Considering the microstructure of tooth surface and the dynamic characteristics of the vibration responses, a compound dynamic backlash model is employed for the gear transmission system. Based on the fractal theory and dynamic center distance, respectively, the dynamic backlash is presented, and the potential energy method is applied to compute the time-varying meshing stiffness, including the healthy gear system and the crack fault gear system. Then, a 16-DOF coupled lateral-torsional gear-rotor-bearing transmission system with the crack fault is established. The fault characteristics in the time-domain waveform and frequency response and statistics data are described. The effect of crack on the time-varying meshing stiffness is analyzed. The vibration response of three backlash models is compared. The dynamic response of the system is explored with the increase in crack depth in detail. The results show that the fault features of countershaft are more obvious. Obvious fluctuations are presented in the time-domain waveform, and sidebands can be found in the frequency domain responses when the tooth root crack appears. The effect of compound dynamic backlash on the system is more obvious than fixed backlash and backlash with changing center distance. The vibration displacement along meshing direction and dynamic meshing force increases with the increase in crack depth. Backlash and variation of center distance show different tendencies with increasing crack depth under different rotational speeds. Amplitude of the sidebands increases with crack depth increasing. The amplitude of multiplication frequency of rotational frequency has an obvious variation with growing crack depth. The sidebands of the multiplication frequency of meshing frequency show more details on the system with complex backlash and crack fault.

1. Introduction

The gear transmission systems are widely used in many machinery fields, which are employed for transmitting power and changing speed. The steady operation is a necessary condition for the gear system. Therefore, the mechanism and dynamic characteristics of gear failure are a major subject in the dynamic field.

The gearbox failure is closely related to gear tooth, including spalling, pitting, crack, and broken tooth, which potentially lead to a complete damage. In order to clearly detect and diagnose in the gear transmission system, the vibration responses and fault features of the gear transmission system with fault are developed [1–3].

The typical kinds of damage are crack failure and spalling failure. The vibration responses of the gear system are closely related to the time-varying meshing stiffness (TVMS) of the gear pair. Yang and Lin [4] calculated TVMS by the potential energy method considering axial compressive energy, Hertzian energy, and bending energy. Tian [5] further investigated TVMS of a gear pair with crack. Govind et al. [6] studied TVMS, crack propagation behaviour, and the vibration responses of spur gear. Chen et al. [7] presented two improved calculation models for gear tooth fillet-foundation stiffness. When a gear pair appeared a large crack length, the computational accuracy of the two models was compared. Chen and Shao [8] developed a gear pair meshing stiffness calculation method

considering tooth profile modification and tooth root crack.

Many outstanding scholars have made great contributions to the research of healthy gear system. Zhou et al. [9] presented a coupled lateral-torsional 16-DOF gear-rotor-bearing system considering piecewise periodic stiffness, friction, and eccentricity, and the motion states and frequency variations were analyzed in detail. In addition, the backlash is an important factor to ensure smooth and reliable operation. Chen et al. [10] investigated the dynamic backlash with the fractal feature and the effect of the dynamic backlash on the 2-DOF gear system. Li et al. [11] researched TVMS that was affected by tooth profile changes and developed bifurcation characteristics of the gear system. Xiang and Gao [12] calculated the differential equation of the gear transmission model with dynamic friction, TVMS, and dynamic backlash on the basis of the 4th order Runge–Kutta method and observed the effect of dynamic backlash and gear eccentricity under different rotational speeds.

Many scholars had made a mountain of work for the gearbox with crack fault. Saxena et al. [13] studied the influences of the meshing stiffness and damping on the flexible rotor-shaft system. They explored vibration responses and frequency characteristics in detail. Mohammed and Rantatalo [14] established a 6-DOF dynamic gear model to study the natural frequency and time-frequency with different crack sizes. Saeed et al. [15] researched vibration responses in the presence of single- and multi-tooth simultaneous crack using the finite element method (FEM). Ma et al. [16] established a perforated gear system with different degree cracks. The gear crack propagation paths, frequency components, and frequency values were analyzed in detail. Ma et al. [17] built a meshing stiffness model for a cracked gear system, and the influences of the crack depth and initial position were analyzed by FEM. Chen et al. [18] presented a meshing stiffness calculation method for the nonuniform tooth root crack along the tooth width. The meshing stiffness and vibration response calculated by three different algorithms were compared. Ma and Chen [19] established a 4-DOF gear system to investigate the dynamic characteristics and vibration responses with local failure and explore the failure mechanism. Hu et al. [20] presented a finite element node dynamic model for gear with crack. The RMS (root-mean-square) of the gear system parameters, vibration waveform, and frequency spectra were analyzed. Chen and Shao [21] investigated the effect of crack on a planetary gear system. Liu et al. [22] studied vibration characteristics of the planetary gear system when sun gear appeared a tooth root crack.

For the research of crack, some scientists devoted to establish a simple gear model, such as simplifying backlash as a fix value, employing a periodic meshing stiffness, and establishing a few-DOF model. In this paper, a 16-DOF coupled lateral-torsional gear-rotor-bearing transmission system considering compound-type dynamic backlash, TVMS, eccentricity, and friction force is established. The compound dynamic backlash on the basis of the microstructure characteristics and vibration features is defined. TVMS is calculated by the potential energy method. This complex model is employed for investigating the effect of crack faults and researching crack failure features. The vibration responses of the gear system are researched by analyzing influences of the rotational speed and crack depth value variation. The differential equations of motion are solved using the Runge–Kutta numerical method. The simulation results, including time-domain waveforms, frequency-domain spectra, and waterfall plots, are shown. We focus on the effect of the crack depth growing on a complex gear system. The amplitude statistics of sideband supply an effective reference for the condition monitoring and fault diagnosis of the gear-rotor-bearing system.

2. Dynamic Model of the Gear-Rotor-Bearing System

2.1. Lumped Mass Model of the Gear System. The lumped mass model of the gear system is consisted of input, gears, shafts, bearing, and output. This model is described in Figure 1. $O_1(x_1, y_1)$ and $O_2(x_2, y_2)$ are the centers of two gears. $G_1(x_{g1}, y_{g1})$ and $G_2(x_{g2}, y_{g2})$ are the barycenters of two gears. m_i ($i = 1, 2$) are quality of gears. J_1 and J_2 represent the moments of gear inertial. m_{bi} ($i = 1, 2, 3, 4$) represent quality of bearing. J_d and J_g are equivalent rotational inertia of input and output terminals. The torsional stiffness and damping of shaft are given by k_{ti} and c_{ti} ($i = 1, 2$). k_{si} and c_{si} ($i = 1, 2$) are, respectively, lateral stiffness and damping. c_{bi} ($i = 1, 2, 3, 4$) are equivalent bearing damping, including x direction and y direction. In the x and y directions, F_{xi} and F_{yi} ($i = 1, 2, 3, 4$) are defined as nonlinear bearing forces. ρ_i ($i = 1, 2$) represent the eccentricity. φ_i ($i = 1, 2, d, g$) are, respectively, angle displacements of gear, pinion, input, and output, and the angle displacements are composed of an angle displacement $\omega_i t$ ($i = 1, 2$) and microscopic displacement $\theta_i(t)$. According to the geometrical relationship, the equations for the displacement of gears and input/output are given by

$$\begin{aligned} \varphi_1 &= \omega_1 t + \theta_1, \\ \varphi_2 &= \omega_2 t + \theta_2, \\ \varphi_d &= \omega_1 t + \theta_d, \\ \varphi_g &= \omega_2 t + \theta_g. \end{aligned} \tag{1}$$

