Gases such as nitric oxide (NO) and carbon monoxide (CO) play important roles both in normal physiology and in disease. Recent studies have shown that hydrogen sulfide (H2S) protects neurons against oxidative stress and ischemia-reperfusion injury and attenuates lipopolysaccharides (LPS) induced neuroinflammation in microglia, exhibiting anti-inflammatory and antiapoptotic activities. The gas H2S is emerging as a novel regulator of important physiologic functions such as arterial diameter, blood flow, and leukocyte adhesion. It has been known that multiple factors, including oxidative stress, free radicals, and neuronal nitric oxide synthesis as well as abnormal inflammatory responses, are involved in the mechanism underlying the brain injury after subarachnoid hemorrhage (SAH). Based on the multiple physiologic functions of H2S, we speculate that it might be a promising, effective, and specific therapy for brain injury after SAH.

The article titled “A Hypothesis: Hydrogen Sulfide Might Be Neuroprotective against Subarachnoid Hemorrhage Induced Brain Injury” [1] was found to contain material from other published articles, including the following sources.

1. Introduction

Nitric oxide (NO) and carbon monoxide (CO) are established physiologic messenger molecules, and the former serving as an endothelial cell-derived relaxing factor (EDRF) has an important role in the regulation of blood pressure [1].
Even though hydrogen sulfide (H$_2$S) has long been known as a noxious and toxic gas, recent accumulated evidence suggests that H$_2$S, as an important endogenous vasodilator and neuromodulator [2, 3], has been implicated in similar functions [4]. A physiologic role for H$_2$S in regulating blood pressure, its potent neuroprotective [5], and anti-inflammatory effects support a hypothesis that H$_2$S might act as an effective agent that may have therapeutic potential against brain damage induced by oxidative stress, inflammation, hypoxic vasoconstriction, and other factors. Brain damage mainly induced by cerebral vasospasm is a potentially incapacitating or lethal complication in patients with aneurysmal SAH. Thus, the development of effective preventive and therapeutic interventions is an urgent and significant need. The objective of this paper is to present an overview of the pathogenesis of brain injury after SAH and the multiple physiologic functions of H$_2$S in the vascular system, based on which a hypothesis is providing that H$_2$S might be an effective therapy agent for brain injury after SAH.

2. Distribution and Level of H$_2$S in Vascular Tissues

There are three known enzymes that produce H$_2$S endogenously in mammalian tissue: cystathionine-synthase (CBS), gamma lyase (CGL or cystathionine-gamma-lyase, CSE), and 3-mercaptopyruvate sulfur transferase (3MST). There are three major fates of H$_2$S in the body. First, most of the H$_2$S produced in the body is oxidized in the mitochondria to an end product of sulfate. The remaining H$_2$S either is methylated by thiol S-methyltransferase (TSMT) to methanethiol and dimethyl sulfide or binds to methemoglobin to form sulfhemoglobin. In most tissues, CBS and CSE, which are responsible for catalyzing the production of H$_2$S, are both pyridoxal-5-phosphate-dependent enzymes that utilize cysteine and homocysteine as substrates to liberate ammonium, pyruvate, and H$_2$S [6]. It was originally believed that CBS was responsible for H$_2$S production in the brain through the activation of the Ca$_2$+/calmodulin pathway. H$_2$S is produced by 3MST from l-cysteine and alpha-ketoglutarate through the metabolism with cysteine aminotransferase (CAT) [7].

H$_2$S production was observed in ileum, portal vein, and thoracic aorta homogenates when L-Cys and PLP were administered. Moreover, the application of aminoxyacetic acid (CBS inhibitor) inhibited H$_2$S production in ileum but failed to affect generation of H$_2$S in portal vein and thoracic aorta, suggesting the lack of CBS in vascular tissues [8, 9]. Many studies have been focused on this issue [3, 10–13]. Endogenous H$_2$S has been paid more and more attention to since its physiological discovery. It is expected that physiological concentration of H$_2$S may vary extensively from synthesizing enzymes in different tissues. It was reported that endogenous concentration of H$_2$S in rat, human, and bovine brains ranged within 50–160 μM [14–16], whereas its serum concentration was about to be 50 μM. Previous study showed that H$_2$S does not circulate in the plasma at high enough concentration to be detectable in blood and plasma from a variety of animals, including trout, mouse, Wistar rat, Dawley rat, pig, and cow [11]. H$_2$S concentration in brain and liver homogenates was measured 14 ± 3 nM and 17 ± 3 nM, respectively [12].

