. GA has a certain convergence, but the objective values are much bigger than those of

FA. It should be noted that FA, GA, and PSD are implemented with the same population initialization as IFA-GA. If the population are initialized randomly, the results of FA, GA, and PSD will be much worse.

To compare the results detailedly, we carry out each algorithm 30 times. More detailed results are given in Table 3.

FIGURE 2: The comparison of objective values obtained by different algorithms.

TABLE 3: Numerical results on the small-scale instance.

Algorithm	Mean	Max	Min	STD	Time
IFA-GA	11641	11780	11529	91	51
FA	26246	26972	25586	555	409
GA	23685	23480	23994	191	123
PSO	22468	22242	22838	225	413

From Table 3, we can find that the proposed IFA-GA has better performance than the other algorithms. The mean, max, and min values of the objective obtained by IFA-GA are less than in the other algorithms. The standard deviation of objective values in IFA-GA is much lower than in other algorithms. Furthermore, the run time of IFA-GA is also less than other algorithms. The results of Table 3 indicate that the IFA-GA has better stability and efficiency in solving our proposed model.

Additionally, we conduct experiments with different problem sizes. Four large-scale instances are experimented for further comparison. The results are shown in Table 4.

From Table 4, we can find that the proposed IFA-GA obtains solutions with the best performance than the other algorithms in each instance. In both four cases, IFA-GA obtains the minimum objective value and the lowest deviation. Furthermore, IFA-GA also has the shortest run time. These gaps are to increase along with the problem size increases. FA has the worst performance in run time and stability. GA outdoes FA in each case, with almost the same objective values as PSD but a much lower run time. Additionally, the increase in LDPs brings more objective costs, but the increase in RTCs takes lower objective costs. The result can be obtained by comparing the case  $I = 20, J = 100$  with the case  $I = 50, J = 100$ . The reason is that the increase in RTCs can reduce the deprivation costs effectively, which

TABLE 4: Numerical results under different problem sizes.

enlightens us that more RTCs are recommended to be established when faced with large-scale disasters.

Based on the simulation results, we can derive some practical implications. First, RTCs should be located closer to rescue demand to decrease the human suffering caused by deprivation. Second, in a large-scale disaster scenario, more RTCs should be established to provide fast relief. In the theoretical aspect, we validated the efficiency of the proposed hybrid algorithm, which has an excellent performance in convergence and computation time.

## 5. Conclusions

Different disasters have affected most areas of the world and caused serious casualties and property losses in recent years. An effective emergency logistics occupies a pivotal position to relieve human suffering and mitigate losses after disasters. This paper proposes a multiobjective optimization model for relief distribution. The relief supplies are transferred in a three-level logistics network which includes an SNS, some RTCs, and LDPs. The location decision of RTCs and resource allocation decision from SNS to RTCs and from RTCs to LDPs should be made in postdisasters. We present three objectives, deprivation costs, unsatisfied demand costs, and logistics cost, in this location-allocation optimization model, in which several cardinality and flow balance constraints are considered simultaneously. Realizing the complexity of the problem, we design a novel IFA-GA algorithm by combining classical FA and GA. Three schemes are proposed to improve the effectiveness of the IFA-GA algorithm. The results from numerical studies provide several insights on the theory and practice of relief distribution, which also illustrate the validity of the proposed solution algorithm.

This study is not exhaustive. We only present a simplified model and ignore some factors which will make the model more complex. For example, the uncertainty factors, such as delivery time and quantity, are not considered in the proposed model. Multiple transport and multiple periods are also not investigated in our model. Therefore, we may extend the proposed model to an uncertain situation by using robust optimization theory or distributionally robust theory for future work. Furthermore, more hybrid algorithms that combine exact and metaheuristic approaches should be exploited to solve the proposed optimization model effectively in the future.

In irrigated areas, the intelligent management and scientific decision-making of agricultural irrigation are premised on the accurate estimation of the ecological water demand for different crops under different spatiotemporal conditions. However, the existing estimation methods are blind, slow, or inaccurate, compared with the index values of the water demand collected in real time from irrigated areas. To solve the problem, this paper innovatively introduces the spatiotemporal features of ecological water demand to the forecast of future water demand by integrating an artificial neural network (ANN) for water demand prediction with the prediction indices of water demand. Firstly, the ecological water demand for agricultural irrigation of crops was calculated, and a radial basis function neural network (RBFNN) was constructed for predicting the water demand of agricultural irrigation. On this basis, an intelligent control strategy was presented for agricultural irrigation based on water demand prediction. The structure of the intelligent control system was fully clarified, and the main program was designed in detail. The proposed model was proved effective through experiments.

## 1. Introduction

As a big agricultural country, China faces a severe shortage of agricultural irrigation water, owing to the low per-capita water resources and the imbalance between water supply and demand [1, 2]. Modern agriculture aims to achieve a high yield of high-quality crops in an ideal cycle. To promote agricultural development in China, it is very meaningful to reconstruct the irrigation water facilities in large irrigated areas, trying to detect an agricultural situation in real time, make reasonable plans for irrigation water consumption, and realize automatic water supply [3–5]. In irrigated areas, the intelligent management and scientific decision-making of agricultural irrigation is premised on the accurate estimation of the ecological water demand for different crops under different spatiotemporal conditions [6–8].

After analyzing the water supply and consumption features in local irrigated areas, Sun et al. [9] adjusted the weights of the indices in the current water consumption evaluation system through analytic hierarchy process (AHP) and constructed a time series prediction model to forecast

the available water resources, industrial water demand, domestic water demand, and agricultural water demand in the irrigated areas with different assurance rates, thereby balancing the water supply with water demand in these areas. Essaid and Caldwell [10] numerically simulated the irrigation water demand of sweet potatoes and peanuts, predicted the accurate water-saving potential of irrigated areas, and put forward an adjustment strategy of the irrigation system to improve the water utilization rate.

To make full use of irrigation water, most irrigated areas choose to renovate the traditional irrigation management mode based on high-resolution remote sensing images. The water demand of irrigated areas is usually inverted and predicted through accurate detection of block changes [11, 12]. Nejatijahromi et al. [13] established a deep semantic segmentation network to classify the planting areas of different types of crops and introduced multiple indices to image fusion during the preprocessing of remote sensing images. In this way, the spectral complexity and spatial resolution were improved, and the feature information of irrigated area images was enhanced. Pani and Mishra [14]

replaced the ordinary convolution and rectified linear unit (ReLU) of the U-Net semantic segmentation network with depthwise separable convolution and Mish activation function, respectively, thereby improving the classification accuracy of the planting areas of different crops. In addition, they constructed an inversion model for the water content in the soil at different depths, which couples the normalized difference vegetation index (NDVI) and automatic water extraction index. Foglia et al. [15] set up a dynamic multifactor prediction model for soil water content. Based on long short-term memory (LSTM) neural network, their model boasts a high prediction accuracy and a low degree of discretization. To predict water demand more accurately, Hassani and Shahdany [16] improved the multiplication of the Jacobian matrix in the Levenberg–Marquardt (LM) algorithm: this operation was replaced with gradient vector calculation and quasi-Hessian matrix. The improved LM algorithm was used as the learning algorithm for the fuzzy neural network of water demand prediction. The results show that the improved algorithm brings higher network learning efficiency and occupies a small storage space. Mimicking the information transmission mode of the cerebral cortex, Li et al. [17] designed a peaking mechanism for the structural growth and pruning of neural network and implemented it to predict the short-term water demand.

To a certain extent, the traditional estimation methods for the water demand in irrigated areas, namely, empirical formulas, hydrological methods, and microclimate methods, are blind and slow. Infrared remote sensing techniques can diagnose the water level by the physiological properties of crops, providing support to decision-makers in water development and management. However, these techniques are not accurate enough. To solve this problem, this paper combines an ANN for water demand prediction with the prediction indices of water demand. Section 2 computes the ecological water demand for nonfixed crops in the agricultural irrigated area, using the simple and direct area quota method. Section 3 predicts the water demand of crops in the agricultural irrigated area by integrating the radial basis function neural network (RBFNN) with autoregression model. Section 4 presents an intelligent control strategy for agricultural irrigation based on water demand prediction and constructs a precision agricultural irrigation intelligent control system, which encompasses a distributed wireless sensor subsystem, a water demand prediction subsystem, and an agricultural irrigation control subsystem. The proposed model was proved effective through experiments.

## 2. Calculation of Ecological Water Demand

The water demand for agricultural irrigation refers to the amount of irrigation water that must be consumed to maintain the normal growth of crops. Given the uneven distribution of population and farmland in China, the planting area of water-demanding regular rice varieties is growing, and the homogeneity of crops is on the rise. To optimize water allocation and realize intelligent control of agricultural irrigation, it is important to scientifically calculate and accurately predict water demand indices of agricultural irrigation.

Firstly, this paper uses the relatively simple and direct area quota method to compute the irrigation water demand of an irrigated area: multiply the size of the irrigated area with the ecological water demand quota of each crop and superimpose the products. Let  $ZS$  be the total water demand of the irrigated area and  $ZS_i$ ,  $P_i$ , and  $Q_i$  the ecological water demand, planting area, and ecological water demand quota of crop  $i$ , respectively. Among them, the quota can be obtained through experimental analysis and theoretical calculation. Assuming that there are  $m$  crops, then  $ZS$  can be calculated by

$$ZS = \sum_{i=1}^m ZS_i = \sum_{i=1}^m P_i \cdot Q_i. \quad (1)$$

In arid areas, crop growth mainly relies on groundwater and irrigation. This paper directly estimates the actual ecological water demand of crops in arid and semiarid areas, using phreatic water evaporation, which requires only a few parameters. Let  $WZS$  be the total ecological water demand of vegetation;  $ZS_{ij}$  and  $DV_{ij}$  the ecological water demand and phreatic water evaporation of crop  $i$  in month  $j$ , respectively; and  $\Psi_V$  the vegetation index of crops. Then,  $ZS$  can be calculated by

$$ZS = \sum_{i=1, j=1}^m ZS_{ij} = \sum_{i=1, j=1}^m P_i \cdot DV_{ij} \cdot \Psi_V. \quad (2)$$

Let  $e_1$  and  $e_2$  be empirically coefficients;  $DB_i$  the buried depth of groundwater at the location of crop  $i$ ;  $DB_{\max}$  the ultimate buried depth for phreatic water evaporation; and  $DV_j^\theta$  the surface evaporation of regular evaporation dish in month  $j$ . Then,  $DV_{ij}$  can be calculated by Aver'yanov's phreatic evaporation formula:

$$DV_{ij} = e_1 \left( \frac{1 - DB_i}{DB_{\max}} \right)^{e_2} DV_j^\theta. \quad (3)$$

During crop growth, transpiration consumes the largest amount of water. In this paper, the actual evapotranspiration is used to determine the ecological water demand of each crop. The calculation assumes that the water supply is sufficient. Let  $DV_j^*$  be the evapotranspiration caused by the transpiration of the reference crop in month  $j$  and  $\Psi_T$  the soil moisture correction coefficient of the irrigated area. Then, the maximum ecological water demand of a crop can be calculated by

$$ZS = \sum_{i=1, j=1}^m ZS_{ij} = \sum_{i=1, j=1}^m P_i \cdot DV_{ij}, \quad (4)$$

where  $DV_{ij}$  can be calculated by

$$DV_{ij} = DV_j^* \times \Psi_V \times \Psi_T. \quad (5)$$

The Penman–Monteith equation, recommended by The United Nations Food and Agriculture Organization (FAO), was adopted to compute the potential evaporation  $DV^*$  of crops in an irrigated area. Let  $\Gamma$  be the slope between the temperature change curve and the saturated vapor pressure;  $FS$  the net radiation of crop surface;  $TH$  the heat flux of the

soil in the irrigated area;  $\delta$  the psychrometer constant;  $T_{AV}$  the mean temperature;  $v_f$  the wind speed at a fixed height; and  $AV_B$  and  $AV_R$  saturated and actual vapor pressures, respectively. Then,  $DV^*$  can be calculated by

$$DV^* = \frac{0.4\Gamma(FS - TH) + \delta(900/(T_{AV} + 273))v_f(AV_B - AV_R)}{\Gamma + \delta(1 + 0.35v_2)}. \quad (6)$$

The slope  $\Gamma$  can be calculated by

$$\Gamma = \frac{4100 \times 0.62(17.3T_{AV}/(T_{AV} + 327.3))}{(T_{AV} + 327.3)^2}. \quad (7)$$

The net radiation of crop surface  $FS$  is the difference between net short-wave radiation  $FS_D$  and net long-wave radiation  $FS_C$ :

$$FS = FS_D - FS_C. \quad (8)$$

Let  $FS_S$  be solar radiation;  $m_S$  the actual sunshine hours; and  $M_S$  the most probable sunshine hours. Then,  $FS_D$  can be calculated by

$$FS_D = 0.78 \left( \frac{1}{4} + \frac{m_S}{2M_S} \right) FS_S. \quad (9)$$

$$FS_C = 4.903 \times 10^{-9} \left( 1.35 \frac{0.25 + 0.5(m_S/M_S)}{0.75 + 2 \times (c/100000)} - 0.35 \right) (0.34 - 0.14\sqrt{AV_R}) \left( \frac{(MT_{\max-j})^4 + (MT_{\min-j})^4}{2} \right). \quad (14)$$

Let  $DT_{\max-k}$  and  $DT_{\min-k}$  be the daily mean maximum and minimum temperatures of day  $k$ ;  $SD_{AV}$  the daily mean relative humidity; and  $v_c$  the wind speed at the altitude of  $c$  meters. Then, the saturated vapor pressure  $AV_B$  can be calculated by

$$AV_B = \frac{r(DT_{\max-k}) + r(DT_{\min-k})}{2}, \quad (15)$$

where  $r$  is exponentiation:

$$r(t) = 0.62e^{17.28t/(t+327.3)}. \quad (16)$$

The actual vapor pressure  $AV_R$  can be calculated by

$$AV_R = \frac{AV_B \times SD_{AV}}{100}. \quad (17)$$

Suppose the height is fixed at 2 m. Then, the mean wind speed can be calculated by

$$v_f = v_c \frac{4.9}{\ln(67.8c - 5.4)}. \quad (18)$$

### 3. RBFNN-Based Water Demand Prediction

**3.1. Network Construction.** To predict the crop water demand in the agricultural irrigated area, this paper sets up a prediction model based on RBFNN, which boasts a strong

approximation ability and a fast convergence speed. As shown in Figure 1, the RBFNN consists of three layers: an input layer that connects and transmits external signals, a hidden layer that realizes RBF mapping, and an output layer that performs linear summation. The input layer receives the sample data about the parameters required to compute the crop water demand in the target irrigated area. The RBF mapping, which underpins the nonlinear transform between the input layer and hidden layer, constitutes the basis of the hidden layer. Therefore, the output of the RBFNN can be regarded as a linear combination of basis functions derived from hidden layer nodes.

Let  $\Phi_S$  be the solar constant;  $\theta$  the latitude; and  $DO$  the day order. Then, solar radiation  $FS_S$  can be calculated by

$$FS_S = \frac{24 \times 60}{\pi} \times \Phi_S \times RDR_{SE} [HA_S \sin \theta \sin \gamma + \cos \theta \cos \gamma HA_S]. \quad (10)$$

The reciprocal  $RDR_{SE}$  of the relative distance between the Sun and the Earth can be calculated by

$$RDR_{SE} = 1 + \frac{1}{30} \cos \left( \frac{2\pi}{365} \times DO \right). \quad (11)$$

The solar hour angle  $HA_S$  in formula (10) can be calculated by

$$HA_S = ar \cos [-\tan \theta \tan \gamma]. \quad (12)$$

The solar magnetic declination  $\gamma$  in formula (10) can be calculated by

$$\gamma = 0.4 \sin \left( \frac{2\pi}{365} DO - 1.4 \right). \quad (13)$$

Let  $MT_{\max-j}$  and  $MT_{\min-j}$  be the maximum and minimum absolute temperatures of month  $j$ . Then, the net long-wave radiation  $FS_C$  can be calculated by

The RBF centers were solved through clustering. Let  $B: \mathbb{R}^K \rightarrow \mathbb{R}^O$  be the mapping response of RBF;  $a_i$  the data of index sample  $i$  imported to the input layer, that is, the real-time data series of water demand indices for agricultural irrigation;  $A = (a_1, a_2, \dots)^T \in \mathbb{R}^K$  the input vector;  $b_k$  the output of output layer node  $k$ ;  $\omega_k$  the connection weight between all hidden layer nodes and output layer node  $k$ ;  $W_G$  the center  $G$  of hidden layer nodes;  $J$  and  $K$  the number of hidden layer centers and the total number of input layer nodes;  $F(\bullet)$  the basis function; and  $\|\cdot\|$  the Euclidean norm. Then, the RBFNN output can be expressed as

$$b_k = \sum_{i=1}^K \sum_{G=1}^J \omega_i(i, H) F \left( \|a_i - W_G\|^2 \right). \quad (19)$$

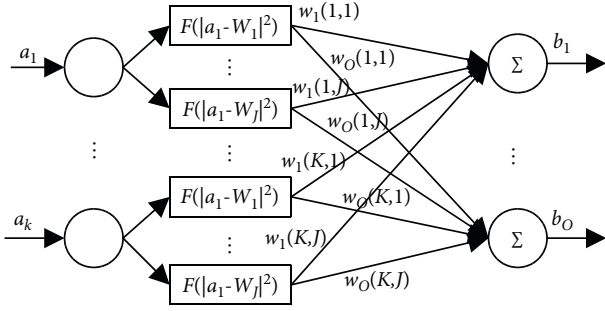

FIGURE 1: Structure of RBFNN.

The hidden layer output based on Gaussian function can be calculated by

$$c_i = \theta \left( \sum_{i=1}^K \sum_{G=1}^J \frac{(a_i - W_G)^2}{\gamma_G^2} \right). \quad (20)$$

To sum up, RBFNN has three adjustable parameters: variance, center position, and output layer weight. Under the premise that training index samples can reflect the essence of crop water demand prediction in the irrigated area,  $n_w$  uniformly distributed centers were selected with an interval of  $q$ , that is, network centers. On this basis, the variance  $s = q / (2n_w)^{-2}$  of the Gaussian function can be solved.

**3.2. Determination of Network Parameters.** The RBF centers were determined through fuzzy  $k$  means (FKM) clustering of unsupervised self-organizational learning. Let  $A_{US} = (A_1, A_2, \dots, A_N)$  be the set of  $N$  index samples imported for unsupervised learning;  $U$  the number of clusters;  $D = [d_{il}]_{U \times N}$  the membership matrix of sample  $l$  in cluster  $i$ ;  $d_{il}$  the membership function of sample  $l$  in cluster  $i$ ;  $O = [o_1, o_2, \dots, o_U]$  the set of cluster centers;  $\xi_{il}$  the distance from  $a_l$  to  $o_i$ ;  $\varepsilon$  the weighted index of the network; and  $\sigma$  the allowable error. To minimize the weighted sum of squares of the distance between sample center and cluster centers, an objective function of classification  $J(D, O) = \sum_{l=1}^N \sum_{i=1}^U (d_{il})^N (\xi_{il}^2)$  can be constructed and minimized. The detailed operations go as follows:

Step 1: initialize the network, set the initial number of iterations  $t = 0$ , and determine the initial values of  $N$ ,  $U$ , and  $D^{(t)}$ .

Step 2: derive the following from  $D^{(t)}$ :

$$o_i = \frac{1}{\sum_{l=1}^N (d_{il})^\varepsilon} \sum_{l=1}^N (d_{il})^N a_{il}, \quad i = 1, 2, \dots, U. \quad (21)$$

Step 3: suppose  $l = 1, \dots, N$ . The set of clusters satisfying the condition that the distance between sample center and cluster center is zero can be expressed as

$$Q_l = \{i | 0 \leq i \leq U, \xi_{il} = \|a_l - o_i\| = 0\}. \quad (22)$$

The set of the other clusters can be described by

$$Q^* = \{1, 2, \dots, U\} - Q_l. \quad (23)$$

If  $Q_l$  is an empty set, then

$$d_{il} = \frac{1}{\sum_{j=1}^U (\xi_{il} / \xi_{jl})^{2/(\varepsilon-1)}}. \quad (24)$$

If  $Q_l$  is not an empty set, then  $d_{il} = 0$ ,  $i$  belongs to set  $Q_l$ , and  $\sum_{i \in Q_l} d_{il} = 1$ . Make  $l = l + 1$ , and return to the start of Step 3.

Step 4: if  $\|D^{(t)} - D^{(t+1)}\|$  is smaller than the learning convergence rate  $\eta$ , then terminate the network training. If  $\|D^{(t)} - D^{(t+1)}\|$  is greater than  $\eta$ , add one to the number of iterations and return to the start of Step 2.

The hidden node width of RBFNN was determined by the  $k$ -nearest neighbors (KNN) algorithm. First, the sum of the distances from a sample center to the centers of the nearest  $K$  clusters was averaged. Then, the width was derived from the mean value. Let  $o'_j$  be the sample center closest to cluster center  $o_i$ . Then, the width of hidden layer nodes can be expressed as

$$HW_i = \frac{1}{l} \sum_{j=1}^l \|o_i - o'_j\|. \quad (25)$$

Let  $\text{Gauss}(a)$  be the Gaussian function. Then, the RBF can be approximated by the following function:

$$AF(a) = \sum_{i=1}^U \omega_i \times \text{Gauss}(\|a - o_i\|). \quad (26)$$

Solving the approximation function is equivalent to minimizing the following cost function by adjusting the weight set  $\{\omega_i | i = 1, 2, \dots, U\}$ :

$$\begin{aligned} \Phi(AF^*) &= \sum_{l=1}^N [\xi_l - AF(a_l)]^2 + \mu \|NOR^*\|^2 \\ &= \sum_{l=1}^N \left[ \xi_l - \sum_{i=1}^g \omega_i \text{Gauss}(\|a_l - o_i\|) \right]^2 + \mu \|NOR^*\|^2, \end{aligned} \quad (27)$$

where the first term is the standard error and the second term is the regularization term to satisfy the requirements on continuity and smoothness. Formula (27) can be sorted out as

$$\begin{aligned} \Phi(U^*) &= \sum_{l=1}^N [\xi_l - \text{Gauss} \cdot \omega]^2 + \mu (NOR^*, NOR^*)_M^2 \\ &= \|\xi_l - \text{Gauss} \cdot \omega\|^2 + \mu \omega^T H_0 \omega, \end{aligned} \quad (28)$$

where

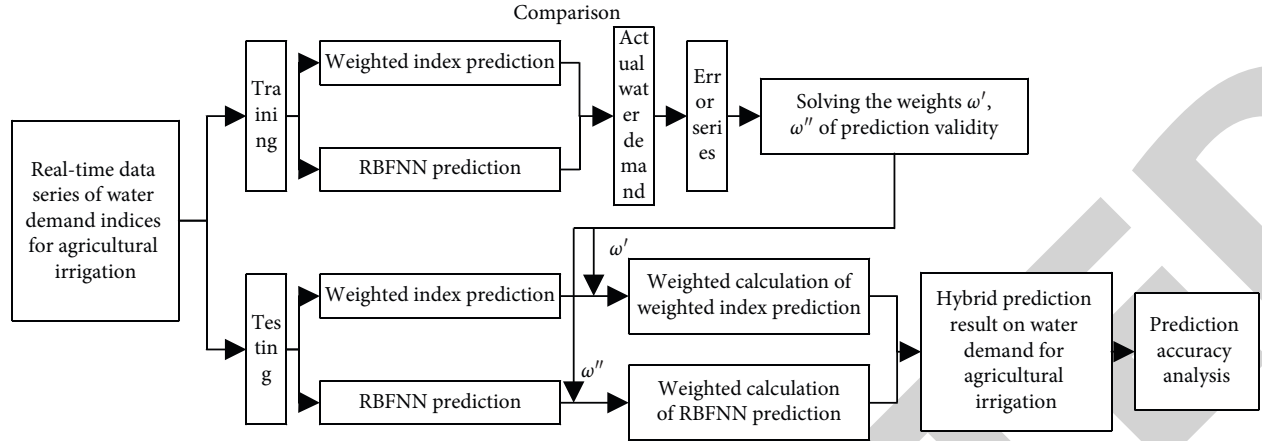

FIGURE 2: Steps of our hybrid prediction model.

$$\begin{aligned} \xi &= (\xi_1, \xi_2, \dots, \xi_N)^T; \\ \omega &= (\omega_1, \omega_2, \dots, \omega_U)^T, \\ \text{Gauss} &= \begin{bmatrix} g(a_1, o_1) & g(a_1, o_2) & \dots & g(a_1, o_U) \\ g(a_2, o_1) & g(a_2, o_2) & \dots & g(a_2, o_U) \\ \vdots & \vdots & \dots & \vdots \\ g(a_N, o_1) & g(a_N, o_2) & \dots & g(a_N, o_U) \end{bmatrix}. \end{aligned} \quad (29)$$

Minimizing  $\Phi(AF^*)$ ,

$$(g^T g + \mu g_0) \omega = g^T \xi. \quad (30)$$

The solution of the RBF approximation function should be normalized by

$$\omega = (g^T g + \mu g_0)^{-1} g^T \xi. \quad (31)$$

After setting  $l=l+1$ , the network iteration can be described by

$$\omega_{l+1} = \omega_l - \chi \frac{\gamma \Phi(U)}{\gamma \omega_k} = \omega_l - \chi [(g^T g + \mu g_0) \omega_l - g^T \xi]. \quad (32)$$

**3.3. Construction of Hybrid Prediction Model.** For accurate prediction of the water demand of agricultural irrigation, this paper combines RBFNN with an autoregression model into a water demand prediction model. In the model, the coefficient of the autoregression function can be approximated by the RBFNN.