Because of the eccentricity of gears, the rotating geometrical centers $O_1(x_1, y_1)$ and $O_2(x_2, y_2)$ and the barycenters $G_1(x_{g1}, y_{g1})$ and $G_2(x_{g2}, y_{g2})$ are at different positions. The relationship equations are found as

$$\begin{aligned} x_{g1} &= x_1 + \rho_1 \cos \varphi_1, \\ y_{g1} &= y_1 + \rho_1 \sin \varphi_1, \\ x_{g2} &= x_2 + \rho_2 \cos \varphi_2, \\ y_{g2} &= y_2 + \rho_2 \sin \varphi_2. \end{aligned} \tag{2}$$

In the *xoy* plane, elastic deformation of the shafts can be determined as

FIGURE 1: The gear system model.

$$\delta_{x1} = x_1 - \xi_1 x_{b1} - \xi_2 x_{b2},$$
$$\delta_{y1} = y_1 - \xi_1 y_{b1} - \xi_2 y_{b2},$$
$$\delta_{x2} = x_2 - \xi_3 x_{b4} - \xi_4 x_{b3}, \tag{3}$$
$$\delta_{y2} = y_2 - \xi_3 y_{b4} - \xi_4 y_{b3},$$

where ξ_i can be computed as

$$\xi_i = \frac{l_{bi}}{l_j}, \quad i = 1, 2, 3, 4; \ j = 1, 2, \tag{4}$$

where l_{bi} represents the distances between the gear's centers and centers of bearing and l_j is the length of shafts. The deformation between two gears along the meshing direction $\delta(t)$ is given by

$$\begin{aligned} \delta(t) &= \left(r_{b1}\varphi_1 - r_{b2}\varphi_2\right) + \left(y_{g1} - y_{g2}\right) - e(t), \\ &= \left(r_{b1}\theta_1 - r_{b2}\varphi_2\right) + \left(y_1 - y_2 + \rho_1 \sin \varphi_1 - \rho_2 \sin \varphi_2\right) \\ &\quad - e(t), \end{aligned} \tag{5}$$

where static transmission error $e(t)$ is caused by manufacture and assembly, and r_{b1} and r_{b2} are gear base circle radii. This error can be treated as a sinusoidal function $e(t) = e_0 + e_r \sin(\omega_m t + \varphi_m)$ [9], where e_0 and e_r severally represent mean and amplitude of the error, and φ_m and ω_m are, respectively, initial phase and meshing frequency. ω_m meshing frequency is expressed as $\omega_m = 2\pi n_1 z_1/60(2\pi n_2 z_2/60)$. z_1 and z_2 are the gears' teeth. n_1 and n_2 are the gears' rotating velocity.

The dynamic meshing force (DMF) F_m ($j = 1, 2$) can be determined as

$$F_m = \sum_{i=1}^{j} F_{mi} = \sum_{i=1}^{j} k_{ti} f(\delta(t)) + c_m \dot{\delta}(t), \tag{6}$$

where the state is the single-tooth meshing at $j = 1$, while the state is double-tooth meshing at $j = 2$. k_{ti} ($i = 1, 2$) and c_m are TVMS and meshing damping, respectively. $f(\delta)$ is the backlash function in the gear system, which is given by [23]

$$f(\delta) = \begin{cases} \delta(t) - (1 - \psi)b_h(t), & \delta(t) > b_h(t), \\ \psi b_h(t), & -b_h(t) < \delta(t) < b_h(t), \ 0 \le \psi \le 1, \\ \delta(t) + (1 - \psi)b_h(t), & \delta(t) < -b_h(t), \end{cases}$$

$$c_m = 2\xi_m \sqrt{\frac{k_t}{(1/m_1) + (1/m_2)}}, \tag{7}$$

where $b_h(t)$ is the gear dynamic backlash and ψ is a nonlinear coefficient. Meshing damping is given by c_m. $b_h(t)$ is presented in Section 2.3.

2.2. Time-Varying Meshing Stiffness for Gears with Tooth Crack.
The meshing stiffness model of a gear pair with a tooth root crack was described by Tian in 2004. The energy method was used to solve the mathematical modeling problem of the gear meshing stiffness. On the basis of the research, we further investigated the gear system with a tooth root crack with time-varying meshing stiffness. The schematic graph of tooth crack is shown in Figures 2(a) and 2(b).

The potential energy of the meshing gear teeth is shown as follows [21]:

$$U_b = \int_0^d \frac{F_b \left[(d - x) - F_a h\right]^2}{2EI_x} dx,$$

$$U_s = \int_0^d \frac{1.2 F_b^2}{2GA_x} dx, \tag{8}$$

$$U_a = \int_0^d \frac{F_a^2}{2EA_x} dx.$$

FIGURE 2: (a, b) Schematic graph of tooth crack.

I_x and A_x are equivalent to the area moment of inertia and the area of the section, respectively [5], and G represents the shear modulus. They are determined as

$$I_x = \frac{1}{12}(2h_x)^3 L,$$

$$A_x = (2h_x)L, \tag{9}$$

$$G = \frac{E}{2(1+v)},$$

where h_x is the distance between the point on the tooth's curve and the tooth's central line [5].

For the single-tooth-pair meshing process, the overall meshing stiffness for the gears with tooth crack could be given by

$$k_t = \frac{1}{(1/k_h)(+1/k_{b1}) + (1/k_{s1}) + (1/k_{a1}) + (1/k_{b2}) + (1/k_{s2}) + (1/k_{a2})}, \tag{10}$$

where k_h is the Hertzian contact stiffness, k_s is the shear stiffness, k_b is the bending stiffness, and k_a is the axial compression stiffness. And k_h can be given by

$$k_h = \frac{\pi E L}{4(1-v^2)}. \tag{11}$$

where E is Young's modulus and L is the tooth face width. $F_f = \mu\lambda(v_S)F_m$ represents Poisson's ratio. In addition, k_b, k_s, and k_a can be expressed as

$$\frac{1}{k_b} = \int_{-\alpha_1}^{\alpha_2} \frac{3\{1 + \cos\alpha_1 [(\alpha_2 - \alpha)\sin\alpha - \cos\alpha]\}^3 (\alpha_2 - \alpha)\cos\alpha}{E(2L[\sin\alpha + (\alpha_2 - \alpha)\cos\alpha]^3)} d\alpha,$$

$$\frac{1}{k_s} = \int_{-\alpha_1}^{\alpha_2} \frac{1.2(1+v)(\alpha_2 - \alpha)\cos\alpha\cos^2\alpha_1}{E(L[\sin\alpha + (\alpha_2 - \alpha)\cos\alpha])} d\alpha, \tag{12}$$

$$\frac{1}{k_a} = \int_{-\alpha_1}^{\alpha_2} \frac{(\alpha_2 - v)\cos\alpha\sin^2\alpha_1}{E(2L[\sin\alpha + (\alpha_2 - \alpha)\cos\alpha])} d\alpha.$$

For the double-tooth-pair meshing process, the overall meshing stiffness for the gears with tooth crack could be given by

$$k_t = k_{t1} + k_{t2} = \sum_{i=1}^{2} \frac{1}{\left(1/k_{h,i}\right) + \left(1/k_{b1,i}\right) + \left(1/k_{s1,i}\right) + \left(1/k_{a1,i}\right) + \left(1/k_{b2,i}\right) + \left(1/k_{s2,i}\right) + \left(1/k_{a2,i}\right)}, \tag{13}$$

where i ($i = 1, 2$) are the first or second pair of meshing teeth.