3. Multiple Physiologic Functions and Beneficial Effects of H$_2$S in Biological Systems

The biological effects of H$_2$S on vascular system have been studied for more than a decade. It was first reported that H$_2$S concentration dependent relaxed norepinephrine precontracted portal vein and thoracic aorta, and this relaxation effect was reversible upon removal of chemicals [8]. This vasodilatory effect was later found to be present not only in thoracic aorta, but also in other types of vascular tissues including mesenteric arteries, pulmonary artery, and tail artery. H$_2$S induced vasorelaxation is mainly brought about by the opening of KATP channels [17, 18]. Other signaling mechanisms for the vasorelaxant effect of H$_2$S may involve depletion of intracellular ATP levels in aortic rings [19] and intracellular acidosis [20]. KATP channels are likely not to be involved in H$_2$S induced vasoconstriction [21]. However, many studies were performed to attempt to unveil the underlying mechanism of H$_2$S induced constrictive effects. Firstly, H$_2$S may react with NO to form a compound, which by itself has no effect on vascular contractility. NO, as a potent physiological vasodilator, quenched by H$_2$S, which might underlie H$_2$S induced vascular constriction response [19, 22]. Moreover, H$_2$S exerted inhibitory effects on endothelial nitric oxide synthase (eNOS) activity [18]. H$_2$S was found to downregulate cAMP levels in vascular smooth muscle cells (SMC) [21]. H$_2$S exerts antihypertensive effects to different extents in different hypertensive models. The antihypertensive role of H$_2$S is confirmed. Slow H$_2$S-releasing compounds and therefore might be as potential therapeutics for hypertension treatment in the future. The data mentioned above suggests that the evidence for H$_2$S’s effects on vascular smooth muscle tone is contradictory.

The mechanisms by which H$_2$S affects injured cells are complicated. Interestingly, in some studies, H$_2$S induced proinflammatory effects which indicates that the background of these immunomodulatory influences still remains elusive [19]. H$_2$S has several effects on mitochondria of cardiac cells such as the reversible inhibition of cytochrome C oxidase, which leads to preservation of mitochondrial structure and function after ischemia/reperfusion. Inhibition of mitochondrial respiration in the injured myocytes results in attenuated generation of reactive oxygen species (ROS) and may alter the function of the affected cell [22]. H$_2$S decreases lipid peroxidation by scavenging hydrogen peroxide and superoxide in a model of isoproterenol induced myocardial injury. Besides these mechanisms, H$_2$S also acts as a direct scavenger neutralizing cytotoxic reactive species like peroxynitrite.

The physiological actions of H$_2$S make this gas ideally suited to protect the heart, brain, liver, kidney, and lungs against injury during ischemia/reperfusion (I/R). In recent years, the cytoprotective effects of endogenous and exogenous H$_2$S have been investigated in models of in vitro and in
vivo ischemic injury [6]. Previous study showed that either endogenous or exogenous increases in H$_2$S at the time of reperfusion limit the extent of myocardial infarction, which was accompanied by a decrease in myocardial inflammation and mitochondrial function preservation [23]. Regulation and cytoprotective, physiological, and chemical roles of H$_2$S in biological systems including ischemic injury of cardiac-cerebral vascular disease have been investigated in many studies [23–30].

The vasodilatory effect of H$_2$S, which might be a potential candidate to be considered as EDRF and was later found to be present in widespread arteries including thoracic aorta, mesenteric arteries, pulmonary, and other types of vascular tissues [30], was particularly involved at the microcirculation level [31, 32]. Based on the accumulated data, several signaling pathways including cyclic adenosine monophosphate (cAMP)/protein kinase A (PKA), NO/cyclic guanosine monophosphate (cGMP)/protein kinase G (PKG) [33, 34], and calcium/calmodulin (CaM) [35] were involved in the vasoregulatory effect of H$_2$S. Previous study also suggested that hypoxia and H$_2$S shared a common and unique pathway in the excitation–contraction process. The inhibition of H$_2$S synthesis can inhibit both hypoxic vasoconstriction and hypoxic vasodilation [36].