Let  $u_b$  be the order of the model;  $O_i^j$  the center of RBFNN index samples;  $\mu_l$  the scale ratio;  $v_0$  and  $v_{bi}$  the state coefficients of the model;  $s_i^0$  and  $s_{il}^s$  the vector constants of the model;  $A(t-1)$  the index sample determining the output state of the time-varying model; and  $NO(t)$  the white noise. Then, the proposed prediction model can be established as

$$\begin{cases} b(t) = v_0 \left( A(t-1) + \sum_{i=1}^{u_b} v_{bi} (A(t-1)) b(t-i) + NO(t) \right), \\ v_0 (A(\tau-1)) = s_0^0 + \sum_{l=1}^N e^{-\mu_l^b} \|A(\tau-1) - O_l^b\|_2^2, \\ v_{bi} (A(\tau-1)) = s_{i0}^b + \sum_{l=1}^N s_{il}^b e^{-\mu_l^b} \|A(\tau-1) - O_l^b\|_2^2, \\ O_l = (O_{l,1}, O_{l,2}, \dots, O_{l,N})^T. \end{cases} \quad (33)$$

The weighted prediction result obtained from the water demand indices in Section 2 was combined with the prediction result of the RBFNN in Section 3, using validity weights. Figure 2 explains the steps of our hybrid prediction model. Firstly, the real-time data series of water demand indices for agricultural irrigation was divided into a training set and a test set. The two sets were used separately to predict

the water demand. Then, the predicted water demand was compared with the actual water demand of the agricultural irrigated area. The error between them was reduced to realize intelligent control of agricultural irrigation. Then, the validity weights  $\omega'$  and  $\omega''$  of the two methods were calculated.

The core of the intelligent control system for agricultural irrigation is a single-chip microcomputer (SCM) connected

to a triode amplifier circuit, which drives a relay. The opening/closing of the solenoid valve is controlled by the contact of the relay. Because of the small power of the selected solenoid valve, the triode type being adopted can stabilize the voltage and current and ensure the reliable functioning of the system. The soil humidity sensor transmits the humidity to the irrigation monitoring control system. The read humidity is compared with the preset lower bound of humidity to control the level at the pins of the SCM, in order to execute the irrigation mode.

During the intelligent control of actual agricultural irrigation,  $\omega'$  and  $\omega''$  change with the updates of the control signals of the irrigation solenoid valve, in order to improve the precision of irrigation control.

Similarly, the test set was predicted separately by two methods. Then, the final hybrid prediction result was obtained through the weighted calculation, using the validity weights  $\omega'$  and  $\omega''$ . The final step is to evaluate the accuracy of water demand prediction.

#### 4. Intelligent Control Strategy Based on Water Demand Prediction

Based on the hybrid prediction of water demand for agricultural irrigation, the authors developed a precision irrigation intelligent control system (Figure 3), which encompasses a distributed wireless sensor subsystem, a water demand prediction subsystem, and an agricultural irrigation control subsystem. The agricultural irrigation control subsystem evaluates whether the target crop needs water by comparing soil humidity with predicted crop water demand. If the crop needs water, the solenoid valve will be launched for irrigation. The duration of irrigation will be controlled by the water quota for agricultural irrigation. Figure 4 shows the signal conversion in the distributed wireless sensor subsystem, which measures soil humidity in real time, and the agricultural irrigation control subsystem, which predicts the indices of crop water demand.

The analog signal from the wireless soil humidity sensor has a low voltage. After passing through the amplifier circuit, the voltage is increased to the useable level. Then, the analog signal is converted by the converter into a digital signal. After that, the SCM level is transformed by the chip into the level for the serial port of the host, which supports intelligent control.

The precision irrigation intelligent control system should operate rapidly while occupying a small memory. For this purpose, Keil  $\mu$  Vision 4.0, which contains efficient C compilers and project managers, was selected to compile the program code of the system. The main program flow is presented in Figure 5. Once the intelligent control system starts, the main program will be initialized, and the command will be read. When the water demand surpasses the actual soil humidity, the solenoid valve will be opened to start sparkling irrigation in the irrigated area. The irrigation will last until the end of the preset duration. Then, the valve will be closed to terminate the irrigation.

TABLE 1: Ecological water demand obtained by area quota method.

Crop	Irrigation quota	Current state			Predicted state		
		Area	Calculated water demand	Actual water demand	Area	Calculated water demand	Actual water demand
Soybean	5,100	35,712	1.856	1.235	78,512	4.371	3.464
Corn	4,960	89,643	4.182	2.372	93,256	4.325	3.375

## 5. Experiments and Results Analysis

In the agricultural irrigated area, the phreatic evaporation of crops is greatly affected by the actual atmospheric evaporation capacity. Figure 6 presents the monthly mean evaporations of different planting zones in the agricultural irrigated area, which were derived from the daily observation data. It can be inferred that the crop evaporation was relatively large from June to September. The change trend meets the actual variation of water demand.

During the estimation of the ecological water demand of vegetation, the key of the area quota method lies in determining the ecological water demand quota of each type of plant. In the target irrigated area, the irrigation quotas for soybean and corn are 5,100 and 4,960  $\text{m}^3/\text{hm}$ , respectively. Considering the planting areas and expansion goals of the crops in the current year, the area quota method was employed to compute the ecological water demands of soybean and corn in the irrigated area. The results (Table 1) show that the current ecological water demand of soybean and corn in the target irrigated area was 1.856 and 4.182  $\text{m}^3$ , respectively. The total water demand reached 6.028  $\text{m}^3$ . Under the expansion goals, the ecological water demand of soybean and corn was predicted as 4.371 and 4.352  $\text{m}^3$ , respectively. The total water demand reached 8.723  $\text{m}^3$ . The traditional agricultural irrigation control systems are very inefficient in water use. The irrigation water utilization coefficient is as low as 0.6. Based on this coefficient, the

actual ecological water demand of soybean and corn in the target irrigated area was 1.235 and 2.372  $\text{m}^3$ , respectively. The total water demand reached 3.607  $\text{m}^3$ . By contrast, our precision irrigation intelligent control system can elevate the utilization coefficient to 0.85. On this basis, the actual ecological water demand of soybean and corn in the target irrigated area was 3.464 and 3.375  $\text{m}^3$ , respectively. The total water demand reached 6.839  $\text{m}^3$ .

By the phreatic evaporation method, the ecological water demand of crops per unit area in the target irrigated area averaged at 2,749  $\text{m}^3/\text{hm}$ . The predicted values under the expansion goals are given in Table 2. It can be seen that the total annual ecological water demand of soybean in the irrigated area was 2.322  $\text{m}^3$ , and that of corn was 2.573  $\text{m}^3$ . The total water demand reached 4.895  $\text{m}^3$ .

By the vegetation evapotranspiration method, the mean ecological water demand of crops per unit area in the target irrigated area was 3,359  $\text{m}^3/\text{hm}$ . The predicted values under the expansion goals are given in Table 3. It can be seen that the total annual ecological water demand of soybean in the irrigated area was 2.841  $\text{m}^3$ , and that of corn was 2.597  $\text{m}^3$ . The total water demand reached 5.438  $\text{m}^3$ .

Figures 7 and 8 compare the predicted water demands for the target irrigated area and prediction errors, respectively. Table 4 sums up the absolute errors of water demand prediction by different methods. The error metrics include maximum absolute error, mean absolute error, and root mean square of absolute error. From Figures 7 and 8 and Table 4, it

	Method	Maximum	Mean	Root mean square
Water demand prediction	Chaotic method	0.3	0.115	0.1235
	RBFNN	0.15	0.0965	0.1053
	Our hybrid prediction method	0.13	0.028	0.0342

can be inferred that the chaotic model, traditional RBF model, and our hybrid prediction model all achieved high accuracy in forecasting the water demand in the irrigated area. However, the three error metrics of our model were way smaller than

those of other models. Therefore, our method can adapt well to the index value fluctuations in prediction and realize stable prediction performance, compared with the chaotic model and traditional RBF model.

## 6. Conclusions

This paper presents an intelligent control method for agricultural irrigation through ANN-based water demand prediction. Firstly, the ecological water demand for agricultural irrigation of crops was calculated, and an RBFNN was constructed for predicting the water demand of agricultural irrigation. Then, the authors developed an intelligent control strategy for agricultural irrigation based on water demand prediction, detailed the structure of the intelligent control system, and designed the main program. Through experiments, the ecological water demand for crops in the targeted irrigated area was separately calculated by the area quota method, the phreatic evaporation method, and the vegetation evapotranspiration method, providing the data support to the weighted prediction of water demand indices. Then, the authors compared the predicted water demands for the target irrigated area and prediction errors, respectively, and demonstrated that our method could predict the water demand in the irrigated area more accurately and stably than other models.

This paper preliminarily explores and discusses the calculation of agricultural irrigation water demand. There are several limitations of the work, which need to be improved in the future. (1) Due to data availability, the meteorological data are the mean of the three stations around the study area. Thus, the calculated evaporation may deviate from the actual evaporation in the study area. (2) The correlation between groundwater level and vegetation area is not fully demonstrated. The vegetation response to groundwater level needs to be deeply analyzed in the future.

## Data Availability

The data used to support the findings of this study are available from the corresponding author upon request.

## Conflicts of Interest

The authors declare that they have no conflicts of interest.

## Acknowledgments

Expressway, as the main artery of urban traffic, realizes the smooth operation of the whole urban road network through reasonably balancing the traffic flow. However, due to the lack of reasonable and effective traffic control, the safety and congestion of expressways are becoming more and more serious. The development of intelligent network technology provides a new idea to solve the control problem of expressways. In this paper, a data-driven ramp control model of urban expressway is constructed. The interaction of traffic information is realized through intelligent network connection technology. The cooperative control strategy of VSL and RM is adopted. The mutual feedback of VSL and RM is realized based on the improved METANET model. The simulation experiment based on VISSIM secondary development shows that the collaborative control strategy under the intelligent network environment could make the vehicle travel time reduced by 20.59% and the speed difference between adjacent sections of the expressway mainline by 34.07%, which realized the coordinated control of the mainline and the on-ramp under the intelligent network environment, alleviate the expressway traffic congestion, reduce the traffic pressure, and improve the efficiency of the road network.

## 1. Introduction

The sustained economic development has promoted the rapid growth of the transportation industry. The surge of motor vehicle ownership and urban traffic demand has also derived various traffic problems. Congestion has become a major problem in urban governance. Among them, the transportation efficiency of expressway has a significant impact on the smooth passage of urban traffic network. Due to the influence of urban traffic and road network, expressways have the characteristics of dense entrance and exit ramps, complex road conditions, and low speed limits [1]. How to improve the operation efficiency of expressways through the implementation of reasonable traffic control has become the focus of scholars at home and abroad.

The research scope of expressway abroad is very wide, including planning, design, operation, management, and other aspects. Ramp control method first appeared in the United States in 1963 and achieved good control effect at that time, which can improve the operation speed of road traffic flow and alleviate traffic congestion [2]. Since then, a

large number of scholars have carried out ramp metering (RM) and variable speed limit control (VSL). The scope of RM includes on-ramp and off-ramp. This study focuses on the analysis of on-ramp control methods. Carlson designed a simple local mainline traffic flow feedback controller; that is, the mainline traffic flow control (MTFC) is realized through VSL. This method does not need traffic demand prediction and is convenient for on-site implementation [3]. Walraven et al. used reinforcement learning to control the maximum allowable speed on the expressway, so as to optimize the mainline traffic flow. A series of simulation experiments show that this strategy can significantly reduce the congestion under high traffic demand, and the introduction of traffic prediction can also improve the control effect. At the same time, this strategy has sufficient robustness for speed and density control [4]. The research proposed above is only for a single ramp, ignoring the overall control of the road network. Carlson et al. combined RM and MTFC through VSL, evaluated its effect by simulation software, and gave the optimal control method by comparing with different control methods [5]. Han et al. proposed a model-based network

coordinated control method. The upper layer of the control system optimizes the total travel time of the system by controlling the total flow of the on-ramp into the mainline, and the lower layer distributes the optimal total flow to each on-ramp of the expressway. The robustness of the system is verified by simulation. The results show that it has less calculation and is suitable for field implementation [6].

Domestic scholars have also made some achievements in the integrated control of urban roads and expressways. Yu et al. proposed an optimal control model for the conditions of implementing VSL in expressway congestion areas and used simulation to prove that, compared with fixed speed limit, this method can reduce the system travel time by 7.45% [7]. Lian introduced CMEM model from the perspective of traffic benefit and environmental benefit and compared the application effect of joint control model through simulation [8]. The difficulty of traffic network integrated control is that when multiple control strategies are adopted at the same time, their mutual effects should be considered; otherwise the control effect will be affected and the traffic network will deteriorate.

To sum up, foreign scholars began to explore ramp control earlier and have many relatively mature control algorithms. Although domestic research started late, it has also made some achievements. Compared with the research on single ramp control, the research on multiramp coordinated control and road network linkage control is less, and the ramp control system of urban expressway still needs further research. At present, the ramp control strategy of expressway is lack of research on real-time control of vehicle flow under different traffic conditions.

The rise and development of intelligent networking technology provides a new idea for solving the problem of ramp control of urban expressway. Intelligent networked transportation system [9] refers to a joint control system formed by cloud computing, big data, and Internet of things technologies. With the continuous advancement of artificial intelligence and network communication technology research, automobile intelligence and network connection have become global research focus. The definition of intelligent connected car is equipped with advanced on-board sensors, controllers, actuators, and other devices and integrates modern communication and network technology to realize vehicle to everything (V2X) intelligent information exchange and sharing, complex environment perception, intelligent decision-making, and collaboration of a new generation of cars with functions such as control, safe, and efficient driving, and ultimately replacing human operation [10, 11]. In the intelligent networking environment, wireless communication technology can be used to complete information exchange between vehicles, vehicles and roadside facilities, which helps managers obtain accurate road conditions in real time and realize accurate control of vehicles.

At present, the research on ramp control in intelligent network environment is still in the exploratory stage. The theory and practical application are far from mature as the classical ramp control strategy. Foreign researches on ramp control in intelligent network environment mostly focus on the control of vehicle merging, the safety

influencing factors of vehicle merging, and related simulation evaluation. Sakaguchi et al. proposed the import control algorithm based on virtual vehicle and the data transmission method of vehicle to vehicle. Lu et al. proposed a vehicle safety import control algorithm based on wireless communication. Qiao et al. used a deep Q network to build a reinforcement learning model to solve the problem of unmanned car ramp merging. These methods mainly discussed the single-point ramp merging control from the perspective of workshop communication and bicycle control and lacked control of vehicles in the ramp area, coordination, and guidance of traffic flow [12]. Zhang proposed a method to control the on-ramp traffic flow of an expressway under the condition of vehicle-road coordination and conducted simulation experiments on the mainline and the ramp in different traffic conditions. The results show that the method can reduce the on-ramp delay in the peak state by 19.2%, and traffic conflicts are reduced by 32.3% [13]. Luo and Jiang proposed an optimization algorithm for ramp merging trajectory in a networked environment. The simulation experiment proved that the proposed model can reduce the total delay of vehicles by 59.7% and realized that vehicles can pass the ramp traffic area at a higher speed [14]. Miao proposed a multiramp collaborative control framework in a vehicle-road collaborative environment and then established a simulation example based on the Paramics simulation platform and analysed the response sensitivity of control cycle, distance cost, and control rate, but the control strategy is mainly through traffic guidance in a larger range that is realized without precise control of bicycles [15]. At present, the research on ramp control and simulation under the environment of intelligent networking focuses on the microresearch on the merging control of ramp vehicles and lacks coordinated control of vehicles in the ramp area of expressways. The reason is that the existing mainstream traffic simulation software does not fully consider the impact of the intelligent network environment on the traffic state and traditional control methods in the ramp area. It is necessary to realize the intelligent network environment and related logic control through secondary development or independent development, which has high requirements for researchers' program design and writing. Therefore, it is of great significance to study the ramp control in the intelligent network environment.

Based on the above analysis, the focus of this paper is to study the cooperative control of vehicles in the ramp area of expressways with the help of intelligent network technology. The framework of expressway ramp control system and the expressway ramp collaborative control model in intelligent network environment is proposed. Considering the cooperative control of mainline VSL and RM, the dynamic change process of mainline traffic flow on expressway is described and predicted based on the improved METANET model. Through the secondary development of simulation software, the reliability of the proposed control model is verified, which lays a foundation for further research.

## 2. Expressway Ramp Control System in Intelligent Networked Environment

*2.1. Communication Requirements of Intelligent Networked Systems.* Traffic information is the core content of the intelligent networked system. The expressway ramp control system in the intelligent networked environment puts forward further requirements for the perception and interaction of traffic information.

*2.1.1. Traffic Information Perception.* In the traditional driving environment, the driver mainly obtains external traffic information through sensory organs, such as vehicle operating conditions and environmental information, road instruction information, etc. In the intelligent networked environment, information can also be obtained through on-board sensors, etc., and information can be shared between vehicles, which greatly reduces the error of traditional information perception. Traffic information perception is the basis of information interaction. It can provide data sources for intelligent networked systems. The specific information it collects includes perception of various operating conditions in vehicle operation; perception of expressway environment; vehicles and objects perception; perception of vehicle location, etc.

*2.1.2. Traffic Information Interaction.* Traffic information interaction is a process of information transmission, sharing, and exchange. Through information interaction, each node of the Internet of Vehicles can independently obtain information about the environment and other nodes [16]. The communication of the intelligent network system mainly includes vehicle-vehicle (V2V), vehicle-infrastructure (V2I), vehicle-pedestrian (V2P), and vehicle-external network (V2N) [17]. V2X is the key technology of the future intelligent transportation system. It enables real-time data exchange between vehicles and the environment, thereby obtaining real-time traffic data information, alleviating congestion, reducing accidents, and improving the overall efficiency of the road network.

*2.2. The Overall Framework of the Expressway Ramp Control System.* This paper proposes an urban expressway ramp control system in an intelligent networked environment. Its control structure is shown in Figure 1. It consists of the mainline, on-ramp, and vehicle control subsystems. The control goal of the expressway mainline control subsystem is to implement VSL on the upstream vehicles of the mainline to relieve the bottleneck of the expressway. The system consists of the mainline, the ramp side unit RSU, on-board equipment, and the traffic information management control centre. The control objective of the on-ramp control system is to restrict the number of vehicles entering the expressway during the control period and reduce traffic delays in the confluence area. The system consists of the mainline, on-ramp RSU, on-ramp queuing detector, on-ramp and traffic information management control centre, and so on. The on-

board control subsystem is composed of vehicles equipped with on-board equipment in the ramp control area. Its main function is to send vehicle information to the roadside unit while receiving instructions from the ramp layer control system and pass through the ramp in turn according to the given traffic strategy.

*2.3. On-Ramp Control System.* The on-ramp control system is composed of the mainline, on-ramp RSU, on-ramp queuing detector, and on-ramp and traffic information management control centre. The function of the mainline and on-ramp RSU is to obtain real-time traffic status information on the upstream section of the mainline and the on-ramp. At the same time, the on-board equipment responds to the demand to send vehicle driving information to the mainline and on-ramp RSU, and the RSU transmits the received information to the on-ramp control centre in real time. The on-ramp control centre determines the on-ramp control strategy by sharing information with the traffic information management control centre, combined with the mainline operation status, and sends this control command to the on-ramp vehicle through the on-ramp RSU. After receiving the instruction, the on-board equipment adjusts the driving behavior of the vehicle and adopts slowing down or stopping and waiting. The function of the on-ramp queuing detector is to detect the length of the ramp queuing and send the detection information to the on-ramp control centre in time. When the ramp queuing has reached the maximum queuing length and the expressway confluence area is blocked, the ramp control centre needs to issue instructions in time to stop the flow of traffic and close the entrance ramp (see Figure 2).

## 3. Cooperative Control Model in the Intelligent Networked Environment

*3.1. The Collaborative Control Process of Expressway Ramps in the Environment of the Internet of Vehicles.* The expressway ramp cooperative control process is specifically described as follows:

- (1) Use the traffic flow model to predict the traffic state of the mainline of the expressway.
- (2) Set the objective function and constraint conditions of the cooperative control system and obtain the optimal ramp regulation rate and variable limit rate through NSGA-II Algorithm solving and act on the system.
- (3) According to the obtained optimal ramp adjustment rate, adjust the ramp inflow to perform ramp control.
- (4) Adjust the vehicle's desired speed according to the obtained optimal variable speed limit for mainline speed guidance control.
- (5) Run the simulation to obtain the traffic flow state after the collaborative control. In the next rolling cycle, repeat the above steps to achieve rolling optimization.

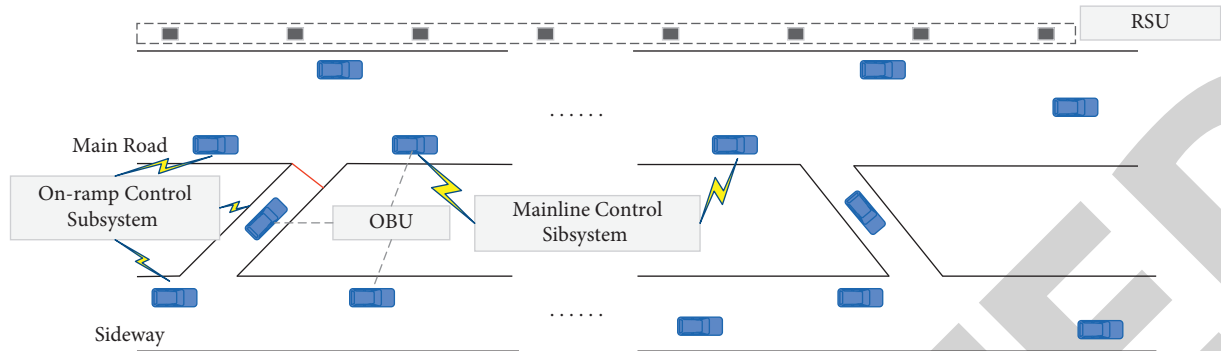

FIGURE 1: Schematic diagram of the expressway ramp control system in the intelligent network environment.

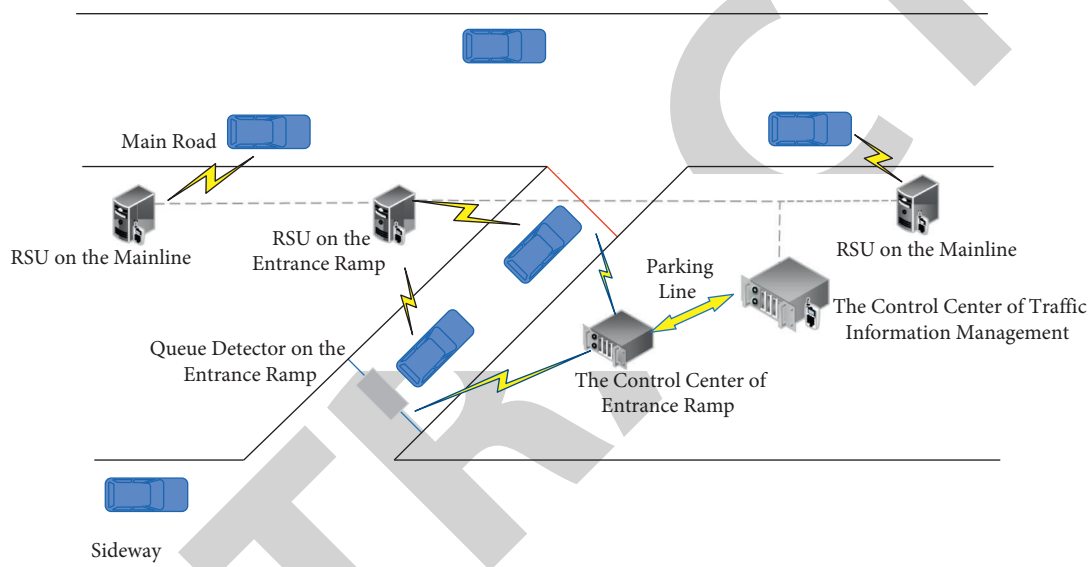

FIGURE 2: Schematic diagram of the on-ramp control system.

### 3.2. Improved METANET Model

**3.2.1. METANET Basic Model.** According to the accuracy of the description of the road state by the traffic flow model, it is divided into three types: macromodel, mesomodel, and micromodel. The micromodel is to study the law of traffic flow at a certain point or section in a short period of time. Currently, the commonly used micromodels include car following and lane changing models; the macromodel mainly discusses the relationship between the three elements of traffic flow (flow, speed, and density) and uses it as a basis to describe the general traffic characteristics of the road, which is specifically expressed as the temporal and spatial changes and distribution laws of the traffic flow state [18]; the mesoscopic model is between the two, and it has less calculations than the microscopic model and is more expensive than the macroscopic model. High accuracy [19] is suitable for analysing regional traffic conditions. After more than half a century of continuous research, the traffic flow model has developed to a relatively complete level, which can accurately describe the real behavior of traffic flow [20].