When the gear pair appears a tooth root crack, I_{xc} and A_{xc} are expressed as

$$I_{xc} = \begin{cases} \dfrac{1}{12}(h_c + h_x)^3 L, & \text{if } x \le g_c, \\[3mm] \dfrac{1}{12}(2h_x)^3 L = \dfrac{2}{3}h_x^3 L, & \text{if } x > g_c, \end{cases} \tag{14}$$

$$A_{xc} = \begin{cases} (h_c + h_x)L, & \text{if } x \le g_c, \\[2mm] 2h_x L, & \text{if } x > g_c, \end{cases}$$

where h_c represents the distance between the root the crack and the central line of the tooth. The other parameters and formulas are given in [4, 5, 21].

The overall effective meshing stiffness is given by the equations. Crack position is a tooth root of pinion. Equation (14) is input into equation (8), and then TVMS can be calculated. The time-varying meshing stiffness can be provided as shown in Figure 3.

2.3. Dynamic Backlash.

In the gear mesh process, the backlash is one of the most important factors. The backlash is the distance between two tooth profiles. In order to prevent the gears from getting stuck and ensure lubrication of gears, the backlash must exist. Rough tooth surfaces are not considered as an inherent characteristic. In the section, the compound dynamic backlash model is established considering rough tooth surface and vibration characteristic of the gear system. The sketch of backlash is shown in Figure 4. The relative displacement is generated when two rough teeth surface gears mesh.

The dynamic backlash $b_h(t)$ is consisted of the microscopic backlash $\Delta b(t)$ and vibration variation backlash $b(t)$. In order to approximate rough tooth surfaces, the W-M fractal function is employed. The microscopic backlash $\Delta b(t)$, which represents the inherent characteristic of the rough tooth surface, can be determined as [24–26]

$$\Delta b(t) = L_s \left(\frac{G_c}{L_s}\right)^{D-1} \sum_{n=0}^{n_{max}} \frac{\cos\left(2\pi\gamma^n t/L_s\right)}{\gamma^{(2-D)n}}, \quad (1 < D < 2, \gamma > 1), \tag{15}$$

where L_s is the sampling width, γ^n represents space frequency of flank profile, G_c is the characteristic scale coefficient, and D represents the fractal dimension controlling the complexity of the fractal curve. The relationship between G_c and R_q is given by

$$R_q = \left[\frac{G_c^{2(D-1)}}{2\ln\gamma} \frac{1}{4-2D}\left(\frac{1}{\omega_k^{(4-2D)}} \frac{1}{\omega_h^{(4-2D)}}\right)\right]^{0.5}, \tag{16}$$

where ω_k and ω_h are, respectively, equivalent to lower cutoff frequency and upper cutoff frequency. When the gear system appeared vibration, the center distance of gears is changed. By changing the center distance of gears, the backlash must be generated with volatility. The vibration variation backlash $b(t)$ and dynamic center distance a can be determined as [27, 28]

$$a = \sqrt{(a_0 \cos\alpha_0 + x_2 - x_1)^2 + (y_2 - y_1 - a_0 \sin\alpha_0)^2},$$
$$b(t) = (a - a_0)\tan\varphi_1 + b_0, \tag{17}$$

where a_0 represents initial center distance, α_0 is the pressure angle, and b_0 represents fixed backlash. The simplified center distance model is shown in Figure 5(a).

When crack occurs on the teeth surfaces, the dynamic center distance a is increased. The dynamic backlash with crack is given by

$$b_h(t) = b(t) + \Delta b(t). \tag{18}$$

2.4. The Friction Force.

Due to the meshing contact points located in different positions, the direction of friction force must be different. Thus, the frictional force changes periodically with the changing of contact points. Friction is given by

$$F_f = \sum_{i=1}^{j} \mu\lambda_i(v_s)F_{mi}, \quad j = 1, 2, \tag{19}$$

$$\lambda(v_s) = \begin{cases} 1, & v_s > 0, \\ 0, & v_s = 0, \\ -1, & v_s < 0, \end{cases}$$

where the state is the single tooth meshing at $j = 1$, while the state is double tooth meshing at $j = 2$. $\lambda(v_s)$ is the direction coefficient of the friction force, μ is the friction coefficient of the gear surface, and F_{mi} is the dynamic meshing force.

v_s represents relative sliding velocity of the meshing point M of the tooth pairs in Figure 5(b), which can be determined as

$$v_S = v_{M1} \sin\varphi_1 - v_{M2} \sin\varphi_2, \tag{20}$$

where v_{M1} and v_{M2} are, respectively, on the meshing point M and are described as follows:

FIGURE 3: The time-varying meshing stiffness.

FIGURE 4: Sketch of backlash.

$$v_{M1} = \omega_1 \overline{O_1 M},$$
$$v_{M2} = \omega_1 \overline{O_2 M}. \tag{21}$$

Friction torque is determined as

$$T_{f1} = F_f \overline{N_1 M},$$
$$T_{f2} = F_f \overline{N_2 M}, \tag{22}$$

where $\overline{N_1 M}$ and $\overline{N_2 M}$ are, respectively, the friction arms and are defined as

$$\overline{N_1 M} = (r_{b1} + r_{b2})\tan\alpha - \sqrt{r_{a2}^2 - r_{b2}^2} + r_{b1}\omega_1 t,$$
$$\overline{N_2 M} = (r_{b1} + r_{b2})\tan\alpha - \overline{N_1 M}. \tag{23}$$

2.5. Ball Bearing Model.

In Figure 6, the ball bearing model is shown. The outer ring is fastened to the bearing chock. The inner ring is fastened to the shaft. The rolling elements are evenly distributed between inner and outer rings. v_i and v_o representing the contact point velocities between the rolling elements and inner/outer rings are given by

$$v_i = \omega_i \cdot r,$$
$$v_o = \omega_o \cdot R, \tag{24}$$

where R and r are radii of inner and outer rings, and the angular velocities of inner and outer rings are ω_i and ω_o. The velocity of cage is expressed as

$$v_b = \frac{(v_o + v_i)}{2} = \frac{(\omega_o R + \omega_i r)}{2}. \tag{25}$$

Due to $\omega_i = \omega$ and $\omega_o = 0$, the angular velocity of cage ω_b is given by

$$\omega_b = \frac{2v_b}{(R + r)} = \frac{\omega_i \cdot r}{(R + r)}. \tag{26}$$

The momentary angular displacement φ_i^1 of the ith rolling element is given by

$$\varphi_i^1 = \omega_b \cdot t + \frac{2\pi(i-1)}{N_b}, \quad i = 1, 2, 3, \ldots, N_b, \tag{27}$$

where N_b is the number of rolling balls and ω_b is the angular velocity of the cage.