This role of H$_2$S on smooth muscle is likely to be a general effect. Besides the recently established vasoregulatory role of H$_2$S, its anti-inflammatory effect in different systems has been investigated. Recent studies have demonstrated that H$_2$S may in fact limit inflammation and free radical damage [37], while another study indicated that H$_2$S might exert an important proinflammatory role in regulating the severity of pancreatitis and associated lung injury [36]. Previous data suggested that ROS were implicated not only in the control of vascular tone in blood, but also in the H$_2$S-induced regulatory function of vascular tissues [33, 38]. These findings raise the possibility that pharmacologic enhancement of H$_2$S formation could be an alternative approach for repairing neuron damage induced by vasospasm, ischemia, oxidative stress, inflammation, and other factors, while previous study has demonstrated that H$_2$S treatment improved endothelium-dependent coronary microvascular relaxation, providing biochemical myocardial protection via attenuation of caspase-independent apoptosis and autophagy in the experimental model [39]. It suggested that the evidence for H$_2$S’s effects on autophagy might be contradictory.

4. Causes and Mechanisms of Brain Injury after Subarachnoid Hemorrhage

Accumulated data indicate that not only delayed ischemic injury [40], which had been considered the most important cause of poor outcome after SAH, but also early brain injury has become the vital determinant of the intensity of later developing neurological complications [41]. Delayed cerebral vasospasm that develops 3–7 days after SAH had traditionally been considered the most important determinant of delayed ischemic injury. In recent years, increasing evidence suggests that several mechanisms, including ionic and physiological, biochemical, molecular, persistent vascular changes, cell death, oxidative stress, and inflammatory cascade activation, were involved in the pathogenesis of early brain injury after SAH [42–44]. Previous papers show that many experimental studies as well as autopsies performed on the brains of patients after SAH demonstrated extensive ischemic damage. Many factors including elevation of intracranial pressure (ICP), release of vasoactive substances during erythrocyte lysis, platelet aggregation, lipid peroxidation, unopposed sympathetic activity, and alterations in the nitric oxide/nitric oxide synthase (NO/NOS) pathways may contribute to this brain injury [45].

Though cerebral vasospasm probably plays some part in brain injury after SAH, neurologic injury may not be entirely explained by ischemia. The relationship between cerebral vasospasm and neurologic outcome might be associated with other coexisting causative factors such as microvascular dysfunction and complex neuronal-glial interactions. Previous study suggested that cerebral infarction contributed to poor outcome by vasospasm-independent effects after SAH [44, 46]. Cortical spreading depression (CSD) as one of the interesting mechanisms in brain damage after SAH has gained increasing attention [47, 48]. It has been previously reported that leukocyte-endothelial cell interactions, which played a significant role in the pathophysiology of cerebral vasospasm, could explain the clinical variability and time course of this disease [49]. Therefore, timely therapeutic targeting of the inflammatory response may prevent vasospasm-related brain damage and improve outcomes in patients with SAH.

Autophagy, being a self-degradative process, which plays a housekeeping role in removing misfolded or aggregated proteins, clearing damaged organelles, and eliminating intracellular pathogens [50, 51], is important for balancing sources of energy at critical times in development and in response to nutrient stress. The autophagy pathway has been reported to be involved in several central nervous system diseases such as cerebral ischemia [52], hypoxia-ischemia induced brain injury, and traumatic brain injury [53]. In the experimental SAH model, it is suggested that autophagy activation could participate in the pathogenesis of early brain injury induced by SAH. That is to say, activation of the autophagy pathway may play a potential role to attenuate the development of brain damage in SAH [51].