At present, the more typical macromodels describing the state of traffic flow include LWR model [21], CTM model [22], and METANET model [23]. Compared with the LWR model and the CTM model, the METANET model considers the dynamic change process of speed more comprehensively. This model is also the most widely used macroscopic model. Therefore, this study uses the METANET model to describe the dynamic process of traffic flow.

The METANET model can be used to describe the macroscopic traffic flow operating state of the road [24]. The main idea is to discretize the traffic wave, divide the expressway traffic flow into several nodes and road sections, and predict the traffic state of each road section at the next moment based on the current traffic state of each road section and the connection between adjacent road sections. In order to realize the estimation of traffic flow status and basic parameters [25], the model is divided into segments  $i$  as shown in Figure 3.

The METANET model mainly focuses on the relationship between flow, speed, and density. The basic model of the road section is as follows:

FIGURE 3: METANET traffic flow model unit diagram.

$$q_i(k) = \rho_i(k) \cdot v_i(k) \cdot \lambda_i, \quad (1)$$

$$\rho_i(k+1) = \rho_i(k) + \frac{T}{L_i \lambda_i} [q_{i-1}(k) - q_i(k) + h_i(k) - s_i(k)], \quad (2)$$

$$v_i(k+1) = v_i(k) + \frac{T}{\tau} \{H[\rho_i(k)] - v_i(k)\} + \frac{T}{L_i} v_i(k) [v_{i-1}(k) - v_i(k)] - \frac{f T}{\tau L_i} \frac{\rho_{i+1}(k) - \rho_i(k)}{\rho_i(k) + \kappa}, \quad (3)$$

$$H[\rho_i(k)] = v_f \cdot \exp\left[-\frac{1}{\alpha_i} \left(\frac{\rho_i(k)}{\rho_{cr}(k)}\right)^{\alpha_i}\right], \quad (4)$$

$$h_i(k) = \min\left\{\left[d_i(k) + \frac{\omega_i(k)}{T}\right], Q_i(k)\right\}, \quad (5)$$

$$\omega_i(k) = \omega_i(k-1) + T[d_i(k-1) - h_i(k-1)]. \quad (6)$$

In equations (1) to (6),  $\rho_i(k)$  is traffic density of road section  $i$  at time  $k$  (veh/km/lane);  $q_i(k)$  is the traffic flow of the road section  $i$  at the moment  $k$  (veh/h);  $h_i(k)$  is the inbound traffic volume of the section  $i$  at the moment  $k$  (veh/h);  $s_i(k)$  is the amount of traffic leaving the road section at the moment of (veh/h);  $T$  is the sampling period ( $h$ );  $L_i$  is length of road section  $i$  (km);  $\lambda_i$  is number of lanes in road section  $i$ ;  $v_i(k)$  is average traffic flow speed of section  $i$  at time  $k$  (km/h);  $H[\rho_i(k)]$  is desired speed (km/h);  $f$  is speed density sensitivity parameter;  $\tau$  is speed adjustment factor;  $\kappa$  is compensation coefficient to prevent  $\rho_i(k)$  from being too small;  $\rho_{cr}(k)$  is critical traffic flow density (veh/km/lane);  $\alpha_i$  is model coefficient;  $Q_i(k)$  is on-ramp capacity (veh/h);  $\omega_i(k)$  is the number of vehicles queuing at the entrance ramp at the moment of the road section  $i$ ;  $d_i(k-1)$  is the traffic demand of the on-ramp on the road section  $i$  at  $(k-1)$ , and 0 if there is no on-ramp.

The original METANET model is used to describe the state of the mainline traffic flow under collaborative control. Since the impact of the mainline VSL and RM on it is not discussed, the description is not accurate. Therefore, this article will comprehensively consider the effects of both to improve the original METANET traffic flow model.

### 3.2.2. METANET Model considering VSL

(1) *Desired Speed.* During the speed control of the mainline, it will have a certain impact on the speed of the expressway section. The expected speed needs to be corrected. The corrected expected speed model is as follows:

$$H[\rho_i(k)] = \min\left\{v_f \cdot \exp\left[-\frac{1}{\alpha_i} \left(\frac{\rho_i(k)}{\rho_{cr}(k)}\right)^{\alpha_i}\right], b_i(k)v_f\right\}, \quad (7)$$

where  $b_i(k)$  is variable speed limit, and value range is  $b_{\min,i}(k) \leq b_i(k) \leq 1$ ,  $b_{\min,i}(k) \in [0, 1]$ .

(2) *Velocity Density Sensitivity Coefficient.* The speed density sensitivity parameter  $f$  essentially means the partial derivative of the expected speed to the density. When the expected speed changes under the variable speed limit control, the speed density sensitivity parameter will also be affected. Therefore, the calculation of  $f_i(k)$  in this paper is as follows:

$$f_i(k) = -\frac{v_f}{\rho_{cr}(k)} \cdot \exp\left[-\frac{1}{\alpha_i} \left(\frac{\rho_i(k)}{\rho_{cr}(k)}\right)^{\alpha_i}\right]. \quad (8)$$

It can be seen from the above formula that the velocity density sensitivity coefficient  $f_i(k) < 0$ ; that is, the speed is inversely proportional to the density, which is in line with the basic theory of traffic flow.

(3) *Ramp Inflow.* The amount of ramp inflow is affected by many factors. Let  $\rho_{jam}$  be the congestion density; then the

amount of ramp inflow considering the influence of the mainline VSL of the expressway is  $Q_i(k)\rho_{jam} - \rho_i(k)/\rho_{jam} - \rho_{cr}$ . At this time, the ramp inflow model can be expressed:

$$h_i(k) = \min \left\{ \left( d_i(k) + \frac{\omega_i(k)}{T} \right), Q_i(k) \frac{\rho_{jam} - \rho_i(k)}{\rho_{jam} - \rho_{cr}} \right\}. \quad (9)$$

### 3.2.3. METANET Model considering RM

(1) *Mainline speed reduction.* When the on-ramp traffic flows into the mainline, it will reduce the speed of the mainline; set  $v_{r,i}(k)$  is the speed at which the ramp volume converges into the mainline. The vehicle speed reduction at the on-ramp is calculated as follows:

$$\Delta v_{r,i}(k) = \frac{\delta T v_i(k) h_i(k)}{L_i \lambda_i [\rho_i(k) + \kappa]}, \quad (10)$$

$$q_i(k) = \rho_i(k) \cdot v_i(k) \cdot \lambda_i, \quad (12)$$

$$\rho_i(k+1) = \rho_i(k) + \frac{T}{L_i \lambda_i} [q_{i-1}(k) - q_i(k) + h_i(k) - s_i(k)], \quad (13)$$

$$v_i(k+1) = v_i(k) + \frac{T}{\tau} \{ H[\rho_i(k)] - v_i(k) \} + \frac{T}{L_i} v_i(k) [v_{i-1}(k) - v_i(k)] - \frac{f_i(k)}{\tau} \frac{T}{L_i} \frac{\rho_{i+1}(k) - \rho_i(k)}{\rho_i(k) + \kappa} - \frac{\delta T v_i(k) h_i(k)}{L_i \lambda_i [\rho_i(k) + \kappa]}, \quad (14)$$

$$H[\rho_i(k)] = \min \left\{ v_f \cdot \exp \left[ -\frac{1}{\alpha_i} \left( \frac{\rho_i(k)}{\rho_{cr}(k)} \right)^{\alpha_i} \right], b_i(k) v_f \right\}, \quad (15)$$

$$h_i(k) = \min r_i(k) \left\{ \left( d_i(k) + \frac{\omega_i(k)}{T} \right), Q_i(k) \frac{\rho_{jam} - \rho_i(k)}{\rho_{jam} - \rho_{cr}} \right\}, \quad (16)$$

$$\omega_i(k) = \omega_i(k-1) + T [d_i(k-1) - h_i(k-1)]. \quad (17)$$

The meanings and expressions of the parameters in the formula are the same as in Section 3.2.1, Section 3.2.2, and Section 3.2.3.

3.3. *Objective Function and Constraints.* In order to reflect the effect of ramp control, the ramp queuing time should be as small as possible, and the queuing length should be as short as possible. The total travel time of vehicles through the

where  $\delta$  is model parameter,  $\delta = 1 - v_{r,i}(k)/v_i(k)$ .

(2) *Ramp Inflow.* When RM is adopted, the traffic volume of the ramp merging into the mainline will also be affected by the on-ramp control rate. Therefore, the ramp control rate can be introduced as a coefficient when calculating the ramp merging volume, that is,

$$h_i(k) = \min r_i(k) \left\{ \left( d_i(k) + \frac{\omega_i(k)}{T} \right), Q_i(k) \frac{\rho_{jam} - \rho_i(k)}{\rho_{jam} - \rho_{cr}} \right\}, \quad (11)$$

where  $r_i(k)$  is on-ramp regulation rate.  $r_{\min,i} \leq r_i(k) \leq r_{\max,i}$  and  $r_{\min,i} \in [0, 1]$ .

3.2.4. *Establishment of Improved METANET Model.* The complete expression of the improved METANET model is as follows:

expressway and ramp can be divided into the sum of the time of passing the expressway mainline and the queuing time of the on-ramp. At the same time, the variable speed limit and ramp control should be as smooth and stable as possible to avoid large fluctuations and ensure road traffic safety. Therefore, the objective function and constraint conditions of the selected cooperative control model are described as follows:

$$\min J = T \sum_{j=1}^{N_p} \sum_{i=1}^M \lambda_i L_i [\rho_i(k+j)] + T \sum_{j=1}^{N_p} \omega(k+j) + T \sum_{j=1}^{N_p} \sum_{i=1}^M [r_i(k+j) - r_i(k+j-1)]^2 + T \sum_{j=1}^{N_p} \sum_{i=1}^M [b_i(k+j) - b_i(k+j-1)]^2, \quad (18)$$

$$\text{s.t.} \begin{cases} q_i(k) \leq Q_{\text{cap},i}(k) \\ |v_{i-1}(k) - v_i(k)| \leq 10 \\ |v_i(k) - v_i(k-1)| \leq 10, \\ \omega_i(k) \leq L_{\text{ramp}}, \end{cases} \quad (19)$$

where  $T$  is the sampling period,  $N_p$  is the calculation step,  $M$  is the number of sections, and  $Q_{cap,i}(k)$  is the capacity of each section of the mainline; the meaning of other parameters is the same as Section 3.2.

**3.4. Solution of Cooperative Control Model Based on NSGA-II Algorithm.** The essence of solving the cooperative control model is to solve the multiobjective optimization problem. Generally, the multiobjective optimization problem could not find a unique optimal solution but can find a set composed of multiple optimal solutions, that is, the Pareto optimal solution set. The conventional solution method is to convert it into a single objective problem for calculation. However, this has obvious defects that the weight selection of each objective depends on experience and the transformed problem is likely to be more complex, which has great limitations. Therefore, this paper selects the improved algorithm NSGA-II of nondominated sorting genetic algorithm (NSGA) to solve the proposed cooperative control model. Compared with other algorithms, this algorithm has a great improvement in performance. NSGA-II Algorithm 1 is specifically described as follows:

## 4. Example Simulation

In order to verify the effectiveness of the proposed collaborative control strategy, VISSIM simulation software is selected to simulate the traffic flow's operating conditions. VISSIM is a microscopic road traffic modeling tool that evaluates plans by simulating traffic conditions, taking full account of the traffic characteristics of motor vehicles, pedestrians, and so on. Its core simulation models include the following: (1) vehicle longitudinal movement adopts the psychophysical vehicle following model proposed by Professor Wiedemann; (2) vehicle lateral movement adopts the psychology-based Sparmann lane change behavior model; (3) VISSIM uses dynamic traffic allocation method in route selection [26, 27].

The simulation road network in this article comes from the Suzhou Central Elevated Expressway. The mainline of this expressway is about 2 km in length. It is a one-way three-lane lane. It is widened to four lanes at the entrance ramp and then becomes a three-lane lane with a lane width of 3.5 m. According to the requirements of the METANET model for road segment division, the research road segment is divided into 4 basic road segments, each with a length of 500 m. The simplified schematic diagram is shown in Figure 4.

This paper selects the evening peak period of 16:30–18:30 on a working day for research. The time interval of data acquisition is 20 s. The types of data collected include induction coil number, acquisition time, lane number, traffic flow, speed, occupancy, and so on. Through certain data processing, the collected data can meet the control requirements under the intelligent network environment so as to improve the accuracy of traffic state data. Since the traffic flow state of expressway is usually studied based on section data, it is necessary to integrate the collected lane data into

section data. The section data can be calculated by using the method in Table 1.

In Table 1,  $x$  is the lane number;  $n$  is the number of section lanes; OCC is the occupation ratio;  $L$  is the length of the detector;  $D$  is the vehicle length.

### 4.1. Model Parameter Calibration

**4.1.1. The Parameters of Improved METANET Model.** The parameters to be calibrated are  $(v_f, \rho_{cr}, \tau, \kappa, \delta, \alpha_i)$ . In this paper, based on peak hour data combined with least squares [28] quantitative calibration and the use of the nonlinear fitting function which is called Lsqnonlin in MATLAB software, the calibration results of each parameter are shown in Tables 2 and 3.

It can be seen from Table 2 that the road sections directly affected by the on-ramp of the expressway (such as road 2 and 3) have relatively greater impact on the actual traffic capacity of the road. The critical density of the road section is higher, and the free-flow speed is lower.

**4.1.2. The Parameters of NSGA-II Algorithm.** Four key parameters of NSGA-II solution algorithm need to be calibrated when solving collaborative control model. After experiments, the values of these parameters are shown in Table 4.

**4.2. Validation of Traffic Flow Simulation Model.** For validation of traffic flow simulation model, speed and density are selected as indicators. The calibrated parameter values are substituted into the METANET model. The numerical simulation function of traffic flow model is implemented by using MATLAB software. With this function, the flow and speed simulation results of each detector section in the study area are obtained and compared with the actual data. According to the characteristics of the road section, this article selects the mainline road 2 of the expressway as the object. Compare the actual value and the predicted result of the speed and density of the road section at each time in the simulation time under the same traffic volume, and use the image to show it, as shown in Figure 5.

According to the flow density equation in the traffic flow model, the traffic flow is equal to the speed multiplied by the density. The relationship between speed and density is complex. Therefore, the measured values of speed and density are compared with the predicted values in Figure 5. It can be seen from Figure 5 that the predicted density value of road 2 was basically consistent with the actual density value. The predicted speed value was 7.68% higher than the actual value. However, its change trend was very close to the change of the actual speed value, which reflected that the simulation effect was good. After calculation, the average absolute percentage error of the improved traffic flow model was 9.3%, so it can be concluded that the calibrated improved METANET model has good applicability.

Step 1: Randomly generate the initial population  $P_t$ ,  $t = 0$  whose size is  $N$  and set the number of iteration times and initial operation parameter values.  
 Step 2: Take the initial population as the parent population, select, cross, and mutate it, and get a new generation of offspring population  $Q_t$ ,  $t = 0$ .  
 Step 3: Combine  $P_t$  and  $Q_t$  to obtain a new population  $R_t$  with the scale of  $2N$ . The nondominated set  $F$  is obtained by fast nondominated sorting. The crowding degree of individuals in each layer is calculated, and the optimal  $N$  individuals are selected to form a new parent population  $P_{(t+1)}$  according to the nondominated sorting hierarchical number and crowding degree.  
 Step 4: Perform selection on population  $P_{(t+1)}$  and cross and mutate the selected individuals to obtain a new offspring population  $Q_{(t+1)}$ .  
 Step 5: Repeat the above operations and output result ending the operation until the number of iterations reaches the upper limit; otherwise return to step 2.

ALGORITHM 1: NSGA-II algorithm.

Sectional velocity $v$	$v = \frac{\sum_{x=1}^n q_x v_x}{\sum_{x=1}^n q_x}$
Sectional density $\rho$	$\rho = 1/n \sum_{x=1}^n \text{occ}_x / (l + d)$

### 4.3. Analysis of Simulation Results

**4.3.1. Analysis of the Effect of the Expressway Ramp Cooperative Control Model.** Considering the actual traffic flow operating conditions in the study area, because there is an on-ramp in Section 2, which is in the expressway ramp confluence area, it is necessary to implement VSL on upstream Section 1 and implement RM on the on-ramp of Section 2. At the same time, it is necessary to analyse the queuing of vehicles in Section 2, so this article takes Section 2 as an example to analyse the effect of the control strategy.

It can be found from the left image of Figure 6 that when no control strategy is used, the traffic flow of road Section 2

encounters a bottleneck when the simulation time reaches about 39 minutes, and the traffic flow deceleration is very serious. This is because the average speed of the traffic flow decreases with the increase of the mainline vehicles and the on-ramp vehicles. When the simulation time reaches 65–90 min, the speed increase of traffic flow is not obvious when only using VSL. This is because the traffic flow of the mainline is too large at this time, and there is no control of the traffic flow on the ramp, resulting in insufficient lane changing gaps for the mainline vehicles, and the VSL control effect is very small. It can be clearly seen that when a serious traffic bottleneck is encountered, the expressway ramp coordinated control strategy has the highest benefit for the improvement of the mainline traffic flow speed.

It can be seen from the right picture of Figure 6, there is a significant increase in road section density during the first 30 minutes of the entire simulation period. This is due to the gradual increase in vehicles approaching the peak hours, and the density of road Section 2 increased due to the on-ramp vehicles merging. The use of variable speed limit control on

Value	100	100	0.9	0.5

FIGURE 5: Comparison of speed and density prediction results of road 2.

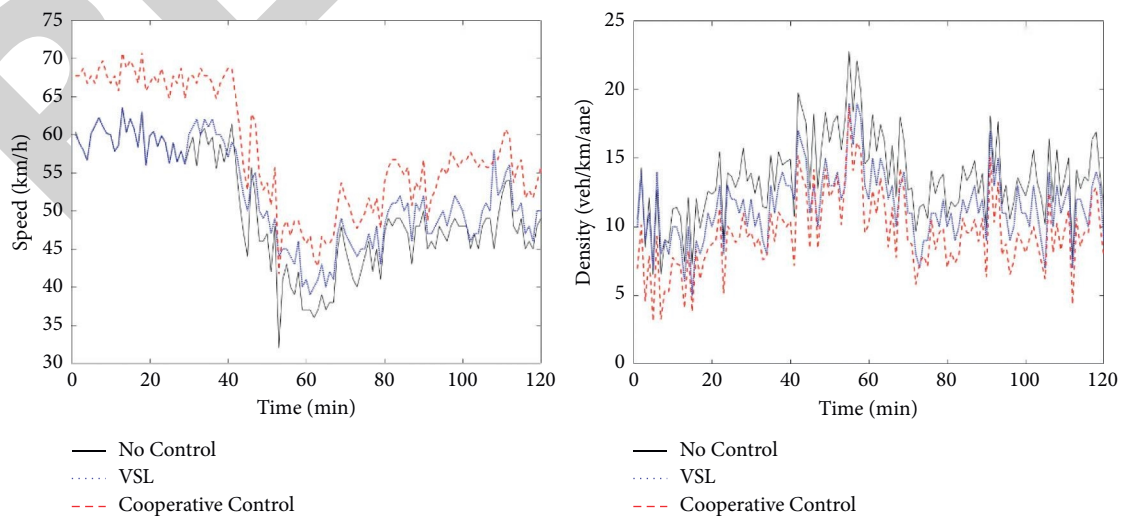

FIGURE 6: Speed and density changes of Section 2 under different control scenarios.

TABLE 5: Comparison of evaluation indicators under different control scenarios.

Evaluation index	No control	Cooperative control	Improve effect (%)	Joint control	Improve effect (%)
Total travel time/h	136	121	11.03	108	20.59
Mainline vehicle travel time/s	78	71	8.97	66	15.38
Average delay time/s	40.46	32.73	19.11	27.15	32.9
Speed difference/(km/h)	9.1	7.4	18.68	6.0	34.07

the upstream of the mainline (that is, Section 1) can reduce the number of vehicles entering Section 2 on the mainline, that is, reducing the upstream traffic demand. However, with the increase in traffic flow from the ramp, it is still impossible to change the congestion situation in the confluence area of the mainline and the on-ramp. After adopting the expressway ramp cooperative control, the average density of the road section is much smaller than before, which shows that the cooperative control of VSL and RM is very important.

#### 4.3.2. Comparative Analysis of Different Control Situations.

In order to quantitatively evaluate the effect of the proposed expressway ramp joint control system, this paper selects the total travel time, the mainline vehicle travel time, the average delay time, and the speed difference between adjacent road sections as evaluation indicators. Compare the operating efficiency and safety of the no-control strategy, only the expressway ramp cooperative control strategy, and the route decision control and expressway ramp cooperative control strategy. The comparison results are shown in Table 5.

It can be seen from the above table that, compared with the case of no control, the total travel time, mainline traffic travel time, average delay, and speed difference are reduced by 11.03%, 8.97%, 19.11%, and 18.68% after adopting the express ramp coordinated control strategy. With the addition of path decision control, the road network has been greatly improved in terms of operational efficiency and safety. In particular, the average delay time of the road network is reduced by 32.9% compared to the uncontrolled scenario, and the speed difference between adjacent road sections is reduced by 34.07%, and the operation of vehicles on the express road is more stable. Therefore, the effectiveness of the expressway ramp joint control system proposed in this paper can be verified. Compared with other control strategies, its control effect is generally better.

## 5. Conclusions

In this paper, a data-driven control strategy for urban express ramp is constructed. The improved METANET traffic flow model which can realize the cooperative control of VSL and RM is proposed and the genetic algorithm NSGA-II is designed to solve the optimal solution problem of the objective function and constraints aiming at traffic efficiency and traffic safety in the cooperative control model. Based on the existing VIS SIM microsimulation software and its COM interface, the ramp control function of expressway in the intelligent network environment is programmed and simulated. The results show that, compared with the traditional driving environment, the intelligent network environment as the premise can provide

more comprehensive traffic information for vehicles and realize real-time information interaction among vehicles, traffic information, and traffic environment on the road. This real-time and effective information exchange mode further ensures that the collaborative control strategy of expressway ramp was significantly better than the single RM or VSL. The total travel time and the speed difference between adjacent sections of expressway mainline are reduced by 20.59% and 34.07%, respectively, which improves the operation efficiency and safety of expressway network. The collaborative control strategy proposed in this paper reflects the synergy, real time, and accuracy in ramp control, which has certain enlightenment and reference significance for the transformation of expressway traffic control mode. On the one hand, the problem of traffic data lag would be solved faced by expressway traffic control for a long time with the support of intelligent network technology. On the other hand, its control object has changed from macrotraffic flow to microvehicles. The further improvement of control accuracy is more conducive to the improvement of traffic efficiency and safety.

Due to the limitation of time and ability, there are many deficiencies and parts to be improved in the research. In the future, the research can be further improved from the following aspects:

- (1) The optimization objective of the expressway ramp collaborative control model proposed in this paper is only considered from the perspective of traffic efficiency and safety, which is not comprehensive enough and fails to achieve the optimal system and user. The optimal system optimally considers the overall operation level of urban expressway traffic, including minimum overall delay and maximum overall throughput. The optimal user considers the priority of special vehicles, such as ambulances, fire engines, public transportation, etc. [29]. These control objectives need to be further studied and realized.
- (2) This paper describes the expressway traffic flow state through the macrotraffic flow model. When establishing the simulation model, the driving behavior was characterized only by modifying the parameters in the intelligent network environment. The consideration of the driver behavior was not accurate and comprehensive, which is possible to result in the difference between the simulation effect of the collaborative control model and the practical application. Therefore, the next research could consider using a more micromodel to describe the driving behavior in the intelligent network environment.

In this paper, we establish two new stochastic orders, DMTFR (decreasing mean time to failure or replaced) and GDMTFR (generalized decreasing mean time to failure or replaced), and mainly investigate properties of the GDMTFR order. Some characterizations of the GDMTFR order are given. The implication relationships between the DMTFR and the GDMTFR orders are considered. Also, closure and reversed closure properties of the new order GDMTFR are investigated. Meanwhile, several illustrative examples that meet the GDMTFR order are shown as well.

## 1. Introduction and Preliminaries

In risk investment fields, we often need to compare or select two risk assets [1]. Similarly, two lifetimes of two systems or units also need to be compared in engineering technologies [2]. To do these things, some refined stochastic orders were defined in statistics. For more details on stochastic orders, one may refer to the studies by Maria Fernandez-Ponce et al. [3], Belzunce [4], Müller and Stoyan [5], Li and Yam [6], Shaked and Shanthikumar [7, 8], Zhao and Balakrishnan [9], Sunoj et al. [10], Kang [11, 12], Yan [13], Kang and Yan [14], Vineshkumar [15], and the references therein. However, sometimes, we need to compare two risk assets by the aid of the third referred system, such as when we compare two risk assets [16], their values are changeable with the settlement time or with the kind of valuation currency [17]. To solve this problem, we establish a new stochastic order by introducing a common measure factor, namely, referred function.