The deformation of the ith rolling ball can be described by

$$\delta_i^1 = x\cos\varphi_i^1 + y\sin\varphi_i^1 - \gamma_0, \tag{28}$$

where γ_0 represents bearing clearance. The Hertz contact theory is employed for computing contact force. Contact force of the ith rolling element f_i can be determined as

$$f_i = K_b\left(x\cos\varphi_i^1 + y\sin\varphi_i^1 - \gamma_0\right)^{3/2}$$
$$\cdot H\left(x\cos\varphi_i^1 + y\sin\varphi_i^1 - \gamma_0\right), \tag{29}$$

where K_b is the Hertz contact stiffness and $H(x)$ is the Heaviside function. So, the bearing forces are given by

$$F_{xj} = \sum_{i=1}^{N_b} f_i \cos\varphi_i^1 = F\cos\varphi_i^1,$$
$$F_{yj} = \sum_{i=1}^{N_b} f_i \sin\varphi_i^1 = F\sin\varphi_i^1, \tag{30}$$

$$j = 1, 2, 3, 4.$$

2.6. Mathematical Model of the GRBS.

The nonlinear differential equation (33) of the GRBS are evolved from Lagrange's equation.

c_{t1}, c_{t2}, c_{s1}, and c_{s2} are torsion and bending damping, respectively, and are given by

$$c_{t1} = 2\xi_t \sqrt{\frac{k_{t1}}{(1/I_d) + (1/I_1)}},$$

$$c_{t2} = 2\xi_t \sqrt{\frac{k_{t2}}{(1/I_2) + (1/I_g)}}, \tag{31}$$

$$c_{s1} = 2\xi_s \sqrt{\frac{k_{s1}}{(1/m_{b1}) + (1/m_1)}},$$

$$c_{s2} = 2\xi_s \sqrt{\frac{k_{s2}}{(1/m_{b3}) + (1/m_2)}}, \tag{32}$$

$$J_d \ddot{\theta}_d + c_{t1}(\dot{\theta}_d - \dot{\theta}_1) + k_{t1}(\theta_d - \theta_1) = T_d,$$

$$m_1 \ddot{x}_1 + c_{s1}(\dot{x}_1 - \xi_2 \dot{x}_{b1} - \xi_1 \dot{x}_{b2}) + k_{s1}(x_1 - \xi_2 x_{b1} - \xi_1 x_{b2})$$
$$= m_1 \rho_1 \ddot{\theta}_1 \sin(\omega_1 t + \theta_1) + m_1 \rho_1 (\omega_1 + \dot{\theta}_1)^2 \cos(\omega_1 t + \theta_1) - F_f,$$

$$m_1 \ddot{y}_1 + c_{s1}(\dot{y}_{11} - \xi_2 \dot{y}_{b1} - \xi_1 \dot{y}_{b2}) + k_{s1}(y_1 - \xi_2 y_{b1} - \xi_1 y_{b2})$$
$$= m_1 \rho_1 (\omega_1 + \dot{\theta}_1)^2 \sin(\omega_1 t + \theta_1) - m_1 \rho_1 \ddot{\theta}_1 \cos(\omega_1 t + \theta_1) - F_m - m_1 g,$$

$$(J_1 + m_1 \rho_1^2) \ddot{\theta}_1 + c_{t1}(\dot{\theta}_1 - \dot{\theta}_d) + k_{t1}(\theta_1 - \theta_d)$$
$$= m_1 \rho_1 \sin(\omega_1 t + \theta_1) \ddot{x}_1 - m_1 \rho_1 \cos(\omega_1 t + \theta_1) \ddot{y}_1 - F_m r_{b1} + T_{f1},$$

$$m_2 \ddot{x}_2 + c_{s2}(\dot{x}_2 - \xi_4 \dot{x}_{b3} - \xi_3 \dot{x}_{b4}) + k_{s2}(x_2 - \xi_4 x_{b3} - \xi_3 x_{b4})$$
$$= m_2 \rho_2 \ddot{\theta}_2 \sin(\omega_2 t + \theta_2) + m_2 \rho_2 (\omega_2 + \dot{\theta}_2)^2 \cos(\omega_2 t + \theta_2) + F_f,$$

$$m_2 \ddot{y}_2 + c_{S2}(\dot{y}_2 - \xi_4 \dot{y}_{b3} - \xi_3 \dot{y}_{b4}) + k_{s1}(y_2 - \xi_4 y_{b3} - \xi_3 y_{b4})$$
$$= m_2 \rho_2 (\omega_2 + \dot{\theta}_2)^2 \sin(\omega_2 t + \theta_2) - m_2 \rho_2 \ddot{\theta}_2 \cos(\omega_2 t + \theta_2) - F_m - m_2 g, \tag{33}$$

$$(J_2 + m_2 \rho_2^2) \ddot{\theta}_2 + c_{t2}(\dot{\theta}_2 - \dot{\theta}_g) + k_{t2}(\theta_2 - \theta_g)$$
$$= m_2 \rho_2 \sin(\omega_2 t + \theta_2) \ddot{x}_2 - m_2 \rho_2 \cos(\omega_2 t + \theta_2) \ddot{y}_2 - F_m r_{b2} - T_{f2},$$

$$m_{b1} \ddot{x}_{b1} + c_{s1}\xi_2(-\dot{x}_1 + \xi_2 \dot{x}_{b1} + \xi_1 \dot{x}_{b2}) + c_{bx1}\dot{x}_{b1} + k_{s1}\xi_2(-x_1 + \xi_2 x_{b1} + \xi_1 x_{b2}) = F_{x1},$$

$$m_{b1} \ddot{y}_{b1} + c_{s1}\xi_2(-\dot{y}_1 + \xi_2 \dot{y}_{b1} + \xi_1 \dot{y}_{b2}) + c_{by1}\dot{y}_{b1} + k_{s1}\xi_2(-y_1 + \xi_2 y_{b1} + \xi_1 y_{b2}) = F_{y1} - m_{b1} g,$$

$$m_{b2} \ddot{x}_{b2} + c_{s1}\xi_1(-\dot{x}_1 + \xi_2 \dot{x}_{b1} + \xi_1 \dot{x}_{b2}) + c_{bx2}\dot{x}_{b2} + k_{s1}\xi_1(-x_1 + \xi_2 x_{b1} + \xi_1 x_{b2}) = F_{x2},$$

$$m_{b2} \ddot{y}_{b2} + c_{s1}\xi_1(-\dot{y}_1 + \xi_2 \dot{y}_{b1} + \xi_1 \dot{y}_{b2}) + c_{by2}\dot{y}_{b1} + k_{s1}\xi_1(-y_1 + \xi_2 y_{b1} + \xi_1 y_{b2}) = F_{y2} - m_{b2} g,$$

$$J_g \ddot{\theta}_g + c_{t2}(\dot{\theta}_g - \dot{\theta}_2) + k_{t2}(\theta_g - \theta_2) = -T_g,$$

where k_{s1}, k_{s2}, k_{t1}, and k_{t2} represent bending stiffness and torsion stiffness of the shafts. c_{bij} ($i = x$, y) ($j = 1, 2, 3, 4$) are equivalent bearing damping in the directions x and y.

The gear-rotor-bearing model with strong nonlinear and time-varying characteristics is established. The dynamic backlash and time-varying meshing stiffness with crack are included in the system. The main parameters are shown in Tables 1 and 2.

3. Dynamic Response and Discussion

3.1. Comparison of Three Backlash Models. In the section, the three models about backlash are explored by the same parameters. The time-domain waveforms and frequency spectra are shown in Figures 7 and 8. The waveform of fixed backlash is stable, as is shown in Figure 7(a). The vibration waveform of dynamic backlash based on the dynamic center
(a)

(b)

FIGURE 5: (a) Simplified center distance model and (b) simplified sketch of meshing.

FIGURE 6: Rolling bearing model.

distance model produces significant fluctuations in Figure 7(b). It is clearly seen that the vibration displacement fluctuations of the compound dynamic backlash model are the biggest in Figure 7(c). In addition, the amplitude of $10f_{r1}$ has an obvious difference among Figures 8(a)–8(c). The frequency components of compound dynamic backlash are more than the others. It is distinct that the waveforms, frequency components, and amplitude are most different for the three models.