5. Involvement of H$_2$S in Vascular Relaxation

H$_2$S, known as a poisonous and toxic gas of the rotten egg, is endogenously produced from the metabolism of L-cysteine through constitutively expressed enzymes (including CBS and CSE) [54, 55]. H$_2$S produced by CSE can enhance the outward flux of K$^+$ by opening the KATP channel, resulting in membrane potential hyperpolarization and vascular smooth muscle relaxation [17, 56]. The vascular effects of H$_2$S are thought to be partially mediated by functional endothelium [57]. It is also suggested to coordinate with NO to regulate smooth muscle tone [8]. Previous studies have reported that CSE knockout mice displayed significant hypertension and reduce endothelium-dependent
vasodilation, while reducing H$_2$S levels in many tissues including serum, heart, and aorta [58]. As an H$_2$S donor, intravenous delivery of NaHS can temporarily reduce systolic blood pressure in mice, suggesting that H$_2$S plays a crucial role in regulating physiological vasodilation and blood pressure.

The effect of H$_2$S on the regulation of vascular smooth muscle tone and blood pressure suggests that it may be involved in the regulation of cerebral blood flow cerebral vasospasm after SAH and may have potential therapeutic effects in preventing and reversing cerebral vasospasm. Although there is limited evidence for H$_2$S and cerebral vasospasm after SAH and may have potential therapeutic effects in preventing and reversing cerebral vasospasm, more research is needed in future basic research.

6. The Effect of NO in Pathophysiology, Reversal of Delayed Cerebral Vasospasm

As the most famous EDRF, NO is produced by eNOS in the intima and neuronal nitric oxide synthase (nNOS) and inducible nitric oxide synthase (iNOS) in the outer membrane of cerebrovascular and smooth muscle cells [59, 60]. Other substances that exhibit the same characteristics of EDRF include CO [61] and H$_2$S [62].

H$_2$S, NO, and nitrite are formed in vivo and are of vital importance in the tissue response to hypoxia. These signaling molecules are involved in a multitude of processes including the regulation of vascular tone, cellular metabolic function, and cytoprotection [63].

NO can directly activate soluble guanosine cyclase (sGC) to catalyze the conversion of GTP to circular GMP in smooth muscle cells. An increase in circulating GMP levels leads to the prevention of Ca$^{2+}$-dependent activation of myosin light chain kinase [64]. It has been suggested that activation of Ca$^{2+}$-dependent KATP channels [65, 66] is associated with NO-induced relaxation of vascular smooth muscle. In addition to causing vasodilation, reducing vascular resistance, NO derived from endothelial cells can reduce smooth muscle proliferation and inhibit platelet aggregation and adhesion [67].

In animals suffering from SAH, oxyhemoglobin (oxyHb), which is gradually released from the blood clot of the subarachnoid space by erythrocyte lysis, is an effective NO scavenger [68]. Together with vasoconstrictors such as endothelin-1 (ET-1), cyclooxygenase (COX) products, and ROS [69], the bioavailability of nitric oxide derived from the endothelium, neurons, and nitrosated nerves will be reduced. Excessive production of NO acts under pathological conditions such as inflammation and cerebral ischemia, resulting in the production of peroxynitrite and other highly toxic compounds. This may partly explain the ischemic neurological deficit after subarachnoid hemorrhage. Similarly, previous studies have shown that inhibition of iNOS may result in a treatment that reduces ischemic brain damage [70]. On the other hand, eNOS-mediated pretreatment may have a beneficial effect on reducing vaso- spasm and cerebral ischemia after SAH [71]. Therefore, based on these data, the primary therapeutic goal of cerebral vasospasm after SAH is to exogenously administering NO donors, inhibiting PDE and BOXs, and prevention of oxyHb neurotoxicity [72]. In animal models, intravenous administration of nitroglycerin (NTG) or sodium nitroprusside (SNAP) in the form of nitrate is effective in preventing cerebral vasospasm [73,74]. Nitrite is an endogenous NO donor in the blood [75], which may provide a means of overcoming the reduction of NO production after SAH [72]. In the primate SAH model, intravenous administration of sodium nitrite for 2 weeks prevented the development of vasospasm without altering blood pressure, suggesting that nitrite can locally release NO in the subarachnoid space [76]. However, further studies of nitrite are needed to elucidate the pharmacokinetics of sodium nitrite in humans and to establish appropriate doses and safety. Local (intracranial/intracranial arterial) delivery of NO donors is clinically unattractive due to increasing the risk of serious complications or surgical approaches [72].