Let  $X$  be a nonnegative and absolutely continuous random variable.  $X$  has distribution function  $F_X$  with 0 being the left endpoint of its support, survival function  $\bar{F}_X = 1 - F_X$ , and density function  $f_X$ . Let again  $F_X^{-1}$  be the right-continuous inverse function of  $F_X$  defined by

$$F_X^{-1}(p) = \sup\{x \mid F_X(x) \leq p\}, \quad 0 < p < 1. \quad (1)$$

In many important real areas, such as reliability, economics, management sciences, information sciences, and other related fields, stochastic comparisons are paid much attention and have been used as sharp tools in dealing with some random problems in recent years. Based on comparisons of residual life, mean residual life, mean inactivity time, failure rate, and many aging concepts are presented earlier or later. In these aspects, interested readers can refer to the studies by Barlow and Proschan [18], Shaked et al. [7], Shaked and Shanthikumar [8], Müller and Stoyan [5], Kochar et al. [19], Ahmad et al. [20], Knopik [21], Kochar et al. [19], and Li and Shaked [22] for some existing results.

In reality, a nonnegative random variable  $X$  is often called a life representing the lifetimes of a device. The life distribution classes IFR (increasing failure rate), IFRA (increasing failure rate average), DMRL (decreasing mean residual life), NBUE (new better than used in expectation), and MTFR (mean time to failure or replaced) classes of life distributions are commonly used to describe the ageing features of units or systems, for example, see Barlow and Proschan [18].

In particular, it is well known that (see Barlow and Campo [23], Klefsjö [24], Marschall [25])

$$\text{IFR} \subset \text{DMRL} \subset \text{NBUE}. \quad (2)$$

Knopik [21] introduced a new ageing class MTFR such that

$$\text{IFR} \subset \text{MTFR} \subset \text{NBUE}. \quad (3)$$

It is worthwhile to mention that, in Barlow's study [26], it is proved for the absolutely continuous distribution that

$$\text{IFRA} \subset \text{MTFR}. \quad (4)$$

Kochar et al. [19] showed that, for any random variable, the inclusion (4) is also valid.

Consider an age replacement policy as the one in which a unit is replaced by  $t$  time units after installation or at failure, whichever occurs first, and then the expected value for the first time to an in-service is (see Barlow and Proschan [18])

$$M_X(t) = \frac{\int_0^t \bar{F}_X(x) dx}{F_X(t)}, \quad \text{for } t \in \{x: F_X(x) > 0\}. \quad (5)$$

When  $M_X(t)$  is monotonic, the case was considered by Barlow and Campo [23], Marschall and Proschan [27], and Klefsjö [24]. In Knopik [21], and the ageing class MTFR (mean time to failure or replaced) of lifetime distribution is introduced, and it is proved that the MTFR class is closed under the operation of maximum for independence. In Kochar et al. [19], it is showed that the class MTFR is closed under weak convergence of distributions and convolution, and the dual family  $\text{MTFR}^D$  is closed under noncrossing mixtures.

*Definition 1.* The random variable  $X$  belongs to the mean time to failure with replacement (MTFR) class if the function  $X$  is decreasing for  $t \in \{x | F_X(x) > 0\}$ .

Assume that  $X$  has finite mean  $\mathbb{E}(X) = \mu_X$ . The residual life of  $X$  at time  $t > 0$  is defined as  $X_t = [X - t | X > t]$ . Then, the mean residual life of  $X$  at time  $t > 0$  is

$$\mu_X(t) = \mathbb{E}(X_t) = \frac{\int_t^{+\infty} \bar{F}_X(x) dx}{\bar{F}_X(t)}, \quad \text{for } t \geq 0. \quad (6)$$

If  $\mu_X(t)$  is decreasing, then we say that  $X$  (or  $F_X$ ) is in the decreasing mean residual (DMRL) life distribution class and denoted by  $X$  (or  $F_X$ )  $\in$  DMRL.

Emad-Edlin [28] proposed and studied the decreasing mean residual life (DMRL) ordering. Maria Fernandez-Ponce et al. [3] and Belzunce [4] proposed and studied the right spread order. Subsequently, Kochar et al. [19] proposed and studied the total time on test transform order and excess wealth order which is equivalent to the right spread order.

The total time on test (TTT) transform functions of  $X$  and  $Y$  are defined, respectively, as

$$\begin{aligned} T_X(p) &\equiv \int_0^{F_X^{-1}(p)} \bar{F}_X(x) dx, \\ T_Y(p) &\equiv \int_0^{G_Y^{-1}(p)} \bar{G}_Y(x) dx, \quad \text{for all } p \in (0, 1). \end{aligned} \quad (7)$$

The right spread (RS, for short) functions of  $X$  and  $Y$  are defined as, for all  $p \in (0, 1)$ , respectively,

$$\begin{aligned} S_X(p) &= \int_{F_X^{-1}(p)}^{\infty} \bar{F}_X(x) dx = \mathbb{E}[(X - F_X^{-1}(p))_+] = \mathbb{E}[\max\{X - F_X^{-1}(p), 0\}], \\ S_Y(p) &= \int_{G_Y^{-1}(p)}^{\infty} \bar{G}_Y(x) dx = \mathbb{E}[(Y - G_Y^{-1}(p))_+] = \mathbb{E}[\max\{Y - G_Y^{-1}(p), 0\}], \end{aligned} \quad (8)$$

where  $\bar{F}_X = 1 - F_X$  and  $\bar{G}_Y = 1 - G_Y$  are the survival functions of  $F_X$  and  $G_Y$ , respectively, and  $(x)_+ = \max\{x, 0\}$ .

Now, we recall several stochastic orders from Shaked and Shanthikumar [8].

*Definition 2.* Let  $X$  and  $Y$  be two nonnegative random variables with distribution functions  $F_X, G_Y$  such that  $F_X(0) = G_Y(0) = 0$ , survival functions  $\bar{F}_X \equiv 1 - F_X, \bar{G}_Y \equiv 1 - G_Y$ , right-continuous inverse functions  $F_X^{-1}, G_Y^{-1}$ , and finite means  $\mu_X, \mu_Y$ , respectively [8].

(1)  $X$  is said to be smaller than  $Y$  in the TTT transform order (denoted by  $X \leq_{\text{ttt}} Y$ ) if

$$\int_0^{F_X^{-1}(p)} \bar{F}_X(x) dx \leq \int_0^{G_Y^{-1}(p)} \bar{G}_Y(x) dx, \quad \text{for all } p \in (0, 1). \quad (9)$$

(2)  $X$  is said to be smaller than  $Y$  in the right spread order (denoted by  $X \leq_{\text{rs}} Y$ ) if

$$\int_{F_X^{-1}(p)}^{\infty} \bar{F}_X(x) dx \leq \int_{G_Y^{-1}(p)}^{\infty} \bar{G}_Y(x) dx, \quad \text{for all } p \in (0, 1). \quad (10)$$

(3)  $X$  is said to be smaller than  $Y$  in the NBUE (new better than used in expectation) order (denoted by  $X \leq_{\text{nbue}} Y$ ) if

$$\frac{\int_{F_X^{-1}(p)}^{\infty} \bar{F}_X(x) dx}{\int_{G_Y^{-1}(p)}^{\infty} \bar{G}_Y(x) dx} \leq \frac{\mu_X}{\mu_Y}, \quad \text{for all } p \in (0, 1). \quad (11)$$

(4)  $X$  is said to be smaller than  $Y$  in the location independent riskier order (denoted by  $X \leq_{\text{lir}} Y$ ) if

$$\int_0^{F_X^{-1}(p)} F_X(x) dx \leq \int_0^{G_Y^{-1}(p)} G_Y(x) dx, \quad \text{for all } p \in (0, 1). \quad (12)$$

(5)  $X$  is said to be smaller than  $Y$  in the DMRL order (denoted by  $X \leq_{\text{dmrl}} Y$ ) if

$$\frac{\mu_Y[G_Y^{-1}(p)]}{\mu_X[F_X^{-1}(p)]} = \frac{\int_{G_Y^{-1}(p)}^{\infty} \overline{G}_Y(x) dx}{\int_{F_X^{-1}(p)}^{\infty} \overline{F}_X(x) dx} \quad (13)$$

is increasing in  $p \in (0, 1)$ .

From Definition 1, we easily have the following result without proof.

**Lemma 1.** *Let  $X$  and  $Y$  be two continuous and nonnegative random variables with respective distribution functions  $F_X$  and  $G_Y$ , density functions  $f_X$  and  $g_Y$ , and the right-continuous inverse functions  $F_X^{-1}(p)$  and  $G_Y^{-1}(p)$  of  $F_X$  and  $G_Y$ , respectively. Then, the following statements are equivalent:*

- (1)  $X \leq_{\text{ttt}} Y$ .
- (2) *The inequality*

$$\int_0^{F_X^{-1}(p)} \overline{F}_X(x) dx \leq \int_0^{G_Y^{-1}(p)} \overline{G}_Y(x) dx, \quad \text{for all } p \in (0, 1), \quad (14)$$

is valid.

- (3) *The inequality*

$$\int_0^t \overline{F}_X(x) \left[ \frac{f_X(x)}{g_Y[G_Y^{-1}(F_X(x))]} - 1 \right] dx \geq 0, \quad \text{for all } t > 0, \quad (15)$$

is valid.

**Definition 3.** Let  $X$  and  $Y$  be two nonnegative random variables with distribution functions  $F_X, G_Y$  such that  $F_X(0) = G_Y(0) = 0$ , survival functions  $\overline{F}_X \equiv 1 - F_X, \overline{G}_Y \equiv 1 - G_Y$ , density functions  $f_X, g_Y$ , and right-continuous inverse functions  $F_X^{-1}, G_Y^{-1}$ , respectively.

- (1)  $X$  is said to be smaller than  $Y$  in the usual stochastic order (denoted by  $X \leq_{\text{st}} Y$ ), if  $\overline{F}_X(x) \leq \overline{G}_Y(x)$  for all  $x > 0$ .
- (2)  $X$  is said to be smaller than  $Y$  in the star-shaped order (denoted by  $X \leq_* Y$ ), if the function  $G_Y^{-1}(F_X(x))/x$  is increasing in  $x > 0$ .
- (3)  $X$  is said to be smaller than  $Y$  in the convex order (denoted by  $X \leq_c Y$ ), if the function  $G_Y^{-1}(F_X(x))$  is convex for  $x > 0$ .
- (4)  $X$  is said to be smaller than  $Y$  in the dispersive order (denoted by  $X \leq_{\text{disp}} Y$ ), if  $f_X[F_X^{-1}(p)] \geq g_Y[G_Y^{-1}(p)]$  for all  $p \in (0, 1)$ .

Let  $X$  and  $X$  be two absolutely continuous nonnegative random variables with respective distribution functions  $F_X$

and  $G_Y$  such that  $F_X(0) = G_Y(0) = 0$ , and density functions  $f_X$  and  $g_Y$ , and right-continuous inverse functions of  $F_X^{-1}$  and  $G_Y^{-1}$ , respectively.

We say that  $X$  is smaller than  $Y$  in the increasing concave order (denoted by  $X \leq_{\text{icv}} Y$ ) if

$$\int_0^t \overline{F}_X(x) dx \leq \int_0^t \overline{G}_Y(x) dx, \quad \text{for all } t > 0. \quad (16)$$

Here,

$$\begin{aligned} \int_0^t \overline{F}_X(x) dx &= \mathbb{E}[\min\{X, t\}], \\ \int_0^t \overline{G}_Y(x) dx &= \mathbb{E}[\min\{Y, t\}]. \end{aligned} \quad (17)$$

Hence, the order  $\leq_{\text{icv}}$  is a direct comparison for the mean service times of  $X$  and  $Y$ . In insurance theory,  $\int_0^d \overline{F}_X(x) dx = \mathbb{E}[\min\{X, d\}]$  is the average losses undertaken by the insured when the deductible excess is  $d$ . Hence,

$$\begin{aligned} T_X(p) &\equiv \int_0^{F_X^{-1}(p)} \overline{F}_X(x) dx = \mathbb{E}[\min\{X, F_X^{-1}(p)\}], \\ T_Y(p) &\equiv \int_0^{G_Y^{-1}(p)} \overline{G}_Y(x) dx = \mathbb{E}[\min\{Y, G_Y^{-1}(p)\}], \end{aligned} \quad (18)$$

that is,  $T_X(p)$  and  $T_Y(p)$  are the mean service times of  $X$  and  $Y$  before the respective equal probability time points. We wish to compare  $T_X(p)$  and  $T_Y(p)$  by means of a ratio  $T_Y(p)/T_X(p)$ . Based on such an idea, we give Definition 4.

Let  $X$  and  $Z$  be two nonnegative continuous random variables with respective distribution functions  $F_X$  and  $H_Z$  such that  $F_X(0) = H_Z(0) = 0$ , right-continuous inverse functions  $F_X^{-1}$  and  $H_Z^{-1}$ , survival functions  $\overline{F}_X$  and  $\overline{H}_Z$ , and density functions  $f_X$  and  $h_Z$ , respectively.

**Definition 4.**  $X$  is said to be smaller than  $Z$  in the decreasing mean time to failure (DMTFR) order (denoted by  $X \leq_{\text{dmtrf}} Z$ ), if

$$\frac{\int_0^{H_Z^{-1}(p)} \overline{H}_Z(x) dx}{\int_0^{F_X^{-1}(p)} \overline{F}_X(x) dx}, \quad (19)$$

is increasing in  $p \in (0, 1)$ .

From Definition 3, the following lemma is obvious, the proof is omitted here.

**Lemma 2.** *The following statements are equivalent:*

- (1)  $X \leq_{\text{dmtrf}} Z$ .
- (2) *The function  $T_Z(p)/T_X(p)$  is increasing in  $p \in (0, 1)$ .*
- (3) *The inequality*

$$\int_0^t \overline{F}_X(x) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0, \quad (20)$$

is valid.

(4) The inequality

$$t\bar{F}_X(t)\left[\frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{H_Z^{-1}(F_X(t))}{t}\right] - \int_0^t x\left(\frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{H_Z^{-1}(F_X(x))}{x}\right)d[\bar{F}_X(x)] \geq 0, \quad \text{for all } t > 0, \quad (21)$$

is valid.

Shaked and Shanthikumar [8] studied the generalized TTT transform and proposed the generalized TTT transform order. Bartoszewicz and Benduch [29] further studied some properties of the generalized TTT transform by iteration. Motivated by their excellent works, we establish the following two new stochastic orders, the RDMTFR and the GDMTFR orders, see Definitions 5 and 6, respectively.

$$\int_0^t g_Y[G_Y^{-1}(F_X(x))]\left[\frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0, \quad (23)$$

is valid.

(4) The inequality

$$tg_Y[G_Y^{-1}(F_X(t))]\left[\frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{H_Z^{-1}(F_X(t))}{t}\right] - \int_0^t x\left(\frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{H_Z^{-1}(F_X(x))}{x}\right)d[g_Y[G_Y^{-1}(F_X(x))]] \geq 0, \quad \text{for all } t > 0, \quad (24)$$

is valid.

It can be easily seen that when  $Y$  is an exponential random variable with a rate  $\lambda > 0$ , that is,  $Y \sim \mathbb{E}(\lambda)$ , there exists a simple relationship between the relative DM TFR order and the DM TFR order:

$$X \leq_{\text{rdmtfr}} Z \text{ r.t. } Y \iff X \leq_{\text{dmtfr}} Z. \quad (25)$$

Assume that  $\psi$  is a real function defined on  $(0, 1)$ . Denote by

$$T_X(p; \psi) = \int_0^{F_X^{-1}(p)} \psi[F_X(x)] dx, \\ T_Z(p; \psi) = \int_0^{H_Z^{-1}(p)} \psi[H_Z(x)] dx, \quad \text{for all } p \in (0, 1). \quad (26)$$

$T_X(p; \psi)$  and  $T_Z(p; \psi)$  are called the generalized TTT transforms of  $X$  and  $Z$  relative to  $\psi$ , respectively. Then, we give the following definition.

**Definition 5.** Let  $X, Z$ , and  $Y$  be three random variables.  $X$  is said to be smaller than  $Z$  relative to  $Y$  in the relative DM TFR order (denoted by  $X \leq_{\text{rdmtfr}} Z$  r.t.  $Y$ ), if

$$\frac{\int_0^{H_Z^{-1}(p)} g_Y[G_Y^{-1}(H_Z(x))] dx}{\int_0^{F_X^{-1}(p)} g_Y[G_Y^{-1}(F_X(x))] dx}, \quad (22)$$

is increasing in  $p \in (0, 1)$ .

From Definition 5, the following lemma is obvious, and the proof is omitted here.

**Lemma 3.** The following statements are equivalent:

- (1)  $X \leq_{\text{rdmtfr}} Z$  r.t.  $Y$ .
- (2) The function  $T_Z(p; Y)/T_X(p; Y)$  is increasing in  $p \in (0, 1)$ .
- (3) The inequality

**Definition 6.** Let  $X$  and  $Z$  be two absolutely continuous nonnegative random variables; assume that  $\psi$  is a real function defined on  $(0, 1)$ .  $X$  is said to be smaller than  $Z$  with respect to  $\psi$  in the generalized DM TFR order (denoted by  $X \leq_{\text{gdm tfr}} Z$  w.r.t.  $\psi$ ), if the function

$$\frac{\int_0^{H_Z^{-1}(p)} \psi[H_Z(x)] dx}{\int_0^{F_X^{-1}(p)} \psi[F_X(x)] dx}, \quad (27)$$

is increasing in  $p \in (0, 1)$ .

**Remark 1.** One can verify that the GDM TFR order is a partial order relation. The reflexive and transitive are evident; the antisymmetric is as follows (see Theorem 1 (30) as follows).

$X \leq_{\text{gdm tfr}} Z$  w.r.t.  $\psi$  and  $Z \leq_{\text{gdm tfr}} X$  w.r.t.  $\psi$  hold simultaneously, if and only if  $Y = kX + b$  almost surely, where  $k$  and  $b$  are any real numbers such that  $Y$  is nonnegative and  $k \neq 0$ .

*Remark 2.* It can be seen that the GDMTFR and DMRL orders do not have necessary implication relations each other. Especially, the DMTFR and DMRL orders do not have direct implication relationships each other.

From Definition 5, the following lemma is obvious, and the proof is omitted here.

It can be easily seen that when  $\psi(u) = g_Y[G_Y^{-1}(u)]$ ,  $u \in (0, 1)$ , there exists a simple relationship between the GDMTFR order and the RDMTFR order:

$$X \leq_{\text{gdmftr}} Z \text{ w.r.t. } \psi \iff X \leq_{\text{rdmftr}} Z \text{ r.t. } Y. \quad (28)$$

Now, we consider a system composed of same components. We say that the system preserves some properties if the components of this system possess some properties, and we conclude from the structure of the system that the system also possesses the same property. And conversely, we say that this system has the reversed preservation for some property if the system has some property. According to the structure of the system, we conclude that the components of this system also have the same property.

For two systems, if their two components satisfy some stochastic order relation, by the structure of these two systems, we conclude that the two systems also satisfy the same stochastic order relation; then, we say that these systems of the structure preserve this stochastic order relation, or equivalently, we say that this stochastic order relation possesses closure property under the structure. Conversely, if two systems satisfy some stochastic order relation, by the structure of these two systems, we conclude that the two components of the two systems also satisfy the same stochastic order relation, and then we say that these systems of the structure reversely preserve this stochastic order relation, or equivalently, we say that this stochastic order relation possesses reversed closure property under the structure.

In reliability theory, such two problems are often of interest: one is to investigate the closure properties of a stochastic order, and the other is to examine the reversed closure properties of a stochastic order under several reliability operations, such as increasing convex transforms and taking of maxima and minima.

To prove our main results, we first introduce the following lemma from Barlow and Proschan [18], which plays a key role in the proofs of this paper and are repeatedly used in the sequel.

**Lemma 4.** *Let  $W$  be a measure on the interval  $(a, b)$ , not necessarily nonnegative, where  $-\infty \leq a < b \leq +\infty$ . Let  $h$  be a nonnegative function defined on  $(a, b)$ . If  $\int_a^t dW(x) \geq 0$ , for all  $t \in (a, b)$  and if  $h$  is decreasing, then*

$$\int_a^b h(x) dW(x) \geq 0. \quad (29)$$

In the next, we assume that all the random variables, under consideration, are nonnegative and continuous.

Throughout this paper, the term *increasing* stands for monotone nondecreasing and *decreasing* stands for monotone nonincreasing. Assume that all the random variables under considerations are nonnegative and absolutely continuous with 0 as the left endpoint of their supports, and that all the integrals and expectations involved are always finite. All the encountered ratios are always supposed to be well defined.

In this paper, we devote our interest to the closure properties of the GDMTFR order. The paper is organized as follows. First, in Section 2, we consider characterizations of GDMTFR order. We investigate the implication relationships between DMTFR and GDMTFR orders in Section 3. The closure and reversed closure properties of the GDMTFR order are studied in Section 4. Finally, in Section 5, we give two examples which meet the GDMTFR order.

In the following, we always assume that  $X$  and  $Z$  are two absolutely continuous and nonnegative random variables with distribution functions  $F_X$  and  $H_Z$  such that  $F_X(0) = H_Z(0) = 0$ , survival functions  $\bar{F}_X \equiv 1 - F$  and  $\bar{H}_Z \equiv 1 - H_Z$ , density functions  $f_X$  and  $h_Z$ , and right-continuous inverse functions  $F_X^{-1}$  and  $H_Z^{-1}$  of  $F_X$  and  $H_Z$ , respectively.

## 2. Characterizations of the GDMTFR Order

Now, we explore some characterizations of the GDMTFR order. First, we give a result by Definition 1.6, which will be useful in the proofs of upcoming theorems.

**Theorem 1.** *The following statements are equivalent:*

- (1)  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ .
- (2) The inequality

$$\int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0, \quad (30)$$

is valid.

(3) The inequality

$$t\psi[F_X(t)]\left[\frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{H_Z^{-1}(F_X(t))}{t}\right] - \int_0^t x\left(\frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{H_Z^{-1}(F_X(x))}{x}\right)d[\psi(F_X(x))] \geq 0, \quad \text{for all } t > 0, \quad (31)$$

is valid.

$$\frac{\int_0^{H_Z^{-1}(p)} \psi[H_Z(x)]dx}{\int_0^{F_X^{-1}(p)} \psi[F_X(x)]dx}, \quad (32)$$

*Proof.* We only give proof for the case of (1) $\iff$ (2). Suppose that the function

is increasing in  $p \in (0, 1)$ . By differentiating, we have that the numerator of the derivative of this ratio is

$$\frac{\psi(p)}{h_Z[H_Z^{-1}(p)]} \int_0^{F_X^{-1}(p)} \psi[F_X(x)]dx - \frac{\psi(p)}{f_X[F_X^{-1}(p)]} \int_0^{H_Z^{-1}(p)} \psi[H_Z(x)]dx, \quad \text{for all } p \in (0, 1). \quad (33)$$

Since the function

is increasing in  $p \in (0, 1)$ , we have

$$\frac{\int_0^{H_Z^{-1}(p)} \psi[H_Z(x)]dx}{\int_0^{F_X^{-1}(p)} \psi[F_X(x)]dx}, \quad (34)$$

$$\int_0^{F_X^{-1}(p)} \frac{f_X[F_X^{-1}(p)]}{h_Z[H_Z^{-1}(p)]} \psi[F_X(x)]dx - \int_0^{H_Z^{-1}(p)} \psi[H_Z(x)]dx \geq 0, \quad \text{for all } p \in (0, 1). \quad (35)$$

Letting  $H_Z(x) = F_X(y)$  in the second integral of the left-hand side of inequality (35) and then letting  $F_X^{-1}(p) = t$ , we obtain that

$$\int_0^t \psi[F_X(x)]\left[\frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right]dx \geq 0, \quad \text{for all } t > 0. \quad (36)$$

And, the above deduction is reversible. Therefore, the proof of the theorem is complete.  $\square$

*Definition 7.* Let  $X$  and  $Z$  be nonnegative absolutely continuous random variables with distribution functions  $F_X, H_Z$  such that  $F_X(0) = H_Z(0) = 0$ , density functions  $f_X, h_Z$ , and right-continuous inverse functions  $F_X^{-1}, H_Z^{-1}$ , respectively.

- (1)  $X$  is said to be smaller than  $Z$  in the starshaped order (denoted by  $X \leq_* Z$ ), if the function  $H_Z^{-1}(F_X(x))/x$  is increasing in  $x > 0$ .

- (2)  $X$  is said to be smaller than  $Z$  in the convex order (denoted by  $X \leq_{\mathcal{C}} Z$ ), if the function  $H_Z^{-1}(F_X(x))$  is convex for  $x > 0$ .

- (3)  $X$  is said to be smaller than  $Z$  in the dispersive order (denoted by  $X \leq_{\text{disp}} Z$ ), if  $f_X[F_X^{-1}(p)] \geq h_Z[H_Z^{-1}(p)]$  for all  $p \in (0, 1)$ .

**Theorem 2.** Let  $\psi$  be a nonnegative function defined on  $(0, 1)$ . Then, for any  $\theta > 0$ ,  $X \leq_{\text{gdmfr}} \theta X$  w.r.t.  $\psi$ .

**Theorem 3.** Let  $\psi$  be a nonnegative function defined on  $(0, 1)$ . If  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ , then for any  $\theta > 0$ ,  $X \leq_{\text{gdmftr}} \theta Z$  w.r.t.  $\psi$ .