3.2. Dynamic Response of the Gear System with a Tooth Root Crack.

On the basis of the gear transmission system model equation (30), the vibration responses of the gear system with different crack depths are listed to investigate the effect on the system. Fractal dimension D is assumed to be 1.5, and friction coefficient $\mu = 0.05$. The crack depth is set from zero to forty percent of the tooth thickness. Considering the different spindle speeds, such as 600 r/min, 1800 r/min, and 3000 r/min, the response characteristics are investigated

under the different crack depths. In Figures 9(a)–9(d), the RMS of each significant parameter is presented, including the dynamic meshing force F_m, variation of dynamic center distance of gears Δa, the comprehensive elastic deformation $\delta(t)$, and the backlash $b_h(t)$ of the gear. Apparently, in Figure 7(a), it is stationary for the 600 r/min of the blue line with increasing crack depth. Within the limits of 0–30%, the RMS green curve of $b_h(t)$ is little different. When the rotational speed is 3000 r/min, the maximum value of the red line of $b_h(t)$ is crack 22%.

The dynamic meshing force F_m increases with the increase in crack depth in the range of 0% and 30% in Figure 9(b), setting to 1800 r/min or 3000 r/min. It indicates that F_m increases with crack depth within the limits of high speed. But, it slightly decreases in the range of low speed. When the crack is severe in the range of 30% and 40%, F_m of 600 r/min and 3000 r/min has a rapid, fluctuating increase. However, F_m of 1800 r/min is a rapid fall.

The RMS of comprehensive elastic deformation $\delta(t)$ speed increases with the increase in crack depth in Figure 9(c). But it is a fall with the increase in speed. The variation of center distance $\Delta a\,(\Delta a = a - a_0)$ is shown in Figures 9(d) and 10(a)–10(c). The larger the speed set, the smaller the variation value of center distance. An enlarged view of each speed is shown in Figure 10.

When the speed is low, the RMS of Δa slowly increases in the range of 0% and 30%, and it grows rapidly within the limit of 30% and 40%. With increasing speed, an increase in volatility is shown in Figures 10(b) and 10(c). The value corresponding to the crack 22% is the minimum value. The value corresponding to the crack 40% is the maximum value.

3.3. Vibration Responses and Frequency Characteristics with Different Crack Depths.

In order to study the effect of crack on dynamic responses of the system, the time-domain waveform and frequency-domain response are shown with different crack depths. The rotational speed is set to 3000 r/min. The crack depth is set to 0%, 10%, and 30% of the tooth thickness. Figures 11(a)–11(e), 12(a)–12(e), and 13(a)–13(e) display the vibration displacements of the gears and the bearings, which are, respectively, at 0%,

TABLE 1: Parameters of the gear-bearing system.

Parameter	Symbol	Numerical value
Pressure angle	α	$20°$
Moment of inertia	J_1/J_2	$7.1 \times 10^{-3}/1.39 \times 10^{-4}$ kg·m^2
Moment of inertia of input/output	J_d/J_g	$1.25 \times 10^{-4}/5.75 \times 10^{-4}$ kg·m^2
Mass	m_1/m_2	2.6/0.9 kg

10%, and 30% of the tooth thickness. Figures (14)–(16) show the frequency domain responses at the different crack depths.

For the healthy gear system shown in Figure 11(b), the fluctuation of the vibration displacement in torsional direction (θ_1) is more obvious than others. It indicates that the

vibration response in torsional direction (θ_1) is more sensitive to nonlinear factors and excitation. In Figure 11(e), those factors have less impact on the vibration of the bearing.

The time-domain waveform will exist as a pulse in theory when a tooth root crack appears. Though the variation of waveform in all directions is obvious in Figures 12 and 13, a pulse is covered with the fluctuation caused by other excitation factors. So, the pulse form that should have been generated is not so obvious. The amplitude of the pinion in x_2 direction is distinctly increased because of the

crack fault, and the change of waveform is also obvious in Figures 12(c) and 13(c). In addition, the amplitude of the other directions has a slight increase, as is shown in Figures 12(a), 12(b), 13(a), and 13(b). The vibration response of the bearing is among those least affected in Figures 12(d), 12(e), 13(d), and 13(e).

Obviously, the effect of a tooth root crack on vibration response of the gear system components is different. In the case of vibration response in x_2 direction, the statistic datum from the results shows that the amplitude of crack 10%
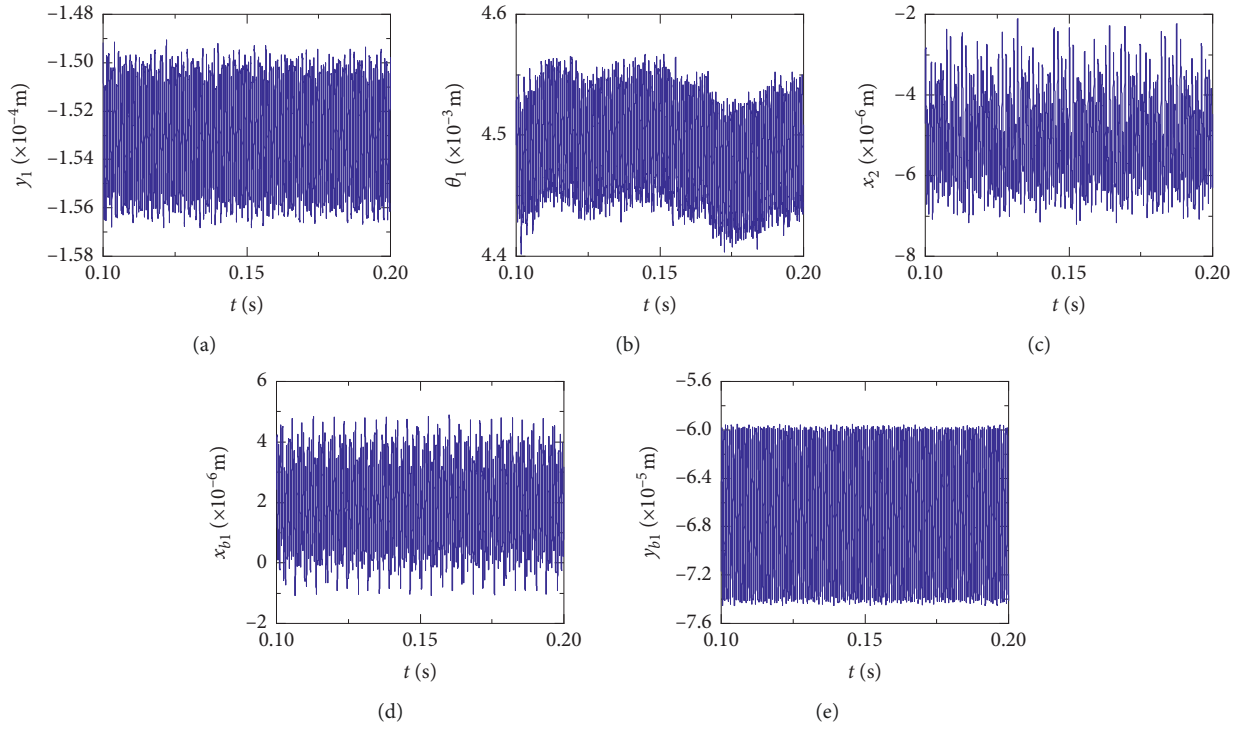

FIGURE 11: Time-domain waveforms of the healthy gear system in (a) y_1, (b) θ_1, (c) x_2, (d) x_{b1}, and (e) y_{b1} directions.