7. The Parallels and Contrastive Effects between NO and H$_2$S: Looking for Crosstalk

NO and H$_2$S are ancient, prebiotic, and chemically reactive molecules, which living organisms have evolved to cope with and ultimately make use of for signaling purposes. The reactivity of NO and H$_2$S is controlled partly by keeping their steady-state levels in vivo rather low (in the nanomolar to low micromolar range) by balancing consumption with production, by the NOS enzymes in the case of NO, and by the enzymes CSE, CBS, or the tandem enzymes cysteine aminotransferase (CAT) and 3-mercaptopyruvate sulfurtransferase (3-MST) in the case of H$_2$S. Another common feature of these enzymatic pathways is that both have an amino acid as substrate: L-Arg is the substrate for NOS and L-Cys is a substrate for CSE and CBS [63]. In the vertebrate circulation, NO and H$_2$S diffuse away from their site of production and react specifically with their biological targets. NO may activate soluble guanylate cyclase present in adjacent smooth muscle cells and trigger vasorelaxation or react with ROS to form secondary reactive nitrogen oxide species (e.g., peroxynitrite). Conversely, H$_2$S may activate potassium channels and, depending on whether the vessel is systemic or pulmonary/gill, may then trigger vasorelaxation or vasoconstriction, respectively, or even both at different time scales [77]. Thus, whereas NO is strictly a vasodilator, H$_2$S may mediate dilation and/or constriction. The prevailing view is that both NO and H$_2$S have a limited radius of effects and have mainly paracrine/autocrine actions. NO, however, can be transported in the blood as plasma and erythrocyte nitrite and S-nitrosothiols, which are relatively stable oxidation products of NO metabolism. Such products may then be recycled back to NO at distant locations and therefore NO can be also regarded as an endocrine signaling molecule. Such endocrine function has not been demonstrated for H$_2$S up to now [63]. Furthermore, it is not yet clear to which extent H$_2$S is capable of generating S-nitrosothiols or other related products. It appears conceivable that a possible crosstalk between the two pathways might involve some thiol-based biochemical compounds common to either pathway [78]. On the other hand, H$_2$S
8. \( \text{H}_2\text{S}: \) A Novel Neuroprotectant for Central Nervous System Diseases Based on Its Role in Physiology

Since 1996, when \( \text{H}_2\text{S} \) was firstly reported, the role of \( \text{H}_2\text{S} \) has been gradually revealed by various contributions worldwide [82]. \( \text{H}_2\text{S} \) has been generally recognized as an important signaling molecule in cardiovascular and nervous systems. The physiological effects of \( \text{H}_2\text{S} \) have been confirmed by understanding the therapeutic implications of \( \text{H}_2\text{S} \) in central nervous system (CNS) related diseases including neurodegenerative diseases, diabetes, and cancer, among others. In the CNS, \( \text{H}_2\text{S} \) ameliorates ischemic injuries but leads to the aggravation of stroke. \( \text{H}_2\text{S} \) concentration enhancement could induce cerebral infarct, while CBS or CSE inhibitors can reverse this effect on the brain. The role of \( \text{H}_2\text{S} \) in neuron protection has been shown in glutamate-induced death with enhancement of cysteine and \( \gamma \)-glutamylcysteine concentrations, which leads to increasing concentrations of GSH [83–86].

Parkinson’s disease (PD) is a common neurodegenerative disease with various manifestations, among which is cognitive deficiency, namely, dementia, which is characterized by progressive loss of dopaminergic neurons in the substantia nigra (SN). In a PD rat model induced by 6-hydroxydopamine (6-OHDA), the endogenous \( \text{H}_2\text{S} \) level significantly decreased in the SN. However, \( \text{H}_2\text{S} \) treatment can specifically inhibit accumulation of proinflammatory factors in the striatum and 6-OHDA-evoked NADPH oxidase activation, oxygen consumption, and microglial activation in the SN [87]. Dementia is usually ascribed to changes in the nucleus basalis of Meynert and the cerebral cortex [88]. \( \text{H}_2\text{S} \) has also been suggested to attenuate vascular dementia injury via inhibition of apoptosis by regulating Bcl-2 and Bax expressions [89].