*Proof.* Suppose that  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ , then from inequality (30), we have

$$\int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0. \quad (37)$$

In turn, from (30),  $X \leq_{\text{gdmftr}} \theta Z$  w.r.t.  $\psi$  if and only if, for all  $t > 0$ ,

$$\begin{aligned} & \int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{h_{\theta Z}[H_{\theta Z}^{-1}(F_X(t))]} - \frac{f_X(x)}{h_{\theta Z}[H_{\theta Z}^{-1}(F_X(x))]} \right] dx \\ &= \theta \int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0. \end{aligned} \quad (38)$$

Clearly, if inequality (37) holds, then inequality (38) also holds, that is,  $X \leq_{\text{gdmftr}} \theta Z$  w.r.t.  $\psi$ . Therefore, the proof of the theorem is complete.  $\square$

*Remark 3.* Theorem 3 states that the order  $\leq_{\text{gdmftr}}$  is scale invariant with respect to the compared variables.

**Theorem 4.** If  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ , then for any  $a > 0$ ,  $X \leq_{\text{gdmftr}} aZ$  w.r.t.  $a\psi$ .

*Remark 4.* Theorem 4 states that the  $\leq_{\text{gdmftr}}$  order is scale invariant with respect to the referred function.

**Theorem 5.** If  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ , then for any  $\theta > 0$ ,  $\theta X \leq_{\text{gdmftr}} \theta Z$  w.r.t.  $\psi$ .

*Remark 5.* Theorem 5 states that the order  $\leq_{\text{gdmftr}}$  is scale equivalent with respect to the compared random variables.

**Theorem 6.** If  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ , then for any  $\theta > 0$  and  $a > 0$ ,  $X \leq_{\text{gdmftr}} \theta Z$  w.r.t.  $a\psi$ .

*Remark 6.* Theorem 6 states that the order  $\leq_{\text{gdmftr}}$  is scale invariant with respect to the compared random variables and the referred random variable.

**Theorem 7.** Let  $H_Z(0) = F_X(0) = 0$ .  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$  and  $X \geq_{\text{gdmftr}} Z$  w.r.t.  $\psi$  if and only if there exists some  $\theta > 0$  such that  $F_X(x) = H_Z(\theta x)$ , that is,  $Z \stackrel{d}{=} \theta X$ , where " $\stackrel{d}{=}$ " means equality in distributions.

*Proof.* Suppose that  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$  and  $X \geq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ . From Definition 6, we have that there exists some  $\theta > 0$  such that

$$\frac{\int_0^{H_Z^{-1}(p)} \psi[H_Z(x)] dx}{\int_0^{F_X^{-1}(p)} \psi[F_X(x)] dx} = \theta. \quad (39)$$

That is,

$$\int_0^{H_Z^{-1}(p)} \psi[H_Z(x)] dx = \theta \int_0^{F_X^{-1}(p)} \psi[F_X(x)] dx. \quad (40)$$

Differentiating both sides of above equality, we obtain  $(H_Z^{-1}(p))' = (F_X^{-1}(p))'$ . Thus,  $H_Z^{-1}(p) = F_X^{-1}(p) + c$ , where  $c$  is any real number. By the assumption of  $H_Z(0) = F_X(0) = 0$ ,  $c = 0$  and then  $H_Z^{-1}(p) = F_X^{-1}(p)$ . Hence,  $Z \stackrel{d}{=} \theta X$ , and this is the stated result.

The following theorem gives a sufficient condition for the GDMTFR order.  $\square$

**Theorem 8.** Let  $\psi$  be a nonnegative function defined on  $(0, 1)$ . If  $X \leq_c Z$ , then  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ .

*Proof.* From (30)  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$  if and only if

$$\int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0. \quad (41)$$

If  $X \leq_c Z$ , then the function  $f_X(x)/g_Y[G_Y^{-1}(F_X(x))]$  is increasing; hence,

$$\frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \leq \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]}, \quad \text{for all } 0 \leq x \leq t. \quad (42)$$

Moreover,  $\psi[F_X(x)] \geq 0$  for all  $x \geq 0$ . From inequality (42), we see that inequality (41) holds. That is,  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ . Therefore, the proof of the theorem is complete.  $\square$

### 3. Implication Relationships between DMTFR and GDMTFR Orders

Recall from [5] that a function  $h: (0, 1) \rightarrow (0, 1)$  is called star-shaped (anti-star-shaped) if  $h(x)/x$  is increasing (decreasing).  $h$  is star-shaped (anti-star-shaped) with respect to the point  $(1, 1)$  if  $[1 - h(x)]/[1 - x]$  is increasing (decreasing) in  $x$ .

Now, we propose the following notions about real functions.

*Definition 8.* For a positive integer number  $n$ , we say that

- (1)  $h$  is star-shaped (anti-star-shaped) with respect to the point  $(1, 0)$  if  $h(x)/(1-x)$  is decreasing (increasing).
- (2)  $h$  is dual (anti-star-shaped) star-shaped of order  $n$  if  $h(x)/(1-x^n)$  is increasing (decreasing).
- (3)  $h$  is star-shaped (anti-star-shaped) of order  $n$  with respect to the point  $(1, 0)$  if  $h(x)/(1-x)^n$  is decreasing (increasing) in  $x \in (0, 1)$ .

Let  $X$  and  $Z$  be two nonnegative continuous random variables with respective distribution functions  $F_X$  and  $H_Z$  having 0 as the common left endpoint of their supports. Let again  $\psi$  be a nonnegative function defined on  $(0, 1)$ . Assume that  $X_1, \dots, X_n$  and  $Z_1, \dots, Z_n$  are the i.i.d. copies of  $X$  and  $Z$ , respectively, and that  $X_{k:n}$  and  $Z_{k:n}$ ,  $k = 1, 2, \dots, n$ , are the order statistics of  $X$  and  $Z$ , respectively. Let  $X_{k:n}$  have distribution function  $F_{X_{k:n}}(x)$ , survival function  $\bar{F}_{X_{k:n}}(x)$ , and density function  $f_{X_{k:n}}(x)$ , then for all  $x \geq 0$ ,

$$\begin{aligned} F_{X_{k:n}}(x) &= B_{k,n-k+1}(F_X(x)), \\ \bar{F}_{X_{k:n}}(x) &= B_{n-k+1,k}(\bar{F}_X(x)), \\ f_{X_{k:n}}(x) &= \beta_{k,n-k+1}(F_X(x))f_X(x) = \frac{n!}{(k-1)!(n-k)!} [F_X(x)]^{k-1} [\bar{F}_X(x)]^{n-k} f_X(x), \end{aligned} \quad (43)$$

where  $B_{k,n-k+1}(\cdot)$  and  $\beta_{k,n-k+1}(\cdot)$  are the distribution function and density function of a beta distribution with parameters  $k$  and  $n-k+1$ , respectively.

The following Theorem 9 gives some conditions under which the DMtFR order implies the GDMtFR order.

### Theorem 9

- (1) Assume that the function  $\psi \circ B_{k,n-k+1}$  is star-shaped with respect to the point  $(1, 0)$ . If  $X \leq_{\text{dmftr}} Z$ , then

$$X_{k:n} \leq_{\text{gdmftr}} Z_{k:n} \text{ w.r.t. } \psi, \quad \text{for all } k = 1, 2, \dots, n, \quad (44)$$

where  $\psi \circ B_{k,n-k+1}$  is the compound of  $\psi$  and  $B_{k,n-k+1}$ .

- (2) Assume that the function  $\psi$  is star-shaped with respect to the point  $(1, 0)$ . If  $X \leq_{\text{dmftr}} Z$ , then

$$X \leq_{\text{gdmftr}} Z \text{ w.r.t. } \psi. \quad (45)$$

- (3) Assume that the function  $\psi$  is star-shaped of order  $n$  with respect to the point  $(1, 0)$ . If  $X_{1:n} \leq_{\text{dmftr}} Z_{1:n}$  then

$$X \leq_{\text{gdmftr}} Z \text{ w.r.t. } \psi. \quad (46)$$

- (4) Assume that the function  $\psi$  is dual anti-star-shaped of order  $n$ . If  $X_{n:n} \leq_{\text{dmftr}} Z_{n:n}$  then

$$X \leq_{\text{gdmftr}} Z \text{ w.r.t. } \psi. \quad (47)$$

- (5) Assume that the function  $\psi$  star-shaped with respect to the point  $(1, 0)$ . If for some  $1 \leq k \leq n$ ,  $X_{k:n} \leq_{\text{dmftr}} Z_{k:n}$  then

$$X_{k:n} \leq_{\text{gdmftr}} Z_{k:n} \text{ w.r.t. } \psi, \quad \text{for all } k = 1, 2, \dots, n. \quad (48)$$

*Proof.* Barlow and Proschan [18] proved that, for all  $x \geq 0$ ,

$$H_{Z_{k:n}}^{-1}[F_{X_{k:n}}(x)] = \bar{H}_{Z_{k:n}}^{-1}[\bar{F}_{X_{k:n}}(x)] = H_Z^{-1}[F_X(x)]. \quad (49)$$

It can be proven that

$$\frac{f_{X_{k:n}}(x)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(x))]} = \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]}. \quad (50)$$

- (1) Suppose that  $X \leq_{\text{dmftr}} Z$ . Then, we have, for all  $t > 0$ ,

$$\begin{aligned} & \int_0^t \bar{F}_X(x) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \\ &= \int_0^t \bar{F}_X(x) \left[ \frac{f_{X_{k:n}}(t)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(t))]} - \frac{f_{X_{k:n}}(x)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(x))]} \right] dx \geq 0. \end{aligned} \quad (51)$$

Since  $\psi \circ B_{k,n-k+1}$  is star-shaped with respect to the point  $(1, 0)$ , then  $\psi \circ B_{k,n-k+1}(u)/(1-u)$  is decreasing in  $u \in (0, 1)$ . Hence, the function

$$h(x) = \psi \circ B_{k,n-k+1} \frac{[F_X(x)]}{(1-F_X(x))} = \psi \frac{[F_{X_{k:n}}(x)]}{\bar{F}_X(x)}, \quad (52)$$

is nonnegative decreasing in  $x \geq 0$ . From Lemma 4 and inequality (51), we have

$$\int_0^t \psi[F_{X_{k:n}}(x)] \left[ \frac{f_{X_{k:n}}(t)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(t))]} - \frac{f_{X_{k:n}}(x)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(x))]} \right] dx \geq 0, \quad \text{for all } t > 0, \quad (53)$$

which is equivalent to

$$X_{k:n} \leq_{\text{gdmftr}} Z_{k:n} \text{ w.r.t. } \psi, \quad \text{for all } k = 1, 2, \dots, n. \quad (54)$$

(2) Suppose that  $X \leq_{\text{dmftr}} Z$ . Then, for all  $t > 0$ ,

$$\int_0^t \bar{F}_X(x) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0. \quad (55)$$

Since the function  $\psi$  is star-shaped with respect to the point  $(1, 0)$ , the function  $\psi(u)/(1-u)$  is decreasing in  $u \in (0, 1)$ . Thus,  $h(x) = \psi[F_X(x)]/\bar{F}_X(x)$  is nonnegatively decreasing. From Lemma 4 and (55), we have

$$\int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0, \quad (56)$$

which states that  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ .

(3) Suppose that  $X_{1:n} \leq_{\text{dmftr}} Z_{1:n}$ . Then, for all  $t > 0$ ,

$$\int_0^t \bar{F}_{X_{1:n}}(x) \left[ \frac{f_{X_{1:n}}(t)}{h_{Z_{1:n}}[H_{Z_{1:n}}^{-1}(F_{X_{1:n}}(t))]} - \frac{f_{X_{1:n}}(x)}{h_{Z_{1:n}}[H_{Z_{1:n}}^{-1}(F_{X_{1:n}}(x))]} \right] dx \geq 0. \quad (57)$$

Since  $\psi$  is star-shaped of order  $n$  with respect to the point  $(1, 0)$ , the function

$$\frac{\psi(x)}{(1-x)^n} \quad (58)$$

is decreasing in  $x$ , which leads to the function

$$h(x) = \frac{\psi[F_X(x)]}{[1-F_X(x)]^n} = \frac{\psi[F_X(x)]}{[\bar{F}_X(x)]^n} = \frac{\psi[F_X(x)]}{\bar{F}_{X_{1:n}}(x)}. \quad (59)$$

being nonnegative decreasing. Moreover,

$$\frac{f_{X_{1:n}}(x)}{h_{Z_{1:n}}[H_{Z_{1:n}}^{-1}(F_{X_{1:n}}(x))]} = \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \quad (60)$$

From Lemma 4, (57), and (60), we have

$$\int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0, \quad (61)$$

which is equivalent to

$$X \leq_{\text{gdmftr}} Z \text{ w.r.t. } \psi. \quad (62)$$

(4) Suppose that  $X_{n:n} \leq_{\text{dmftr}} Z_{n:n}$ . Then, for all  $t > 0$ ,

$$\int_0^t F_{X_{n:n}}(x) \left[ \frac{f_{X_{n:n}}(t)}{h_{Z_{n:n}}[H_{Z_{n:n}}^{-1}(F_{X_{n:n}}(t))]} - \frac{f_{X_{n:n}}(x)}{h_{Z_{n:n}}[H_{Z_{n:n}}^{-1}(F_{X_{n:n}}(x))]} \right] dx \geq 0. \quad (63)$$

Since  $\psi$  is dual anti-star-shaped of order  $n$ , the function  $\psi(x)/(1-x^n)$  is nonnegative decreasing in  $x \in (0, 1)$ , which leads to the function

$$h(x) = \frac{\psi[F_X(x)]}{1 - [F_X(x)]^n} = \frac{\psi[F_X(x)]}{\bar{F}_{X_{n:n}}(x)}. \quad (64)$$

being nonnegative decreasing. Moreover,

$$\frac{f_{X_{n:n}}(x)}{h_{Z_{n:n}}[H_{Z_{n:n}}^{-1}(F_{X_{n:n}}(x))]} = \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \quad (65)$$

From Lemma 4, (63)–(65), we have

$$\int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0, \quad (66)$$

and this asserts that

$$X \leq_{\text{gdmftr}} Z \text{ w.r.t. } \psi. \quad (67)$$

(5) Let the function  $\psi$  be anti-star-shaped with respect to the point  $(1, 0)$ . Suppose that, for some  $1 \leq k \leq n$ ,  $X_{k:n} \leq_{\text{dmftr}} Z_{k:n}$ , then for all  $t > 0$ ,

$$\int_0^t F_{X_{k:n}}(x) \left[ \frac{f_{X_{k:n}}(t)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(t))]} - \frac{f_{X_{k:n}}(x)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(x))]} \right] dx \geq 0. \quad (68)$$

Since the function  $\psi$  is star-shaped with respect to the point  $(1, 0)$ , the function  $\psi(x)/(1-x)$  is nonnegatively decreasing in  $x \in (0, 1)$ . Thus,  $\varphi(x) = \psi[F_{X_{k:n}}(x)]/\bar{F}_{X_{k:n}}(x)$

is nonnegatively decreasing. From Lemma 4 and (68), we have

$$\int_0^t \psi[F_{X_{k:n}}(x)] \left[ \frac{f_{X_{k:n}}(t)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(t))]} - \frac{f_{X_{k:n}}(x)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(x))]} \right] dx \geq 0, \quad \text{for all } t > 0, \quad (69)$$

which asserts that

$$X_{k:n} \leq_{\text{gdmftr}} Z_{k:n} \text{ w.r.t. } \psi, \quad \text{for all } k = 1, 2, \dots, n. \quad (70)$$

Therefore, the proof of the theorem is complete.

Theorem 10 gives some conditions under which the GDMTFR order implies the DMFTR order.  $\square$

### Theorem 10

(1) Assume that the function  $\psi$  is anti-star-shaped with respect to the point  $(1, 0)$ . If for some  $1 \leq k \leq n$ ,  $X_{k:n} \leq_{\text{gdmftr}} Z_{k:n}$  w.r.t.  $\psi$ , then

$$X_{k:n} \leq_{\text{dmftr}} Z_{k:n}, \quad \text{for all } k = 1, 2, \dots, n. \quad (71)$$

(2) Assume that the function  $\psi$  is anti-star-shaped with respect to the point  $(1, 0)$ . If  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ , then

$$X \leq_{\text{dmftr}} Z. \quad (72)$$

(3) Assume that the function  $\psi$  is dual star-shaped of order  $n$ . If  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ , then

$$X_{n:n} \leq_{\text{dmftr}} Z_{n:n}. \quad (73)$$

(4) Assume that the function  $\psi$  is anti-star-shaped of order  $n$  with respect to the point  $(1, 0)$ . If  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ , then

$$X_{1:n} \leq_{\text{dmtr}} Z_{1:n}. \quad (74) \quad \text{Proof}$$

(5) Assume that the function  $\psi$  is increasing in  $u \in (0, 1)$ .  
If  $X \leq_{\text{dmtr}} Z$  w.r.t.  $\psi$ , then

$$X_{k:n} \leq_{\text{gdmtr}} Z_{k:n}, \quad \text{for all } k = 1, 2, \dots, n. \quad (75)$$

(1) Suppose that, for some  $1 \leq k \leq n$ ,  $X_{k:n} \leq_{\text{gdmtr}} Z_{k:n}$   
w.r.t.  $\psi$ . Then, for all  $t > 0$ ,

$$\int_0^t \psi[F_{X_{k:n}}(x)] \left[ \frac{f_{X_{k:n}}(t)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(t))]} - \frac{f_{X_{k:n}}(x)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(x))]} \right] dx \geq 0. \quad (76)$$

Since the function  $\psi$  is anti-star-shaped with respect to the point  $(1, 0)$ , the function  $(1-u)/\psi(u)$  is nonnegatively decreasing in  $u \in (0, 1)$ . Thus,  $h(x) =$

$\bar{F}_{X_{k:n}}(x)/\psi[F_{X_{k:n}}(x)]$  is nonnegatively decreasing. From Lemma 4 and (76), we have

$$\int_0^t \bar{F}_{X_{k:n}}(x) \left[ \frac{f_{X_{k:n}}(t)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(t))]} - \frac{f_{X_{k:n}}(x)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(x))]} \right] dx \geq 0, \quad \text{for all } t > 0, \quad (77)$$

which asserts that

$$X_{k:n} \leq_{\text{dmtr}} Z_{k:n}, \quad \text{for all } k = 1, 2, \dots, n. \quad (78)$$

(2) Suppose that  $X \leq_{\text{gdmtr}} Z$  w.r.t.  $\psi$ . Then, for all  $t > 0$ ,

$$\int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0. \quad (79)$$

Since the function  $\psi$  is anti-star-shaped with respect to the point  $(1, 0)$ , the function  $(1-u)/\psi(u)$  is decreasing in  $u \in (0, 1)$ . Thus,  $h(x) = \bar{F}_X$

$(x)/\psi[F_X(x)]$  is nonnegatively decreasing. From Lemma 4 and (79), we have

$$\int_0^t \bar{F}_X(x) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0, \quad (80)$$

which states that

$$X \leq_{\text{dmtr}} Z. \quad (81)$$

(3) Suppose that  $X \leq_{\text{gdmtr}} Z$  w.r.t.  $\psi$ . Then, for all  $t > 0$ ,

$$\int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0. \quad (82)$$

Since  $\psi$  is dual star-shaped of order  $n$ , the function  $(1-u^n)/\psi(u)$  is nonnegative decreasing in  $u \in (0, 1)$ , which leads to the function

$$\varphi(x) = \frac{1 - [F_X(x)]^n}{\psi[F_X(x)]} = \frac{\bar{F}_{X_{n:n}}(x)}{\psi[F_X(x)]}, \quad (83)$$

being nonnegative decreasing. Moreover,

$$\frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} = \frac{f_{X_{n:n}}(x)}{h_{Z_{n:n}}[H_{Z_{n:n}}^{-1}(F_{X_{1:n}}(x))]} \quad (84)$$

From Lemma 4, (82)–(84), we have

$$\int_0^t \bar{F}_{X_{n:n}}(x) \left[ \frac{f_{X_{n:n}}(t)}{h_{Z_{n:n}}[H_{Z_{n:n}}^{-1}(F_{X_{n:n}}(t))]} - \frac{f_{X_{n:n}}(x)}{h_{Z_{n:n}}[H_{Z_{n:n}}^{-1}(F_{X_{n:n}}(x))]} \right] dx \geq 0, \quad \text{for all } t > 0, \quad (85)$$

and this asserts that

$$X_{n:n} \leq_{\text{dmtr}} Z_{n:n}. \quad (86)$$

(4) Suppose that  $X \leq_{\text{gdmtr}} Z$  w.r.t.  $\psi$ . Then, for all  $t > 0$ ,

$$\int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0. \quad (87)$$

Since  $\psi$  is anti-star-shaped of order  $n$  with respect to the point  $(1, 0)$ , the function  $(1-u)^n/\psi(u)$  is decreasing in  $u \in (0, 1)$ , and this leads to the function

$$h(x) = \frac{[1 - F_X(x)]^n}{\psi[F_X(x)]} = \frac{\bar{F}_{X_{1:n}}(x)}{\psi[F_X(x)]}, \quad (88)$$

being nonnegatively decreasing. Moreover,

$$\frac{f_{X_{1:n}}(x)}{h_{Z_{1:n}}[H_{Z_{1:n}}^{-1}(F_{X_{1:n}}(x))]} = \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \quad (89)$$

From Lemma 4, (87)–(89), we have

$$\int_0^t \bar{F}_{X_{1:n}}(x) \left[ \frac{f_{X_{1:n}}(t)}{h_{Z_{1:n}}[H_{Z_{1:n}}^{-1}(F_{X_{1:n}}(t))]} - \frac{f_{X_{1:n}}(x)}{h_{Z_{1:n}}[H_{Z_{1:n}}^{-1}(F_{X_{1:n}}(x))]} \right] dx \geq 0, \quad \text{for all } t > 0, \quad (90)$$

which is equivalent to

$$X_{1:n} \leq_{\text{dmtr}} Z_{1:n}. \quad (91)$$

(5) Suppose that  $X \leq_{\text{dmtr}} Z$  w.r.t.  $\psi$ . Then, we have, for all  $t > 0$ ,

$$\begin{aligned} & \int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \\ &= \int_0^t \psi[F_X(x)] \left[ \frac{f_{X_{k:n}}(t)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(t))]} - \frac{f_{X_{k:n}}(x)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(x))]} \right] dx \geq 0. \end{aligned} \quad (92)$$

Since  $\psi$  is increasing in  $u \in (0, 1)$ , then  $\bar{F}_{X_{k:n}}(x)/\psi[F_X(x)]$  is nonnegatively decreasing in  $x > 0$ . From Lemma 4 and inequality (92), we have

$$\int_0^t \psi[F_{X_{k:n}}(x)] \left[ \frac{f_{X_{k:n}}(t)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(t))]} - \frac{f_{X_{k:n}}(x)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(x))]} \right] dx \geq 0, \quad \text{for all } t > 0, \quad (93)$$

which is equivalent to

$$X_{k:n} \leq_{\text{gdmftr}} Z_{k:n}, \quad \text{for all } k = 1, 2, \dots, n. \quad (94)$$

Therefore, the proof of the theorem is complete.

Denote by  $X_{1:N} = \min(X_1, X_2, \dots, X_N)$  and  $X_{N:N} = \max(X_1, X_2, \dots, X_N)$ .  $Z_{1:N}$  and  $Z_{N:N}$  are similar. Let  $\varphi_N(\cdot)$  be the probability generating function of  $N$ .  $\square$

**Theorem 11.** Assume that  $X_1, X_2, \dots$ , and  $Z_1, Z_2, \dots$ , are the i.i.d. copies of  $X$  and  $Z$ , respectively.

(1) Let the function  $\psi \circ \varphi_N$  be star-shaped with respect to the point  $(1, 0)$ . If  $X \leq_{\text{dmftr}} Z$ , then

$$X_{N:N} \leq_{\text{gdmftr}} Z_{N:N} \text{ w.r.t. } \psi. \quad (95)$$

(2) Let the function  $\psi \circ \varphi_N$  be anti-star-shaped with respect to the point  $(1, 0)$ . If  $X_{N:N} \leq_{\text{gdmftr}} Z_{N:N}$  w.r.t.  $\psi$ , then

$$X \leq_{\text{dmftr}} Z. \quad (96)$$

(3) Let  $\psi$  be a function defined on the interval  $(0, 1)$  such that the function  $\psi(1 - \varphi_N(u))/u$  is increasing in  $u \in (0, 1)$ . If  $X \leq_{\text{dmftr}} Z$ , then

$$X_{1:N} \leq_{\text{gdmftr}} Z_{1:N} \text{ w.r.t. } \psi. \quad (97)$$

(4) Let  $\psi$  be a function defined on the interval  $(0, 1)$  such that the function  $u/\psi(1 - \varphi_N(u))$  is increasing in  $u \in (0, 1)$ . If  $X_{1:N} \leq_{\text{gdmftr}} Z_{1:N}$  w.r.t.  $\psi$ , then

$$X \leq_{\text{dmftr}} Z. \quad (98)$$

*Proof*

(1) Suppose that  $X \leq_{\text{dmftr}} Y$ . This asserts that

$$\int_0^t \bar{F}_X(x) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0. \quad (99)$$

Shaked and Shanthikumar [8] showed that

$$H_{Z_{N:N}}^{-1}(F_{X_{N:N}}(x)) = H_Z^{-1}(F_X(x)). \quad (100)$$

It can be proven that

$$\frac{f_{X_{N:N}}(x)}{h_{Z_{N:N}}[H_{Z_{N:N}}^{-1}(F_{X_{N:N}}(x))]} = \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \quad (101)$$

Since the function  $\psi \circ \varphi_N$  is star-shaped with respect to the point  $(1, 0)$ , the function  $\psi[\varphi_N(u)]/(1-u)$  is decreasing in  $u \in (0, 1)$ , and this leads to the function

$$h(x) = \frac{\psi[\varphi_N(F_X(x))]}{(1 - F_X(x))} = \frac{\psi[F_{X_{N:N}}(x)]}{\bar{F}_X(x)}, \quad (102)$$

being nonnegative decreasing. From Lemma 4, (99), and (101), we have for all  $t > 0$ ,

$$\int_0^t \psi[F_{X_{N:N}}(x)] \left[ \frac{f_{X_{N:N}}(t)}{h_{Z_{N:N}}[H_{Z_{N:N}}^{-1}(F_{X_{N:N}}(t))]} - \frac{f_{X_{N:N}}(x)}{h_{Z_{N:N}}[H_{Z_{N:N}}^{-1}(F_{X_{N:N}}(x))]} \right] dx \geq 0. \quad (103)$$

That is,  $X_{N:N} \leq_{\text{gdmftr}} Z_{N:N}$  w.r.t.  $\psi$ .