increases by 1.428 times than the healthy system. The amplitude increases by 1.735 times than the healthy system. But the rate of increase of vibration amplitude on the bearing does not exceed 15%. In addition, the time-domain waveform fluctuates more intense in x_2 direction. For transverse (x_{b1}) and longitudinal (y_{b1}) vibrations of the bearing, the vibration waveforms become more disordered because a tooth root crack appears, as is shown in
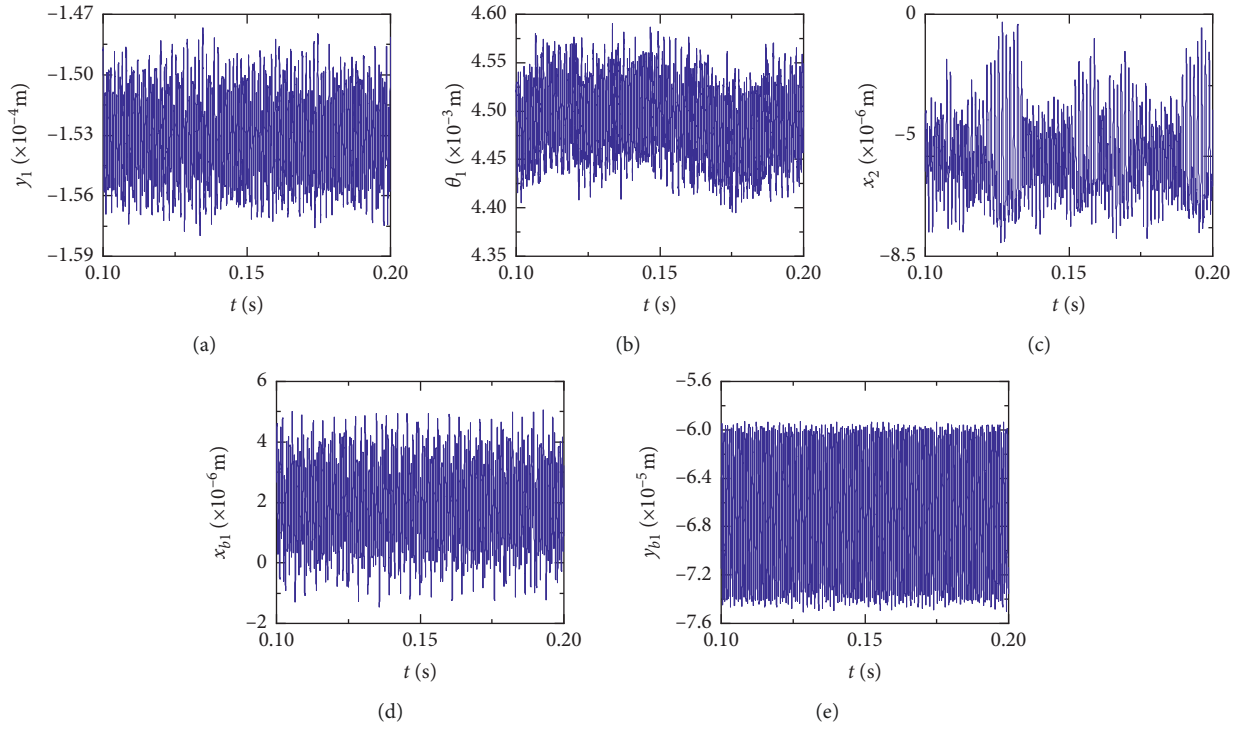

FIGURE 13: Time-domain waveforms of crack 30% in (a) y_1, (b) θ_1, (c) x_2, (d) x_{b1}, and (e) y_{b1} directions.

Figures (14)–(16) display, respectively, the frequency spectra of the healthy gear system, gear system with crack 10%, and gear system with crack 30%. The vibration frequency on the healthy gear system is explained in Figures 14(a)–14(i). In the healthy frequency spectra, it is obviously shown that the rotating frequency f_{r1} ($f_{r1} = n_1/60 = 50$ Hz) and the mesh frequency f_m ($f_m = n_1 z_1/60 = 1500$ Hz) are presented in Figure 14. However, besides