Alzheimer’s disease (AD) is the most common form of dementia, which is pathologically characterized by the accumulation of senile plaques containing activated microglia and amyloid beta peptides (A-beta) [90]. As mentioned above, endogenous \( \text{H}_2\text{S} \) is predominantly produced in the brain from cysteine by CBS. In the brains of AD patients, lower levels of \( \text{H}_2\text{S} \) are a strong risk factor for the development of AD [91, 92]. Localized increases in \( \text{H}_2\text{S} \) could delay aggravation and exacerbation of symptoms in patients with AD [85, 93, 94]. In addition, patients with Down syndrome overproduce \( \text{H}_2\text{S} \) due to high level of the urinary excretion of thiosulfate, suggesting a positive relationship between \( \text{H}_2\text{S} \) concentration and the aggravation of this disease [94–96]. Accordingly, it has been demonstrated that \( \text{H}_2\text{S} \) has protective effects against A-beta-induced cell injury by inhibiting inflammation, promoting cell growth, and preserving mitochondrial function [97]. Moreover, \( \text{H}_2\text{S} \) can protect neurons from oxidative stress, which is responsible for neuronal damage and degeneration in AD. \( \text{H}_2\text{S} \) protects neurons against glutamate-mediated oxidative stress by enhancing the activities of \( \gamma \)-GCS and cystine transport, which results in increasing glutathione levels [98]. Neurotoxicity of elevated Hcy is associated with inhibition of endogenous \( \text{H}_2\text{S} \) generation. It has been suggested that \( \text{H}_2\text{S} \) could reduce neurotoxicity induced by Hcy and that enhancement of \( \text{H}_2\text{S} \) synthesis may be a useful therapeutic strategy against Hcy-induced AD [99]. These lines of evidences suggest that \( \text{H}_2\text{S} \) is a promising therapeutic target for treating neurodegenerative diseases.

9. Hypothesis and Theoretical Aspects Fundamental to This Hypothesis

At present, the mainstay treatment of brain injury after SAH is neurocritical care management aimed at reducing secondary brain injury, oral nimodipine, hemodynamic therapy, statin/magnesium/nicardipine therapy, cerebrospinal fluid (CSF) drainage, and endovascular techniques to improve cerebral vasospasm. Most of these treatments are aimed at one or two physiological and pathological mechanisms of brain injury after SAH. Then, a therapy or therapies focused on multiple mechanisms may prevent the brain injury and improve the long-term outcome of SAH better. In fact, the possible roles and target of endogenous \( \text{H}_2\text{S} \) in pathophysiological regulation of SAH have not been investigated. In light of the multiple physiologic roles and beneficial effects of \( \text{H}_2\text{S} \) in mammalian tissue mentioned above, our hypothesis is that \( \text{H}_2\text{S} \) might act as an effective agent which might provide a novel approach to the treatment of brain injury after SAH. This hypothesis is based on the following facts: it is suggested that vascular contractility is regulated by endogenous and exogenous \( \text{H}_2\text{S} \) at physiologically relevant concentrations [17]. Furthermore, some studies reported that vasorelaxation response elicited by \( \text{H}_2\text{S} \) was greater in small mesenteric arteries as compared to that.
in larger vascular tissues such as aorta [100]. H$_2$S is an endogenous substance that is also produced, reaching an endogenous level of 50–160 μM. Cerebral vascular smooth muscle cells would be exposed to significant amounts of H$_2$S [58, 101]. Previous study indicated that exogenous H$_2$S, generated as sodium sulfide, could limit the inflammatory response to acute myocardial I/R injury in an animal model [102].