(2) Suppose that  $X_{N:N} \leq_{\text{gdmftr}} Z_{N:N}$  w.r.t.  $\psi$ . This asserts that, for all  $t > 0$ ,

$$\int_0^t \psi[F_{X_{N:N}}(x)] \left[ \frac{f_{X_{N:N}}(t)}{h_{Z_{N:N}}[H_{Z_{N:N}}^{-1}(F_{X_{N:N}}(t))]} - \frac{f_{X_{N:N}}(x)}{h_{Z_{N:N}}[H_{Z_{N:N}}^{-1}(F_{X_{N:N}}(x))]} \right] dx \geq 0. \quad (104)$$

Since the function  $\psi \circ \varphi_N(\cdot)$  is anti-star-shaped with respect to the point  $(1, 0)$ , the function  $(1-u)/\psi[\varphi_N(u)]$  is decreasing in  $u \in (0, 1)$ , and this leads to the function

$$h(x) = \frac{(1 - F_X(x))}{\psi[\varphi_N(F_X(x))]} = \frac{\bar{F}_X(x)}{\psi[F_{X_{N:N}}(x)]}, \quad (105)$$

being nonnegatively decreasing. From Lemma 4, (104), and (101), we have

$$\int_0^t \bar{F}_X(x) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0. \quad (106)$$

That is,  $X \leq_{\text{dmftr}} Y$ .

(3) Suppose that  $X \leq_{\text{dmftr}} Z$ . Then,

$$\int_0^t \bar{F}_X(x) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0. \quad (107)$$

Shaked and Shanthikumar [8] showed that

$$H_{Z_{1:N}}^{-1}(F_{X_{1:N}}(x)) = H_Z^{-1}(F_X(x)). \quad (108)$$

It can be proven that

$$\frac{f_{X_{1:N}}(x)}{h_{Z_{1:N}}[H_{Z_{1:N}}^{-1}(F_{X_{1:N}}(x))]} = \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \quad (109)$$

Since the function  $\psi(1 - \varphi_N(u))/u$  is increasing in  $u \in (0, 1)$ , the function

$$h(x) = \frac{\psi[\varphi_N(\bar{F}_X(x))]}{\bar{F}_X(x)} = \frac{\psi[F_{X_{1:N}}(x)]}{\bar{F}_X(x)}, \quad (110)$$

is nonnegative decreasing. From Lemma 4, (107), and (109), we have, for all  $t > 0$ ,

$$\int_0^t \psi[F_{X_{1:N}}(t)] \left[ \frac{f_{X_{1:N}}(t)}{h_{Z_{1:N}}[H_{Z_{1:N}}^{-1}(F_{X_{1:N}}(t))]} - \frac{f_{X_{1:N}}(x)}{h_{Z_{1:N}}[H_{Z_{1:N}}^{-1}(F_{X_{1:N}}(x))]} \right] dx \geq 0. \quad (111)$$

That is,  $X_{1:N} \leq_{\text{gdmftr}} Z_{1:N}$  w.r.t.  $\psi$ .

(4) Suppose that  $X_{1:N} \leq_{\text{gdmftr}} Z_{1:N}$  w.r.t.  $\psi$ . Then, for all  $t > 0$ ,

$$\int_0^t \psi[F_{X_{1:N}}(x)] \left[ \frac{f_{X_{1:N}}(t)}{h_{Z_{1:N}}[H_{Z_{1:N}}^{-1}(F_{X_{1:N}}(t))]} - \frac{f_{X_{1:N}}(x)}{h_{Z_{1:N}}[H_{Z_{1:N}}^{-1}(F_{X_{1:N}}(x))]} \right] dx \geq 0. \quad (112)$$

Since the function  $u/\psi(1 - \varphi_N(u))$  is increasing in  $u \in (0, 1)$ , the function

$$h(x) = \frac{\bar{F}_X(x)}{\psi[\varphi_N(\bar{F}_X(x))]} = \frac{\bar{F}_X(x)}{\psi[F_{X_{1:N}}(x)]}, \quad (113)$$

is nonnegatively decreasing. From Lemma 4, (112), and (109), we have for all  $t > 0$ ,

$$\int_0^t \bar{F}_X(x) \left[ \frac{f_{X_{1:N}}(t)}{h_{Z_{1:N}}[H_{Z_{1:N}}^{-1}(F_{X_{1:N}}(t))]} - \frac{f_{X_{1:N}}(x)}{h_{Z_{1:N}}[H_{Z_{1:N}}^{-1}(F_{X_{1:N}}(x))]} \right] dx \geq 0. \quad (114)$$

That is,  $X_{1:N} \leq_{\text{gdmftr}} Z_{1:N}$ . Therefore, the proof of the theorem is complete.  $\square$

**Theorem 12.** Assume that  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ ,  $\psi(u) = B_{n-k+1,k}(u)$ ,  $u \in (0, 1)$ , for some  $1 \leq k \leq n$ , where

$B_{n-k+1,k}$  is the distribution function of a beta distribution with parameters  $n - k + 1$  and  $k$ . Then, we have

$$X_{k:n} \leq_{\text{dmtfr}} Z_{k:n}, \quad \text{for all } k = 1, 2, \dots, n. \quad (115)$$

*Proof.* Suppose that  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ . This asserts that

$$\int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0. \quad (116)$$

By taking  $\psi(u) = B_{n-k+1,k}(u)$ ,  $u \in (0, 1)$ , we get that

$$\int_0^t \bar{B}_{n-k+1,k}(F_X(x)) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0. \quad (117)$$

In view of the fact that

$$B_{n-k+1,k}(\bar{F}_X(x)) = \bar{F}_{X_{k:n}}(x),$$

$$\frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} = \frac{f_{X_{k:n}}(x)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(x))]}, \quad (118)$$

thus

$$\int_0^t \bar{F}_{X_{k:n}}(x) \left[ \frac{f_{X_{k:n}}(t)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(t))]} - \frac{f_{X_{k:n}}(x)}{h_{Z_{k:n}}[H_{Z_{k:n}}^{-1}(F_{X_{k:n}}(x))]} \right] dx \geq 0, \quad \text{for all } t > 0, \quad (119)$$

which is equivalent to

$$X_{k:n} \leq_{\text{dmtfr}} Z_{k:n}, \quad \text{for all } k = 1, 2, \dots, n. \quad (120)$$

Hence, the proof is complete.

Let  $k = 1$  and  $k = n$  in Theorem 12, respectively, we have the following corollary.  $\square$

**Corollary 1.** Assume that  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ .

- (i) If  $\psi(u) = B_{n,1}(u) = \int_0^u nx^{n-1} dx = u^n$ ,  $u \in (0, 1)$ . Then,  $X_{1:n} \leq_{\text{dmtfr}} Z_{1:n}$ .
- (ii) If  $\psi(u) = B_{1,n}(u) = \int_0^u n(1-x)^{n-1} dx = 1 - (1-u)^n$ ,  $u \in (0, 1)$ . Then  $X_{n:n} \leq_{\text{dmtfr}} Z_{n:n}$ .

**Theorem 13.** Assume that  $X_1, X_2, \dots$ , and  $Z_1, Z_2, \dots$ , are the i.i.d. copies of  $X$  and  $Z$ , respectively. Let  $N$  be a positive integer-valued random variable that is independent of  $X_i$ 's and  $Y_i$ 's.

(1) Let the function  $\psi$  be star-shaped with respect to the point  $(1, 0)$ .

- (i) If  $X_{1:N} \leq_{\text{dmtfr}} Z_{1:N}$ , then  $X_{1:N} \leq_{\text{gdmftr}} Z_{1:N}$  w.r.t.  $\psi$ .
- (ii) If  $X_{N:N} \leq_{\text{dmtfr}} Z_{N:N}$ , then  $X_{N:N} \leq_{\text{gdmftr}} Z_{N:N}$  w.r.t.  $\psi$ .

(2) Let the function  $\psi$  be anti-star-shaped with respect to the point  $(1, 0)$ .

- (i) If  $X_{1:N} \leq_{\text{gdmftr}} Z_{1:N}$  w.r.t.  $\psi$ , then  $X_{1:N} \leq_{\text{dmtfr}} Z_{1:N}$ .
- (ii) If  $X_{N:N} \leq_{\text{gdmftr}} Z_{N:N}$  w.r.t.  $\psi$ , then  $X_{N:N} \leq_{\text{dmtfr}} Z_{N:N}$ .

*Proof.* We only give the proof for the case (1) (b), the proofs for other cases are similar and hence omitted. If  $X_{N:N} \leq_{\text{dmtfr}} Z_{N:N}$ , from (30), we obtain that, for all  $t \geq 0$ ,

$$\int_0^t \bar{F}_{X_{N:N}}(x) \cdot \left[ \frac{f_{X_{N:N}}(t)}{h_{Z_{N:N}}[H_{Z_{N:N}}^{-1}(F_{X_{N:N}}(t))]} - \frac{f_{X_{N:N}}(x)}{h_{Z_{N:N}}[H_{Z_{N:N}}^{-1}(F_{X_{N:N}}(x))]} \right] dx \geq 0. \quad (121)$$

Since the function  $\psi$  is star-shaped with respect to the point  $(1, 0)$ , then the function

$$\frac{\psi(u)}{(1-u)}, \quad (122)$$

is decreasing in  $u \in (0, 1)$ . Hence,  $\psi[F_{X_{N:n}}(x)]/\bar{F}_{X_{N:n}}(x)$  is decreasing in  $x \geq 0$ ; from Lemma 4 and inequality (121), we have for all  $t \geq 0$ ,

$$\int_t^\infty \psi[F_{X_{N:n}}(x)] \cdot \left[ \frac{f_{X_{N:n}}(t)}{h_{Z_{N:n}}[H_{Z_{N:n}}^{-1}(F_{X_{N:n}}(t))]} - \frac{f_{X_{N:n}}(x)}{h_{Z_{N:n}}[H_{Z_{N:n}}^{-1}(F_{X_{N:n}}(x))]} \right] dx \geq 0. \quad (123)$$

That is,  $X_{N:n} \leq_{\text{gdmftr}} Z_{N:n}$  w.r.t.  $\psi$  as claimed.  $\square$

(2) Let the function  $\psi$  be dual anti-star-shaped of order  $n$ . If  $X_{n:n} \leq_{\text{dmftr}} Z_{n:n}$ , then  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ .

#### Theorem 14

(1) Let the function  $\psi$  be star-shaped of order  $n$  with respect to the point  $(1, 0)$ . If  $X_{1:n} \leq_{\text{dmftr}} Z_{1:n}$ , then  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ .

*Proof.* We only give the proof for case (1), the proof for case (2) is similar, and hence omitted. If  $X_{1:n} \leq_{\text{dmftr}} Z_{1:n}$ , from (30), we obtain that

$$\int_0^t \bar{F}_{X_{1:n}}(x) \cdot \left[ \frac{f_{X_{1:n}}(t)}{h_{Z_{1:n}}[H_{Z_{1:n}}^{-1}(F_{X_{1:n}}(t))]} - \frac{f_{X_{1:n}}(x)}{h_{Z_{1:n}}[H_{Z_{1:n}}^{-1}(F_{X_{1:n}}(x))]} \right] dx \geq 0, \quad \text{for all } t \geq 0. \quad (124)$$

Shaked and Shanthikumar [8] showed that  $H_{Z_{n:n}}^{-1}(F_{X_{n:n}}(x)) = H_Z^{-1}(F_X(x))$ . It can be proven that

$$\frac{f_{X_{1:n}}(x)}{h_{Z_{1:n}}[H_{Z_{1:n}}^{-1}(F_{X_{1:n}}(x))]} = \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]}, \quad \text{for all } x \geq 0. \quad (125)$$

Since the function  $\psi(x)$  is star-shaped of order  $n$  with respect to the point  $(1, 0)$ , then the function  $\psi(x)/(1-x)^n$  is decreasing in  $x \in (0, 1)$ . Hence, the function

$$\frac{\psi[F_X(x)]}{[\bar{F}_X(x)]^n}, \quad (126)$$

is nonnegatively decreasing in  $x \geq 0$ . From Lemma 4, inequality (124), and equation (125), we have

$$\int_0^t \psi[F_X(x)] \cdot \left[ \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} - \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} \right] dx \geq 0, \quad \text{for all } t > 0. \quad (127)$$

That is,  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$  as claimed.

At the end of this section, we show the relation between the orders DMFTR, RDMFTR, and GDMFTR:

$$\begin{aligned} X \leq_{\text{gdmftr}} Z \text{ w.r.t. } \psi, \quad \psi(u) = 1-u, u \in (0, 1) &\iff X \leq_{\text{dmftr}} Z, \\ X \leq_{\text{gdmftr}} Z \text{ w.r.t. } \psi, \quad \psi(u) = g_Y[G_Y^{-1}(u)], u \in (0, 1) &\iff X \leq_{\text{rdmftr}} Z, \\ X \leq_{\text{rdmftr}} Z \text{ w.r.t. } Y, \quad Y \text{ is exponential} &\iff X \leq_{\text{dmftr}} Z. \end{aligned} \quad (128)$$

## 4. Closure and Reversed Closure Properties of the GDMFTR Order

In this section, we investigate the closure and reversed closure properties of the GDMFTR order with respect to the

referred functions and the compared random variables, respectively.

The following Theorem 15 indicates that the GDMFTR order has the closure property with respect to the referred function under multiplication of functions.

**Theorem 15.** If  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ , and  $\varphi$  is nonnegative decreasing in  $x \in (0, 1)$ , then

$$X \leq_{\text{gdmftr}} Z \text{ w.r.t. } \varphi \cdot \psi. \quad (129)$$

*Proof.* Suppose that  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ . Then, from (30), we have

$$\int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{g_Y[G_Y^{-1}(F_X(t))]} - \frac{f_X(x)}{g_Y[G_Y^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0. \quad (130)$$

Since  $\varphi[F_X(t)]$  is nonnegatively decreasing in  $x \in (0, 1)$ , from (130) and Lemma 4, we obtain for all  $t > 0$ ,

$$\int_0^t \varphi[F_X(x)] \cdot \psi[F_X(x)] \left[ \frac{f_X(t)}{g_Y[G_Y^{-1}(F_X(t))]} - \frac{f_X(x)}{g_Y[G_Y^{-1}(F_X(x))]} \right] dx \geq 0, \quad (131)$$

which is equivalent to that  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi \cdot \varphi$ . Therefore, the proof of the theorem is complete.

From Theorem 15, we have the following corollary.  $\square$

**Corollary 2.** If  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi$ , and  $\psi$  is decreasing in  $x \in (0, 1)$ , then

$$X \leq_{\text{gdmftr}} Z \text{ w.r.t. } \psi^n. \quad (132)$$

**Theorem 16.** Let  $\psi_1$  and  $\psi_2$  be two continuous nonnegative functions defined on  $(0, 1)$ ,  $X$  and  $Z$  be two continuous nonnegative random variables. Then, the following statements are true.

(1) If  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi_i$ ,  $i = 1, 2$ , then

$$X \leq_{\text{gdmftr}} Z \text{ w.r.t. } \psi_1 + \psi_2. \quad (133)$$

(2) If  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi_1$  and  $\psi_2$  is increasing in  $x \in (0, 1)$ , then

$$X \leq_{\text{gdmftr}} Z \text{ w.r.t. } \frac{\psi_1}{\psi_2}. \quad (134)$$

(3) If  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi_2$ ,  $\psi_1$  is star-shaped and  $\psi_2$  is decreasing, then

$$X \leq_{\text{gdmftr}} Z \text{ w.r.t. } \psi_1 \circ \psi_2, \quad (135)$$

where  $\psi_1 \circ \psi_2$  is the compound of  $\psi_1$  and  $\psi_2$ .

(4) If  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi_2$ ,  $\psi_1$  is anti-star-shaped and  $\psi_2$  is increasing, then

$$X \leq_{\text{gdmftr}} Z \text{ w.r.t. } \psi_1 \circ \psi_2, \quad (136)$$

(5) If  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi_1/\psi_2$  and  $\psi_2$  is decreasing in  $x \in (0, 1)$ , then

$$X \leq_{\text{gdmftr}} Z \text{ w.r.t. } \psi_1. \quad (137)$$

(6) If  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi_2$  and  $\psi_1/\psi_2$  is decreasing in  $x \in (0, 1)$ , then

$$X \leq_{\text{gdmftr}} Z \text{ w.r.t. } \psi_1. \quad (138)$$

*Proof.* We only give the proofs for the case of (3); the proofs for the other cases are similar and omitted. (3) Suppose that  $X \leq_{\text{gdmftr}} Z$  w.r.t.  $\psi_2$ . Then, from (30), we have

$$\int_0^t \psi_2[F_X(x)] \left[ \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} - \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} \right] dx \geq 0, \quad \text{for all } t > 0. \quad (139)$$

Since the function  $\psi_2$  is decreasing,  $\psi_2[F_X(x)]$  is then decreasing. Moreover,  $\psi_1$  is star-shaped on the interval  $(0, 1)$ , and then  $\psi_1(u)/u$  is increasing in  $u \in (0, 1)$ ; thus,

the function  $\psi_1[\psi_2(F_X(x))]/\psi_2[F_X(x)]$  is decreasing in  $x \geq 0$ . From Lemma 4 and inequality (139), we have for all  $t > 0$ ,

$$\int_0^t \psi_1[\psi_2(F_X(x))] \left[ \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} - \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} \right] dx \geq 0, \quad (140)$$

which asserts that  $X \leq_{\text{gdmtr}} Z$  r.t.  $\psi_1 \circ \psi_2$  as claimed.

Let  $X$  be a nonnegative absolutely continuous random variable and  $\phi$  be a nonnegative increasing function defined on  $[0, \infty)$  with  $\phi(0) = 0$ . We call that  $\phi$  is a generalized scale function and  $\phi(X)$  is the generalized scale transform of  $X$ . In the accelerated life testing, the  $\phi$  is called an accelerating factor.

If a function  $\phi$  is increasing convex with  $\phi(0) = 0$ , then  $\phi$  is called a risk preference function, and  $\phi(X)$  is called the risk preference transform of  $X$ . If  $\phi$  is increasing concave with  $\phi(0) = 0$ , then  $\phi$  is called a risk aversion function, and  $\phi(X)$  is called the risk aversion transform of  $X$ . If  $\phi$  is a risk aversion function, we say that  $-\phi''/\phi'$  is the absolute risk aversion coefficient of  $\phi$ . If  $\phi$  is a risk preference function, we say that  $-\phi''/\phi'$  is the risk preference coefficient of  $\phi$ .  $\square$

**Theorem 17.** Let  $\psi$  be a nonnegative function defined on  $(0, 1)$  and  $\phi$  be a nonnegative function defined on  $[0, +\infty)$

with  $\phi(0) = 0$ . Suppose that the function  $\phi$  is increasing concave with  $-\phi''/\phi'$  being decreasing in  $x \geq 0$ , and  $X \geq_{\text{disp}} Z$ . Then,

$$X \leq_{\text{gdmtr}} Z \text{ w.r.t. } \psi \Rightarrow \phi(X) \leq_{\text{gdmtr}} \phi(Z) \text{ w.r.t. } \psi. \quad (141)$$

*Proof.* Suppose that  $X \leq_{\text{gdmtr}} Z$  w.r.t.  $\psi$ . Then, from (30), we have for all  $t > 0$ ,

$$\int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0. \quad (142)$$

Since the function  $\phi(x)$  is increasing concave,  $\phi'(x)$  is nonnegatively decreasing in  $x \geq 0$ . From Lemma 4 and (142), we have

$$\int_0^t \psi[F_X(x)] \phi'(x) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0. \quad (143)$$

On the other hand,  $\phi(X) \leq_{\text{gdmtr}} \phi(Z)$  w.r.t.  $\psi$  if and only if for all  $t > 0$ ,

$$\begin{aligned} & \int_0^t \psi[F_{\phi(X)}(x)] \left[ \frac{f_{\phi(X)}(t)}{h_{\phi(Z)}[H_{\phi(Z)}^{-1}(F_{\phi(X)}(t))]} - \frac{f_{\phi(X)}(x)}{h_{\phi(Z)}[H_{\phi(Z)}^{-1}(F_{\phi(X)}(x))]} \right] \\ &= \int_0^t \psi[F_X(x)] \phi'(x) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} \cdot \frac{\phi'[\alpha(t)]}{\phi'(t)} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \cdot \frac{\phi'[\alpha(x)]}{\phi'(x)} \right] dx \geq 0, \end{aligned} \quad (144)$$

where  $\alpha(x) = H_Z^{-1}(F_X(x))$ . Under the given conditions of the theorem, we have that the function

$$\frac{\phi'[\alpha(x)]}{\phi'(x)}, \quad (145)$$

is increasing and nonnegative for all  $x > 0$ . Hence, from (143), we obtain for all  $t > 0$ ,

$$\begin{aligned} & \int_0^t \psi[F_X(x)] \phi'(x) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} \cdot \frac{\phi'[\alpha(t)]}{\phi'(t)} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \cdot \frac{\phi'[\alpha(x)]}{\phi'(x)} \right] dx \geq \\ & \frac{\phi'[\alpha(t)]}{\phi'(t)} \int_0^t \psi[F_X(x)] \phi'(x) \left[ \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} - \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} \right] dx \geq 0. \end{aligned} \quad (146)$$

That is to say, inequality (144) is valid, so the proof of the theorem is complete.  $\square$

*Remark 7.* Theorem 17 says, under some appropriate conditions, that the order  $\leq_{\text{gdmtr}}$  has the closure property under the concave generalized scale transform.

*Remark 8.* Theorem 17 also says, under some appropriate conditions, that the order  $\leq_{\text{gdmtr}}$  has the closure property under the action of an increasing concave accelerating factor.

*Remark 9.* Theorem 17 also says, under the condition of  $X \geq_{\text{disp}} Z$ , that the GDMTFR order has the closure property under the risk averse transform  $\phi$  with an increasing absolute risk aversion coefficient  $-\phi''/\phi'$ .

With a similar manner of the proof of Theorem 17, Theorem 18 can be proven, and the detailed proof is omitted.

**Theorem 18.** Let  $\psi$  be a nonnegative function defined on  $(0, 1)$  and  $\phi$  be a nonnegative function defined on  $[0, +\infty)$  with  $\phi(0) = 0$ . Suppose that the function  $\phi$  is increasing and convex with  $\phi''/\phi'$  being increasing in  $x \geq 0$ . If  $\phi(X) \leq_{\text{gdmtr}} \phi(Z)$  w.r.t.  $\psi$  and  $X \geq_{\text{disp}} Z$ , then

$$X \leq_{\text{gdmtr}} Z \text{ w.r.t. } \psi. \quad (147)$$

*Remark 10.* Theorem 18 says, under some appropriate conditions, that the order  $\leq_{\text{gdmtr}}$  has the reversed closure property under the convex generalized scale transform.

*Remark 11.* Theorem 18 also says, under some appropriate conditions, that the order  $\leq_{\text{gdmtr}}$  has the reversed closure property under the action of an increasing and convex accelerating factor.

*Remark 12.* Theorem 18 also says, under the condition of  $X \geq_{\text{disp}} Z$ , that the GDMTFR order has the reversed closure property under the risk preference transform  $\phi$  with an increasing risk preference coefficient  $\phi''/\phi'$ .