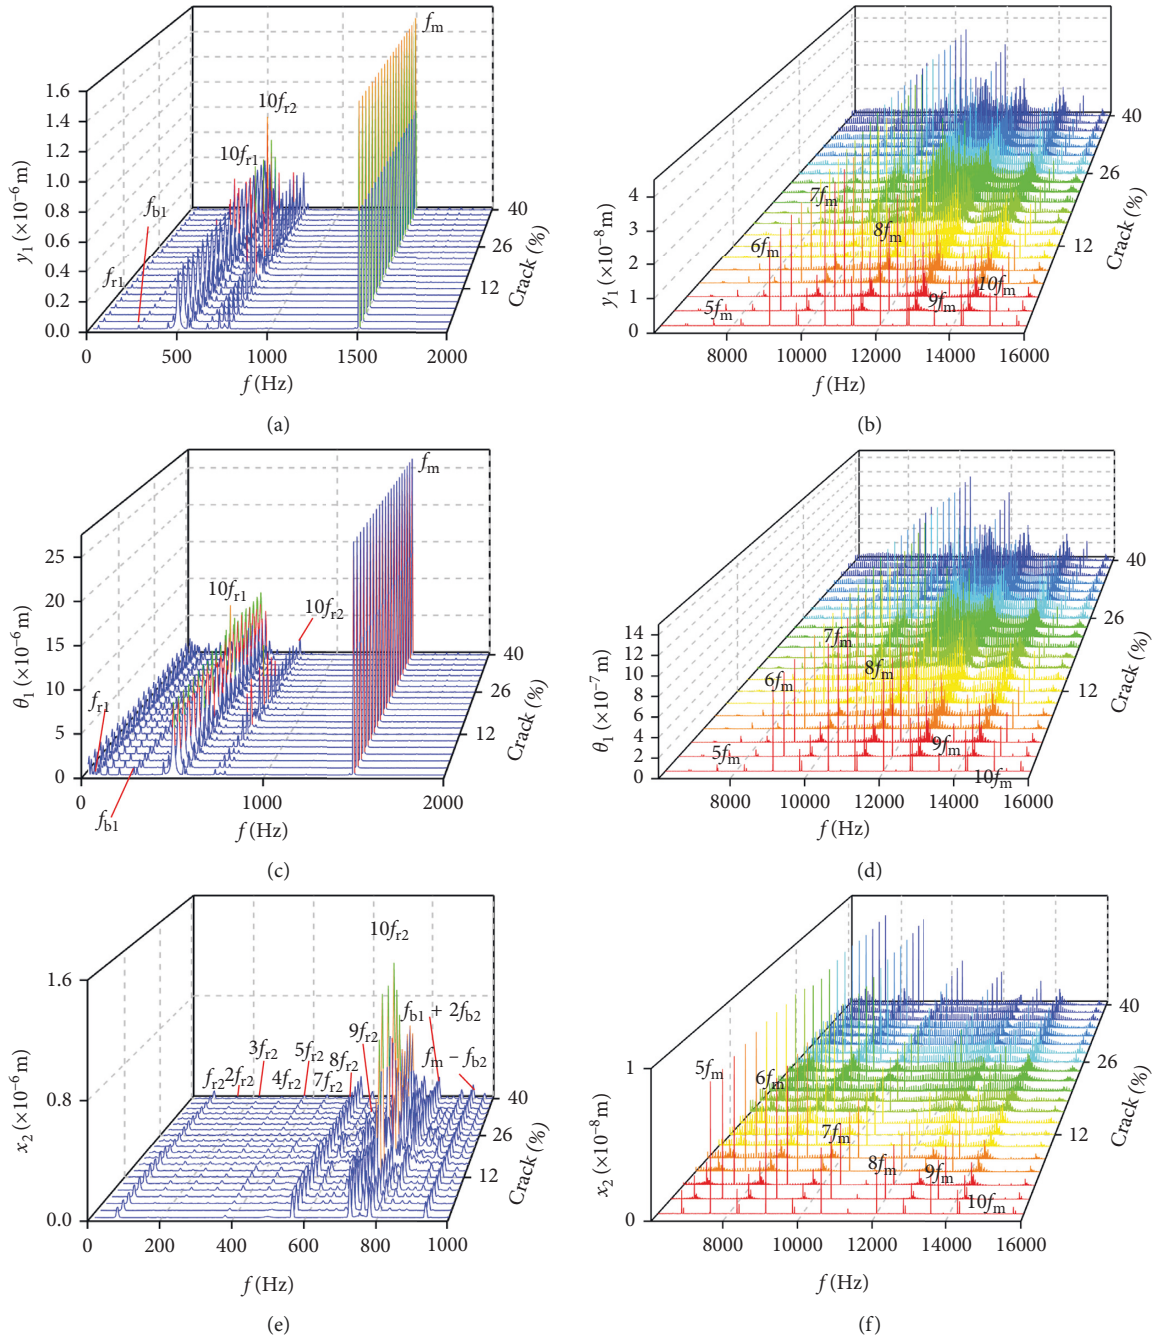

FIGURE 17: The waterfall maps in (a) y_1, (b) y_1, (c) θ_1, (d) θ_1, (e) x_2, and (f) x_2 directions.

f_{r1} and f_m, the rotating frequency f_{r2} ($f_{r2} = n_2/60 = 75$ Hz), variable stiffness frequencies f_{b1} ($f_{b1} = N_1 r_1 n_1/60(R_1 + r_1) = 274.3$ Hz) and f_{b2} ($f_{b1} = N_2 r_2 n_2/60(R_2 + r_2) = 563.4$ Hz), and combination frequency $0.5 f_m(10 f_{r2})$, $2 f_m$, $3 f_m$, $f_m - f_{b1}$, $f_m + f_{b1}$, and $f_m - f_{b2}$ can be observed in the frequency spectra.

The meshing frequency f_m is the highest amplitude and the $(0.5 f_m) 10 f_{r1}$ is the second highest in y_1 and θ_1 direction, as is shown in Figures 14(a) and 14(b). Besides, multiplication frequency of meshing frequency f_m can be seen in Figures 14(d) and 14(e), including $2 f_m$, $3 f_m$, $4 f_m$, $5 f_m$, $6 f_m$, $7 f_m$, $8 f_m$, $9 f_m$, $10 f_m$, and $11 f_m$. In order to further explore the bearing vibration frequency, Figures 14(f)–14(i) are

presented. It is clearly observed that f_m are the highest amplitude frequency. But the frequency components of the transverse (x_{b1}, x_{b3}) are more abundant than longitudinal (y_{b1}, y_{b3}).

For crack 10%, the sidebands near multiplication frequency components can be found in Figures 15(b) and 15(d). The range of the whole sideband of $8 f_m$ is $20 f_{r2}$. In addition, it is a significant phenomenon for the early cracked gear system that obvious multiplication frequency of f_{r2} (75 Hz) is observed in Figures 15(f)–15(i). This phenomenon is not found from the healthy gear system. In bearing frequency spectra, sidebands in x_{b1} and x_{b3} directions are
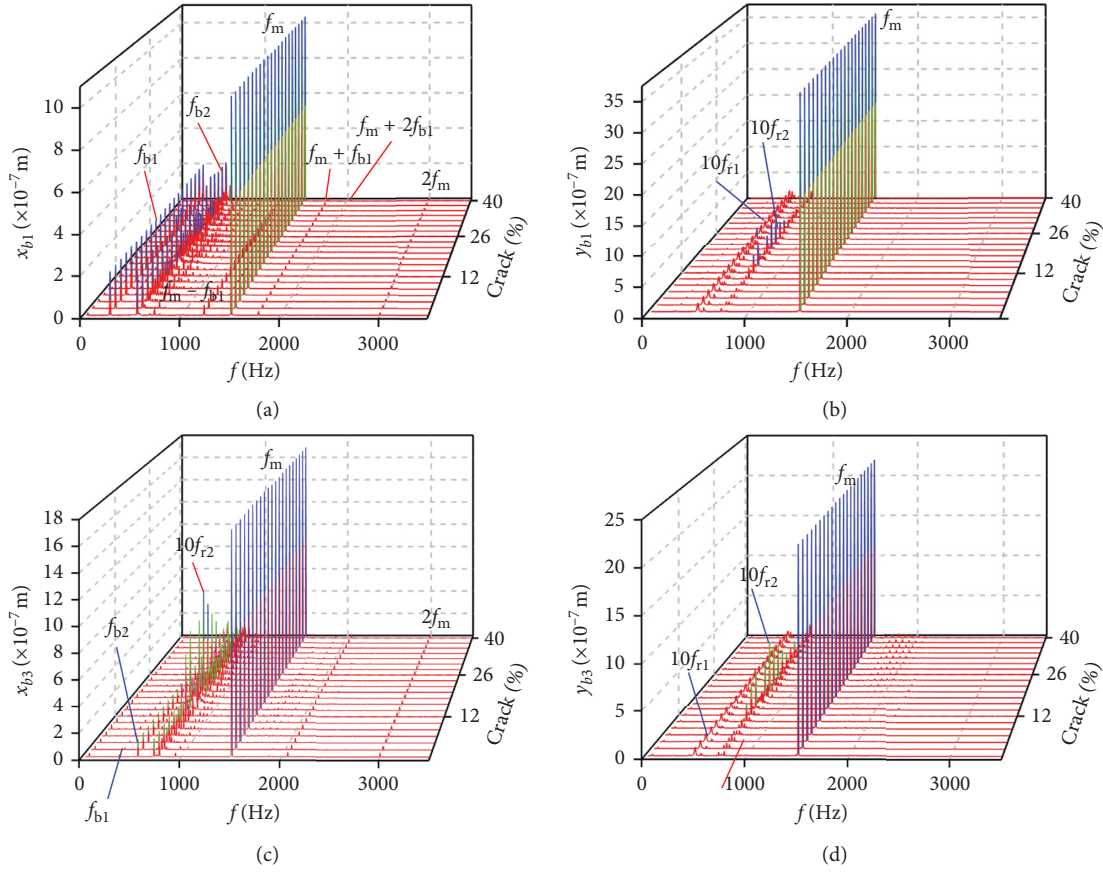

(a)

(b)

(c)

(d)

Figure 18: The waterfall maps in (a) x_{b1}, (b) y_{b1}, (c) x_{b3}, (d) y_{b3} directions.

more obvious than in y_{b1} and y_{b3} directions. In addition, $0.5f_m(10f_{r2})$ amplitude increases in all directions.

As the crack depth increases, the changes in the amplitudes of meshing frequency and the multiplication frequency are not obvious. But sidebands of the multiplication frequency of f_m are distinctly changed by the crack. In Figures 15(c), 15(e), 16(c), and 16(e), the amplitude of the sideband gradually increases with the increase in crack depth. For crack 30%, the frequency component becomes more complex than early crack (10%) and healthy system. $0.5f_m(10f_{r2})$ and f_m are the dominant frequencies in all directions.

The statistics data of the sidebands are shown in Tables 3 and 4. In Tables 3 and 4, the amplitudes of sideband sharply increase when the crack depth changes from 10% to 20%. From 20% to 30%, the variations will become a slow increase or decrease.