It has been known that the mechanism underlying the brain injury after SAH is interlaced with multiple causative and/or pathogenic factors, including free radicals reactions, inflammatory processes, apoptosis, an imbalance between vasoconstrictor and vasodilator substances (endothelium derived substances, NO, endothelin, arachidonic acid metabolites, etc.), an upheaval of factors which regulate vascular tone, and endothelial proliferation [103]. As mentioned above, autophagy could participate in the pathogenesis of brain injury induced by SAH, which will provide novel ideas for pursuing therapeutic agents for SAH-induced brain injury. The success of these current therapies in reducing incidence of cerebral vasospasm without reduction in brain injury and improved quality of life indicates that treating vasospasm alone may not achieve favorable result. Therefore, therapies against SAH designed to direct towards inhibiting brain injury may prove more beneficial in preventing neurological deterioration.

10. Conclusion

In light of a wide range of physiological roles of H$_2$S as mentioned above, it produces physiological and pathological functions in many organs and systems. Previous papers have reported that H$_2$S could protect against reperfusion injury, lethal hypoxia, and exerted anti-inflammatory and anti-apoptotic activities and oxidative stress effects [104] as well as effect of autophagy activation. Furthermore, as an endogenous gaseous transmitter and a potential treatment, H$_2$S has distinct advantages over pharmaceutical drugs: its tissue compatibility and high blood-brain barrier permeability are stronger than many other antioxidants and it is an endogenous substance. We speculate that H$_2$S could be a potentially effective approach to the treatment of brain injury including vasospasm after SAH. With our existing knowledge about the beneficial effects of H$_2$S, the future of H$_2$S as a potential therapy against brain injury after SAH is deemed to be promising and exciting.

11. Looking Forward: Challenges for Translation of the Toxic Molecule H$_2$S and Its Therapeutic Application

Investigation of the role of H$_2$S is still in its infancy. H$_2$S has both scientific and technological values. The latter tends to dominate because of its financial value and direct applicability. The scientific investigation of H$_2$S is also important for the elucidation of its base fundamental roles. Certainly, problems and challenges will arise and the limitations of experimental materials will constrain further research in the field of H$_2$S. A sustained and controlled H$_2$S-releasing donor that functions both in vitro and in vivo has not been found yet. With an increased understanding of the various H$_2$S mechanisms in the body, further study of H$_2$S becomes more difficult and complicated. H$_2$S is known as a third gaseous signaling molecule, which means that it plays the role of a messenger. The concentration of H$_2$S has been proven to have relevance in particular diseases; for instance, it is overproduced in sepsis and found at inadequate levels in AD [105]. Therefore, the mechanism controlling the actual concentration of H$_2$S in certain tissues may become the ultimate problem for H$_2$S-related research. It should be emphasized that a relevant relationship does not mean a relationship of causation. By regulating the H$_2$S concentration in particular tissues, symptoms of a specific disease can be controlled, which implies that the origin of the disease has not been addressed. That is to say, the regulation of H$_2$S can only provide transient protection from certain diseases, such as hypertension. The challenges of the sustained and controlled release of H$_2$S-releasing drugs were mentioned above. Another difficulty in H$_2$S related research comes from the multiple functions of H$_2$S, which cause a shortage of specific effects which are dose-, time-, and tissue-dependent.

The pathophysiology of cerebral vasospasm after SAH is complex and needs further clarification. The role of NO in regulating cerebral blood flow, pathogenesis, and treatment of cerebral vasospasm as well as delayed ischemic neurological deficits after SAH has been extensively studied. As one of other EDRFs, H$_2$S may provide potential targets for the development of preventive and therapeutic measures, including cerebral vasospasm. The interaction between these factors also needs to be studied. The inflammatory response associated with SAH may represent a key pathway in the pathogenesis of cerebral vasospasm and delayed ischemic neurological deficits [106, 107]. The role of EDRF, such as H$_2$S, is needed to be elucidated in regulating cerebral blood flow and cerebral vasospasm, preventing neuroischemic defects. For patients with different diseases, H$_2$S may need to be administered as different drugs. Therefore, a focus on the general effects of H$_2$S, such as on brain injury after SAH, is rational.