**Theorem 19.** Let  $\psi$  be a nonnegative increasing function defined on  $(0, 1)$  and let  $\phi$  be a nonnegative increasing concave function defined on  $[0, +\infty)$  with  $\phi(0) = 0$  and with  $\phi''/\phi'$  being decreasing in  $x > 0$ . Suppose that  $X \geq_{\text{disp}} Z$ . Then,

$$X \leq_{\text{gdmtr}} Z \text{ w.r.t. } \psi \Rightarrow \phi(X) \leq_{\text{gdmtr}} \phi(Z) \text{ w.r.t. } \phi \circ \psi. \quad (148)$$

*Proof.* Suppose that  $X \leq_{\text{gdmtr}} Z$  w.r.t.  $\psi$ . Then, from (30), we have

$$\int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0. \quad (149)$$

Since the function  $\phi(x)$  is increasing concave,  $\phi'(x)$  is nonnegatively decreasing in  $x > 0$ . From Lemma 4 and (149), we have

$$\int_0^t \psi[F_X(x)] \phi'(x) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0. \quad (150)$$

Since  $\phi$  is nonnegatively increasing concave,  $\phi(x)/x$  is nonnegatively decreasing and  $\psi$  being nonnegatively increasing leads to increasing  $\psi(F_X(x))$ , so

$\phi[\psi(F_X(x))]/\psi(F_X(x))$  is nonnegatively decreasing. From Lemma 4 and (150), we obtain that

$$\int_0^t \phi[\psi(F_X(x))] \phi'(x) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0, \quad \text{for all } t > 0. \quad (151)$$

On the other hand,  $\phi(X) \leq_{\text{gdmtr}} \phi(Z)$  w.r.t.  $\phi \circ \psi$  if and only if for all  $t \geq 0$ ,

$$\begin{aligned} & \int_0^t \phi[\psi(F_{\phi(X)}(x))] \left[ \frac{f_{\phi(X)}(t)}{h_{\phi(Z)}[H_{\phi(Z)}^{-1}(F_{\phi(X)}(t))]} - \frac{f_{\phi(X)}(x)}{h_{\phi(Z)}[H_{\phi(Z)}^{-1}(F_{\phi(X)}(x))]} \right] \\ &= \int_0^t \phi[\psi(F_X(x))] \phi'(x) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} \cdot \frac{\phi'[\alpha(t)]}{\phi'(t)} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \cdot \frac{\phi'[\alpha(x)]}{\phi'(x)} \right] dx \geq 0, \end{aligned} \quad (152)$$

where  $\alpha(x) = H_Z^{-1}(F_X(x))$ . Since  $\phi''/\phi'$  is decreasing, and  $X \geq_{\text{disp}} Z$ , we have that the function

$$\frac{\phi'[\alpha(x)]}{\phi'(x)}, \quad (153)$$

is nonnegatively increasing in  $x > 0$ . Therefore, for all  $t > 0$ ,

$$\begin{aligned} & \int_0^t \phi[\psi(F_X(x))] \phi'(x) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} \cdot \frac{\phi'[\alpha(t)]}{\phi'(t)} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \cdot \frac{\phi'[\alpha(x)]}{\phi'(x)} \right] dx \\ & \geq \frac{\phi'[\alpha(t)]}{\phi'(t)} \int_0^t \phi[\psi(F_X(x))] \phi'(x) \left[ \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(t))]} \right] dx \geq 0. \end{aligned} \quad (154)$$

From (151) and (154), we see that inequality (152) is valid. That is to say,  $\phi(X) \leq_{\text{gdmtr}} \phi(Z)$  w.r.t.  $\phi \circ \psi$ . Therefore, the proof of the theorem is complete.  $\square$

*Remark 13.* Theorem 19 says that, under some appropriate conditions, the order  $\leq_{\text{gdmtr}}$  has the closure property with respect to both the compared random variables and the referred function under the concave generalized scale transforms.

*Remark 14.* Theorem 19 also says that, under some appropriate conditions, the order  $\leq_{\text{gdmtr}}$  has the closure property with respect to both the compared random variables and the referred function under the action of a concave accelerating factor.

*Remark 15.* Theorem 19 also says that, under the condition of  $X \geq_{\text{disp}} Z$ , the GDMTR order has the closure property with respect to both the compared random variables and the referred function under the risk aversion transform  $\phi$  with an increasing absolute risk aversion coefficient  $-\phi''/\phi'$ .

**Theorem 20.** Let  $\psi$  be a nonnegative increasing function defined on  $(0, 1)$ , and let  $\phi$  be a nonnegative increasing convex function defined on  $[0, +\infty)$  with  $\phi(0) = 0$  and with  $-\phi''/\phi'$  being decreasing in  $x > 0$ . Assume that  $X \geq_{\text{disp}} Z$ . Then,

$$\phi(X) \leq_{\text{gdmtr}} \phi(Z) \text{ w.r.t. } \phi \circ \psi \Rightarrow X \leq_{\text{gdmtr}} Z \text{ w.r.t. } \psi. \quad (155)$$

*Proof.* Suppose that  $\phi(X) \leq_{\text{gdmtr}} \phi(Z)$  w.r.t.  $\phi \circ \psi$ . Then, from (30), we have, for all  $t > 0$ ,

$$\begin{aligned} & \int_0^t \phi[\psi(F_{\phi(X)}(x))] \left[ \frac{f_{\phi(X)}(t)}{h_{\phi(Z)}[H_{\phi(Z)}^{-1}(F_{\phi(X)}(t))]} - \frac{f_{\phi(X)}(x)}{h_{\phi(Z)}[H_{\phi(Z)}^{-1}(F_{\phi(X)}(x))]} \right] \\ &= \int_0^t \phi[\psi(F_X(x))] \phi'(x) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} \cdot \frac{\phi'[\alpha(t)]}{\phi'(t)} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \cdot \frac{\phi'[\alpha(x)]}{\phi'(x)} \right] dx \geq 0. \end{aligned} \quad (156)$$

Since  $\phi$  is increasing convex,  $\phi(y)/y$  is increasing, and  $\psi$  is increasing. This leads to  $\psi(F_X(x))$  is nonnegatively increasing. Combining these facts, we obtain that the function

$$\frac{\psi(F_X(x))}{\phi[\psi(F_X(x))]}, \quad (157)$$

is nonnegative decreasing in  $x > 0$ . Moreover, since  $\phi$  is increasing convex,  $1/\phi'$  is nonnegatively decreasing. So,

$$\int_0^t \psi(F_X(x)) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} \cdot \frac{\phi'[\alpha(t)]}{\phi'(t)} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \cdot \frac{\phi'[\alpha(x)]}{\phi'(x)} \right] dx \geq 0. \quad (159)$$

Under the given conditions that  $\phi$  is increasing convex with  $\phi''/\phi'$  being decreasing in  $x \geq 0$ , and  $X \geq_{\text{disp}} Z$ , we get

$$\begin{aligned} 0 &\leq \int_0^t \psi(F_X(x)) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} \cdot \frac{\phi'[\alpha(t)]}{\phi'(t)} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \cdot \frac{\phi'[\alpha(x)]}{\phi'(x)} \right] dx \\ &\leq \frac{\phi'[\alpha(t)]}{\phi'(t)} \int_0^t \psi(F_X(x)) \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx, \quad \text{for all } t > 0. \end{aligned} \quad (160)$$

Thus,

$$\int_0^t \psi[F_X(x)] \left[ \frac{f_X(t)}{h_Z[H_Z^{-1}(F_X(t))]} - \frac{f_X(x)}{h_Z[H_Z^{-1}(F_X(x))]} \right] dx \geq 0. \quad (161)$$

That is to say,  $\phi(X) \leq_{\text{gdmtr}} \phi(Z)$  w.r.t.  $\phi \circ \psi$ . Therefore, the proof of the theorem is complete.  $\square$

*Remark 16.* Theorem 20 says that, under some appropriate conditions, the order  $\leq_{\text{gdmtr}}$  has the reversed closure property with respect to both the compared random variables and the referred function under the convex generalized scale transforms.

*Remark 17.* Theorem 20 also says that, under some appropriate conditions, the order  $\leq_{\text{gdmtr}}$  has the reversed closure property with respect to both the compared random variables and the referred function under the action of a convex accelerating factor.

*Remark 18.* Theorem 20 also says that, under the condition of  $X \geq_{\text{disp}} Z$ , the GDMTFR order has the reversed closure property with respect to both the compared random variables and the referred function under the risk preference transform  $\phi$  with a decreasing risk preference coefficient  $\phi''/\phi'$ .

$$\frac{\psi(F_X(x))}{\phi[\psi(F_X(x))]\phi'(x)}, \quad (158)$$

is nonnegatively decreasing in  $x > 0$ . From Lemma 4 and (156), we obtain that, for all  $t > 0$ ,

that  $\phi'[\alpha(x)]/\phi'(x)$  is nonnegatively decreasing in  $x > 0$ . Hence,

## 5. Examples

We give several illustrative examples that meet the GDMTFR order.

*Example 1.* Let  $\psi$  be a nonnegative function defined on the interval  $(0, 1)$ . Now, we consider comparing two Weibull random variables in the GDMTFR order. Let  $X_i, i = 1, 2$ , be two Weibull random variables with respective survival function  $\bar{F}_{X_i}$ . Specifically, let  $X_i \sim W(\alpha_i, \lambda)$ ,  $i = 1, 2$ ,  $\bar{F}_{X_i}(x) = e^{-\lambda x^{\alpha_i}}$ ,  $x \geq 0$ . Hence, the density functions of  $X_i$  are, respectively,

$$f_{X_i}(x) = \lambda \alpha_i x^{\alpha_i - 1} e^{-\lambda x^{\alpha_i}}, \quad x \geq 0. \quad (162)$$

Then, the GDMTFR order is determined by the parameters  $\alpha_i$ . Indeed, it is easy to verify that

$$\begin{aligned} F_{X_2}^{-1}[F_{X_1}(x)] &= x^{\alpha_1/\alpha_2}, \\ f_{X_2}(x) &= \lambda \alpha_2 x^{\alpha_2 - 1} e^{-\lambda x^{\alpha_2}}. \end{aligned} \quad (163)$$

Hence,

$$\frac{f_{X_1}(x)}{f_{X_2}[F_{X_2}^{-1}(F_{X_1}(x))]} = \frac{\alpha_1}{\alpha_2} x^{\alpha_1/\alpha_2 - 1}. \quad (164)$$

(1) If  $\alpha_1 \geq \alpha_2 > 0$ , then from (164), it is clear that the function  $f_{X_1}(x)/f_{X_2}[F_{X_2}^{-1}(F_{X_1}(x))]$  is increasing in

$x > 0$ . From this fact and (30), we have that  $X_1 \leq_{\text{gdmftr}} X_2$  w.r.t.  $\psi$ .

- (2) If  $0 < \alpha_1 \leq \alpha_2$ , then from (164), it is clear that the function  $f_{X_1}(x)/f_{X_2}[F_{X_2}^{-1}(F_{X_1}(x))]$  is decreasing in  $x > 0$ . From this fact and (21), we have that  $X_1 \geq_{\text{gdmftr}} X_2$  w.r.t.  $\psi$ .

*Example 2.* Consider a comparison of two beta random variables in the GDMTFR order. Let  $\psi$  be a nonnegative function defined on the interval  $(0, 1)$ . Let  $X_i, i = 1, 2$ , be two Beta random variables with respective distribution functions  $F_{X_i}$ . Specifically, let  $X_i \sim \text{Beta}(\alpha_i, 1)$ ,  $F_{X_i}(x) = x^{\alpha_i}$ ,  $x \in (0, 1)$ . Hence, the density functions of  $X_i$  are given by, respectively,

$$f_{X_i}(x) = \alpha_i x^{\alpha_i - 1}, \quad x \in (0, 1). \quad (165)$$

It is readily verified that

$$\begin{aligned} F_{X_2}^{-1}[F_{X_1}(x)] &= x^{\alpha_1/\alpha_2}, \\ f_{X_2}(x) &= \lambda \alpha_2 x^{\alpha_2 - 1} e^{-\lambda x^{\alpha_2}}, \quad x \in (0, 1). \end{aligned} \quad (166)$$

Hence,

$$\frac{f_{X_1}(x)}{f_{X_2}[F_{X_2}^{-1}(F_{X_1}(x))]} = \frac{\alpha_1}{\alpha_2} x^{(\alpha_1/\alpha_2) - 1}. \quad (167)$$

- (1) If  $\alpha_1 \geq \alpha_2 > 0$ , it can be seen that the function  $f_{X_1}(x)/f_{X_2}[F_{X_2}^{-1}(F_{X_1}(x))]$  is increasing in  $x \geq 0$ . From this fact and (30), we see that  $X_1 \leq_{\text{gdmftr}} X_2$  w.r.t.  $\psi$ .
- (2) If  $0 < \alpha_1 \leq \alpha_2$ , from (171), we see that the function  $f_{X_1}(x)/f_{X_2}[F_{X_2}^{-1}(F_{X_1}(x))]$  is decreasing in  $x \geq 0$ . From this fact and (30), we have that  $X_1 \geq_{\text{gdmftr}} X_2$  w.r.t.  $\psi$ .

*Example 3.* Consider a comparison of another two beta random variables in the GDMTFR order. Let  $\psi$  be a nonnegative function defined on the interval  $(0, 1)$ . Let  $X_i, i = 1, 2$ , be two beta random variables with respective distribution function  $F_{X_i}$ . Specifically, let  $X_i \sim \text{Beta}(1, \beta_i)$ , then the density functions of  $X_i$  are given by, respectively,

$$f_{X_i}(x) = \beta_i (1-x)^{\beta_i - 1}, \quad x \in (0, 1), \quad i = 1, 2. \quad (168)$$

The distribution functions of  $X_i$  are thus

$$F_{X_i}(x) = 1 - (1-x)^{\beta_i}, \quad x \in (0, 1), \quad i = 1, 2, \quad (169)$$

respectively.

It can be verified that

$$\begin{aligned} F_{X_2}^{-1}[F_{X_1}(x)] &= 1 - (1-x)^{\beta_1/\beta_2}, \\ f_{X_2}(x) &= \beta_2 (1-x)^{\beta_2 - 1}, \quad x \in (0, 1). \end{aligned} \quad (170)$$

Hence,

$$\frac{f_{X_1}(x)}{f_{X_2}[F_{X_2}^{-1}(F_{X_1}(x))]} = \frac{\beta_1}{\beta_2} (1-x)^{(\beta_1/\beta_2) - 1}. \quad (171)$$

- (1) If  $\beta_1 \geq \beta_2 > 0$ , it is clear that the function  $f_{X_1}(x)/f_{X_2}[F_{X_2}^{-1}(F_{X_1}(x))]$  is decreasing in  $x > 0$ . From this fact and (30), we see that  $X_1 \geq_{\text{gdmftr}} X_2$  w.r.t.  $\psi$ .
- (2) Assume that  $0 < \beta_1 \leq \beta_2$ . From (171), we see that  $f_{X_1}(x)/f_{X_2}[F_{X_2}^{-1}(F_{X_1}(x))]$  is increasing in  $x > 0$ . From this fact and (30), we see that  $X_1 \leq_{\text{gdmftr}} X_2$  w.r.t.  $\psi$ .

*Example 4.* Let  $\psi$  be a nonnegative function defined on the interval  $(0, 1)$ ; we consider to compare two Pareto random variables in the GDMTFR order. Specifically, assume that

$$X \sim \mathbb{P}(\alpha_1, \lambda), \quad Y \sim \mathbb{P}(\alpha_2, \lambda), \quad (172)$$

where  $\alpha_1, \alpha_2, \lambda$  are positive real numbers. That is, for all  $x \geq 0$ ,

$$\bar{F}_X(x) = \left( \frac{\lambda}{\lambda + x} \right)^{\alpha_1}, \quad (173)$$

$$\bar{G}_Y(x) = \left( \frac{\lambda}{\lambda + x} \right)^{\alpha_2},$$

$$f_X(x) = \frac{\alpha_1}{\lambda} \left( \frac{\lambda}{\lambda + x} \right)^{\alpha_1 + 1}, \quad (174)$$

$$g_Y(x) = \frac{\alpha_2}{\lambda} \left( \frac{\lambda}{\lambda + x} \right)^{\alpha_2 + 1}.$$

Then,

$$G_Y^{-1}(F_X(x)) = \bar{G}_Y^{-1}(\bar{F}_X(x)) = \lambda \left( 1 + \frac{x}{\lambda} \right)^{\alpha_1/\alpha_2} - \lambda. \quad (175)$$

Hence,

$$\frac{f_X(x)}{g_Y[G_Y^{-1}(F_X(x))]} = \frac{\alpha_1}{\alpha_2} \left( 1 + \frac{x}{\lambda} \right)^{(\alpha_1/\alpha_2) - 1}. \quad (176)$$

- (1) If  $\alpha_1 \geq \alpha_2 > 0$ , then from (176), we see that the function  $f_X(x)/g_Y[G_Y^{-1}(F_X(x))]$  is increasing in  $x > 0$ ; hence, from (30), we have  $X \leq_{\text{gdmftr}} Y$  w.r.t.  $\psi$ .
- (2) If  $0 < \alpha_1 \leq \alpha_2$ , then  $f_X(x)/g_Y[G_Y^{-1}(F_X(x))]$  is decreasing in  $x > 0$ ; from (30), we get that  $X \geq_{\text{gdmftr}} Y$  w.r.t.  $\psi$ .

## Data Availability

In the examples of this research, we mainly use random variables to verify the correctness of the theory.

## Conflicts of Interest

The authors declare that they have no conflicts of interest.

Considering the importance of energy in our lives and its impact on other critical infrastructures, this paper starts from the whole life cycle of big data and divides the security and privacy risk factors of energy big data into five stages: data collection, data transmission, data storage, data use, and data destruction. Integrating into the consideration of cloud environment, this paper fully analyzes the risk factors of each stage and establishes a risk assessment index system for the security and privacy of energy big data. According to the different degrees of risk impact, AHP method is used to give indexes weights, genetic algorithm is used to optimize the initial weights and thresholds of BP neural network, and then the optimized weights and thresholds are given to BP neural network, and the evaluation samples in the database are used to train it. Then, the trained model is used to evaluate a case to verify the applicability of the model.

## 1. Introduction

In the era of big data, the application of big data technology in the energy field is a trend to promote industrial development and innovation. Both the deep application of big data technology in the energy field and the deep integration of energy production, consumption, and related technology revolution with big data concept will accelerate the development of energy industry [1].

With the implementation of the global energy big data strategy, the rapid development of “Internet plus” smart energy and the comprehensive construction of intelligent energy layout make the energy industry more widely distributed, more data collection points, more data types, more complex business relationships, and a wider range of data usage and users [2]. So while bringing convenience, it also brings risks to energy big data management. Due to the critical infrastructure of each country, energy is bound to become the preferred target of attack in case of cyber war. With the frequent occurrence of more and more energy security and privacy incidents, such as “Blackout in Ukraine” and “Stuxnet virus” attack on Iran’s nuclear facilities, big

data has become a usable and attachable carrier [3]. Through the big data value information obtained by the attack, the energy distribution of the target location can be analyzed, and the key data such as the monitoring and early warning information and operation instructions of key nodes will be tampered, resulting in energy system failure or major security accidents.

Therefore, the management research based on energy big data has been widely concerned by scholars all over the world. At present, for the huge amount of data and the particularity of management in the energy industry, scholars carry out data management and architecture design through various technical or nontechnical means, including the establishment of big data layer to store and process renewable energy data [4] and the establishment of energy big data processing system, supporting memory distributed computing [5]. In the research on the security and privacy of big data, it is found that most scholars used a single model for risk assessment, such as analytic hierarchy process (AHP), factor analysis, grey theory [6], fuzzy evaluation method [7], and cloud model [8]. Such methods are based on statistical theory and cannot completely get rid of the influence of

subjectivity and theoretical assumptions. In recent years, machine learning has become an important research tool in the field of security and privacy [9]. When using machine learning methods to evaluate and predict risks, the accuracy is often higher than that of traditional statistical methods [10]. Common machine learning methods include neural network, SVM, and clustering algorithm; BP neural network is the most widely used neural network in risk prediction and evaluation [11], but which is easy to fall into local minimum in practical application [12]. Therefore, scholars often use other algorithms as assistance to improve the accuracy of prediction and evaluation. For example, Zhang (2021) established a regression model through BP network and used PSO algorithm to optimize connection weights to evaluate the slow convergence of BP network, in order to improve the accuracy of rockburst prediction [13]. Wang (2019) et al. used LM algorithm to improve the operation efficiency and accuracy of traditional BP neural network and provided an effective theoretical basis and modeling method for risk prediction of power communication network [14].

This greatly improves the accuracy of prediction and evaluation, but a review of the relevant literature shows that the analysis of the importance of the impact of indexes is often neglected. Thus, in this paper, based on the consideration of machine learning, according to the different degrees of risk impact, AHP method is used to determine the index weight, which overcomes the deficiency of subjective consideration in previous studies [15]; the genetic algorithm optimized BP neural network (hereinafter referred to as GABP) with better prediction and evaluation effect is used for evaluation [16], which is a successful attempt to realize the combination of energy field and deep learning. In addition, for the security and privacy risk assessment of energy big data, the current literature pays more attention to theoretical analysis and lacks a relatively perfect assessment reference system. Starting from the whole life cycle of big data and considering the cloud environment, this paper establishes a risk assessment index system of energy big data security and privacy, which enriches the theoretical basis and framework in this field to a certain extent.

## 2. The Index System of Security and Privacy Risk Assessment of Energy Big Data in Cloud Environment

*2.1. Principles for the Construction of the Index System.* In the process of risk assessment, the probability of risk occurrence, loss range, and other factors need to be considered comprehensively to get the possibility and degree of system risk occurrence, determine the risk level, and then decide whether to take corresponding control measures and to what extent [17].

Therefore, the construction of risk assessment index system should follow the principles of comprehensiveness, scientificity, representativeness, and practicability, select the representative risk elements from a scientific perspective, quantify the risk based on the practical principle, and strive to show the risk management level comprehensively and accurately.

*2.2. Identification of Risk Factors.* Data security management is the most prominent risk faced by big data application. Although the massive data is stored centrally, it is convenient for data analysis and processing, but the loss and damage of big data caused by improper security management will cause devastating disaster. Due to the development of new technology and new business, the infringement of privacy right is not limited to physical and compulsory invasion, but is derived in a subtler way through various data, and the data security and privacy risks caused by this will be more serious [18].

Compared with the previous Internet and computer technology, the application advantage of big data in the cloud environment is more obvious. Big data platform has strong sharing ability, which can manage the security of information use and improve the efficiency of resource utilization. The construction of cloud platform and system application have strict standards. Cloud computing technology provides more comprehensive technical support and makes privacy management more reasonable, which is consistent with the level of technology development in the new era [19]. But from another point of view, it is under the influence of cloud platform sharing features that part of the data information is easy to be exposed, which provides opportunities for some illegal intrusion. Therefore, we must pay full attention to its risks.

Based on the literature of Xu [20], Tawalbeh [21], and He [22], combined with the analysis of relevant cases and the consultation of professionals, this paper follows the above evaluation index setting principle, combines with the development characteristics of energy big data security factors, and considers the impact of cloud environment. From the perspective of the whole life cycle of big data, this paper summarizes the current privacy security risks of cloud computing and big data and divides the risk assessment factors into five stages: data collection, data transmission, data storage, data use, and data destruction, with a total of 22 indexes, as shown in Figure 1.

*2.3. Index Quantification.* In terms of data collection, for the quantification of energy big data security and privacy risk indexes, this study introduces the concept of risk degree. According to the occurrence possibility and loss degree of each risk index, the product of possibility and loss degree is used as the reference standard of risk degree quantification, and the specific value can be reasonably floating around the product. The quantification of probability and loss degree can be divided into five levels: very high risk (5 points), high risk (4 points), medium risk (3 points), low risk (2 points), and very low risk (1 point).

$$R = P * L. \quad (1)$$

In formula (1),  $P$  is the probability of occurrence and  $L$  is the degree of loss.

The normalized input value is multiplied by the corresponding weight of each index as the input of the neural network for training, combined with the output value; the risk assessment level can be obtained, as shown in Table 1.