In order to further research the influences of a tooth root crack, waterfall maps of different crack depths in all directions can be seen in Figure 17. The amplitude of $0.5f_m(10f_{r2})$ in y_1 direction increases in the range of (0%, 22%) in Figure 17(a). When the crack depth is 22%, the amplitude of $0.5f_m(10f_{r2})$ is the biggest. Then the amplitude decreases in the range of (24%, 40%). The amplitude of $10f_{r1}$ only appears a slight fluctuation near crack 22%. The amplitude of f_m shows less variation. In Figure 17(b), the multiplication frequency of f_m is shown, including $5f_m$, $6f_m$, ...,

$10f_m$. The sidebands appear near multiplication frequency. These sidebands are irregular, and the amplitude of sidebands is different. The change rules of $0.5f_m(10f_{r2})$, f_m, and $10f_{r1}$ in θ_1 direction are similar to those in y_1 direction, as is shown in Figure 17(c). In addition, some noise frequency occurs in the lower frequency. In x_2 direction, f_{r2} and its multiplication frequency $2f_{r2}$, $3f_{r2}$, ..., $10f_{r2}$ appear and some compound frequencies $f_{b1} + f_{b2}$, $f_m - f_{b2}$ also exist in Figure 17(e). The multiplication frequency of f_m in x_2 direction is different from that in y_1 and θ_1 directions (compare Figure 17(f) with Figures 17(b) and 17(d)). The amplitude of sidebands increases with crack growing in all directions, as is shown in Figures 17(b), 17(d), and 17(f).

Influences of crack growing on the bearing is shown in Figures 18(a)–18(d). It can be seen that the frequency changes of transverse (x_{b1}, x_{b3}) vibrations are more violent than those of the longitudinal (y_{b1}, y_{b3}) vibrations. f_{b1}, f_{b2}, $0.5f_m$, and f_m are found from the bearings in x_{b3} direction, and the amplitude of $0.5f_m(10f_{r2})$ is changed as the crack depth increases, as is shown in Figure 18(a). The number of noise frequencies in the spectra of transverse vibration is more than that in the frequency spectra of longitudinal vibration.

In Figures 18(b) and 18(d), the frequency components include $0.5f_m(10f_{r2})$, $10f_{r1}$, and f_m.

For the comprehensive comparison, the impact in the transverse vibration is more dramatic than that in the

longitudinal vibration from the change of the crack, whether the bearings or the gears. Moreover, besides the sidebands, $0.5f_m(10f_{r2})$ and the noise frequency, the amplitude variation of other frequency components is inconspicuous, as shown in Figure 18.

4. Conclusion

A nonlinear model with the crack fault, compound backlash, and dynamic stiffness has been built to investigate the coupled lateral-torsional fault features of the 16-DOF gear-rotor-bearing system. The potential energy method is employed for analyzing effective meshing stiffness, and assumed that the dynamic backlash is time varying. This time-varying backlash is composed of two parts. One is the dynamic backlash with fractal characteristics based on the microstructure of the tooth surface. The other is time-varying center distance based on the gear vibration characteristics. The comparison between the healthy gear system and crack fault system, including time-domain waveforms and frequency-domain responses, is analyzed in detail. The analysis results are shown as follows:

(1) The effect of crack growing on meshing force of the gear system is distinct at high rotational speed. With the increase in crack, different crack degrees show different vibration responses. In addition, for high speed, the meshing force slowly increases in the range of crack (0, 30%). But the meshing force rapidly increases within the limits of 30% and 40% when the rotational speeds are 600 r/min and 3000 r/min. The meshing force declines in the range of 30% and 40% when the speed is 1800 r/min. The comprehensive elastic deformation $\delta(t)$ and the variation of center distance Δa are mainly affected by rotational speed. In addition, $\delta(t)$ and Δa slowly increase with growing crack depth. Moreover, the dynamic backlash RMS exhibits peak at crack 22% when the speed is 3000 r/min. The backlash is a main reason causing the amplitude variation of $0.5f_m(10f_{r1})$.

(2) The shaft frequency and multiplication frequency of the dominant frequency can be found in the frequency domain spectra when the gear system appears crack fault. And the amplitudes of these sidebands and the amplitudes of part multiplication frequency go up with the growing of the crack depth, yet the amplitude of frequency components is not changed. For this spur gear model, the pinion and shaft 2 show more obvious fault characteristics due to which sideband effect and time-domain waveforms are more complex as the crack increases.

Nomenclature

A_x: Area of the tooth cross section at point x
A_{xc}:   After appearing crack, area of the tooth cross section at point x
$b(t)$:   Dynamic backlash
$\Delta b(t)$:   Microscopic backlash
$b_h(t)$:   Vibration variation backlash

c_{bij}: $i = x$, y, and $j = 1$–4, bearing damping in x and y directions
c_m: Mesh damping
c_{si}: $i = 1$-2, bending damping
c_{ti}: $i = 1$-2, torsion damping
D: Fractal dimension controlling the complexity of the fractal curve
E: Young's modulus
$e(t)$:   Static transmission error
e_0:   Mean error
e_r: Amplitude error
F_f: Friction
f_i: $i = 1$–N, contact force of the ith rolling element
F_{mj}: $j = 1$-2, dynamic force
F_{xj}:   Bearing force in x direction
F_{yj}:   Bearing force in y direction
G: Shear modulus
G_c: Characteristic scale coefficient
H: Heaviside function
h_c: Distance between the root the crack and the central line of the tooth
h_x: Distance between the point on the tooth's curve and the tooth's central line
I_x: Area moment of inertia of the tooth cross section at point x
I_{xc}:   After appearing crack, area moment of inertia of the tooth cross section at point x
k_a: Axial compression stiffness of gear
k_b: Bending stiffness of gear
k_h: Hertzian contact stiffness of gear
k_s: Shear stiffness of gear
k_{si}: $i = 1$-2, bending stiffness of shafts
k_t: TVMS
k_{ti}: $i = 1$-2, torsion stiffness of shafts
L: Width of tooth
L_s: Sampling width
l_{bi}: $i = 1$–4, distances between gear's centers and centers of bearing
l_j: $j = 1$-2, length of shafts
$\overline{N_1M}$:   Friction arm
$\overline{N_2M}$:   Friction arm
r_{b1}:   Basic circle of gear
r_{b2}:   Basic circle of pinion
R_q: RMS roughness
T_{f1}:   Friction torque
T_{f2}:   Friction torque
U_a: Axial compression energy
U_b: Bending energy
U_s: Shear energy
v_b: Velocity of cage
v_i: Contact point velocities between the rolling elements and inner ring
v_o: Contact point velocities between the rolling elements and outer ring
v_{M1}:   Velocity on the meshing point of gear
v_{M2}:   Velocity on the meshing point of pinion
v_s: Relative sliding velocity of the meshing point M of the tooth pairs

x_{gi}: Abscissa of centers of mass
y_{gi}: Ordinate of centers of mass
φ_i: $i = 1, 2, d, g$ angle displacement
φ_i^1: $i = 1-N$, rotational angle of the ith rolling ball
$\delta(t)$: Deformation between two gears along meshing direction
δ_{xi}: Elastic deformations of the shaft in x direction
δ_{yi}: Elastic deformations of the shaft in y direction
δ_i^1: Deformation of the ith rolling ball
$\lambda(vs)$: Direction coefficient
ω_b: Angular velocity of cage
ω_h: Upper cutoff frequency
ω_i: Angular velocity of the inner ring
ω_o: Angular velocity of the outer ring
ω_k: Lower cutoff frequency
ω_m: Meshing frequency
ρ_i: $i = 1-2$, eccentricity
ξ_m: Meshing damping ratio
γ^n: Space frequency of flank profile
μ: Friction coefficient.