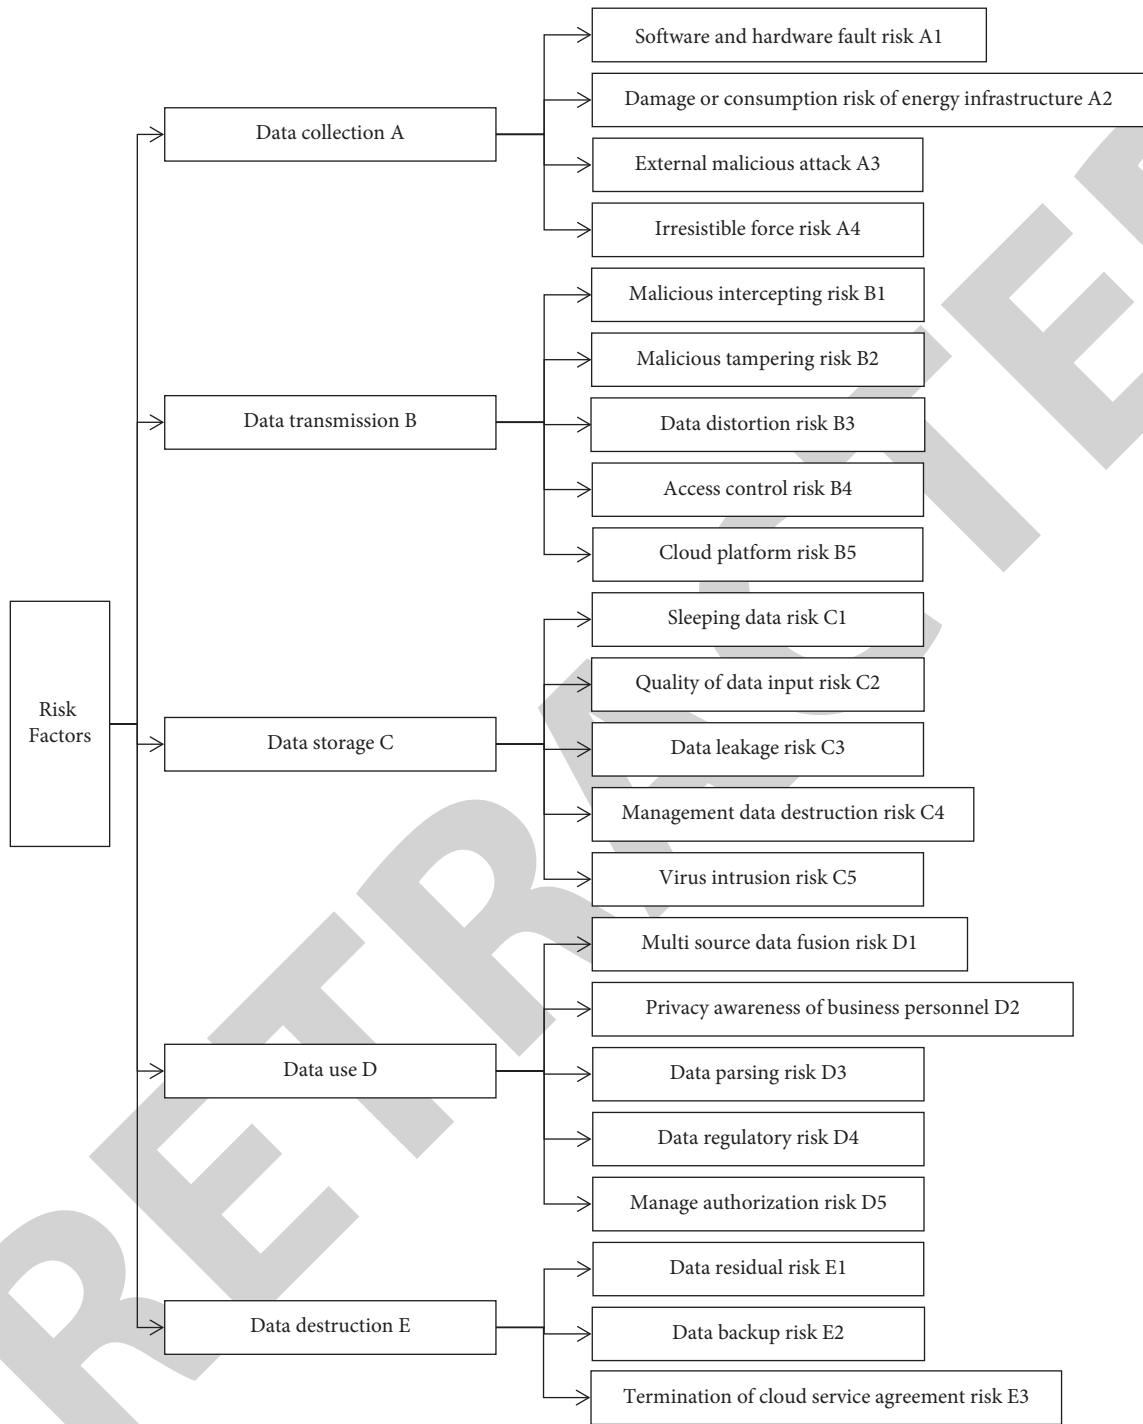

FIGURE 1: Security and privacy risk assessment index system based on the whole life cycle of energy big data.

TABLE 1: Risk assessment level.

Risk level	Meaning
First class ( $0 \leq R \leq 0.2$ )	The risk level is very low, so it is not necessary to pay special attention to it. The plan and general prevention can be made.
Second class ( $0.2 < R \leq 0.4$ )	The risk level is low, the plan and general prevention should be made, and need to be checked regularly.
Third class ( $0.4 < R \leq 0.6$ )	The risk level is medium; the major risk factors should be paid attention to in combination with the specific situation, and the corresponding countermeasures should be formulated.

TABLE 1: Continued.

Risk level	Meaning
Fourth class ( $0.6 < R \leq 0.8$ )	The risk level is high; it is necessary to pay attention to all the risk factors that may threaten the security of energy data, formulate the process sequence after the occurrence of the risk according to the importance degree, and track the inspection and evaluation.
Fifth class ( $0.8 < R \leq 1.0$ )	The risk level is very high; if necessary, it can be stopped and maintained, and the comprehensive inspection and special evaluation should be carried out immediately and can be continued after improvement.

### 3. Assessment Model of Energy Big Data Security and Privacy Risk in Cloud Environment

**3.1. AHP Method.** In the existing BP neural network part of the process, all kinds of risk factors are default to the same degree of impact, without a rigorous distinction, which is adverse to the establishment of neural network model.

Considering the particularity of energy big data security and privacy risk, quantitative analysis method may not be able to reasonably determine the real impact degree of indexes. Therefore, AHP method is used to give weight to indexes in this paper, and various factors in complex problems are divided into interconnected and ordered levels to make them methodical. According to the subjective judgment structure of certain objective reality, the expert opinions and the objective judgment results of analysts are directly and effectively combined, and the importance of pairwise comparison of one level elements is quantitatively described.

Therefore, after the establishment of energy big data security privacy and risk assessment index system, according to the influence degree of each risk factors, the Delphi method is used to invite experts to quantify the importance between them, and the AHP method is used to give corresponding weights to 22 indexes.

- (1) Construct the judgment matrix.

The judgment matrix  $A = (a_{ij})_{n \times n}$  is established by pairwise comparison. In order to make the judgment quantitative, the quantitative scale is given for the evaluation of different situations. The scale specification is shown in Table 2.

- (2) Calculate the eigenvalue and eigenvector by the square root method and calculate the product of elements in each row of judgment matrix.

$$M_i = \prod_{j=1}^n a_{ij} \quad (i = 1, 2, \dots, n). \quad (2)$$

Calculate the  $n$ th root of  $M_i$ .

$$\bar{W}_i = \sqrt[n]{M_i} \quad (i = 1, 2, \dots, n). \quad (3)$$

Normalize the eigenvectors as the weight.

$$W_A = [W_1, W_2, \dots, W_n]^T. \quad (4)$$

Calculate the largest eigenvalue, where  $(AW)_i$  is the  $i$ th component of the vector  $AW$ .

$$\lambda_{\max} = \sum_{i=1}^n \frac{(AW)_i}{nW_i}. \quad (5)$$

- (3) Check for consistency.

The consistency index  $C.I.$  is

$$C.I. = \frac{\lambda_{\max} - n}{n - 1}. \quad (6)$$

Generally,  $C.I. \leq 0.10$  represents that the judgment matrix is consistent.

Obviously, with the increase of value  $n$ , the judgment error will increase, so the influence of  $n$  should be considered when judging the consistency, and the random consistency ratio  $C.R. = C.I./R.I.$  should be used, where  $R.I.$  is the average random consistency index. Table 3 shows the average random consistency index test values calculated by the judgment matrix.

**3.2. BP Neural Network.** BP neural network is a kind of multilayer neural network, which was proposed by Rumelhart in 1986. It is one of the most widely used neural network models at present. It can learn and store a large number of input-output pattern mapping relations. Its learning rule is to use the steepest descent method to continuously adjust the weights and thresholds of the network through back propagation, so as to minimize the mean squared errors of the network. It is usually composed of input layer, hidden layer, and output layer [23], and its network model is shown in Figure 2.

The basic unit of neural network is neuron. The principle formula is shown in formula (7); the commonly used activation functions are threshold function, sigmoid function, and hyperbolic tangent function. In formula (7), the input of neurons is represented by  $x_i$  ( $i = 1, 2, \dots, n$ ), the connection weights between neurons are represented by  $w_i$  ( $i = 1, 2, \dots, n$ ), the threshold of neurons is  $b$ , the activation function is  $f$ , and the output of neurons is  $y$ .

$$y = f\left(\sum_{i=1}^n x_i w_i + b\right). \quad (7)$$

For BP neural network, the mean square error  $E$  is often used as the index to judge the training performance of the model, shown in formula (8). The principle of minimizing the mean square error by adjusting the network weights is shown in formula (9), where  $e$  is the network error vector,  $y_i$  is the model output, and  $t_i$  is the target output.

TABLE 2: Scale specification.

Scale	Meaning ( $a_i$ vs $a_j$ )
1	The former is as important as the latter
3	The former is slightly more important than the latter
5	The former is obviously more important than the latter
7	The former is strongly more important than the latter
9	The former extremely is more important than the latter
2, 4, 6, and 8	The intermediate value of the above two adjacent judgments
The reciprocal of the above values	If the ratio of factors $i$ and $j$ is $a_{ij}$ , then the factor of the ratio of factors $j$ and $i$ is $a_{ji} = 1/a_{ij}$

TABLE 3: R.I. value.

Order number	1	2	3	4	5	6	7	8	9	10
R.I.	0	0	0.58	0.90	1.12	1.24	1.32	1.41	1.45	1.49

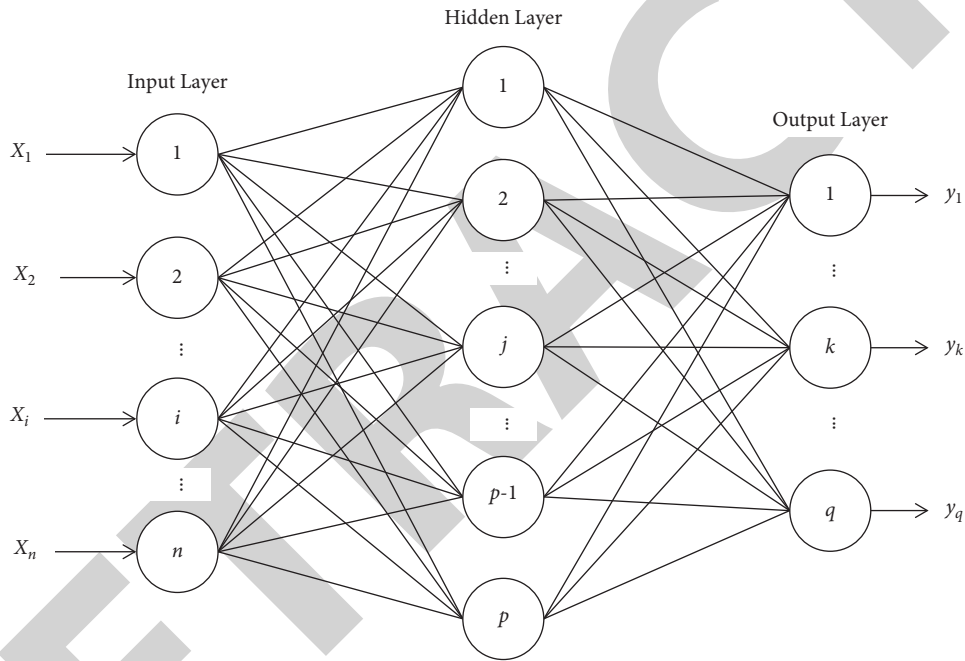

FIGURE 2: Structural model of neural network.

$$E = \frac{1}{n} \sum_{i=1}^n w_i (y_i - \hat{y}_i)^2. \quad (8)$$

$$\min E(e^T e) = \min E[(t - y)^T (t - y)]. \quad (9)$$

For the training model, the LM algorithm of neural network is used in this study. The basic method to reduce the error is as follows:

$$x(k+1) = x(k) - (J^T J + \mu J)^{-1} J^T e, \quad (10)$$

$$J^T J = H,$$

where  $H$  is the Jacobi matrix of the first derivative of the MSE function with respect to weights and thresholds.

**3.3. Genetic Algorithm.** Genetic algorithm (GA) is a computational model simulating the natural selection and genetic mechanism of Darwinian biological evolution theory. It is a method to search the optimal solution by simulating the natural evolution process [24].

Using genetic algorithm to get the optimal network weights and thresholds as the initial network weights and thresholds of the subsequent neural network model can not only overcome the defect that the traditional BP neural network is easy to fall into the local minimum, but also greatly improve the accuracy of model evaluation, so that the optimized BP neural network can better evaluate the samples. The elements of genetic algorithm include population initialization, fitness function, selection operator, crossover operator, and mutation operator.

Compared with binary coding, real coding can significantly reduce the length of coding and avoid the later decoding, with high accuracy. A series of parameters to be optimized, such as the connection weight, hidden layer node threshold, and output layer node threshold, are encoded by the  $s$ -order real matrix with the value range of  $[-1, 1]$ .

After coding, the selection, crossover, and mutation are performed. These three operations are based on the fitness value calculated by the fitness function as the assessment standard. The smaller the value, the larger the fitness value, and the better the individual. The fitness function of this study is the reciprocal of mean square error function, as follows:

$$F[f(x)] = \frac{1}{f(x)}. \quad (11)$$

In the selection operation, the most common roulette method is used. The probability of each individual being selected is positively proportional to its fitness value.  $N$  represents the population size,  $F_i$  represents the fitness function value of individual  $i$ , and  $p_i$  represents the probability of the  $i$ th individual being selected. The calculation way is as follows:

$$p_i = \frac{F_i}{\sum_{j=1}^N F_j}. \quad (12)$$

By using arithmetic crossover as formula (13), a new individual is obtained by using the linear combination between two individuals, where  $d$  is a random number uniformly distributed in  $[0, 1]$ :

$$\begin{aligned} c_1 &= p_1 * d + p_2 * (1 - d), \\ c_2 &= p_1 * (1 - d) + p_2 * d. \end{aligned} \quad (13)$$

Mutation operation refers to the random mutation of individual gene of the population, enhancing the local search ability of the algorithm and maintaining the diversity of individual population. The operation method of mutation of the  $j$  gene of the  $i$  individual  $a_{ij}$  is as follows:

$$a_{ij} = \begin{cases} a_{ij} + (a_{ij} - a_{\max}) * f(g), & r \geq 0.5, \\ a_{ij} + (a_{\min} - a_{ij}) * f(g), & r < 0.5, \end{cases} \quad (14)$$

where  $a_{\max}$  is the upper bound of gene  $a_{ij}$ ,  $a_{\min}$  is the lower bound of gene  $a_{ij}$ ,  $f(g) = r_2(1 - g/G_{\max})^2$ ,  $r_2$  is a random number,  $g$  is the current iteration number,  $G_{\max}$  is the maximum evolution number, and  $r$  is the random number of  $[0, 1]$  interval.

**3.4. Construction of AHP-GABP Model.** Compared with the traditional BP neural network, GABP model has a process of using genetic algorithm to optimize the weights and thresholds of the network, and this process can optimize the prediction performance of BP neural network to a certain extent. At the same time, using the AHP method to confirm the indicator weights can better define the importance of

indicators. The flowchart is shown in Figure 3. The steps to build the AHP-GABP model are as follows:

- (1) Use AHP method to process data.
- (2) Determine the topological structure of BP neural network.
- (3) After the weights are given by AHP, determine the input and output sample set and test sample set of training.
- (4) The network parameters to be optimized are real-coded to form their own chromosomes.
- (5) Determine the parameters of selection, crossover, and mutation.
- (6) Set the population size popu.
- (7) After inputting samples, each chromosome produces corresponding output after network transmission.
- (8) The fitness value of each chromosome is calculated by fitness function, and the selection operation is carried out according to the fitness value.
- (9) A new generation of population is generated by crossover and mutation.
- (10) Repeat steps 6–8 until the fitness value of the optimal individual and the fitness value of the population do not rise within the specified number interval, or the fitness value of the optimal individual reaches the set threshold, or the number of iterations reaches the algebra set in advance, the algorithm stops, and the optimized network parameters are obtained.

## 4. Evaluation Process

### 4.1. Model Training

#### 4.1.1. Network Design

(1) *Network Structure Determination.* The paper selects 22 assessment indexes to assess the security and privacy risk of energy big data, so the number of input layer nodes is 22. In general, if the number of hidden layers is more, the error of assessment results will be smaller, but it will also bring the disadvantages of network complexity, thus reducing the efficiency of training [25]. For the multi-input single-output network model established in this paper, in order to increase the approximation effect and convergence, and reduce the oscillation in the simulation process, the number of hidden layer nodes is determined by referring to equation (15) and combining with the actual simulation results.

$$S_1 = \sqrt{m + n} + a, \quad (15)$$

where  $m$  represents the number of input layer nodes,  $n$  represents the number of output layer nodes,  $a$  takes a random integer between 1 and 10, and  $S_1 = 12$  is determined after trial calculation. The final MATLAB structure is shown in Figure 4.

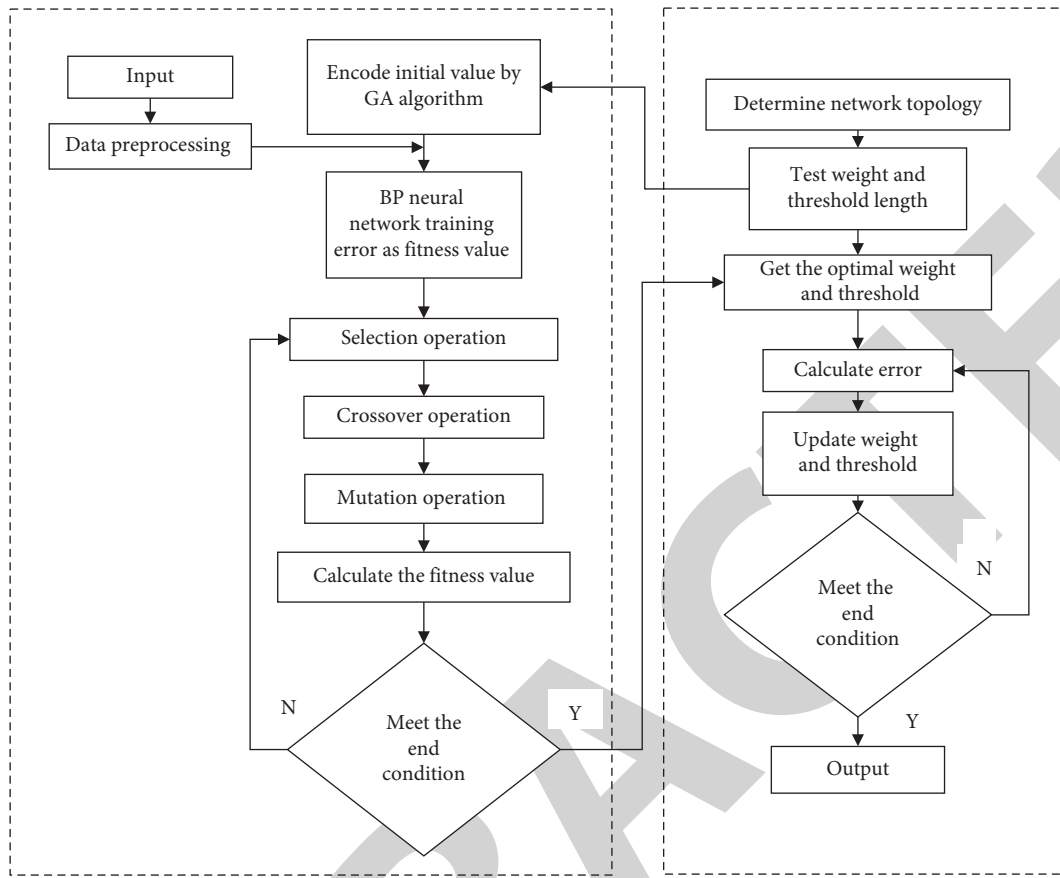

FIGURE 3: AHP-GABP flowchart.

(2) *Parameter Setting.* This study uses feedforward net to create function, trainlm to train function, logsig to transfer function, sigmoid to activate function, and MSE to express error  $E$ . The training times is 100, the learning rate is 0.01, and the training error target is 0.01. For the part of genetic algorithm, the number of population is set to 100, the maximum evolution algebra is set to 100, the variable precision is  $1e - 6$ , the crossover probability is 0.8, and the mutation probability is 0.2.

4.1.2. *Training Results.* After reading the literature and cases about the security and privacy risk of energy big data, a total of 44 samples are collected, including 36 training samples and 8 test samples. Some of the training data are shown in Table 4. The model training is realized by MATLAB programming and the development of Goat genetic algorithm toolbox.

The training data is input into the program, and the convergence curve of genetic algorithm optimized BP neural network is shown in Figure 5. It can be seen from the figure that the BP neural network algorithm after genetic algorithm optimization finds an optimal path optimal solution when the population iteration is about 60 generations, which shows the superiority of genetic algorithm in optimizing the weight and threshold of BP neural network. It can also be seen that the optimal function tends to be stable when the iteration reaches nearly 70 generations.

The BP neural network and the optimized genetic BP neural network are compared, and their error values are calculated. The final experimental results are shown in Table 5. Through analysis and comparison, in 8 groups of test samples, AHP-GABP prediction has significant advantages over BP prediction, with smaller error, shorter evaluation cycle, and greater improvement in evaluation performance. As shown in Table 5 and Figure 6, the BP neural network optimized by genetic algorithm improves the shortcomings of BP neural network, thus greatly improving the predictability of neural network. At the same time, the application assessment results of the BP neural network optimized by genetic algorithm in the energy big data security and privacy risk are basically consistent with the actual expert assessment results, which proves that the training network has high accuracy.

## 4.2. Model Applications

4.2.1. *Background.* Z power grid system uses its energy big data information to provide data services related to economic development. It can provide more reliable data support for poverty alleviation effect evaluation, credit evaluation, census, pollution monitoring, and work resumption evaluation. According to the energy big data security and privacy risk assessment index system designed above, the complete evaluation steps of big data security and privacy risk of this power grid system are as follows:

	Data regulatory risk D4	0.0165
	Manage authorization risk D5	0.0071
Data destruction E	Data residual risk E1	0.0135
	Data backup risk E2	0.0245
	Termination of cloud service agreement risk E3	0.0074

TABLE 7: Case assessment result.

Sample	AHP-GABP result	Risk level
1	0.1710	1
2	0.1715	1
3	0.1033	1

- (i) Calculate the index weights using AHP method.
- (ii) Collect relevant data of this grid system, invite relevant department heads to score the 22 risk assessment indicators, and standardize the data with the weights as the input values of the AHP-GABP model.
- (iii) Use the above trained AHP-GABP network model; the output values are evaluated, and the risk level is defined according to the risk classification method.

**4.2.2. Initial Index Weight of AHP Method.** In this study, AHP method is used to assign weights to the primary and secondary indexes, respectively. After the consistency check, the final weights of 22 indexes are obtained as shown in Table 6.

**4.2.3. Assessment Results.** In this study, three groups of relevant data collected by the power grid system are selected. After training, the AHP-GABP neural network model is established. Firstly, it is necessary to verify whether the evaluation model is reasonable. Secondly, it is necessary to assess the risk. The assessment results are shown in Table 7, which shows that the risk level of the power grid system is class 1, which is similar to the conventional risk performance of the power grid system. The risk level is low, and there is no need to do special treatment, and regular inspection should be done. It also shows that the AHP-GABP algorithm is reasonable and correct in the evaluation and prediction, with high prediction accuracy, objective and fair evaluation results, wide application range, and high practical application value.

## 5. Conclusion and Development Suggestions

To sum up, in the process of controlling the energy big data security and privacy risk, the risk of each stage cannot be ignored. On the premise of comprehensively considering the cloud environment and risk factors, this paper divides the potential energy big data security and privacy risk of each stage as comprehensively as possible according to the life cycle of big data, and uses AHP method to allocate weights for the indexes, which provides a reference for the future energy big data research. At the same time, this paper optimizes the BP neural network model based on the evaluation, and tries to apply the AHP-GABP method to the risk evaluation of energy big data security and privacy, which greatly reduces the risk that the random selection of initial weights and thresholds in BP algorithm leads to the model training easily falling into the local minimum, and improves the accuracy of neural network model assessment and predication and realizes the application of AI related knowledge in the field of energy.

The AHP-GABP model is applied to evaluate the security and privacy of the energy big data, and the evaluation results are good. According to the case and expert interviews, the following development suggestions are summarized for the common risks of energy big data security and privacy.

**5.1. Pay Attention to the Security of the Whole Life Cycle of Energy Big Data.** Energy big data comes from production data and operation and management data, and its protection should focus on the whole life cycle of data collection, transmission, storage, use, and destruction. From policy and system requirements to technical management and control, we should comprehensively assess the threat exposure of critical data and make targeted protection strategies at all stages to ensure the security of core data assets.

**5.2. Strengthen Technical Protection of Energy Industry Based on Big Data Security.** The energy industry should establish a comprehensive threat early warning technology based on security big data, break through the traditional mode, and more actively detect potential security threats. The introduction of big data analysis technology in threat detection can more comprehensively detect attacks on data assets, software assets, physical assets, personnel assets, service assets, and other intangible assets supporting business [26]. At the same time, the scope of the analysis content can be expanded. The threat analysis window can span several years of data, so the threat detection ability is stronger and can effectively respond to the attack [27].

**5.3. Consider Security and Privacy Issues from a Strategic and Long-Term Perspective.** Big data brings opportunities and challenges to the energy industry. The more widely it is applied, the greater the value it brings. The concept of security management centered on data security will change the traditional working ideas [28]. We must recognize the new changes, new features, and new trends of big data security, and deeply analyze the outstanding problems existing in big data security under the current situation. In order to ensure that the development strategy of energy big data information security is consistent with the national conditions and constantly improves, it is necessary to plan the key layout of big data application, key technology research and development, data protection, laws and regulations.

With the rapid development of cloud computing and the continuous improvement of digital level, the energy big data security and privacy risk evaluation index system can be further improved. At the same time, with the enrichment of data indicators and training models, the model proposed in this paper can also be better optimized and expanded to other fields for more accurate evaluation and prediction in the future.
